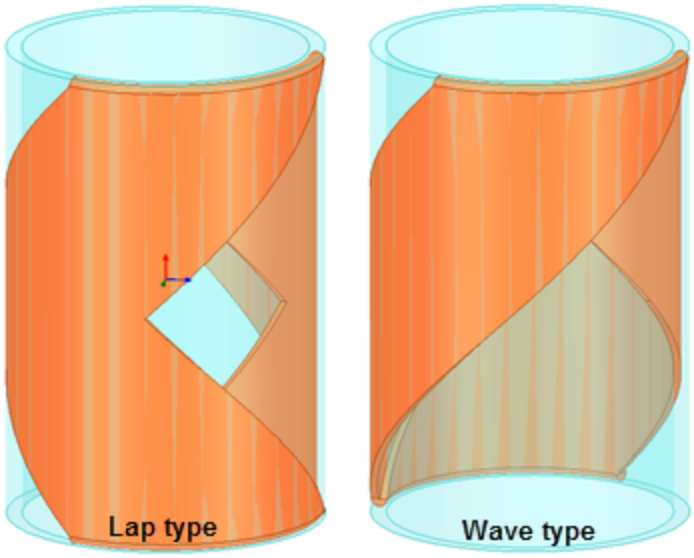
When **CoilType** = 1 , the created coil is a lap-type. When **CoilType** = 2, the created coil is a wave-type. For a wave-type coil, the bottom span will be skewed in the same direction as the top span, and therefore, the bottom tip will shift from the top tip by one pole pitch. The pole pitch will be 180°, 90°, 60°, …, for 2, 4, 6, …, poles, respectively. The input value of **CoilPitch** will be adjusted to the closest value of possible pole pitches. The following figure compares a wave-type coil with a lap-type coil.

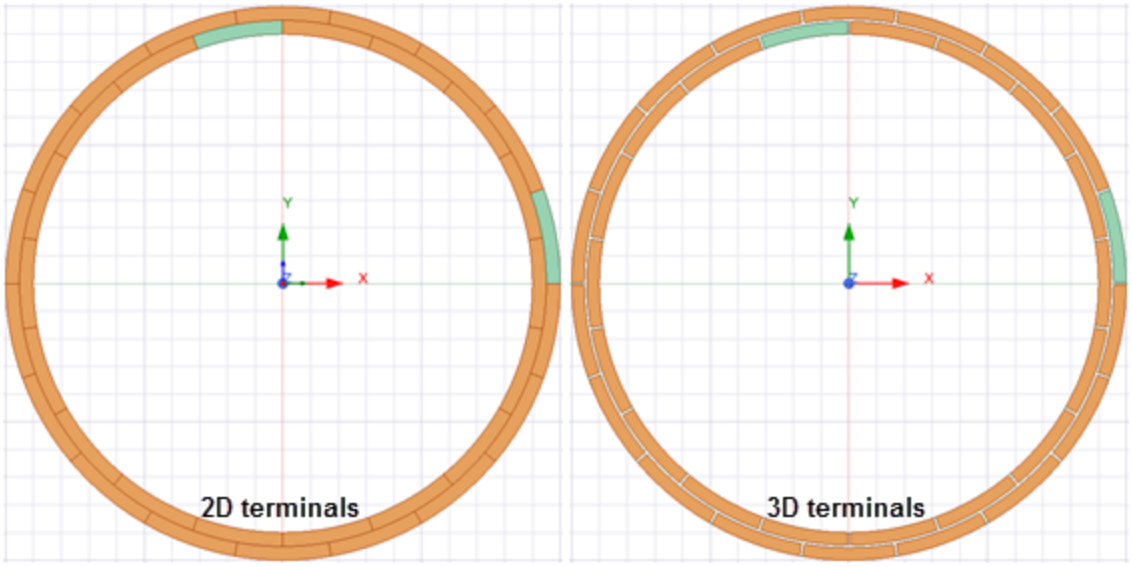
Lap-type coil compared with a wave-type coil



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can set **LenTotal** = 0 to create coils or terminals in 2D, or directly use **InfoCoil** = 2 and **InfoCoil** = 3 with **LenTotal** > 0 to draw 3D terminals for 2D coils. The difference between 2D terminals and 3D terminals is that: there will be a gap between any two adjacent 3D coil terminals, but there will be no gap between 2D terminals to improve mesh quality, as compared in the figure below.

2D terminals compared with 3D terminals



A user needs to input an average CoilPitch to create coil terminals for 2D FEA model. For a wave-type coil, because the bottom span is continuously skewed without changing the skew direction from the top span, the average coil pitch is the same as the real CoilPitch. For a lap-type coil, the average coil pitch can be derived from:

PitchAve = (Length x CoilPitch + (LenCore – Length) x (CoilPitch + PitchMin) / 2) / LenCore

where **LenCore** is the length of the inner and outer cores which carry magnetic field, and

PitchMin = (LenTotal – 2 x RadTip – LenCore) / (LenTotal – 2 x RadTip – Length) x CoilPitch

which must be limited within (0, CoilPitch). In the equation above, **RadTip** is the radius of top and bottom coil tips, which is obtained from:

RadTip = (DiaOuter – DiaInner) / 4

The skew angle for multi-slice 2D FEA model can be obtained from:

AngSkew = (PitchAve – PitchMin) x 2

which is applicable for both lap-type and wave-type coils.

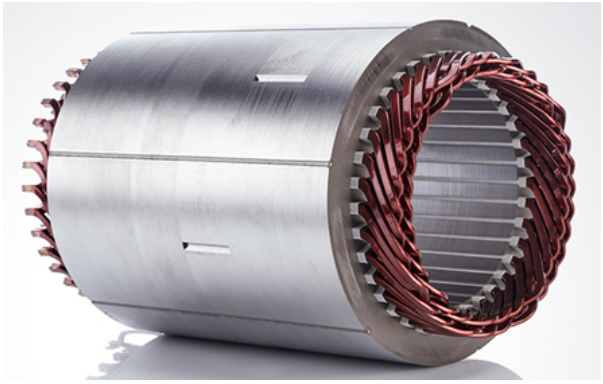
HairpinCoil UDP

The HairpinCoil UDP is used to create a hairpin-type coil. Hairpin coils are used to make a hairpin winding in a slotted core. All hairpin coils belonging to the same phase are welded in series to perform a hairpin winding.

Hairpin Coil



Stator with Hairpin Winding

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores
Length	Core length, 0 for 2D
Skew	Skew angle in core length range
Slots	Number of slots
SlotType	Slot Type: 1 to 7
Hs0	Slot opening height
Hs1	Slot wedge height.
Hs2	Slot body height
Bs0	Slot opening width
Bs1	Slot wedge maximum width
Bs2	Slot body bottom width; 0 for parallel teeth
Rs	Slot body bottom fillet
FilletType	0: a quarter circle; 1: a tangent connection; 2&3: arc bottom; 4&5: V bottom
Layers	Number of total coil layers in a slot; must be an

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
	even number
CoilPitch	Coil pitch measured in slots
EndExt	One-side end extended length
SpanExt/SpanGap	> 0: axial span extension; = 0: 45° span angle; < 0: negative span gap
SegAngle	Deviation angle for slot arches (5~15, <5 for true surface)
1stPitch	Going-side leg-span pitch
2ndPitch	Returning-side leg pitch; see explanation below.
2ndSpanExt/SpanGap	> 0: axial span extension; = 0: 45° span angle; < 0: negative span gap
WireWidth	Wire width in slot width direction
WireThick	Wire thickness in slot depth direction
WireRad	Wire fillet radius; used to calculate equivalent wire size based on wire area.
LayerSetGap	Gap between two layer-sets; one layer-set is two layers of one coil.
LayerSetIdx	Layer-set index for the location of the coil to be drawn
LayerGap	Gap between two layers in a layer set
WindingType	1: whole-coiled (2 coil sets per pole pair) 2: half-coiled (1 coil set per pole pair)
CoilSetIdx	0: create 1st coil set 1: create the 2nd coil set (for whole-coiled winding only)
LenRegion	Region length, to limit lead length for open coils
InfoCoil	0: winding; 1: one coil set; 2: terminal1; 3: terminal2; 4: coil; 5: end-tip; 6: lead1; 7: lead2; 100: region

Parameter Considerations

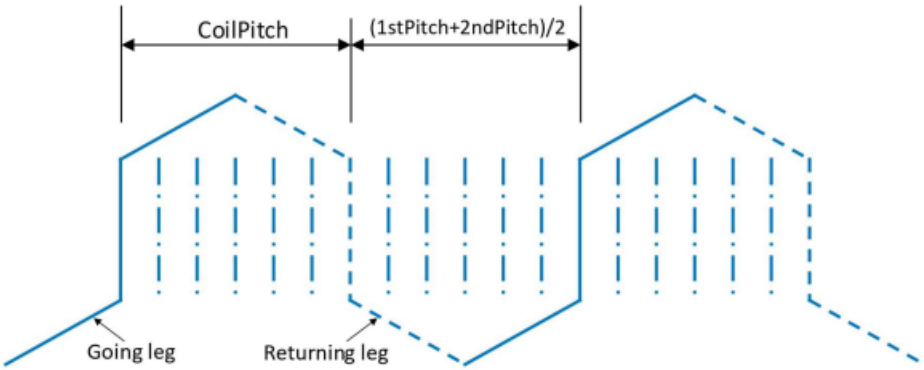
- Parameter **Layers** defines the total number of layers, or total number of conductors per slot. The value must be an even number. Two layers related to one coil are referred as one layer-set.
- For the parameter **SpanExt/SpanGap**, when its value > 0, it defines the span extension length in axial direction (including span connectors, but not including U-type end tips) . When the value is 0, the span extension will be automatically derived based on a 45° span

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

slope angle at the inner diameter of the whole winding.
When the value < 0, the minimum span gap between two adjacent coils at the inner diameter of the whole winding will be defined as a negative value based on which the span extension is automatically derived. In this way, all span extensions at different layers will have the same length.

- Parameters **1stPitch** and **2ndPitch** define the going-side and returning-side leg-span pitches, respectively, as shown in the figure that follows. The going-side and returning-side span tips of two adjacent coils are to be welded. The default value of 0 for the **1stPitch** means symmetrical leg spans, that is **1stPitch** = **2ndPitch**.

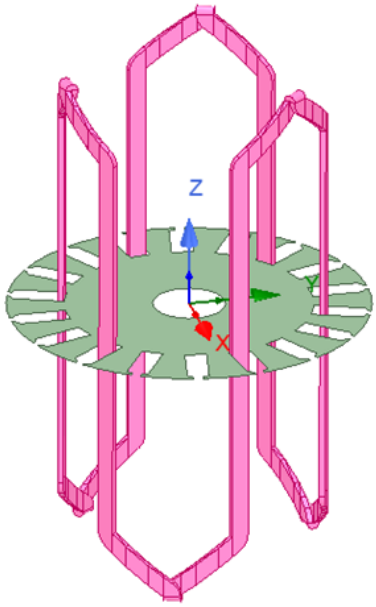
  To be consistent with the previous-version definition, one side leg-span corresponds to a half-span pitch.



Parameters for CoilPitch and 2ndPitch

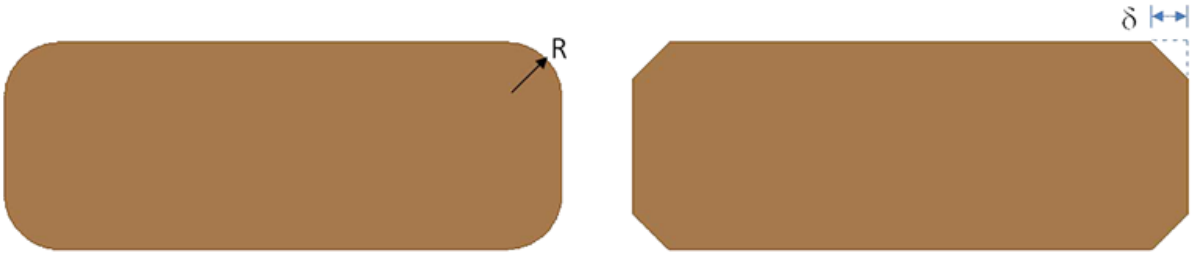
For an integer-slot winding with symmetrical lag spans, the **Slots** value is a multiple of **2ndPitch** plus **CoilPitch** values. In such a case, the last coil in a coil chain will close the first coil, resulting in a closed coil chain, as shown below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Closed hairpin-coil chain with 2ndPitch = 3 in an 18-slot core lamination

- Parameter **2ndSpanExt/SpanGap** defines the span extension length for the returning side leg spans, please refer to the **SpanExt/SpanGap** consideration above.
- As a good compromise between accuracy and geometrical modeling effort, for 3D models, the UDP will convert the round corner fillets of the conductors' cross-section to 45-degree chamfers at the corners as shown in (b) of the figure that follows. This conversion is done in such a way that the cross-sectional area of the conductor is maintained. In 2D models, equivalent conductors with 45-degree corner will be used when SegAngle ≥ 5°, and conductors with true round corner will be used when SegAngle < 5°.



Equivalent conductors with the same area: δ = R (2-π/2)^0.5

(a) Conductor with true round corner

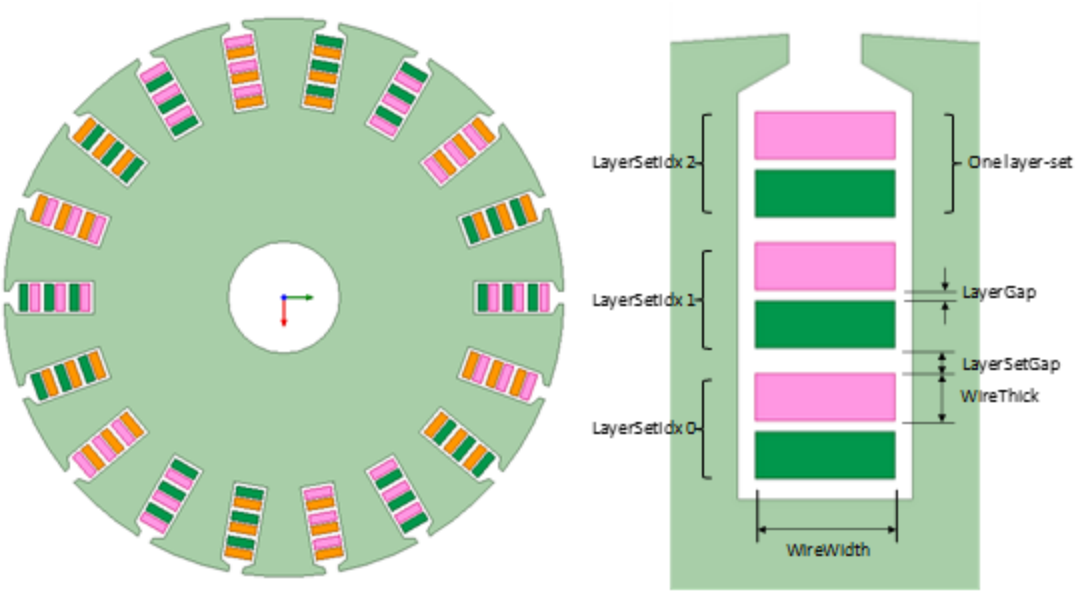
(b) Conductor with 45-degree line corner

- In order to obtain good mesh quality, the UDP will not create wire with wire fillet radius, as shown above, but the effect of wire fillet radius on the wire area will be considered using a scaling factor for both **WireWidth** and **WireThick**. The scaling factor k = (WireArea /

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

WireWidth / WidthThick) ^ 0.5, where WireArea is the wire cross-section area considering wire fillet.

- The UDP will get the maximum available rectangular space inside a slot via an optimization process for wire arrangement. The minimum gap between a wire and a rectangle side will be default as 0.3 mm, considered as the thickness of a slot liner insulation. The gap between two layers in one layer-set is the same for all layer-sets. The value is automatically derived from the height of the rectangular space minus total wire thickness and total layer-set gap.
- **WindingType** and **CoilSetIdx** are used for fractional-slot windings only. You do not need to input these values for integer-slot windings. For a fractional-slot winding, the last coil in a coil chain will not close the first coil, and the coil chain will continue to include all coils belong to the same coil set. Finally, the UDP will create an opened coil set. Two lead wires will extend the opened coil set to touch one region end. For whole-coiled windings, since the two coil sets may have different coil arrangement, we need to create two coil sets separately. Parameter **CoilSetIdx** indicates which coil set is being created. The coil arrangement is based on three-phase windings.



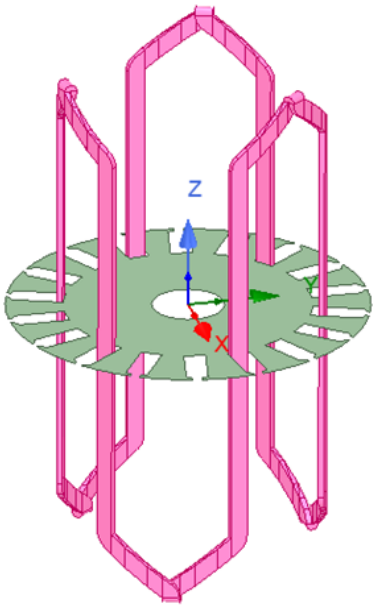
- For other parameters, refer to *LapCoil UDP*.

Creating Closed Three-Phase Hairpin Windings (HairpinCoil)

1. In Maxwell 3D, launch HairpinCoil UDP with default setting, that is **Slots**=18, **Layers**=6, **CoilPitch**=3, **2ndPitch**=3, **LayerSetIdx**=0, and **InfoCoil**=1. Because the ratio of **Slots** to (**2ndPitch** + **CoilPitch**) is 3 (an integer number), the UDP will create a closed-coil chain,

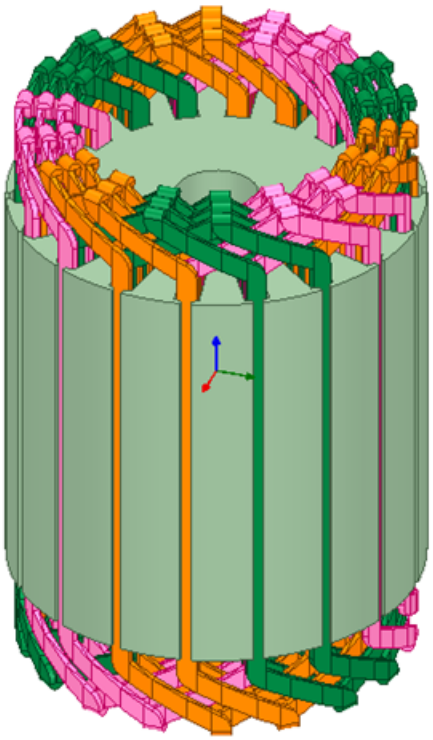
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

or a coil loop, located at slot bottom, as shown below (excluding the core lamination).



2. Make a copy of the coil loop, and change **LayerSetIdx** to 1, this copied coil loop is changed to locate at the slot center.
3. Make a copy of the coil loop again, and change **LayerSetIdx** to 2, this copied coil loop is changed to locate at the slot top.
4. Duplicate all these three coil loops with the following parameters in **Duplicate/Around Axis** command: **Angle** = 20deg, **Total Number** = 6, and change colors for different phases, then you will get the final three-phase windings, as shown below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Closed three-phase hairpin windings

Creating One Phase Half-Coiled Windings (HairpinCoil)

Set **Slots**=15, **Layers**=2, **CoilPitch**=4, **2ndPitch**=4, **LayerSetIdx**=0, and **InfoCoil**=1. Because the ratio of **Slots** to (**2ndPitch** + **CoilPitch**) is 15/8 (not an integer number), the UDP will create an opened coil set. In this UDP, the software will support a fractional-slot winding that satisfies:

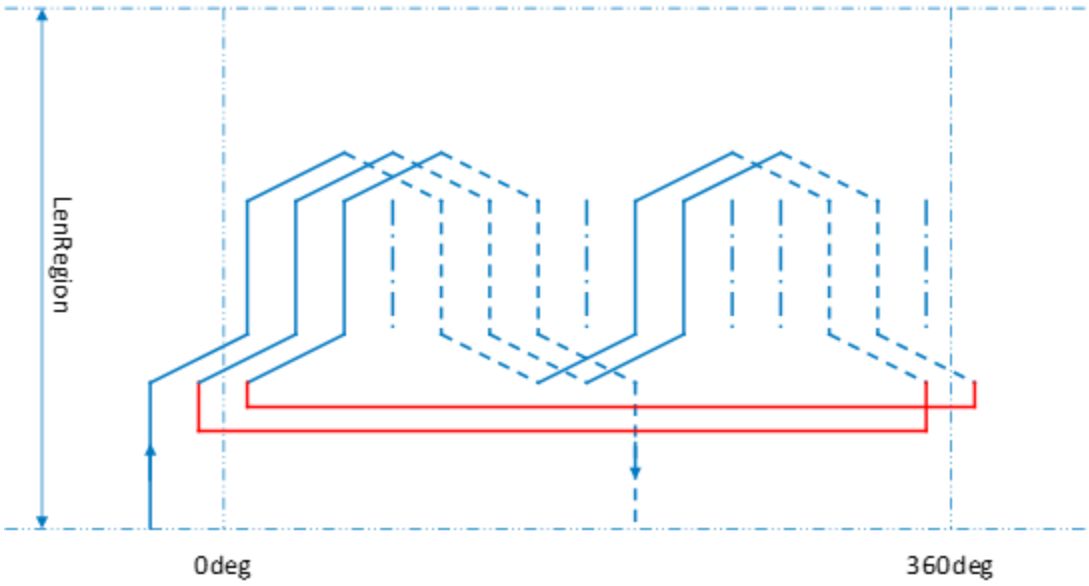
(2ndPitch + CoilPitch) x PolePairs = Slots ± 1

For this example, the number of pole pairs is 2, and the winding arrangement, for top coil side only, will be:

AAABBCCCAABBBCC

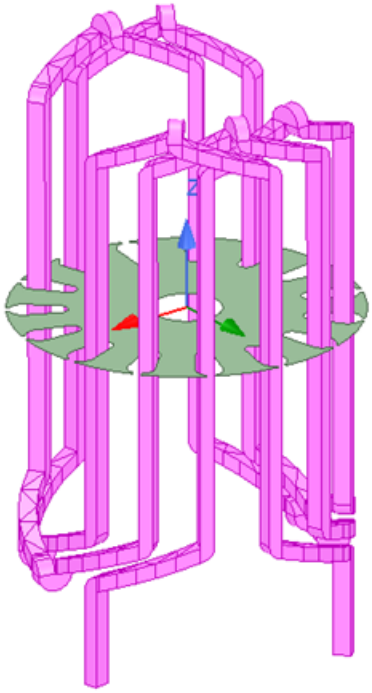
For this half-coiled winding, all hairpin coils labeled with “A” are included in one opened coil set, which has already contained all phase A coils, as shown below, where red lines indicate the short-circuit connection without using physical wires.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Flat expanded view of phase-A hairpin winding containing only one opened coil set

The created 3D opened winding is shown below.



3D view of phase-A hairpin winding containing only one opened coil set

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating One Phase Whole-Coiled Windings (HairpinCoil)

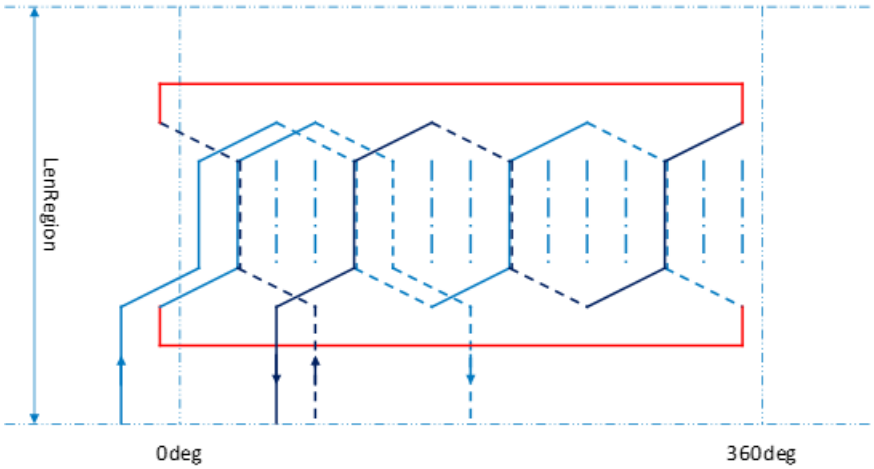
Set **Slots**=15, **Layers**=2, **CoilPitch**=4, **2ndPitch**=4, **LayerSetIdx**=0, **WindingType** = 1, **CoilSetIdx** = 0, and **InfoCoil**=1. Because the ratio of **Slots** to (**2ndPitch** + **CoilPitch**) is 15/8 (not an integer number), the UDP will create an opened coil chain. This fractional-slot winding satisfies:

(2ndPitch + CoilPitch) x PolePairs = Slots ± 1

where the number of pole pairs is 2. The winding arrangement, for top coil side only, is:

AAZBXCCYAZBBXCY

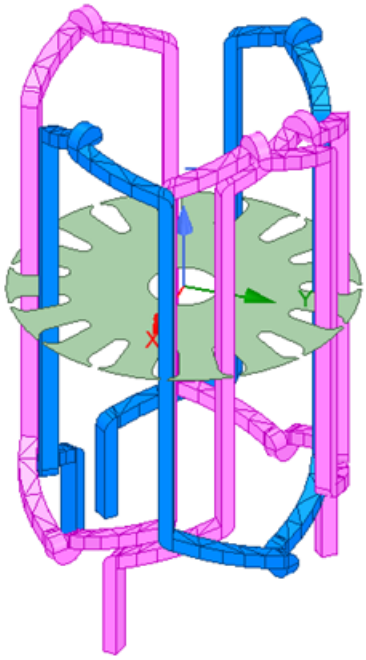
With the above parameter setting, this UDP will create an opened coil set including all coils related to all “A” coils of the above winding arrangement. Copy the coil set, and change **CoilSetIdx** to 1. The coil set is modified to include all coils related to all “X” coils of the winding arrangement. The phase-A winding is made up of these two coil sets, as shown below, where red lines indicate the short-circuit connection without using physical wires.



Flat expanded view of phase-A hairpin winding containing two opened coil sets (all coils with light blue color relate to “A” coils, and all coils with dark blue color relate to “X” coils, in the winding arrangement)

The created 3D opened winding is shown below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

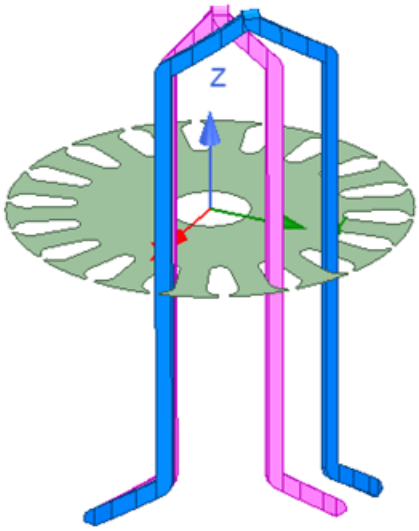


3D view of phase-A hairpin winding containing two opened coil sets

Creating Two Hairpin Coils Connected with End-Tip and Leads

1. Set **Slots**=18, **Layers**=6, **CoilPitch**=2, **2ndPitch**=3, **LayerSetIdx**=0, and **InfoCoil**=4. These parameter settings will create a single hairpin coil located at the slot bottom, as shown by the pink-color coil in the figure below.

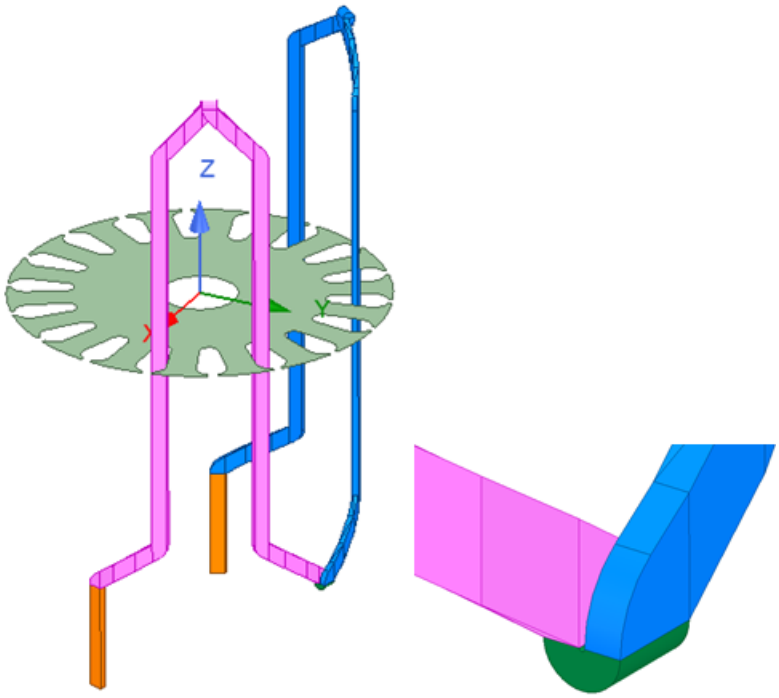
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Two hairpin coils with different coil pitch at different slot locations

2. Make a copy of the coil, and change **CoilPitch** to 3, and **LayerSetIdx** to 1. The copied coil is modified to be located at the slot center, as shown by the blue-color coil in the above figure.
3. Rotate the blue-color coil by 100 deg, or 5 slot-angle, the bottom leg-span of the blue-color coil will align with the top leg-span of the pink-color coil, as shown in the figure below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Two hairpin coils at different slot locations connected with end-tip and leads

4. Make a copy of the blue-color coil, and change **LayerSetIdx** to 0.5 (for end-tip between layer-set index of 0 and 1) and **InfoCoil** to 4. The copied coil is modified to an end tip, as shown by the green-color object in the above figure.
5. Make a copy of the pink-color coil and change **InfoCoil** to 6, the copied coil is modified to a going lead; and make a copy of the blue-color coil and change **InfoCoil** to 7. The copied coil is modified to a returning lead, as shown by the golden-color objects in the figure.

The two hairpin coils, two leads, and one end-tip can thus be united to become a single connected coil set.

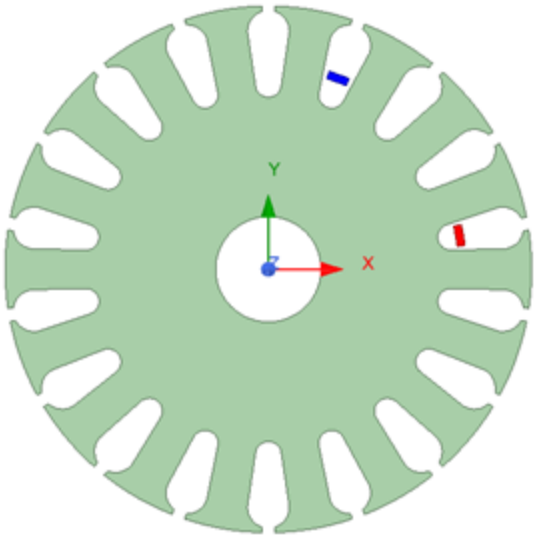
> **Note:** In order for the end-tip and leads to be able to perfectly connect two hairpin coils, the parameter value of **2ndSpanExt** for all components must be the same to keep the same axial span length. If you see a message such as: “HairpinCoil - 2ndSpanExt is modified from xxx to xxx”, you need to increase the value of **2ndSpanExt** for all components to be at least the maximum modified value of all components.

Creating a Terminal for a Hairpin Coil

A terminal is a 2D cross-section of a 3D coil that can be used to assign current or voltage excitations. You can create a *going* terminal by setting **InfoCoil** to 2; or you can create a

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

returning terminal by setting **InfoCoil** to 3. In a connected 3D coil set, you need to create only one terminal, but you need to create both *going* and *returning* terminals for each hairpin coil for a 2D model. *Going* and *returning* terminals are shown below.



***Going* terminal (red) and *returning* terminal (blue) inside two slots**

UDPs for Pole Cores and Coils

UDPs defined for pole cores and coils include

- SalientPoleCore UDP
- DCMCore UDP
- ShadedPoleCore UDP
- UnivMCore UDP
- SRMCore UDP
- SynRMCore UDP
- ClawPoleCore UDP
- PMCore UDP
- IPMCore UDP
- PMDamperCore UDP
- StepMCore UDP
- Square Yoke UDP
- UPMCore UDP
- VPMCore UDP
- VentCore UDP

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

SalientPoleCore UDP

The SalientPoleCore UDP is used to create a salient-pole core, a field winding, and a damper for salient-pole synchronous machines. It can also create a coil cross-section used as a terminal for current assignment.

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length
Skew	Skew angle in core length range
Slots	Number of slots
SlotType	Slot Type: 1 to 4
Hs0	Slot opening height
Hs01	Slot closed bridge height
Hs1	Slot wedge height
Hs2	Slot body height
Bs0	Slot opening width
Bs1	Slot wedge maximum width
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet
FilletType	0: a quarter circle; 1: a tangent connection; 2 and 3: arc bottom; 4 and 5: V bottom.
SlotPitch	Slot pitch in mechanical degrees, refer to offset point.
CenterPitch	Center slot pitch in mechanical degrees, refer to offset point.
Poles	Number of poles
PoleType	Pole type: 1 or 2 (not valid for inner cores)
WidthShoe	Pole shoe width
HeightShoe	Pole shoe height at pole center
FilletShoe	Pole shoe tip fillet radius
WidthBody	Pole body width
HeightBody	Pole body height
AirGap2	Second air gap length
Offset	Pole arc offset
Off2_x	The second pole arc offset perpendicular to the pole-center line
Off2_y	The second pole arc offset parallel with the pole-center line

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
Bp1/Rp1	Bp1: for pole type 1; or Rp1: shoe fillet radius for pole type 2.
Bp2/Rp2	Bp2: for pole type 1; or Rp2: shoe fillet radius for pole type 2.
CoilEndExt	One-side coil end extended length
EndRingType	0: whole press board; 1: pole press board; 2: pole ring; 3: whole ring.
BarEndExt	One-side damper bar end extended Length; for types 2 and 3 only.
RingLength	One-side axial ring length, or conductor press board thickness.
RingHeight	Radial ring height, for types 2 and 3 only.
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface)
LenRegion	Region length
InfoCore	0: core; 1: core & coils; 2: coil; 3: damper; 4: terminal1; 5: terminal2; 6:poles; 7: yoke; 100: region.

These parameters are used in the following figures. In figures with both gray and red objects, the gray objects are used as references.

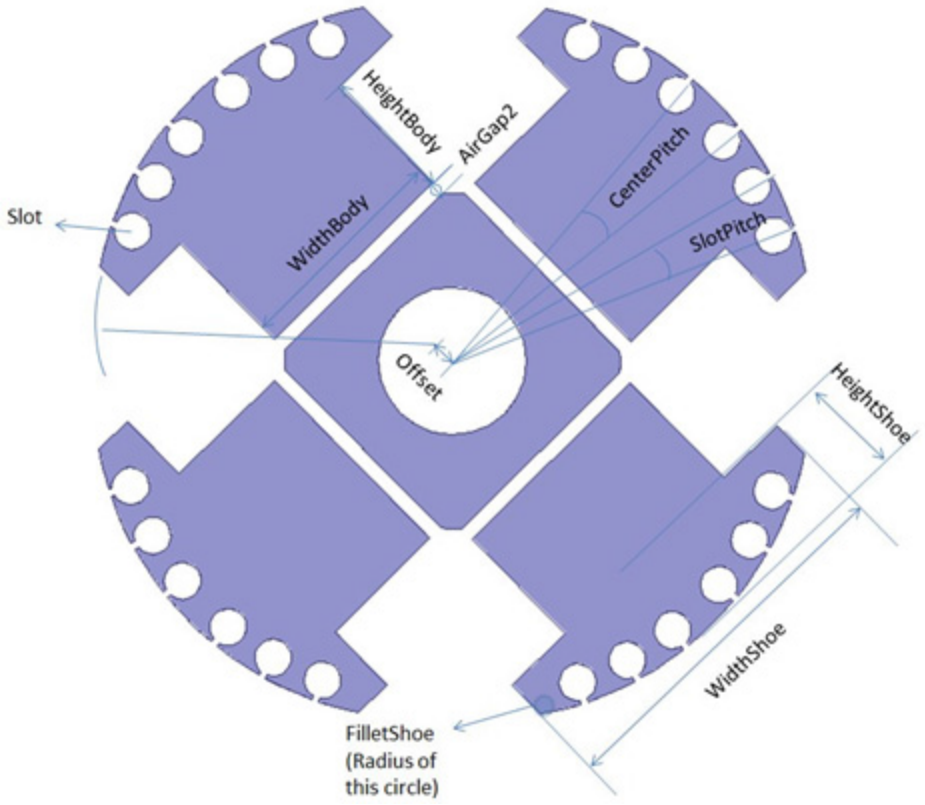


Figure 9-18 Salient Pole Core (InfoCore set to 0)

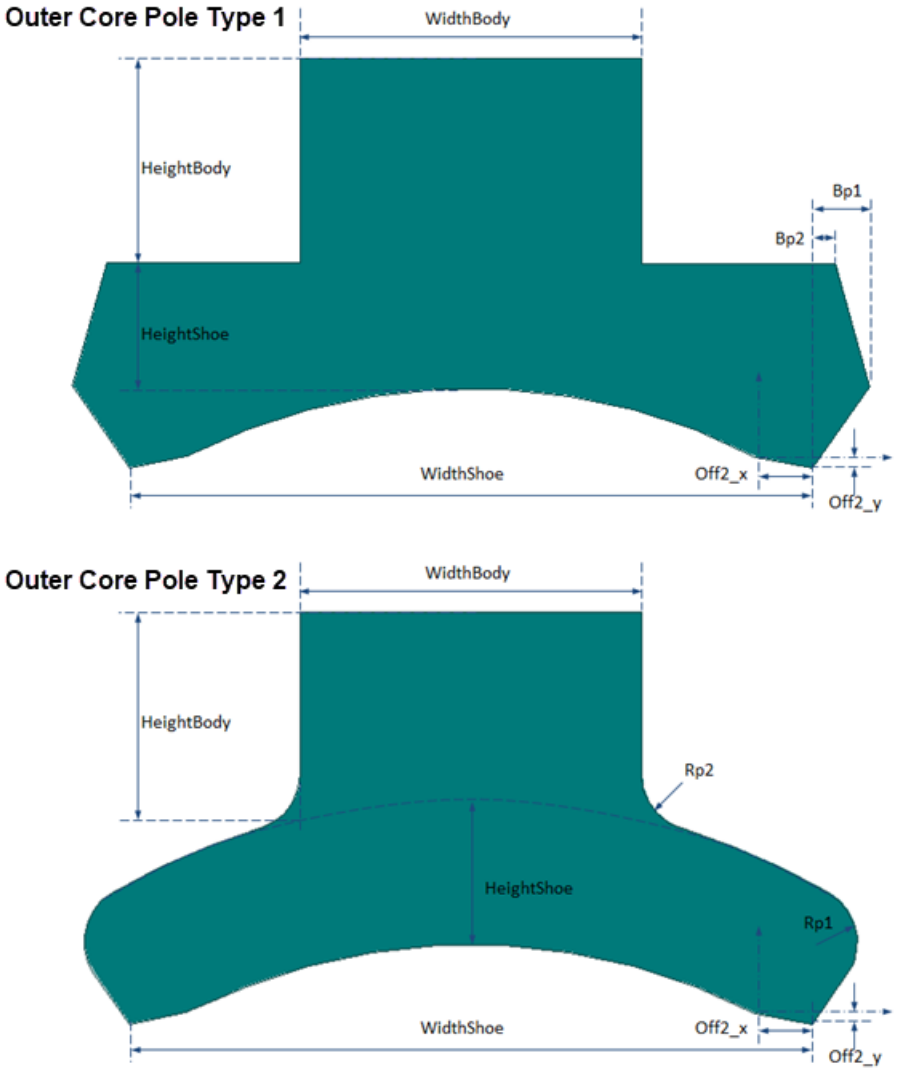
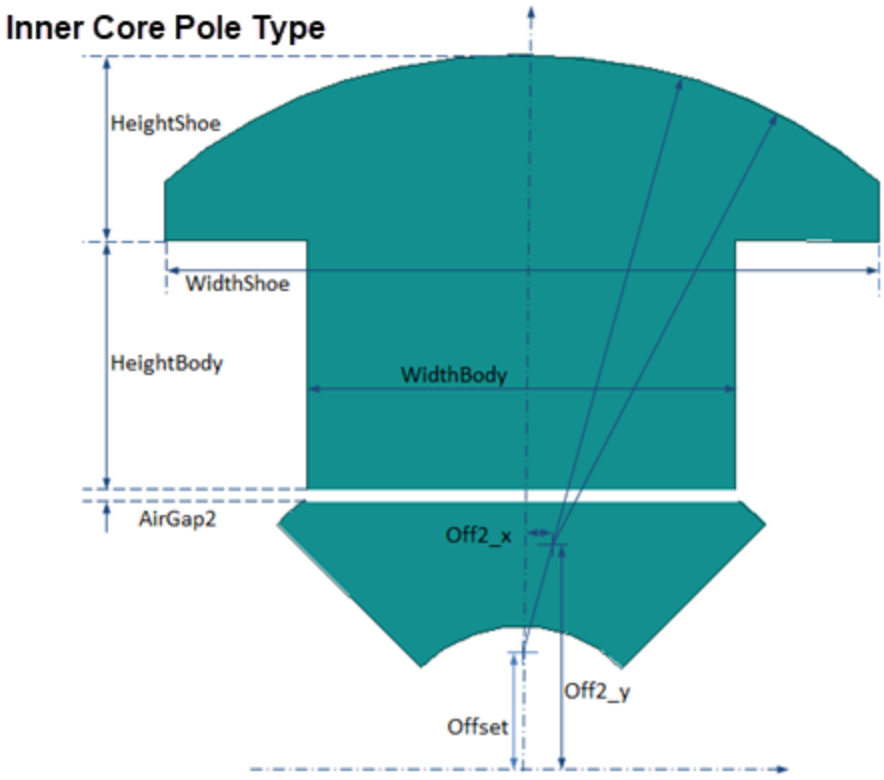
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This UDP supports two pole types for outer cores, as shown below:



But this UDP supports only one pole type for inner cores:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Axial parameters for coils are shown in the following figure:

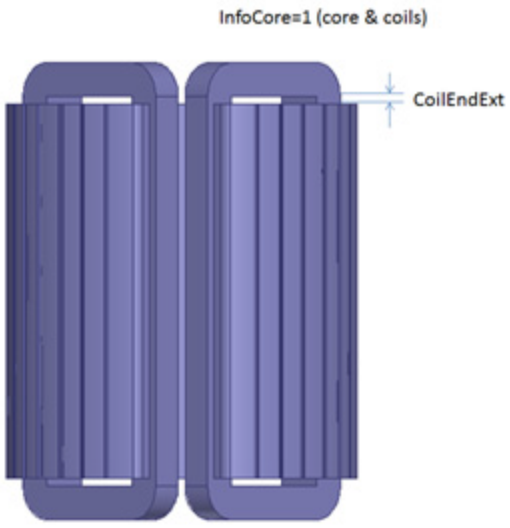


Figure 9-19 3D Salient Pole Core and Coils (InfoCore set to 1)

Axial parameters for dampers are shown in this next figure:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

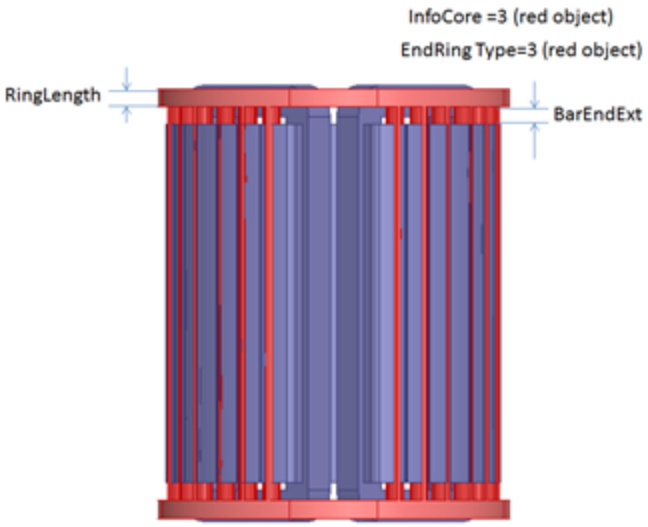

Figure 9-20 SalientPoleCore Damper (InfoCore set to 3)

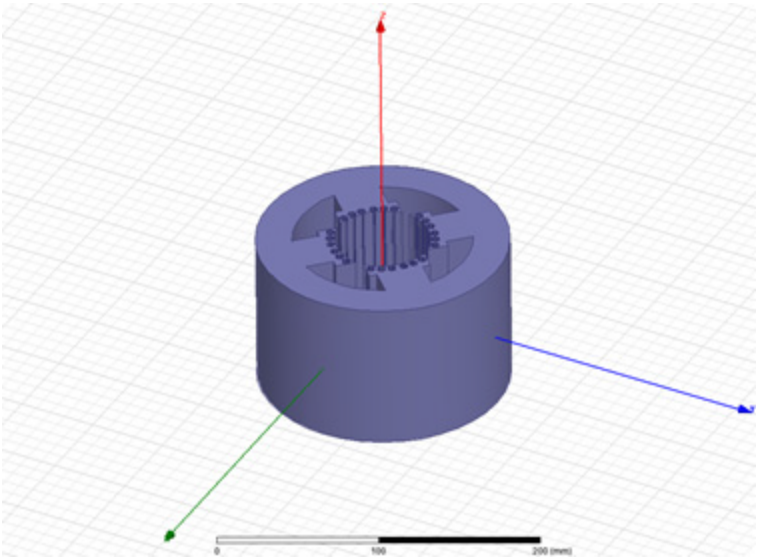
Creating an Inner or Outer Salient Pole Core

Set the value of **DiaYoke** and **DiaGap** as **DiaYoke** < **DiaGap** to create inner cores or **DiaGap** < **DiaYoke** for outer cores.

For an example of an inner salient pole core, see SalientPoleCore UDP. An outer salient pole core with **InfoCore** value of 0 is shown in the following figure:



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can set the values either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating a Coil and its Terminals (Salient Pole)

You can create a coil of a salient pole core by manually setting the property of **InfoCoil** to 2. An example is shown below.

Its terminals are created manually by setting the property of **InfoCoil** to 4 or 5 (Terminal1 or Terminal2). The red sheet in the figure shows terminal 1 of the coil.

You can assign values for these properties either when creating a salient pole core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

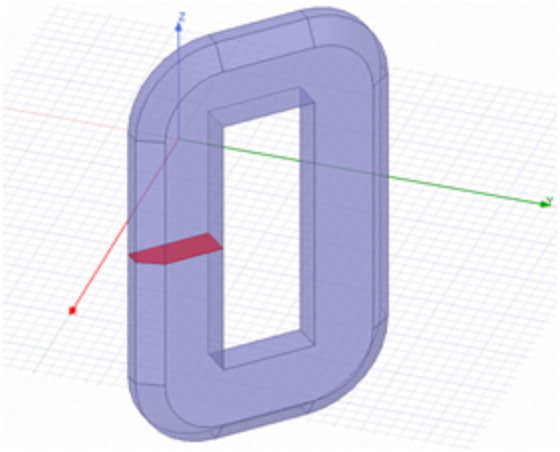


Figure 9-21 Salient pole core coil and its terminal

Creating a Damper (Salient Pole)

You can create a damper of a salient pole core by manually setting the property of **InfoCoil** to 3. An example is shown in " SalientPoleCore Damper (InfoCore set to 3)" on the previous page as a red object.

"Damper with EndRing Type set to 3 " on the facing page,"Damper with EndRing Type set to 2" on the facing page, "Damper with EndRing Type set to 1 " on page 9-88 , and "Damper with EndRing Type set to 0" on page 9-88 illustrate the shapes of the damper (InfoCore set to 3) with different EndRingType values. Gray objects are used as references.

You can assign the value of these properties either when creating a salient pole core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

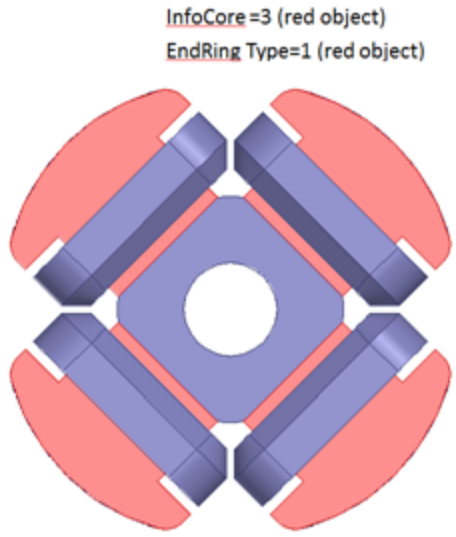
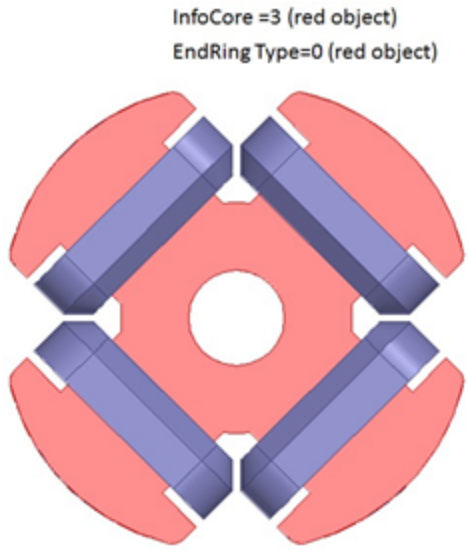
Damper with **EndRing Type** set to 1



Damper with **EndRing Type** set to 0



Creating Poles or the Yoke

You can create poles or the yoke of SalientPoleCore UDP through assigning the **InfoCore** parameter to 6 or 7, respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can assign the value of this property either when creating a Salient Pole Core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Examples of poles and the yoke are shown in "Poles of salient pole core" below and "Yoke of salient pole core" below, respectively.

Poles of salient pole core

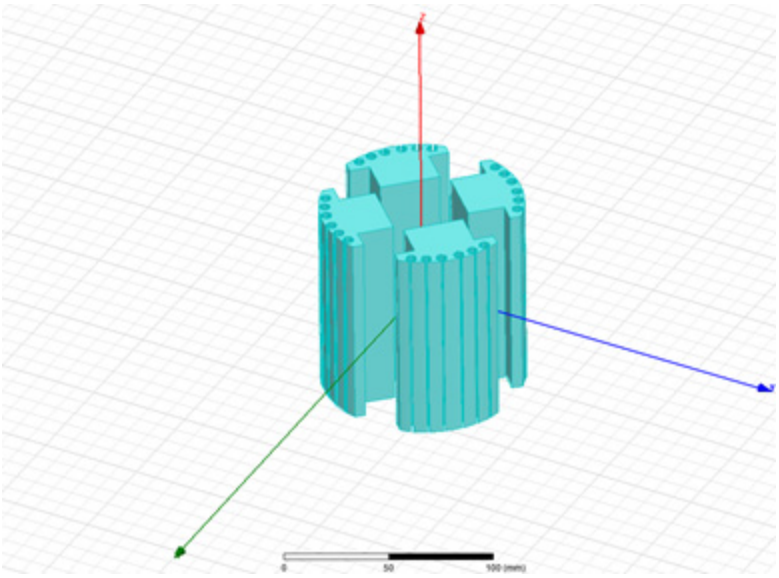


Figure 9-22

Yoke of salient pole core

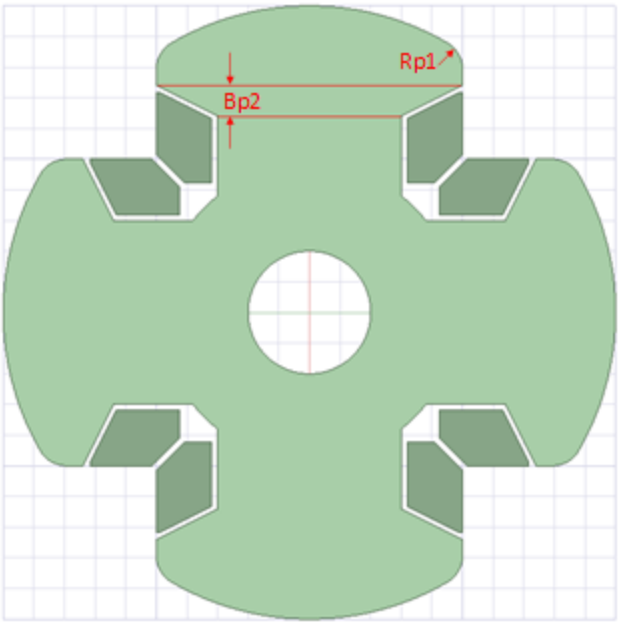
Creating Inner Poles with Shoe Slope

For inner-core type-1 pole, parameters **Rp1/Bp1** and **Rp2/Bp2** stand for shoe-tip fillet radius and shoe-slope height, respectively, as shown below, where all coils are included.

Parameters **Rp1** and **Bp2** for inner core type 1 pole:



DCMCore UDP

The DCMCore UDP is used to create a stator core with or without a compensating winding, a shunt and/or a series field winding, and a commutating pole with a commutating winding for DC machines. It can also create coil terminals for all windings for current assignment.

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length
Skew	Skew angle in core length range
FrameWidth	Overall width of a racetrack frame
FrameThick	Frame thickness
FrameLength	Frame length
Poles	Number of poles
PoleType	Pole type: 1 to 2

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
Dmax	Diameter of shoe tip with maximum air gap length
Bp0	Pole arc width with uniform air gap; 0 for eccentric air gap.
Bp1	Total pole width (the width between shoe tips)
Bp2/Rp0	Bp2 (max shoe width for pole type 1), or Rp0 (shoe fillet radius for pole type 2)
Bp3/Rp1	Bp3 (min shoe width for pole type 1), or Rp1 (pole fillet radius for pole type 2)
Hp	Pole body height
Bm	Pole body width
FieldWndgs	Number of field windings, 2 for both series and shunt windings.
EndExt	Coil one-side end extended length
SlotsPerPole	Compensating slots per pole distributed under pole arc surface
Bc0	Opening width of compensating slots
Hc0	Opening height of compensating slots
Bc2	Width of compensating slots
Hc2	Height of compensating slots
CmpEndExt	One-side end extended length of compensating coils
ComPoleWidth	Width of the commutating poles
ComPoleHeight	Height of the commutating poles
ComPoleLength	Length of the commutating poles
ComShoeWidth	Shoe width of the commutating poles
ComShoeHeight	Shoe height of the commutating poles
ComShoeLength	Shoe length of the commutating poles
ComGap2	Air gap length between commutating poles and the frame
CmtEndExt	One-side end extended length of commutating coils
LenRegion	Region length
InfoCore	0: core & coils; 1: poles; 2: frame; 3: com poles; 4: shunt coil; 5: series coil; 6: com coil; 100: region
Info Term	0: whole coil; 1: terminal1; 2: terminal2

The DC Machine core is complex compared with other UDPs. When creating a DCM core in a Maxwell 3D design, it looks at first like the following figure in the coordinate system window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

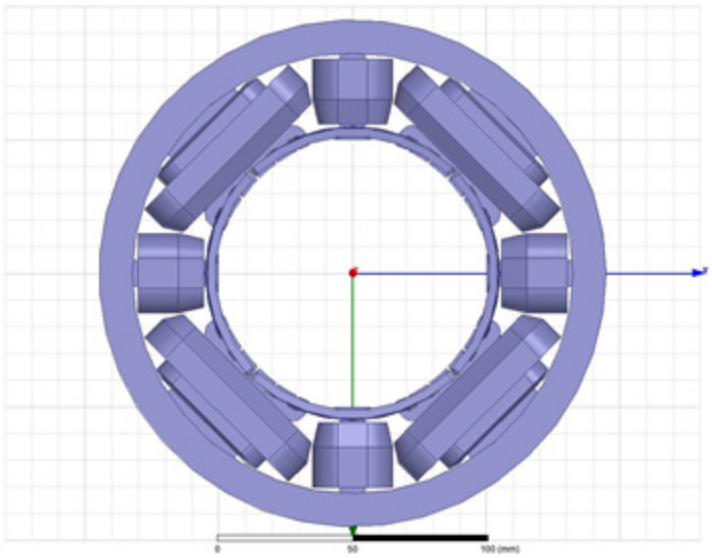


Figure 9-23 Initial DCM Core

In order to better describe the parameters in this UDP, a slot core was added inside the DCM core and their lengths were set to be 0. Also the **DiaGap** of slot core was changed to 92 to show the air gap between two UDPs. The model now looks like the following example:

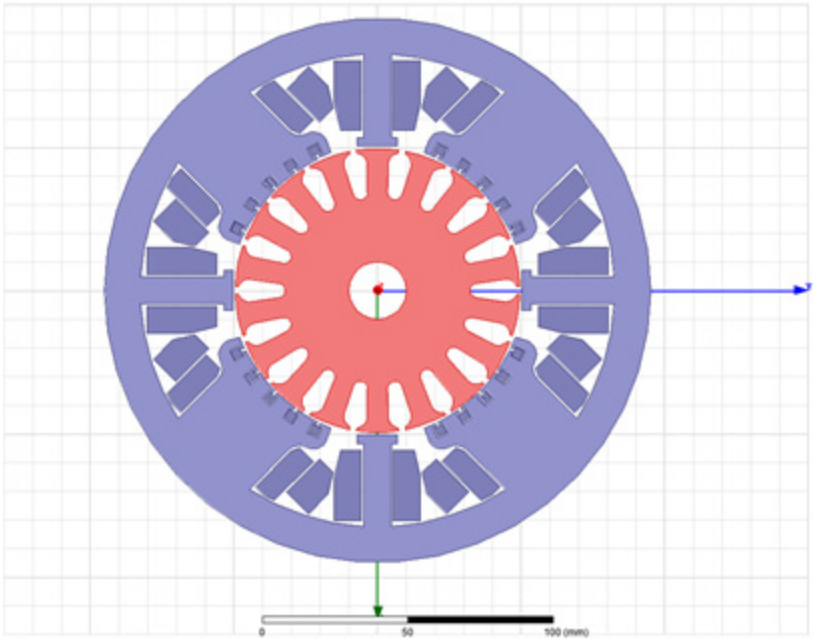

Figure 9-24 DCM Core Sheet (gray) with Slot Core Sheet (red)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The following figures show two different overviews of the gray, transparent DCM core and the referencing red slot core from different angles.

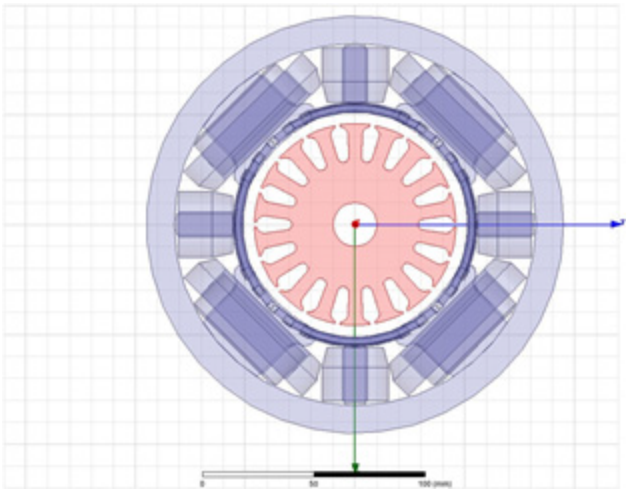

Figure 9-25 Transparent DCM core (gray) with Slot Core from different angles

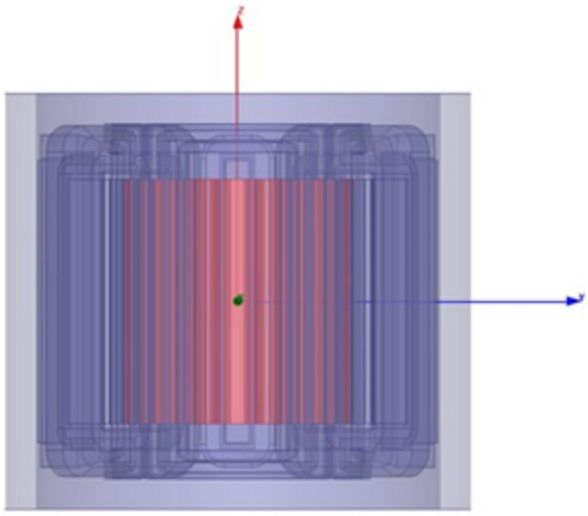

Figure 9-26 Transparent DCM core (gray) with Slot Core from different angles

The following figures show the parameters of a DCM core.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

1. A slot core in red is drawn as reference.
2. Because the structure of a DCM core is complicated and there are many parameters, figures are drawn using different **InfoCore** values of DCM core UDP to clearly describe parameters.
3. " Parameters of PoleType 1 " below and " Parameters of PoleType 2" on the facing page show parameters of two different pole types in the DCM core UDP. In these two figures, **Bp0** is not 0, whereas in " Parameters of DCM Core on 2D plane" on the facing page, **Bp0** is 0, which means the air gap is eccentric.
4. **Dmax**, by definition, is the diameter of shoe tip with maximum air gap length, which means **Dmax**=Drout+2*Gmax. “Drout” means the outer diameter of the rotor (which means **DiaGap** of slot core in this example and is shown in " Parameters of DCM Core on 2D plane" on the facing page), and “Gmax” is the maximum air gap between poles and rotor, which is shown in " Parameters of PoleType 1 " below and " Parameters of PoleType 2" on the facing page.
5. Correspondingly, there is **Dmin** (which is called **DiaGap** in DCM UDP and " Parameters of DCM Core on 2D plane" on the facing page) and **Gmin**. Their relationship is **Dmin**=Drout+2*Gmin. They are also shown in" Parameters of PoleType 1 " below, " Parameters of PoleType 2" on the facing page, and " Parameters of DCM Core on 2D plane" on the facing page.
6. The value of **ComGap2** in " Parameters of DCM Core on 2D plane" on the facing page is 0, whereas it is positive in "Parameters of a commutating pole (when ComGap is non-zero)" on page 9-96 . In order to make the value of **ComGap2** larger than 0, make sure to reserve enough space for **ComGap2**. This can be done by reducing the value of **ComPoleHeight** or **ComShoeHeight** or both.

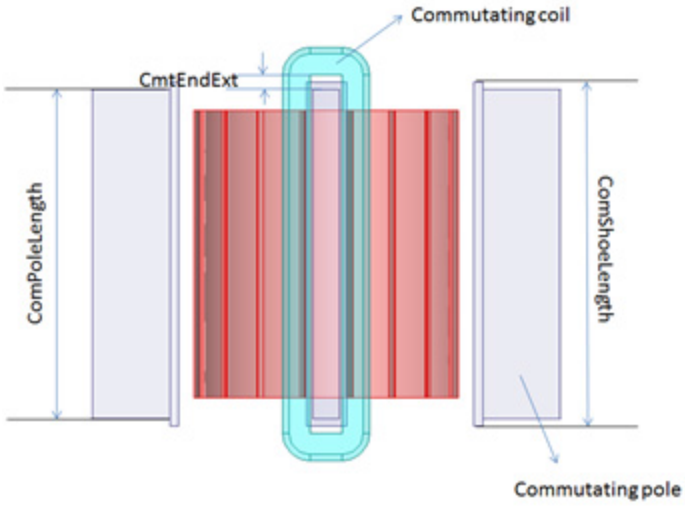

Figure 9-34 Axial parameters of commutating poles and commutating coils

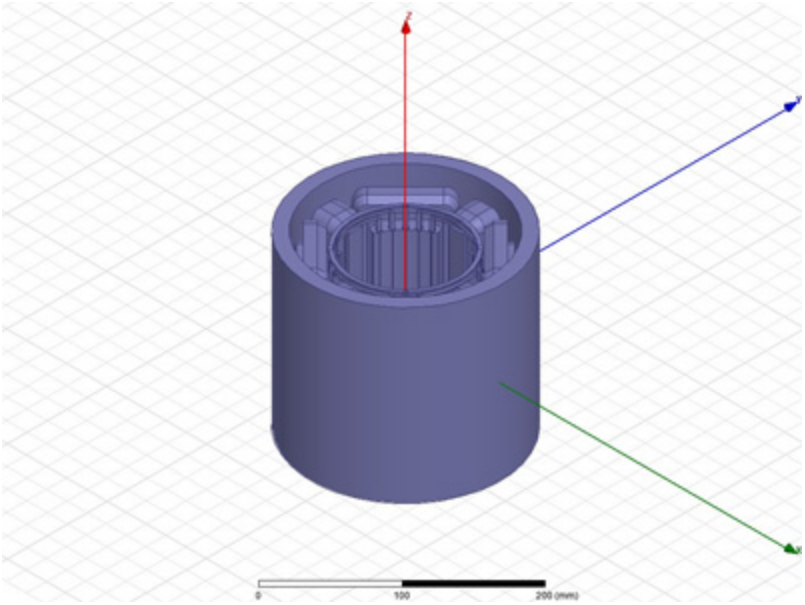
Creating an Outer DC Machine Core and All Coils

This core is used only as outer core, which means the value of **DiaYoke** is larger than that of **DiaGap**. Also, set both **InfoCore** and **Info Term** values to be 0. You can set the value either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

An example of an outer DC machine core is shown in the following figure:



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9-35 Outer DC Machine core and all coils

Creating Main Poles, Frame and Commutating Poles Separately

To create the main poles of a DC Machine core, manually set the property of **InfoCore** to 1 and **Info Term** to 0. The result is shown as the gray object in " Length of poles" on page 9-96 and " Axial parameters of poles and field windings" on page 9-97 .

To create the frame of a DC Machine core, manually set the property of **InfoCore** to 2 and **Info Term** to 0. The result is shown as the gray object in " Length of frame" on page 9-97 .

To create the commutating poles of a DC Machine core, manually set the property of **InfoCore** to 3 and **Info Term** to 0. The result is shown as the gray object in " Axial parameters of commutating poles and commutating coils" on the previous page.

You can assign the values of these properties either when creating a DC Machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating a Shunt Coil and its Terminals

To create a shunt coil of a DC Machine core, manually set the property of **InfoCore** to 4 and **Info Term** to 0. The result is shown as a blue object in " Axial parameters of poles and field windings" on page 9-97 .

To create its terminals, set the property of **InfoCore** to 4 and **Info Term** to 1 or 2 (for terminal1 and terminal2, respectively).

You can assign the values of these properties either when creating a DC Machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating a Series Coil and its Terminals

To create a series coil of a DC Machine core, manually set the property of **InfoCore** to 5 and **Info Term** to 0. An example is shown in the following figure.

To create its terminals, set the property of **InfoCore** to 5 and **Info Term** to 1 or 2 (for terminal1 and terminal2, respectively).

You can assign the values of these properties either when creating a DC Machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

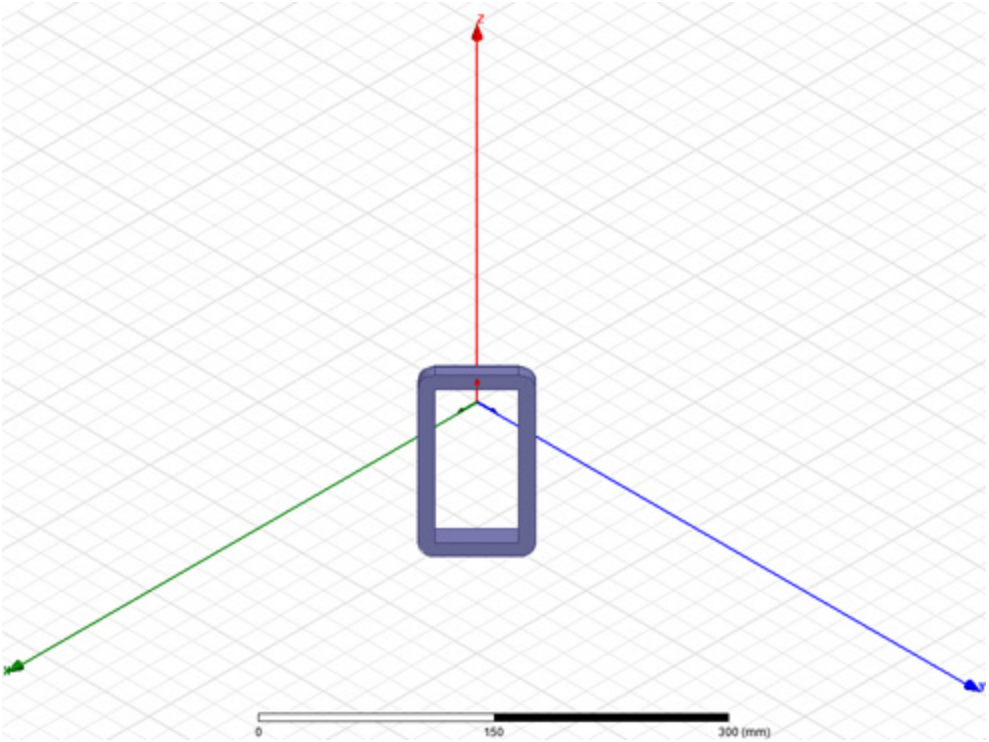


Figure 9-36 A series coil of DCM Core

Creating a Commutating Coil and its Terminals

To create a commutating coil of a DC Machine core, manually set the property of **InfoCore** to 6 and **Info Term** to 0. The result is shown as a blue object in " Axial parameters of commutating poles and commutating coils" on page 9-98 .

To create its terminals, set the property of **InfoCore** to 6 and **Info Term** to 1 or 2 (for terminal1 and terminal2, respectively).

You can assign the values of these properties either when creating a DC Machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

ShadedPoleCore2 UDP

The ShadedPoleCore2 UDP is used to create the stator core for shaded-pole induction motors.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

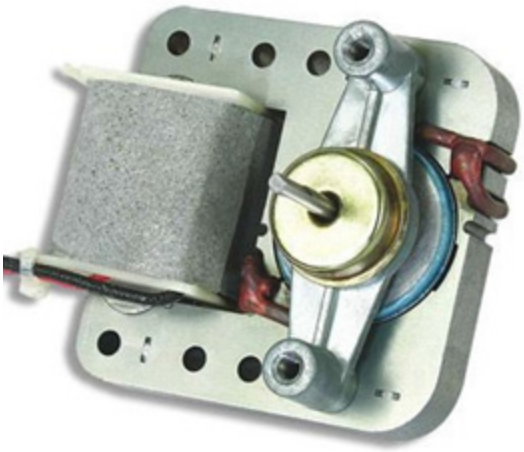

Figure 9-37 Shaded pole induction motor example 1

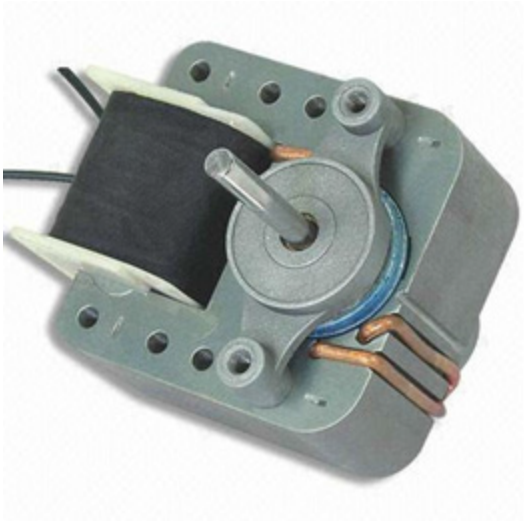

Figure 9-38 Shaded pole induction motor example 2

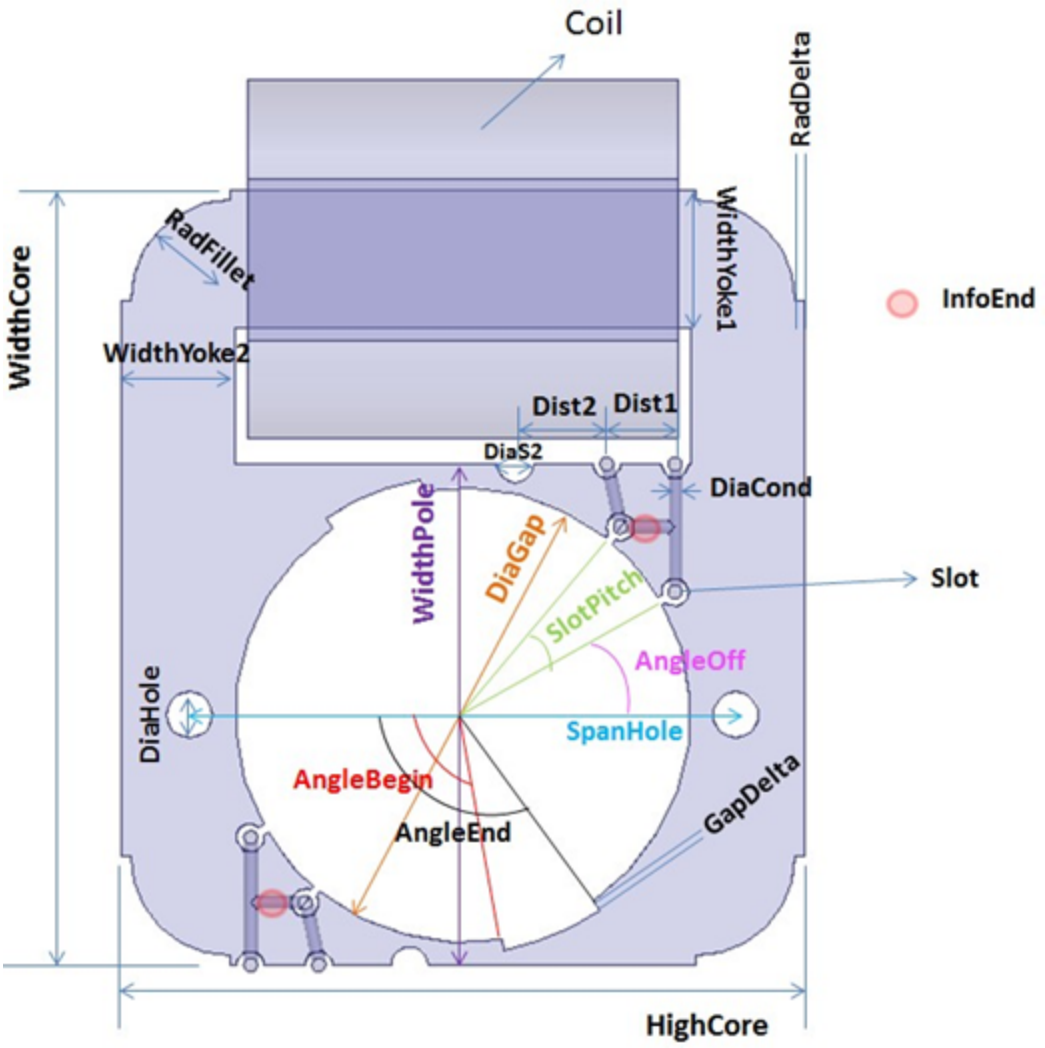
Property	Description
DiaGap	Core diameter on gap side, or inner diameter
HighCore	Core height in d-axis direction
WidthCore	Core width in q-axis direction
WidthPole	WidthPole = DiaGap + 2 * (pole bridge thickness)
Length	Core length in the axial direction

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
WidthYoke1	Width of the winding-core yoke
WidthYoke2	Width of the parallel yokes
Slots	Number of slots per pole (1 or 2)
Hs0	Slot opening height
Bs0	Slot opening width
Bs1	Slot diameter
DiaCond	Diameter of the short-circuit solid conductor
AngleOff	Angle offset in mechanical degrees from the first slot to d-axis
SlotPitch	Slot pitch in mechanical degrees for two slots
Dist1	Outer-slot center-to-center distance when Slots = 2
DiaS2	Additional outer-slot diameter
Dist2	Additional outer-slot distance
InfoEnd	0: Separated end connectors; 1: Jointed end connectors
GapDelta	Maximum gap - minimum gap
AngleBegin	Begin angle of maximum gap in mechanical degrees
AngleEnd	End angle of maximum gap in mechanical degrees
RadFillet	Radius of outer-corner fillet
RadDelta	Step depth in outer-corner fillet
DiaHole	Diameter of holes for shaft bearing covers
SpanHole	Hole span in d-axis direction
LenRegion	Region length
InfoCore	0: Core; 1: All; 2: Coil; 3: Cond1; 4: Cond2; 5: Hole filler; 100: Region
InfoTerm	0: Whole coil; 1: Terminal1; 2: Terminal2

These parameters are demonstrated in the following figure (**InfoCore** set to 1, **Info Term** set to 0):

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note:

- The number of parameters is large in this UDP, so different colors are used to indicate different parameters in the stator bore (area of the circle of **DiaGap**). Each parameter is shown with an arc/line and text in the same color.
- For parameters such as **Length** and parameters related to slots, refer to SlotCore UDP parameters.

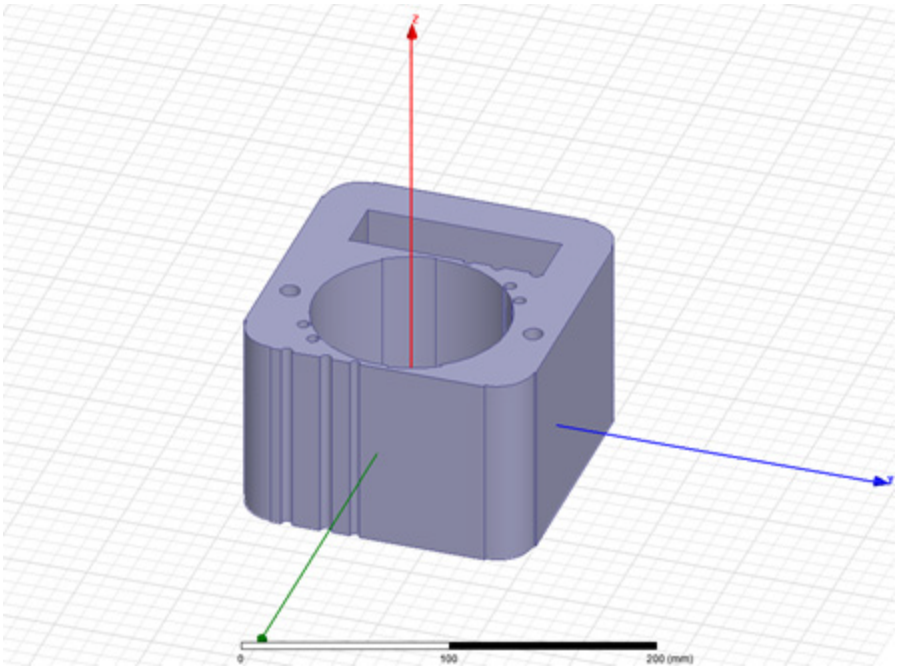
Creating an Outer Shaded Pole Core

This core is used only as an outer core. There is no **DiaYoke** parameter in this UDP, so to create an outer shaded pole core, set both **InfoCore** and **Info Term** values to be 0. You can set the

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

values either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

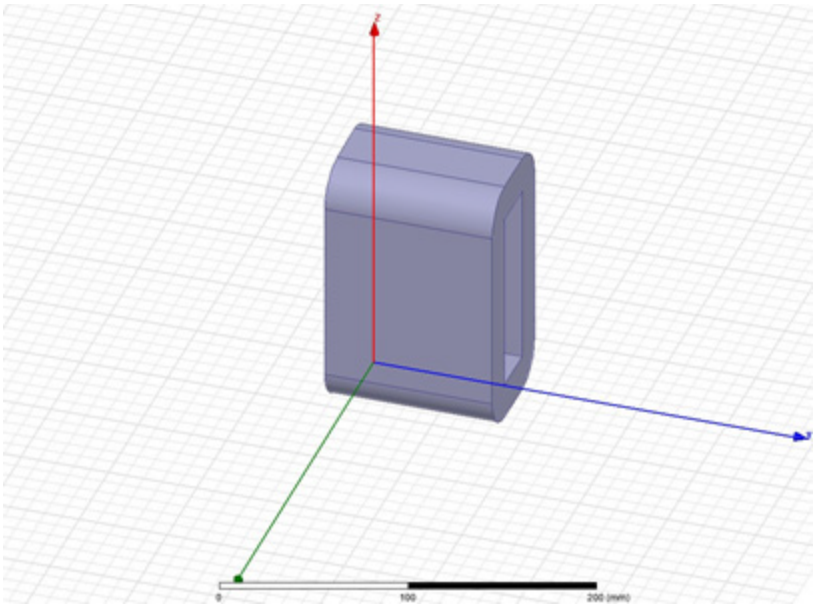
An example of the core for a ShadedPoleCore2 is shown in the following figure:



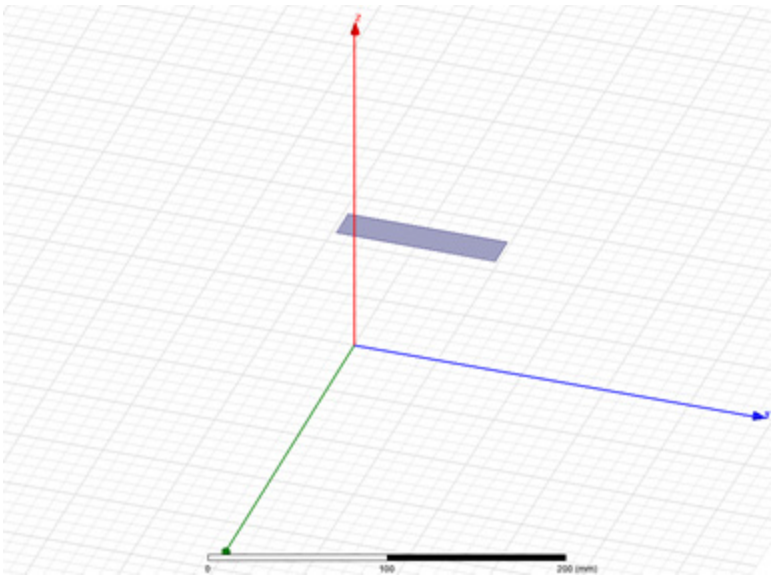
Creating a Coil and its Terminals (Shaded Pole Core)

A coil of a shaded pole core is created by manually setting the property of **InfoCore** to 2 and **Info Term** to 0. The following figure is an example of the coil for a ShadedPoleCore2 UDP:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can create its terminals by setting the property of **InfoCore** to 2 and **Info Term** to 1 or 2 (for terminal1 and terminal2 respectively). The following figure is an example of a terminal:



You can assign the values of these properties either when creating a shaded-pole core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating a Jointed or a Separated Shaded Conductor and Its Terminals

To create a jointed conductor, manually set the parameter **InfoCore** to 3 and **Info Term** to 0. At the same time, set **InfoEnd** to 1 to make the conductor connected. An example of a jointed conductor is shown in the following figure.

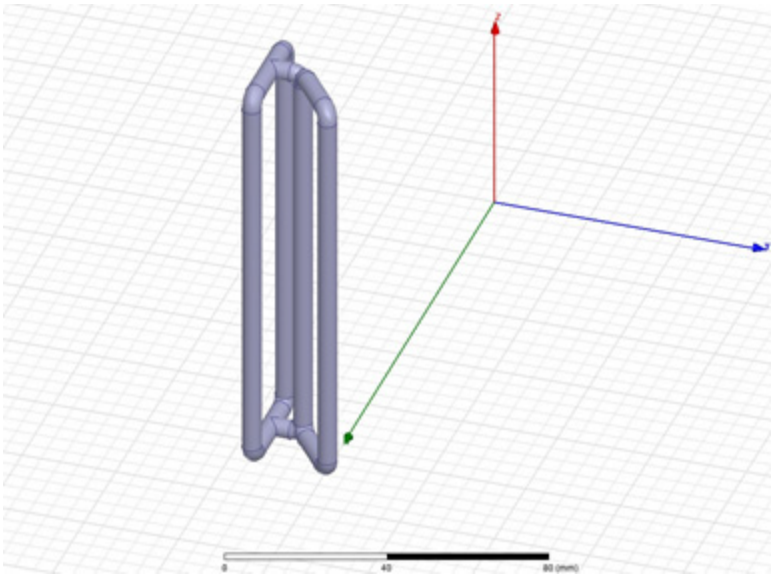


Figure 9-39 A jointed shaded conductor for a ShadedPole Core

To create a separated conductor, change **InfoEnd** to 0. Set **InfoCore** to 3 or 4 to create conductor 1 or 2, respectively. **Info Term** remains 0. The following figure provides an example of the separated conductor.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

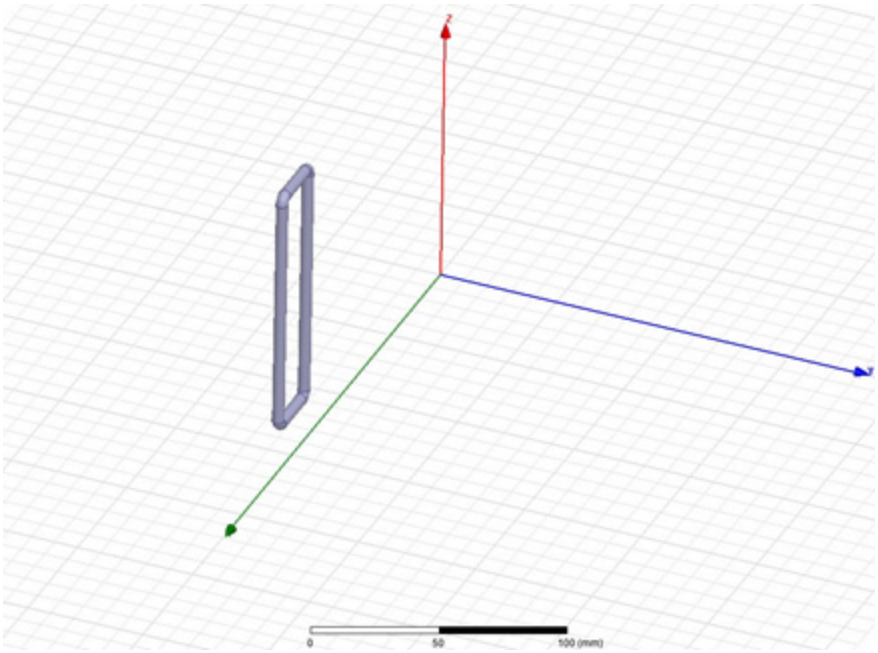

Figure 9-40 A separated shaded conductor for a ShadedPole Core

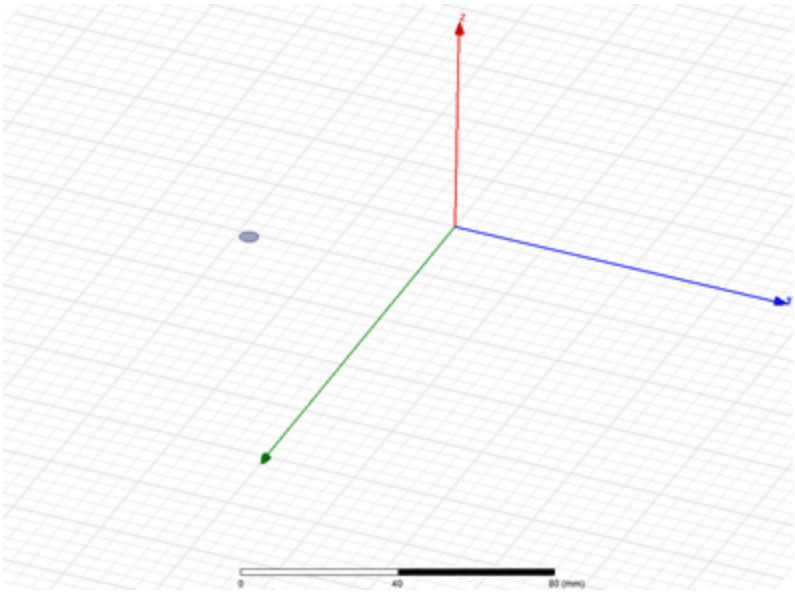
To create terminals of a conductor, change the **Info Term** to 1 or 2 for terminal1 or terminal2, respectively. At the same time, **InfoCore** should be 3 or 4. " A terminal of conductor for a ShadedPole Core" on the next page shows the results of setting the parameters.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9-41 A terminal of conductor for a ShadedPole Core

Creating a Core with Poly Holes

Normally a Shaded Pole Core UDP has only one pair of holes. In order to create a poly-hole Pole Core UDP, you need to use subtraction and move commands. Detailed steps are as follows.

1. Create a core as described in Creating an Outer Shaded-Pole Core.

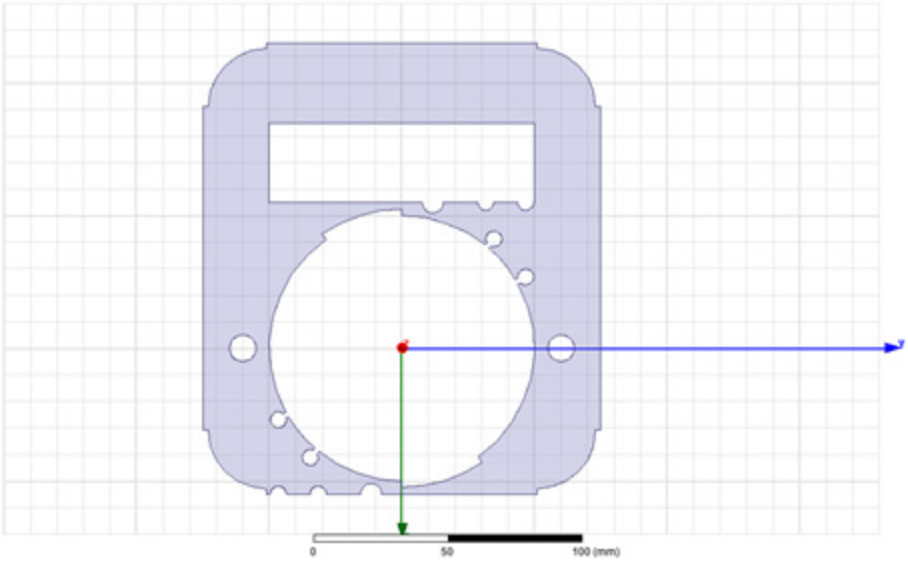


Figure 9-42 Original ShadedPoleCore

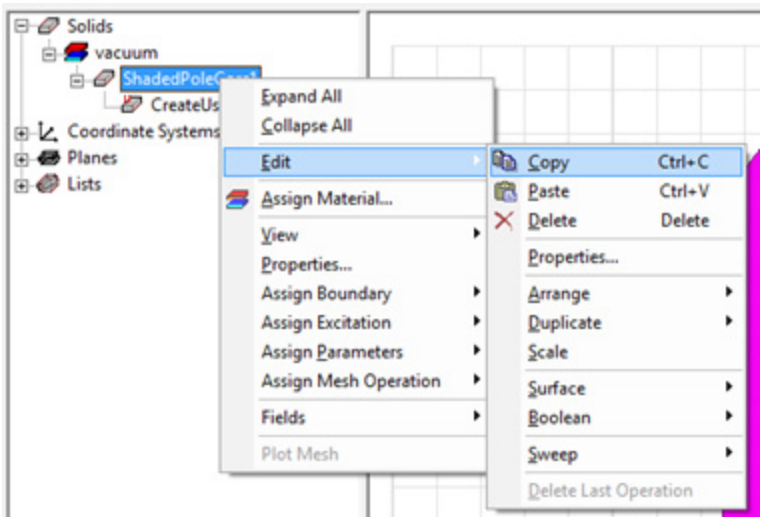
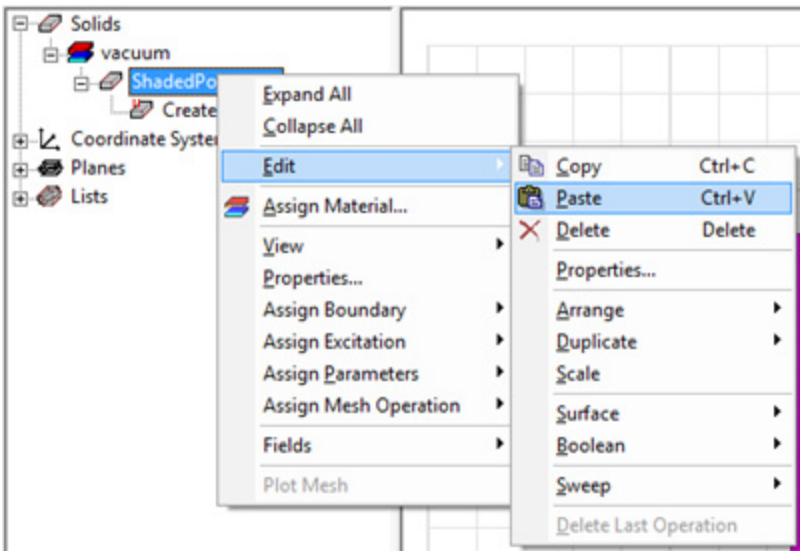
2. Make a copy of the current core.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Select the desired inner core in the history tree, and right-click to choose **Edit** > **Copy**.



4. Then right-click the same object in the history tree to choose **Edit** > **Paste**. This process is shown in the following figure:



5. Change the new object to a Hole filler.

   Click on **CreateUserDefinedPart** of ShadedPoleCore2 object, and set **InfoCore** property to **5** in the pop-up window. The objects in the coordinate system window are shown in the following figure:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

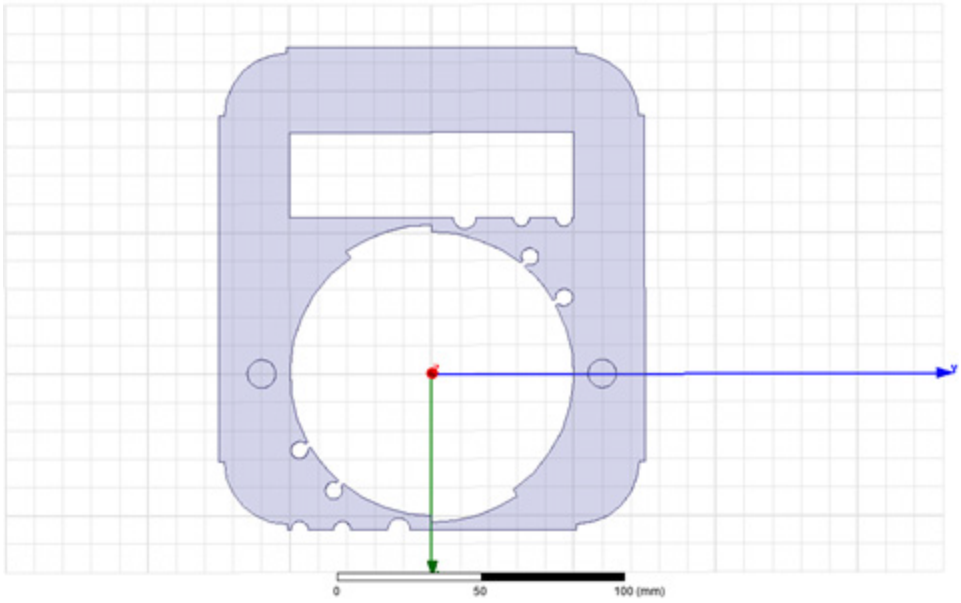


Figure 9-43 Change the InfoCore of the second ShadedPoleCore

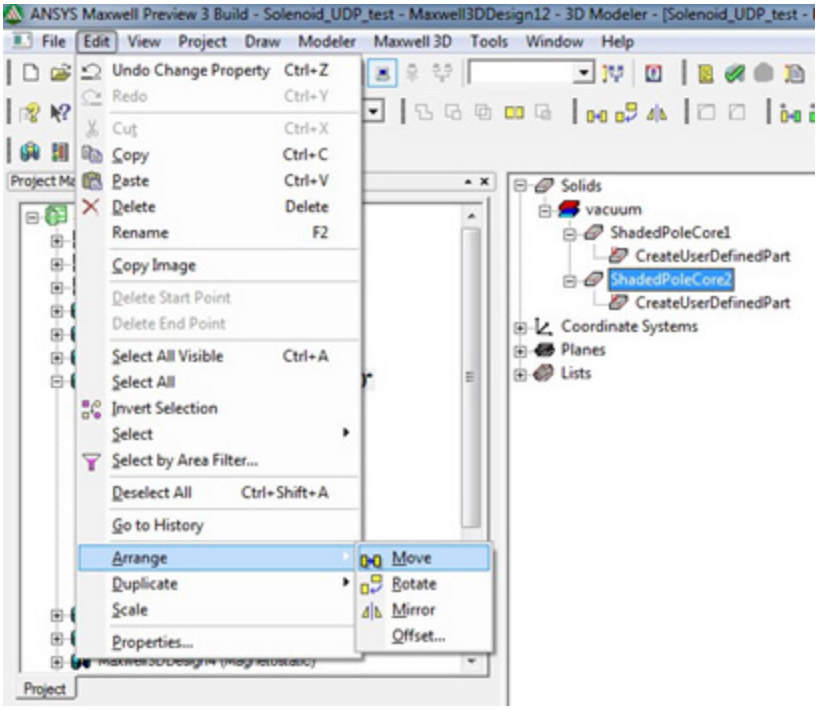
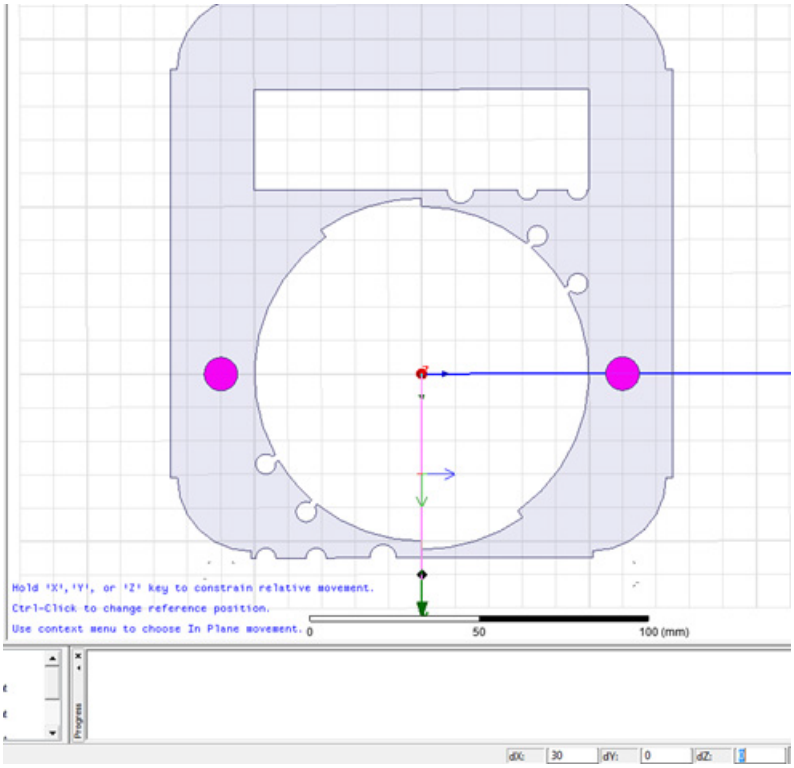
6. Move the hole filler to another position for subtraction.
7. Select the hole filler (ShadedPoleCore2) in the history tree.
8. Click **Edit** > **Arrange** > **Move** from the menu. The modeler switches to move mode and prompts you for a reference point in the status bar.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



9. Enter a reference point by clicking at the origin. Another option is to enter **(0, 0, 0)** in the keyboard entry area of the status bar, and press **Enter**.
10. Enter a target point along the Z-axis by clicking the mouse along the axis. Another option is to enter **(30, 0, 0)** in the keyboard entry area, and press **Enter**, which is shown in the following figure.

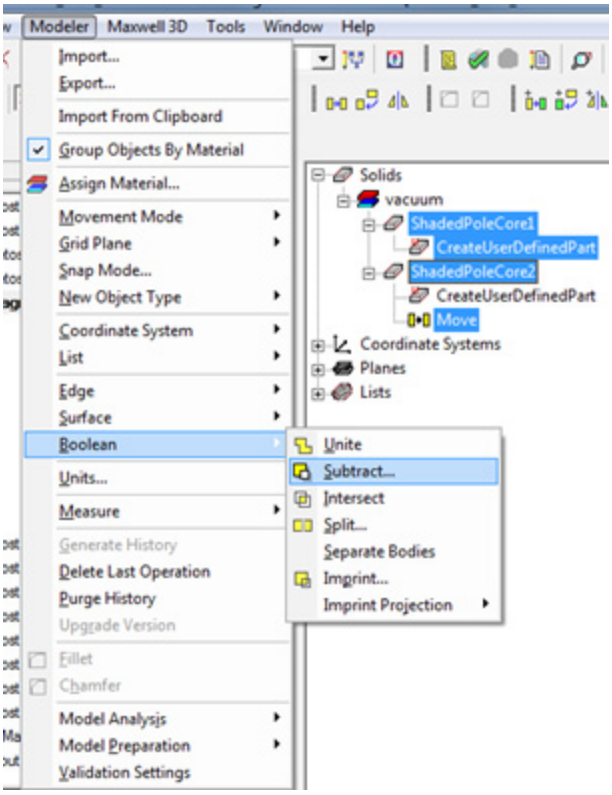
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



11. Choose the core (ShadedPoleCore1) and the hole filler (ShadedPoleCore2) to make a subtraction.
12. Select both the core and hole filler by pressing **Ctrl** on the keyboard.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

13. Click **Modeler** > **Boolean** > **Subtract** to subtract the two selected objects.



14. In the **Subtract** dialog box, put core (ShadedPoleCore1) in the **Blank Parts** and hole filler (ShadedPoleCore2) in **Tool Parts**.

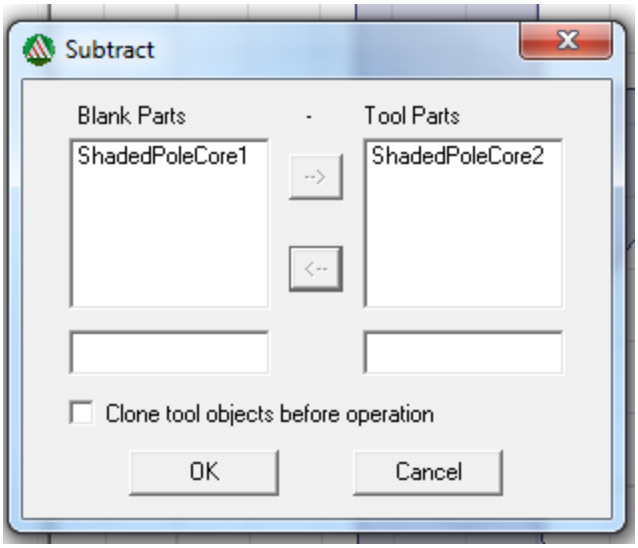


Figure 9-44 Select the Blank Parts and Tool Parts

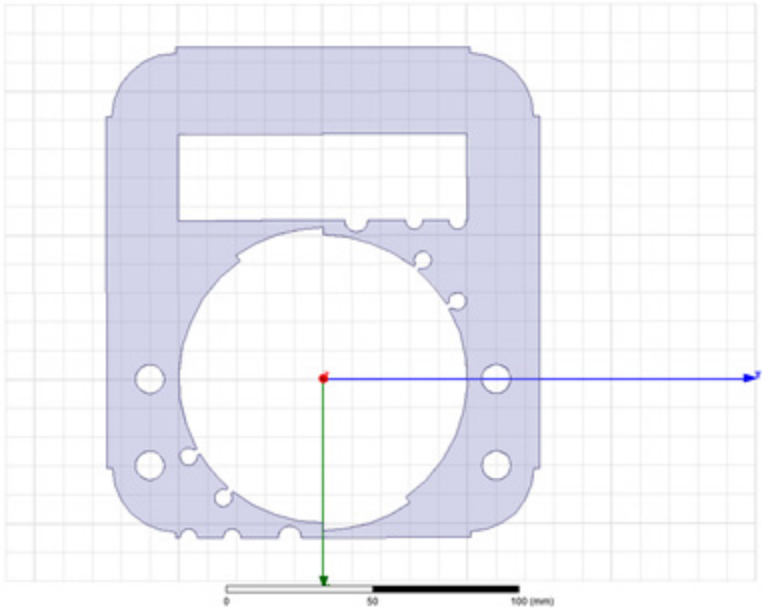
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

15. Click **OK** to finish subtraction. The core look likes the following figure:



Another option is to copy and paste multiple cores, change them to hole fillers and move them to different positions to create a core with more than 2 pairs of holes. The following figure shows a sample hole:

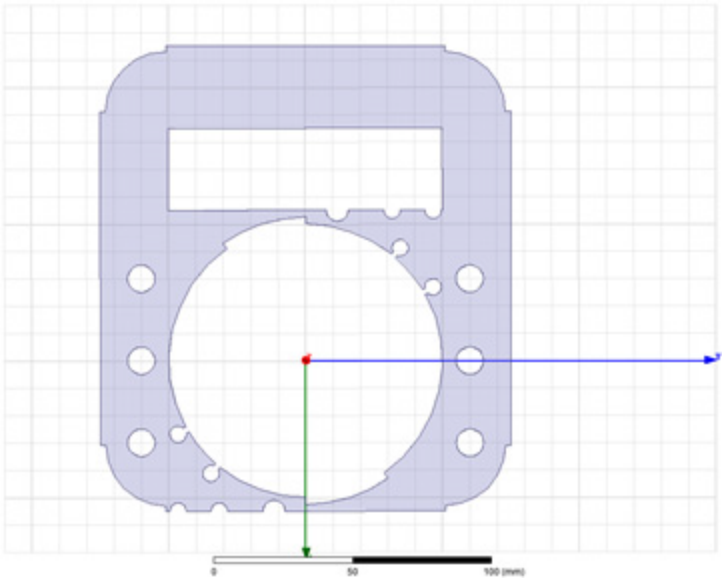


Figure 9-45 ShadedPoleCore with multiple holes

UnivMCore UDP

The UnivMCore UDP is used to create the stator core and the field winding of a universal motor. It can also create a coil terminal for current assignment.

Property	Description
DiaGap	Core diameter on gap side, or inner diameter
DiaYoke	Core diameter on yoke side, or outer diameter
Length	Core length
Skew	Skew angle in core length range
Poles	Number of poles
PoleType	Pole type: 1 to 2
WidthCore	Overall width of a racetrack core
Embrace	Pole embrace (the ratio of pole arc to pole pitch)
Offset	Pole arc offset
WidthPole	Minimum width at pole root
Ty	Yoke thickness
Ts	Shoe-tip thickness
R1	Radius of the screw holes in pole center
R2	Radius of the side fillet arc at pole root
R3	Radius of the side fillet arc center layout circle
R4	Radius of the shoe connecting arc, 0 for auto-design
R5	Inner radius of the screw holes in between two poles
R6	Outer radius of the screw holes in between two poles.
EndExt	Coil one-side end extended length
LenRegion	Region length
InfoCore	0: core; 1: coils; 2: one coil; 3: terminal1; 4: terminal2; 100: region

These parameters are used in the following figures:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

- In figures with both gray and red objects, gray objects are used as references.
- Universal motor core is used as outer core, which means the value of DiaYoke is larger than that of DiaGap.
- Although R4 is drawn in " Parameters in UnivM Core" below, it is not easy to be understood. It is the radius of a circle which is externally tangential to the circle of radius R2 and internally tangential to the circle of diameter of Ts on the same side of a pole. R4 and the two circles that it is tangential to are marked in red. When the value of R4 is 0, the length of it is automatically designed.

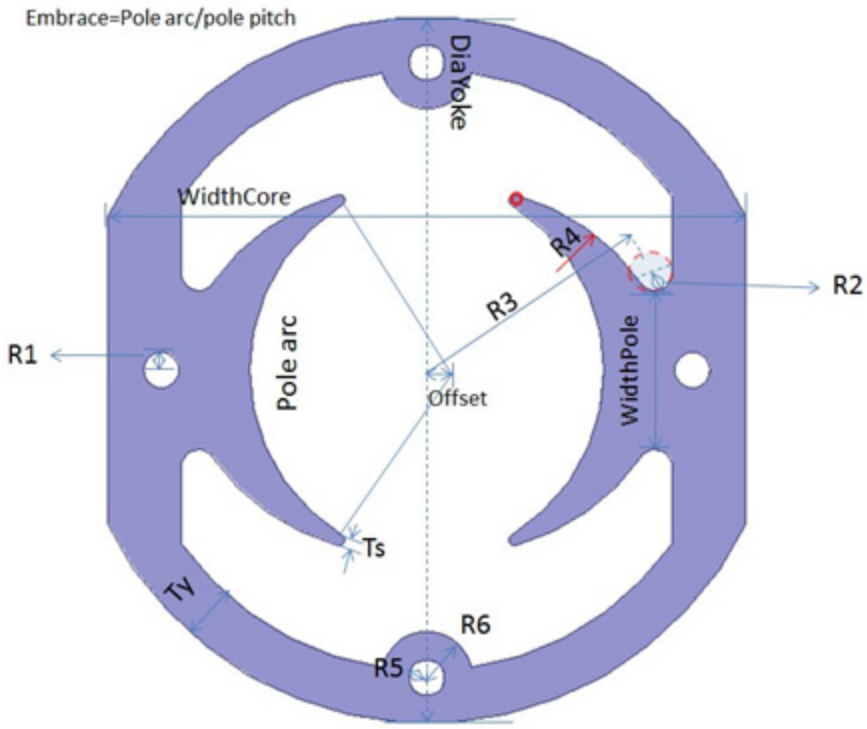

Figure 9-46 Parameters in UnivM Core

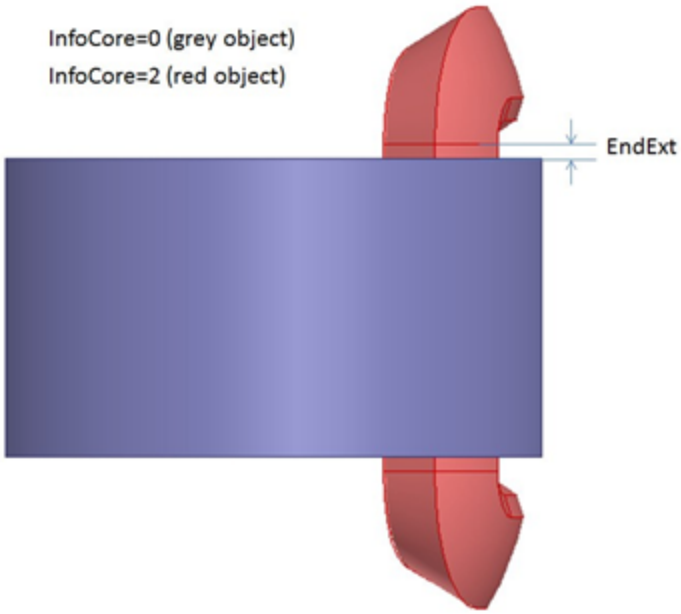

Figure 9-47 Two UnivM Core with different InfoCore value

Creating an Outer Universal Motor Core

This core is used only as an outer core. To create an outer universal motor core, set the value of **DiaYoke** and **DiaGap** as **DiaYoke** > **DiaGap**. Set the **InfoCore** value to 0.

You can set the values either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

The following figure shows the results.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

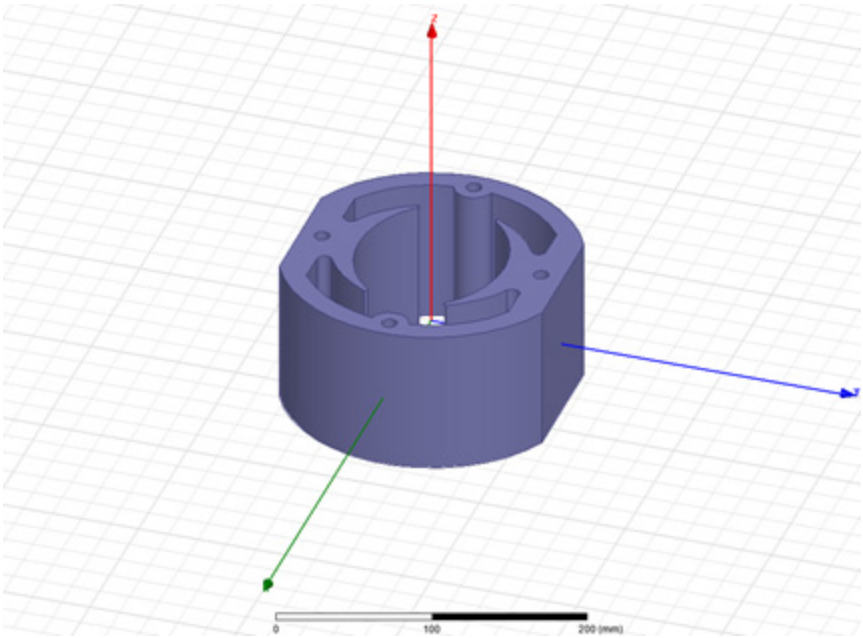

Figure 9-48 Outer universal-motor core

Creating All Coils (UnivMCore)

To create all coils of a universal-motor core, manually set the property of **InfoCoil** to 1.

You can assign the value of this property either when creating a universal-motor core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

The following figure gives an example of all coils for this UDP.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

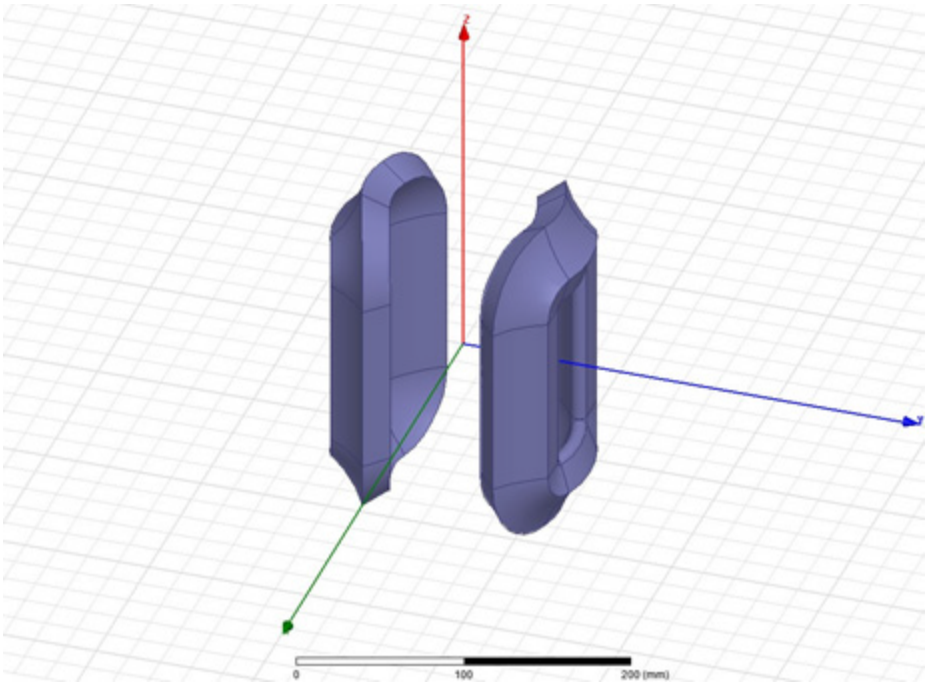

Figure 9-49 Coils of Universal-Motor Core

Creating a Coil and its Terminal (UnivMCore)

To create a coil of a universal-motor core, manually set the property of **InfoCoil** to 2, shown in " Two UnivM Core with different InfoCore value" on page 9-117 as a red object.

To create its terminals, set the property of **InfoCoil** to 3 or 4 (for terminal1 and terminal2 respectively)." A terminal of a coil of Universal-Motor Core" on the next page shows what a terminal looks like.

You can assign the value of this property either when creating a universal-motor core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

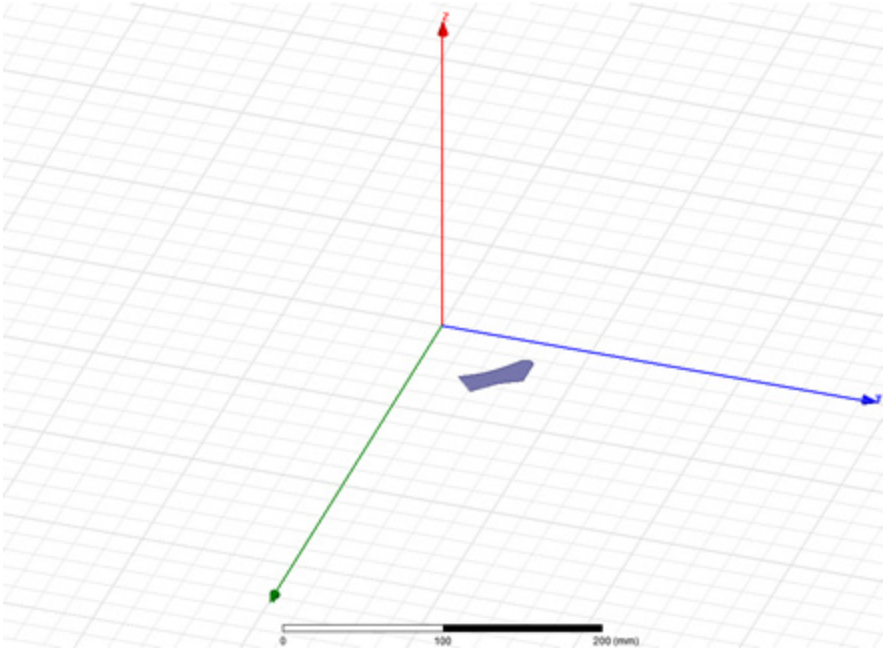

Figure 9-50 A terminal of a coil of Universal-Motor Core

SRMCore UDP

The SRMCore UDP is used to create the stator core, a stator winding, and the rotor core for switched reluctance motors. It can also create a coil terminal for current assignment.

Property	Description
DiaGap	Core diameter on gap side, DiaGap<DiaYoke for outer cores
DiaYoke	Core diameter on yoke side, DiaYoke<DiaGap for inner cores
Length	Core length
Poles	Number of poles
ThkYoke	Yoke thickness
Embrace	Pole embrace (the ratio of pole arc to pole pitch)
Delta	One side pole-edge angle, 0 for parallel pole edges
RFillet	RFillet > 0 for SRM cores with fillet corner; RFillet < 0, its absolute value defines the height of the V-shape slot bottom.
EndExt	Coil one-side end extended length
LenRegion	Region length
InfoCore	0: core; 1: core & coils; 2: coil; 3: terminal1; 4: terminal2; 100: region

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

These parameters are used in the following figures.

" Core & coils of SRM Core (InfoCore set to 1)" on the next page shows the parameter **EndExt**, which is a parameter of a coil. The **InfoCore** value of **EndExt** is 1 (core & coils) to better describe the parameter.

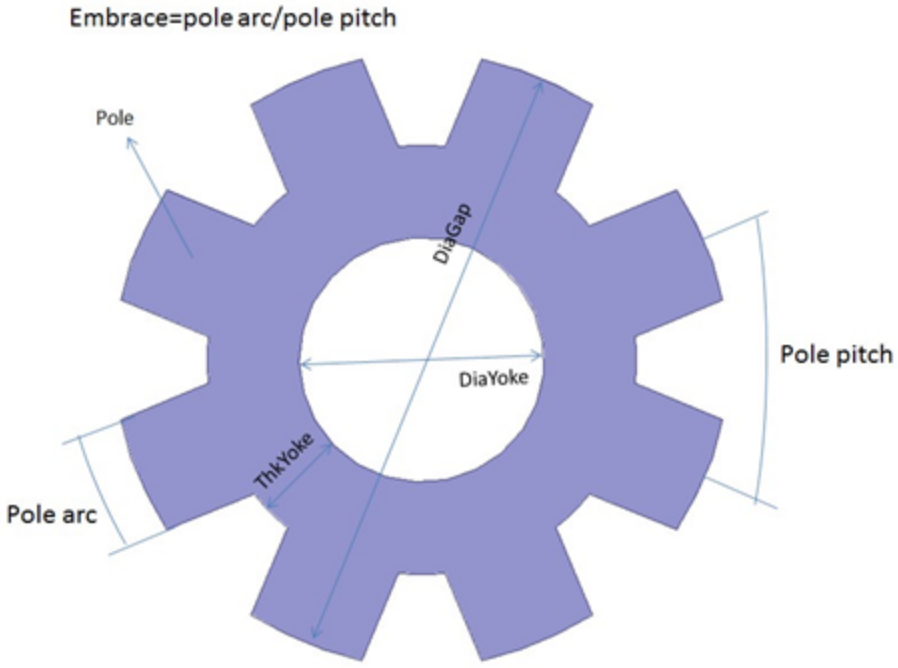

Figure 9-51 Inner core of SRM Core (InfoCore set to 0)

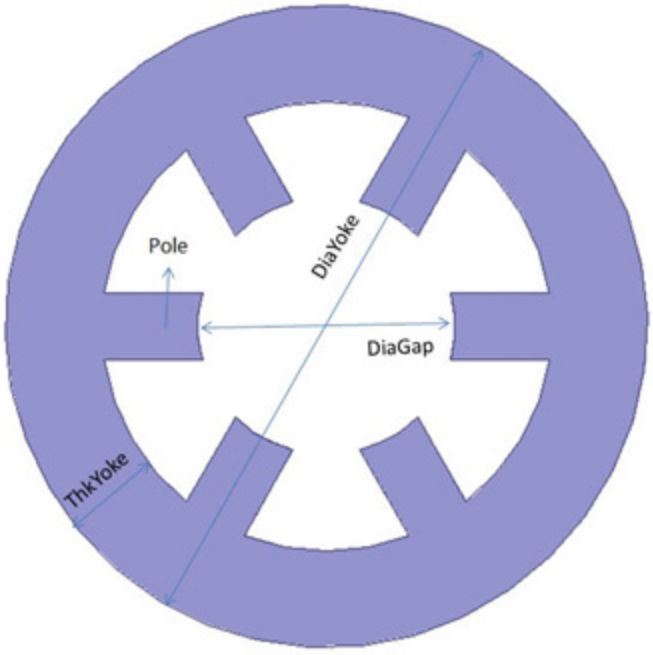

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9-52 Outer core of SRM Core (InfoCore set to 0)

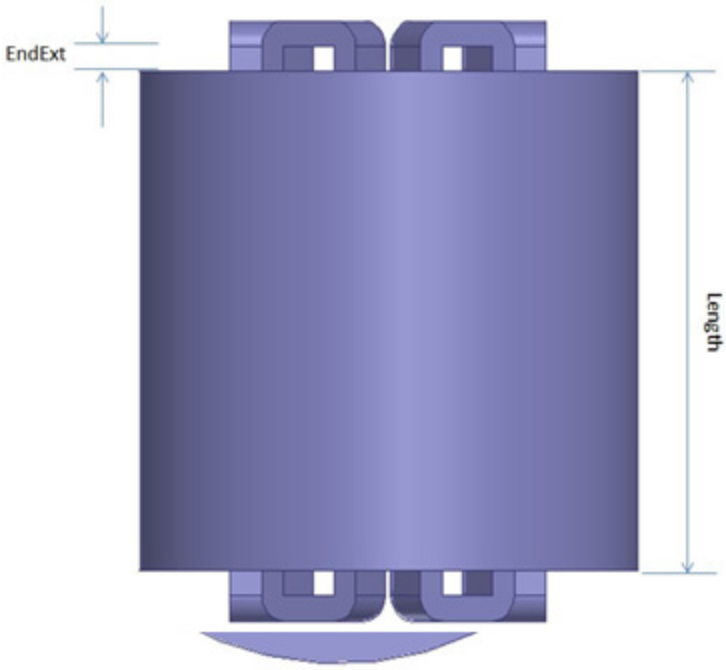

Figure 9-53 Core & coils of SRM Core (InfoCore set to 1)

Creating an Inner or Outer Core for Switched Reluctance Machines

To create an inner core, set the value of **DiaYoke** and **DiaGap** as **DiaYoke** < **DiaGap.** To create an outer core, set the value of **DiaYoke** and **DiaGap** as **DiaGap** < **DiaYoke**. Set the **InfoCore** value to 0.

You can set the values either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Examples of inner SRM core are shown in " Inner core of SRM Core (InfoCore set to 0)" on the previous page and " 3D inner core of SRM Core (InfoCore set to 0)" on the facing page. For outer core, refer to " Outer core of SRM Core (InfoCore set to 0)" above and " 3D outer core of SRM Core (InfoCore set to 0)" on the facing page.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

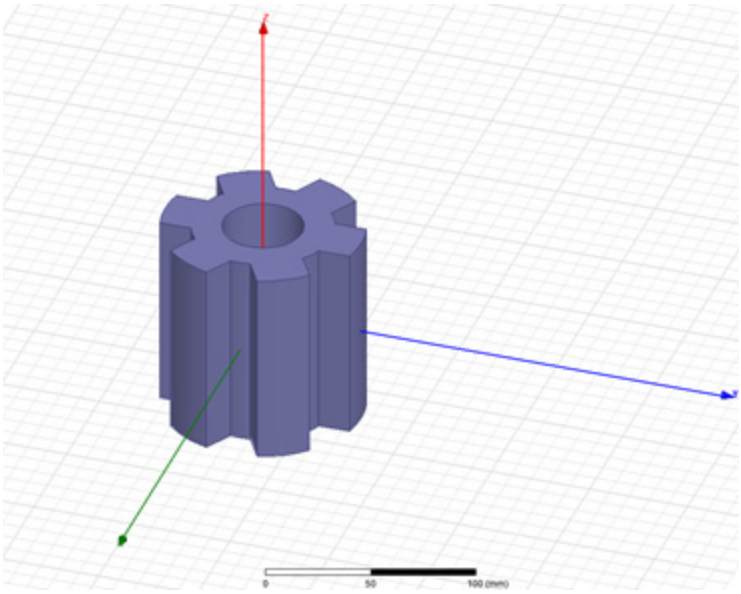

Figure 9-54 3D inner core of SRM Core (InfoCore set to 0)

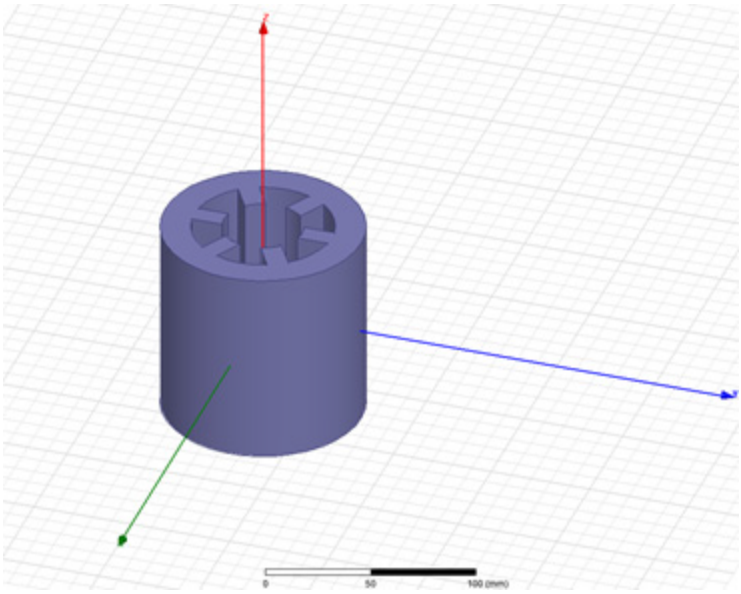

Figure 9-55 3D outer core of SRM Core (InfoCore set to 0)

Creating Core and All Coils (SRMCore)

To create a core and all coils of an SRM Core, manually set the value of **InfoCoil** to 1.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can assign the value of this property either when creating an SRM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Core and all coils can be created only when the core is an outer core (value of **DiaYoke** > **DiaGap**).

Examples of this core are shown in " Core & coils of SRM Core (InfoCore set to 1)" on page 9-122 and " 3D core and coils of SRM Core (InfoCore set to 1)" below.

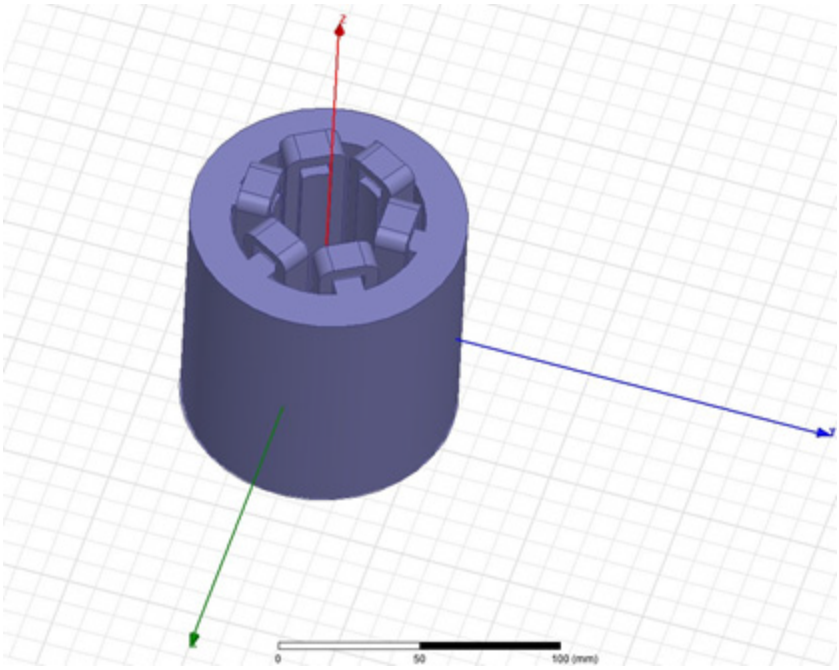

Figure 9-56 3D core and coils of SRM Core (InfoCore set to 1)

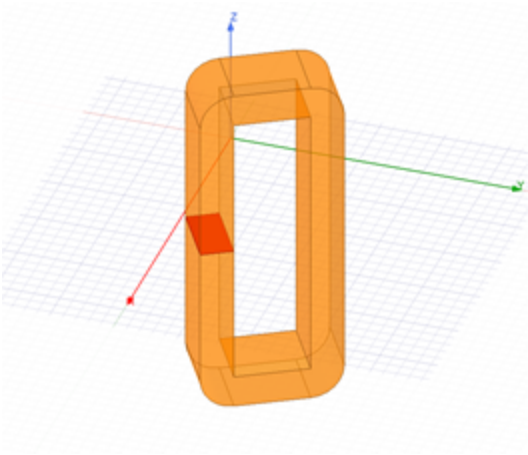
Creating a Coil and its Terminal (SRMCore)

To create a coil of an SRM core, manually set the value of **InfoCoil** to 2. An example is shown below.

To create a terminal, manually sett the property of **InfoCoil** to 3 or 4, for terminal1 or terminal2 respectively. An example is shown by the red sheet in the figure.

You can assign the value of this property either when creating an SRM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

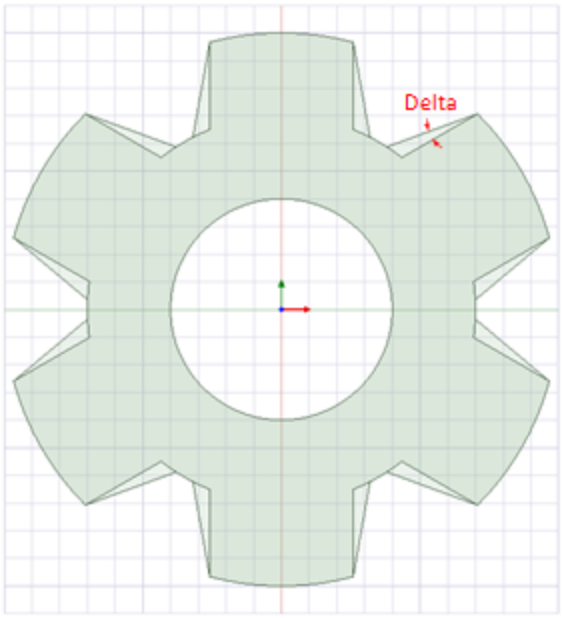
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Single coil and its terminal created by SRMCore

Creating Core with Unparallel Pole Edges (SRMCore)

Parameter **Delta** is introduced to define one side pole-edge angle, as shown below. When **Delta** = 0, the two pole-edge sides are parallel.

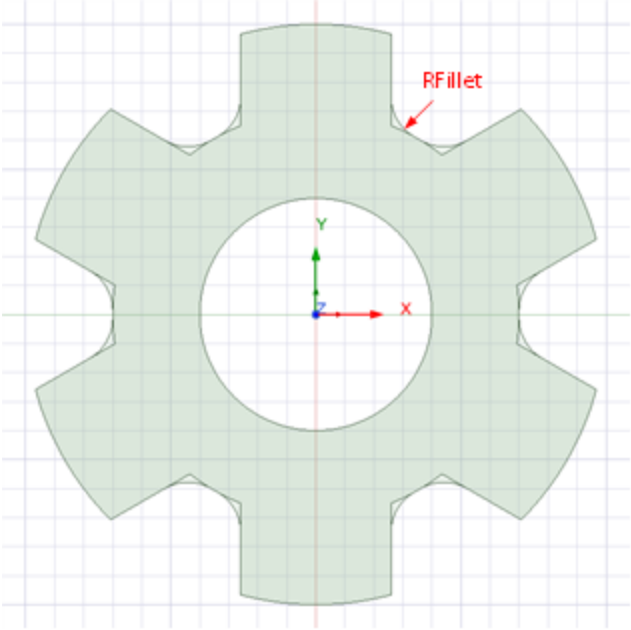


Parameter **Delta** for unparallel pole edges

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

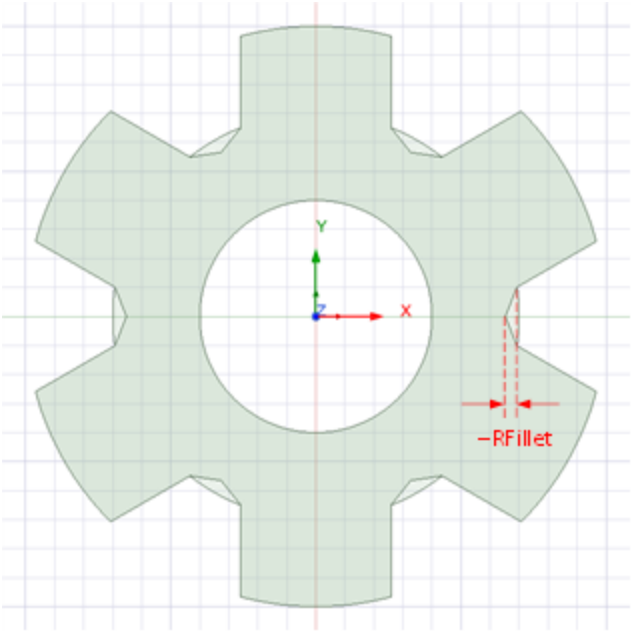
SRM Core with Slot Corner Fillet and V-Shape Bottom

Parameter **RFillet** is introduced to define corner fillet radius. **RFillet** > 0 for SRM cores with fillet corner as shown below.



When parameter **RFillet** < 0, its absolute value defines the height of the V-shape slot bottom as shown below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



SynRMCore UDP

The SynRMCore UDP is used to create the rotor core for synchronous reluctance machines.

Property	Description
DiaGap	Core diameter on gap side, or outer diameter
DiaYoke	Core diameter on yoke side, or inner diameter
Length	Core length
Poles	Number of poles
PoleType	1: ALA; 2: arc; 3: hyperbolic; 4: hyperbolic line
Barriers	Barriers per Pole, for PoleType 2 & 3 only
H	Bridge thickness, for PoleType 2 & 3 only
W	Rib width, for PoleType 2 & 3 only
R	Barrier fillet radius, for PoleType 2 & 3 only
R0	Radius of the bottom barrier arch, for PoleType 2 only
Rb	Barrier bottom minimum radius
Y0	Yoke bottom thickness
B0	Barrier bottom thickness, for PoleType of 2 & 3 only
LenRegion	Region length

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
InfoCore	0: core; 1: one barrier; 100: region

The SynRM UDP supports four pole types:

- **Type 1** – axially laminated core
- **Type 2** – barriers with concentric arcs and lines
- **Type 3** – barriers with hyperbolic curves
- **Type 4** – barriers with hyperbolic polylines

Type 1

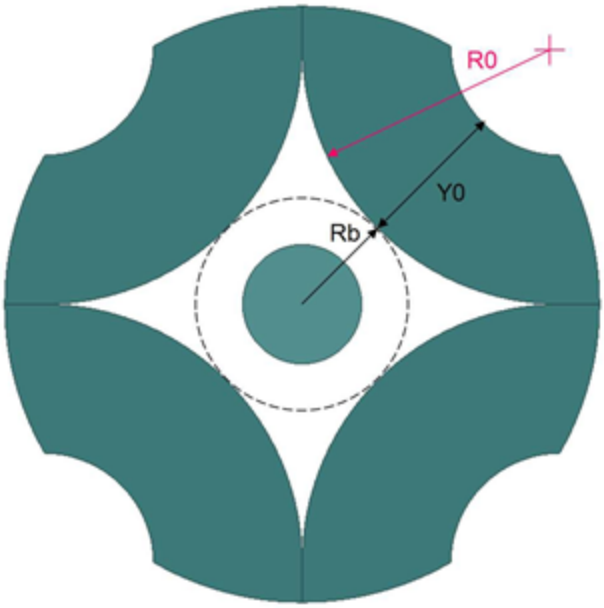
Type 2

Type 3

Type 4

Parameters for SynRM core with PoleType = 1

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In the figure, *R0* is a derived parameter, as given below:

$$R0 = Rb\sin\theta/(1 - \sin\theta)$$

where $\theta = \pi/p$, and p, the number of poles, should be ≥ 4.

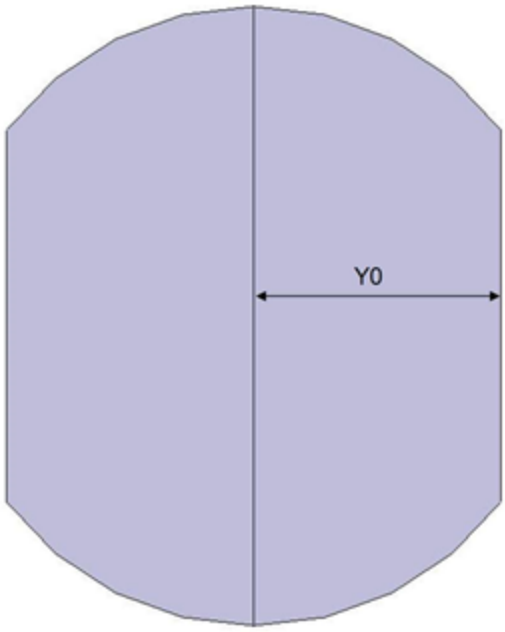
The center point (x, y) of the *R0* circle is:

$$x = (Rb + R0)\cos\theta$$

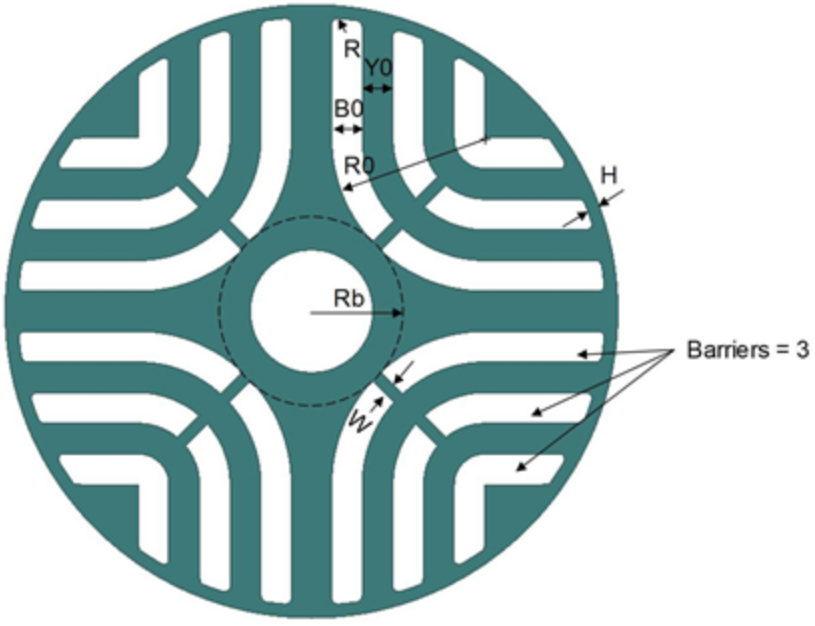
$$y = (Rb + R0)\sin\theta$$

Below is a two-pole SynRM core with PoleType = 1.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

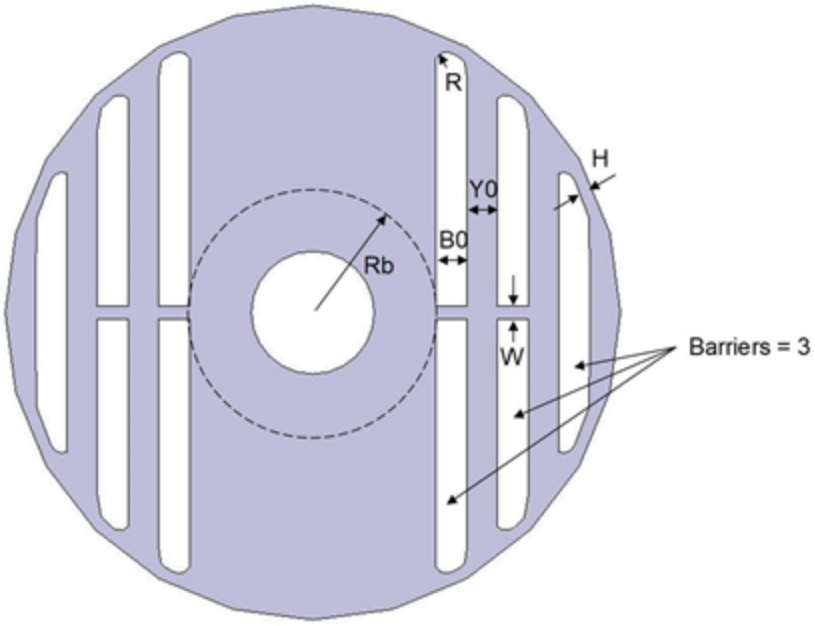


Parameters for SynRM core with PoleType = 2

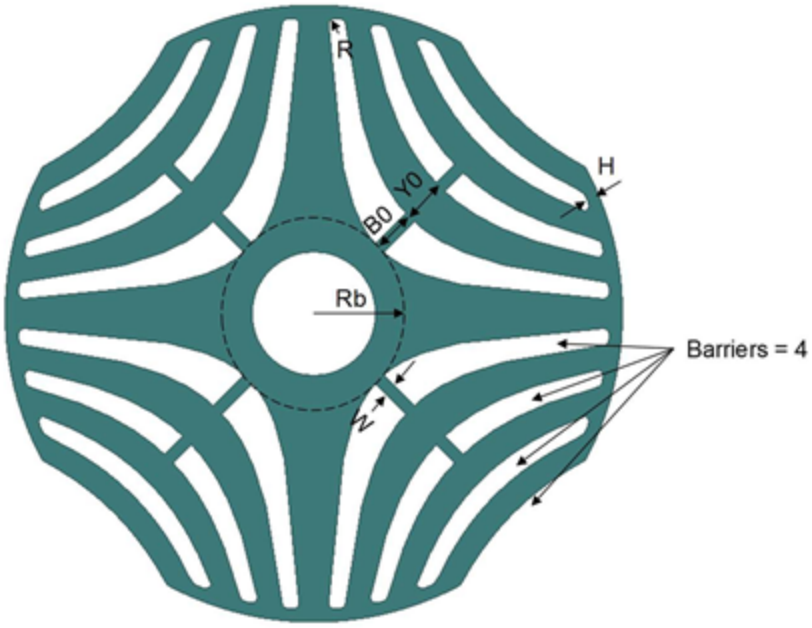


Below is a two-pole SynRM core with PoleType = 2

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Parameters for SynRM core with PoleType = 3



The main edges of barriers for Type 3 are hyperbolic curves defined by

$r^2 \sin(pp \bullet \theta) = R_m^2$

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$x = r \bullet \cos\theta$

$y = r \bullet \sin\theta$

where *pp* is the number of pole pairs, $\pi/pp > \theta > 0$, and R_m is the minimum radius of a hyperbolic line. For different R_m values, you will get different hyperbolic curves.

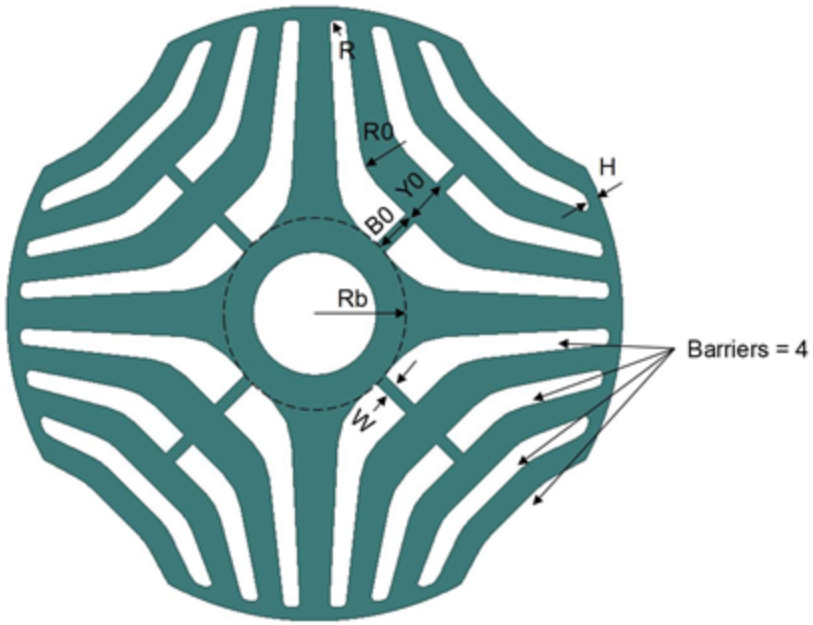
The first barrier is created based on the following two hyperbolic curves:

- for the bottom hyperbolic curve, *Rm2* = *Rb*
- for the top hyperbolic curve, *Rm1* = *Rb* +*B0*

The second and all other barriers are created based on a constant minimum barrier width and minimum tooth width at maximum limit radius which is derived from outer radius minus the value of bridge thickness parameter H.

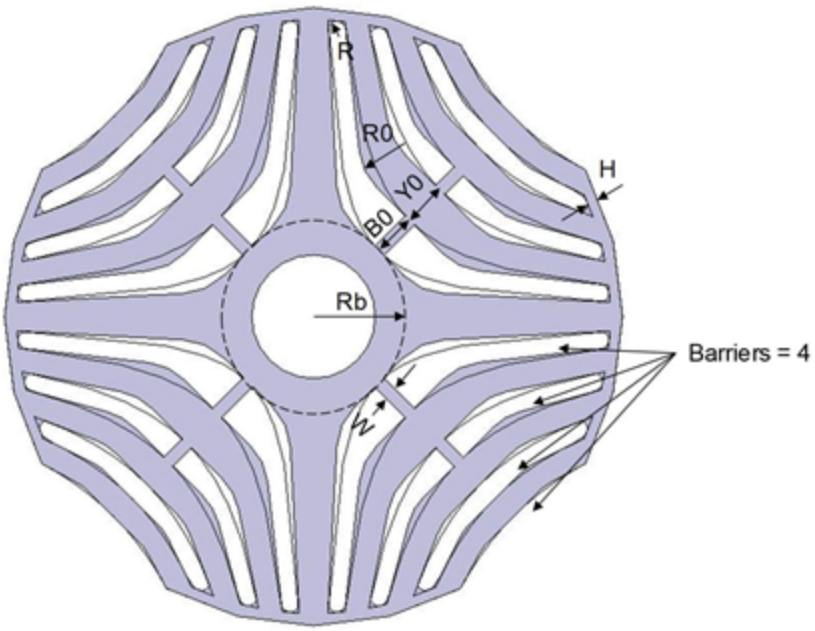
The minimum barrier width and minimum tooth width can be derived from *B0* and *Y0*, respectively. If the top and bottom hyperbolic curves are defined by *Rm1* and *Rm2*, respectively, and let *r* to be the maximum limit radius, you can obtain two points (*x1*, *y1*) and (*x2*, *y2*) at the maximum limit circle intersected with the top and bottom hyperbolic curves, respectively, based on the above hyperbolic curve equation. Note that the distance between these two intersection points is not the minimum width because the connection line is not perpendicular to the center hyperbolic curve. The angle between the connection line and normal line is the angle between the *r* line and the tangent line which can be computed from *dy*/*dx* and θ of the center hyperbolic curve at the maximum limit radius.

Parameters for SynRM core with PoleType = 4



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The main edges of barriers for Type 4 are hyperbolic polylines. A hyperbolic polyline is derived from a hyperbolic curve. It consists of one bottom line (tangent to the bottom points of the hyperbolic curve), two side lines (tangent to the point on the hyperbolic curve at the maximum limit radius), and fillet arcs defined *R0*. The value of fillet radius *R0* is the same for all hyperbolic polylines. All parameters for hyperbolic curves to derive hyperbolic polylines are defined in the same way as those for pole Type 3. The following figure shows how barriers of Type 4 are derived from those of Type 3.



Note: Two-pole SynRM cores for Types 3 and 4 will be the same as those of Type 2.

Creating an Inner Core for a Synchronous Reluctance Machine

To create an inner core, set the value of **DiaYoke** and **DiaGap** as **DiaYoke** < **DiaGap**. You can set the value either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

" 3D SynRM Core" on the next page gives an example of an inner core for SynRM.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

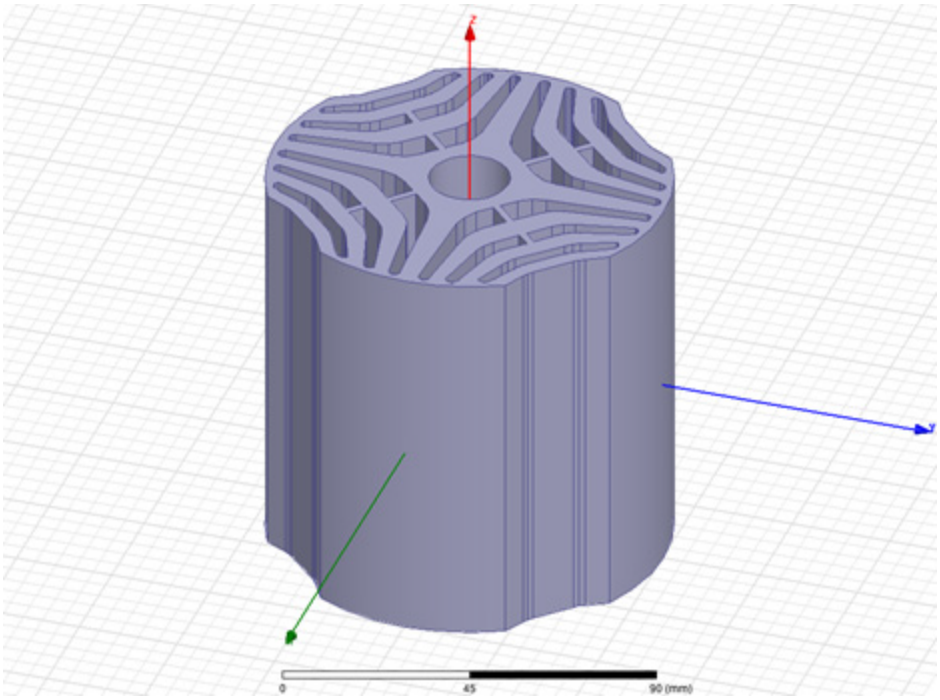


Figure 9-57 3D SynRM Core

Creating a SynRMCore with Different Barriers

You can create a SynRMCore with different barriers through several steps, as follows.

1. Create a SynRMCore as shown in Creating an Inner Core for a Synchronous Reluctance Machine.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Change the value of Barriers to 1. The result is shown in the following figure.

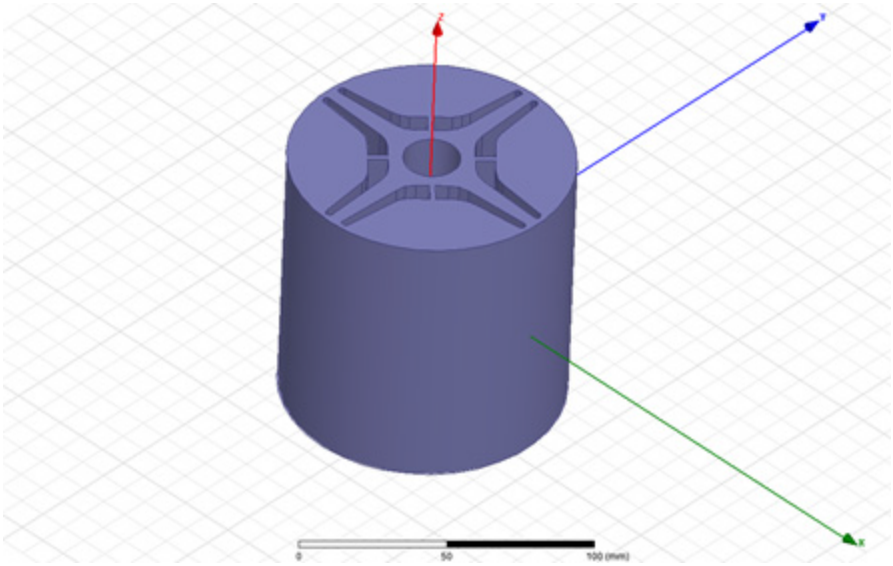

Figure 9-58 A SynRMCore with one barrier

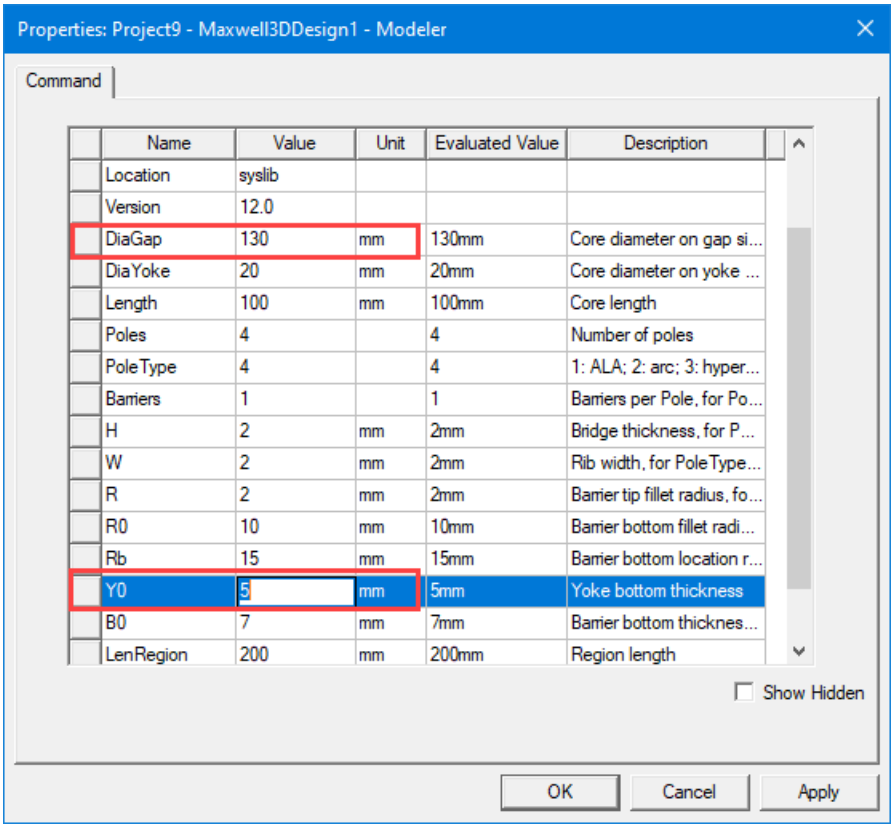
3. Change the value of **DiaGap** to be larger and make the value of **Y0** smaller to make enough space for other barriers. You can modify these values by clicking on **CreateUserDefinedPart** in the history tree under the SynRMCore, as shown in the following figure.

   As an example, the values of **DiaGap** and **Y0** are changed to 130 and 5, respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

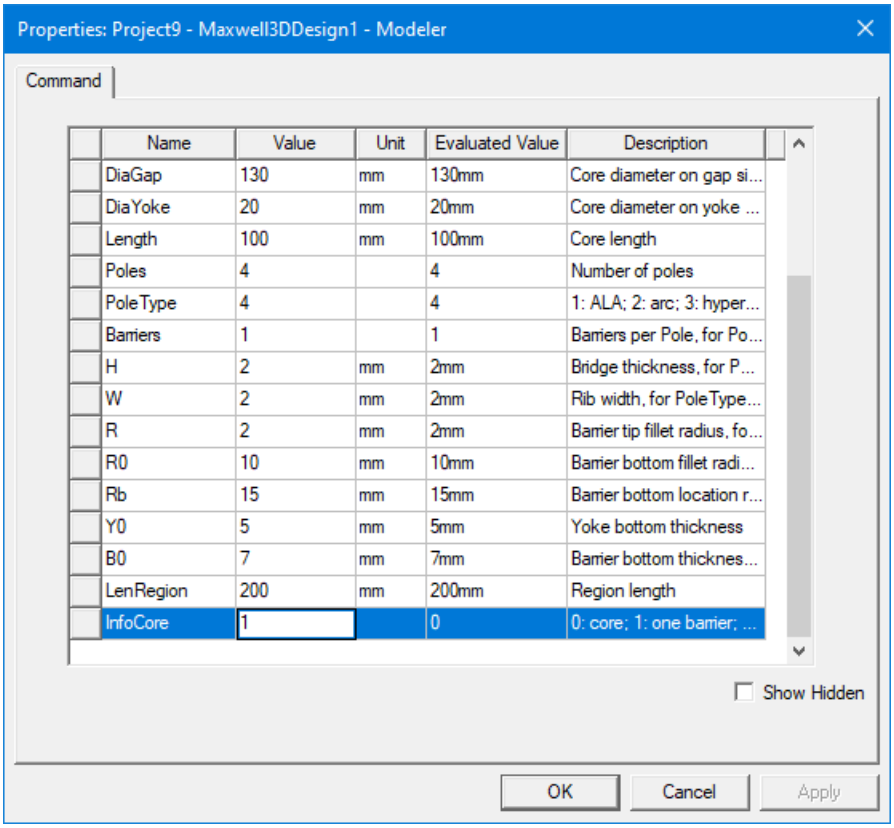


4. Make a copy (or multiple copies if more than 1 barrier is needed) of the current SynRMCore object.

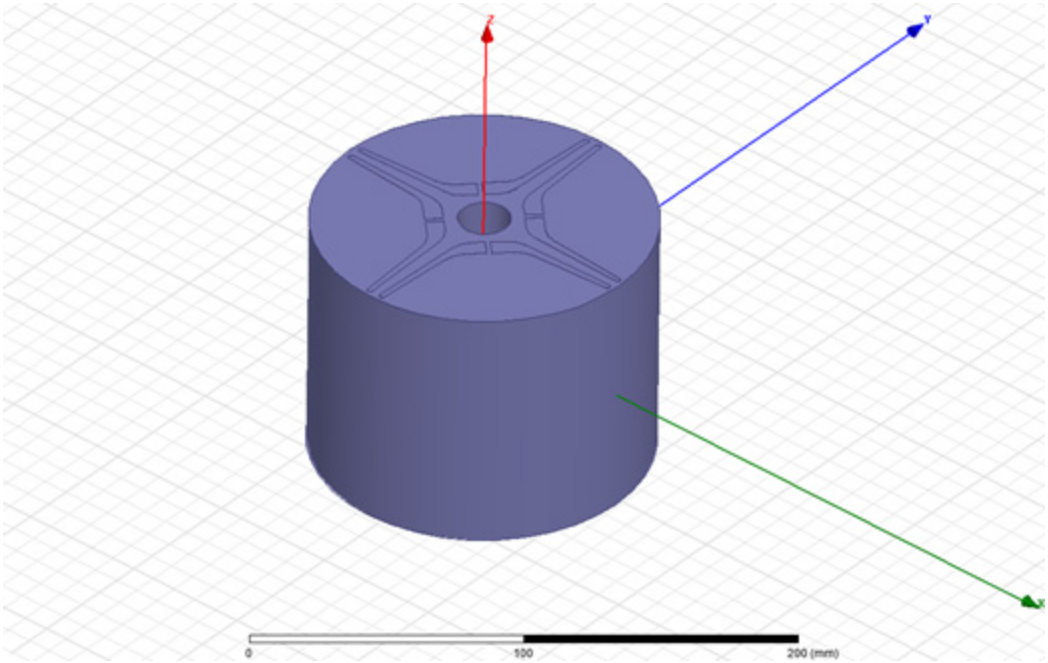
   In the history tree, click **SynRMCore1**, press **Ctrl**+**C**, and then press **Ctrl**+**V** to duplicate the SynRMCore.

5. Change the value of **InfoCore** of SynRMCore2 to 1 to create a barrier.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The result of this change is shown in the following figure.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9-59 Result of InfoCore of SynRMCore2 being changed

6. Change the value of **Rb** of SynRMCore2 (barrier) to make it larger, and thus make the barrier away from the center of the core.

   As an example, the value of **Rb** of SynRMCore2 is changed from 15 to 25 by clicking on **CreateUserDefinedPart** in the history tree under the SynRMCore2, as shown in the following figure.

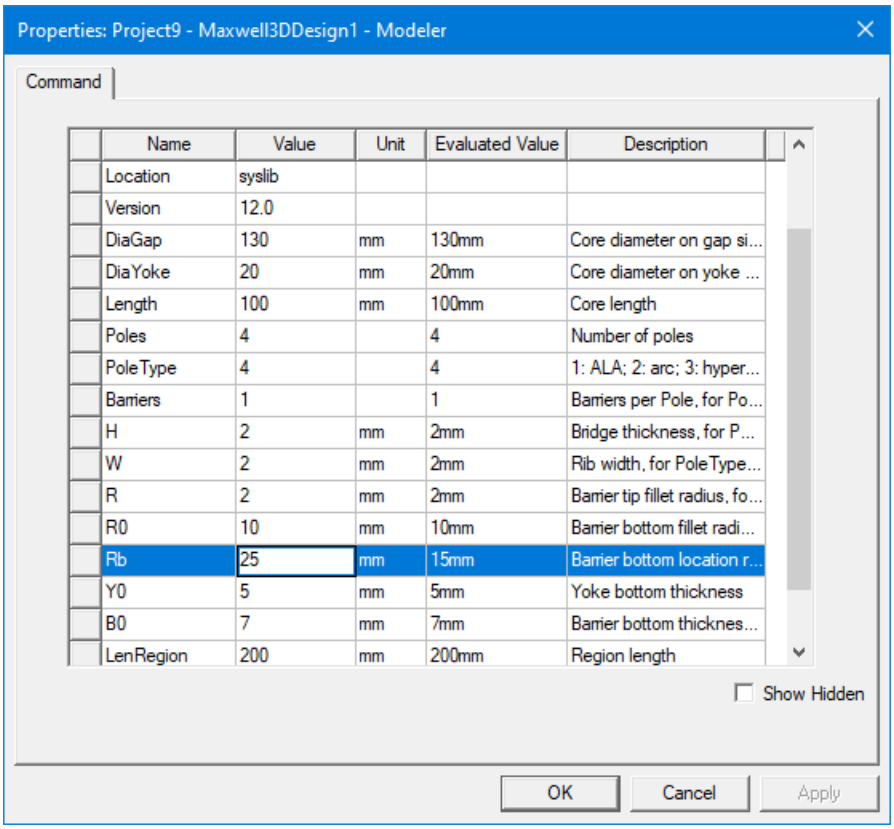


Figure 9-60 Changing the value of Rb of SynRMCore2

   Another option is to change other values of SynRMCore2 (barrier) according to different needs, such as set the value of **W** to 0.

7. Then rotate the coordinate system. Objects in it should look like those in the following figure:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

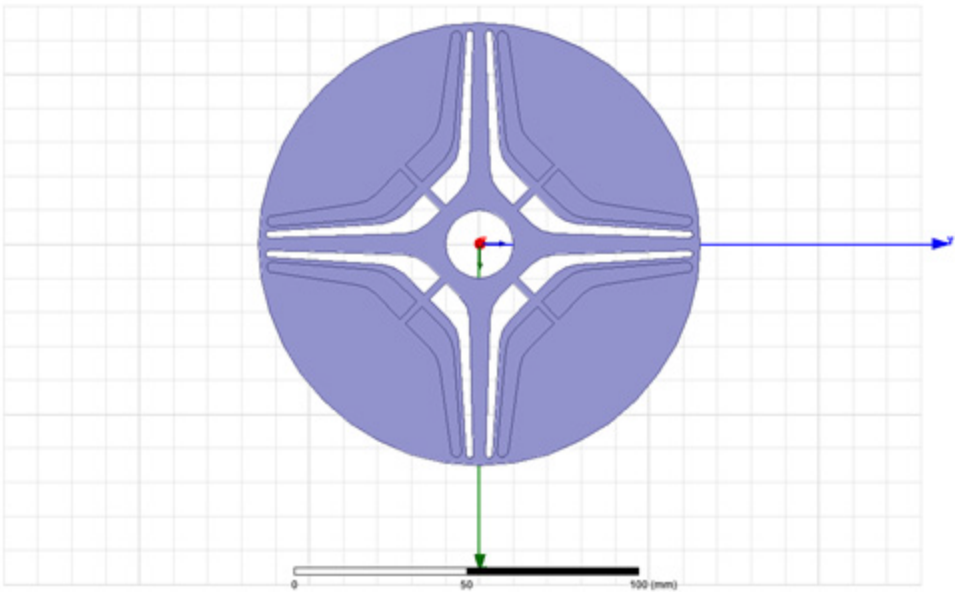

Figure 9-61 Before subtraction of two objects

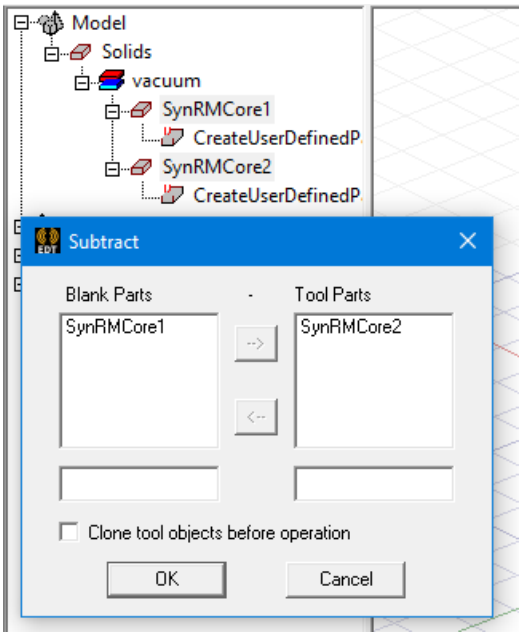
8. Make a subtraction for two objects:

   Choose both objects simultaneously by pressing **Ctrl** and clicking on two objects in the history tree on the screen.

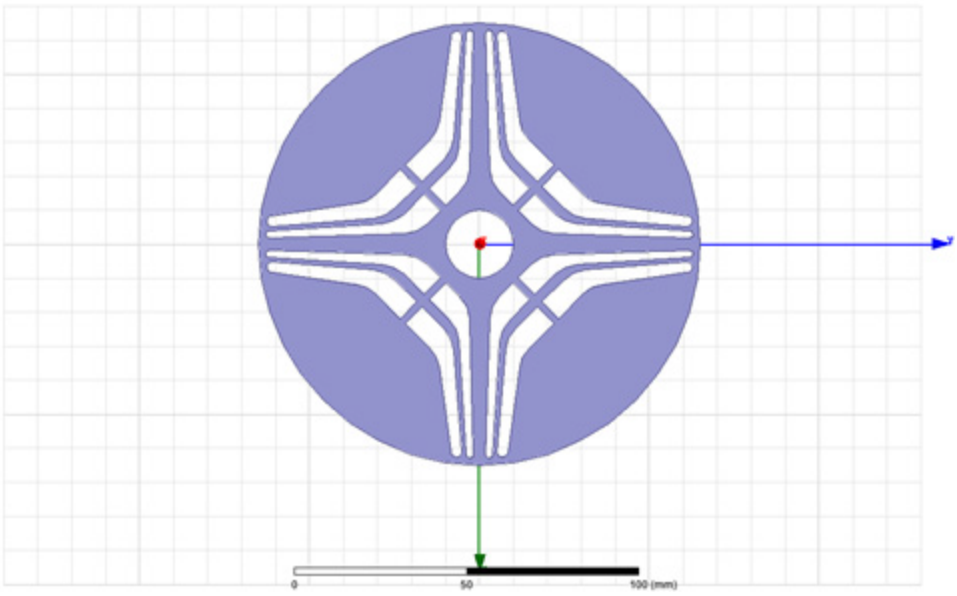
   Then click **Modeler** > **Boolean** > **Subtract** to do the subtraction.

   The SynRMCore1 should be in **Blank Parts** whereas SynRMCore2 is in **Tool Parts**, as shown in the following figure:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



9. Click **OK** to finish subtraction. A SynRMCore with different barriers is shown in the following figure:



To make the barriers look different, you can change the parameters of barriers like **W** and **B0**. Also, repeating the processes can make multiple barriers.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ClawPoleCore UDP

The ClawPoleCore UDP is used to create the claw-pole rotor core, a field winding and/or a PM for claw-pole alternators. It can also create a coil terminal for current assignment.

Property	Description
DiaGap	Core diameter on gap side, DiaGap<DiaShaft for outer cores.
DiaShaft	Core diameter on shaft side, DiaShaft<DiaGap for inner cores.
Length	Core length.
Poles	Number of poles.
EmbraceTip	Embrace of pole tip.
EmbraceRoot	Embrace of pole root.
ThickTip	Thickness of pole tip.
ThickRoot	Thickness of pole root.
ThickShoe	Thickness of side shoes.
DepthSlot	Depth of slot between two poles.
ThickYoke	Thickness of yoke.
LengthPole	Length of pole from tip to tip.
LengthMag	Length of magnet or the second air-gap.
SegAngle	Deviation angle for skewed pole sides (1~10, <1 for true surface).
LenRegion	Region length.
InfoCore	0: core; 1: core & coil; 2: coil; 3: magnet; 4: terminal; 100: region.

These parameters are used in the following figures. " Transparent Claw Pole Core (InfoCore set to 0)" on the next page is in transparent to show parameters **EmbraceTip** and **EmbraceRoot** which otherwise are hard to show. For **LengthMag** parameter, refer to Creating a Magnet (Claw Pole) .

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

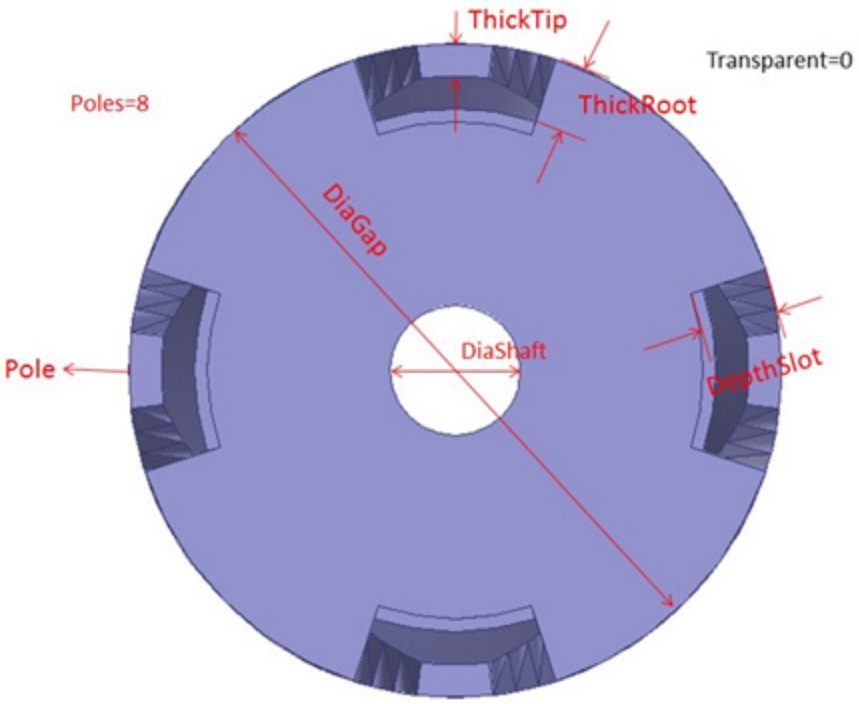


Figure 9-62 Claw Pole Core (InfoCore set to 0)

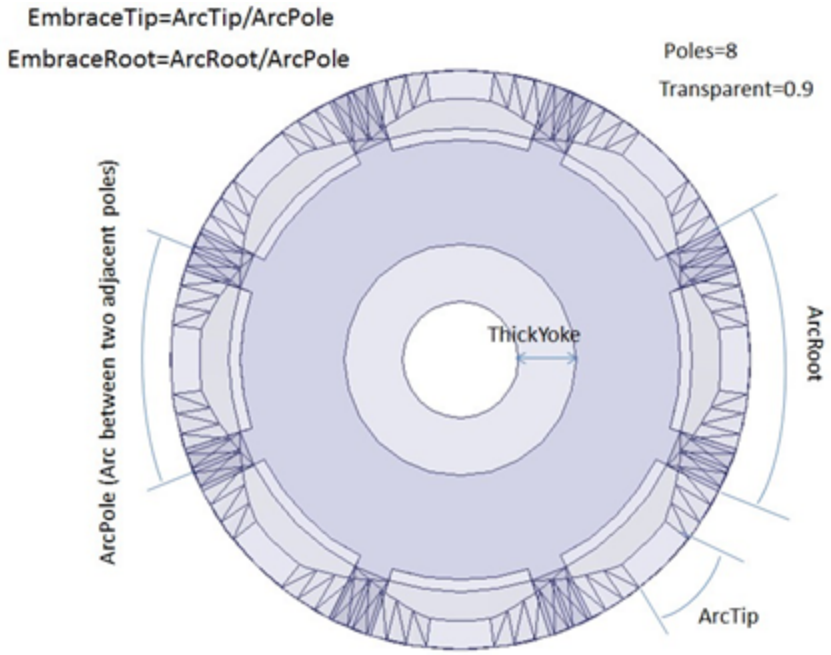

Figure 9-63 Transparent Claw Pole Core (InfoCore set to 0)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

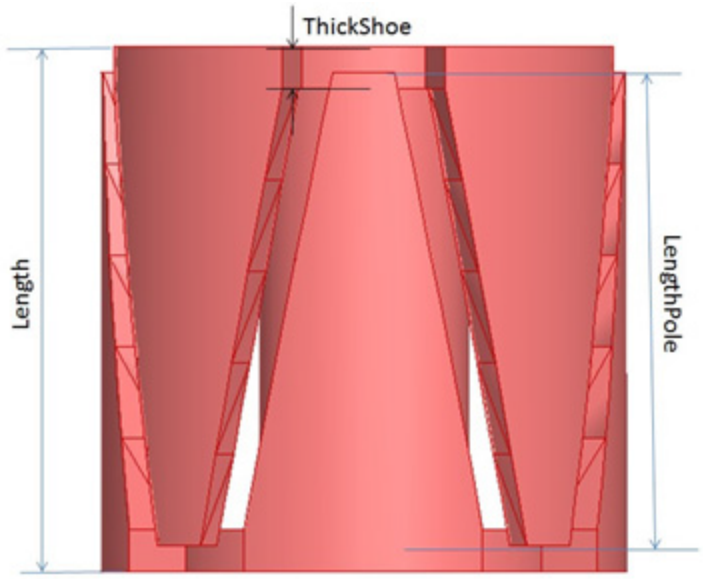

Figure 9-64 3D Claw Pole Core (InfoCore set to 0)

Creating an Inner Claw Pole Core

Set the value of **DiaShaft** and **DiaGap** as **DiaShaft** < **DiaGap** to create an inner claw pole core. You can set the value either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value 0.

Examples of inner claw-pole core are shown in Figure 1-1, Figure 1-2, and Figure 1-3.

Creating a Coil and its Terminal (Claw Pole)

You can create a coil of a claw pole core manually by setting the value of **InfoCoil** to 2. An example is shown in" Coil of a claw-pole core" on the next page.

You can create a terminal of a claw pole core manually by setting the value of **InfoCoil** to 4. " A terminal of coil in this claw-pole core" on the next page gives an example of this terminal.

You can assign the value of this property either when creating a claw-pole core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

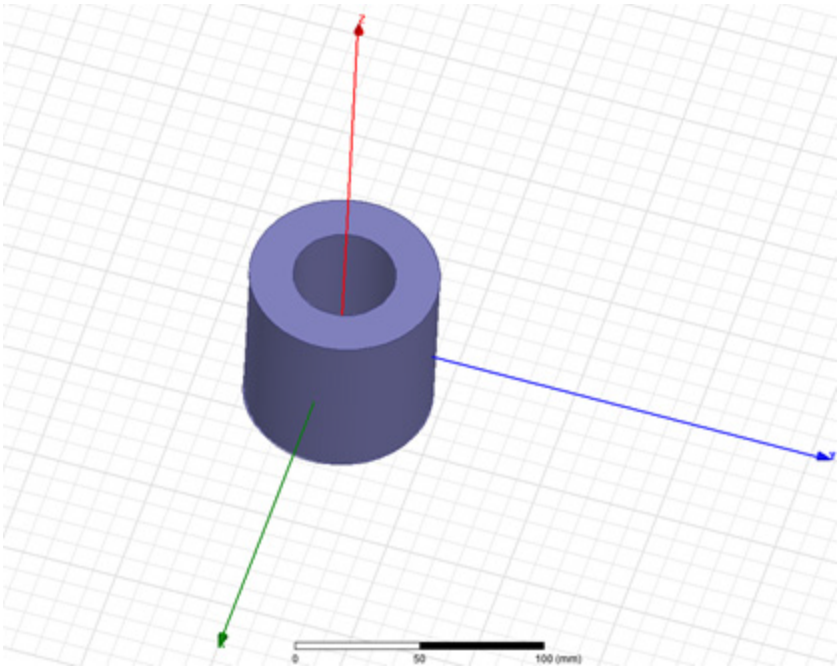

Figure 9-65 Coil of a claw-pole core

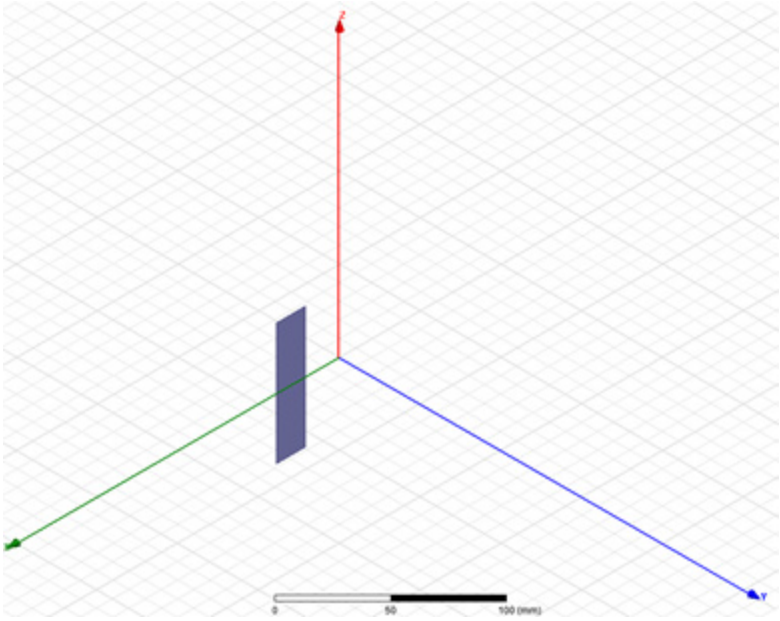

Figure 9-66 A terminal of coil in this claw-pole core

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating a Magnet (Claw Pole)

To create a magnet, you need to set the value of **LengthMag** larger than 0 (by default, it is 0) and value of **InfoCore** to be 3. An example is shown in the following figure.

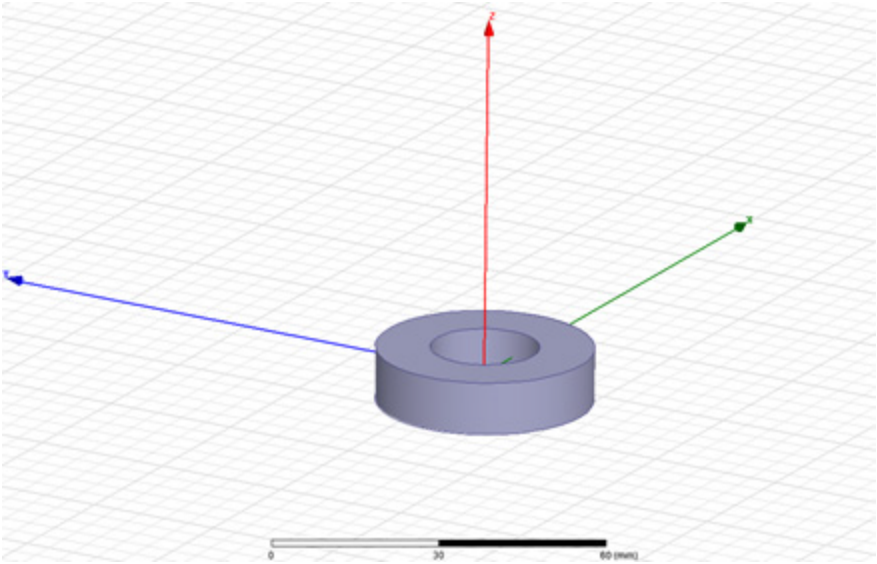

Figure 9-67 A magnet of ClawPoleCore

The following figure visualizes the **LengthMag** parameter.

Figure 9-68 LengthMag of a magnet of ClawPoleCore

You can assign the value of these properties either when creating a claw-pole core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

PMCore UDP

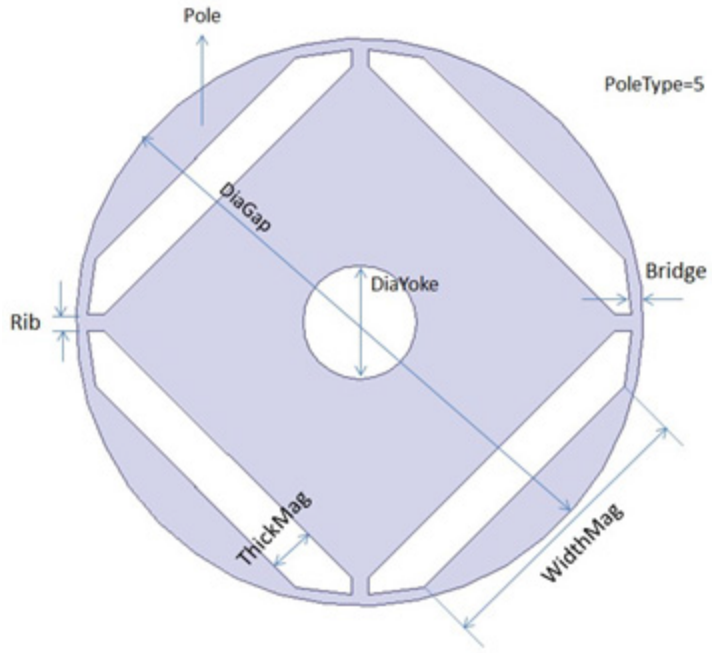
The PMCore UDP is used to create a PM stator/rotor core and a PM for PM commutating DC machines, PM adjustable-speed synchronous machines, or PM brushless DC motors.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
DiaGap	Core diameter on gap side, DiaGap<DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke<DiaGap for inner cores.
Length	Core length.
Poles	Number of poles.
PoleType	Pole type: 1 to 5.
Embrace	Pole embrace (not for type 4).
ThickMag	Max thickness of magnets.
WidthMag	Magnet width (for types 4 & 5).
Offset	Pole arc offset (for types 1, 2 & 3).
Bridge	Bridge thickness (for type 5 only).
Rib	Rib width (for type 5 only), Rib=0 for rectangle ducts.
LenRegion	Region length.
InfoCore	0: core; 1: magnets; 2: magnet; 100: region.

These parameters are used in the figures that follow.

" PM Core with PoleType set to 3 (InfoCore set to 0)" on the facing page shows the **Offset** parameter when value of **PoleType** is 3.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9-69 PM Core with PoleType set to 5 (InfoCore set to 0)

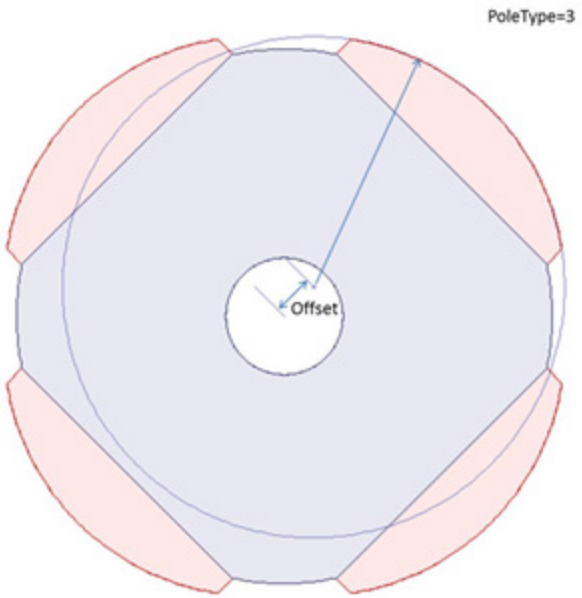


Figure 9-70 PM Core with PoleType set to 3 (InfoCore set to 0)

Creating an Inner or Outer PM Core

Set the value of **DiaYoke** and **DiaGap** as **DiaYoke** < **DiaGap** to create inner cores or **DiaGap** < **DiaYoke** for outer cores. In addition, r to create an outer core, the **Pole Type** must be 1 or 2. You can set the values either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

An inner PM core and an outer PM core are shown in Figure 1-1 and Figure 1-2 , respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

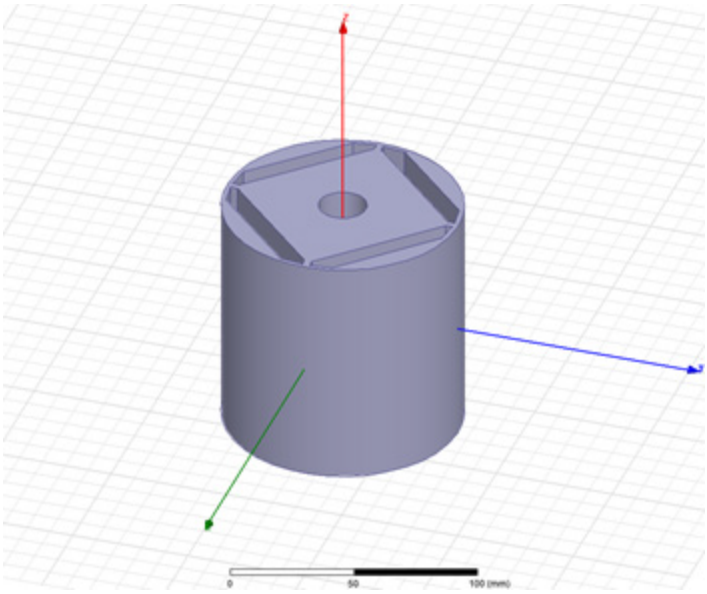

Figure 9-71 Inner PM core with PoleType set to 5 (InfoCore set to 0)

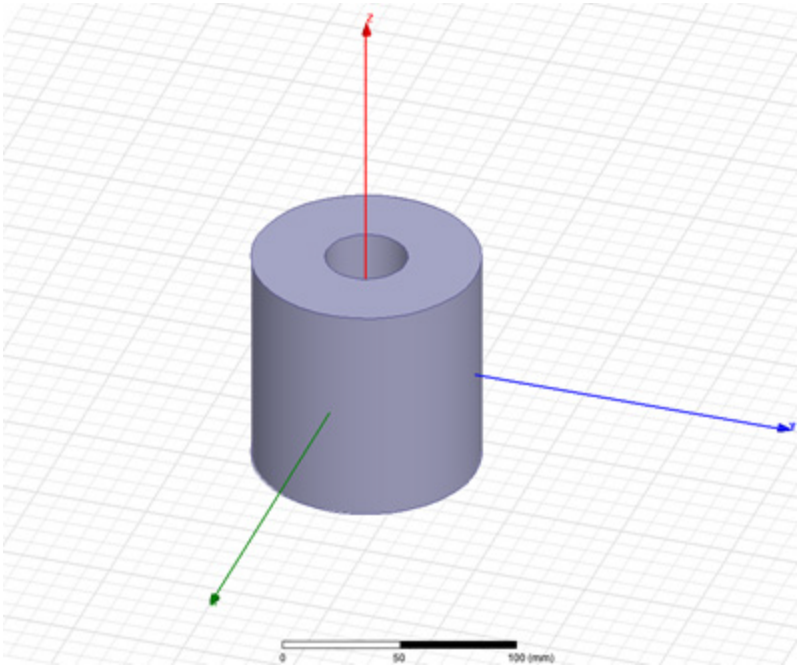

Figure 9-72 Outer PM core with PoleType set to 2 (InfoCore set to 0)

Creating All Magnets (PMCore)

You can create all magnets of a PM core manually by setting the value of **InfoCore** to 1. An example is shown by the four inner blue objects in the following figure, for which InfoCore has been set to 0 allowing the OuterPM core (gray object) and all magnets for PoleType=2 to be shown.

You can assign the value of this property either when creating a PM Core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

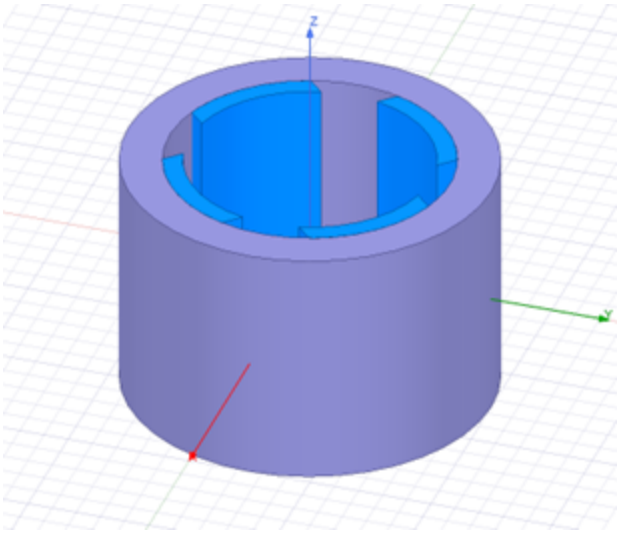

Figure 9-73 All magnets of a PM core

Creating a Magnet (PM Core)

You can create a magnet of a PM core manually by setting the value of **InfoCore** to 2. An example is shown in the following figure.

You can assign the value of this property either when creating a PM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

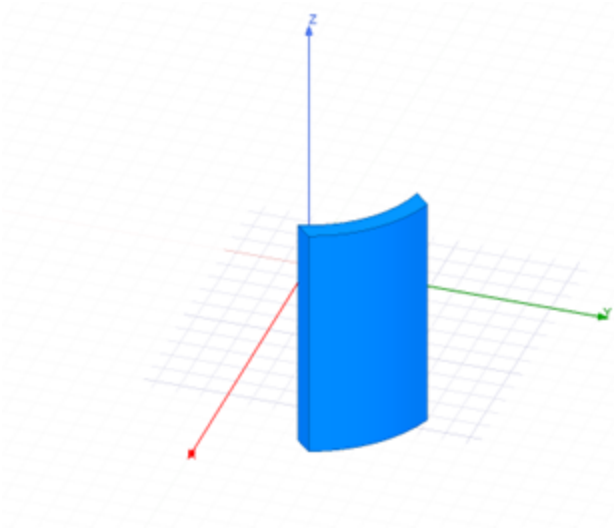

Figure 9-74 A magnet of PM Core

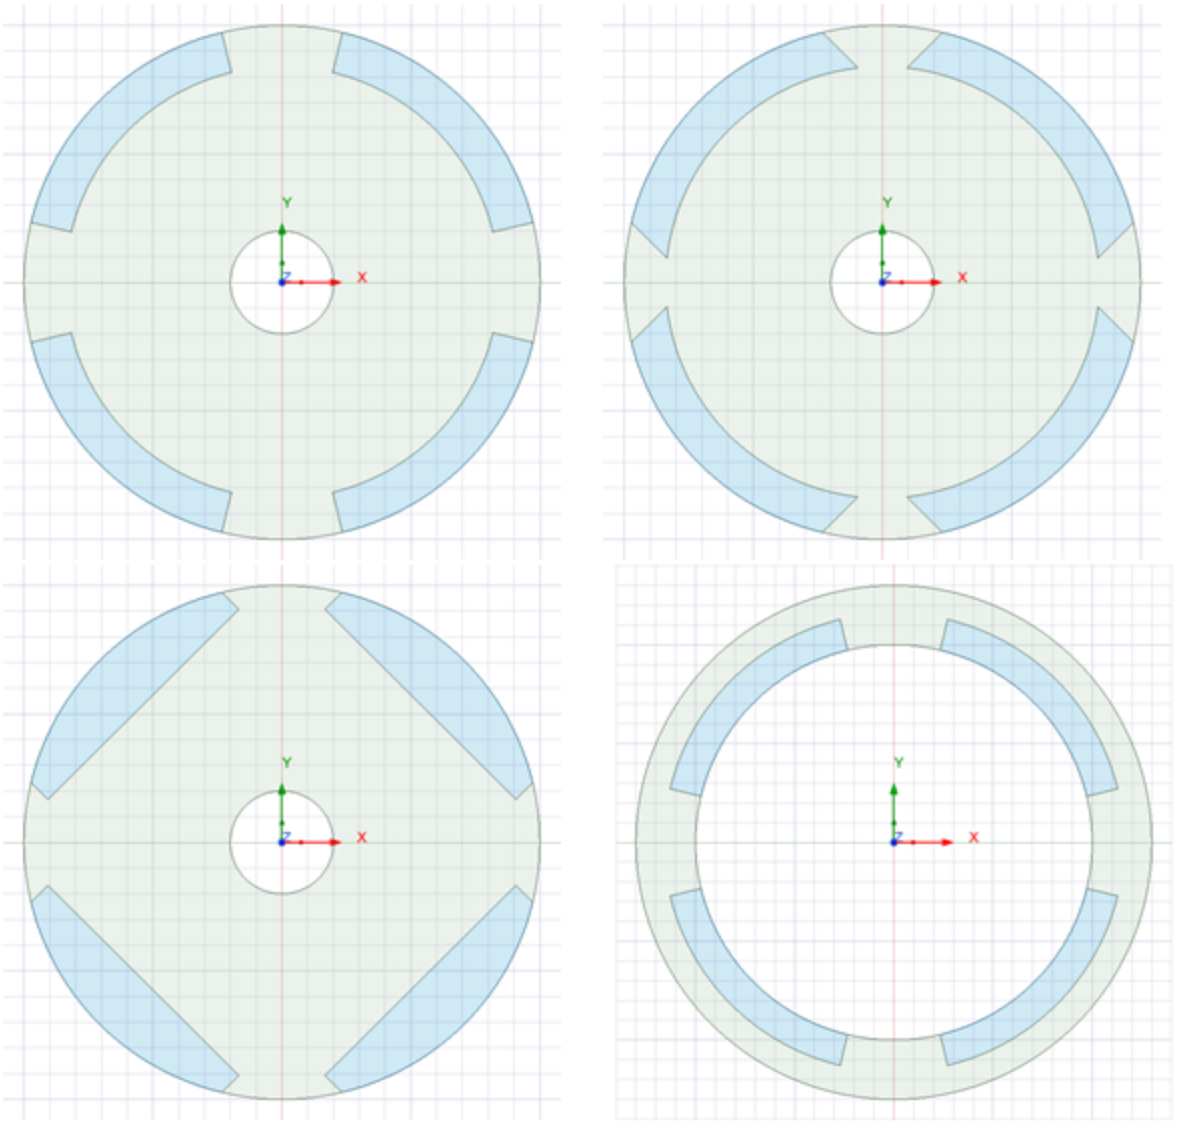
Creating an Insert Surface PM Core

When the value of **PoleType** is 1 to 3, you can create an insert surface PM core by setting **Embrace** to a negative value as shown in the examples below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



IPMCore UDP

The IPMCore UDP is used to create an IPM core and a PM for IPM synchronous machines or IPM brushless DC motors.

Property	Description
DiaGap	Core diameter on gap side, or outer diameter.
DiaYoke	Core diameter on yoke side, or inner diameter.
Length	Core length.
Poles	Number of poles.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
PoleType	Pole type: 1 to 6.
D1	Limited diameter of PM ducts.
O1	Bottom width for separate or flat-bottom duct (for types 3~6).
O2	Distance from duct bottom to shaft surface (for types 2~6).
B1	Duct thickness.
Rib	Rib width.
HRib	Rib height (for types 3~5).
DminMag	Minimum distance between side magnets (for types 3~5).
ThickMag	Magnet thickness.
WidthMag	Total width of all magnet per pole.
LenRegion	Region length.
InfoCore	0: core; 1: magnets; 2: ducts; 3: one-pole magnet; 100: region.

Most parameters of IPMCore UDP are shown in the following figure except those common parameters like **DiaGap**, **DiaYoke** and **Length**.

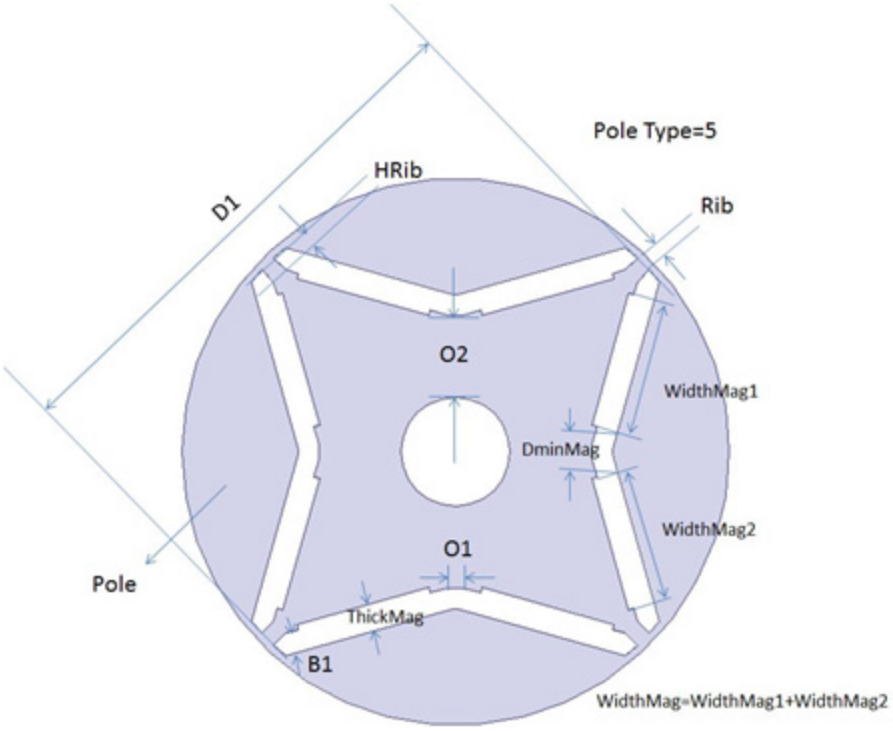


Figure 9-75 Parameters of IPM Core

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating an Inner IPM Core

Set the value of **DiaYoke** and **DiaGap** as **DiaYoke** < **DiaGap** to create an inner IPM core. You can set the value either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

An example is shown in the following figure.

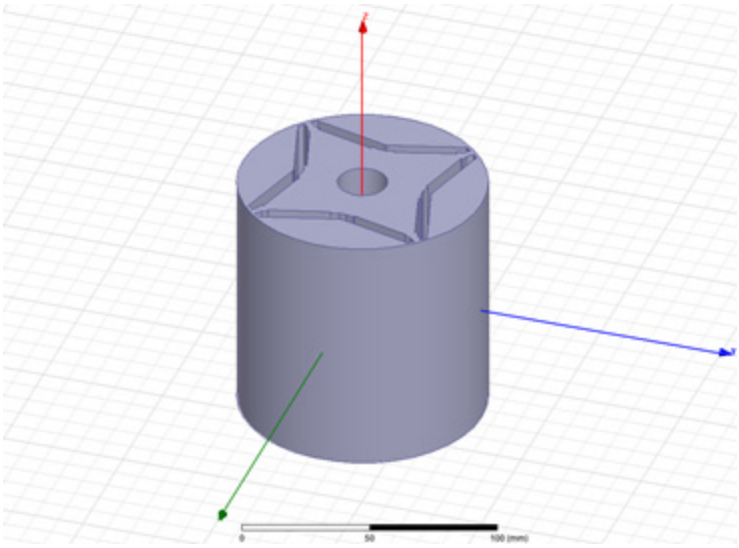

Figure 9-76 Inner IPM Core

Creating All Magnets (IPM Core)

You can create all magnets of an IPM core manually by setting the value of **InfoCoil** to 1.

You can assign the value of this property either when creating an IPM Core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

An example is shown in the following figure.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

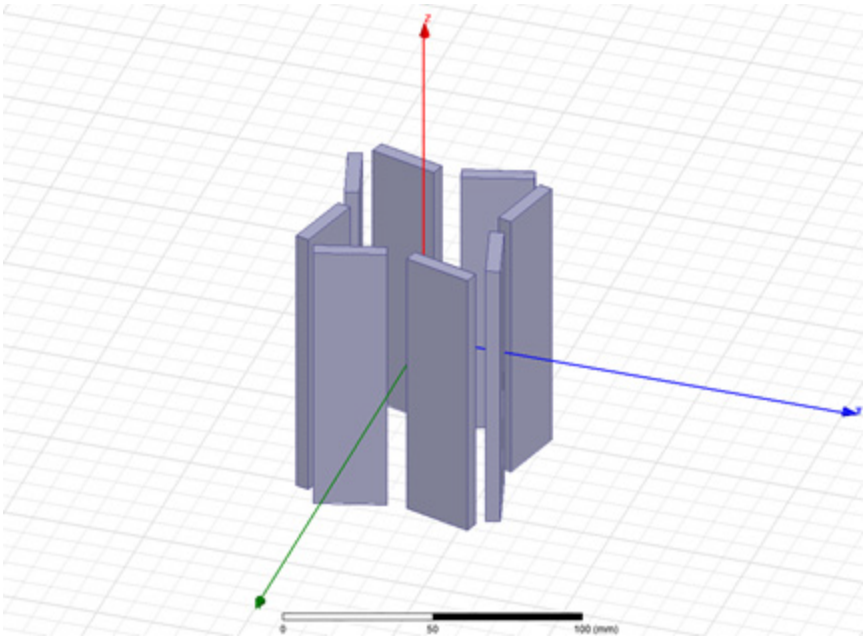

Figure 9-77 All magnets of IPM core

Creating One-Pole Magnets

You can create one-pole magnets of an IPM core manually by setting the property of **InfoCoil** to 3.

You can assign the value of this property either when creating an IPM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

The following figure shows an example of one-pole magnets.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

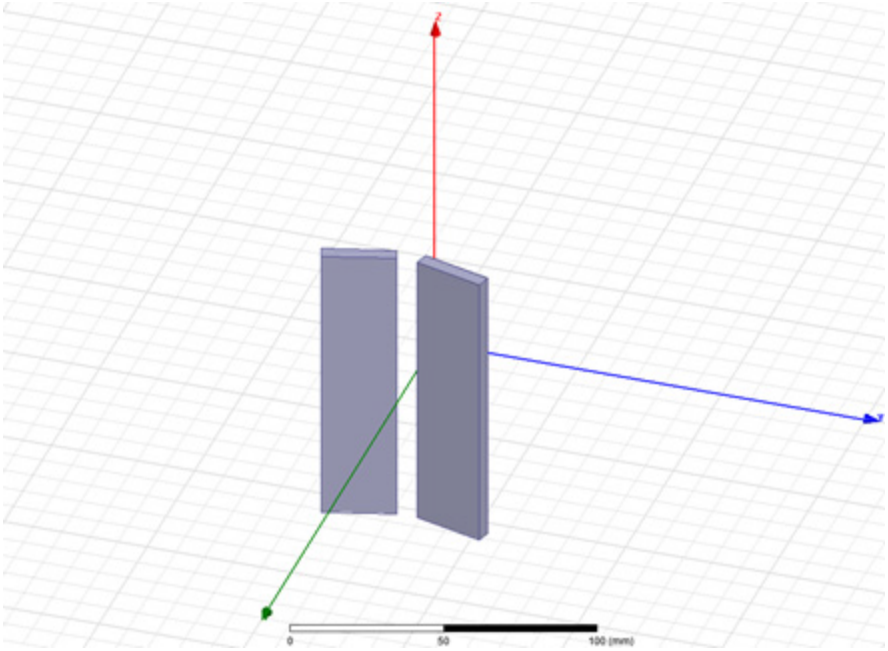

Figure 9-78 One-pole magnets of an IPM Core

PMDamperCore UDP

The PMDamperCore UDP is used to create the PM rotor core with damper for line-start PM synchronous machines.

Property	Description
DiaGap	Core diameter on gap side, or outer diameter.
DiaYoke	Core diameter on yoke side, or inner diameter.
Length	Core length.
Skew	Skew angle in core length range.
Slots	Number of damper slots per pole.
SlotType	Slot type: 1 to 4.
Hs0	Slot opening height.
Hs01	Slot closed bridge height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: tangent connection; 2&3: arc bottom.
Poles	Number of poles.
PoleType	Pole type: 1 to 8.
D1	Limited diameter of PM ducts.
O1	A locating dimension of PM ducts, for pole types 3, 4, 7 & 8.
O2	A locating dimension of PM ducts, for pole types 1, 3, 5, 6, 7 & 8.
B1	Barrier width, for pole types 1, 2 & 3.
Rib	Rib to hold PM ducts, for pole types 1 to 7.
ThickMag	Magnet thickness.
WidthMag	Total width of all magnet per pole.
BarEndExt	One-side damper bar end extended length.
RingLength	One-side axial ring length.
RingHeight	Radial ring height.
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface).
LenRegion	Region length.
InfoCore	0: core; 1: magnets; 2: damper; 100: region.

These parameters are used in the figures that follow.

Note:

- Parameters O1 and O2 are locating dimensions of PM ducts. They may have different meanings in different pole types. For example, " PMDamperCore with Pole Type set to 3 " on the facing page shows what O1 and O2 refer to in PMDamper Core with Pole Type 3.
- In " Damper of PMDamperCore (red) " on the facing page and " 3D Damper of PMDamperCore (red)" on page 9-158 , the gray object (a PMDamperCore with InfoCore set to 0) is used as reference to show the red object (a PMDamperCore with InfoCore set to 2)
- For parameters such as **DiaGap, DiaYoke, Length,Skew**, **FilletType**, **SegAngle** and parameters related to slots, refer to SlotCore UDP parameters

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

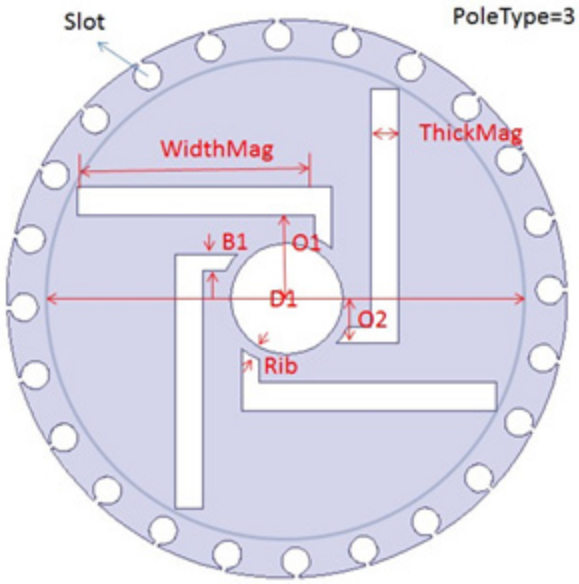

Figure 9-79 PMDamperCore with Pole Type set to 3

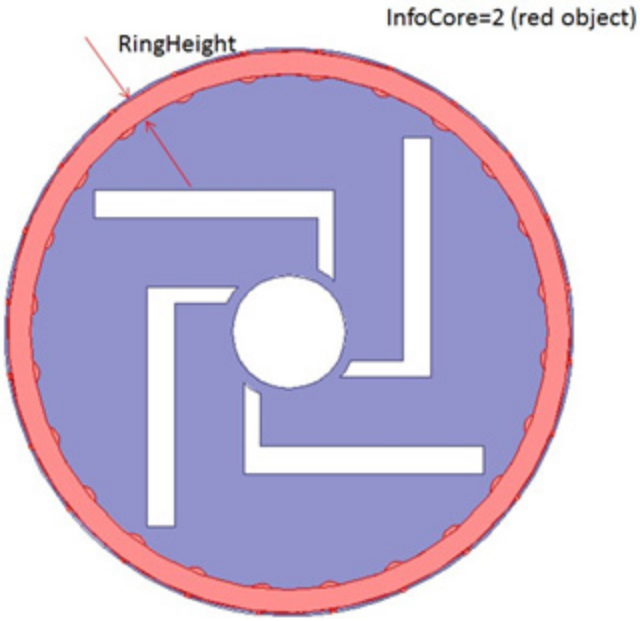

Figure 9-80 Damper of PMDamperCore (red)

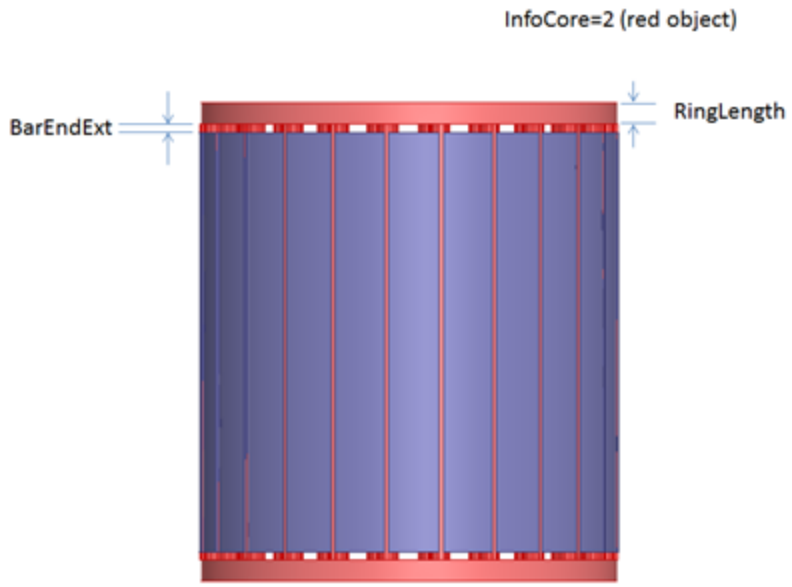

Figure 9-81 3D Damper of PMDamperCore (red)

Creating an Inner PM Damper Core

Set the value of **DiaYoke** and **DiaGap** as **DiaYoke** < **DiaGap** to create an inner PM damper core. You can set the value either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

An example is given in the following figure.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

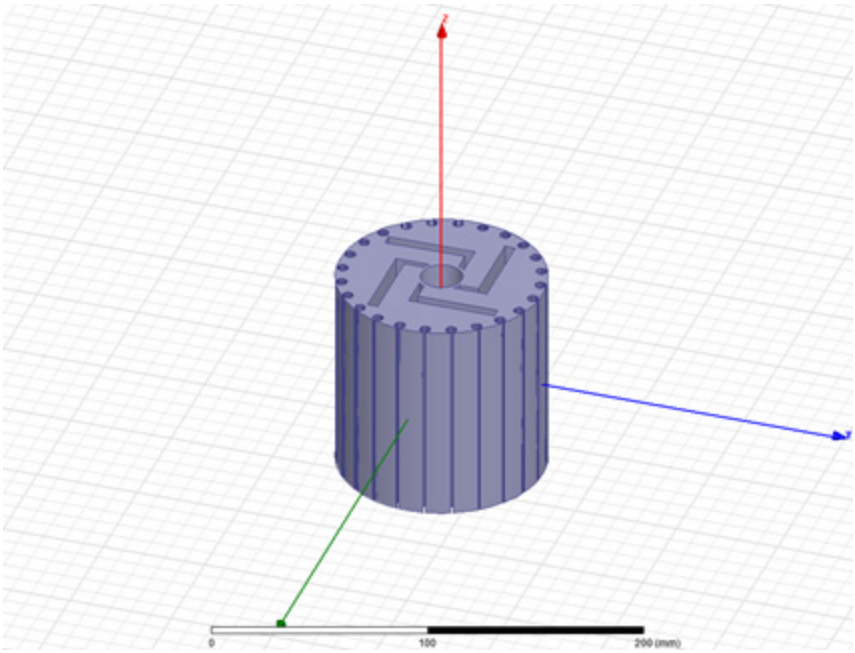

Figure 9-82 Inner PM damper core

Creating a Damper (PM Damper Core)

You create a damper of a PM damper core manually by setting the value of **InfoCoil** to 2.

You can assign the value of this property either when creating a PM damper core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Examples are shown in " 3D Damper of PMDamperCore (red)" on the previous page as a red object and "A damper" on the next page.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

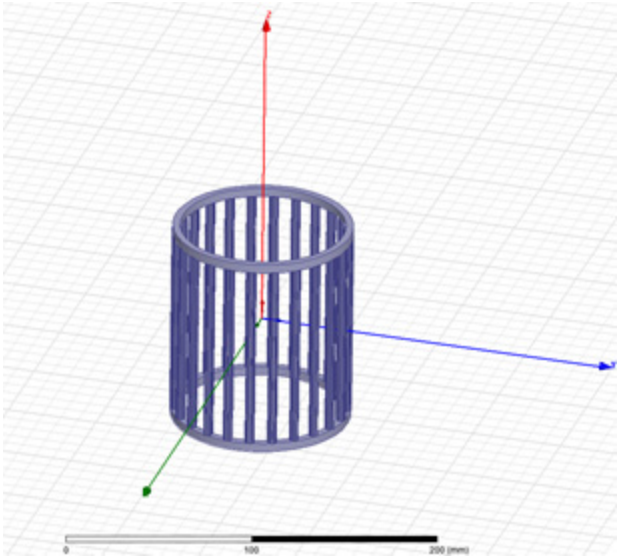

Figure 9-83 A damper

Creating all Magnets (PM Damper Core)

You can create all magnets of a PM damper core manually by setting the value of **InfoCoil** to 1.

You can assign the value of this property either when creating a PM damper core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

An example is shown in the following figure. Note that this example is realized when the value of **PoleType** is 3.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

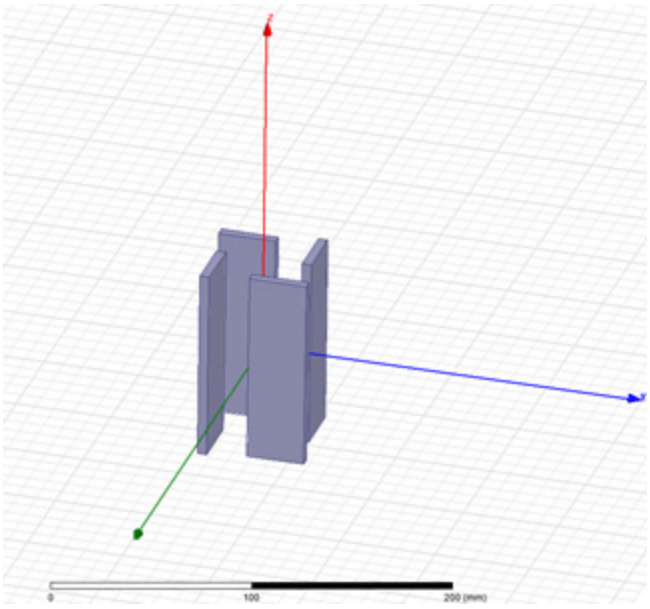

Figure 9-84 All Magnets

Creating a Magnet (PM Damper Core)

You can create a magnet of a PM damper core by setting the **InfoCore** value to -1, -2 or -3 according to the number of magnets for each pole of the core.

For instance, when **Pole Type** is equal to 3 (which is shown in " All Magnets" above), there is only one magnet for a pole. In this situation, setting the value of **InfoCore** to be -1 can create a magnet. An example is shown in the following figure.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

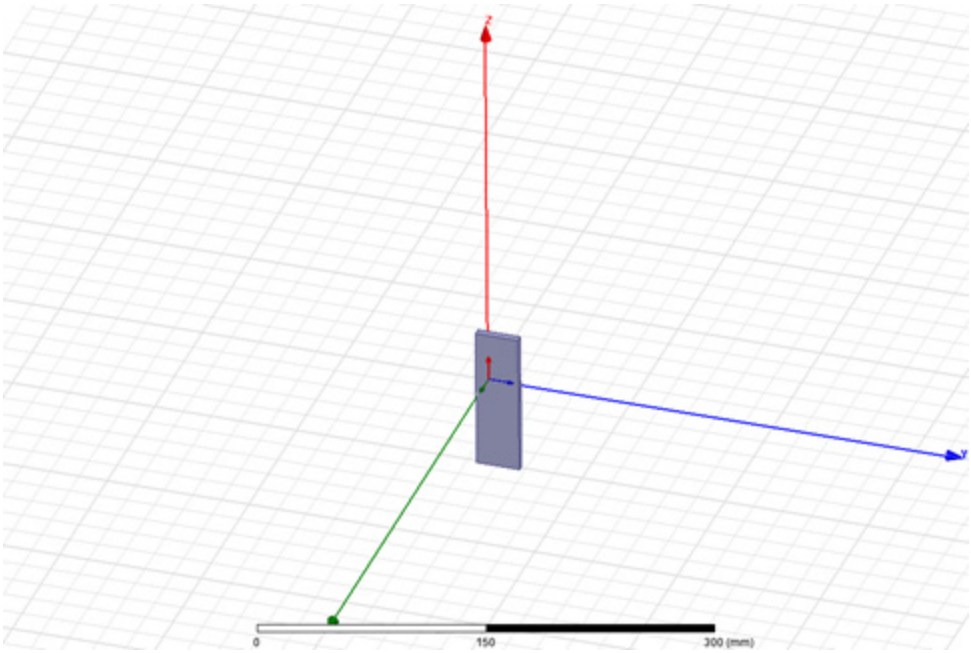

Figure 9-85 A magnet when Pole Type is set to 3

When there are two magnets for a pole of a PM damper core (for example, when **Pole Type** is 5), setting the value of **InfoCore** to be -1 can create one of these two magnets while setting the value of **InfoCore** to be -2 can create another one.

For instance, " A PM damper core when Pole Type is 5 and InfoCore is 1" on the facing page shows all magnets of a PM damper core when **Pole Type** is 5, whereas " A PM damper core when Pole Type is 5 and InfoCore is -1" on the facing page and " A PM damper core when Pole Type is 5 and InfoCore is -2" on page 9-164 present one of two magnets for a pole, by setting **InfoCore** value to be -1 and -2 respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

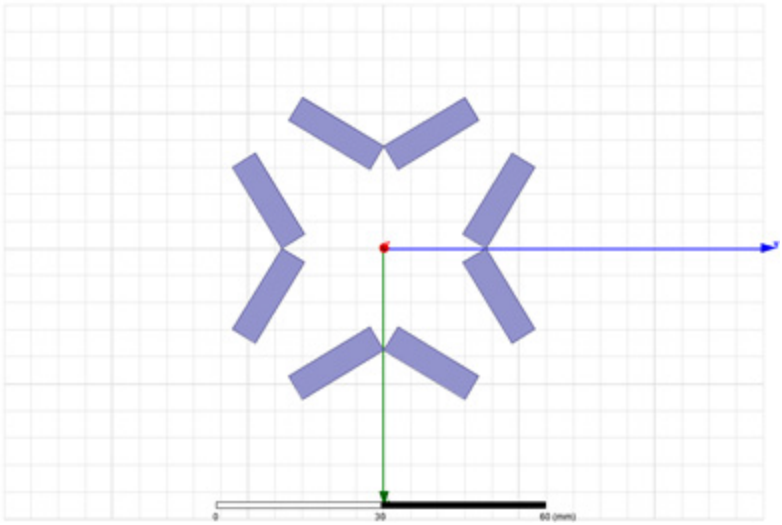

Figure 9-86 A PM damper core when Pole Type is 5 and InfoCore is 1

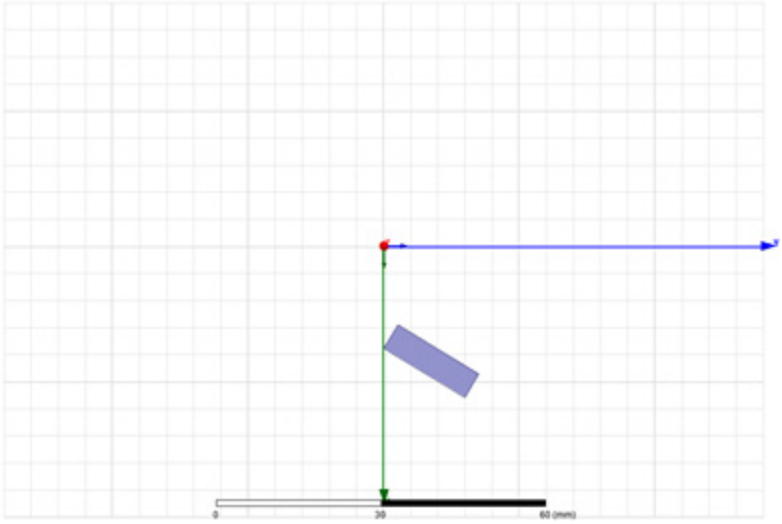

Figure 9-87 A PM damper core when Pole Type is 5 and InfoCore is -1

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

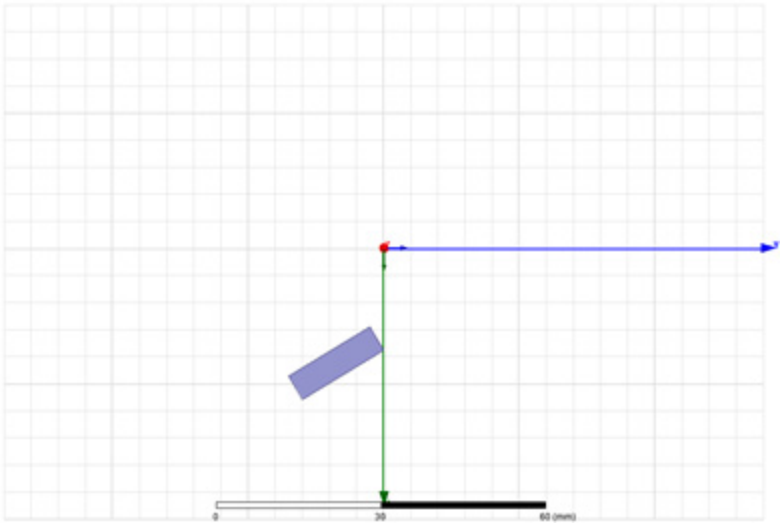

Figure 9-88 A PM damper core when Pole Type is 5 and InfoCore is -2

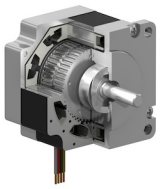
Similarly, when a pole of PM damper core has 3 or more magnets (such as when **InfoCore** is 6), you can create a single magnet by setting the value of InfoCore to -1, -2, -3 and so on.

You can assign the value of these properties either when creating a PM damper core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

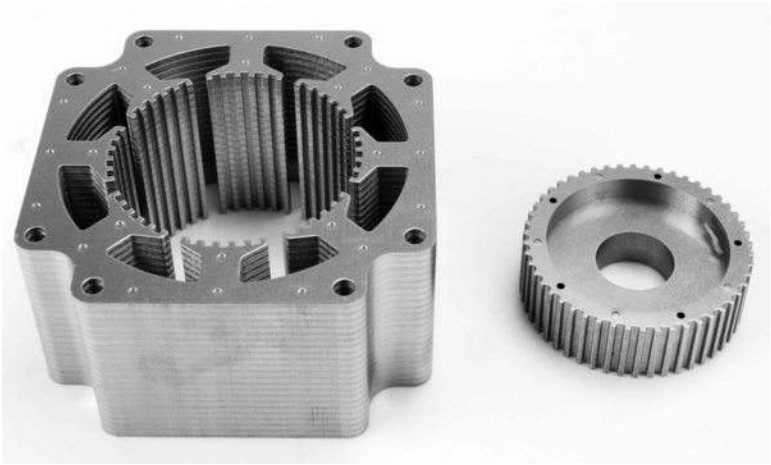
StepMCore UDP

The StepMCore UDP is used to create stator and rotor cores for Variable Reluctance (VR), or Hybrid, stepper motors, as shown as in the first figure for a stepper motor and in the second figure for the stator and rotor.



Hybrid Stepper Motor

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Stator and rotor of a stepper motor

Parameter Definitions

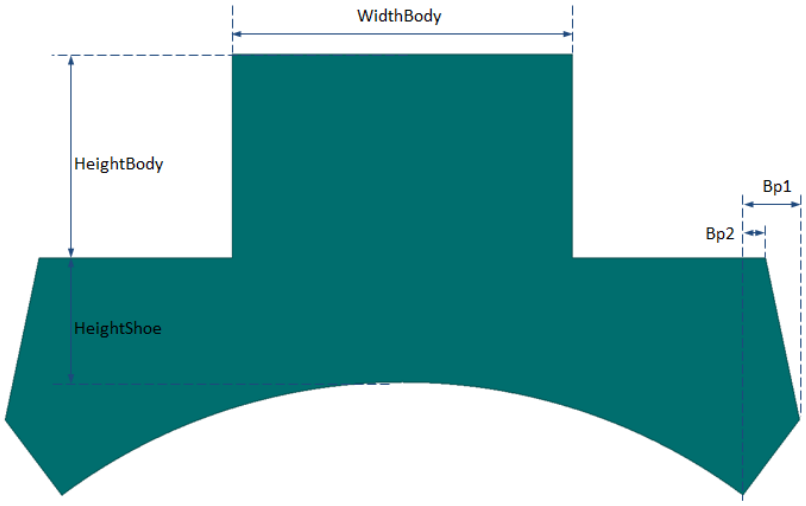
Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores
Length	Core Length
Poles	Number of poles
PoleType	Pole type: 0, 1, or 2 (not valid for inner cores)
EmbraceShoe	Pole shoe embrace related to pole pitch for WidthShoe computation
HeightShoe	Pole shoe height at pole center
WidthBody	Pole body width
HeightBody	Pole body height
Bp1/Rp1	Bp1 for pole type 1; or Rp1 for pole type 2; not valid for type 0
Bp2/Rp2	Bp2 for pole type 1; or Rp2 for pole type 2; not valid for type 0
SurfaceTeeth	Number of surface teeth per pole (>=1)
IndexingTeeth	Number of indexing teeth for tooth pitch computation, not valid for SurfaceTeeth=1
EmbraceTooth	Tooth embrace related to tooth pitch, not valid for SurfaceTeeth=1
HeightTooth	Surface tooth height, or slot depth, not valid for SurfaceTeeth=1
FilletSlot	Fillet radius at slot bottom
GapCore	Gap of two core sections in radial direction (>0 for Hybrid core)
ThickYoke	Thickness of solid yoke in radial direction for Hybrid core
ThickMag	Magnet thickness in radial direction for Hybrid core

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
LengthMag	Magnet length in axial direction for Hybrid core (>=GapCore)
CoilEndExt	One-side coil end extended Length
LenRegion	Region length
InfoCore	0: core; 1: core & coils; 2: coil; 3: magnet; 4: terminal1; 5: terminal2; 6: poles; 7: yoke; 100: region

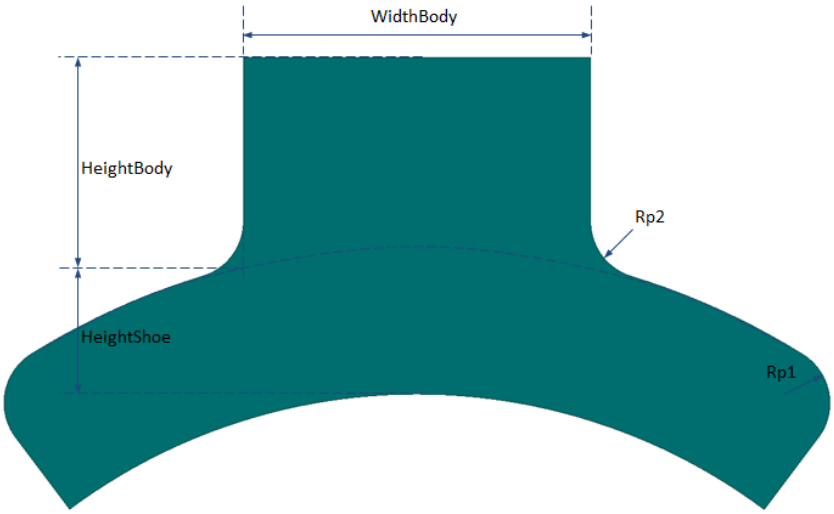
Main parameters described in the table above for different pole types are shown in the figures below.

Pole parameters for PoleType = 0

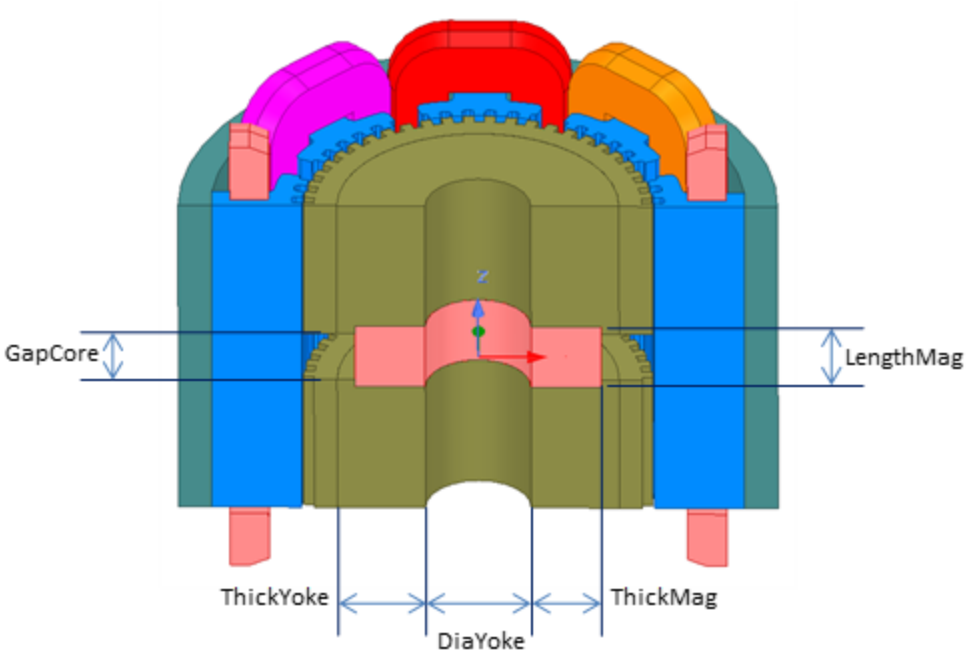


Pole parameters for PoleType = 1

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Pole parameters for PoleType = 2



Pole parameters for hybrid rotor

EmbraceShoe is the ratio of the pole shoe angle to pole pitch, and **EmbraceTooth** defines the ratio of a tooth angle to tooth pitch is: ToothPitch = 360°/**IndexingTeeth**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

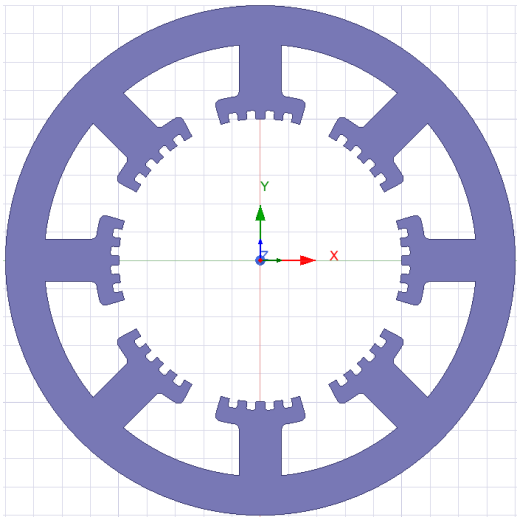
When **SurfaceTeeth** = 1, which means there are no slots on the shoe surface, the shoe width, noted as WidthShoe, will be directly obtained from **EmbraceShoe**. When **SurfaceTeeth** > 1, the minimum shoe angle AngShoeMin will be obtained from the minimum angle to be able to create the specified number of surface teeth, that is

AngShoeMin = (**SurfaceTeeth** – 1 + **EmbraceTooth**) x ToothPitch

and the maximum shoe angle is defined to add a half slot in each shoe side, that is

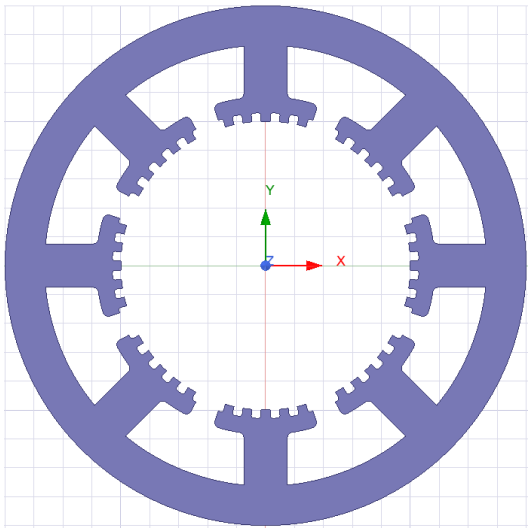
AngShoeMax = AngShoeMin + (1 – **EmbraceTooth**) x ToothPitch = **SurfaceTeeth** x ToothPitch.

When the shoe angle corresponding to the specified **EmbraceShoe** is out of the range of (AngShoeMin, AngShoeMax), the UDP will automatically adjust the value of **EmbraceShoe**, as shown below.



EmbraceShoe = 0.7

(Automatically adjust to 0.72)



EmbraceShoe = 0.9

(Automatically adjust to 0.8)

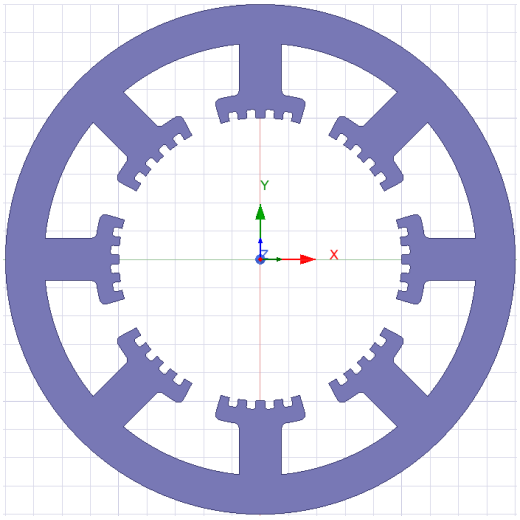
In this example, an 8-pole stepper motor stator has **SurfaceTeeth** = 5, **IndexingTeeth** = 50 and **EmbraceTooth** = 0.5. Therefore, ToothPitch = 7.2°, and AngShoeMin and AngShoeMax will be 32.4° and 36°, corresponding to minimum and maximum shoe embrace of 0.72 and 0.8, respectively. The value of **EmbraceShoe** will automatically be adjusted to 0.72, or 0.8, if the input value is out of the range.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating an Inner or Outer Core for a Variable Reluctance Stepper Motor

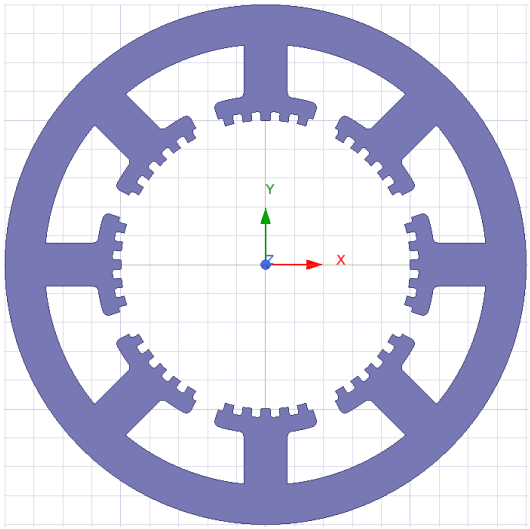
You can set the value of **DiaYoke** and **DiaGap** as **DiaYoke** < **DiaGap** to create inner cores or **DiaGap** < **DiaYoke** for outer cores.

Keeping **GapCore** = 0 and **InfoCore** = 0, outer stator cores of a variable reluctance stepper motor with different **EmbraceShoe** are created, as shown in the figures below.



EmbraceShoe = 0.7

(Automatically adjust to 0.72)

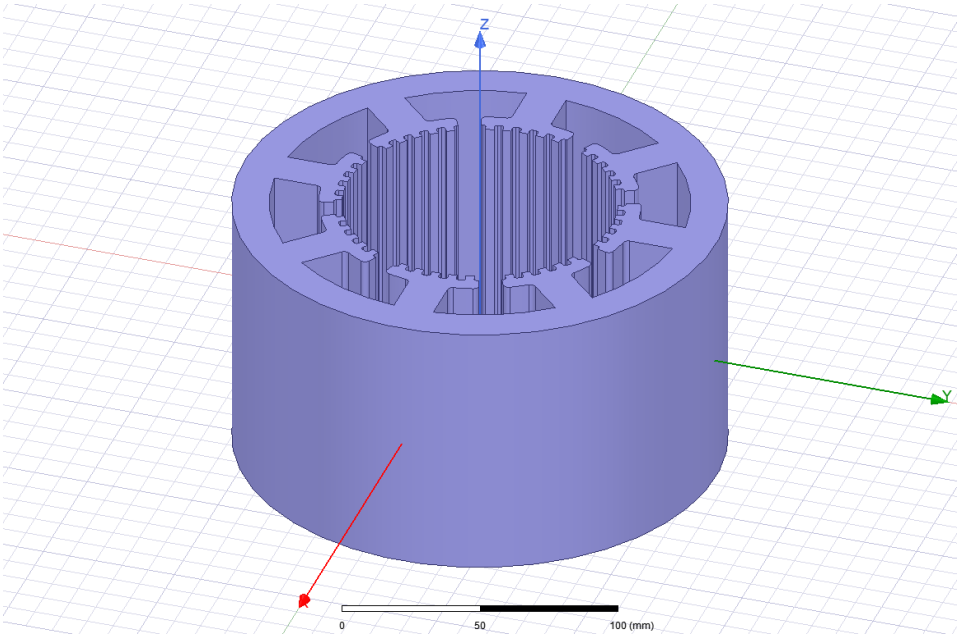


EmbraceShoe = 0.9

(Automatically adjust to 0.8)

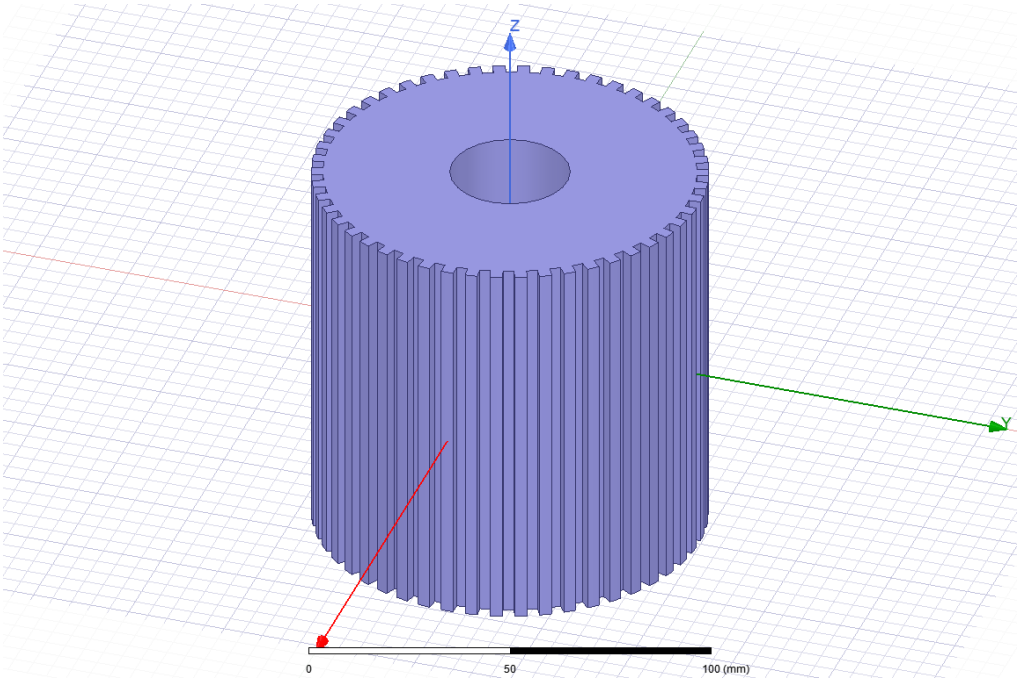
Outer stator cores with different shoe embraces in 2D.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Outer stator core in 3D (PoleType = 2).

A 3D inner rotor core with 50 poles, which is the same number as the stator indexing teeth, is shown below:



Inner rotor core in 3D (PoleType = 0)

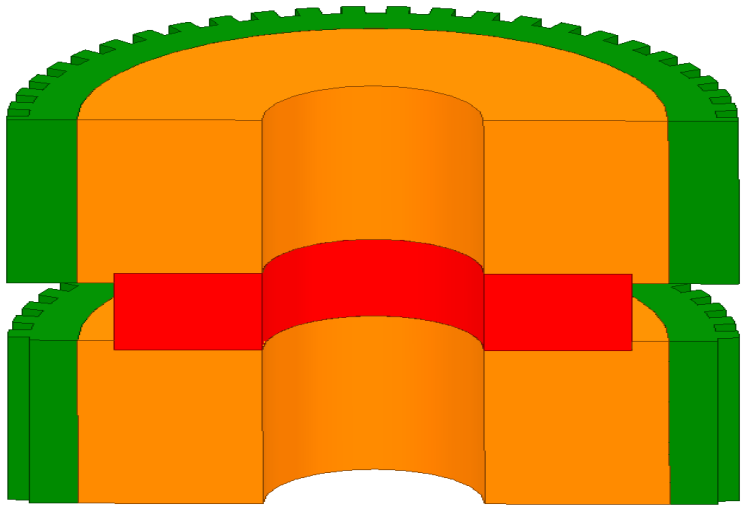
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating an Inner Rotor Core for a Hybrid Stepper Motor

The stator structure of a hybrid stepper motor is similar to that of a variable reluctance stepper motor, but the rotor structure is quite different. The rotor core is divided into two separate parts. The two parts are shifted by a half tooth pitch in circumferential direction, as shown below. The top pole part, in green color created with **InfoCore** = 6, is cut by the symmetry plan through the pole center, or the tooth center, however, the bottom pole part is cut through the slot center.

The rotor core could be laminated, solid, or laminated for poles and solid for yoke. In the example, the poles, in green color, are laminated, and the yoke, in golden color created with **InfoCore** = 7, is solid. The magnet, in red color created with **InfoCore** = 3, is magnetized in vertical direction. The fluxes in both top and bottom parts are in the radial direction, one from rotor to stator, and the other from stator to rotor.

The hybrid rotor can be created only in 3D.

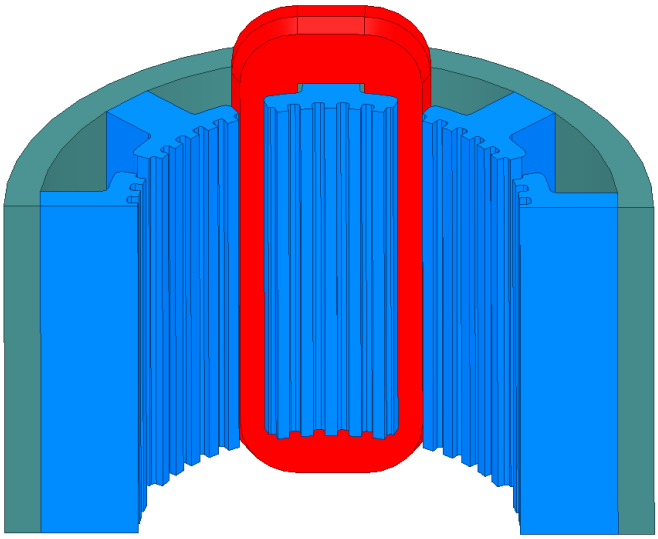


Inner rotor core in 3D (PoleType = 0)

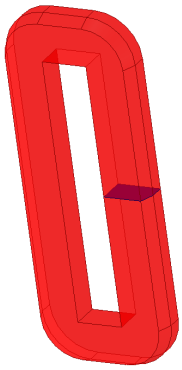
Creating a Coil and Coil Terminals for a Stepper Motor

A coil can be created by setting **InfoCoil** = 2, as shown below,

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



and a coil terminal can be created by setting **InfoCoil** = 4 or 5. (Coil terminal created by **InfoCore** = 4 shown below.)



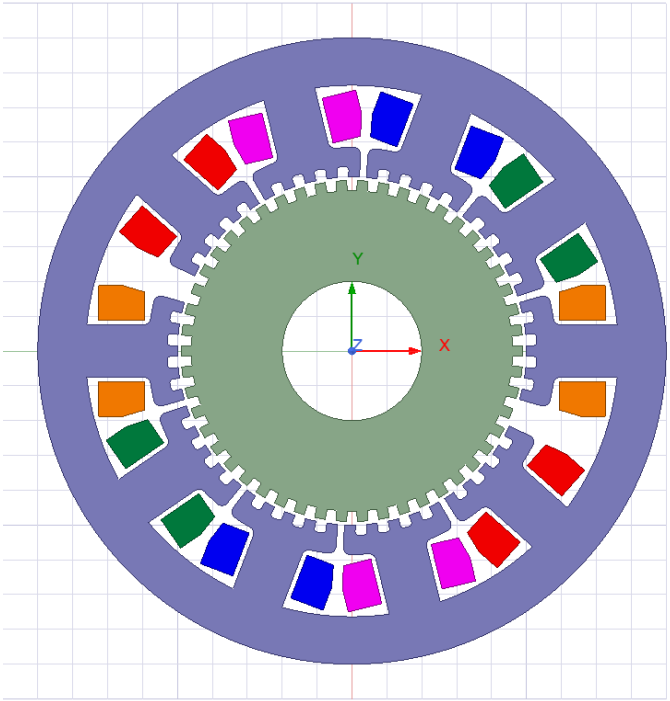
In 2D, you can create a coil by setting **InfoCoil** = 2 with two united terminals. You can also create two separate terminals by setting **InfoCoil** = 4 and 5 for convenient coil setup.

Creating a Stator Core with Non-uniform Pole Pitch

To be able to create torque when stator windings are excited phase by phase (a phase winding normally consists of two coils in two poles shifted by 180 degrees), the number of rotor poles should be the same as the number of indexing teeth for the stator pole surface teeth, and the number of indexing teeth should not be integer multiples of the number of stator poles. However, in some applications, the number of indexing teeth may be integer multiples of the number of

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

stator poles. For example, in widely used 5-phase stepper motors, the stator contains 10 poles, while the rotor has 50 poles, or teeth. The tooth pitch in both stator and rotor is 7.2°. In order to be able to produce continuous torque, the 5 stator pole pairs should be shifted from their uniform positions by 0, 1.44, 2.88, 4.32, 5.76, successively.

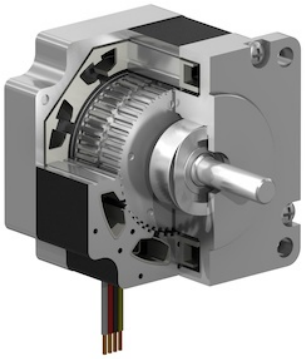


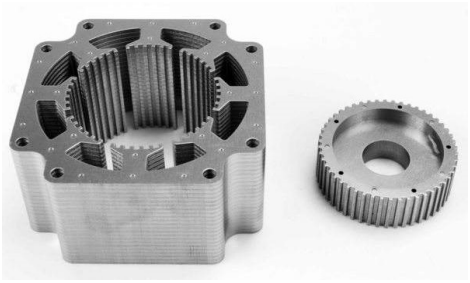
2D Stator core and coils with non-uniform pole pitch

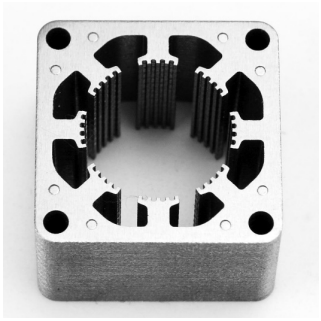
Square Yoke UDP

The SquareYoke UDP is used to create outer square yokes, which can be combined with various stator types to be able to directly mount with end caps for small-size machines, as shown in the examples below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.







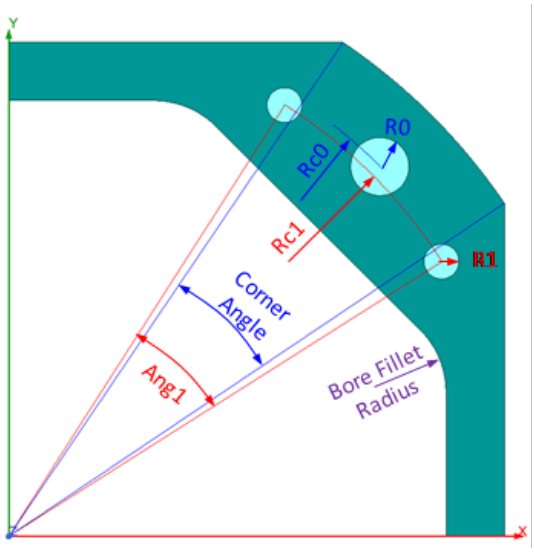
Parameter Definitions

Property	Description
WidOuter	Outer width of square profile
DiaInner	Inner diameter or minimum width
Length	Yoke Length
YokeType	0: Circle; 1: Square Circle; 2: Square Bulged; 3: Square Flat; 4: Square Dented
AngCorner	Corner angle related to bore center, not valid for CornerType = 0
BoreType	1: Circle; 2: Square; 3: Octagon; BoreType is always 1 for CornerType = 0
BoreFillet	Inner bore fillet radius, for square or octagon bore type only
R0	Radius of mounting hole or dented fillet, not valid for CornerType = 0
Rc0	Radius of mounting hole location or bulged fillet, not valid for CornerType = 0
R1	Radius of two corner holes, not valid for CornerType = 0
Rc1	Radius of corner hole location, not valid for CornerType = 0
Ang1	Angle of two corner-hole centers related to bore center, not valid for CornerType = 0
LenRegion	Region length

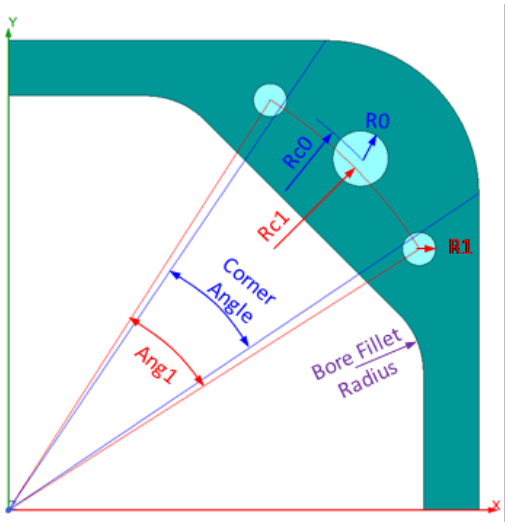
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
InfoCore	0: core; 1: holes; 2: 100: region

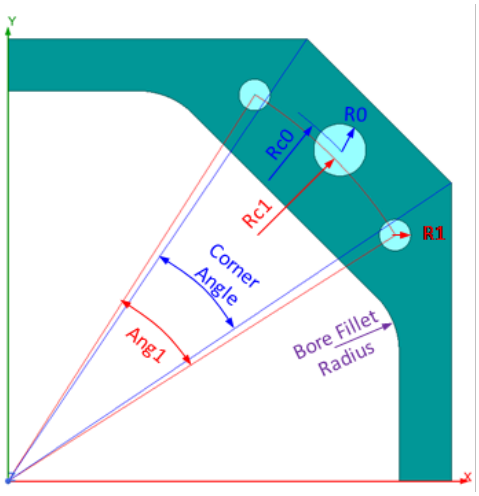
Main parameters described in the table above for the four yoke corner types are shown below, where "Corner Angle" is **AngCorner**, and "Bore Fillet Radius" is **BoreFillet**.



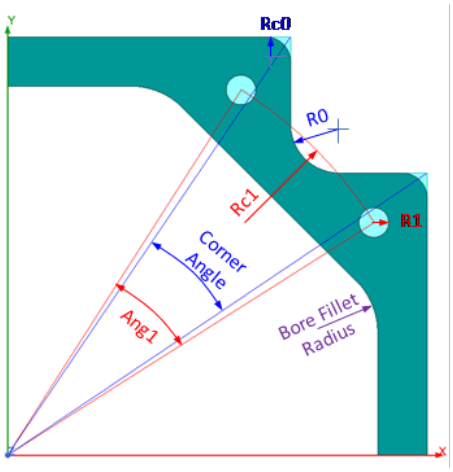
Yoke parameters for YokeType = 1



Yoke parameters for YokeType = 2



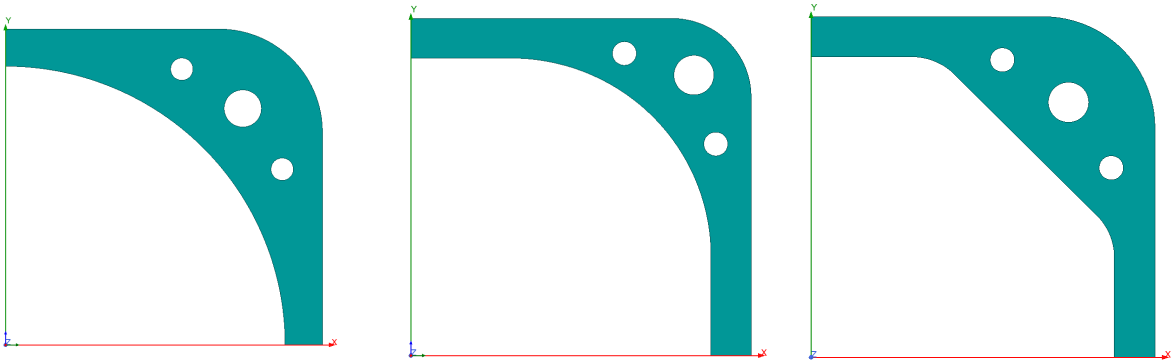
Yoke parameters for YokeType = 3



Yoke parameters for YokeType = 4

The three bore types are shown below.

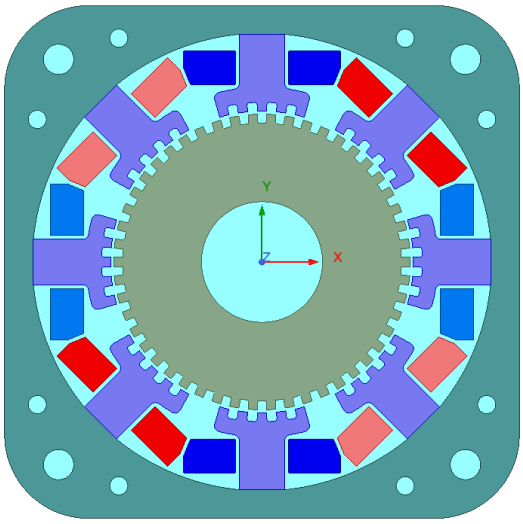
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



BoreType = 1 BoreType = 2 BoreType = 3

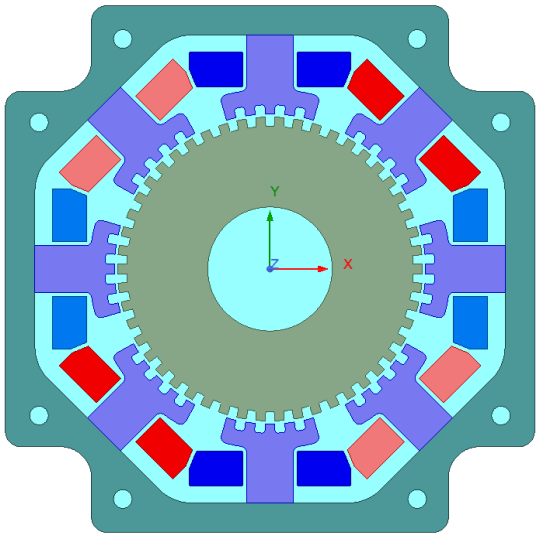
Creating a Stator Yoke to Match Stator Poles of Stepper Motors

The figure below shows an example for a variable reluctance stepper motor in which the stator poles are mounted to a square yoke with **YokeType**= 2 and **BoreType**= 1, where **BoreFillet** is set as **WidthBody** in StepMCore UDP to fit the pole bottom.

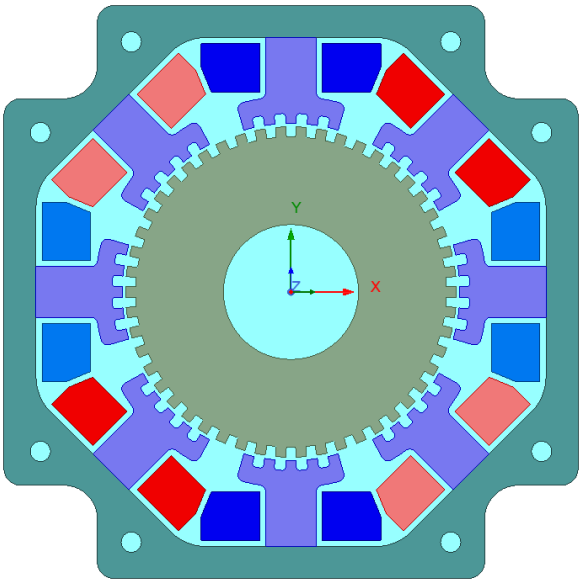


The figure below shows a stepper motor in which the stator poles are mounted to a square yoke with **YokeType**= 4 and octagon **BoreType**= 3 in which the coil area is that of circular bore type (**BoreType**= 1) as shown in the previous figure.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For bore type (**BoreType**= 3), the coil area can be larger. To do this, you can set a negative value for StepMCore UDP parameter **CoilEndExt** to create the coils. The modified coils are shown below.



Coil area modified by setting StepMCore UDP parameter **CoilEndExt** < 0.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

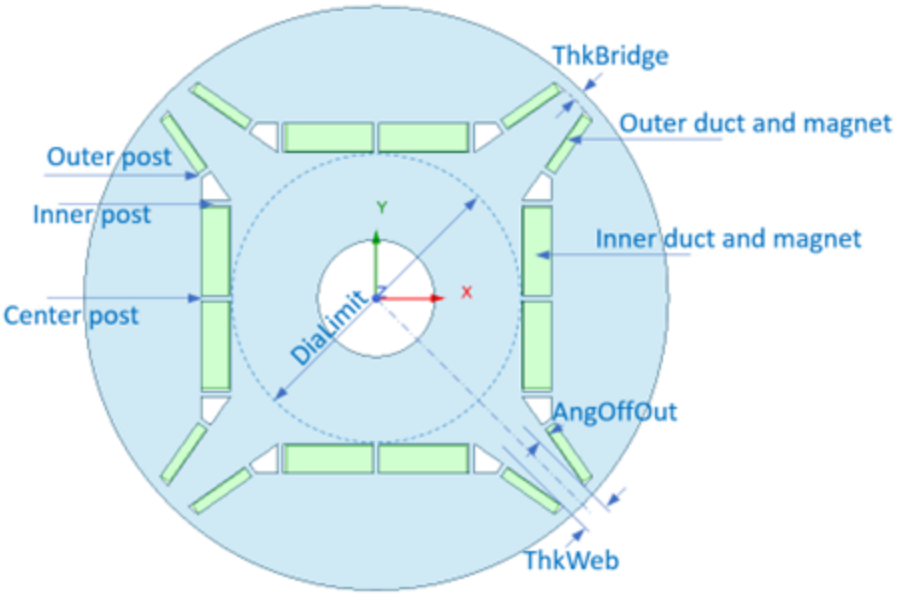
UPMCore UDP

The UPMCore UDP is used to create a single- or poly-layer U-type IPM core and PMs for IPM synchronous machines, or IPM brushless DC motors.

Property	Description
DiaGap	Core diameter on gap side, or outer diameter.
DiaYoke	Core diameter on yoke side, or inner diameter.
Length	Core length.
Poles	Number of poles.
DiaLimit	Inner limited diameter of PM ducts
ThkBridge	Bridge thickness
ThkWeb	Web thickness
AngOffOut	Outer (web) angle offset
ThkDuctOut	Outer duct thickness
ThkDuctIn	Inner duct thickness
ThkPostOut	Outer post thickness
ThkPostIn	Inner post thickness, <0 for duct bottom corner radius
ThkPostMid	Center post thickness
WidMagOut	One-side width of outer magnets
GapMagOut	Two-side gap of outer magnets (ThkMagOut = ThkDuctOut – GapMagOut)
WidMagIn	Total width of inner magnets per pole
GapMagIn	Two-side gap of inner magnets (ThkMagIn = ThkDuctIn – GapMagIn)
LenRegion	Region length.
InfoCore	0: core; 1: magnets; 2: ducts; 3: inner magnet; 4: left magnet; 5: right magnet; 100: region.

Most parameters for a UPMCore UDP are shown in the figure below except common parameters like **DiaGap**, **DiaYoke**, and **Length**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Parameters of a UPMCore UDP with **AngOffOut** = -10°.

Note that when **AngOffOut** = 0, the edges of outer PM ducts between two adjacent poles are parallel. When **AngOffOut** > 0, the inner web thickness is smaller than the outer web thickness which is labeled as **ThkWeb**. When **AngOffOut** < 0, the inner web thickness is larger than the outer web thickness, as shown above.

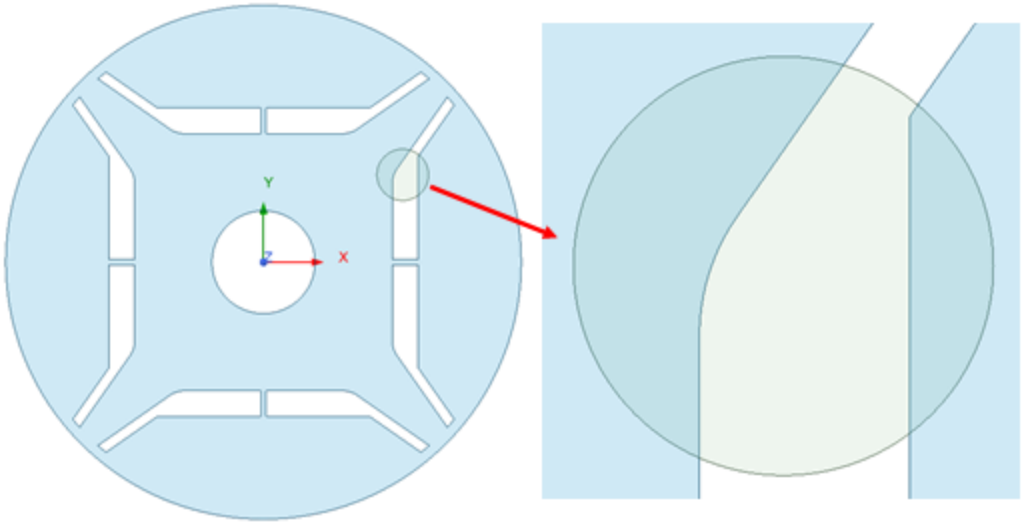
Creating a U-Type IPM Core

You can create a U-type IPM core with **InfoCore** = 0.

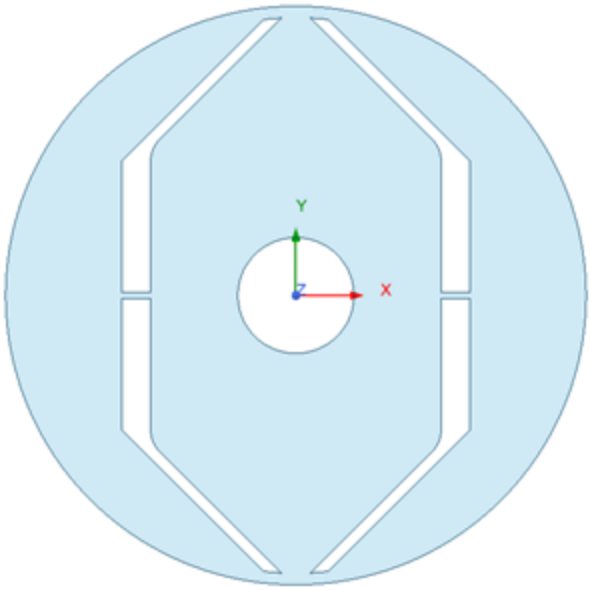
With the default settings of the UPMCore UDP, the created U-type IPM core is shown below.

You can input a negative value for **ThkPostIn**. When **ThkPostIn** < 0, its absolute value, Rc = abs(**ThkPostIn**), is the radius of a fillet at the bottom corner of the PM ducts. The upper limited value of Rc is the maximum value of thickness of the inner and outer ducts. That is, the center point of the fillet arc will always within PM ducts. When **ThkPostIn** < 0, there will be no outer post, that is, the value of **ThkPostOut** will be automatically changed to 0.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can also create a U-type IPM core of two poles. The following figure is an example of a two-pole U-type IPM core, where the setting value of **AngOffOut** is -45.

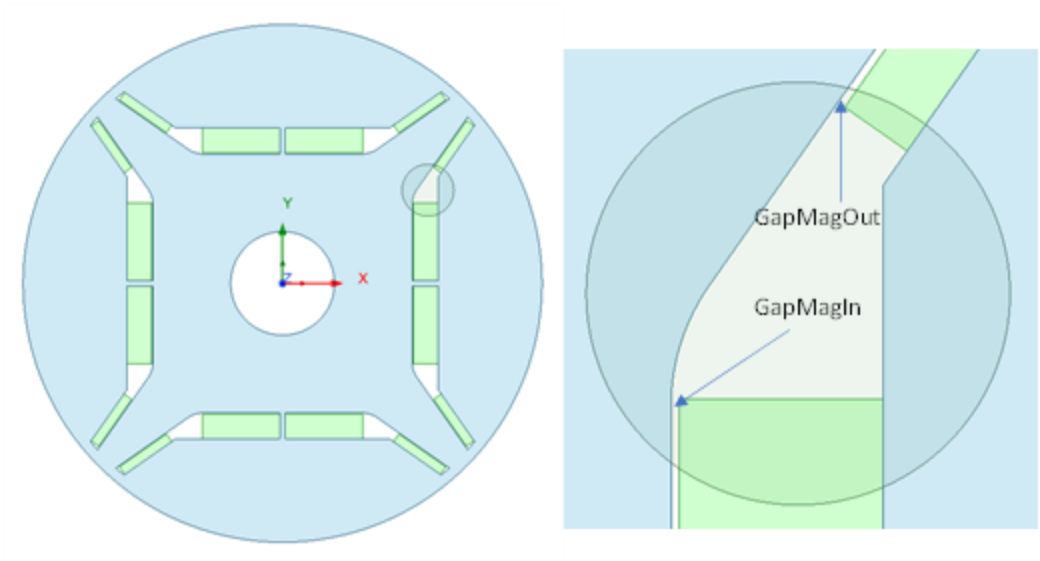


Creating Magnets (UPM Core)

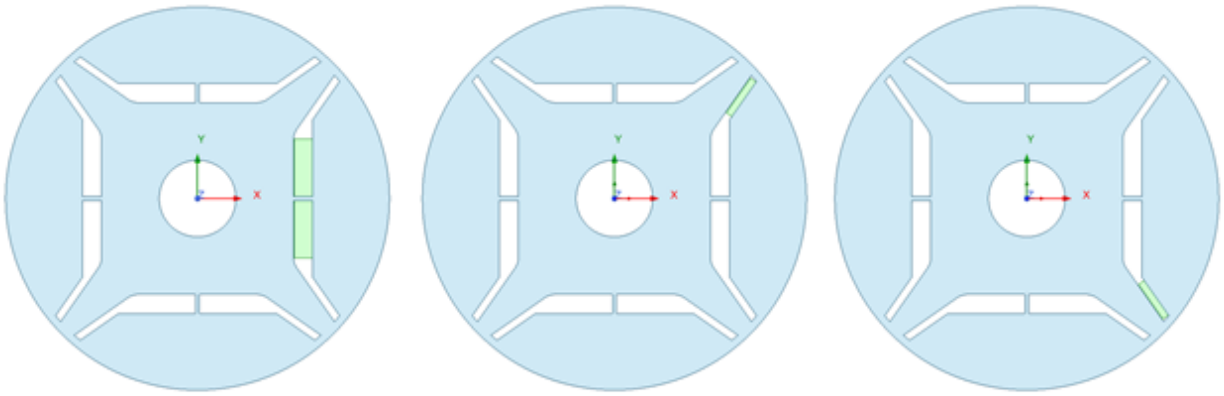
All magnets of a U-type IPM Core are created by setting the value of **InfoCore** to 1, as shown below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Notice that **GapMagOut** and **GapMagIn** include all gaps of both top and bottom sides. If both top and bottom gaps are 0.1 mm, the created magnets will be located inside the PM ducts in such a way that the top gap is 0, and the bottom gap is 0.2 mm. This will not affect the performance solutions. However, this enhances the mesh quality greatly.



To easily assign the direction of magnet excitation, magnets can be created one-by-one by setting the value of **InfoCore** to 3, 4, or 5. The setting of **InfoCore** = 3 is used to create inner magnet(s) as one object no matter whether it is separated by the center post or not, and the value of **WidMagIn** stands for the total width of inner magnet(s). **InfoCore** = 4 is used to create the left-side magnet, and **InfoCore** = 5 to create the right-side magnet, as shown below.

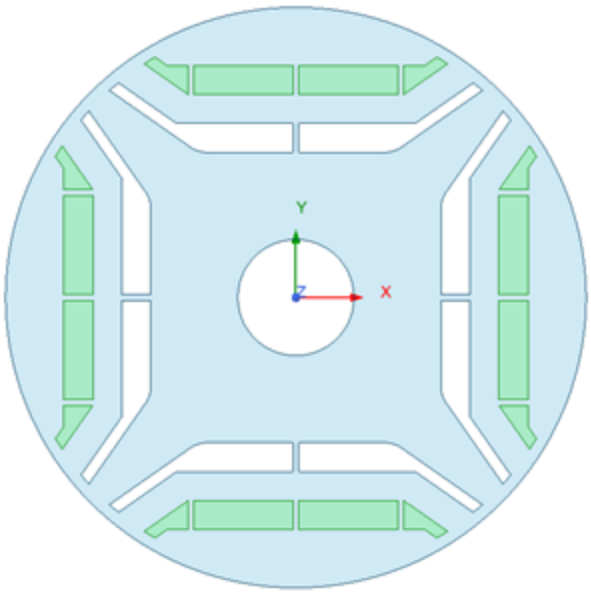


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating PM Ducts (UPM Core)

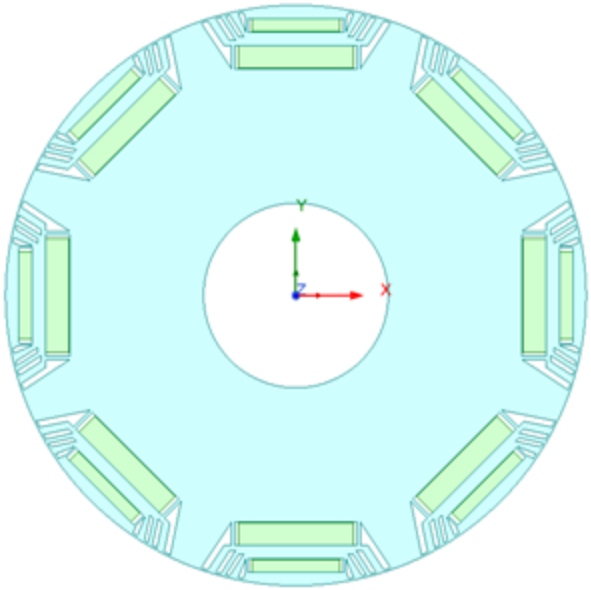
All PM ducts of a U-type IPM Core are created by setting the value of **InfoCore** to 2. Subtracting a PM duct set, the software can create a poly-layer U-type IPM core.

A U-type PM duct set, together with a U-type IPM core, is shown below. The parameters of the additional ducts can be totally different from those of the original core.



If you subtract the additional PM duct set from the core, you can get a core with two-layer PM ducts. Continuing to create and subtract additional PM duct sets, the software can create an IPM core with an arbitrary number of layers of PM ducts. The figure below shows an IPM core with four-layer PM ducts. Notice that when **ThkDuctIn** = 0, the PM ducts will have only the outer parts, and when **ThkDuctOut** = 0, the PM ducts will have only the inner parts.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



VPMCore UDP

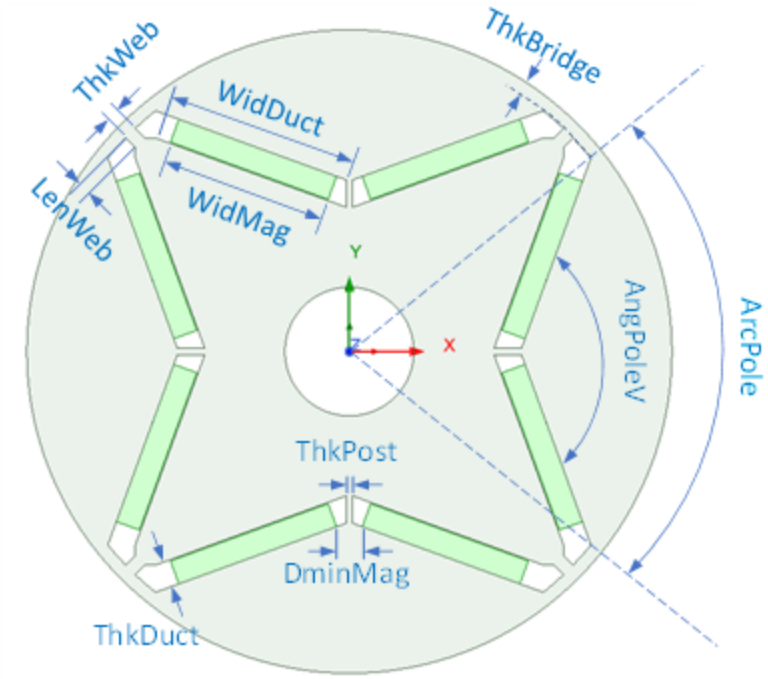
The VPMCore UDP is used to create a single- or poly-layer V-type IPM core and PMs for IPM synchronous machines, or IPM brushless DC motors.

Property	Description
DiaGap	Core diameter on gap side, or outer diameter.
DiaYoke	Core diameter on yoke side, or inner diameter.
Length	Core length.
Poles	Number of poles.
PoleType	0: web; 1: simple.
ThkBridge	Bridge thickness.
ThkDuct	Magnet duct thickness.
WidDuct	Magnet duct width.
ThkWeb/ExtOut	Web thickness (web type), or outer extension (simple type).
LenWeb/ExtIn	Web length (web type), or inner extension (simple type).
AngPoleV	Pole-V angle
ArcPole	Pole arc, in electric degrees, for web pole type only.
ThkPost	Center post thickness, < 0 for duct bottom corner radius (web type)
DminMag	Minimum distance between two-side magnets
WidMag	One-side width of magnets

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

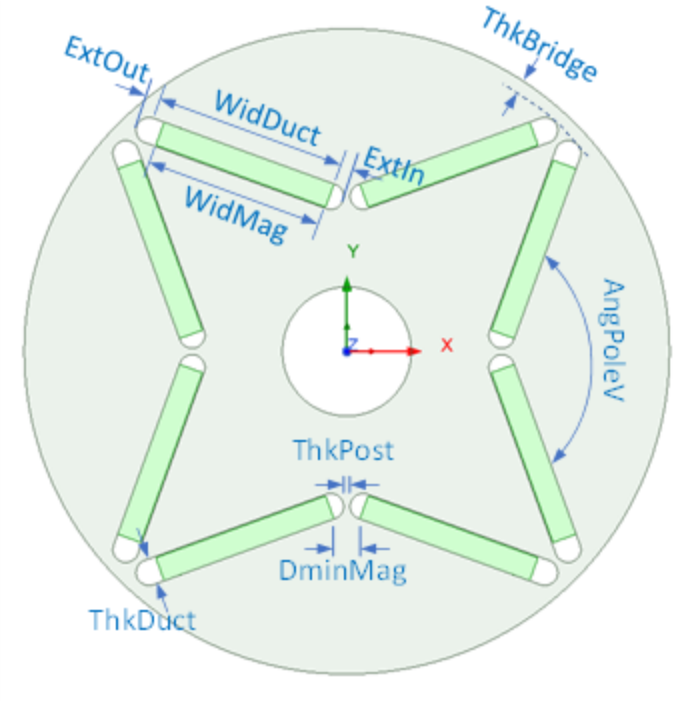
Property	Description
GapMag	Two-side gap of magnets (ThkMag = ThkDuct – GapMag)
LenRegion	Region length.
InfoCore	0: core; 1: magnets; 2: ducts; 3: left magnet; 4: right magnet; 100: region.

Most parameters for a VPMCore UDP are shown in the figures below except common parameters like **DiaGap**, **DiaYoke**, and **Length**.



Parameters of VPMCore UDP (**PoleType** = 0).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Parameters of VPMCore UDP (**PoleType** = 1).

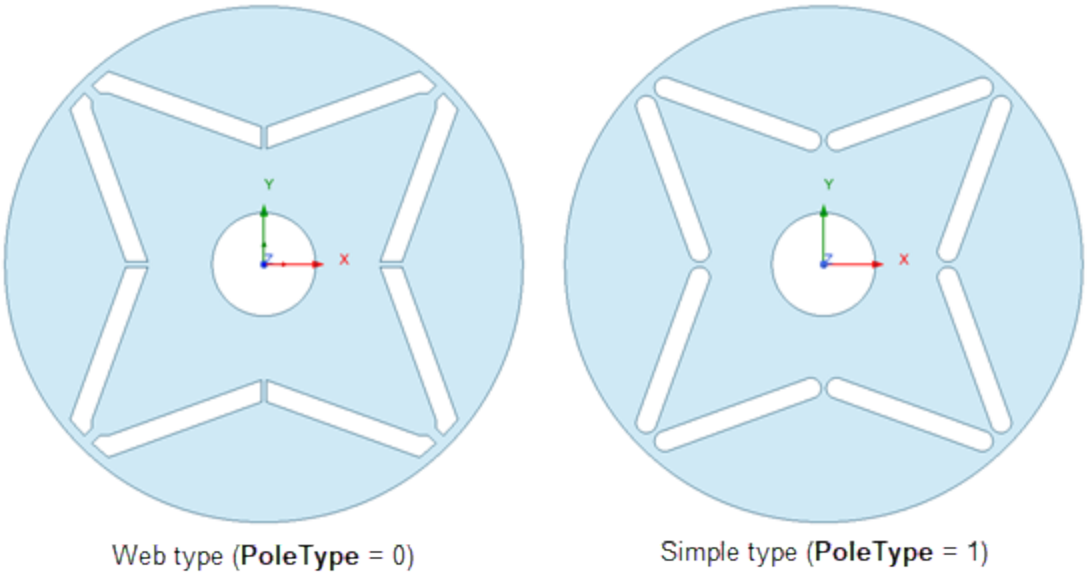
Creating a V-Type IPM Core

You can create a V-type IPM core by setting **InfoCore** = 0.

With the default settings of the VPMCore UDP, the created V-type IPM cores of web type (**PoleType** = 0) and simple type (**PoleType** =1) are shown below.

For a web-type core, you can input a negative value for **ThkPost**. When **ThkPost** < 0, its absolute value, Rc = abs(**ThkPost**), is the radius of a fillet at the bottom corner of the PM ducts. The upper limited value of Rc is the thickness of the PM ducts. For a simple-type core, the upper limit value for **ExtOut** and **ExtIn** is a half thickness of PM ducts.

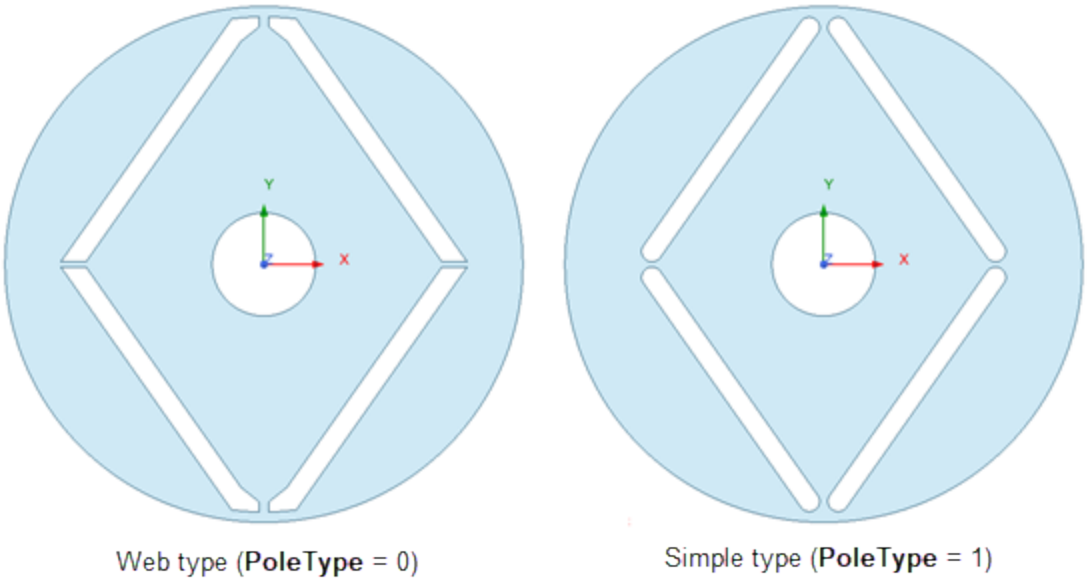
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Web type (**PoleType** = 0) Simple type (**PoleType** = 1)

4-pole V-type IPM cores

The software can create a V-type IPM core of 2 poles. The figure that follows is an example of 2-pole V-type IPM core, where the value of **AngPoleV** is 250.



Web type (**PoleType** = 0) Simple type (**PoleType** = 1)

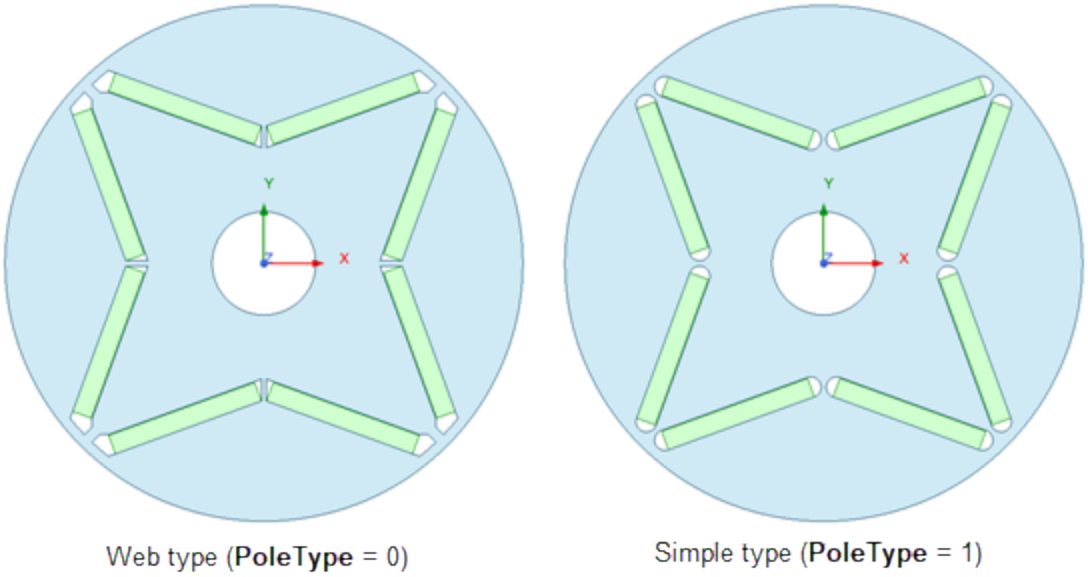
2-pole V-type IPM cores

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating Magnets (VPM Core)

All magnets of a V-type IPM Core are created by setting the value of **InfoCore** to 1. V-type IPM cores of web type and simple type with all magnets are shown below.

Notice that **GapMag** includes total gaps of both top and bottom sides. If both top and bottom gaps are 0.1 mm, the created magnets will be located inside the PM ducts in such a way that the top gap is 0, and the bottom gap is 0.2 mm. This will not affect the performance solutions. However, this enhances the mesh quality greatly.

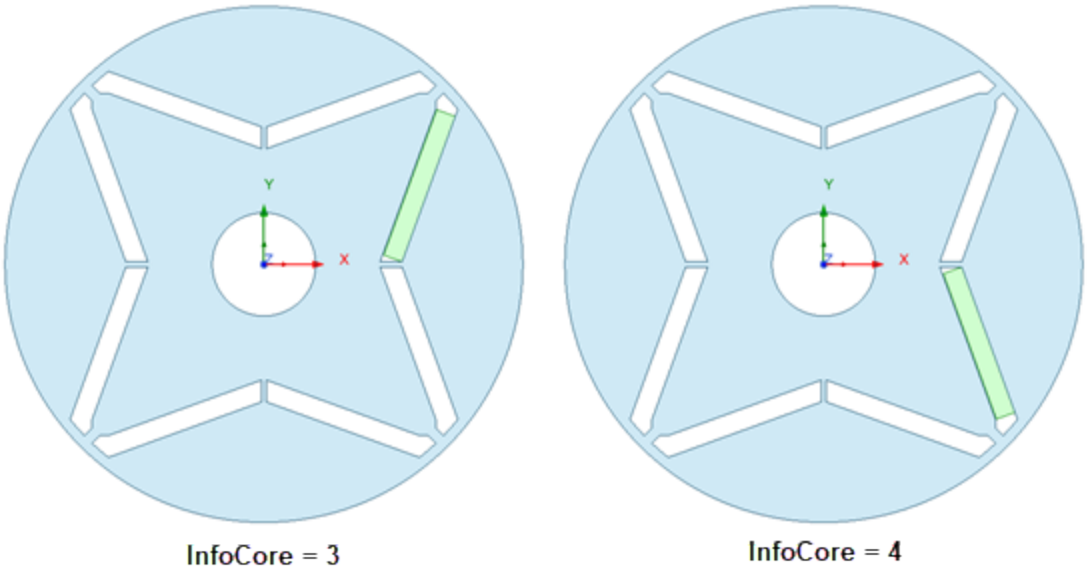


Web type (**PoleType** = 0) Simple type (**PoleType** = 1)

V-type IPM cores with all magnets

To easily assign the direction of magnet excitation, magnets can be created one-by-one by setting the value of **InfoCore** to 3, or 4. The setting of **InfoCore** = 3 is used to create the left-side magnet and **InfoCore** = 4 is used to create the right-side magnet as shown below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



V-type IPM core with a single magnet

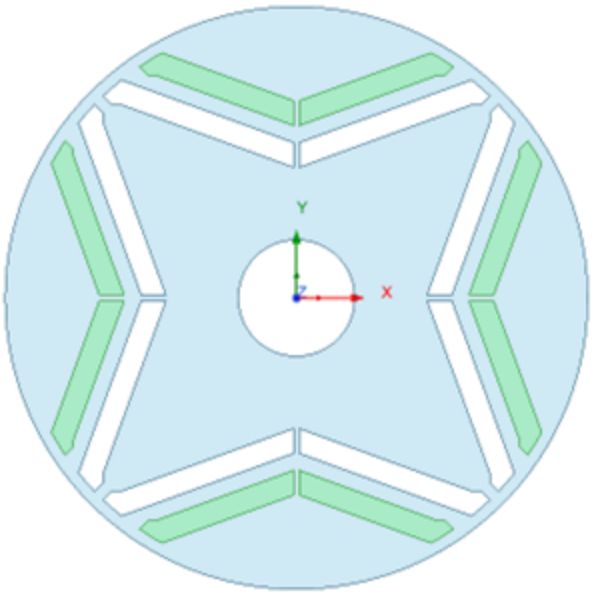
When the input values of magnet width are too large to fit in the PM ducts, they will be modified based on the maximum possible sizes.

Creating PM Ducts (VPM Core)

All PM ducts of a V-type IPM Core are created by setting the value of **InfoCore** to 2. Subtracting a PM duct set, you can create a poly-layer V-type IPM core

A V-type PM duct set, together with a V-type IPM core, is shown below. The parameters of the additional ducts can be totally different from those of the original core.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If you subtract the additional PM duct set from the core, you can get a core with two-layer PM ducts. Continuing to create and subtract additional PM duct sets, the software can create an IPM core with an arbitrary number of layers of PM ducts.

VentCore UDP

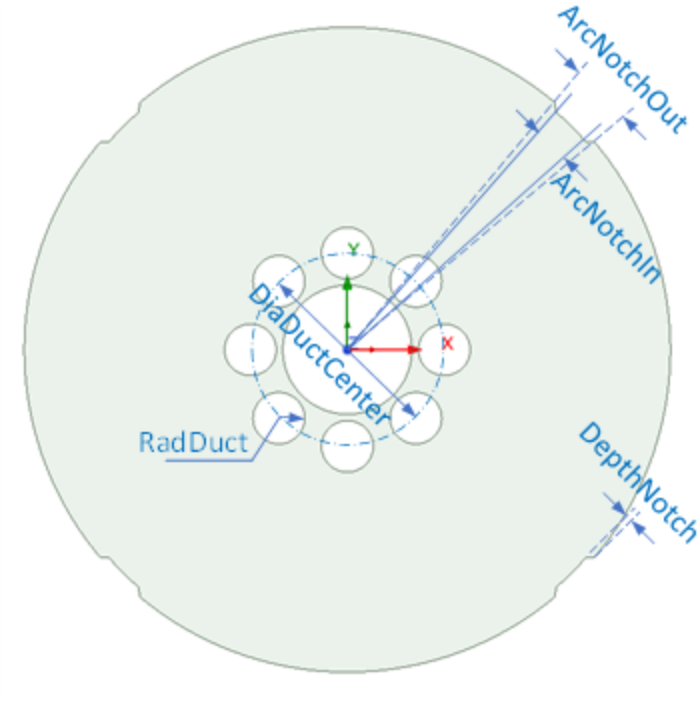
The VentCore UDP is used to create a vent core, a vent shaft, vent ducts, as well as notches, for various cores of electrical machines. A vent core can be used as a base object from which some tool objects can be subtracted to form various machine cores. The vent ducts and notches can also be used as tools to be subtracted from other machine cores.

Property	Description
DiaGap	Core diameter on gap side, or outer diameter.
DiaYoke	Core diameter on yoke side, or inner diameter.
Length	Core length.
Poles	Number of poles for notches.
DepthNotch	Notch depth.
ThkBridge	Bridge thickness.
ArcNotchOut	Notch outer arc, in electric degrees.
ArcNotchIn	Notch inner arc, in electric degrees.
Ducts	Number of axial vent ducts.
DuctType	0: none; 1: circular; 2: shaft spoke; 3: arc; 4: rectangular.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

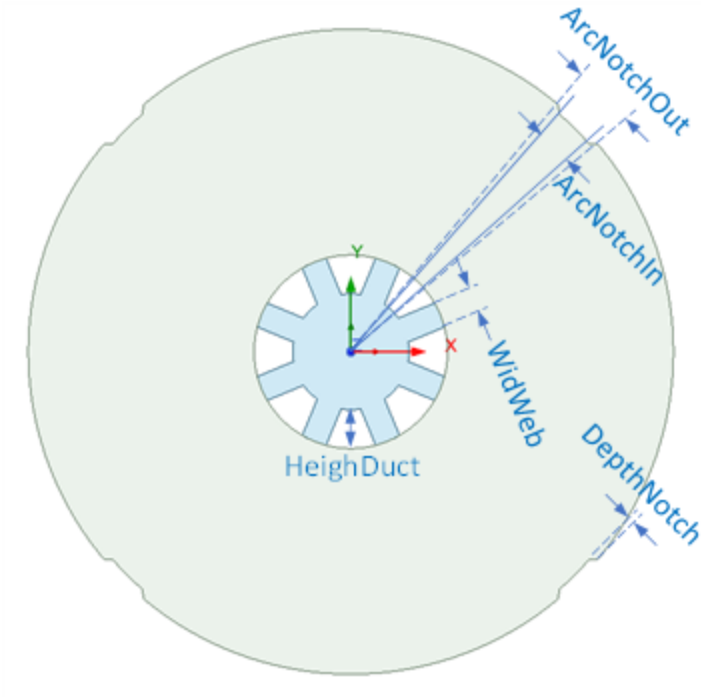
Property	Description
DiaDuctCenter	Diameter of duct center (not for shaft spoke).
HeightDuct	Duct height in radial direction.
WidDuct/WidWeb	Duct width (rectangular) or web width (shaft spoke, arc).
RadDuct	Duct radius (circular) or corner radius (arc, rectangular).
AngDuctShift	Duct shift angle.
LenRegion	Region length.
InfoCore	0: core; 1: shaft; 2: ducts; 3: notches; 100: region.

Most parameters for a VentCore UDP are shown in the figures below except common parameters like **DiaGap**, **DiaYoke**, and **Length**.



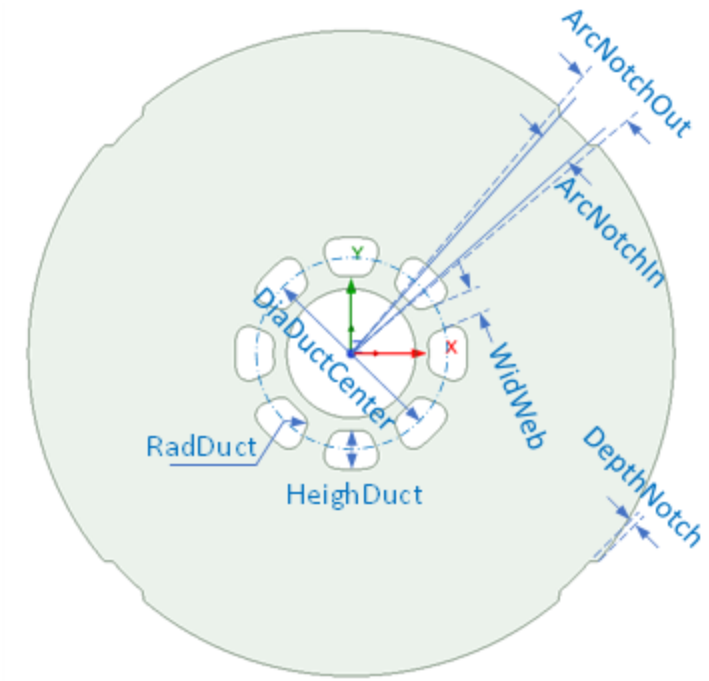
Parameters of VentCore UDP (**DuctType** = 1).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



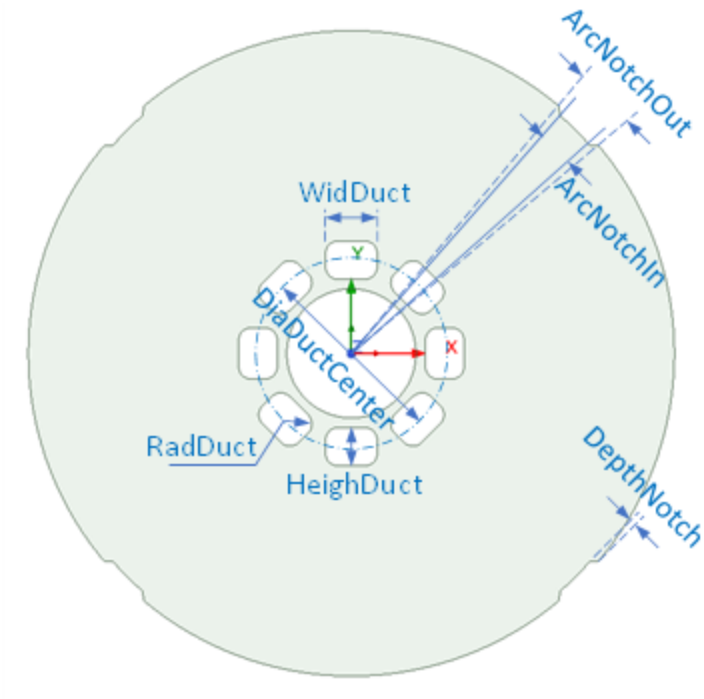
Parameters of VentCore UDP (**DuctType** = 2).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Parameters of VentCore UDP (**DuctType** = 3).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



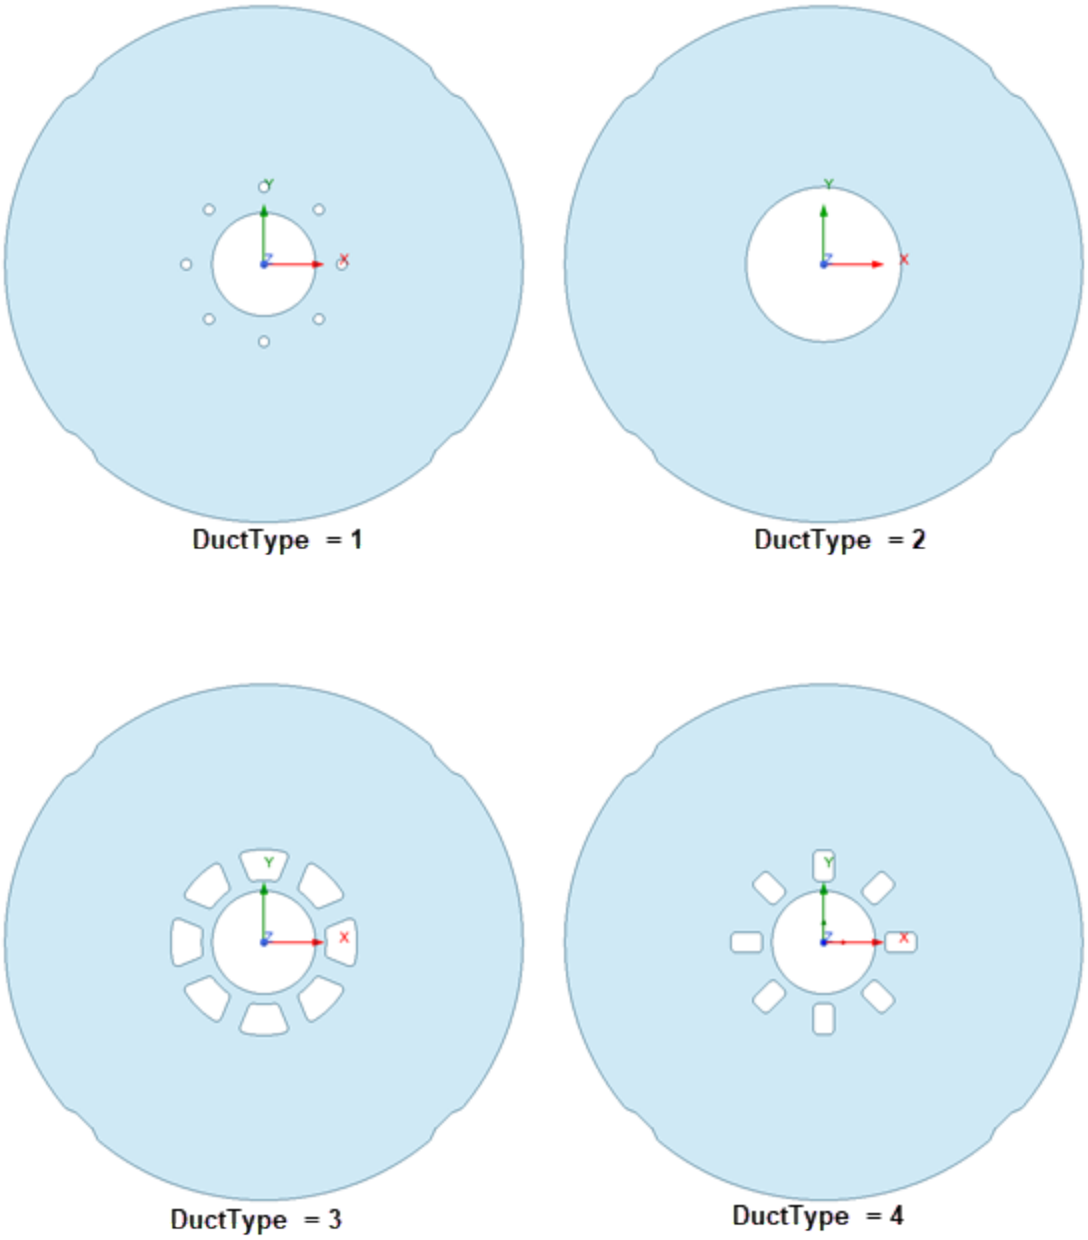
Parameters of VentCore UDP (**DuctType** = 4).

Creating a VentCore

You can create a vent core from VentCore UDP by setting **InfoCore** = 0.

With the default parameter settings of the VentCore UDP, the created vent cores of different duct types are shown in the figures below. Note that the value of **DiaYoke** for **DuctType** = 2 is modified to 30 mm to pass the validation.

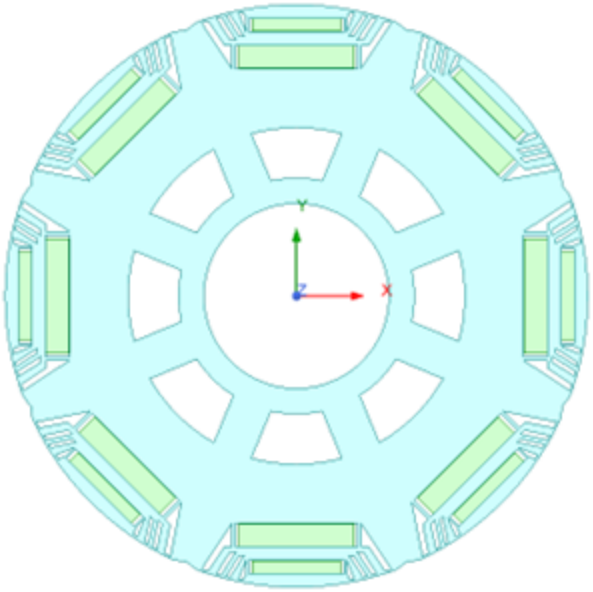
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



VentCores of various Duct Types

The following figure shows an example in which a vent core is used as a base object, and several U-type IPM ducts are used as tool objects to be subtracted from the vent core to form a poly-layer IPM core with vent ducts.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

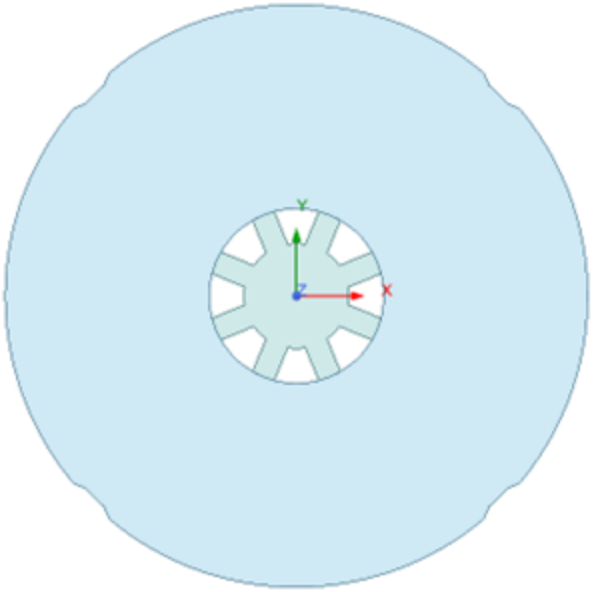


A poly-layer IPM core with vent ducts

Creating a Shaft (VentCore)

You can create a vent core shaft using the VentCore UDP by setting the value of **InfoCore** to 1.

A shaft, together with a V-type IPM core with **DuctType** = 2, is shown below.

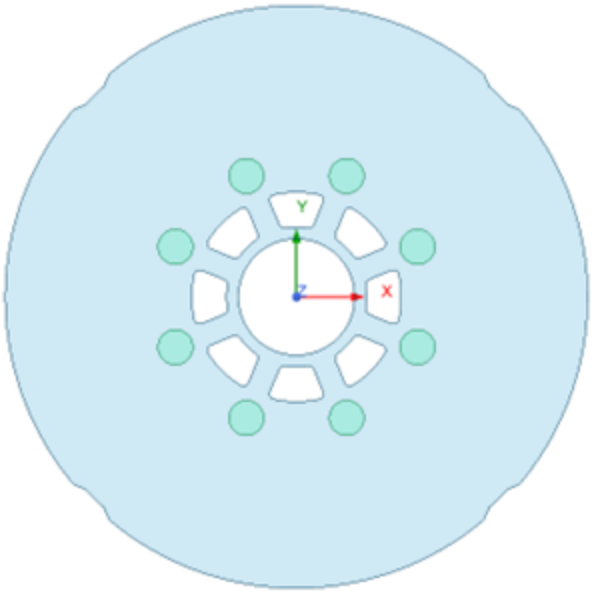


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating Vent Ducts (VentCore)

All vent ducts of a vent core are created by setting the value of **InfoCore** to 2. Subtracting a vent duct set, you can create a vent core with poly-layer vent ducts.

A vent duct set, together with a vent core, is shown in the figure below. The parameters of the additional ducts can be totally different from those of the original core.



A vent duct set of **DuctType** = 1, with a vent core of **DuctType** = 3.

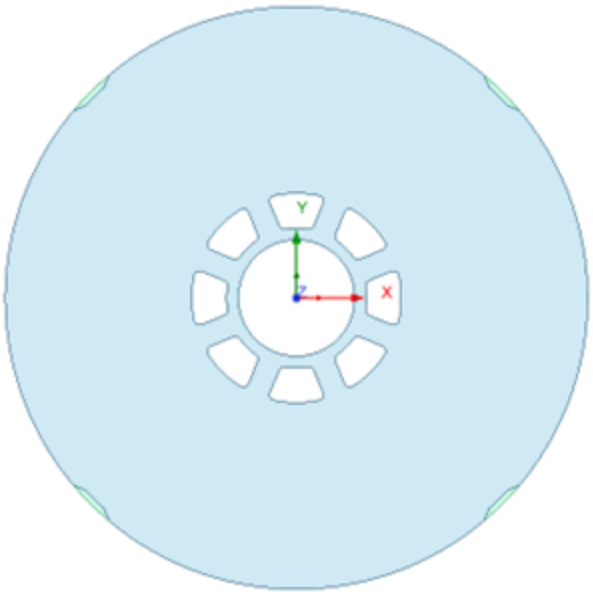
If you subtract the additional vent duct set from a vent core, you can get a core with two-layer vent ducts. Continuing to create and subtract additional vent duct sets, you can create a vent core with an arbitrary number of layers of vent ducts.

Creating Notches (VentCore)

All notches of a vent core are created by setting the value of **InfoCore** to 3, which can be subtracted from an IPM core to improve the air-gap flux density waveforms.

All created notches, together with a vent core of **DuctType** = 3, are shown in the figure below. The parameters of the additional Notches can be totally different from those of the original core.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Notches together with a vent core of **DuctType** = 3.

UDPs for Other Cores and Coils

UDPs defined for other cores and coils include

- DiskSlotCore UDP
- DiskCoil UDP
- DiskPMCore UDP
- LinearMCore UDP
- TransCore UDP
- TransCoil UDP
- TransTwist UDP

DiskSlotCore UDP

The DiskSlotCore UDP is used to create a stator/rotor core for axial-flux machines. It can also create a squirrel-cage winding of the axial-flux type.

Property	Description
DiaOuter	Core outer diameter
DiaInner	Core inner diameter
Thickness	Core axial thickness per side

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
Gap	Gap between core & xy plane (>0: upper; <0: lower; =0: double-sided)
Skew	Skew angle
Slots	Number of slots
SlotType	Slot type: 1 to 6
Hs0	Slot opening height
Hs01	Slot closed bridge height
Hs1	Slot wedge height
Hs2	Slot body height
Bs0	Slot opening width
Bs1	Slot wedge maximum width
Bs2	Slot body bottom width, 0 for parallel teeth
Rs	Slot body bottom fillet
FilletType	0: a quarter circle; 1: tangent connection
HalfSlot	0: symmetric slots; 1: half slots
RingLength	One-side radial ring length
RingHeight	Axial ring height
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface)
InfoCore	0: core only; 1: squirrel cage only

These parameters are used in the following figures.

Note:

- For parameters such as **Skew**, **FilletType**, **SegAngle**, **HalfSlot** and parameters related to slots, refer to SlotCore UDP parameters.
- Figures are shown in pairs to compare parameters when the **InfoCore** value varies

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

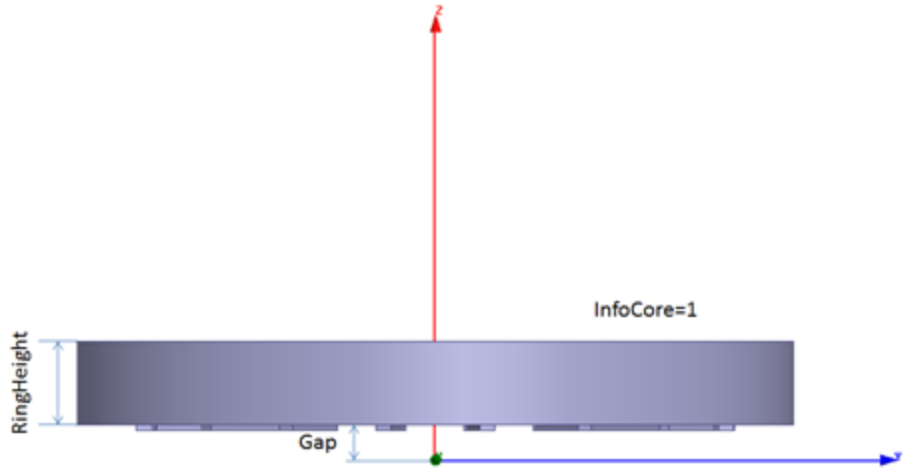

Figure 9-93 3D DiskSlot Core (InfoCore set to 1)

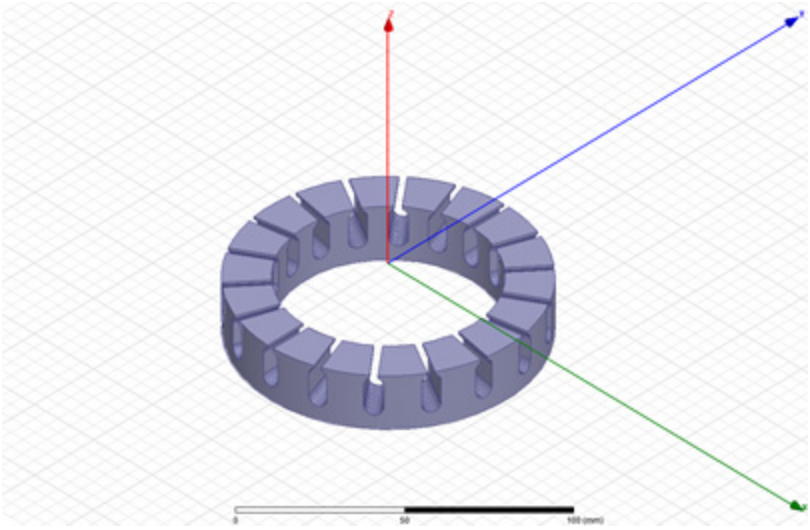
Creating an Upper or Lower Axial-FluxSlot Core (DiskSlot Core)

You can create an axial-flux slot core of a DiskSlot Core manually by setting the value of **InfoCore** to 0.

For an upper core, set the value of **Gap** to be larger than 0, as shown in " Overview of DiskSlotCore (InfoCore set to 0)" on page 9-199 and " 3D DiskSlot Core (InfoCore set to 0)" on the previous page; for a lower core, set this value to be smaller than 0, which is shown in " Lower axial-flux slot core" on the next page.

You can assign the value of this property either when creating a DiskSlot core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9-94 Lower axial-flux slot core

Creating a Squirrel-Cage Winding

You can create squirrel-cage winding of a DiskSlot core manually by setting the property of **InfoCore** to 1. An example of squirrel-cage winding is shown in " DiskSlot Core (InfoCore set to 1)" on page 9-200 .

You can assign the value of this property either when creating an axial-flux slot core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

DiskCoil UDP

The DiskCoil UDP is used to create a lap-type coil in an axial-flux slotted core created by the DiskSlotCore UDP for axial-flux machines. It can also create a coil terminal for current assignment.

Property	Description
DiaOuter	Core outer diameter
DiaInner	Core inner diameter
Thickness	Core axial thickness per side
Gap	Gap between core & xy plane (>0: upper; <0: lower; =0: double-sided)
Skew	Skew angle
Slots	Number of slots
SlotType	Slot type: 1 to 7
Hs0	Slot opening height
Hs1	Slot wedge height
Hs2	Slot body height
Bs0	Slot opening width
Bs1	Slot wedge maximum width
Bs2	Slot body bottom width, 0 for parallel teeth
Rs	Slot body bottom fillet
FilletType	0: a quarter circle; 1: tangent connection
Layers	Number of winding layers
CoilPitch	Coil pitch measured in slots
EndExt	One-side radial end extended length
EndClr	Clearance between two end spans; 0 for no span
SegAngle	Deviation angle for end span (5~15, <5 for true surface)
InfoCoil	0: winding; 1: coil; 2: terminal

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

- For parameters such as **Skew**, **FilletType**, **SegAngle**, **HalfSlot** and parameters related to slots, refer to SlotCore UDP parameters.
- " One disk coil (InfoCore set to 1)" on the next page can be used in comparison to " All disk coils (InfoCore set to 0)" below to show **CoilPitch** parameter.
- A DiskSlot core is used as reference in " EndExt and EndClr parameters (InfoCore set to 0)" on the next pageto show **EndExt** and **EndClr** parameters.

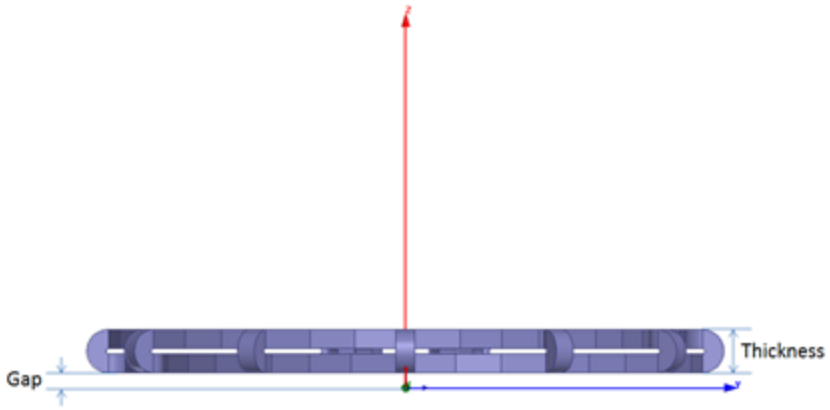

Figure 9-98 Gap and Thickness parameters (InfoCore set to 0)

Creating a Whole Winding (Upper or Lower)

You can create a whole winding of a DiskCoil Core manually by setting the property of **InfoCoil** to 0.

For an upper core, set the value of **Gap** to be larger than 0, which is shown in " Gap and Thickness parameters (InfoCore set to 0)" above; for a lower core, set this value to be smaller than 0, which is shown in " Lower whole winding" below.You can assign the value of this property either when creating the DiskCoil or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

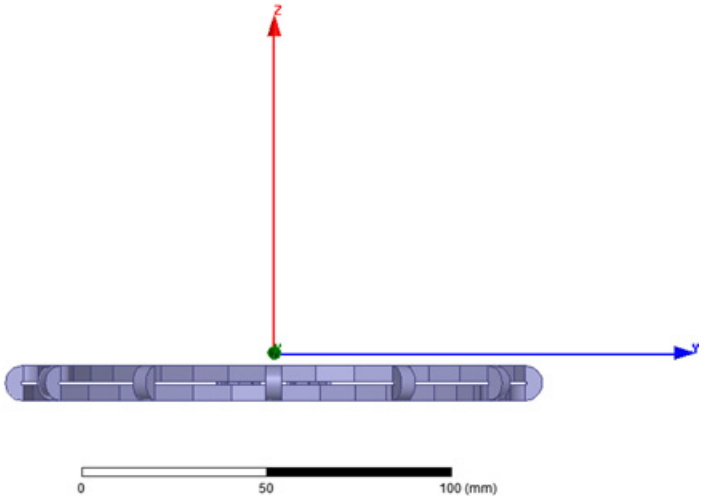

Figure 9-99 Lower whole winding

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating a Lap Coil and its Terminals

You can create a lap coil of a DiskCoil manually by setting the value of **InfoCoil** to 1. An example is shown in " One disk coil (InfoCore set to 1)" on page 9-204 .

You can create a terminal of a DiskCoil manually by setting the value of **InfoCoil** to 2. An example is shown in " A terminal of a DiskCoil UDP" below.

You can assign the value of this property either when creating a DiskCoil or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

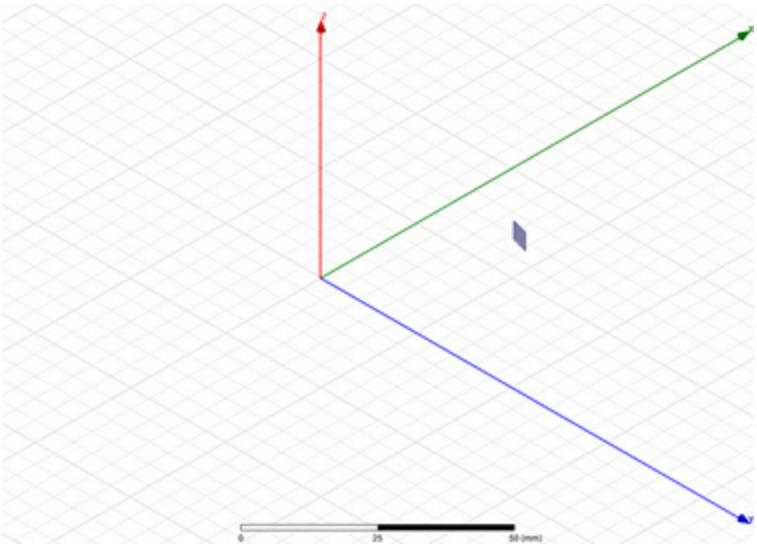

Figure 9-100 A terminal of a DiskCoil UDP

DiskPMCore UDP

The DiskPMCore UDP is used to create a PM core of the axial-flux type for axial-flux PM machines.

Property	Description
DiaOuter	Core outer diameter
DiaInner	Core inner diameter
Thickness	Core axial thickness per side
Gap	Gap between core & xy plane (>0: upper; <0: lower; =0: double-sided)
Skew	Skew angle
Poles	Number of poles

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
Embrace	Pole embrace
ThickMag	Magnet axial thickness per side
InfoCore	0: core only; 1: all PMs; 2: one PM only

Note: There are two objects in each of the following figures. Both objects in each figure are DiskPMCore. The value of **InfoCore** of one DiskPMCore is 1 (red object), the other is 0 (gray object).

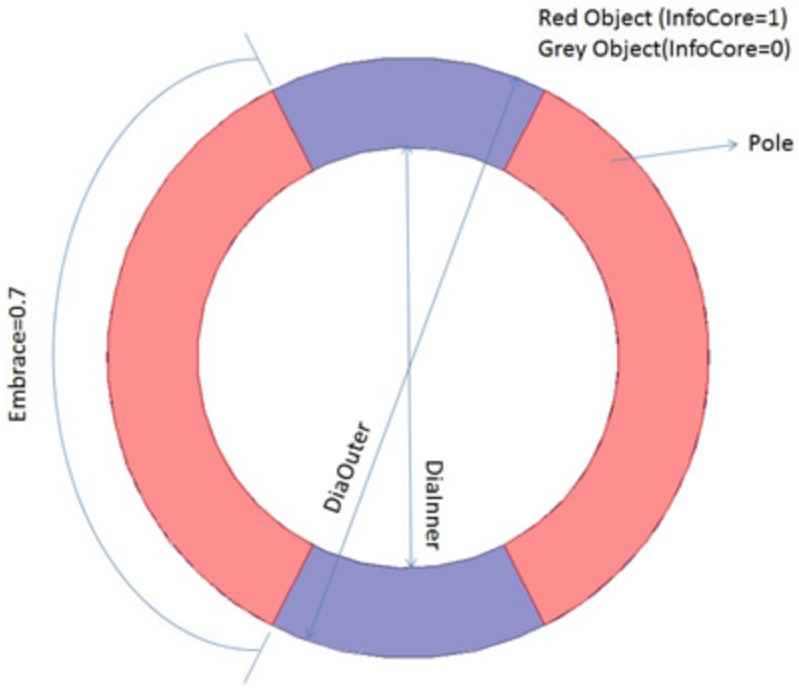

Figure 9-101 DiskPM core parameters on x-y plane

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

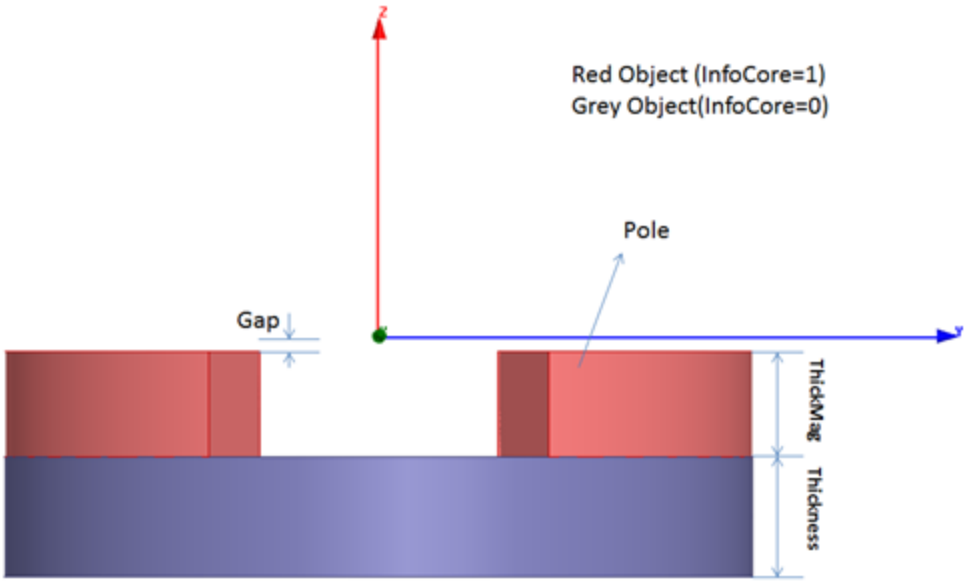

Figure 9-102 DiskPM core parameters in axial direction

Creating an Upper or Lower Axial-Flux PM Core

You can create an axial-flux PM core of a DiskPM core manually by setting the value of **InfoCore** to 0.

For an upper core, set the value of **Gap** to be larger than 0; for a lower core, set this value to be smaller than 0.

An example of an upper core is shown in "Upper axial-flux PM core" on the facing page, whereas a lower core is in " Lower axial-flux PM core" on the facing page.

You can assign the value of this property either when creating a Disk PM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

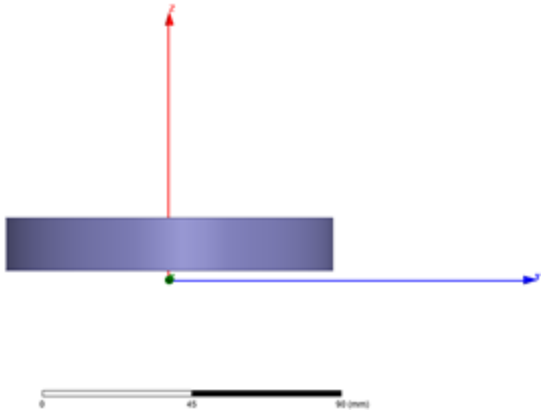

Figure 9-103 Upper axial-flux PM core

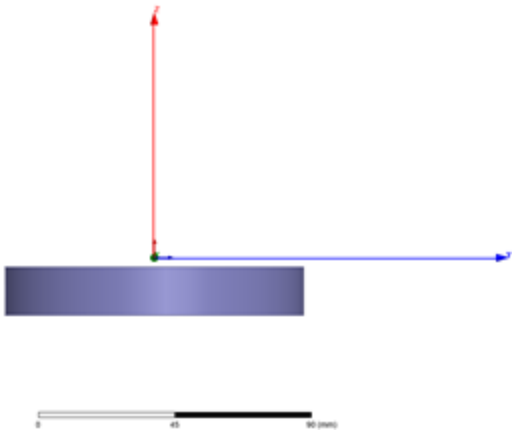

Figure 9-104 Lower axial-flux PM core

Creating All Magnets (Disk PM Core)

You can create all magnets of a disk PM core manually by setting the value of **InfoCoil** to 1. An example of all magnets is shown in " DiskPM core parameters on x-y plane" on page 9-207 and " DiskPM core parameters in axial direction" on the previous page as a red object.

You can assign the value of this property either when creating a disk PM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating One Magnet Only (Disk PM Core)

You can create a single magnet of a disk PM core manually by setting the property of **InfoCoil** to 2. An example of one magnet is shown in " One magnet of disk PM core" on the next page.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can assign the value of this property either when creating a disk PM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

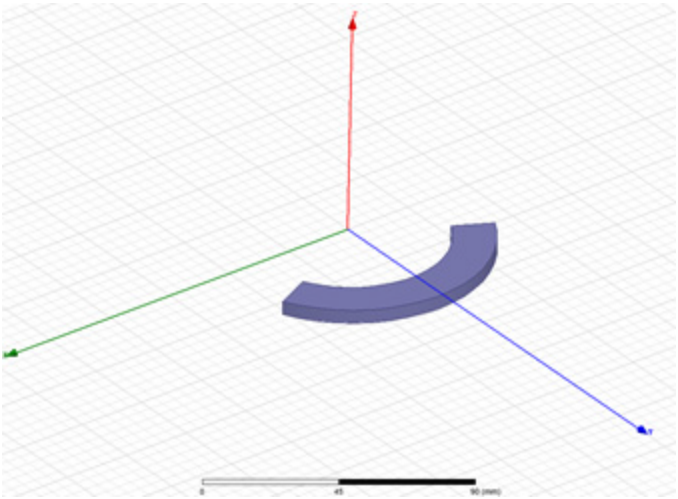

Figure 9-105 One magnet of disk PM core

LinearMCore UDP

The LinearMCore UDP is used to create the mover core and the armature winding for linear motors. It can also create a coil terminal for current assignment.

Property	Description
WidthCore	Core width in motion direction
ThickCore	Core thickness
Length	Core length
SlotPitch	The distance between two slots
Slots	Number of slots
SlotType	Slot type: 1 to 7
Hs0	Slot opening height
Hs1	Slot wedge height
Hs2	Slot body height
Bs0	Slot opening width
Bs1	Slot wedge maximum width
Bs2	Slot body bottom width, 0 for parallel teeth
Rs	Slot body bottom fillet
Layers	Number of winding layers

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
CoilPitch	Coil pitch measured in slots
EndExt	One-side end extended length
SpanExt	Axial length of end span; 0 for no span
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface)
InfoCore	0: core only; 1: core & all coils; 2: one coil only

Note:

- For parameters such as **SegAngle** and parameters related to slots, refer to SlotCore UDP parameters.
- The InfoCore values of the following two figures are both 1 to better describe other parameters such as **EndExt** and **SpanExt**

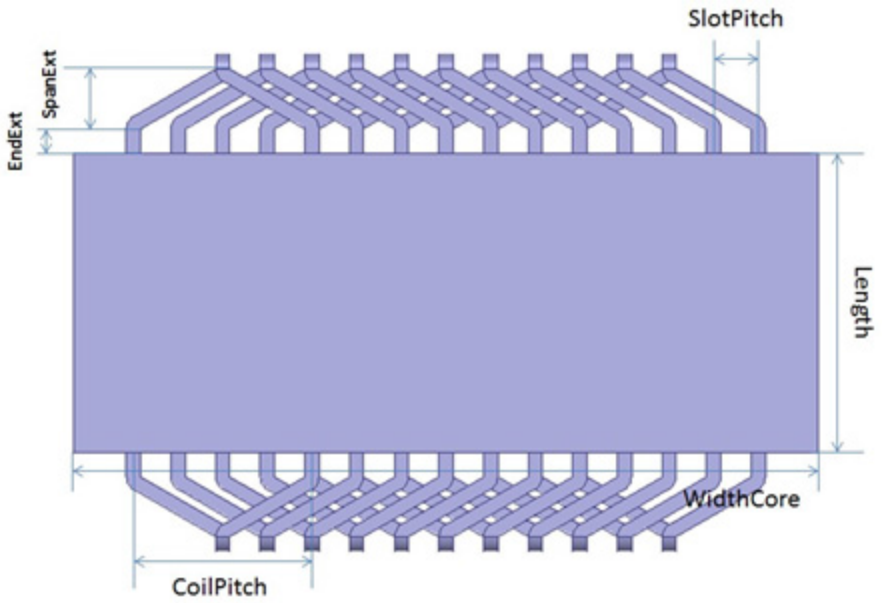

Figure 9-106 Parameters of LinearMCore in x-y plane (InfoCore set to 1)

Creating a Linear Machine Core

You can create a linear machine core manually by setting the value of **InfoCore** to 0.

An example of a linear machine core is shown in " Linear Machine Core (InfoCore set to 0)" below.

You can assign the value of this property either when creating a linear-machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

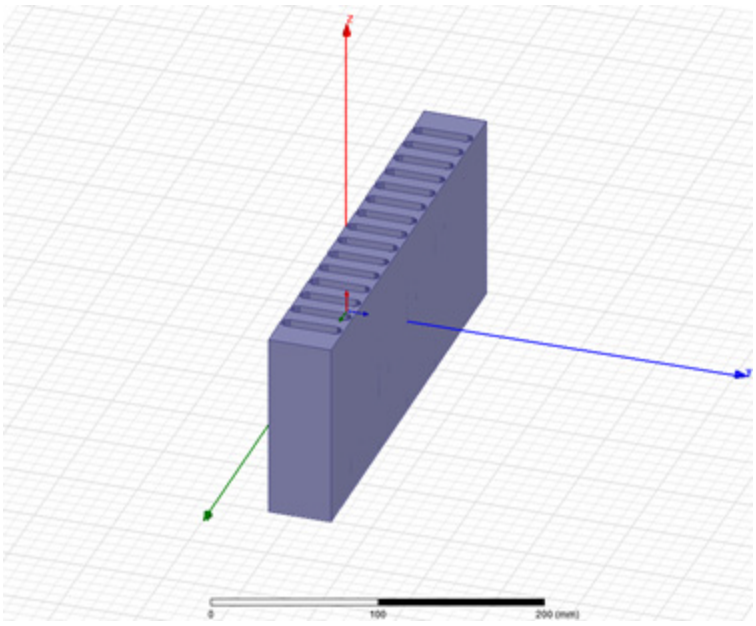

Figure 9-108 Linear Machine Core (InfoCore set to 0)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating a Core and All Coils (Linear Machine Core)

You can create a core and all coils manually by setting the value of **InfoCore** to 1. An example of a core and all coils of a linear-machine core is shown in "A core and all coils of a linear machine core (InfoCore set to 1)" below.

You can assign the value of this property either when creating a linear machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

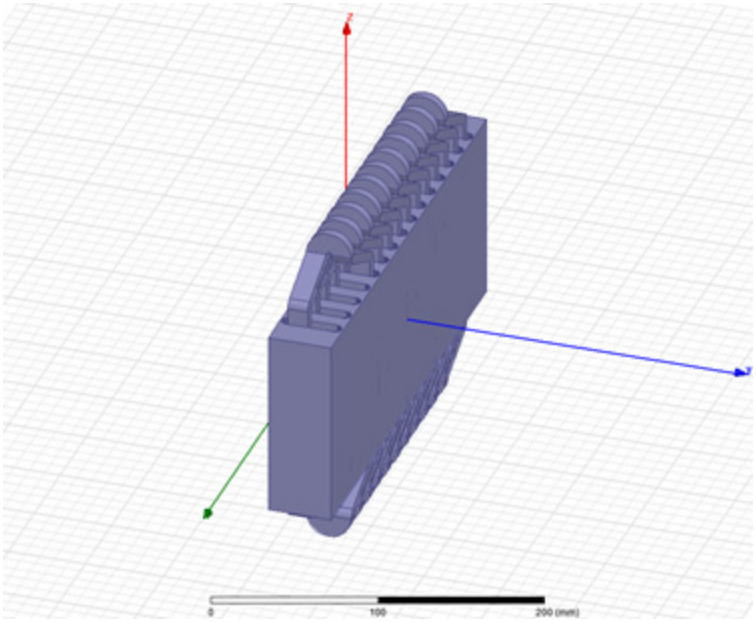

Figure 9-109 A core and all coils of a linear machine core (InfoCore set to 1)

Creating One Coil Only (Linear Machine Core)

You can create a one coil only manually by setting the value of **InfoCore** to 2.

An example of a coil of a linear machine core is shown in " One coil of a linear machine core (InfoCore set to 2)" on the next page.

You can assign the value of this property either when creating a linear machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

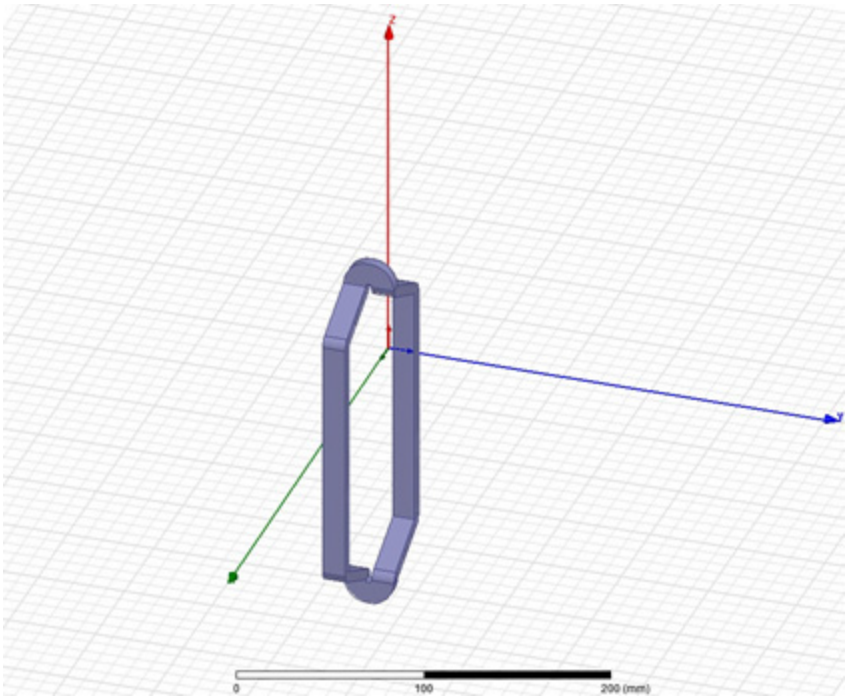

Figure 9-110 One coil of a linear machine core (InfoCore set to 2)

TransCore UDP

The TransCore UDP is used to create a three-leg transformer core for three-phase transformers.

Property	Description
DiaLeg	Outer diameter of leg cross-section
DistLeg	Leg center to center distance
DistYoke	Yoke center to center distance
Stages	Number of stages of leg cross-section
ThickCore	Core thickness, only used for Stages = 1
WidthYoke	Yoke width, =0 for same cross-section as leg's
InfoCore	0: whole core; 1: legs only; 2: yokes only

Note: " TransCore when Stages is not 1 and WidthYoke is 0" on the facing page, " TransCore when Stages is not 1 and WidthYoke is not 0" on the facing page, and " TransCore when Stages is 1 and WidthYoke is not 0" on page 9-216 show a TransCore UDP with different values of **Stages** and **WidthYoke**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

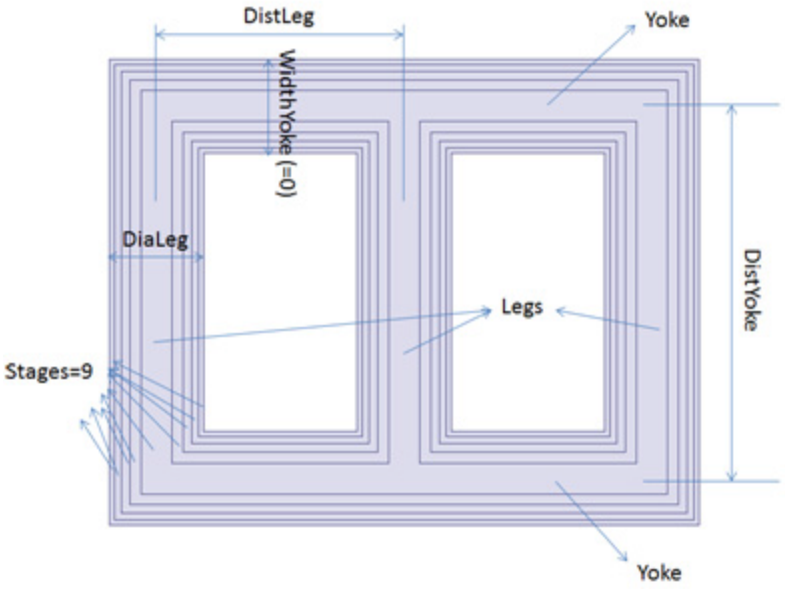

Figure 9-111 TransCore when Stages is not 1 and WidthYoke is 0

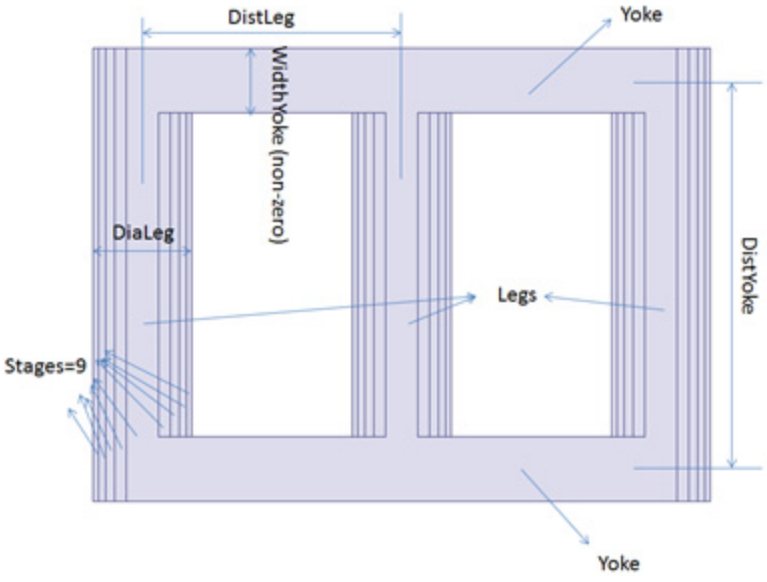

Figure 9-112 TransCore when Stages is not 1 and WidthYoke is not 0

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

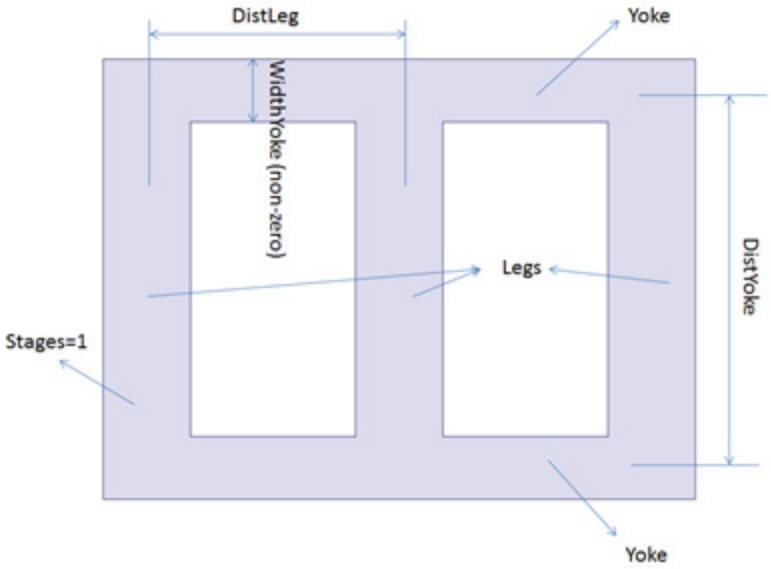

Figure 9-113 TransCore when Stages is 1 and WidthYoke is not 0

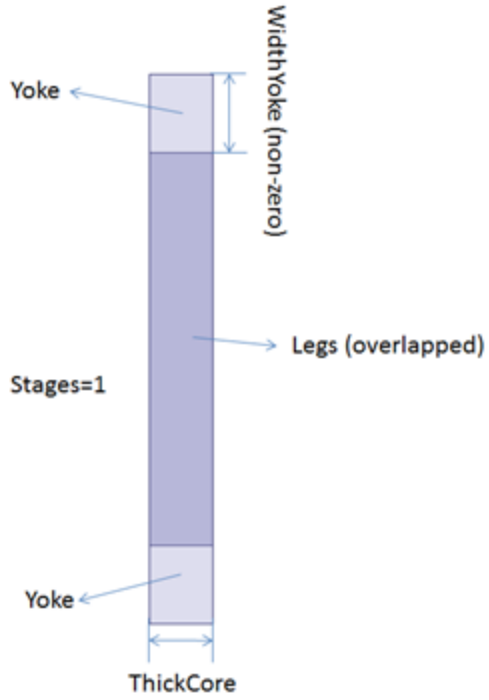

Figure 9-114 Parameters of TransCore in axial direction (when Stages is 1 and WidthYoke is not 0)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating a Three-Leg Transformer Core

You can create a three-leg transformer core manually by setting the value of **InfoCore** to 0.

Examples of a three-leg transformer core are shown in " TransCore when Stages is not 1 and WidthYoke is 0" on page 9-215 , " TransCore when Stages is not 1 and WidthYoke is not 0" on page 9-215 , " TransCore when Stages is 1 and WidthYoke is not 0" on the previous page, and " Parameters of TransCore in axial direction (when Stages is 1 and WidthYoke is not 0)" on the previous page.

You can assign the value of this property either when creating a three-leg transformer or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating Three Legs Only

You can create three legs of the core manually by setting the value of **InfoCore** to 1.

An example of three legs is shown in " Three legs of TransCore (InfoCore set to 1)" below.

You can assign the value of this property either when creating a three-leg transformer core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

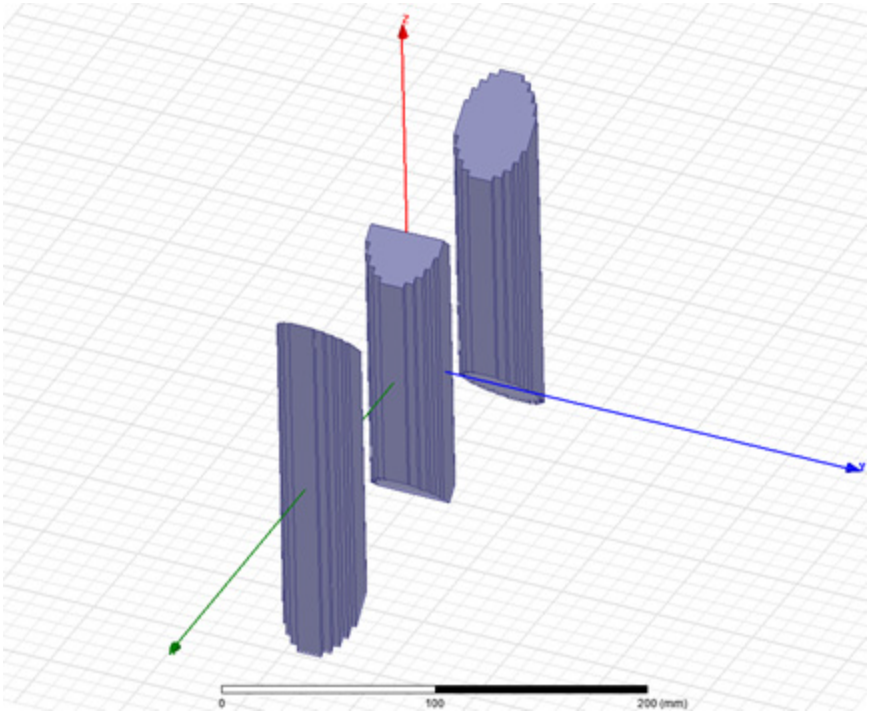

Figure 9-115 Three legs of TransCore (InfoCore set to 1)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating Two Yokes Only

You can create two yokes of the core manually by setting the value of **InfoCore** to 2.

An example of two yokes is shown in " Two Yokes of TransCore (InfoCore set to 2)" below.

You can assign the value of this property either when creating a three-leg transformer core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

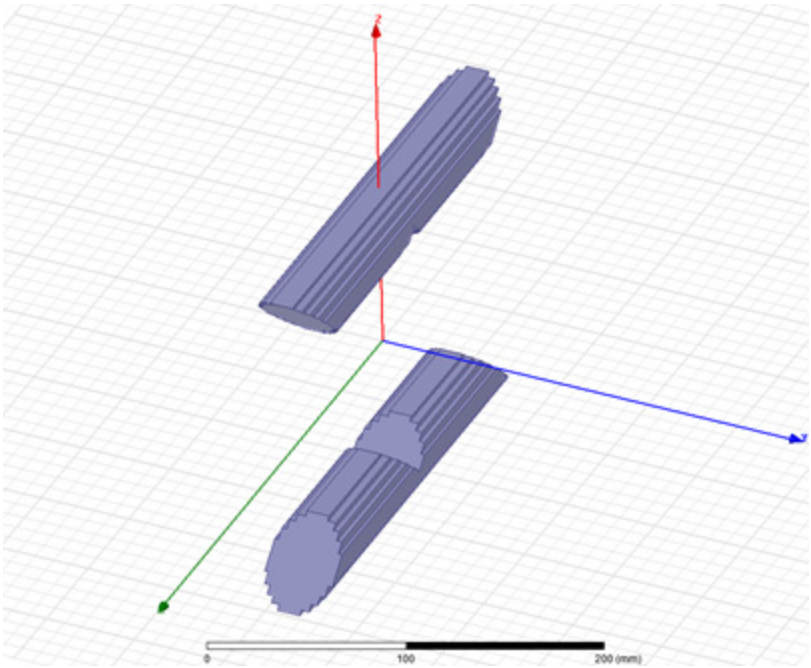

Figure 9-116 Two Yokes of TransCore (InfoCore set to 2)

TransCoil UDP

The TransCoil UDP is used to create a coil in a three-leg transformer core created by the TransCore UDP for three-phase transformers. It can also create a coil terminal for current assignment.

Property	Description
DistLeg	Leg center to center distance
CoilType	Coil type: 1 for solenoid coil; 2 for pancake coil
WidthIn	Coil width between two inner sides
DepthIn	Coil depth between two inner ends

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
RadiusIn	Coil inner fillet radius
ThickCoil	Coil thickness of one side
HighCoil	Coil height
Layers	Number of layers
GapLayer	Gap between two layers
InfoCore	0: all coils; 1: one coil only

Note: The key to making the cross-section of each layer of a coil to be a circle is to set the value of **WidthIn** equal to that of **DepthIn** and at the same time set the value of **RadiusIn** to be half of that of **WidIn**. That is, **WidthIn**=**DepthIn**=2***RadiusIn**.

The cross-section of a layer could be a non-circle if the value of **WidthIn** is not equal to that of **DepthIn** or **RadiusIn**'s value is not half of **WidthIn**'s. " RadiusIn of TransCoil" on the next page shows a situation where a layer is a non-circle.

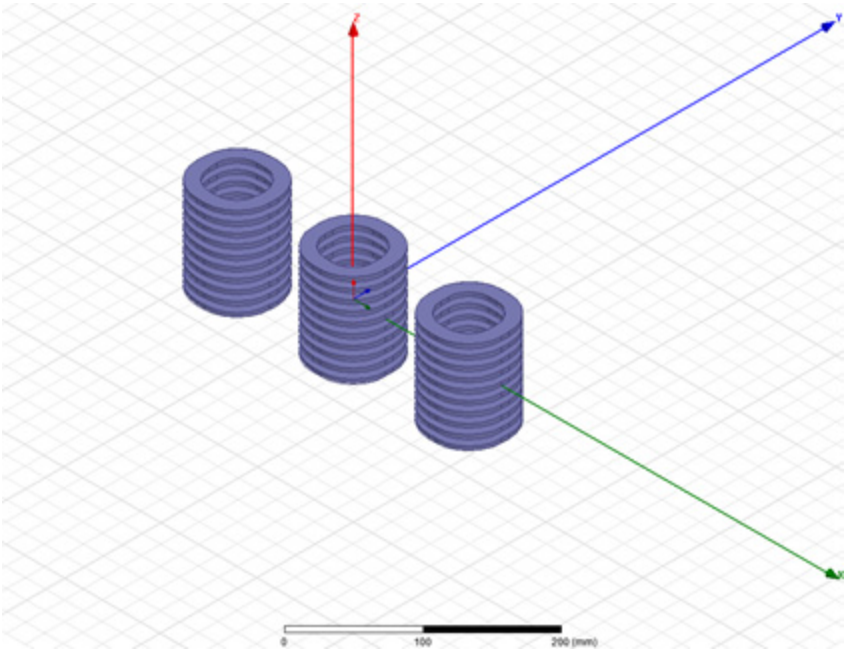

Figure 9-117 Overview of TransCoil (InfoCore set to 0)

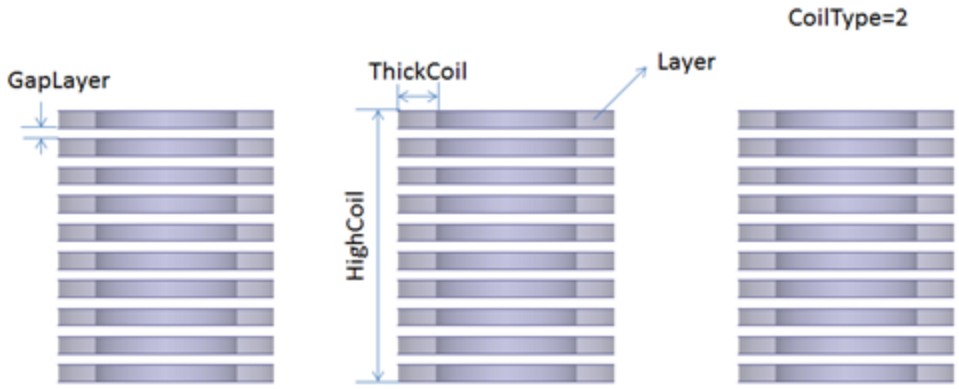

Figure 9-120 Parameters of TransCoil in axial direction (InfoCore set to 0)

Creating Coils for All Three Legs

You can create coils for three legs manually by setting the value of **InfoCore** to 0.

Examples of coils for TransCoil UDP are shown in " Overview of TransCoil (InfoCore set to 0)" on page 9-219 , " Parameters of TransCoil in x-y plane (InfoCore set to 0)" on the previous page, and " Parameters of TransCoil in axial direction (InfoCore set to 0)" above.

You can assign the value of this property either when creating a TransCoil UDP or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating One-Leg Coil Only

You can create a one-leg coil manually by setting the value of **InfoCore** to 1.

An example of a one-leg coil for a TransCoil UDP is shown in " One-leg coil for TransCoil UDP" on the next page.

You can assign the value of this property either when creating a TransCoil UDP or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

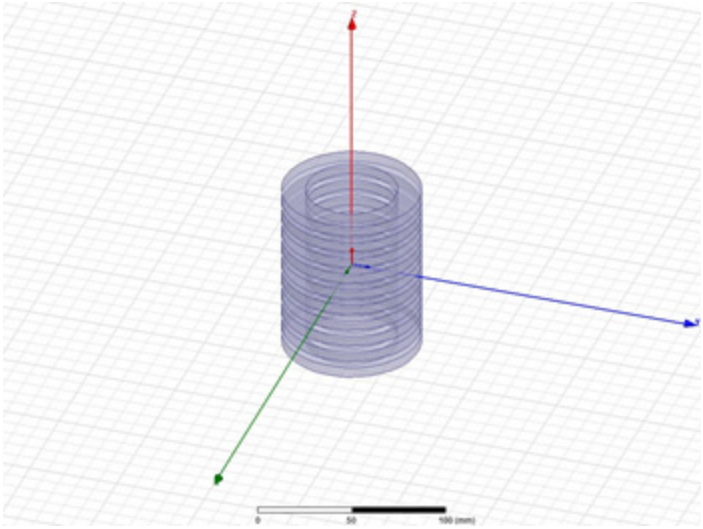

Figure 9-121 One-leg coil for TransCoil UDP

TransTwist UDP

Property	Description
CoreType	1: shell-type; 2: core-type
WidthOut	Core outer width
DepthOut	Core outer depth in coil turn direction
RadiusOut	Core outer fillet radius
WidthIn	Core window width
DepthIn	Core window depth in coil turn direction
RadiusIn	Core window fillet radius
DistCenters	Window center-to-center distance, for shell-type only
HeightCore	Core height
Coils	Number of coils: 1 or 2
WiresCoil	Wires per coil: 1, 2, 3, or 4 (no twist for 1 wire)
TurnsCoil	Number of turns per coil
TurnsTwist	Total twist turns in one coil turn; 360 degrees in one twist turn
DiaWire	Wire diameter
Segments	Polygon segments for wire cross section: <=2 for true circle
InsType	Insulator type: 1: round insulator; 2: filleted square insulator
ThickIns	Outer minimum thickness of insulator
GapWires	The gap between two round wire profiles

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
GapEndTurns	The gap between two end turns of round insulator profiles
GapCoreIns	The gap between core and round insulator profiles inside two windows and at two ends
LeadExt	Lead extension from lead terminal to core end terminal
InfoCore	0: All; 1: Core; 2: Insulator; 3-6: Wires of coil#1; 7-10: Wires of coil#2
InfoTerm	0: 3D wire; 1: 2D go-term; 2: 2D re-term (for InfoCore = 3-10 only)

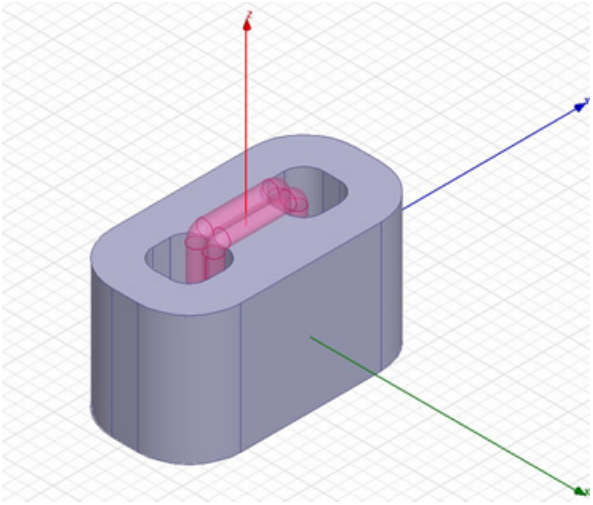

Figure 9-122 Overview of TransTwist UDP (without wires)

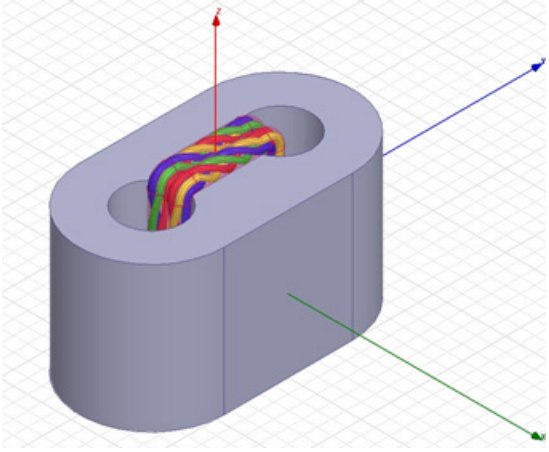

Figure 9-123 Overview of TransTwist UDP (with colorful wires)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

- " Overview of TransTwist UDP (without wires)" on the previous page and " Overview of TransTwist UDP (with colorful wires)" on the previous page give an overview of the TransTwist UDP. The difference between them is " Overview of TransTwist UDP (with colorful wires)" on the previous page has 4 colorful wires inside the insulator whereas " Overview of TransTwist UDP (without wires)" on the previous page has nothing in its insulator.
- In" Overview of TransTwist UDP (without wires)" on the previous page and " Overview of TransTwist UDP (with colorful wires)" on the previous page and also other figures like " Gaps-related parameters of TransTwist UDP (gray Object: InfoCore set to 1, Red Object: InfoCore set to 2, Colorful Wires: InfoCore set to 3 to 6)" on page 9-227 , objects in different colors are all TransTwist UDP but with different **InfoCore** values. For example, in Figure 1-6 , the gray object is a TransTwist UDP whose **InfoCore** value is 1(core), while red, blue, green and yellow objects (wires) are also TransTwist UDPs whose **InfoCore** values are 3, 4, 5, and 6 respectively. Also, the value of the **InfoCore** of pink tube that covers the wires is 2 (insulator). To draw this kind of figure, copy and paste the TransTwist UDP (or manually create multiples of this UDP) and then change their **InfoCore** values and colors.
- The reason for making colorful figures here is to show the parameters of the TransTwist UDP more clearly.
- The difference between " 3D parameters of TransTwist UDP (gray Object: InfoCore set to 1, Red Object: InfoCore set to 2)" on page 9-226 and " 3D parameters of TransTwist UDP (gray Object: InfoCore set to 1, Red Object: InfoCore set to 2)" on page 9-226 is the parameter **TurnsCoil**, which means the number of turns for each coil (only one coil in each figure). There are 2 turns for the coil in Figure 1-4 whereas there is only 1 turn for the coil in " 3D parameters of TransTwist UDP (gray Object: InfoCore set to 1, Red Object: InfoCore set to 2)" on page 9-226 .
- The purpose of" Coil-related parameters of TransTwist UDP (gray Object: InfoCore set to 1, Red Object: InfoCore set to 2)" on page 9-227 is to show the concept of the parameter **Coils**. Note that when the value of **Coils** is 2 in this figure, the two coils are disconnected. For a comparison, see the one coil shown in " Gaps-related parameters of TransTwist UDP (gray Object: InfoCore set to 1, Red Object: InfoCore set to 2, Colorful Wires: InfoCore set to 3 to 6)" on page 9-227 .
- The purpose of " GapEndTurns of TransTwist UDP (gray Object: InfoCore set to 1, Red Object: InfoCore set to 2)" on page 9-228 is to show the parameter of **GapEndTurns**, which is useful only when the value of **TurnsCoil** is larger than 2.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The results of parameter **TurnsTwist** are difficult to show in a figure. It is used to define the number of twist turns in one coil turn for each coil (or wire). As shown in " LeakEndExt of TransTwist UDP (gray Object: InfoCore set to 1, Red Object: InfoCore set to 2, Colorful Wires: InfoCore set to 3 to 6)" on page 9-229 , the green wire is twisted 0.5 turn at the bottom of the core. Then, for the entire coil turn, it may be twisted 3 to 3.5 twist turns (0.5 to 1 turn on the top of the core, and 1 turn on each side of the core).

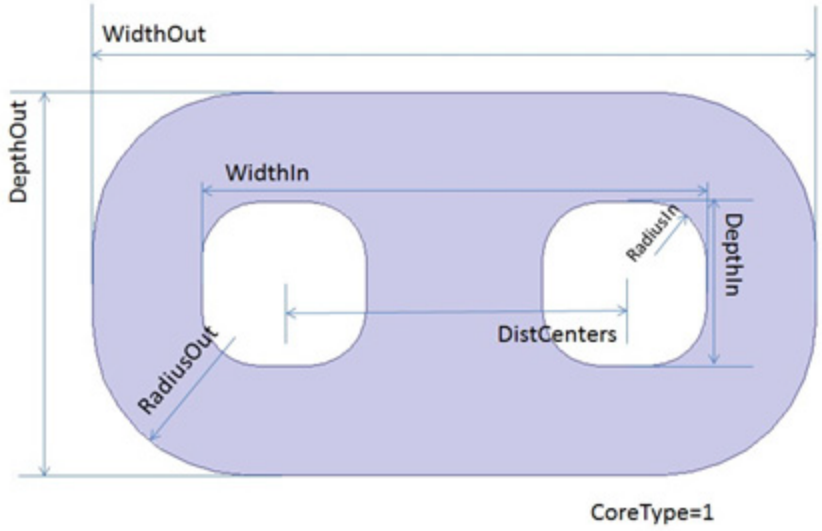

Figure 9-124 2D parameters of TransTwist UDP (InfoCore set to 1)

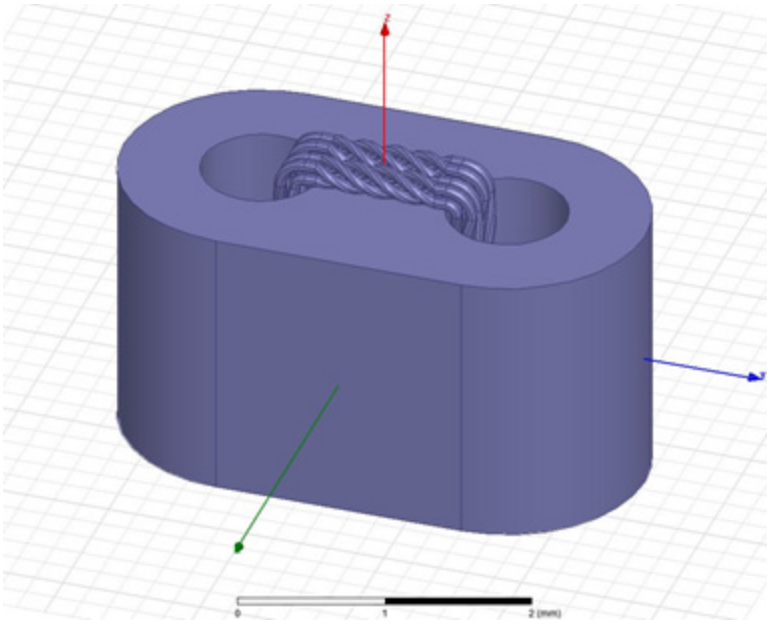
Creating a Core and All Twist Coils

You can create a core and all twist coils manually by setting the value of InfoCore to 0, which is set by default in Maxwell.

An example of a core and all twist coils is shown in " TransTwist UDP (InfoCore set to 0)" on the next page.

You can assign the value of this property either when creating the UDP or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9-132 TransTwist UDP (InfoCore set to 0)

Creating a Twist Wire and its Terminals

You can create a twist wire of a TransTwist manually by setting the value of **InfoCore** to 3 to 6 (or 7-10 for coil #2) and **Info Term** to 0. Examples are shown in " Overview of TransTwist UDP (with colorful wires)" on page 9-223 , " 3D parameters of TransTwist UDP (gray Object: InfoCore set to 1, Red Object: InfoCore set to 2)" on page 9-226 , " Wires-related parameters of TransTwist UDP (gray Object: InfoCore set to 1, Red Object: InfoCore set to 2, Colorful Wires: InfoCore set to 3 to 6)" on page 9-228 , and " LeakEndExt of TransTwist UDP (gray Object: InfoCore set to 1, Red Object: InfoCore set to 2, Colorful Wires: InfoCore set to 3 to 6)" on the previous page as red, green, blue and yellow objects.

You can create a terminal of a wire manually by setting the value of **InfoCore** to 3 to 6 (or 7-10 for coil #2) and **Info Term** to 1 or 2 (for 2D go-term and 2D re-term respectively). An example is shown in " 2D go-terminal of a wire" below below.

You can assign the value of this property either when creating a TransTwist or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

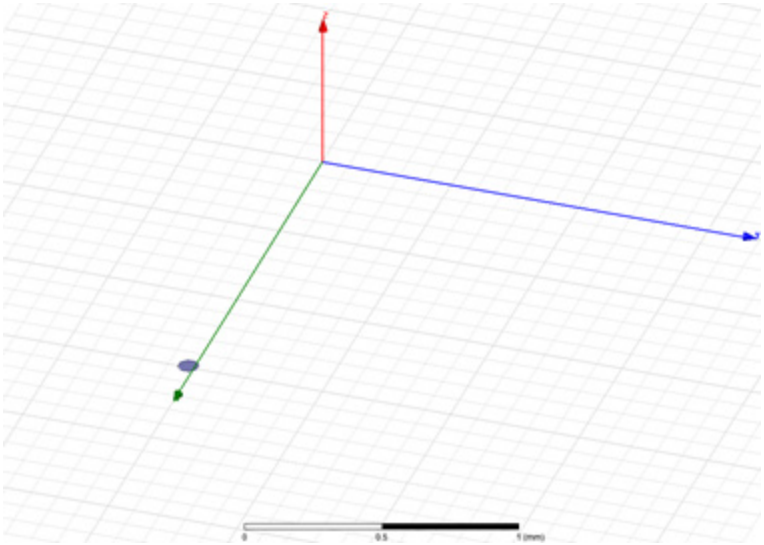


Figure 9-133 2D go-terminal of a wire

Creating a Twist Insulator of All Coils

You can create an insulator of all coils manually by setting the value of **InfoCore** to 2 and **Info Term** to 0. An example is shown in " Twist insulator of all coils" on the facing page.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can assign the value of this property either when creating a TransTwist or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

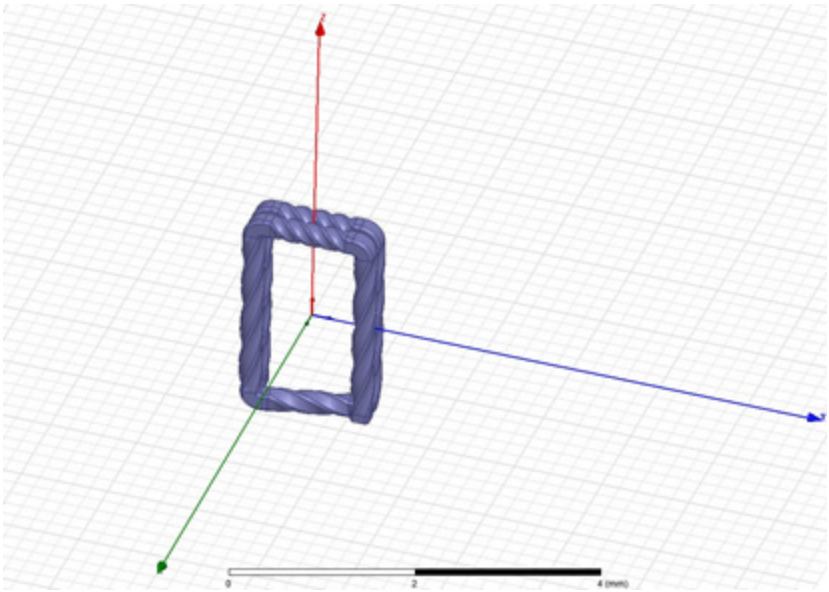

Figure 9-134 Twist insulator of all coils

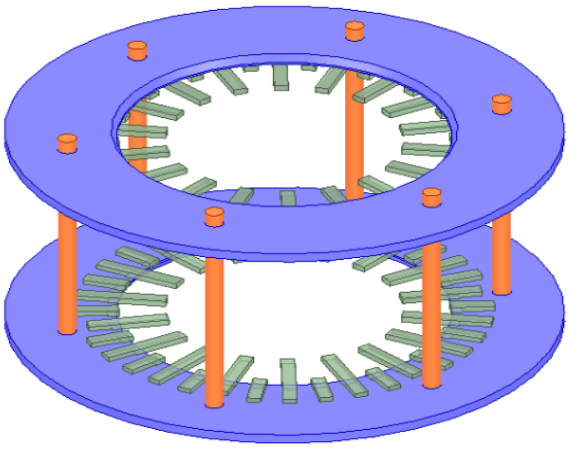
UDPs for Other Machine Parts

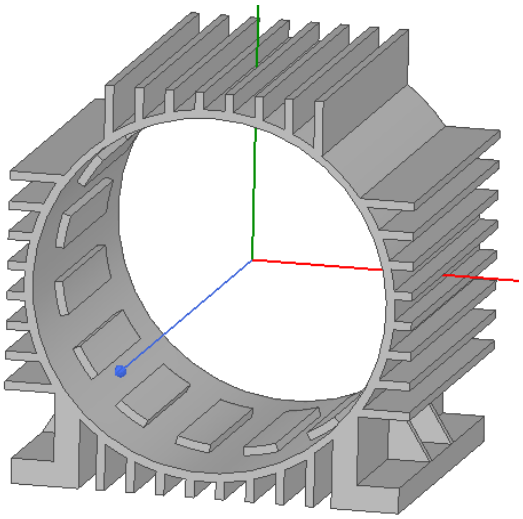
RMxprt includes UDPs to add various other types of machine parts. These include

- PressPlate UDP - used to add press plates, fingers, and stems that are used to hold together the stack of core laminations in large AC and DC machines.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

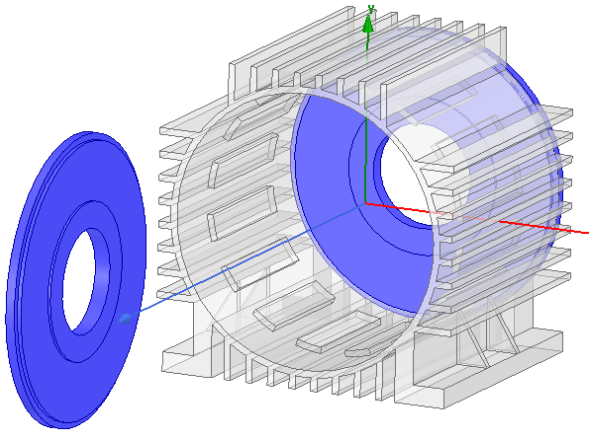


- Housing UDP - used to add machine housings and their associated fins, cooling ducts, and support feet.



- EndCap UDP - used to add the end caps and associated bearing surfaces for a housing.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



PressPlate UDP

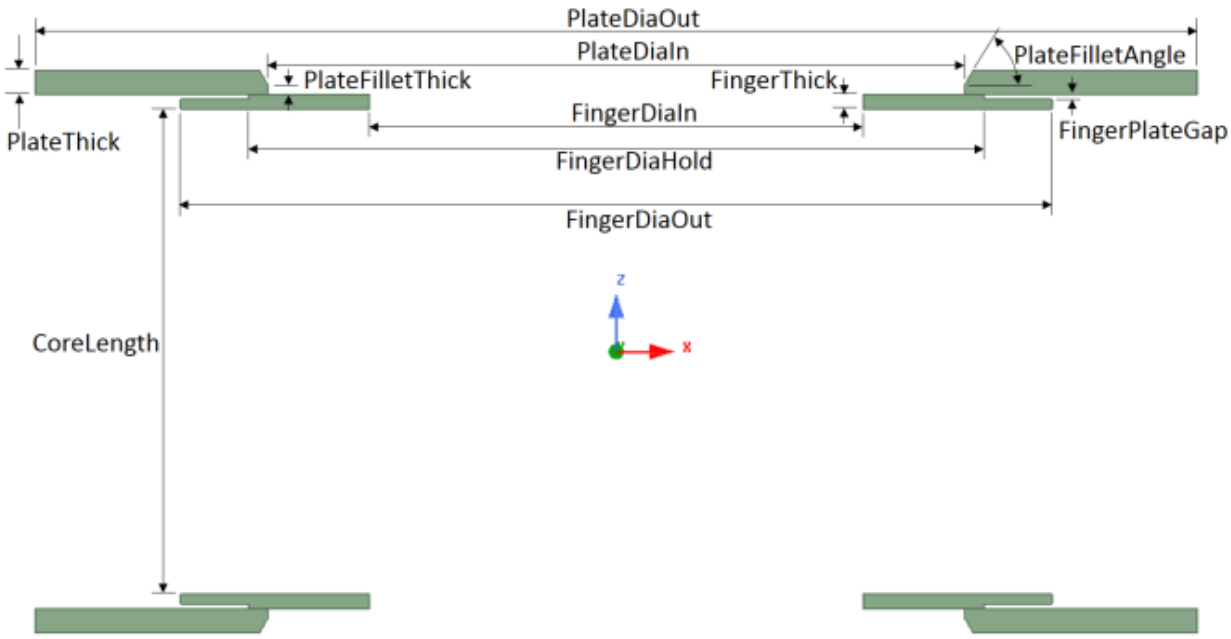
The PressPlate UDP is used to create press plates, fingers, and stems for large AC or DC machines. Press plates and fingers are put at two ends of a large laminated slot core and are locked in place by the stems so that the core laminations can be pressed tightly together.

Property	Description
CoreLength	Axial length of the core inside press plates
PlateDiaIn	Press plate inner diameter
PlateDiaOut	Press plate outer diameter
PlateThick	Press plate axial thickness
PlateFilletThick	Plate fillet thickness at inner diameter
PlateFilletAngle	Plate fillet angle at inner diameter
Fingers	Number of end fingers, or the number of core slots
FingerDiaIn	Inner diameter for distributed fingers
FingerDiaOut	Outer diameter for distributed fingers
FingerDiaHold	Finger holder outer diameter
FingerDiaBot	Inner diameter for slot-bottom fingers, 0 without bottom fingers
FingerWidth	Finger width to cover tooth width
FingerThick	Finger holder axial thickness
FingerPlateGap	Length of the axial gap between fingers and plates
Stems	Number of stems to lock two end press plates.
StemLength	Axial stem length
StemDia	Stem diameter
StemLocDia	Diameter of stem center layout circle

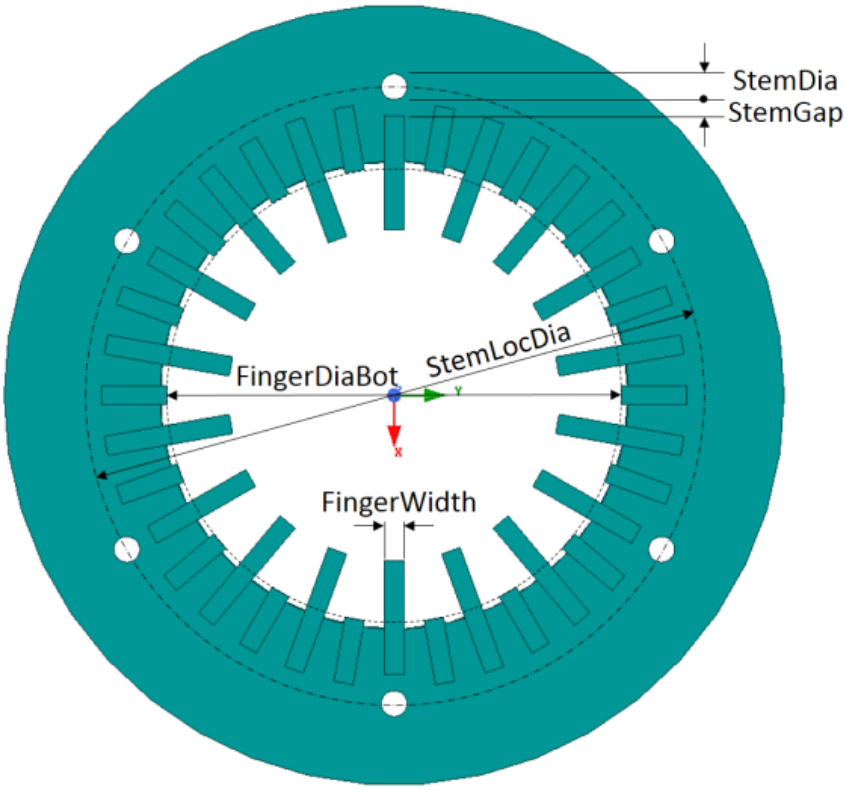
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

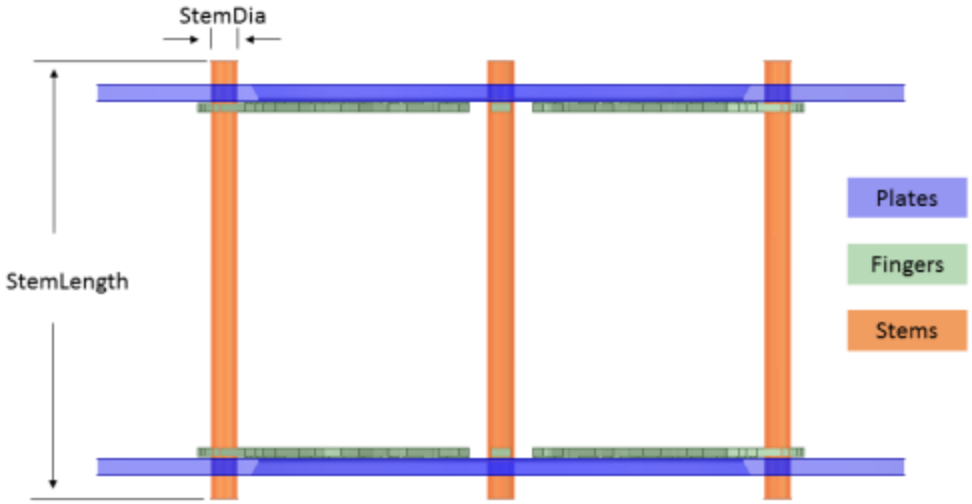
Property	Description
StemGap	Clearance gap around a stem
InfoPart	Enter 0 to generate all parts (plates, fingers, and stems); 1 for press plates only; 2 for fingers; 3 for stems

These parameters are shown in the following 2D examples:



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

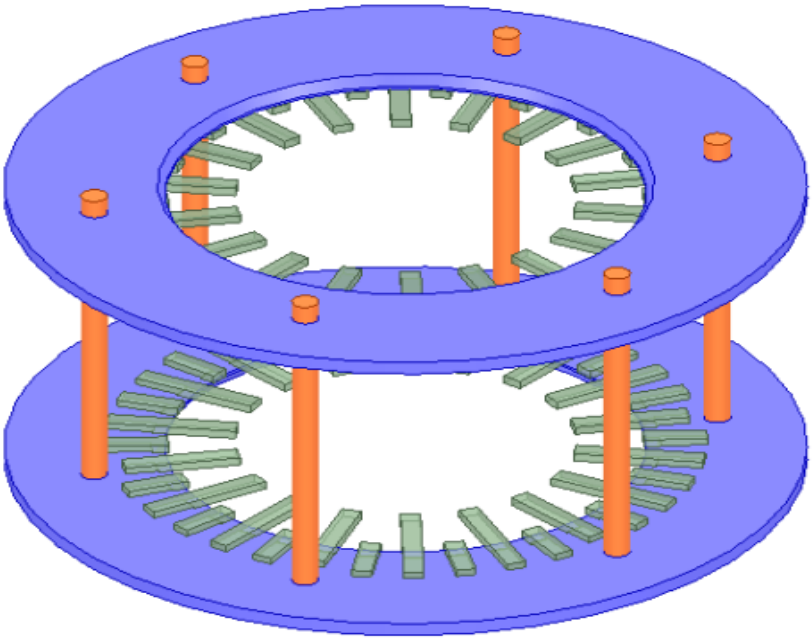




Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The following figure shows a typical arrangement of press plates, fingers, and stems in which their are 18 fingers under the press plates. The 6 stems serve to "lock" these parts at the two ends of the machine's laminated core (not shown), holding the entire assembly firmly together.

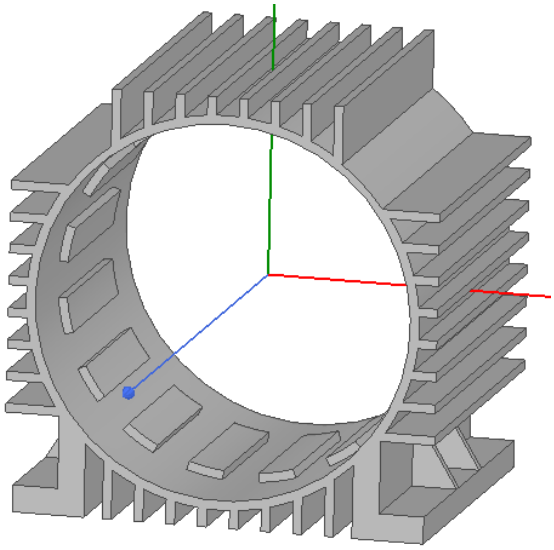
Press plates with fingers, and stems



Housing UDP

The Housing UDP is used to create the housing parts for machines. These include the fins, cooling ducts, and feet that support machines.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



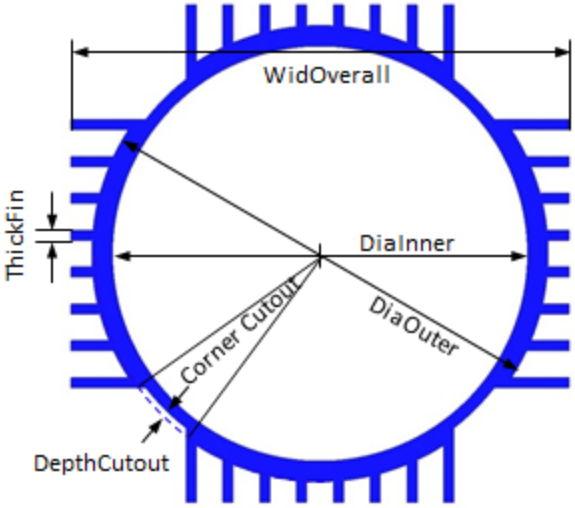
Property	Description
DiaOuter	Housing outer diameter
DiaInner	Housing inner diameter
WidOverall	Housing overall width
Length	Housing length
Fins	Number of fins; Fins = 0 for uniform distribution
FinType	1: radial round; 2: radial square; 3: parallel round; 4: parallel square; 5: square ring; 6: servo ring
RatioCutout	Corner cutout ratio for FinType≠5
DepthCutout	Corner cutout depth for FinType≠5; min fin depth for FinType=5
ThickFin	Fin thickness
Ducts	Number of ducts
DuctType	1: axial wind duct; 2: axial water jacket; 3: spiral water jacket (see below)
HeightDuct	Duct height in radial direction
EmbraceDuct	Ratio of the duct span, or duct width, to duct pitch 0 < EmbraceDuct < 1
LengthDuct	Axial duct length for axial wind ducts only
SegAngle	Deviation angle for spiral water jacket; 0 for true-surface circular jacket

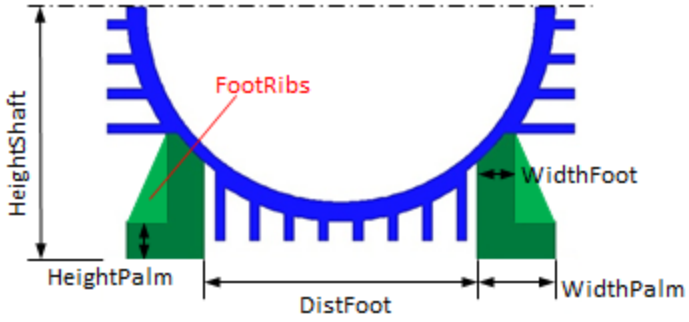
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

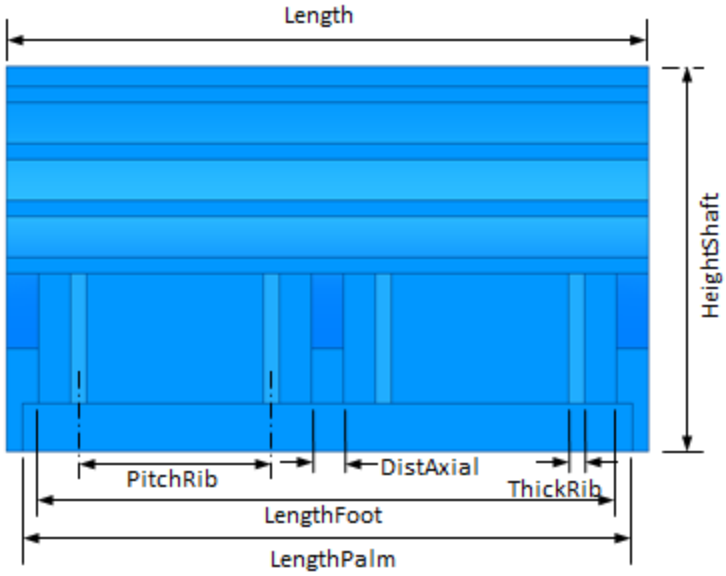
Property	Description
WidthFoot	Foot width at the junction with housing
LengthFoot	Foot end-to-end length in axial direction
DistFoot	Distance between two feet
DistAxial	Foot distance in axial direction
WidthPalm	Palm width at the junction with base plate
HeightPalm	Palm Height
LengthPalm	Palm length in axial direction
HeightShaft	Shaft-center Height from palm bottom
FootRibs	Number of reinforcing ribs for foot and palm
ThickRib	Reinforcing-rib thickness
PitchRib	Pitch between two reinforcing ribs
OffsetFoot	Axial offset of foot center to housing center (not currently used)
OffsetPalm	Axial offset of palm center to housing center (not currently used)
InfoPart	0: housing; 100: ducts

These parameters are shown in the following 2D examples:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

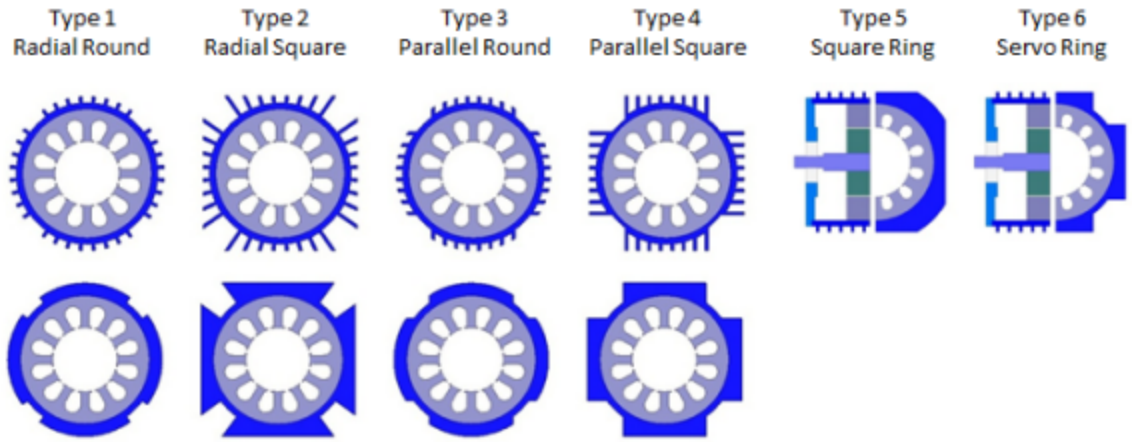




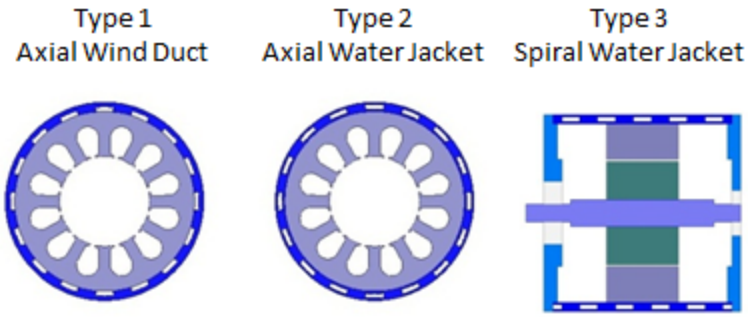


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Housing FinType



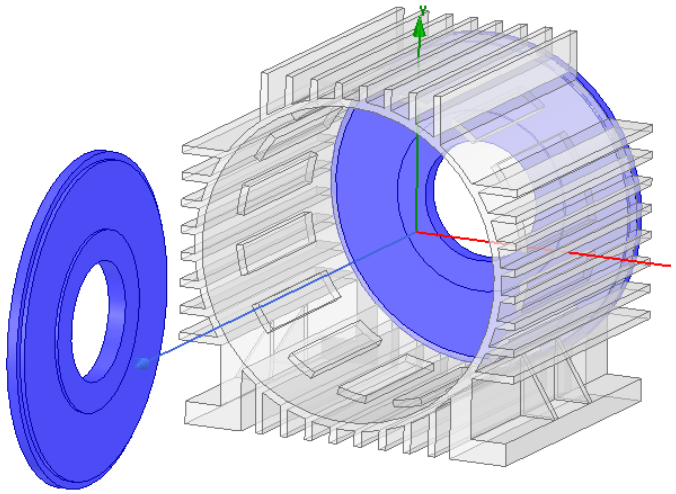
Housing DuctType



EndCap UDP

The EndCap UDP is to used to add the end caps, bearing surfaces, and rectangular cooling plate for a housing.

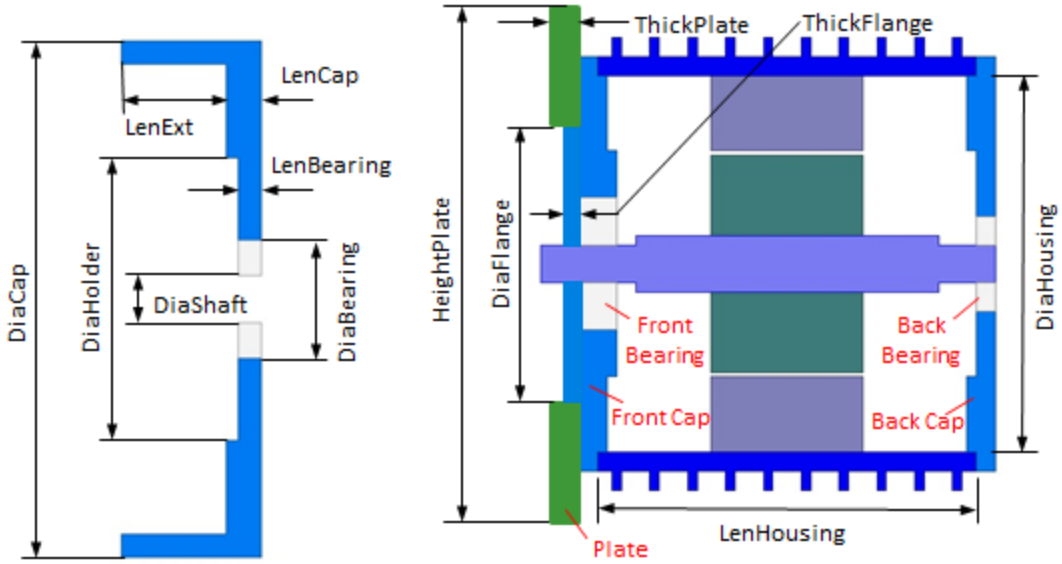
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Property	Description
DiaHousing	Housing rabbet inner diameter
LenHousing	Housing axial length
DiaCap	End cap outer diameter
LenCap	Axial length, or thickness, of end cap
LenExt	Length from housing end to cap inner surface, <0 for rabbet length
DiaHolder	Outer diameter of bearing holder
DiaBearing	Bearing outer diameter
LenBearing	Bearing axial length
DiaShaft	Shaft diameter, or bearing inner diameter
DiaFlange	Diameter of the flange section that covers the front bearing
ThickFlange	Thickness of the flange section that covers the front bearing
HeightPlate	Height of the rectangular cooling plate
WidthPlate	Width of the rectangular cooling plate
ThickPlate	Thickness of the rectangular cooling plate
InfoPart	0: front cap; 1: back cap; 2: front bearing; 3: back bearing; 4: flange.

These parameters are shown in the following 2D example:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Helix UDPs

Helix UDPs are shapes of inductance design and are widely used in electronic devices and signal integrity area.

Helix UDPs consist of the following types:

- PolygonHelix UDP
- RectHelix UDP

PolygonHelix UDP

The shape of the cross-section of a PolygonHelix is a polygon.

Property	Description
PolygonSegments	Number of cross-section polygon segments, 0 for circle
PolygonRadius	Outer radius of cross-section polygon
StartHelixRadius	Start radius from polygon center to helix center
RadiusChange	Radius change per turn
Pitch	Helix pitch
Turns	Number of turns
SegmentsPerTurn	Number of segments per turn, 0 for true surface
RightHanded	Helix direction, non-zero for right handed

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

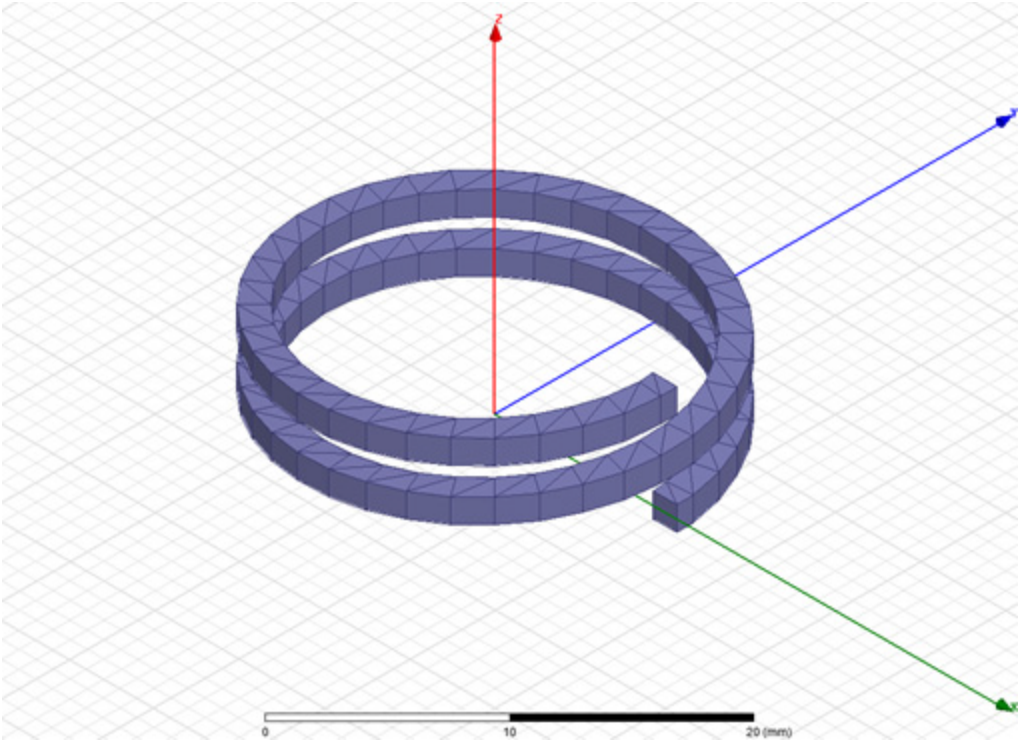


Figure 9-135 Overview of PolygonHelix UDP

Note:

" Overview of PolygonHelix UDP" above is an overview of the PolygonHelix UDP. “Polygon” means the cross-section of the helix is a polygon, which by default is a square (**PolygonSegments** set to 4).

Polygon helices in " Parameters of PolygonHelix UDP on x-y plane." on the next page and " Parameters of PolygonHelix UDP on axial direction." on the next page have the default settings of this UDP, whereas each of the polygon helices in " Different RadiusChange value (non-zero); the value in " Parameters of PolygonHelix UDP on x-y plane." on the previous page is 0." on page 9-245 to " Different Turns value (3); the value in" Parameters of PolygonHelix UDP on axial direction." on page 9-244 is 2." on page 9-247 has only one parameter value that is different from the defaults shown in " Parameters of PolygonHelix UDP on x-y plane." on the next page and " Parameters of PolygonHelix UDP on axial direction." on the next page.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

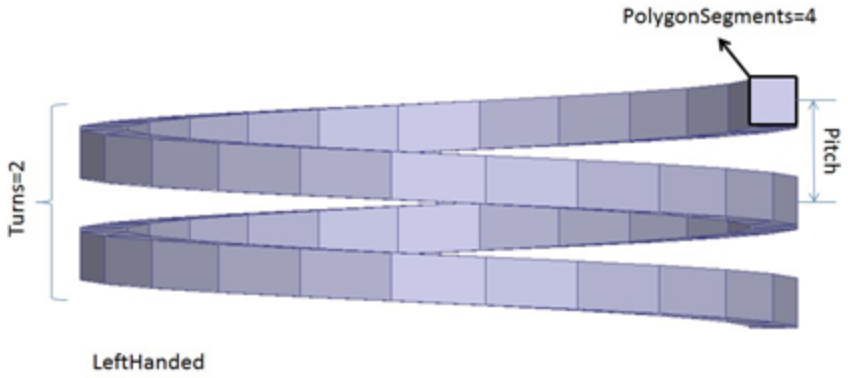

Figure 9-140 Left-handed (RightHanded set to 0) helix; " Parameters of PolygonHelix UDP on axial direction." on page 9-244 shows a right-handed helix.

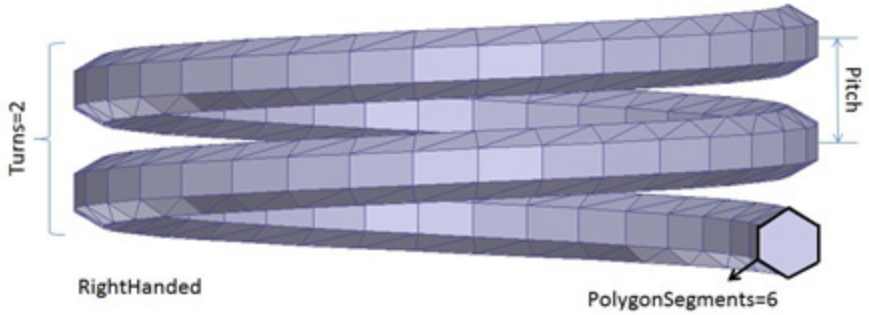

Figure 9-141 Different PolygonSegments value (6); the value in " Parameters of PolygonHelix UDP on axial direction." on page 9-244 is 4.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

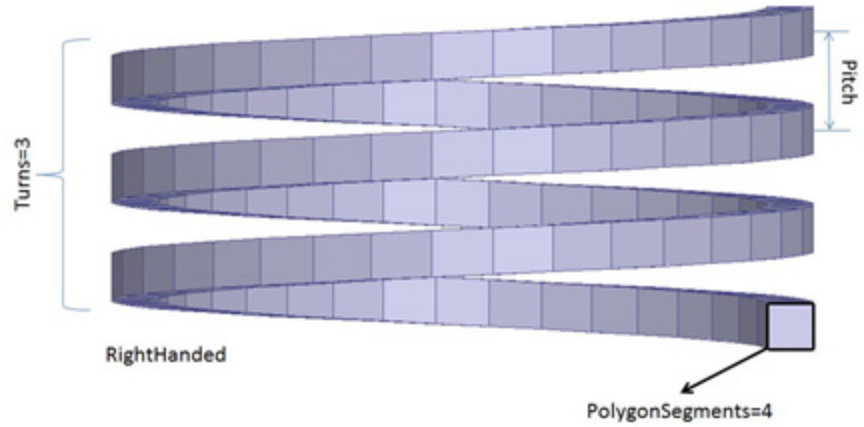

Figure 9-142 Different Turns value (3); the value in" Parameters of PolygonHelix UDP on axial direction." on page 9-244 is 2.

Creating a Right-Handed or Left-Handed Polygon Helix

You can create a right-handed polygon helix manually by setting the value of **RightHanded** to 1 (or any non-zero value), which is set by default in Maxwell.

You can create a left-handed polygon helix by setting **RightHanded** to 0.

Examples of right- and left-handed polygon helices are shown in " Parameters of PolygonHelix UDP on axial direction." on page 9-244 and " Left-handed (RightHanded set to 0) helix; " Parameters of PolygonHelix UDP on axial direction." on page 9-243 shows a right-handed helix." on the previous page, respectively.

You can assign the value of this property either when creating the UDP or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

RectHelix UDP

The shape of the cross-section in a RectHelix is a rectangle.

Property	Description
RectHeight	Cross-section rectangle height in z direction
RectWidth	Cross-section rectangle width in r direction
StartHelixRadius	Start radius from rectangle center to helix center
RadiusChange	Radius change per turn
Pitch	Helix pitch
Turns	Number of turns

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Property	Description
SegmentsPerTurn	Number of segments per turn, 0 for true surface
RightHanded	Helix direction, non-zero for right handed

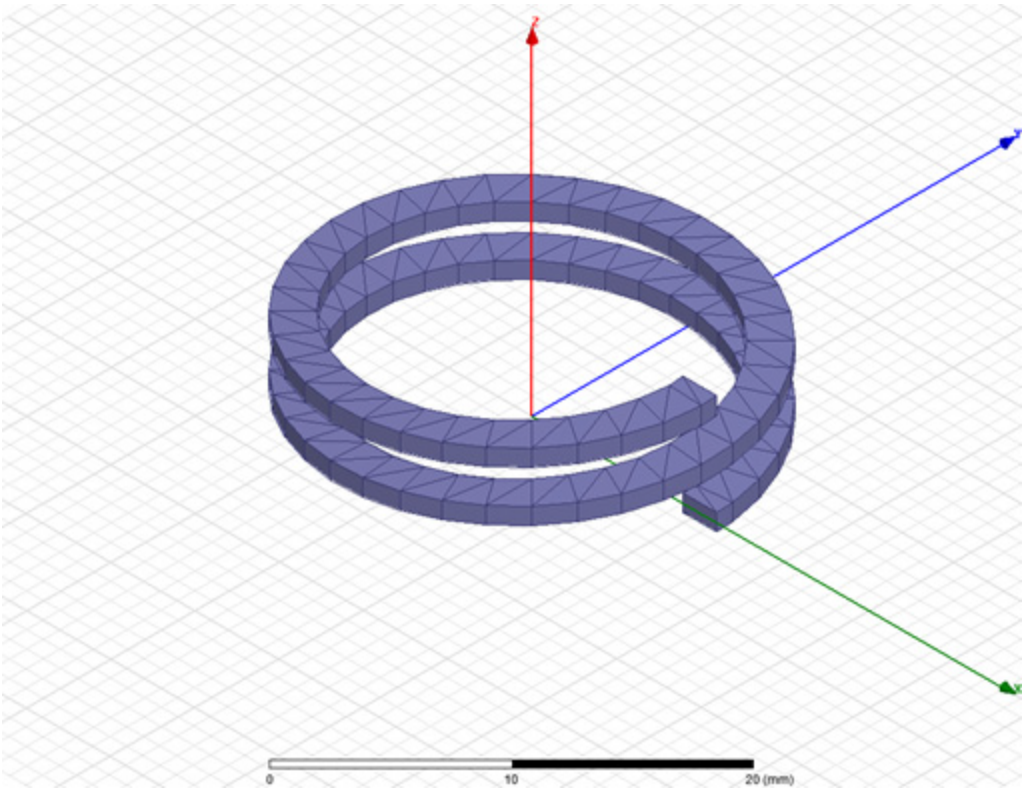

Figure 9-143 Overview of RectHelix UDP

Note:

- The major difference between the RectHelix UDP and the PolygonHelix UDP is the shape of the cross-sections of the helices. In RectHelix, the shape of its cross-section is a rectangle whereas that of PolygonHelix is a polygon.
- Except for **RectHeight** and **RectWidth**, parameters are the same as those in the Polygon Helix UDP. The one figure in this section describes **RectHeight** and **RectWidth**.
- For *all other* parameters, refer to Polygon Helix UDP.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

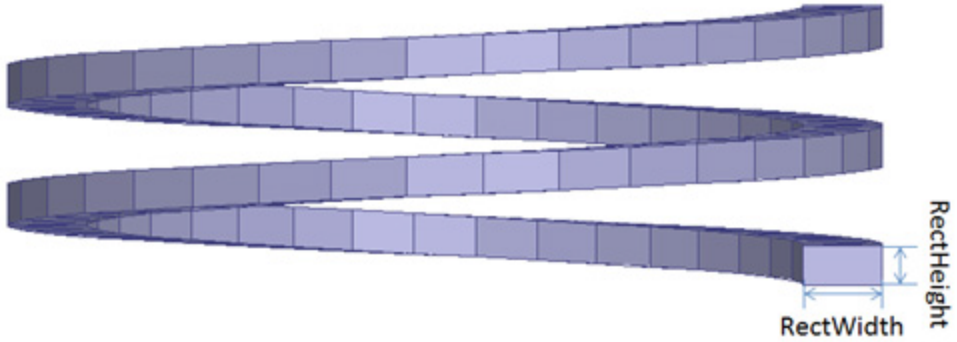

Figure 9-144 RectHeight and RectWidth in RectHelix UDP

Creating a Right-Handed or Left-Handed Rectangle Helix

You can create a right-handed rectangle helix manually by setting the value of **RightHanded** to 1 (or any non-zero value), which is set by default in Maxwell.

You can create a left-handed rectangle helix by setting **RightHanded** to 0.

Examples of right-handed and left-handed rectangle helices are shown in " Different Turns value (3); the value in" Parameters of PolygonHelix UDP on axial direction." on page 9-243 is 2." on page 9-247 and " Left-handed rectangle helix" below, respectively.

You can assign the value of this property either when creating the UDP or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

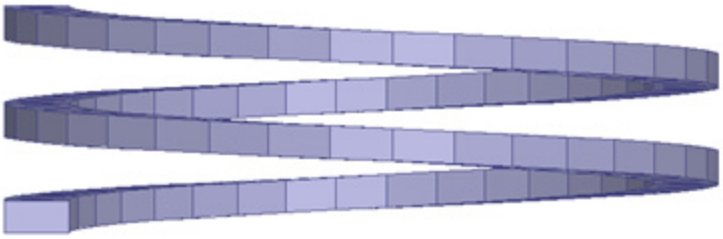

Figure 9-145 Left-handed rectangle helix

Information about Coding UDPs

This chapter uses an example of a Band UDP to provide information about how to write source code for a new UDP class when needed.

- Intrinsic Head Files presents some of the intrinsic structures and functions for all UDPs
- Code Implementation uses a Band UDP to illustrate what functions or procedures are needed to create a new UDP

Intrinsic Head Files

The following sections provide information on Intrinsic Structure Definitions and Intrinsic Function Declarations.

Head File for Intrinsic Structure Definition

Many intrinsic structures are written in C++ for UDPs. These intrinsic structures are provided in the UserDefinedPrimitiveStructures.h file (under directory: "...\ANSYS Inc\[%Primary.VersionNumber%]\AnsysEM\UserDefinedPrimitives\Examples\Headers").

Here are some common intrinsic structures that you need to know before starting coding for UDPs:

UDPPosition

Defines the most common and basic structure in a coordinate system, which is used to describe a point in the system.

```
struct UDPPosition
{
double x;
double y;
double z;
};
```

UDPPolylineDefinition

Defines the structure of polyline in a UDP, which is used to create sheets or lines in a UDP.

```
struct UDPPolylineDefinition
{
int noOfPoints;
struct UDPPosition* arrayOfPosition;
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
int noOfSegments;
struct UDPPolylineSegmentDefinition* arrayOfSegmentDefinition;
int isClosed;
int isCovered; /* Only if it is closed, then it can be covered */
};
```

UDPPrimitiveParameterDefinition

Defines the parameter/property definition of each UDP, such as *DiaGap*, *DiaYoke* and *Length* in the Properties window of each UDP. A definition for a parameter includes the name of the parameter, description of the parameter, unit of parameter, and default value of it.

```
struct UDPPrimitiveParameterDefinition
{
char* name; /* Name of the parameter */
char* description; /* some description of the parameter */
UDPUnitType unitType; /* No unit/length/angle */
double defaultValue;
};
```

UDPPolylineSegmentDefinition

Defines line segments used to form a polyline.

```
struct UDPPolylineSegmentDefinition
{
UDPPolylineSegmentType segmentType;
int segmentStartIndex;

/* Below information is required to be set only if you are using
Spline */
int numberOfPoints;

/* Below information is required to be set only if you are using
Angular Arc */
double angle; /* in degrees */
UDPPosition centerPoint;
UDPCoordinateSystemPlane arcPlane;
};
```

UDPSweepOptions

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Sweep is a kind of operation to move an object from one position to another and meanwhile creating another object based on the track of the movement. For instance, sweep operations can be used to create a sheet from a line or a 3D object from a sheet. Different kinds of sweep types (and sweep angles) are used in SweepAlongAxis and SweepAroundAxis functions to make a sheet or a 3D object.

```
struct UDPSweepOptions
{
UDPSweepDraftType draftType;
double draftAngle;
double twistAngle;
};
```

UDPVector

Vector structures are used in UDP coding, mainly for rotation, moving or other kinds of transformations of geometry.

```
struct UDPVector
{
double x;
double y;
double z;
};
```

Head File for Intrinsic Function Declaration

Intrinsic function declarations are inside the same file (UserDefinedPrimitiveStructures.h) as intrinsic structure definitions. Functions are declared by `typedef` keyword and function pointer. Some function declarations are shown below as examples:

Add a Message to the Message Window, with Desired Severity Level

This declaration is used in the DisplayInfo function in UDPs:

```
typedef void (*UDPAddMessageFP)
(
 UDPMessageSeverity, /* Message severity */
const char*, /* message string */
void* /* callbackData */
);
```

Function Pointers Used to Create Primitives

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
/* The return type for all primitives (except for spiral and helix)
is the ID of
 * the body created -1 is an invalid ID, which means the operation
failed.
 *
 * Spiral and helix are like sweep operations and operate on a
profile.
 * The return value indicates if the operation succeeded,
 * return value 0 means operation failed, any other value
 * means operation succeeded.
 */
/* 1D/2D ENTITIES */
typedef long (*UDPCreatePolylineFP)
(
const struct UDPPolylineDefinition* , /* polylineDefinition */
void* /* callbackData */
);

/* 3D ENTITIES */
typedef long (*UDPCreateCylinderFP)
(
UDPCoordinateSystemAxis, /* axis */
const struct UDPPosition*, /* center */
double, /* radius */
double, /* height */
void* /* callbackData */
);
```

Sweep Functions

Sweep functions are used to create a sheet from a line or create a solid (3D object) from a sheet, as shown below:

```
  /* Sweep operations (Sweep along vector, around axis and
 * along path) modify the profile body. The resultant body
 * id is same as the profile id.
 *
 * In case of path sweep, the path body is consumed during the
 * sweep operation.
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
 *
 * The return value indicates
 * if the operation succeeded, return value 0 means operation
 * failed, any other value means operation succeeded.
 */
/* SweepAlongPath is used to sweep along a specific path to create a
sheet (from a line) or a solid (from a sheet)*/
typedef long (*UDPSweepAlongPathFP)
(
long, /* profileID */
long, /* pathID */
const struct UDPSweepOptions*, /* sweepOptions */
void* /* callbackData */
);

/* SweepAroundAxis is used to sweep around a specific axis (x, y or
z) to create a sheet (from a line) or a solid (from a sheet)*/
typedef long (*UDPSweepAroundAxisFP)
(
long, /* profileID */
UDPCoordinateSystemAxis, /* sweepAxis */
double sweepAngle, /* sweepAngle */
const struct UDPSweepOptions*, /* sweepOptions */
void* /* callbackData */
);
```

Transform Operations

The following two functions are used for transformations:

```
/* Transform operations (Translate: move, rotate, mirror and
 * scale) modify the part body. The resultant body
 * id is same as the part id. The return value indicates
 * if the operation succeeded, return value 0 means operation
 * failed, any other value means operation succeeded.
 */
/* Translate function is used to do translational motion for a given
object. */
typedef long (*UDPTranslateFP)
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
(
long, /* partID */
const struct UDPVector*, /* translation vector */
void* /* callbackData */
);

/* Rotate function is used to rotate a given object. */
typedef long (*UDPRotateFP)
(
long, /* partID */
UDPCoordinateSystemAxis, /* axis */
double, /* angle */
void* /* callbackData */
);
```

Duplicate Operation

```
/* Duplicate operations (Duplicate along line, around axis
 * and duplicate and mirror) create new bodies.
 *
 * In case of duplicate and mirror, only 1 duplicate can be
 * created. The ID of the duplicate body is returned by the
 * function. ID of -1 means the operation failed.
 *
 * For the other two cases multiple duplicates can be created.
 * The IDs of all such duplicates are returned in the function
 * parameter. The function return value indicates if the operation
 * succeeded, return value 0 means operation failed, any other
 * value means operation succeeded.
 */
/* Duplicate an object around a given axis (of course can be used to
create either single or multiple copies around the axis) */
typedef long (*UDPDuplicateAroundAxisFP)
(
long, /* partID */
UDPCoordinateSystemAxis, /* axis */
double, /* angle */
int, /* num of clones (including original) */
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
long*, /* returned clone ids */
void* /* callbackData */
);
```

Boolean Operations

Boolean operations are used to unite, subtract, or intersect two objects.

```
/* Boolean operations (unite, subtract and intersect) modify the
 * blank body. The resultant body id is same as the blank id.
 * Tool bodies are consumed during the operation.
 * The return value indicates if the operation succeeded,
 * return value 0 means operation failed, any other value
 * means operation succeeded.
 */
/* Unite two objects */
typedef long (*UDPUniteFP)
(
long*, /* objectIDs */
int, /* numObjects */
void* /* callbackData */
);

/* Subtract two objects */
typedef long (*UDPSubtractFP)
(
long*, /* blankIDs */
int, /* numBlanks */
long*, /* toolIDs */
int, /* numTools */
void* /* callbackData */
);
```

Function Library with a Collection of UDP Functions

When coding for a UDP, you should declare an instance of UDPFunctionLib in the UDP and then use functions directly when needed.

For example:

```
UDPFunctionLib* functionLib;
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
functionLib->addMessage(kUDPInfoMessage, msg0, callbackData);

struct UDPFunctionLib
{
/* Utility functions */
UDPAddMessageFP addMessage;
UDPNameAFaceFP nameAFace;
UDPNameAEdgeFP nameAEdge;
UDPNameAVertexFP nameAVertex;
UDPGetFaceIDFromPositionFP getFaceIDFromPosition;
UDPGetEdgeIDFromPositionFP getEdgeIDFromPosition;
UDPGetTempDirPathFP getTempDirPath;
UDPGetInstallDirPathFP getInstallDirPath;
UDPGetSysLibDirPathFP getSysLibDirPath;
UDPGetUserLibDirPathFP getUserLibDirPath;
UDPGetPersonalLibDirPathFP getPersonalLibDirPath;
UDPSetProgressFP setProgress;

/* Primitives */
/* 1D/2D ENTITIES */
UDPCreatePolylineFP createPolyline;
UDPCreateRectangleFP createRectangle;
UDPCreateArcFP createArc;
UDPCreateCircleFP createCircle;
UDPCreateEllipseFP createEllipse;
UDPCreateRegularPolygonFP createRegularPolygon;
UDPCreateEquationBasedCurveFP createEquationBasedCurve;
UDPCreateEquationBasedSurfaceFP createEquationBasedSurface;
UDPCreateSpiralFP createSpiral;

UDPGetProjectPathFP getProjectPath;

/* BEGIN - RESERVED FOR FUTURE 1D/2D PRIMITIVES */
/* DO NOT INVOKE THESE RESERVED FUNCTIONS IN YOUR UDP DLL CREATION

};
```

Code Implementation

This section provides several sample functions and structures to show how to write real code for a UDP. All codes are from a sample source file written for Band UDP.

There are two files, UDPBase.h and UDPBase.cpp, that include basic structures and functions for all UDPs. All UDPs should be built based on these two files.

Define UDP Parameters and Default Values

A structure is needed for parameters and default values at the beginning of each UDP. In the following code, UDPPrimitiveParameterDefinition, an intrinsic structure of UDP shown in Head File for Intrinsic Structure Definition, is used to create an array of parameters for a UDP.

```
struct UDPPrimitiveParameterDefinition primParams[] =
{
{"DiaGap", "Band diameter in gap center, DiaGap<DiaYoke for outer
band",
kUDPLengthUnit, 101},
{"DiaYoke", "Band diameter on yoke side, DiaYoke<DiaGap for inner
band",
kUDPLengthUnit, 40},
{"Length", "Band length", kUDPLengthUnit, 200},
{"SegAngle", "Deviation angle for band (0.1~5 degrees).",
kUDPAngleUnit, 3},
{"Fractions", "Number of circumferential fractions, 1 for circular
region.",
kUDPNoUnit, 1},
{"HalfAxial", "0: full model; 1: half model in axial direction.",
kUDPNoUnit, 0},
{"InfoCore", "0: band; 1: tool; 2: independent; 3: dependent; 100:
region.", kUDPNoUnit, 0}
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
};
```

Function Inside Band UDP

```
int AreParameterValuesValid(char ** error, double* paramValues)
{
obj.IniParameters(paramValues, numOfParameters);
return obj.AreParametersValid(error);
}
```

IniParameters() and AreParametersValid() are two member functions, which are defined in the UDP base class (in UDPBase.cpp file) and shown below.

Initialize Parameters and Check Validity

First initialize parameters using IniParameters(), and then check the validity of values for parameters. These two functions are inside the UDPBase class and do not need to be implemented.

```
// set oriParams pointer, and make a copy of data to paramValues
void CUDPBase::IniParameters(double* paramValues0, int num)
{
oriParams = paramValues0; // set oriParams pointer
numOfParams = num;
delete[] paramValues;
paramValues = new double [num];
for (int i=0; i<num; i++) paramValues[i] = oriParams[i]; // make a
copy
}
```

The following function is not required to be implemented, but it calls three other functions, **GetParameters()**, **ValidateParameters**, and **PutParameters()**, which should be implemented in the new UDP class.

```
int CUDPBase::AreParametersValid(char ** error)
{
GetParameters(); // the implementation is shown below
checkOK = 0;
char *err = ValidateParameters(); // the implementation is shown
below
if (err) {
*error = err;
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
return 0;
}
PutParameters(); // the implementation is shown below
checkOK = 1;
return 1;
}
```

Parameter Validation Functions

This section covers the three functions that you need to implement in the new UDP classes. The functions could be used as templates for new UDP classes.

These functions are very straightforward. You should follow the examples to add or remove parameters for a new UDP.

GetParameters()

```
/* To get the values from array of parameters*/
void CBand::GetParameters()
{
diaGap = diaYoke = 0;
length = 0;
infoCore = 0;
infoOut = -1;

segAng = 3;
numFras = 1;
infoHalf = 0;

for (int i=0; i<numOfParams; i++) {
if (GetValue(i, "DiaGap", diaGap)) continue;
if (GetValue(i, "DiaYoke", diaYoke)) continue;
if (GetValue(i, "Length", length)) continue;

if (GetValue(i, "SegAngle", segAng)) continue;
if (GetValue(i, "Fractions", numFras)) continue;
if (GetValue(i, "HalfAxial", infoHalf)) continue;
if (GetValue(i, "InfoCore", infoCore)) continue;
}
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
rRegion = diaYoke / 2;
}
```

PutParameters()

```
/* To store the values into array of parameters*/
void CBand::PutParameters()
{
for (int i=0; i<numOfParams; i++) {
if (PutValue(i, "DiaGap", diaGap)) continue;
if (PutValue(i, "DiaYoke", diaYoke)) continue;
if (PutValue(i, "Length", length)) continue;

if (PutValue(i, "SegAngle", segAng)) continue;
if (PutValue(i, "Fractions", numFras)) continue;
if (PutValue(i, "InfoCore", infoCore)) continue;
}
}
```

ValidateParameters()

```
/* To check parameters one by one to see if their values are valid */
char* CBand::ValidateParameters()
{
if (!paramValues) return 0;

if (diaYoke < 0) diaYoke = 0;
if (diaGap <= 0) return "DiaGap must be larger than 0.";
if (length < 0) length = 0; // length==0 for 2D geometry
infoOut = diaYoke>diaGap ? 1 : -1;

if (numFras < 1) numFras = 1;
if (segAng > 5) segAng = 5;
if (segAng <= 0) segAng = 0;
else if (segAng < 0.1) segAng = 0.1;
if (segAng > 0) {
numSegs = (int)(360/segAng + 0.5);
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
int remain = numSegs % numFras;
if (remain > 0) numSegs += numFras - remain;
segAng = 360.0 / numSegs;
}
else numSegs = 0;

if (infoCore < 100) {
if (infoCore < 0) infoCore = 0;
if (infoCore > 3) infoCore = 3;
}

if (infoCore >= 100) {
if (diaYoke <= 0) return "DiaYoke must be larger than 0.";
}
else if (infoCore >= 1) { // for tool; independent & dependent
if (diaYoke <= diaGap) return "DiaYoke must be larger than DiaGap.";
}

return 0;
}
```

Implement Main Function to Create Primitive

In this part, functions are used to create the UDP. You need to write two functions for UDP creation.

- The first function is the main function to create this UDP. It calls two other functions, one of which is shown in part 2.

```
extern "C" DLLEXPORT
long CreatePrimitive(struct UDPFunctionLib* functionLib, void*
callbackData,
double* paramValues)
{
obj.SetParameterPointer(paramValues);
return obj.CreatePrimitive(functionLib, callbackData);
}
```

- The following function is used to create a UDP based on different **InfoCore** values. For instance, a region is created when **InfoCore** is equal to 100 while a tool is created when **InfoCore** is equal to 2.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For functions to create specific object like region, tool and independent, refer to Source Code Files for more detail.

```
long CBand::CreatePrimitive(UDPFunctionLib* functionLib, void*
callbackData)
{
if (!checkOK) return 0;

// display information of modified parameters
SetFunctionLib(functionLib, callbackData);
DisplayInfo();

// create region
if (infoCore == 100) {
long region = CreateRegion();
return region==-1 ? 0 : 1;
}

// create tool
if (infoCore == 1) {
long tool = CreateTool();
return tool==-1 ? 0 : 1;
}

// create independent
if (infoCore == 2) {
long independent = CreateIndependent();
return independent==-1 ? 0 : 1;
}

// create dependent
if (infoCore == 3) {
long dependent = CreateIndependent(false);
return dependent==-1 ? 0 : 1;
}

// create band
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
long band = CreateBand();
return band==-1 ? 0 : 1;
}
```

Map Parameters between Different Versions

Parameters mapping function is used when the UDP version changes or some new parameters are added into a UDP.

You should implement the following function MapParametersDefinitionVersions(). It calls two other functions IniParameters() and MapParameters(), which is in the UDPBase class.

```
extern "C" DLLEXPORT
int MapParametersDefinitionVersions(double** newParamValues, char*
oldVersion,
int oldNumberOfParams, struct UDPPrimitiveParameterDefinition*
oldParamDefinition)
{
obj.IniParameters(*newParamValues, numOfParameters);
obj.MapParameters(oldParamDefinition, oldNumberOfParams);// map para
by keywords

int verN = getVerNum(oldVersion);
if (verN < 200) {
obj.SetDefaultParameter(*newParamValues, "HalfAxial", 0);
}

return 1;
}
```

The following function is the MapParameters() function, which has already been implemented in the UDPBase class.

```
// map parameter values of old version to new version based on
keywords,
// which is written in UDPBase class and does not need to be
implemented by user
void CUDPBase::MapParameters(UDPPrimitiveParameterDefinition* params,
int oldNum)
{
if (!primParams) return;
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
int i, j, j0=0;
for (i=0; i<numOfParams; i++) {
oriParams[i] = primParams[i].defaultValue;
if (j0<oldNum && strcmp(primParams[i].name, params[j0].name)==0) {
oriParams[i] = params[j0++].defaultValue;
continue;
}
for (j=0; j<oldNum; j++) {
if (strcmp(primParams[i].name, params[j].name) == 0) {
oriParams[i] = params[j].defaultValue;
j0 = j+1;
break;;
}
}
}
}
```

Source Code Files

This section provides examples for the following:

- UDPBase.h
- UDPBase.cpp
- Band.h
- Band.cpp

UDPBase.h

```
// File: UDPBase.h

#if !defined (UDP_BASE_H)
#define UDP_BASE_H

#include <math.h>
#include <string.h>
#include <stdio.h>

#include "../Headers/UserDefinedPrimitiveDLLInclude.h"
```

10 - Assigning Boundaries and Excitations for 3D Designs

For every project, you need to assign boundaries and excitations. For 3D designs, you can use the **Maxwell 3D** menu or the project tree to do the following:

- Define boundary conditions that control how the electric or magnetic field behaves at object faces, planes of symmetry and periodicity, and edges of the problem region.
- Define excitations of voltage, charge, coil, and current.
- Identify conductors in which eddy currents are induced.
- For eddy current and magnetic transient projects, set up a winding and an external circuit connection.

Each field solver requires you to specify excitations of electric or magnetic fields and references for computing these fields.

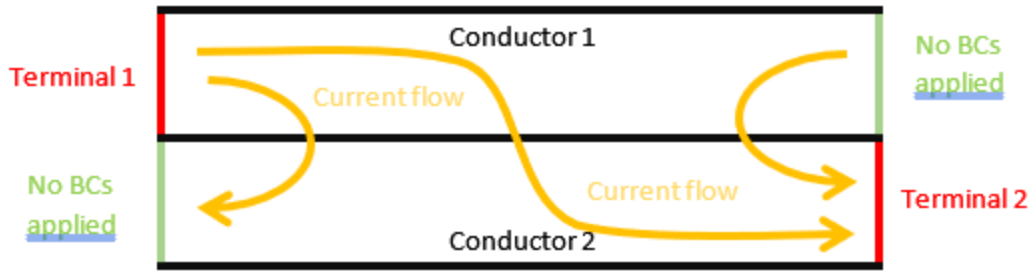
- Magnetostatic Boundaries and Excitations
- Eddy Current T-Omega Boundaries and Excitations
- Eddy Current A-Phi Boundaries and Excitations
- Transient Boundaries and Excitations
- Transient A-Phi Formulation Boundaries and Excitations
- Electrostatic Boundaries and Excitations
- DC Conduction Boundaries and Excitations
- Electric Transient Boundaries and Excitations
- AC Conduction Boundaries and Excitations

You must specify at least one of the boundary conditions or excitations listed in these sections, so that the simulator can compute accurate values for fields and parameters.

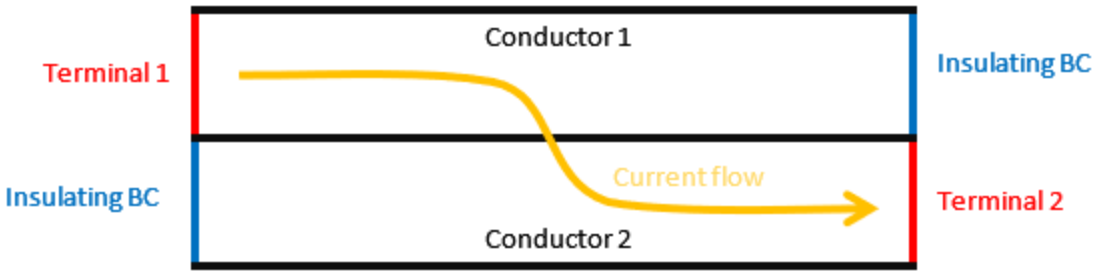
Depending on the problem to be solved, you must also define the current flowing through the conducting domain faces touching the domain boundaries (ports) by assigning them excitations or setting their current to zero by defining insulating boundary conditions. If no constraint is applied to that boundary, the current will flow freely through these ports, which may lead to undesired but still physical results.

Case 1: Conducting faces without boundary conditions (BCs) applied (green lines). The current flows freely through these faces.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Case 2: Insulating boundary conditions applied (blue lines). No current is allowed to flow through these faces.



Selecting Objects and Faces in the Geometry

Before creating a boundary or excitation, you must specify its location by selecting the object or surface on which to assign the boundary condition or source excitation.

Defining Boundary Conditions

To assign a boundary condition:

1. Select the section of the geometry on which you want to apply the boundary condition.
2. Click **Maxwell 3D** > **Boundaries** > **Assign**, or right-click **Boundaries** in the Project Manager tree and click **Assign**.
3. Select the desired boundary type from the submenu. The specific boundary types you can define depend on the solver you have chosen for your project.

    - Magnetostatic Boundary Conditions
    - Electrostatic Boundary Conditions
    - DC Conduction (Electric) Boundary Conditions

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Eddy Current T-Omega Boundary Conditions
- Eddy Current A-Phi Boundary Conditions
- Transient Boundary Conditions
- Transient A-Phi Formulation Boundary Conditions

4. Enter the name for the boundary or accept the default.
5. Depending on the boundary type, you may need to define additional parameters.
6. Click **OK** to create the new boundary.

The new boundary is added to the **Boundaries** list in the Project Manager tree.

Defining Excitations

The specific excitations you can define depend on the solver you have chosen for your project.

- Magnetostatic Excitations
- Electrostatic (Electric) Excitations
- AC Conduction (Electric) Excitations
- DC Conduction (Electric) Excitations
- Eddy Current T-Omega Excitations
- Eddy Current A-Phi Excitations
- Transient Excitations
- Transient A-Phi Formulation Excitations
- Electric Transient Excitation

To assign an excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 3D** > **Excitations** > **Assign**, or right-click **Excitations** in the Project Manager tree, and click **Assign**.

   A submenu appears.

3. Select an excitation type from the submenu. The choices vary depending on the solver type you have chosen. Choices include
   - Voltage
   - Voltage Drop
   - Charge
   - Volume Charge Density
   - Current Density
   - Current

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Permanent Magnet Field
- Sink

4. Enter the name for the excitation type or accept the default.
5. Enter the desired parameter values, units, and other settings for the excitation in the dialog box. You can also enter a mathematical function to determine values for voltage, current density, charge density, and other parameters. The Permanent Magnet Field excitation also requires you set up a link to a source project.

   > **Note:** When entering current, current density terminals, or coil terminals, the arrow associated with current in the selected object shows the direction as if a positive value is entered for the current. If a negative value is entered the actual current flow direction is opposite to what the arrow shows. Click **Swap Direction** if you want to reverse the direction of the arrow.

6. Click **OK** to create the new excitation.

The new excitation is added to the excitation list in the Project Manager tree.

Viewing Boundaries and Excitations

To view a list of all boundaries or excitations set for the project:

1. In the Project Manager tree, right-click **Boundaries** or **Excitations**.

   A shortcut menu appears.

2. Select **List** from the shortcut menu.

   The **Design List** window appears, with the tab page visible for the item you selected. This window contains tabs for **Model**, **Boundaries**, **Excitations**, **Parameters**, **Mesh Operations**, and **Analysis Setup**.

3. To view the properties for an item in the list, select the item, and click **Properties**.
4. To delete an item from the list, select the item, and click **Delete**.
5. When you are finished in the **Design List** window, click **Done** to close it.

Setting the Visibility for Boundaries and Excitations

To show or hide a boundary:

1. Click **View** > **Active View Visibility**.

   The **Active View Visibility** dialog box appears.

2. Click the **Boundaries** tab.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Select or clear the **Visibility** check box for each boundary listed.
4. Click **Done**.

To show or hide a excitation:

1. Click **View** > **Active View Visibility**.

   The **Active View Visibility** dialog box appears.

2. Click the **Excitations** tab.
3. Select or clear the **Visibility** check box for each excitation listed.
4. Click **Done**.

Functional Boundaries and Excitations

Functional boundaries and excitations can be used to do the following:

- Define the value of a boundary or excitation quantity (such as the voltage, magnetic field, or current density) using a mathematical relationship — such as one relating its value to that of another quantity.
- Define the value of a boundary or excitation as a function of position.
  - Current Density Excitation (Magnetostatic or Eddy Current solver type)
  - Voltage Excitation (Electric solver types)
  - Volume Charge Density Excitation (Electrostatic or Electrostatic + DC solver types)
- If the parametric analysis capability was purchased, identify which boundary or excitation quantities are to be varied during a parametric sweep. These variables are always set to constant values in the parametric analysis.

Setting Eddy Effects and Displacement Current

(Eddy Current and/or Transient Solvers)

For both eddy current and transient solvers, you may need to specify the following additional setting:

- The behavior of eddy currents and the AC magnetic field in conductors. When you activate the **Eddy Effect** setting, the solver computes the induced eddy currents.

For 3D eddy current solvers only, you may need to specify the following additional setting:

- The **Displacement Current** on the objects in the model.

Typically, background objects are excluded from eddy and displacement current settings.

To set eddy effects:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the elements of the geometry on which you want to apply the excitation.
2. Click **Maxwell** > **Excitations** > **Set Eddy Effects**.

   The **Set Eddy Effect** dialog box appears.
3. For each object in the list, select or clear the check boxes for **Eddy Effect** and **Displacement Current** (3D Eddy Current T-Omega solver). When selecting multiple entries, the changes are synchronized for all selected rows.

   > **Note:** Multi-select is supported by holding the **Ctrl** or **Shift** key while clicking.
4. Click the **Select Object By Name** button to enter the name of a specific object for selection.
5. Optionally, click the **Use suggested values** button to set the **Eddy Effects** for all elements recommended by Maxwell 3D.
6. Click **OK**.

The **Deselect All** button will deselect all selected objects in the list.

Displacement Current for the 3D Eddy Current A-Phi

For the 3D Eddy Current A-Phi solver, the displacement current effect is set for the whole domain rather than for each object. As a consequence, the number of unknowns will increase and the simulation may require more memory and more simulation time.

To enable the displacement current effect:

1. From the Project Manager tree, right-click **Excitations** and select **Set Eddy Effects**.
2. Enable the **Displacement Current** check box.

Setting Core Loss for Transient and Eddy Current Solvers

For a Transient or an Eddy Current solver design, you may include core loss calculations in the simulation on any object that has a corresponding **core loss definition** (with core loss coefficient settings) in the material library.

To set core loss:

1. Click **Maxwell** > **Excitations** > **Set Core Loss**.

   The **Set Core Loss** dialog box appears.

   You can also open the **Set Core Loss** dialog box by right-clicking **Excitations** in the Project Manager, then selecting **Set Core Loss** on the context menu; or by right-clicking in the Modeler window and selecting **Assign Excitation** > **Set Core Loss**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. For each **Object** in the list, select or clear the check box for **Core Loss Setting** (if a corresponding core loss definition has been set). The **Defined in Material** column indicates whether the material assigned to each object contains a core loss definition. When selecting multiple entries, the changes are synchronized for all selected rows. Multi-select is supported by holding the **Ctrl** or **Shift** key while clicking.
3. Click the **Select By Name** button to enter the name of a specific object for selection. Regular expressions are also supported.
4. Optionally, click the **Deselect All** button to deselect all selected objects in the list.
5. For 3D and 2D transient solvers only, on the **Advanced** tab of the dialog box, you may select the option to **Consider core loss effect on field**. When selected, this option will estimate the core loss and subsequently modify the field solution, causing the resulting fields to be affected by the presence of the core loss. This option provides improved solution accuracy for materials exhibiting high core loss at the expense of increased solution time.

   Note:

   - If the core loss model “hysteresis model” is chosen, then the “Consider core loss effect on field” checkbox is ignored, as the hysteresis model always models the effects of the hysteresis loss.
   - An iteration is required to consider loss effects on the field. For most really soft materials, the iteration is converged. However, if the loss coefficients kh and ke for magnetic steels, or Cm for power ferrites, are too large, the iteration could be diverged. In such cases, users need to double check the specified values, or not to consider core loss effects.

   The default is to exclude this effect. In this case, the field calculation is performed without the core loss and the loss calculation is performed after the field solution is complete.

6. Click **OK**.

Specifying a Custom Core Loss

In addition to the standard core loss excitation detailed in Setting Core Loss for Transient and Eddy Current Solvers, users can also specify a custom core loss formulation. Using a Python script and a data file, the user defines fields and mesh information that are passed on the solver through the Solve Setup window. The core loss formulation in the Python script is used by Maxwell to evaluate core loss, element by element.

This custom core loss capability extends the available core loss formulation for the Maxwell 2D Magnetic Transient solver and the Maxwell 3D Magnetic Transient solver (T-Omega formulation only). It can be used with Distribute solve technology (DSO) and Large-Scale Distribute solve technology (LS-DSO) on Windows and Linux. Time Domain Decomposition is not supported.

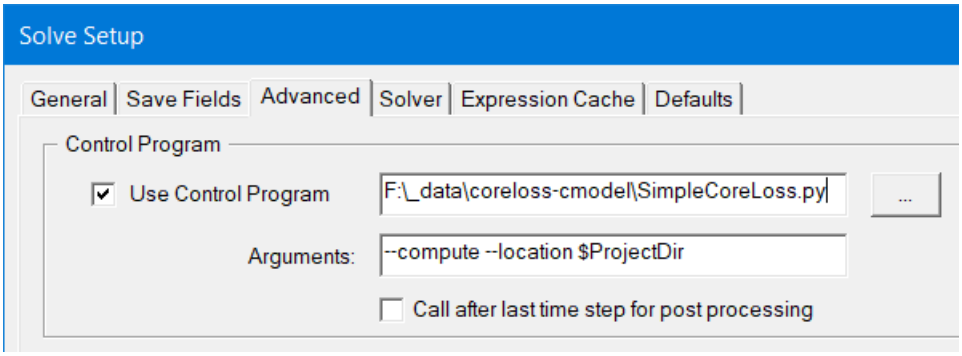
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Several specialty formulations are included in the *//AnsysEM/SoftwareVersion#/ComputerPlatform/Examples/Maxwell/CustomCoreloss* directory.

Required Files

To use a custom core loss excitation, the user must provide two files: the control program Python file and the data file that contains the core loss settings.

The control program (a Python file) must be referenced in the **Advanced** tab of the Solve Setup window:



- In the Arguments field, the command `--compute --location $ProjectDir` must be specified (most common use case; see below for all the options for arguments).
- The **Call after last timestep for post processing** check box can be used to delete all temporary files.

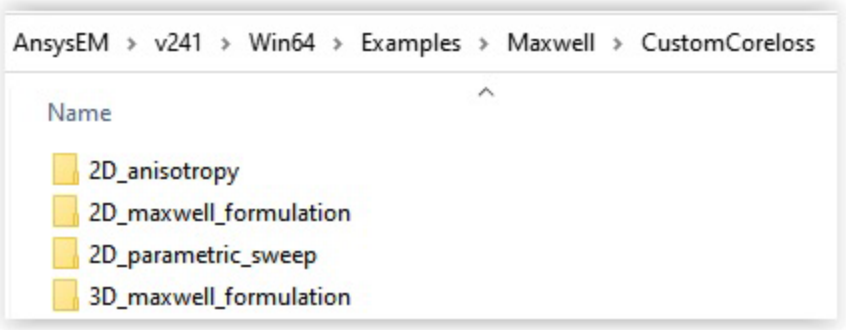
The file that contains the core loss settings must be named *coreloss_user.data* and be placed in same directory as the Maxwell project (if `-location $ProjectDir` argument is used). Its format is described below.

When running the Maxwell magnetic transient simulation, the core loss program will be called at each timestep. The core loss values are exported in a text file (*Result_CoreLoss.txt*). In the case of a parametric sweep, the text file name is indexed with the sweep variables (*i.e.*, *Im_100A_Gamma_90deg_Results_CoreLoss.txt*)

Examples and Templates

Ansys Electronic Desktop provides users with examples and templates, which are located in the \\AnsysEM\VersionNumber\OS\Examples\Maxwell\CustomCoreloss.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The following example formulations are available for the users, without having the necessity to know any Python programming skills:

- Same core loss model as Maxwell (Steinmetz's model)
- Steinmetz's model with anisotropy (different values of core loss coefficients for X, Y and Z directions)

The material properties to enable those formulations are specified in *coreloss_used.data* file, which is included in each example directory.

The following templates are available and can be readily modified:

- 2D_maxwell_formulation replicates the Maxwell model.
- 2D_parametric_sweep contains a 2D transient model with anisotropy, along with an example of parametric sweep. For the model to function, the user has to provide Khx, Khy, Kcx, Kcy, Kex, Key coefficients for each object.
- 3D_maxwell_formulation contains *ExampleCoreLoss3D.py*, which allows anisotropy. The user has to provide Khx, Khy, Khz, Kcx,Kcy,Kcz,Kex,Key,Kez coefficients for each object.

Defining the coreloss_user.data File

The custom core loss program does not use material properties from Maxwell. The *coreloss_user.data* file contains all the material properties and settings for the core loss simulation. Here is an example for calculating the core loss on the object Stator using the Steinmetz method, in 2D:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
#This provides user input data for the User Defined Core Loss Model
begin_data
    SimType 0
    Ncoord 2
    UseFreqDomain 0
    VarKhKc 0
    SymmMultiplier 8
    ObjectNames Stator
    ObjectIDs 928
    Kh 200.0
    Kc 0.5
    Ke 0.5
    Beta 2.0
    Alpha 0.75
    Stacking 1
    ModelDepth 0.083566
end_data
```

The file must start with `begin_data` and ends with `end_data`. Comments can be added, as shown in line 1.

The following keywords can be entered and provide information on the settings:

Keyword	Description	Default
SimType	1 for electric machine, 0 otherwise	0
Ncoord	2 for Maxwell 2D, 3 for Maxwell 3D	2
SymmetryMultiplier	Enter the Symmetry multiplier present in Maxwell	1
ObjectNames	Names of the objects where the custom core loss is applied	None
ObjectIDs	IDs of the objects listed with ObjectNames; see below for instructions on how to get IDs	None
Kh,Kc,Ke (or Khx,Khy,Khz, Kcx,Kcy,Kcz, Kex,Key,Kez), Alpha, Beta, Stacking, ModelDepth	Coreloss coefficients for each object as well as the stacking factor and the ModelDepth (in meters, for 2D only)	None
VarNames	Names of the swept variables when a parametric sweep is defined	None

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To obtain the ID of the object, open the Python console (**Tools** > **Open Command Window**) and type the following commands, in order (this example assumes there is an object names Stator in the project):

```
>>> project=oDesktop.GetActiveProject()
>>> design=project.GetActiveDesign()
>>> editor=design.SetActiveEditor("3D Modeler")
>>> editor.GetObjectIDByName("Stator")
928
```

Examples of coreloss_user.dat

Ansys Electronic Desktop provides *coreloss_user.data* file samples for the most common use cases in the \\Examples\Maxwell\CustomCoreloss directory:

- 2D simulation, similar core loss model to the Maxwell model
- 2D simulation, core loss model with anisotropy
- 2D simulation, core loss model used with a parametric sweep

Writing Your Own Formulations

When writing your own Python formulations, you can use existing examples as starting point or you can start from scratch.

To use an existing example as starting point:

1. From the list of examples available in \\Examples\Maxwell\CustomCoreloss, copy the file and rename it.
2. Provide a Python file to Maxwell that does the following:
    - Imports libraries (import `Coreloss`, `import` utilities)
    - Writes a class that derives from the base method
    - Defines your own version of the method `compute_coreloss_loss_in_a_2D_element`, or `compute_coreloss_loss_in_a_3D_element`.
    - Calls the `compute_coreloss` method from the main function.

To write your own Python formulation from scratch:

1. Set up the Python environment: You do not need to install Python itself. Instead, you need to ensure that Ansys Electronic Desktop is installed on your computer and you have the licenses needed to run a Maxwell transient solve.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Create your own `coreloss` routine: Use existing examples of `compute_core_loss_in_a_2D_element` or `compute_core_loss_in_a_3D_element` to define imports/inputs and outputs.
3. Add your own parameters/material properties to *coreloss_user.data*. You can add any parameter (integer/floating/list …) in *coreloss_user.data* that is needed for your formulation. In the example below, we have added 3 new parameters: KH_0, KC_0 and KE_0. Those parameters will be available in your local coreloss definition.

```
begin_data
    SimType 0
    Ncoord 3
    UseFreqDomain 0
    VarKhKc 0
    NG 1
    SymmMultiplier 4
    ObjectNames Sheet_10
    ObjectIDs 29921
    Khx 0.0
    Kcx 0.6
    Kex 37.4215
    Khy 0.0
    Kcy 0.6
    Key 37.4215
    Khz 41.7100
    Kcz 0.0
    Kez 0.0
    Beta 2.0
    Alpha 0.75
    Stacking 1
    VarNames
    #
    KH_0 = 46.4792
    KC_0 = 0.3286
    KE_0 = 0.0
```

4. Read your parameters in core loss definition. To use KH_0, KC_0 and KE_0 in your own core loss definition, use the syntax below. Note that the parameters are read as strings:

```
KH_0 = float(self.all_parameters.name_values.get("KH_0",0.0))
KC_0 = float(self.all_parameters.name_values.get("KC_0",0.0))
KE_0 = float(self.all_parameters.name_values.get("KE_0",0.0))
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Send your core loss calculation back to the framework. Once you have defined your own formulation, return the values into the following predefined variables:

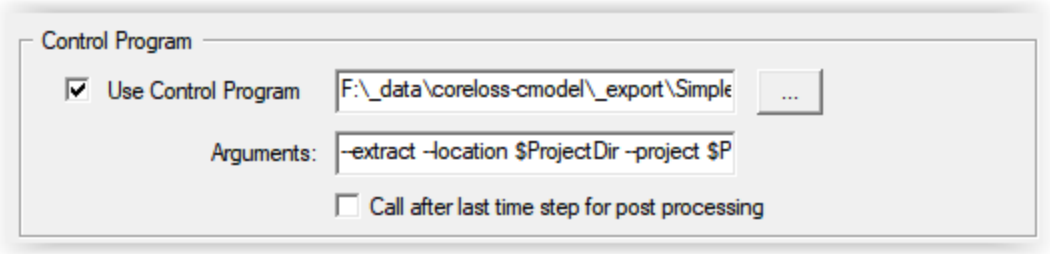
```
coreLossCoeffComponents.CHYS = CHYS
coreLossCoeffComponents.CEXC = CEXC
coreLossCoeffComponents.CEDDY = CEDDY

return True
```

Using Your Control Program with a Maxwell Design

To use your control program with a Maxwell design:

1. Open the project in Ansys Electronics Desktop.
2. Open the properties of the desired analysis setup.
3. In the **Advanced** tab, for the Control Program Path:
    - Update the **Control Program Path** property in your Ansys Electronics Desktop project file to point to the location of your final Python calculation program.
    - Ensure that the path is correctly specified, including the file name and extension, and that it matches the actual location of your Python program on your system.
4. For the Control Program Arguments:
    - Update the **Control Program Arguments** property in your Ansys Electronics Desktop project file to include the appropriate arguments for your computation process.
    - The argument string can begin with the keyword `extract` instead of `compute`. With `Extract` mode, you can run the custom core loss simulation without having to run the Maxwell simulation. Contact Ansys support for more details.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Frequently Asked Questions

1. What are the key features and functionalities provided by the library?
    - Custom computation in Python: Enables Maxwell's core loss formulation to be replaced or extended using code written in Python.
    - Output file format: Core loss data to be saved in any format, which enables easier processing.
    - Input file format: The *coreloss_user.data* file can be in user specified format (such as json).
2. Do I need to install Python? What version of Python is supported?
    - The custom coreloss module uses the CPython version from the Ansys Electronic Desktop installation. It uses version 3.10.
3. Can you explain how the library integrates with Ansys Electronics Desktop and supports core loss computations?
    - The library enables you to write a control program and provide data to control the core loss computation.
    - Ansys Electronic Desktop runs the control program for each timestep of transient analysis, including at the beginning and at the end.
    - During initialization, the library uses your input data file to create a *user.ctl* file as needed by Ansys Electronic Desktop .
    - During each timestep, the library reads the field information provided by Ansys Electronic Desktop and calls your code to compute core loss for each element in the specified interesting objects.
4. How does the library handle the specific engineering parameters or calculations relevant to core loss computation?
    - In your input data file, you can specify material properties for each object of interest.
    - In the time domain, it computes the value of magnetic field vectors and their derivatives needed for core loss computation.
5. What is the level of customization and extensibility offered by the library to accommodate my specific requirements?

    You can override many of the methods of the base class and write your own methods.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Permanent Magnet Field Excitations for 2D and 3D Transient and Magnetostatic Solvers

(Maxwell 2D/3D Transient and Magnetostatic Solvers)

Links to demagnetization and magnetization computation *source* designs can be added as permanent magnet field excitations in *target* designs. A permanent magnet field excitation can be either *object-based* (assigned to geometry) or *design-based* (not assigned to geometry). This topic details how to add or edit a permanent magnet field excitation.

Note:

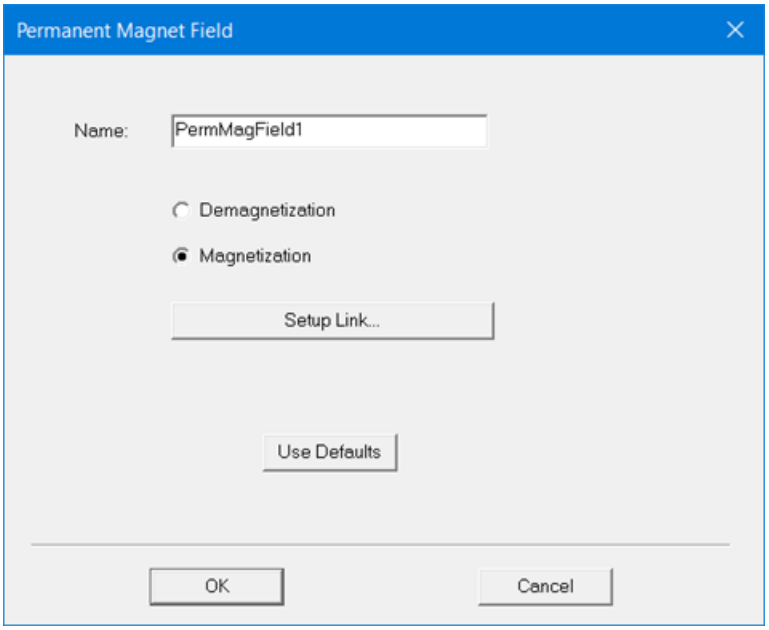
The following procedure assumes that a *source* design, in which either the demagnetization or magnetization operating points computations of the magnet have been modeled, is available for linking.

The *target* design object on which the Permanent Magnet Field is assigned should have a local coordinate system assigned.

- This coordinate system must be right-(or left-)handed, the same as in the *source* design.
- The *target* design object should be in the same quadrant of the new local coordinate system as the matching object in the *source* design.

1. Do one of the following:
   - If you are adding a new *design-based* permanent magnet field excitation, select **Maxwell 2D** or **3D** > **Excitations** > **Assign** > **Permanent Magnet Field**. Alternatively, in the Project Manager you can right-click **Excitations** to open its context menu, then select **Assign** > **Permanent Magnet Field**.
   - If you are adding a new *object-based* permanent magnet field excitation, select one or more objects (magnets) that you wish to include in the permanent magnet field excitation, then either select **Maxwell 2D** or **3D** > **Excitations** > **Assign** > **Permanent Magnet Field**, right-click **Excitations** in the Project tree to open its context menu and select **Assign** > **Permanent Magnet Field**.
   - If you are editing an existing permanent magnet field excitation, right-click on the excitation in the project tree and select **Properties** from the context menu.
2. In the **Permanent Magnet Field** dialog box, enter (or edit) the **Name** for the excitation - or accept the default.

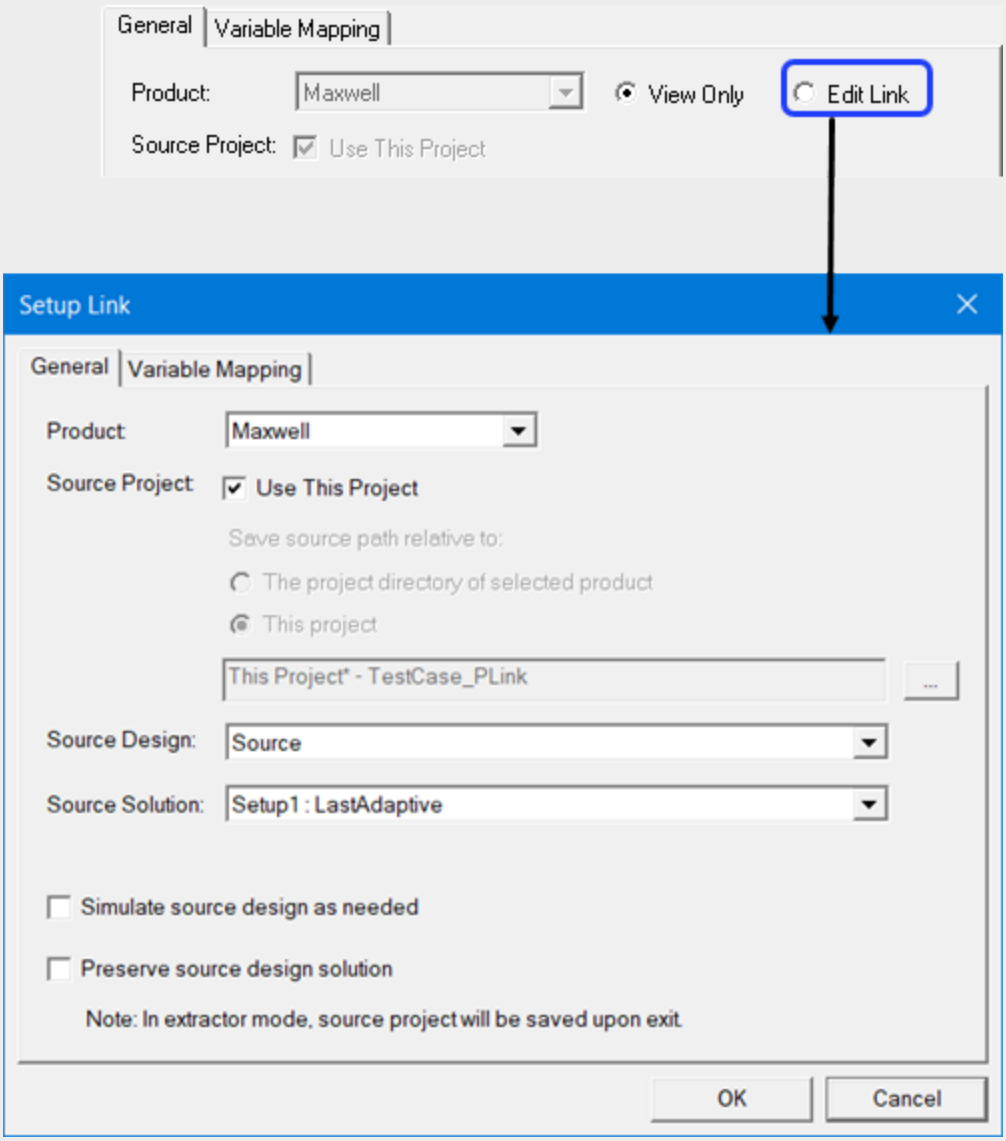
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Depending on how the *source* design which is to be linked has been configured using **Set Demagnetization/Magnetization Computations**, choose either **Demagnetization** or **Magnetization** for the excitation type, then click **Setup Link**.
4. By default, the **Setup Link** dialog opens on the **General** tab with only the **This project** radio button selected.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: If a link had previously been set up, the **Setup Link** dialog box opens in **View Only** mode with all settings disabled.



To enable settings, you can select **Edit Link**.

5. To select a source project do one of the following:

   - To use the current project as the source, check **Use This Project**. This disables the **Save source path relative to:** radio buttons and the ellipsis **[...]** button and its associated text field.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To specify a source project file other than the current project click the ellipsis **[...]** button to open a file browser window. When you have selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to **Open as read only**.

  Use the radio buttons to specify whether to save the source path relative to **The project directory of selected product** or **This project**.

6. When you select a source project file, the **Source Design** and the **Source Solution** fields are filled in with default values, and their drop-down menus contain any available designs and solutions. You can use the drop-down menus to choose from the available designs and solutions.

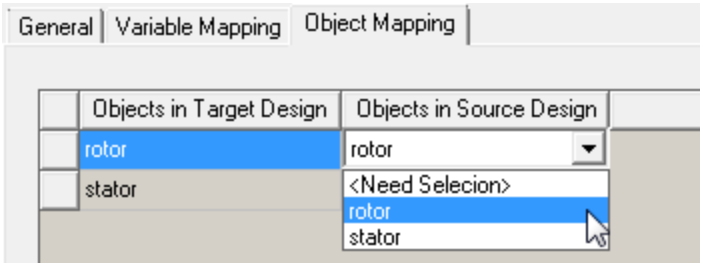
   The “Default” solution is the product-dependent solution of the first Setup. That is the setup listed first in the source design's project tree (alphanumerical order). A product-specific solution of this setup becomes the default solution. In most products, it is “LastAdaptive.”

7. Use the check box to specify whether to **Simulate source design as needed**.
8. Use the check box to specify whether to **Preserve source design solution**. Note that in the extractor mode, the source project will be saved upon exit. Extractor mode means that the software is opened during the link solely for the purpose of solving.
9. The **Variable Mapping** tab lets you view any variables contained in the selected project.

   When there are variables in the source design, you can choose to “map” these variables to constant values, expressions or variables in the target designs. Variable mapping becomes more important when the datalink type requires source and target design to be geometrically identical and source design is geometrically parameterized.

   For linked designs with variables of the same name, you can click **Map Variable by Name** to automatically map same named variables.

10. For object-based permanent magnet field excitations only, the **Object Mapping** tab lets you map objects in the target design to objects in the source design.



11. Click **OK** to close the **Setup Link** dialog box and return to the **Permanent Magnet Field** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12. Optionally, the **Defaults** tab allows you either to save the user-defined data for the excitation as the default for initializing new excitations of this type, or to clear any existing user-defined defaults and revert to standard defaults.
13. When finished, click **OK** to accept the settings and close the dialog box.

Setting Demagnetization/Magnetization Computations for Source Designs

(2D and 3D Magnetostatic and Transient Solvers)

When a magnetic device with permanent magnets is overloaded, or after a short circuit, irreversible demagnetization may occur due to magnetic field and temperature changes. As a result, the subsequent operating point will no longer lie along the original BH curve, but along the demagnetized recoil line at the worst operating condition.

This process can be modeled in Maxwell using **Set Demagnetization/Magnetization Computations**. The demagnetization/magnetization process of the magnet is modeled in the *source* design, and the practical normal application is modeled in the *target* design.

The linked demagnetization or magnetization designs act as sources (excitations) in the target design. These links are managed as Permanent Magnet Field excitations. Users can setup either object-based or design-based links. The Hc outputs from the source design are mapped to the target design mesh, thus eliminating the restriction of target/source designs employing the same geometries.

Note: This mapping is straightforward for non-hysteresis based models because the Hc output from the source design is a single value plus direction per mesh element. For hysteresis-based models, the Hc output from the source design is a demagnetizing curve per mesh element, and a mapping approach is non-trivial. Thus this process is not applicable when the design has any object modeled with hysteresis materials. Demagnetization/magnetization links for this type of design continues to require the same mesh between target and source designs.

Limitations

- A design can only be the target for either magnetization or demagnetization, but not both.
- A design can compute either magnetized or demagnetized operating points, but not both.
- Object-based and design-based links cannot coexist.
- Object-based links are not supported when there is any object assigned with a hysteresis-based material model.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For the magnetization computation, Maxwell provides two possibilities: **anisotropic magnetization**, and **isotropic magnetization**.

For **anisotropic magnetization**, the magnetization direction is determined by the direction specified by the user in the field for the Unit Vector input of Magnetic Coercivity on the panel of View/Edit Material during material setup.

> **Warning:** The combination of anisotropic and inhomogeneous magnetization (varying magnetization direction) is not supported in Maxwell because the magnetization state in the material volume must be connected to a single coordinate system.

For **isotropic magnetization**, the magnetization direction is determined by the orientation of the computed magnetizing field from the field solution. In such a case, the user has to set *all three* components of the Unit Vector input of Magnetic Coercivity to *zero (0)* on the panel of View/Edit Material window during material setup so that Maxwell knows the direction is computed, rather than specified by user.

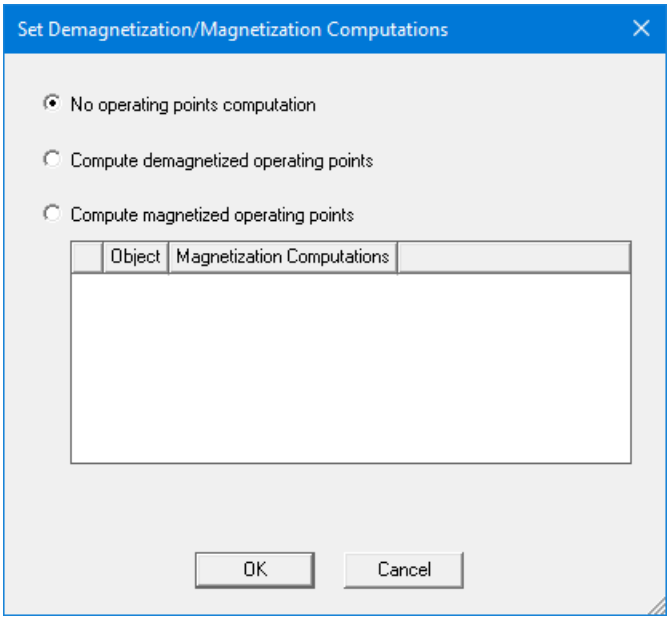
General Procedure for Setting Demagnetization/Magnetization Computations for Source Designs

To set demagnetization/magnetization process computations for a *source* design:

> **Note:** Demagnetization/Magnetization points computation settings specific to the Hysteresis Model-Based Magnetization Approach are described in the Using the Hysteresis Model-Based Magnetization Approach section.

1. Click **Maxwell** > **Excitations** > **Set Magnetization Computation** to open the **Set Demagnetization/Magnetization Computations** dialog box. You can also open the dialog box by right-clicking **Excitations** in the Project Manager, then selecting **Set Magnetization Computation** on the context menu; or by right-clicking in the Modeler window and selecting **Assign Excitation** > **Set Magnetization Computation**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



By default, **No operating points computation** is selected.

2. Select either the **Compute demagnetized operating points** or **Compute magnetized operating points** radio button. At least one object must be selected to compute data if **Compute magnetized operating points** is selected.

   > **Note:** Multi-select is supported by holding the **Ctrl** or **Shift** key while clicking.

   > **Note:** An object coordinate system (CS) must be created and assigned to each magnet object in the history tree.

3. Click **OK** to accept the settings and close the dialog.

The configured source design can now be linked to if you want to create Permanent Magnet Field Excitations for 2D and 3D Transient and Magnetostatic Solvers.

Using the Hysteresis Model-Based Demagnetization/Magnetization Approach

(Transient Solver Only)

> **Note:** Transient A-Phi Formulation does not support the Hysteresis Model.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Currently, demagnetization is modeled based on single demagnetization curve in the second quadrant, possibly extended to the third quadrant in the user-specified direction. Hysteresis-based demagnetization is able to consider magnetization and demagnetization behavior at the same time in all directions, not just user-specified initial direction.

To enable hysteresis model-based demagnetization, and set the Demagnetization/Magnetization computations for source designs:

- Define the hysteresis loop by inputting the descending branch of a hysteresis loop (not supported by defining Hysteresis Model under Core Loss Model).
- Set the initial demagnetizing direction for the starting point on the hysteresis loop by setting the direction in the field for the Unit Vector input of Magnetic Coercivity on the panel of View/Edit Material during material setup. (The initial value is inherently described by the point (Hc = 0 and B = Br).

If a problem setting does not satisfy the above two conditions at the same time, the transient solver will use the “classic” approach to simulate demagnetization process if possible. Note that the valid descending branch of a hysteresis loop should be input with the same absolute values (H and B) for the 1st point and the last point. This modeling approach is not supported for TDM since the modeling of hard hysteresis material cannot be supported by Time decomposition Method (TDM).

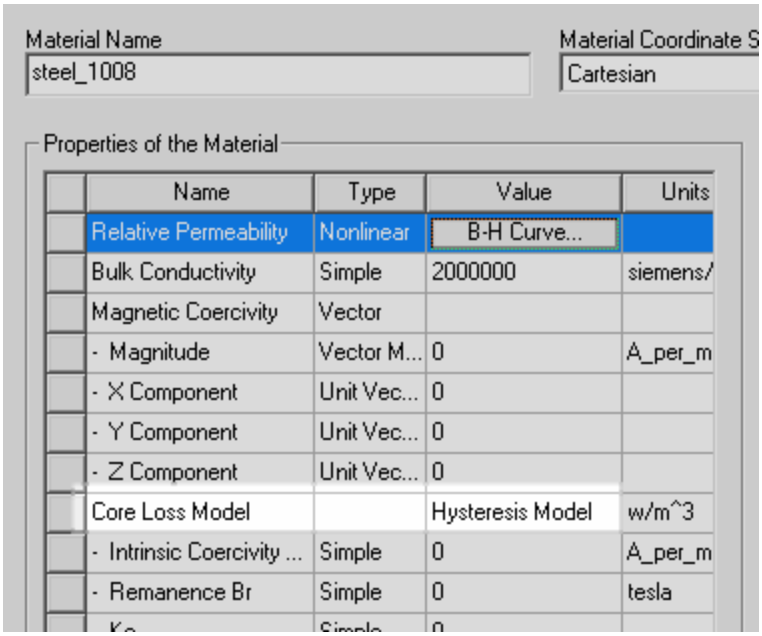
Using the Hysteresis Model-Based Magnetization Approach

(Transient Solver Only)

> **Note:** Transient A-Phi Formulation does not support the Hysteresis Model option.

With the introduction of vector hysteresis modeling capability in the transient solver, it is now possible to simulate the hysteresis model-based magnetization process if a user defines a normal nonlinear BH curve in the 1st quadrant together with the input of Hc (or additional Br for better accuracy of hysteresis loop construction) by selecting **Hysteresis Model** under **Core Loss Model** for the material.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



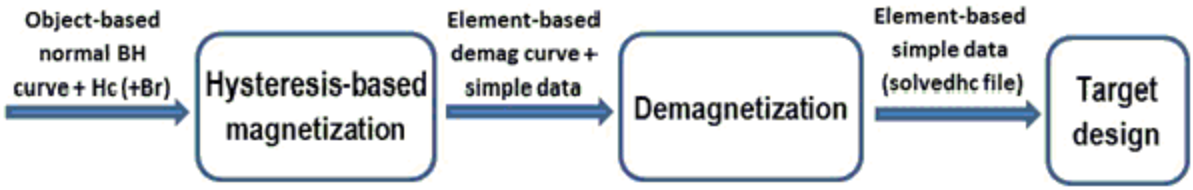
In such a case, magnetization is always considered as isotropic magnetization, that is, magnetization direction is determined by the orientation of the computed field. If a user defines only a normal nonlinear BH curve in the 1st quadrant without defining the Hysteresis model, the transient solver will use the “classic” approach to simulate magnetization process.

Classic Magnetization Approach

Using the classic magnetization approach, if the geometry in the source and target designs is the same, Maxwell maps the computed magnetization data element–by–element. However, the geometry in the source and target designs need not be identical, in which case the geometries in the two designs will be mapped by the solver using the object name. For example, magnetization data on “Box1” in the source design will be applied to the object called “Box1” in the target design. The user must ensure that the source and target object names are identical. The source design will compute magnetization data on the selected objects, while the target design will use the dynamic data in its simulation.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Hysteresis Model-Based Magnetization Approach



Using the hysteresis model-based magnetization approach, after the completion of the last time step before stop, the hysteresis model for each element will generate the element-based demagnetization curve originated at the last operating point. As a result, the output from the magnetization modeling process is an element-based demagnetization curve, rather than a constant. Consequently, an additional demagnetization process is required based on the element-based demagnetization curve. In this approach, use of the same mesh between the source and the two target designs is required due to the use of the element-based demagnetization curve as the output of magnetization simulation.

Note:

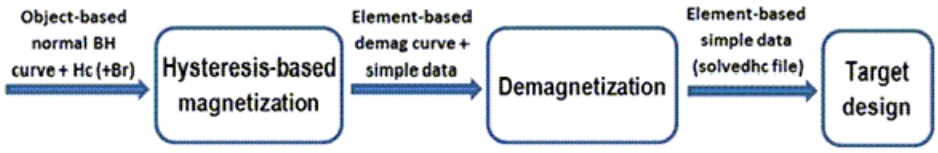
- If an object is defined as hysteresis model, but not selected for magnetization, the object is no longer considered as a hysteresis material because magnetization and hysteresis modeling cannot be conducted in the same design.
- Hysteresis based magnetization is always considered as isotropic magnetization, that is, its direction is determined by the orientation of the computed field.
- For objects that have been selected for magnetization, but not defined as hysteresis models, the existing classic approach (*simple data* in the diagram above) will be used. Mixing hysteresis model-based magnetization method with the classic magnetization method is supported.
- For the classic approach, no demagnetization step is required; while for the hysteresis model-based magnetization approach, a demagnetization step is normally required. For the demagnetization step, the input is the element-based demagnetization curve derived from the magnetization run.
- When **Clean Stop** is invoked for projects in which a TDM transient source design is linked to a transient target design, after completion of the source design the solution process can continue from the target design. In such a case, the target design must be non-TDM.

Design Criteria

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The source design must have objects assigned with non-linear, non-permanent-magnet material properties.
- The same design cannot be the source for both magnetization and demagnetization links.
- The source design cannot also be a target of a demagnetization link.
- The target design cannot also be a target or source of a demagnetization link.

The hysteresis model-based magnetization approach requires three designs.

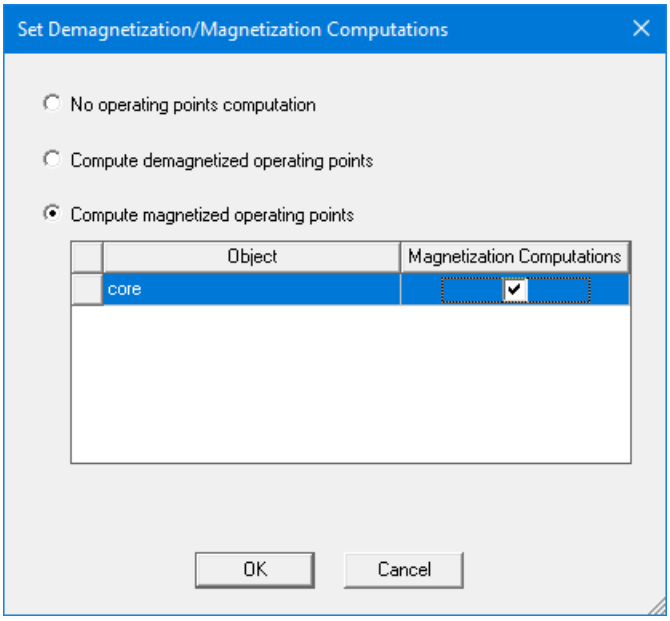


First Design: Set up a Hysteresis-Based Magnetization Computation Design (source design)

1. Create a Maxwell 2D or 3D magnetic transient design (the *Hysteresis-based magnetization* design in the figure shown above).
2. Click **Maxwell** > **Excitations** > **Set Magnetization Computation** to open the **Set Demagnetization/Magnetization Computations** dialog box.

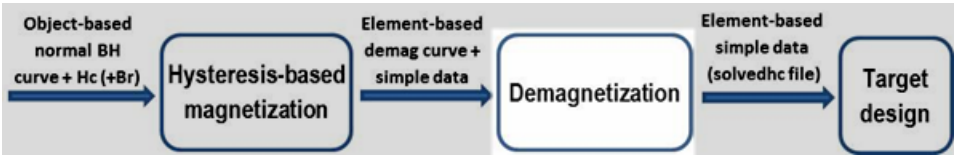
   You can also open the **Set Demagnetization/Magnetization Computations** dialog box by right-clicking **Excitations** in the Project Manager, then selecting **Set Magnetization Computation** on the context menu; or by right-clicking in the Modeler window and selecting **Assign Excitation** > **Set Magnetization Computation**.
3. Select **Compute magnetized operating points**, and select the objects for magnetization and/or hysteresis-based magnetization computation, then click **OK** to accept the settings and close the dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



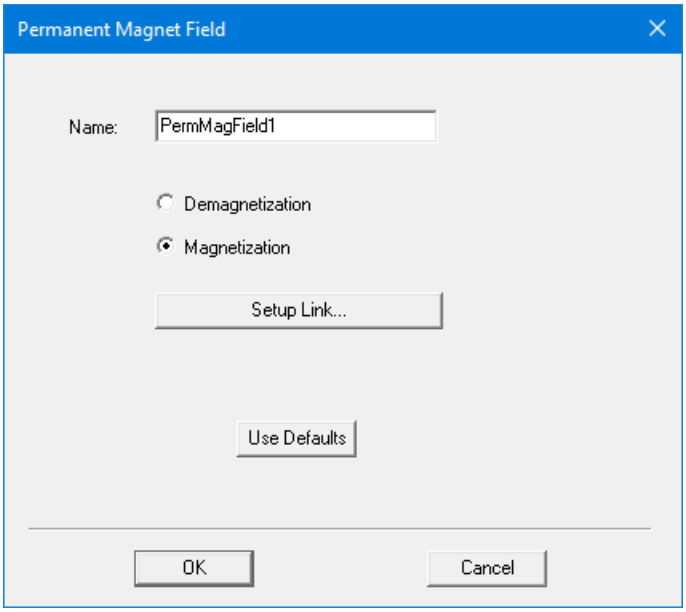
4. Solve the design and the solution will include the element-based magnetization data, and/or hysteresis-based demagnetization curve if the design uses nonlinear materials with non-zero Hc defined.

Second Design: Set up a *Demagnetization* design with Output of the Hysteresis-Based Magnetization Computation

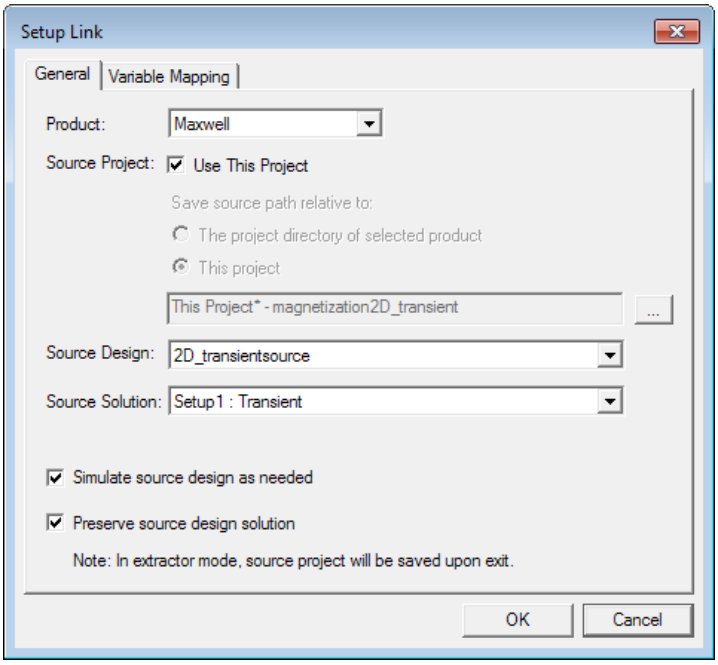


1. Create another Maxwell 2D or 3D magnetic transient design to be used as the *Demagnetization* design (highlighted above).
2. In the Project tree, right-click **Excitations** and select **Assign** > **Permanent Magnet Field**.
3. In the **Permanent Magnet Field** dialog box, select **Magnetization**, then click **Setup Link.**

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

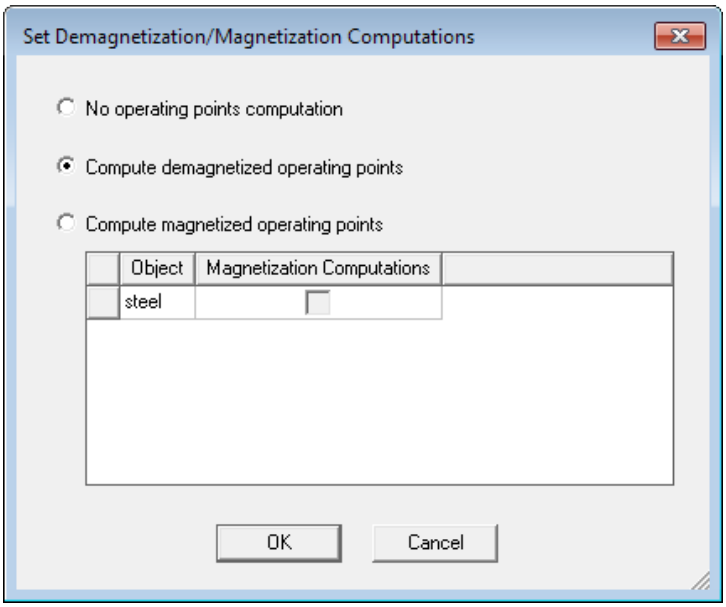


4. Set up a link to the *Hysteresis-based magnetization computation* source design (the first design you set up), which provides the hysteresis-based magnetization solution data. Check **Simulate source design as needed** and **Preserve source design solution**. If the source design is not set up to **Compute magnetized operating points**, an error message will be issued.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Right-click **Excitations** in the Project tree and select **Set Magnetization Computation** on the context menu to open the **Set Demagnetization/Magnetization Computations** dialog box, and select **Compute demagnetized operating points**.



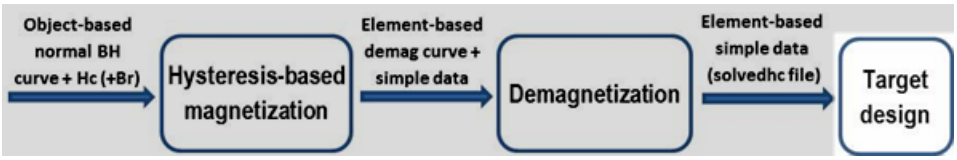
> **Note:** Steps 6 and 7 are applicable only for *object-based* magnetization/demagnetization links. Omit these steps if *design-based* magnetization/demagnetization links are used.

6. Open the **Solve Setup** dialog and select **Import mesh** on the **Advanced** tab to open the **Setup Link** dialog box.
7. In the **Setup Link** dialog box, for the **Source Design**, choose the *Hysteresis-based magnetization computation* (the first design you set up).
8. Solve the design and the solution will include the element-based demagnetization distribution curve (which is based on the Hysteresis-based magnetization data). If the source design has not been solved, solving the current (demagnetization) design causes the source design to be solved first.

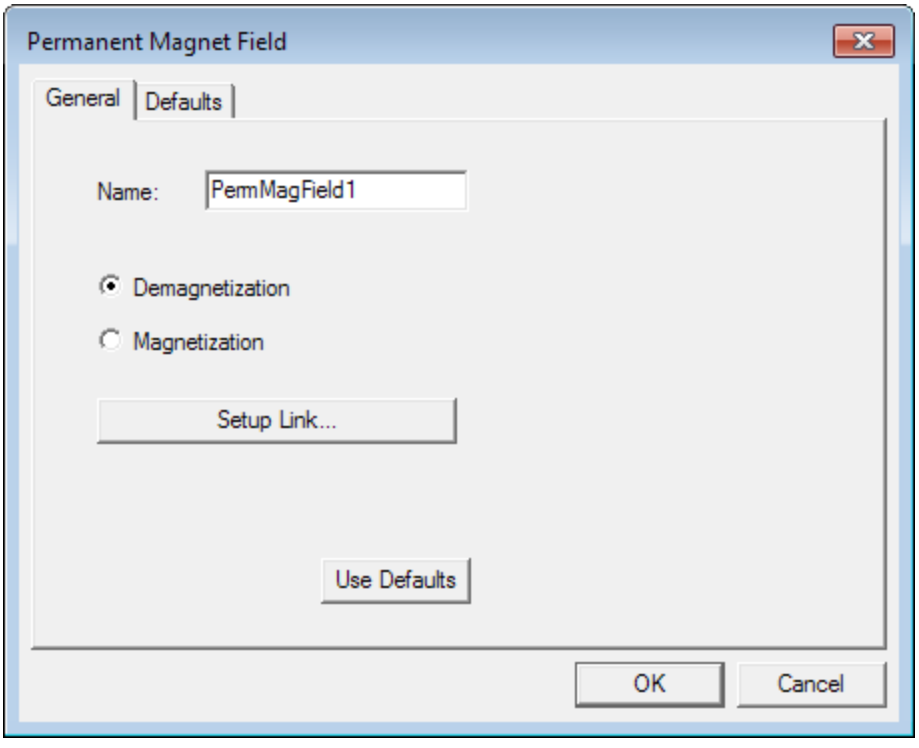
> **Note:** To ensure that new data from the source design is used if the source design has been modified, right-click the Analysis icon of the source design in the project tree, and click **Clear Linked Data**. This flushes existing linked data so that solving the current design will force the source design to be solved first.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Third Design: Set up the *Target* Design

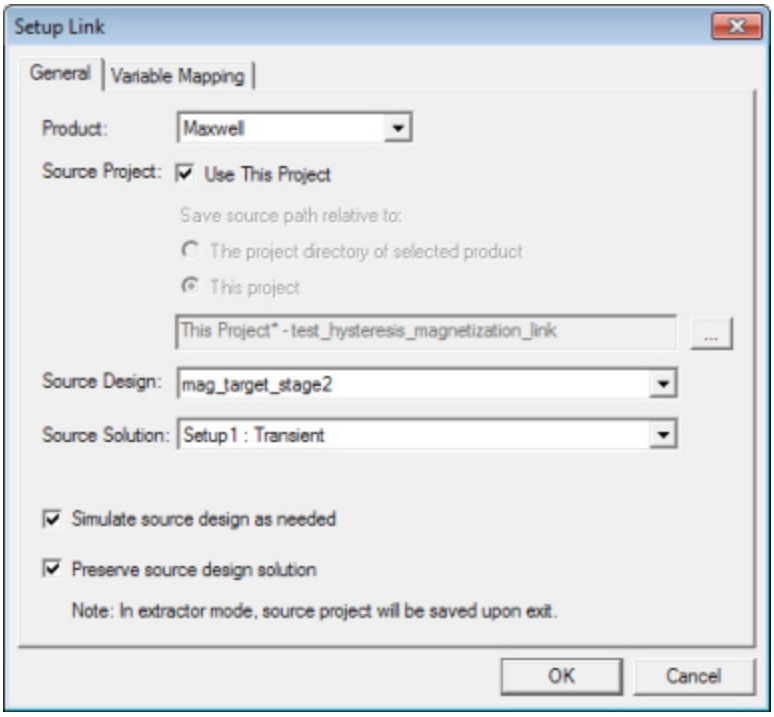


1. Create a third Maxwell 2D or 3D magnetic transient design to be used at the *Target* design (highlighted above).
2. In the Project Manager tree, right-click **Excitations** and select **Assign** > **Permanent Magnet Field**.
3. In the **Permanent Magnet Field** dialog box, select **Demagnetization**, then click **Setup Link.**



4. Set up a link to the *Demagnetization* design (the second design created above), which provides the dynamic demagnetization distribution solution data (based on the *Hysteresis-based magnetization* solution data from the first design). Be sure to check **Simulate source design as needed** and **Preserve source design solution**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



> **Note:** Steps 5 and 6 are applicable only for *object-based* magnetization/demagnetization links. Omit these steps if *design-based* magnetization/demagnetization links are used.

5. Open the **Solve Setup** dialog and select **Import mesh** on the **Advanced** tab to open the **Setup Link** dialog box.
6. In the **Setup Link** dialog box, for the **Source Design**, choose the *Demagnetization* design (the second design created above).
7. Solve the *Target* design. If the source designs for hysteresis-based magnetization computation and demagnetization are not yet solved, solving the current (target) design causes the two source designs to be solved in sequence first.

> **Note:** To ensure that new data from the source designs is used if the source designs have been modified, right-click the Analysis icon of each source design in the Project Manager tree, and click **Clear Linked Data**. This flushes existing linked data so that solving the current design will force the source designs to be solved first.

Showing and Verifying Conduction Paths

To show the conduction paths in the geometry:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click **Maxwell** > **Excitations** > **Conduction Paths** > **Show Conduction Paths**.

   The **Conduction Path Visualization** window appears.

2. Click a path in the list.
   The path is highlighted in the model.
3. Click **Close** when you are done viewing conduction paths.

To verify conduction paths:

- Click **Maxwell** > **Excitations** > **Conduction Paths** > **Verify Conduction Paths**.

  The paths are traced in the model diagram.

Recalculating Conduction Paths

Conduction paths are not recalculated unless a design changes results in a different outcome.

You can force a recalculation by using the **Maxwell** > **Excitations** > **Conduction Paths** > **Recalculate Conduction Paths** command.

The **Recalculate Conduction Paths** command is similar to the **Verify Conduction Paths** command. The only difference is that the **Recalculate** command recalculates every time, even if there are no changes that influence the conduction paths.

> **Note:** The **Recalculate Conduction Paths** command does not apply for electrostatic solution types.

To recalculate conduction paths for the active project, click **Maxwell** > **Excitations** > **Conduction Paths** > **Recalculate Conduction Paths**.

Modifying Boundary Conditions and Excitations

Save your project before modifying boundary conditions and excitations. You can modify boundary conditions and excitations after a solution has been generated, but you may lose some solution data.

Duplicating Boundaries and Excitations

To duplicate a boundary or excitation when its geometry is pasted or duplicated:

1. Click **Tools** > **Options** > **General Options** to open the **Options** dialog box, displaying a hierarchical list of options. Click the + next to **Maxwell 2D** and select **Boundary Assignment**.
2. Select **Duplicate boundaries/mesh operations with geometry**.
3. Click **OK**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

All boundaries and excitations are duplicated with their associated geometries until you clear this option.

Tip: Use this option to copy and paste boundaries. For example, do the following to use the same boundary on multiple objects:

1. Select the face to which you want to assign the boundary.
2. Click **Modeler** > **Surface** > **Create Object From Face** to create a new object from the existing face.
3. Assign the boundary to the new face object.
4. Copy and paste the new face object to copy and paste the boundary.

Showing and Hiding Boundaries and Excitations

You can choose to show or hide a boundary or excitation's geometry, name, or vectors in the active view window or in all view windows.

Showing and Hiding Boundaries and Excitations in Every View Window

1. Click **Maxwell** > **Boundaries** > **Visualization** or **Maxwell** > **Excitations** > **Visualization**. The **Visualization Options** window appears.
2. Select one of the following from the **Select** drop-down menu:
   - All
   - All Boundaries
   - All Excitations
   - All Ports
   - By Name
3. If you select **By Name**, enter a name in the **Select By Name** window, and click **OK**.
4. To clear the selection of all boundaries and excitations, click **Deselect All**.
5. Click **Close** to close the **Visualization Options** window.

Setting Default Values for Boundaries and Excitations

When assigning a boundary or excitation, many of the fields in the boundary and excitation dialog boxes have default values associated with them. These default values are initially set by Maxwell, but can be overridden.

To modify the default values associated with a specific boundary or excitation type:

1. Assign a boundary or excitation.
2. Modify any default values.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Close the boundary or excitation's dialog box.
4. Re-open the new boundary or excitation's dialog box. It now includes a **Defaults** tab.
5. Under the **Defaults** tab, click **Save Defaults**.

   The values assigned to this boundary are saved as the default values and are assigned when new boundaries of this type are created.

6. Optionally, click **Revert to Standard Defaults**.

The default values you set for this boundary type are cleared and will revert to the default values set by Maxwell.

Reassigning Excitations

You can reassign an excitation to another surface. This is useful when you have modified objects with assigned excitations, invalidating the excitations. For example, if you unite two objects with assigned excitations, the second object's excitation will become invalid because united objects maintain the characteristics of the first object selected. In this case, you would need to reassign the excitation or delete it. You can use a **Reassign Excitation** dialog box accessed through the **Maxwell** > **Excitation** > **Reassign** menu, or right-click on the Excitation of interest in the Project tree, and select from the shortcut menu to **Reassign**, **Add to Assignment**, or **Remove from Assignment**. You can also determine a current assignment by right-clicking on the excitation in the **Project** tree and by using the **Select Assignment** command on the short cut menu.

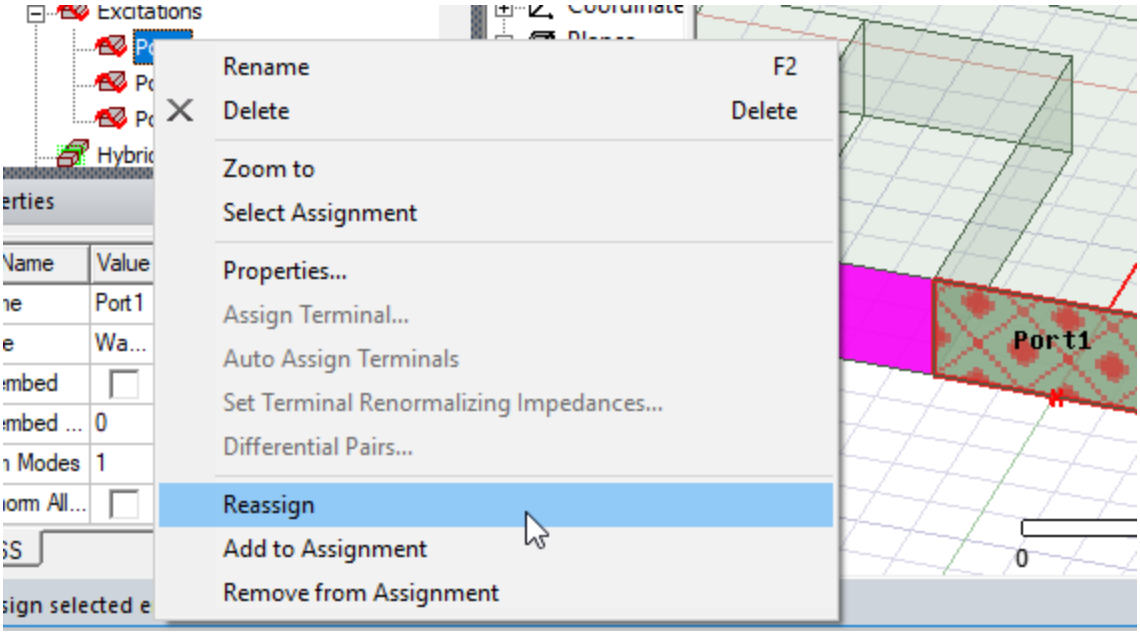
Prerequisites:

- The surface to which you want to **Reassign**, or **Add to Assignment** must be on the same plane as existing assignment. It does not have to be in contact to **Reassign**, but must be in contact to **Add to Assignment**.
- You must first select the surface that you want to reassign or add to an assignment.

To use the short-cut menu to reassign or add an excitation:

1. With the target surface selected, right-click on the Excitation of interest to invoke the menu.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Select **Reassign** to change the assignment to the selected surface, or **Add to Assignment** to include surface.

To use the shortcut menu to Remove a selected surface from an assignment:

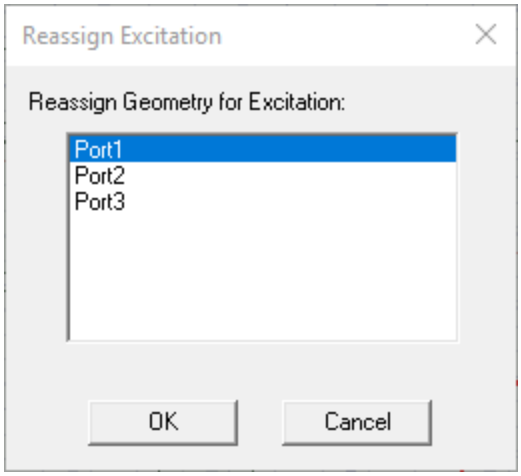
1. With the target surface selected, right-click on the Excitation to invoke the menu.
2. Click **Remove from Assignment**.

To use the Maxwell Menu and the Reassign Excitation dialog box:

1. Select the object or object face to which you want to assign an existing excitation.
2. Click **Maxwell** > **Excitations** > **Reassign**.

The **Reassign Excitation** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Select an existing excitation from the list, and then click **OK**.

The excitation is reassigned to the object or object face.

> **Tip:** When reassigning an excitation that includes vectors in its definition, Maxwell attempts to preserve the vectors with the new assignment, but this is not always possible.

Deleting All Boundaries and/or Excitations

To delete all boundaries or excitations:

- Click **Maxwell** > **Boundaries** > **Delete All** or **Maxwell** > **Excitations** > **Delete All**.

Viewing and Editing Boundary or Excitation Properties

To open the **Properties** window for a boundary or excitation that is already assigned:

1. In the project tree, under either **Boundaries** or **Excitations**, right-click a specific boundary or excitation, and select **Properties**.
   The **Properties** window for that boundary/excitation appears.
2. Make the desired changes, and click **OK**.

Magnetostatic Boundaries and Excitations

Define at least one of the following as a source of static magnetic fields:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The current in a conduction path, which can be either stranded or solid.

  > **Note:** For stranded conductors, it is assumed that the current density is uniform on the cross-section of the respective conductors. Thus, the stranded option for current excitations should mostly be used only in cases where the cross-section of conductors is constant, consistently with the assumption that the respective object is a coil built with strands of wire. For this reason, conductors (coils) could be created by either sweeping around an axis using zero segments or sweeping along a path having only true surface segments in order to create a smooth surface coil having a completely uniform cross-sectional area over its entire length.

- The current density in a conductor.
- The voltage differential across a conduction path.
- The magnetic field on an outside surface.
- A permanent magnet.

If currents or current densities are the only sources of static magnetic fields in your model, set at least one of the following as the outer boundary:

- The default boundary conditions.
- An odd symmetry (flux tangential) boundary.
- An even symmetry (flux normal) boundary.

Magnetostatic Boundaries

The magnetostatic field solver allows you to define the following types of boundaries:

Boundary Type	H-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — **H** is continuous across the boundary. • Neumann boundaries — **H** is tangential to the boundary and flux cannot cross it.	Ordinary field behavior. Initially, object interfaces are natural boundaries; outer boundaries, and excluded objects are Neumann boundaries.
Zero Tangential H Field	Flux is perpendicular if tangent components are zero or if a zero tangential H-field boundary was applied.	External magnetic fields.
Tangential H	The tangential components of **H** are set to	External magnetic

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Field	predefined values.	fields.
Integrated Zero Tangential H Field	For applications such as a motor with the shaft excluded, there remains a hole in the middle. In such cases, on the hole's boundary, neither the Tangential H Field boundary (where integration of the tangential H field is non-zero), nor the Zero Tangential H Field boundary (where the tangential H field is zero everywhere) can be applied because – for the hole boundary case – integration of the tangential H field is zero, but the tangential H field is not zero everywhere. Integrated Zero Tangential H Field can be used for such applications.	Cases such as the boundary around the hole that remains when a motor's shaft is excluded.
Insulating	Same as Neumann, except that current cannot cross the boundary.	Thin, perfectly insulating sheets between touching conductors.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) — **H** is tangential to the boundary; its normal components are zero. • Even Symmetry (Flux Normal) — **H** is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.
Matching (Independent and Dependent)	The H-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the H-field on the independent boundary.	Planes of symmetry in periodic structures where **H** is oblique to the boundary.
Thin Layer	When two parts of the domain are separated by a thin volume representing an air gap, it can be modeled by a surface with an appropriate boundary condition. This boundary creates a field discontinuity between the two sides of the selected surface based on its thickness. The relative magnetic permeability of the air gap is assumed to be equal to one.	Narrow air gaps

Default Boundary Conditions for a Magnetostatic Solver

These boundary conditions are automatically defined for a magnetostatic model:

- Natural boundaries are assigned to the surfaces between objects.
- Neumann boundaries are assigned to the outside edges of the problem region.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Magnetic H Field for a Magnetostatic Solver

This type of boundary defines external magnetic fields in a model. Assign it only to the outer surfaces of the problem region.

> **Warning:** When using tangential magnetic field boundary conditions, always double-check that Ampere's law is not violated.

> **Note:**
> The specific boundary types you can define depend on the solver you have chosen for your project.
> - Electrostatic Boundary Conditions
> - DC Conduction Boundary Conditions
> - Magnetostatic Boundary Conditions
> - Eddy Current Boundary Conditions

To define a zero tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Zero Tangential H Field**.
   The **Zero Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

To define a tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition.
2. Click **Maxwell** > **Boundaries** > **Assign** > **Tangential H Field**.
   The **Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the value of the field component in the x-direction in the **U(X)** box and the value of the field component in the y-direction in the **V(Y)** box.
5. In the **Coordinate System** section, do the following to define the vectors:
   a. Select **New Vector** from the **U Vector** drop-down menu.
      The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. Click two points to specify the vector.
The vector is set, and the **Tangential H Field** window reappears, with **Defined** listed for **U Vector**.
c. To reverse the direction of the vector, click the **Reverse Direction** check box.

6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the Project Manager tree.

Assigning an Integrated Zero Tangential H Field Boundary for a Magnetostatic Solver

This type of boundary is applied when the integral of the tangential H field is zero.

> **Warning:** When using integrated zero tangential magnetic field boundary conditions, always double-check that Ampere's law is not violated.

To define an integrated zero tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Integrated Zero Tangential H Field**.
The **Integrated Zero Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the project tree.

Assigning an Insulating Boundary for a Magnetostatic Solver

This boundary condition is used to model very thin sheets of perfectly Insulating material between touching conductors. Current cannot cross an insulating boundary.

To set an insulating boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Insulating**.
The **Insulating Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning a Symmetry Boundary Condition for a Magnetostatic Solver

This boundary condition defines a plane of geometric or magnetic symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Symmetry**.
   The **Symmetry Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Tangential)	**H** is tangential to the boundary; its normal components are zero.
Even (Flux Normal)	**H** is normal to the boundary; its tangential components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the boundary to the selected object.

> **Warning:** When using even symmetry boundaries, double-check that Ampere's law is not violated.

Assigning an Independent Boundary for a Magnetostatic Solver

Independent and dependent boundaries enable you to model planes of periodicity where the H-field at every point on the dependent boundary surface is forced to match the H-field of every corresponding point on the independent boundary surface. The transformation used to map the H-field from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the face to which you want to assign the independent boundary.
2. Click **Maxwell** > **Boundaries** > **Assign** > **Matching** > **Independent**.
   The **Independent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Coordinate System** section, do the following to define the coordinate system:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** drop-down menu.
      The **Create Line** message appears, asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Independent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.
   c. Select a point on the u-axis.
      The **Independent Boundary** dialog box reappears
5. To reverse the direction of the vector, select the **Reverse Direction** check box.
6. Click **OK**.

The Maxwell solver computes the H-field on this boundary and maps it to the dependent boundary using the transformation defined by the independent and dependent coordinate systems.

Assigning a Dependent Boundary for a Magnetostatic Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

> **Note:** You must define an independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Matching** > **Dependent**.

   The **Dependent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** drop-down menu.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. To specify the coordinate system, do the following in the Coordinate System section:

   > **Note:** You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** drop-down menu.
   The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Dependent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

      > **Note:** The U vector's origin must be on the boundary's surface.

   c. Select a point on the u-axis in the same way.
   When the second point is identified, the vector is set, and the **Dependent Boundary** window reappears, with **Defined** listed in the **U Vector** drop-down menu.
   d. To specify the direction of the V vector, select or clear the **Reverse Direction** check box.
6. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Hdep = Hind	Click this radio button if the dependent and independent boundaries have the same magnitude and direction.
Hdep = -Hind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. Click **OK** to assign the boundary to the selected object.

> **Note:** The origin must be a vertex point of one of the objects.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning a Thin Layer (Air Gap) Boundary for a Magnetostatic or Transient Solver

When two parts of the domain are separated by a thin volume representing an air gap, it can be modeled using a **Thin Layer** boundary condition. This boundary creates a scalar potential discontinuity across the two sides of the surface based on its thickness. The magnetic permeability of the air gap is assumed to be equal to that of free space.

This boundary condition can be used to model narrow air gaps, such as those in power transformers, inductors, or any other electric device forming a magnetic circuit with an air gap without needing to explicitly model (and mesh) this gap.

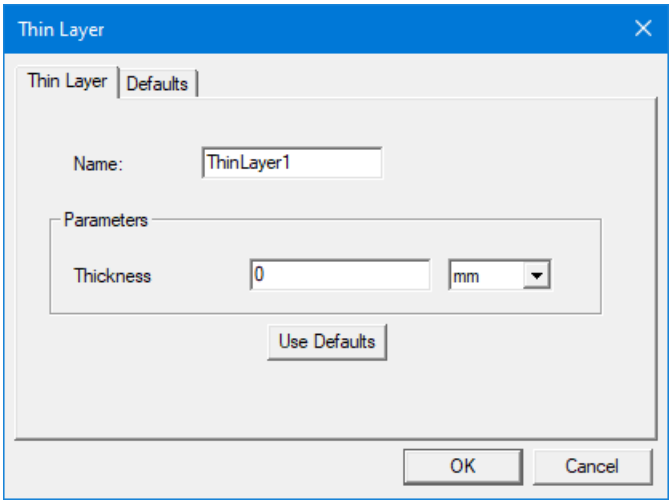
> **Note:**
>
> - The thin layer cannot be a closed shell encompassing a conductor.
> - The thin layer does not support a mechanical movement, *i.e.*, the boundary condition cannot be applied to the interface of moving and stationary bodies.
> - The thin layer cannot be defined on a conductor boundary or as a sheet object that touches or crosses any conducting body. In such cases, the Maxwell solver displays an error message indicating the name of the conducting body that the thin layer is touching.

For the 3D Magnetostatic and Transient solvers, the thin layer for an air gap is defined purely in terms of its thickness. It is assumed to be made of air (non-conducting material with relative magnetic permeability equal to one).

To define a thin layer boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a sheet object or face of a 3D body).
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Thin Layer** to open the **Thin Layer** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



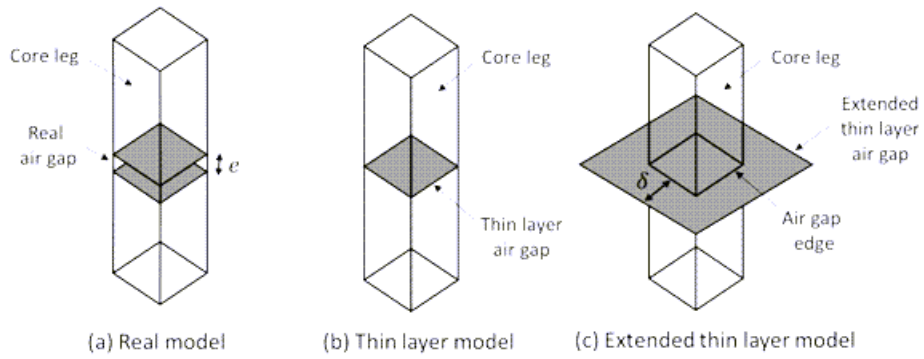
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter the thickness of the thin layer and the unit of measure. It must be a value greater than zero. The use of variables is supported.
5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **Thin Layer** tab as the defaults to be assigned to new impedance boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.
7. Click **OK** to assign the boundary to the selected object.

The Project Manager tree lists the newly assigned thin layer boundary in the tree. You can select the boundary in the tree to view and edit its thickness in the Properties window. You can also double-click the boundary entry in the tree to open it for editing in the Thin Layer dialog box.

Getting Better Convergence with the Thin Layer Model

For a magnetostatic or transient simulation, the thin layer model for air gaps requires the duplication of the scalar potential to create a field discontinuity beyond the dimension of the sheet object and correctly represent the fringing flux effects. The Maxwell solver automatically duplicates the potential in one layer of elements from the gap edges. However, during the mesh adaptive process, the lateral elements may become too small and thus too close to the gap sides. This results in a low convergence of the mesh adaptive steps as the magnetic energy on such elements becomes more important. To improve convergence, the user can extend the sheet object manually (see figure below). Better convergence is observed by raising its lateral sides from one to three times the air gap thickness ($\delta \cong 3e$) depending on the model geometry.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Assigning a Resistive Sheet Boundary for the 3D Magnetostatic Solver

> **Note:** For transient designs, refer to Assigning a Resistive Sheet Boundary for the Transient Solver.
> For eddy current designs, refer to Assigning a Resistive Sheet Boundary for the Eddy Current Solver.

The Maxwell 3D magnetostatic solution can include a nonlinear resistive sheet boundary condition. The linear resistive sheet boundary condition is equivalent to a resistive sheet in the eddy solver and the transient solver (see links above). The nonlinear relationship between conductivity σ and current density J is as follows:

$$\sigma\left(J\right) = L\frac{c+J^d}{a+bJ^{d-1}}$$

where L is the resistive sheet thickness, and a, b, c, and d are constants. For electric arc simulation, the nonlinear relationship is applied to both anode and cathode , so a total of eight constants are required – four for the anode and four for the cathode.

The ohmic loss on the nonlinear resistive sheet can be calculated using

$$P = \lim_{L\to 0}\int_V \frac{J^2}{\sigma(\mathrm{J})}dV = \lim_{L\to 0}\int_S \frac{J^2}{f(\mathrm{J})}dS$$

where V is the resistive sheet volume, S is the resistive sheet surface, and

$$\left(J\right) = \frac{c+J^d}{a+bJ^{d-1}}$$

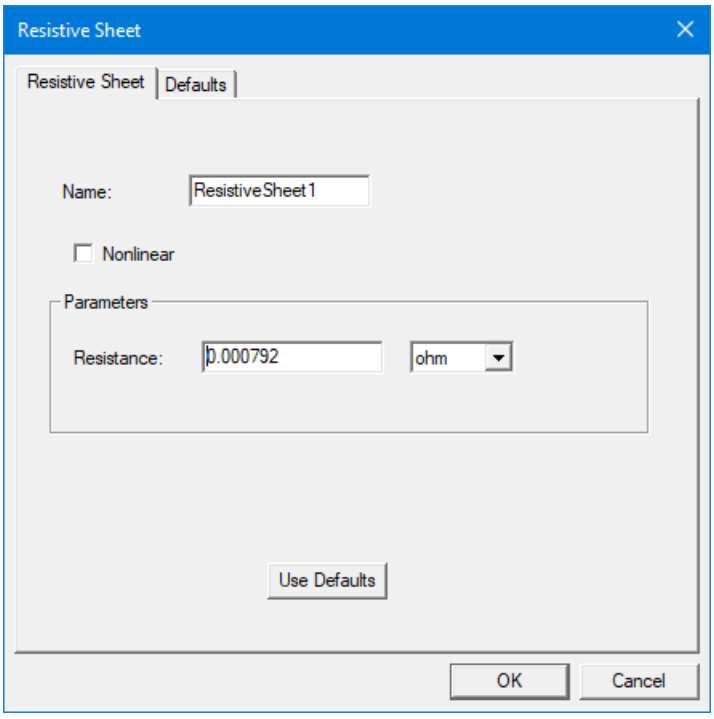
To define a resistive sheet boundary:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the section of the geometry on which you want to apply the boundary condition (typically a sheet object or face of a 3D conducting body touching another conducting body or face of a 3D conducting body touching the Region).

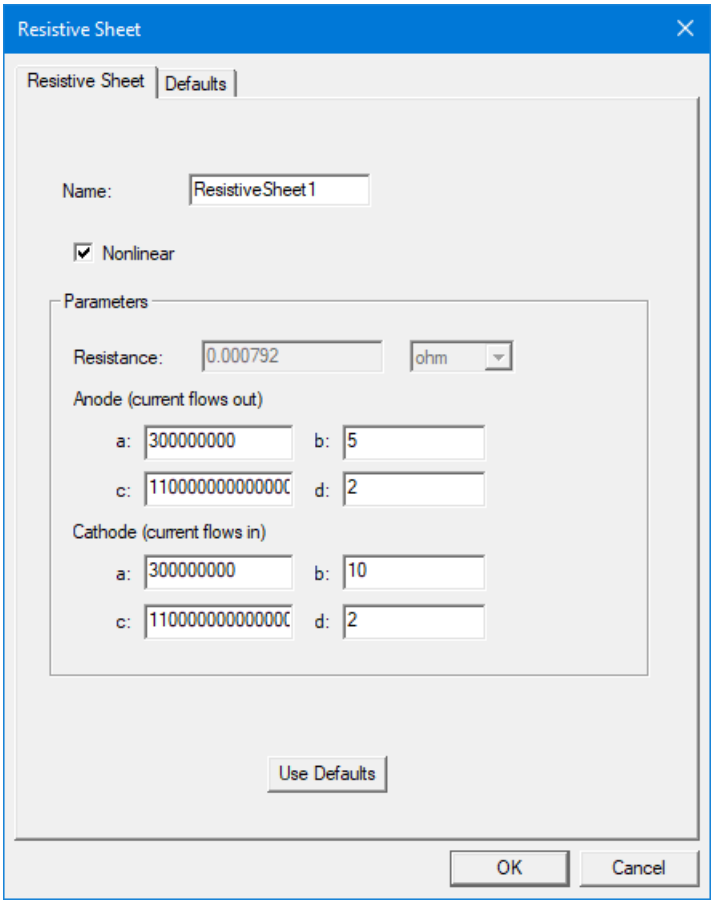
   Note:
   - The sheet must be completely inside a conductor or on its surface.
   - The sheet must have conductors touching both of its faces.
   - The resistance value cannot be dependent on an intrinsic variable.

2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Resistive Sheet** to open the **Resistive Sheet** dialog box. Alternatively, you can select the sheet/surface, right-click, select **Assign Boundary** > **Resistive Sheet**.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. If **Nonlinear** is unchecked, enter a constant resistance value in the **Resistance** field, and select a unit of measure. Use of variables is supported. Constant resistance cannot be a negative value.



5. If **Nonlinear** is checked, additional fields display for entering **Anode** and **Cathode** values. These values correspond to the *a*, *b*, *c*, and *d* coefficients in the equations above. The *a* and *b* values cannot both be 0.

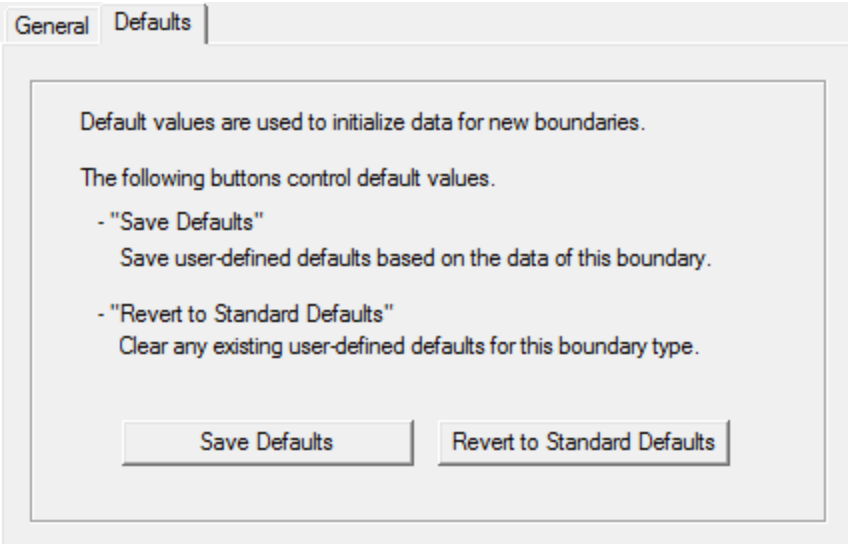
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



6. Optionally, click **Use Defaults** to revert to the default value (1 ohm) in the window.

   The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **General** tab as the defaults to be assigned to new impedance boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



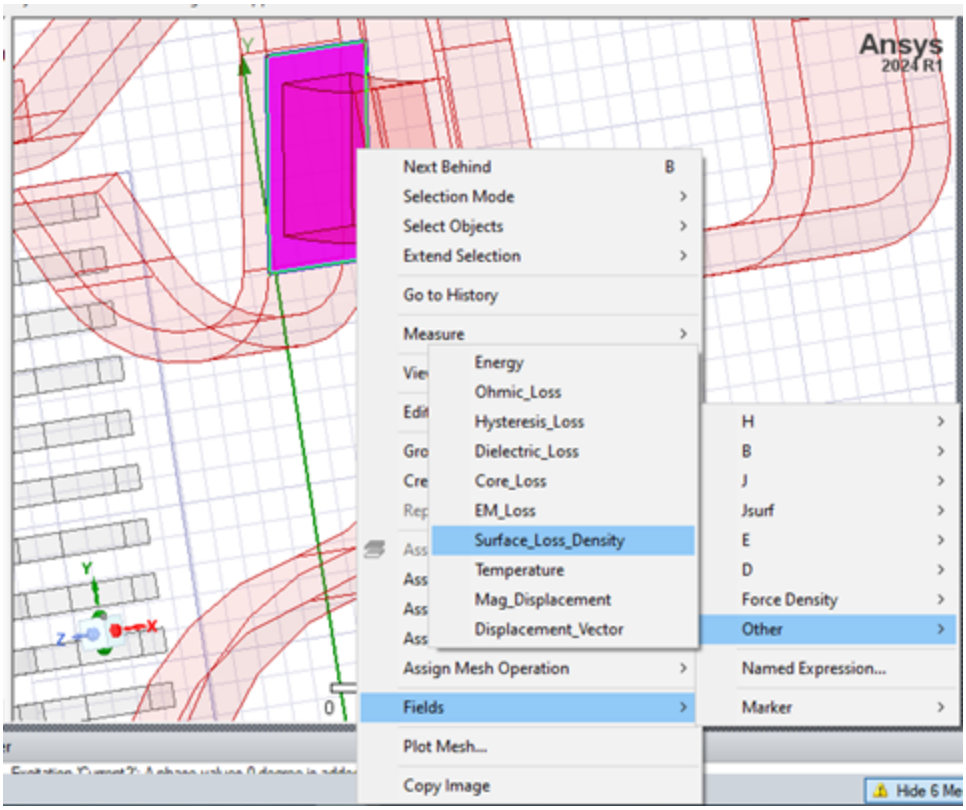
7. Click **OK** to assign the boundary to the selected object.

   The Project Manager lists the newly assigned resistive sheet boundary in the tree. You can select the boundary in the tree to view and edit its properties in the Properties Window. You can also double-click the boundary entry in the tree to open it for editing in the **Resistive Sheet** dialog box.

> **Note:** When switching the solution type between transient and eddy current, resistive sheet boundaries will be kept.

The losses incurred due to a Resistive Sheet boundary are output as **Surface Loss Density**. These losses are counted as losses in solid conductors and are reported together with the losses in other solid conductors under Solid Loss. If the Surface Loss Density is mapped to **Mechanical**, it should be assigned to a face as Heat Flux. The Surface Loss Density plot is accessed from **Fields** > **Other**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Magnetostatic Excitations

The following excitations of magnetic fields are available for magnetostatic problems:

Excitation	Type of Excitation
Voltage	The DC voltage on a surface or a sheet object.
Voltage Drop	The voltage drop across a sheet object.
Current Density	The known current density distribution in a conductor. In this case, the current density terminal must also be defined.
Current	The total current in a conductor.
Winding With Current	Current for both a stranded and solid conductor.
Winding With Resistance Voltage Drop	Resistance Voltage Drop for both a stranded and solid conductor.

In addition, permanent magnets serve as sources of magnetic fields.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Warning: If voltage sources are used as excitations, for current to flow, you must define a minimum of two voltage excitations or a voltage drop per conduction path. Each excitation must be set to a different voltage. Current flows from surfaces at higher voltages to surfaces at lower voltages.

Note: When a source conductor touches an outer boundary, Maxwell assumes current will flow perpendicular to the boundary. If you do not want current to cross the outer boundary, an insulating boundary should be used.

Assigning a Voltage Excitation for a Magnetostatic Solver

This type of excitation sets the voltage on a surface to a specific value. Use it to set up a voltage drop across a conduction path to cause current to flow.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell** > **Excitations** > **Assign** > **Voltage**.
   The **Voltage Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter a value for the voltage in the **Value** box, and select the units from the drop-down menu.
5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

Warning: For current to flow, you must define a minimum of two voltage excitations or a voltage drop. Each excitation must be set to a different voltage. Current flows from surfaces at higher voltages to surfaces at lower voltages.

Assigning a Voltage Drop Excitation for a Magnetostatic Solver

This type of excitation sets the voltage drop across a sheet object to a specific value. The voltage drop applies only to sheet objects:

To set a voltage drop:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell** > **Excitations** > **Assign** > **Voltage Drop**.
   The **Voltage Drop Excitation** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the voltage drop on the surface in the **Value** box, and select the units from the drop-down menu.
5. To change the direction of the voltage drop, click **Swap Direction**.
6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Current Density Excitation for a Magnetostatic Solver

This command specifies the x-, y-, and z-components of the current density in a conduction path. If the current density is a function of position, the value is entered in ampere/m^2, even if you change the units in the problem.

To define the current density:

1. Select the section of the geometry (*i.e.*, the conductor) on which you want to apply the excitation (typically a 3D object).
2. Click **Maxwell 3D** > **Excitations** > **Assign** > **Current Density**.
   The **Current Density Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter the **X Component**, **Y Component**, and **Z Component** values to define the respective components of the current density vector.
   b. Do the following in the two **Coordinate System** drop-down menus:
      - From the first drop-down menu, select either **Global** or **RelativeCSx** (where x = 1,2,3… if any relative coordinate systems have been defined).
      - From the second drop-down menu, select **Cartesian**, **Cylindrical**, or **Spherical**.
5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

To complete the current density definition, you also need to specify any related current density terminals, which must be assigned to a 2D object or face of the respective conduction path.

To define a current density terminal:

1. Select the 2D object or face to which to assign the terminal.
2. Click **Maxwell** > **Excitations** > **Assign** > **Current Density Terminal**.
   The **Current Density Terminal Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Click **OK** to assign the excitation to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning a Current Excitation for a Magnetostatic Solver

Specifies the total current in a conduction path. The conduction path may be contained completely within the problem region (for example, a coil), or may touch the edges of the problem region.

To set a current excitation:

1. Select the section of the geometry (i.e., the conductor) on which you want to apply the excitation (typically a face or other 2D planar object).
2. Click **Maxwell 3D** > **Excitations** > **Assign** > **Current**.
   The **Current Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter a value for the current in the **Value** box, and select the units from the drop-down menu.
   b. Select **Solid** or **Stranded** as the **Type** of conductor. For a stranded conductor, a uniformly distributed current density is assumed.
   c. Click **Swap Direction** to change the direction of the current flow.
5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Winding Setup for a Magnetostatic Solver

> **Note:**
>
> - If you wish to define a winding for an Eddy Current solution type, refer to Assigning a Winding Setup for an Eddy Current Solver.
> - If you wish to define a winding for a Transient solution type, refer to Assigning a Winding Setup for a Transient Solver.

You can use the predefined coil terminal(s) to define one or more current or voltage windings.

To define a winding for your model:

1. Click **Maxwell 3D** > **Excitations** > **Add Winding**. to open the **Winding** dialog box.
2. Enter a name for the winding in the **Name** box, or accept the default.
3. In the **Parameters** section:
   a. Select **Current**, or **Resistance Voltage Drop** from the **Type** drop-down menu.
   b. Select the **Solid** or **Stranded** radio button to specify the type of conductor.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. Enter values in the following fields (enabled according to winding type), and select the desired units.

For a current winding	For a resistance voltage drop winding[1]
Current	Resistance
	Voltage

> **Note:** You can also type a function as an expression for any of these fields.

d. Enter a value in the **Number of parallel branches** text box.

> **Note:** Parallel branches for solid windings assume there are no circulating currents in the parallel branches.

4. Optionally, click **Use Defaults** to revert to the default values in the window.
5. Click **OK** to assign the excitation to the selected object.

A winding is now defined for your model.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: To add a coil terminal to this winding, do the following:

1. In the project tree, right-click the winding, and select **Add Terminals**.
   The **Add Terminals** dialog box appears, listing all coil terminals that do not already belong to that winding.
2. Select the coil terminal (s) you want to add. To select multiple terminals, press **Ctrl** and click each terminal.
3. Click **OK**.

To assign a coil terminal excitation and add it to this winding, do the following:

1. Select the section of the geometry on which you want to apply the coil terminal excitation.
2. In the project tree, right-click the winding, and select **Assign Coil Terminal**.
   The **Coil Terminal Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box.

   Note: This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.

5. Click **Swap Direction** to change the reference direction for the coil terminal. You can also change this direction in the coil terminal's Properties window by selecting either **Point into terminal**, or **Point out of terminal** for the **Direction** parameter.
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the coil terminal excitation. The coil terminal excitation is assigned and is added to the winding.

To delete all coil terminal excitations that belong to this winding, do the following:

- In the project tree, right-click the winding, and select **Delete All Terminals**.
  All coil terminal excitations are removed from the winding and deleted from the excitations.

---

1. For a solid winding, the resistance term can represent: the resistance of a portion of the winding, which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source resistance. (The main winding resistance is calculated directly by the solver.) For a stranded winding, the resistance term is the complete DC resistance of the winding (since the solver does not determine resistance of a stranded winding) as well as the resistance of the end-effects, leads, source, etc. For both solid and stranded windings, the inductance term can represent: the extra inductance for a portion of the winding of the winding, which is not modeled (for instance, end-effects),

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the leads connecting the winding to the source, or the source inductance. (The main winding inductance itself is calculated directly by the solver.)

Assigning a Coil Terminal for a Magnetostatic Solver

To assign a coil terminal as a magnetostatic excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D planar object).
2. Click **Maxwell** > **Excitations** > **Assign** > **Coil Terminal**. (You can also right-click an existing winding in the project tree, and select **Assign Coil Terminal**.)
   The **Coil Terminal Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil terminal in the **Number of Conductors** box.

   > **Note:** This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.

5. If you want to switch the direction for the coil terminal, click **Swap Direction**.

   > **Note:** The direction is shown in the model by a bold red arrow.

6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the coil terminal to the selected object.

> **Note:**
>
> To add this coil terminal to an existing winding:
>
> 1. In the project tree, right-click the coil terminal, and select **Add to Winding**.
>   The **Add to Winding** dialog box appears.
> 2. Select the winding to which you want to add the coil terminal, and click **OK**.

> **Note:** To remove a coil terminal from an existing winding: In the project tree, right-click the coil terminal, and select **Remove from Winding**.
> The terminal is removed from the winding and moved up one level in the project tree (directly beneath **Excitations**).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Electrostatic Boundaries and Excitations

Specify at least one of the following excitations as a source of electric fields:

- The charge on a surface or object.
- The volume charge density inside an object.
- The voltage difference between conducting surfaces and objects. Define the electric potential on each surface and object using a voltage excitation.

Include at least one of the following as a reference for computing the electric potential:

- A voltage excitation.
- An odd symmetry (flux normal) boundary.

> **Note:** If a conductor is not assigned any excitation, it is automatically assigned a floating excitation with zero charge.

Electrostatic Boundaries

The following boundary conditions are available for 3D electrostatic problems:

Boundary Type	E-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — The normal component of **D** changes by the amount of surface charge density. No special conditions are imposed. • Neumann boundaries — **E** is tangential to the boundary. Flux cannot cross a Neumann boundary.	Ordinary E-field behavior on boundaries. Object interfaces are initially set to natural boundaries; outer boundaries are initially set to Neumann boundaries.
Symmetry	Field behaves as follows: • Even Symmetry (Flux Tangential) — **E** is tangential to the boundary; its normal components are zero. • Odd Symmetry (Flux Normal) — **E** is normal to the boundary; its tangential components are zero.	Planes of geometric and electrical symmetry.
Matching	The E-field on the dependent	Planes of symmetry in periodic

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(Independent and Dependent)	boundary is forced to match the magnitude and direction (or the negative of the direction) of the E-field on the independent boundary.	structures where **E** is oblique to the boundary.
Insulating	E-fields can be discontinuous across the insulating boundary.	Thin layer with two input values: **relative permittivity** and **thickness** of the thin layer.

Default Boundary Conditions for an Electrostatic Solver

These boundary conditions are automatically defined for an electrostatic model:

- Natural boundaries are assigned to the surfaces between dielectrics.
- Neumann boundaries are assigned to the outside edges of the problem region.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically revert to the default boundary conditions.

Assigning a Symmetry Boundary Condition for an Electrostatic Solver

This boundary condition defines a plane of geometric or electric symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Symmetry**.
   The **Symmetry Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Normal)	**E** is normal to the boundary; its tangential components are zero.
Even (Flux Tangential)	**E** is tangential to the boundary; its normal components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the boundary to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning an Independent Boundary for an Electrostatic Solver

Independent and dependent boundaries enable you to model planes of periodicity where the E-field at every point on the dependent boundary surface is forced to match the E-field of every corresponding point on the independent boundary surface. The transformation used to map the E-field from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the face to which you want to assign the independent boundary.
2. Click **Maxwell** > **Boundaries** > **Assign** > **Matching** > **Independent**.
   The **Independent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Coordinate System** section, do the following to define the coordinate system:

   > **Note:** You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** drop-down menu.
      The **Create Line** message appears, asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Independent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.
   c. Select a point on the u-axis.
      The **Independent Boundary** dialog box reappears
5. To reverse the direction of the vector, select the **Reverse Direction** check box.
6. Click **OK**.

The Maxwell solver computes the H-field on this boundary and maps it to the dependent boundary using the transformation defined by the independent and dependent coordinate systems.

Assigning a Dependent Boundary for an Electrostatic Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the Independent boundary is mapped to the dependent boundary.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** You must define an Independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Matching** > **Dependent**.
   The **Dependent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** drop-down menu.
5. To specify the coordinate system, do the following in the Coordinate System section:

   > **Note:** You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** drop-down menu.
      The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Dependent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

        > **Note:** The U vector's origin must be on the boundary's surface.

   c. Select a point on the u-axis in the same way.
      When the second point is identified, the vector is set, and the **Dependent Boundary** window reappears, with **Defined** listed in the **U Vector** drop-down menu.
   d. To specify the direction of the V vector, select or clear the **Reverse Direction** check box.
6. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

   Edep = Click this radio button if the dependent

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Eind	and independent boundaries have the same magnitude and direction.
Edep = -Eind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. Click **OK** to assign the boundary to the selected object.

> **Note:** The origin must be a vertex point of one of the objects.

Assigning an Insulating Boundary for an Electrostatic Solver

To set an insulating boundary:

1. Select the geometry face on which you want to apply the insulating boundary condition.
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Insulating**.

The **Insulating Boundary** dialog box appears.

3. On the **Insulating Boundary** tab, enter a name for the boundary in the **Name** box, or accept the default.
4. The **Parameters** section of the **Insulating Boundary** tab allows you to set the relative permittivity and thickness of the insulating boundary. Values can be defined using variables and also support Optimetrics.
   a. Enter the desired value for **Relative Permittivity**, or accept the default value of 1.
   b. Enter the desired value for **Thickness**, or accept the default value of 0.

   Note that changing data values will invalidate the solutions.
5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the boundary to the selected object.

Electrostatic Excitations

The following excitations are available for electrostatic problems:

Excitation	Type of Excitation
Voltage	The DC voltage on a surface or object. This excitation type is available for both electrostatic and DC conduction Electric solvers.
Charge	The total charge on a surface or object (dielectric). This excitation type is available for electrostatic solvers only.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Floating	Used to model conductors at unknown potentials. This excitation type is available for electrostatic solvers only.
Volume Charge Density	The volume charge density in an object. This excitation type is available for electrostatic solvers only.

> **Note:** If a conductor is not assigned any excitation, it is automatically assigned a floating excitation with zero charge.

Assigning a Voltage Excitation for an Electrostatic Solver

Voltage excitations are identical to voltage boundaries in previous versions of Maxwell. Maxwell no longer has voltage boundaries in the electric solvers. Instead, a voltage excitation can be assigned to any surfaces, 2D objects, or solids. These assignments could include spatial functions. This type of excitation sets the electric potential (voltage) on a surface to a specific value.

> **Note:** When calculating capacitance, a voltage source should be assigned to an entire object, not just a single face located on that object.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell** > **Excitations** > **Assign** > **Voltage**.
   The **Voltage Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the electric potential in the **Value** box, and select the units from the drop-down menu. You can enter a numerical value or a spatial function.
5. For a spatial function, select a coordinate system from the **Coordinate System** drop-down menu.
6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Charge Excitation for an Electrostatic Solver

This type of excitation defines the total charge on a surface or object. The potential on the charge is computed during the solution.

To define a charge excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell** > **Excitations** > **Assign** > **Charge**.
   The **Charge Excitation** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the charge in the **Value** box.
5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Floating Excitation for an Electrostatic Solver

This type of excitation models conductors at unknown potentials and specifies the total charge on the conductor.

To define a floating conductor:

1. Select the section of the geometry on which you want to apply the excitation. This can be a 2D surface or a 3D solid.
2. Click **Maxwell** > **Excitations** > **Assign** > **Floating**.
   The **Floating Excitation** window appears.
3. Click the **General** tab.
4. Enter a name for the excitation in the **Name** box, or accept the default.
5. In the **Parameters** section, enter the charge on the boundary in the **Value** box.
6. Optionally, click **Use Defaults** to revert to the default values in the window. You can also click the **Defaults** tab to save new default settings or to revert to the standard default values.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Volume Charge Density Excitation for an Electrostatic Solver

This type of excitation defines the volume charge density on an object.

To define the charge density on a 3D object:

1. Select the 3D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell** > **Excitations** > **Assign** > **Volume Charge Density**.
   The **Volume Charge Density Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the charge density in the **Value** box.
5. In the **Parameters** section, select the type of coordinate system from the **Coordinate System** drop-down menu.
6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the excitation to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3D AC Conduction Boundaries and Excitations

The following boundaries can be specified for this solver:

- Symmetry
- (Matching) Independent/Dependent
- Thin Layer
- Insulating

The following excitations can be specified for this solver:

- Voltage
- Current
- Sink

Include at least one of the following as a reference for computing the electric potential:

- A voltage excitation (with a potential difference)
- An odd symmetry (flux normal) boundary
- A sink excitation

3D AC Conduction Boundaries

The following boundary conditions are available for 3D AC conduction electric problems:

Boundary Type	E-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries - The normal and tangent components of **J** and **E** are continuous across discontinuity surfaces. • Neumann boundaries - **E** and **J** vectors are tangential to the boundary. Flux cannot cross a Neumann boundary.	Object interfaces are initially set to natural boundaries; outer boundaries are initially set to Neumann boundaries.
Symmetry	Field behaves as follows: • Even Symmetry (Flux Tangential) - **E and J vectors are** tangential to the boundary; its normal components are zero. • Odd Symmetry (Flux Normal) - **E and J vectors are** normal to the boundary; its tangential components are zero.	Planes of geometric and electrical symmetry.
Matching	The E-field on the dependent boundary is forced to	Planes of symmetry

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(Independent and Dependent)	match the magnitude of the E-field on the independent boundary if the plus sign is used. If the minus sign is used, the field on the dependent boundary will oscillate with opposite phase angle (180 degrees phase shift).	in periodic structures where **E** is oblique to the boundary.
Insulating	The current cannot cross the boundary.	Thin, perfectly insulating sheets between touching conductive domains.
Thin Layer	When two parts of the domain are separated by thin volume, it can be modeled by a Thin Layer. This boundary creates a field discontinuity (voltage drop) between the two sides of the selected surface based on the material bulk properties and thickness.	Thin and non-perfect (possibly lossy) domains.

Default Boundary Conditions for a 3D AC Conduction Solver

These boundary conditions are automatically defined for a AC conduction model:

- Natural boundaries are assigned to the surfaces between objects. The normal component of **J** and the tangential component of **E** are continuous across discontinuity surfaces.
- Neumann boundaries are assigned to the outside edges of the problem region. **E** and **J** vectors are tangential to the boundary. Flux cannot cross a Neumann boundary.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically revert to the default boundary conditions.

Assigning a Symmetry Boundary Condition for a 3D AC Conduction Solver

This boundary condition defines a plane of geometric or electric symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Symmetry**.

   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

   Odd Voltages have opposite sign on the two sides of the symmetry

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(Flux Normal)	plane.
Even (Flux Tangential)	Voltages have same sign on the two sides of the symmetry plane.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning an Independent Boundary for a 3D AC Conduction Solver

Independent and dependent boundaries enable you to model planes of periodicity where the **E**-field at every point on the dependent boundary surface is forced to match the **E**-field of every corresponding point on the independent boundary surface. The transformation used to map the E-field from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the face to which you want to assign the independent boundary.
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Matching** > **Independent**.

   The **Independent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Coordinate System** section, do the following to define the coordinate system:

   > **Note:** You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the V-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** drop-down menu.
   The **Create Line** message appears, asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Independent Boundary** dialog box disappears while you draw the U vector.

   b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:

      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

   c. Select a point on the U-axis.

      The **Independent Boundary** dialog box reappears

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. To reverse the direction of the vector, select the **Reverse Direction** check box.
6. Click **OK**.

The Maxwell solver computes the E-field on this boundary and maps it to the dependent boundary.

Assigning a Dependent Boundary for a 3D AC Conduction Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the Independent boundary is mapped to the dependent boundary.

> **Note:** You must define an Independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Matching** > **Dependent**.

   The **Dependent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** drop-down menu.
5. To specify the coordinate system, do the following in the Coordinate System section:

   > **Note:** You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** drop-down menu.
   The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Dependent Boundary** dialog box disappears while you draw the U vector.

   b. Select the U vector's origin in one of the following ways:

   > **Note:** The U vector's origin must be on the boundary's surface.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Click the point.
- Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

c. Select a point on the u-axis in the same way.
When the second point is identified, the vector is set, and the **Dependent Boundary** window reappears, with **Defined** listed in the **U Vector** drop-down menu.

d. To specify the direction of the V vector, select or clear the **Reverse Direction** check box.

6. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Edep = Eind	Click this radio button if the dependent and independent boundaries have the same magnitude and direction.
Edep = -Eind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. Click **OK** to assign the boundary to the selected object.

Note: The origin must be a vertex point of one of the objects.

Assigning an Insulating Boundary for the 3D AC Conduction Solver

This boundary condition is generally used to model very thin sheets of perfectly insulating material between touching conductors, as well as infinitely thin cracks inside conductors. Current cannot cross an insulating boundary, that is, $n \cdot J = 0$.

To set an insulating boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Insulating**.

   The **Insulating Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** If you apply the insulating boundary condition on sheet objects (inside conductors), always make sure that the respective entities are selected as faces and not as objects before attempting to assign the insulating boundary condition to them.

Assigning a Thin Layer Boundary for a 3D AC Conduction Solver

When two parts of the domain are separated by a thin volume, it can be modeled using a **Thin Layer** boundary condition. This boundary creates a field discontinuity (voltage drop) across the two sides of the surface based on the material bulk parameters and thickness.

This boundary condition can be used to model thin domains, for example: the contact resistance between two conductive domains, the capacitive effect of thin insulating materials or thin lossy domains in electronic boards without needing to explicitly model (and mesh) a 3D object having a finite thickness.

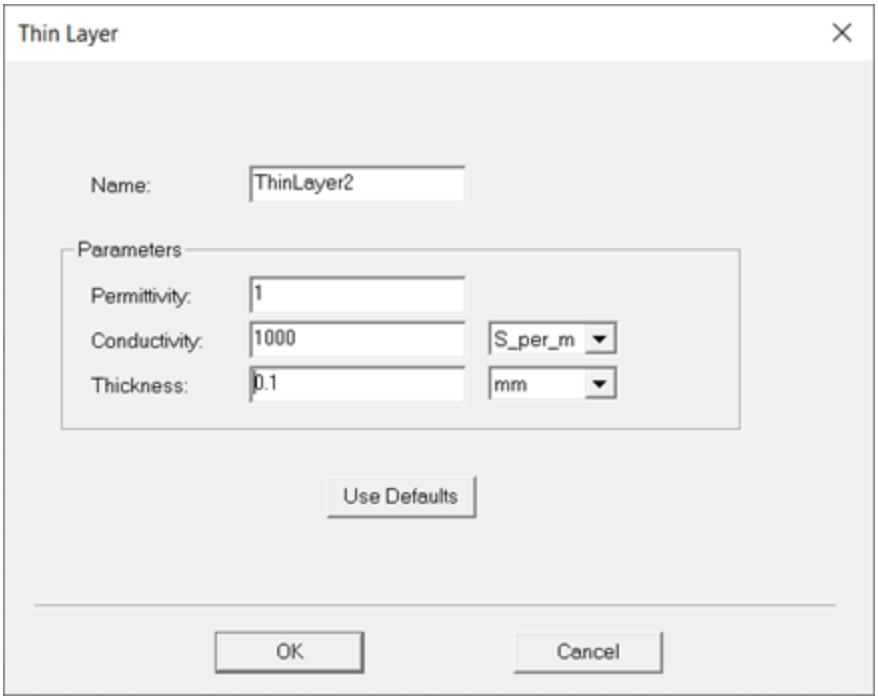
> **Note:** The thin layer can be only applied to a coincident surface shared by two different bodies. It cannot be applied to a 2D cross-sectional sheet inside of a single body.

For the 3D AC conduction solver, the thin layer is defined by its bulk conductivity, permittivity, and thickness.

To define a resistive sheet boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a sheet object or face of a 3D body).
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Thin Layer** to open the Thin Layer dialog box.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter the thin layer parameters in the **Conductivity**, **Permittivity**, and **Thickness** fields, and select the units of measure. Use of variables is supported.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. Optionally, click **Use Defaults** to revert to the default values in the window.

   The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **General** tab as the defaults to be assigned to new boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.

6. Click **OK** to assign the boundary to the selected object.

The Project Manager lists the newly assigned thin layer boundary in the tree. You can select the boundary in the tree to view and edit its properties in the Properties Window. You can also double-click the boundary entry in the tree to open it for editing in the thin layer dialog box.

3D AC Conduction Excitations

The following excitations are available for 3D electric AC conduction problems:

Excitation	Type of Excitation
Voltage	The AC voltage on a surface or object.
Current	The current across a surface.
Sink	Applied only to surfaces which are grounded with reference potential value. It is the same as applying zero voltage excitation on those surfaces.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** All field quantities oscillate with the same frequency, equal to the frequency specified in the solution setup. The phase of quantities computed in the solution space however will be different in general.

Assigning a Voltage Excitation for a 3D AC Conduction Solver

This excitation sets the electric potential (voltage) on a surface or object to a specific value.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 3D** > **Excitations** > **Assign** > **Voltage**.
   The **Voltage Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section:
   a. Enter the electric potential in the **Value** box, and select the unit from the drop-down menu. You can enter a numerical value or a spatial function. For a spatial function, select a coordinate system from the **Coordinate System** drop-down menu.
   b. Enter a value in the **Phase** text box, and select a unit from the drop-down menu.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Current Excitation for a 3D AC Conduction Solver

To define a current across a surface:

1. Select the 2D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 3D** > **Excitations** > **Assign** > **Current**.
   The **Current Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section:
   a. Enter the current strength in the **Value** box, and select the unit from the drop-down menu.
   b. Enter the phase angle in the **Phase** box, and select the unit from the drop-down menu.
   c. Select either **Solid** or **Stranded** to define the **Type** for the conductor. For a stranded conductor, a uniformly distributed current density is assumed without considering eddy effects.
   d. Optionally, to change the direction of the current flow, click **Ref. Direction**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Sink Excitation for a 3D AC Conduction Solver

To define a sink excitation on a surface:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell 3D** > **Excitations** > **Assign** > **Sink**.
   The **Sink Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Click **OK** to assign the excitation to the selected object.

DC Conduction Boundaries and Excitations

The following excitations can be specified as the source of electric fields:

- The voltage difference between surfaces and objects. Define the electric potential on each surface and object using a voltage excitation.
- Using the current excitation, define the total current flowing through a surface or a 2D object.
- Using the sink excitation, define a collection of surfaces or 2D objects as a sink. Sink excitations are applied when only current excitations are defined in a conduction path and there is no voltage excitation. In fact, in this case, a sink excitation has to be defined and it ensures that the total current flowing through the outside surface of a conduction path is exactly zero.

Include at least one of the following as a reference for computing the electric potential:

- A voltage excitation.
- A sink excitation.
- An odd symmetry (flux normal) boundary.

DC Conduction Boundaries

The following boundary conditions are available for DC conduction electric problems:

Boundary Type	E-Field Behavior	Used to model...
Default Boundary Conditions (Natural and	Field behaves as follows: • Natural boundaries — The normal component of **D** changes by the amount of surface charge density. No special	Ordinary E-field behavior on boundaries. Object interfaces are initially set to natural boundaries; outer

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Neumann)	conditions are imposed. • Neumann boundaries — **E** is tangential to the boundary. Flux cannot cross a Neumann boundary.	boundaries are initially set to Neumann boundaries.
Insulating	Same as Neumann, except that current cannot cross the boundary. An insulating boundary is *only* available for electrostatic solutions that include a DC conduction analysis.	Thin, perfectly insulating sheets between touching conductors.
Symmetry	Field behaves as follows: • Even Symmetry (Flux Tangential) — **E** is tangential to the boundary; its normal components are zero. • Odd Symmetry (Flux Normal) — **E** is normal to the boundary; its tangential components are zero.	Planes of geometric and electrical symmetry.
Matching (Independent and Dependent)	The E-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the E-field on the independent boundary.	Planes of symmetry in periodic structures where **E** is oblique to the boundary.
Thin Layer	When two parts of the domain are separated by a thin volume, it can be modeled by a Thin Layer. This boundary creates a field discontinuity (voltage drop) between the two sides of the selected surface based on the material bulk properties and thickness.	Thin conducting domains

Default Boundary Conditions for a DC Conduction Solver

These boundary conditions are automatically defined for a DC conduction model:

- Natural boundaries are assigned to the surfaces between objects.
- Neumann boundaries are assigned to the outside edges of the problem region.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically revert to the default boundary conditions.

Assigning an Insulating Boundary for a DC Conduction Solver

This boundary condition is used to model very thin sheets of perfectly insulating material between touching conductors. Current cannot cross an insulating boundary.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

An insulating boundary is *only* available for electrostatic solutions that include a DC conduction analysis.

To set an insulating boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Insulating**.
   The **Insulating Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning a Symmetry Boundary Condition for a DC Conduction Solver

This boundary condition defines a plane of geometric or electric symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Symmetry**.
   The **Symmetry Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Normal)	Current flows in opposite directions on either side of the symmetry plane.
Even (Flux Tangential)	Current flows in the same direction on both sides of the symmetry plane.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the boundary to the selected object.

Warning: When using even symmetry boundaries, double-check the following two points:

- Do not violate Ampere's law!
- All magnetic field boundaries must be connected to each other. Defining disconnected magnetic field boundaries and even symmetry boundaries can produce unexpected results, as there is no unique solution to such problems.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning a Independent Boundary for a DC Conduction Solver

Independent and dependent boundaries enable you to model planes of periodicity where the H-field at every point on the dependent boundary surface is forced to match the H-field of every corresponding point on the independent boundary surface. The transformation used to map the H-field from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the face to which you want to assign the independent boundary.
2. Click **Maxwell** > **Boundaries** > **Assign** > **Matching** > **Independent**.
   The **Independent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Coordinate System** section, do the following to define the coordinate system:

   > **Note:** You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the V-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** drop-down menu.
      The **Create Line** message appears, asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Independent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.
   c. Select a point on the u-axis.
      The **Independent Boundary** dialog box reappears
5. To reverse the direction of the vector, select the **Reverse Direction** check box.
6. Click **OK**.

The Maxwell solver computes the E-field on this boundary and maps it to the dependent boundary using the transformation defined by the independent and dependent coordinate systems.

Assigning a Dependent Boundary for a DC Conduction Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the Independent boundary is mapped to the dependent boundary.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** You must define a Independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Matching** > **Dependent**.
   The **Dependent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** drop-down menu.
5. To specify the coordinate system, do the following in the Coordinate System section:

   > **Note:** You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** drop-down menu.
      The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Dependent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin in one of the following ways:

      > **Note:** The U vector's origin must be on the boundary's surface.

      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.
   c. Select a point on the u-axis in the same way.
      When the second point is identified, the vector is set, and the **Dependent Boundary** window reappears, with **Defined** listed in the **U Vector** drop-down menu.
   d. To specify the direction of the V vector, select or clear the **Reverse Direction** check box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** When entering current, current density terminals, or coil terminals, the arrow associated with current in the selected object shows the direction as if a positive value is entered for the current. If a negative value is entered the actual current flow direction is opposite to what the arrow shows. Click **Reverse Direction** if you want to reverse the direction of the arrow.

6. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Edep = Eind	Click this radio button if the dependent and independent boundaries have the same magnitude and direction.
Edep = -Eind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. Click **OK** to assign the boundary to the selected object.

> **Note:** The origin must be a vertex point of one of the objects.

Assigning a Thin Layer Boundary for a 3D DC Conduction Solver

When two parts of the domain are separated by a thin volume, it can be modeled using a **Thin Layer** boundary condition. This boundary creates a field discontinuity (voltage drop) across the two sides of the surface based on the material bulk parameters and thickness.

This boundary condition can be used to model thin domains, for example, the contact resistance between two conductive domains without needing to explicitly model (and mesh) a 3D object having a finite thickness.

> **Note:** The thin layer can be only applied to a coincident surface shared by two different bodies. It cannot be applied to a 2D cross-sectional sheet inside of a single body.

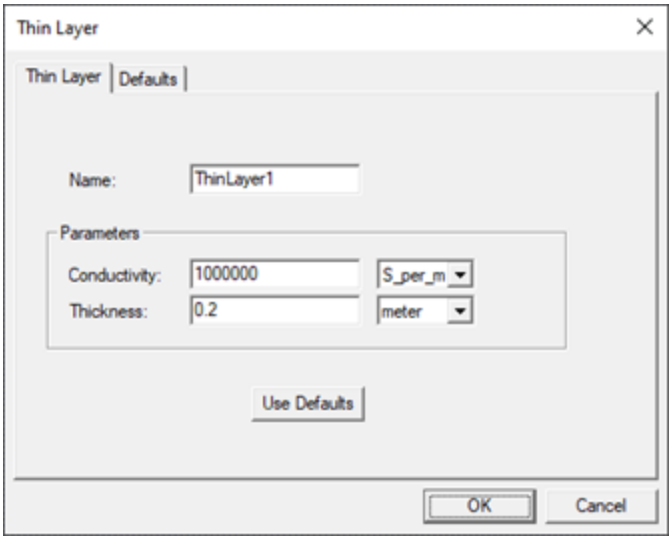
For the 3D DC conduction solver, the thin layer is defined by its bulk conductivity, and thickness.

To define a thin layer boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a sheet object or face of a 3D body).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Thin Layer** to open the Thin Layer dialog box.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter the thin layer parameters in the **Conductivity** and **Thickness** fields, and select the units of measure. Use of variables is supported.



5. Optionally, click **Use Defaults** to revert to the default values in the window.

   The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **Thin Layer** tab as the defaults to be assigned to new boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.

6. Click **OK** to assign the boundary to the selected object.

The Project Manager tree lists the newly assigned thin layer boundary in the tree. You can select the boundary in the tree to view and edit its properties in the Properties Window. You can also double-click the boundary entry in the tree to open it for editing in the thin layer dialog box.

DC Conduction Excitations

The following excitations are available for electric DC conduction problems:

Excitation	Type of Excitation
Voltage	The DC voltage on a surface or object. This excitation type is available for both electrostatic and DC conduction solvers.
Current	The current across a 2D object. This excitation type is available for DC conduction solvers only. A current excitation must be applied across a 2D

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	surface.
Sink	This excitation type is available for DC conduction solvers only.

For a DC conduction solution, if a current excitation is assigned, at least one sink or voltage excitation must also be defined. However, you cannot define both a voltage excitation and a sink excitation at the same time.

Assigning a Voltage Excitation for a DC Conduction Solver

This type of excitation sets the electric potential (voltage) on a surface or object to a specific value.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell** > **Excitations** > **Assign** > **Voltage**.
   The **Voltage Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the electric potential in the **Value** box, and select the units from the drop-down menu. You can enter a numerical value or a spatial function.
5. For a spatial function, select a coordinate system from the **Coordinate System** drop-down menu.
6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Current Excitation for a DC Conduction Solver

To define a current across a surface:

1. Select the 2D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 3D** > **Excitations** > **Assign** > **Current**.
   The **Current Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the current strength in the **Value** box.
5. Optionally, to change the direction of the current flow, click **Swap Direction**.
6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Sink Excitation for a DC Conduction Solver

To define a sink excitation on a surface:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell** > **Excitations** > **Assign** > **Sink**.
   The **Sink Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Click **OK** to assign the excitation to the selected object.

DC Conduction + Electrostatic Boundaries and Excitations

In the case of a problem when you are interested in the electric solution in both the conductors and the insulators, you can define a **DC Conduction + Electrostatic** solution type. The Insulator/Conductor threshold defines which objects are conductors or insulators. The solver first solves the conduction problem in all conduction paths and then, using the calculated voltage on the conductors as a voltage excitation, computes the electrostatic field in the insulators. As a consequence, you can define the DC-conduction excitations and boundary conditions in the conducting regions and the electrostatic excitations and boundary conditions in the insulators.

Eddy Current T-Omega Boundaries and Excitations

Specify at least one of the following as a source of AC magnetic fields in your model:

- The current in a conduction path, which can be either stranded or solid.

  > **Note:** For stranded conductors, it is assumed that the current density is uniform on the cross-section of the respective conductors. Thus, the stranded option for current excitations should mostly be used only in cases where the cross-section of conductors is constant, consistent with the assumption that the respective object is a coil built with strands of wire. For this reason, conductors (coils) could be created by either sweeping around an axis using zero segments or sweeping along a path having only true surface segments in order to create a smooth surface coil having a completely uniform cross-sectional area over its entire length.

- The current density in a conductor.
- The magnetic field on an outside surface.

If currents or current densities are the only sources of AC magnetic fields in your model, set at least one outer boundary to the following:

- The default boundary conditions.
- An odd symmetry (flux tangential) boundary.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- An even symmetry (flux normal) boundary.

Eddy Current T-Omega Boundaries

The Eddy Current T-Omega field solver allows you to define the following types of boundaries:

Boundary Type	H-Field Behavior	Used to model…
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries – **H** is continuous across the boundary. • Neumann boundaries – **H** is tangential to the boundary and flux cannot cross it.	Ordinary field behavior. Initially, object interfaces are natural boundaries; outer boundaries and excluded objects are Neumann boundaries.
Zero Tangential H Field	Flux is perpendicular if tangent components are zero or if a zero tangential H-field boundary condition was applied.	External AC magnetic fields.
Tangential H Field	The tangential components of **H** are set to predefined values.	External AC magnetic fields
Integrated Zero Tangential H Field	For applications such as a motor with the shaft excluded, there remains a hole in the middle. In such cases, on the hole's boundary, neither the Tangential H Field boundary (where integration of the tangential H field is non-zero), nor the Zero Tangential H Field boundary (where the tangential H field is zero everywhere) can be applied because – for the hole boundary case – integration of the tangential H field is zero, but the tangential H field is not zero everywhere. Integrated Zero Tangential H Field can be used for such applications.	Cases such as the boundary around the hole left when a motor's shaft is excluded.
Insulating	Same as Neumann, except that current cannot cross the boundary.	Perfectly insulating sheets between conductors.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) – **H** is tangential to the boundary; its normal components are zero.	Planes of geometric and magnetic symmetry.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Boundary Type	H-Field Behavior	Used to model…
	• Even Symmetry (Flux Normal) – **H** is normal to the boundary; its tangential components are zero.	
Matching (Independent and Dependent)	The H-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the H-field on the independent boundary.	Planes of symmetry in periodic structures where **H** is oblique to the boundary.
Radiation	No restrictions on the field behavior.	Unbounded eddy currents.
Impedance	Includes the effect of induced currents beyond the boundary surface.	Conductors with very small skin depths.
Resistive Sheet	When two conductors are in contact within a conduction path, a voltage drop normally exists across the contact surface due to the imperfection of the contact between the two conductors. This boundary condition assigns a resistive sheet to consider the impact of this kind of voltage drop. The resistive sheet is defined by a lumped resistance in ohms.	Voltage drop and loss on the contact surface between two different objects within a conduction path.
Thin Layer	This boundary creates a field discontinuity between the two sides of the selected surface based on its thickness and the given electric and magnetic material proprieties. When the air gap option is selected, the conductivity is assumed to be zero and the relative magnetic permeability is assumed to be equal to one.	Thin conductors and ferromagnets, and narrow air gaps

Default Boundary Conditions

F or the Eddy Current T-Omega solver, these boundary conditions are automatically defined for an eddy current model:

- Natural boundaries are assigned to the surfaces between objects.
- Neumann boundaries are assigned to the outside edges of the problem region.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning a Magnetic H Field

This type of boundary defines external magnetic fields in a model. Assign it only to the outer surfaces of the problem region. Regardless of the model's drawing units, magnetic field values are entered in s/m.

> **Warning:** When using tangential magnetic field boundary conditions, always double-check that Ampere's law is not violated!

To define a zero tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Zero Tangential H Field**.
   The **Zero Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

To define a tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition.
2. Click **Maxwell** > **Boundaries** > **Assign** > **Tangential H Field**.
   The **Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the value of the field component in the x-direction in the **U(X)** box and the value of the field component in the y-direction in the **V(Y)** box.
5. In the **Coordinate System** section, do the following define the vectors:
   a. Select **New Vector** from the **U Vector** drop-down menu.
      The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face.
   b. Click two points to specify the vector.
      The vector is set, and the **Tangential H Field** window reappears, with **Defined** listed for **U Vector**.
   c. To reverse the direction of the vector, click the **Reverse Direction** check box.
6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the Project Manager tree.

Assigning an Integrated Zero Tangential H Field Boundary

This type of boundary is applied when the integral of the tangential H field is zero.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Warning: When using integrated zero tangential magnetic field boundary conditions, always double-check that Ampere's law is not violated!

To define an integrated zero tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Integrated Zero Tangential H Field**. The **Integrated Zero Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the project tree.

Assigning an Insulating Boundary

This boundary condition is generally used to model very thin sheets of perfectly insulating material between touching conductors, as well as infinitely thin cracks inside conductors. Current cannot cross an insulating boundary.

To set an insulating boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Insulating**. The **Insulating Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Note: An insulating boundary condition can be used to control the flow of induced eddy currents inside conductors that contain sheet objects with an applied insulating boundary condition. In case you apply the insulating boundary condition on sheet objects (inside conductors), always make sure that the respective entities are selected as faces and not as objects before attempting to assign the insulating boundary condition to them.

Assigning a Symmetry Boundary

This boundary condition defines a plane of geometric or magnetic symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Symmetry**.
   The **Symmetry Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Tangential)	H is tangential to the boundary; its normal components are zero.
Even (Flux Normal)	H is normal to the boundary; its tangential components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the boundary to the selected object.

> **Warning:** When using even symmetry boundaries, always double-check that Ampere's law is not violated!

Assigning an Independent Boundary

Independent and dependent boundaries enable you to model planes of periodicity where the H-field at every point on the dependent boundary surface is forced to match the H-field of every corresponding point on the independent boundary surface. The transformation used to map the H-field from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the face to which you want to assign the independent boundary.
2. Click **Maxwell** > **Boundaries** > **Assign** > **Matching** > **Independent**.
   The **Independent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Coordinate System** section, do the following to define the coordinate system:

   > **Note:** You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** drop-down menu.
      The **Create Line** message appears, asking you to draw the U vector of the

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

coordinate system in the plane of the selected face, and the **Independent Boundary** dialog box disappears while you draw the U vector.

b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

c. Select a point on the u-axis.
   The **Independent Boundary** dialog box reappears.

5. To reverse the direction of the vector, select the **Reverse Direction** check box.
6. Click **OK**.

The Maxwell solver computes the H-field on this boundary and maps it to the dependent boundary using the transformation defined by the independent and dependent coordinate systems.

Assigning a Dependent Boundary

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

> **Note:** You must define a independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Matching** > **Dependent**.
   The **Dependent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** drop-down menu.
5. To specify the coordinate system, do the following in the Coordinate System section:

   > **Note:** You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** drop-down menu.
      The **Create Line** message appears asking you to draw the U vector of the

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

coordinate system in the plane of the selected face, and the **Dependent Boundary** dialog box disappears while you draw the U vector.

b. Select the U vector's origin in one of the following ways:

> **Note:** The U vector's origin must be on the boundary's surface.

- Click the point.
- Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

c. Select a point on the u-axis in the same way.
When the second point is identified, the vector is set, and the **Dependent Boundary** window reappears, with **Defined** listed in the **U Vector** drop-down menu.

d. To specify the direction of the V vector, select or clear the **Reverse Direction** check box.

> **Note:** When entering current, current density terminals, or coil terminals, the arrow associated with current in the selected object shows the direction as if a positive value is entered for the current. If a negative value is entered the actual current flow direction is opposite to what the arrow shows. Click **Reverse Direction** if you want to reverse the direction of the arrow.

6. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Hdep = Hind	Click this radio button if the dependent and independent boundaries have the same magnitude and direction.
Hdep = -Hind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. Click **OK** to assign the boundary to the selected object.

> **Note:** The origin must be a vertex point of one of the objects.

Assigning a Radiation Boundary

To simulate problems that allow fields to radiate infinitely far into space, you can define surfaces to be radiation boundaries. The system absorbs the field at the radiation boundary, essentially

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ballooning the boundary infinitely far away from the structure. In a far field region, field components are expressed by

$$E = -Zn \times H$$

where

$$Z = \sqrt{\frac{\mu}{\varepsilon}}$$

and *Z* is the component of the E-field that is tangential to the surface.

Using the field impedance, the equation becomes

$$n \times E = -Zn \times (n \times H)$$

which is used as a radiation boundary. The radiation boundary condition should be placed far enough from the source of radiation so that the approximation of the far field in the region of the boundary holds.

The second-order radiation boundary condition is an approximation of free space. The accuracy of the approximation depends on the distance between the boundary and the object from which the radiation emanates.

A radiation surface does not have to be spherical. However, it should be exposed to the background, convex with regard to the radiation source, and located at least one-quarter of a wavelength away from the radiating sources. In some cases you may want to use smaller distances.

To assign a radiation boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Radiation**.
   The **Radiation Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Optionally, click **Use Defaults** to revert to the default values in the window.
5. Click **OK** to assign the boundary to the selected object.

Assigning an Impedance Boundary

> **Note:** To define an impedance boundary for the transient solver, refer to Assigning an Impedance Boundary for the Transient Solver.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This boundary condition is used to simulate the effect of induced currents in a conductor without explicitly computing them. The conductor must be excluded from the model (saving time needed to mesh and solve for currents), so assign the impedance boundary condition to an outside edge of the problem region or to an excluded object.

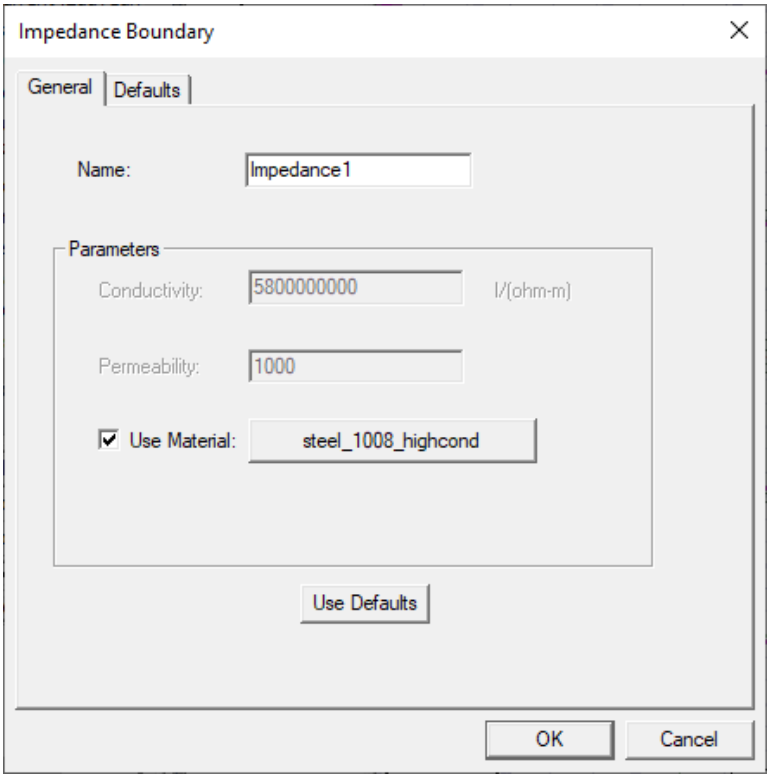
To define an impedance boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Impedance** to open the **Impedance Boundary** dialog box.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Do one of the following:

    - If the **Use Material** check box is unchecked, enter the conductivity (in inverse ohm-meters) in the **Conductivity** field, and the conductor's relative permeability in the **Permeability** field.

    - If you wish to select a material from the library, check the **Use Material** check box, then use the button to select the desired material.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



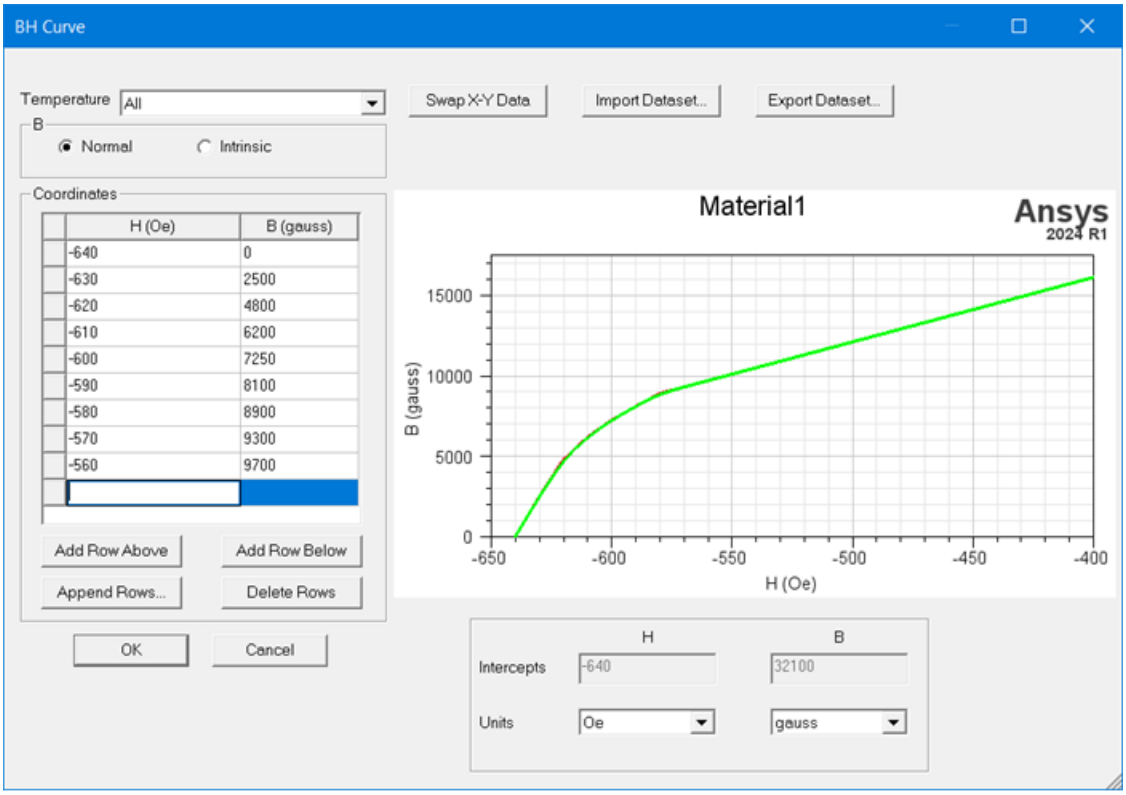
- **Nonlinear Permeability**

  If you select a material that has nonlinear permeability, the nonlinear coefficient is computed automatically.

  The nonlinear relative permeability of the material is determined by the B-H curve. If the desired B-H curve of the permeability belongs to an existing material, you can directly use that existing material.

  Otherwise, you can edit a new material with the desired B-H curve.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Refer to Relative Permeability for a Maxwell or RMxprt Material for details on using nonlinear relative permeability.

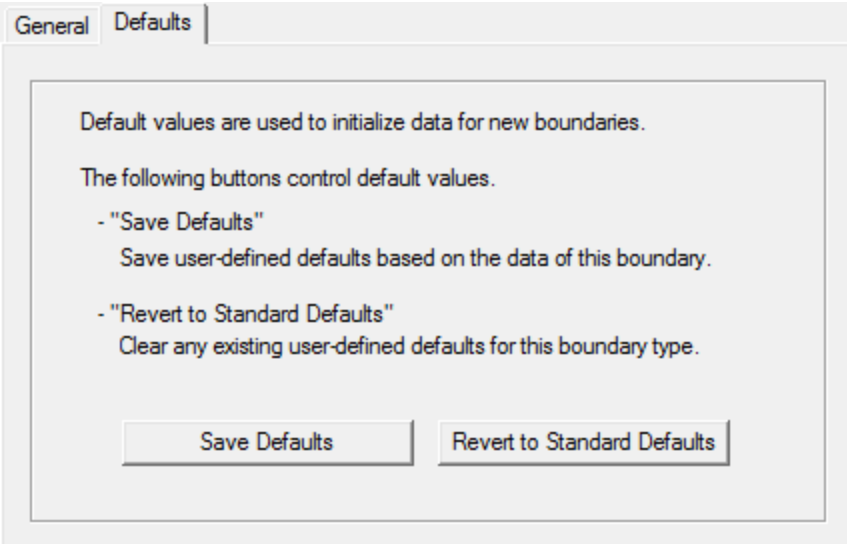
- **Temperature-Dependent Impedance Boundary**

  The electrical conductivity and permeability of a material used for an impedance boundary condition can be temperature dependent. The Maxwell 3D eddy solver provides an option to allow you to input functions as thermal modifiers to consider the effect of temperature on those properties. To enable this feature, check the **Use Material** check box as above. You can then click **Material** to open the material properties panel in which you can add a thermal modifier. (Refer to Setting the Temperature of Objects for additional information on using temperature-dependent impedance boundaries).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Optionally, click **Use Defaults** to revert to the default values in the window.

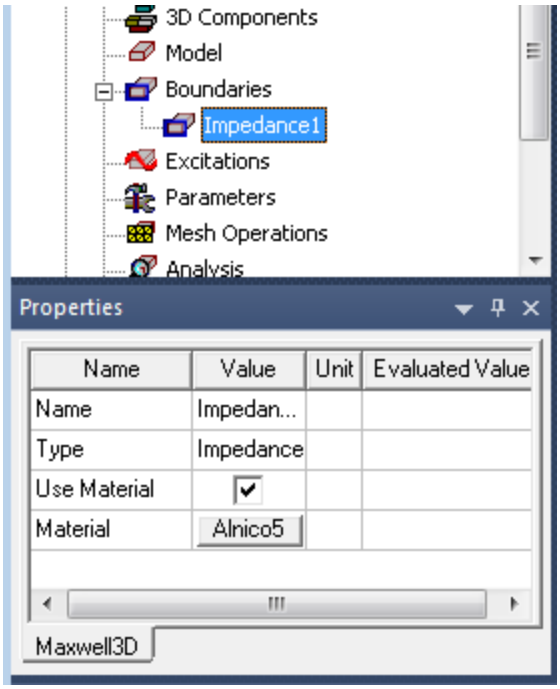
The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **General** tab as the defaults to be assigned to new impedance boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.



6. Click **OK** to assign the boundary to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Project Manager lists the newly assigned impedance boundary in the tree. You can select the boundary in the tree to view and edit its properties in the Properties Window. You can also double-click the boundary entry in the tree to open it for editing in the Impedance Boundary dialog box.



Impedance Boundary

Impedance boundaries allow you to simulate the effect of induced currents in a conductor without explicitly computing them. Use this boundary condition for models where:

- The skin depth in the conductor is less than two orders of magnitude smaller than the dimensions of the structure. In models like this, the mesher may not be able to create a fine enough mesh in the conductor to compute eddy currents.
- The magnetic field decays much more rapidly inside the conductor in the direction that's normal to the surface than it does in directions that are tangential to the surface.
- The AC current source is relatively far away from the surface where eddy currents occur, compared to the size of the skin depth.

The conductor itself must be excluded from the solution region. When setting up the model, do one of the following:

- For external boundaries, when drawing the model, make the surface along which eddy currents are to be computed an outer surface of the problem region.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For internal impedance boundaries, assign perfect conductor to the object in the Material Manager or uncheck **Solve Inside** to exclude the object from the solution domain.

Then, when defining boundaries, assign an impedance boundary to the individual surfaces of the problem region (for external boundaries) or to the entire object (for internal boundaries). By entering the conductivity, s, and the relative permeability, mr, of the object, you specify the skin depth of induced eddy currents. The simulator uses this skin depth value when computing the electromagnetic field solution. It assumes that the H-field falls off exponentially inside the conductor. The ohmic loss due to induced currents can then be computed from the tangential components of the H-field along the impedance boundary — the surface of the object that you are interested in.

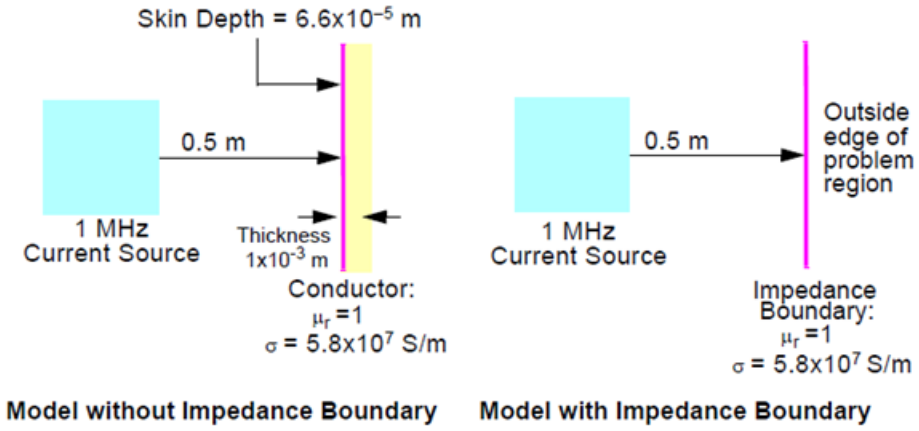
> **Note:** An impedance boundary only approximates the effect of eddy currents acting at a shallow skin depth. It does not directly compute them. In general, the fields modeled using an impedance boundary will closely match the field patterns that would actually occur in the structure. However, at discontinuities in the surface (such as corners), the field patterns may be different.

> **Note:** For the current version of the Maxwell solver, when a project includes all three of the following at the same time: an impedance boundary condition, a material with anisotropic permeability, and a winding, the project cannot be solved by the Maxwell eddy current solver and the Maxwell 3D transient solver.

When to Use Impedance Boundaries

A typical situation where impedance boundaries can be used to reduce the complexity of a model is shown below. Suppose you want to compute eddy current losses in the conductor next to the current source shown below on the left. If the source carries AC current at a frequency of 1 MHz, the skin depth in the conductor is 6.6 x 10–5 meters. This is several orders of magnitude smaller than the conductor’s thickness. Because the conductor where currents are induced is also relatively far away from the current source, an impedance boundary can be used to model the induced currents — as shown on the right.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Model without Impedance Boundary **Model with Impedance Boundary**

The conductor itself must be excluded from the model. Instead, the outside boundary of the model is moved to the inside surface of the conductor. This outside surface is defined as an impedance boundary, using the conductivity and permeability specified previously. Since the simulator does not have to actually compute a solution inside the conductor, the field solution is computed more quickly and uses less memory. After solving, you can compute the ohmic loss for the surface using the solution calculator and plot the loss density on the boundary.

Assigning a Resistive Sheet Boundary

> **Note:**
>
> This topic describes assigning a resistive sheet boundary for the 3D Eddy Current T-Omega solver. For Transient designs refer to Assigning a Resistive Sheet Boundary for the Transient Solver.
> For 3D Magnetostatic designs refer to Assigning a Resistive Sheet Boundary for the 3D Magnetostatic Solver.

When two conductors are in contact within a conduction path, a voltage drop normally exists across the contact surface due to the imperfection of the contact between the two conductors. This boundary condition assigns a resistive sheet to consider the impact of this kind of voltage drop. The resistive sheet is defined by a lumped resistance in ohms.

The following are usages of the resistive sheet boundary:

- **Typical usage**: Modeling contact resistance by applying Resistive Sheet boundary to a contacting surface (face) of two conductive objects.
- **Other possible usages**: Resistive Sheet boundary can be applied to any sheet object inside a conductive object or on a conductive object surface in order to increase the total

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

resistance of the conducting path and to introduce localized loss density to the place of the sheet location.

This boundary can also be used to model terminal contact resistance (for stranded or solid conductors). For example, by applying it to the conductor cross section touching the region. In this case the Excitation Terminal and Resistive Sheet boundary are not allowed to be on the same sheet object.

The losses incurred due to a Resistive Sheet boundary are output as Surface Loss Density. These losses are counted as losses in solid conductors and are reported together with the losses in other solid conductors under Solid Loss. If the Surface Loss Density is mapped to Mechanical, it should be assigned to a face as Heat Flux.

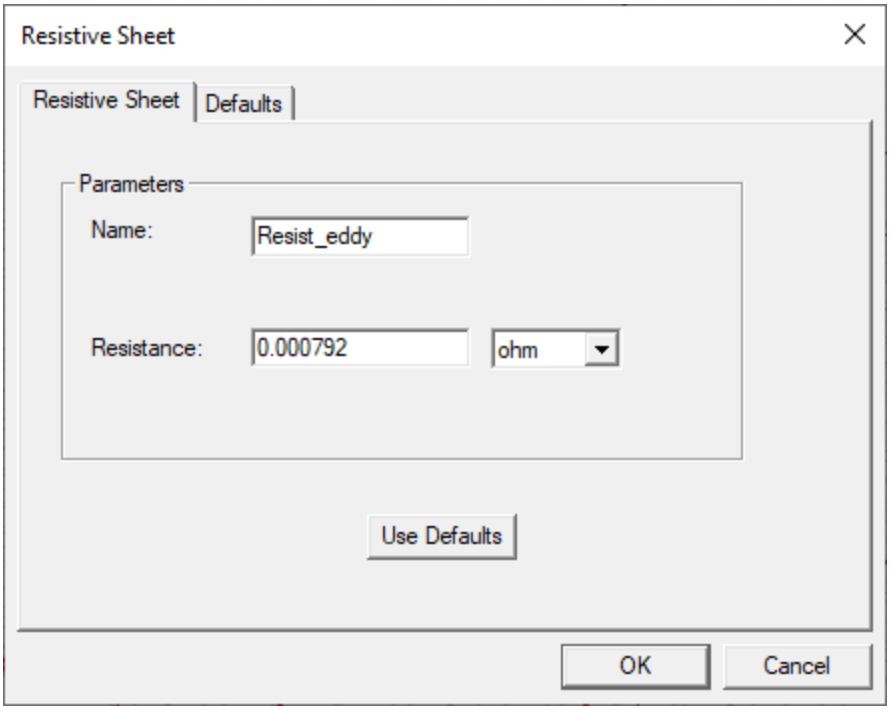
To define a resistive sheet boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a sheet object or face of a 3D conducting body touching another conducting body or face of a 3D conducting body touching the region).

   Note:
   - The sheet must be completely inside a conductor or on its surface.
   - The sheet must have conductors touching both of its faces.
   - The resistance value cannot be dependent on intrinsic variable.

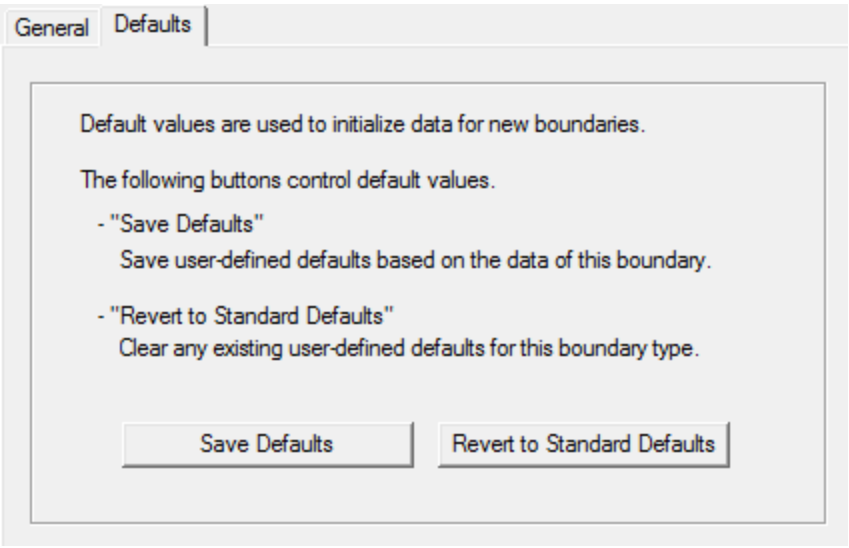
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Resistive Sheet** to open the **Resistive Sheet** dialog box.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter the resistance value in the **Resistance** field, and select a unit of measure. Use of variables is supported.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. Optionally, click **Use Defaults** to revert to the default value (1 ohm) in the window.

   The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **General** tab as the defaults to be assigned to new impedance boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. Click **OK** to assign the boundary to the selected object.

   The Project Manager tree lists the newly assigned resistive sheet boundary in the tree. You can select the boundary in the tree to view and edit its properties in the Properties window. You can also double-click the boundary entry in the tree to open it for editing in the **Resistive Sheet** dialog box.

> **Note:** When switching the solution type between transient and eddy current, resistive sheet boundaries will be kept.

Assigning a Thin Layer Boundary

This boundary creates a field discontinuity between the two sides of the selected surface based on its thickness and the given electric and magnetic material proprieties. This allows representing eddy currents flowing inside the thin layer. When the air gap option is selected, the conductivity is assumed to be zero and the relative magnetic permeability is assumed to be equal to one. The thin layer is defined purely in terms of its thickness in this case.

This boundary condition can be used to model thin conductors and ferromagnets such as shields and narrow air gaps, as those in power transformers, inductors, or any other electric devices without needing to explicitly model (and mesh) the thin structure.

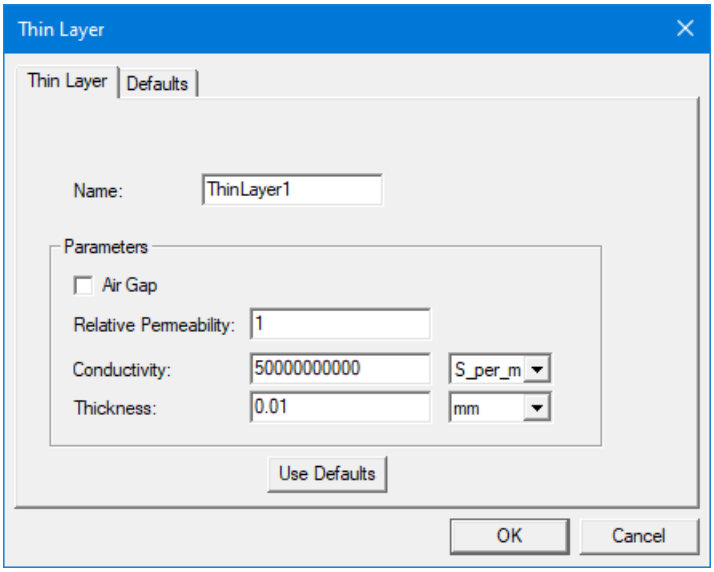
> **Note:**
> - The thin layer cannot be a closed shell encompassing a conductor.
> - The thin does not support a mechanical movement, *i.e.*, the boundary condition cannot be applied to the interface of moving and stationary bodies.
> - The thin layer cannot be defined on a conductor boundary or as a sheet object that touches or crosses any conducting body. In such cases, the Maxwell solver displays an error message indicating the name of the conducting body that the thin layer is touching.

To define a thin layer boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a sheet object or face of a 3D body).
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Thin Layer** to open the **Thin Layer** dialog box.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. If air gap is being modeled, check the **Air Gap** checkbox. The **Conductivity** and **Relative Permeability** fields will be grayed out (non-editable); the **Conductivity** of the thin layer will automatically be set to zero, and the **Relative Permeability** set to one.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Enter the **Thickness** of the air gap and the unit of measure. It must be a value greater than zero. The use of variables is supported.
6. If the **Air Gap** checkbox is unchecked, the thin layer can represent a thin conductor or ferromagnet. In this case, enter the material **Conductivity** with unit, and the **Relative Permeability** in the respective fields.



7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **Thin Layer** tab as the defaults to be assigned to new impedance boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.
9. Click **OK** to assign the boundary to the selected object.

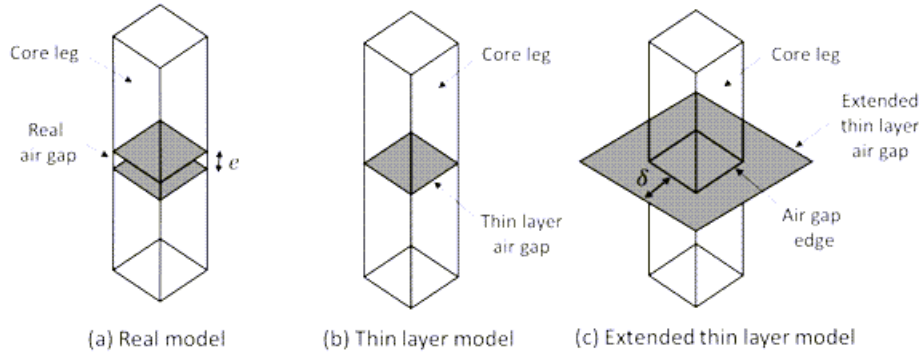
The Project Manager tree lists the newly assigned thin layer boundary in the tree. You can select the boundary in the tree to view and edit its properties in the Properties window. You can also double-click the boundary entry in the tree to open it for editing in the Thin Layer dialog box.

Getting Better Convergence with the Thin Layer Model

For an eddy current simulation, the thin layer model for air gaps requires the duplication of the scalar potential to create a field discontinuity beyond the dimension of the sheet object and correctly represent the fringing flux effects. The Maxwell solver automatically duplicates the potential in one layer of elements from the gap edges. However, during the mesh adaptive process, the lateral elements may become too small and thus too close to the gap sides. This results in a low convergence of the mesh adaptive steps as the magnetic energy on such elements becomes more important. To improve convergence, the user can extend the sheet

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

object manually (see figure below). Better convergence is observed by raising its lateral sides from one to three times the air gap thickness (δ≅3e) depending on the model geometry.



Eddy Current T-Omega Excitations

For the Eddy Current T-Omega solver, the sources of AC magnetic fields listed below are available. Excitations are assumed to be peak quantities (not RMS).

Excitation	Type of Excitation
Current Density	The current density in a conductor. In this case, you must also define the current density terminals for the conductor.
Current Density Terminal	Specifies the cross-section of the conductor where current density is specified, to be used as a terminal object. Current Density and Current Density Terminal are required to be used in conjunction.
Current	The total current in a conductor.
Coil Terminal	Used to define one or more model windings.
Winding With Current	Current for both a stranded and solid conductor.
Winding With Voltage	Voltage for both a stranded and solid conductor.
Winding With External Circuit Connection	External circuit connection for both a stranded and solid conductor.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: When entering current, the arrow associated with current in the selected object shows the direction as if a positive value is entered for the current. If a negative value is entered the actual current flow direction is opposite to what the arrow shows. Click **Reverse Direction** if you want to reverse the direction of the arrow.

Note: When a source conductor touches an outer boundary, Maxwell assumes current will flow perpendicular to the boundary. If you do not want current to cross the outer boundary, an insulating boundary should be used.

Note: The 3D Eddy Current T-Omega solver can be used to get harmonic losses on nonlinear systems and can be an alternative to a transient simulation. See Using the Eddy Current Solver to Generate Harmonic Losses for more details.

Assigning a Current Density Excitation

This command specifies the x-, y-, and z-components of the AC current density in a conduction path. If the current density is a function of position, the value is entered in A/m^2, even if you change the units in the problem.

To define the current density:

1. Select the section of the geometry (*i.e.*, the conductor) in which you want to apply the excitation (typically a 3D object).
2. Click **Maxwell 3D** > **Excitations** > **Assign** > **Current Density**.

   The **Current Density Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter the **X Component**, **Y Component**, and **Z Component** values to define the respective components of the current density vector.
   b. Do the following in the two **Coordinate System** drop-down menus:
      - From the first drop-down menu, select either **Global** or **RelativeCS1** (where x = 1,2,3… if any relative coordinate systems have been defined).
      - From the second drop-down menu, select **Cartesian**, **Cylindrical**, or **Spherical**.
   c. Enter the phase angle, θ, of the current density in the **Phase** field.
5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To complete the current density definition, you also need to specify any related current density terminals, which must be assigned to a 2D object or face of the respective conduction path.

> **Note:** Select the names of the sheet objects to serve as the current density terminals. This object must form an exact cross-section of the current density conduction path. You must create 2D objects which represent locations where current flows into and out of the problem region, or branches at any location in the conduction path. In current loops, any exact 2D cross-section may serve as a terminal.

Assigning a Current Density Terminal Excitation

To define the current density terminal:

1. Select the section of the geometry (*i.e.*, the conductor) in which you want to apply the excitation (typically a 3D object).
2. Click **Maxwell 3D** > **Excitations** > **Assign** > **Current Density Terminal**.
   The **Current Density Terminal Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Click **OK** to assign the excitation to the selected target(s).

Assigning a Current Excitation

Specifies the total AC current in a conduction path. The conduction path may be contained completely within the problem region (for example, a coil), or may touch the edges of the problem region.

To specify the total AC current:

1. Select the 2D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 3D** > **Excitations** > **Assign** > **Current**.
   The **Current Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Enter the current strength in the **Value** box.
5. Enter the phase for the current in the **Phase** box.
6. Select either **Solid** or **Stranded** to define the **Type** for the conductor. For a stranded conductor, a uniformly distributed current density is assumed without considering eddy effects.

   > **Note:** The Solid/Stranded setting is not available for a 3D Eddy Current A-Phi design. The Solid type is always used for this type of design.

7. Optionally, click **Swap Direction** to change the direction of the current flow.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. Optionally, click **Use Defaults** to revert to the default values in the window.
9. Click **OK** to assign the excitation to the selected object.

Assigning a Coil Terminal

To assign a coil terminal as an eddy-current excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D planar object).
2. Click **Maxwell** > **Excitations** > **Assign** > **Coil Terminal**. (You can also right-click an existing winding in the project tree, and select **Assign Coil Terminal**.)

   The **Coil Terminal Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil terminal in the **Number of Conductors** box. For a solid winding, the number should be 1.

   > **Note:** This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.
5. If you want to switch the direction for the coil terminal, click **Swap Direction**.

   > **Note:** The direction is shown in the model by a bold red arrow.
6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the coil terminal to the selected object.

> **Note:**
> To add a coil terminal to an existing winding:
> 1. In the project tree, right-click the coil terminal, and select **Add to Winding**. The **Add to Winding** dialog box appears.
> 2. Select the winding to which you ant to add the coil terminal, and click **OK**.

> **Note:** To remove a coil terminal from an existing winding: In the Project Manager tree, right-click the coil terminal, and select **Remove from Winding**. The terminal is removed from the winding and moved up one level in the Project Manager tree (directly beneath **Excitations**).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning a Winding Setup

> **Note:**
>
> - If you wish to define a winding for a Transient solution type, refer to "Assigning a Winding Setup " on page 10-146
> - If you wish to define a winding for a Magnetostatic solution type, refer to "Assigning a Winding Setup for a Magnetostatic Solver " on page 10-52 .

You can use the predefined coil terminal(s) to define one or more current or voltage windings.

To define a winding for your model:

1. Click **Maxwell** > **Excitations** > **Add Winding** to open the **Winding** dialog box.
2. Enter a name for the winding in the **Name** box, or accept the default.
3. In the **Parameters** section:
   a. Select **Current**, **Voltage**, or **External** from the **Type** drop-down menu. The winding type selected enables only those fields (Initial Current, Resistance, Inductance, Voltage, Phase) applicable for the chosen type.
   b. Select the **Solid** or **Stranded** radio button to specify the type of conductor.
   c. For the 3D Eddy Current T-Omega solver, there is a **Get Databases from FFT** button. This feature allows the user to get frequency domain signals from transient signals, and solve on the frequencies in Eddy Current designs. For more information, see Using an Eddy Current Excitation to Generate Harmonic Losses.
   d. Enter values in the following fields (enabled according to winding type), and select the desired units. You can also type a function as an expression for any of these fields except Initial Current.

For a current winding	For a voltage winding[1]	For an external winding
Current	Resistance	(no settings required)
Phase	Inductance	
	Voltage	
	Phase	

   e. Enter a value in the **Number of parallel branches** text box.

> **Note:** Parallel branches for solid windings assume there are no circulating currents in the parallel branches.

4. Optionally, click **Use Defaults** to revert to the default values in the dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Optionally, on the Defaults tab, click **Save Defaults** to save the current settings or click **Revert to Standard Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

A winding is now defined for your model.

> **Note:** For an external winding, you must also set up an external circuit connection.

> **Note:**
>
> To add a coil terminal to this winding:
>
> 1. In the project tree, right-click the winding, and select **Add Terminals**.
>   The **Add Terminals** dialog box appears, listing all coil terminals that do not already belong to that winding.
> 2. Select the coil terminal(s) you want to add. To select multiple terminals, press **Ctrl** and click each terminal.
> 3. Click **OK**.
>
> To assign a coil terminal excitation and add it to this winding:
>
> 1. Select the section of the geometry on which you want to apply the coil terminal excitation.
> 2. In the project tree, right-click the winding, and select **Assign Coil Terminal**. The **Coil Terminal Excitation** dialog box appears.
> 3. Click **OK** to assign the coil terminal excitation.
>   The coil terminal excitation is assigned and is added to the winding.
>
> To delete all coil terminal excitations that belong to this winding:
>
> - In the project tree, right-click the winding, and select **Delete All Terminals**. All coil terminal excitations are removed from the winding and deleted from the excitations.

---

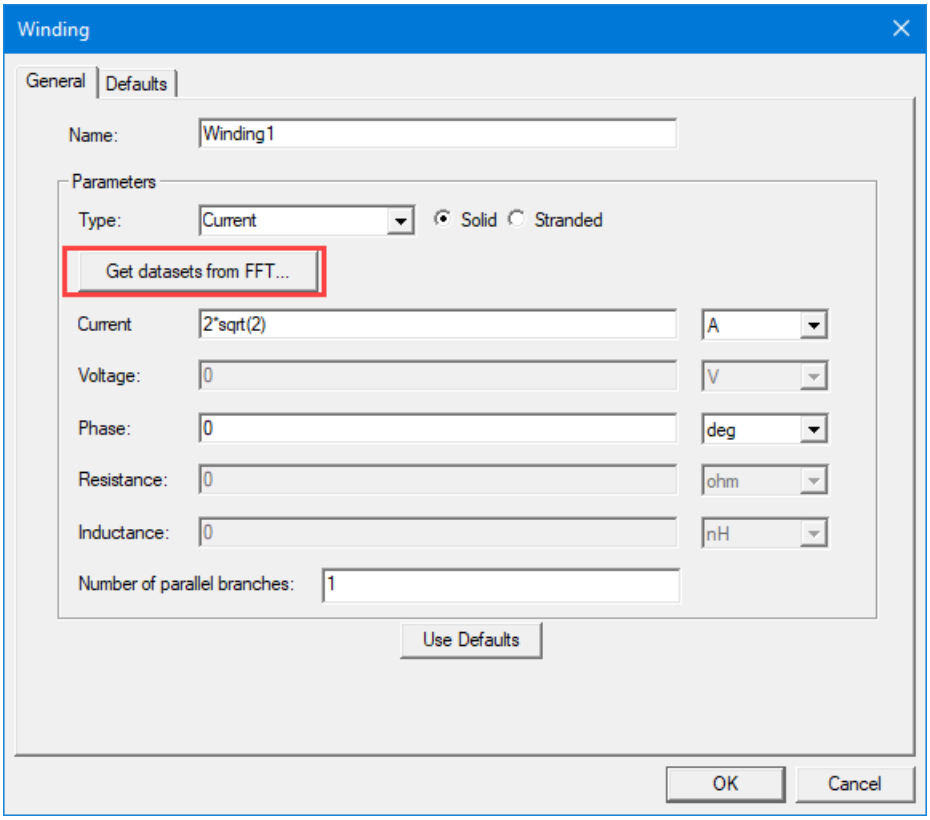
1. For a solid winding, the resistance term can represent: the resistance of a portion of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source resistance. (The main winding resistance is calculated directly by the solver.) For a stranded winding, the resistance term is the complete DC resistance of the winding (since the solver does not determine resistance of a stranded winding) as well as the resistance of the end-effects, leads, source, etc. For both solid and stranded windings, the inductance term can represent: the extra inductance for a portion of the winding of the winding which is not modeled (for instance, end-effects), the leads

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

connecting the winding to the source, or the source inductance. (The main winding inductance itself is calculated directly by the solver.)

Using Eddy Current Excitation to Generate Harmonic Losses

The 2D Eddy Current and 3D Eddy Current T-Omega solvers can be used to get harmonic losses on nonlinear systems and can be an alternative to a transient simulation. The Eddy Current Excitations\Winding and Current windows have a **Get datasets from FFT** option that can be used to reconstruct the signal vs time using a certain amount of harmonics from an FFT plot.



To generate the harmonic losses:

1. For each signal, input the broadband spectrum as datasets of amplitude (A) vs. frequency, phase (ϕ) vs. frequency. While each dataset might have different amplitudes, signals must have the same frequency points.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

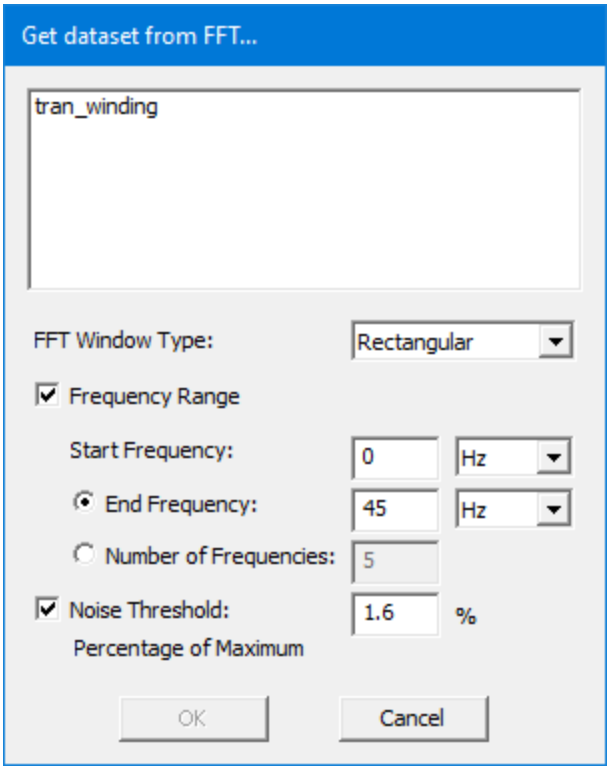
> **Note:** To use transient data as an Eddy Current excitation, you have the following options:
>
> - Get transient data from a third-party simulation (or from a Maxwell transient simulation) and perform FFT outside of Ansys Electronics Desktop to obtain two datasets as Amplitude vs Frequency and Phase vs Frequency. These two can be imported into Ansys Electronic Desktop as datasets and used as arguments within the pwl function of the excitation definition.
> - Get transient data from a third-party simulation (or from a Maxwell transient simulation) and import them as datasets and perform the built-in FFT function within excitation window. This action will automatically generate a pwl function with corresponding arguments.
> - Define new frequency-dependent datasets within the excitation window by manually introducing the corresponding data pairs, Amplitude vs Frequency and Phase vs Frequency and manually defining the pwl function within corresponding excitation field definition.

2. Solve the frequency sweep and get EM losses on the broadband frequencies.
3. Perform IFFT to get the reconstructed transient signals.

To use existing transient signals, they have to be defined in datasets with the format of signal values versus time.

To retrieve the datasets, click the **Get dataset from FFT** button in the Windings or Current excitations window. The following dialog box opens:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



1. Select transient excitation to use as the dataset (**tran_winding** in the example above).
2. Select the FFT window type.
3. Set the **Frequency Range**:
    - Users can input start and end frequency to specify the range or
    - Users can input start frequency and frequency number to specify the range. The Number of Frequencies defines the harmonic content where an upper frequency isn't necessarily the limit of interest. The Number of Frequencies is based on multiples of the fundamental frequency, which is defined by the duration of the transient dataset created by the user during pushback.
4. Set the **Noise Threshold**, which automatically drops harmonics that fall below the defined threshold regardless of the method used to create the list of harmonics.
    - The input is a percentage of maximum magnitude value.
    - Data of (A, f) and (ϕ, f) whose magnitudes are smaller than the value will not be added to frequency-domain datasets.
5. Click **OK**.

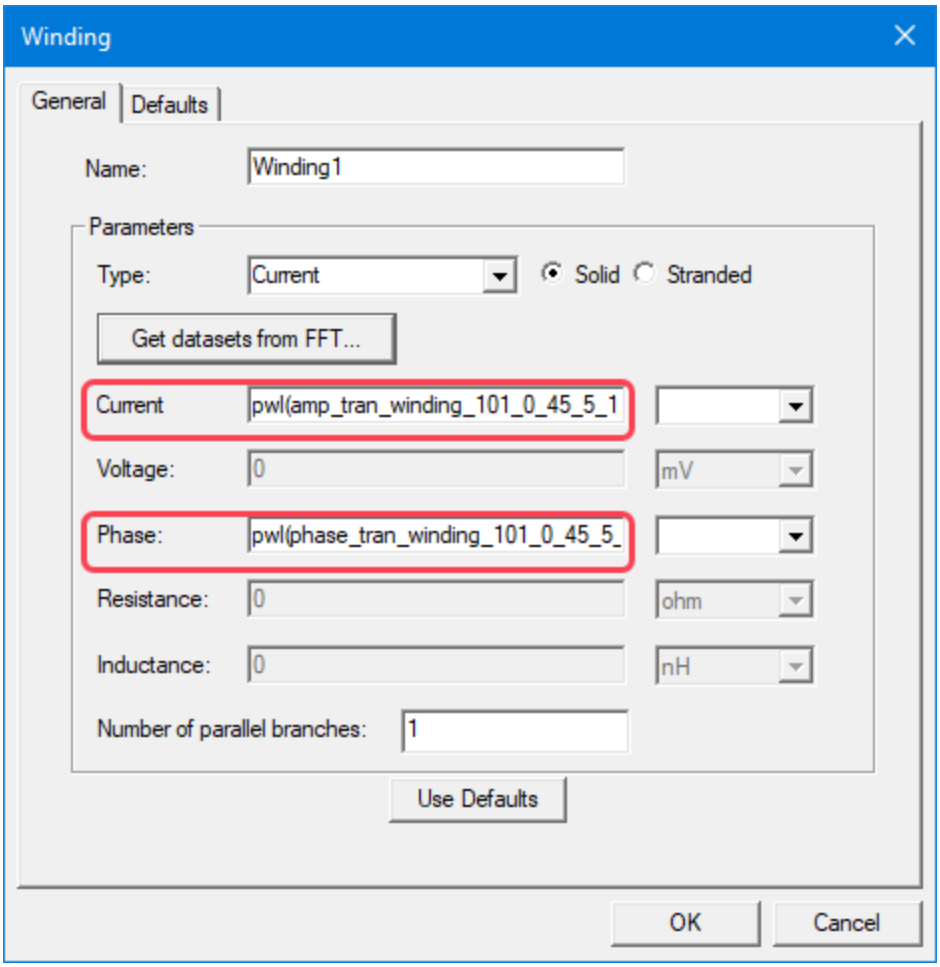
After clicking the **OK** button, the following operations occur:

1. Two datasets (A, f) and (ϕ , f) are generated and included in the list of design datasets (accessed from **Maxwell** > **Design Datasets**). Note that after the datasets are generated,

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

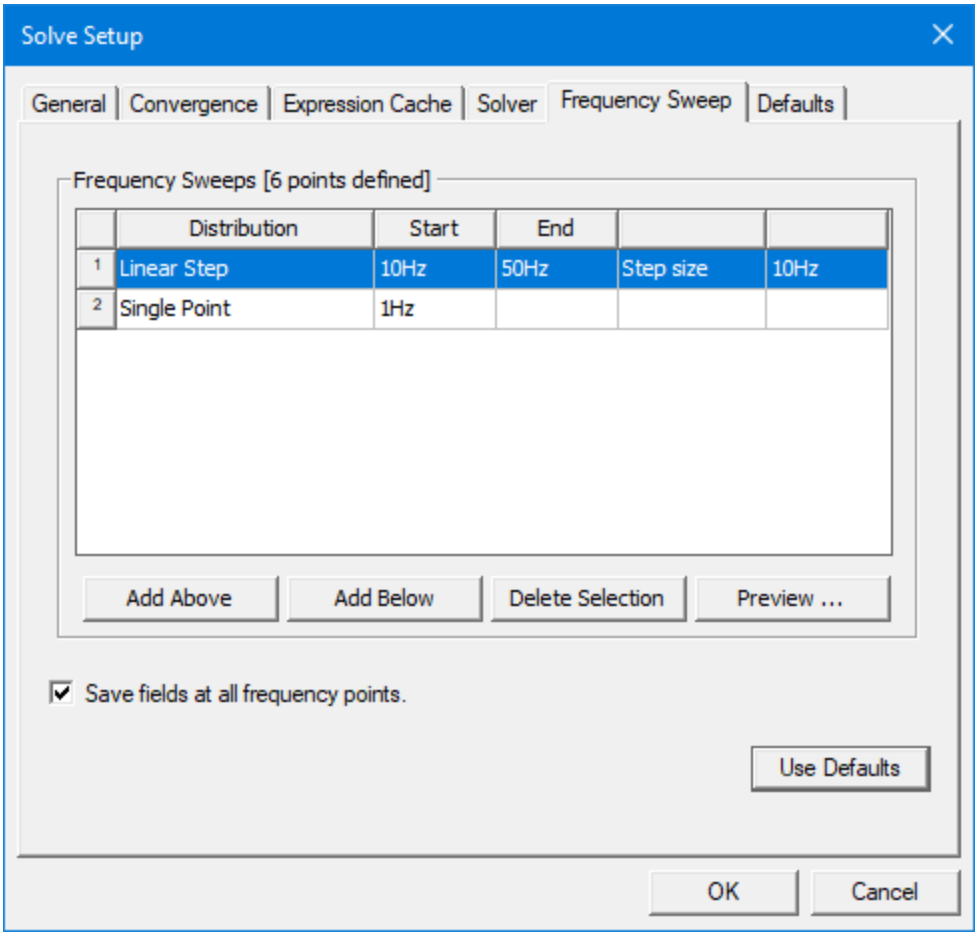
users can modify them.

2. Winding values (current/voltage, phase) will be updated with the PWL of these datasets.



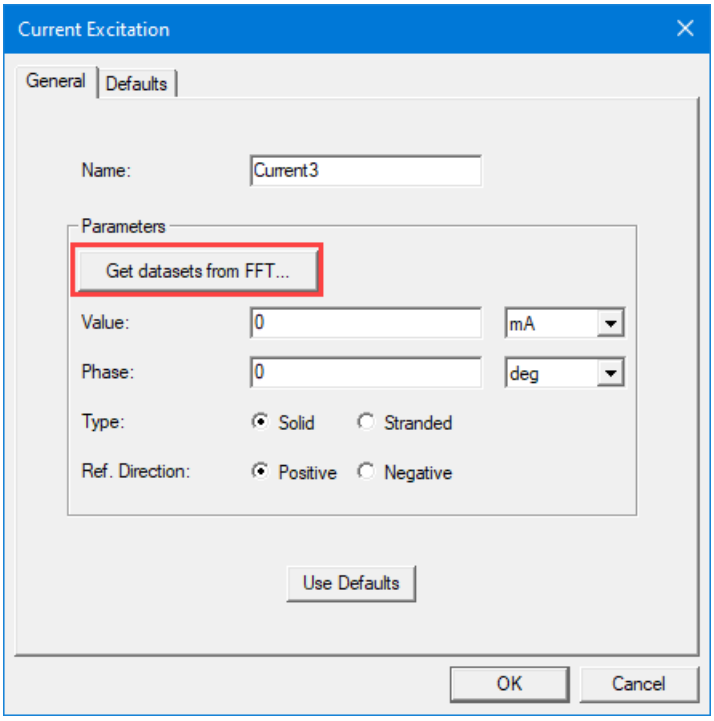
3. Frequencies from the FFT process will be added to **Solve Setup** frequency sweep.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



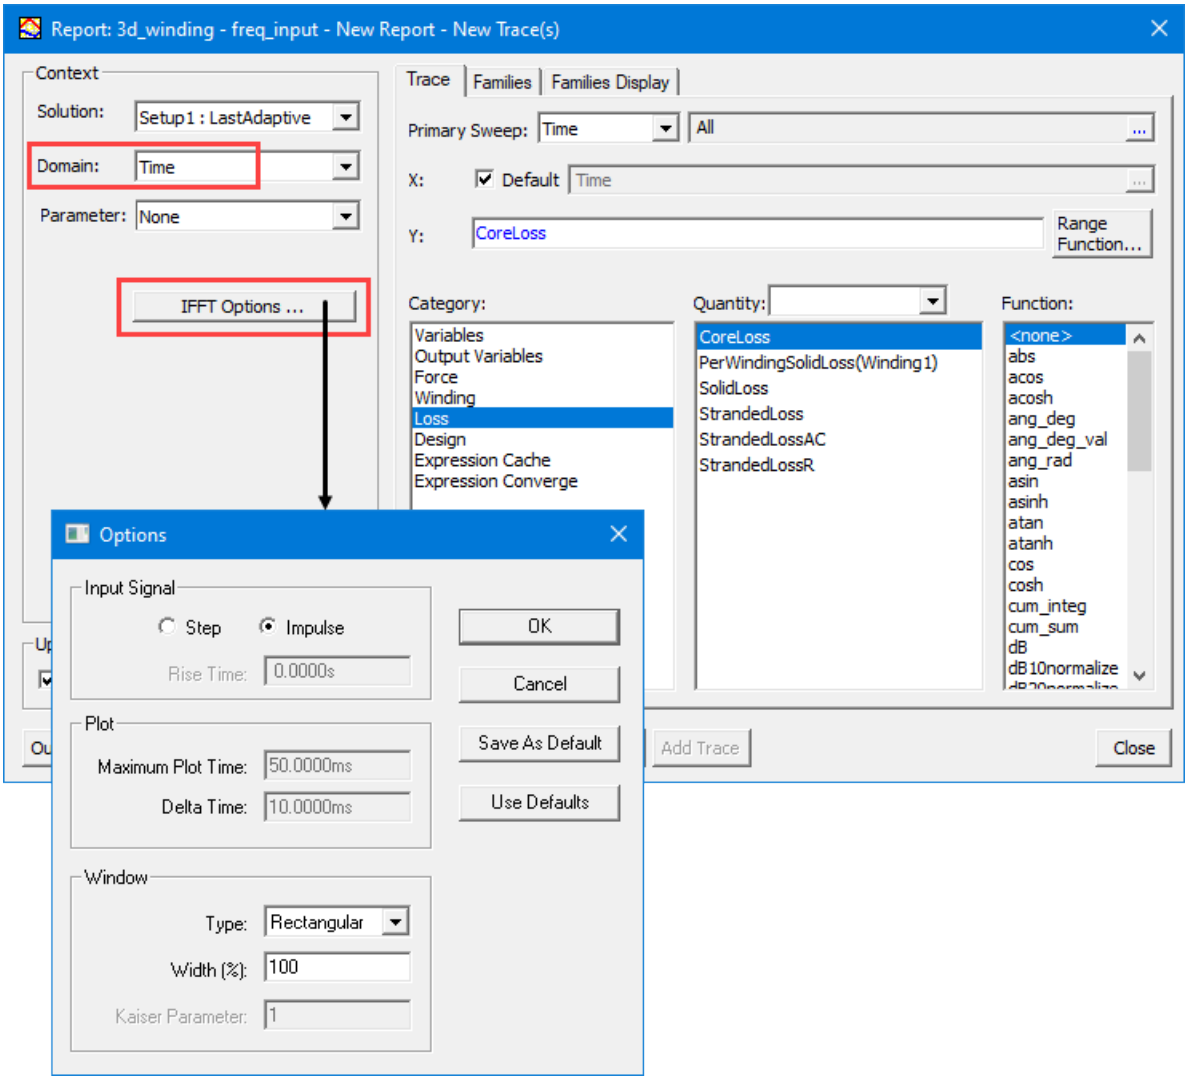
Similarly, for current, the window will also have the button to get datasets from FFT:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



After the Eddy Current simulation is complete, users can use the IFFT function in the Report window to reconstruct the signals. Note that the Domain needs to be **Time**. Users can also specify the parameters of the IFFT from the **IFFT Options** window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Validation

For each signal, the frequency points of (A, f) and (ϕ , f) datasets should be the same.

For all signals, the frequency points of all datasets should be the same.

> **Note:** This feature also supports Harmonic Loss coupling with EM Icepak and Ansys WorkBench.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

External Circuit Setup

The Maxwell Circuit design editor is used to set up the external circuit excitation for windings in Maxwell 2D and 3D Eddy current solutions. Because the Eddy Current solver is a frequency domain solver, only linear circuit components are supported, which include Resistance, Inductance, Capacitance, and Transformer. In addition, only sinusoidal sources should be used as sources. Sinusoidal Current Source and Sinusoidal Voltage Source, designed for transient solutions, can also be used for eddy current solutions. For example, to use the sinusoidal current source, you should set the parameters as follows:

- Set **I0**, **Td**, and **Df** to zero, where I0 is offset current in Amps, Td is the delay time in seconds, and Df is the damping factor in 1/seconds.
- Set **TIME** as the **Type**.
- Use **Ia** to set the peak amplitude in Amps.
- Use **IFreq** to set the signal frequency. Note that setting IFreq is not necessary as it will be internally set to the frequency defined in the Maxwell design setup.
- Use **Phase** to set the phase delay.

With these specifications, the time signal can be written as

$$I(t) = I_a \sin\left(2\pi I_{freq} - Phase\right)$$

Note that *Phase* is the signal phase delay. The complex source in the eddy current solver is represented in phasor form as:

$$I = I_a \; e^{j\theta}$$

and the time signal can be written in terms of (I_a, θ) as:

$$I\left(t\right) = Im\left\{I_a \; e^{j\left(2\pi I_{freq} + \theta\right)}\right\}$$

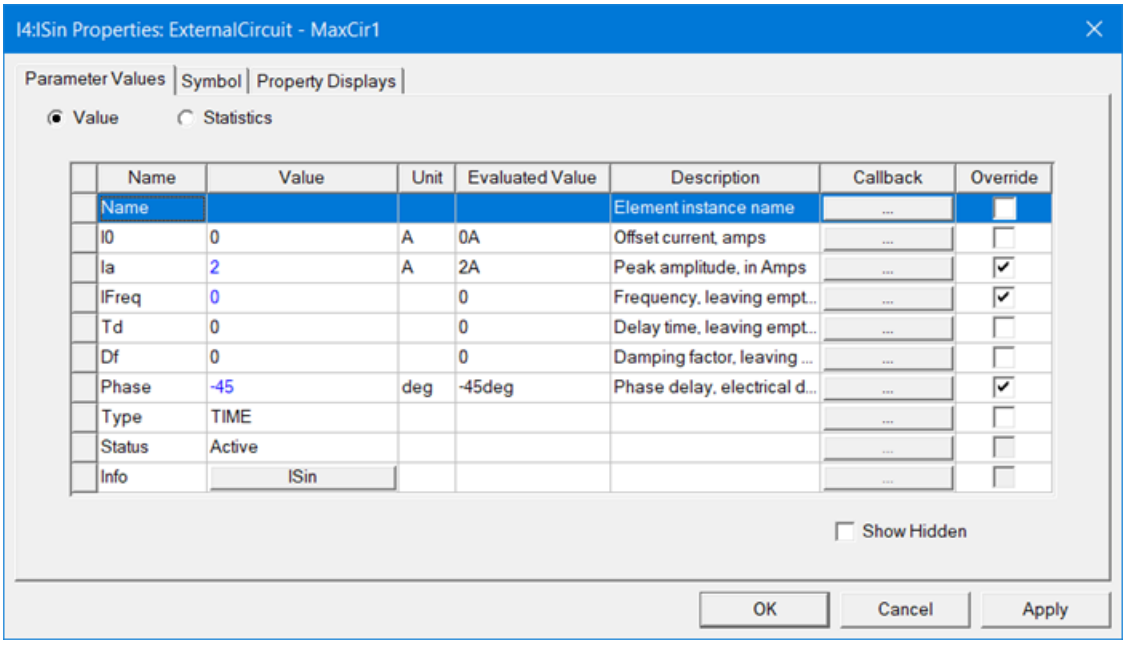
In the complex expression, θ is defined as phase, while in Maxwell Circuit, *Phase* is defined as phase delay. Thus:

$$Phase = -\theta$$

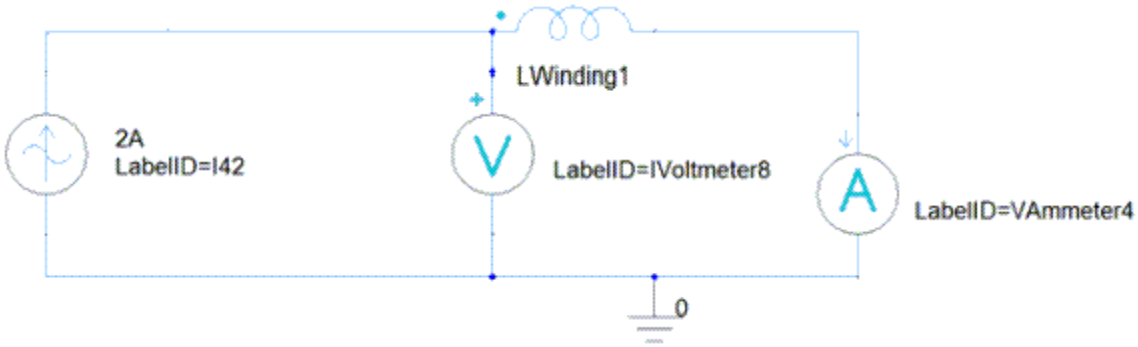
As a result, you should enter the negative of phase of the complex signal as the Phase value.

An example of such a setup for $I = 2e^{j45^\circ}$ is shown below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



An example of an external circuit excitation for the winding for an Eddy current solver is shown below.



> **Note:** For frequency domain eddy current solutions, only linear circuit components are supported, which include Resistor, Inductor, Capacitor, and Transformer. Only sinusoidal sources should be used as sources

To set up an external circuit connection for an External winding type:

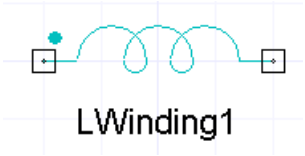
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click **Maxwell 3D** > **Excitations** > **External Circuit** > **Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit** > **Edit External Circuit**.

    a. If no external winding connections have been set up for your model, the **Winding Information** tab lists the external winding(s) in the design. Continue with step 2.

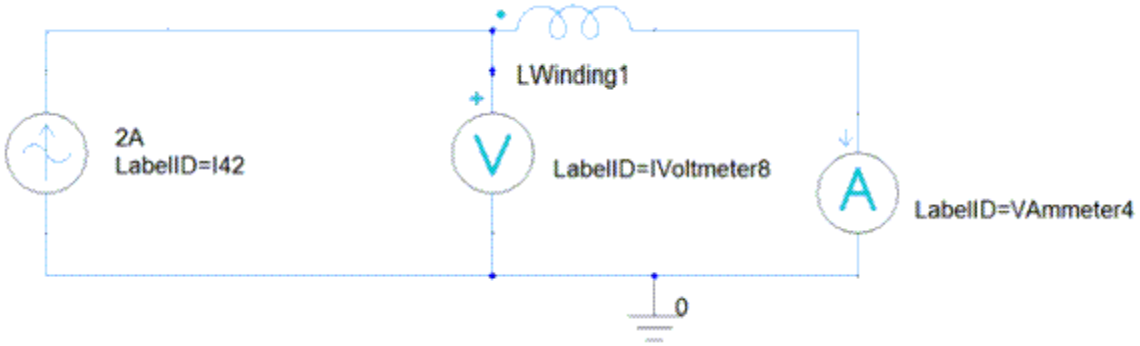
    b. If external windings have already been set up, continue with step 7.

2. On the **Winding Information** tab, click **Create Circuit** to add a circuit design to the project. The new circuit design automatically opens for editing in the Maxwell Circuit Editor. The circuit includes one inductor for each external winding in the original Maxwell transient design. The following example is for a design having one external winding.



3. Add the components needed to complete the external circuit design such as shown the following example.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. When the circuit design is finished, click **Maxwell Circuit** > **Export Netlist** and export the netlist **.sph** file to the desired location.
5. Return to the Maxwell design and click **Maxwell 3D** > **Excitations** > **External Circuit** > **Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit** > **Edit External Circuit**.
6. On the **Winding Information** tab, click **Import Circuit** to import the circuit.
7. To view a list of inductors in the imported circuit, click the **Available Inductors** tab.
8. To view the sources used in the externally connected windings, click the **Source Type** tab.
9. If variables are used in the imported circuit, they and their design values are listed on the **Parameter Values** tab. You can link to variables within the imported circuit as follows:
    a. On the **Parameter Values** tab, click in the **Value** column of the parameter to be mapped.
    b. Enter a new local variable name and press the **Enter** key to open the **Add Variable** dialog.
    c. Select a **Unit Type** and **Unit**, enter a **Value** for the variable, and click **OK**. The new Maxwell variable is now mapped to the variable in the imported circuit, and can be varied directly by Maxwell or used for optimetrics analyses.
10. If the imported file is a .**sph** file, you can click the **Circuit Path** tab to view the original project and design names.

> **Note:** After you import a circuit netlist, the **Create Circuit** button changes to **Update Netlist from Circuit**. Use **Update Netlist from Circuit** to reimport the netlist to keep it current.

11. Click **OK** to close the **Edit External Circuit** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Eddy Current A-Phi Boundaries and Excitations

The following boundaries can be specified for this solver:

- Flux Tangential

The following excitations can be specified for this solver:

- Voltage
- Current

Include at least a voltage excitation (with a potential difference) as a reference for computing the electric potential.

Eddy Current A-Phi Boundaries

The Eddy Current A-Phi field solver allows you to define the following types of boundaries:

Boundary Type	H-Field Behavior	Used to model…
Default Boundary Conditions (Natural and Neumann)	For natural boundaries, the fields behave as follows: • B: normal component is continuous across the boundary • J: tangent component is continuous For Neumann boundaries, the fields behave as follows: • B: normal to the boundary • J: tangential on the boundary	Object interfaces are initially set to natural boundaries; outer boundaries are initially set to Neumann boundaries.
Flux Tangential	• B: tangential to the boundary and flux cannot cross it. • J: normal to the boundary. Problems with flux tangential at outer boundary.	Problems with flux tangential at outer boundary.

Eddy Current A-Phi Excitations

The following excitations are available for Eddy Current A-Phi solver. Excitations are assumed to be peak quantities (not RMS).

Excitation	Type of Excitation
Voltage	This excitation sets the electric potential (voltage) on a surface or object to a specific value.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Excitation	Type of Excitation
Current	The AC current flowing across a surface (2D sheet).

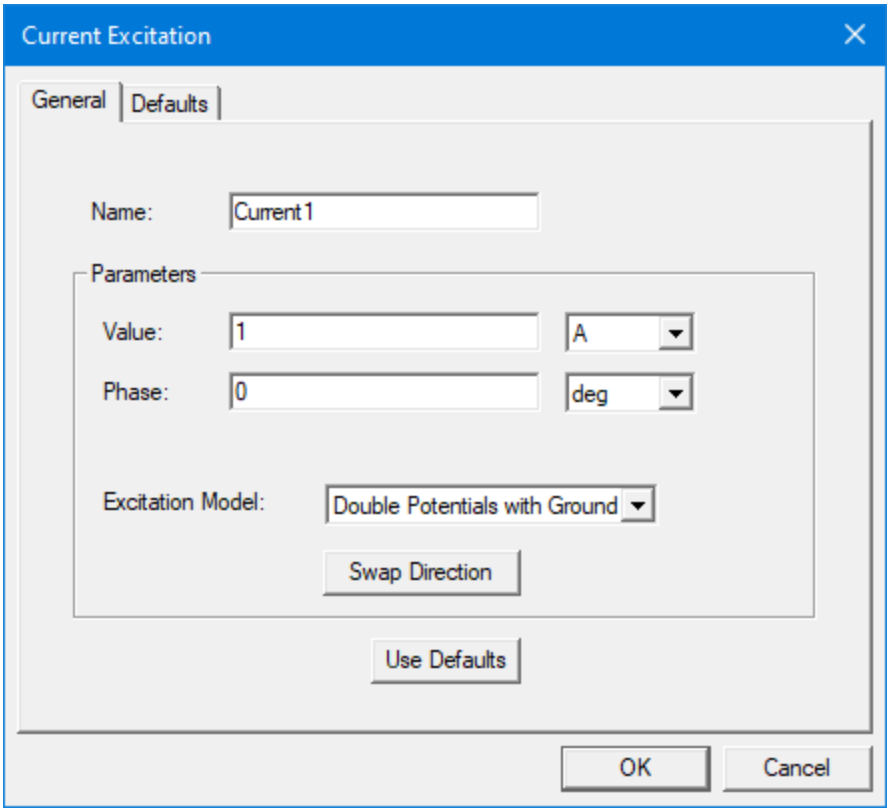
Assigning a Current Excitation

To define a current across a surface for the Eddy Current A-Phi Solver:

1. Select the 2D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 3D** > **Excitations** > **Assign** > **Current**.

   The Current Excitation window appears.
3. Enter a name for the excitation in the **Name** field or accept the default.
4. In the Parameters section:
   a. Enter the current strength in the **Value** field, and select the unit from the drop-down menu.
   b. Enter the phase angle in the **Phase** field, and select the unit from the drop-down menu.
   c. Choose the **Excitation Model**. Refer to the next section for details.
   d. Optionally, to change the direction of the current flow, click **Swap Direction**.
5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Excitation Models

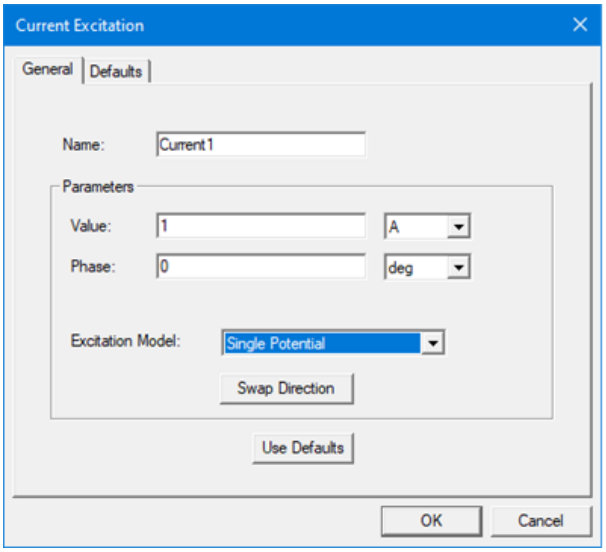
Current excitation supports three different excitation models for a Solid conductor type based on how the potential DOF is assigned on the face: **Single Potential**, **Double Potentials**, and **Double Potentials with Ground**.

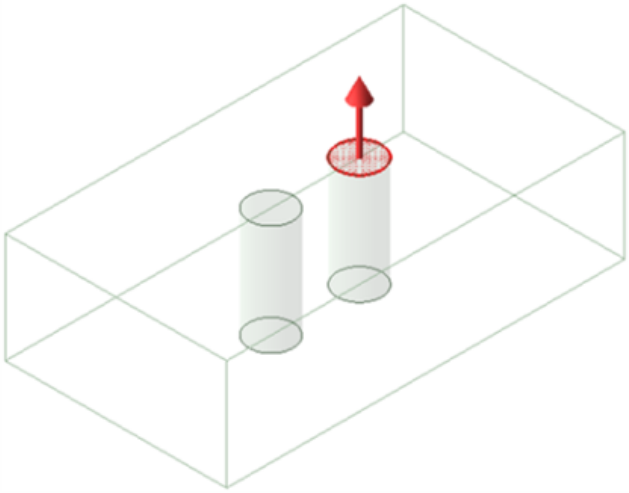
Single Potential:

Only one scalar electric potential DOF is assigned to the surface, and it is unknown.

> **Important:** This model must be used only at the external boundaries of the problem domain.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

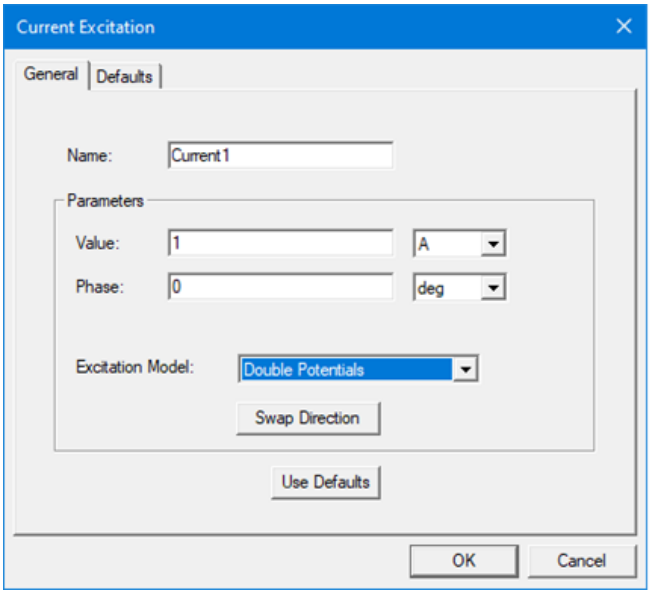


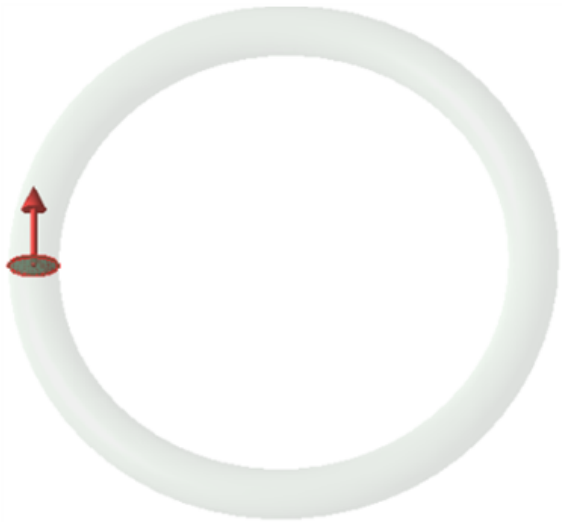


Double Potentials:

At the terminal face, two electric scalar potential DOFs are defined and the DOFs are unknown. There is a potential drop at the terminal. The current will be unidirectional, and it will flow in the direction that user specifies if the current value entered is a positive quantity.

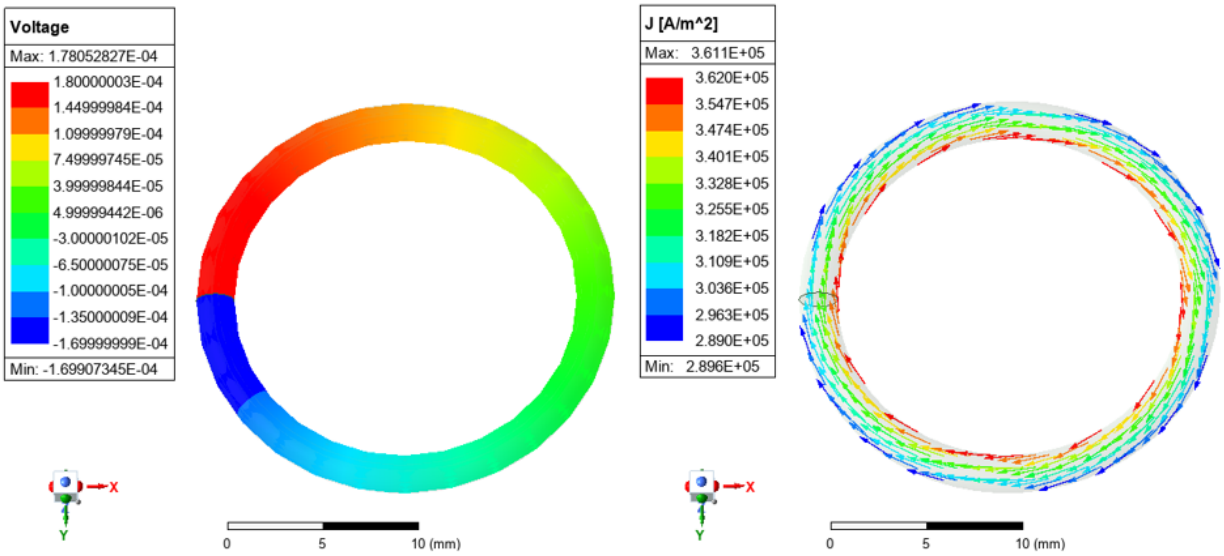
> **Important:** This model must be used on faces inside the problem domain.





The results are shown below:

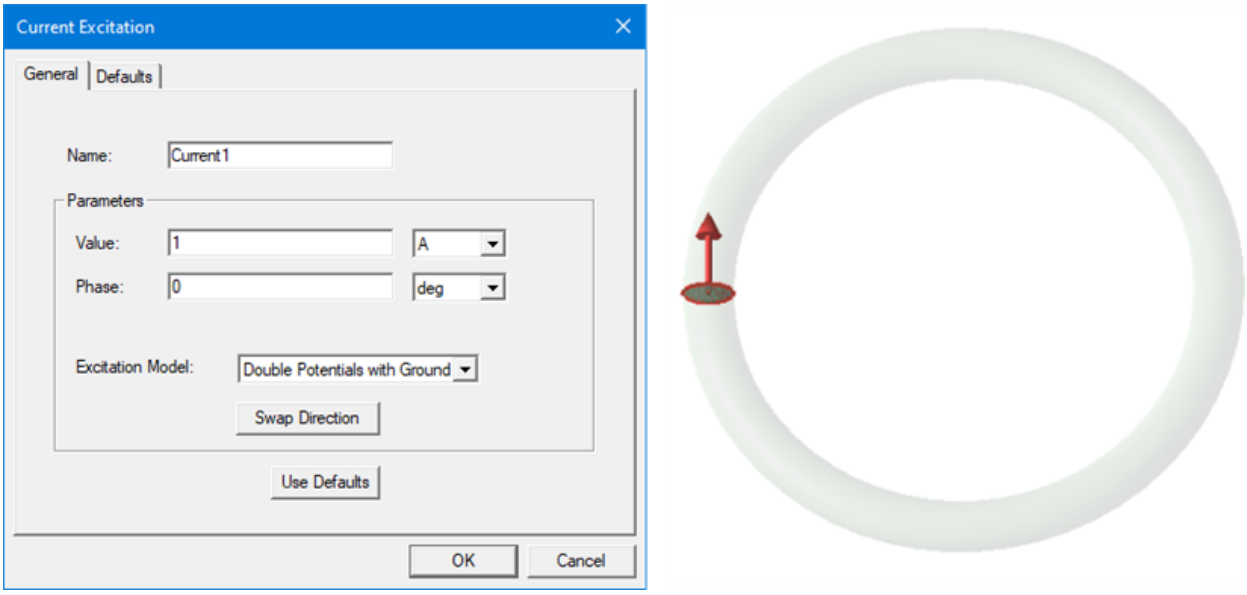
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Double Potentials with Ground:

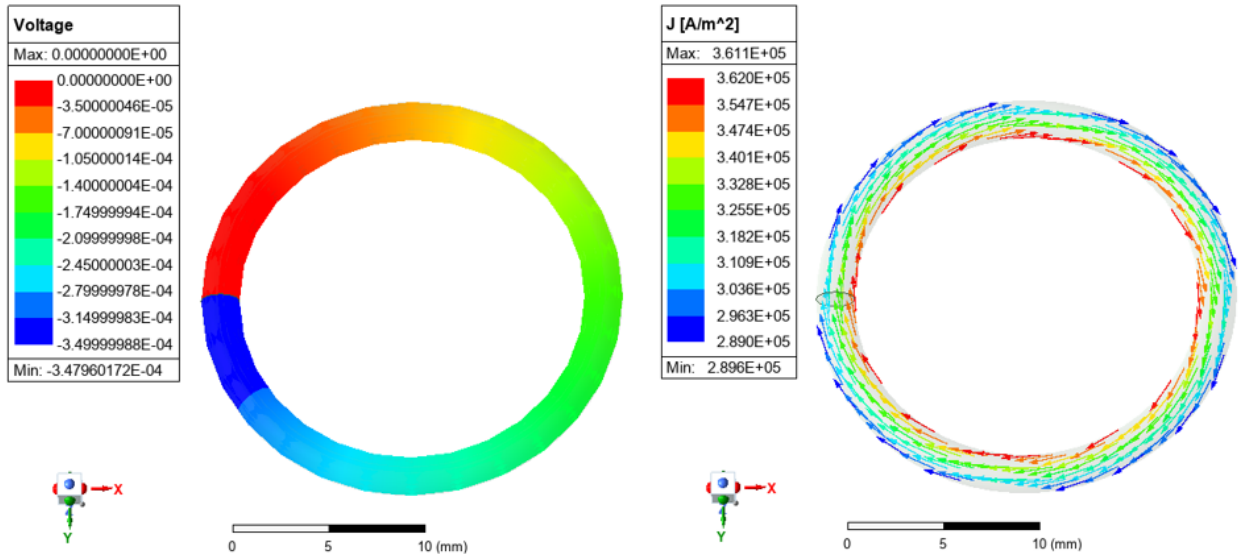
At the terminal face, two scalar electric potential DOFs are defined. The potential on the opposite side of the direction that the user specified is set to 0. The current will be unidirectional, and it will flow in the specified direction if the current value entered is a positive quantity.

> **Important:** This model must be used on faces inside the problem domain.



The results are shown below:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

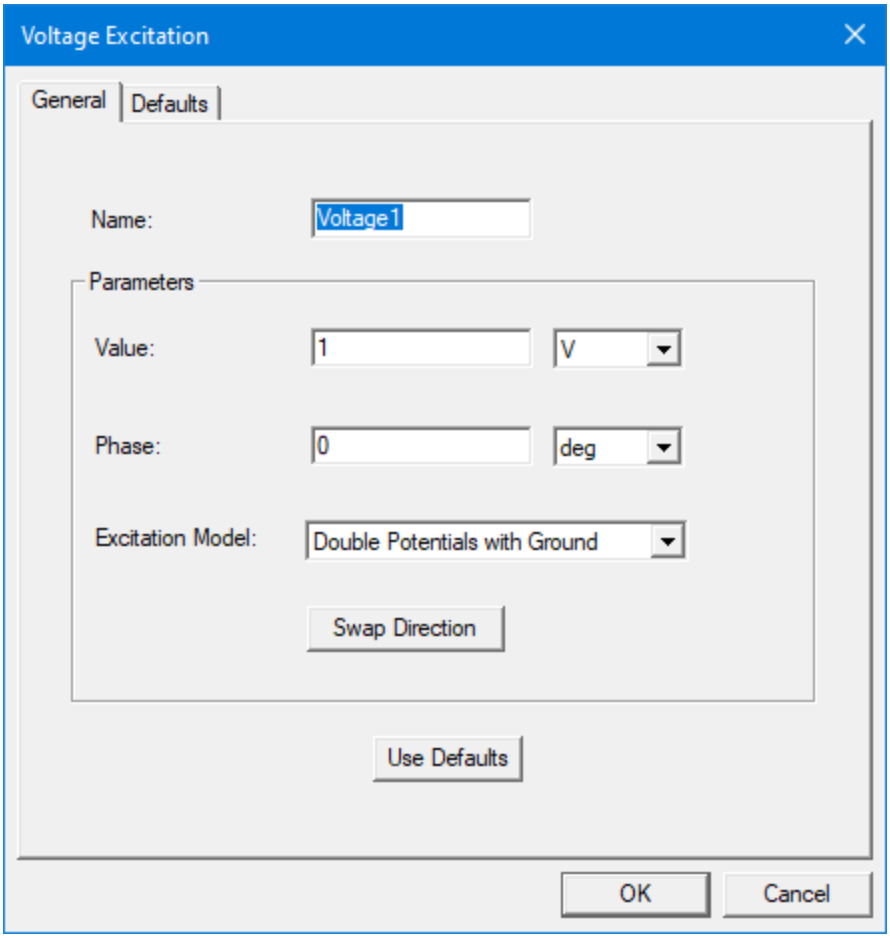


Assigning a Voltage Excitation

To set a voltage excitation for the 3D Eddy Current A-Phi Solver:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 3D** > **Excitations** > **Assign** > **Voltage**. The Voltage Excitation window appears.
3. Enter a name for the excitation in the **Name** field, or accept the default.
4. In the Parameters section:
    a. Enter the electric potential in the **Value** field, and select the unit from the drop-down menu. You can enter a numerical value.
    b. Enter a value in the **Phase** field, and select a unit from the drop-down menu.
    c. Choose the Excitation model. Refer to the next section for details on the options.
    d. Optionally, to change the direction of the voltage flow, click **Swap Direction**.
5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Excitation Models

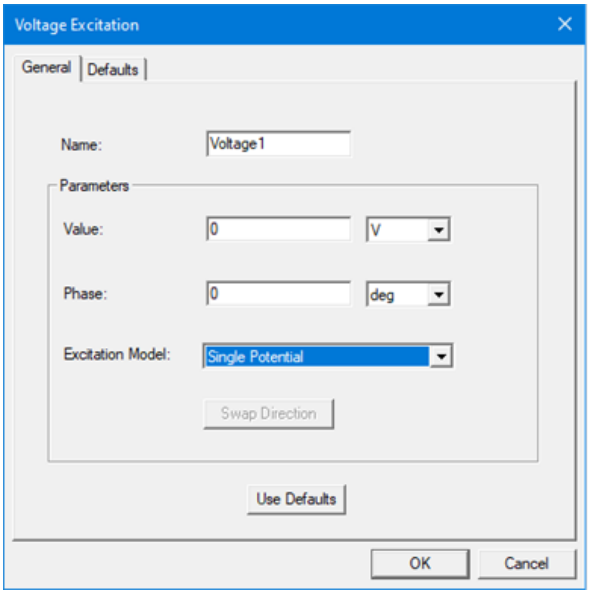
Voltage excitation supports three different excitation models: **Single Potential**, **Double Potentials**, and **Double Potentials with Ground**.

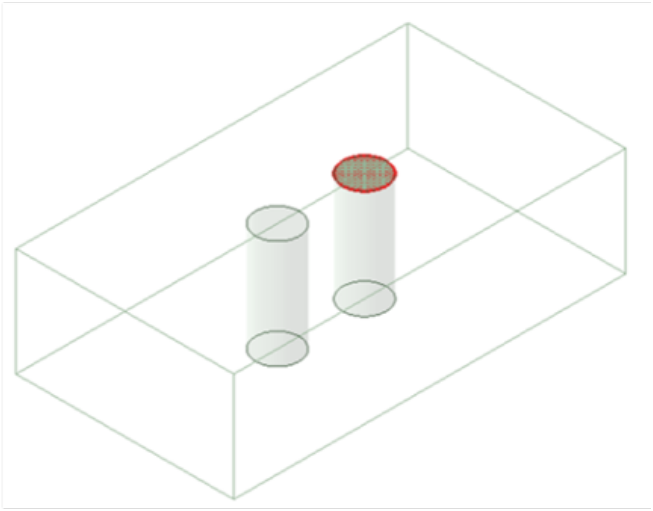
Single Potential

The solver treats the terminal as an equipotential terminal. Only one scalar electric potential DOF (Degree of Freedom) is assigned to the surface, and the value of the DOF is set to the value that the user inputs.

> **Important:** This model must only be used at the external boundaries of the problem domain.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



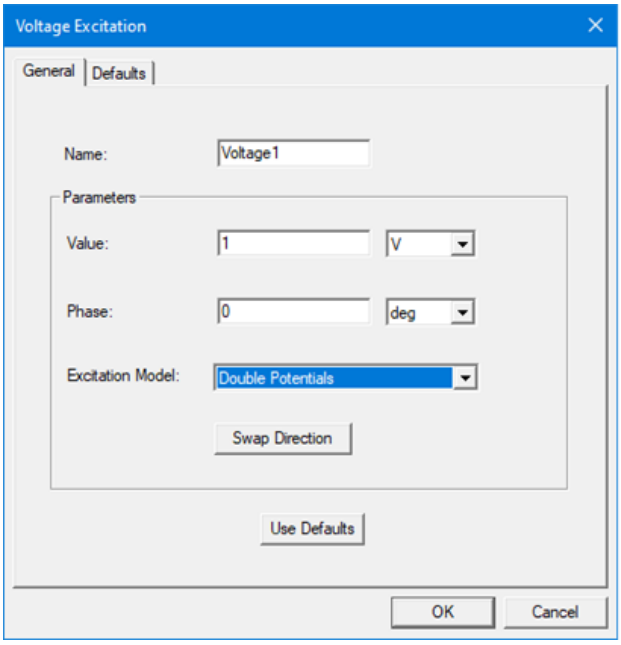


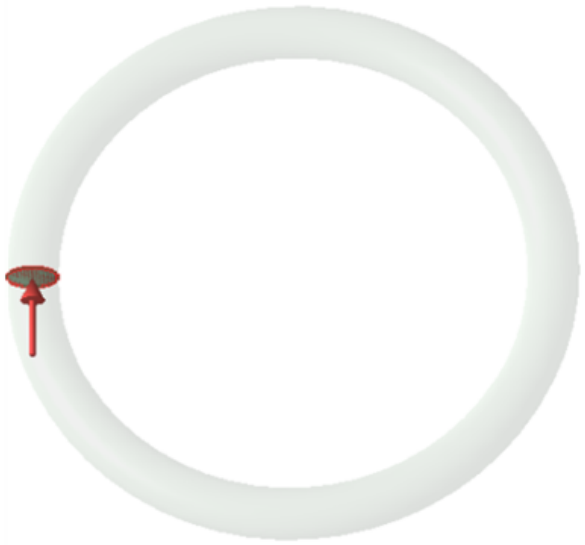
Double Potentials

The solver treats the terminal as a voltage (potential drop) terminal. At the terminal face, two scalar electric potential DOFs are defined, and the DOFs are unknown. The difference between those potentials equals the voltage value that the user specified. If the voltage value is a positive quantity, the higher potential is in the specified direction.

> **Important:** This model must be used on faces inside the problem domain.

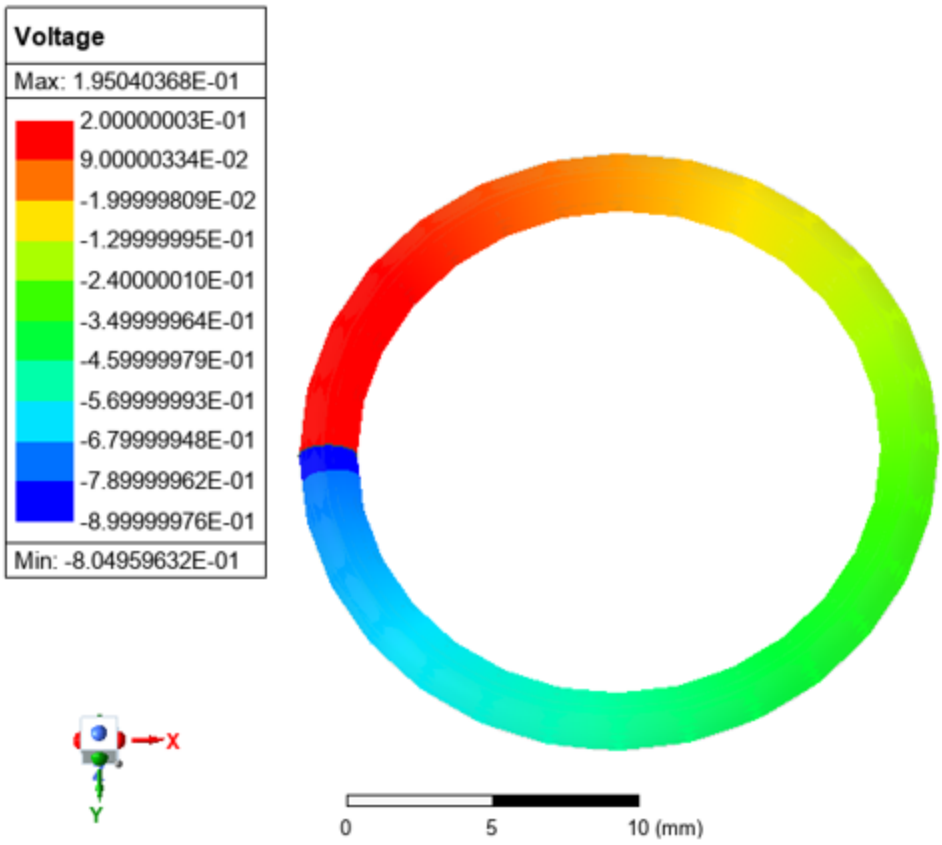
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





The voltage profile for **Double Potentials** is shown below:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

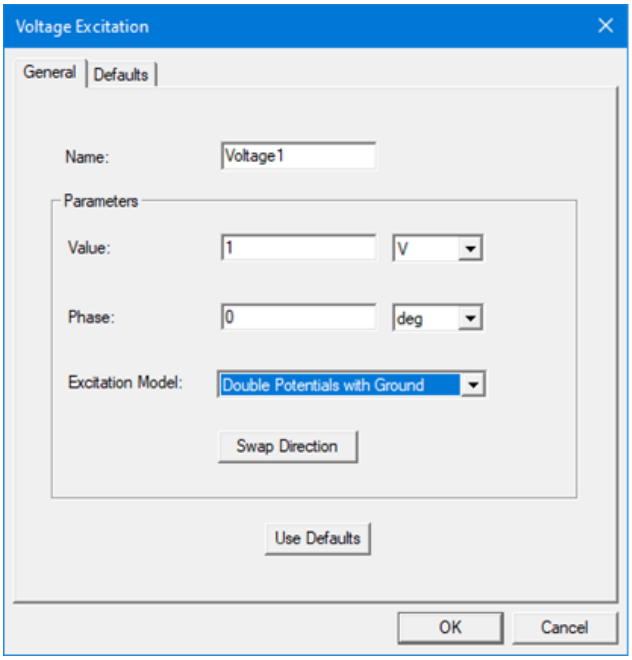


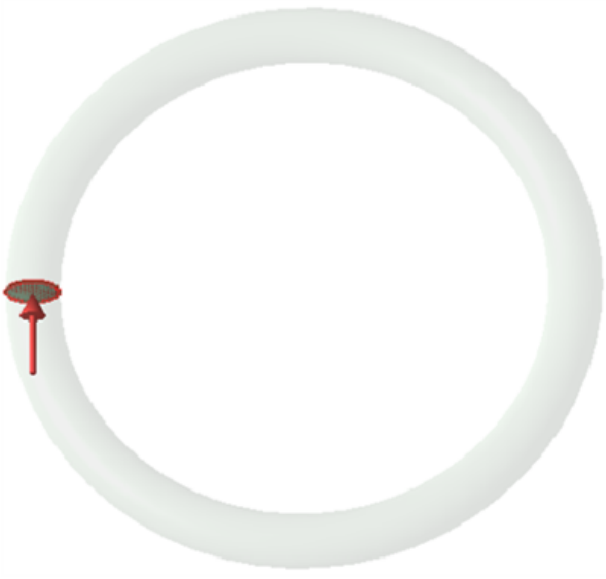
Double Potentials with Ground

The solver treats the terminal as a voltage (potential drop) terminal. At the terminal face, two scalar electric potential DOFs are defined, and both DOFs are known. The difference between those potentials equals the voltage value that the user specified. If the voltage value is a positive quantity, the DOF in the specified direction is set to the specified voltage value, and the DOF in the opposite direction is set to 0.

> **Important:** This model must be used on faces inside the problem domain.

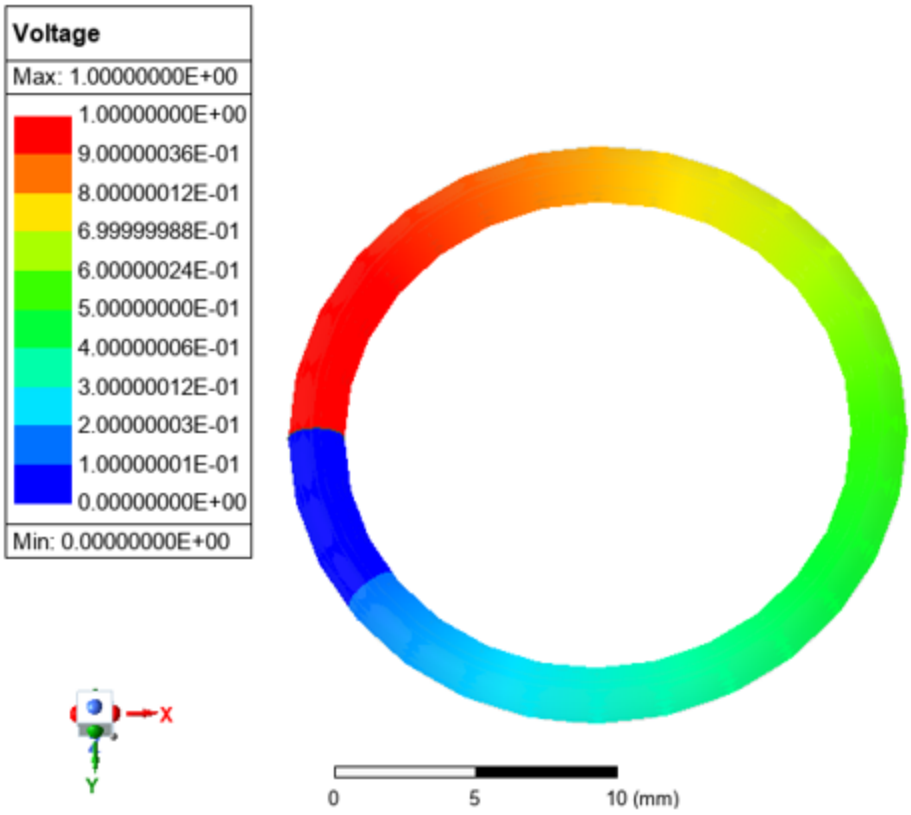
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





The voltage profile for **Double Potentials with Ground** is shown below:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Transient Boundaries and Excitations

Define at least one of the following as a source of magnetic fields:

- The stranded or solid windings, with a voltage or current supply or connected to an external circuit winding.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** For stranded conductors, it is assumed that the current density is uniform on the cross-section of the respective conductors. Thus, the stranded option for current excitations should mostly be used only in cases where the cross-section of conductors is constant, consistent with the assumption that the respective object is a coil built with strands of wire. For this reason, conductors (coils) could be created by either sweeping around an axis using zero segments or sweeping along a path having only true surface segments in order to create a smooth surface coil having a completely uniform cross-sectional area over its entire length.

- A permanent magnet.

You may need to set at least one outer boundary to the following:

- The default boundary conditions.
- An odd symmetry (flux tangential) boundary.
- An even symmetry (flux normal) boundary.

Transient Boundaries

The transient field solver allows you to define the following types of boundary conditions.

Boundary Type	H-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — **H** is continuous across the boundary. • Neumann boundaries — **H** is tangential to the boundary and flux cannot cross it.	Ordinary field behavior. Initially, object interfaces are natural boundaries; outer boundaries, and excluded objects are Neumann boundaries.
Zero Tangential H Field	The tangential components of **H** are set to zero. Flux is perpendicular.	External magnetic fields.
Integrated Zero Tangential H Field	For applications such as a motor with the shaft excluded, there remains a hole in the middle. In such cases, on the hole's boundary, neither the Tangential H Field boundary (where integration of the tangential H field is non-zero), nor the Zero Tangential H Field	Cases such as the boundary around the hole that remains when a motor's shaft is excluded.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	boundary (where the tangential H field is zero everywhere) can be applied because – for the hole boundary case – integration of the tangential H field is zero, but the tangential H field is not zero everywhere. Integrated Zero Tangential H Field can be used for such applications.	
Insulating	Same as Natural boundary, except that current cannot cross the boundary.	Thin, perfectly insulating sheets between touching conductors.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) — **H** is tangential to the boundary; its normal components are zero. • Even Symmetry (Flux Normal) — **H** is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.
Matching (Independent and Dependent)	The H-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the H-field on the independent boundary.	Planes of symmetry in periodic structures where **H** is oblique to the boundary.
Resistive Sheet	Same as Natural boundary.	Voltage drop and loss on the contact surface between two different objects within a conduction path.
Impedance	Includes the effect of induced currents beyond the boundary surface.	Conductors with very small skin depths.
Touching	Same as Natural boundary.	Interface between a moving part and a stationary part.
Thin Layer (Air Gap)	When two parts of the domain are separated by a thin volume representing an air gap, it can be modeled by a surface with an appropriate boundary condition. This boundary creates a field discontinuity between the two sides of the selected surface based on its thickness. The relative magnetic permeability of the air gap is assumed to be equal to one.	Narrow air gaps

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Default Boundary Conditions

These boundary conditions are automatically defined for a transient model:

- Natural boundaries are assigned to the surfaces between objects.
- Neumann boundaries are assigned to the outside edges of the problem region.

To leave a surface set to its default boundary condition, you do not need to set any boundary conditions. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Zero Tangential H Field Boundary

For the transient solver, this type of boundary defines external magnetic fields in the model.

> **Warning:** When using zero tangential magnetic field boundary conditions, always double-check that Ampere's law is not violated!

To define a zero tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Zero Tangential H Field**.
   The **Zero Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning an Integrated Zero Tangential H Field Boundary

For a transient solver, this type of boundary is applied when the integral of the tangential H field is zero.

> **Note:** When using integrated zero tangential magnetic field boundary conditions, always double-check that Ampere's law is not violated!

To define an integrated zero tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Integrated Zero Tangential H Field**.
   The **Integrated Zero Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning an Insulating Boundary

For the Transient solver, this boundary condition is used to model very thin sheets of perfectly insulated material between touching conductors. Current cannot cross an insulating boundary.

To set an insulating boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Insulating**.
   The **Insulating Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

> **Note:** An insulating boundary condition can operate on the source current. It can also be used to control the flow of induced eddy currents.

Assigning a Symmetry Boundary

F or a Transient solver, this boundary condition defines a plane of geometric or magnetic symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Symmetry**.
3. In the **Symmetry Boundary** window that opens, enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Tangential)	H is tangential to the boundary; its normal components are zero.
Even (Flux Normal)	H is normal to the boundary; its tangential components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the boundary to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Warning:** When using even symmetry boundaries, always double-check that Ampere's law is not violated!

Assigning a Independent Boundary

Independent and dependent boundaries can be used to model planes of periodicity where the H-field at every point on the dependent boundary surface is forced to match the H-field of every corresponding point on the independent boundary surface. The transformation used to map the H-field from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the face to which you want to assign the independent boundary.
2. Click **Maxwell** > **Boundaries** > **Assign** > **Matching** > **Independent**.
3. In the **Independent Boundary** window that opens, enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Coordinate System** section, do the following to define the coordinate system:

   > **Note:** You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** drop-down menu.
   The **Create Line** message appears, asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Independent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.
   c. Select a point on the u-axis.
   The **Independent Boundary** dialog box reappears
5. To reverse the direction of the vector, select the **Reverse Direction** check box.
6. Click **OK**.

The Maxwell solver computes the H-field on this boundary and maps it to the dependent boundary using the transformation defined by the independent and dependent coordinate systems.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning a Dependent Boundary

For the transient solver, assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

> **Note:** You must define an independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Matching** > **Dependent**.
   The **Dependent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** drop-down menu.
5. To specify the coordinate system, do the following in the Coordinate System section:

   > **Note:** You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** drop-down menu.
      The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Dependent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin in one of the following ways:

      > **Note:** The U vector's origin must be on the boundary's surface.

      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.
   c. Select a point on the u-axis in the same way.
      When the second point is identified, the vector is set, and the **Dependent Boundary** window reappears, with **Defined** listed in the **U Vector** drop-down menu.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

d. To specify the direction of the V vector, select or clear the **Reverse Direction** check box.

6. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Hdep = Hind	Click this radio button if the dependent and independent boundaries have the same magnitude and direction.
Hdep = -Hind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. Click **OK** to assign the boundary to the selected object.

> **Note:** The origin must be a vertex point of one of the objects.

Assigning a Resistive Sheet Boundary

> **Note:**
>
> This topic explains how to assign a resistive sheet boundary for the transient solver.
>
> For Eddy Current designs refer to Assigning a Resistive Sheet Boundary for the Eddy Current Solver.
>
> For 3D Magnetostatic designs refer to Assigning a Resistive Sheet Boundary for the 3D Magnetostatic Solver.

When two conductors are in contact within a conduction path, a voltage drop normally exists across the contact surface due to the imperfection of the contact between the two conductors. This voltage drop should be taken into account when the winding is a voltage excitation. This boundary condition assigns a resistive sheet to consider the impact of this kind of voltage drop. The resistive sheet is defined by a lumped resistance in ohms.

To assign a resistive sheet boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a sheet object or face of a 3D conducting body touching another conducting body).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> - The sheet must have conductors touching both of its faces.
> - The sheet can not be smaller than the contacting surface.
> - The sheet cannot span multiple faces.

2. Click **Maxwell** > **Boundaries** > **Assign** > **Resistive Sheet**.
3. In the **Resistive Sheet** window that opens, enter a name for the boundary in the **Name** box, or accept the default.
4. Enter a resistance value in the **Resistance** box and select the unit of measure, or accept the default (1 ohm).
5. Optionally, the **Defaults** tab allows you to save the current resistance value for future use, and to revert to the standard defaults.
6. Click **OK** to assign the boundary to the selected object.

> **Note:** When switching the solution type between transient and eddy current, resistive sheet boundaries will be kept.

Assigning an Impedance Boundary

> **Note:** This topic explains how to assign an impedance boundary for the transient solver. To define an impedance boundary for the eddy current solver, refer to Assigning an Impedance Boundary for the Eddy Current Solver.

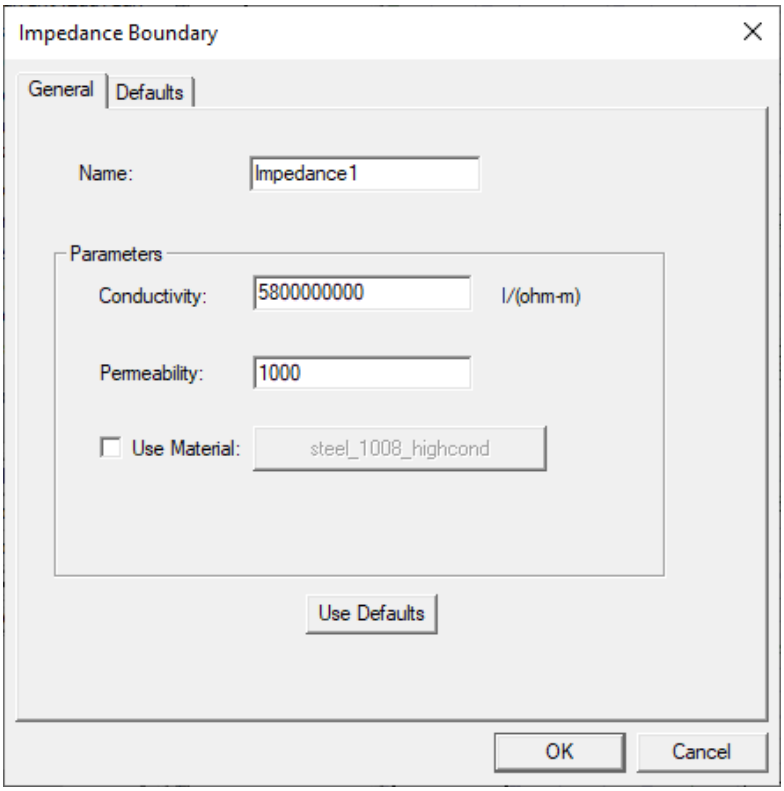
This boundary condition is used to simulate the effect of induced currents in a conductor without explicitly computing them. The conductor must be excluded from the model (saving time needed to mesh and solve for currents), so assign the impedance boundary condition to an outside edge of the problem region or to an excluded object.

To define an impedance boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Impedance** to open the **Impedance Boundary** dialog box.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Do one of the following:

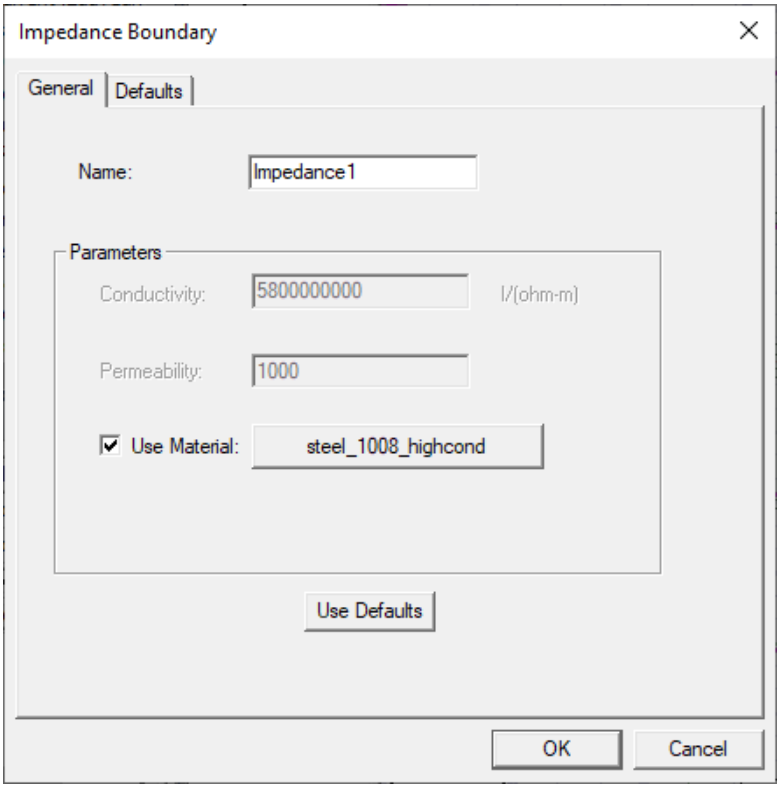
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If the **Use Material** check box is unchecked, enter the conductivity (in inverse ohm-meters) in the **Conductivity** field, and the conductor's relative permeability in the **Permeability** field.



- If you wish to select a material from the library, check the **Use Material** check box, then use the button to select the desired material.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



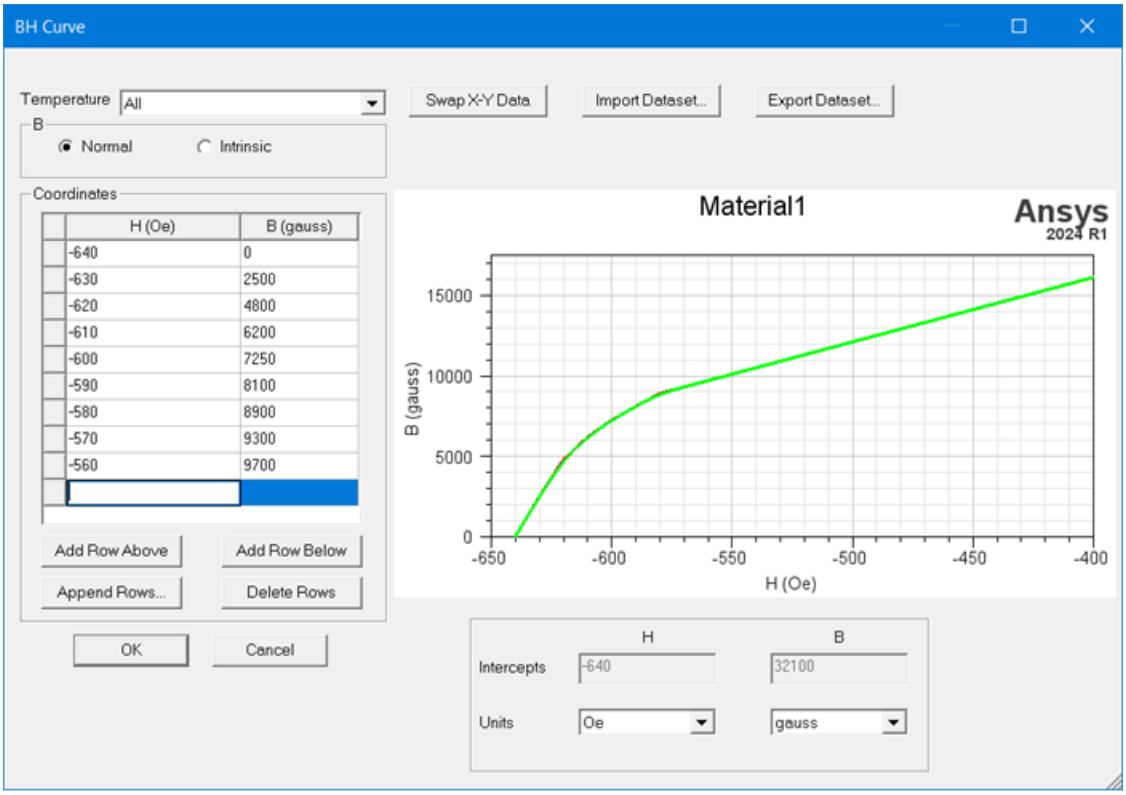
- **Nonlinear Permeability**

  If you select a material that has nonlinear permeability, the nonlinear coefficient is computed automatically.

  The nonlinear relative permeability of the material is determined by the B-H curve. If the desired B-H curve of the permeability belongs to an existing material, you can directly use that existing material.

  Otherwise, you can edit a new material with the desired B-H curve.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Refer to Relative Permeability for a Maxwell or RMxprt Material for details on using nonlinear relative permeability.

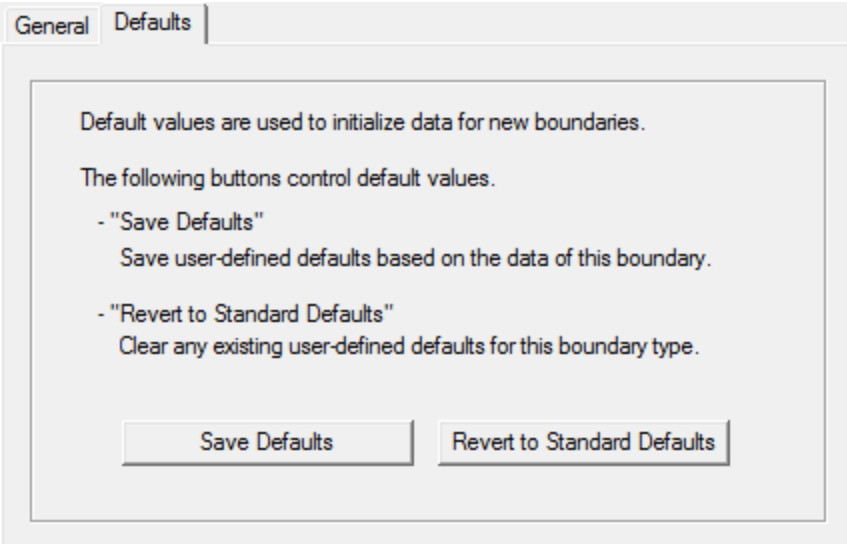
- **Temperature-Dependent Impedance Boundary**

  The electrical conductivity and permeability of a material used for an impedance boundary condition can be temperature dependent. The Maxwell 3D transient solver provides an option to allow you to input functions as thermal modifiers to consider the effect of temperature on those properties. To enable this feature, check the Use Material check box as above. You can then click Material to open the material properties panel in which you can add a thermal modifier. (Refer to *Setting the Temperature of Objects* for additional information on using temperature-dependent impedance boundaries).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Optionally, click **Use Defaults** to revert to the default values in the window.

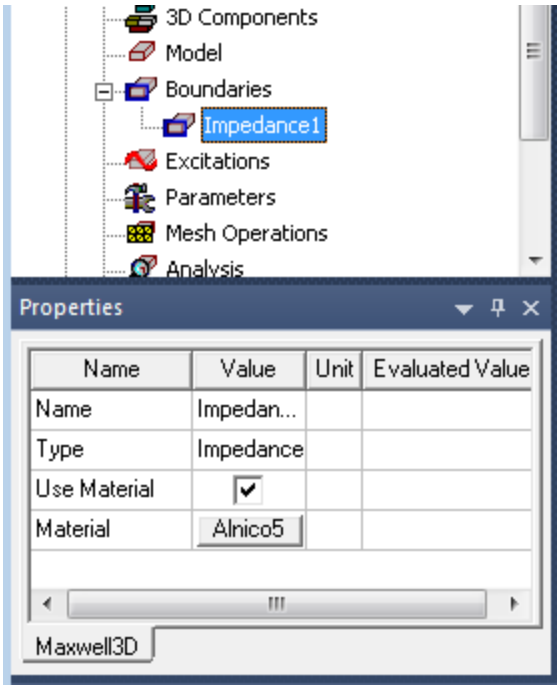
The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **General** tab as the defaults to be assigned to new impedance boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.



6. Click **OK** to assign the boundary to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Project Manager tree lists the newly assigned impedance boundary in the tree. You can select the boundary in the tree to view and edit its properties in the Properties window. You can also double-click the boundary entry in the tree to open it for editing in the Impedance Boundary dialog box.

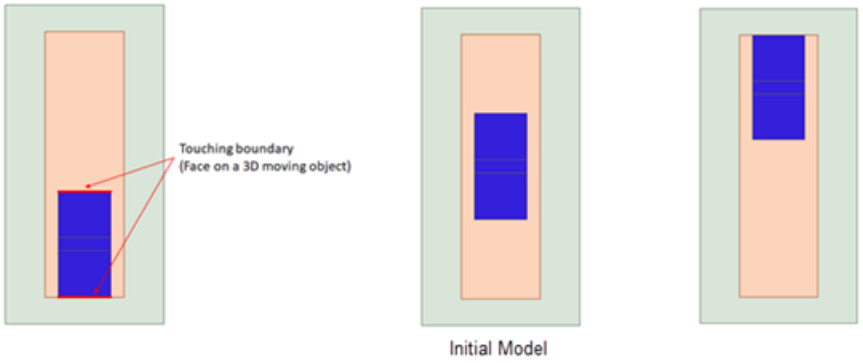


Assigning a Touching Boundary

For non-periodic translational motion designs in which a moving part contacts a stationary part this boundary condition assigns a touching boundary to the face of the moving part that contacts the stationary part. When the model is created, there must be an airgap between the moving objects and the stationary objects although these can touch during the simulation (either at beginning or end).

For example, with this feature, the linear actuator can be modeled from one end directly touching the stationary part to the other end also directly touching the stationary part as shown; however the initial model must be drawn without touching the ends as shown in the center image below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To assign a touching boundary to a non-periodic translational motion part:

1. Select the face of the geometry on which you want to apply the boundary condition (the face of the 3D moving body that will touch a stationary part).

   Note:

   - The touching boundary should be defined on the surface of the moving part.
   - The touching boundary can only be applied to the moving part with non-periodic translation motion.
   - At any timestep, each touching boundary must either fully touch the stationary part or be completely separated from the stationary part. The touching boundary can not partially touch the stationary part at any time.
   - The moving and stationary parts are not allowed to be on one conduction path.
   - Moving object(s) cannot touch the stationary objects in the initial model.

2. Click **Maxwell** > **Boundaries** > **Assign** > **Touching**.
   The **Touching Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning a Thin Layer Boundary

Maxwell 3D supports Thin Layer boundary types for the following solvers:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Thin Layer Boundary for a 3D AC Conduction Solver

  This boundary condition can be used to model thin domains, for example: the contact resistance between two conductive domains, the capacitive effect of thin insulating materials or thin lossy domains in electronic boards without needing to explicitly model (and mesh) a 3D object having a finite thickness.

- Thin Layer Boundary for a 3D DC Conduction Solver

  This boundary condition can be used to model thin domains, for example, the contact resistance between two conductive domains without needing to explicitly model (and mesh) a 3D object having a finite thickness.

- Thin Layer Boundary for a Magnetostatic or Transient Solver

  This boundary condition can be used to model narrow air gaps, such as those in power transformers, inductors, or any other electric device forming a magnetic circuit with an air gap without needing to explicitly model (and mesh) this gap.

- Thin Layer Boundary for an Eddy Current Solver.

  This boundary creates a field discontinuity between the two sides of the selected surface based on its thickness and the given electric and magnetic material proprieties. When the air gap option is selected, the conductivity is assumed to be zero and the relative magnetic permeability is assumed to be equal to one.

Assigning a Thin Layer (Air Gap) Boundary for a Magnetostatic or Transient Solver

When two parts of the domain are separated by a thin volume representing an air gap, it can be modeled using a **Thin Layer** boundary condition. This boundary creates a scalar potential discontinuity across the two sides of the surface based on its thickness. The magnetic permeability of the air gap is assumed to be equal to that of free space.

This boundary condition can be used to model narrow air gaps, such as those in power transformers, inductors, or any other electric device forming a magnetic circuit with an air gap without needing to explicitly model (and mesh) this gap.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

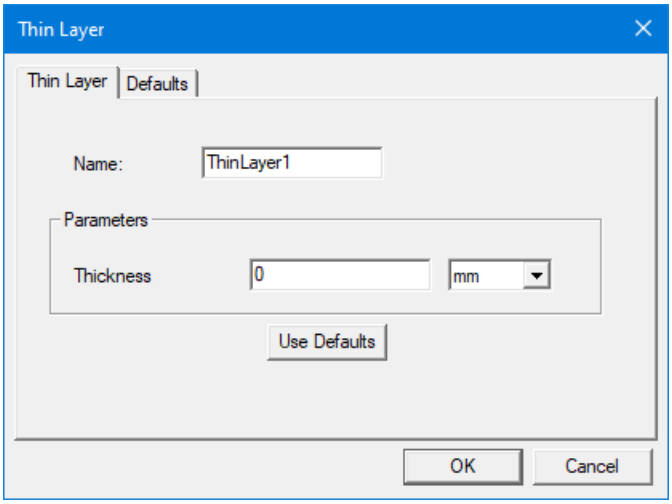
Note:

- The thin layer cannot be a closed shell encompassing a conductor.
- The thin layer does not support a mechanical movement, *i.e.*, the boundary condition cannot be applied to the interface of moving and stationary bodies.
- The thin layer cannot be defined on a conductor boundary or as a sheet object that touches or crosses any conducting body. In such cases, the Maxwell solver displays an error message indicating the name of the conducting body that the thin layer is touching.

For the 3D Magnetostatic and Transient solvers, the thin layer for an air gap is defined purely in terms of its thickness. It is assumed to be made of air (non-conducting material with relative magnetic permeability equal to one).

To define a thin layer boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a sheet object or face of a 3D body).
2. Click **Maxwell 3D** > **Boundaries** > **Assign** > **Thin Layer** to open the **Thin Layer** dialog box.



3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter the thickness of the thin layer and the unit of measure. It must be a value greater than zero. The use of variables is supported.
5. Optionally, click **Use Defaults** to revert to the default values in the window.

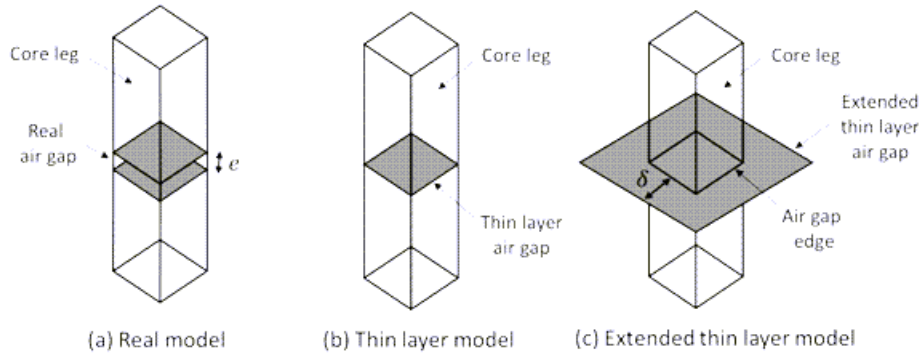
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **Thin Layer** tab as the defaults to be assigned to new impedance boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.
7. Click **OK** to assign the boundary to the selected object.

The Project Manager tree lists the newly assigned thin layer boundary in the tree. You can select the boundary in the tree to view and edit its thickness in the Properties window. You can also double-click the boundary entry in the tree to open it for editing in the Thin Layer dialog box.

Getting Better Convergence with the Thin Layer Model

For a magnetostatic or transient simulation, the thin layer model for air gaps requires the duplication of the scalar potential to create a field discontinuity beyond the dimension of the sheet object and correctly represent the fringing flux effects. The Maxwell solver automatically duplicates the potential in one layer of elements from the gap edges. However, during the mesh adaptive process, the lateral elements may become too small and thus too close to the gap sides. This results in a low convergence of the mesh adaptive steps as the magnetic energy on such elements becomes more important. To improve convergence, the user can extend the sheet object manually (see figure below). Better convergence is observed by raising its lateral sides from one to three times the air gap thickness ($\delta \cong 3e$) depending on the model geometry.



Transient Excitations

After defining the coil terminals for the model, you can use these terminals to define one or more windings using the **Maxwell** > **Excitations** > **Add Winding** option. Transient problems use the following sources of magnetic fields:

Excitation	Type of Excitation
Coil Terminal	Used to define one or more model windings.
Winding With Current	Current for both a stranded and solid conductor.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Winding With Voltage	Voltage for both a stranded and solid conductor.
Winding With External Circuit Connection	External circuit connection for both a stranded and solid conductor.

> **Note:** A winding is a flexible excitation. Six different combinations can be used: Current, Voltage, and External Circuit — each with a solid or stranded conductor. The Coil Terminal type of excitation is needed to set up a winding.

> **Note:** When a source conductor touches an outer boundary, Maxwell assumes current will flow perpendicular to the boundary. If you do not want current to cross the outer boundary, an insulating boundary should be used.

In addition, permanent magnets serve as sources of magnetic fields.

Assigning a Coil Terminal

To assign a coil terminal as a transient excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D planar object).
2. Click **Maxwell** > **Excitations** > **Assign** > **Coil Terminal**. (You can also right-click an existing winding in the project tree, and select **Assign Coil Terminal**.)
   The **Coil Terminal Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil terminal in the **Number of Conductors** box.

   > **Note:** This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.

5. If you want to switch the direction for the coil terminal, click **Swap Direction**.

   > **Note:** The direction is shown in the model by a bold red arrow.

6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the coil terminal to the selected object.

To add this coil terminal to an existing winding:

1. In the Project Manager tree, right-click the coil terminal, and select **Add to Winding**.
   The **Add to Winding** dialog box appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Select the winding to which you ant to add the coil terminal, and click **OK**.

To remove a coil terminal from an existing winding:

- In the project tree, right-click the coil terminal, and select **Remove from Winding**. The terminal is removed from the winding and moved up one level in the project tree (directly beneath **Excitations**).

> **Note:** For 3D transient solutions using the A-Phi Formulation, refer to the Winding Excitations for A-Phi Formulation section for information on Ordering the Coil Terminals.

Assigning a Winding Setup

> **Note:**
>
> This topic explains how to assign a winding setup for a transient solver.
>
> - If you wish to define a winding for an Eddy Current solution type, refer to Assigning a Winding Setup for an Eddy Current Solver.
> - If you wish to define a winding for a Magnetostatic solution type, refer to Assigning a Winding Setup for a Magnetostatic Solver.

You can use the predefined coil terminal(s) to define one or more current or voltage windings.

To define a winding for your model:

1. Click **Maxwell 3D** > **Excitations** > **Add Winding** to open the **Winding** dialog box.
2. Enter a name for the winding in the **Name** box, or accept the default.
3. In the **Parameters** section:
    a. Select **Current, Voltage**, or **External** from the **Type** drop-down menu.

    > **Note:** Maxwell transient designs can be dynamically coupled to Twin Builder components through the Twin Builder user interface. You can enable this feature on the Advanced Product Coupling tab of the **Design Settings** dialog box. Source windings set to **External** are available as conservative pins in Twin Builder. For more information, refer to the Twin Builder Help.

    b. Select the **Solid** or **Stranded** radio button to specify the type of conductor.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. Enter values in the following fields (enabled according to winding type), and select the desired units.

For a current winding	For a voltage winding[1]	For an external winding
Current	Resistance	Initial Current
	Inductance	
	Voltage	
	Initial Current	

> **Note:** You can also type a function as an expression for any of these fields except Initial Current.

d. Enter a value in the **Number of parallel branches** text box.

> **Note:** For the **Number of parallel branches** setting, the basic assumption is that the windings are symmetric and balanced, so the current split is forced to be equal in parallel branches. For solid or stranded windings, the **Number of parallel branches** setting assumes there are no circulating currents in the parallel branches.
>
> For solid windings, the **Number of parallel branches** setting is intended for applications meeting these conditions: For example, a periodic electric machine wedge model having solid hairpin windings, where the parallel branches are in the symmetric parts of the periodic model. In order to include unbalanced circulating currents this **Number of parallel branches** setting is not applicable, and you must use separate windings for each parallel branch that is connected in an external circuit.

4. Optionally, click **Use Defaults** to revert to the default values in the window.
5. Click **OK** to assign the excitation to the selected object.

A winding is now defined for your model.

To add a coil terminal to this winding, do the following:

1. In the project tree, right-click the winding, and select **Add Terminals**.
   The **Add Terminals** dialog box appears, listing all coil terminals that do not already belong to that winding.
2. Select the coil terminal (s) you want to add. To select multiple terminals, press **Ctrl** and click each terminal.
3. Click **OK**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To assign a coil terminal excitation and add it to this winding:

1. Select the section of the geometry on which you want to apply the coil terminal excitation.
2. In the project tree, right-click the winding, and select **Assign Coil Terminal**.
   The **Coil Terminal Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductor**s box.

   > **Note:** This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled

5. Click **Swap Direction** to change the reference direction for the coil terminal. You can also change this direction in the coil terminal's Properties window by selecting either **Point into terminal**, or **Point out of terminal** for the **Direction** parameter.
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the coil terminal excitation.
   The coil terminal excitation is assigned and is added to the winding.

To delete all coil terminal excitations that belong to this winding:

- In the Project Manager tree, right-click the winding, and select **Delete All Terminals**.
  All coil terminal excitations are removed from the winding and deleted from the excitations.

> **Note:** For 3D transient solutions using the A-Phi Formulation, refer to Winding Excitations for A-Phi Formulation for information on ordering the coil terminals.

---

1. For a solid winding, the resistance term can represent: the resistance of a portion of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source resistance. (The main winding resistance is calculated directly by the solver.) For a stranded winding, the resistance term is the complete DC resistance of the winding (since the solver does not determine resistance of a stranded winding) as well as the resistance of the end-effects, leads, source, etc. For both solid and stranded windings, the inductance term can represent: the extra inductance for a portion of the winding of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source inductance. (The main winding inductance itself is calculated directly by the solver.)

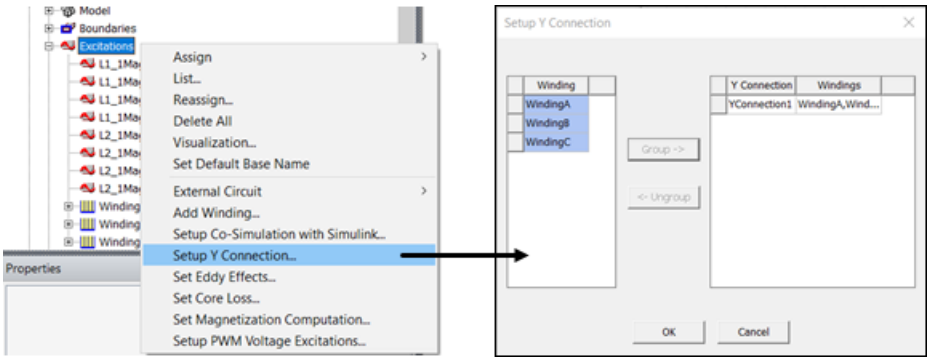
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setting Up an SVPWM Excitation

Pulse Width Modulation (PWM) is a term used for any method that produces a square wave signal with varying duty cycle and frequency to control the average power delivered to a load. PWM is widely used in applications such as light dimming, switching power supplies, and electric motor drive. In these types of designs, the AC motor needs to be powered by an alternating current excitation, which is supplied by the DC supply voltage through an inverter circuit using power device switches. Controlling how the power switches are turned on and off is accomplished by PWM.

For 3D magnetic transient T-Omega and 2D magnetic transient solutions, Space Vector Pulse Width Modulation (SVPWM) can be directly created in Maxwell for three-phase voltage-excited windings. For all three phases, Maxwell will calculate and create design datasets for the PWM voltage waveforms based on user inputs and automatically set up the winding excitations to use these datasets in transient simulations. The generated waveform represents the Phase-Neutral voltage, and it is only applicable to star (or Y) connected winding. Therefore, ensure that the Y connection is set up for the three windings applied to the SVPWM excitation.

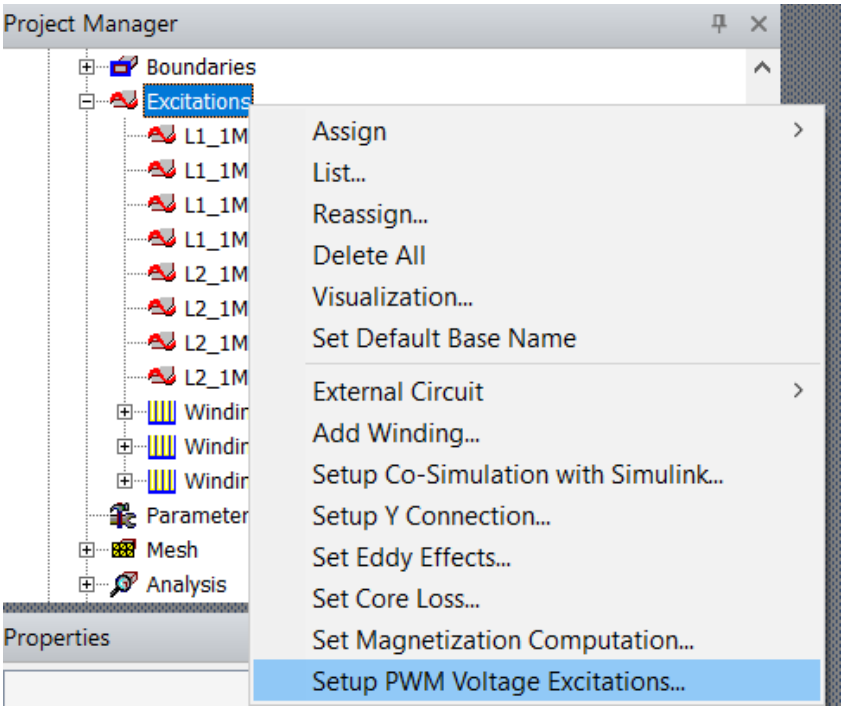
1. Before setting up the SVPWM excitation:
   a. Define three voltage windings.
   b. Set up the Y connection for the winding. Note that the Y connection is currently available for stranded winding, but it is not supported for solid winding.



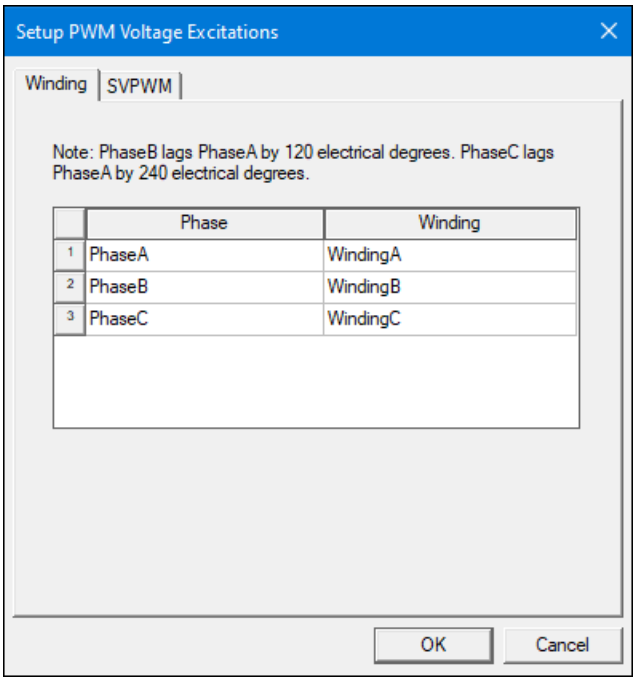
2. In the Project Manager tree, right click **Excitations**, and select **Setup PWM Voltage Excitations...**

   Alternatively, from the menu bar, select **Maxwell 2D/3D** > **Excitations** > **Setup PWM Voltage Excitations**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

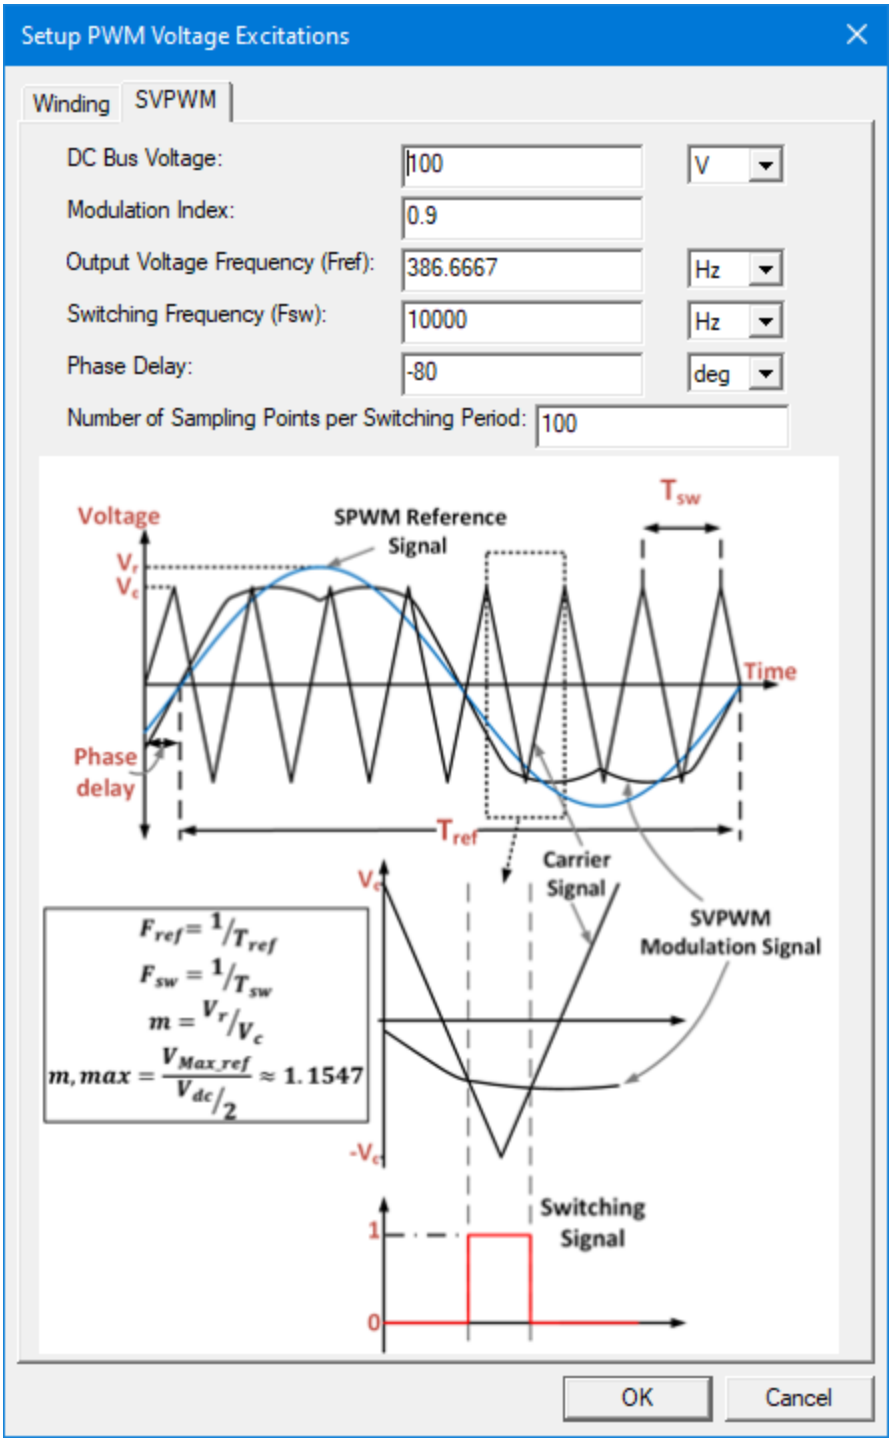


3. In the Setup PWM Voltage Excitations window that opens, arrange the three windings to represent the three phase windings (PhaseA, PhaseB and PhaseC) accordingly.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click on the **SVPWM** tab, and input the corresponding parameters for SVPWM. Example parameters are shown below:



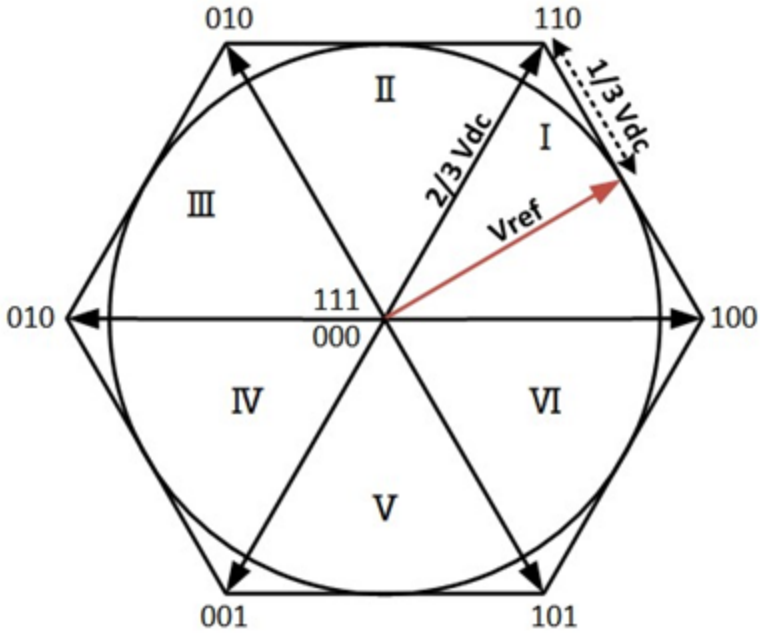
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **DC Bus Voltage** – Specifies the voltage available at the main DC bus as input to the inverter. This value can be entered directly or defined using a design variable.
- **Modulation Index** (m) – Specifies the ratio between the reference signal to the carrier signal; it determines the amplitude of the fundamental output voltage with respect to the available DC bus voltage as described by the equation below.

$$V_{peak,\ Phase-Neutral} = m * \frac{V_{DC}}{2}$$

The range of the modulation index is 0 < modulation index ≤ 2/sqrt(3) (*i.e.*, approx. 1.1547) for SVPWM. Note that this value cannot be defined with a variable.

To understand how the maximum modulation index is calculated, start with the figure below, which shows the space vector hexagon (represented by six sectors and eight vectors). Each vector represents a different switching state of the inverter.



The vector V_{ref} is the reference revolving voltage vector formed from the three phase sinusoidal voltages; at each sector, this vector is realized by alternating between the two nearest space vectors along with the zero vectors.

The circle inside the hexagon represents the maximum value possible for V_{ref} (and hence the output voltage) that can be produced with the SVPWM technique.

Knowing that the magnitude of each vector is 2/3 V_{DC}, the maximum value of the output voltage (V_{ref}) can be computed as

$$V_{RefMax} = \sqrt{\left(\frac{2}{3}V_{dc}\right)^2 - \left(\frac{1}{3}V_{dc}\right)^2}$$

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$V_{RefMax} = \frac{\sqrt{3}}{3} V_{DC}$$

From these definitions, the maximum modulation for SVPWM can be derived as

$$m_{Max} = \frac{V_{RefMax}}{\frac{V_{DC}}{2}} = \frac{2*\sqrt{3}}{3} \approx 1.1547$$

- **Output Voltage Frequency (Fref)** – Defines the fundamental frequency of the reference signal, and therefore, the PWM output voltage.
- **Switching Frequency (Fsw)** – Defines the carrier signal frequency that is used to generate the PWM switching signal. A typical value for traction inverters is between 10 – 20 kHz.
- **Phase Delay** – Defines the phase delay angle of the reference signal (and hence the output voltage). The phase delay depends on the operating point, and it can be provided from system-level simulation or by running a transient simulation with an ideal sinusoidal current and checking the phase delay on the output of the phase voltage.
- **Number of Sampling Points per Switching Period** – Defines the rate at which the carrier signal and the reference signal are compared to generate the switching signals. This value is important to correctly capture the switching events. The default (recommended value) is 100.

5. Click **OK**.

The technique used by the Maxwell application to implement SVPWM excitation computes the pattern of voltage pulses for each of the three datasets by comparing a triangular carrier wave with frequency Fsw and amplitude 1 to three reference functions.

Unlike for sinusoidal PWM, where the reference functions are sinusoidal, for this SVPWM implementation, the three reference functions (V_{a_Ref}, V_{b_Ref}, V_{c_Ref}) need to be constructed as a first step. This is achieved by superposing the common mode voltage (V_{CM}) to the three sinusoidal signals (V_{a_0}, V_{b_0}, V_{c_0}) of a three-phase system:

$$V_{a_Ref} = V_{a_0} + V_{CM}$$

$$V_{b_Ref} = V_{b_0} + V_{CM}$$

$$V_{c_Ref} = V_{c_0} + V_{CM}$$

V_{a_0} is defined as ModulationIndex*sin(2*pi*Fref*time-Phase Delay). V_{b_0} and V_{c_0} lag V_{a_0} by 120° and 240°, respectively.

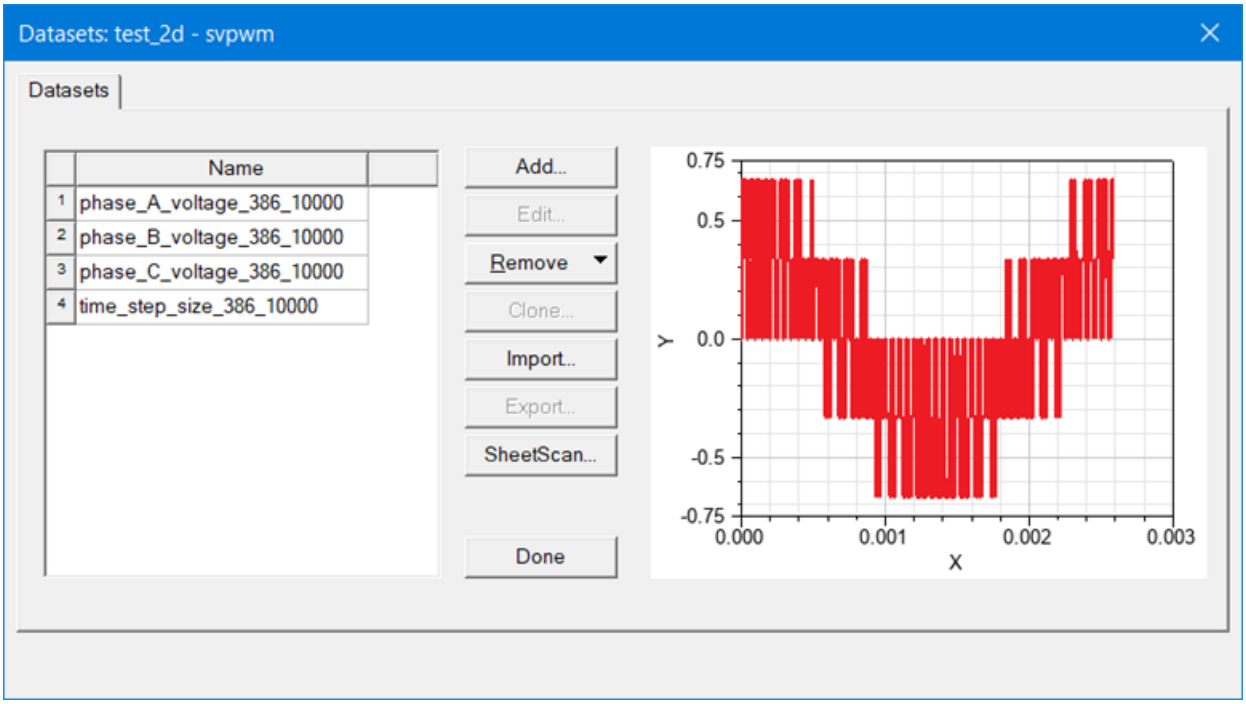
The amplitude V_{max} can be calculated as (DC Bus Voltage)/2 * Modulation Index.

At every timestep, the common mode voltage is calculated as half of the mid-valued function among V_{a_0}, V_{b_0}, V_{c_0}.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

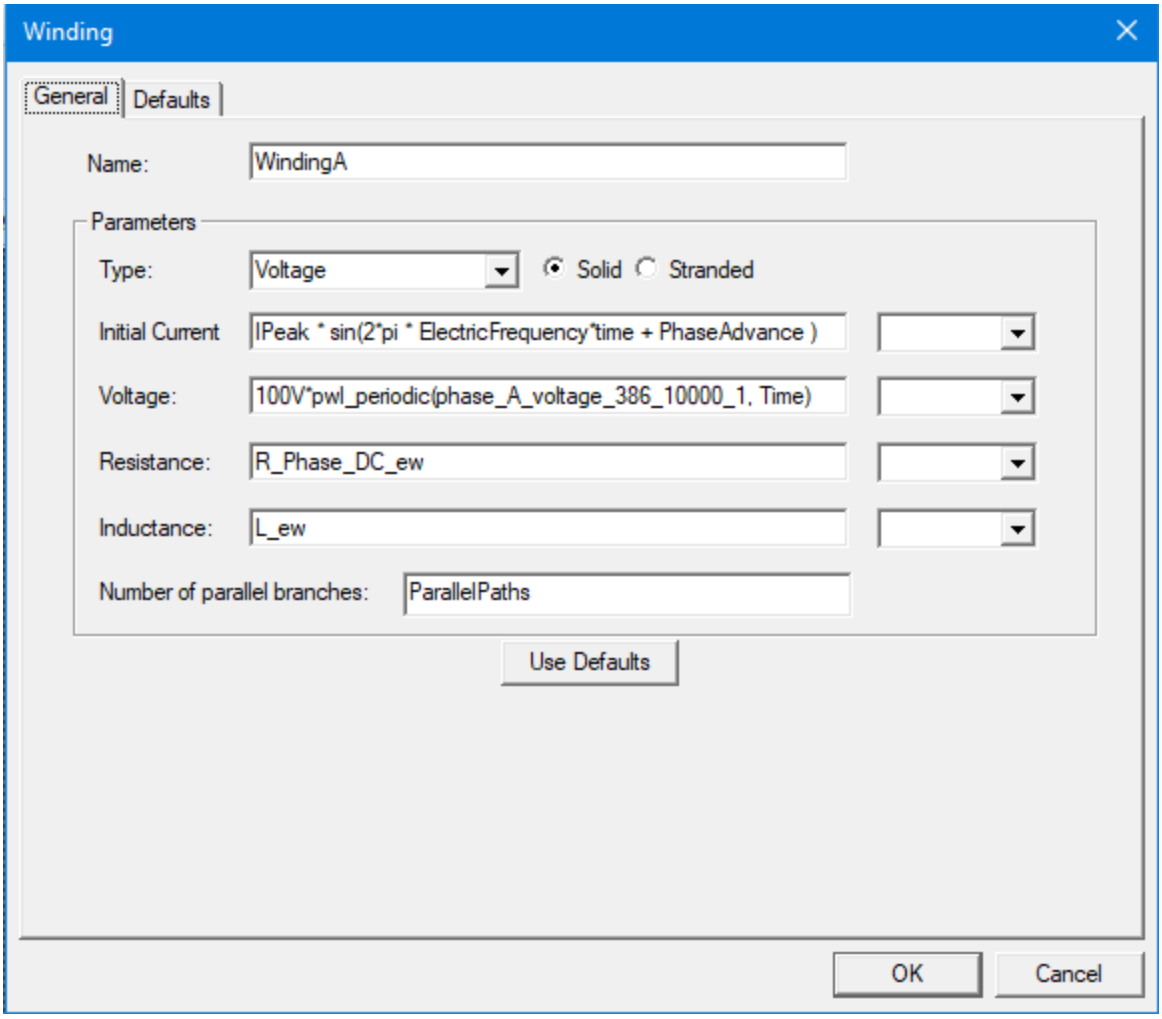
Three datasets of the voltage (Phase_X_voltage_<Fref>_<Fsw>) vs. time will be generated. The datasets are generated by comparing the reference signal to the triangular carrier at a sampling frequency Fsw*Number of Sampling Points per Switching Period. Subsequently, the datasets are reduced by removing the timesteps where no change of the voltage values occurs.

The datasets represent the three normalized PWM phase voltages for one electrical cycle. The phase sequence of the generated dataset is A-B-C with Phase B and C lagging Phase A with 120 deg and 240 deg, respectively. The generated datasets can be accessed from **Maxwell** > **Design Datasets** or by right clicking on the model in the Project Manager tree and selecting **Design Datasets**. The datasets shown below are based on previous example settings; the plot for phase_A_voltage is displayed.



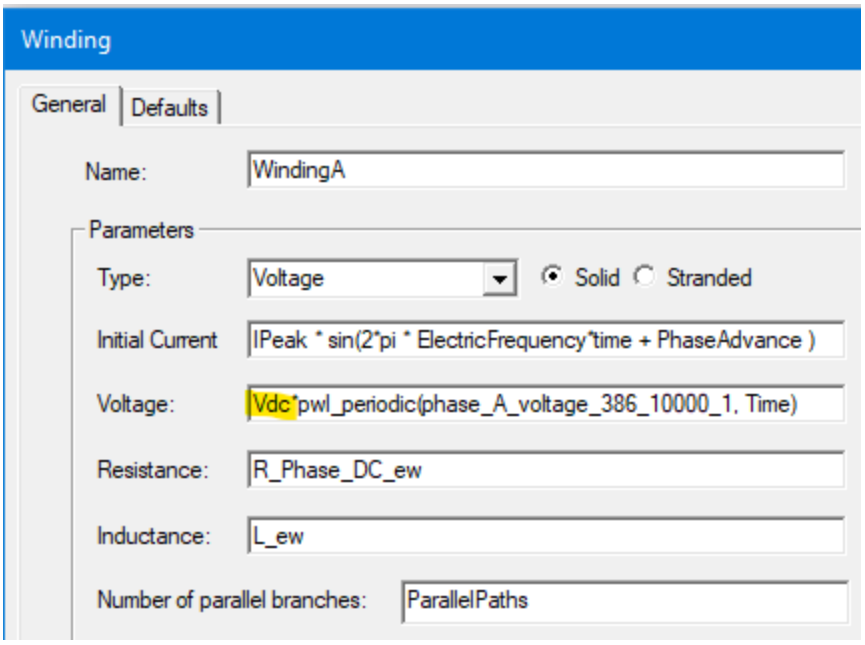
The phase datasets generated are added to the corresponding Winding Voltage value field in the format of **pwl_periodic**, which is used to ensure the voltage is periodic in case the simulation is longer than one electric cycle. WindingA is shown as an example:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



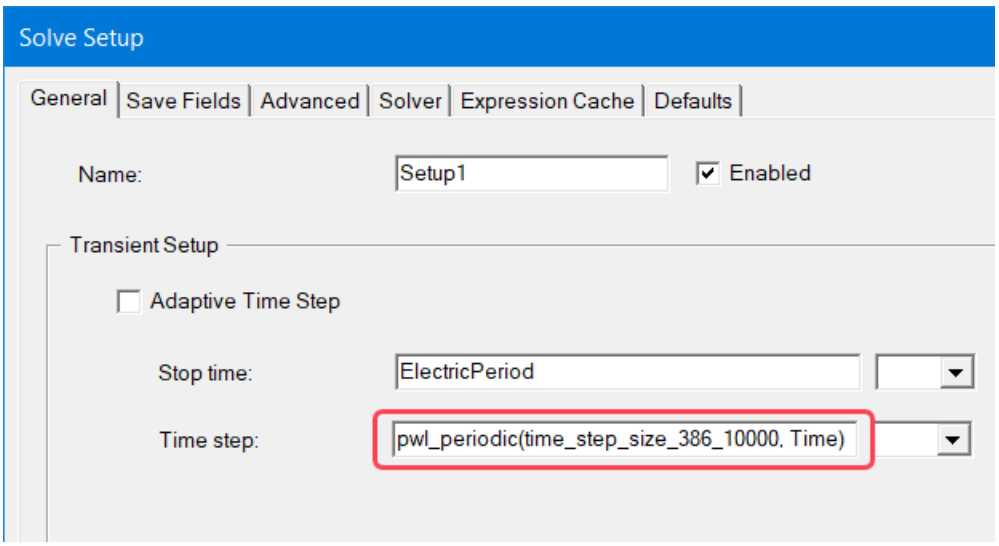
The expression is multiplied by the DC bus voltage that is defined on the **PWM Voltage Excitations** tab. All the other inputs will not be changed. If the DC Bus Voltage was defined as a variable, the variable will be used instead:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



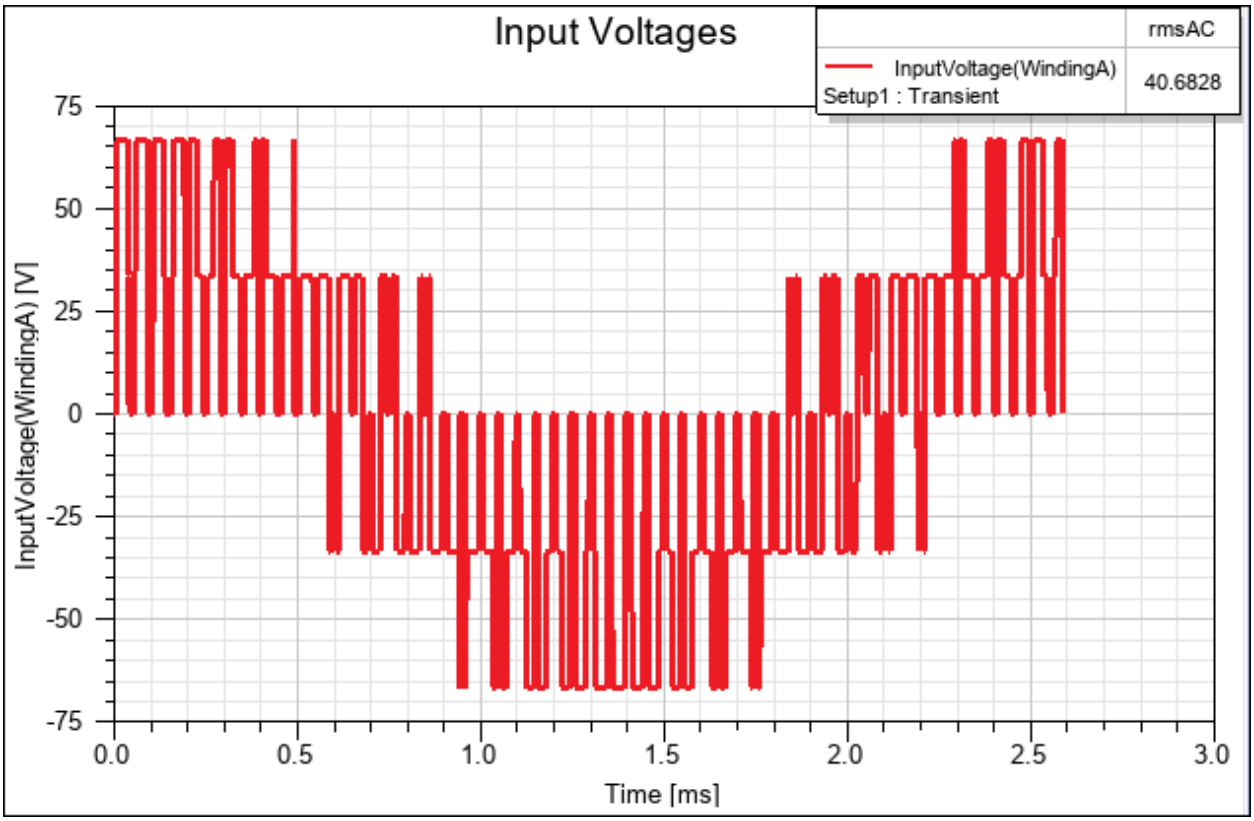
Users can change the Voltage value by adding multiples to the pwl_periodic function.

An additional dataset time_step_size_<Fref>_<Fsw> is created. This dataset tracks the exact instance the switching happens and will be used to define the variable time step in the transient setup to ensure that all switching events are captured with the minimum number of time steps possible. This dataset will be added to the Solve Setup Time step value field in the pwl_periodic format:

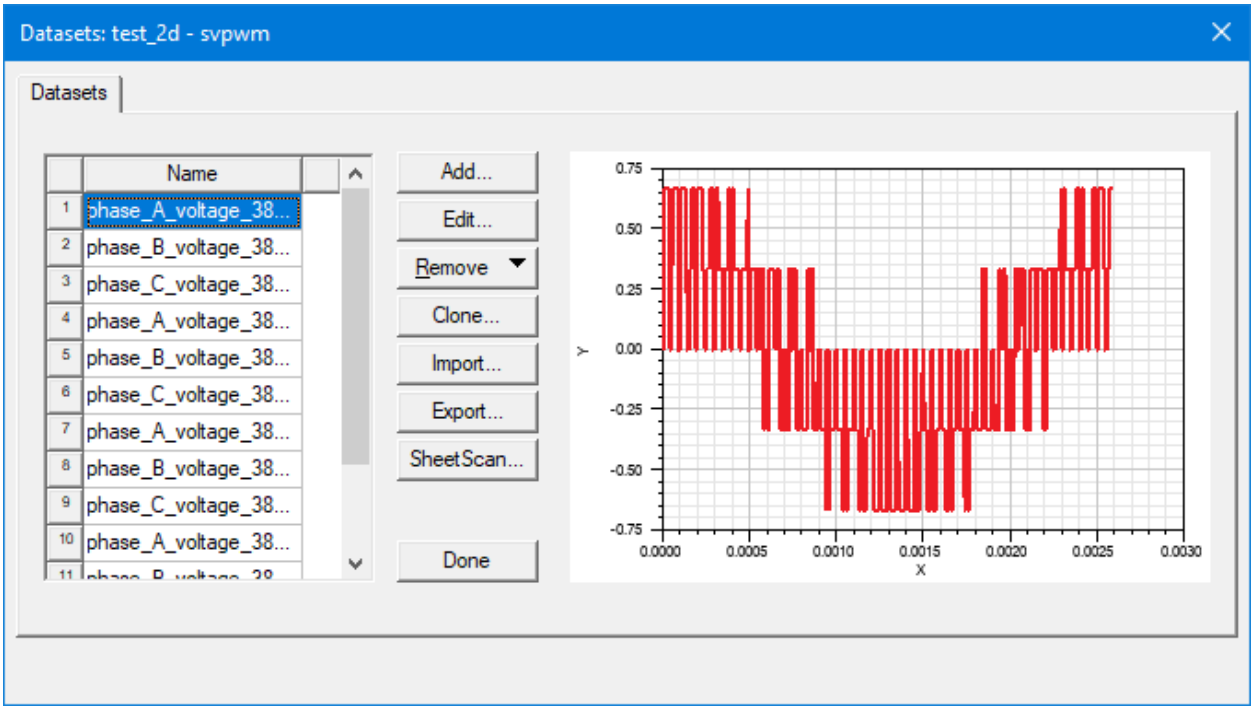


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once the design is analyzed, the user can plot the PWM voltage applied to the windings, which resembles the dataset created by PWM Voltage Excitations function, as shown in the following images:

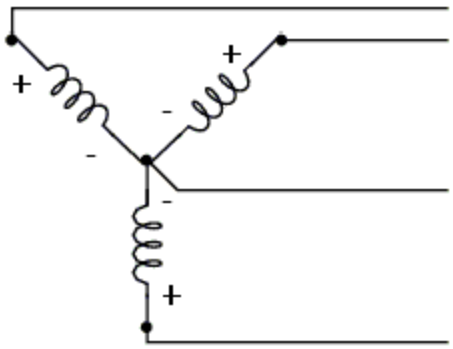


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Setting Up a Y Connection

The Y Connection function available in 2D and 3D Transient solution types allows multiple windings to be connected in a classical Y (sometimes referred to as wye) configuration with the negative terminals connected to a common node as illustrated below.



Setup Y Connection requires voltage winding definitions be set and the negative voltage terminal for each winding will be connected to form the common node of the circuit.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Each voltage source specified in the winding description drives the positive side of the coil. Y Connections are commonly used in motor and transformer applications driven by 3-phase voltage; however, any number of windings may be connected to a common node in Maxwell.

> **Note:**
>
> - Only one Y Connection is allowed in a given Maxwell design.
> - A Y Connection requires use of stranded voltage windings.
> - Duplicate windings are not allowed.

To define a Y-connection:

1. Click **Maxwell 2D** (or **Maxwell 3D**) > **Excitations** > **Setup Y Connection**.

   The **Setup Y Connection** dialog box appears.
2. In the **Winding** list on the left, select the windings to be grouped into a Y connection.
3. Click the **Group** button to create a Y Connection group with the selected windings.
4. Click **OK** when all required grouping have been created.

Setting Up an External Circuit Connection for an External Winding Type

The Maxwell Circuit design editor is used to set up the external circuit excitation for windings in Maxwell 2D and 3D transient solutions.

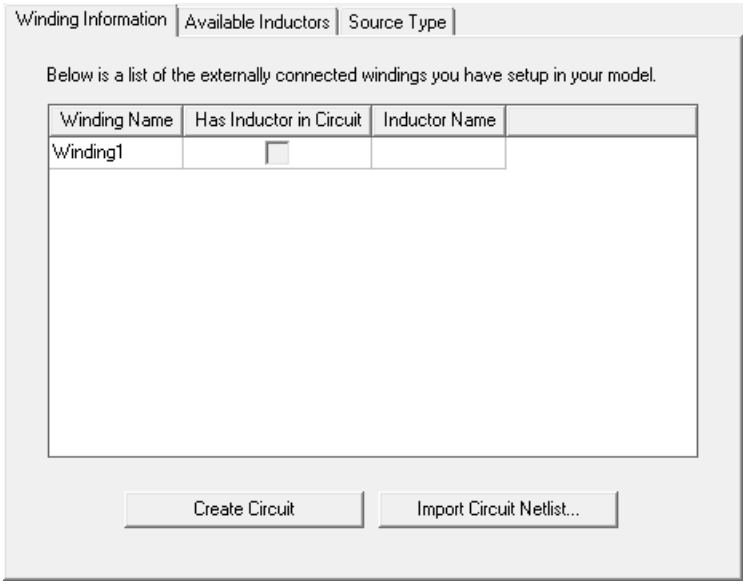
> **Note:** External circuits intended for use with the Time Decomposition Method (TDM) can only support basic circuit elements that are solution-independent. This is because, for TDM, all timesteps (or all timesteps in a subdivision) are solved simultaneously - and thus the circuit topology and its parameters must be known before solving. Therefore some circuit elements, such as solution-dependent switches, diodes, capacitors, and inductors which are not directly connected to windings in series, are not supported.

To set up an external circuit connection for an External winding type:

1. Click **Maxwell 3D** > **Excitations** > **External Circuit** > **Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit** > **Edit External Circuit**.

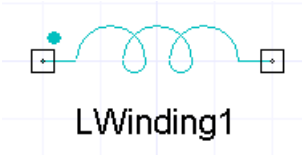
   a. If no external winding connections have been set up for your model, the **Winding Information** tab lists the external winding(s) in the design. Continue with step 2.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



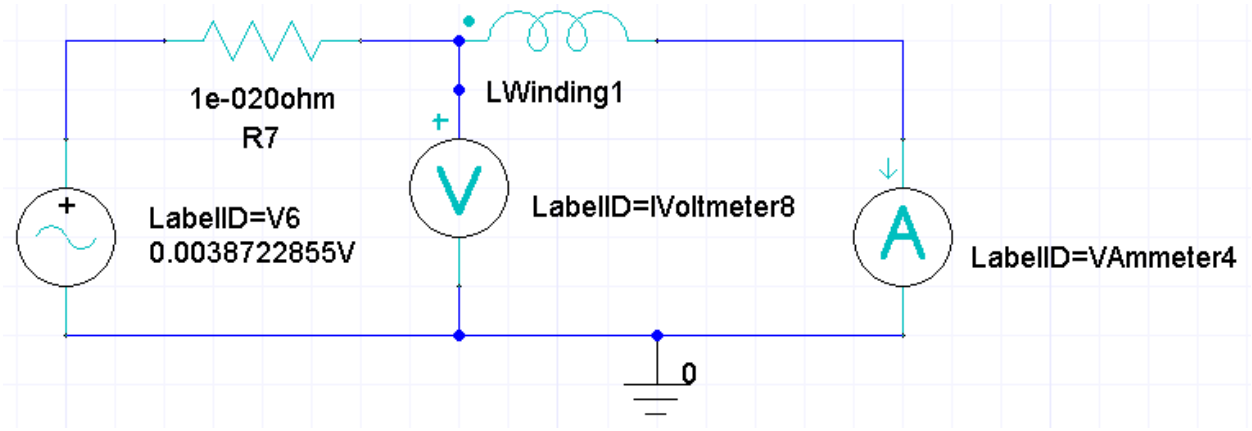
b. If external windings have already been set up, continue with step 7.

2. On the **Winding Information** tab, click **Create Circuit** to add a circuit design to the project. The new circuit design automatically opens for editing in the Maxwell Circuit Editor. The circuit includes one inductor for each external winding in the original Maxwell transient design. The following example is for a design having one external winding.



3. Add the components needed to complete the external circuit design such as shown the following example.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. When the circuit design is finished, click **Maxwell Circuit** > **Export Netlist** and export the netlist **.sph** file to the desired location.
5. Return to the Maxwell design and click **Maxwell 3D** > **Excitations** > **External Circuit** > **Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project Manager tree and select **External Circuit** > **Edit External Circuit**.
6. On the **Winding Information** tab, click **Import Circuit** to import the circuit.
7. To view a list of inductors in the imported circuit, click the **Available Inductors** tab.
8. To view the sources used in the externally connected windings, click the **Source Type** tab.
9. If variables are used in the imported circuit, they and their design values are listed on the **Parameter Values** tab. You can link to variables within the imported circuit as follows:
    a. On the **Parameter Values** tab, click in the **Value** column of the parameter to be mapped.
    b. Enter a new local variable name and press the `Enter` key to open the **Add Variable** dialog.
    c. Select a **Unit Type** and **Unit**, and enter a **Value** for the variable and click **OK**. The new Maxwell variable is now mapped to the variable in the imported circuit, and can be varied directly by Maxwell or used for optimetrics analyses.
10. If the imported file is a .**sph** file, you can click the **Circuit Path** tab to view the original project and design names (which are removed after you import a non-sph file).

> **Note:** After you import a circuit netlist, the **Create Circuit** button changes to **Update Netlist from Circuit**. Use **Update Netlist from Circuit** to reimport the netlist to keep it current.

11. Click **OK** to close the **Edit External Circuit** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

For transient designs, the user-set timesteps can be modified when external circuits are used to drive the windings of a transient finite element model. Following is a list of situations that will lead to a timestep change:

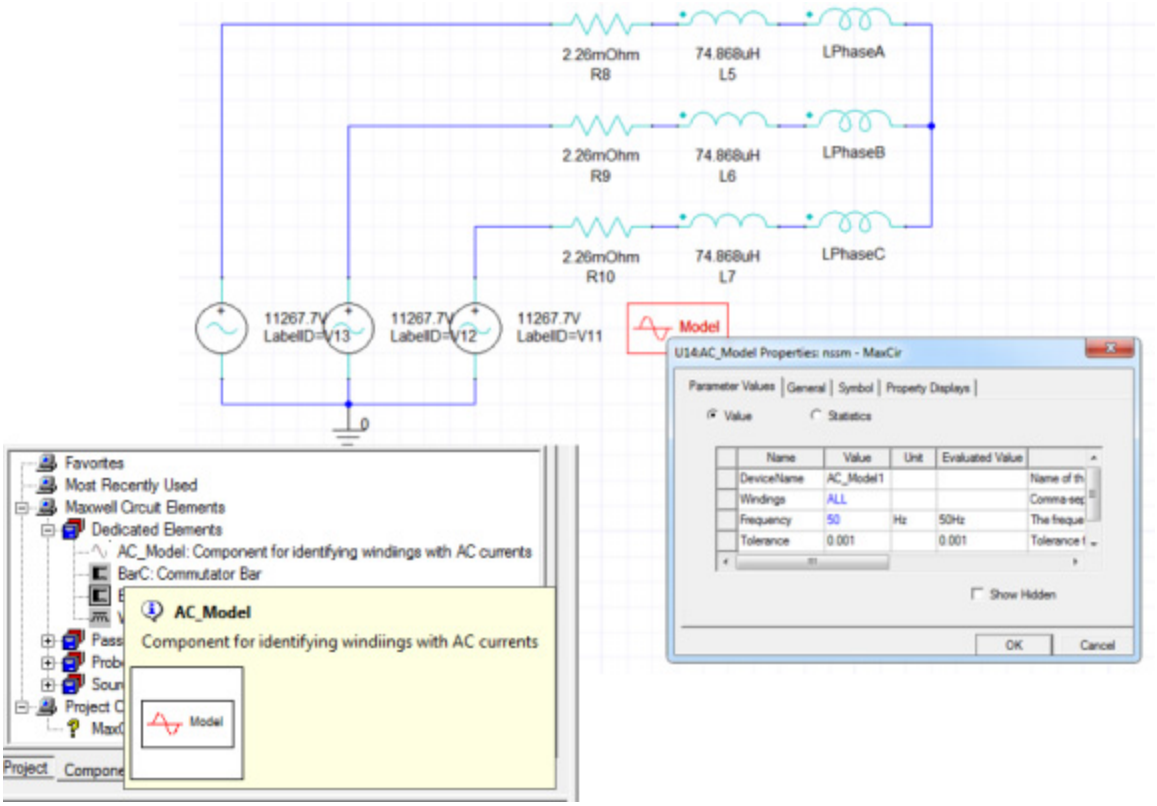
- All power electronic switching instances that do not coincide with user-specified solve times request a new solution time from the transient solver. The respective switching generating a new solve time request for the transient solver can be time, position, or speed dependent.
- When current and/or voltage sources with a piecewise linear variation are used, a new solution time is requested from the transient solver at each (time) definition point used in the corresponding source definition table.
- When the change in any winding inductance value is excessive, a new timestep (smaller) is calculated and a new solution generated (recalculated) accordingly.

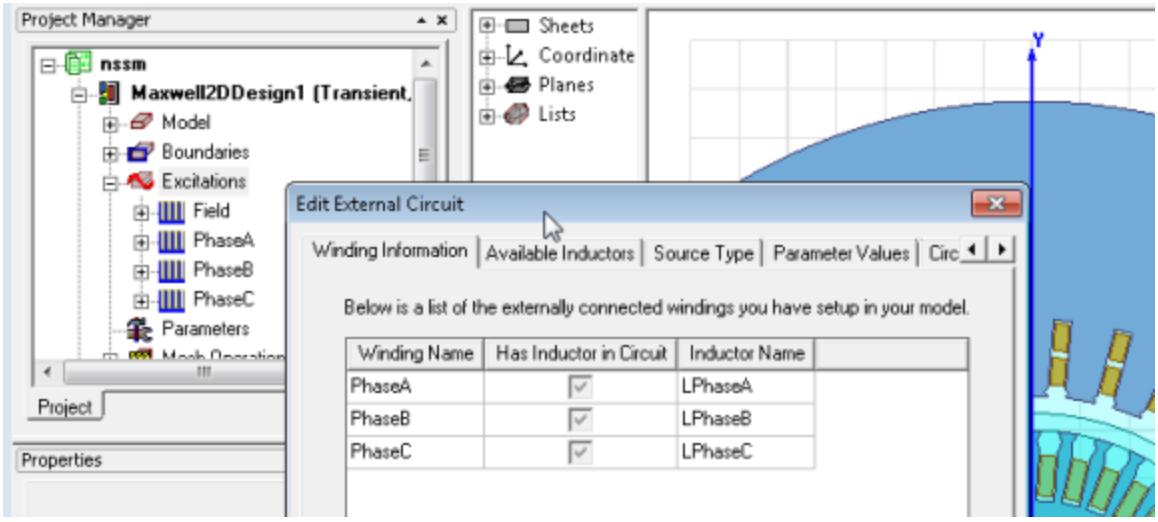
If a user-specified save field time is missed because of the above reasons, the next solved timestep fields are saved instead.

Using the AC_Model Component to Speed Up Analysis

Use of the AC_Model component when setting up an external circuit design can improve transient analysis time to steady state significantly.

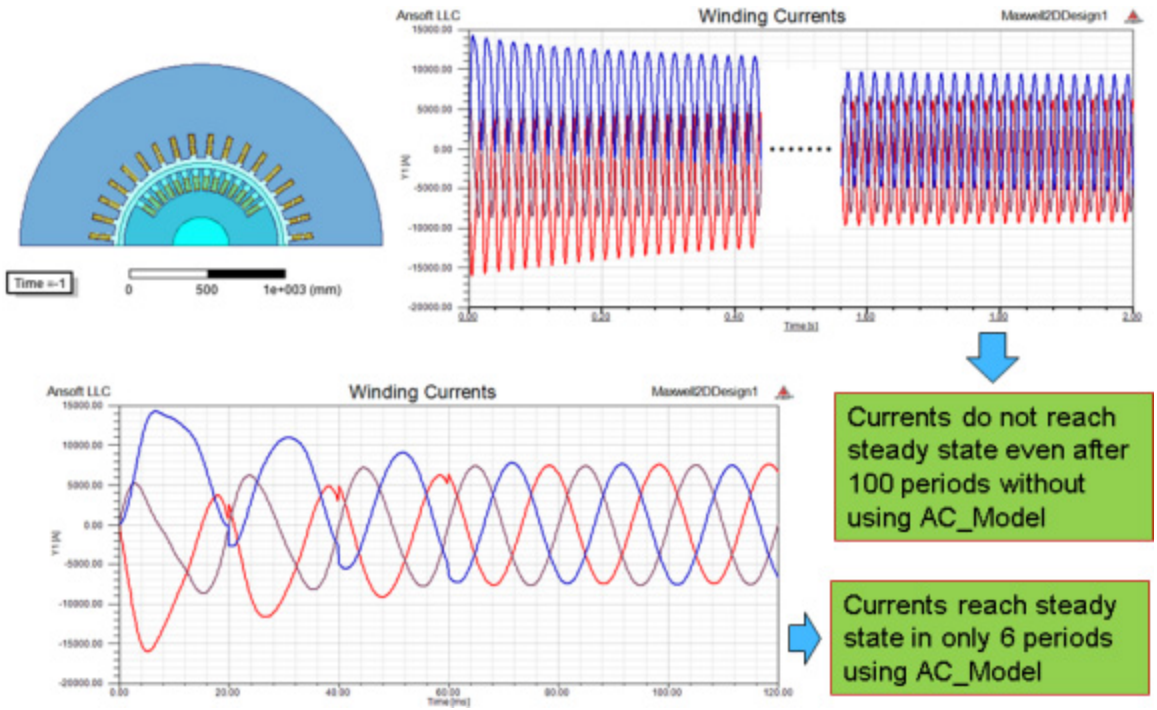
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





In the above example the AC_Model is associated with ALL three of the phase windings. The AC_Model modifies currents for the AC windings at the beginning of each period without interrupting the transient process - thus improving the analysis time.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Setting Up an External Circuit Using Simulink

In addition to using the Maxwell Circuit Editor to set up an external circuit, you also can use MATLAB® Simulink® to set up an external circuit for both Maxwell 2D and 3D transient designs.

Supported Simulink versions are

- R2019b
- R2020a
- R2020b
- R2021a
- R2021b
- R2022a
- R2022b
- R2023a

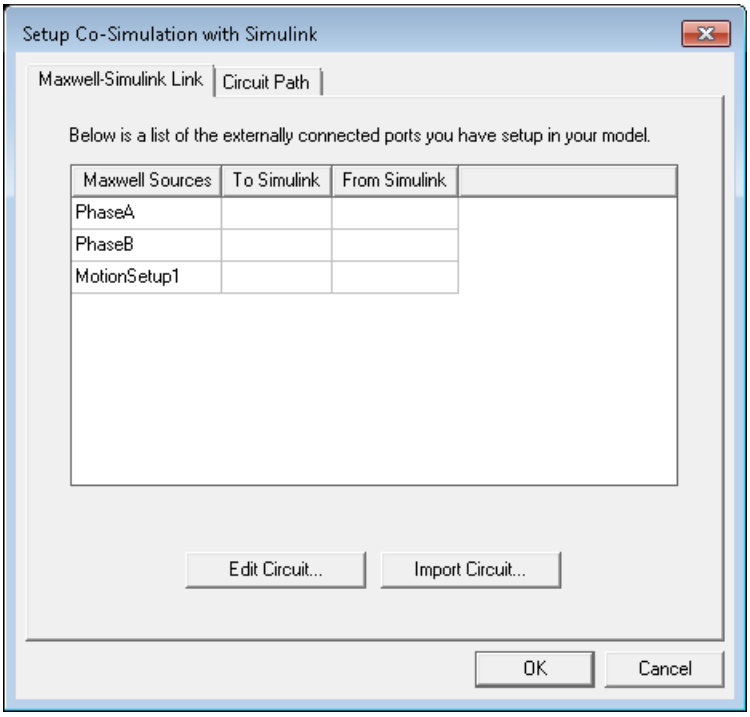
In addition to winding sources, motion sources can also be linked in the external circuit.

- Winding sources ("External" type only): voltage, current, and flux linkage.
- Motion sources: speed, position, and force/torque

To set up an external circuit using Simulink:

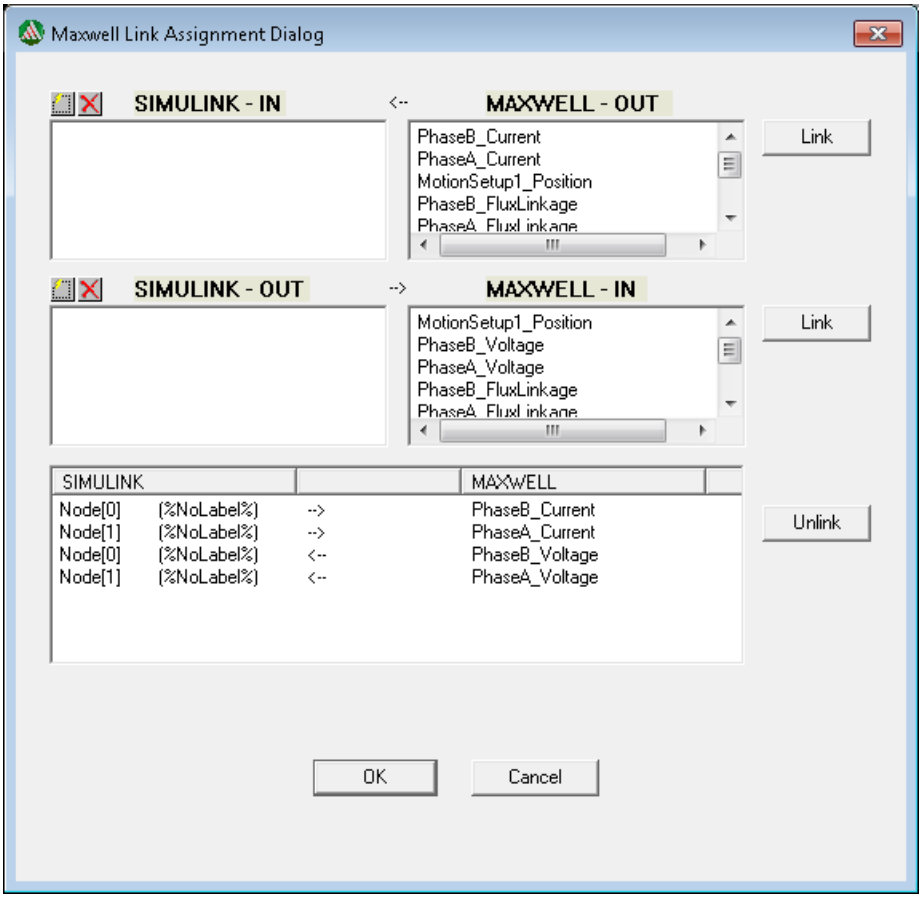
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the Maxwell Project Manager, right-click **Excitations** and select **Setup Cosimulation with Simulink** to open the **Setup Cosimulation with Simulink** dialog box. You can also open the dialog box from the main **Maxwell 2D** or **3D** > **Excitations** menu. If an external Simulink circuit has already been created and linked, **To Simulink** and **From Simulink** connections information is shown. Otherwise, these table cells are empty.



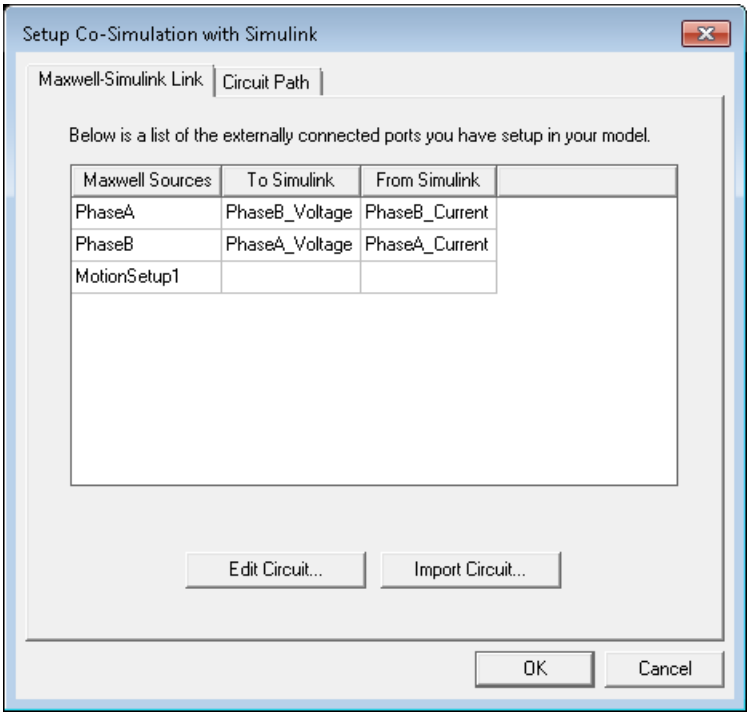
2. On the Maxwell-Simulink Link tab, click the **Edit Circuit** button to launch Simulink. The Maxwell sources are listed in the in the **Maxwell Link Assignment Dialog** box. If a circuit has already been created, the circuit also displays in the Simulink circuit editor window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Add **Link** SIMULINK - IN and SIMULINK- OUT connections to the desired Maxwell parameters to set up the Maxwell component ports. You can also **Unlink** connections as needed. Click **OK** once the ports are set up. The ports will show in the Simulink circuit editor window.

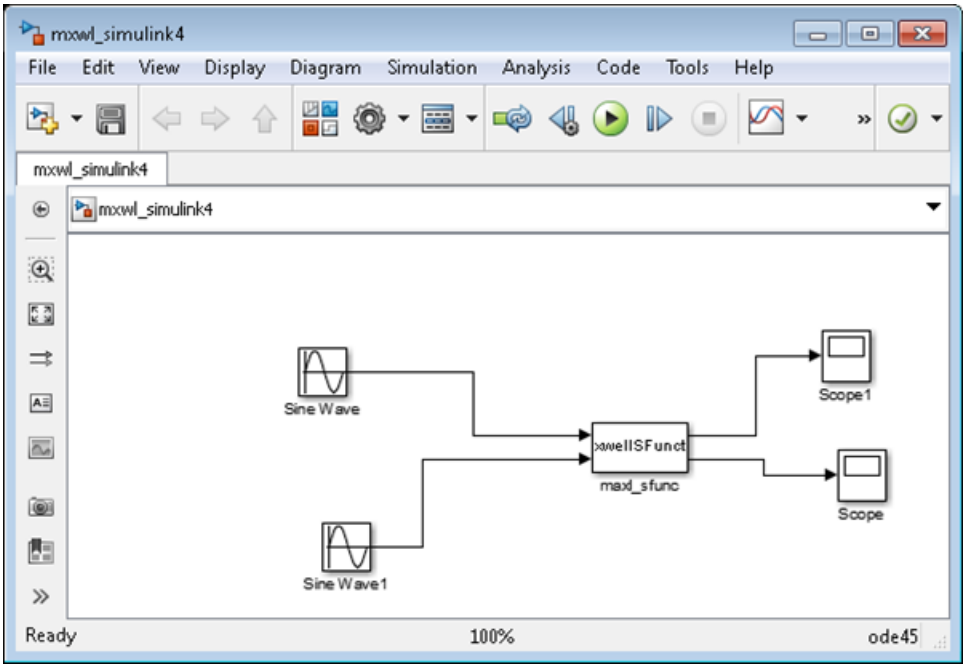
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If changes are needed, click **Edit Circuit** to reopen the **Maxwell Link Assignment** dialog box.

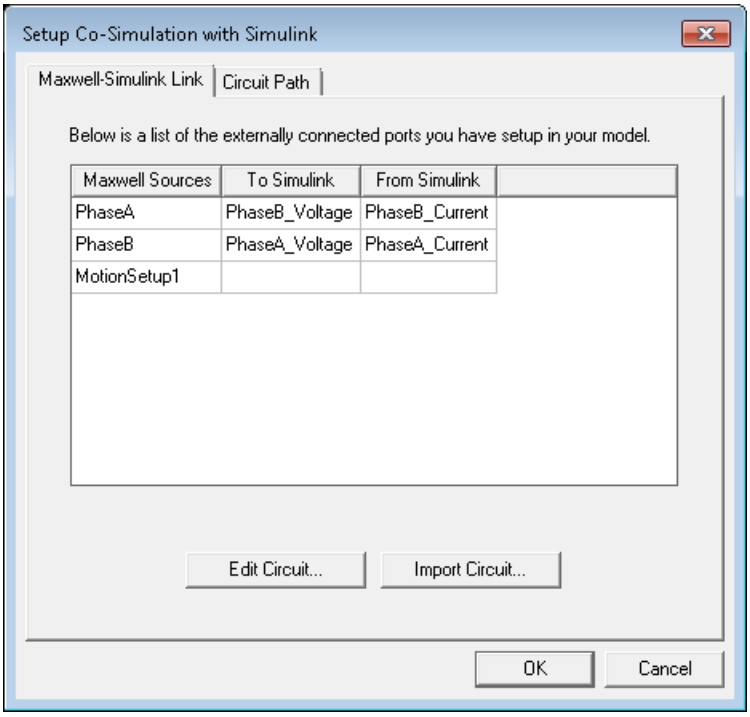
4. Modify (or create) the circuit in the Simulink circuit editor window as needed, and save the Simulink circuit project.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. In the Maxwell **Setup Cosimulation with Simulink** dialog box, click the **Import Circuit** button to import the Simulink circuit project into the Maxwell project. The linked connections appear in the **Edit External Circuit** dialog box. The **Circuit Path** tab shows the path to the location from which the Simulink circuit file was imported.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



> **Note:** You can also modify an existing Simulink circuit by opening the circuit file directly in Simulink, and then importing the modified circuit file back into the Maxwell design.

6. When you start the Maxwell design analysis, the cosimulations are started between Maxwell and Simulink.

> **Note:**
>
> - Making changes to the Maxwell winding and motion setups invalidate the external circuit.
> - Making changes to the external Simulink circuit setup invalidates the solutions.

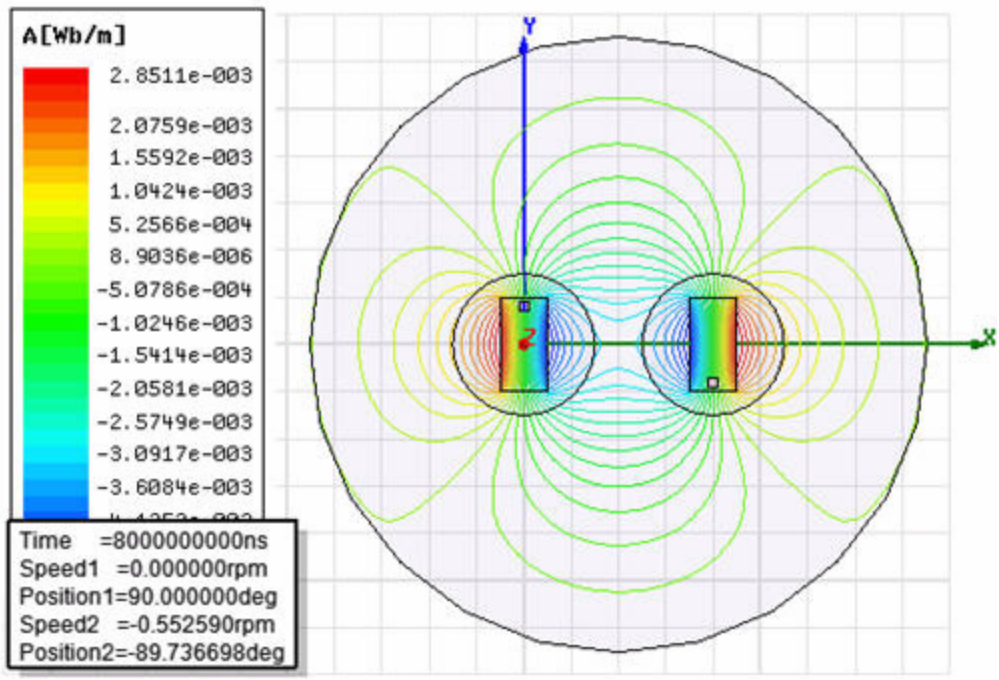
Setting Up Motion for Transient Projects

For projects where you selected transient as the solution type, you can define how the model components move in relation to one another. This is accomplished by assigning a **MotionSetup** to a **Band** object. Two or more motion bands may be assigned, each with its own independent motion characteristics. Multiple motion bands are used primarily for certain types of motors where multiple rotors may rotate about a common central axis; however, other applications are possible as shown in the following examples.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Example - Two Bands of Motion

The project shown below comprises two rectangular magnets, each surrounded by a band object with a MotionSetup assigned to it. When one magnet moves, the other magnet realigns itself. Also note that the solution context display shows the position and speed for both motion setups.

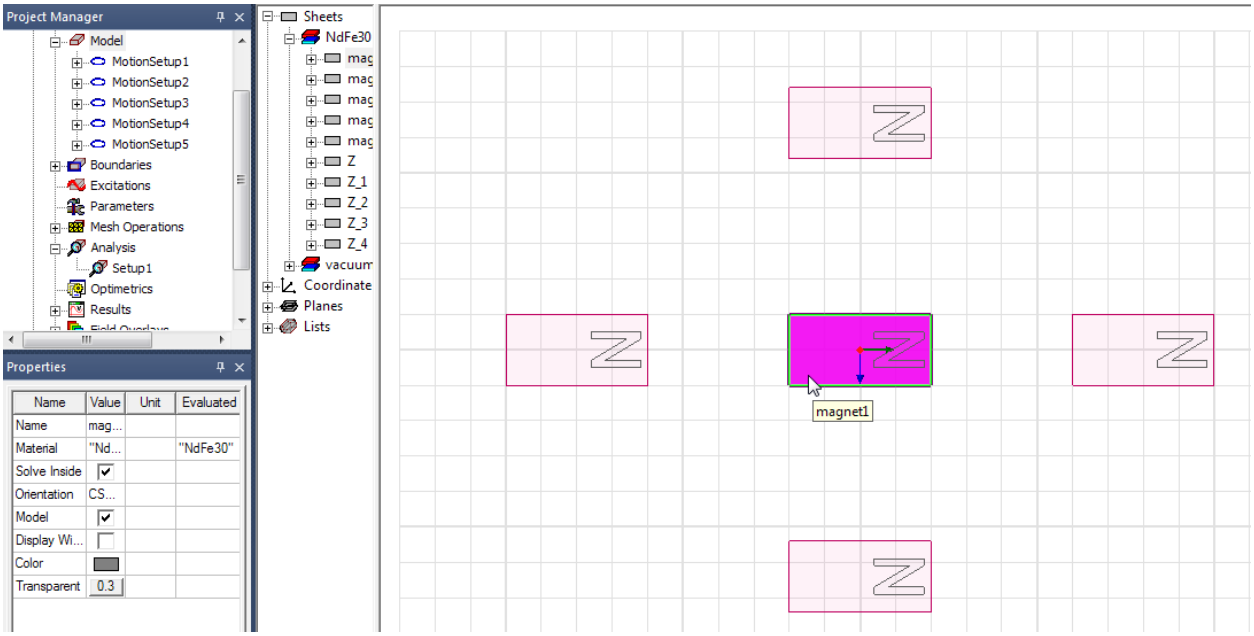


> **Note:** The two moving bands must not touch each other. There must be some stationary region between the two bands, even if it is filled only with vacuum.

Example - Multiple Bands of Motion

The magnet project shown below comprises five bar magnets. When the center magnet (MotionSetup1) moves, the other magnets also move.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note: The moving bands may not touch each other. There must be some stationary region between the bands, even if it is filled only with vacuum.

Assigning a Band of Motion

You can assign a band of motion in both Maxwell 2D and Maxwell 3D projects. For both Maxwell 2D and 3D projects, two or more motion bands may be assigned.

Note: Overlapping bands are not supported so they cannot be located inside of each other.

For both rotational and translational problems, the band object must always enclose all of the moving objects. For rotational problems, this means the band object should be a solid cylinder or a solid wedge – not a hollow shell or segment of a shell. If the band object encloses all moving aspects, it is easier to identify the moving objects and reduces errors related to misidentifying them.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: An inner region (or wrapper object) enclosed by the band can normally be used as a “fake” moving object for two reasons:

- The first is to avoid creating holes inside the band which would result in the band having multiple connected domains.
- The second is due to the torque/force computation being carried out by one layer of elements inside the band region that directly touches moving objects. If an inner region is not included, the torque/force computation will be very sensitive to mesh noise - thus leading to an inaccurate solution.

Note: For 2D and 3D translational motion, here are some additional recommendations:

- An all-encompassing inner region (non-magnetic, non-conductive wrapper such as air or vacuum) must be used around all moving objects in a band.
- The inner region wrapper object, like the Band itself, should be a simplified shape, such as a rectangle or polygon in 2D, or a polyhedral or segmented sweep section in 3D. Any simplifications to the inner region and band object will result in better re-meshing for each time-step and faster overall simulation times.
- In order to give more accurate forces, if there is sufficient clearance between moving and stationary objects, you can provide some padding between the inner region and the moving objects and the band. At a minimum, the inner region should be the same size as the outside of the enclosed objects (like shrink wrap) with no gap between the wrapper and objects inside.
- Ansys highly recommends that the band not touch any outer stationary objects, with the only exception being for symmetry boundaries on the outer region. It is suggested to locate the band halfway in the air-gap between fixed and moving objects or equally spaced with the inner region object if there is sufficient clearance at the gap.
- In order to get stable force results, length-based mesh operations (approximately equal to the distance between the band and the inner region) should be applied using the Length-Based-Inside mesh refinement assigned to the Band object so that the mesh length is refined in the band region that is re-meshed for each time-step.

To assign the band of motion:

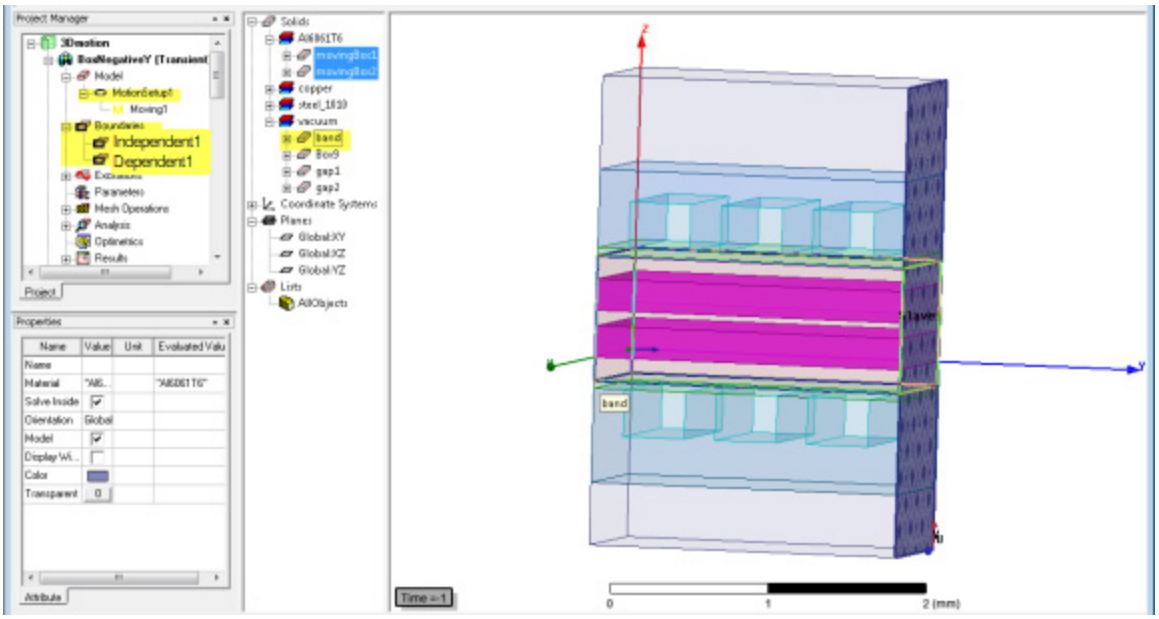
1. Select the band object.
2. Click **Maxwell** > **Model** > **Motion Setup** > **Assign Band**.

   The **Motion Setup** window appears.
3. On the **Type** tab: select either **Translation** or **Rotation** as the **Motion Type**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For **Rotation** about a fixed point you may select the **Non-Cylindrical** check box.
- For **Translation**, you may select the **Periodic** check box.

For **Periodic** motion, you must define independent and dependent boundary conditions. Both band and the object(s) inside it move, and both should touch the independent and dependent boundaries as shown in the following example.



4. Set the motion direction:
   a. For **Translation** (including **Periodic**), select the desired X, Y, or Z (for 3D) axis of motion from the **Moving Vector** drop-down menu; then select either **Positive** or **Negative** direction.
   b. For **Rotation**, from the **Moving Axis** drop-down menu, select an axis of rotation. Use the radio buttons to select either **Positive** or **Negative** rotation.

   Note:
   - For 2D XY rotation, only **Positive** rotation is allowed.
   - If the expected moving vector does not exist, click **Modeler** > **Coordinate System** > **Create** > **Relative CS** to create a new coordinate system.

5. On the **Data** tab: type a value in the **Initial Position** box, and select the units from the drop-down menu.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. To set the motion limits, do the following in the **Translate Limit** or **Rotate Limit** section:

   Note: For Periodic motion, you do not need to define motion limits because the solver does not consider the limits for periodic motion; thus the **Translate Limit** section is not present.

   a. For rotational motion, click the **Rotate Limit** check box.
   b. For translational (non-**Periodic**) or rotational motion, type a value in the **Negative** box, and select the units from the drop-down menu.
   c. For translational (non-**Periodic**) or rotational motion, type a value in the **Positive** box, and select the units from the drop-down menu.

7. On the **Mechanical** tab, do one of the following to specify the object velocity (dynamic or constant):

   Note: When you select **Consider Mechanical Transient**, you are telling the solver to use the calculated force and user-specified mass, damping, and other parameters to dynamically determine how the object moves, rather than giving it a constant velocity.

   Note:
   - For Maxwell 2D/3D designs for motor applications, the computed output mechanical power at given constant speed may not reach the desired rated power. Therefore, it is useful to apply constant power as the mechanical load. In Maxwell 2D/3D designs created by RMxprt, the mechanical transient is set up according to the rated mechanical output power, and equivalent damping is added to accelerate the process approaching to the rated output power. This setup is visible when **Consider Mechanical Transient** is checked.
   - The **Consider Mechanical Transient** setup is only for the sake of getting the operating point with given output power. it is not related to any mechanical load type you may set in RMxprt.
   - 2D/3D designs generated from RMxprt include the setup data, but **Consider Mechanical Transient** is unchecked initially. To ensure that the setup data is preserved, make sure that you check **Consider Mechanical Transient** before saving the project.

   - To dynamically change how the object moves, click the **Consider Mechanical Transient** check box, complete the following fields, and select any corresponding units:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Initial Velocity** (translational) or **Initial Angular Velocity** (rotational)
- **Mass** (translational) or **Moment of Inertia** (rotational)

Use the **Calculate** button to have Maxwell calculate the Mass or Moment of Inertia with the following restrictions:

- For 2D problems, the moving bodies are assumed to be of model-unit thinness.
- Rotating bodies must be symmetric about the axis of rotation. Partial models (e.g., half a motor with implied symmetry) are not supported.
- **Damping** (rotational motion) – A value for damping for rotational motion (for electric machines) can be calculated by the windage and friction loss in Watts divided by the speed in rad/sec (at which those losses are defined); the resulting units are in W / $(rad/sec)^2$ or N*m * sec/rad.
- **Damping** (linear motion) – A value for damping for linear motion can be calculated by the windage and friction loss in Watts divided by the speed in m/sec (at which those losses are defined); the resulting units are in W / $(m/sec)^2$ or N*m * sec/m.
- **Load Force** (translational) or **Load Torque** (rotational)

  Note:
  - For translational motion, the load force is positive if it is applied in the same direction as the moving vector and negative if applied in the opposite direction.
  - For rotational motion, the load torque sign is determined based on the moving vector, using the right-hand rule. Point your thumb in the direction of the moving vector. If the load torque is applied in the same direction as your fingers, then the load torque is positive. If it is applied in the opposite direction, then the load torque is negative.

- To set a constant velocity (and disable the mechanical transient), clear the **Consider Mechanical Transient** check box, type a value in the **Velocity** or **Angular Velocity** box, and select the units from the drop-down menu.

8. For translational motion, a **Post-Processing** tab is available to set the coordinate system for post processing calculation.
9. Click **OK**.

- A **MotionSetup*x*** is created and added to the **Model** folder in the **Project Manager** window.
- For Maxwell 3D projects only, if cylindrical **Rotation** was specified and a **CylindricalGap** mesh operation does not already exist, a **CylindricalGap** mesh operation is automatically added to the **Mesh** folder. Only one **CylindricalGap** mesh operation is permitted.

Modifying Motion Setup Properties

To modify existing motion setup properties:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the Project Manager **Model** folder, right-click on **MotionSetup*x*** and select **Properties** from the context menu to open the **Motion Setup** dialog box.
    - Alternatively, you can double-click the **MotionSetup*x*** icon.
2. Edit the desired properties in the **Motion Setup** dialog box. Refer to *Assigning a Band of Motion* for detailed information on the various **Motion Setup** dialog box settings.

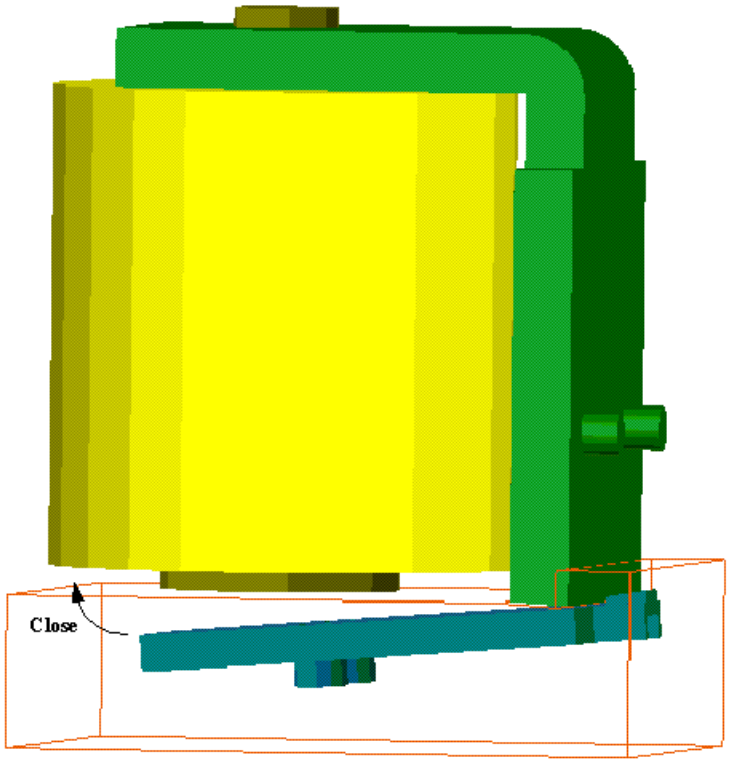
> **Note:**
>
> For Maxwell 3D projects only:
>
> - If you change the motion type to cylindrical **Rotation** and a **CylindricalGap** mesh operation does not already exist, a **CylindricalGap** mesh operation is automatically added to the **Mesh** folder. Only one **CylindricalGap** mesh operation is permitted.
> - If you change a cylindrical **Rotation** motion type to another motion type, the **CylindricalGap** mesh operation remains in the **Mesh Operation** folder.
> - Alternatively, you can edit many of the motion setup properties in the **Properties** window.

Non-Cylindrical Rotational Motion

With cylindrical rotation, the moving objects are free to rotate completely, and the mesh remains fixed as the moving objects rotate. With non-cylindrical motion, the geometry shape of the band region changes as the moving objects rotate, and the mesh is recreated.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- A motor is an example of cylindrical motion.
- A relay is an example of non-cylindrical motion.



Reassigning a Band of Motion

When a **MotionSetup** has been created, the object that the setup is assigned to is changed using the **Reassign** command, allowing you to identify the motion setup parameters with a new object without losing the motion setup parameters themselves. To reassign a **MotionSetup**:

1. Select the object that the **MotionSetup** will be reassigned to in the modeler window or in the history tree.
2. Right-click on **MotionSetup*x*** in the Project Manager window and select **Reassign**.

> **Note:** An existing **CylindricalGap** mesh operation's assignment will be synced up to a rotational cylindrical motion setup's assignment when you reassign the band object of the motion setup.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Adding and Deleting Objects from a Band of Motion

To add objects to, or delete objects from a motion setup without changing the parameters of the **MotionSetup** do the following:

1. Select the object to be added or deleted from the **MotionSetup** in the modeler window or in the history tree.
2. Right-click **Model** > **MotionSetup*x*** > **Moving*x*** in the Project Manager window and choose **Add Selected Objects** or **Remove Selected Objects** from the shortcut menu.
3. To verify the addition or deletion of the object from the MotionSetup definition, use **Select Assignment** from the shortcut menu to view the objects assigned to the band.

Showing and Hiding Motion Objects

1. Click **Maxwell** > **Model** > **Motion Setup** > **Visualization**.
2. From the **Motion Setup Visualization Options** window that appears, select **All**, **Band**, or **Moving** from the **Select** drop-down menu.
3. Click **Deselect All** to hide all motion objects.
4. Click **Close** to close the window.

Setting the Visibility for Motion Objects

To show or hide a parameter:

1. Click **View** > **Active View Visibility**.
2. From the **Active View Visibility** dialog box that appears, click the **Motion** tab.
3. Select or clear the **Visibility** check box for each motion object listed.
4. Click **Done**.

Modeling Maxwell Motion Eccentricity

You can model motion eccentricity for Maxwell 2D and 3D transient designs that have cylindrical rotational motion set up. Ansys Electronics Desktop provides a **Maxwell Eccentricity Wizard** with settings for

- rotating part eccentricity
- rotation axis eccentricity

For rotating part eccentricity modeling, the eccentricity is only applied to rotating objects, not to a motion axis. More specifically, these rotating objects are all objects enclosed by the band, but not the band itself.

For rotation axis modeling, the eccentricity is only applied to the motion axis, which is equivalent to moving the band itself, but not any rotating objects inside the band.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Using these two basic settings, you can model the following physics.

- **Static eccentricity**: To model static eccentricity, you need to set the rotating part eccentricity and rotation axis eccentricity to the same values.
- **Dynamic eccentricity**: To model dynamic eccentricity, set the rotating part eccentricity values only.
- **Mixed eccentricity**: This is the combination of static and dynamic eccentricities. To model mixed eccentricity, set both rotating part eccentricity and rotation axis eccentricity, but with different values.

Using the Maxwell Eccentricity Wizard

> **Note:**
>
> The **ACT Extensions** window and the design wizards it contains (*5G Wizard, HFSS Antenna Design Toolkit, HFSS-EMA3D Link,* and *Maxwell Eccentricities*) are only available for the Windows version of the Ansys Electronics Desktop software. These items are not available when the software is installed on a Linux platform.

You can use the Maxwell Eccentricity wizard to model both 2D and 3D transient designs that have cylindrical rotational motion setup.

> **Note:** If you want to generate a 3D rotational eccentricity motor design from an RMxprt-generated Maxwell 3D design, you must enter **Eccentricity 1** in the RMxprt **Design Setting** window's **User Defined Data tab** for the RMxprt design *before* generating the Maxwell 3D design.

1. Select **View** > **ACT Extensions** to open the ACT Extensions window.
2. Click the **Wizards** button to open the Wizards page, then click **Maxwell Eccentricity** to load the Maxwell Eccentricity setup page.
3. Select the project and design you want to use.

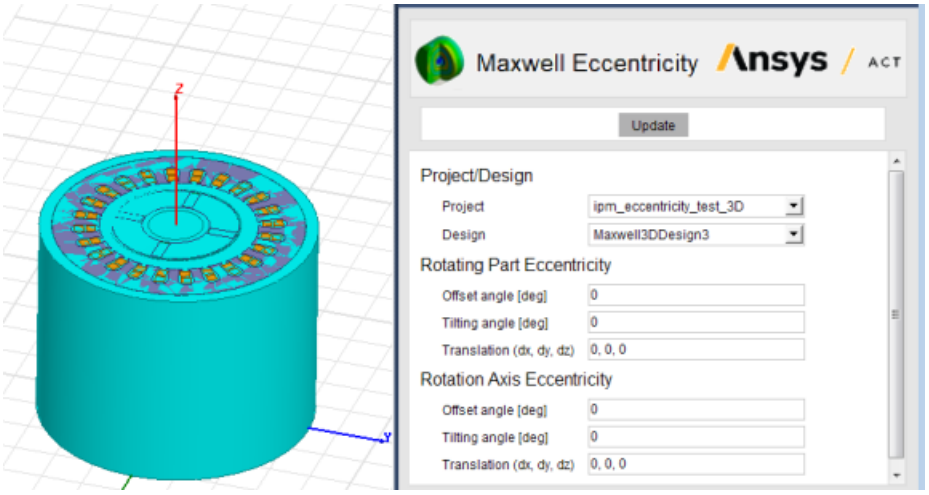
   > **Note:**
   >
   > - The **Update** button synchronizes the project and design selection lists with those currently loaded in the Desktop.
   > - You can click **Exit Wizard** to close the eccentricity wizard and return to the wizard start page without executing any changes.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

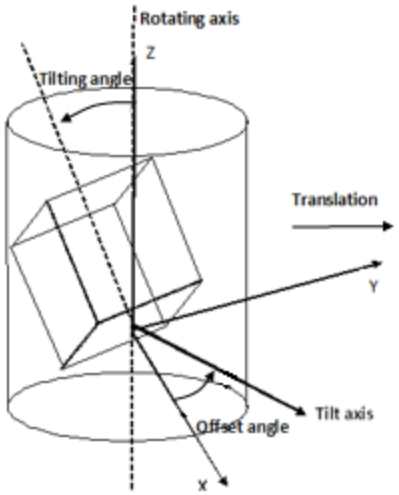
4. Depending on whether your design is 2D or 3D, do one of the following:
    - For a 2D Maxwell project, enter the desired dx and dy translation values to set up the Rotating Part Eccentricity and Rotation Axis Eccentricity. The unit of measure for translation values is the model's unit, which is set using **Modeler** > **Units**.

    - For a 3D Maxwell project, enter the desired dx, dy , and dz translation values, the offset angle, and the tilting angle for the rotating part eccentricity axis and rotation axis. The unit of measure for translation values is the model's unit, which is set using **Modeler** > **Units**.

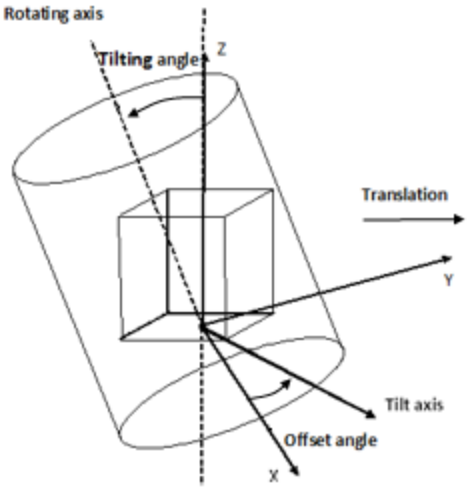
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Rotation Part Eccentricity



Rotation Axis Eccentricity



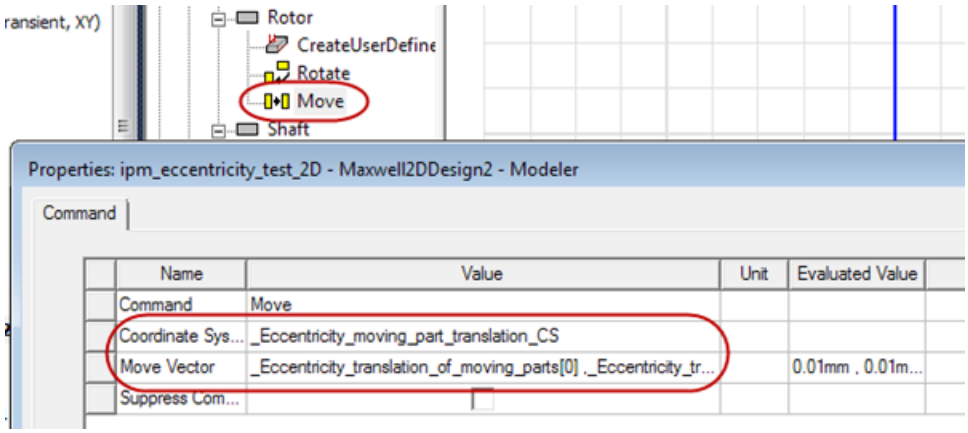
5. Click the **Finish** button at the bottom of the page. The page closes and the wizard adds a new design in the same project, in which the Maxwell geometry has been updated in accordance with the eccentricity setup values you entered, as explained in the sections that follow.

For 2D Designs

- Design variables are created for each of the data entered in the wizard.
  - For rotating part eccentricity: _Eccentricity_translation_of_moving_parts
  - For rotation axis eccentricity:_Eccentricity_translation_of_rotating_axis

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The moving parts in the design motion setup are shifted according to the data defined for **Rotating Part Eccentricity** in the Wizard. New coordinate systems are generated as the object coordinate systems for moving parts, according to the same operations.
- The band is translated according to the data defined for **Rotation Axis Eccentricity** in the wizard.
- The **Moving Vector** entry in the design's motion setup is replaced with the new direction (represented by an axis of a new coordinate system) generated according to the data defined for **Rotation Axis Eccentricity** in the Wizard.



- New design coordinate systems are created.

  _Eccentricity_rotating_axis_translation_CS

  _Eccentricity_moving_part_translation_CS

  _Eccentricity_moving_part_CS_<*part name*> – one for each moving part

> **Note:**
>
> - All the above operations of translation, as well as the creation of new coordinate systems, are dependent on the eccentricity design variables.
> - You can modify these design variables to adjust the eccentricity.
> - The newly added coordinate systems should not be changed manually by the user.
> - Using the wizard to modify a design that has already been set up for eccentricity is not recommended.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For 3D Designs

- Design variables are created for each of the data entered in the wizard.

  For rotating part eccentricity:

  - _Eccentricity_offset_angle_of_moving_parts
  - _Eccentricity_translation_of_moving_parts
  - _Eccentricity_tilting_angle_of_moving_parts

  For rotation axis eccentricity:

  - _Eccentricity_offset_angle_of_motion_axis
  - _Eccentricity_translation_of_motion_axis
  - _Eccentricity_tilting_angle_of_motion_axis
- The moving parts in the design motion setup are rotated and shifted according to the data defined for **Rotating Part Eccentricity** in the Wizard. New coordinate systems are generated as the object coordinate systems for moving parts, according to the same operations.
- The band is rotated and translated according to the data defined for **Rotation Axis Eccentricity** in the wizard.
- The **Moving Vector** entry in the design's motion setup is replaced with the new direction (represented by an axis of a new coordinate system) generated according to the data defined for **Rotation Axis Eccentricity** in the Wizard.
- New design coordinate systems are created.

  For the motion moving vector:

  - _Eccentricity_motion_axis_CS
  - _Eccentricity_motion_axis_tilting_axis_CS

  For the moving parts:

  - _Eccentricity_moving_part_tilting_axis_CS
  - _Eccentricity_moving_part_translation_CS
  - _Eccentricity_moving_part_CS_*<part name>* – one for each moving part

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

- All the above operations of rotation and translation, as well as the creation of new coordinate systems, are dependent on the eccentricity design variables.
- You can modify these design variables to adjust the eccentricity.
- The newly added coordinate systems should not be changed manually by the user.
- Using the wizard to modify a design that has already been set up for eccentricity is not recommended.

Note: When modeling motion eccentricity, the position and direction of the moving objects and/or band are adjusted based on the eccentricity setup. In such cases, all the adjustments are referenced to the original position and direction of the geometry of each object, As a result, after you finish the eccentricity setup and click the **Finish** button, all the geometries in the design created by the wizard are updated to new positions based on the eccentricity setup. If you want to edit geometry, you should do so in the original design. After editing the geometry, you can then redo the eccentricity setup to create a new design.

Transient A-Phi Formulation Boundaries and Excitations

The Transient A-Phi solver is an alternative to the default TAU transient solver. The A-Phi solver allows multi-terminal conductors and it supports sources of various types on a single conduction path; the J and E fields are calculated directly because it is a first-order approximation. *A* is the Magnetic Vector Potential and Φ (Phi) is the Electric Scalar Potential.

To use this solver, define at least one of the following as a source of magnetic fields:

- A voltage or current.
- Stranded or solid windings, with a voltage or current supply or connected to an external circuit winding.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** For stranded conductors, it is assumed that the current density is uniform on the cross-section of the respective conductors. Thus, the stranded option for current excitations should mostly be used only in cases where the cross-section of conductors is constant, consistently with the assumption that the respective object is a coil built with strands of wire. For this reason, conductors (coils) could be created by either sweeping around an axis using zero segments or sweeping along a path having only true surface segments in order to create a smooth surface coil having a completely uniform cross-sectional area over its entire length.

- A permanent magnet.

You may need to set at least one outer boundary to the following:

- The default boundary conditions.
- An odd symmetry (flux tangential) boundary.
- An even symmetry (flux normal) boundary.

Transient A-Phi Formulation Boundaries

The transient A-Phi field solver allows you to define the following types of boundary conditions.

> **Note:** The setup for Insulating, Symmetry, Independent, Dependent, and Resistive Sheet boundaries is the same for both Transient and Transient A-Phi Formulation solvers.

Boundary Type	H-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries –The tangential component of **H** and the normal component of **J** are continuous across the boundary. • Neumann boundaries – **H** is normal to the boundary; its tangential components are zero. **J** field is tangential to the boundary.	Ordinary field behavior. Initially, object interfaces are natural boundaries; outer boundaries, and excluded objects are Neumann boundaries.
Flux Tangential	**H** is tangential to the boundary and flux cannot cross it.	Problems with flux tangential at outer boundary.
Insulating	Same as Natural boundary, except that	Thin, perfectly insulating sheets

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	current cannot cross the boundary.	between touching conductors.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) – **H** is tangential to the boundary; its normal components are zero. The potential value at the boundary is zero. • Even Symmetry (Flux Normal) – **H** is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.
Matching (Independent and Dependent)	The **H**-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the **H**-field on the independent boundary.	Planes of symmetry in periodic structures where **H** is oblique to the boundary.
Resistive Sheet	Same as Natural boundary.	Voltage drop and loss on the contact surface between two different objects within a conduction path.

Default Boundary Conditions for a Transient A-Phi Solver

These boundary conditions are automatically defined for a transient model:

- Natural boundaries are assigned to the surfaces between objects.
- Neumann boundaries are assigned to the outer surface of the problem region. **J** field is tangential to the boundary, and **H** field is normal to the boundary.

To leave a surface set to its default boundary condition, you do not need to set any boundary conditions. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Flux Tangential Boundary for a Transient A-Phi Solver

> **Note:** This setting is also applicable to the 3D Eddy Current A-Phi Solver.

This type of boundary is applied when the **H** field is tangential to the boundary.

To define a zero tangential **H** field boundary:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell** > **Boundaries** > **Assign** > **Flux Tangential**.
3. The **Flux Tangential** window appears.
4. Enter a name for the boundary in the **Name** box, or accept the default.
5. Click **OK** to assign the boundary to the selected object.

Transient A-Phi Formulation Excitations

Transient A-Phi formulation supports the following excitations:

Excitation	Type of Excitation
Coil Terminal	Used to define windings.
Winding With Current	Current for a stranded or solid conductor.
Winding With Voltage	Voltage for a stranded or solid conductor.
Winding With External Circuit Connection	External circuit connection for a stranded or solid conductor.
Voltage	Voltage for a solid conductor.
Current	Current for a stranded or solid conductor.
Permanent Magnet Field	Permanent magnets serve as sources of magnetic fields.

Note: A winding is a flexible excitation. Six different combinations can be used: Current, Voltage, and External Circuit — each with a solid or stranded conductor. The Coil Terminal type of excitation is needed to set up a winding.

Note: Winding excitation is assigned as in the transient solver. However, coil terminals must be ordered according to the physical potential distribution as explained in Boundaries and Excitations > Winding Excitations for A-Phi Formulation.

Electric Transient Solver Boundaries and Excitations

The following boundaries can be specified for this solver:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Symmetry
- (Matching) Independent/Dependent
- Insulating

Specify at least one of the following excitations as a source of electric fields:

- The total charge on object.
- The volume charge density inside an object.
- The current.
- Define the electric potential on each surface using a voltage excitation.
- Floating models conductors at unknown potentials and specifies the total charge on the conductor.
- Sink can be applied only to 2D surfaces which are grounded with reference potential value. It is the same as applying zero voltage excitation on those surfaces.

Electric Transient Excitations

The following excitations are available for electric transient problems:

- **Charge** – This excitation can be applied to 2D surfaces or 3D volume bodies, if a body has net charge q. This type of excitation defines the total charge on a surface or object.
- **Current** – This excitation can be applied only to 2D surfaces, where the total current flowing in/out of that surface is specified.
- **Floating** – This excitation can be applied to 2D surfaces or 3D volume bodies; then these 2D or 3D objects are with equipotential. This type of excitation models conductors at unknown potentials and specifies the total charge on the conductor.
- **Sink** – This excitation can be applied only to 2D surfaces that are grounded with reference potential value. It is the same as applying zero voltage excitation on those surfaces.
- **Voltage** – This excitation specifies the value of the electric scalar potential value on 2D surfaces or 3D volume bodies.
- **Volume Charge Density** – This excitation can be applied only to 3D volume bodies. If the body has net charge q, the charge density is q/VOL, where VOL stand for the volume of that body.

Assigning a Voltage Excitation for an Electric Transient Solver

To define a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell** > **Excitations** > **Assign** > **Voltage**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Voltage Excitation** dialog box appears.

3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the voltage in the **Value** box, and select the units. Then, select a **Coordinate System**.
5. Optionally, click **Use Defaults** to revert to the default values.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Charge Excitation for an Electric Transient Solver

To define a charge excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell** > **Excitations** > **Assign** > **Charge**.

   The **Charge Excitation** dialog box appears.

3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the charge in the **Value** box.
5. Optionally, click **Use Defaults** to revert to the default values.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Floating Excitation for an Electric Transient Solver

To define a floating excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell** > **Excitations** > **Assign** > **Floating**.

   The **Floating Excitation** dialog box appears.

3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the floating excitation in the **Value** box.
5. Optionally, click **Use Defaults** to revert to the default values.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Volume Charge Density Excitation for an Electric Transient Solver

To define a volume charge density excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell** > **Excitations** > **Assign** > **Volume Charge Density**.

   The **Volume Charge Density Excitation** dialog box appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the volume charge density in the **Value** box. Then, select a **Coordinate System**.
5. Optionally, click **Use Defaults** to revert to the default values.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Current Excitation for an Electric Transient Solver

To define a current excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 3D** > **Excitations** > **Assign** > **Current**.

   The **Current Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the current excitation in the **Value** box, and select the units.
5. To swap the direction of the current, click **Swap Direction**.
6. Optionally, click **Use Defaults** to revert to the default values.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Sink Excitation for an Electric Transient Solver

To define a current excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell** > **Excitations** > **Assign** > **Sink**.

   The **Sink Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Click **OK** to assign the excitation to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

11 - Assigning Boundaries and Excitations for 2D Designs

For every design, you need to assign boundaries and excitations. You can use the **Maxwell 2D** menu or the project tree to do the following:

- Define boundary conditions that control how the electric or magnetic field behaves planes of symmetry, periodicity, or edges of the problem region.
- Define solution type specific excitations of voltage, charge, coil, and current.
- For magnetic transient designs, if needed, set up a winding and an external circuit connection.

Each field solver requires you to specify excitations of electric or magnetic fields and references for computing these fields.

- Magnetostatic Boundaries and Excitations
- Electrostatic Boundaries and Excitations
- AC Conduction Boundaries and Excitation
- DC Conduction Boundaries and Excitations
- Eddy Current Boundaries and Excitations
- Transient Boundaries and Excitations

You must specify at least one of the boundary conditions or excitations listed in these sections so that the simulator can compute accurate values for fields and parameters.

Selecting Objects and Faces in the 2D Geometry

Before creating a boundary or excitation, you must specify its location by selecting the object or surface on which to assign the boundary condition or source excitation.

Defining Boundary Conditions in 2D

To assign a boundary condition:

1. Select the section of the geometry on which you want to apply the boundary condition.
2. Click **Maxwell 2D** > **Boundaries** > **Assign**, or right-click **Boundaries** in the Project Manager tree and click **Assign**.
3. Select the desired boundary type from the sub-menu. The specific boundary types you can define depend on the solver you have chosen for your project.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Magnetostatic Boundary Conditions
- Electrostatic Boundary Conditions
- AC Conduction (Electric) Boundary Conditions
- DC Conduction (Electric) Boundary Conditions
- Eddy Current Boundary Conditions
- 2D Transient Boundary Conditions

4. Enter the name for the boundary or accept the default.
5. Depending on the boundary type, you may need to define additional parameters.
6. Click **OK** to create the new boundary.

The new boundary is added to the boundary list in the project tree.

Defining 2D Excitations

The specific excitations you can define depend on the solver you have chosen for your design.

- Magnetostatic Excitations
- Electrostatic (Electric) Excitations
- AC Conduction (Electric) Excitations
- DC Conduction (Electric) Excitations
- Eddy Current Excitations
- 2D Transient Excitations

To assign an excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 2D** > **Excitations** > **Assign**, or right-click **Excitations** in the project tree and click **Assign**.

   A submenu appears with choices that depend upon the solver type.
3. Select one of the following excitation types from the submenu:
   - Voltage
   - Charge
   - Floating
   - Charge Density
   - Current Density
   - Current
   - Coil
   - End Connection
   - Permanent Magnet Field

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Enter the name for the excitation type or accept the default.
5. Enter the desired parameter values, units, and other settings for the excitation in the dialog box. You can also enter a mathematical function to determine values for voltage, current density, charge density, and other parameters. The Permanent Magnet Field excitation also requires you set up a link to a source project.

   > **Note:** When entering current, or coil terminals, the arrow associated with current in the selected object shows the direction as if a positive value is entered for the current. If a negative value is entered the actual current flow direction is opposite to what the arrow shows. Click **Swap Direction** if you want to reverse the direction of the arrow.

6. Click **OK** to create the new excitation.

The new excitation is added to the excitation list in the project tree.

Viewing 2D Boundaries and Excitations

To view a list of all boundaries or excitations set for the design:

1. In the project tree, right-click **Boundaries** or **Excitations**.
   A shortcut menu appears.
2. Select **List** from the shortcut menu.
   The **Design List** dialog box appears, with the tab page visible for the item you selected. This dialog box contains tabs for **Model**, **Boundaries**, **Excitations**, **Parameters**, **Mesh Operations**, and **Analysis Setup**.
3. To view the properties for an item in the list, select the item, and click **Properties**.
4. To delete an item from the list, select the item, and click **Delete**.
5. When you are finished in the **Design List** dialog box, click **Done** to close it.

Setting the Visibility for 2D Boundaries and Excitations

To show or hide a boundary:

1. Click **View** > **Active View Visibility**.
   The **Active View Visibility** dialog box appears.
2. Click the **Boundaries** tab.
3. Select or clear the **Visibility** check box for each boundary listed.
4. Click **Done**.

To show or hide a excitation:

1. Click **View** > **Active View Visibility**.
   The **Active View Visibility** dialog box appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click the **Excitations** tab.
3. Select or clear the **Visibility** check box for each excitation listed.
4. Click **Done**.

Functional Boundaries and Excitations in 2D

Functional boundaries and excitations can be used to do the following:

- Define the value of a boundary or excitation quantity (such as the voltage, magnetic field, or current density) using a mathematical relationship — such as one relating its value to that of another quantity.
- Define the value of a boundary or excitation as a function of position.
- Current Density Excitation (Magnetostatic or Eddy Current solver type)
- Voltage Excitation (Electric solver types)
- Volume Charge Density Excitation (Electrostatic or Electrostatic + DC solver types)
- If the parametric analysis capability is installed, identify which boundary or excitation quantities are to be varied during a parametric sweep. These variables are always set to constant values in the parametric analysis.

Setting Eddy Effects and Displacement Current in 2D

(2D Eddy Current and/or Transient Solvers)

For both eddy current and transient solvers in 2D, you may need to specify the following additional settings:

- The behavior of eddy currents and the AC magnetic field in conductors. When you activate the **Eddy Effect** setting, the solver computes the induced eddy currents.
- For 2D Transient, source settings override the eddy effect settings. Objects assigned as “solid” sources will have eddy effects turned on, while objects assigned as “stranded” sources will have eddy effects turned off (regardless of the eddy effect settings). The eddy effect settings will be respected for non-sources.

Typically, background objects are excluded from eddy current settings.

To set eddy effects:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 2D** > **Excitations** > **Set Eddy Effects**.
   The **Set Eddy Effect** dialog box appears showing only objects which are valid for eddy effect calculation, specifically objects with conductivity greater than 1.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. For each object in the list, select or clear the check boxes for **Eddy Effect**. When selecting multiple entries, the changes are synchronized for all selected rows.

   > **Note:** Multi-select is supported by holding the **Ctrl** or **Shift** key while clicking.

4. Click the **Select By Name** button to enter the name of a specific object for selection. Multiple objects may be selected using the * and ? wildcards.
5. Optionally, click the **Use suggested values** button to set the **Eddy Effects** for all elements recommended by Maxwell 2D.
6. Click **OK**.

The **Deselect All** button will deselect all selected objects in the list.

Modifying 2D Boundary Conditions and Excitations

Save your project before modifying boundary conditions and excitations. You can modify boundary conditions and excitations after a solution has been generated, but you may lose some solution data.

Duplicating 2D Boundaries and Excitations

To duplicate a boundary or excitation when its geometry is pasted or duplicated:

1. Click **Tools** > **Options** > **Maxwell 2D Options**.

   The **Maxwell 2D Options** dialog box appears.

2. Click the **General Options** tab.
3. Select **Duplicate boundaries with geometry**.
4. Click **OK**.

All boundaries and excitations are duplicated with their associated geometries until you clear this option.

> **Tip:**
> Use this option to copy and paste boundaries. For example, do the following to use the same boundary on multiple objects:
>
> 1. Select the face to which you want to assign the boundary.
> 2. Click **Modeler** > **Surface** > **Create Object From Face** to create a new object from the existing face.
> 3. Assign the boundary to the new face object.
> 4. Copy and paste the new face object to copy and paste the boundary.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Showing and Hiding Boundaries and Excitations in 2D

You can choose to show or hide a boundary or excitation's geometry, name, or vectors in the active view window or in all view windows.

Showing and Hiding 2D Boundaries and Excitations in Every View Window

1. Click **Maxwell 2D** > **Boundaries** > **Visualization** or **Maxwell 2D** > **Excitations** > **Visualization**.
   The **Boundary Visualization Options** dialog box appears.
2. Select one of the following from the **Select** drop-down menu:
   - All
   - All Boundaries
   - All Excitations
   - By Name
3. If you select **By Name**, enter a name in the **Select By Name** dialog box, and click **OK**.
4. To clear the selection of all boundaries and excitations, click **Deselect All**.
5. Click **Close** to close the **Boundary Visualization Options** dialog box.

Setting Default Values for 2D Boundaries and Excitations

When assigning a boundary or excitation, many of the fields in the boundary and excitation dialog boxes have default values associated with them. These default values are initially set by **Maxwell 2D**, but can be overridden.

To modify the default values associated with a specific boundary or excitation type:

1. Assign a boundary or excitation.
2. Modify any default values.
3. Close the boundary or excitation's dialog box.
4. Re-open the new boundary or excitation's dialog box by right-clicking the boundary or excitation in the project manager and selecting **Properties**. The dialog now includes a **Defaults** tab.
5. Under the **Defaults** tab, click **Save Defaults**.

   The values assigned to this boundary are saved as the default values and are assigned when new boundaries of this type are created.

6. Optionally, click **Revert to Standard Defaults**.

The default values you set for this boundary type are cleared and will revert to the default values set by **Maxwell 2D**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reassigning 2D Boundaries

You can reassign a boundary to another surface. This is useful when you modify objects with assigned boundaries, invalidating the boundaries. For example, if you unite two objects with assigned boundaries, the second object's boundary becomes invalid because united objects maintain the characteristics of the first object selected. In this case, you would need to reassign the boundary or delete it.

To reassign a boundary:

1. Select the object or object face to which you want to assign an existing boundary.
2. Click **Maxwell 2D** > **Boundaries** > **Reassign**.
   The **Reassign Boundary** dialog box appears.

   > **Tip:** Alternatively, select the object or object face to which you want to assign an existing boundary. Right-click the existing boundary in the project tree, and then click **Reassign** on the shortcut menu.

3. Select the boundary you want to reassign, and click **OK**.

> **Note:** When reassigning a boundary that includes vectors in its definition, Maxwell attempts to preserve the vectors with the new assignment, but this is not always possible.

Reassigning 2D Excitations

To reassign an excitation:

1. Select the object or object face to which you want to assign an existing excitation.
2. Click **Maxwell 2D** > **Excitations** > **Reassign**.
   The **Reassign Excitation** dialog box appears.

   > **Tip:** Alternatively, select the object or object face to which you want to assign an existing excitation. Right-click the existing excitation in the Project Manager tree, and then click **Reassign** on the shortcut menu.

3. Select the excitation you want to reassign, and click **OK**.

> **Note:** When reassigning an excitation that includes vectors in its definition, Maxwell attempts to preserve the vectors with the new assignment, but this is not always possible.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Deleting All 2D Boundaries and/or Excitations

To delete all boundaries or excitations:

- Click **Maxwell 2D** > **Boundaries** > **Delete All** or **Maxwell 2D** > **Excitations** > **Delete All**.

Viewing and Editing 2D Boundary or Excitation Properties

To open the **Properties** dialog box for a boundary or excitation that is already assigned:

1. In the Project Manager tree, under either **Boundaries** or **Excitations**, right-click a specific boundary or excitation, and select **Properties**.
2. In the **Properties** dialog box that appears, make the desired changes, and click **OK**.

2D Magnetostatic Boundaries and Excitations

Define at least one of the following as a source of static magnetic fields:

- The current in a conduction path, which can be either stranded or solid.
- The current density in a conductor.
- The magnetic field on an outside surface.

2D Magnetostatic Boundaries

The magnetostatic field solver allows you to define the following types of boundaries:

Boundary Type	H-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • At the interface between objects, the H tangent and B normal are continuous. • On outer boundaries, B field is normal. As a rule, this behavior needs to be modified at least for some portions of the outer boundary to insure uniqueness of the solution.	Initially, object interfaces are natural boundaries; outer boundaries, and excluded objects are Neumann boundaries.
Vector Potential	Sets the magnetic vector potential A_z, or rA_ϕ, on the boundary. The behavior of H depends on whether A_z or rA_ϕ is constant or functional.	Outer boundaries at specific vector potentials; externally applied magnetic fields.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Balloon	This boundary is considered to be far away from the other sources in the problem.	Actual behavior is context dependent. In general, if a Dirichlet BC is not applied elsewhere to insure uniqueness, the "balloon" will be assigned a Dirichlet boundary condition.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) — **Magnetic Field** is tangential to the boundary; its normal components are zero. • Even Symmetry (Flux Normal) — **Magnetic Field** is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.
Matching (Independent and Dependent)	The **Magnetic Field vector** on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the **Magnetic Field** vector on the independent boundary.	Planes of symmetry in periodic structures where **Magnetic Field** is oblique to the boundary.

Default Boundary Conditions

These boundary conditions are automatically defined for a magnetostatic model:

- Natural boundaries are assigned to the surfaces between objects. At the interface between objects, the H tangent and B normal are continuous.
- Neumann boundaries are assigned to the outside edges of the problem region. On outer boundaries, B field is normal. As a rule, this behavior needs to be modified at least for some portions of the outer boundary to insure uniqueness of the solution.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Vector Potential

To define a vector potential boundary for a 2D Magnetostatic solver:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge). **Maxwell 2D** requires that the Vector Potential be assigned on a 1D object such as an edge or a line.
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Vector Potential**.
   The **Vector Potential Boundary** dialog box appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the value of the potential. The value may be specified as a single numeric value or a functional value.
5. If a functional value is specified, select a **Coordinate System** from the drop-down menu:
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the project tree.

Assigning a Symmetry Boundary Condition

For the 2D Magnetostatic Solver, this boundary condition defines a plane of geometric or magnetic symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Symmetry**.
   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Tangential)	**Magnetic Field** is tangential to the boundary; its normal components are zero.
Even (Flux Normal)	**Magnetic Field** is normal to the boundary; its tangential components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning a Balloon Boundary Condition

To set a balloon boundary for the 2D Magnetostatic solver:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Balloon**.
   The **Balloon Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning an Independent Boundary

Independent and dependent boundaries enable you to model planes of periodicity where the **Magnetic Field** at every point on the dependent boundary surface is forced to match the **Magnetic Field** of every corresponding point on the independent boundary surface.

To set a independent boundary for the 2D Magnetostatic solver:

1. Select the edge to which you want to assign the independent boundary.
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Matching** > **Independent**.
   The **Independent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. To reverse the direction of the vector, select the **Reverse Direction** check box.
5. Click **OK**.

Assigning a Dependent Boundary

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

> **Note:** You must define a independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary for the 2D Magnetostatic solver:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Matching** > **Dependent**.
   The **Dependent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** drop-down menu.
5. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Bdep = Bind	Click this radio button if the magnetic fields on the dependent and independent boundaries have the same magnitude and direction.
Bdep = -Bind	Click this radio button if the magnetic fields on the dependent boundary have the same

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

magnitude as but the opposite direction from the independent boundary.

6. To reverse the direction of the vector, select the **Reverse Direction** check box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

2D Magnetostatic Excitations

The following excitations of magnetic fields are available for magnetostatic problems:

Excitation	Type of Excitation
Current Density	The known current density distribution in the cross-section of a conductor.
Current	The total current in a conductor.
Winding With Current	Current for both a stranded and solid conductor.
Winding With Resistance Voltage Drop	Resistance Voltage Drop for both a stranded and solid conductor.

In addition, permanent magnets materials serve as sources of magnetic fields.

Assigning a Current Density Excitation

For the 2D Magnetostatic solver, this command (depending upon solution type, either **X-Y** or **R-Z**) specifies the applicable components of the current density in the cross-section of an object. If the current density is a function of position, the value is entered in ampere/m^2, even if you change the units in the problem.

To define the current density:

1. Select the section of the geometry (i.e., the conductor) on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Current Density**.
   The **Current Density Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter a value for the current density in the **Value** box. The value may be a single numeric quantity or a functional quantity.
   b. If a functional quantity is entered in the **Value** box, which depends on the applicable coordinates, select a **Coordinate System** from the drop-down menu.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Current Excitation

For the 2D Magnetostatic solver, the current excitation specifies the total current in the cross-section of an object.

To set a current excitation:

1. Select the section of the geometry (i.e., the conductor) on which you want to apply the excitation (typically a face or other 2D planar object).
2. Click **Maxwell 2D** > **Excitations** >**Assign** > **Current**.
   The **Current Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter a value for the current in the **Value** box, and select the units from the drop-down menu.
   b. Select **Positive** or **Negative** as the **Ref. Direction**.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Winding Setup

> **Note:** If you wish to define a winding for a 2D Eddy Current solution type, refer to Assigning a Winding Setup for a 2D Eddy Current Solver.
> If you wish to define a winding for a 2D Transient solution type, refer to Assigning a Winding Setup for a 2D Transient Solver.

You can use the predefined coil terminal(s) to define one or more current or voltage windings.

To define a winding for a 2D Magnetostatic solver:

1. Click **Maxwell 2D** > **Excitations** > **Add Winding** to open the **Winding** dialog box.
2. Enter a name for the winding in the **Name** box, or accept the default.
3. In the **Parameters** section, select **Current**, or **Resistance Voltage Drop** from the **Type** drop-down menu.
4. Select the **Solid** or **Stranded** radio button to specify the type of conductor.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Enter values in the following fields, and select the desired units:

For current winding	For resistance voltage drop winding[1]
Current	Resistance
	Voltage

> **Note:** You can also type a function as an expression for any of these items.

6. Enter a value in the **Number of parallel branches** text box.

> **Note:** Parallel branches for solid windings assume there are no circulating currents in the parallel branches

7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the excitation to the selected object

The definition of a winding is final only after specifying the coils which belong to it. **To add a coil terminal to this winding**, do the following:

1. In the Project Manager tree, right-click the winding, and select **Add Coils**.
   The **Add Terminals** dialog box appears, listing all coil terminals that do not already belong to that winding.
2. Select the coil terminal (s) you want to add. To select multiple terminals, press **Ctrl** and click each terminal.
3. Click **OK**.

To assign a coil terminal excitation and add it to this winding, do the following:

1. Select the section of the geometry on which you want to apply the coil terminal excitation.
2. In the Project Manager tree, right-click the winding, and select **Assign Coil**.
   The **Coil Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box.

> **Note:** This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.

5. Select one of the following for the **Polarity**:
   - **Positive**
   - **Negative**

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Function**

6. If you selected **Function** as the **Polarity**, enter a function in the text box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the coil terminal excitation.
   The coil terminal excitation is assigned and is added to the winding.

To delete all coil terminal excitations that belong to this winding, do the following: In the Project Manager tree, right-click the winding, and select **Delete All Coils**.
All coil terminal excitations are removed from the winding and deleted from the excitations.

---

1. For a solid winding, the resistance term can represent: the resistance of a portion of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source resistance. (The main winding resistance is calculated directly by the solver.) For a stranded winding, the resistance term is the complete DC resistance of the winding (since the solver does not determine resistance of a stranded winding) as well as the resistance of the end-effects, leads, source, etc. For both solid and stranded windings, the inductance term can represent: the extra inductance for a portion of the winding of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source inductance. (The main winding inductance itself is calculated directly by the solver.)

Assigning a Coil

To assign a coil as a 2D magnetostatic excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Coil**. (You can also right-click an existing winding in the project tree, and select **Assign Coil**.)
   The **Coil Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box.
5. Select one of the following for the **Polarity**:
   - **Positive**
   - **Negative**
   - **Function**
6. If you selected **Function** as the **Polarity**, enter a function in the text box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the coil to the selected object.

To add this coil to an existing winding, do the following:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the Project Manager tree, right-click the coil terminal, and select **Add to Winding**. The **Add to Winding** dialog box appears.
2. Select the winding to which you ant to add the coil terminal, and click **OK**.

To remove a coil terminal from an existing winding, do one of the following:

- In the Project Manager tree, right-click the coil terminal, and select **Remove from Winding**.
  The terminal is removed from the winding and moved up one level in the project tree (directly beneath **Excitations**).
- Alternatively, all coils assigned to a winding may be deleted by right-clicking the winding in the Project Manager tree and selecting **Delete All Coils**.

2D Electrostatic Boundaries and Excitations

Specify at least one of the following excitations as a source of electric fields:

- The charge on a surface or object.
- The charge density inside an object.
- Define the electric potential on each surface and object using a voltage excitation.

Include at least one of the following as a reference for computing the electric potential:

- A voltage excitation.
- An odd symmetry (flux normal) boundary.

2D Electrostatic Boundaries

The following boundary conditions are available for electrostatic problems:

Boundary Type	E-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — The normal component of **D** changes by the amount of surface charge density, tangent component of **E** is continuous. No special conditions are imposed. • Neumann boundaries — **E** is tangential to the boundary. Flux cannot cross a Neumann boundary.	Ordinary E-field behavior on boundaries. Object interfaces are initially set to natural boundaries; outer boundaries are initially set to Neumann boundaries.
Symmetry	Field behaves as follows:	Planes of geometric and electrical

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	• Even Symmetry (Flux Tangential) — **E** is tangential to the boundary; its normal components are zero. • Odd Symmetry (Flux Normal) — **E** is normal to the boundary; its tangential components are zero.	symmetry.
Balloon	Two options are available: Charge — The charge at “infinity” balances the charge in the drawing region. The net charge is zero. Use for capacitance calculations. Voltage — The voltage at “infinity” is zero.	Electrically insulated structures (Charge option) or electrically grounded structures (Voltage option). For the voltage case, the balloon boundary will not be equipotential in general.
Matching (Independent and Dependent)	The E-field vector on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the E-field vector on the independent boundary.	Planes of symmetry in periodic structures where **E** is oblique to the boundary.

Default Boundary Conditions

These boundary conditions are automatically defined for a 2D electrostatic model:

- Natural boundaries are assigned to the interfaces between objects. The normal component of **D** changes by the amount of surface charge density, tangent component of **E** is continuous.
- Neumann boundaries are assigned to the outside edges of the problem region. **E** is tangential to the boundary. Flux cannot cross a Neumann boundary.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically revert to the default boundary conditions.

Assigning a Symmetry Boundary Condition

For the 2D Electrostatic solver, this boundary condition defines a plane of geometric or electric symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Symmetry**.
   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Select one of the following as the type of symmetry:

Odd (Flux Normal)	**E** is normal to the boundary; its tangential components are zero.
Even (Flux Tangential)	**E** is tangential to the boundary; its normal components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning a Balloon Boundary Condition

To set a balloon boundary for the 2D Electrostatic Solver :

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Balloon**.
   The **Balloon Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select **Voltage** or **Charge** as the **Balloon Type**.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning a Independent Boundary

Independent and dependent boundaries enable you to model planes of periodicity where the E-field vector at every point on the dependent boundary surface is forced to match the E-field vector of every corresponding point on the independent boundary surface. The transformation used to map the E-field from the independent to the dependent is determined by specifying the orientation of a local, predefined coordinate system, indicated by an arrow, on both the independent and dependent boundaries.

To set an independent boundary for the 2D Electrostatic solver :

1. Select the edge to which you want to assign the independent boundary.
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Matching** > **Independent**.
   The **Independent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. To reverse the direction of the vector, select the **Reverse Direction** check box.
5. Click **OK**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning a Dependent Boundary

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the Independent boundary is mapped to the dependent boundary.

> **Note:** You must define an Independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary for the 2D Electrostatic solver:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Matching** > **Dependent**.
   The **Dependent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** drop-down menu.
5. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Edep = Eind	Click this radio button if the dependent and independent boundaries have the same magnitude and direction.
Edep = -Eind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

6. To reverse the direction of the vector, select the **Reverse Direction** check box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

2D Electrostatic Excitations

The following excitations are available for electrostatic problems:

Excitation	Type of Excitation
Voltage	DC voltage on a surface or object
Charge	Total charge on a surface or object.
Floating	Models conductors at unknown

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	potentials
Charge Density	Charge density over an object (dielectric)

Assigning a Voltage Excitation

Voltage excitations are identical to voltage boundaries in previous versions of Maxwell. A voltage excitation can be assigned to any surfaces or 2D objects. These assignments could include spatial functions.

For the 2D Electrostatic solver, this type of excitation sets the electric potential to a specific value.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Voltage**.
   The **Voltage Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the electric potential in the **Value** box, and select the units from the drop-down menu. You can enter a numerical value, parameter (design or project variable) or a spatial function.
5. For a spatial function, select a coordinate system from the **Coordinate System** drop-down menu.
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Charge Excitation

For the 2D Electrostatic solver, this type of excitation defines the total charge on a surface or object. The potential distribution on the object with charge excitation is computed during the solution.

To define a charge excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Charge**.
   The **Charge Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the numerical value, parameter (design or project variable) or a spatial function in the **Value** box.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning a Floating Excitation

For the 2D Electrostatic solver, this type of excitation models conductors at unknown potentials and specifies the total charge on the conductor.

To define a floating conductor:

1. Select the section of the geometry on which you want to apply the excitation. This can be a 2D or 1D geometry entity. If it is a 2D object, it doesn't have to be a conductor (but it will behave like one when the solution becomes available).
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Floating**.
   The **Floating Excitation** dialog box appears.
3. Click the **General** tab.
4. Enter a name for the excitation in the **Name** box, or accept the default.
5. In the **Parameters** section, enter the charge value or parameter in the **Value** box.
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box. You can also click the **Defaults** tab to save new default settings or to revert to the standard default values.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Charge Density Excitation

For the 2D Electrostatic solver, this type of excitation defines the volume charge density on an object.

To define the charge density on a dielectric object:

1. Select the object on which you want to apply the excitation.
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Charge Density**.
   The **Charge Density Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the charge density in the **Value** box. You can enter a numerical value, parameter (design or project variable) or a spatial function.
5. For a spatial function, select the type of coordinate system from the **Coordinate System** drop-down menu.
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the excitation to the selected object.

2D AC Conduction Boundaries and Excitations

The following excitations can be specified as the source of electric fields:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The voltage difference between surfaces and objects. Define the electric potential on each surface and object using a voltage excitation.

Include at least one of the following as a reference for computing the electric potential:

- A voltage excitation.
- An odd symmetry (flux normal) boundary.

2D AC Conduction Boundaries

The following boundary conditions are available for AC conduction electric problems:

Boundary Type	E-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries - The normal component of **J** and the tangential component of **E** are continuous across discontinuity surfaces. No special conditions are imposed. • Neumann boundaries - **E** and **J** vectors are tangential to the boundary. Flux cannot cross a Neumann boundary.	Object interfaces are initially set to natural boundaries; outer boundaries are initially set to Neumann boundaries.
Symmetry	Field behaves as follows: • Even Symmetry (Flux Tangential) - **E and J vectors are** tangential to the boundary; its normal components are zero. • Odd Symmetry (Flux Normal) - **E and J vectors are** normal to the boundary; its tangential components are zero.	Planes of geometric and electrical symmetry.
Balloon	Balloon boundaries model the region outside the drawing space as being nearly infinitely large — effectively isolating the model from other voltage sources.	Electrically insulated structures, equipotential lines can cross this type of boundary. In general, they are neither tangent nor perpendicular to the balloon boundary.
Matching (Independent and Dependent)	The E-field on the dependent boundary is forced to match the magnitude of the E-field on the independent boundary if the plus sign	Planes of symmetry in periodic structures where **E** is oblique to the boundary.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	is used. If the minus sign is used, the field on the dependent boundary will oscillate with opposite phase angle (180 degrees phase shift).

Default Boundary Conditions

These boundary conditions are automatically defined for a AC conduction model:

- Natural boundaries are assigned to the surfaces between objects. The normal component of **J** and the tangential component of **E** are continuous across discontinuity surfaces.
- Neumann boundaries are assigned to the outside edges of the problem region. **E** and **J** vectors are tangential to the boundary. Flux cannot cross a Neumann boundary.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically revert to the default boundary conditions.

Assigning a Symmetry Boundary Condition

For the 2D AC Conduction solver, this boundary condition defines a plane of geometric or electric symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Symmetry**.
   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Normal)	Voltages have opposite sign on the two sides of the symmetry plane.
Even (Flux Tangential)	Voltages have same sign on the two sides of the symmetry plane.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning a Balloon Boundary Condition

To set a balloon boundary for the 2D AC Conduction solver :

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Balloon**.
   The **Balloon Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning an Independent Boundary

Independent and dependent boundaries enable you to model planes of periodicity where the **E**-field at every point on the dependent boundary surface is forced to match the **E**-field of every corresponding point on the independent boundary surface.

To set an independent boundary for the 2D AC Conduction solver:

1. Select the edge to which you want to assign the independent boundary.
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Matching** > **Independent**.
   The **Independent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. To reverse the direction of the vector, select the **Reverse Direction** check box.
5. Click **OK**.

The Maxwell solver computes the E-field on this boundary and maps it to the dependent boundary.

Assigning a Dependent Boundary

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the Independent boundary is mapped to the dependent boundary.

> **Note:** You must define an Independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary for the 2D AC Conduction solver,

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Matching** > **Dependent**.
   The **Dependent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Parameters** section, select the independent boundary to which the dependent is to be assigned from the **Independent** drop-down menu.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Under **Relation**, select one of the following to specify the field behavior on the boundary:

Edep = Eind	Click this radio button if the dependent and independent boundaries have the same magnitude and oscillate in phase.
Edep = -Eind	Click this radio button if the dependent boundary field has the same magnitude as the independent boundary field and oscillate 180 degrees out of phase.

6. To reverse the direction of the vector, select the **Reverse Direction** check box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

2D AC Conduction Excitations

The following excitations are available for electric AC conduction problems:

Excitation	Type of Excitation
Voltage	The AC voltage on a surface or object. This excitation type is available for all three of the 2D electric solvers.

> **Note:** All field quantities oscillate with the same frequency, equal to the frequency specified in the solution setup. The phase of quantities computed in the solution space however will be different in general.

Assigning a Voltage Excitation

For the 2D AC Conduction solver, this type of excitation sets the electric potential (voltage) on a surface or object to a specific value.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Voltage**.
   The **Voltage Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the electric potential in the **Value** box, and select the units from the drop-down menu. You can enter a numerical value or a spatial function.
5. For a spatial function, select a coordinate system from the **Coordinate System** drop-down menu.
6. Enter a value in the **Phase** text box, and select a unit from the drop-down menu.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the excitation to the selected object.

2D DC Conduction Boundaries and Excitations

The following excitations can be specified as the source of electric fields:

- The voltage difference between surfaces and objects. Define the electric potential on each surface and object using a voltage excitation.

Include at least one of the following as a reference for computing the electric potential:

- A voltage excitation.
- An odd symmetry (flux normal) boundary.

2D DC Conduction Boundaries

The following boundary conditions are available for DC conduction electric problems:

Boundary Type	E-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — Normal component of **J** and tangential component of **E** are continuous across discontinuity surfaces. No special conditions are imposed. • Neumann boundaries — **E** and **J** vectors are tangential to the boundary. Flux cannot cross a Neumann boundary.	Object interfaces are initially set to natural boundaries; outer boundaries are initially set to Neumann boundaries.
Symmetry	Field behaves as follows: • Even Symmetry (Flux Tangential) — **E** and **J** vectors are tangential to the boundary; their normal components are zero. • Odd Symmetry (Flux Normal) — **E** and **J** vectors are normal to the boundary; their tangential components are zero.	Planes of geometric and electrical symmetry.
Balloon	Balloon boundaries model the region outside the drawing space as being nearly “infinitely” large — effectively isolating the model from other voltage sources.	Electrically insulated structures.
Resistance	A resistance boundary models a very thin	Use this boundary condition

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	layer of resistive material (such as that caused by deposits, coatings or oxidation on a metallic surface) on a conductor at a known potential.	when the resistive layer's thickness is much smaller than the other dimensions of the model.
Matching (Independent and Dependent)	The **E**-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the **E**-field on the independent boundary.	Planes of symmetry in periodic structures where **E** is oblique to the boundary.

Default Boundary Conditions

These boundary conditions are automatically defined for a DC conduction model:

- Natural boundaries are assigned to the surfaces between objects. Normal component of **J** and tangential component of **E** are continuous across discontinuity surfaces. No special conditions are imposed.
- Neumann boundaries are assigned to the outside edges of the problem region. **E** and **J** vectors are tangential to the boundary. Flux cannot cross a Neumann boundary.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically revert to the default boundary conditions.

Assigning a Symmetry Boundary Condition

This boundary condition defines a plane of geometric or electric symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary for a 2D DC Conduction solver:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Symmetry**.
   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Normal)	Voltages have opposite signs on the two sides of the symmetry plane.
Even (Flux Tangential)	Voltages have same signs on the two sides of the symmetry plane.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning a Balloon Boundary Condition

To set a balloon boundary for a 2D DC Conduction solver:

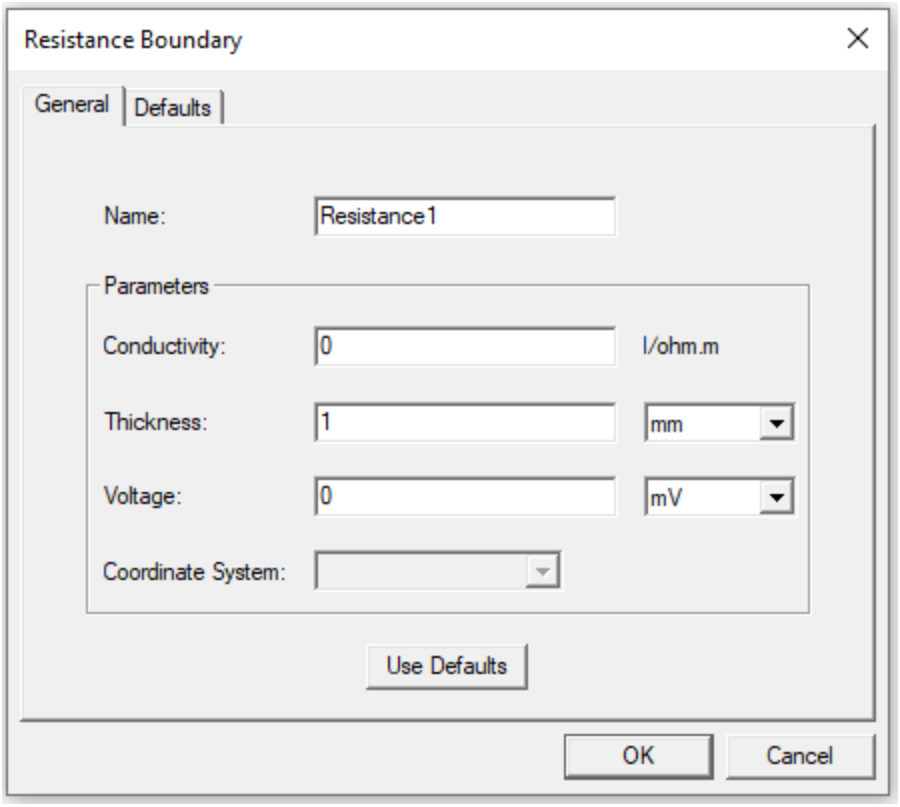
1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Balloon**.
   The **Balloon Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning a Resistance Boundary Condition

To set a resistance boundary for a 2D DC Conduction solver:

1. Select the edge of the geometry on which you want to apply the boundary condition.
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Resistance**.
   The **Resistance Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter the boundary parameters in the **Conductivity**, **Thickness**, and **Voltage** fields, and select the units of measure. Use of variables is supported.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

> **Note:** Apply resistance boundaries only to the outside edge of the problem space. The external region touching to a resistance boundary is assumed to be a PEC (perfect conductor) with a known potential value that is specified in the resistance boundary setup. Refer to *Resistance* for technical details.

Assigning an Independent Boundary

Independent and dependent boundaries enable you to model planes of periodicity where the **E**-field at every point on the dependent boundary surface is forced to match the **E**-field of every corresponding point on the independent boundary surface.

To set an independent boundary for a 2D DC Conduction solver:

1. Select the edge to which you want to assign the independent boundary.
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Matching** > **Independent**.
   The **Independent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. To reverse the direction of the vector, select the **Reverse Direction** check box.
5. Click **OK**.

Assigning a Dependent Boundary

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

> **Note:** You must define an Independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary for a 2D DC Conduction solver:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Matching** > **Dependent**.
   The **Dependent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** drop-down menu.
5. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Edep = Eind	Click this radio button if the **E** field on the dependent and independent boundaries have the same magnitude and direction.
Edep = -Eind	Click this radio button if the **E** field on the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

6. To reverse the direction of the vector, select the **Reverse Direction** check box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

2D DC Conduction Excitations

The following excitations are available for electric DC conduction problems:

Excitation	Type of Excitation
Voltage	The DC voltage on a surface or

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

object.

Assigning a Voltage Excitation

For the 2D DC Conduction solver, this type of excitation sets the electric potential (voltage) on a surface or object to a specific value.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Voltage**.
   The **Voltage Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the electric potential in the **Value** box, and select the units from the drop-down menu. You can enter a numerical value or a spatial function.
5. For a spatial function, select a coordinate system from the **Coordinate System** drop-down menu.
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the excitation to the selected object.

2D Eddy Current Boundaries and Excitations

Specify at least one of the following as a source of AC magnetic fields in your model:

- The current in the cross-section (object), which can be either stranded or solid.
- The current to be divided among several parallel conductors.
- The current density in an object.
- The external magnetic field.

If currents or current densities are the only sources of AC magnetic fields in your model, set at least one outer boundary to the following:

- The default boundary conditions.
- An odd symmetry (flux tangential) boundary.
- An even symmetry (flux normal) boundary.

2D Eddy Current Boundaries

The eddy current field solver allows you to define the following types of boundaries:

Boundary Type	H-Field Behavior	Used to model…
Default	Field behaves as follows:	Initially, object

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Boundary Type	H-Field Behavior	Used to model…
Boundary Conditions (Natural and Neumann)	• Natural boundaries — Tangential **H** and normal **B** are continuous across surfaces without current density distribution; tangential **H** has a jump if the surface has current density distribution. • Neumann boundaries — **Magnetic Field** is tangential to the boundary and flux cannot cross it.	interfaces are natural boundaries; outer boundaries and excluded objects are Neumann boundaries.
Vector Potential	Sets the magnetic vector potential $A_z(t)$, or $rA_\phi(t)$, on the boundary. The behavior of H depends on whether $A_z(t)$ or $rA_\phi(t)$ is constant or functional.	Magnetically isolated structures.
Impedance	Includes the effect of induced currents beyond the boundary surface based on tangent component of **H** along the impedance boundary.	Conductors with very small skin depths.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) — **Magnetic Field** is tangential to the boundary; its normal components are zero. • Even Symmetry (Flux Normal) — **Magnetic Field** is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.
Balloon	Models the case where the structure is “infinitely” far away from other magnetic fields or current sources.	Magnetically isolated structures.
Matching (Independent and Dependent)	The **Magnetic Field** on the dependent boundary is forced to match the magnitude and direction of the **Magnetic Field** on the independent boundary. If a plus sign is used, the fields oscillate in phase, if a minus sign is used the fields will oscillate 180 degrees out of phase. **Note:** In the Maxwell 2D Eddy Current solver, when a solid conductor or a coil in the solid winding touches the matching boundary, refining the mesh on the edge where the conductor or coil touches the matching boundary is recommended.	Planes of symmetry in periodic structures where **Magnetic Field** is oblique to the boundary.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Default Boundary Conditions

These boundary conditions are automatically defined for an eddy current model:

- Natural boundaries are assigned to the surfaces between objects. Tangential **H** and normal **B** are continuous across surfaces without current density distribution; tangential **H** has a jump if the surface has current density distribution.
- Neumann boundaries are assigned to the outside edges of the problem region. **Magnetic Field** is tangential to the boundary and flux cannot cross it.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Vector Potential

To define a vector potential boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Vector Potential**.
   The **Vector Potential Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the value of the potential. The value may be specified as a single numeric value or as a spatial function.
5. If a functional value is specified, select a **Coordinate System** from the drop-down menu:
6. Enter a value in the **Phase** text box, and select a unit from the drop-down menu.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the project tree.

Assigning an Impedance Boundary

This boundary condition is used to simulate the effect of induced currents in a conductor without explicitly computing them. Since the conductor must be excluded in the model (saving time needed to mesh and solve for currents), assign the impedance boundary condition to an outside edge of the problem region or to an excluded object. Exclude the object from the problem region and make the object a perfect conductor in the Material Manager.

To define an impedance boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Impedance**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Impedance Boundary** dialog box appears.

3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter the conductivity (in inverse ohm-meters) in the **Conductivity** field.
5. Enter the conductor's relative permeability in the **Permeability** field.
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the boundary to the selected object.

2D Impedance Boundary

Impedance boundaries allow you to simulate the effect of induced currents in a conductor without explicitly computing them. Use this boundary condition for models where:

- The skin depth in the conductor is less than two orders of magnitude smaller than the dimensions of the structure. In models like this, the mesh generator may not be able to create a fine enough mesh in the conductor to compute eddy currents.
- The magnetic field decays much more rapidly inside the conductor in the direction that's normal to the surface than it does in directions that are tangential to the surface.
- The AC current source is relatively far away from the surface where eddy currents occur, compared to the size of the skin depth.

The conductor itself must be excluded from the solution region. When setting up the model, do one of the following:

- For external boundaries, when drawing the model, make the surface along which eddy currents are to be computed an outer surface of the problem region.
- For internal boundaries: assign a perfect conductor to the object in the Material Manager, and also exclude the object from the solution by unchecking **Solve Inside** under the object attributes. The solver does not find solutions inside a perfect conductor.

Then, when defining boundaries, assign an impedance boundary to the individual surfaces of the problem region (for external boundaries) or to the entire object (for internal boundaries). By entering the conductivity, s, and the relative permeability, μ_r, of the object, you specify the skin depth of induced eddy currents. The simulator uses this skin depth value when computing the electromagnetic field solution. It assumes that the **Magnetic Field** falls off exponentially inside the conductor. The ohmic loss due to induced currents can then be computed from the **Magnetic Vector Potential** along the impedance boundary – on the surface of the object that you are interested in – according to the formula below or by using the quantity **EdgeLossDensity** in the 2D calculator.

$$EdgeLossDensity\left(W/m^2\right) = \pi f \sqrt{\frac{\pi f \sigma}{\mu_0 \mu_r}} \left[A_z \cdot A_Z^*\right]$$

where

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A_z = z component of the Magnetic Vector Potential

A_z^* = complex conjugate of the z component of the Magnetic Vector Potential

μ_0 = permeability of free space

μ_r = relative permeability of the impedance boundary

σ = conductivity of the impedance boundary (S/m)

f = frequency (Hz)

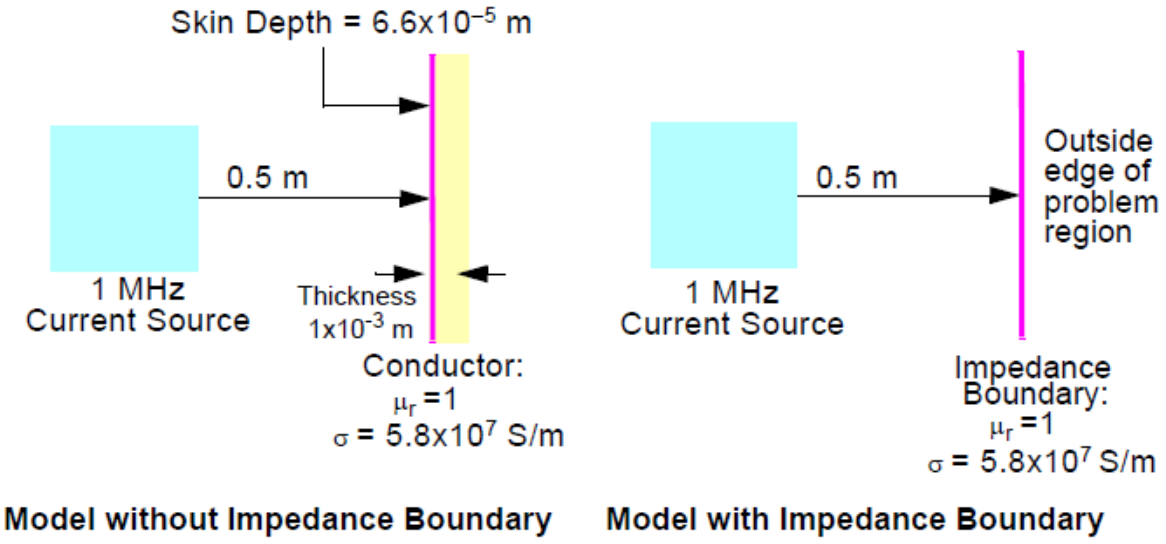
You can also use **EdgeLossDensity** to plot the loss along an edge containing an impedance boundary.

> **Note:** An impedance boundary only approximates the effect of eddy currents acting at a shallow skin depth. It does not directly compute them. In general, the fields modeled using an impedance boundary will closely match the field patterns that would actually occur in the structure. However, at discontinuities in the surface (such as corners), the field patterns may be different.

When to Use Impedance Boundaries in 2D

A typical situation where impedance boundaries can be used to reduce the complexity of a model is shown below. Suppose you want to compute eddy current losses in the conductor next to the current source shown below on the left. If the source carries AC current at a frequency of 1 MHz, the skin depth in the conductor is 6.6 x 10–5 meters. This is several orders of magnitude smaller than the conductor's thickness. Since the conductor where currents are induced is also relatively far away from the current source, an impedance boundary can be used to model the induced currents — as shown on the right:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The conductor must be excluded from the model by making it a perfect conductor. The outside boundary of the model is moved to the inside surface of the conductor. This outside surface is defined as an impedance boundary, using the conductivity and permeability specified previously. Since the simulator does not have to actually compute a solution inside the conductor, the field solution is computed more quickly and uses less memory. After solving, you can compute the ohmic loss for the surface using the solution calculator and plot the loss density on the boundary.

Assigning a Symmetry Boundary

For the 2D Eddy Current solver, this boundary condition defines a plane of geometric or magnetic symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Symmetry**.
   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Tangential)	Magnetic field is tangential to the boundary; its normal components are zero.
Even (Flux Normal)	Magnetic field is normal to the boundary; its tangential components are zero.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning a Balloon Boundary Condition

To set a balloon boundary for the 2D Eddy Current solver:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Balloon**.
   The **Balloon Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning an Independent Boundary

Independent and dependent boundaries enable you to model planes of periodicity where the **Magnetic Field** at every point on the dependent boundary surface is forced to match the **Magnetic Field** of every corresponding point on the independent boundary surface. For the 2D Eddy Current solver, the transformation used to map the **Magnetic Field** from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the edge to which you want to assign the independent boundary.
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Matching** > **Independent**.
   The **Independent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. To reverse the direction of the vector, select the **Reverse Direction** check box.
5. Click **OK**.

> **Note:** In the Maxwell 2D Eddy Current solver, when a solid conductor or a coil in the solid winding touches the matching boundary, refining the mesh on the edge where the conductor or coil touches the matching boundary is recommended.

Assigning a Dependent Boundary

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** You must define an independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary for the 2D Eddy Current solver:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Matching** > **Dependent**.
   The **Dependent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** drop-down menu.
5. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Bdep = Bind	Click this radio button if the magnetic fields on the dependent and independent boundaries have the same magnitude and the fields oscillate in phase.
Bdep = -Bind	Click this radio button if the magnetic fields on the dependent boundary have the same magnitude as the independent boundary field but the fields oscillate 180 degrees out of phase.

6. To reverse the direction of the vector, select the **Reverse Direction** check box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

2D Eddy Current Excitations

The eddy current solver allows you to define the following sources of AC magnetic fields:

Excitation	Type of Excitation
Current	The total current in a conductor.
Parallel Current	The total current to be divided among several conductors in parallel. The method of dividing the current depends upon the choice of solid or stranded.
Current Density	The current density in a conductor. In this

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	case, you must also define the current density terminals for the conductor.
Coil	Used to define one or more model windings.
End Connection	End connection is used to model details of the "squirrel cage" winding of induction machines, dampers in synchronous machines, etc.
Winding With Current	Current for both a stranded and solid conductor.
Winding With Voltage	Voltage for both a stranded and solid conductor.
Winding With External Circuit Connection	External circuit connection for both a stranded and solid conductor.

> **Note:** The 2D Eddy Current solver can be used to get harmonic losses on nonlinear systems and can be an alternative to a transient simulation. See Using the Eddy Current Solver to Generate Harmonic Losses for more details.

Assigning a Current Excitation

For the 2D Eddy Current solver, a current excitation specifies the total AC current in a conduction path. The conduction path may be contained completely within the problem region (for example, a coil), or may touch the edges of the problem region.

To specify the total AC current:

1. Select the 2D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Current**.
   The **Current Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Enter the current strength in the **Value** box.
5. Enter the phase for the current in the **Phase** box.
6. Select the **Solid** or **Stranded** radio button to specify the type of conductor.
7. Select either **Positive** or **Negative** as the **Ref. Direction** for the conductor.
8. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
9. Click **OK** to assign the excitation to the selected object.

Assigning a Parallel Current Excitation

For the 2D Eddy Current solver, a parallel current excitation specifies the total AC current in a parallel conduction path consisting of at least two conductors.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To specify the total AC current:

1. Select the 2D sections of the geometry on which you want to apply the excitation. At least two section must be specified
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Parallel Current**.
   The **Parallel Current Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Enter the current strength in the **Value** box.
5. Enter the phase for the current in the **Phase** box.
6. Select the **Solid** or **Stranded** radio button to specify the type of conductor.

   > **Note:** For parallel solid conductors, the current split will be based upon the overall field solution including eddy effects (the currents in individual parallel conductors will have complex values, which are proportional with the respective admittances, and in general will have different phase angles between them). If stranded conductors are specified, the current is split based upon the relative areas of the selected conductors.

7. Select either **Positive** or **Negative** as the **Ref. Direction** for the conductor.
8. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
9. Click **OK** to assign the excitation to the selected object.

Assigning a Current Density Excitation

For the 2D Eddy Current solver, this command specifies the applicable component (depending on XY or RZ solution type) of the AC current density. If the current density is a function of position, the value is entered in ampere/m^2, even if you change the units in the problem.

To define the current density:

1. Select the section of the geometry (for example, the conductor) in which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Current Density**.
   The **Current Density Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter the current strength in the **Value** box. The value may be a single numeric value or a spatial function.
   b. If the value is specified as a spatial function, select the **Coordinate System** from the drop-down menu.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. Enter the phase angle, θ, of the current density in the **Phase** field, and select a unit from the drop-down menu.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Coil

To assign a coil as an 2D Eddy Current excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Coil**. (You can also right-click an existing winding in the project tree, and select **Assign Coil**.)

   The **Coil Excitation** dialog box appears.

3. On the **General** tab, enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box.
5. Select one of the following for the **Polarity**:
   - **Positive**
   - **Negative**
   - **Function**
6. If you selected **Function** as the **Polarity**, enter a function in the text box.
7. Optionally, on the Defaults tab, click **Save Defaults** to save the current settings or click **Revert to Standard Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the coil to the selected object.

To add this coil to an existing winding:

1. In the Project Manager tree, right-click the coil terminal, and select **Add to Winding**. The **Add to Winding** dialog box appears.
2. Select the winding to which you ant to add the coil terminal, and click **OK**.

To remove a coil terminal from an existing winding:

- In the Project Manager tree, right-click the coil terminal, and select **Remove from Winding**. The terminal is removed from the winding and moved up one level in the project tree (directly beneath **Excitations**).
- Alternatively, all coils assigned to a winding may be deleted by right-clicking the winding in the project tree and selecting **Delete All Coils**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning an End Connection

For the 2D Eddy Current solver, an End Connection excitation is used to model details of the "squirrel cage" winding of induction machines, dampers in synchronous machines, *etc*.

To define an end connection:

1. Select the section of the geometry (*i.e.*, the conductor) across which you want to apply the excitation.
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **End Connection**.

   The **End Connection Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter the **End resistance between adjacent conductors**, and select a unit of measurement from the drop-down menu.
   b. Enter the **End inductance between adjacent conductors**, and select a unit of measurement from the drop-down menu.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Winding Setup

> **Note:**
> If you wish to define a winding for a 2D transient solution type, refer to Assigning a Winding Setup for a 2D Transient Solver.
> If you wish to define a winding for a 2D magnetostatic solution type, refer to Assigning a Winding Setup for a 2D Magnetostatic Solver.

For the 2D Eddy Current solver, you can use the predefined coil terminal(s) to define one or more current or voltage windings.

To define a winding for your model:

1. Click **Maxwell 2D** > **Excitations** > **Add Winding** to open the **Winding** dialog box.
2. Enter a name for the winding in the **Name** box, or accept the default.
3. In the **Parameters** section:
   a. Select **Current**, **Voltage**, or **External** from the **Type** drop-down menu. The winding type selected enables only those fields (Initial Current, Resistance, Inductance, Voltage, Phase) applicable for the chosen type.
   b. Select the **Solid** or **Stranded** radio button to specify the type of conductor.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. For the 2D Eddy Current solver, there is a **Get Databases from FFT** button. This feature allows the user to get frequency domain signals from transient signals, and solve on the frequencies in Eddy Current designs. For more information, see Using an Eddy Current Excitation to Generate Harmonic Losses.

d. Enter values in the following fields (enabled according to winding type), and select the desired units:

For a current winding	For a voltage winding[1]	For an external winding
Current	Resistance	(no settings required)
Phase	Inductance	
	Voltage	
	Phase	

> **Note:** You can also type a function as an expression for any of these fields except Initial Current.

e. Enter a value in the **Number of parallel branches** text box.

> **Note:** Parallel branches for solid windings assume there are no circulating currents in the parallel branches.

4. Optionally, click **Use Defaults** to revert to the default values in the dialog box
5. Optionally, on the Defaults tab, click **Save Defaults** to save the current settings or click **Revert to Standard Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

The definition of a winding is final only after specifying the coils which belong to it. **To add a coil terminal to this winding**:

1. In the **Project Manager** tree, right-click the winding, and select **Add Coils**. The **Add Terminals** dialog box appears, listing all coil terminals that do not already belong to that winding.
2. Select the coil terminal (s) you want to add. To select multiple terminals, press **Ctrl** and click each terminal.
3. Click **OK**.

To assign a coil terminal excitation and add it to this winding:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the section of the geometry on which you want to apply the coil terminal excitation.
2. In the **Project Manager** tree, right-click the winding, and select **Assign Coil**. The **Coil Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box.

   > **Note:** This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.

5. Select one of the following for the **Polarity**:
   - **Positive**
   - **Negative**
   - **Function**
6. If you selected **Function** as the **Polarity**, enter a function in the text box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the coil terminal excitation. The coil terminal excitation is assigned and is added to the winding.

To delete all coil terminal excitations that belong to this winding:

- In the **Project Manager** tree, right-click the winding, and select **Delete All Coils**. All coil terminal excitations are removed from the winding and deleted from the excitations.

---

1. For a solid winding, the resistance term can represent: the resistance of a portion of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source resistance. (The main winding resistance is calculated directly by the solver.) For a stranded winding, the resistance term is the complete DC resistance of the winding (since the solver does not determine resistance of a stranded winding) as well as the resistance of the end-effects, leads, source, etc. For both solid and stranded windings, the inductance term can represent: the extra inductance for a portion of the winding of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source inductance. (The main winding inductance itself is calculated directly by the solver.)

External Circuit Setup

The Maxwell Circuit Design Editor is used to set up the external circuit excitation for windings in Maxwell 2D and 3D Eddy Current solutions. Because the Eddy Current solver is a frequency domain solver, only linear circuit components are supported, which include Resistance, Inductance, Capacitance, and Transformer. In addition, only sinusoidal sources should be used

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

as sources. Sinusoidal Current Source and Sinusoidal Voltage Source, designed for transient solutions, can also be used for eddy current solutions. For example, to use the sinusoidal current source, you should set the parameters as follows:

- Set **I0**, **Td**, and **Df** to zero, where I0 is offset current in Amps, Td is the delay time in seconds, and Df is the damping factor in 1/seconds.
- Set **TIME** as the **Type**.
- Use **Ia** to set the peak amplitude in Amps.
- Use **IFreq** to set the signal frequency. Note that setting IFreq is not necessary as it will be internally set to the frequency defined in the Maxwell design setup.
- Use **Phase** to set the phase delay.

With these specifications, the time signal can be written as

$$I(t) = I_a \sin\left(2\pi I_{freq} - Phase\right)$$

Note that “Phase” is the signal phase delay. The complex source in the eddy current solver is represented in phasor form as

$$I = I_a \; e^{j\theta}$$

and the time signal can be written in terms of (I_a, θ) as

$$I\left(t\right) = Im\left\{I_a \; e^{j(2\pi I_{freq}+\theta)}\right\}$$

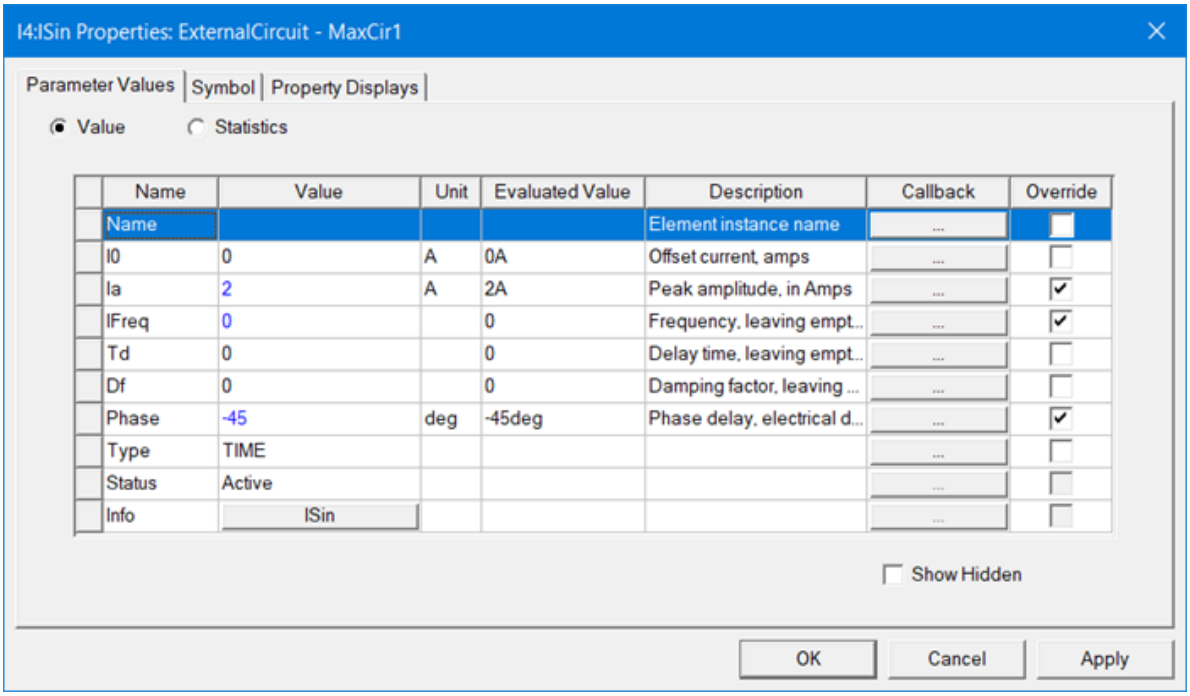
In the complex expression, θ is defined as phase, while in Maxwell Circuit, *Phase* is defined as phase delay. Thus,

$$Phase = -\theta$$

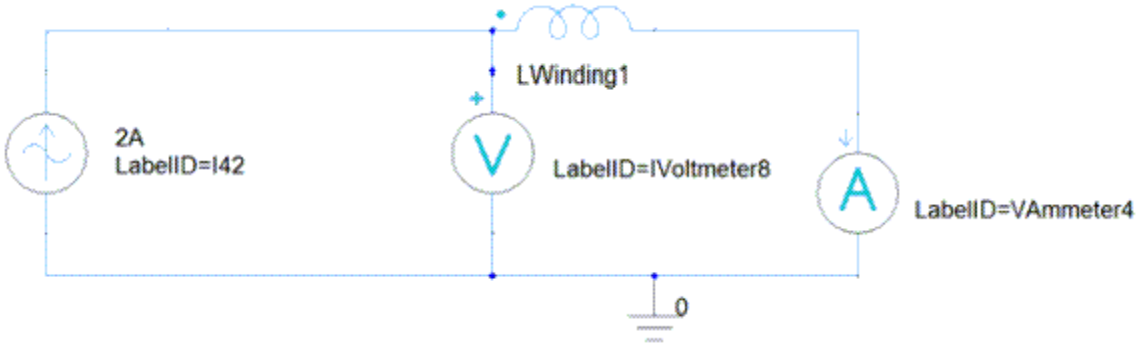
As a result, you should enter the negative of phase of the complex signal as the Phase value.

An example of such a setup for $I = 2e^{j45^\circ}$ is shown below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



An example of an external circuit excitation for the winding for an Eddy current solver is shown below.



> **Note:** For frequency domain eddy current solutions, only linear circuit components are supported, which include Resistor, Inductor, Capacitor, and Transformer. Only sinusoidal sources should be used as sources.

To set up an external circuit connection for an External winding type:

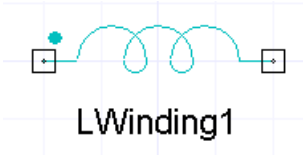
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click **Maxwell 2D** > **Excitations** > **External Circuit** > **Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project Manager tree and select **External Circuit** > **Edit External Circuit**.

    a. If no external winding connections have been set up for your model, the **Winding Information** tab lists the external winding(s) in the design. Continue with step 2.

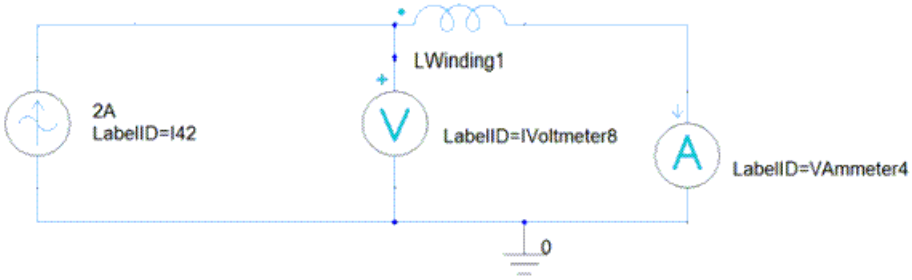
    b. If external windings have already been set up, continue with step 7.

2. On the **Winding Information** tab, click **Create Circuit** to add a circuit design to the project. The new circuit design automatically opens for editing in the Maxwell Circuit Editor. The circuit includes one inductor for each external winding in the original Maxwell transient design. The following example is for a design having one external winding.



3. Add the components needed to complete the external circuit design such as shown the following example.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. When the circuit design is finished, click **Maxwell Circuit** > **Export Netlist** and export the netlist **.sph** file to the desired location.
5. Return to the Maxwell design and click **Maxwell 2D** > **Excitations** > **External Circuit** > **Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit** > **Edit External Circuit**.
6. On the **Winding Information** tab, click **Import Circuit** to import the circuit.
7. To view a list of inductors in the imported circuit, click the **Available Inductors** tab.
8. To view the sources used in the externally connected windings, click the **Source Type** tab.
9. If variables are used in the imported circuit, they and their design values are listed on the **Parameter Values** tab. You can link to variables within the imported circuit as follows:
    a. On the **Parameter Values** tab, click in the **Value** column of the parameter to be mapped.
    b. Enter a new local variable name and press the `Enter` key to open the **Add Variable** dialog box.
    c. Select a **Unit Type** and **Unit**, and enter a **Value** for the variable and click **OK**. The new Maxwell variable is now mapped to the variable in the imported circuit, and can be varied directly by Maxwell or used for Optimetrics analyses.
10. If the imported file is a .**sph** file, you can click the **Circuit Path** tab to view the original project and design names.

    > **Note:** After you import a circuit netlist, the **Create Circuit** button changes to **Update Netlist from Circuit**. Use **Update Netlist from Circuit** to reimport the netlist to keep it current.

11. Click **OK** to close the **Edit External Circuit** dialog box.

2D Transient Boundaries and Excitations

Define at least one of the following as a source of magnetic fields:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The stranded or solid windings, with a voltage or current supply or connected to an external circuit.
- Permanent magnet(s).

You will need to set at least one outer boundary to the following:

- Value (vector potential) boundary conditions.
- An odd symmetry (flux tangential) boundary.
- An even symmetry (flux normal) boundary.

2D Transient Boundaries

The transient field solver allows you to define the same types of boundary conditions as magnetostatic ones.

Boundary Type	H-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — Tangential **H** and normal **B** are continuous across surfaces without current density distribution. Tangential **H** has a jump if the surface has current density distribution. • Neumann boundaries — Magnetic field is normal to the boundary.	Initially, object interfaces have natural boundaries; outer boundaries, and excluded objects have Neumann boundaries.
Vector Potential	Sets the magnetic vector potential A_Z, or $rA\phi$, on the boundary. The behavior of H depends on whether A_Z or $rA\phi$ is constant or functional.	Outer boundaries at specific vector potentials; externally applied magnetic fields.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) — **Magnetic Field** is tangential to the boundary; its normal components are zero. • Even Symmetry (Flux Normal) — **Magnetic Field** is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.
Balloon	Models the case where the structure is “infinitely” far away from other magnetic fields, permanent magnets, or current sources.	Magnetically isolated structures.
Matching (	The **Magnetic Field** on the dependent boundary is forced to match the magnitude	Planes of symmetry in periodic structures where

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Independent and Dependent)	and direction (or the negative of the direction) of the **Magnetic Field** on the independent boundary. **Note:** In the Maxwell 2D transient solver, when a solid conductor or a coil in the solid winding touches the matching boundary, refining the mesh on the edge where the conductor or coil touches the matching boundary is recommended.	**Magnetic Field** is oblique to the boundary.

Default Boundary Conditions

These boundary conditions are automatically defined for a 2D transient model:

- Natural boundaries are assigned to the surfaces between objects. Tangential **H** and normal **B** are continuous across surfaces without current density distribution. Tangential **H** has a jump if the surface has current density distribution.
- Neumann boundaries are assigned to the outside edges of the problem region. Magnetic field is normal to the boundary.

To leave a surface set to its default boundary condition, you do not need to set any boundary conditions. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Vector Potential

To define a vector potential boundary for a 2D Transient solver:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge). Maxwell 2D requires that the **Vector Potential** be assigned on a 1D object such as an edge or a line.
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Vector Potential**.
3. In the **Vector Potential Boundary** dialog box that appears. enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the value of the potential. The value may be specified as a single numeric value or a spatial function.
5. If a functional value is specified, select a **Coordinate System** from the drop-down menu:
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the Project Manager tree.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning a Symmetry Boundary

This boundary condition defines a plane of geometric or magnetic symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary for the 2D Transient solver:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Symmetry**.
   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Tangential)	**Magnetic Field** is tangential to the boundary; its normal components are zero.
Even (Flux Normal)	**Magnetic Field** is normal to the boundary; its tangential components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning a Balloon Boundary Condition

To set a balloon boundary for the 2D Transient solver:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Balloon**.
   The **Balloon Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning an Independent Boundary

Independent and dependent boundaries enable you to model planes of periodicity where the **Magnetic Field** at every point on the dependent boundary surface is forced to match the **Magnetic Field** of every corresponding point on the independent boundary surface.

To set an independent boundary for the 2D Transient solver:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the edge to which you want to assign the independent boundary.
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Matching** > **Independent**.
   The **Independent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. To reverse the direction of the vector, select the **Reverse Direction** check box.
5. Click **OK**.

The Maxwell solver computes the **Magnetic Field** on this boundary and maps it to the dependent boundary using the transformation defined by the independent and dependent coordinate systems.

> **Note:** In the Maxwell 2D transient solver, when a solid conductor or a coil in the solid winding touches the matching boundary, refining the mesh on the edge where the conductor or coil touches the matching boundary is recommended.

Assigning a Dependent Boundary

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

> **Note:** You must define an independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary for the 2D Transient solver:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell 2D** > **Boundaries** > **Assign** > **Matching** > **Dependent**.
   The **Dependent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** drop-down menu.
5. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Bdep = Bind	Click this radio button if the magnetic field on the dependent and independent boundaries have the same magnitude and direction.
Bdep = -Bind	Click this radio button if the magnetic field on the dependent boundary has the same

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

magnitude as but the opposite direction from the independent boundary field.

6. To reverse the direction of the vector, select the **Reverse Direction** check box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

2D Transient Excitations

Transient problems use the following types of excitations:

Excitation	Type of Excitation
Current	The total current in a conductor
Current Density	The known current density distribution in a conductor.
Coil	Used to define one or more model windings.
End Connection	End connection is used to model details of the "squirrel cage" winding of induction machines, dampers in synchronous machines, etc.
Winding With Current	Current for both a stranded and solid conductor.
Winding With Voltage	Voltage for both a stranded and solid conductor.
Winding With External Circuit Connection	External circuit connection for both a stranded and solid conductor.

In addition, permanent magnet materials serve as sources of magnetic fields.

> **Note:** A winding is a versatile type of excitation. Six different combinations can be used: Current, Voltage, and External Circuit — each with a solid or stranded conductor. The Coil Terminal type of excitation needs to be defined prior to setting up a winding.

Assigning a Current Excitation

For the 2D Transient solver, this excitation specifies the total transient current in an object.

To specify the total transient current:

1. Select the 2D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Current**.

   The **Current Excitation** dialog box appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Enter the current magnitude, time dependent, in the **Value** box, and select a unit from the drop-down menu.
5. Select the **Solid** or **Stranded** radio button to specify the type of conductor.
6. Select either **Positive** or **Negative** as the **Ref. Direction** for the conductor.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the excitation to the selected object.

Assigning a Current Density Excitation

For the 2D Transient solver, this command specifies the applicable component (depending on the XY or RZ type of application) of the transient current density in an object. If the current density is a function of position, the value is entered in ampere/m^2, even if you change the units in the problem.

To define the current density:

1. Select the section of the geometry (*i.e.*, the conductor) in which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Current Density**.
   The **Current Density Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter the current strength in the **Value** box. The value may be a single numeric value or a spatial function.
   b. If a spatial function is entered for the **Value**, select the **Coordinate System** from the drop-down menu.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Coil

To assign a coil as a 2D transient excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **Coil**. (You can also right-click an existing winding in the project tree, and select **Assign Coil**.)
   The **Coil Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Select one of the following for the **Polarity**:
    - **Positive**
    - **Negative**
    - **Function**
6. If you selected **Function** as the **Polarity**, enter a function in the text box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the coil to the selected object.

To add this coil to an existing winding:

1. In the project tree, right-click the coil terminal, and select **Add to Winding**.
   The **Add to Winding** dialog box appears.
2. Select the winding to which you ant to add the coil terminal, and click **OK**.

To remove a coil terminal from an existing winding, do one of the following:

- In the Project Manager tree, right-click the coil terminal, and select **Remove from Winding**.
  The terminal is removed from the winding and moved up one level in the Project Manager tree (directly beneath **Excitations**).
- Alternatively, all coils assigned to a winding may be deleted by right-clicking the winding in the Project Manager tree and selecting **Delete All Coils**.

Assigning an End Connection

The End Connection is used to model details of the "squirrel cage" winding of induction machines, dampers in synchronous machines, etc.

To define an end connection for the 2D Transient solver:

1. Select the section of the geometry (i.e., the conductor) across which you want to apply the excitation.
2. Click **Maxwell 2D** > **Excitations** > **Assign** > **End Connection**.
   The **End Connection Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
    a. Enter the **End resistance between adjacent conductors**, and select a unit of measurement from the drop-down menu.
    b. Enter the **End inductance between adjacent conductors**, and select a unit of measurement from the drop-down menu.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning a Winding Setup

> **Note:**
>
> - If you wish to define a winding for a 2D Eddy Current solution type, refer to Assigning a Winding Setup for a 2D Eddy Current Solver.
> - If you wish to define a winding for a 2D Magnetostatic solution type, refer to Assigning a Winding Setup for a 2D Magnetostatic Solver.

You can use the predefined coil terminal(s) to define one or more current or voltage windings.

To define a winding for the 2D Transient solver:

1. Click **Maxwell 2D** > **Excitations** > **Add Winding** to open the **Winding** dialog box.
2. Enter a name for the winding in the **Name** box, or accept the default.
3. In the **Parameters** section, select **Current**, **Voltage**, or **External** from the **Type** drop-down menu.

   > **Note:** Maxwell transient designs can be dynamically coupled to Twin Builder components through the Twin Builder user interface. You can enable this feature on the Advanced Product Coupling tab of the **Design Settings** dialog box. Source windings set to **External** are available as conservative pins in Twin Builder. For more information, refer to the Help for Twin Builder.

4. Select the **Solid** or **Stranded** radio button to specify the type of conductor.
5. Enter values in the following fields, and select the desired units:

For a current winding	For a voltage winding[1]	For an external winding
Current	Initial Current	Initial Current
	Resistance	
	Inductance	
	Voltage	

   > **Note:** You can also type a function as an expression for any of these items except initial current.

6. Enter a value in the **Number of parallel branches** text box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** Parallel branches for solid windings assume there are no circulating currents in the parallel branches.

7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the excitation to the selected object

The definition of a winding is final only after specifying the coils which belong to it. **To add a coil terminal to this winding**:

1. In the Project Manager tree, right-click the winding, and select **Add Coils**.
   The **Add Terminals** dialog box appears, listing all coil terminals that do not already belong to that winding.
2. Select the coil terminal (s) you want to add. To select multiple terminals, press **Ctrl** and click each terminal.
3. Click **OK**.

To assign a coil terminal excitation and add it to this winding:

1. Select the section of the geometry on which you want to apply the coil terminal excitation.
2. In the Project Manager tree, right-click the winding, and select **Assign Coil**.
   The **Coil Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box.

> **Note:** This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.

5. Select one of the following for the **Polarity**:
   - **Positive**
   - **Negative**
   - **Function**
6. If you selected **Function** as the **Polarity**, enter a function in the text box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the coil terminal excitation.
   The coil terminal excitation is assigned and is added to the winding.

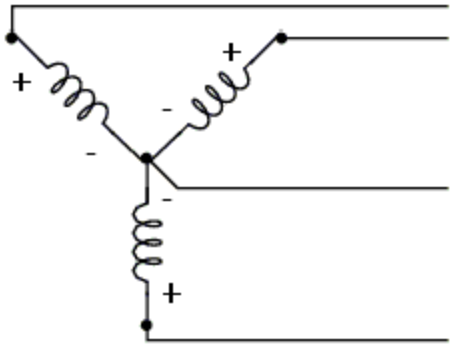
To delete all coil terminal excitations that belong to this winding: In the Project Manager tree, right-click the winding, and select **Delete All Coils**. All coil terminal excitations are removed from the winding and deleted from the excitations.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. For a solid winding, the resistance term can represent: the resistance of a portion of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source resistance. (The main winding resistance is calculated directly by the solver.) For a stranded winding, the resistance term is the complete DC resistance of the winding (since the solver does not determine resistance of a stranded winding) as well as the resistance of the end-effects, leads, source, etc. For both solid and stranded windings, the inductance term can represent: the extra inductance for a portion of the winding of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source inductance. (The main winding inductance itself is calculated directly by the solver.)

Setting Up a Y Connection

The Y Connection function available in 2D and 3D Transient solution types allows multiple windings to be connected in a classical Y (sometimes referred to as wye) configuration with the negative terminals connected to a common node as illustrated below.



Setup Y Connection requires voltage winding definitions be set and the negative voltage terminal for each winding will be connected to form the common node of the circuit.

Each voltage source specified in the winding description drives the positive side of the coil. Y Connections are commonly used in motor and transformer applications driven by 3-phase voltage; however, any number of windings may be connected to a common node in Maxwell.

> **Note:**
>
> - Only one Y Connection is allowed in a given Maxwell design.
> - A Y Connection requires use of stranded voltage windings.
> - Duplicate windings are not allowed.

To define a Y-connection:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click **Maxwell 2D** (or **Maxwell 3D**) > **Excitations** > **Setup Y Connection**.

   The **Setup Y Connection** dialog box appears.

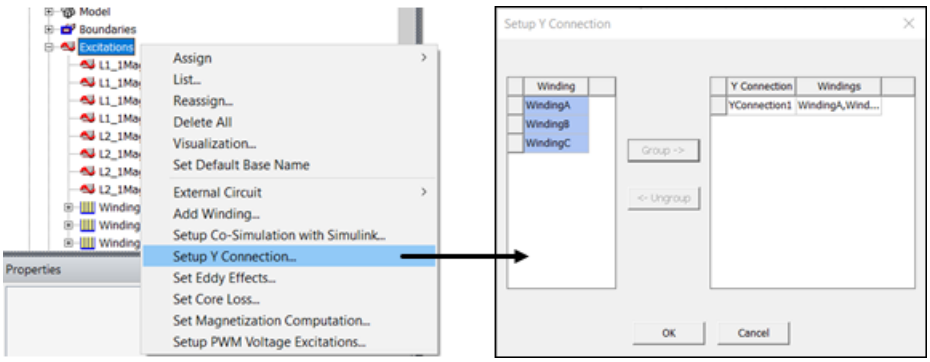
2. In the **Winding** list on the left, select the windings to be grouped into a Y connection.
3. Click the **Group** button to create a Y Connection group with the selected windings.
4. Click **OK** when all required grouping have been created.

Setting Up an SVPWM Excitation

Pulse Width Modulation (PWM) is a term used for any method that produces a square wave signal with varying duty cycle and frequency to control the average power delivered to a load. PWM is widely used in applications such as light dimming, switching power supplies, and electric motor drive. In these types of designs, the AC motor needs to be powered by an alternating current excitation, which is supplied by the DC supply voltage through an inverter circuit using power device switches. Controlling how the power switches are turned on and off is accomplished by PWM.

For 3D magnetic transient T-Omega and 2D magnetic transient solutions, Space Vector Pulse Width Modulation (SVPWM) can be directly created in Maxwell for three-phase voltage-excited windings. For all three phases, Maxwell will calculate and create design datasets for the PWM voltage waveforms based on user inputs and automatically set up the winding excitations to use these datasets in transient simulations. The generated waveform represents the Phase-Neutral voltage, and it is only applicable to star (or Y) connected winding. Therefore, ensure that the Y connection is set up for the three windings applied to the SVPWM excitation.

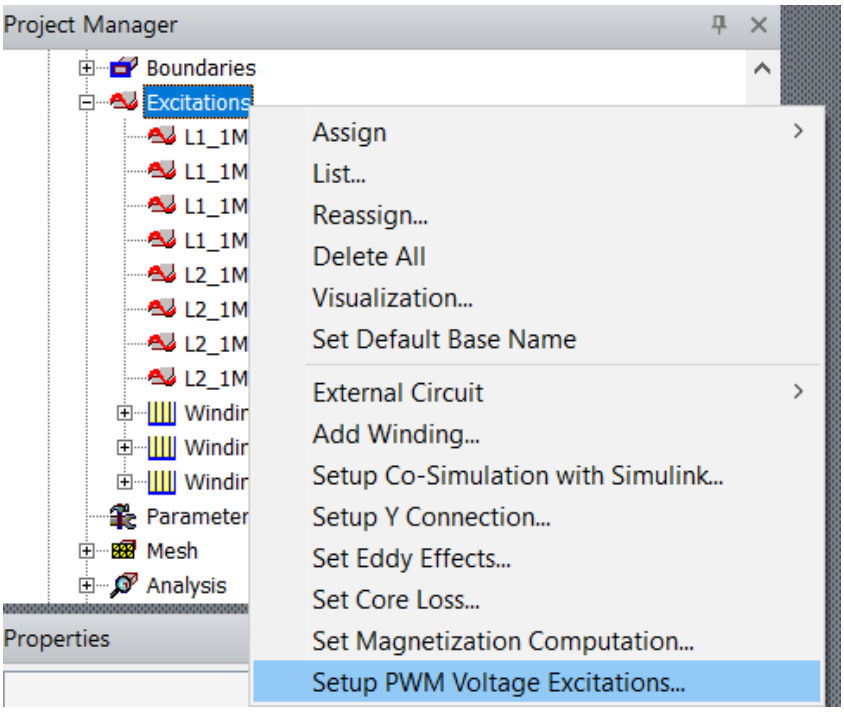
1. Before setting up the SVPWM excitation:
   a. Define three voltage windings.
   b. Set up the Y connection for the winding. Note that the Y connection is currently available for stranded winding, but it is not supported for solid winding.



2. In the Project Manager tree, right click **Excitations**, and select **Setup PWM Voltage Excitations...**

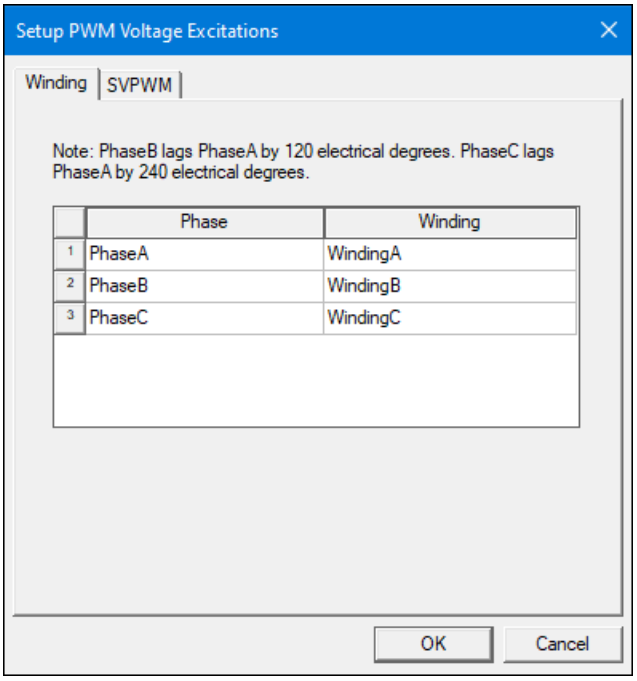
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Alternatively, from the menu bar, select **Maxwell 2D/3D** > **Excitations** > **Setup PWM Voltage Excitations**.



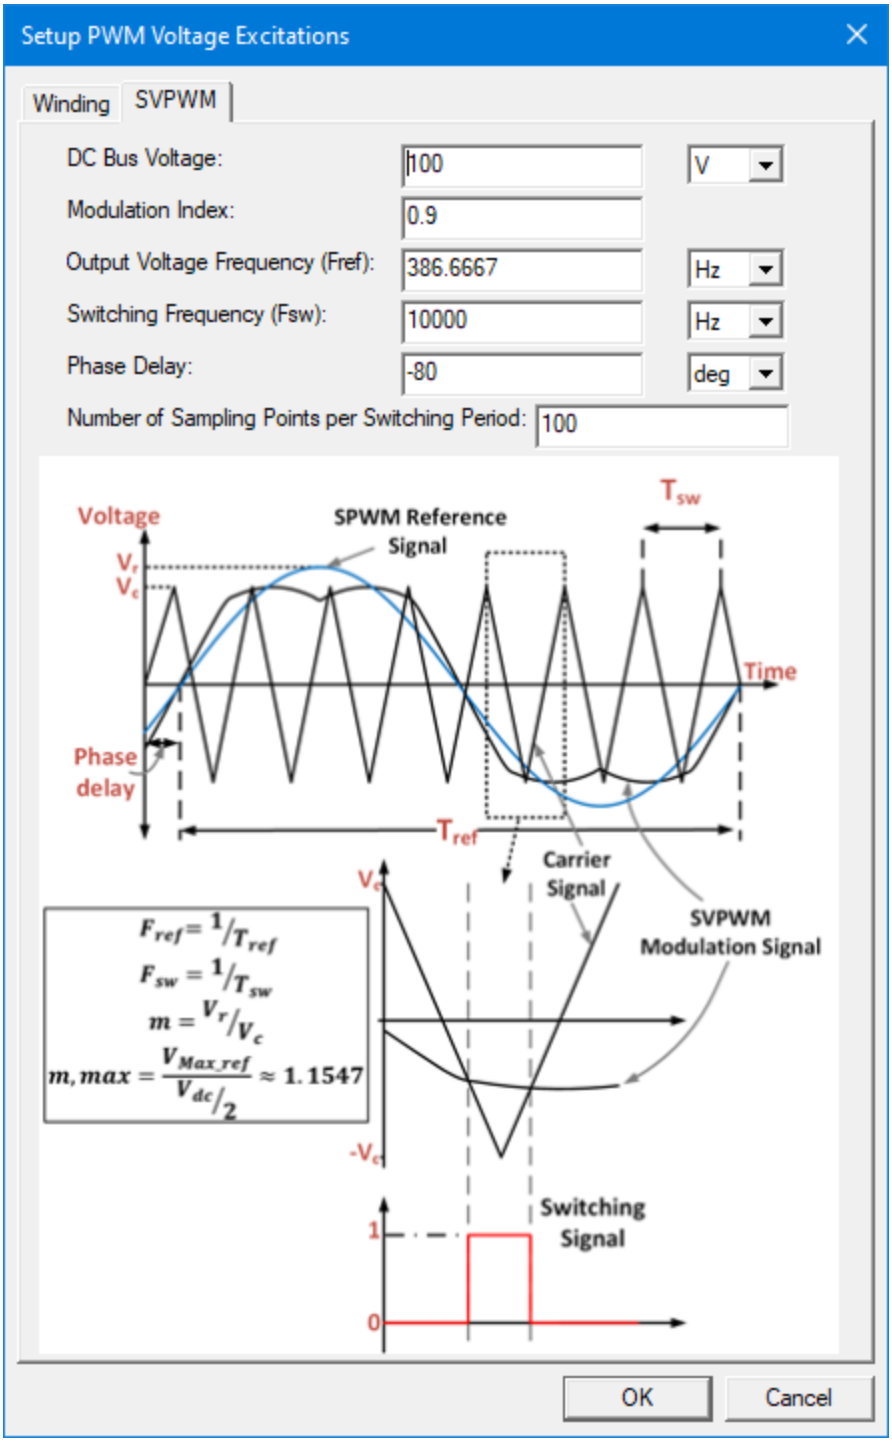
3. In the Setup PWM Voltage Excitations window that opens, arrange the three windings to represent the three phase windings (PhaseA, PhaseB and PhaseC) accordingly.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. Click on the **SVPWM** tab, and input the corresponding parameters for SVPWM. Example parameters are shown below:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- **DC Bus Voltage** – Specifies the voltage available at the main DC bus as input to the inverter. This value can be entered directly or defined using a design variable.

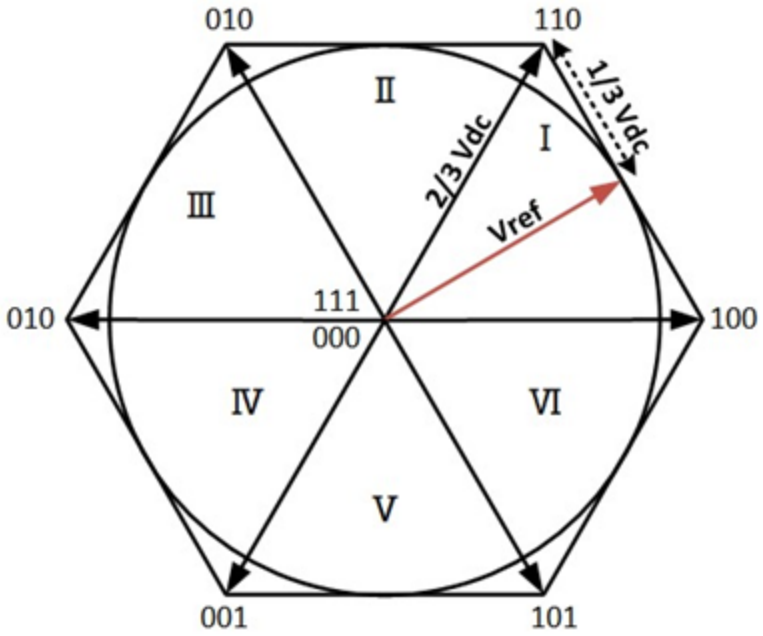
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Modulation Index** (m) – Specifies the ratio between the reference signal to the carrier signal; it determines the amplitude of the fundamental output voltage with respect to the available DC bus voltage as described by the equation below.

$$V_{peak,\ Phase-Neutral} = m * \frac{V_{DC}}{2}$$

The range of the modulation index is 0 < modulation index ≤ 2/sqrt(3) (*i.e.*, approx. 1.1547) for SVPWM. Note that this value cannot be defined with a variable.

To understand how the maximum modulation index is calculated, start with the figure below, which shows the space vector hexagon (represented by six sectors and eight vectors). Each vector represents a different switching state of the inverter.



The vector V_{ref} is the reference revolving voltage vector formed from the three phase sinusoidal voltages; at each sector, this vector is realized by alternating between the two nearest space vectors along with the zero vectors.

The circle inside the hexagon represents the maximum value possible for V_{ref} (and hence the output voltage) that can be produced with the SVPWM technique.

Knowing that the magnitude of each vector is 2/3 V_{DC}, the maximum value of the output voltage (V_{ref}) can be computed as

$$V_{RefMax} = \sqrt{\left(\frac{2}{3}V_{dc}\right)^2 - \left(\frac{1}{3}V_{dc}\right)^2}$$

$$V_{RefMax} = \frac{\sqrt{3}}{3}V_{DC}$$

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

From these definitions, the maximum modulation for SVPWM can be derived as

$$m_{Max} = \frac{V_{RefMax}}{\frac{V_{DC}}{2}} = \frac{2*\sqrt{3}}{3} \approx 1.1547$$

- **Output Voltage Frequency (Fref)** – Defines the fundamental frequency of the reference signal, and therefore, the PWM output voltage.
- **Switching Frequency (Fsw)** – Defines the carrier signal frequency that is used to generate the PWM switching signal. A typical value for traction inverters is between 10 – 20 kHz.
- **Phase Delay** – Defines the phase delay angle of the reference signal (and hence the output voltage). The phase delay depends on the operating point, and it can be provided from system-level simulation or by running a transient simulation with an ideal sinusoidal current and checking the phase delay on the output of the phase voltage.
- **Number of Sampling Points per Switching Period** – Defines the rate at which the carrier signal and the reference signal are compared to generate the switching signals. This value is important to correctly capture the switching events. The default (recommended value) is 100.

5. Click **OK**.

The technique used by the Maxwell application to implement SVPWM excitation computes the pattern of voltage pulses for each of the three datasets by comparing a triangular carrier wave with frequency Fsw and amplitude 1 to three reference functions.

Unlike for sinusoidal PWM, where the reference functions are sinusoidal, for this SVPWM implementation, the three reference functions (V_{a_Ref}, V_{b_Ref}, V_{c_Ref}) need to be constructed as a first step. This is achieved by superposing the common mode voltage (V_{CM}) to the three sinusoidal signals (V_{a_0}, V_{b_0}, V_{c_0}) of a three-phase system:

$$V_{a_Ref} = V_{a_0} + V_{CM}$$

$$V_{b_Ref} = V_{b_0} + V_{CM}$$

$$V_{c_Ref} = V_{c_0} + V_{CM}$$

V_{a_0} is defined as ModulationIndex*sin(2*pi*Fref*time-Phase Delay). V_{b_0} and V_{c_0} lag V_{a_0} by 120° and 240°, respectively.

The amplitude V_{max} can be calculated as (DC Bus Voltage)/2 * Modulation Index.

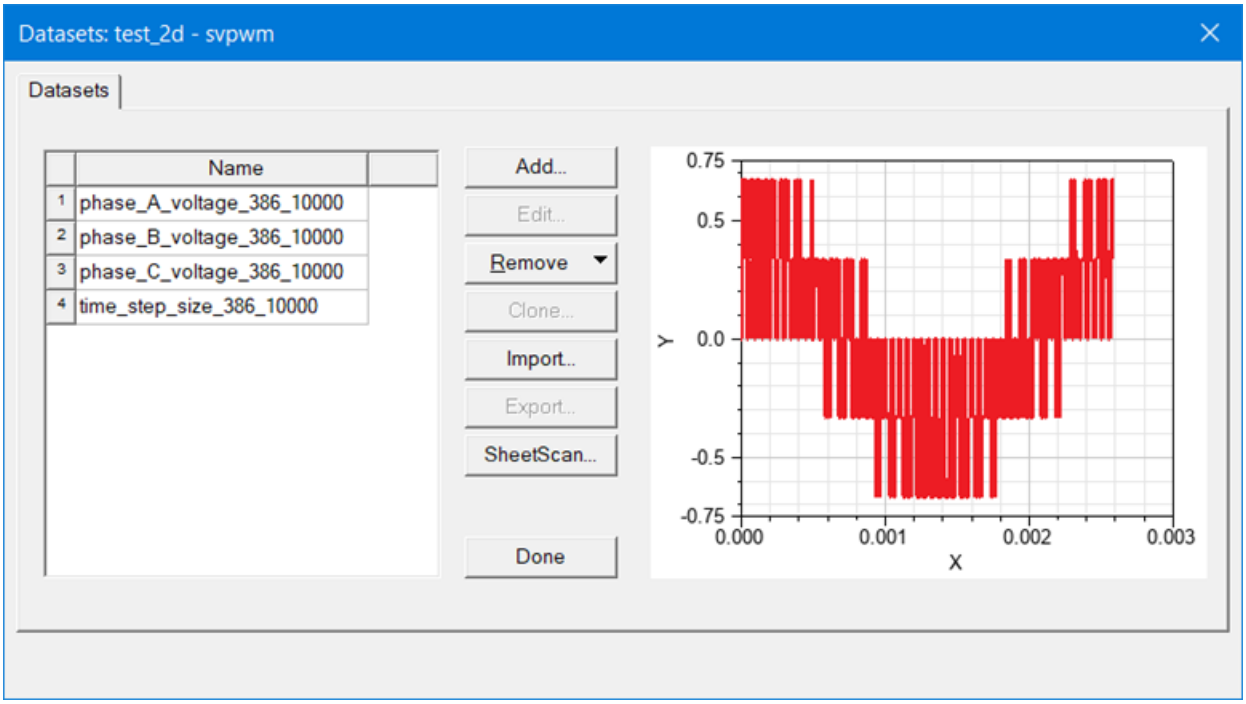
At every timestep, the common mode voltage is calculated as half of the mid-valued function among V_{a_0}, V_{b_0}, V_{c_0}.

Three datasets of the voltage (Phase_X_voltage_<Fref>_<Fsw>) vs. time will be generated. The datasets are generated by comparing the reference signal to the triangular carrier at a

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

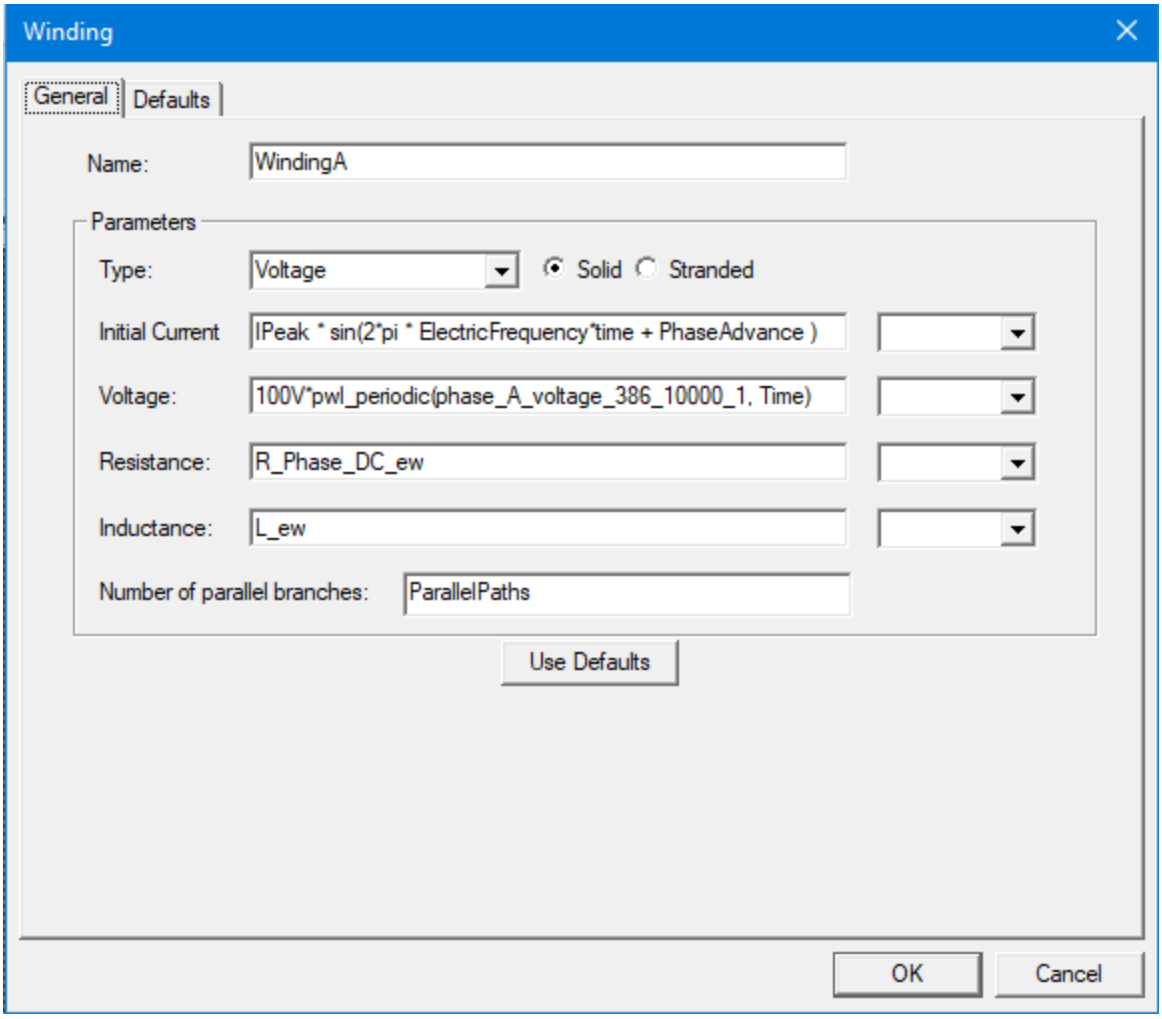
sampling frequency Fsw*Number of Sampling Points per Switching Period. Subsequently, the datasets are reduced by removing the timesteps where no change of the voltage values occurs.

The datasets represent the three normalized PWM phase voltages for one electrical cycle. The phase sequence of the generated dataset is A-B-C with Phase B and C lagging Phase A with 120 deg and 240 deg, respectively. The generated datasets can be accessed from **Maxwell** > **Design Datasets** or by right clicking on the model in the Project Manager tree and selecting **Design Datasets**. The datasets shown below are based on previous example settings; the plot for phase_A_voltage is displayed.



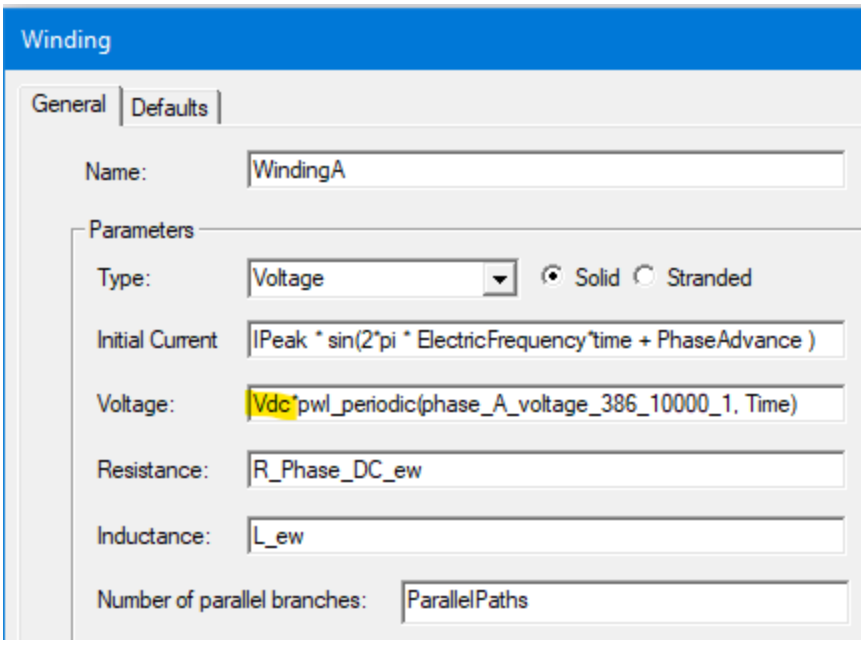
The phase datasets generated are added to the corresponding Winding Voltage value field in the format of **pwl_periodic**, which is used to ensure the voltage is periodic in case the simulation is longer than one electric cycle. WindingA is shown as an example:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



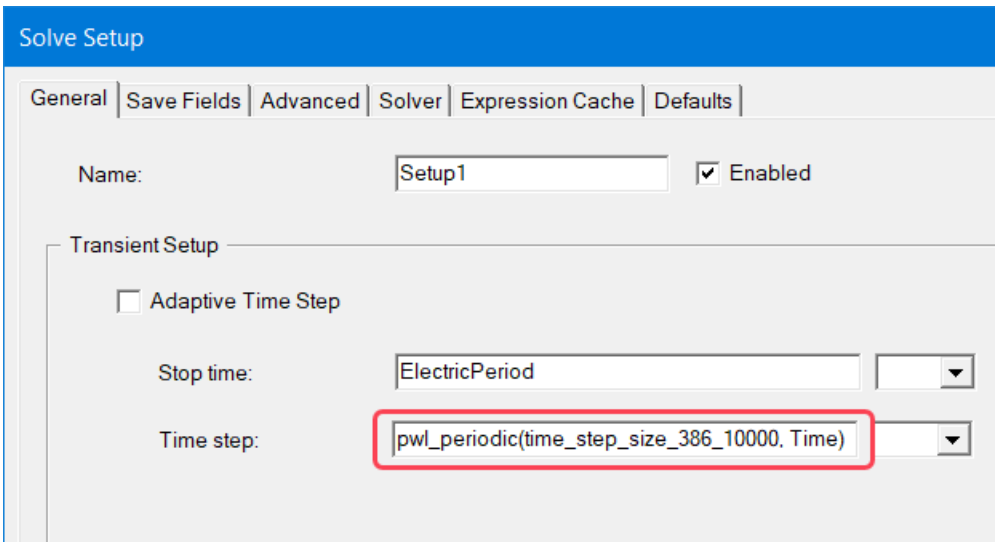
The expression is multiplied by the DC bus voltage that is defined on the **PWM Voltage Excitations** tab. All the other inputs will not be changed. If the DC Bus Voltage was defined as a variable, the variable will be used instead:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



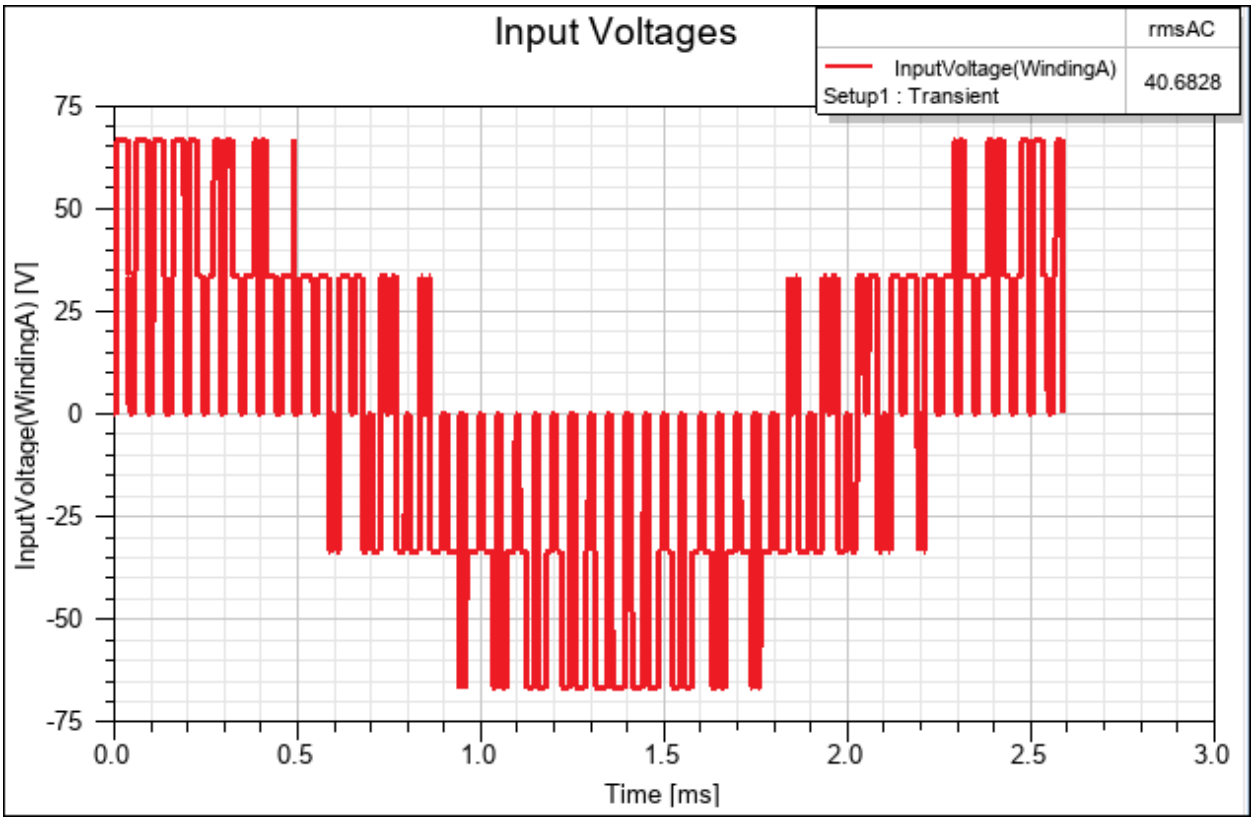
Users can change the Voltage value by adding multiples to the pwl_periodic function.

An additional dataset time_step_size_<Fref>_<Fsw> is created. This dataset tracks the exact instance the switching happens and will be used to define the variable time step in the transient setup to ensure that all switching events are captured with the minimum number of time steps possible. This dataset will be added to the Solve Setup Time step value field in the pwl_periodic format:

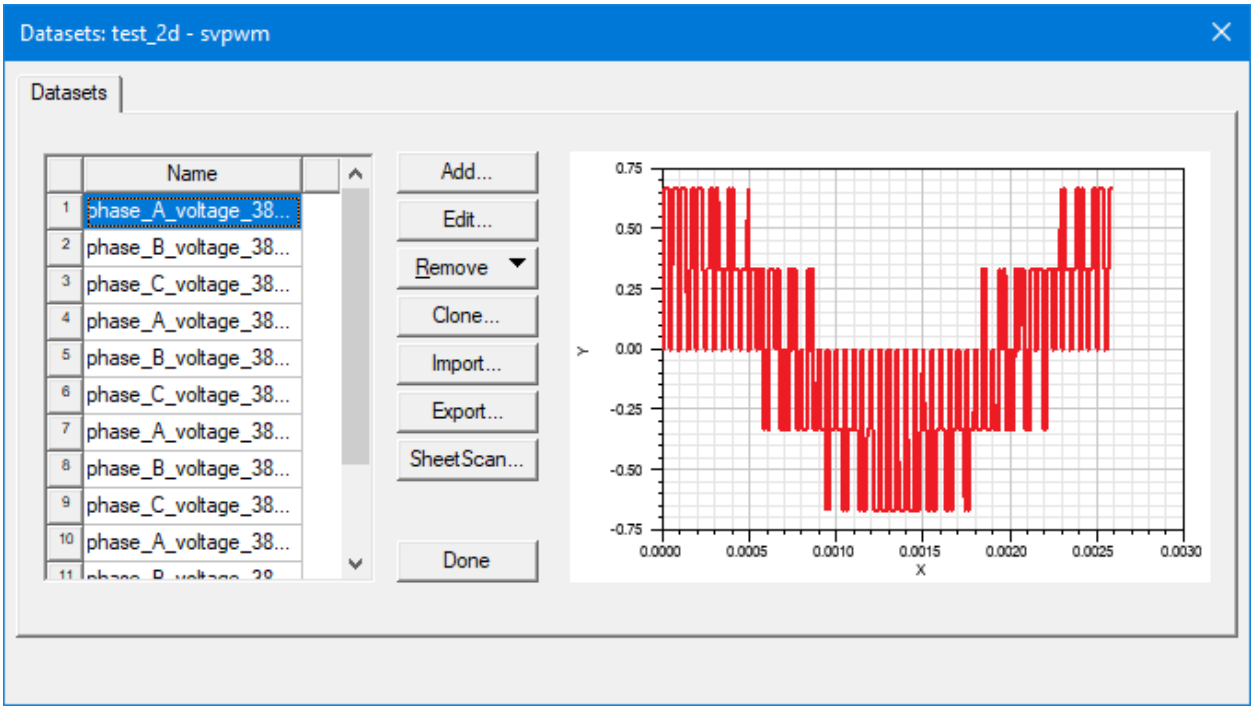


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once the design is analyzed, the user can plot the PWM voltage applied to the windings, which resembles the dataset created by PWM Voltage Excitations function, as shown in the following images:



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



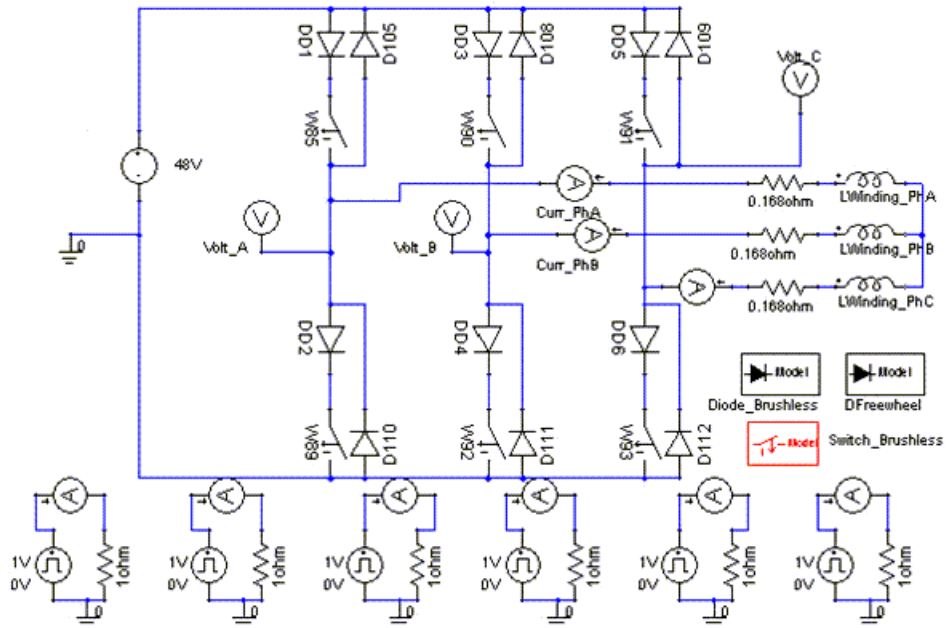
Setting Up an External Circuit

> **Note:** Use of external circuits is indicated when more complex excitation circuits such as rectifiers, inverters, etc., containing components such as diodes, transistors, complex sources, etc. are needed. There is no need to use an external circuit for simple current or voltage sources supplying the windings.

> **Note:** External circuits intended for use with the Time Decomposition Method (TDM) can only support basic circuit elements that are solution-independent. This is because, for TDM, all timesteps (or all timesteps in a subdivision) are solved simultaneously - and thus the circuit topology and its parameters must be known before solving. Therefore some circuit elements, such as solution-dependent switches, diodes, capacitors, and inductors which are not directly connected to windings in series, are not supported.

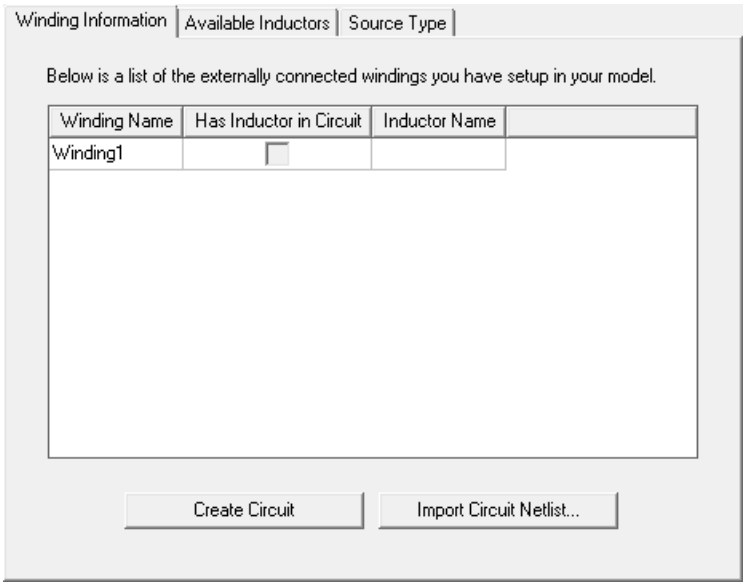
An external circuit netlist can be complex as shown in the example below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For the 2D Transient solver, to set up an external circuit connection for an External winding type:

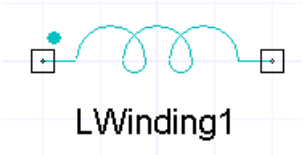
1. Click **Maxwell 2D** > **Excitations** > **External Circuit** > **Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit** > **Edit External Circuit**.
    a. If no external winding connections have been set up for your model, the **Winding Information** tab lists the external winding(s) in the design. Continue with step 2.



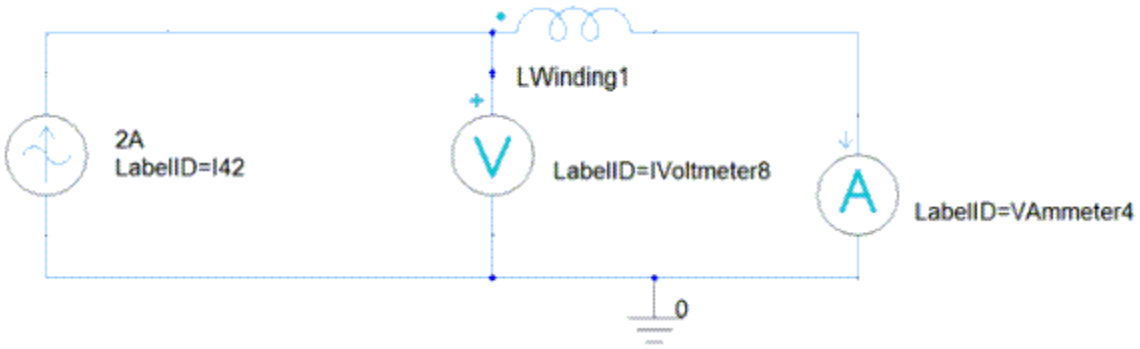
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. If external windings have already been set up, continue with step 7.

2. On the **Winding Information** tab, click **Create Circuit** to add a circuit design to the project. The new circuit design automatically opens for editing in the Maxwell Circuit Editor. The circuit includes one inductor for each external winding in the original Maxwell transient design. The following example is for a design having one external winding.



3. Add the components needed to complete the external circuit design such as shown the following example.



4. When the circuit design is finished, click **Maxwell Circuit** > **Export Netlist** and export the netlist **.sph** file to the desired location.
5. Return to the Maxwell design and click **Maxwell 2D** > **Excitations** > **External Circuit** > **Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit** > **Edit External Circuit**.
6. On the **Winding Information** tab, click **Import Circuit** to import the circuit.
7. To view a list of inductors in the imported circuit, click the **Available Inductors** tab.
8. To view the sources used in the externally connected windings, click the **Source Type** tab.
9. If variables are used in the imported circuit, they and their design values are listed on the **Parameter Values** tab. You can link to variables within the imported circuit as follows:
   a. On the **Parameter Values** tab, click in the **Value** column of the parameter to be mapped.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. Enter a new local variable name and press the `Enter` key to open the **Add Variable** dialog box.
c. Select a **Unit Type** and **Unit**, and enter a **Value** for the variable and click **OK**. The new Maxwell variable is now mapped to the variable in the imported circuit, and can be varied directly by Maxwell or used for optimetrics analyses.

10. If the imported file is a .**sph** file, you can click the **Circuit Path** tab to view the original project and design names.

> **Note:** After you import a circuit netlist, the **Create Circuit** button changes to **Update Netlist from Circuit**. Use **Update Netlist from Circuit** to reimport the netlist to keep it current.

11. Click **OK** to close the **Edit External Circuit** dialog box.

> **Note:** The user-set timesteps can be modified when external circuits are used to drive the windings of the transient finite element model. Following is a list of situations that will lead to a time-step change:
>
> - All power electronic switching instances that do not coincide with user-specified solve times request a new solution time from the transient solver. The respective switching generating a new solve time request for the transient solver can be time, position, or speed dependent.
> - When current and/or voltage sources with a piecewise linear variation are used, a new solution time is requested from the transient solver at each (time) definition point used in the corresponding source definition table.
> - When the change in any winding inductance value is excessive, a new timestep (smaller) is calculated and a new solution generated (recalculated) accordingly.
>
> If a user-specified save field time is missed because of the above reasons, the next solved time-step fields are saved instead.

Add the Circuit Elements for 2D Transient

To add the circuit elements in Maxwell Circuit design editor:

1. Click **Project** > **Insert Maxwell Circuit Design**. The circuit sheet appears.
2. On the **Components** tab in the Component Libraries panel, locate the winding circuit element and place it on the sheet:
   a. In the component library tree, under **Maxwell Circuit Elements/Dedicated Elements**, select the **Winding** element.
   b. Drag it onto the sheet.
   c. Right-click, and select **Finish** to place the component.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

d. To view the properties, double-click the component in the Schematic window. The **Properties** dialog box appears.
e. Change the **Name** to **currentwinding**, the same name you used when defining the winding in the Maxwell design.
f. Click **OK**.
g. Click **Draw** > **Rotate**, and position the winding vertically.

3. Place a resistor on the sheet:
   a. In the component library tree, under **Passive Elements**, select **Resistor**.
   b. Drag the resistor onto the sheet.
   c. Right-click, and select **Finish** to place it where desired.
   d. Double-click the symbol of the resistor, change the value of the resistor, **R**, to **3.09**, keep the **Unit** value set to **ohm**, and click **OK**. The default is 100 Ohms.
4. Place a voltage pulse on the sheet:
   a. In the component library tree, under **Sources** select a **VPulse** element (Pulse Voltage Source).
   b. Drag it to the sheet, and then right-click and select **Finish** to place it onto the sheet.
   c. Double-click the source element symbol on the sheet, and then specify the following source characteristics:

Parameter	Value	Description
V1	0	Initial voltage
V2	5.97	Peak voltage
Tr	0.001	Rise time
Tf	0.001	Fall time
Pw	1	Pulse width
Period	2	

5. Leave the other fields set to the default values, and click **OK**.

Setting Up an External Circuit Using Simulink

In addition to using the Maxwell Circuit Editor to set up an external circuit, you also can use MATLAB® Simulink® to set up an external circuit for both Maxwell 2D and 3D transient designs.

Supported Simulink versions are

- R2019b
- R2020a
- R2020b
- R2021a
- R2021b

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- R2022a
- R2022b
- R2023a

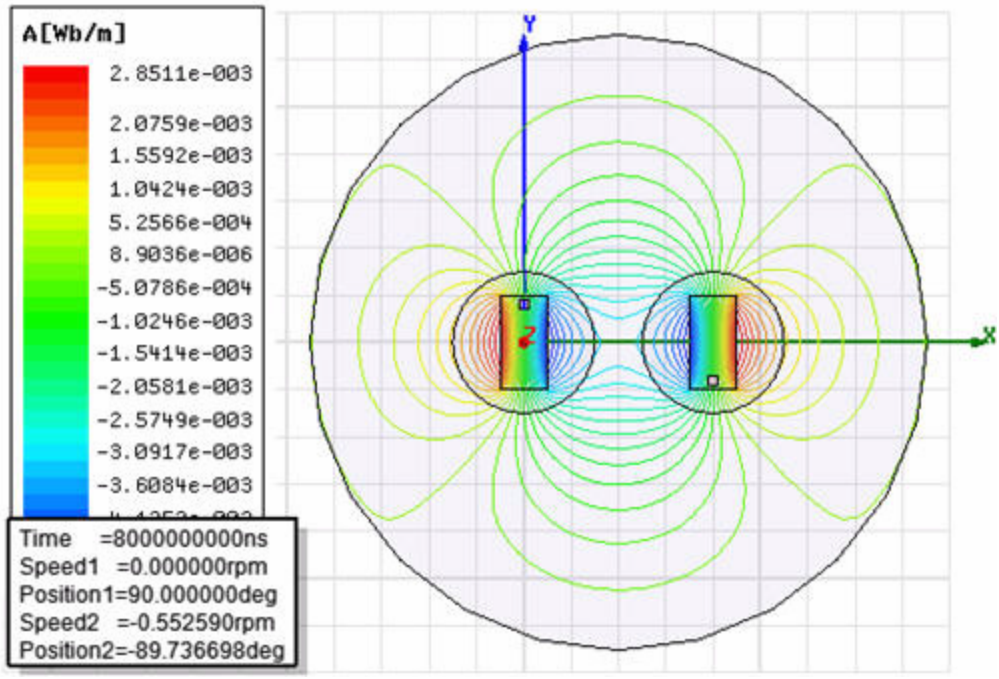
Refer to Setting Up an External Circuit Using Simulink for detailed information.

Setting Up Motion for Transient Projects

For projects where you selected transient as the solution type, you can define how the model components move in relation to one another. This is accomplished by assigning a **MotionSetup** to a **Band** object. Two or more motion bands may be assigned, each with its own independent motion characteristics. Multiple motion bands are used primarily for certain types of motors where multiple rotors may rotate about a common central axis; however, other applications are possible as shown in the following examples.

Example - Two Bands of Motion

The project shown below comprises two rectangular magnets, each surrounded by a band object with a MotionSetup assigned to it. When one magnet moves, the other magnet realigns itself. Also note that the solution context display shows the position and speed for both motion setups.

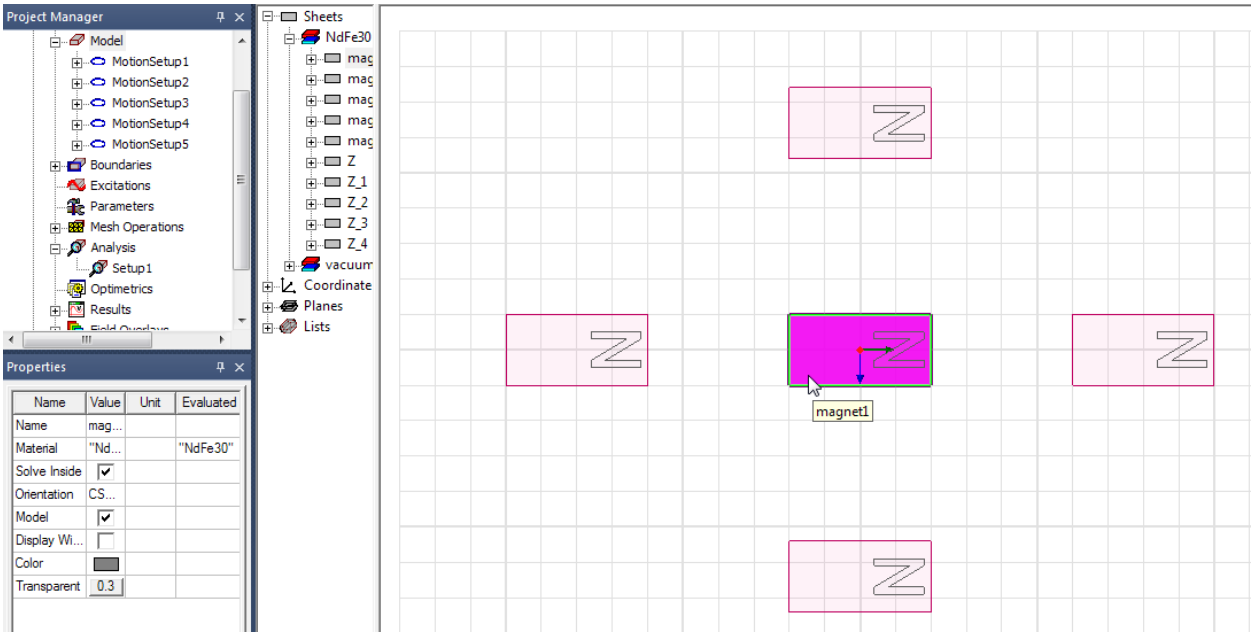


Note: The two moving bands must not touch each other. There must be some stationary region between the two bands, even if it is filled only with vacuum.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Example - Multiple Bands of Motion

The magnet project shown below comprises five bar magnets. When the center magnet (MotionSetup1) moves, the other magnets also move.



> **Note:** The moving bands may not touch each other. There must be some stationary region between the bands, even if it is filled only with vacuum.

Assigning a Band of Motion

You can assign a band of motion in both Maxwell 2D and Maxwell 3D projects. For both Maxwell 2D and 3D projects, two or more motion bands may be assigned.

> **Note:** Overlapping bands are not supported so they cannot be located inside of each other.

For both rotational and translational problems, the band object must always enclose all of the moving objects. For rotational problems, this means the band object should be a solid cylinder or a solid wedge – not a hollow shell or segment of a shell. If the band object encloses all moving aspects, it is easier to identify the moving objects and reduces errors related to misidentifying them.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: An inner region (or wrapper object) enclosed by the band can normally be used as a “fake” moving object for two reasons:

- The first is to avoid creating holes inside the band which would result in the band having multiple connected domains.
- The second is due to the torque/force computation being carried out by one layer of elements inside the band region that directly touches moving objects. If an inner region is not included, the torque/force computation will be very sensitive to mesh noise - thus leading to an inaccurate solution.

Note: For 2D and 3D translational motion, here are some additional recommendations:

- An all-encompassing inner region (non-magnetic, non-conductive wrapper such as air or vacuum) must be used around all moving objects in a band.
- The inner region wrapper object, like the Band itself, should be a simplified shape, such as a rectangle or polygon in 2D, or a polyhedral or segmented sweep section in 3D. Any simplifications to the inner region and band object will result in better re-meshing for each time-step and faster overall simulation times.
- In order to give more accurate forces, if there is sufficient clearance between moving and stationary objects, you can provide some padding between the inner region and the moving objects and the band. At a minimum, the inner region should be the same size as the outside of the enclosed objects (like shrink wrap) with no gap between the wrapper and objects inside.
- Ansys highly recommends that the band not touch any outer stationary objects, with the only exception being for symmetry boundaries on the outer region. It is suggested to locate the band halfway in the air-gap between fixed and moving objects or equally spaced with the inner region object if there is sufficient clearance at the gap.
- In order to get stable force results, length-based mesh operations (approximately equal to the distance between the band and the inner region) should be applied using the Length-Based-Inside mesh refinement assigned to the Band object so that the mesh length is refined in the band region that is re-meshed for each time-step.

To assign the band of motion:

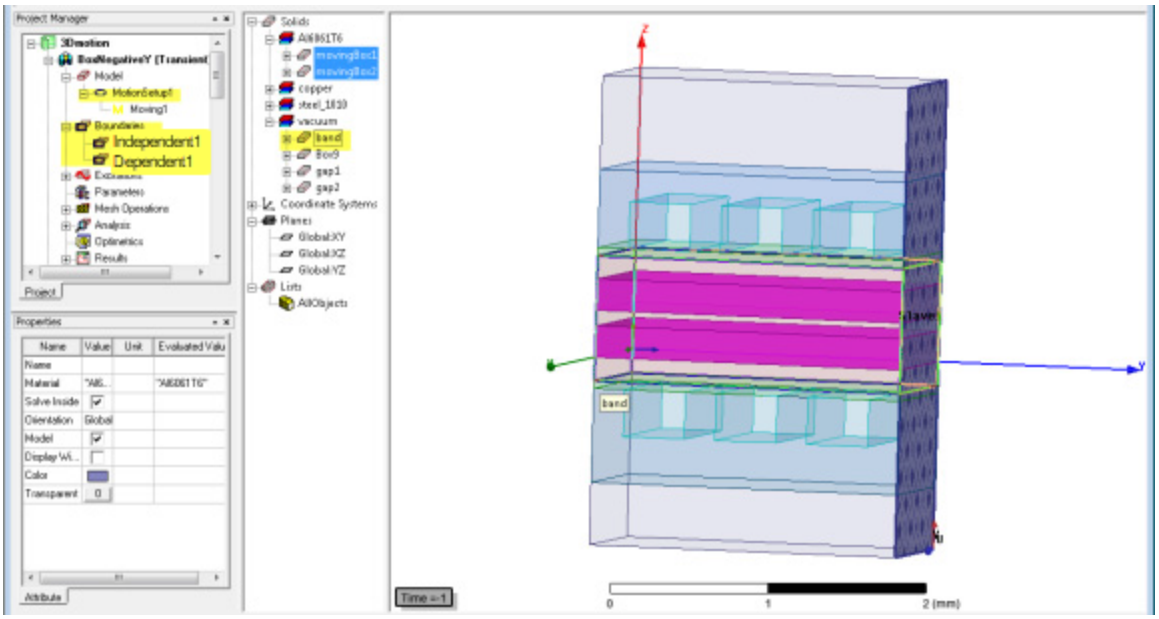
1. Select the band object.
2. Click **Maxwell** > **Model** > **Motion Setup** > **Assign Band**.

   The **Motion Setup** window appears.
3. On the **Type** tab: select either **Translation** or **Rotation** as the **Motion Type**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For **Rotation** about a fixed point you may select the **Non-Cylindrical** check box.
- For **Translation**, you may select the **Periodic** check box.

For **Periodic** motion, you must define independent and dependent boundary conditions. Both band and the object(s) inside it move, and both should touch the independent and dependent boundaries as shown in the following example.



4. Set the motion direction:
   a. For **Translation** (including **Periodic**), select the desired X, Y, or Z (for 3D) axis of motion from the **Moving Vector** drop-down menu; then select either **Positive** or **Negative** direction.
   b. For **Rotation**, from the **Moving Axis** drop-down menu, select an axis of rotation. Use the radio buttons to select either **Positive** or **Negative** rotation.

   Note:
   - For 2D XY rotation, only **Positive** rotation is allowed.
   - If the expected moving vector does not exist, click **Modeler** > **Coordinate System** > **Create** > **Relative CS** to create a new coordinate system.

5. On the **Data** tab: type a value in the **Initial Position** box, and select the units from the drop-down menu.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. To set the motion limits, do the following in the **Translate Limit** or **Rotate Limit** section:

   Note: For Periodic motion, you do not need to define motion limits because the solver does not consider the limits for periodic motion; thus the **Translate Limit** section is not present.

   a. For rotational motion, click the **Rotate Limit** check box.
   b. For translational (non-**Periodic**) or rotational motion, type a value in the **Negative** box, and select the units from the drop-down menu.
   c. For translational (non-**Periodic**) or rotational motion, type a value in the **Positive** box, and select the units from the drop-down menu.

7. On the **Mechanical** tab, do one of the following to specify the object velocity (dynamic or constant):

   Note: When you select **Consider Mechanical Transient**, you are telling the solver to use the calculated force and user-specified mass, damping, and other parameters to dynamically determine how the object moves, rather than giving it a constant velocity.

   Note:
   - For Maxwell 2D/3D designs for motor applications, the computed output mechanical power at given constant speed may not reach the desired rated power. Therefore, it is useful to apply constant power as the mechanical load. In Maxwell 2D/3D designs created by RMxprt, the mechanical transient is set up according to the rated mechanical output power, and equivalent damping is added to accelerate the process approaching to the rated output power. This setup is visible when **Consider Mechanical Transient** is checked.
   - The **Consider Mechanical Transient** setup is only for the sake of getting the operating point with given output power. it is not related to any mechanical load type you may set in RMxprt.
   - 2D/3D designs generated from RMxprt include the setup data, but **Consider Mechanical Transient** is unchecked initially. To ensure that the setup data is preserved, make sure that you check **Consider Mechanical Transient** before saving the project.

   - To dynamically change how the object moves, click the **Consider Mechanical Transient** check box, complete the following fields, and select any corresponding units:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Initial Velocity** (translational) or **Initial Angular Velocity** (rotational)
- **Mass** (translational) or **Moment of Inertia** (rotational)

Use the **Calculate** button to have Maxwell calculate the Mass or Moment of Inertia with the following restrictions:

- For 2D problems, the moving bodies are assumed to be of model-unit thinness.
- Rotating bodies must be symmetric about the axis of rotation. Partial models (e.g., half a motor with implied symmetry) are not supported.
- **Damping** (rotational motion) – A value for damping for rotational motion (for electric machines) can be calculated by the windage and friction loss in Watts divided by the speed in rad/sec (at which those losses are defined); the resulting units are in W / $(rad/sec)^2$ or N*m * sec/rad.
- **Damping** (linear motion) – A value for damping for linear motion can be calculated by the windage and friction loss in Watts divided by the speed in m/sec (at which those losses are defined); the resulting units are in W / $(m/sec)^2$ or N*m * sec/m.
- **Load Force** (translational) or **Load Torque** (rotational)

  Note:
  - For translational motion, the load force is positive if it is applied in the same direction as the moving vector and negative if applied in the opposite direction.
  - For rotational motion, the load torque sign is determined based on the moving vector, using the right-hand rule. Point your thumb in the direction of the moving vector. If the load torque is applied in the same direction as your fingers, then the load torque is positive. If it is applied in the opposite direction, then the load torque is negative.

- To set a constant velocity (and disable the mechanical transient), clear the **Consider Mechanical Transient** check box, type a value in the **Velocity** or **Angular Velocity** box, and select the units from the drop-down menu.

8. For translational motion, a **Post-Processing** tab is available to set the coordinate system for post processing calculation.
9. Click **OK**.

- A **MotionSetup*x*** is created and added to the **Model** folder in the **Project Manager** window.
- For Maxwell 3D projects only, if cylindrical **Rotation** was specified and a **CylindricalGap** mesh operation does not already exist, a **CylindricalGap** mesh operation is automatically added to the **Mesh** folder. Only one **CylindricalGap** mesh operation is permitted.

Modifying Motion Setup Properties

To modify existing motion setup properties:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the Project Manager **Model** folder, right-click on **MotionSetup*x*** and select **Properties** from the context menu to open the **Motion Setup** dialog box.
    - Alternatively, you can double-click the **MotionSetup*x*** icon.
2. Edit the desired properties in the **Motion Setup** dialog box. Refer to *Assigning a Band of Motion* for detailed information on the various **Motion Setup** dialog box settings.

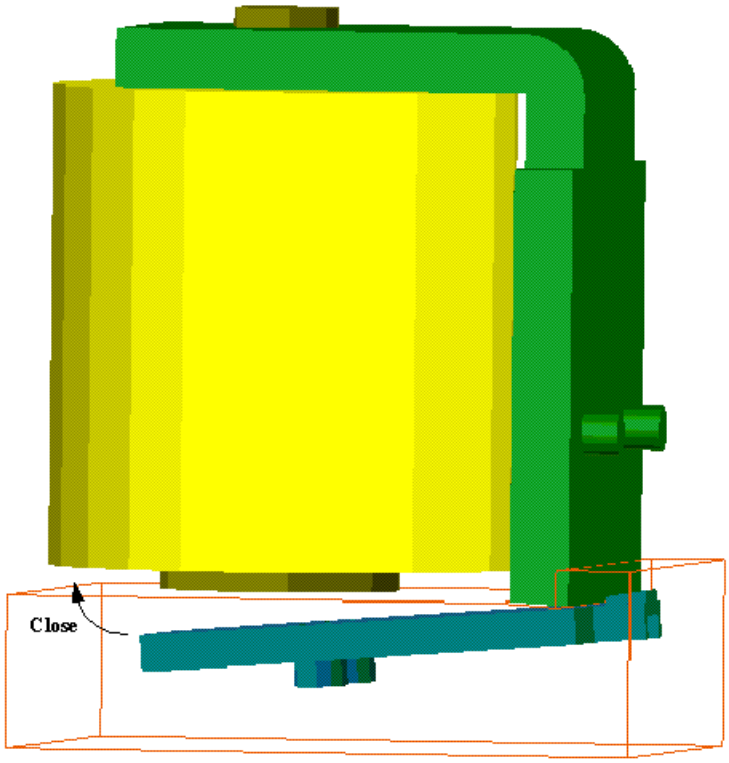
> **Note:**
>
> For Maxwell 3D projects only:
>
> - If you change the motion type to cylindrical **Rotation** and a **CylindricalGap** mesh operation does not already exist, a **CylindricalGap** mesh operation is automatically added to the **Mesh** folder. Only one **CylindricalGap** mesh operation is permitted.
> - If you change a cylindrical **Rotation** motion type to another motion type, the **CylindricalGap** mesh operation remains in the **Mesh Operation** folder.
> - Alternatively, you can edit many of the motion setup properties in the **Properties** window.

Non-Cylindrical Rotational Motion

With cylindrical rotation, the moving objects are free to rotate completely, and the mesh remains fixed as the moving objects rotate. With non-cylindrical motion, the geometry shape of the band region changes as the moving objects rotate, and the mesh is recreated.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- A motor is an example of cylindrical motion.
- A relay is an example of non-cylindrical motion.



Reassigning a Band of Motion

When a **MotionSetup** has been created, the object that the setup is assigned to is changed using the **Reassign** command, allowing you to identify the motion setup parameters with a new object without losing the motion setup parameters themselves. To reassign a **MotionSetup**:

1. Select the object that the **MotionSetup** will be reassigned to in the modeler window or in the history tree.
2. Right-click on **MotionSetup*x*** in the Project Manager window and select **Reassign**.

> **Note:** An existing **CylindricalGap** mesh operation's assignment will be synced up to a rotational cylindrical motion setup's assignment when you reassign the band object of the motion setup.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Adding and Deleting Objects from a Band of Motion

To add objects to, or delete objects from a motion setup without changing the parameters of the **MotionSetup** do the following:

1. Select the object to be added or deleted from the **MotionSetup** in the modeler window or in the history tree.
2. Right-click **Model** > **MotionSetup*x*** > **Moving*x*** in the Project Manager window and choose **Add Selected Objects** or **Remove Selected Objects** from the shortcut menu.
3. To verify the addition or deletion of the object from the MotionSetup definition, use **Select Assignment** from the shortcut menu to view the objects assigned to the band.

Showing and Hiding Motion Objects

1. Click **Maxwell** > **Model** > **Motion Setup** > **Visualization**.
2. From the **Motion Setup Visualization Options** window that appears, select **All**, **Band**, or **Moving** from the **Select** drop-down menu.
3. Click **Deselect All** to hide all motion objects.
4. Click **Close** to close the window.

Setting the Visibility for Motion Objects

To show or hide a parameter:

1. Click **View** > **Active View Visibility**.
2. From the **Active View Visibility** dialog box that appears, click the **Motion** tab.
3. Select or clear the **Visibility** check box for each motion object listed.
4. Click **Done**.

Modeling Maxwell Motion Eccentricity

You can model motion eccentricity for Maxwell 2D and 3D transient designs that have cylindrical rotational motion set up. Ansys Electronics Desktop provides a **Maxwell Eccentricity Wizard** with settings for

- rotating part eccentricity
- rotation axis eccentricity

For rotating part eccentricity modeling, the eccentricity is only applied to rotating objects, not to a motion axis. More specifically, these rotating objects are all objects enclosed by the band, but not the band itself.

For rotation axis modeling, the eccentricity is only applied to the motion axis, which is equivalent to moving the band itself, but not any rotating objects inside the band.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Using these two basic settings, you can model the following physics.

- **Static eccentricity**: To model static eccentricity, you need to set the rotating part eccentricity and rotation axis eccentricity to the same values.
- **Dynamic eccentricity**: To model dynamic eccentricity, set the rotating part eccentricity values only.
- **Mixed eccentricity**: This is the combination of static and dynamic eccentricities. To model mixed eccentricity, set both rotating part eccentricity and rotation axis eccentricity, but with different values.

Using the Maxwell Eccentricity Wizard

> **Note:**
>
> The **ACT Extensions** window and the design wizards it contains (*5G Wizard, HFSS Antenna Design Toolkit, HFSS-EMA3D Link,* and *Maxwell Eccentricities*) are only available for the Windows version of the Ansys Electronics Desktop software. These items are not available when the software is installed on a Linux platform.

You can use the Maxwell Eccentricity wizard to model both 2D and 3D transient designs that have cylindrical rotational motion setup.

> **Note:** If you want to generate a 3D rotational eccentricity motor design from an RMxprt-generated Maxwell 3D design, you must enter **Eccentricity 1** in the RMxprt **Design Setting** window's **User Defined Data tab** for the RMxprt design *before* generating the Maxwell 3D design.

1. Select **View** > **ACT Extensions** to open the ACT Extensions window.
2. Click the **Wizards** button to open the Wizards page, then click **Maxwell Eccentricity** to load the Maxwell Eccentricity setup page.
3. Select the project and design you want to use.

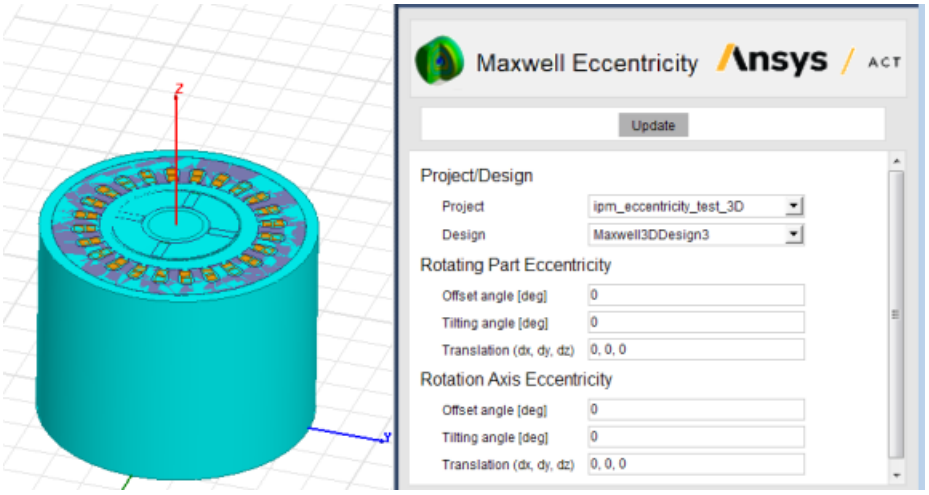
   > **Note:**
   >
   > - The **Update** button synchronizes the project and design selection lists with those currently loaded in the Desktop.
   > - You can click **Exit Wizard** to close the eccentricity wizard and return to the wizard start page without executing any changes.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

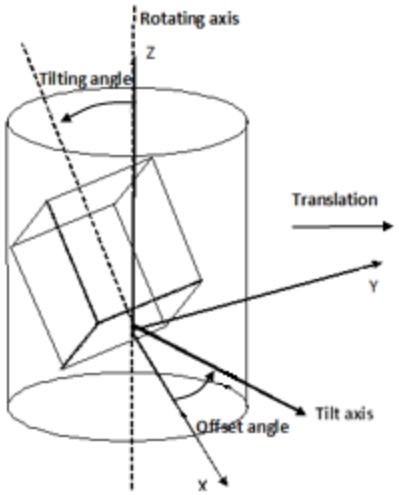
4. Depending on whether your design is 2D or 3D, do one of the following:
    - For a 2D Maxwell project, enter the desired dx and dy translation values to set up the Rotating Part Eccentricity and Rotation Axis Eccentricity. The unit of measure for translation values is the model's unit, which is set using **Modeler** > **Units**.

    - For a 3D Maxwell project, enter the desired dx, dy , and dz translation values, the offset angle, and the tilting angle for the rotating part eccentricity axis and rotation axis. The unit of measure for translation values is the model's unit, which is set using **Modeler** > **Units**.

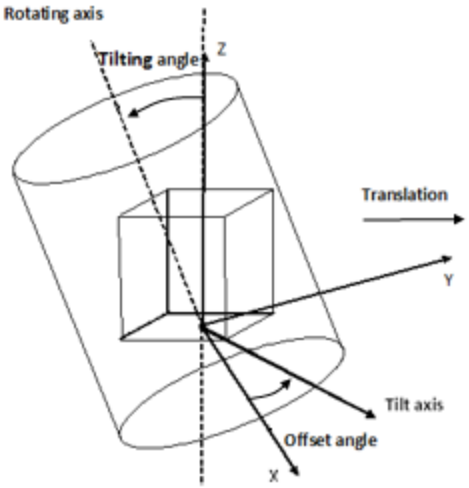
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Rotation Part Eccentricity



Rotation Axis Eccentricity



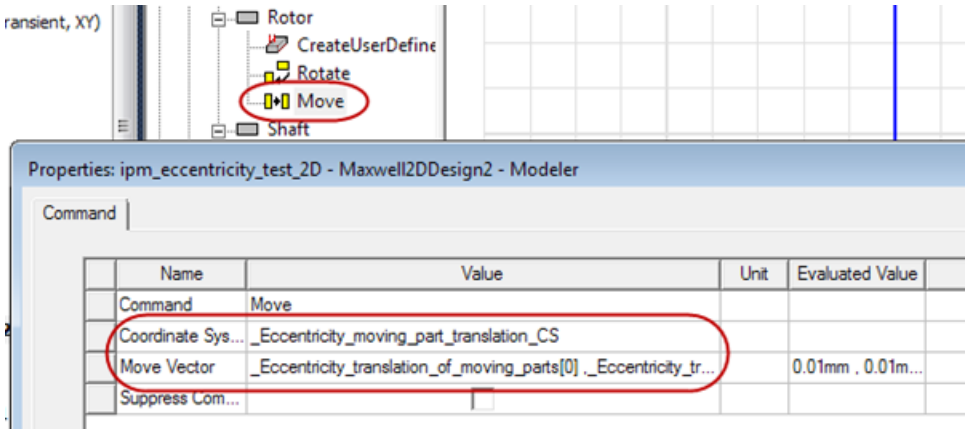
5. Click the **Finish** button at the bottom of the page. The page closes and the wizard adds a new design in the same project, in which the Maxwell geometry has been updated in accordance with the eccentricity setup values you entered, as explained in the sections that follow.

For 2D Designs

- Design variables are created for each of the data entered in the wizard.
  - For rotating part eccentricity: _Eccentricity_translation_of_moving_parts
  - For rotation axis eccentricity:_Eccentricity_translation_of_rotating_axis

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The moving parts in the design motion setup are shifted according to the data defined for **Rotating Part Eccentricity** in the Wizard. New coordinate systems are generated as the object coordinate systems for moving parts, according to the same operations.
- The band is translated according to the data defined for **Rotation Axis Eccentricity** in the wizard.
- The **Moving Vector** entry in the design's motion setup is replaced with the new direction (represented by an axis of a new coordinate system) generated according to the data defined for **Rotation Axis Eccentricity** in the Wizard.



- New design coordinate systems are created.

  _Eccentricity_rotating_axis_translation_CS

  _Eccentricity_moving_part_translation_CS

  _Eccentricity_moving_part_CS_<*part name*> – one for each moving part

> **Note:**
>
> - All the above operations of translation, as well as the creation of new coordinate systems, are dependent on the eccentricity design variables.
> - You can modify these design variables to adjust the eccentricity.
> - The newly added coordinate systems should not be changed manually by the user.
> - Using the wizard to modify a design that has already been set up for eccentricity is not recommended.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For 3D Designs

- Design variables are created for each of the data entered in the wizard.

  For rotating part eccentricity:

  - _Eccentricity_offset_angle_of_moving_parts
  - _Eccentricity_translation_of_moving_parts
  - _Eccentricity_tilting_angle_of_moving_parts

  For rotation axis eccentricity:

  - _Eccentricity_offset_angle_of_motion_axis
  - _Eccentricity_translation_of_motion_axis
  - _Eccentricity_tilting_angle_of_motion_axis
- The moving parts in the design motion setup are rotated and shifted according to the data defined for **Rotating Part Eccentricity** in the Wizard. New coordinate systems are generated as the object coordinate systems for moving parts, according to the same operations.
- The band is rotated and translated according to the data defined for **Rotation Axis Eccentricity** in the wizard.
- The **Moving Vector** entry in the design's motion setup is replaced with the new direction (represented by an axis of a new coordinate system) generated according to the data defined for **Rotation Axis Eccentricity** in the Wizard.
- New design coordinate systems are created.

  For the motion moving vector:

  - _Eccentricity_motion_axis_CS
  - _Eccentricity_motion_axis_tilting_axis_CS

  For the moving parts:

  - _Eccentricity_moving_part_tilting_axis_CS
  - _Eccentricity_moving_part_translation_CS
  - _Eccentricity_moving_part_CS_*<part name>* – one for each moving part

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

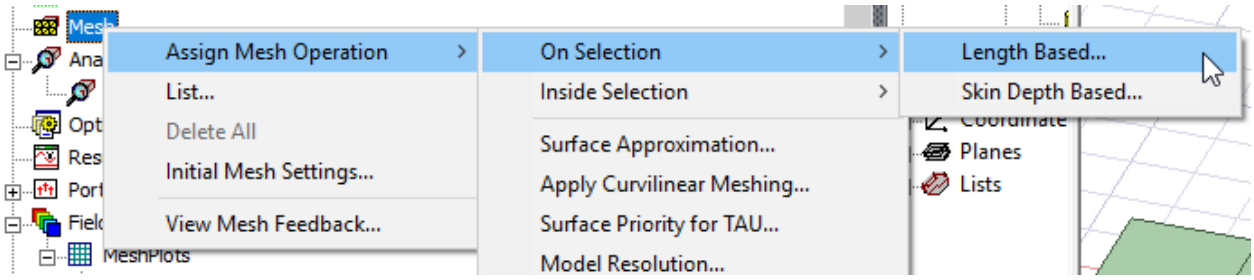
- All the above operations of rotation and translation, as well as the creation of new coordinate systems, are dependent on the eccentricity design variables.
- You can modify these design variables to adjust the eccentricity.
- The newly added coordinate systems should not be changed manually by the user.
- Using the wizard to modify a design that has already been set up for eccentricity is not recommended.

Note: When modeling motion eccentricity, the position and direction of the moving objects and/or band are adjusted based on the eccentricity setup. In such cases, all the adjustments are referenced to the original position and direction of the geometry of each object, As a result, after you finish the eccentricity setup and click the **Finish** button, all the geometries in the design created by the wizard are updated to new positions based on the eccentricity setup. If you want to edit geometry, you should do so in the original design. After editing the geometry, you can then redo the eccentricity setup to create a new design.

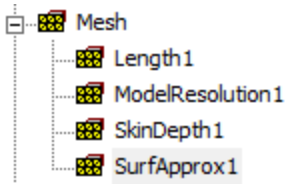
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12 - Defining Mesh Operations

In Project Manager, mesh operations are optional mesh refinement settings that provide the solvers with mesh construction guidance. This technique of guiding mesh construction is referred to as "seeding" the mesh. Seeding is performed using the **Assign Mesh Operation** commands on the respective solver menu.



Each mesh operation you define appears in the Project tree.



Note:

There are no restrictions against assigning multiple mesh operations to the same entities. The *type* of mesh operation can differ between overlapping assignments. For example, length-based refinement could be assigned inside a body, and skin-depth seeding on one or more of its faces. Additionally, overlapping mesh operations of the *same type* can have differing, or even redundant, parameter values (such as element length) without causing an error condition.

Typically, the operation that dictates the finest local meshing results will control the outcome in overlapping assignment areas or volumes.

When defining a mesh, you typically assign the mesh operations first (using the **Maxwell 3D** > **Mesh** or **Maxwell 2D** > **Mesh** commands) and then create the mesh (using the **Maxwell 3D** or **Maxwell 2D** menu and selecting **Analysis Setup** > **Generate Mesh** command). However, you can also refine the mesh after the initial mesh has been created.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can instruct the solvers to reduce the maximum size of tetrahedral elements on a surface or within a volume until they are below a certain value (length-based mesh refinement) or you can instruct solvers to refine the surface triangle length of all tetrahedral elements on a surface or volume to within a specified value (skin depth-based mesh refinement). These types of mesh operations are performed on the *current mesh*, that is, the most recently generated mesh.

In a few circumstances, you may also want to create a mesh operation that modifies a solver's surface approximation settings for one or more faces. Surface approximation settings are only applied to the *initial mesh*, that is, the mesh that is generated the first time a design variation is solved.

In some circumstances, you may also want to assign a cylindrical gap treatment mesh operation. For Maxwell 2D, which uses the TAU mesher is selected in the Initial Mesh Settings dialog box, you can define the Skin Depth Layers mesh setting corresponding to the selected edges.

You can also specify Initial Mesh Settings to apply to all objects; however, if you apply separate surface approximation mesh operations to specific objects, the object settings take precedence over the general setting.

> **Note:** Mesh operations on the target design of a mu (permeability) link are ignored.

You can also choose to override automatic choice of which mesher a product uses, by using the [*solverName*] > Mesh > Initial Mesh Settings command.

See the technical notes for more details about Ansys Electronics Desktop's application of mesh operations.

What do you want to do?

- Length Based Mesh Refinement
- Perform length-based mesh refinement on object faces
- Perform length-based mesh refinement inside objects
- Perform skin depth-based mesh refinement on object faces
- Assign Cylindrical Gap Treatment
- Apply Skin Depth Layer Settings
- Modify surface approximation settings for one or more faces
- Modifying the Model Resolution (Maxwell 3D only)
- Apply Curvilinear Elements
- Specify automatic or specified model resolution for a selection
- Specify the initial mesh settings
- TAU Flex Meshing

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

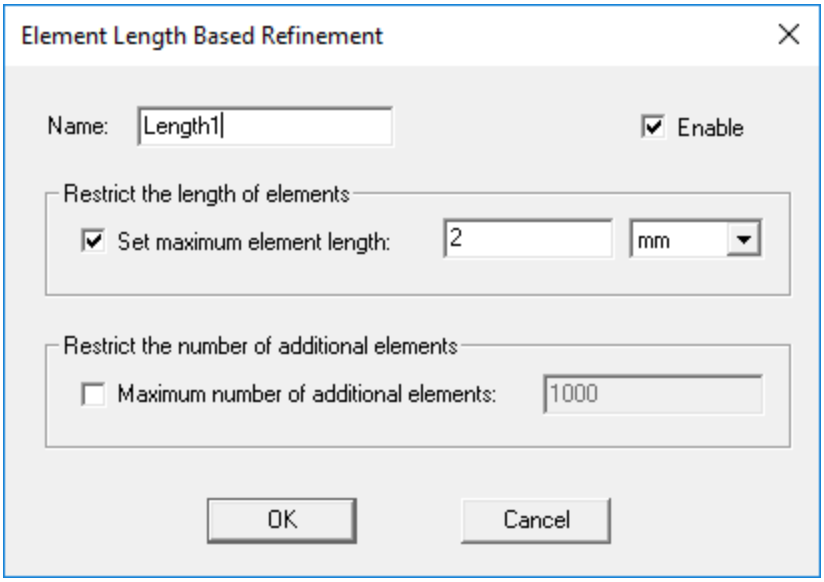
Length Based Mesh Refinement

Length-based mesh refinement settings help control the length of the tetrahedral elements and the growth of the whole mesh. If you are not sure how big a refinement is needed, by way of mesh refinement you can set a ceiling on the mesh growth with the option **Restrict the Number of Additional Elements**.

To apply a length based mesh operation either to an object face or inside an object:

1. Select the object in the modeling workspace.
2. In the Project Manager, right-click **Mesh** > **Assign Mesh Operation** > **[On Selection / Inside Selection]** > **Length Based**.

   The **Element Length Based Refinement** dialog box appears.



3. Enter a **Name** for the mesh operation, or leave the default.
4. Select the **Enable** check box to set the operation as active. You can later deselect this to deactivate it.
5. To restrict the length of tetrahedra edges, select the **Set maximum element length** check box and specify values and units using the drop-down menus.
6. To restrict the number of elements added during refinement, select the **Maximum number of additional elements** check box and specify a value.
7. Click **OK**.

When you set a mesh operation on a selection of objects (more than one) and set a maximum length, it applies to the whole mesh. Even if you selected just one object, when you refine its boundary, elements are added both inside and outside of that object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When there are no more elements to refine or when no more elements can be added, the refinement process stops because it has either met the growth limit or the element length target. However, there are more quality improvement swaps, smoothing, matching boundary issues performed at the finishing stage that might slightly alter the mesh size.

If you restrict the number of elements to say 10000, it will add 10000 elements. If you have multiple mesh operations each for 10000 elements, each mesh operation will add 10000 elements (assuming there was no element length targets).

If you set a restriction of say 2000 elements on an object which creates 1100 elements after lambda refinement without any mesh operation, the starting mesh will contain more than 3000 elements.

Assigning Length-Based Mesh Refinement on Object Faces

1. Select the faces you want to refine.

   Alternatively, select an object if you want to refine every face on the object.

2. Click **Maxwell** > **Mesh** > **Assign Mesh Operations** > **On Selection** > **Length-Based** or right-click **Mesh** in the Project Manager and select **Assign Mesh Operation** > **On Selection** > **Length-Based.**

   The *Element Length-Based Refinement* dialog box appears.

3. Type a name for the mesh operation in the **Name** text box or accept the default name.
4. To restrict the length of tetrahedra edges touching the faces:

   a. Select **Restrict Length of Elements**.
   b. Type the maximum length of the tetrahedral edges touching the faces in the **Maximum Length of Elements** text box.

   The solver will refine the element edges touching the selected faces until their lengths are equal to or less than this value.

   The default value is set to 20% of the maximum edge lengths of the bounding boxes of each selected face.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. To restrict the number of elements added during refinement of the faces:

   a. Select **Restrict the Number of Elements**.
   b. Enter the **Maximum Number of Elements** to be added.
   c. Click **OK**.

When the mesh is generated, the refinement criterion you specified is used. If the maximum number of elements is reached, some elements may exceed the requested maximum element length.

You can also specify Initial Mesh Settings to apply to all objects; however, if you apply separate surface approximation mesh operations to specific objects, the object settings take precedence over the general setting.

Assigning Length-Based Mesh Refinement Inside Objects

Length-based mesh operations inside volumes can be applied to non-model box primitives. If an error occurs, you may be trying to assign a mesh to a non-model box that is not a box primitive (such as boxes with chamfers or non-model cylinders).

To instruct a solver to refine every face of an object and its interior:

1. Select the object you want to refine.
2. Click **Maxwell** > **Mesh> Assign Mesh Operation** > **Inside Selection** > **Length-Based**, or right-click **Mesh** in the Project Manager, and select **Assign Mesh Operation** > **Inside Selection** > **Length-Based...**.

   The *Element Length-Based Refinement* dialog box appears.

3. Type a name for the mesh operation in the **Name** text box or accept the default name.
4. To restrict the length of the tetrahedral element edges inside the object:
   a. Select **Restrict Length of Elements**.
   b. Type the maximum length of the edges inside the object in the **Maximum Length of Elements** text box.

   The default value is set to 20% of the maximum edge lengths of the bounding boxes of each selected object's faces.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The solver will refine the element edges inside the object until they are equal to or less than this value.

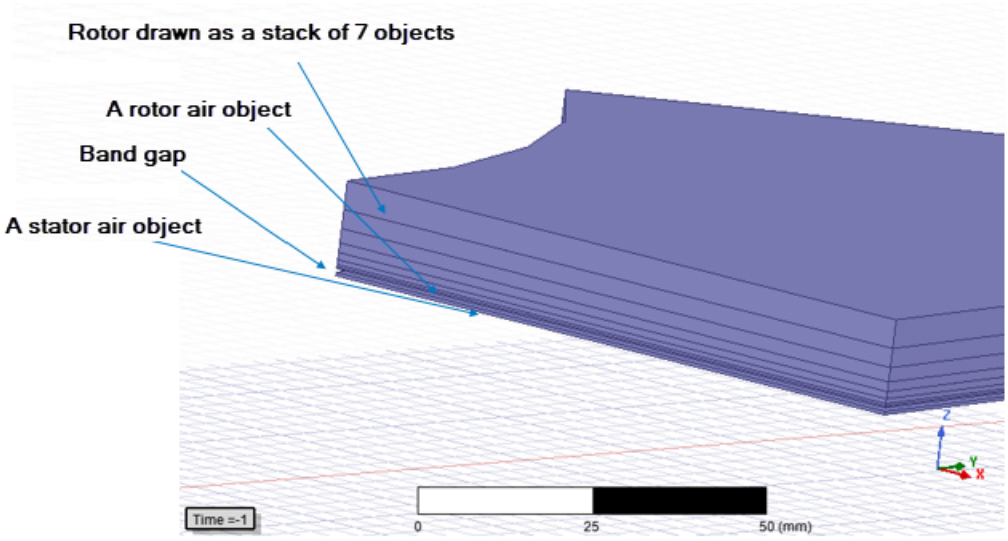
5. To restrict the number of elements added during the refinement inside the object:
   a. Select **Restrict the Number of Elements**.
   b. Enter the **Maximum Number of Elements** to be added.
   c. Click **OK**.

When the mesh is generated, the refinement criterion you specified will be used. If the maximum number of elements are reached, it may result in some elements exceeding the requested maximum element length.

You can also specify Initial Mesh Settings to apply to all objects; however, if you apply separate surface approximation mesh operations to specific objects, the object settings take precedence over the general setting.

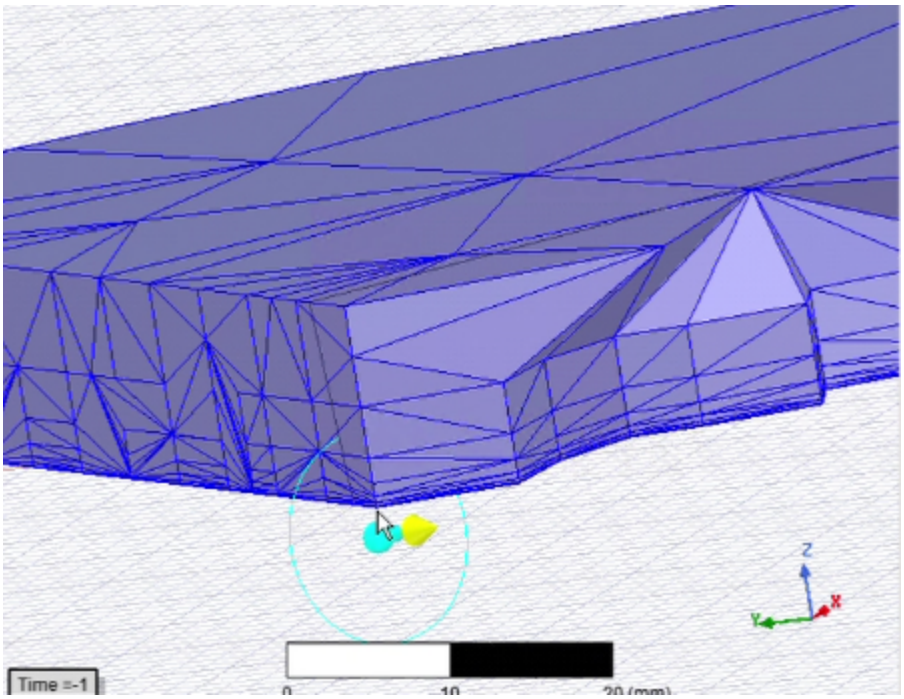
Assigning Skin Depth-Based Mesh Refinement on Object Faces

The Skin Depth-based mesh refinement lets you calculate or specify a skin-depth for mesh refinement. You can also specify the number of layers of elements for refinement where the skin depth is the total depth of all layers combined. These layers provide an easy, alternative approach than by creating physical models of each layer, pseudo-sheet bodies. Whereas creating and adjusting a complex, layered physical model is difficult, changing the skin depth parameters and number of layers is very easy. For example, consider a Maxwell rotor, drawn as a stack of seven objects:



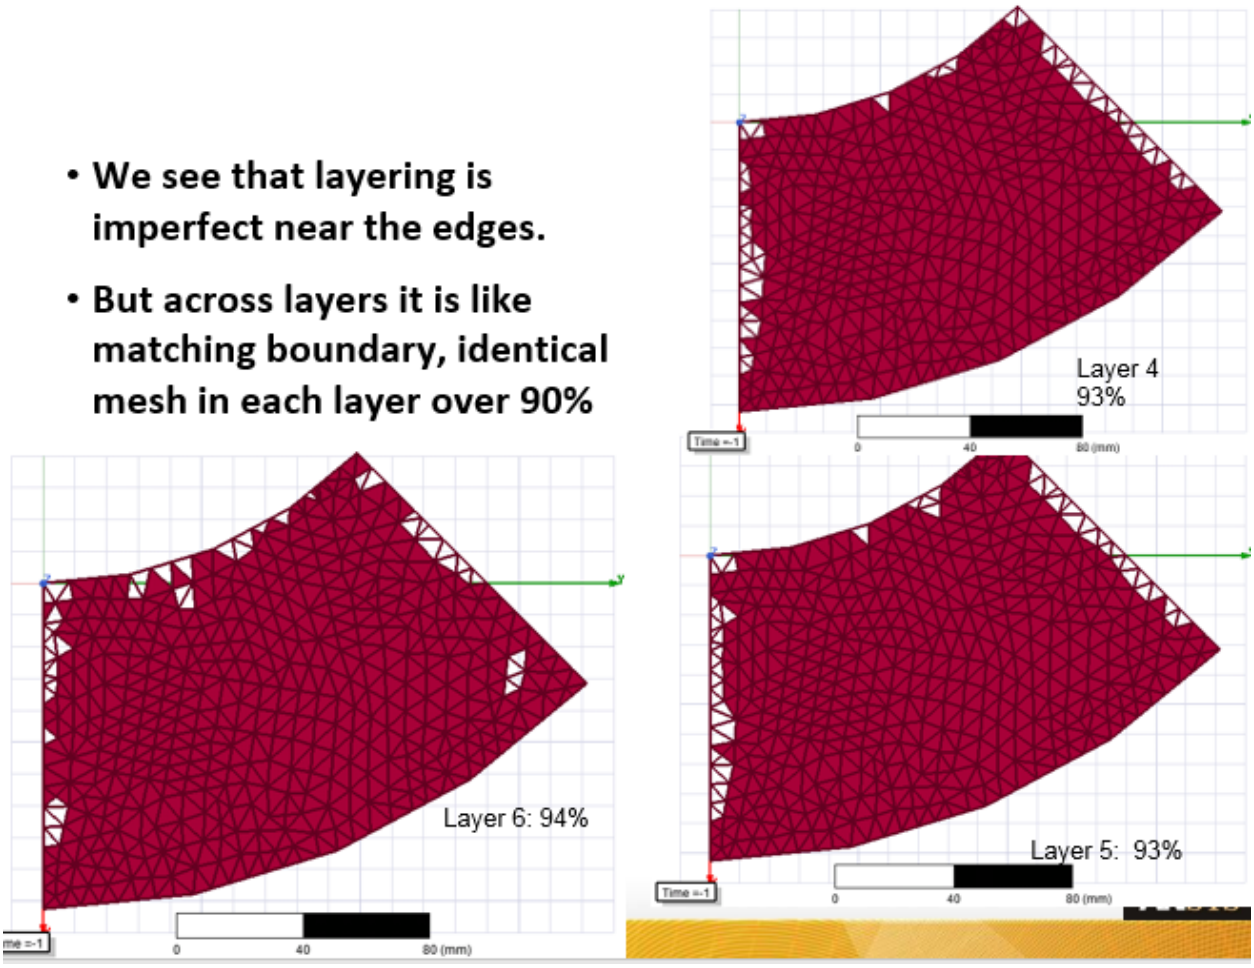
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To test various stacking models with pseudo bodies involves recreating the model with different thicknesses and remaking the entire initial mesh. The Tau mesher may not be available for all layer heights. You can achieve comparable results by using skin depth based refinement by reverting to the initial mesh, changing settings and applying mesh operations. The following figure shows a cut-plane image of the interior of a model that uses skin-depth based refinement and layers of elements. The Skin Depth is the total depth of all layers combined. Layered elements apply to the selected faces of solid bodies. The elements are stretched parallel to face, and are compressed in the normal direction.



While in some places the edges have imperfect layering, the interior is very good. You can also view the results layer by layer by using the Model Analysis dialog.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The layered skin depth mesh operation provides a tool toward finding a good solution. You can try different settings to improve results toward a good solution. For instance, for this example, these different settings were tried. For comparison, a model built with seven layers required 85K tets.

Tri length target mm	Total skin depth mm	Number of layers	Mesh Size element count	Perfect layering by tri count	Perfect layering by area
15.0	6.3	6	63K	43%	65%
10.0	6.3	6	68K	95%	94%
8.0	6.3	6	76K	96%	93%
6	6.3	6	97K	97%	94%

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The goal is not to have perfect layering, but to have a good solution that is much easier to achieve.

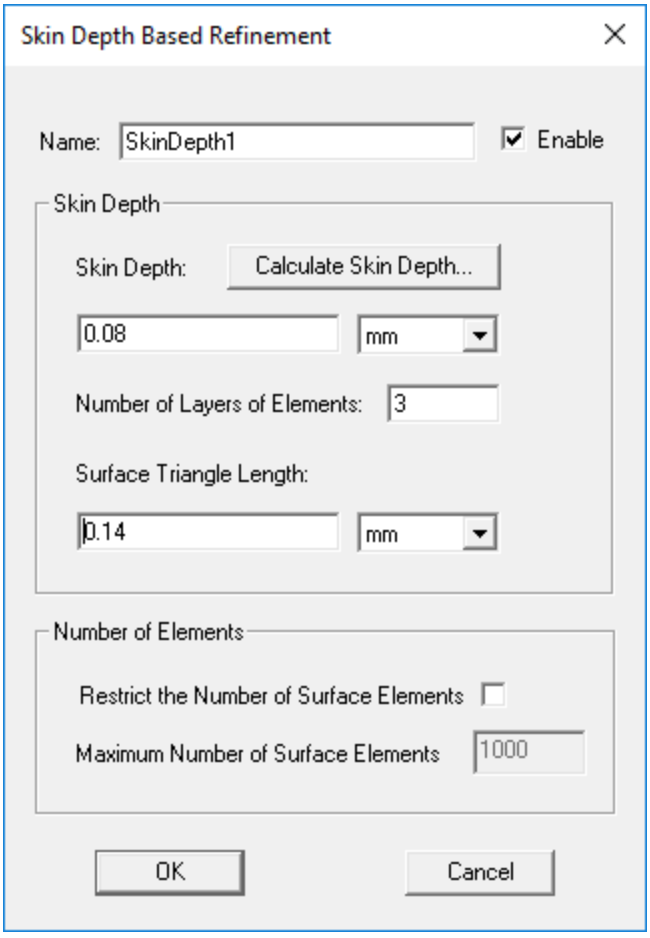
To use Skin Depth-Based Refinement:

1. Select the faces you want to be refined.

   > **Note:**
   >
   > It is possible to select a body and convert it to selecting all faces of the body. The user can use this method to select all faces and toggle a few faces out of selection. Selecting the whole body might select very large regions for refinement and increase the element count a lot.

2. Click **Maxwell** > **Assign Mesh Operation** > **On Selection** > **Skin Depth Based**.

   The *Skin Depth Based Refinement* dialog box appears.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. To calculate the skin depth based on the object's material permeability and conductivity and the frequency at which the mesh will be refined, click **Calculate Skin Depth**.

   The **Calculate Skin Depth** dialog box appears with values based on the selected object's material properties and the solution setup frequency.

   Accept or edit these values. When you click **OK** the solver calculates the skin depth and enters its value in the Skin Depth text box. You can accept the calculated values or provide your own.

4. In the **Number of Layers of Elements** text box, type the number of layers to add perpendicular to the object's surface. The skin depth is the total depth of all layers combined.

   The solver will add an equivalent number of mesh points to each layer. For example, if HFSS added 10 points to satisfy the **Surface Triangle Length**, it will add 10 points to each layer.

5. Optionally, provide the maximum edge length of the surface mesh in the **Surface Triangle Length** text box. The default value is set to 20% of the maximum edge lengths of the bounding boxes of each selected face.

   The solver will refine the surface triangle mesh (the faces of the tetrahedra touching the surface) until their edge lengths are less than or equal to the specified value.

6. By default, the Restrict Number of Surface Elements setting is unchecked. This allows the mesher to use symmetry more effectively. If you Restrict the number of surface elements, this may affect symmetry but can be used to protect against runaway refinement in specific cases. To restrict the number of elements added during refinement on the faces uncheck the box to enable the field for Maximum Number of Surface Elements. With the box unchecked, the field, unavailable, the number in the box provides an estimate of mesh growth.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When the mesh is generated, the refinement criteria you specified will be used. This operation will be approximately the same as having slabs of tetrahedra, but it is not guaranteed to prevent tetrahedra from crossing slab interfaces. Caution should be used with this mesh operation, as very thin layers may cause a reduction in mesh quality or unnecessarily cause the generation of a very large mesh. Further regions refined under this operation and its close neighbors do not participate in solution adaptive refinement. This is another reason to use this seeding operation with caution.

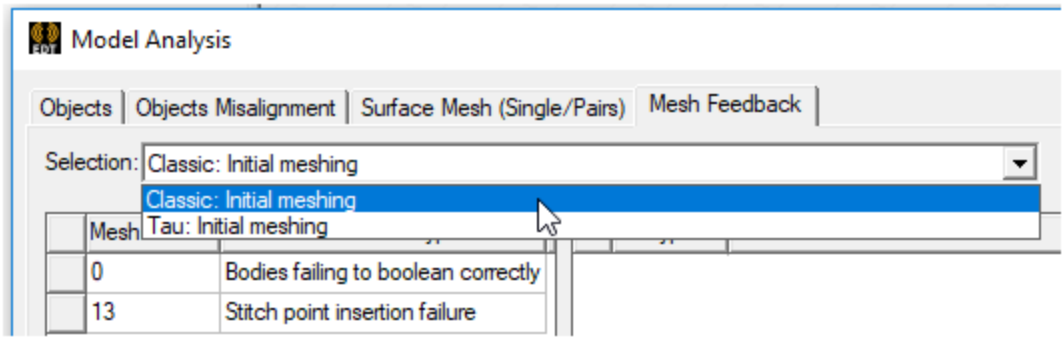
You can also specify Initial Mesh Settings to apply to all objects; however, if you apply separate surface approximation mesh operations to specific objects, the object settings take precedence over the general setting.

Visualization for Skin Depth Refinement Mesh Results

You can visualize the mesh to assess results either by using the clip-plane feature on a model with a mesh plot, or by using the Model Analysis dialog box as follows:

1. Select the object on which you have generated a meshplot, and click **Modeler** > **Model Analysis** > **Show Analysis Dialog** > **View Mesh Feedback**.

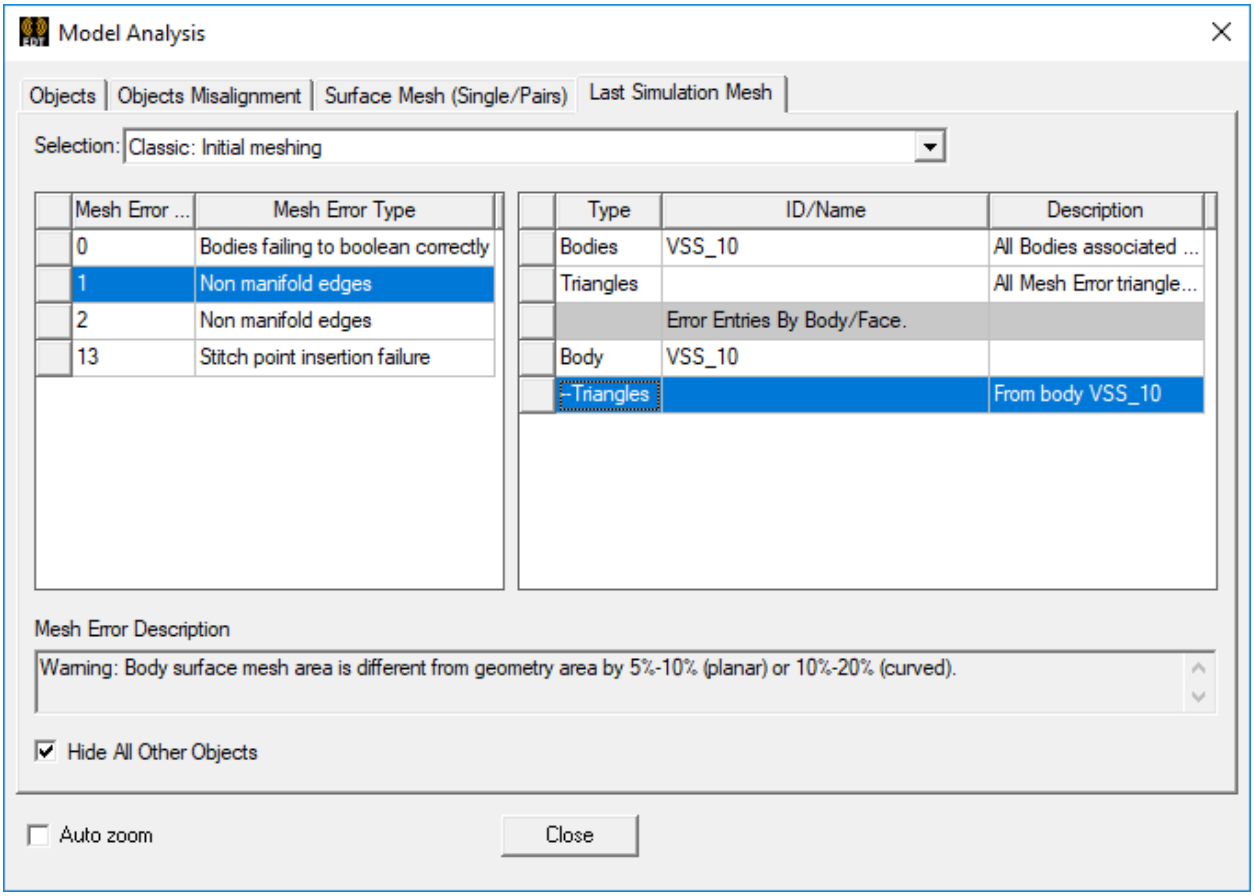
   The **Model Analysis** dialog box appears. If the project has solutions by different solvers, the **Selection** drop-down menu lets you select which mesh to view.



2. On the upper left table, under Mesh Error, select 0 through n , where 0 is the selected body, 1 is the layer closest to the face, 2 is the next, up to layer "n" as farthest.

   Selecting one of these rows causes a **Mesh Error Description** to display for the selected layer or body. The message gives the Total Expected count for triangles, as compared with the Success percentage by count and by area.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. On the upper right table, select the body, face, or triangle desired, scrolling the list to find any object, face, triangle, or area of interest.

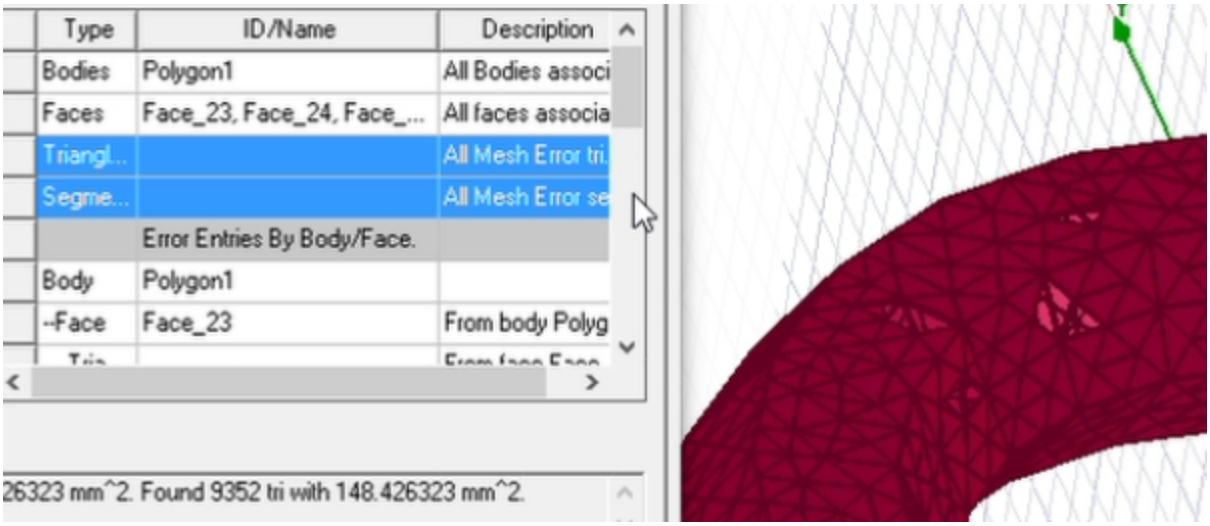
   Click Face, to see the selected face.

   Select Triangles to see the actual triangles created.

   Select Segment to show the triangles attempted.

   The following figure shows Triangle and Segment both selected (using Shift+click). Visually, the unfilled triangles represent places where the triangle is not on the desired layer. However the mesh is still very good and supports an accurate solution.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. Check boxes allow you to **Hide All Other Objects** checked by default, and **Auto zoom to selection**, unchecked by default.

Assigning Edge Cut Mesh Operation

1. Select the faces you want Maxwell to refine.

   Alternatively, select an object if you want Maxwell to refine every face on the object.

2. Click **Maxwell 3D** or **2D** > **Mesh** > **Assign Mesh Operation** > **Inside Selection** > **Edge Cut Based**.

   The **Edge Cut Based Refinement** dialog box appears.

3. Type a name for the mesh operation in the **Name** box, or accept the default name.
4. Specify the **Layer Thickness**, and select the units.
5. Click **OK**.

When the mesh is generated, the refinement criteria you specified are used. When the maximum number of elements is reached, some elements may exceed the requested maximum element length.

For 2D designs, edge cut works only if the Clone Mesh works. Refer to Layer Mesh Generation for 3D Rotational Models for information on edge cut for 3D designs.

You can also specify Initial Mesh Settings to apply to all objects; however, if you apply separate surface approximation mesh operations to specific objects, the object settings take precedence over the general setting.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning Cylindrical Gap Treatment

1. Select the object you want refined.
2. Click **Maxwell 3D or Maxwell 2D** > **Mesh** > **Assign Mesh Operation** > **Cylindrical Gap Treatment**

   A **Cylindrical Gap** mesh operation is applied to the selected object, and a **Cylindrical Gap** icon appears in the Project Manager's Mesh Operations folder.

   The Cylindrical Gap operation only works for the TAU (tolerant) mesher. It is a specific mesh operation assigned to the “Band” object for a rotational transient simulation.

   While you can select any object and assign the Cylindrical Gap operation to it in any Maxwell or Mechanical–Thermal simulation, the Cylindrical Gap operation is effective only for rotational transient simulations, for which cases the TAU (tolerant) mesher will be chosen as the default mesher; or for which you have manually selected the TAU (tolerant) mesher.

   > **Note:** For 2D transient simulations of rotational models only, refer to TAU2D: Band Mapping Angle Mesh.

   The TAU (tolerant) mesher analyzes the “Band” object, calculates the surface normal angle for the band rotational surface, and automatically assigns the desired mesh operation; or adjusts the existing mesh operations to the adjacent true surfaces at both static and moving sides to ensure a smooth and uniform mesh for the “Band” mesh.

   If the Cylindrical Gap mesh operation is assigned to a regular object, TAU analysis finds the object is not suitable for transient mesh, in which case the regular TAU mesh will be applied. A Warning message is then displayed in the message window.

   > **Note:**
   >
   > - There can be only one cylindrical gap operation per design.
   > - The operation cannot be assigned to multiple objects.

3. If you wish to change the name of the mesh operation, you can double-click the **Cylindrical Gap** icon to open the **Cylindrical Gap Mesh Operation** dialog box in which you can type a name for the mesh operation in the **Name** box.
4. Optionally, for 3D transient simulations of rotational models only, if you wish to apply a clone mesh operation, check **Clone Mesh**. This option is unchecked by default.
   - When **Clone Mesh** is selected, the **Band Mapping Angle** setting is enabled. The valid range of angles is 0.1 through 3.0 degrees, inclusive. The default band mapping angle is 3 degrees. (For more information on this setting, refer to *Band*

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mapping Angle.)

> **Note:**
>
> If the model is not suitable to make a clone mesh or the clone mesh process fails, the program automatically falls back to the regular TAU 3D mesher. Because the clone mesh is generated in the initial mesh, the initial mesh is deleted and regenerated once this option is changed and you click **OK**.

- When **Clone Mesh** is selected, the **Number of Layers** setting is enabled. You can input the number of mesh layers on the **Moving Side** and **Static Side**, respectively. The valid ranges for these settings are integers ≥ 1. The default values are 1. (For more information on this setting, refer to *Layers in Band Mesh*.)

3D Clone Mesh Generation

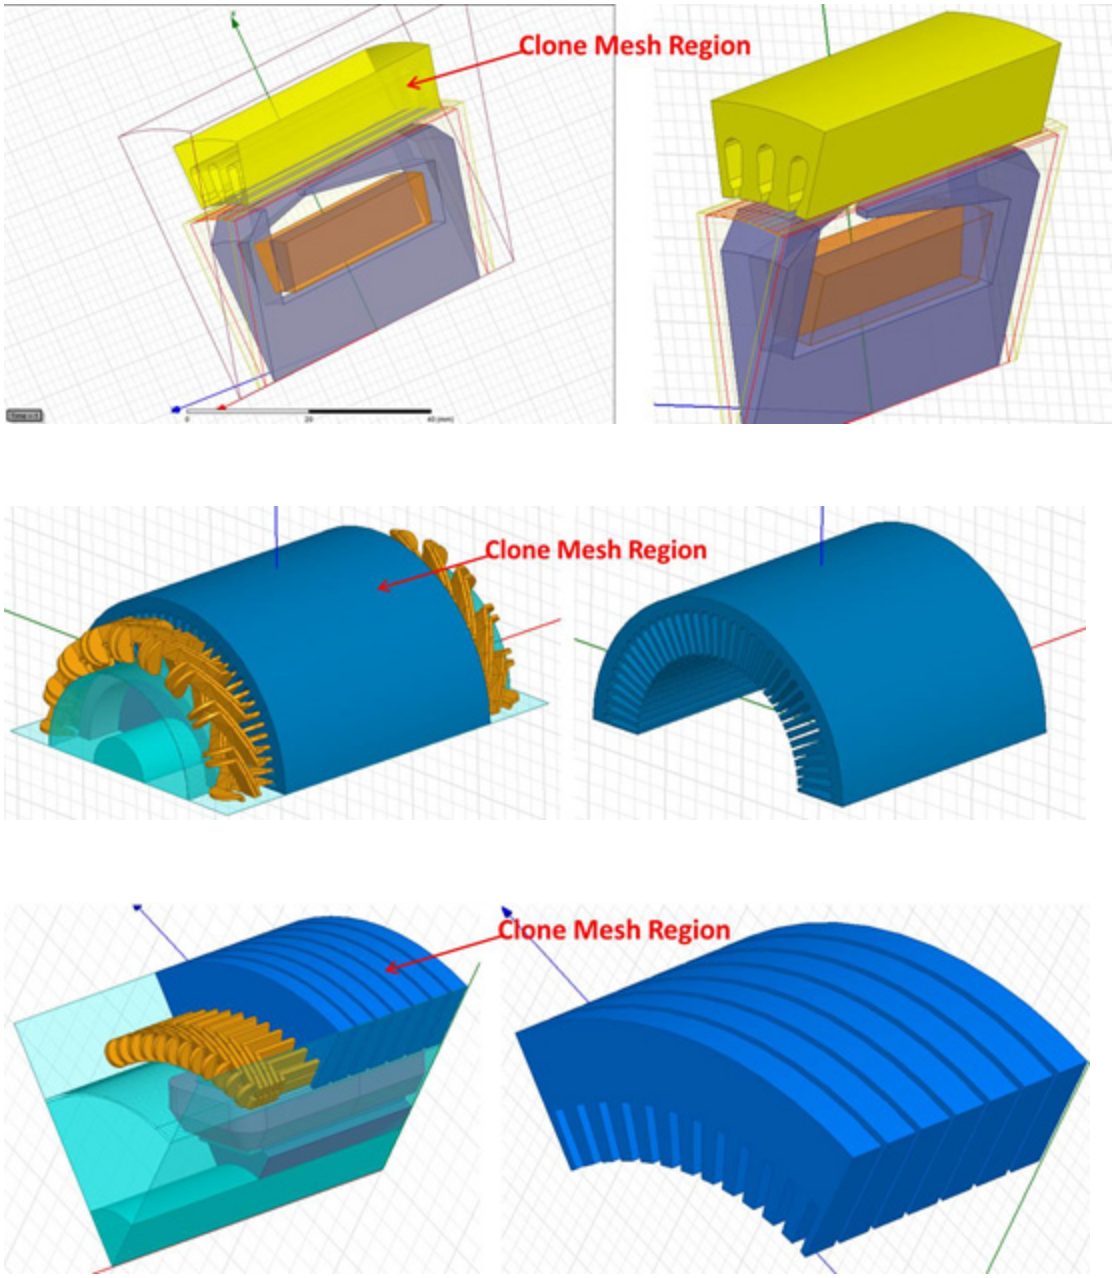
The 3D clone mesh is generated only when the following three conditions are met:

- The Clone Mesh check box is checked.
- The CylindricalGap mesh operation has been assigned.
- The model has a non-skewed stator with more than two teeth.

> **Note:**
>
> When Clone Mesh is used, the only additional mesh operation that can be used is surface approximation. If any other mesh operation is used, the clone mesh operation will be ignored.

The solid bodies adjacent to the band are detected to identify the clone object. If the object has more than two teeth that are close to the band, the teeth will be verified to see they have the identical geometric features. If the teeth are skewed, TAU will fall back to the regular mesh. Otherwise the region from the radius of teeth to the outer edge of the object will be further classified and verified to see if the object has the multiple 3D identical sub-regions.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



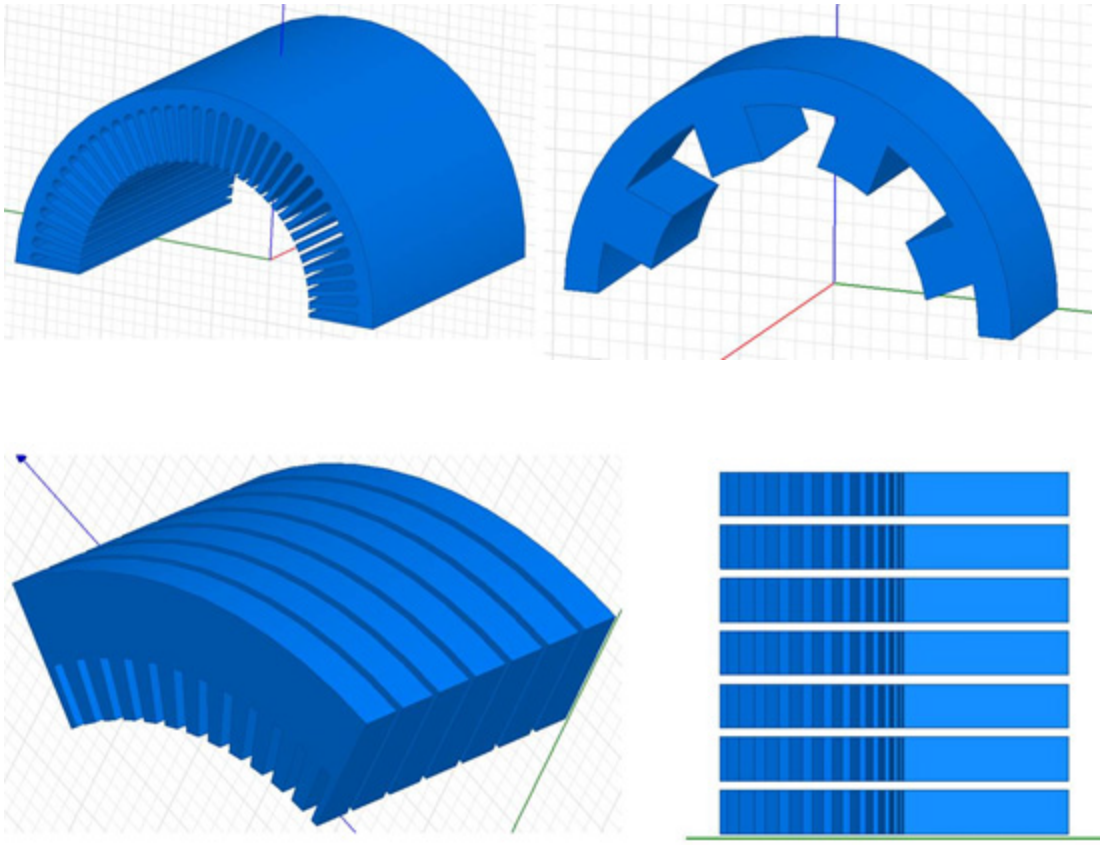
If a 3D clone region has been identified, TAU will classify the 3D rotational model into a static region and a moving region by the band object radius. The Static region includes the clone region and skewed coils regions at one side or two sides. Clone mesh method will then be used to generate the mesh in the clone region, while the TAU regular mesh method will be used to generate the mesh at other skewed regions.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The moving region includes skewed coils regions in which the TAU regular mesh method is used to generate the mesh, and also the non-skewed sweep regions in which the TAU sweep mesh method is used to make the mesh.

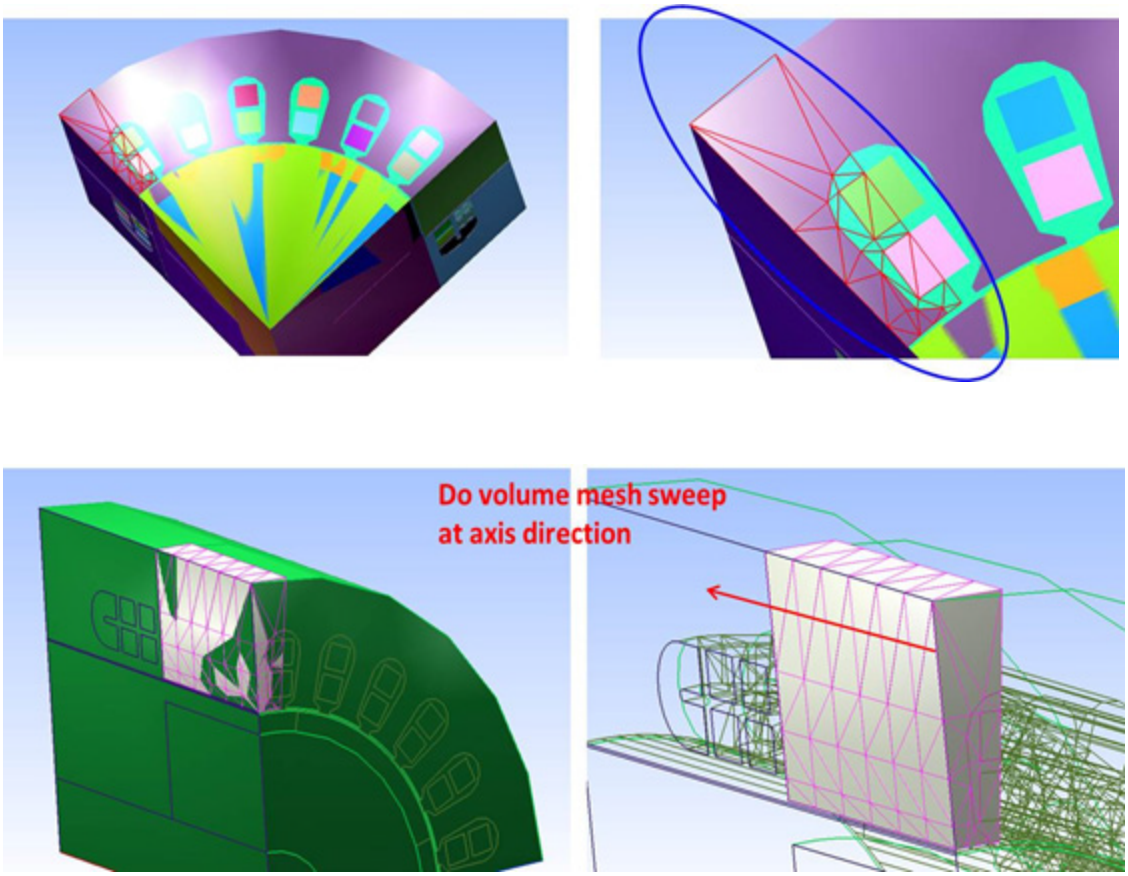
3D Clone Mesh

A 3D clone region may have only one simple object, or several sections of clone objects with the gap between as shown in the following images.



To ensure the identical volume mesh in each sub-region, the volume mesh is generated in the Master region, then by using a copy-and-paste method to duplicate the mesh at all child regions. In the 3D master region, if the region is also symmetric, then a symmetric mesh is generated. “Sweeping mesh” technology is used to make the volume mesh in the master region. In the half of the master region, a surface mesh is generated at the axis side. The volume mesh is generated by sweeping the surface mesh in the axis direction to fulfill the clone master region.

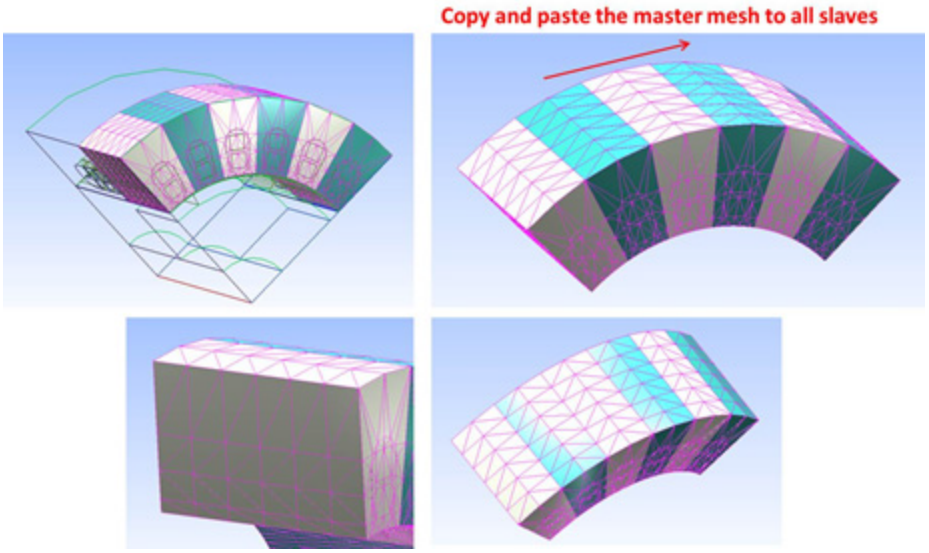
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The volume mesh will be mirrored to the other half of the master region to produce the symmetric mesh in the master region.

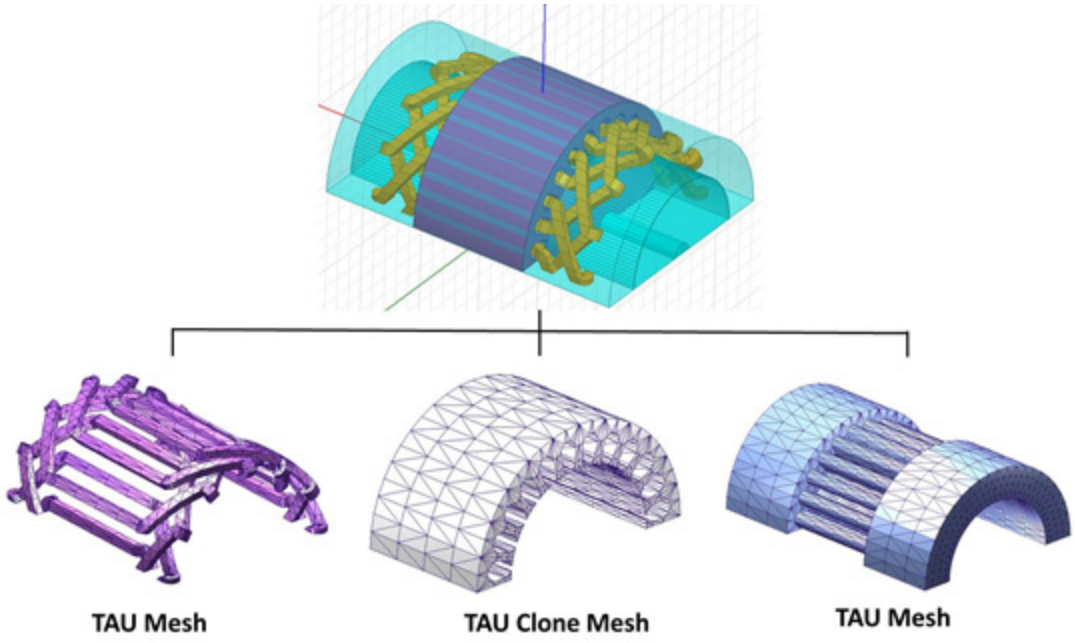
The volume mesh in the master region is then duplicated and translated to the child regions with copy and paste technology in TAU to complete the 3D clone region mesh.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3D TAU Mesh

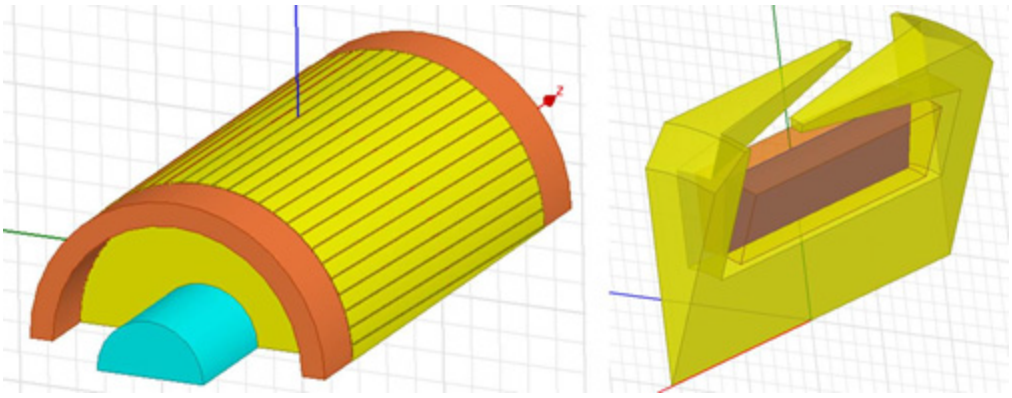
Beyond the 3D clone region, normally the regions have skewed coils. Therefore, the TAU regular mesher will be used to make the mesh.



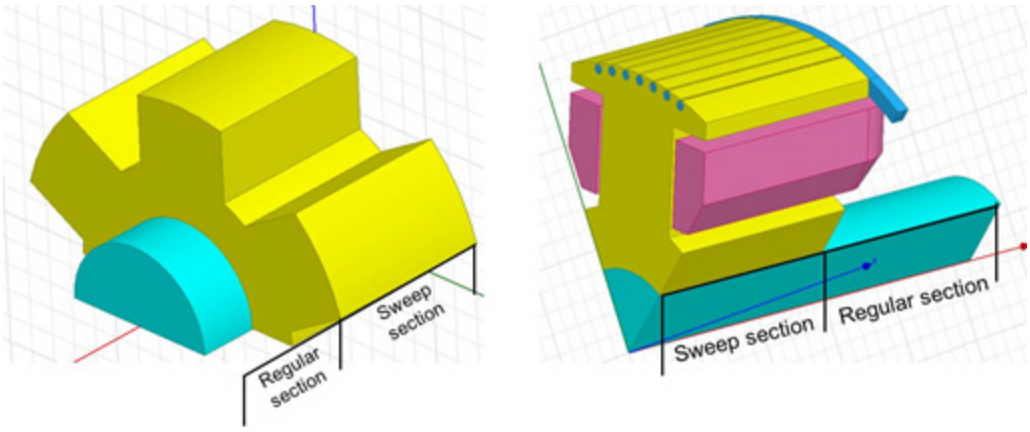
3D Sweep Mesh

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The rotational model for a moving region may have different structures. It may have all skewed coils and rotors. In this case, the TAU regular mesh will be used to make the mesh.

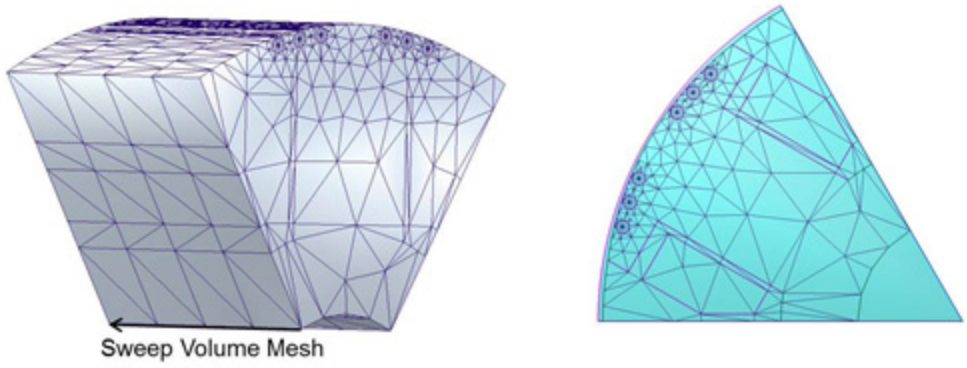


At the axis direction, the moving region can be classified into several specific regions. If the region has skewed objects, it is called a “regular section,” and the TAU regular mesh is applied. If the region can be geometrically sweeping at the axis direction, the region is called a “sweep region,” and the TAU sweep mesh method is applied.

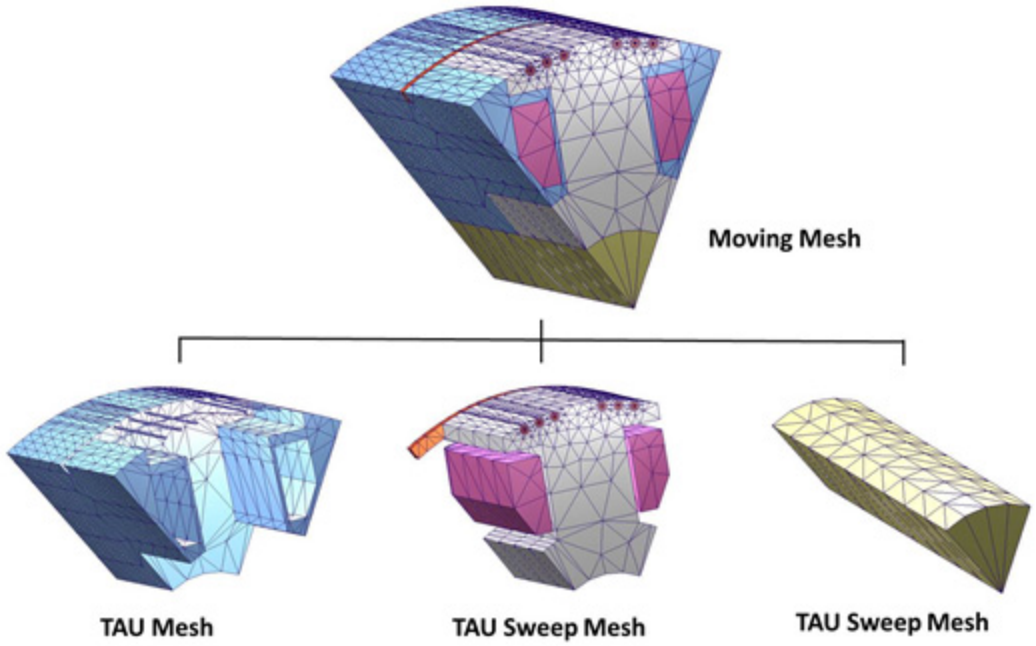


For the “sweep section,” a surface mesh is generated at the side, then the volume mesh is made by sweeping the surface mesh in the axis direction. This ensures a uniform mesh in the rotational direction, while maintaining the long aspect ratio in the axis direction to keep the mesh size small.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The volume mesh for the rest of the regions is made by the TAU regular mesher.



Band Mapping Angle

Because mesh mapping errors can occur at the interface between the band of motion and the stationary objects when mesh segmentation is performed, the band mapping angle allows these errors to be corrected by making the rotating angle per time step equal to the angle of each mesh segment in the direction of rotation. Thus, the band mesh will match the mesh on the stationary region for each time step. Reducing the mesh mapping error also reduces the noise for the torque calculation and improves simulation accuracy.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Band Mapping Angle** setting on the Cylindrical Gap Mesh Operation dialog box, enabled when **Clone Mesh** is selected, supports 3D transient designs for which:

- The band of motion is a true surface.
- The model is not skewed.
- The model is suitable for clone mesh – that is, the model can be segmented into identical sections in the direction of rotation.

The recommended band mapping angle (the angle the rotor rotates in one time step) typically equals the rotational speed multiplied by the time step. For example, if the rotational speed is 1.5 degrees per second and the time step is 2 seconds, then the band mapping angle should be 1.5 x 2 = 3 deg.

The starting position of the simulation should also be considered. In the above example, if the starting position is 0 deg or 3 deg, then 3 deg would be a good band mapping angle. If the starting position is 1.5 deg, the mesh will not be mapped at the starting position, in which case 1.5 deg is the recommended setting.

Another approach for determining the band mapping angle is to start with the model. For example, assume that the stator has 90 slots in the full model, with the solution domain angle equaling 1/6 of the full 360 degree model or 15 slots for 60 mechanical degrees. If you would like to solve with each slot having 8 mesh segments, there would be 120 total mesh segments (15 slots x 8 segments per slot). In this case, the band mapping angle would be 60 (deg) /120 = 0.5 deg. To ensure rotation through one mesh segment per time step, assuming the rotational speed is 1200 rpm, the time step should be set as:

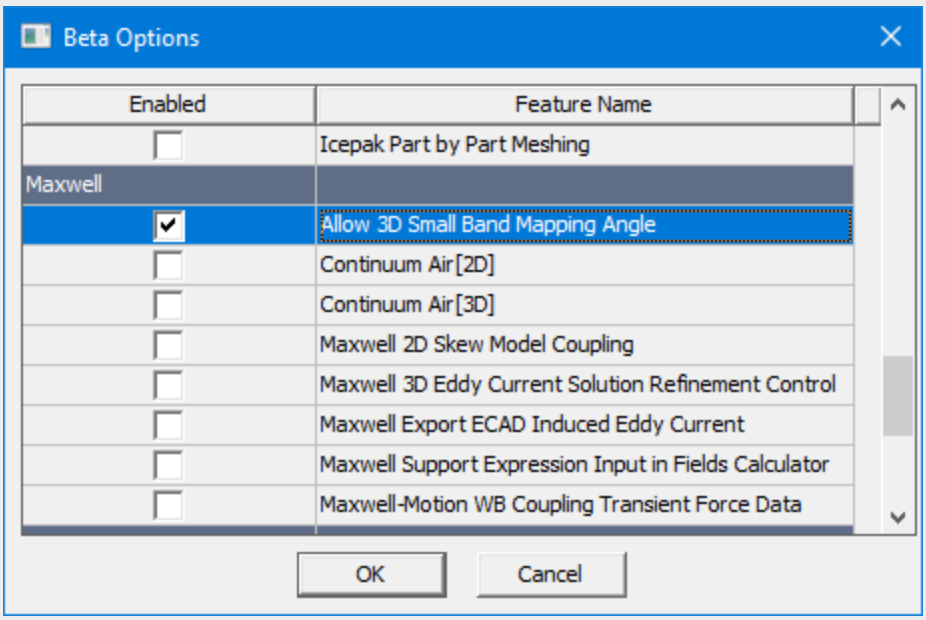
$$Timestep = \frac{1}{(speed_{rpm}/60seconds) \times TotalSegmentNumber \times (360^\circ/DomainAngle^\circ)}$$

$$Timestep = \frac{1}{(1200/60) \times 120 \times (360/60)} = \frac{1}{14400} seconds$$

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

For band mapping angles less than 0.5 degrees, clone meshing may improve with the **Allow 3D Small Band Mapping Angle** beta feature. This feature is accessed from **Tools** > **Options** > **General Options** > **Beta Options** button, which opens the following window:



TAU2D: Band Mapping Angle Mesh (Clone+Symmetry)

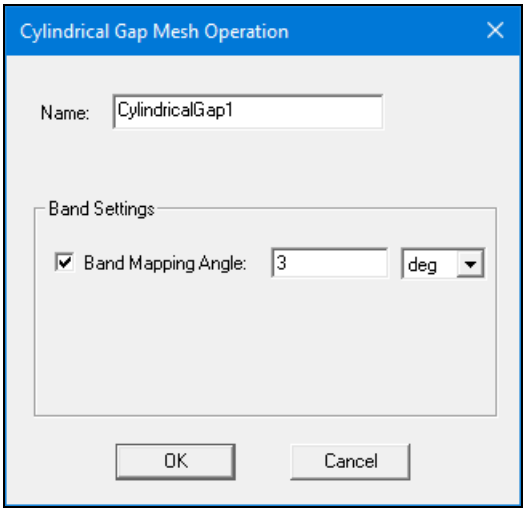
Band Mapping Angle is a new meshing option for transient simulation of motors in Maxwell 2D. When selected, the meshing process will ensure that each mesh segment on the outside of the band (the curve that separates the static and moving regions) has exactly the sweep angle that has been specified by the user. For example, for a quarter model with 90 degrees of matching boundaries, specifying a band mapping angle of 0.5 degree will result in a band outline having 180 mesh segments of equal length.

Because the meshing angle is determined by this setting, the band object must have a curved outline, using zero segments.

To use the 2D Band Mapping Angle function:

1. When you open a 2D transient project, select **Maxwell 2D** > **Mesh** > **Assign Mesh Operation** > **Cylindrical Gap Treatment**, which opens the **Cylindrical Gap Mesh Operation** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Select **Band Mapping Angle**, set the desired mapping angle, then click **OK**.

   Note that it is best to synchronize the transient simulation timestep with the band mapping angle. For example, suppose the following mapping angle is used to accurately model the cogging torque:

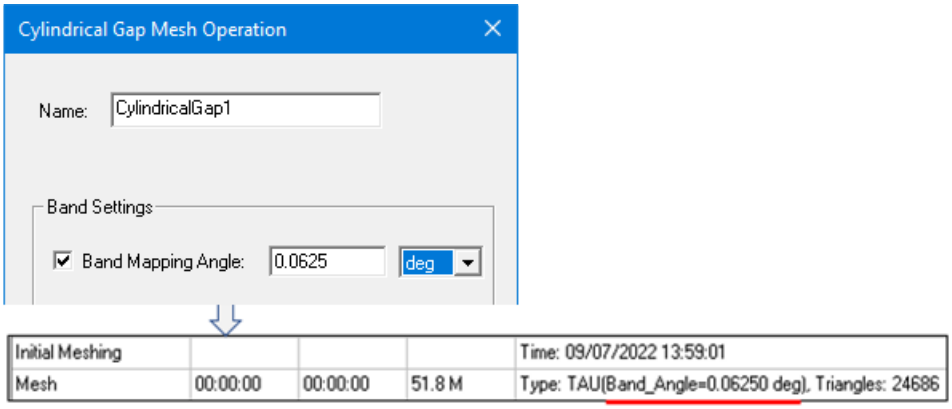
   If the motor's rotational velocity is 1 degree/second, then the following timestep should be used:

   This practice will help to remove numerical noise in the results.

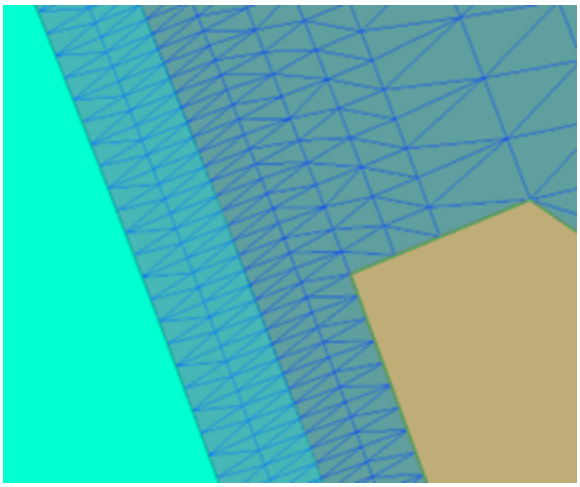
There are two ways to verify that the band mapping angle has been applied to a simulation:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

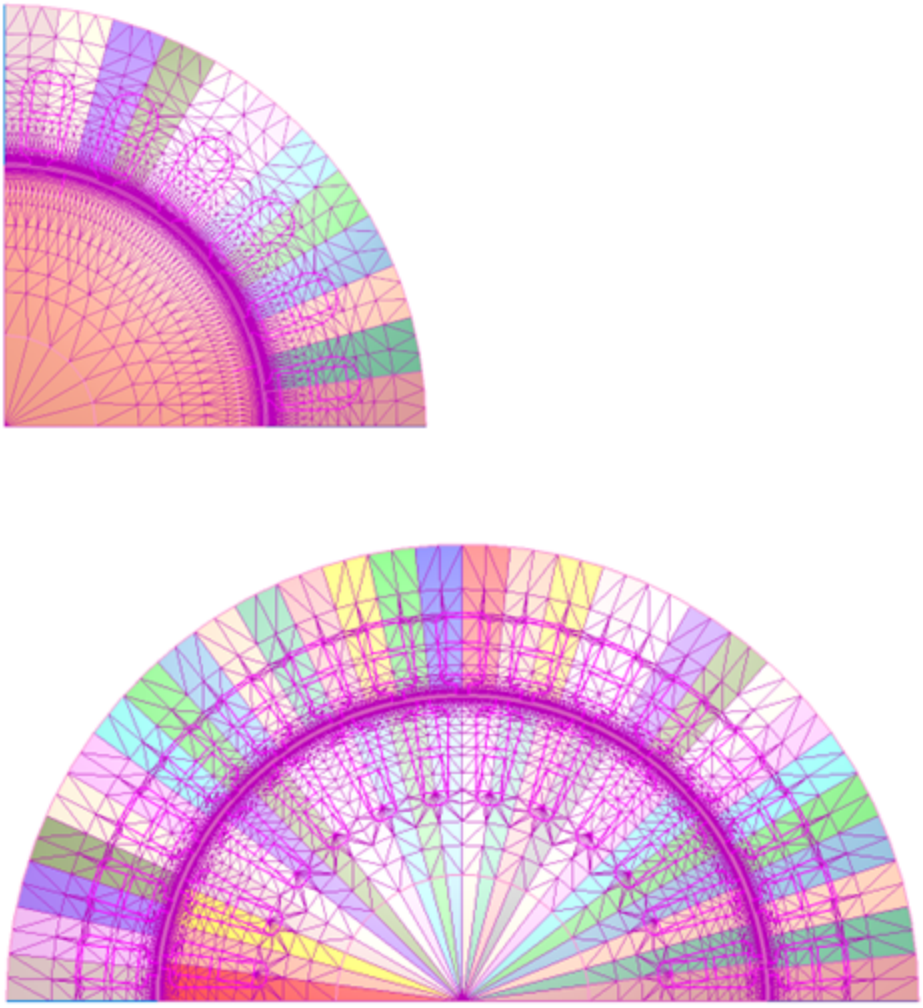
- The specified angle will appear under Initial Meshing, on the Mesh line after “TAU”:



- The effects of the mapping angle will be seen in mesh plots:
  - An additional layer will be created on both sides of the band.
  - The triangle orientation will be exactly the same on each side of band, to eliminate noise.
  - The layered structure will extend to the moving and static regions.
  - Mesh density will smoothly transition from fine to coarse with distance from the band.
  - Clone mesh if the region is repeatable.
  - Mirror mesh if the region is symmetrical.
  - Sweep layer mesh if the region is not repeatable.



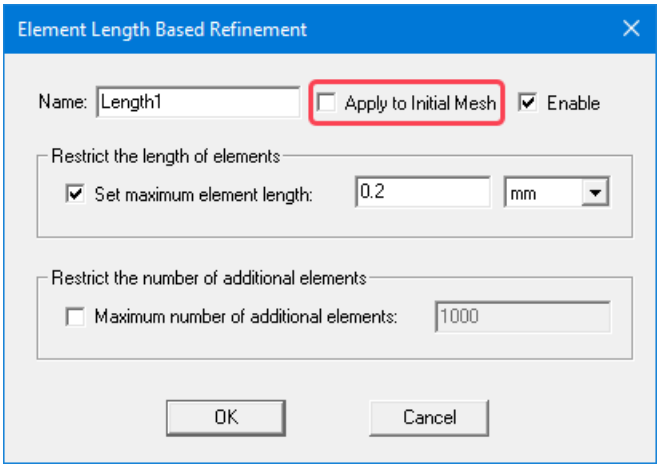
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



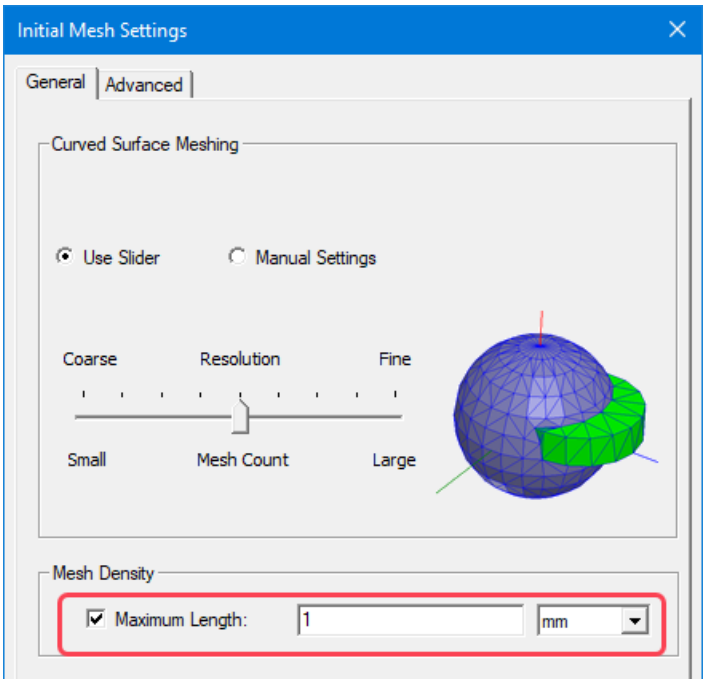
Notes

- This feature is intended to replace the use of wire bodies to guide meshing in the band. However, if wire bodies are included, the mesh will respect them along with the band mapping angle.
- Length-based mesh operations applied to an initial mesh (on objects, faces, or edges) are not yet supported. These mesh operations will be ignored by the mesher if a band mapping angle mesh is requested. However, these mesh operations can be used if **Apply to Initial Mesh** is **not** activated in the Element Length Based Refinement dialog box:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In addition, the global **Maximum Length** setting in the Initial Mesh Setting window can be used in conjunction with the Band Mapping Angle function to control mesh size.



- Eccentricity is not supported.
- Segmented circular edge is not supported.
- This feature is limited to Maxwell 2D transient models with a Cylindrical Gap mesh operation.
- The Band Mapping Angle mesh operation does not currently support models with translational motion.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Layers in Band Mesh *(Maxwell 3D Magnetostatic and Transient)*

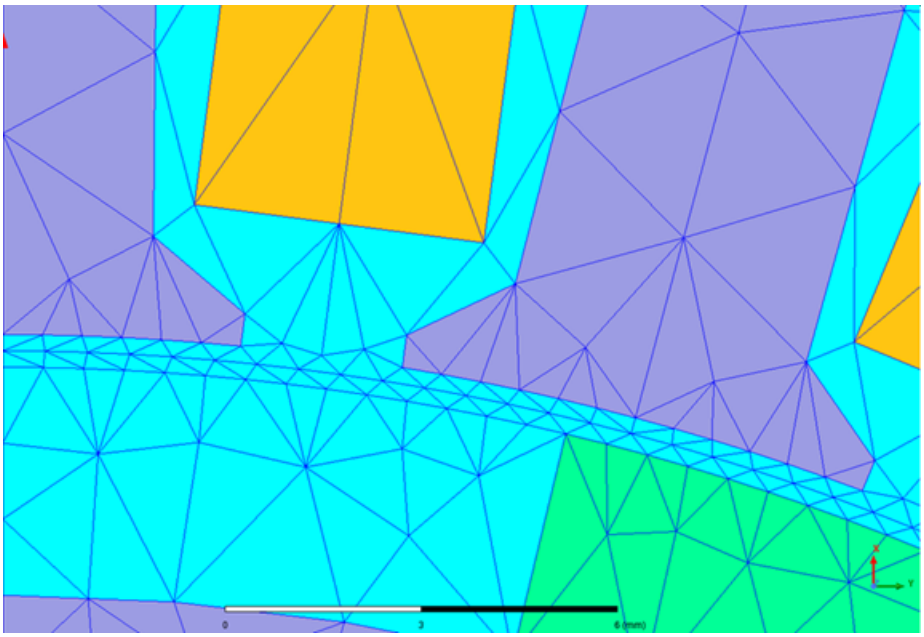
Maxwell rotating machine models need very precise cloned mesh to get accurate estimates of cogging torque. Thus, the mesh near the interface of the static side and moving side, *i.e.*, band surface, is crucial to the accuracy of this simulation result.

Clone mesh is an initial mesh process and currently provides one layer mesh between band and stator and one layer mesh between band and rotor. However, one layer may not provide sufficient accuracy for some designs. For such cases, multiple layers in band for clone mesh can be used to improve accuracy. By assigning this mesh operation, you can control the number of layers near the band on *both* the static and the moving side without losing the repeatability of the clone mesh.

> **Note:** This feature is applicable only to Maxwell 3D magnetostatic and transient solution types.

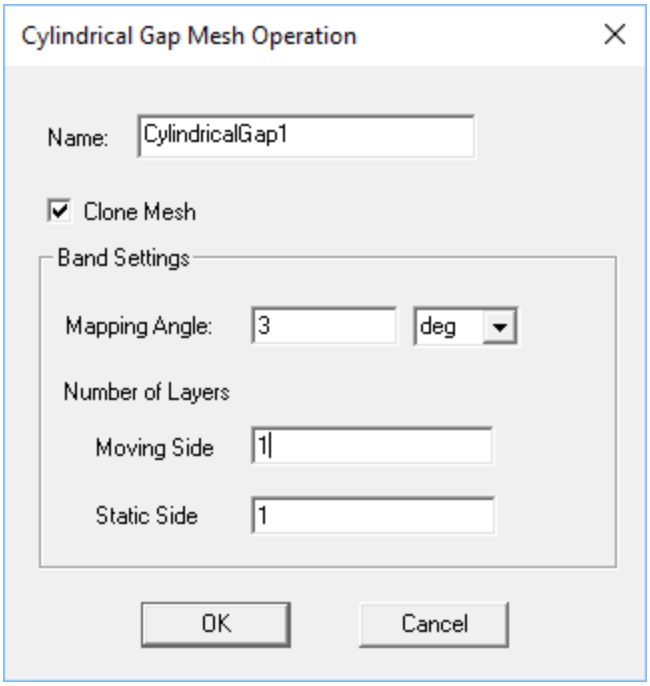
Example

Without multiple layers in the band mesh, when the model is cloned, the static side has clone geometry for which clone mesh is provided. The moving side does not have clone geometry so sweeping mesh is provided for it. This simple mesh type is shown below.

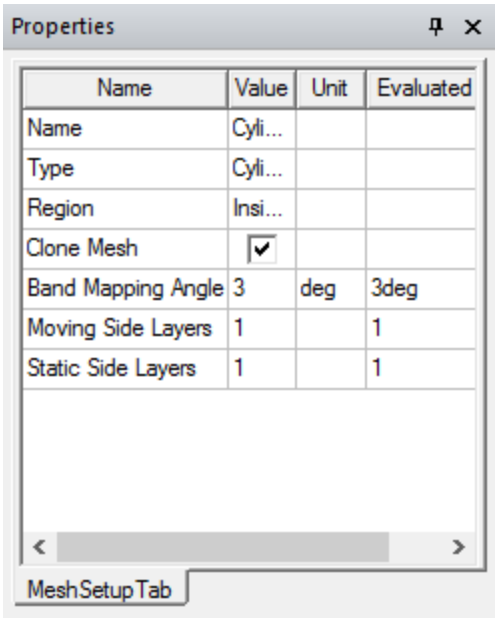


To improve accuracy of results, multiple layers can be specified for a **Clone Mesh** in the **Band Settings** section of the **Cylindrical Gap Mesh Operation** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

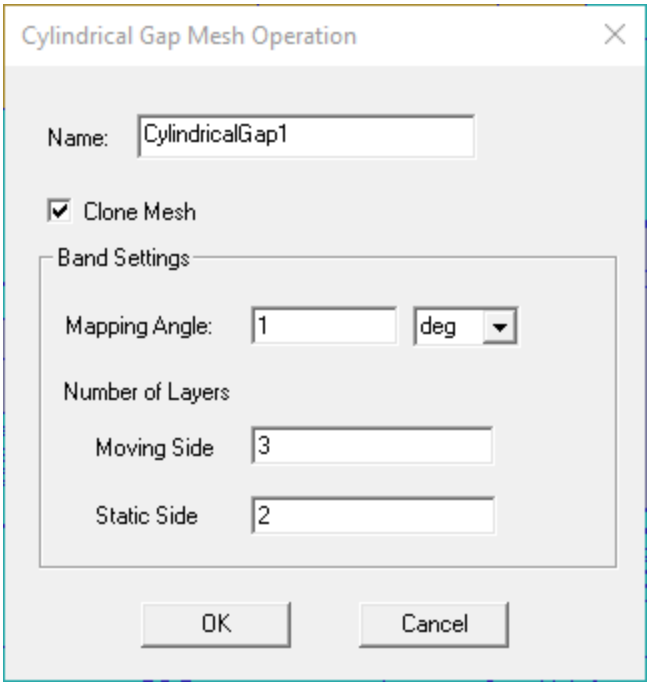


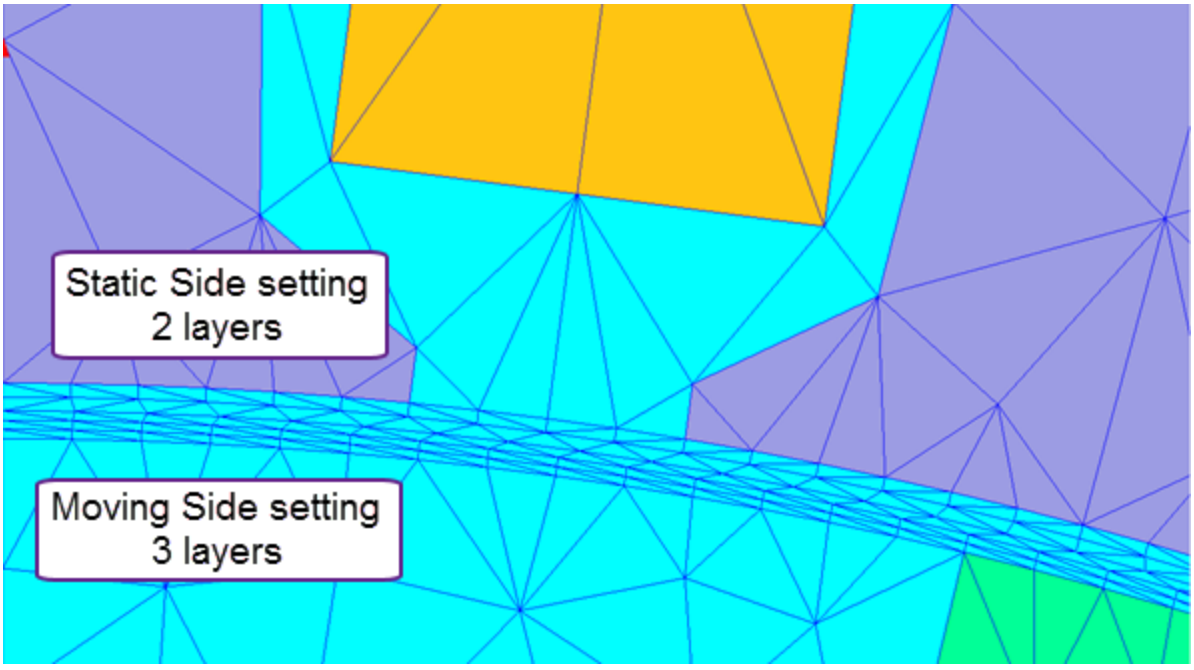
The layers options are also available in the **Properties** window's **Mesh Setup** tab when the cylindrical gap mesh operation is selected in the Project Manager tree.



By setting the **Number of Layers** for the **Moving Side** and/or the **Static Side** to integer values greater than 1, the number of band layer meshes will be increased accordingly.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



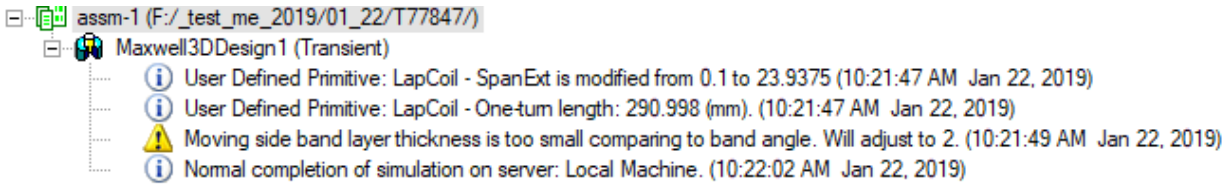


Considerations and Limitations

- If you specified a number of layers that would result in a lowering of mesh quality, clone mesh will adjust the number of layers, and give a warning message similar to the

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

following:



- If the model it not suitable for clone mesh, or if clone mesh fails to mesh it, this setting will not be respected in TAU regular 3D mesh. A warning message will be given by mesh in this situation.
- Postprocessing seeding refinement will respect the layers in the mesh. Adding any postprocessing mesh operation will not destroy the layers; however, the clone mesh might be destroyed.

Clone Mesh Density

For Maxwell 3D rotational transient designs and Mechanical–Thermal designs of rotating machines, this meshing operation allows you to specify the clone mesh density while keeping the identical mesh in identical sub-regions. Different from Length-Based Mesh Refinement, this Clone Mesh Density mesh operation will only be applied to clone mesh. Only when clone mesh is enabled under cylindrical mesh operation, mesh will respect this mesh operation. Mesh density can be controlled while identical mesh is maintained.

To control the clone mesh density:

1. Select the object.
2. Click **Maxwell** > **Mesh Operations** > **Assign** > **Inside Selection** > **Clone Mesh Density**.

   The **Clone Mesh Density** dialog box appears.
3. Type a name for the mesh operation in the **Name** box, or accept the default name.
4. To specify the radial direction density, enable the radial direction option. Type the maximum length of the element size required inside the object(s) in the **Maximum element length** box, and select the units. Maxwell refines the element edges inside the object(s) until they are equal to or less than this value. The default value is set to 10% of the maximum dimension of the bounding box of the model.
5. To specify the axial direction density, enable the axial direction option. Enter the **Number of layers** to be added. Maxwell refines the mesh in axial direction inside the object(s) until the number of mesh layers in the axial direction are equal to or more than this value.
6. Click **OK**. You need to specify mesh density in at least one direction to enable this mesh operation.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

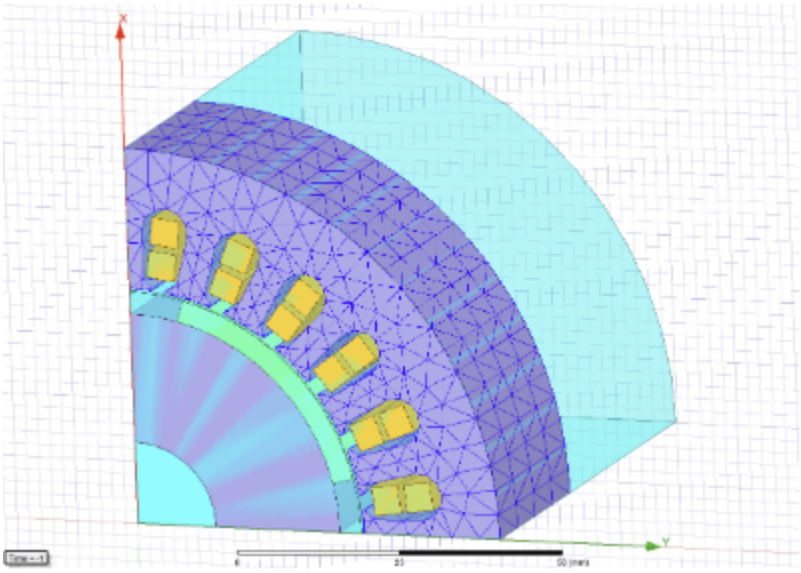
When the clone mesh is generated, the refinement criteria you specified are used. You can specify different maximum length of the element size on different objects. Note that identical density setting should be applied to identical objects to ensure the specified density to be applied on those objects.

You can also specify different axial direction number of layers on different objects. Note that the number of layers in axial direction are maintained separately inside and outside of the band. If objects share a same region in axial direction on the same side of the band, the mesh refinement will refines until the layer thickness equal or smaller than the smallest average layer thickness in this region.

The Clone Mesh Density can not be applied to band object. To control the element size on band, use the **Band Mapping Angle** setting.

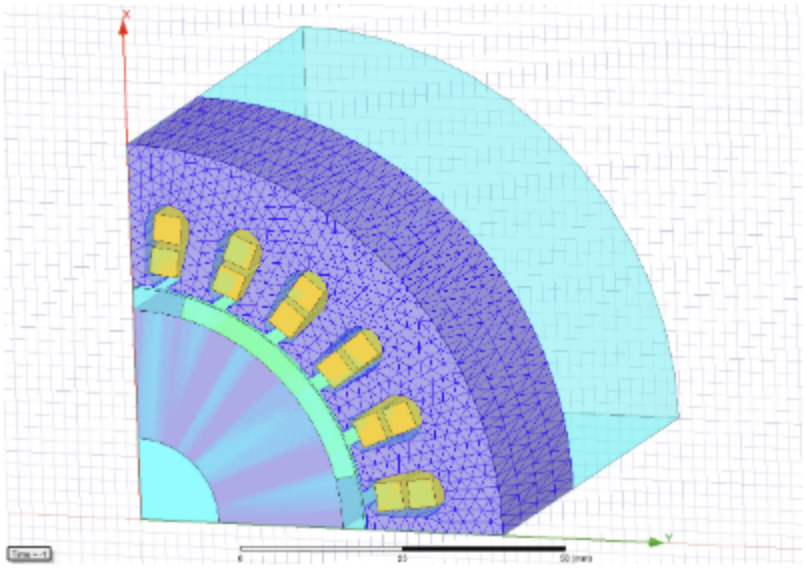
Clone Mesh Density can only be respected in clone mesh region. Mesh density in regions that are skewed or not clonable may not be controlled as precise as it is in clone region.

Original clone mesh without Clone Mesh Density mesh operation:

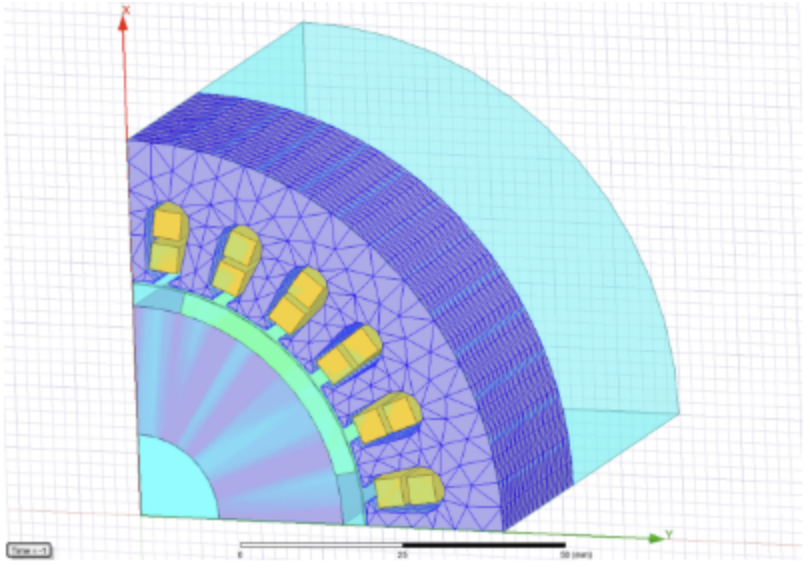


Clone mesh with Clone Mesh Density mesh operation on Stator. Radial direction mesh is refined according to maximum element length specification:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Clone mesh with Clone Mesh Density mesh operation on Stator . Axial direction mesh is refined according to number of layers specification:



Skin Depth Layers Setting for 2D

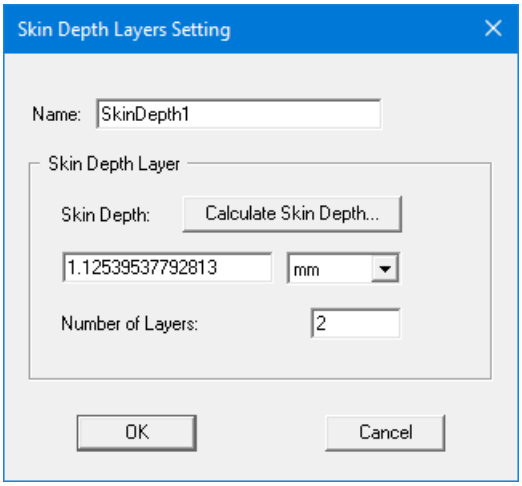
You can apply these settings only to the edges of sheet bodies in Maxwell 2D when the TAU mesher has been selected in the **Initial Mesh Settings** window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

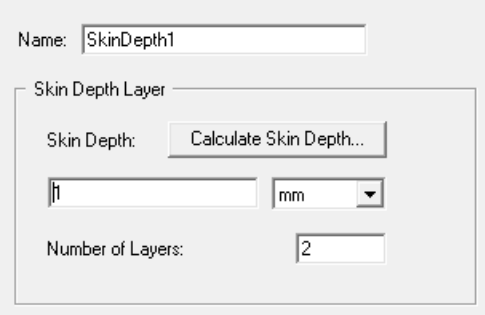
Note:

Any changes you make using these settings will invalidate the initial mesh, as well as the current mesh and solutions, if any.

1. Select the edge of a sheet body, and click **Maxwell 2D** > **Mesh** > **Assign Mesh Operation** > **On Selection** > **Skin Depth Based...** to open the **Skin Depth Layers Setting** dialog box:



2. Type a name for the mesh operation in the **Name** text box or accept the default name.
3. Type the skin depth within which to refine the mesh in the **Skin Depth** text box.

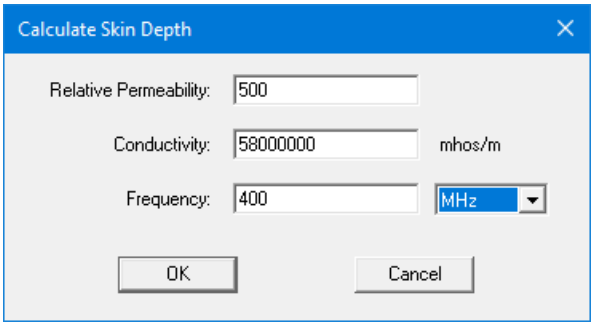


Alternatively, calculate the skin depth based on the object's material permeability and conductivity and the frequency at which the mesh will be refined:

a. Click **Calculate Skin Depth**.

   The **Calculate Skin Depth** dialog box appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



b. Enter the material's **Relative Permeability** and **Conductivity**.
c. Specify the **Frequency** at which to refine the mesh.
d. Click **OK**.

   Maxwell calculates the skin depth and enters its value in the **Skin Depth** text box.

4. In the **Number of Layers of Elements** text box, type the number of layers to add perpendicular to the object's surface.

Maxwell will add an equivalent number of mesh points to each layer. For example, if Maxwell added 10 points to satisfy the **Surface Triangle Length**, it will add 10 points to each layer.

> **Note:**
>
> Caution should be used with this mesh operation, as very thin layers may cause a reduction in mesh quality or unnecessarily cause the generation of a very large mesh. Furthermore, regions refined under this operation and its close neighbors do not participate in solution adaptive refinement. This is another reason to use this seeding operation with caution.

Modifying Surface Approximation Settings

Each solver applies surface approximation settings for selected objects when it generates the initial mesh. If you modify a solver's default settings after the initial mesh has been generated, they will not affect the mesh for that design variation. Surface approximation makes sense for curved surfaces, for which the mesh will not exactly reproduce the surface shape. It also can be used to restrict the aspect ratio of triangles on planar surfaces. For a given surface approximation slider setting, the approximation is more refined for IE and SBR+ solvers than for FEM solvers.

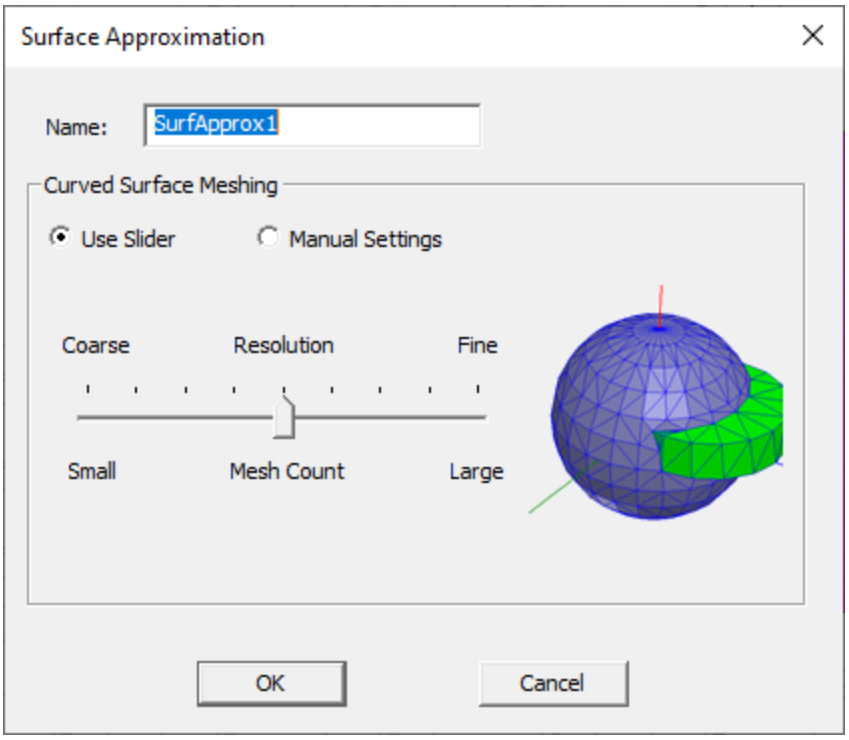
1. Select the faces for which you want to modify the surface approximation settings.

   Alternatively, select an object if you want to modify the surface approximation settings of every face on the object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click **Maxwell** > **Mesh** > **Assign Mesh Operation** > **Surface Approximation** or right click on **Mesh** in the Project Manager and select **Assign Mesh Operation** > **Surface Approximation**.

   The *Surface Approximation* dialog box appears.

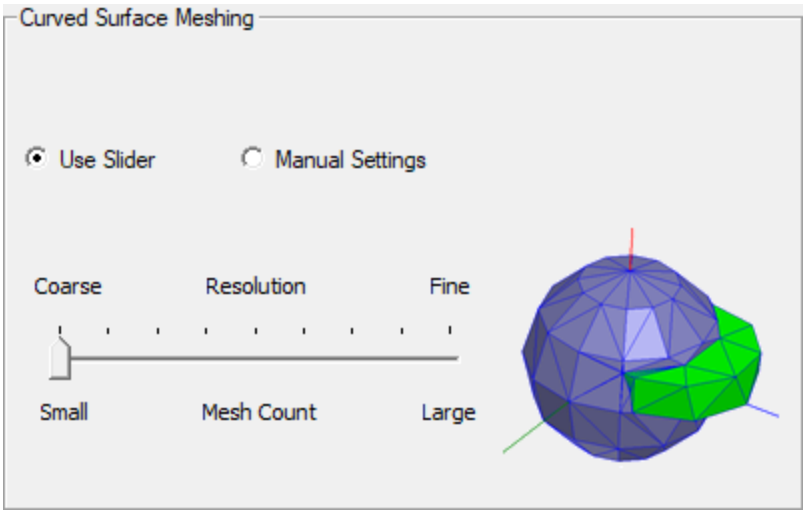


3. Type a name for the group of settings in the **Name** text box or accept the default name.
4. Under **Curved Surface Meshing**, you can select **Use Slider** or specify **Manual Settings**.

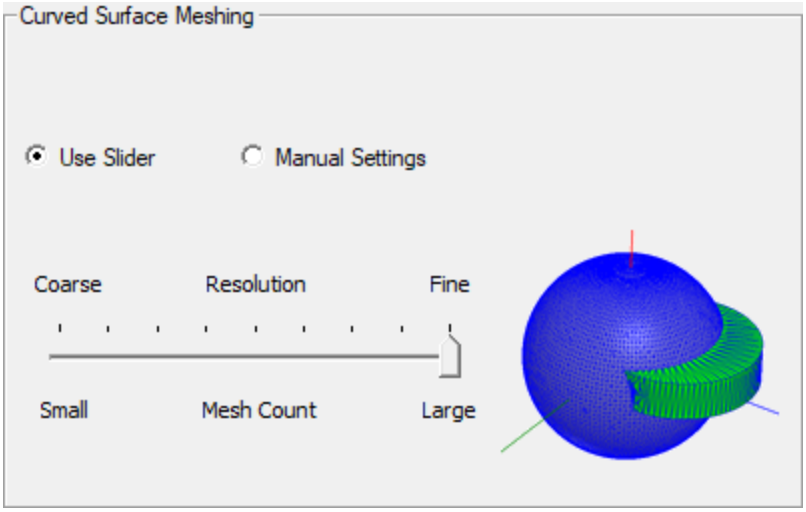
   The slider includes a visual representation of your choice, ranging from a ***Coarse*** *Resolution* (with a ***Small*** *Mesh Count*) through a nine position scale to a ***Fine*** *Resolution* (with a ***Large*** *Mesh Count*). Here, "*Mesh Count*" refers to the number of elements comprising the mesh.

   Coarse Resolution, Small Mesh Count:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

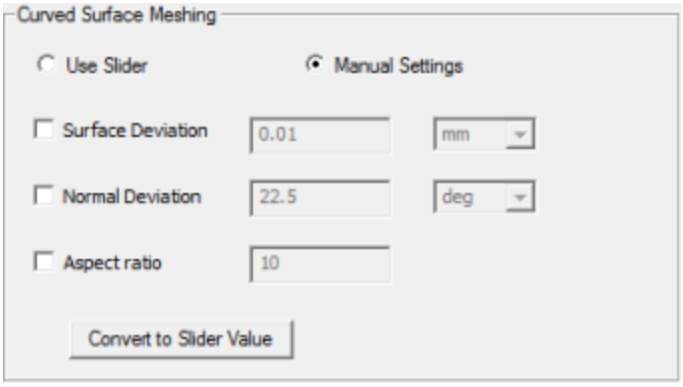


Fine Resolution, Large Mesh Count:



5. If you choose **Manual Settings**, the dialog box changes to show text fields.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



> **Note:**
>
> If you selected **Use dynamic surface resolution** in Initial Mesh Settings, use of **Manual Settings** is not permitted. You must use slider bar to specify one of three levels of surface representation: coarse (1-3), normal (4-6), and fine (7-9).

6. Select **Surface Deviation**. Use the drop-down menu to select a unit of measure and then enter the distance between the true surfaces of the selected faces and the meshed faces.
7. Select **Normal Deviation**. Use the drop-down menu to select a unit of measure and then enter the angular distance between the normal of the true surface and the corresponding mesh surface.
8. Select **Aspect Ratio** and then type a value in the text box. This value determines the shape of the triangles. The higher the value, the thinner the triangles. Values close to 1 will result in well-formed, wide triangles.
9. Click **OK**.

   The settings are applied to the initial mesh generated on the selected surface. The group of settings is listed in the project tree under **Mesh**.

   You can also specify Initial Mesh Settings to apply to all objects. However, if you apply separate surface approximation mesh operations to specific objects, the object settings take precedence over the general setting.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

Selecting **Use dynamic surface resolution** in the Initial Mesh Settings specifies the best-practice mesh operations over the geometric models. The default mesh operations or user-defined mesh operations may or may not be replaced by optimized mesh operations with model analysis. In general, large curve faces, curve faces with small gaps, or skewed cables get smoother curvature representation while small curve faces, such as fillets and small curve objects, get relatively coarse triangulations to reduce overall mesh size.

This dynamic surface resolution mesh operation supports 3D volume mesh and surface mesh in all products.

Surface Approximation

Object surfaces in Maxwell may be planar, cylindrical or conical, toroidal, spherical, or splines. The original model surfaces are called true surfaces. To create a finite element mesh, Maxwell first divides all true surfaces into triangles. These triangulated surfaces are called faceted surfaces because a series of straight line segments represents each curved or planar surface.

For planar surfaces, the triangles lie exactly on the model faces; there is no difference in the location or the normal of the true surface and the meshed surface. When an object's surface is non-planar, the faceted triangle faces lie a small distance from the object's true surface. This distance is called the surface deviation, and it is measured in the model's units. The surface deviation is greater near the triangle centers and less near the triangle vertices.

The normal of a curved surface is different depending on its location, but it is constant for each triangle. (In this context, "normal" is defined as a line perpendicular to the surface.) The angular difference between the normal of the curved surface and the corresponding mesh surface is called the normal deviation and is measured in degrees.

The aspect ratio of triangles used in planar surfaces is based on the ratio of circumscribed radius to the in-radius of the triangle. It is unity for an equilateral triangle and approaches infinity as the triangle becomes thinner.

You can modify the surface deviation, the maximum permitted normal deviation, and the maximum aspect ratio of triangles settings on one or more faces at a time in the **Surface Approximation** dialog box. (Click **Maxwell** > **Mesh** > **Assign Mesh Operation** > **Surface Approximation**.)

The surface approximation settings are applied to the initial mesh.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** For the initial mesh, all the vertices of the triangles lie on the true surfaces. During mesh refinement, all the points are first added to the faceted surface for all products, not to the true surfaces. Then, for all Maxwell projects, and for curvilinear meshing enabled HFSS and HFIE projects, the points on the faceted surfaces will be moved to the curved surface locations when such movement does not degrade the quality of the mesh.

Guidelines for Modifying Surface Approximation Settings

If you intend to modify the surface approximation settings for an object face or faces, keep the following guidelines in mind:

- When necessary, override the default surface approximation settings to represent curved surfaces more accurately. More accurate representation will increase the mesh size and consume more CPU time and memory. The default settings are adequate for most circumstances.
- If you want to obtain a faster solution by using a cruder representation of curved surfaces, set the coarser setting for the whole object, not just a single face.
- It is difficult for Maxwell to satisfy aspect ratio demands if the aspect ratio value is set close to 1 because an arbitrary shape cannot be filled with only equilateral triangles. Therefore, setting the aspect ratio to 1 can lead to unreasonably large meshes. Maxwell limits the aspect ratio to 4 for planar objects and 1.2 for curved objects.

Applying Curvilinear Elements

For **HFSS**, **Maxwell**, and **Mechanical** designs, Curvilinear elements provide an accurate representation of the CAD model geometry by improving the conformity of element nodes to curved CAD surfaces. You can apply curvilinear elements as a Mesh Operation on selected curved model faces see procedure below or as a global option in the Initial Mesh Settings dialog box.

For **Maxwell** designs:

When curvilinear elements are applied globally or to specific CAD faces, the meshing process attempts to pull corner nodes of elements added during mesh refinement to the curved CAD faces. The following figures explain the effects with and without curvilinear elements applied:

- With the **Apply Curvilinear Elements** option *not* selected:

  Corner nodes of an initial coarse mesh are located on curved CAD surfaces. However, as the mesh is refined, the corner nodes of any additional elements remain along the plane of the initial mesh's element faces. Therefore, the number of facets along a curved face (in the circumferential direction) does not increase, and the facets remain coarse. This effect

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

is shown in the first mesh plot below. Note the red-circled nodes. These nodes were added as a result of mesh refinement, and they were not pulled to the curved CAD face:

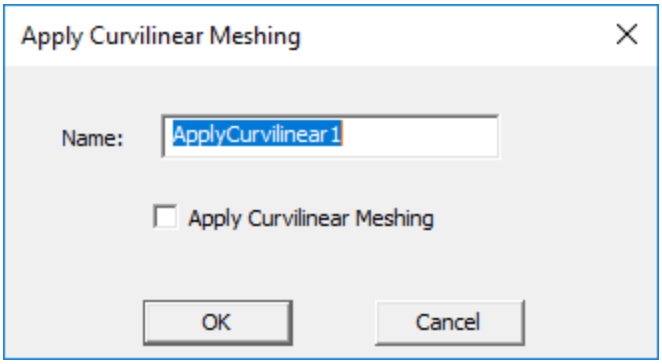
- With the **Apply Curvilinear Elements** option *selected*:

  The meshing process will attempt to pull all corner nodes of additional elements added during mesh refinement to the curved CAD faces. Therefore, the facets along curved faces are finer, and the conformity of the mesh to the curved CAD faces is improved. The effect is as shown in the following, second mesh plot:

How to Apply Curvilinear Elements to Specific Curved Faces:

1. Select the object or face to which you want to apply curvilinear elements.
2. Select **Mesh** in the Project Manager, right-click for the short cut menu and select **Assign Mesh Operation** > **Apply Curvilinear Meshing**.

   The **Apply Curvilinear Meshing** dialog box appears.



3. Either accept the default name or provide one of your own.
4. Select **Apply Curvilinear Meshing**.
5. Click **OK**.

The defined Mesh Operation appears in the Project Manager.

Cloning a Mesh

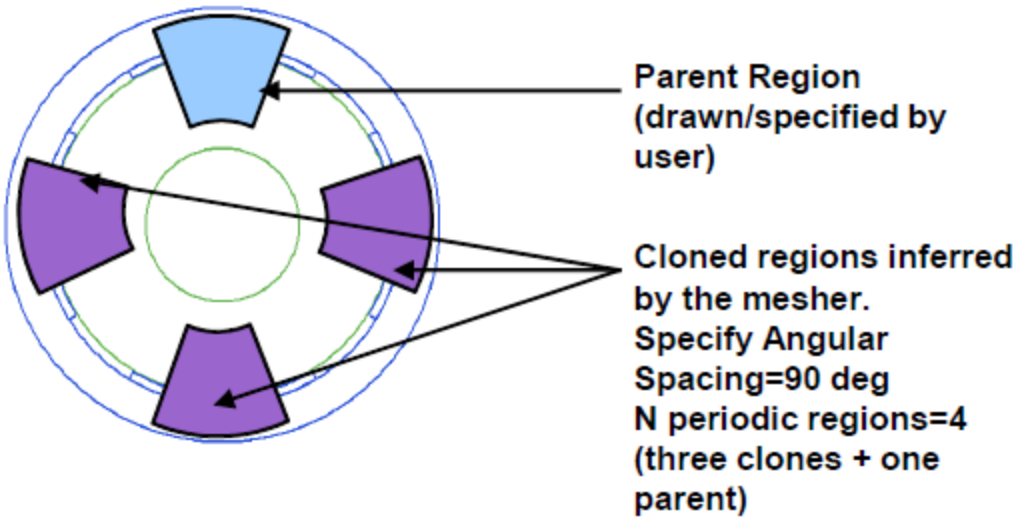
> **Note:** The Clone Mesh operation described in this topic only applies to Maxwell 2D designs. For more information on clone meshing for a 3D Maxwell design, see 3D Clone Mesh Generation.

The clone mesh operation allows users to use the mesh data from a user-specified parent region of a Maxwell 2D design to apply identical meshes to its cloned regions. In the example shown

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

below, three cloned regions have been generated with an angular spacing of 90 degrees from the user-drawn parent region.

> **Note:** For non-transient solution types, this operation is applied only on the initial mesh. If you do adaptive refinement, the meshes will no longer match; the operation is not reapplied during adaptive refinement.

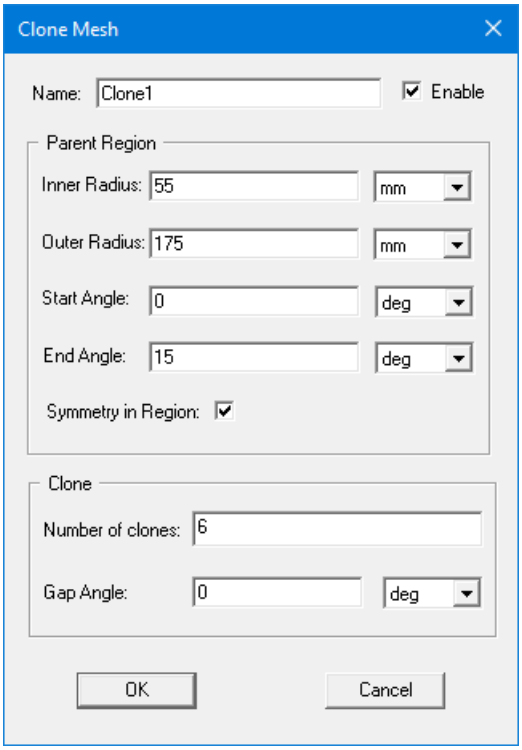


Clone mesh operations are performed after all other mesh operations are done.

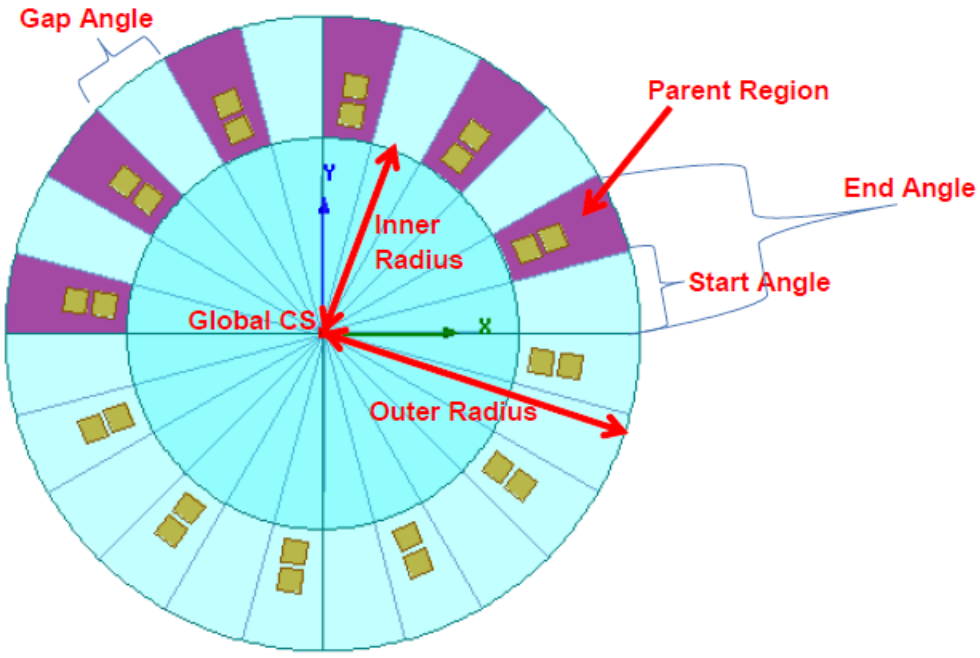
> **Note:** To use clone mesh, you must also setup Length-Based Mesh Refinement Inside Objects.

1. To begin a clone mesh operation, select **Maxwell 2D** > **Mesh** > **Assign Mesh Operation** > **Clone Mesh...** to open the **Clone Mesh** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. First set up a **Parent Region**. (Refer to the following figure.)



To set up the parent region, define the following parameters:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Inner Radius**
- **Outer Radius**
- **Start Angle** (default=0)
- **End Angle**
- **Symmetry in Region** - treat the region (parent and clone) as symmetric inside the region

3. Specify how to clone the parent region by defining the following parameters:
   - **Gap Angle** (default=0) - angular spacing between clones
   - **Number of clones** - number of periodic regions (including the parent)
4. Like other mesh operations, the user can enter a **Name**, which can be enabled and disabled. Multiple clone mesh operations (with different names) can be created.
5. When finished, click **OK**.
6. To edit the clone mesh setup data, use the Clone Mesh or the Properties window.

Modifying the Model Resolution

(Setting Model Resolution applies to Maxwell 3D Designs only)

The model resolution parameter is used by the mesh generator to distinguish large features from small features in the model. This setting controls how large a feature must be to be resolved by the mesher. For example, if you set the model resolution length to 20 mm, any model features smaller than 20 mm are not represented in the mesh. Neither the model nor the model files are changed. The resolution only controls how the mesh for the model is represented.

While removing small details, if the mesh generator finds that the representation of the model is not accurate enough, it returns an error condition. The mesh generator then starts with the most accurate representation and prunes away the details smaller than the model resolution length. It returns an error if the specified model resolution length forces the final representation to deviate too greatly from the model.

You can set Model Resolution on one or more objects to remove unnecessary details from the mesh representation. This can be used to reduce the mesh complexity of the selected objects.

A cautionary note is needed concerning the use of model resolution. It can sometimes make model faces fail to be represented in the mesh, which can effectively remove some of your boundary conditions. This can only happen if faces are closer together than the model resolution distance you specify.

To modify the model resolution:

1. Select the object or objects on which to specify a Model Resolution operation.
2. Click **Maxwell 3D** > **Mesh** > **Assign Mesh Operation** > **Model Resolution**.

   The **Model Resolution Mesh Operation** dialog box appears.

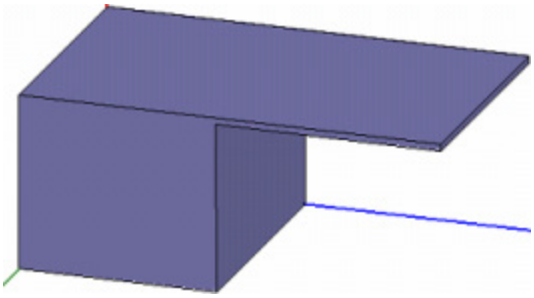
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Alternatively, you can display the same dialog using these steps:

a. Right-click on **Mesh** in the Project Tree to display the shortcut menu.
b. Click on **Assign Mesh Operation** > **Model Resolution** on the shortcut menu.

The **Model Resolution Mesh Operation** dialog box contains text fields for the mesh operation Name and radio buttons with choices for the following

- **Auto Simplify Using Effective Thickness** – The mesher calculates the resolution length based on each object's effective thickness. One mesh operation can be assigned to many objects, and each will be simplified based on its own dimensions. Use the **Auto Simplify** selection:
    - To remove many details while retaining an object's overall shape and size
    - For objects of generally uniform thickness
    - To assign one mesh operation to many objects
- **Use Model Resolution length** – Enables fields for you to specify the resolution value and units. Use this selection for:
    - Tighter control of mesh accuracy.
    - Objects of non-uniform thickness. For example, the thin section of the object shown below might be lost with **Auto Simplify**.



3. After defining the operation, click **OK**.

   This adds the named Model Resolution operation under the **Mesh** icon in the Project Manager tree.

> **Note:** Setting Model Resolution will invalidate any existing solutions. When two objects in contact have different model resolution lengths, the smaller length will apply for the common regions.

Reverting to the Initial Mesh

The initial mesh is the mesh that is generated the first time a design variation is solved. It includes surface approximation settings, but does not include lambda refinement or defined

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

mesh operations.

If you have modified the design setup, and do not want to use the existing current mesh, revert to the initial mesh prior to solving.

- On the **Maxwell** > **Analysis Setup**> **Revert to Initial Mesh**.

Reverting to the initial mesh is useful when you want to evaluate how a different solution frequency affects the mesh generated during an adaptive analysis. You lose all solution data for a solve setup and all of its sweeps when you revert to the initial mesh for that setup. You can do this for all solve setups at once by selecting the command through Analysis in the menu system or project tree, or for a specific solve setup via its right mouse click menu in the project tree.

Generating Mesh without Solving

If you want to refine the mesh on a face or volume but do not want to generate a solution, define mesh operations. Then do one of the following:

- Select [**Maxwell**] > **Analysis Setup** > **Generate Mesh**.
- Right-click the **Analysis** or **Setup** icon in the **Project** window and select **Generate Mesh**.

The same solve machine rules that apply to solving any other setup also apply here. The mesh operation will be sent to the default solve machine. If you specified "Prompt for analysis machine when launching analysis" under **Tools** > **Options** > **General Options** > **Analysis Options**, the **Server Setup** dialog box appears and you can specify a solve machine.

- If a current mesh has been generated, the solver will refine it using defined mesh operations.
- If a current mesh has not been generated, the solver will apply the mesh operations to the initial mesh.
- If an initial mesh has not been generated, the solver will generate it and apply the mesh operations to the initial mesh.
- If the defined mesh operations have been applied to the selected face or object, the current mesh will not be altered.

> **Tip:**
>
> Define a new mesh operation rather than modify an existing mesh operation. The solver will not re-apply a modified mesh operation.

> **Note:** Mesh operations at the target design of a mu (permeability) link are ignored.

Applying mesh operations without solving enables you to experiment with mesh refinement in specific problem regions without losing design solutions. You cannot undo the applied mesh

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

operations, but you can discard them by closing the project without saving them or by reverting to the initial mesh.

Specifying Initial Mesh Settings

You can specify the initial mesh settings, including the surface approximation and the meshing approach for both Maxwell 3D and Maxwell 2D designs. Initial Mesh Settings apply to all objects; however, if you apply separate surface approximation mesh operations to specific objects, the object settings take precedence over the general setting.

> **Note:**
>
> When you have defined mesh linking between a source and target design, all parameters within the *Initial Mesh Settings* dialog box are ignored for the target design. The mesh is copied from the source design without modification.

For most Maxwell 3D designs, you can let the solver automatically choose which of two meshing approaches to take. Each solver predicts which one gives the best results, balancing mesh reliability, speed, quality, size and design characteristics.

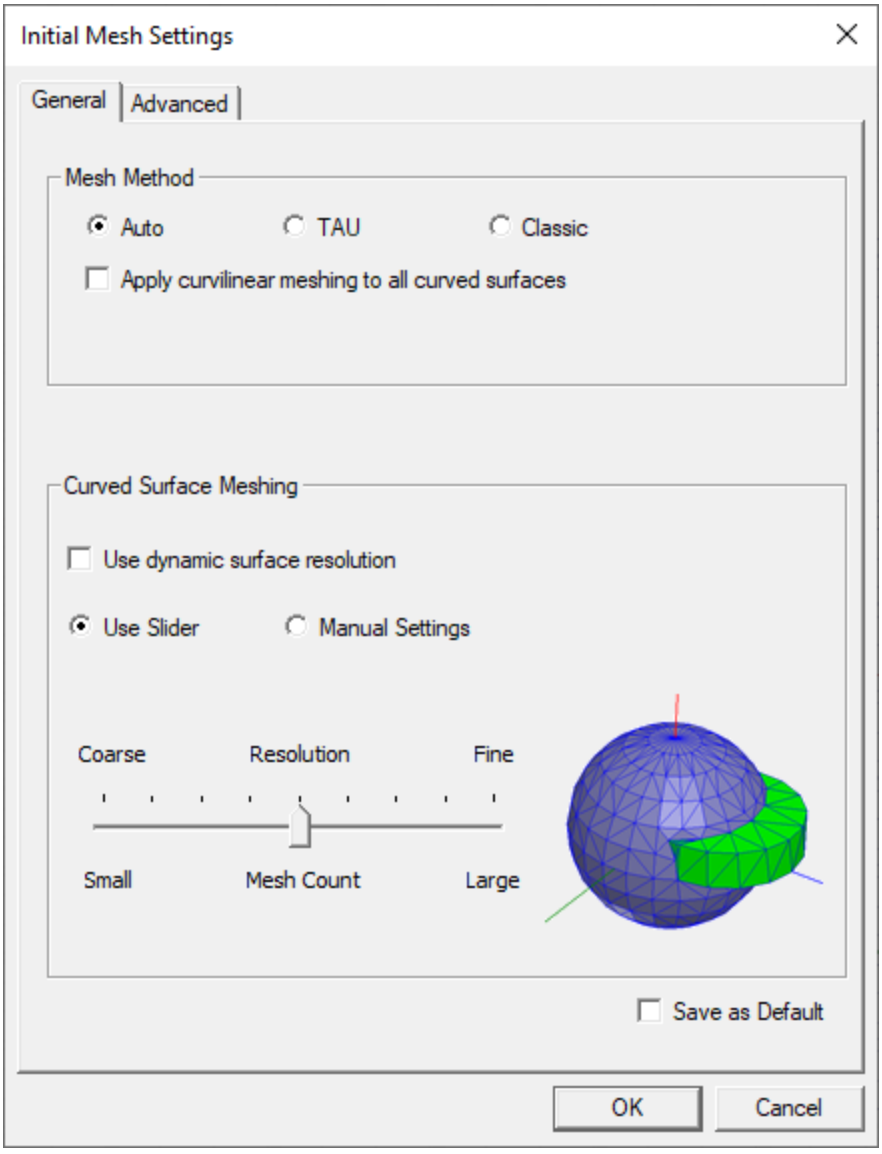
In most cases, Maxwell uses TAU mesh, rather than the classic mesh. In general, it looks for specific features (for example, stacks of large planar parallel facets with small gaps) and situations where the initial Tau mesh is 4 times larger than the Classic. For Maxwell 2D designs, the TAU mesh is used.

In a few cases, you may decide to override the automatic choice and designate the mesher to use. To do so:

1. Access the **Initial Mesh Settings** one of two ways:
   - Select **Maxwell** > **Mesh** > **Initial Mesh Settings...**
   - In the Project Manager, right-click **Mesh**, and select **Initial Mesh Settings** from the shortcut menu.
   - On the **Simulation** tab of the ribbon, select **Mesh Settings**.

   The **Initial Mesh Settings** window appears, with the **General** tab selected.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. For Maxwell 3D, the **Mesh Method** options you can select are:
   - **Auto** – the solver automatically selects the mesher. This is the default setting. In most cases, this will be TAU.
   - **TAU** – only specific curve faces will be remeshed (for example, equation-based axisymmetric faces). If a curve face connects to non-remeshed curve faces, the curve face will not be remeshed. If a curve face cannot be remeshed, faceting triangles will be used as the surface mesh. Mesh quality depends on how the faceting triangles are made. If the surface mesh is generated by TAU, it shows in the profile as Mesh TAU (Surface). If you check **Use alternative mesh methods as fall back** on the **Advanced** tab, this can fall back to Mesh TAU(Wrapper). This, in turn, can fall back to Mesh (stitch), which is classic.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Classic** – Classic mesh uses a Bowyer algorithm to create compact meshes for the model with very large length scales. It represents the model very accurately. Depending on the model, Classic mesh may converge using fewer resources whereas TAU or Phi Plus may converge faster. This setting must be used if you wish to use the Phi Mesher, for which you must also check **Allow Phi for layered geometry (Classic only)** on the **Advanced** tab.

For Maxwell 2D, the TAU mesher is used; there are no selection options.

3. For Maxwell models with curved surfaces, you can select or deselect **Apply curvilinear meshing to all curved surfaces**. This increases accuracy, but costs more memory.
4. Under **Curved Surface Meshing**, you can choose to **Use dynamic surface resolution**, select **Use Slider** or specify **Manual Settings**.

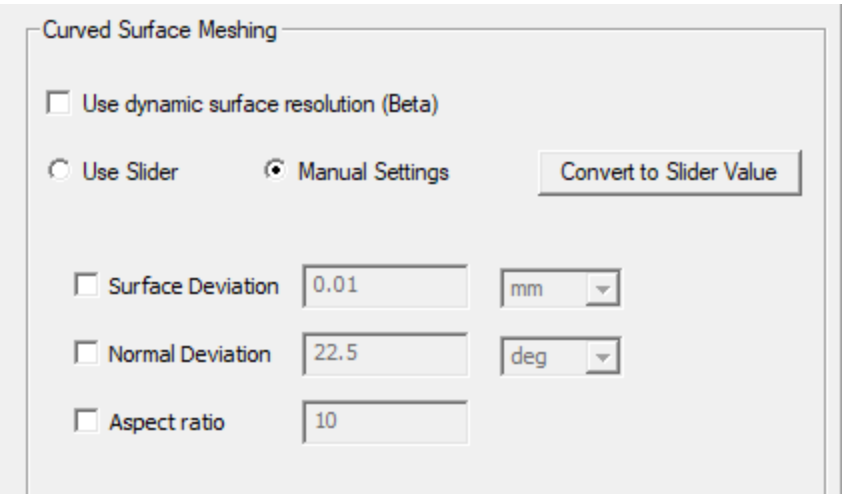
   If you select **Use dynamic surface resolution**, the **Manual Settings** option is disabled.

   The slider includes a visual representation of your choice, ranging from a ***Coarse*** *Resolution* (with a ***Small*** *Mesh Count*) through a nine position scale to a ***Fine*** *Resolution* (with a ***Large*** *Mesh Count*. Here, "*Mesh Count*" refers to the number of elements comprising the mesh.

   Selecting **Use dynamic surface resolution** in the *Curved Surface Meshing* section specifies the best-practice mesh operations over the geometric models. This mesh operation will support 3D volume mesh and surface mesh in all products. The default mesh operations or user-defined mesh operations may or may not be replaced by the optimized mesh operations with model analysis. In general, large curve faces, curve faces with small gaps, or skewed cables get more smooth curvature representation while small curve faces, such as fillets, small curve objects, and so forth, get relatively coarse triangulations so that the overall mesh count will be reduced.

   If you select dynamic surface resolution, you can optionally use the slider bar to adjust surface representation levels as: coarse (1-3), normal (4-6), and fine (7-9). You can also adjust the surface representation level for a specific group of faces by specifying slider bar, as described in Modifying Surface Approximation Settings.
5. If you choose **Manual Settings**, the window changes to show text fields. See: Modifying Surface Approximation Settings.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

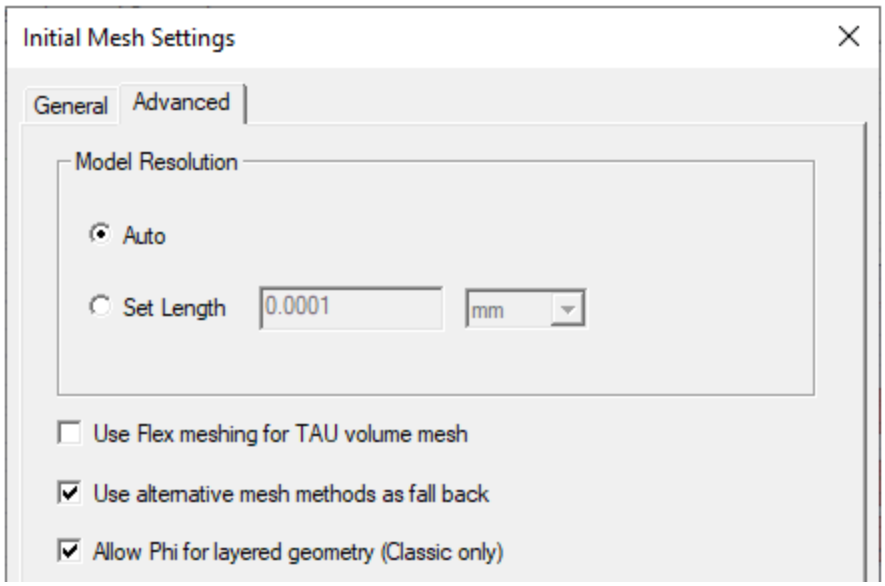


Use the check boxes to enable the fields and specify values:

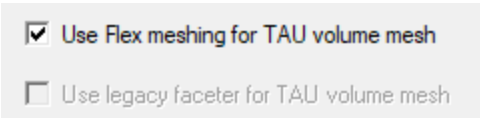
- **Surface Deviation** – the distance between the true surfaces of the selected faces and the meshed faces.
- **Normal Deviation** – the angular distance between the normal of the true surface and the corresponding mesh surface. Maxwell 3D's default normal deviation setting for the selected faces is 15 degrees. Maxwell 2D's default normal deviation setting is 3 degrees.
- **Aspect Ratio** – determines the shape of the triangles. The higher the value, the thinner the triangles. Values close to 1 will result in well-formed, wide triangles. Maxwell's default aspect ratio settings for the selected faces are 10 for curved surfaces and 200 for planar surfaces.
- Clicking **Convert to Slider Value** converts the manually entered values to an equivalent slider setting, and returns the panel to the slider view.

6. To make your choices the default, use the **Save as default** check box.
7. The **Advanced** tab lets you optionally specify a **Set Length** for **Model Resolution**. This is for experienced users who have a good understanding of how particular values will affect their models. In general, the **Auto** setting provides good results.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



8. **Use Flex meshing for TAU volume mesh** enables a version of the TAU mesher that will rarely fail to generate a mesh (for Maxwell 3D models only). In most cases, the TAU Flex mesh is as accurate as traditional TAU or Classic meshes. However, for some complex models with bad translation or poorly defined surfaces that would fail to produce a strict mesh on all objects, relaxed tolerances will be applied. In these cases the user should review the mesh to evaluate whether it is acceptable for simulation. See TAU Flex meshing for more details.



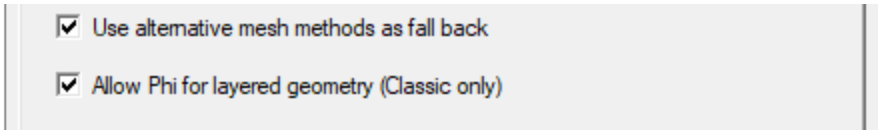
> **Note:**
>
> TAU Flex meshing does not support RMxprt models.

9. **Use legacy faceter for TAU volume mesh**(for both Maxwell 2D and 3D models) – By default, TAU uses the latest faceter to generate geometric model for meshing. Occasionally, the mesher may fail, and TAU will automatically fall back to use the legacy faceter to make a second attempt. In such cases, directly using the legacy faceter can get the mesh in the first attempt so total meshing time will be saved. The legacy faceter is not actively maintained by Spatial and will be retired soon. This option should be used only as a last resort.
10. For Maxwell 3D models only, selecting **Use alternative mesh methods as fall back** enables the **TAU** and **Classic** mesh methods (chosen on the **General** tab) to fall back to

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

alternative mesh methods if the solver fails to generate the initial mesh.

You can also select **Allow Phi for layered geometry (Classic only)**, which enables the **Classic** mesh method (chosen on the **General** tab) to use the Phi mesher for layered geometry.



For example, the the sequence of mesher methods might go like this: When the mesh method is **TAU**: TAU(>Phi)>Classic. When mesh method is **Classic**: Classic(>Phi)>TAU. Note: the options do not affect the Auto mesh setups.

11. Click **OK** to apply your choices.

The settings will be applied to the initial mesh generated.

TAU Flex Meshing

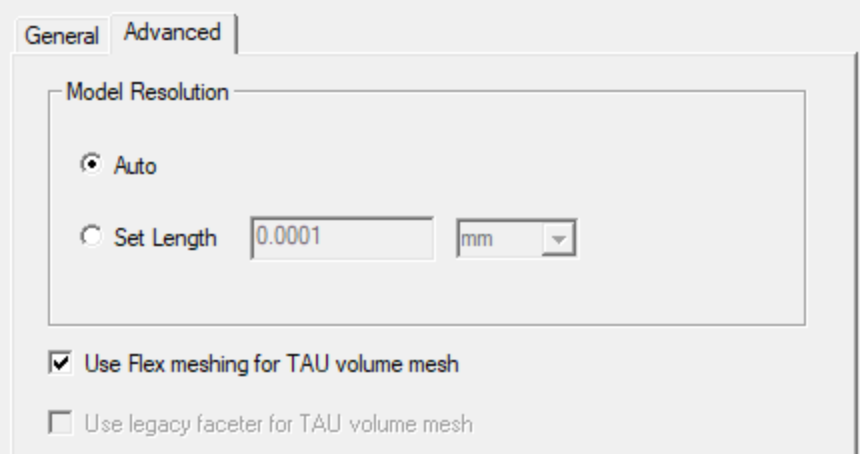
TAU Flex is designed for guaranteed mesh success, and may also reduce meshing time. It provides a mesh even for complex and “dirty” geometry model without any preliminary geometric healing or repair.

TAU Flex is a multi-domain, priority mesher which provides more efficient and reliable meshing. The priority mesh generation is driven by solver requirements for materials (metal/non-metal), boundary conditions (ports, radiation,...), conduction paths, and so forth. The constraint-tolerant meshing method gives the TAU Flex mesher flexibility to excuse mesh difficulties in lower-priority regions so that the resulting mesh can still provide acceptable simulation results.

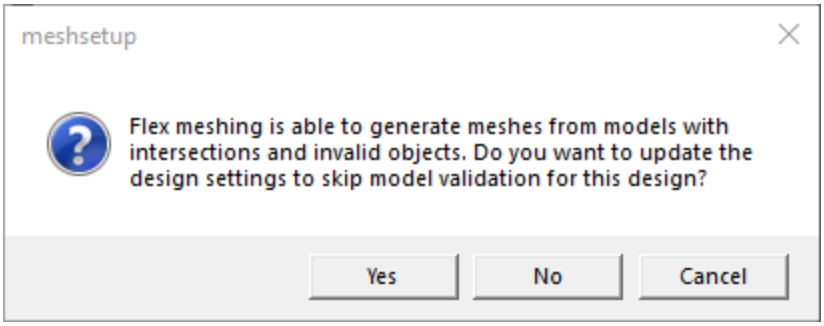
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Steps for Using TAU Flex

1. Navigate to the **Initial Mesh Settings** window.
2. Click the **Advanced** tab and select **Use Flex meshing for TAU volume mesh**.

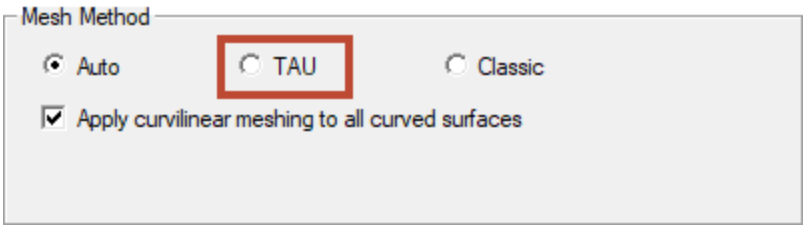


Selecting this option opens a dialog box. Select **Yes** to continue.



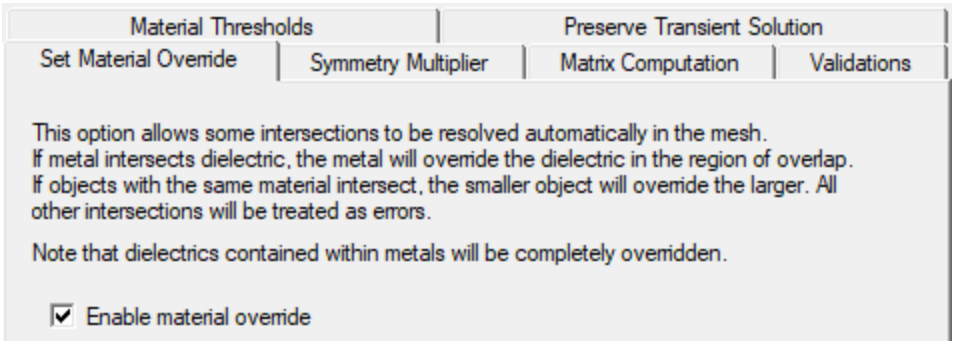
To get the full benefits of TAU Flex, especially for complex or "dirty" models, follow these recommended steps:

1. On the **General** tab of the **Initial Mesh Settings** window, select **TAU**.



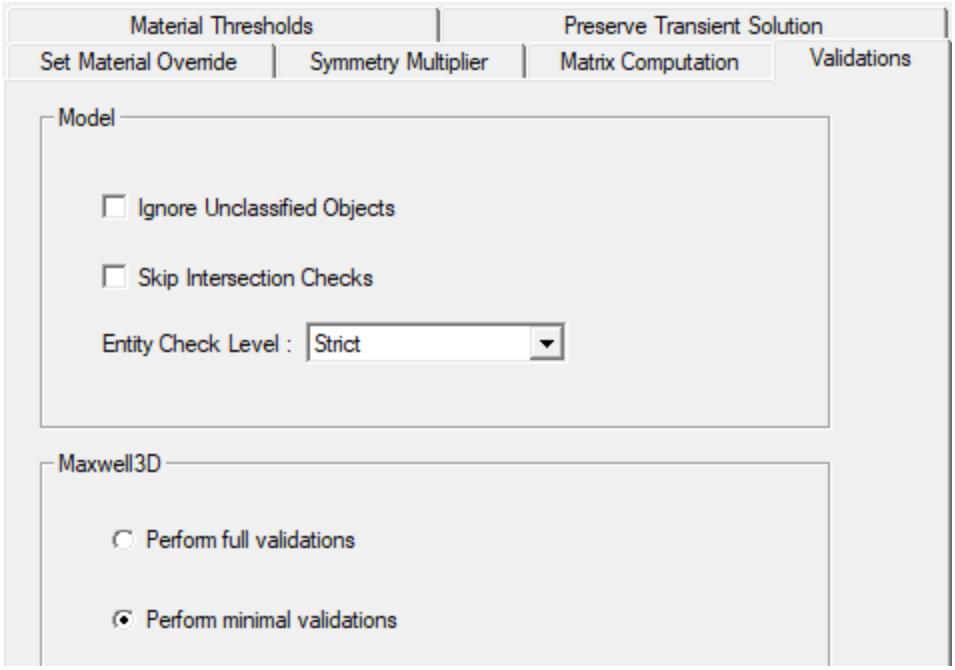
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click **Maxwell** > **Design Settings** to open the **Design Settings** window.
3. On the Set Material Override tab, select **Enable material override**.



This activates TAU's priority meshing method based on metal/non-metal materials.

4. Still in the Design Settings window, click the **Validations** tab and select **Perform minimal validations**.



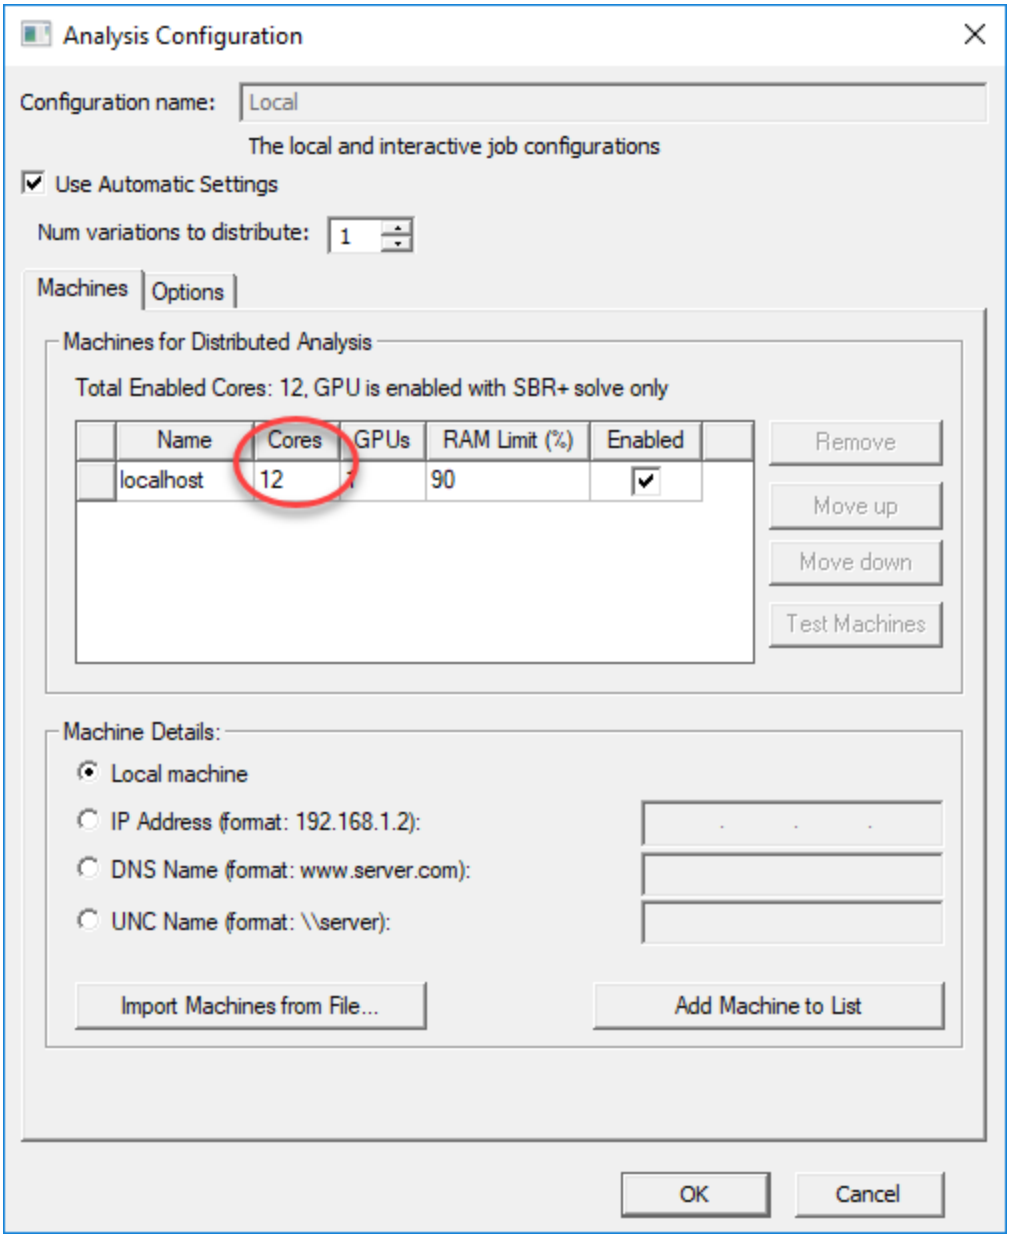
This reduces preprocessing time for complex models, and allows simulation of "dirty" geometry for which TAU Flex can provide a mesh.

5. Because TAU Flex is a parallel mesher for many processes, you should specify multiple cores in **HPC and Analysis Options** to speed up the meshing process. Access the Analysis Configuration window one of two ways:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Select the Simulation tab on the ribbon and click **Analysis Config**.
- Use **Tools** > **Options** > **HPC and Analysis Options** or select the **Simulation** tab on the ribbon and click **HPC Options**. Then double-click a configuration.

The **Analysis Configuration** window appears.

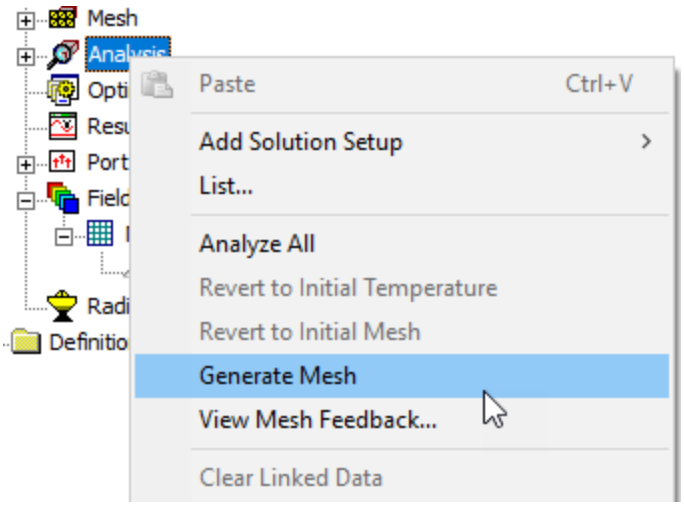


Specify the number of cores to use.

6. In most cases, TAU Flex can provide mesh as accurate as TAU or Classic, but not always. Therefore, we recommend that you **Generate Mesh** without solving, and that you review

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the mesh before proceeding the simulation.



TAU Flex Warning Messages

In cases where TAU Flex has difficulty making a strict mesh on some objects, mesh warnings are given for those objects. You should review the mesh on those objects before proceeding to the simulation. You can exercise discretion in deciding whether a given mesh issue needs to be addressed (for example, critical antenna geometry) or can be ignored (for example, a small "leak" in a dielectric substrate far from the source).

There are three types of warnings:

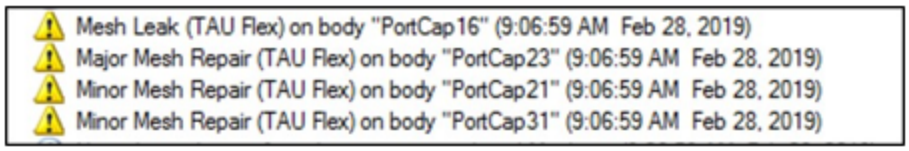
- **"Mesh Leak"** – *The most severe warning*. A body does not have any mesh element, or it has mesh elements with a significant mismatch of surface area between the mesh and geometry – larger than 10% of planar area, or 20% of curved area.
- **"Major Mesh Repair"** – A body has major surface area mismatch between the mesh and geometry – larger than 5% of planar area, or 10% of curved area.
- **"Minor Mesh Repair"** – *The least severe warning*. A body has minor surface area mismatch between the mesh and geometry – less than 5% for planar area, or 10% for curved area.

Reviewing TAU Flex Mesh Warnings

TAU offers three ways to view mesh warnings.

1. **Message Manager** – Immediately after the mesh generation is done, if a tolerant mesh is given, warnings display in the Message Manager. If the window is hidden, click **Show Messages**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



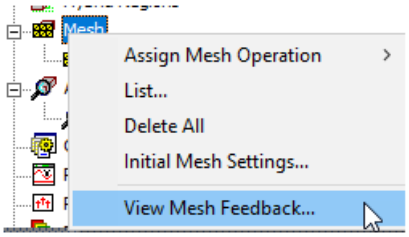
2. **Mesh Statistics** – On the **Results** tab of the ribbon, click **Solution Data** to open a **Solutions** window.

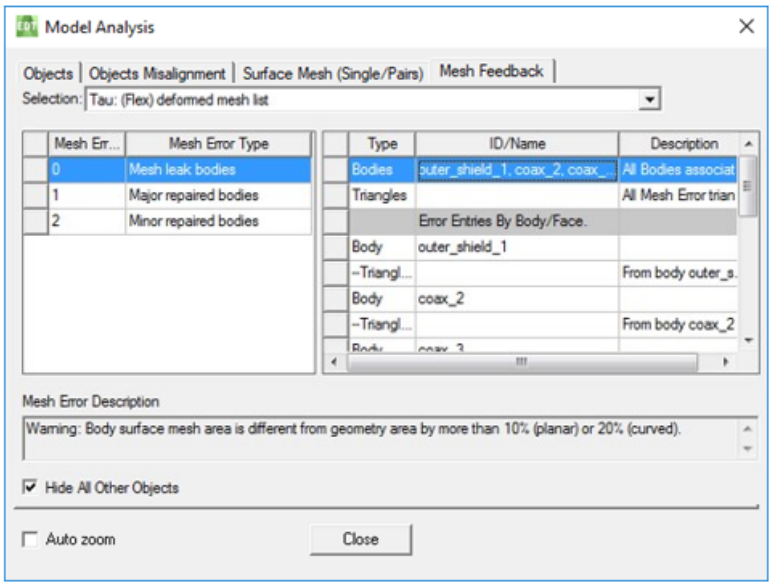
   On the **Mesh Statistics** tab of the **Solutions** window, if a tolerant mesh is generated, the surface area difference between the mesh and geometric model at body level is listed as "RecoveredPlanarArea" and "RecoveredCurveArea". 100% means that the body has a strict mesh. You can click the surface area tab to sort the body list and see the tolerant mesh bodies first.

	Nu...	RecoveredPlanarArea %	RecoveredCurvedArea %	
coax	338...	100	100	0
coax_2	176...	100	99.9961	0
coax_3	168...	100	99.9961	0
coax_4	367...	100	100	0
coax_5	537...	100	100	0
coax_5_1	162...	100	99.9961	0
coax_5_2	220...	100	99.9996	0

3. **Model Analysis** – To view the details of the tolerant mesh, click **Modeler** > **Model Analysis** > **Show Analysis Dialog** > **View Mesh Feedback** to launch the **Model Analysis** window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





Click on the top list to display objects that have tolerant mesh.

Click the "Triangles" to display the mesh on the tolerant objects.

Individual objects are listed under "Error Entities By Body/Face". You can select one or multiple bodies to view the mesh at a more detailed level.

Addressing TAU Flex Mesh Issues

In cases where TAU Flex has difficulty making a strict mesh on some objects, you can address the problem using one of the following techniques:

1. Redraw the geometry in question in the native modeler.
2. Heal the geometry, either with integrated healers or perhaps in Discovery.
3. If the object has curved or true surfaces, consider applying a localized surface mesh operation which creates a finer than default mesh.
4. Remove difficult objects that are not critical to the simulation.

Specifying Surface Priority for TAU Mesher

You can choose to specify the surface representation priority for the TAU mesher. For most designs, you can let the solver automatically choose which of two meshing approaches to take. The solver predicts which one gives the best results, balancing mesh reliability, speed, quality, size and design characteristics. In most cases, the solver uses TAU mesh, rather than the classic mesh. In general, it looks for specific features (for example, stacks of large planar parallel facets with small gaps) and situations where the initial TAU mesh is 4 times larger than the

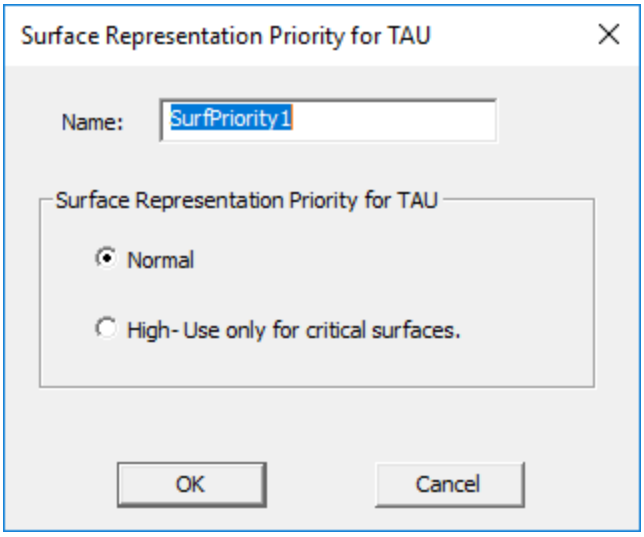
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Classic. Experienced users may choose to designate a high surface representation priority for the critical surfaces with the TAU mesh is used.

> **Important:**
>
> Use this mesh operation with caution. Use this option only if the model has tiny elements or critical boundary conditions since the solver performs several additional strict mesh verification steps on the selected objects.

1. Select the surface of interest.
2. If desired, specify a Name for the Mesh operation.
3. Right-click the **Mesh** icon in the Project tree to view the shortcut menu and select **Assign Mesh Operation** > **Surface Priority for Tau**.

   The **Surface Representation Priority for Tau** dialog box appears.



4. Select **High** for the critical surface.
5. Click **OK**.

   The Mesh operation appears in the Project Manager.

TAU 2D Mesh Generation

The Maxwell TAU (Triangular Adaptive Uniform) 2D mesher provides a fully automated initial mesh generation method that creates a uniform, high quality, solver-driven mesh. It is designed for solvers without adaptive passes, or demanding high quality mesh. Several meshing methods

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

are used by the TAU 2D mesher, such as skin depth layer mesh, clone mesh, rotational sweep mesh, and remeshing.

To benefit from these meshing technologies for Maxwell 2D designs, ensure that **TAU** is selected as the **Mesh Method** on the **Initial Mesh Settings** dialog **General** tab by right-clicking the Mesh icon in the Project Manager and selecting **Mesh** > **Initial Mesh Setting**, or by selecting **Maxwell** > **Mesh** > **Initial Mesh Settings...**. Note that **TAU** mesh is the default setting for new 2D designs.

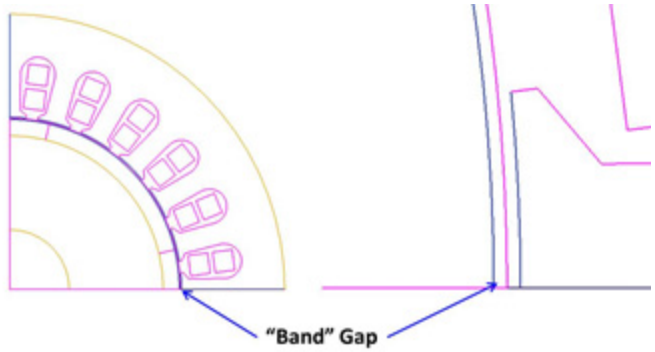
When TAU 2D mesh is selected, its meshing methods are applied to specific local regions. The local regional meshes are then assembled as the final step for the simulation.

The following sections describe TAU 2D mesh generation methods for rotational models, for non-rotational models; and the Skin Depth Layer Mesh Generation method, which can be applied to any model.

TAU 2D Mesh Generation for Rotational Models

If the mesher determines that a model is a rotational model, it uses a rotational mesh generation with either the clone mesh or rotational sweep mesh method.

To determine if the model is a rotational model, the curves around the origin are calculated. The smallest rotational gap is defined as the “Band” gap. The model shown below is an example of a rotational transient model:



Two major regions, a static region and a moving region, are classified by the Band gap.

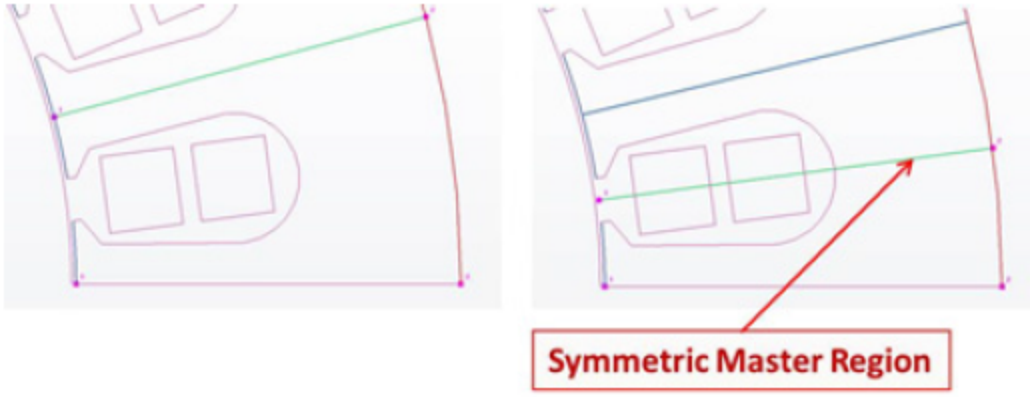
TAU 2D Clone Mesh Generation

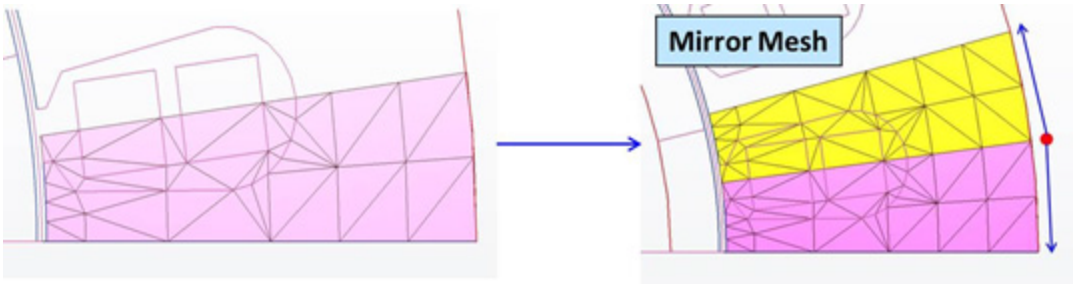
> **Note:** To use clone mesh, you must also setup Length-Based Mesh Refinement Inside Objects.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The static geometric model in the local rotational region is analyzed to determine whether it has duplicate subregions. If a model has duplicate subregions, the TAU clone meshing is automatically activated and will generate the mesh so that each subregion has the topologically identical mesh. The following example shows a static clone region with six identical subregions - a master and clone regions:

In the clone region, the master region is calculated and analyzed. If the master region has a symmetric feature, the symmetric mesh is generated; see "Maxwell 2D Symmetry Mesh" on page 12-63 below.

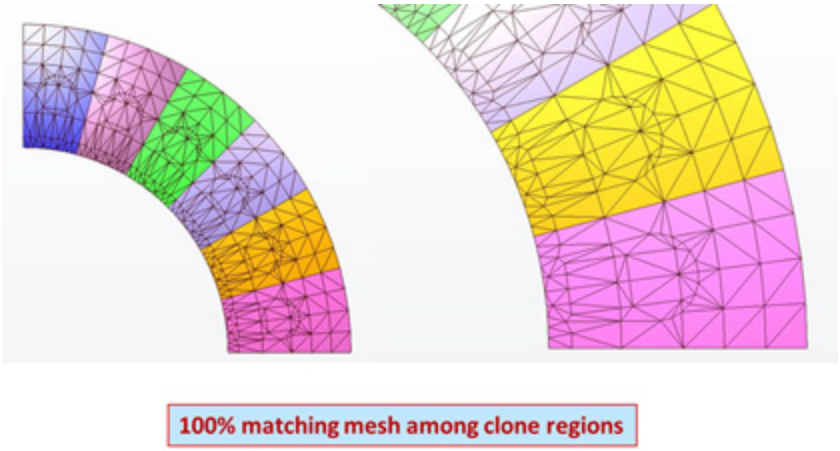




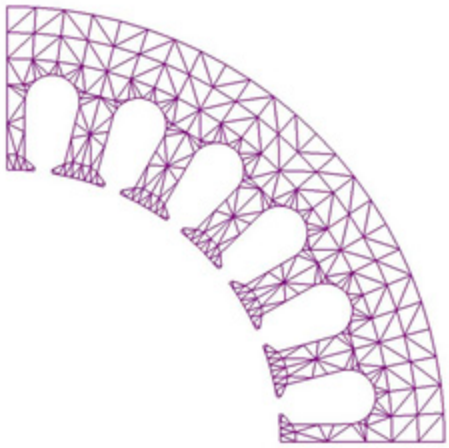
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

As shown above, a uniform mesh will be generated in one half of the master region first, then the mesh is mirrored about the symmetric central line to generate the symmetric mesh in the master region.

Because all the child regions have identical geometric features, the mesher uses copy-paste to replicate the master mesh at each of the child regions, rotating it to the appropriate angles.



This ensures the identical mesh in the different regions, especially for the teeth.



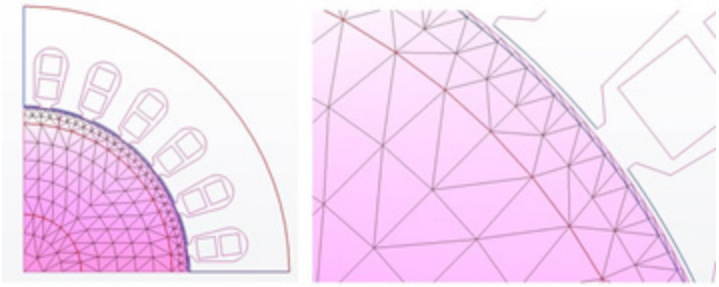
TAU 2D Rotational Sweep Mesh Generation

If the local region does *not* have identical geometric subregions and thus the clone mesh is *not* generated, a geometric analysis is performed to verify whether the region is rotational.

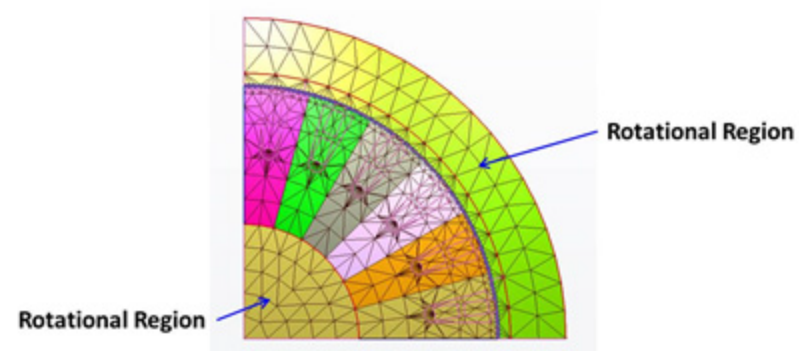
Around the rotational center, if a region has two or more rotational curves, this region can be defined as a “rotational” region. In this case, rotational sweep mesh generation is used

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

proceeding in the radial direction with layers while using uniform sweep elements in the rotational direction. This meshing method controls the aspect ratio in the radial direction, while maintaining the uniform sweep in the rotational direction.



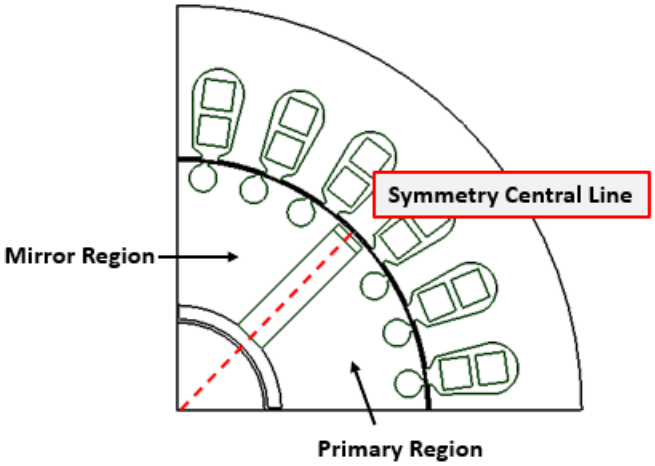
Rotational Sweeping Mesh



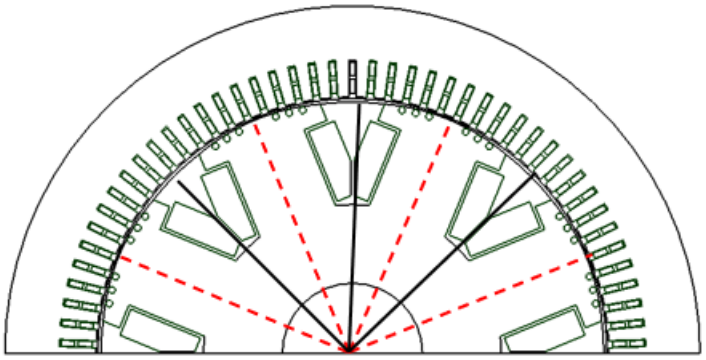
Maxwell 2D Symmetry Mesh

A symmetry pattern is characterized by the existence of a symmetry central line. The objects/outlines at one side of the symmetry central line can be constructed mirroring the objects/outlines at the other side of the symmetry line:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

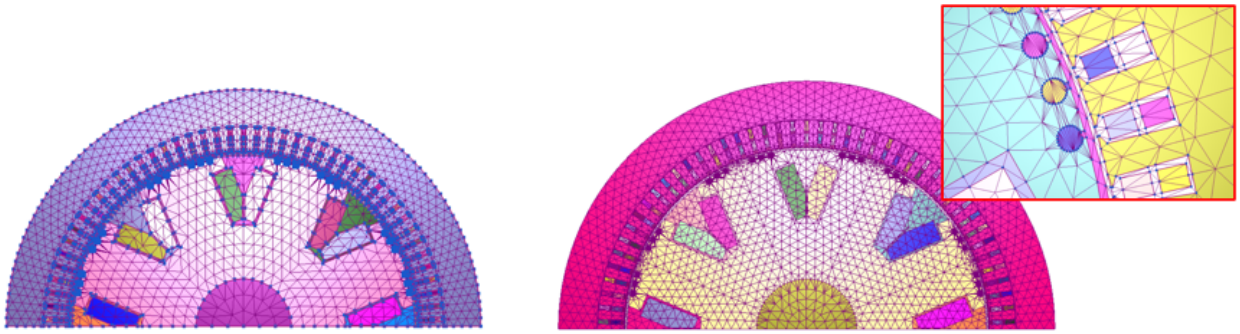


A specific geometry can be a combination of a mirror and a circular pattern. For example, in the transient simulation of motors, the design may contain one or multiple symmetry patterns, as shown below:



The TAU mesher will automatically detect such patterns regarding their inner symmetry and their circular periodicity. It will then create a symmetric and periodic mesh to reduce simulation noise. The resulting mesh can be plotted to verify its symmetry:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Non-Symmetry Mesh

Symmetry Mesh

Symmetry mesh can be combined with mesh density control when this mesh operation is applied to the initial mesh.

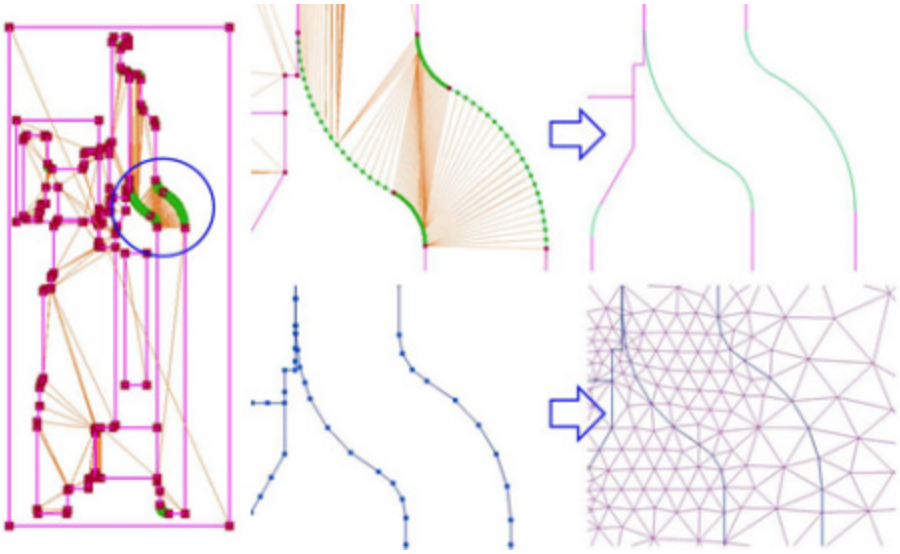
Note the following:

1. To generate a symmetry mesh, the band of motion must be defined using a curved, *i.e.*, non-segmented, object such as an unsegmented circle with one outer edge.
2. In addition to (1), no segmented outlines should be defined around the band (*e.g.*, inner region object). If required, these objects should also be defined by unsegmented, curved geometry.
3. Symmetry mesh is currently not compatible with a band mapping angle mesh.

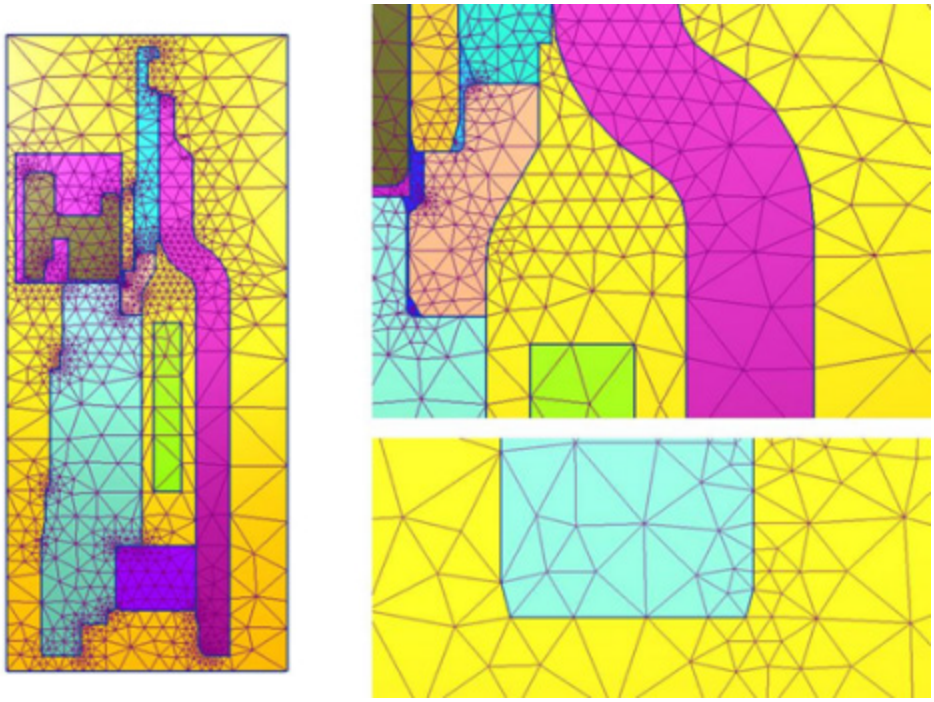
TAU 2D Regular Mesh Generation (Non-Rotational Models)

If the model is not identified as a rotational model, the TAU 2D regular mesher is used to generate the mesh. TAU 2D mesher does not use Parasolid union as the Classic mesher does. Instead it reads the objects individually as-is. Remesh technology is used to get the best representation of the curves with minimum mesh points.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The TAU 2D regular mesher uses a top down meshing algorithm that starts the mesh from a uniform base mesh, then adapts the mesh in the necessary regions, and does the boundary recovery later. Mesh quality is controlled and maintained during the entire meshing process. To maintain a uniform mesh, 1:2 splitting method is used for the transitions from small elements to large elements.



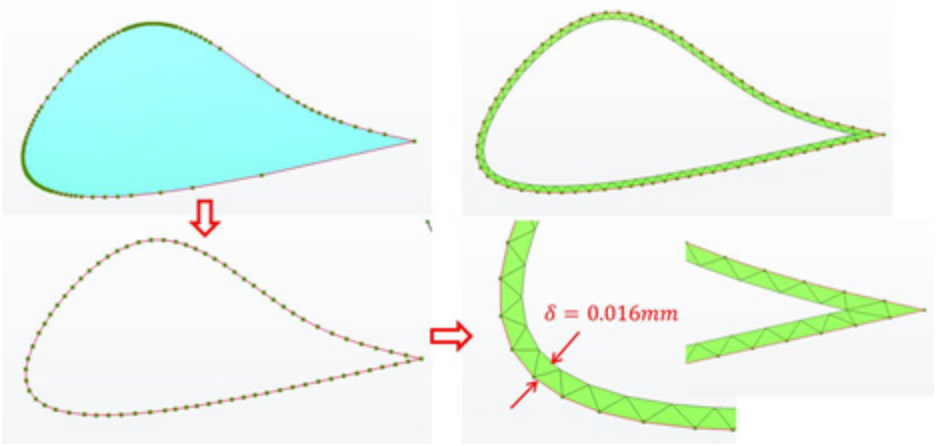
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In most cases, users do not need to add any additional seed refinement mesh operations. The mesh can be directly used to do the transient simulation. For solvers with adaptive passes, a few passes can be saved for the convergence although the initial mesh is larger since it is high quality and uniform.

TAU 2D Skin Depth Layer Mesh Generation

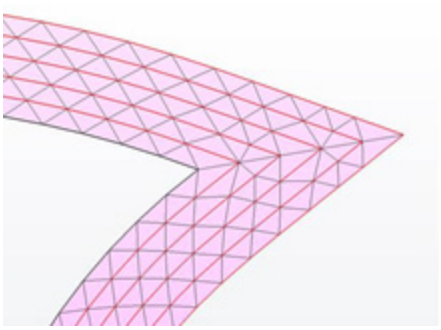
For this mesh generation method, the number of layers and the thickness can be specified by selecting one or more body edges. They will be exactly respected in the TAU mesh unless the layer thickness is too large, or layers from other directions overlap, intersect, or leave a narrow gap.

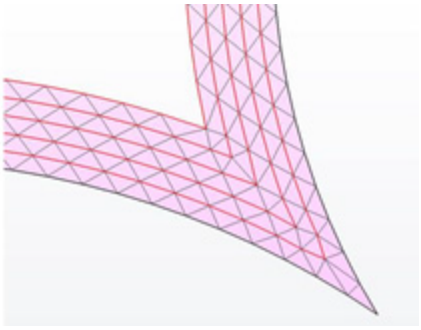
The layer mesh starts from the specified edges, and advances toward the direction of the body region layer-by-layer. If two bodies contact each other, the edges from these two bodies at the contact region may coincide, *appearing* as one edge even though there actually are two or more edges. Therefore, be careful when picking the edges in multiple body contact regions. In such cases, it is recommended that you hide all other bodies and only display the desired body, then make the edge selections. Remesh technology is then used to generate the mesh on the edges based on the thickness of the first layer to maintain the mesh quality.



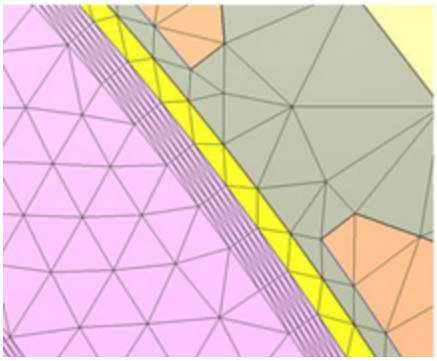
The aspect ratio in the layer mesh is defined by the element length in the tangential and normal directions. The ratio will be in the range of 1 to 40 based on the smallest thickness in the layers. Different layer mesh methods are using depending on the ratios. If the ratio is smaller than 4.0, the middle points of the edges are used to advance layers forward as shown below.

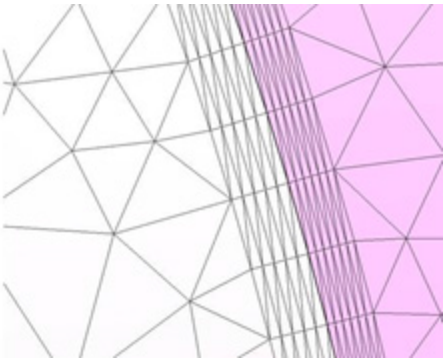
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





If the ratio is more than 4.0, edge points are used to advance layers.

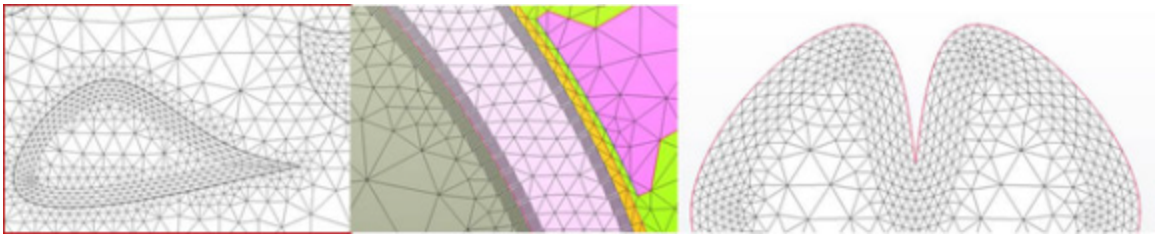




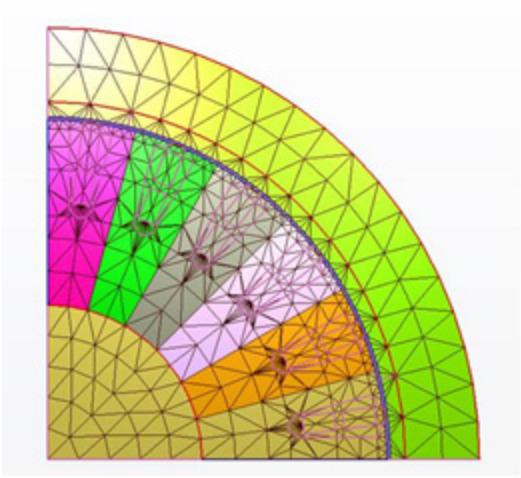
Messages are displayed if the thickness is too small or too large.

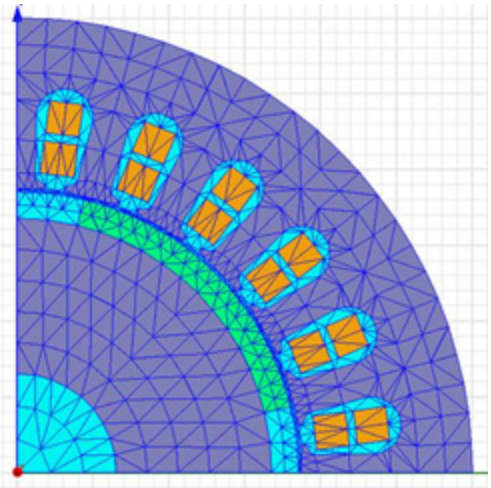
TAU 2D Mesh Assembly

The final step to get a conformal mesh for the entire model, assembles the local region meshes generated by the clone mesh, rotational sweep mesh, and skin depth layer mesh methods with the mesh generated by the TAU 2D regular meshing method as the final step.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





Related Topics

TAU 2D Mesh Generation for Rotational Models

TAU 2D Regular Mesh Generation (Non-Rotational Models)

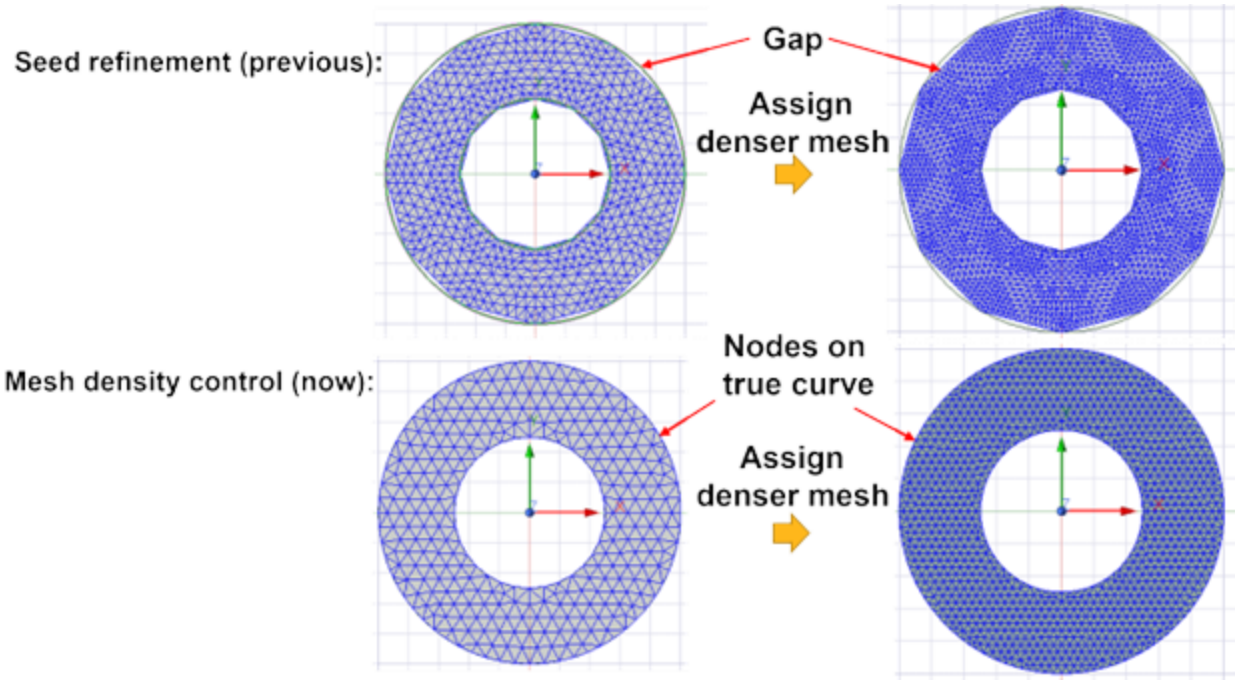
TAU 2D Skin Depth Layer Mesh Generation

TAU2D: Mesh Density Control Over Selected Objects

Mesh density control is a mesh feature used to control the mesh length on selected objects in the phase of initial mesh generation. When you request a desired mesh length on selected parts of the model, the mesh length over the selected part will not be larger than the requested length.

Previously, mesh density was controlled by seed refinement. After the initial mesh is generated, the size of the triangles over the selected body will be refined to meet the specified requirement. However, seed refinement will destroy the cloned mesh pattern generated by the initial mesh. Now, mesh density can be controlled in the phase of initial mesh generation. Combined with clone mesh, mesh density control guarantees that all clone regions have clone mesh pattern. If mesh density is assigned over a body in the primary region, all the clone bodies associated with the selected primary body will have the same density of mesh. It also provides a better geometric approximation of curves.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Mesh density can be controlled at three levels:

- model level
- body level
- edge level

If model level mesh density is specified, mesh over the entire model will be finer than the requested length. If body or edge level mesh density is specified, only the mesh over the selected bodies or edges will be finer than the requested length.

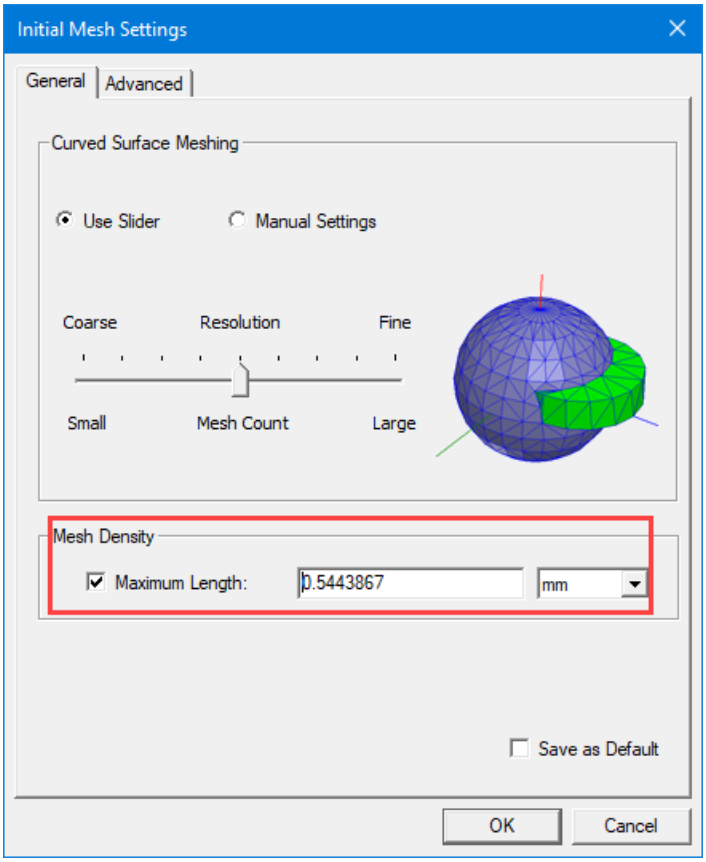
Different mesh densities can be specified over different parts of the model. If multiple mesh densities are requested on the same object, the mesh over the object will be finer than the minimum of all declared lengths. For example, if you request 1 mm of desired mesh length over the entire model and 2 mm of mesh length over a selected object, the generated mesh length over the selected object will be finer than 1 mm. On the other hand, if the user requests 0.5 mm over the object, the generated mesh length over the selected object will be finer than 0.5 mm.

Setting up model level mesh density

1. Select **Maxwell** > **Mesh** > **Initial Mesh Settings...** or in the Project tree, right-click on **Mesh**, and select **Initial Mesh Settings** from the shortcut menu. Alternatively, on the **Simulation** tab of the ribbon, select **Mesh Settings**.

   The **Initial Mesh Settings** dialog box appears with the **General** tab selected.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



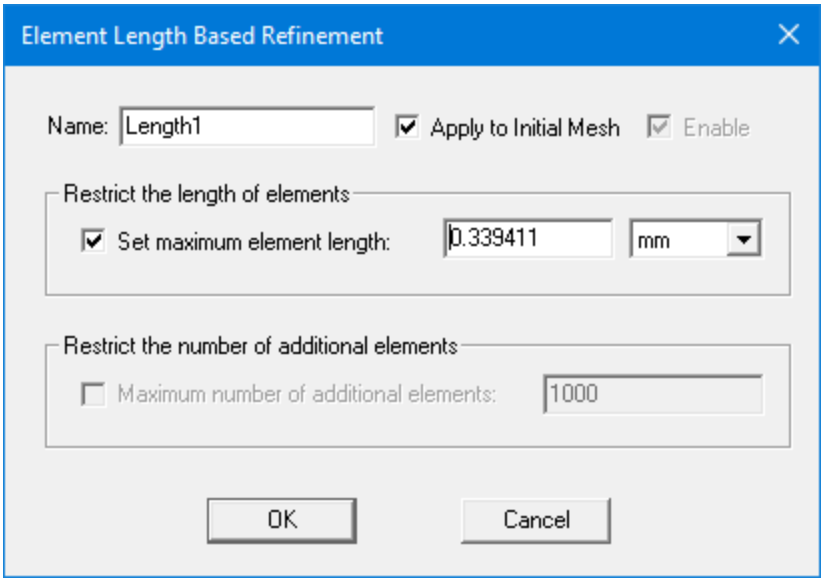
2. In the **Mesh Density** section, enable the **Maximum Length** check-box, and enter the desired value and unit, which must be greater than zero.
3. Click **OK** to close the dialog box.

Setting up body level mesh density on selected objects

1. When you open a 2D project, select the body (or multiple bodies) on which you want to apply the mesh density operation.
2. Right-click on the selected object(s) and select **Assign Mesh Operation** > **Inside Selection** > **Length Based**.

   The **Element Length Based Refinement** dialog box opens.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Enable the **Apply to Initial Mesh** check box, then enter the desired value, which must be greater than zero, in the **Set maximum element length** box, then click **OK** to close the dialog box.

> **Note:** If **Apply to Initial Mesh** is checked, input for **Maximum number of additional elements** will be ignored and grayed out.

Setting up mesh density on selected edges

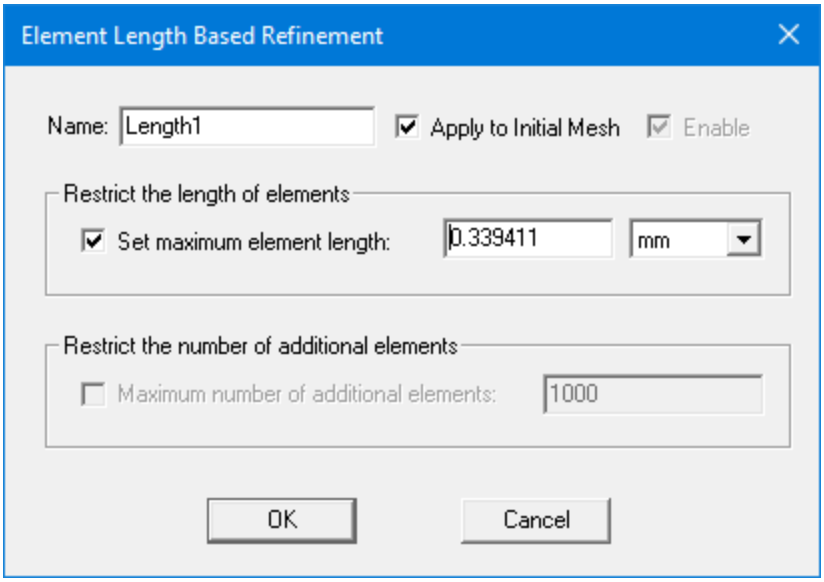
1. When you open a 2D project, first make sure that **Select Mode** is set to **Edges** by right-clicking on the model, and choosing **Selection Mode** > **Edges**.

   Select the edge (or multiple edges) on which you want to apply the mesh density operation.

2. Right-click on the selected edge(s) and select **Assign Mesh Operation** > **On Selection** > **Length Based**.

   The **Element Length Based Refinement** dialog box opens.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

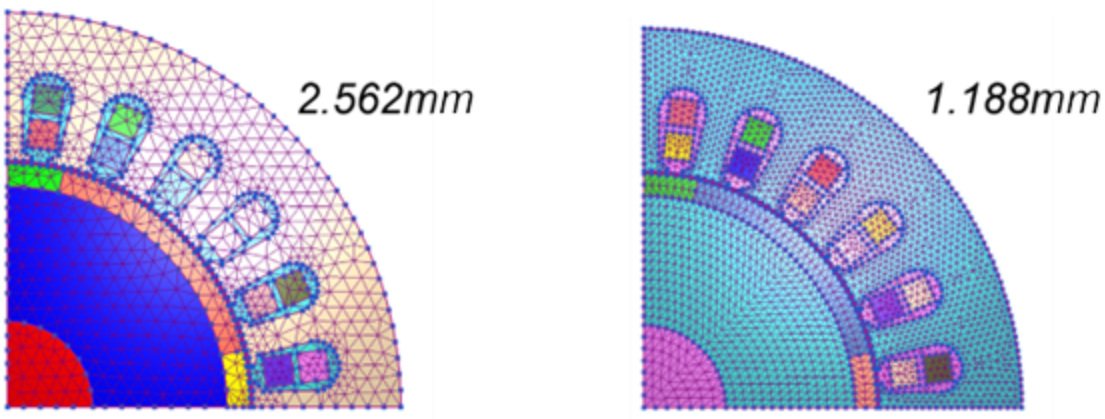


3. Enable the **Apply to Initial Mesh** check box, then enter the desired value, which must be greater than zero, in the **Set maximum element length** box, then click **OK** to close the dialog box.

> **Note:** If **Apply to Initial Mesh** is checked, input for **Maximum number of additional elements** will be ignored and grayed out.

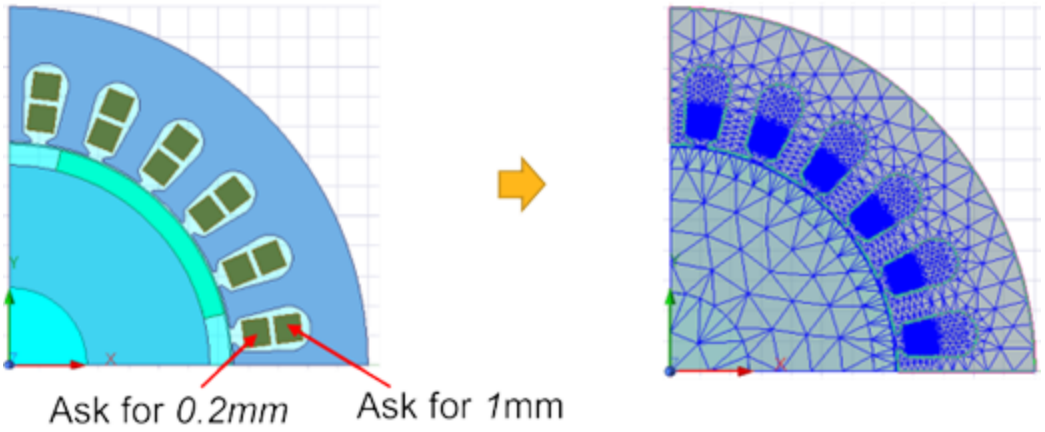
The effects of the mesh density control can be seen in mesh plots:

Model Level

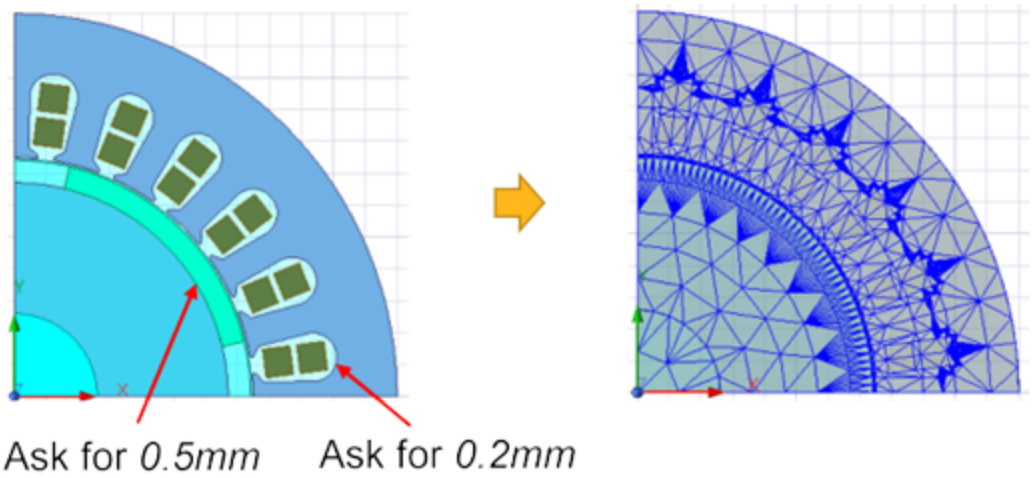


Body Level

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Edge Level



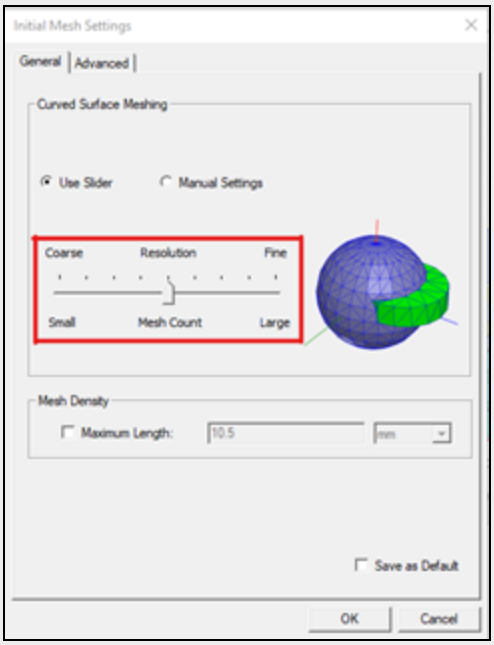
Note: For clone mesh, you should select objects in the primary region to get clone mesh pattern.

Note: For clone mesh, if the region is not repeatable, mesh density is not working yet in the current release. You can assign seed refinement to get the dense mesh as a workaround.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: If band mapping angle is enabled, only apply *model* level mesh density control. Neither *body* nor *edge* level mesh density control should be assigned as these may break the cogging torque mesh pattern.

Note: The **Mesh Count** slide bar must be set to 5 in the **Initial Mesh Settings** dialog box if you assign mesh density to spline curves.



Layer Mesh Generation for 3D Rotational Models

Layer mesh generation for 3D rotational models can only be applied to non-skewed bodies in Maxwell rotational models in which the CylindricalGap mesh operation is used.

- Only body-level selection is allowed.
- Rotational layer mesh can only be generated on non-skewed objects for current release.
- User can select multiple bodies, and assign a layer mesh operation to all of them.
- Rotational layer mesh is only generated for bodies near the band.
- For selected bodies, no layer mesh will be generated in the axial direction, or for matching boundaries.

There are three types of layer meshes for 3D rotational models.

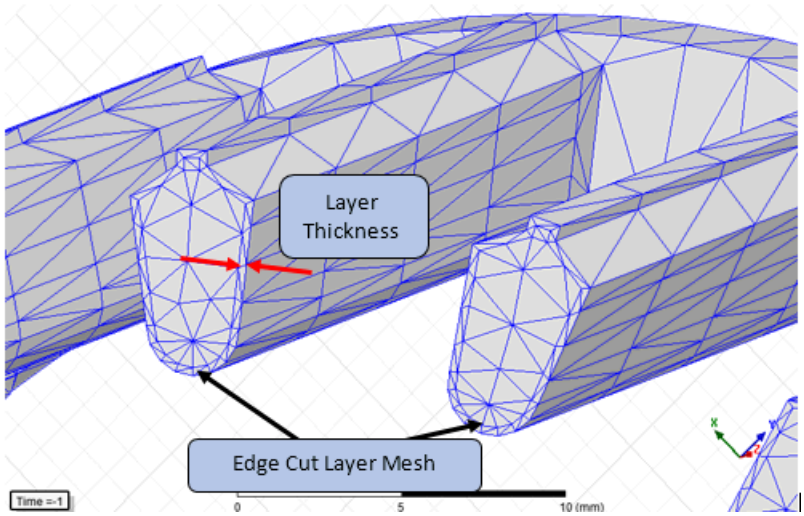
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Edge Cut Layer Mesh
- Rotational Layer Mesh
- Edge Cut + Rotational Layer Mesh

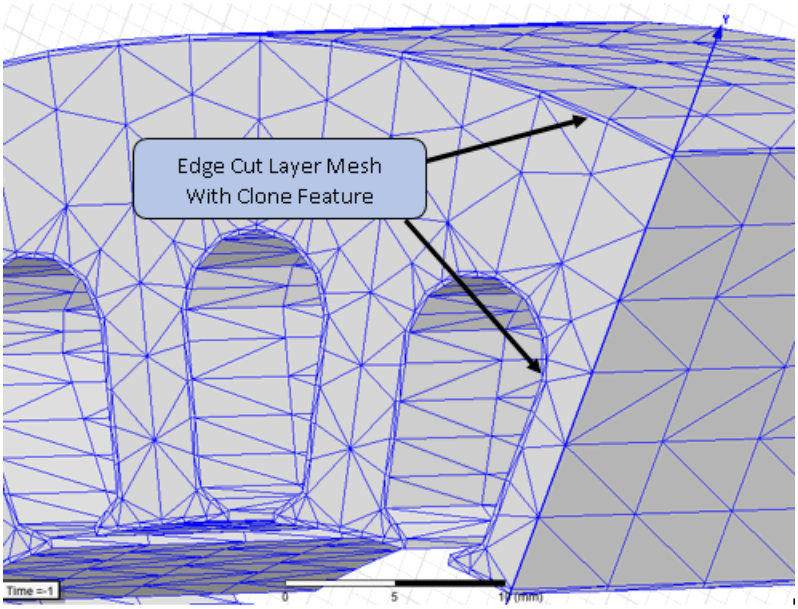
These mesh operations will work only if the clone mesh works.

Edge Cut Layer Mesh Generation

Edge Cut Layer Mesh creates one layer of mesh on the bodies with the layer thickness defined by user input. Layer mesh will not be created at the top or bottom of the axial direction and matching boundary faces. If the object has clone feature, the layer mesh will be coupled with the clone mesh.

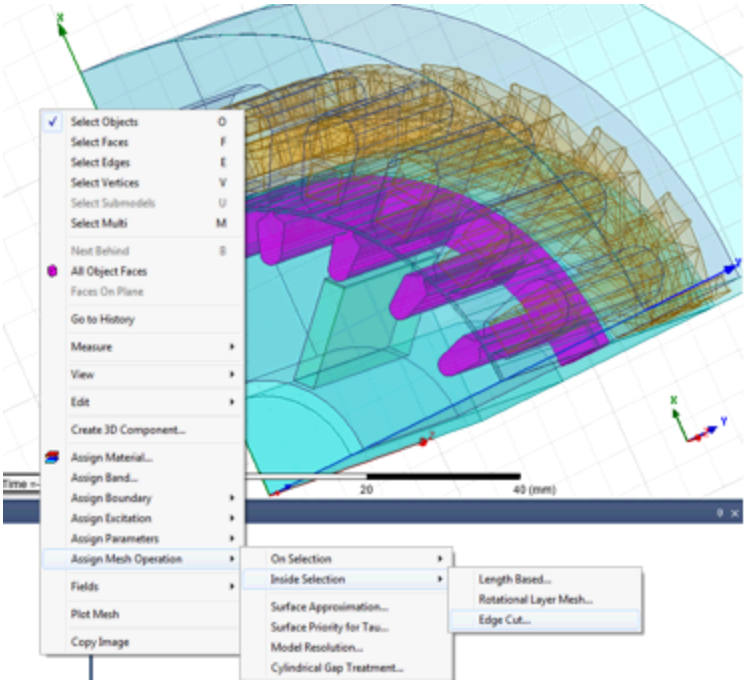


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



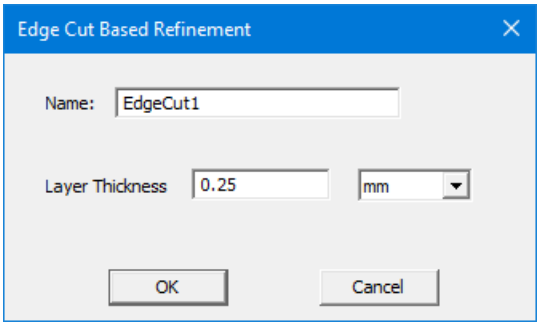
To apply Edge Cut Layer Mesh:

1. Select the desired bodies near the band.
2. Right-click to open the context menu, and select **Assign Mesh Operation** > **Inside Selection** > **Edge Cut Based**.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

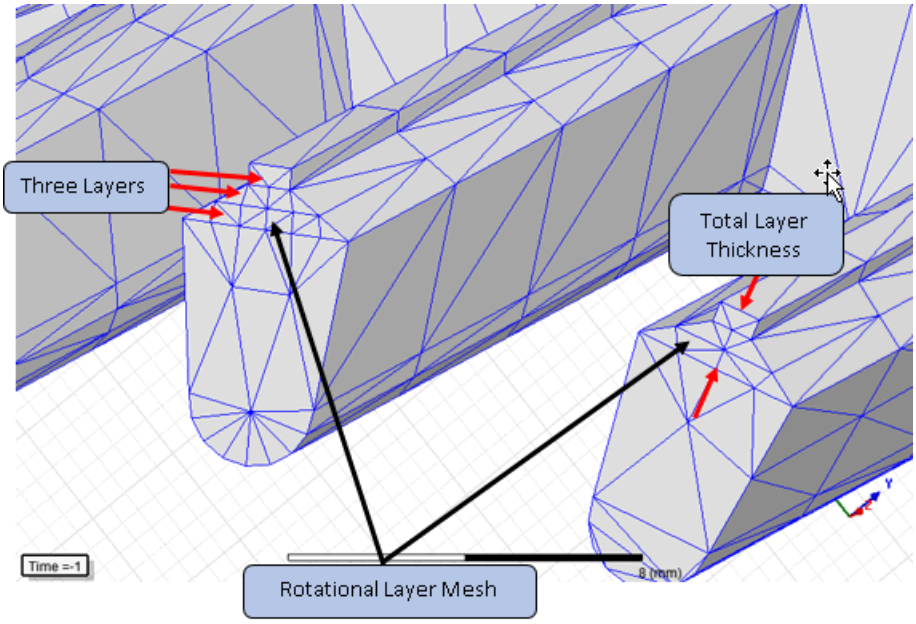
3. In the **Edge Cut Based Refinement** dialog box, you can rename the mesh operation, and specify the layer thickness. The recommended layer thickness is the band gap distance.



4. Click **OK**.

Rotational Layer Mesh Generation

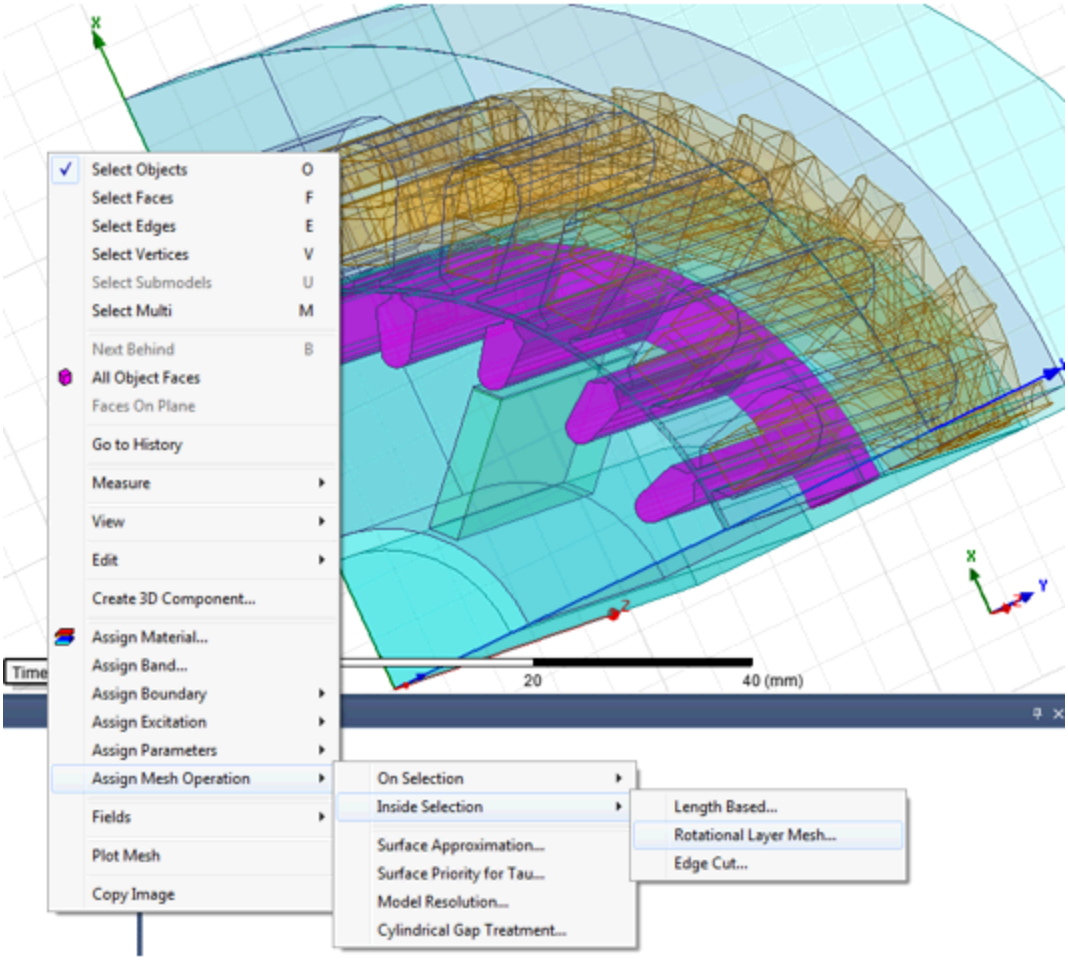
Rotational Layer Mesh creates up to three layers in the radial direction starting from the faces most adjacent to the “Band”. You can define the **Number of Layers** (up to three) and **Total Layer Thickness**.



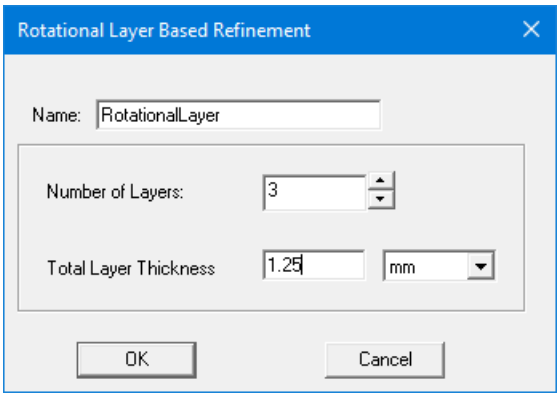
To apply Rotational Layer Mesh:

1. Select the desired bodies near the band.
2. Right-click to open the context menu, and select **Assign Mesh Operation** > **Inside Selection** > **Rotational Layer Mesh**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. In the **Rotational Layer Based Refinement** dialog box, you can rename the mesh operation, specify the number of layers (maximum of 3), and the total thickness of all the layers combined.

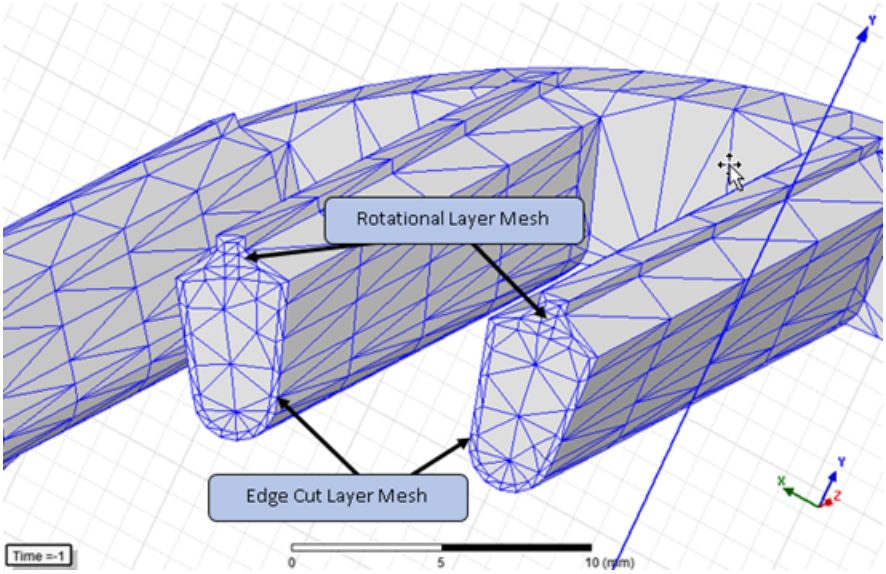


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click **OK**.

Edge Cut + Rotational Layer Mesh Generation

These settings are a combination of Edge Cut Layer Mesh and Rotational Layer Mesh settings, and as such has the properties of both. One layer of edge cut mesh will be generated first, then extra multiple layers will be added by the rotational layer mesh settings.



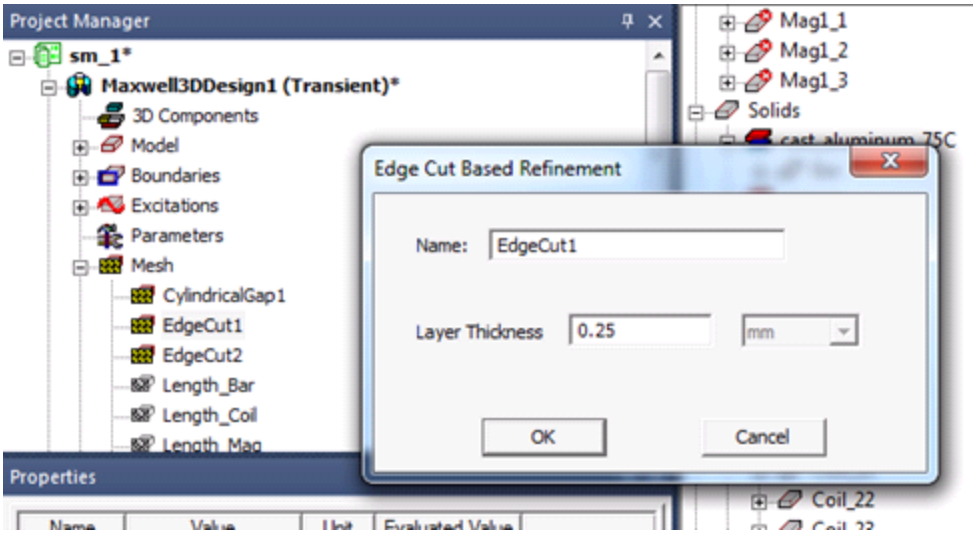
To apply Edge Cut + Rotational Layer Mesh:

1. Select the desired bodies near the band.
2. Right-click to open the context menu, and select **Assign Mesh Operation** > **Inside Selection** > **Edge Cut**.
3. In the **Edge Cut Based Refinement** dialog box, you can rename the mesh operation, and specify the layer thickness. The recommended layer thickness is the band gap distance.
4. Reselect the same bodies.
5. Right-click to open the context menu, and select **Assign Mesh Operation** > **Inside Selection** > **Rotational Layer Mesh**.
6. In the **Rotational Layer Based Refinement** dialog box, you can rename the mesh operation, specify the number of layers (maximum of 3), and the total thickness of all the layers combined.
7. Click **OK**.

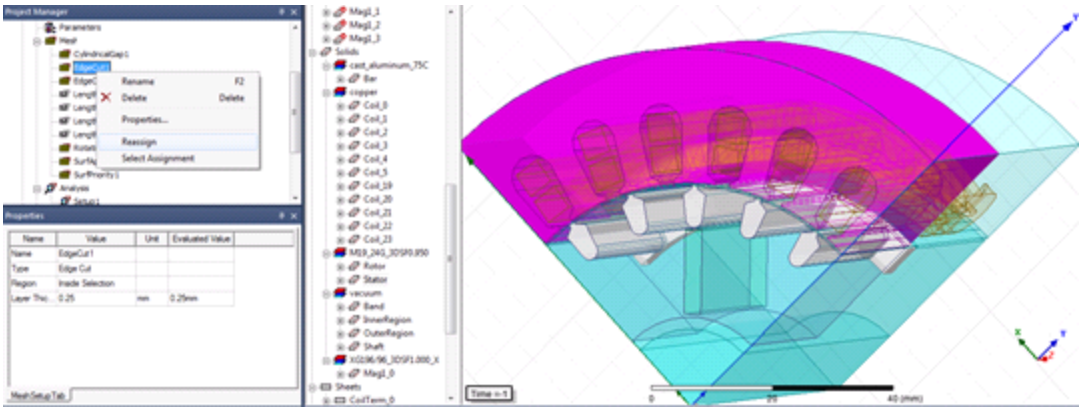
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Changing Properties and Reassigning Mesh Operations

To alter the mesh settings, find the entry under **Mesh** in the Project Manager tree. Double-click to bring up the dialog box. Change the layer thickness or number of layers as necessary.



To reassign which bodies the mesh operations are applied to, first select all the bodies you would like to assign the bodies to. Then right-click the mesh operation in the Project Manager and select **Reassign**. The mesh operation will now be reassigned to the selected objects.



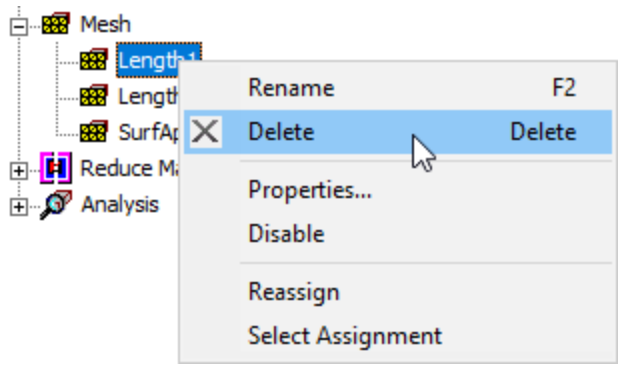
Deleting Previously Assigned Mesh Refinements

You can delete an individual mesh refinement, or delete all previously assigned mesh refinements.

To delete a single refinement:

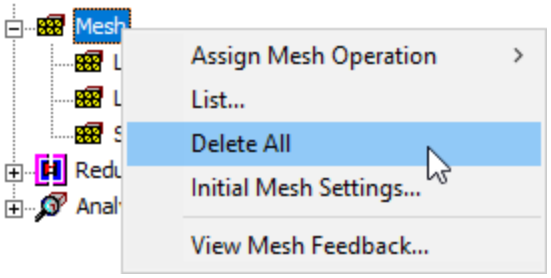
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- In the Project Manager, right-click the mesh refinement and click **Delete**, or press the **Delete** key.



To delete all previously assigned mesh refinement data:

- Click **Maxwell 3D**, **Maxwell 2D**, or **RMxprt** > **Mesh** > **Delete All**.
- In the Project Manager, right-click **Mesh** and select **Delete All**.



> **Note:**
>
> This will not alter any existing meshes that have already made use of one or more mesh refinement operations. However, deleted mesh operations will not be used again after reverting to the initial mesh.

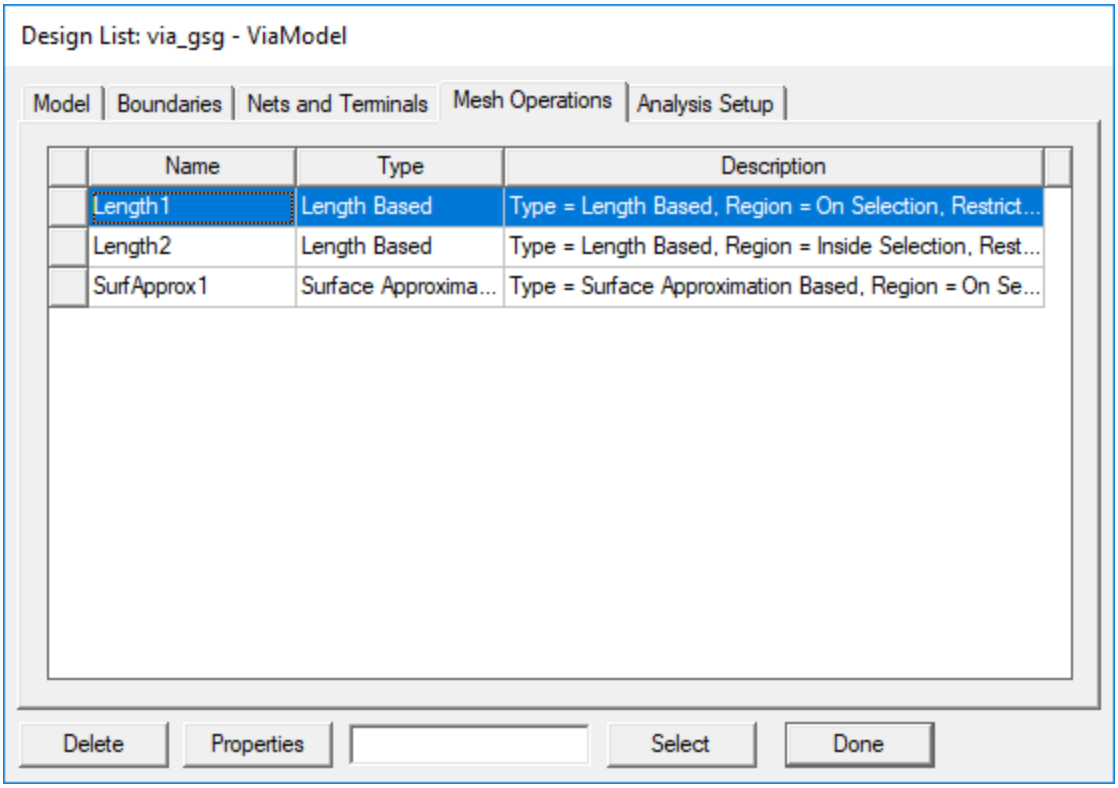
Viewing List of Mesh Operations

To list all mesh operations for the project:

1. In the Project Tree, right-click **Mesh** and select **List**.

   The **Design List** window appears, on the **Mesh Operations** tab.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

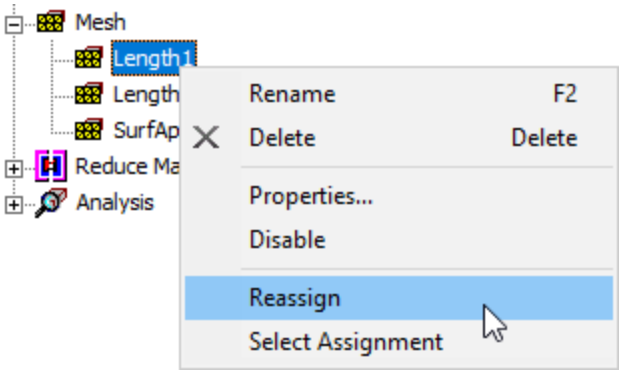


2. Click **Done** to close the window.

Reassigning a Mesh Operation

To reassign a previously assigned mesh setup:

1. Select the object(s) to which you want to reassign the mesh operation.
2. In the Project Tree, under **Mesh**, right-click the mesh refinement you had previously defined and select **Reassign**.



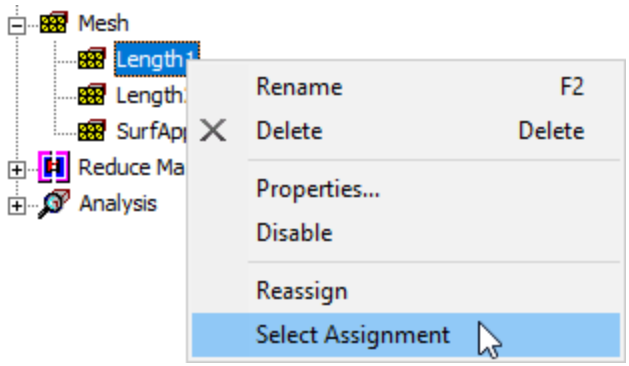
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The mesh operation is reassigned to the currently selected objects.

> **Note:**
>
> This pertains to mesh setup operations only. If you want to see information about a mesh that has been generated, see Viewing Mesh Statistics.

To view the objects to which a mesh operation is assigned:

1. In the Project Tree, select the mesh operation.
2. Right-click the previously completed mesh refinement and select **Select Assignment**.

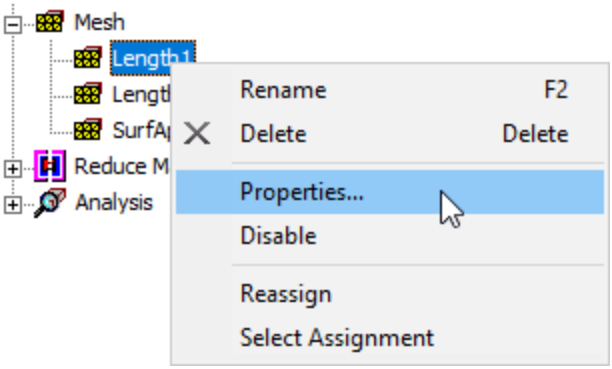


The objects to which the operation is assigned are selected in the modeling workspace.

Viewing Mesh Properties

To view mesh properties:

- In the Project Tree under **Mesh**, right-click a previously completed mesh refinement and select **Properties**.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A dialog box opens with properties specific to that mesh (length-based, surface approximation, etc.). You can edit the mesh settings as appropriate.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

13 - Adding Solution Parameters

When you assign a solution parameter, the solver calculates the parameter value as part of the solution process. The table below shows the solution parameters that may be calculated based upon the solver type.

Parameter	3D Solvers	2D Solvers
Force/Torque	Magnetostatic Electrostatic Eddy Current 3D AC Conduction Transient Electric Transient	Magnetostatic Electrostatic Eddy Current Transient
Matrix	Magnetostatic Electrostatic Eddy Current DC Conduction AC Conduction	Magnetostatic Electrostatic Eddy Current AC Conduction DC Conduction

Assigning a Force Parameter

> **Note:** Force parameters are available for calculation in the 2D and 3D Magnetostatic, Electrostatic, Eddy Current, and Transient solvers, and for the 3D AC Conduction and 3D Electric Transient solvers.

To solve for a force parameter:

1. Select the object on which you want to apply the parameter.
2. Click **Maxwell 2D** or **Maxwell 3D,** and then select **Parameters** > **Assign** > **Force**. You can also right-click on **Parameters** in the Project Manager tree, and then select **Assign** > **Force** from the context menu.

The **Force Setup** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Type a name for the force in the **Name** box.
4. For **Maxwell 3D** projects only, select **Virtual** or **Lorentz** as the **Type** for the force.

   Note:

   - For 3D Magnetostatic, Electrostatic, Eddy Current T-Omega, and Transient solvers, you can select either **Virtual** or **Lorentz** force to be calculated.
   - For the 3D Eddy Current A-Phi solver, only **Lorentz** force is supported.
   - For 3D AC Conduction and 3D Electric Transient solvers, only **Virtual** force is calculated.
   - See Average Force in an Eddy Current Solution for a discussion on DC, AC, and instantaneous components of force.

5. Select the **Post-Processing** tab to specify the coordinate system reference for calculating the force parameter.

   Note: If object or face coordinate systems are used as reference in the post processing tab of the force setup in a transient analysis with motion, it should be noted that the original position of the CS will be used for this coordinate transformation. This coordinate transformation will not consider the motion enforced by the motion setup.

6. Select the appropriate coordinate system from the **ReferenceCS** drop-down menu.
7. Click **OK**.

Note: The calculation of forces using the A-Phi formulation requires an extremely fine mesh because B is solved as 0th order and is constant at each node of each tetrahedral element.

Assigning a Torque Parameter

Note: Torque parameters are available for calculation in the 2D and 3D Magnetostatic, Electrostatic, Eddy Current, and Transient solvers, and for the 3D AC Conduction and 3D Electric Transient solvers.

To solve for a torque parameter:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the object on which you want to apply the parameter.
2. Click **Maxwell 2D or Maxwell 3D**, and then select **Parameters** > **Assign** > **Torque**. You can also right-click on **Parameters** in the Project Manager tree, and then select **Assign** > **Torque** from the context menu.

   The **Torque** setup window appears.
3. Type a name for the torque in the **Name** box.
4. Select **Virtual** or **Lorentz** as the **Type** for the torque.

   > **Note:** For 3D AC Conduction, 3D Transient and Electric Transient solvers, only **Virtual** torque is calculated.

   > **Note:** For the 3D Eddy Current A-Phi solver, only the **Lorentz** torque is calculated.
5. To assign an axis:
   a. Select the axis from the **Axis** drop-down menu.
   b. Select either the **Positive** or **Negative** radio button.
6. Click **OK**.

Assigning a Matrix

To solve for a capacitance, inductance, impedance, or conductance matrix:

1. Click **Maxwell 2D** or **Maxwell 3D**, and then select **Parameters** > **Assign** > **Matrix**.

   The **Matrix** dialog box appears.
2. Click the **Setup** tab.
3. Type a name for the matrix in the **Name** box.
4. To specify the sources to be included in the matrix, do one of the following:
   - For 3D Electrostatic, 2D and 3D Magnetostatic, 2D Eddy Current, and 3D Eddy Current T-Omega designs, select or clear the **Include** check box for any of the listed sources. For **Maxwell 2D** designs, the return path for each source may be specified. By default, the return path is at infinity; however, any conductor with a source specified can act as the return path.
   - For 2D Electrostatic, 2D and 3D DC Conduction, 2D and 3D AC Conduction, and 3D Eddy Current A-Phi, select or clear the **Signal** or **Ground** check box for any of the listed sources. Grounded terminals are treated as reference voltages with zero voltage values. Excitations checked as **Signal** will be in the matrix (excited one at a time with 1 V during the parameters extraction process). Those excitations checked

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

as **Ground** will be kept at 0 V and will not be part of the matrix. Any excitations not checked will not be considered.

5. For Magnetostatic designs, click the **Post Processing** tab.

   If more than one source is listed on the left side, you can click the **Post Processing** tab and **Group** them to organize multiple sources into a single group. The calculations defined in the Post Processing tab do not impact the field solution and can be set up or changed after the solution has been completed.

   To **Group** multiple sources together:

   a. If desired, set the number of **Turns** for each source.
   b. Select the sources to group in the list **Entry** list. Multiple source can be selected by holding the **Ctrl** key and clicking each source line.
   c. With all sources selected, click **Group** to combine the sources into one series winding.
   d. Set the number of parallel **Branches** the winding should be divided into and click **OK**.
   e. The results of the post processing calculation on the matrix can be seen by selecting **PostProcessed** on the **Matrix** tab of the solutions dialog box.

6. Click **OK**.

Note:

- For a matrix setup, the elements are defined based on excitations, not solids. Only excitations will be available in the **Matrix** dialog box, regardless of the current geometry selection. Also, changes made to the excitations after matrix setup will not be flagged until the setup validation performed prior to the solution process.
- Matrix setups are recognized when coupling Maxwell designs to Twin Builder components such as Equivalent Circuit, Dynamic Inductance and Capacitance, and State Space. For more information on coupling Maxwell designs to Twin Builder components, refer to the *Maxwell Component Subcircuits* topic in the Twin Builder Help.
- For 2D Eddy Current and 3D Eddy Current T-Omega designs, you can also *Assign a Reduce Matrix*.
- For the 3D AC Conduction and 3D Eddy Current A-Phi solvers, the current excitations might also be considered during the matrix extraction. They will be considered in the same way as the regular voltage excitations.
- The 3D Eddy Current A-Phi allows to extract both RL and CG matrices. For more information about the matrices setup, refer to Technical Notes: 3D Eddy Current A-Phi Parameter Extraction.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In a matrix calculation:

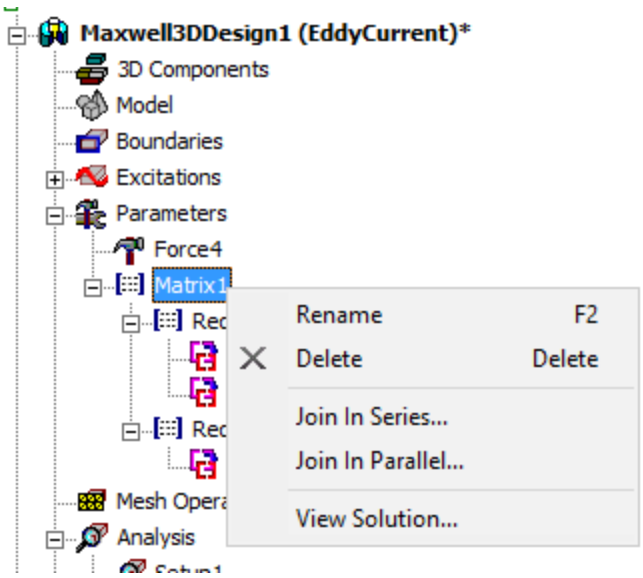
- For coil terminals, all terminals are listed and can be selected.
- For outer terminals, the solver can only handle a conduction path with two terminals, and only one terminal is listed for each conduction path:
- If they are current terminals, the listed terminal is in the “in” direction.
- If they are current density terminals, the first terminal is listed and can be selected.
- When setting up an inductance matrix, the source must be a current excitation. Voltage sources cannot be used in this case.
- In 2D matrix calculations, the solver calculates loop currents; therefore, the direction of return path current is always opposite of the source current. If a conductor with excitation is specified as the return path, the polarity setting of the excitation in the nominal problem setup is not respected.

Assigning a Reduce Matrix for 2D and 3D Eddy Current Designs

For 2D and 3D Eddy Current designs, you can join (group) two or more excitations to one excitation in either a series or a parallel connection. The result of each join (group) operation is known as a Reduce Matrix. This would be useful when analyzing designs such as a motor with four poles, each pole having three wires coming into it, with the physical design having each set of three wires in series, and the four bundles of wires in parallel.

To create a reduce matrix:

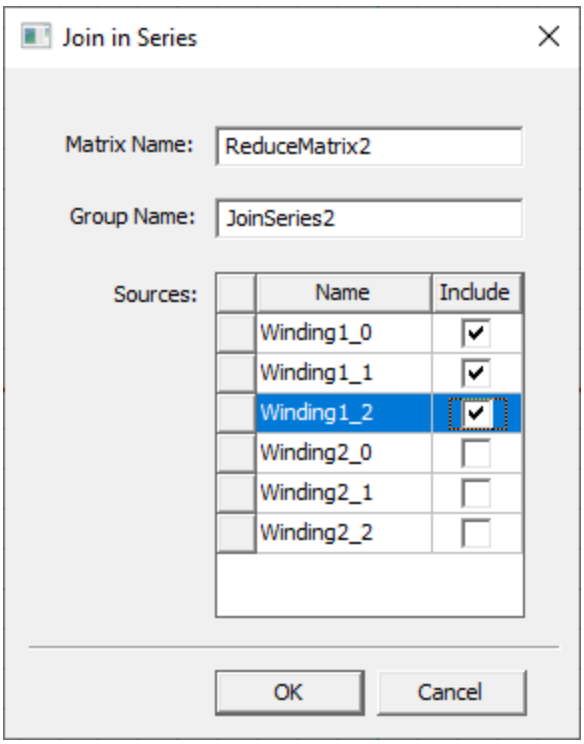
1. Right-click on an existing Matrix parameter in the Project Manager tree.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Select either **Join in Series** or **Join in Parallel**.

   A corresponding **Join in Series** or **Join in Parallel** dialog box opens. You can accept the default reduce **Matrix Name**, or enter the desired name.



3. You can enter a **Group Name** (or accept the default), and check **Include** for those sources you wish to join in series (or parallel).

   > **Note:** Multiple group operations are supported. For example, you could join conductors 1, 2, and 3 in one series; and conductors 4, 5, and 6 in another series.

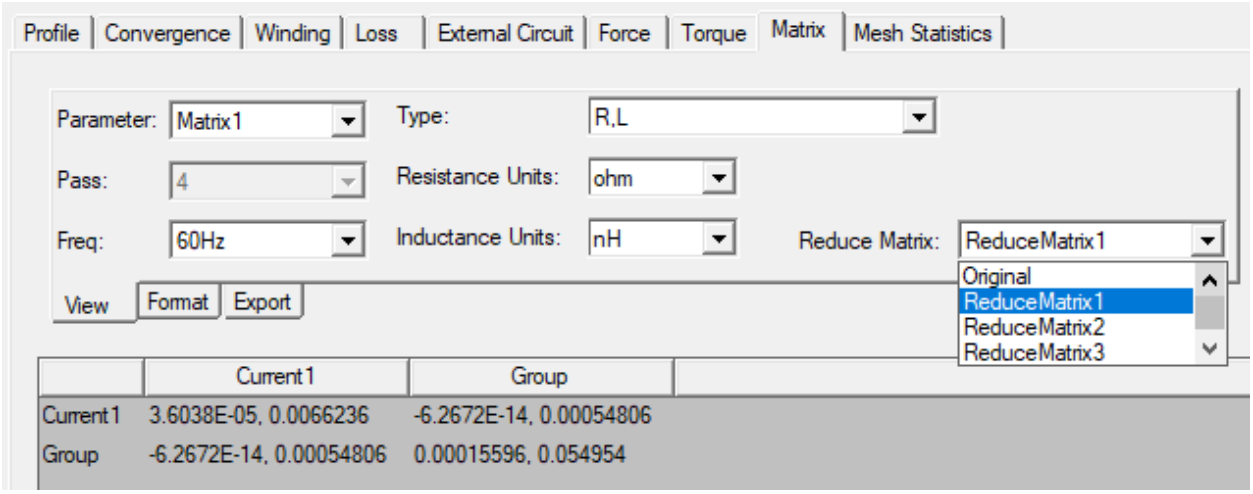
4. Click **OK** to close the dialog and add the new reduce matrix group under its parent Matrix.

> **Note:** If you want to make changes to a reduce matrix, you can double-click on the reduce matrix group item in the tree to reopen the dialog box. You can also right-click the item to rename or delete it.

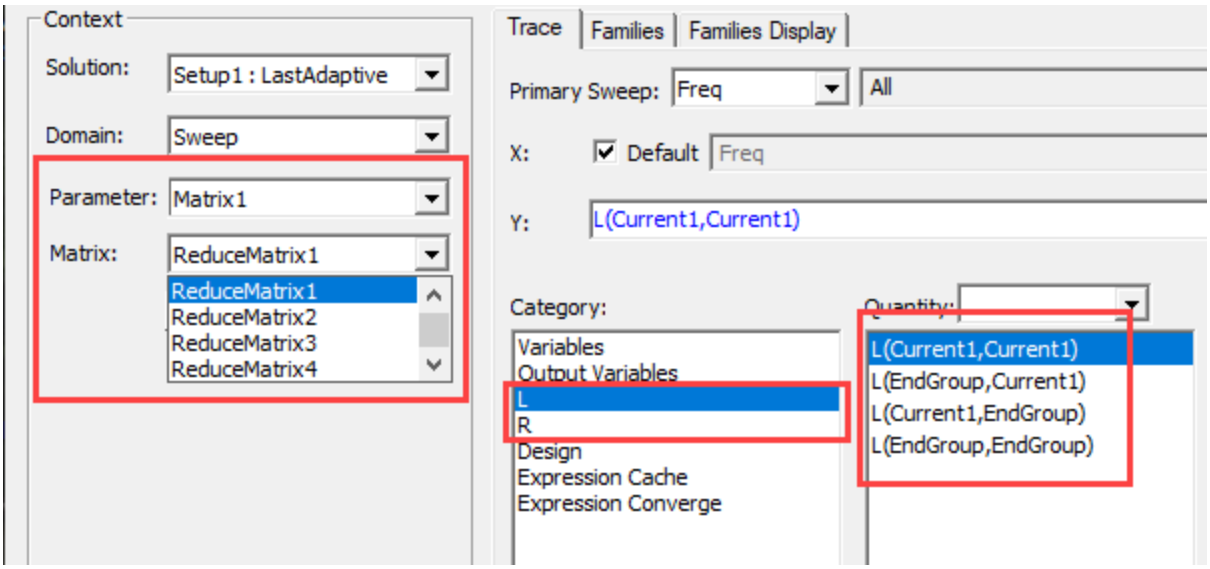
If you want to make changes, you can double-click on the reduce matrix group item in the tree to reopen the dialog box. You can also right-click the item to rename or delete it.

You can view the results of reduce matrix calculations on the Matrix tab of the Solutions dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can select reduce matrices to plot inductance and resistance quantities for various report types.



Reassigning Parameters

To reassign the geometry a parameter applies to:

1. Select the new object to which you want to assign an existing parameter.
2. Click **Maxwell 2D** or **Maxwell 3D**, and then select **Parameters** > **Reassign.**
   The **Reassign Parameter** window appears.
3. Select the force or torque you want to reassign from the **Reassign Geometry for** list.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click **OK**.
   The parameter is reassigned to the new object.

Viewing Parameter List

To view a list of all parameters in the design:

1. Click **Maxwell 2D** or **Maxwell 3D,** and then select **Parameters** > **List**.
   The **Design List** window appears, with the **Parameters** tab visible.
2. To view other design choices, click one of the following tabs:
   - Model
   - Boundaries
   - Excitations
   - Mesh Operations
   - Analysis Setup

Deleting All Parameters

To delete all parameters assigned in the model:

Click **Maxwell 2D** or **Maxwell 3D**, and then select **Parameters** > **Delete All**.
All parameters are deleted.

> **Note:** Maxwell provides no warning or option to stop deletion. If you accidentally delete all parameters, click **Edit** > **Undo Delete All Parameters** before you take any other action.

Showing and Hiding Solution Parameters

1. Click **Maxwell 2D** or **Maxwell 3D**, and then select **Parameters** > **Visualization**.
   The **Parameter Visualization Options** window appears.
2. Select the type of parameter you want to view from the **Select** drop-down menu, or click the row in the table. Choices include **All**, **All Forces**, **All Torques**, **All Matrices**, and **By Name**.
   The object is highlighted in the geometry.
3. Select or clear the check boxes for each parameter to show or hide geometry, name, and vectors for each force or torque parameter.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click **Deselect All** to hide all parameters.
5. Click **Close** to close the window.

Setting the Visibility for Parameters

To show or hide a parameter:

1. Click **View** > **Active View Visibility**.
2. From the **Active View Visibility** dialog box that appears, click the **Parameters** tab.
3. Select or clear the **Visibility** check box for each parameter listed.
4. Click **Done**.

Changing the Parameter Setup

To change a parameter's setup:

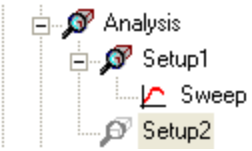
1. In the Project Manager tree, expand the **Parameters** entry.
2. Right-click the parameter you want to change.
   A shortcut menu appears.
3. Select **Properties** from the shortcut menu.
4. Make the desired changes, and then click **Close**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

14 - Specifying Solution Settings

Specify how Maxwell computes a solution by adding a *solution setup* to the design. You can define more than one solution setup per design.



Each solution setup includes general data about the solution's generation and adaptive mesh refinement parameters if you want the mesh to be refined iteratively in areas of highest error.

To add a solution setup to a design:

1. Select a design in the Project Manager tree.
2. Click **Maxwell 3D** > **Analysis Setup** > **Add Solution Setup** or **Maxwell 2D** > **Analysis Setup** > **Add Solution Setup**.

   Alternatively, right-click **Analysis** in the Project Manager tree, and then click **Add Solution Setup** on the shortcut menu.

   The **Solve Setup** dialog box appears containing several tabs, which are determined by the solution type (see Available Tabs by Solution Type).
3. Specify the desired settings on the tabs.
4. If you want to disable an individual analysis, uncheck the **Enabled** check box. Refer to Disabling and Enabling an Analysis Setup for additional information.
5. If you want to use the default values, click **Use Default**.
6. Click **OK**.

Available Tabs by Solution Type

For Non-Transient Solutions, the following tabs are present:

General	Includes general solution settings. Also contains a button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
Convergence	Includes settings for convergence.
Expression Cache	Contains an optional list of expressions that you can specify for convergence criteria.
Solver	Includes settings for nonlinear residual and matrix solver types.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	• If an Eddy Current solution is selected and the Maxwell 3D Eddy Current Solution Refinement Control has been enabled from **Tools** > **Options** > **General Options** > **Desktop Configuration** > **Beta Options**, this tab will also include Loss Adaptive Control for better modeling of skin effects. • If it is a Maxwell 2D design, this tab will also include a Thermal Two-Way Coupling\Relaxation setting.
Frequency Sweep	Includes setting for varying the frequency of an Eddy Current or AC Conduction solution. **NOTE:** This tab is present only for Eddy Current and AC Conduction solutions.
Defaults	Enables you to save the current settings as the defaults for future solution setups or to revert the current settings to Maxwell's standard settings.

For Transient Solutions, the following tabs are present:

General	Includes general solution settings. Also contains a button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
Save Fields	Enables you to create a time point list for saving field solutions.
Advanced	Supports user control program, import mesh options, and starting/continuing from a previously solved setup.
Solver	• Includes settings for nonlinear residual solver type, for enabling the solver to fast reach steady-state, and for selecting the Time Decomposition Method. • If it is a Maxwell 2D design, this tab will also include a Thermal Two-Way Coupling\Relaxation setting.
Expression Cache	Contains an optional list of expressions that you can specify for evaluating solutions.
Defaults	Enables you to save the current settings as the defaults for future solution setups or to revert the current settings to Maxwell's standard settings.

For Electric Transient Solutions, the following tabs are present:

General	Includes general solution settings. Also contains a button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
Solver	Includes settings for initial condition, temporal tolerance, computing power loss data, and importing a mesh.
Expression	Contains an optional list of expressions that you can specify for evaluating

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cache	solutions.
Defaults	Enables you to save the current settings as the defaults for future solution setups or to revert the current settings to Maxwell's standard settings.

Analysis Parameters

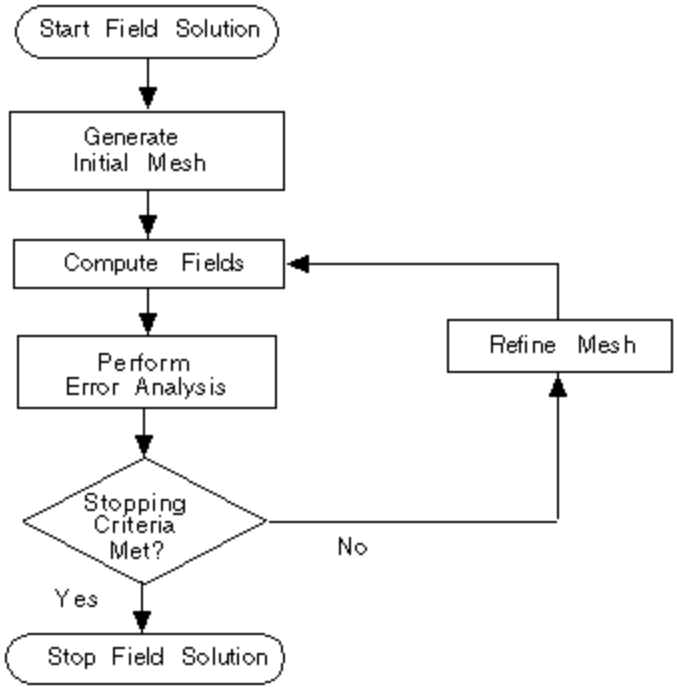
During adaptive analysis, the system iteratively refines the starting mesh in order to reduce the size of individual elements in areas of high error — thus improving the accuracy of the solution.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



When an adaptive analysis is performed, the following steps are executed:

- The Maxwell application generates a field solution using the specified mesh.
- It then analyzes the accuracy of the solution by calculating an energy value based on the error in the solution. The exact mechanism for evaluating the error varies by solution type. For example, in magnetostatic it can use Curl H to find the current density and then subtract all input currents and other sources. For a perfect solution the result would be zero, for a real, finite mesh the result is some amount of residual current density. An energy value calculated from this residual current density is called the error energy. The “Energy Error %” is the error energy as a percentage of the total energy (calculated with the original sources).
- If more than one pass has been completed, the software also calculates the change in total energy from the previous pass. The percentage difference is the “Delta Energy (%)”. Adaptive refinement continues until both the “Energy Error %” and the “Delta Energy (%)” are below the target Percent Error specified by the user (or until it reaches the Maximum Number of Passes requested).
- When the error targets are not satisfied the mesh is refined. This is generally done by subdividing the elements with the highest error energy into smaller elements.
- The user can optionally request to “Use Output Variable Convergence”. This is an additional stopping criterion. The Energy Error % and the Delta Energy must still be below the target Percent Error, but the software will also compute the specified Output Variable for each adaptive pass and will calculate the percentage change in that value for each

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

pass after the first (this is the “Output Var. Delta (%)”). The solution will continue until the energy error criteria are met and the Output Var. Delta is below the target “Max. Delta Per Pass” specified by the user for output variable convergence (or until Maximum Number of Passes).

Setting Analysis Parameters for Non-Transient Solutions

To set up a non-transient analysis, define the parameters on the following tabs of the **Solve Setup** dialog box (which appears when you click **Maxwell** > **Analysis Setup** > **Add Solution Setup**):

- General (Name, Adaptive Setup, Parameters)
- Convergence
- Expression Cache
- Solver
- Frequency Sweep (Eddy Current and AC Conduction solutions only)
- Defaults

Defining Settings on the General Tab for Non-Transient Solutions

The following settings can be defined on the **General** tab of the **Solve Setup** dialog box for non-transient solutions:

- Setup Name
- Adaptive Setup
- Parameters

Setup Name for Non-Transient Solutions

By default, **Setup1** appears as the name of the first analysis you set up.

To change the name of the setup, type the new name in the **Name** text box on the **General** tab of the **Solve Setup** dialog box.

To disable the setup, uncheck the **Enabled** check box. Refer to *Disabling and Enabling an Analysis Setup* for additional information.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Adaptive Setup for Non-Transient Solutions

To specify adaptive settings, click the **General** tab in the **Solve Setup** dialog box and use the options in the **Adaptive Setup** section. Adaptive settings include the following:

- **Maximum Number of Passes**: Defines the maximum number of mesh refinement cycles you would like Maxwell to perform. This value is a stopping criterion for the adaptive solution; if the maximum number of passes has been completed, the adaptive analysis stops. If the maximum number of passes has not been completed, the adaptive analysis continues unless the convergence criteria are reached.

  > **Note:** The size of the finite element mesh — and the amount of memory required to generate a solution — increases with each adaptive refinement of the mesh. Setting the maximum number of passes too high can result in Maxwell requesting more memory than is available or taking excessive time to compute solutions.

- **Percent Error**: Controls the desired solution accuracy. Smaller values produce more accurate (but slower) solutions; larger values produce less accurate (but faster) solutions. At each step in the adaptive process, the energy and error energy are computed, and you can view the most recent solutions as soon as they are completed. After the mesh is refined, the matrix is calculated on the refined mesh. The relative change between the previous matrix and the current matrix is then computed and reported as the matrix delta; the target matrix delta is the **Percent Error**. A small delta indicates that further mesh refinement will probably not change the solution.

Parameter Settings

On the **General** tab of the **Solve Setup** dialog box, if you want to solve for fields only and no other parameters, then click the **Solve Fields Only** check box.

When this check box is cleared, the following options are available:

- **Solve Matrix**: Select **After last pass** or **Only after converging**.

Defining Settings on the Convergence Tab for Non-Transient Solutions

To set the convergence data, click the **Convergence** tab in the **Solve Setup** dialog box. Convergence settings can be standard or optional. Standard convergence settings include the following:

- **Refinement Per Pass** – The percent you set for **Refinement Per Pass** determines how many tetrahedra are added at each iteration of the adaptive refinement process. The

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

tetrahedra with the highest error are refined.

- **Minimum Number of Passes** – The minimum number of adaptive passes even if the convergence criteria are reaches.
- **Minimum Converged Passes –** The minimum number of adaptive passes to continue after the convergence criteria are reached.

Optionally, convergence criteria can also be based on the value of an output variable. This condition is in addition to the normal stopping criteria. To base the convergence criteria on an output variable value, refer to Defining Expressions for Non-Transient Solutions.

For 2D Eddy Current solutions only, improved accuracy may be obtained by including loss in the convergence criteria. To include the loss calculation in convergence, select the **Use Loss Convergence** check box.

> **Note:** Maxwell 2D versions prior to version 12 did not use loss in the convergence calculation.

Defining Expressions for Non-Transient Solutions

> **Note:** For information on defining expressions for transient solutions see
>
> - Defining Expressions for Transient Solutions
> - Defining Expressions for Electric Transient Solutions

You can specify additional convergence criteria through the use of expressions and output variables. The **Max Delta** or the **Max Percent Delta** defined for expression convergence represents the difference in values of the expressions between consecutive adaptive passes. If the difference in the value of the expression between consecutive passes is less than the **Max Delta** or the **Max Percent Delta** value, this part of the convergence criteria is satisfied.

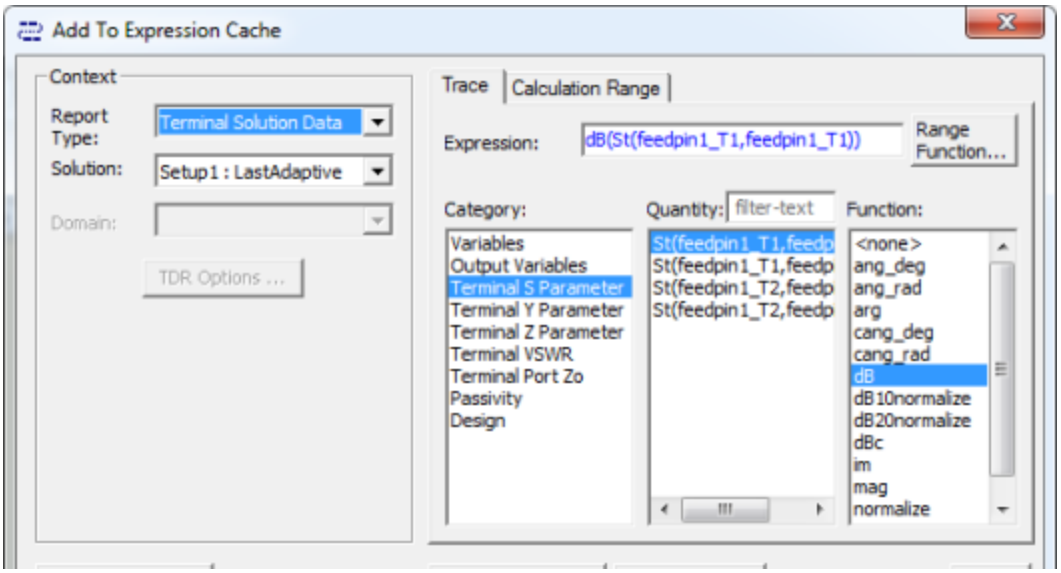
- For **driven solutions**, if the **Maximum Delta S**, **Maximum Delta E**, or alternate matrix convergence criteria are achieved in addition to any specified expression convergence criteria, the adaptive analysis stops. Otherwise, the solution continues until the requested number of passes is completed.
- For **eigenmode solutions,** if the **Maximum Delta Frequency Per Pass** criteria is achieved in addition to any specified expression convergence criteria, the adaptive analysis stops. Otherwise, the solution continues until the requested number of passes is completed.

To set expressions as **Convergence** criteria:

1. Double-click the Analysis setup icon in the Project tree to open the **Solution Setup** dialog.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click the **Expression Cache** tab in the **Solution Setup** and click **Add...** to open the **Add to Expression Cache** dialog box.



3. Specify the context for the expression you define. For Modal Solution Data, you do not need context other than the Solution. Other selections require more context:
   - Far Field also requires a geometry such as an infinite sphere.
   - Fields or Near Fields also require a geometry such as a polyline.
4. Under the **Trace** tab, select from the Category, Quantity and Function lists to create expressions.

   Selecting a listed category lists the Quantities and Functions available for each category. If you have defined one or more output variables, you can see them listed as Quantities by selecting the **Output Variables** Category. The Output Variables button opens a dialog that lets you define additional output variables.

   When you have created an expression, it appears in the Expression field of the **Trace** tab. If desired, you can use the Range Function button to select range functions to apply to the expression.

   Under the **Calculation Range** tab, you can view the values of available sweep variables. Clicking the ellipsis [...] button in the Edit column opens a list of values.

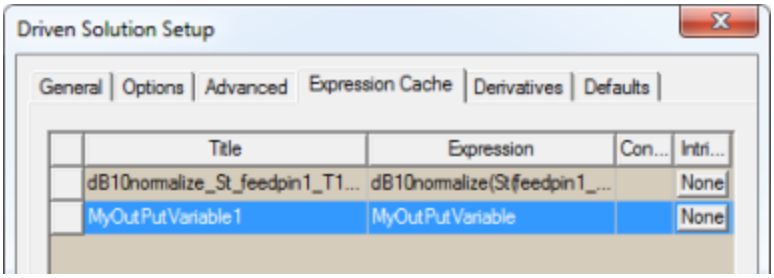
5. When you have created an expression that you want to add to the cache, click **Add Calculation**.

   This adds the selected expression and the associated context to a table in the **Expression Cache** tab. You can select any additional expressions with contexts and add them in the same way.

6. When you have added the expressions you want, click **Done** to close the **Add to Expression Cache** window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Expression Cache** tab of the **Solution Setup** lists the expressions you have added as a table.



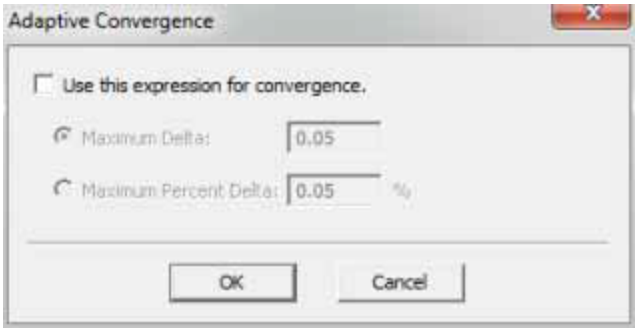
- The Title field is editable, by default showing the name as built from the expression, but removing underscores.
- The Expression field shows the full expression. If necessary, you can resize the **Solution Setup** dialog box. You can also resize each column in the table.
- The Context column shows None for Modal solutions, or the appropriate geometry for Fields calculations.
- The Intrinsics column shows a clickable button that opens an **Edit Calculation Range** dialog box. If the column button shows None you cannot edit the value. If the button shows variables, click the ellipsis [...] in the Edit column to display a list of the variable values that you can select. Click **OK** to close the **Edit Calculation Range** dialog box and apply your selections to the Expression Cache.
- The Convergence column contains a check box that lets you designate post processing variables, such as for renormalization or de-embedding. You can also use this feature to assign variables to non-model objects (for example, the properties of a solid, sheet or lines used for field calculations). You can also assign a PP Variable to a coordinate system (CS) that is not associated with model objects.

To excite particular sources for particular output variables, you can assign a post process variable to the magnitude of sources you might want to edit, and assign the expression value in the Expression Cache. With PP Variables, you can control convergence based on several combinations of active sources.

7. To designate one or more expressions for convergence, click the field for the Convergence column for each expression.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This opens an **Adaptive Convergence** dialog box.



Check **Use this expression for convergence** to enable the radio buttons. You can then specify the **Max Delta** between passes or the **Max Percent Delta** criteria. The **Max Delta** solves a potential issue if your expression is essentially zero and the numeric noise from pass to pass causes the maximum percentage delta to remain high. In that case adaptive refinement continues until you get to the maximum number of passes.

> **Note:** If you check **Use this expression for convergence**, the pass will be considered converged if both the energy error **and** the expression cache results have converged, not just expression cache.

8. For Eddy Current: only check boxes allow you to save the expression cache either with **Evaluate Cache vs. Pass**, **Evaluate Cache vs. Freq**, or both.
9. Click **OK** to close the **Solution Setup** window.

Defining Settings on the Solver Tab for Non-Transient Solutions

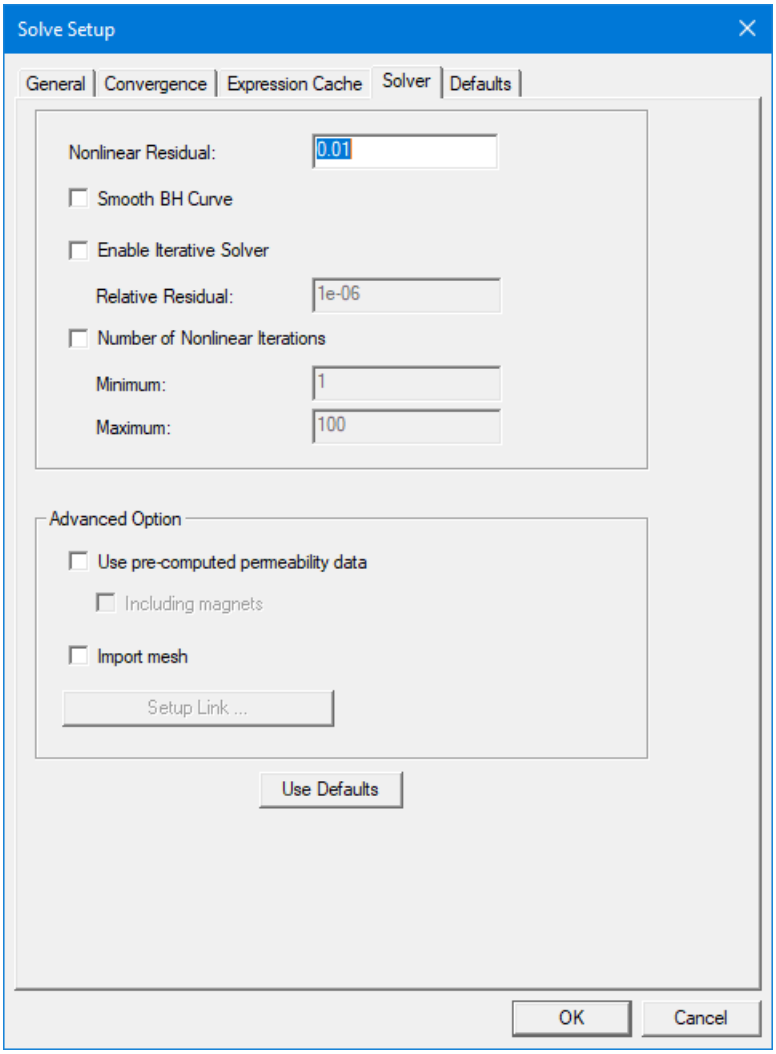
The settings on the **Solver** tab of the **Solve Setup** dialog box depend on the solution type selected for that project.

- Magnetostatic Solver Settings
- Eddy Current Solver Settings
- Electrostatic Solver Settings
- AC Conduction Solver Settings
- DC Conduction Solver Settings

Magnetostatic Solver Settings

For magnetostatic solutions, you can define the following settings on the **Solver** tab of the **Solve Setup** window:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Enter a value in the **Nonlinear Residual** text box. This value specifies how close each solution must come to satisfying the equations that are used to compute the magnetic field.
- For both 2D and 3D magnetostatic designs, you can select the **Smooth BH Curve** check box. This allows the solver to "smoothen" the list of points to make a refined B-H curve for better solving. If this option is not selected, the solver just uses the discrete points.
- For 3D magnetostatic designs only, you can Enable Iterative Solver.
- For both 2D and 3D magnetostatic designs, you can select the **Number of Nonlinear Iterations** check box. This provides an option for you to set both a **Minimum** iteration number to avoid non-converged solution, and a **Maximum** iteration number to avoid taking too much computation time. These values must be integers greater than 0. By default the values for **Minimum** and **Maximum** are 1 and 100, respectively. Maximum number should be greater than the Minimum number.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Advanced Option** settings allow you to perform more sophisticated simulations of the magnetostatic field.
  - **Use precomputed permeability data** (for general soft magnetic materials) uses a previously solved mu (apparent permeability) distribution from a linked source design. Selecting this option enables the **Setup Link** button, and automatically opens the **Setup Link** dialog in which you set up the link. Optionally, you can override the solved mu with a user-specified program, which you can specify on the **Advance** tab of the **Setup Link** dialog box. Select the **Including magnets** check box if magnets are included in the distribution. Refer to "Permeability Options for Magnetostatic Solutions " on the facing page for details on using these settings.
  - The **Import mesh** check box can be selected in the target design if the mesh for the same geometry in the linked source design is to be used in the analysis. Selecting this option enables the **Setup Link** button, and automatically opens the **Setup Link** dialog in which you set up the link. Refer to "Import Mesh for Non-Transient Solutions " on page 14-42 for details on using this setting.
  - If an advanced option has previously been set up, you can click the **Setup Link** button to open the **Setup Link** dialog and edit the link settings.

    > **Note:** The data link used to link source and target designs uses data caching technology. Therefore, if the design changes, to make sure the new data (from the source design) is used in the target design, right-click the **Analysis** field of the target design in the project tree, and select **Clear Linked Data**. This flushes existing data.

- For **2D** designs, the **Thermal Two-Way Coupling\Relaxation** setting can be used to improve two-way coupling convergence by applying the relaxation factor to the temperature field. When the thermal modifier takes on a nonlinear form, the convergence of the solution field in Maxwell's equations may fail during two-way coupling iterations. With nonlinear iterations, using an under-relaxation factor can mitigate the risk of overshooting in the property updating process.

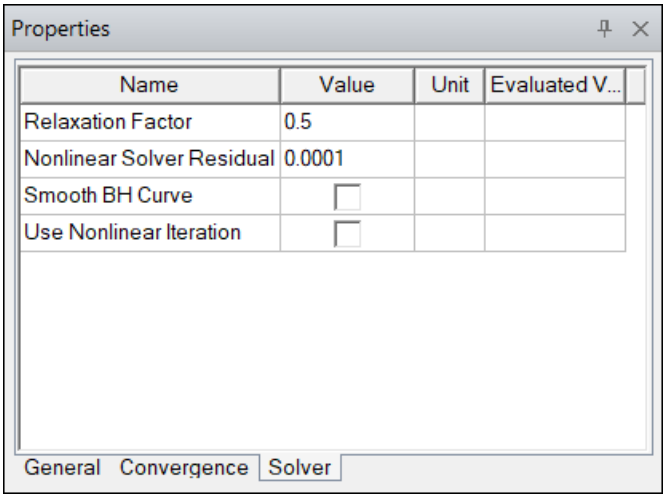
  The range of the relaxation factor is from 0 to 1. In general, a smaller relaxation value helps convergence, but may increase the total number of iterations. The default relaxation factor is 1.0.

  The **Thermal Two-Way Coupling\Relaxation** setting is applicable only when **Enable Feedback** is checked in Temperature of Objects window, which invokes two-way coupling instead of one-way coupling. The relaxation setting is

  - applicable to all Maxwell 2D designs,
  - applicable to both geometry modes (Cartesian XY and Cylindrical about Z),
  - does not support non-intrinsic and intrinsic variables.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If activated in the Solve Setup window, the Relaxation Factor is also available in the Solve Properties window:



Permeability Options for Magnetostatic Solutions

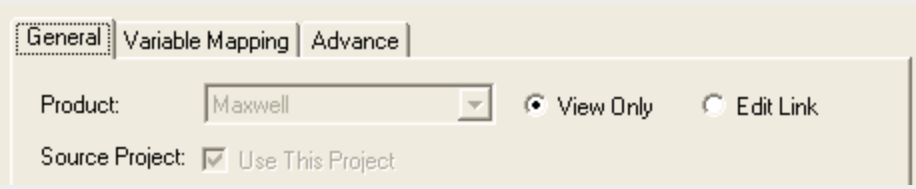
To set permeability options in the **Solve Setup** window:

1. Click **Maxwell** > **Analysis Setup** > **Add Solution Setup** to open the **Solve Setup** window.
2. Click the **Solver** tab.
3. In the **Advanced Option** section, select **Use precomputed permeability data**, which uses a previously solved mu (apparent permeability) distribution from a linked source design. Selecting this option enables the **Setup Link** button, and the **Setup Link** dialog opens, allowing you to specify the source project, design, and solution containing the desired information. The mesh between the two linked designs is the same. You can use the apparent permeability that has been frozen from a previously solved source design.

   By default, the **Setup Link** dialog opens on the **General** tab with only the **This project** radio button selected.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: If a link had previously been set up, the **Setup Link** dialog opens in **View Only** mode with all settings disabled.



To enable settings, you can select **Edit Link**.

4. To select a source project:
   - To use the current project as the source, check **Use This Project**. This disables the **Save source path relative to:** radio buttons and the ellipsis **[...]** button and its associated text field.
   - To specify a source project file other than the current project click the ellipsis **[...]** button to open a file browser window. When you have selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to **Open as read only**.

   Use the radio buttons to specify whether to save the source path relative to **The project directory of selected product** or **This project**.

5. When you select a source project file, the **Source Design** and the **Source Solution** fields are filled in with default values, and their drop down menus contain any available designs and solutions. You can use the drop down menus to choose from the available designs and solutions.

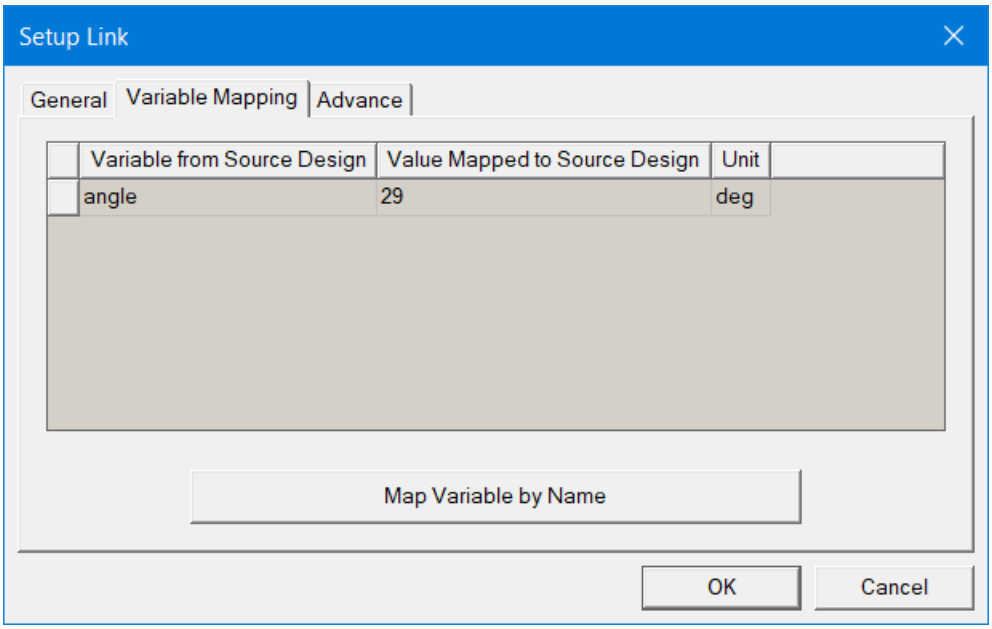
   The “Default” solution is the product-dependent solution of the first Setup – the setup listed first in the source design's project tree (alphanumerical order). A product-specific solution of this setup becomes the default solution. In most designs, it is LastAdaptive.

6. Use the check box to specify whether to **Simulate source design as needed**.
7. Use the check box to specify whether to **Preserve source design solution**. Note that in the extractor mode, the source project will be saved upon exit. Extractor mode means that the software is opened during the link solely for the purpose of solving.
8. The **Variable Mapping** tab lets you view any variables contained in the selected Project.

   When there are variables in the source design, you can choose to “map” these variables to constant values, expressions or variables in the target designs. Variable mapping becomes more important when the datalink type requires source and target design to be geometrically identical and source design is geometrically parameterized.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For linked designs with variables of the same name, you can click **Map Variables by Name** to automatically map same named variables.



9. Optionally, you can override the solved mu with a user-specified control program, which you can specify on the **Advance** tab of the **Setup Link** dialog box. Additionally, because the nonlinear characteristics of many magnetic materials are too complex to be defined through the definition of a BH-Curve, an advanced feature allows the permeability characteristic of the target design to be obtained by mathematical manipulation of the permeability from the source design via a user-defined control program. To use this feature:
    a. Check **Enable user program**.
    b. Specify the **Absolute path of program** to the user control program.
    c. Specify any **Additional arguments** needed by the user control program.

    > **Note:** For detailed information on using this feature, refer to Using the Advanced Permeability Option.

10. Click **OK** to accept the setup and close the Setup Link dialog and return to the Solve Setup window.
11. After setting up the link, you can select the **Including magnets** check box if magnets are included in the distribution.
12. When you are finished specifying solution settings, click **OK** to close the **Solve Setup** dialog box and finalize the solution setup.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** The usual way to create the linked designs is by copying and pasting an existing design from the project of your choice once the design is complete. Occasionally an existing design (possibly from a different project) can be used as a source.
>
> The data link automatically attempts to solve the linked (source) design if necessary (if no solution exists), then automatically copies the mesh and necessary data (calculated distribution of permeability), and finally performs the requested calculation in the target design. This data link allows you to calculate the magnetic field to be performed in a design with, for example, modified sources while keeping the permeability in a "frozen" state calculated in a different design (the same geometry and mesh but with different sources).

Using the Advanced Permeability Option

The nonlinear characteristics of many magnetic materials are too complex to be defined through the definition of a B-H Curve. This feature enhances the existing permeability link by enabling the permeability characteristic of the target design to be obtained by mathematical manipulation of the permeability from the source design. The nonlinear “apparent” permeability from the source design is frozen (linearized) and used by the target design. Because the permeability in the target design is linear, the apparent and the incremental permeabilities will be identical and the apparent and incremental inductances will also match.

This manipulation is done via a user-supplied control program. A user-specified executable is launched at the beginning of target design simulation and the linked permeability data (i.e., the “frozen” mu) from the source design is overridden by the values calculated by the user control program. The target design solver is then launched and uses the overridden value in its calculation.

The user control executable program is launched with two file names as arguments:

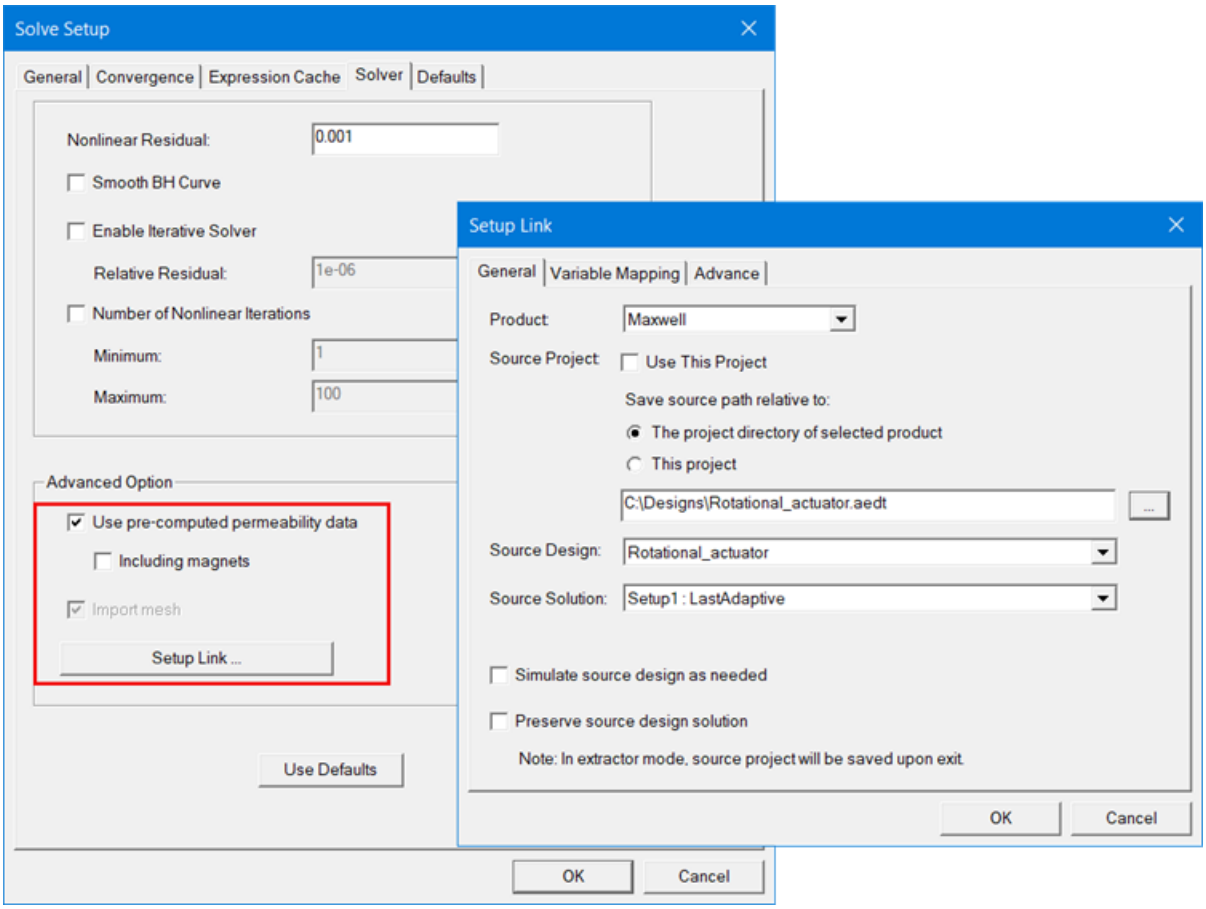
1. **Per mesh element permeability value.** This is the solved mu (*i.e.*, the apparent permeability not the incremental permeability) from the source design. Note that the format of this file is different between 2D and 3D designs.
2. **Per mesh element information.** Information includes the centroid location (x, y, z), Bx, By, Bz at the centroid and Hx, Hy, Hz at the centroid. The format of this file is the same between 2D and 3D designs.

> **Note:** Refer to Advanced Permeability Option File Formats for information on these file formats.

Considerations for Using this Feature

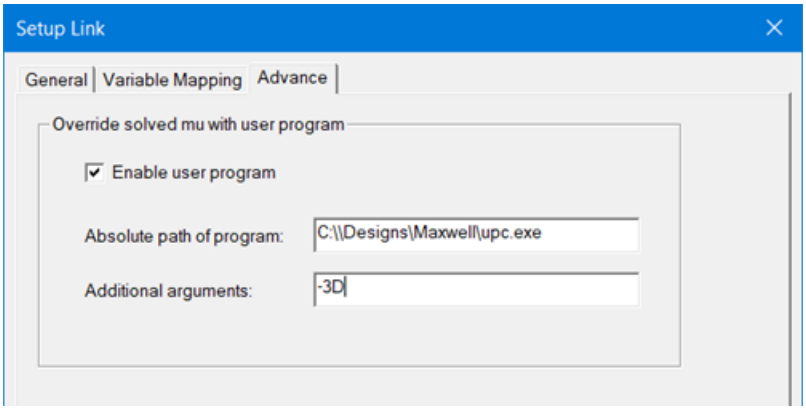
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. To set up the advanced user control program option for permeability, select **Setup Link** on the Solver tab to open the Setup Link dialog.



2. Specify the **Source Design** on the **General** tab.
3. On the **Advance** tab, select the check box **Enable user program** and provide the absolute path to the executable, and provide any **Additional arguments** needed by the user program.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. Simulate the target design.

   Simulation of the source design will be automatically started if it is not already simulated. The user-supplied executable is launched. Additional information is logged in **Setup>Profile** regarding the launch of user executable.

5. Simulation of the target design continues after user executable exits.

Note the following:

- Field post processing of target design will use the user-overridden mu.
- Editing boundary/excitation setup in the target design invalidates the current solution in target design.
- Linked data remains valid when boundary/excitation is changed. On next simulation of the target design, the prior user-overridden permeability will be used.
- Edit of the link setup (this includes the path to the user control program), or “removing” the user control program will invalidate the current solution and also the cached linked data. On the next simulation of the target design, the “frozen” permeability will be extracted again from the source design. If the link setup has opted to enable the user control program, the currently designated user program will be launched. If the link setup has opted *not* to override the linked data, the extracted mu from the source design will be used as is.
- **Clear Linked Data** in the target design invalidates the current solution and cached linked data in the target design.
- On the next simulation of the target design, the frozen permeability will be extracted again from the source design. The user executable will be launched to allow the permeability to be overridden.
- Editing the source design has no effect on the existing solution in the target design. Users need to **Clear Linked Data** in target design if a new simulation in the target design is desired.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- After the simulation of the target design, the user-overridden mu becomes part of the solution of the target design and this target design can then be used as the source of another design.

Advanced Nonlinear Options for Magnetostatic Solutions

For the magnetostatic solution type, the **Advanced Option** settings allow you to perform more sophisticated simulations of the magnetostatic field. The available setup options refer to permeability (for general soft magnetic materials) and magnetization vector (for permanent magnets).

Permeability	Demagnetization
Nonlinear B-H curve To use a nonlinear BH curve (this is the default)	**Nonlinear B-H curve** To use a nonlinear BH curve (this is the default)
From Link To use a previously solved mu (apparent permeability) distribution	**From Link** To use a previously computed magnetization (Hc) distribution
Including magnets To specify whether or not the distribution includes magnets (enabled only when **From Link** is selected)	**Compute Demagnetized operating points** (in the **Compute Data For Link** section) To specify whether or not to compute demagnetized operating points when using a nonlinear BH curve (enabled only when is **Nonlinear B-H curve** selected)

> **Note:** The data link used to link source and target designs uses data caching technology. Therefore, after the design changes, to make sure the new data (from the source design) is used in the target design, right-click the **Analysis** field of the target design in the project tree, and select **Clear Linked Data**. This flushes existing data.

Advanced Permeability Option File Formats

The following are the file formats for this feature:

3D Per Mesh Element Permeability Value

This is the solved mu (*i.e.*, the apparent permeability not the incremental permeability) from the 3D source design.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
SolidID  6   14
h  230  79578.5
h  231  79578.5
h  232  79578.5
h  233  79578.5

h  1965  79578.5
E_DATA
```

2D Per Mesh Element Permeability Value

This is the solved mu from the 2D source design. The format is

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

<number of total elements>

<objectID> <elementID> <X/R center position of element> <Y/Z center position of element> <mu>

For example, the following solved mu indicates that there is ONE object that has TWO mesh elements. The first element has a mu value of 2.7482 and the second element has a mu of 2.76553.

```
2
76 1   0.000866667  6.66667e-005 2.7482
76 15  0.000733333 -6.66667e-005 2.76553
end
```

The following solved mu indicates a total of 16 mesh elements that belong to two objects.

```
16
64 24   0.000733333 -0.000533333 1.90406
64 27   0.000866667 -0.000266667 1.88459
64 28   0.000733333 -0.000266667 1.89191
64 41   0.000666667 -0.000333333 1.88789

E_DATA

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Demagnetization Options for Magnetostatic Solutions

To set demagnetization options in the **Solve Setup** window:

1. Click **Maxwell** > **Analysis Setup** > **Add Solution Setup**.
   The **Solve Setup** window appears.
2. Click the **Solver** tab.
3. In the **Demagnetization Option** section, under **Advanced Material Option**, select one of the following two radio buttons:
   - **Nonlinear B-H Curve**. Using B-H curves is the default. Select this option when a normal computation is used with the normal adaptive mesh refinement capability.
   - **From Link**. You can use the magnetization (Hc) that has been frozen from a previously solved design. To do so, use the data link for subsequent field computations. When the **From Link** radio button is selected, the **Setup Link** command becomes active, allowing you to specify the project, design, and solution containing the desired information. The same mesh between the two linked designs is recommended. If the two meshes are not the same, an object-wise average Hc is used.
4. If you selected **Nonlinear B-H Curve**, select or clear the **Demagnetized operating points** check box in the **Compute Data for Link** section. **Note**

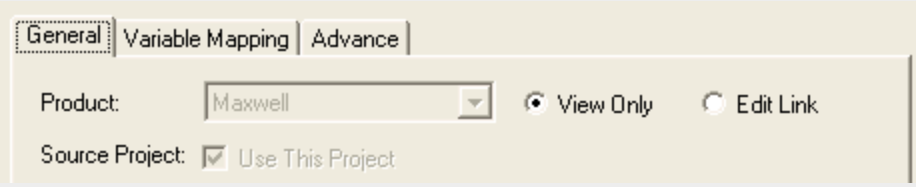
   > **Note:** When demagnetization effects need to be taken into account (meaning nonlinear permanent magnets are used in the model), you should select **Demagnetized operating points** in the linked (source) design and select the **From Link** radio button in the target design.

5. If you selected **From Link**, click **Setup Link** to specify the project, design, and solution containing the information you want to use.

   By default, the **Setup Link** window opens on the **General** tab with only the **This project** radio button selected.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: If a link had previously been set up, the **Setup Link** window opens in **View Only** mode with all settings disabled.



To enable settings, you can select **Edit Link**.

6. To select a source project do one of the following:
   - To use the current project as the source, check **Use This Project**. This disables the **Save source path to:** radio buttons and the ellipsis **[...]** button and its associated text field.
   - To specify a source project file other than the current project click the ellipsis **[...]** button to open a file browser window. When you have selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to **Open as read only**.

     Use the radio buttons to specify whether to save the source path relative to **The project directory of the selected project** or **This project**.
7. When you select a source project file, the **Source Design** and the **Source Solution** fields are filled in with default values, and their drop down menus contain any available designs and solutions. You can use the drop down menus to choose from the available designs and solutions.

   The “Default” solution is the product-dependent solution of the first Setup. That is the setup listed first in the source design's project tree (alphanumerical order). A product-specific solution of this setup becomes the default solution. In most products, it is “LastAdaptive.” In a Transient solution type, it is “Transient.”
8. Use the check box to specify whether to **Simulate source design as needed**.
9. Use the check box to specify whether to **Preserve the source design solution**. Note that in the extractor mode, the source project will be saved upon exit. Extractor mode means that the software is opened during the link solely for the purpose of solving.
10. The **Variable Mapping** tab lets you view any variables contained in the selected Project.

    When there are variables in the source design, you can choose to “map” these variables to constant values, expressions or variables in the target designs. Variable mapping becomes more important when the datalink type requires source and target design to be geometrically identical and source design is geometrically parameterized.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For linked designs with variables of the same name, you can click **Map Variables by Name** to automatically map same named variables. In this example the variables “height” and “weight” are mapped to the Source, whereas the “current” variable does not have a same named counterpart, and retains its value in the source design.

11. Click **OK** to accept the setup and close the Setup Link dialog box.
12. When you are finished specifying solution settings, click **OK** to close the **Solve Setup** dialog box and finalize the solution setup.

Note: The data link automatically attempts to solve the linked (source) design if necessary (if no solution exists), then automatically copies the mesh and necessary data (new values for the magnetization vector) in the target design, and finally perform the requested calculation in the target design. This data link allows you to calculate the magnetic field to be performed in a design with, for example, modified sources while keeping the magnetization in a "frozen" state calculated in a different design (the same geometry and mesh but with different sources).

For advanced nonlinear options for magnetization, the two meshes in the source and target models do not have to be identical. If the two meshes are identical, an element by element new magnetization vector is calculated (based on the respective calculated demagnetized operation points) and used in subsequent calculations. If the two meshes are different, Maxwell calculates in the target model an object-wise average magnetization vector and applies it globally to the respective object(s).

Therefore, when the **From Link** radio button is checked, the **Setup Link** command becomes active, allowing you to specify the project design and solution containing the desired information.

Unlike the case of presolved permeability, the mesh between the two linked designs does not have to be the same (as explained above).

Eddy Current Solver Settings

The settings available in the Eddy Current Solve Setup**Solver** tab are determined by the type of design selected (2D, 3D T-Omega, or 3D A-Phi).

For an Eddy Current 2D Solution:

1. **Adaptive Frequency** – This value specifies the nominal problem frequency, which will be used in the adaptive mesh process. The units are specified by the user. The value can be specified using variables and expressions.
2. **Nonlinear Residual** – This value specifies how close each solution must come to satisfying the equations that are used to compute the electric field.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

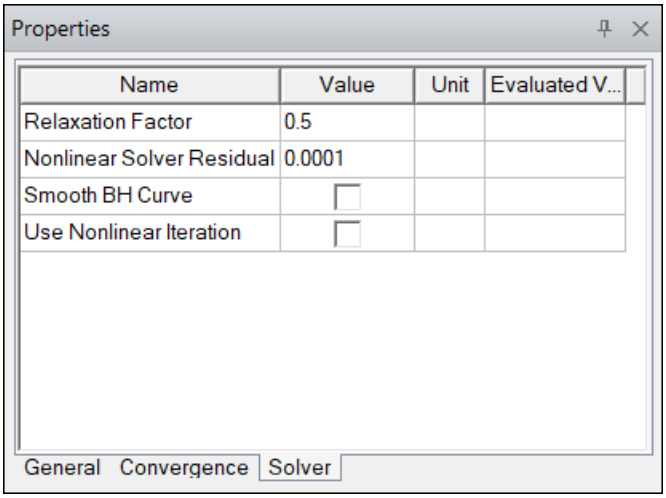
3. **Smooth BH Curve** – This option allows the solver to smoothen the list of points to make a refined BH curve for better solving. If this option is not selected, the solver just uses the discrete points.
4. **Number of Nonlinear Iterations** – This provides an option for you to set both a **Minimum** iteration number to avoid non-converged solution, and a **Maximum** iteration number to avoid taking too much computation time. These values must be integers greater than 0. By default the values for **Minimum** and **Maximum** are 1 and 100, respectively. Maximum number should be greater than the Minimum number.
5. **Thermal Two-Way Coupling\Relaxation** – This setting can be used to improve two-way coupling convergence by applying the relaxation factor to the temperature field. When the thermal modifier takes on a nonlinear form, the convergence of the solution field in Maxwell's equations may fail during two-way coupling iterations. With nonlinear iterations, using an under-relaxation factor can mitigate the risk of overshooting in the property updating process.

   The range of the relaxation factor is from 0 to 1. In general, a smaller relaxation value helps convergence, but may increase the total number of iterations. The default relaxation factor is 1.0.

   The **Thermal Two-Way Coupling\Relaxation** setting is applicable only when **Enable Feedback** is checked in Temperature of Objects window, which invokes two-way coupling instead of one-way coupling. The relaxation setting is

   - applicable to all Maxwell 2D designs,
   - applicable to both geometry modes (Cartesian XY and Cylindrical about Z),
   - does not support non-intrinsic and intrinsic variables.

   If activated in the Solve Setup window, the Relaxation Factor is also available in the Solve Properties window:



6. If desired, you can Import Mesh.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For an Eddy Current 3D T-Omega Solution:

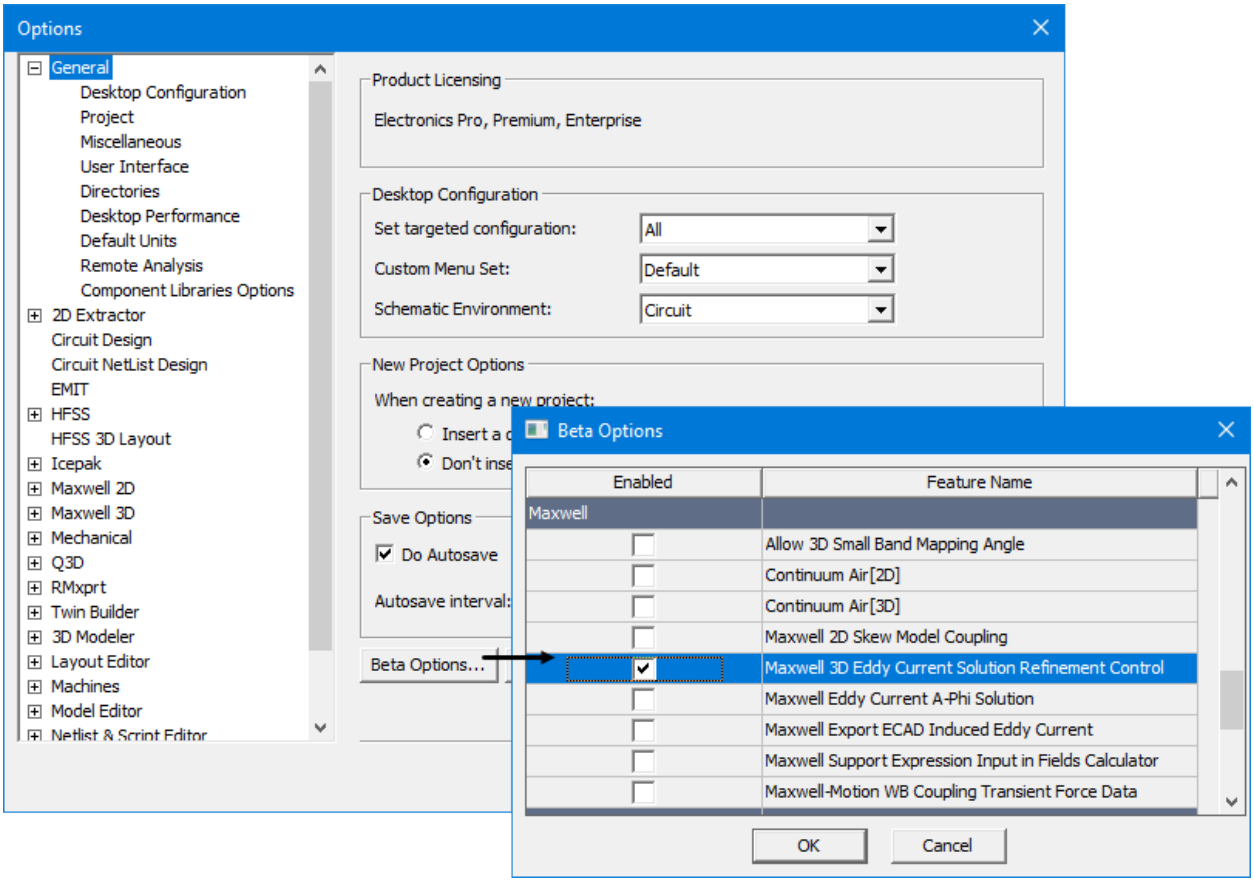
1. **Adaptive Frequency** – This value specifies the nominal problem frequency, which will be used in the adaptive mesh process. The units are specified by the user. The value can be specified using variables and expressions.
2. **Nonlinear Residual** – This value specifies how close each solution must come to satisfying the equations that are used to compute the electric field.
3. **Smooth BH Curve** – This option allows the solver to smoothen the list of points to make a refined BH curve for better solving. If this option is not selected, the solver just uses the discrete points.
4. Enable an Iterative Solver – This option enables the iterative solver, rather than the direct solver. For more information, see Iterative Matrix Solver.
5. **Use higher order shape functions –** This optional setting will increase the order of electric vector potential to 2 from the default order of 1. Enabling the higher order option gains better accuracy for eddy current regions.

   > **Note:** Higher-order shape functions are not supported for a project with windings. For this case, the solver falls back to lower-order shape functions.

6. **Number of Nonlinear Iterations** – This provides an option for you to set both a **Minimum** iteration number to avoid non-converged solution, and a **Maximum** iteration number to avoid taking too much computation time. These values must be integers greater than 0. By default the values for **Minimum** and **Maximum** are 1 and 100, respectively. Maximum number should be greater than the Minimum number.
7. **Loss Adaptive Control** – For a typical analysis in Ansys Maxwell, the energy error generated by an FEM residual is used as the mesh adaptive refinement criterion, but for modeling the skin effects of the eddy current problem, the eddy current region may not be sufficiently refined. To better model the skin effects, it is more efficient to use a combination of energy error and the power loss of the eddy current effects as a mixed criterion for mesh adaptive refinement. Better accuracy of skin effects modeling gives more accurate power loss. The Loss Adaptive Control slider bar controls the weight of energy error and the power loss. The value of 0 means that the mesh adaptive refinement is purely based on energy error while any nonzero value means that the mesh adaptive refinement is based on the mixed criterion. A value of 1 means that the mesh adaptive refinement is purely based power loss; although setting Loss Adaptive Control to 1 can give the most accurate power loss calculation, it may result in less accurate energy calculation and potentially need more adaptive passes. The default value for Loss Adaptive Control is 0.5, and projects created in earlier versions of Ansys Maxwell will use this value.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: The Loss Adaptive Control setting is only accessible if it has been activated from **Tools** > **Options** > **General Options** > **Desktop Configuration** > **Beta Options** dialog box. Select the **Maxwell 3D Eddy Current Solution Refinement Control** feature.



8. **Use precomputed permeability data** – Optional setting that allows the use of the permeability data calculated in a source 3D magnetostatic design. Note that this option is not available if **Include DC Fields** is selected in the Solver Type window because permeability data will automatically included in this type of simulation; refer to Including DC Fields in a 3D Eddy Current T-Omega Solution for details.
9. If desired, you can Import Mesh. This setting is not available if **Include DC Fields** is selected.

For an Eddy Current 3D A-Phi Solution:

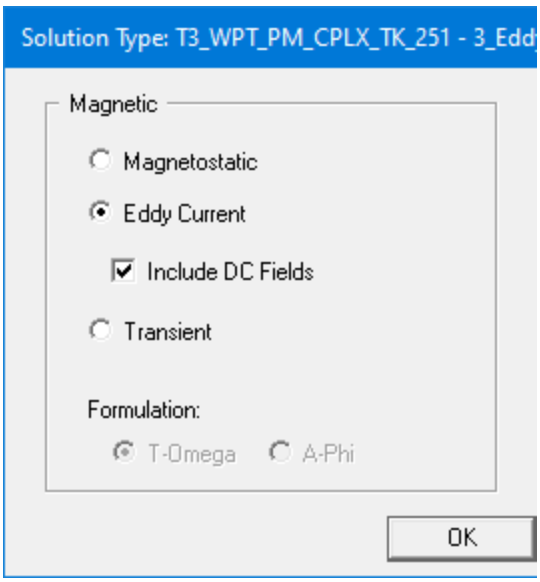
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: The Eddy Current 3D A-Phi solver is only accessible if it has been activated from **Tools** > **Options** > **General Options** > **Desktop Configuration** > **Beta Options** dialog box. Select the **Maxwell Eddy Current A-Phi Solution** feature.

1. **Adaptive Frequency** – This value specifies the nominal problem frequency, which will be used in the adaptive mesh process. The units are specified by the user. The value can be specified using variables and expressions.
2. **Nonlinear Residual** – This value specifies how close each solution must come to satisfying the equations that are used to compute the electric field.
3. **Number of Nonlinear Iterations** – This provides an option for you to set both a **Minimum** iteration number to avoid non-converged solution, and a **Maximum** iteration number to avoid taking too much computation time. These values must be integers greater than 0. By default the values for **Minimum** and **Maximum** are 1 and 100, respectively. Maximum number should be greater than the Minimum number.
4. If desired, you can Import Mesh.

Including DC Fields in a 3D Eddy Current T-Omega Solution

For projects with materials whose permeability is nonlinear, permeability can be included in the 3D Eddy Current T-Omega calculations by checking the **Include DC Fields** option in the Solution Type dialog box:



When this option is selected, the solver runs a Magnetostatic simulation (DC) and then an Eddy Current simulation (AC). The Eddy Current design operating point on the nonlinear B-H curve is

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

calculated based on the DC fields, and permeability is determined by slope of B-H curve at the operating point.

After the simulation is complete, the AC field results and DC field results, such as the B and H fields, are available for plotting.

This feature can be used for small-signal analysis as the operating point in the B-H curve does not change significantly from the magnetic solution to the harmonic solution.

For the Eddy Current\Include DC Fields analysis, note the following:

- DC and AC simulations can use independent adaptive meshes.
- Mesh operations are applied to both the AC and DC simulations except **Skin Depth**, which is not applicable for DC.
- Boundaries are applied to both AC and DC simulation, except **Impedance** and **Radiation**, which are not supported for DC.
- Settings in the tabs of the Solve Setup window only apply to AC simulation; the DC simulation is only configured from the Solve Setup's **DC** tab.
- Any matrix, force, and torque parameters set up will only apply to AC simulation.
- The Inductance type in the Magnetostatic simulation is **Incremental**, *i.e.*, defined as the ratio of delta flux to delta current at a certain operating condition. See Inductance Type Settings for 3D Magnetostatic Solutions for more details.
- If an object's material composition is a Litz wire, its properties are only applied to AC simulation. DC simulation does not support Litz wire and will treat it as solid composition.

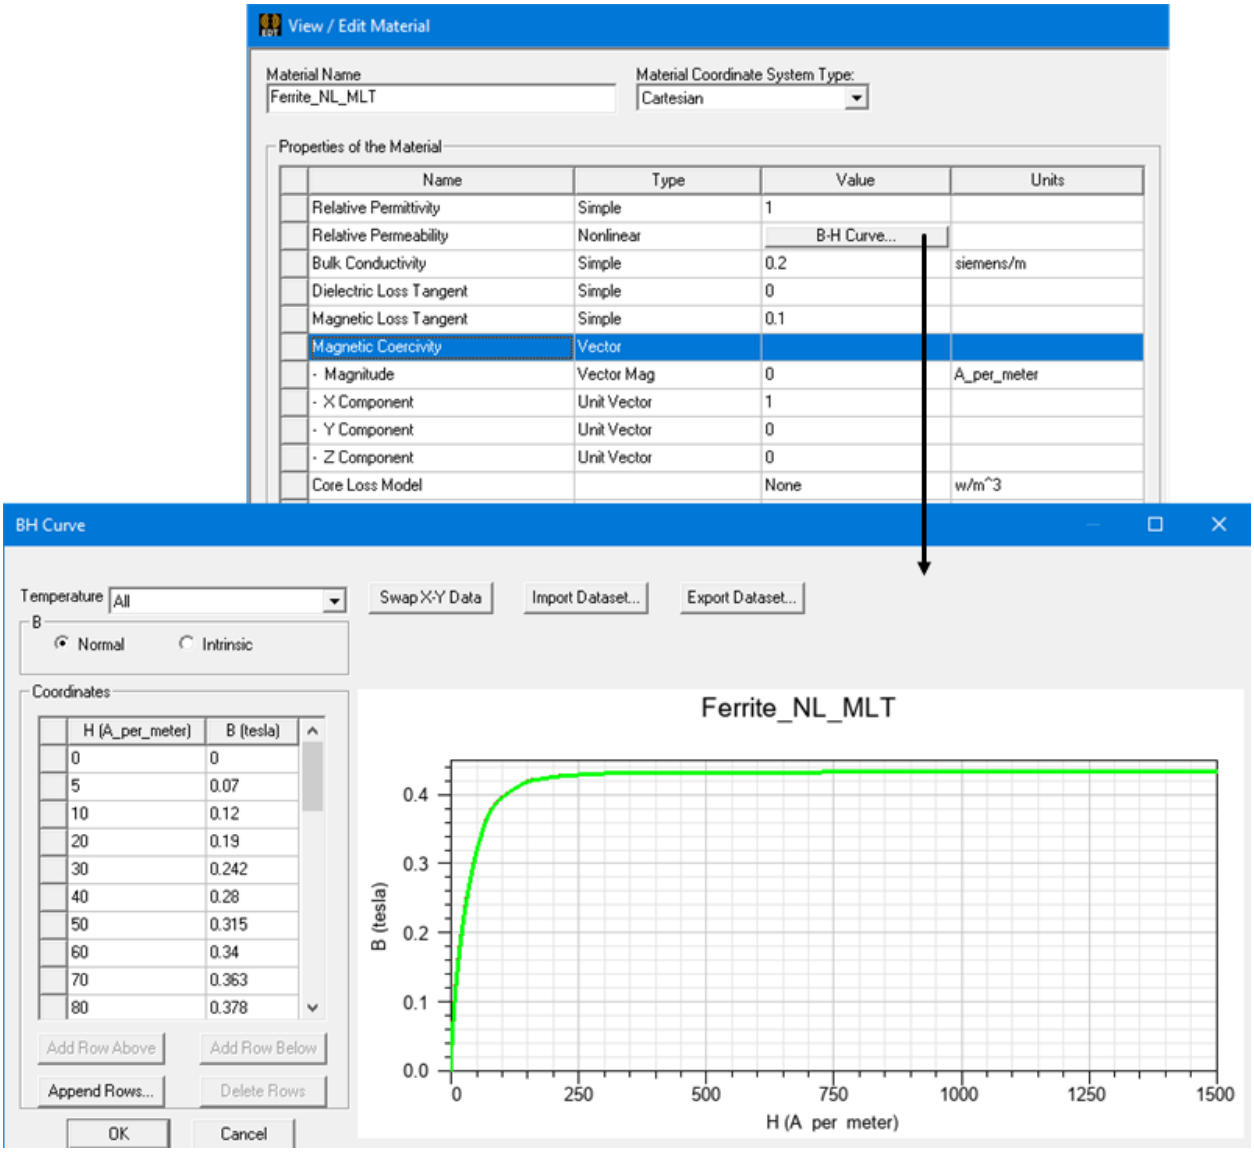
> **Note:** In the previous release, this type of simulation required two models: a source 3D Magnetostatic design and a 3D Eddy Current target design. With the 25r1 release, only one design is needed for both DC and AC simulations.

To set up this type of analysis:

1. Create a Maxwell 3D design.
2. In Solution Type dialog box, select **Eddy Current**, and check **Include DC Fields**.
3. For the permanent magnet material, define the **Relative Permeability** with a BH-curve, and define **Magnetic Coercivity** parameters. Below is an example of a soft magnetic and a nonlinear permanent magnet.

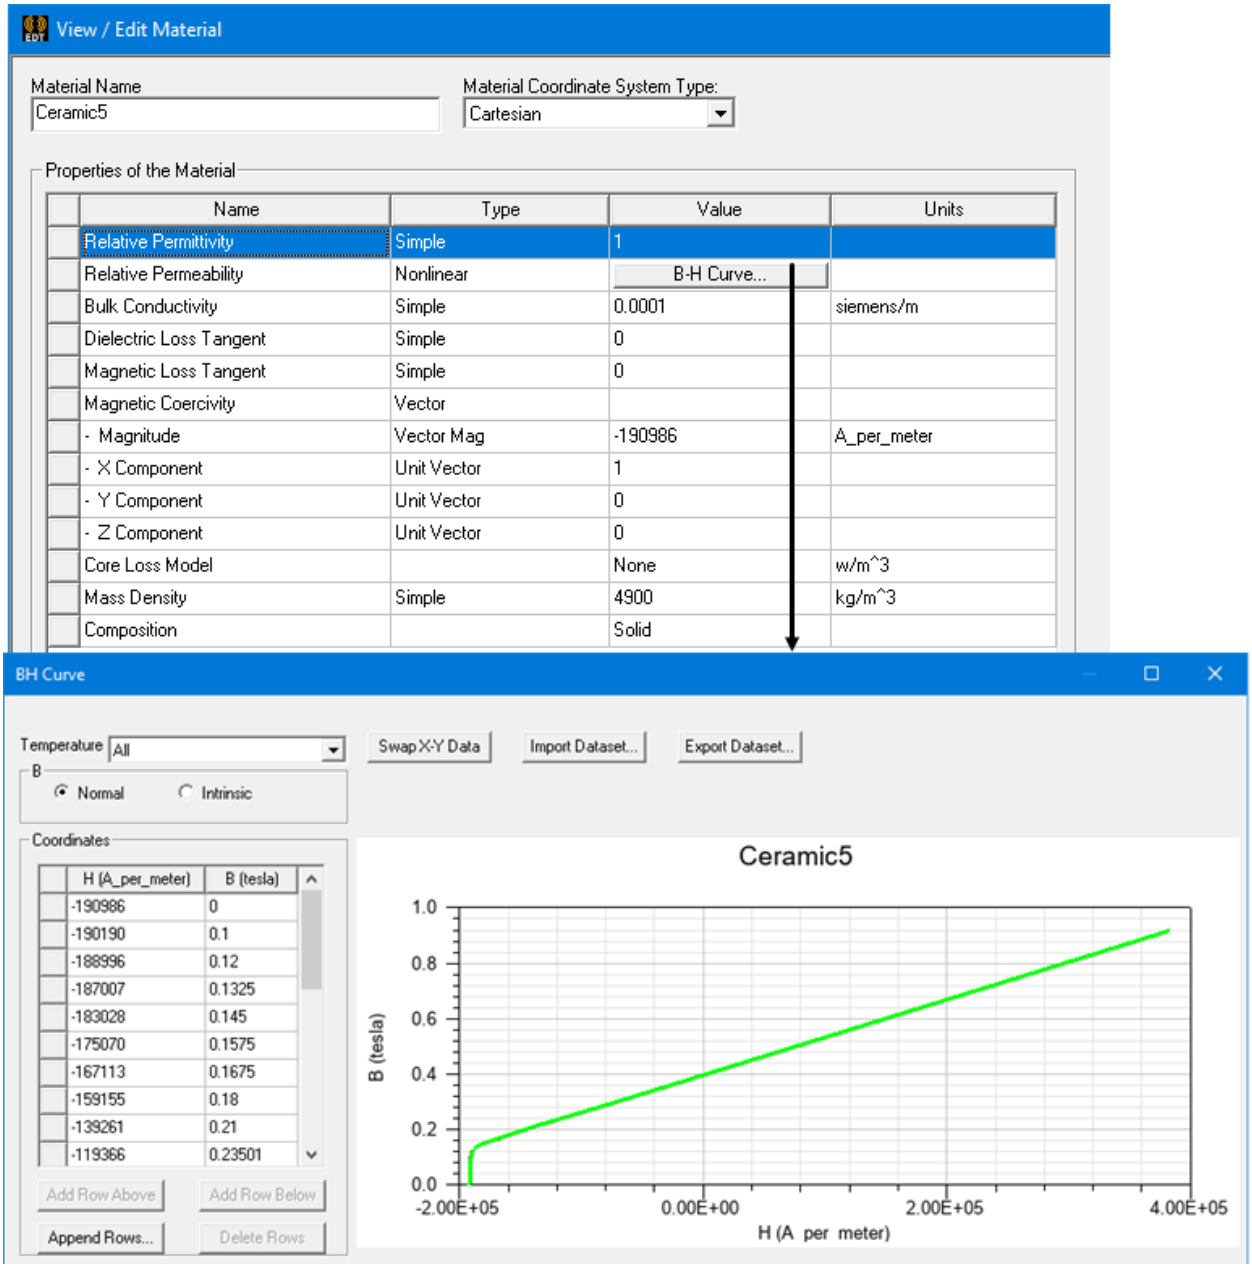
   Relative Permeability BH Curve for a Soft Magnet:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



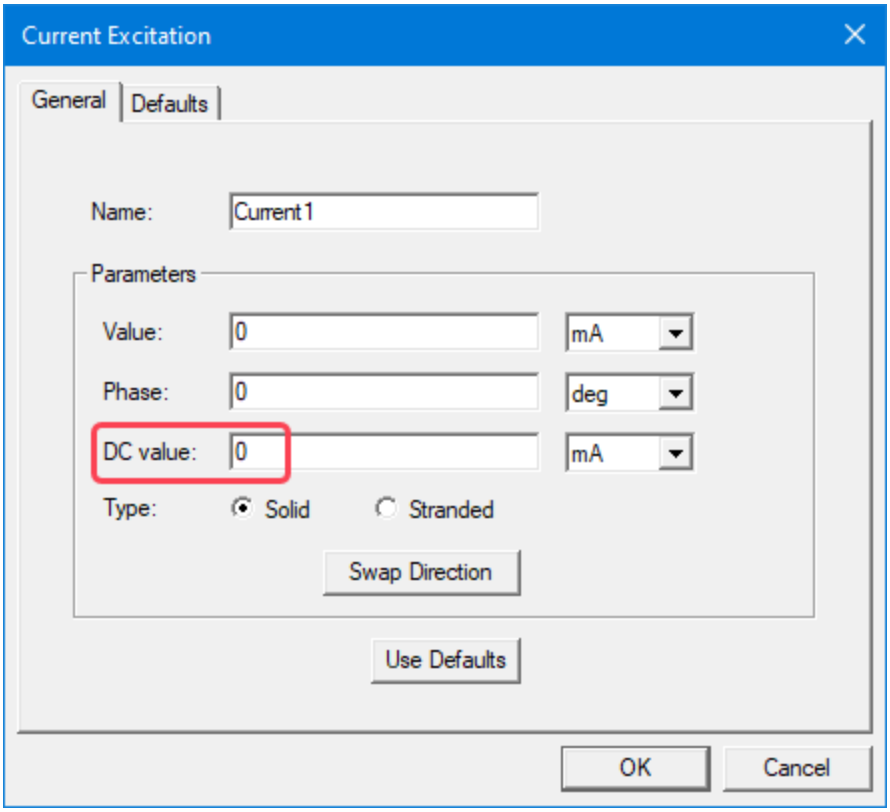
Relative Permeability BH Curve for a Nonlinear Permanent Magnet:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



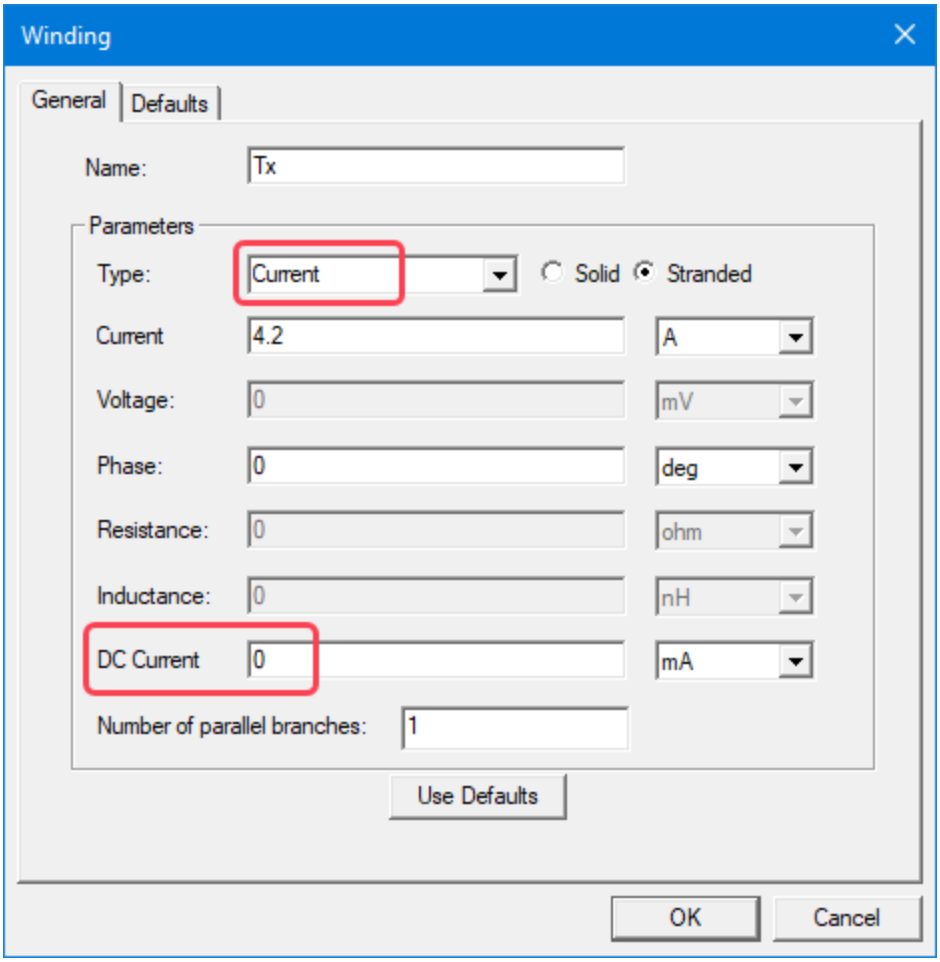
4. Define a DC input. The **Current** and **Winding** excitations will include a DC input field:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

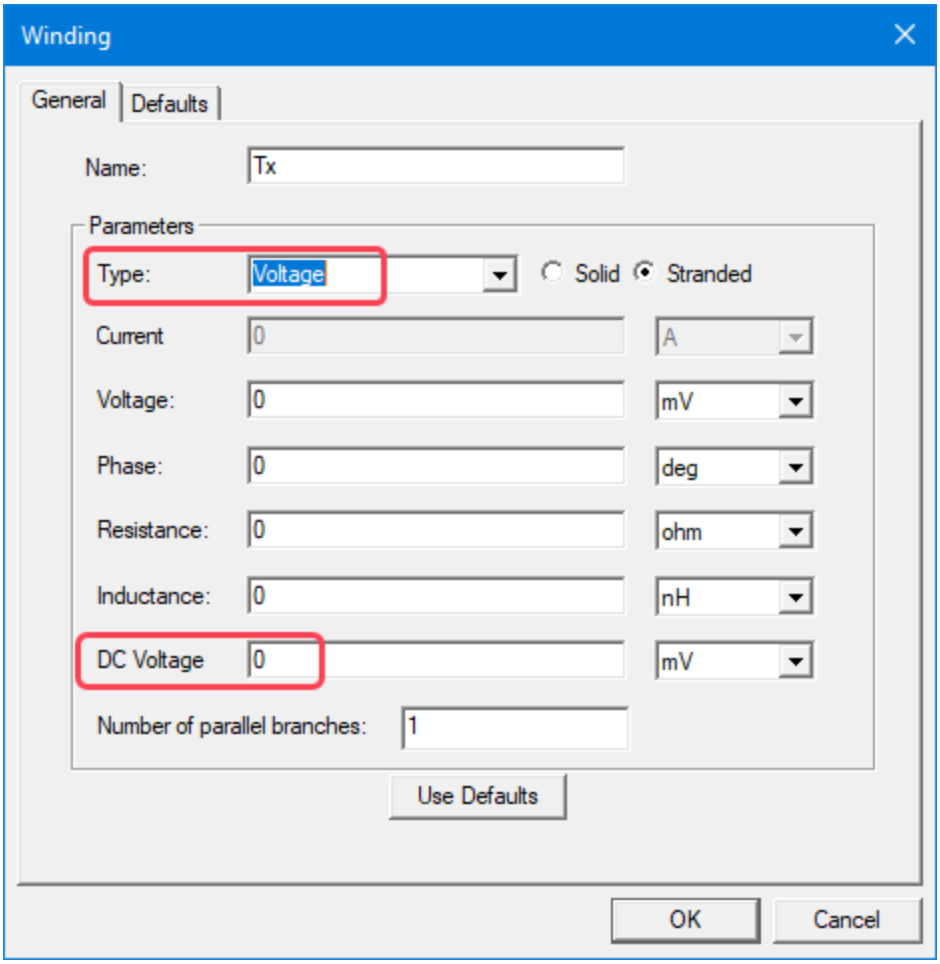


The DC input for a Winding excitation depends on the winding Type:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

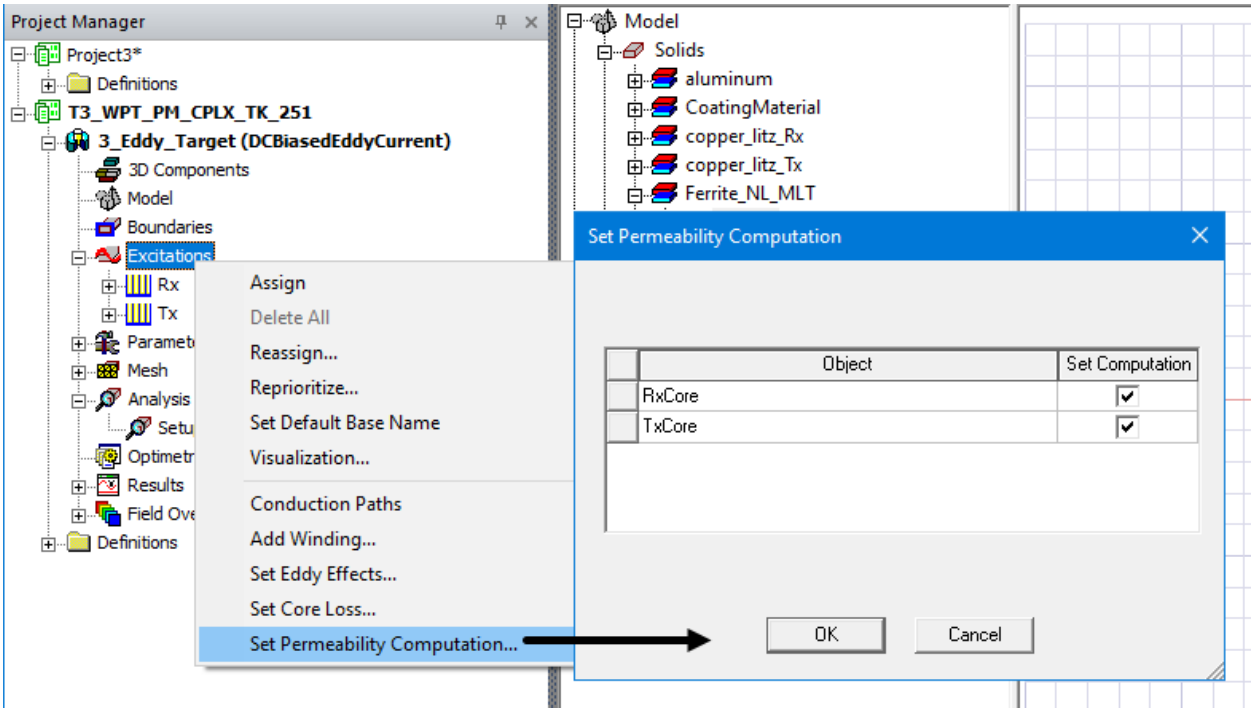


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



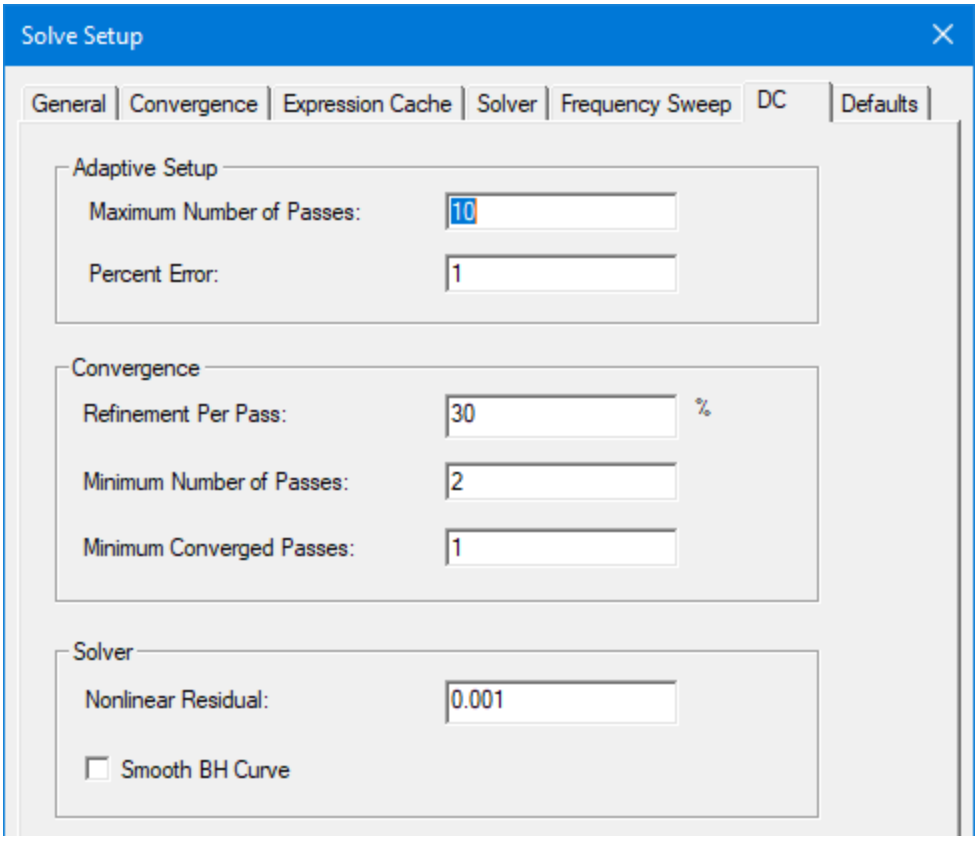
5. Right-click on **Excitations** > **Set Permeability Computation**. By default, all objects with nonlinear B-H curve material, including soft magnets and nonlinear permanent magnets, are selected. Click **OK** to add to the simulation.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



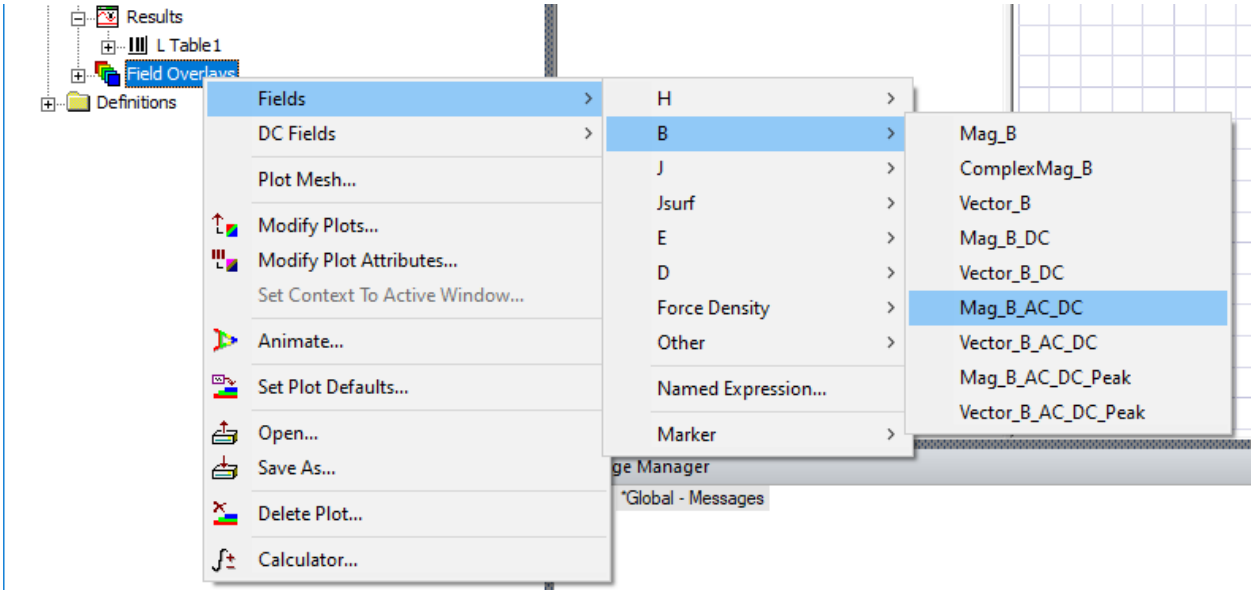
6. In the Solve Setup window, make sure to configure the **DC** tab:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

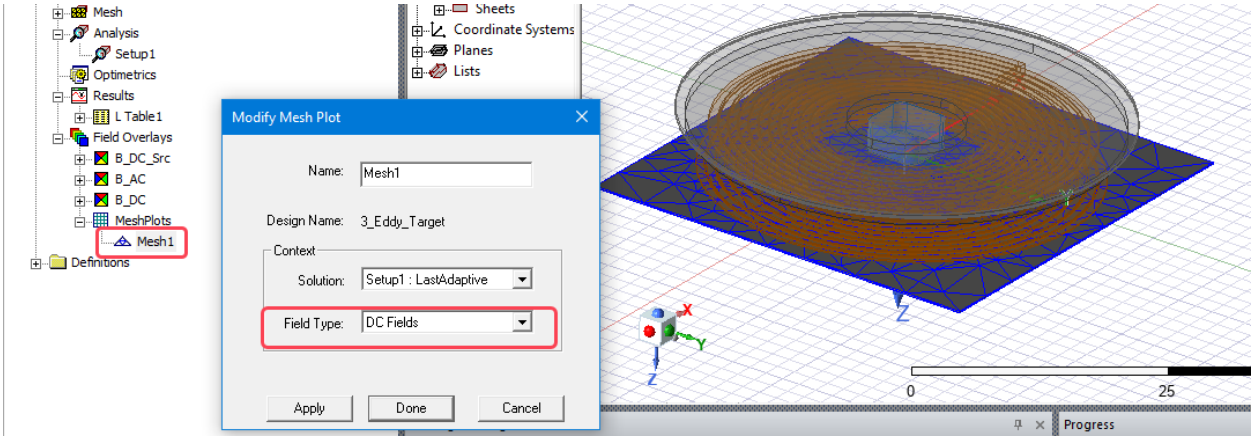


7. Solve the 3D Eddy Current design.
8. Create B, H, and J field plots from the AC, AC+DC, and DC results.
    a. The Mag_B_DC, Vector_B_DC is the DC field mapped from magnetostatic solution.
    b. The Mag_B_AC_DC, Vector_B_AC_DC is the addition of AC field from eddy-current solution and DC field from magnetostatic solution.
    c. The Mag_B_AC_DC_Peak, Vector_B_AC_DC_Peak is the peak value of AC+DC field among all AC phases.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

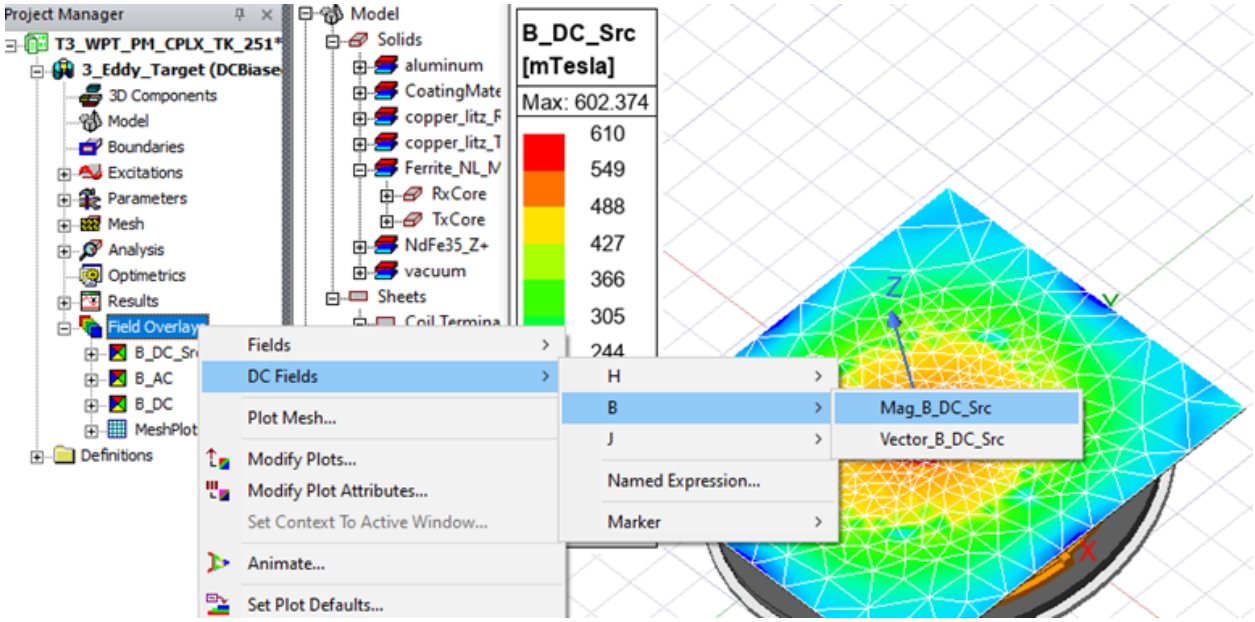


9. Plot the Magnetostatic solution DC mesh:



10. Plot the magnetostatic solution DC fields B, H, and J.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



11. Both the AC and DC Solution Data are available in the Solution Data window (right click on **Results** and select **Solution Data**).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For the **DC** option, only the **Profile**, **Convergence**, and **Mesh Statistics** tabs are applicable.

Electrostatic Solver Settings

For an electrostatic solution you can do the following:

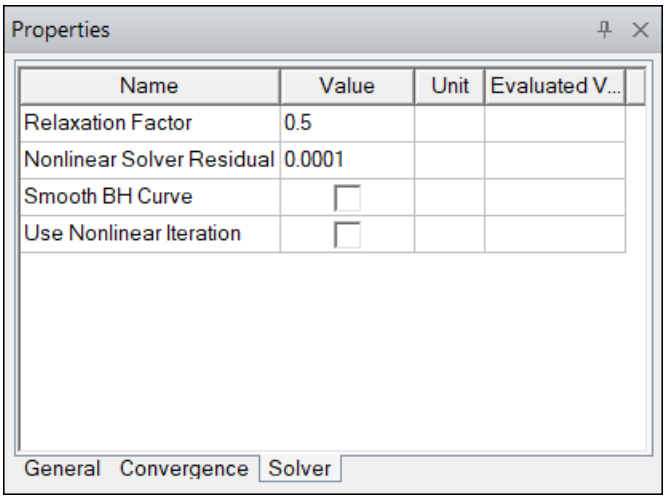
- For 3D designs, you can Enable an Iterative Solver.
- Import Mesh
- For **2D** designs, the **Thermal Two-Way Coupling\Relaxation** setting can be used to improve two-way coupling convergence by applying the relaxation factor to the temperature field. When the thermal modifier takes on a nonlinear form, the convergence of the solution field in Maxwell's equations may fail during two-way coupling iterations. With nonlinear iterations, using an under-relaxation factor can mitigate the risk of overshooting in the property updating process.

  The range of the relaxation factor is from 0 to 1. In general, a smaller relaxation value helps convergence, but may increase the total number of iterations. The default relaxation factor is 1.0.

  The **Thermal Two-Way Coupling\Relaxation** setting is applicable only when **Enable Feedback** is checked in Temperature of Objects window, which invokes two-way coupling instead of one-way coupling. The relaxation setting is

  - applicable to all Maxwell 2D designs,
  - applicable to both geometry modes (Cartesian XY and Cylindrical about Z),
  - does not support non-intrinsic and intrinsic variables.

  If activated in the Solve Setup window, the Relaxation Factor is also available in the Solve Properties window:



AC Conduction Solver Settings

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. For 2D and 3D designs, enter a frequency value in the **Adaptive Frequency** text box, and select the desired units. Use of variables and expressions are also supported.
2. For 3D designs, enter a value in the **Nonlinear Residual** text box. This value specifies how close each solution must come to satisfying the equations that are used to compute the electric field.
3. If desired, you can Import Mesh.
4. For 2D and 3D designs, selecting the **Number of Nonlinear** Iterations check box allows you to set both a **Minimum** iteration number to avoid non-converged solution, and a **Maximum** iteration number to avoid taking too much computation time. These values must be integers greater than 1. The default values for **Minimum** and **Maximum** are 2 and 50, respectively. The **Maximum** number should be greater than the **Minimum** number.
5. For **2D** designs, the **Thermal Two-Way Coupling\Relaxation** setting can be used to improve two-way coupling convergence by applying the relaxation factor to the temperature field. When the thermal modifier takes on a nonlinear form, the convergence of the solution field in Maxwell's equations may fail during two-way coupling iterations. With nonlinear iterations, using an under-relaxation factor can mitigate the risk of overshooting in the property updating process.

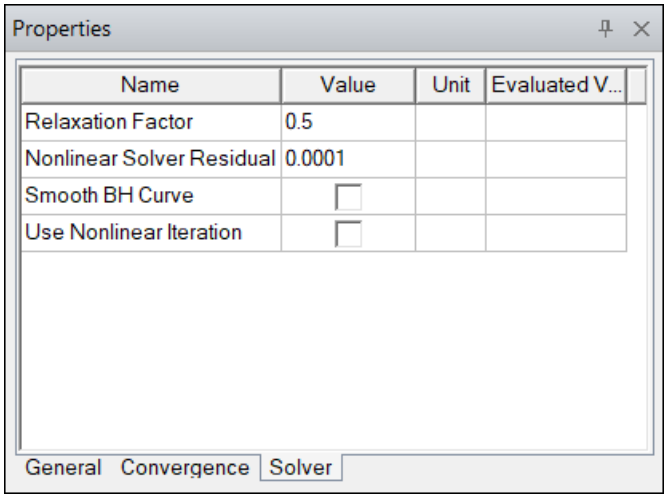
   The range of the relaxation factor is from 0 to 1. In general, a smaller relaxation value helps convergence, but may increase the total number of iterations. The default relaxation factor is 1.0.

   The **Thermal Two-Way Coupling\Relaxation** setting is applicable only when **Enable Feedback** is checked in Temperature of Objects window, which invokes two-way coupling instead of one-way coupling. The relaxation setting is

   - applicable to all Maxwell 2D designs,
   - applicable to both geometry modes (Cartesian XY and Cylindrical about Z),
   - does not support non-intrinsic and intrinsic variables.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If activated in the Solve Setup window, the Relaxation Factor is also available in the Solve Properties window:



DC Conduction Solver Settings

For a DC Conduction solution:

1. If desired, you can Import Mesh.
2. For 3D designs, optionally Enable an Iterative Solver.
3. For **2D** designs, the **Thermal Two-Way Coupling\Relaxation** setting can be used to improve two-way coupling convergence by applying the relaxation factor to the temperature field. When the thermal modifier takes on a nonlinear form, the convergence of the solution field in Maxwell's equations may fail during two-way coupling iterations. With nonlinear iterations, using an under-relaxation factor can mitigate the risk of overshooting in the property updating process.

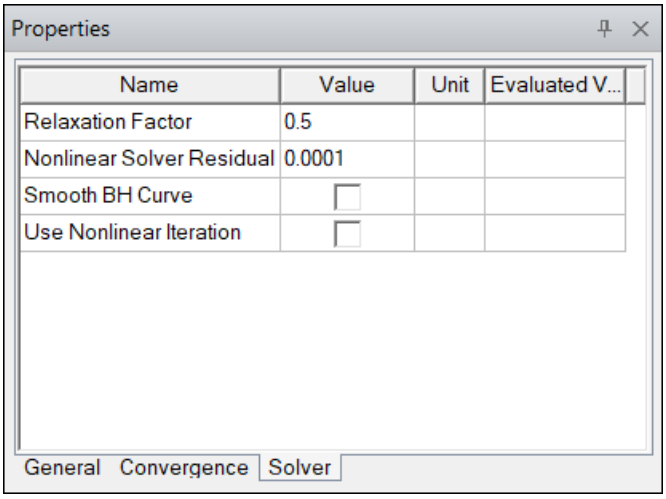
   The range of the relaxation factor is from 0 to 1. In general, a smaller relaxation value helps convergence, but may increase the total number of iterations. The default relaxation factor is 1.0.

   The **Thermal Two-Way Coupling\Relaxation** setting is applicable only when **Enable Feedback** is checked in Temperature of Objects window, which invokes two-way coupling instead of one-way coupling. The relaxation setting is

   - applicable to all Maxwell 2D designs,
   - applicable to both geometry modes (Cartesian XY and Cylindrical about Z),
   - does not support non-intrinsic and intrinsic variables.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If activated in the Solve Setup window, the Relaxation Factor is also available in the Solve Properties window:



Import Mesh for Non-Transient Solutions

The **Import mesh** check box can be selected in the “target” design if the mesh for the same geometry is to be used in the analysis. This setup is designed to be generally applicable to all solutions.

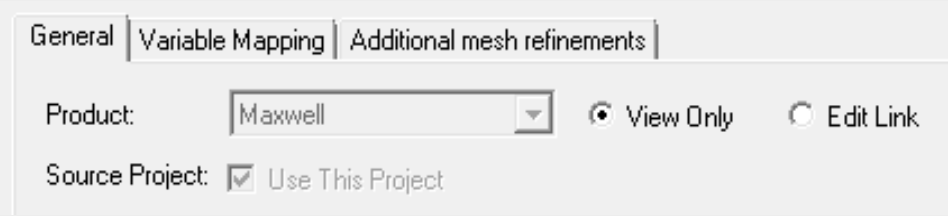
If the **Import mesh** feature is selected, the **Setup Link** button becomes active, the **Setup Link** dialog box automatically appears, and the mesh will be imported from the source design to the target design.

> **Note:** The usual way to create geometrically equivalent designs is by copying all geometry objects from one design and then using **Import From Clipboard** in the other design.

1. By default, the **Setup Link** dialog opens on the **General** tab with only the **This project** radio button selected.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: If a link had previously been set up, the **Setup Link** dialog opens in **View Only** mode with all settings disabled.



To enable settings, you can select **Edit Link**.

2. To select a source project, do one of the following:

   - To use the current project as the source, check **Use This Project**. This disables the **Save source path to:** radio buttons and the ellipsis **[...]** button and its associated text field.
   - To specify a source project file other than the current project click the ellipsis **[...]** button to open a file browser window. When you have selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to **Open as read only**.

     Use the radio buttons to specify whether to save the source path relative to **The project directory of the selected project** or **This project**.

3. When you select a source project file, the **Source Design** and the **Source Solution** fields are filled in with default values, and their drop down menus contain any available designs and solutions. You can use the drop down menus to choose from the available designs and solutions.

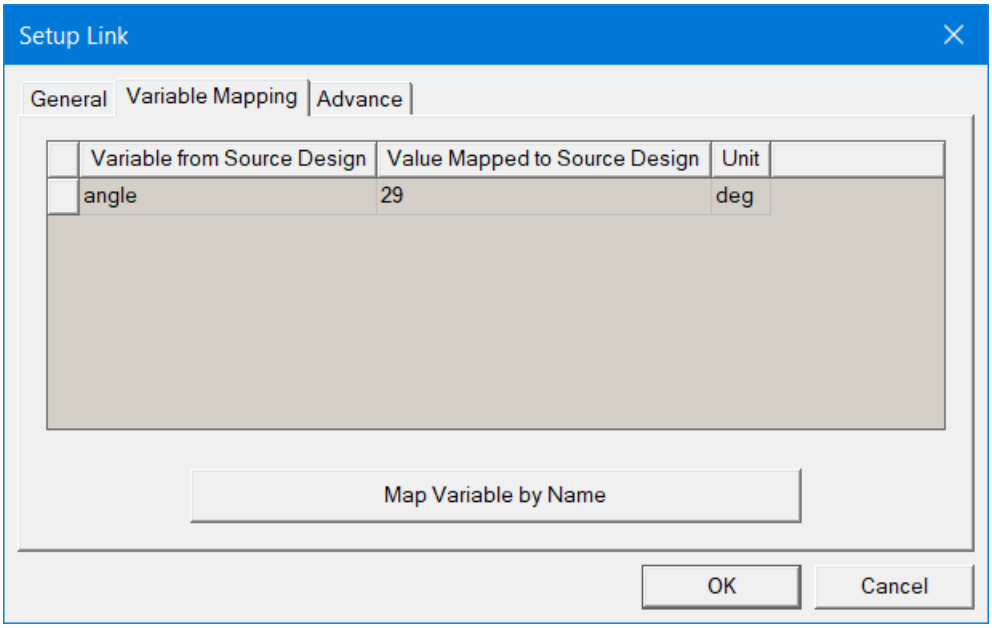
   The “Default” solution is the product-dependent solution of the first Setup. That is the setup listed first in the source design's project tree (alphanumerical order). A product-specific solution of this setup becomes the default solution. In most products, it is “LastAdaptive.” In a Transient solution type, it is “Transient.”

4. Use the check box to specify whether to **Simulate source design as needed**.
5. Use the check box to specify whether to **Preserve the source design solution**. Note that in the extractor mode, the source project will be saved upon exit. Extractor mode means that the software is opened during the link solely for the purpose of solving.
6. The **Variable Mapping** tab lets you view any variables contained in the selected Project.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When there are variables in the source design, you can choose to “map” these variables to constant values, expressions or variables in the target designs. Variable mapping becomes more important when the datalink type requires source and target design to be geometrically identical and source design is geometrically parameterized.

For linked designs with variables of the same name, you can click **Map Variables by Name** to automatically map same named variables. If a variable does not have a same named counterpart, it retains its value in the source design.



7. You can select the **Additional mesh refinements** tab to either **Apply mesh operation in target design on the imported mesh** (default), or **Ignore mesh operations in target design**.
8. Click **OK** to accept the setup and close the **Setup Link** dialog box.

Setup Link for Non-Transient Solutions

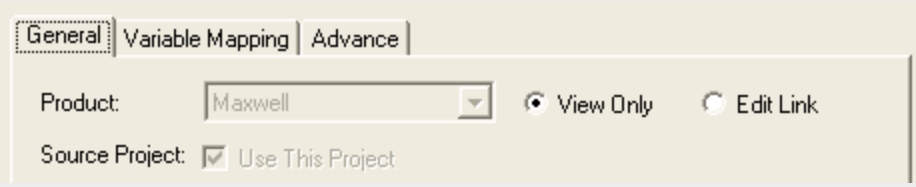
If you selected the **Use precomputed permeability data** option (refer to Permeability Options for Magnetostatic Solutions or Include DC Fields in 3D Eddy Current T-Omega Solutions), or **Import mesh**, do the following to specify the source project, design, and solution containing the information you want to use. You can also view and map variables and, for Import Mesh, specify additional mesh refinements.

General Tab

1. By default, the **Setup Link** window opens on the **General** tab with only the **This project** radio button selected.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: If a link had previously been set up, the **Setup Link** dialog opens in **View Only** mode with all settings disabled.



To enable settings, you can select **Edit Link**.

2. To select a source project do one of the following:
   - To use the current project as the source, check **Use This Project**. This disables the **Save source path to:** radio buttons and the ellipsis **[...]** button and its associated text field.
   - To specify a source project file other than the current project click the ellipsis **[...]** button to open a file browser window. When you have selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to **Open as read only**.

   Use the radio buttons to specify whether to save the source path relative to **The project directory of the selected project** or **This project**.

3. When you select a source project file, the **Source Design** and the **Source Solution** fields are filled in with default values, and their drop down menus contain any available designs and solutions. You can use the drop down menus to choose from the available designs and solutions.

   The “Default” solution is the product-dependent solution of the first Setup. That is the setup listed first in the source design's project tree (alphanumerical order). A product-specific solution of this setup becomes the default solution. In most products, it is “LastAdaptive.” In a Transient solution type, it is “Transient.”

4. Use the check box to specify whether to **Simulate source design as needed**.
5. Use the check box to specify whether to **Preserve the source design solution**. Note that in the extractor mode, the source project will be saved upon exit. Extractor mode means that the software is opened during the link solely for the purpose of solving.

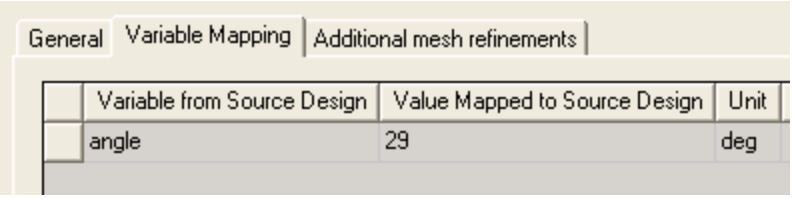
Variable Mapping Tab

The **Variable Mapping** tab lets you view any variables contained in the selected Project.

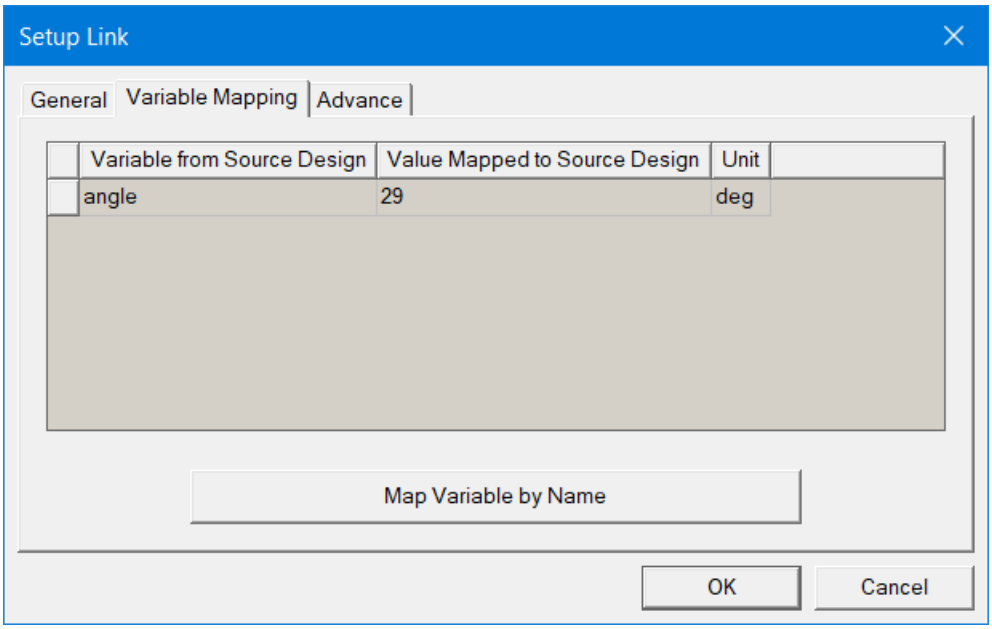
When there are variables in the source design, you can choose to “map” these variables to constant values, expressions or variables in the target designs. Variable mapping becomes

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

more important when the datalink type requires source and target design to be geometrically identical and source design is geometrically parameterized.



For linked designs with variables of the same name, you can click **Map Variables by Name** to automatically map same named variables. If a variable does not have a same named counterpart, it retains its value in the source design.



Additional Mesh Refinements Tab

> **Note:** This tab is present only for **Import mesh** link operations.

If you are setting up an Import mesh link you can use the radio buttons on the **Additional mesh refinements** tab to either **Apply mesh operation in target design on the imported mesh** (default), or **Ignore mesh operations in target design**.

Advance Tab

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** This tab is present only when using Permeability Options for Magnetostatic Solutions.

If you are setting up a link for the magnetostatic solver **Use precomputed permeability data** option, you can select the **Advance** tab to override the solved mu value from the source file with a user-specified control program. Refer to Permeability Options for Magnetostatic Solutions for details on using this feature:

Enabling the Iterative Solver

The iterative solver provides an alternative to the direct solver. When you select the **Enable Iterative Solver** option, Maxwell invokes the iterative solver. Maxwell automatically switches to the direct solver if the iterative solver fails in convergence.

For more detail, see the technical notes for *Iterative Matrix Solver*.

To enable the iterative solver:

1. On the **Solution Setup** dialog box **Solver** tab, check the **Enable Iterative Solve** check box.

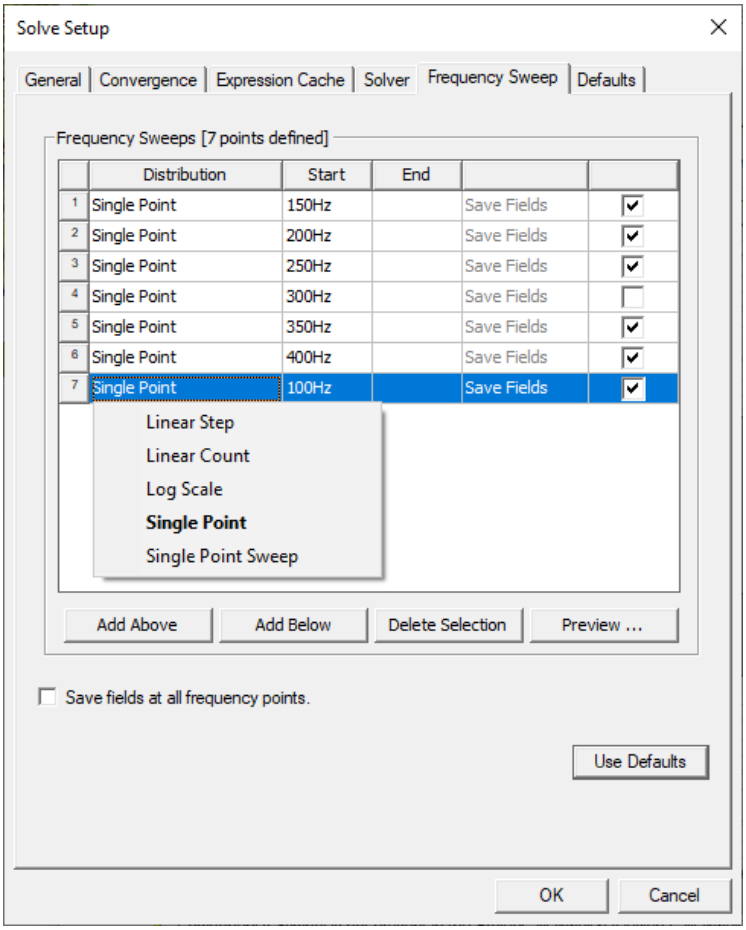
   This enables the **Relative Residual** input field.

2. Enter a value for the **Relative Residual**. The residual measures the convergence of the iterative solver. The default value is **1e-6** for the magnetostatic and electrostatic solvers and **1e-4** for the eddy current solver.

Defining Settings on the Frequency Sweep Tab for Eddy Current and AC Conduction Solutions

On the **Frequency Sweep** tab of the **Solve Setup** window:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



1. Use the **Add Above**, **Add Below**, and **Delete Selection** buttons to add or remove sweeps. Each row represents a separate sweep. Selecting a sweep's **Distribution** activates a drop-down menu allowing you to select the type of sweep. Information in the columns varies with the type of sweep.

    - **Linear Step** – A linear range of frequency points for which you specify a constant step size. Maxwell will solve the frequency point at each step in the specified frequency range, including the start and stop frequencies. For example, specifying 10 Hz for the **Start** frequency, 20 Hz for the **End** frequency, and 2.5 Hz for the step size instructs Maxwell to compute a solution for frequencies of 10, 12.5, 15, 17.5, and 20 Hz.
    - **Linear Count** – A linear range of frequency points for which you specify the number (count) of points within the frequency range defined by the **Start** and **End** frequencies. Maxwell will divide the frequency range, which includes the start and end frequencies, by the count you specify and solves each frequency point in the

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

count.

- **Log Scale** – A range of points for which you specify the **Start**, **End**, and number of samples. Maxwell assigns the sampled points using intervals based on a logarithmic scale.
- **Single Point** – Individual frequency points for which you specify the **Start** value only. A check mark in the **Save Fields** column indicates that the fields for the point will be saved.
- **Single Point Sweep** – Converts the current selection to single points. This is convenient if you want to save (or not save) fields at specific frequency points.

2. Click the **Preview** button to display the currently defined sweep(s).
3. Optionally, you can check **Save fields at all frequency points** to save fields for the entire set of sweep ranges – except for **Single Point** entries that are unselected.

Defining Settings on the Defaults Tab for Non-Transient Solutions

Default analysis parameters are used to initialize the data for new setups.

To set up the default analysis parameters, define the following parameters under the **Defaults** tab of the **Solve Setup** dialog box:

1. Click **Save Defaults** if you want to save the defaults based on the data for the current setup.
2. Click **Revert to Standard Defaults** to clear the existing values.
3. Click **OK**.

Setting Analysis Parameters for Transient Solutions

When you set up an analysis, define the parameters on the following tabs of the **Solve Setup** dialog box (which appears when you click **Maxwell** > **Analysis Setup** > **Add Solution Setup**):

- General
- Save Fields
- Advanced
- Solver
- Expression Cache
- Defaults

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Defining Settings on the General Tab for Transient Solutions

The following settings can be defined on the **General** tab of the **Solve Setup** dialog box for transient solutions:

- Setup Name
- Transient Setup (2D) or Transient Setup (3D)
- HPC and Analysis Options

Setup Name for Transient Solutions

By default, **Setup1** appears as the name of the first analysis you set up.

To change the name of the setup, type the new name in the **Name** text box on the **General** tab of the **Solve Setup** dialog box.

To disable the setup, uncheck the **Enabled** check box. Refer to *Disabling and Enabling an Analysis Setup* for additional information.

Transient Setup (2D)

To set up a 2D transient analysis, define the following parameters on the **General** tab of the **Solve Setup** window:

Adaptive Time Step

1. Determine whether you want the software to adaptively alter the time step during the simulation to optimize the solution for speed and accuracy. If so, check the **Adaptive Time Step** check box. If not, continue with step _ .
2. Enter the **Stop Time**, which is the value at which the solution will stop, and select the units.
3. Enter the **Initial Time Step**. This will be the time step used to start the simulation and begin the adaptive process.
4. Enter the **Maximum Time Step** and **Minimum Time Step** to set the allowable range the adaptive process use to alter the time step
5. Enter a value for the **Error Tolerance**. Generally this value should be smaller than the minimum time step specified by at least an order of magnitude.

Non-Adaptive Time Step

1. Enter the **Stop Time**, which is the value at which the solution will stop, and select the units.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Enter the **Time Step** for the analysis, which defines the time increments, and select the units. The time step can also be defined as the function of time, speed, and position.

> **Note:**
>
> When you have an external circuit, the Time Step is controlled from the circuit simulator, and the time step settings in the Solve Setup window are ignored. This can be controlled using the **Maxwell 2D** > **Excitations** > **External Circuit** > **Set Minimum Time Step command**.
>
> Time Step settings in the Solve Setup window are also ignored for transient-transient simulation in which case Twin Builder controls the time step.

Transient Setup (3D)

To set up a 3D transient analysis, define the following parameters on the **General** tab of the **Solve Setup** window:

1. Enter the **Stop Time**, which is the value at which the solution will stop, and select the units.
2. Enter the **Time Step** for the analysis, which defines the time increments, and select the units. The time step can also be defined as the function of time, speed, and position.

> **Note:** When you have an external circuit, the Time Step is controlled from the circuit simulator, and the time step settings in the Solve Setup window are ignored. This can be controlled using the **Maxwell 3D** > **Excitations** > **External Circuit** > **Set Minimum Time Step command**.
>
> Time Step settings in the Solve Setup window are also ignored for transient-transient simulation in which case Twin Builder controls the time step.

Defining Settings on the Save Fields Tab for Transient Solutions

Fields are automatically saved for the last completed time step for the transient analysis. The **Save Fields** tab can be used to specify additional time points at which to save fields and to limit the objects for which the fields are saved.

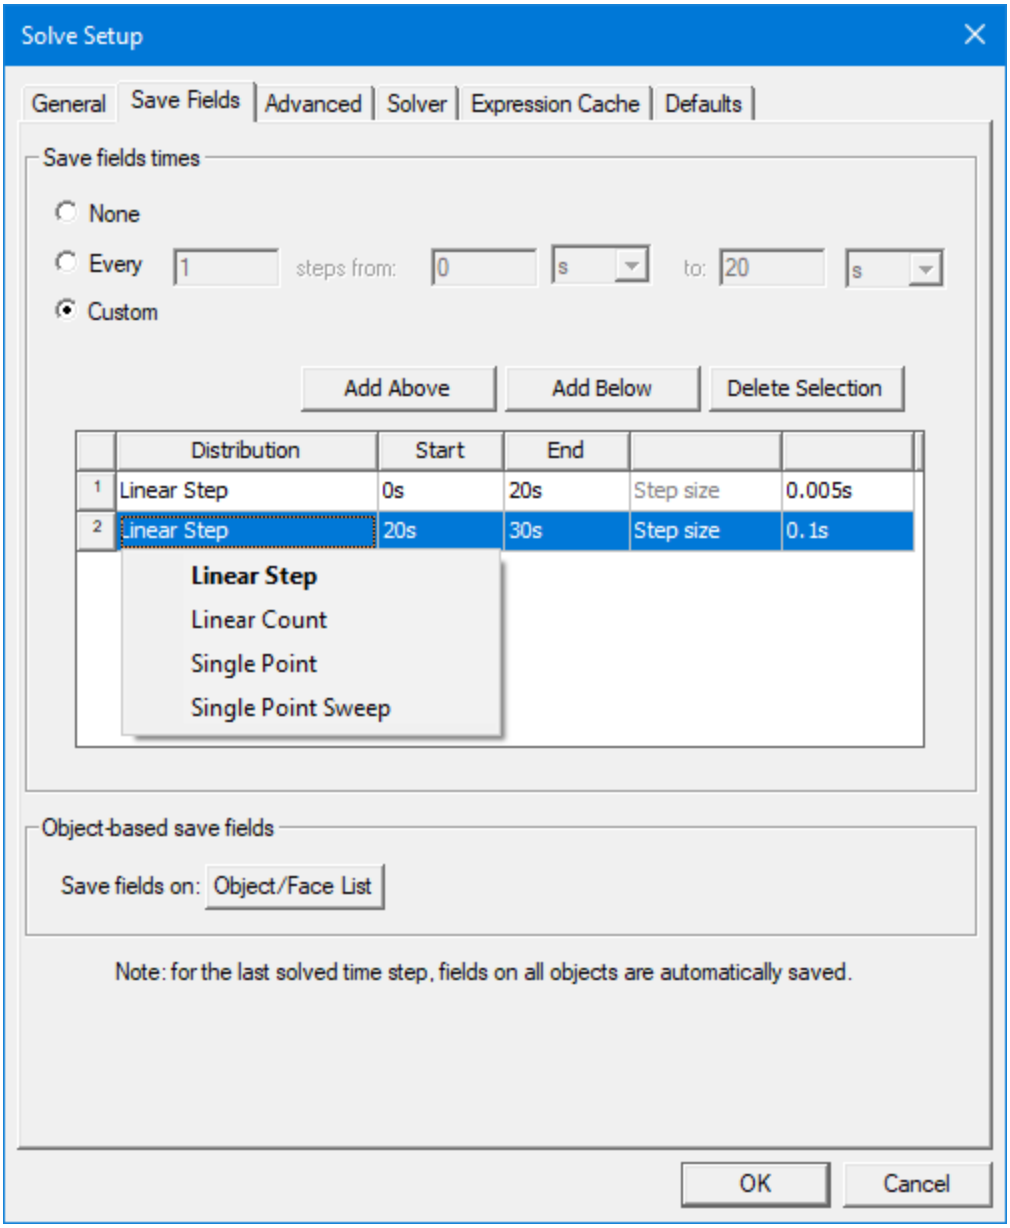
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Specify the field save times:
   - **None** - only the last completed time step is saved. This is the default.
   - Every **N** timesteps - Enter the number of steps, start time, stop time and select the units. The values can be constants, variables or expressions. Note that the results for last completed time step will also be included.

     For example, if the variable start is 2 ms, delta is 1ms, and end is 12 ms, and the solution is calculated every ms, fields would be saved at 3 ms, 5 ms, 7 ms, 9 ms, 11 ms, and 12 ms.

   - **Custom** - select this option to add time points as desired.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



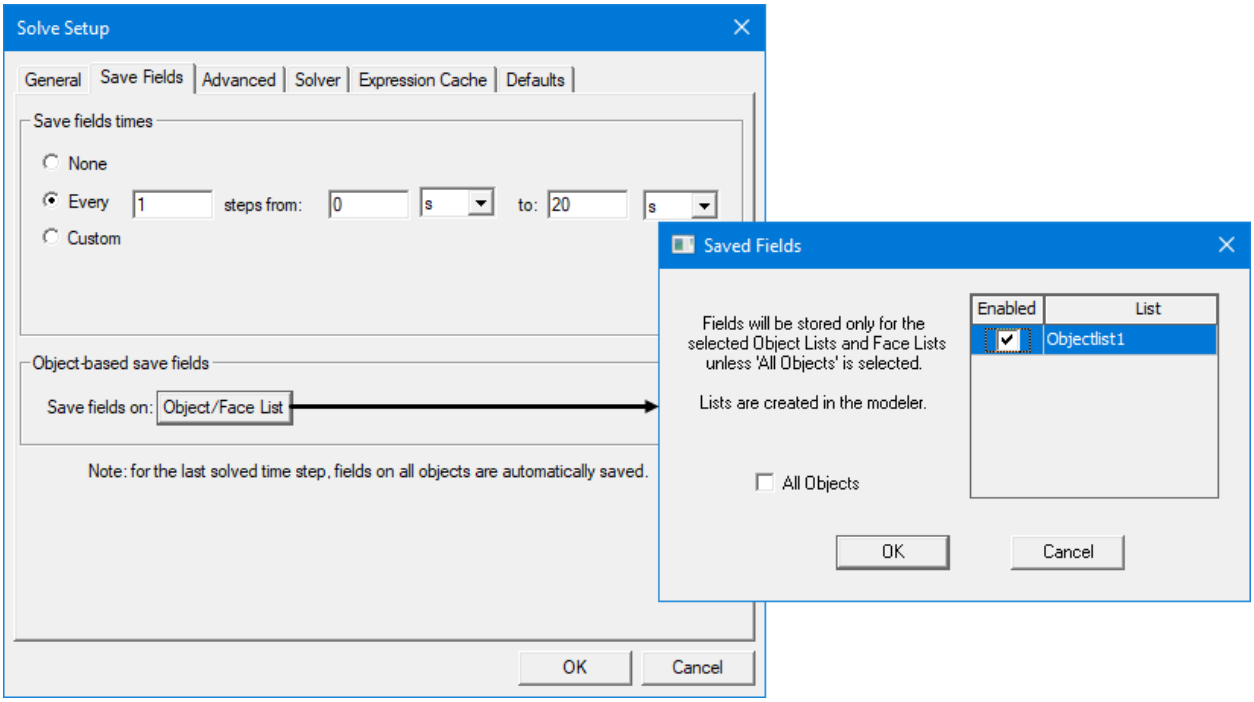
2. For **Custom**, click the **Preview** button to view the save field times. Some cases do not support a preview (for example, when variables are used to define the settings or when a user-control program is used). You can add and remove rows at your desired locations using the **Add Above**, or **Add Below**, and **Delete Selection** buttons.
3. Click **OK**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Save Fields on Object/Face List

By default, a transient solution saves fields on all objects in the design for the specified Save Field Times. To save simulation time and disk space, you can specify a list of objects and/or faces that are most relevant to the simulation so that only the fields on those entities will be saved and be available for postprocessing.

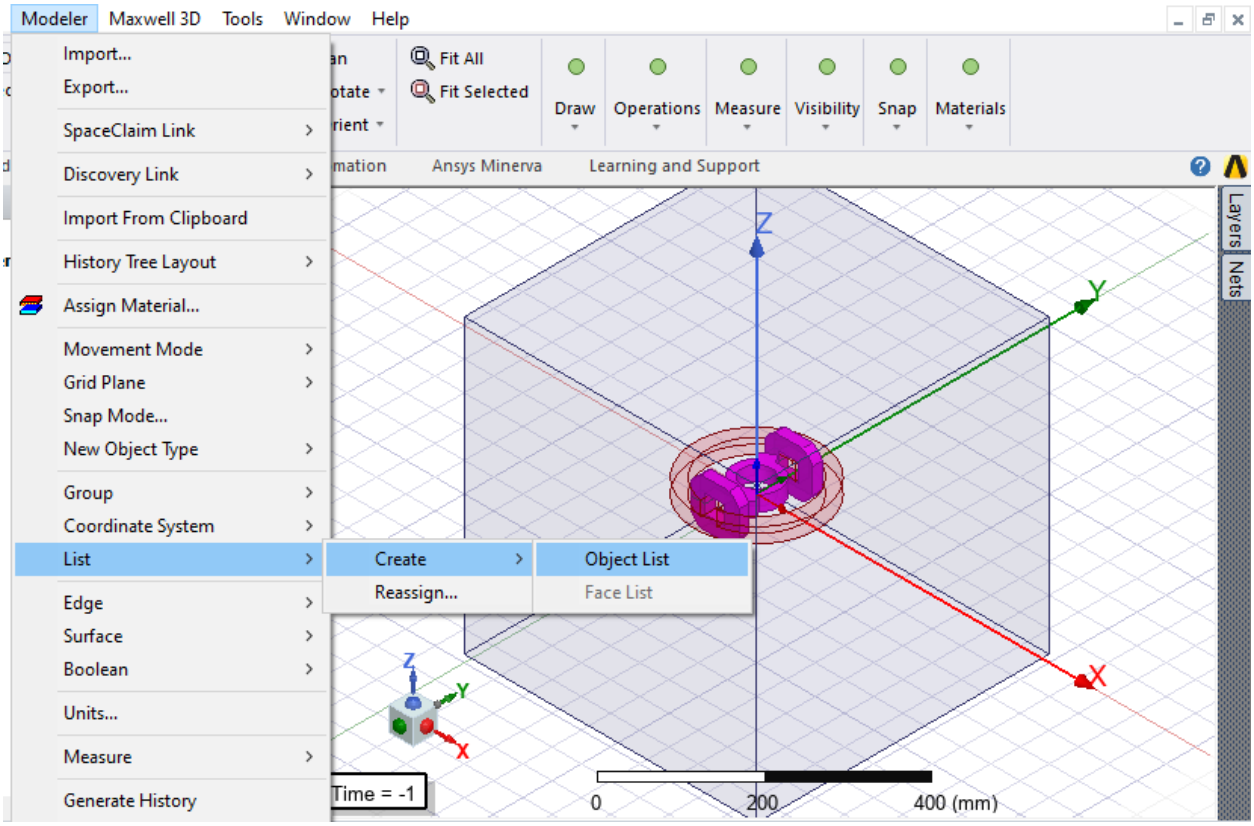
> **Note:** Field results/plots at the last completed timestep will automatically include fields for all objects.



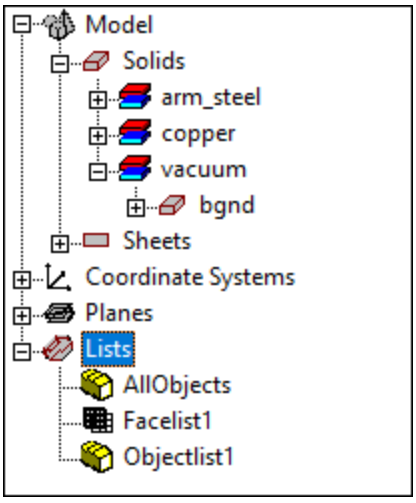
To create an object or face list:

1. Select the objects or faces you would like to save fields for.
2. Select **Modeler** > **List** > **Create** > **Object List** or **Face List**. The example that follows shows the creation of an object list.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The resulting list is added to the history window under the **Lists** entry. The list is named numerically, but you can change its name in its Properties window.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Defining Settings on the Advanced Tab for Transient Solutions

The following settings can be defined on the **Advanced** tab of the **Solve Setup** window:

- Control Program
- Start/Continue from a previously solved setup
- Import mesh

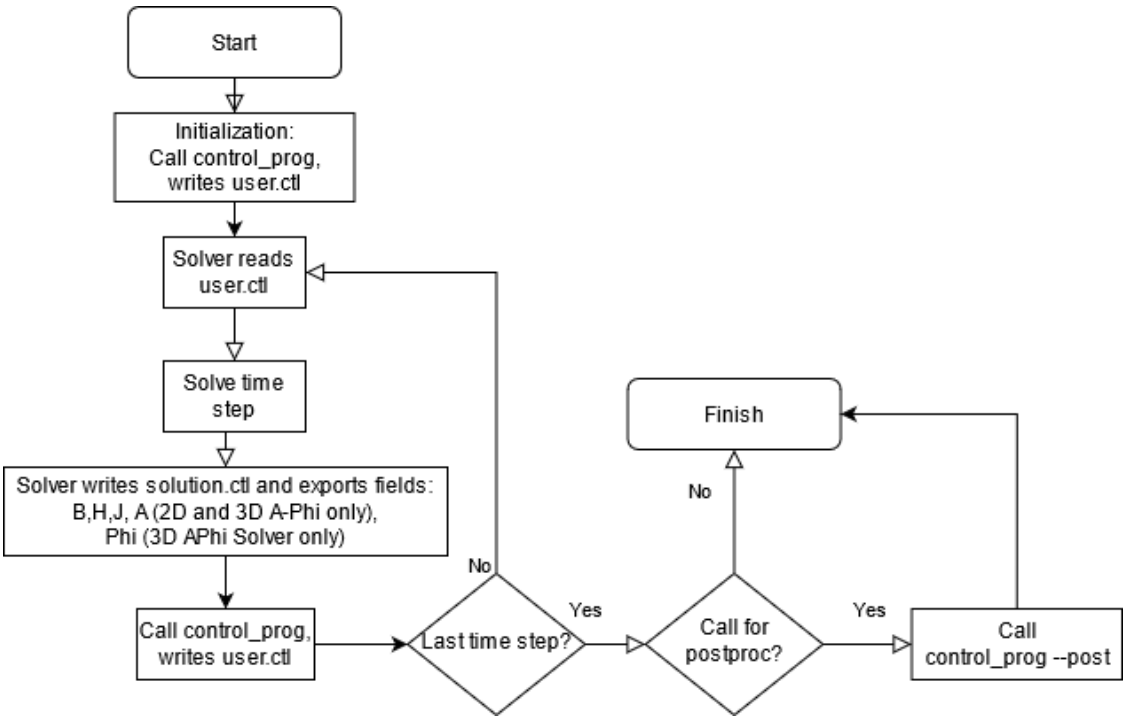
Using a Control Program in Maxwell 2D and 3D Transient Solutions

User control programs are externally created executable files, or Python (`*.py`) scripts that are called after each time step, and allow you to control the source input, circuit elements, mechanical quantities, time step, and stopping criteria, based on the updated solutions.

> **Note:** The control program is executed from a temp directory that Maxwell creates for every setup run (For parametric setup a temp folder is create for each task). The solver copies a control program file with name <**setup_name**>**.py** for Python, or <**setup_name**>**.ctrlprog** for compiled program to the temp directory.

The user control program uses the file with fixed name **user.ctl** to output control parameters to control the execution of the transient solver. Each file must use a predefined syntax which is flexible enough to cover a wide range of items.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The process shown in the flowchart can be summarized as:

1. The solver calls the user-control program on initialization.
2. The user-control program writes control information to file **user.ctl**.
3. The transient solver reads control parameters from **user.ctl**.
4. The transient solver solves the current time step.
5. The transient solver copies the previous solution to **previous.ctl** and writes out solution information to **solution.ctl**. If requested, the solver exports:
   - B, H, J fields (**bfield.ctl**, **hfield.ctl**, **jfield.ctl**, respectively)
   - A field **afield.ctl** (available in 2D and 3D A-Phi only)
   - Phi field **phifield.ctl** (available in 3D A-Phi only).
6. Return to the transient solver if the control program succeeds with exit status 0 or fails with exit status non-zero.
7. Return to step 1 for the next time step.
8. (Optional) Call script after last time step for post processing. If user selects the **Call after last time step for post processing** check box (refer to *Activating a Control Program in Transient Solutions*), then the control program is called after the simulation is completed.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you use a Python control program, the script is called with `--post` flag

(for example: `my_script.py --post`).

For a compiled control programs the script is called with `-post` flag

(for example: `my_tool.exe -post`).

Note: By default a control program script will be called by the pre-installed Python interpreter:
`<install_path>\ANSYS Inc\v251\AnsysEM\commonfiles\CPython\3_10\winx64\Release\python\python.exe`
however, the user can specify a custom python interpreter to be used by setting following environment variable:
EM_CTRL_PROG_PYTHON_PATH=<*path_to*\python.exe>

Activating a Control Program in Transient Solutions

Use the following steps to access and invoke a user-control program to use with the Maxwell 2D or 3D transient solver. User control programs can be either externally created executable (`.exe`) files, or Python (`*.py`) scripts.

To specify a control program to use to generate the solution:

1. Select the **Use Control Program** check box.

   The control program field becomes active, allowing you to enter the name of the user control program.

2. Click the **...** button to select the user control program you want to use during the solution generation process.

   The **Open** window appears.

3. Select the control program, and click **Open** to return to the **Advanced** tab of the **Solve Setup** dialog box.

4. Enter the arguments to pass to the control program in the **Arguments** text box. The solver calls the program in the following format:

   ```
   program_name specified_arguments
   ```

5. If you select the **Call after last timestep for post processing** check box, then the control program is called after the simulation is completed.

   If you use a Python control program, the script is called with `--post` flag

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(for example: `my_script.py --post`).

For a compiled control programs the script is called with `-post` flag

(for example: `my_tool.exe -post`).

6. Click **OK** to accept the configuration or **Cancel** to ignore the settings. You return to the **Solve Setup** window.

Control Program File Formats in Transient Solutions

User control programs and related files have their own file formats that should be followed when creating control program files.

- User-Control File Format
- Solution and Previous Control File Formats
- User-Control Fields Extraction Format
- Output variable values are output to a file with a fixed name of **outputvar.ctl**. The file contents use the following format:

```
<output variable name> <output variable value>
<output variable name> <output variable value>
...
```

The following summarizes the files related to user control programs for transient solutions.

File Name	Functionality
user.ctl	Input data that controls Maxwell Solver
solution.ctl	Data for global quantities such torque, current, speed, etc.
previous.ctl	Same data as solution.ctl but for previous timestep
outputvar.ctl	Contains expression cache variables
var.data	Variations information from design and project variables
afield.ctl	Magnetic potential (available only in 2D and 3D A-Phi solver)
bfield.ctl	Magnetic flux density
hfield.ctl	Magnetic field strength
jfield.ctl	Electric current density
phifield.ctl	Electric Scalar Potential (available only in 3D A-Phi solver)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

User Control File Format

The **user.ctl** file is created by the user control program. Below are descriptions of the keywords that can be used in a **user.ctl** file, and indicating the solver types for which they are valid.

Keyword	Description	2D	3D	3D A-Phi
windingSrc <winding_name> <val>***	Voltage [V]/Current [A] value for Winding	X	X	X
windingR <winding_name> <val>***	Resistance value [Ohm] for Voltage Winding	X	X	X
windingL <winding_name> <val>***	Inductance value [H] for Voltage Winding	X	X	X
loadTorque <value>	Load Torque [N*m] for rotational motion only	X	X	
loadForce <value>	Load force in MotionSetup [N] for translational only	X	X	
damping <value>	Damping coefficient [translational: N*s/m; rotation: N*m*s/rad]	X	X	
loadInertia <value>	Load Inertia in MotionSetup [kg*m²] for rotational only	X	X	
mass <value>	Mass in MotionSetup [kg] for translational only	X	X	
speed <value>	Speed of the moving object [translation - m/s; rotation - rad/s]	X	X	
position <value>	Position of the moving object [[translation - user unit (from Motion Setup); rotation – rad]	X	X	
timeStep <value>	Time step size [s]	X	X	X
stop <0 or 1>	Stop solver if value is equal to 1	X	X	X
exportFieldAtMeshNodeOnAllObjects	Request to export fields on all objects in design[1]	X	X	X
exportFieldAtMeshNodeOnObject <objectID>*	Request to export fields on specific object	X	X	X

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Keyword	Description	2D	3D	3D A-Phi
NStep <value>	Export fields only every N steps (works only in conjunction with exportFieldAtMeshNode<...>)	X		
FieldSelect <value>**	Export only specific field (one of A,B,H,J) (works only in conjunction with exportFieldAtMeshNode<...>)	X		
Binary <0 or 1>	Export fields in binary format (works only in conjunction with exportFieldAtMeshNode<...>)	X		
voltageSrc <voltage_name> <source_value>***	Voltage source value [V]			X
currentSrc <current_name> <source_value>***	Current source value [A]			X
Full line could be repeated for *multiple object IDs; **multiple fields; ***multiple excitation names				

[1] Regarding a skewed, multi-slice model, for the first slice, the output file name is "FieldName.ctl", which is same as that in non-skew model, and for the other slices, the output file name is "FieldName_%d.ctl", where %d is a number from 1 to (numSlice-1).

The following **user.ctl** file example:

- Sets the time step to 5 ms.
- Sets Resistance to 1 μOhm and Inductance to 1 μH for Winding A and Winding B.
- Sets Voltage for Winding A to 10 V and for Winding B to -10 V.
- After time step is completed all fields for the object with ID 88 will be exported.

```
begin_data
 windingSrc WindingA 10
windingR WindingA 1e-6
windingL WindingA 1e-6
windingSrc WindingB -10
windingR WindingB 1e-6
windingL WindingB 1e-6
exportFieldAtMeshNodeOnObject 88
timeStep 5e-3
stop 0
end_data
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

User Control Fields Extraction Format

The **user.ctl** file is created by the user control program. Depending on the solver the following field types are available during export:

Field	2D	3D	3D A-Phi
B – Magnetic Flux Density	X	X	X
H – Magnetic Field Strength	X	X	X
J – Current Density	X	X	X
A – Magnetic Vector Potential	X		X
Phi - Electric Scalar Potential			X

To extract fields from Maxwell, the control program must create a **user.ctl** file with one of the two following syntax strings:

> **Note:** You can combine field export keywords with other keywords.

Extract fields on all objects

user.ctl

```
begin_data
exportFieldAtMeshNodeOnAllObjects
end_data
```

Extract fields by object ID

user.ctl

```
begin_data
exportFieldAtMeshNodeOnObject <objectID>
exportFieldAtMeshNodeOnObject <objectID>
end_data
```

You can get the desired object IDs as follows:

1. Select **Tools** > **Open Command Window**.
2. In the following example code snippet, replace "Stator" in the `object_name` with the name of the desired object.

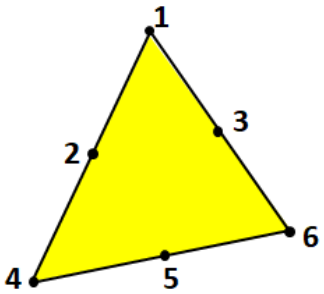
```
object_name = "Stator"
oProject = oDesktop.GetActiveProject()
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
oDesign = oProject.GetActiveDesign()
oEditor = oDesign.SetActiveEditor("3D Modeler")
object_id = oEditor.GetObjectIDByName(object_name)
print(object_id)
AddInfoMessage(str(object_id))
```

3. Copy and paste the code snippet into the Command Window and execute.
4. Repeat as needed for additional objects.

Data Structure and Nodes Order for 2D Fields Extraction



Node order in Maxwell 2D element

The Maxwell 2D solver writes the data and updates field files (**afield.ctl**, **bfield.ctl**, **hfield.ctl**, **jfield.ctl**) at each time step with the following structure:

Time
M
ID K x_1 y_1 x_4 y_4 x_6 y_6 B_{x1} B_{y1} B_{x2} B_{y2} B_{x3} B_{y3} B_{x4} B_{y4} B_{x5} B_{y5} B_{x6} B_{y6}

where:

- Time – is the time corresponding to the time-stepping FE solution
- M – is the total number of elements
- ID – is the object ID
- K – is the element number
- x_i, y_i – are the coordinates of node i, for i in [1, 4, 6]
- B_{xi} B_{yi} – is the field X, Y component value of node i, for i in range 1 to 6

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

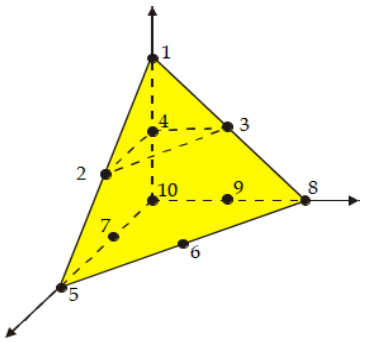
> **Note:** For vector potential, the **afield.ctl** file has one component of the field, which is A_z.

> **Note:** Coordinates of the element are given for the vertices (1, 4, 6) only. Middle points (2, 3, 5) can be calculated from the other given coordinates since they are located in the middle as shown above, for example: $x_2 = (x_1+x_4)/2$.

The following is an example for **bfield.ctl** data extracted in an object with ID 761 that consists of 2 elements at t = 0.04 sec.

```
0.040000
2
761 550 0.002 0.037 0.003 0.037 0.003 0.037 -2.220 0.488 -1.540 0.783 -1.799 0.950 -0.860 1.077 -1.119 1.245 -1.379 1.413
761 573 0.018 0.032 0.021 0.032 0.020 0.031 -0.695 1.266 -0.626 1.433 -0.810 1.378 -0.556 1.599 -0.740 1.544 -0.924 1.490
```

Data Structure and Nodes Order for 3D Fields Extraction



Node order in Maxwell 3D element

The Maxwell 3D solver writes the data and updates field files (**bfield.ctl**, **hfield.ctl**, **jfield.ctl**) at each time step with the following structure:

Time
M
ID K x_1 y_1 z_1 x_5 y_5 z_5 x_8 y_8 z_8 x_{10} y_{10} z_{10} B_{x1} B_{y1} B_{z1} B_{x2} B_{y2} B_{z2} … B_{xi} B_{yi} B_{zi} … B_{x10} B_{y10} B_{z10}

where:

- Time – is the time corresponding to the time-stepping FE solution
- M – is the total number of elements

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- ID – is the object ID
- K – is the element number
- x_i, y_i, and z_i– are the coordinates of node i, for i in [1, 5, 8, 10]
- B_{xi} B_{yi}, B_{zi} – is the field X, Y, Z component value of node i, for i in range 1 to 10

> **Note:** The coordinates of the 3D element are given for the vertices (1, 5, 8, 10) only. Middle points (2, 3, 4, 6, 7, 9) can be calculated from the other given coordinates since they are located in the middle as shown above, for example: $x_2 = (x_1+x_5)/2$

Solution and Previous Control File Formats

The **solution.ctl** and **previous.ctl** files are created by the transient solver. Below is a list of keywords and definitions applicable to these files.

Keyword	Description	2D	3D	3D A-Phi
time <value>	Current time in simulation [s]	X	X	X
position <value>	Position when motion setup is assigned[translation - user unit (from Motion Setup); rotation – rad]	X	X	
speed <value>	Speed when motion setup is assigned[translation - m/sec; rotation - rad/sec]	X	X	
torque moving_group <value>	Torque [N*m]	X	X	
force moving_group <value>	Force on moving objects [N]	X	X	
strandLoss <value>	Stranded loss for all objects [W]	X	X	X
solidLoss <value>	Solid loss for all objects [W]	X	X	X
coreLoss <value>	Core loss for all objects [W]	X	X	X
timeStep <value>	timestep size [s]	X	X	X
windingFlx <winding_name> <value>*	Winding Flux value [Wb]	X	X	X
windingEmf <winding_name> <value>*	Winding EMF value [V]	X	X	X
windingI <winding_name> <value>*	Winding Current value [A]	X	X	X
windingV <winding_name> <value>*	Winding Voltage value [A] (voltage windings only)	X	X	X
voltageV <voltage_name> <value>*	Voltage value on voltage excitation [V]			X
voltageI <voltage_name> <value>*	Current value on voltage excitation [A]			X
currentV <current_name> <value>*	Voltage value on current excitation [V]			X
currentI <current_name> <value>*	Current value on current excitation [A]			X
* Could be repeated for multiple excitation names				

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

An example `solution.ctl` file for 2D/3D solvers:

```
begin_data
 time <current_time>
 strandLoss <value>
 solidLoss <value>
 coreLoss <value>
 torque <torque>
 speed <speed>
 position <position>
 windingI <winding_name> <value>
 windingEMF <winding_name> <value>
 windingFlx <winding_name> <value>
end_data
```

An example `solution.ctl` file for the A-Phi solver:

```
begin_data
 time <current_time>
 strandLoss <value>
 solidLoss <value>
 coreLoss <value>
 windingI <winding_name> <value>
 windingEMF <winding_name> <value>
 windingFlx <winding_name> <value>
 voltageV <voltage_name> <value>
 voltageI <voltage_name> <value>
end_data
```

Start/Continue from a Previously Solved Setup

Enabling the **Start/Continue from a previously solved setup** option allows the source design solution to be linked to a set of different target designs, where the user can continue the solution based on a different parameter/circuit setup. For example, to speed up the process of either a 2D or 3D transient solution reaching a steady state, you can use this option to link a 2D (or 3D) eddy current solution as the initial condition for a corresponding transient solution.

Source and target designs linked through this workflow are required to have the same FEM degrees of freedom. Therefore, the excitations on the source and the target need to be of the same type. If an external circuit is used to excite a winding excitation, the same external circuit netlist needs to be coupled in both designs. However, numerical values (and parameters' values) defining the excitations can be different.

If the **Start/Continue from a previously solved setup** check box is selected, the **Setup Link** button becomes active, and the **Setup Link** dialog box automatically appears in which the user

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

can link the current design to a project solution set based on a different parameter/circuit setup. Refer to Setup Link for Transient Solutions for details on setting up this link.

> **Note: Power loss** and **Force density distribution** cannot be computed when **Start/Continue from a previously solved setup** is enabled.

Import Mesh for Transient Solutions

The **Import mesh** check box can be selected in the "target" design if the mesh for the same geometry is to be used in the analysis. This setup is designed to be generally applicable to all transient solutions. This feature is not necessarily related to the dynamic demagnetization distribution capability.

If the **Import mesh** feature is selected, the **Setup Link** button becomes active, the **Setup Link** dialog box, which includes an **Additional mesh refinements** tab automatically appears, and the mesh will be imported from the source design to the target design. Refer to Setup Link for Transient Solutions for details on setting up this link.

> **Note:** The usual way to create geometrically equivalent designs is by copying all geometry objects from one design and then using **Import From Clipboard** in the other design.

Compute Data For Link

If the current design is to be used as a “source” design for calculating the operating point of a recoil line, the **Dynamic demagnetization distributionbased on B-H curve input** check box should be checked, which instructs the solver to find the worst dynamic demagnetization operation point element-by-element during the entire transient solution, then use the data for the target design.

In the “source” design the recoil curve data will be computed for all nonlinear permanent magnet objects. This information is stored element by element in searching for a “worst case” demagnetization during the entire transient analysis and can be used in the “target” design in a subsequent transient solution.

Compute Data For Link - Demagnetization Option (Transient)

If the current design is to be used as a “target” design, you must provide information for the datalink to the “source” design.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the **Demagnetization Option** section, select one of the following two radio buttons:
   - **Nonlinear B-H curve**. Using B-H curves is the default. Select this option when setting up a normal transient nonlinear application with or without motion.
   - **Use dynamic magnetization data**. Select this option in the target design if there is a corresponding "*source*" design with the **Compute Data For Link: Dynamic demagnetization distribution based on object BH curve input** check box selected. The mesh between the two linked designs is the same. However, the source and target designs can have different timestep settings. If the source design is not solved, the data link functionality used here tries to automatically solve the source design and then use the "worst case" dynamic magnetization data of the entire transient solution in the target design. Thus, once the two projects have been set up properly, it is not absolutely necessary to solve the source design first. In this case, starting the target design solution process initiates the transient solution process of the source design and then solves the transient solution of the target design automatically.

     > **Note:** If you select **Use dynamic magnetization data**, the **Import mesh** check box is automatically selected, and the **Setup Link** button becomes active. After completing the Setup Link dialog box, you may unselect the Import Mesh if desired without affecting the link status.

2. In **Compute Data For Link** section, if you selected **Nonlinear B-H Curve** in the previous step, you can select **Dynamic demagnetization distribution based on object BH curve input**, which instructs the solver to find the worst dynamic demagnetization operation point element-by-element during the entire transient solution, then use the data for the target design.
3. Make any other desired changes.
4. When you are finished specifying solution settings, click **OK** to close the **Solve Setup** dialog box and finalize the solution setup.

   > **Note:** The data link automatically attempts to solve the linked (source) design if necessary (if no solution exists), then automatically copies the mesh and necessary data (new values for the magnetization vector) in the target design, and finally perform the requested calculation in the target design. This data link allows you to calculate the magnetic field to be performed in a design with, for example, modified sources while keeping the magnetization in a "frozen" state calculated in a different design (the same geometry and mesh but with different sources).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** The data link used to link source and target designs uses data caching technology. Therefore, after the design changes, to make sure the new data (from the source design) is used in the target design, right-click the **Analysis** field of the target design in the project tree, and select **Clear Linked Data**. This flushes existing data.

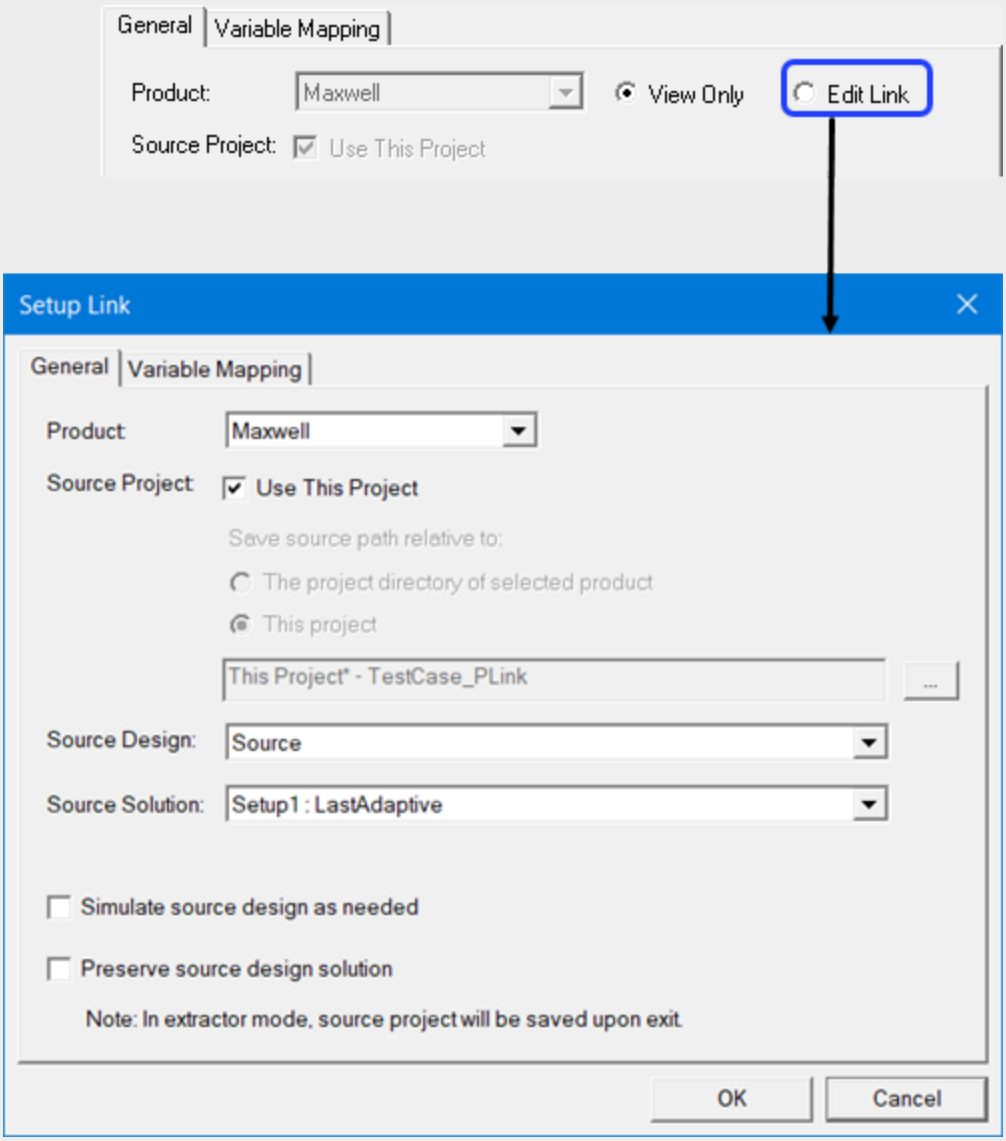
Setup Link for Transient Solutions

If you selected **Start/Continue from a previously solved setup**, or **Import mesh**, do the following to specify the source project, design, and solution containing the information you want to use. You can also view and map variables and, for Import Mesh, specify additional mesh refinements.

1. If the **Setup Link** dialog is not already open, click **Setup Link** (located at the bottom of the **Solve Setup** dialog box **Advanced** tab) to open the **Setup Link** dialog box.
2. By default, the **Setup Link** dialog opens on the **General** tab with only the **This project** radio button selected.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: If a link had previously been set up, the **Setup Link** dialog opens in **View Only** mode with all settings disabled.



To enable settings, you can select **Edit Link**.

3. To select a source project do one of the following:

    - To use the current project as the source, check **Use This Project**. This disables the **Save source path relative to:** radio buttons and the ellipsis **[...]** button and its associated text field.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To specify a source project file other than the current project click the ellipsis **[...]** button to open a file browser window. When you have selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to **Open as read only**.

  Use the radio buttons to specify whether to save the source path relative to **The project directory of selected product** or **This project**.

4. When you select a source project file, the **Source Design** and the **Source Solution** fields are filled in with default values, and their drop down menus contain any available designs and solutions. You can use the drop down menus to choose from the available designs and solutions.

   The **Default** solution is the product-dependent solution of the first Setup. That is the setup listed first in the source design's project tree (alphanumerical order). A product-specific solution of this setup becomes the default solution. In most products, it is **LastAdaptive**.

5. Use the check box to specify whether to **Simulate source design as needed**.
6. Use the check box to specify whether to **Preserve source design solution**. Note that in the extractor mode, the source project will be saved upon exit. Extractor mode means that the software is opened during the link solely for the purpose of solving.
7. The **Variable Mapping** tab lets you view any variables contained in the selected Project.

   When there are variables in the source design, you can choose to “map” these variables to constant values, expressions or variables in the target designs. Variable mapping becomes more important when the datalink type requires source and target design to be geometrically identical and source design is geometrically parameterized.

   For linked designs with variables of the same name, you can click **Map Variable by Name** to automatically map same named variables.

8. The **Additional mesh refinements** tab, which is present only if you chose Import Mesh on the **Solve Setup** dialog **Solver** tab, allows you to choose either to **Apply mesh operations in target design on the imported mesh** (default) or **Ignore mesh operations in target design**.
9. Click **OK** to close the **Setup Link** dialog box and return to the **Solve Setup** window's **Advanced** tab.

Using an Eddy Current Solution as the Initial Condition for a Transient Solution

In order to speed up the process of either a 2D or 3D transient solution reaching a steady state, you can set the solution from a 2D or 3D eddy current solver as the initial condition for the corresponding transient solver.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: Because the eddy current solution corresponds to a stationary operating condition (zero speed), in order to generate the initial condition for the transient solution with non-zero speed, a transformation of conductivity on the moving objects where eddy current is taken into account is required in the eddy current simulation. The transformation is

$$\sigma_0 = \sigma \cdot s_n$$

where σ_0 is the transformed conductivity from speed n to speed zero, which is to be set in the eddy current simulation, σ is the real conductivity in transient simulation, and s_n is the slip, defined as:

$$s_n = \frac{n_s - n}{n_s}$$

where n_s is the synchronous speed.

If there is an end connection, the end resistance R used in the transient simulation also has to be referred to the value R_0 associated with zero speed before being used in the eddy current solution by:

$$R_0 = R/s_n$$

Prerequisites

- Source design - Maxwell 2D (or 3D) Eddy Current (Last Adaptive solution only)
- Target design - Maxwell 2D (or 3D) Transient
- The source and target designs must be identical (identical geometries, boundaries, excitations, windings, etc).

To setup and use a 2D (or 3D) eddy current solution as the initial condition for a corresponding 2D (or 3D) transient solution:

1. Create an eddy current source design, and ensure that **Solve Matrix: After last pass** is selected on the **General** tab of the eddy current **Solve Setup** dialog.
2. Solve the eddy current design.
3. Create a transient target design, whose geometry, boundary conditions, excitations, windings, etc., are identical to the the source eddy current design.
4. On the transient target design's **Solve Setup** dialog box, **Advanced** tab, click **Start/Continue from a previously solved setup** to open the **Setup Link** dialog.
5. On the **Setup Link** dialog **General** tab, select the source eddy current design and solution (Last Adaptive solution only). Refer to "Setup Link for Transient Solutions " on page 14-70

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

for details on setting up this link.

6. Solve the target transient design.

Note:

- If the source and target designs are not identical, an error message displays.
- If the eddy current source design has not been solved, an error message displays.
- If a legacy eddy current design solved with a previous release of Maxwell is used as the source design, you must re-solve the eddy current design before solving the target transient design or an error message will be displayed.

Defining Expressions for Transient Solutions

You can specify additional evaluation criteria through the use of expressions and output variables.

To set expressions as evaluation criteria:

1. Right-click on the Analysis icon in the Project Manager tree to open the **Solve Setup** window.
2. Click the **Expression Cache** tab and click the **Add...** button to open the **Add to Expression Cache** dialog box.
3. Specify the Context for the expression, including **Report Type**, **Solution**, and **Parameter**.
4. Under the **Trace** tab, select from the **Category**, **Quantity**, and **Function** lists to create expressions.

   Selecting a listed category lists the Quantities and Functions available for each category. If you have defined one or more output variables, you can see them by selecting the **Output Variables** category. The **Output Variables** button opens a dialog box that lets you define output variables. See Specifying Output Variables.

   When you have created an expression, it appears in the **Expression** field of the **Trace** tab. If desired, you can use the **Range Function** button to select range functions to apply to the expression.

   Under the **Calculation Range** tab, you can view the values of available sweep variables. Clicking the ellipsis **[...]** button in the **Edit** column opens a list of values from which you can select.

5. When finished defining the expression that you want to add to the cache, click the **Add Calculation** button.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This adds the selected expression and the associated context to a table in the **Expression Cache** tab. You can define additional expressions with contexts and add them in the same way.

6. When finished adding expressions, click **Done** to close the **Add to Expression Cache** dialog box.

   The **Expression Cache** tab lists the expressions you have added in a table:

   - The **Title** field is editable, by default showing the name as built from the expression (with underscores removed).
   - The **Expression** field shows the full expression. If necessary, you can resize the **Solve Setup** window. You can also resize each columns in the table.
   - The **Context** column for non-field types lists the parameter type specifying the force, torque or matrix setup. For these types the context also can be given as part of the expression. For example, the expression *Force1.Force_x* with a context of *None* is equivalent to an expression of *Force_x* with a context of *Force1*.
     For field quantities, the **Context** can be the geometry on which to evaluate the field quantity - a point or line. If you use a line you need to use some range function to reduce the dimensionality to a single value (or use the Calculation Range tab to specify a single point along the line). Note that, if you create a named expression in the field calculator that already evaluates to a single value, then the **Context** here will likely be *None*.
   - The **Intrinsics** column shows a clickable button that opens an **Edit Calculation Range** dialog box. If the **Intrinsics** column button shows **None** you cannot edit the value. If the button shows variables, click the ellipsis **[...]** in the **Edit** column to display a list of the variable values from which you can select. Click **OK** to close the **Edit Calculation Range** dialog box and apply your selections to the **Expression Cache**.
     The **Intrinsics** field lists the values you may have set in the **Calculation Range** tab when you added the expression. This is used to set the values of “other” sweeps. Usually there are no other sweeps because the values of the variables are set in the definition of each variation. In some cases you may need to specify the values of “other” sweeps. For field values with a line for the context, you can specify the (normalized) distance along the line For eddy current field quantities you can also specify the phase for the calculation.

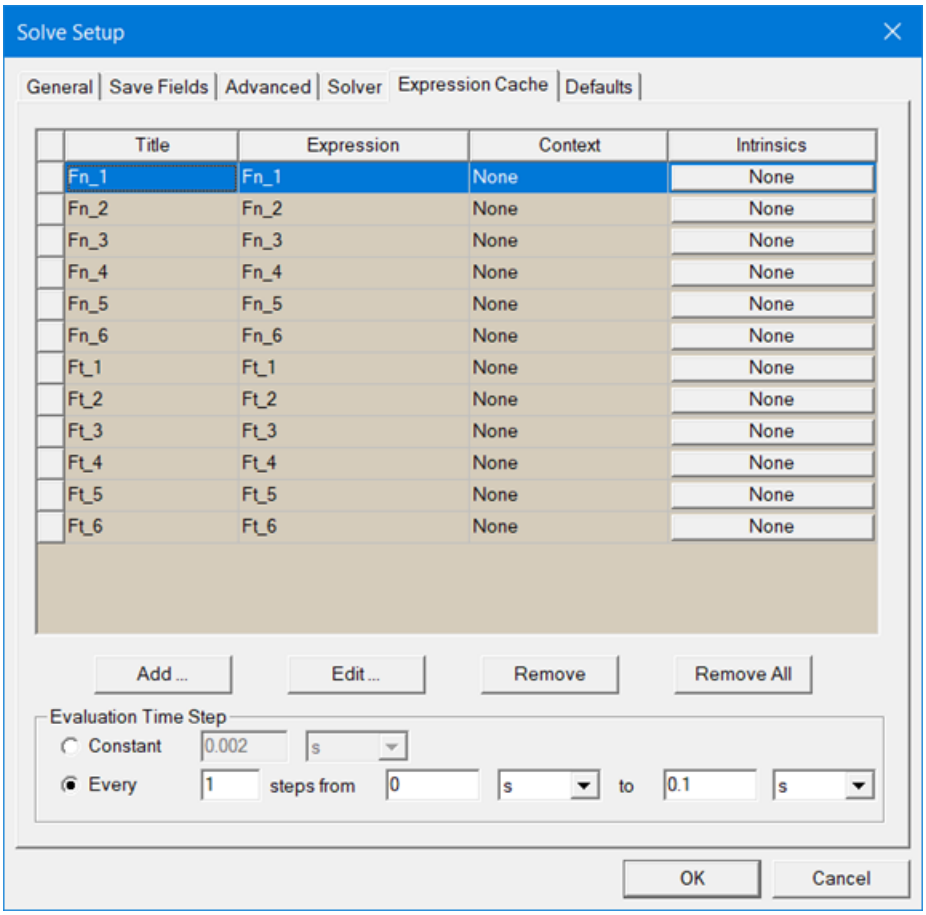
7. In the **Evaluation Timestep** panel, set how often the solver is to output field solutions. Select **Constant** to output solutions at a preset time interval (e.g., every 0.1 s); or **Number of solve steps** to output solutions each preset number of timesteps (for example, every three timesteps).
8. Optionally, buttons allow you to **Edit** and **Remove** selected expressions, and to **Remove All** expressions in the table.
9. When finished defining expressions, click **OK** to close the **Solve Setup** window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Speeding Up a Maxwell 2D Parametric Transient Design that Uses Expression Cache

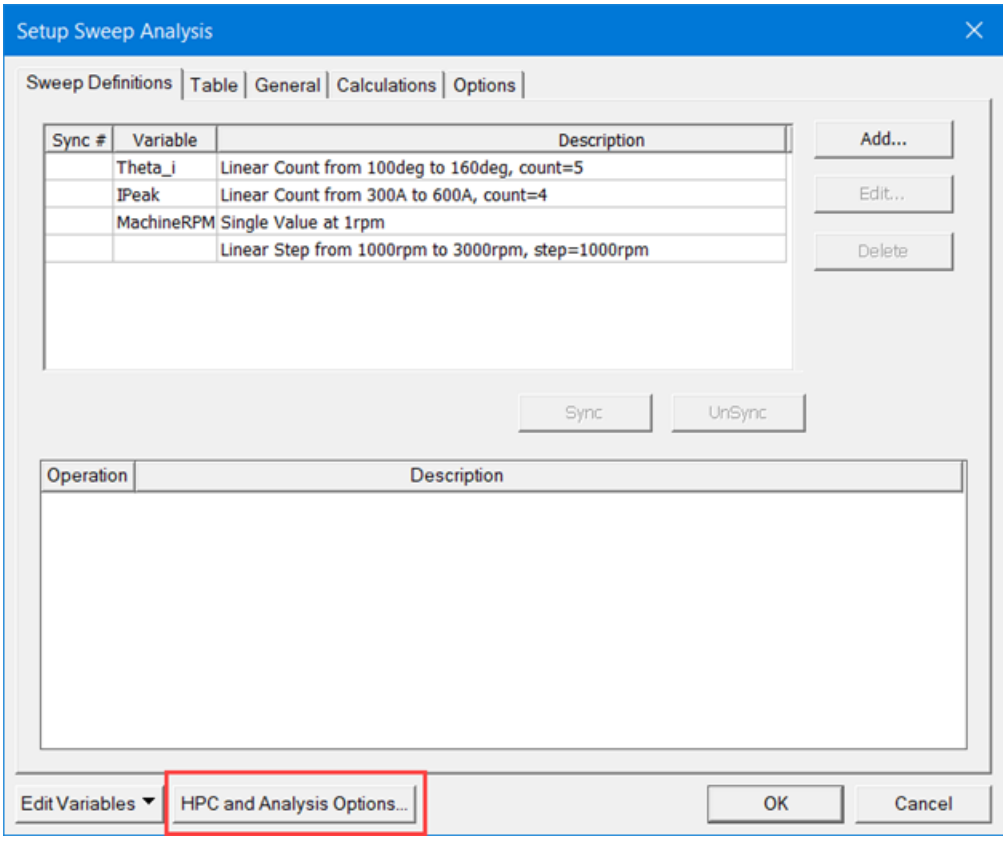
A Optimetrics\Parametric analysis of a Maxwell 2D transient design that uses expression cache can require substantial simulation time. To cut down on simulation time for this type of analysis, use the **Optimetrics Variations** and **Single level only** HPC settings.

The following example demonstrates how to configure these settings. The Solve Setup **Expression Cache** tab has been configured to have several expressions:



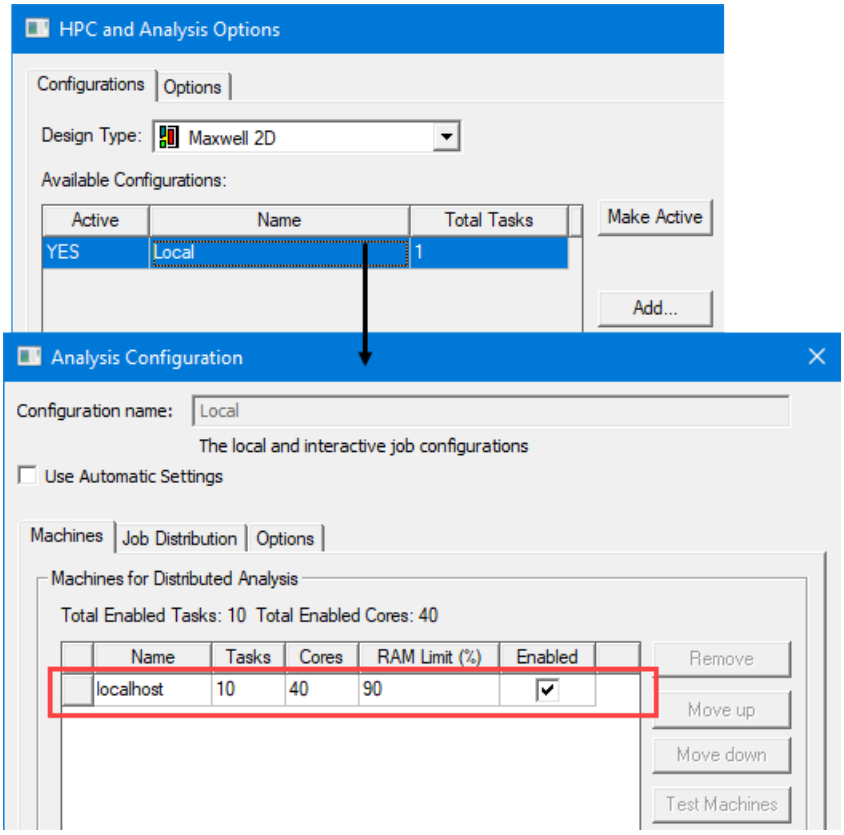
1. Open the **Optimetrics**\ParametricSetup window, and click **HPC and Analysis Options**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



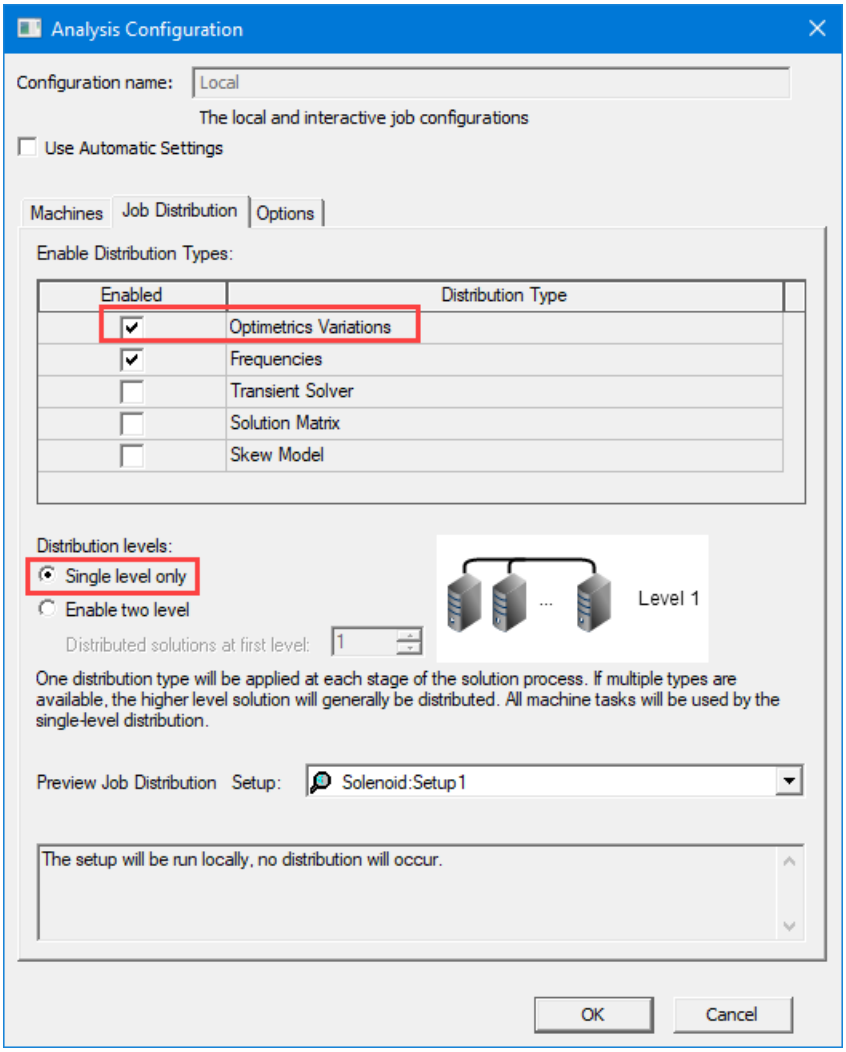
2. In the window that opens, double-click an active configuration to open the Analysis Configuration.
3. From the **Machines** tab, specify multiple tasks to run.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. Click the **Job Distribution** tab.
5. From the Enable Distribution Types list, select **Optimetrics Variations**. And for Distribution, select **Single level only**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



6. In the Project Manager tree, right-click the Optimetrics\ParametricStudy, and select **Analyze**.

Defining Settings on the Solver Tab for Transient Solutions

To define solver settings on the **Solver** tab of the **Solve Setup** dialog box for transient solutions:

1. Enter a residual value in the **Nonlinear Residual** text box.

   To specify a time-dependent nonlinear residual, type in a function of TIME, such as **sin (TIME)**, or enter an expression that uses a dataset, such as **pwlx(*<name of dataset>*, TIME)**. A time-dependent variable can also be used.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can save the time-dependent expression as the default for the nonlinear residual by clicking the **Save Defaults** button on the **Defaults** tab of the **Solve Setup** dialog box. A new solve setup will then use the user-saved default if the expression can be evaluated. A value of “0” will be used when the expression cannot be evaluated. For example, if the expression depends on a variable that is not yet defined in the design/project.

Changing the definition of the residual will NOT invalidate any existing solution; and the next simulation will continue from the stop time of the last simulation.

Changing the definition of a *variable* used for the residual value will NOT invalidate any existing solution. The next simulation will be for a different “design variation”.

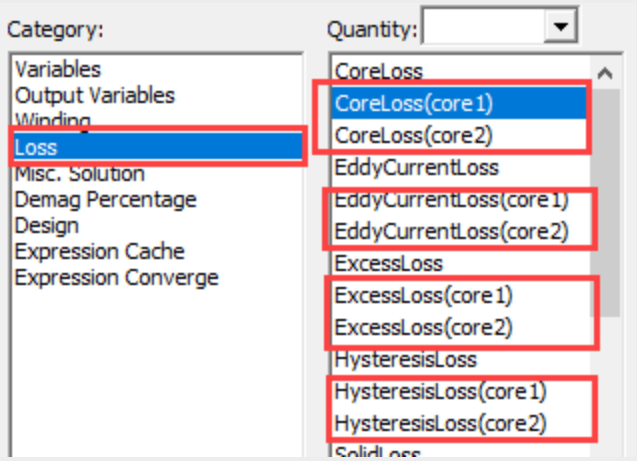
Changing the definition of a *dataset* used for the residual will NOT invalidate any existing solution. The next simulation will continue from the stop time of the last simulation.

If a variable is used, you can choose to plot a family of curves based on the solved variations of the variable.

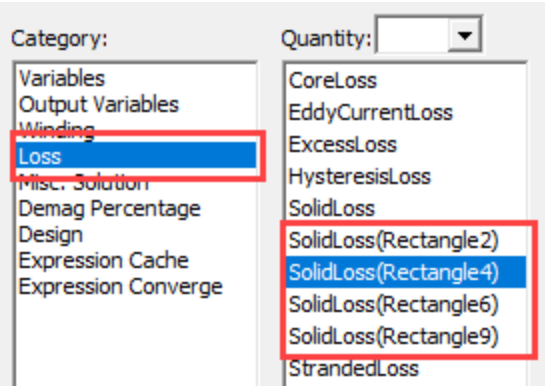
2. For both 2D and 3D Transient designs, you can select the **Smooth BH Curve** check box. This allows the solver to smoothen the list of points to make a refined B-H curve for better solving. If this option is not selected, the solver just uses the discrete points.
3. Select or clear **Output per object core loss**. When this check box is selected:
    - For steel material, the solver will output core loss for each object, as well as the individual components (hysteresis loss, eddy current loss, and excess loss).
    - For ferrite material, the solver will output only core loss.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: To report core loss on objects, the objects must be selected in the **Set Core Loss** dialog box. The loss quantities for the core loss objects will show in the reporter.

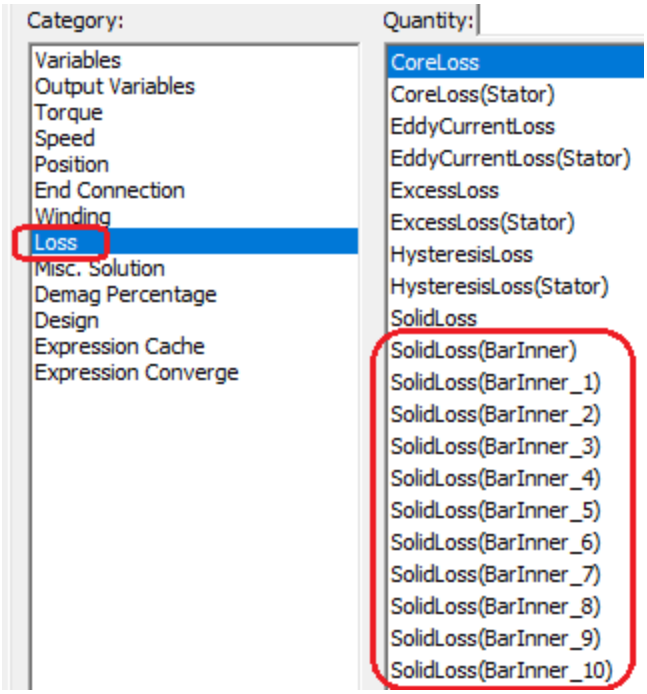


4. Select or clear **Output per object solid loss**. When this check box is selected, solid loss will be output for :
    - The solid loss quantities of the objects selected in the Set Eddy Effects dialog will show in the reporter. (Objects selected should not belong to stranded winding or stranded conductor.)
    - Coil objects in solid windings.
    - For 2D designs:
        - Solid loss quantities of the coil objects assigned with the solid Current Excitation will show in the reporter.

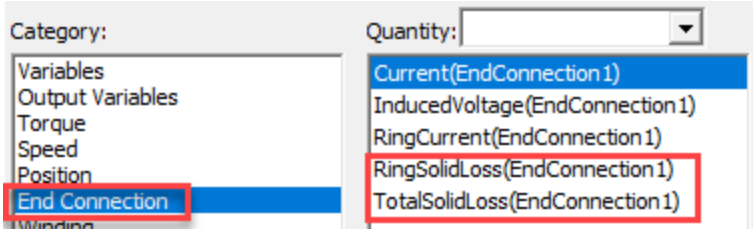


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Each bar in an end connection will be considered as a separate object for solid loss output.



- All ring segments in one end-connection will be combined together as one virtual object for solid loss output.



If there are N end-connections (such as double cages), there will be N virtual objects.

5. Select or clear the **Output error** check box. When this check box is selected, the transient solver generates the output error data, which is then sent back to the desktop. The data can be viewed or used in the post processor, just as other transient solution data (such as power loss or winding).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** Output error is the percentage error in the total energy of the solution. This is a measure of the accuracy of the finite element approximation and can be used to judge if the mesh is good enough. Output error is calculated by finding the residual energy (the left-over energy calculated from the field after subtracting out the sources) divided by the total energy including the sources. Computing output error uses significant computation time.

6. For 3D Transient analysis only, select the desired **Scalar Potential** shape function: either **Second Order** (default), or **First Order** from the drop-down menu. You can also select the desired **Scalar Potential** on the **Solver** tab in the Properties window.

   Use of the First Order scalar shape function, rather than the Second Order shape function, may be desirable for any of the following cases:

   - If computational time is a main concern and solution accuracy is secondary. This might be useful for the initial design stage, before switching to using the more time consuming, and more accurate, second order scalar shape function.
   - If the contour of the geometry is very complicated, it may not be possible to use the higher second order shape function due to the inability of relatively larger element size to properly represent the original geometry shape
   - If the gradient of the magnetic field changes sharply, it may not be possible to use the higher second order shape function with large element size. Using a larger element size may not be able to adequately model the large change of material property with large element size, and nonlinear convergence may be difficult to achieve.

7. For 2D and 3D Transient designs, you can select the **Number of Nonlinear Iterations** check box. This provides an option for you to set both a **Minimum** iteration number to avoid non-converged solution, and a **Maximum** iteration number to avoid taking too much computation time. These values must be integers greater than 0. By default the values for **Minimum** and **Maximum** are 1 and 100, respectively. Maximum number should be greater than the Minimum number.

8. For 2D Transient analysis only, select the algorithm for the **Time Integration Method** using the drop-down menu.

   - **Backward Euler** – Default
   - **Runge-Kutta** – third-order algorithm for greater accuracy

9. Select or clear the **Fast Reach** check box.

   For transient simulations whose winding excitations are an AC voltage source, the DC flux linkage component may take a very long time to decay, especially for a device with a large time constant. Selecting **Fast Reach** adds an additional voltage component to the original

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

voltage definition during the first half-cycle to quickly eliminate the DC flux linkage, thus speeding up the solution process. You must also provide a **Frequency of Added Voltage Source** value that is greater than zero. The default value for **Frequency of Added Voltage Source** is 60 Hz. This frequency value is applied to all winding voltage sources.

> **Note:**
>
> - This speedup capability is only applicable to voltage sources whose integration of voltage quantity over one period is zero. This means the DC component of all voltage sources is zero.
> - This feature is intended to be used in conjunction with windings of the type "voltage". If the winding is fed by an external circuit, a similar functionality is available using the alternating flux model defined in the properties of sinusoidal voltage sources. Alternatively, the dedicated **AC_Model** component can be applied if an external circuit is feeding the winding.

10. Select or clear the **Auto Detect** check box.

    This option enables automatic detection of when steady state is reached based on a check of the flux linkage. When this option is selected, you must provide both a **Frequency of Added Voltage Source** value that is greater than zero (default value is 60 Hz), and a **Stop criterion** value that is greater than 0 and less than 1 (default value is 0.005). The smaller the **Stop criterion** value, the longer it will take to auto detect when steady-state is reached. For additional information on auto detect operation, refer to Automatic Detection of Reaching Steady State for Transient Simulations.

11. As needed for your design, select or clear settings in the **Time Decomposition Method Option** panel.

    The Time Decomposition Method (TDM) is an HPC distributed analysis type based on domain decomposition along the time-axis, (rather than the normal geometry division) to parallelize the transient solution. Instead of solving Maxwell transient problems sequentially for each timestep, TDM enables timesteps to be solved simultaneously in parallel. Thus, TDM can be implemented on distributed memory parallel platforms based on MPI. TDM has very good scalability, resulting in significant speedup for both 2D and 3D transient solutions.

    > **Note:** Maxwell 3D A-Phi transient solver supports only General Transient TDM.

    If you have enabled the **Use Automatic Settings** option in the **Analysis Configuration** dialog box, or if you have enabled the **Transient Solver** distribution type in the **Analysis Configuration** dialog box, you can select one of the following:

    General For general transient (Non-Periodic) TDM applications, select

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Transient	**General Transient**. Using this method, TDM solves a collection of many timesteps simultaneously. TDM method intended for use in steady-state simulation. In such a case, all the setup and solutions at the first timestep will be the same as those at the last timestep of one period. Setup includes source, boundary, and position in electrical degrees. The solutions include all electrical and magnetic quantities. To use this method, all current in windings and all induced eddy currents in the conducting region should have the same time period. For example, an induction machine cannot be solved using the Periodic method because the time period of the currents in the stator winding is different from the time period of induced eddy current in the rotor bars.
Periodic	Periodical TDM is computationally very efficient if a problem is applicable. But because all timesteps over one period have to be solved simultaneously (cannot be divided into subdivision as the case for general TDM transient), the memory requirement may prevent users from using periodical TDM. To this end, the support of half-periodical TDM is able to effectively cut memory usage to roughly half. You can also select a **Half-periodic** option. This TDM option can cut your computer's memory usage when solving Maxwell transient problems. If all physical quantities satisfy anti-periodic condition along Time axis, a problem can be solved using this option so that memory usage can be cut to almost half. Also, since the total timesteps to be solved are halved, the total computation time is also cut roughly by half.

12. For **2D** designs, the **Thermal Two-Way Coupling\Relaxation** setting can be used to improve two-way coupling convergence by applying the relaxation factor to the temperature field. When the thermal modifier takes on a nonlinear form, the convergence of the solution field in Maxwell's equations may fail during two-way coupling iterations. With nonlinear iterations, using an under-relaxation factor can mitigate the risk of overshooting in the property updating process.

    The range of the relaxation factor is from 0 to 1. In general, a smaller relaxation value helps convergence, but may increase the total number of iterations. The default relaxation factor is 1.0.

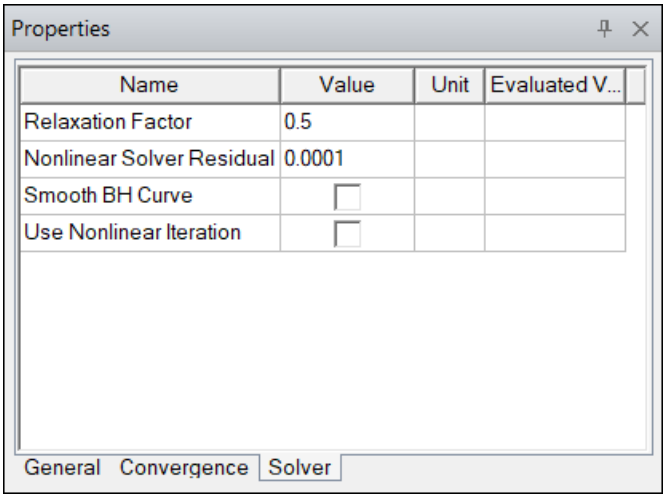
    The **Thermal Two-Way Coupling\Relaxation** setting is applicable only when **Enable Feedback** is checked in Temperature of Objects window, which invokes two-way coupling instead of one-way coupling. The relaxation setting is

    - applicable to all Maxwell 2D designs,
    - applicable to both geometry modes (Cartesian XY and Cylindrical about Z),

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

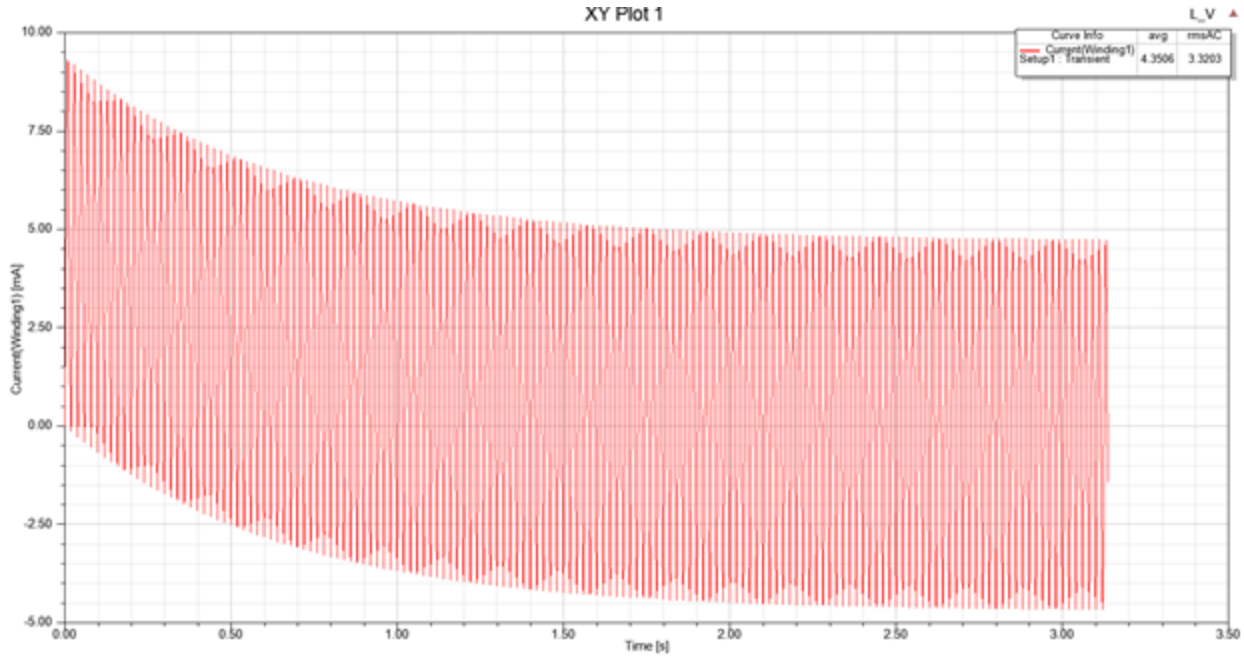
- does not support non-intrinsic and intrinsic variables.

If activated in the Solve Setup window, the Relaxation Factor is also available in the Solve Properties window:



Automatic Detection of Reaching Steady State for Transient Simulations

For transient simulations, when the time constant of the design is large, many cycles may be needed to reach steady state.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Because it is often difficult to predict how many cycles are needed to reach the steady state, the user typically must preset a very long simulation time range (a large stop time) to ensure that steady state can be reached before the end of the simulation. This can result in the waste of significant simulation time for cases in which steady state is reached long before the set stop time.

Enabling the **Auto Detect** setting using a preset **Stop Criterion** causes the solver to check whether steady state has been reached during the simulation, automatically stopping the simulation when steady state is detected. This allows the user to set a very large stop time without concern for wasting needless simulation time, thus improving the efficiency of the simulation without losing the accuracy of the solutions.

Design Considerations

All windings in a project are divided to three categories: AC winding, DC winding, Non-applicable winding.

- For an AC winding, the winding source is periodic with the same frequency as the user-set frequency (**Frequency of Added Voltage Source**) and it has no DC component. A winding which is connected to an external circuit is treated as AC winding.
- For a DC winding the value of the winding source doesn't change throughout the simulation.
- A non-applicable winding is a winding which cannot be included in either of the first two categories, such as the case when the frequency of the source is different from the frequency set by users.

If a project only includes AC windings and DC windings, automatic detection will be conducted by checking the flux linkages of all AC windings. If a project includes a Non-applicable winding, the automatic detection feature will be disabled.

How Auto Detection Works

Winding information is checked during simulation to determine whether steady state has been reached. If rotational motion is included in the project, the torque is also checked.

Of the three winding parameters that can be used to check whether steady state has been reached during the simulation: *current*, *induced voltage*, and *flux linkage*, **Auto Detect** uses flux linkage for the following reasons:

- Compared with the induced voltage, which is the time derivative of the flux linkage, the flux linkage itself is less sensitive to numerical noise.
- Similarly, current calculations are not as smooth as flux linkage. Also, when the winding excitation is current, the current is not applicable for detecting steady state.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The automatic check for steady state is carried out at the end of each cycle. The cycle time, T is calculated based on the input frequency (**Frequency of Added Voltage Source**) supplied by the user: $T=1/f$.

For example, if the check is carried out at time instant t_c, the flux linkage values over the last cycle $[t_c–T, t_c]$ and the second last cycle $[t_c–2T, t_c–T]$ will be used. The first checkpoint, t_c, is at $3T$ since, in general, the first cycle is unsuitable for checking for steady state – especially when **Fast Reach Steady State** is enabled (in which case the first cycle is not even a physical result).

The DC component and the fundamental component of the flux linkage of the two cycles are compared to check for steady state. These components are calculated as follows:

DC component:

$$D = \frac{1}{T}\int_0^T f(t)dt$$

Fundamental component:

$$F = \frac{1}{T}\int_0^T f\left(t\right)e^{-2\pi j\frac{t}{T}}dt$$

Assuming the DC component of the flux linkage at the last cycle is D_1, and the fundamental components are denoted by F_1 and F_2 at the last and the second last cycle, the following two criteria are implemented to check for steady state:

$$|D_1| < r$$

$$|F_1 - F_2| < r$$

where the reference value r is calculated by

$$r = |F_1| \times c$$

Coefficient c is the **Stop Criterion** for reaching steady state and is set by the user on the solver tab for transient solutions and must be greater than 0 but less than 1 (default = 0.005). Thus the smaller the coefficient is, the stricter the stop criterion for reaching steady state is, and the longer it will take to auto detect when steady state is reached.

If rotational motion is involved, after the flux linkage has converged, the solver will further check whether the torque has reached steady state. In steady-state, the torque should be constant with small deviation. Such deviation can come from mesh noise, cogging torque, slot effects, etc. This deviation should be small compared to the rms value of the torque. To check whether the torque has reached steady state, the solver compares the difference of the average torques in the last two cycles. The difference should be smaller than the tolerance value. (The tolerance value is normalized by the rms value of the torque in one cycle.)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The average value of the torque and the rms value of the torque in one cycle are calculated as follows:

The average value of the torque is

$$DT = \frac{1}{T}\int_0^T Tor(t)dt$$

The rms value of the torque is

$$RT = \frac{1}{T}\int_0^T Tor(t)^2 dt$$

The following criterion is implemented in the solver to check for steady state for torque:

$$|DT_1 - DT_2| < RT \times 10c$$

As above, *c* is the user-supplied **Stop Criterion**.

> **Note:** Because torque is usually noisier than flux linkage, the tolerance of the torque check is looser than the tolerance of flux linkage.

Time Decomposition Method for Maxwell Transient Designs

If a Maxwell 2D or 3D transient design problem is too large to solve efficiently on one machine, Maxwell can use the **Time Decomposition Method** (**TDM**). The Time Decomposition Method (TDM) is an HPC distributed analysis type based on domain decomposition along the time axis (rather than the normal geometry division) to parallelize the transient solution. Instead of solving Maxwell transient problems sequentially for each timestep, TDM enables timesteps to be solved simultaneously in parallel. Thus, TDM can be implemented on distributed memory parallel platforms based on MPI. TDM has very good scalability, resulting in significant speed up for both 2D and 3D transient solutions.

> **Note:** Maxwell 3D A-Phi transient solver supports only General Transient TDM.

Maxwell supports two time decomposition methods:

- **General Transient (Non-Periodic)** – This method is intended for general transient applications.

  For this method, TDM solves a collection of many timesteps simultaneously – a collection of many timesteps being defined as one time subdivision. For example, if the end time of the entire transient simulation is 4 seconds, and if we want to solve all time-step solutions together for every 1 second, then this 1 second is defined as one time subdivision, and the total time subdivisions is 4. For the same problem, we can also define every 2 seconds as one time subdivision. Accordingly, the total time subdivisions becomes 2.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Periodic** – This method is intended for use in steady-state simulation. In such a case, all the setup and solutions at the first timestep will be the same as those at the last timestep of one period. Setup includes source, boundary, and position in electrical degrees. The solutions include all electrical and magnetic quantities. To use this method, all current in windings and all induced eddy currents in the conducting region should have the same time period. For example, an induction machine cannot be solved using this method because the time period of the currents in the stator winding is different from the time period of induced eddy current in the rotor bars.

  You can also select a **Half-periodic** option if all physical quantities satisfy anti-periodic condition along Time axis. In this case, the memory usage can be cut to almost half.

Periodic TDM has the advantage that the problem just needs to be solved over one period of time, while **General Transient** TDM uses many cycles to reach steady state. But to enforce periodical condition along the Time axis, all timesteps over one period of time must be solved together. This may require extensive memory usage.

Using TDM

To use TDM, you must do the following:

- Have and use the HPC license Workgroup option (Refer to).
- Set the total number of Tasks, N, (at least three Tasks) for the solve workgroup. The actual number of Tasks for parallel computation is N-1 (dependent tasks) because the first Task is used as the independent task, which is responsible for task assembly, dependent task control, synchronization, etc.
- Enable the **Transient Solver** distribution type in the **Analysis Configuration** dialog box (Refer to .)

> **Note:** In Maxwell 2D, for **General Transient** TDM, the expression cache will be updated every 10 subdivisions, that is to say, every (task number - 1)*10 timesteps. For **Periodic** TDM, the expression cache is updated after the entire solution is completed.

Limitations to using TDM

- Mechanical transient is not supported. This means all moving positions for every timestep have to be known in advance so that FEA will take place at that predetermined position.
- The solution at a timestep cannot depend on the arbitrary history of previous timesteps (allowed for previous couple of timestep solutions required due to the time integration scheme itself). Traditional core loss computation is supported because core loss

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

computation is done in post-processing.

Strictly speaking, TDM cannot support hysteresis modeling. But for soft hysteresis materials, especially for lamination core loss computation, the hysteresis loop, or the coercivity Hc, is very small. In such a case, the impact of hysteresis on the nonlinear operating point can be ignored. This means we can decouple the nonlinear iteration process with consideration of hysteresis impact. For the first step of the nonlinear iteration process, distributed parallel TDM can still be applied. After the nonlinear iteration has converged, that is, the nonlinear problem has been linearized for all timesteps (or all timesteps in the sub-division), the second step is applied to take into account the impact of hysteresis. In such a case, the solution process is sequential – to consider the impact of hysteresis behavior from the previous time-step solution on the solution at current timestep. It can be expected that the results with TDM enabled and with TDM disabled might differ slightly due to ignoring the impact of hysteresis on the nonlinear operating point. However, from a practical application point of view, the solutions can be considered as sufficiently accurate –especially for lamination core loss computation.

- The purpose of the demagnetization process in a transient simulation is to find the worst operating point during the entire transient simulation. After a new worst operating point is discovered, a linearized representation of the permanent magnet characteristic will be used to construct a new recoil line, which is applied to the simulation for subsequent timesteps. Thus, strictly speaking, TDM cannot support demagnetization modeling because all timesteps (or all timesteps in a subdivision) are solved simultaneously. However, as a reasonable approximation, we can solve all timesteps in one subdivision simultaneously based on distributed parallel TDM – and then search for the worst operating point among the solutions of these just-solved timesteps. Thereafter, this new worst operating point is used to construct a new recoil line, which is applied to all timesteps in the *next* subdivision. This means the impact of previous solutions on subsequent searches for the worst operating point is taken into account subdivision-by-subdivision, rather than timestep-by-timestep.

  It can be expected that the results of the discovered *final* worst operating point might differ slightly between TDM- enabled solutions and TDM-disabled solutions. However, from a practical application point of view, the solutions can be considered as sufficiently accurate. This error can be reduced with the use of few timesteps in one subdivision.

Defining Settings for Output Variables for Transient Solutions

Any output quantity or expression within either the **Transient Report** or **Field Report** type can be defined as an output variable in the **Output Variables** dialog box, accessed via **Results** in the Project Manager tree.

To add an output variable to output with time:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Click **Add** to select the output variables to be added to the list for output with time. The newly defined variable is added to the list.

> **Note:** The **Add** button will not be enabled if there are no variables defined in the project.

To delete an output variable:

- Select the variable from the list, and click **Delete**.

Do one of the following in the **Evaluation Timestep** section on the **Output Variables** tab of the **Solve Setup** window:

- Select **Using Constant**, type a value, and select the units. Select this option if you want to use a constant value for when you calculate output variable values.
- Select **Evaluate every Nth timestep**, and type a value. Select this option if you want to evaluate the output variable after a certain number of solution timesteps, that is, instead of calculating the output variable every fixed time interval, you want to calculate it every certain number of timesteps. For example, if you want to evaluate the output variable every third timestep, type **3** in this text box.

Defining Settings on the Defaults Tab for Transient Solutions

Default analysis parameters are used to initialize the data for new setups.

To set up the default analysis parameters, define the following parameters under the **Defaults** tab of the **Solve Setup** window:

1. Click **Save Defaults** if you want to save the defaults based on the data for the current setup.
2. Click **Revert to Standard Defaults** to clear the existing values.
3. Click **OK**.

Setting Analysis Parameters for Electric Transient Solutions

When you set up an electric transient analysis, define the parameters on the following tabs of the **Solve Setup** window (which appears when you click **Maxwell** > **Analysis Setup** > **Add Solution Setup**):

- General (Name, Transient Setup)
- Expression Cache

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Solver
- Defaults

Defining Settings on the General Tab for Electric Transient Solutions

The following settings can be defined on the **General** tab of the **Solve Setup** dialog box for transient solutions:

- Setup Name
- Timesteps Setup

Setup Name for Electric Transient Solutions

By default, **Setup1** appears as the name of the first analysis you set up.

To change the name of the setup, type the new name in the **Name** text box on the **General** tab of the **Solve Setup** dialog box.

To disable the setup, uncheck the **Enabled** check box. Refer to *Disabling and Enabling an Analysis Setup* for additional information.

Timestep Setup for Electric Transient Solutions

To set up a transient analysis, define the following parameters on the **General** tab of the **Solve Setup** window:

1. Enter the **Stop Time**, which is the value at which the solution will stop, and select the units.
2. Enter the **Initial Timestep**, which is the time step used to start the simulation and begin the adaptive process.

   > **Note:** The solver calculates the initial time step based on relaxation time Tau=Eps/Sigma of each material and then compares the results with the initial time step defined by the user. The smaller value is used.

3. Also enter the **Maximum Timestep** to set the allowable range the adaptive process use to alter the timestep.
4. Check **Save Fields** to enable saving the fields data.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Defining Expressions for Electric Transient Solutions

You can specify additional evaluation criteria through the use of expressions and output variables.

To set expressions as evaluation criteria:

1. Right-click on the Analysis icon in the Project Manager tree to open the **Solve Setup** window.
2. Click the **Expression Cache** tab and click the **Add...** button to open the **Add to Expression Cache** dialog box.
3. Specify the Context for the expression, including **Report Type**, and **Solution**.
4. Under the **Trace** tab, select from the **Category**, **Quantity**, and **Function**lists to create expressions.

   Selecting a listed category lists the Quantities and Functions available for each category. If you have defined one or more output variables, you can see them by selecting the **Output Variables** category. The **Output Variables** button opens a dialog box that lets you define output variables. See Specifying Output Variables.

   When you have created an expression, it appears in the **Expression** field of the **Trace** tab. If desired, you can use the **Range Function** button to select range functions to apply to the expression.

   Under the **Calculation Range** tab, you can view the values of available sweep variables. Clicking the ellipsis **[...]** button in the **Edit** column opens a list of values from which you can select.

5. When finished defining the expression that you want to add to the cache, click the **Add Calculation** button.

   This adds the selected expression and the associated context to a table in the **Expression Cache** tab. You can define additional expressions with contexts and add them in the same way.

6. When finished adding expressions, click **Done** to close the **Add to Expression Cache** dialog box.

   The **Expression Cache** tab lists the expressions you have added in a table:

   - The **Title** field is editable, by default showing the name as built from the expression (with underscores removed).
   - The **Expression** field shows the full expression. You can resize the **Solve Setup** window, and also each column in the table, to view the contents of the fields.
   - The **Context** column for non-field types lists the parameter type specifying the force, torque or matrix setup. For these types the context also can be given as part of the expression. For example, the expression *Force1.Force_x* with a context of *None* is equivalent to an expression of *Force_x* with a context of *Force1*.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For field quantities the **Context** can be the geometry on which to evaluate the field quantity - a point or line. If you use a line you need to use some range function to reduce the dimensionality to a single value (or use the Calculation Range tab to specify a single point along the line). Note that, if you create a named expression in the field calculator that already evaluates to a single value, then the **Context** here will likely be *None*.

- The **Intrinsics** column shows a clickable button that opens an **Edit Calculation Range** dialog box. If the **Intrinsics** column button shows **None** you cannot edit the value. If the button shows variables, click the ellipsis **[...]** in the **Edit** column to display a list of the variable values from which you can select. Click **OK** to close the **Edit Calculation Range** dialog box and apply your selections to the **Expression Cache**.

  The **Intrinsics** field lists the values you may have set in the **Calculation Range** tab when you added the expression. This is used to set the values of “other” sweeps. Usually there are no other sweeps because the values of the variables are set in the definition of each variation. In some cases you may need to specify the values of “other” sweeps. For field values with a line for the context, you can specify the (normalized) distance along the line For eddy current field quantities you can also specify the phase for the calculation.

7. In the **Evaluation timestep** panel, set how often the solver is to output field solutions. Select **Constant** to output solutions at a preset time interval (e.g., every 0.1 s); or **Number of solve steps** to output solutions each preset number of timesteps (*e.g.*, every 3 timesteps).
8. Optionally, buttons allow you to **Edit** and **Remove** selected expressions, and to **Remove All** expressions in the table.
9. When finished defining expressions, click **OK** to close the **Solve Setup** window.

Defining Settings on the Solver Tab for Electric Transient Solutions

To define solver settings on the **Solver** tab of the **Solve Setup** window for transient solutions:

1. Enter a value in the **Temporal Tolerance** text box.
2. For the Initial Condition, select either a preset **Value** or a **Static Field**.

   If **Static Field** is selected, the **Setup Link** button becomes active, and the **Setup Link** dialog box automatically appears, and the field will be imported from the source design to the target design.

3. The **Import mesh** check box can be selected in the "target" design if the mesh for the same geometry is to be used in the analysis.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If the **Import mesh** feature is selected, the **Setup Link** button becomes active, the **Setup Link** dialog box automatically appears, and the mesh will be imported from the source design to the target design.

> **Note:** The usual way to create geometrically equivalent designs is by copying all geometry objects from one design and then using **Import From Clipboard** in the other design.

Setup Link for Electric Transient Solutions

If you selected **Import mesh** or **Static Field**, do the following to specify the project, design, and solution containing the mesh information you want to use:

1. Click **Setup Link** in the **Solve Setup** window.

   The **Setup Link** window appears.
2. Click the **General** tab.
3. Select the project from the **Project File** drop-down menu.
4. Select the saved design from the **Design** drop-down menu.
5. Select the specific solution you want to link to from the **Solution** drop-down menu.
6. Click the **Parameters** tab.
7. Optionally, edit the **Value** and **Unit** columns for any of the parameters listed
8. Click **OK** to close the **Setup Link** window and return to the **Solve Setup** window.

Defining Settings on the Defaults Tab for Electric Transient Solutions

Default analysis parameters are used to initialize the data for new setups.

To set up the default analysis parameters, define the following parameters under the **Defaults** tab of the **Solve Setup** window:

1. Click **Save Defaults** if you want to save the defaults based on the data for the current setup.
2. Click **Revert to Standard Defaults** to clear the existing values.
3. Click **OK**.

Resetting Analysis to Time Zero

Before rerunning a transient simulation that has data associated with it, you need to reset the analysis to time zero; otherwise, Maxwell will not overwrite the data that is already present because it will not rerun the simulation. Resetting the analysis to time zero invalidates the

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

current solution and will instruct the software to start over from the beginning when you rerun the simulation.

If you have changed simulation parameters, the transient analysis will rerun without the user having to select **Reset Time Zero**.

To reset the analysis, do one of the following:

- Click **Maxwell** > **Analysis Setup** > **Reset to Time Zero**.
- In the Project Manager tree, right-click **Setup** under **Analysis**, and select **Reset to Time Zero** from the shortcut menu.

Changing Memory Settings

The Maxwell solver has to make trade-offs between the solution time and the amount of memory used in the solution process.

The software automatically determines the amount of RAM installed on the computer, assuming that it can use up to 75% of this during the solution process. You can override this choice by changing the following two memory settings:

- Desired RAM Limit
- Maximum RAM Limit

Generally, set the RAM value as high as possible to obtain the fastest solutions.

These settings are not an absolute limit on the amount of RAM to be used. When solving small problems, Maxwell tries to respect this limit by choosing to run more slowly with a smaller amount of RAM. When solving a large problem, Maxwell may be unable to use less RAM than the specified limit. In this case, the amount of memory used exceeds the specified limit but tries to minimize how far it goes beyond.

Specifying the Desired RAM Limit

The **Desired RAM Limit** setting requests a restriction on the amount of physical random access memory (RAM) the MPS solver used in Maxwell may use before it must stop solving *on-core - solving processes entirely in RAM* - and start solving off-core. In *off-core mode*, Maxwell creates temporary solution files to which it spills, or shifts, data from RAM, instead of relying on the operating system to start disk swapping. The location of these temporary files is specified in the General Options (**Tools** > **Options** > **General Options** > **Directories**). The MPS solver is finely tuned at handling its own memory, and can optimize loading only those blocks of memory required for its immediate needs.

Using this option may help to keep the entire solver from being swapped out in the normal course of process management on your computer. This kind of control may be especially important when multiple solvers are running on the same machine. Of course, if the total

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

memory requirement of all processes grows large enough, the operating system will be forced into disk swapping.

> **Note:** The Iterative solver doesn't go off-core for efficiency reasons. Because the Desired RAM Limit (the soft memory limit) is used for off-core run, it is not appropriate for the iterative solver. Instead, the iterative solver uses the Maximum RAM Limit (the hard memory limit). Once the limit is exceeded, the iterative solver will issue an "Out of memory" error message.

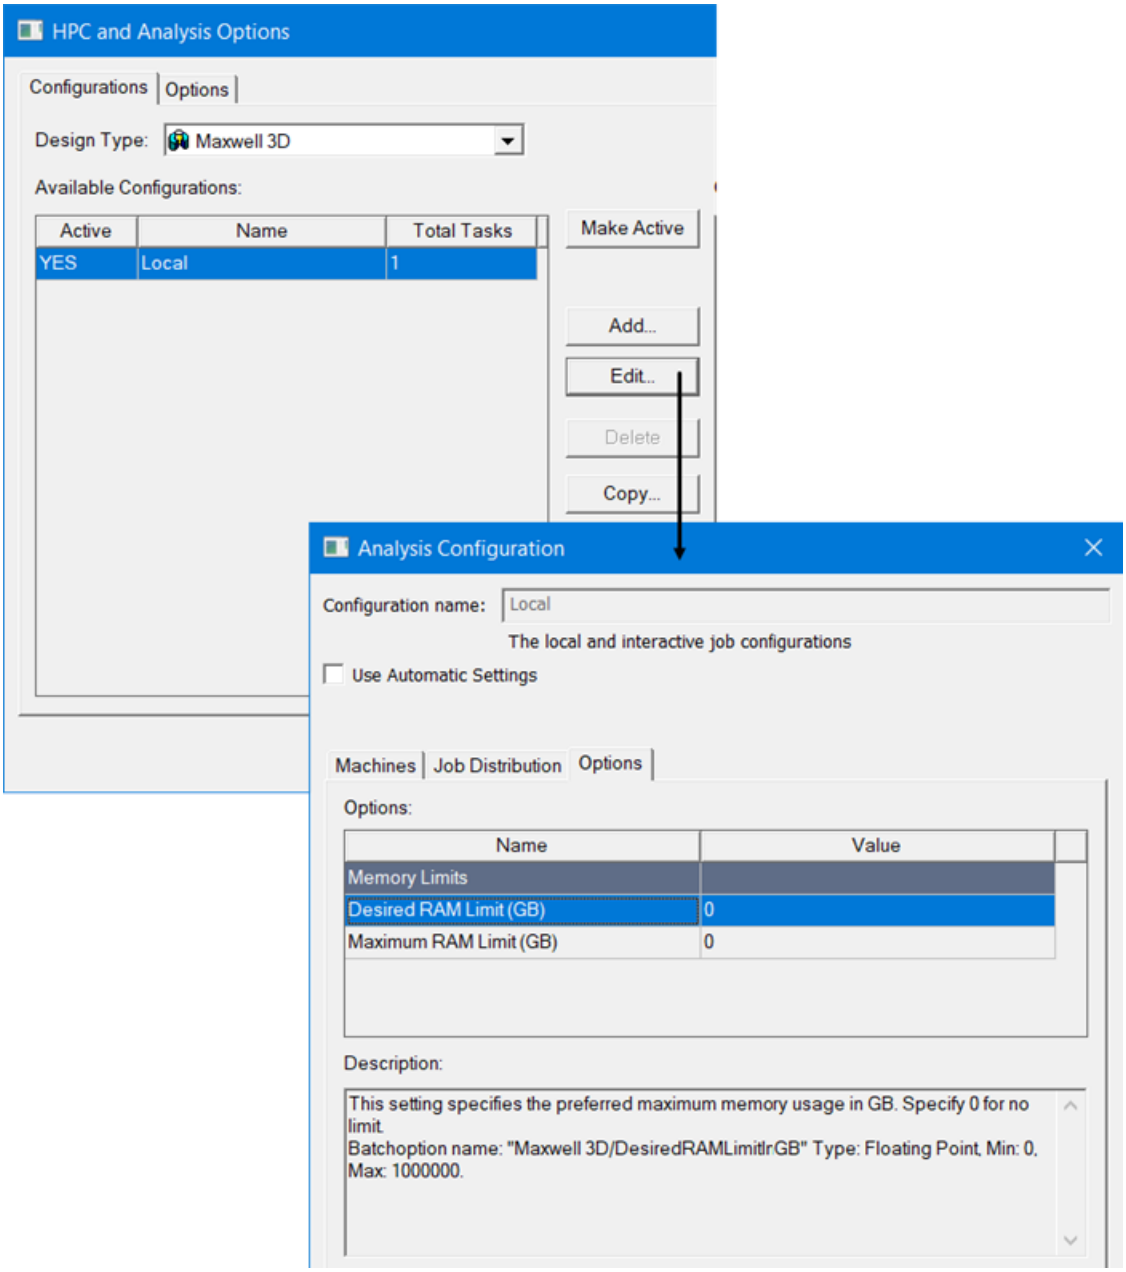
Regardless of this setting, processes are limited to 4TB of address space on 64 bit operating systems - no matter how much physical memory is installed.

> **Note:** Regardless of the **Desired RAM Limit** setting, if allocation fails, the Maxwell solver automatically switches to off-core mode.

In case you receive an error message regarding insufficient memory on a 64-bit operating system, you may have reached a point where the sum of physical RAM plus available swap space exceeds the minimum amount of RAM needed by the off-core solver. Even for the off-core solver, the RAM usage cannot be made arbitrarily small. In that case you can consider increasing the swap space (the virtual memory) in the settings of your system.

To specify the Desired RAM Limit of the machine on which Maxwell is installed, select **Tools** > **Options** > **HPC and Analysis Options**, then click **Edit**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



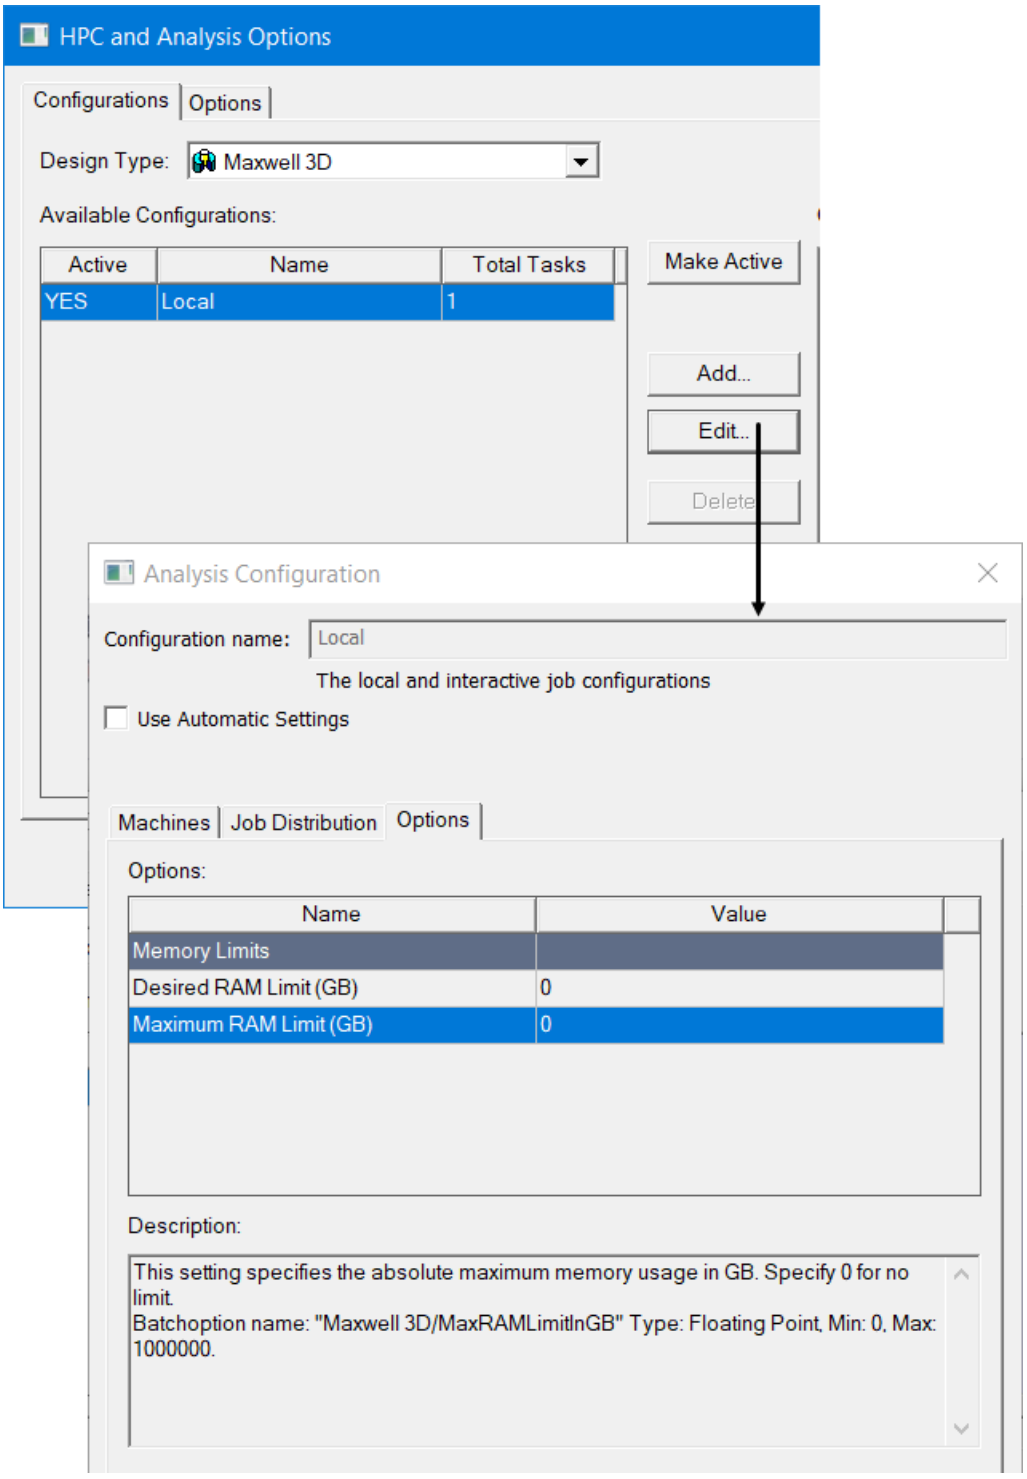
Refer to the *HPC and Analysis Options* section for more details.

Specifying the Hard Memory Limit

The **Maximum RAM Limit** setting specifies the absolute limit on the amount of physical memory that the solver can use. If the solver attempts to allocate more memory than this setting, the solution process terminates abnormally, and incorrect error messages may appear.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To specify the **Maximum RAM Limit** for the current user and machine, select **Tools** > **Options** > **HPC and Analysis Options**, then click **Edit**.



Refer to the *HPC and Analysis Options* section for more details.

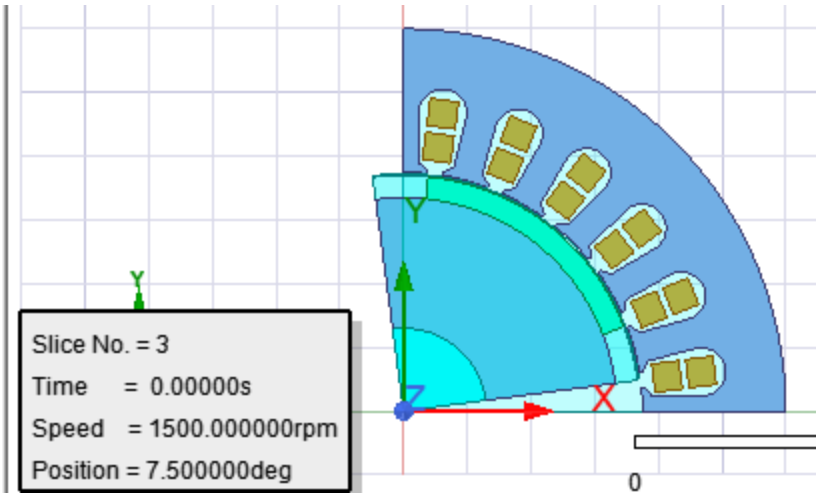
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: Ansys recommends that you use the **Desired RAM Limit** setting if you want to limit the RAM the solver may allocate.

Setting View Context for Transient Solutions

To set the view context:

1. Click **View** > **Set Solution Context**.
   The **Set View Context** dialog box appears.
2. Select a solution from the **Solution Name** drop-down menu.
3. Select a time instance from the **Time** drop-down menu.
4. For Maxwell 2D transient solutions only, in which **Use Skew Model is enabled on the Model Settings tab**, an additional **Slice** field displays, which allows you to select the skew model slice to be displayed in the modeler window.



5. In the **View** area of the dialog, you can choose the location to display the **Solution Context** within the modeler window. **Lower left** was selected for the image above.
6. The position and speed values may be displayed in the **Solution Context** by selecting the **Display Speed and Position values** check box.
7. Click **OK**.

Note: You can also change the view context by double-clicking the solution context text label in the bottom left of the model window.
Example of text label showing solution view context: Time='0s'

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Speed and Position Display Settings

To set the display setting for speed and position in the view context:

1. Click **View** > **Set Solution Context**.
   The **Set View Context** window appears.
2. Select the **Motion View Format** tab.
3. In the **Format Speed Unit** section:
   a. Specify the **Unit Type** from the drop-down menu.
   b. Specify the **Field Width** for the display and the number of digits of **Precision** to display.
   c. If you prefer **Scientific Notation**, select the check box.
4. Click **OK**.

> **Note:** You can also change the view context by double-clicking the solution context text label in the bottom left of the model window.
> Example of text label showing solution view context: Time='0s'

Renaming a Solution Setup

Do the following to rename a solution setup:

1. In the Project Manager tree, under **Analysis**, right-click the setup you want to rename.
   A shortcut menu appears.
2. Select **Rename** from the shortcut menu.
   The setup name text is highlighted in the Project Manager tree.
3. Type the new name for the setup, and press **Enter**.

You can also rename the solution setup by changing the text in the **Name** text box of the **Solve Setup** window.

Copying a Solution Setup

Solution setups may be copied and pasted within a design or across designs of the same type. This is beneficial for setups having a large number of parameters to specify such as an RMxprt design, or where minor changes to a setup are being evaluated.

> **Note:** Setups cannot be pasted across solution types, across geometry modes such as from 3D to 2D, or across machine types in RMxprt.

To copy a solution setup:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the Project Manager tree, under **Analysis**, right-click the setup you want to copy.

   A shortcut menu appears.

2. Select **Copy** from the shortcut menu.

   The setup parameters are copied to the clipboard.

3. In the Project Manager tree, right-click on the **Analysis folder to receive the copied setup**.

   A shortcut menu appears.

4. Select **Paste** from the shortcut menu.

The setup parameters are copied to the **Analysis** folder as a new setup.

Disabling and Enabling an Analysis Setup

To disable an **Analysis** setup definition without deleting it:

1. Expand the tree hierarchy under the Analysis icon in the Project Manager tree.
2. Right-click on the icon for the setup definition. In the shortcut menu that appears, click **Disable Setup**.

You can also disable an analysis setup by selecting **Properties** from the shortcut menu to open the **Edit Properties** window. In the upper right corner of the Edit Properties window, uncheck the **Enabled** box. Then click **OK**.

To reactivate an **Analysis** setup:

1. Expand the tree hierarchy under the **Analysis** icon in the Project Manager tree.
2. Right-click on the icon for the setup definition. In the shortcut menu that appears, click **Enable Setup**.

You can also reactivate the analysis setup by selecting **Properties** from the shortcut menu for the sweep to open the **Edit Properties** window. Check the **Enabled** box in the upper right corner, and click **OK** to apply the change and close the window.

Setup Link Window

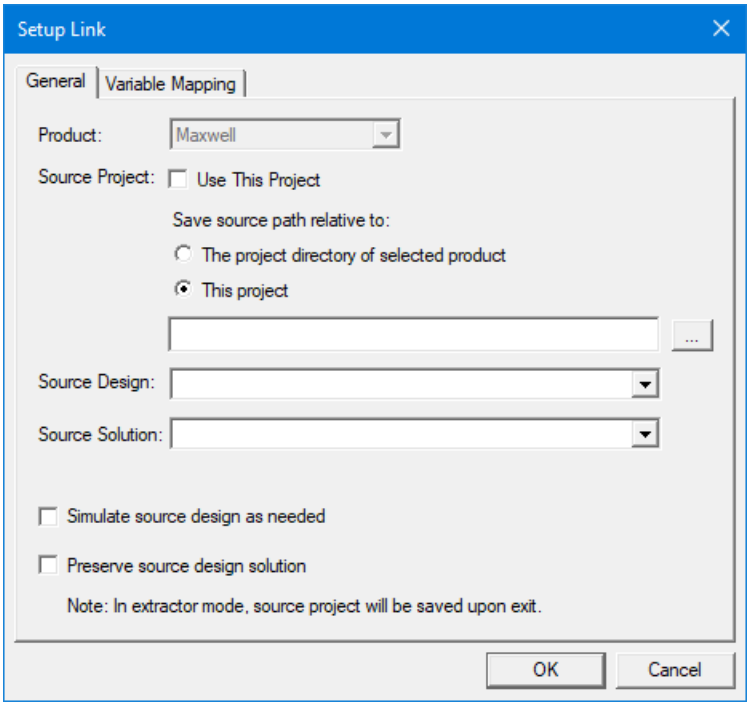
The **Setup Link** window permits you to link the current project to another as described in the following topics:

- Setup Link for Non-Transient Solutions
- Import Mesh for Non-Transient Solutions
- Setup Link for Transient Solutions

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Import Mesh for Transient Solutions
- Setup Link for Electric Transient Solutions

The **General** and **Variable Mapping** tabs are common to all **Setup Link** windows.



Depending on the type of link being set up, other tabs such as **Additional Mesh Refinements**, and **Advance** may also appear. Details of the use of the various tab settings may be found in the topics linked above.

Clearing Linked Data

If you have previously set up links, the **Maxwell** > **Analysis Setup** menu contains an option to **Clear Linked Data**. This removes the linked data for all links in a target design, therefore invalidating the solutions. Clearing linked data for some link types requires Maxwell to revert to the initial mesh. Thus, in some cases, this command removes the current mesh of the target design.

Setting the Report Updating During Analysis Options

Updating numerous reports may take a significant amount of time. Updating reports during the analysis process can impact the overall time to solution. You may want to vary the times when your reports get updated relative to the impact on overall solve time.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Five options exist for updating reports during solutions:

- **After each variation** - when performing an Optimetric or parametric analysis, all reports are updated after analysis of each variation has been completed.
- **Automatically** - the default. It means update most things immediately.
  For **AdaptivePass** plot context, plots are updated at the end of each solution pass. For **LastAdaptive** or **Transient**, the plot is updated at the end of the transient or adaptive solution.
  This option balances report and field plot updating with solution time. For example, reports may be updated after each adaptive pass but field plots will not be updated until the solution is complete.
- **Immediately** - update reports and plots as soon as data comes from the solver.
  This option will have the greatest impact on the overall solution time but will have the most rapid updating of reports and field plots. Caution should be used in selecting this option. Some types of reports and field plots may take a long time to update, especially as the mesh size increases.
- **Never** - only manual intervention updates reports.
  This option will prevent updates from impacting the solution time.
- **On Completion** - as with **Never**, but a single update is done when the solve completes.
  This option should be considered when using dynamic links to other products to provide best solution time with the final data available for the link.

To change the setting for the current project, see Desktop Performance options.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

15 - Coupling in the Maxwell Application

Coupling is provided in specific contexts between the Maxwell application and the products listed below.

Ansys Workbench™ Application

Coupling of the Maxwell 2D/3D solvers with the Ansys Workbench application is supported via the Workbench schematic. The following types of coupling with Workbench are supported:

- Thermal feedback is supported for Maxwell magnetostatic, eddy current, and transient solution types.
- Stress feedback is supported for Maxwell magnetostatic, eddy current, and electrostatic solution types.
- Harmonic force is supported for Maxwell transient and eddy current solutions.
- Partial Model Coupling

For more information, see "Maxwell to Ansys Thermal Coupling" and "Maxwell to Ansys Stress Feedback Coupling," and "Coupling Maxwell with Both Ansys Thermal and Structural via Workbench."

> **Note:** To use couple Maxwell with Ansys Workbench, you must integrate the Maxwell application with Ansys: from the Start menu, select **Ansys EM Suite 2025 R1** > **Modify Integration with Ansys 2025 R1**.

Ansys HFSS™ Application

There are two possible coupling mechanisms between the HFSS and Maxwell applications:

- Near field coupling.
- Magnetic bias source coupling.

While they serve different application objectives, they are similar in neither requires the geometry in the coupled designs to be identical.

For more information, see "Near Field Coupling between Maxwell and HFSS" and "Magnetic Bias Source Coupling between Maxwell and HFSS."

Ansys Twin Builder® Application

Coupling between the Maxwell and Twin Builder applications can take the following forms (initiated through the Twin Builder user interface):

- Export a parametric matrix from Maxwell to an ECE model file for placement in Twin Builder.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Dynamically link a Maxwell capacitance or inductance project to a component in Twin Builder.
- Dynamically link a Maxwell Transient design to Twin Builder to perform Transient-Transient cosimulation.
- Dynamically link a Maxwell design to Twin Builder to perform State Space cosimulation.
- Dynamically link to RMxprt through Dynamic SML.

Because the thermal and/or stress solutions are derived from the distributed power loss and force density, they are likely to be more accurate than analyses based on average losses/force.

For more information, see "Coupling Maxwell to a Twin Builder Component."

Ansys Fluent® Application

Coupling without using the Ansys Workbench application is supported between the Ansys Fluent application and Maxwell 3D magnetostatic and Eddy current designs in the Maxwell application. A transient Ansys Fluent simulation can use a Maxwell solution to simulate the magnetic effect in the electric arc of contactors.

For more information, see "Coupling Maxwell Magnetostatic and Eddy Current Designs with Ansys Fluent."

LMS Virtual.Lab™

The Maxwell application supports one-way coupling with Siemens® LMS Virtual.Lab™.

Maxwell to Ansys Thermal Coupling

Coupling Maxwell 2D/3D with Ansys applications is supported via the Workbench schematic. Thermal feedback is supported for Maxwell magnetostatic, eddy current, AC and DC conduction, and transient types. Users also need to set up the design and geometry appropriately. An appropriate design should be temperature-dependent, and have one or more solve setups that are enabled for thermal feedback.

> **Note:** A Maxwell system can also be coupled with both thermal and stress systems via Workbench.

Maxwell-Specific Considerations

- If there is thermal feedback, each frequency point in an eddy current sweep will be solved with the same feed-back data.
- Temperature distribution data that has already been exported from Ansys Thermal will be invalidated when users continue the Maxwell solution in a way such that the Maxwell mesh is being regenerated.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Once the Maxwell solution has been integrated with a thermal effect, the adaptive process of a static simulation will be disabled. Users must then manually invalidate the temperature data in the existing solution before the adaptive process will be re-enabled.
- Maxwell solutions can incorporate feedback from both thermal and stress.
- When setting up loss transfers from Maxwell to WorkBench, if the user wants to map loss density on a face shared by two objects, this face only has to be used once in the setup.

Maxwell 2D Coupling Considerations

For Maxwell 2D in RZ mode, geometry either must be exported into the XY plane, or the geometry must be rotated into the XY plane after it is imported into **Ansys Mechanical**. This is because Mechanical 2D requires geometry to be in XY plane.

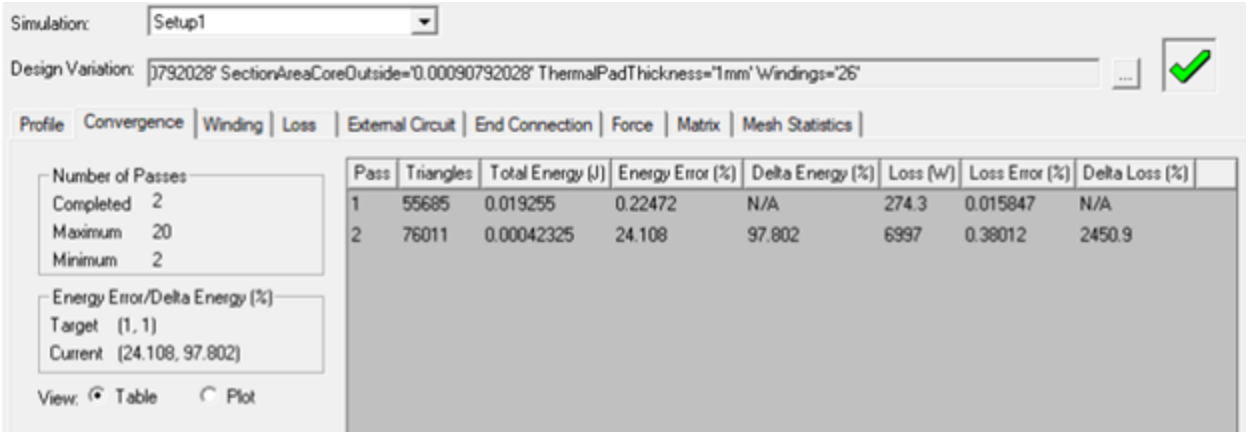
There are two modes in Ansys Thermal 2D. The default mode is called **Planed Stress** where zero stress and non-zero strain are assumed in the z-direction. This is similar to the XY mode in Maxwell 2D. The other mode is called **Axisymmetric**. This mode will be used when a 3D model can be generated by revolving a 2D section 360 degree. This is similar to the RZ mode in Maxwell 2D. Users must ensure that they use the correct geometry mode in Thermal 2D. Invalid geometry mode selection is prohibited by the Thermal2D interface.

There are two types of **Import Load** in Mechanical: **Heat Generation** and **Heat Flux**. **Heat Generation** is used when mapping losses from *objects* in Maxwell 2D/3D and **Heat Flux** should be used to map the loss from the *edges* of objects in Maxwell 2D/3D. **Heat Flux** is supported only for eddy current designs with impedance boundary. Users can insert multiple **Heat Generation** or **Heat Flux** loads via the **Imported Load (Maxwell 2D/3DSolution)** objects.

Convergence of Maxwell-Mechanical Two-Way Thermal Coupling

In two-way thermal coupling between the Maxwell static solver (magnetostatic, eddy, AC, DC) and the Mechanical thermal solver, the user may be confused by the **Loss** value reported in the solution profile (see figure below): when two-way coupling is finished, the difference of the Loss value between the last pass and previous pass is sometimes huge and is NOT aligned with **Loss Error(%)**. The uncertainty arises as to whether the two-way coupling process has truly converged.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The convergence reported in the solution profile primarily reflects the convergence history in mesh refinement, aiming for a field solution independent of mesh size. This mesh refinement process occurs within the AEDT environment.

Instead of relying on the convergence reported in the Maxwell solution profile, users should focus on examining properties of the **Feedback Iterator** in the Workbench:

Properties of Schematic D2: Feedback Iterator

	A	B
1	Property	Value
2	General	
3	Component ID	FeedbackIterator
4	Directory Name	FeedbackIteratorComponent
5	Update Condition Parameter (Beta)	None
6	Notes	
7	Notes	
8	Used Licenses	
9	Last Update Used Licenses	Ansys Mechanical Enterprise [12]
10	Iterations	
11	Iterations Completed	4
12	Max Iterations	15
13	Callback	
14	Script	
15	Temperature Convergence	
16	Target Delta Temperature %	1
17	Latest Delta Temperature %	0.00194419
18	Displacement Convergence	
19	Target Delta Displacement %	5
20	Latest Delta Displacement %	Not Available

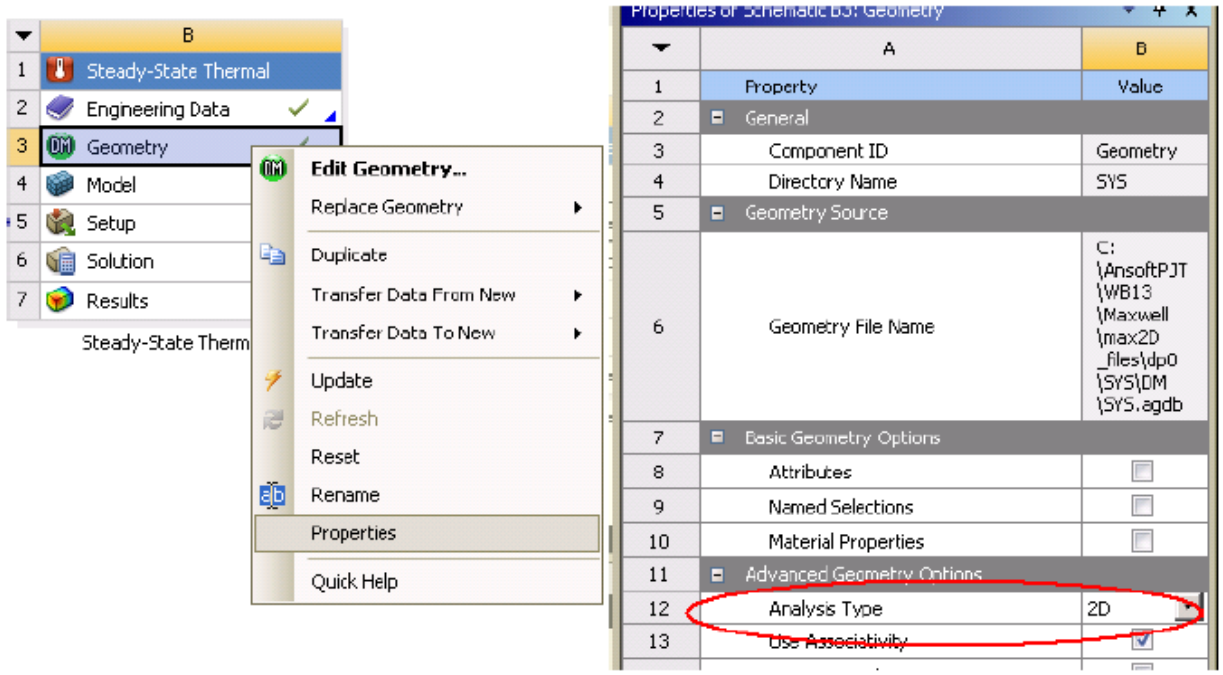
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The true convergence of the two-way thermal coupling process implies the attainment of a steady temperature field and steady loss distribution in Maxwell. The mesh refinement process serves as a preprocessing step for the Maxwell static solvers. In two-way thermal coupling feedback iterations, the mesh in Maxwell solver remains unchanged, but the Maxwell field solution is changing because the material properties are temperature dependent, which affect the solution profile of the last pass.

Coupling Maxwell Designs with Ansys Thermal via Workbench

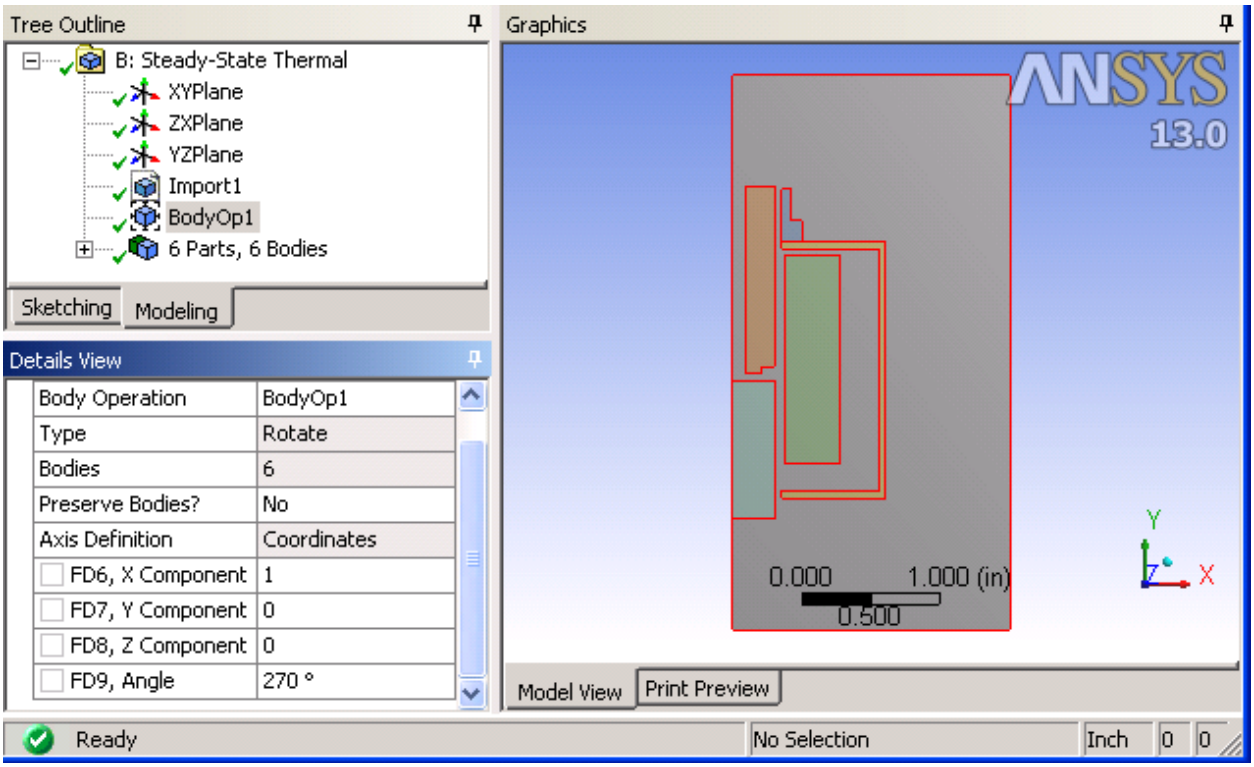
Coupling Maxwell 2D/3D with Ansys applications is supported via the Workbench schematic. Thermal feedback is supported for Maxwell magnetostatic, eddy current, AC and DC conduction, and transient types. Users also need to set up the design and geometry appropriately. An appropriate design should be temperature-dependent, and have one or more solve setups that are enabled for thermal feedback.

1. The easiest way to add a Maxwell 2D or 3D design to a Workbench schematic is to import a working design via **Workbench File** > **Import**. The imported design is placed in the **Workbench** schematic after it is successfully imported.
2. Next, insert a **Steady-State Thermal** system and change its **Analysis Type** to **2D** or **3D**, (depending on the Maxwell design type) by right-clicking on the **Geometry** cell and selecting **Properties**. It is important to change the **Steady-State Thermal** system's analysis type *before* setting up its geometry.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. To set up the **Steady-State Thermal** system's geometry, you must first export the Maxwell geometry using **sat** or **step** format as follows:
   a. Select the **Modeler** > **Export** menu item.
   b. Select the desired model geometry format (**sat** or **step**), and the save location in the dialog box and save the file for use by Ansys Workbench.
4. Import the file via the **Geometry** module of the **Steady-State Thermal** system.
   a. To access the **Geometry** module, double-click on the **Geometry** cell in the **Steady-State Thermal** system to launch **Design Modeler**.
   b. Select **File** > **Import External Geometry File** and browse for the geometry file exported from Maxwell.
   c. After the geometry file is imported, right-click on the root folder of the modeler project tree and select **Generate**. (When the geometry file is of a Maxwell 2D RZ design, users can rotate the geometry in **Design Modeler** by creating a body operation.)

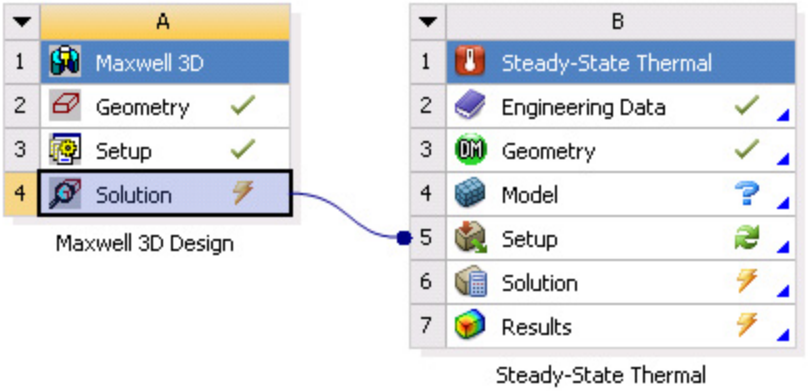


5. Close **Design Modeler** and refresh the **Model** cell of the **Steady-State Thermal** system by right-clicking the **Model** cell and selecting **Refresh**.
6. The geometry mode of the **Steady-State Thermal** system can be changed via the Ansys **Mechanical** user interface.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

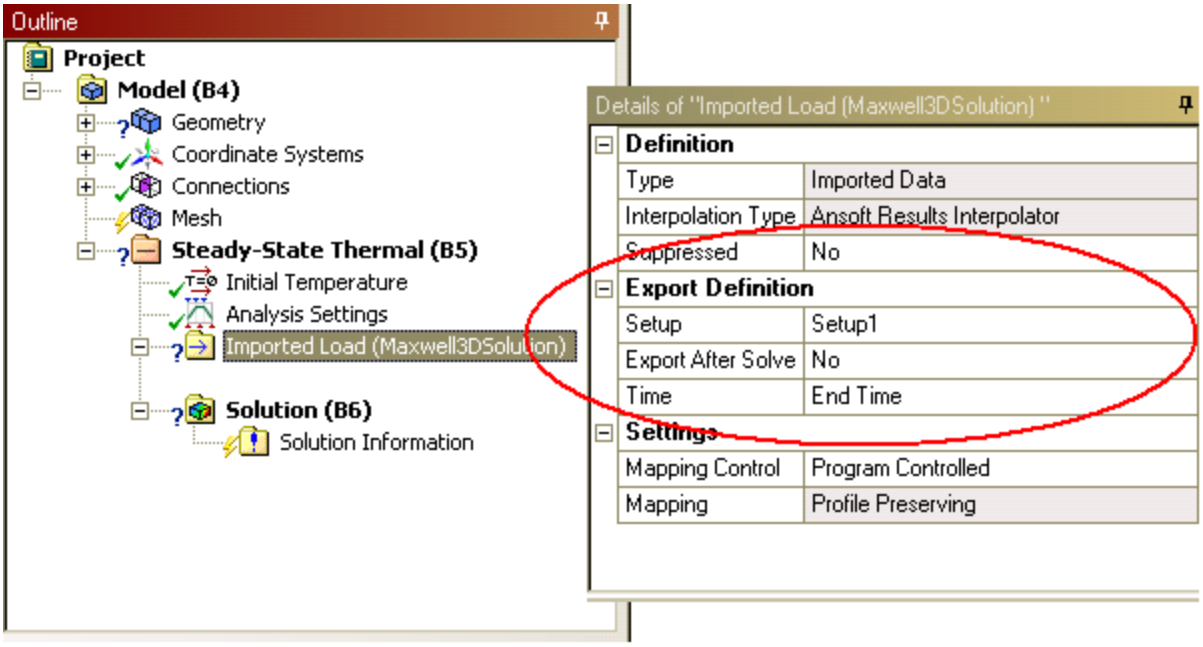
a. Launch **Mechanical** by double-clicking the **Setup** cell of the **Steady-State Thermal** system.
b. Select **Geometry** in the project tree and the **Definition** of **Geometry** will be shown in the **Detail** window.
c. Select either **Plane Stress** or **Axisymmetric** as the value for the property 2D (or 3D) **Behavior**.

7. To set up the coupling, drag the **Solution** cell of the Maxwell system and drop it on the **Setup** cell of the **Steady-State Thermal** system.



8. Note that the Maxwell **Solution** cell is tagged with a “Lighting Bolt” symbol. Right-click on the Maxwell **Solution** cell and select **Update**. This will initiate a Maxwell simulation if it is not already solved. Once Maxwell's solution is available, the “Lighting Bolt” changes to a “Green Check” symbol.
9. To “push” the coupling into **Steady-State Thermal**, right-click on the **Steady-State Thermal Setup** cell and select **Refresh**.
10. After refresh is finished, you can launch Ansys **Mechanical** by double-clicking the **Setup** cell to finish the coupling setup.
11. In the Ansys **Mechanical** application project tree, an **Imported Load (Maxwell2DSolution)** or **(Maxwell3DSolution)** item should already be inserted. Select the **Imported Load** folder to view its details. Because the inserted Maxwell 2D (or 3D) system supports thermal feedback, the **Details** window shows information regarding how the temperature result should be exported, and what type of mesh mapping should be used.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

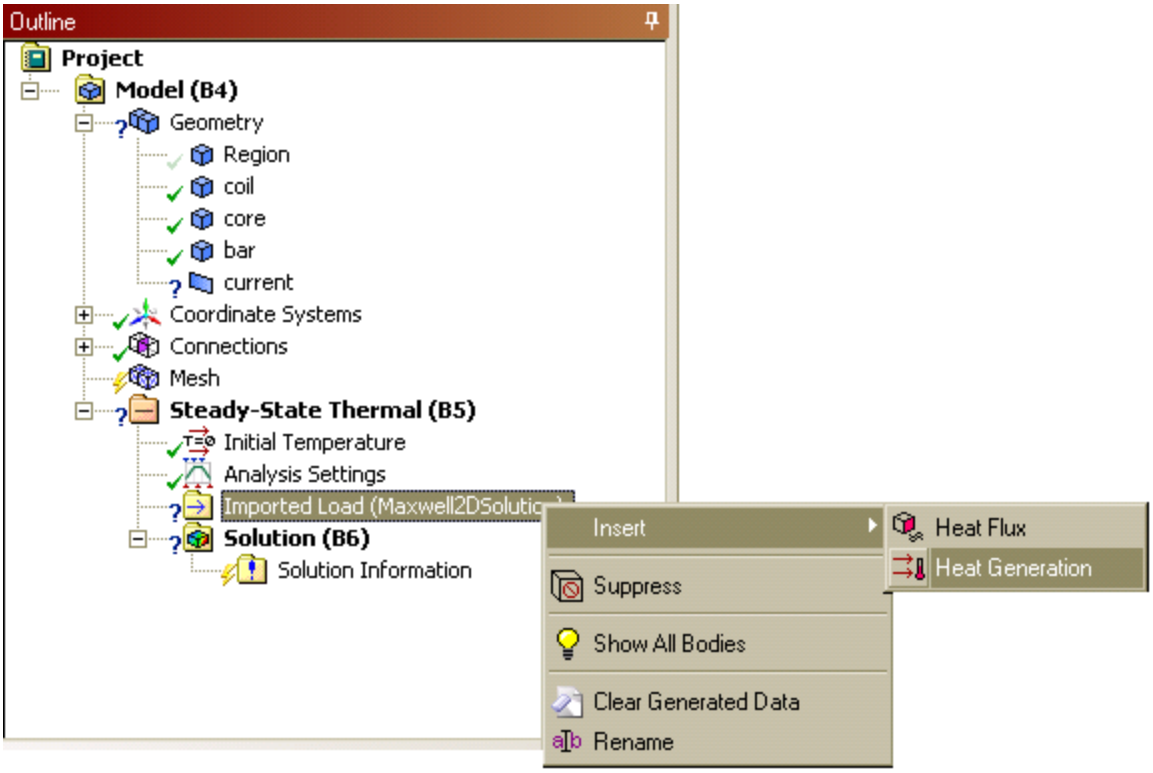


12. To finish the coupling setup, you must insert either an **imported Heat Generation** or an **imported Heat Flux** boundary condition. **Heat Generation** is used when mapping loss from objects in Maxwell; and **Heat Flux** should be used to map the loss from the edges of objects in Maxwell. Users can insert multiple **Heat Generation** or **Heat Flux** loads via the **Imported Load (Maxwell2DSolution)**, or **Imported Load(Maxwell3DSolution)** objects.

    > **Note:** When setting up loss transfers from Maxwell to any other product within the WorkBench framework, if the user wants to map loss density on a face shared by two objects, this face only has to be used once in the setup.

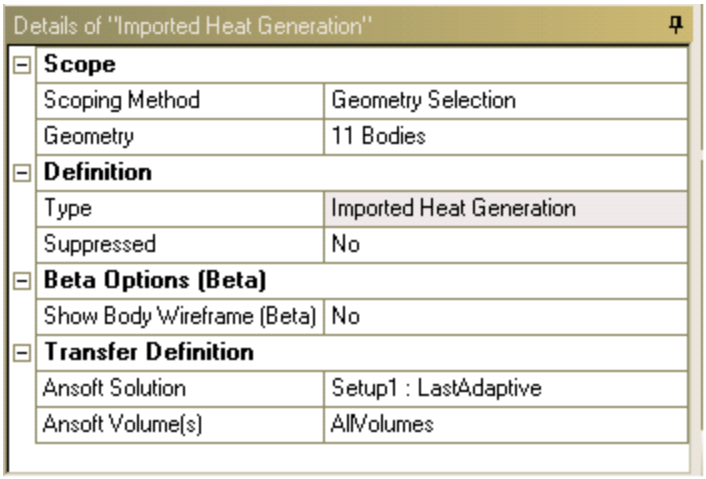
13. To insert a **Heat Generation**, use **Body** select by clicking the icon in the **Mechanical Toolbar**. Then click on the objects where the EM loss should be imported. After all the desired objects are selected, right-click on **Imported Load (Maxwell2DSolution)** > **Insert** > **Heat Generation**, or **Imported Load (Maxwell3DSolution)** > **Insert** > **Heat Generation**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



A sub-item named **Imported Heat Generation** will appear in the project tree.

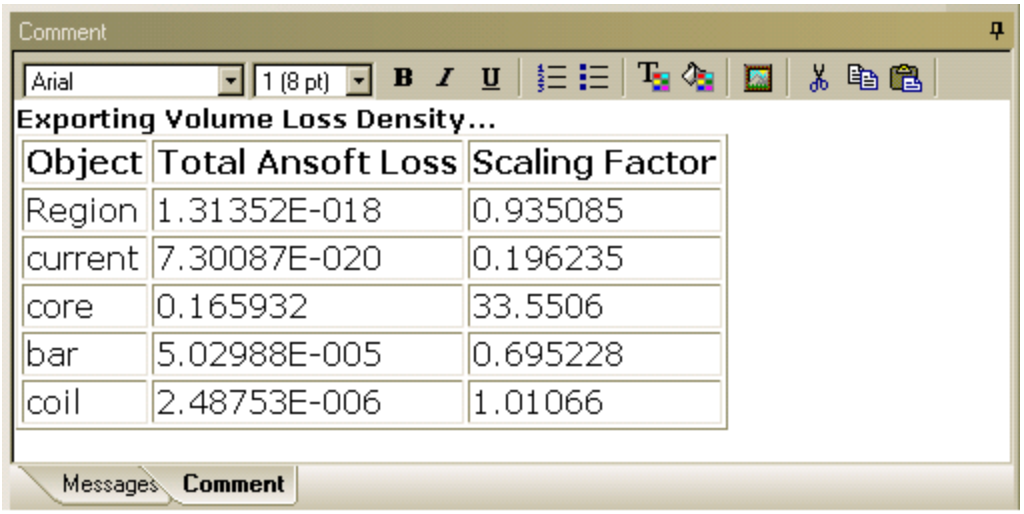
14. Click on the **Imported Heat Generation** tree item to view its details.



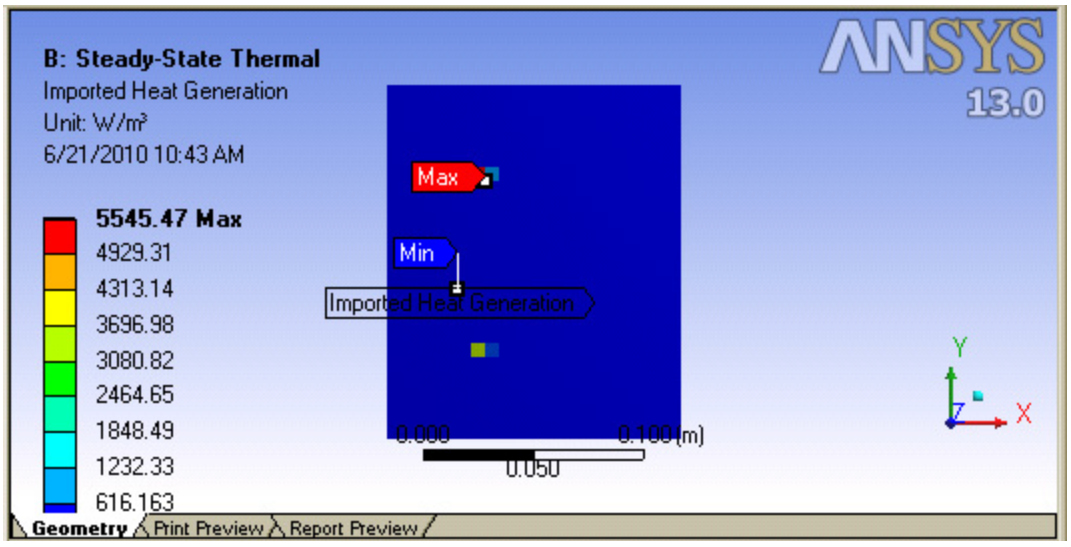
15. In the **Transfer Definition** section, users can set up the source Maxwell solution by pulling down the **Ansoft Solution** combo box and select one of the listed Maxwell solutions.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

16. Right-clicking on **Imported Heat Generation** > **Import Load** will import loss from the **Ansoft Solution** selected for this load. After import has completed, the **Import Heat Generation** item becomes a folder, and an entry called **Imported Load Transfer Summary** is listed. Select the **Imported Load Transfer Summary** entry and the scaling factors used to export the load from Maxwell will be displayed in the **Comment** window.

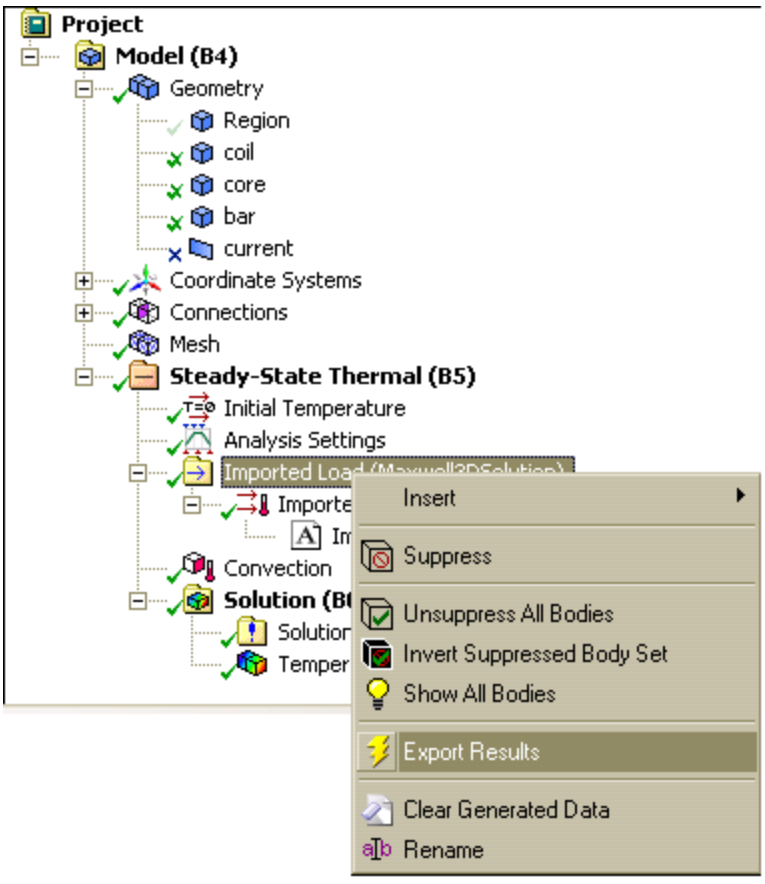


17. Selecting **Import Heat Generation** should show an overlay plot of the imported load. The loss mapping from Maxwell can be verified by comparing this overlay plot with an Ohmic-Loss field overlay plot in Maxwell.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

18. Create a **Convection** boundary to complete the thermal setup:
    a. Use **Edge** select by clicking the icon at the **Mechanical Toolbar** and then **Edit** > **Select All**.
    b. With the edges selected, right-click on the **Steady-State Thermal** project tree item and insert a **Convection**.
    c. With the **Convection** item selected, change its **Film Coefficient** to **5 W/m2** via the **Detail** window.
    d. Right-click on the **Solution** tree item and select **Solve**.
    e. After the thermal solution is finished, insert a **Temperature** plot by right-clicking on **Solution** and selecting **Insert > Thermal** > **Temperature**.
    f. Right-click on the newly inserted **Temperature** item and select **Evaluate All Results**.
19. To export the thermal result to Maxwell, right-click on the **Imported Load (Maxwell2DSolution)**, or **Imported Load(Maxwell3DSolution)** and select **Export Results**.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

20. To fully utilize the automation capabilities provided in **Ansys Workbench**, select **Imported Load (Maxwell2DSolution)**, or **Imported Load(Maxwell3DSolution)**; and in its **Detail** window, select **Yes** for **Export after Solve**. With this option selected, users can continue the iteration between Maxwell/Thermal simulations from the Workbench schematic.

    To “push” the exported thermal results back to Maxwell, right-click on Maxwell's **Solution** cell on the Workbench schematic and select **Enable Update**. Then, right-click again on Maxwell's **Solution** cell and select **Update**. This will trigger Maxwell to re-simulate its solution with thermal results.

    To continue the solve iterations, repeat the following steps as needed:

    a. Right-click on Thermal's **Setup** cell and select **Refresh**.
    b. Right-click on Thermal's **Setup** cell and select **Update**.
    c. Right-click on Maxwell's **Solution** cell and select **Enable Update**.
    d. Right-click on Maxwell's **Solution** cell and select **Update**.

Maxwell to Ansys Stress Feedback Coupling

Maxwell supports stress feedback coupling for 2D/3D transient, magnetostatic, eddy current, and electrostatic designs via the Ansys Workbench schematic.

> **Note:** A Maxwell system can also be coupled with **both** thermal and stress systems via Workbench.

Maxwell-Specific Considerations

- Users must select object/s (i.e., geometry) in Maxwell upon which displacement data from Ansys Mechanical should be considered. This is done to avoid applying displacement to the whole model while only certain part(s) are sensitive to stress. This is a per-design setting similar to the Set Object Temperature setting for thermal feedback.
- Each frequency point in an eddy current sweep will be solved with the same feedback data.
- Displacement data that has already been exported from Ansys Mechanical Stress is invalidated when the Maxwell design is edited such that the previously simulated solution is considered as invalid or non-current. These edits include
    - Modifying the geometries or selecting “Revert To Initial Mesh.”
    - Modifying the boundary/excitation settings, such as changing the value of a “Current excitation” in a magnetostatic design.
- Maxwell solutions can incorporate feedback from both thermal and stress.
- Once the Maxwell solution has been integrated with displacement/temperature, the adaptive simulation process of a static simulation is disabled. Users must then manually

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

invalidate the displacement/temperature data in the existing solution before the adaptive simulation process is re-enabled.

- Simulation iteration is controlled by user.

Maximum Force Density (AC) Components Calculation

In Maxwell, there are two options to couple the eddy solver with the Mechanical structure static solver. You can choose either DC force density or Maximum force density. The maximum force density includes the contribution from AC components.

In Maxwell stress tensor,

$$\sigma_{ij} = B_i B_j - \frac{1}{2\mu_0} B^2 \delta_{ij}$$

The DC (averaged) components of B_iB_j is calculated by

$$B_i B_j|_{DC} = \frac{1}{2\mu_0} Re\left[\dot{B}_i \grave{B}_j\right]$$

and the AC (fluctuation) components

$$B_i B_j|_{AC} = \frac{1}{2\mu_0} Re\left[\dot{B}_i \grave{B}_j\right]$$

where

$$\dot{B} = B_{Re} + jB_{im}$$

And $\grave{B}$ is the complex conjugate of $\dot{B}$. The maximum force is calculated as

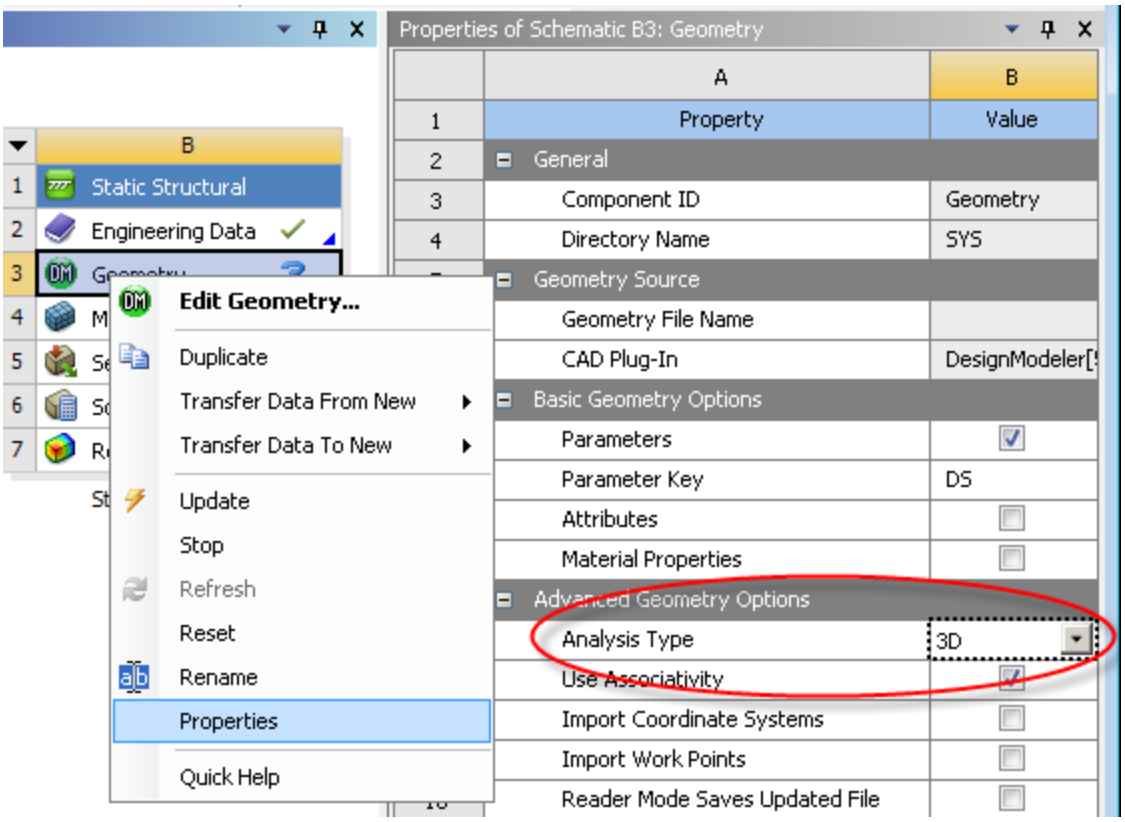
$$\vec{F} = \frac{\vec{F}_{DC}}{\left|\vec{F}_{DC}\right|}\left(\left|\vec{F}_{DC}\right| + \left|\vec{F}_{AC}\right|\right)$$

Coupling Maxwell Designs with Ansys Structural via Workbench

Stress feedback coupling between Maxwell 2D/3D and Ansys Structural is supported via the Workbench schematic. Stress feedback is supported for Maxwell magnetostatic, eddy current, and transient types. Users also need to set up the design and geometry appropriately. An appropriate design has one or more solve setups that are enabled for stress feedback. The process for stress feedback coupling between Maxwell and Ansys Structural is similar to that described in Coupling Maxwell Designs with Ansys Thermal via Workbench.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

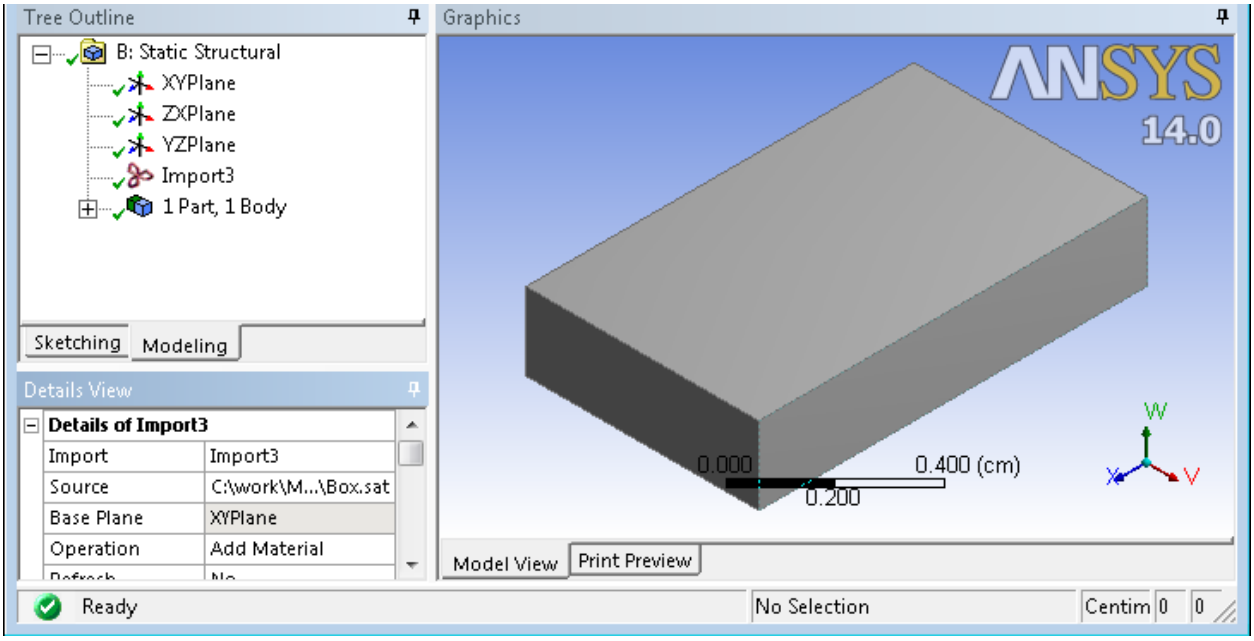
1. The easiest way to add a Maxwell 2D or 3D design to a Workbench schematic is to import a working design via **WorkbenchFile** > **Import**. The imported design is placed in the **Workbench** schematic after it is successfully imported.
2. Next, insert a **Static Structural** system and change its **Analysis Type** to **2D** or **3D**, (depending on the Maxwell design type) by right-clicking on the **Geometry** cell and selecting **Properties**. It is important to change the **Steady-State Thermal** system's analysis type *before* setting up its geometry.



3. To set up the **Static Structural** system's geometry, you must first export the Maxwell geometry using **sat** or **step** format as follows:
    a. Select the **Modeler** > **Export** menu item.
    b. Select the desired model geometry format (**sat** or **step**), and the save location in the dialog box and save the file for use by Ansys Workbench.
4. Import the file via the **Geometry** module of the **Static Structural** system.
    a. To access the **Geometry** module, double-click on the **Geometry** cell in the **Static Structural** system to launch **Design Modeler**.
    b. Select **File** > **Import External Geometry File** and browse for the geometry file exported from Maxwell.

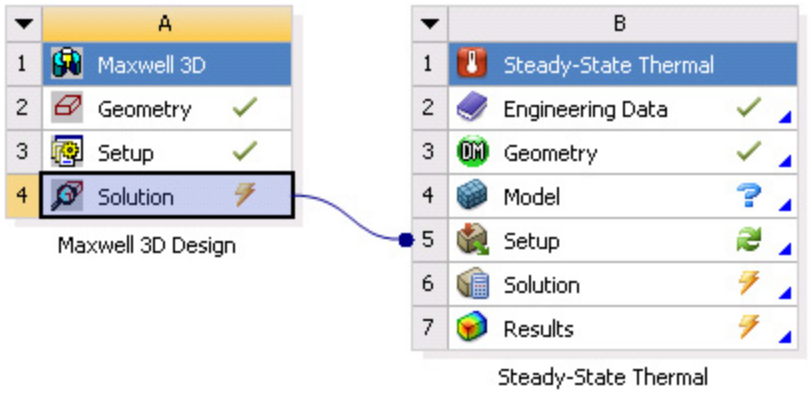
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. After the geometry file is imported, right-click on the root folder of the modeler project tree and select **Generate**. (When the geometry file is of a Maxwell 2D RZ design, users can rotate the geometry in **Design Modeler** by creating a body operation.)



5. Close **Design Modeler** and refresh the **Model** cell of the **Static Structural** system by right-clicking the **Model** cell and selecting **Refresh**.
6. The geometry mode of the **Static Structural** system can be changed via the Ansys **Mechanical** user interface.
    a. Launch **Mechanical** by double-clicking the **Setup** cell of the **Static Structural** system.
    b. Select **Geometry** in the project tree and the **Definition** of **Geometry** will be shown in the **Detail** window.
    c. Select either **Flexible** or **Rigid** as the value for the property 2D (or 3D) **Stiffness Behavior**.
7. To set up the coupling, drag the **Solution** cell of the Maxwell system and drop it on the **Setup** cell of the **Static Structural** system.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



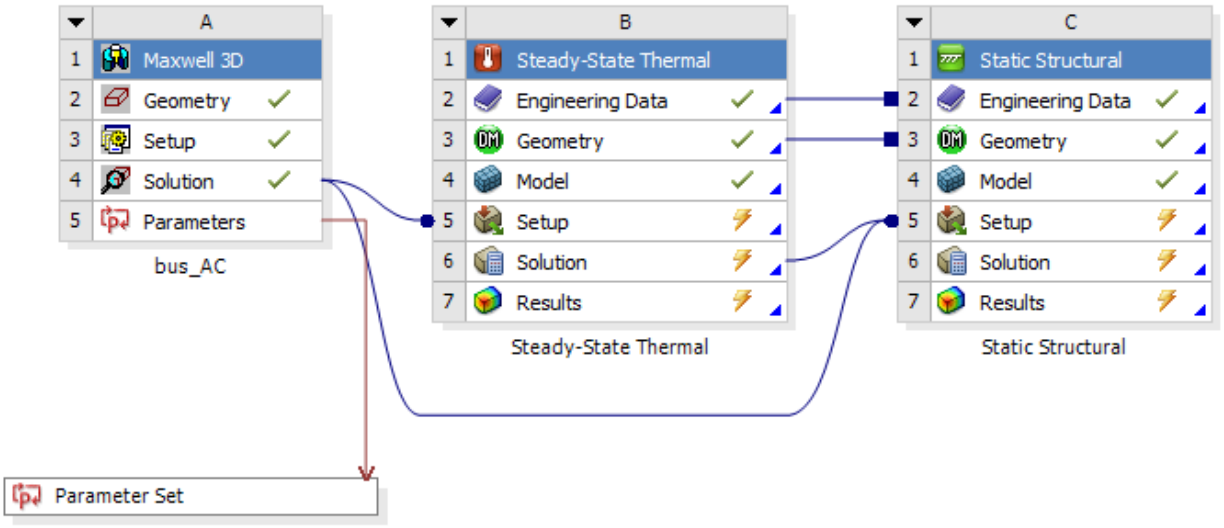
8. Note that the Maxwell **Solution** cell is tagged with a “Lighting Bolt” symbol. Right-click on the Maxwell **Solution** cell and select **Update**. This will initiate a Maxwell simulation if it is not already solved. Once Maxwell's solution is available, the “Lighting Bolt” changes to a “Green Check” symbol.
9. To “push” the coupling into **Static Structural**, right-click on the **Static Structural Setup** cell and select **Refresh**.
10. After refresh is finished, you can launch Ansys **Mechanical** by double-clicking the **Setup** cell to finish the coupling setup, which is similar to that described in Coupling Maxwell Designs with Ansys Thermal via Workbench.

Coupling Maxwell with Both Ansys Thermal and Structural via Workbench

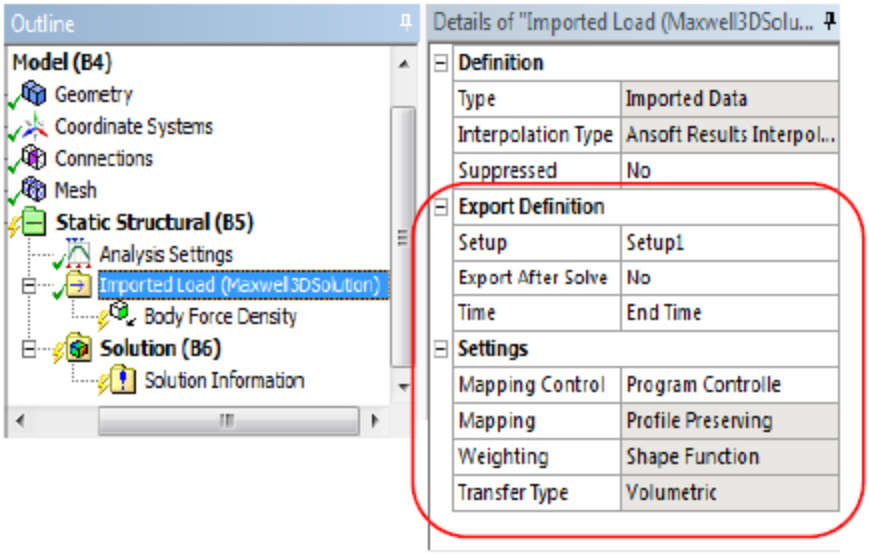
A Maxwell system can also be coupled with *both* thermal and stress systems via Workbench. The thermal system then serves as an “up-stream” system for the stress system. This means that the stress analysis takes both electromagnetic and thermal forces into consideration. In this scenario the user must select the same object(s) in the thermal and stress systems to apply the respective imported loads.

To set up the coupling, drag the **Solution** cell of the Maxwell system and drop it at the **Setup** cell of a Thermal and Static Structural (Stress) system. The user also needs to couple the Thermal and Static Structural systems to capture the effect of thermal force.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



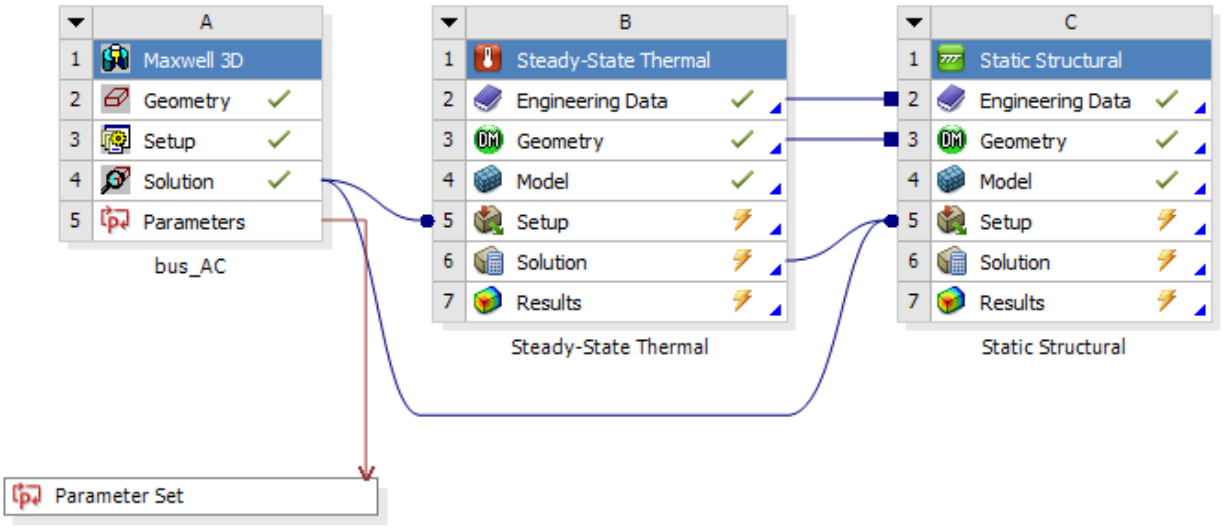
The coupling framework is built on top of the existing Thermal Feedback. The Stress system will have additional Export Definition and Mapping Settings like Thermal.



Example 1: One Iteration

The following image illustrates a coupling setup where both the Thermal and Stress system are ready to be updated. The Maxwell adaptive solution has converged in 3 passes. The Maxwell system has both thermal and stress feedback enabled.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

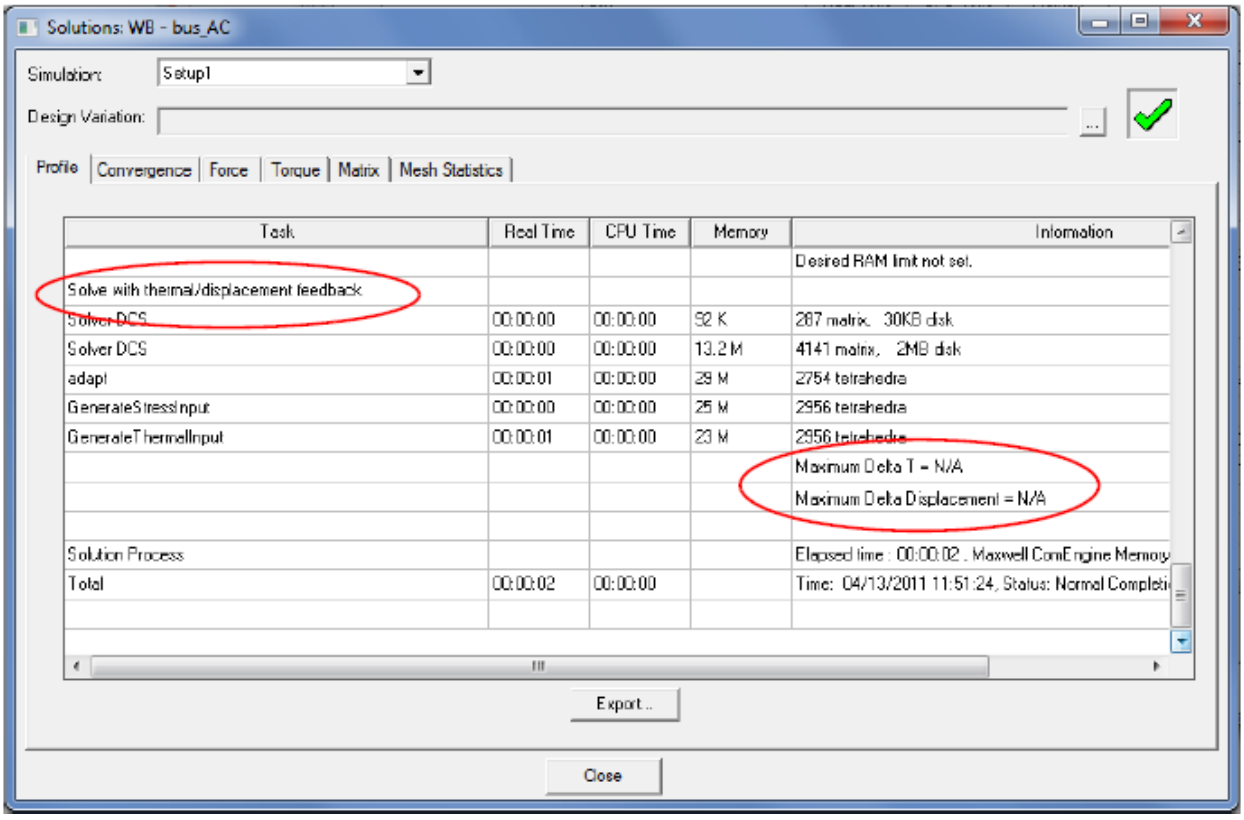


1. Right-click on the **Solution** cell of Stress (Static Structural) and select **Update**.
   a. The **Setup** of Thermal will be Updated with “em” loss from Maxwell.
   b. The **Solution** of Thermal will be Updated and temperature will be exported to Maxwell.
   c. The **Setup** of Stress will be Updated with thermal force from Thermal and force density from Maxwell.
   d. Displacement will be exported to Maxwell after Stress finishes simulation.
2. Right-click on the **Solution** cell of Maxwell and select **Enable Update**.
3. Right-click on the **Solution** cell of Maxwell and select **Update**.

Maxwell resimulates the third pass with its mesh and the temperature/displacement feedback.

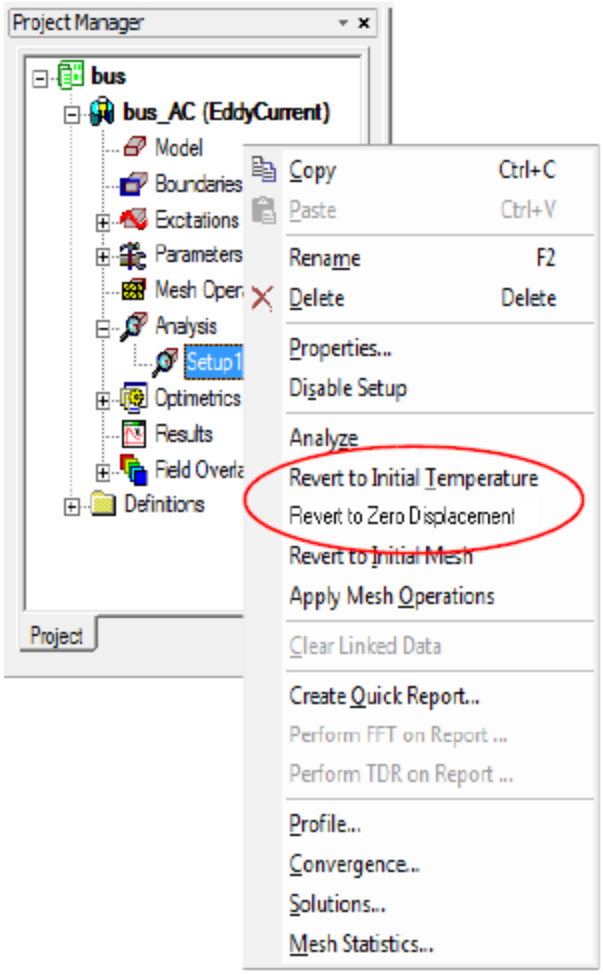
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The profile will show information about the feedback:



Both Revert to Initial Temperature and Revert to Zero Displacement menus are present in the analysis setup context menu.

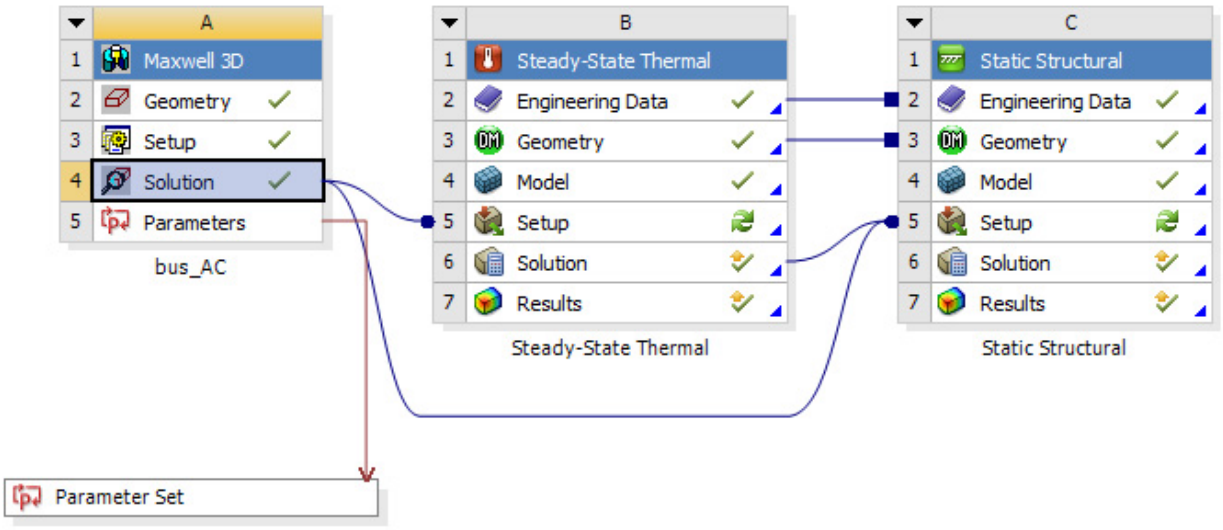
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Example 2: Manual Iteration

The following image illustrates the Workbench schematic after Example 1, where the 1st iteration has completed.

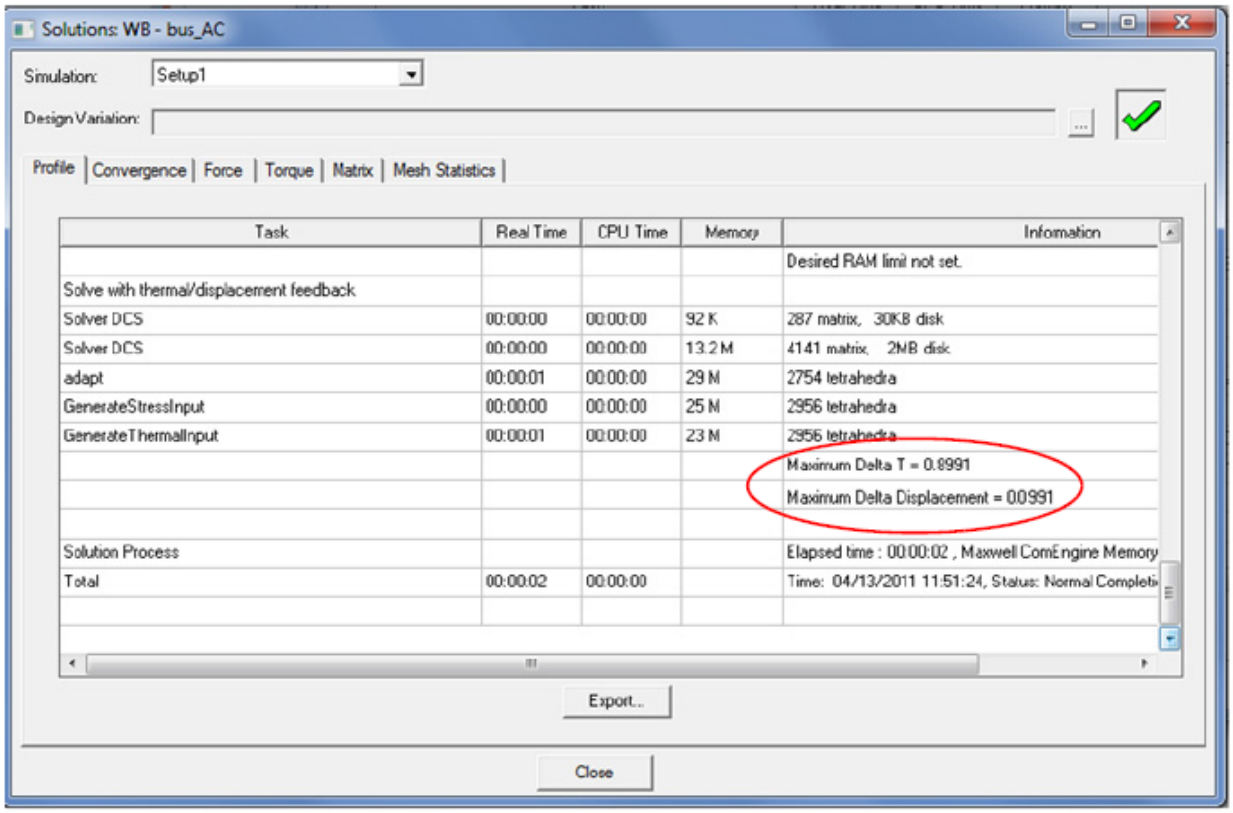
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



1. Right-click on the **Solution** cell of Stress and select **Update**.
   - The **Setup** of Thermal will be Refreshed and Updated with “em” loss from Maxwell.
   - The **Solution** of Thermal will be Updated and temperature will be exported to Maxwell.
   - The **Setup** of Stress will be Refreshed and Updated with thermal force from Thermal and force density from Maxwell.
   - Displacement will be exported to Maxwell after Stress finishes simulation.
2. Right-click on the **Solution** cell of Maxwell and select **Enable Update**.
3. Right-click on the **Solution** cell of Maxwell and select **Update**.

Maxwell resimulates the third pass with its mesh and *new* temperature/displacement feedback. The profile will show information about the feedback:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



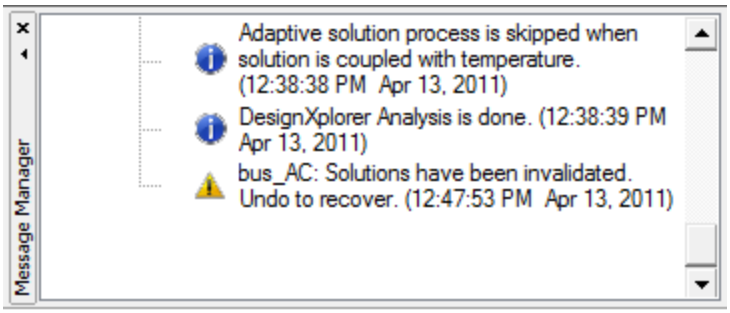
Note that the delta temperature and displacement is being reported in the profile.

Example 3: Revert Maxwell Solution

The temperature and displacement in the Maxwell solution can be reverted separately.

1. Select **Revert to Initial Temperature** in Maxwell.

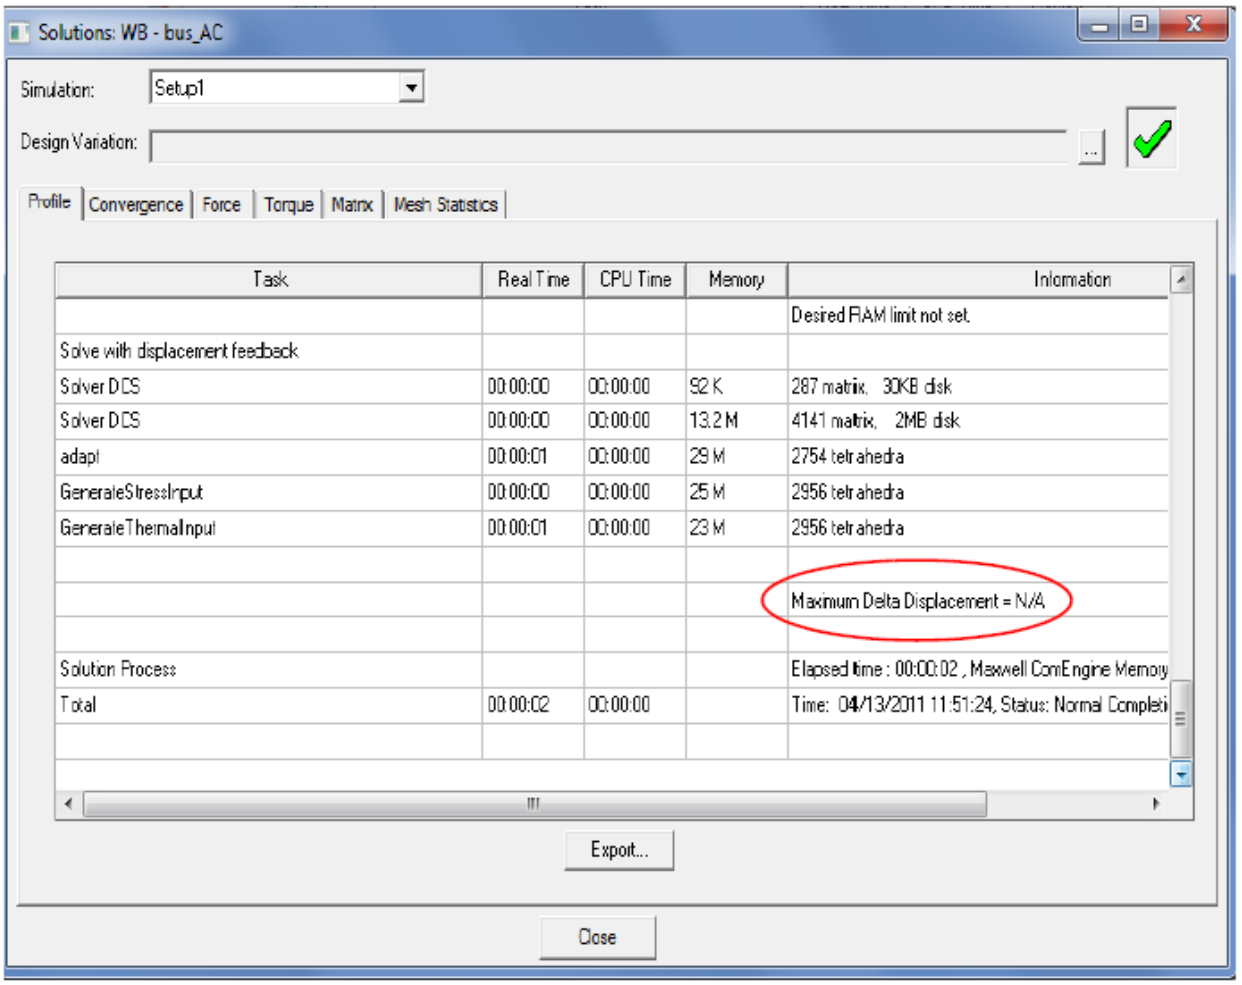
   A warning message displays notifying users about the invalidation of solution.



2. Right-click on Maxwell analysis setup and select **Analyze**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

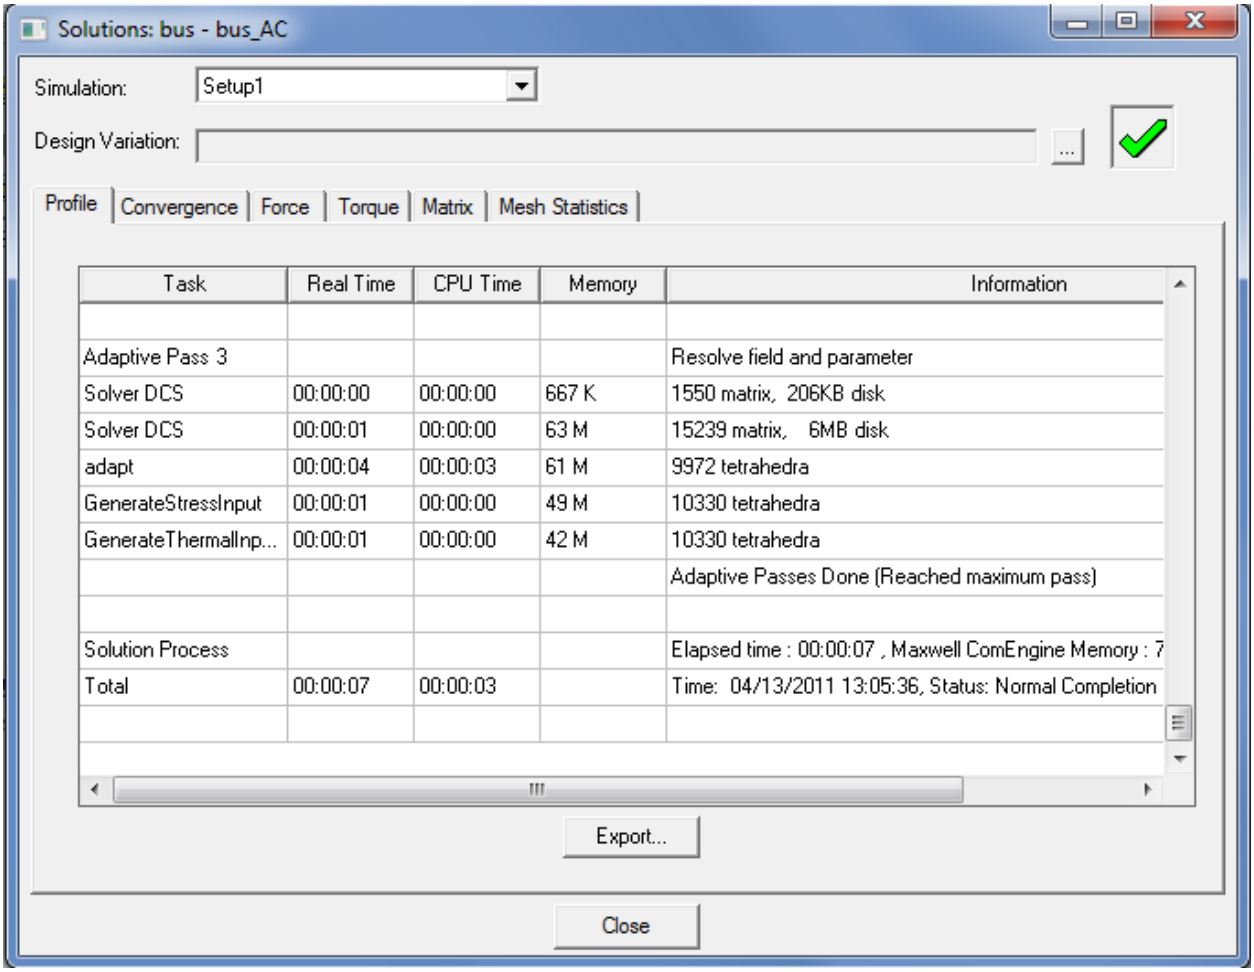
Maxwell resimulates the third pass with its mesh and displacement that was previously exported from Mechanical, but without temperature.



3. Select **Revert to Zero Displacement** in Maxwell, then right-click on Maxwell analysis setup and select **Analyze**.

Maxwell resimulates the third pass with its mesh without either temperature nor displacement.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



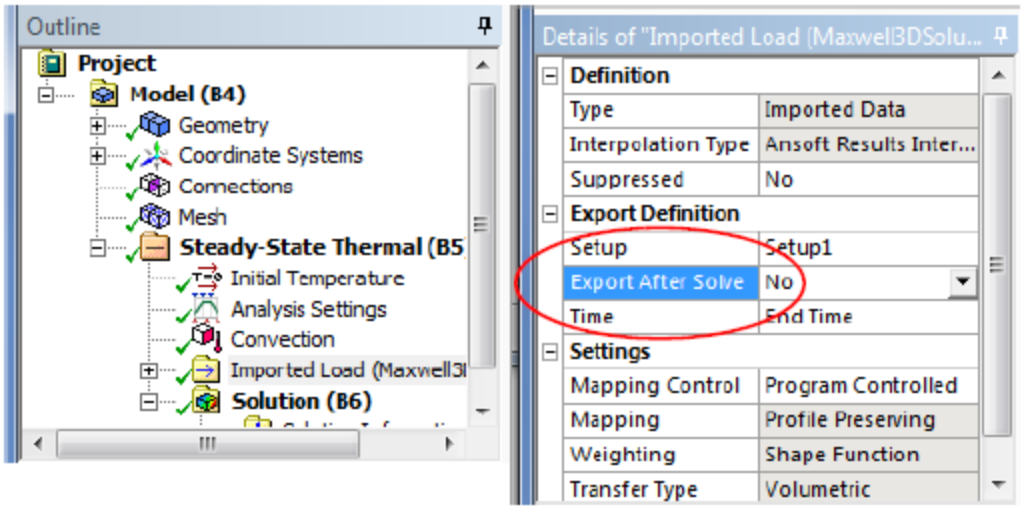
Example 4: Only Stress Feedback

The coupling setup is the same as in Example 1, with either one of the following differences:

- The Maxwell system is not enabled for thermal feedback (via SetObjectDisplacement). Note that because Maxwell is not enabled to support feedback, the **Export Result** properties should be available in the thermal system.
- The Maxwell system is enabled for thermal feedback, but users choose not to **Export**

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Result in the thermal system. which disables the automatic **Export Results**.



1. Right-click on the **Solution** cell of Stress and select **Update**.
   - The **Setup** of Thermal will be updated with EM loss from Maxwell.
   - The **Solution** of Thermal will be ppdated.
   - The **Setup** of Stress will be updated with thermal force from Thermal and force density from Maxwell.
   - Displacement will be exported to Maxwell after Stress finishes simulation.
2. Right-click on the **Solution** cell of Maxwell and select **Enable Update**.
3. Right-click on the **Solution** cell of Maxwell and select **Update**.

Maxwell resimulates the third pass with its mesh and the displacement feedback.

The profile shows information about the feedback and **Revert to Zero Displacement** will be available in the solve setup context menu.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

System Coupling Analyses Using Maxwell

System Coupling facilitates and manages the execution of coupled simulations between multiple physics solvers, coupling active cosimulation participants using either System Coupling's graphical user interface (GUI) or its command-line interface (CLI).

Maxwell can engage as a coupling participant in thermal cosimulations with Ansys Fluent and Ansys Mechanical and in electrical arc modeling simulation with Anys Fluent and Ansys Twin Builder. System Coupling provides enhanced control over coupled simulation processes, including automatic starts and restarts for participants, the ability to manipulate the System Coupling data model, an interactive solution workflow, and multiple output formats for reviewing and postprocessing results.

In System Coupling analyses, each participant completes its physics and coupling setups in its own user interface generating a Participant Setup (.scp) file along with its solver file(s). The coupled analysis itself includes loading participants, setting values for coupling-related settings, specifying coupled analysis settings, and starting the run. Once the solution has started, System Coupling directs the execution of the coupled analysis – including general coupling management, participant communications, and transfers of data between participants.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: For detailed information on System Coupling in general, refer to the System Coupling User's Guide. For details on working in System Coupling's GUI or CLI, refer to the Using System Coupling's User Interfaces section.

Note: For examples of Maxwell participating in cosimulations, review the coil-and-core induction heating, bar-and-coil induction heating, bus bar, and electric motor examples in System Coupling Tutorials. Also see Electrical Arc Modeling Using System Coupling.

Supported Capabilities and Limitations

The following capabilities are supported for System Coupling analyses with Maxwell:

- Multi-region data transfers for Maxwell participants.
- Maxwell 3D Eddy Current, Maxwell 3D Transient, and Maxwell 2D Transient Cartesian, XY geometry mode solutions.
- Update frequency controls for a Maxwell participant running a steady solution.
- Automatic and manual distribution parameters for parallel execution
- Dynamic remeshing and remapping during the execution of Maxwell 3D Eddy Current simulations with time-dependent motion or excitation defined. For details, see Mapping Process in the System Coupling User's Guide.
- Variable displacement for simulations with time-dependent motion defined.
- Thermal data transfers on bodies. EM loss can be provided to other coupling participants, and temperature can be received from them.
- Motion data transfers on coupled bodies.
- Parallel/distributed processing.
- Electrical arc modeling:
    - Maxwell provides losses (including surface loss) and Lorentz forces to Fluent, and Fluent feeds electrical conductivity, temperature, and simulation time back to Maxwell. Note that to enable correct quantities transfer (namely, force, loss, temp, and conductivity), turn on Energy and Potential Models on in the Fluent Setup\Models list.
    - Maxwell provides voltage to an external circuit (Twin Builder), and Twin Builder provides current to Maxwell (with user's circuit model).

The following are known limitations when using System Coupling with Maxwell:

- Only Maxwell 3D Eddy Current, Maxwell 3D Transient, and Maxwell 2D Transient, Cartesian, XY geometry mode solution types are supported.
- For electrical arc modeling, only Maxwell 3D magnetostatic designs are supported.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Maxwell 3D Eddy Current solution type is limited to a single frequency.
- Variable velocity is not supported for designs with time-dependent motion and/or excitations.
- Update frequency controls are not supported when Maxwell runs a solution with time dependencies.

Using HPC Distribution Settings for Coupled Analyses

System Coupling supports the use of Maxwell's automatic and manual HPC distribution parameters for distributed coupled analyses. Each of these **Execution Control** settings corresponds to one of Maxwell's distributed analysis parameters.

- **Auto Distribution Settings**: Whether job distribution is performed automatically.

When auto-distribution is disabled, the following manual settings are available:

- **Include HPC Distribution Types**: List of the HPC distribution types to be included for distributed runs.
- **Number of Cores Per Task**: Number of HPC cores to be used per task.
- **Batch Options**: Batch option arguments to be applied to the run.

For more information, see *Using AEDT HPC Distribution Options* in the *System Coupling User's Guide*.

Variables Available for System Coupling

The following variables will be available on convective boundaries:

Name / Internal Name	Transfer Direction	Data Type	Physical Type
Loss / Loss	Output	Scalar	Heat Rate
Temperature / Temperature	Input	Scalar	Temperature

The following variables will be available for magnetostatic simulations:

Name / Internal Name	Transfer Direction	Data Type	Physical Type
Arc Voltage	Output	Scalar	Voltage
Arc Current	Input	Scalar	Current
Loss / Loss	Output	Scalar	Heat Rate
Lorentz Force	Output	Vector	Force
Electrical Conductivity	Input	Scalar	Electrical conductivity
Temperature	Input	Scalar	Temperature

System Coupling Related Settings

System Settings

To enable coupling with Maxwell, the environment variable **ANSYSEM_ROOT251** must be set to the location of your Ansys Electromagnetics installation.

> **Note:** The environment variable name is ANSYSEM_ROOT<*major*><*minor*>, where <*major*> is the two digit major version number (the last two digits of the year); and <*minor*> is the one digit minor version number. For example, for the Ansys Electronics 2025 R1 release, the environment variable name is ANSYSEM_ROOT251. For the Student Version of the software, the variable name is ANSYSEM_ROOTSV<*major*><*minor*>.

- For Windows, this environment variable is automatically set during the installation of the Ansys Electromagnetics Suite (for example, *C:\Program Files\ANSYS Inc\v251\AnsysEM*).
- For Linux, you must set this environment variable manually (for example, */opt/ansys_inc/v251/AnsysEM*).

> **Note:** The environment variable must be set on all hosts if the analysis is distributed to multiple hosts. For Windows, this environment variable must generally be set as a System environment variable (not a user environment variable) for distributed analysis so that it is set for the Ansoft RSM Service. For Linux, the user must ensure that the environment variable is set for the AnsoftRSM Service daemon processes.

You must also integrate Maxwell with Ansys: from the Start menu, select **Ansys EM Suite 2025 R1** > **Modify Integration with Ansys 2025 R1**.

Maxwell Settings

Solution Type:

Must be set to one of the following:

- **Eddy Current** for Maxwell 3D designs only.
- **Transient** for either Maxwell 3D or Maxwell 2D designs. For Maxwell 2D designs, you must also specify the **Cartesian, XY** geometry mode when selecting this solution type.
- **Magnetostatic** for Maxwell 3D designs only.

Materials:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Bodies to receive temperature data must have temperature-dependent properties. Note that when the same materials are used in multiple participants, common properties (e.g., conductivity) must be consistently defined.

Motion:

Motion must be appropriately and consistently defined for all bodies involved in the analysis.

Stationary bodies must not move from the reference position or participate in multiple reference frames during the cosimulation.

Motion should be defined with a (rigid body) displacement.

For more information, see Additional Participant Setup Considerations in the *System Coupling User's Guide*.

Creating a System Coupling Setup

The **System Coupling Setup** enables the exchange of data between participants by creating an interface between regions on the participant models.

To create a coupling setup, select (**Optimetrics** > **Add** > **System Coupling Setup**), and do one of the following:

- For Eddy Current designs, select the desired solution **Setup**, **Frequency**, and input/output quantities. For the **Temperature** quantity, click the **Object temperature** button to open the **Temperature of Objects** dialog in which you can choose to **Include Temperature Dependence**, and to set the temperatures for model objects composed of materials having temperature-dependent properties.
- For Eddy Current designs with time-dependent motion, create a dataset to define the position of the moving body, and design variables for the coupling time as provided by System Coupling and the displacement vector of the body.
- For 3D Magnetostatic designs:
    - For Maxwell\Twin Builder coupling, input a current excitation; the voltage value output to Twin Builder will be calculated from loss/current.
    - For Maxwell\Fluent system coupling, input temperature, system coupling time, and electrical conductivity.
    - For an example of system coupling involving Maxwell, Twin Builder, and Fluent, see Using System Coupling for Electrical Arc Modeling.
- For Transient designs, select the desired solution **Setup**, **Start time**, **End time**, and input/output quantities. For the **Temperature** quantity, click the **Object temperature** button to open the **Temperature of Objects** dialog in which you can choose to **Include Temperature Dependence**, and to set the temperatures for model objects composed of materials having temperature-dependent properties.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For Transient designs with time-dependent motion/excitation:
  - Define motion on coupled bodies.

    > **Note:** A profile or expression can be used to define rigid body motion using total displacement relative to the original object location.

  - Create design variables for both the coupling time (as provided by System Coupling) and the displacement vector of the body.
  - For Transient designs, Ansys Electromagnetics time is associated with System Coupling time. Maxwell uses this time to calculate excitation and position, but itself always begins its calculations at time zero.
  - Optionally, the following inputs can also be defined as a function of System Coupling time: **Maxwell Timestep Size**, **Loss Averaging Start Time**, **Loss Averaging Stop Time/Duration**.

Generating a System Coupling Participant Setup File

System Coupling uses each participant's Participant Setup (.scp) file and the corresponding Python (.py) configuration file to load the participant and its information into the data model.

To use System Coupling, you must generate a System Coupling participant file (**.scp**). Once the Maxwell setup is complete, generate the file using either of the following options:

- In the **System Coupling Setup** window, the system coupling configuration files are generated when you click the **OK** button.
- In the **Project Manager** under **Optimetrics**, right-click your System Coupling Setup and select **Generate Configuration Files**.

In both cases, the configuration files needed by System Coupling (an **.scp** file and a **.py** file) are generated at the same time and in the same location as the Maxwell project file.

Licensing Considerations when using System Coupling

A distinct license is required for each coupling participant product, but no additional licenses are required for the System Coupling infrastructure itself.

Note, however, that Ansys EnSight is required for the postprocessing of System Coupling's interface results. If you are using a Multiphysics Licensing Bundle that does not include an EnSight license (e.g., the Ansys Mechanical Maxwell bundle), you will need a separate EnSight license to visualize cosimulation results.

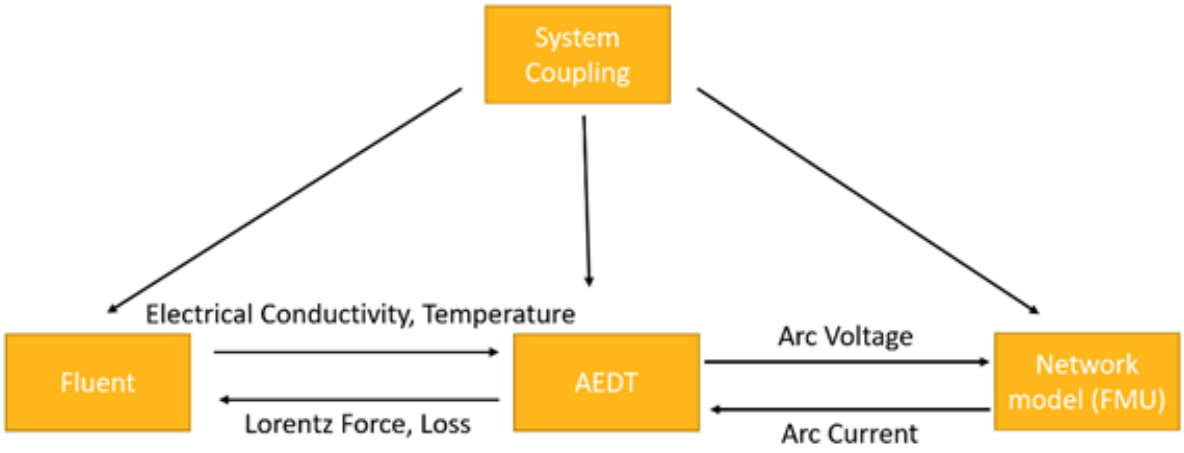
For more information on applicable licenses, see **Product Licensing Considerations** in the *System Coupling User's Guide*.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Example: Using System Coupling for Electrical Arc Modeling

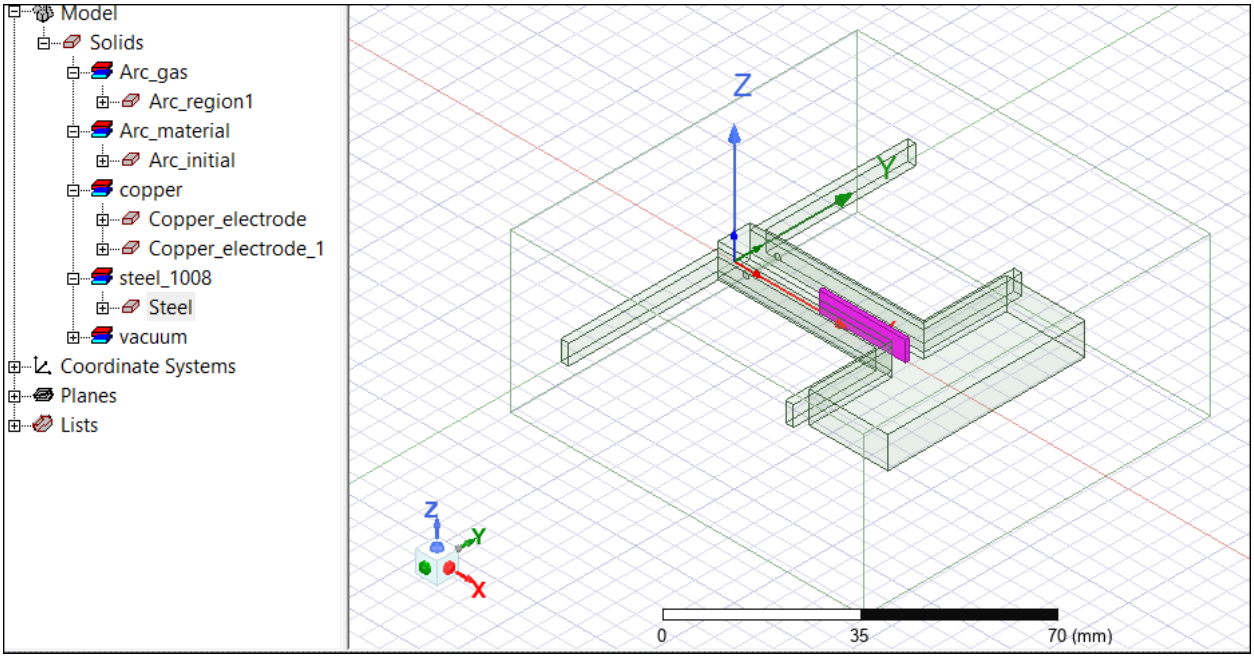
To model an electrical arc, System Coupling can be used with Maxwell and Fluent, as well as with Twin Builder. All participants in the System Coupling are coupled and dependent on each other. The workflow for this type of modeling has the following order: **Twin Builder** > **Maxwell** > **Fluent**. Multiple iterations (data exchanges) can occur between each two participants.

As seen in the flow chart, Maxwell provides voltage to an external circuit in Twin Builder (through a FMU model), and then Twin Builder feeds a current to Maxwell through a circuit model. Then Maxwell generates volume loss, surface loss (including nonlinear resistance thin layer losses on Electric Arc Anode and Cathode surfaces) and Lorentz forces for Fluent. Fluent can consume heat rate (surface loss from Maxwell) on solid-fluid interfaces, and it feeds electrical conductivity and temperature back to Maxwell.



The model used for this example is an electric arc between two run rails. The Maxwell model is shown below:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

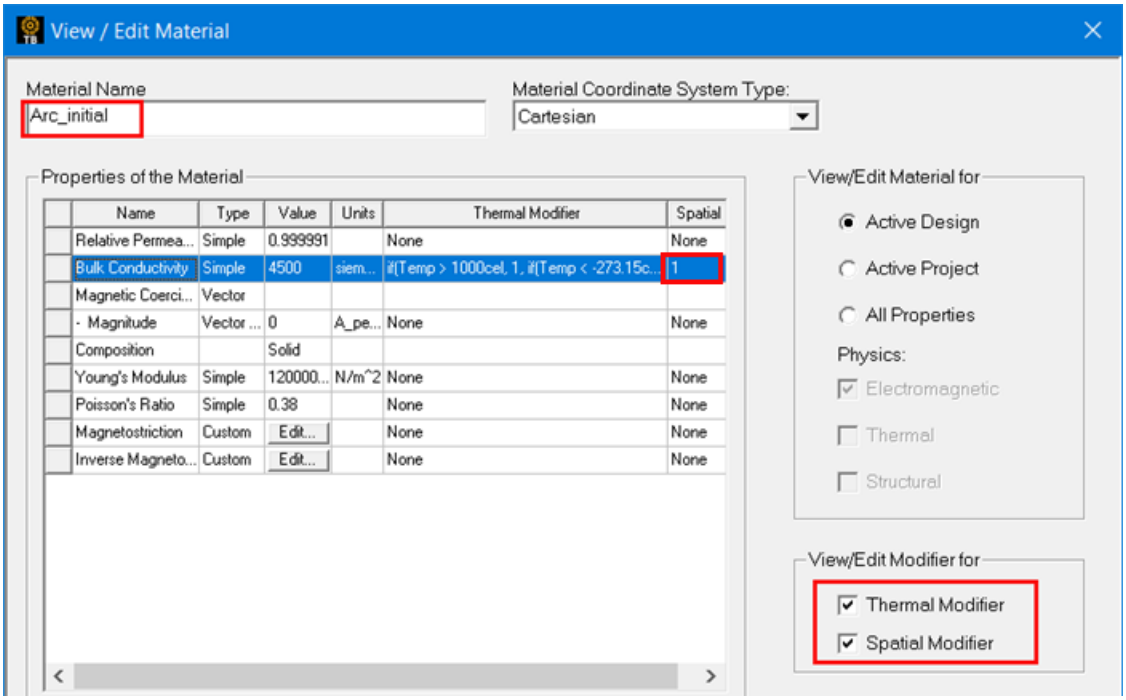


This example assumes that the user is familiar with the Twin Builder, Maxwell, and Fluent tools, so it will only detail the requirements for the System Coupling setup. For details on the individual tools, see the corresponding reference and tutorial topics.

Maxwell Setup

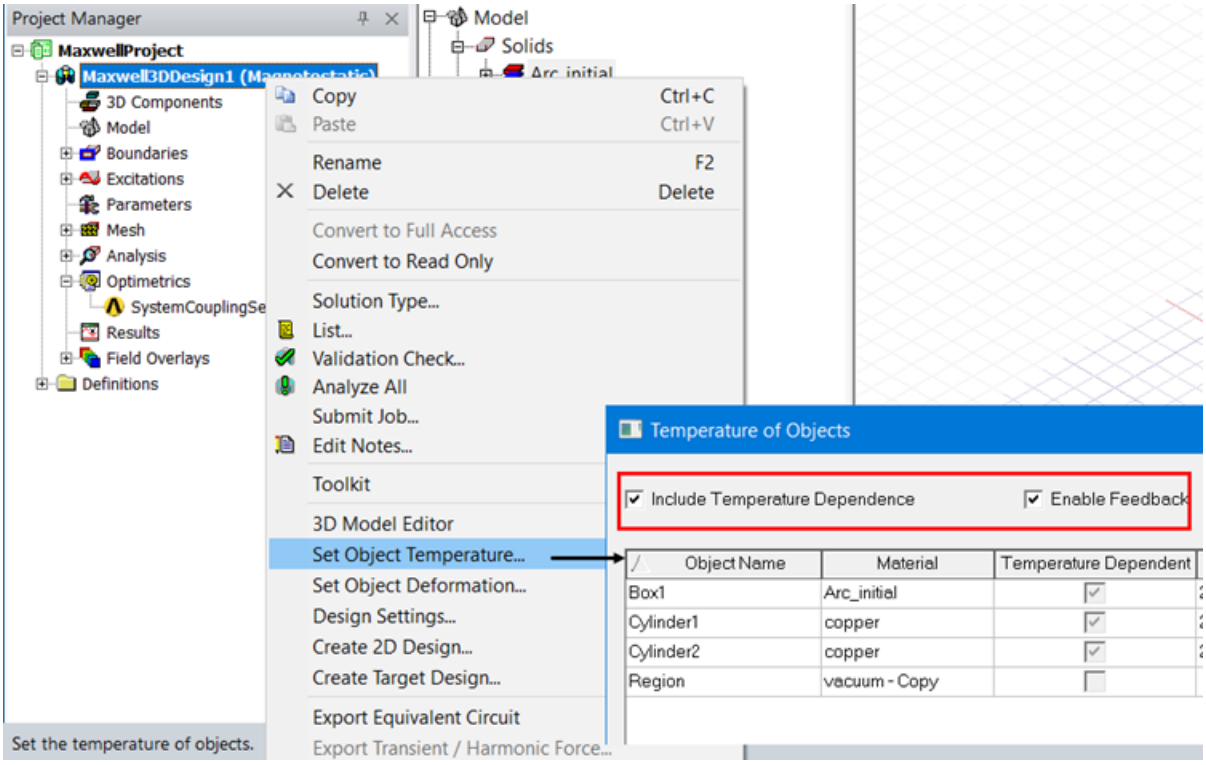
For the Maxwell model, the arc material should have the **Thermal Modifier** and **Spatial Modifier** options checked for Bulk Conductivity, and the **Spatial Modifier** should be set to **1**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

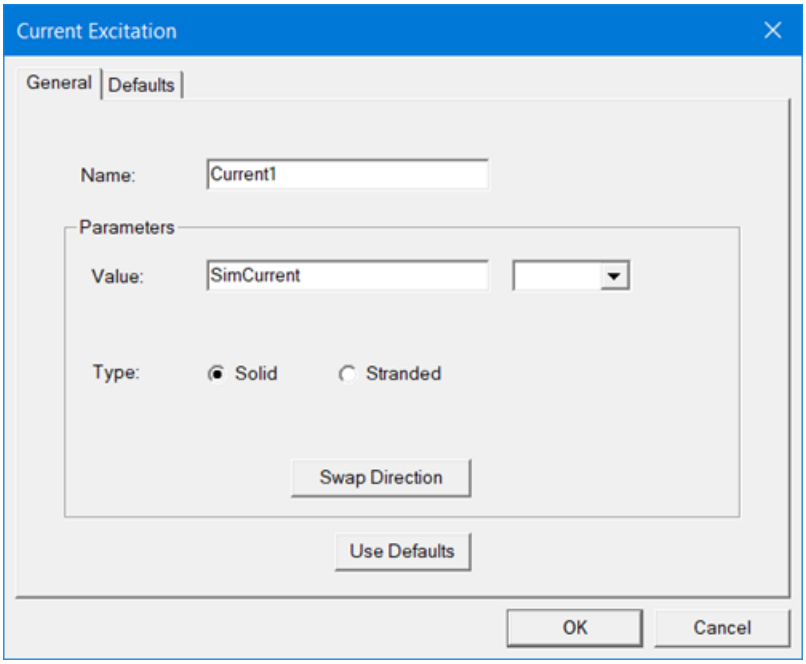


For the model Temperature of Objects, check **Include Temperature Dependence** and **Enable Feedback**:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



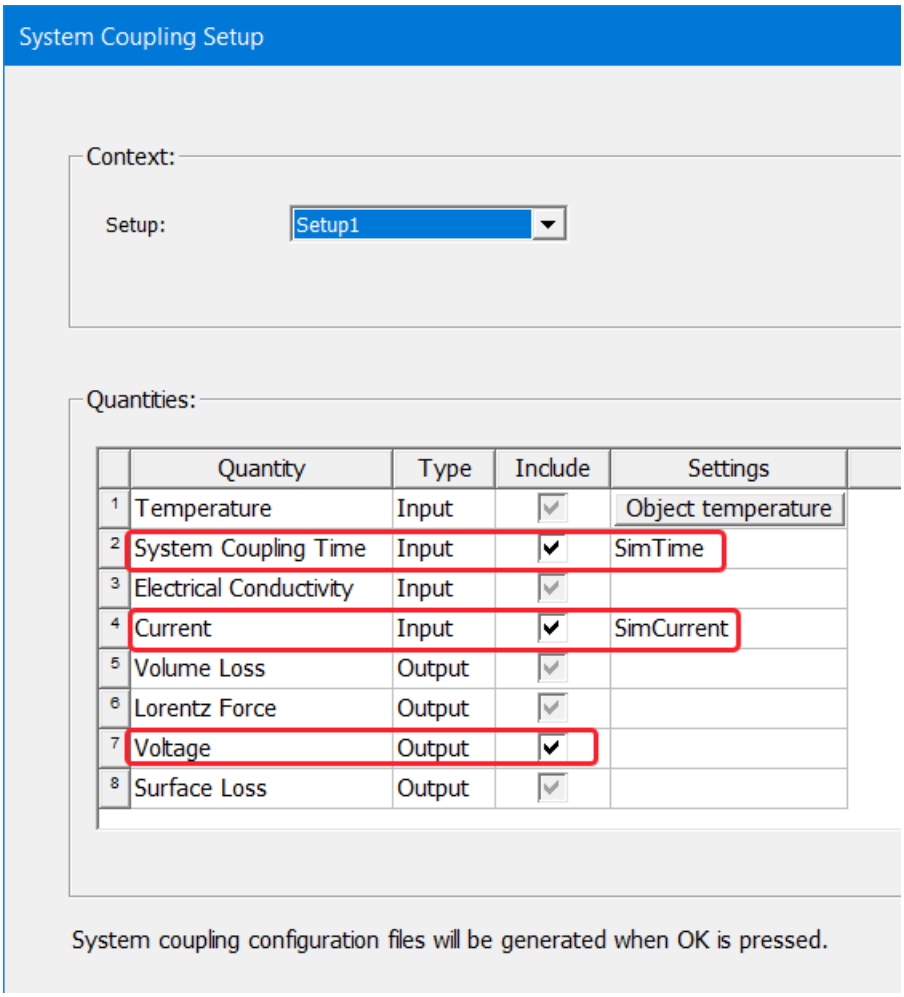
Set up the desired magnetostatic simulation, including boundaries, current excitations, and simulation time:



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

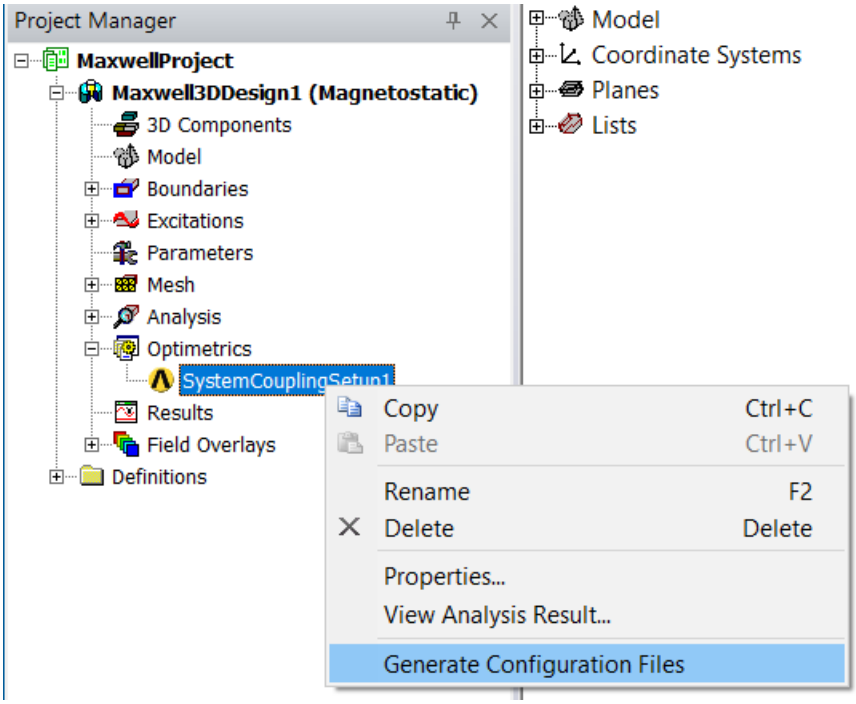
Add a System Coupling Setup to the Optimetrics folder, and set the following:

- Check **System Coupling Time**, and set the **Settings** variable to **SimTime**.
- Check **Current**, and set the **Settings** variable to **SimCurrent**.
- Check **Voltage**.



After finishing the Maxwell setup, generate the configuration files needed for System Coupling:

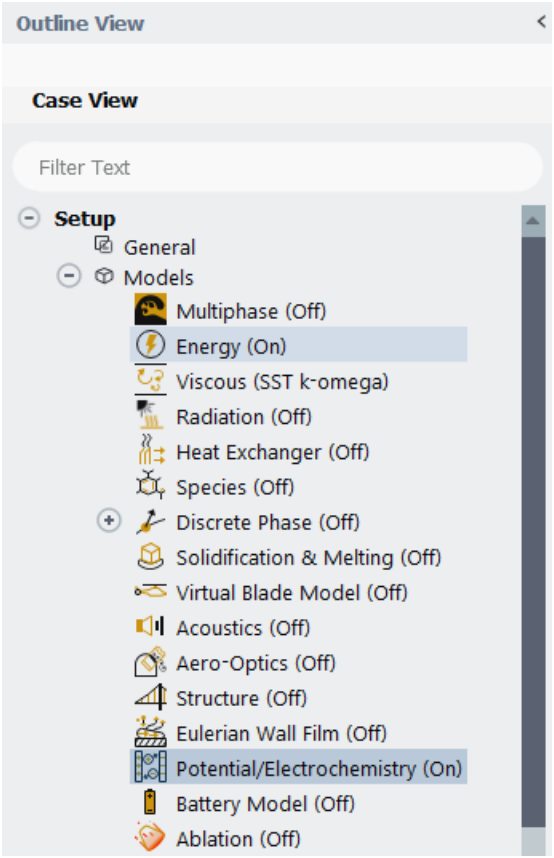
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Fluent Setup

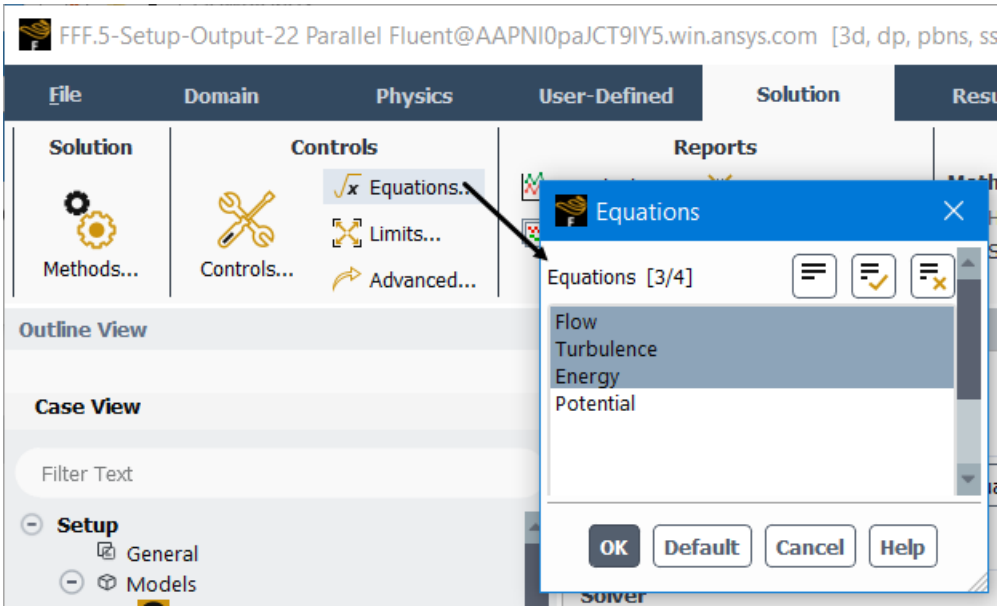
For the Fluent model, the materials should have the same properties as the Maxwell model. The Energy and the Potential/Electrochemistry models should be turned on. Potential is needed because it is used to calculate the Electrical Conductivity required by Maxwell.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

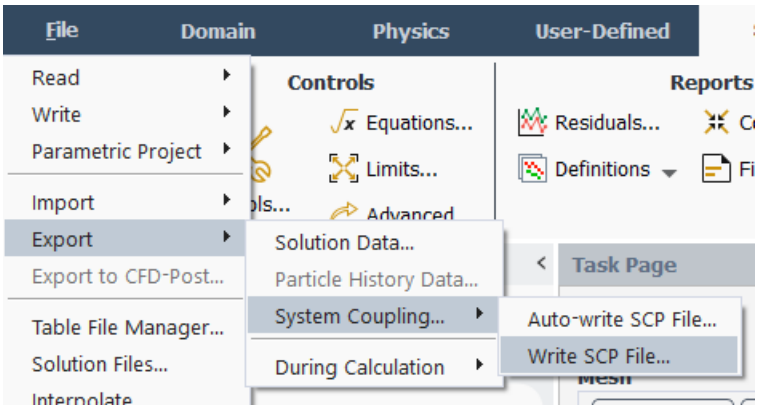


From the **Solution** panel, the **Potential** equation must be deactivated because electromagnetics will be simulated in Maxwell:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



After setting any required properties and boundary conditions for your model, export the Fluent setup to a System Coupling file:



System Coupling Setup

Load the System Coupling participants one by one following the order Twin Builder FMU Model

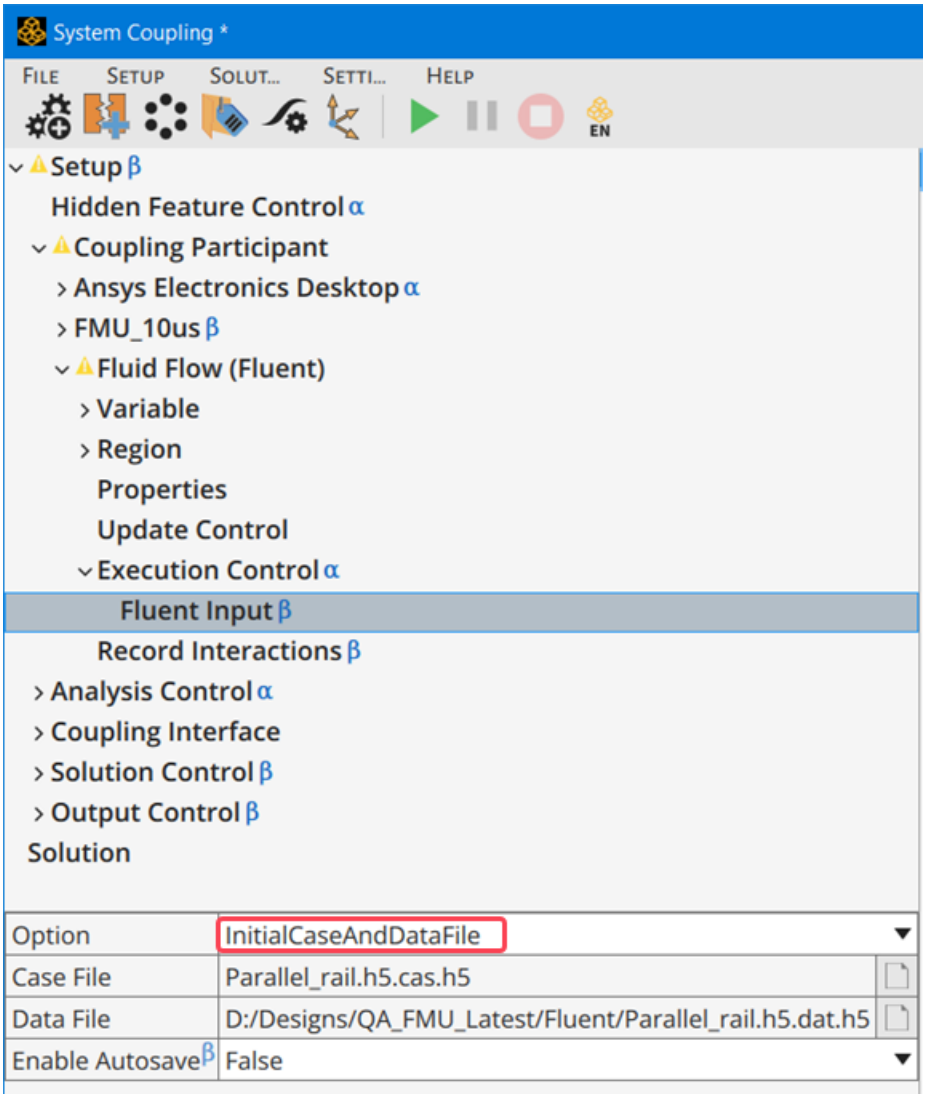
> Ansys Electronics Desktop Maxwell > Fluid Flow: click **Add Participant** icon , and in the dialog box that opens, find the input files for each participants and add one by one.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The input file for TwinBuilder is a .fmu file.
- The input file for AEDT is a \\MaxwellProject_Maxwell3DDesign_SystemCouplingSetup1.scp file.
- The input file for Fluid Flow is a \\Fluent\fluent.scp file.

Note that the order in which they were added reflects the order in which they have to be solved.

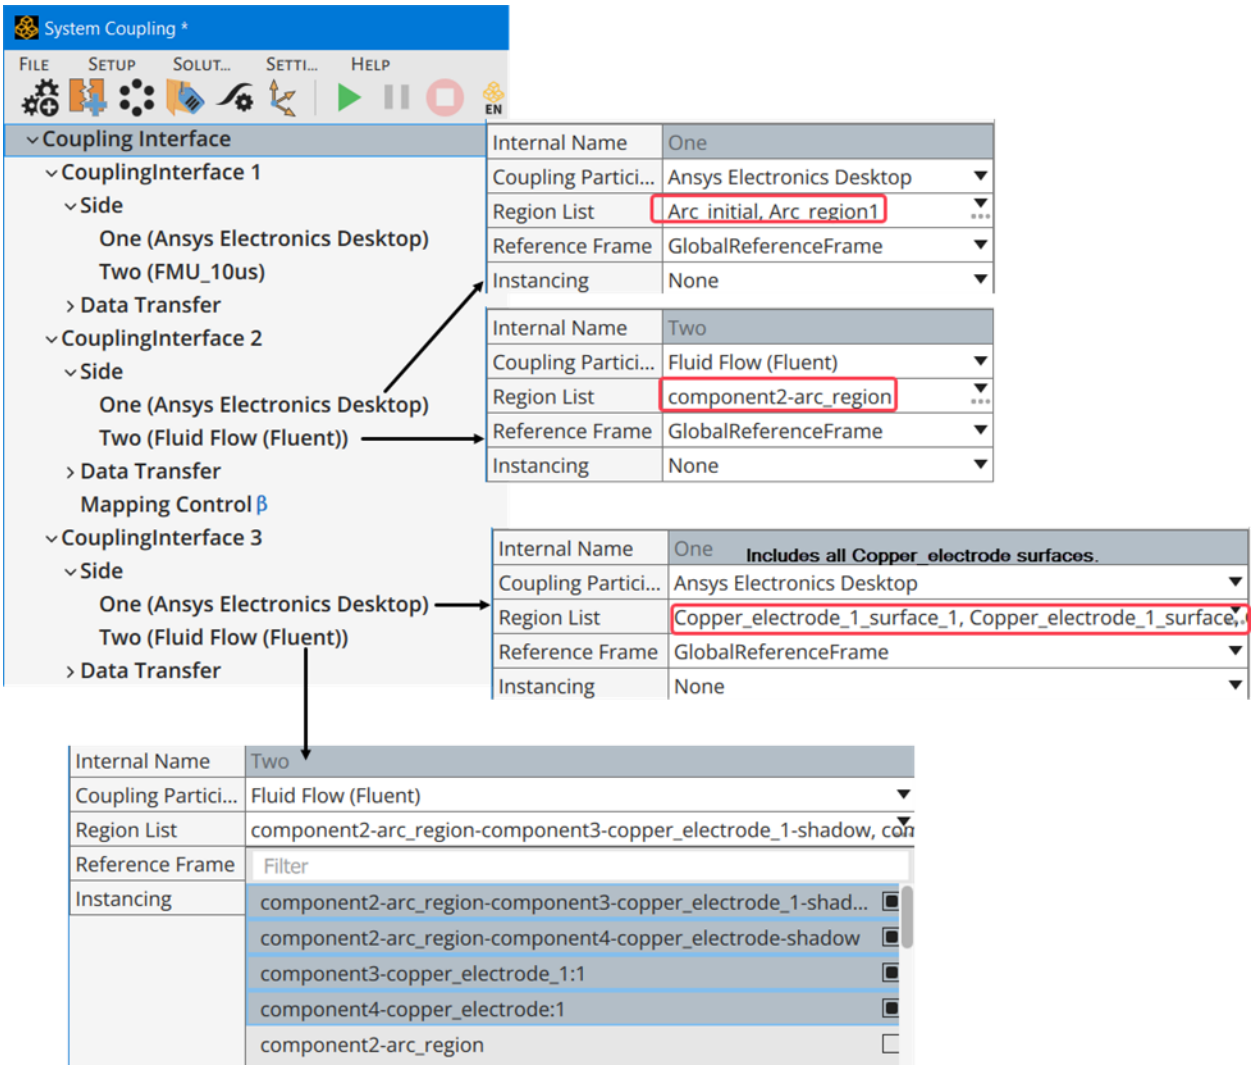
For the **Fluid Flow\Fluent Input**, add the Fluent case and data files in from the \\Fluent directory:



Add three Coupling Interfaces: One between the FMU model and Maxwell and two between Maxwell and Fluent. For Maxwell\Fluent interfaces, select a region or regions for each side where the data will be exchanged: for CouplingInterface2/Side 2, the region specified for Fluent

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

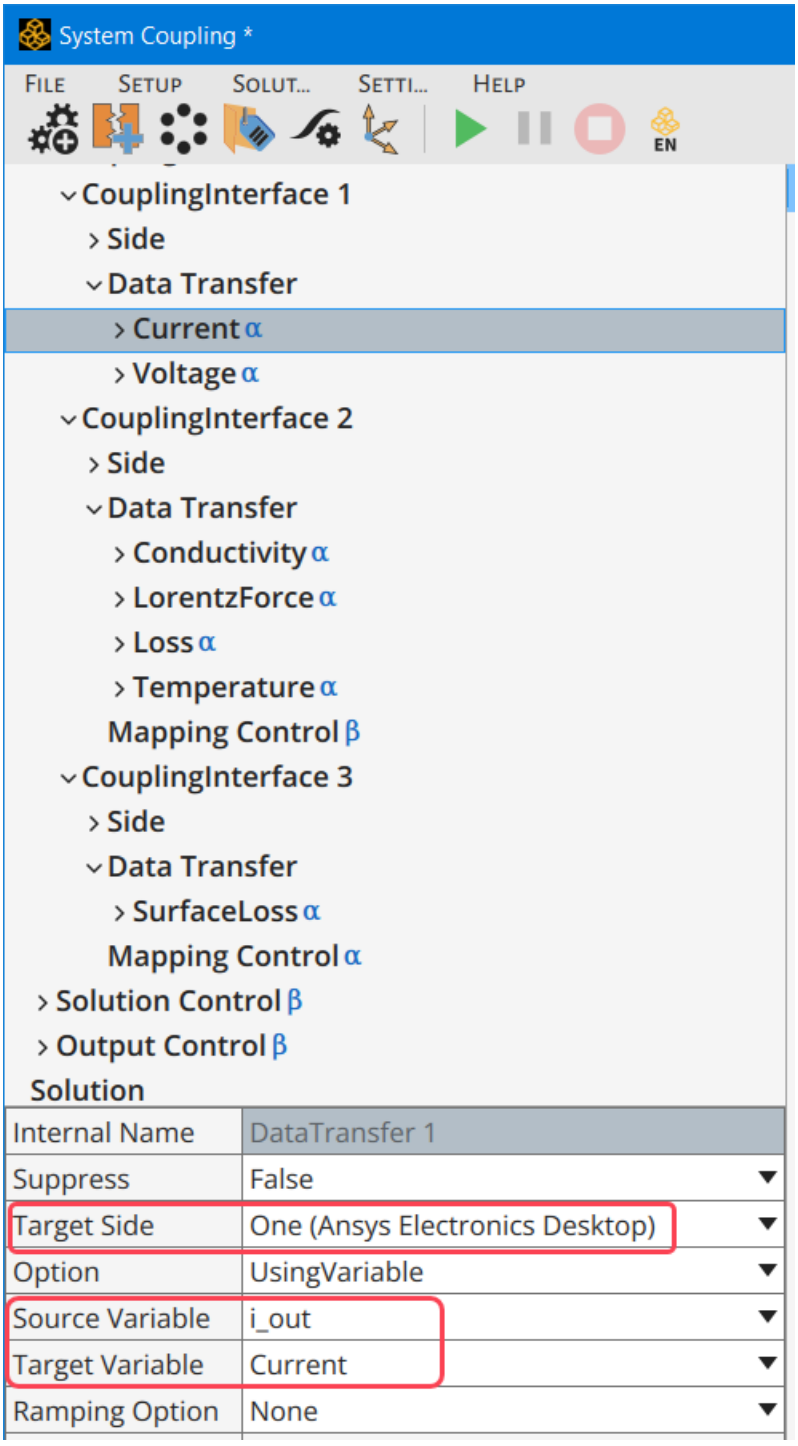
is a fluid; for CouplingInterface3/Side 2, the regions specified for Fluent are the solid-fluid interfaces.



For each coupling interface, specify the data that will be transferred. The example setup includes the following:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- CouplingInterface1\DataTransfer 1: i_out is transferred to Side 1(Maxwell) as Current.

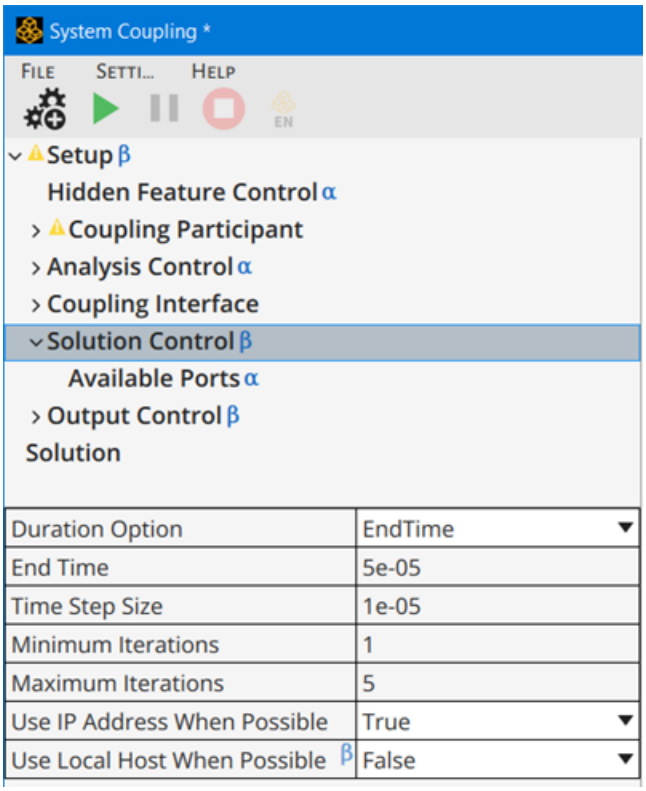


- CouplingInterface1\DataTransfer 2: Voltage is transferred to Side 2 (Twin Builder model) as voltage in.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- CouplingInterface2\DataTransfer 1: Electrical Conductivity is transferred to Side 1 (Maxwell) as conductivity.
- CouplingInterface2\DataTransfer 2: LorentzForce is transferred to Side 2 (Fluent) as Lorentz_Force
- CouplingInterface2\DataTransfer 3: Loss is transferred to Side 2 (Fluent) as heatrate.
- CouplingInterface2\DataTransfer 4: temperature is transferred to Side 1 (Maxwell) as Temperature.
- CouplingInterface3\DataTransfer 1: SurfaceLoss is transferred to Side 2 (Fluent) as heatrate.

When the System Coupling is executed, it will run according to the end time, timestep and iterations specified in the Solution Control setup:



When the system coupling is executed, Maxwell will output the arc voltage (calculated through loss/current) to the external circuit arc voltage interaction with network, and Maxwell will input the arc current from the external circuit (Twin Builder FMU). Maxwell loss and surface loss calculations will be output to Fluent, which will input conductivity and temperature into Maxwell.

The simulation can be monitored from the **Command Console** tab, and plotted results will be available from the **Chart** tab when the simulation is finished.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

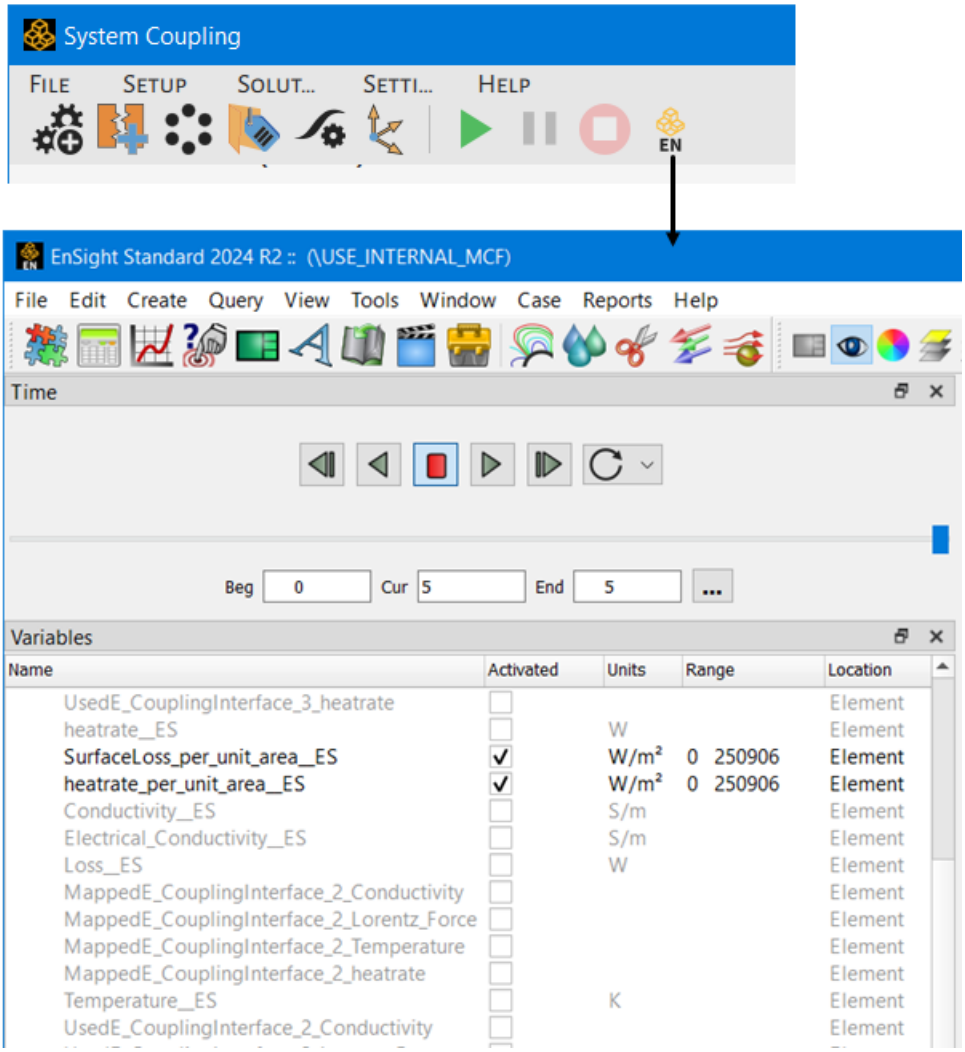
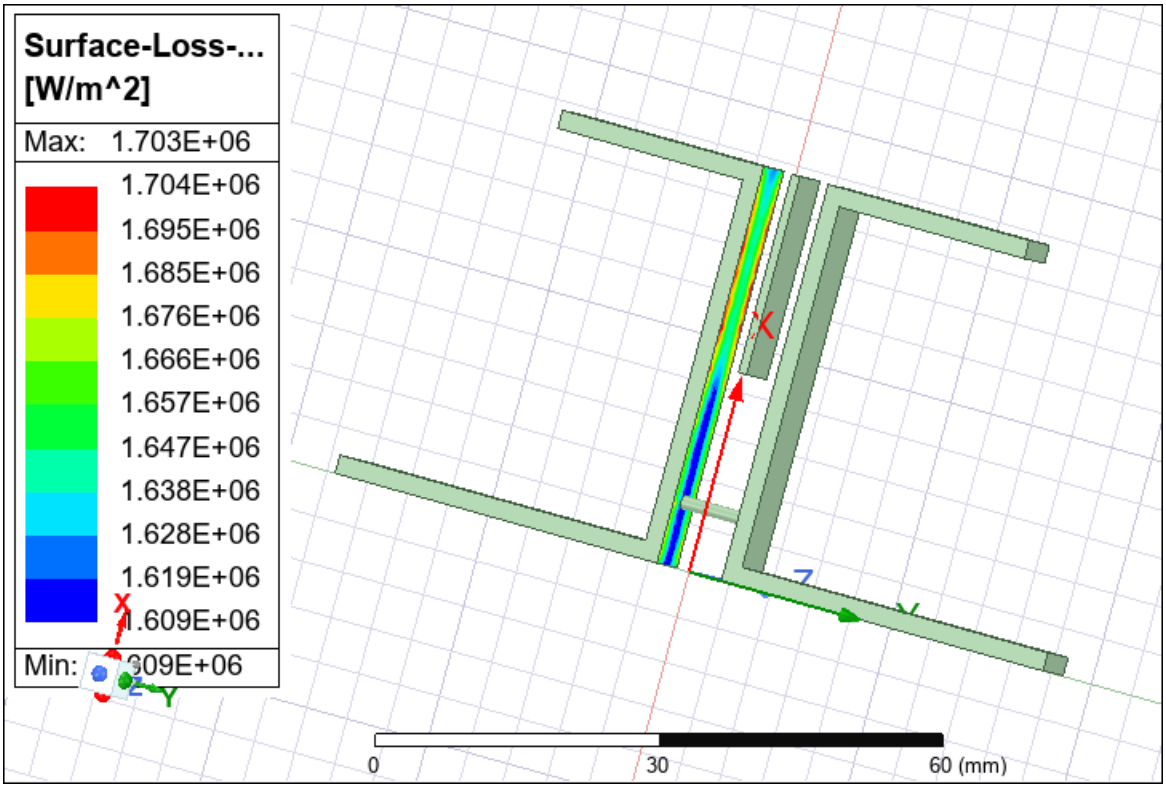
To see how well data is transferred from one region to another, we can use Ensight to compare Maxwell surface loss to Fluent heat rate:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To visualize surface loss in Maxwell, right-click on the **surface** in the Modeler window, and select **Fields** > **Other** > **Surface Loss Density**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note: For detailed information on System Coupling in general, refer to the System Coupling User's Guide. For details on working in System Coupling's GUI or CLI, see the Using System Coupling's User Interfaces section.

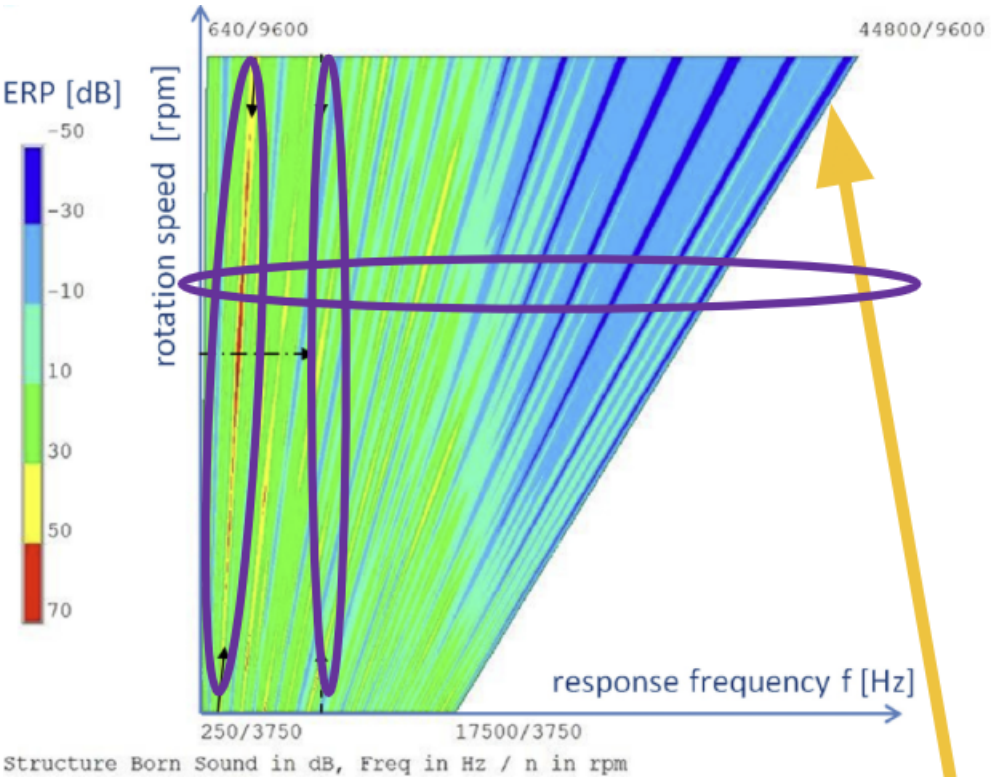
Note: For more examples of Maxwell participating in cosimulations, review the coil-and-core induction heating, bar-and-coil induction heating, bus bar, and electric motor examples in System Coupling Tutorials.

Maxwell Multiple RPM Harmonic Force Coupling

Waterfall analysis is a tool that is often used to evaluate the acoustic and/or vibratory performance of rotating machinery. Maxwell multiple RPM coupled with Ansys Harmonic Response provides a powerful tool to generate acoustic performance map of electric machines. The process involves calculating harmonic force using discrete Fourier transform (DFT) methods at each rpm (revolutions per minute), and performing harmonic response analysis at every selected frequency with calculated harmonic force loads.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Waterfall computation is given by ERP=ERP(f, rpm) making use of load interpolation between computed RPM.



The Waterfall contour map shows the full acoustic fingerprint of the machine, where:

- Vertical Line: Given by one fixed eigenfrequency excited at different speeds of rotation.
- Horizontal Line: Single rpm load case yielding one frequency response function.
- Inclined Line: Excitation order of the electromagnetic force-density revealing a large ERP zone with its origin in single eigenfrequency that is met by both frequency and spatial load pattern of excitation and system mode.

To set up a Maxwell design for multiple RPMs coupling:

1. In the **Mechanical** tab of the **Motion Setup** window, specify angular velocity (RPM) with a design variable.
2. In the **General** tab of the **Solve Setup** window, specify the appropriate stop time and timestep using the same design variable.
3. Add a parametric setup to sweep the variable.
4. Select the parametric setup as **Embedded Parametric Analysis** in the DesignXplorer setup.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** For multiple RPM harmonic force interpolation of inverter-fed electric motors, it is best to use the technique outlined in Harmonic Force Coupling for Inverter-Fed Motors.

Harmonic Force Coupling for Inverter-Fed Machines

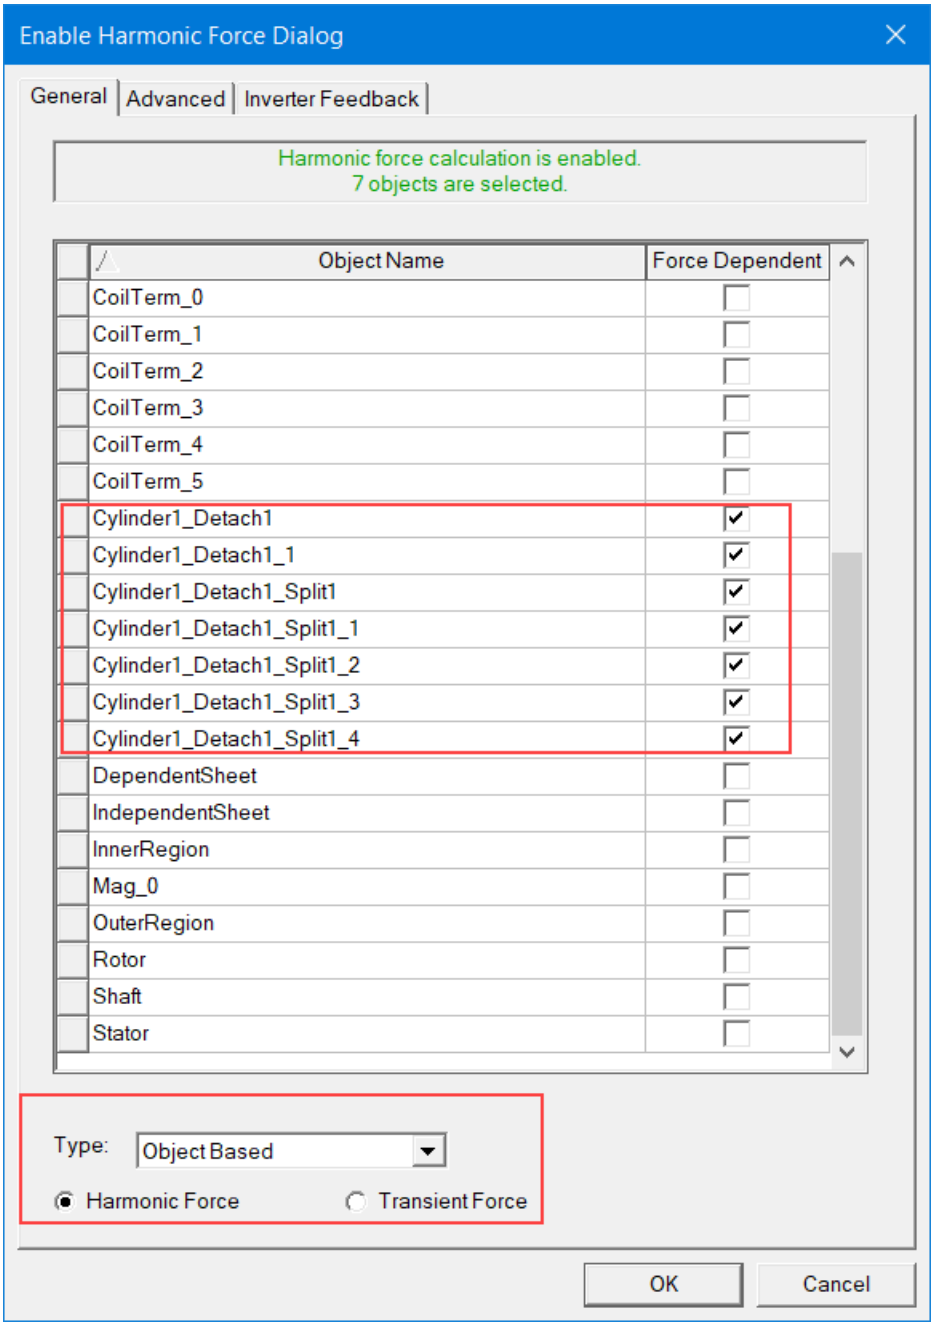
While the approach described in Maxwell Multiple RPM Harmonic Force Coupling is a good technique for E-motors with sinusoidal feeding, it does not work well for inverter-fed machines. The linear interpolation as done in Maxwell Multiple RPM Harmonic Force Coupling assumes that ALL the harmonics of force and of the response quantities are proportional to the speed. But for an inverter-fed machine, the motor's excitation, and thus the forces, have a frequency content that is independent of the speed.

This topic outlines how to use inverter feedback to generate a 2D interpolation of quantities in the frequency-speed plane. It will derive excitation forces in the frequency domain for speeds not directly calculated in Maxwell and will generate a continuous plot from discrete result data in the mechanical domain. It is applicable to Maxwell 2D and 3D transient T-Omega designs that include object-based harmonic force.

Generate Inverter-Fed Harmonic Force Results

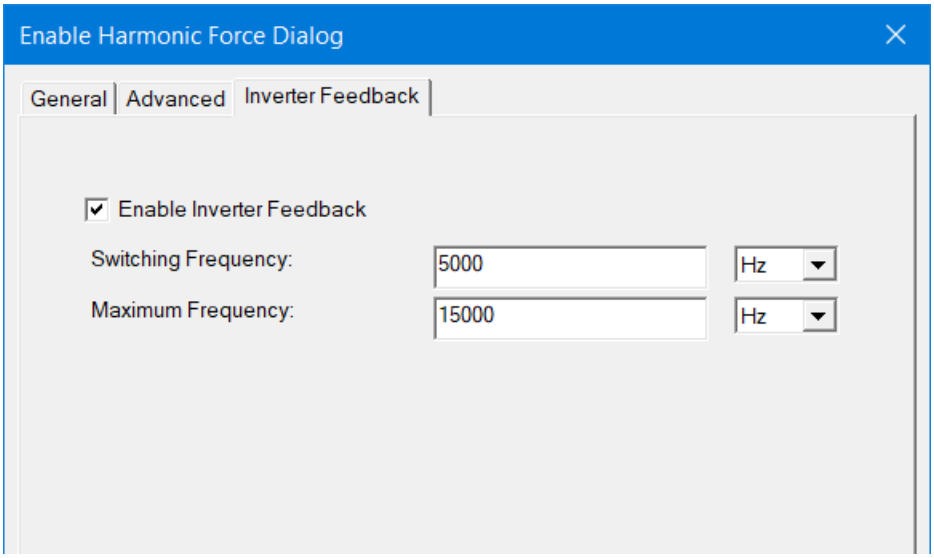
1. For a Maxwell 2D or 3D transient design, select **Maxwell** > **Enable Harmonic Force Calculation**.
2. In the window that opens, select the objects that are force dependent, and make sure the Type is **ObjectBased** and **Harmonic Force** is selected.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. From the **Inverter Feedback** tab, enable feedback, and specify the switching frequency and the maximum frequency. The switching and maximum frequencies are only available if **Enable Inverter Feedback** is checked; their default values are 4000 Hz and 8000 Hz, respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

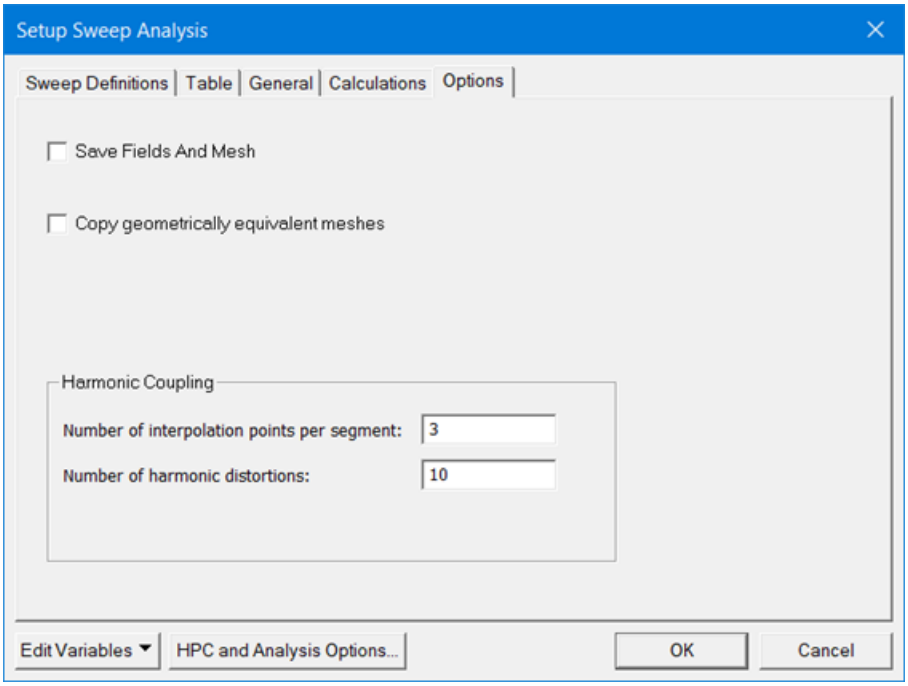


> **Note:** The Switching Frequency should be greater than 0 and can be defined as a variable as long as it does not depend on intrinsic variables.

> **Note:** The Maximum Frequency should be greater than the Switching Frequency, and it **cannot** be defined as a variable.

4. In the Project Manager tree, right-click on the **Optimetrics** entry and select **Add** > **Parametrics and Designs of Experiments** > **Parametric** to create a parametric analysis. In addition to the desired sweep setup, under the **Options** tab, specify number of harmonic distortions; the default value is 10.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

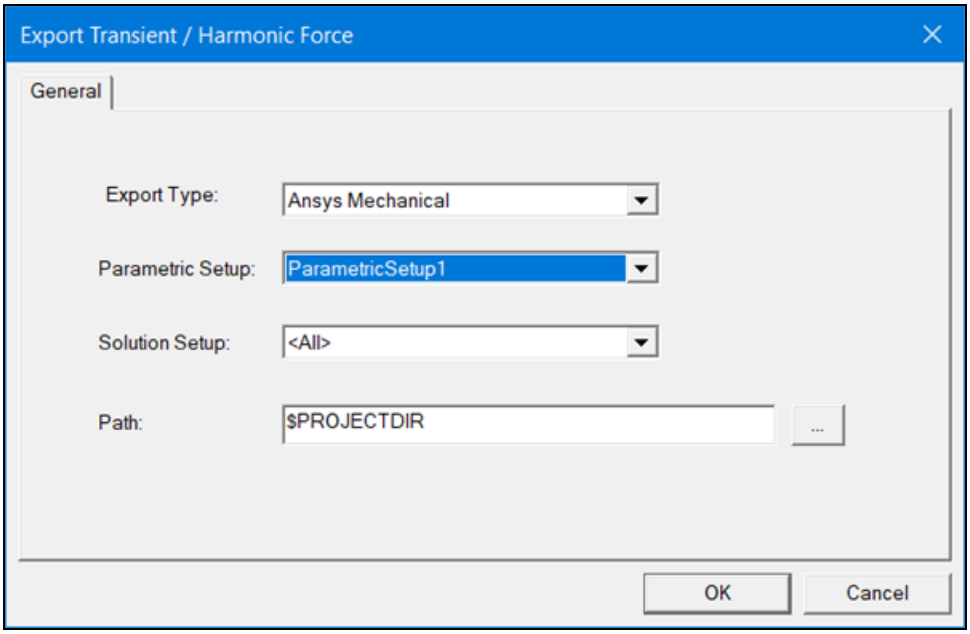


Note: If **Enable Inverter Feedback** is not checked in Enable Harmonic Force dialog box, the **Number of harmonic distortions** will not be available. The **Number of harmonic distortions** should be an integer equal or greater than 2 and **cannot** be defined with a variable.

Note: When setting up harmonic coupling in Ansys Workbench, make sure to use the same **Number of interpolation points per segment** and **Number of harmonic distortions** as you specified in the Setup Sweep Analysis; otherwise, the values specified in DesignXplorer will override the setting of the embedded parametrics setup.

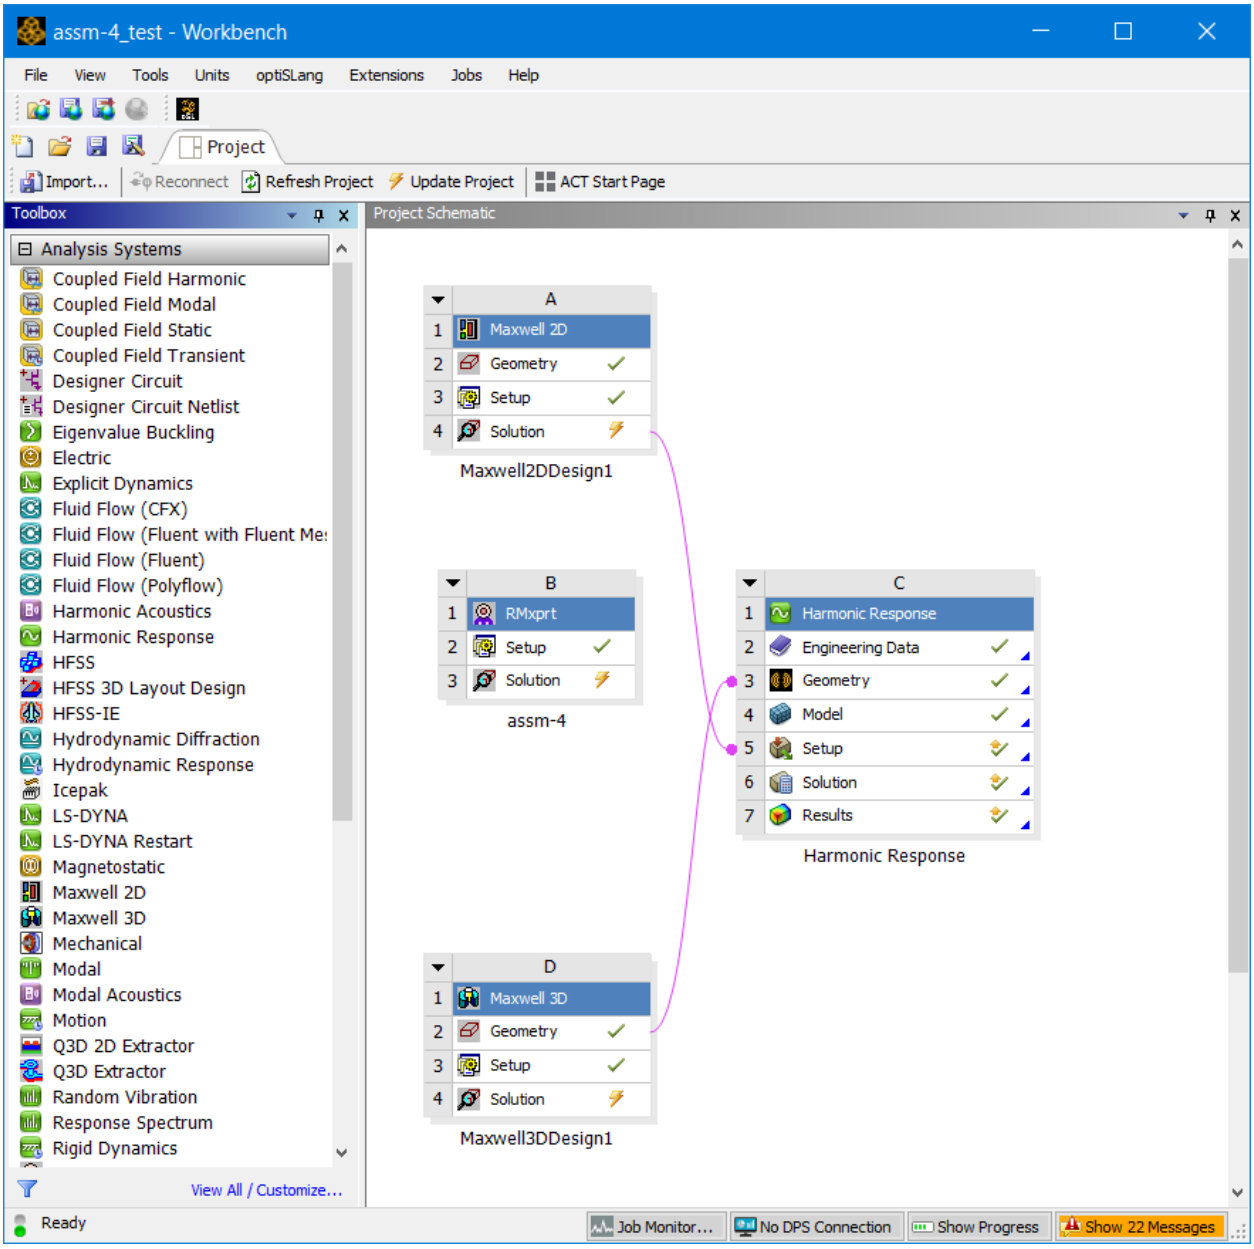
5. After running the analysis in Maxwell, select **Maxwell** > **Export Transient / Harmonic Force** to export harmonic force files to Ansys Workbench:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note: To use Maxwell results in Ansys Workbench, the two modules must be integrated. If you have not already done so, expand the Ansys EM **Suite** entry in the Start Menu, and select **Modify Integration with Ansys 2025 R1.**

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



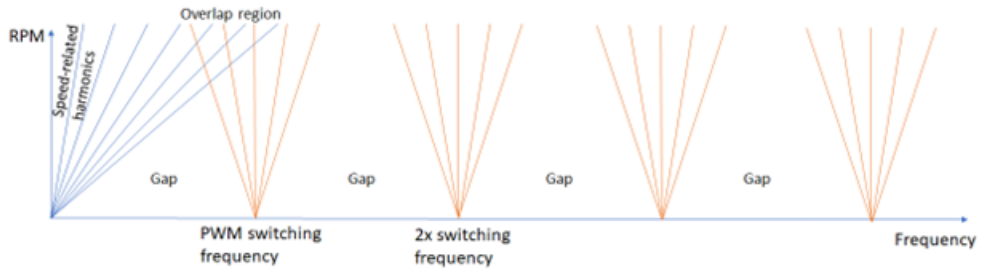
Note: For more information on Maxwell integration with Workbench, see Ansys Workbench Integration Overview.

Limitations

For this feature, there are some limitations, as explained below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When the machine is excited by an inverter with constant PWM switching frequency, harmonic forces can be categorized into two groups: The frequency of harmonic forces excited directly by the machine are directly proportional to the machine's speed (speed-related harmonics). In contrast, harmonic forces excited by the inverter feeding are dependent on both the PWM frequency and machine's speed. This leads to "so-called" forward and backward spectral lines in the frequency-speed plane. This pattern of forward and backward lines occurs around the switching frequency and multiples of it.

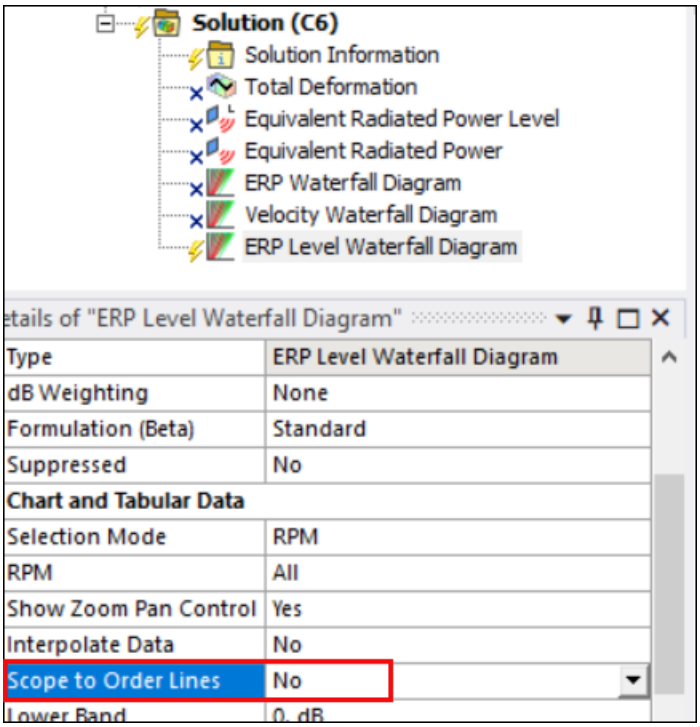


The force interpolation method for inverter-fed electrical machines is based on identifying which forces are excited by the machine or by the inverter feeding; different interpolations are used for these two. So when using this feature, keep in mind the following:

- For the speed-related harmonics, only the first 50 orders are used, and higher frequency data is not used. (This order is based on the number of periods run in the model.)
- When lines of speed-related harmonics intersect with the harmonic lines from the switching frequency, shown as "Overlap region" in the image above, the interpolation for inverter-excited forces will overwrite the interpolation performed for speed-related harmonics. Thus, the interpolated force will be based on the inverter-excited forces only. This can lead to numerical errors when the region of overlap is significant; for example, when a low switching frequency is used.
- In the "Gap" region between different components, no interpolated forces are calculated (a small value is assigned for numerical reasons).
- When generating waterfall diagrams in Harmonic Response analysis in Ansys Mechanical, please set **Scope to Order Lines** to **No** as this option is only valid for speed-

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

related harmonics.



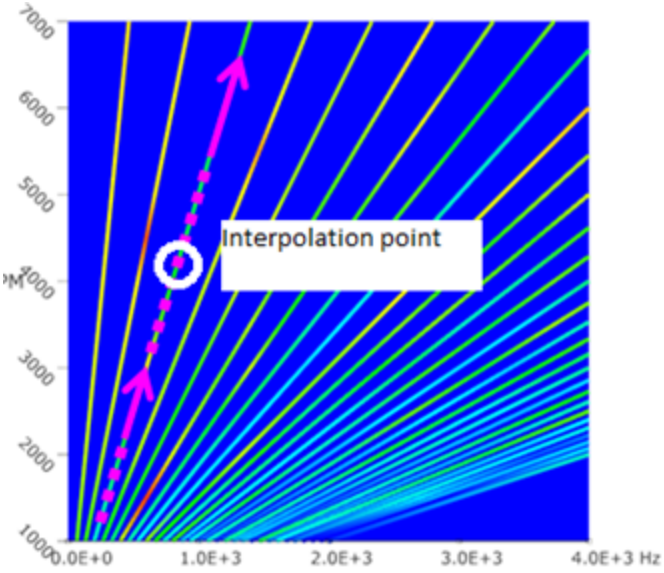
Harmonic Force Interpolation in Frequency-Speed Plane

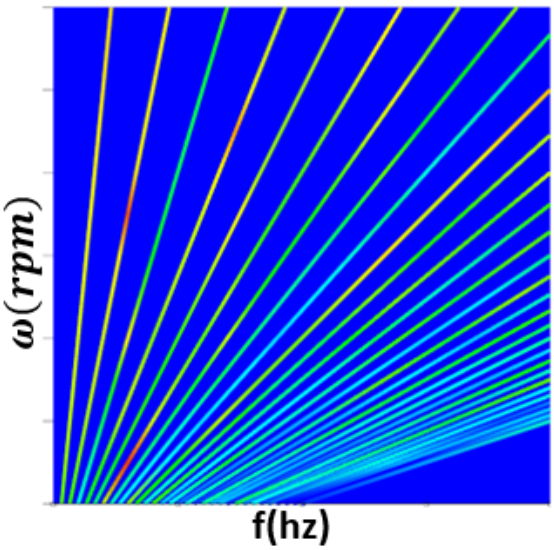
For Electrical Machines

In order to generate the ERP waterfall diagram of electrical machines in Ansys Mechanical Harmonic Response, harmonic force distribution at different rotation speeds from Maxwell solver is provided as excitations of Mechanical. In general, the quality of the ERP diagram depends on the number of speed points that are solved. To reduce the workload in Maxwell, an option is provided to interpolate harmonic force in the frequency-speed plane with a limited number of solved speed points.

In electrical machines, harmonic forces only exist at certain frequencies (harmonics) at a given speed (as shown below):

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





Force components and corresponding frequencies at any given speed can be obtained by interpolation along those lines of harmonics:

$$F_k = F_{i-1,k} + \frac{(\omega - \omega_{i-1})}{\omega_i - \omega_{i-1}}(F_{i,k} - F_{i-1,k})$$

$$f_k = f_{i-1,k} + \frac{(\omega - \omega_{i-1})}{\omega_i - \omega_{i-1}}(f_{i,k} - f_{i-1,k})$$

$$i = 2, \cdots\cdots M$$

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where

F : force vector

f : frequency

ω : speed of rotation

k : index of harmonics

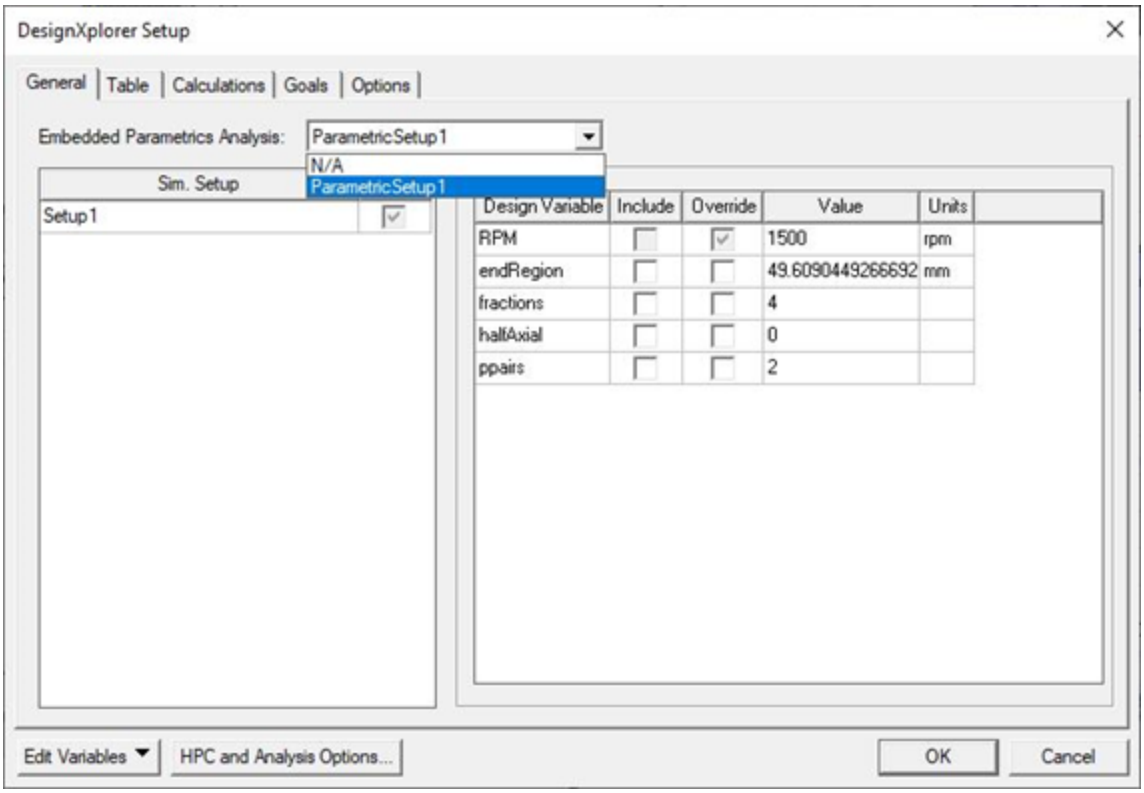
i : index of solved speed points

M : total number of solved speed points

Note: To use this feature you must open Maxwell from within Workbench. For detailed information on setting up and using harmonic force coupling in Workbench, refer to the Workbench help topic: *Importing Data into a Harmonic Analysis*.

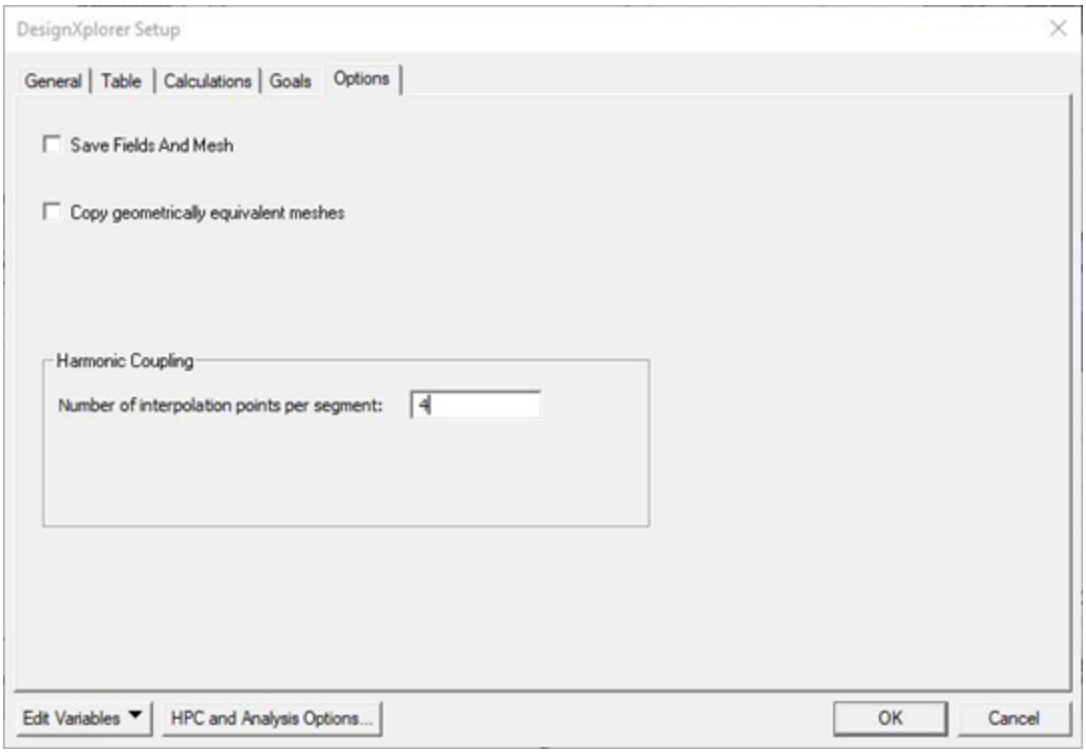
To set up the number of interpolation points per segment:

1. Open the **DesignXplorer Setup** panel and set Parametric Sweep (RPM sweep) as the **Embedded Parametric Analysis**.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. On the **Options** tab, enter the **Number of interpolation points per segment**. (This value must be a non-negative integer.)

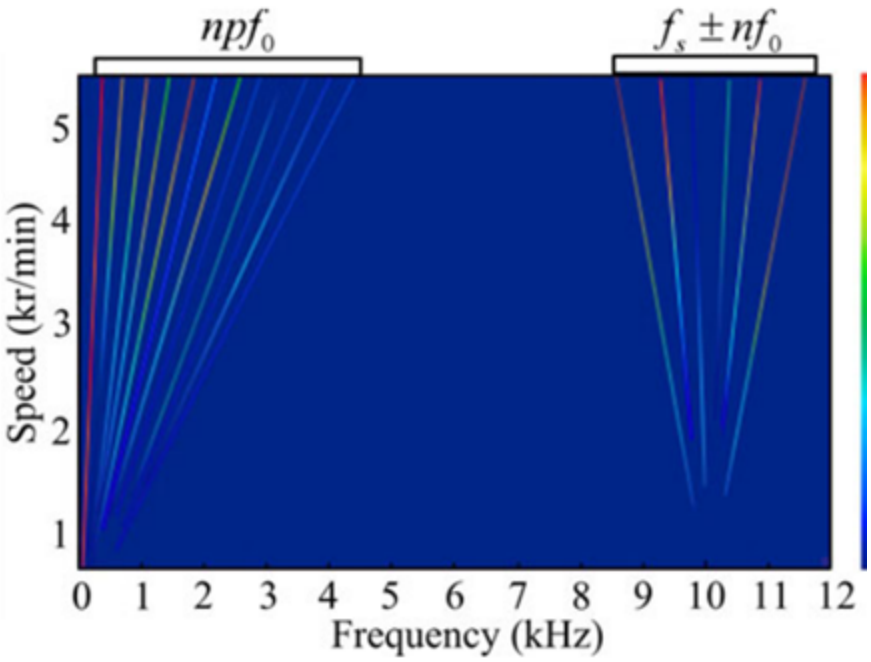


> **Note:** This topic details harmonic force interpolation in a frequency-speed plane for electric machines. For details on harmonic force interpolation for inverter-fed motors, see Harmonic Force Interpolation for Inverter-Fed Motors.

For Inverter-Fed Motors

The interpolation scheme described for electrical machines is valid for harmonics related to mechanical rotation speed of electric machines. When the electric machine is fed from an inverter with a fixed switching frequency, the high-frequency harmonics due to the switching frequency have to be interpolated differently. Below is a typical waterfall phase current for inverter-fed electrical machine:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The diagram shows that there are two types of current harmonics: One is the current order harmonics npf_0. The other is the switching-frequency sideband harmonics $f_s \pm nf_0$. The harmonic force resulting from the speed-related part can be interpolated with RPM by using algorithms described for electrical machines. The current harmonics related to switching frequency will generate harmonic force components at frequencies around switching-frequency and its multiples:

$f = mf_s + nf_0$

Where f_s is switching frequency, f_0 is the mechanical rotating frequency, m and n are integers. In the Maxwell solver, m is calculated by:

$$m = \frac{f_{max}}{f_s}$$

Here f_{max} is the input maximum frequency by user, and n is the number of harmonic distortions.

The harmonic force interpolation scheme for inverted-fed machines is similar to the one described for electrical machines:

1. The speed-frequency lines are constructed at and around switching-frequency and its multiples based on the calculated harmonic force data at specified RPM sweep.
2. Linear interpolation takes place along speed-frequency lines.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In order to distinguish different zones of harmonic force interpolation, the harmonics in the speed-related region is set to a maximum of 50.

> **Note:** The interpolation for electrical machines is order-based, related to mechanical speed. The interpolation for inverted-fed machines is related to inverter switching. Interpolation results from switching frequency will overwrite the results obtained by order-based interpolation because the order-based interpolation is done first.

Maxwell Harmonic Force Calculations and Coupling

- For 2D/3D *transient* and *eddy current* designs Maxwell supports *object-based* one-way harmonic force coupling via Ansys Workbench. Maxwell enables you to select multiple objects for force calculations for harmonic coupling with Workbench projects.
- For 2D/3D *eddy current* designs, Maxwell provides *element-based* solutions for one-way harmonic force coupling via Ansys Workbench. For eddy current element-based solutions, there is no need to select objects in Maxwell, because the harmonic surface force is a default output in the solver.
- For 2D/3D *transient* designs, Maxwell provides *element-based* solutions for one-way harmonic force coupling via Ansys Workbench. Element-based harmonic force calculations can also be enabled for stand-alone transient designs.
- Maxwell supports one-way coupling with various third-party software for transient designs.
- Maxwell supports one-way coupling with Ansys motion for transient designs.

Maxwell to Ansys Object-Based Harmonic Force Coupling

Maxwell 2D/3D supports object-based one-way harmonic force coupling for *transient* and *eddy current* designs via the Workbench schematic. Maxwell enables the user to select multiple objects for force calculations for harmonic coupling with Workbench. You can also setup multiple RPM Harmonic Force Coupling.

> **Note:** For object-based harmonic force calculation, a full-axial model is required.

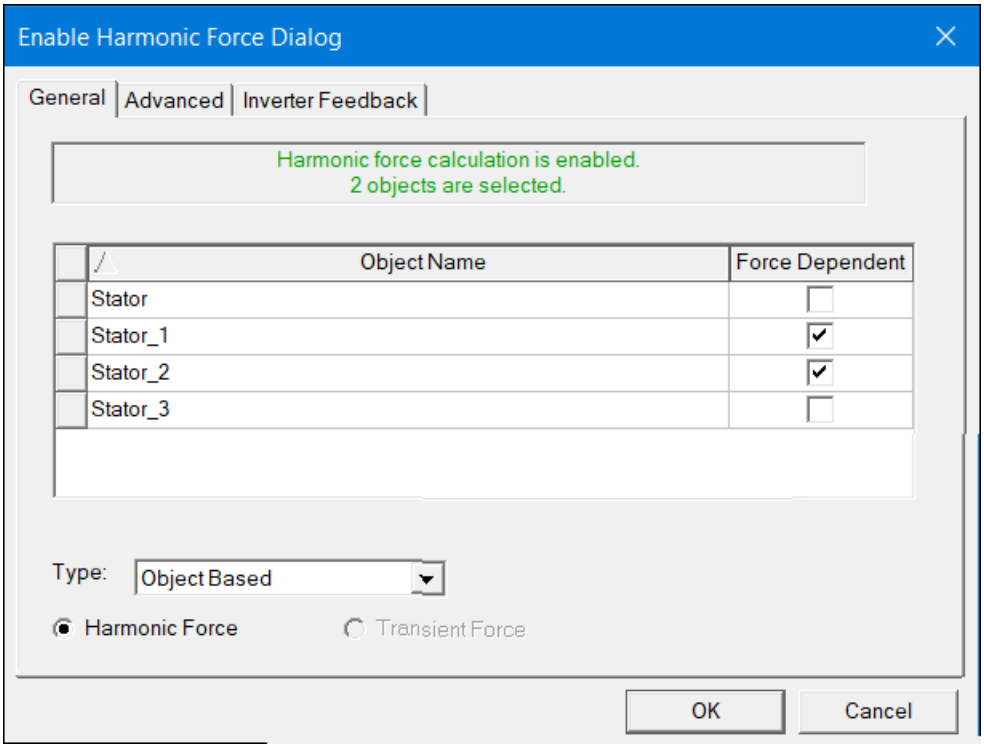
For detailed information on setting up and using harmonic force coupling in Workbench, refer to the Workbench help topics: *Importing Data into a Harmonic Analysis* and *Importing Data into a Thermal or Structural (Static or Transient) Analysis*.

To enable object-based harmonic force calculations in Maxwell:

1. Either select **Maxwell 2D** (or **Maxwell 3D**) > **Enable Harmonic Force Calculation**, or right-click on the design in the Project Manager tree and select **Enable Harmonic Force Calculation** to open the **Enable Harmonic Force Dialog** window. The window has two tabs: **General** and **Advanced**.

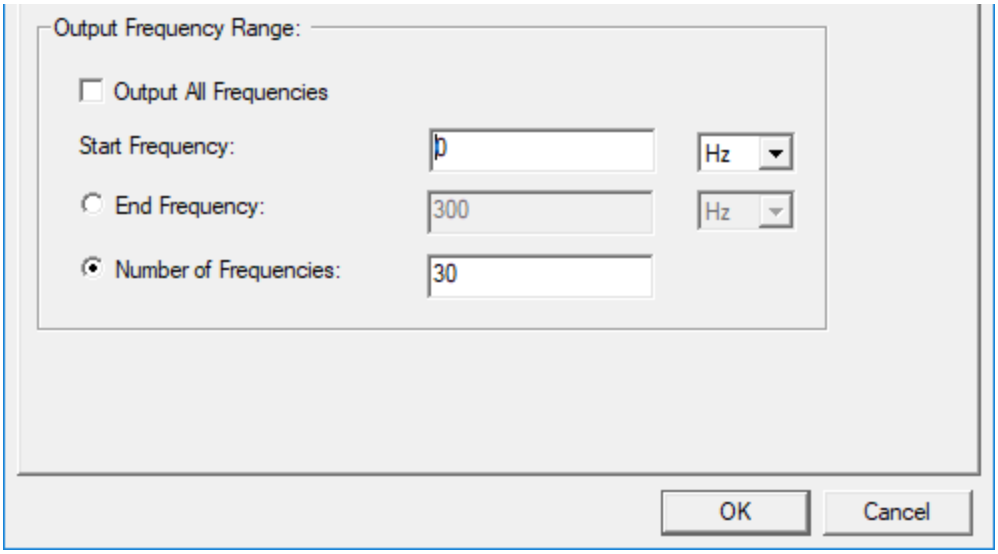
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Do one of the following:
   - For *eddy current* designs, on the **General** tab, check the **Force Dependent** objects for which force calculations are desired.
   - For *transient* designs, on the **General** tab, select **Object Based** as the harmonic force **Type**. Select the **Harmonic Force** radio button. Then check the **Force Dependent** objects for which force calculations are desired.

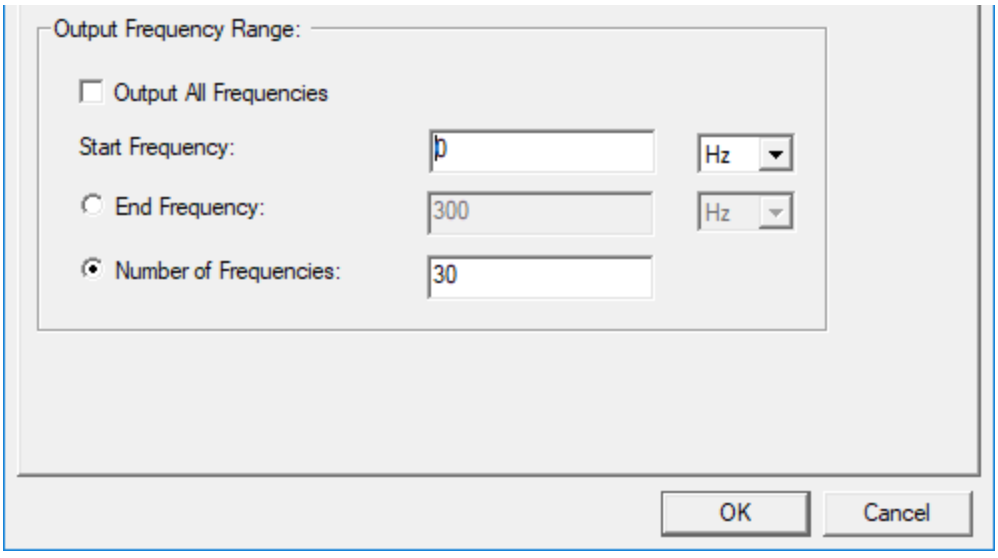


3. The **Advanced** tab provides additional settings to allow you to control collection of data from the force calculations.
   - For *2D and 3D transient* designs (either with rotational motion or with non-rotational motion), the **Output Frequency Range** panel allows you to specify the frequency range of calculated harmonic force components. The default is to **Output All Frequencies** that are calculated. There are two options to set the range of output frequencies:
     - **Use Range** – specify the **Start Frequency** and **End Frequency**. Parameterization of **Start Frequency** and **End Frequency** is supported.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- **Use Number** – specify the **Start Frequency** and the **Number of Frequencies**; the latter defines the harmonic content where an upper frequency isn't necessarily the limit of interest. The Number of Frequencies is based on multiples of the fundamental frequency, which is defined by the duration of the transient dataset created by the user during pushback. Note that parameterization of **Number of Frequencies** is supported.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

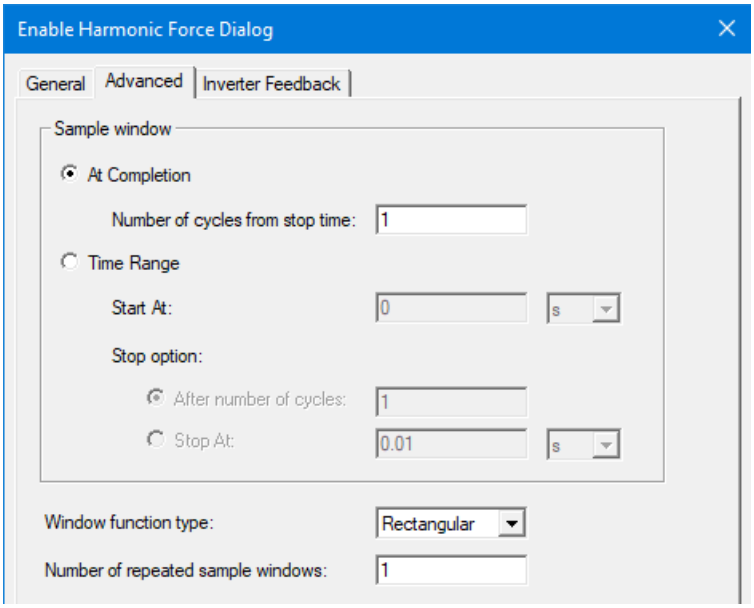
- For *transient* designs that include rotational motion:

  > **Note:** When using Partial Simulation for Full Rotational Machine Models, select *all* teeth tips as objects for harmonic force calculation.

  - The **Sample Window**'s collect samples **At completion** setting allows you to choose the **Number of cycles from stop time** for which data is collected. For example, if one cycle equals 1 second, and you solve for 3.5 seconds, setting the **Number of cycles from stop time** to 2 results in data being collected for the period from 1.5 seconds to 3.5 seconds. Alternatively, user can specify a **Time Range** to collect data, for which user can set a data collection **Start At** and a data collection **Stop option** – either stop data collection after a user-specified number of cycles (**After number of cycles**) or at a user-specified **Stop At** time.
  - The **Window function type** options setting is used for Discrete Fourier Transform (DFT) of harmonic forces. Refer to Window Function Options for DFT of Harmonic Forces for details on this setting.
  - In the frequency domain of harmonic force, the base frequency is determined by the range of time window of data collection ($f=1/\Delta T$). In order to get lower base frequencies, one must increase the time window of data collection, which means increasing the simulation time. It is waste of resources to do so when the solution reaches steady state/periodic in a transient simulation. Instead, you can set the **Number of repeated sample windows** to expand the range of time window of data collection without increasing simulation time by repeating the collected data *n* times before doing DFT. By applying this option, you can get a lower base frequency and higher frequency resolution, but the magnitudes of force components are close to zero at the introduced frequencies.

    > **Note:** The **Number of repeated sample windows** setting is enabled only for the **Rectangular** (the default) **Window function type**.

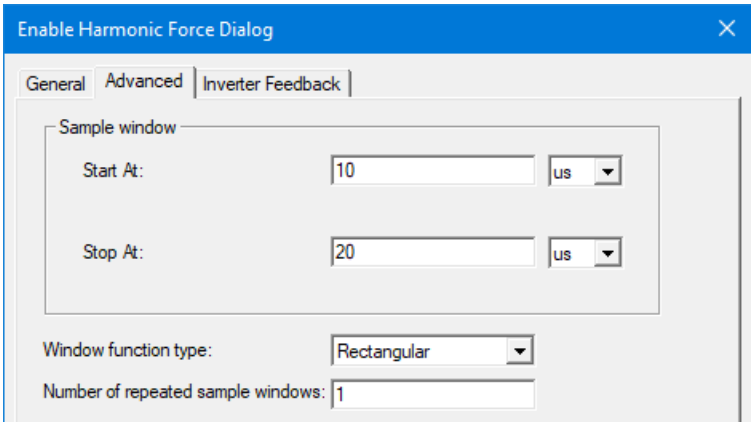
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- For *transient* non-rotational motion designs:
  - The **Sample Window** of the **Advanced** tab allows you to set the data collection **Start At** and **Stop At** times.
  - The **Window function type** options setting is used for Discrete Fourier Transform (DFT) of harmonic forces. Refer to Window Function Options for DFT of Harmonic Forces for details on this setting.
  - You can set the **Number of repeated sample windows** to expand the range of time window of data collection.

    > **Note:** The **Number of repeated sample windows** setting is enabled only for the **Rectangular** (the default) **Window function type**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- For *Eddy current* designs, the Advanced tab allows you to set the Rotation Axis and the axis direction so that the Maxwell solver can generate a full model if a partial model is used in the design. You can create relative coordinate systems to add more axes.

  Harmonic Eddy force solutions are kept as part of Maxwell design solutions. If Workbench harmonic design settings are changed, the Maxwell solutions will be invalidated.

4. Click **OK** to close the window.

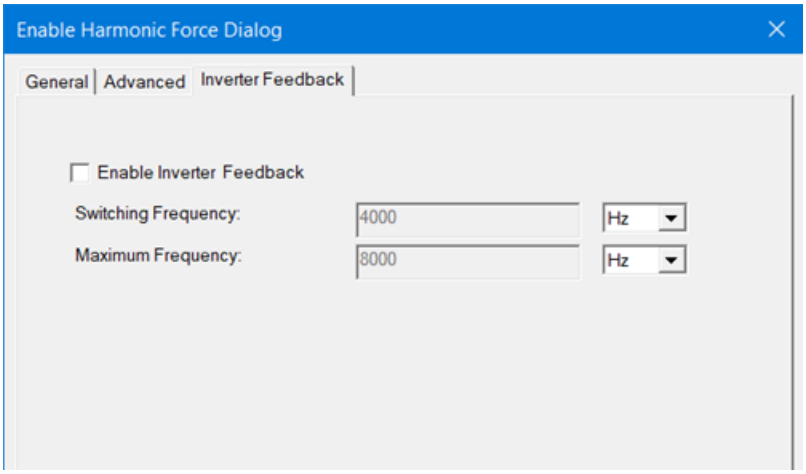
Inverter Feedback Tab



Force Densities in Maxwell

Let $T_{\alpha\beta}$ be the Maxwell stress tensor (refer to reference [1] for detail of the Maxwell stress tensor). Then the force acting on an object can be calculated by

$$F_\alpha = \sum_\beta \int_V \frac{\partial}{\partial x_\beta} T_{\alpha\beta} d^3x \quad (1)$$

Application of the divergence theorem to volume integral gives

$$F_\alpha = \oint_S \sum_\beta T_{\alpha\beta} n_\beta ds \quad (2)$$

Note that $\sum_\beta T_{\alpha\beta} n_\beta$ is the force per unit area transmitted across the surface. Namely, it is the surface force density, which is denoted as

$$f_\alpha^S = \sum_\beta T_{\alpha\beta} n_\beta \quad (3)$$

Also, from (1), you can define a volume force density by stress tensor as

$$f_\alpha^v = \sum_\beta \frac{\partial}{\partial x_\beta} T_{\alpha\beta} \quad (4)$$

For a magnetostatic field (similar forms for electric field), the explicit form of the Maxwell stress tensor is

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$T_{\alpha\beta} = H_\alpha B_\beta - \frac{1}{2}\vec{B} \bullet \vec{H}\delta_{\alpha\beta} \quad (5)$$

So the surface force density can be calculated as

$$f_\alpha^s = \left(\vec{B} \bullet \vec{n}\right)\vec{H} - \frac{1}{2}\vec{B} \bullet \vec{H}\vec{n} \quad (6)$$

The volume force density can be calculated by (4) and using the virtual work principle (refer to reference [2] for details).

Reference [1] J.D. Jackson, *Classical Electrodynamics*, 3rd edition, Wiley, 1999.

Reference [2] A. Bossavit: "Eddy-currents and forces in deformable conductors", in *Mechanical Modelings of New Electromagnetic Materials* (Proc. IUTAM Symp., Stockholm, April 1990, R.K.T. Hsieh, ed.), Elsevier (Amsterdam), 1990, pp. 235-42.

Force Density Calculation in Maxwell

Maxwell solvers can be coupled with Ansys Mechanical either one-way or two-way. Maxwell solvers provide volumetric force density/surface force density as load to the mechanical solvers. Force density is calculated by Maxwell stress tensor.

Maxwell stress tensor for magnetic fields:

$$\bar{S} = \frac{1}{\mu_0}\begin{bmatrix} B_x^2 - B^2/2 & B_x B_y & B_x B_z \\ B_x B_y & B_y^2 - B^2/2 & B_y B_z \\ B_x B_z & B_y B_z & B_x^2 - B^2/2 \end{bmatrix}$$

where

$$B^2 = B_x^2 + B_y^2 + B_z^2$$

The force on a surface can be calculated as

$$\vec{F} = \frac{1}{\mu_0}\int\int dA\bar{S} \cdot n$$

where *n* is outward normal direction of the face.

The surface force density is calculated from

$$\vec{f} = \frac{\vec{F}}{A}$$

where ***A*** is the area of the surface.

The volumetric force density in an element is calculated from

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\vec{f} = \frac{1}{V}\sum_{i=0}^{N}\overrightarrow{F_i}$$

where ***V*** is volume of the element, and ***N*** is the number of surfaces (sides in 2D) of this element.

Harmonic Force Calculation from Maxwell

Maxwell can calculate the harmonic force on each tooth of a rotating machine. This feature enables the one-way coupling between Maxwell and Harmonic Response of Ansys. The force is object based, not element based. The harmonic momentum reference to the geometric center of the object is also provided at the same time. This feature is also extended to any individual object.

There are two options to calculate the force of an individual tooth:

- Split the stator/rotor to form separate tooth object, and integrate forces on all out surfaces of this tooth except the splitting surfaces.
- Draw an arc (2D) or a cylindrical face (3D) near the tooth in the air gap, and integrate forces on this face.

Discrete Fourier Transform (NDFT) with Non-Uniform Time Interval

In the general case, the definition of the Non-uniform Discrete Fourier Transform (NDFT) is the same as the definition with constant time interval, taking into consideration that the samples can be taken at irregular intervals in time (t_n). That is to say that the samples x(k) of the irregular Fourier transform are taken at multiples of a quantity $\Delta\omega$, which is a fixed quantity in the Fourier domain. The fixed quantity, $\Delta\omega$, in the regular case corresponds to 2π/T. The extension from regular to irregular sampling, therefore, depends on the duration of the signal *x(t)* and not on the fact that the samples are taken at regular or irregular intervals.

A finite sample measured at ***N*** points in a period of T:

$$x(k) = \begin{cases} 0, & k < 0 \\ F(t_k), & 0 \le k \le (N-1) \\ 0, & k \ge N \end{cases}$$

The definition of the non-uniform discrete Fourier transform (NDFT)is as follows:

$$X(k) = \frac{1}{N}\sum_{n=0}^{N-1} x(n)\, e^{-j(t_n - t_0)k\frac{2\pi}{T}}$$

The inverse NDFT is given by

$$x(t_n) = \sum_{k=0}^{N-1} X(k)\, e^{j2\pi\frac{k(t_n - t_0)}{T}}$$

Data Collection

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The solver records the components of force and momentum at all teeth at every timestep:

$$\begin{array}{llllll} F_x : F_x(0), & F_x(\Delta t), & F_x(2\Delta t), & \cdots\cdots, & F_x(K\Delta t) \\ F_y : F_y(0), & F_y(\Delta t), & F_y(2\Delta t), & \cdots\cdots, & F_y(K\Delta t) \\ F_z : F_z(0), & F_z(\Delta t), & F_z(2\Delta t), & \cdots\cdots, & F_z(K\Delta t) \\ M_x : M_x(0) & M_x(\Delta t), & M_x(2\Delta t), & \cdots\cdots, & M_x(K\Delta t) \\ M_y : M_y(0), & M_y(\Delta t), & M_y(2\Delta t), & \cdots\cdots, & M_y(K\Delta t) \\ M_z : M_z(0), & M_z(\Delta t), & M_z(2\Delta t), & \cdots\cdots, & M_z(K\Delta t) \end{array}$$

If $t_{end} - t \leq \frac{2\pi}{period * rotationSpeed}$, then the solver keeps recording.

Generate Harmonic Force from Partial Model to Full Model

With symmetry-multiplier (period in 3D) > 1, Maxwell solvers automatically generate harmonic force for the full model from the partial model *r** = *Ar*.

where *r* is the vector to be rotated, *r** is the vector after rotation. The rotation matrix in 3D:

$$A = \begin{bmatrix} cos\theta + u_x^2\,(1 - cos\theta) & u_x u_y\,(1 - cos\theta) - u_z sin\theta & u_x u_z\,(1 - cos\theta) + u_y sin\theta \\ u_x u_y\,(1 - cos\theta) + u_z sin\theta & cos\theta + u_y^2\,(1 - cos\theta) & u_y u_z\,(1 - cos\theta) - u_x sin\theta \\ u_x u_z\,(1 - cos\theta) - u_y sin\theta & u_y u_z\,(1 - cos\theta) + u_x sin\theta & cos\theta + u_z^2\,(1 - cos\theta) \end{bmatrix}$$

The rotation matrix in 2D:

$$A = \begin{bmatrix} cos\theta & -sin\theta \\ sin\theta & cos\theta \end{bmatrix}$$

Vectors that need to be rotated: position (**r**), force (**F**) and moment (**M**)

Spatial and Temporal 2D Discrete Fourier Transform (DFT)

Electromagnetic force components on teeth inside an electric machine are spatial (in circumferential direction) and temporal (transient). The magnetic force density acting on the stator along the air gap is dependent on time and on space. This spatial and temporal force distribution can be expanded by means of Fourier analysis to calculate its time and space harmonic waves. This analysis can be used to improve NVH (noise, vibration, and harshness) performance.

The magnetic force density acting on the stator along the air gap is dependent on time and on space. This spatial and temporal force distribution can be expanded by means of Fourier analysis to calculate its time and space harmonic waves.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The force components on teeth can be expressed as function f(x, t), where x represents spatial, and t denotes temporal. The function f (x, t) is decomposed to a linear combination of harmonic (sines and cosines, more generally orthogonal) functions.

Direct Transformation

$$F(u,v) = \frac{1}{MN} \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} f(m,n) \exp\left[-2\pi i \left(\frac{mu}{M} + \frac{nv}{N}\right)\right]$$

where:

u = 0, 1, …… M-1, wave number in spatial,

v = 0, 1, ……. N-1, wave number in temporal.

Window Function Options for DFT of Harmonic Forces

Window function options for Discrete Fourier Transform (DFT) of harmonic forces are available for Maxwell 2D and 3D transient solvers and support both rotational and non-rotational models.

The Discrete Fourier Transform (DFT) operates on a finite-length time sequence to compute its spectrum. For a continuous signal like a sine wave, you need to capture a segment of the signal in order to perform the DFT. Usually, you also need to apply a window function to the captured signal before taking the DFT. A window function (also known as an apodization function or tapering function) is a mathematical function that is zero-valued outside of some chosen interval, normally symmetric around the middle of the interval, usually near a maximum in the middle, and usually tapering away from the middle. The mismatch in amplitude between the two ends of the signal distorts the spectrum, a phenomenon called spectral leakage. Spectral leakage can be caused by discontinuities in the non-integer number of periods in sampled signals that usually happen in asynchronous machines. This can be improved using windowing. Maxwell provides several window functions for the DFT of harmonic forces. These include

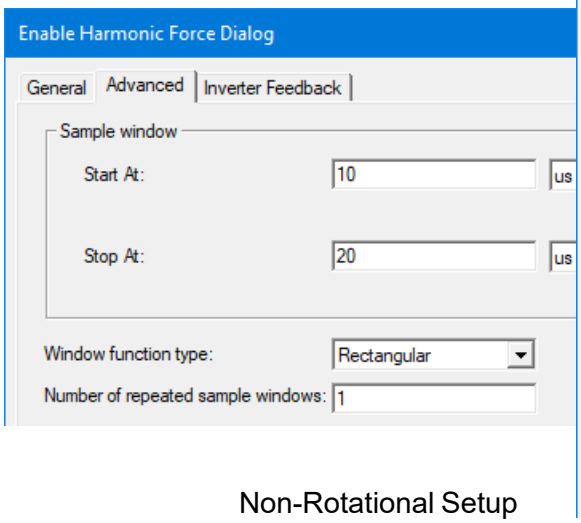
- Rectangular (default)
- Triangular
- Van Hann
- Hamming
- Blackman
- Lanczos
- Welch

Refer to FFT Window Functions for detailed information on each of these window function types.

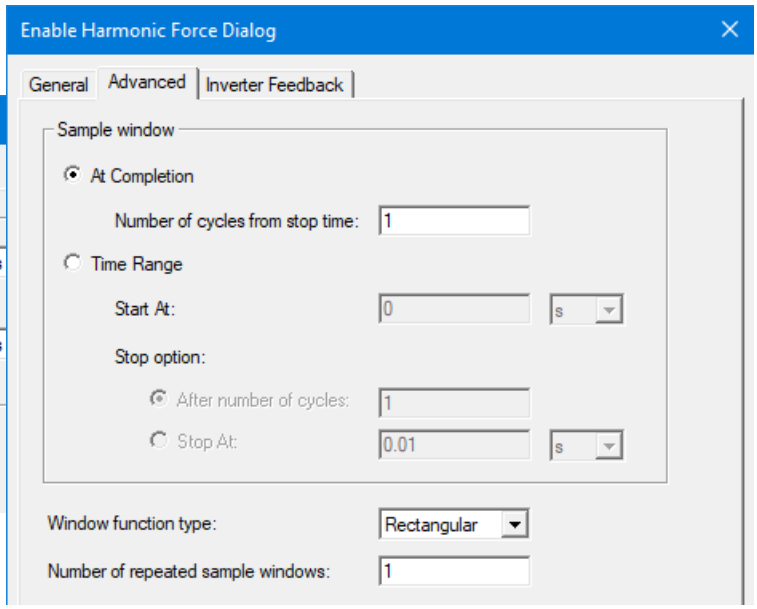
To select the various window function options:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Either select **Maxwell 2D** (or **Maxwell 3D**) > **Enable Harmonic Force Calculation**, or right-click on the design in the Project Manager tree and select **Enable Harmonic Force Calculation** to open the **Enable Harmonic Force Dialog** box.
2. Specify the **Window function type** using the drop-down menu on the **Advanced** tab.



Non-Rotational Setup



Rotational Setup

Harmonic Force Calculation in Maxwell 2D with Skew Model

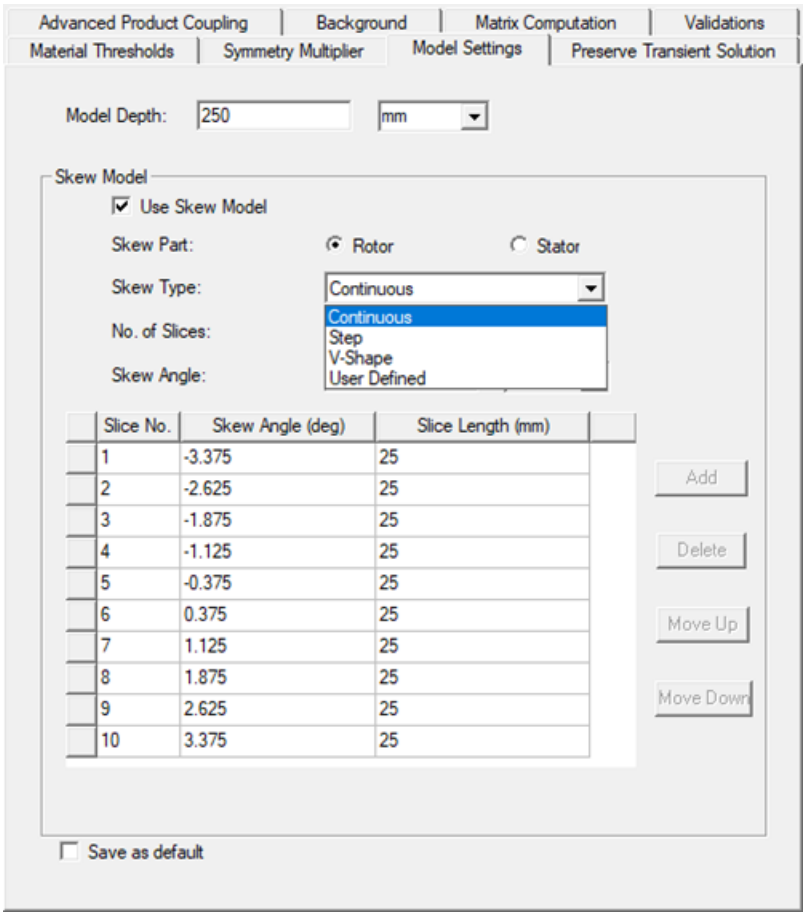
Maxwell 2D supports object-based harmonic force calculation using a multi-slice skew model along the axial direction of rotating machines. (Element-based harmonic force calculation is not applicable to 2D multi-slice skew model.)The multi-slice skew model can improve the accuracy of Maxwell 2D simulation when the slot/teeth on the stator/rotor are skewed. By using a skew model, 2D vibration modeling in Ansys Mechanical is no longer valid; thus, 3D simulation must be performed instead by applying object-based harmonic force calculation slice-by-slice.

Skew Model Setup

> **Note:** For detailed information on Skew Model settings, refer to the Model Settings Tab topic.

Skew model setup in Maxwell 2D is defined on the **Model Settings** tab of the **2D Design Settings** dialog as described in the Model Settings Tab topic.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To create 3D geometry, the center position of each slice must be set properly:

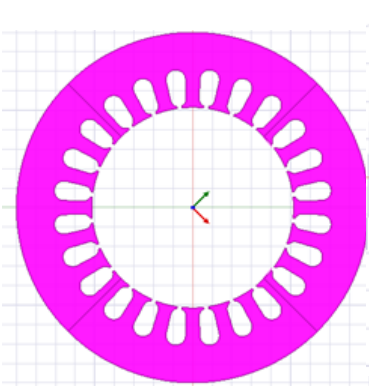
1. Create a 2D full model in Maxwell (do not unite half teeth at the M-S boundary), and generate 3D geometry of one slice; then create a Maxwell 3D design, and duplicate one slice in the Maxwell 3D.
2. Move the center of the 3D geometry to the origin of the global coordinate system; then set the Z axis as the rotating axis.
3. Rotate each slice to its individual circumferential position: slice angle is taken from the skew model settings (see figure above). The slice number indices are arranged from least to greatest, corresponding to Z coordinates of slice position (from least to greatest).

   For object-based harmonic force calculation, only one group of harmonic force components is generated for each selected object when skew model in not enabled in Maxwell 2D transient solver; and the Z coordinate of the object is set to zero by default.

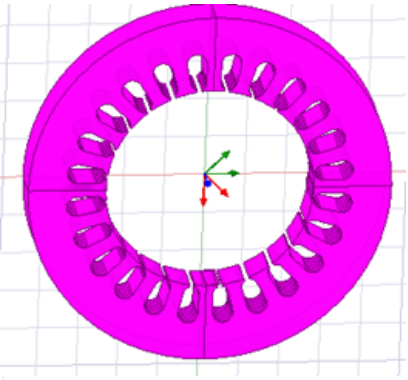
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The “zero” Z position is used to match the selected geometry in Mechanical if coupled with the Harmonic response 3D solver.

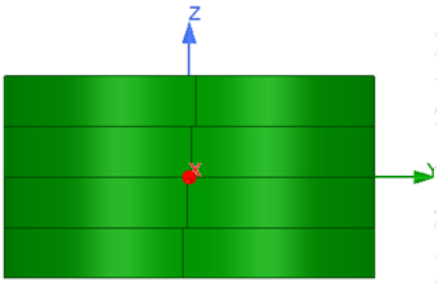
Maxwell 2D Partial Model



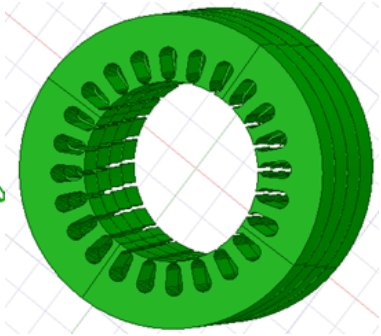
2D full model (stator only)



3D geometry of stator (one slice)



3D geometry after moving and rotating



3D geometry in harmonic response solver

Harmonic Force Calculation Requirements for Maxwell 2D Slice Model

Because the harmonic force calculated from the 2D slice model will be applied to a 3D model in Ansys Mechanical, it is very important to have a rule to link the skew angle to the slice number, and the slice number to the z-position in the Maxwell 2D solver. The relationship between slice number and z-position will determine how the 3D model will be generated.

The general rule is as follows:

- The sequence of slice number: from least to greatest with z position (this is for customer, not in the solver)
- The z-position: from least to greatest
- The skew angle: one-to-one with slice number, from slice 1 to slice N

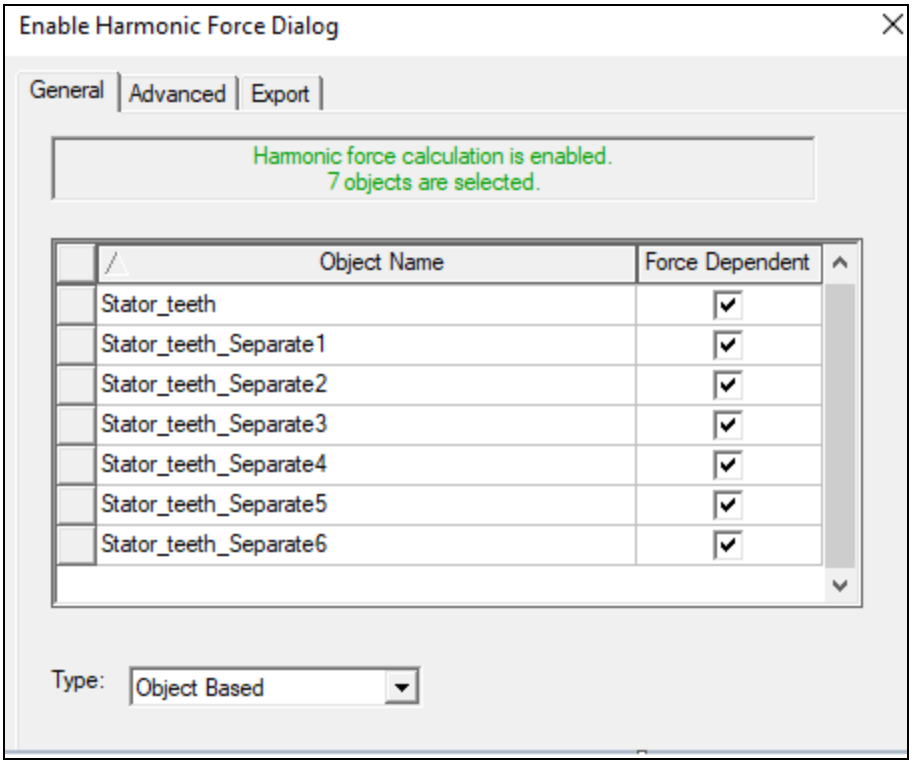
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The user generates 3D model based on skew angle, slice by slice, from least z-position to greatest z-position.

Transient Report of Object-Based Harmonic Force Components

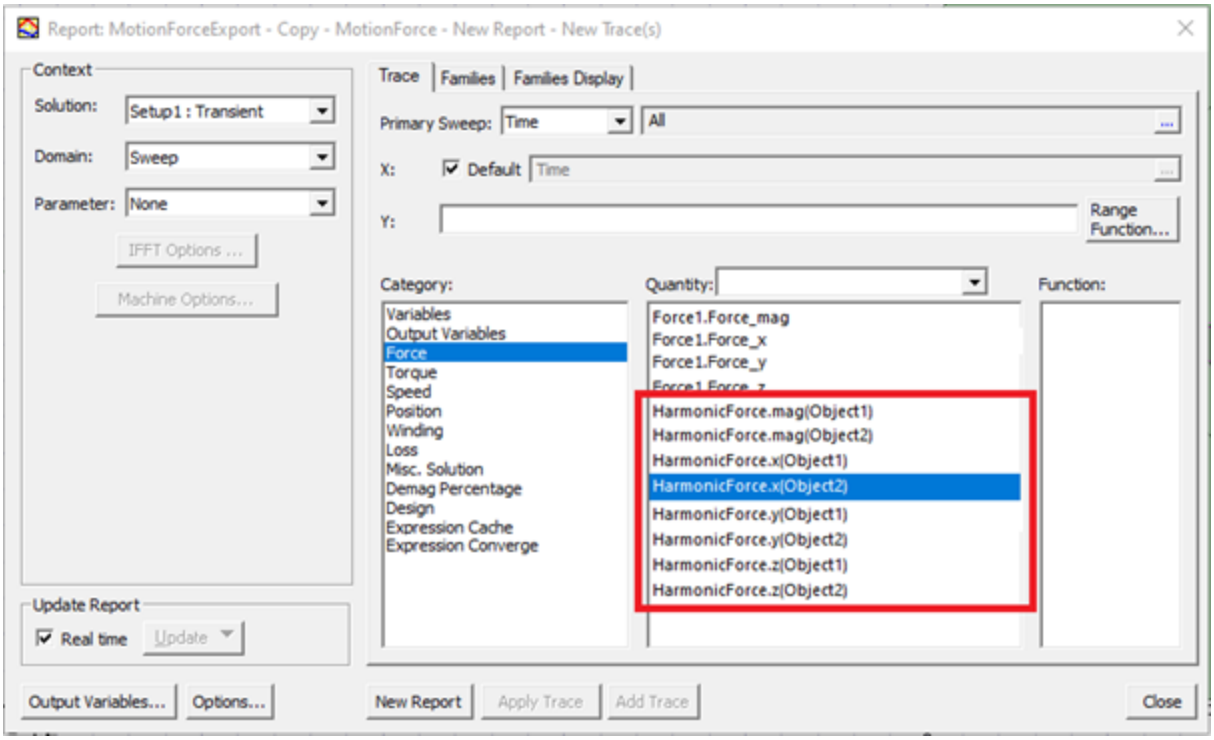
When object-based harmonic force is activated, the transient force data of selected harmonic force objects are available for plot in Maxwell transient solvers. The force component data is recorded at every timestep, starting from time zero. To create a transient report of object-based harmonic force components:

1. In the **Enable Harmonic Force Calculation** dialog box, on the **General** tab, select **Object Based** as the harmonic force **Type**. Then check the **Force Dependent** objects for which force calculations are desired.



2. Create a **Transient Report** under **Results** in the Project Manager tree.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

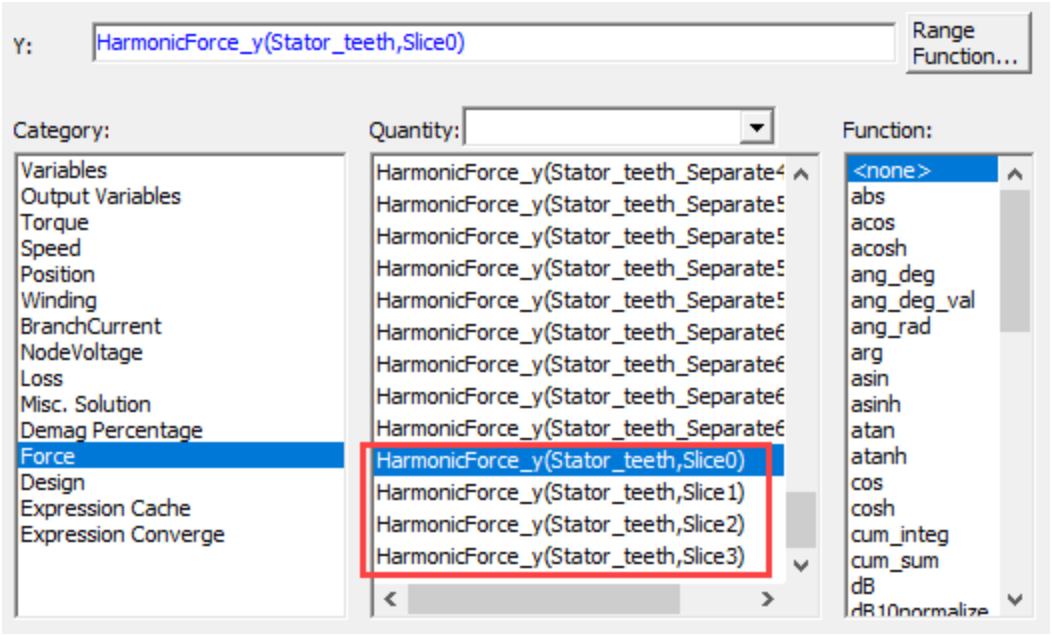


3. Select **Force** as the **Category**, and then select the harmonic force components you want to plot:

    - For 2D (XY) designs: **HarmonicForce_mag**, **HarmonicForce_x**, **HarmonicForce_y**.
    - For 3D designs: **HarmonicForce_mag**, **HarmonicForce_x**, **HarmonicForce_y**, **HarmonicForce_z**.
    - For 2D (RZ) designs: **HarmonicForce.z**.

Transient force reports also support Maxwell 2D with skew slice model. The transient force is calculated on each slice, and there are *n* forces available to be plotted for each selected object.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note: For detailed information on Skew Model settings, refer to the *Model Settings Tab* topic.

Maxwell to Ansys Element-Based Harmonic Force Coupling

Maxwell provides element-based solutions for one-way harmonic force coupling via Ansys Workbench schematic for

- 2D/3D Eddy Current design element-based harmonic force coupling
- 2D/3D Transient design element-based harmonic force coupling

For detailed information on setting up and using harmonic force coupling in Workbench, refer to the Workbench help topics: *Importing Data into a Harmonic Analysis* and *Importing Data into a Thermal or Structural (Static or Transient) Analysis.*

Element-Based Harmonic Force Calculations and Coupling for Transient Designs

Maxwell 2D/3D supports *element-based* one-way harmonic force coupling for *transient* designs via the Workbench schematic. Maxwell enables the user to select multiple objects for force calculations for harmonic coupling with Workbench.

- For element-based (Surface) harmonic coupling, the force density is calculated at each surface element of the selected objects at every timestep in the specified time window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Then, Discrete Fourier Transform is performed to transfer data from the time domain to the frequency domain. In the WB Harmonic response solver, surface force density is applied as surface pressure to the selected surfaces. There is no restriction on surface selection. Mapping is involved and it is done by the post-processor. Magnetostriction is not included for surface element-based harmonic force.

- For element-based (Volumetric) harmonic coupling, the force density is calculated at each element of the selected objects at every timestep in the specified time window. Then, Discrete Fourier Transform is performed to transfer data from the time domain to the frequency domain. In the WB Harmonic response solver, volumetric force density is applied as body force to the selected objects. There is no restriction on object selection. Mapping is involved and it is done by the postprocessor. Magnetostriction can be included for volumetric element-based harmonic force.

You can also set up multiple RPM Harmonic Force Coupling.

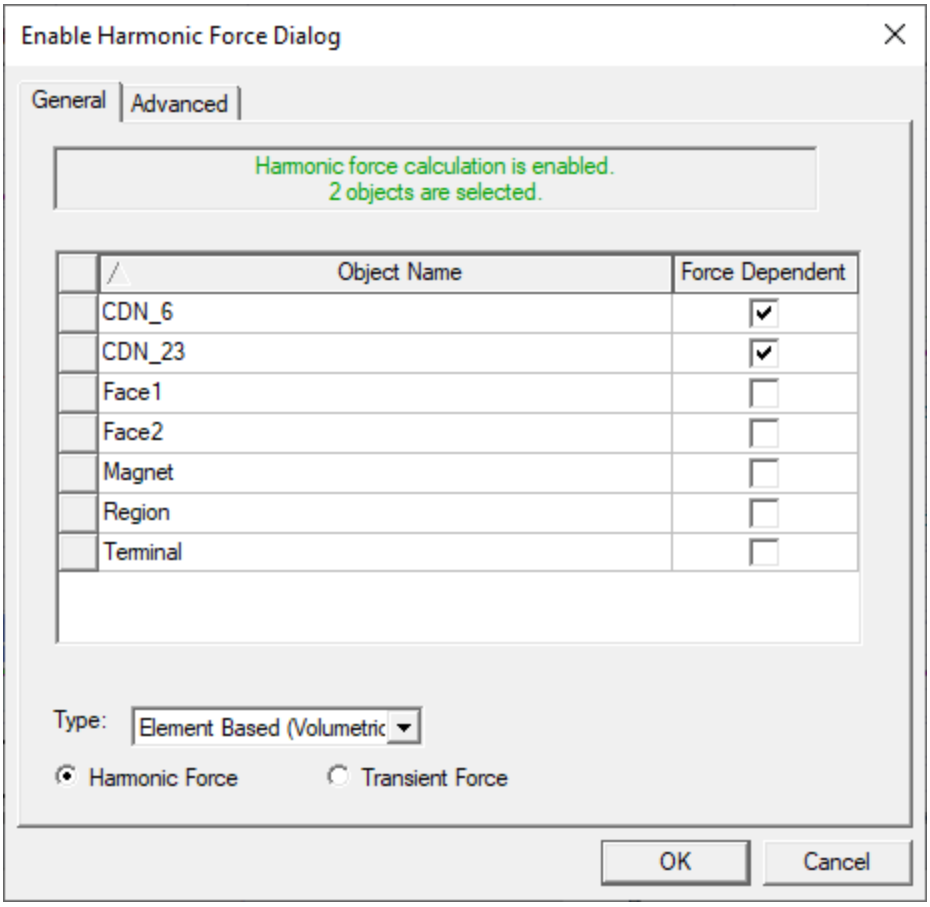
> **Note:** Element-based harmonic force calculations can also be enabled for stand-alone transient designs.

For detailed information on setting up and using harmonic force coupling in Workbench, refer to the Workbench help topics: *Importing Data into a Harmonic Analysis* and *Importing Data into a Thermal or Structural (Static or Transient) Analysis*.

To enable element-based harmonic force calculations for transient designs in Maxwell:

1. Either select **Maxwell 2D** (or **Maxwell 3D**) > **Enable Harmonic Force Calculation**, or right-click on the design in the project tree and select **Enable Harmonic Force Calculation** to open the **Enable Harmonic Force Dialog** window.
    - For *transient* designs, the dialog has two tabs: **General**, and **Advanced**.
2. On the **General** tab, select **Element Based (Surface)** or **Element Based (Volumetric)** as the harmonic force **Type**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Check the **Force Dependent** objects for which force calculations are desired.

3. The **Advanced** tab provides additional settings to allow you to control collection of data from the force calculations.

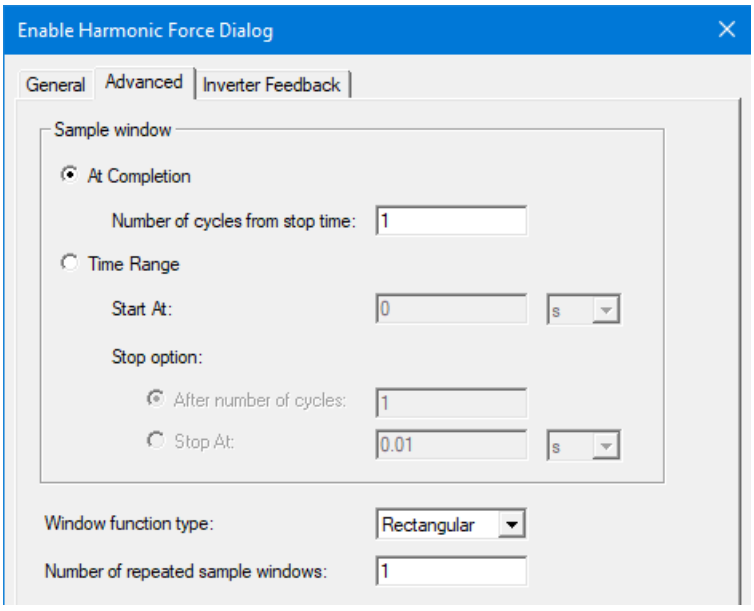
    - For *transient* designs that include rotational motion:
        - The **Sample Window**'s collect samples **At completion** setting allows you to choose the **Number of cycles from stop time** for which data is collected. For example, if one cycle equals 1 second, and you solve for 3.5 seconds, setting the **Number of cycles from stop time** to 2 results in data being collected for the period from 1.5 seconds to 3.5 seconds. Alternatively, user can specify a **Time Range** to collect data, for which user can set a data collection **Start At** and a data collection **Stop option** – either stop data collection after a user-specified number of cycles (**After number of cycles**) or at a user-specified **Stop At** time.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** The term "cycle" refers to the mechanical cycle, equivalent to 60/rpm/(Symmetry Multiplier) [in seconds].

- The **Window function type** options setting is used for Discrete Fourier Transform (DFT) of harmonic forces. See Window Function Options for DFT of Harmonic Forces for details on this setting.
- In the frequency domain of harmonic force, the base frequency is determined by the range of time window of data collection ($f = 1/\Delta T$). In order to get lower base frequencies, one must increase the time window of data collection, which means increasing the simulation time. It is waste of resources to do so when the solution reaches steady state/periodic in a transient simulation. Instead, you can set the **Number of repeated sample windows** to expand the range of time window of data collection without increasing simulation time by repeating the collected data *n* times before doing DFT. By applying this option, you can get a lower base frequency and higher frequency resolution, but the magnitudes of force components are close to zero at the introduced frequencies

> **Note:** The **Number of repeated sample windows** setting is enabled only for the **Rectangular** (the default) **Window function type**.

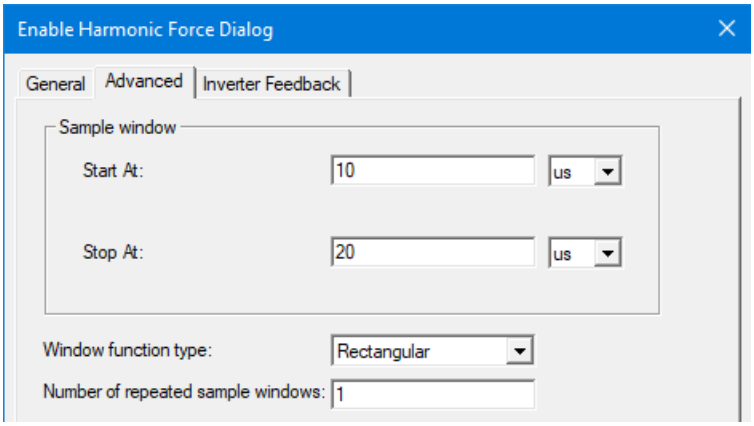


- For *transient* non-rotational motion designs:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

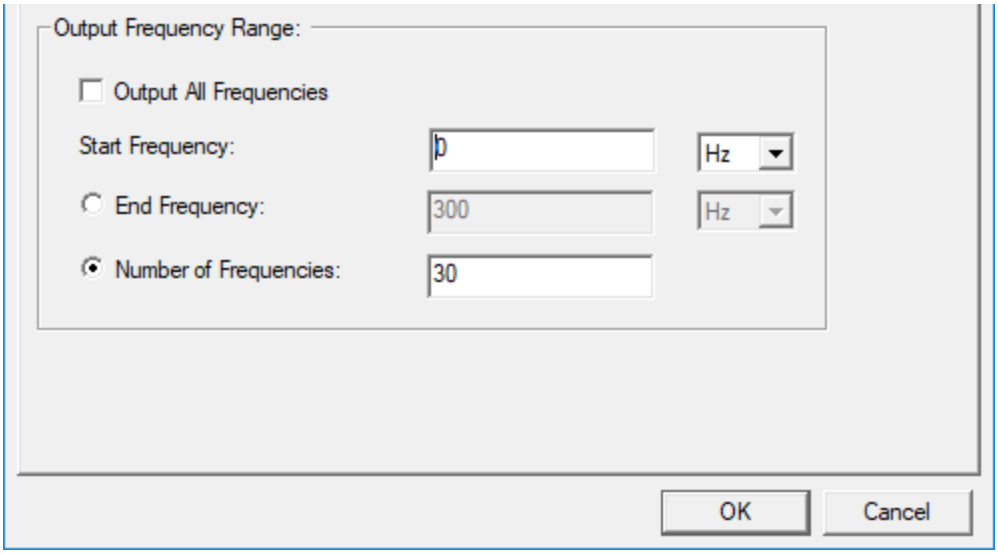
- The **Sample Window** of the **Advanced** tab allows you to set the data collection **Start At** and **Stop At** times.
- The **Window function type** options setting is used for Discrete Fourier Transform (DFT) of harmonic forces. See Window Function Options for DFT of Harmonic Forces for details on this setting.
- You can set the **Number of repeated sample windows** to expand the range of time window of data collection.

> **Note:** The **Number of repeated sample windows** setting is enabled only for the **Rectangular** (the default) **Window function type**.

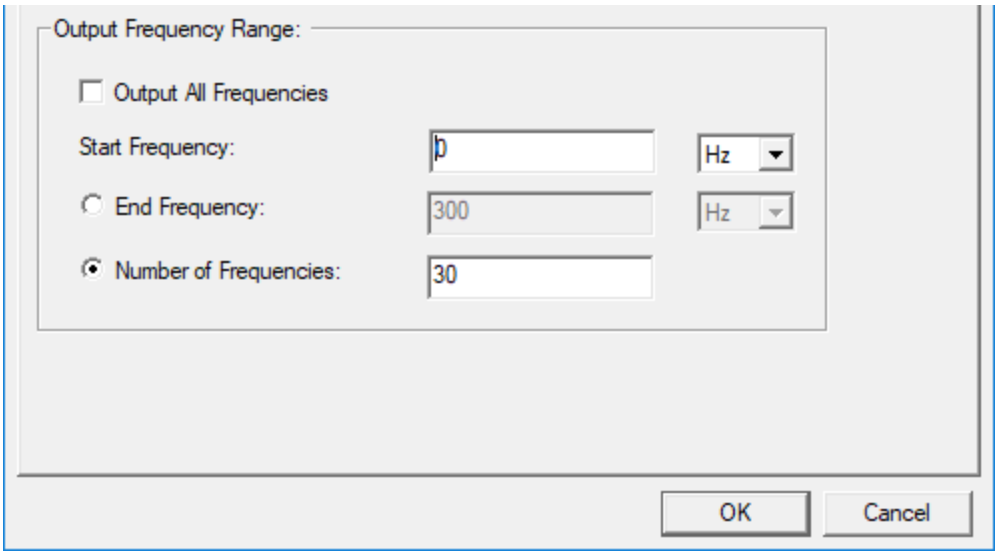


- For *2D and 3D transient* designs (either with rotational motion or with non-rotational motion), the **Output Frequency Range** panel allows you to specify the frequency range of calculated harmonic force components. The default is to **Output All Frequencies** that are calculated. If the **Output All Frequencies** is unchecked, there are two options to set the range of output frequencies:
  - Specify the **Start Frequency** and **End Frequency**. Parameterization of **Start Frequency** and **End Frequency** is supported.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Specify the **Start Frequency** and the **Number of Frequencies**; the latter defines the harmonic content where an upper frequency isn't necessarily the limit of interest. The Number of Frequencies is based on multiples of the fundamental frequency, which is defined by the duration of the transient dataset created by the user during pushback. Note that parameterization of **Number of Frequencies** is supported.



4. Click **OK** to close the window.

Once Maxwell is linked to the Workbench harmonic solver, it can export the harmonic force results to the Workbench Harmonic design. Harmonic transient force solutions are kept as part

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

of Maxwell design solutions. If Workbench harmonic design settings are changed, the Maxwell solutions will be invalidated.

Element-Based Harmonic Force Coupling for Eddy Current Designs

For 2D/3D *eddy current* designs, Maxwell provides *element-based* solutions for one-way harmonic force coupling via Ansys Workbench. For element-based solutions, there is no need to select objects in Maxwell, because harmonic surface force is a default output in the solver.

For element-based (surface) coupling, there is a harmonic force vector on each surface node for objects. The user must select surfaces on the Workbench Mechanical side before these forces can be mapped. This mapping is done by the Maxwell post-processor.

For element-based (volumetric) harmonic coupling, the force density is calculated at each element of selected objects. The user must select bodies on the Workbench Mechanical side before these forces can be mapped. This mapping is done by the Maxwell post-processor.

For detailed information on setting up and using harmonic force coupling in Workbench, refer to the Workbench help topics: *Importing Data into a Harmonic Analysis* and *Importing Data into a Thermal or Structural (Static or Transient) Analysis*

Export Transient/Harmonic Force from Maxwell

There are four options to export transient forces and one option to export transient/harmonic force from Maxwell transient solvers:

- **LMS** – provides element-based transient surface node force and mesh to link to Virtual lab, only for stator of electric machine.
- **Romax** – provides object-based transient force for the stator of electric machines and torque information.
- **UNV** – UNV file format is a standard universal file format, and it can be read by most of third-party software. Element-based transient surface/volumetric node force will be outputted with mesh.
- **Ansys Motion** – provides object-based transient force, and element-based volumetric/surface transient force to Ansys-Motion for structure and acoustic simulation.

  > **Note:** Ansys Motion does not currently support harmonic force.

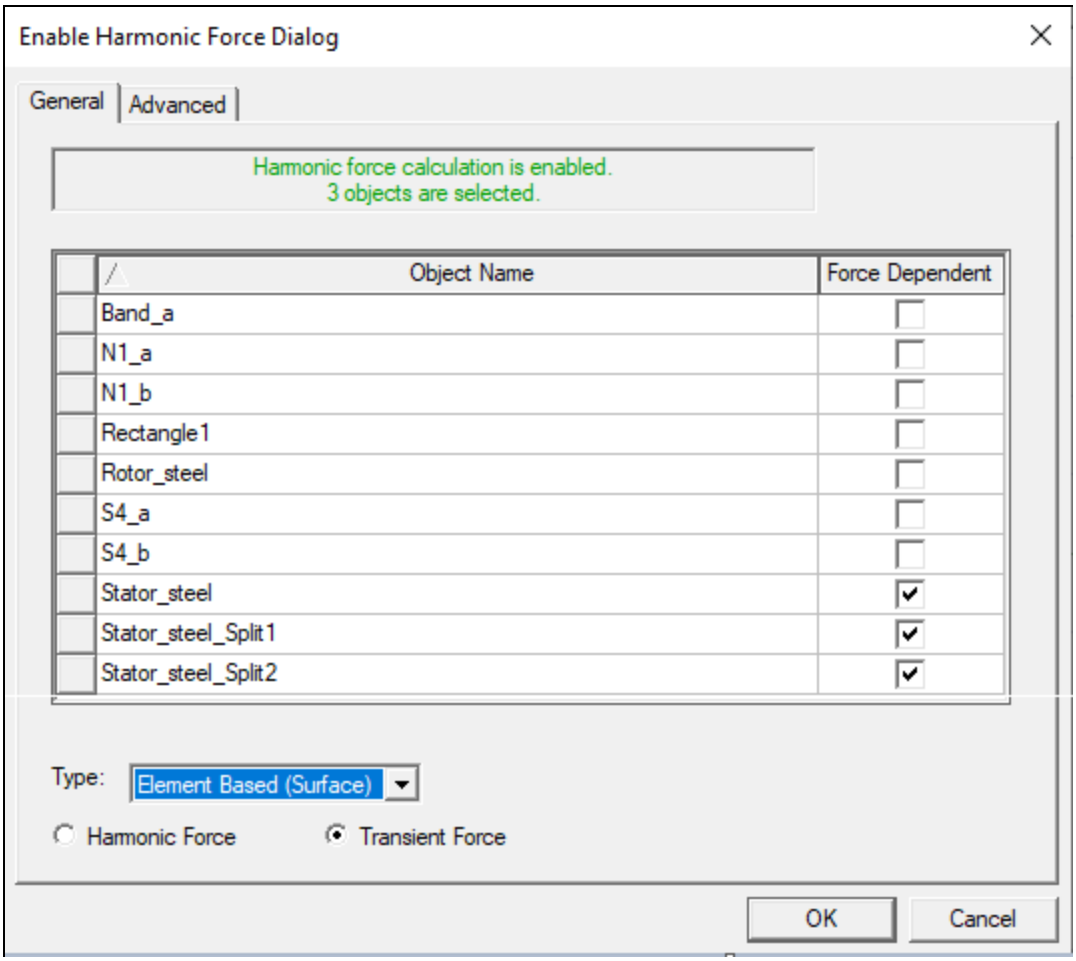
- **Ansys Mechanical**
  - For 3D transient solver, if **Element Based (Volumetric)** harmonic force selected, this option provides element-based volumetric harmonic force in `.csv` file format to *Ansys-Harmonic Response* for acoustic simulation.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If **Object Based** harmonic force is selected, this option provides object-based harmonic force with RPM parametric sweep to generate waterfall diagram in *Ansys Mechanical*.

All forces and mesh are output with the full model. To export transient/harmonic force from Maxwell, following steps must be done before solving the design:

1. Either select **Maxwell 2D** (or **Maxwell 3D**) > **Enable Harmonic Force Calculation**, or right-click on the design in the Project Manager tree and select **Enable Harmonic Force Calculation** to open the **Enable Harmonic Force Dialog** window.



2. On the **General** tab, select the **Force Dependent** objects for which force calculations are desired. For LMS, select only one object (stator).
3. Select **Type** of force for output. Choices are: **Object Based**, **Element Based (Surface)**, or **Element Based (Volumetric)**.
4. Check **Transient Force** if you want to export transient forces. (**Harmonic Force** is for Workbench Harmonic Response Coupling.)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Check **Harmonic Force** if you want to export element-based volumetric harmonic force in .csv file format. This export option is only available for the Maxwell 3D magnetic transient solver.

   > **Note:** Both Transient Force and Harmonic Force can be exported; check both options to export them for the same simulation.

6. The **Advanced** tab provides additional settings to allow you to control collection of data from the force calculations. For more details, see Element-Based Harmonic Force Coupling for Transient Designs.

After solving the design, select **Maxwell 2D** (or **Maxwell 3D**) > **Export Transient/Harmonic Force** to generate transient forces. For details on the export window, see Maxwell One- Way Coupling with Ansys Mechanical.

Maxwell to LMS Virtual.Lab Coupling

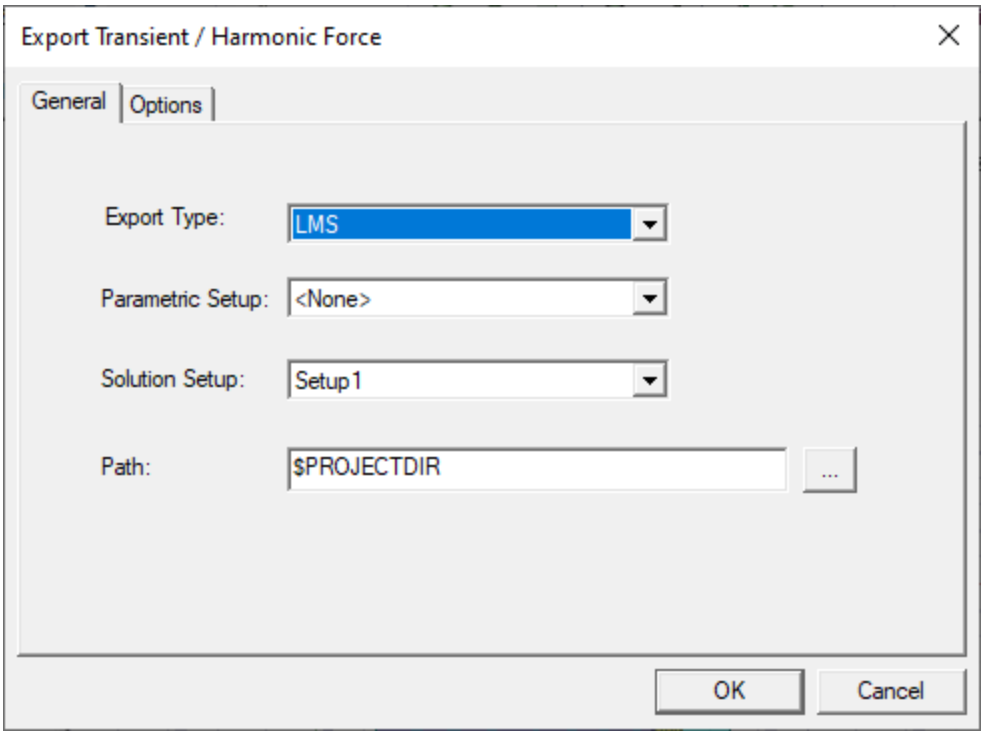
Maxwell supports one-way coupling with Siemens® LMS Virtual.Lab™.

To enable output of Maxwell solutions for use in Virtual.Lab:

1. Follow the steps in **Export Transient/Harmonic Force from Maxwell** to enable transient force output before solving the Maxwell design.
2. After solving, either select **Maxwell 2D** (or **Maxwell 3D**) > **Export Transient/Harmonic Force**, or right-click on the Design in the project tree and select **Export Transient/Harmonic Force** to open the **Export Transient/Harmonic Force Dialog** panel.
3. On the **General** tab:
   - Select **LMS** for the **Export Type**.
   - Specify a **Parametric Setup** if any (If **<None>** is selected, only the nominal results will be exported).
   - Select a **Solution Setup**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Specify the path of the location of output file (the default is the project directory).

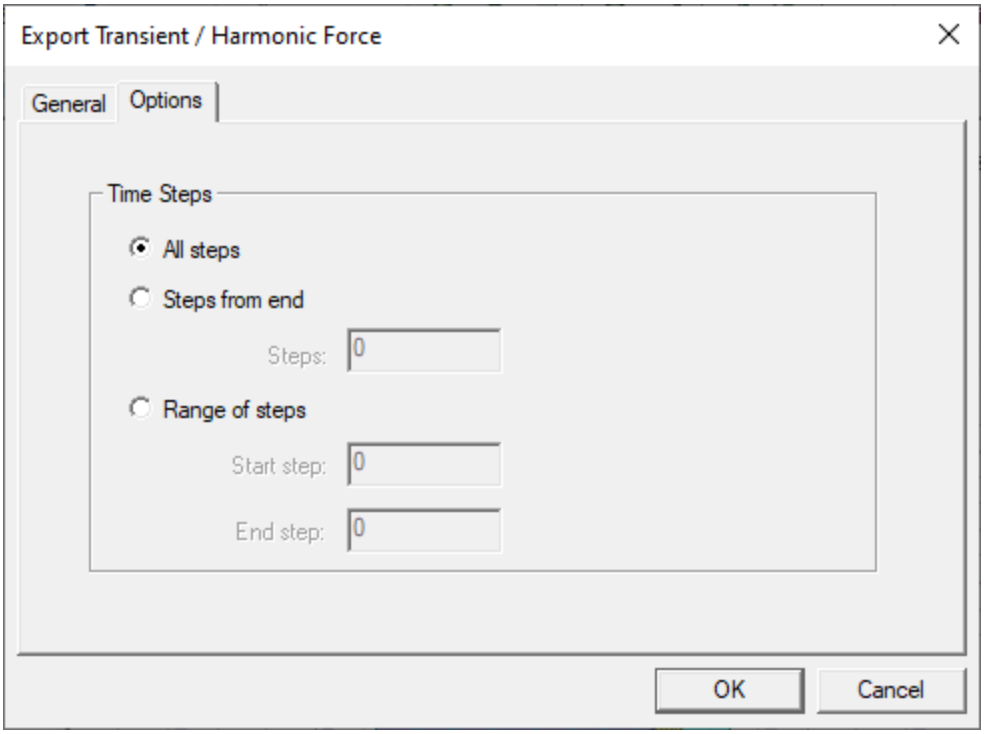


4. On the **Option** tab, settings allow you to control collection of data for export to Virtual.Lab. You can choose to include **All steps**. The **Steps from end** setting allows you to choose the number of **Steps** from the end for which data is collected.

   > **Note:** If rotation motion is defined in the project, the input number of steps will be ignored. Instead the last cycle will be the time window.

   Alternatively, you can select a **Range of steps**, for which you can set a data collection **Start step** and a data collection **End step**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. Click **OK** to close the window. When you click **OK**, all the results (nominal or parametric solution) will be exported to the specified folder.

Maxwell to Romax Coupling

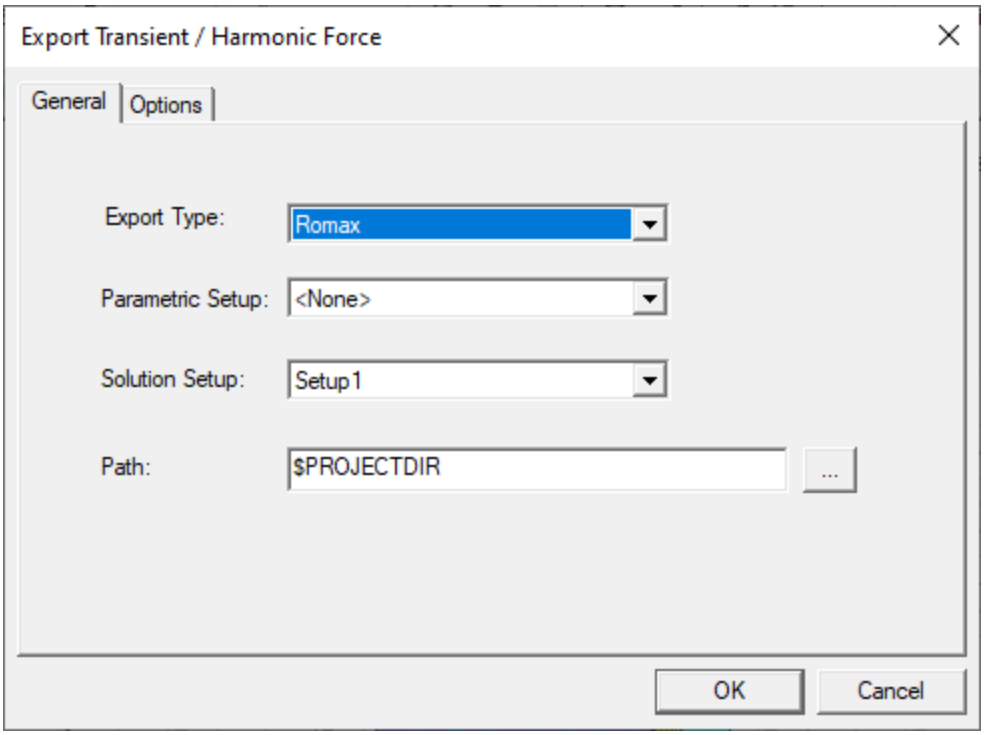
Maxwell provides object-based transient force and torque components on selected objects. Maxwell supports one-way coupling with Romax.

To enable output of Maxwell solutions for use with Romax:

1. Follow the steps in **Export Transient/Harmonic Force from Maxwell** to enable transient force output before solving the Maxwell design.
2. After solving, either select **Maxwell 2D** (or **Maxwell 3D**) > **Export Transient/Harmonic Force**, or right-click on the design in the Project Manager tree and select **Export Transient/Harmonic Force** to open the **Export Transient/Harmonic Force Dialog** panel.
3. On the **General** tab:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Select **Romax** for the **Export Type**.
- Specify a **Parametric Setup** if any (If **<None>** is selected, only the nominal results will be exported).
- Select a **Solution Setup**.
- Specify the path of the location of output file (the default is the project directory).

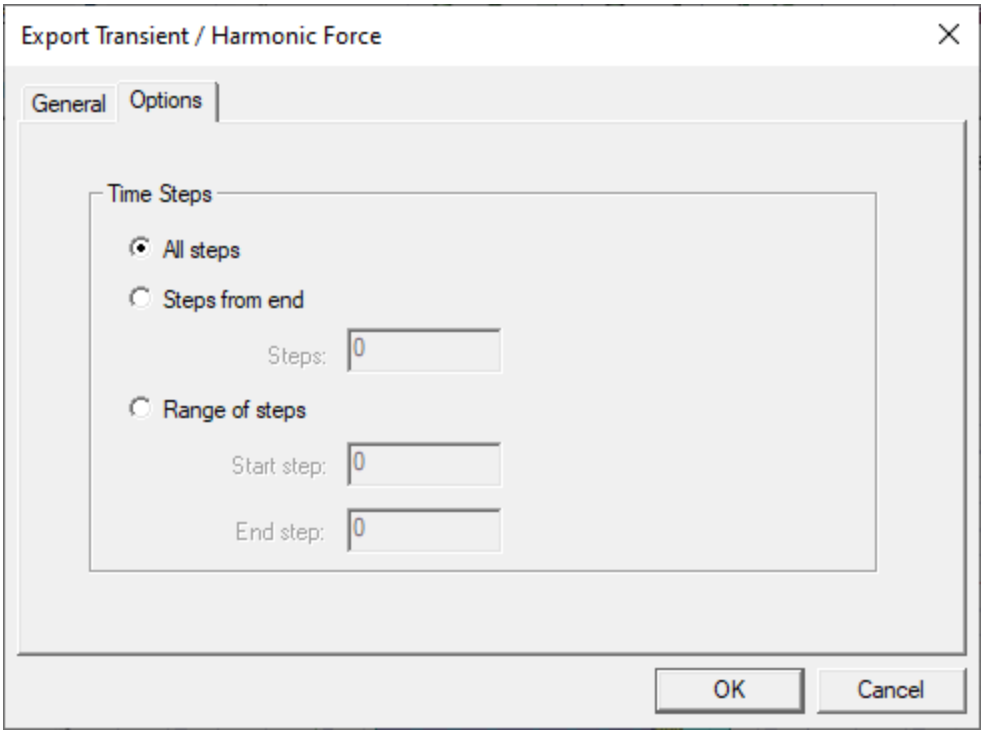


4. On the **Option** tab, settings allow you to control collection of data for export to Romax. You can choose to include **All steps**. The **Steps from end** setting allows you to choose the number of **Steps** from the end for which data is collected.

   > **Note:** If rotation motion is defined in the project, the input number of steps will be ignored. Instead the last cycle will be the time window.

   Alternatively, you can select a **Range of steps**, for which you can set a data collection **Start step** and a data collection **End step**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. Click **OK** to close the window. When you click **OK**, all the results (nominal or parametric solution) will be exported to the specified folder.

Maxwell to Third-Party Coupling by UNV File

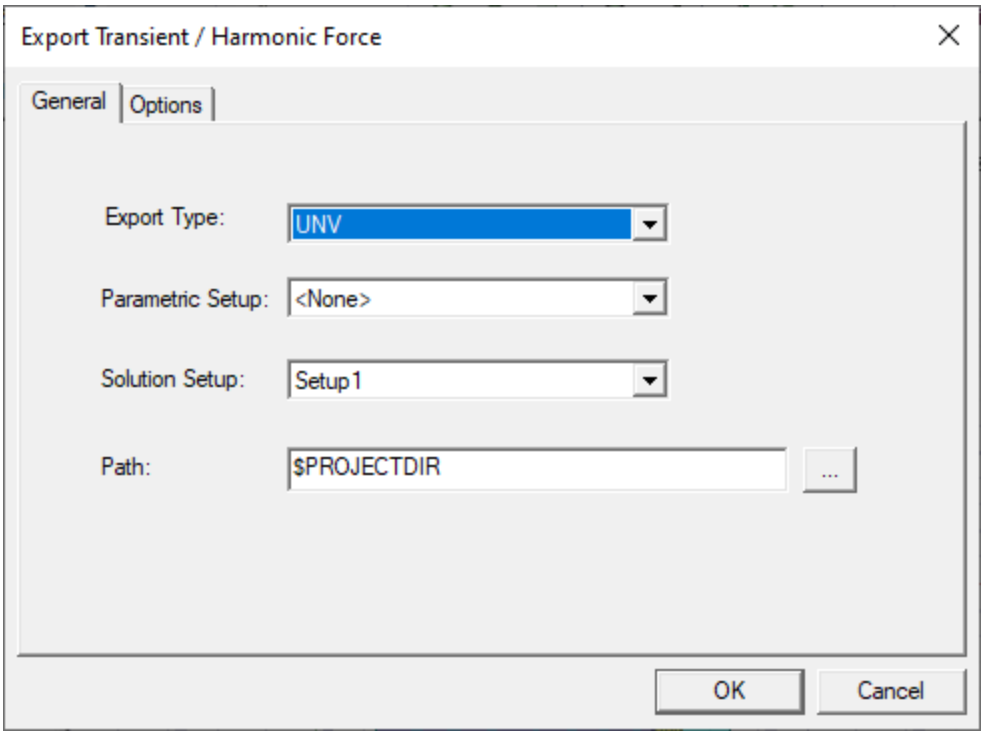
Maxwell provides option of one-way transient force coupling with any third party through standard universal (**UNV**) file format.

To enable output of Maxwell solutions for use with any third-party through UNV file format:

1. Follow the steps in **Export Transient/Harmonic Force from Maxwell** to enable transient force output before solving the Maxwell design.
2. After solving, either select **Maxwell 2D** (or **Maxwell 3D**) > **Export Transient/Harmonic Force**, or right-click on the Design in the Project Manager tree and select **Export Transient/Harmonic Force** to open the **Export Transient/Harmonic Force Dialog** panel.
3. On the **General** tab:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Select **UNV** for the **Export Type**.
- Specify a **Parametric Setup** if any (If **<None>** is selected, only the nominal results will be exported).
- Select a **Solution Setup**.
- Specify the path of the location of output file (the default is the project directory).

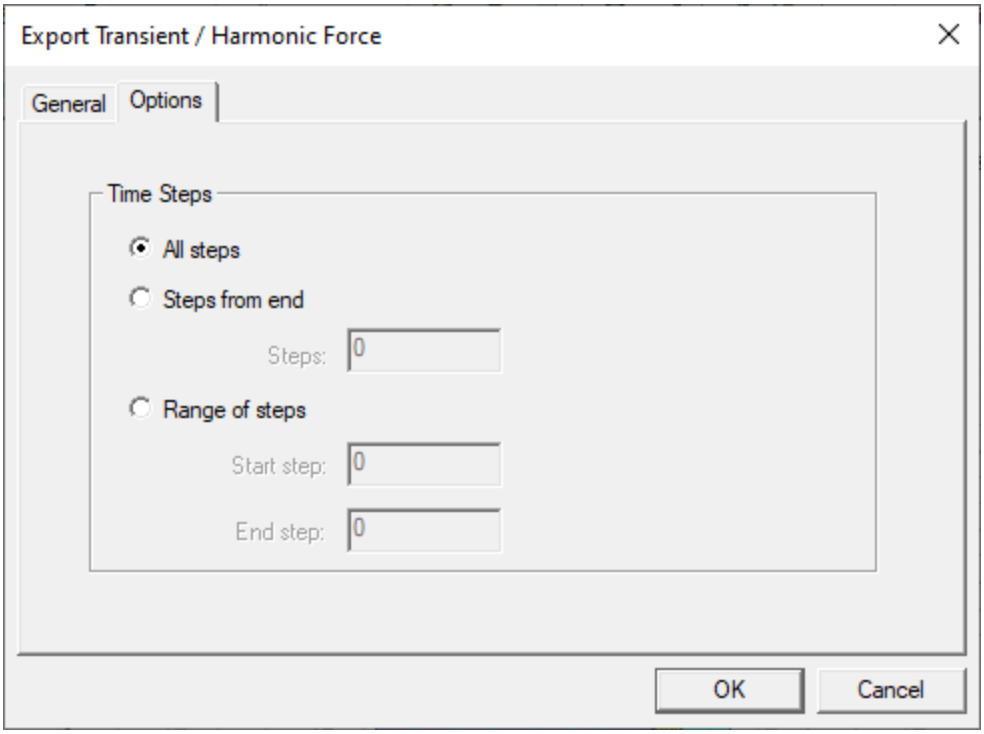


4. On the **Option** tab, settings allow you to control collection of data for export to a UNV file. You can choose to include **All steps**. The **Steps from end** setting allows you to choose the number of **Steps** from the end for which data is collected.

   Note: If rotation motion is defined in the project, the input number of steps will be ignored. Instead the last cycle will be the time window.

   Alternatively, you can select a **Range of steps**, for which you can set a data collection **Start step** and a data collection **End step**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. Click **OK** to close the window. When you click **OK**, all the results (nominal or parametric solution) will be exported to the specified folder.

Maxwell One-Way Coupling with Ansys Motion

Maxwell exports transient force to couple with Ansys Motion for acoustic simulation. There are two options to link to Motion software in Maxwell:

- Object-based: provides object based transient force and torque components on selected objects.
- Element-based (surface): provides element-based transient surface node force and mesh.
- Element-based (volumetric): provides element-based transient volumetric node force and mesh.

All forces and mesh are output with full model.

To enable output of Maxwell transient force solutions for link with Ansys Motion:

1. Follow the steps in **Export Transient/Harmonic Force from Maxwell** to enable transient force output before solving the Maxwell design.

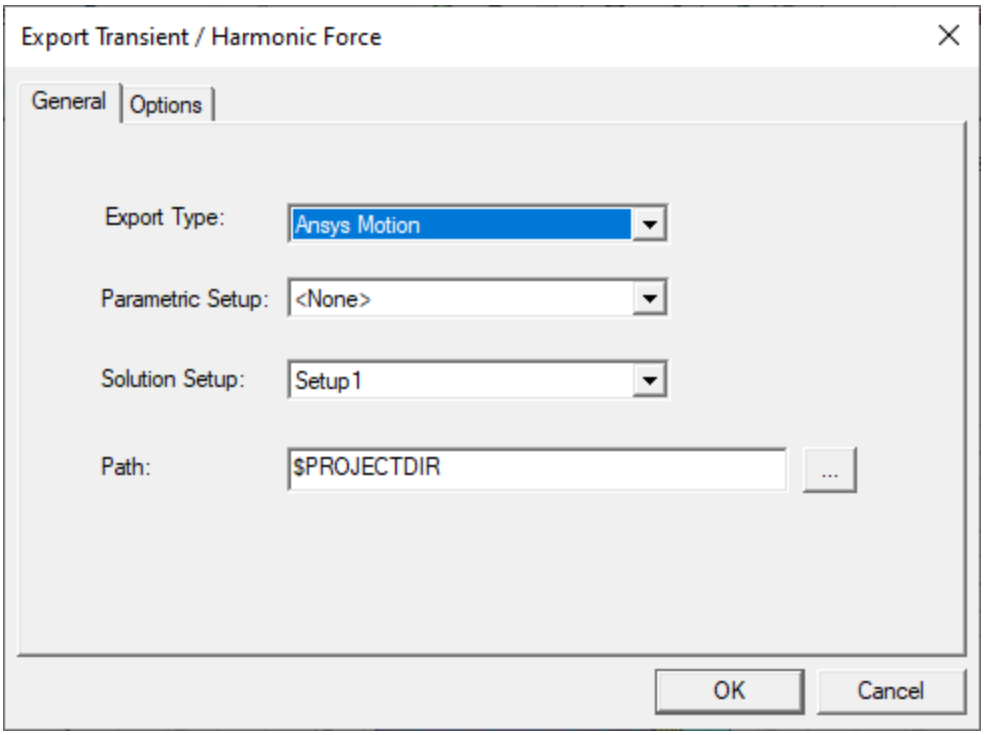
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. After solving, either select **Maxwell 2D** (or **Maxwell 3D**) > **Export Transient/Harmonic Force**, or right-click on the Design in the Project Manager tree and select **Export Transient/Harmonic Force** to open the **Export Transient/Harmonic Force Dialog** panel.

   > **Note:** Ansys Motion does not currently support harmonic force.

3. On the **General** tab:

   - Select **Ansys Motion** for the **Export Type**.
   - Specify a **Parametric Setup** if any (If **<None>** is selected, only the nominal results will be exported).
   - Select a **Solution Setup**.
   - Specify the path of the location of output file (the default is the project directory).

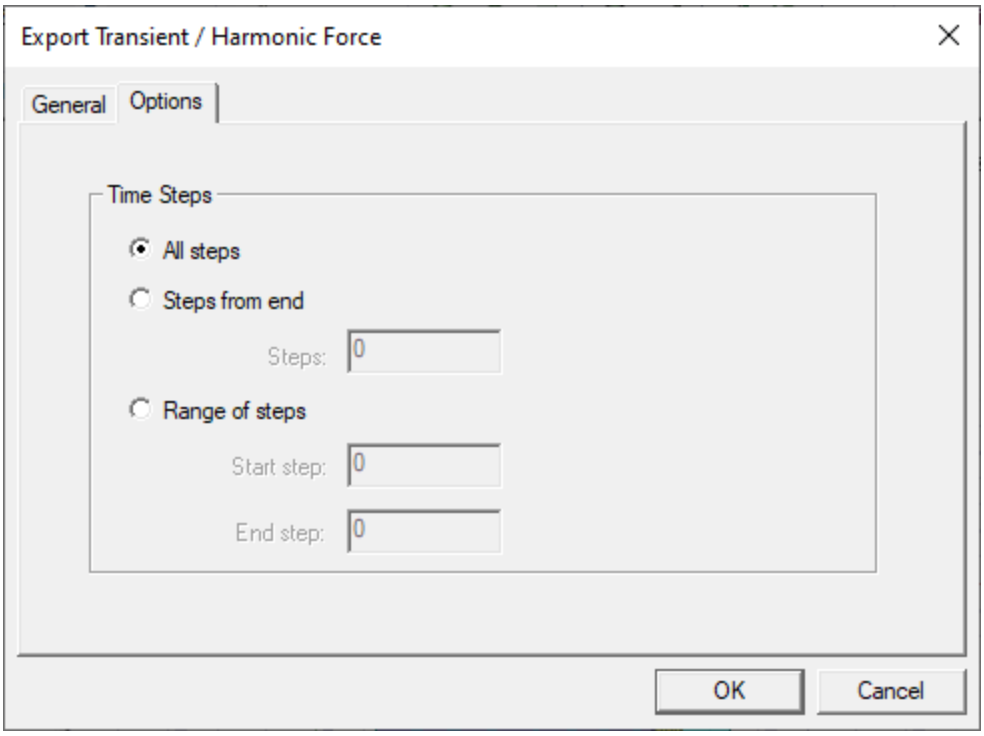


4. On the **Option** tab, settings allow you to control collection of data for export to UNV file (and .AMESH and .ANF files if element-based selected). You can choose to include **All steps**. The **Steps from end** setting allows you to choose the number of **Steps** from the end for which data is collected.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** If rotation motion is defined in the project, the input number of steps will be ignored. Instead the last cycle will be the time window.

Alternatively, you can select a **Range of steps**, for which you can set a data collection **Start step** and a data collection **End step**.



5. Click **OK** to close the window. When you click **OK**, all the results (nominal or parametric solution) will be exported to the specified folder.

Maxwell One-Way Coupling with Ansys Mechanical

Maxwell 2D and 3D transient designs can export object-based harmonic force to couple with Ansys Mechanical for acoustic simulation.

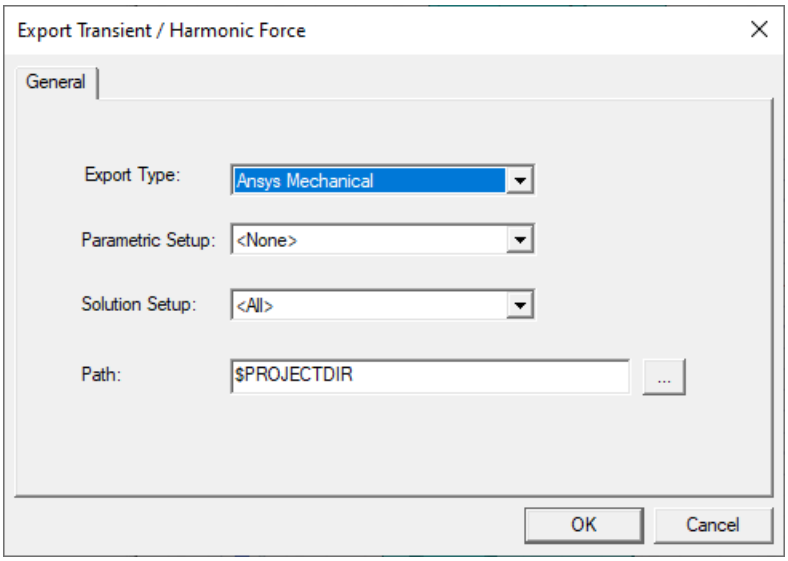
To enable output of Maxwell harmonic force solutions for link with Ansys Mechanical:

1. Follow the steps in **Maxwell to Ansys Object-Based Harmonic Force Coupling** to enable object-based harmonic force output before solving the Maxwell design.
2. After solving, either select **Maxwell 2D** (or **Maxwell 3D**) > **Export Transient/Harmonic Force**, or right-click on the design in the Project Manager tree and select **Export Transient/Harmonic Force** to open the **Export Transient/Harmonic Force Dialog**

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

panel.

3. On the **General** tab:
   - Select **Ansys Mechanical** for the **Export Type**.
   - Specify a **Parametric Setup** if any (If **<None>** is selected, only the nominal results will be exported).
   - All solved solution setups will be exported, so the **Solution Setup** drop-down menu will always be **<All>**.
   - Specify the path of the location of output file (the default is the project directory).



4. Click **OK** to close the window. When you click **OK**, all the results (nominal or parametric solution) will be exported to the specified folder.

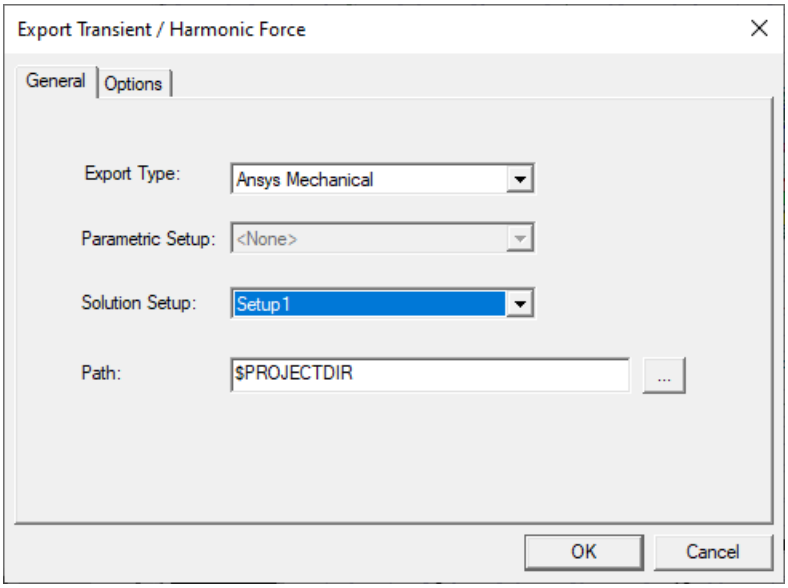
   You can then import the file into a WB harmonic component. For detailed information on setting up and using harmonic force coupling in Workbench, refer to the Workbench help topic: *Importing Data into a Harmonic Analysis*.

To enable output of Maxwell harmonic force solutions in a `.csv` file to couple with Ansys Mechanical:

1. Follow the steps in Maxwell to Ansys Element-Based Harmonic Force Coupling to enable element-based harmonic force output before solving the Maxwell design.
2. After solving, either select **Maxwell 3D** > **Export Transient/Harmonic Force**, or right-click on the Design in the project tree and select **Export Transient/Harmonic Force** to open the **Export Transient/Harmonic Force** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. On the **General** tab:
    - Select **Ansys Mechanical** for the **Export Type**.
    - Specify a **Parametric Setup** as **<None>**.
    - Select a **Solution Setup** in the drop-down menu.
    - Specify the path of the location of output file (the default is the project directory).



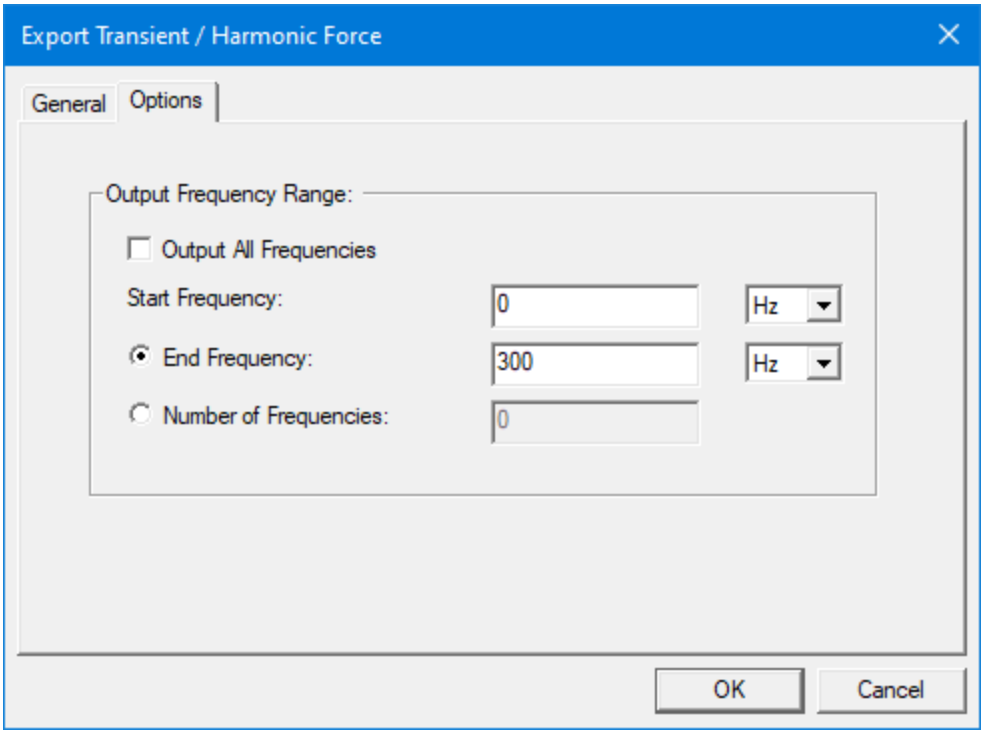
On the **Options** tab, specify the **Output Frequency Range**. The file format in `.csv` file is (in line): Xc, Yc, Zc, Volume, Fx_re, Fx_im, Fy_re, Fy_im, Fz_re, Fz_im, Frequency1, Fx_re, Fxim, ……., Frequency2, ……

Note:

The frequency 0 (DC component) will be exported for either of the following conditions:

- for **Output All Frequencies**: the first frequency will be 0.
- for a specified range or number of frequencies: if the **Start Frequency** is zero.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



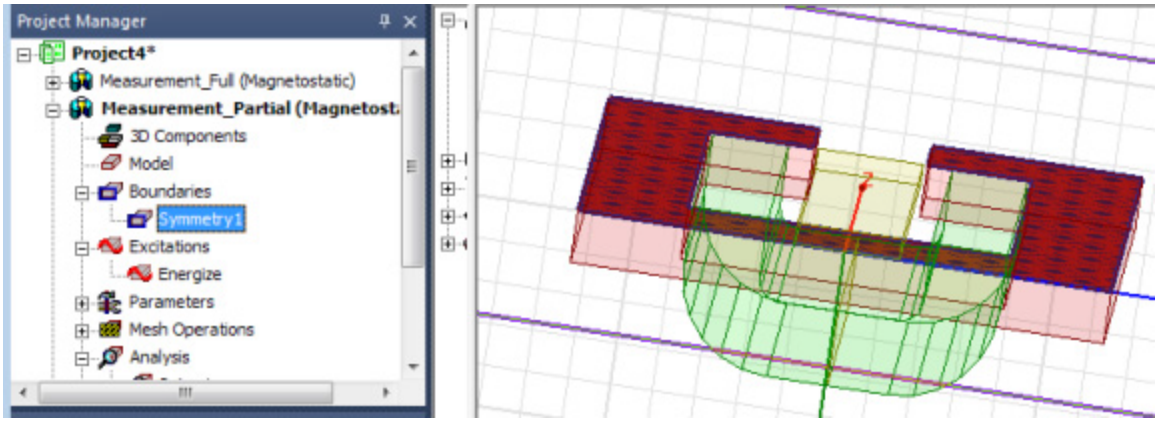
The **Number of Frequencies** defines the harmonic content where an upper frequency isn't necessarily the limit of interest. The Number of Frequencies is based on multiples of the fundamental frequency, which is defined by the duration of the transient dataset created by the user during pushback.

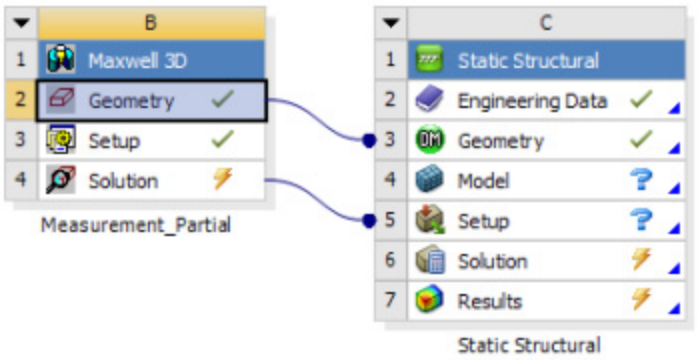
4. Click **OK** to close the window. When you click **OK**, the `.csv` file will be exported to the specified folder. You can then import the file into a WB harmonic component.

Maxwell Partial Model Coupling with Workbench

This feature allows Maxwell 2D and 3D partial model coupling with Workbench applications such as Mechanical and Thermal. The full model geometry and solution can be extracted through symmetry from the partial model. Symmetry boundary conditions are used to solve problems with symmetry and, thus, allow the users to take advantage of the significantly reduced problem size for a given accuracy.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



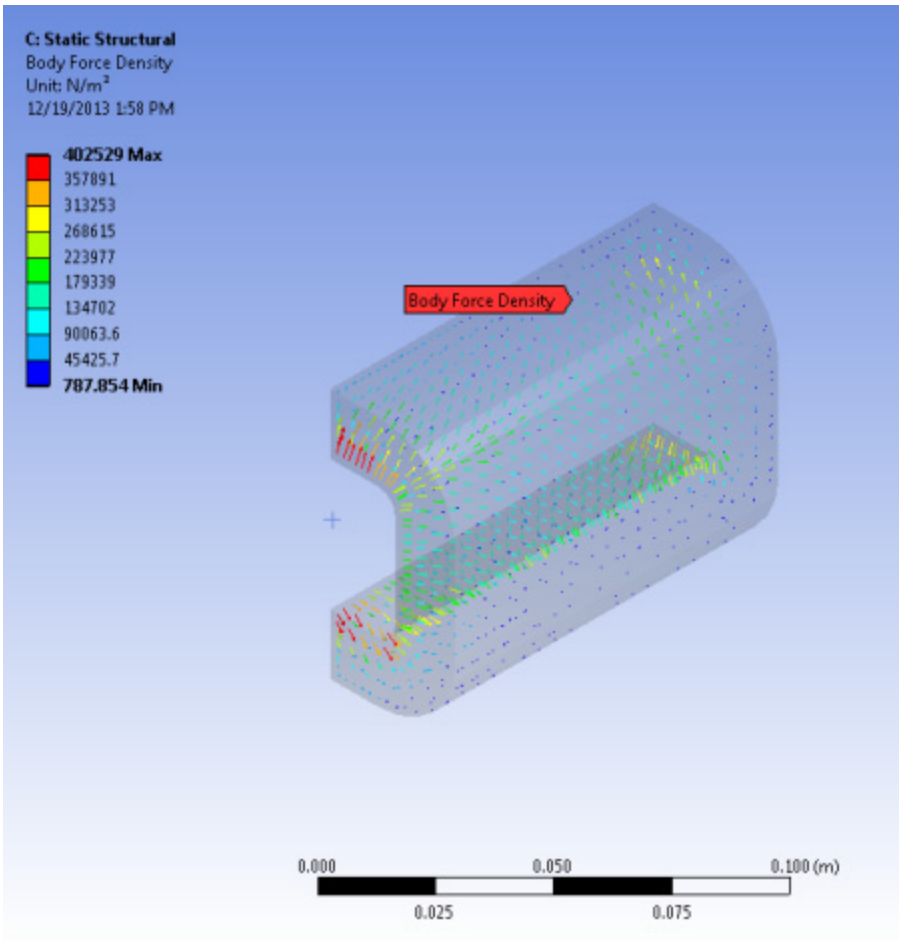


The following conditions must be observed for the Maxwell partial model:

- The model must be physically correct.
- Independent and dependent boundaries must be planar. If there is more than one pair of independent and dependent boundaries, all independents are coplanar and all dependents are coplanar.
- There are at most three mirroring symmetries, which are orthogonal to each other. If there is a pair of independent and dependent boundaries, then only one mirroring symmetry is allowed and it must be perpendicular to the axis of the independent and dependent boundaries.
- When the Maxwell side is a partial model and the Mechanical side is full model, full model loss / force will be mapped to the Mechanical side.
- When the Maxwell side is a partial model and the Mechanical side is also a partial model, only partial model loss / force will be mapped to the Mechanical side.
- When setting up loss transfers from Maxwell to WorkBench, if the user wants to map loss density on a face shared by two objects, this face only has to be used once in the setup.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

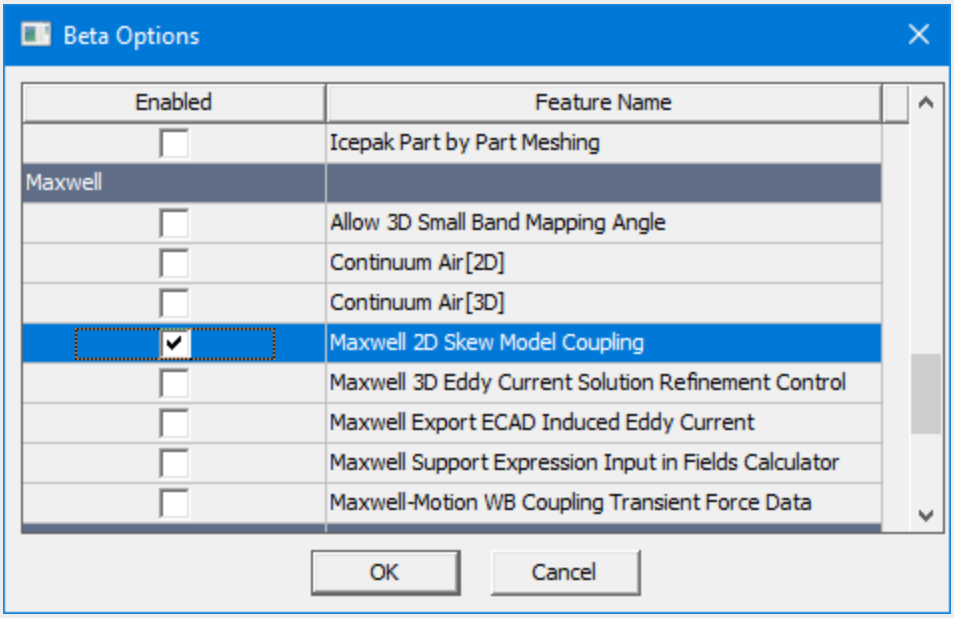
The user must ensure that the Maxwell partial model is physically correct, and that the full model in Workbench Mechanical, Thermal, etc. matches the partial model. The loss/force data from the partial Maxwell model is then mapped to the full model in Workbench Mechanical, etc. for solving. The mapping is handled implicitly.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

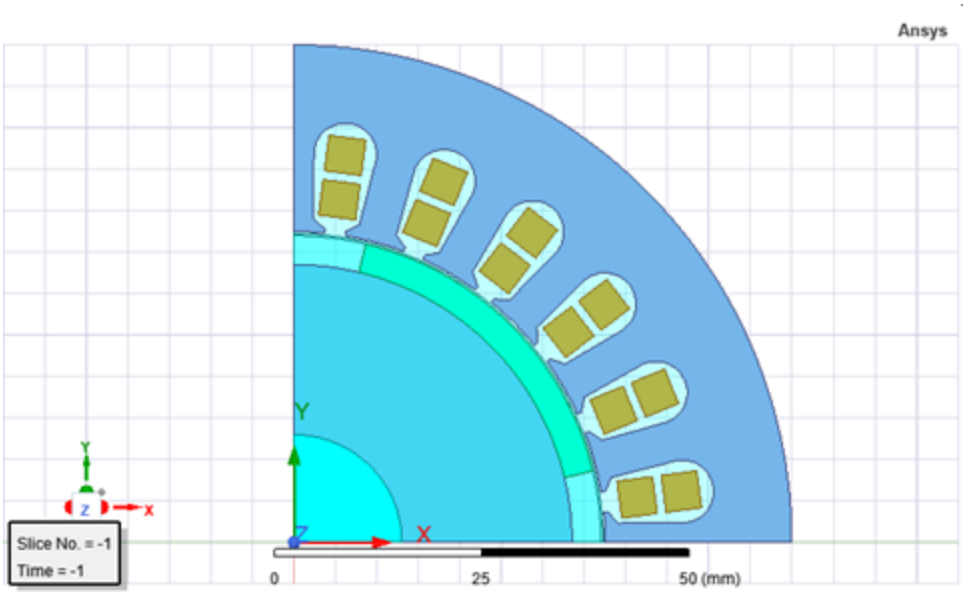
[Beta] Element-Based Multiphysics Coupling for 2D Multislice Skew Model

Note: You must enable this feature in General Options:Desktop Configuration > Beta Options before you can use it.



For Maxwell 2D transient skew models, this beta feature enables element-based multiphysics coupling to steady-state thermal and static/transient structural designs in Work bench. The target design could be 2D with matching geometry or 3D with equivalent geometry, *i.e.*, extrusion of 2D geometry with matching skew type.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Currently, RMxprt can only generate corresponding 3D models from electric machines with the continuous skew type, and corresponding 3D designs cannot be automatically generated from 2D skew model designs.

The Maxwell 2D skew model itself can be a partial model with an independent/dependent boundary, in which case, the target could be either a partial or a full model. If the target geometry is 2D, data from the default slice (middle) will be mapped. If the target geometry is 3D, it should be an extrusion of the 2D geometry with matching skew type. Any geometry in 3D that is beyond the 2D model depth will not be mapped.

Limitations

- 3D geometry creation from 2D Skew models is not supported. This needs to be done manually and then couple the two designs.
- Stress feedback on Structural is not supported. Regarding 3D to 3D coupling, Maxwell-Structural coupling provides forces from Maxwell and receives displacement and stress from Structural.
- 2D to 3D EM coupling is not supported.

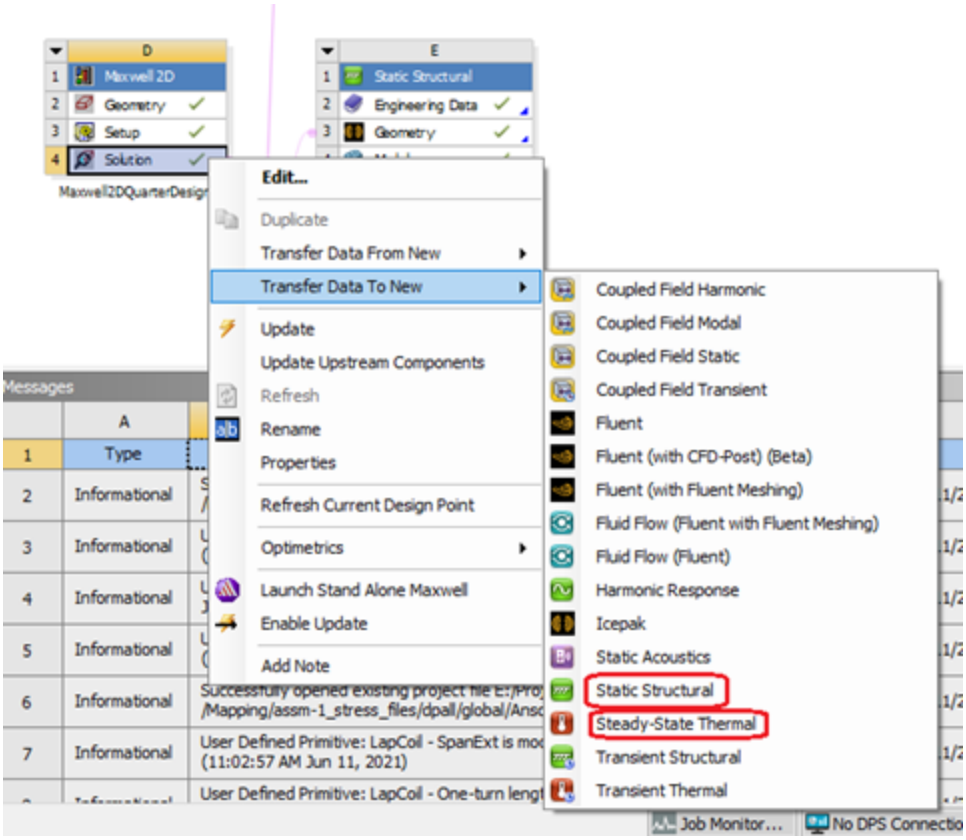
Use the following work flow:

1. From RMxprt, create a 2D skew model design and corresponding 3D design.

   > **Note:** For detailed information on Skew Model settings, refer to the *Model Settings Tab* topic.

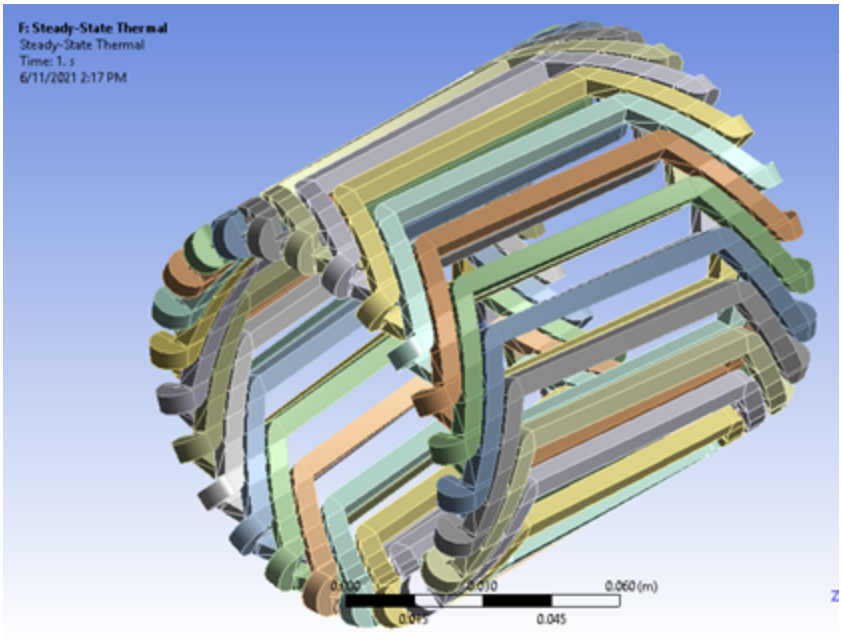
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Solve the 2D design and save the project.
3. Drag the project into Workbench.
4. In the Maxwell 2D design, select **Solution** > **Transfer Data To New** > **Steady-State Thermal** or **Static Structural**.

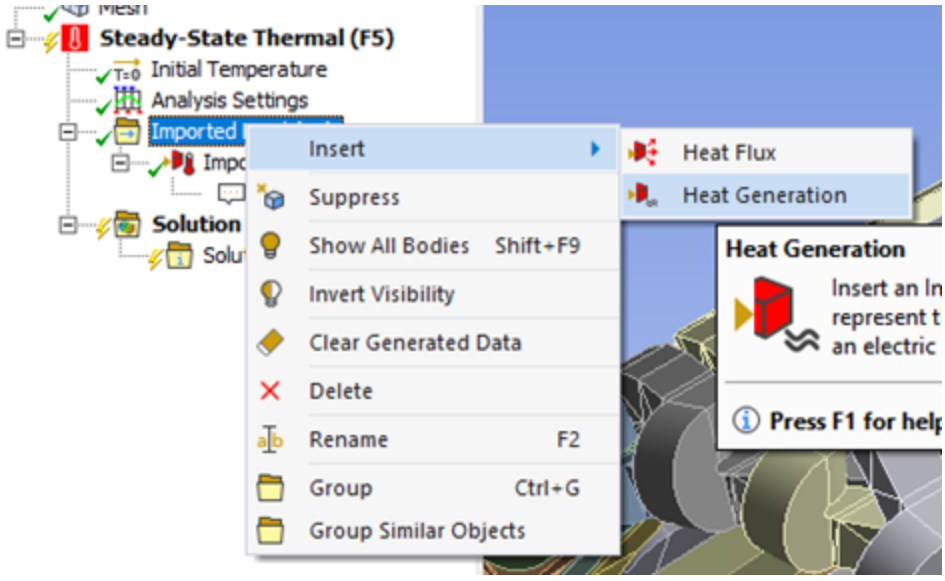


5. Drag the Geometry from the Maxwell 3D design to the Geometry of the newly created Mechanical design.
6. Refresh and/or Update the Geometry and Model in the Mechanical design.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

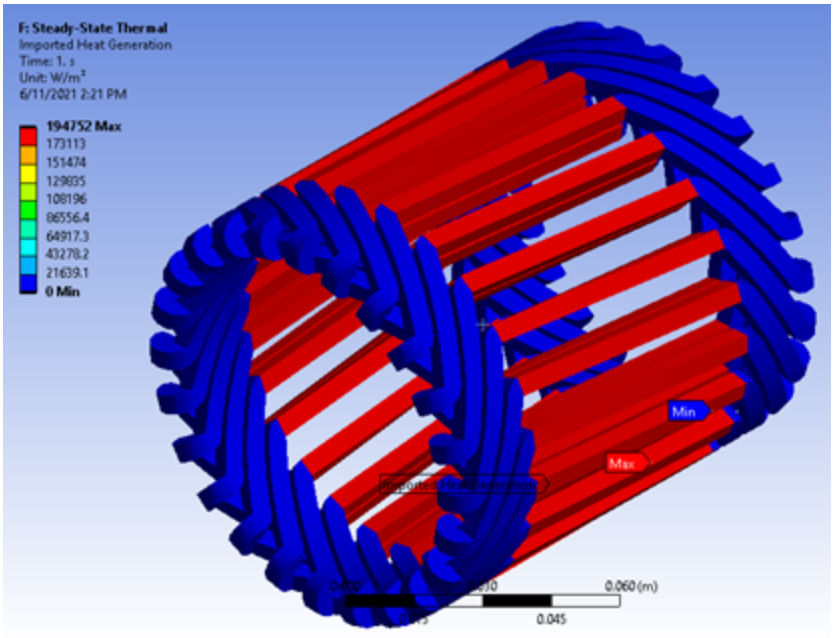


7. In the Maxwell 2D, select **Solution** > **Update**.
8. In the Mechanical design, **Setup** > **Refresh**.
9. Double-click **Setup**.
10. **Imported Load** > **Insert** > **Heat Generation**, select lossy objects and set end time.



11. Import the loads. Forces could be imported similarly.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Near Field Coupling between Maxwell and HFSS

The purpose of this coupling is to allow **Maxwell 3D** frequency domain solution magnetic fields to be used as a near field source in the coupled **HFSS** design at exactly matched frequency.

> **Note:** There is no **Far Field Wave** coupling datalink between **HFSS** and **Maxwell**.

The suggested sequence of steps to create the link between **Maxwell** and **HFSS** is as follows.

1. Create and solve the **Maxwell 3D** frequency domain application at the chosen frequency.
2. Create the **HFSS** model.
3. Add "mapping" object to **HFSS** model.
4. Select all faces of the mapping object and apply a radiation boundary:
   - check the **Advanced Options** check box.
   - select the **Enforced field** radio button.
5. Click **HFSS** > **Excitations** > **Assign** > **Incident Wave** > **Near Field Wave**.

   The **Incident Wave** wizard appears.
6. In the wizard, enter a **name** for the source or accept the default name and click **Next**.
7. In the **Incident Wave Source: Near Field Wave Options** dialog box, leave the translation and rotation data fields at their default zeros if the objects in the coupled designs have the desired location / orientation or change the values as needed.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** You can change the location of the source design origin and orientation (rotation) to perform different **HFSS** simulations without re-solving the **Maxwell** design.

8. Click the **Setup Link** button to specify the location of the source Maxwell design.
9. Select **OK** to exit the **Setup Link** dialog box.
10. Select **Finish** to finalize the Near Field link setup.

Magnetic Bias Source Coupling between Maxwell and HFSS

HFSS designs featuring ferrite materials can take advantage of non-uniform, static magnetic biasing fields to provide accurate design and simulation results. To achieve this goal it is possible to set up a coupling datalink between **HFSS** (target design) and a **Maxwell 3D** magnetostatic design (source).

The suggested sequence of steps to create the link between the **HFSS** and **Maxwell 3D** designs is as follows:

1. Create and solve the **Maxwell 3D** design which contains the ferrite object and the corresponding non-uniform biasing fields.
2. Create the **HFSS** design which can have entirely different geometry but which contains the ferrite object(s) present in the linked **Maxwell 3D** design.

   > **Note:** Make sure that in the coupled designs (**HFSS** and **Maxwell**) the ferrite objects have the same position and orientation in the global coordinate system.

3. In the **HFSS** design, assign appropriate ferrite material property to object.
4. In the **HFSS** design, set the magnetic bias source (only one allowed per **HFSS** design):
   - Select the object(s) to be assign the non-uniform magnetic bias.
   - Click **HFSS** > **Excitation** > **Assign** > **Magnetic Bias** in the menu.

   The **Magnetic Bias Source** dialog box appears:

   a. Enter a **Name** for the source.
   b. Select the **Non-Uniform** radio button.
   c. Click the **Setup Link** button to specify the applicable **Maxwell 3D** project, design and solution for the link.
   d. Select **OK** when done.
5. Select **Finish** to finalize the Magnetic Bias link setup.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Tip: It is possible to have the datalink create the **Maxwell** project automatically if it doesn't exist. When selecting the "Setup Link" button above, entering nonexistent **Maxwell** project and design names will result in the creation of the needed **Maxwell** entities with the entire **HFSS** geometry included. All unneeded **HFSS** objects can be removed, and the rest of the **Maxwell** model can be built around the ferrite object(s).

Coupling Maxwell with Ansys Motion (Stand-Alone)

Direct cosimulation between Maxwell and Ansys Motion makes possible magnetic latch modeling, which is typically used for modeling magnetic latching structures such as magnetic chargers used by mobile devices. Ansys Motion is the primary (controlling) design, while Maxwell serves as the secondary design. During the cosimulation, Motion provides objects position data to Maxwell, then Maxwell feeds force/torque data for these objects back to Motion.

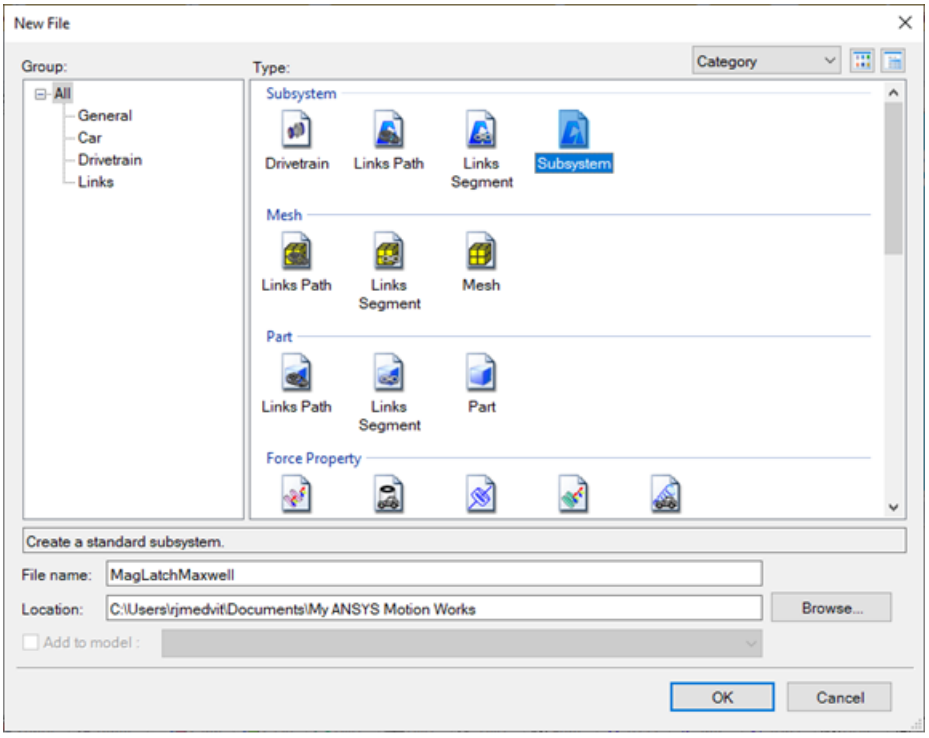
Note: For cosimulation between Maxwell and the Ansys Motion integrated in Workbench, see *Coupling Maxwell with Ansys Motion in Workbench*.

The suggested workflow for magnetic latch modeling using cosimulation with the Ansys Motion stand-alone preprocessor and Maxwell is outlined in this topic.

Note: For details on using the Motion Preprocessor for the following steps, see the *Ansys Motion Preprocessor Manual* installed with the Ansys Motion software.

1. In **Ansys Motion Preprocessor**, create a new **Subsystem** file for which you specify a project path and project name.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



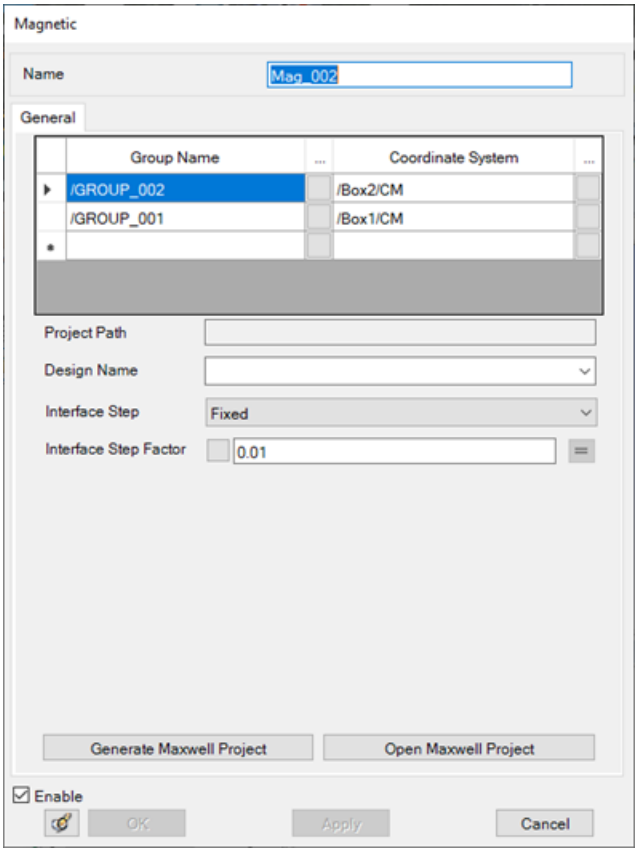
2. Import a CAD file of the model. You can modify object properties such as materials as needed.
3. After creating the model, **Group** objects of interest that have position changes and/or need force/torque calculations in the Maxwell design.

> **Note:** For performance considerations, it is recommended that you not perform force/torque calculations on all objects.

> **Note:** The Ansys Motion software interface is only available on Windows, but you can set up an Ansys-Maxwell cosimulation on Windows, and then run the simulation on Linux, see Running an Ansys Motion-Maxwell Cosimulation on Linux for details.

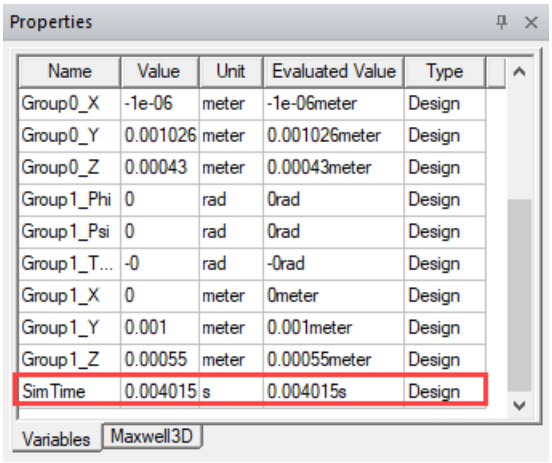
4. On the Ansys Motion Preprocessor **Force** tab, click the **Magnetic** button, pick the desired **Groups**, then click **OK**. In the **Magnetic** dialog box enter the desired **Interface Step Factor** (in seconds) or accept the default 0.01. This sets the Maxwell simulation rate. The **Coordinate System** assigned to each group defaults to center-of-mass.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. Click **Generate Maxwell Project**. A Maxwell desktop will be launched automatically with the generated Maxwell magnetostatic design, which includes the following:
    - The model geometry (including necessary coordinate systems)
    - If a Material is not found in the Maxwell system or user libraries, a new material with the default properties of *vacuum* will be created.
    - Force/torque calculation setups
    - A [default] Solve setup
    - Data table for force/torque parameters
    - Field plot for magnetic objects
    - Ansys Motion passes the Motion solve timestep as a variable named **SimTime** to Maxwell. Excitations can be created depending on this variable.

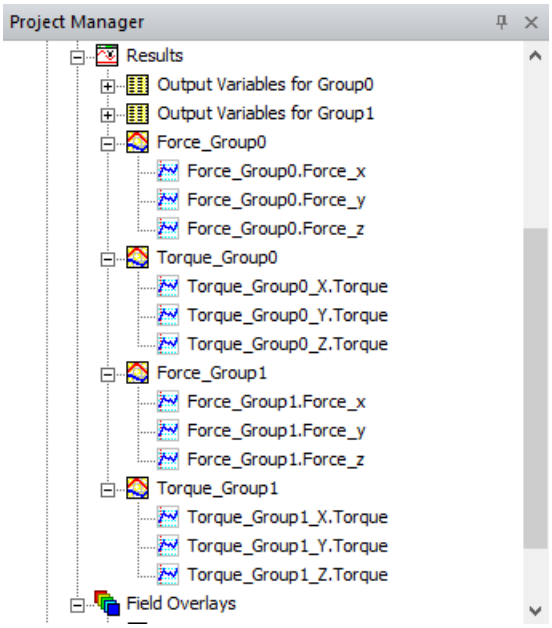
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- A parametric setup called **MotionHistory** will be automatically created and will be updated for each timestep, keeping a table of variations for all the simulation steps. This data can be used to create an animation of all the simulation steps.

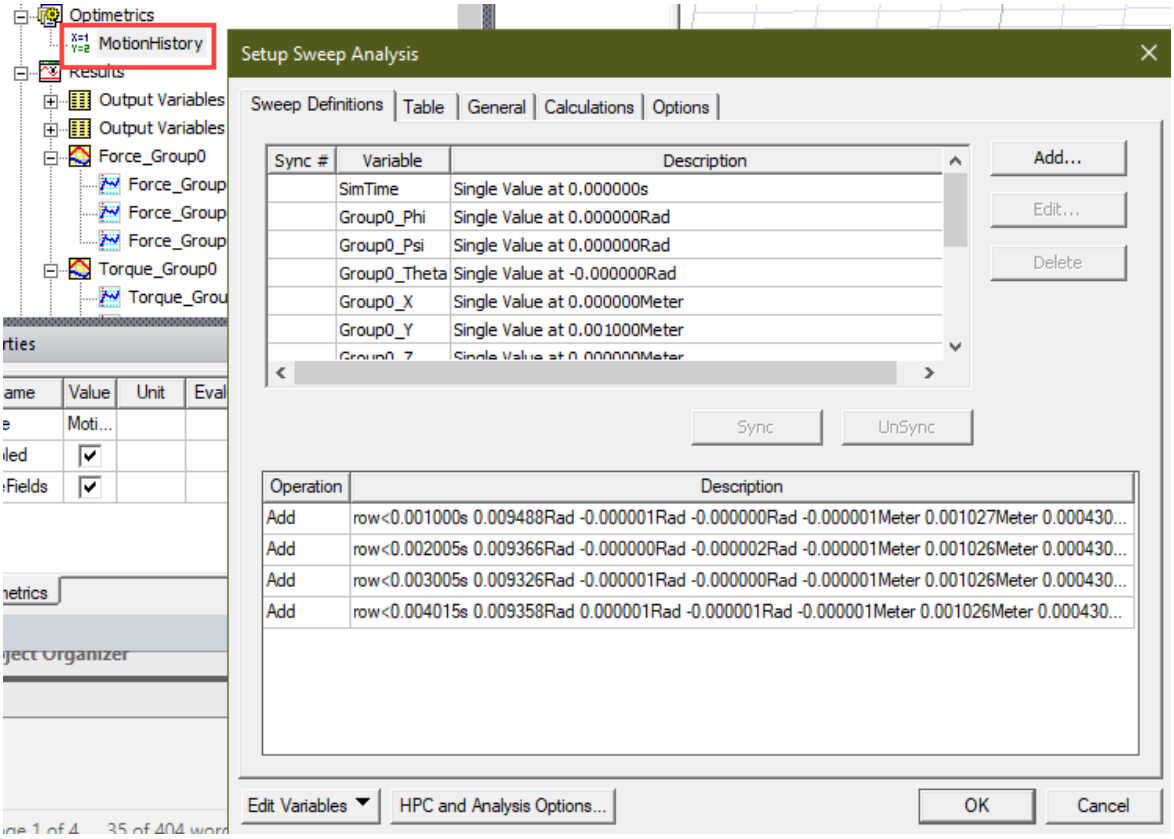
6. Optionally, you can customize various settings manually in Maxwell, such as:
   - Material properties for objects, especially characteristics for permanent magnets
   - Excitations can be created dependent on the **SimTime** variable.
   - Coordinate system settings
   - Mesh setup
   - Solve setup
7. After the setups on both Ansys Motion and Maxwell (if any) are completed, you can start the cosimulation solve in Motion by selecting **Simulation** > **Run** on the **Home** tab.
8. After cosimulation is completed, Maxwell Project Manager Results should show two reports for each group, one for force, one for torque. The reports plots are force/torque against **SimTime**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



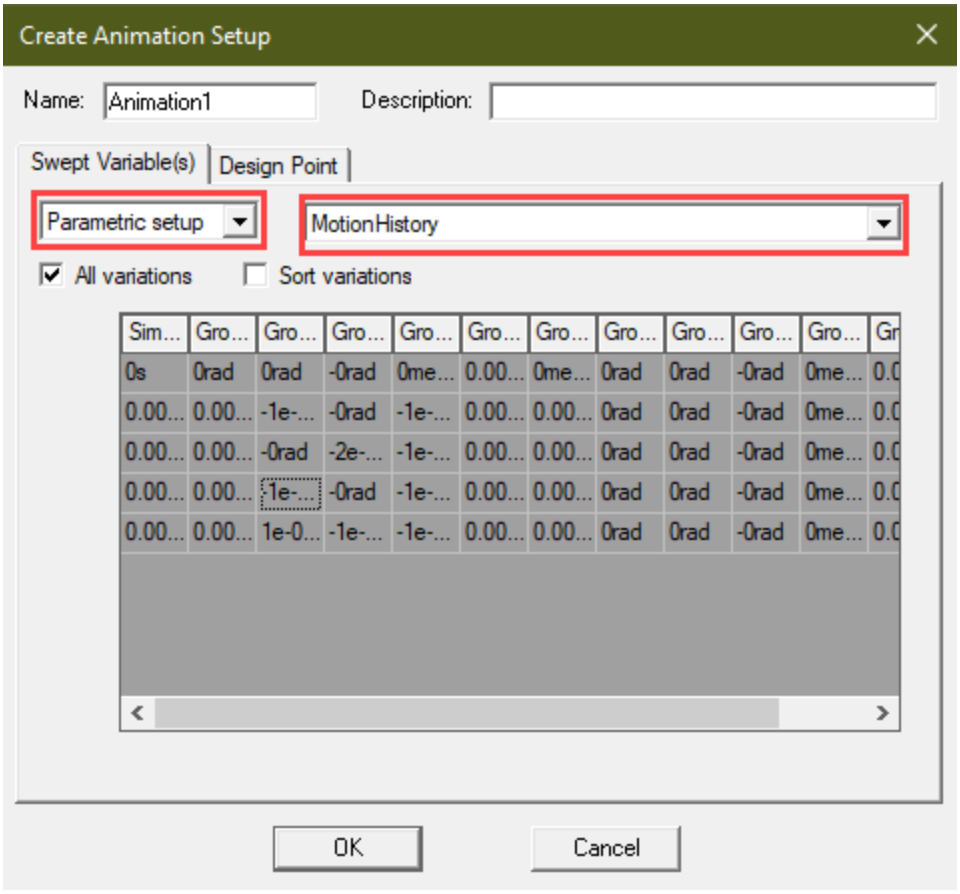
9. Optionally, you can create an animation of all the simulation steps. A parametric setup called **MotionHistory** is automatically created and updated for each timestep, keeping a table of variations for all the simulation steps.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



10. Optionally, to create an animation using the automatically generated **MotionHistory** parametric setup:
    a. Right-click on the desired field plot and click **Animate…**
    b. In the **Create Animation Setup** dialog, select **Parametric setup** in the first box, then select the parametric design called **MotionHistory** in the second box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



c. Click **OK** to create the animation.

Coupling Maxwell with Ansys Motion in Workbench

Running an Ansys Motion-Maxwell Cosimulation on Linux

Running an Ansys Motion-Maxwell Cosimulation on Linux

For users who would like to use the compute power of a Linux machine, an Ansys Motion-Maxwell cosimulation can be set up on a Windows machine, and then executed on a Linux machine. This topic details this procedure.

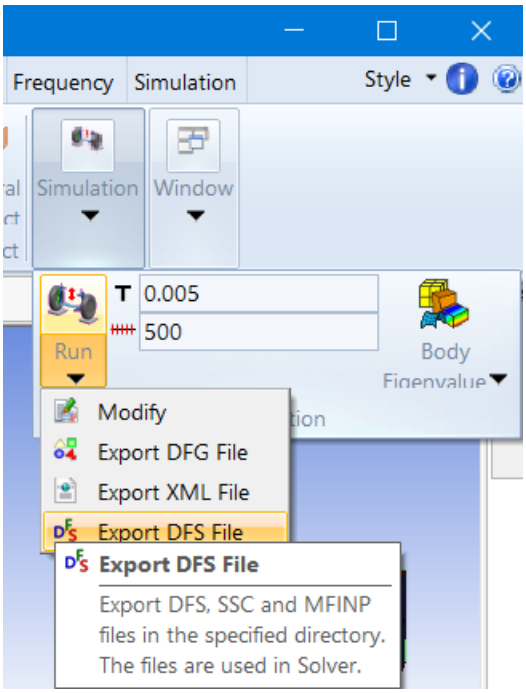
1. Install the pyaedt package in the CPython of the ANSYS installation: In a Linux terminal, enter

   ```
   <path to ansys_inc>/commonfiles/CPython/3_
   10/linx64/Release/python/runpython -m pip install pyaedt
   ```

2. On a Windows machine, open the stand-alone version of Anys Motion Preprocessor.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Set up the Motion-Maxwell cosimulation; see Coupling Maxwell with Ansys Motion (Stand-Alone) for more details.
   The Ansys Motion subsystem file (.dfsub file) and the Maxwell project generated by Motion (.aedt file) must be in the same folder.
4. Export a DFS file for use on Linux: from the Motion **Home** tab, select **Simulation** > **Run** > **Export DFS file**. It should be exported to the same folder as the Motion and Maxwell files.



5. Export the DFG file to the same folder as the Motion and Maxwell files: from the Motion **Home** tab, select **Simulation** > **Run** > **Export DFG file**. This file is necessary to postprocess the solved model on Windows.
6. Copy the entire folder from the Windows machine to a Linux machine.
7. On the Linux Machine, cd to the copied folder, and use the rundfs.sh script in the Motion installation folder to run the cosimulation:

   ```
   <path to ansys_inc>/v242/Motion/solver/rundfs.sh -i Name of dsub file
   ```

   There will be a message when the simulation runs to completion:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

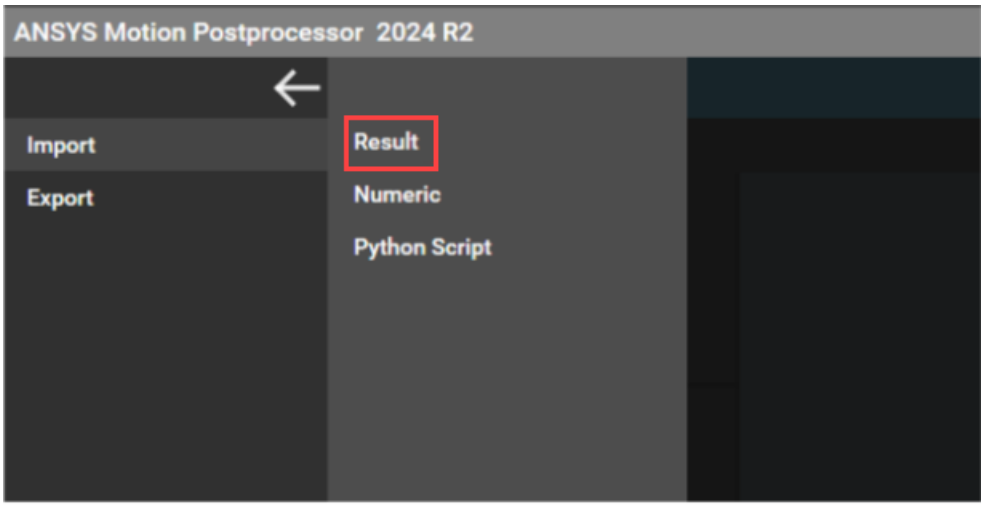
```
* END TIME = Wed Feb 28 01:25:28 2024

< END OF ANSYS LINUX SOLVER >

End : FeeLibrary
*   ANSYS LINUX SOLVER IS SUCCESSFULLY FINISHED
* ENDING ANSYS LINUX SOLVER ( VERSION: 24.20 )

{tyu@seoc7motiondv02}{/home/tyu/Case1}$
```

8. Copy the entire folder back to the Windows machine for postprocessing.
9. Open the Ansys Motion Postprocessor to read the solved files in the solved folder:



The animation will be displayed after opening the .dfr file.

Coupling Maxwell with Ansys Motion in Workbench

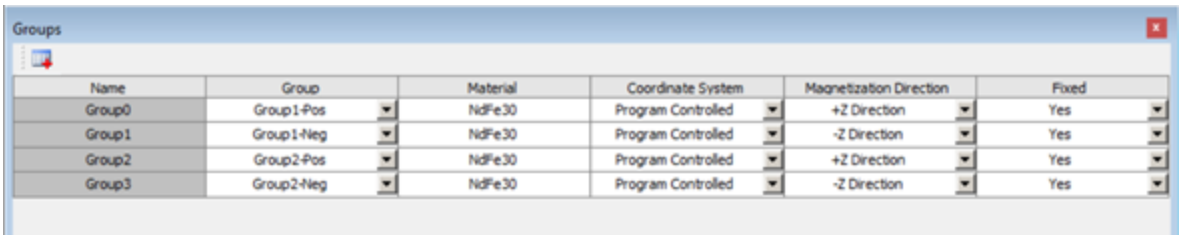
Direct cosimulation between Maxwell and Ansys Motion in Workbench makes possible magnetic latch modeling, which is typically used for modeling magnetic latching structures such as magnetic chargers used by mobile devices. Ansys Motion in Workbench is the primary (controlling) design, while Maxwell serves as the secondary design. During the cosimulation, Motion provides objects position data to Maxwell, then Maxwell feeds force/torque data for these objects back to Motion.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: The Maxwell project is not a part of the Workbench project. Instead, the Motion project in Workbench keeps a path pointing to the Maxwell project, which it generates and launches to calculate magnetic force/torque.

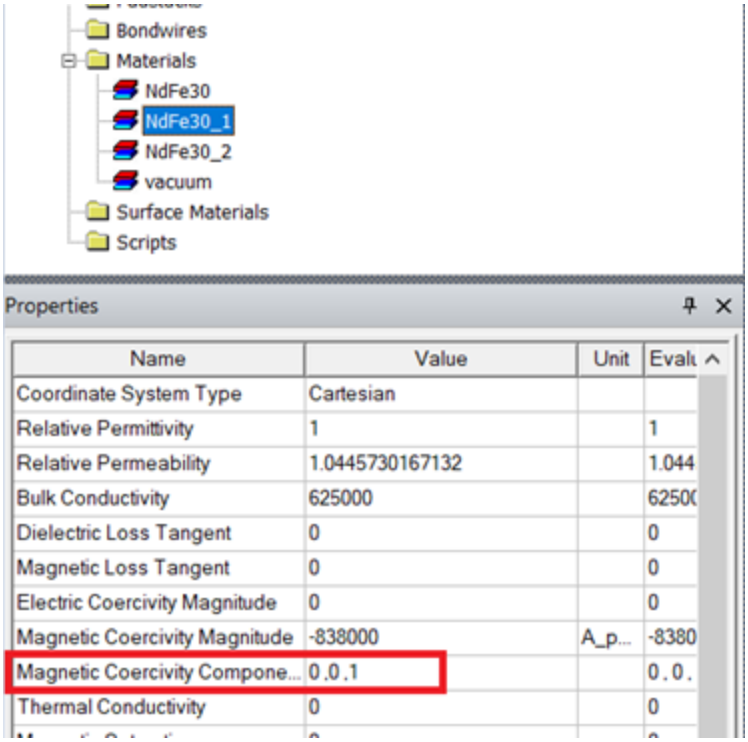
Note: For cosimulation between Maxwell and the stand-alone Ansys Motion Preprocessor, see to Coupling Maxwell with Ansys Motion (Stand-Alone).

Ansys Motion in Workbench can define the material name, coordinate system, and magnetization direction of a group.



The material name and the magnetization direction are passed to Maxwell. Maxwell creates the materials with the correct Magnetic Coercivity Component, then assign them to the corresponding objects. If the material has a different direction than the system default value, a new clone of the material will be created with a new name adding a number at the end.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

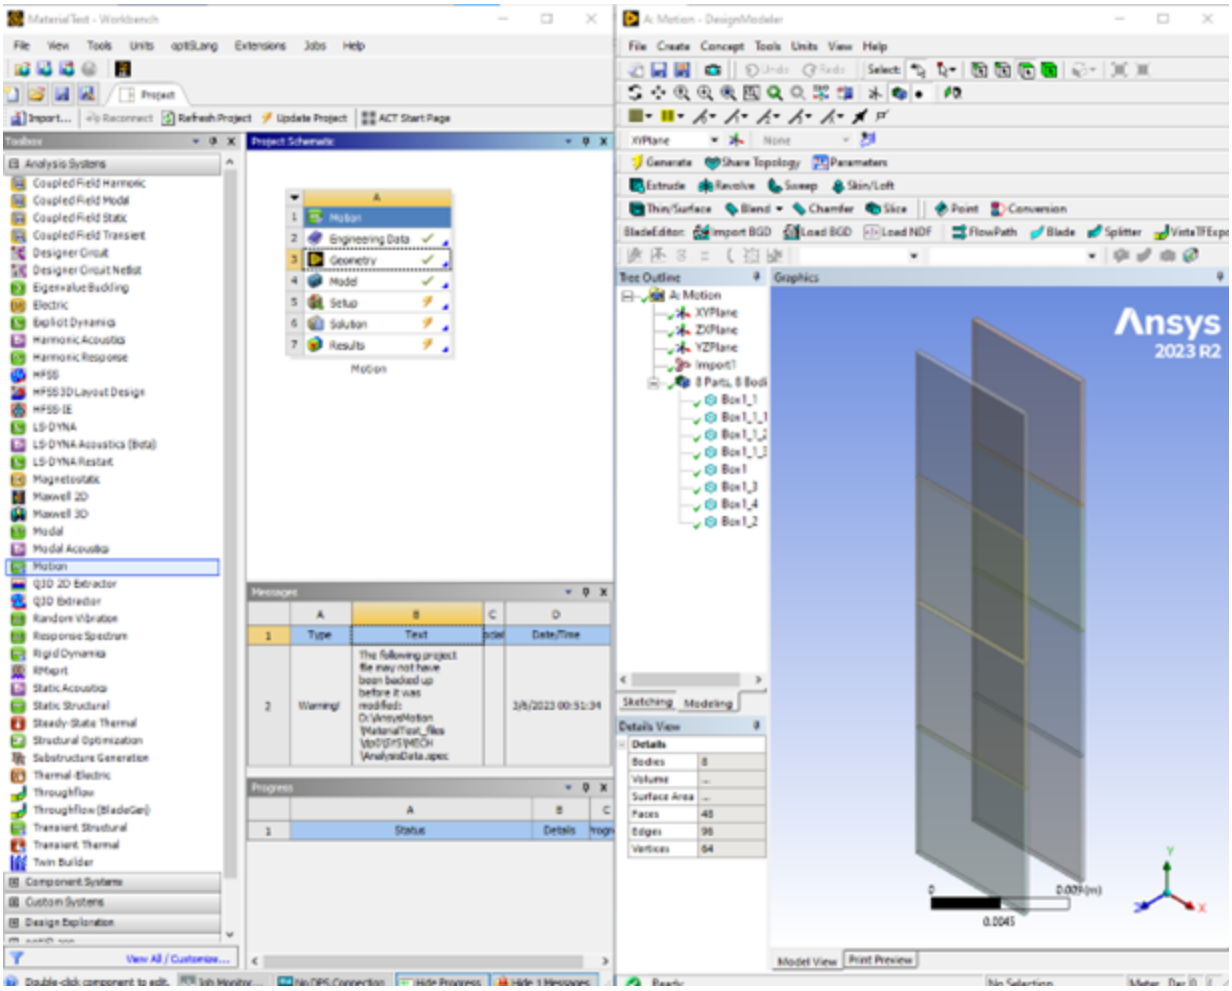


The suggested workflow for magnetic latch modeling using cosimulation between Ansys Motion in Workbench and Maxwell is as follows:

> **Note:** For details on using the Motion in Workbench for the following steps, refer to the *Ansys Motion in Workbench User Guide* installed with the Ansys Motion software.

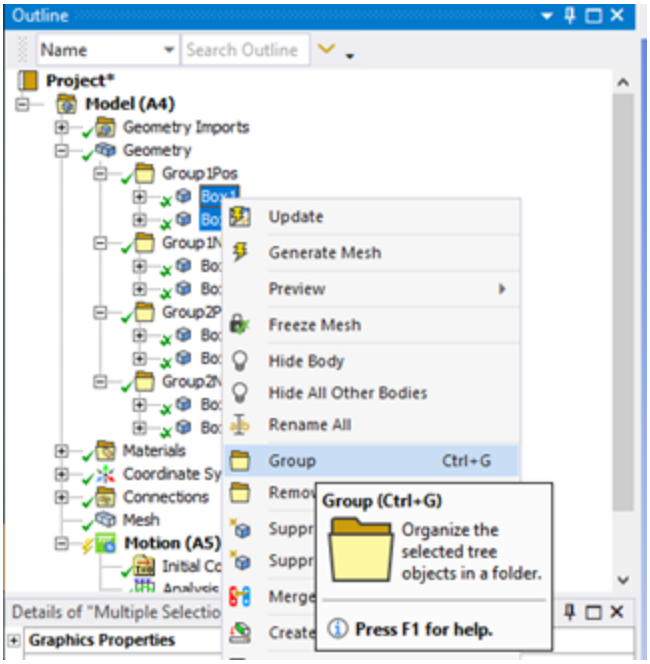
1. Create a Motion project in Workbench; then draw or import geometry in the design modeler.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

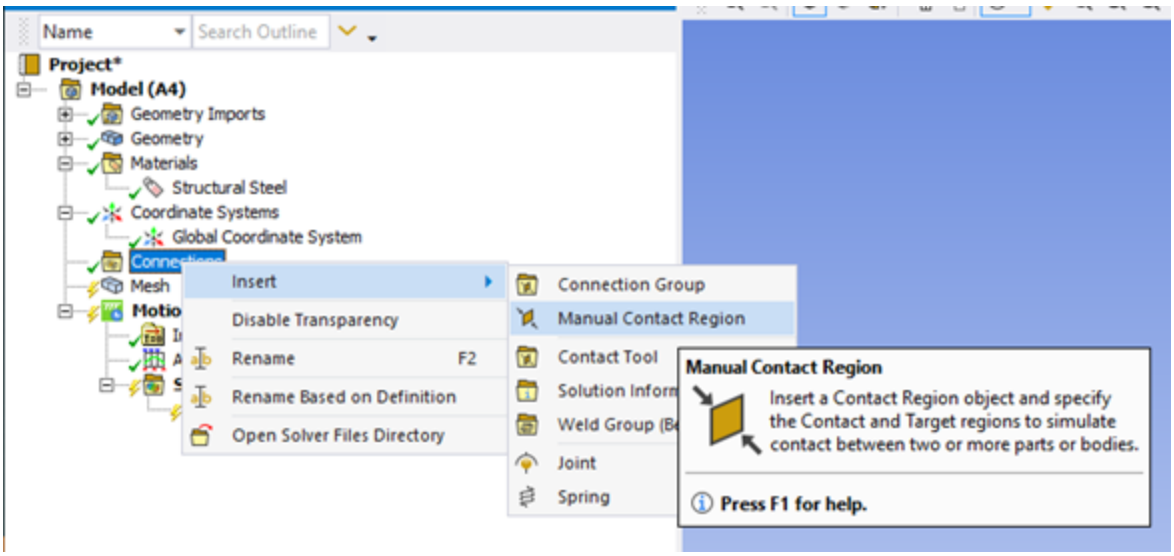


2. Create groups of objects that are fixed together and have the same material in Motion.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

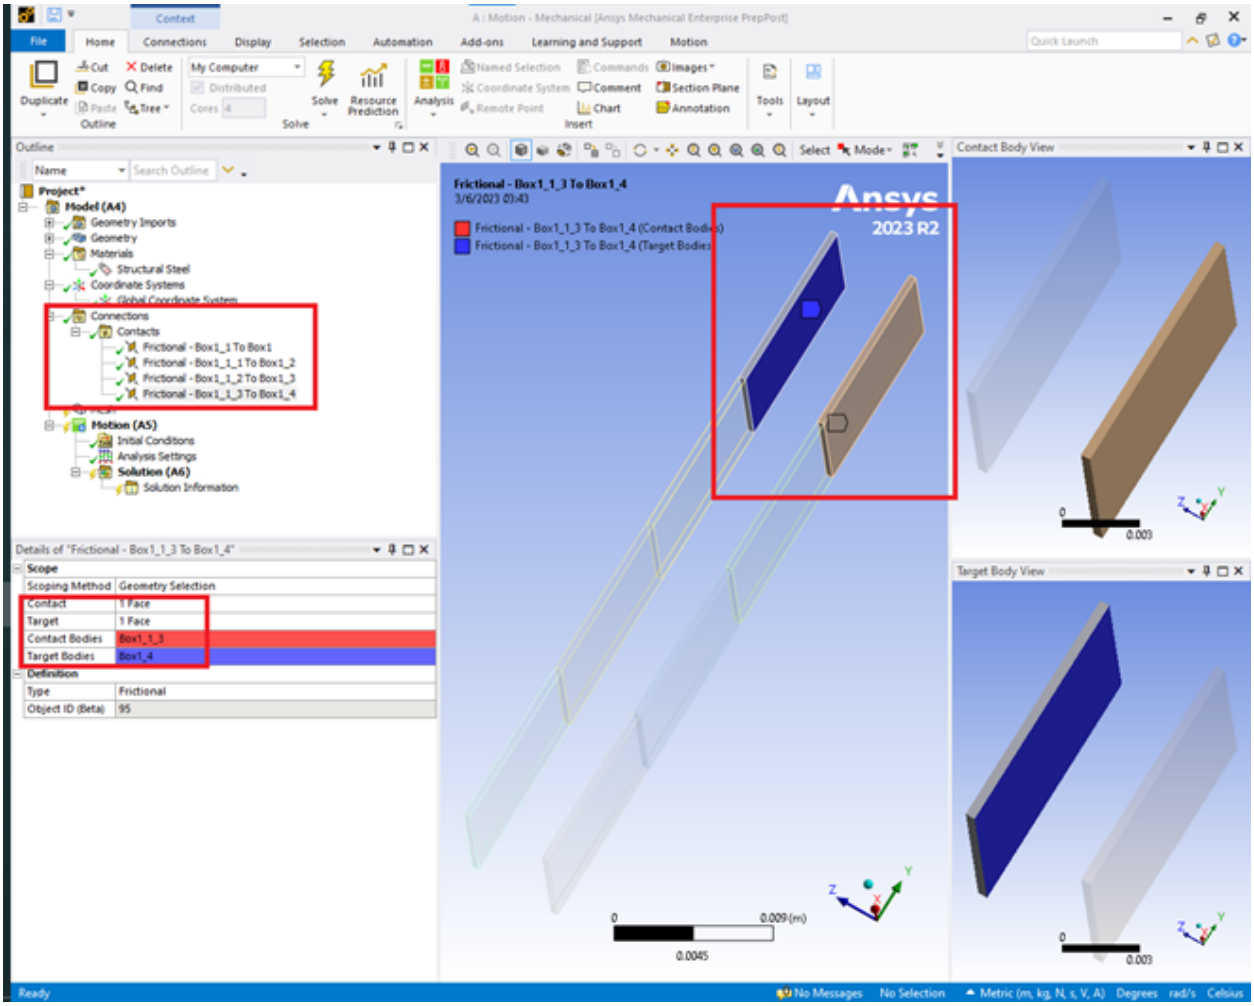


3. Delete the automatically created contacts and create Contact connections between the faces that will be touching each other.



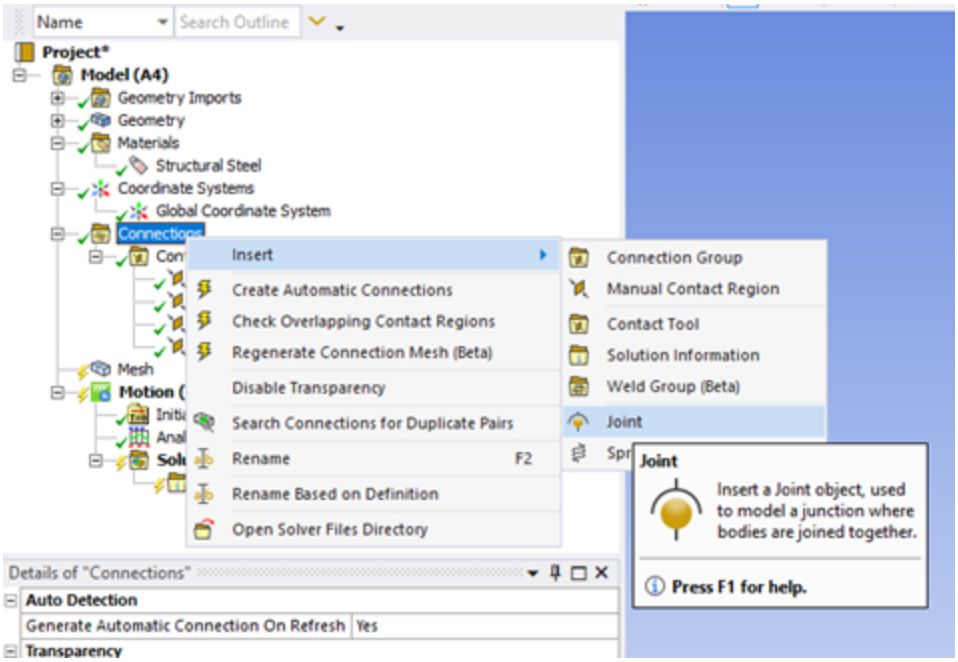
This is an example of creating four contacts between four pair of faces:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



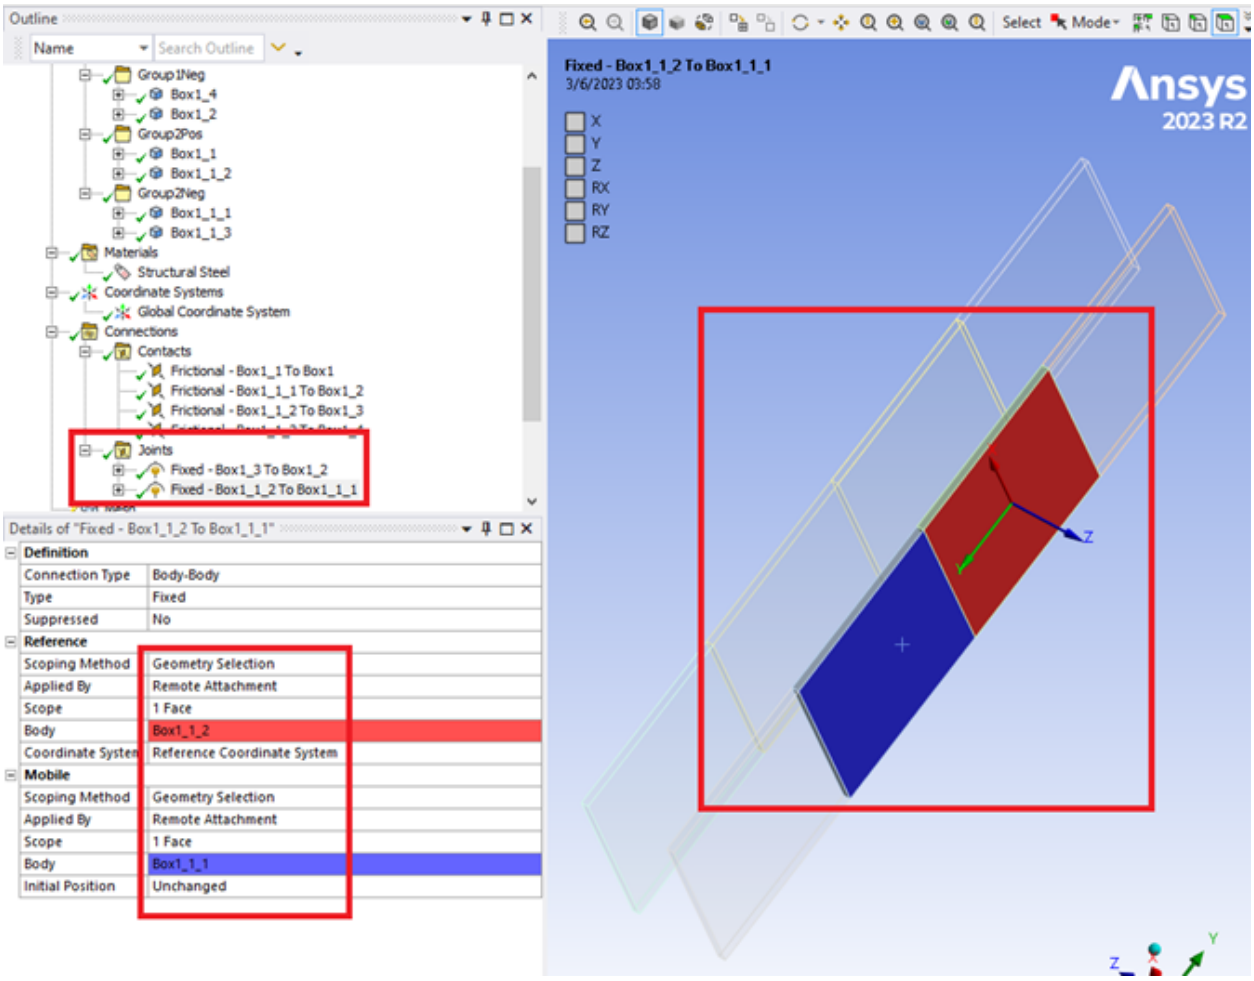
4. Create Fixed Joints on the groups that move together.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



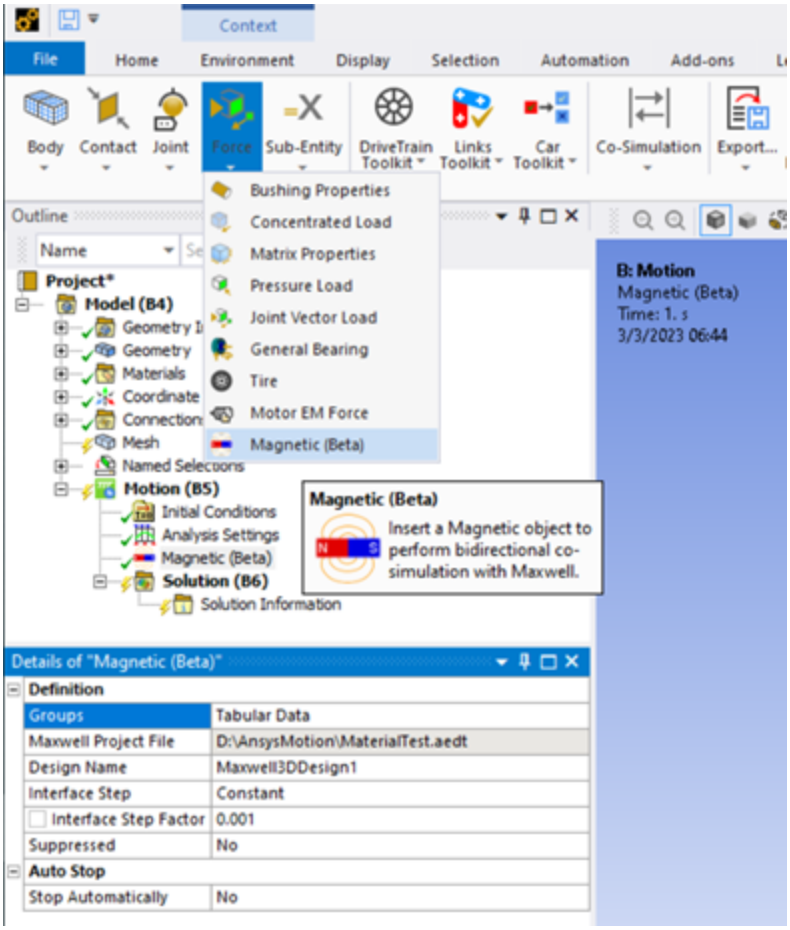
The objects within a group are fixed together by default, so only one Fixed Joint is required to connect two groups:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

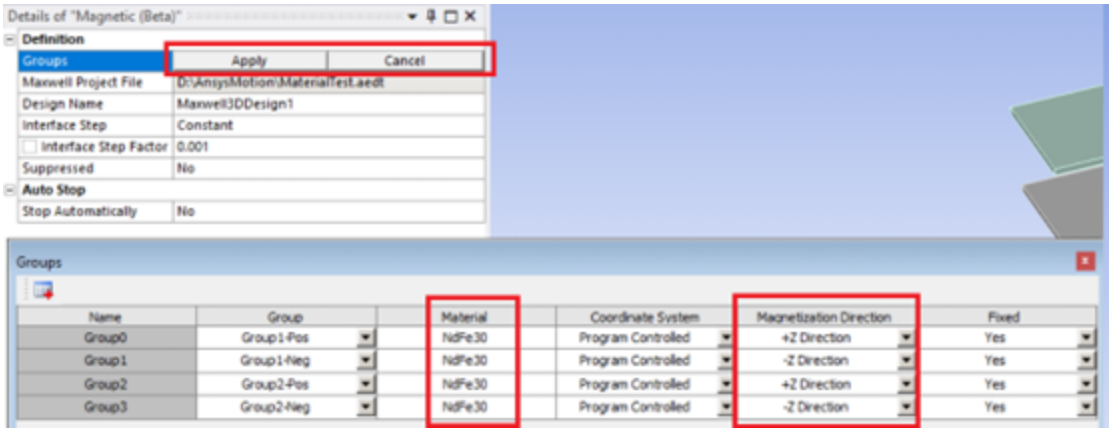


5. Create a Magnetic Force in Motion.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

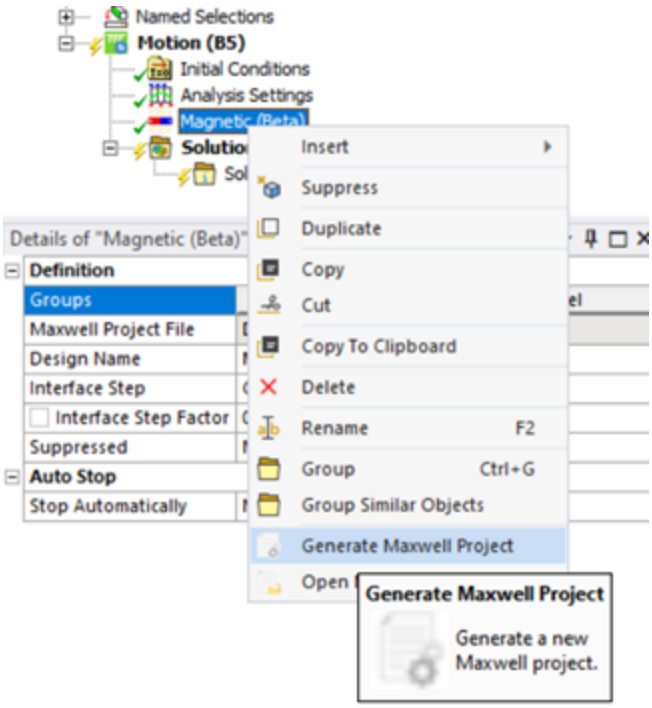


6. Assign the material name and magnetization direction to the groups.

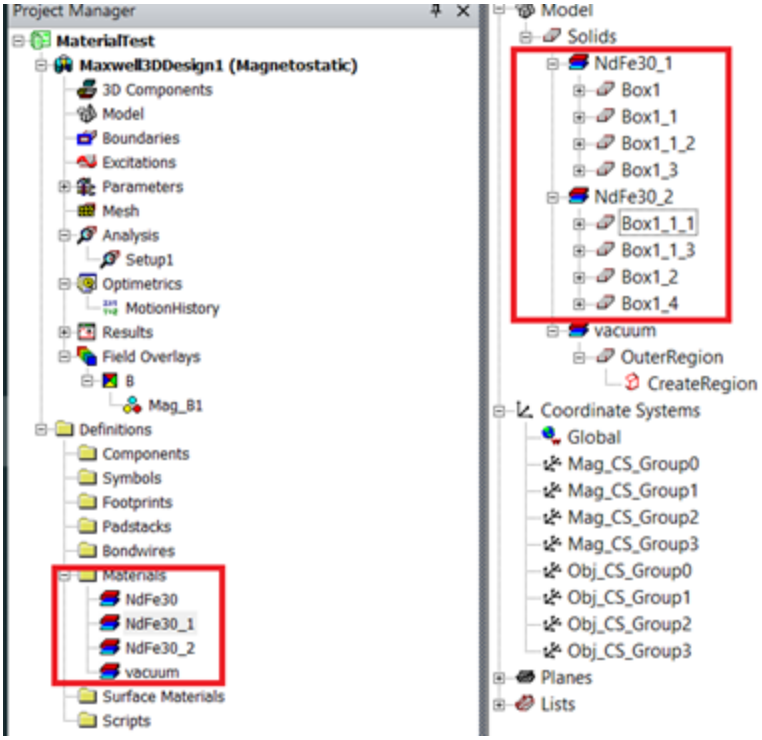


7. Generate the Maxwell project.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The objects in the groups should be assigned to the corresponding materials.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Tip:** With the stand-alone Ansys Motion, you can set up a Maxwell cosimulation on a Windows machine, and then run the simulation on a Linux machine. For more information on this capability, see Running an Ansys Motion-Maxwell Cosimulation on Linux.

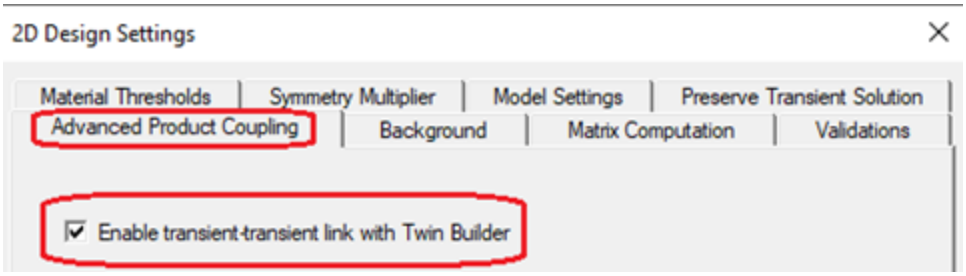
Related Topics

Coupling Maxwell with Ansys Motion (Stand-Alone)

Coupling Maxwell to a Twin Builder Component

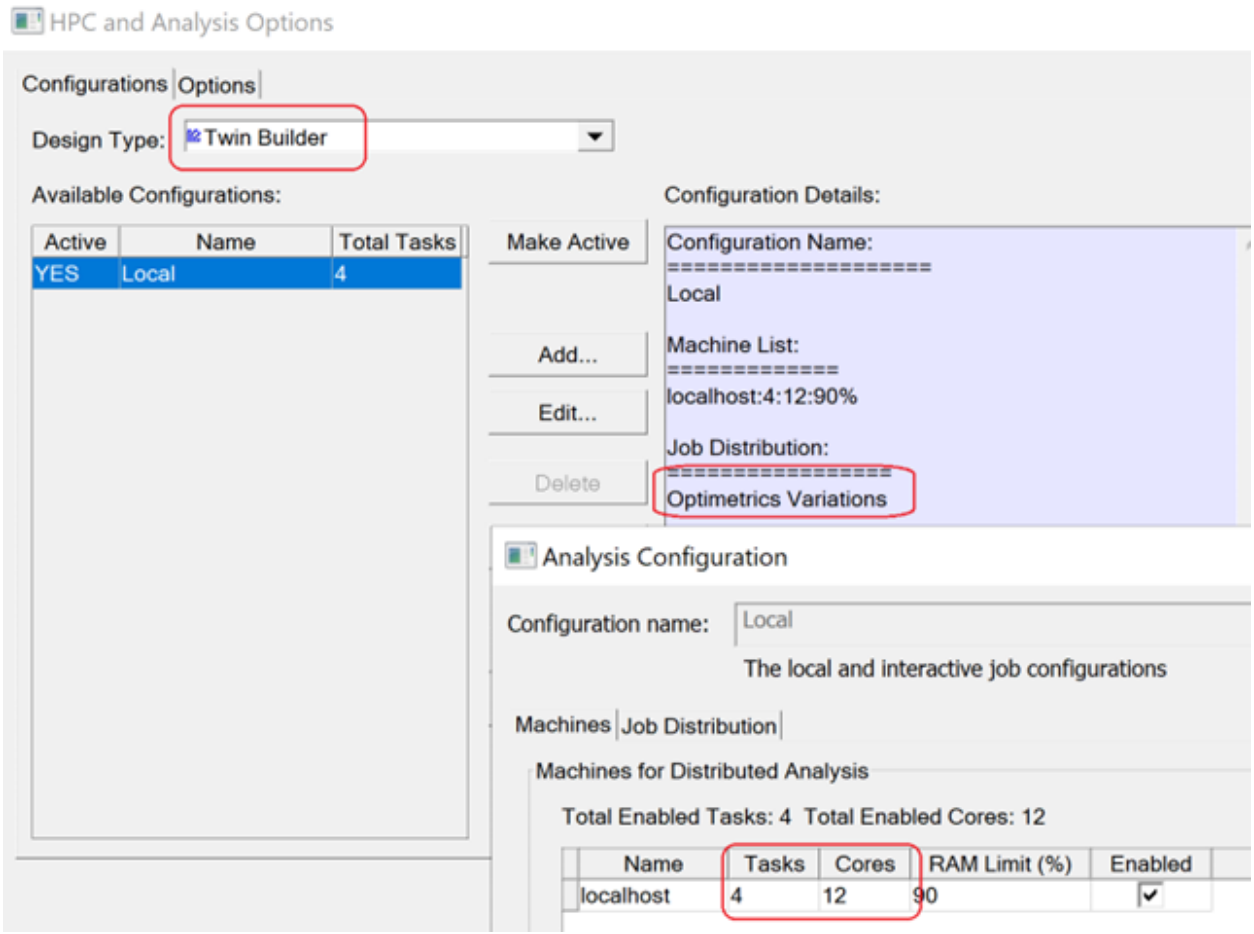
Maxwell designs may be dynamically coupled to Twin Builder components through the Twin Builder user interface. The Twin Builder interface allows Maxwell 2D, 3D, and RMxprt designs to be linked as dynamic components. Source windings set to **External** are available as conservative pins in Twin Builder.

Transient coupling links must be enabled in Maxwell on the **Design Settings** > **Advanced Product Coupling** tab for Transient Cosimulation with Twin Builder.



For parametric HPC solve of Maxwell 2D and 3D transient coupling designs, HPC setup must be done on the Twin Builder side. Maxwell will use the same HPC setup from Twin Builder; and any HPC settings on the Maxwell side will be ignored. The Twin Builder HPC setup includes user inputs for Number of tasks and Number of cores. Specify the task number to be greater than 1; and the core number to be equal or greater than the task number. Only one level HPC (Optimetric Variations) is supported. OpenMP is supported. For OpenMP, the number of cores divided by number of tasks should be greater than 1 (multiple cores per task).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



> **Note:** A variable, **TBOptiVariation**, will be added in the Maxwell design for such cosimulation. A warning message will display when this variable is added to the Maxwell design for the first time. Any changes in the Twin Builder design will reset the value of the variable to 0 and Maxwell solutions will be invalidated.

The ECEIM_Model component must be used in a Maxwell eddy current design to enable Twin Builder to couple to the design.

Dynamically linked components provide the ability to have Twin Builder vary a variable in a Maxwell design and have Maxwell solve the design at the new design point and provide the solution data back to Twin Builder for use in the circuit simulation.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

For more information on coupling Maxwell designs to Twin Builder components, refer to the *Maxwell Coupling Components* and *RMxprt Dynamic Coupling Component* topics in the **Twin Builder Help**.

For more information on setting up HPC in Twin Builder with a coupled Maxwell design, refer to the *Maxwell Coupling Components* and *Setting HPC and Analysis Options* topics in the **Twin Builder Help**.

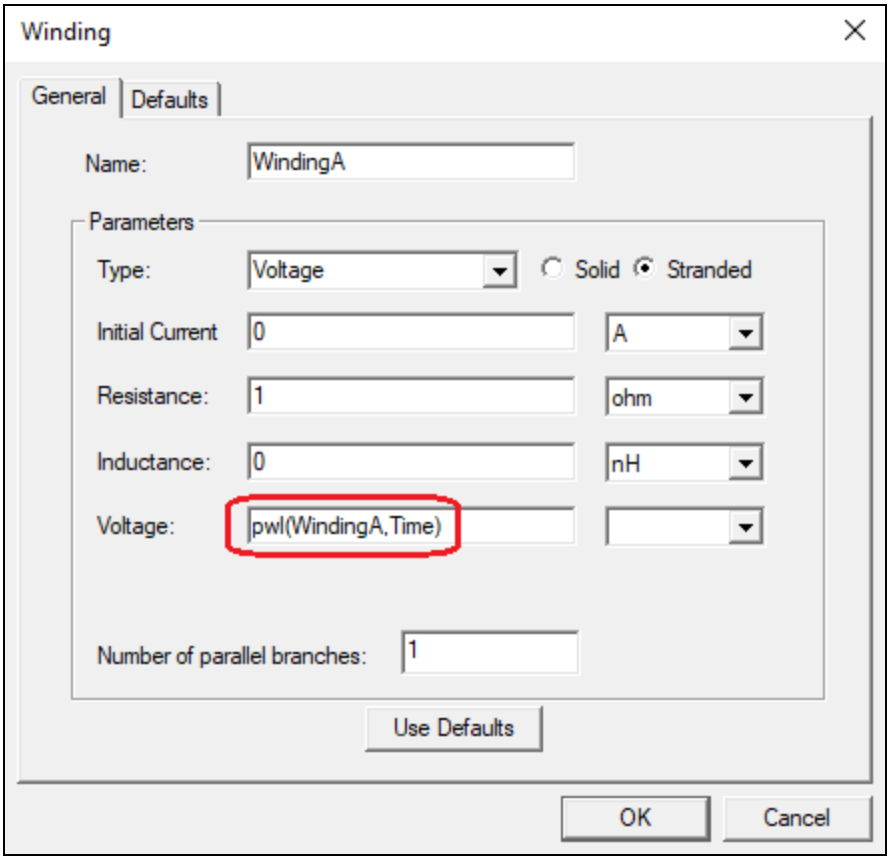
Coupling Maxwell to a Twin Builder Excitation Component

You can couple a Maxwell 2D or 3D transient, or a 3D A-Phi transient design using the Twin Builder **Excitations Component**. The Excitations component user interface allows you to assign output quantities in the Twin Builder design to windings in the coupled Maxwell design. Based on Maxwell excitations (voltage/current), Twin Builder will perform simulation, then generate detailed PWL expressions and dataset data. These expressions and data can then be pushed back to Maxwell as excitations for further analysis.

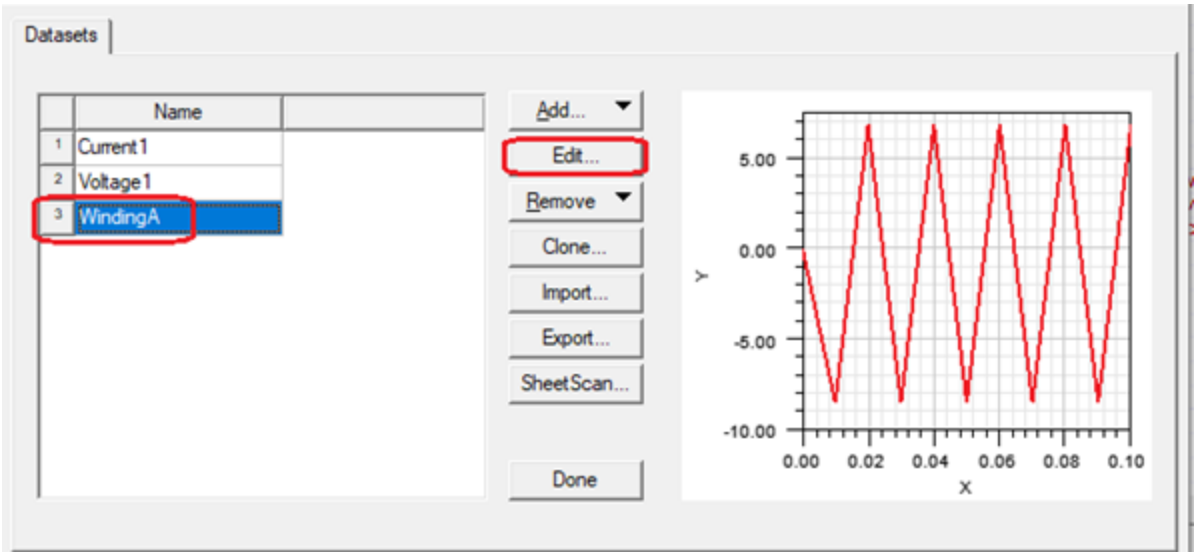
Refer to the *Maxwell Excitation Component* section in the **Twin Builder** help for the procedures on coupling a Twin Builder **Excitations Component** to a Maxwell 2D or 3D transient, or a 3D A-Phi transient design; and sending **Push Excitations** data back to the coupled Maxwell design.

After the excitations push-back, you can see the push-back excitation expression in Maxwell. For example, for winding voltage:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

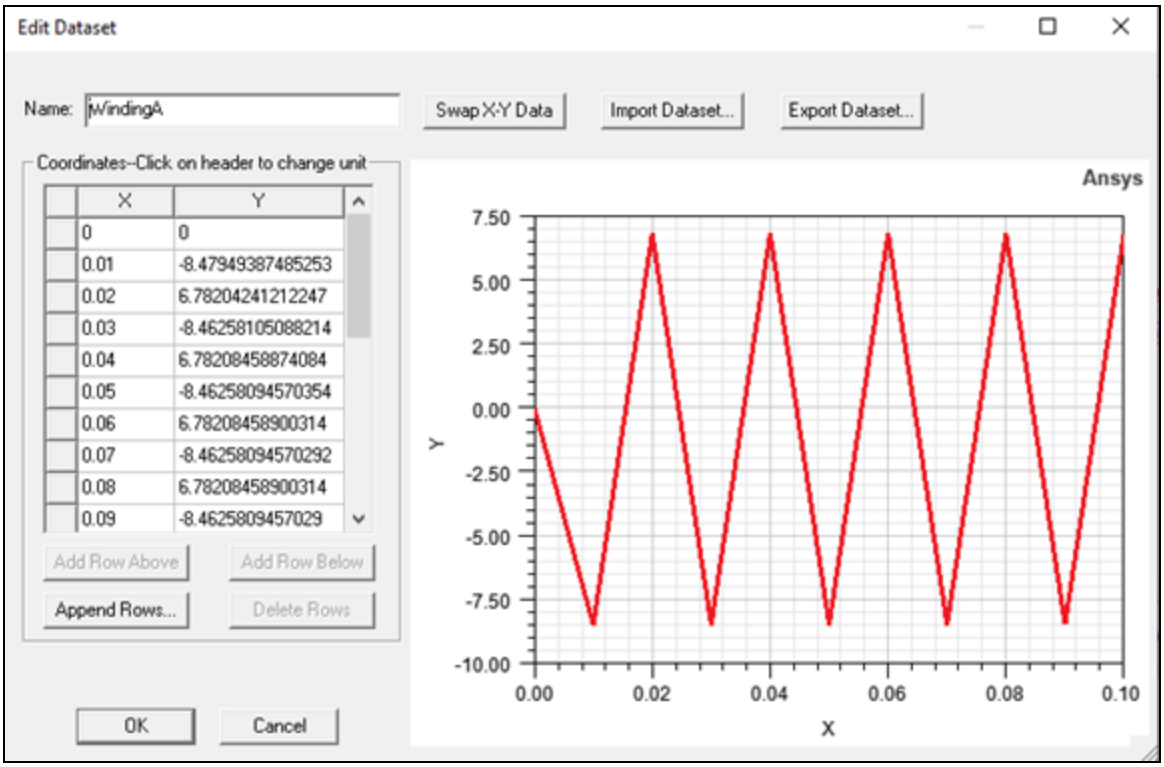


The dataset for the PWL function can be viewed by selecting **Maxwell** > **Design Datasets**. In the Dataset window, you can see the data set details.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To view the data set in a table, click **Edit**.



Coupling Maxwell Magnetostatic and Eddy Current Designs with Ansys Fluent

Coupling is supported between Ansys Fluent and Maxwell 3D magnetostatic and eddy current designs. For example, a transient Fluent simulation can use a Maxwell solution to simulate the magnetic effect of the electric arc of contacts. This coupling supports designs that have a datalink defined, such as mesh, demagnetization, and so on. A design that is enabled for thermal and stress feedback is not supported.

In Ansys Fluent, during a transient simulation that requires exchanging data with Maxwell, a user-defined function (UDF) invokes the Maxwell solver. Ansys Fluent and Maxwell exchange inputs and solution data in a coupling directory that you specify. Maxwell calculates the B field based on the mesh-based conductivity (and meshed-based permeability in eddy current designs); and current excitation provided by Ansys Fluent. Ansys Fluent calculates flow field, temperature, and feedback electrical conductivity (and permeability in eddy current designs) to Maxwell. The Maxwell software does not provide direct access to the data in this coupling directory.

Follow these steps to set up the coupling:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Set up the magnetostatic or eddy current project in Maxwell 3D.
2. In the Project Manager tree, right-click **Setup** under **Analysis** and select **Configure Fluent Conductivity Coupling**.
3. In the **Configure Fluent Conductivity Coupling** window, browse to select the coupling directory or type a path, and click **OK**. You can enter a local directory, such as where Maxwell desktop is running, or you can enter a mapped network location.
    - If you enter an existing directory that contains files, a warning notifies you that all files in that directory will be permanently deleted. Click **Yes** to use that directory and delete all files contained in it. Click **No** if you do not want to select that directory. When you click **No**, the dialog box stays open for you to enter a different directory.
    - If the directory you entered does not exist, Maxwell creates the directory. If the directory is not successfully created, the dialog remains open.

    Note:
    - If there are errors during the process or if you terminate the process, the coupling directory is not configured.
    - If there is version incompatibility between Ansys Fluent and Maxwell, the process is stopped and an error message is displayed.
    - If you Clean Stop the process and there is enough solution data to configure the directory, the coupling directory will still be configured.
4. Set up the Ansys Fluent project as described in the *Ansys Fluent User's Guide*.
5. Build and load the UDF that was developed for your application. For more information about UDFs, see the *Ansys Fluent UDF Manual*.
6. In the **input.txt file** that is specific to the UDF, provide the information that is required by the UDF. For more information about the required information and format, see Sample Input.txt File Format.

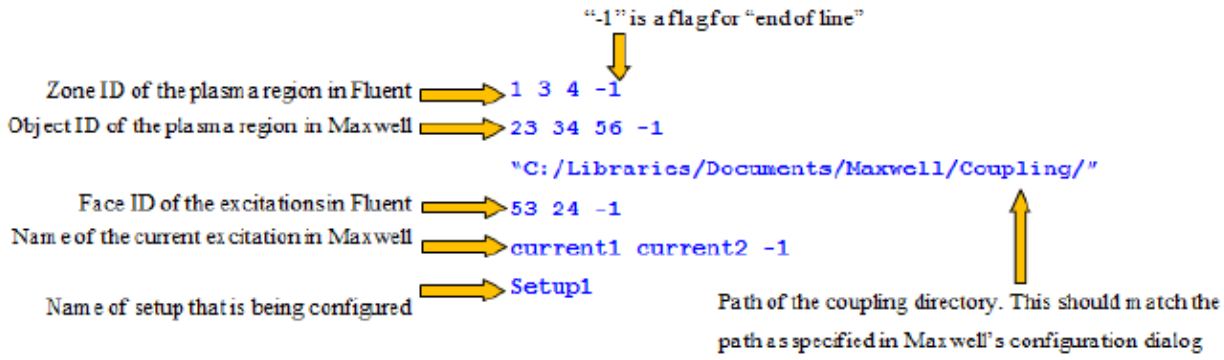
The UDF is invoked during the transient simulation. When there is a need to exchange data, the UDF invokes the Maxwell solver.

Sample Input.txt File Format

The **input.txt file** is used by the UDF during the coupling between Ansys Fluent and Maxwell.

The following example shows the format and provides information about the parts of the file.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Determining the Zone ID in Ansys Fluent

You can determine the Zone ID in Ansys Fluent as follows:

1. In the navigation pane under **Solution Setup**, select **Cell Zone Conditions**.
2. Select a zone on the task page.

The ID of the zone you selected is displayed in the ID text box.

Determining the Face ID in Ansys Fluent

You can determine the Face ID in Ansys Fluent as follows:

1. In the navigation pane under **Solution Setup**, select **Boundary Conditions**.
2. Select a boundary on the task page.

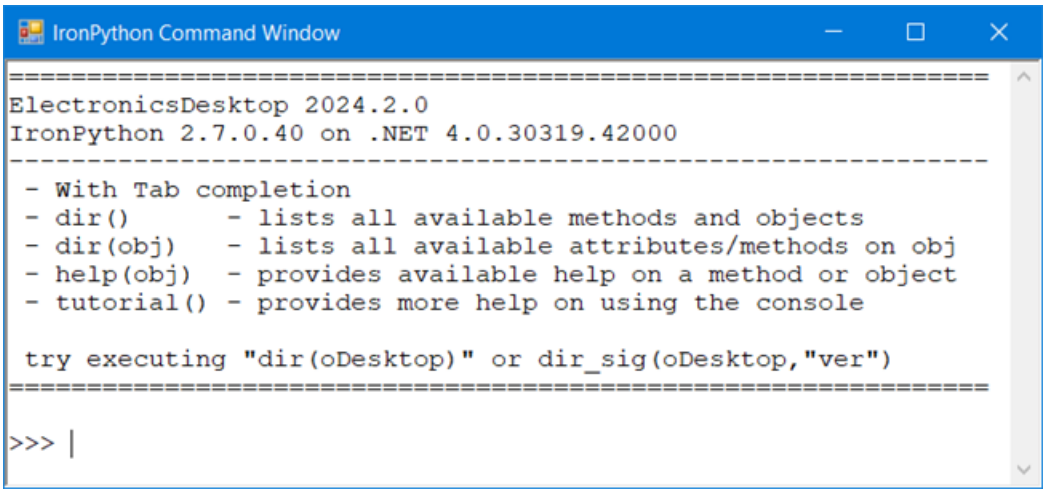
The ID of the face assignment is displayed in the ID text box.

Determining the Object ID in Maxwell

You can determine the Object ID in Maxwell as follows:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click **Tools** > **Open Command Window**.
2. In the **IronPython Command Window**, query the object ID by its name.



For example:

You can use `oEditor.GetNumObjects()` to find the total number of objects; and then use `oEditor.GetNumObjects(i)` to return the name of *i*th object.

Magnetostriction in Maxwell Magnetostatic to Workbench Mechanical Coupling

Maxwell supports magnetostriction and inverse magnetostriction forces in Workbench Mechanical coupling for Maxwell 2D/3D magnetostatic designs. Both one-way and two-way coupling are supported.

One-Way Coupling

The Maxwell solver calculates force density, which includes magnetostriction force data. The force density data including magnetostriction force data is output to the Workbench Mechanical system.

Two-Way Coupling

- Maxwell provides force density data to the mechanical system as it does for one-way coupling.
- The Workbench Mechanical system solves and sends stress/strain data (plus displacement data) to Maxwell, which will be used in the Maxwell solution for the next iteration.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

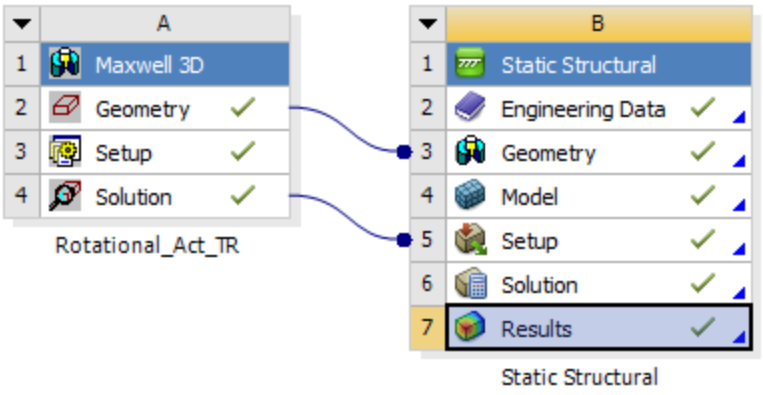
Magnetostriction Stress Coupling Between Maxwell 2D/3D Transient and Workbench Mechanical

Maxwell supports magnetostriction forces in two-way coupling between Workbench Mechanical and Maxwell 2D/3D Transient designs.

- Maxwell 2D/3D transient provides force density data to the Mechanical system.
- The Workbench Mechanical system solves and sends stress/strain data (plus displacement data) to Maxwell, which will be used in the Maxwell solution for the next iteration.

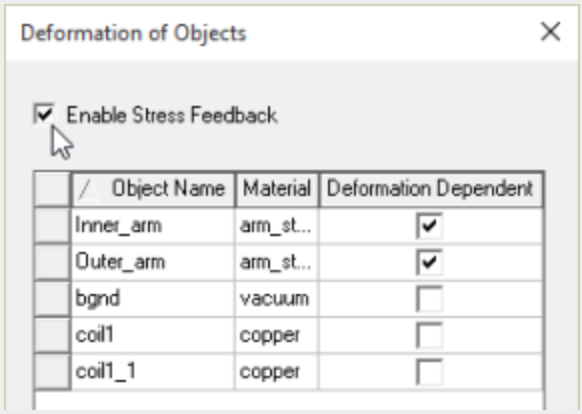
To analyze the effect of stress due to magnetostriction forces on objects in a design using two-way coupling between a Maxwell 2D/3D transient design and Workbench Mechanical:

1. Set up the Maxwell 3D/2D transient Mechanical structure coupling.

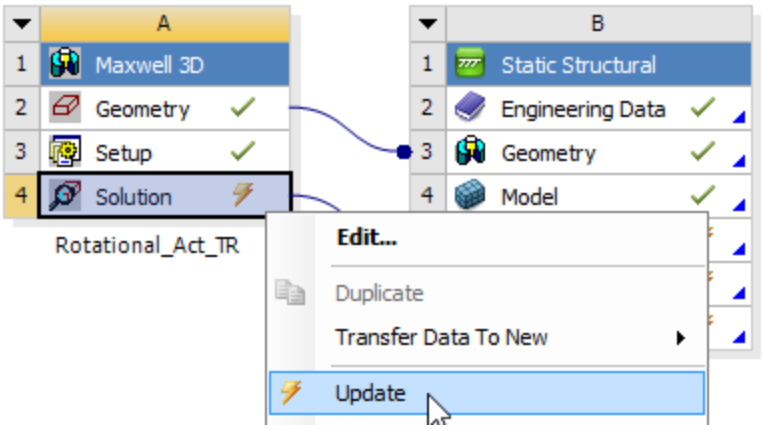


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: You must manually Enable Stress Feedback and select the desired stress feedback objects in the Maxwell design.



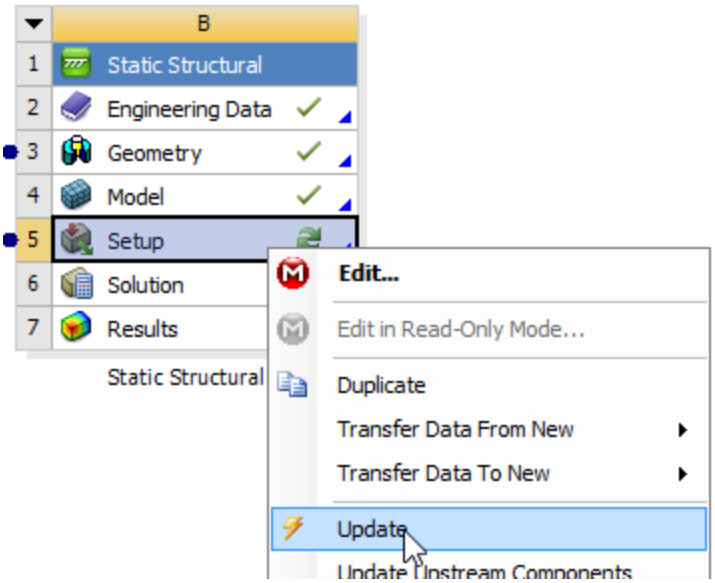
2. **Update** the Maxwell **Solution** cell to initiate a Maxwell solve.



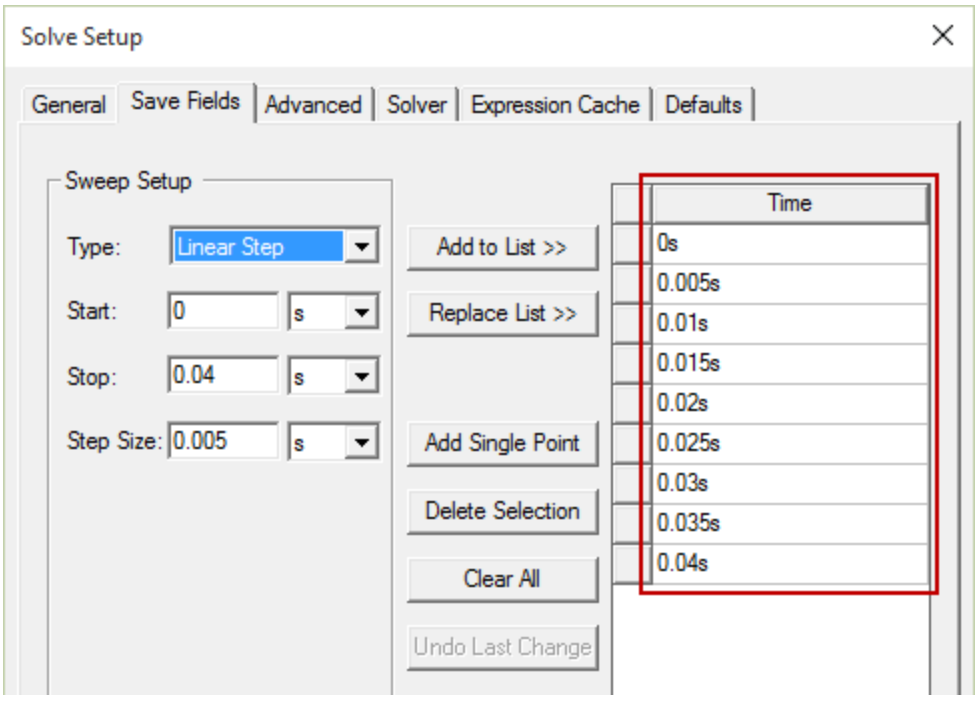
The Maxwell transient solver generates force density data, which can be used by Workbench Mechanical.

3. **Update** the Workbench Mechanical **Setup** cell to import the force density data generated by Maxwell.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

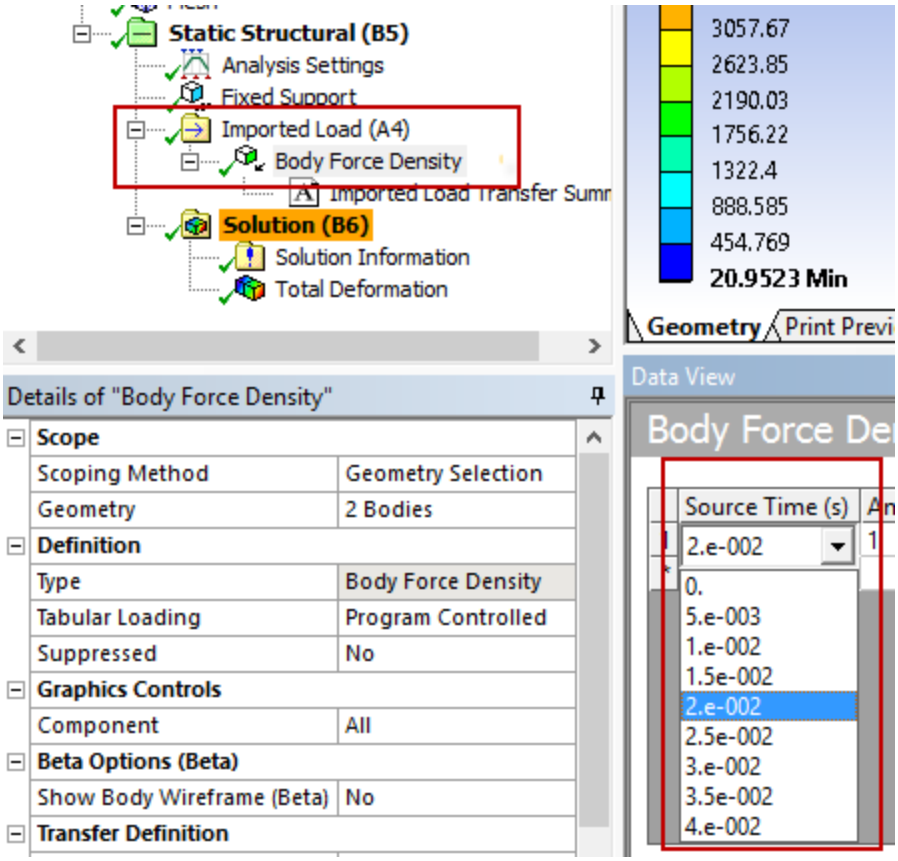


Maxwell maps the Maxwell mesh to the Workbench Mechanical mesh; and the calculated force density values for the time points you set up on the Maxwell transient **Solve Setup** dialog **Save Fields** tab are loaded into Workbench Mechanical.



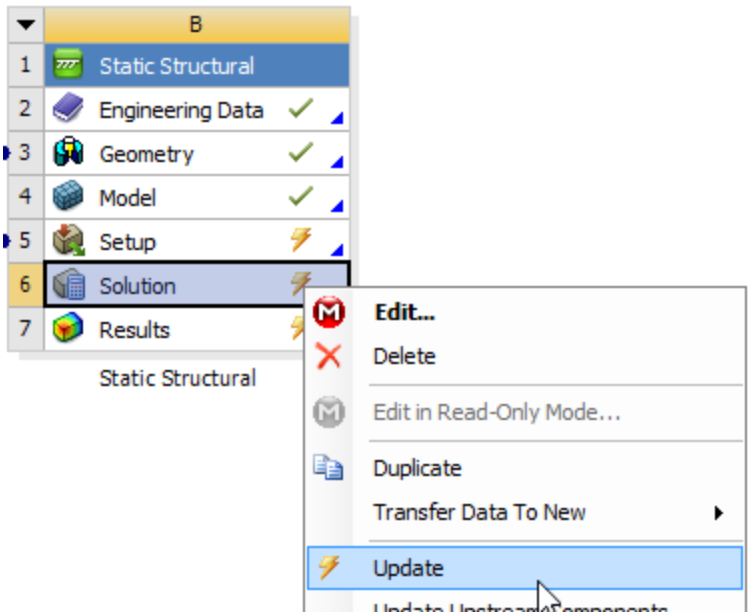
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. In Workbench Mechanical, select the desired source time point you want to use for the force density calculations.



5. **Update** the **Solution** cell of the Mechanical panel.

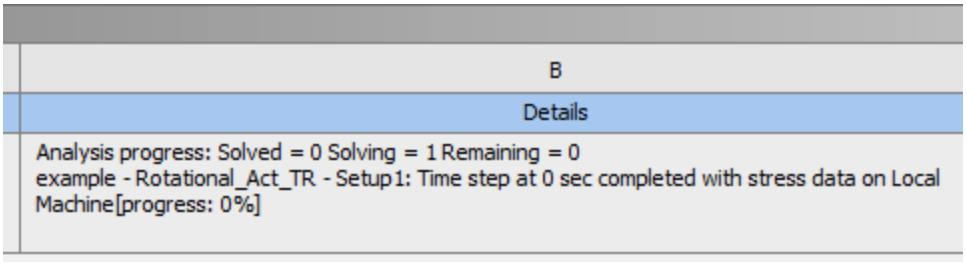
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Workbench Mechanical solves the structural project using the force density at the selected source time, then outputs displacement and stress/strain data to be used as feedback by the Maxwell transient solver.

6. To re-solve using the feedback data, set the **Solution** cell of the Maxwell panel to **Enable Update**, then perform an **Update** for the Solution cell. (You can also use the feedback iterator to automatically update the Maxwell Solution cell.)

   The Maxwell 3D/2D transient solver uses the feedback displacement and stress/strain data to re-solve from time 0.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

16 - High Performance Computing

Ansys Electronics Desktop affords High Performance Computing (HPC) options that allow you to speed up processing. HPC leverages multiple cores through matrix multiprocessing, distributed frequency points (called spectral decomposition method or SDM), domain decomposition (DDM), parallel hybrid FEM/IE solving or the finite antenna array DDM. In addition, hierarchical HPC solving is possible where frequency points can be distributed with each frequency point using multiple cores or machines for large scale DDM analysis at each frequency point, all in parallel. Maxwell intelligently determines which jobs are to be performed and how to distribute them for the simulation. It automatically apportions the jobs during the simulation process and makes optimum use of the available resources. This computing technology enables generating accurate solutions for large, complex, higher-fidelity models.

See the following topics for more information and configuration tips:

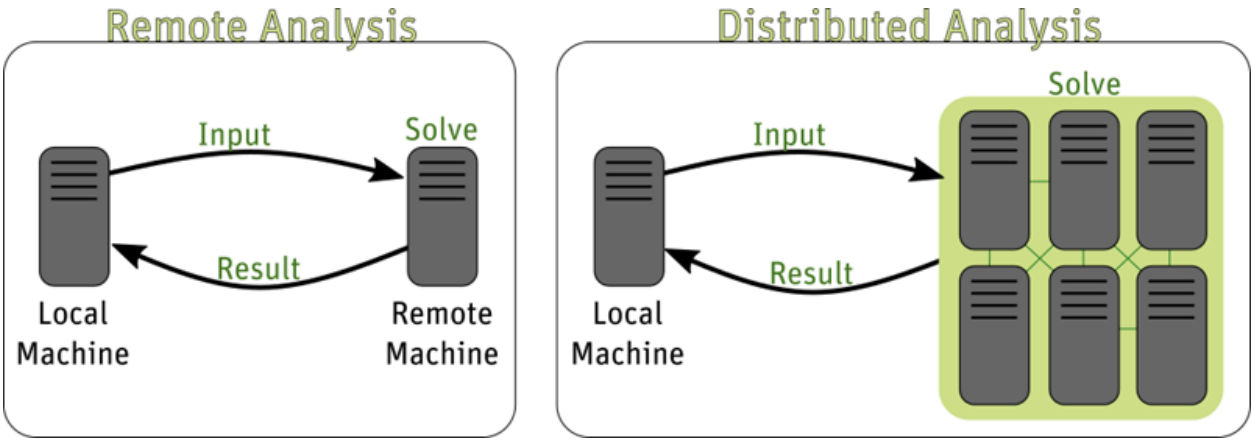
- Remote Analysis
- Distributed Analysis
- Ansys Cloud Direct Support for HPC Job Management
- Large Scale DSO for Parametric Analysis
- Interactive Scheduler Jobs
- HPC Integration
- Multi-Step Job Submission
- Windows to Linux Job Submission
- Distribution Command Line Options
- GPU Acceleration

Remote Analysis

It is possible to solve a project on a different machine from the one on which you are running Ansys Electronics Desktop. This is particularly useful when you want to take advantage of a more powerful machine but it is not convenient to access that machine. This process involves configuring the machine that will perform the solve (the remote machine), as well as the machine from which the simulation is to be launched (the local machine).

This can also be extended into distributed analysis, where a specified analysis, if supported, is concurrently solved on multiple machines.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Important:

In both Remote and Distributed Analysis, communication between machines can drastically affect performance. Use of a high-speed network system, such as Gigabit or Infiniband, is recommended for optimal performance.

The rest of this topic covers the following:

- Prerequisites for Remote and Distributed Analysis
- Configuring the Local Machine to Solve Remotely
- Remote Analysis Options
- Running Remote Analysis

The **Export Options Files** command writes XML files containing options settings at all levels to the specified directory. **Tools** > **Options** > **Export Options** makes it easier for different users to use Ansys EM tools installed on shared directories or network drives. For some example use cases, see: Example Uses for Export Options Features.

Prerequisites for Remote and Distributed Analysis

1. You must have installed Ansys Remote Simulation Manager (RSM) or a supported High Performance Computing (HPC) management software program (See: High Performance Computing (HPC) Integration).

   For a list of currently supported HPC software, select the topic, *Ansys 2025 R1 - Job Schedulers and Queuing Systems Support* from the Platform Support page.

2. Ansys Electronics Desktop must be accessible from all remote machines as well as on the local machine. If the analysis uses MPI, then the path of the Ansys Electronics Desktop installation must be the same on all of the machines used for the analysis (remote and local). This may be a shared network path accessible from all hosts. Alternatively, it may

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

be a local installation on each host; in this case the installation path must be the same for all hosts. If using a shared network path, there should not be a local installation of the same Ansys Electronics version on any of the hosts. See Distributed Analysis for information on whether MPI is needed for the analysis.

3. If you use RSM, it must be accessible from all remote machines. In addition, the Ansys Electronics Desktop engines must be registered with each initialization of RSM.

   To do this on each machine:

   - From Windows, click **Start** > **Programs** > **Ansys EM Suite 2025 R1** > **Register with RSM**. You can also run **RegisterEnginesWithRSM.exe**, located in the product subdirectory (for example, C:\Program Files\ANSYS Inc\v251\AnsysEM\RegisterEnginesWithRSM.exe).

     In each case, you see a dialog box confirming the registration. Click **OK** to confirm.

   - From Linux, run **RegisterEnginesWithRSM.pl**, located in the product installation directory (for example, /opt/ansys_inc/v251/AnsysEM/RegisterEnginesWithRSM.pl).

     If the RSM service cannot run due to permission issues for the configuration file, it issues an error message and exits.

     If your product is not registered with RSM, the analysis will run locally.

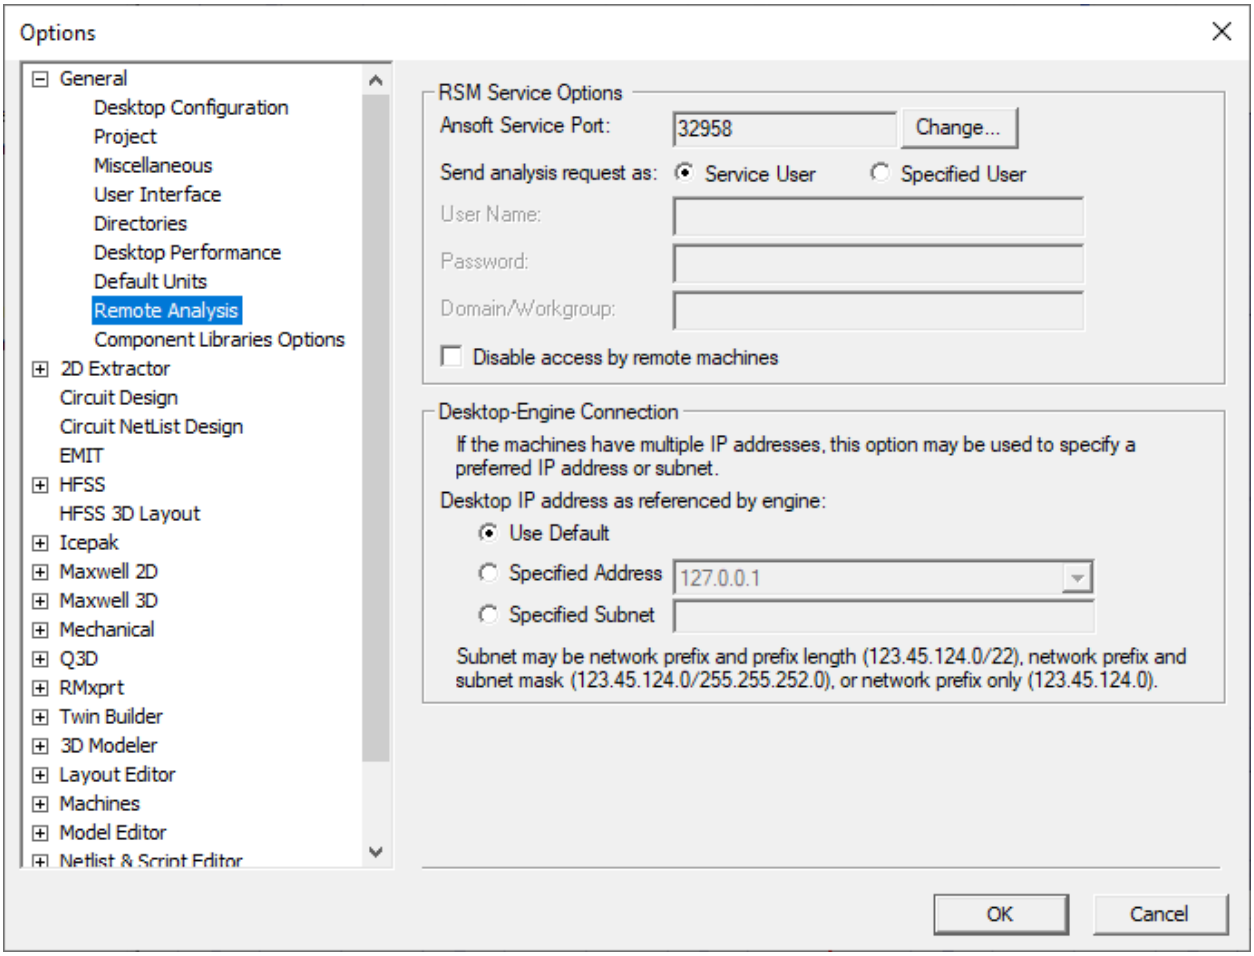
Configuring the Local Machine to Solve Remotely

To set Maxwell Analysis options, see: Distributed Analysis.

Remote Analysis Options

You can also set Remote Analysis Options from **Tools** > **Options** > **General Options** > **General** > **Remote Analysis**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Select whether to run simulation processes as the user running RSM (Service User), or sd a Specified User. If you select Specified user, you must provide the User Name, Password, and any Domain/Workgroup on which this user is defined. If the name or password is incorrect, the Messages window issues a warning, and the solver attempts to perform the analysis as the Service User.

Running Remote Analysis

When you run a simulation remotely, you should see a message in the Progress window identifying the design name and the specified remote machine. You will see Progress messages as the simulation continues. When the simulation is complete, you will see a message in the **Messages** window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Troubleshooting

> **Note:**
>
> Functionality featured in the example(s) in this section applies to multiple design types.

Problem:

When you try to solve from local to remote machine, a COM engine process starts on the remote machine, but the user interface hangs indefinitely.

This occurs if the remote solve option is enabled after the COM daemon is started, or when the option "Don't allow exceptions" is selected for the Windows firewall.

Resolution:

Remote solve needs either firewall exceptions to be turned on, or firewall to be completely turned off.

Problem:

When you try to solve from a local to a remote machine, you receive the following error message:

[error] Unable to locate or start COM engine on 'nomachine' : Unable to reach AnsoftRSMService. Check if the service is running and if the firewall allows communication. (10:57:13 PM Aug 13, 2019)

Resolution:

This message can happen if the machine is not present, the network connection is down, if there are firewall issues, or if the service is not running.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Problem:

A solve that is distributed to multiple hosts using MPI fails because the AnsysEM installation path is different on different hosts.

Resolution:

Ansys Electronics Desktop must be accessible from all remote machines as well as on the local machine. If the analysis uses MPI, then the path of the Ansys Electronics Desktop installation must be the same on all of the machines used for the analysis (remote and local). This may be a shared network path accessible from all hosts. Alternatively, it may be a local installation on each host; in this case the installation path must be the same for all hosts. If using a shared network path, there should not be a local installation of the same Ansys Electronics version on any of the hosts. See Distributed Analysis for information on whether MPI is needed for the analysis.

Problem:

The command `ansoftrsmservice stop` will not work as root.

Resolution:

Use systemctl command to stop the service:

```
sudo systemctl stop ansoftrsmservice
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Remote Solve Node = Windows

Error:

"Unable to locate or start COM engine on <remote node> : Unable to reach AnsoftRSMService. Check if the service is running and if the firewall allows communication."

Resolution:

1. Try disabling the firewall.
2. Confirm that you have not changed the Service Port in **Tools** > **Options** > **General Options** > **General** > **Remote Analysis**. If you have, change it back to the default (32958), restart Ansys Electromagnetics Desktop, and try to solve again.
3. Make sure that the local machine is able to contact the RSM port on the remote node. Open a command prompt on the local machine and type:
   `telnet <remote node name> 32958`
   If the terminal appears to hang, the connection was successful.
4. Make sure the user listed in the service is an administrator.
5. Make sure the COM engine is registered with the RSM Service. From the Windows menu, choose **Start** > **All Programs**> **Ansys EM Suite 2025 R1** > **Register with RSM** to register the engines.
6. If none of these steps fixes the problem, contact Ansys Support.

Error:

"Unable to locate or start COM engine on <remote node>: Engine is not registered with the Ansoft RSM service which is running on this machine."

Resolution:

1. To register the engine from the Windows menu, select **Start** > **All Programs** > **Ansys Electromagnetics Suite 2025 R1** > **Register with RSM**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Remote Solve Node = Linux

Error:

"Unable to locate or start COM engine on <remote node>: Unable to reach AnsoftRSMService. Check if the service is running and if the firewall allows communication."

Resolution:

1. Try disabling the firewall.
2. Confirm that you have not changed the Service Port in **Tools** > **Options** > **General Options** > **General** > **Remote Analysis**. If you have, change it back to the default (32958), restart Ansys Electromagnetics Desktop, and try to solve again.
3. Make sure that the local machine is able to contact the RSM port on the remote node. Open a command prompt on the local machine and type:
   `telnet <remote node name> 32958`
   If the terminal appears to hang, the connection was successful.
4. Check to make sure Remote Simulation Manager is running:
   a. Go to the rsm subdirectory of the Remote Simulation Manager installation directory, <RSM installdir>/rsm.
   b. Type
      `./ansoftrsmservice status`
   c. If the status query indicates that the service is stopped, type ./ansoftrsmservice start.
5. Make sure the COM engine is registered with RSM. Type:
   `./RegisterEnginesWithRSM.pl status`
   from within the Electronics Desktop installation directory. If the status query indicates "Not registered", type:
   `./RegisterEnginesWithRSM.pl add`
6. If none of these steps fixes the problem, contact Ansys Support.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Error:

"Unable to locate or start COM engine on <remote node>: Engine is not registered with the Ansoft RSM service which is running on this machine."

Resolution:

1. To register the engine, go to the Ansys Electromagnetics product installation directory and type:
   `./RegisterEnginesWithRSM.pl add`

Distributed Analysis

Distributed analysis allows users to split certain types of analyses and solve each portion of an analysis simultaneously on multiple machines. Simulation times can be greatly decreased by using this feature.

> **Note:** When using distributed analysis, the Temp folder must be accessible by all machines set up in the HPC configuration.

Maxwell supports the following form(s) of distributed analysis:

- Distributing rows of a parametric table, either as a regular DSO or as Large Scale DSO performed through command line.
- Distributing single or discrete interpolating sweeps.
- Maxwell 2D and Maxwell 3D designs support distribution of frequencies, transient solver, solution matrix and skew model.

> **Note:**
>
> Communication between machines in remote analysis and distributed analysis can drastically affect performance. Use of a high-speed network system, like Gigabit or Infiniband, is recommended for optimal performance.

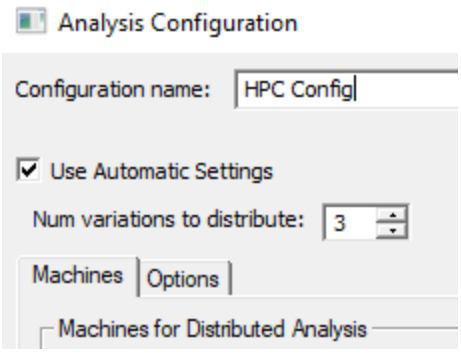
All types of distribution use MPI, except when only distributing rows of a parametric table, either as a regular DSO or as Large Scale DSO performed through command line. MPI may also be used if Auto mode is specified, and rows of a parametric table are distributed. MPI must be correctly configured if the distributed analysis uses MPI. See Setting HPC and Analysis Options for setting MPI Licensing and the appropriate Ansys Windows or Linux Installation Guide for details on installing MPI.

> **Note:** Maxwell Circuit and RMxprt designs do not support MPI.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Beta Feature: Parallel Component Mesh Adapt for 3D Component Array

If you enable the Beta Feature for Parallel Component Mesh Adapt, you can have parallel mesh adaption for 3D Component arrays. This feature works only with Use Automatic Settings enabled on the active Analysis Configuration.



When running a suitable design with this feature enabled, the Solution Profile will show multiple frequencies being adapted at the same time.

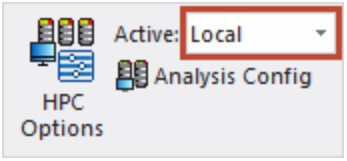
Configure a Distributed Analysis

To configure a distributed analysis, you must select a distributed machine configuration containing a list of machines to use for a simulation, based on memory and CPU considerations (See: Selecting an Optimal Configuration for Distributed Analysis). To create an new distributed machine configuration or to edit an existing one, see Editing Distributed Machine Configurations.

Before you can select a configuration, it must be active. See: Setting HPC and Analysis Options.

To select an existing, active configuration:

- From the **Simulation** tab, use the **Active** drop-down menu to select a configuration.



Distributed Analysis Configuration

After you have selected the active distributed machine configuration, you can edit its configuration in the **Analysis Configuration** window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

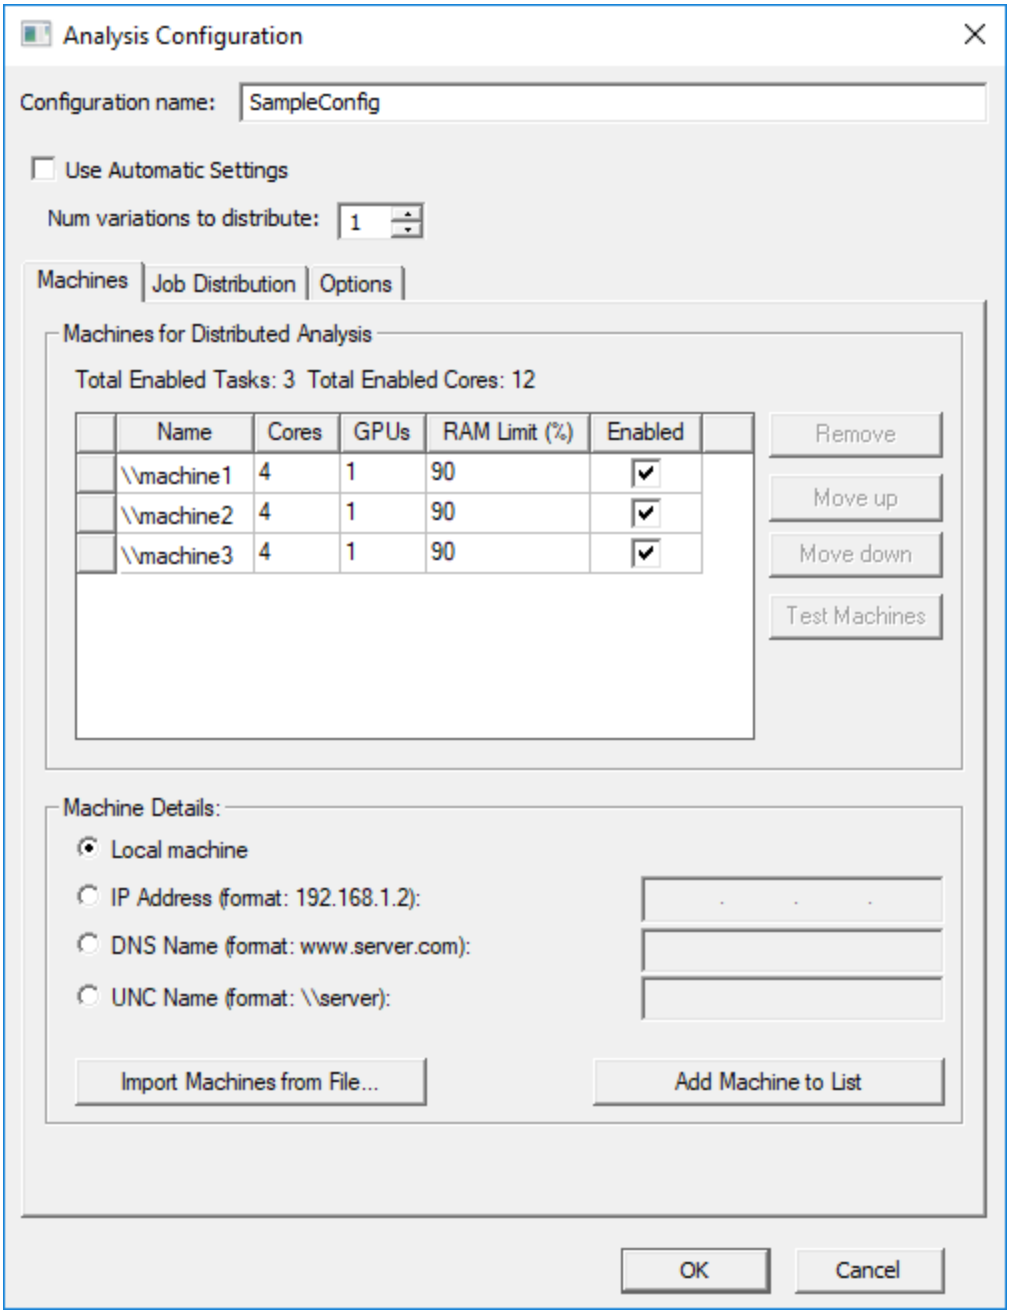
To edit the configuration:

1. Access the **Analysis Configuration** window one of three ways:
   - From the **Simulation** tab, click **Analysis Config**.
   - Click **Tools** > **Edit Active Analysis Configuration**.
   - From the **HPC and Analysis Options** window (opened from the **HPC Options** icon on the **Simulation** ribbon or **Tools** > **Options** > **HPC and Analysis Options**), select the configuration and click **Edit**.

   > **Note:**
   >
   > You can also access the Analysis Configuration window from the **HPC and Analysis Options** window by clicking **Add** or **Copy**. When using **Add** or **Copy**, the steps are the same as below, but you will need to specify a **Configuration Name**. The name cannot be empty and it cannot be a reserved name.

   The **Analysis Configuration** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



> **Note:**
>
> Available options may vary slightly depending on the solver and design.

2. If automatic settings are supported, the **Use Automatic Settings** check box allows you to select this option and set parameters based on the best use of available resources for the

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

current analysis. Deselecting it enables the **Job Distribution** tab, where you can assign resources manually.

For Maxwell, this setting is currently only supported for 2D and 3D Transient and for 3D eddy current designs.

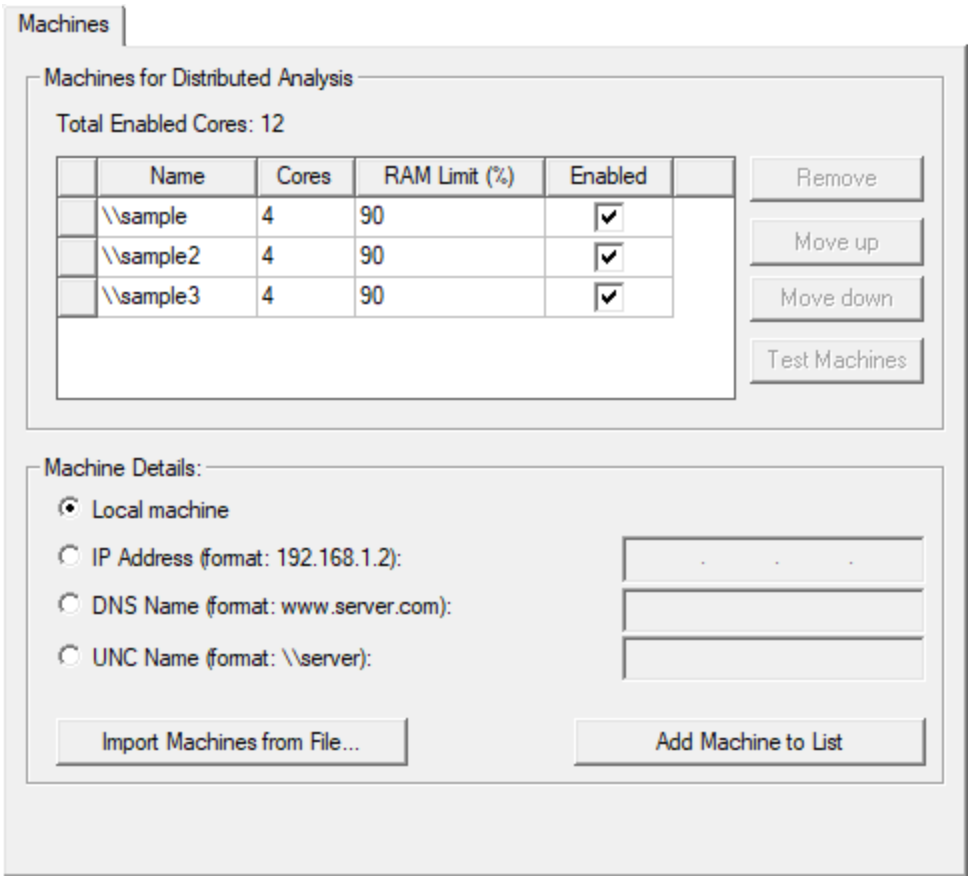
For 2D and 3D Transient designs, the **Use Automatic Settings** option distributes one excitation to each machine listed in the configuration. When this option is enabled, a minimum of 2 cores must be assigned. Each machine uses all cores assigned to it while solving its excitation. Unlike automatic frequency setup, the machines are assigned sequentially without regard to machine capability. For 3D eddy current design with **Use Automatic Settings**, you must assign a minimum of 4 cores.

3. Use the tabs to navigate through the rest of the settings:
    - **Machines** – contains the machine list. You can add, enable, remove, test, and reorder machines from the list.
    - **Job Distribution** – when **Use Automatic Settings** is deselected, this tab appears and allows you to select job distribution settings manually.
    - **Options** – allows you to specify additional options, depending on the design type.
4. Click **OK** to save the configuration settings.

Distributed Analysis Configuration - Machines Tab

On the **Analysis Configuration** window, the **Machines** tab allows you to provide machine information, either by specifying remote machine details, or by importing a list of machines from a file. You can then add, enable, remove, test, and reorder machines from the list.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Manually Adding a Machine

You can add the **Local machine**, or add a machine by **IP Address**, **DNS Name**, or **UNC Name**. Select the applicable radio button, enter the machine's information in the specified format, then click **Add Machine to List**.

> **Important:**
>
> The remote machines must have the same Ansys Electromagnetics Suite version installed on the same OS version, and have active RSM service.

The added machine(s) will appear under **Machines for Distributed Analysis**.

Importing a Machine List

You can import a machine list from a text file. Each line of the file should contain a machine's information in the following format:

```
<MachineName>:<NumTasks>:<NumCores>
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Machine List Details

The **Machines for Distributed Analysis** area lists machines in the order in which you entered them, irrespective of the load on the machines. To control the list order, select one or more machines, and use the **Move up** and **Move down** buttons. To remove one or more machines, select the machine(s) and click **Remove**.

The following columns can appear in the list:

- **Name** – the machine name.
- **Tasks** – this column allows you to specify the number of tasks a given machine will perform simultaneously. *Each separate solver or instance counts as one task.*

  If you have selected **Use Automatic Settings**, this column does not appear because there is no need for it.

- **Cores** – specifies the total number of cores that will be used on the given machine. The total number of Tasks and Cores are described just above the machine list.

  For distributed tasks, the software will allocate the total cores on a given machine to that machine's tasks. If a machine with 8 cores is running 2 distributed tasks, the software will automatically allocate 4 cores to each task. If it is running 4 distributed tasks, each gets 2 cores. And if it is running 3 distributed tasks, the first two tasks get 3 cores and the last task gets 2 cores. *The number of Cores must always be greater than or equal to the number of Tasks.*

  For a given variation (for example, frequency or geometry), you should make assignments so that each task has the same number of cores. This is because the solvers attempt to make each task computationally balanced. For example, with two machines, one with eight cores and another with four, assuming that the memory is proportionally equivalent, you could assign two tasks for machine 1, and one task for machine 2, giving all tasks the same number of cores.

- **GPUs** – supports GPU acceleration. See: Enabling GPU.
- **RAM Limit (%)** – specifies the maximum percentage of each machine's RAM you would like to be in use by the solver.
- **Enabled** – use the check boxes to enable or disable machines.

In general, Ansys Electromagnetics Suite solvers use machines in the distributed analysis machines list in the order in which they appear. If you select a distributed configuration (rather than Local) from the Toolbar menu and you launch multiple analyses from the same UI, Ansys Electromagnetics Suite solvers select the machines that are running the fewest number of engines in the order in which the machines appear in the list. For example, if the list contains 4 machines, and you launch a simulation that requires one machine, the solver chooses the first machine in the list. If another simulation is launched while the previous one is running, and this simulation requires two machines, the solver chooses machines 2 and 3 from the list. If the first

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

simulation then terminates and we launch another simulation requiring three machines, the solver chooses 1, 4, and 2 (in that order).

Testing Machines

When multiple users on a network are using distributed solve or remote solve, they should check the status of their machines before launching a simulation to ensure that no other Ansys EM processes are running on the machine. To do this, select one or more machines and click **Test Machines**.

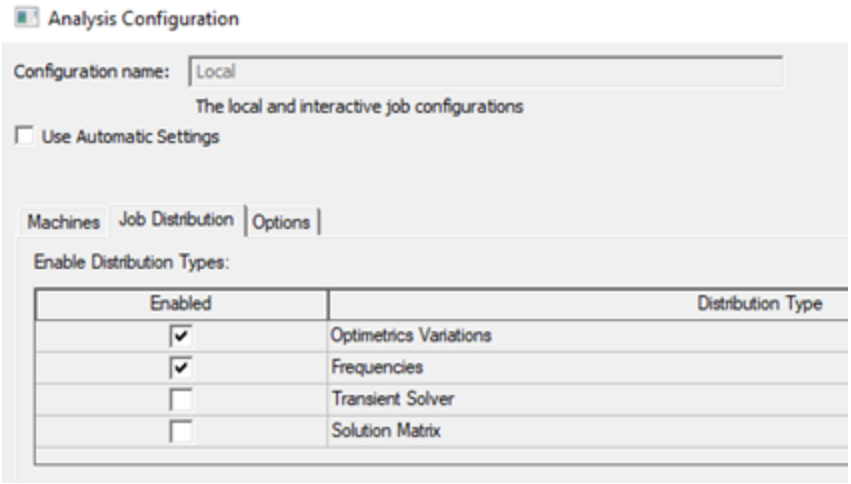
The **Test Machines** dialog box appears. The test goes through the current machine list and gives a report on the status of each machine. A progress bar shows testing progress. When the test is complete, click **OK** to close the dialog box. If you need to disable or enable machines based on the report, you can do so in the **Analysis Configuration** window.

Distributed Analysis Configuration - Job Distribution Tab

On the **Analysis Configuration** window, the **Job Distribution** tab allows you to manually enable specific types of job distribution and enable multi-level solves.

The **Job Distribution** tab is disabled if you selected **Use Automatic Settings**.

> **Note:**
>
> Different design types have different job distribution types.



The job distribution list allows you to specify which job distribution types to allow for the current analysis configuration. Use the check boxes enable and disable distribution types. At solve time, Maxwell automatically selects the best distribution type from the enabled types.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Enabling a distribution type does not mean it will be used. It must be also allowed by the solve setup. If you enable a distribution type for a given setup, and distribution is allowed, the preview window updates to describe the distributions. Note that enabled distribution types apply to all setups of the given design type, so it is possible for different setups in a design to be solved using different distribution types.

For example, the **Transient Solver** distribution type that enables use of the Time Decomposition Method, will only be *used* with Maxwell 2D and Maxwell 3D transient designs. Note that the enabled distribution types will apply to all setups of the given design type, so it is possible for different setups in a design to be solved using different distribution types. The **Solution Matrix** distribution type that enables use of the Matrix-based Domain Decomposition Method will be *used* with both 3D eddy current designs and 3D magnetostatic designs.

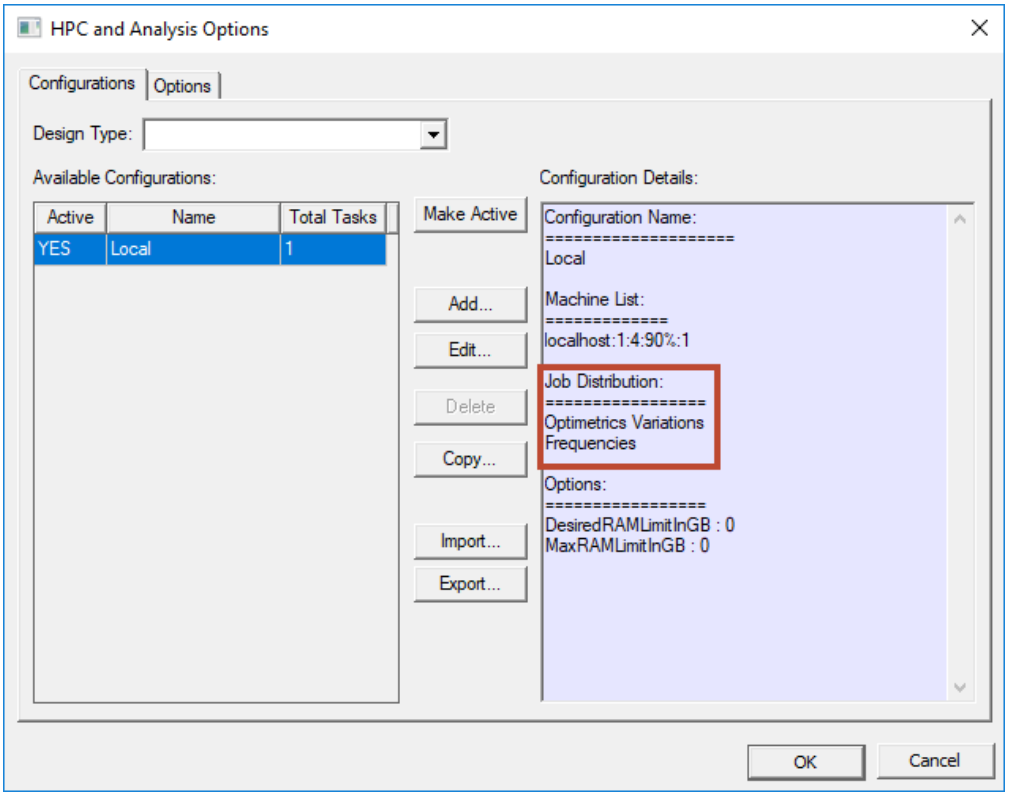
The concurrent initial mesh generation workflow with Distributed Mesh Assembly relies on the MPI based distribution technology inside the MeshAssemblyManager. The decision whether to launch sequential or parallel mesh generation is based on the combination of the number of individual meshes present, the HPC setting, and the number of tasks available.

- If there's only one single mesh or if curvilinear contact exists: then normal initial mesh workflow with single G3dmesher will be launched.
- If there are more than one individual mesh and no curvilinear contact exists:
    - If Use Automatic Setting is not selected, under the **Job Distribution** tab, if "Mesh Assembly" is not enabled, then meshes will be generated sequentially. If "Mesh Assembly" is enabled and user assigns more than 1 tasks, then parallel mesh generation will be launched.
    - If Use Automatic Setting is selected and user assigns more than 1 core, then parallel mesh generation will be launched.
    - If Use Automatic Setting, the number of MPI tasks will be the number of cores user assigned or the number of geometries to be meshed, whichever is smaller. If there are more geometries than cores, the geometries will be dynamically assigned to tasks. If there are more cores than geometries, the remaining available cores will provide some of the tasks with multi-thread capabilities.

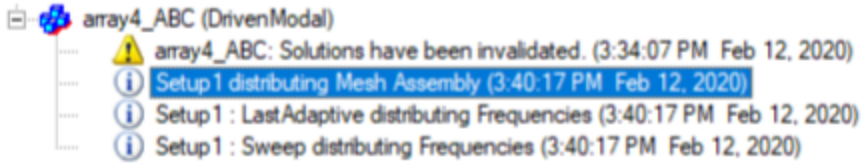
All the detailed progress information from the Mesher is suppressed and the progress will report the number of meshes being finished. All the mesh profiles will be available under profile report and the mesh feedback will also be available under mesh feedback tool.

Enabled distribution types are listed when you select a configuration in the **HPC and Analysis Options** window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

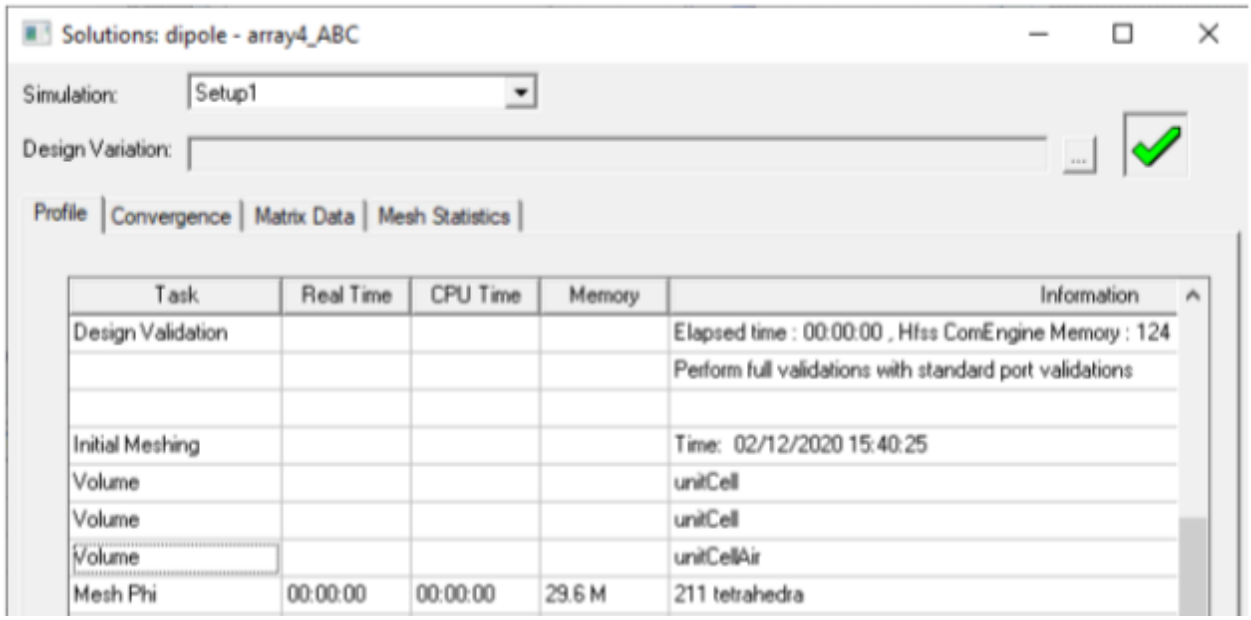


When you run a simulation, the **Messages** window describes distributions.



When you view the Solution Profile, distributions for unitCell show as parallel Volume Tasks.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



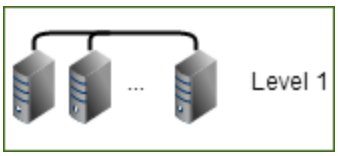
Distribution Levels

For products and designs that support two-level distribution, you can select either single or two-level distribution.

If you select single level, one distribution type will be applied at each stage of the solution process. If multiple types are available, the higher-level solution will generally be distributed. All machine tasks will be used by the single-level distribution.

Single-level Distributions

In a single-level distribution, one distribution type is applied at each stage of the solution process. Common stages include LastAdaptive, Sweep, and Parametric. All machine tasks will be used by the single-level distribution.



Supported distribution types include:

- Optimetrics Variations
- Frequencies
- Mesh Assembly

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Transient Solver
- Solution Matrix

Solver distributions require MPI. See: Setting HPC and Analysis Options.

Parallel distribution types (such as Optimetrics Variations, and Frequencies) do not require distribution. If these types are not able to distribute, the simulation can run sequentially.

Memory distribution types (such as Transient Solver and Solution Matrix) are set to require distribution. If these types are enabled, the software will assume that distribution is necessary to extend the simulation scale or add fundamental solution capabilities.

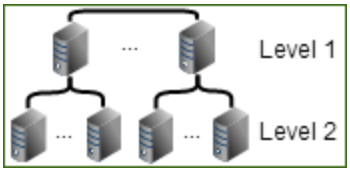
When multiple distribution types are available, the higher level solution will generally be distributed. The priority order is : Optimetrics Variations, Transient Solver, Frequencies, Mesh Assembly and Solution Matrix. If Iterative Solver is enabled in the Eddy Current solve setup, the priority order will be: Solution Matrix, Optimetrics Variations, Transient Solver, and Frequencies. For example, Optimetrics Variations will be distributed when both Optimetrics Variations and Transient Solver are selected.

Two-Level Distributions

Selecting **Enable two-level** enables the **Distributed solutions at first level** box.

In a two-level distribution, the first level distributes the specified number of solutions. Each solution will then use a subset of machine tasks to distribute the second level. A solver distribution type must be available for the second level; otherwise, single-level distribution will be applied. The Transient Solver distribution type must be available for the second level for a Transient design; otherwise single-level distribution will be applied. The Solution Matrix or Frequencies distribution type must be available for the second level for an Eddy Current design; otherwise single-level distribution will be applied.

For two-level distribution, the total number of tasks must be greater than or equal to the number of tasks for level 1.



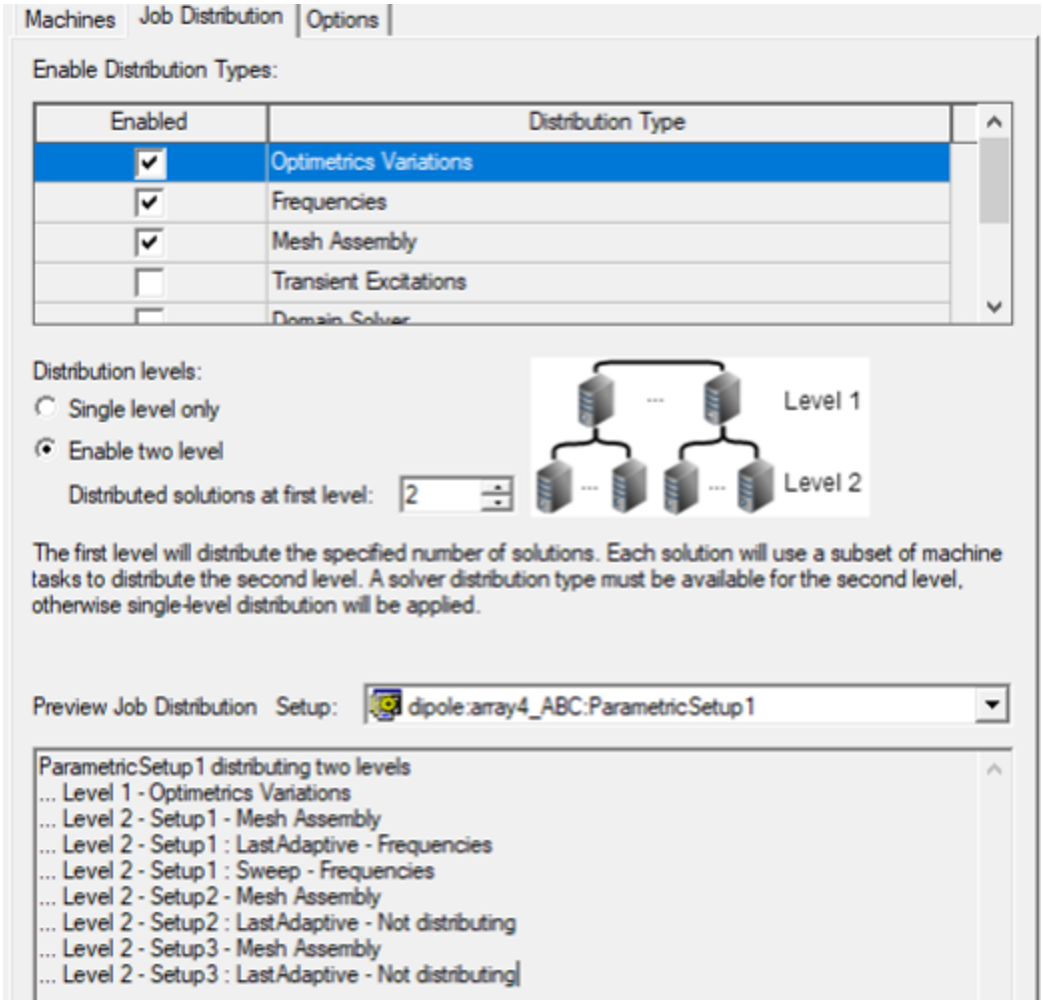
The following is an example of a two-level distribution:

- A parametric setup distributing **Optimetrics Variations** as level 1, and a **Frequencies** distribution as level 2.
- A parametric setup distributing Optimetrics variations as level 1, and Mesh Assembly distribution as level 2.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Analysis Configuration** window displays a preview of the job distribution, if allowed for that configuration:

Here is another example:



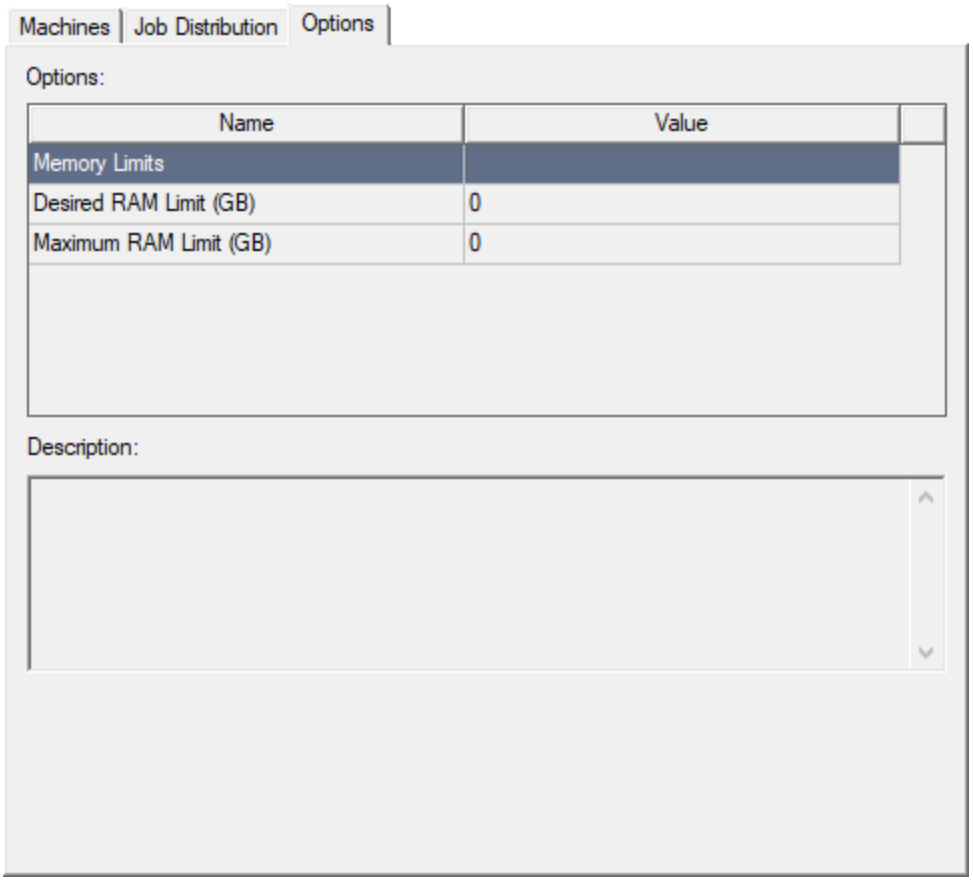
For more information, see: Two-Level Distribution Guidelines.

Distributed Analysis Configuration - Options Tab

On the **Analysis Configuration** window, the **Options** tab allows you to specify options for the current analysis configuration.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> Different design types have different options.



These options settings will be in effect only when all the following are true:

- A design is being solved whose design type matches the analysis configuration design type.
- The analysis configuration is the active configuration for its design type.
- You have not specified corresponding `batchoptions` on the command line.

Relation to Batchoptions

Command line `batchoptions` can be used to override the options specified by the active configuration.

Analysis configuration option settings can be overwritten by specifying the option name and value inside a `-batchoption` string.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To add batchoptions from the UI, click **Maxwell** > **Submit Job**. Under **Analysis Options**, click **Add**. This opens the **Add Batchoption** window.

See: Running Electronics Desktop from the Command Line and Batchoptions Command Line Examples.

Adding Configurations or Accepting Edits

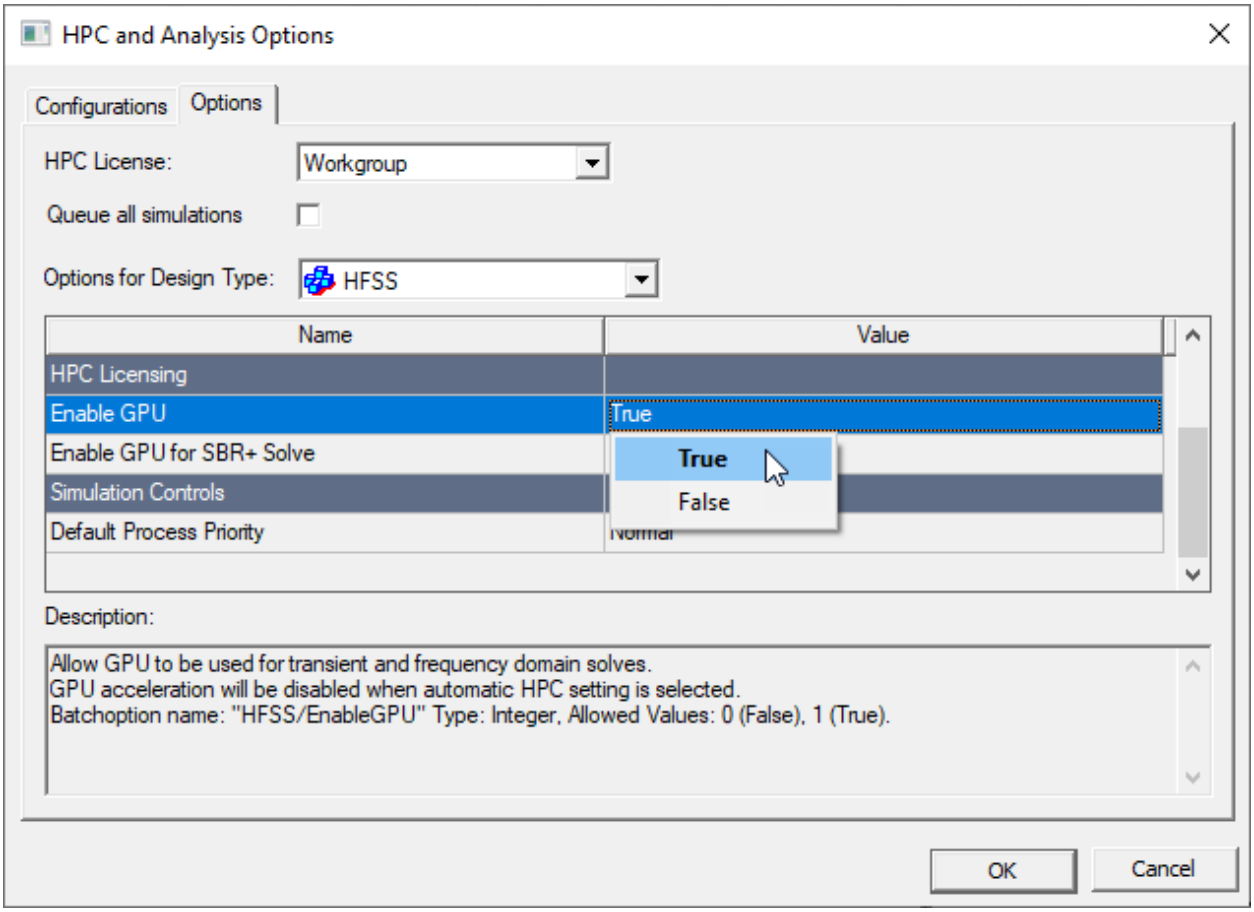
Click **OK** to accept the changes and close the **Analysis Configuration** window. Only machines marked **Enabled** appear in the machine list.

Regardless of the machine(s) on which the analysis is actually run, the number of processors and RAM Limit (%) settings, and the default process priority settings are now read from the machine from which you launch the analysis. See: Setting HPC and Analysis Options.

Enabling GPU

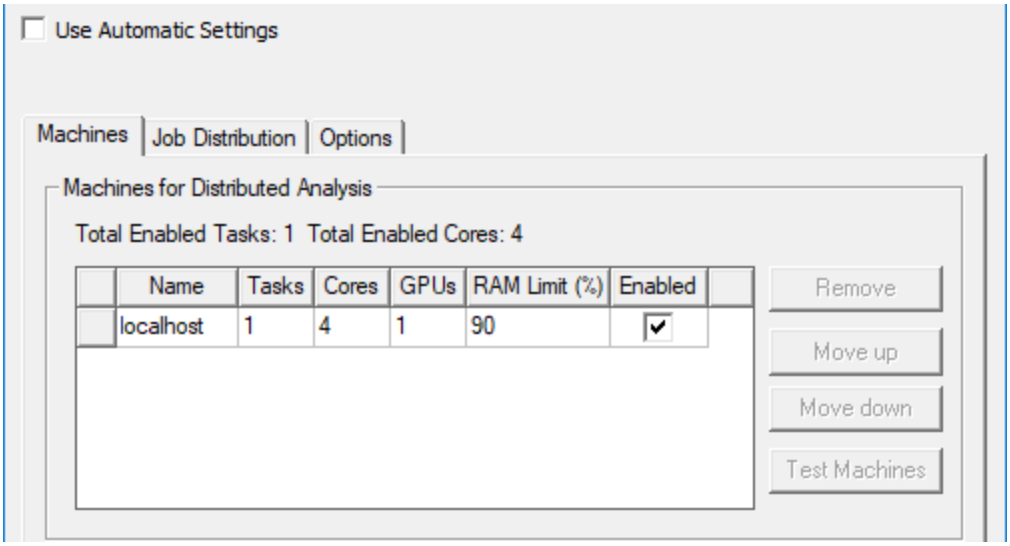
Ansys Electronics Desktop supports GPU acceleration for transient, frequency domain, and Maxwell 3D eddy current matrix simulations. For details on the requirements for GPU use, see: GPU Acceleration.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To enable use of GPU or MIC acceleration, you can set **Enable GPU** to **True** and set **Use Automatic Settings** to **off** in the window. The matrix solver automatically determines if all cores should be used, or if one GPU should be used to give the best performance. For example, for a Maxwell Eddy Current Solution Matrix, if you specify 4 cores for the simulation, the 3D Eddy current solver will use 4 cores in parallel during matrix assembly while the matrix solver will use either 4 cores or 1 GPU.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For solvers that can use GPUs, when you uncheck **Use Automatic Settings**, the analysis configuration lets you specify the number of GPUs to be used by each machine, along with the existing settings for cores and RAM Limit. This makes sense, because GPUs, cores, and RAM are all resources that the user is managing, and GPUs and cores both contribute to HPC count. Each machinehas tasks and GPUs. The GPUs are distributed among the tasks, similarly to how cores are distributed. For example, if a machine has 3 tasks and 2 GPUs, then the first two tasks will get one GPU each, and the third task will get no GPU.

For design types like HFSS that support GPU for different types of solve (frequency, transient, SBR+), the GPU setting when **Use Automatic settings** is unchecked applies to all types. To use GPU for some solves and not for others, you can create multiple configurations.

Determining When a GPU or MIC is Being Used

You can determine if a GPU or MIC is being used for acceleration by viewing the **Solutions** dialog box, **Profile** tab. If a GPU is successfully locked for use by the solver process, the profile shows the GPU's CUDA device ID and its name.

If the GPU is not used, the Solution Profile indicates that, and the CPU cores are used.

When GPU is used:

- GPU must be enabled for HFSS/Maxwell.
- Both Windows and Linux are supported.
- Only complex symmetric matrices can be solved by CUDA.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The matrix (number of unknowns to be solved) must be large enough. By default, its dimension should be larger than 2,000,000.
- The times using CUDA and CPU only are estimated. If GPU is faster, it will be used. If not, the solver falls back to multi-core CPU.

GPU and CPU:

- The estimation is based on the structure of the matrix, not just the dimension.
- The generation and model of GPU are considered. The newer the model is, the faster the GPU estimation is.
- The clock rate and number of cores of CPU are considered. The higher the rate is, the more the cores are, the faster the CPU estimation is.
- Finally, the faster device (GPU or CPU) is selected based on the estimation.

Why GPU is Not Used

- The estimation is based on the whole matrix, not just the size. Having larger matrices doesn't mean GPU will be used.
- The bandwidth is not useful either. It is possible to have two matrices with exactly the same size and bandwidth, one favoring GPU and the other CPU.
- If GPU is of older models while CPU is not, GPU may not be used.
- If CPU has high clock rate, GPU may not be used.
- If CPU has many cores, GPU may not be used.
- If Use Automatic settings in Analysis Configuration is checked.
- Nvidia GPU drivers are downloaded from certain repository (e.g. RedHat) instead of directly from Nvidia website

Multiple GPUs

When there are multiple GPU cards in the same machine, the first solver process (hf3d, 3dedy) locks the first GPU card available (not locked or used by other processes, not used for display, etc.), the second process locks the second card available, and so on. After all cards are locked, solver uses CPU only.

Selecting Optimal Configurations for Distributed Analysis

This section provides some basic guidelines for configuring a distributed analysis, including how to choose the number of tasks for Distributed Direct and Distributed Iterative solvers, and when to use two-level distribution. In this section, assume that a fixed number of machines and cores are available, and that the goal is to use them as efficiently as possible.

In the majority of situations, configuring a Distributed Solution Option (DSO) in combination with the multiprocessing option to take optimal advantage of the available hardware results in improved speed.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

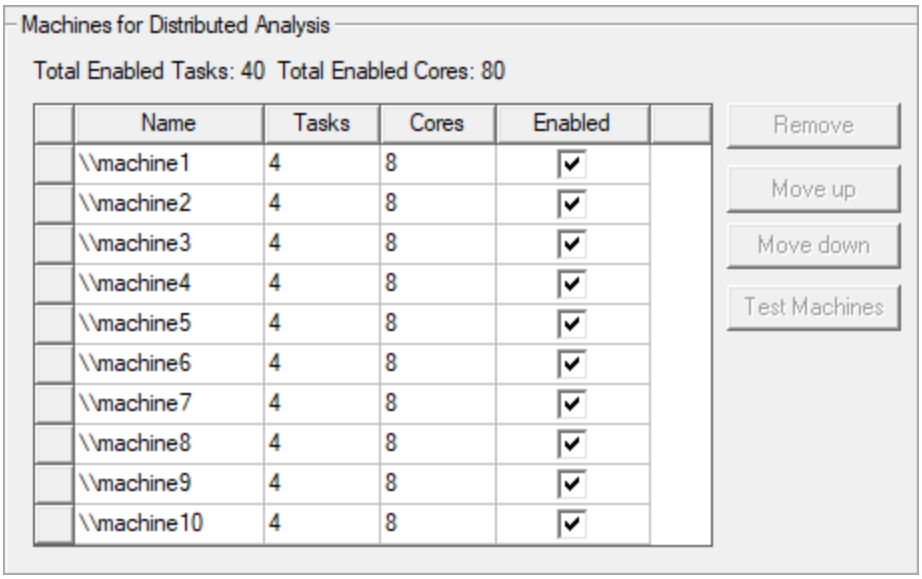
Note:

This topic assumes that there is enough hard drive space and memory for DSO simulations. For multiple DSO simulations on a single machine, the total memory needed is the sum of the memory used by each simulation. For example, consider a discrete frequency sweep in which each frequency point needs 3.5GB. A quad core system with 8GB of RAM would rely heavily on swap, which is highly inefficient. In this case, updating the number of tasks in the machine list is ideal.

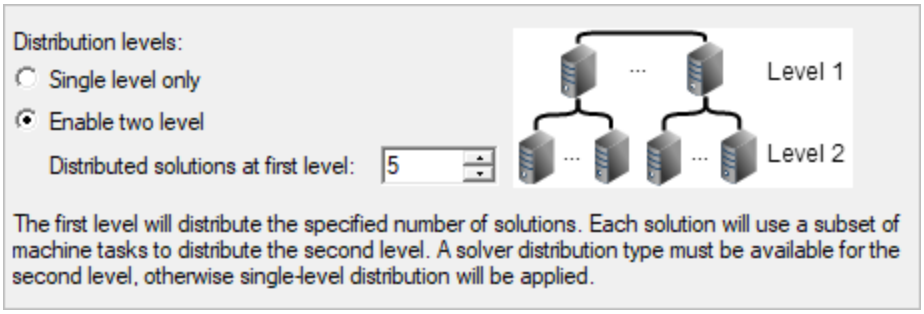
Two-Level Distribution Guidelines

Ansys recommends that you focus resources for the highest level of distribution (level one). In other words, allocate the resources so that a maximum number of frequencies or variations are solved in parallel. First, determine the minimum number of machines required to solve one frequency or variation based on your prior knowledge of the type of model being solved. Then allocate the resources so that a maximum number of solutions can be solved in parallel.

For example, suppose that a given model requires at least 100 GB of memory to solve using DDM. Assume that you have 10 machines, each with 60 GB and 8 cores. One solution will require two machines for the DDM solver. This means that, at most, 5 frequencies can be distributed. Each DDM solution requires at least 3 tasks, but since more cores are available you should set 4 tasks per machine, resulting in 2 cores for each Domain . A machine configuration based on the machines and number of tasks described above is shown in the figures below.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Distributed Direct Solver Guidelines for HPC Configuration

The dependence of Distributed Direct solver on number of tasks is very similar to the Maxwell solver. For distributed direct solver, the number of tasks increases the total memory but also typically increases the speed of the simulation.

Some general guidelines:

1. If memory usage is critical, use 1 task/machine using all cores.
2. If memory usage is not critical, use 4 cores/task for optimal speed.

Distributed Iterative Solver Guidelines for HPC Configuration

The distributed iterative solver distributes excitations for faster simulations and to access less memory to solve a large problem. Each task corresponds to a number of excitations and, therefore, more excitations are solved in parallel when the number of tasks increases.

The first consideration for the number of tasks is the memory requirement. Each task uses a similar amount of memory, and the total memory usage doubles as the number of tasks doubles. Thus the number of tasks on each compute node should be restricted to avoid an "Out of Memory" failure.

The second consideration for the number of tasks is the number of excitations. Maxwell designates one of the tasks as the master, which does not participate in the iterative process. ***Thus the number of tasks should be no more than the Total Number of Excitations + 1***.

In summary, assuming that you have enough memory, if the number of excitations N is less than the total number of cores M and you choose 4 cores per task, then the number of tasks is ceil (N/4) + 1, where ceil() stands for the ceiling function and the extra "1" is dedicated to the master task; if the number of excitations N is more than the total number of cores M and you choose 4 cores per task, then the number of tasks is ceil(M/4). For example, if you have a design with 64 excitations and you have 32 cores available, you could define a possible setup having 8 tasks with 4 cores per task.

Large Scale DSO for Parametric Analysis

Large Scale DSO for parametric analysis operates through a non-graphical batch application called desktopjob. You can run the desktopjob command line to perform parametric analysis DSO. The command-line interface supported by this batch program is similar to the command line used for regular DSO jobs.

Large Scale DSO is used for large scale parallel jobs, which either fail or scale poorly as regular DSO jobs. A Large Scale DSO job does not support the output of full parametric results, but produces reduced datasets corresponding to predefined rectangular plots. The extracted columns of data are saved as CSV files. Typically, there is one CSV file per-trace, per-variation. These CSV outputs can be used directly in downstream applications (for example, Microsoft Excel). They can also be imported as dataset solutions for post-processing. Non-rectangular plots of the design (such as statistical eye or digital plot) are not extracted. In order to produce a new output you must rerun the analysis.

> **Note:**
>
> For a machine with *n* cores, it should be expected that running *n*, single core, distributed simulations in parallel will encounter additional overhead due to the need to spawn *n* unique solve processes. Therefore, it should not be expected to observe an *n* times speed up over the time taken to run *n* analyses in series with a single core. The relative impact of this overhead increases as the size of the simulation and time to complete a single solve shrink.

The basic Large Scale DSO process involves

1. Preparing the model for Large Scale DSO Analysis.
2. Submitting the Large Scale DSO job through **Tools** > **Job Management** or via command line.
3. Monitoring the job's progress.
4. Postprocessing the results.

For details, refer to the following sections:

- Prerequisites for Large Scale DSO
- Job Management Interface for Large Scale DSO
- Command Line Syntax
- Deployment/Configuration
- Tutorial Example for HFSS
- Job Outputs
- Job Monitoring

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Process Limits for Large Scale DSO on Windows
- Known Issues/Troubleshooting for Large Scale DSO

Large Scale Distributed Solve Operation could submit a parametric setup to be solved in multiple machines, each machine may launch multiple EM-Desktop processes to solve the assigned variations (Design Points). Variations are distributed to each task (EM-Desktop process) equally, regardless of the machine hardware and each variation's complexity. In practice, some tasks may finish earlier than others, in some extreme case some tasks may hours behind fastest task. DSO can redistribute tasks when a task finishes before other task. Variations are removed from slow tasks and reassigned to fast tasks. If you abort a task, they can be reassigned to the running task, when the running task finish its original assignment. For more information, see Large Scale DSO theory.

Large Scale DSO offers two new batchoptions related to the redistribution ability.

LargeScaleDSO/VarRedistribution, where 0 disables redistribution (default), and 1 enables it.

LargeScaleDSO/RedistributionLimit, is a positive integer specifying the minimum estimated remaining time (in minutes) for variations to redistribute to another task. The default is 3.

Aborting a Large Scale DSO Simulation

To abort the whole Job, select the **Abort** button on the Job Monitor dialog.

To abort using the Job progress bar, click the button next to the Job progress bar, Click the **Abort** menu item in the popup.

To abort all tasks in a Node(host), click the button next to the node progress bar., and click the **Abort** menu item in the popup. Aborted Variations will be redistributed to other running Nodes, if redistribution is turned on.

To abort an individual task, click the button next to the node progress bar, and click the "Detail" menu item in the popup. In the Task status dialog box, click the **Task** button in the grid. In the variation status dialog box, click **Abort** button. Aborted Variations will be redistributed to other running tasks, if redistribution is turned on.

To terminate a hanging EM-Desktop process, the hanging ansysedt.exe process won't respond to the first abort command. Send a second abort command to terminate the hanging process. Remaining variations will be redistributed to other running tasks, if redistribution is turned on.

For an EM-Desktop process crashed or killed by Windows Task manager or other tools, the task status will be shown as aborted, Remaining variations will be redistributed to other running tasks, if redistribution is turned on.

Prerequisites for Large Scale DSO

General Prerequisites

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Ansys Electronics Desktop must be installed on the cluster which runs either a supported scheduler or Ansys RSM.
- The cluster is compatible with Large Scale DSO requirements.
- Every node of the cluster supports the disk space (in temp directory) and memory requirements of multiple engines that run in parallel.
- All the machines allocated to Large Scale DSO job must all come from the same platform, either Windows or LINUX.
- On the Windows platform, Ansys RSM is started as an admin account, rather than as a system account.

  > **Important:**
  >
  > Large Scale DSO does not support RSM Service running with system login credentials.

- On each machine of the cluster, the 'desktopjob' application is registered with Ansys RSM service using the command shown below:

  Windows: `<installation-directory>/<platform> desktopjob.exe -regserver`

  LINUX: `<installation-directory>/<platform> desktopjob -regserver`

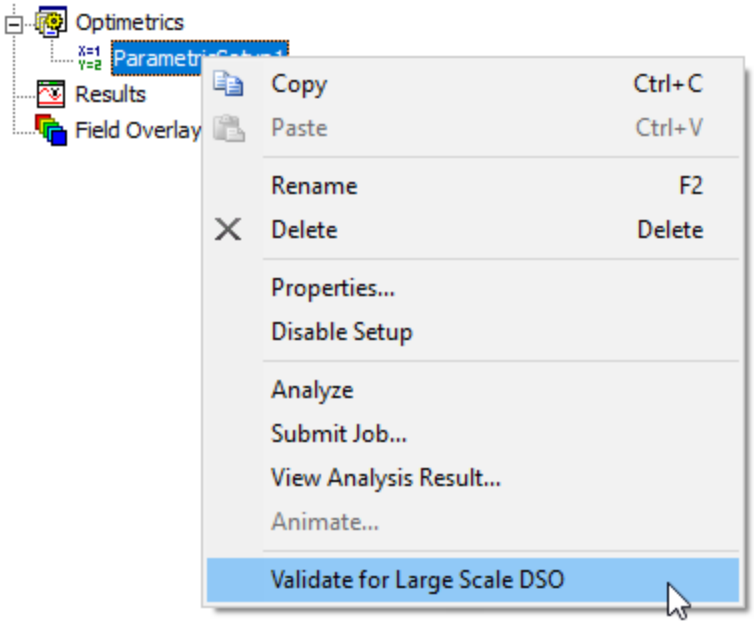
Job Management Interface for Large Scale DSO

Large Scale DSO jobs run only in non-graphical batch mode, irrespective of the scheduler environment. This is in contrast to a Regular DSO job, which can run in graphical mode. This consideration implies that projects corresponding to Large Scale DSO job must be saved and closed prior to job submission. Secondly, the command to submit a Large Scale DSO job is only available through **Tools** > **Job Management** or via a command window, while a Regular DSO job can be run in an RSM environment by right-clicking directly on the parametric setup. The Job Management window is accessed by running Ansys Electromagnetics product Desktop on the designated Postprocessing Node of the cluster. The Desktop provides UI commands for scheduler selection, job submission and job monitoring/control.

When you have selected the scheduler, perform the following steps to submit a Large Scale DSO job:

1. Set up and prepare the model on your local workstation. Right-click the desired solution setup and select **Validate for Large Scale DSO**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Correct any errors and save the project.
3. Close Electronics Desktop.
4. Copy the project (or folder, if the project references external files) from a personal workstation to a shared drive on cluster.

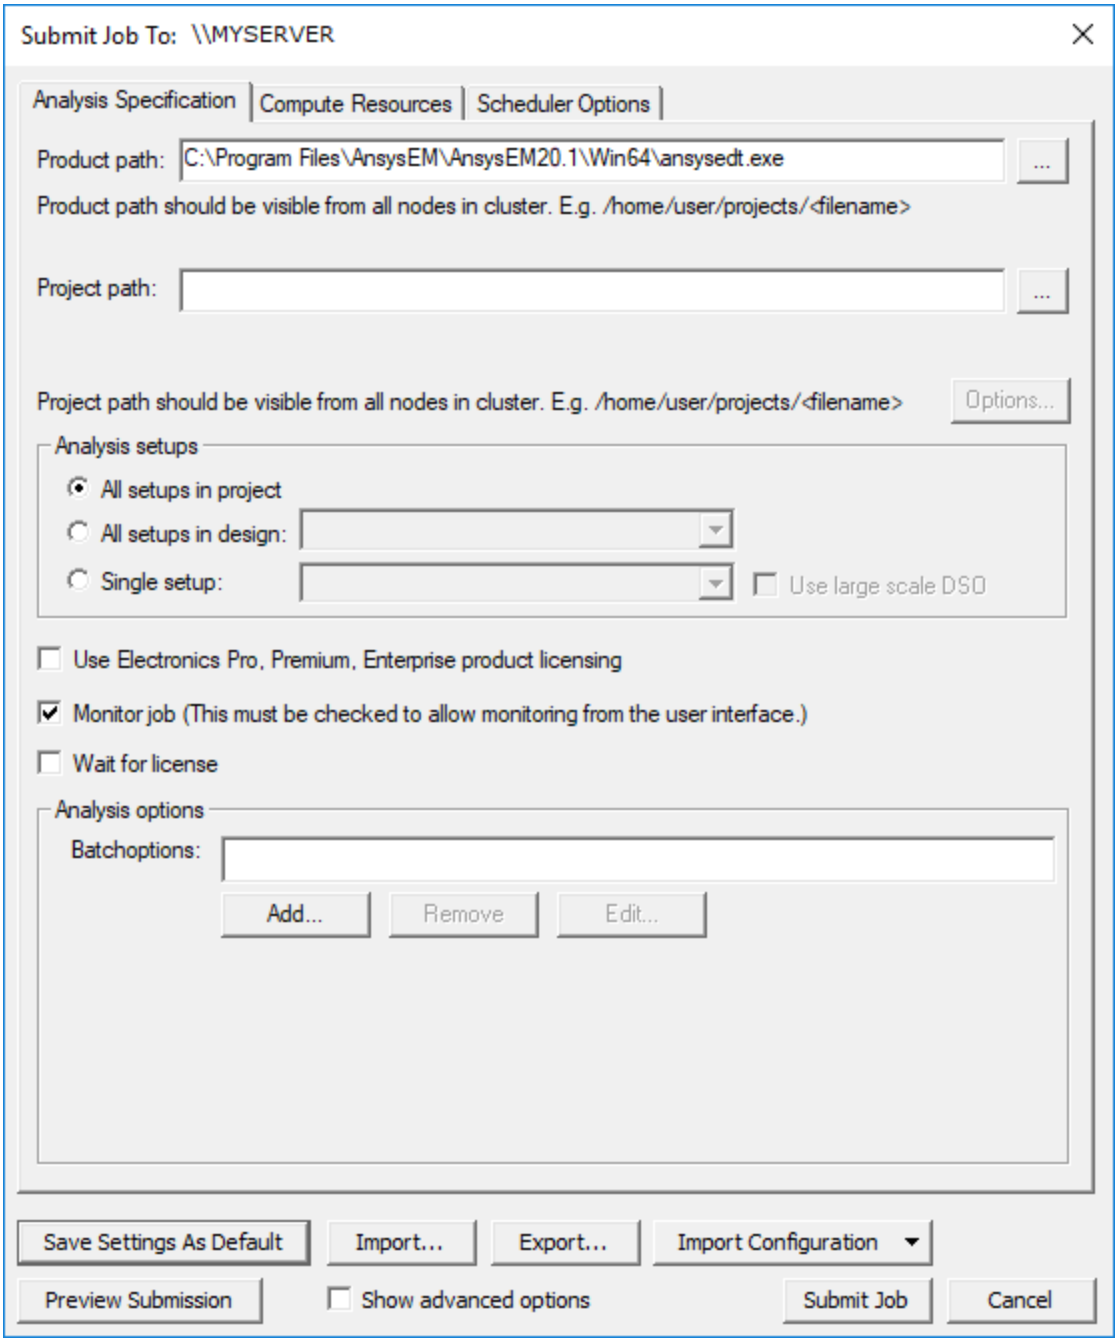
   In the RSM environment, you must specify a machine list (See: HPC and Analysis Options).

   In a Linux scheduler environment, a cluster must have a designated Postprocessing Node.

5. Open a remote desktop session (or equivalent) on the node corresponding to the first machine in the machine list (the designated Postprocessing Node on Linux).
6. Launch Electronics Desktop on that node and open the project.
7. Verify that the model has been prepared correctly.
8. Close the project.
9. Submit the job one of several ways:
   - Click **Tools** > **Job Management** > **Submit Job**.
   - Click **Project** > **Submit Job**.
   - Click **Maxwell 3D**, **Maxwell 2D**, or **RMxprt** > **Submit Job**.
   - Select the **Simulation** tab and click the **Submit** icon.

   The **Submit Job To** window appears, on the **Analysis Specification** tab.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note:

Options vary slightly depending on the selected scheduler. See: HPC Integration.

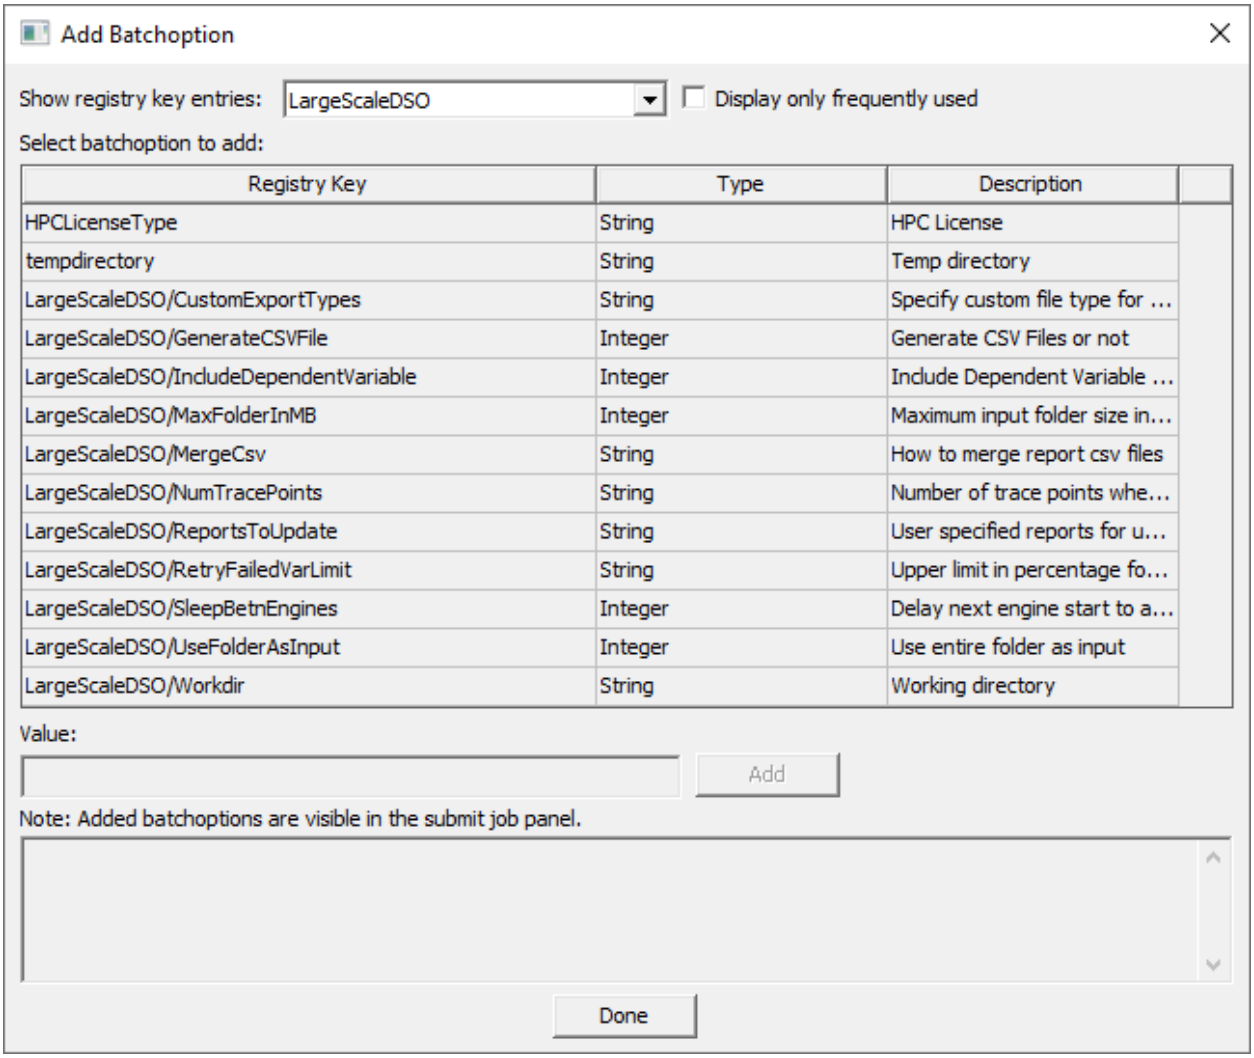
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

10. Specify information for all fields:
    - Most options will not be enabled until you select a **Project path**.
    - Under **Analysis setups**, select setups for analysis.

      For Large Scale DSO, select a **Single setup** from the drop-down menu and ensure the **Use large scale DSO** check box is selected.

    - Determine whether to **Use Electronics Pro, Premium, Enterprise product licensing**, whether to **Monitor job**, and whether to **Wait for license.** If you wish to monitor jobs through **Tools** > **Job Management**, you must enable job monitoring.
    - Add **Batchoptions**, if desired.

      The following shows batchoptions specific to Large Scale DSO.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

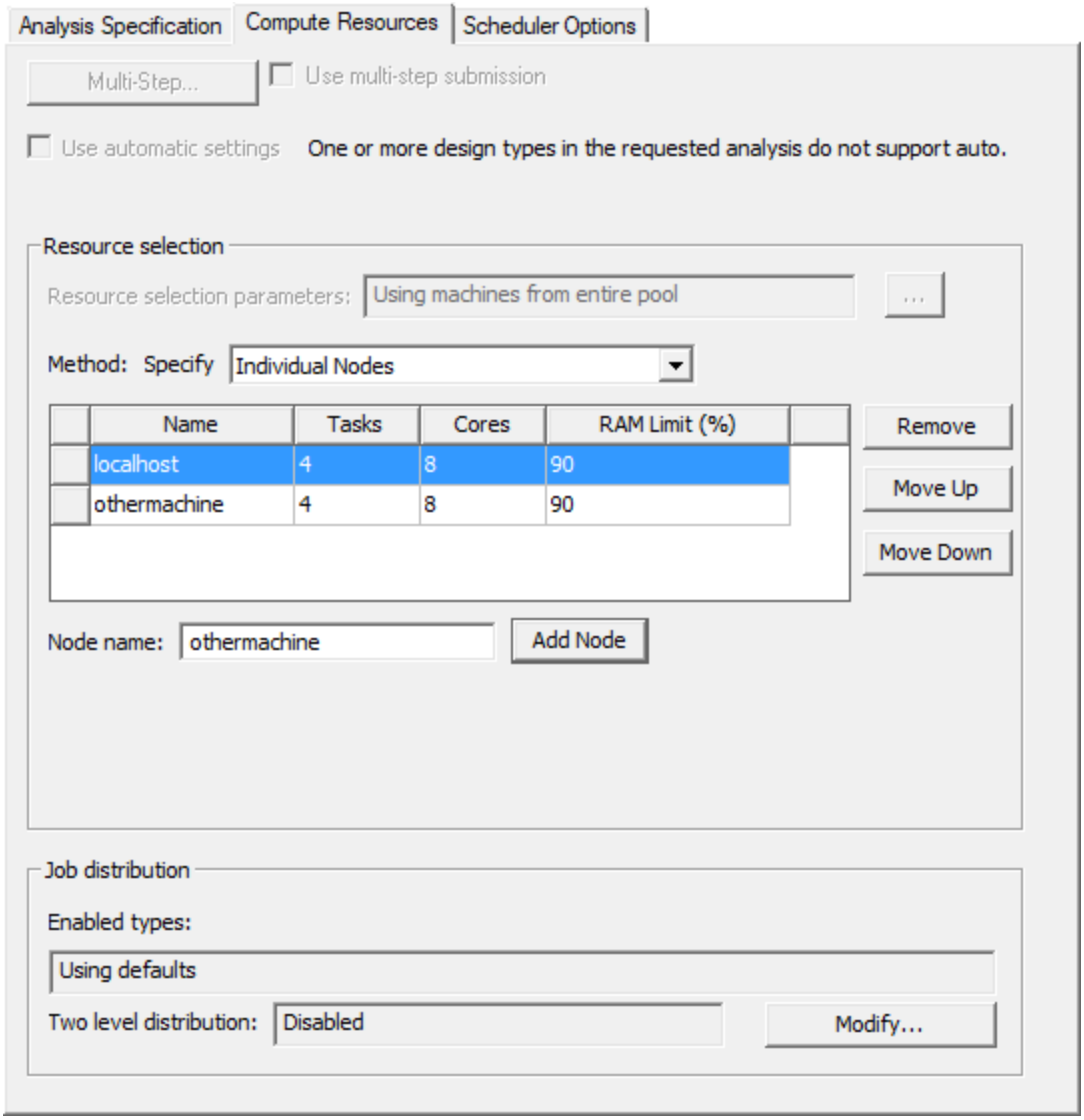
11. Select the **Compute Resources** tab.

    When available, **Use automatic settings** may be selected. If it is selected, also select the Number of variations to distribute.

    The values you specify represent minimal requirements for each condition that can interact in leading to the total resources the Scheduler derives from them. A submission preview shows the number of resources assigned.

    When automatic settings are not available or not selected, additional options appear:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For RSM Large Scale DSO jobs submitted from the Job Submission panel, localhost must be the first node in the resource selection panel. Otherwise, the job will fail.

In the **Job distribution** area, you can enable or disable **Two-level distribution** by clicking **Modify**. See: Two-level Distribution Guidelines.

12. If desired, click **Preview Submission** to view a summary of the commands to be sent to the scheduler. The text can be copied to the clipboard.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

13. To submit the commands to the scheduler, click **Submit Job**.

    > **Note:**
    >
    > The RSM environment does not support queuing, so clicking **Submit Job** starts it immediately.

14. If you enabled job monitoring, you can monitor the job via **Tools> Job Management > Monitor Jobs**. See: Monitoring Jobs.

Large Scale DSO Command Line Syntax

Large Scale DSO operates through a non-graphical batch application called `desktopjob`. You can run the `desktopjob` command line to perform parametric analysis DSO. The command-line interface supported by this batch program is consistent with the command line used for current DSO jobs. `desktopjob -help` lists all available command-line options as shown below:

Command Line Syntax:

```
desktopjob.exe <options> <project-path-on-shared-drive>
```

Note that the project path can be to an archive file.

Options:

- **-help**

  Prints the help text.

- **-cmd**

  Specifies the command to run.

  Available choices: dso

- **-ng**

  Runs the analysis in non-graphical mode.

- **-monitor**

  Outputs progress and messages to standard output/error.

- **-waitforlicense**

  Queues the job until licenses are available.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **-preserve**

  Preserves the local storage space of the distributed job for investigation into the job's run. If local storage directory (for example, the temp directory) is provisioned by scheduler, ensure it is also configured to preserve the job's local storage. *This storage should be deleted manually*.

- **-batchoptions**

  Overrides the Tools/Option entries through either a batchoptions file or batchoptions string.

  -batchoptions specific for Large Scale DSO include:

  To retry failed variations, new batch option LargeScaleDSO/FailedVarRetryCount.

  For each task to re-simulate its failed variations when its assigned variations are finished, specify the FailedVarRetryCount batch option with positive integer. Default 0; Value-Zero(0) will disable the re-simulation for failed variations. Value ranges from 0 or positive integer.

  Redistribution batch option, LargeScaleDSO/VarRedistribution .Value 0 disables redistribution (default). Value 1 enables redistribution.

  Redistribution limit batch option, LargeScaleDSO/RedistributionLimit. Minimum estimated remaining time (in minutes) for variations to redistribute to another task. Value must be positive integer. Default 3 minutes

  Example:

  ```
  -batchoptions <config-file-on-shared-drive>
  -batchoptions "'name1'='val1' 'n2'='v2' "
  ```

- **-jobid**

  Specify a custom job ID for the job. The job's output is organized into a folder with job ID name. This parameter is ignored when run under a scheduler.

- **-machinelist**
  - In the context of **Ansoft RSM**:

    Specify machines for distributed analysis. Machine list is specified either inline (as a comma separated machine names) or through a file. Multiple cores are specified by repeating the name of machine or by embedding number of cores in the machine name, using a colon separator.

    Example 1:

    ```
    -machinelist "list=m1,m1,m1,m2,m2,m3"
    ```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Example 2:

```
-machinelist "list=m1:3,m2:2,m3"
```

Example 3:

```
-machinelist "list=m1:1:3,m2:2:2"
```

Example 4:

```
-machinelist "file=machines.txt"
```

- In the context of **a scheduler such as LSF**:

  Specify the portion of total machines for distributed analysis. Use remaining for overhead or shared memory multiprocessing.

  Manual Example:

  ```
  -machinelist "Num=10"
  ```

  Auto Example:

  ```
  -machinelist "NumCores=40"
  ```

  Note: In a scheduler environment, the machinelist argument can be omitted, but the results may not be as expected or desired. If there is no machinelist argument, the scheduler-assigned resources will be used, assuming one core per task. E.g., if the scheduler assigns 40 cores, there will be 40 variations solved in parallel, with only one core used per variation. Since one core per task may not make sense in many cases or may not be what the user desires, a warning message that machinelist is missing will be output, but the job will proceed.

- **-auto**
  - Run the leaf jobs in auto mode. See Submitting Large Scale DSO Job Examples.
- **-numdistributedvariations**:

  Specify the number of parallel leaf jobs to run in auto mode. Required when running under a scheduler. If not specified when not running under a scheduler, then the number of tasks for each machine must be specified in the machine list. The total number of tasks will be the number of parallel variations (leaf jobs) to run.

  Example:

  ```
  -machinelist NumCores=40 -auto -NumDistributedVariations 10
  ```

- **-usefolderasinput**

  Choose this option if the job's input represents an entire folder rather than just the project file.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **-maxfolderInMB**

  Specify the maximum size input folder that is allowed for a valid job (in MBytes). By default, the maximum size allowed for input is 10MB. Specify a value of 0 to remove this size restriction and enable inputs of any size. This option applies when `-usefolderasinput` is used.

- **-workdir**

  Specifies the shared drive folder for status and result files generated by analysis. By default, the results folder of input project is used as the work directory.

- **-meregecsv: [acrossDPs | singleDP | both]**

  across DPs: Merge report csv files for all design-points (variations). One file is created per trace, across all variations.
  singleDP: Merge csv files within a single design-point (variation). One file is created per variation, per a set of traces that can be merged.
  both: Merge all traces that have the same primary sweep for all design-points (variations) into one csv file.
  Interpolation note: If primary sweep values are not uniformly spaced, mergecsv is enabled with traced values and are re-sampled uniformly using '-batchoptions' syntax as shown below:

  ```
  -batchoptions "'LargeScaleDSO/NumTracePoints'=500"
  -batchoptions
  "'LargeScaleDSO/NumTracePoints'='PrimarySweepName:200'""
  -batchoptions
  "'LargeScaleDSO/NumTracePoints'='ReportName1:Trace1:100;ReportNam
  e1:Trace1:100;ReportName1:TraceName2:200'"
  ```

- **-abort**

  Abort a running job identified through the job's working directory. Example: `-abort <projectresultsfolder-path>/>jobid>`. For a complete discussion of methods for aborting jobs or specific tasks, see the discussion of Aborting a Large Scale DSO Simulation under Large Scale DSO for Parametric Analysis.

- **-repackageresults**

  Choose this option to add simulations results to the input archive file. Note: this option only applies if an archive file is provided as input.

- **-batchsolve**

  Solves the specified parametric setup.

  Syntax for the setup:

  ```
  <design-name>:Optimetrics:<parametric-setup>
  ```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Large Scale DSO Job Outputs

A Large Scale DSO analysis does not support the output of full parametric results. Instead, it extracts a subset of results using predefined rectangular plots, which are created by the user before running the job. The extracted columns of data are saved as CSV files. Typically, there is one CSV file per-trace, per-variation. The outputs can be either imported as datasets for post-processing in the desktop also as function of parametric variations, or used directly in downstream applications (for example, Excel, or custom programs that parse .csv files).

> **Note:**
>
> Non-Rectangular plots of the design (for example, statistical eye and digital plot) are not extracted.

Output Location and Organization

The results of a Large Scale DSO job are located in the `<workdir>/<jobid>/results` folder. If `workdir` is not specified on the job command line, it is same as the input project's results folder. For example, the default `workdir` corresponding to `\\shared\projects\tee.aedt` is `\\shared\projects\tee.aedtresults`. Within this results folder, there is one folder per variation. The name of the variation's folder is an integer number corresponding to variation's index in the parametric table. For example, a variation folder named '4' has results for the fifth row of parametric table, while a variation-folder named '0' has results for the first row of the table. Each variation's folder contains a CSV file for each trace.

CSV File Contents

The initial header rows of the CSV file define the solved variation. For each such row, the first column contains a variable name and the second contains a variable value. The row following variation rows has the name of primary sweep and the name(s) of extracted quantities. Subsequent rows contain data—quantity values as a function of primary sweep.

These examples provide context:

- **Traces of an S-parameter Report** – The data portion of the CSV file contains two columns of data: the first contains Freq values and the second contains values for the trace's s-parameter component.
- **Trace of a Far Field Report** – Suppose there is a far field report with a trace (magrE), whose primary sweep is phi and whose secondary sweep is theta. Further suppose that two values of theta are chosen and all values of phi are chosen. For this trace, the data portion of CSV file contains three columns of data: the first containing phi values, the second containing magrE values for the first value of theta, and the third column containing values for second value of theta. The magrE output columns are titled as 'magrE_crv1' and 'magrE_crv2' respectively.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Advanced Sweeps** – In the case of a trace with special primary sweep (such as the trace of a time domain quantity), one CSV file is created per curve of trace, per variation. These CSV files always have two columns, irrespective of the number of values chosen for secondary/higher sweeps.

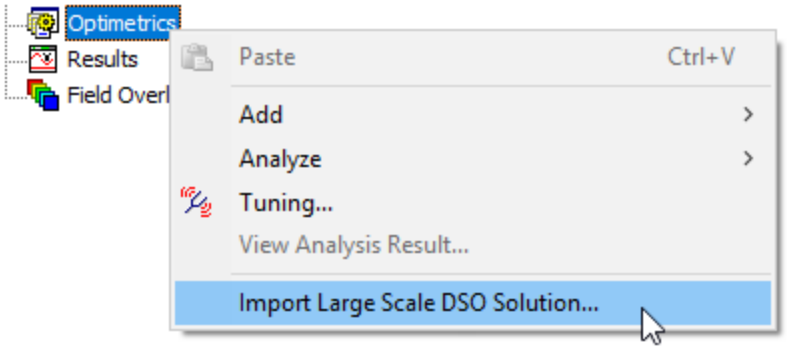
Postprocessing Large Scale DSO Dataset Solutions

In Ansys Electronics Desktop, the **Import Large Scale DSO Solution** command allows you to post-process Large Scale DSO dataset solutions.

Importing a Large Scale DSO Solution

To import a Large Scale DSO solution:

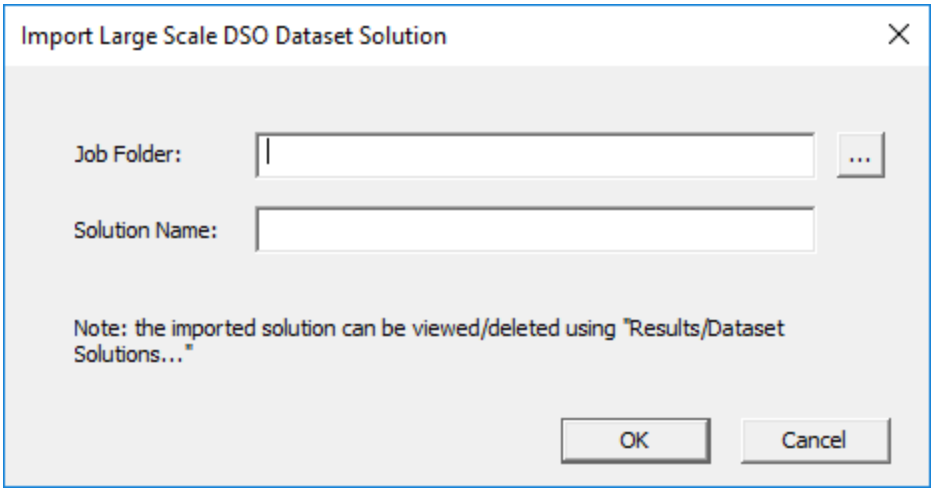
1. In the Project Manager, right-click **Optimetrics** and select **Import Large Scale DSO Solution**.



> **Note:**
>
> You can also access this window by right-clicking **Results** > **Dataset Solutions**.

The **Import Large Scale DSO Dataset Solution** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Click the ellipsis button (**...**) and browse to select a job folder. To select a results dataset, double-click the results folder name. Results folders are organized by the scheduler prefix (for example, RSM) and job number.
3. Click **Open** to return to the **Import Large Scale DSO Solution** window.
4. Review the **Job Folder** path and **Solution Name**, then click **OK**.

   The dataset is imported.

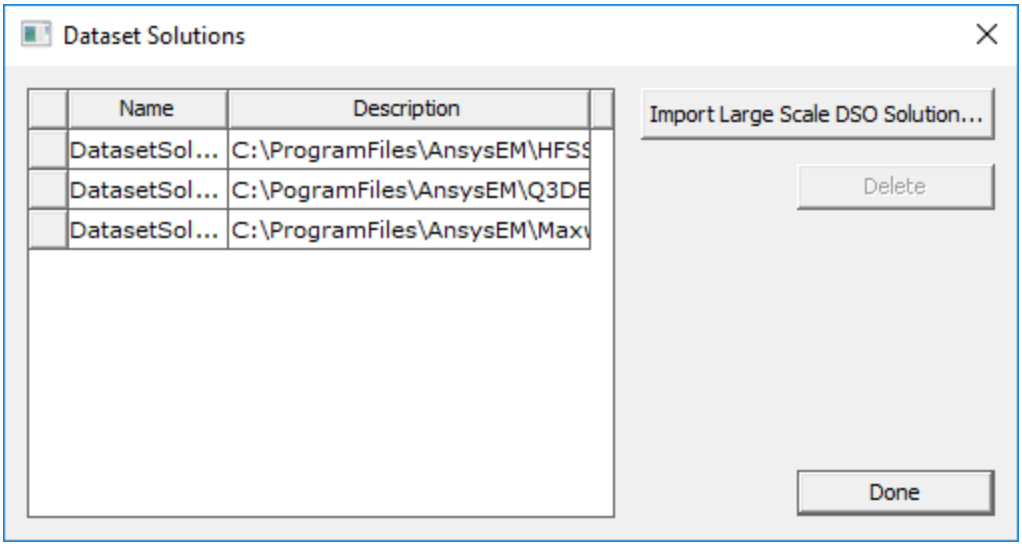
Viewing Imported Solutions

To view a list of imported datasets:

1. In the Project Tree, right-click **Results** and select **Dataset Solutions...**

   The **Dataset Solutions** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Selecting a dataset enables the **Delete** button, which you can click to remove it.

2. Click **Done** to close the window.

Creating a Dataset Report

After importing one or more DSO solutions, you can create a dataset report.

To do so:

1. In the Project Tree, right-click **Results**. Select **Create Dataset Report** > **[Report Type]**.

   The **Report** window for the report type opens. See Creating Reports.

Cloning a Dataset Solution

If you reopen a project that was solved using Large Scale DSO, you can quickly clone the solution report:

1. In the Project Tree, under **Results**, right-click the report and select **Clone from Dataset Solution** > **[Solution Name]**.

   The cloned solution appears. You can now reuse the existing report definition rather than creating a new report.

Large Scale DSO Results Database Organization

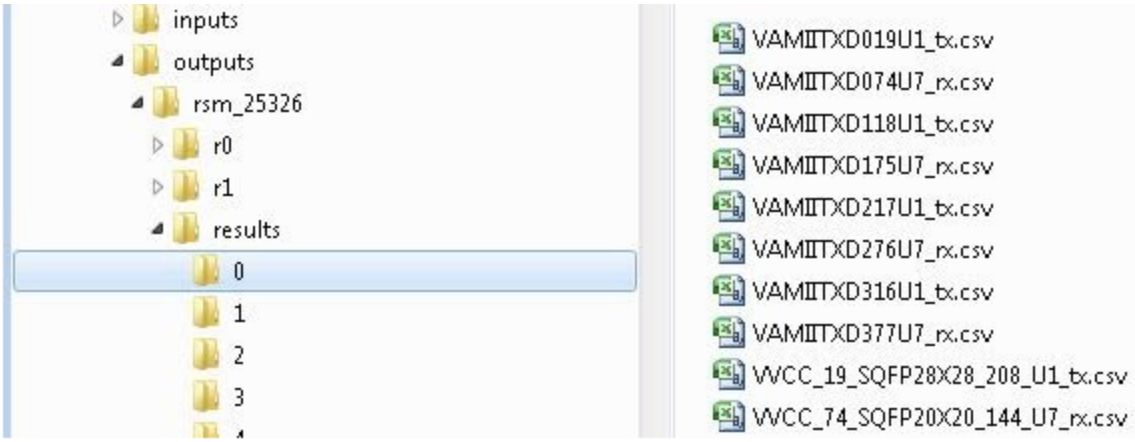
A large scale DSO analysis does not support the output of full parametric results. Instead, it extracts 'subset' results using predefined Rectangular plots, which are created by the user before the job is run. The extracted columns of data are saved as CSV files. Typically, there is

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

one CSV file per-trace, per-variation. (Note: Non-Rectangular plots of the design (for e.g. statistical eye, digital plot) are not extracted)

The results of a large scale DSO job are located in the *<workdir>/<jobid>/results* folder. If 'workdir' is not specified on the job command-line, it is same as the input project's results folder. For example the default 'workdir' corresponding to *\\shared\projects\relay.aedt* is *\\shared\projects\relay.aedtresults*. Within this results folder, there is one folder per variation. The name of the variation's folder is an integer number corresponding to variation's index in the parametric table. For example, a variation-folder named '4' has results for the fifth row of parametric table, while a variation-folder named '0' has results for the first row of the table.

Below is a sample results folder showing the contents corresponding to results of first variation. There are ten CSV files corresponding to ten predefined traces:



Large Scale DSO Job Monitoring

The **Monitor Job window** allows you to monitor the progress and status of Large Scale DSO jobs, including information on variations solved so far, variations currently solving, and the number of variations remaining.

Additional Resources for Large Scale DSO Monitoring

Large Scale DSO avoids detailed intra-variation monitoring, as it increases network traffic for large-scale jobs. Additional monitoring resources include:

- **Cluster Monitoring Tools** – Standard cluster monitoring tools are ideal for job-neutral resource monitoring as they use negligible network bandwidth.
- **Detailed Monitoring of Analysis of a Variation** – For detailed monitoring, you may want to examine a job's log files. Large Scale DSO writes detailed logs about the machines where engines are running and the local storage location of per-engine distributed databases. You can log in to individual machines for deeper probing of each distributed engine.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The following logs are available:

- **Per-Node Logs** – There is one desktopjob.log file per node assigned to the job. This log contains information regarding the node such as name, local storage folder, and number of engines started on this node. It is located in <workdir>/<jobid>/r<nodeIndex>. For example, <workdir>/<jobid>/r0 contains the desktopjob.log corresponding to the engines running on the first node of job, while <workdir>/<jobid>/r2 contains the log corresponding to engines running on the third node.
- **Per-Engine Logs** – There is one desktopjob.log file per distributed engine. It is located in <workdir>/<jobid>/r<nodeIndex>/r<taskIndex>. For example, <workdir>/<jobid>/r0/r0 contains the log corresponding to first engine running on first node, while <workdir>/<jobid>/r1/r2 contains the log corresponding to the third engine running on the second node. Engine unique information (such as local storage of this engine) is logged here.
- **Parametric Analysis Log** – This log file is located in'<workdir>/<jobid>/r<nodeIndex>/r<taskIndex> and corresponds to Desktop's local-machine parametric batchsolve. It is available only at the end of analysis and contains information regarding the variations solved by this engine and any info/warning/error messages.
- **Root Log** – This is the top-level desktopjob.log file that logs job distribution information such as hierarchical activation and the list of nodes assigned to this job.

For a complete discussion of methods for aborting jobs or specific tasks, see the discussion of Aborting a Large Scale DSO Simulation under Large Scale DSO for Parametric Analysis.

Large Scale DSO Deployment/Configuration

LINUX Cluster Configuration

- 'Temp directory' configuration.

  Temp directory is either on 'local storage' or on storage that has equivalent speed characteristics. The I/O rates of the storage should be invariant to network traffic

  Temp directory on a host has sufficient space to hold results database for the variations that are solved on it. (Note: This storage is freed at the end of the analysis.)

  The amount of required space depends on the number of engines per node and the cumulative variations solved on this node

  The amount of required space depends on the project's compression-options. For example, if 'Save Fields' of a parametric setup is OFF, the space requirement is smaller by the amount of space taken up by field solution data.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Ansoft RSM environment: In the case of supported scheduler environments, there is no extra configuration needed. In the case of Ansoft RSM environment, following additional steps are needed:

  Ansoft RSM must be running on all the nodes of cluster. The credentials of 'RSM service' allow read/write to shared drive. Reason: the remote engine processes are launched using the credentials of RSM service

  Registration of 'desktopjob.exe' with RSM service: 'desktopjob' program must be registered with Ansoft RSM using 'desktopjob -regserver". To ensure that the registration is successful, check that the 'desktopjob' entry in '<RSM-installation-folder>/AnsoftRSMService.cfg' file is valid.

> **Note:**
>
> LINUX specific critical note: Edit AnsoftRSMService.cfg and replace 'desktopjob.bin' with 'desktopjob'

Major limitation: In the Ansoft RSM environment, Large Scale DSO can only be enabled for one product.

Troubleshooting hints (Ansoft RSM environment only): "shared drive read/write" requirement is a new constraint introduced in Large Scale DSO. So if user runs into a situation where Regular DSO jobs run and Large Scale DSO jobs fail, one possible cause for the failure: RSM service does not have privileges to read and write to project folder located on shared-drive.

Windows Cluster Configuration

All the above steps apply, except for steps that are stated as LINUX-specific. Additional instructions:

- Ansoft RSM and Ansys Electromagnetics products are either installed locally on each node of cluster OR installed on a single shared-drive available to all nodes of cluster.
- Registration of 'desktopjob.exe' with RSM service.
- Network installation: desktopjob.exe is registered with RSM service once, on any of the nodes of cluster
- Local installation: Since each node has it's own RSM installation, desktopjob.exe must be registered with RSM on each node.

> **Important:**
>
> Ansoft RSM service must be started using the credentials of a non-system 'admin' account, which has read/write permissions to project's shared drive. If RSM service runs as 'system' user, large-scale-dso jobs will fail

Heterogeneous Cluster configuration

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Limitation: Currently heterogeneous cluster (with both linux and windows nodes) is not supported. This is due to the shared drive requirement.

Large Scale DSO Tutorial Example

> **Note:**
>
> Functionality featured in the example(s) in this section applies to multiple design types.

This section provides an example of the use of Large Scale DSO to distribute parametric variations of an HFSS model across the nodes of a cluster or to multiple cores of a single machine.

This example presumes that your configuration satisfies the Prerequisites for Large Scale DSO. For this example, pre-suppose that we have a Windows cluster. Further suppose that the shared drive folder, which contains the input projects and computed results is at the location *\\sjo7na1\hfssprojs*.

Major steps for Large Scale DSO Example

1. Prepare the model for Large Scale DSO Analysis
2. Submit the Large Scale DSO Job
3. Post process the results

Prepare the Model for Large Scale DSO Analysis

> **Note:**
>
> Functionality featured in the example(s) in this section applies to multiple design types.

1. Launch the desktop.
2. Create the input project on the shared drive.

   For this example, start with the standard HFSS OptimTee.aedt example and copy it to the shared drive.

   Copy "<installation-directory>\<platform>Examples\RF_Microwave\OptimTee.aedt" to "\\sjo7na1\hfssprojs\OptimTee.aedt"

3. set up the parametric table.

   For this example, use the existing 'ParametricSetup1' as the parametric setup to solve.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Prepare the outputs.

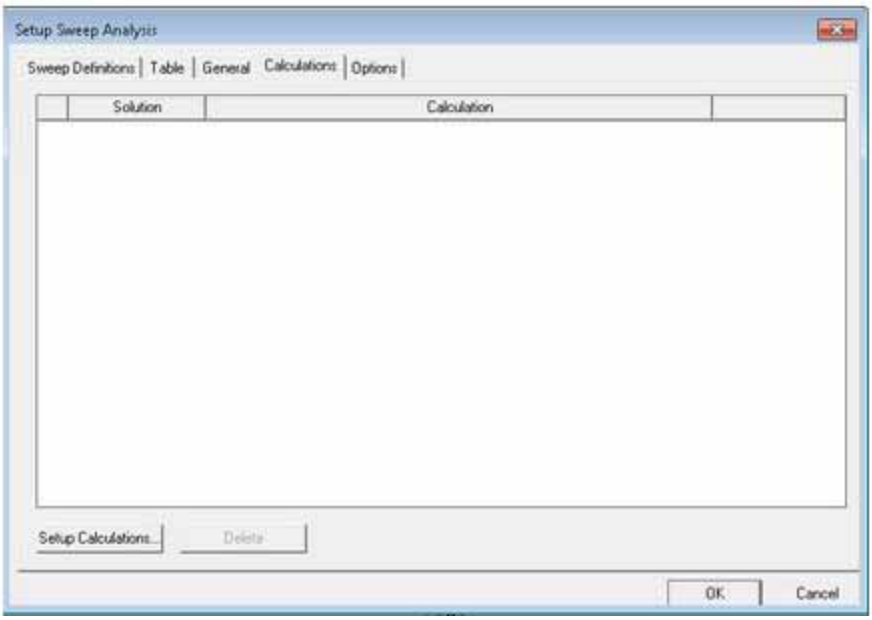
   Outputs from Large Scale DSO come from pre-defined rectangular plots that are created before the Analysis command is issued. Follow the steps below:

   a. Because these DSO outputs come solely from Rectangular Plots, delete all other postprocessing setups, and then turn off Save Fields And Mesh as shown below.

      Open ParametricSetup1 for editing. You will see that the OptimTee parametric setup contains three calculations, as shown below.

   b. Delete all three calculations. When you have done so, the Setup Sweep Analysis Calculations tab looks like this:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



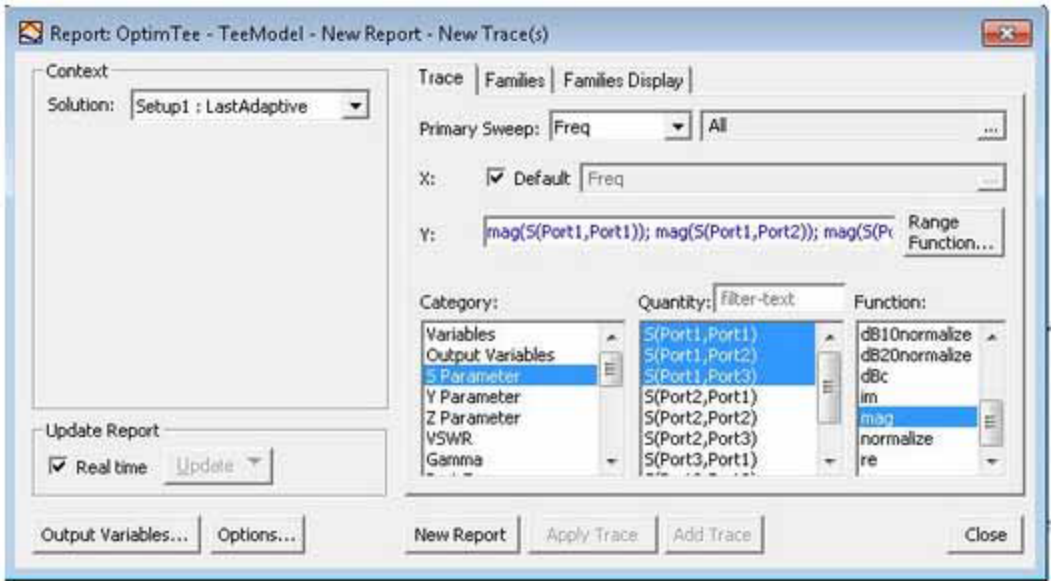
c. Click on the **Options** tab and uncheck Save Fields And Mesh, as shown below:

5. Use the Reporter to define outputs.

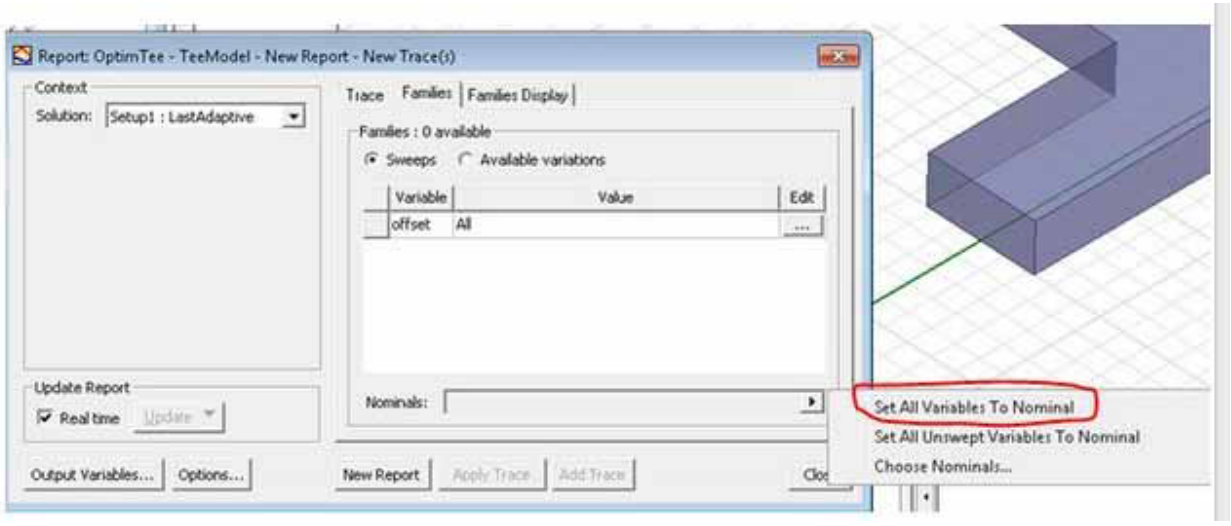
   For this example, you add six traces that correspond to six csv outputs of the Large Scale DSO job: mag(S11), mag(S12), mag(S13), Power11, Power12, and Power13.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. As shown below, select three quantities: mag(S11), mag(S12), and mag(S13).



b. Click on the Families tab and ensure that all variables are set to Nominal, as shown below.



Note:

For Large Scale DSO, outputs are not extracted correctly unless all variables on the **Families** tab are set to nominal.

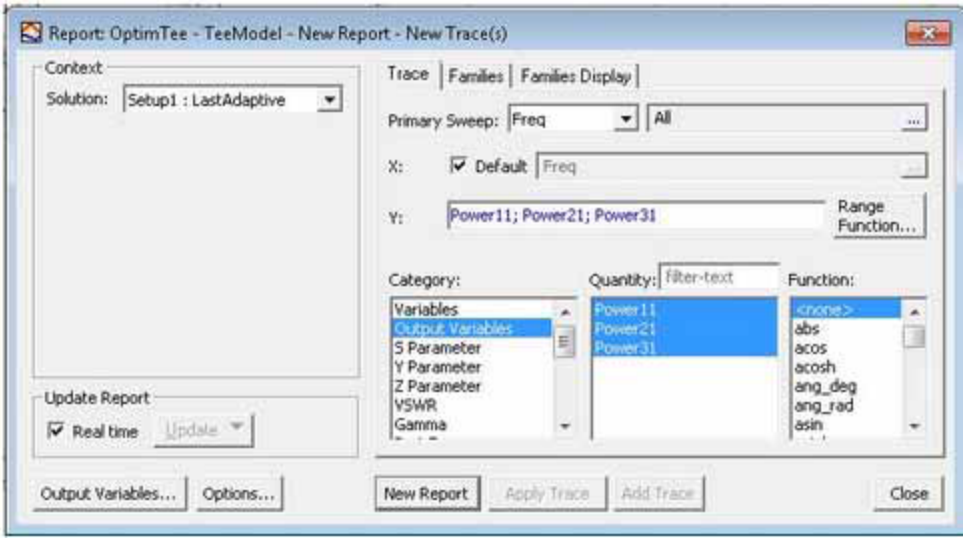
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. Click the **New Report** button.

   Use the Report to create a Power distribution plot that has three power distribution traces.

d. To create an S-parameter plot that has three traces, click **Results> Create Modal Solution Data Report> Rectangular Plot**.

e. As shown below, select three quantities, Power11, Power21, and Power31.

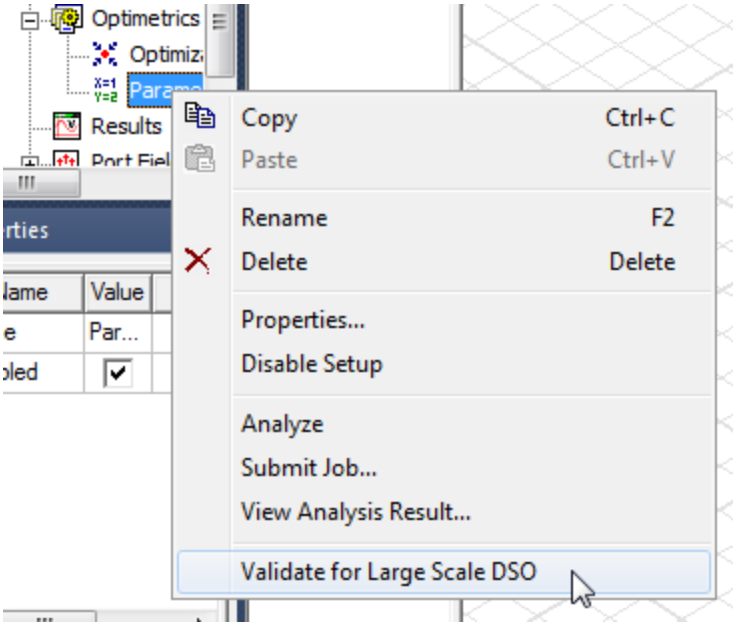


f. Click on the Families tab and ensure that all variables are set to Nominal.

g. Click the **New Report** button.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. Right-click the parametric sweep, and select Validate for Large Scale DSO.



7. A dialog reports any errors. These may occur if the steps just taken are neglected:

   ```
   [error] Please remove all the calculations in Parametric Setup/Calculation page.
   ```

   ```
   [error] Please turn off "Save Fields And Mesh" in Parametric Setup/Options page.
   ```

   ```
   [error] No rectangular plot exist in the design. Please create a rectangular report.
   ```

8. Correct any errors, if necessary to pass validation.
9. Save and Close the project.

Next

Submit the Large Scale DSO Job: Examples

Submit the Large Scale DSO Job: Examples

This section includes examples of submitting a Large Scale DSO job using Ansoft RSM and a Scheduler.

> **Note:**
>
> Functionality featured in the example(s) in this section applies to multiple design types.

Using the Ansoft RSM Environment

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Before submitting the job make sure that the input project is not open in any Ansys Electronics Desktop window.
2. For this example, suppose that there are two quad-core machines on your cluster with the names "m1" and "m2". Further suppose that there are two engines per machine, for a total of four parallel engines. Let the number of processors allocated to each engine be 1.
3. From a command prompt, issue the following command:

   ```
   "<installation-directory>\ANSYS
   Inc\v251\AnsysEM\desktopjob.exe" -cmd dso -machinelist
   "list=m1:2,m2:2" -batchoptions
   \\sjo7na\aedtprojs\hfssoptions.txt -batchsolve
   "TeeModel:Optimetrics:ParametricSetup1"
   \\sjo7na\aedtprojs\OptimTee.aedt
   ```

   where the file \\sjo7na\hfssproj\hfssoptions.txt has the following contents:

   ```
   $begin Config
     'Desktop/Settings/ProjectOptions/NumberOfProcessors'=1
     'HFSS/Preferences/SaveBeforeSolving'=0
     'HFSS/Preferences/HPCLicenceType'='pack'
   #end 'Config'
   ```

4. Suppose the above job is assigned ID "jobID".

Using a Scheduler Environment (such as LSF)

1. Suppose you want to solve variations using four parallel engines, each engine being assigned a single core.
2. From a command prompt, run the following command:

   ```
   bsub -n 4 "<installation-directory>\ANSYS
   Inc\v251\AnsysEM\desktopjob.exe" -cmd dso -batchoptions
   \\sjo7na\hfssprojs\hfssoptions.txt -batchsolve
   "TeeModel:Optimetrics:ParametricSetup1"\\sjo7na\hfssprojs\Opti
   mTee.aedt
   ```

   where the file \\sjo7na\hfssproj\hfssoptions.txt has the same contents as the RSM example above.

3. Suppose the above job is assigned an ID "jobid"

For example with 2 nodes of 44 cores each (with multiple distributed variations per machine):

MANUAL: `bsub -n 88 <installation-directory>\v<version>\<platform>\desktopjob -cmd dso -machinelist num=8 -monitor -useelectronicsppe=1 -ng -batchoptions " 'Maxwell 3D/NumCoresPerDistributedTask'=11 'Maxwell 3D/RAMLimitPercent'=90`

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
'HPCLicenseType'='Pack'" -batchsolve
TeeModel:Optimetrics:ParametricSetup1 OptimTee-v232-1.aedt
```

AUTO: `bsub -n 88 <installation-directory>\v<version>\<platform>\desktopjob -cmd dso -machinelist numcores=88 -auto -NumDistributedVariations 8 -monitor -useelectronicsppe=1 -ng -batchoptions " 'Maxwell 3D/RAMLimitPercent'=90 'HPCLicenseType'='Pack'" -batchsolve TeeModel:Optimetrics:ParametricSetup1 OptimTee-v232-1.aedt`

For example, with 16 nodes of 44 cores each (note each distributed variation will span 2 machines):

AUTO: `bsub -n 704 <installation-directory>\v<version>\<platform>\desktopjob -cmd dso -machinelist numcores=704 -auto -NumDistributedVariations 8 -monitor -useelectronicsppe=1 -ng -batchoptions " 'Maxwell 3D/RAMLimitPercent'=90 'HPCLicenseType'='Pack'" -batchsolve TeeModel:Optimetrics:ParametricSetup1 OptimTee-v232-1.aedt`

Next

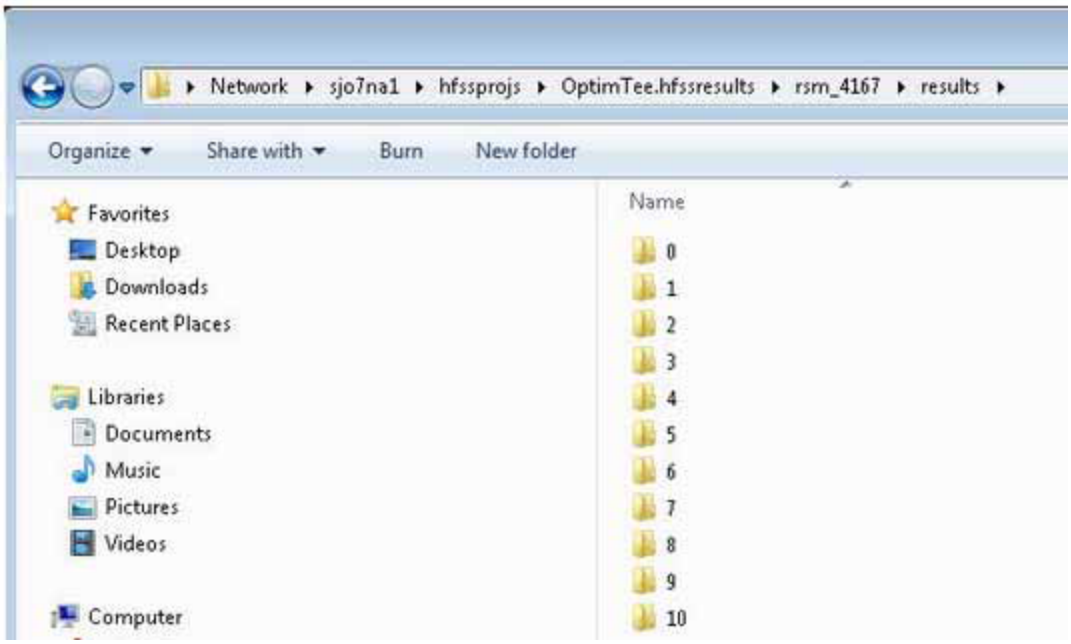
Large Scale DSO Example: Post Process the Results

Large Scale DSO Example: Post Process the Results

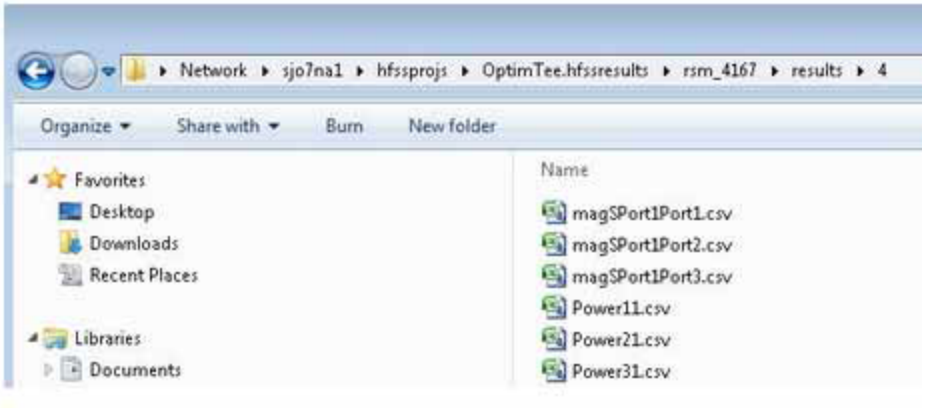
Once the job is done, output is available in the ~\OptimTee.aedt\jobid\results folder. Each variation creates a subfolder, which in turn has one csv file per trace of each report. See the detailed information regarding job monitoring and the location of the analysis logs.

The following figure shows the results for 10 variations as located in 10 folders.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



There are six csv files corresponding to three S-parameter traces and three power distribution traces, as shown below for the fourth variation.

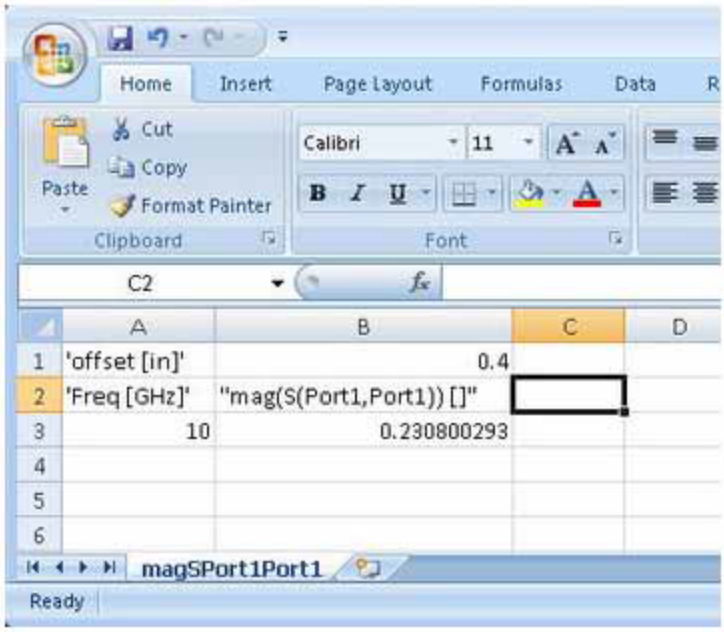


You have three options for postprocessing csv files.

- Import Large Scale DSO Dataset Solution
- Use Microsoft Excel or any other application that has csv post processing functionality.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

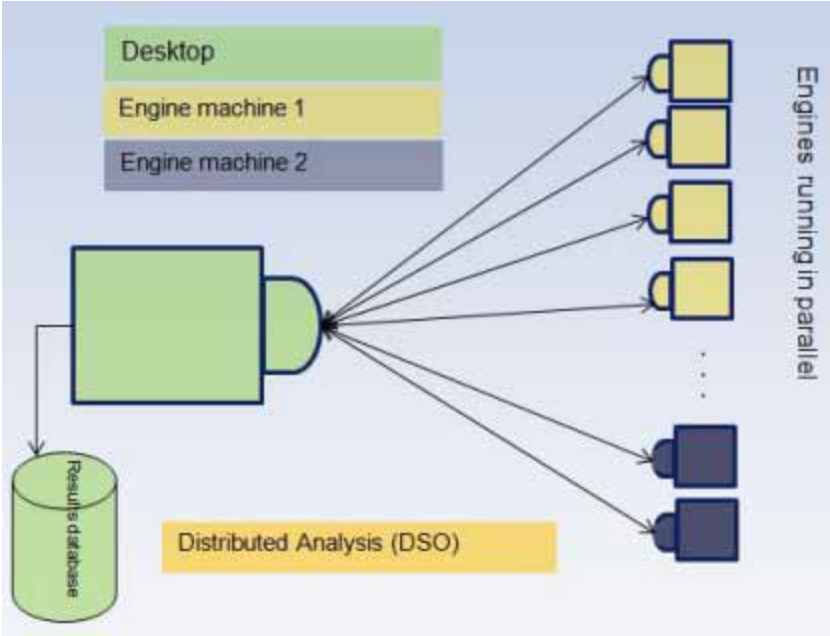
- Parse the csv output into your custom program, for any downstream flow.



Large Scale DSO Theory

The parametric analysis command in Desktop computes simulation results as a function of model parameters, such as geometry dimensions, material properties and excitations. The parametric analysis is either performed on a local machine, where each variation is analyzed serially by a single engine, or distributed across machines through a DSO license. Desktop's DSO analysis runs multiple engines in parallel, thus generating results in a shorter time. In the Regular DSO algorithm, the parametric analysis job (Desktop) runs on master node, which in turn launches one or more distributed-parallel engines on each machine allocated to the job. Desktop distributes parametric variations among these engines running in parallel. As variations are solved, the progress/messages and variation results are sent back to Desktop, where they are persisted into the common results database on master node, as illustrated below:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



A single engine can now span multiple machines with auto multi-level DSO.

Regular DSO Bottleneck

As per above illustration, Regular DSO's speedup is limited by the resources of the centralized 'Desktop' bottleneck. It's been observed that DSO becomes unreliable at a certain point, as the number of engines and number of variations is increased. The term 'large scale parallel' can be used to define this tipping point. For a given model, a 'large-scale parallel' job denotes scenarios, in terms of the number of distributed-parallel engines and the number of parametric variations, where the Regular DSO runs into centralized bottlenecks that result in one or both of: progressively smaller speedups, unreliability.

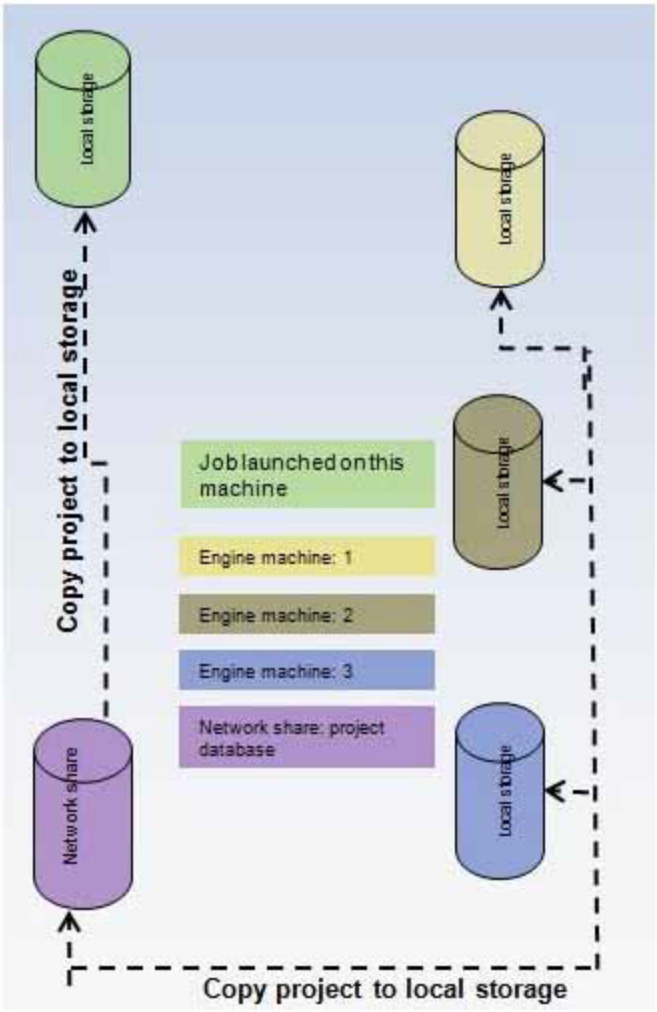
With the advent of economical availability and timely provisioning of compute resources, product designers have access to large compute clusters to run their simulations. And they are throwing larger and larger number of compute resources at simulation jobs, in order to obtain results faster. The parametric DSO needs to meet this challenge and target linear speedup for 'large-scale parallel' jobs. The Large Scale DSO feature is targeted toward 100% reliability and linear speedup of large-scale parallel DSO jobs.

Key Algorithms/Concepts for Large Scale DSO

- **Embarrassingly Parallel algorithm**: Large Scale DSO exploits the embarrassingly parallel nature of parametric runs. The solve of each variation is made fully independent of another variation, by replacing Regular DSO's centralized database with per-engine distributed databases
- **Distributed databases**: For each distributed-parallel engine, the database of the input model is cloned to local storage of engine's compute node (as illustrated in the following

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

picture). Parallel analysis is performed on these cloned models and the analysis results also go the corresponding location on local storage. As each engine has it's own database, there is no 'shared database' contention between any two engines. There is negligible network traffic as analysis/computations are contained in a single machine and use just the 'local resources'.



- **Hierarchical activation of engines**: In the Large Scale DSO algorithm, engine activation is done hierarchically, where the overhead of launching of engines is also shared across the nodes. Such hierarchical activation improves reliability of the activation phase of large-scale parallel jobs. A new 'desktopjob' program encapsulates hierarchical activation, as illustrated in the following pictures. In this approach, the 'root' desktopjob (Root DJ) activates a 'level-one' child desktopjob (DJ(L1)) for each unique node allocated to the DSO job. Each level-one desktopjob activates one or more 'leaf' desktopjobs (DJ(L2)) equal to the number of distributed engines per node. A leaf desktopjob in turn runs Desktop in batch mode, to perform local-machine parametric analysis to solve the variations assigned to this engine.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Decentralized Load balancing:** A parametric table is divided into regions of equal number of variations, with the number of regions equal to the number of engines. In the following illustration, the analysis of 30 parametric variations is distributed among 5 engines. Each engine solves it's assigned region as a 'local machine' parametric analysis. Large Scale DSO job is considered done once all engines are done with their assigned variations.
- **Distributed results postprocessing**: As engine is done with the solve of a variation, it extracts results for the solved variation before progressing to the analysis of next variation. The extracted results are saved to the local storage. When the engine is done with analysis of all variations, the extracted results are transferred from local storage to the results folder of the input project.

Redistribution Feature

Large Scale Distributed Solve Operation could submit a parametric setup to be solved in multiple machines, each machine may launch multiple EM-Desktop processes to solve the assigned variations(Design Points). Variations are distributed to each task(EM-Desktop process) equally, regardless of the machine hardware and each variation's complexity. That may resultin some tasks finishing earlier than others, in some extreme case some tasks may hours behind fastest task.

Now, redistribution occurs when a task finished its own assignment, it calls back to the L2 to ask for new assignment, L2 forward the request to L1, L1 forward it to L0, L0 may pick one of the slow task to remove some variations or return with no more assignment. When a task is picked to remove unsolved variation, L0 calls L1(may be different L1), L1 forward it to the selected L2, L2 makes a request to the EM-Desktop to remove some variations from its queue. EM-Desktop returns the removed variation indexes, or error code if it fails. In L0 if error is returned, it marks the selected task failed to respond the remove request, to void picking it again. L0 returns the result through L1-L2 back the EM-Desktop.

The Ansys Electronics Desktop will enqueue the new assignment and then start solving those new variations. If the return data indicates error, it makes another call to L2 to get new assignment. If no more variations return, the Ansys Electronics Desktop finishs the simulation and exit.

Large Scale DSO Known Issues/Troubleshooting

Node Order

For Large Scale DSO jobs that are submitted from job submission panel using RSM, localhost must be the first node in the resource selection node list, otherwise Large Scale DSO solve with RSM will fail. Set the order in the **Submit Job To** window, **Compute Resources** tab:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	Name	Tasks
	localhost	1
	othermachine	1

Parallel Task Limitation for LS-DSO Parametric Variations

There some limitations of running short parametric runs in parallel and using a subset of cores and/or running across multiple machines instead of just one. LS-DSO does help in getting close to linear scalability for parametric runs in many scenarios, it has some overheads and typically they are small in comparison to total time of run. However, a few factors in particular scenarios can make them prominent.

The startup of each task involves copying the project and launching ansysedt to solve a subset of parametric table. Typically, one task solves several variations and this startup cost is negligible in comparison to total time. Consider a case where each task is solving only single variation. Additionally the actual solve time of one variation is relatively small, 3-5 minutes. These factors make the startup cost significant. There is also some variance in solve times of different variations. When all variations are solved in parallel, the total time is determined by slowest variation, even though the expectation intuitively might be relative to average time. That could make the perception of overhead worse in this case.

Another important factor is the number of parallel tasks on each machine relative to the total number of cores on the machine. Each task is effectively running an ansysedt of its own and solving subset of parametric table on a copy of project. The solve process does involve significant disk IO. If you run too many tasks on a single machine, they may end up competing with each other for single disk, and that could cause them to slowdown. The conflict in memory access may also become a factor.

In a particular case, 26 tasks were run on one 26 core machine, and this caused significant slowdowns. Spreading the tasks across machines helped scalability as an example with a 32 core machines in a Linux Cloud, we ran this job with 26 tasks on a single machine and then another one over two machines with 13 tasks per machine. The single machine job finishes in about 14 mins, while the job on two machine finishes in about 8.5 mins. This indicates that spreading tasks across machines helps with scalability by minimize file read/write conflicts.

Job Restart

There is no provision for stopping and restarting a job. A new job does not reuse solved results; it always solves all rows in the table. An abort or failure of a job restarts from the beginning, unless a new parametric table with the unsolved rows is created.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Linux-Only Issues

- Deployment/Installation errors (such as mainsoft-related) are not captured. If there is such an issue, the Large Scale DSO job will fail without useful messages in the logs.
- Report-based extraction fails if traces and parametric-setup are not prepared as per the Getting Started guides.
- Job status: The exit code of job doesn't indicate success or failure correctly. The error messages from multiple log files needs to be combined to determine the reason for failure. In many situations, the reason for a failure is apparent only after re-running the job after turning ON the 'debug logging'.
- In some LINUX scenarios, the analysis appears to finish successfully with valid results, except that the exit code is '134'. In this case, although the exit is abnormal, the failed exit code can be ignored.
- Load Balancing: For models with 'unbalanced variations table' (variations that take considerably different amount of time to solve are clustered in few regions of table), job will take longer time to solve than a Regular DSO as the job's overall completion time is determined by the slowest solving region. Workaround: rearrange the rows in the parametric table so that each region takes a similar time to solve.
- GM Specifics: the model used for 'Report-based extractor' jobs is NOT compatible with the 'Ansys-extractor-for-GM' jobs. A valid model for Ansys-extractor-for-GM cannot contain any of: reports, overlay plots, Optimetrics calculations.

Interactive Scheduler Jobs

This document includes information, guidelines, and caveats for users running interactive scheduler jobs on Linux.

In most cases, jobs run under a scheduler run as a batch job. These jobs may be submitted using the Ansys Electromagnetics Desktop job submission GUI, using cluster job submission commands on a command line or using a cluster GUI, if available.

Some customers use an alternative method for submission of scheduler jobs. For convenience, we call such jobs "interactive scheduler jobs." In this approach, the user submits an interactive job to the scheduler. From the interactive job prompt, the user launches an Ansys Electromagnetics Desktop product, which starts in interactive (GUI) mode, not batch mode. The user selects a project and then runs one or more analysis commands using the GUI. The intent is that these analysis commands should use all resources allocated to the job, whether on the same host as the GUI or on other hosts.

This approach is supported on Linux, where the user may set up an X Window System server for interacting with the Ansys Electromagnetics Desktop product GUI. The user needs to configure

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the cluster environment and/or the interactive environment so that the user may view and interact with the product GUI. This approach is not supported on Microsoft Windows.

Specifying Options for Interactive Scheduler Jobs

DSO Configuration for Interactive Scheduler Jobs

Design Type Options for Interactive Scheduler Jobs

Specifying Options for Interactive Scheduler Jobs

Batch scheduler jobs use command line options for specifying options rather than GUI controls. For interactive scheduler jobs, options may be specified on the command line, using GUI controls, or obtained from the registry. The machines specified in the **Configurations** tab of the **HPC and Analysis Options** window will be ignored for interactive scheduler jobs. If the command line used to launch the product contains a list of specific machines (using option -machinelist list=...), then the job will use the specified machines and cores. If the command line used to launch the product does not contain a specific machine list, then the machines and cores allocated to the job by the scheduler will be used for the job. In general, the job distribution settings for interactive scheduler jobs should be specified on the command line, instead of using the **HPC and Analysis Options** window.

- The UI shows the settings that will be used for analysis, even if they come from the command line, not the registry.
- If you make changes to the settings in the UI, and the changed settings will be used for the analysis, even if the changed settings conflict with the command line (including batchoptions).
- If you makes no changes to the settings in the UI, then the command line settings (including batchoptions) will be used for analysis.

Batchoptions settings that are automatically generated for batch jobs submitted using the AnsysEM job submission GUI will need to be manually included in the product command line. Some use cases require that certain settings be made on the command line when the product is launched, rather than using the GUI.

Batchoptions for Interactive Scheduler Jobs

> **Note:**
>
> Functionality featured in the example(s) in this section applies to multiple design types.

For interactive scheduler jobs, only a limited set of batchoptions are supported. These batchoptions include the DSO configuration options, the design-type-specific options, and the following additional design-type-specific options that are not currently listed in the user interface or command line help windows:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **CreateStartingMesh:** Create the starting mesh only. Do not solve any other steps. Often used for multi-step jobs where the mesh creation is solved in a separate step using fewer resources than the rest of the analysis.
- **NumCoresPerDistributedTask:** Specifies the number of cores that are allocated to the job to use for each distributed task, used when running jobs under a scheduler. The scheduler communicates the number of cores allocated to the job on each host. This setting is used to determine how to allocate the cores to each task.
- **RAMLimitPercent:** Specifies the percentage of system RAM that the analysis is expected to use on each host. Running out of memory can cause processes to be killed by the Operating System or other failures. The analysis will be gracefully terminated if it requires more than this limit. Typical limits are about 90%, to allow some RAM for the Operating System and other services. If there are multiple jobs running on a single host, then the RAM limit should be reduced accordingly. For example, if there are two jobs running on a host, then the limit could be 45%, which would allow 10% of the RAM for the Operating System and other services.
- **RAMLimitPerCoreInGB:** This is an alternative way to specify the RAM limit, instead of using the RAMLimitPercent. In this case, the RAM limit is the limit per core multiplied by the number of cores allocated to the job on each host. Typically used for jobs running under a scheduler to ensure that the scheduler memory limit and the ansysedt memory limit are consistent.
- **SolveAdaptiveOnly:** Solve adaptive passes only. Do not solve any other steps. Often used for multi-step jobs where the adaptive passes are solved in a separate step using fewer resources than the rest of the analysis.
- **TotalNumOfCores:** The total number of cores for the job. This option is only used for EKM (Engineering Knowledge Manager).
- **ValidateOnly:** Only validate the specified setup, design, or project. Do not analyze the specified setup, design or project.

Any other batchoptions will result in a warning message and will be ignored.

Command Line Example:

```
desktopjob.exe" -cmd dso -jobid RSM_27086 -machinelist
list=localHost:2:2:90%
-monitor -ng -batchoptions "
'LargeScaleDSO/MergeCsv'='acrossDPsAndTraces'"
-batchsolve TeeModel:Optimetrics:ParametricSetup2 E:\work\2018\LS_
DSO\OptimTee.aedt
desktopjob.exe" -cmd dso -jobid RSM_25248 -machinelist
list=localHost:2:2:90%
-monitor -ng -batchoptions "
'LargeScaleDSO/MergeCsv'='acrossDPsByRow'"
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
-batchsolve TeeModel:Optimetrics:ParametricSetup2 E:\work\2018\LS_
DSO\OptimTee.aedt
ansysedt -batchoptions " 'TempDirectory'='C:\\TEMP'
'HFSS/SelectedDSOConfiguration'='Local'
'Desktop/Settings/ProjectOptions/DoAutoSave'=1
'LargeScaleDSO/MaxFolderInMB'=100 "
```

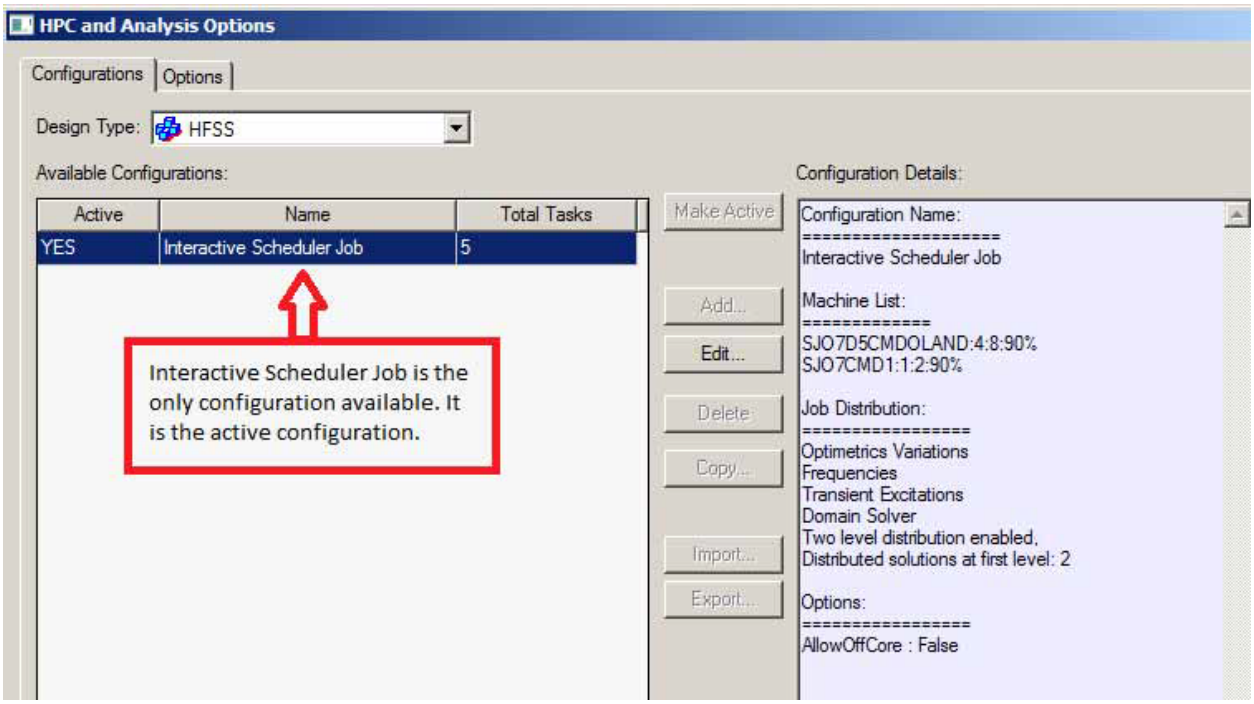
DSO Configuration for Interactive Scheduler Jobs

> **Note:**
>
> Functionality featured in the example(s) in this section applies to multiple design types.

When running an interactive scheduler job, there is only one DSO configuration available for each design type. Each configuration is named "Interactive Scheduler Job". This configuration is always the active configuration for an interactive scheduler job. and it is the only configuration displayed in the list of available configurations shown in the "HPC and Analysis Options" dialog box. No configurations can be added or removed, but the "Interactive Scheduler Job" configuration may be modified using the "Edit" button, which pops up the "Analysis Configuration" dialog.

Because the "Interactive Scheduler Job" configuration is the only configuration accessible for interactive scheduler jobs and it is not accessible in other modes, there is no sharing of the "Interactive Scheduler Job" configuration settings with other modes.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



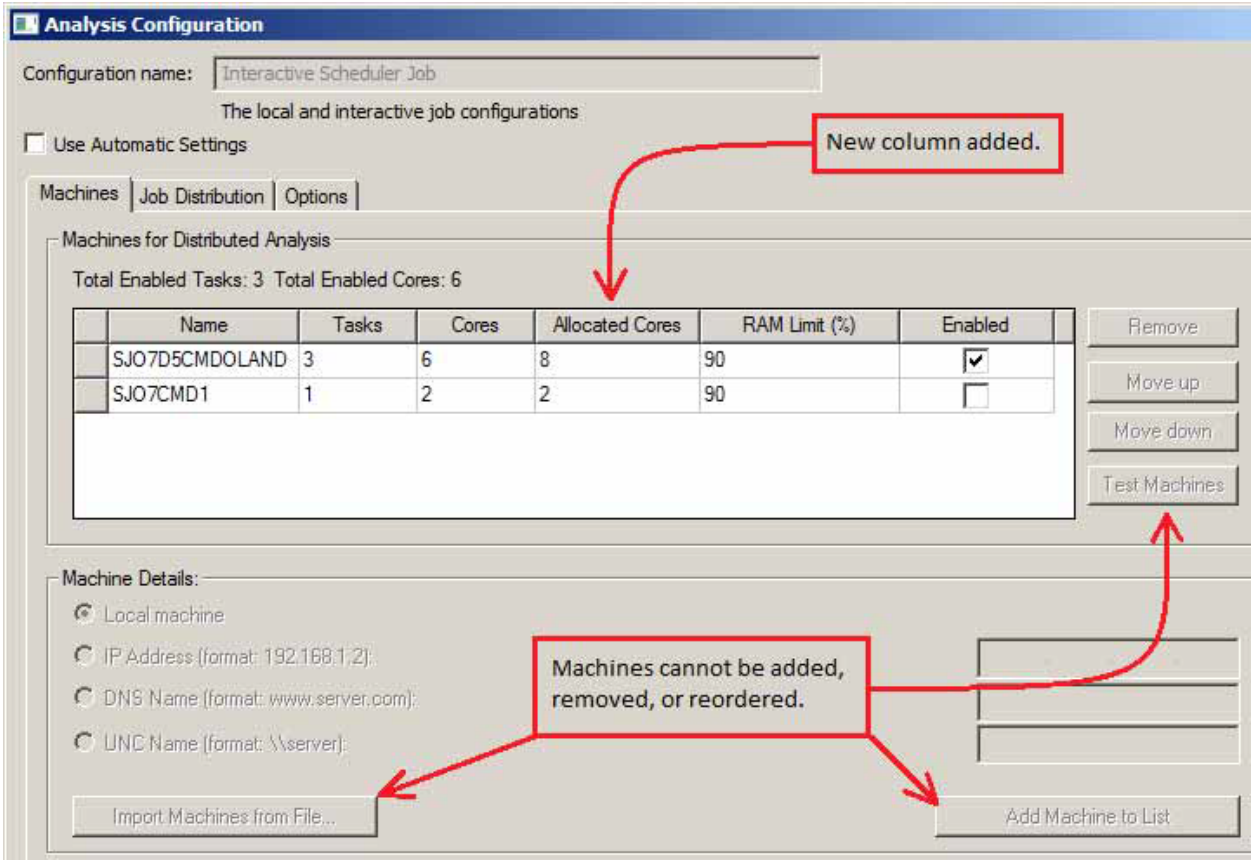
One major difference between interactive scheduler mode and batch mode or normal interactive mode is:

- In interactive scheduler mode, DSO configuration settings and design type options in the UI override command line options and batchoptions.
- When not in interactive scheduler mode, DSO configuration settings and design type options specified on the command line (including batchoptions) override UI settings.

Analysis Configuration - Machines Tab

The most obvious changes for interactive scheduler jobs are visible in the **Machines** tab of the **Analysis Configuration** window. The grid of machine information is prepopulated with the list of machines allocated to the job. It also contains an additional column in interactive scheduler mode. This column, "Allocated Cores", indicates the number of cores allocated to the job by the scheduler on each host. You cannot add or remove machines from the list, or modify the allocated cores for any machines. You can modify the tasks, cores, and RAM limittasks and cores for any machine, or specify that a machine is enabled or disabled.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Analysis Configuration - Job Distribution Tab

The **Job Distribution** tab of the **Analysis Configuration** window only appears if the **Use Automatic Settings** check box is not checked. The state of this check box, and the settings shown on this tab are initialized from the command line or from the registry. The command line options that affect the **Use Automatic Settings** check box or the job distribution settings are:

- -distributed
- -local
- -auto
- -machinelist

The registry contains the last value of these settings for an interactive scheduler job for the same user on the same host. Settings on the command line override settings from the registry. Any changes in the GUI will override the initial settings, even if the initial settings are from the command line. Any changes in the GUI also update the registry settings for the "Interactive Scheduler Job" configuration for the current design type.

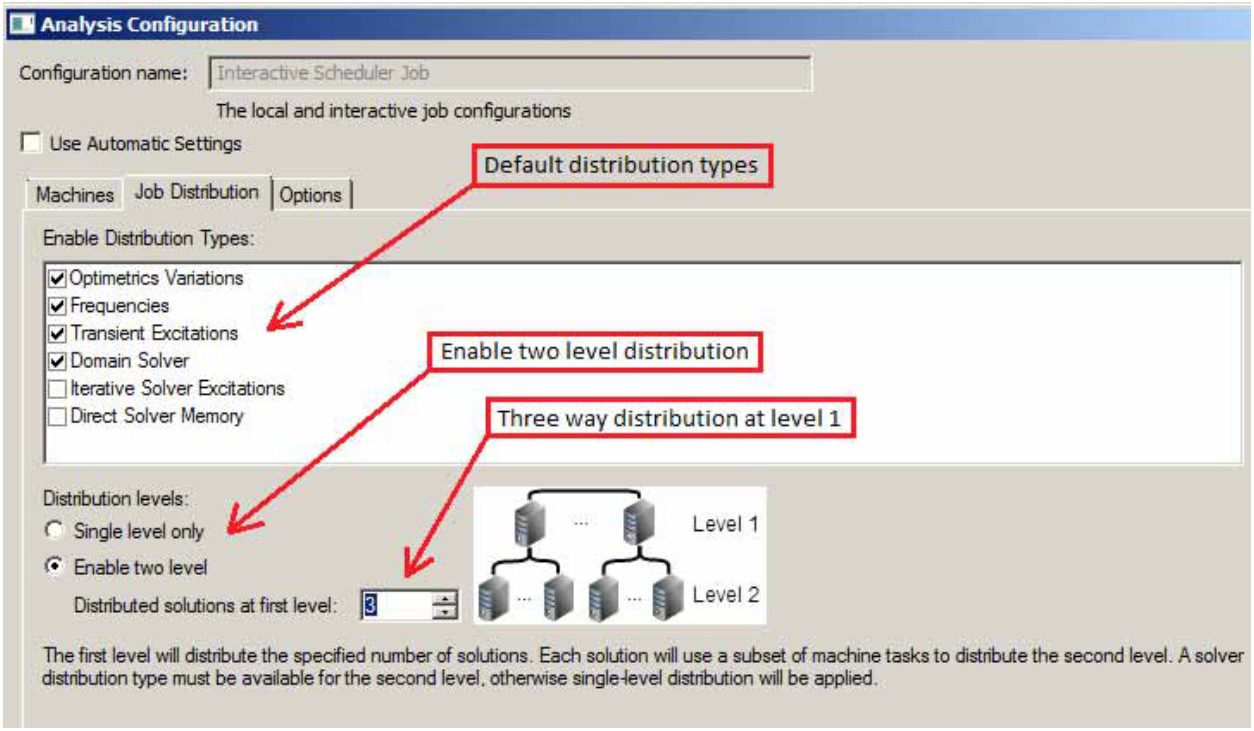
Example

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Command line:

```
ansysedt -distributed includetypes=default maxlevels=2 numlevel1=3
```

Initial "Job Distribution" settings:



Analysis Configuration - Options Tab

You can use the **Options** tab of the **Analysis Configuration** window to examine or modify the DSO configuration options. The DSO configuration options are handled like the design type options, except that the Interactive Scheduler Job configuration settings are not shared with other modes.

The settings on this tab are initialized from the command line (using the -batchoptions command line option) or from the registry. The registry contains the last value of these settings for an interactive scheduler job for the same user on the same host. Settings on the command line override settings from the registry. Any changes in the GUI will override the initial settings, even if the initial settings are from the command line. Any changes in the GUI also update the registry settings for the "Interactive Scheduler Job" configuration for the current design type.

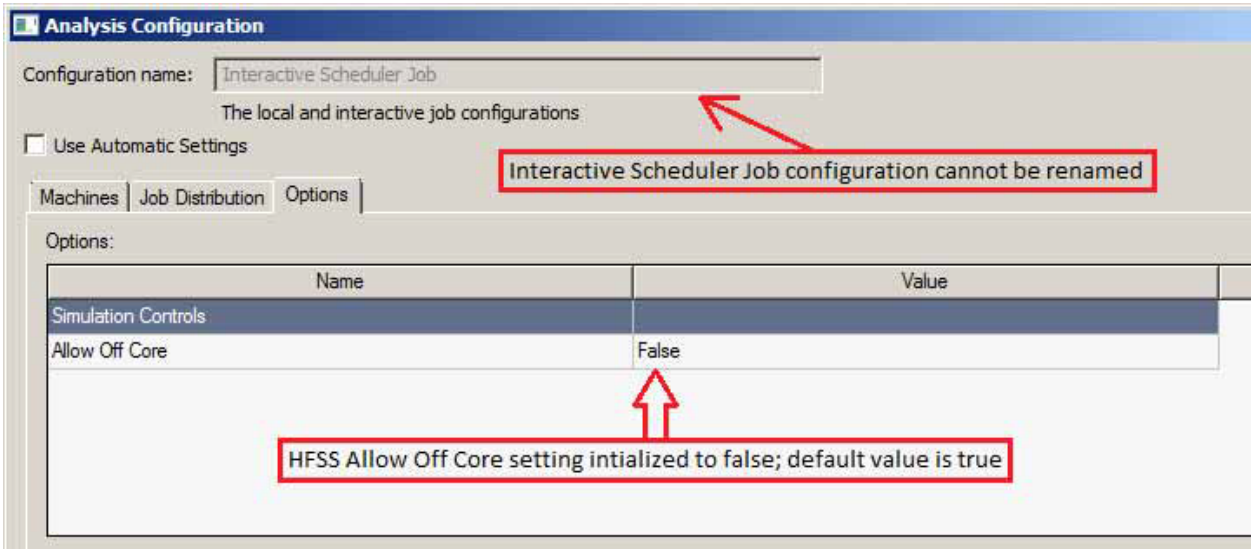
Example

Command line:

```
ansysedt -batchoptions 'HFSS/AllowOffCore'=0
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Initial Analysis Configuration Options:



Design Type Options for Interactive Scheduler Jobs

> **Note:**
>
> Functionality featured in the example(s) in this section applies to multiple design types.

You can use the **Options** tab of the **HPC and Analysis Options** window to examine or modify the design type options. The settings on this tab are initialized from the command line (using the -batchoptions command line option) or from the registry. The registry contains the last value of these settings for the same user on the same host. Settings on the command line override settings from the registry. Any changes in the GUI will override the initial settings, even if the initial settings are from the command line. Any changes in the GUI also update the registry settings for the current design type.

These settings are shared between interactive scheduler mode and other modes.

Example

The following example includes two command line options, one that is applicable to HFSS ('EnableGPU') and one that is applicable to all design types ('HPCLicenseType'). These opitons would be included as part of the complete job submission command line syntax.

Command Line Excerpt:

```
-batchoptions 'HFSS/EnableGPU'=1 'HPCLicenseType'='Pack'
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Distribution Command Line Options

The user should include options specifying how the job should be distributed in the command line. These command line options will override options specified using the **HPC and Analysis Options** dialog box or obtained from the registry. See Running Ansys Electronics Desktop from a command line for more information on command line options.

For both scheduler batch jobs and interactive scheduler jobs, the -MachineList num=<num distributed tasks> format is the most common way to specify the number of tasks for the job. The other formats (-MachineList list=... or -MachineList file=...) allow the user to specify the number of tasks and cores to use on each host. These formats may be useful with clusters of heterogeneous machines, by allowing the user to specify different numbers of tasks or cores for different hosts. If either of the latter two formats is used, the user must ensure that the hosts and cores specified on the product command line are compatible with the hosts and cores allocated to the job.

Batchoptions for Interactive Scheduler Jobs

For interactive scheduler jobs, only a limited set of batchoptions are supported. These batchoptions include the DSO configuration options, the design-type-specific options, and the following additional design-type-specific options that are not currently listed in the user interface or command line help windows:

- **CreateStartingMesh:** Create the starting mesh only. Do not solve any other steps. Often used for multi-step jobs where the mesh creation is solved in a separate step using fewer resources than the rest of the analysis.
- **NumCoresPerDistributedTask:** Specifies the number of cores that are allocated to the job to use for each distributed task, used when running jobs under a scheduler. The scheduler communicates the number of cores allocated to the job on each host. This setting is used to determine how to allocate the cores to each task.
- **RAMLimitPercent:** Specifies the percentage of system RAM that the analysis is expected to use on each host. Running out of memory can cause processes to be killed by the Operating System or other failures. The analysis will be gracefully terminated if it requires more than this limit. Typical limits are about 90%, to allow some RAM for the Operating System and other services. If there are multiple jobs running on a single host, then the RAM limit should be reduced accordingly. For example, if there are two jobs running on a host, then the limit could be 45%, which would allow 10% of the RAM for the Operating System and other services.
- **RAMLimitPerCoreInGB:** This is an alternative way to specify the RAM limit, instead of using the RAMLimitPercent. In this case, the RAM limit is the limit per core multiplied by the number of cores allocated to the job on each host. Typically used for jobs running under a scheduler to ensure that the scheduler memory limit and the ansysedt memory limit are consistent.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **SolveAdaptiveOnly:** Solve adaptive passes only. Do not solve any other steps. Often used for multi-step jobs where the adaptive passes are solved in a separate step using fewer resources than the rest of the analysis.
- **TotalNumOfCores:** The total number of cores for the job. This option is only used for EKM (Engineering Knowledge Manager).
- **ValidateOnly:** Only validate the specified setup, design, or project. Do not analyze the specified setup, design or project.

Any other batchoptions will result in a warning message and will be ignored.

Example:

```
ansysedt -batchoptions " 'TempDirectory'='C:\\TEMP'
'HFSS/SelectedDSOConfiguration'='Local'
'Desktop/Settings/ProjectOptions/DoAutoSave'=1
'LargeScaleDSO/MaxFolderInMB'=100 "
```

Batchoptions

Batchoptions may be specified in the command line used to launch the product. Any valid batchoptions specified in the command line will override the associated registry settings. Batchoptions also override options specified using **HPC and Analysis Options** window or other dialog boxes used to specify options.

Setting the Number of Cores per Distributed Task

When submitting a job using the Ansys Electromagnetics Desktop job submission GUI, the number of cores per distributed task for a job is specified using the batchoption with pathname '<*DesignType*>/NumCoresPerDistributedTask', where <*DesignType*> is the design type to analyze. The batchoption setting is automatically included in the product command line when the job is submitted to the scheduler.

For interactive scheduler jobs, the user must include the associated batchoption setting or settings in the product command line when the product is launched. Multiple batchoption settings are required if the user analyzes multiple design types using the same product process. Batchoptions are the only way to specify this setting for batch jobs. There is an alternative to using the NumCoresPerDistributedTask batchoption for Interactive Scheduler Jobs, . The user may specify the total number of tasks and the total number of cores for each machine using the **Machines** tab of the **Analysis Configuration** window. You may use **Edit** in the **HPC and Analysis Options** to open the **Analysis Configuration** window for the "Interactive Scheduler Job" configuration.

Setting the Ram Limit Per Core in GB

When cores and RAM per core are requested, the cores could be allocated in an arbitrary/non-uniform way across nodes that themselves could be non-uniform/heterogeneous. For example, nodes could range from 4 cores to 20 cores and from 64 GB to 384 GB. In such environments,

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the RAM percentage set in the HPC configuration, Job Submission Compute Resources, or batch option may not be appropriate. In such cases, you can use the batchoption for RAMLimitPerCoreInGB. This setting specifies the Maximum amount of RAM used for each core allocated by the scheduler in GB. This batchoption cannot b e combined with RAM limit percent and is only valid when solving in a Linux scheduler environment.

The scheduler GUI automatically passes this new batch option instead of percent limit. From a scheduler GUI, such a request is available only for auto.

You can also use this new batch option for command line submission. The desktop does the computations and passes the percent limit to product/solver.

Setting the Remote Spawn Command Option to Scheduler

The Remote Spawn Command setting is only meaningful when running on the Linux Operating System. The value 'Scheduler' is valid if the job is a scheduler job running under an LSF, SGE or SLURM scheduler, and only if the MPI Vendor is 'Intel'.

When submitting a job using the AnsysEM job submission GUI, the Remote Spawn Command for an analysis may be specified using the batchoption with pathname 'DesignType/RemoteSpawnCommand', where DesignType is the Design Type to analyze. The Remote Spawn Command setting is only meaningful when running on the Linux Operating System. The value 'Scheduler' is valid if the job is a scheduler job running under an LSF, SGE or SLURM scheduler, and only if the MPI Vendor is 'Intel'. To specify the value 'Scheduler' for this option for a scheduler job, the Remote Spawn Command must be specified using the 'DesignType/RemoteSpawnCommand' batchoption in the product command line when the product is launched. In addition, the 'DesignType/MPIVendor' batchoption must be specified with value 'Intel' in the product command line when the product is launched. For interactive scheduler jobs, the Remote Spawn Command and the MPI Vendor may be specified with batchoptions or as design type options in the **HPC and Analysis Options** dialog box.

Setting MPI Version

When submitting a job using the Ansys Electromagnetics job submission GUI, the MPI Version may be specified using the batchoption with pathname DesignType/MPIVersion, where DesignType is the type of design to analyze (e.g. HFSS). It allows selection of which Intel MPI version to use, for both Windows and Linux. Valid values are "Default", "2018", and "2021".

For interactive solves, the MPI version may be specified with the batchoption in the command line used to launch the product, or as a design type option in the HPC and Analysis Options dialog box.

High Performance Computing (HPC) Integration

Ansys Electromagnetics products offer a direct integration with a number of High Performance Computing (HPC) software programs.

The list of currently supported schedulers includes:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Ansys Cloud Direct
- Ansys Cloud Burst Compute
- Microsoft Windows HPC Server (Windows Only)
- Grid Engine (GE) (Linux Only)
- Platform's Load Sharing Facility (LSF) (Linux Only)
- PBS Pro or PBS Torque (Linux Only)

Electronics Desktop also supports custom integration.

A job scheduler may also be described as a batch system, a Distributed Resource Management System (DRMS) or Distributed Resource Manager (DRM). The features supported on each scheduler are included in the documents for each. For each job scheduler, the versions or revisions that have been tested are included.

A user may submit jobs using the command line tools or other tools provided by the scheduler. The Desktop includes a GUI to help the user submit jobs to a job scheduler. This generic Job Submission GUI is shared across the Ansys EM products. The general procedure is to specify the scheduler and head node, describe and submit the job, and monitor the results. Using “Ansys Cloud Direct” or “Ansys Cloud Burst Compute will require a login through a browser instead.

Scheduler Terminology

This help uses some specific terminology when discussing HPC and schedulers. See definitions below.

Term	Definition
Core	Unit of processing.
Compute Cluster	Network of machines on which jobs run. Typically consists of head nodes and many compute nodes.
Distributed Processing	Multiple engines are launched simultaneously on the same machine *or* on different machines.
Engine	Electronics Desktop application (aka. executable) launched during analysis commands to generate analysis results.
Job	Application (aka. program, executable) with command line options that uses resources to produce results. For example, `hfss.exe -ng -BatchSolve`
Machine/Host/Node	Consists of one or more processors, memory, disk, etc.
Multiprocessing	A single engine uses multiple cores on the same machine.
Parallel Job	Job that runs on multiple cores belonging to the same or different machines.
Processor	Consists of one or more cores.
Resource	Machines, licenses, etc. that a job uses.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Term	Definition
Serial Job	Job that runs on a single core.
Service	Program that runs in the background (for example, RSM Service) and listens on a port. The OS provides the programming interface through which Applications communicate with services, once the machine and port number are known. Launching an executable on a remote machine requires a service to run on the remote machine.

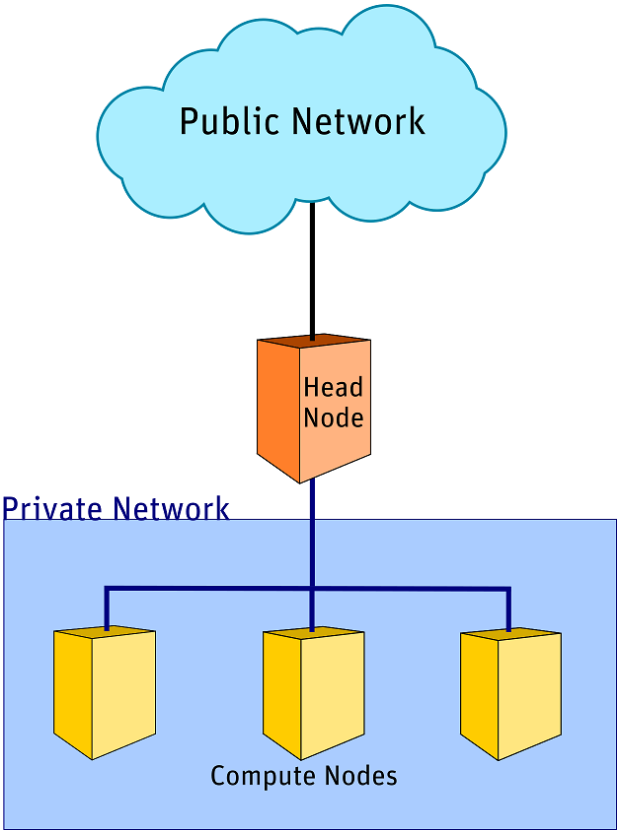
What a Scheduler Does

Schedules are responsible for the following:

- Enabling effective/efficient utilization of cluster's resources consistent with organization's goals
- Maintaining queue(s) of jobs
- Maximizing throughput of jobs by processing all jobs as quickly as possible (typically, one job per CPU)
- Allowing a choice of various scheduling policies (for example, First Come First Serve, Priority-Based, and Preemption)
- Providing a suite of tools or utilities (graphical or command line) for end users to submit, monitor, suspend, and abort jobs
- Managing a compute cluster by running various interacting services on head nodes and compute nodes
- Providing a programming interface to access services

Scheduler-Managed Compute Cluster

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Head node(s) typically maintain queues. Compute nodes are typically on a high speed network to improve scalability of parallel jobs. Services running on nodes interact with each other to manage resources. End user tools communicate with services to manage jobs.

Configuring Electronics Installation for HPC

In HPC applications, Ansys Electromagnetics Suite must be available on each cluster host where jobs may be run.

- On the Linux platform, Ansys EM may be installed on a shared drive that is accessible to all machines in the cluster.
- On the Windows platform, Ansys EM must be installed separately on each host of the cluster.

Ansys EM must be accessible using the same path on each host. All cluster users running Ansys EM jobs must have permission to read and execute the files in the installation directory and its subdirectories.

The temp directory selected during installation must be readable and writable by all user accounts used to run the Ansys Electromagnetics Suite. This temp directory path should be the

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

same on all machines of the cluster and should be local to every machine. For example, C:\temp on Windows, /tmp on Linux.

Because HPC is offered as a direct integration, you need only install the Ansys EM software. No additional configuration is required.

Firewall Configuration

If firewall is turned *off* between the machines of the cluster, there is no need for any configuration.

If firewall is turned *on*:

- For a Windows cluster: Configure firewall by adding exceptions that allow Ansys EM programs and services to communicate with each other. If you are using a standard Windows Firewall, this is automatically done for you by the installation program. If you are using a third-party firewall software, it needs to be configured in a similar manner.
- For a Linux cluster: Open up the firewall for range of ports denoting ephemeral (or dynamic) ports. Check with your system administrator on how this can be done on each machine of cluster.

Installation Directory Examples

Microsoft Windows

Install the Ansys Electromagnetics Suite in directory "C:\Program Files\ANSYS Inc\v251\AnsysEM" on each node of the cluster. The same directory pathname must be used on all hosts.

Linux

Install the Ansys Electromagnetics Suite in a common directory that is accessible using the path /opt/ansys_inc/v251/AnsysEM on each execution node of the cluster.

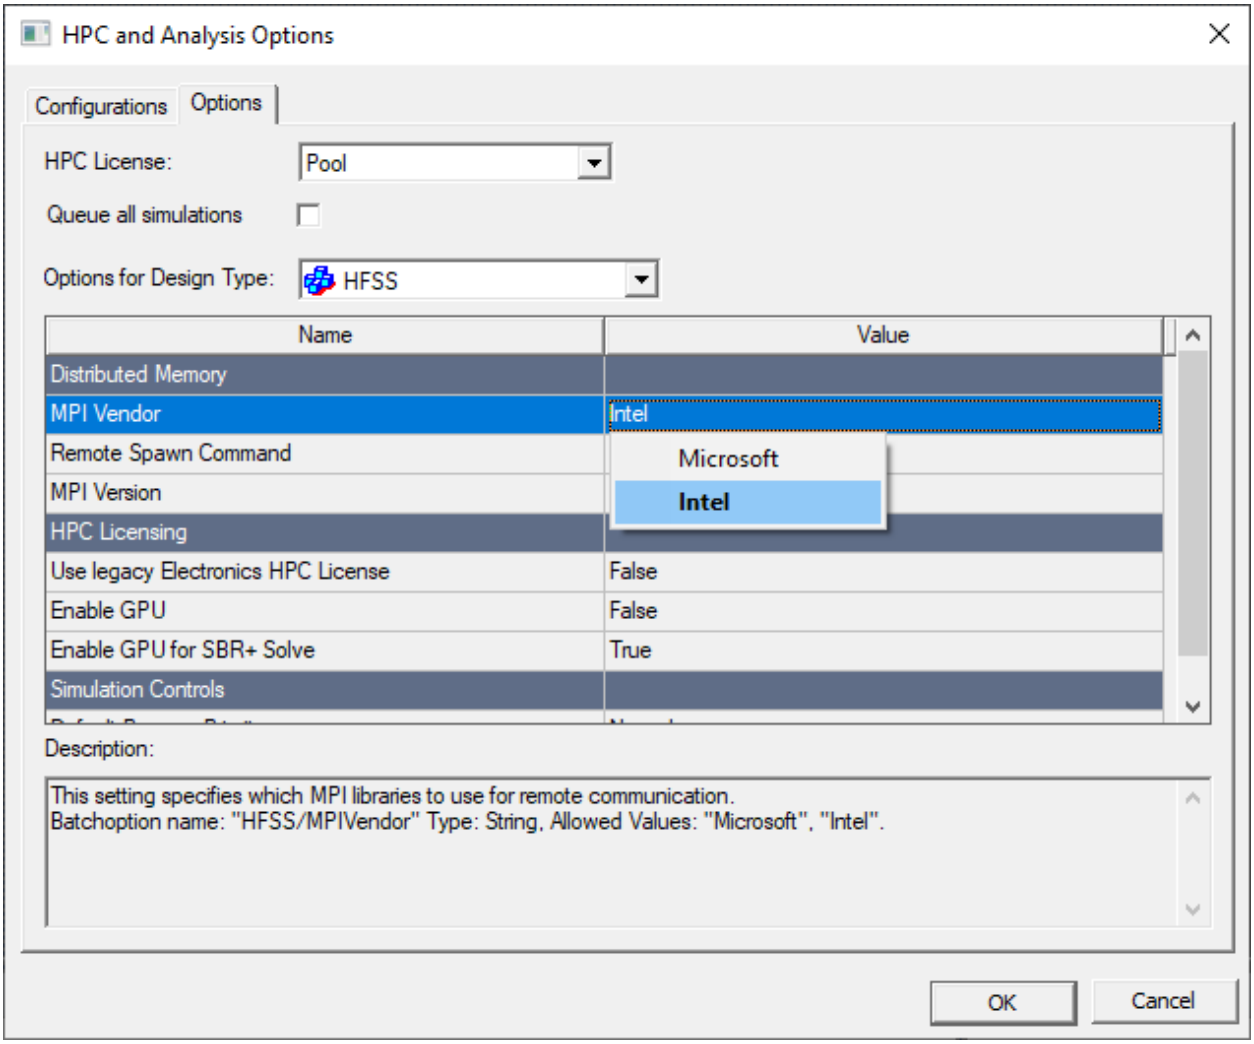
MPI Vendor and MPI Version

For HFSS, HFSS 3D Layout, Q3D Extractor, Maxwell, and Icepak design types:

These settings may be used to specify the MPI Vendor and Version for distribution via MPI.

Go to the **Options** tab of the **HPC and Analysis Options** dialog box, and select the design type. Then you can select the MPI Vendor and MPI version.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



MPI Vendor

The default MPI Vendor is "Intel". On Linux, "Intel" is the only supported MPI vendor. On Windows, both "Intel" and "Microsoft" are supported MPI vendor options. For jobs distributed to multiple hosts, the "Microsoft" MPI Vendor is only supported when running as a Windows HPC job.

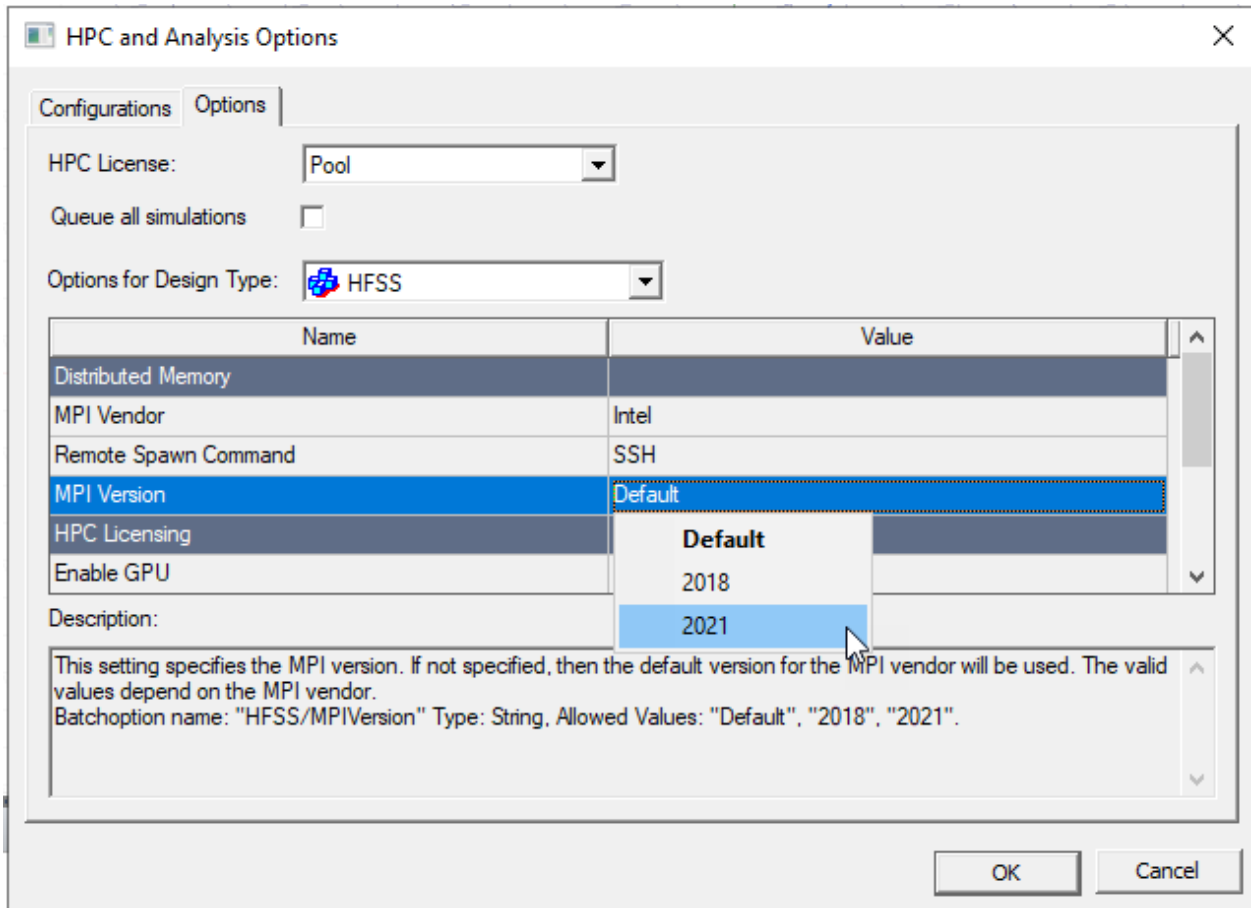
MPI Version

If only a single MPI Version is supported for the selected MPI Vendor, then the MPI Version option is ignored. Multiple versions are only supported for Intel MPI, as follows:

- The value "Default" indicates that the default Intel MPI version should be used. This is Intel MPI 2021 in most cases.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The value "2018" indicates that Intel MPI 2018 should be used.
- The value "2021" indicates that Intel MPI 2021 should be used.



Also see Setting Intel MPI Interconnect for more details.

Integration with Microsoft Windows® HPC Scheduler

The Windows HPC scheduler is only supported on Windows.

Jobs may be submitted in any of the following ways:

- Using Windows HPC GUIs from Microsoft: Job Manager or Cluster Manager
- Using Windows HPC command line tools
- Using Ansys Electronics Desktop UI commands for scheduler selection, job submission and job monitoring/control.

General Guidelines for Submitting Ansys EM Jobs

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A Job submitted to Windows HPC Cluster is defined by Job properties, Task List and Task properties. Priority, resource requirements, node preferences, etc. come from Job properties. In the case of Ansys Electromagnetics jobs, Task List consists of a single task. Properties of this task specify the command line that runs Ansys Electromagnetics desktop in non-graphical mode to perform analysis of a project.

Specifying the Number of Compute Resource Units for HPC Jobs

You can either select **Use automatic settings** on the *Compute Resources* tab, or you either enter the number of tasks and total cores per machine, or individual nodes. HFSS, HFSS 3D Layout, and Icepak have **Use automatic settings** selected by default. This release permits options in setting whether nodes are exclusive for the submission. See Windows HPC Non-exclusive Jobs.

Ansys EM Project File and Project Directory for use with Windows HPC Scheduler

Ansys Electromagnetics Suite tools write their results to a subdirectory of the directory containing the Ansys EM project file. The Project Directory (the directory containing the project file) must be accessible to all of the cluster hosts that may run Ansys EM jobs. The user account for the job must have permission to read the project directory, and to create and modify files and subdirectories of this directory. The pathname of the project file must be accessible to all cluster hosts using the same path name, which is generally expressed as a UNC pathname.

Example:

The project file is on the user's workstation (with hostname user1_PC) in directory C:\user1\projects\new\project1.aedt, and the directory C:\user1\projects is shared with sharename projects.

Correct

When submitting the job, you should use the following pathname to specify the project file:

```
\\user1_PC\projects\new\project1.aedt
```

Incorrect

If a local pathname is used, the cluster hosts will not be able to find the user's project on the workstation

```
user1_PC: ' C:\user1\projects\new\project1.aedt '
```

Submitting and Monitoring Ansys EM HPC Jobs

Jobs may be submitted to the Windows HPC Scheduler using any of the following methods:

- Using the *Submit HPC Job* dialog box
- Using the Windows HPC Job Manager GUI

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Using the Windows HPC Command Line Tools
- Using the Windows PowerShell

Client Utilities from the Microsoft HPC Pack, must be installed on the submit host to use any of these methods to submit a job to a cluster. The *Submit HPC Job* dialog box will be unable to contact the cluster head node if the client utilities are not installed.

This document covers the first method. See the Microsoft documentation for information on the other three methods.

- Submitting and Monitoring Jobs for Windows HPC
- Specifying the Number of Compute Resource Units for HPC Jobs

Jobs may be submitted from any Microsoft Windows host meeting the following requirements:

- For submitting jobs to the Windows HPC scheduler, the Desktop process must run on a node that is configured for submission of jobs to the Windows HPC cluster. That is, the Windows HPC Client Utilities must be installed on the node, and network communication from the Desktop node to the head node of the cluster must be allowed. For Ansys Electromagnetics Suite 2025 R1, Windows HPC Server 2008 R2 (or later) client utilities are required. Using a computer on the network is not supported for submission of jobs to the Windows HPC cluster.
- When submitting jobs to a Windows HPC cluster, the user must also specify the head node of the cluster to which the jobs will be submitted. When the user selects the "Windows HPC" scheduler in the "Choose scheduler" list, the Head Node edit control is enabled. The user may enter the Windows HPC cluster head node name into the edit box. Alternatively, the head node may be selected using a "Browse for Computer" browser by pressing the ellipsis [...] button.
- The Windows HPC Pack client utilities are installed on the submission host.
- Network communication between the submission host and the Windows HPC Cluster head node is permitted; there is a network connection between these hosts that is not blocked by any firewall or the like.
- The submission user is permitted to submit jobs to the Windows HPC Cluster.

Job Monitoring

1. Windows HPC Jobs may be monitored using the *Monitor Job* dialog box, which is brought up by the **Tools > Job Management > Monitor Jobs...** command. This dialog bos may also be brought up by checking the **Begin monitoring this job now** check box when a job is successfully submitting using the job submission dialog box. You can also select the **Simulation** tab of the ribbon and select the **Monitor** icon. You can monitor this job either automatically (by checking the option) or through the **Tools> Job Management> Monitor Jobs...** command. For more details, see Monitor Jobs window.

In addition to the above requirements to allow job monitoring the following is also necessary:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Network communication between the submission host and all Windows HPC Cluster nodes where the job may run is permitted; there is a network connection between these hosts that is not blocked by any firewall or the like.

Cluster Configuration

Any job running on a Windows HPC Cluster that is distributed over multiple compute hosts requires network communication between processes running on these hosts. The cluster must be configured to allow this communication. Any firewall or other security software must be disabled or configured to allow communication between any of the compute hosts were a job could run.

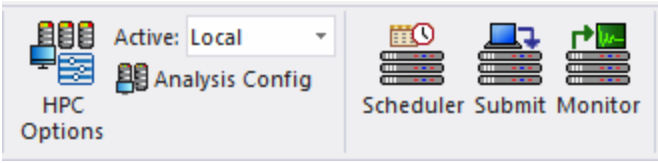
Job Submission User Profile on Cluster Compute Nodes

In order for a job to run correctly, the submission user's profile must be accessible and properly initialized on the cluster compute nodes where the job runs. If the Ansoft/temp subdirectory of the user's "My Documents" directory does not exist or is not accessible on the compute cluster nodes where a job runs, the batchoptions for the job will not be processed correctly, resulting in job failure. One way to ensure that this directory is created on each compute host is for the submission user to login to each compute host and run the product GUI one time.

Submitting and Monitoring Jobs for Windows HPC

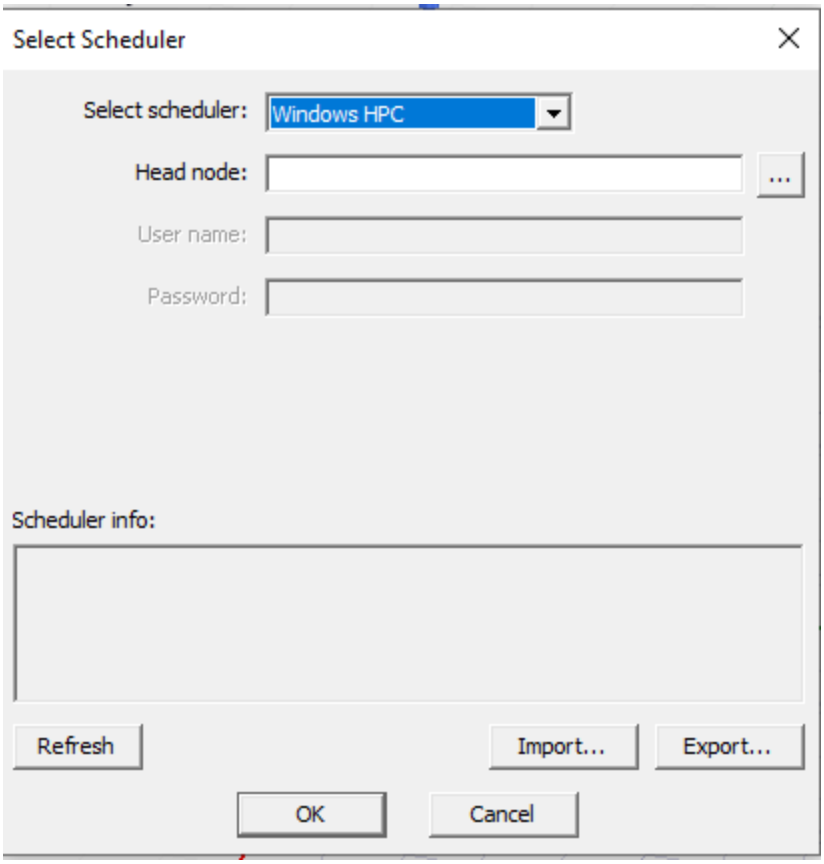
In order to submit jobs using **Windows HPC**:

- Click **Tools** > **Job Management** > **Select Scheduler**, or
- Select the **Simulation** tab of the ribbon, and click the **Scheduler** icon.



This opens the **Select Scheduler** dialog box. Specify **Windows HPC** as the scheduler.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For Windows HPC, specify the head node of the cluster.

After specifying the cluster head node, click **Refresh**. This verifies that the head node may be contacted, and displays the scheduler name, a brief description (including the head node name), and the version of the Windows HPC head node.

Pressing **Cancel** discards changes made in this dialog box. Pressing **OK** verifies that the head node can be contacted before accepting the changes. If no problem occurs, the dialog box will close. If there is a problem contacting the head node, the dialog box will not close and the changes will not be accepted.

After setting the job submission node, perform *one* of the following:

- Select **Tools** > **Job Management** > **Submit Job...**
- Click **Project** > **Submit Job...**
- Click **Maxwell** > **Submit Job...**
- Select the **Simulation** tab and click the **Submit** icon.
- Use a shortcut menu to select **Submit Job**.

This opens the **Submit Job To** dialog box.

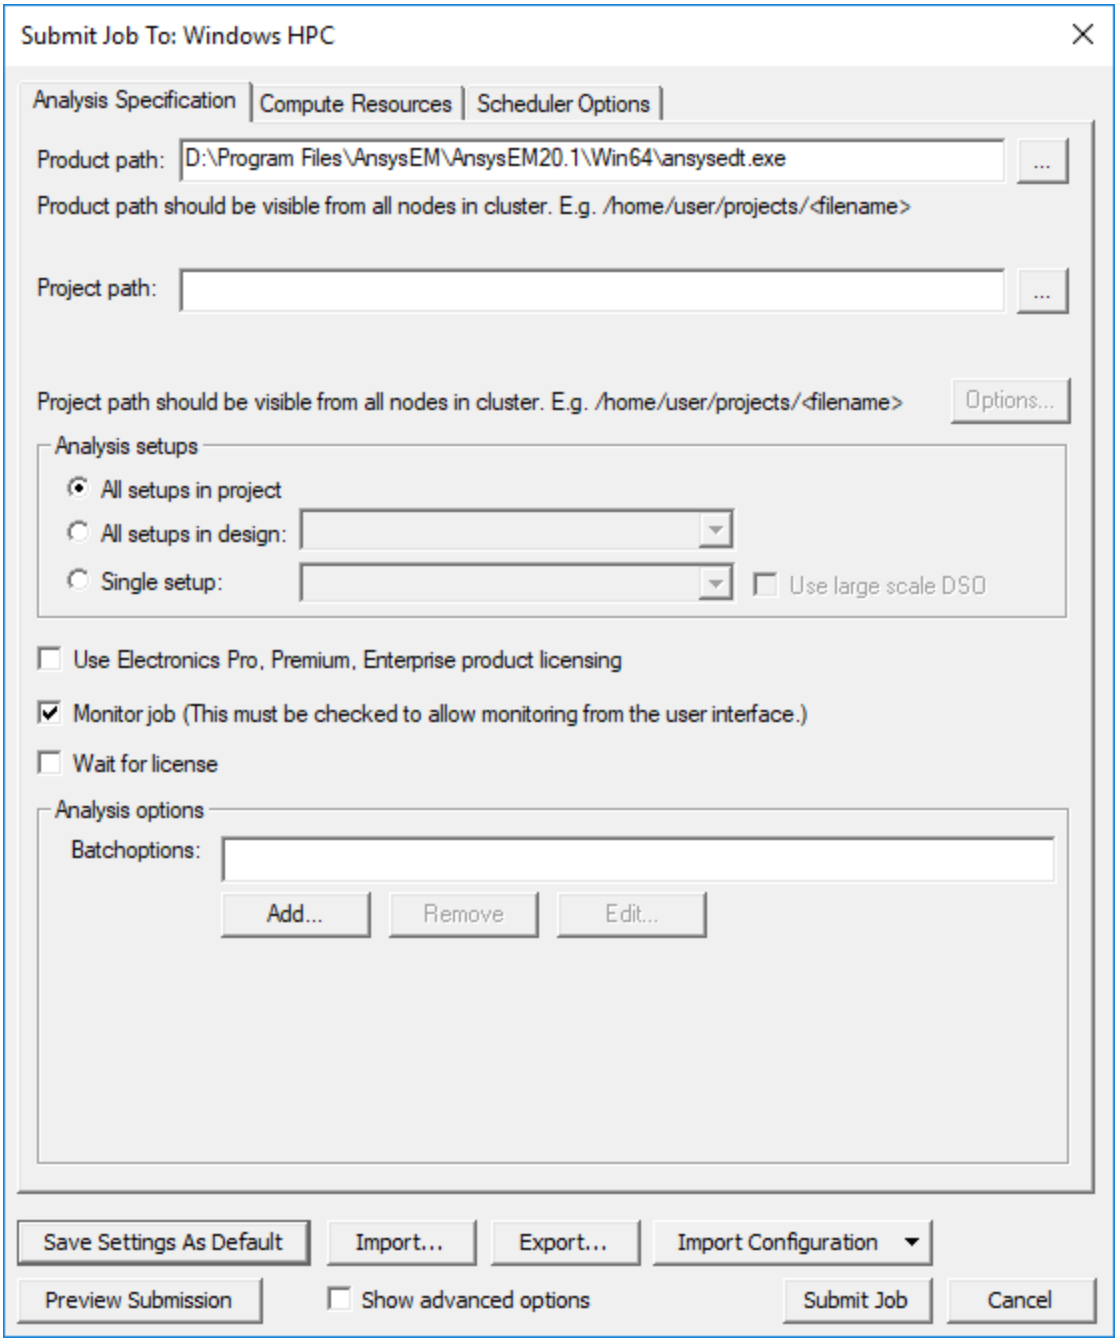
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Submit Job To** dialog box contains three tabs:

- **Analysis Specification**– specify the Product path, Project name, the setups, and analysis options such as batchoptions, or, for advanced users, Environment variables. If you select the Analysis or Optimetrics setup, the Analysis Specification is pre-populated.
- **Compute Resources**– this tab can be populated either by automatic settings, by predefined Analysis Configuration, or specifying parameters in the fields for resource selection, for job parallelization and enabled forms of parallelization.
- **Scheduler Options**– contains fields for Job name and priority. The customization options shown by checking advanced are not used for Windows HPC.

On the **Analysis Specification** tab, enter path names for the Product and Project. These must be UNC paths that are accessible from each compute host used for Ansys Electromagnetics jobs. The Project can be an archive. The submission user must have permission to write to the directory containing the project file.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can select which setups are analyzed in the **Analysis Setups** area of the dialog box. There are radio buttons to select:

- All setups in the project
- All setups in a specified design (you select the design from the drop-down menu)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

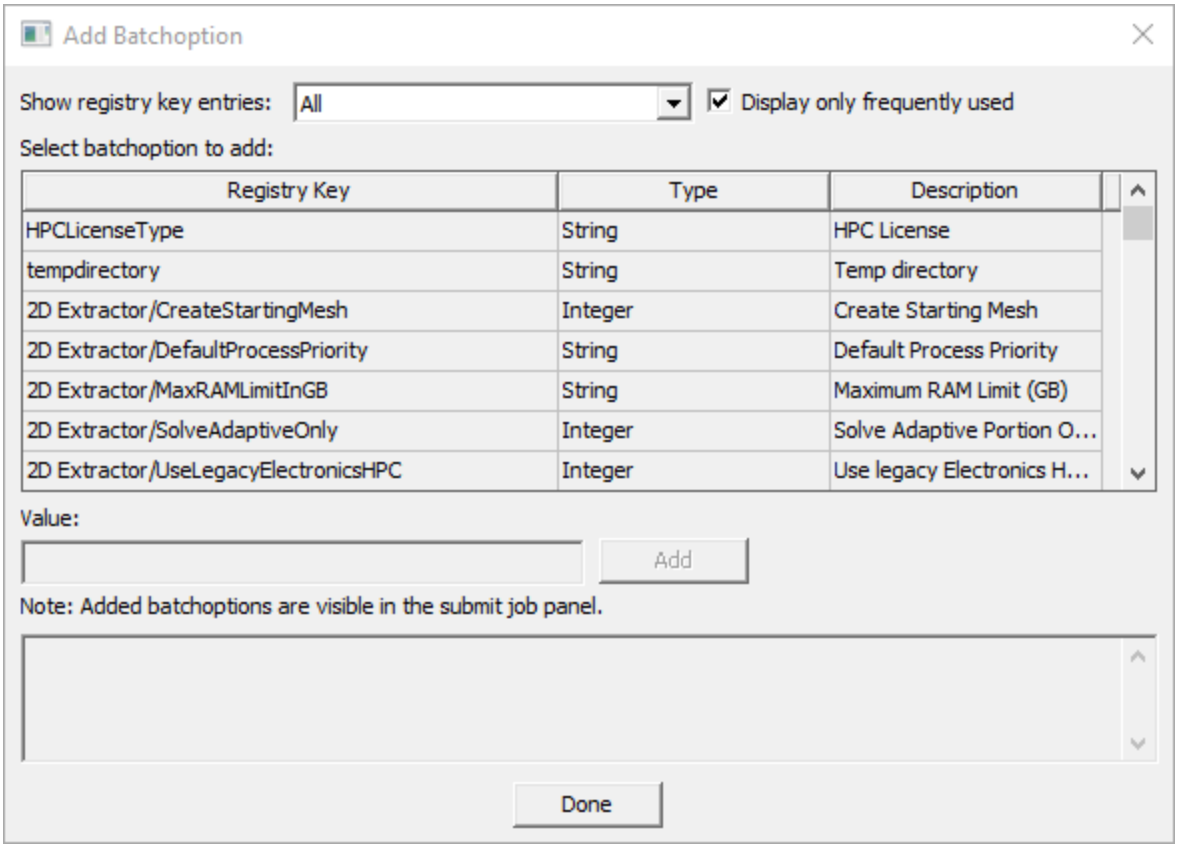
- Single setup (if you selected the Submit Job command from the shortcut menu, the setup name populates the field)

If you specify multiple setups, they will be processed sequentially in the order displayed in the edit box.

The Analysis options include:

- Monitor job – you must enable this option to monitor the job from the user interface.
- Wait for license – specify whether to wait until a license if available before starting a simulation.
- Batch options – optionally specify -batchoptions in the text field. See detailed discussion of -batchoptions beginning under Running Ansys Electronics Desktop from a Command Line.

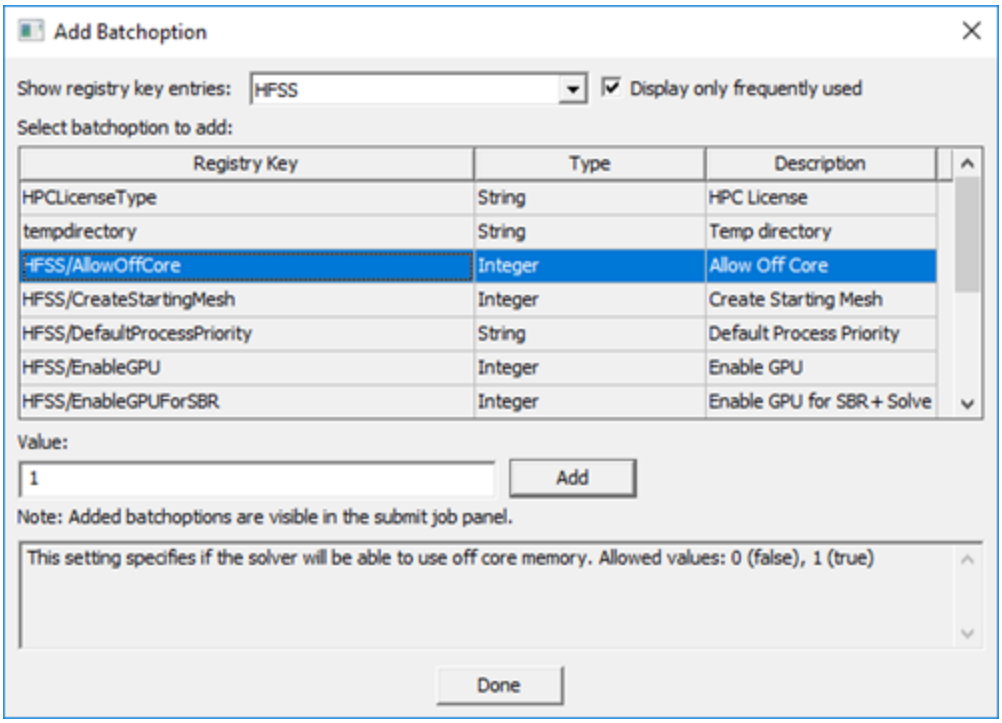
The **Add...** button opens the **Add Batchoption** dialog box.



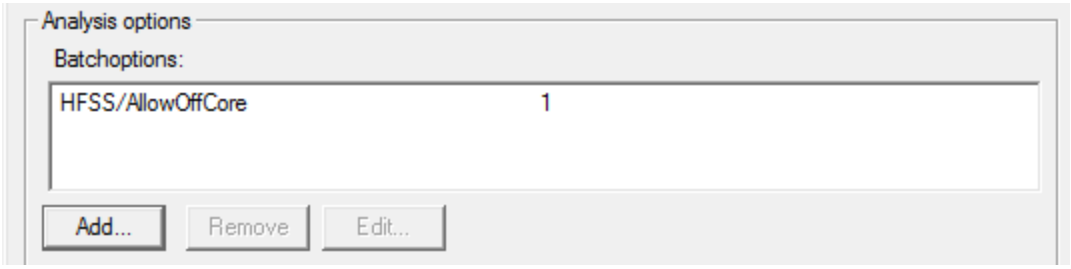
This dialog box provides access to all -batchoption commands. The drop-down menu lets you select specific categories, and you can choose to display only frequently used commands. You can edit and remove any batch options you specify.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Select a Registry Key in order to show the current Value for the type. The lower field explains the meaning of the Type Value.

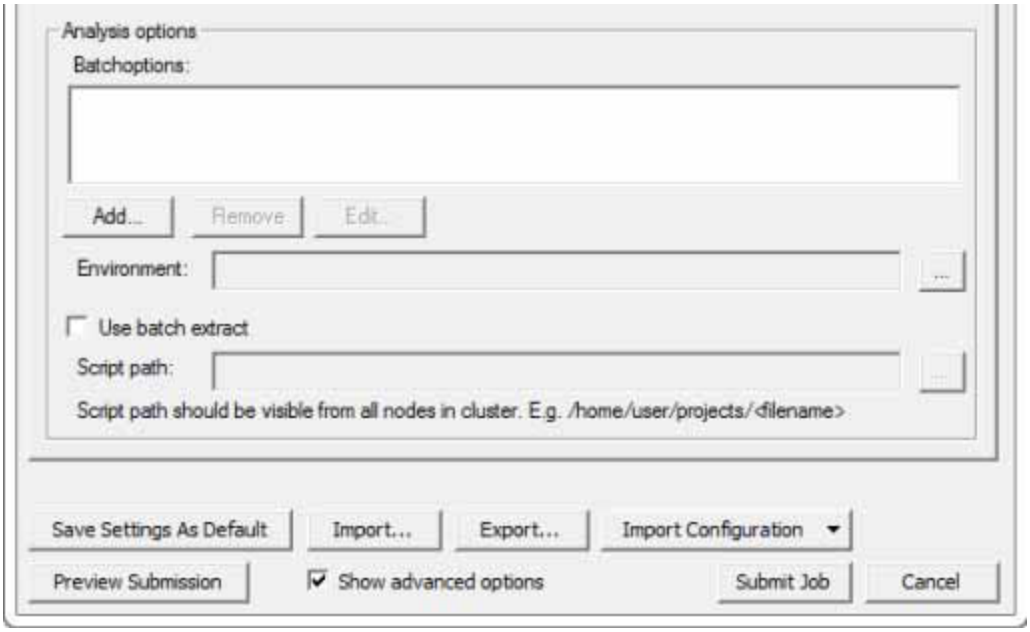


Any batchoptions for which you select **Add** will be visible in the **Submit Job** dialog box.

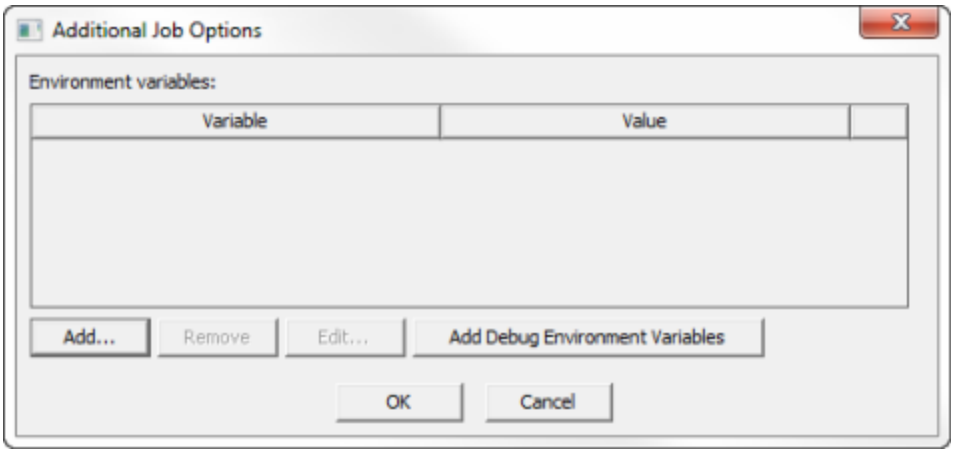


If you have the **Show advanced options** box checked in the **Submit Job** dialog box, the Environment field and the Use batch extract fields display.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

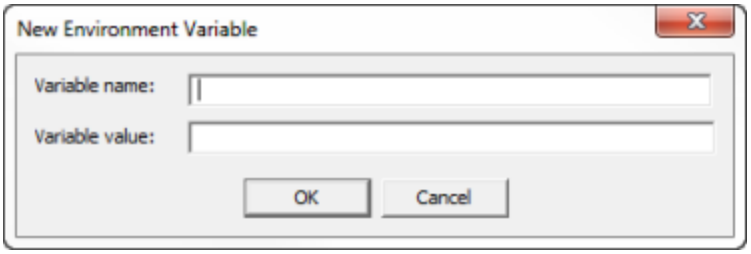


The **Environment** field lets you specify any environment variables. Click the ellipsis button [...] to display the **Additional Job Options** dialog box.



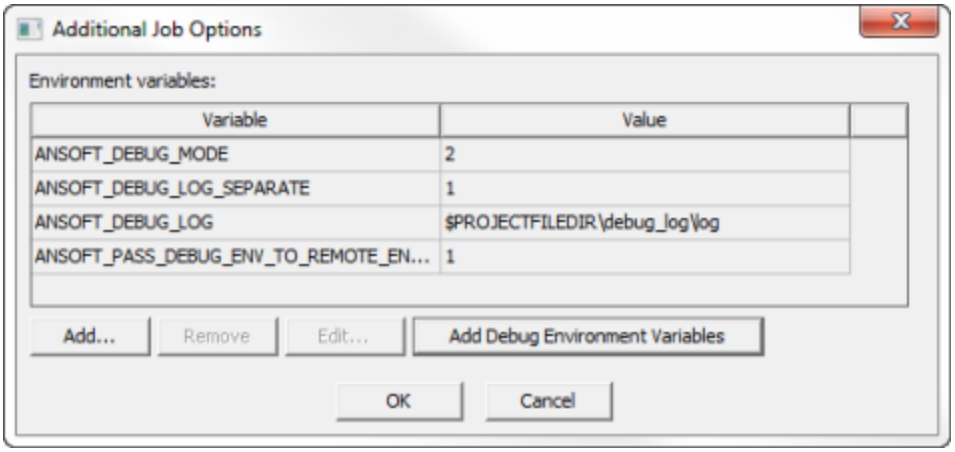
Click the **Add...** button to open the **New Environment Variable** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Here you can provide a Variable name and Variable value. Click **OK** to display the variable in the **Additional Job Options** dialog box.

Select a variable to enable the **Remove** and **Edit...** buttons. You can also click **Add Debug Environment Variables**.



Note:

For certain methods of resource selection for Windows HPC job submission, Ansys Electronics Desktop checks for nodes being online. In an auto-scaling cluster, nodes can fail the online check because they're not online until a job is running. An environment variable allows customers to bypass this check:

ANSYSEM_SKIP_NODE_ONLINE_CHECK

Set the variable value to 1 to disable the online check. Debug logging fully verifies what aspects of the cluster are causing this check to fail.

Job submission in Windows works without changing settings if environment variable ANSYSEM_SUBMIT_JOB_REQ_NODE_ONLINE is set with value 0. The installation doesn't set this environment variable. ANSYSEM_SUBMIT_JOB_REQ_NODE_ONLINE accepted

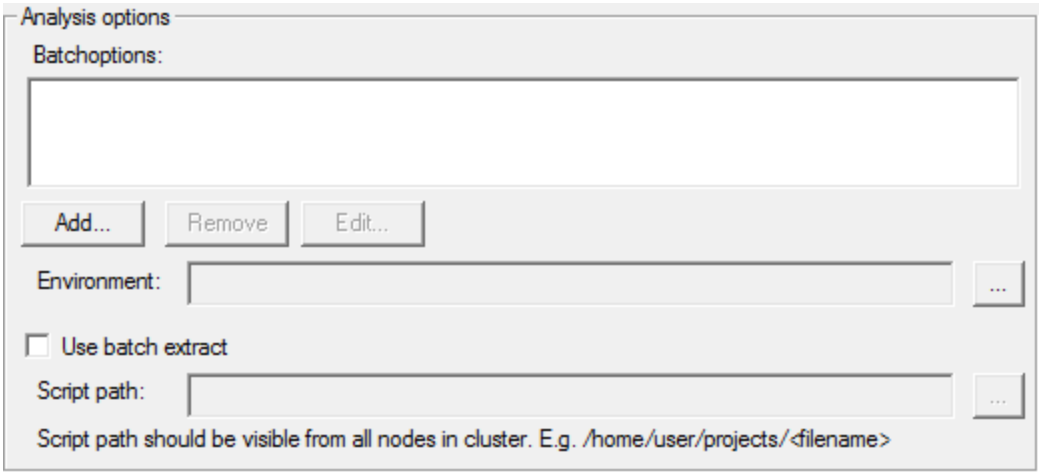
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

values: 0 or 1 (0 = disable; 1 = enable, i.e. require nodes to be online for submission). Default: 1 (if not set, Ansys Electronics Desktop requires nodes to be online for submission).

If you have enabled **Show Advanced Option**s, any variables that you add will be displayed in the **Environment** field of the **Submit Job** dialog box.

Use Batch Extract for Windows HPC

Enabling **Show Advanced Options** for Windows HPC also displays the **Use batch extract** check box and script path field.

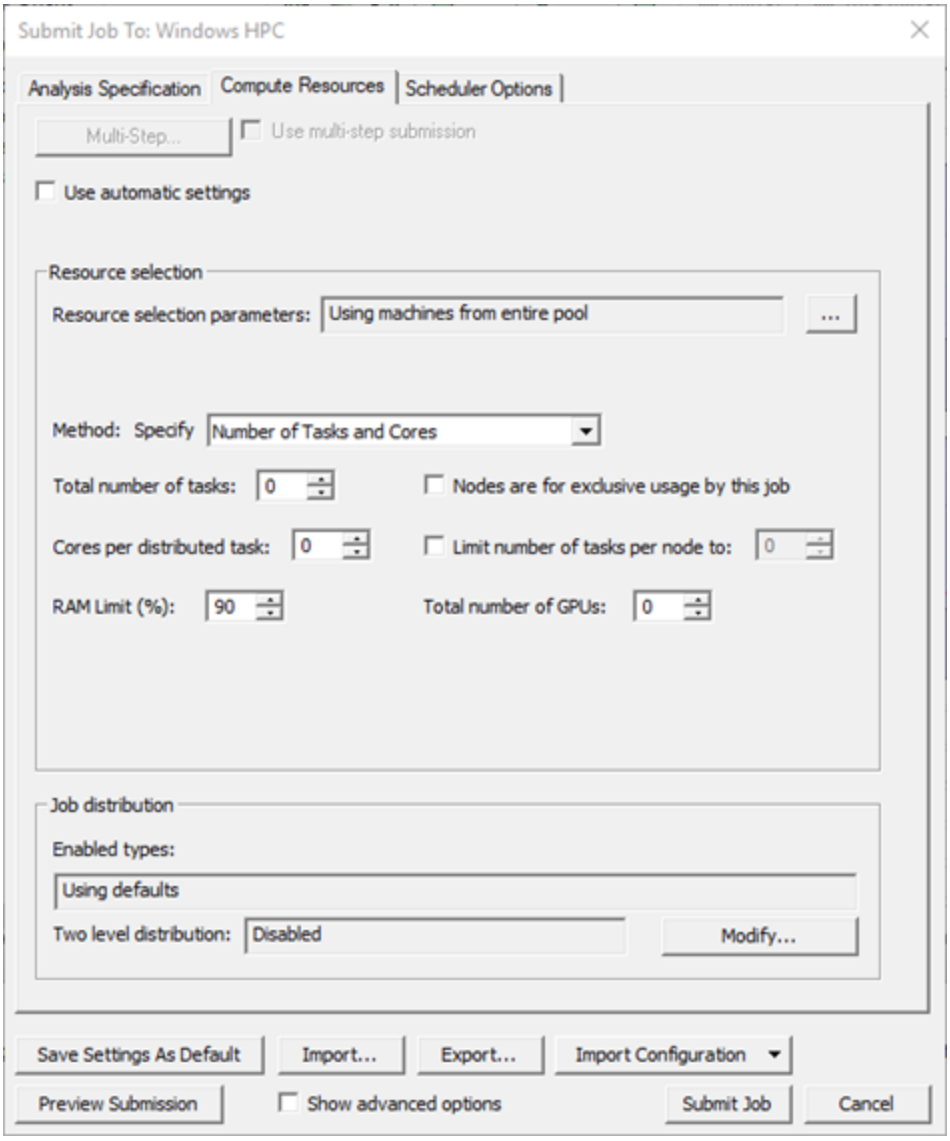


See Running Ansys Electronics Desktop from a Command line for an explanation of the solve information available through batch extract.

The **Preview Submission** button opens a window that shows the text commands that will be sent to the scheduler.

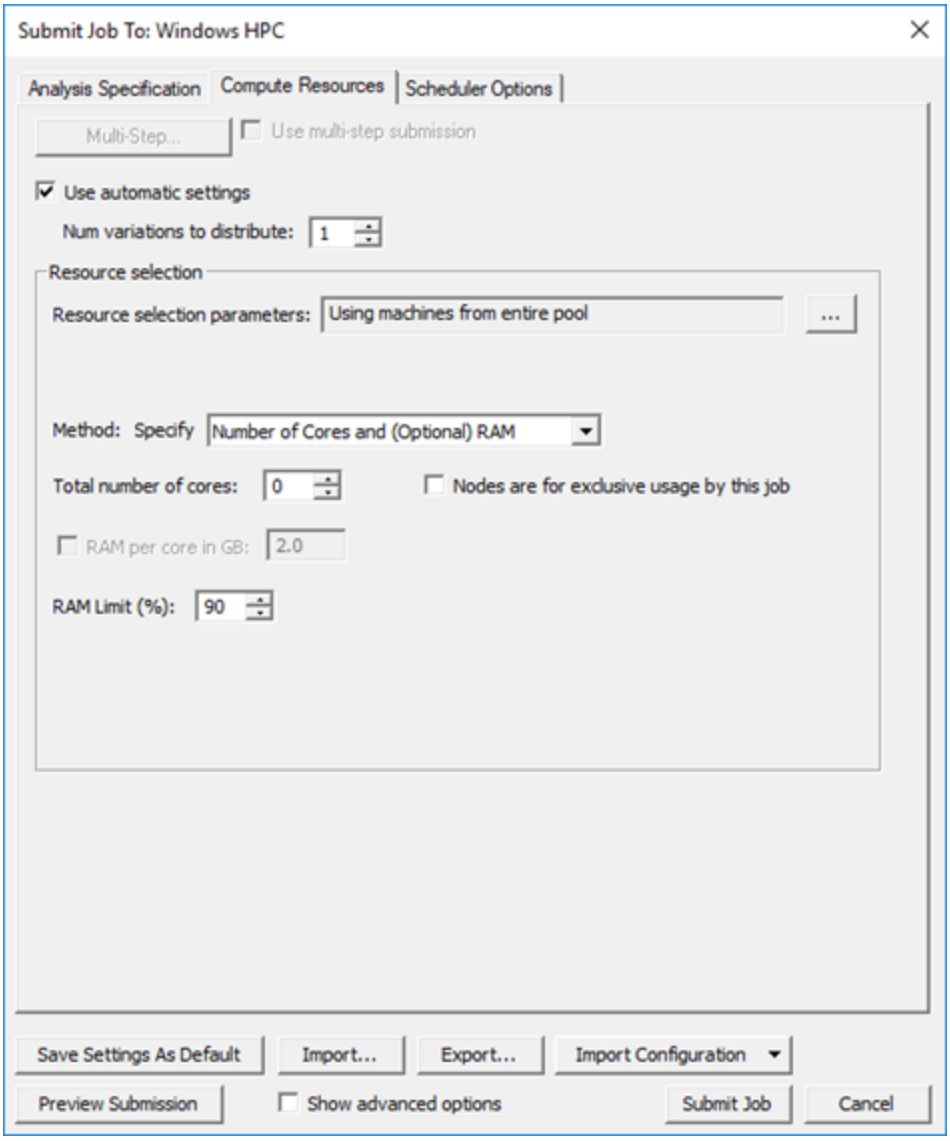
The following figure shows the **Compute Resources** tab of the **Submit Job To** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For Ansys Electronics Desktop configurations, the **Submit Job To** dialog box includes a **Use automatic settings** check box that simplifies the **Compute Resources** tab.

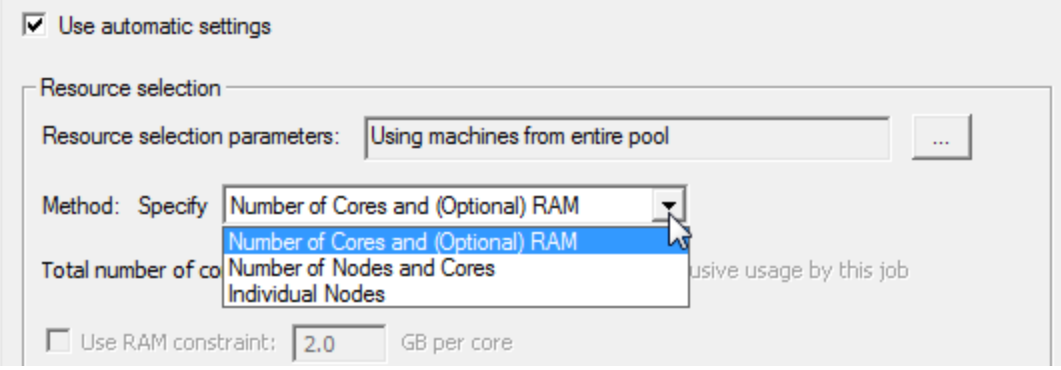
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



With **Use automatic settings** selected, the **Job distribution** field is removed. When using automatic settings, you can specify **Resource selection** parameters. The ellipsis button [...] opens the Compute Resource Selection Parameters dialog box. If you do not specify any parameters, the default is "Using machines from entire pool."

The Method field of the **Submit Job To** dialog box has a drop-down menu with two or three selections, depending on whether you select **Use automatic settings**.

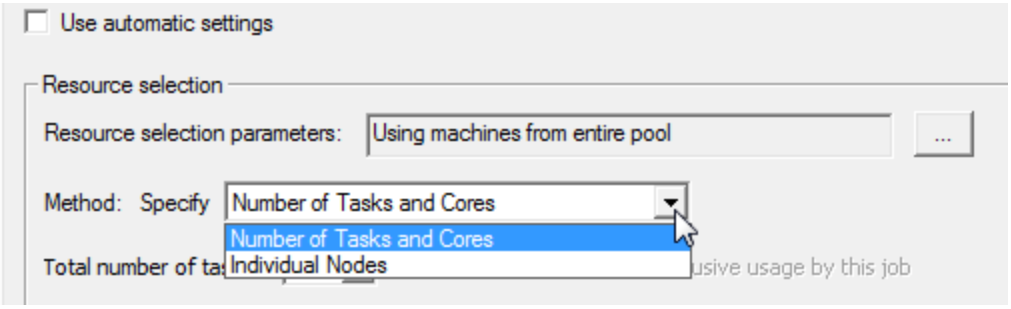
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note:

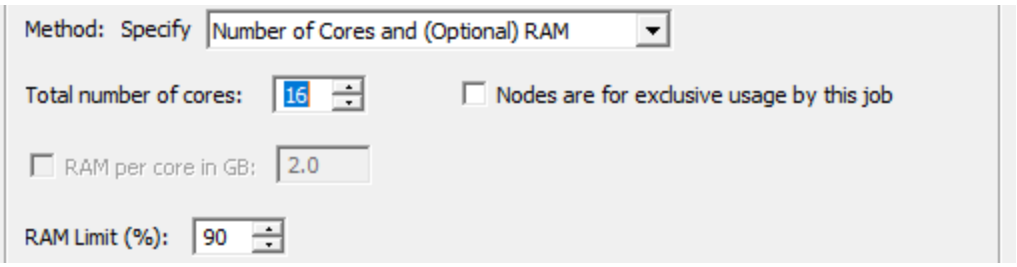
If you select Use automatic settings, Optimetrics variations will be solved sequentially. Other distribution types will be distributed automatically. It does distribute frequencies, domains, and use of multiple level domains.

If you uncheck or cannot access Use automatic settings, these two Methods are listed:



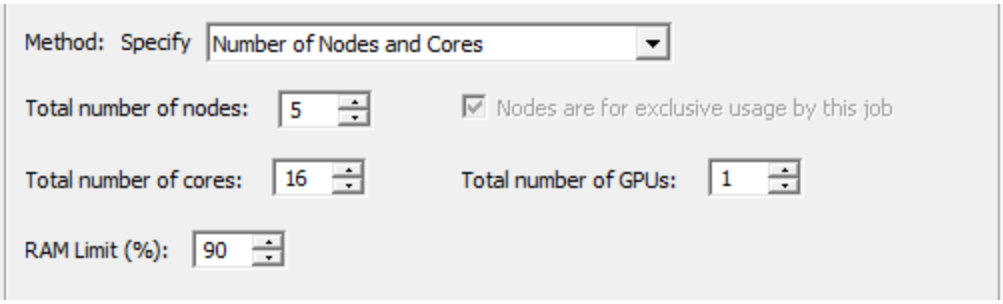
For Windows, there is a 64 core limit for a single machine. Each Method selection changes the available options listed:

- Specify Number of Cores and (Optional) RAM

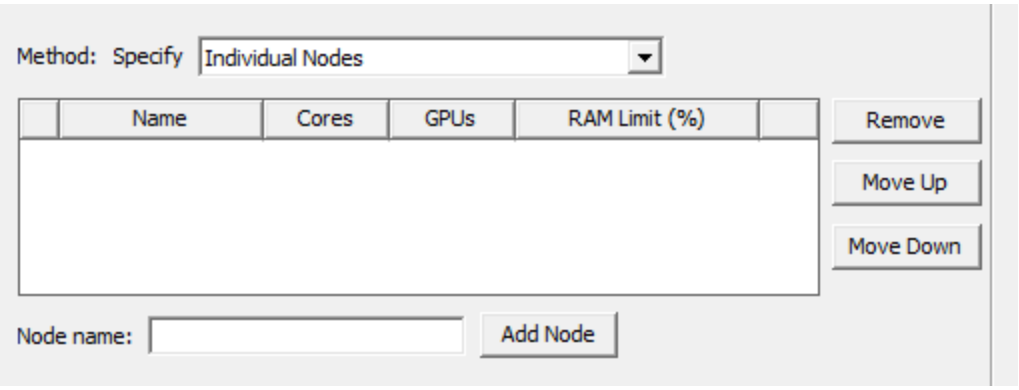


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Number of Nodes and Cores

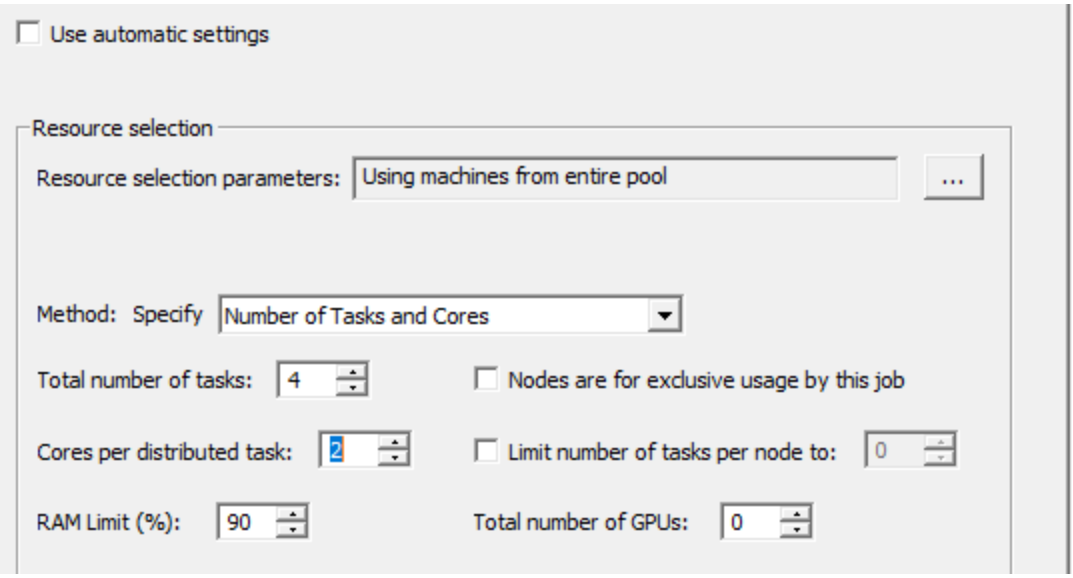


- Individual Nodes



- Number of Tasks and Cores ("Use automatic settings" is unchecked for this option. Checking "Use automatic settings" means that you do not have to specify tasks or core parameters):

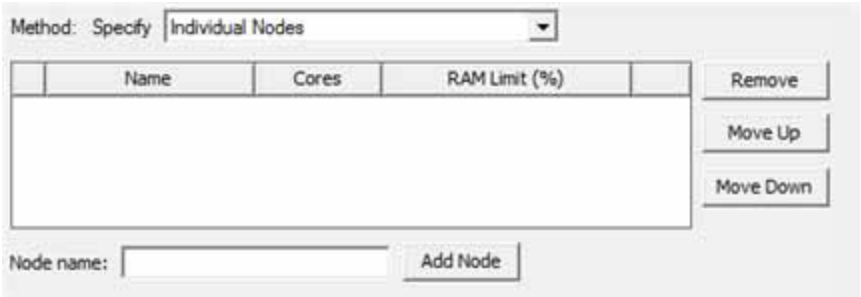
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Individual Node List

For Windows HPC jobs, you may either specify a node list, or specify job parallelization parameters, but not both.

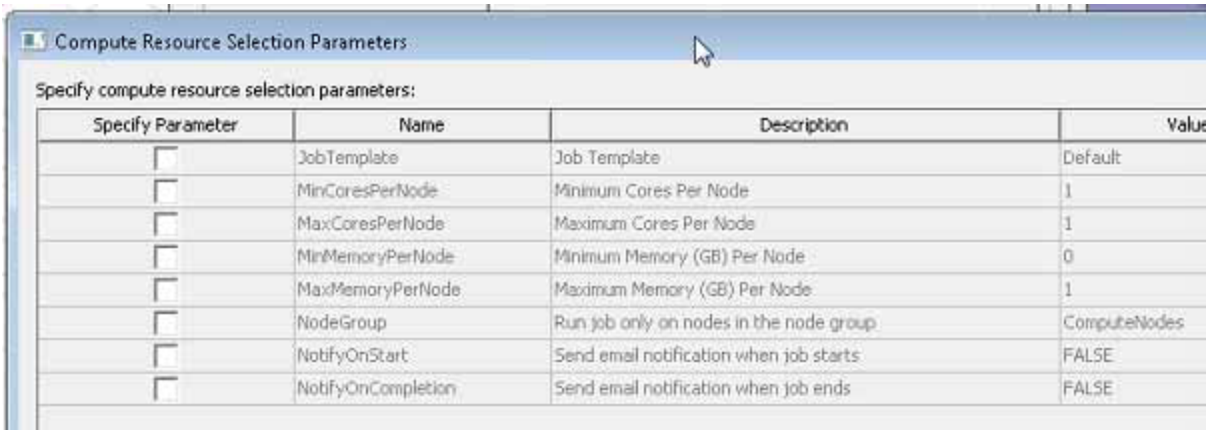
If you select the Individual Nodes Method, you may specify a node list, and the Job parallelization controls are disabled. In this case, the node list should only include cluster nodes that are valid for the job. For each node, you enter the node name and add the node. In the table, you can specify the number of cores and the RAM limit as a percentage. You can use the Remove, Move Up and Move Down buttons to edit and order the list.



Compute Resource Selection Dialog

By default, you can draw from the entire pool. You can also click the ellipsis button [...] to open a **Compute Resource Selection** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The resource selection parameters for Windows HPC jobs are:

- JobTemplate: Job Template - The JobTemplate may limit the job parameters or specify defaults values for job parameters
- MinCoresPerNode: Minimum Cores Per Node
- MaxCoresPerNode: Maximum Cores Per Node
- MinMemoryPerNode: Minimum Memory (GB) Per Node
- MaxMemoryPerNode: Maximum Memory (GB) Per Node
- NodeGroup: Run job only on nodes in the node group
- NotifyOnStart: If True, send email notification when job starts. Email notifications must be configured and enabled for the cluster by the administrator. (The cluster head node must run Windows HPC Server 2008 or above.)
- NotifyOnCompletion: If True, send email notification when job ends. Email notifications must be configured and enabled for the cluster by the administrator. (The cluster head node must run Windows HPC Server 2008 or above.)

Job Parallelization

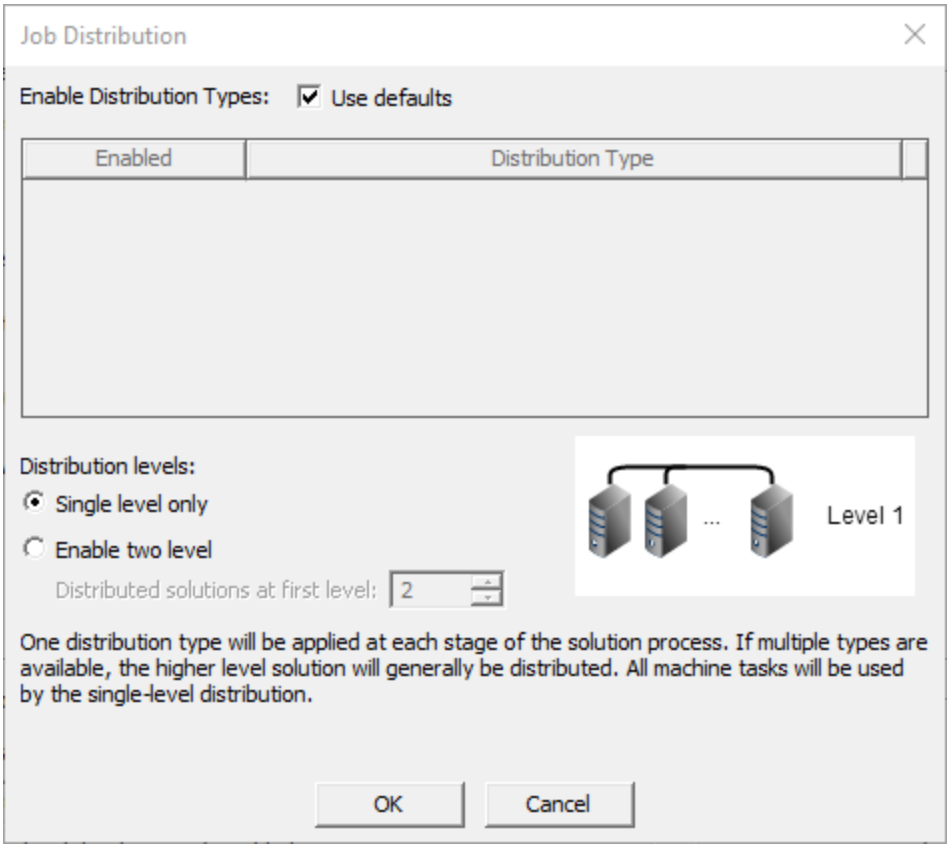
For Windows HPC jobs, you may either specify a node list, or specify the job parallelization parameters, but not both. The Job parallelization fields let you specify:

- Total number of tasks: The number of nodes requested for the job is the total number of tasks divided by limit on the number of tasks per node, rounded up if it is not an integer.
- Cores per distributed task. This determines the amount of multiprocessing per task.
- Whether nodes are for exclusive usage by this job
- Whether to limit the number of tasks per node to a value. If the "Limit number of tasks per node" check box is not checked, then the job is submitted with a job unit type of "Core".

Job Distribution

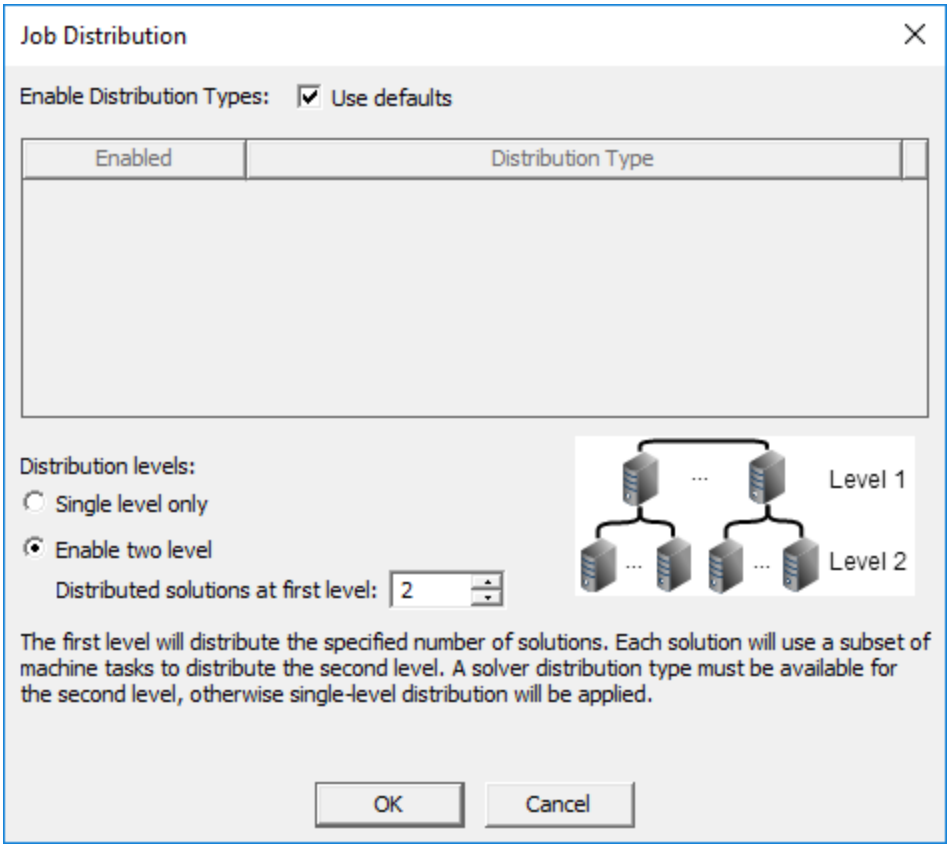
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Single level or two level distribution (*single level* is the default). Click **Modify** to display the **Job Distribution** dialog box and select the **Enable two level** option if applicable and desired.



- Second level distribution operates within DSO. If available and enabled you can specify the number distributed solutions for level 1.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

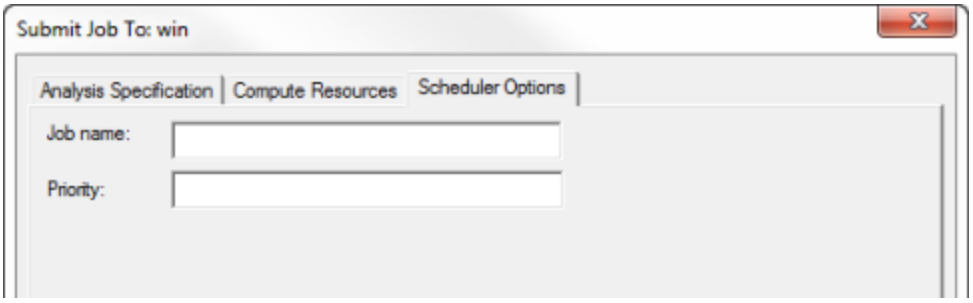


In response to a set of minimal constraints, the Scheduler may increase the resources assigned beyond the minimal values in order to meet the full set of requirements. For example, if you specify 7 distributed engines, with two processors per engine, and also limit the number of engines per node to 4, the scheduler may increase the number of cores used in order to meet the limit specified for engines per node. Notice that a preview of the Submit Job Results shows the number of resources assigned, and that the scheduler generated code includes an MPI specification.

Scheduler Options

The **Scheduler Options** tab provides for specifying the job name and/or the job priority. While the **Show advanced options** check box enables the display of Job submission options, no job submission options should be specified for Windows HPC.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Preview Submission

The Preview Submission button opens a window that shows a text description of the job to be submitted and the task used to start the product on one of the nodes.

The JOB PARAMETERS section contains information on parameter that apply to the job as a whole.

- The "Job resource parameters" section indicates whether the job has exclusive use of nodes, the job unit type, and the minimum and maximum number of units requested for the job, node group, and email notifications.
- The "Job attributes" section displays the job name and job priority.
- The "User Specified Compute Resource Attributes" displays the Resource selection settings.

The TASK PARAMETERS section contains information on parameters that apply to the Desktop task, which is the main task of the job.

- The "Desktop task resource parameters" section indicates the job unit type (which is the same as in the JOB PARAMETERS), and the minimum and maximum number of units requested for the Desktop task.
- The "Command Line section" displays the desktop task command line, including all arguments.
- The "Environment variables" section displays the environment variables that are set for the Desktop task; the same environment variables will also apply to all other tasks of the job.
- The "Working directory" section indicates the working directory in which the Desktop task will run.

Monitor Job

If you have checked the Monitor Job option on the **Submit Job To** dialog box, **AnalysisSpecification** tab, you can invoke the **Monitor Job** window by clicking **Tools** > **Job Management** > **Monitor Jobs...** This dialog box may also be brought up by checking the **Begin**

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

monitoring this job now check box when a job is successfully submitting using the job submission dialog box. For more details, see: Monitor Jobs Window.

Windows® HPC Job Templates

The job templates are managed by the Windows HPC cluster administrator. Every cluster has at least one job template, the "Default" job template. Every job has an associated job template. If no job template is specified, then the "Default" job template is used. The job template controls two related aspects of the job submission process. When a job is submitted, there are a number of job parameters which may be specified. Each parameter has a set of valid values. For example, the Priority parameter has five valid values, Highest, AboveNormal, Normal, BelowNormal, and Lowest. The job template controls the default value of each parameter; this is the value that the parameter has if it is not specifically overridden by the submitter. For example, in the Default job template, the default value of the Priority parameter is Normal. The job template may also limit the allowed values of each parameter to a subset of the valid values. For example, a job template for privileged users could allow all five Priority values, which a job template for unprivileged users could limit the allowed Priority values to Normal, BelowNormal and Lowest.

Each job template is a Windows object with access controlled by an ACL (access control list). Instead of the usual "Read" or "Read & Execute" permissions, there is a "Submit Job" permission which corresponds to the right to submit a job with this job template. The cluster administrator may create job templates to limit or control access to cluster resources. For example, a job template with limited allowed job run times, or access to a limited set of compute nodes could be created by the cluster administrator. Specific users or user groups could be forced to use this limited job template by omitting access to the other job templates or by adding a deny access entry for the specified user or group to the other job templates. See the *Microsoft HPC Pack 2019: Job Templates* white paper from Microsoft for additional details:

https://learn.microsoft.com/en-us/powershell/high-performance-computing/job-templates?view=hpc19-ps

Job templates may also be created to allow users to run jobs with limited knowledge of the appropriate job parameters. The cluster administrator creates a job template which has reasonable default values for the type of job to be run, and informs users which job template to use for each type of job. The template could also limit some parameters to only the subset of all values that are useful for the type of job associated with the template.

Selecting Computation Resource Units (Job Unit Type)

The Job Unit Type is the smallest unit of processing resources used to schedule the job. This is one of the most important job properties. There are three options for the Job Unit Type: cores, nodes or sockets.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Cores**: Jobs are scheduled in units of cores, which may be also described as a CPU cores, logical processors, or CPUs. This is the smallest unit of granularity available. This selection allows the scheduler to start multiple tasks on a processor, if the total number of cores needed by the tasks is less than or equal to the number of cores on the processor. This selection may also allow the scheduler to distribute more of the computational load to processors with more cores than to processors with fewer cores. For Windows, there is a 64 core limit for a single machine.
- **Nodes**: Jobs are scheduled in units of nodes, hosts or machines. This is the coarsest level of granularity that may be selected. When this option is selected, only one task will run on any give node at any given time. This is useful in cases where it is not desirable to run multiple tasks on a single host. For example, if each task is multi-threaded, running multiple tasks on the same node may not be needed to fully utilize the computing resources on the node. This may also be preferred if the tasks are memory intensive, and multiple tasks would be competing for the limited memory resources.
- **Sockets**: A socket (which may also be called a NUMA node) is a collection of cores sharing a direct connection to memory. A socket will contain at least one core, and it may contain several cores. The socket concept may not necessarily correspond to a physical socket. Scheduling at the socket level may be useful in cases in which each task requires extensive use of the memory bus, and scheduling multiple tasks on the same socket would result in excessive bus contention.

Windows® HPC Non-Exclusive Jobs

Windows HPC allows three choices for the Cluster AffinityType setting:

- No Jobs: Affinity is not set for any jobs
- Non Exclusive Jobs (default): Affinity is not set for exclusive jobs
- All Jobs: Affinity is set for all jobs

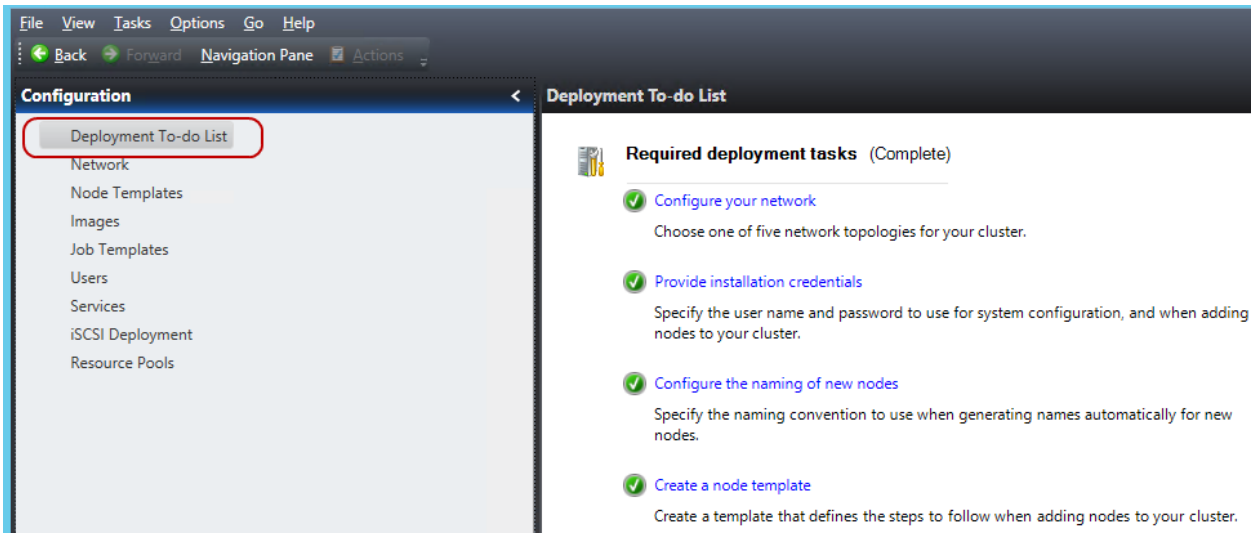
If the AffinityType is set to “No Jobs,” then we can allow non-exclusive jobs in many cases, but non-exclusive jobs will be disallowed if you specify an explicit host list (because all resources on all specified hosts are used), if you specify nodes and cores (to ensure that the job has exclusive access to the specified number of nodes), or if you specify multi-threading (to prevent a single task from being split across hosts). If the AffinityType is set to “Non Exclusive Jobs,” then exclusive jobs will be disallowed for all cases, the same as the restrictions for the previous release.

The previous job submission dialog always has the “exclusive” check box disabled for Windows HPC jobs, so that “exclusive” jobs cannot be submitted to a Windows HPC cluster. The “exclusive” check box is now enabled for Windows HPC jobs. This allows you to submit exclusive jobs to a Windows HPC cluster. If this check box is checked, but the submission parameters and Windows HPC cluster AffinityType do not allow submission of an exclusive job, then an error message is displayed when you submit or preview the job.

Setting the Windows HPC Cluster Affinity Type

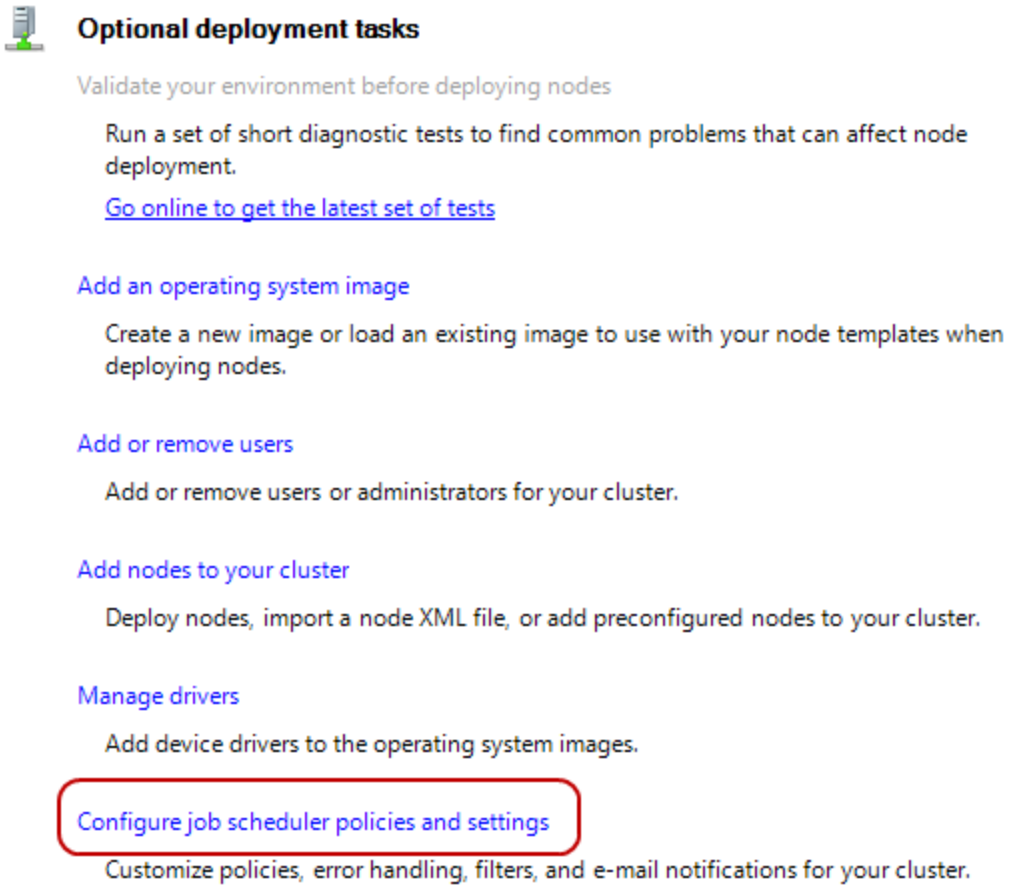
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A Windows HPC Cluster administrator is able to modify the Affinity Type setting for the cluster. The administrator should start the Windows HPC Cluster Manager. The first step is to select the Configuration button on the lower left pane, then select the Deployment To-do List in the upper left pane. Then, the upper right pane displays the Deployment To-do List, as shown below.



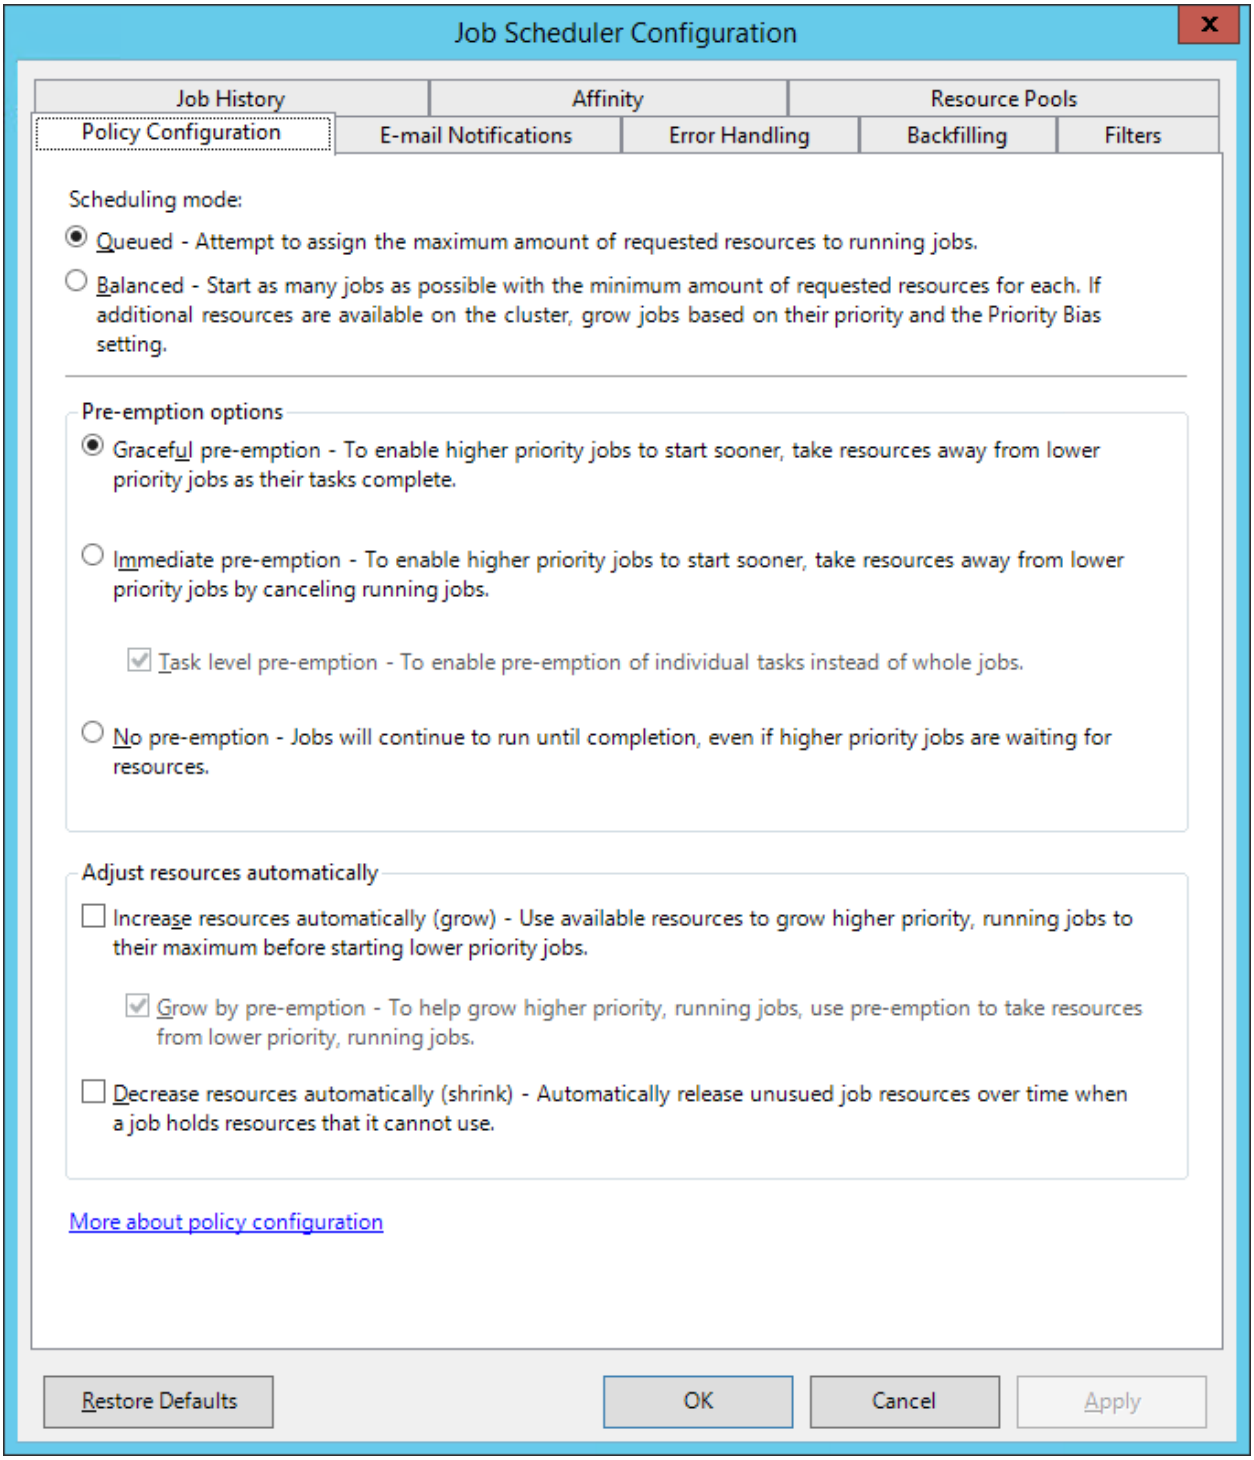
Next, the "Configure job scheduler policies and settings" should be selected. This is under the heading "Optional deployment tasks."

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



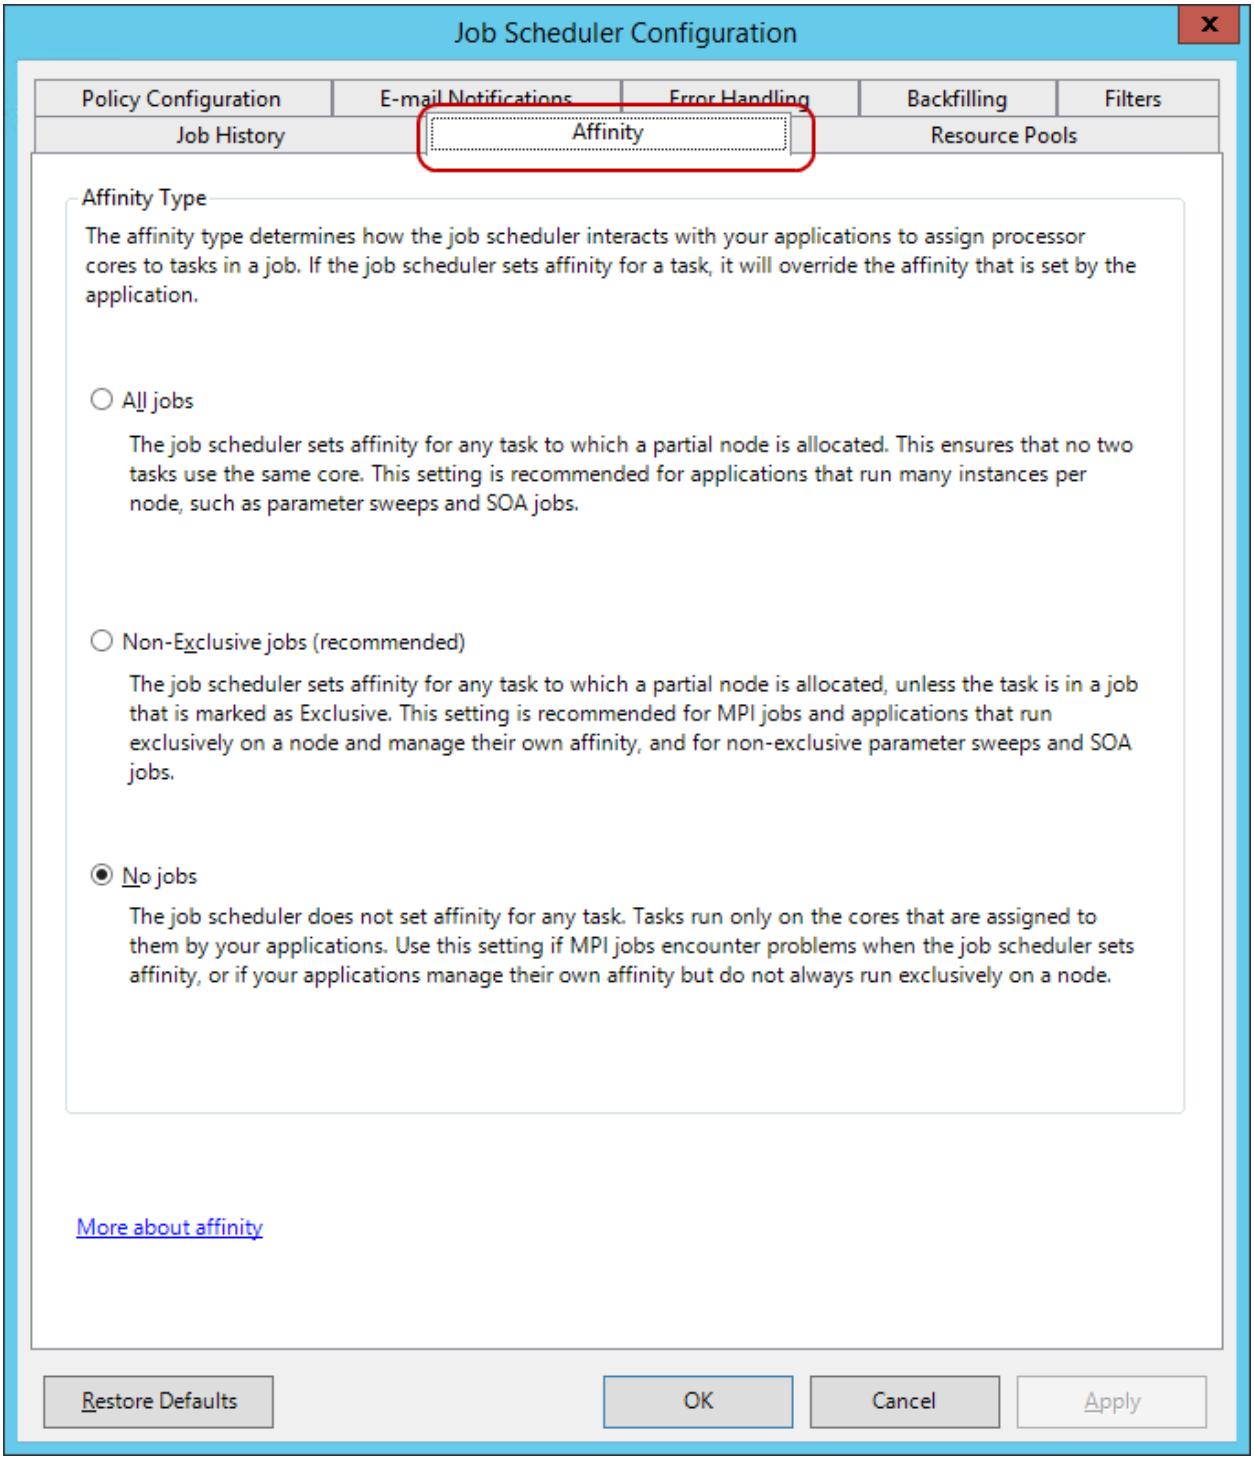
The *Job Scheduler Configuration* dialog box pops up, as shown below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Next, select the "Affinity" tab should be selected.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The cluster administrator may now select a radio button to select the desired Affinity Type:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- All jobs
- Non-Exclusive jobs
- No jobs

In order to submit non-exclusive jobs, the "No jobs" option should be selected. The "Non-Exclusive jobs" option may be selected, but this will not allow non-exclusive Ansys Electromagnetics jobs to be submitted to the cluster. The "All jobs" option is not supported for Ansys Electromagnetics jobs. The OK or Apply buttons may be used to apply the selected option to the cluster.

Examples with "Submissions with Nodes are for exclusive usage by this job" Unchecked and Checked

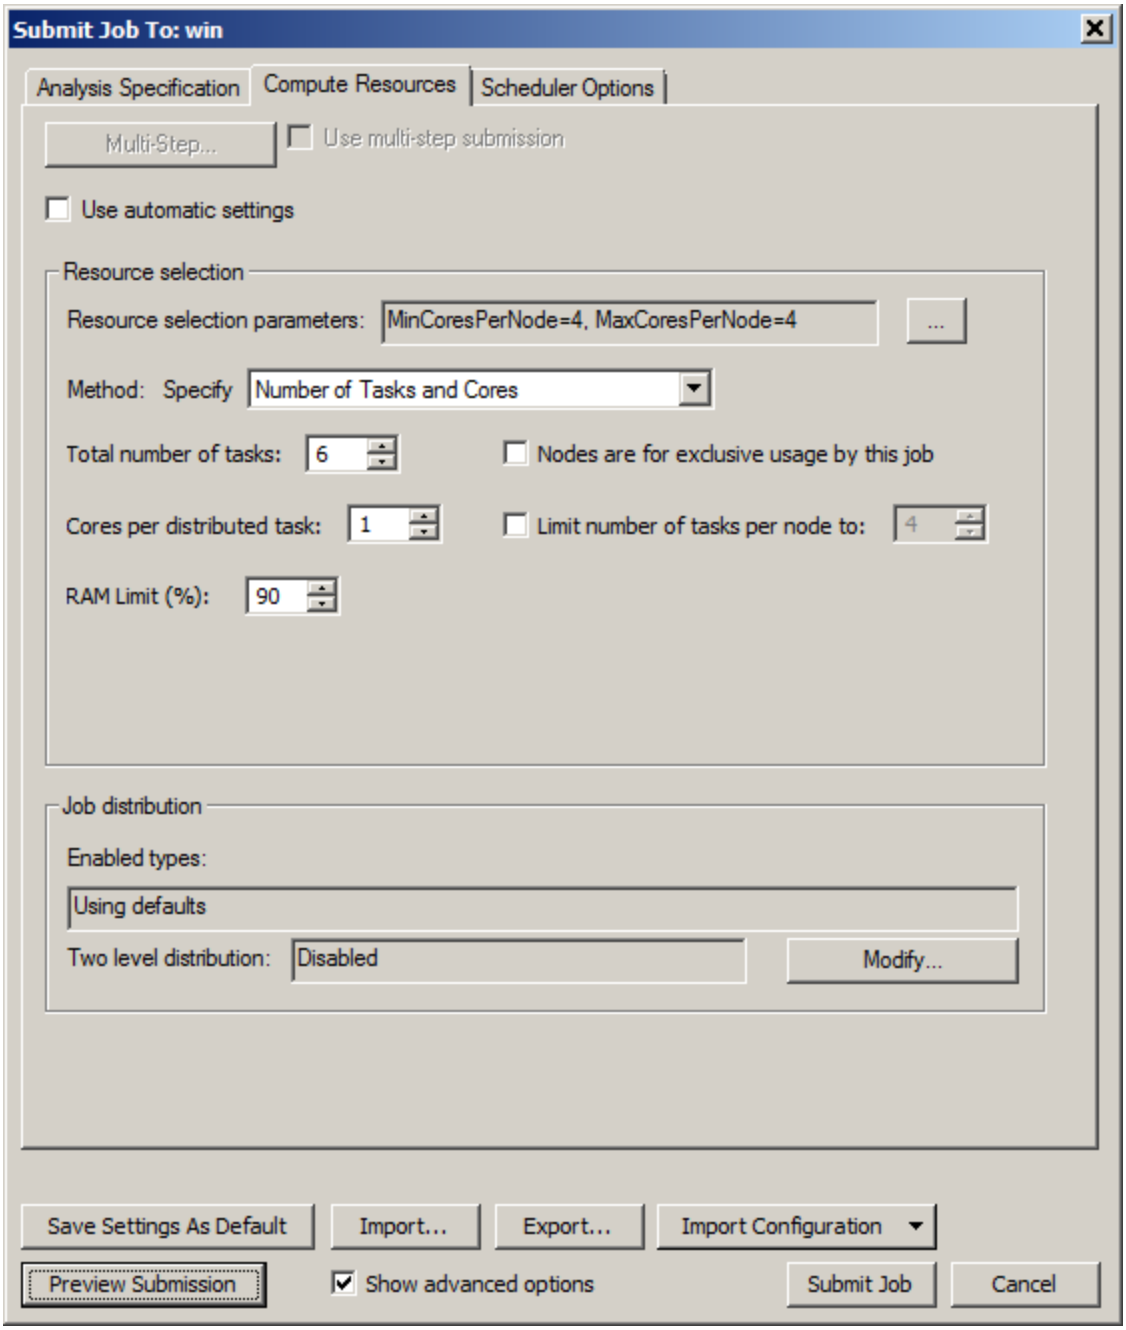
Most of the following screen shots are for the same project file submitted to a Windows HPC cluster with the AffinityType set to "No Jobs". The scheduler resource selection parameters are the same for all of these screen shots:

- MinCoresPerNode=4
- MaxCoresPerNode=4

The first set of screen shots show submission of a job to a Windows HPC cluster in which the "Use automatic settings" check box is not checked, and the resource selection method is "Specify Number of Tasks and Cores". The exclusive setting for the job is controlled by the "Nodes are for exclusive usage by this job" check box. In previous releases, this check box was always disabled and checked for Windows HPC jobs. Now, it is enabled, and the user may select whether it is checked or unchecked. If it is checked, then the behavior is the same as previous releases. If it is unchecked, then the job is submitted with the exclusive parameter for the job set to false.

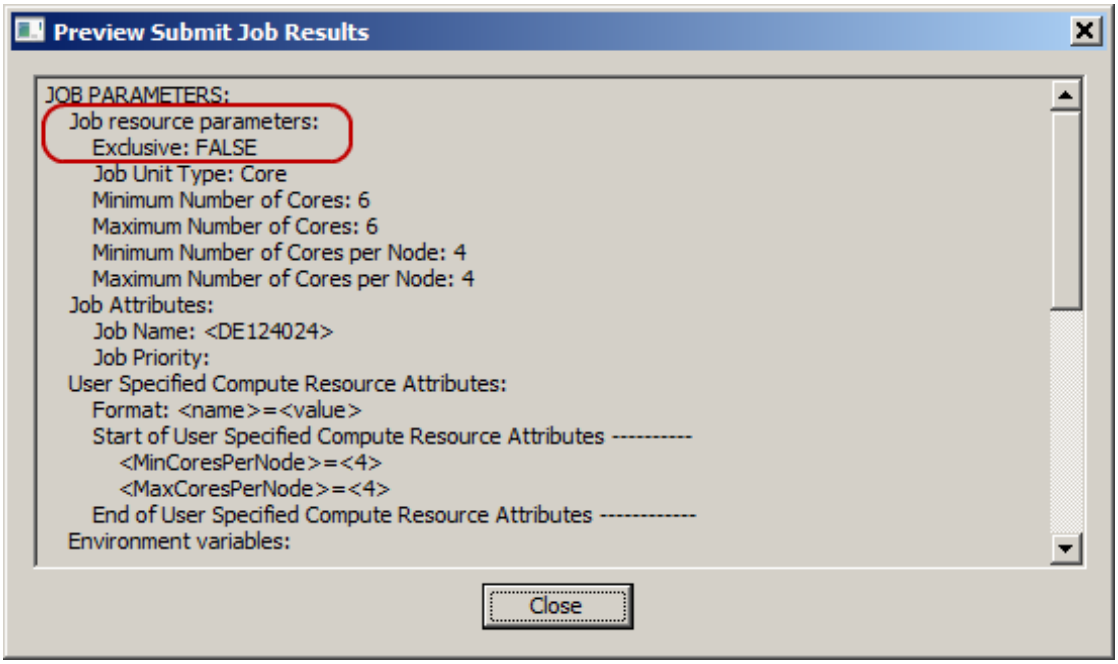
The following screen shot shows this configuration with a Submit Job with Task and Cores specified and nodes as non-exclusive.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The next figure shows Preview for the job submission indicating that the exclusive parameter for the job is false.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

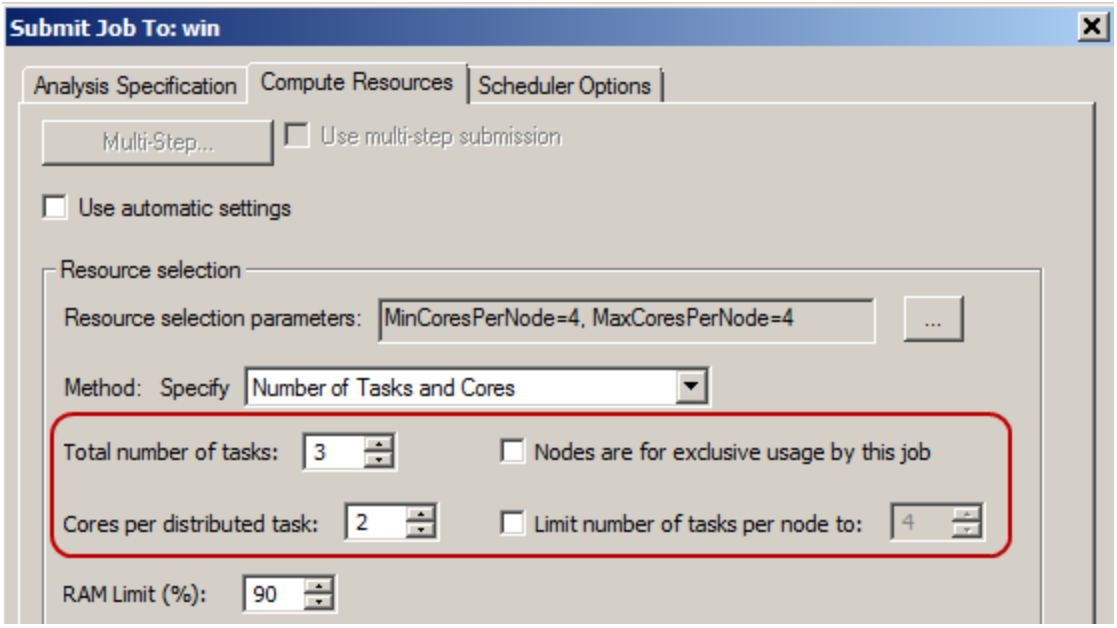


Jobs may only be submitted using this resource selection method with the exclusive parameter set to false if all three of the following conditions are met:

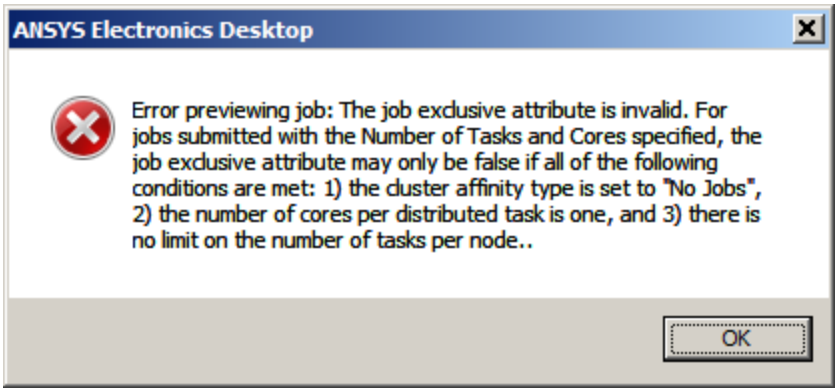
1. The cluster AffinityType is "No Jobs",
2. There is no multiprocessing, and
3. There is no limit on the number of tasks per node.

If any of these requirements are not met, then the job is not submitted or previewed, and an error message appears. The following figure shows this configuration.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



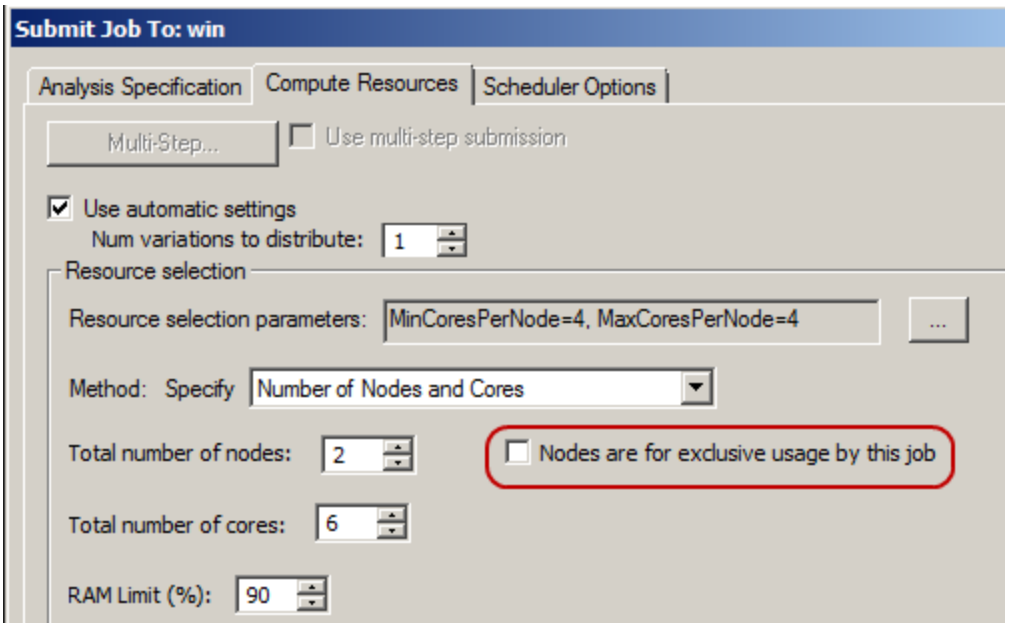
The following figure and screen shot ErrorMsgTasksAndCoresNonExMP.png shows the error message box shown to the user.



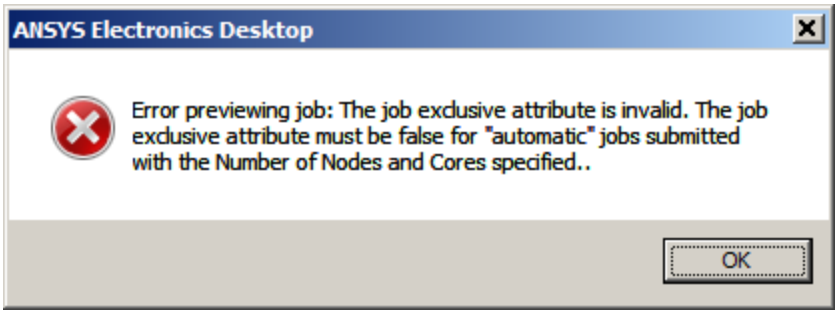
The next example shows submission of a job to a Windows HPC cluster in which the "Use automatic settings" check box is checked, and the resource selection method is "Specify Number of Nodes and Cores". If you select *Use automatic settings* with *Num variations to distribute* set to 1, Optimetrics variations will be solved sequentially. Other distribution types will be distributed automatically. It does distribute frequencies, domains, and use of multiple level domains. If you set Num variations to distribute to 2 or more, Optimetrics variations will be solved in parallel. Other distribution types will be distributed automatically. The exclusive setting for the job is controlled by the "Nodes are for exclusive usage by this job" check box. In previous releases, this check box was always disabled and checked for Windows HPC jobs. Now, it is enabled, and the user may select whether it is checked or unchecked. If it is checked, then the

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

behavior is the same as previous releases. If it is unchecked, then the job is not submitted or previewed because only exclusive jobs are allowed when using this resource selection method, and an error message box is shown to the user in this case. The following figure shows this configuration:

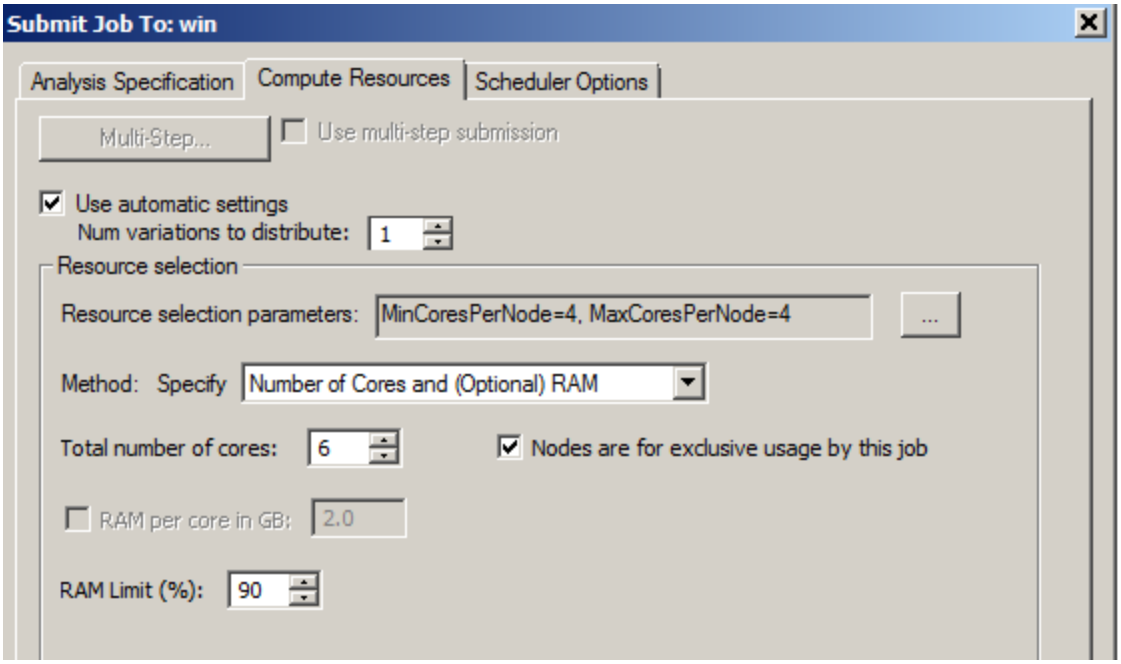


The following figure shows the error message.

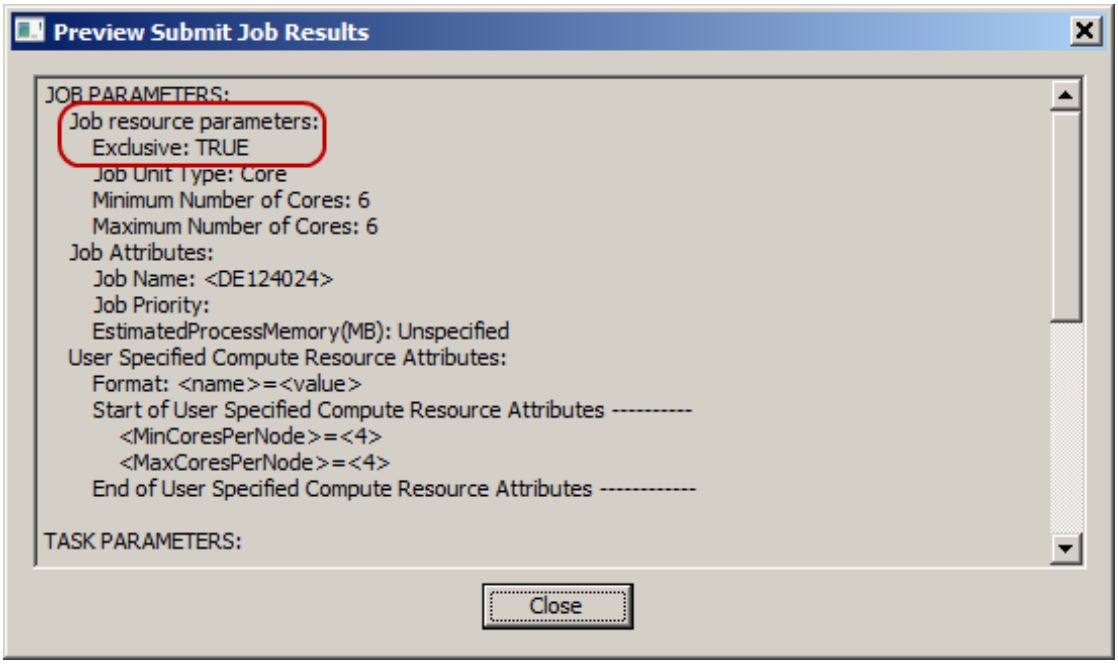


The next example show submission of a job to a Windows HPC cluster in which the "Use automatic settings" check box is checked, and the resource selection method is "Specify Number of Cores and (Optional) RAM". The exclusive setting for the job is controlled by the "Nodes are for exclusive usage by this job" check box. In previous releases, this check box was always disabled and checked for Windows HPC jobs. Now, it is enabled, and you may select whether it is checked or unchecked. If it is checked, then the behavior is the same as previous releases. The following figure shows this configuration.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

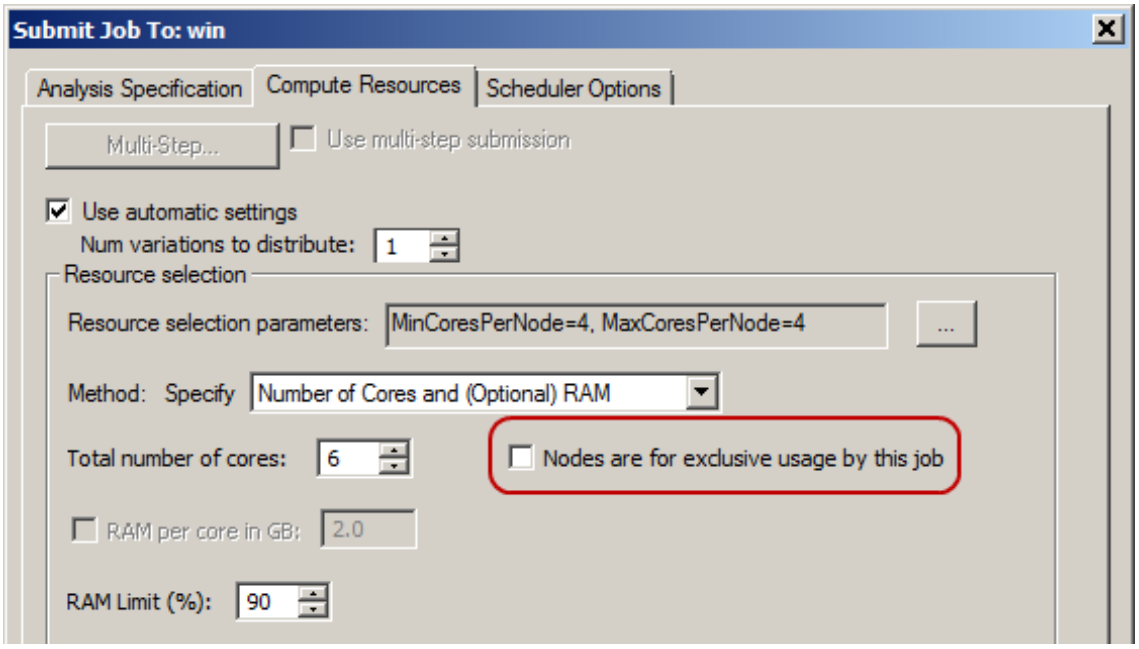


The following figure shows the Job Preview for this case, indicating that the exclusive parameter for the job is true.

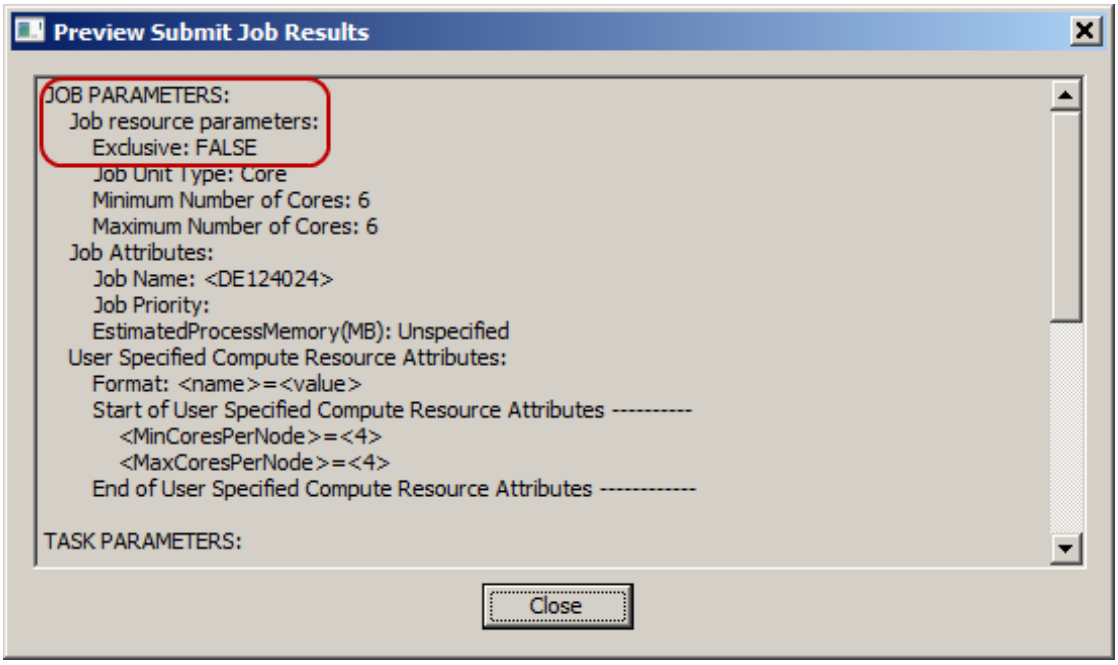


If the exclusive check box is unchecked, then the job is submitted with the exclusive parameter set to false. The following figure shows this configuration.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



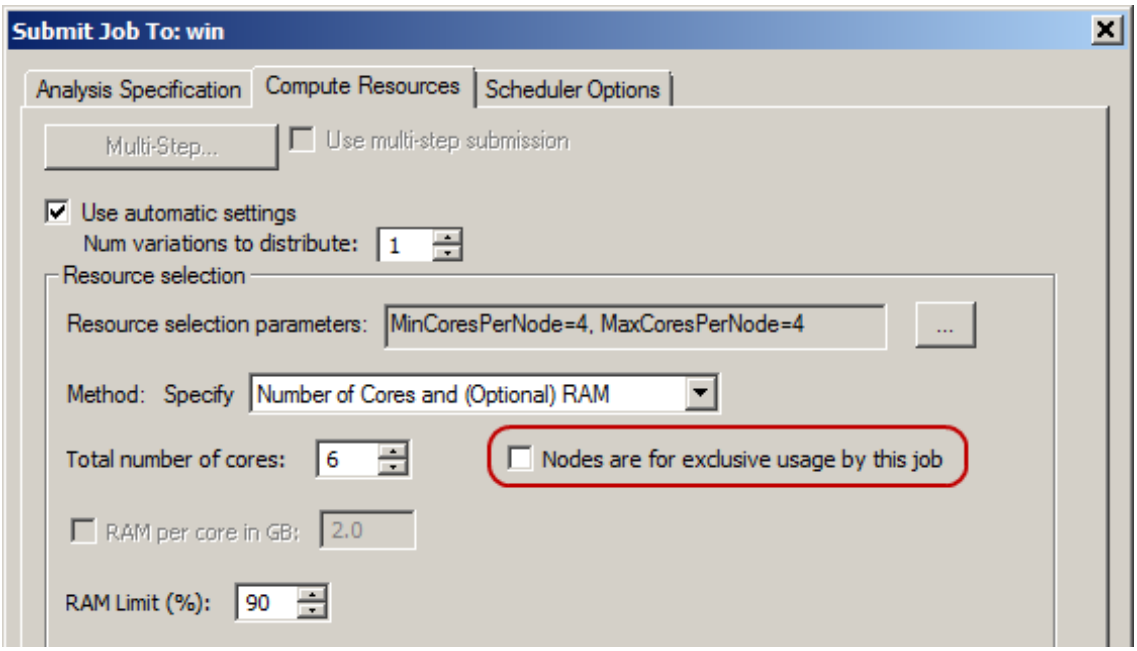
The following figurescreen shot PreviewCoresAndRAMNonEx.png shows the Job Preview for this case, indicating that the exclusive parameter for the job is false.



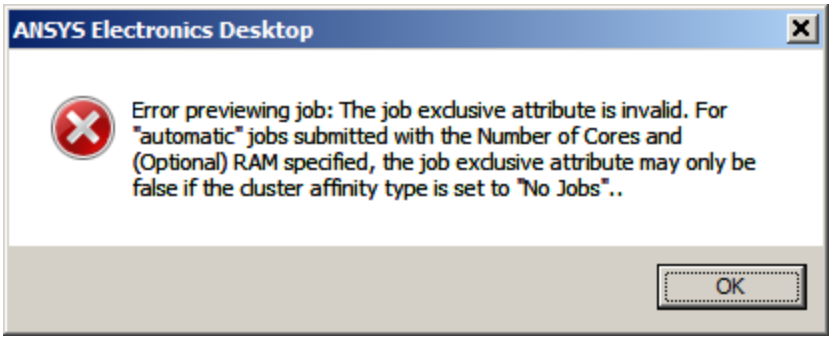
The last example resembles the previous one, except that the Windows HPC cluster AffinityType is set to "Non Exclusive Jobs" in this case. The job is submitted with the "Use

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

automatic settings" check box in the checked state, and the resource selection method set to "Specify Number of Cores and (Optional) RAM". Because the AffinityType is not "No Jobs", only exclusive jobs may be submitted to this cluster. If the exclusive check box is not checked, then the job is not submitted or previewed, and an error message box is displayed to the user. The following figure shows this configuration.



The following figure shows the error message.



Windows® HPC Job Credentials

Normally, a user will be prompted for the credentials used to submit a job. One way to simplify this process is to use the "cluscfg setcreds" command to set the user's credentials in the credentials cache. If this is done, then no password needs to be supplied for a job submitted for

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the specified user. Here is a cluscfg command that may be used to set the user credentials in the credentials cache:

```
cluscfg setcreds /password:* /scheduler:cluster_name
/user:domain\user_name
```

Here:

- cluster_name = the name of the cluster (hostname of the head node)
- domain = optional domain name; if omitted, the following \ should also be omitted
- user = user name

When this form of the command is used, the user is prompted for the password and also asked if the password should be remembered (cached).

See the following web page for more information on the cluscfg setcreds command:

http://technet.microsoft.com/en-us/library/cc947669(WS.10).aspx

Integration with Grid Engine (GE)

The Grid Engine (GE) scheduler (also known as OGE and SGE) is only supported on Linux. With GE, jobs may be submitted in any of the following ways:

- Using GE commands (qsub, etc.) or the SGE gui (qmon)
- Using the generic scheduler GUI in local mode
- Using the generic scheduler GUI in service mode

For additional information on supported schedulers, visit the Platform Support page. Then, locate and click the following link:

Ansys 2025 R1 - Job Schedulers and Queuing Systems Support

Ansys Electromagnetics products support Grid Engine (GE) for Serial analysis, Multi Processing and Distributed Analysis. Models with parametric sweeps can use Large Scale DSO. With GE, the Ansys EM job doesn't require graphics. Ansys EM job's progress can be monitored through GE commands or through Electronics Desktop's Job Management interface.

GE Job Management

You can use Ansys Electronics Desktop to submit batch jobs to GE and monitor those jobs.

This involves the following steps:

1. Use **Tools** > **Job Management** > **Select Scheduler** to select SGE/OGE/GE as the scheduler.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Use **Tools** > **Job Management** > **Submit Job** to submit a batch job to GE.

   GE-specific Settings:

   - On the **Compute Resources** tab, click the **Resource Selection Parameters** ellipses button (**...**) to specify the **ParallelEnvironment** parameter. If you do not specify anything, the scheduler will select a parameter.
   - On the **Compute Resources** tab, select **Specify node list** if you wish to specify the nodes. In a computing environment where the available cores are not uniform, you can use this to have control over which resources your job will use. If your Analysis configuration contains a node list, you can use Populate this Page from Analysis Configuration.
   - Memory resource behavior is dependent on the GE version as well as the particular scheduler settings. The output of the `qconf -sc` command shows all of the complexes available to GE schedulers. For a complex to be considered valid for memory resource selection, it must be of type "MEMORY", have relop "<=", be requestable (could be "forced" as well, instead of "YES"), and be consumable. At least one valid memory complex must be available to submit jobs using the Automatic Cores and RAM method.

     For Univa GE 8.3 and later, there is an additional column for whether resources are available to a preempting job after preemption of a running job. It is up to the cluster administrator to determine the appropriate Available After Pre-Emption (aapre) setting for memory complexes. This setting is ignored for memory complex validation.

     Determining the correct memory complex by default is error-prone. Because the correct choice of memory complex can vary from cluster to cluster, the memory complex selection is now exposed by default under the compute resource selection parameters, allowing the user to make the selection without having to set an environment variable. Only complexes that have been validated (meeting the requirements specified above) can be selected. The cluster administrator (or someone who has knowledge of the specifics of the cluster in use) should be able to determine the correct memory complex to use for Ansys Electronics jobs. To disable exposure of this selection option, the following environment variable can be set to "0": ANSOFT_SGE_ENABLE_MEM_RES_ATTRIB
   - On the **Scheduler Options** tab, you can **Customize Job Submission**. When the **Override job submission** radio button is selected, user-specified options replace most of the job submission options. When the **Additional job submission options** radio button is selected, user-specified options are appended to the bsub command.

   Click **Preview Submission** to view the qsub commands to be used to submit the job.

3. Use **Tools** > **Job Management** > **Monitor Job** to monitor the job's progress.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Installation of Ansys EM Tools on GE

Windows:

Install on every node of cluster

Setup 'temp directory' to a path that is same on all nodes. For example, c:\temp

LINUX:

Install on a single node, on a shared drive.

Setup 'temp directory' to a path that is same on all nodes. For example, /tmp

Ensure that the product is available using the same path on all nodes

Permissions:

All users of the cluster should have read/write permissions to temp directory

All users should have read/execute permissions to installation directory

When a desktop scheduler GUI is run the same node as the job submission node, no other configuration is necessary: installation is sufficient. You select the scheduler through the desktop GUI. You need to ensure that scheduler commands are available in the path before you launch desktop.

> **Note:**
>
> There is no need to install RSM unless the you are using the scheduler GUI on a post processing node that is different from the job submission node. In this case, RSM must be configured with the scheduler type and path.
>
> A post processing nodes is a node in the cluster that can run the Ansys Electromagnetics desktop in graphical mode. A job submission node is a node in the cluster in which job submission commands are available.

Turn OFF firewall between cluster nodes.

Scenario 1: The post-processing node and job-submission node roles are served by distinct machines.

In this case, perform the following configuration:

The job-submission node should be configured to run RSM service, which serves as a proxy to scheduler. The RSM Service should be running as 'root' in order to facilitate jobs running using the credentials of the job's owner. A **configuration file in the RSM installation folder should be edited** to specify information regarding the scheduler that manages jobs on this cluster. A

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

block labeled 'Scheduler' must be included within the 'AnsoftCOMDaemon' block. This block contains two string entries:

- SchedulerName: this contains the unique part of the scheduler proxy library name
- ConfigString: this contains a scheduler specific configuration string

The case of the SchedulerName string is significant on Linux because Linux file names are case sensitive. The case of the SchedulerName string is not significant on Microsoft Windows. In Ansys Electromagnetics Suite 2025 R1, the possible scheduler names are: lsf and sge. The ConfigString entry is a scheduler specific configuration string, described below.

In addition, the AnsoftRSMService must be started with appropriate environment variables set. Generally, the environment variables must be set the same as they would be set for using the scheduler via command lines.

SGE Details

For SGE, the ConfigString entry must contain the search path for the SGE commands. It may contain a single directory, the directory containing the SGE commands. Alternatively, it may be a path, with directories separated by the colon character ":", where the SGE command directory appears before any other directory containing files with the same name as any SGE commands.

Example ansoftrsmservice.cfg configuration file:

```
$begin 'AnsoftCOMDaemon'
$begin 'Managed COM Servers'
$end 'Managed COM Servers'
$begin 'Scheduler'
'SchedulerName'='sge'
'ConfigString'='/opt/sge6.2u4/bin/lx24-amd64'
$end 'Scheduler'
$end 'AnsoftCOMDaemon'
```

Scenario 2: The post-processing node and job-submission node roles are served by the same machine.

The **Select Scheduler...** command is used to gather details about the scheduler. In this case, the Desktop process should be started in an environment suitable for submitting jobs to the scheduler. See: Selecting a Scheduler.

The environment should be configured so that all SGE commands are found using the standard search path. In particular, search for the following commands in the search path should result in the SGE command being found: "qsub", "qdel", "qstat", and "qconf". No other command with the same name should appear before the SGE command in the search path.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

GE Commands for Information about Jobs and Cluster Configuration

The following GE commands are especially useful for getting information about the cluster configuration or for getting information about running or completed jobs. This list only contains a few of the most common commands. Consult Grid Engine help for more information.

qconf -help: The first line displays the SGE version

qacct -j *job-id*: Displays a log of the completed job with the specified job ID (if accounting is enabled)

qstat -j *job-id*: Displays a log of the running job with the specified job ID

qconf -sc: Show all complex attributes

qconf -spl: Show a list of all parallel environments

qconf -sp *pe-name*: Show details of the parallel environment with the specified name

qconf -sql: Show a list of all queues

qconf -sq *queue-name*: Show details of the queue with the specified name

qconf -sconf: Show configurations

Submitting Ansys EM SGE Batch Jobs via the Command Line

The SGE qsub command may be used to submit Ansys EM jobs. Typical command formats are:

```
qsub qsub_args ansysEM_exe ansys_args
qsub qsub_args job_script
qsub qsub_args[ -]
```

where:

- *qsub_args* are the options of the qsub command,
- *ansysEM_exe* is the pathname of the Ansys EM tool executable to launch,
- *ansys_args* are the arguments to the Ansoft tool command, and
- *job_script* is a shell script containing the Ansys Electromagnetics desktop command to run.

In the first format, the Ansys EM desktop command and its arguments are specified on the **qsub** command line. In the second format, the pathname of a shell script containing the Ansys EM desktop command and its arguments is specified on the **qsub** command line. In the third format, the command is omitted or replaced with a hyphen; this indicates that the command or script will be taken from stdin.

Quoting Ansys EM Command or Arguments for SGE

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If the Ansys EM tool executable pathname (*ansysEM_exe*) or any of the arguments of the Ansys EM tool command (*ansysEM_args*) contain characters which are interpreted by the command shell, then these special characters must be properly quoted to ensure that the correct command is launched by SGE. This is especially important when using the first form of the **qsub** command, as the Ansys EM desktop command is processed by the shell twice in this case. It is processed by the shell when the **qsub** command is processed, and again when the job is started.

Serial SGE Batch Jobs

In general, Ansys EM batch jobs may be submitted as SGE serial jobs without any special considerations.

See Monitoring Ansys EM SGE Batch Jobs for options for monitoring Ansys EM batch jobs.

Parallel SGE Batch Jobs

When an Ansys EM batch job is run as an SGE parallel job, the SGE scheduler will select the hosts for the distributed analysis job, and start the desktop process on one of these hosts. The desktop process will obtain the list of hosts from the SGE scheduler, and start analysis processes, as needed, using the SGE scheduler facilities. To run an SGE parallel job, the job must be submitted to an SGE parallel environment (PE).

If the qmaster tcp port is not configured as a service, but rather via the environment variable SGE_QMASTER_PORT, this variable must be set in the Ansys EM batch job environment. This is needed because the ANSOFT EM desktop uses the "qrsh -inherit" command to launch engine processes.

See Monitoring Ansys EM SGE Batch Jobs for options for monitoring Ansoft batch jobs.

Setting Up an SGE Parallel Environment (PE)

To allow Ansys EM batch jobs to distribute analysis engines to multiple hosts, the job must be run in a parallel environment (PE) in which the control_slaves parameter is set to TRUE. This setting is required to allow the Ansys EM desktop to start analysis engines on hosts other than the local host.

Here is a sample parallel environment configuration:

```
pe_name ans_test1
slots 999
user_lists NONE
xuser_lists NONE
start_proc_args /bin/true
stop_proc_args /bin/true
allocation_rule $round_robin
control_slaves TRUE
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
job_is_first_task FALSE
urgency_slots min
accounting_summary TRUE
```

The user_lists and xuser_lists parameters are ACLs (access control lists) used to control which users have permission to use the parallel environment. The user_lists setting gives permission to use the PE. The xuser_lists setting denies permission to use the parallel environment. The xuser_lists settings override the user_lists settings.

The start_proc_args and stop_proc_args parameters contain the pathname and arguments for the parallel environment startup and shutdown scripts. No startup or shutdown scripts are needed for parallel Ansys Electromagnetics batch jobs. The setting /bin/true may be used as the value for these scripts; this utility does nothing and returns an exit code indicating success (0).

The parallel environment allocation_rule parameter will affect how the analysis engine tasks are distributed across the hosts allocated to the job. The $round_robin setting distributes the tasks across the hosts in a round robin fashion, resulting in the load being relatively evenly distributed over all of the hosts. The $fill_up setting allocates all slots on a host before distributing the tasks to another host; the result is that most hosts are either fully utilized or completely unused. See the sge_pe man page for other settings for this parameter.

The control_slaves parameter must be set to TRUE, as described above.

The job_is_first_task parameter also affects how tasks are allocated. When submitting a job to run in a parallel environment, the number of parallel tasks, n, is specified on the command line. If this setting is TRUE, then the job process is considered one of the tasks, and only (n-1) additional tasks are allocated to the job. If the setting is FALSE, then the job process is not considered to be one of the tasks, and n additional tasks are allocated for the job.

See the sge_pe man page for more information about these and other PE parameters.

A parallel environment does not run tasks directly. Instead, the tasks are distributed to queues associated with the parallel environment. In order to complete the setup of a parallel environment, one or more queues need to be associated with the parallel environment. The queue pe_list parameter is used to specify the parallel environments (PEs) supported by the queue. This is an important step; **if no queues support a given PE, then jobs submitted to that PE will not run**.

Parallel Batch Job Command Line Considerations

The number of engines run on a host will depend on the total number of distributed engines, and the number of hosts allocated to the job. The memory required on a host depends on the number of engines running on the host and on the memory needed for each engine. The **qsub** command **-l resource=** *value*,... or **-q** *queue_list* > command line options specify that the parallel batch job run on machines with sufficient memory and other resources.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Monitoring GE Serial and Parallel Batch Jobs

You can monitor jobs through the Electronics Desktop user interface, or through the command line.

The suggestions below are for GE serial jobs and GE parallel jobs.

GE qstat Command

The SGE **qstat** command may be used to display information on jobs and queues. If the **-j** option is included, then information on jobs is displayed. If the option includes a job list (**-j [** *job_list* **]**), then the displayed information is limited to the jobs in the job list.

The **-u***user*,... option limits the output to jobs associated with users in the user list. If the **-u***user*,... option is not specified, then information on queues or jobs of the current user are displayed.

The **-t** option displays extended information about the subtasks of each displayed job. This is equivalent to the **-g t** option. The **-r** option displays extended information about the resource requirements of the displayed jobs.

See the SGE manual pages for more information.

Ansys EM Desktop -monitor Command Line Option for SGE

The **-monitor** command line option enables batch job output to the standard output and standard error streams. The warning, info, and progress messages are sent to the standard output stream. The error and fatal messages are sent to the standard error stream.

The SGE scheduler redirects the standard output and standard error streams of batch jobs to files specified in the **qsub -o [[** *hostname* **]:]** *path*,... and the **-e [[** *hostname* **]:]** *path*,... command line options, respectively. If either option is not specified, then the associated stream is redirected to the default file pathname.

The **qsub -j y[es] | n[o]** controls whether the standard output and standard error streams are merged. If the y or yes value is specified, then the standard error stream is merged into the standard output stream. If the **-e** *host_and_path* option is also specified in this case, the *host_and_path* setting is ignored. If the n or no value is specified, or if this option is not specified, then the standard error stream and standard output stream are not merged.

You can monitor the progress of a job by checking the standard output file for progress, info and warning messages, and checking the standard error file for error and fatal messages.

Example SGE qsub Command Lines

All of the following examples show how to submit Linux HFSS jobs on SGE, but similar command lines will work for all Ansys Electromagnetics products.

Serial job using command line:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
qsub -b y /opt/ansys_inc/v251/AnsysEM/ansysedt -ng -BatchSolve
 ~/projects/OptimTee.aedt
```

- The **-b y** option indicates that hfss is launched directly from the command line, instead of using a script.
- No queue is specified, so the default queue will be used.

Serial job with a hard runtime limit of 15 minutes:

```
qsub -b y -l h_rt=00:15:00 /opt/ansys_inc/v251/AnsysEM/ansysedt
 -ng -BatchSolve ~/projects/OptimTee.aedt
```

- The -l h_rt=00:15:00 option indicates that this job has a "hard" runtime limit of 15 minutes.

Serial job using a script, with a runtime limit specified in the script:

```
qsub ~/sge/scripts/OptimTee.csh
```

- The **-b y** option is absent, so the script ~/sge/scripts/OptimTee.csh will be run when the job starts.
- The script file OptimTee.csh may contain SGE directives in addition to the command(s) to run. In this example, a directive with a hard runtime limit if 15 minutes is included in the script.

Script file contents:

```
#!/bin/csh
#$ -l h_rt=00:15:00
/opt/ansys_inc/v251/AnsysEM/ansysedt -ng -BatchSolve
 ~/projects/OptimTee.aedt
```

- The SGE directive #$ -l h_rt=00:15:00 is equivalent to including -l h_rt=00:15:00 on the qsub command line.

Distributed processing job using 4 engines:

```
qsub -b y -pe pe1 4 /opt/ansys_inc/v251/AnsysEM/ansysedt
 -ng -BatchSolve -Distributed -machinelist num=4
~/projects/OptimTee.aedt
```

- The **-b y** option indicates that hfss is launched directly from the command line, instead of using a script.
- The **-pe pe1 4** command_line option indicates that this is a parallel job running under the pe1 parallel environment, and that 4 cores or processors are allocated to this parallel job.
- The "-machinelist num=n" option is now required for batch jobs.
- The **-Distributed** option indicates that this is a DSO job, so that multiple engines will be started. Because 4 cores are allocated to the job, the job will run 4 engines. The -Distributed option may now have additional options, such as includetypes=xxx, excludetypes=xxx, maxlevels=n, and numlevel1=n, where n indicates and integer, and xxx indicates a list of distribution types or "default".

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Recommended Practices for GE Clusters

The following subsections contain recommendations on how to set up an GE cluster for efficiently running Ansys Electromagnetics Suite serial and parallel jobs. These recommendations require the cluster administrator to make configuration changes.

Submitting Exclusive Jobs

Consumable Memory Limits

Serial Jobs in SGE

Parallel Jobs in SGE

Using Multithreading with Parallel Jobs

Submitting Exclusive Jobs

In many cases, clusters are used to run "large" Ansys Electromagnetics Suite batch jobs. That is, these are jobs that may require a large quantity of resources, such as processors, memory, disk space, or run time. One way to ensure that the resources needed by the batch job are available to the job is to run the job in an "exclusive" mode. That is, any host running the job is not available for use by any other jobs. There is no GE built in mechanism for specifying that a job is "exclusive". GE is extensible, and it is not difficult to configure the cluster to allow exclusive jobs. The steps below show one way to do this. This example requires GE 6.2u3 or later. Note that specifying a job as "exclusive" may delay the start of the job if there are not enough hosts available to run the job exclusively.

1. Use the command qconf -mc to add a new complex to the table of complexes. Recommended attributes are:
    - name : exclusive
    - shortcut : excl
    - type : BOOL
    - relop : EXCL
    - requestable : YES
    - consumable : YES
    - default : 0
    - urgency : 0
2. Set the value of "exclusive" to TRUE for each execution host using the command qconf -me hostname, where hostname is the name of the host. The values of all host configuration parameters may be displayed using the command qconf -se hostname. The "complex_values" line should look similar to:

    complex_values exclusive=TRUE, but other values may also be included.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. When submitting a job, the job will be "exclusive" if the value "excl" is included in the resource list specified by the qsub -l option. If the resource list does not include "excl" then the job will not be exclusive, and other jobs may run on the same host or hosts as this job.
4. Example qsub command line for exclusive serial job:

   ```
   qsub -b y -l excl /opt/ansys_inc/v251/AnsysEM/ansysedt -ng -
   BatchSolve -machinelist num=1 ~/projects/OptimTee.aedt.
   ```

   Although serial jobs use only one slot, no other jobs will run on the host where this job is running, even if additional slots are present.

5. Example qsub command line for exclusive parallel job using eight engines, each using a single thread of execution:

   ```
   qsub -b y -l excl -pe pe1 8 /opt/ansys_inc/v251/AnsysEM/ansysedt
   -ng -BatchSolve -Distributed -machinelist num=8
   ~/projects/OptimTee.aedt
   ```

   None of the hosts used for this job will be allowed to run other jobs while this job is running.

Consumable Memory Limits

GE contains several built-in complexes related to memory, including mem_total, for example, but none of these are "consumable". If a job is submitted with resource list including one of these non-consumable memory complexes (such as mem_total), then the job will run on a host or hosts only if sufficient memory is available. If a second job is submitted, the memory request for the second job is compared to the original total when determining if the job may run on a host. This may result in both jobs running out of memory. For example, if host A has mem_total=16G of memory, and two jobs are submitting with option "-l mt=16G", then both jobs could run on host A, if sufficient slots are available on host A.

GE allows complexes to be "consumable" to avoid this type of problem. If a complex is consumable and a job requests x amount of the complex in the -l resource list, then the available amount of the resource is decreased by x for subsequent jobs. For the same example as above, if the mem_total complex was consumable, then the first job would run on host A. This would decrease the available mem_total from 16G to 16G-16G = 0. The second job could not run on host A because there is no memory available for this job.

We do not recommend changing the behavior of the built-in complexes (such as mem_total) because other scripts may expect normal behavior of the built-in complexes.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> Recent versions of UGE (Univa Grid Engine) come with "m_mem_free" and "mem_free" complexes already configured, and if so then there is no more configuration required. You can just use mem_free when per-host memory request is desired, and m_mem_free when per-core (per-slot really) memory request is desired. SGE may already have "mem_free" which can be used for per-host memory request.

Below shows how to configure the mem_free consumable resource.

Recommended attributes are:

- name : mem_free
- shortcut : mf
- type : MEMORY
- relop : <=
- requestable : YES
- consumable : YES
- default : 0
- urgency : 0

> **Note:**
>
> Ansys Electronics Desktop has the capability in auto cores and RAM to automatically select the memory complex (if one is available) and create this command line option for the user, if you check the "Use RAM constraint" and enter a non-zero amount of GB to use per core.

Serial Jobs in GE

If a serial job is submitted with the option -l phys_mem=mem_neededincluded, then the job may only run on a host in which the remaining physical_memory is equal to or greater than the mem_neededvalue.

Example 1: Host A has physical_memory=16G, and host B has physical_memory=8G. If mem_neededis 8G, the job may run on either host A or host B. If mem_neededis 16G, then the job may only run on host A.

Example 2: Host A has physical_memory=16G, and host B has physical_memory=8G. Job 1 is already running on host A, and it was submitted with option -l phys_mem=8G. If job 2 is submitted with option -l phys_mem=16G, then job 2 cannot start until job 1 finishes, because only host A has 16GB of physical_memory. If job 2 is submitted with option -l phys_mem=8G,

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

then job 2 may start immediately, and run on either host A or host B, because both hosts have 8G of physical_memory remaining.

Parallel Jobs in GE

Because the consumable setting for physical_memory is YES (and not JOB), each slot of the job requires a physical_memory of mem_needed. The number of slots on a host assigned to the job is limited by the number of available slots on the host. It is also limited by the physical_memory available on the host; the number of slots assigned to the job cannot exceed the available physical_memory on the host divided by the mem_neededspecification.

Example 1: Execution host A and execution host B both have 4 slots per host (configured in the queue associated with the parallel environment). Host A has physical_memory=16G and host B has physical_memory=8G (shown by commands qconf -se Aand qconf -se B). If a job is submitted that requires 6 slots and 4G per slot, it will be able to run, with 4 slots on host A and 2 slots on host B. The qsub command might look like: qsub -l phys_mem=4G -pe pe_name 6 command args

Example 2: Same as example 1, except that 7 slots are requested. In this case, the job will never run. Although there are 8 slots available on hosts A and B, only two of the slots on host B are usable by this job because it only has physical_memory of 8G. With only 6 slots total available to this job (4 on host A and 2 on host B), the job can not start. In this case the command might look like: qsub -l phys_mem=4G -pe pe_name 7 command args

Using Multithreading with Parallel Jobs

For large jobs it may be useful to combine multiprocessing with distributed processing. Distributed processing refers to starting multiple processes, in which each process performs a portion of the analysis. These processes may run on the same host or on different hosts. The number of processes running at the same time is known as the number of "analysis engines". Multiprocessing refers to using multiple threads within a single process to decrease the run time of the process. Multiprocessing may also be called multi-threaded processing.

As a concrete example of combining multiprocessing with distributed processing, an analysis could run with four engines, where each engine uses two threads. In order to distribute the processing load so that no processor is overloaded, one slot is generally allocated per thread, so 8 slots would be needed for this example (4 engines * 2 threads per engine = 8 threads). The four engines could all run on a single host, or they could be distributed across 2, 3 or 4 hosts, depending on available slots. Each engine represents a single process, so the two slots for each engine must be allocated on the same host.

This section describes how to set up a GE cluster so that a specified number of slots per host may be requested when a job is submitted. This procedure will require the cluster administrator privileges. This capability may be used to submit parallel jobs in which one engine runs on each host, and the number of slots per host matches the number of threads used by each engine.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Let n be the largest number of slots available on any host used for the jobs. Create a separate parallel environment for each value of the number of slots per host from 1 to n. For example, pe_sph1 is a parallel environment in which one slot is allocated to the job per host, and pe_sph2 is a parallel environment in which two slots are allocated to the job per host, etc. The command qconf -ap pe_name may be used to create each new parallel environment. The allocation_rule parameter should be set to the number of slots per host, an integer from 1 to n. The control_slaves parameter should be set to TRUE, as described above. The slots parameter should be set to the maximum number of slots managed by this parallel_environment, which is typically set to a large number, such as 999. The other parameters should be set to values appropriate for the cluster. For example, the pe_sph2 parallel environment might have the following parameters:
    - pe_name : pe_sph2
    - slots : 999
    - user_lists : NONE
    - xuser_lists : NONE
    - start_proc_args : /bin/true
    - stop_proc_args : /bin/true
    - allocation_rule : 2
    - control_slaves : TRUE
    - job_is_first_task : FALSE
    - urgency_slots : min
    - accounting_summary : TRUE
2. When submitting a job, use the parallel environment where the slots per host matches the number of threads per engine.

The batchoptions setting -machinelist num=n is required. This should be set to match the number of slots per host. With any analysis, a portion of the analysis may not be distributed across multiple engines.

Example qsub command line for running distributed processing with four engines and multiprocessing with two threads per engine:

```
qsub -V -b y -pe pe_sph2 8 /opt/ansys_inc/v251/AnsysEM/ansysedt -ng -
BatchSolve -Distributed -machinelist num=4 -batchoptions
"projects/OptimTee.aedt"
```

The -Voption indicates that the all environment variables in the submission environment should be copied to the job environment.

- The -b y option indicates that hfss is launched directly from the command line, instead of using a script.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The -pe sph2 8 command_line option indicates that this is a parallel job running under the pe_sph2parallel environment so that two slots are allocated to this job from each host, and that 8 slots in total are allocated to this parallel job.
- The -Distributed option indicates that this is a DSO job, so that multiple engines will be started. The -Distributed option may now have additional options, such as includetypes=xxx, excludetypes=xxx, maxlevels=n, and numlevel1=n, where n indicates and integer, and xxx indicates a list of distribution types or "default".
- The -machinelist num=4option indicates that a total of four engines will be started.
- The entire hfss command is in double quotes, and the double quotes enclosing the -batchoptions value are escaped. Each of these double quotes is replaced by the sequence "\"".

Issue with qrsh (SGE)

Ansys EM parallel batch jobs use the SGE **qrsh** command to launch engine processes on remote hosts. If the **qrsh** command is not working correctly, then the parallel job is unable to launch engine processes on remote hosts. If this problem occurs, the batch log for the job typically includes one or more error messages indicating that a COM engine was unable to be started on a remote host. If this occurs, the user or cluster administrator should verify that the SGE qrsh command is working correctly, and correct the problem if the SGE **qrsh** command is not working correctly.

The **qrsh** command may be tested by running a simple command on a specified host, such as **qrsh -l hostname=host1 hostname** or **qrsh -l hostname=host1 ls /tmp**, where host1 is the remote host name. The first test should simply echo back the hostname of the remote machine. The second test should list the contents of the /tmp directory on the remote machine.

The failures of the SGE qrsh command are associated with the following global sge configuration parameters, listed below with values that may cause the failures:

```
qrsh_command /usr/bin/ssh -t
rsh_command /usr/bin/ssh -t
rlogin_command /usr/bin/ssh -t
```

If these parameter settings are removed, then the SGE built-in mechanisms are used for qrsh, rsh, and rlogin. No problems with the built-in versions have been reported. The SGE qconf -sconf global command may be used to view these parameter settings. The SGE qconf -mconf global command may be used to modify or remove these parameter settings.

Issue with MainWin Core Services for SGE

By default, SGE creates a temporary directory for each SGE batch job, and deletes this temporary directory and its contents when the job finishes. SGE sets the TMP and TMPDIR environment variables of the job environment to point to this temporary directory. Ansys EM desktop software starts the MainWin Core Services on startup, if they are not already running.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

After the Ansys EM desktop software finishes, the MainWin Core Services time out and automatically shut down. The MainWin Core Services use the TMP and/or TMPDIR directories to store temporary data. If this temporary data is removed before the services shut down, then the services do not shut down automatically. Normally, SGE will remove the temporary directory and its contents before the services time out. The result is that these extraneous service processes run forever. If this problem occurs, each Ansoft batch job starts an additional set of these services that never shut down. This can result in an excessive number of processes running on the host where the Ansys EM desktop is started. The names of the service processes are:

- watchdog
- regss
- mwrpcss

Workaround for Issue with MainWin Core Services

One way to avoid this problem is to modify the environment in which the Ansys EM desktop runs so that the TMP and TMPDIR environment variables do not point to the directory which will be immediately removed by SGE when the job finishes. This can be done by copying the value of the TMPDIR environment variable to the ANS_SGE_TMPDIR environment variable, and unsetting the TMPDIR and TMP environment variables. The services ignore the ANS_SGE_ TMPDIR environment variable, but if this variable is set, then it will be used as the temporary directory for the rest of the Ansys EM software.

Here is an example bash wrapper script that may be used to work around this issue. In this example, the product is hfss, but the same approach will work for any Ansys EM product. In this example, the script is named sge_hfss and is in the AnsysEM software installation directory. When an Ansys Electromagnetics desktop job is submitted to the SGE scheduler, the script (sge_hfss, in this example) should be submitted instead of hfss. The script will modify the environment, as needed, then start hfss. When the analysis finishes, the script returns the exit status of hfss.

An alternative is to place the script in an arbitrary directory, and modify the script to include an absolute path to the product (hfss in this example).

Script contents:

```
#! /bin/bash

# This script will not correctly process arguments containing
# spaces or other characters special to the shell.

# Create hfss command line
# In this example, sge_hfss and hfss are in the same directory
# An alternative is to use an absolute path for the hfss command
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
cmd0=$0
cmd="${cmd0/%sge_hfss/hfss} $@"

# Fix environment variables
export ANS_SGE_TMPDIR=${TMPDIR}
unset TMPDIR
unset TMP

# Run the hfss command and return the exit status
${cmd}
exit $?
```

Integration with Platform's Load Sharing Facility (LSF)

The Load Sharing Facility (LSF) scheduler is only supported on Linux. Jobs may be submitted in any of the following ways:

- Job Submission GUI
- Using LSF commands (qsub, etc.)

For additional information on supported schedulers, visit the Platform Support page. Then, locate and click the following link:

Ansys 2025 R1 - Job Schedulers and Queuing Systems Support

> **Note:**
>
> If a temp directory is setup by the LSF cluster administrator, analysis engines use this temp directory, overriding the setting in the Ansys EM product.

LSF Job Management

You can use Ansys Electronics Desktop to submit batch jobs to LSF and monitor those jobs.

This involves the following steps:

1. Use **Tools** > **Job Management** > **Select Scheduler** to select LSF as the scheduler.
2. Use **Tools** > **Job Management** > **Submit Job** to submit a batch job to LSF.

   LSF-specific Settings:

   - On the **Compute Resources** tab, click the **Resource Selection Parameters** ellipses button (**...**) to specify the following:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Queue** – a drop-down menu lets you select Normal, chkpn_rerun_queue, idle, license, night, normal_allow_excl, owners, priorityu, or short.
- **MinCoresPerNode** – the minimum number of cores allowed on a node to be eligible for selection; translates to bsub -R select[ncpus>=N]
- **MaxCoresPerNode** – the maximum number of cores allowed on a node to be eligible for selection; translates to bsub -R select[ncpus<=N]
- **MinMemoryPerNode** – the minimum amount of physical memory (specified in integer GigaBytes) allowed on a node to be eligible for selection; translates to bsub -R select[maxmem>=M]
- **MaxMemoryPerNode** – the maximum amount of physical memory (specified in integer GigaBytes) allowed on a node to be eligible for selection; translates to bsub -R select[maxmem<=M]

If you do not specify parameters, the scheduler does so.

- For LSF, the only non-automatic method of **Resource Selection** is **Number of Tasks and Cores**. You can specify the number of tasks, whether they are for exclusive use by the job, cores per distributed task, a limit number of tasks per node, and RAM limit as percentand a limit number of tasks per node.

3. Use **Tools** > **Job Management** > **Monitor Job** to monitor the job's progress.

LSF Job Submission Guidelines

Before submitting an LSF job, ensure the following are true:

- The project is available in a shared drive that is accessible to all machines in the cluster.
- The project is available using the same path on all machines of cluster.
- There is sufficient space in the project directory and temp directories.
- There is sufficient memory per engine.
- The number of compute resources (Distributed Analysis machines and Multi Processing cores) will achieve the desired scale factor and effective resource utilization.

Integration of Ansys EM Products with LSF

With LSF you do not need to set 'Distributed Analysis Machines' or 'Remote Machine' options. Instead, you submit a job to LSF, requesting the appropriate resources for the job (number of processors, memory per processor, etc.).

For example:

```
bsub -n 1 ansysedt.exe -Batchsolve -ng -local -machinelist num=1
OptimTee.aedt
bsub -n 4 ansysedt.exe -Batchsolve -ng -Distributed -machinelist
num=4 OptimTee.adsn
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The job is queued by LSF until the requested resources are available. Upon resource availability, LSF starts Electronics Desktop with the specified command line on one of the allocated machines. During analysis, Electronics Desktop dynamically obtains the allocated 'Distributed Analysis Machines' from LSF. Electronics Desktop interfaces with LSF to launch engines on remote machines without going through Ansys RSM.

Installing Ansys EM Tools on LSF Cluster

The LSF scheduler is supported on Linux only.

lsf.conf should contain this line:

```
LSF_UNIT_FOR_LIMITS=MB
```

The administrator should have this line in the lsb.params file to ensure that memory reservations are per-slot (per-core):

```
RESOURCE_RESERVE_PER_SLOT=Y
```

Jobs may be submitted in any of the following ways:

- Using LSF commands (bsub, etc.)
- Using the generic scheduler GUI in local mode
- Using the generic scheduler GUI in service mode

For additional information on supported schedulers, visit the Platform Support page. Then, locate and click the following link:

Ansys 2025 R1 - Job Schedulers and Queuing Systems Support

Setup:

1. Install on a single node, on a shared drive.
2. Setup 'temp directory' to a path that is same on all nodes (for example, /tmp).
3. Ensure that the product is available using the same path on all nodes.

Permissions:

- All users of the cluster should have read/write permissions to temp directory.
- All users should have read/execute permissions in the installation directory.
- Turn OFF any firewall between cluster nodes.

When a desktop scheduler GUI is run the same node as the job submission node, no other configuration is necessary; installation is sufficient. Select the scheduler through the Electronics Desktop GUI. Ensure that scheduler commands are available in the path before you launch Electronics Desktop.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> There is no need to install RSM unless you are using the scheduler GUI on a post-processing node that is different from the job submission node. In this case, RSM must be configured with the scheduler type and path.
>
> A post-processing node is a node in the cluster that can run Electronics Desktop in graphical mode. A job submission node is a node in the cluster in which job submission commands are available.

Per-slot Resource Reservation

Set the cluster for per-slot resource allocation if the automatic cores and RAM resource selection method is to be used. You can check the cluster to see if per-slot resource allocation is configured by using the "bparams -a" command. Search the output for "RESOURCE_ RESERVE_PER_SLOT" to determine the setting (either "Y" or "N"). If set to "N" then consult the LSF administration guide on how to change this to "Y".

Scenario 1: The post-processing node and job-submission node roles are served by distinct machines.

In this case, perform the following configuration:

The job-submission node should be configured to run RSM service, which serves as a proxy to scheduler. The RSM Service should be running as 'root' in order to facilitate jobs running using the credentials of the job's owner. A **configuration file in the RSM installation folder should be edited** to specify information regarding the scheduler that manages jobs on this cluster. A block labeled 'Scheduler' must be included within the 'AnsoftCOMDaemon' block. This block contains two string entries:

- SchedulerName: this contains the unique part of the scheduler proxy library name
- ConfigString: this contains a scheduler specific configuration string

The case of the SchedulerName string is significant on Linux because Linux file names are case sensitive. In Ansys Electromagnetics Suite 2025 R1, possible scheduler names are: lsf and sge. The ConfigString entry is a scheduler specific configuration string, described below.

In addition, the AnsoftRSMService must be started with appropriate environment variables set. Generally, the environment variables must be set the same as they would be set for using the scheduler via command lines.

LSF Details

For the LSF scheduler proxy library, the ConfigString entry in the ansoftrsmservice.cfg configuration file is ignored. It may be empty or omitted entirely.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The AnsoftRSMService must be started with the environment set as it would be set for submitting jobs to the LSF cluster.

- For Linux, the cshrc.lsf or the profile.lsf file may be sourced to set up the environment, depending on the shell.

Example ansoftrsmservice.cfg configuration file:

```
$begin 'AnsoftCOMDaemon'
$begin 'Managed COM Servers'
$end 'Managed COM Servers'
$begin 'Scheduler'
'SchedulerName'='lsf'
'ConfigString'=''
$end 'Scheduler'
$end 'AnsoftCOMDaemon'
```

Scenario 2: The post-processing node and job-submission node roles are served by the same machine.

The **Select Scheduler...** command (as described in the Job Management User Interface for LSF section) is used to gather details about the scheduler. In this case, the Desktop process should be started in an environment suitable for submitting jobs to the scheduler. See below for details.

The environment should be configured so that the following LSF environment variables are set appropriately for the LSF cluster in use: LSF_BINDIR, LSF_SERVERDIR, LSF_LIBDIR, and LSF_ENVDIR. In addition, the following LSF commands should be found in the LSF_BINDIR directory: "bsub", "bjobs", "bkill", "lsid", "lsrun", "lshosts", "bmgroup", "bparams" and "bqueues".

Using the bsub Command to Submit Batch Jobs

The LSF bsub command may be used to submit jobs. The typical command format is:

`bsub` *`bsub_args ansys_exe ansys_args`*

where:

- *bsub_args* are the options of the bsub command,
- *ansysEM_exe* is the pathname of the Ansys Electromagnetics desktop executable to launch, and
- *ansys_args* are the arguments to the Ansys Electromagnetics desktop executable.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

bsub Arguments

The **bsub** command has a large number of options that may be used to control the submission process. Only a few options that are often used with Ansys Electromagnetics jobs are listed here. The following options may be used to submit serial or parallel LSF jobs.

-n*min_proc*, *max_proc* or **-n***min_proc*

Submits a parallel job, specifying the number of processors (or slots) required for the job. Here, *min_proc* is the minimum number of processors, and *max_proc* is the maximum number of processors. If no maximum is specified, then exactly *min_proc* processors are requested. If PARALLEL_SCHED_BY_SLOT=Y in lsb.params, this option specifies the number of slots required to run the job, not the number of processors. If the **-n** command line option is not specified, then the job is submitted as a serial batch job.

-R "span[ptile=n]"

There are many ways to use the -R "res_req" option to the bsub command. We only cover -R "span[ptile=n]" here, because this option is very useful for Ansys Electromagnetics jobs. When this option is specified, the LSF scheduler will allocate n processors (or slots) on each host to this job, even if more processors are available on the host.

-x

All hosts running this job operate in exclusive execution mode. The job will only run on a host having no other jobs running on that host. No other batch jobs will be started on a host while this job is running on that host.

See LSF documentation for a complete list of options for the **bsub** command.

> **Important:**
>
> If the Ansys EM tool executable pathname (*ansys_exe*) or any of the arguments of the Ansys tool command (*anssys_args*) contain characters which are interpreted by the command shell, these special characters must be properly quoted to ensure that the correct command is launched by LSF. A similar problem may occur if any of the *ansoft_args* require single quote, double quote or space characters. Note that the Ansys Electronics Desktop command is processed by the shell twice: once when the **bsub** command is processed, and again when the job starts. See: Example Command Lines.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Example LSF bsub Command Lines (Linux Only)

> **Note:**
>
> The following examples use HFSS as the product, but similar command lines will work for all Ansys EM products.

Serial Job

```
bsub -n 1 "C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt" -ng
-BatchSolve -machinelist num=4 ~/projects/OptimTee.aedt
```

The -n 1 option indicates that this job runs on one core.

Serial Job Requiring a Minimum of 4GB

```
bsub -n 1 -R "select[mem>4000]"
"C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt" -ng
-BatchSolve -machinelist num=4 ~/projects/OptimTee.aedt
```

The -R "select[mem>4000]" option indicates that this needs a minimum of 4 GB memory.

Multi-processing Job using 4 Cores

```
bsub -n 4 -R "span[ptile=4]"
"C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt" -ng -BatchSolve
-batchoptions -machinelist num=4 ~/projects/OptimTee.aedt"
```

- The -R "span[ptile=4]" option indicates that the four cores need to be on the same machine.
- The -batchoptions option indicates that HFSS should use four cores for multi-processing.
- The entire hfss command is in double quotes, and the double quotes enclosing the -batchoptions value are escaped. Each of these double quotes is replaced by the sequence "\"".

Distributed Processing Job using 4 Engines

```
bsub -n 4 "C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt" -ng -
BatchSolve -Distributed ~/projects/OptimTee.aedt
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The -n 4 option indicates that the four cores are needed for the job.
- The -Distributed option indicates that this is a DSO job, so that multiple engines will be started. Because 4 cores are allocated to the job, the job will run 4 engines. The -Distributed option can have additional options, such as includetypes=xxx, excludetyeps=xxx, maxlevels=n, and numlevel1=n, where n indicates and integer, and xxx indicates a list of distribution types or "default".

Distributed Processing and Multi-processing Job using 4 Cores, with 2 Cores for Multi-processing

```
bsub -n 4 -R "span[ptile=2]" ~/projects/OptimTee.csh
```

Shell Script (~/projects/OptimTee.csh):

If a command is included in the **bsub** command line, the entire command will be processed by the command shell two times. The command is processed when the **bsub** command is processed by the shell and is processed again when the command is started by the scheduler. This example shows how to use a shell script so that the command line will be processed only once. The command is placed in the shell script, and then the shell script pathname is placed in the **bsub** command line. Then, the command is only processed by the command processor when the job is started. When using this approach, the shell script should be accessible from all of the cluster hosts.

```
#!/bin/csh
"C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt" -ng -BatchSolve
-Distributed -machinelist num=2 -batchoptions
~/projects/OptimTee.aedt
```

- The **-n 4** option indicates that the four cores are needed for the job.
- The **-R "span[ptile=2]"** option indicates that the cores must be allocated in groups of two cores on the same machine.
- The **-machinelist num=2** option indicates that this is a DSO job and that a total of two engines will be started.
- The **hfss** command is placed in the shell script (~/projects/OptimTee.csh). In the **bsub** command line, the **hfss** command is replaced by the shell script pathname.

Monitoring LSF Batch Jobs

You can monitor jobs through the Electronics Desktop user interface, or through the command line.

The suggestions below are for batch jobs run under LSF.

Ansys Electronics Desktop -monitor Command Line Option

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The -monitor command line option enables batch job output to the standard output and standard error streams. The warning, info, and progress messages are sent to the standard output stream. The error and fatal messages are sent to the standard error stream.

LSF bpeek Command

The LSF bpeek command may be used to monitor job progress. The command **pbeek [-f]** *job_id* displays the standard output and standard error produced by the job with id *job_id* from the job start to the current time (the time when the command is executed). This command is only valid for jobs that have not yet finished. When used with the **-f** option on Linux, the output of the job is displayed using the command tail **-f**, so that ongoing progress may be monitored.

In order to display messages to standard output and standard error, specify the **-monitor** command line option on the Ansys EM tool command line. Then, these messages can be seen using the LSF bpeek command.

Terminating LSF Batch Jobs

To cancel or terminate an Ansys EM LSF batch job, we recommend using the job monitoring UI to terminate jobs cleanly, rather than using the bkill commands. Using this approach will allow the batch job to shut down in an orderly fashion.

Using the LSF **bkill** command without the **-s SIGTERM** option or simply terminating the job processes may cause some of the following problems:

- Some engine processes are not shut down and continue to run.
- LSF job is not fully removed.
- Project .lock file is not removed.
- MainWin core service processes (watchdog, mwrpcss and/or regss) are not stopped.

Some of these may interfere with submission of additional LSF batch jobs. For example, it may be necessary to manually remove the project lock file to submit another batch job for the same project. MainWin core service processes may also interfere with starting subsequent Ansoft batch jobs. Normally, these processes should timeout and end 15 seconds after the Ansys Electromagnetics product shuts down. Any MainWin core service processes (watchdog, mwrpcss and/or regss) that continue to run for more than 15 seconds after the product has stopped may be hung. The hung processes may need to be manually killed, after ensuring that these processes are associated with an Ansys EM job that has finished or terminated.

Stop a job cleanly - ensures that the results obtained until now are preserved:

```
bkill -s TERM <jobid>.
```

Stop an job abruptly - results are most likely lost. You have to manually remove the project lock file:

```
bkill <jobid>
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

LSF Known Issues and Workarounds

The following are known issues. Workarounds are noted when available:

- Desktop or remote machine cannot have multiple IP addresses. This is unsupported.
- Core dump files may appear when a job has finished running. Results are still computed correctly. Workaround: Limit size of core dumps to 0 through the following job submit option: `bsub -C 0 -n <number-of-cores> -q <queue-name>`
- Firewall should be turned off on all machines in the cluster.
- Sometimes LSF ends a job (for example, a job may be preempted due to a high priority job). This may result in the presence of a .lock file in the project directory. You must manually delete the .lock file before continuing with further analysis.
- When an LSF job is ended, MainWin services (watchdog, regss, and mwrcpss) could keep running. The result is that later jobs cannot start on the machine. The fix is to end these processes before starting a new job.
- Analysis fails abruptly when running out of resources (cpu/memory/disk). Ensure sufficient resources are provided.

LSF Troubleshooting

The following are general troubleshooting steps:

1. Ensure the LSF `lsrun` command is enabled.
2. Look for user errors.

   For example:

   - Are the executable path and project path correct and complete?
   - Are there sufficient resources (CPU/Memory/Disk) allocated to the job?
   - Is the project available on the execution host?
   - Does the job submitter have read/writer permissions on the project directory and read/execute permissions on the installation directory?
   - Is the project locked?
3. Determine whether this is a standalone product issue.
   - Run Electronics Desktop on the machine outside of the scheduler and see if it opens and analyzes.
4. Examine outputs and logs.
   - Output of the LSF batch job. Obtain this using LSF commands: "`bacct -l <jobid>`"
   - Batch log (typically <projectname>.log, located in the project directory.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Enable additional debug logs using the steps below.

   In the job submission window, set the following environment variables:

   - ANSOFT_DEBUG_MODE = 1
   - ANSOFT_DEBUG_LOG = <*path to directory accessible by all machines in the cluster*>
   - ANSOFT_DEBUG_LOG_SEPARATE = 1
   - ANSOFT_LSF_LOG = <*path to a specific .log file in the directory set under ANSOFT_DEBUG_LOG*>
6. For each pair of machines between which remote analysis fails, run `ping remote-machine` and note the output.
7. For each machine in the network, dump network interfaces (for example, run `ifconfig -a`) and note the output.

Integration with PBS (Portable Batch System)

The PBSPro and PBS/Torque schedulers are only supported on Linux. Jobs may be submitted in any of the following ways:

- Job Submission GUI
- Using PBS commands (qsub, etc.) or the PBS gui (xpbs)

For information about supported schedulers, visit the Platform Support page. Then locate and click the following link:

Ansys 2025 R1 – Job Schedulers and Queuing Systems Support

PBS Job Management

You can use Ansys Electronics Desktop to submit batch jobs to PBS and monitor those jobs.

This involves the following steps:

1. Use **Tools** > **Job Management** > **Select Scheduler** to select PBS as the scheduler.
2. Use **Tools** > **Job Management** > **Submit Job** to submit a batch job to PBS.

   PBS-specific Settings:

   - On the **Compute Resources** tab, click the **Resource Selection Parameters** ellipses button (**...**) to specify either the **Queue** or **QueueAtServer** parameter.

     For **Queue**, you may select a queue for the job from the list of queues configured for the default server. Only queues that are enabled and that do not have the from_ route_only attribute set to true are listed.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For **QueueAtServer**, you may specify a queue at the default server or at another server by entering text into this field in one of three formats:

- queue_name
- @server_name
- queue_name@server_name

The queue_name format submits with the name queue_name. The other formats submit with the name server_name. The *destination* value of the -q *destination* option on the qsub command line is the user-specified string. *This string will not be validated by the scheduler proxy library*.

Either **Queue** or **QueueAtServer** may be specified, but both may not be specified. If neither **Queue** nor **QueueAtServer** is specified, the job is submitted to the default queue at the default server.

3. Use **Tools** > **Job Management** > **Monitor Job** to monitor the job's progress.

Non Standard Installations for PBS

PBSPro

If the environment variable PBS_DEFAULT is set, then the value of this environment variable will be used as the name of the default server, instead of obtaining the default server name from the PBSPro configuration file. The default pathname of the PBSPro configuration file is /etc/pbs.conf. The environment variable PBS_CONF may be used to specify a different pathname for the PBSPro configuration file.

PBS/Torque

If the environment variable PBS_DEFAULT is set, then the value of this environment variable will be used as the name of the default server, instead of obtaining the default server name from the PBS/Torque server file. The name of the PBS/Torque server file is server_name, and it is installed in the TORQUEHOME directory. By default, TORQUEHOME is /var/spool/torque. To specify a different TORQUEHOME directory, the environment variable ANSOFT_TORQUEHOME should be set to the pathname of the desired directory.

PBS Limitations

General Limitations

- There is no support for GPUs when submitting jobs via the GUI.
- Support for PBSPro and PBS/Torque is only available on Linux; Windows is not supported.
- Staging of input or output files is not supported for jobs submitted using the GUI.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- All jobs submitted via the GUI are independent jobs. Neither job dependencies nor job arrays are supported.
- If the user specified server is not the default server, then there is no check for sufficient resources before submitting the job.
- If the user specified server is not the default server, then the limit on the number of tasks per node is ignored for both PBSPro and PBS/Torque. For PBS/Torque, only one task will be allocated for each node. For PBSPro, the scheduler may allocate any number of tasks to a node, provided that the node has sufficient cores for all of the tasks.
- For jobs submitted to a routing queue, the check for sufficient nodes and cores only verifies that there are sufficient nodes and cores associated with the server.
- The queue attributes “resources_max” and “resources_min” are not checked when determining whether there are adequate resources to run the job.

PBSPro Limitations

- The PATH in the submission user’s default environment must include the directory containing the PBSPro commands.
- Failover is not supported.
- HPC Basic Profile Jobs are not supported.
- Globus vnodes are not supported. When checking for sufficient nodes and cores for the job, only nodes of type PBS are considered.
- For jobs submitted to an execution queue, the only vnode attribute used to determine if a vnode is available to the job is the “queue” attribute.

PBS/Torque Limitations

- When checking for sufficient nodes and cores for the job, only nodes of type cluster are considered.
- The “exclusive” check box has no effect for PBS/Torque.
- For PBS/Torque, even if a job is submitted to an execution queue at the default server, there is no check for sufficient nodes and cores available to the queue. All of the server’s execution nodes are assumed to be available for the job.
- For PBS/Torque, there are significant limitations when submitting a job in which the number of tasks and number of cores per task are specified. Unlike PBSPro, there is no capability to specify that the cores should be allocated in “chunks”. Instead, the submission command includes the number of groups of nodes and the number of processors per node (ppn) for each node in the group. To determine the size of each group and the ppn setting for each group, the server nodes are examined from largest number of cores to smallest. This may not be optimal because some of these nodes may not be usable by the queue specified for the job, or because the nodes with the largest number of cores may be busy. Similar issues could occur for PBSPro, but they should be less likely, because only the nodes usable by the queue are considered.

Submitting Jobs Via Ansoftrsmservice on a Different Host

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Before starting the ansoftrsmsevice as a daemon on a job submission host, the 'Scheduler' section of the ansoftrsmservice.cfg must be specified.

This section contains two settings, 'SchedulerName', which must be set the string 'pbs', and 'ConfigString', which must be set to the pathname of the directory containing the PBSPro or PBS/Torque commands.

Here is an example ansoftrsmservice.cfg file, showing the format of this file and an example 'ConfigString' setting:

```
$begin 'AnsoftCOMDaemon'
$begin 'Managed COM Servers'
$end 'Managed COM Servers'
$begin 'Scheduler'
'SchedulerName'='pbs'
'ConfigString'='/share/pbs/default/bin'
$end 'Scheduler'
$end 'AnsoftCOMDaemon'
```

Submitting Ansys EM PBS Batch Jobs

The PBS qsub command may be used to submit Ansys EM batch jobs. The typical command format is:

qsub *qsub_args script*

where:

- *qsub_args* are the options of the **qsub** command,
- *script* is the pathname of the job script.

The job script is a shell script containing the Ansys batch command or commands to be run. If a batch command line contains any characters that are special to the shell running the script, then these special characters should be quoted, as needed. The job script may also contain PBS directives on lines before the first executable line of the script. Any **qsub** options on the command line will take precedence over the PBS directives in the job script.

When a PBS batch job is started, the job script runs as the job user in a new shell. In this shell environment, the path must include the directory containing the PBS commands.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

You should ensure that the PATH variable set in the shell startup script (e.g., .cshrc, .profile, .bashrc) includes the directory containing the PBS commands. For example:

```
export PATH=/opt/pbs/default/bin:$PATH
```

If the PATH variable is not set correctly, the job runs only locally, the batch log file shows the list of allocated hosts as empty, and the error file shows an error (sh: qstat: command not found.)

Further PBS directives need to be on top of the job script file. This is discussed in the PBS documentation.

Serial PBS Batch Jobs

In the PBS documentation, serial batch jobs are also called single-node jobs. In general, any job submitted without specifying the -l nodes=value command line argument, will run as a serial or single-node job.

See Monitoring PBS Batch Jobs for options that can facilitate monitoring of Ansys Electromagnetics batch jobs.

Parallel PBS Batch Jobs

In the PBS documentation, parallel batch jobs are also called multi-node jobs. When an Ansys Electromagnetics batch job is run as an PBS parallel job, the PBS scheduler will select the hosts for the distributed analysis job based on the qsub command line arguments, the PBS resource directives from the job script, and the status of the hosts when the job is run. The desktop process will be started on one of these hosts. The desktop process will obtain the list of hosts allocated to the job from the PBS scheduler, and start analysis processes on these hosts, as needed, using the PBS scheduler facilities. To run a PBS parallel job, the job must be submitted with a -l nodes=value **qsub** command line argument or with a -l nodes=value PBS directive in the job script.

Monitoring PBS Batch Jobs

You can monitor jobs through the Electronics Desktop user interface, or through the command line.

The suggestions below are for batch jobs run under PBS.

PBS qstat Command

The PBS **qstat** command may be used to display information on jobs and queues. In this section, several qstat command line options that may be used to monitor job progress are described.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **qstat -a** command displays information about all jobs in the system.

The **qstat -r** command displays information about all running jobs in the system.

The **qstat -s** command resembles the **qstat -r** command; the only difference is that a comment from the scheduler or batch administrator is also shown for each job.

The **qstat -au** *userid* command displays information about all jobs owned by user userid.

The **qstat -f** *jobid* command displays all available information about the job with id *jobid*.

See the PBS manual pages for more information.

Ansys EM -monitor Command Line Option for PBS

The Ansys EM **-monitor** command line option enables batch job output to the standard output and standard error streams. The warning, info, and progress messages are sent to the standard output stream. The error and fatal messages are sent to the standard error stream.

The PBS scheduler redirects the standard output and standard error streams of batch jobs to files specified in the **qsub -o** [*hostname*:]*pathname* and the **-e** [*hostname*:]*pathname* command line options, respectively. If either option is not specified, then the associated stream is redirected to the default file pathname for that stream.

The **qsub -j join** option controls whether the standard error stream for the job will be merged with the standard output stream for the job. A join value of **oe** indicates that the interleaved standard output and standard error will be sent to the standard output file or stream. A join value of **oe** indicates that the interleaved standard output and standard error will be sent to the standard error file or stream. A join value of n indicates that the standard output and standard error streams will not be joined. If the **qsub -j join** option is not specified, then the standard error and standard output streams will not be joined.

A user can monitor the progress of a job by checking the standard output file for progress, info and warning messages, and checking the standard error file for error and fatal messages.

qsub Arguments

The PBS **qsub** command has a large number of options for control of the submission process. In this section, we review the -l nodes=*value* command line option with Ansoft parallel batch jobs.

This option or directive has the following format:

`-l nodes=`*`node_spec`* `[+`*`node_spec...`*`][#`*`suffix`*`]`

where *node_spec* is one of the following

`nodename[:`*`pc_spec`*`[:`*`pc_spec...`*`]]`

Host name of the specified node, followed by optional **ppn** or **cpp** specifiers.

`[`*`N`*`][:`*`property`*`[:`*`property...`*`]][:`*`pc_spec`*`[:`*`pc_spec...`*`]]`

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Optional number of nodes, followed by optional node properties, followed by optional **ppn** or **cpp** specifiers. If the number *N* is omitted, then the default value of 1 host is used.

Here, the optional **ppn** or **cpp** specifiers *pc_spec* are of form:

`ppn=X`

Number of processes (tasks) per node. Default is 1 if not specified.

`cpp=Y`

Number of CPUs (threads) per process. Default is 1 if not specified.

The optional global suffix, #suffix, which applies to all hosts has one of the following values:

`#excl`

This suffix requests exclusive access to the allocated nodes.

`#shared`

This suffix requests shared access to the allocated nodes.

The total number of requested processes is determined by adding up the product of the number of nodes and the number of processes per node for each *node_spec*. In general, this should match the number of distributed engines specified in the Ansys Electromagnetics desktop - Machinelist num=*num_distributed_engines* command line option.

The number of CPUs per process (**cpp**) specified in the PBS **qsub** command line or in the PBS directives in the script file should generally match the number of processors per engine specified in the Desktop **-batchoptions** value.

See the PBS documentation for a complete list of options for the **bsub** command, and further information on running multi-node jobs.

Example PBS qsub Command Lines

All of the following examples show how to submit Linux hfss jobs on PBS, but similar command lines and job scripts will work for all Ansys EM products. Most of the following examples are PBS "Single-node jobs." The last example is a PBS "multi-node jobs"; this example demonstrates how to specify the allocation of threads, tasks and nodes to a job.

Serial job:

```
qsub ~/pbs_scripts/OptimTee.sh
```

Job Script File:

```
#!/bin/sh
/opt/ansys_inc/v251/AnsysEM/ansysedt -ng -BatchSolve
~/projects/OptimTee.aedt
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Serial job that needs a minimum of 4GB memory and two hours of real (wallclock) time:

```
qsub ~/pbs_scripts/OptimTee.sh
```

Job Script File:

```
#!/bin/sh
#PBS -l walltime=2:00:00
#PBS -l mem=4gb
/opt/ansys_inc/v251/AnsysEM/ansysedt -ng -BatchSolve
~/projects/OptimTee.aedt
```

Multi-processing job using 4 cores:

```
qsub ~/pbs_scripts/OptimTee.sh
```

Job Script File:

```
#!/bin/sh
#PBS -l ncpus=4
/opt/ansys_inc/v251/AnsysEM/ansysedt -ng -BatchSolve -batchoptions
-machinelist num=4
~/projects/OptimTee.aedt
```

- The #PBS -l ncpus=4 directive indicates that four cores or CPUs are allocated to this job.
- The -batchoptions option indicates that Ansys Electronics Desktop should use four cores for multi-processing.

Distributed processing job using 4 engines on a single host:

```
qsub ~/pbs_scripts/OptimTee.sh
```

Job Script File:

```
#!/bin/sh
#PBS -l ncpus=4
/opt/ansys_inc/v251/AnsysEM/ansysedt -ng -BatchSolve -Distributed -
machinelist num=4
~/projects/OptimTee.aedt
```

- The #PBS -l ncpus=4 directive indicates that four cores or CPUs are allocated to this job.
- The -Distributed option indicates that this is a DSO job, so that multiple engines will be started. Because 4 cores are allocated to the job, the job will run 4 engines. The -Distributed option may now have additional options, such as includetypes=xxx, excludetyeps=xxx, maxlevels=n, and numlevel1=n, where n indicates and integer, and xxx indicates a list of distribution types or "default".

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Distributed processing and multi-processing job using 8 cores on two nodes, running 4 engines (two per node) with 2 cores for multi-processing:

```
qsub ~/pbs_scripts/OptimTee.sh
```

Job Script File:

```
#!/bin/sh
#PBS -l nodes=2:ppn=2:cpp=2#excl
/opt/ansys_inc/v251/AnsysEM/ansysedt -ng -BatchSolve -Distributed
-machinelist num=4 -batchoptions ~/projects/OptimTee.aedt
```

- The PBS directive **#PBS -l nodes=2:ppn=1:cpp=2#shared** indicates that two nodes are requested [2], two processes (engines) run on each node [ppn=2], and each process will use two cores [cpp=2]. The hosts allocated to this job may not be used for any other jobs while this job is running [#excl].
- The **-machinelist num=4** option indicates that this is a DSO job and that a total of four engines will be started. This option is required for all batch jobs.

Integration with SLURM Scheduler (Linux Utility)

For Linux customers, Electronics Desktop supports the SLURM (Simple Linux Utility for Resource Management) scheduler for job submission, monitoring, and control (abort). In addition, this provides Windows-to-Linux support for the same functionality. Using SLURM as a starting point, customers should be able to develop their own integrations for other schedulers. Electronics Desktop can check job states in SLURM scheduler within the current job monitoring GUI. Persistence mode provides more efficient management between Desktop and scheduler proxies. Windows-to-Linux submission also provides convenient access to generic scheduler in Linux environments through Remote RSM Service.

When you submit a job to SLURM scheduler or Remote RSM to a SLURM cluster, you can use their own job options to override job options in the **Scheduler Options** tab. If you want to do that, the override job options must have "--export=None".

For additional information on supported schedulers, visit the Platform Support page. Then, locate and click the following link:

Ansys 2025 R1 - Job Schedulers and Queuing Systems Support

See also: Integrating Ansys EM Tools with Third Party Schedulers.

Configuration of the generic scheduler with SLURM

Requirements

Files must be under ${ANSYS_EM_INSTALL_DIR}/schedulers directory. Desktop and RSM service use the same required file list below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The required files are listed here:

- ${ANSYS_EM_INSTALL_DIR}/schedulers/libgeneric_scheduler.so
- ${ANSYS_EM_INSTALL_DIR}/schedulers/proxies.cfg
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/persistence.py
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/SLURM_GetInfo_linux.py
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/SLURM_GetRunInfo_linux.py
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/SLURM_SubmitJob_linux.py
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/SLURM_ControlJob_linux.py
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/SLURM_GetJobState_linux.py
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/SLURM_LaunchProcess_linux.py
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/utils/ComputeResourceList.py
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/utils/ErrorAndDebug.py
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/utils/__init__.py
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/utils/RunCommand.py
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/utils/SiteCustomize.py
- ${ANSYS_EM_INSTALL_DIR}/schedulers/scripts/utils/slurm_srun_wrapper.sh

Environment Variables

There are some environment variables for the Generic Scheduler proxy. All environment variables apply on both Desktop and RSM Service.

`ANSYSEM_GENERIC_SCRIPT_DIR`

This variable adds a customized directory to be searched for proxy scripts. The path can be any form of following addresses. Persistence script path will not change.

- absolute address to any folder with read access
- relative address to folder under the Electronics Desktop installation directory
- relative address to folder under the schedulers directory
- relative address to folder under the schedulers/scripts directory

`ANSYSEM_GENERIC_EXEC_PATH`

This variable adds customized directories to be searched for proxy executables. Mono executable and IronPython executable should be specified when they are not in the Ansys Electronics Desktop installation. This environment variable must be set for RSM Service.

`ANSYSEM_GENERIC_PROXY_PERSISTENCE`

If set, this variable redirects the persistence script location to be used; otherwise, the default persistence script path is used.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`ANSYS_EM_EXEC_DIR`

Set this variable to the same value with ANSYS_EM_INSTALL_DIR (not the RSM service path). To ensure the RSM service can accurately locate the essential script files required for MPI integration, it is necessary to set this variable within the RSM service environment.

Configuration File

The configuration file "proxies.cfg" is located at ${ANSYS_EM_INSTALL_DIR}/schedulers/. The file can have multiple scheduler configurations. The file content and explanation are below.

[slurm] ***# Unique scheduler name***

DisplayName=SLURM ***# Display name in GUI***

 # Proxy Scripts

SubmitJob=scripts/SLURM_SubmitJob_linux.py

ControlJob=scripts/SLURM_ControlJob_linux.py

GetSchedInfo=scripts/SLURM_GetInfo_linux.py

GetJobState=scripts/SLURM_GetJobState_linux.py

GetRunInfo=scripts/SLURM_GetRunInfo_linux.py

LaunchProcess=scripts/SLURM_LaunchProcess_linux.py

 # Persistence Mode

Persistence=Yes

Persistence Mode

Persistence mode uses a persistent process to communicate with Ansys Electronics Desktop and proxy scripts. If persistence mode is disabled, Ansys Electronics Desktop uses proxy scripts directly. Enabling persistence mode may help speed up communication with proxy scripts. **Note**: disabling persistence will cause large delays in GUI functionality. The primary use case of disabling persistence is to support troubleshooting.

- To enable persistence mode, make sure "Persistence=Yes" is in configuration file before launching Ansys Electronics Desktop.
- To disable persistence mode, make sure "Persistence=No" is in configuration file before launching Ansys Electronics Desktop.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Remote RSM Service Support

In ansoftrsmservice.cfg, fill your scheduler information from configuration file proxies.cfg as below. `SchedulerName` must be generic. Change `"Proxy"` as needed.

```
$begin 'Scheduler'
  'SchedulerName'='generic'
  'ConfigString'='{"Proxy":"slurm"}'
$end 'Scheduler'
```

Then, set the environment variable “ANSYSEM_GENERIC_EXEC_PATH” with Mono and IronPython path. Multiple paths can be filled with delimiter “:”. Ansys Electronics Desktop has built-in components in AnsysEM installation path, and you can replace the installation path like:

```
ANSYSEM_GENERIC_EXEC_PATH= <INSTALL_DIR>/ansys_
inc/v251/AnsysEM/common/mono/Linux64/bin:<INSTALL_DIR>/ansys_
inc/v251/AnsysEM/common/IronPython
```

Also set environment variable “ANSYS_EM_GENERIC_COMMON_TEMP” to a directory widely accessible to users using Remote RSM Service on the cluster. This environment variable specifies a temporary folder to use. Thus, it must be accessible for most users.

```
ANSYS_EM_GENERIC_COMMON_TEMP=/tmp
```

Then, launch **ansoftrsmservice** in the AnsysEM RSM installation folder. (Be sure not to confuse AnsysEM (Ansoft) RSM with Ansys RSM since these are two very different things.) It is recommended that the user for **ansoftrsmservice** should be a dedicated service user account for only running **ansoftrsmservice**. This account should have limited permissions for security reasons. The service user should not have a login. It is recommended to disable login, so that the only way to run as the user is to “su” to that user from the root (or other accounts with sudo permissions). Other users can use any account credentials in the Desktop Select Scheduler GUI to submit jobs as the requested user.

Using the generic scheduler with SLURM

To select the scheduler and get scheduler information:

1. Click **Tools** > **Job Management** > **Select Scheduler...**, or select the **Simulation** tab on the ribbon, and click the **Scheduler** icon.

   This opens the **Select Scheduler** dialog box.

2. Select **SLURM** from the drop-down menu; or, if the Remote RSM service is used, fill in scheduler master node address, and use valid account credentials.
3. Click **Refresh**.

   Scheduler Information should show.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click **OK** to select the scheduler.

   Submit Jobs and Monitor Jobs with SLURM

   Job submission and monitoring follow the same process and method as using other schedulers. Currently, submission using a node-list is not supported.

5. Use **Tools** > **Job Management** > **Monitor Job** to monitor the job's progress.

Using MPI Tight Integration

By default, jobs would be submitted with SSH as remote spawn command method. If MPI tight integration preferred, you should submit the job with an additional batch option setting in the Submit Job Browser:

Enable MPI Tight Integration:

```
<design-type>/RemoteSpawnCommand = "Scheduler"
```

Enable SSH:

```
<design-type>/RemoteSpawnCommand = "SSH"
```

Using the Command Line to Submit HPC Jobs

Ansys Electronics Desktop can be run from the command line. When using the command line to perform HPC jobs, take the following into consideration.

Distributed Jobs

An Ansys EM batch job which distributes the analysis over several hosts may also be called a distributed job. To submit a distributed job, the following Ansys EM desktop command line options should be used:

- The -Distributed option should be present, and the -Local option should be absent. When running as a batch job under one of the schedulers with direct integration, this option is a directive to the job to 1) obtain the list of hosts allocated to the job, directly from the scheduler, and to 2) use the scheduler to launch the analysis engines on the hosts allocated to the job. The -Distributed option may now have additional options, such as includetypes=xxx, excludetypes=xxx, maxlevels=n, and numlevel1=n, where n indicates and integer, and xxx indicates a list of distribution types or "default".
- The -Machinelist num=*num_distributed_engines* option must be included, where *num_distributed_engines* is the total number of analysis engines to be started on the hosts assigned to the job.

Other examples:

- "Serial Job on a Single Processor" on the next page
- "Distributed Job Using Four Processors" on the next page

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- "Multiprocessing Job Using Four Cores" below
- "Distributed Analysis and Multi-Processing in the Same Job" on the facing page

Serial Job on a Single Processor

Suppose Ansys Electronics Desktop is installed at "C:\Program Files\ANSYS Inc\v251\AnsysEM\" and you are using RSM for DSO:

```
"C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt.exe" -ng -
BatchSolve -machinelist num=2
-monitor \\shared_drive\projs\OptimTee.aedt
```

User is using LSF for remote-analysis/DSO

```
bsub -n 1 "C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt.exe" -ng
-BatchSolve -machinelist num=3 -monitor -local \\shared_
drive\projs\OptimTee.aedt
```

Distributed Job Using Four Processors

Ansoft RSM

```
"C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt.exe" -ng -
Batchsolve -monitor -Distributed
-machinelist list="10.1.1.221, 10.1.1.222, 10.1.1.223, 10.1.1.224"
\\shared_drive\projs\OptimTee.aedt
```

LSF

```
bsub -n 4 "C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt.exe" -ng
-Batchsolve -monitor
-Distributed -machinelist num=4
\\shared_drive\projs\OptimTee.aedt
```

Multiprocessing Job Using Four Cores

Multi-processing job using 4 cores

```
bsub -n 4 -R span[ptile=4] "C:\Program Files\ANSYS
Inc\v251\AnsysEM\ansysedt.exe" -ng -monitor
-Local -BatchSolve -machinelist num=4 -batchoptions \\shared_
drive\registry.txt \\shared_drive\projs\OptimTee.aedt
```

This requests 4 cores to come from the same machine, as multi-processing needs cores to be on the same machine

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Distributed Analysis and Multi-Processing in the Same Job

Distributed-processing using 4 engines and multi-processing using 4 cores, using a total of 16 cores

```
bsub -n 16 -R "span[ptile=4]" "C:Program Files\ANSYS
Inc\v251\AnsysEM\ansysedt.exe" -ng
-BatchSolve -Distributed -machinelist num=4
-batchoptions \\shared_drive\registry.txt
\\shared_drive\projs\OptimTee.aedt
```

Integrating Ansys EM Tools with Third-Party Schedulers

This document indicates how to create a dynamically linked library to allow integration of Ansys EM tools with an arbitrary scheduler environment. Each scheduler proxy library is used for a single specific scheduler environment. If the library is installed with a valid name and in the correct location, it is then automatically loaded and used by Ansys EM tools.

- Introduction
- Common Requirements for Running Jobs
- Using a Shared Library (Linux) or a DLL (Microsoft Windows)
- Scheduler Proxy Interfaces
- Using an IronPython Program for Scheduler Integration

Introduction

Ansys EM Software Tools may be run as serial or parallel jobs on a cluster under control of a scheduler. Serial jobs are run using a single analysis engine at any one time on a single host. If the tool performs multiple analyses (for a frequency sweep or a parametric analysis, for example), the analyses are performed one after the other. Parallel jobs are run using multiple analysis engines running in parallel on the same host or on separate hosts. For parts of the analysis (such as meshing), the parallel job may use only a single analysis engine on a single host. Other parts of the analysis (such as a frequency sweep, parametric analysis or DDM) may be distributed to multiple analysis engines running in parallel.

- Serial Jobs
- Parallel Jobs

Serial Jobs

When an Ansys EM batch analysis runs as a serial job, the analysis engines run on the same host as the desktop process. The desktop process does not need to interact with the scheduler to get the names of hosts allocated to the job or to start processes on other hosts.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Parallel Jobs

For a parallel job, the desktop process starts multiple analysis engines that run in parallel. These engines may be started on the host where the desktop process is running, or on other hosts allocated to the job. The desktop process interacts with the scheduler to obtain information on the hosts that are allocated to the job, and to start engines on the local host or on other hosts allocated to the job. This document provides information on how to facilitate this interaction between the desktop process and the scheduler controlling the cluster.

For some popular job schedulers in a standard configuration, Ansys EM provides an "out of the box" integrated solution that will work with the scheduler. In this case, the Ansys EM installation includes code that will determine if the analysis is running as a scheduler job and communicate with the scheduler when needed. For other schedulers, the code to obtain information about the hosts allocated to a job and to distribute portions of the job to hosts assigned to the job is not provided in the installation. In order to facilitate using Ansys EM Software Tools with other schedulers, the user may provide a way for Ansys EM Tools to interact with the scheduler. Currently, two general approaches are available to users.

In the first approach, the user creates a shared library (on Linux) or a dynamically linked library (on Microsoft Windows) to provide communication between the Ansys EM Tool and the scheduler. This library is loaded by the Ansys EM Tool at runtime, and if the Ansys EM Tool is running as part of a scheduler job, the Ansys EM Tool interacts with the library to get information from the scheduler, and to start additional processes on specified hosts. Each such library implements the same set of extern "C" functions needed to mediate the interactions between the Ansys EM Tool and the scheduler.

In the second approach, the user creates an IronPython program to provide communication between the Ansys EM Tool and the scheduler. This program is loaded by the Ansys EM Tool at runtime, and if the Ansys EM Tool is running as part of a scheduler job, the Ansys EMs Tool uses the IronPython program to get information from the scheduler, and to start additional processes on specified hosts. Each python script contains a class implementing a specified interface, which contains functions needed to mediate the interactions between the Ansys EM Tool and the scheduler. The details of the interface are described below. The IronPython interface is equivalent to the extern "C" functions used in the first approach.

Common Requirements for Running Jobs

The following requirements must be met for serial and parallel jobs to run successfully. They apply whether using "out of the box" scheduler integration or scheduler integration using a library or using an IronPython program. *Host requirements* apply to all hosts that may be allocated to an Ansys EM serial or parallel batch job.

Installation Requirements

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Ansys EM installation directory must be accessible from all cluster hosts using the same path. One way to achieve this is to place the Ansys EM installation on a shared drive that is accessible to the cluster hosts using the same pathname. On Windows, this may require the use of UNC names to refer to the installation directory. Another option is to install the Ansys EM tool locally on each cluster host using the same local directory path.

Project File and Directory Requirements

The directory containing the project file must also be available from all cluster hosts using the same path. The project file and the containing directory must be readable and writable by the user account used to run the job. The controlling process for a distributed job is called the Desktop process, and it reads from and writes to the project file and other files in the same directory and its subdirectories. Although only the Desktop process reads from and writes to this directory, the Desktop process may be started on any of the hosts allocated to the job, so all hosts should have access to this directory using the same path.

For cloud submission such as Cloud Direct, Ansys HPC Platform Services, and Ansys Cloud Burst Compute there are no requirements for shared drives or shared directories (installation or project).

Using a Shared Library (Linux) or a DLL (Microsoft Windows)

This section describes how to create a dynamically linked library to allow integration of Ansys Electromagnetics Suite 2025 R1 with an arbitrary scheduler environment. Each scheduler proxy library is used for a single specific scheduler environment. If the library is installed with a valid name and in the correct location, then it will automatically be loaded and used by Ansys Electromagnetics Suite 2025 R1.

Installation Details

The scheduler proxy library must be installed in the schedulers subdirectory of the Ansoft installation directory. For example, if the Ansys EM installation directory is "C:\Program Files\v251\AnsysEM", then the scheduler proxy library must be installed in directory "C:\Program Files\ANSYS Inc\v251\AnsysEM\schedulers.

The scheduler proxy library base name must match "libprefix_scheduler" on Windows and "liblibprefix_scheduler" on Linux. The extension must be a valid extension for a dynamically loaded library on the platform where it is used. The scheduler proxy library name prefix libprefix shall be unique, so it does not conflict with other scheduler proxy libraries in the same directory. To avoid confusion, the scheduler proxy library name should be all lower case on OSs where file names are case sensitive.

Build Information for Scheduler Proxy Library

This section contains the recommended compiler and linker settings for building a scheduler proxy library.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- 64-Bit Microsoft Windows
- Linux

64-Bit Microsoft Windows

The proxy library should be compiled and linked as a 64-bit DLL, using the following recommended compiler and linker options:

Compiler Options

- Use of MFC: Use Standard Windows Libraries
- Character Set: Use Multi-Byte Character Set [/D "_MBCS"]
- Runtime Library: Multi-threaded DLL [/MD]
- Calling Convention: __cdecl [/Gd (default)]

Linker Options:

- Create a DLL [/DLL]
- 64-bit code [MACHINE:X64]

Linux

The proxy library should be compiled and linked as shared library (*.so) file. The following compiler and linker options are recommended when building using gcc/g++:

Compiler Options

- Generate position-independent code, suitable for use in a shared library: [-fpic]
- Generate code compatible with pthreads library: [-pthread]

Linker Options:

- Create a shared object file: [-shared]
- Generate position-independent code, suitable for use in a shared library: [-fpic]
- Generate code compatible with pthreads library: [-pthread]

Implementation Details for Custom Scheduler Integration

Function Name Prefix

Each exported function will have a scheduler specific function name prefix. The function name prefix will be the same as the library name prefix, except that it is converted to upper case. For example, if the library name prefix is "lsf", then the function name prefix is "LSF". In the examples below, we use FN_PREFIX to denote the function name prefix.

The scheduler proxy library must provide implementations of the following extern "C" functions:

- IsProductLaunchedInYourEnvironment
- GetTempDirectory

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- GetMachineListAvailableForDistribution
- GetMessageStringToRegisterForSigTerm
- LaunchProcess
- GetUseRsmForEngineLaunch
- GetThisJobID
- GetSchedulerDisplayName

IsProductLaunchedInYourEnvironment

Purpose

Determine if the program is running in the context of the scheduler for which this library was written.

Signature

```
extern "C" bool FN_PREFIX_IsProductLaunchedInYourEnvironment();
```

Arguments

None.

Return Value

Returns true if the current process is running as a job of the scheduler. Otherwise, false is returned.

> **Note:**
>
> For many schedulers, the presence of certain environment variables or their values may be checked to determine if the current process is running as a job of the scheduler.

GetTempDirectory

Purpose

Get the pathname of the temporary directory provided by the scheduler for the current job. The pathname is an empty string if the scheduler does not provide a temporary directory for the current job.

Signature

```
extern "C" bool FN_PREFIX_GetTempDirectory(char * buffer,
unsigned int* length);
```

Arguments

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

buffer: Pointer to a character buffer to contain the temporary directory path name or NULL.

length: Pointer to a location to contain the length of the buffer. Must be a valid pointer to an unsigned int.

Return Value

If argument buffer is NULL, then then required length of the buffer is stored in the location to which argument length points, and true is returned.

If argument buffer is not NULL, then the value to which argument length points (the buffer length) is checked. If it is large enough to contain the pathname of the temporary directory, including the terminal null byte, then the pathname is copied to the buffer and true is returned. If the buffer length is insufficient for the pathname of the temporary directory, then the buffer is unchanged, and false is returned.

> **Note:**
>
> To get the pathname of the temporary directory, the infrastructure first calls this function with a NULL buffer, and obtains the required length of the buffer for the pathname. After creating a buffer of the appropriate size, the infrastructure calls this function again, passing the pointer to the buffer in the buffer argument and a pointer to the size of the buffer in the length argument.

GetMachineListAvailableForDistribution

Purpose

Get the list of hosts allocated to the current job. A host will appear in the list multiple times if the scheduler has allocated multiple processors or cores on the host to the job. The number of times the host appears in the list is equal to the number of processors or cores of the host that are allocated to the current job. The list is a text string containing a space separated list of hostnames.

Signature

```
extern "C" bool FN_PREFIX_GetMachineListAvailableForDistribution
(char * buffer, unsigned int* length);
```

Arguments

buffer: Pointer to a character buffer to contain the list of machines available for distribution or NULL.

length: Pointer to a location to contain the length of the buffer. Must be a valid pointer to an unsigned int.

Return Value

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If argument buffer is NULL, then then required length of the buffer is stored in the location to which argument length points, and true is returned.

If argument buffer is not NULL, then the value to which argument length points (the buffer length) is checked. If it is large enough to contain the lists of hosts, including the terminal null byte, then the list is copied to the buffer and true is returned. If the buffer length is insufficient for the list of hosts, then the buffer is unchanged, and false is returned.

Note:

- To get the list of hosts for distribution, the infrastructure first calls this function with a NULL buffer, and obtains the required length of the buffer for the list. After creating a buffer of the appropriate size, the infrastructure calls this function again, passing the pointer to the buffer in the buffer argument and a pointer to the size of the buffer in the length argument.
- The hostnames in the list provided by this function shall be used in calls to LaunchProcess(). These host names must be in a format that is accepted by that function. See the section below on LaunchProcess.

GetMessageStringToRegisterForSigTerm

Purpose

Obsolete. The string copied to the buffer should be an empty string.

Signature

```
extern "C" bool FN_PREFIX_GetMessageStringToRegisterForSigTerm
(char * buffer, unsigned int* length);
```

Arguments

buffer: Pointer to a character buffer to contain the string or NULL.

length: Pointer to a location to contain the length of the buffer. Must be a valid pointer to an unsigned int.

Return Value

If argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned.

If argument buffer is not NULL, then the value to which argument length points (the buffer length) is checked. If it is large enough to contain the string, including the terminal null byte, then the string is copied to the buffer and true is returned. If the buffer length is insufficient for the string, then the buffer is unchanged, and false is returned.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> To get the string, the infrastructure first calls this function with a NULL buffer, and obtains the required length of the buffer for the string. After creating a buffer of the appropriate size, the infrastructure calls this function again, passing the pointer to the buffer in the buffer argument and a pointer to the size of the buffer in the length argument.

LaunchProcess

Purpose

Launch a local or remote process to run an analysis engine. This function is called by the Ansys Electromagnetics desktop application to launch an engine process on a specified host. The hostname is one of the names in the list provided by the GetMachineListAvailableForDistribution function. If the hostname does not refer to the local host, then this function shall use the scheduler to launch the engine on the specified host. If the hostname refers to the local host, then the engine may be started as a child process, or it may be started using the scheduler.

Signature

```
extern "C" int FN_PREFIX_LaunchProcess(const char* hostName,
const char* exePathName, const char* arg1, const char* arg2);
```

Arguments

hostName: The name of the host where the process is to be launched.

exePathName: The pathname of the analysis engine executable to be started.

arg1: The first argument of the analysis engine command line.

arg2: The second argument of the analysis engine command line.

Return Value

Returns 0 on success. Returns a non-zero value if an error occurs.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

- The hostName argument will be one of the hostnames provided by the function GetMachineListAvailableForDistribution().
- If the hostName argument is the same as the current host, then the analysis engine process may be started as a child process. If the hostName argument is not the same as the current host, then the analysis engine process will be started on the remote host using the facilities available in the scheduler environment. The command line of the analysis engine process is exePathName arg1 arg2. The command line arguments arg1 and arg2 may contain newlines, tabs, spaces or other characters that are interpreted by the command processor, such as single quote (') or double quote (") characters, or dollar signs ($). Newlines or tabs may be replaced by spaces, if the newline or tab characters cannot be easily handled. If the analysis engine command is processed by a shell, then it may be necessary to quote any special characters in the exePathName or in the arguments so that the special meaning is removed. If a scheduler command is used to request the scheduler to launch the command to start the engine process, the analysis engine command may be processed by the shell twice: once when the scheduler command is processed, and a second time when the analysis engine process is started. If this is the case, then the quoting of special characters needs to account for two passes through the command processor.

GetUseRsmForEngineLaunch

Purpose

This function is optional. If this feature is not needed, then the function need not be implemented. Most schedulers should not need this feature.

For some schedulers, it may be desirable for the Ansoft RSM service to launch the engine processes instead of using the scheduler proxy library. For example, if the scheduler proxy library is limited to launching one process per host, then the scheduler proxy library may be used to launch one Ansoft RSM service executable per host, and the Ansoft RSM executable will launch all of the engine processes.

If the Ansoft RSM service should be used to launch engine processes for this scheduler, then this function shall be implemented and it shall return true.

If the Ansoft RSM service should not be used to launch engine processes for this scheduler, then this function is not required. If it is implemented, it should return false. If it is not implemented, it will be treated the same as if it was implemented and returns false.

Signature

```
extern "C" bool FN_PREFIX_GetUseRsmForEngineLaunch(void)
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Arguments

None.

Return Value

Returns true if the Ansoft RSM service should be used to launch engine processes for this scheduler. Returns false if the Ansoft RSM service should not be used to launch engine processes for this scheduler.

> **Note:**
>
> This function is optional. If not implemented, then it is treated the same as if it was implemented and returns false.

GetThisJobID

Purpose

Get a string identifying the job currently running in the scheduler environment. This string is displayed to the end user to identify the job.

Signature

```
extern "C" bool FN_PREFIX_GetThisJobID(char * buffer, unsigned
int* length);
```

Arguments

buffer: Pointer to a character buffer to contain the Job ID or NULL.

length: Pointer to a location to contain the length of the buffer. Must be a valid pointer to an unsigned int.

Return Value

If argument buffer is NULL, then then required length of the buffer is stored in the location to which argument length points, and true is returned.

If argument buffer is not NULL, then the value to which argument length points (the buffer length) is checked. If it is large enough to contain the string identifying the current job, including the terminal null byte, then the job ID is copied to the buffer and true is returned. If the buffer length is insufficient for the job ID, then the buffer is unchanged, and false is returned.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

- To get the job ID, the infrastructure first calls this function with a NULL buffer, and obtains the required length of the buffer for the job ID. After creating a buffer of the appropriate size, the infrastructure calls this function again, passing the pointer to the buffer in the buffer argument and a pointer to the size of the buffer in the length argument.
- For many schedulers, the job ID may be obtained from the value of an environment variable.

GetSchedulerDisplayName

Purpose

Get a string identifying the scheduler associated with the current scheduler proxy library. This string is displayed to the end user to identify the scheduler.

Signature

```
extern "C" bool FN_PREFIX_GetSchedulerDisplayName(char * buffer,
unsigned int* length);
```

Arguments

buffer: Pointer to a character buffer to contain the scheduler display name or NULL.

length: Pointer to a location to contain the length of the buffer. Must be a valid pointer to an unsigned int.

Return Value

If argument buffer is NULL, then required length of the buffer is stored in the location to which argument length points, and true is returned.

If argument buffer is not NULL, then the value to which argument length points (the buffer length) is checked. If it is large enough to contain the scheduler display name, including the terminal null byte, then the scheduler display name is copied to the buffer and true is returned. If the buffer length is insufficient for the scheduler display name, then the buffer is unchanged, and false is returned.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

- To get the scheduler display name, the infrastructure first calls this function with a NULL buffer, and obtains the required length of the buffer for the scheduler display name. After creating a buffer of the appropriate size, the infrastructure calls this function again, passing the pointer to the buffer in the buffer argument and a pointer to the size of the buffer in the length argument.
- The scheduler display name is generally a fixed string.

Extending Scheduler Integration with Tight-Integration for MPI

AnsysEM supports tight-integration with a few popular schedulers by leveraging built-in tight-integration capabilities of intel MPI. Specifically on Linux, this works out of the box with LSF, SGE and Ansys Cloud Burst Compute. For other Linux based schedulers, this note describes how scheduler integration developers can extend scheduler integration to provide tight integration for MPI based solves.

MPI Based Solves

Like many other simulation applications, AnsysEM also uses an MPI-based message passing approach to provide portable parallel execution on shared, distributed and distributed shared memory computers.

An MPI solve involves running a mpiexec (or mpirun) command that runs the simulation's executable on each allocated/specified host. For most applications, the entire simulation is just a single MPI solve. However, an AnsysEM simulation consists of multiple MPI solves which are organized as following:

1. Multiple MPI solves in series: Each AnsysEM simulation runs multiple MPI solves.
2. Different host list: Each such MPI solves may use different amount of resources (mostly cores per host) that is specified using the host list and count of ranks.
3. Multiple MPI solves in parallel: In some case, multiple MPI solves may be launched in parallel from different hosts. So multiple MPI solves may be running simultaneously.
4. Multi-processing: Finally, within each MPI based solve, each rank can use multi-processing as well.

To launch an MPI based solve AnsysEM code uses an MPI integration related wrapper file, called mpirun.fl, which in turn invokes MPI's mpirun/mpiexec. Ansys EM installation includes all the needed files for the supported MPI implementation's.

Scheduler integration for MPI

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When a scheduler runs a simulation, each scheduler job usually runs just a single MPI solve. Each time MPI needs to launch a process on a remote allocated host, it will do so either with password-less ssh (loose integration), or with a scheduler specific script/command (tight-integration).

Custom Tight Integration

For custom tight integration, you provide a script that uses scheduler's utilities to launch processes on a remote host. The script needs to be a drop-in replacement for ssh. For AnsysEM to use this script for MPI solves, you need to specify the following environment variables and provide bootstrap selector and bootstrap script file.

Environment Variables	Value	Description
ANSYSEM_HPC_MPI_USE_SCHEDULER_CMD	A keyword that identifies the scheduler	Scheduler for which to enable tight-integration
ANSYSEM_HPC_MPI_CUSTOM_SCRIPT_FILE	Fully qualified path to the custom script file	Script that implements a function that returns the switch to be used for MPI implementation's command line.

Script Files

Script Files	Content	Description
Bootstrap selector BASH script file	implements a bash function that returns the switch to be used for MPI implementation's command line.	**Intel MPI**: Implements `ansysem_hpc_intel_mpi_bootstrap` either returns -bootstrap or -bootstrap-exec with a suitable argument
Bootstrap BASH script file	Shell script that is a ssh drop-in replacement	Launches a process on a remote host. Accepts the same arguments as ssh

Example: PBSPro

For custom tight integration with PBSPro, you provide a script that uses pbsdsh utility to launch processes on a remote host. The script is a drop-in replacement for ssh. It assumes that the first two arguments are -x and -q. and provide bootstrap selector and bootstrap script file

For an AnsysEM batch solve runnning under PBSPro to use this script for MPI solves, the job script will set the following environment variables.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Job script excerpt:

```
# The selector script will specify the MPI options for PBSPro
export ANSYSEM_HPC_MPI_USE_SCHEDULER_CMD=pbspro
# Bootstrap selector BASH script file
export ANSYSEM_HPC_MPI_CUSTOM_SCRIPT_FILE=${INSTALL_DIR}/ansys_
inc/v251/AnsysEM/schedulers/utils/pbspro-intelMPI-integration.sh
# Special environment variable to enable PBS Node file to become
available in Bootstrap script file.
export ANSYSEM_HPC_MPI_SCHEDULER_NODEFILE=$PBS_NODEFILE
```

pbspro-intelMPI-integration.sh

```
#!/bin/bash
function ansysem_hpc_intel_mpi_bootstrap()
{
  local custom_scheduler="$1"
  local bootstrap_switch=""
  if [[ -n "$custom_scheduler" ]]
  then
    if [[ "$custom_scheduler" == "pbspro" ]]
    then
      exec_file=$(dirname $ANSYSEM_HPC_MPI_CUSTOM_SCRIPT_FILE)
      exec_file_name=pbspro_dsh_wrapper.sh
      bootstrap_switch="-bootstrap-exec $exec_file/$exec_file_name"
    fi
fi
  echo "$bootstrap_switch"
}
```

pbspro_dsh_wrapper.sh

```
#!/bin/bash
# Bootstrap BASH script file for PBSPro
# Assumes that the first two arguments are -x and -q
# For debugging, set it to a suitable path
# DEBUG_DIR=$(HOME)/Ansoft/Test/DebugLog
PBS_BINDIR=/opt/pbs/bin
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
shift 2
host_name=$1
# Assumes that the next argument is host name shift 1
# Compute the index for the first entry
index1=$(( $(grep -n -m 1 $host_name $ANSYSEM_HPC_MPI_SCHEDULER_
NODEFILE | cut -f1 -d:) - 1))
if [[ -n "$DEBUG_DIR" ]]
then
  echo "running pbsdsh ON $host_name as index $index1 $@" >>
  ${DEBUG_DIR}/wrapper.log
  cat $ANSYSEM_HPC_MPI_SCHEDULER_NODEFILE >> ${DEBUG_
  DIR}/wrapper.log
fi
$PBS_BINDIR/pbsdsh -v -n $index1 -- "$@"
```

Intel MPI custom bootstrap feature

From Intel MPI docs:

```
-bootstrap-exec <bootstrap server>
```

Use this option to set the executable to be used as a bootstrap server. For example:

```
> mpiexec -bootstrap-exec <bootstrap_server_executable> -f hostfile
-env <VAR1> <VAL1> -n 2 test.exe
```

This -bootstrap-exec switch lets you specify a shell script that is a ssh drop-in replacement. For custom tight-integration, AnsysEM uses Intel MPI, and leverages its special switch. This -bootstrap-exec switch lets you specify a shell script that is a ssh drop-in replacement. Using it requires a small patch to an MPI integration related wrapper file, called mpirun.fl. This file, which is available in AnsysEm installation, is used by AnsysEM code to launch an MPI based solve (similar to using mpirun). Each time Intel MPI needs to launch a process on a remote allocated host, it will call a scheduler (or user) specified script using arguments that are same as those for password-less ssh.

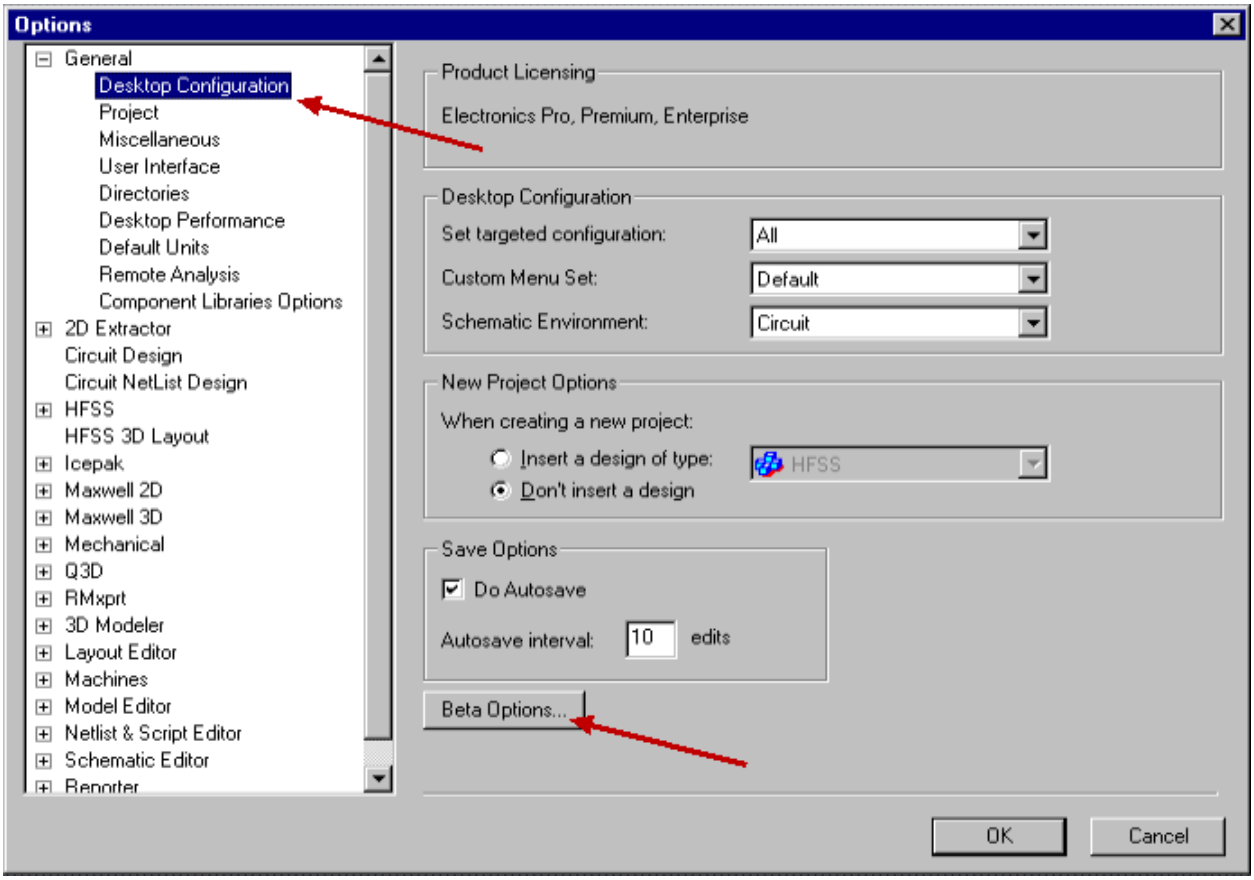
Support for Open MPI on Linux [Beta]

Support for Open MPI on Linux is available as a beta feature for HFSS, HFSS 3D Layout, Icepak, Maxwell (3D and 2D), and Q3D designs.

To enable the beta feature:

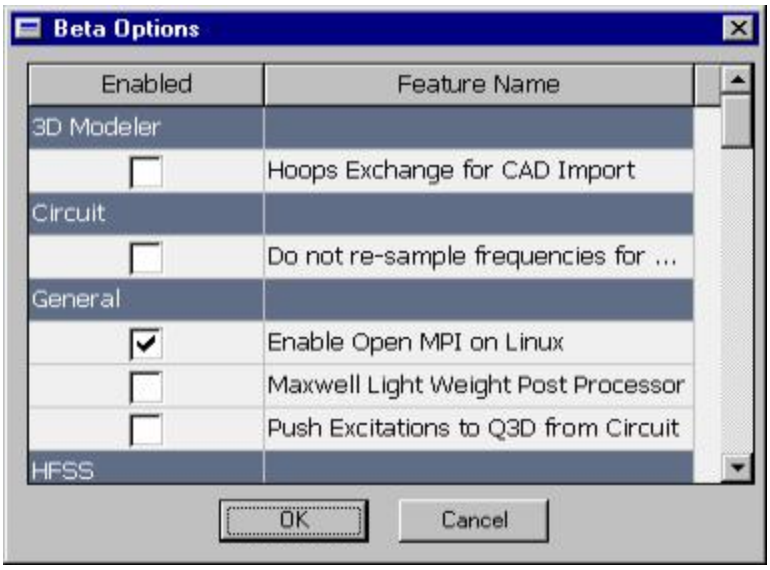
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Access the *Options* dialog box using one of the following two mehtods:
   - From the menu bar, click **Tools** > **Options** > **General Options**.
   - On the **Desktop** ribbon tab, click **General Options**.
2. In the tree on the left side of the dialog box, expand **General** and select **Desktop Configuration**.
3. Click **Beta Options**:



4. Select **Enable Open MPI on Linux**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. When making a change to any beta option, you may be prompted to restart the Ansys Electronics Desktop application. If prompted, click **Yes** to do so.

   The **Open MPI** option will now be available in the **MPI Vendor** drop-down menu within the *Options* tab of the *HPC and Analysis Options* dialog box. You only need to perform this procedure once; the Open MPI option will remain available for future sessions and projects.

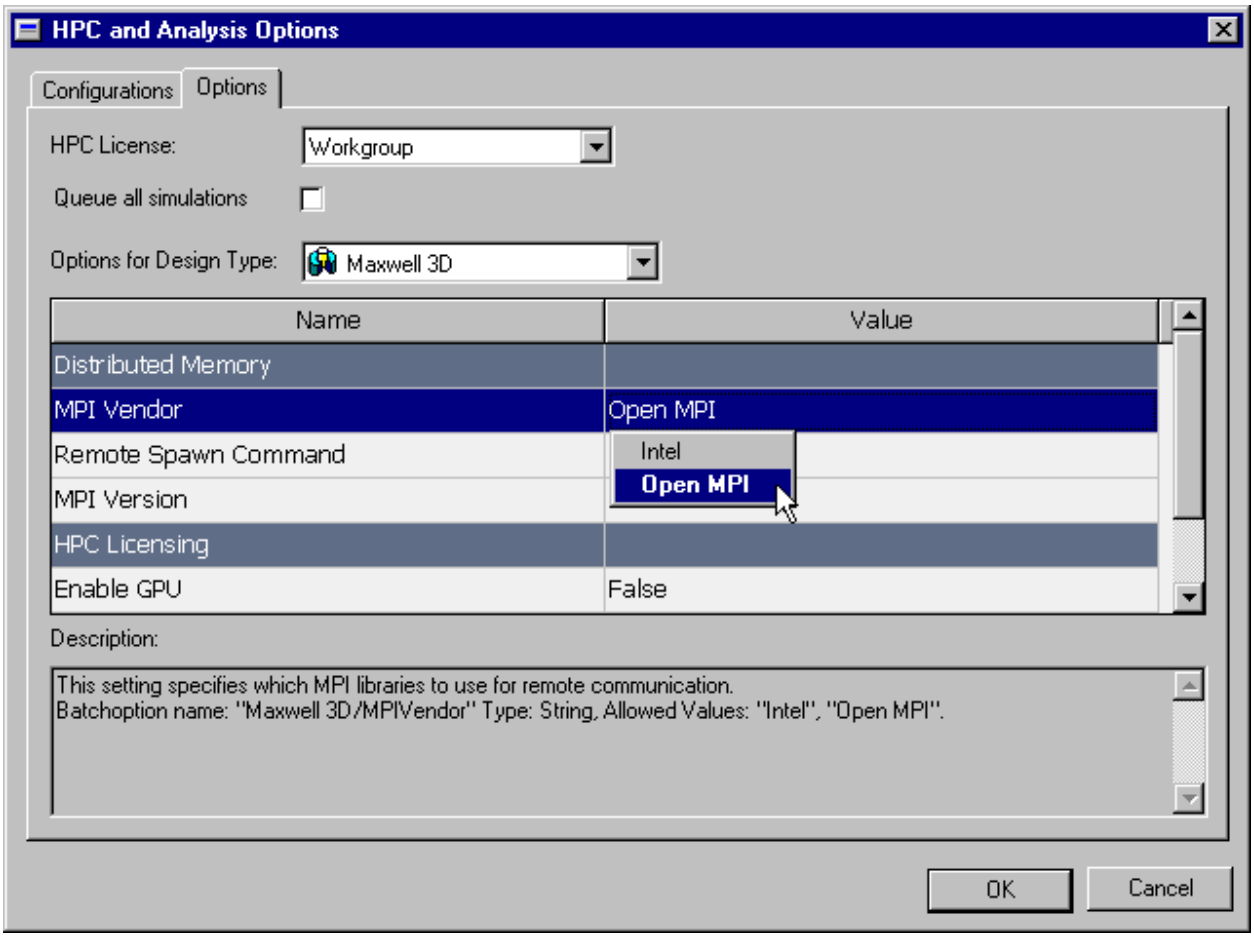
To choose Open MPI as the MPI Vendor:

1. Open the project in the Ansys Electronics Desktop application (interactive mode).
2. From the **Simulation** ribbon tab, click **HPC Options**
3. In the *HPC and Analysis Options* dialog box, select the **Options** tab.

   The contents of this tab vary by design type.

4. Select **Open MPI** from the **MPI Vendor** drop-down menu:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. Click **OK**.

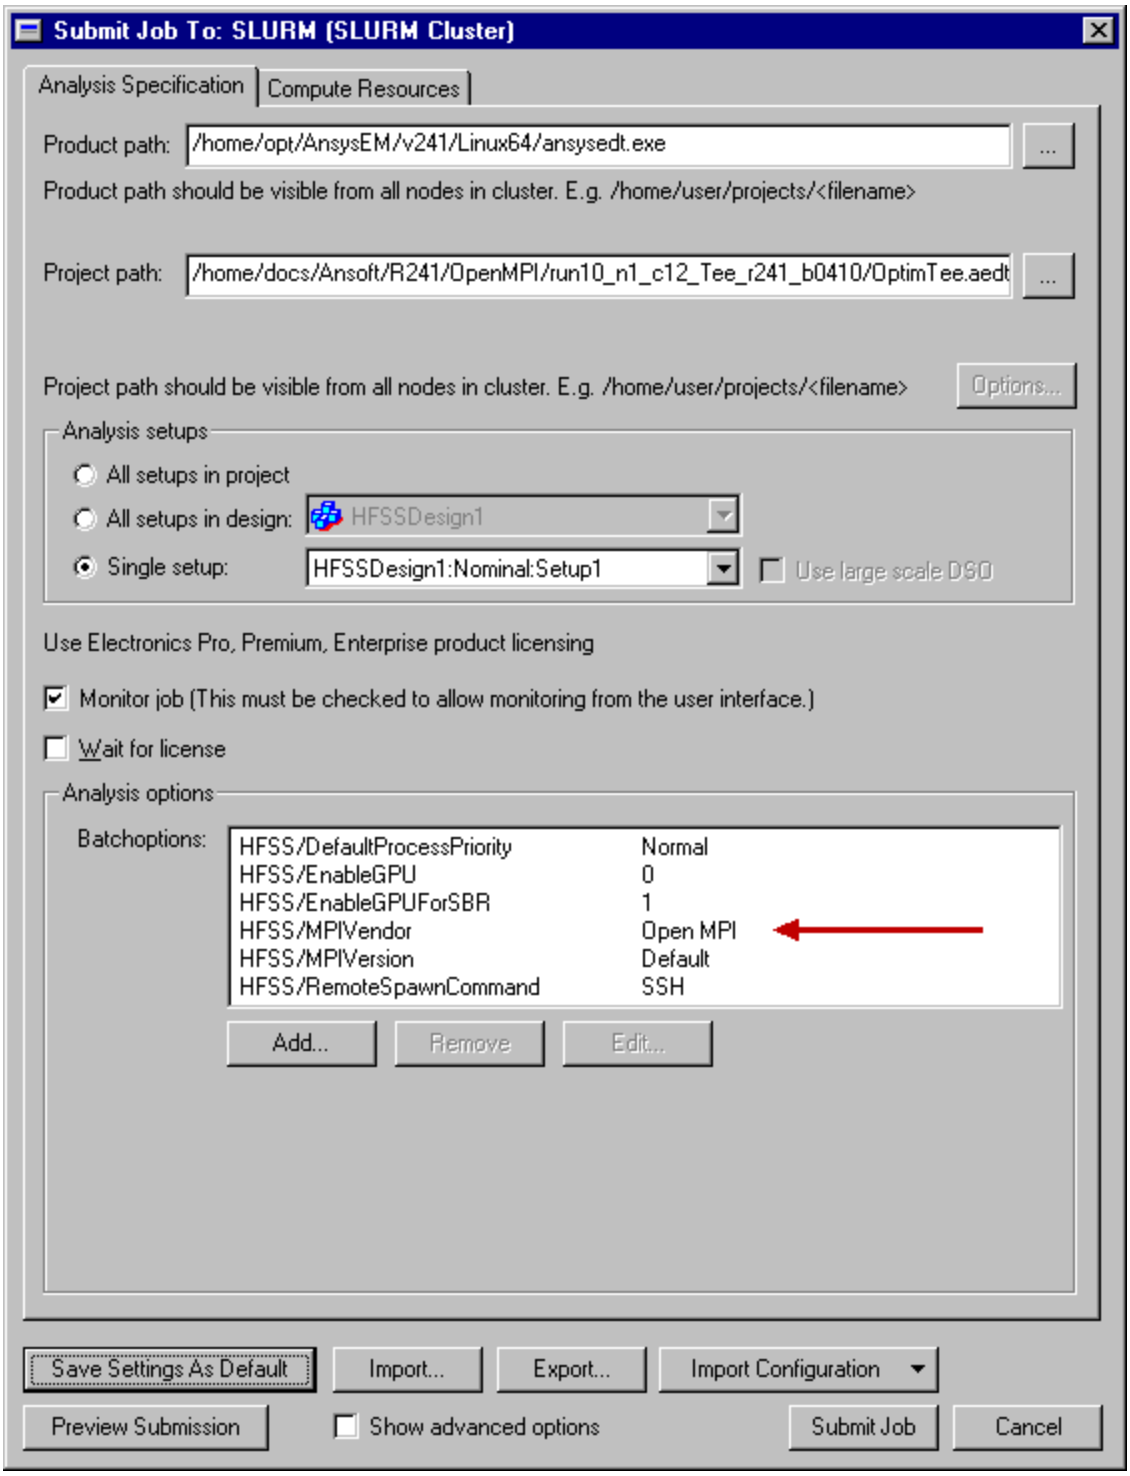
   You can then run the simulation on a Linux cluster as follows.

6. In the Project Manager, right-click the solution setup to solve and choose **Submit Job** from the shortcut menu.
7. Specify the desired parameters and click **Submit Job**.

   In the *Submit Job* dialog box, *Open MPI* is included as a batch option for each supported design type along with other applicable batch options.

   The following example is for an HFSS design:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Scheduler Proxy Interfaces

Scheduler proxy supports following new graphical interface functions. The scheduler specific prefix of each function is not shown in this listing.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

void Initialize(const std::string& config):

Initialize the proxy library for scheduler interaction. The **config** argument contains scheduler specific initialization information.

int CheckEnvironment(std::string& msg):

Check the environment in which the proxy library is running.

- Returns 0 (success) if the environment is appropriate for submitting jobs to the scheduler.
- Returns a non-zero error code if the environment is incorrect. If a non-zero error code is returned, an error message to display to the user is written to the msg argument.

int GetSchedulerInfo(std::string& msg, std::string& schedulerName, std::string& schedulerDescription, std::string& schedulerVersion):

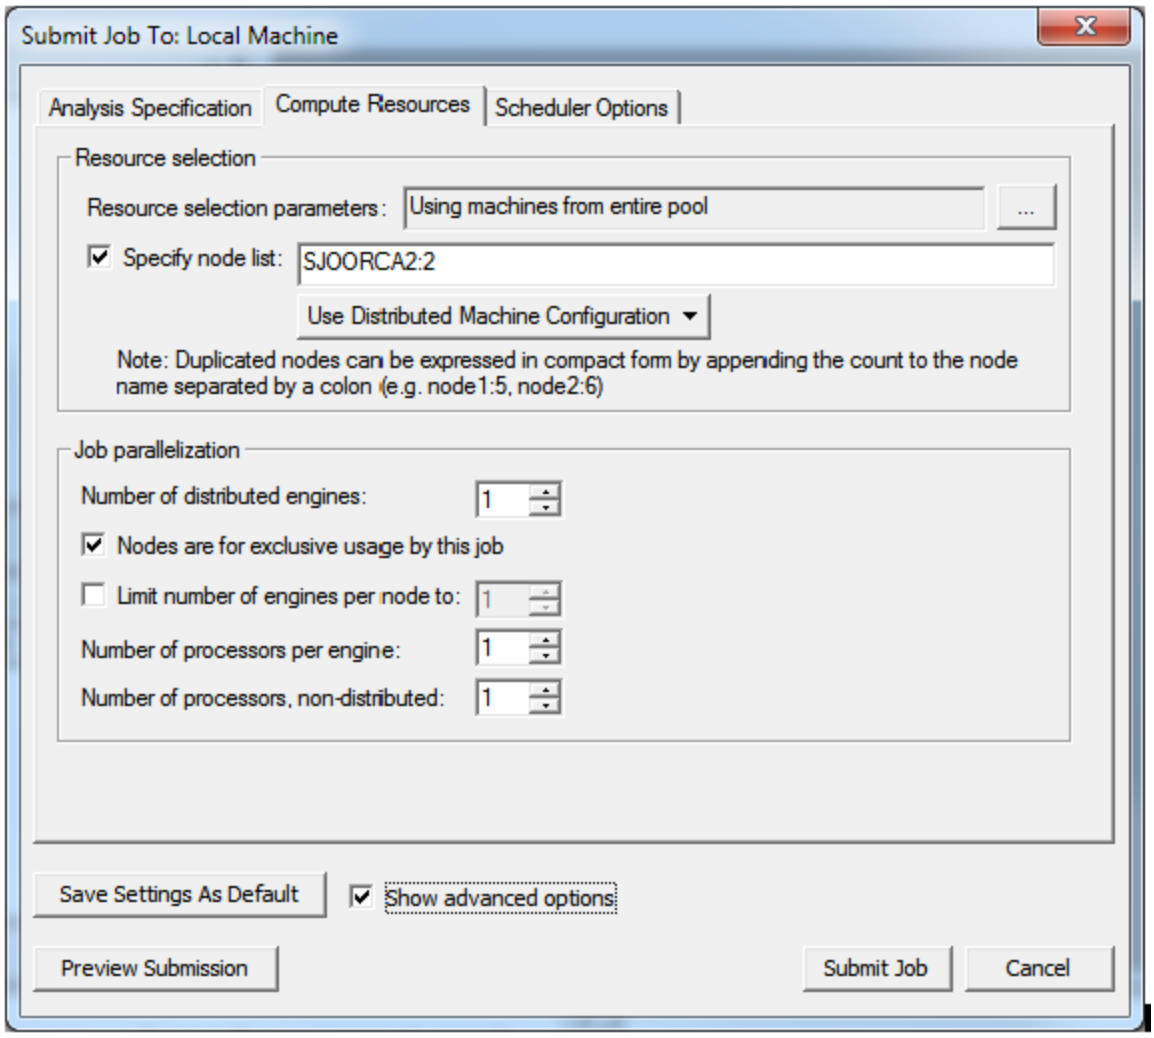
This function returns some basic information about the scheduler with which the scheduler proxy library interacts.

- On success, 0 is returned, and the scheduler name, scheduler description, and scheduler version are written to the **schedulerName**, **schedulerDescription** and **schedulerVersion** arguments.
- On failure, a non-zero error code is returned, and an error message to display to the user is written to the msg argument.

int GetComputeResourceAttributes(std::string& msg, AttributeDefinitionsStruct& attributeDefs):

The *Compute Resource* tab or the *Submit Job To* dialog box allows the user to specify scheduler specific resources. This function returns the information used to create and populate the *Compute Resource* tab.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Each line in the dialog box is defined by a single attribute definition in the **attributeDefs** argument. An attribute definition defines the name and description of an attribute, as well as information about the allowed values and the default value. In general, only the most commonly specified job attributes are included in the **attributeDefs** argument.

- On success, 0 is returned, and the attribute definitions are written to the **attributeDefs** argument.
- On failure, a non-zero error code is returned, and an error message to display to the user is written to the msg argument.
- If the scheduler proxy library does not support any attributes using this approach, the **attributeDefs** argument will contain no attribute definitions, and 0 will be returned.

int AbortJob(std::string& msg, const std::string& jobID, bool force, const SubmissionUserStruct& submissionUser):

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This function requests the scheduler to abort a job identified by the **jobID** argument. If the force argument is true, then errors should be ignored (the exact behavior is scheduler specific). The **submissionUser** argument contains information about the client user (the user running the Desktop process). The request to abort the job should run in the context of this user. If no user is specified, then the request to abort the job runs as the user of the process or thread running the function.

- If the request is successfully submitted, then 0 is returned.
- If there is an error, then a non-zero error code is returned, and an error message to display to the user is written to the msg argument.

int SubmitUniformJob(std::string& msg, std::string& jobID, const CmdLineStruct& cmdLineInfo, const JobParallelizationStruct& jobParallelization, const UniformComputeResourcesStruct& computeResources, const JobOptionsStruct& jobOptions, const JobAtributesStruct& jobAttributes, const SubmissionUserStruct& submissionUser,const IJobParameters* jobParametersCB):

This function submits a job to the scheduler.

- On success, 0 is returned, and the job identifier of the newly submitted job is written to the **jobID** argument.
- On failure, a non-zero error code is returned, and an error message to display to the user is written to the msg argument.

This function is used to submit jobs to the scheduler in which the resources allocated to the job are uniformly distributed across the nodes allocated to the job. All other arguments are input arguments, and they are described below:

The **cmdLineInfo** argument contains the command line arguments. The first argument is the command name.

The **jobParallelization** argument contains information on how the job should be parallelized. It contains the following integral parameters:

- the total number of distributed engines,
- the number of cores to allocate for each distributed engine,
- the maximum number of engines to allocate to a single node (optional), and
- the number of cores to allocated for the non-distributed portion of the analysis.
- It also contains a boolean parameter indicating whether nodes used for this job should be exclusively allocated to this job.

The **computeResources** argument is a reference to an object of type **UniformComputeResourcesStruct**. This **struct** contains zero or more resource attribute settings for the job. Each resource attribute setting consists or a resource name and a resource value. The resource name is the name of one of the resources defined in the **AttributeDefinitionsStruct** filled in by the **GetComputeResourceAttributes()** function. The

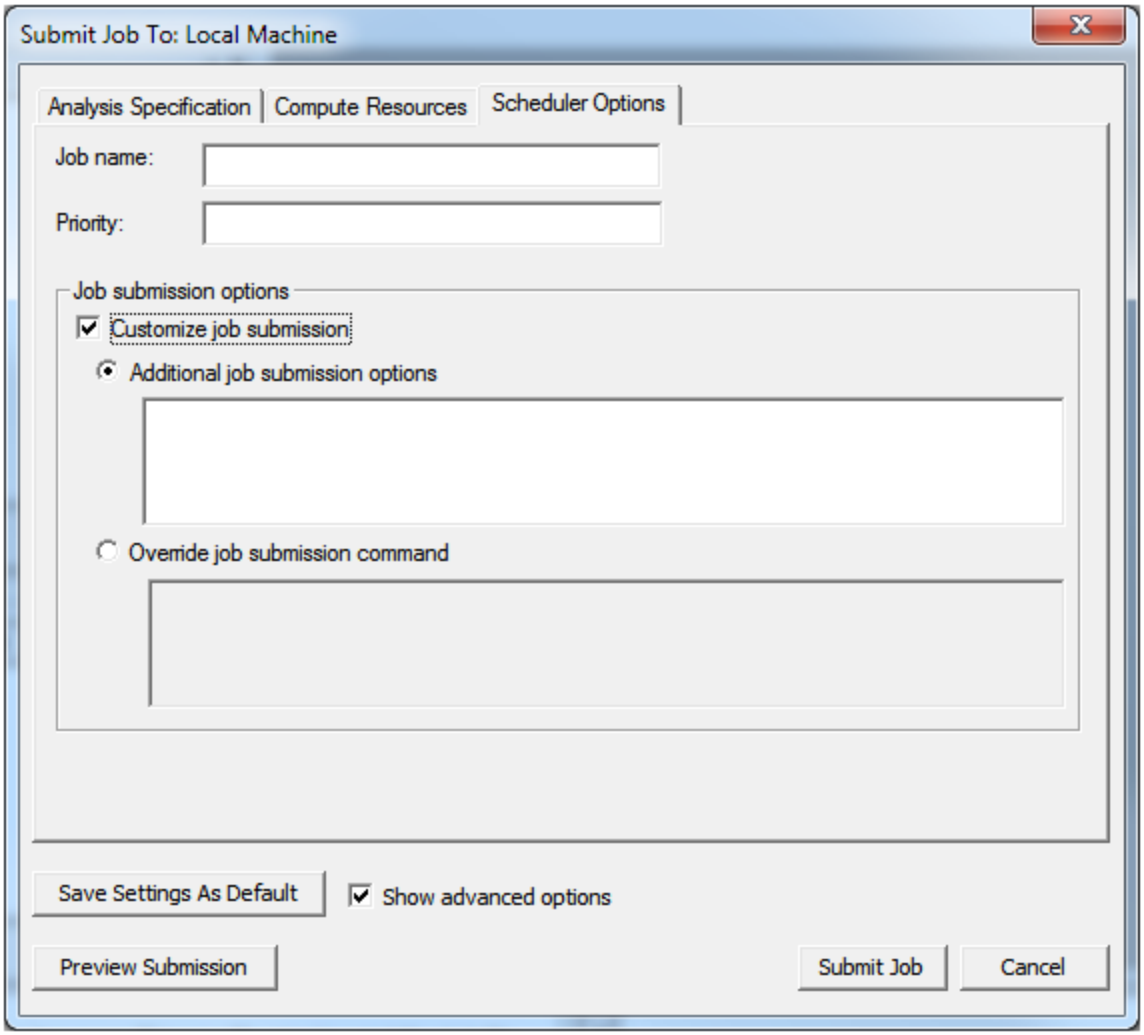
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

resource attribute value is the value specified for the resource attribute by the user using the *Compute Resource* tab of the *Submit Job To* dialog box. If no resource attributes are specified by the user in this dialog box, then the **computeResources** argument will contain no resource attribute settings.

The **jobOptions** argument contains the environment variable settings for the job.

The **jobAttributes** argument contains job submission attributes which are not necessarily related to the compute resources allocated to the job. The job name and the requested job priority are included in this data structure.

The *Scheduler Options* tab of the *Submit Job To* dialog box allows the user to either specify additional job submission options or to specify all submission options, replacing the settings from the other *Submit Job To* dialog box controls.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The user-specified submission options are included in this data structure, as well as a boolean setting indicating whether the user specified options are in addition to the automatically generated options, or whether they replace the automatically generated submission options.

The **submissionUser** argument contains information about the client user (the user running the Desktop process). The job is submitted to the scheduler to run as this user.

The **jobParametersCB** argument is a pointer to an object that implements the **IJobParameters** interface. This interface allows the scheduler proxy library to get additional information about the job. Specifically, the **GetWorkingDirectory()** interface function returns the working directory to be used for the job.

The **cmdLineInfo** argument contains the command line arguments. The first argument is the command name.

int SubmitNonUniformJob(std::string& msg, std::string& jobID, const CmdLineStruct& cmdLineInfo, const JobParallelizationStruct& jobParallelization, const NonUniformComputeResourcesStruct& computeResources, const JobOptionsStruct& jobOptions, const JobAtributesStruct& jobAttributes, const SubmissionUserStruct& submissionUser,const IJobParameters* jobParametersCB):

This function submits a job to the scheduler.

- On success, 0 is returned, and the job identifier of the newly submitted job is written to the **jobID** argument.
- On failure, a non-zero error code is returned, and an error message to display to the user is written to the msg argument.

This function is used to submit jobs to the scheduler in which the nodes to use and the number of engines to run on each node are specified by the user. All other arguments are input arguments, as for the **SubmitUniformJob()** function. These input arguments are the same as for the **SubmitUniformJob()** function, except that the **computeResources** argument is a reference to a **NonUniformComputeResourcesStruct**, as described below:

The **computeResources** argument is a reference to an object of type **NonUniformComputeResourcesStruct**. This object contains a vector of pairs, where each pair consists of the name of a node in the cluster, and the number of engines to run on the node.

int PreviewUniformJob(std::string& msg, std::string& preview, const CmdLineStruct& cmdLineInfo, const JobParallelizationStruct& jobParallelization, const UniformComputeResourcesStruct& computeResources, const JobOptionsStruct& jobOptions, const JobAtributesStruct& jobAttributes, const SubmissionUserStruct& submissionUser, const IJobParameters* jobParametersCB):

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This function is similar to the **SubmitUniformJob()** function, but instead of submitting the job, text representing how the job will be submitted is written to the preview argument. Typically the preview text includes the job submission command and the contents of the job script created for the job. For some schedulers, this content may not be meaningful, so the text returned could be different.

- On success, 0 is returned, and the job preview text is written to the preview argument.
- On failure, a non-zero error code is returned, and an error message to display to the user is written to the msg argument.

The other arguments are input arguments with the same meaning as for the **SubmitUniformJob()** function. The **submissionUser** argument is ignored for this function.

Testing Scheduler Integration

One way to test these functions is to run the analysis for an Ansys EM product in batch mode. When running in batch mode, a batch log file is created in the same directory as the project file. The batch log file has the same base name is the project file, with an extension of ".log". For example, if the project file is TestProject123.aedt, then the batch file is TestProject123.log. The batch log file contains useful information about the analysis run.

See the product specific help for details on running the product in batch mode, and for the command line options to use for distributed analysis.

- Testing IsProductLaunchedInYourEnvironment
- Testing GetSchedulerDisplayName and GetThisJobID
- Testing GetTempDirectory
- Testing GetMachineListAvailableForDistribution
- Testing LaunchProcess
- Testing GetUseRsmForEngineLaunch

Testing IsProductLaunchedInYourEnvironment

This function should be tested first. If the Ansys EM application is not able to load and run this function, or if it returns false, then none of the other functions will be called. If the batch analysis is running in a scheduler environment, and this function returns true, then there will be an "info" message near the beginning of the batch log indicating that the analysis is running as a scheduler job. This message will include the scheduler display name returned by the function GetSchedulerDisplayName, and it will also include the job ID returned by the function GetThisJobID. If the batch analysis is not running in a scheduler environment, then none of the messages will include a scheduler display name or job ID.

If this message does not appear when running in a scheduler environment, ensure that the scheduler proxy library is named correctly, that it is built correctly, that it is installed in the

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

correct directory, and that the function name prefix is the same is the library prefix converted to upper case.

Testing GetSchedulerDisplayName and GetThisJobID

As described above, when running a batch job in a scheduler environment, the scheduler display name and the job ID will appear in an "info" message near the beginning of the batch log. The values returned by these functions are copied to this message verbatim, so they can be directly compared to the expected values.

Testing GetTempDirectory

Many schedulers create a temporary directory for each job and delete the directory after the job finishes. One way to verify that this function is working correctly is to determine the pathname that the scheduler uses for the temporary directory and to monitor the contents of the temp directory as the job is running. If the analysis engines write files to this directory as the job runs, then this function is working.

Testing GetMachineListAvailableForDistribution

This function is used for distributed analysis. The analysis may be distributed across several machines if portions of the analysis are independent. For example, frequency sweeps, parametric analysis and domain decomposition allow different portions of the analysis to be distributed across machines. The analysis in a batch job will be distributed to multiple processors or hosts if the analysis includes a setup that may be distributed (e.g., frequency sweep, parametric analysis) and the **-Distributed** option is included in the desktop command line. The list of machines is displayed in an "info" message near the beginning of the batch log. The list in the info message can be directly compared to the expected list of machines.

To verify that the machine list is constructed correctly for a variety of cases, it may be necessary to test several jobs with different resource requirements and verify that the machine list is correct in each case. For example, one may run batch analyses with the following resource requirements:

- One processor on one host
- Several processors on one host
- One processor on each of several hosts
- Several processors on each of several hosts

Testing LaunchProcess

This function is used to launch analysis engines in the case where the analysis is distributed across multiple hosts. The analysis may be distributed across several machines if portions of the analysis are independent. For example, frequency sweeps, parametric analysis and domain decomposition allow different portions of the analysis to be distributed across machines. The

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

analysis in a batch job will be distributed to multiple processors or hosts if the analysis includes a setup that may be distributed (e.g., frequency sweep, parametric analysis) and the **-Distributed** option is included in the desktop command line. The list of machines is displayed in an "info" message near the beginning of the batch log. The batch log may also contain info messages when portions of the analysis distributed to different machines start or finish. These messages usually include the name of the host when the analysis ran or will run. One can verify that the analysis is actually running on the expected host or hosts using the Linux ps command or the Windows Task Manager.

In general, one analysis engine is started for each occurrence of each host in the list of machines available for distribution. For example, if the list of hosts is "hostA hostA hostA hostB hostB", then a total of 5 engines would be started, three on hostA and two on hostB. In some cases, an additional engine is started to perform the portion of the analysis which is not distributed; if this is the case, the non-distributed engine is idle during the portion of the analysis which is distributed. If this occurs in the case where the list of hosts is "hostA hostA hostA hostB hostB", then a total of 6 engines would be started, but at most 5 engines would be active at any given time. When each analysis engine is running, it may start additional child processes to do a portion of the analysis, but these are not counted as additional analysis engines because the parent of the sub-engine is inactive (waiting for the sub-engine results) when the sub-engine is active.

Testing should be sufficient to demonstrate that the scheduler proxy library can start multiple engine processes on the desktop host, and can also start multiple engine processes on other hosts.

Testing GetUseRsmForEngineLaunch

In most cases, this function will not be implemented or tested. If this function is implemented and returns true, then the Ansys Electromagnetics desktop application will not start the analysis engines using the LaunchProcess function directly. Instead, the Ansys Electromagnetics desktop application will start one AnsoftRSMService process on each host using the LaunchProcess function, and the engine processes will be started by these AnsoftRSMService processes. One may check for these processes using the Linux ps command or the Windows Task Manager. One AnsoftRSMService process should run on each host. These processes will be named ansoftrsmservice.exe or AnsoftRSMService.exe. These processes will be started on each host before any analysis engine is started on the host, and will remain running until the job is complete.

Troubleshooting Custom Scheduler Integration

- None of the Proxy Functions are Called
- Troubleshooting IsProductLaunchedInYourEnvironment Function
- Troubleshooting GetSchedulerDisplayName
- Troubleshooting GetThisJobID

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Troubleshooting GetTempDirectory
- Troubleshooting GetMachineListAvailableForDistribution
- Troubleshooting LaunchProcess
- Troubleshooting GetUseRsmForEngineLaunch

None of the Proxy Functions are Called

There are several problems which could result in none of the proxy functions being called.

The scheduler proxy library must be installed in the schedulers subdirectory of the Ansys Electronics Desktop installation directory.

The scheduler proxy library name must match "*_scheduler.dll" on Windows and "lib*_scheduler.so" on Linux. If the library name does not match this format, then the library will not be loaded. In addition, the function name prefix must be the same as the library name prefix converted to upper case. For example, if the library name prefix is "abc", then the function name prefix is "ABC". In this example, the library name is "abc_scheduler.dll" on Windows, and "libabc_scheduler.so" on Linux. In this example, the full name of the IsProductLaunchedInYourEnvironment function is ABC_IsProductLaunchedInYourEnvironment on Windows and Linux, and it must have extern "C" linkage.

Verify that the compile and link flags follow the guidelines in the section "Build Information", above. Incorrect compile or link flags may prevent the library from being loaded by the Ansys Electromagnetics product.

If there is a problem with calling the IsProductLaunchedInYourEnvironment function, then none of the other functions will be called. The other functions are only called if the IsProductLaunchedInYourEnvironment function is successfully called and returns true.

Troubleshooting IsProductLaunchedInYourEnvironment Function

Verify that the conditions specified in the section "None of the Proxy Functions are Called" are met.

Verify that this function returns true when called in an environment running under the scheduler, and that it returns false when called in an environment not running under the scheduler.

Troubleshooting GetSchedulerDisplayName

Verify that the IsProductLaunchedInYourEnvironment function returns true when running in the scheduler environment.

Verify that the scheduler display name is a valid ASCII string.

Verify that, if argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned. The required buffer length must include space for the string null terminator.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Verify that, if argument buffer is not NULL and the value to which argument length points (the buffer length) is large enough to contain the display name, including the terminal null byte, then the display name is copied to the buffer and true is returned.

Troubleshooting GetThisJobID

Verify that the IsProductLaunchedInYourEnvironment function returns true when running in the scheduler environment.

Verify that the job ID is a valid ASCII string.

Verify that, if argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned. The required buffer length must include space for the string null terminator.

Verify that, if argument buffer is not NULL and the value to which argument length points (the buffer length) is large enough to contain the job ID, including the terminal null byte, then the job ID is copied to the buffer and true is returned.

Troubleshooting GetTempDirectory

Verify that the IsProductLaunchedInYourEnvironment function returns true when running in the scheduler environment.

Verify that the temporary directory name is a valid ASCII string.

Verify that, if argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned. The required buffer length must include space for the string null terminator.

Verify that, if argument buffer is not NULL and the value to which argument length points (the buffer length) is large enough to contain the temporary directory pathname, including the terminal null byte, then the temporary directory pathname is copied to the buffer and true is returned.

Troubleshooting GetMachineListAvailableForDistribution

Verify that the IsProductLaunchedInYourEnvironment function returns true when running in the scheduler environment.

Verify that the list of hosts is a valid ASCII string containing a space separated list of host names. A host name will appear in the list a number of times equal to the number of processors or cores available to the job on that host.

Verify that, if argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned. The required buffer length must include space for the string null terminator.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Verify that, if argument buffer is not NULL and the value to which argument length points (the buffer length) is large enough to contain the list of hosts, including the terminal null byte, then the list of hosts is copied to the buffer and true is returned.

Troubleshooting LaunchProcess

Verify that the IsProductLaunchedInYourEnvironment function returns true when running in the scheduler environment.

The hostName argument is a host name from the list returned by the GetMachineListAvailableForDistribution function. Verify that the LaunchProcess function can accept host names in the format returned by the GetMachineListAvailableForDistribution function.

The exePathName argument is the pathname of the analysis engine executable to be started. This pathname may contain spaces or other characters special to the shell. Ensure that the LaunchProcess function is able to handle such cases.

The arg1 and arg2 arguments may contain newlines, tabs, single quotes, spaces, dollar signs, and other characters which may be special to the shell. Ensure that the LaunchProcess function is able to handle such cases. If needed, the newline characters may be replaced by other whitespace characters. One or both of these arguments could also be an empty string; verify that the empty string is correctly passed to the engine process command line.

If a scheduler command is used to launch the engine process on a remote machine, the engine command line may be processed by the shell twice, once when the scheduler command is processed by the shell, and again when the engine command is processed by the shell. In such cases, the quoting of characters special to the shell will need to be take these two passes through the shell into account. In some implementations, it may be necessary or convenient to use different approaches for launching engine processes on the local machine and on remote machines; if this is done, verify that the approach used to determine whether the hostName argument represents the local machine is correct.

Troubleshooting GetUseRsmForEngineLaunch

In most cases, this function will not be implemented. If it is implemented, then follow the suggestions below.

Verify that the IsProductLaunchedInYourEnvironment function returns true when running in the scheduler environment.

If the RSM should be used for launching engines, verify that this function returns true. Otherwise, verify that this function returns false.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Using an IronPython Program for Integration with a Scheduler

This section describes how to create an IronPython program for integration with a scheduler. Each such program is used for a single specific scheduler environment. If the program is installed with a valid name and in the correct location, then it will automatically be loaded and used by Ansys EM tools.

Installation Details

The IronPython program must be installed in the schedulers subdirectory of the Ansys EM installation directory. For example, if the installation directory is "C:\Program Files\ANSYS Inc\v251\AnsysEM", then the IronPython program must be installed in directory C:\Program Files\ANSYS Inc\v251\AnsysEM\schedulers".

The program file extension must be ".py". Select the program name so that it does not conflict with other IronPython programs in the same directory. If the Operating System or file system treat file names in a case sensitive manner, the file extension ".py" must be lower case.

Python Programming Notes

The scheduler program will be run in the IronPython environment both on Microsoft Windows and on Linux. There are some differences between IronPython and CPython. The version of IronPython in use is 2.7.0.40

Implementation Details

The program must contain the following:

Import the ISchedulerPluginExtension interface as follows:

```
from Ansys.Ansoft.SchedulerPluginDotNet import
ISchedulerPluginExtension
```

Define a class which implements the ISchedulerPluginExtension interface. In this document, this class is named SamplePluginExtension, but any class name may be used. The class member functions are described in the next section. The class definition will look similar to the following:

```
class SamplePluginExtension(ISchedulerPluginExtension):

def GetName(self):
return "SamplePluginExtension"

def GetDescription(self):
return "Example python script plugin extension"
. . .
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Include the following line in the program so that the class that you have defined, SamplePluginExtension, is loaded by the infrastructure:

```
ExtensionRegistrar.RegisterPluginExtension(SamplePluginExtension())
```

The infrastructure will make the EntensionRegistrar object available in the environment where the program is loaded.

Each of the functions to be implemented in the SamplePluginExtension class is described below.

- GetName
- GetDescription
- IsProductLaunchedInYourEnvironment
- GetSchedulerDisplayName
- GetThisJobID
- GetUseRsmForEngineLaunch
- GetTempDirectory
- GetMessageStringToRegisterForSigTerm
- GetMachineListAvailableForDistribution
- LaunchProcess

GetName [IronPython]

Purpose

Return a short string containing the name of the plugin extension. This string is used to identify the scheduler plugin extension in logs or program output.

Signature

```
GetName(self)
```

Arguments (excluding self)

None.

Return Value

Returns a string containing the name of the plugin extension.

> **Note:**
>
> The plugin extension name is generally a fixed string.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

GetDescription [IronPython]

Purpose

Return a string containing the description of the plugin extension. This string is used to identify the scheduler plugin extension in logs or program output.

Signature

```
GetDescription(self)
```

Arguments (excluding self)

None.

Return Value

Returns a string containing the description of the plugin extension.

> **Note:**
>
> The plugin extension description is generally a fixed string.

IsProductLaunchedInYourEnvironment [IronPython]

Purpose

Determine if the program is running in the context of the scheduler for which this program was written.

Signature

```
IsProductLaunchedInYourEnvironment(self)
```

Arguments (excluding self)

None.

Return Value

Returns True if the current process is running as a job of the scheduler. Otherwise, False is returned.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> For many schedulers, the presence of certain environment variables or their values may be checked to determine if the current process is running as a job of the scheduler.

GetSchedulerDisplayName [IronPython]

Purpose

Get a string identifying the scheduler associated with the current plugin extension. This string is used to identify the scheduler.

Signature

```
GetSchedulerDisplayName(self)
```

Arguments (excluding self)

None.

Return Value

Returns a string containing the description of the scheduler for which this plugin extension was written.

> **Note:**
>
> The scheduler display name is generally a fixed string.

GetThisJobID [IronPython]

Purpose

Get a string identifying the job currently running in the scheduler environment. This string is displayed to the end user to identify the job.

Signature

```
GetThisJobID(self)
```

Arguments (excluding self)

None.

Return Value

Returns a string containing the Job ID for the current job.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> For many schedulers, the job ID may be obtained from the value of an environment variable.

GetUseRsmForEngineLaunch [IronPython]

Purpose

For some schedulers, it may be desirable for the AnsoftRSM program to launch the engine processes instead of using the scheduler plugin extension directly. For example, if the plugin extension is limited to launching one process per host, then the plugin extension may be used to launch one AnsoftRSM executable per host, and the AnsoftRSM executable will launch all of the engine processes.

If AnsoftRSM should be used to launch engine processes for this scheduler, then this function shall return True.

If AnsoftRSM should not be used to launch engine processes for this scheduler, then this function shall return False.

Signature

```
GetUseRsmForEngineLaunch(self)
```

Arguments (excluding self)

None.

Return Value

Returns True if AnsoftRSM should be used to launch engine processes for this scheduler. Returns False if the plugin extension should be used to directly launch engine processes for this scheduler.

> **Note:**
>
> If this function returns True, then the plugin extension will directly launch only one process on each host.

GetTempDirectory [IronPython]

Purpose

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Get the pathname of the temporary directory provided by the scheduler for the current job. The pathname is an empty string if the scheduler does not provide a temporary directory for the current job.

Signature

```
GetTempDirectory(self)
```

Arguments (excluding self)

None.

Return Value

Returns a string containing the pathname of the temporary directory provided by the scheduler for the current job. Returns an empty string if no temporary directory is provided by the scheduler for the current job.

> **Note:**
>
> If the return value is an empty string, then the temporary directory specified on the command line or in the registry will be used.

GetMessageStringToRegisterForSigTerm [IronPython]

Purpose

Obsolete. This function should return an empty string.

Signature

```
GetMessageStringToRegisterForSigTerm(self)
```

Arguments (excluding self)

None.

Return Value

Returns an empty string.

> **Note:**
>
> This function should always return an empty string.

GetMachineListAvailableForDistribution [IronPython]

Purpose

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Get the names of the hosts allocated to the current job. A host name will appear in the output string multiple times if the scheduler has allocated multiple processors or cores on the host to the job. The number of times the host name appears in the string is equal to the number of processors or cores of the host that are allocated to the current job. The output is a text string containing the host names separated by space characters.

Signature

```
GetMachineListAvailableForDistribution(self)
```

Arguments (excluding self)

None.

Return Value

A string containing the names of the hosts allocated to the job, separated by space characterss. The number of times the host appears in the string is equal to the number of processors or cores of the host that are allocated to the current job.

> **Note:**
>
> The hostnames in the string provided by this function shall be used in calls to LaunchProcess(). The host names must be in a format that is accepted by that function. See the section below on LaunchProcess.

LaunchProcess [IronPython]

Purpose

Launch a local or remote process to run an analysis engine. This function is called by the Ansys Electromagnetics desktop application to launch an engine process on a specified host. The hostname is one of the names provided by the GetMachineListAvailableForDistribution function. See the GetMachineListAvailableForDistribution section above. If the hostname does not refer to the local host, then this function shall use the scheduler to launch the engine on the specified host. If the hostname refers to the local host, then the engine may be started as a child process, or it may be started using the scheduler.

Signature

```
LaunchProcess(self, hostName, exePathName, arg1, arg2)
```

Arguments (excluding self)

hostName: The name of the host where the process is to be launched.

exePathName: The pathname of the analysis engine executable to be started.

arg1: The first argument of the analysis engine command line.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

arg2: The second argument of the analysis engine command line.

Return Value

Returns 0 on success. Returns a non-zero value if an error occurs.

Note:

- The hostName argument will be one of the hostnames provided by the function GetMachineListAvailableForDistribution().
- If the hostName argument is the same as the current host, then the analysis engine process may be started as a child process. If the hostName argument is not the same as the current host, then the analysis engine process will be started on the remote host using the facilities available in the scheduler environment. The command line of the analysis engine process is exePathName arg1 arg2. The command line arguments arg1 and arg2 may contain spaces or other characters that are interpreted by the command processor, such as backslash (\), single quote (') or double quote (") characters, or dollar signs ($). If the analysis engine command is processed by a shell, then it may be necessary to quote any special characters in the exePathName or in the arguments so that the special meaning is removed. If a scheduler command is used to request the scheduler to launch the command to start the engine process, and that command is processed by a command shell, then the analysis engine command may be processed by the shell twice: once when the scheduler command is processed, and a second time when the analysis engine process is started. If this is the case, then the quoting of special characters needs to account for two passes through the command processor.
- The command line arguments arg1 and arg2 may be empty strings. These arguments must be preserved, even if they are empty strings. In some versions of the IronPython subprocess module, empty argument strings are discarded, resulting in an incorrect number of command line arguments. A workaround for this issue is to replace an empty string argument by a string consisting of a single space character.

Ansys Cloud Direct Support for HPC Job Management

Ansys Electromagnetics Desktop supports the Ansys Cloud Direct service that allows quick and easy access to cloud-based HPC resources. The service is accessible through both the Simulation Ribbon and **Tools** > **Job Management**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Important:**
>
> For this release, you can submit HFSS, HFSS 3D Layout, Icepak, Maxwell 3D, Maxwell 2D, Mechanical, Q3D Extractor, and 2D Extractor jobs, monitor their progress, and download and post process the results. Other solvers are either in Beta or are not yet supported for Ansys Cloud Direct.

Uploads to and downloads from Ansys Cloud Direct use archives to improve speed. The Project browser shows both .aedt and .aedtz (archive) files. If you submit an unarchived project, an archive will be automatically created for upload. When the job completes, the results are packaged into an archive. When the download is initiated, the repackaged archive file is transferred to the download folder along with the other job-related files, such as the log.

For single setups, you can use multi-step submission. This separates the resource specification and reporting as appropriate for each stage of the solve.

Prerequisites for Using Ansys Cloud Direct with Ansys Electronics Desktop

- You will need an "Ansys Cloud Compute Essentials" subscription associated with your Ansys Account. The Ansys Account is an extension of the Ansys Discovery account that includes those products and services that require sign-in, such as the AppStore, Cloud Compute and others. Contact your account manager or service representative to obtain a subscription invitation.
- You must select Ansys Cloud as your Job Management Scheduler, and, if necessary, log in to the Ansys Cloud Service using the Ansys Discovery Account and associated password.

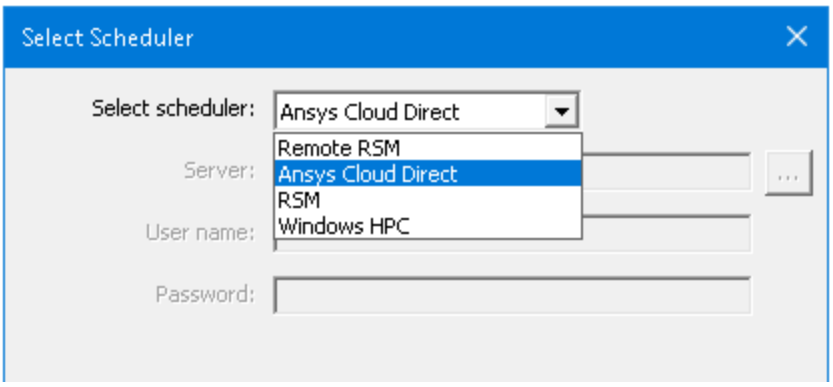
Job Management UI for Ansys Cloud Direct

You can use Ansys Electronics Desktop to submit batch jobs to Ansys Cloud Direct and monitor those jobs.

This involves the following steps:

1. Use **Tools** > **Job Management** > **Select Scheduler** to select Ansys Cloud Direct as the scheduler.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Click **Log in** to launch a login window for Ansys Cloud Direct.

   After a successful login, you may not need to log in again for several days if you do not log out.

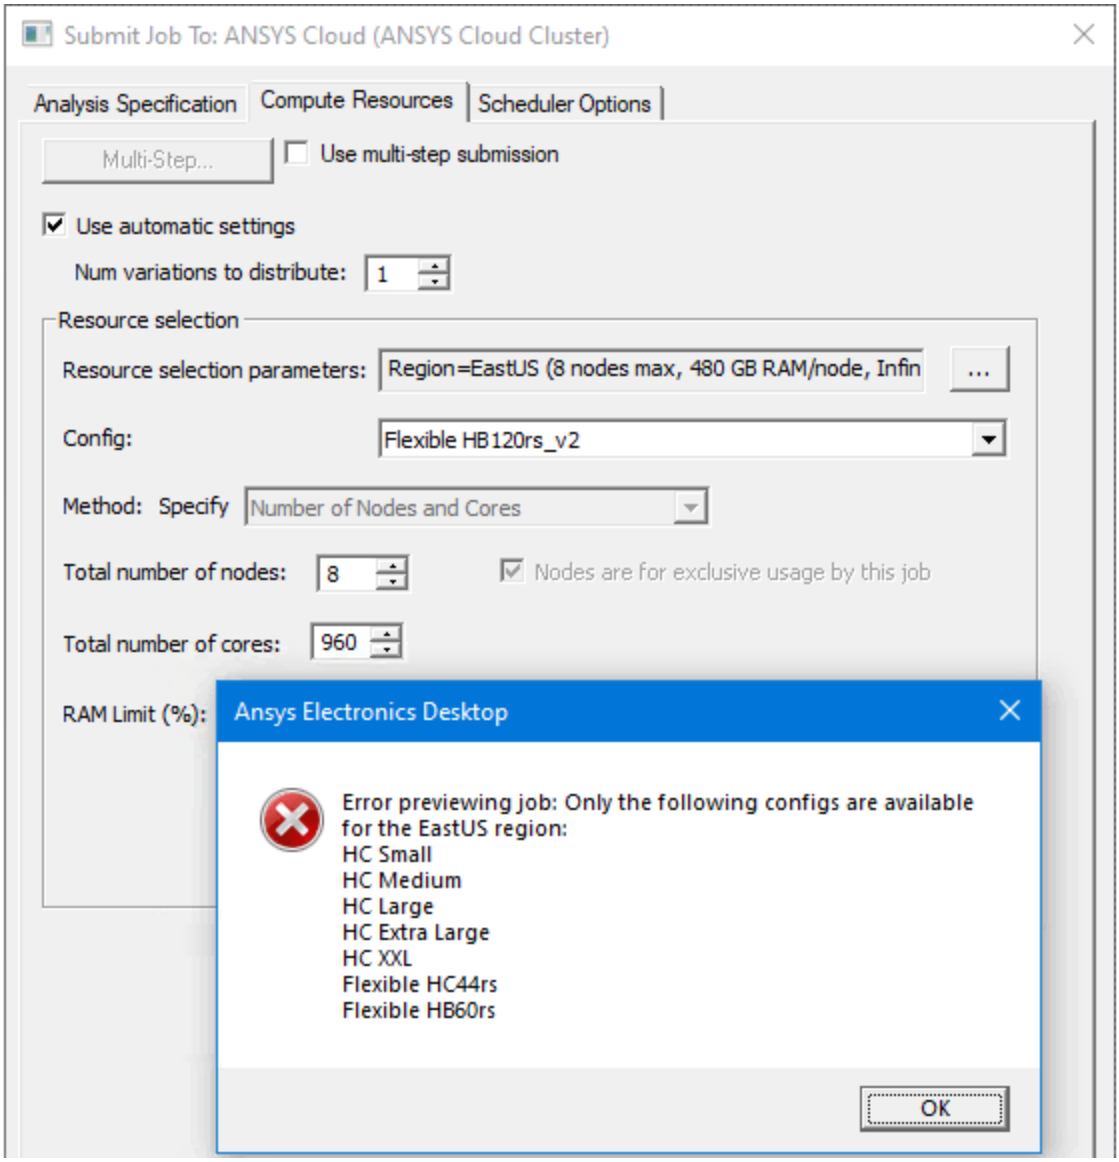
   If you wish to log out, click **Log out** from the **Select Scheduler** window.

3. Use **Tools** > **Job Management** > **Submit Job** to submit a batch job to Ansys Cloud Direct.

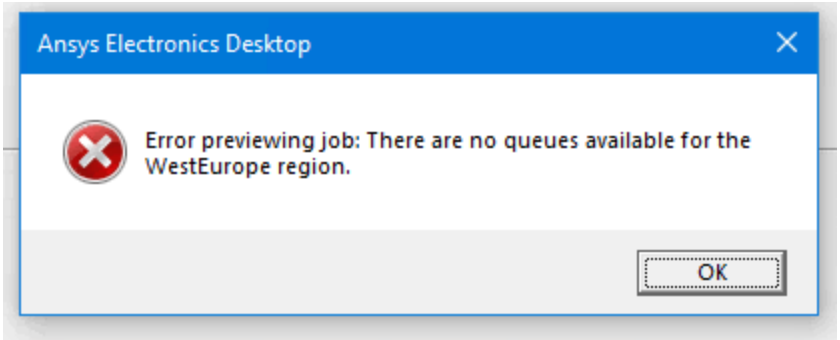
   Ansys Cloud Direct-specific Settings:

   - On the **Compute Resources** tab, **Resource Selection Parameters** will allow you to select a **Region** (for example, EastUS, JapanEast, WestEurope). The **Config** drop-down menu does not display configurations that are not available in any of the selectable regions. That is, if the regions are EastUS, WestEurope, and SouthwestUS, and none of these regions have the smallhc-based queues, then the "HC Small" configuration does not appear. If you select a resource that is not available in the specific region you select, an error messages shows the available choices for that region.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

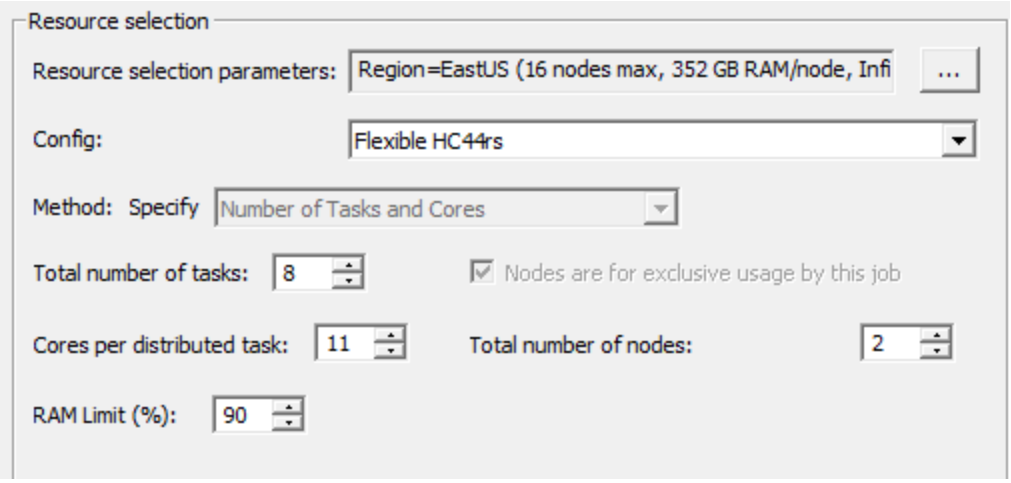


If no queues are available, an error message provides that message:



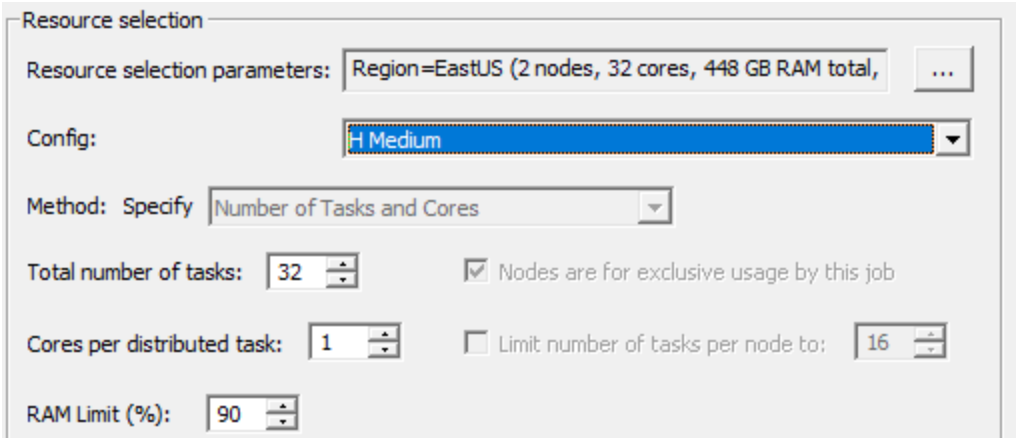
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- On the **Compute Resources** tab, select a **Config** size and style (Flexible or fixed) based on the following:
  - **Small:** 16 cores, 1 node, 224 GB RAM total
  - **Medium:** 32 cores, 2 nodes, 448 GB RAM total, Infiniband
  - **Large:** 128 cores, 8 nodes, 1792 GB RAM total, Infiniband
  - **Extra Large:** 256 cores, 16 nodes, 3584 GB RAM total, Infiniband
  - **XXL:** Even larger.
  - **Flexible**: Flexible queues permit the following resource selection methods: Automatic Number of Nodes and Cores, Manual Number of Tasks and Cores. If you select a Flexible queue for manual Number of Tasks and Cores, you will see a new item in **Resource Selection** for "Total number of nodes" replacing the "Limit number of tasks per node to" option that appears for fixed queues.



In comparison, if you selected a fixed configuration, the **Resource selection** panel appears like this:

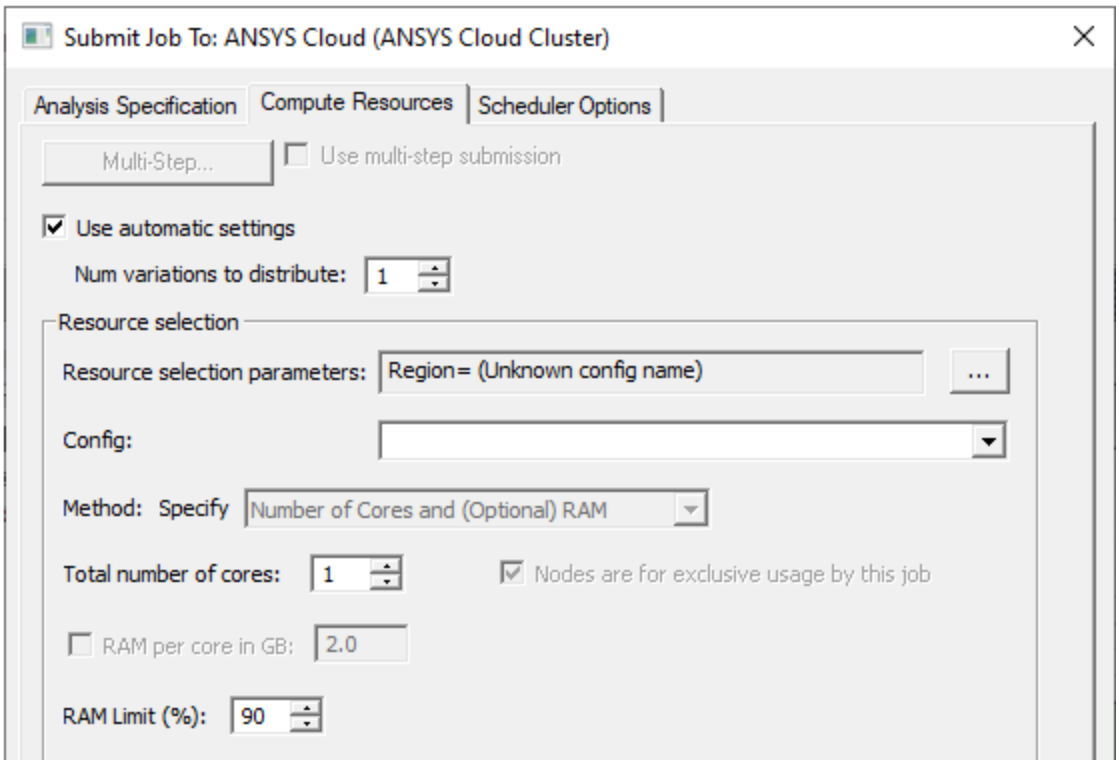
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



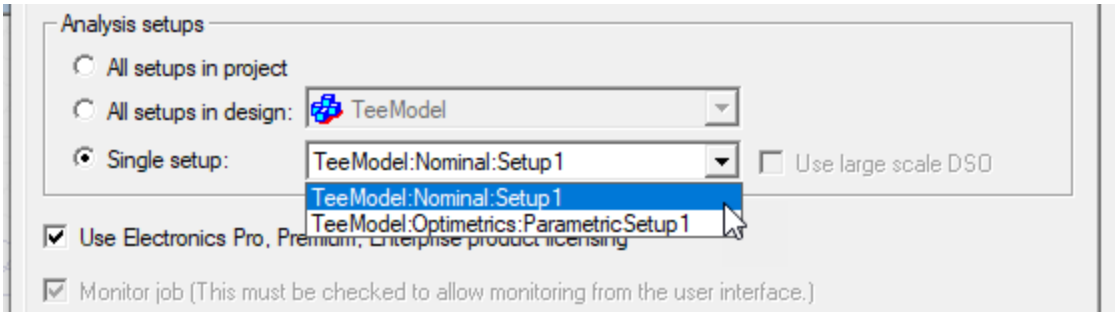
> **Important:**
>
> Attempts to use more for submission will result in error messages.

- On the **Compute Resources** tab, if you select **Use automatic settings** with **Num variations to distribute** set to 1, Optimetrics variations will be solved sequentially. Other distribution types will be distributed automatically. If you set **Num variations to distribute** to 2 or more, Optimetrics variations will be solved in parallel. Other distribution types will be distributed automatically.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

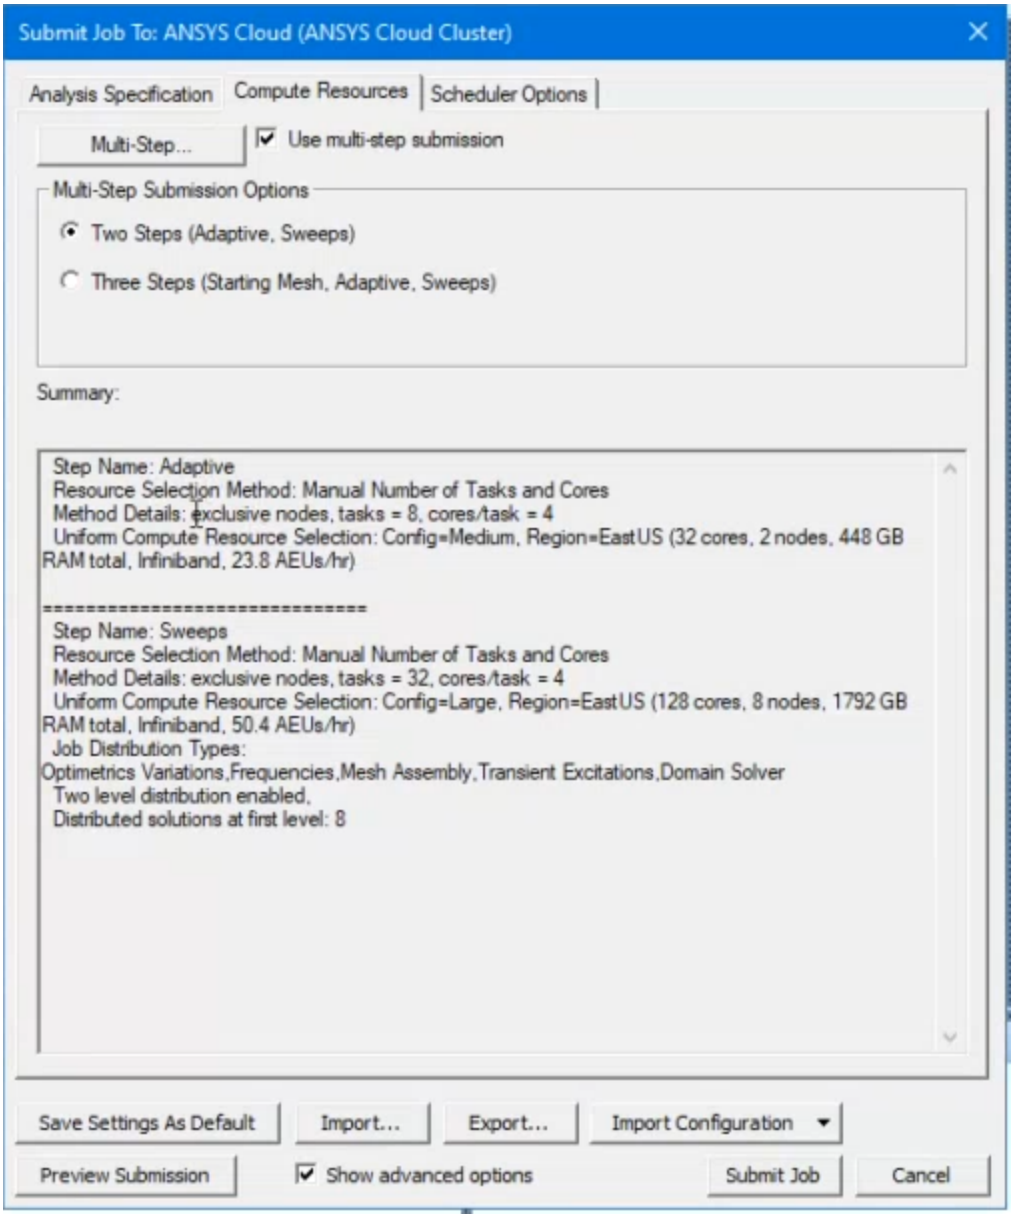


- In response to a set of minimal constraints, Ansys Cloud Direct scheduler may increase the resources assigned beyond the minimal values in order to meet the full set of requirements. For example, if you specify 7 distributed engines with two processors per engine and also limit the number of engines per node to 4, the scheduler may increase the number of cores used in order to meet the limit specified for engines per node. Click **Preview Submission** to see the number of resources assigned, and that the scheduler-generated code includes an MPI specification.
- To use **Multi-Step Submission** on Ansys Cloud Direct, you must specify a single setup on the **Analysis Specification** tab.



This enables **Multi-Step** options on the **Compute Resources** tab.

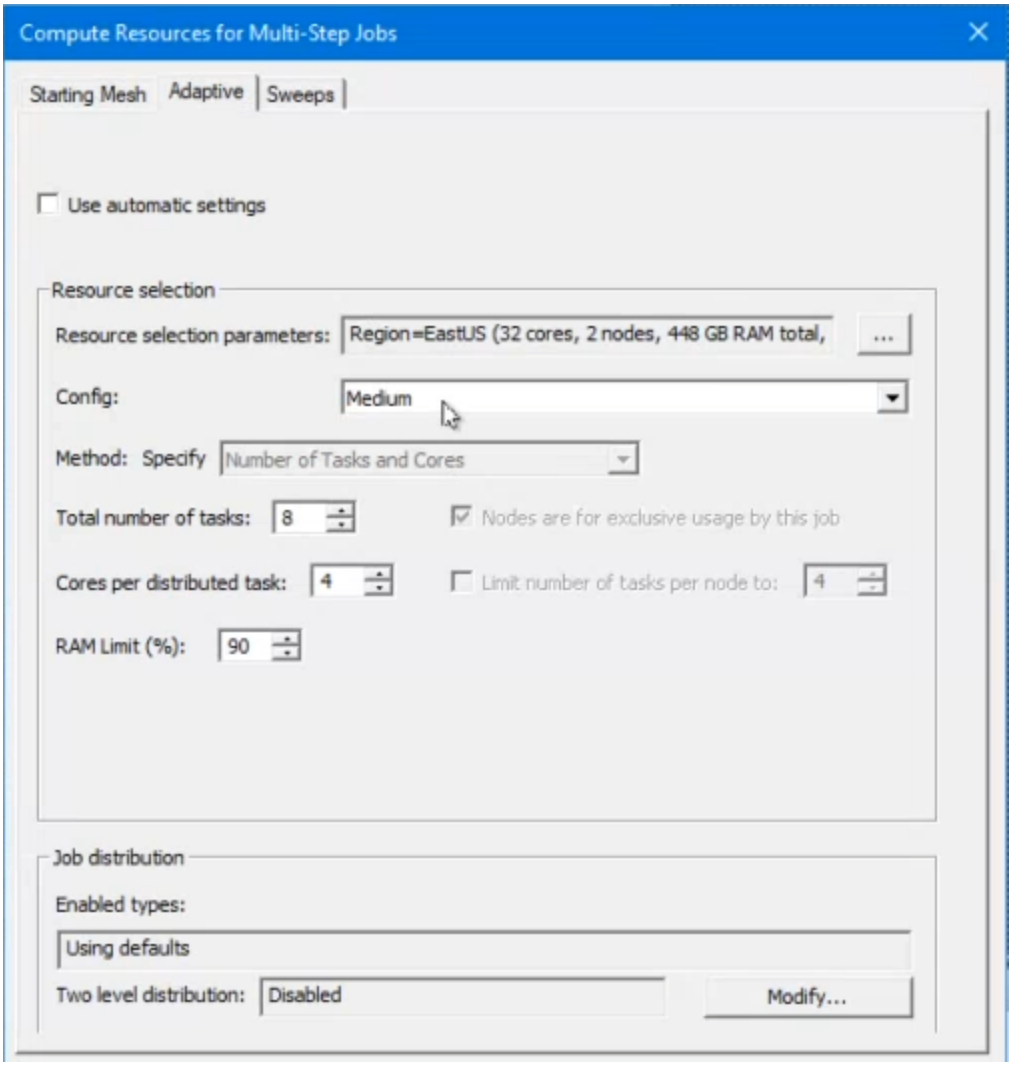
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Click the **Multi-Step** button to open the **Compute Resources for Multi-Step Jobs** dialog box. It has tabs for **Starting Mesh**, **Adaptive**, and **Sweeps**.

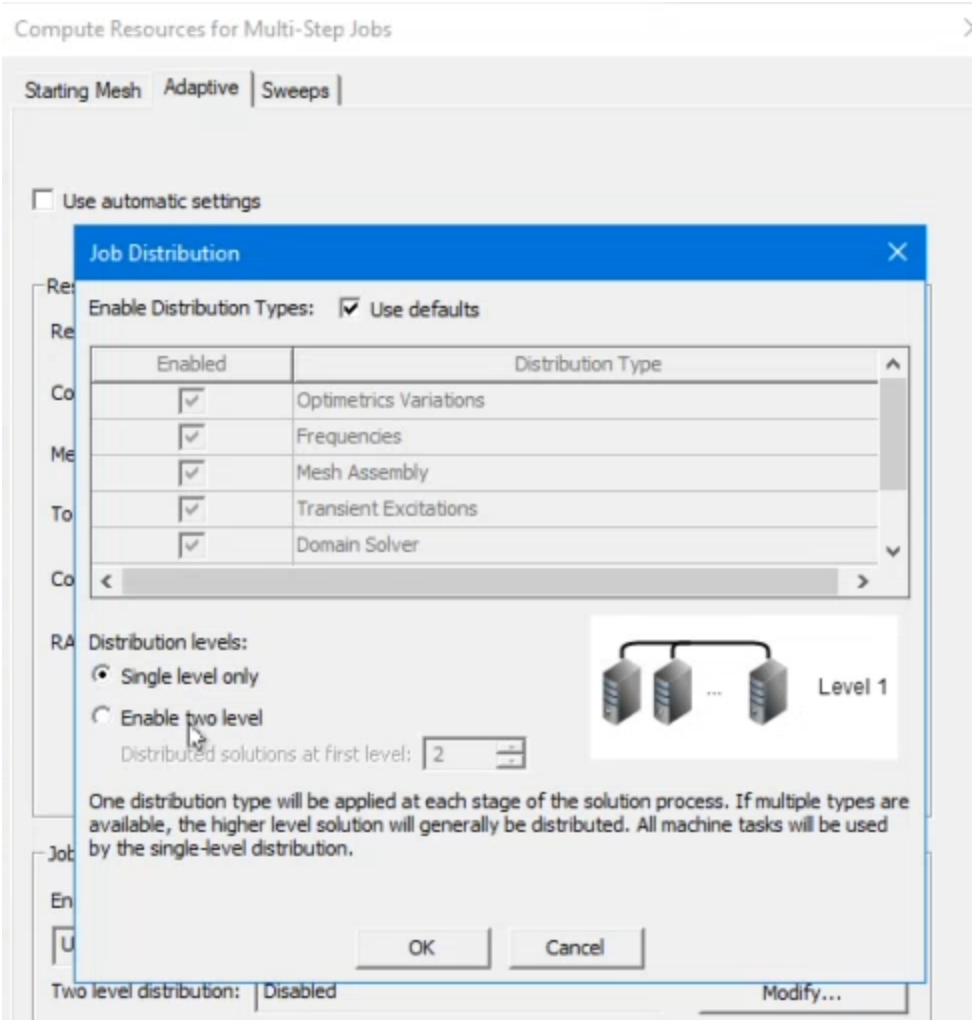
On the **Adaptive** tab, you can **Use automatic settings**, or specify **Resource Selection**

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



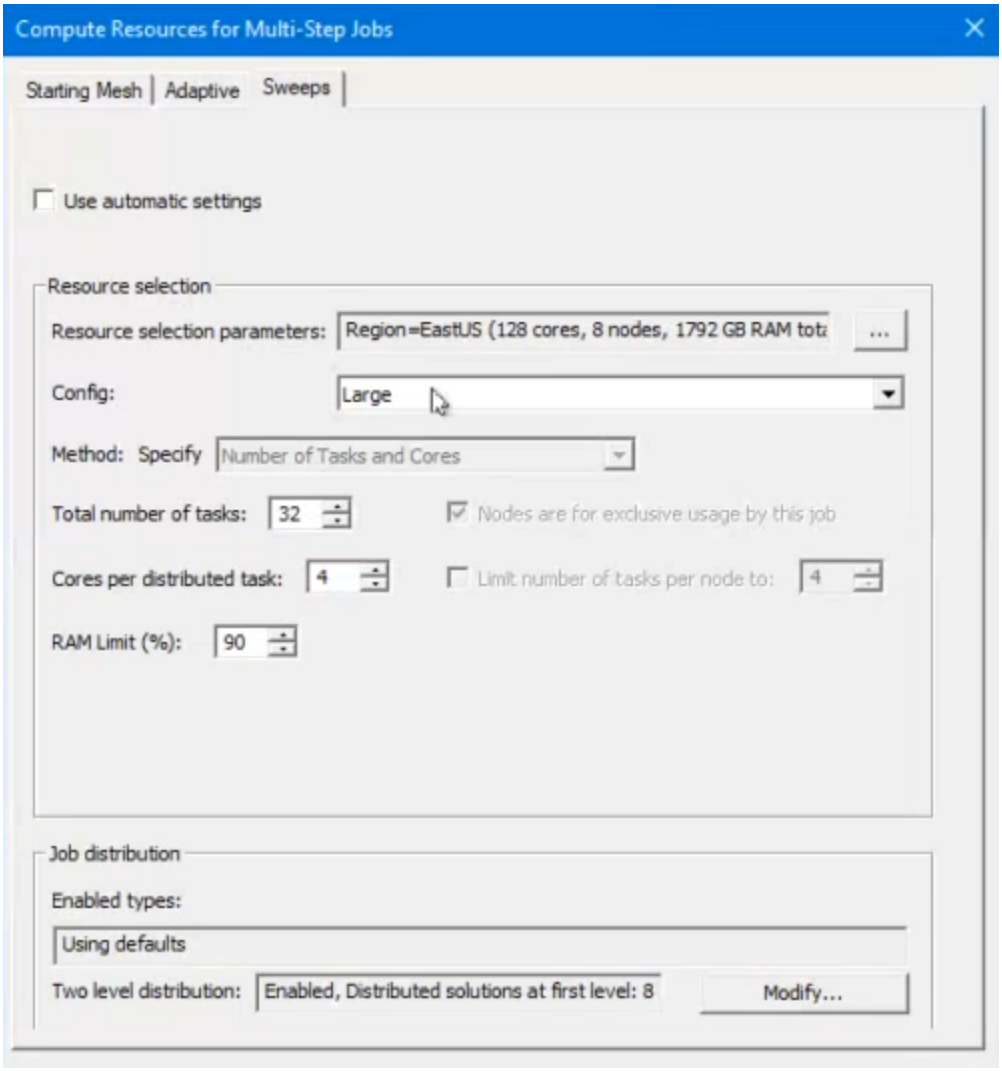
Click the **Modify...** button on the **Adaptive** tab to open the **Job Distribution** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Sweeps** tab lets you specify resources or **Use automatic settings**.

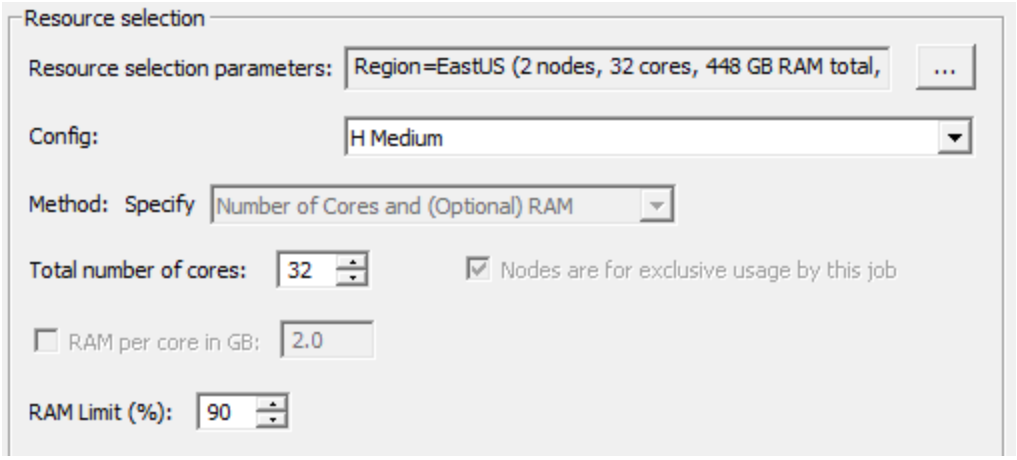
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



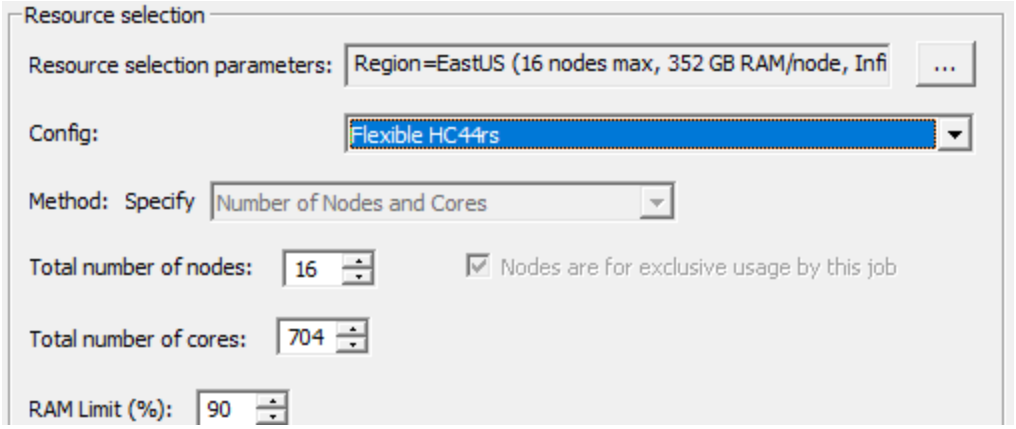
The **Sweeps** tab includes an independent **Modify...** button to specify **Job Distribution**.

Select automatic settings, or specify different resources for each step. When a job is finished, that is, on the last step, reports update and traces are extracted into CSV files. If select fixed queue for automatic sections, the **Resource selection** panel only allows cores and has RAM with RAM disabled:

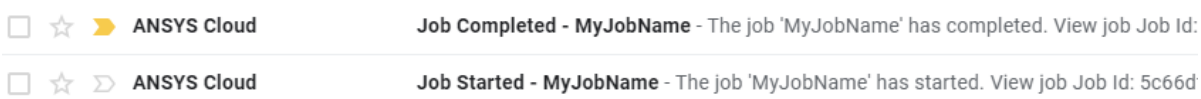
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If you select flexible queue for automatic settings, The **Resource selection** panel only allows nodes and cores for a flexible queue:

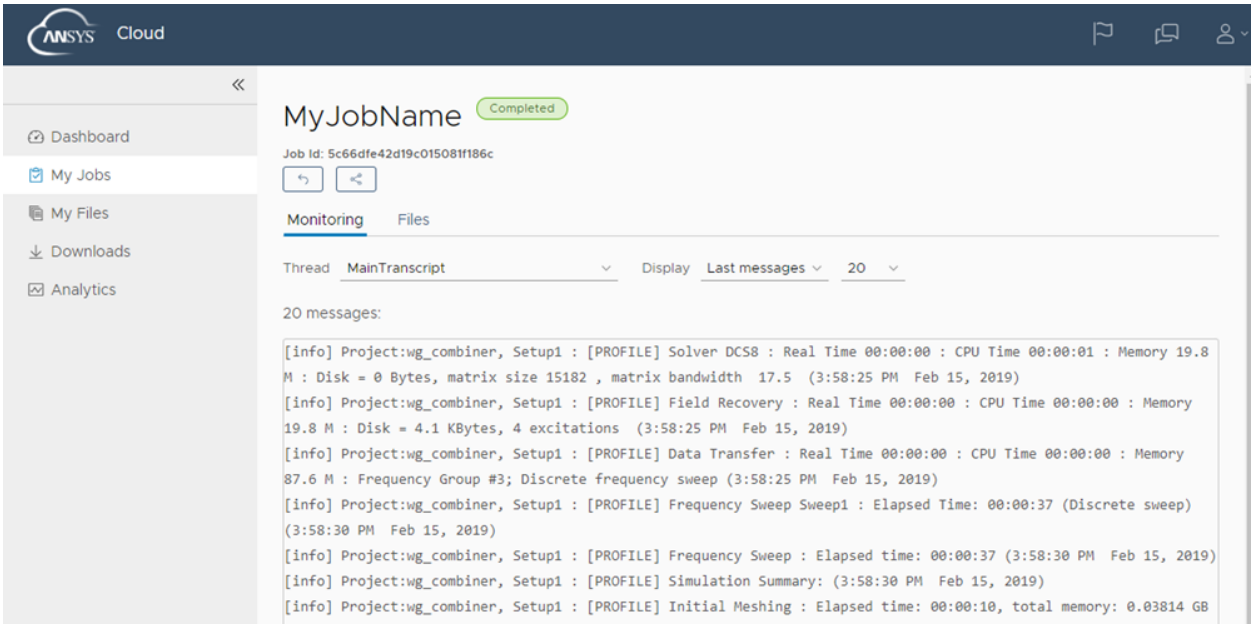


4. Use **Tools** > **Job Management** > **Monitor Job** to monitor the job's progress.
5. You will receive an email when the job has started, and another when it has finished.



6. Use the link in the email (or the **Portal** button on the job monitoring window) to launch the Ansys Cloud Portal and view detailed results:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Environment Variable Settings for Ansys Cloud Direct

When submitting jobs to Ansys Cloud Direct from Electronics Desktop, certain environment variables and batchoption settings must be made to ensure proper operation on the cloud. These settings are done automatically through the job submission window.

These environment variable settings will override any attempts from the user to set the same environment variables:

- ANS_NODEPCHECK=1
- ANSYSEM_FIX_REVERSE_LOOKUP=1
- ANSYSEM_DESKTOP_SUBNET_FROM_COMENGINE_ADDR=1

The environment variable ANSYSEM_ENV_VARS_TO_PASS contains a semicolon-separated list of filters for environment variables to be passed from ansysedt.exe to COM engines. You are allowed to set this environment variable. After being prepared for the job it will have the following filters set at minimum (with the user-requested filters following these):

```
ANSOFT_*;ANS_*;ANSYSEM_*;ANSYSLMD_LICENSE_*;I_MPI*
```

Troubleshooting and Debugging Environment Variables

To keep downloaded files that help with troubleshooting, enable the environment variable ANSYS_EM_PRESERVE_DOWNLOAD_FILES.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Debug logs (and other files generated in the working directory) from remote nodes are automatically collected.

Option Settings for Ansys Cloud Direct

The following option is automatically added for Ansys Cloud Direct jobs:

- -autoextract
- For single step jobs it will include "-autoextract reports".
- For multi-step jobs, the last step will include "-autoextract reports" but the first steps will only include "-autoextract" (no reports). Reports are only extracted on the last step.

See: Running Electronics Desktop from a Command Line.

Automatic Batchoption Settings

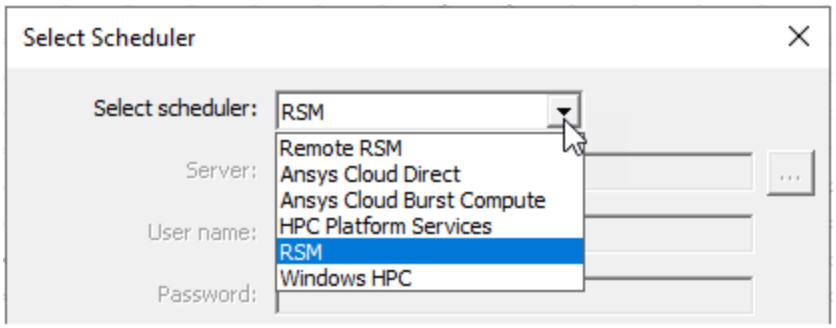
The license type batch option ("HPCLicenseType") is forced to be "Pack" because Cloud is configured to only work with pack licensing. The following MPI batchoptions are automatically set as "Intel" because Ansys Cloud Direct is configured to only work with Intel MPI.

- HFSS 3D Layout Design/MPIVendor
- HFSS/MPIVendor
- Icepak/MPIVendor
- Maxwell 2D/MPIVendor
- Maxwell 3D/MPIVendor
- Q3D Extractor/MPIVendor

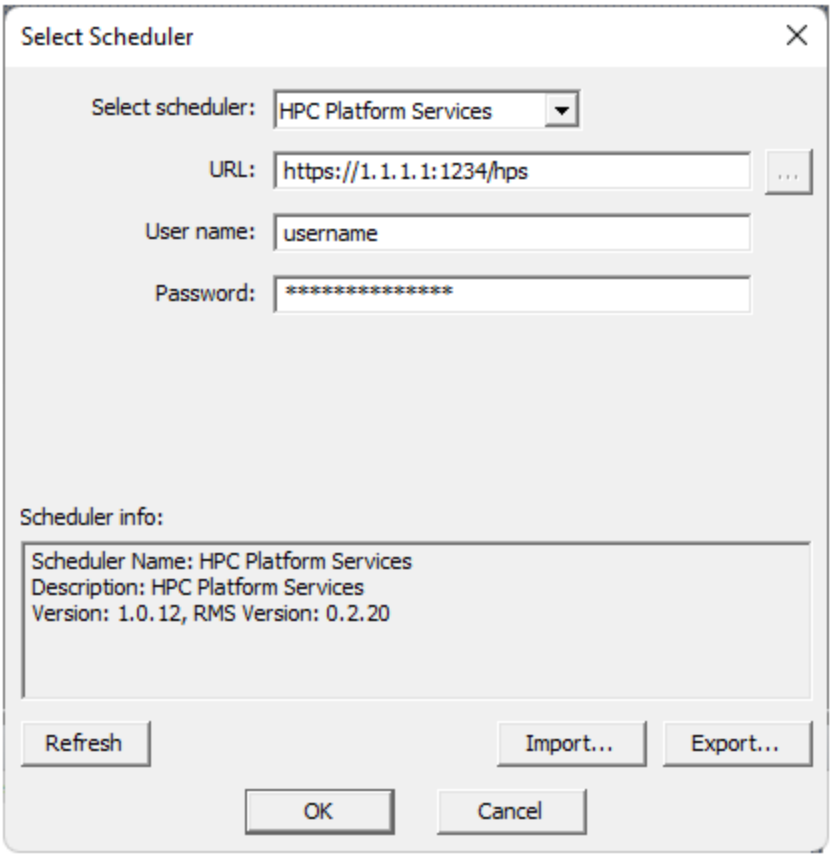
Ansys HPC Platform Services Support for HPC Job Management

Ansys Electromagnetics Desktop supports the Ansys HPC Platform Services mechanism that allows quick and easy access to HPC resources, to include Ansys Cloud Direct Gateway. HPC Platform Services can be selected through both the **Simulation Ribbon (Scheduler** button) and **Tools > Job Management > Select Scheduler**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This opens the **Select Scheduler** window.



You must supply the URL for the HPC Platform Services. You must also enter the username and password for the HPC Platform Services account to be used for job submission. If you press the **Refresh** button, the versions of the HPC Platform Services server and the JMS (Job Management Service) are reported in this dialog.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Uploads to and downloads from Ansys HPC Platform Services use archives to improve speed. The Project browser shows both .aedt and .aedtz (archive) files. If you submit an unarchived project, an archive will be automatically created for upload. When the job completes, the results are packaged into an archive. When the download is initiated, the repackaged archive file is transferred to the download folder along with the other job-related files, such as the batch log.

Prerequisites for Using Ansys HPC Platform Services with Ansys Electronics Desktop

You must select HPC Platform Services as your Job Management Scheduler, including an endpoint URL, username, and associated password.

Job Management UI for Ansys HPC Platform Services

You can use Ansys Electronics Desktop to submit batch jobs to Ansys HPC Platform Services and monitor those jobs.

- To select HPC Platform Services as the scheduler, use **Tools** > **Job Management** > **Select Scheduler**.
- To submit a batch job to Ansys HPC Platform Services, use **Tools** > **Job Management** > **Submit Job**.

Ansys HPC Platform Services-Specific Settings:

The main use case for Ansys HPC Platform Services is where a SLURM cluster is used for computing at the endpoint.

Other schedulers could potentially be used in a compute cluster for Ansys HPC Platform Services.

When a job is submitted from AEDT, HPC Platform Services in turn submits a job to the compute cluster using the scheduler running on that cluster.

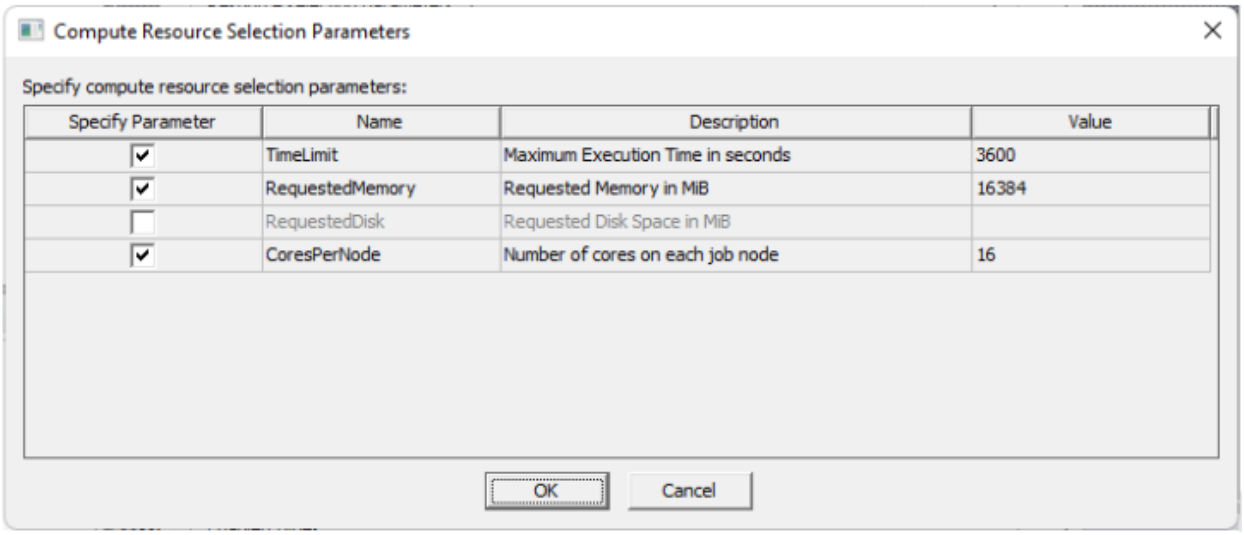
In case there are multiple queues (SLURM partitions) set up in the cluster, the **Compute Resources** tab has a drop-down list box for selecting the queue.

See your cluster administrator for the correct queue/partition name.

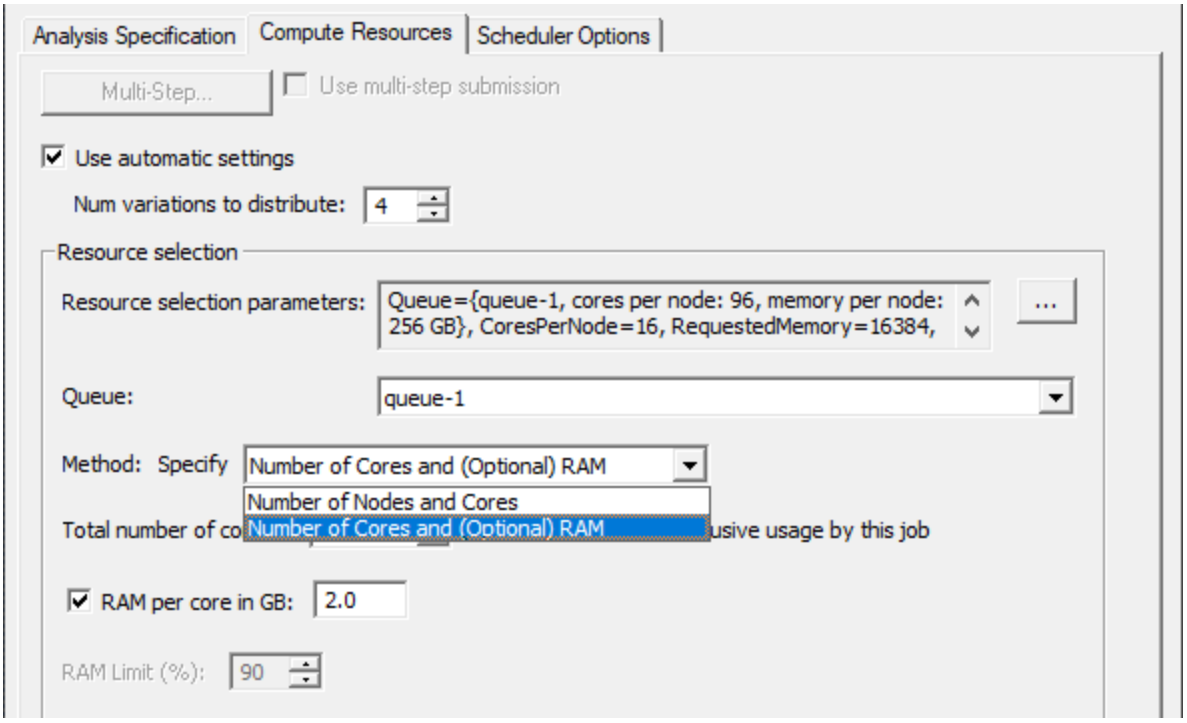
On the **Compute Resources** tab, **Resource Selection Parameters** allows you to select the following:

- **TimeLimit**: Maximum execution time for the job in seconds
- **RequestedMemory**: Requested memory for the job (all nodes combined) in megabytes
- **RequestedDisk**: Requested disk space for the job (all nodes combined) in megabytes
- **CoresPerNode**: The number of cores allocated to the job on each node

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



On the **Compute Resources** tab, if you select **Use automatic settings** with **Num variations to distribute** set to 1, Optimetrics variations will be solved sequentially. Other distribution types will be distributed automatically.



If you check the **Use automatic settings** checkbox, then you may select one of the following methods for specifying job resources:

Specify Number of Cores and (Optional) RAM

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

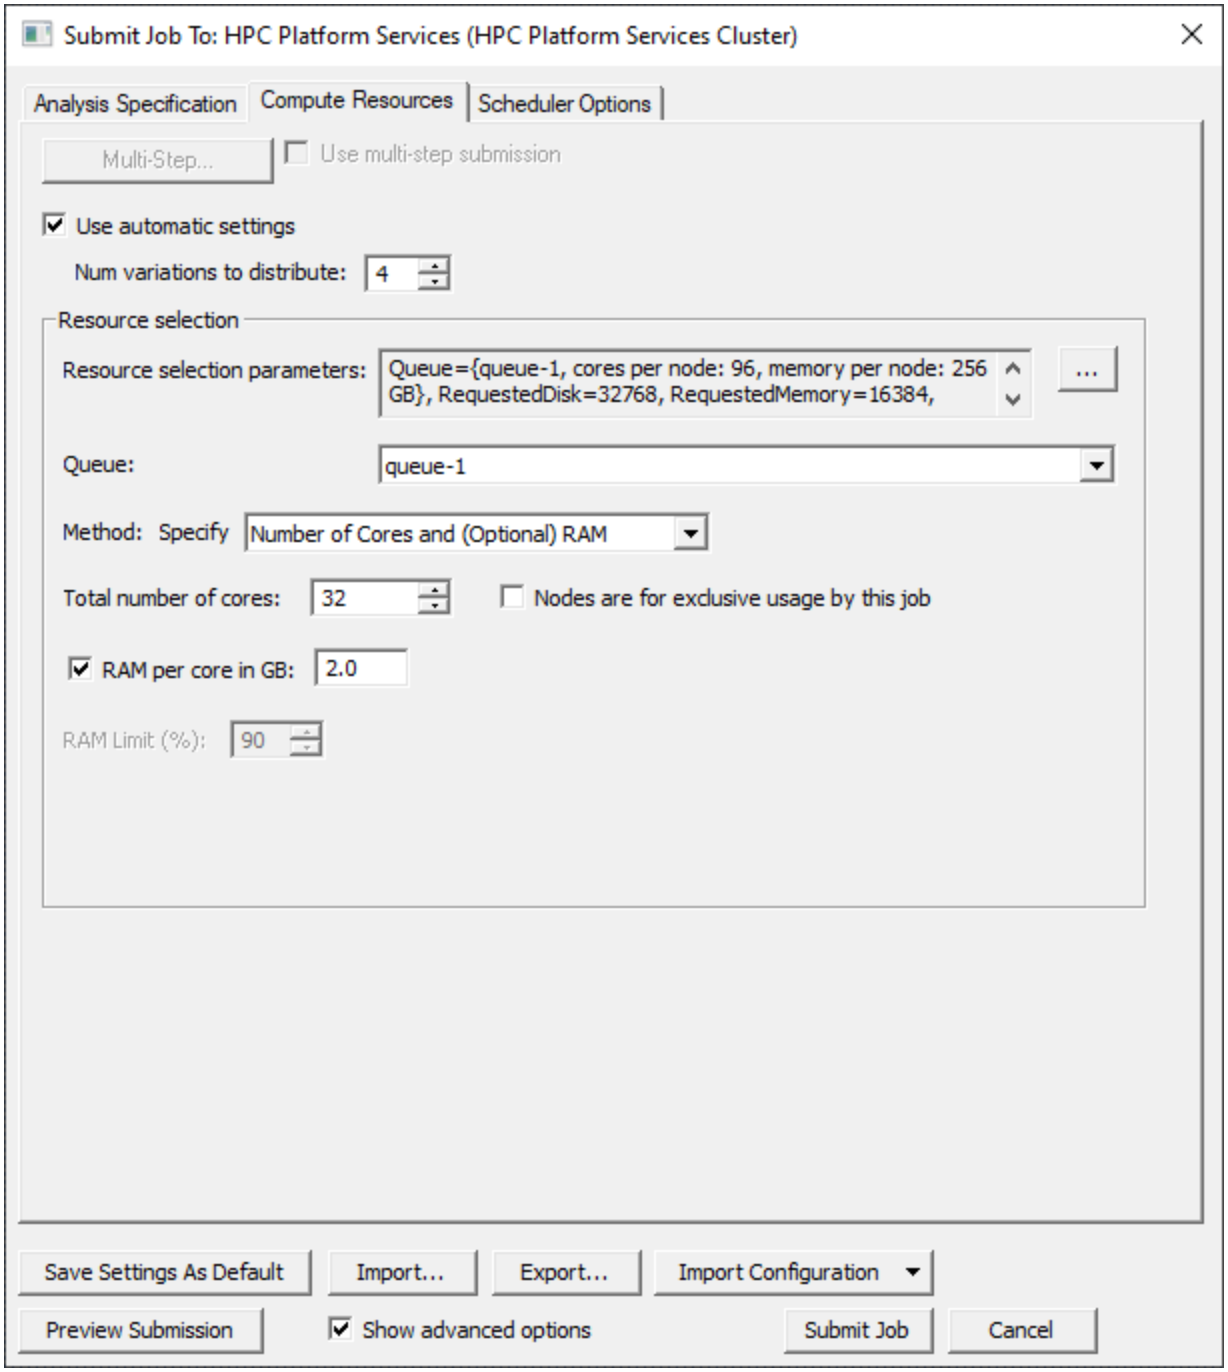
You must select the total number of cores for the job. If you check the associated checkbox is checked, you may also specify the RAM per core for the job. The total RAM requested will be the product of the RAM per core and the number of cores for the job.

Specify Number of Nodes and Cores

The job will request all cores on the specified number of nodes. The analysis will be limited to the specified number of cores; this may be useful to limit the licenses used by the job. This method may only be used if a queue is specified and if all queue execution nodes have the same number of cores. The number of cores specified must be less than or equal to the number of cores available on the specified number of nodes. If these requirements are not met, then the job will not be submitted, and an error message will be displayed.

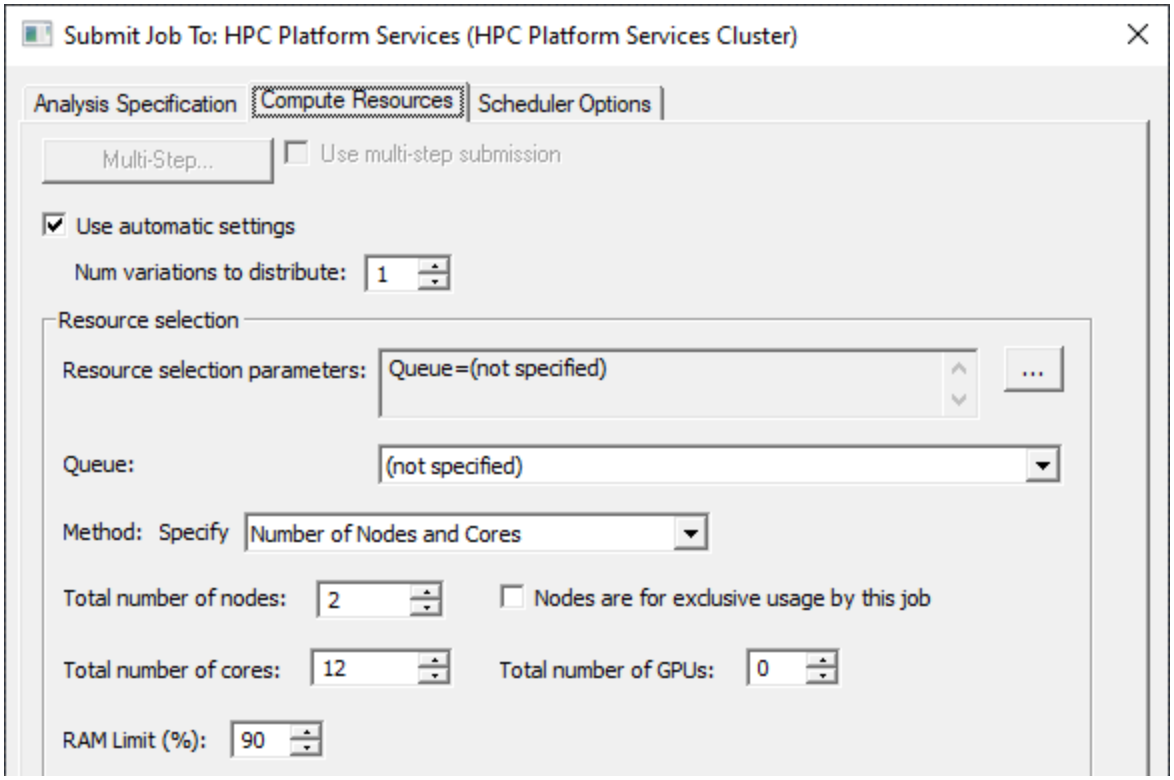
If you set **Num variations to distribute** to 2 or more, Optimetrics variations will be solved in parallel. Other distribution types will be distributed automatically.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If you set **Num variations to distribute** to 1, Optimetrics variations will be solved in sequentially. Other distribution types will be distributed automatically.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

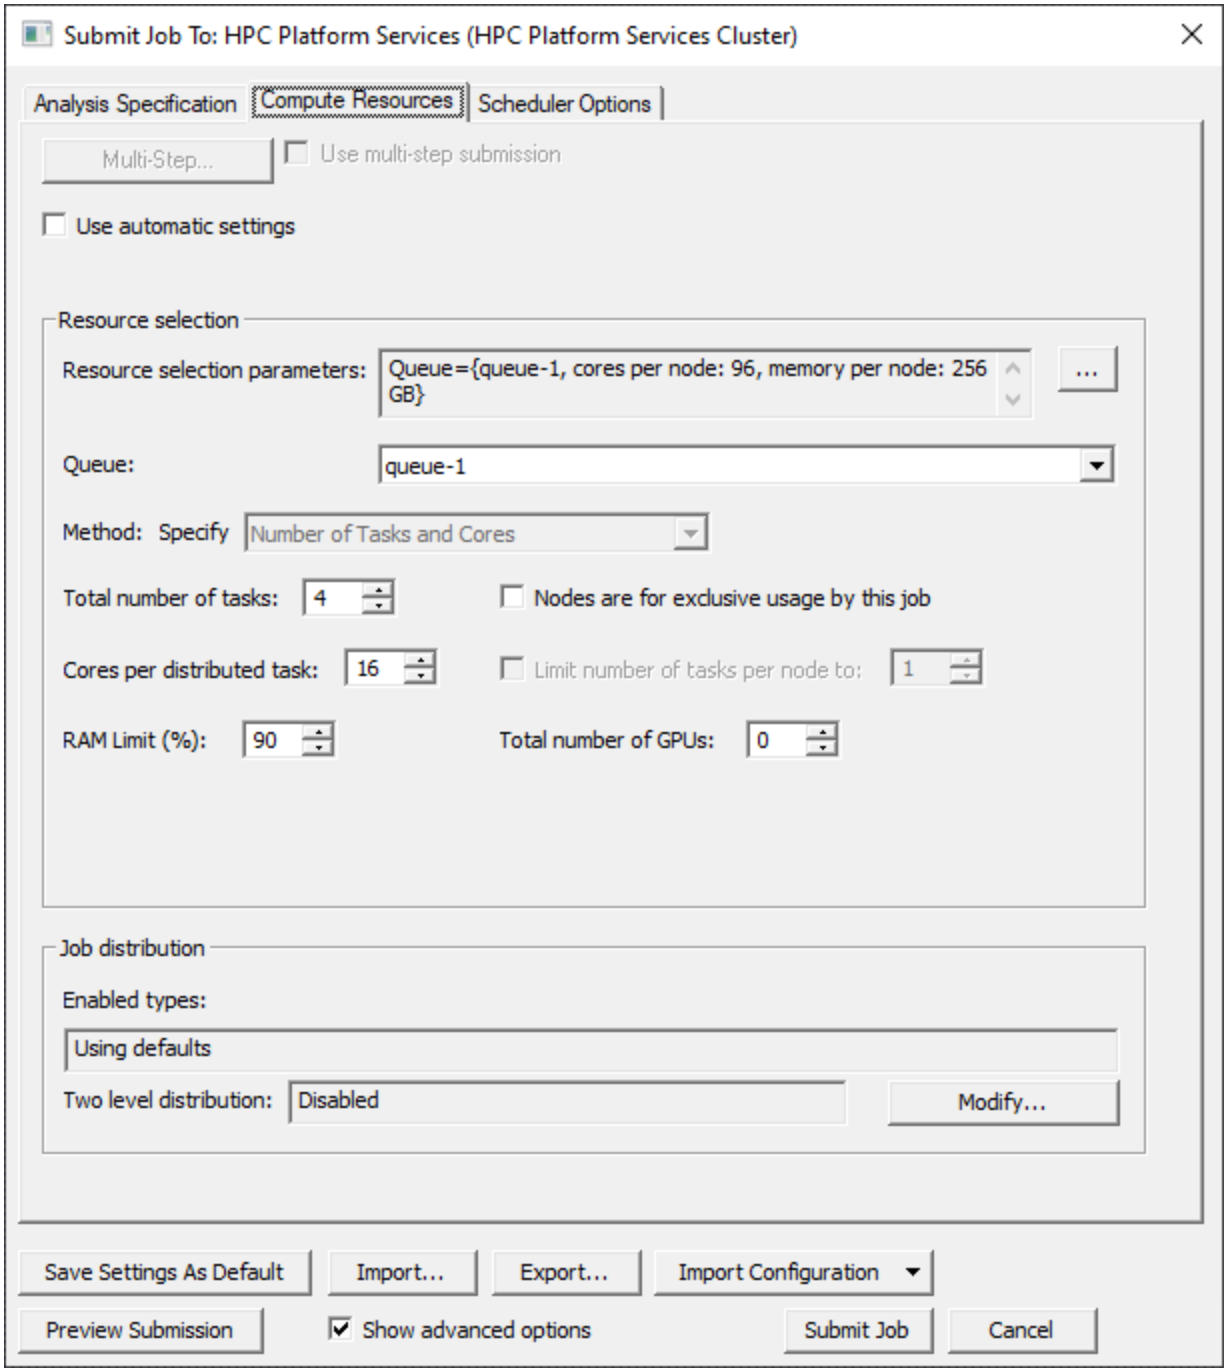


If you do not check **Use automatic settings**, then you may only select the following method for specifying job resources:

Specify Number of Tasks and Cores

You must specify the number of distributed tasks and the number of cores for each distributed task. The number of cores allocated to the job on each host must be an integral multiple of the number of cores per distributed task. If this requirement is not met, then the job will not start, and an error message will be output. In this case, you may specify a different submission method, or set the CoresPerNode resource selection parameter to an integral multiple of the number of cores per task and resubmit the job.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



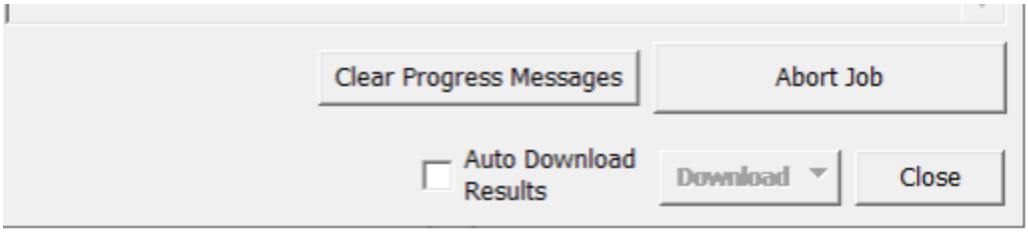
Use **Tools > Job Management > Monitor Job** to monitor the job's progress.

To get more detailed monitoring information, there is a **Job Management Service** that can be accessed from the base endpoint URL (without "/hps" at the end).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Aborting an Analysis

Jobs submitted via Ansys HPC Platform Services from can be aborted through the **Monitor job** dialog. To abort a job in a Queued state, you should press the **Abort Job** button on the **Monitor Job** dialog.



To abort any running job, you can either **Abort** or **Clean-Stop** the job. Using either of these abort types, debug logs can be collected from all compute nodes in the job.

For more information, please see Aborting an Analysis.

Cluster Specific Considerations

Ansys HPC Platform Services

Job Submission Methods

Manual:

- Number of Tasks and Cores: allows specification of Total number of tasks, Cores per distributed task, and RAM Limit %. Also allows manual specification of allowed Job distribution types and two-level distribution.

Automatic:

- Number of Nodes and Cores: allows specification of Total number of nodes, Total number of cores, Total number of GPUs, RAM Limit %, and Num variations to distribute.
- Number of Cores and (Optional) RAM: allows specification of Total number of cores, RAM Limit %, and Num variations to distribute.

Configuration Guidelines

Compute resource selection for Ansys HPC Platform Services involves choice of queue. These will depend on the cluster setup. The queue can also be left as “(not specified)” unless the submission method is automatic and Method is Number of Nodes and Cores. Information for the selected queue can be seen in the Resource selection parameters box. This includes cores per node and memory per node in GB.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option Settings for Ansys HPC Platform Services

The following option is automatically added for Ansys HPC Platform Services jobs:

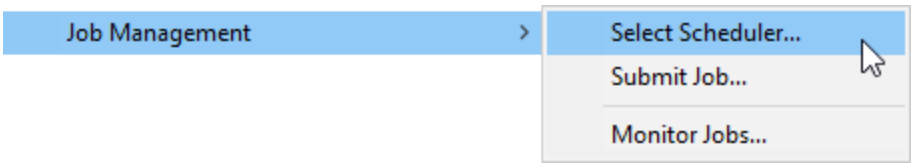
"-autoextract reports".

See: Running Electronics Desktop from a Command Line.

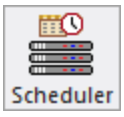
Selecting a Scheduler

Access the **Select Scheduler** window one of three ways:

- Click **Tools** > **Job Management** > **Select Scheduler...**



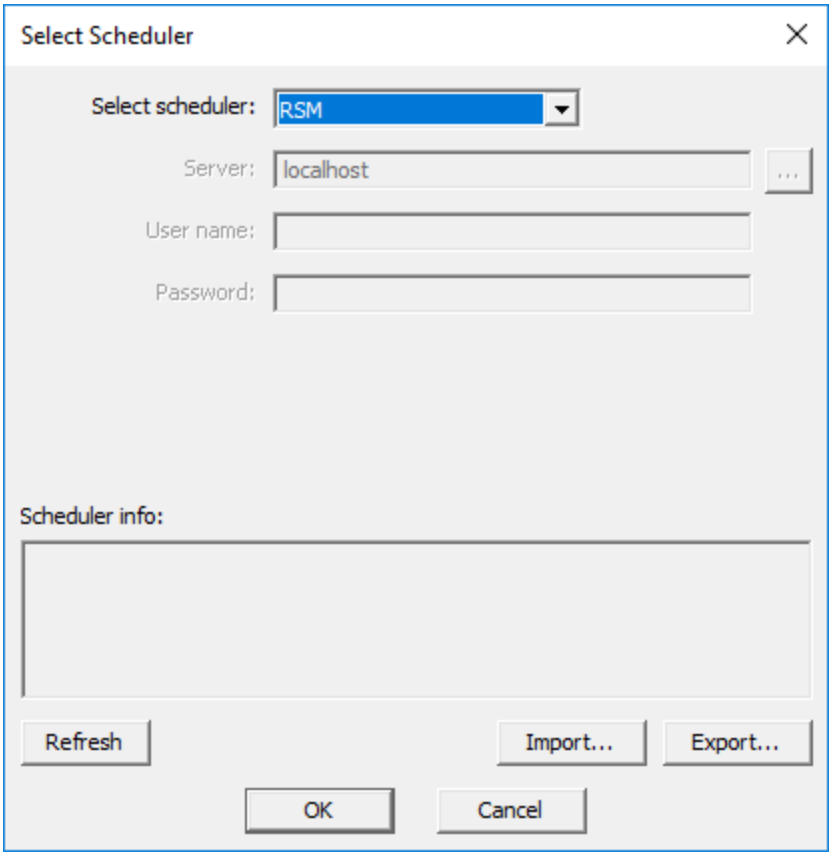
- Select the **Simulation** tab and click the **Scheduler** icon.



- From a command window, use the -showselectscheduler command.

The **Select Scheduler** window appears:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



From the **Select Scheduler** window:

1. Use the **Select scheduler** drop-down menu to select a scheduler.

   > **Note:**
   >
   > If you select a scheduler that is unsupported in your environment, you will receive a warning message.
   >
   > See HPC Integration for a list of currently supported schedulers.

2. If applicable for the scheduler type, enter server and user information. If Ansys Cloud Direct or Ansys Cloud Burst Compute is selected then the “Login” button will open the default browser and prompt for login.

   Information about the selected scheduler appears in the **Scheduler info** field.

3. Click **OK** to complete your selection.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Submitting a Job

Ansys Electromagnetics Desktop supports its own Remote Simulation Management (RSM) and Ansys Cloud Direct along with other High Performance Computing (HPC) software management programs (See: HPC Integration). The **Simulation** tab of the ribbon includes icons for setting HPC Options, creating and selecting analysis configuration, selecting the scheduler, submitting jobs, and monitoring jobs.

There are two ways that the GUI may be used to submit jobs. The first (and most common) mode requires that the Desktop (UI) process run on a host which is also a submission host for the job scheduler. This mode is called local mode or working mode.

The second mode is only supported on Linux in the Ansys Electromagnetics Suite. In the second mode, an administrator configures the RSM Service to act as an interface to the job scheduler, and starts the RSM Service on a submission host for the cluster. The user runs the Desktop (UI) process on another host (which may be called the post-processing host). To submit a job, the user specifies the host where the RSM Service is running, and the Desktop process connects to the RSM Service over the network to submit the job. In this mode, some configuration is required, and the RSM Service typically must run as a privileged user (for example, root), so that it can launch processes as any user. This mode is useful for cases in which the submission hosts are not able to run graphical processes.

> **Note:**
>
> For certain methods of resource selection for Windows HPC job submission, Ansys Electronics Desktop checks for nodes being online. In an auto-scaling cluster, nodes can fail the online check because they're not online until a job is running. An environment variable allows customers to bypass this check:
>
> ANSYSEM_SKIP_NODE_ONLINE_CHECK
>
> Set the variable value to 1 to disable the online check. Debug logging fully verifies what aspects of the cluster are causing this check to fail.

Job submission in Windows works without changing settings if environment variable ANSYSEM_SUBMIT_JOB_REQ_NODE_ONLINE is set with value 0. The installation doesn’t set this environment variable. ANSYSEM_SUBMIT_JOB_REQ_NODE_ONLINE accepted values: 0 or 1 (0 = disable; 1 = enable, i.e. require nodes to be online for submission). Default: 1 (i.e. if not set, Ansys Electronics Desktop requires nodes to be online for submission).

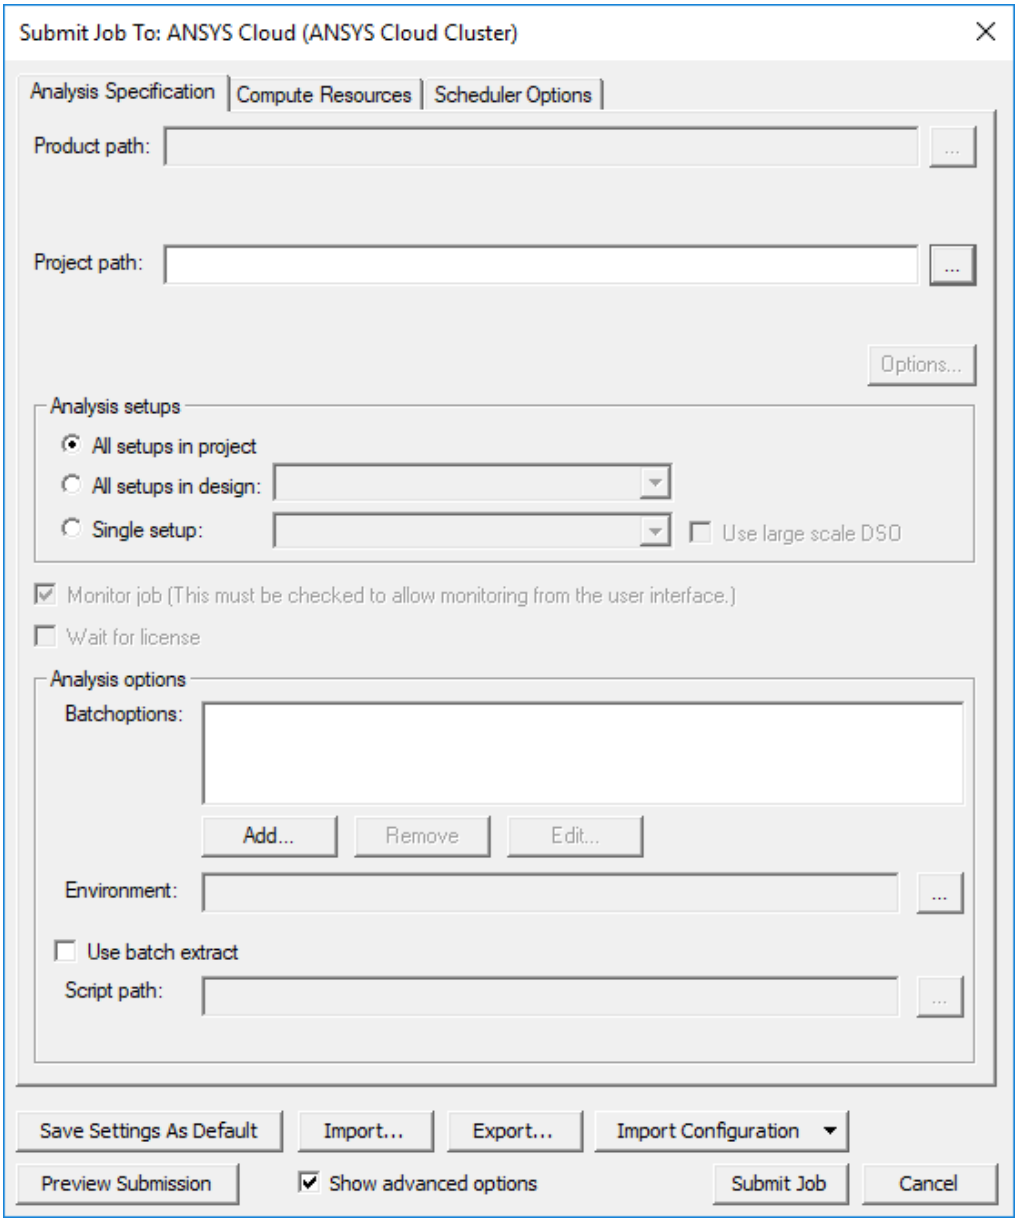
To submit a job:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Prepare your design.
2. Open the **Submit Job To** window one of the following ways:
   - On the **Simulation** tab, click the **Submit** icon.
   - Select **Tools** > **Job Management** > **Submit Job**.
   - Select **Maxwell 3D**, **Maxwell 2D**, or **RMxprt** > **Submit Job**.
   - Right-click a solution setup and select **Submit Job**. *In this case, the information in the **Submit Job To** window will be pre-populated from the setup*.
   - From a Command window, use the -showsubmitjob command.

   The **Submit Job To** window appears. The window header indicates your selected scheduler.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This window contains up to three tabs:

- **Analysis Specification** – allows you to specify the product path, project name, setup and analysis options, batchoptions, and environment variables (for advanced users).
- **Compute Resources** – allows you to specify whether to use automatic settings, and to set resource selection and job distribution parameters.
- **Scheduler Options** – allows you to specify the job name and priority. *This tab does not appear if you have selected local RSM as the scheduler*.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. On the **Analysis Specification** tab, specify your desired options.

   The **Product path** and **Project** fields support mapped drives. Click the ellipses (**...**) to select files.

   The project can be an archive. The project file pathname must be a UNC path that is accessible from each compute host used for Ansys Electromagnetics jobs. After clicking the **Project path** field's ellipsis button (**...**), a check box allows you to **Use converted UNC path if mapped drive specified**. If you select a project or product on a mapped drive, and check the option, the converted UNC path equivalent to the mapped drive pathname is used.

   Note:

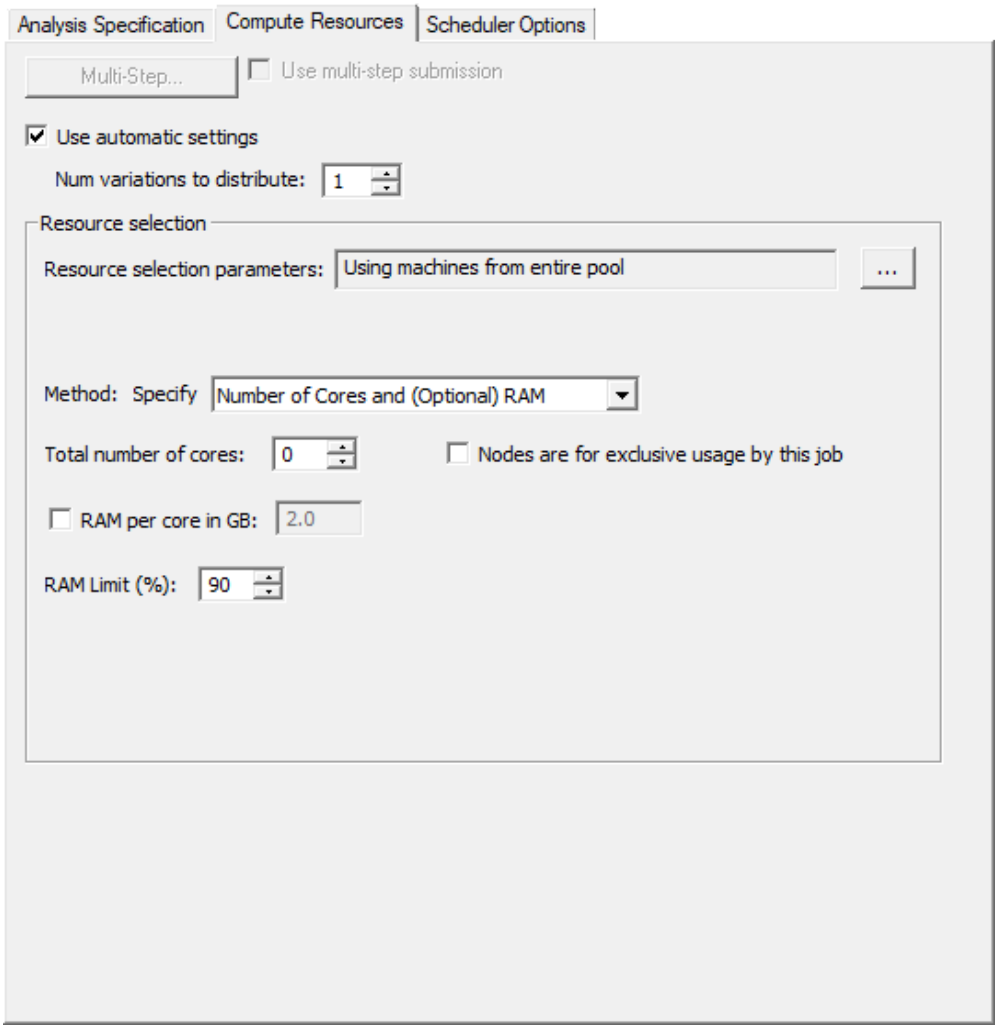
   If you select Ansys Cloud as your scheduler for a design type that is in Beta, you will receive a warning:

   
   In the **Analysis Setups** area, select the radio button for **All setups in project**, **All setups in design**, or a **single setup**.

   For Parametric setups, you have the option to select **Use Large Scale DSO**. See: Large Scale DSO for Parametric Analysis.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Select the **Compute Resources** tab.



Options may vary slightly depending on your selected scheduler.

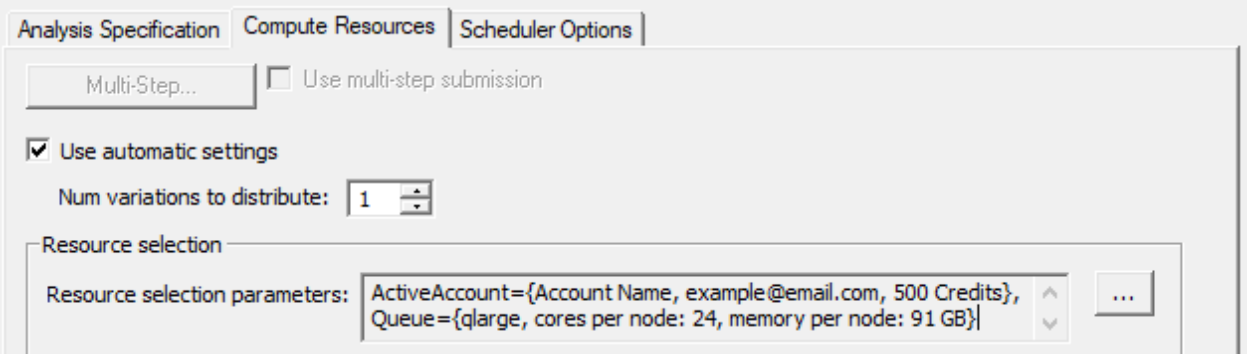
5. If applicable, determine whether or not to **Use multi-step submission**.
6. Determine whether or not to **Use automatic settings**.

> **Note:**
>
> Ansys strongly recommends using Automatic settings.

7. Use the buttons in the **Resource selection** area to allocate resources. See: Job Management for Large Scale DSO. If you are using Ansys Cloud Burst Compute select an active account using the ellipsis […] button to the right of the **Resource selection parameters:** text box and ensure that it has sufficient Core Hour Balance. This balance

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

will be displayed in the **Resource selection parameters:** text box.



8. If you opted not to use automatic settings, you can also set **Job distribution** parameters. See: Distributed Analysis.
9. If applicable, select the **Scheduler Options** tab and set the **Job name** and **Priority**.

10. If desired, import or export job configurations.
11. If desired, click **Save Settings as Default** to save the current settings and overwrite defaults. These settings are saved on a per-scheduler basis.
12. If desired, click **Show advanced options** to see options for advanced users. See: Running Electronics Desktop from a Command Line.
13. If desired, click **Preview Submission** to view the commands to be sent to the scheduler. Ansys Cloud Direct submissions contain queue (pool) configuration details, including the job's hourly cost in Ansys Elastic Units (AEUs).

    The preview text can be copied to the clipboard.
14. Click **Submit Job** to submit the job to your selected scheduler.

Using Advanced Job Submission Options

From the job submission window, you can select **Show advanced options** to enable additional analysis options and job submission options.

This topic covers the following:

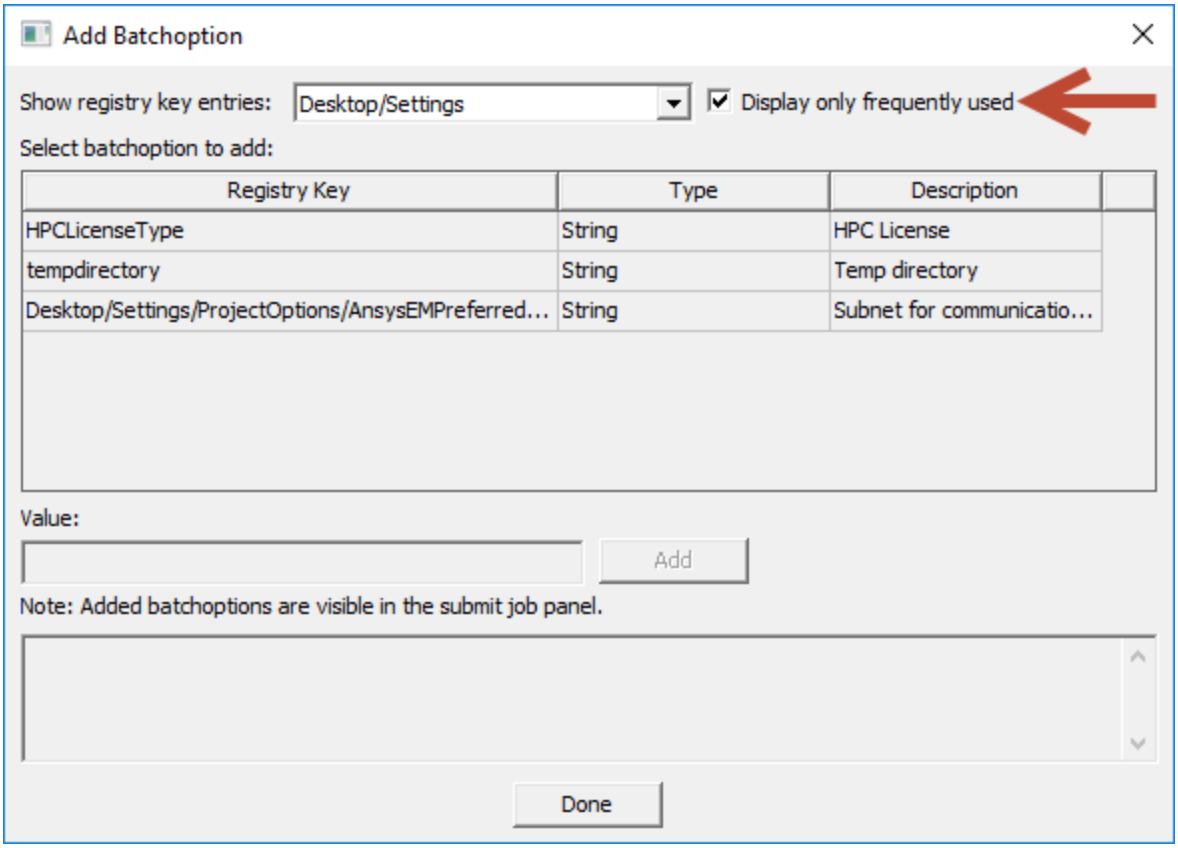
- Batchoptions
- Environment Variables

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Batch Extract
- Customize Job Submission

Batchoptions

In the **Submit Job To** window, under **Batchoptions**, click **Add** to open the **Add Batchoption** window.

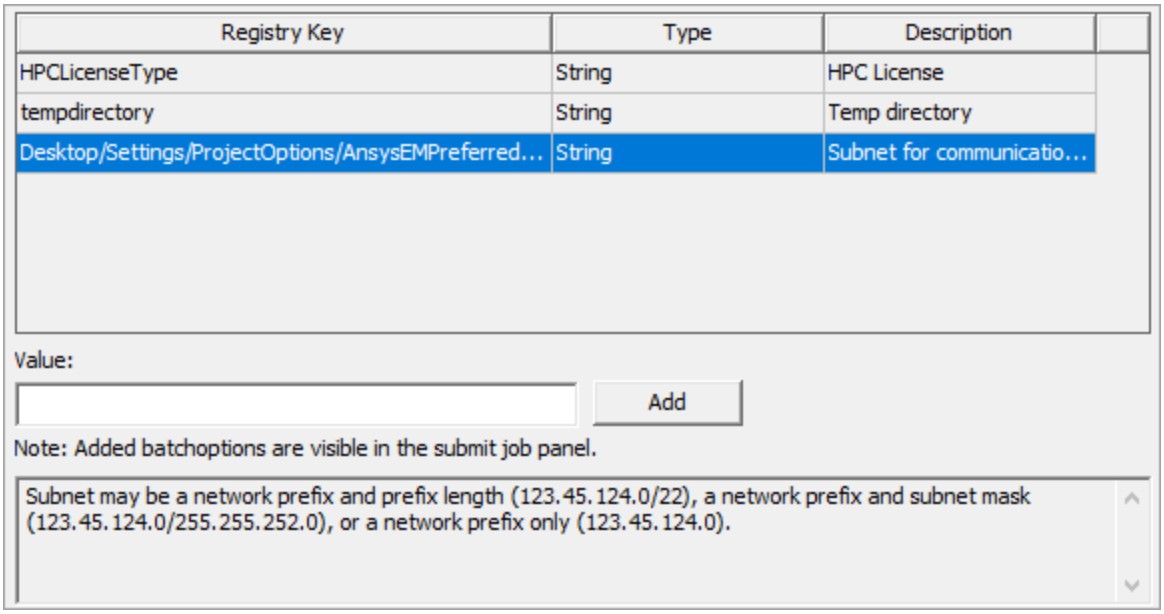


The **Show registry key entries** drop-down menu allows you to select categories of registry keys to display.

Note that **Display only frequently used** is selected by default. Deselect this to view all options for the selected category.

Select a registry key to activate the **Value** field, where you can enter a value. Selecting a key also populates the bottom of the window with a description of that key:

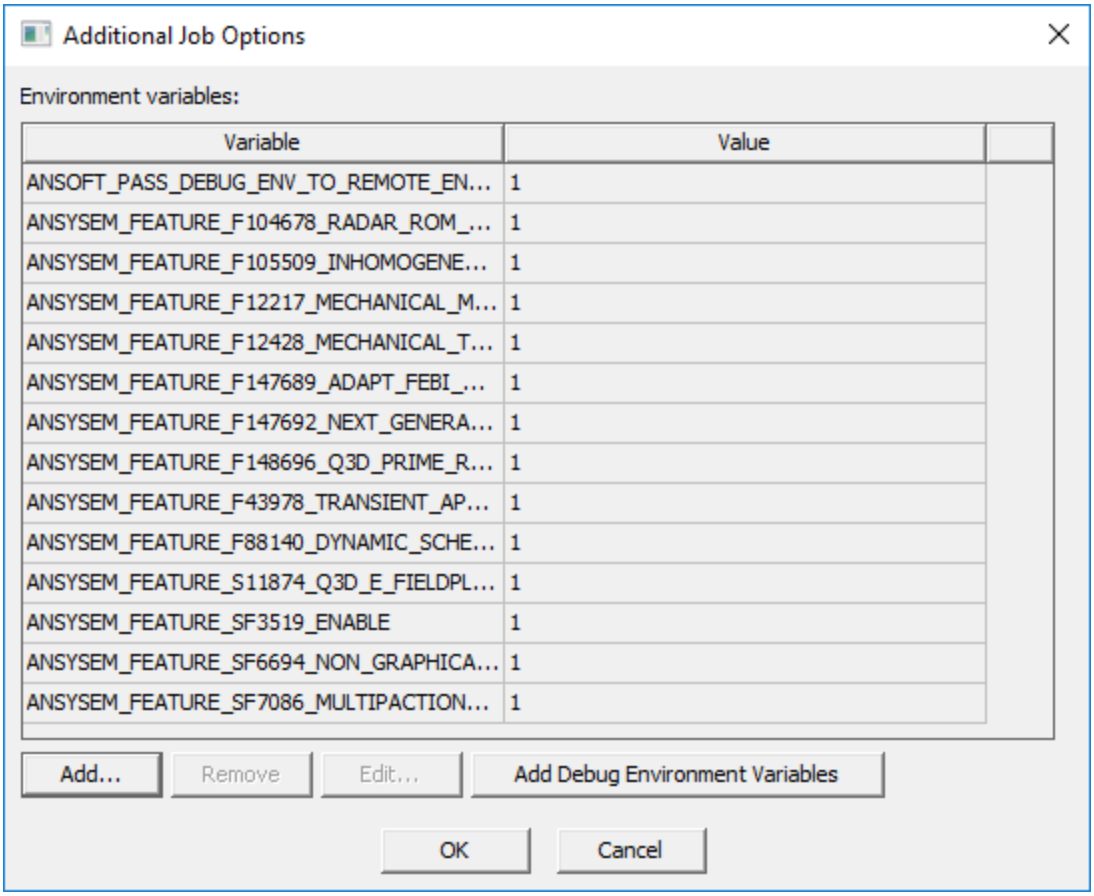
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Environment Variables

In the **Submit Job To** window, under **Environment**, click the ellipses (**...**) to open the **Additional Job Options** window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This window lists all currently activated environment variables.

Active variables display a value of 1. Inactive variables display a value of 0. Non-binary variables may contain project paths, integer values, etc.

You can perform the following actions:

- **Add** – Add an environment variable. You will be prompted to enter the variable name and value.
- **Remove** – Select and remove an environment variable from the list.
- **Edit** – Select an environment variable and enter a new value.
- **Add Debug Environment Variables** – Activates a selection of debugging variables and adds them to the list. The log files created are only useful to development and if a customer or an application engineer needs to set these environment variables they should be working with a developer directly or indirectly who will know what needs to be set.

Batch Extract

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In the **Submit Job To** window, select **Use batch extract** to enable the **Script path** field. Click the ellipses (**...**) to browse and select a VBscript or Python script to execute along with the job. See: Running Ansys Electronics Desktop from the Command Line for a description of Batch Extract.

Customize Job Submission

In the **Submit Job To** window's **Scheduler Options** tab, advanced options for some schedulers allow you to **Customize job submission**. When the **Override job submission** radio button is selected, user-specified options replace most of the job submission options. When the **Additional job submission options** radio button is selected, user-specified options are appended to the bsub command.

Using the Command Line to Submit HPC Jobs

Ansys Electronics Desktop can be run from the command line. When using the command line to perform HPC jobs, take the following into consideration.

Distributed Jobs

An Ansys EM batch job which distributes the analysis over several hosts may also be called a distributed job. To submit a distributed job, the following Ansys EM desktop command line options should be used:

- The -Distributed option should be present, and the -Local option should be absent. When running as a batch job under one of the schedulers with direct integration, this option is a directive to the job to 1) obtain the list of hosts allocated to the job, directly from the scheduler, and to 2) use the scheduler to launch the analysis engines on the hosts allocated to the job. The -Distributed option may now have additional options, such as includetypes=xxx, excludetypes=xxx, maxlevels=n, and numlevel1=n, where n indicates and integer, and xxx indicates a list of distribution types or "default".
- The -Machinelist num=*num_distributed_engines* option must be included, where *num_distributed_engines* is the total number of analysis engines to be started on the hosts assigned to the job.

Other examples:

- "Serial Job on a Single Processor" on the next page
- "Distributed Job Using Four Processors" on the next page
- "Multiprocessing Job Using Four Cores" on the next page
- "Distributed Analysis and Multi-Processing in the Same Job" on page 16-225

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Serial Job on a Single Processor

Suppose Ansys Electronics Desktop is installed at "C:\Program Files\ANSYS Inc\v251\AnsysEM\" and you are using RSM for DSO:

```
"C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt.exe" -ng -
BatchSolve -machinelist num=2
-monitor \\shared_drive\projs\OptimTee.aedt
```

User is using LSF for remote-analysis/DSO

```
bsub -n 1 "C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt.exe" -ng
-BatchSolve -machinelist num=3 -monitor -local \\shared_
drive\projs\OptimTee.aedt
```

Distributed Job Using Four Processors

Ansoft RSM

```
"C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt.exe" -ng -
Batchsolve -monitor -Distributed
-machinelist list="10.1.1.221, 10.1.1.222, 10.1.1.223, 10.1.1.224"
\\shared_drive\projs\OptimTee.aedt
```

LSF

```
bsub -n 4 "C:\Program Files\ANSYS Inc\v251\AnsysEM\ansysedt.exe" -ng
-Batchsolve -monitor
-Distributed -machinelist num=4
\\shared_drive\projs\OptimTee.aedt
```

Multiprocessing Job Using Four Cores

Multi-processing job using 4 cores

```
bsub -n 4 -R span[ptile=4] "C:\Program Files\ANSYS
Inc\v251\AnsysEM\ansysedt.exe" -ng -monitor
-Local -BatchSolve -machinelist num=4 -batchoptions \\shared_
drive\registry.txt \\shared_drive\projs\OptimTee.aedt
```

This requests 4 cores to come from the same machine, as multi-processing needs cores to be on the same machine

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Distributed Analysis and Multi-Processing in the Same Job

Distributed-processing using 4 engines and multi-processing using 4 cores, using a total of 16 cores

```
bsub -n 16 -R "span[ptile=4]" "C:Program Files\ANSYS
Inc\v251\AnsysEM\ansysedt.exe" -ng
-BatchSolve -Distributed -machinelist num=4
-batchoptions \\shared_drive\registry.txt
\\shared_drive\projs\OptimTee.aedt
```

Job Import and Export

The bottoms of the scheduler selection and job submission window contain buttons for **Import...**, **Export...**, and **Import Configuration**. Import and Export may be used to save and then restore a frequently used collection of job submission settings, to save multiple sets of settings, or to transfer settings from one machine to another. Electronics Desktop uses Ansoft Electronics Registry Settings (*.areg) files for these purposes:

- **Export...** – exports most of the settings of this window (all tabs) to an *.areg file.
- **Import...** – updates most of the settings in this window (all tabs) from an *.areg file.
- **Import Configuration** – updates DSO settings in this window from any DSO configuration, as shown in the **Configurations** and **Options** tabs of **HPC and Analysis Options**.

> **Important:**
>
> The Design Type of the DSO configuration must match the design type of one of the designs in the project, so the **Project path** must be specified before using the **Import Configuration** button.

Scripting

The SubmitJob scripting command uses job submission settings that have been exported from the **Submit Job** window to an *.areg file. The path to this *.areg file is the first argument to the SubmitJob scripting command. See: Job Submission Scripting.

Multi-Step Job Submission

Multi-step job submission allows you to divide the simulation of a project on a cluster as two or more jobs, each of which has unique resource specifications. For example, creating the initial mesh and doing adaptive refinement can use a single machine, while frequency sweeps can easily be distributed over many machines. Breaking up the simulation into multiple steps allows

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

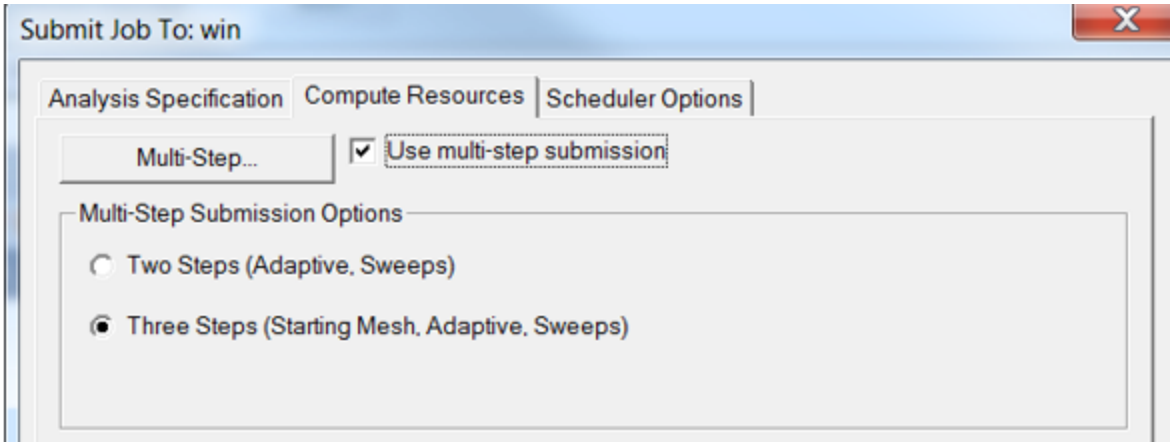
the first job to do initial meshing and adaptive passes, only reserving a single compute node, or maybe even reserving just a partial node. The second job can then do the frequency sweep(s), reserving and using multiple nodes. Note that while the first job runs, because it may only be using one node, other nodes are available for other jobs. The Ansys Electronics Desktop job submission GUI allows you to submit multi-step jobs, and specify compute resources individually for each step. Electronics Desktop can also be used to monitor the execution of multi-step jobs.

Limitations

Multi-step job submission is only allowed for a single setup of a project. Only certain design types (or setup types for a given design type) offer this functionality. Ansoft RSM does not support multi-step jobs because it does not have queuing capabilities.

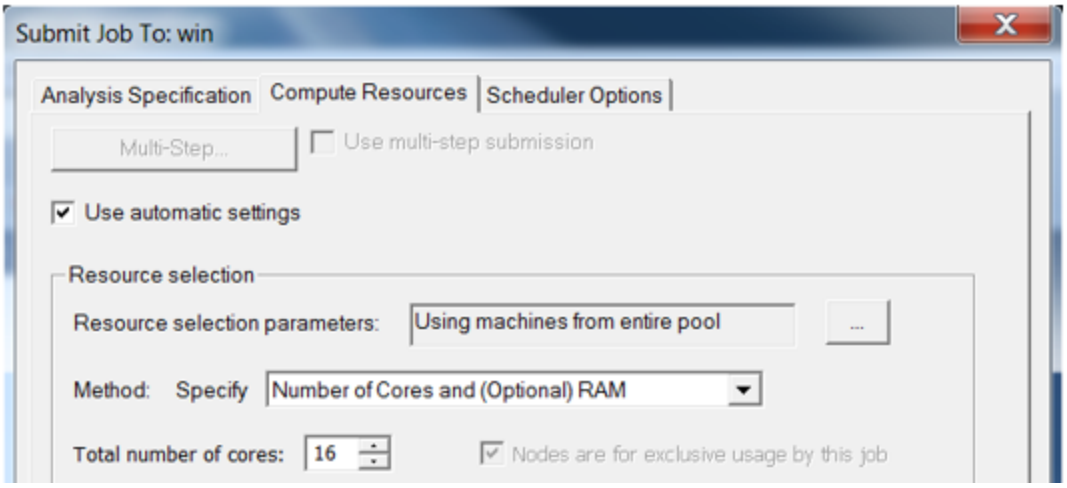
How-to Specify Multi-Step Job Submission

From an open project, right-click a setup in the project tree, and select **Submit Job...** on the shortcut menu. This pre-populates the **Submit Job To** window's **Analysis Specification** tab for the selected setup. Select the **Compute Resources** tab. If the design setup and selected scheduler allow for multi-step submission, and your computing resource supports it, the **Compute Resources** tab shows the **Multi-Step...** button and the **Use multi-step submission** check box is enabled.



If the **Multi-Step** button and check box are not enabled, it could be because you have not selected a single setup, the design type of the setup does not support Multi-Step, or the scheduler type (e.g., RSM) does not support it.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

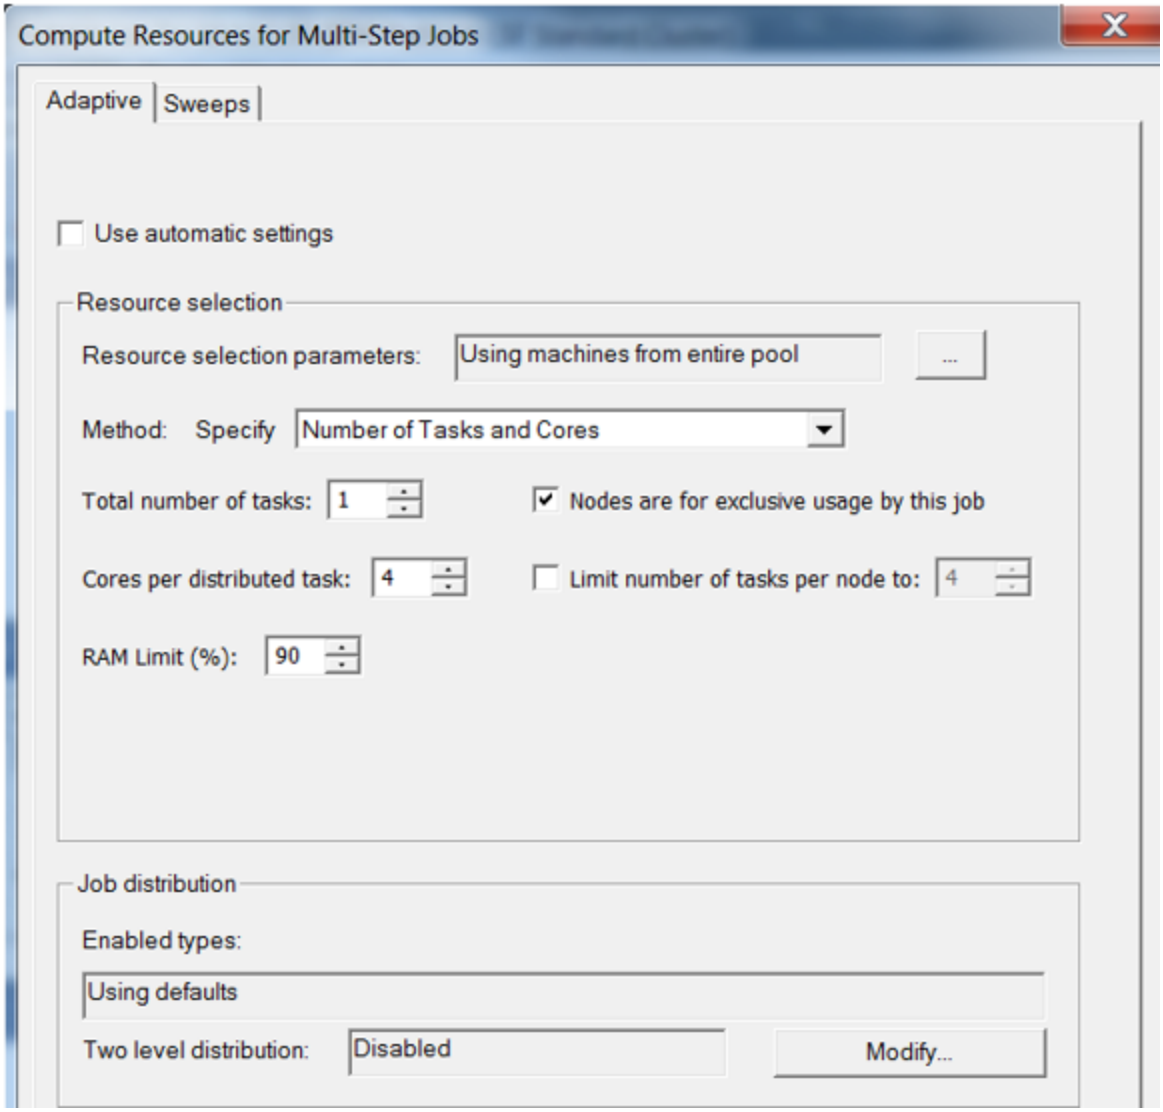


On the **Compute Resources** tab, check the **Use multi-step submission** box and select the appropriate submission option:

- Two Steps for Adaptive and Sweeps
- Three Steps for Mesh, Adaptive, and Sweeps

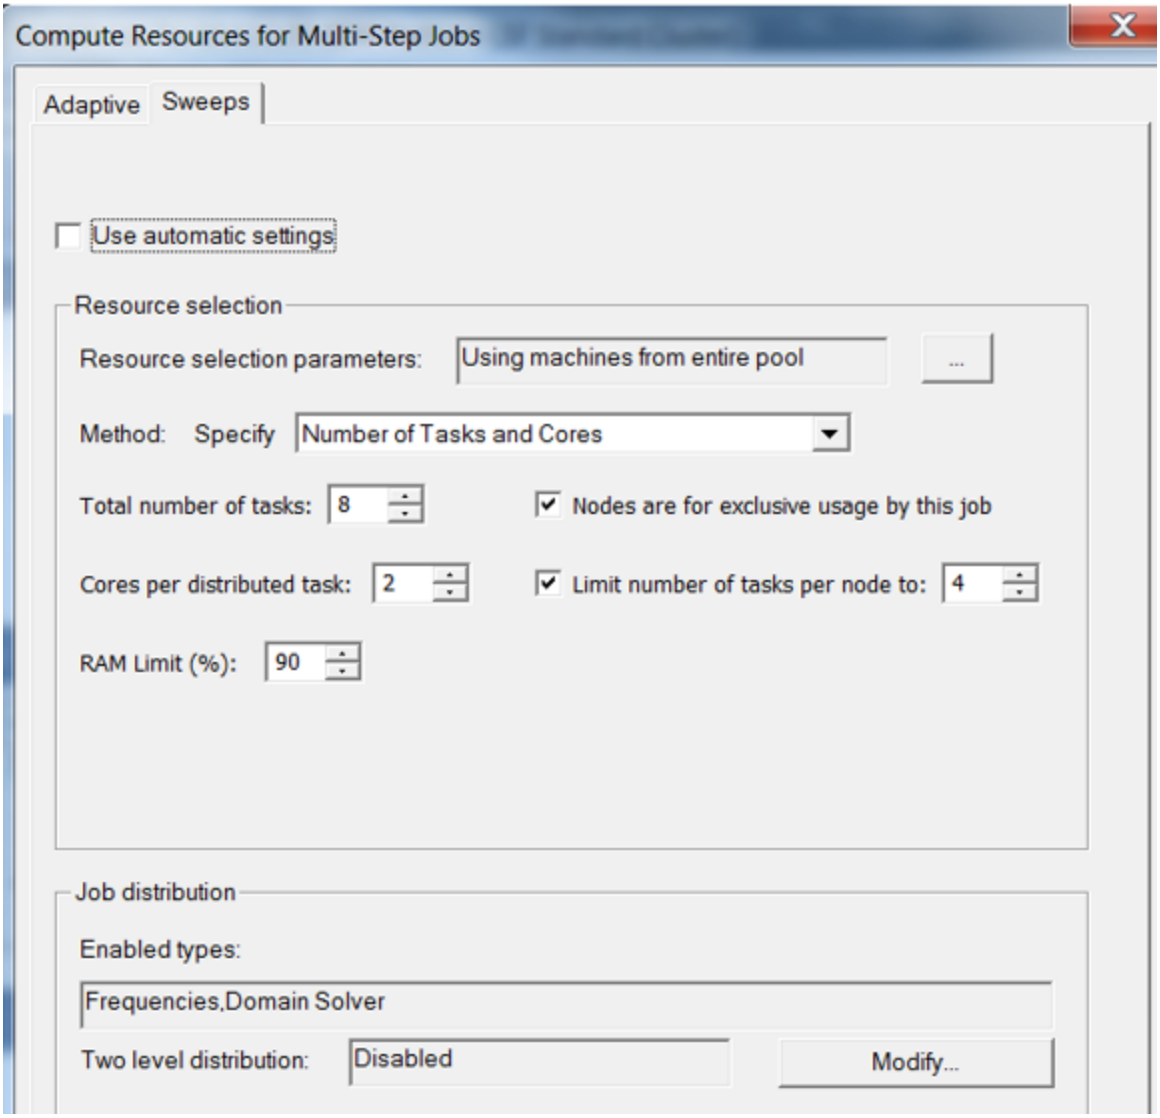
Then click **Multi-Step…**, which will bring up a **Compute Resources for Multi-Step Jobs** dialog box where there is a tab for each step used, that is for potential for Mesh, Adaptive, and Sweeps.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Notice, for example, that the **Sweeps** tab lists the same resources choices but they can be assigned differently.

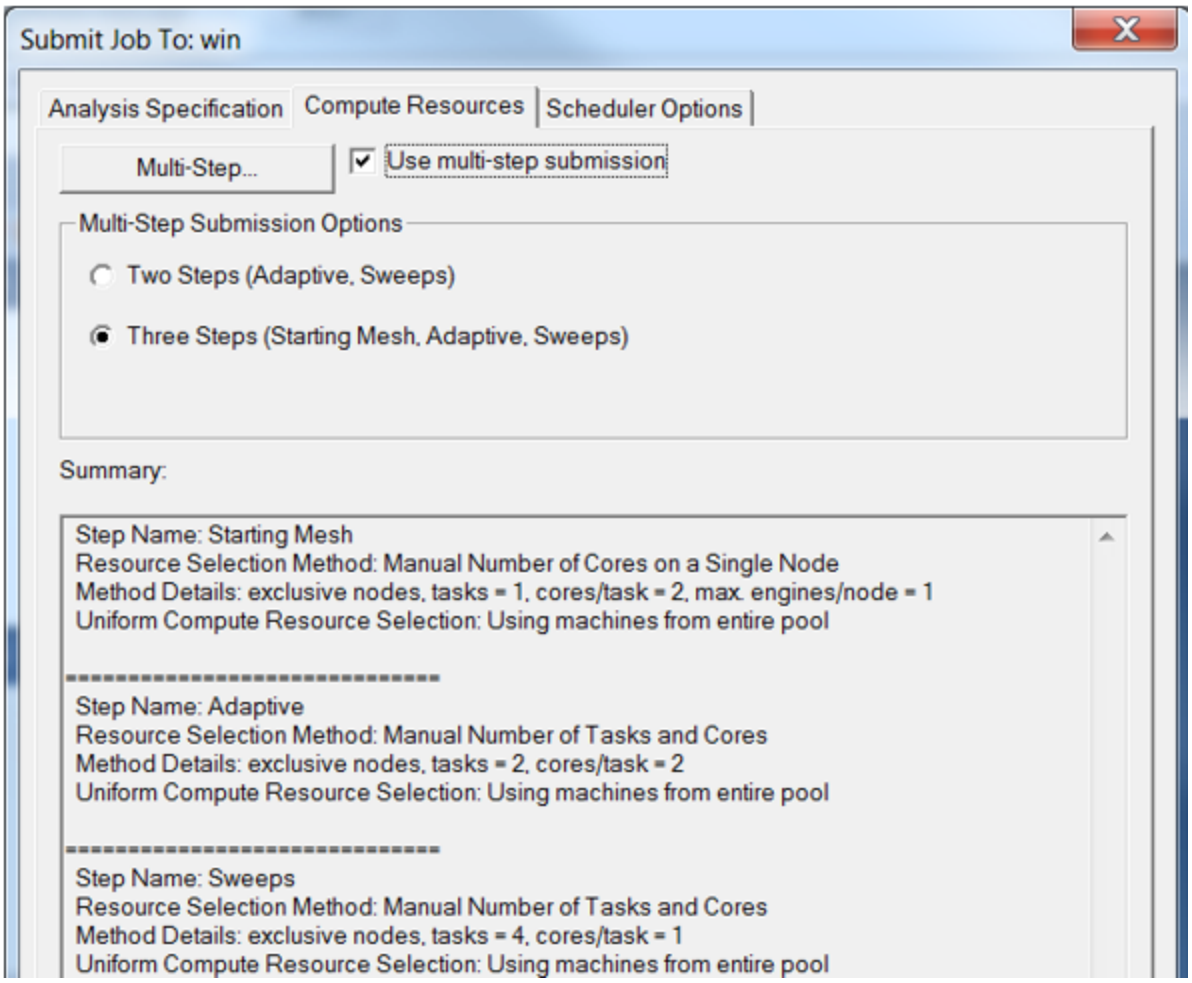
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



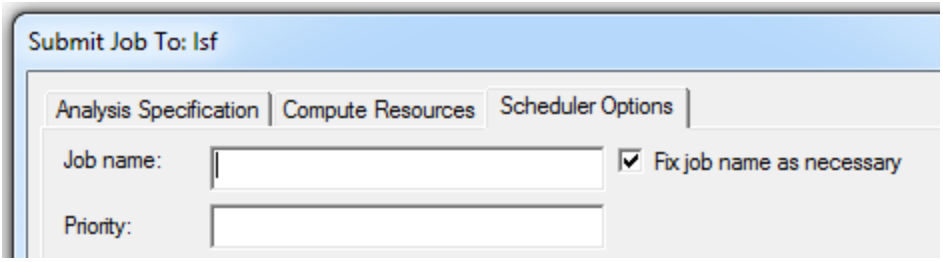
Set the desired compute resources for each step and click **OK**.

The Summary field of the **Compute Resources** tab shows a text summary of resource specifications used for each step.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



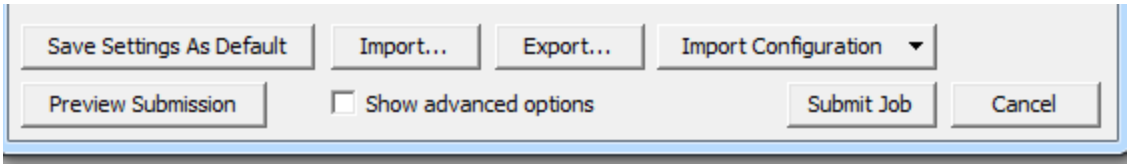
If desired, set the job name on the **Scheduler Options** tab. When the jobs are submitted, each will have a name given by job name (if any) appended with the name of the step for the job. For example, if the job name entered is “MultiStep”, then the individual jobs might be named “MultiStep-Adaptive” and “MultiStep-Sweeps”.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

There is a new **Fix job name as necessary** check box for the job name. This applies only to certain schedulers where there are constraints on the job name. It is useful to ensure proper submission in the case where appending the step name results in an invalid job name.

When you click **Preview Submission**, you see a preview for each step, all in the same output window. Any errors or warnings for a step, generated during preview validation, are displayed with the text for the preview of that step.



When you click **Submit Job**, each job is submitted individually, and dependencies are set with the scheduler so that subsequent jobs wait for the prior step's job to complete before starting. Any errors in job submission for any step prevent further steps from being submitted.

The window reporting successful submission has been modified slightly for multi-step jobs. It will show the jobs IDs of all jobs that are part of the multi-step job sequence.

Multi-Step Job Monitoring

You can monitor the job step in progress. When one job completes, the status shows "Completed", but monitoring restarts once the next job step is running.

Aborting a Job Step

You can also abort the job step in progress. With multi-step jobs submitted from the Electronics Desktop GUI, this will also cause remaining jobs (which would otherwise remain queued in the scheduler) to be canceled.

Archive Projects for Multi-Step Job Submission

Note that you can submit archive projects. Monitoring is based on the archive for the first step, then on the extracted project for subsequent steps.

Submitting a Job without Opening the Project

You can also submit a job without opening the project. This can be done by choosing **Tools** > **Job Management** > **Submit Job…** and then manually entering the project path (You can also use **Browse** can to select the project.) Note that you must also select a single nominal setup before the **Use multi-step submission** check box is enabled on the **Compute Resources** tab.

Windows to Linux Job Submission

Given a set of prerequisites, Ansys Electronics Desktop can permit Windows to Linux job submission as part of HPC.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Prerequisites for Job Submission

Directory Shared between Windows and Linux

For all jobs submitted to a Linux cluster, the project file is required to be in a directory that is accessible from all execution hosts used by the job. For submission of jobs from a Windows host to a Linux cluster, the project file must also be accessible from the Windows host where the GUI runs. There must be a directory shared with both Windows and Linux hosts, and the project file may be in a subdirectory (at any level) of the shared directory.

Network Access from Windows Host to Linux Job Management Host

The job is submitted to the cluster from a Linux host configured for submission of jobs to the Linux cluster. We call this Linux host the “Job Management” host. The information about the job to be submitted is transmitted to the Job Management host over the network. As a result, the Windows host where the GUI runs must have network access to the Job Management host. If this communication is blocked, then job submission from a Windows host to the Linux cluster will not be possible. Communication could be blocked if there is a firewall or if the Linux cluster is only on a private network, for example.

RSM Service Running on Job Management Host

The **ansoftrsmservice** must be running on the Linux Job Management host. Before the ansoftrsmservice is started, it must be configured for submission of jobs to the cluster. The SchedulerName and ConfigString fields in the Scheduler block of the ansoftrsmservice.cfg configuration file must be specified. The contents of these fields are described in the following table:

Field Name	Contents	Examples
SchedulerName	Identifier of Scheduler	IBM Spectrum LSF: ’`lsf`’ PBSPro or Torque: ’`pbs`’ Univa, SGE, etc.: ’`sge`’ SLURM: 'generic'
ConfigString	Directory containing scheduler commands	IBM Spectrum LSF: ’’ (not required) PBSPro or Torque: ’`/opt/pbspro/PBSPro_13.0.0/default/bin`’ Univa, SGE, etc.: ’`/opt/univa/bin/lx-amd64`’ SLURM:'{"Proxy":"slurm"}'

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The environment should be configured for job submission before starting the ansoftrsmservice. The ansoftrsmservice should be run as a non-privileged user; no special privileges are required. It should be run as a user without login privileges, so that only privileged users have access to this process.

Prerequisites for Job Monitoring

For job monitoring, all prerequisites for job submission are required. One additional requirement, described below, is also required for job monitoring.

Network Access from Windows Host to Linux Cluster Hosts

In order to obtain full monitoring information from a job, the Windows host needs access to some of the job processes. That is, the Windows monitoring host requires network access to the processes running on the Linux cluster execution hosts. If this communication is blocked, then only limited monitoring information is available.

Supported Schedulers

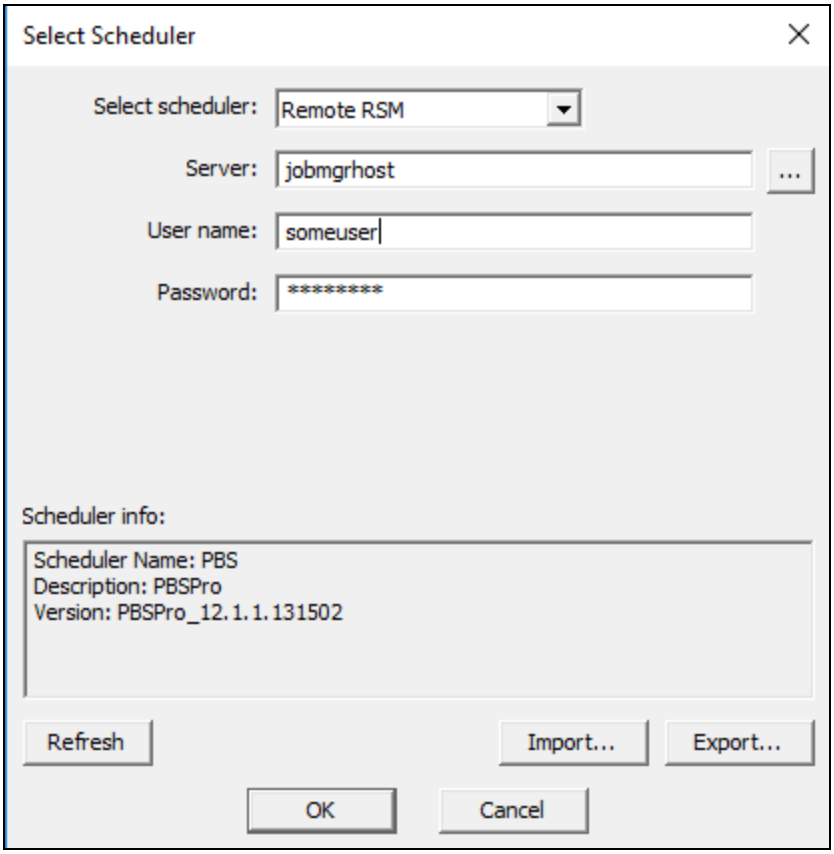
This feature may be used with all Linux schedulers for which job submission from the GUI is supported:

- IBM Spectrum LSF
- Univa Grid Engine (GE)
- PBSPro
- Torque

Select Scheduler Dialog

If you select the **Use a computer on the network** option, you can enter a username and password. This username and password are used when the job is submitted to the Linux scheduler.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

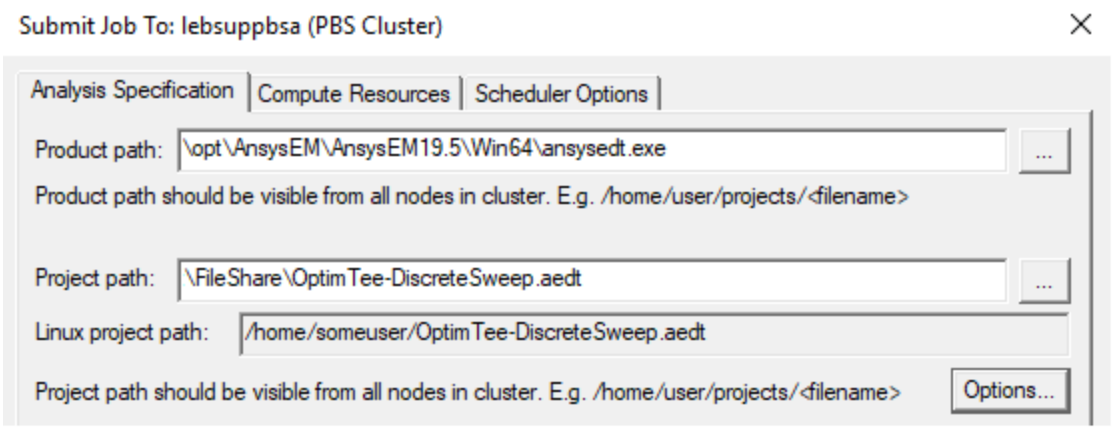


Submit Job

In the ***Submit Job To*** window, you must enter the Linux path to the product in the Product path edit control. The browse button (labeled "...") may not be used to browse for the product. There is no requirement for the product installation directory to be accessible from the Windows GUI host.

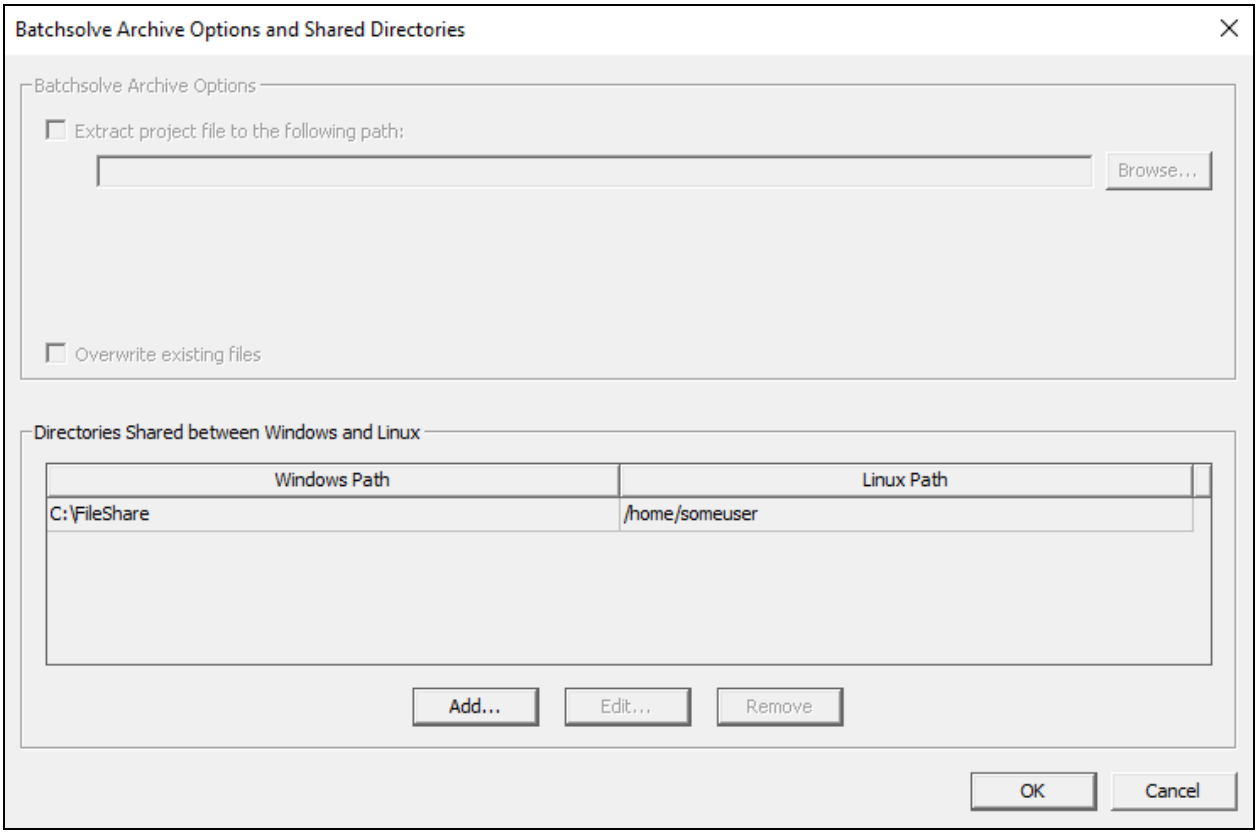
You must enter the Windows path of the project file in the Product path edit control or use the browse button (labeled "...") to select the Windows path of the project file. If the Linux path of the project file can be determined from the specified Windows path and the directories shared between Windows and Linux, then the Linux path of the project file is shown in the Linux project path edit control. This edit control cannot be edited directly.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



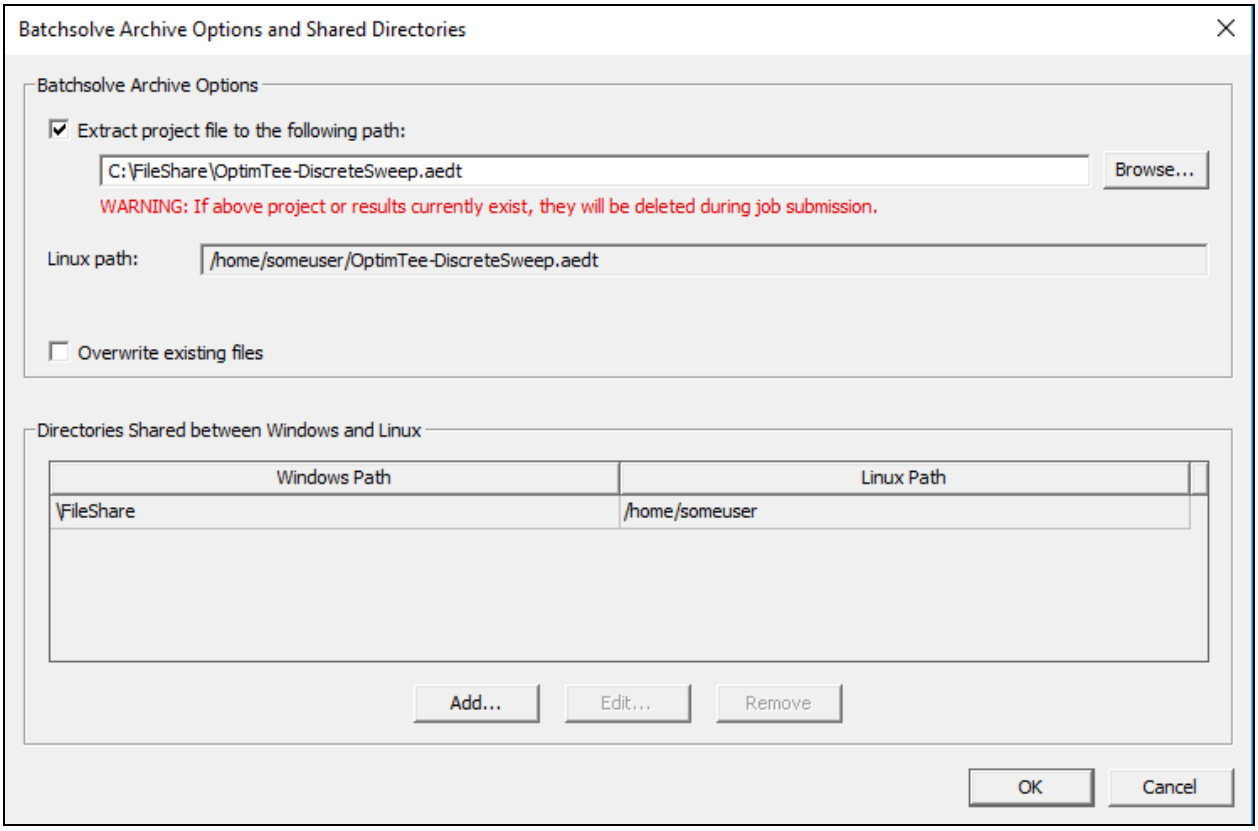
The **Options** button opens a window that you can use to specify archive options for a job. The lower portion of this window allows you to specify one or more directories shared between Windows and Linux. The mapping of directories between Windows and Linux is shown in a grid which displays the Windows path and the Linux path for each shared directory. There are also buttons to add a new shared directory, to edit an existing shared directory, or to delete one or more shared directories. The Windows path or the Linux path of any shared directory may be selected in the grid and directly edited, as well.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



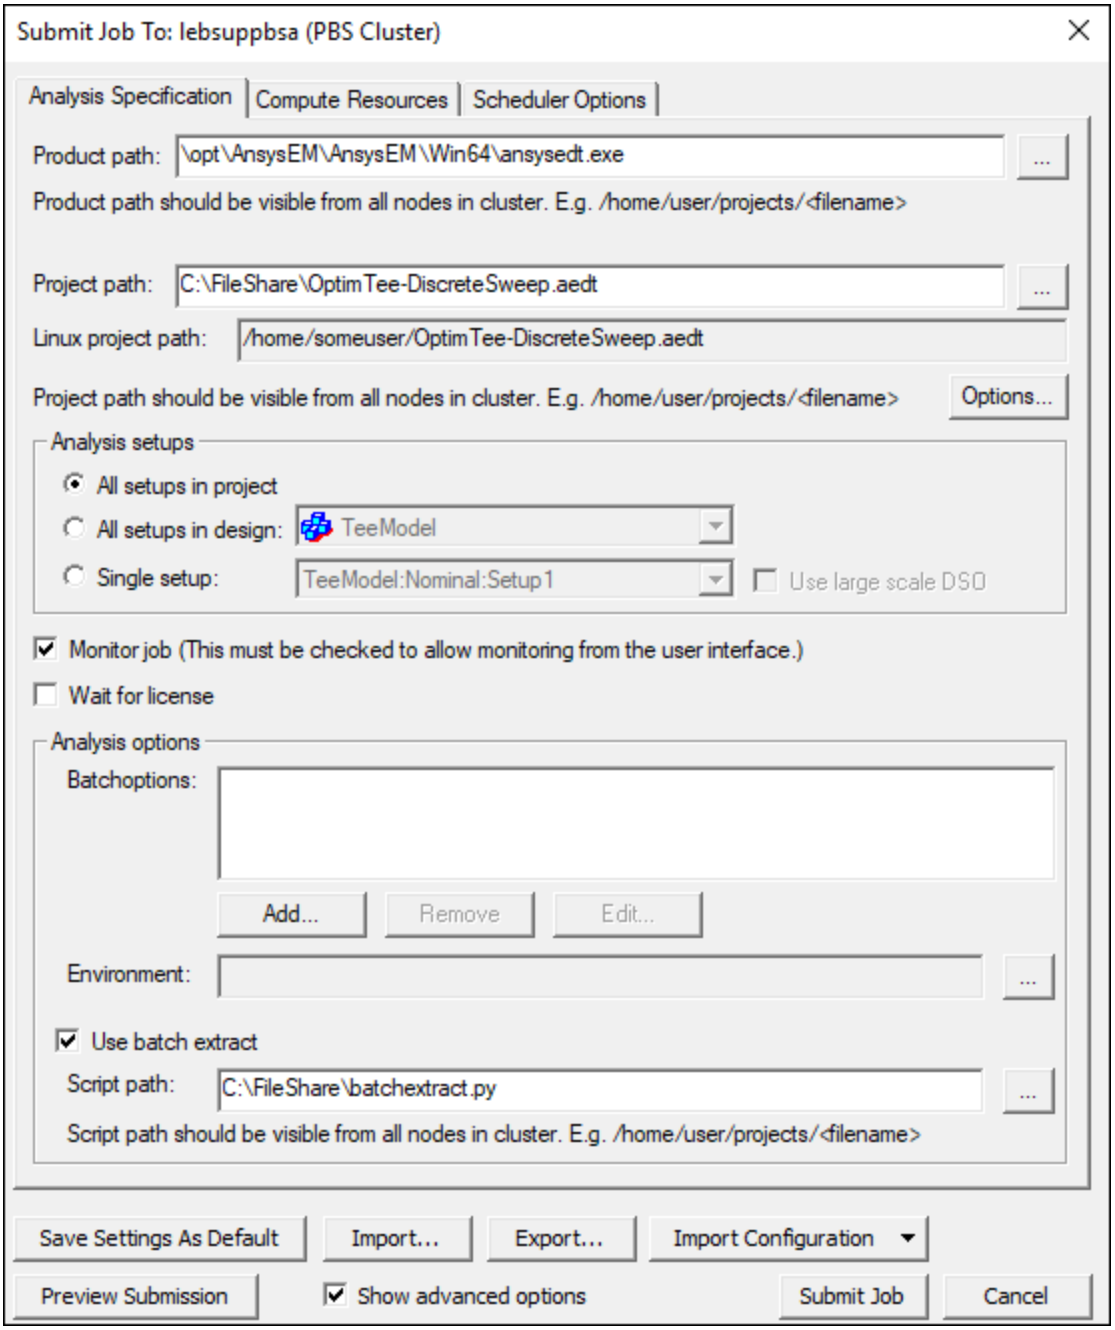
If you specify a project in an archive, the window may be used to specify the Windows pathname of the project to be extracted from the archive. If this is done, the Linux pathname of the target project is determined from the directories shared between Windows and Linux and shown in the upper portion of this window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If you specify a batchextract script, the Linux path of the batchextract script is determined from the Windows path of the batchextract script and the directories shared between Windows and Linux.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



User Passwords are Encrypted

Jobs are submitted to the Linux cluster using the user name and password entered in the **Select Scheduler** window. These settings are persistent; in general, these settings need to be entered only if they change. To ensure security, user passwords are stored in an encrypted format. When a job is submitted from a Windows host using the ansoftrsmservice running on a Linux submission host, the user credentials are sent over the network in an encrypted format.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Job Submission Scripting

To help with automation, you can submit batch jobs can through script commands of the **oDesktop** object. The **SubmitJob** script command uses job submission settings that have been exported from the **Submit Job** window to an .areg file. The path to this .areg file is thus the first argument to the SubmitJob command. Additional arguments include the path to the project file, the design name (if restricting the solve to a particular design), and the setup name (if further restricting the solve to a single setup within a design).

For further automation, you can use the **SelectScheduler** scripting command to determine what scheduler to use for submission, to include options for head node, username, and whether to require password entry from the user. (If the username differs from the cached username, or the force password flag is set, then the *Select Scheduler* dialog box appears.) If there are any issues with the scheduler selection (for example, a password is required or the requested host wasn't found), then the *Select Scheduler* window appears. If Ansys Cloud Direct or Ansys Cloud Burst Compute are selected then the "Login" button will open the default browser and prompt for an AnsysID login. This is the only part of job submission scripting that may required user intervention. This same mechanism is used if, from within the SubmitJob command, there is failure to connect to the scheduler. Even though there are allowances for graphical user intervention if something goes wrong, if the password (if required) is cached and all settings are correct, the entire submission process can run non-graphically and fully automated.

Limitations

All settings besides the arguments passed to the **SubmitJob** command must be stored in the .areg file containing settings exported from the job submission window. These include (but aren't limited to) batch options, environment variables, batch extract settings, and compute resource selections. To run many job submission scripts with variation of these settings, there must be multiple .areg files available.

Note that the same project can be submitted multiple times with a single script. Care must be taken in this situation because each time a project is submitted, the state-keeping files used for monitoring are removed so that the job can create them from scratch to ensure consistency. While this ensures proper monitoring for a job that is just being submitted, it could interfere with monitoring (or even correct solving if a lock file is deleted) of a job that is already in progress. Because of this, if the same project is to be resubmitted from within a single script, the job should be monitored (waiting for completion) before trying to submit it again. This monitoring/waiting can be done with a combination of a single **LaunchJobMonitor** command followed by a loop that checks the result of a **RefreshJobMonitor** command.

How to Perform Job Submission Scripting

The typical scenario for job submission scripting would be to do the following:

1. Manually select the scheduler. Use the **Select Scheduler** window to open the **Submit Job To** window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Choose a representative project (with the desired design type), and select appropriate analysis settings.
3. Make the required compute resource selections and try to preview the job.
4. If preview is successful, export the dialog settings and record the path to the new .areg file.
5. Create a script containing at a minimum a **SubmitJob** command with the path to the .areg file, and the path to the project file. Note that there must be double backslashes for each backslash of a path because the backslash is an escape character. When the script is run, and all is successful, there should be a message in the message windows stating that the job was submitted, including the job ID(s). There could be multiple job IDs if multi-step submission is used.

See the Scripting help (click **Help** > **MaxwellScripting Help**) for details on the **SelectScheduler**, **SubmitJob**, **LaunchJobMonitor** and **RefreshJobMonitor** commands.

Monitoring Jobs

There are a number of tools that allow you to monitor jobs, including the **Monitor Job** window and detailed .log files.

- Monitor Job Window
- Monitoring Ansys Cloud Direct Jobs
- Monitoring Ansys Cloud Burst Jobs
- Monitoring Large Scale DSO Jobs
- Web Client for Batch Solve Monitoring and Reporting

Monitor Job Window

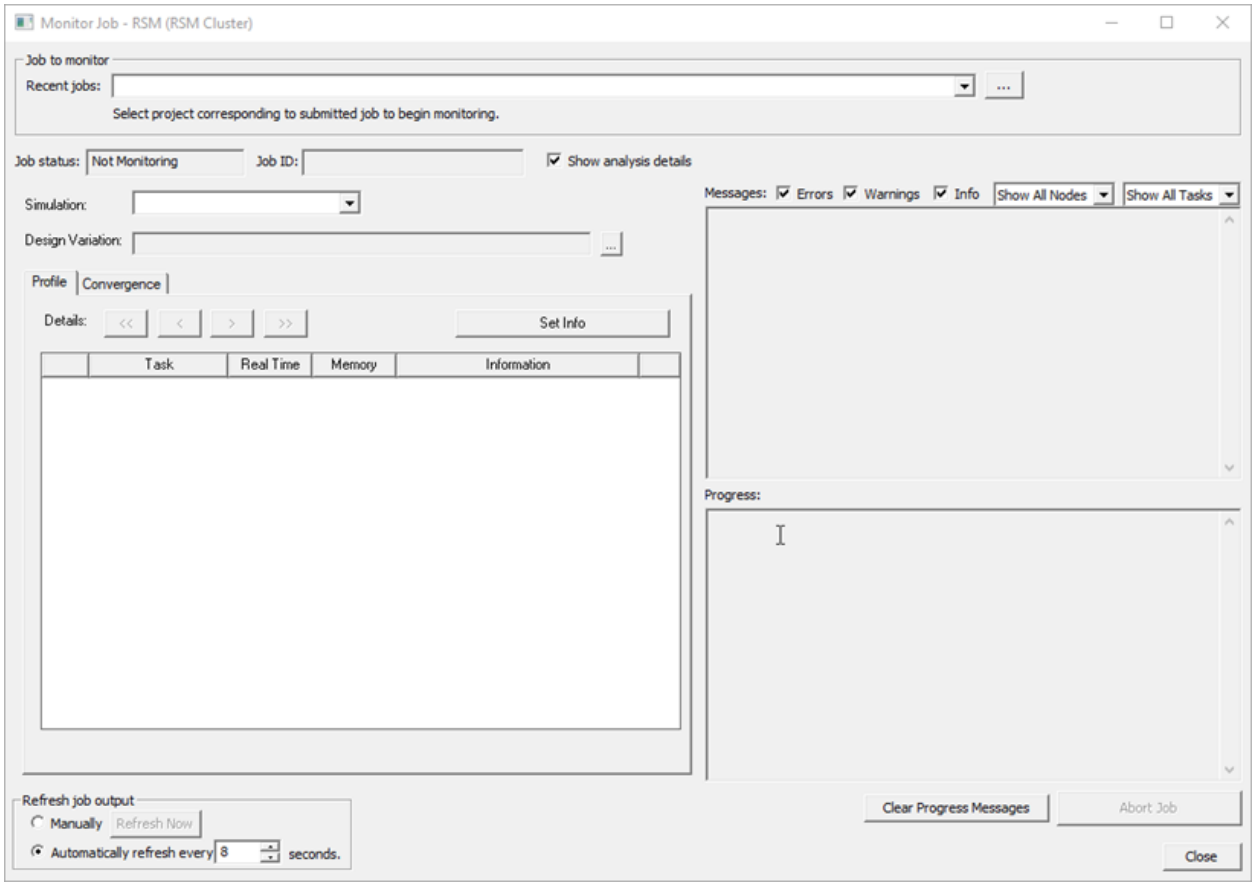
The **Monitor Job** window allows you to monitor the progress and status of jobs, including information on variations solved so far, variations currently solving, and the number of variations remaining.

To monitor jobs:

1. Access the Monitor Job window one of the following ways:
   - Click **Tools** > **Job Management** > **Monitor Jobs**.
   - Select the **Simulation** tab and click the **Monitor** icon.
   - From a Command window, use the -showmonitorjobs command.

   The **Monitor Job** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



> **Note:**
>
> The window may look slightly different, depending on your selected scheduler and design type.

The **Monitor Job** window contains the following areas:

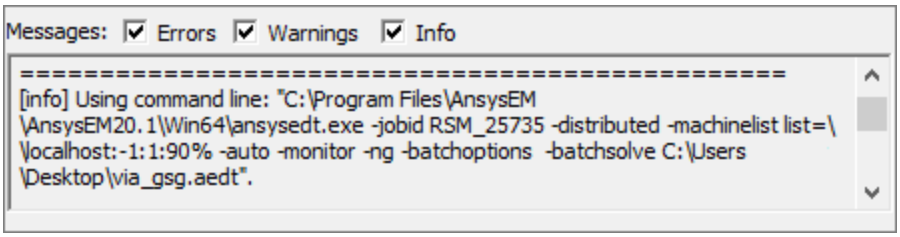
- **Job to Monitor** – Allows you to select either a recent job, or a project containing the job you want to monitor. You can select an archive.
- **Job Status** – The current job status. The normal progression is: Starting Monitoring, Queued, Running, Shutting Down, Completed. A status of Unknown may indicate a connection problem.
- **Job ID** – Identified by the scheduler prefix and job number.
- **Simulation** – Drop-down menu that allows you to select an individual simulation setup.
- **Design Variation** – Click the ellipses button (**...**) to select or deselect design variations.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

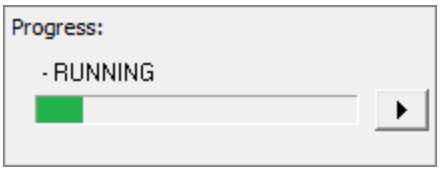
- **Profile Tab** – Displays detailed information about completed tasks, including execution time and memory usage.

Task	Real Time	CPU Time	Memory	Information
Start				Time: 10/16/2019 14:17:38; Host:: Processor: 12;
				Executing from C:\Program Files\AnsysEM\AnsysEM20.1\Win64\Q
				Performing minimal design validations
InitMesh	00:00:08	00:00:07	106 M	70131 triangles
PreProc	00:00:00	00:00:00	106 M	70131 triangles
AdaptMesh_1	00:00:01	00:00:00	107 M	78514 triangles
Solve(1p)_1	00:00:00	00:00:00	126 M	51207 unknowns
ErrorCalc_1	00:00:00	00:00:00	126 M	78514 triangles
PostProc	00:00:01	00:00:00	126 M	995 elements
Solution Process				Elapsed Time: 00:02:15
Stop				Time: 10/16/2019 15:15:30; Status: Normal Completion

- **Convergence Tab** – Displays the completed, maximum, and minimum **Number of Passes**.
- **Messages** – Displays errors, warnings, and job information. Use the check boxes to choose which of these to display.



- **Progress** – Displays progress bars when tasks are currently in progress.



The arrow button opens a menu that allows you to either **Abort** that analysis, or perform a **Clean Stop**.

- **Refresh Job Output** – Allows you to select either manual or automatic refresh for the **Monitor Job** window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

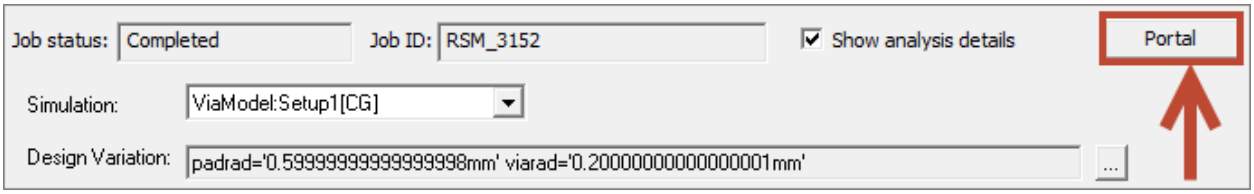
To display less information, deselect **Show analysis details**. This removes the **Simulation**, **Design Variation**, **Profile**, and **Convergence** information, instead displaying only **Messages** and **Progress**.

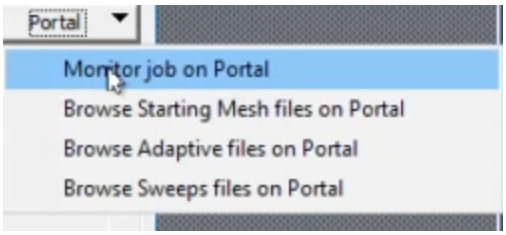
2. Click **Close** when you are done monitoring.

Monitoring Ansys Cloud Direct Jobs

For Ansys Cloud Direct submissions, the **Monitor Job** window includes two additional items:

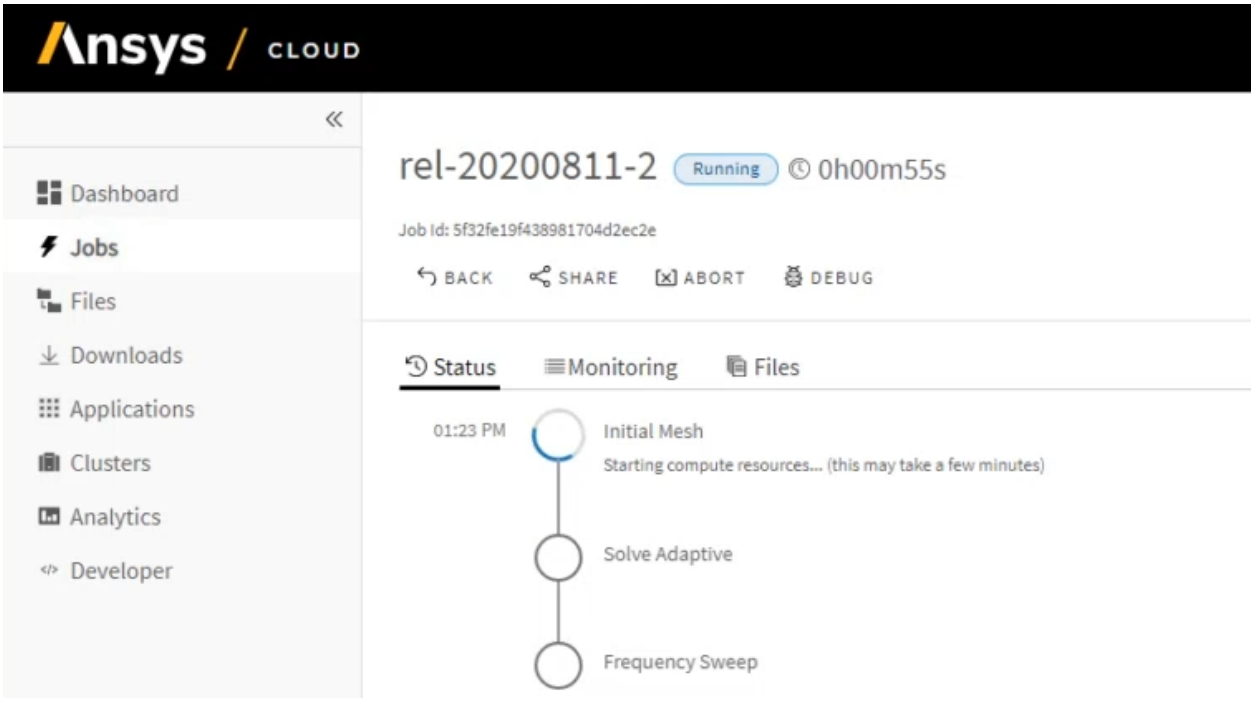
- **Portal** – link to the Ansys Cloud Direct Portal, where job details and additional monitoring information are available.



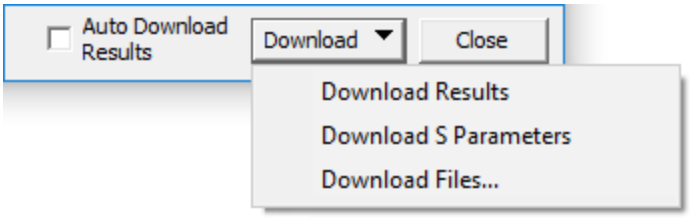


Monitor job on Portal Opens a Portal Web interface that lets you monitor an Ansys Cloud Direct job. The additional menu options for **Portal** are for multi-step submissions, opening the Portal Web interface directly to folders with Starting Mesh Files, Adaptive Files, or Sweeps files.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

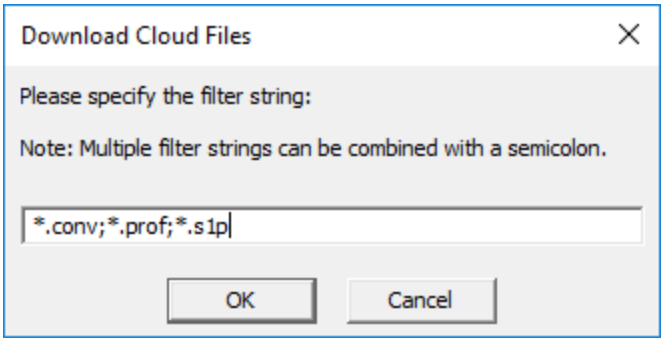


- **Download** – button that allows you to download the results, s-parameters, or specified files. These are saved in a folder with same name as the job ID inside the `/<project-name>.aedtdownload` folder (or `/<project-name>.aedtzdownload` folder, if the submission was based on an archive). You can also select the **Auto Download Results** check box to have the results downloaded to this location automatically.



If you choose to **Download Files**, the **Download Cloud Files** dialog box appears:

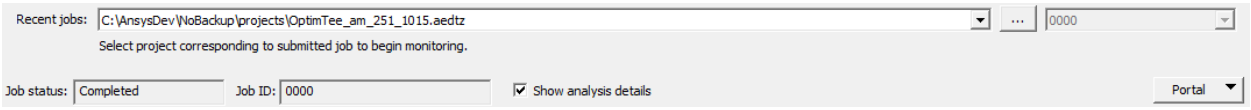
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



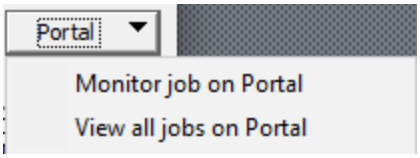
Specify the types of files you want to download (separated by semicolons) and click **OK**.

Monitoring Ansys Cloud Burst Jobs

When you submit a job to Ansys Cloud, the job status is shown in the **Monitor Jobs** window. The Job ID shown here is a short numeric identifier used to distinguish multiple jobs for the same project. Use the drop-down list at the upper right to select a different job for the same project. **The Monitor Job** window includes two additional items, **Portal**, and **Download**.



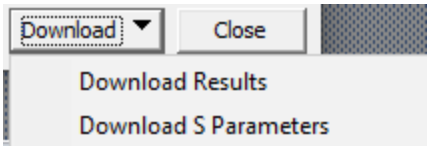
The **Portal** drop-down button provides a link to the Ansys Portal, where job details and additional monitoring information are available. For more information, see the Ansys Portal Guide.



Monitor job on Portal opens a job details view for the current job in Ansys Portal. **View all jobs on Portal** opens a job list view in Ansys Portal, enabling you to select a job to monitor.

Download allows you to download the results or s-parameters. These are saved in a folder with same name as the job ID inside the /<*project-name*>.`aedtdownload` folder (or /<*project-name*>.`aedtzdownload` folder, if the submission was based on an archive). You can also select the **Auto Download Results** check box to have the results downloaded to this location automatically.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

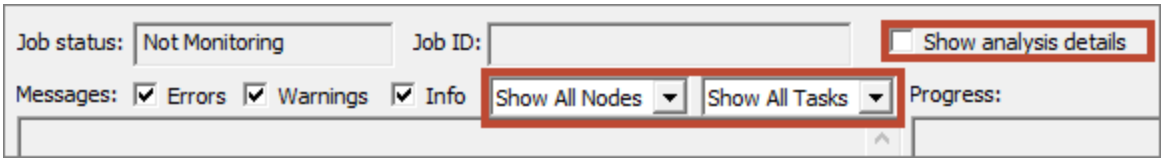


Monitoring Large Scale DSO Jobs

For Large Scale DSO submissions, the Monitor Job window includes the following items:

- **Show Messages in Node Tree** – Instead of viewing job details, you can select this option to view nodes and tasks in a tree format.

- Drop-down boxes allow you to filter which Nodes and Tasks to display in the tree.



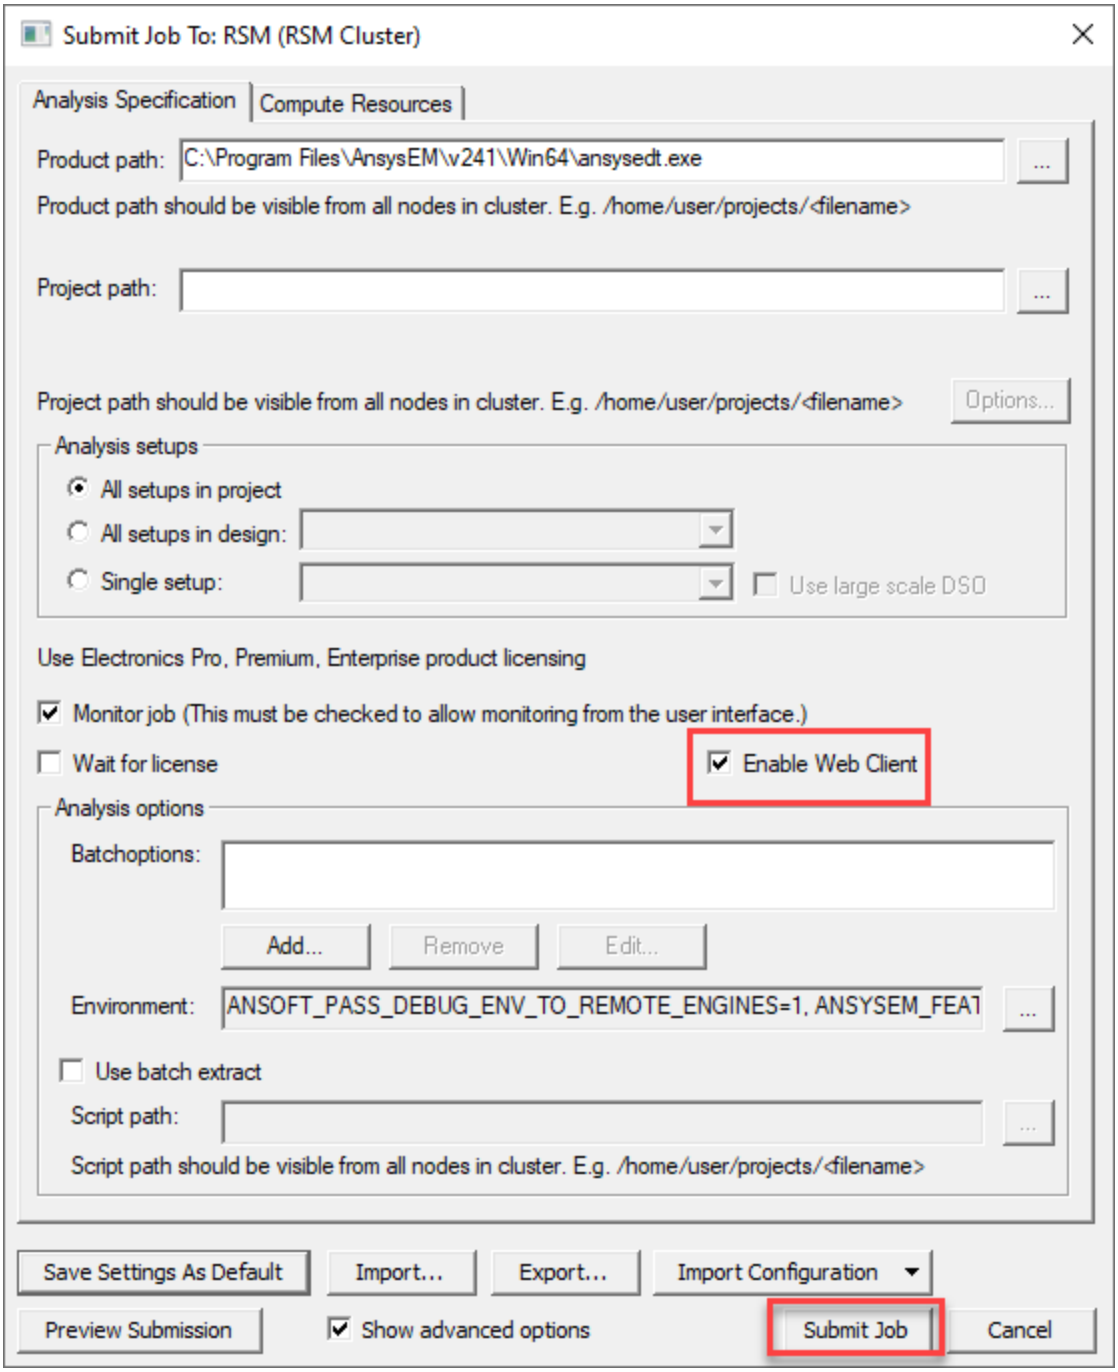
To leave this mode, select **Show analysis details**.

Web Client for Batch Solve Monitoring and Reporting

There is a Beta Option to use a Web client for batch solve monitoring and reporting. If you set the Beta Option f under General for Enable Web Client for Monitoring, you will have access to the feature.

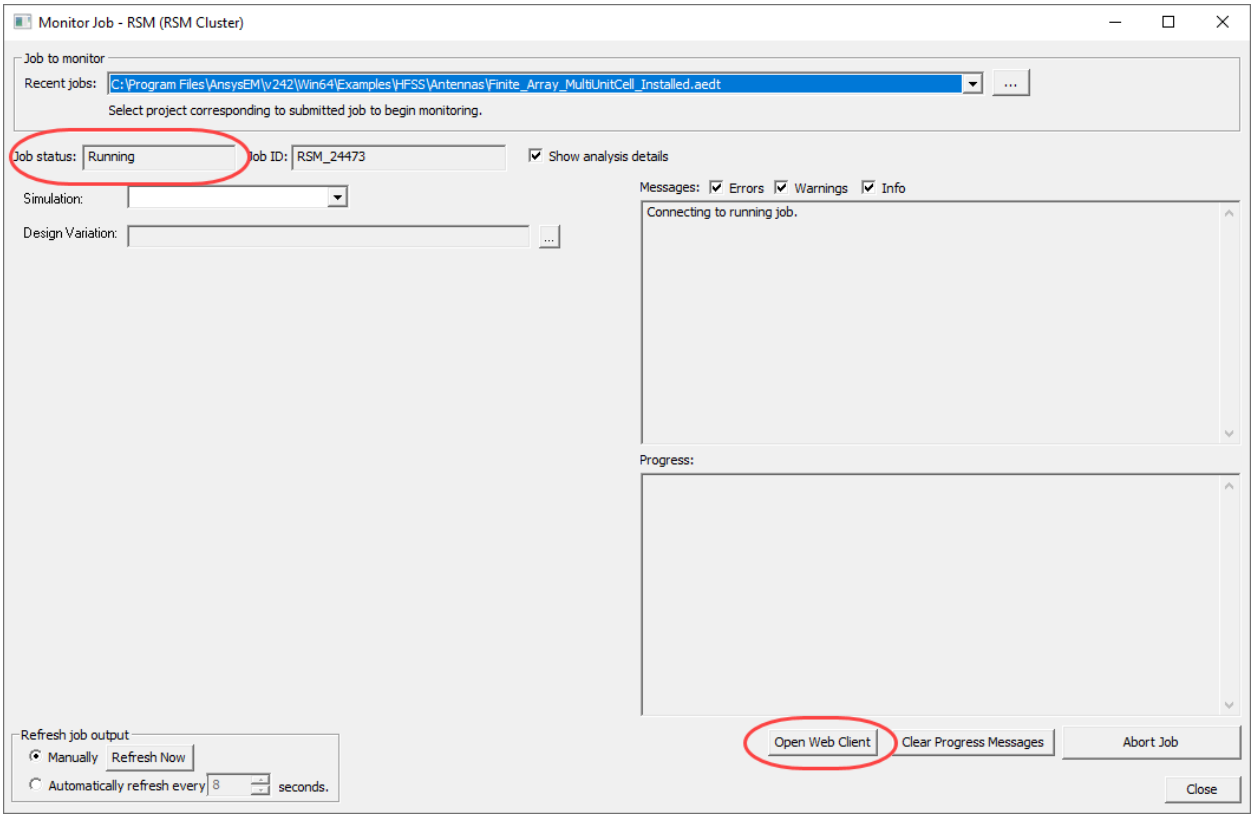
After you have selected the scheduler to use, when you access the **Submit Job To:** dialog, you well see Enable Web Client checked.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



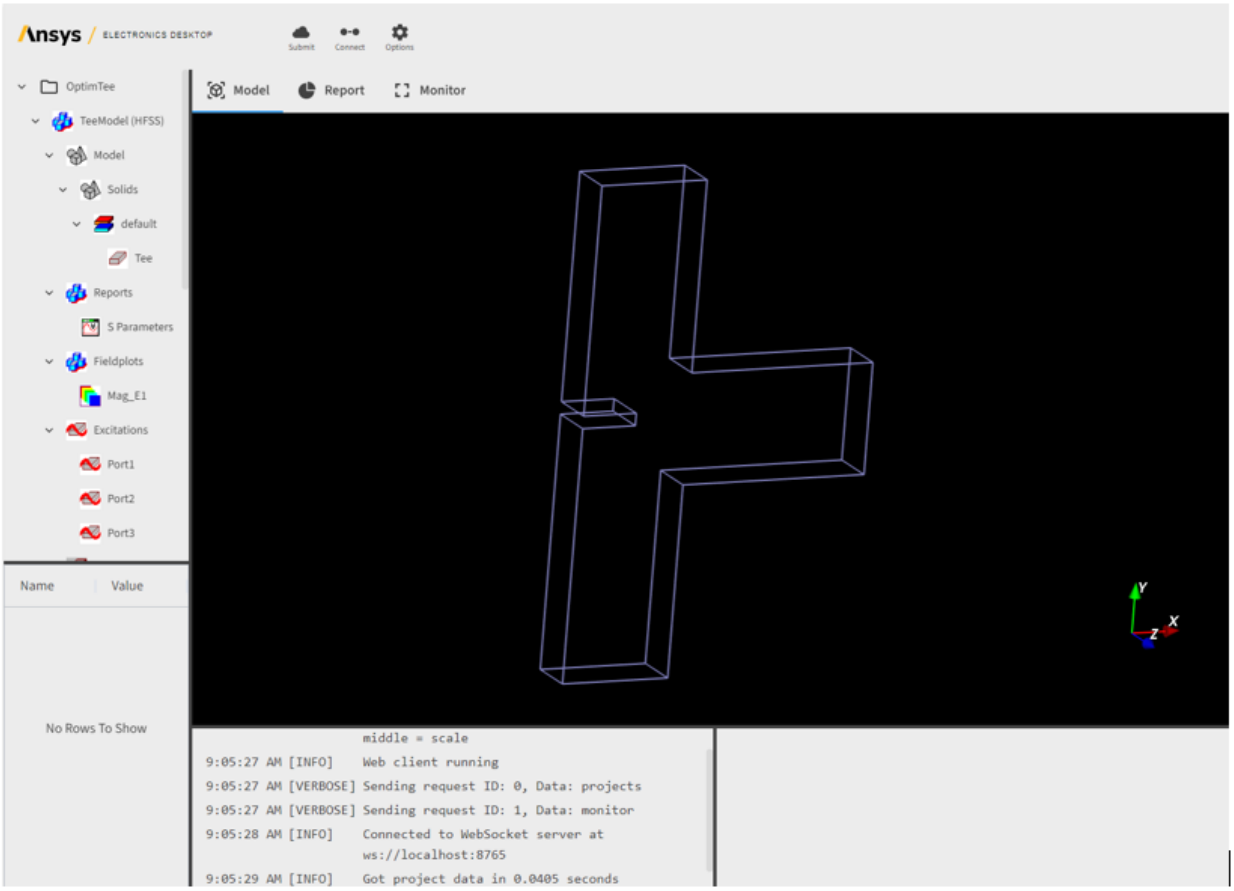
After specifying the project path and setting other parameters, you can then select **Submit Job**. This opens the Monitor Job dialog for your scheduler. Once the **Job Status** changes to Running, press **Open Web Client**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



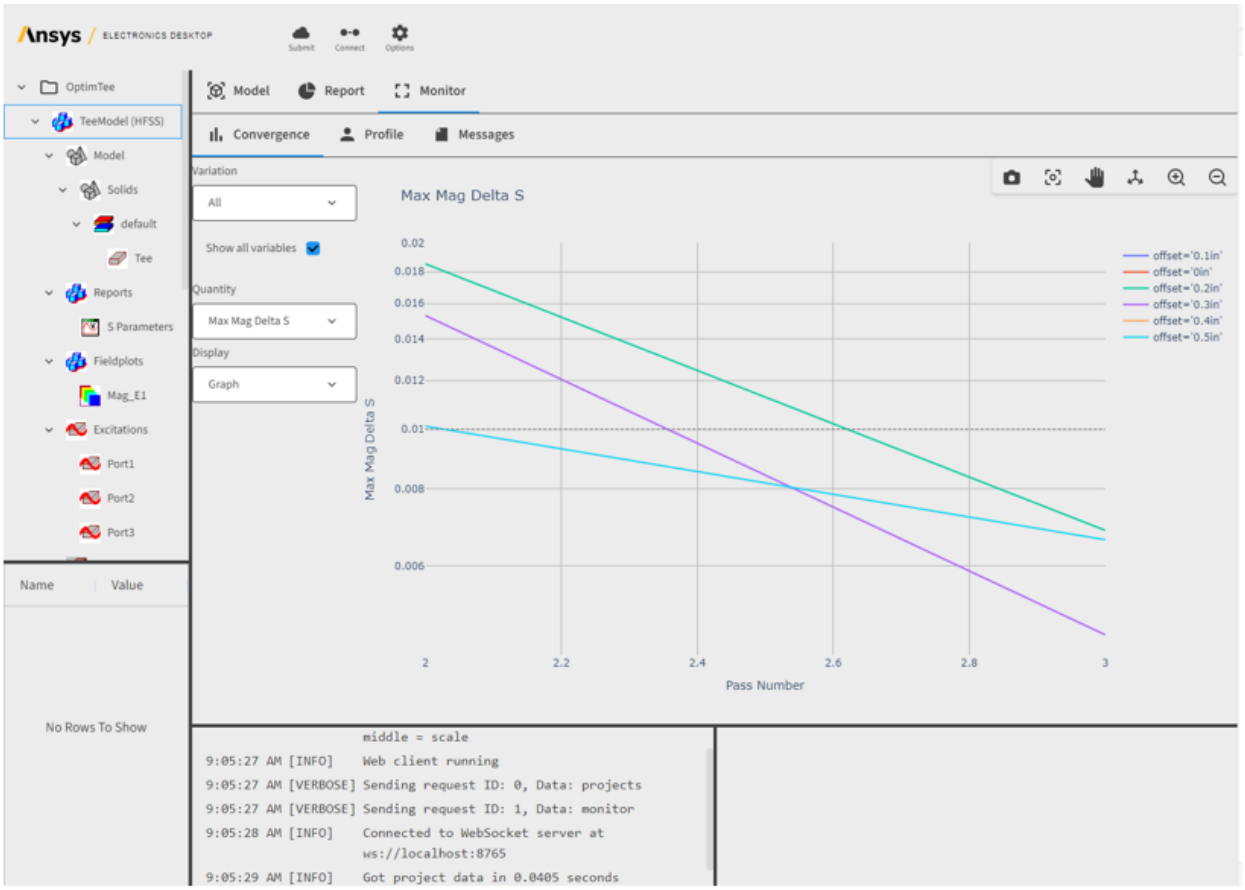
Click **Open Web Client** to open the Web Client in your default browser.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



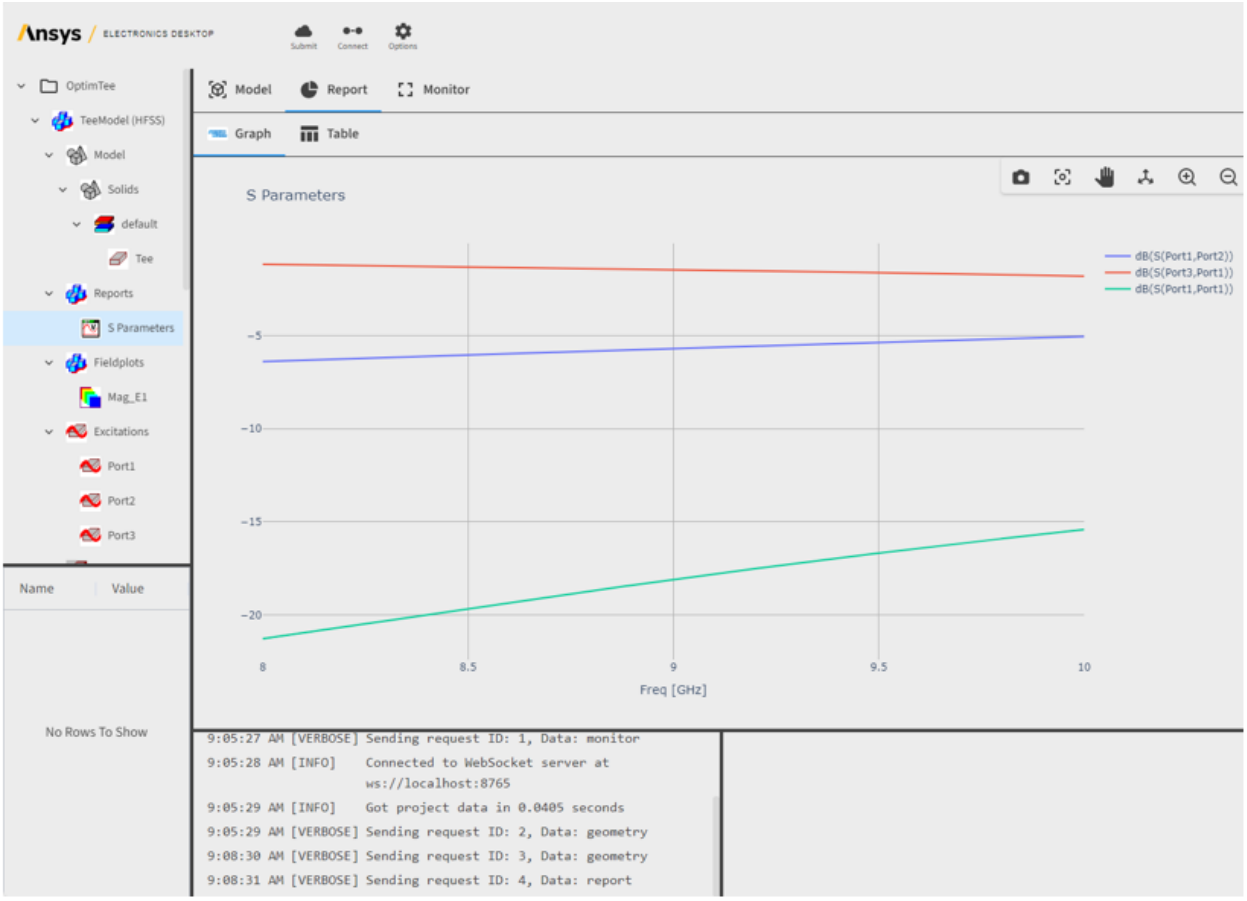
Switch to the **Monitor** tab to gain access to the subtabs for Convergence, Profile and Messages.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



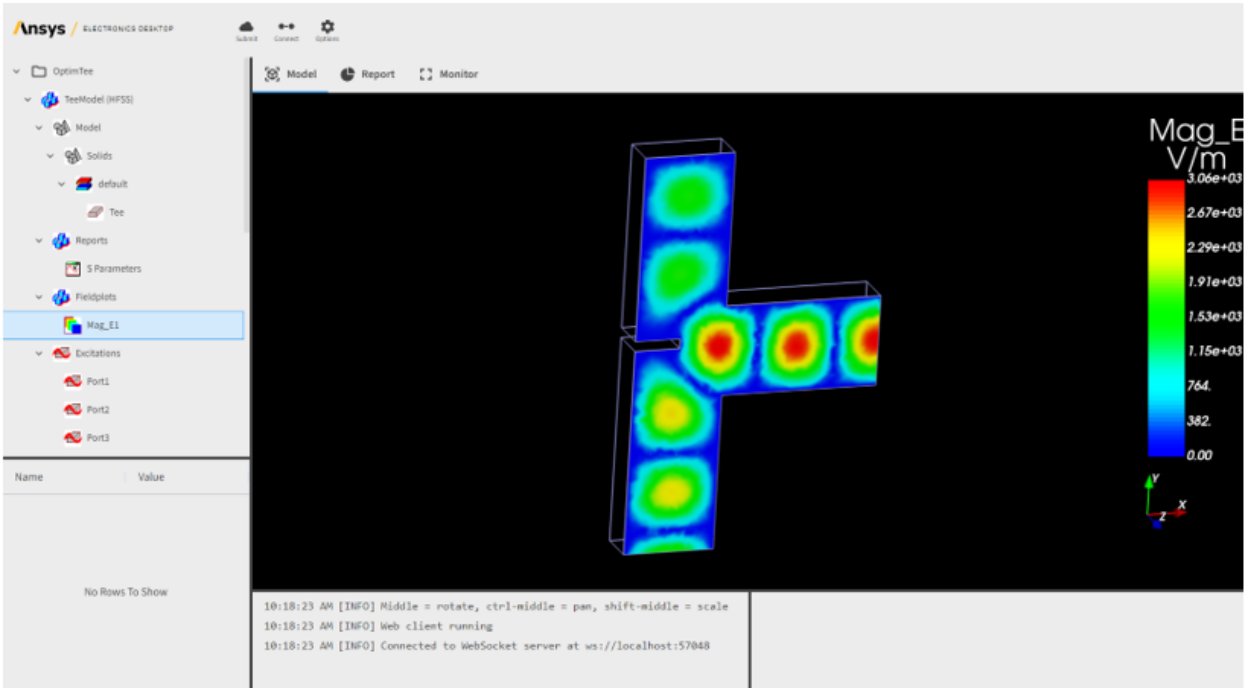
Select a Report in the **Project Tree** to view it.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Select a Field Plot in the **Project Tree** to view it.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Aborting an Analysis

To end the solution process before it is complete:

- Right-click In the **Progress** window and click **Abort** or click on drop-down button next to progress bar(s).

  The solver ends the analysis immediately.

The solver ends the analysis immediately. The data for the currently running adaptive pass, frequency point, time step, or variation is lost. Previously completed solutions may or may not be retained (depending on what process was interrupted by the **Abort** command). If you want to ensure that the results of all completed solutions are saved, use **Clean Stop** instead of **Abort**.

To abort the solution process after the current adaptive pass or solved frequency point is complete:

- Right-click the **Progress** window, or click on drop-down button next to progress bar(s) and click **Clean Stop** on the shortcut menu.

  The analysis ends after the currently running adaptive pass, frequency point, time step, or variation has been solved. Solutions completed before the stop request are retained.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you request a clean stop during the third adaptive pass, the solution for the third pass will be available once the third pass has finished solving, but the fourth pass will not run.

Ansys EM Application as an LSF Job

If you have an Ansys EM application running as an LSF job, you can use the command "bkill -s SIGTERM *jobid*" to terminate that application. Here *jobid* is the LSF job id. The response will be "Job <jobid> is being signaled". The response is the same whether the job is actually being signaled or not.

In cases where the SIGTERM parameter is ignored, the command kills the LSF job, but does not clean the lock files, and other files may not be in a consistent state.

Linux

For Linux, you can use TERM commands. Sigterm handling is done in the Desktop library. You can abort a running batchsolve by sending a TERM signal to hfss.exe.

GPU Acceleration

Several Ansys Electronics Desktop solvers can benefit from GPU acceleration:

- HFSS frequency domain, transient, and SBR+ solvers.
- HFSS 3D Layout for matrix solves.
- Maxwell 3D eddy current matrix solves.
- EMIT

License Options

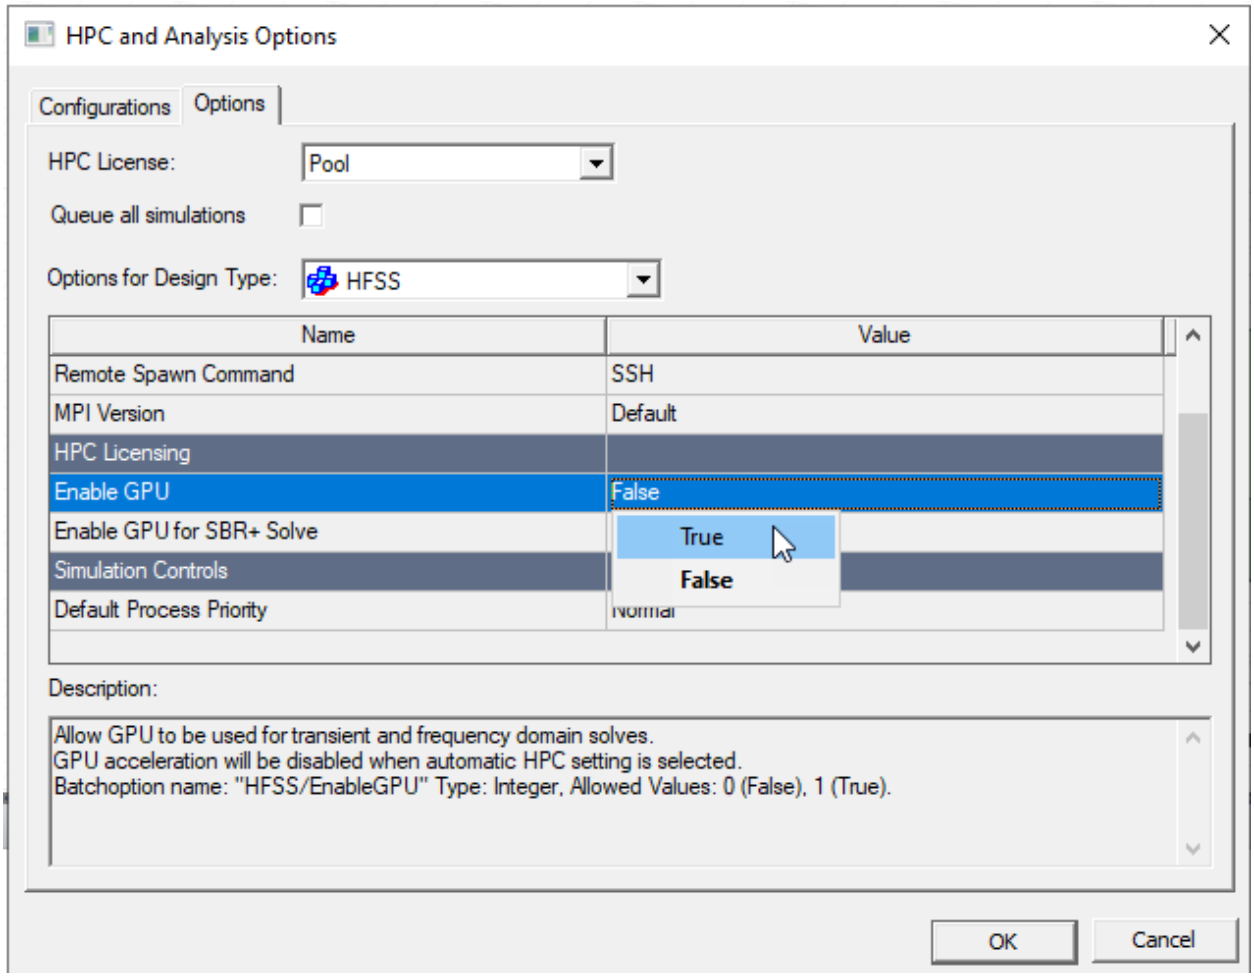
HPC licensing enables the use of cores and GPUs to accelerate simulations. In general, each core requires one unit of HPC, while each GPU requires eight units. The selected HPC license type determines which license is used, and how units of HPC are converted to license counts. For details, see the discussion of licensing under Options in Setting HPC and Analysis Options.

If the number of simulation jobs exceeds the number of GPUs in a system, the excessive jobs will fall back to CPUs and will be accelerated by up to 8 CPU cores for each job.

Enable/Disable GPU Acceleration from the Ansys Electronics Desktop Solver User Interface

To turn on or off GPU acceleration for supported solvers, click **Tools** > **Options** > **HPC and Analysis Options** and select the **Options** tab. Click on the value of Enable GPU and toggle it to either True or False. HFSS includes a separate toggle for Enable GPU for SBR+ Solve.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



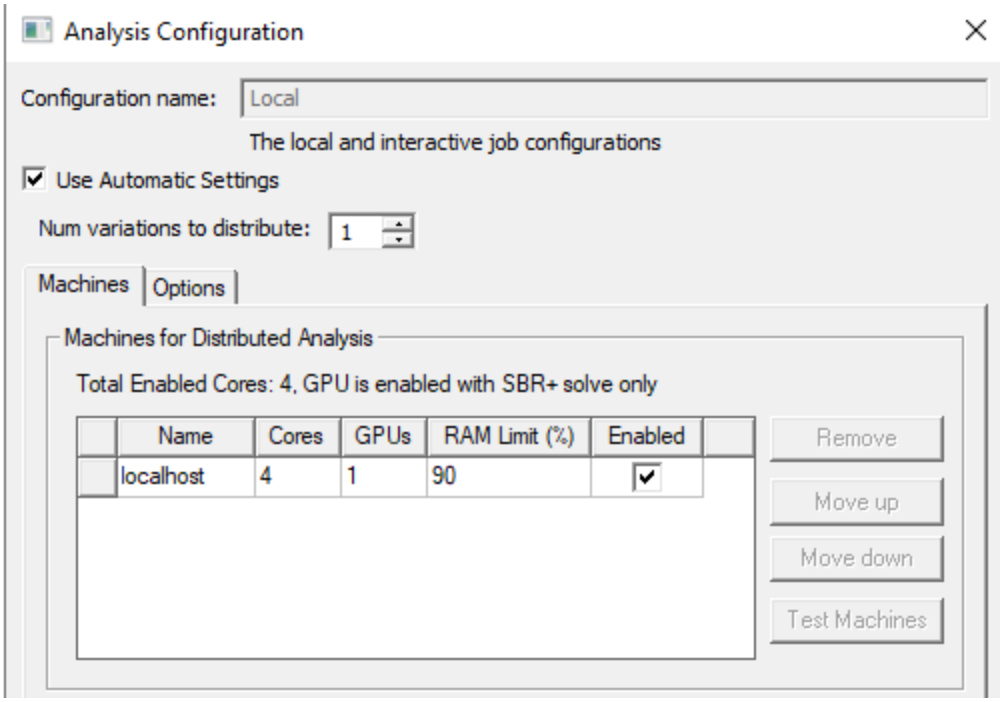
Enabling GPU-Distributed

There are two steps for setting up GPU-distributed.

1. Go to **Tools** > **Options** > **HPC and Analysis Options** and click **Edit** in the dialog box, or select the **Simulation** tab of the ribbon, and click **Analysis Config** to edit Analysis Configurations.

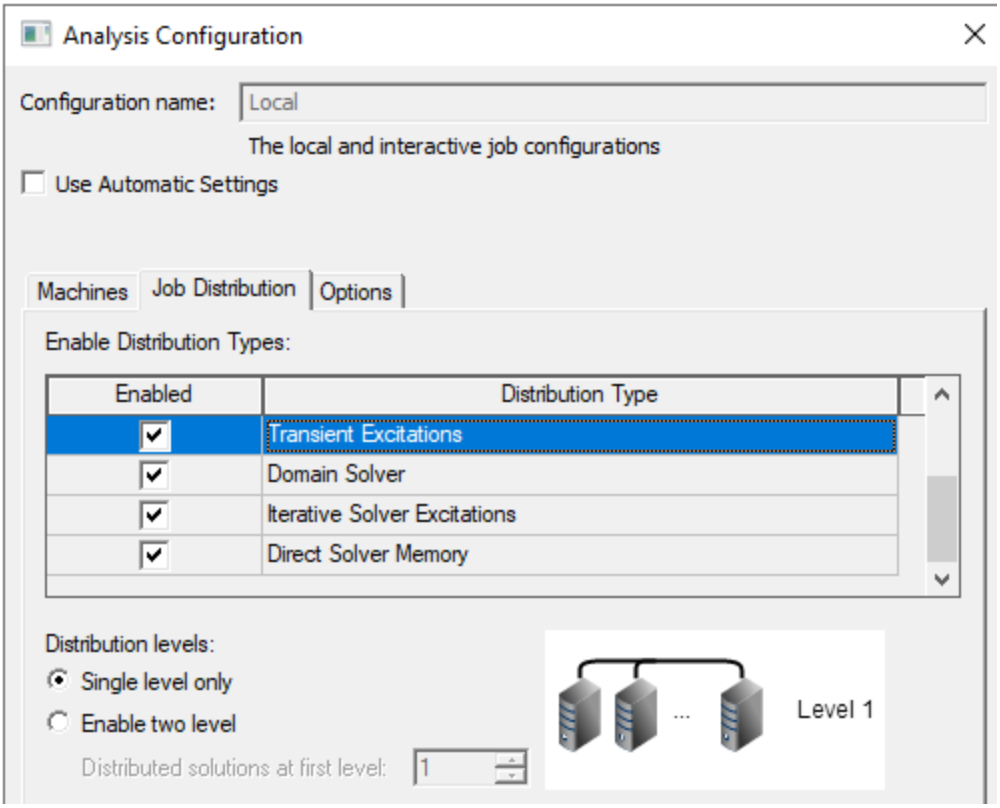
   If Use Automatic Settings is checked and the solver is HFSS, a message notes that only SBR+ has GPU Enabled.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Uncheck **Use Automatic Settings**, select the **Job DIstribution** tab, and select the appropriate Distribution Types for the solver. For example, GPU-DSO in HFSS Transient can be used either for parametric sweep (Variations) or Transient Network analysis of multiport networks (Transient Excitations).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

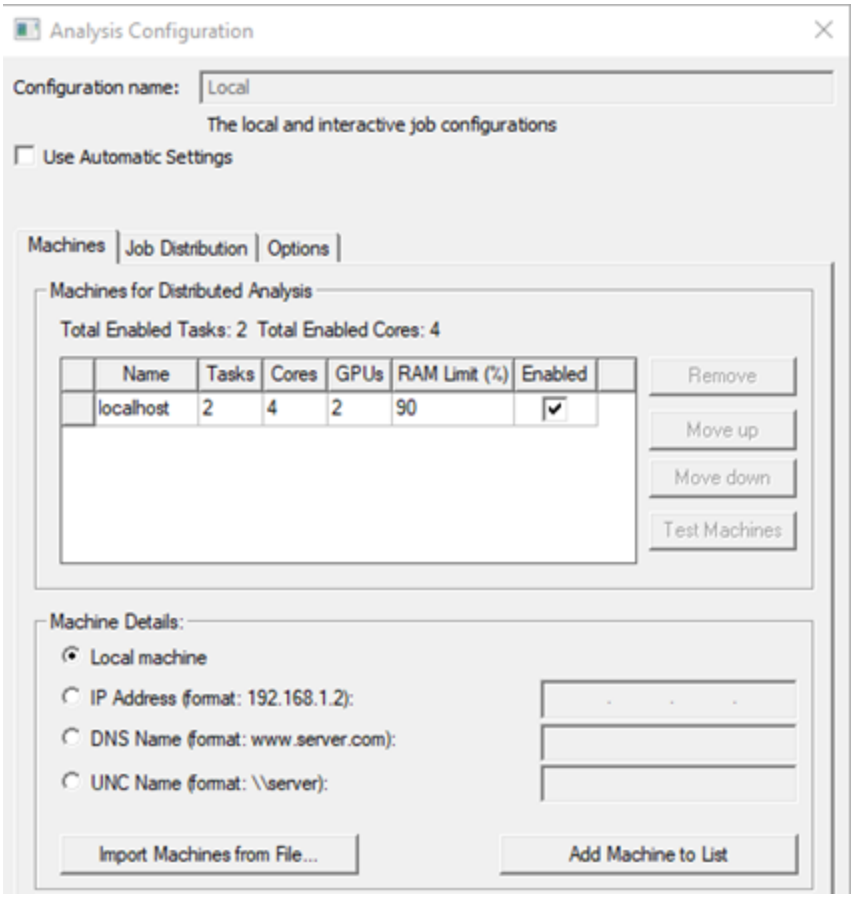


2. Set up the Machines for GPU-Distributed.

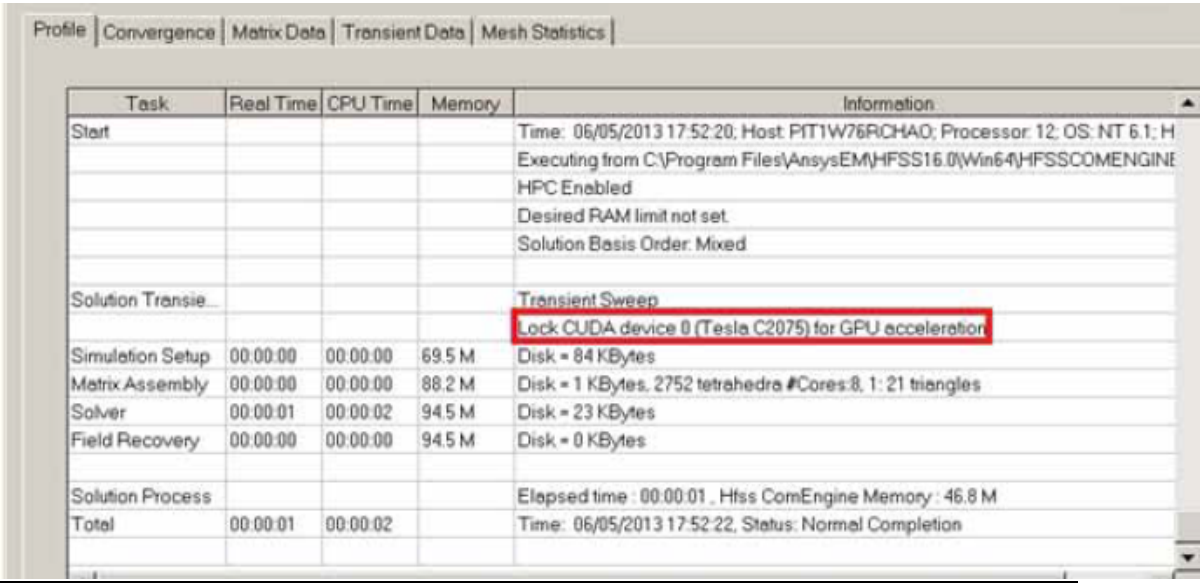
   In the following figure, two simulation jobs are allowed to run on the local host, or up to two GPUs can be used for acceleration depending on the availability of licenses and GPU

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

cards.

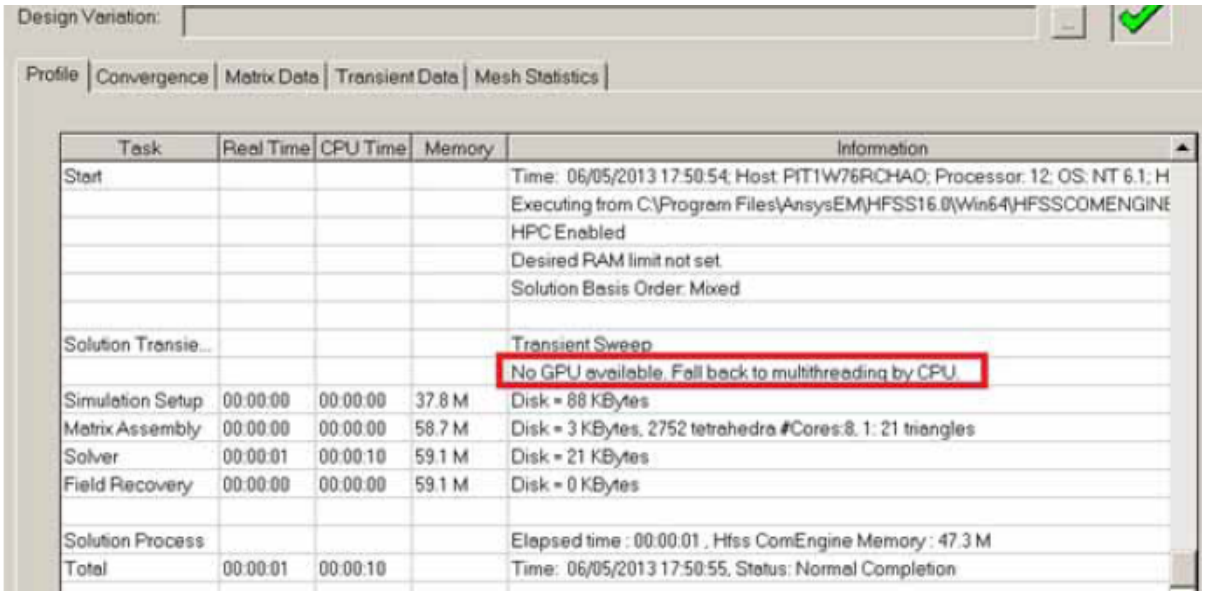


Whether GPU is used for acceleration can be checked by viewing the **Solutions** dialog box, **Profile** tab. If a GPU is successfully locked for the use by an hf3d process, the profile will show the GPU's CUDA device ID and its name.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Otherwise, the profile will indicate the fallback to CPUs. More information about why GPUs are not available for acceleration can be found in the log file. See further discussion under Step 5 of Setting HPC and Analysis Options.



Enable/Disable GPU Acceleration from the Command Line

GPU acceleration can be toggled by the `-batchoptions` command line argument:

`EnableGPU=[0/1].`

For example, the following command turns on GPU acceleration.

```
ansysedt.exe -batchsolve -batchoptions "'EnableGPU'=1"
projectname.aedt
```

Integration with Ansys Remote Simulation Management (RSM)

Ansys Electromagnetics supports its own Remote Simulation Management (RSM) software along with other High Performance Computing (HPC) software management programs (see High Performance Computing (HPC) Integration).

When do you need RSM?

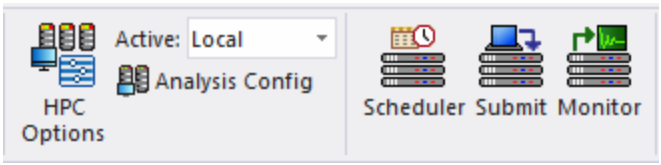
RSM is generally required if you want to run remote or distributed simulations. However, if you have a separate scheduling system that Ansys Electromagnetics supports, and you plan to run batchsolve simulations only, you may not need to install RSM. For details of installation and configuration of RSM, see the *Ansys Electromagnetics Installation Guides*.

Job Management UI for RSM

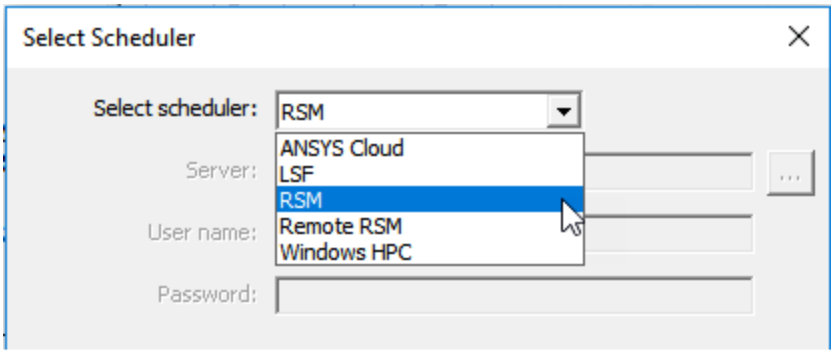
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can use the Job Management UI to submit batch jobs to RSM. The Job Management UI is accessed by running Ansys Electronics Desktop on the designated 'Postprocessing node' of the cluster. The Desktop provides UI commands for Scheduler selection, Job submission and Job monitoring/control. You access the Scheduler User Interface by clicking **Tools** > **Job Management** > **Select Scheduler...**

You can also select the **Simulation** tab of the ribbon, and click the **Scheduler** icon.



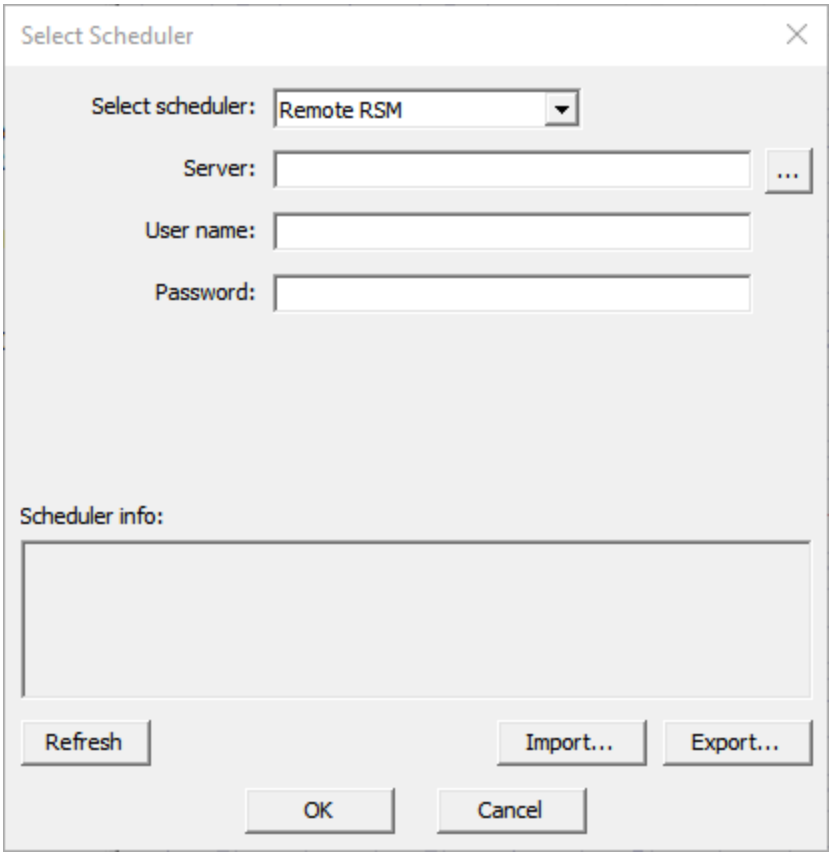
This displays the selection dialog box. The **Select scheduler** drop-down menu lists potential schedulers (which can include RSM, LSF, Windows HPC, or SGE, depending on the environment).



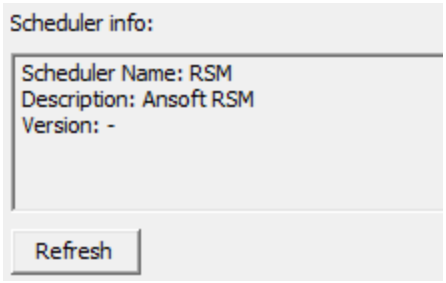
If you select a scheduler that is not supported in your environment, you receive a warning.

If you select Remote RSM and your environment has been configured , you can select a computer, user name, and password.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



After selecting a scheduler, click **Refresh** to display information for that scheduler.



Once you have selected a scheduler supported in your environment, you can go through the following steps to submit a batch job.

1. Set up and prepare model on local workstation.
2. Copy the input project (or folder, if the project references external files) from a personal workstation to a shared-drive on cluster (say project is copied to /home/projects/spool/test.adsn).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- In the RSM environment, you are required to specify a machine-list. See: HPC and Analysis Options. For example, say the machine-list is: 3 cores from 'm1' and 3 cores from 'm2', for a total of 6 engines. You select the list on the **Compute Resources** tab of the **Submit Job to RSM** window, as described below.

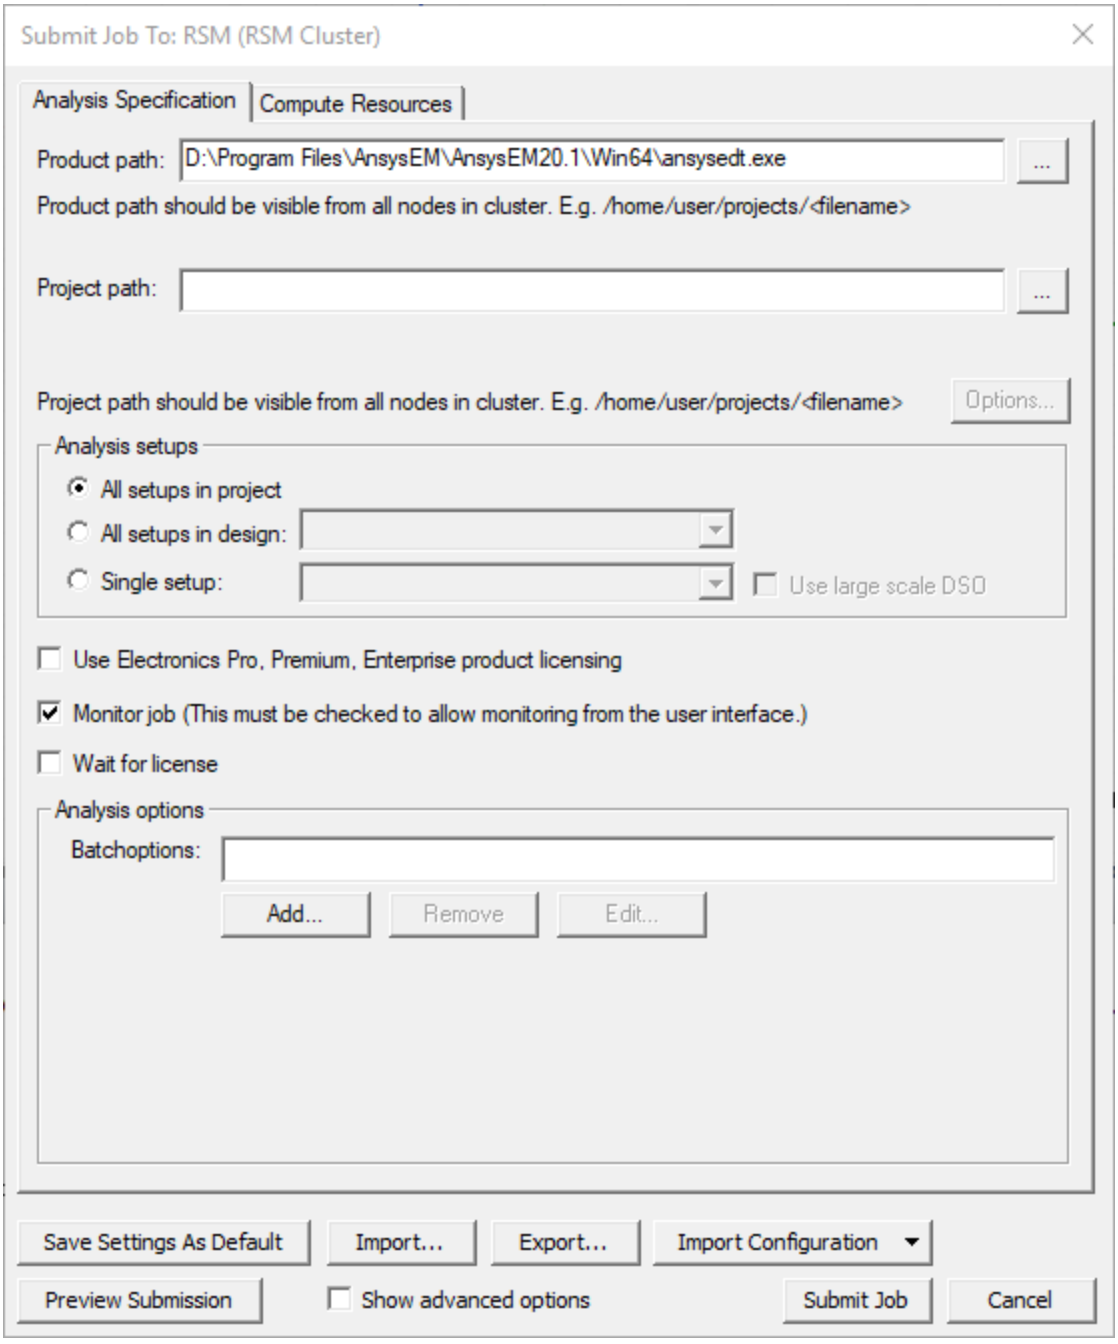
3. Open a remote-desktop session (or equivalent such as vnc session) on the node corresponding to the first machine of job's machine-list, 'm1' in this case. Launch Desktop graphically on 'm1'.
4. After setting the job submission node, select **Tools** > **Job Management** > **Submit Job...** or **Project** > **Submit Job...** or **[ProductName]** > **Submit Job...** to open the **Submit Job To:** window. You can also access **Submit Job** from the shortcut menus for the Project Name, Design name, Analysis Setup, or Optimetrics Setup.

   The **Submit Job To:** window contains two tabs:

   - **Analysis Specification**– specify the Product path, Project name, the setups, and analysis options such as batchoptions, or, for advanced users, Environment variables. If you select the Analysis or Optimetrics setup, the Analysis Specification is pre-populated.
   - **Compute Resources** – specify the amount of compute resources and how to select specific resources from those available, and automatic settings, if supported by the design types.

   The standard Job Submission window displays.

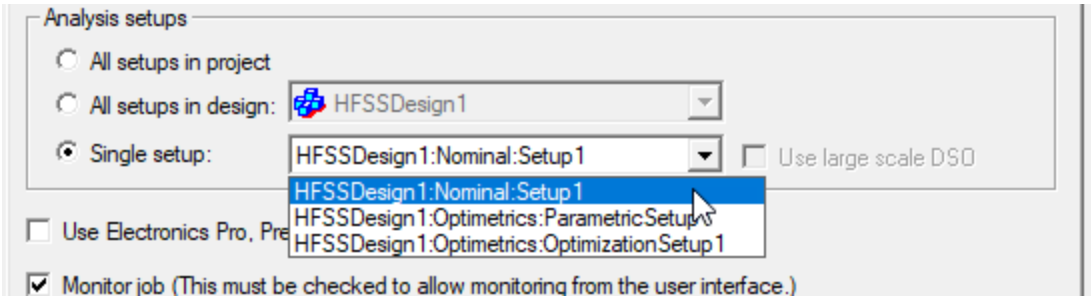
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. Use the ellipsis button [**...**] to open a browser to select the project. The project can be an archive.
6. In the **Analysis setups** area, you can select radio buttons for **All setups in the project**, **All setups in the design**, or a **single setup**. For instance, the OptimTee example includes setups for Nominal, Parametric, and Optimization. If you accessed the **Submit Job** window from the right-click menus for Setup or Optimetrics Setup, this field can be

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

pre-populated.

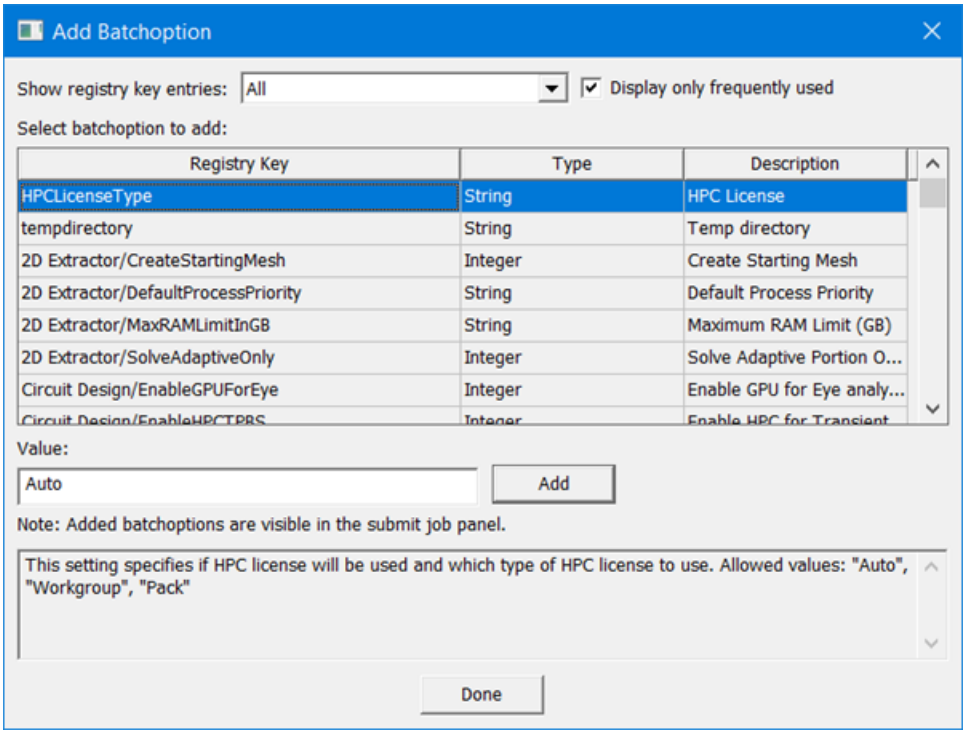


For Parametric setups, you have the option to select **Use Large Scale DSO**. For details on how and when you use this feature, see Job Management Interface for Large Scale DSO.

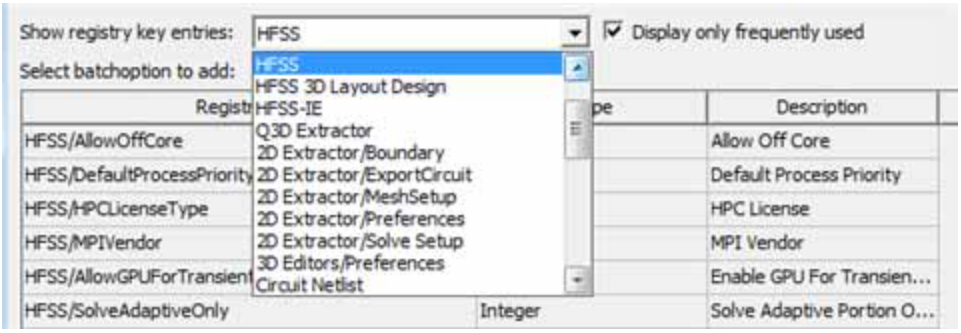
7. The Analysis options include check boxes for Monitoring the job, whether to wait for a license, and a field for adding Batchoptions via a graphical interface, or as text.
    - If you intend to monitor the job through a user interface, you must select **Monitor job**. You can then monitor this job through the **Tools** > **Job Management** > **Monitor Jobs...** command or by checking the dialog that opens when you submit the job.
    - The Batchoptions field allows you to add additional -batchoptions parameters, either as text, or by using a dialog with selection menus. Click the **Add** button to

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

view the **Add Batchoption** dialog box.



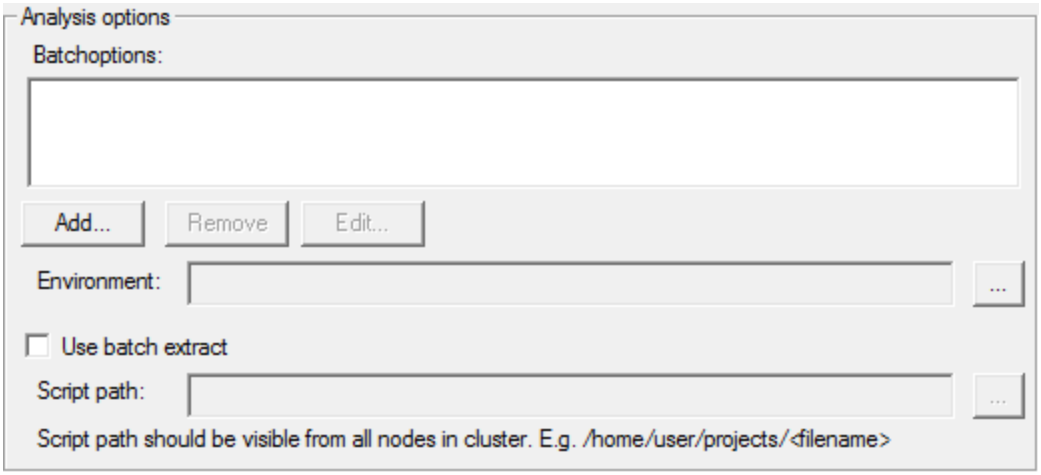
The **Show registry key entries** field lets you filter the entries displayed, by means of drop-down menu selection, and a check box to **Display only frequently used entries**.



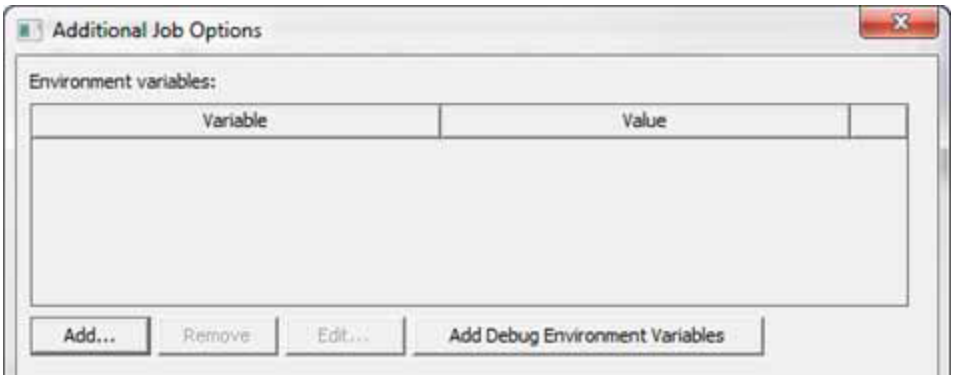
- When you have selected a batchoption, you can type the value in the field, and click the **Add** button to add the option to the batchcommand.
- In the **Submit Job To:** window, you can enable **Show advanced options** to display additional fields for environment variables, and whether to **Use batch**

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

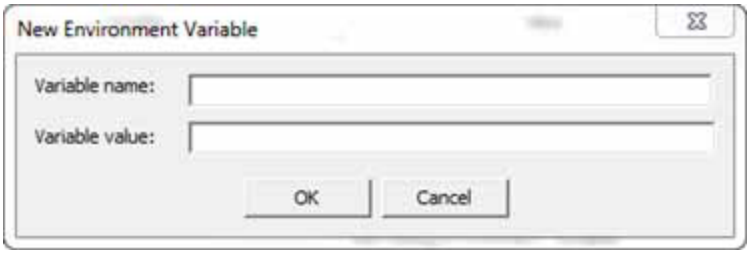
extract.



The Environment field is for environment variables, for instance, for debugging features or other variable controlled features. Click the ellipsis [**...**] button to open a dialog box for **Additional Job Options**.

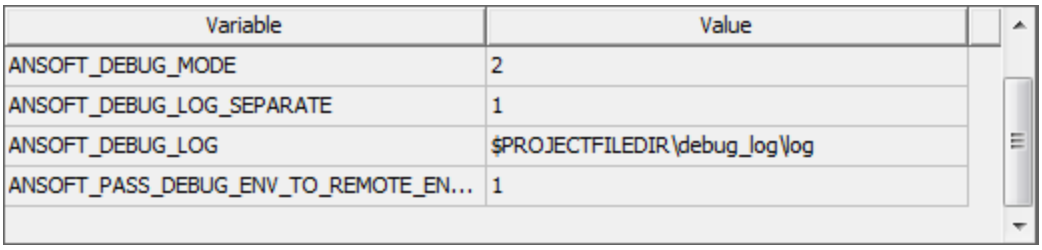


The **Add...** button opens a **New Environment Variable** dialog box in which you can include a variable name and value.



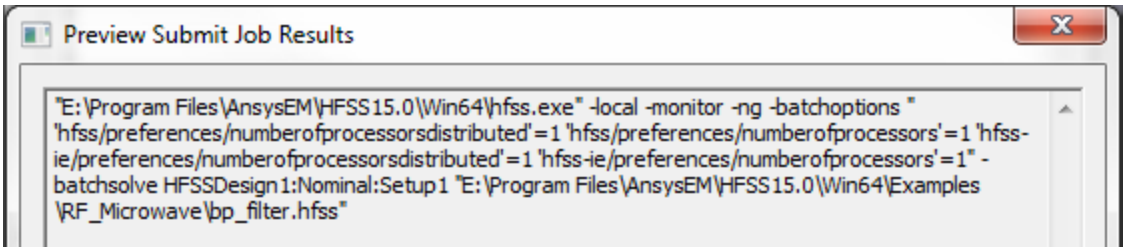
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Clicking the **Add Debug Environment Variables** button automatically adds a set of debug variables. This can be useful in working with Ansys Application Engineering support.



Selecting a variable in the dialog enables the **Remove** and **Edit** buttons. The **Edit** button opens a dialog box where you can change the variable and value.

8. To see the command-line to be submitted to the scheduler, click **Preview Submission.** This opens a dialog box showing the command to be sent to the scheduler.

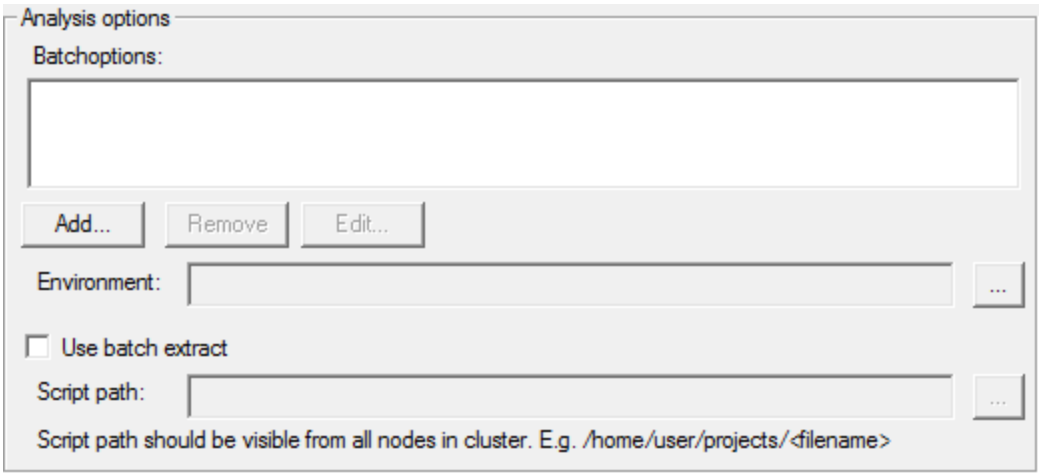


The text can be copied to the clipboard, if desired.

Use Batch Extract for RSM

Selecting **Show advanced options for RSM** also shows the Use batch extract fields.

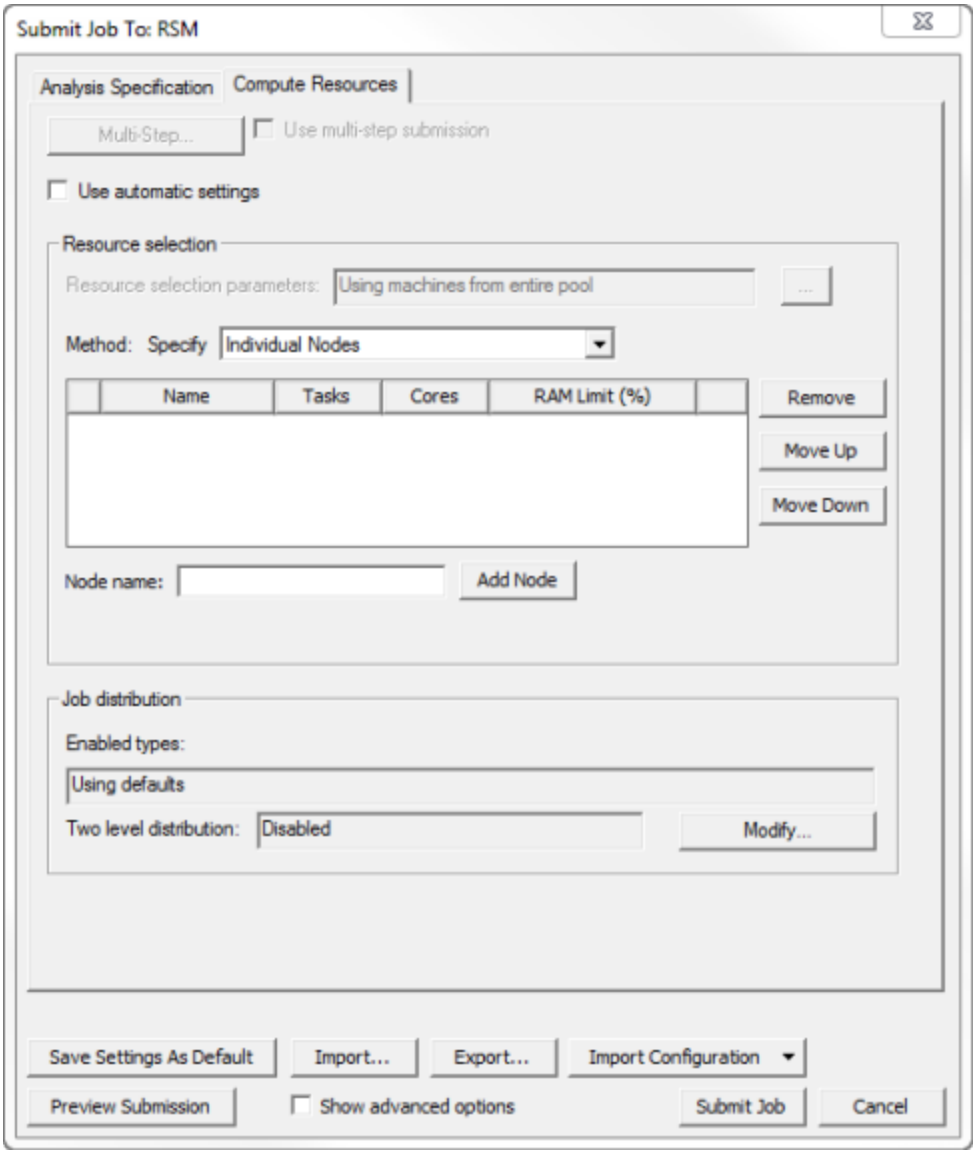
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



See the discussion on Running Ansys Electronics Desktop from a Command line for a discussion of the solve information available through batch extract.

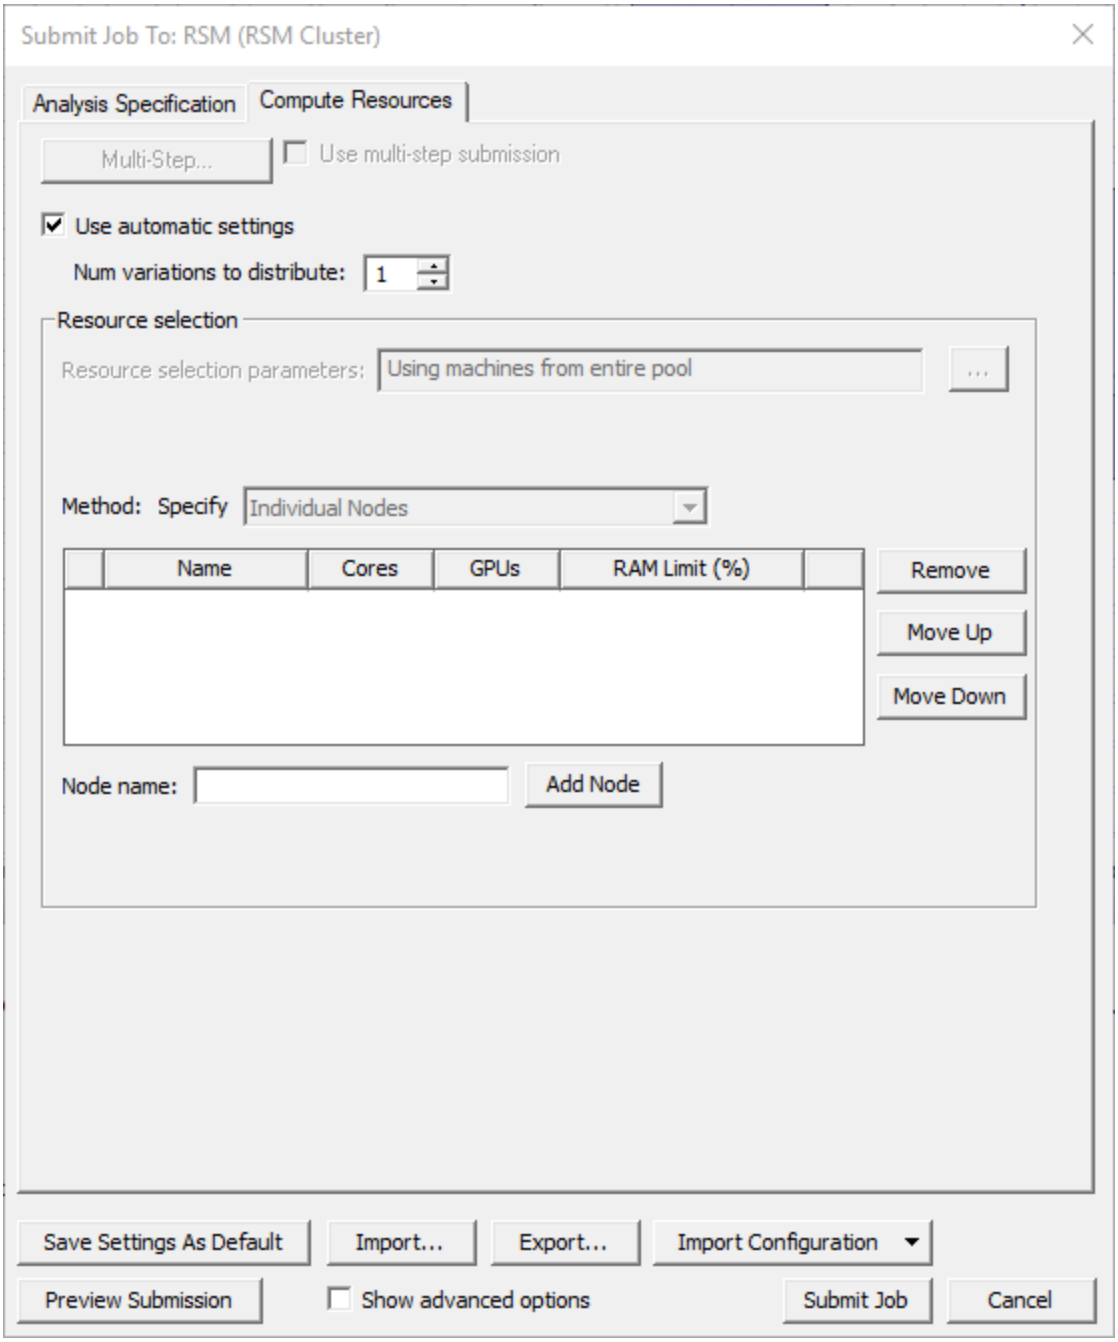
9. The **Compute Resources** tab of the **Submit Job to: RSM** window displays other parameters. Depending on the resources available for a scheduler environment, some of the fields may be disabled.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



With **Use automatic settings** selected, the **Job distribution field** is removed and the **Use automatic settings** check box and **Num variations to distribute** field appear.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



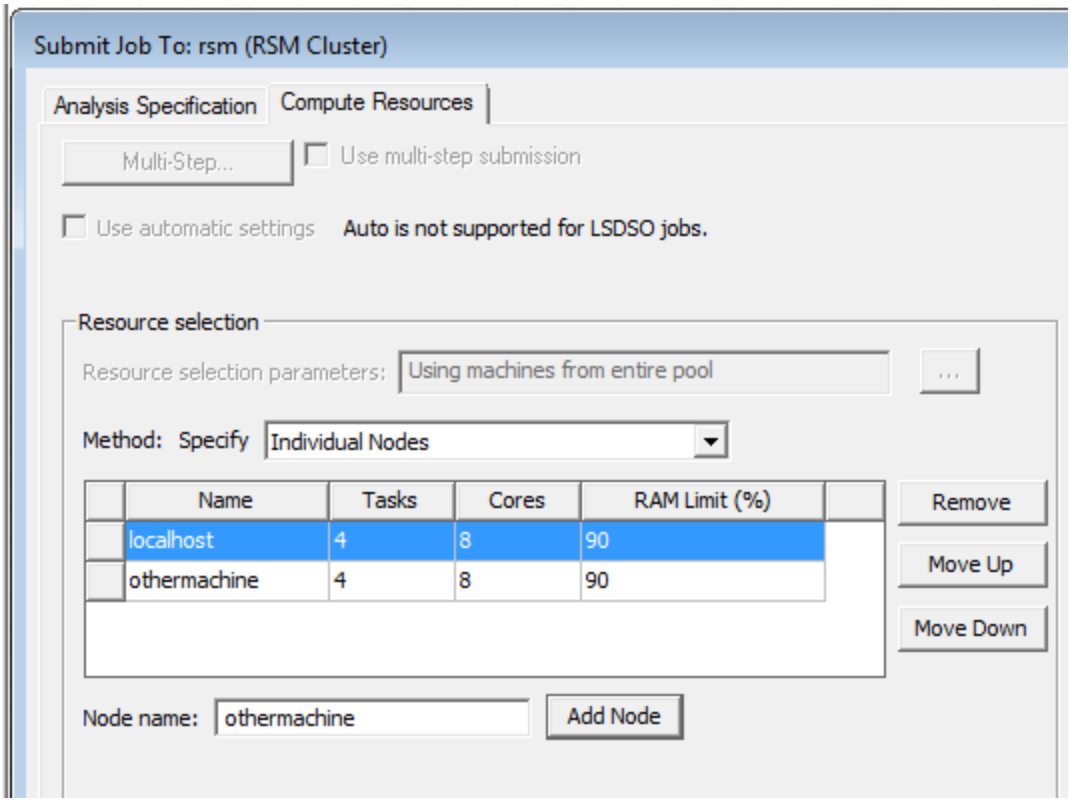
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> If you select **Use automatic settings** with **Num variations to distribute** set to 1, Optimetrics variations will be solved sequentially. Other distribution types will be distributed automatically. It does distribute frequencies, domains, and use of multiple level domains. If you set **Num variations to distribute** to 2 or more, Optimetrics variations will be solved in parallel. Other distribution types will be distributed automatically.

Otherwise:

- Specify node list

  Here you can specify a node list. In a computing environment where the available cores are not uniform, you can use this to control which resources your job will use. For use with Large Scale DSO for RSM, for jobs that are submitted from job submission panel, localhost must be the first node in the resource selection node list, other wise LSDSO solve with RSM will fail.

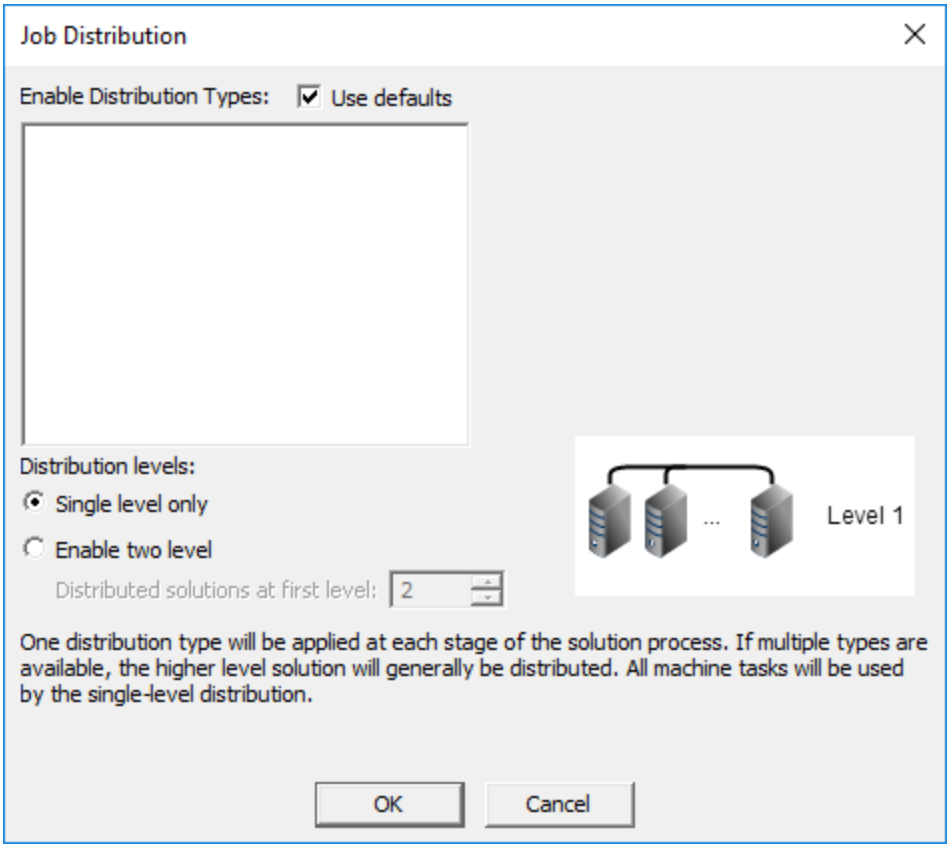


Job Distribution

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you disable User automatic selection, you can modify the Job distribution settings.

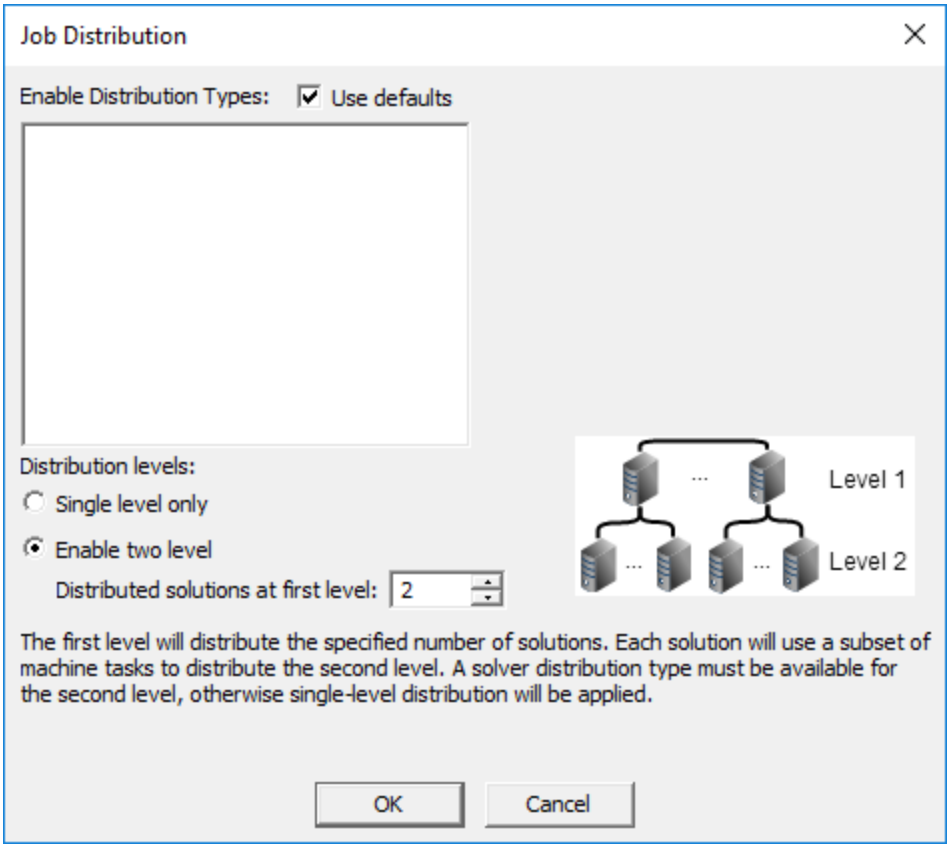
- Single level or two level distribution (*single level* is the default). Click **Modify** to display the *Job Distribution* dialog box and select the **Enable two level** option if appplicable and desired.



Enabled distribution types can be modified here.

Second-level distribution operates within DSO. If available and enabled you can specify a number of engines for level 1.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



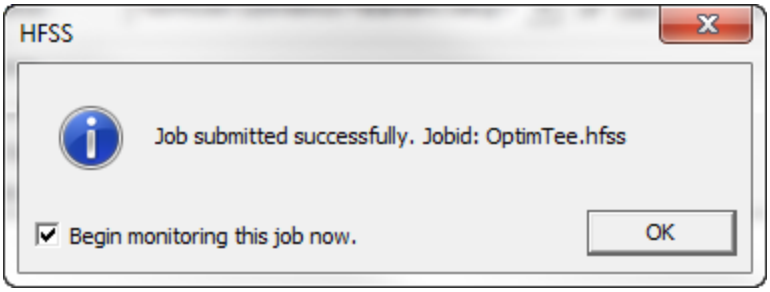
In response to a set of minimal constraints, the Scheduler may increase the resources assigned beyond the minimal values in order to meet the full set of requirements. For example, if you specify 7 distributed engines, with two processors per engine, and also limit the number of engines per node to 4, the scheduler may increase the number of cores used in order to meet the limit specified for engines per node. Notice that a preview of the Submit Job Results shows the number of resources assigned, and that the scheduler generated code includes an MPI specification.

1. To submit the command with the specified parameters, click **Submit Job**.

> **Note:**
>
> The RSM environment does not support for queuing, so **Submit Job** will immediately start running the job.

A dialog box displays. You can select **Begin monitoring this job now** and click **OK**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. You can monitor this job either automatically (by selecting the option above) or through the **Tools** > **Job Management** > **Monitor Jobs...** command. For more details, see Monitor Jobs window.

Process for Changing the Listening Port used by AnsoftRSM Service

To change the listening port used by the AnsoftRSMService, you need to change the configuration file, ansoftrsmservice.cfg, as follows:

You must specify the ListenPort within a 'CommDetails' block, which must be within a 'Default:CommDetails' block, which must be within the top level block of the file, the 'AnsoftCOMDaemon' block. The following example shows the listen port changed from 32958 to 32957, with these blocks at the beginning of the file:

```
$begin 'AnsoftCOMDaemon'
  $begin 'Default:CommDetails'
    $begin 'CommDetails'
      ListenPort='32957'
    $end 'CommDetails'
  $end 'Default:CommDetails'
  . . . .
$end 'AnsoftCOMDaemon'
```

For the second level block, ensure that there is a single colon character and no spaces or tabs separating the two parts of the block name 'Default:CommDetails'. The third level block, with name 'CommDetails' is also required. Use caution when editing this file by hand, because any typos in the block or value names may cause the data to be ignored.

Changing the AnsoftRSMService Listening Port

For Remote Analysis or Distributed Analsysis, processes may need to be started on multiple hosts. If the Ansys Electromagnetics Desktop needs to start a process on a remote host, the AnsoftRSMService is used to start these remote processes. By default, the AnsoftRSMService listens for socket connections from the Ansys Electromagnetics Desktop on port 32958.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This section describes how to change the port number used by the AnsoftRSMService.

To change the port number, both the AnsoftRSMService and the Ansys Electromagnetics Desktop must be configured to use the new port number. The same port number must be used for Ansys Electromagnetics Desktop and for the AnsoftRSMService process running on each host used for the analysis.

AnsoftRSMService Configuration

The AnsoftRSMService port number is configured in the ansoftrsmservice.cfg configuration file. This configuration file is located in the platform specific subdirectory of the RSM installation directory.

The default location of this directory is "C:\Program Files\ANSYS Inc\v251\EM_RSM" on Windows.

The default location of this directory is /opt/ansys_inc/v251/EM_RSM on Linux.

To modify the AnsoftRSMService configuration, first stop the ansoftrsmservice, then modify the ansoftrsmservice.cfg configuration file, then restart the ansoftrsmservice.

> **Note:**
>
> When using Linux, root maintains exclusive control over systemd-managed services. Once the startonboot command has been given, only root users can start and stop AnsoftRSMService, using the commands:
>
> ```
> sudo ansoftrsmservice start
>
> sudo ansoftrsmservice stop
> ```

The beginning of the configuration file should appear as follows:

```
$begin 'AnsoftCOMDaemon'
$begin 'Default:CommDetails'
$begin 'CommDetails'
'ListenPort'='32958'
$end 'CommDetails'
$end 'Default:CommDetails'
```

If there are additional lines between the following two lines, then they should not be modified:

```
$begin 'AnsoftCOMDaemon'
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$begin 'Default:CommDetails'

To change the port number, modify the ListenPort setting within the single quotes from 32958 to the desired port number. The single quotes should not be removed or changed.

For previous versions of the software, the ansoftrsmservice.cfg file may not contain the lines:

$begin 'Default:CommDetails'

$begin 'CommDetails'

'ListenPort'='32958'

$end 'CommDetails'

$end 'Default:CommDetails'

If these lines are not present, then add them to the ansoftrsmservice.cfg file after the first line of the file, and change the ListenPort to the desired port number. For example, to change the port number to 32000, the beginning of the ansoftrsmservice.cfg file should look like the following after the changes:

$begin 'AnsoftCOMDaemon'

$begin 'Default:CommDetails'

$begin 'CommDetails'

'ListenPort'='32000'

$end 'CommDetails'

$end 'Default:CommDetails'

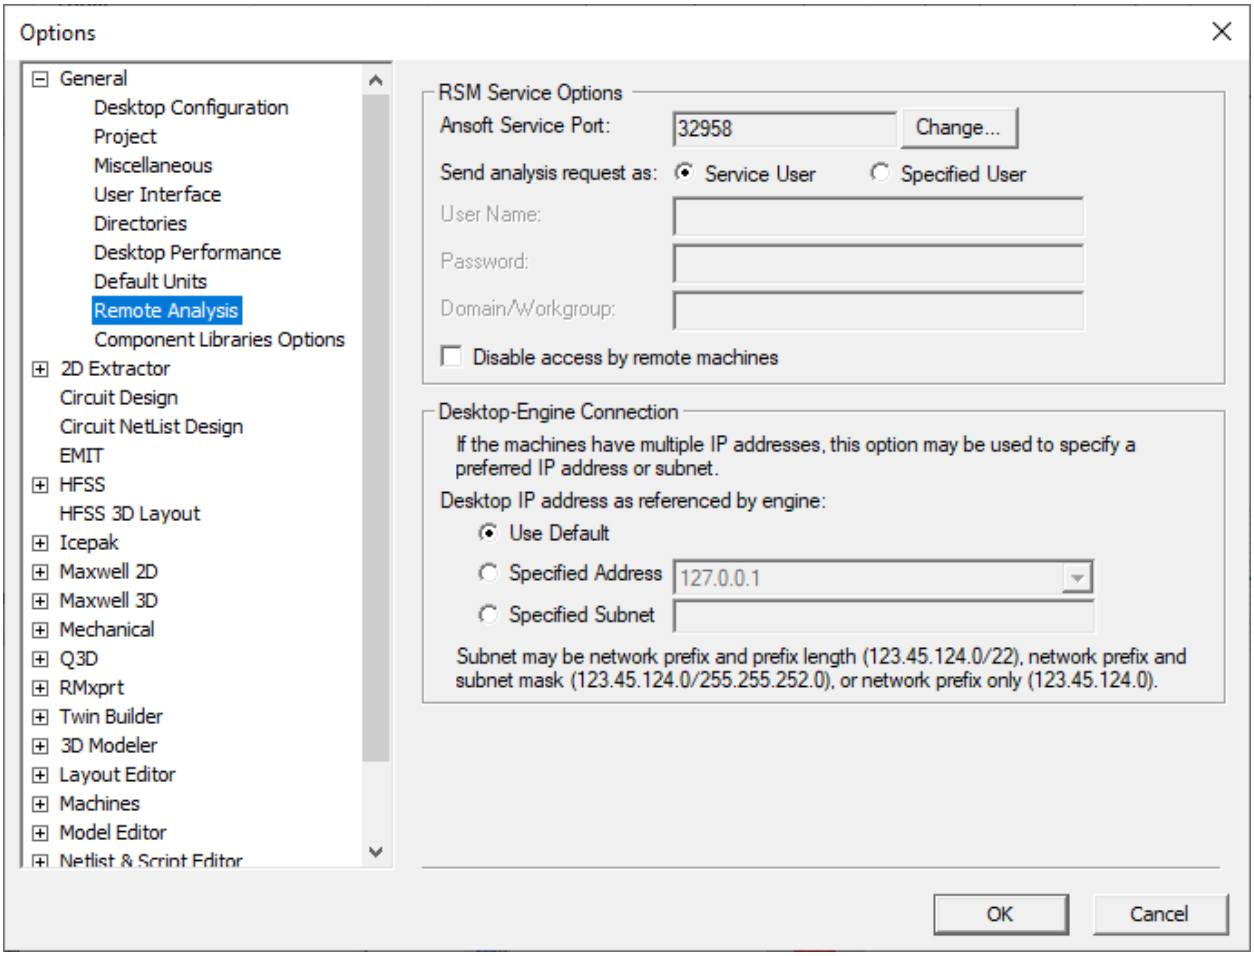
Ansoft Electromagnetics Desktop Configuration

The port number for connecting to the AnsoftRSMService is configured from the **General Options** window.

To access these options:

- Select **Tools** > **Options** > **General Options** to open the **General Options** window.
- If it is not already expanded, expand the **General** tree and click **Remote Analysis**.

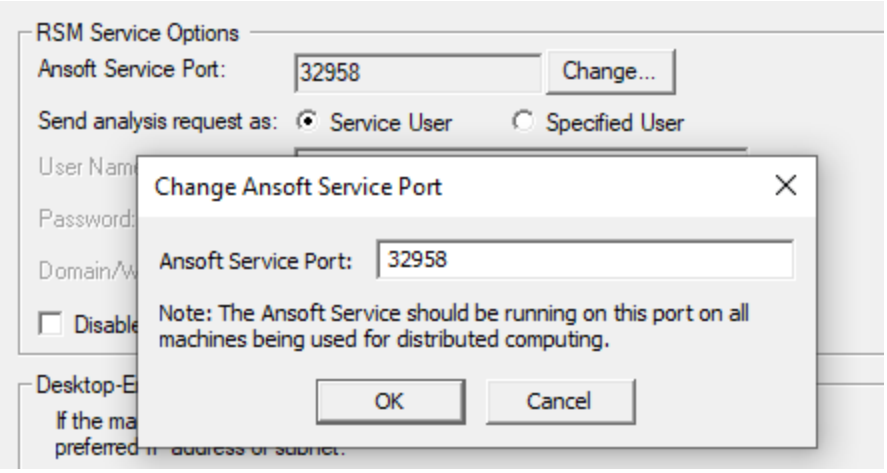
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Under **RSM Service Options**, the **Ansoft Service Port** field shows the current AnsoftRSMService port number.

1. Click **Change** to modify this setting. This opens the **Change Ansoft Service Port** dialog box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Enter the new port number in the **Ansoft Service Port** field.
3. Click **OK** to close the dialog box and accept the new port number.
4. Click **OK** to close the **General Options** window and accept the changes.

Running HPC Diagnostics

The Ansys EM HPC diagnostics tool simplifies HPC troubleshooting by automating diagnosis of routine issues. The diagnostics tool is run on the cluster as a scheduler managed job. Using its HTML based diagnostics report, cluster administrator or Ansys support staff can either resolve the issue, or guide the user with steps for further troubleshooting. In some cases, Ansys support staff may request to rerun the diagnostics with additional diagnostics tests. The user may extend the diagnostic scripts to suite their HPC environment.

This note describes how to use the diagnostics tool.

- Supported schedulers
- Running the diagnostics job
- Standard diagnostic job
- Using diagnostics scripts on Linux clusters
- Using Windows HPC job file
- Diagnostic report
- Site-specific diagnostics job
- Environment variables
- ANSYSEM_DIAG_PROD_DIR contents
- ANSYSEM_DIAG_RESULTS_DIR contents
- How does the diagnostic tool work

Supported Schedulers

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The tool supports diagnosis of issues on Linux and windows clusters managed by the following schedulers:

- LSF
- SGE
- PBS/Torque
- Windows HPC

For the above schedulers (see High Performance Computing (HPC) Integration), the tool includes basic diagnostic scripts. Further, if password-ssh has been enabled, it also supports generic Linux clusters using ssh. Please note that currently diagnostics tool does not support PBSPro and LSF/Windows.

Running the Diagnostics Job

The diagnostics are run as a scheduler managed job. Once the job finishes, you locate the resulting HTML file and provide it to the cluster administrator or to Ansys support staff. In case, there are any job or test failures, please also provide the networking*.json files from the Hosts subdirectory as well.

Basic Diagnostic Job

To run the basic diagnostics, submit a diagnostic job to the scheduler using a provided job submission script. Each basic diagnostic job is a 12 core job with 4 cores per host. On Linux, running this script submits a scheduler job to run the diagnostic tool on the cluster. On Windows, you need to submit a job using a job file.

Basic scripts for each supported scheduler are available in diagnostics subdirectory of schedulers directory.

Linux:

```
opt/ansys_inc/v251/AnsysEM/schedulers/diagnostics
```

Windows:

```
"C:\Program Files\ANSYS Inc\v251\AnsysEM\schedulers\diagnostics
```

Using Diagnostics Scripts on Linux Clusters

The following basic scripts are provided in the diagnostics directory (.../ansys_inc/v251/AnsysEM/schedulers/diagnostics):

These job submission scripts are scheduler specific.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scheduler	Basic job submission script	Comment
LSF	test_lsf	Supports both lsrun and blaunch
SGE	test_sge	Supports both qrsh and rsh
PBS/Torque	test_torque	Requires changing the PATH and PBS_BINARY_PATH environment variable
Generic Linux cluster	test_ssh	Supports only ssh. Requires password-less ssh. Requires creating a file with the names of hosts and saving it in ${HOME}/ansysem_hostfile

Using Windows HPC Job File

A sample job file winhpctest.xml is available in the diagnostics directory:

`...\schedulers\diagnostics.`

To submit this diagnostic job, you must change the job description to suite your environment as following:

1. Select a directory for saving the diagnostic results. This directory must be accessible at the same path from all the hosts of the cluster.
2. Locate the directory for Ansys EM installation. This directory also must be accessible at the same path from all the hosts of the cluster.
3. Locate the winhpctest.xml in the diagnostics subdirectory of schedulers directory in Ansys EM installation.
4. Start Windows HPC job manager, and choose "New job from XML File…" action.
5. Select the winhpctest.xml job file.
6. Change the value of both the following environment variables with the directories located in the first two steps:

   ANSYSEM_DIAG_PROD_DIR

   ...

   ANSYSEM_DIAG_RESULTS_DIR
7. Now submit the job.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> After making the above changes, you can also save the resulting XML file using "Submit Job XML File…". Then you can submit the job using the job command as following:
>
> job submit /jobfile: XMLfile name

Diagnostic Report

The diagnostic report is an HTML file that (along with other related diagnostics results) is placed in the following directory

Linux:

```
${HOME}/Ansoft/HPCDiag/Results/JOBID
```

Windows:

```
%ANSYSEM_DIAG_DIR%\Results\JOBID
```

Report file:

```
.../HTML/report.html
```

where JOBID is the job ID assigned by the scheduler. On Windows, the user must specify ANSSEM_DIAG_DIR directory.

Site-Specific Diagnostics Job

To run a diagnostic job with job submission parameters of your choice, you need to create your own job submission script. For example, you may want to specify a different LSF queue, or select a different SGE parallel environment. To run such a job, you need to create your own job submission script starting from the basic diagnostic scripts with the following steps:

1. Locate the relevant basic diagnostic script in the diagnostics subdirectory of schedulers directory in Ansys EM installation.
2. Make a copy of the diagnostics script into a directory that is accessible from a submit host for the cluster.
3. Edit the script file to change the value of ANSYSEM_DIAG_PROD_DIR environment variable to point it to the installation directory (See below).
4. Modify the job submission parameters as needed.
5. Optionally, copy any site-specific diagnostic tests provided by Ansys support staff in the *../Custom* subfolder of the *ANSYSEM_DIAG_RESULTS_DIR* directory.
6. Run the diagnostics script from a submit host for the cluster.

Environment Variables

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The following environment variables are applicable for both Linux and Windows environment.

ANSYSEM_DIAG_PROD_DIR

Environment variable	**ANSYSEM_DIAG_PROD_DIR**
Description	Location of the Ansys EM installation. This must be available at the same path from all the hosts of the cluster.
Windows example	"\\filer\AnsyEM\v251\AnsysEM"
Linux example	/shared/ansys_inc/v251/AnsysEM
Comments	Windows: Required. Linux: Optional. Export this environment variable if you make a copy of the diagnostic script.

ANSYSEM_DIAG_RESULTS_DIR

Environment variable	**ANSYSEM_DIAG_RESULTS_DIR**
Description	Location of the diagnostic report and other results on a shared drive. This must be available at the same path from all the hosts of the cluster
Example	\\filer\Home\User\Ansoft\HPCDiag
Linux example	/shared/home/user/Ansoft/HPCDiag
Comments	Windows: Required. Linux: Optional. Export this environment variable if the home directory for the user is not accessible from the cluster.

ANSYSEM_DIAG_CUSTOM_DIR

Environment variable	**ANSYSEM_DIAG_CUSTOM_DIR**
Description	Location of the configuration of product tests and other custom site-specific tests. This location must be on a shared drive that is available at the same path from all the hosts of the cluster
Example	\\filer\Home\User\Ansoft\HPCDiag\Custom
Linux example	/shared/home/user/Ansoft/HPCDiag/Custom

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Environment variable	**ANSYSEM_DIAG_CUSTOM_DIR**
Comments	Windows: Optional. You may want to specify it if the path %ANSYSEM_DIAG_RESULTS_DIR%\..\Custom is not suitable Linux: Optional. Export this environment variable if the home directory for the user is not accessible from the cluster.

How the Diagnostic Tool Works

The diagnostics are run as a scheduler managed job. Running the diagnostic script submits a scheduler job that runs the diagnostic tool on the hosts allocated to the job. Once the diagnostic job starts, the tool executes a set of diagnostic tests. These tests run on each host allocated to the job, and collect diagnostic information relevant for running HPC jobs. The tool combines the diagnostic information to produce an HTML report. The tool saves HTML diagnostic report and other results in a shared drive, which must be available at the same path from all the hosts of the cluster. On Linux, the default is Ansoft/HPCDiag subdirectory under user's home directory. On Windows, the user must specify this location using ANSYSEM_DIAG_RESULTS_DIR environment variable.

Changing Solution Priority for System Resources

You can modify the priority of Ansys Electronics Desktop simulations so that system resources are allocated to other computer processes before the solver. If you reduce the priority of Ansys Electronics Desktop simulations, your other software tools will respond as they normally would, but Ansys Electronics Desktop simulations may take longer.

> **Note:**
>
> The Windows Task Manager does not indicate a reduced priority for the Ansys Electronics Desktop solvers. It only lists the priority of the engine manager, which appears normal, not the actual engine. The actual engine is in a separate thread, whose priority is not visible in the Windows Task Manager.

To change the priority of simulations for the system's resources:

1. While a solution is running, right-click the **Progress** window, and click **Change Priority** on the shortcut menu.
    - To affect priority for future simulation runs, click **Tools** > **Options** > **HPC and Analysis** to access the **HPC and Analysis** dialog box, and click the **Options** tab.
2. From the **Change Priority** menu (or the **Default Process Priority** drop-down menu), select one of the following priorities:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Lowest Priority	
Below Normal	
Normal	The default.
Above Normal	
Highest	

3. Click **OK**.

desktopproxy Utility to Abort or Cleanstop a BatchSolve

The desktopproxy Utility to abort or cleanstop a batch solve is available in the installation directory: ("...\ANSYS Inc\v251/AnsysEM" on Windows, ".../ansys_inc/v251/AnsysEM" on Linux).

To abort a job, run it on a host which has network access to the first execution host of the job, as well as has access to the directory of the project file. This utility does not abort Large scale DSO jobs for which you need to use desktopjob utility itself.

Usage:

```
desktopproxy -abort <projectpath>
-cleanstop <projectpath>
```

Where the <projectpath> is the full path to the project file.

The behavior (e.g., saving the results computed so far) should be same as if you interactively aborted AnsysEDT solve. if AnsysEDT is 'busy' (e.g., doing Optimetrics calculation, computing a report), abort (using desktopproxy) might take a long time.

The utility exits silently after it requests ansysedt process to abort the job cleanly. After the job ends, the batch log file may contain a message such as:

```
[error] Project:TestProject, Design:HFSSDesign1 (DrivenModal),
Simulation was aborted by user on server: sjohpc-lsf-0.ansys.com.
(3:52:30 PM Oct 11, 2013)
```

The lock file will be automatically deleted.

Example (Linux):

```
desktopproxy -abort /home/user/test/Diff_Via.aedt
```

Example (Windows):

```
desktopproxy -abort \\server\share\projectfolder\Diff_Via.aedt
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Limitations:

- Aborting a job makes a best effort to delete all the temp directories on all the hosts
- For a hung job, a clean shutdown may not be possible. In that case, the user must use OS/scheduler's facilities to kill the job.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

17 - Ansys Workbench Integration Overview

Ansys Workbench combines the strength of its core product solvers with the project management tools necessary to manage project workflow. In Ansys Workbench, analyses are built as *systems*, which can then be combined into a *project*. The project is driven by a schematic workflow that manages the connections between the systems.

From the schematic, you can interact with applications (called workspaces) that are native to Ansys Workbench and that display within the Ansys Workbench interface. Native workspaces include: Project Schematic, Engineering Data, and Design Exploration (Parameters and Design Points).

You can also launch applications that are data-integrated with Ansys Workbench, meaning the application's interface remains separate, but the data from the application communicates with the native Ansys Workbench data. Thus, data can be passed back and forth between any Ansys Electromagnetics product on a Workbench Project Schematic and any supported Ansys or Ansys Electromagnetics desktop product. Depending on the application, data integration can include basic actions such as saving projects, as well as more complex actions such as the coupling of Ansys Electromagnetics product variables to Workbench Design Exploration parameters.

Data-integrated applications include the following Ansys Electromagnetics products:

Circuit, HFSS, Icepak, Maxwell/RMxprt, Mechanical, Q3D Extractor, and Twin Builder.

> **Note:**
>
> For detailed information on working with Ansys Workbench, please refer to the Workbench documentation.

Integrating Ansys EM Suite with Ansys Workbench

You can integrate the Ansys Electromagnetics Suite with the Ansys Workbench application after both have been installed on your system. For successful integration, both preinstalled applications must be of the same version. A single operation completes the integration process for all supported design types.

The same procedure is used to integrate the applications or to decouple them (if they had previously been integrated). The procedure is as follows:

1. From the Windows Start Menu, select **All Programs** > **Ansys EM Suite 20*yy* R*n*** > **Modify Integration with Ansys 20*yy* R*n***.

   A *Modify Integration with Ansys 20yy Rn* command window appears.

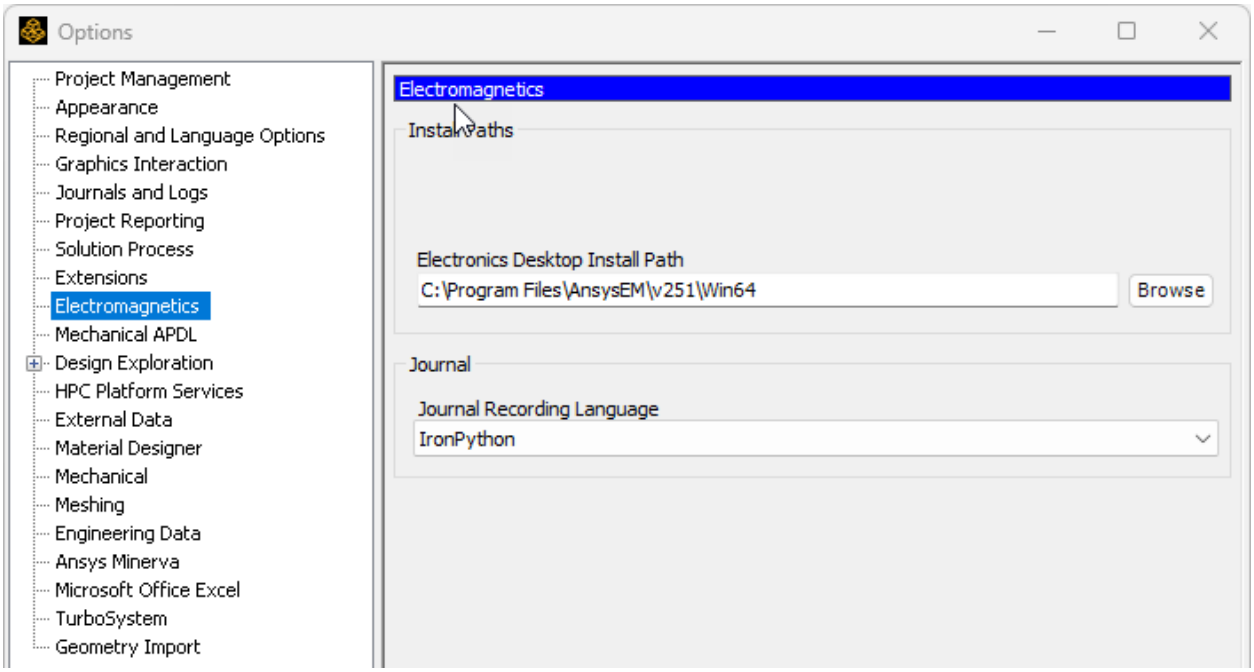
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If both applications are present on the system, their installation paths will be reported, and you will be asked if you wish to integrate them.
- Alternatively, if integration has already been preformed, you will be asked if you wish to decouple them.

2. Type **yes** to perform the prompted action or **no** to abort the operation without making any changes. Then press **Enter**
   - If you enter *"yes,"* a confirmation line appears in the command window indicating that integration (or decoupling) has been completed, and the window remains open.

     Press **Enter** again to close the command window.
   - If you enter *"no,"* the operation aborts and the command window closes immediately.

> **Note:**
>
> You can confirm that the Ansys 20*yy* R*n* application is “aware” of the integrated application via the *Options* dialog box in Workbench. The path to the integrated Electronics Desktop application is listed in the *Electromagnetics* group of settings.



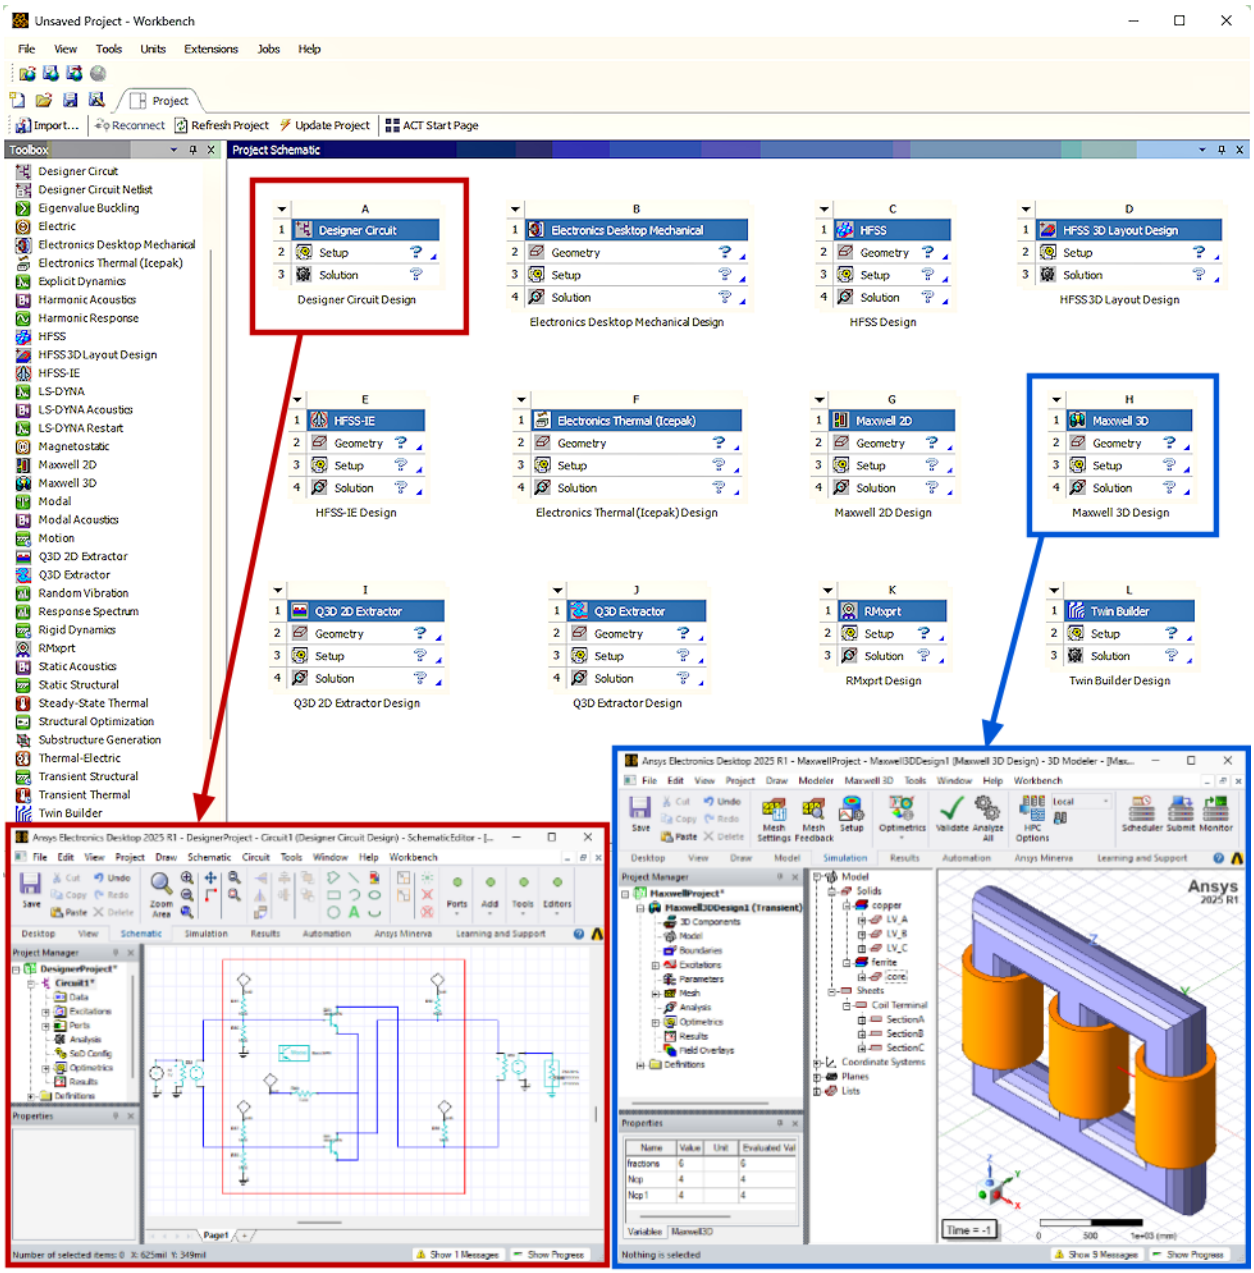
In this group of options, you can also specify Workbench's default **Journal Recording Language** for use when interoperating with the Ansys Electromagnetics products. **Iron Python** is the default language, and the alternative choice is **Visual Basic** (VB). Changes applied here

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

affect any new Workbench or Ansys Electronics Desktop session launched after the change. Any open instance will continue recording in the language that was in effect when the program was launched.

Workbench Data Integration Overview

Ansys EM data-integrated applications can reside on a Workbench **Project Schematic**, as shown.

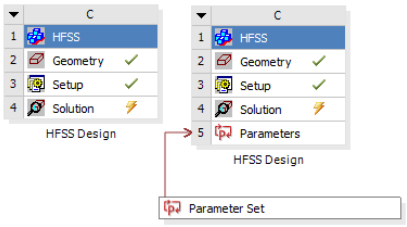


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Objects placed on a Workbench Project Schematic (such as instances of Ansys Electromagnetics projects) are referred to as *systems*. The number of cells in the system depend on the desigh type, as follows:

- **RMxprt, Circuit, HFSS 3D Layout,** and **Twin Builder:** Appear on the Workbench Project Schematic as systems with three cells: **<*System_Type_Name*>, Setup,** and **Solution**.
- **HFSS, Maxwell, Q3D Extractor, Icepak,** and **Mechanical:** Include an additional **Geometry** cell along with the **<*System_Type_Name*>, Setup,** and **Solution** cells, for a total of four cells.

If you invoke Ansys **DesignXplorer** to use variables for refining a design, a **Parameters** cell is added, with a link to the associated Workbench **Parameter Set**. Refer to the Ansys Workbench help for details on working with systems, cells, and parameter sets.



All supported Ansys Electromagnetics Suite products integrate with Workbench commands, services, and DesignXplorer in a similar manner. Some capabilities include:

- Adding New Analysis Systems
- Importing Existing Ansys EM Projects into Workbench
- Editing Ansys EM Models in Workbench
- Ansys EM to Workbench Geometry Transfer
- Ansys EM to Workbench Material Data Transfer
- Analyzing Ansys EM Models in Workbench
- Performing Parameter Studies in Workbench
- Scripting in Workbench

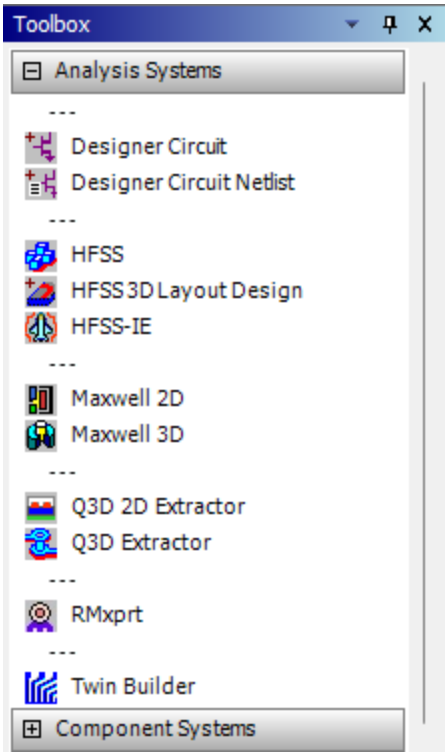
In addition to these major features, Workbench can archive, save, back up, duplicate, and delete Ansys Electromagnetics projects used in a Workbench project. Progress information and messages from integrated Ansys EM projects are also displayed in Workbench.

> **Note:**
>
> Look in the *Ansys Workbench Help* to find detailed information about performing the above-listed operations.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

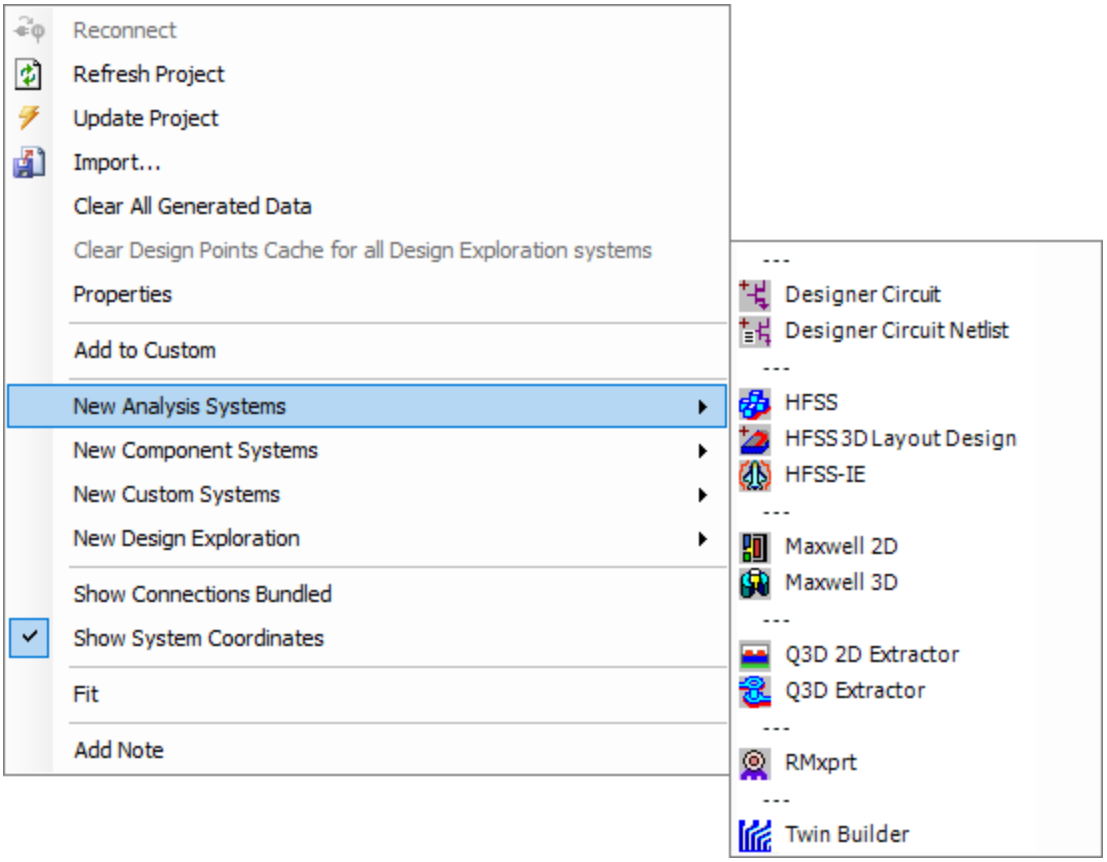
Adding New Analysis Systems

A new Ansys Electromagnetics Analysis System can be added to a Workbench Project Schematic by dragging and dropping it from the Toolbox:



Alternately, you can add a system by right-clicking in the Workbench Project Schematic area and selecting **New Analysis Systems** > **[System Type]**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

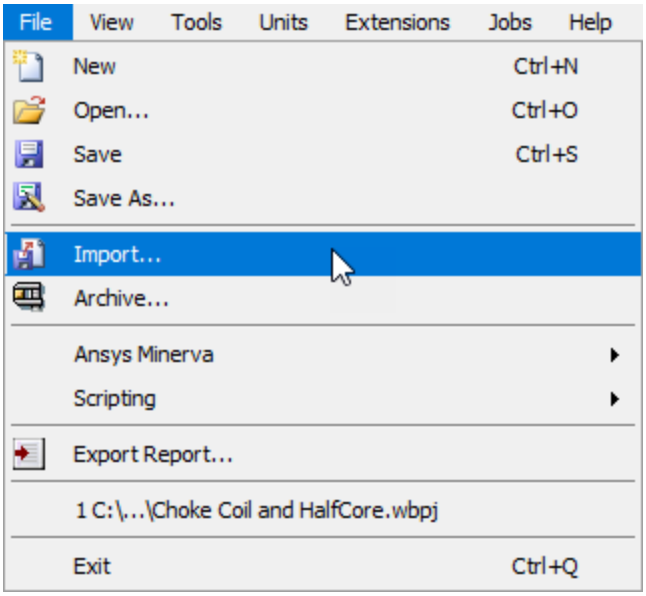


Importing Existing Ansys EM Projects into Workbench

You can import existing Ansys Electromagnetics Suite projects into a Workbench project schematic using **File** > **Import**. When you do, a copy of the Ansys Electromagnetics project is placed in the Workbench project folder. The original Ansys Electromagnetics project remains intact.

> **Note:**
>
> Object, material, and parameter names with non-ASCII characters are not allowed for data transfer. Such transfers fail and produce an error message.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

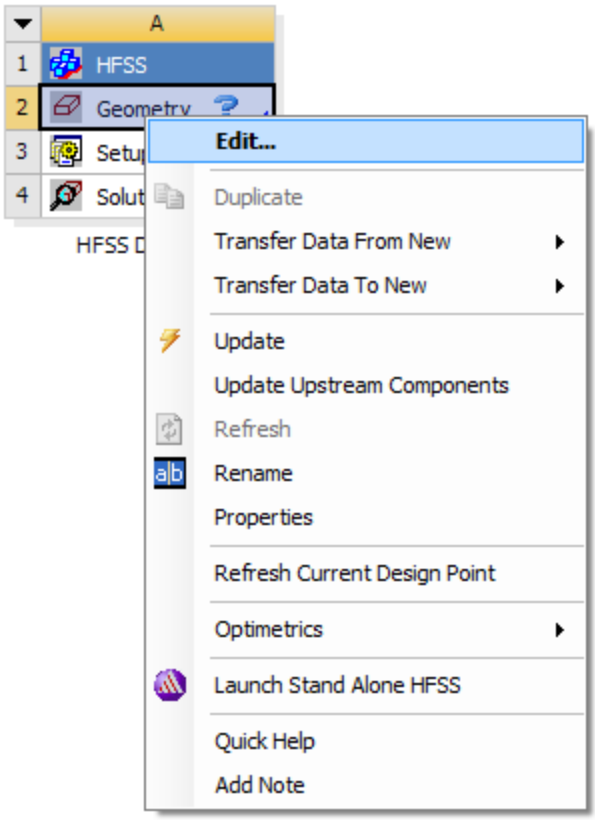


Editing Ansys EM Models in Workbench

You can edit various properties and parameters of the Ansys Electromagnetics project (geometry, setup, solution, etc.) either by right-clicking the project in Workbench and selecting **Edit**, or by double-clicking the project.

Doing so launches the Ansys Electromagnetics desktop application and loads the project so that you can set up your project in a familiar desktop environment. Changes made to the Ansys Electromagnetics project are saved to the project instance in the Workbench project folder.

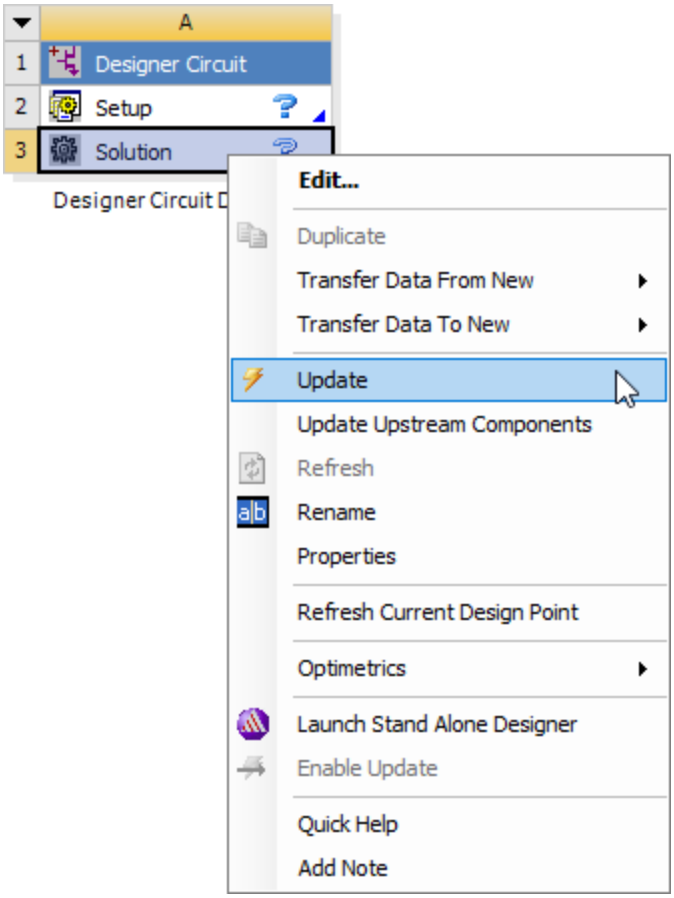
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



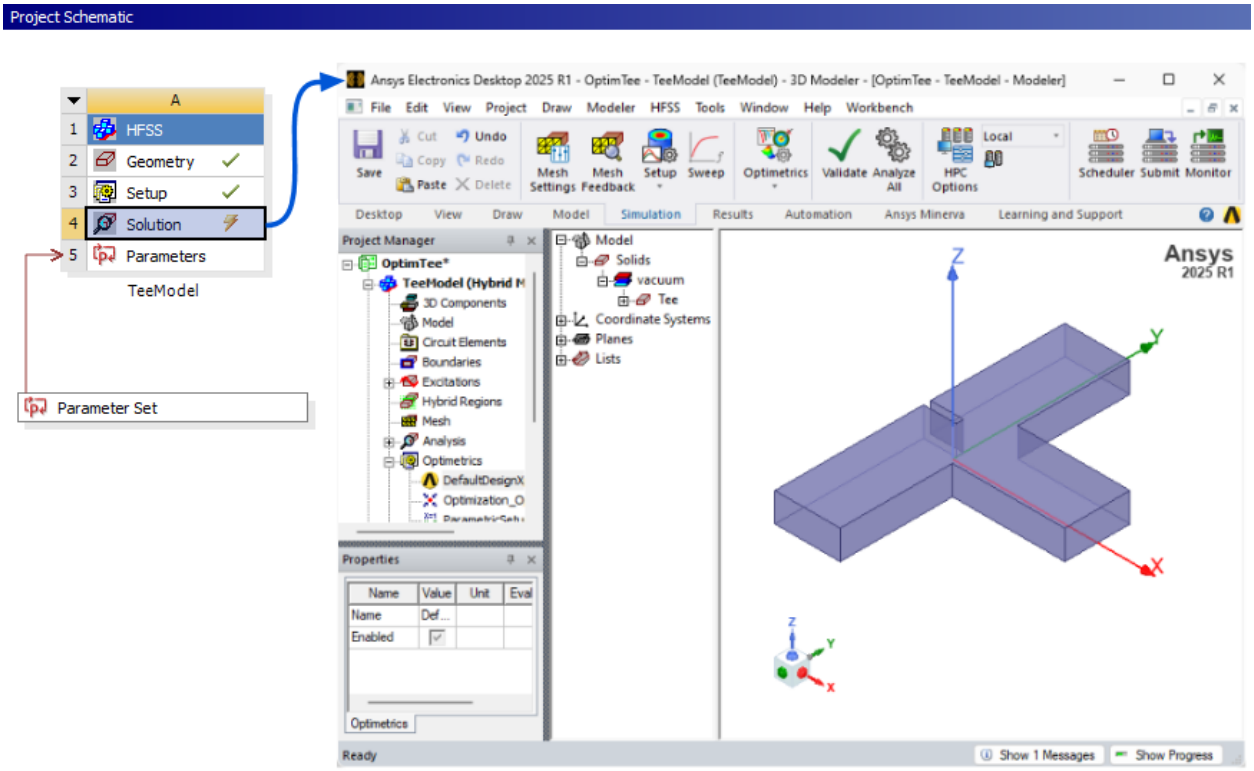
Analyzing Ansys EM Models in Workbench

You can use Workbench's **Update** command to run analyses in the integrated Ansys Electromagnetics project. Progress information is also shown in Workbench.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



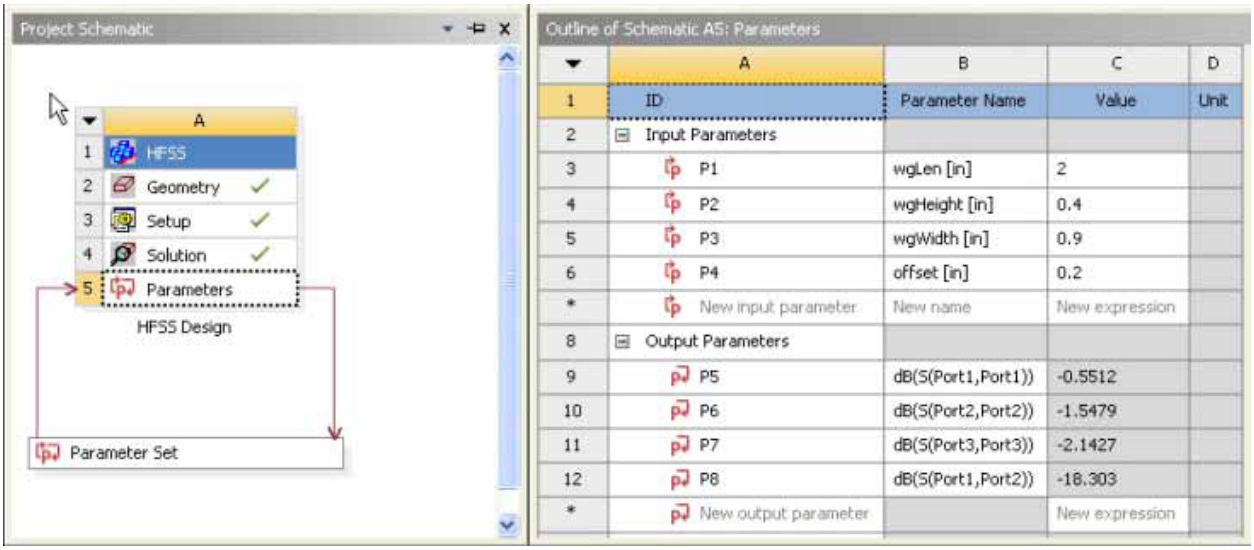
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Performing Parameter Studies in Workbench

Workbench **Parameter Sets** allow you to change parameter values and units of measure, or add new parameters. Parameter data is passed back to the Ansys Electromagnetics application for updated analyses. After analysis, the Workbench Parameter table should be updated correctly for all design points.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

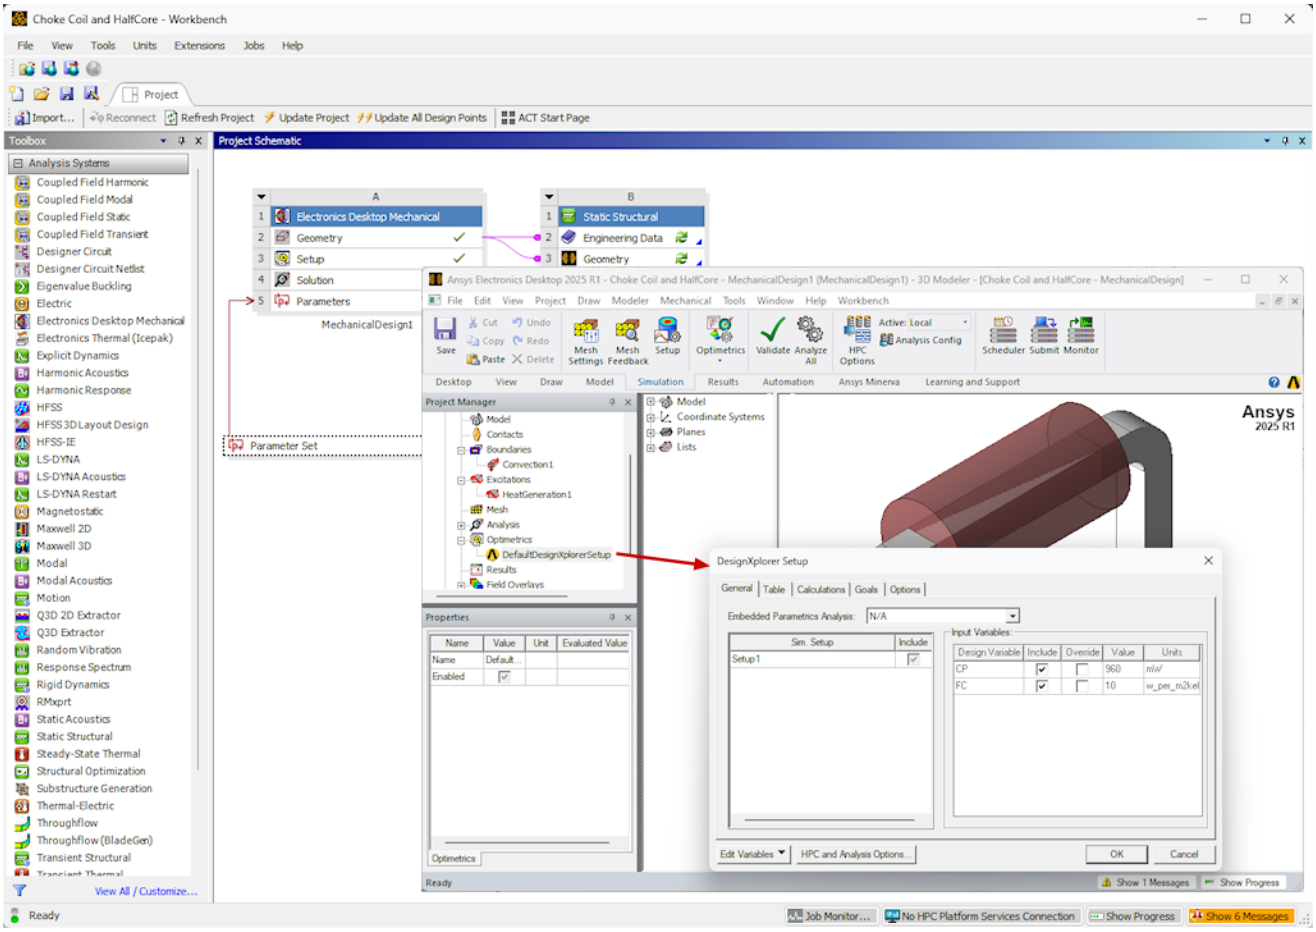


Note:

Because Workbench and Ansys Electromagnetics Desktop have different unit systems, units defined in Desktop are Dimensionless in the Workbench Parameters table and thus cannot be changed. Refer to the *Ansys Design Modeler User's Guide* > *Project Schematic Operations* > *Parameters in Project Schematic* > *Parameter Units* topic for additional information.

Parameters from the Ansys Electromagnetics project are exposed to Workbench through the **DesignXplorer** setup. The Ansys Electromagnetics system's cell status on the Workbench project is updated as changes are made in the Ansys Electromagnetics application. The following example is a Mechanical, Steady-State Thermal design in which two variables have been defined. One variable (CP) is the coil power (960 mW heat generation) and the other (FC) is the film coefficient of the assigned convection boundary:

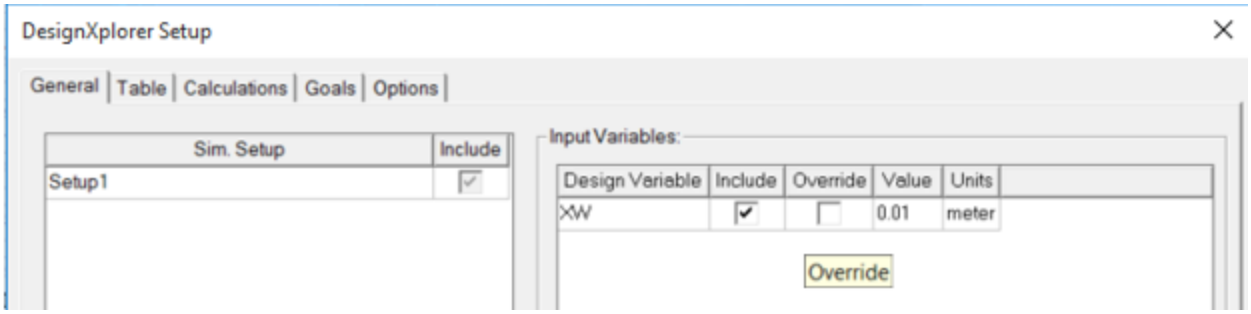
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



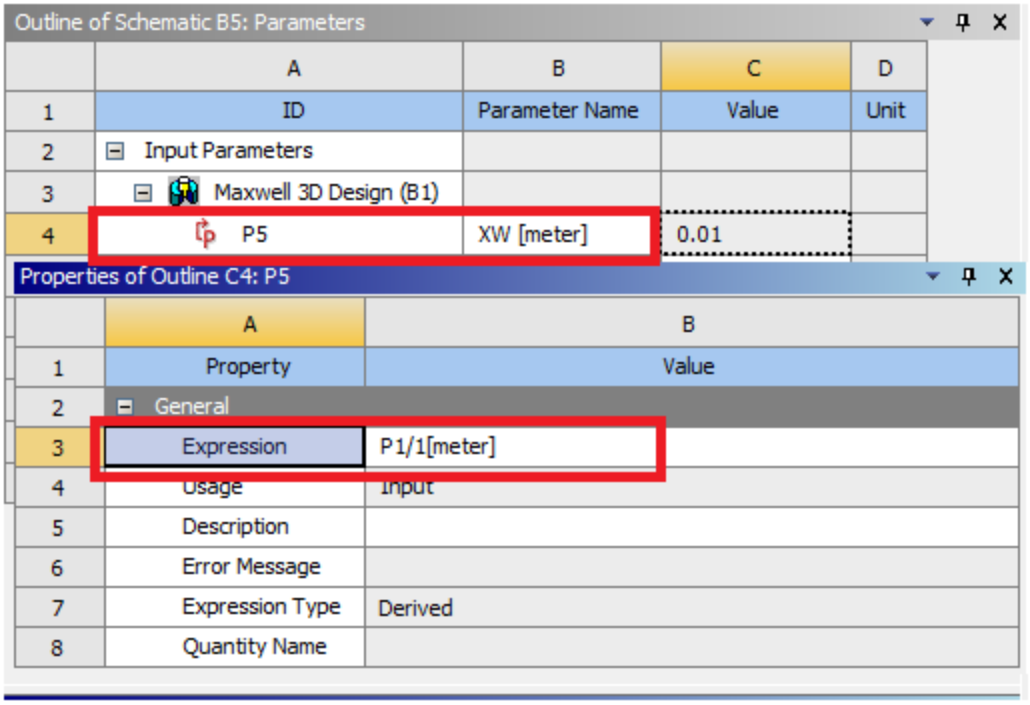
The workflow for using Electronics Desktop systems with the Workbench to take advantage of Distributed Analysis is as follows:

1. In the Ansys Electronics Desktop, specify a variable an as input parameter. The following figure shows a DesignXplorer Setup that includes a geometry variable called XW This variable is mapped to a variable in the corresponding Workbench Design, in this example, P5.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

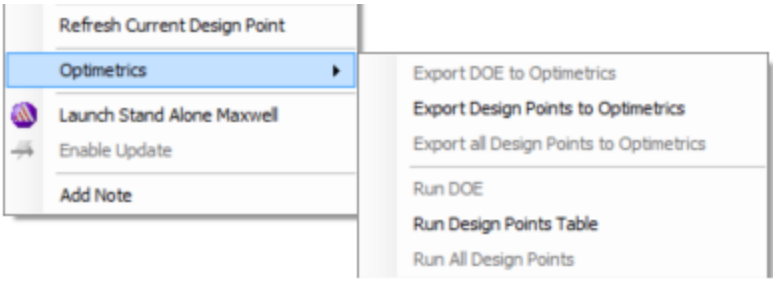


2. In the Workbench Design, change the P5 expression to a new value (in this example figure, the P5 parameter is assigned an expression of P1/1[meter] to tie it to the geometry system's variable.



In Workbench, the **Export Design Points to Optimetrics** and **Run Design Points Table** commands are enabled.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

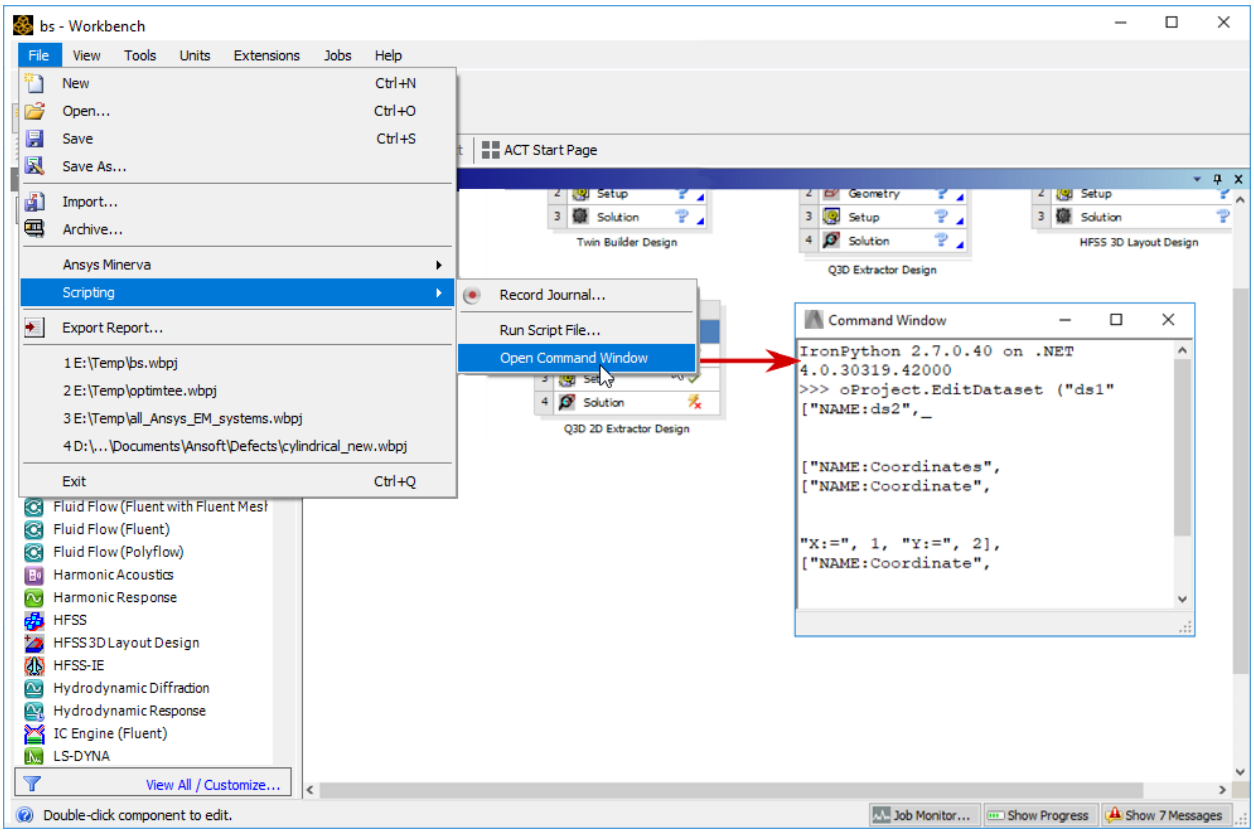


3. In Electronics Desktop, you can click on the default DesignXplorer Setup, and choose **Generate Variation Data**.

If you have configured your Analysis Configuration for multiple machines, the Project is ready for Distributed Analysis. After analysis, the Workbench Parameter table should be updated correctly for all design points.

Scripting in Workbench

Scripts that include Ansys Electromagnetics projects can be recorded and run in Workbench.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When a Workbench journal is run from the command line, Electronics Desktop allows the Ansys EDT portion to also run in batch mode (that is, when using RunWB2 -b).

Example: From a Windows Command prompt, enter the following command to replay the journal named "myReplayJournal.wbjn":

```
RunWB2 -b -r myReplayJournal.wbjn
```

Ansys EM - Ansys Multiphysics Coupling

Data integration provides an improved multiphysics workflow between Ansys Electromagnetics designs and Ansys applications such as Mechanical and Thermal. Coupling is provided through project schematic links. Heat losses and force data are automatically transferred to Ansys Mechanical, and there is no need to export or import transfer XML files. Edits made in Ansys Electromagnetics applications are automatically transferred to the Ansys application through the Workbench **Refresh** command. Workbench commands also enable easier automation of iterative coupling of thermal feedback.

The following sections provide some examples of multiphysics coupling.

Multiphysics Coupling on Workbench with Ansys Thermal

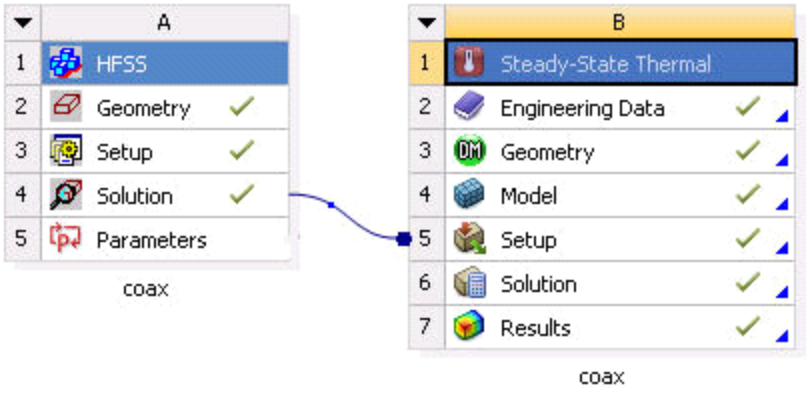
Multiphysics Coupling on Workbench with Ansys Structural

Multiphysics Coupling between Ansys EM Field Systems on Workbench

Multiphysics Coupling on Workbench with Ansys Thermal

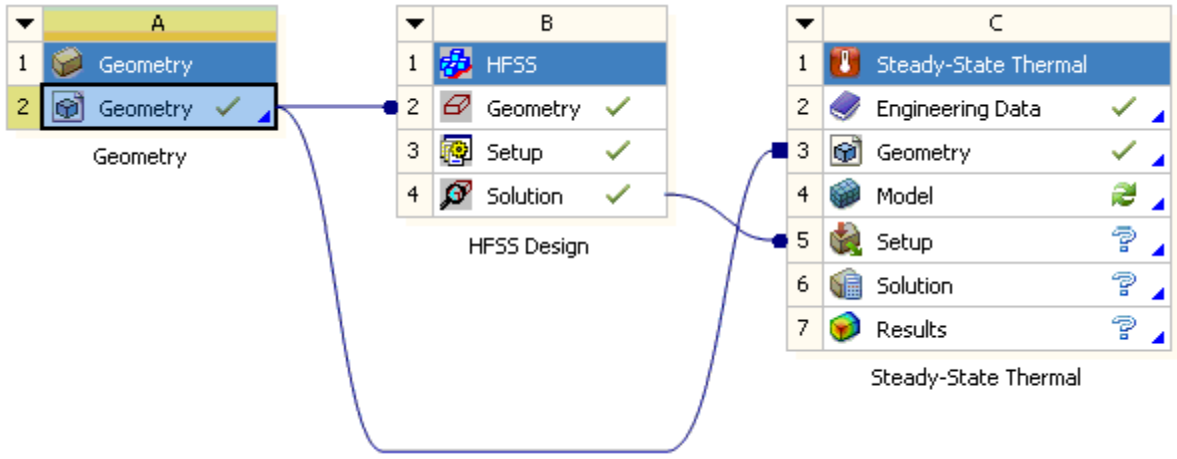
Using data integration, HFSS, Maxwell, and Q3D Extractor provide heat losses (heat generation and heat flux) to Ansys Thermal. In HFSS, both Driven and Eigenmode projects can be coupled for multiphysics. You first need to enable feedback as described in Setting the Temperature of Objects.

Note how the HFSS design is linked visually to Ansys Thermal on the Workbench project schematic.

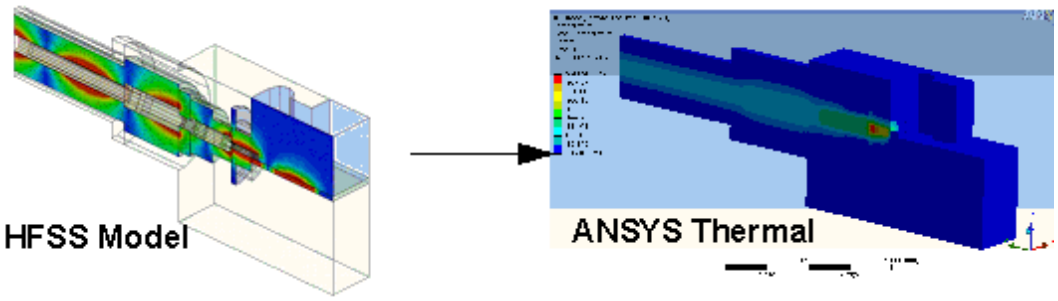


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Geometry sharing is possible, provided you activate Beta Options in Workbench. A geometry from the Component Systems in the Toolbox in Workbench Schematic can be shared as shown in the image below.



In this example, HFSS coax model Solution provides heat loss data as a thermal load to the Ansys Thermal Setup. The resulting analysis shows a thermal "hotspot", providing the user with the information needed to adjust the design's material to fix the problem.

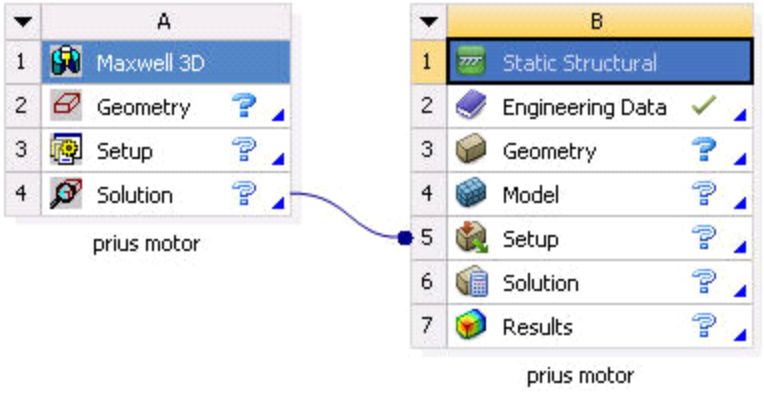


You enable this feature by checking Enable Feedback in the dialog for Setting the Temperature of Objects.

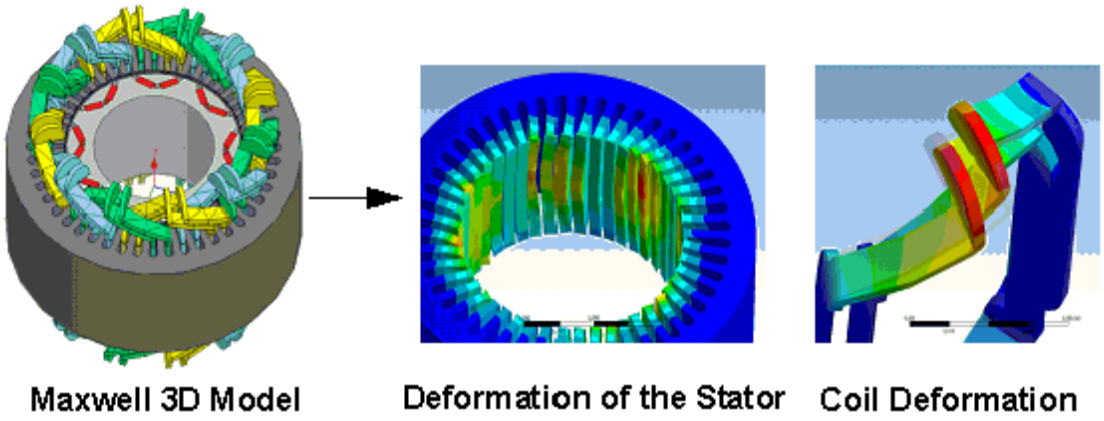
Multiphysics Coupling on Workbench with Ansys Structural

Using data integration, Maxwell 2D and Maxwell 3Dcan provide forces to Ansys Structural.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In this example, the Maxwell 3D electromagnetic force density **Solution** is used as the load in Ansys Structural to determine how these forces deform the motor's stator and coils.

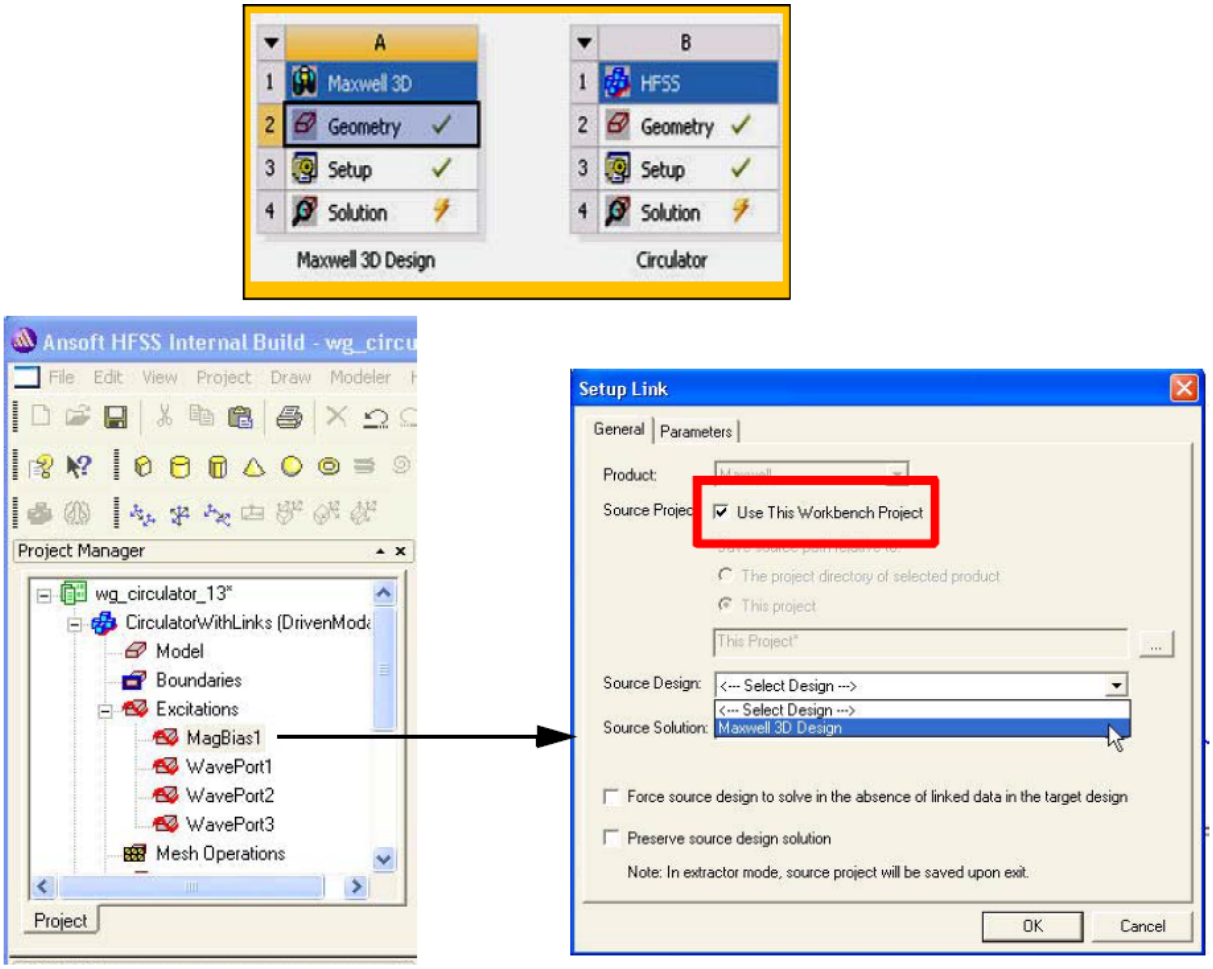


Multiphysics Coupling between Ansys EM Field Systems on Workbench

You can set up links between Ansys Electromagnetics field systems that reside on a Workbench project schematic. Linking is set up in the Ansys Electromagnetics application as shown in the

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

following example.

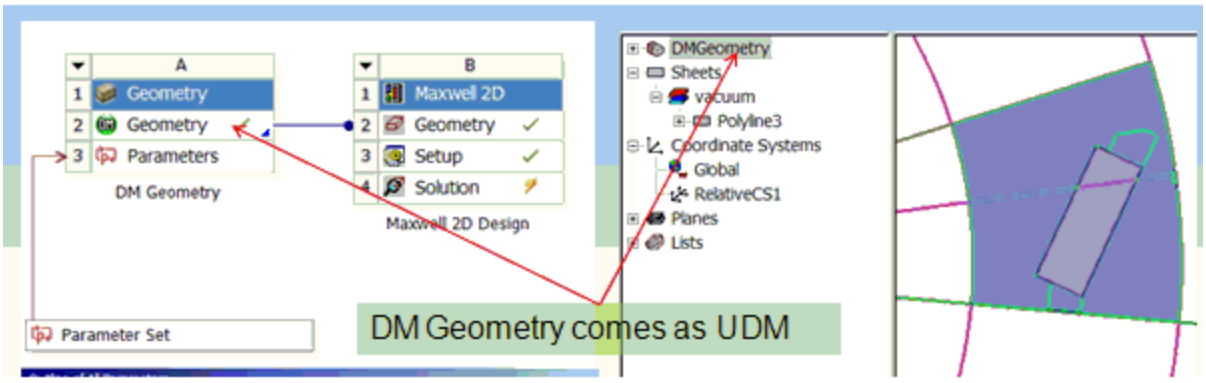


Ansys EM CAD Integration through Workbench

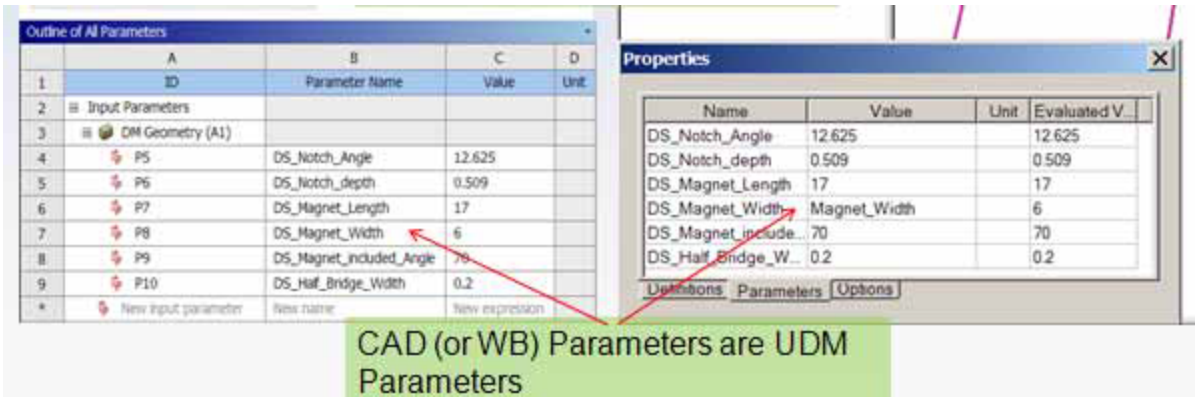
Ansys Electromagnetics CAD integration is a Workbench feature available for Ansys Electromagnetics 3D Products - HFSS, Maxwell, Q3D, Icepak, and Mechanical, as the Ansys Framework. The feature is available only through Workbench, and is not available via standalone Ansys Electromagnetics products.

Ansys CAD integration provides a bi-directional dynamic link through Workbench. This makes it possible to get updated geometry from CAD, modify CAD parameters in Ansys Electromagnetics products, and return an updated geometry. The feature is non-associative due to a need to reassign boundaries if a modified CAD model is used. The process creates a User Defined Model (UDM) for each geometry source.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



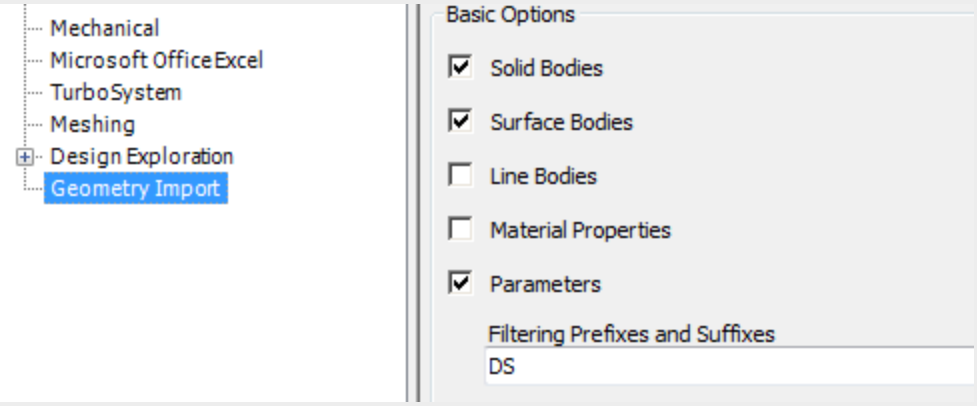
The UDM format makes it possible to exchange parameters. Ansys online help contains further description of the UDM feature and function.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

The parameters shown in the previous example all have a DS prefix. This is the default for the Workbench **Tools>Options** for **Geometry Import**. To import parameters with different prefixes or names, assign an appropriate prefix or clear the **Filtering Prefixes and Suffixes** field.



Ansys Electromagnetics CAD integration makes it possible to consume geometry from multiple upstream sources (any CAD or Ansys Electromagnetics product).

This feature supports direct interfaces with major CAD systems, including

- Creo Parametric
- UG NX
- CATIA V5
- SOLIDWORKS
- Autodesk Inventor
- Ansys Design Modeler (DM)
- Discovery UDM model

Note:

The CAD software must be installed on the user machine (not required for solve nodes).

The following sections contain additional information:

CAD Integration Functionality

CAD Integration and Geometry Sharing

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Bi-Directional CAD Integration

CAD Integration Model Edits

Multiple Geometry Links for CAD Integration

Creating Dynamic Links to EDT Designs

CAD Integration Functionality

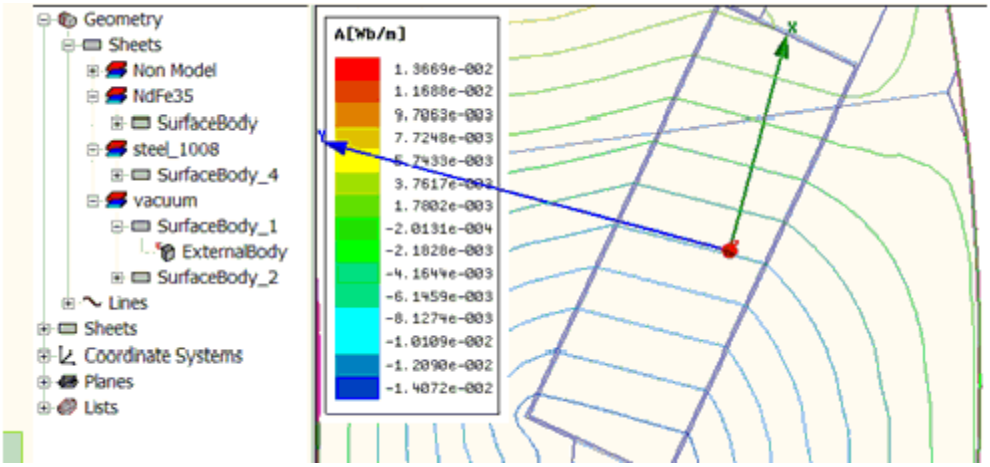
Healing with CAD Integration

Important Geometry Options for CAD Integration

CAD Integration Functionality

CAD Integration includes the following functionality:

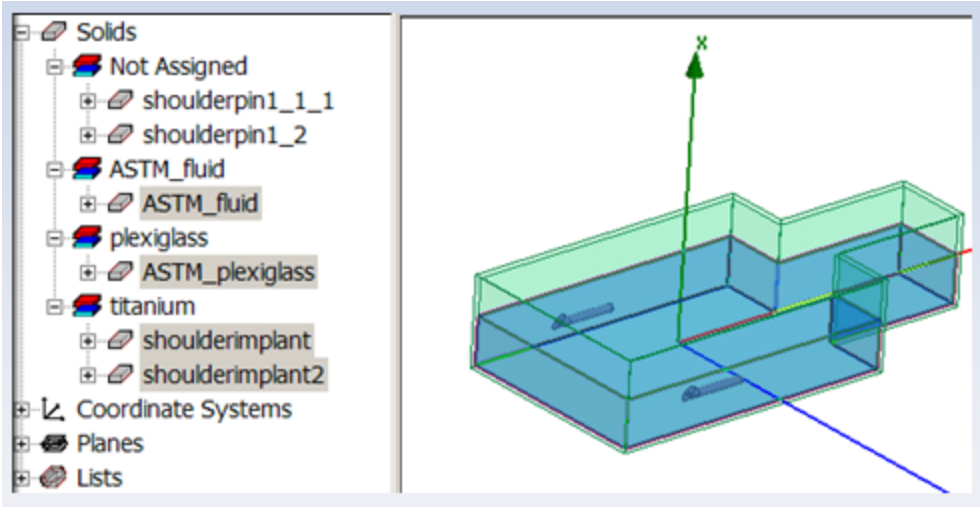
- DX analysis
- WB Update Project
- WB Update All Design Points
    - Parametric analysis with DSO
    - Animation
    - Geometry
    - Field plots



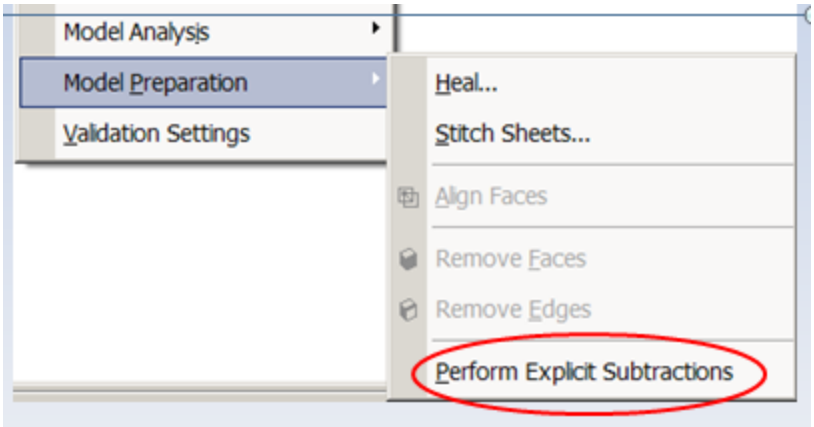
Ansys Mechanical does not do implicit subtraction. Ansys Electromagnetics products can do explicit subtractions before sending geometry to Ansys using **Modeler > Model Preparation > Perform Explicit Subtraction**.

For example, consider the following model.

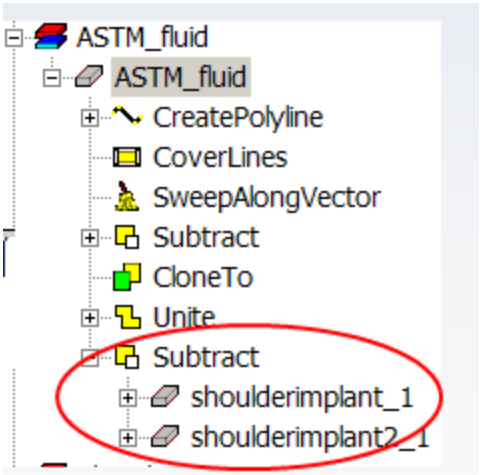
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Perform Explicit Subtractions can be performed.

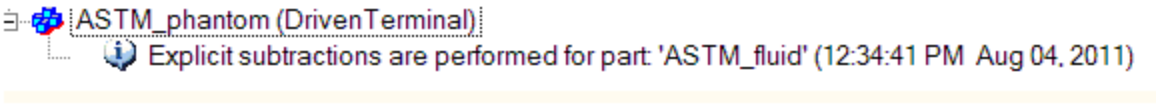


Results appear in the History tree, as shown:



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Messages** window reports this action.

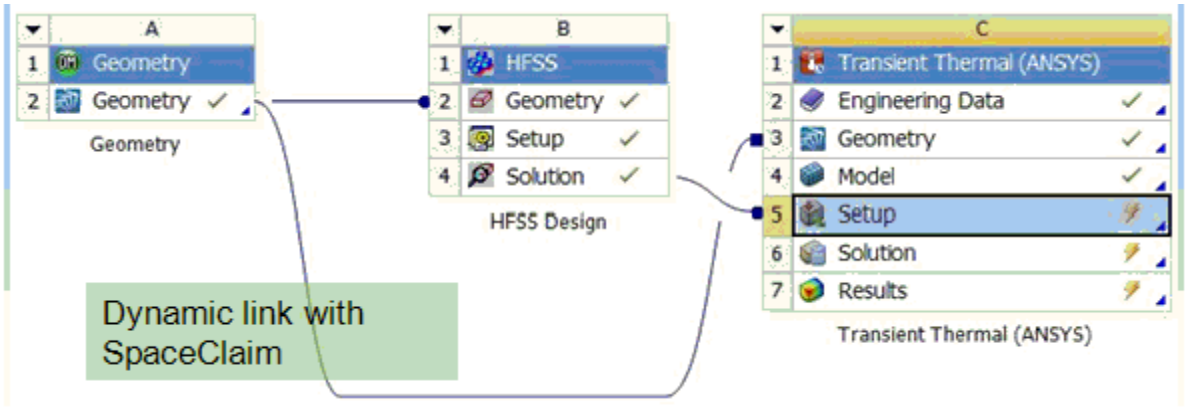


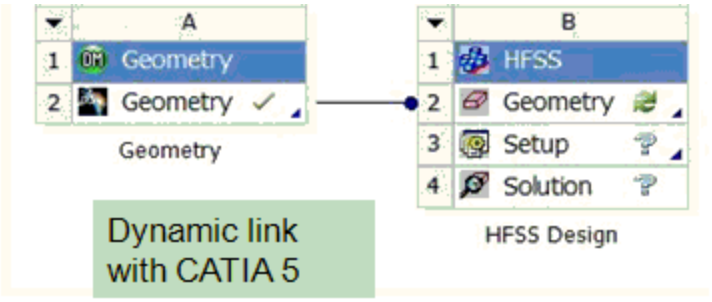
CAD Integration and Geometry Sharing

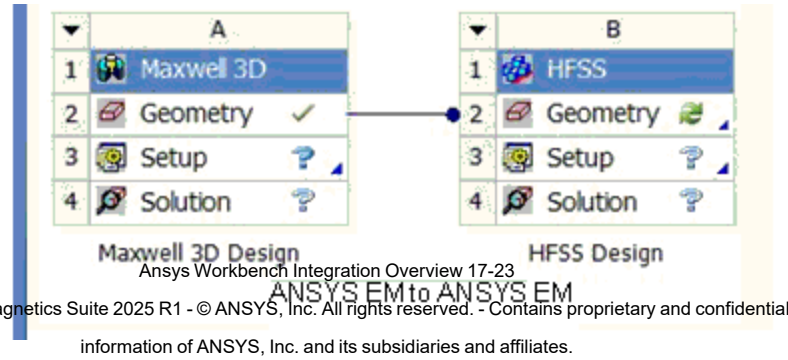
A CAD model comes into Ansys Electromagnetics as a User Defined Model (UDM).

The inputs to Ansys Electromagnetics from CAD are:

- Geometry/Topology with persistent IDs
- CAD parameters
- Material assignment
- Attributes, such as name and color

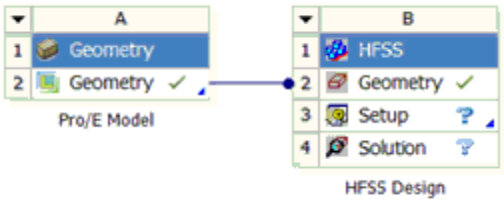




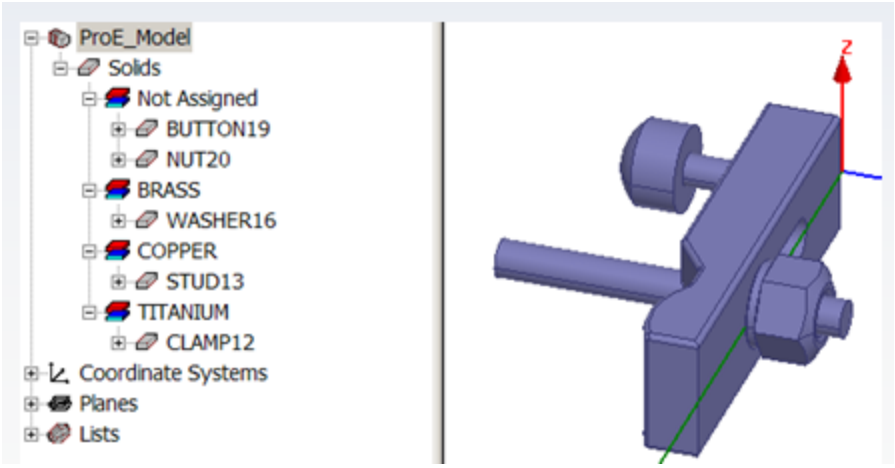


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For example, in Workbench, a Pro/E Model can be linked to Ansys.



The geometry can then be viewed in HFSS as a UDM.



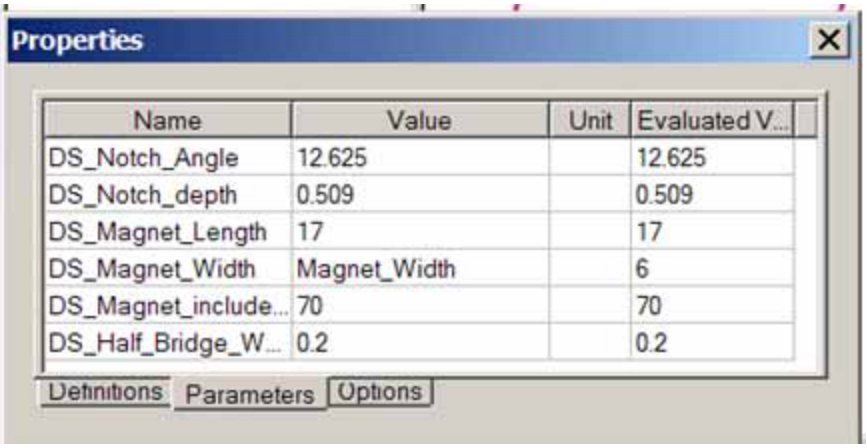
The CAD or WB model parameters appear in the Workbench:

Outline of All Parameters

	A	B	C	D
1	ID	Parameter Name	Value	Unit
2	Input Parameters			
3	DM Geometry (A1)			
4	P5	DS_Notch_Angle	12.625	
5	P6	DS_Notch_depth	0.509	
6	P7	DS_Magnet_Length	17	
7	P8	DS_Magnet_Width	6	
8	P9	DS_Magnet_included_Angle	70	
9	P10	DS_Half_Bridge_Width	0.2	
*	New input parameter	New name	New expression	

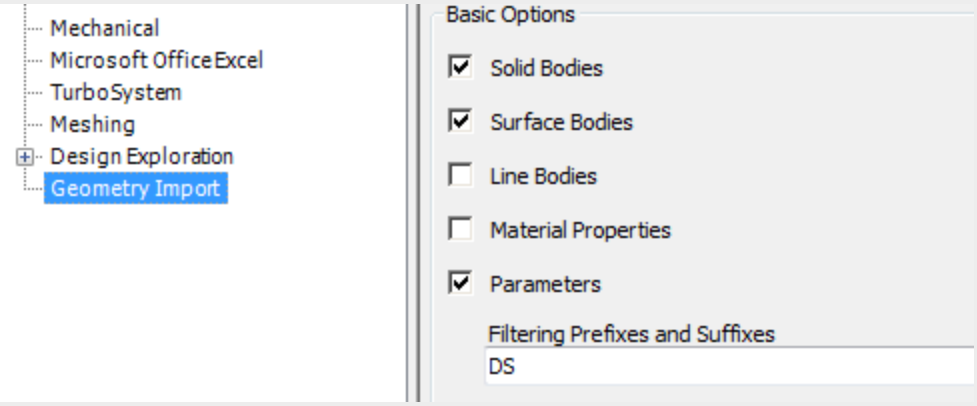
Through the Ansys Electromagnetics CAD integration, the linked UDM includes the same parameters.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



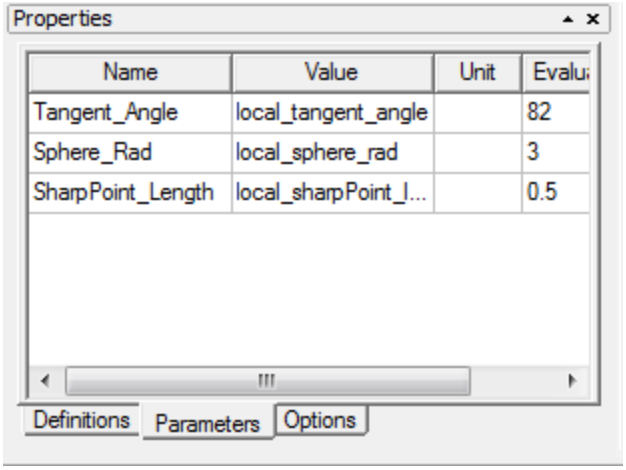
Note:

The parameters shown in these examples all have a DS prefix. This is the default for the Workbench **Tools>Options** for **Geometry Import**. To import parameters with different prefixes or names, assign an appropriate prefix or clear the **Filtering Prefixes and Suffixes** field.



Once you import a geometry with parameters to an Electromagnetics application in the desktop, you need to map to local variables. In the target Electromagnetics application, select the geometry associated with the parameters. Update the geometry and view the **Parameters** tab in the **Properties** window. The **Value** column shows the values of the imported parameters. Type names for local variables in the **Name** column.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Once you have local variables for the imported Design Modeler parameters, you are ready to use Design Xplorer for multiple design parameters.

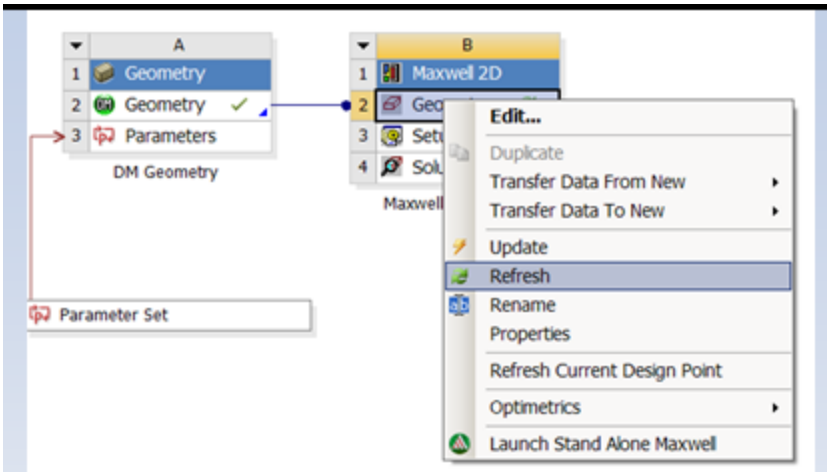
Table of Schematic D2: Design of Experiments (Custom)

	A	B	C
1	Name	P3 - Tangent_Angle (degree)	P4 - Sphere_Rad (in)
2	1	80	3
3	2	75	3
4	3	85	3
5	4	80	2.7

Bi-Directional CAD Integration

Ansys Electromagnetics CAD Integrations uses **Refresh** or **Generate** to pass updates.

You make an edit in a CAD application and run **Refresh** on an Ansys Electromagnetics Geometry Cell.

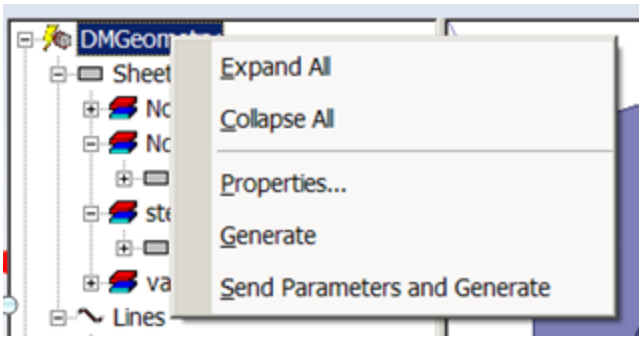


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refresh pulls the current state of CAD model (geometry, parameters, materials etc) and updates the corresponding data in the Ansys Electromagnetics application.

Alternatively, you can run **Generate** on the UDM in the Ansys Electromagnetics window.

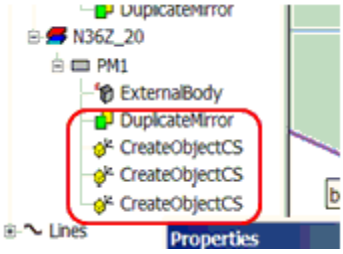
If you edit UDM (CAD) parameters in the Ansys Electromagnetics modeler window you can run the **Send Parameters and Generate** command.



The command passes the edited parameters to the linked CAD application and then pulls corresponding CAD geometry.

CAD Integration Model Edits

Several modeling operations are allowed on a CAD model in the Ansys Electromagnetics Modeler window. Operations are included in the History tree and retained during model **Refresh**.

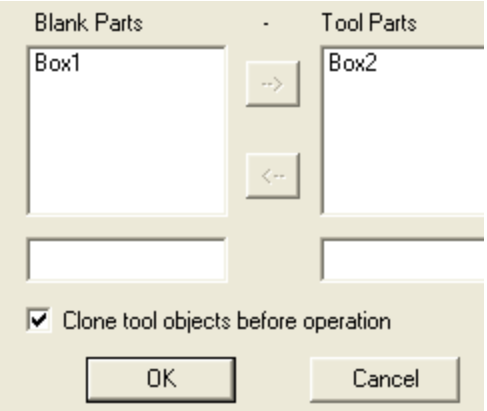


The following operations are not allowed:

- Non-history tree operations like Heal or defeature.
- Operations that use UDM parts as tools, such as Sweep

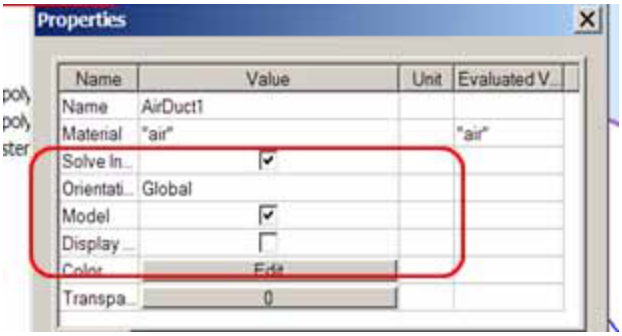
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Boolean operations like Split or Unite (allowed when you select the clone tool option)



The following part attributes can be modified for UDM parts:

- Model/Non Model flag
- Solve Inside flag
- Part orientation
- Color
- Display Wireframe



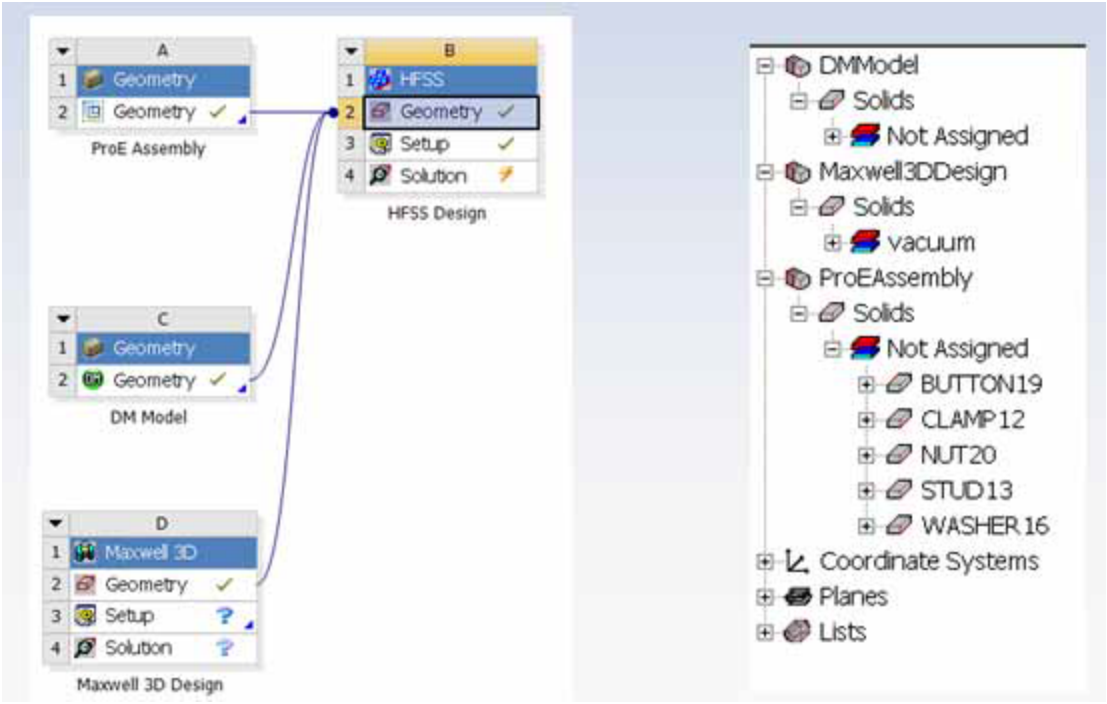
It is not possible to delete individual parts of UDM.

Multiple Geometry Links for CAD Integration

With CAD Integration you can consume geometry from multiple upstream sources. The source can be any of supported CAD or Ansys Electromagnetics products. This creates a UDM for each geometry source.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

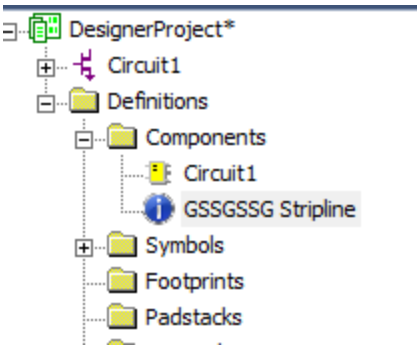
For example, the following figure shows a DM Model, a Maxwell model, and ProE model linked to HFSS in Workbench, and displayed in the HFSS History tree as three UDMs.



Creating Dynamic Links to EDT Designs

If you have a Circuit Design and one or more HFSS, 2D Extractor, Q3D, Icepak, or Mechanical designs open in a Workbench project, you can create dynamic links to those designs.

Update the Circuit Design to open the Electronics Desktop. In the menu bar, select **Workbench > Update Dynamic Link Components**. This command will create components in the project tree for each design in the Workbench project.

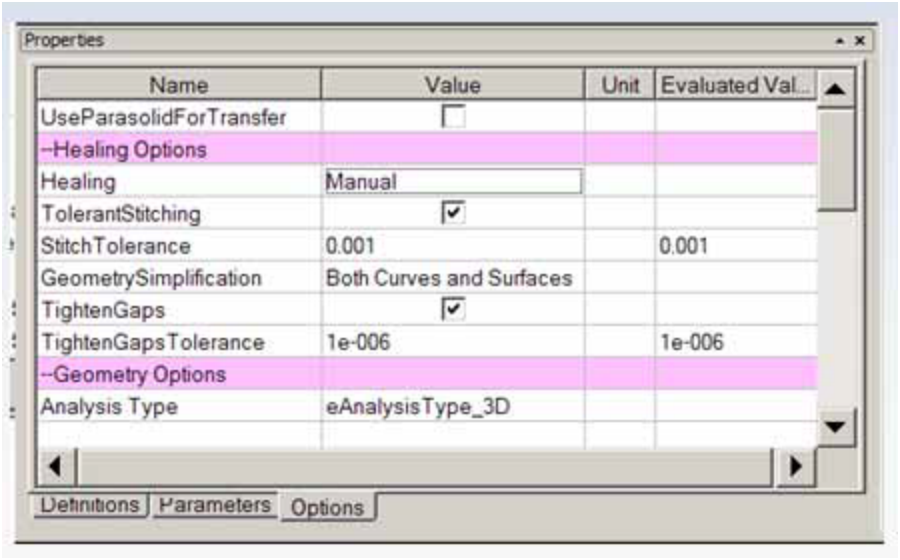


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that in this example, a GSSGSSG Stripline component was created corresponding to the GSSGSSG Stripline design in WorkBench. Once created, you can drag the component into a schematic to place it.

Healing with CAD Integration

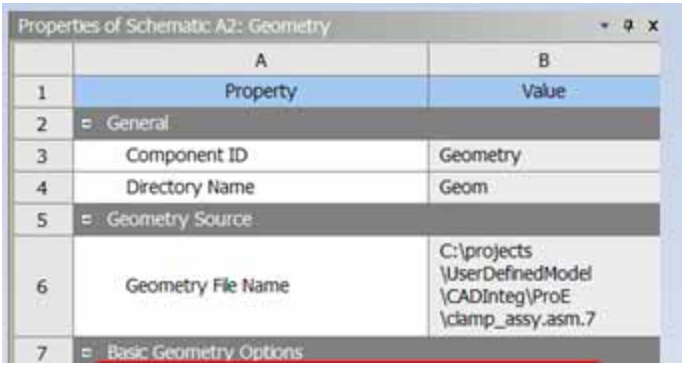
It is not possible to use the Heal command in Ansys Electromagnetics Modeler. Instead similar healing options are available under UDM properties option tab.



Healing options are None, Auto and Manual. By default, healing is off (None) and should be turned on only if required.

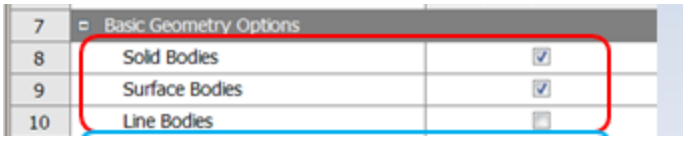
Important Geometry Options for CAD Integration

Select a Geometry Cell in Workbench to see options in the Properties window.



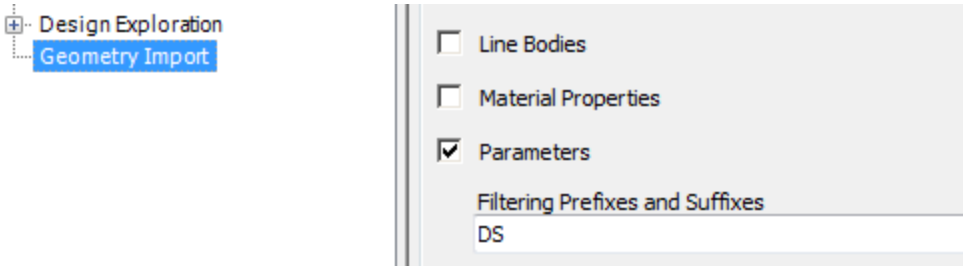
Control dimension of bodies coming from CAD

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Make sure **Parameters** is checked and that the parameter key (filter) is appropriate for CAD parameters.

The default parameter key filtering means that only parameters whose names start with DS will come through. This is the default for the Workbench **Tools>Options** for **Geometry Import**. To import parameters with different prefixes or names, assign an appropriate prefix or clear the **Filtering Prefixes and Suffixes** field.



The **Attribute Key** should be empty or "Color" to bring in CAD colors.

Material Properties must be checked to bring in the material assignment.

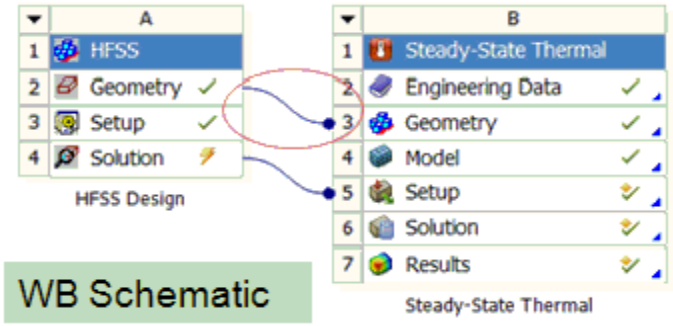
The **Mixed Import Resolution** option is used to resolve parts with mixed dimension (typically from Pro/E)

Refer to Ansys Help for details.

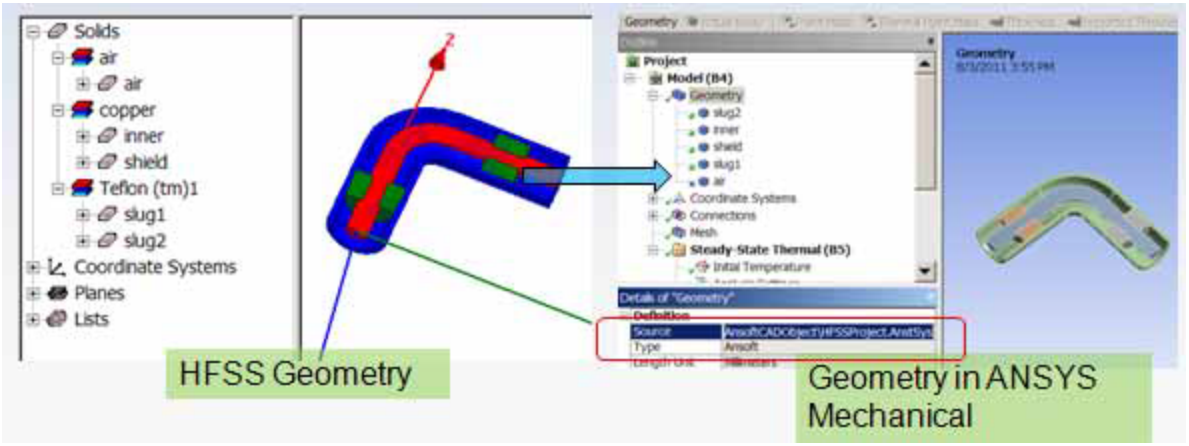
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys EM to Ansys Geometry Transfer

Ansys Electromagnetics CAD Integration transfers model information based on Workbench links.

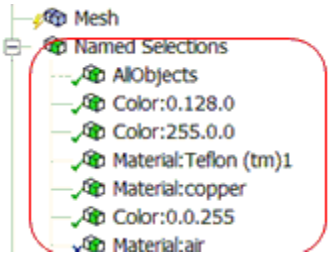


The following figure shows how the information is transferred between simulators.



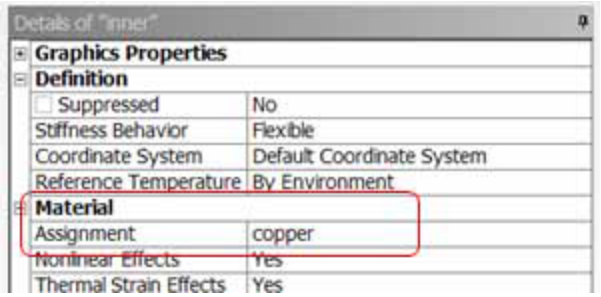
Information transferred includes:

- Geometry
- Ansys Electromagnetics lists and material assignment as Named Selection



- Material assignment

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The CAD Integration geometry link is dynamic (you can get updated geometry from Ansys Electromagnetics) and associative (IDs persist between Ansys Electromagnetics model and Ansys model during model refresh).

Boundary conditions in Ansys are preserved. Object, material, and parameter names with non-ASCII characters are not allowed for data transfer. Such transfers fail and produce an error message.

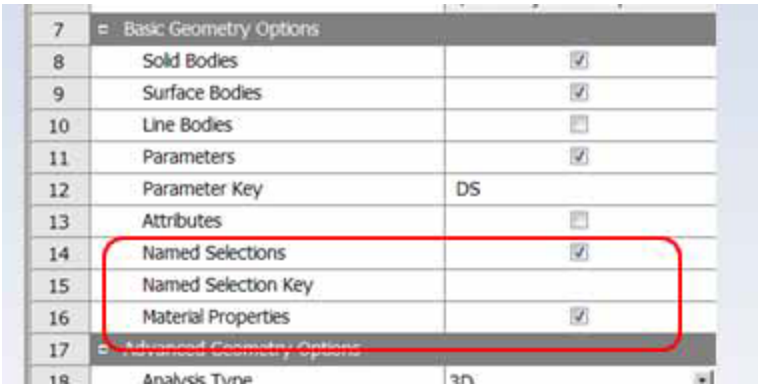
Material Assignment Transfer

There are two prerequisites for material assignment transfer:

- Engineering Data should have materials used in Ansys Electromagnetics model and material names should match (including case)
- Material Properties in Geometry Options must be checked

Before transferring as a named selection, **Named Selections** must be checked in **Basic Geometry Options**.

The Named Selection Key should either be empty or contain "Material."

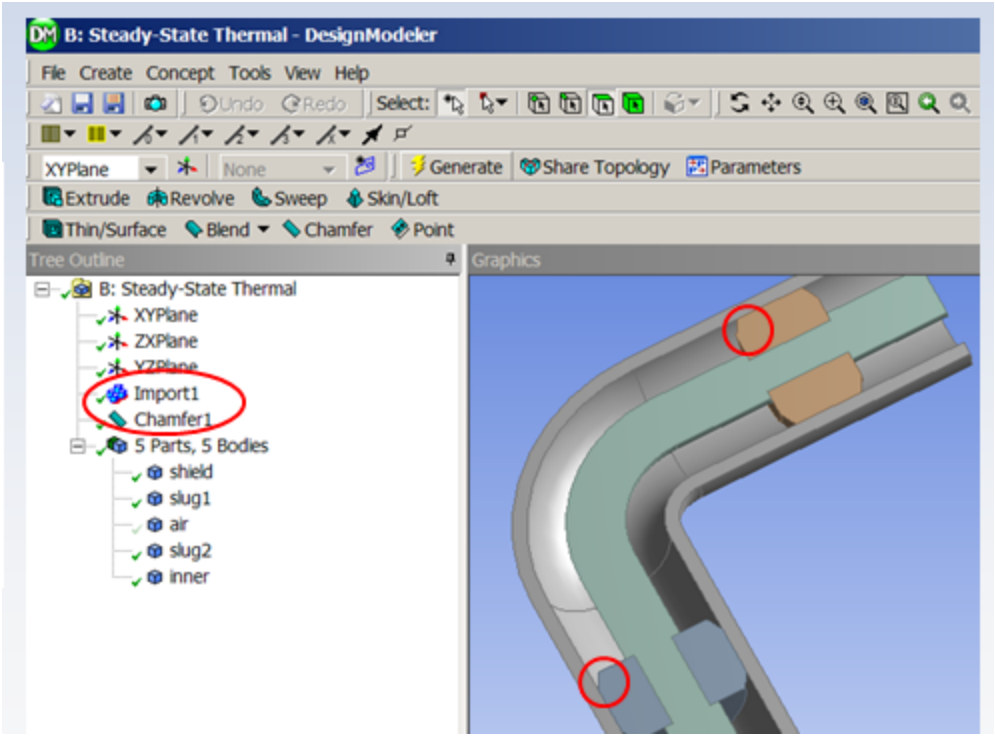


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Geometry Transfer through Ansys DesignModeler (DM)

It is possible to edit geometry in Ansys DesignModeler (DM) before consuming it in Mechanical. This is useful when geometry requires pre-processing for Ansys simulation.

Consider an HFSS model linked to DM through the Workbench. In the following example, a chamfer operation on geometries is being imported.

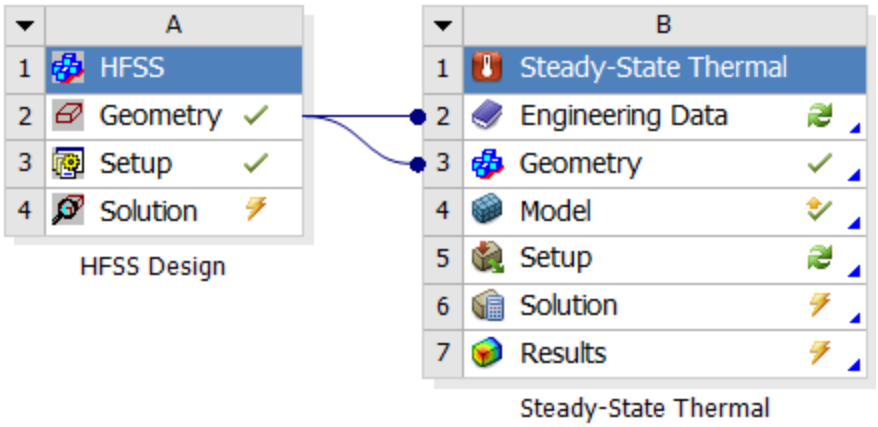


Workbench Material Data Transfer

A link can be created from an Ansys Electromagnetics Desktop system (e.g., HFSS) geometry cell to a downstream Engineering Data (ED) cell. When the downstream ED cell is refreshed, it updates with materials (names and properties) used by the upstream project. This ensures that the geometry-to-geometry link connecting the same two systems, which specifies the material assignments for various parts, refers to the correct materials and their properties.

Detailed Behavior

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The geometry-to-ED link can be created by dragging the Ansys Electromagnetics Desktop system geometry cell to the ED cell of a downstream system. When the downstream system's ED cell refreshes, the upstream system generates a MatML format XML file, which is consumed by Workbench to update the downstream system. This file is stored in the workbench project files according to design point. Note that Workbench ED cell material names are case-sensitive, as are material names within Ansys Electromagnetics Desktop products.

For material assignments to work with the ED in the downstream model, the downstream geometry cell must have the **Material Properties** check box selected. A convenient way to do this is to have this property checked by default, by setting this in **Tools > Options > Geometry Import**. Systems created after this default option is set will have **Material Properties** automatically checked for the geometry cell.

When the downstream model cell is refreshed or updated, material properties from the ED in the same system are used in the model's materials, based on material assignments set during the geometry cell refresh. Note that if material assignment fails, the Workbench default material (Structural Steel) is used.

Workbench resolves name conflicts by changing the name of any materials being transferred over from the upstream system. For example, if the upstream Ansys Electromagnetics Desktop system uses a material named "Structural Steel", this will conflict with the existing downstream default material of the same name. The update will result in the Ansys Electromagnetics Desktop material being named "Structural Steel 2" in the downstream ED, but the downstream model will still use the properties supplied by Ansys Electromagnetics Desktop for the material.

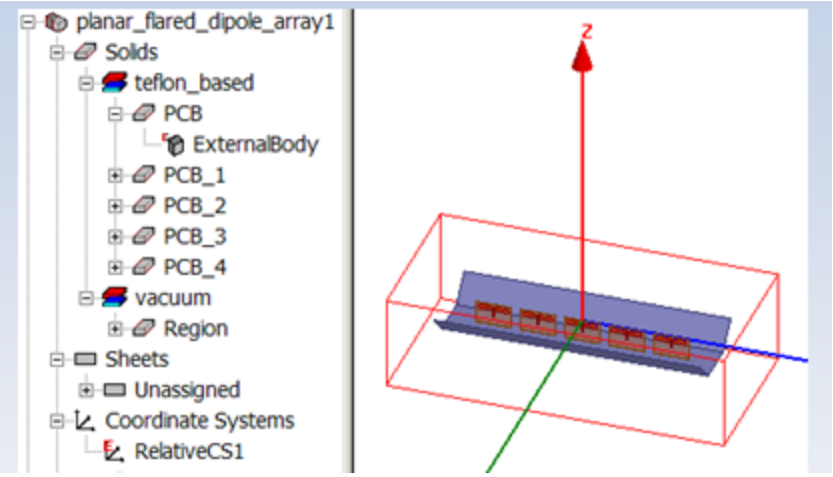
Note that some materials may not satisfy all requirements for downstream system physics. For example, vacuum has no thermal conductivity, but downstream steady state thermal systems require a non-zero value for this property. Material properties in the workbench ED cell of the downstream system can be modified after refresh to ensure that validity criteria can be met. Any property added to a material in the downstream ED is preserved in subsequent ED cell updates. However, any existing property that is edited in the downstream ED will be overwritten by a subsequent ED cell update.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

User-Defined Model (UDM)

A User-Defined Model (UDM) is collection of externally defined parts imported into an Ansys EM 3D Modeler or created using a C or Python script. It has the following attributes:

- UDM includes part attributes (like name, color etc) and material assignment
- UDM can also have external coordinate systems and corresponding planes
- UDM parts can be parameterized and manipulated in Ansys Electromagnetics modeler just like any other part

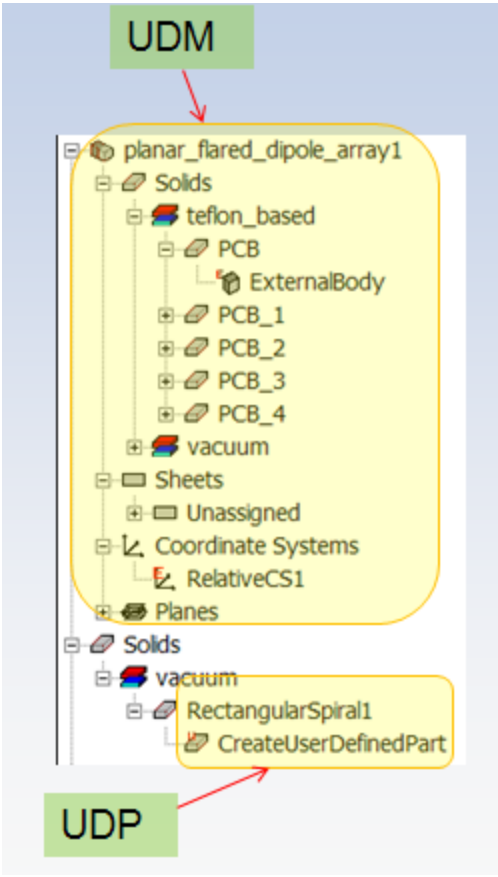


- UDM can either represent Static geometry models or Dynamic links to models of external geometry editors.
- It can be used for supporting CAD integration in WorkBench.
- UDM uses same plugin technology as User Defined Part (UDP)

UDM Compared to User-Defined Primitives

User-Defined Models (UDM) resemble User-Defined Primitives (UDP):

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ansys Electromagnetics products can be extended by users through new UDMs.

UDM plugins are discovered by searching standard directory paths. Plugins for static UDMs can build a model using ‘callback interfaces’ (like create-box, create-cylinder, subtract etc) similar to UDP.

UDMs run inside Ansys Electromagnetics application and provide geometry, topology, persistence, and parameters.

In contrast to UDP:

- A UDM provides multiple parts/CS/etc.

  A UDP provides primitive operation only for a single part.

- A UDM provides part attributes and material assignment.

  A UDP does not define part attributes or material.

UDM Properties have four tabs – Definitions, Parameters, Options and Info.

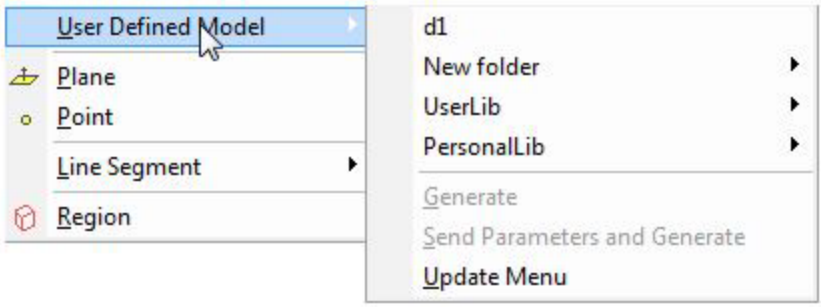
- Definition tab has UDM name, and the coordinate system used to position UDM. It may have external reference to file.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Info tab has UDM dll name, dll location, version, *etc*.
- Option tab may have options.

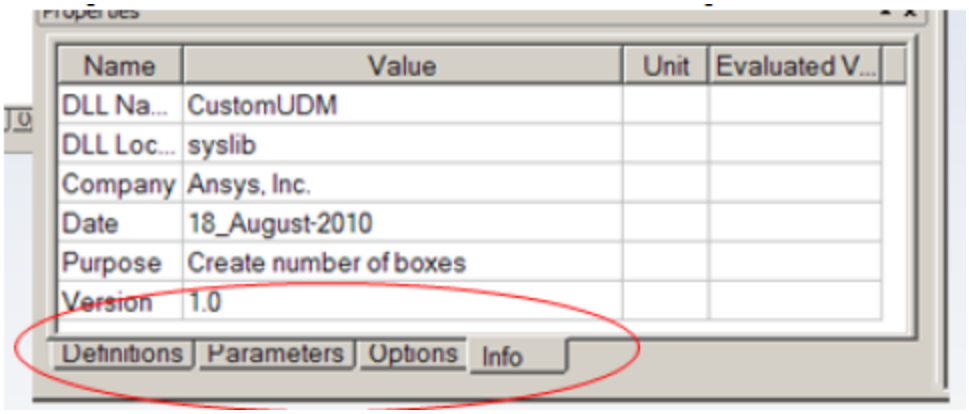
Insert UDM Command on Draw Menu

To insert a UDM into a design, use the **User Defined Model** command on the **Draw** menu for the Modeler window.



UDM Properties

UDM Properties have four tabs – **Definitions**, **Parameters**, **Options** and **Info**.



Definition tab has

- the UDM name
- Coordinate system used to position UDM
- May have external reference to file

Info tab has the UDM dll name, dll location, version, *etc*.

Option tab may or may not have any options.

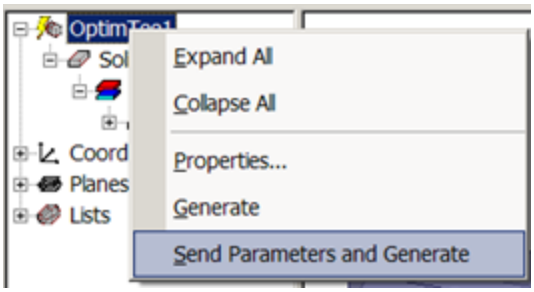
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

UDM Parameters

UDM geometry can be manipulated through its parameters. It can be mapped to a design or project variable for animation, parametric analysis.

IDs are persisted (allowing to retain boundaries) during a parameter edit. Note that UDM geometry is not dynamically updated upon parameter edits. The UDM shows a lightning bolt icon by the model name when parameters are edited:

You must run the **Send Parameters and Generate** command to synchronize parameters with geometry:



UDM Part Edits

Several modeling operations are allowed on UDM parts. Operations will be part of the history tree and will be retained during a model refresh.

The following operations are not allowed:

- Non-history tree operations like healing, defeature.
- Operations that use UDM parts as tool, such as sweep or boolean (but allowed when clone tool option is selected)

The following part attributes can be modified for UDM parts:

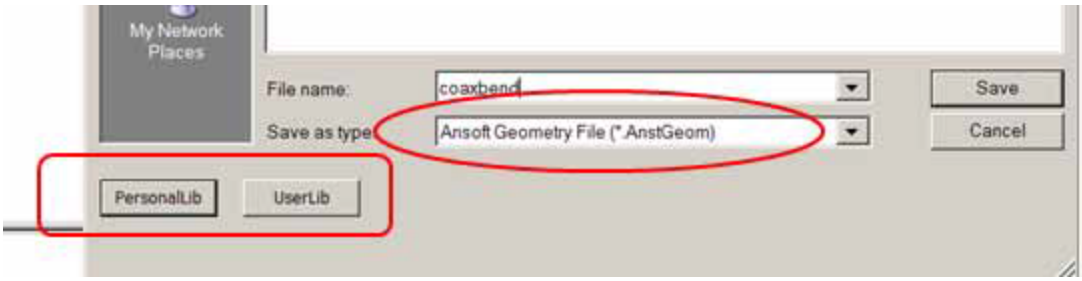
- Model/Non-model flag
- Solve Inside flag
- Part orientation

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

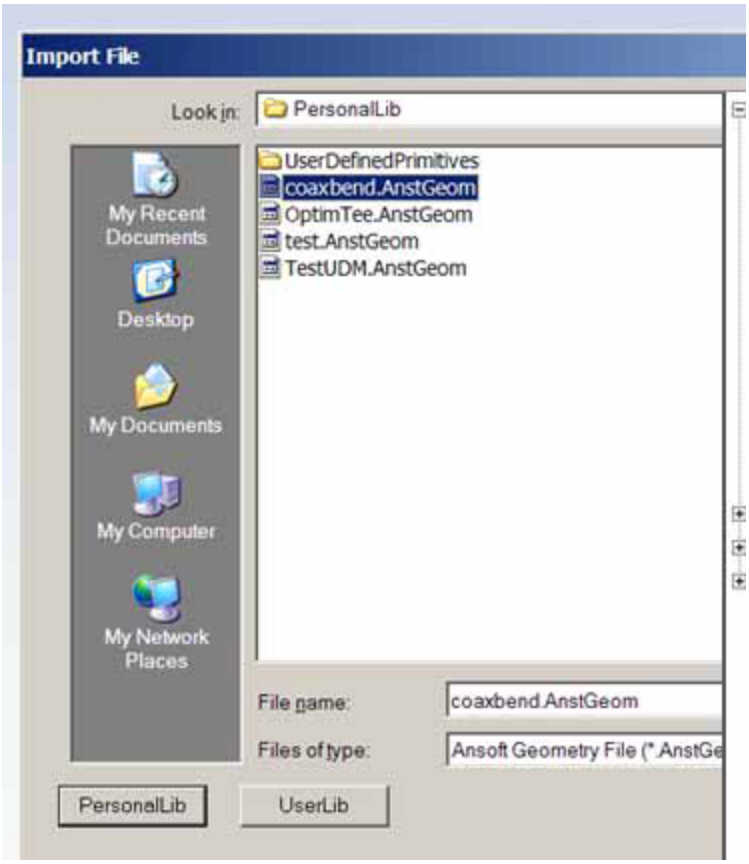
Library of Models for CAD Integration

UDM technology allows a library of models

- Any Ansys EM model can be exported as 'Ansoft Geometry File'

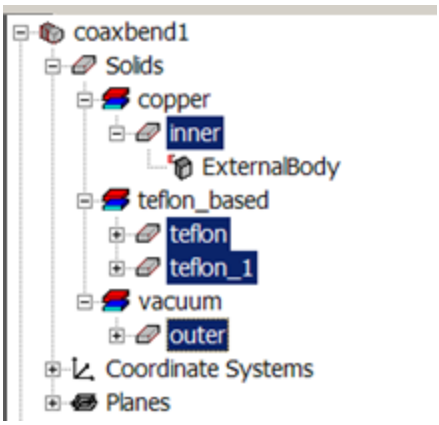


- An Ansoft Geometry File can be imported back as a UDM.



- Any Design/project variables associated with model are brought in as UDM parameters.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Geometry computation for UDM (and also UDP) can be specified in the Modeler options as either done on.

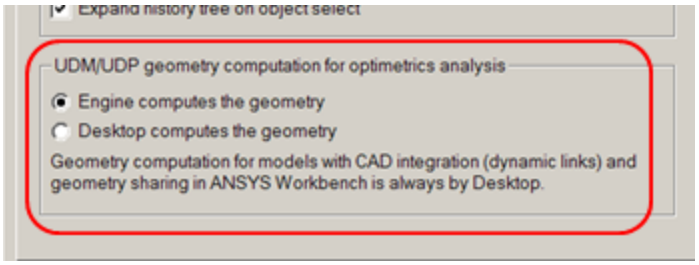
- Engine side (default):

  Requires deployment of UDM on each node

- Desktop side:

  UDM need not be deployed on each engine

  Desktop will be busy during parametric analysis



Feedback Iterator

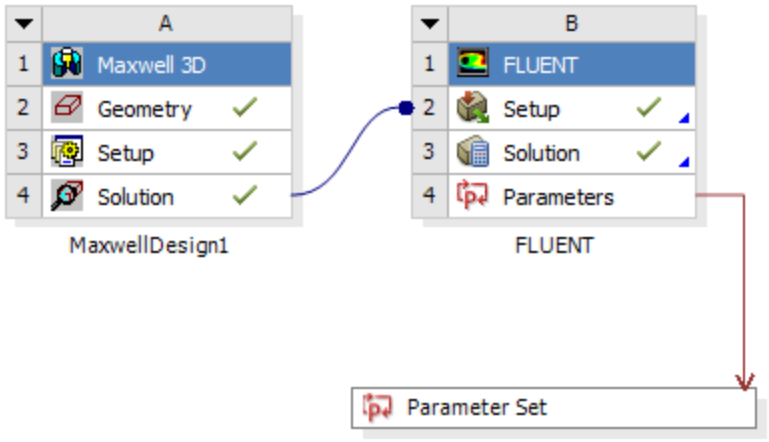
Background Information

Prior to the introduction of the Feedback Iterator, Ansys Workbench supported a two-way loose-coupling protocol with Ansys Electromagnetics products.

SystemCoupling already uses the word coupling to mean low-level solver coupling. Existing Electromagnetics product coupling is loose compared to SystemCoupling and is limited to file transfers at the end of a complete solve in a standalone system/product. No communication occurs during a solve. The coupling is two-way.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The one way portion (Upstream source component to Downstream target component) is handled via existing workbench data/transfer connection mechanism.

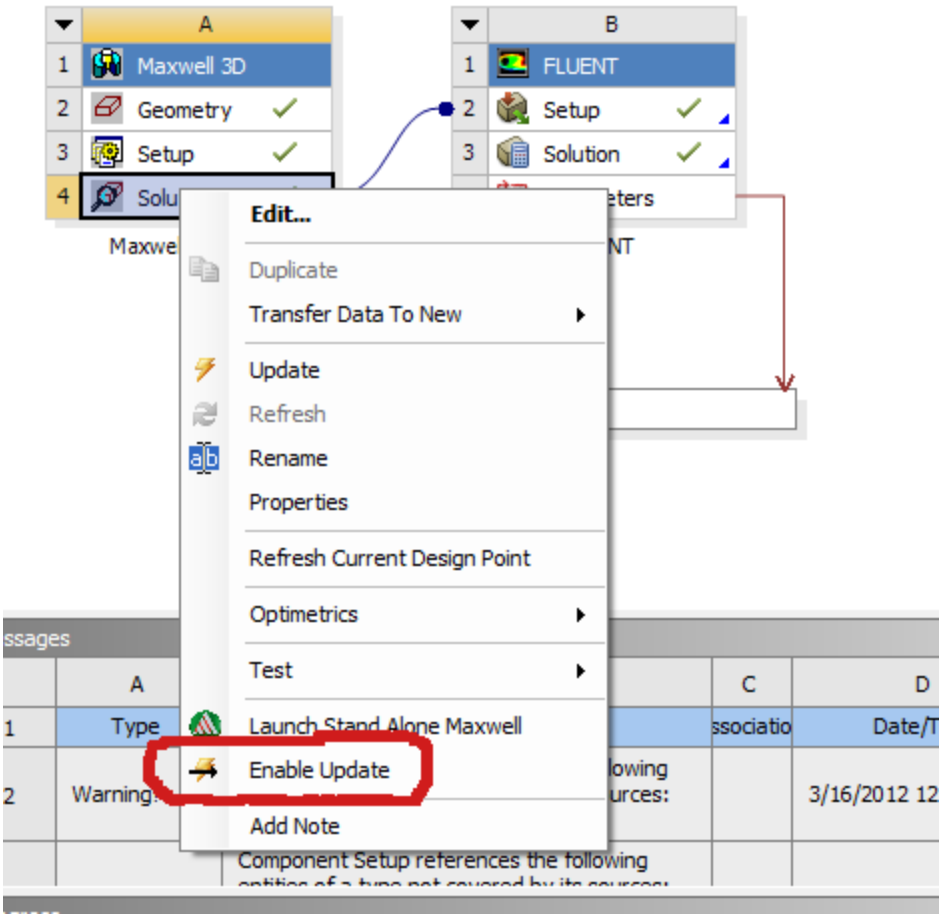


The round trip is handled by a separate protocol, agreed upon by the participating systems, whereby the downstream system exports a set of files to a location specified by the upstream system via its one-way transfer. This exported data is then incorporated by the upstream system in its next update.

To run the next coupled solve iteration, invoke the **Enable Update** operation, as shown below, which updates all systems involved.

These steps (**Enable Update**, **Update Project**) are continued as long as needed.

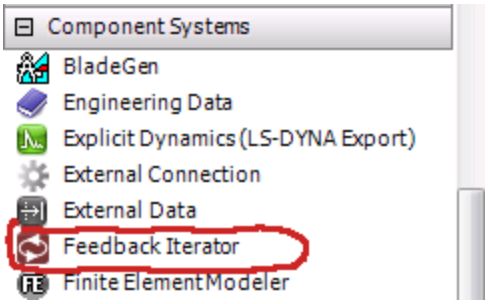
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The Feedback Iterator System

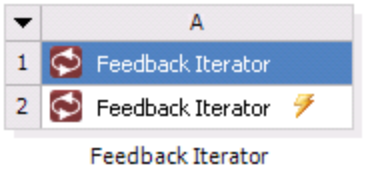
Ansys Electromagnetics Suite provides the Feedback Iterator system for automating the manual steps needed for driving a feedback utilizing system-pair to convergence. In addition to automating feedback incorporation over a user-specified number of iterations, the Feedback Iterator also allows control over the number of iterations (iteration termination criteria), target temperature, and displacement convergence criteria.

The **Feedback Iterator** appears in the Workbench Toolbox user interface under **Component Systems**.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

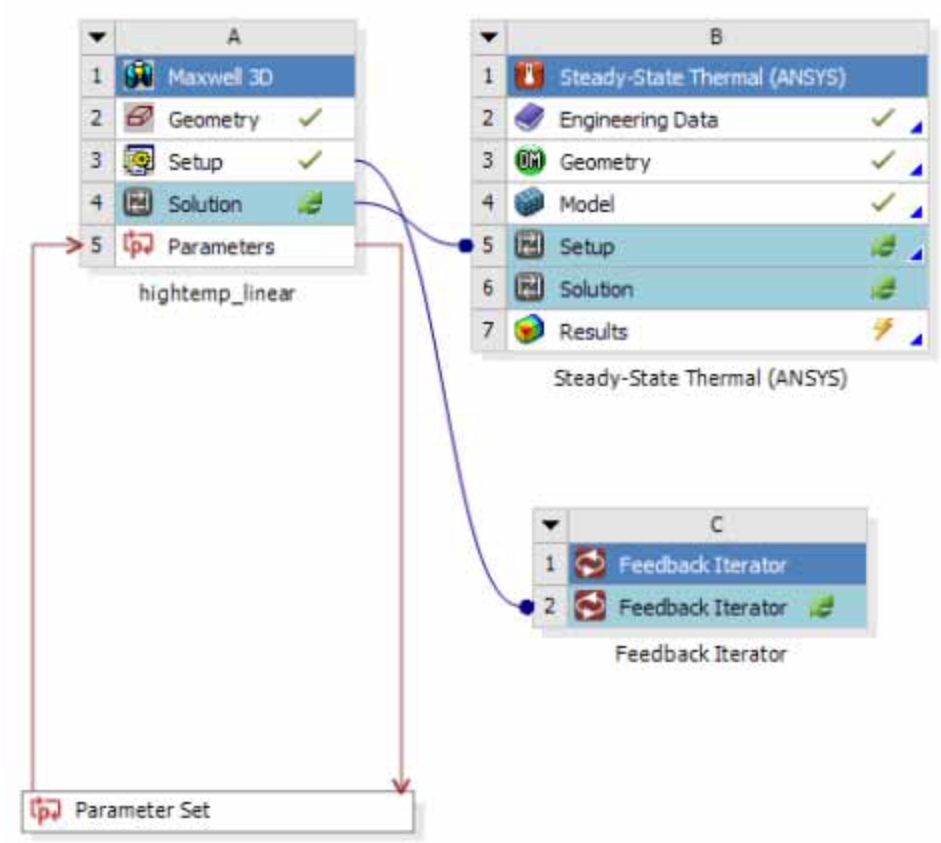
If you drag and drop an instance of the Feedback Iterator into Workbench Schematic, the default system name is Feedback Iterator.



Feedback Iterator in Use

The Feedback Iterator system attaches to the Workbench schematic like any other system.

In the following example, a Maxwell system provides AnsoftHeatLossData to a fluent system. Dropping the Maxwell setup cell onto the Feedback Iterator component results in the links shown.



The Feedback Iterator Addin functions the same way with all systems that participate in Electromagnetics product two-way loose coupling (Maxwell and HFSS for sources and Fluent, Thermal, and Structural for targets).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Feedback Iterator Component Properties

The Feedback Iterator's primary role is to control iterative solves and its properties target this end.

For Maxwell and HFSS, the Feedback Iterator properties are

- **Iterations Completed** – a read-only property that displays the number of iterations completed.
- **Max Iterations** – sets the maximum number of iterative solve loops to perform before terminating iterations in case the *Target Delta Temperature %* or *Target Delta Displacement %* is not achieved. The default value is 100.
- **Target Delta Temperature %** – specifies the maximum *Target Delta Temperature %* that signifies convergence. The default value is 5%, and the value must be 0.01 or greater.

  > **Note:**
  >
  > • The delta temperature error is calculated in Kelvins.
  >
  > • The Maxwell and HFSS design Profile tab displays absolute/relative delta data, while the delta temperate in Workbench means the relative delta (expressed as %).

- **Target Delta Displacement %** – specifies the maximum *Target Delta Displacement %* that signifies convergence. The default value is 5%, and the value must be 0.01 or greater.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

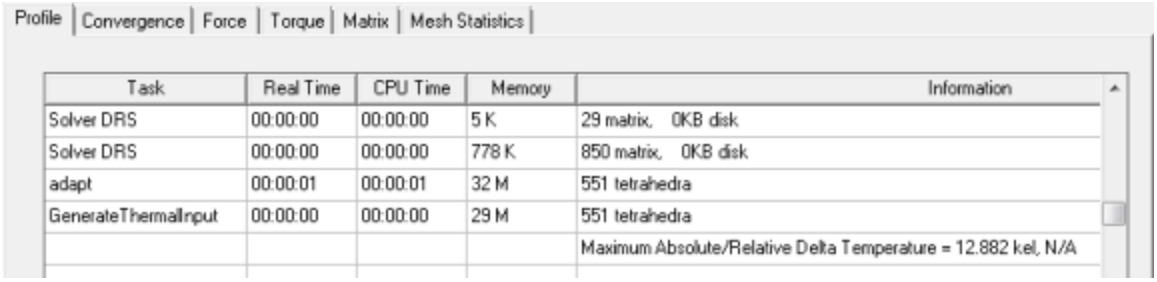
	A	B
1	Property	Value
2	⊟ General	
3	Component ID	FeedbackIterator
4	Directory Name	FeedbackIteratorComponent
5	⊞ Notes	
7	⊞ Used Licenses	
9	⊟ Iterations	
10	Iterations Completed	0
11	Max Iterations	100
12	⊞ Callback	
14	⊟ Temperature Convergence	
15	Target Delta Temperature %	5
16	Latest Delta Temperature %	Not Available
17	⊟ Displacement Convergence	
18	Target Delta Displacement %	5
19	Latest Delta Displacement %	Not Available

The Feedback Iterator properties also display the most recently achieved *Latest Delta Temperature %* and *Latest Delta Displacement %* values, allowing the user to manually abort when satisfied with the achieved deltas.

> **Note:**
>
> Both the Temperature and Displacement Convergence properties sections are always shown irrespective of which feedback types are enabled for the project.

Running a two-way feedback simulation from Workbench while keeping the Maxwell or HFSS Profile tab open shows that the 3D solver keeps track of two feedback related quantities:

- Maximum Absolute/Relative Delta Temperature (if temperature feedback is enabled)
- Maximum Absolute/Relative Delta Displacement (if displacement feedback is enabled)



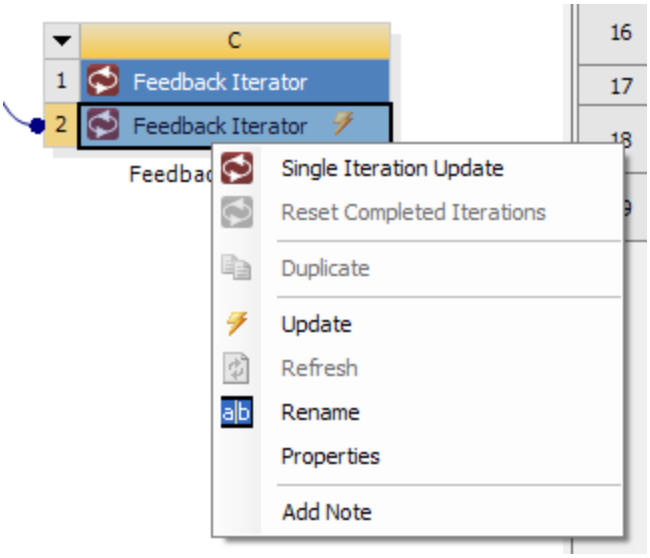
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

These signify the maximum difference on the solution mesh of the quantity in question from one feedback iteration to the next (thus the value is only available from the second iteration onward). This data forms the basis for the convergence controls in the FeedbackIterator. These controls allow the user to base the termination of feedback iterations on a target max delta T and/or max delta displacement. The target max delta forms the convergence condition.

Feedback Iterator GUI Operations

The **Single Iteration Update** action allows you to run a single iteration worth of updates, as follows:

1. Updates the Electromagnetics product system, which will incorporate any previous feedback from the downstream system.
2. Updates the downstream system.
3. All coupled systems (Electromagnetics product, Electromagnetics product Downstream, and Iterator) are in the UpToDate state.
4. Iterator's “Iterations Completed” property increments by 1.



Right-clicking the Feedback Iterator component and selecting **Update** allows you to run iterations automatically. Iterations continue to run either until convergence criteria are met, or until the Max Iterations value is reached.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** After getting temperature feedback from Fluent, Maxwell solving starts from the *last adaptive*, which means there is NO more adaptive pass solving. Consequently, instead of looking for the expression cache value in the adaptive solution, users should look for it in the *last adaptive* solution. For *Last Adaptive*, the expression cache value can be displayed from **Results** > **Create Fields Report** > **Data Table**.

Resetting the Feedback Iterator

Resetting the iterator essentially means starting from iteration-0 conditions, that is:

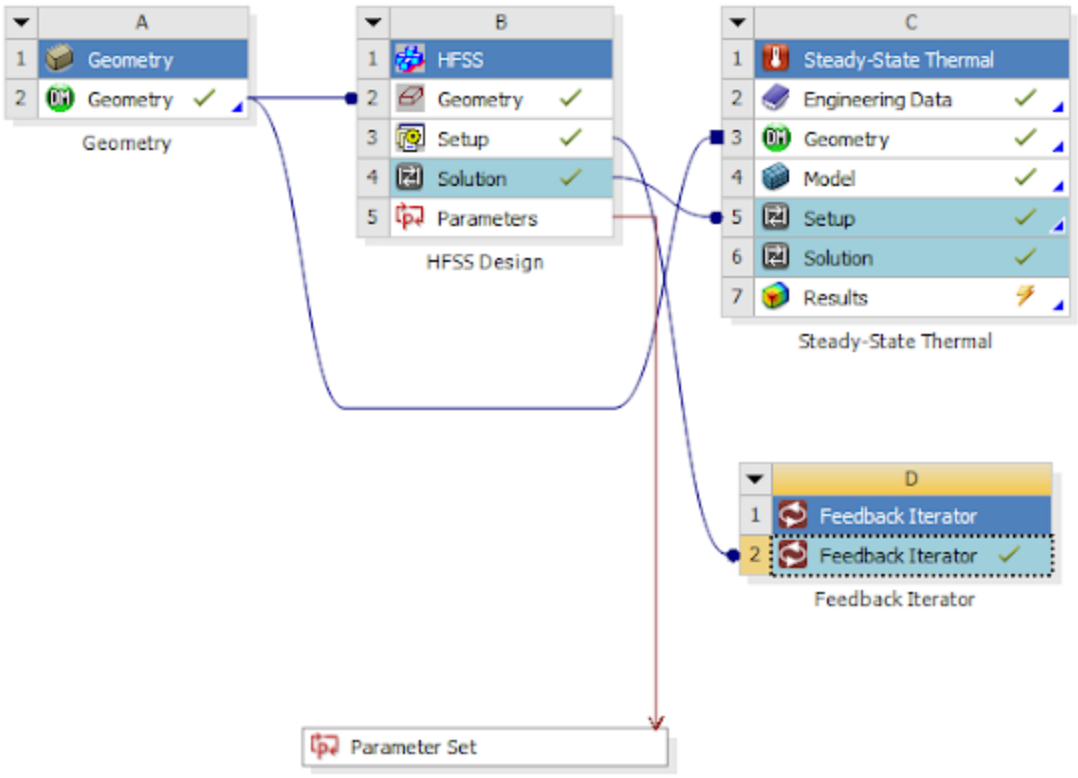
- No Displacement or Temperature feedback from another system is incorporated.
- The first iteration solution will be purely an Ansys EM analysis solution.

Resetting the Feedback Iterator cannot easily be done entirely within Workbench. However, the following two processes can be used:

- Resetting via the Ansys EM user interface
- Resetting via a WB journal script

The following example uses an HFSS/Thermal project. (This same approach applies to the other Ansys EM design types.)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



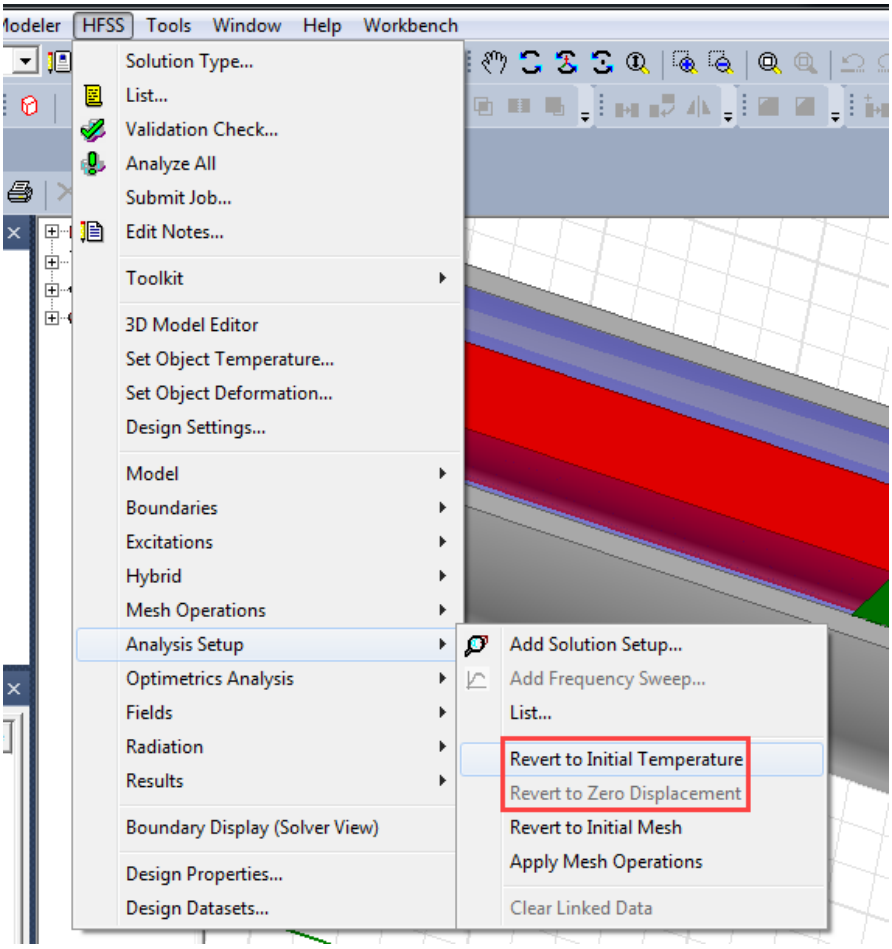
Resetting via the Ansys EM User Interface

Depending on the type(s) of feedback involved, this typically means reverting back to initial conditions for one or both of the following settings:

- **Revert to Initial Temperature**
- **Revert to Zero Displacement**

You can find these under the respective design type menu, such as HFSS shown below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Resetting via a WB Journal Script

> **Note:** The above Ansys EM user interface actions can be recorded into a WB journal script and played back for the easiest approach.

You also can build a script from scratch using the following as the template – simply update the system name as appropriate, include the appropriate "Revert..." commands, and either save as a script or enter into the WB Command window.

```
oDesign = Ansoft.GetDesign(GetSystem(Name="HFSS"))

oDesign.GetModule("AnalysisSetup").RevertAllToInitialTemperature()

oDesign.GetModule("AnalysisSetup").RevertAllToZeroDisplacement()
```

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Callback Interface

The callback interface allows you to react to each step of the iteration process as implemented by the FeedbackIterator component. This is useful for implementing special iterations or solving transient simulations with a limited scope.

There are four main API features provided:

- Callback functions, which the FeedbackIterator calls at various points in each iteration
- Utility functions, which the Callback functions can use to extra properties of the containers being processed
- Output functions, which allow script debugging and supply additional messages
- Limited state management, which allows the script to store and retrieve state across callback functions and iterations

Callback and State API

State is managed in a limited fashion. All the API methods take a final dictionary argument. This dictionary is limited to using **string keys** and **number or string values**. Within this limitation, add new keys, read old keys, clear the dictionary, etc., and it will be persisted across functions calls and even across Updates. When the **Iterations Completed** property is **rest**, the dictionary is also cleared out.

It is advisable for the callback script to initialize the dictionary at Iteration 1.

All the API methods use a subset of the following arguments:

`iterationNumber`	An integer representing the current iteration. This always starts from 1.
`ContainerList`	A Python list of containers (DataContainerReference). This is the entire list of the coupled containers managed by the Feedback Iterator. You typically loop through them and using the utility methods listed below, identities them.
`Container`	A single container that is being processed. This is a DataContainerReference.
`State`	A read/write Python dictionary that is used to maintain state across function calls and iterations.

Only return values from `BeforeIterationEx` are processed. Returns from all other functions are discarded.

1. `BeforeIteration(IterationNumber, ContainerList, State)`: This method is called before each iteration. Ideally used to initialize the state dictionary, open editors as

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

required, or initialize setups as needed for each iteration.

2. `BeforeIterationEx(IterationNumber, ContainerList, State)`: Similar to the `BeforeIteration` method except that this allows you to control the number of iterations via the return value.
    - Return: `"more"` to request one more iteration
    - Return `"last"` to indicate that this is the last iteration
    - Any other return (including none) will be treated as a return of `"last"` and terminate iterations.
3. `AfterIteration(IterationNumber, ContainerList, State)`: This method is called after each iteration. This can be used to copy result files over, check results, implement any possible convergence calculations, logging of results, *etc*.
4. `BeforeContainerRefresh(IterationNumber, Container, ContainerList, State)`: Is called before each of the coupled containers is refreshed. The `Container` argument represents the container about to be refreshed.
5. `AfterContainerRefresh(IterationNumber, Container, ContainerList, State)`: Is called after each of the coupled containers is refreshed. The `Container` argument represents the container just refreshed.
6. `BeforeContainerUpdate(IterationNumber, Container, ContainerList, State)`: Is called before each of the coupled containers is Update (after a refresh). The `Container` argument represents the container about to be updated.
7. `AfterContainerUpdate(IterationNumber, Container, ContainerList, State)`: Is called after each of the coupled containers is updated. The `Container` argument represents the container just updated.

If the callback scripts uses other files to send commands to various containers (vb, js, apdl, python, etc.), all of those files are best saved under the user_files directory. This allows you to use the `FBGetUserFilePath(str)` to get the absolute path of the file and allows the files to be packaged with any created archive.

Utility Functions

`FBSystemForContainer` (container)	system	Given a container, returns the system it belongs to
`FBSystemDisplayName` (system)	string	Given a system, returns its display name on the schematic
`FBSystemID`(system)	string	Given a system, returns its ID. This is the same as the `UniqueDIrectory` for the system
`FBGetUserFilesPath` (relativePath)		Given a relative path located under the user_files directory, say "hello.py", this returns the absolute path of the file

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Output/Debugging Functions

`FBAddInfoMessage (string)`	Adds an info message to the WB message window
`FBAddWarningMessage (string)`	Adds a warning message to the WB message window
`FBAddErrorMessage (string)`	Adds an error message to the WB message window
`FBMessageBox (string)`	Pops up a dialog box with the supplied string with an **OK** button

Example Scenarios for Feedback Iterator

This section describes several scenarios for using the Feedback Iterator:

Setting up Iteration with Feedback Iterator

Breaking Iteration Control

Starting an Iterative Update

Running a Single Iteration

Interrupting an Iterative Loop

Resuming an Interrupted Iterative Loop

Modifying any of the Systems Involved in Iteration (coupled clients)

Iterating to Convergence

Setting up Iteration with Feedback Iterator

Scenario	Steps to execute	Outcome
Electromagnetics product solution provides solution data to a single downstream setup	• Drop Feedback Iterator system on the setup component of Electromagnetics product OR • Create Feedback iterator system and connect	Electromagnetics product setup component is connected to the Iterator. Electromagnetics product solution and downstream setup and solution components are coupled as clients to the iterator. The iterator component is the coupled master and the rest are coupled clients. Any coupling changes schematic visuals: • Coupled cells including coupling master are colored differently from normal cells

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scenario	Steps to execute	Outcome
	Electromagnetics product setup component to the TwoWay iterator component AND User clicks on the Iterator component and sets the desired Feedback Iterator properties.	• Coupled cell icons change to reflect the icon of the coupling master • Coupled client cells no longer display the **Update** context menu item and cannot be updated via script commands • The cell states of all coupled cells (master and clients) are synchronized to be the most pessimistic state among any of them (e.g., after an update, any modification will set all of them to the "Modified" state).
Electromagnetics product solution provides to multiple downstream setup cells	same as above	All the downstream components (setup and solution in each downstream system) are coupled as clients. The update order in this case depends on any additional data-flow connections between the systems that consume the upstream Electromagnetics product solution data.
Electromagnetics product solution cell does not have any downstream targets	same as above	No changes occur beyond what is expected when you create a new connection (no coupling). Coupling only occurs when Electromagnetics product solution cell has a downstream connection. If a downstream connection is added after the link to the iterator, coupling will be performed as described in the first row.

Breaking Iteration Control

Scenario	Steps to execute	Outcome
Iterator coupled to Electromagnetics product solution cell and downstream setup/solution cells	• Break Electromagnetics product solution cell's provides link OR • Break Electromagnetics product setup link	In addition to what is normally expected from the user actions, all coupled clients are de-coupled (their icons and colors on UI are restored)

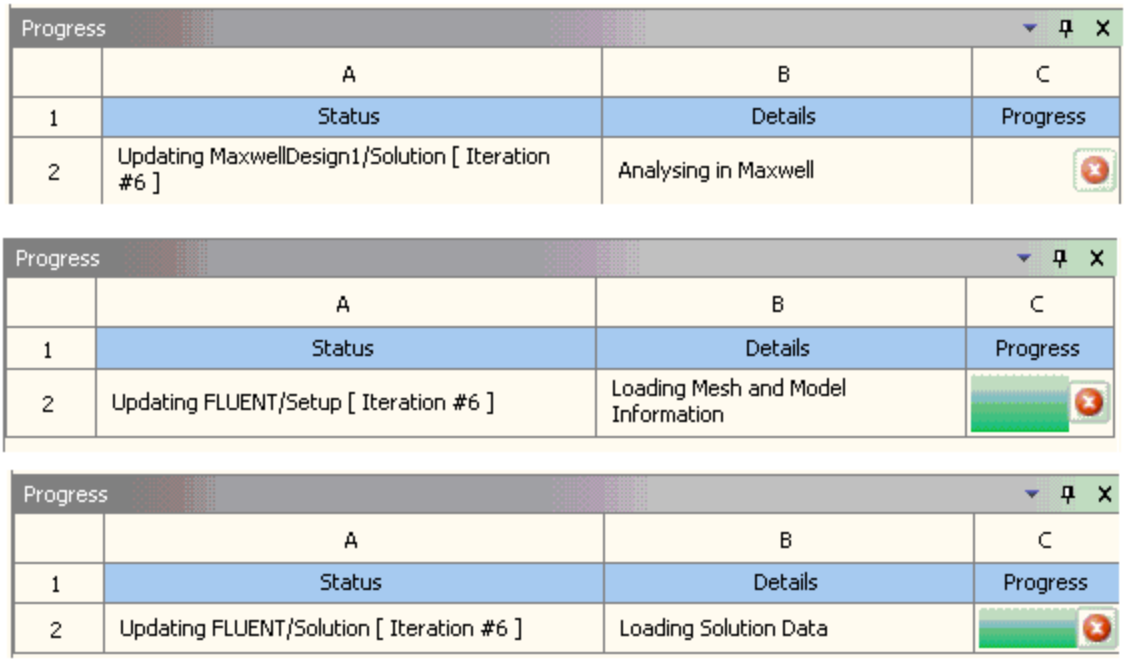
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scenario	Steps to execute	Outcome
	to iterator OR • Delete Electromagnetics product solution consumer system OR • Delete Iterator system	
Electromagnetics product setup cell is connected to iterator but Electromagnetics product solution does not provide anything. No components are coupled to the iterator	• Break Electromagnetics product setup link to iterator • Delete Iterator system	No coupling exists in this scenario so nothing visible changes beyond what is expected from the user actions

Starting an Iterative Update

Scenario	Steps to execute	Outcome
Standard update scenario	• RMB on iterator component and select Update GUI operation OR • Update Project OR • Update all design points OR • DX Update	For each iteration, the Electromagnetics product solution is updated followed by the downstream setup and the downstream solution. Each of the client component updates display their progress monitor and can be aborted (resulting in aborting the current iteration)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Running a Single Iteration

Scenario	Steps to execute	Outcome
NumCompleted < NumIterations	RMB on iterator component and select Single Iteration Update	One iteration is run. "Completed Iterations" property is incremented.
NumCompleted ≥ NumIterations	same as above	same as above

Interrupting an Iterative Loop

Currently, there is no special progress or interruption control. The progress monitor for individual components displays as they are updated and any control they choose to provide (interrupt, abort or both) is available. Choosing to abort any of the client component updates aborts the current iteration, and the Completed Iterations property remains unchanged from the previous iteration.

Resuming an Interrupted Iterative Loop

Scenario	Steps to execute	Outcome
Single step	RMB on iterator component and select Single Iteration Update	One iteration is always run and the Completed iterations property is incremented.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scenario	Steps to execute	Outcome
Run until completion	• RMB on iterator component and select Update OR • Select the Project Update menu option from the toolbar, etc.	If the user specified number of operations are already completed, nothing is done. Otherwise, the remaining iterations are run.

Modifying any of the Systems Involved in Iteration (Coupled Clients)

When any coupled client components are modified (either in Workbench or in an external editor), the coupled clients and master are marked as modified. The Completed Iterations property is set to 0.

Maxwell in a Thermal Deformation Use Case

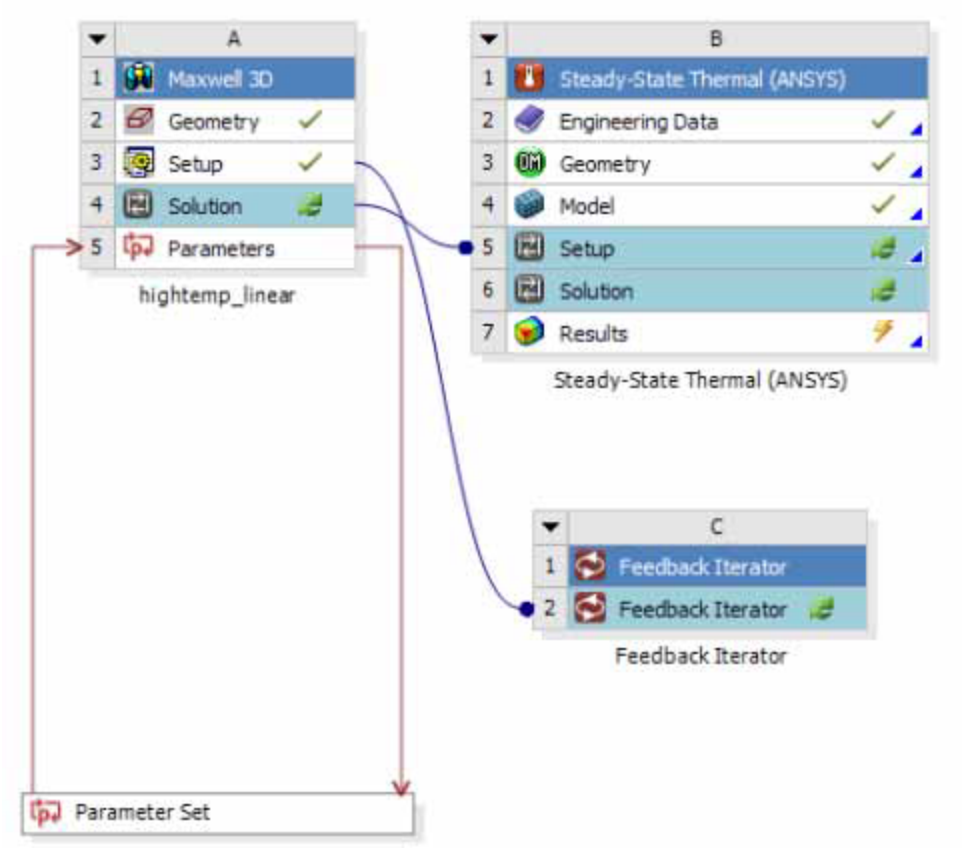
This is a more complex and involved use case. The feedback iterator works identically.

Iterating to Convergence

Scenario	Steps to execute	Outcome
Standard update scenario	• Right-click on the Feedback Iterator component and select Update OR • Update Project OR • Update all design points OR • DX Update	For each iteration, the Electromagnetics product solution is updated, followed by the downstream setup and the downstream solution. Each of the client component updates display their progress monitor and can be aborted (resulting in aborting the current iteration)

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

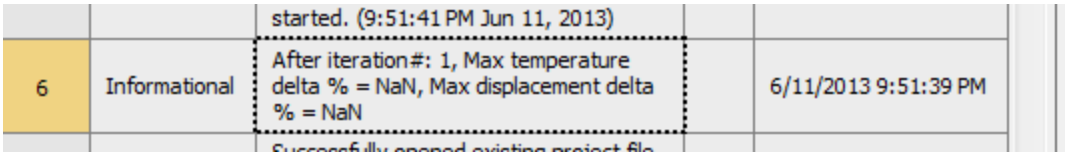
The following temperature convergence example uses Feedback Iterator with a Maxwell design, coupled with a Steady-State Thermal component. Iterating to convergence operates similarly for HFSS projects.



The example uses defaults of 5% for the convergence targets and a value of 100 max iterations. Recall that the max iterations value is set as a safety measure to ensure that iterations do not continue indefinitely if the solution does not converge. As we progress through the iterations, we observe the following:

End of Iteration #1

The first iteration, because it has no previous iteration, cannot return a meaningful delta value.



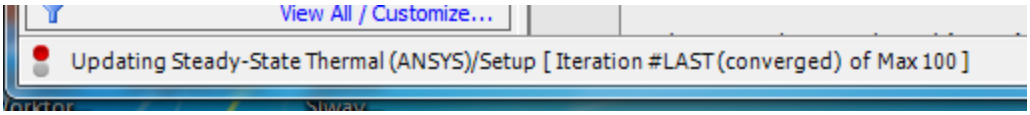
At the end of this iteration, the Latest Delta value is listed as Not Available.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

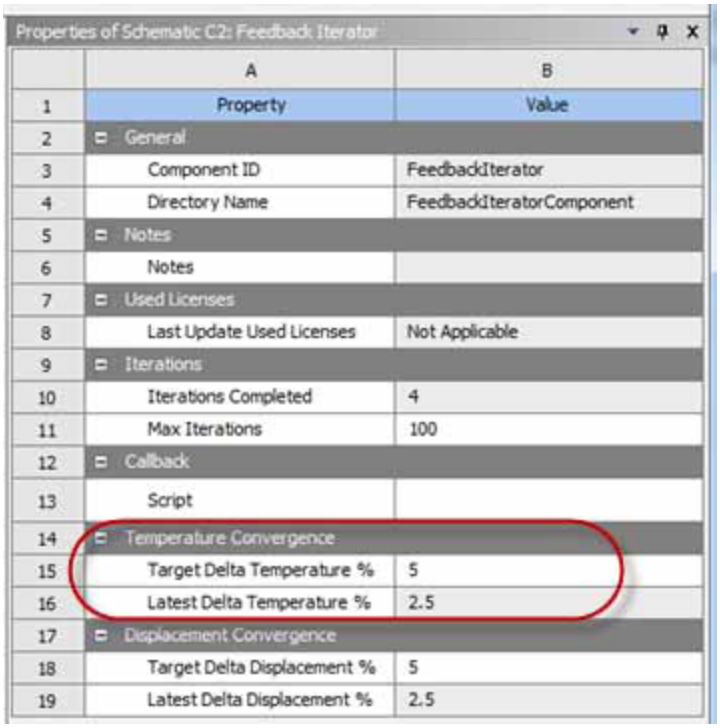
	A	B
1	Property	Value
2	General	
3	Component ID	FeedbackIterator
4	Directory Name	FeedbackIteratorComponent
5	Notes	
6	Notes	
7	Used Licenses	
8	Last Update Used Licenses	
9	Iterations	
10	Iterations Completed	1
11	Max Iterations	100
12	Callback	
13	Script	
14	Temperature Convergence	
15	Target Delta Temperature %	5
16	Latest Delta Temperature %	Not Available
17	Displacement Convergence	
18	Target Delta Displacement %	5
19	Latest Delta Displacement %	Not Available

Convergence Achieved

In this example, convergence has been achieved by the third iteration.

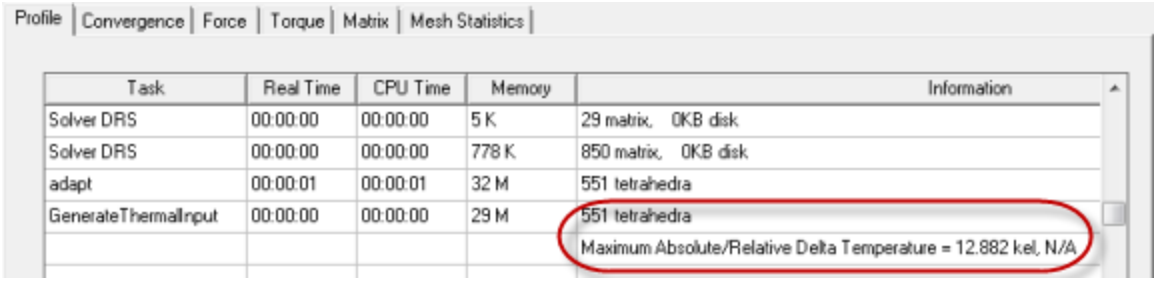


Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



When convergence criteria are met, the simulation stops. If you attempt to update after convergence has been achieved, the simulation will not be launched since the current solutions satisfy the convergence criteria.

You can monitor the iteration progress by opening the Maxwell editor and selecting **Results** > **Solution data**. Choose the **Profile** tab and keep the window open. As you solve each iteration, you can observe the reported Delta-T (with thermal feedback) and/or delta-displacement (with displacement feedback) and abort the iterations (or stop single iteration updates) when the values reach acceptable convergence levels.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

18 - Scripting

Information about creating, editing, and using IronPython scripts and VB scripts is in the product's scripting guide in the help. You can also access PDF versions of the scripting guide from the help system.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

19 - Exporting Equivalent Circuit Data

You can export lumped R, L, C data from a Maxwell solution to Ansys Twin Builder. Importing the new data file to Twin Builder enables you to include wave effects in the circuit simulations.

> **Note:** An equivalent circuit can be exported from a parametric solution or from an imported table.
>
> You can only export an equivalent circuit from a parametric solution when the following two criteria are met:
>
> - The solution type is **Magnetostatic** or **Electrostatic**.
> - A parametric setup exists.

Exporting a Circuit From a Parametric Solution

To create a circuit from parametric solutions, you first need to set up and solve a problem that contains a parametric sweep. Any force, torque, and matrix solutions are automatically available to use in the equivalent circuit. Other solutions can be treated as extra inputs/outputs if they have been added as calculations in the parametric setup — that is, extra inputs/outputs come from the parametric table.

> **Note:** In Maxwell, global variable names begin with the **$** character. However, when you are creating an ECE **.sml** model, this character causes the circuit to fail when importing it to Twin Builder. To resolve this, when the circuit is exported, the **$** character is replaced by the **_** character. For example, the project variable **$MyVar** is converted to **_MyVar**.

To export a circuit from a parametric solution:

1. Click **Maxwell 2D** or **Maxwell 3D** > **Export Equivalent Circuit** > **From Parametric Solutions**.
   The **General** window appears, allowing you to specify basic information about the circuit model.

   > **Note:** This command is enabled only when the following two criteria are met:
   >
   > - The solution type is **Magnetostatic** or **Electrostatic**.
   > - A parametric setup exists.

2. Select one of the following from the **Model Type** drop-down menu depending upon the Design Type (2D or 3D):

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Linear Motion**
- **Rotational Motion**
- **Transformer**
- **Matrix**
- **Lookup Table**

3. Select a **Parametric Setup** from the drop-down menu.
4. Select a **Solution Setup** from the drop-down menu.
5. Select a **Matrix Setup** from the drop-down menu.
6. Select a **Force Setup** or a **Torque Setup** from the drop-down menu, depending on which parameter you have set up for your design.
7. For the force or torque setup, select **X**, **Y**, or **Z** as the **Component**.
8. Select either **Ampere-Turns** or **Amperes** as the **Current Source Variables** option.
9. Click **Next**.

   The **Table** window appears, allowing you to set up the inputs and outputs for the circuit equivalent. Most of the values have been automatically filled in, based on your design. You can keep the defaults or change the selections and values for the various parameters.

10. To apply deep spline interpolation to all inputs in the circuit PWL model, select the **Use Bezier Interpolation** check box.
11. To export the data to a table that you can edit and use to export an equivalent circuit at a later time, do the following:
    a. Click **Export Table**. The **Save As** dialog box appears.
    b. Select a location, and type a name in the **File name** box.
    c. Click **Save**.

    The **Table** window reappears. The file that is created contains header rows with information such as name, i/o, and type, plus all of the actual data. You may export the table to view or use in external programs. You can also modify the exported table file and then re-import it to create an equivalent circuit. On import, the information in the header rows is used as default settings in the circuit export dialog box.

    > **Note:** The **Table** window is the last step for the **Lookup Table** model type. For all other model types, there is one more step: the **Terminals** window.

12. For model types **Linear Motion**, **Rotational Motion**, **Transformer** and **Matrix**, click **Next**.

    The **Terminals** window appears, allowing you to set up terminals, which are nodes with "through" and "across" data. Most of the values have been automatically filled in, based on your design. You can keep the defaults or change the selections and values for the various parameters.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

13. Enter a **Scaling Factor** in the text box. The scaling factor is applied to all output quantities and can be used, for example, to scale data from partial models that take advantage of symmetry.
14. Optionally, specify the **Model depth** for 2D XY models for scaling.
15. Optionally, for 2D XY **Rotational Motion** model type, specify the **Skew** angle.

    When a stator core or rotor core is skewed for a 2D Rotational Motion model, the flux linkages and torque of the look-up table will be modified based on the skew angle θ_k .

    For any output of the look-up table, f(θ), where θ is rotor position, the modified output will be

$$f_m(\theta) = \frac{1}{\theta_k} \int_{\theta-\theta_k/2}^{\theta+\theta_k/2} f(\theta)\, \delta\theta$$

16. Specify the **Terminals**:

    To specify a coil terminal:

    a. Select a **Source** for the **Flux** or **Charge**, depending on whether your design is mechanical or electrical.
    b. Enter a **Resistance**.
    c. Enter the number of **Turns** in the coil winding.
    d. Enter the number of **Branches**.

    To specify a mechanical terminal:

    a. Select the **Force** (or **Torque)** variable from the drop-down menu.
    b. Select the **Position** variable from the drop-down menu.
    c. Optionally, for Rotational Motion model type, select **Use rotational velocity**.
17. Click **Finish** to export the equivalent circuit.

Types of Equivalent Circuit Models

Currently, you can generate the following model types:

- **Linear Motion** - Models inductance (or capacitance) and force as functions of current (or voltage) and position. The parametric solution should cover the range of motion and conductor current (or voltage).
- **Rotational Motion** - Models using rotational rotor position sweep.
- **Transformer** - For one coil only, models nonlinear mutual (magnetizing) inductance with a linear leakage inductance branch. Therefore, this model is only valid for 1-phase transformers. The parametric solution should cover the range of current for one coil only in an open-circuit test. Nonlinear mutual inductances for 3-phase (or more) transformers are better solved using the transient solver.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Matrix** - Models an inductance or capacitance matrix for one or more conductors, as a function of current or voltage. The parametric solution should cover the range of each conductor's current or voltage.
- **Lookup Table** - This option creates a lookup table model in Simplorer format.

Exporting a Circuit From an Imported Table

To create a circuit from an imported table, you need to have a table file containing tabular data. The first row in the file must contain the column names. The table export feature writes other useful information into subsequent rows, but the import succeeds whether or not this information is present. The rows of tabular data come next.

> **Note:** In Maxwell, global variable names begin with the **$** character. However, when you are creating an ECE **.sml** model, this character causes the circuit to fail when importing it to Twin Builder. To resolve this, when the circuit is exported, the **$** character is replaced by the **_** character. For example, the project variable **$MyVar** is converted to **_MyVar**.

To export a circuit from an imported table:

1. Click **Maxwell 3D or Maxwell 2D** > **Export Equivalent Circuit** > **From Imported Table**.

   The **Select File** dialog box appears.

2. Find and select the file containing the table you want to use.
3. Click **Open**.

   The **General** window appears, allowing you to specify basic information about the circuit model.

4. Select one of the following from the **Model Type** drop-down menu:
   - **Linear Motion**
   - **Rotational Motion**
   - **Matrix**
   - **Lookup Table**
5. Select either **Ampere-Turns** or **Amperes** as the **Current Source Variables** option.
6. Click **Next**.

   The **Table** window appears, allowing you to set up the inputs and outputs for the circuit equivalent. Most of the values have been automatically filled in, based on your design. You can keep the defaults or change the selections and values for the various parameters.

7. To apply deep spline interpolation to all inputs in the circuit PWL model, select the **Use Bezier Interpolation** check box.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. To export the data to a table that you can edit and use to export an equivalent circuit at a later time, do the following:
    a. Click **Export Table**. The **Save As** dialog box appears.
    b. Select a location, and type a name in the **File name** box.
    c. Click **Save**.

    The **Table** window reappears. The file that is created contains header rows with information such as name, i/o, and type, plus all of the actual data. You may export the table to view or use in external programs. You can also modify the exported table file and then re-import it to create an equivalent circuit. On import, the information in the header rows is used as default settings in the circuit export dialog box.

    > **Note:** The **Table** window is the last step for the **Lookup Table** model type. For all other model types, there is one more step: the **Terminals** window.

9. For model types **Linear Motion**, **Rotational Motion**, and **Matrix**, click **Next**.

    The **Terminals** window appears, allowing you to set up terminals, which are nodes with "through" and "across" data. Most of the values have been automatically filled in, based on your design. You can keep the defaults or change the selections and values for the various parameters.

10. Enter a **Scaling Factor** in the text box. The scaling factor is applied to all output quantities and can be used, for example, to scale data from partial models that take advantage of symmetry.
11. Optionally, specify the **Model depth** for 2D XY models for scaling.
12. Optionally for 2D XY **Rotational Motion** model type, specify the **Skew** angle.

    When a stator core or rotor core is skewed for a 2D Rotational Motion model, the flux linkages and torque of the look-up table will be modified based on the skew angle θ_k.

    For any output of the look-up table, f(θ), where θ is rotor position, the modified output will be

$$f_m(\theta) = \frac{1}{\theta_k} \int_{\theta-\theta_k/2}^{\theta+\theta_k/2} f(\theta)\, \delta\theta$$

13. Specify the **Terminals**:
    - To specify a coil terminal:
        a. Select a **Source** for the **Flux** or **Charge**, depending on whether your design is mechanical or electrical.
        b. Enter a **Resistance**.
        c. Enter the number of **Turns** in the coil winding.
        d. Enter the number of **Branches**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To specify a mechanical terminal:
  a. Select the **Force** (or **Torque)** variable from the drop-down menu.
  b. Select the **Position** variable from the drop-down menu.
  c. Optionally for Rotational Motion model type, select **Use rotational velocity**.

14. Click **Finish** to export the equivalent circuit.

Setting Up Current Variables

For problems with current, the **Current Variables Represent** setting allows you to specify one of the following two options:

- **Ampere-Turns**
- **Amperes**

This setting provides flexibility in setting up current sources with different numbers of turns and branches.

In Maxwell, current source values are specified in Ampere-turns, meaning that if a given source is driven with 2 Amps through 100 turns, then the source value must be set to 200. Inductance is calculated per-turn; therefore, to calculate EMF, the flux must be scaled by the number of turns to give the total flux.

You can create two kinds of circuit models:

- A model format where the data table is based on current in Amp-turns and flux per turn. This model internally converts currents and fluxes using the specified turn ratio. This model format was the only one available in versions of Maxwell before Maxwell 11.
- A model format where the data table is based on current in Amps and total flux. This model does *no* internal scaling of values, since the data is already in a form the outside circuit expects. This model format is available in Maxwell 11 and later versions.

For either model type, you can view the inductance setup to obtain information about the specified groups, turns, and branches.

Current Variables Represent Ampere-Turns

How to use this format:

1. Apply variables directly to sources. *Source1* value = *Current1*.
2. Sweep variable values in Ampere-turns. *Current1* sweeps from 100 to 200.
3. In an inductance setup, specify the number of turns consistent with the source setup. Make sure all sources in a group have the same number of turns.

When to use this format:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If all sources in a group have the same number of turns.
- If you want to be able to modify the number of turns in the exported circuit.
- If you are more comfortable thinking of variables in Ampere-turns.

When using this format, the grouping is taken from the inductance setup. The number of turns and branches per group from the inductance setup are used as a default but can be modified either before exporting the circuit or in the exported circuit.

Current Variables Represent Amperes

How to use this format:

1. Define sources as the current variable times turns. *Source1* value = *100*Current1*.
2. Sweep variable values in Amperes. *Current1* sweeps from 1 to 2.
3. In an inductance setup, specify the number of turns consistent with the source setup.

When to use this format:

- In cases where one current is applied through sources with different numbers of turns.
- If you do *NOT* need to modify the number of turns in the exported circuit.
- If you are more comfortable thinking of variables in Amperes.

When using this format, the groups, turns, and branches are taken from the inductance setup and are used as is. You will *not* be able to modify them during circuit export or in the exported circuit.

Setting Inputs and Outputs in the Table Window

The table includes rows for all of the following that are appropriate to the model type:

- Swept variables from the parametric setup.
- Components of flux or charge from the selected matrix.
- Force or torque.
- Calculations from the parametric setup.

Where possible, the columns are set with reasonable defaults based on the information from the design. In many cases, you should not have to change anything.

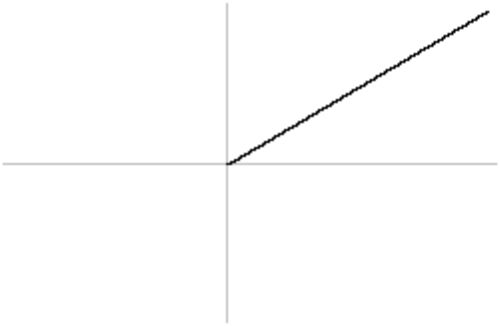
Additional information about the columns:

- Under **I/O**, the choices are **Input**, **Output**, or **Unused**. **Unused** means that the quantity will not be included in the circuit.
- Under **Type**, the choices are **Position**, **Rotation**, **Current**, **Voltage**, **Flux**, **Charge**, **Force**, **Torque**, and **Other**. These choices affect the terminal setup in the next window. **Other** is typically used for extra inputs/outputs.

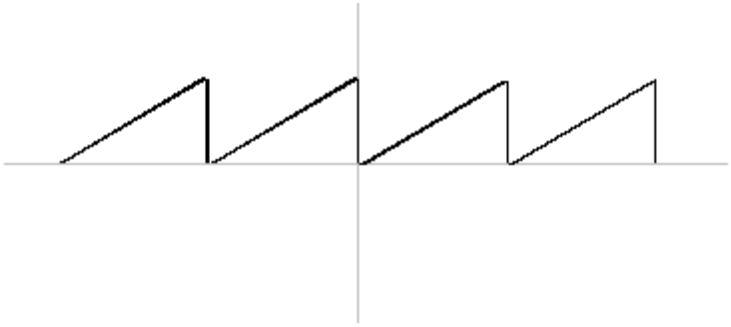
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Under **Extrapolate**, the choices are all standard extrapolations plus **None**. For inputs, the **Extrapolate** column is automatically set to **None** and is disabled.

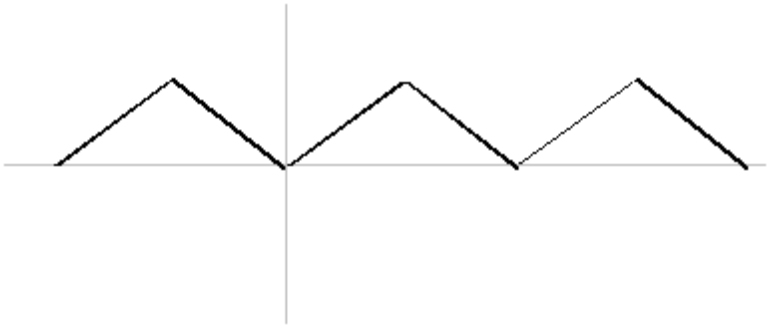
Linear This option takes the last two points of the data and generates a straight line extending beyond the range of the parametric sweep.



Periodic This option repeats the data outside the range of the parametric sweep.

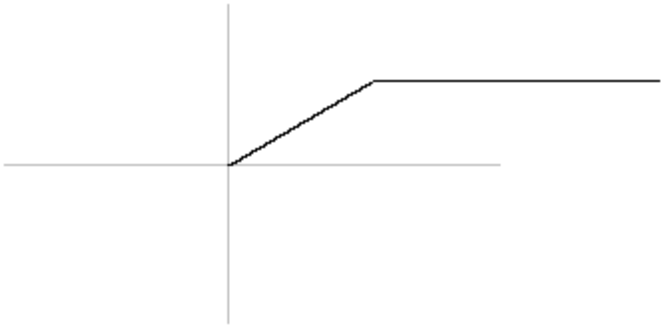


HalfPeriod This option mirrors then repeats the waveform outside the range of parameter sweep.

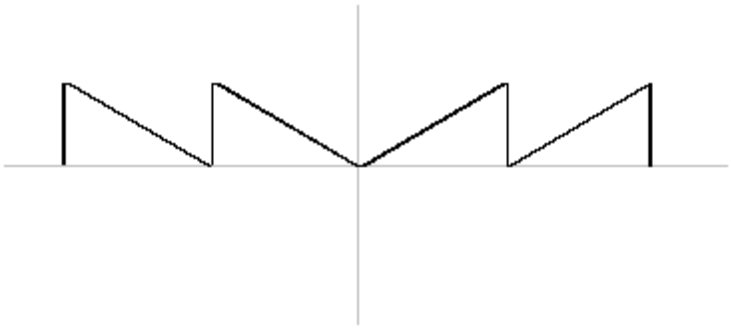


Constant This option extrapolates a constant value from the last point in the interpolation.

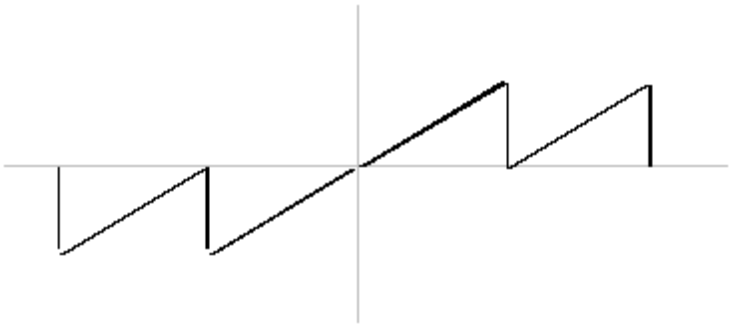
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Even This option repeats the wave outside the range of parametric sweep.



Odd This option repeats a reflection of the waveform outside the range of the parametric sweep.



Setting Coil and Mechanical Terminals

There are currently two types of terminals:

- Coil Terminals
- Mechanical Terminals

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For models with motion, the mechanical terminal setup determines which force (or torque) causes the motion and which position (or rotation) is affected.

When setting up coil terminals, flux and current are used for magnetic models, and charge and voltage are used for electric models.

In the coil terminal setup, there is one row for each flux (or charge) group. In the **Current** (or **Voltage**) column, each cell is a selection box where you can choose the current (or voltage) that applies to that flux (or charge) group. Usually the software can choose the correct current by default, based on the source setup in the design. The **Resistance** column is set to **0** by default; you can enter any value here. The **Turns** and **Branches** columns only appear for magnetic models where current variables represent Ampere-turns. These columns are initialized with the turns and branches specified in the inductance matrix setup.

In the **Current** column, in addition to each current, there is another choice, **<Dependent>**. This feature allows you to solve some problems using fewer parametric rows. This is explained using the following example:

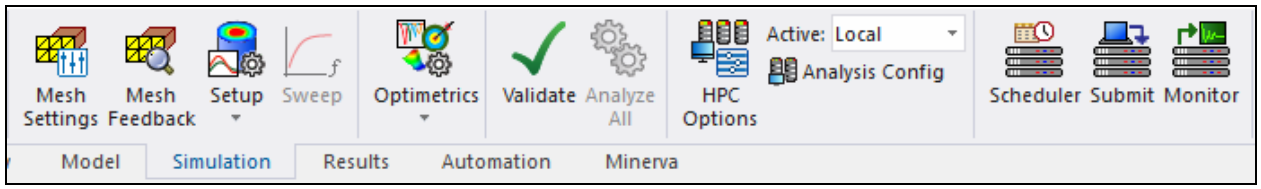
> Suppose you are working on a three-phase machine. You create three sources: CurrentA, CurrentB, and CurrentC. In Maxwell, you can create only variables iA and iB and then set the value of CurrentC to -(iA + iB). The parametric table will have ten values each for iA and iB, so it will only have 100 rows. When exporting the circuit, you would set the current for Flux [CurrentA] to iA, Flux[CurrentB] to iB, and Flux[CurrentC] to <Dependent>. In the circuit model, the PWL table will contain two input currents (iA and iB), but it will contain all three fluxes. So it will look up all three flux values based on only the two current values. As long as you always connect a current of -(iA + iB) to CurrentC, this model will be valid.

Note: A dependent source can have a different number of turns from the sources that it depends on (in the example above, CurrentA, CurrentB, and CurrentC can all have different numbers of turns). But in this case, you would have set up the current variables as Amperes instead of Ampere-turns — otherwise there would be no way to obtain the correct scaling of currents iA and iB for both their own current sources and for CurrentC. Therefore, this is another case where specifying current variables in Amperes (rather than in Ampere-turns) is useful.

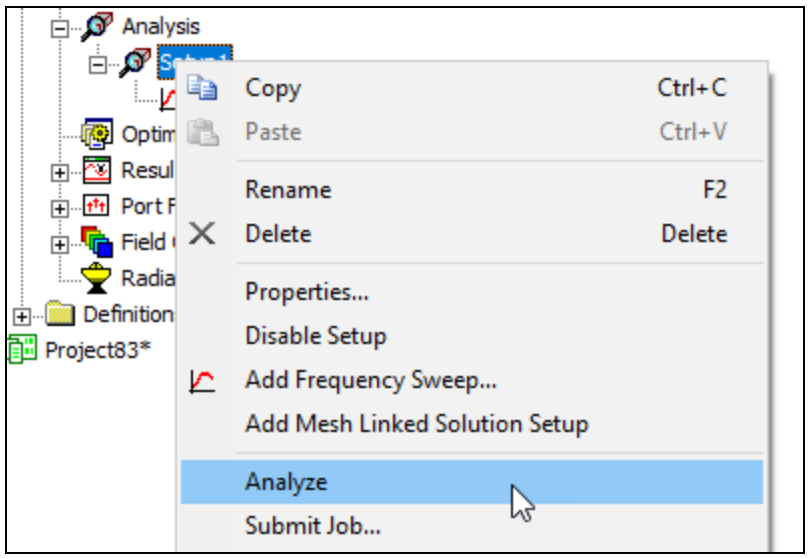
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

20 - Running Simulations

After you specify how Ansys Electronics Desktop is to compute the solution, you need to begin the solution process. You can access the **Analyze** commands for a specific setup by right-clicking on a solution or sweep in the **Project** tree and selecting from the shortcut menu, you by selecting the **Analyze All** from the solver menu, or the **Analyze All** icon on the **Simulation** tab of the ribbon.

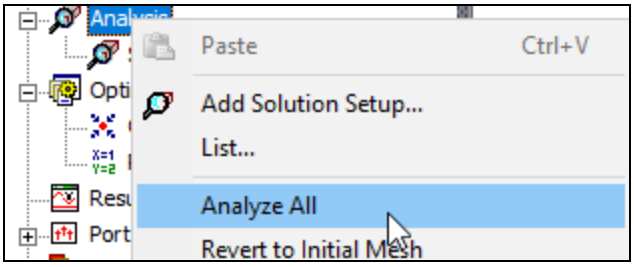


In general, the **Analyze** command on the shortcut menu applies to the selected setup and associated sweeps, if any, or to a selected sweep. To use this command, right-click on a setup or sweep in the Project Manager and click the command on the context menu.



The **Analyze All** command applies to allenabled setups, , and sweeps at or below the level invoked in the Project Manager. To use this command, either click **Maxwell**> **Analyze All** or right-click the **Analysis** icon in the *Project Manager* and select **Analyze All**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



What do you want to do?

- Local Analysis
- Solve a single setup with or without sweeps (when applicable)
- Solve a specific sweep
- Enable a queue so that multiple simulations can run sequentially as resources become available.
- Run more than one simulation, whether multiple setups, or multiple sweeps under a single setup, or setups with dependencies.
- Enable or Disable one or more solution setups or sweeps.
- Submit Job to RSM or HPC Scheduler
- Monitor queued simulations
- Monitor the solution process
- Change a solution priority for system resources
- Abort an analysis
- Re-solve after modifying a design
- Re-solve after Ansys Workbench Feedback

Local Analysis

Ansoft RSM Service does not need to be installed or running for local analysis and should not be running if the user only will be running local analysis. If running a distributed analysis, consult Distributed Analysis.

> **Note:**
>
> MPI distribution may be affected by starting or stopping a VPN, even if the MPI distribution is limited to the local host.

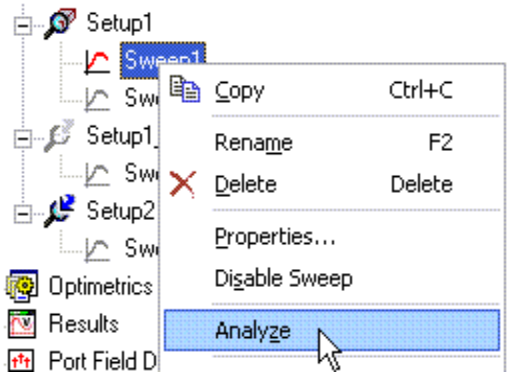
To run more than one analysis at a time, follow the same procedure while a simulation is running. If you have enabled queuing, the next solution setup will be solved when the previous solution is complete.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solving a Single Setup or Sweep

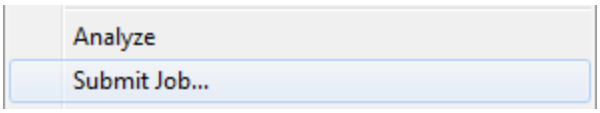
To run a single setup or sweep:

1. Select a solution setup or sweep in the Project Manager.
2. Right-click and select **Analyze** from the shortcut menu. The graphic shows a single sweep selected for analysis.



The 3D field solution is computed inside the structure for a solution. For a select sweep, it is computed for the sweep variables.

When you right-click a Setup, rather than a Sweep, the shortcut menu also includes the **Submit Job...** command.



For more information on the **Submit Job...** command see, Distributed Analysis and High Performance Computing (HPC) Integration.

To run more than one analysis at a time, follow the same procedure while a simulation is running. If you have enabled queuing, the next solution setup will be solved when the previous solution is complete.

> **Note:**
>
> If a linked dependency in the setup is already simulating (for example, due to setup links to the same external source for a near or far field wave, or a magnetic bias), Ansys Electronics Desktop will not allow another dependent simulation to start until the first use of the source has completed.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

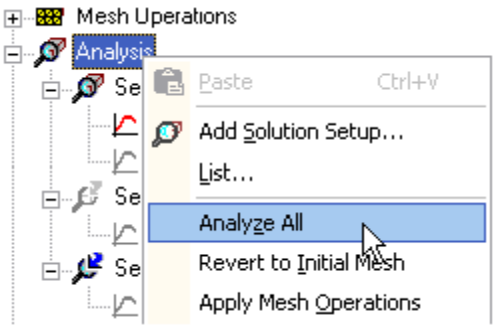
Running More than One Simulation

To solve every enabled solution setup in a design:

1. In the project tree, under the design you want to solve, select **Analysis**.
2. Click **Maxwell**> **Analyze All**.

Each enabled solution setup is solved in the order it appears in the Project Manager.

The example here shows an analysis invoked from the Project Manager shortcut menu with three setups: one disabled, two enabled. The first setup has one sweep enabled, and one disabled (shaded icon). The second setup is disabled, and the third is enabled, with a disabled sweep.



Note:

The **General** tab for the Setup includes an **Enabled** check box. By default, this is checked. Clearing the **Enabled** check box excludes a setup from running

Note:

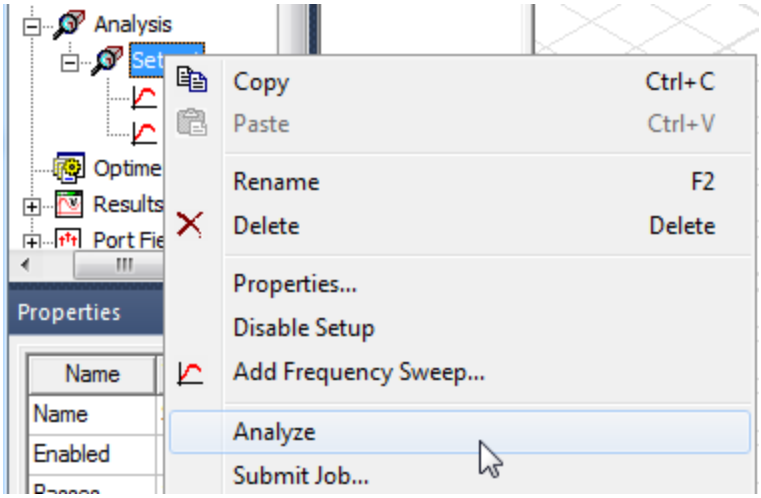
You can simulate all designs in a project by clicking **Project** > **Analyze All**.

To solve *two or more sweeps or two or more parametric analyses under a setup*:

1. In the project tree, under the design you want to solve, right-click **the setup** icon that includes the sweeps of interest.
2. Click **Analyze** on the shortcut menu.

   Each solution sweep under that setup is solved in the order it appears in the Project Manager, using the available machines. The following example shows a setup with two enabled sweeps.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Monitoring Queued Simulations

If you have multiple setups for a design and have selected **Analyze All**, the simulations can be queued until there is a machine available. You enable queuing in the HPC and Analysis Options: Options tab. If queuing is enabled, and you run multiple setups, they are solved in the order that they appear in the Project Manager. You can prioritize setups by changing their order in the queue.

1. To view the solution queue, click **Tools> Show Queued Simulations**.

   This displays a dialog box showing all the simulations and their current status. You can select and remove any simulation from the queue.

   You can also select any setup and use the **Move up** and **Move down** buttons to prioritize them.

2. To remove a simulation from the queue, select the simulation and click **Remove from Queue**.

   This removes the selected simulation from the queue.

Monitoring the Solution Process

While a simulation is running, you can monitor the solution's progress in the **Progress** window. The progress bar shows the relative progress of the simulation.

You can also view the following solution data at any time during or after the solution:

- The convergence data
- The matrices computed for the S-parameters, impedances, and propagation constants

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- A profile showing the status of the analysis process, including the progress and number of valid passes completed for adaptive solutions, elapsed time, memory usage, and more
- Mesh statistics (numbers of elements, lengths, volumes, and volume standard deviation; all on a per-object basis).
- A profile showing the status of the analysis process, elapsed time, memory usage, and more

To view the *Solutions* window:

1. Right-click the solution **Setup** in the Project Manager.

   A shortcut menu appears.

2. Select **Convergence**, **Solutions**, **MatrixData**, **Mesh Statistics**, or **Profile** from the shortcut menu.

   The *Solutions* window appears with the corresponding tab selected and the current data displayed.

For "out of core" problems, quite different amounts of memory may be used for factorization and for solution. So if the amount for factorization is displayed under the progress bar and the amount used is calculated for the profile at the end of the solution, they may be quite different numbers.

To view the solution status:

- Click **Maxwell** > **Results** > **Browse Solutions**.

  The *Solutions* dialog box appears with the **Browse** tab selected. It displays data about the number of valid passes completed (when adaptive solutions are applicable). It contains a tree structure showing the solutions listed according to Setup, Solution, and Variation. A table lists the setup, the solution, the sweep variable (when applicable), and the state of the solution.

- You can use the **Properties** button to display a dialog box that lets you change the way the Setup, Solution, and Variation are listed in the tree structure of the *Solutions* dialog box.
- You can delete one or more solutions by selecting from the table and clicking **Delete**. Click on a solution to select it, and use Ctrl+click to select multiple solutions, or Shift+click to select a range of solutions. You can also select all solutions using the **Select All** button.

  > **Note:**
  >
  > If a license is lost, the software waits for the license to be regained, checking every 2 minutes or until you abort.

- The **Statistics** tab of the *Solutions* dialog box displays path information as well as format, number of files, and size.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Changing a Solution Priority for System Resources

You can modify the priority of Ansys Electronics Desktop simulations so that system resources are allocated to other computer processes before the solver. If you reduce the priority of Ansys Electronics Desktop simulations, your other software tools will respond as they normally would, but Ansys Electronics Desktop simulations may take longer.

> **Note:**
>
> The Windows Task Manager does not indicate a reduced priority for the Ansys Electronics Desktop solvers. It only lists the priority of the engine manager, which appears normal, not the actual engine. The actual engine is in a separate thread, whose priority is not visible in the Windows Task Manager.

To change the priority of simulations for the system's resources:

1. While a solution is running, right-click the **Progress** window, and click **Change Priority** on the shortcut menu.
   - To affect priority for future simulation runs, click **Tools> Options> HPC and Analysis** and click the **Options** tab of the resulting dialog box.
2. From the **Change Priority** menu (or the **Default Process Priority** drop-down menu), select one of the following priorities:

Highest	
Above Normal	
Normal	The default.
Below Normal	
Lowest Priority	

3. Click **OK**.

Monitoring Queued Simulations

Aborting an Analysis

To end the solution before the currently running process is complete:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Right-click in the **Progress** window and click **Abort**.

  The solver ends the analysis immediately. The data for the currently running adaptive pass, frequency point, time step, or variation is lost. Previously completed solutions may or may not be retained (depending on what process was interrupted by the Abort command). If you want to ensure that the results of all completed solutions are saved, use *Clean Stop* instead of *Abort*.

To abort the solution after the currently running process is complete:

- Right-click the **Progress** window and click **Clean Stop** on the shortcut menu.

  The analysis ends after the currently running adaptive pass, frequency point, time step, or variation has been solved. Solutions completed before the stop request are retained.

If you request a clean stop during the third adaptive pass, the solution for the third pass will be available once the third pass has finished solving, but the fourth pass will not run.

Ansys EM Application as an LSF Job

If you have an Ansys EM application running as an LSF job, you can use the command "bkill -s SIGTERM *jobid*" to terminate that application. Here *jobid* is the LSF job id. The response will be "Job <jobid> is being signaled." The response is the same whether the job is actually being signaled or not.

In cases where the SIGTERM parameter is ignored, the command kills the LSF job, but does not clean the lock files, and other files may not be in a consistent state. See http://www.vital-it.ch/support/LSF/programmer/advanced.html for a detailed description under *Signal Handling in Windows*.

Linux

For Linux, you can use TERM commands. Sigterm handling is done in Desktop library. You can abort a running batchsolve by sending a TERM signal to hfss.exe.

Re-solving after Modifying a Design

In some cases, if you modify a design after generating a solution, the solution in memory will no longer match the design. In such cases you receive a warning message that "Solutions have been invalidated. Undo to recover."

To generate a new solution after modifying a design, follow the procedure for running a simulation.

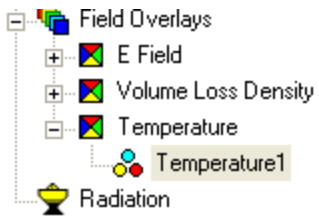
Also see Re-Solving with Ansys Workbench Thermal Feedback.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Re-solving after Ansys Workbench Thermal Feedback

With the Enable Feedback box in Setting the Temperature of Objects dialog box is checked, you can manage analysis with feedback in Ansys Workbench. After solving an HFSS or Q3D Extractor or Maxwell design, after performing the corresponding linked thermal analysis in Ansys Workbench, you can receive a temperature distribution back from the thermal solution. Ansys Workbench will write the feedback files directly to the Project Solution directory.

After an analysis that includes thermal feedback from Ansys Workbench, you can see temperature changes expressed in Temperature field overlays (both visually in the overlay and in the color key) as well as in the Solution data.



In the **Solution** data Profile tab you will see a new entry for Maximum Delta T, for the change in temperature from the previous simulation. The solver calculates delta in the first iteration by comparing the temperature distribution output from thermal with the initial temperature setting in HFSS/Maxwell/Q3D. Subsequent simulation iterations provide a number for the temperature delta.

Solver MCS4	00:00:00	00:00:00	31.4 M	Disk = 0 KBytes, matrix size 3468 , matrix bandwidth
Field Recovery	00:00:00	00:00:00	31.4 M	Disk = 310 KBytes, 2 excitations
				Maximum Delta T = 7.0685

This simulation feedback loop from Ansys Electronics Desktop to Ansys Workbench and back can continue until you decide that Temperature delta reported in the Solution Report low and stable for the designs.

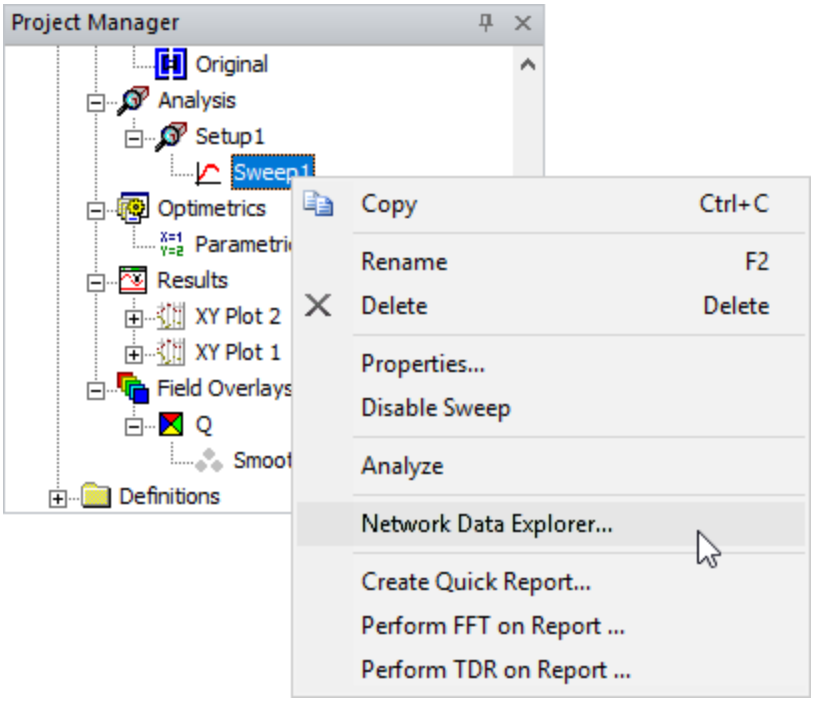
21 - Network Data Explorer

The Network Data Explorer provides visualization, analysis, and manipulation tools for network data.

To access Network Data Explorer, click **Tools** > **Network Data Explorer**.

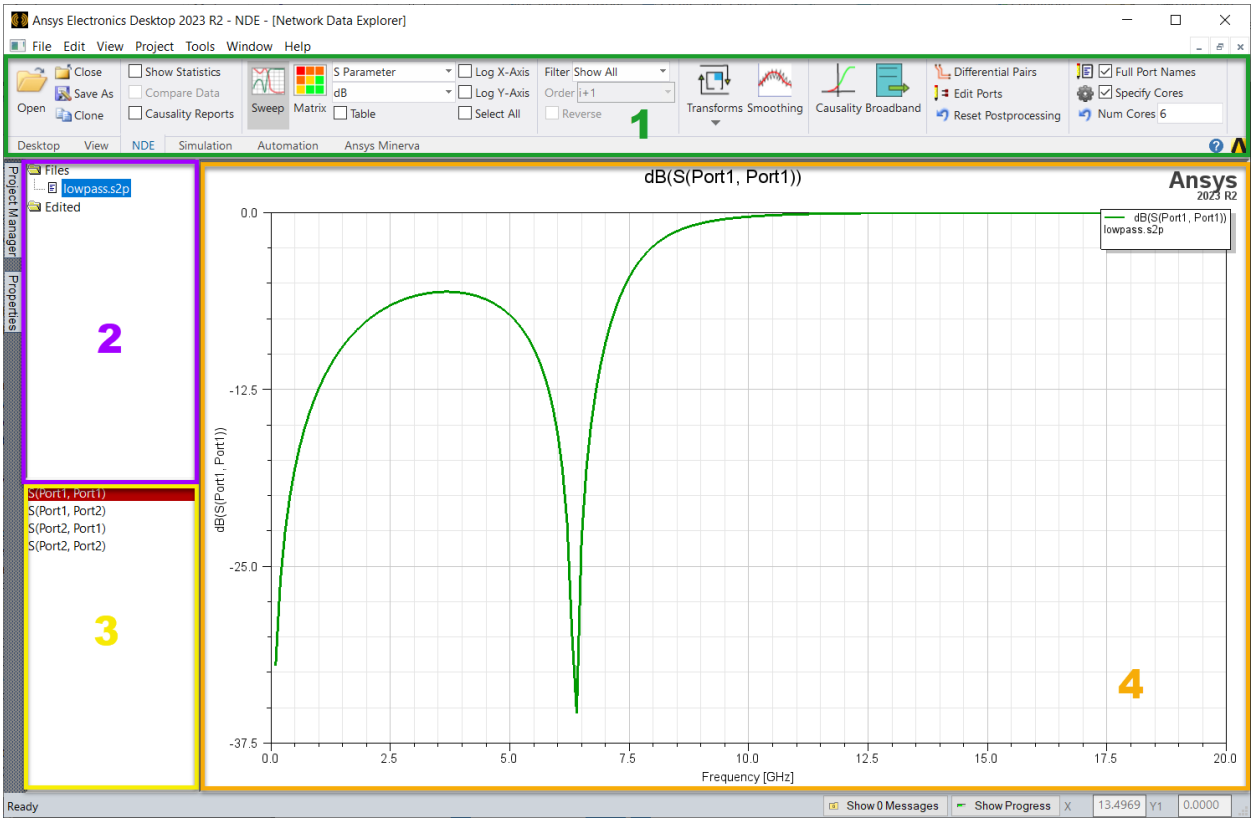
If you have run a simulation with data that can be converted into network data, you can also access Network Data Explorer through the shortcut menu in the Project Manager.

> **Note:**
>
> Accessing Network Data Explorer from this menu automatically loads sweep data.



The **Network Data Explorer** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



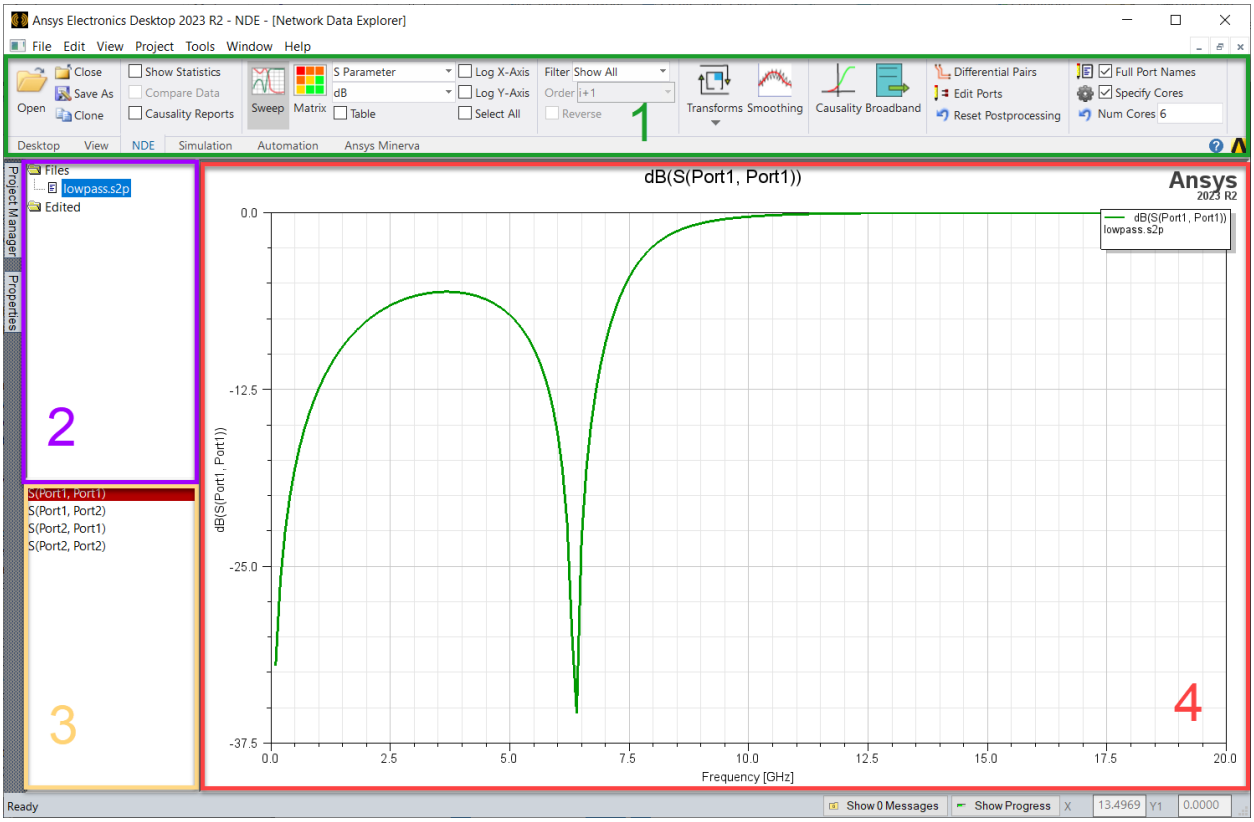
Network Data Explorer Overview

The Network Data Explorer window is divided into the following panes:

1. **NDE ribbon** – allows you to perform many functions of the Network Data Explorer.
2. **Network Data Selection pane** – allows you to select a network data file.
3. **Cell and Frequency Selection pane** – allows you to narrow your selection.
4. **Data View pane** – displays data in table or plot format.

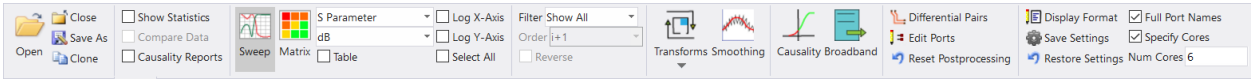
The panes are shown in the following figure. Additional information about each pane follows.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



NDE Ribbon

The ribbon provides access to many of the Network Data Explorer's functions and display options.



On this ribbon, you can control:

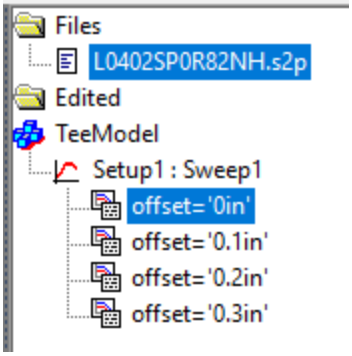
- Plotting - allows you to determine how the data is displayed.
- Quantity – allows you to select the type of quantity to display (parameter values, matrix statistics, or causality plots).
- Parameter Type – allows you to choose the parameter for display (S, Y, or Z parameters, Port Impedance, or Gamma).
- Format – allows you to decide the display function to apply to the data (e.g., magnitude, phase, dB, real, imaginary).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Export – allows you to export either SYZ data (*.s1p, *.ts, *.nmf, *.tab, *.m, *.cit) or Broadband data (*.sp).
- Check – allows you to check causality.
- Cores – allows you to enable or disable multithreading.
- Post-Process Selection – allows you to choose between Terminal Data and Differential Pairs, if your design includes Differential Pairs

Network Data Selection Pane

This pane allows you to view and compare various data sets. Original data sets appear under **Files**. Click one of these to see the data set as it was when it was opened. Altered data sets are listed under **Edited**. These data sets appear here when they have been smoothed, transformed, or changed in some way.



This pane also lists available variations for AEDT design solution data. Variations are listed under a setup name icon (for example “Setup1 : Sweep1”) that is listed under a design icon (“TeeModel”). Variations can be selected and displayed just like other data sets.

Use the **Shift** and **Ctrl** keys to select and display data sets from multiple files simultaneously. Multiple data sets can be selected to display multiple traces in sweep plots, but not in tables. Click the **Files** icon to select all data sets under **Files**. Click the **Edited** icon or a design/setup icon to do the same.

Cell and Frequency Selection Pane

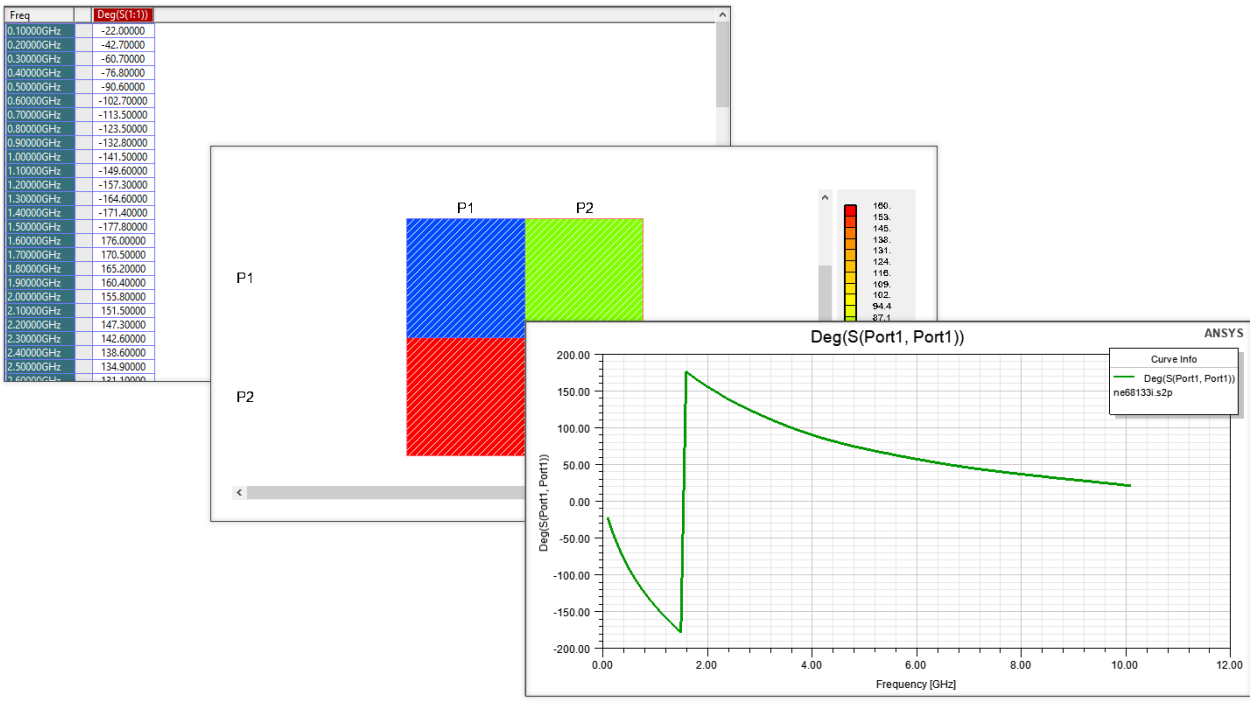
Select the **Sweep** button on the NDE ribbon to display cell entries, for example S(1,1). Select the **Matrix** button to display frequencies. When displayed by frequency, the entire matrix is presented in the Data View pane for each selected frequency. When displayed by matrix cell, the data for the individually chosen cells is shown across all frequencies. Use the **Select All** check box to select all frequencies or cells.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** For Maxwell 2D solutions when the geometry is in XY mode, a Model Depth selection is available. The default Matrix selection is the alphabetically first defined matrix parameter. The default Model Scale setting is 1. The default Model Depth setting is 1 meter.

Data View Pane

The Data View Pane displays data for **Sweep** or **Matrix** in either plots or a table, depending on your selection.



Loading Data into Network Data Explorer

You can launch **Network Data Explorer** from within several Ansys products. In the Project Manager, open <project> > **Analysis** > **Setup***n* > **Sweep***n*. Right click on the sweep and click **Network Data Explorer** in the shortcut menu. The current solution data is automatically loaded and ready for viewing. Otherwise, you must load a data file into Network Data Explorer.

> **Note:** When solution data that is loaded into NDE is modified and resimulated in another Ansys product, the NDE data automatically updates.

You can import the following file types:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Touchstone Format (*.s*p)
- Touchstone 2 Format (*.ts, *.sp)
- Citifile (*.cit)
- Neutral Format (*.nmf)
- State Space File (*.sss)

> **Note:**
>
> When this type of file is loaded, Network Data Explorer regenerates s-parameter data based on the file.
>
> You can compare the regenerated s-parameters to the original data.

To import a file into Network Data Explorer, either drag and drop an analysis from the Project Manager into Network Data Explorer or

1. On the **NDE** ribbon, click **Open**. An **Open** window opens.
2. Navigate to and select a file.
3. Click **Open**. The file appears in the **Files** tree.

The file browser allows you to open multiple files at a time. However, the displayed data always corresponds to the data set indicated in the Network Data Selection pane. Click the file you want in that pane to switch between data sets.

Exporting Data from Network Data Explorer

Network Data Explorer allows you to export data to a variety of different file formats.

In this section, you will learn about:

Exporting SYZ Data

Exporting Macro Model

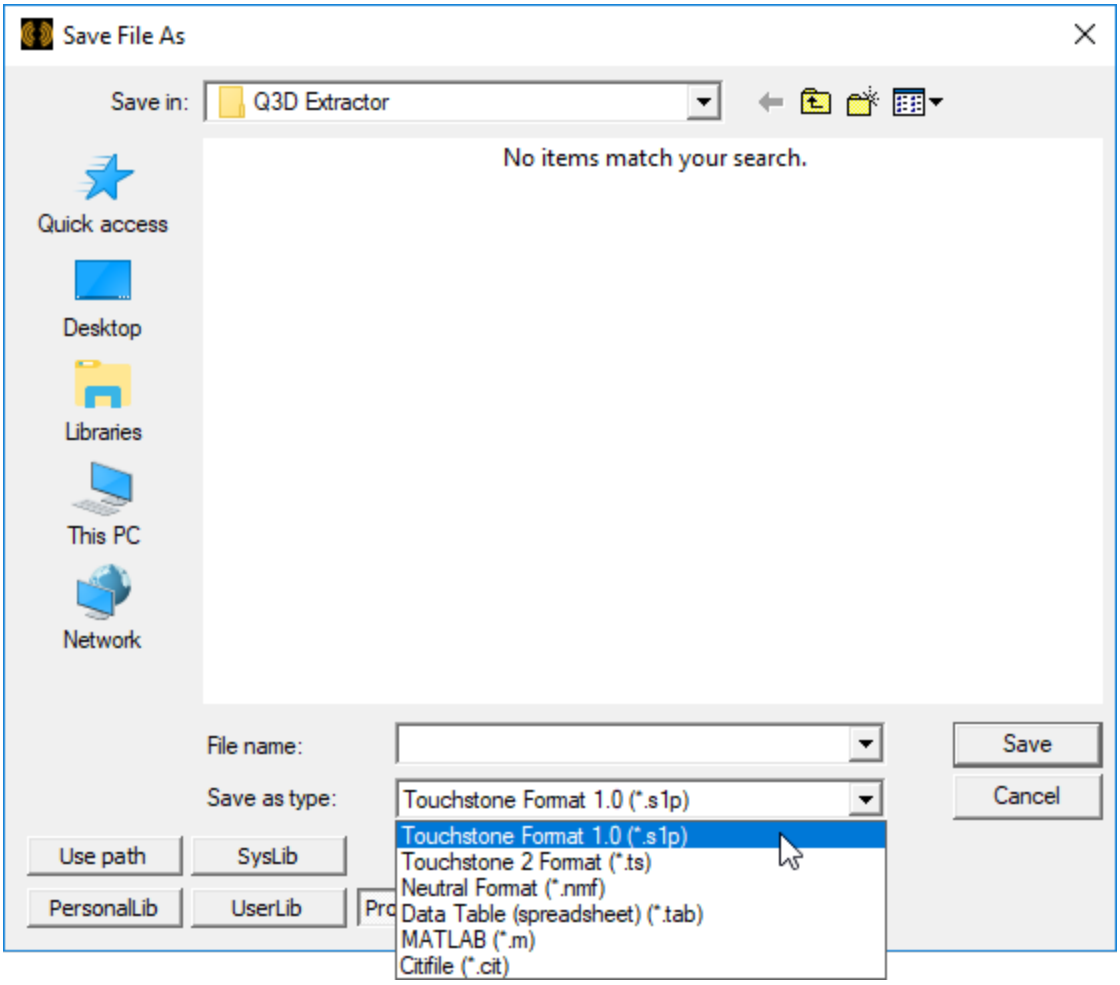
Creating an NPort Model

Scripting for Network Data Explorer

Exporting SYZ Data

To export SYZ data from within Network Data Explorer, click the **Save As** icon on the **NDE** ribbon. The **Save File As** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

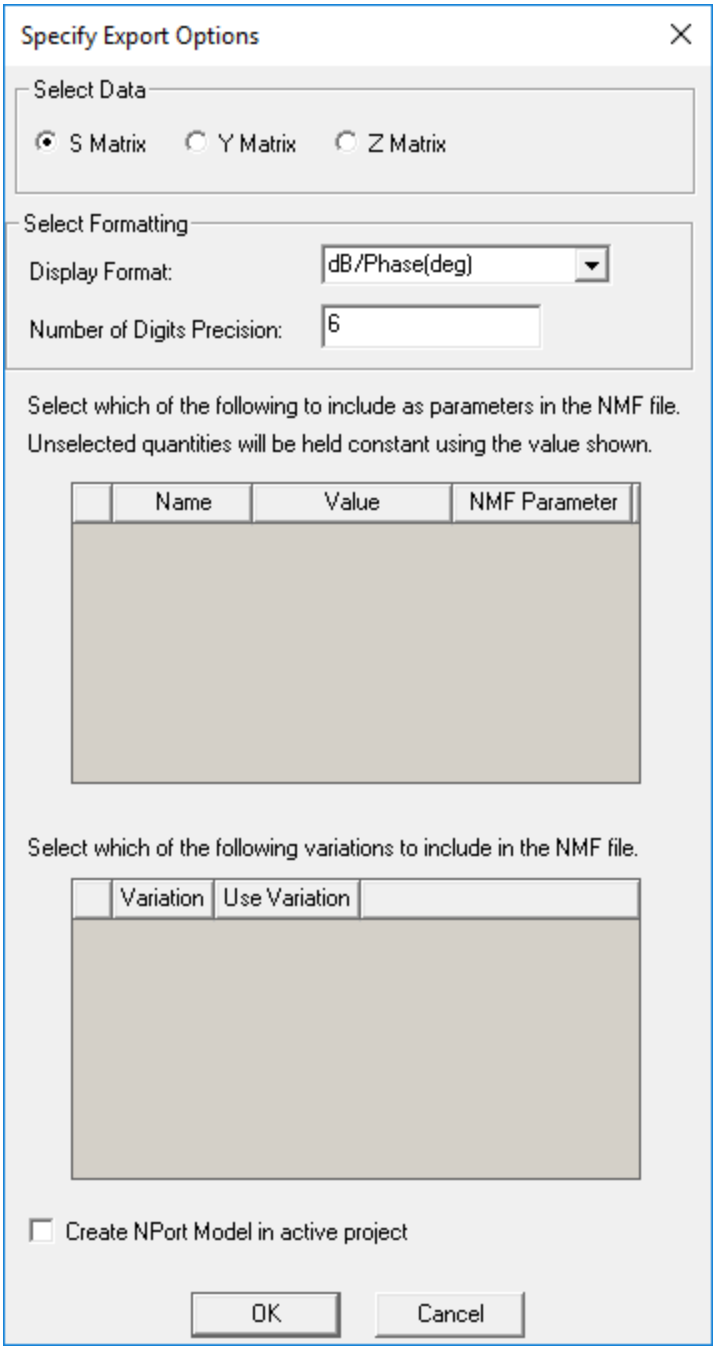


You can export data in any of six file types:

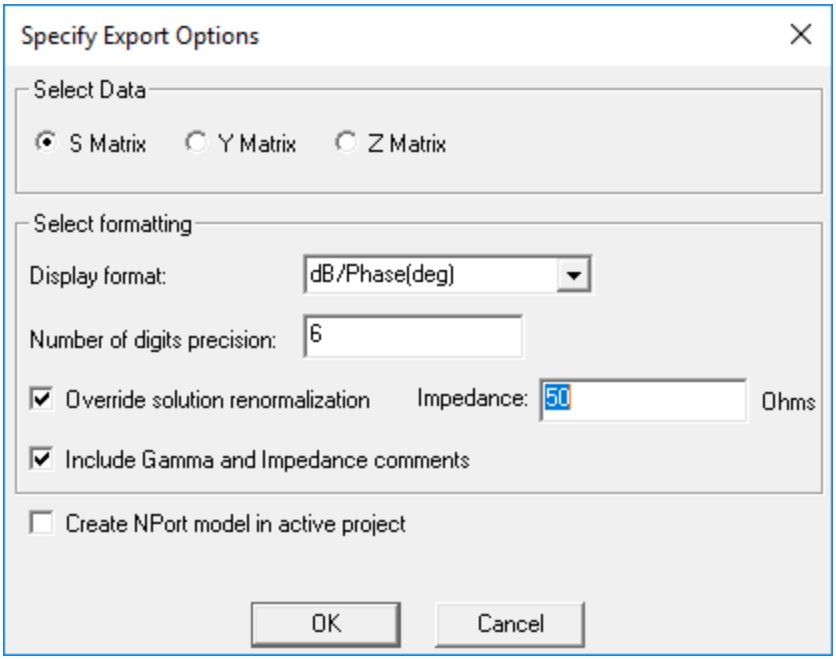
- Touchstone Format 1.0 (*.s*p)
- Touchstone 2 Format (*.ts)
- Neutral Format (*.nmf)
- Data Table Spreadsheet (*.tab)
- MATLAB (*.m)
- Citifile (*.cit)

Select a file type and name for export. A **Specify Export Options** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Depending on the type of export file, different options appear. However, all file types allow you to:

- Select from **S Matrix**, **Y Matrix**, and **Z Matrix** data.
- Select the **Display Format**.

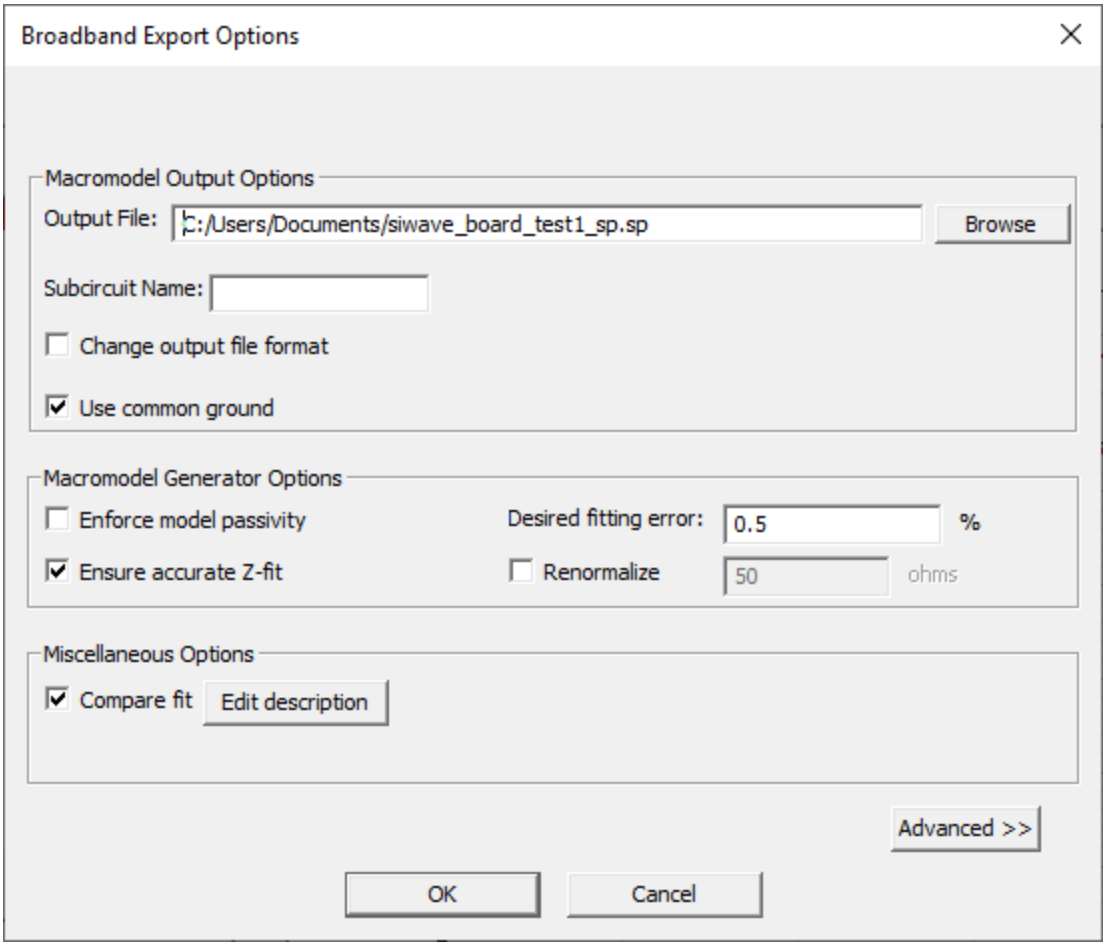
Some types allow you to create an NPort Model in the active project.

Exporting Macro Model

Network Data Explorer lets you export macro model data. To export data, click the **Broadband** icon on the **NDE** ribbon.

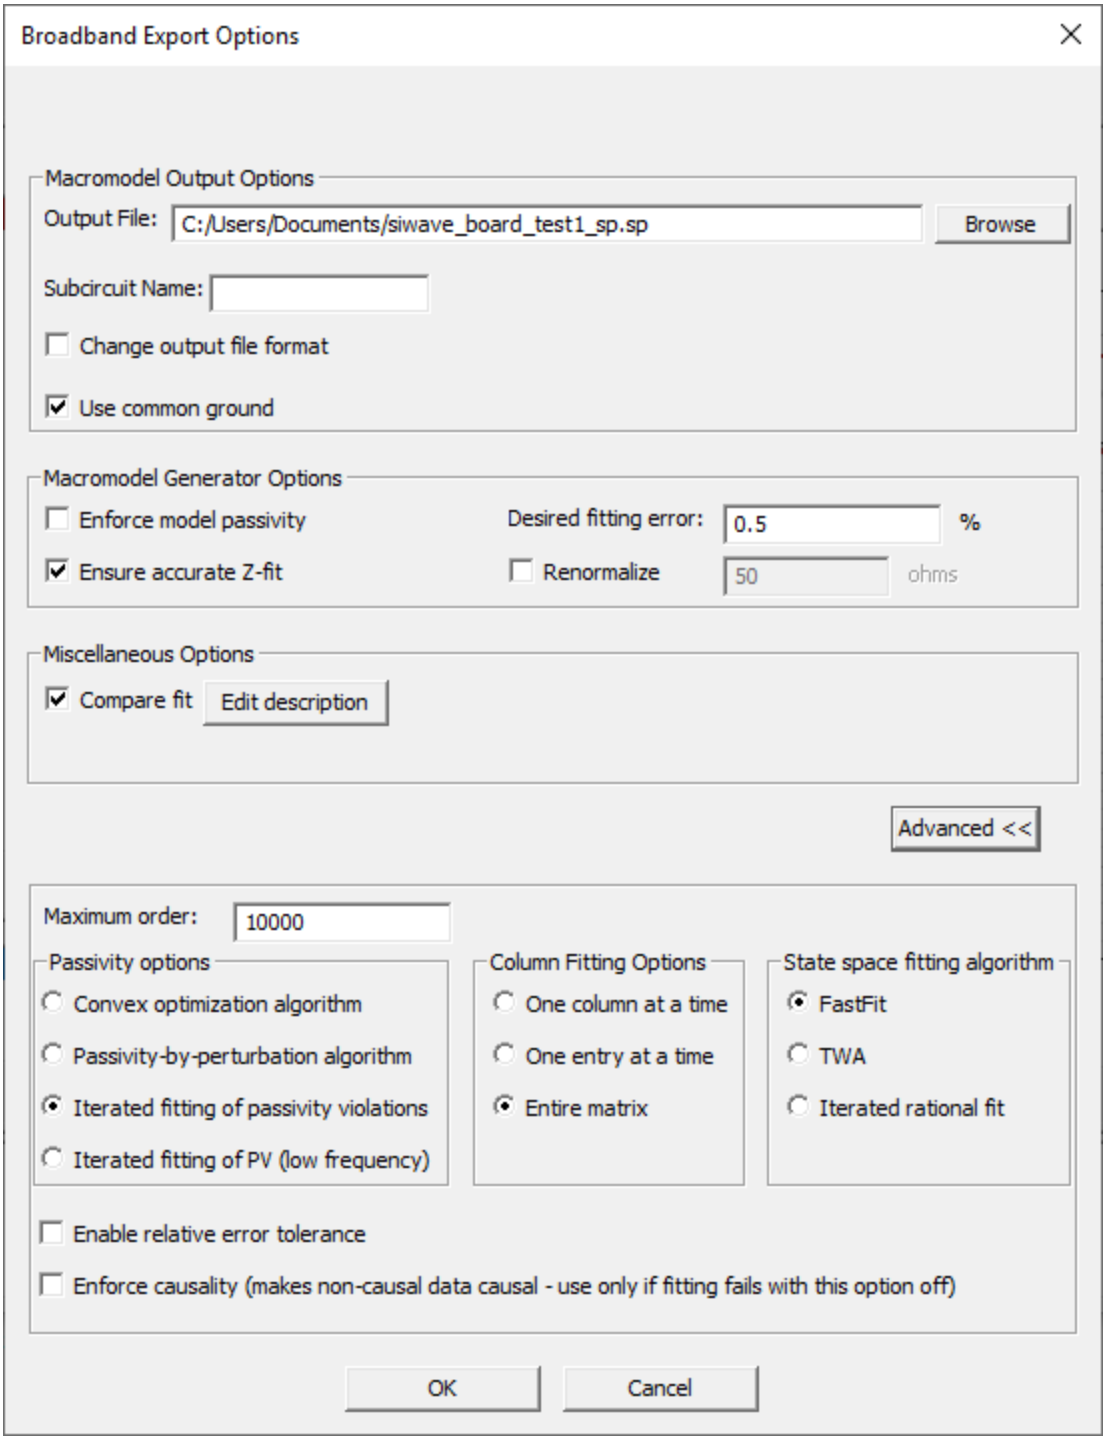
The **Broadband Export Options** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Click **Advanced >>** to view all options.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Macromodel Output Options include:

- **Output File** – Allows you to choose the name and location of the file.
- **Subcircuit Name** – Use this field to name the subcircuit.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Change Output File Format** – Check this box to open a submenu allowing you to select a new output format.
- **Use Common Ground** – Check this box to use common ground. When this option is on, ports are referenced to ideal ground (node 0). When this option is off, extra ports are generated to provide the reference levels. Common grounding is best when the pins are physically near to each other and ideal ground is suitable. For distant connections and circuits with non-ideal reference levels such as differential pairs, common grounding is not used.

> **Note:**
>
> - R and L values may be quite sensitive to the values of the S-parameters. This is an issue if the actual impedance value is much greater than or much less than the reference impedance of the S-parameters.
> - Since resistances of power cables is typically in the milliohms range at DC, using a reference impedance of 50 ohms is 5000 times higher. This causes any fitting errors in the state space model to get multiplied by 5000 times when the R and L values are computed.
> - As a general rule, for high power applications a reference impedance of 1 ohm is probably a better choice than 50 ohms.

Macromodel Generator Options include:

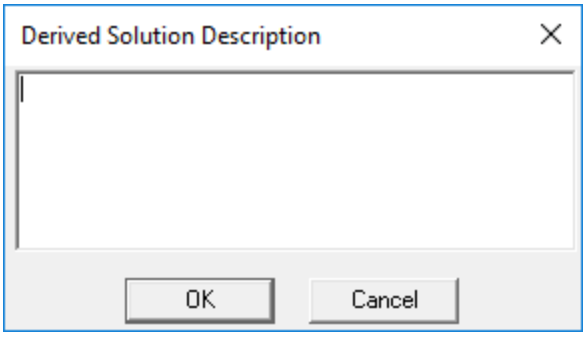
- **Enforce Model Passivity** – Check this box to enforce passivity.
- **Ensure Accurate Z-fit** – Check this box when state-space fitting of Y-parameters or Z-parameters does not produce an accurate fit.
- **Desired Fitting Error** – Allows you to select the value at which rational fitting fails (if the fitting error exceeds this value).
- **Renormalize** – Check this box to renormalize using the specified impedance item. 50 ohms is the default setting, but you can type a different value.

> **Note:**
>
> - R and L values may be sensitive to S-parameter values. This presents an issue if the actual impedance value is much greater than or much less than the reference impedance of the S-parameters.
> - Since resistances of power cables are typically in the milliohms range at DC, using a reference impedance of 50 ohms is 5000 times higher. This causes any fitting errors in the state space model to be multiplied by 5000 when the R and L values are computed.
> - For high-power applications, a reference impedance of 1 ohm is generally a better choice than 50 ohms.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Miscellaneous Options include:

- **Compare Fit** – When this box is checked, the original and derived solution will be available for comparison. You can click **Edit Description** to open the **Derived Solution Description** window and add a text description to better identify the export.



Advanced Options include:

- **Maximum Order** – Allows you to specify the number of poles. See Note below.
- **Passivity Options** – If you enabled **Enforce Model Passivity**, this area allows you to select the passivity enforcement method.
  - **Convex optimization algorithm** – guarantees a passive state-space realization, but is very slow and memory-intensive. Not practical for numbers of ports beyond ten.
  - **Passivity-by-perturbation algorithm** – designed for systems with a large number of ports. Less accurate than the Convex optimization method.
  - **Iterated fitting of passivity violations (IFPV)** (default) – less accurate than other algorithms but more suitable for larger numbers of ports.
  - **Iterated fitting of PV (low frequency)** – similar to IFPV while improving the fit to "Z" at DC and low frequencies. A better choice of passivity enforcement when the fit to corresponding "Z-data" is important such as power delivery, EMI/EMC applications.

    > **Note:**
    >
    > For a more detailed explanation on any of the passivity options, see the technical note section of the Circuit help.

- **Column Fitting Options** – This area allows you to choose how poles are matched to columns:
  - **One Column at a Time** – The set of poles will be shared across all entries of a single column.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **One Entry at a Time** – Each entry will be fitted using a separate set of poles.
- **Entire Matrix** – The set of poles will be shared across all entries of the matrix being fitted.

> **Note:**
>
> - Typically, using the same set for all entries is adequate, and yields the most compact models. However, if all the entries of the matrix have completely unrelated transfer functions, it may be better to fit them using separate pole sets.
> - The options **One column at a time** and **One entry at a time** do not work when either **Ensure accurate *Z*-fit** or FastFit is used.

- **State Space Fitting Algorithm** – Allows you to select FastFit, TWA, Iterated rational fitting.
  - **FastFit** (default) – FastFit is the Ansys-proprietary method for state-space fitting. Network Data Explorer uses FastFit for calculating the state-space matrices from the network data. The FastFit algorithm for state-space fitting is an alternative to the Tsuk-White algorithm (TWA) and Iterated Rational Fitting (IRF) methods. FastFit is generally as accurate as TWA, but is significantly faster than both TWA and IRF. It also aims to fit the lower frequencies with higher fidelity.
  - **TWA** – The Tsuk-White Algorithm is an Ansys-proprietary method for fitting a state space model to extracted s-parameter data. It uses techniques based on Singular Value Decomposition (SVD) to quickly determine required number of poles for fitting a model.
  - **Iterated Rational Function** – The IRF fitting approach takes a matrix of S-parameter data and, for each matrix entry, tries a succession of different pole-zero approximations (increasing the number of poles used at each iteration) until it can find an acceptable fit to the data. For broad frequency sweeps and large numbers of excitations, this process can be time consuming because of all the iterations and is not guaranteed to produce a good fit to the data. It is retained as a fallback if the TWA algorithm fails.
- **Enable Relative Error Tolerance** – Allows you to enable relative error tolerance, which works best with TWA fitting.

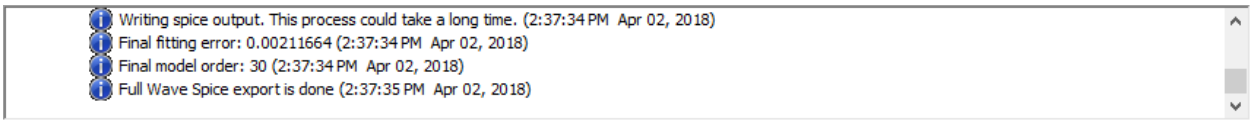
> **Note:**
>
> The **Enable Relative Error Tolerance** option works best with the TWA fitting algorithm, is not recommended for use with iterated rational fitting, and is disabled when either FastFit or **Ensure accurate Z-fit** is used.

- **Enforce Causality** – Allows you to make non-causal data causal. Use this option only if fitting fails without it.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> Broadband models are built from a rational-function approximation of the data. The fidelity of this approximation can be controlled by setting the Maximum order (number of poles).

Click **OK** to begin the export. The **Messages** pane details the export process.



Comparing Original S-Parameters with Exported S-Parameters

If **Compare Fit** was checked during export, the **Data Selection** pane updates to list both the original and exported solution *and* the **Compare** checkbox is checked.

Creating an NPort Model

Touchstone, Neutral Format, and Citifile exports allow you to select an option to **Create NPort Model in active project**.

Creating an NPort Model exports the active data set back to the design, either as a static n-port model or as a parametric n-port model. If there are multiple variations, a parametric n-port model is automatically created containing all variations. When only a single variation exists, the user can create a static n-port model that either links to a file (the data is exported first) or stores the data itself. Linking to a file reduces the size of the ADSN file. The newly created model can be placed as a component in a circuit. This is particularly useful after reducing the number of ports via termination.

The import of the exported solution is done by reading the exported Touchstone file.

Scripting for Network Data Explorer

Scripting is available for each Network Data Explorer export method, which means a script can be recorded to duplicate the export process.

Network Data Explorer can be invoked in the following contexts, and scripting is available from the Project Context and the Design Instance Context (simulation setup):

- **Project Context** – In the context of a project, you can open a touchstone file and then export.
- **Design Instance Context** – In the context of a solution (RCM from the simulation setup in a design), you can export the corresponding network data solution.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

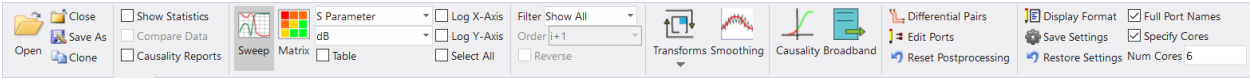
When there is no design available, export functionality and scripting are not available.

When there is no design available, export functionality and scripting are not available.

For more information, see Network Data Explorer Script Commands in the *Ansys Electronics Desktop Scripting Guide*.

Network Data Explorer Ribbon

The **NDE** ribbon provides access to many of the Network Data Explorer's functions.



In this section, you will learn about:

Data Sources

Setting Display Format

Displaying Full Port Names

Saving or Resetting Default Settings

Smoothing All Frequencies

Cell Filtering

Editing Port Properties

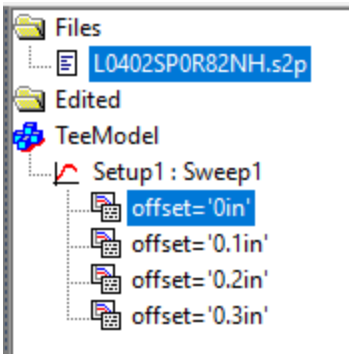
Defining Differential Pairs and Displaying Mixed Mode Parameters

Resetting All Port Properties

Network Data Explorer Data Sources

Network Data Explorer allows you to easily view all data sources in the **Network Data Selection** pane.

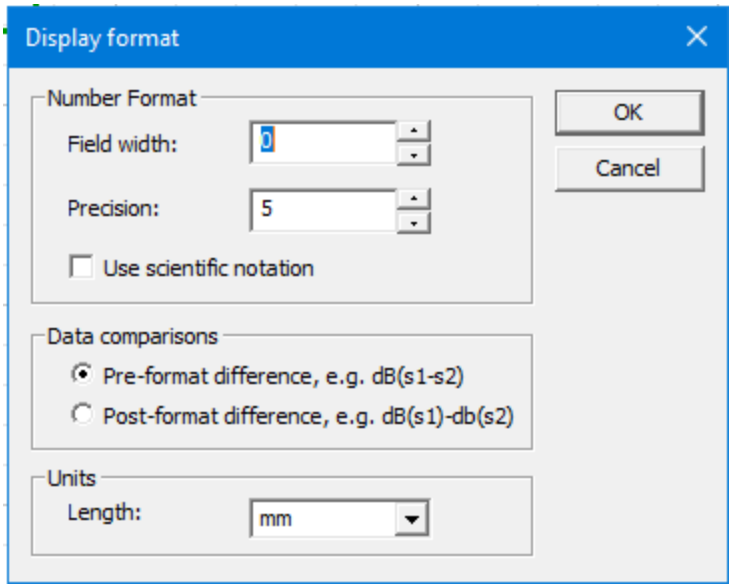
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Network Data Explorer Display Format

The **Display Format** window affords additional control over the display of values in Network Data Explorer.On the **NDE** ribbon, click the **Display Format** icon.

The **Display Format** window appears.



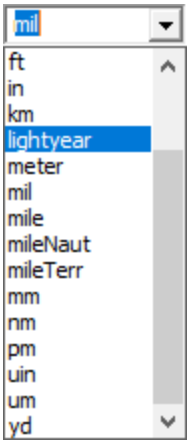
The **Number Format** options allow you to specify **Field Width** (the minimum number of characters used to display a number) and **Precision** (the number of decimals to display). You can also check the **Use scientific notation** check box, if desired.

The **Data comparisons** options allow you to choose Post-format difference or Pre-format difference.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Pre-format difference**- when comparing data sets, subtract values before applying the formatting function (e.g. dB, magnitude); the values displayed will be the magnitude, dB, etc., of the complex difference.
- **Post-format difference** – when comparing data sets, subtract values after applying the formatting function (e.g. dB, magnitude); the values displayed will be the difference between the magnitude, dB, and so on.

The **Units** option allows you to specify the **Length** unit (the unit used to display and interpret length values). The default is mm.

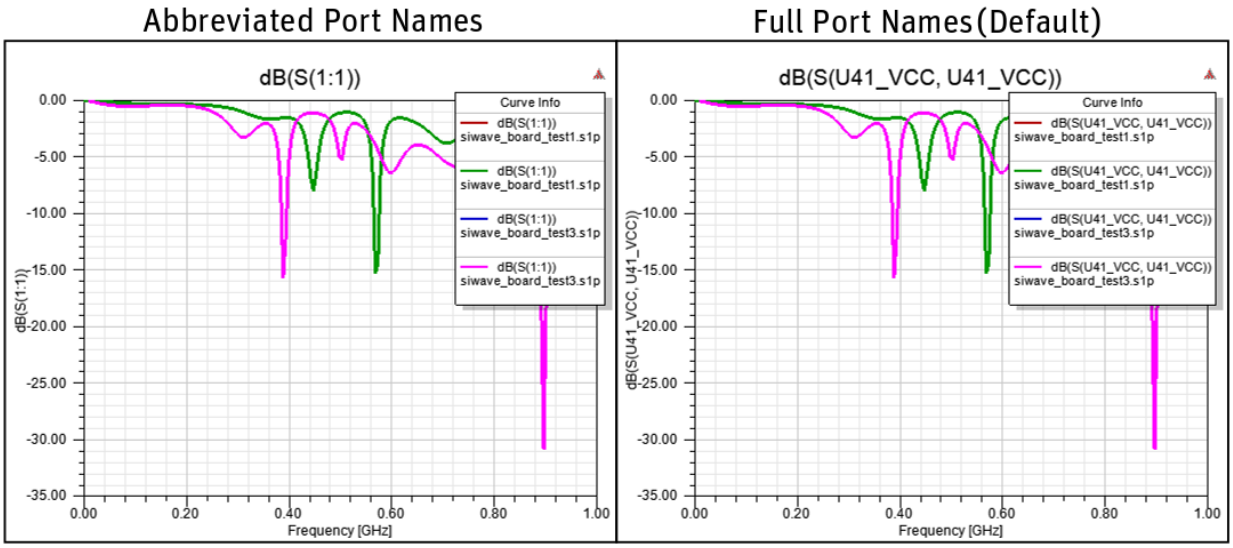


Network Data Explorer Display Full Port Names

By default, full port names are displayed. This applies to both the Data Selection pane and the Data View pane. To change this so that port names in Network Data Explorer are displayed in an abbreviated form (P1, P2, etc.), click the **Full Port Names** check box on the **NDE** ribbon.

The following figure shows the difference in display for a plot.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note:

Tool-tips always display the full port name.

Network Data Explorer Save or Reset Default Settings

To save field settings as the default, click the **Save Settings** icon on the **NDE** ribbon. The next time Network Data Explorer is opened, the chosen settings will be selected by default.

To restore the default settings (i.e. the settings previously saved using the **Save Settings** button), click the **Restore Settings** icon on the **NDE** ribbon. The next time Network Data Explorer is opened, the original settings will be selected by default.

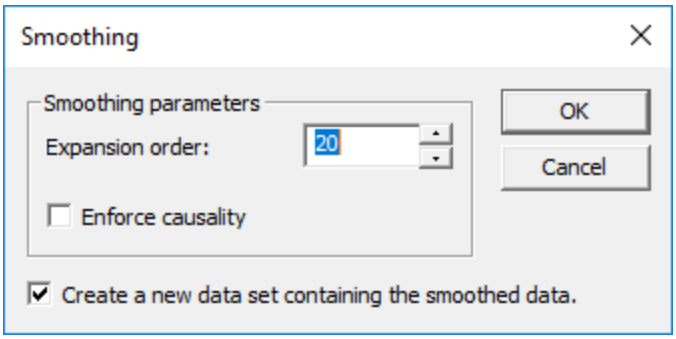
Smoothing

To access data smoothing options:

1. Click the **Smoothing** icon on the **NDE** ribbon.

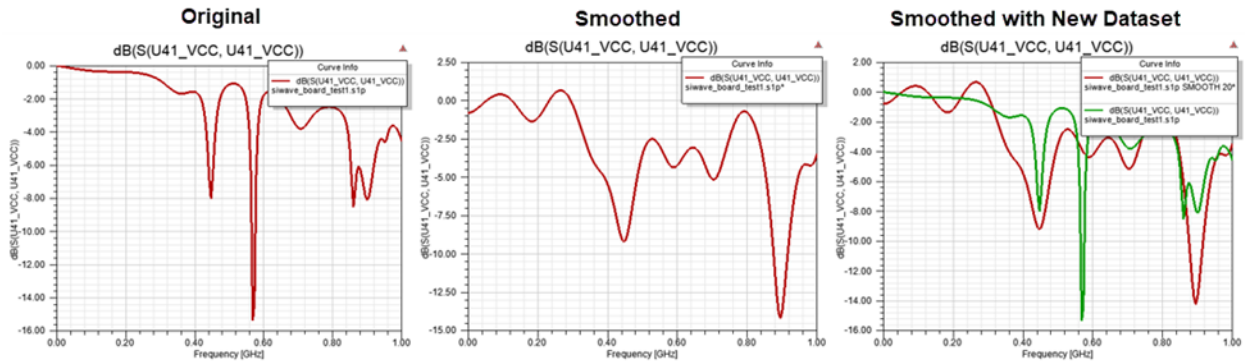
The **Smoothing** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. The **Smoothing Parameters** area allows you to choose the **Expansion Order**. This can be any discrete value between 1 and 150.
3. If desired, check the **Enforce Causality** check box.
4. If desired, check the **Create a new data set containing the smoothed data** check box. If selected, the smoothed data appears alongside the original data.
5. Click **OK**.

The Data View Pane updates. The following image shows a plotted result with **Create a new data set containing the smoothed data** unchecked and checked.

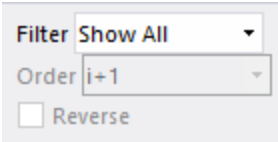


A least-squares polynomial fit of the specified order is used to interpolate new data points for the magnitude and phase components of the S-parameters.

Cell Filtering

The cells available in the data selection pane may be restricted using cell filtering. The **Cell Filtering** control are located on the **NDE** ribbon.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Cell filtering is modeless, and filters are immediately applied to the cell list. Filtering remains in effect when the window has been closed.

For an n-port model with a total of 2n pins in the standard arrangement, the choices are:

- **Show all** – display all available cells. There are n-squared choices.
- **Return loss** – show S(i, i). There are n choices.
- **Insertion loss** – show S(i, i+1). There are n choices.
- **Lower triangle** – show S(i, j) for all j < i. There are n(n-1)/2 choices.

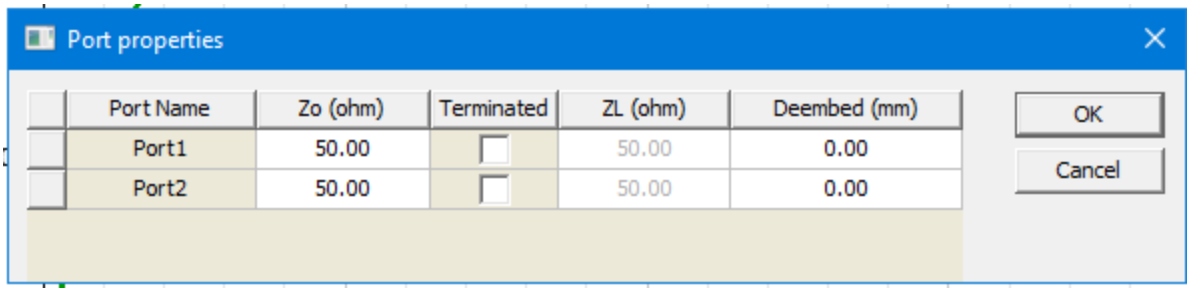
Three pin arrangements are recognized:

- S(i, **i+1**) and its **Reverse order**, S(i, i-1)
- S(i, **i+n**) and its **Reverse order**, S(i, i-n)
- S(i, **2*n-i+1**) and its **Reverse order**, S(i, 2*n-i-1)

Changing Port Properties and Reducing Matrix Size

The normalization impedance, termination, port order, gamma values, and de-embedding distance may all be edited from the **Port Properties** window.

To access these options, click **Edit Ports** 
on the **NDE** tab. The **Ports Properties** window opens.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** For HFSS Driven Terminal designs, selecting the solution data will disable this ribbon button. The user must make port/differential pair changes directly in the HFSS Design and re-import the solution.

Ports appear in a table. Click a column heading to sort by that column. Click within a cell to edit the port property:

- **Zo (ohm)** and **ZL (ohm)** – specify Impedance values. Accepted syntaxes are:
  - real (e.g., 50)
  - real + imag i (e.g., 50+5i)
  - imag i (e.g., 5i).
- **Terminated** – use the check box to terminate a port. Terminated ports are eliminated from the matrix, reducing the matrix size. Existing data sets with mismatching port numbers will no longer be available for data comparisons.
- **De-Embedding** – this column appears only if gamma values are available. Default units can be changed from the Set Display Format window.

To reorder ports, click and drag a row to a new location.

To save changes, click **OK**.

Displaying Mixed-Mode Parameters using Differential Pairs

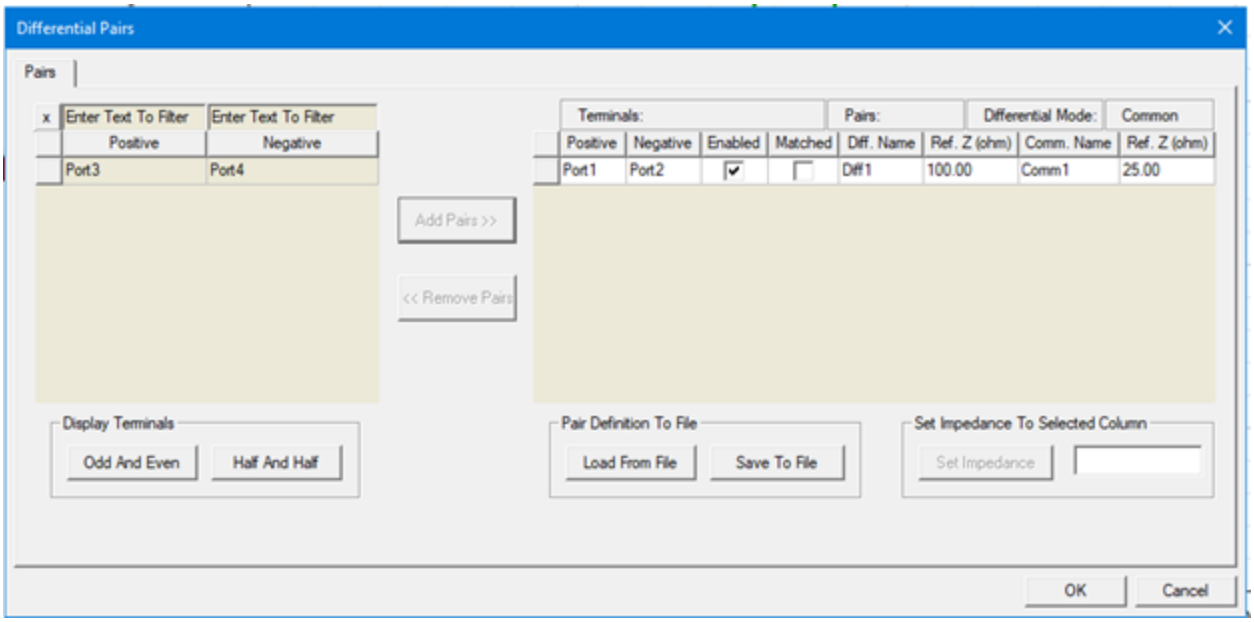
Network Data Explorer displays mixed-mode parameters when differential pairs are both defined and activated.

To define differential pairs:

1. Select existing ports.
2. Open Network Data Explorer (**Tools**>**Network Data Explorer**).
3. On the **NDE** ribbon, select **Differential Pairs**.

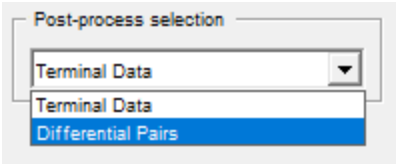
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Differential Pairs** window appears.



4. Select a pair from the list on the left and click **Add Pairs**.
5. Click **OK**.
6. To disable all differential pairs, click the **Enabled** column header in the **Differential Pairs** dialog to deselect all pairs.

For HFSS Driven Terminal designs, selecting the solution data will disable this ribbon button. The user must make port/differential pair changes directly in the HFSS Design and re-import the solution. When the HFSS Driven Terminal Design has differential pairs defined, NDE shows this drop down menu and you can change between showing reports for Terminals or Differential Pairs.Select **Differential Pairs** from the **Post-process selection** field to view mixed-mode parameters.



Note:

The Network Data Explorer **Edit** menu option **Reset All Port Properties** deactivates all pairs, but it does not clear the differential pair settings. And since **Reset All Port Properties** also clears reference impedances and terminations, it should not be used when the user simply wishes to disable all differential pairs.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reset All Port Properties

Reset All Ports resets all changes in the **Edit Ports** window. It also deactivates all differential pairs defined in the **Differential Pairs** window but does not remove the definitions.

> **Note:** For HFSS Driven Terminal designs, selecting the solution data will disable this ribbon button. The user must make port/differential pair changes directly in the HFSS Design and re-import the solution.

Data View Pane Context Menus

The Data View pane presents different right-click menu options, depending on the context. Some commands are the same as those on the NDE ribbon. Others appear only in the context menus.

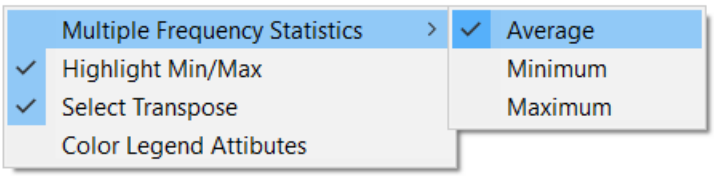
Network Data Explorer commands unique to the context menus are:

- Multiple Frequency Statistics
- Highlight Min/Max
- Select Transpose
- Color Legend Attributes
- Matrix Entries Plot Menu

Multiple Frequency Statistics

The **Multiple Frequency Statistics** menu option determines the statistical composite to display when multiple frequencies have been selected for the matrix display. The statistical data is always the first matrix displayed, followed by matrices for each individual frequency. The **Multiple Frequency Statistics** option also indicates the data used in the colored matrix plot when multiple frequencies have been selected.

This right click menu option appears in the **Matrix** plot, regardless of whether you are in Table or Plot view.



The menu options are:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

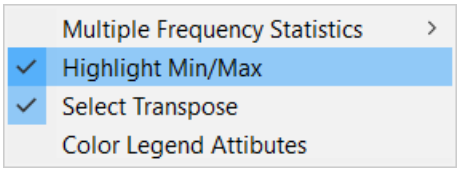
- **Average** – display the average of the matrix values across selected frequencies.
- **Minimum** – display the minimum matrix values across selected frequencies.
- **Maximum** – display the maximum matrix values across selected frequencies.

The selected information also appears in a tool-tip when you hover the cursor over a cell.

Highlight Min/Max

The **Highlight Min/Max** menu option determines whether the minimum and maximum matrix entries should be highlighted in the matrix table and color plot view.

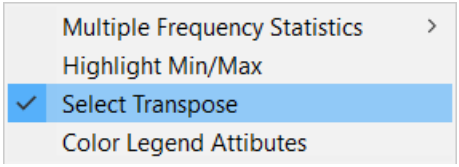
This right click menu option appears in the **Matrix** plot, regardless of whether you are in Table or Plot view.



Select Transpose

The **Select Transpose** menu option determines whether transpose cells are highlighted along with selected cells.

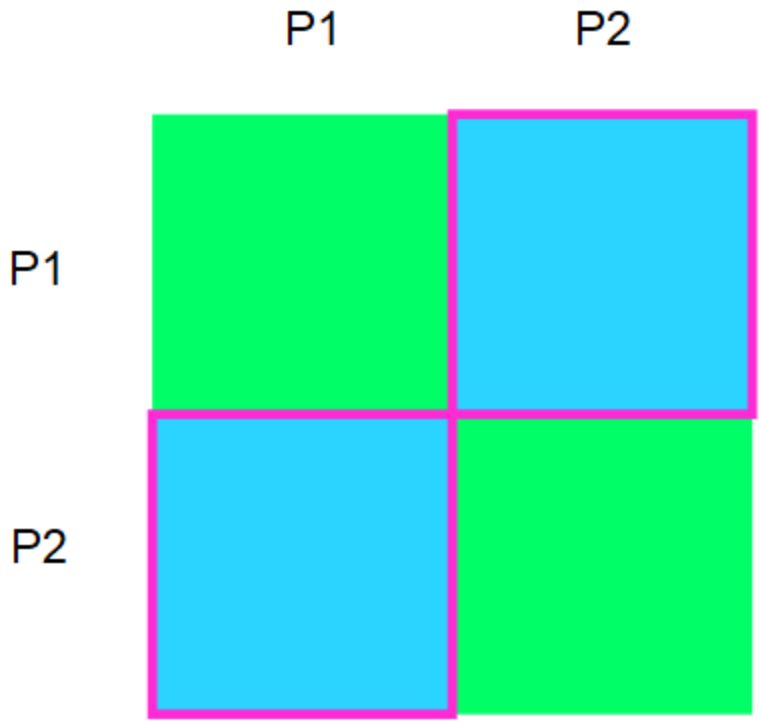
This right click menu option appears in the **Matrix** plot, regardless of whether you are in Table or Plot view.



Transpose cells are highlighted in Table or Plot view, as shown below.

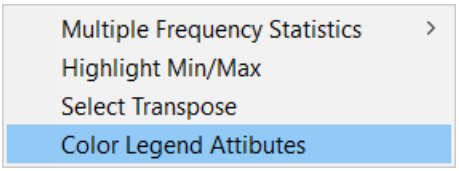
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

0.01000GHz	P1	-57.10340, -81.97841	-57.72581, 85.70836	-0.00213, -0.18916
	P2	-57.72582, 85.70825	-57.09556, -81.98749	-66.27113, 99.16916
	P3	-0.00213, -0.18916	-66.27110, 99.16941	-57.10246, -81.95892
	P4	-66.27112, 99.16942	-0.00213, -0.18929	-57.72556, 85.71465



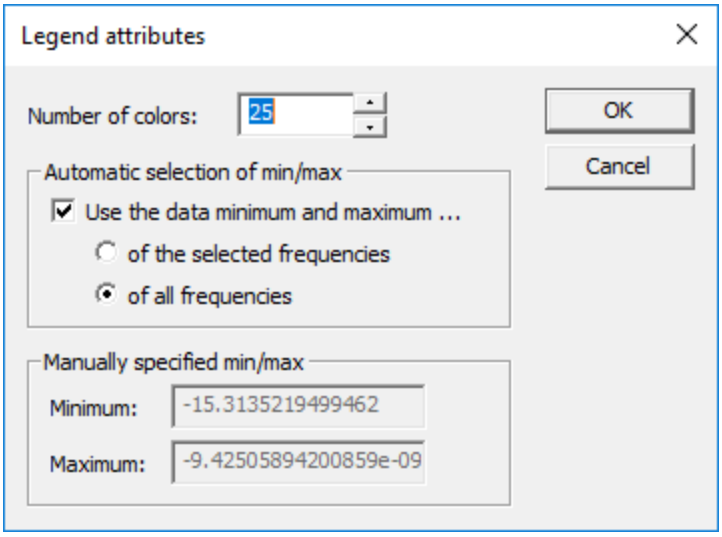
Color Legend Attributes

The **Color Legend Attributes** menu option allows you to change the granularity of the color scheme and the value range for plots. This right click menu option appears in the **Matrix** plot.



Alternatively, double-click the matrix plot's legend to open the **Legend Attributes** window.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



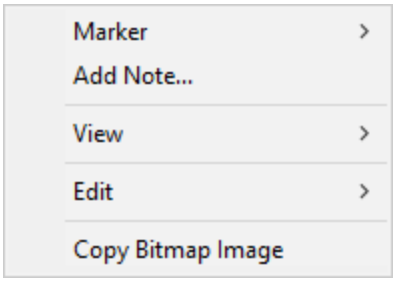
Options include:

- **Number of colors** – allows you to select number of color entries in the legend (the number of divisions between the start/end of the data range). This can be set to any discrete number between 1 and 50.
- **Automatic selection of min/max** – check the **Use the data minimum and maximum** check box to automatically select the data range using the minimum and maximum values from either selected frequencies or all frequencies in the data set.
- **Manually specified min/max** – when the when the range is not automatically determined, these fields permit the user to manually enter hard values. For example, for S parameter data magnitude data, you could enter a minimum of 0 and a maximum of 1.

Using a standard range across all frequencies permits you to quantitatively compare plots, and ndExplorer remembers legend settings for each data-type and display-format pair.

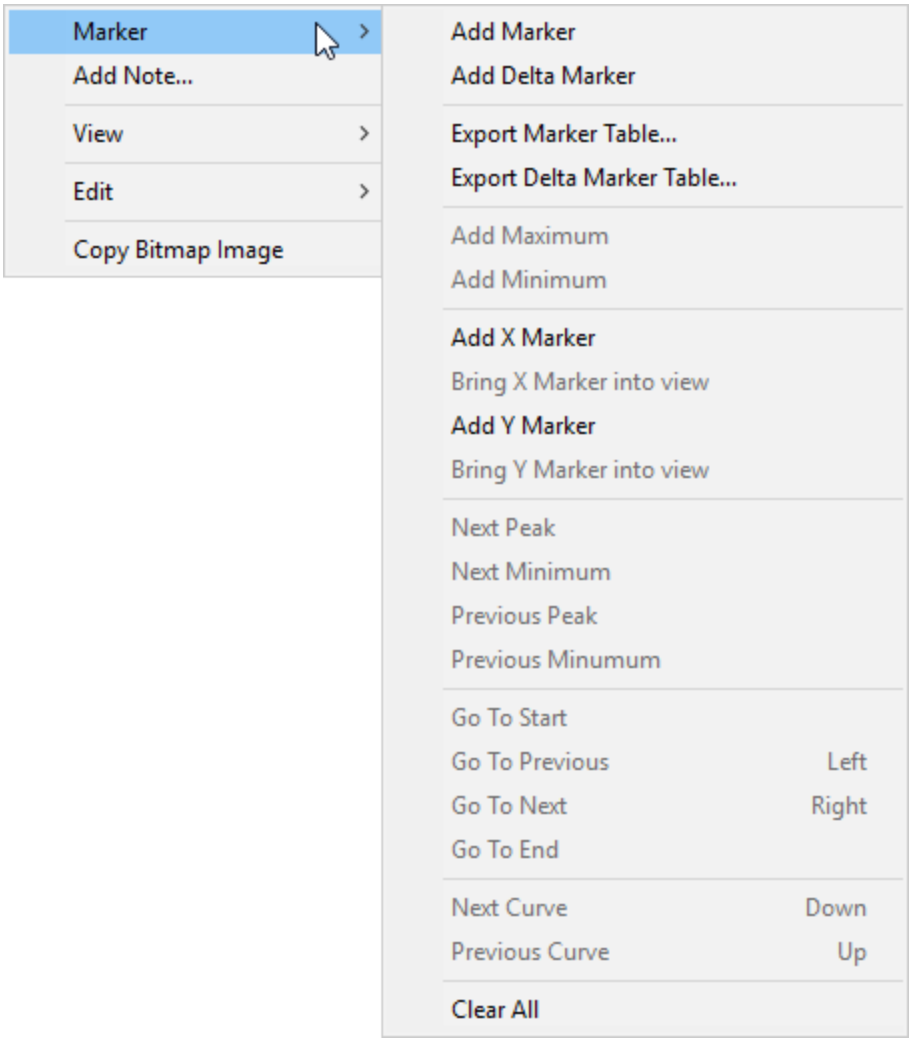
Matrix Entries Plot Menu

On the **Matrix** plot, several new right-click menu options appear.

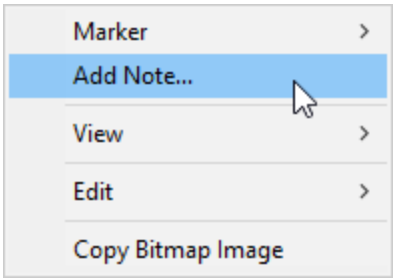


The **Marker** sub-menu provides commands for adding markers to plots.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

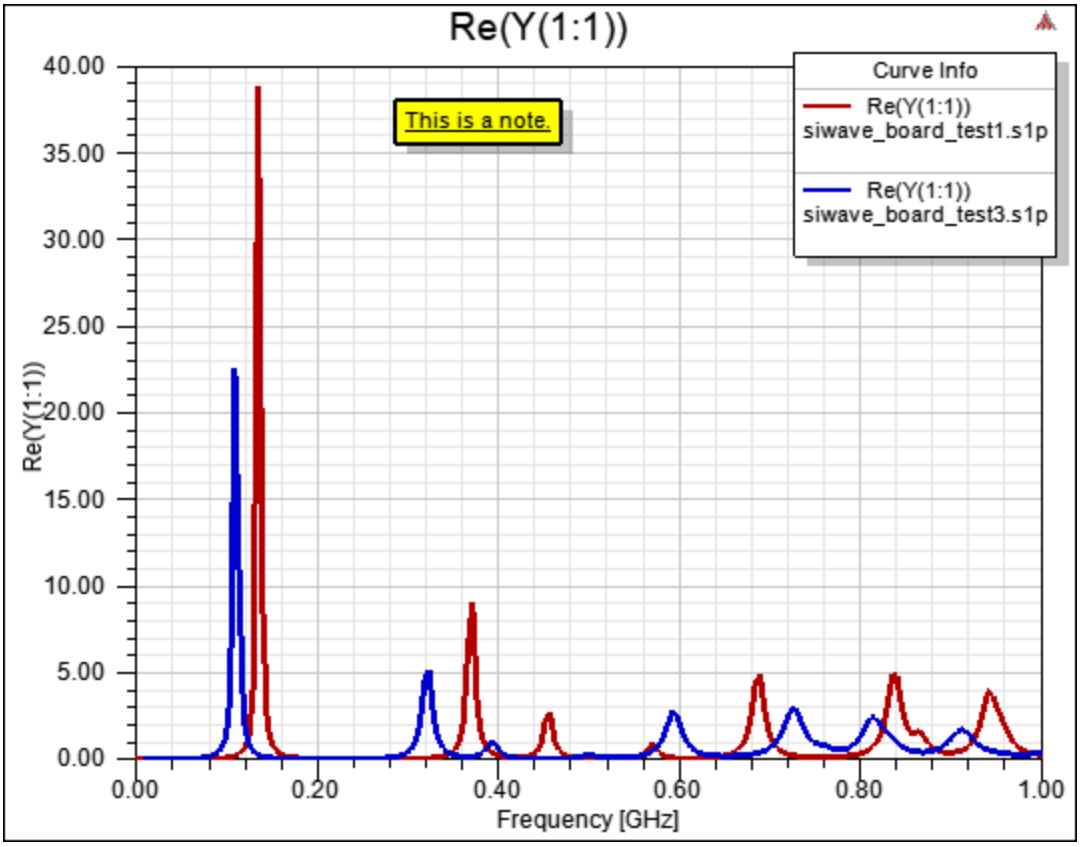


The **Add Note** menu option allows you to add a note to the plot.



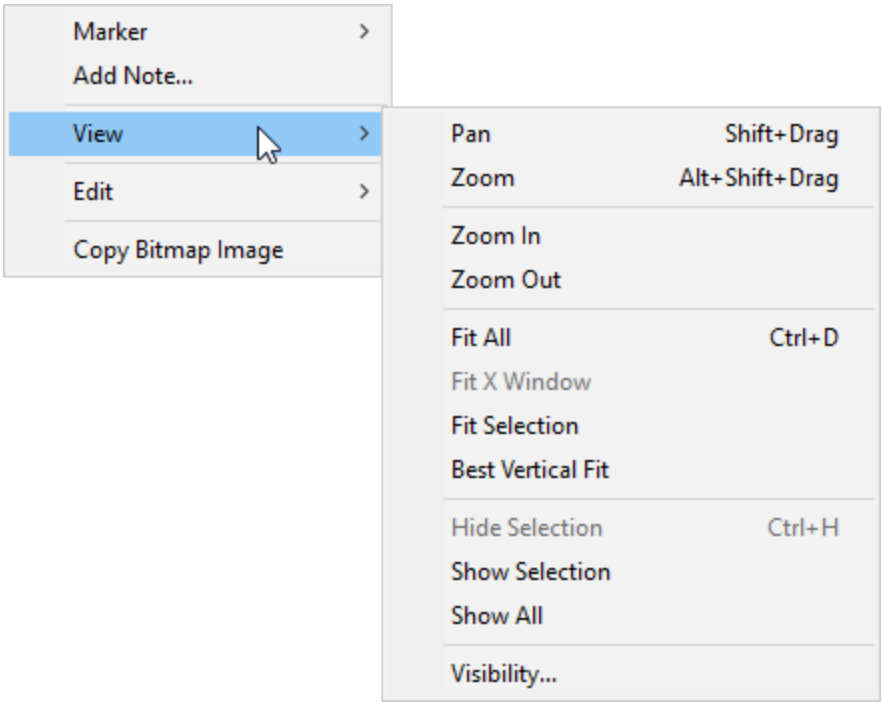
The note appears at the location you right-clicked. You can click and drag the note to a new location, or double-click the note to change its color and font.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



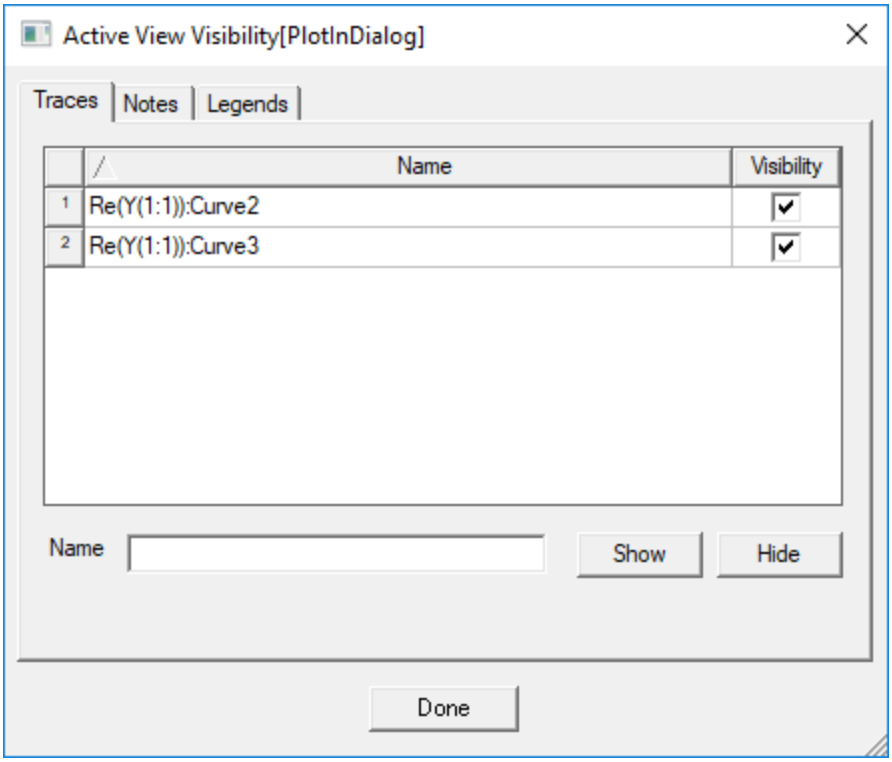
The **View** sub-menu provides commands for viewing, panning, zooming, and fitting elements to your plot.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

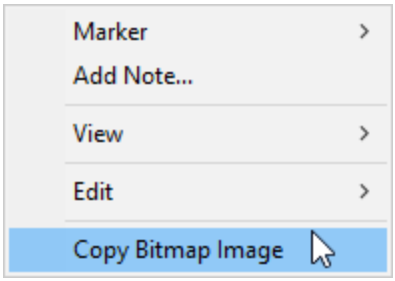


Click **Visibility** to open the **Active View Visibility** window, where you can select the visibility of traces, notes and legends.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Copy Bitmap Image** menu option copies the plot to your clipboard. You can then paste it into a graphics editor.



Exploring Network Data and Modifying the Display

Network Data Explorer allows you to view data and modify various aspects of the display, including color plots, color coding, viewing across frequencies, and displaying individual statistics. This section provides examples of Network Data Explorer capabilities:

- Viewing the S, Y, or Z Matrix for a Frequency
- Viewing a Color-coded Matrix Plot
- Displaying a Cell Graph Across All Frequencies

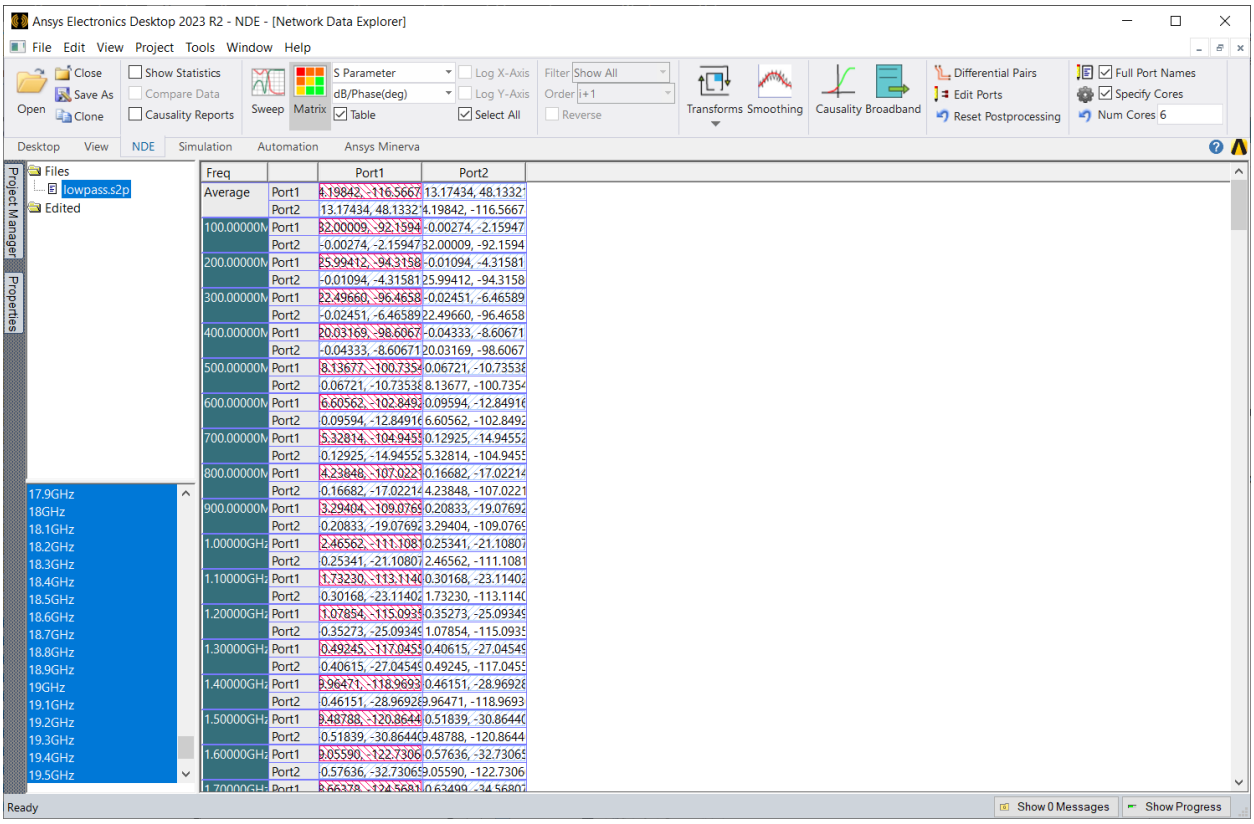
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Displaying Matrix Statistics by Frequency
- Displaying Individual Statistics for All Frequencies
- Creating a Statistics Plot
- Comparing Variations

Viewing a Matrix Table

To view the S, Y or Z matrix:

1. On the **NDE** ribbon, click **Matrix**.
2. Click the **Table** check box.
3. Use the **Parameter** type drop-down menu to select **S parameter**, **Y parameter**, **Z parameter**, or another choice.
4. Choose a format from the drop-down menu, for example dB or Mag.
5. In the Cell and Frequency Selection pane, select frequencies to display or click the **Select All** check box on the **NDE** ribbon to select all frequencies. The S, Y, or Z matrix displays.



6. Hover over a cell to see more information in a tool tip.
7. Right click to see a right click menu with other commands.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Maximum values are highlighted in red stripes. If Select Transpose is enabled, transposes are highlighted in red stripes as well.

Minimum values are highlighted in blue stripes.

Selected cells appear in solid blue. If Select Transpose is enabled, the transpose is highlighted in blue as well.

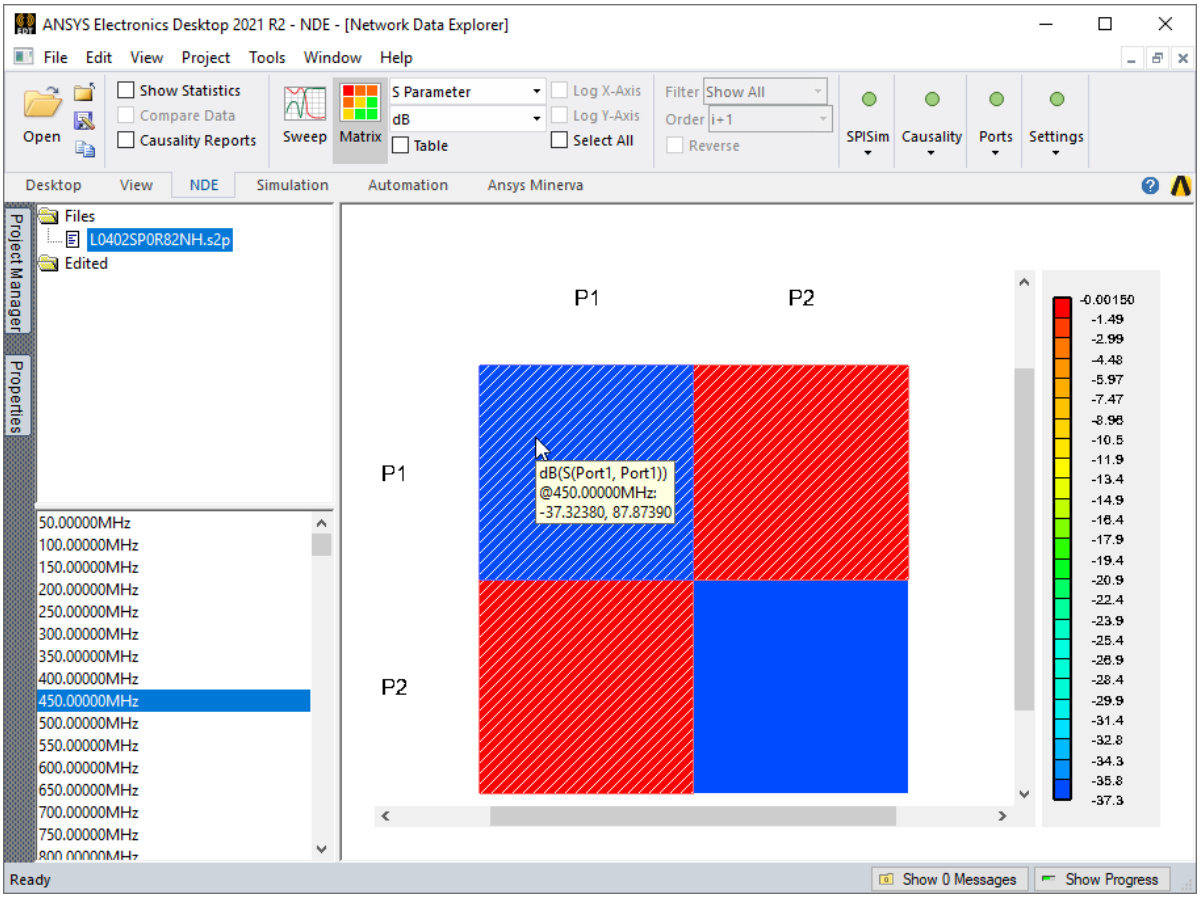
Double-clicking a cell switches to a matrix cell view, in which values for all frequencies for that cell are displayed. The double-clicked frequency is highlighted with solid red shading

Complex values are compared using their modulus. When multiple frequencies are selected, the data display depends on the Multiple Frequency Statistics setting.

Viewing a Color-Coded Matrix Plot

1. On the **NDE** ribbon, click **Matrix**.
2. Use the **Parameter** type drop-down menu to select **S parameter**, **Y parameter**, **Z parameter**, or another choice.
3. In the Cell and Frequency Selection pane, select the frequencies you want to plot or click the **Select All** check box on the **NDE** ribbon to select all frequencies.
4. Hover over a cell to see more information in a tool tip.
5. Right click to see a right click menu with other commands.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Matrix values display in a color-coded grid. If the selected **Format** is a complex value, only the real component is used to determine the display color. When multiple frequencies or variations are selected, the data display depends on the Multiple Frequency Statistics setting. Maximum values are highlighted in red. Minimum values are highlighted in dark blue.

Hover the cursor over any cell to view information about it.

Click any cell to select it. Selected cells appear with a pink outline. If Select Transpose is enabled, the transpose is selected in pink as well.

Double-click any cell to view a matrix cell plot in which all frequency values for that matrix cell are displayed as a graph.

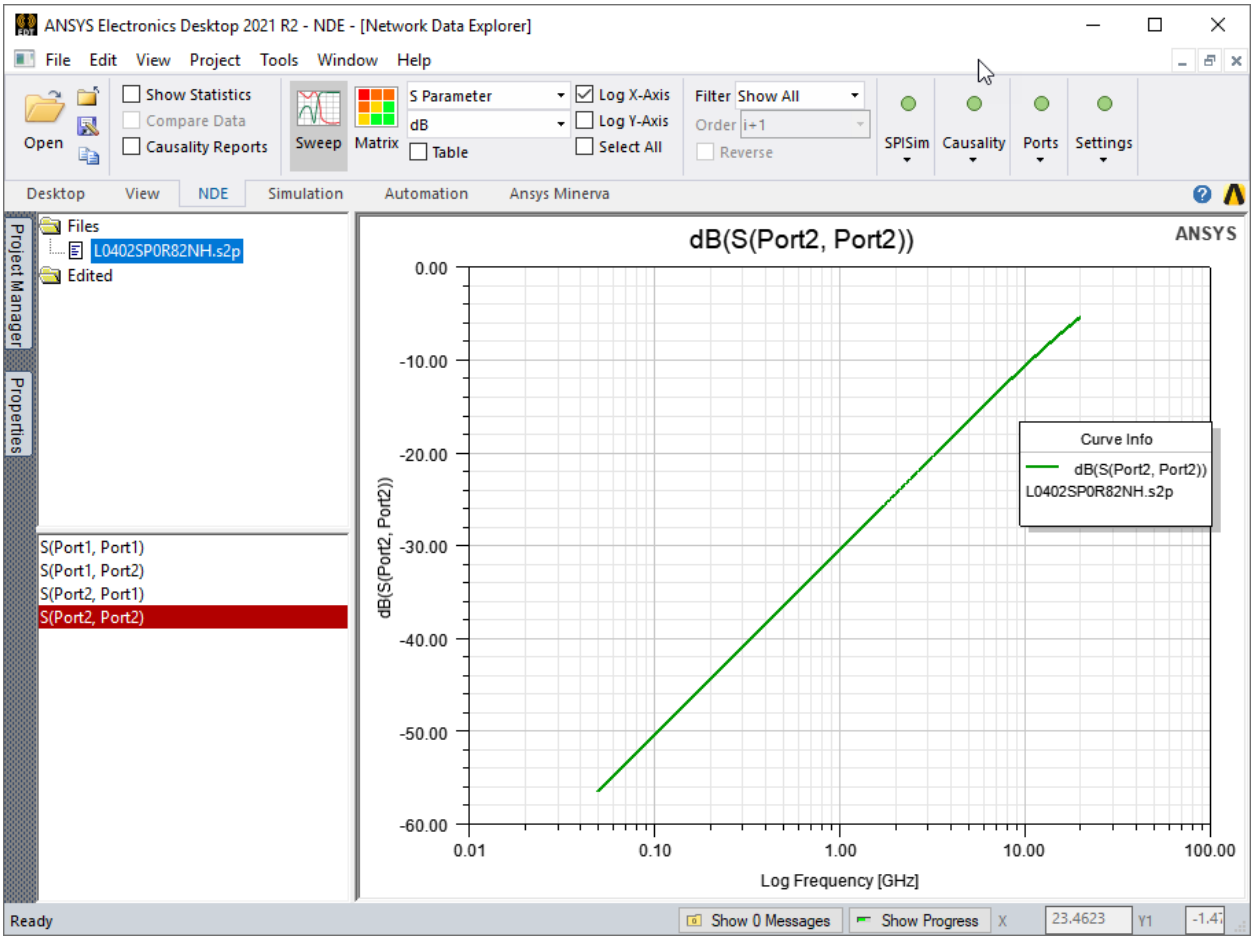
Displaying a Cell Graph Across All Frequencies

Network Data Explorer can plot a cell across all frequencies.

1. On the **NDE** ribbon, click **Sweep**. The Data View Pane updates if necessary.
2. Use the **Parameter** type drop-down menu to select **S parameter**, **Y parameter**, or **Z parameter**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. In the Cell and Frequency Selection pane, select cells to display or click the **Select All** check box on the **NDE** ribbon to select all cells.
4. To add a log scale to the X-axis, click **Log X-Axis** on the **NDE** ribbon.



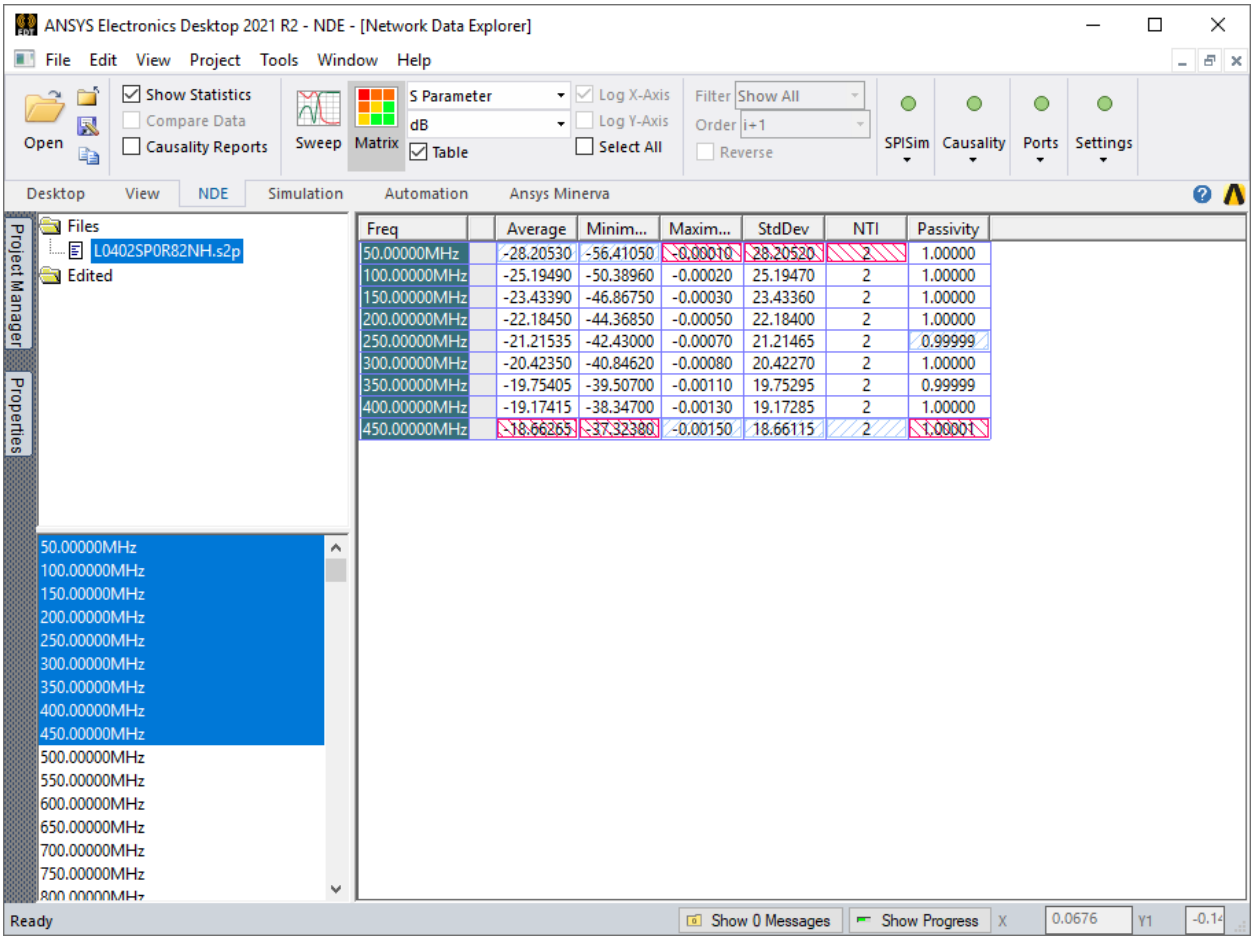
5. To add a log scale to the Y-axis, click **Log Y-Axis** on the **NDE** ribbon.
6. Right click to see a right click menu with other commands.

Displaying Matrix Statistics by Frequency

Network Data Explorer can display various statistical measurements.

1. On the **NDE** ribbon:
   a. Click **Matrix**.
   b. Click **Table**.
   c. Click **Show Statistics**.
2. In the Cell and Frequency Selection pane, select frequencies to display.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Click a column header to sort data by that column.

Hover the cursor over a cell to view information about it.

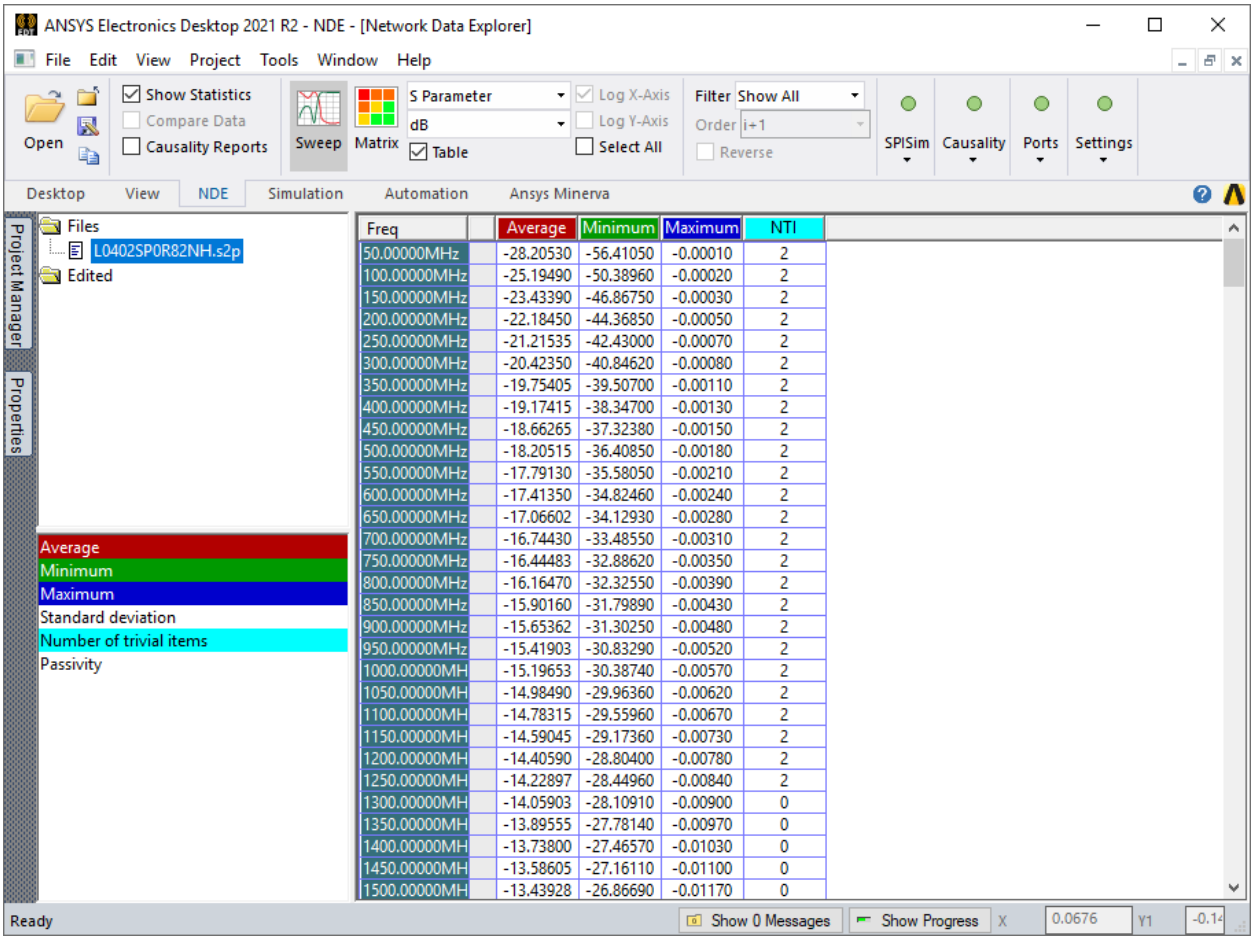
Only real (not complex) data formats are offered for statistical analysis. **Passivity** is only available for S-parameter data (comparisons inactive). **NTI** refers to the number of trivial items; for S-parameters, this includes all zeros and ones; for all other data (and data comparisons), only zeros are counted as trivial. The minimum value for each column is highlighted in blue; the maximum is highlighted in red.

Displaying Individual Statistics for All Frequencies

1. On the **NDE** ribbon:
    a. Click **Sweep**.
    b. Click **Table**.
    c. Click **Show Statistics**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the Cell and Frequency Selection pane, select statistics to display. The information displays in a table in the Data View pane.



Selected statistics are displayed for all frequencies.

Passivity is only available for S-parameters (comparisons inactive).

For S-parameters, the **Number of Trivial Items (NTI)** includes all values of 0 and 1. For other data and data comparisons, only values of 0 are counted as trivial.

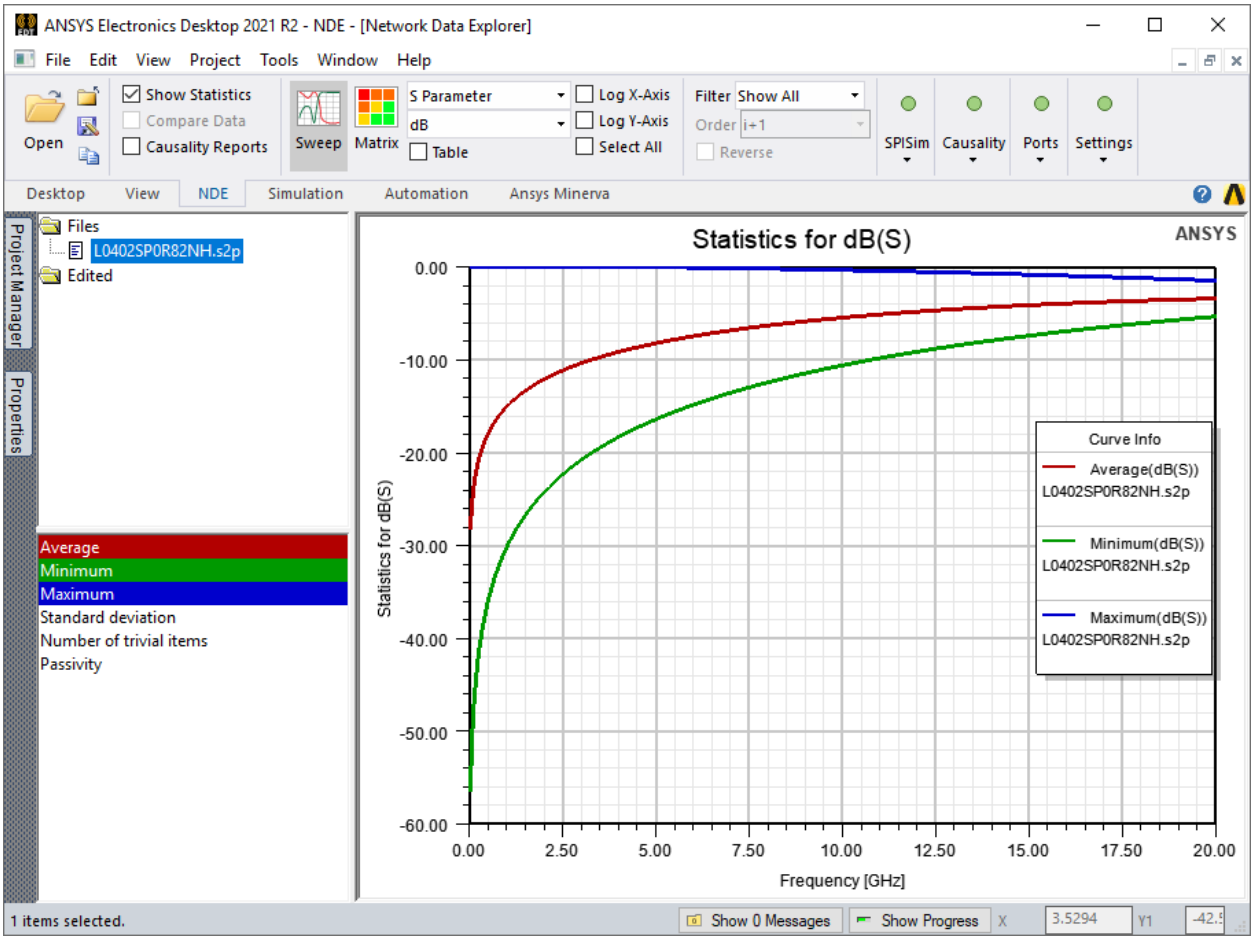
Creating a Statistics Plot

Network Data Explorer can display a graph of selected statistical measures across all frequencies.

1. On the **NDE** ribbon:
    a. Click **Sweep**.
    b. Click **Show Statistics**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the Cell and Frequency Selection pane, select statistics to display. The selected statistics are plotted.



Hover the cursor over a statistic to view more information about it.

Passivity is only available for S-parameters (comparisons inactive).

For S-parameters, the **Number of Trivial Items (NTI)** includes all values of 0 and 1. For other data and data comparisons, only values of 0 are counted as trivial.

Comparing Network Data

Network Data Explorer can compare variations for two network data sets that are the same size.

1. On the **NDE** ribbon, click **Sweep**.
2. In the Network Data Selection pane, select exactly two data sets.
3. On the **NDE** ribbon, click **Compare Data**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. In the Cell and Frequency Selection pane, select which cells you want to compare . For each value along the X-axis, the Y-axis values are subtracted, one from the other, to create the comparison plot. The second selected data is subtracted from the first selected data.
5. Optionally, check **Show Statistics** to show values applied to all cells and all frequencies

It is not possible to compare a data set against itself *unless the data set has been cloned.* Then, you can compare the original data set to the clone.

Traces for a given cell or statistical measure are displayed for all data sets; you can use tool tips to distinguish between them.

If a single cell or statistical measure is displayed, different colors are used for each data trace. If multiple cells or statistical measures are selected, a single color is used for all data traces for each cell or statistical measure.

In a data comparison, traces are shown for all selected data sets. This is true for both cell and statistical traces.

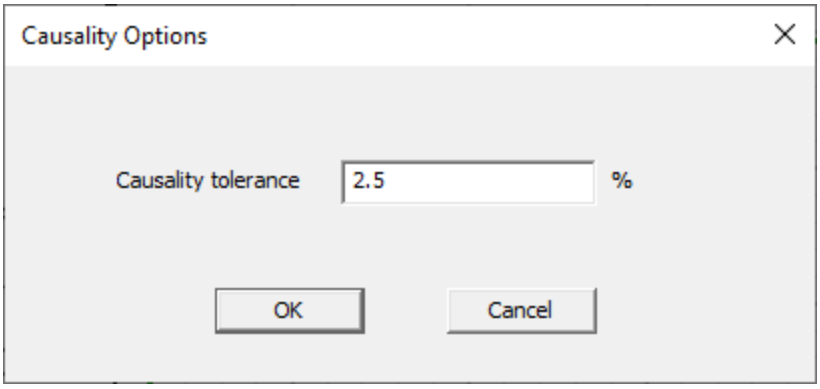
If **dB** format is shown, you can either subtract values before or after applying the dB function. See Display Format to make this choice.

Causality Checking and Plots

Network Data Explorer can perform a causality check on S-parameter data from any source (solution or file), and provide plots of the results in various formats.

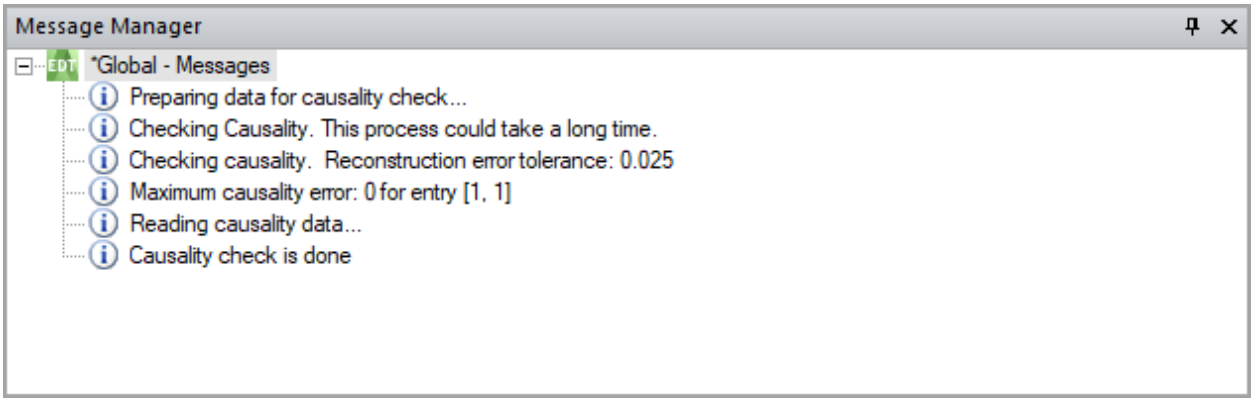
When S-parameter data is loaded into Network Data Explorer, the **Causality** button is enabled.

1. On the **NDE** ribbon, click **Causality**. The **Causality Options** dialog opens.



2. Enter a **Causality tolerance** and click **OK** to start the causality check. Depending on the size of the S-parameter data, the causality check may take several minutes to complete. The check's status displays in the Message Manager.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

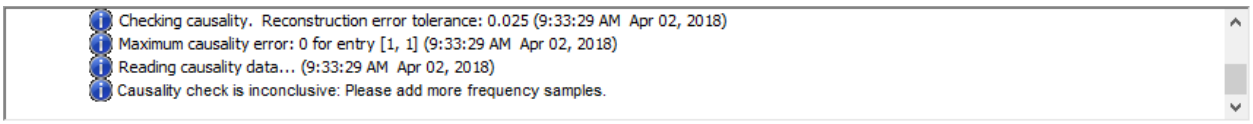


When the check completes, the Message Manager updates to display a summary of results.

Reconstruction Error Tolerance – Causality of a frequency response is determined by calculating the generalized Hilbert transform of the data at all frequencies. A causal frequency response is equal to its generalized Hilbert transform. The reconstruction error is the difference between the tabulated data and its transform at a given frequency. The message shows the maximum reconstruction error tolerance for a causal frequency response. The default tolerance of 0.01 is equal to the state-space fitting tolerance.

Maximum Causality Error – The maximum causality error for all port pairs and all frequencies, along with the matrix indices (port numbers) where the maximum noncausality occurs. A noncausal response is one where all matrix entries can be conclusively analyzed, and at least one entry exceeds the causality tolerance. The maximum reconstruction appears first, followed by port numbers in brackets (e.g., [port number, port number]). When all results are conclusive but no matrix reconstruction error exceeds the tolerance, the maximum causality error is reported as zero, and no matrix entry is listed.

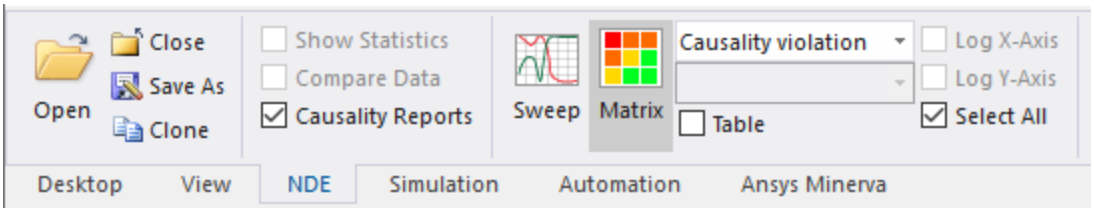
If the data does not contain enough frequency points to determine whether the data is or is not causal, the Messages Pane will note an inconclusive result. Network Data Explorer will also report the data set as inconclusive if any cells are inconclusive, even if other entries exhibit causality violations.



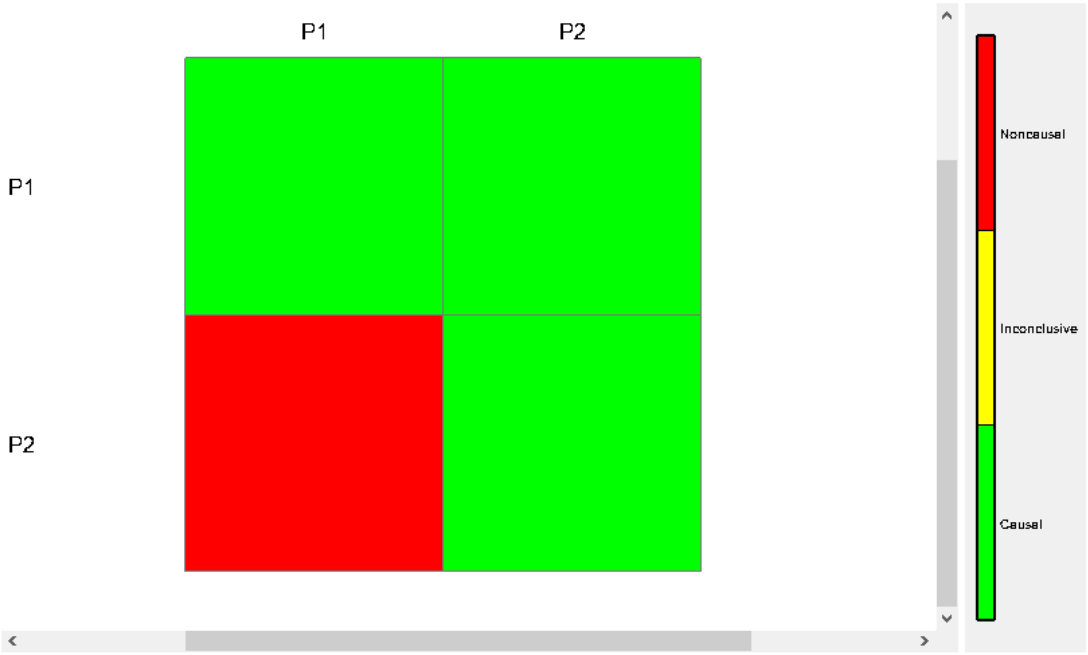
To see the plotted results of the causality check:

1. On the **NDE** ribbon, click **Causality Reports**.
2. Either click the **Matrix** icon or select **Causality violation** in the **Parameter** type drop-down menu.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



A rectangular plot displays, with dimension N x N and color-coding to indicate the causality status of each port pairing.



In this plot, the cells go from (Port 1, Port 1) at the upper-left area to (Port N, Port N) at the lower-right corner. The result shows the causality over all frequencies in the data. In this example, the matrix is asymmetric, so that S12 is noncausal, while S11, S21, and S22 are causal.

To see the details for each frequency, click the **Table** check button on the **NDE** ribbon.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Freq		Port1	Port2	Port1	Port2

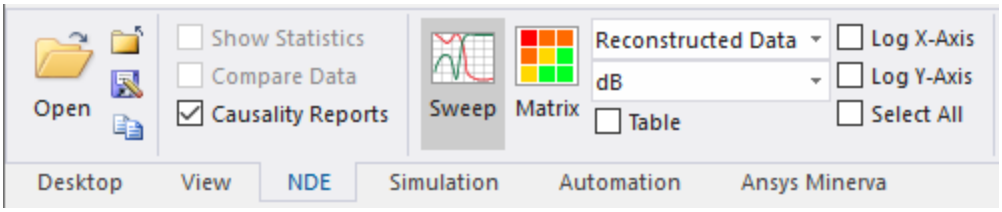
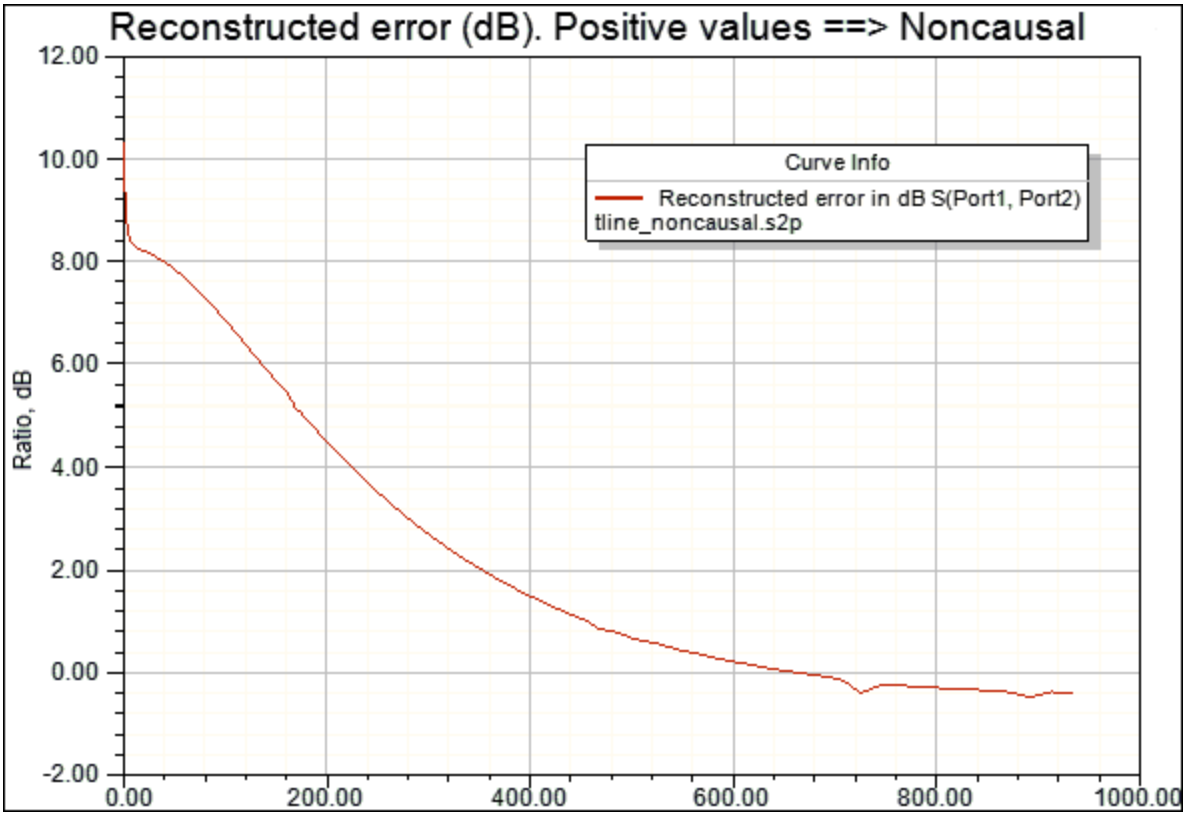
To plot the reconstructed frequency response generated by the causality checker:

1. On the **NDE** ribbon, click **Causality Reports**.
2. Either click the **Sweep** icon or select **Reconstructed Data** in the **Parameter** type drop-down menu.
3. In the **Format** drop-down menu, select the desired format. **dB** is selected by default.



The plot appears, showing the reconstruction error at each frequency divided by the tolerance.

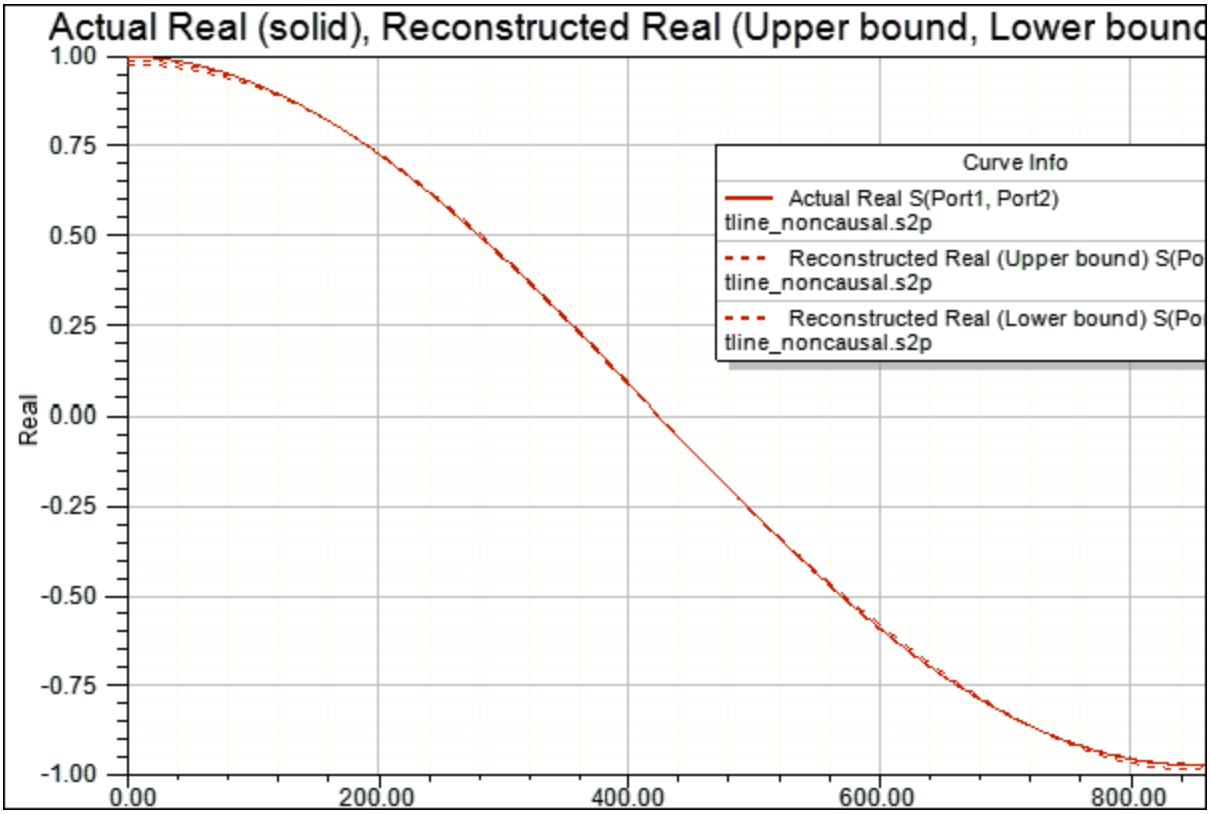
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The reconstruction error ratio for parameter S12 is positive for frequencies less than about 680MHz, indicating a broad range of noncausal behavior.

4. To compare the real part of the reconstructed data to the real part of the actual data, set the **Format** to **Real**.

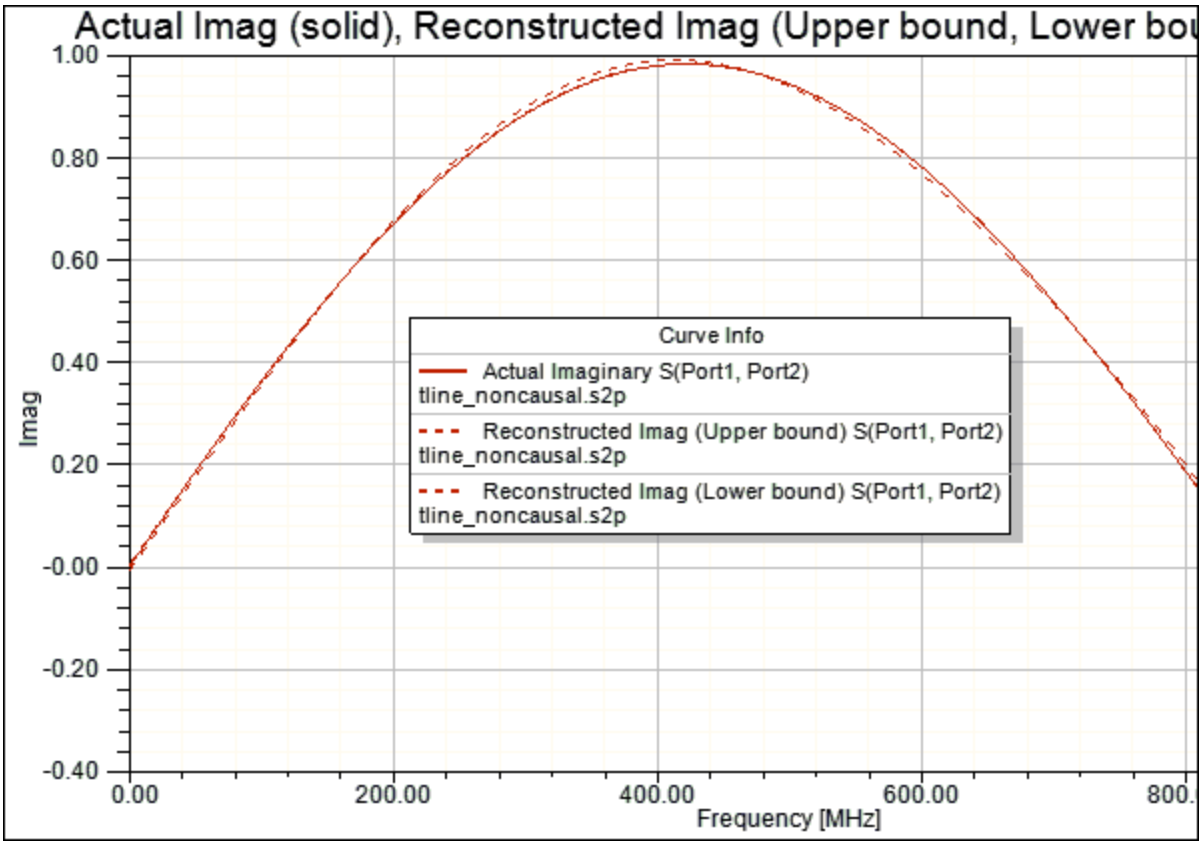
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For a causal frequency response, the actual data (solid line) will be within the upper and lower bounds of the reconstruction (dotted lines) at all frequencies.

5. To compare the imaginary part of the reconstructed data to the imaginary part of the actual data, set the **Format** to **Imaginary**.

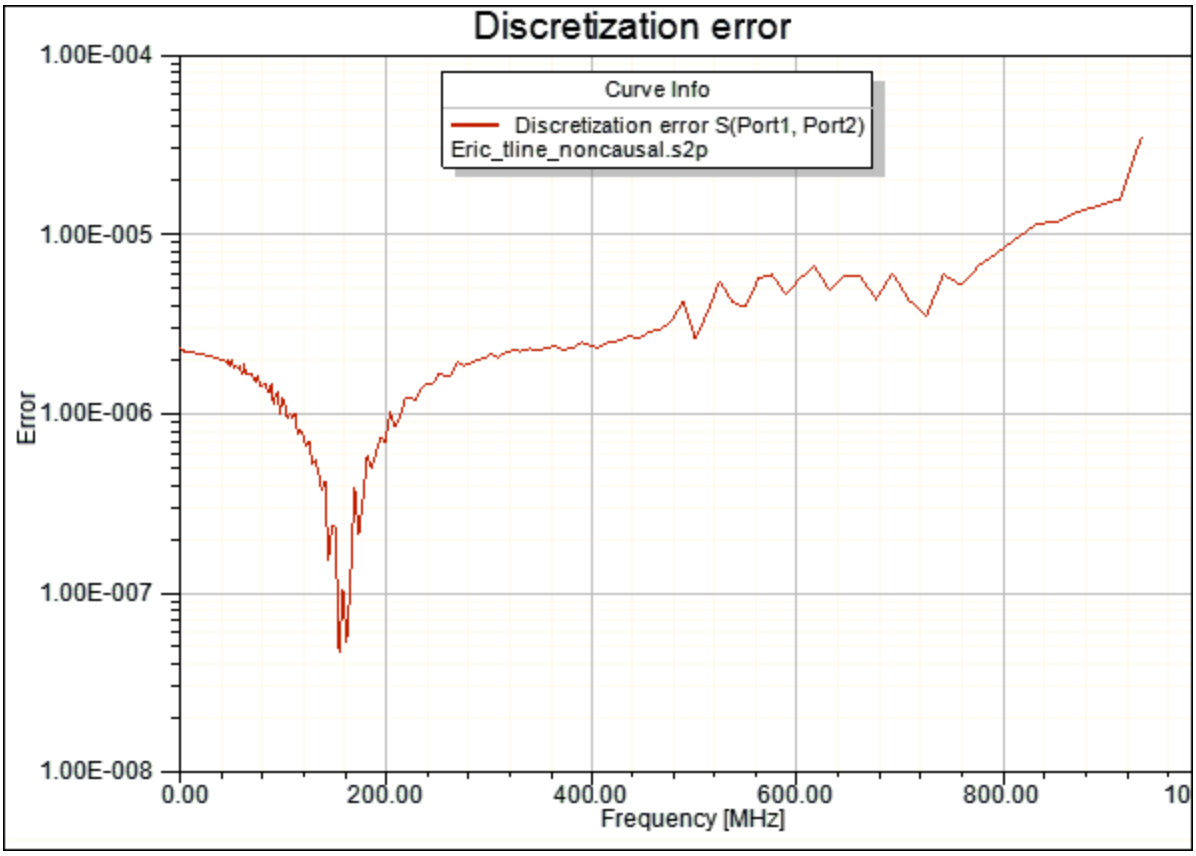
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For a causal frequency response, the actual data (solid line) will be within the upper and lower bounds of the reconstruction (dotted lines) at all frequencies.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. To view the frequency-dependent discretization error, set the **Format** to **Discretization**.



The discretization error is the error that is due to the fact that the data are available only at discrete frequencies rather than for a continuous spectrum. A discretization error near or greater than the causality tolerance renders the causality check inconclusive. Data at more frequencies could reduce the discretization error and render the analysis conclusive. This set of data exhibits low discretization errors (<<0.01) at all frequencies, and the causality check is conclusive (conclusively noncausal in this example).

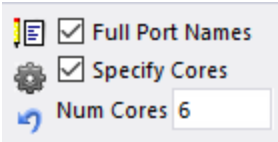
Multithreading

By default, multithreading (execution on multiple cores) is enabled for Causality Checking and Macro Model export. Multithreading saves significant time in the Causality Check calculation, and improves the time for other state-space fitting operations. See Technical Notes.

The **Cores** field in the Network Data Explorer Control Pane defaults to half the number of cores detected on your computer.

For best performance, disable hyper-threading on your computer. When hyper-threading is enabled, the number of cores includes the physical cores and an equal number of logical cores. With hyper-threading disabled, the display shows only half the number of physical cores.

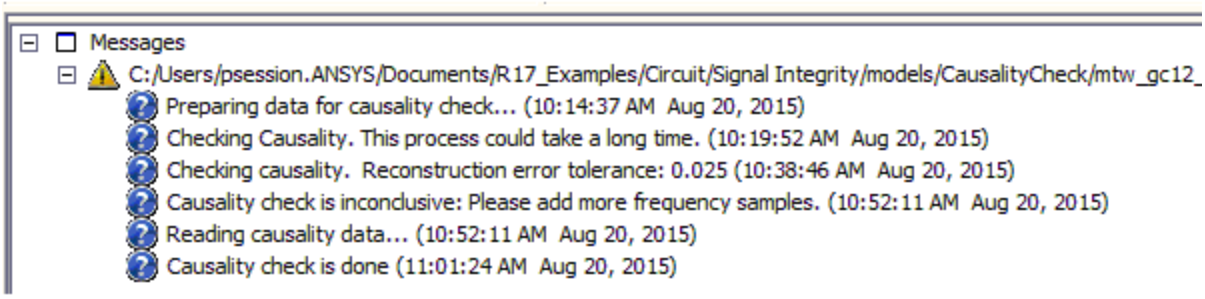
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To disable multithreading, uncheck the check box.

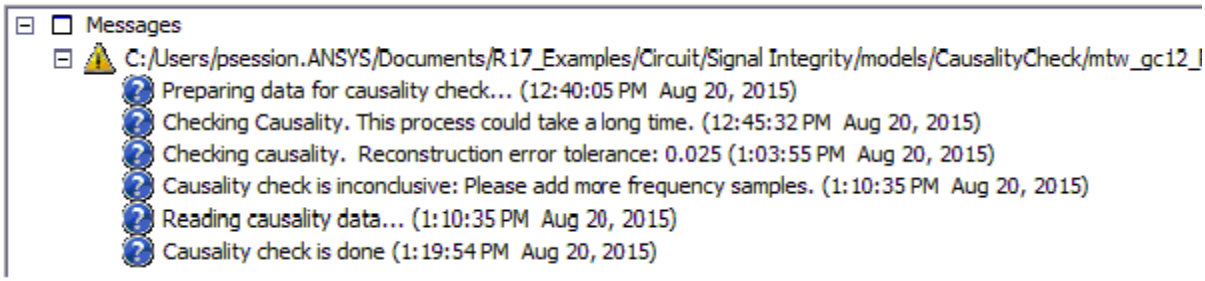
Multithreading Technical Notes

Multithreading can save significant time in the causality check calculation, especially for data sets with large number of ports or a large number of frequencies. The Network Data Explorer contributes a fixed amount of overhead time in preparing the data, and this overhead is not reduced by multithreading. Here are the messages from the causality check of a 278-port Touchstone file using two cores.



The causality check itself happens between the message `Checking causality. Reconstruction error tolerance: 0.025 (time 10:38:46)` and the message `Causality check is inconclusive: Please add more frequency samples (time 10:52:11)`. The difference between these two times is the time for the causality check after setup, 13:25 or thirteen minutes and twenty-five seconds. There is a fixed overhead of around 25 minutes involved in the overall time duration for this example.

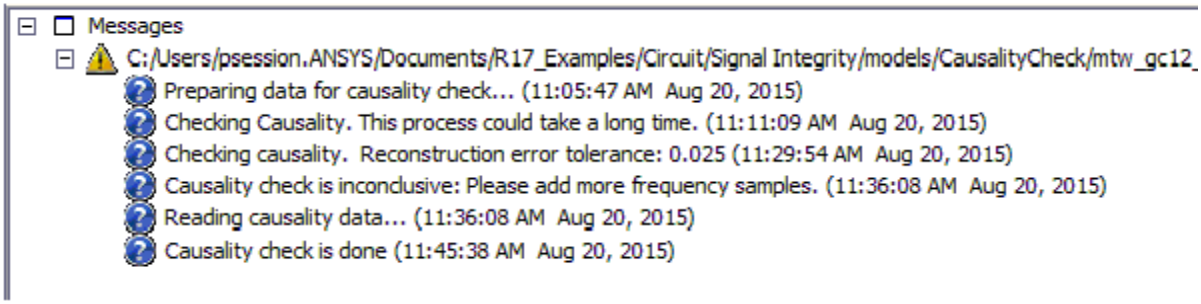
Here are the causality check messages for the same 278-port file using eight cores:



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

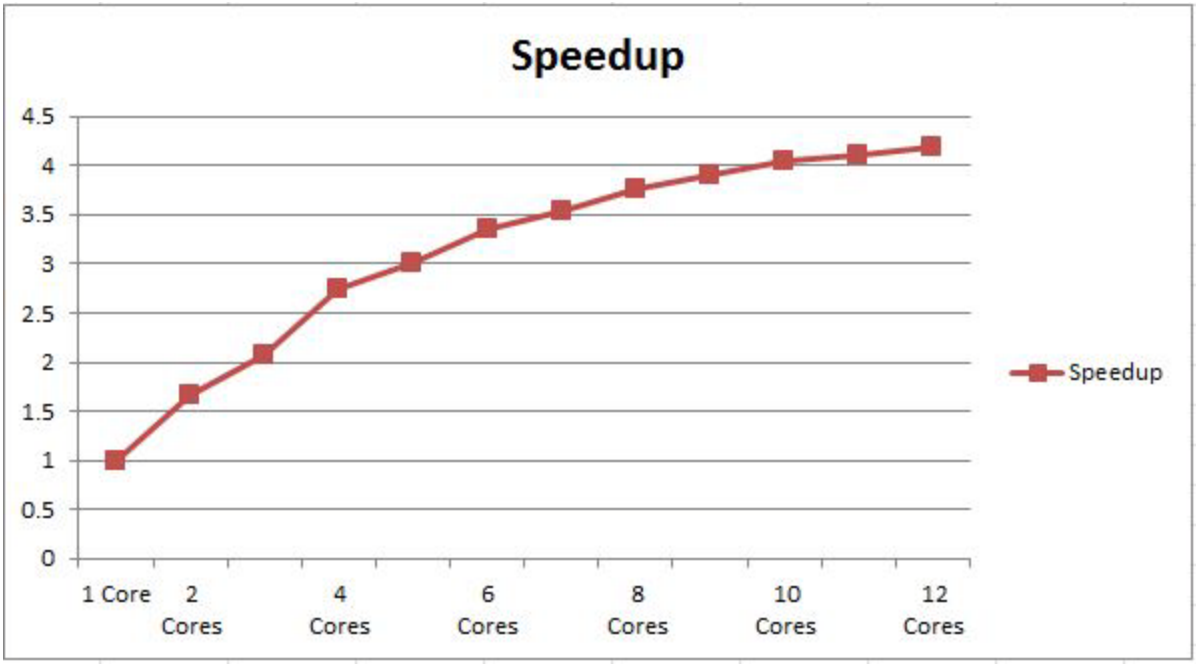
Now the causality check happens between times (1:03:55) and (1:10:35), a difference of (6:40) or six minutes and forty seconds, about half the time for the two-core example.

The speedup from multithreading is not linear in practice. Here are the messages from the same 278-port file using sixteen cores:



Now the causality check happens between times (11:29:54) and (11:36:08), a difference of (6:14) or six minutes and fourteen seconds, not significantly better than the eight-core performance.

Here is a graph showing the speedup of the causality checker using multithreading on this 278-port file. The plot is generated using data from runs with 1, 2, 4, 6, 8, 10, and 12 cores, then averaging the known times to approximate the speedup for 3, 5, 7, 9, and 11 cores. The speedup for N cores is the time with one core divided by the time with N cores.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

22 - Postprocessing and Generating Reports

As Ansys Electronics Desktop completes a solution, you can display and analyze the results:

- View solution data including the following: convergence information, computing resources that were used during the solution process, mesh statistics, and matrices computed for the S-parameters, impedances, and propagation constants during each adaptive, non-adaptive, or sweep solution. For eigenmode solutions, you can view the real and imaginary parts of the frequency and quality factor Q computed for each eigenmode. Solution data can also be viewed while Ansys Electronics Desktop is generating a solution.
- View analysis results for Optimetrics solutions.
- Plot field overlays - representations of basic or derived field quantities - on surfaces or objects.
- Overlay Field Plots on Models
- Create 2D or 3D reports of S-parameters, basic and derived field quantities, and radiated field data.
- Plot the finite element mesh on surfaces or within 3D objects.
- Create animations of field quantities, the finite element mesh, and defined project variables.
- Scale an excitation's magnitude and modify its phase.
- Apply Derivative Tuning to Reports

> **Note:**
>
> Except in the case of non-model boxes drawn in the global coordinate system (CS), non-model objects cannot be used for any fields post processing operation You can use non-model boxes drawn in the global CS for post processing operations, including integration and solution domaining.

Viewing Solution Data (Maxwell)

While Maxwell is generating a solution, or when it is complete, you can view the following types of information about the solution in the **Solutions** dialog box. The information actually available will vary with the solution type and setup of your design.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Convergence information

  > **Note:** Because adaptive mesh refinement is not performed for transient solutions, convergence data is not available for **Transient** analysis.

- Computing resources, or profile information, that were used during the solution process.
- Output Parameters (for example Force and Torque), and Matrix Data computed during each adaptive, non-adaptive, or sweep solution.
- Mesh data
- State of solved solutions
- Winding results (for eddy current solutions only)
- End Connection results (for eddy current solutions only)
- Loss results (for eddy current solutions only)

To access the **Solutions** dialog box, in which the information above can be viewed, do one of the following:

- Click **Maxwell 3D**, **Maxwell 2D,** or **RMxprt**, and then select **Results** > **Solution Data**.
- Right-click **Results** in the project tree, and then click **Solution Data** on the shortcut menu.

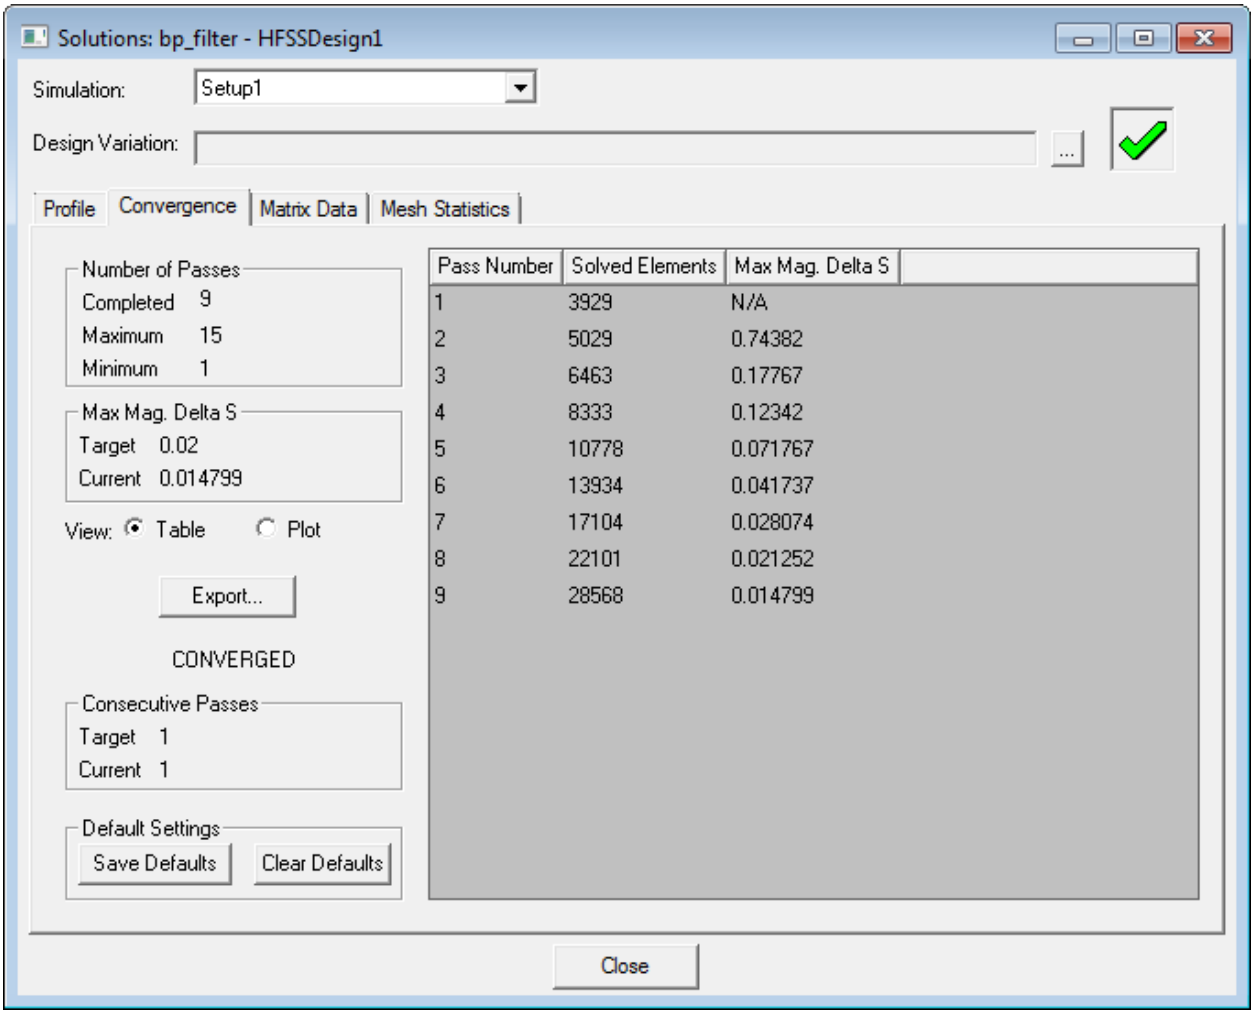
Viewing Convergence Data

To view an adaptive solution's convergence information, either during or after the solution process:

1. In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

   The **Solution Data** window appears. The **Convergence** tab is selected. You can also select the **Results** tab of the ribbon, click the **Solution Data** icon, and click the **Convergence** tab when the **Solution Data** window appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



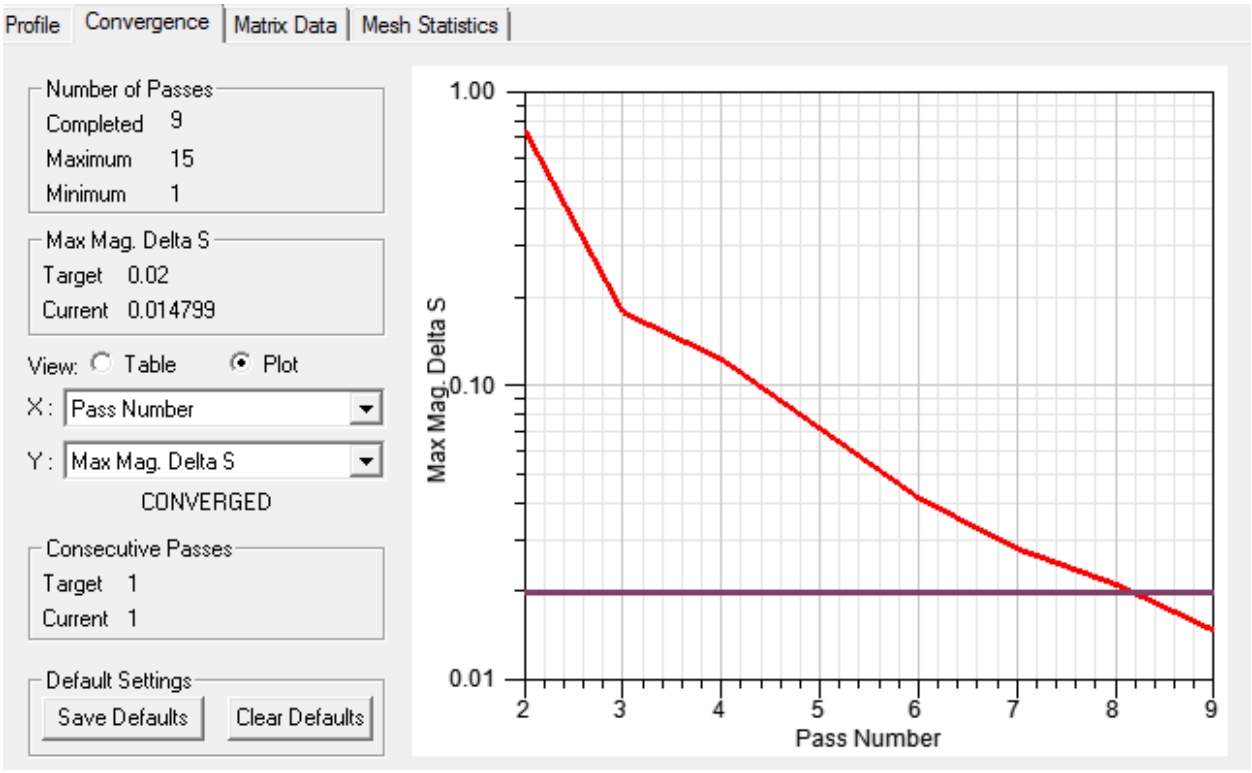
2. If you have run multiple simulations, from the **Simulation** list, select the solution setup for which you want to view convergence data.

   By default, the most recently solved solution is selected.

3. Under the **Convergence** tab, depending on your design setup, you can review the following convergence data:
   - Whether the solution is converged or not converged.
   - Number of adaptive passes completed and remaining.
   - The number of tetrahedra or triangles created at each adaptive pass.
   - Solution type dependent parameters such as Loss, Total Loss, Loss Error.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Select **Table** to display the convergence data in table format or **Plot** to plot the convergence data on a rectangular (X - Y) plot.



5. If you select **Save Defaults**, the settings for Table vs. Plot, and for Plot, the X and Y axis selections, those settings apply, based on the design-type, each time you open the desktop. You can also select **Clear Defaults** to reset to the original settings.

> **Note:**
>
> In the case of the 3D AC Conduction solver, even though the convergence columns names refer to the loss as a solution criteria, the convergence parameter considered is the magnitude of the apparent power.

Viewing the Number of Completed Passes

At any time during the solution process, you can view the number of adaptive passes (solve — error analysis — refine cycles) that have been completed and that have yet to be completed. When the solution is complete, you can view the number of adaptive passes that were performed. If the solution converged within the specified stopping criteria, fewer passes than requested may have been performed.

To view the number of passes:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

The **Solution Data** window appears. The **Convergence** tab is selected.

The number of completed and remaining passes is listed in the **Number of Passes** area.

Viewing Output Variable Convergence

At any time during or after the solution process, you can view the values of the output variable.

To view the output variable convergence:

- In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

The **Solutions** window appears. The **Convergence** tab is selected.

The **Output Var** column lists the value of the output variable for each pass. The **Output Var. Delta (%)** column lists the delta change between the current and previous passes as a percentage of the previous pass value. If output variable convergence is not used, the columns are not used in the table.

Plotting Convergence Data

To display convergence data vs. pass on a rectangular (x - y) plot:

1. In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

   The **Solution Data** window appears. The **Convergence** tab is selected.

2. In the lower-left corner of the window, select **Plot** as the view type.
3. Select the data you want to plot on the x-axis from the **X** drop-down menu.
4. Select the data type you want to plot on the y-axis from the **Y** pull-down list.

The x -y plot appears in the view window.

Viewing a Solution Profile

At any time during or after the solution process, you can examine the computing resources or profile data that were used by Ansys Electronics Desktop solvers during the analysis. The profile data is essentially a log of the tasks performed by Ansys Electronics Desktop during analysis. The log indicates the length of time each task took and how much physical and disk memory was required.

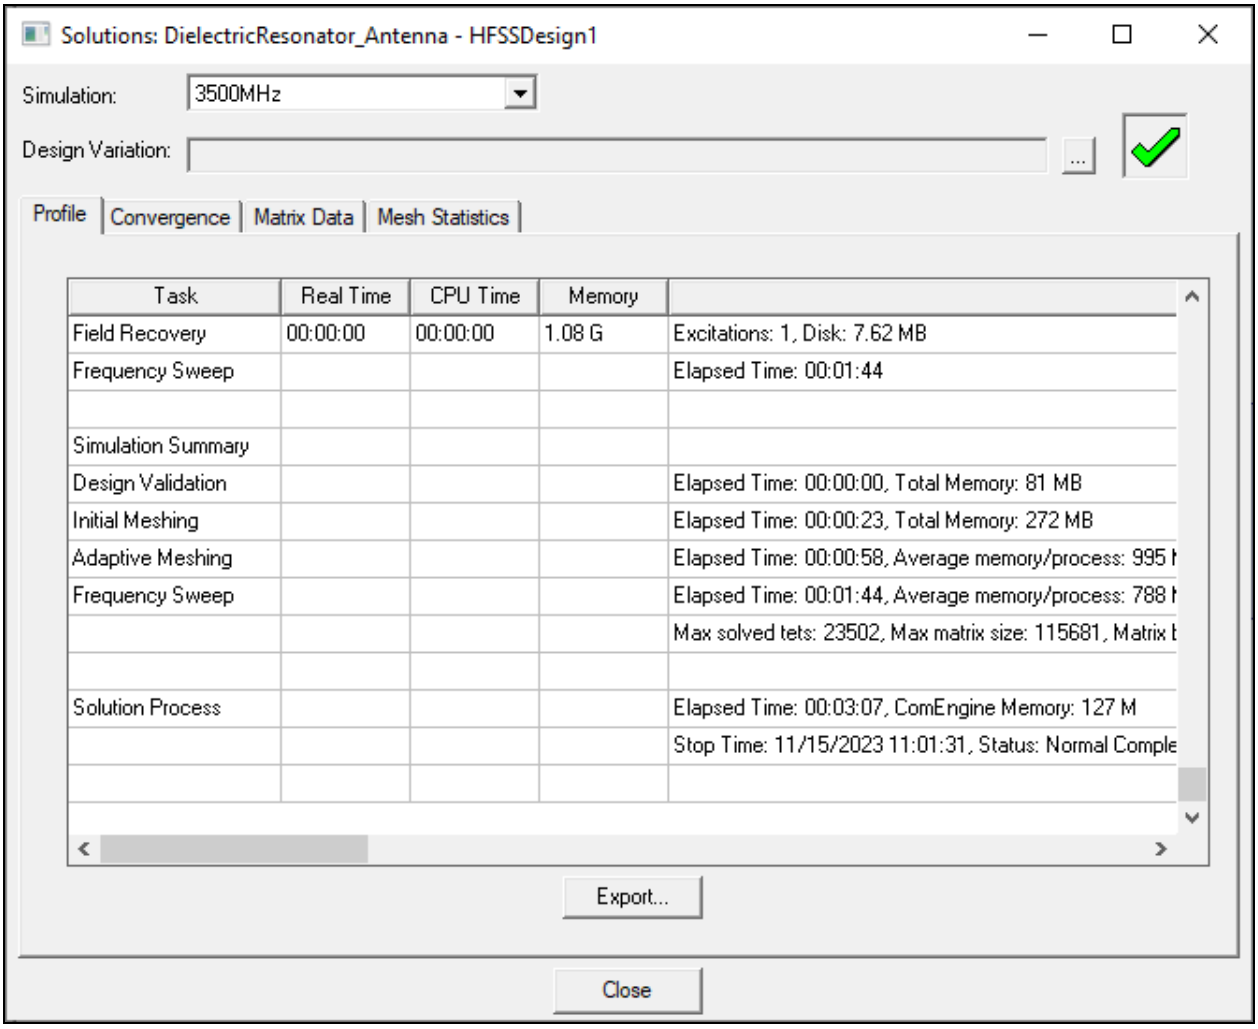
Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the project tree, right-click a solution setup, and select **Profile**.

   The **Solutions** dialog box appears, with the **Profile** tab selected. You can also click the **Solution Data** icon on the ribbon to open the **Solutions** dialog box, and then select the **Profile** tab.

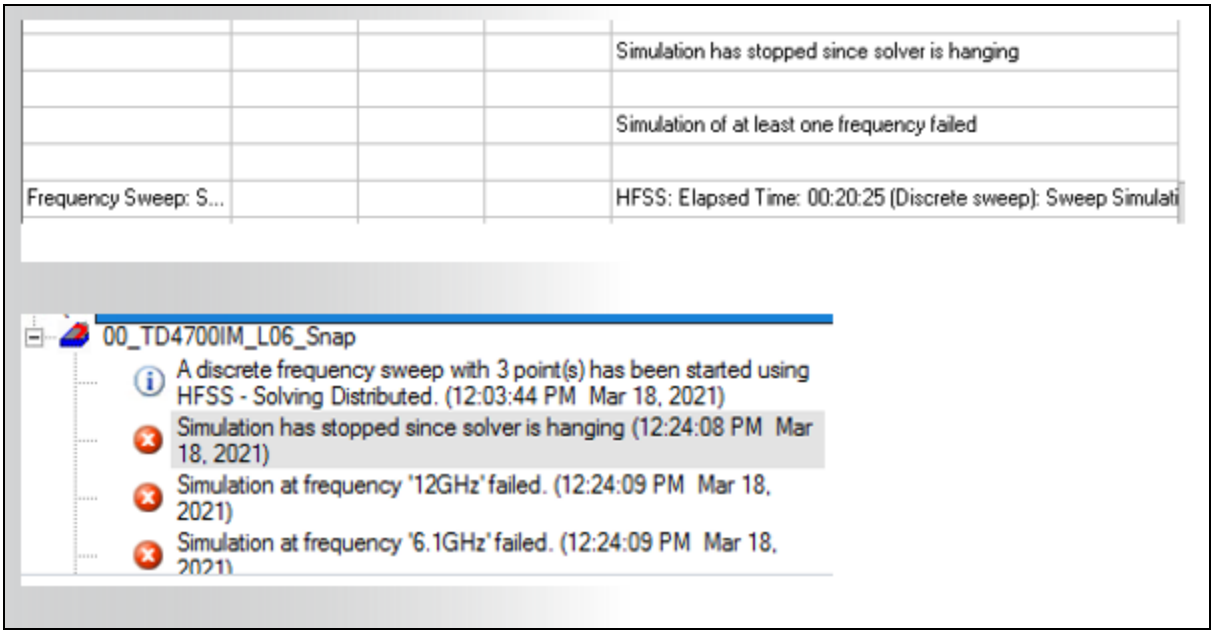
   The displayed data depends on the type of problem and solution setup.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If the simulation hangs, equivalent messages appear in the Message window and the Solution **Profile** tab.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. If one or more exist, you can select the desired profile information from the **Simulation** drop-down menu. In general, the information displayed includes:

Task	Lists the type of task that was performed. Tasks include
Real Time	The difference in time between the start of the task and the end of the task (elapsed time).
CPU Time	The amount of CPU time required to perform the task.
Memory	The peak amount of physical memory (RAM) used by the individual executable running the task. The memory is freed for other uses after each task is complete.
Information	General information about the solution (for example, the number of tetrahedra used in the mesh, disk use, solver information, sweep information, and totals).

The matrix solver writes specific information in some of these fields, as outlined below:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Task	The matrix solver task reports the type of solution performed by the solver, based on the physics of the problem. It has the form "Solver *pdsn*" (e.g., Solver MRS2, Solver DCS4-L2), where: • *p*, the precision type is: M (mixed for direct solver), or Mxx (for distributed direct solver), or D (double for direct and iterative solver) or E (extended precisions solve) • *d*, the matrix data type is: R (real) or C (complex) • *s*, the symmetry type is: S (symmetric), A (asymmetric), or H (hermitian) • *n*, the number of processors used. You specify the number of available processors on the local machine in the solver options. If a solve does not use all available processors (local or distributed), the number reported may be less than the number available. If a simulation uses the iterative solver, the Solver designation can include a level indicator appended. to an Iterative solver designation (L2 in the example above). The higher the Level number the lower the memory, you will never see L1 (this would be equivalent to direct solver. And a first order solve will only display L2 since it only has one level of order to go down for preconditioning. A second or mixed order solve may display L3 depending on the mesh quality. If the solver switches from the Iterative Solver to the Matrix solver, you see a Matrix solver warning: Switch from Iterative Solver to Direct Solver.
Information	The matrix solver information line includes, for example, Disk = 0 KBytes, matrix size 11137 , matrix bandwidth 20.3. • **Disk** – The amount of hard disk space used during the calculation of the matrix solution. If the disk usage for matrix solver is non-zero in profile, it usually indicates off-core matrix solver. If the matrix solver must solve off-core, smaller blocks of the data to be solved are created on disk, each block is then solved in physical memory, and then the matrix solution is reassembled. As a result of this additional processing, the time required to calculate a solution is higher. • **Matrix size** – The size of the matrix that was solved (the number of unknowns) • **Matrix bandwidth** – An FEM matrix is a sparse matrix. The solver only stores the non-zero entries. The matrix bandwidth is the average number of non-zeros per row. It gives an idea of the sparsity of a FEM matrix.Storage for the sparse matrix is proportional to the total number of nonzeros = #rows x bandwidth. The higher the bases order, the larger the bandwidth. • **Iterations** – For the Iterative Solver.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To export the profile data:

1. Open the **Solutions** dialog box and select the **Profile** tab.
2. Click **Export Profile**.

   This opens a file save dialog box that lets you provide a file name and location.

3. Click **Save**.

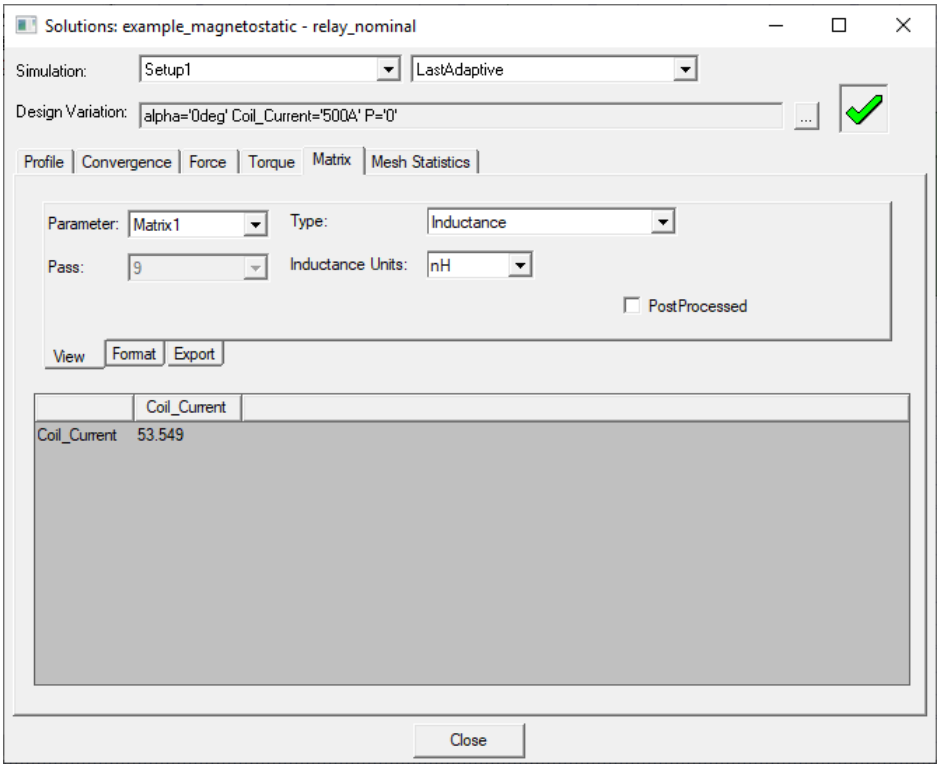
   The data is saved in a text file with a .prof extension.

Viewing Matrix Data

To view matrix parameter data:

1. In the Project Manager tree, right-click the solution setup of interest, and then click **Solutions** on the shortcut menu.

   The **Solutions** window appears. Select the **Matrix** tab. A typical example is shown below.



2. The **Design Variation** field shows the current design.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

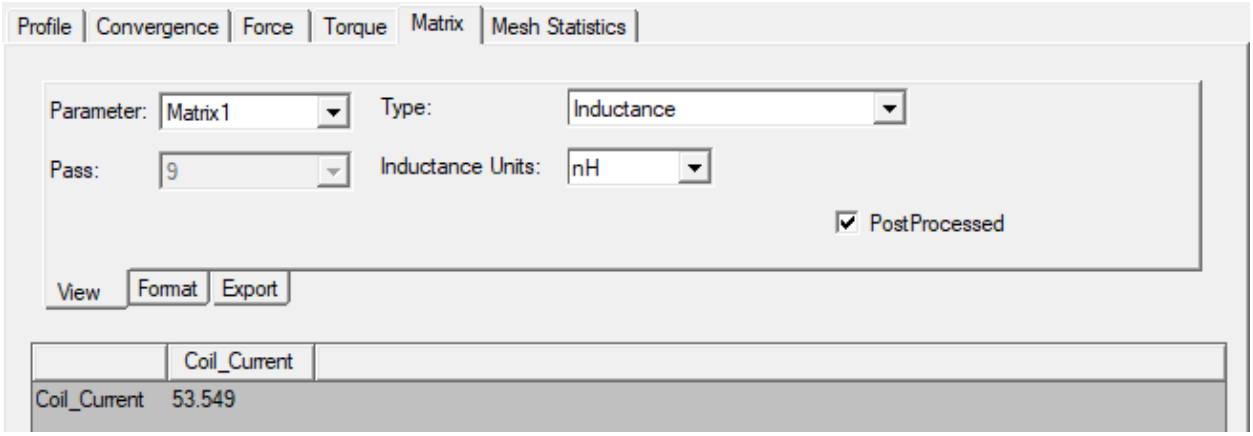
Optionally, click the **...** button, and choose a design variation solved during an optimization or parametric analysis from the **Set Design Variation** window, which lists all the solved variations in the design.

3. In the **Simulation** drop-down menus:
   - Select the solution setup from the left drop-down menu.
   - Select the solved pass data you wish to view from the right drop-down menu, either the **LastAdaptive** pass or an intermediate **AdaptivePass**. If you select **AdaptivePass** you must also select the desired intermediate pass form the **Pass** drop-down menu.
4. Select a **Parameter**.
5. Select one of the items from the **Type** drop-down menu. Items available in the **Type** list depend upon the design's solution type setting. For example:
   - **Inductance** (for magnetostatic and 3D transient A-Phi solutions)
   - **Re(Z), Im(Z)** (for Eddy Current T-Omega solutions)
   - **R, L** (for Eddy Current T-Omega and A-Phi solutions) The extracted resistance values of designs that use Litz wire windings take into consideration the stranded AC loss effects due to skin effect and proximity effects.)
   - **G,C** (for ACConduction and 3D Eddy Current A-Phi solutions)
   - **Resistance** (for 3D transient A-Phi solutions)
   - **Capacitance** (for electrostatic and 3D transient A-Phi solutions)
   - **Conductance** (for DC Conduction solutions)
   - **Flux Linkage** (for magnetostatic and eddy current solutions)
   - **Inductive Coupling Coefficient** (for magnetostatic and Eddy Current T-Omega and A-Phi solutions)
   - **Capacitive Coupling Coefficient** (for electrostatic, AC Conduction, and Eddy Current A-Phi solutions)
   - **Conductive Coupling Coefficient** (for DC Conduction solutions)

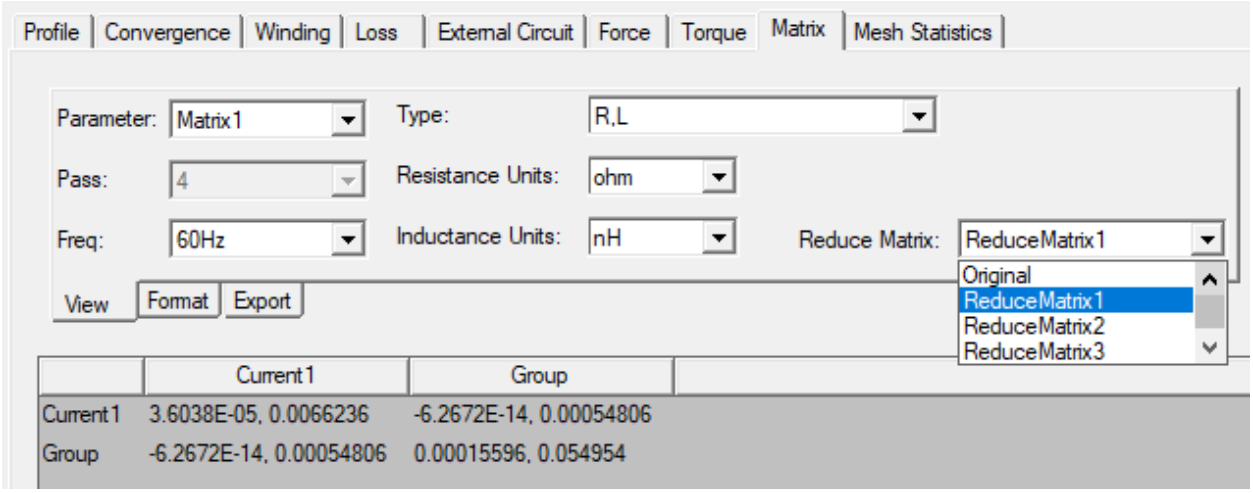
   Depending on the solution type you selected, you may have to specify the **Units** in which to display the information. The available units depend on the matrix type that is displayed.

   The bottom pane displays values for the selected type. The **Format** tab allows you to customize how values are displayed by setting the desired width, precision, and whether to use scientific notation.
6. (Optional) For Magnetostatic designs, the results of the postprocessing calculation on the matrix, including grouped sources defined on the Matrix window's **Post Processing** tab, can be seen by selecting **PostProcessed**.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



7. (Optional) For 2D and 3D Eddy Current designs, you can join (group) two or more excitations to one excitation in either a series or a parallel connection. The result of each set of join (group) operations is known as a Reduce Matrix. For Eddy Current designs that include one or more reduce matrices, select the reduce matrix of interest from the **Reduce Matrix** drop-down menu. For reduced matrix selections, only the **R, L Type** values are available for viewing. (Refer to Assigning a Reduce Matrix for information on creating reduced matrices.)



8. (Optional) To export the matrix data (as specified by the **Type** list):
   a. On the **Export** tab, click **Export Solution**.

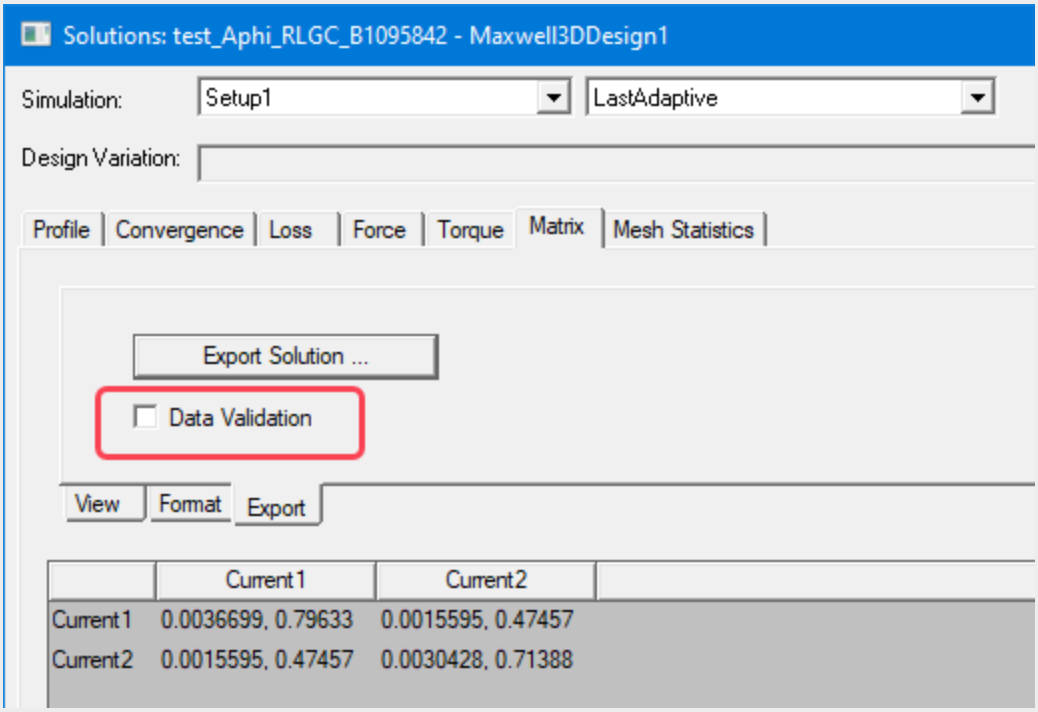
      The **Export Solution** dialog box appears.

   b. Select a location for the solution data.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. Type a filename in which to store the data in the **File name** text box.
d. Click **Save**. The solution is saved as a data table in the specified file.

Note: If you are writing out a spreadsheet with Eddy Current A-Phi\RLGC data, uncheck the **Data Validation** option on the Solutions\Matrix**Export** tab. Leaving this option checked may result in an error during export.



9. (Optional) For 2D and 3D Magnetostatic designs only, you may export a circuit based on the matrix parameter type by clicking **Export Circuit** on the **Export** tab. The **Export Circuit** button appears in the dialog box when a supported type is selected.

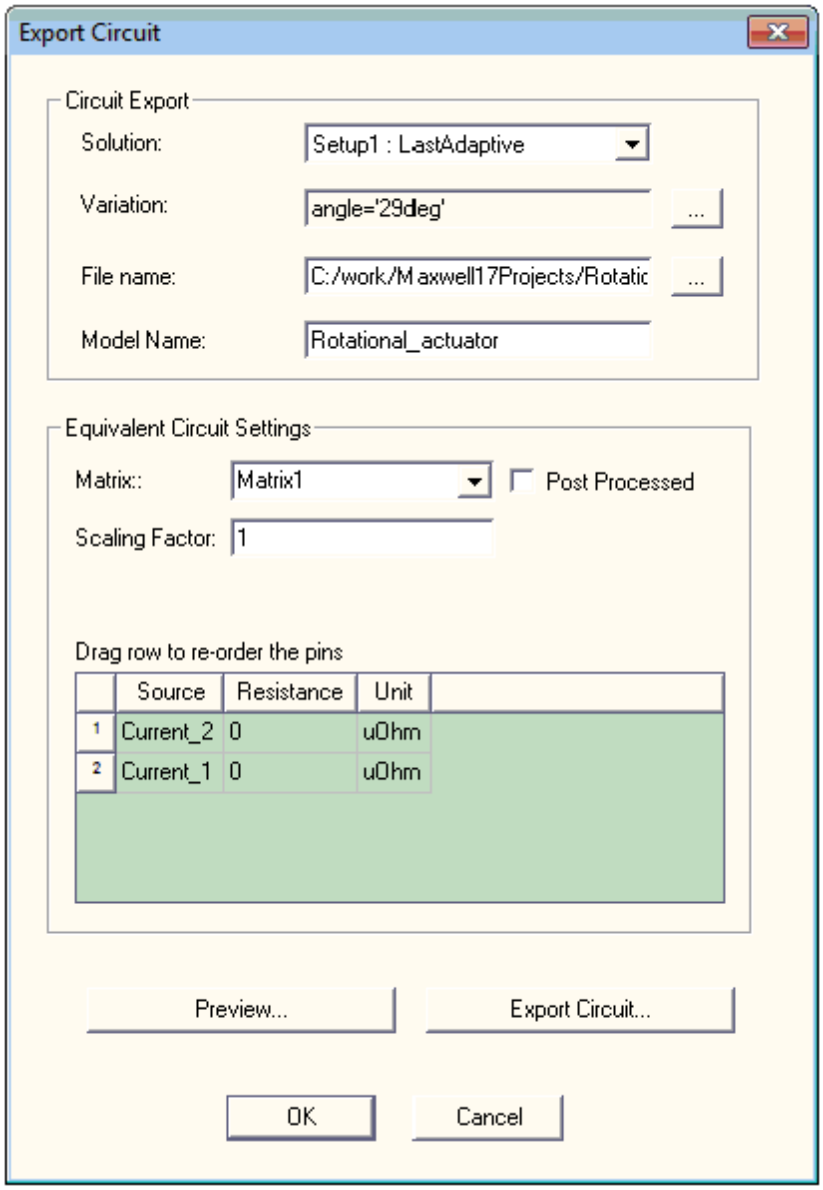
Exporting a Circuit Model

To export the circuit:

1. In the **Solutions** window, click **Export Circuit**.

   The **Export Circuit** dialog box appears.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. In the **Equivalent Circuit Settings** section, select the matrix you want to export from the **Matrix** drop-down menu.
3. (Optional) Type a scaling factor in the **Scaling Factor** text box. You may want to provide a scaling factor if you are using symmetry to analyze a portion of the model.
4. For an induction matrix, type a **Resistance** for each source listed in the table.
5. (Optional) If desired, drag table rows to re-order the circuit pins.
6. (Optional) The results of the post processing calculation (defined on the Matrix dialog's **Post Processing** tab) on the matrix can be included by selecting **PostProcessed.**
7. In the **Circuit Export** section, select a setup from the **Solution Setup** drop-down menu.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. (Optional) Click the **...** button to open the **Set Design Variation** dialog box to choose a **Variation**.
9. Type the path and file name in the **File name** text box, or click the **...** button to select the desired location for the exported circuit.
10. (Optional) To view the netlist:
    a. Click **Preview**.

       The **Circuit Model Preview** dialog box appears. You can also click **Export Circuit** from within this dialog box.

    b. Click **Close** to close the netlist.
11. To export the circuit to the specified file, click **Export Circuit**.
12. Click **OK** to close the **Export Circuit** dialog box.
13. Click **Close** to close the **Solutions** window.

Coupling Coefficient Matrix

For a matrix with entries M_{ij}, i, j = 1,..., N, the coupling coefficient for row i and column j is given by the following equation:

$$k = \frac{M_{ij}}{\sqrt{M_{ii} \times M_{jj}}}$$

This coefficient indicates how much flux in one coil is linked with the other coil.

If all the flux in one coil reaches the other coil, $|k| = 1$ (and coupling is 100%).

Inductors with $|k| > 0.5$ are tightly coupled. Inductors with $|k| > 0.5$ are loosely coupled.

The mutual inductance (M) falls between 0 and $\sqrt{M_{ii} \times M_{jj}}$ (the geometric mean of the inductances).

AC Loss Effects of Litz Wire on Impedance Matrix

The impedance matrix of polyphase windings is expressed as

$$[Z] = \begin{pmatrix} R_{11} + jX_{11} & \cdots & R_{1n} + jX_{1n} \\ \vdots & \ddots & \vdots \\ R_{1n} + jX_{1n} & \cdots & R_{nn} + jX_{nn} \end{pmatrix}$$

where n is the number of windings.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Litz wire eddy-current losses are computed in during postprocessing. When the total number of windings includes some Litz wire windings, the final AC impedance matrix, including an additional resistance matrix due to Litz wire eddy current losses, is expressed as

$$[Z'] = \begin{pmatrix} R_{11} + jX_{11} & \cdots & R_{1n} + jX_{1n} \\ \vdots & \ddots & \vdots \\ R_{1n} + jX_{1n} & \cdots & R_{nn} + jX_{nn} \end{pmatrix} + \begin{pmatrix} r_{11} & \cdots & r_{1n} \\ \vdots & \ddots & \vdots \\ r_{1n} & \cdots & r_{nn} \end{pmatrix}$$

where resistances denoted by r_{ij} are additional Litz wire eddy-current resistance components.

To compute Litz wire eddy-current resistance components, a permeability freezing algorithm is needed. After nonlinear iteration is convergent and permeabilities in all mesh components are frozen, the original impedance matrix *[Z]* is derived by injecting 1 A exciting current into each phase winding one by one. The self-impedance is obtained from the induced voltage in the excited winding, and all mutual impedances are obtained from the induced voltages in all other windings.

However, the Litz wire eddy-current resistance matrix is derived in a different way. When a winding is excited with 1 A rms current and all other windings with zero-value currents, the value of the total eddy-current loss (no matter in the excited winding, or in other zero current windings), is the value of the self-resistance. That is, if I_1 = 1 A rms current in winding 1 produces total eddy-current loss P_1, then the self-resistance of winding 1 is

$$r_{11}{I_1}^2 = r_{11} = P_1$$

Similarly, if I_2 = 1 A rms current in winding 2 produces total eddy-current loss P_2, then the self-resistance of winding 2 is

$$r_{22}{I_2}^2 = r_{22} = P_2$$

To calculate the mutual resistance between winding 1 and winding 2, 1 A currents in both winding 1 and winding 2 need to be injected. In such a case, the total eddy-current loss is

$$r_{11}{I_1}^2 + 2r_{12}I_1I_2 + r_2{I_2}^2 = r_{11} + 2r_{12} + r_{22} = P_{12}$$

where P_{12} is the total eddy-current loss in all Litz wire windings caused by 1 A currents in both winding 1 and winding 2. Therefore,

$$r_{12} = \frac{P_{12} - r_{11} - r_{12}}{2}$$

Viewing Parameter Data

To view parameter solution data such as force and torque:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the Project Manager tree, right-click the solution of interest in the **Parameters** folder, and then click **View Solution** on the shortcut menu.

   The **Solutions** window appears.

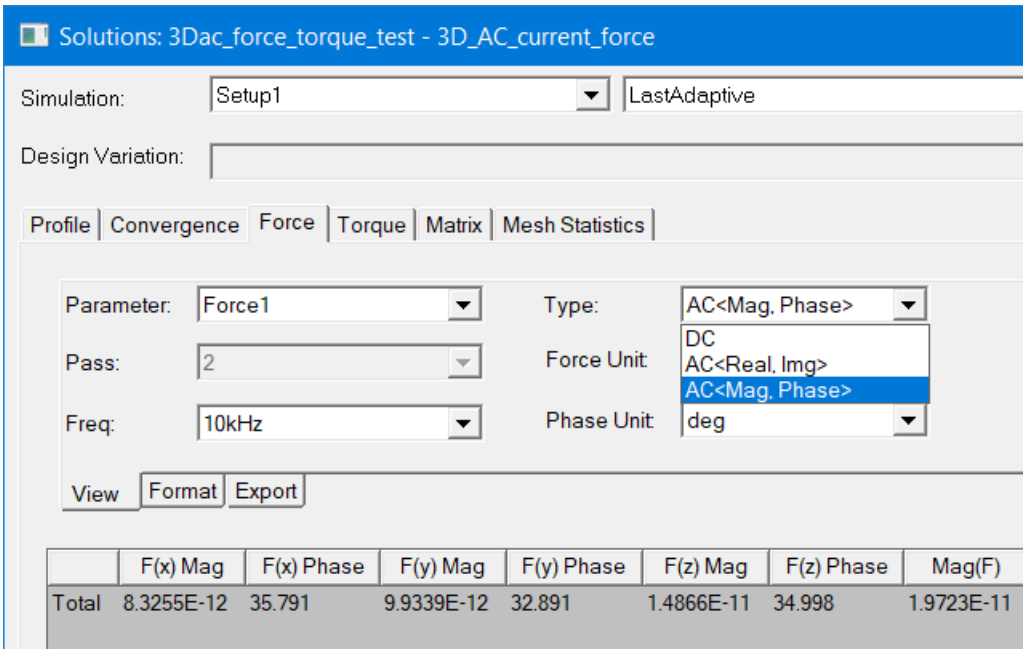
2. The **Design Variation** box shows the current design.

   Optionally, click the **[...]** button, and choose a design variation solved during an optimization or parametric analysis from the **Set Design Variation** dialog box.

3. In the **Simulation** drop-down menus:
   - Select the solution setup from the first drop-down menu.
   - Select the solved pass data you wish to view from the second drop-down menu, either the last adaptive pass or one of the intermediate passes.
4. On the desired parameter tab, such as **Force** or **Torque**, select a **Parameter** and optionally an adaptive **Pass** to view.

   Depending on the solution type you selected, you may have to specify

   - **Type** – In the screenshot the follows, the simulation was a 3D AC Conduction analysis, so the user has three types of simulation results to select from.
   - **Force Units** – Specifies the units in which to display the information. The available units depend on the matrix type being displayed.
   - **Phase Unit** – This setting is available if the **Type** of result includes phase data.



5. Optionally, to export the parameter solution data:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. Click **Export Solution** to open the **Export Solution** dialog box appears.
b. Select a location for the solution data.
c. Type a filename in which to store the data in the **File name** text box.
d. Click **Save**.

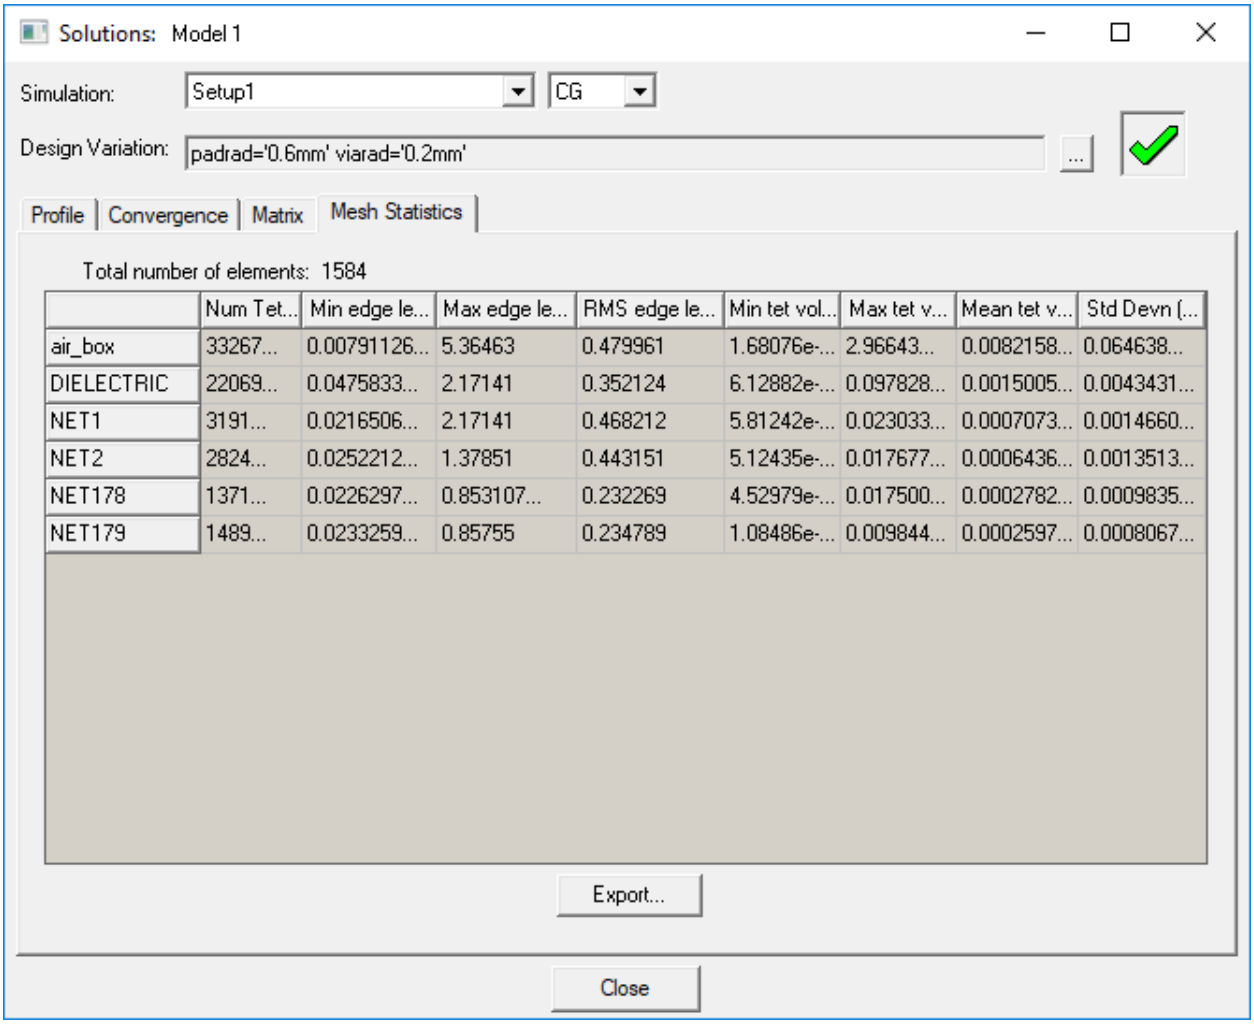
6. Click **Close** to close the **Solutions** window.

Viewing Mesh Statistics

To view an adaptive solution's mesh information, either during or after the solution process:

1. In the Project Tree, right-click the solution setup of interest, and then click **Mesh Statistics**. Alternately, click the **Solution Data** icon on **Results** tab of the ribbon.

   The **Solutions** window appears with the **Mesh Statistics** tab displayed.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The table lists design elements and for each includes: Num Tets, Min edge length, Max edge length, RMS edge length, min tet vol., max tet vol., mean tet vol. and standard deviation (min elem area, max elem area, mean elem area and standard deviation for 2D designs).

If mesh repairs have been performed, two additional columns appear in the table: **Recovered %** and **Repaired %**. These columns indicate the fraction of an object that was successfully recovered, and the fraction that needed some repair.

To sort mesh statistics by column from low to high values or vice-versa, click a column header. This displays a shadowed triangle pointing down to indicate a list ordered from highest to lowest; and a triangle pointing up to indicate a list ordered from lowest to highest. Clicking again inverts the order.

Click on a blank cell above the object list to invert the order of objects. In this case, the cell does not display a directional triangle.

Viewing Winding Results for Eddy Current T-Omega Solutions

To view winding results for Eddy Current T-Omega solutions:

1. In the Project Manager tree, right-click the **Results** folder, and then click **Solution Data** on the shortcut menu.

   The **Solutions** window appears.

2. The **Design Variation** box shows the current design. Optionally, click the **[...]** button, and choose a design variation solved during an optimization or parametric analysis from the **Set Design Variation** dialog box.
3. In the **Simulation** drop-down menus:
   - Select the solution setup from the left drop-down menu.
   - Select the solved pass data you wish to view from the right drop-down menu – either the **LastAdaptive** pass, or an intermediate **AdaptivePass**. If LastAdaptive is selected, the **Freq** drop-down menu is enabled for you to choose frequency. If AdaptivePass is selected, the **Pass** drop-down menu is enabled for you to choose the desired intermediate pass.
4. If the design includes windings, the **Winding** tab displays the following columns: **Flux Linkage[Wb]**, **Induced Voltage[V]**, **Input Current[A]**, **Input Voltage[V]**, and **Current [A]**. Results listed in these columns are complex quantities. The **Format** tab allows you to customize how values are displayed by setting the desired width, precision, and whether to use scientific notation.
   - For Current type windings: Flux Linkage, Induced Voltage, and Input Current results are shown. The other quantities are shown as N/A (not applicable).

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For Voltage type windings: Flux Linkage, Induced Voltage, Input Current, and Current results are shown. The other quantities are shown as N/A (not applicable).
- For External type windings: Flux Linkage, Induced Voltage, and Current results are shown. The other quantities are shown as N/A (not applicable).

5. Click **Close** to close the **Solutions** window.

Viewing End Connection Results (2D Eddy Current)

To view end connection results for Maxwell 2D Eddy current solutions:

1. In the Project Manager tree, right-click the **Results** folder, and then click **Solution Data** on the shortcut menu.

   The **Solutions** window appears.

2. The **Design Variation** box shows the current design. Optionally, click the **[...]** button, and choose a design variation solved during an optimization or parametric analysis from the **Set Design Variation** dialog box.
3. In the **Simulation** drop-down menus:
   - Select the solution setup from the left drop-down menu.
   - Select the solved pass data you wish to view from the right drop-down menu – either the **LastAdaptive** pass, or an intermediate **AdaptivePass**. If **LastAdaptive** is selected, the **Freq** drop-down menu is enabled for you to choose frequency. If **AdaptivePass** is selected, the **Pass** drop-down menu is enabled for you to choose the desired intermediate pass.
4. If the design includes end connections, the **End Connection** tab displays columns for: **Induced Voltage[V]**, and **Current[A]**. Results listed in these columns are complex quantities. The **Format** tab allows you to customize how values are displayed by setting the desired width, precision, and whether to use scientific notation.
5. Click **Close** to close the **Solutions** window.

Viewing Loss Results (Eddy Current)

To view loss results for Eddy current solutions:

1. In the Project Manager tree, right-click the **Results** folder, and then click **Solution Data** on the shortcut menu.

   The **Solutions** window appears.

2. The **Design Variation** box shows the current design. Optionally, click the **[...]** button, and choose a design variation solved during an optimization or parametric analysis from the **Set Design Variation** dialog box.
3. In the **Simulation** drop-down menus:

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Select the solution setup from the left drop-down menu.
- Select the solved pass data you wish to view from the right drop-down menu – either the **LastAdaptive** pass, or an intermediate **AdaptivePass**. If LastAdaptive is selected, the **Freq** drop-down menu is enabled for you to choose frequency. If **AdaptivePass** is selected, the **Pass** drop-down menu is enabled for you to choose the desired intermediate pass.

4. Review the loss results from the **Loss** tab.

   For Eddy Current T-Omega results, the **Loss** tab displays the following columns: **Core Loss[W]**, **Solid Loss[W]**, **Stranded Loss[W]**, **Stranded Loss R[W]**and **Stranded Loss AC[W]**.

   For Eddy Current A-Phi results, the **Loss** tab displays **Core Loss** and **Solid Loss**.

   Results listed in these columns are real quantities. The **Format** tab allows you to customize how values are displayed by setting the desired width, precision, and whether to use scientific notation.

5. Click **Close** to close the **Solutions** window.

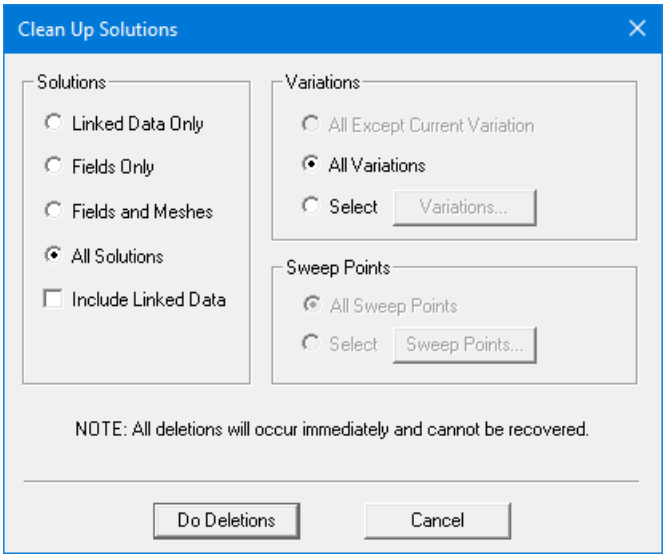
Deleting Solution Data

You can use **Clean Up Solutions** to selectively make deletions, or remove all solutions from the results.

To use **Clean Up Solutions**:

1. Click **Maxwell** > **Results** > **Clean Up Solutions**.

   The **Clean Up Solutions** dialog box appears.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Under **Solutions**, select whether you want to delete only fields data, only fields and mesh data, only linked data, or all solution data. Deleting all solution data erases all mesh, matrix, and fields data for all adaptive passes and frequency sweeps for the selected **Variations**.

   By option, you can **Include Linked Data** in the deletions.

   Linked data can be mesh, field or some other post-processing data that the source design generated. The target design for the link caches these data internally to minimize the need to activate the source design. If you don't need to resolve the source design, for example, if it has a lengthy solution time, you should not check **Include Linked Data**. If you need to make some change in the source design that would affect the solution, and you want to ensure that the next solve result includes those changes, you should check Include **Linked Data**.

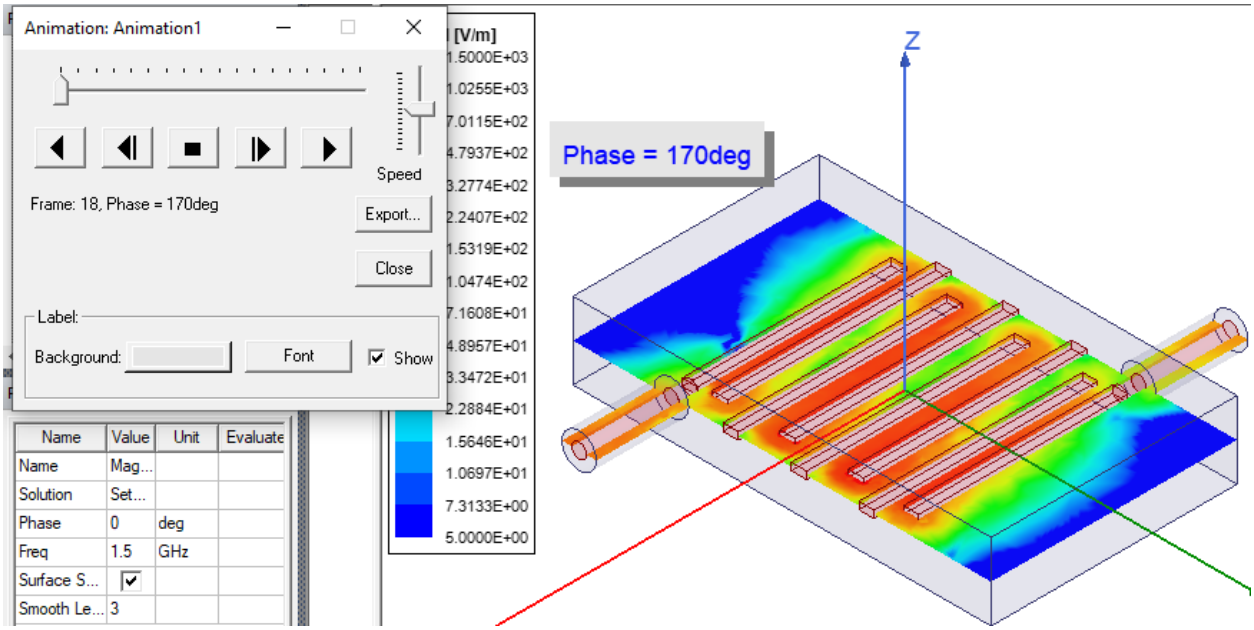
3. Under **Variations**, select which solution data you want to delete:
   - Select **All Except Current Variation** to delete all solution data that does not correspond to the current project and design variable values for the current design.
   - Select **All Variations** to delete all solution data for the current design.
   - Select **Select** to specify the variations you wish to delete. Click **Variations** to select the variations for deletion.
4. Click **Do Deletions**.

   The solution data you selected are deleted. Any post processing reports or field overlays you created that included data you deleted will be marked with an X in the project tree. They will be invalid until new solution data are generated.

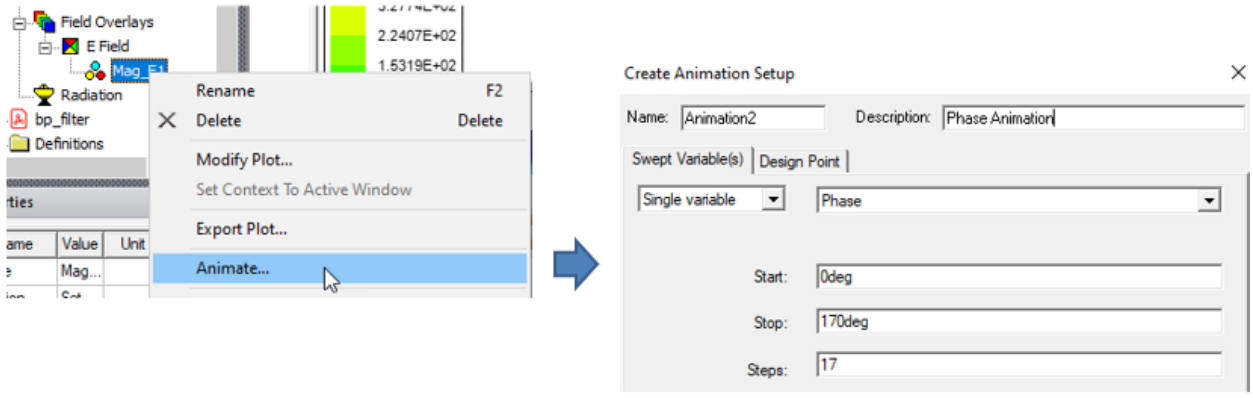
Creating Animations

An animated plot is a series of frames that displays a field, frequency, parametric value, mesh, virtual ray trace or geometry at varying values.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To create an animated plot, you specify the values of the plot that you want to include, just as an animator takes snapshots of individual drawings that make up a cartoon. Each value is a frame in the animation. You specify how many frames to include in the animation.



The following sections describe how to create different kinds of animations.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

Each animation frame requires memory for storage which depends upon the mesh size and type of plot. Memory usage may become very large during plot animations. To reduce memory usage, specify the minimum number of frames possible. See General Options for more information.

Note:

Graphics System requirements for Optimal Performance

In order to obtain optimal performance improvements on fields overlay plot, a workstation-class 3D-capable graphics card with at least 512 MB of memory that supports OpenGL version 2.0 or higher is needed.

On Windows, the default OpenGL version support is v1.1, so you might need to update graphics driver to the latest version;

If you access the application through Windows Remote Desktop which only supports Generic GDI (functionally equivalent to OpenGL v1.0), the performance improvement will also not be available;

To view OpenGL version/extensions supported by your card, the OpenGL Extension Viewer tool is accessible via softpedia.com.

If animation is slow, especially for complex models, for some older graphics cards, you can improve performance by accessing **NVIDIA Control Panel**> **3D Settings**> **Manage 3D Settings – Global Settings** tab and choosing the **Workstation App – Dynamic Streaming** option from the **Global Presets** drop-down menu.

You can export the animation to animated Graphics Interchange Format (GIF), to Audio Video Interleave (AVI) format, or to WebM (.webm) format.

Creating Geometry Animations

You can create geometry animations to evaluate the effect of varying geometry variables on the model. You can also create more complex animations by creating time variables associated with object locations. This section describes the general procedure for geometry animation, and shows a geometry animation with a field overlay, and a second animation for an HFSS Antenna Example project that includes multiple objects moving with respect to a time variable.

Prerequisites

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You must define at least one variable associated with the geometry before you create a geometry animation.

If you want to overlay a Field Solution on a geometry animation you must have solved fields for an Optimetrics setup using the same variable.

Procedure:

Following is the general procedure for creating an animation that varies a part of the model geometry.

1. Right-click in the *Modeler* window, and click to **View** > **Animate...** or

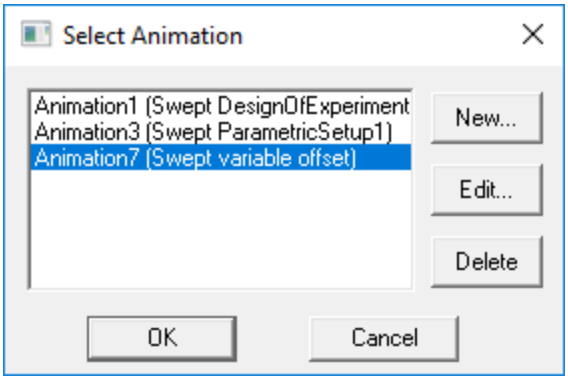
   Select the **View** tab of the ribbon, and click the **Animate** icon.

   If multiple geometries can be varied in the design, the *Select Drawing* dialog box appears; proceed to step 2. If only one geometry is variable, proceed to step 3.

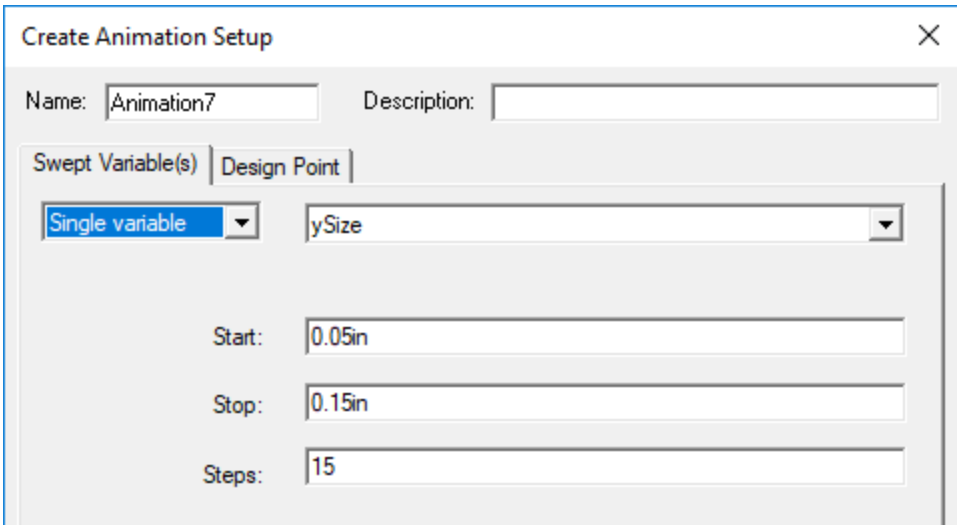
2. In the *Select Drawing* dialog box, select the object that you want to animate.

   If previous animations have been created for this project, the *Select Animation* dialog box will appear. Selecting an existing animation from that list starts it when you click **OK**. Click **Edit...** to open the *Modify Animation Setup* dialog box. You may choose an animation setup from the list if one is associated with the geometry variable of interest, and the animation will start. If no existing animation setup is acceptable, select **New** and continue at Step 3 below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

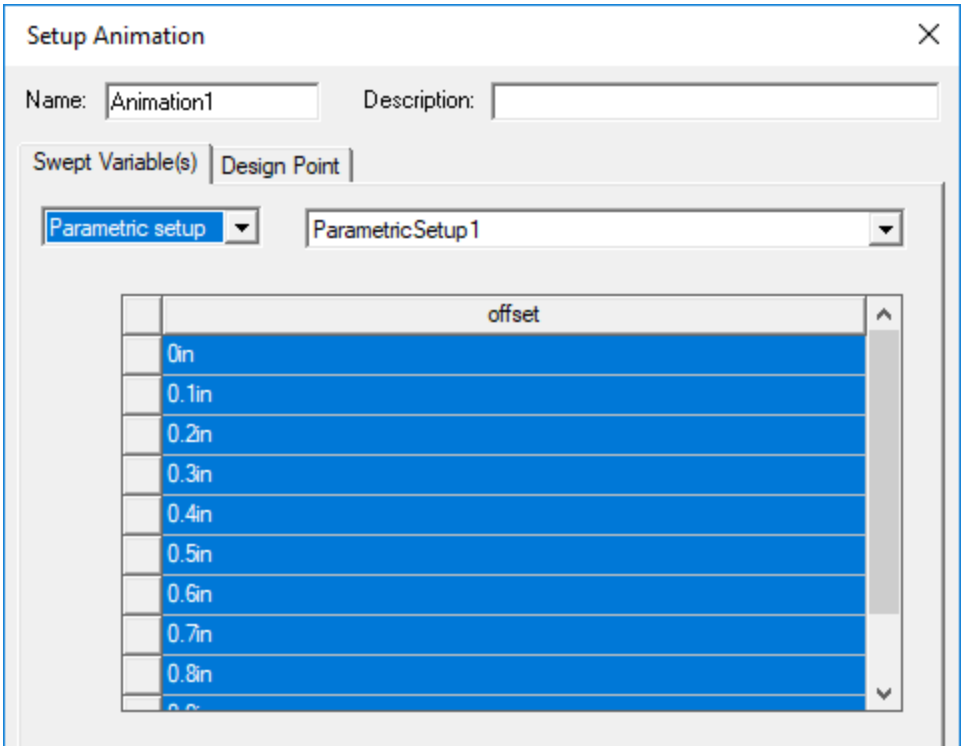


The *Create Animation Setup* dialog box appears:



3. For single variable:
    a. Select the geometry variable that you want to animate from the **Swept Variable** list.
    b. Specify the Start, Stop, and Steps values to include in the animation.
4. If your have created one or more Parametric Sweeps for one or more geometric variable, you can select, **Parametric setup**, the setup to use, and the variable values to animate.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. If you have created a **Design of Experiments** setup, you can select to define an animation based on that setup and values.
6. If the design has multiple project or intrinsic variables, you use the **Design Point** tab to set the values of the non-animated variables.
7. Click **OK**.

   The animation begins in the view window. It will display one frame for each variable value.

Creating Field Plot Animations

To animate an existing field plot:

1. Right-click on the plot name in the Project Manager tree, and then select **Animate**. The **Setup Animation** dialog box appears.

   > **Note:** If previous animations have been created for this project, the **Select Animation** dialog will appear. You may choose an animation setup from the list if one is associated with the geometry variable of interest and the animation will start. Otherwise select **New** and continue at Step 2 below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Type a name for the animation in the **Name** box, or accept the default name.
3. Optionally, type a description of the animation in the **Description** box.
4. Under the **Swept Variable** tab, the **Swept Variable** list includes all of the defined project and design variables. Select the variable that you want to animate from the **Swept Variable** drop-down menu.
5. The **Select Values** table lists all solved values for the variable selected in **Swept Variable**. Select the values to include in the animation. By default, all solved values will be included.
6. *(For Electric Transient Solver plots only)*
    a. Type the starting value of the variable in the **Start** box.
    b. Type the stopping value of the variable in the **Stop** box.
    c. Type the number of **steps** to include in the animation in the **Steps** box.
    For example, if the **Start** value is **0.15 in**, the **Stop** value is **0.45 in**, and the step size is **15**, the animation displays the geometry at 15 values between 0.15 inches and 0.45 inches. The animation also includes the start value, which is the first frame displayed, resulting in a total of 16 frames in the animation.
7. If the design has multiple project or intrinsic variables, click the **Design Point** tab to set the values of the non-animated variables.
    a. Deselect the **Use defaults** check box.
    b. In the table, select the row corresponding to the variable setting of interest.
    c. If intrinsic variables are available, select the value of interest in the **Intrinsic variables** section of the dialog.
8. Click **OK**.

The animation begins in the view window, displaying one frame for each variable value.

The play panel appears in the upper-left corner of the desktop, enabling you to stop, restart, and control the speed and sequence of the frames.

Creating Parametric Animations

Parametric animations can be based on parametric sweeps. Following is the general procedure for creating an animation of a plot based a parametric sweep.

Prerequisites

- For animation of a field plot/overlay plot over a geometric variable, you must define and solve at least one optimetric sweep with same variable values and Save Fields selected before you can create a parametric animation of a field solution. See Creating Geometry Animations.
- For animation of geometry and VRT plots, solving parametric setup is not required.
- Animations can be based on time variables and objects whose location is linked to the time variable. See the animated example below.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Procedure:

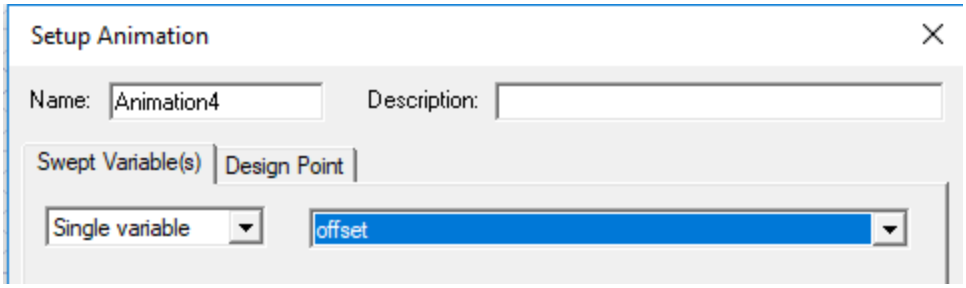
1. Right-click in the **Modeler** window, and click **View**> **Animate...**, or select the **View** tab of the ribbon, and click the **Animate** icon.

   If multiple geometries can be varied in the design, the *Select Drawing* dialog box appears; proceed to step 2. If only one geometry is variable, proceed to step 3.

2. In the *Select Drawing* dialog box:
   a. Select the geometry variable to vary in the animation.
   b. Select the object you want to animate.

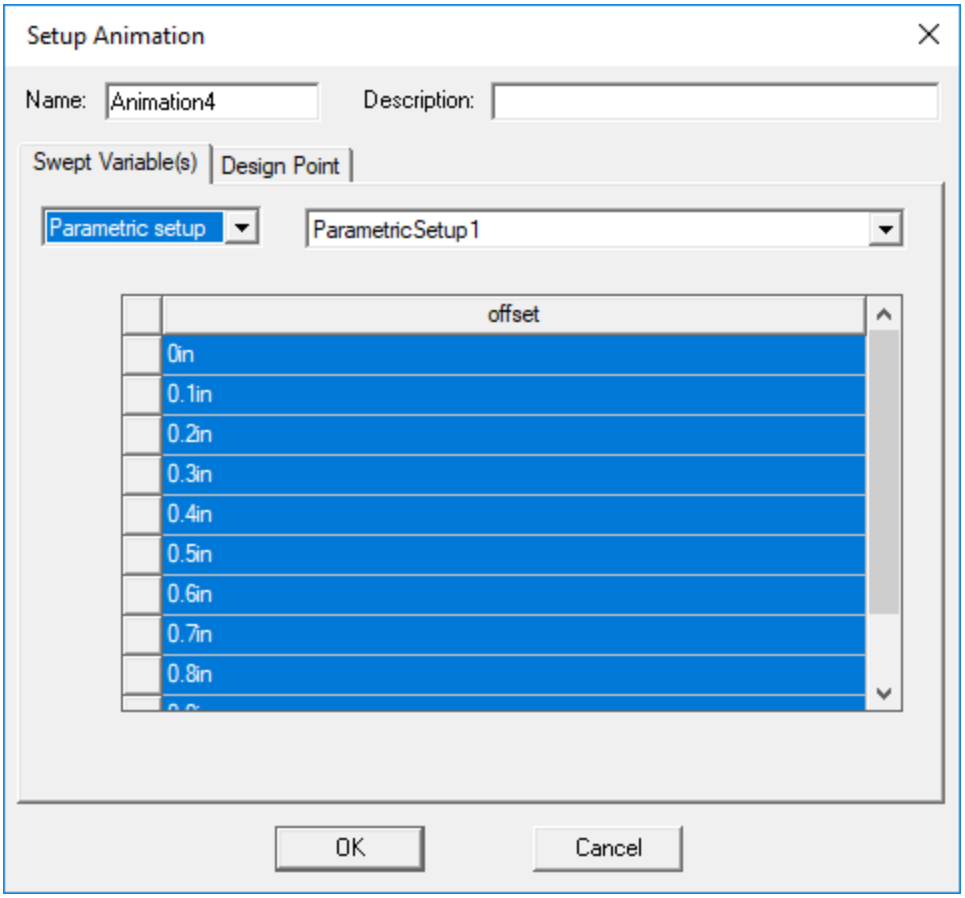
> **Note:**
>
> If previous animations have been created for this project, the *Select Animation* dialog box will appear. You may choose an animation setup from the list if one is associated with the geometry variable of interest, and the animation will start. If no existing animation setup is acceptable, select **New** and continue at Step 3 below.

   The *Setup Animation* dialog box appears.



3. If your have created one or more Parametric Sweeps for one or more geometric variables, you can select **Parametric setup**, the setup to use, and the variable values to animate.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

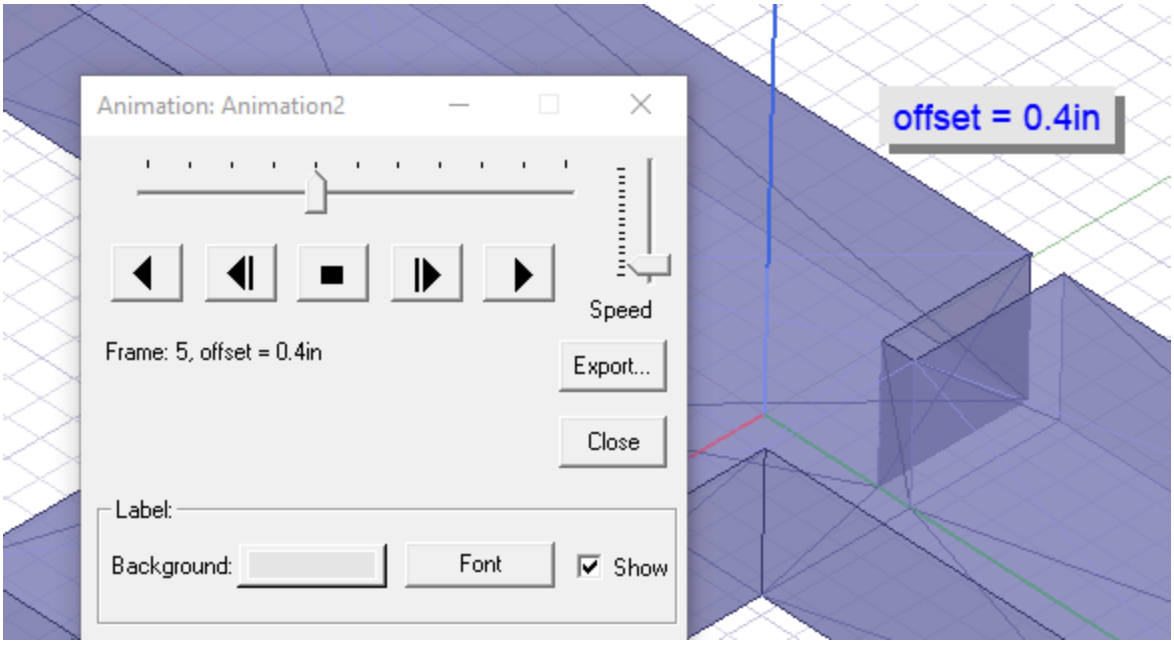


4. Click **OK**.

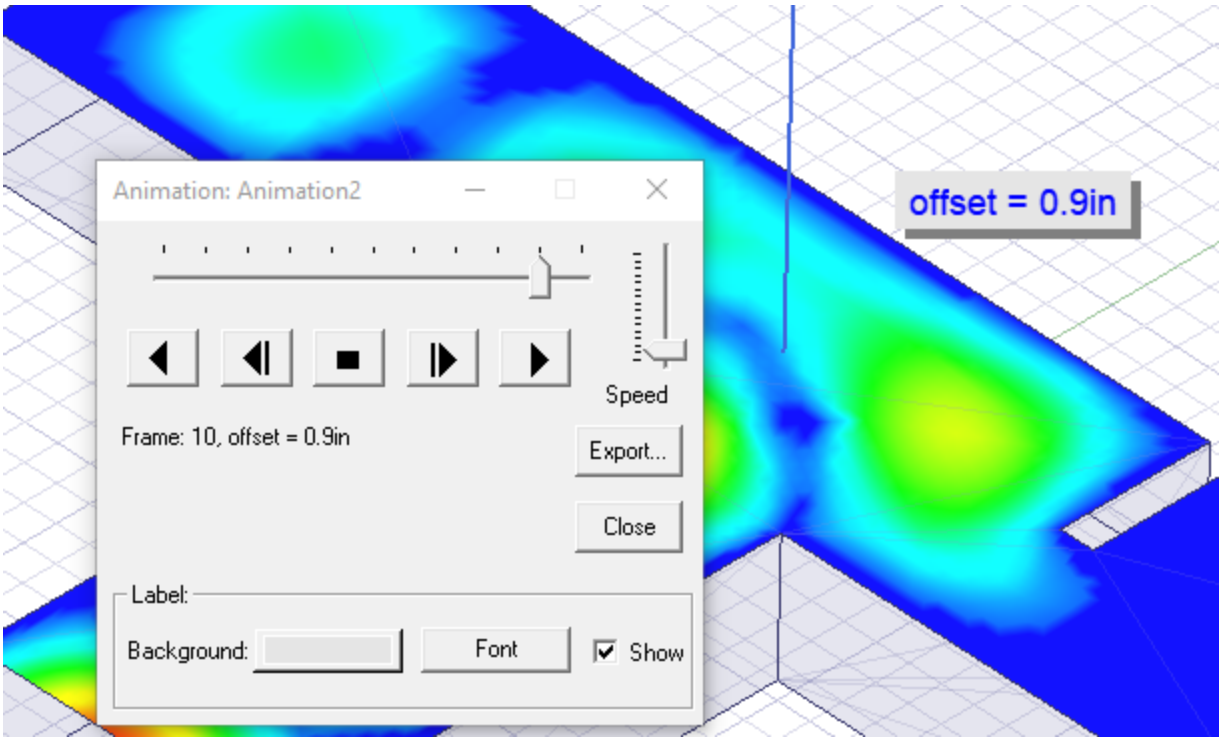
   The animation begins in the view window. It will display one frame for each variable value.

   The **Animation** control panel lets you to stop, restart, and control the speed and sequence of the frames.

Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



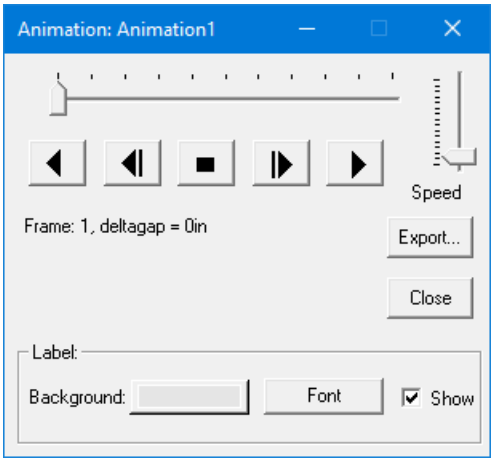
While a parametric animation is running, you can also turn on other field plots.



Ansys Electromagnetics Suite 2025 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Controlling the Animation's Display

When an animation is displayed in the view window, the **Animation** window (also called the *play panel*) appears in the upper-left corner of the desktop. It has buttons that enable you to control the speed and sequence of the frames, start and stop the animation, and export the animation. Click an area of the window image below to learn its function.



Animation slider	Each dot on the slider represents a frame in the animation. Drag the slider to the right to display the next frame in the animated plot. Drag the slider to the left to display the previous frame in the animation.
	Plays the plot's animation sequence backwards.
	Steps backward through the animated plot one frame at a time.
	Stops the animation.
	Steps forward through the animated plot one frame at a time.
	Plays the plot's animation sequence forwards.
	Drag the **Speed** slider to the top to increase the speed of the animation. Drag the **Speed** slider to the bottom to decrease its speed.
Frame information	The current frame and phase at which the plot is being displayed is listed below the control buttons.
