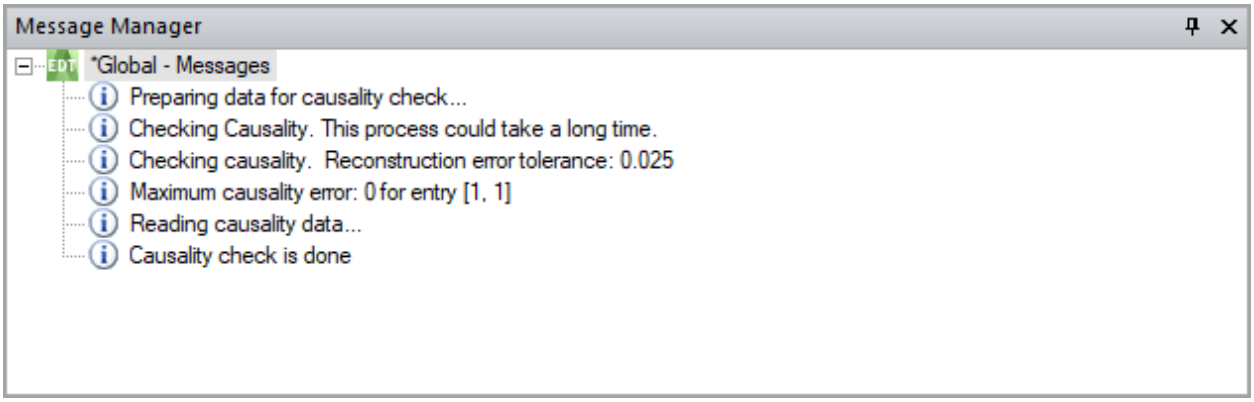
2. Enter a **Causality tolerance** and click **OK** to start the causality check. Depending on the size of the S-parameter data, the causality check may take several minutes to complete. The check's status displays in the Message Manager.



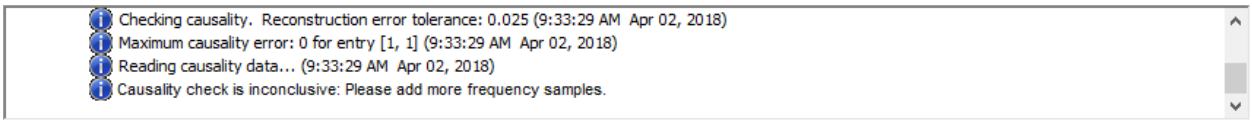
When the check completes, the Message Manager updates to display a summary of results.

Reconstruction Error Tolerance – Causality of a frequency response is determined by calculating the generalized Hilbert transform of the data at all frequencies. A causal frequency response is equal to its generalized Hilbert transform. The reconstruction error is the difference between the tabulated data and its transform at a given frequency. The message shows the maximum reconstruction error tolerance for a causal frequency response. The default tolerance of 0.01 is equal to the state-space fitting tolerance.

Maximum Causality Error – The maximum causality error for all port pairs and all frequencies, along with the matrix indices (port numbers) where the maximum noncausality occurs. A noncausal response is one where all matrix entries can be conclusively analyzed, and at least one entry exceeds the causality tolerance. The maximum reconstruction appears first, followed by port numbers in brackets (e.g., [port number, port number]). When all results are conclusive but no matrix reconstruction error exceeds the tolerance, the maximum causality error is reported as zero, and no matrix entry is listed.

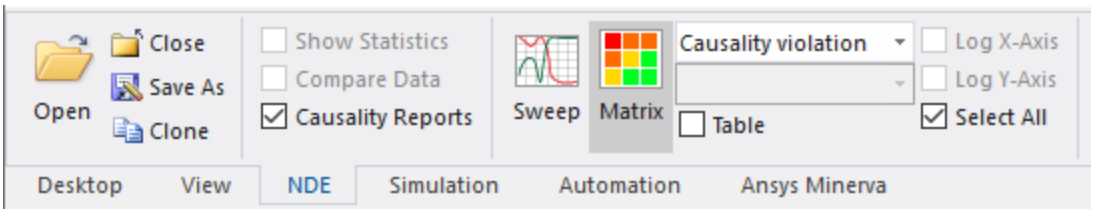
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If the data does not contain enough frequency points to determine whether the data is or is not causal, the Messages Pane will note an inconclusive result. Network Data Explorer will also report the data set as inconclusive if any cells are inconclusive, even if other entries exhibit causality violations.



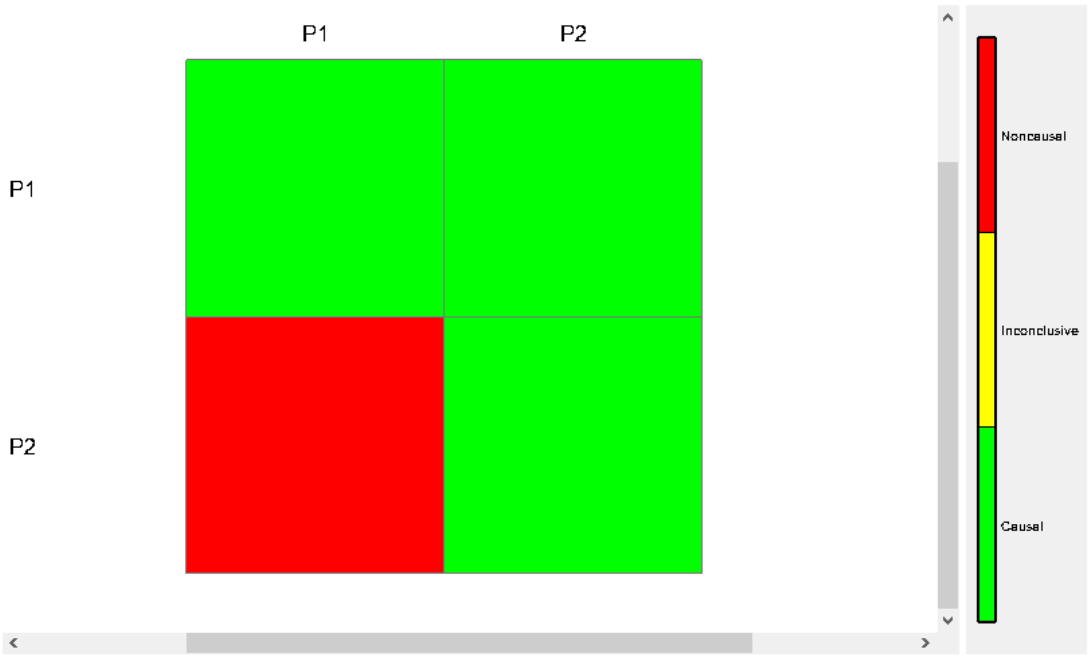
To see the plotted results of the causality check:

1. On the **NDE** ribbon, click **Causality Reports**.
2. Either click the **Matrix** icon or select **Causality violation** in the **Parameter** type drop-down menu.



A rectangular plot displays, with dimension N x N and color-coding to indicate the causality status of each port pairing.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In this plot, the cells go from (Port 1, Port 1) at the upper-left area to (Port N, Port N) at the lower-right corner. The result shows the causality over all frequencies in the data. In this example, the matrix is asymmetric, so that S12 is noncausal, while S11, S21, and S22 are causal.

To see the details for each frequency, click the **Table** check button on the **NDE** ribbon.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

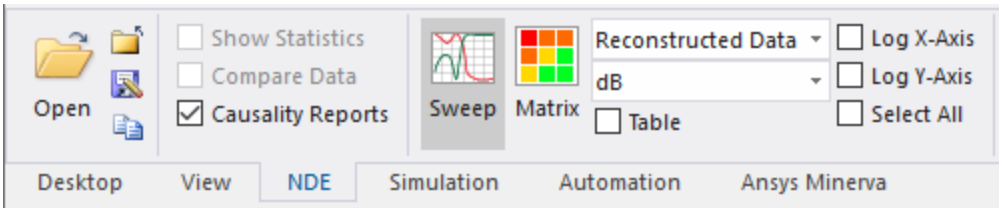
	Port2	0.06069, 0.00000	0.00152, 0.00000	0.00101, 0.00000	0.00021, 0.00000

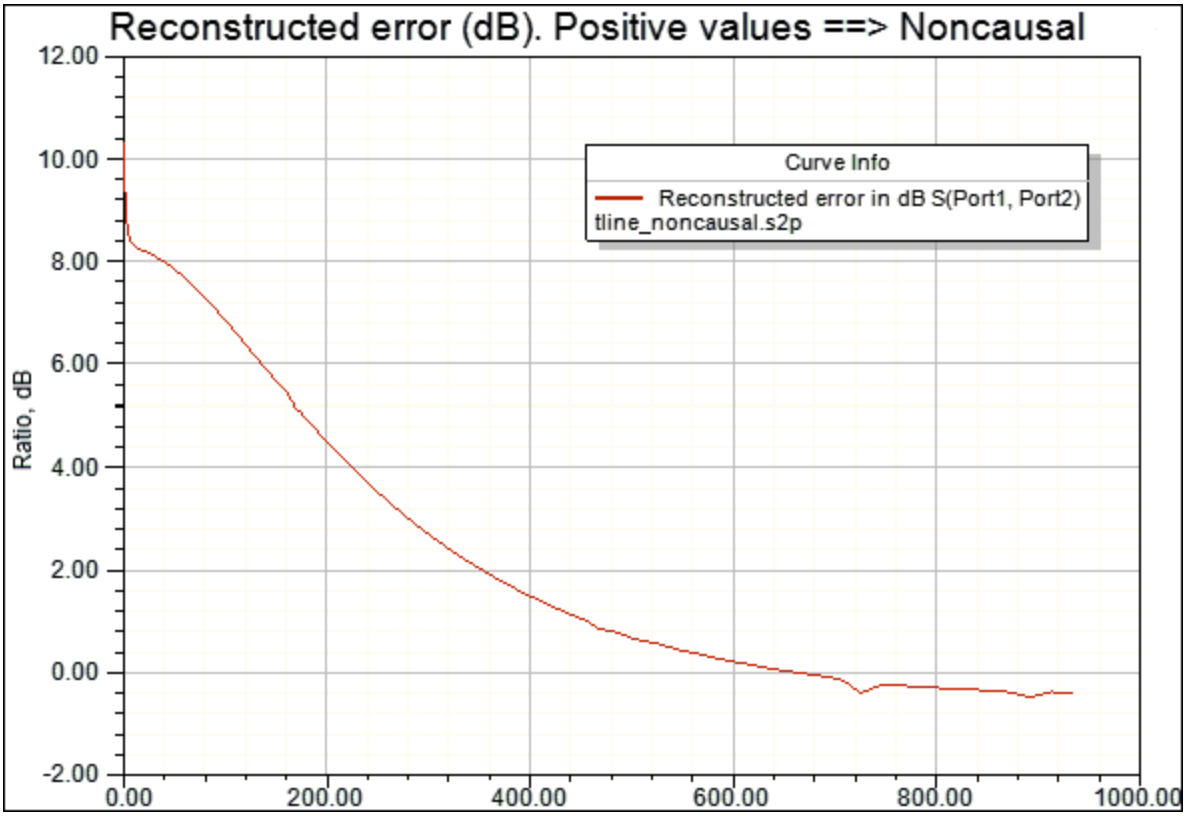
To plot the reconstructed frequency response generated by the causality checker:

1. On the **NDE** ribbon, click **Causality Reports**.
2. Either click the **Sweep** icon or select **Reconstructed Data** in the **Parameter** type drop-down menu.
3. In the **Format** drop-down menu, select the desired format. **dB** is selected by default.



The plot appears, showing the reconstruction error at each frequency divided by the tolerance.

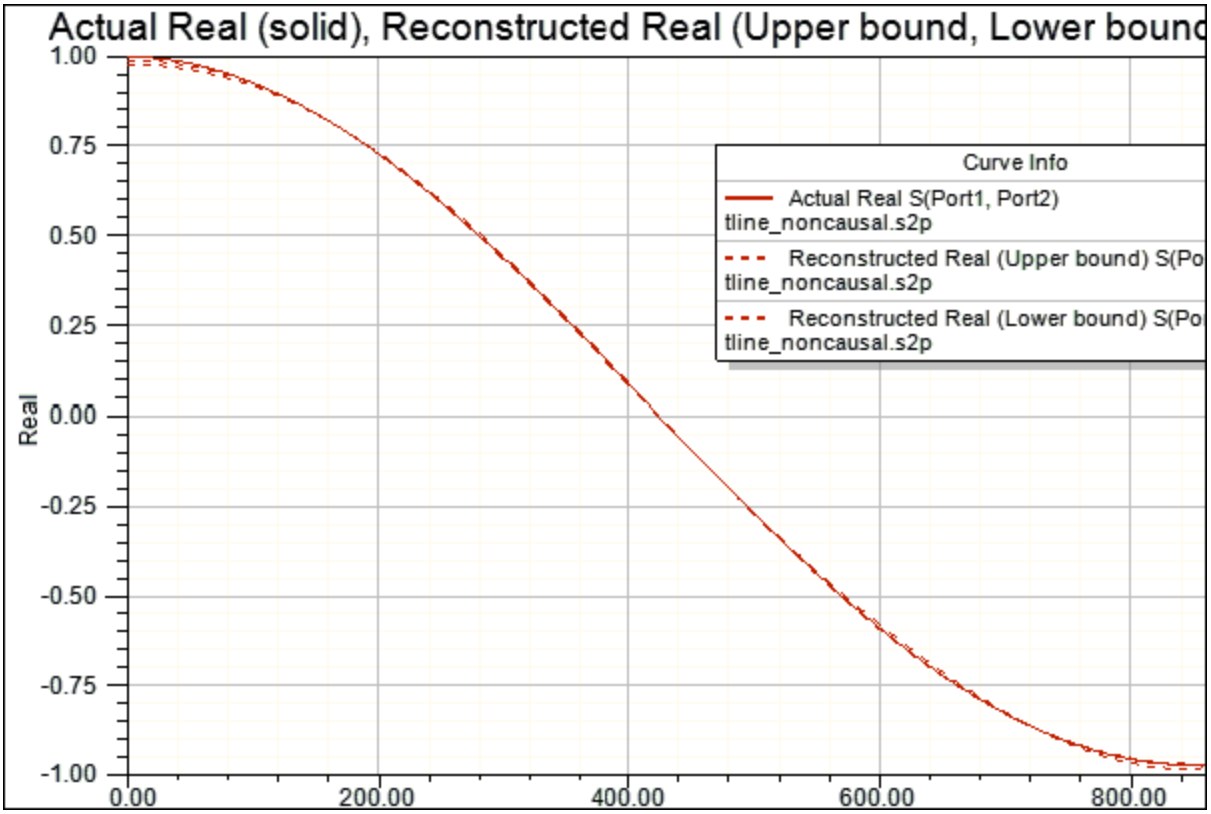
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The reconstruction error ratio for parameter S12 is positive for frequencies less than about 680MHz, indicating a broad range of noncausal behavior.

4. To compare the real part of the reconstructed data to the real part of the actual data, set the **Format** to **Real**.

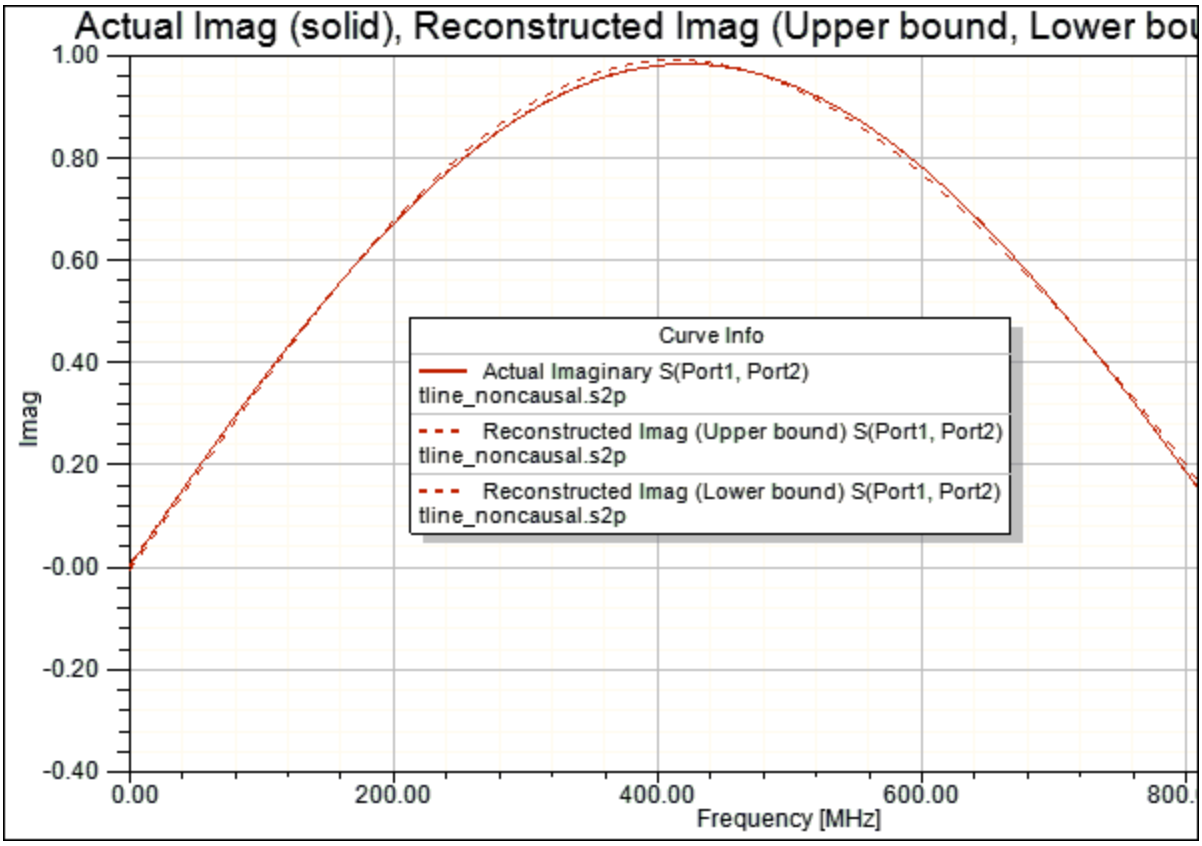
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For a causal frequency response, the actual data (solid line) will be within the upper and lower bounds of the reconstruction (dotted lines) at all frequencies.

5. To compare the imaginary part of the reconstructed data to the imaginary part of the actual data, set the **Format** to **Imaginary**.

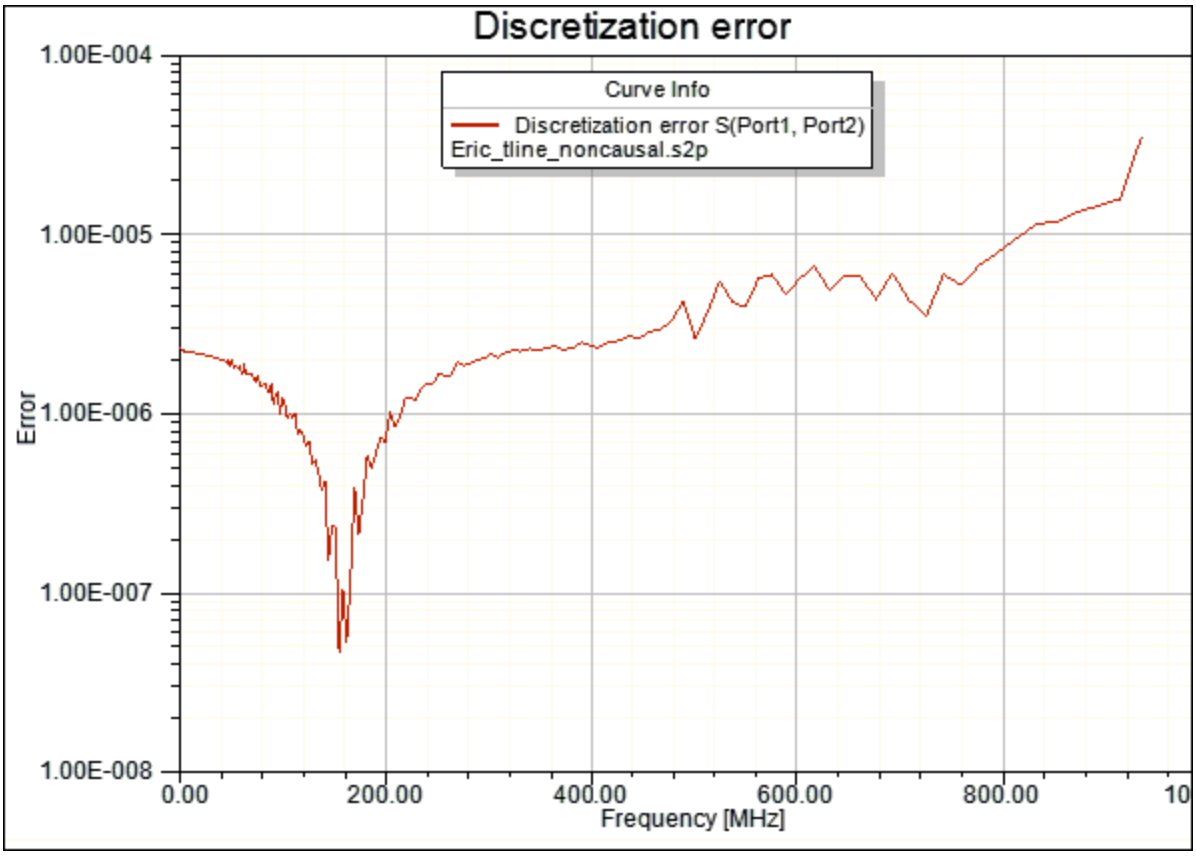
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For a causal frequency response, the actual data (solid line) will be within the upper and lower bounds of the reconstruction (dotted lines) at all frequencies.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. To view the frequency-dependent discretization error, set the **Format** to **Discretization**.



The discretization error is the error that is due to the fact that the data are available only at discrete frequencies rather than for a continuous spectrum. A discretization error near or greater than the causality tolerance renders the causality check inconclusive. Data at more frequencies could reduce the discretization error and render the analysis conclusive. This set of data exhibits low discretization errors (<<0.01) at all frequencies, and the causality check is conclusive (conclusively noncausal in this example).

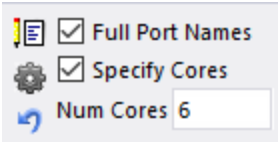
Multithreading

By default, multithreading (execution on multiple cores) is enabled for Causality Checking and Macro Model export. Multithreading saves significant time in the Causality Check calculation, and improves the time for other state-space fitting operations. See Technical Notes.

The **Cores** field in the Network Data Explorer Control Pane defaults to half the number of cores detected on your computer.

For best performance, disable hyper-threading on your computer. When hyper-threading is enabled, the number of cores includes the physical cores and an equal number of logical cores. With hyper-threading disabled, the display shows only half the number of physical cores.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To disable multithreading, uncheck the check box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

21 - Nexxim Design Examples

Nexxim is a simulator for high-speed, high-density circuit designs. Nexxim provides analyses in the time and frequency domains for all levels of projects; on the characterizing of individual transistor models to the analysis of large-scale integrated devices and communication channels. The following topics provide examples of circuit analysis using Nexxim.

This topic assumes that you are already familiar with **Electronics Desktop** and Nexxim basics discussed in the online Getting Started Guides. Work through the sequence of design topics described in this topic to learn to:

- Load schematic example designs into **Electronics Desktop** (**Electronics Desktop**) for analysis using Nexxim.
- Set up and run the applicable analyses.
- Display simulation results using the **Electronics Desktop** reporting functions.

The examples are grouped by focus:

- Nexxim RF
- Nexxim SI

Nexxim RF

Nexxim RF focuses on radio-frequency designs and provides analyses in the time and frequency domains for all levels of RF projects, from individual component models to large-scale transmitter/receiver systems. The following examples demonstrate Nexxim analyses with RF issues:

Transient Analysis with Sweeps

Transient Analysis Method Option

Harmonic Balance Analysis Example

Oscillator and Phase Noise Analyses

TV Noise and PXF Analyses

Loadpull Analysis Example

Envelope Analysis Example

Time Domain Reflectometer Example

Nonlinear Loadpull Amplifier Example

X-Parameter Example

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Nexsys Timestep Example

Nexsys MPSK Example

System Frequency Domain Analysis: Receiver Circuit

System Frequency Domain Analysis: Mixer Data

DC-IV Characteristics Transistor Example

Nexxim SI

Nexxim SI provides powerful tools for analyzing Signal Integrity problems, and also provides analyses in the time domain for analyzing channel responses and displaying eye diagrams and other useful reports. The following examples demonstrate Nexxim analyses with SI issues:

Eye Analysis Example

Transmit Jitter Demonstration

CTLE Gain with USB3.0 Parameters

CTLE Gain with USB3.0 Parameters from a File

CTLE Gain with PCIe3.0 Parameters

CTLE Gain with PCIe3.0 Parameters from a File

CTLE using a Generic Rational Transfer Function

PCIe3.0 Crosstalk Example

AMI Analysis Example

"HDMI Filter Demonstration " on page 21-234

External Step Response Example

Transient Parallel Bus Speedup Demonstration

Time Domain Reflectometer Example

Transient Analysis with Sweeps

In this example you runs transient analysis of a simple mixer circuit:

- Open a parameterized schematic circuit on the Examples directory.
- Run a transient analysis simulation at a single value of the variable, and view the results.
- Run transient analysis over several sweeps of the variable, and view the results.

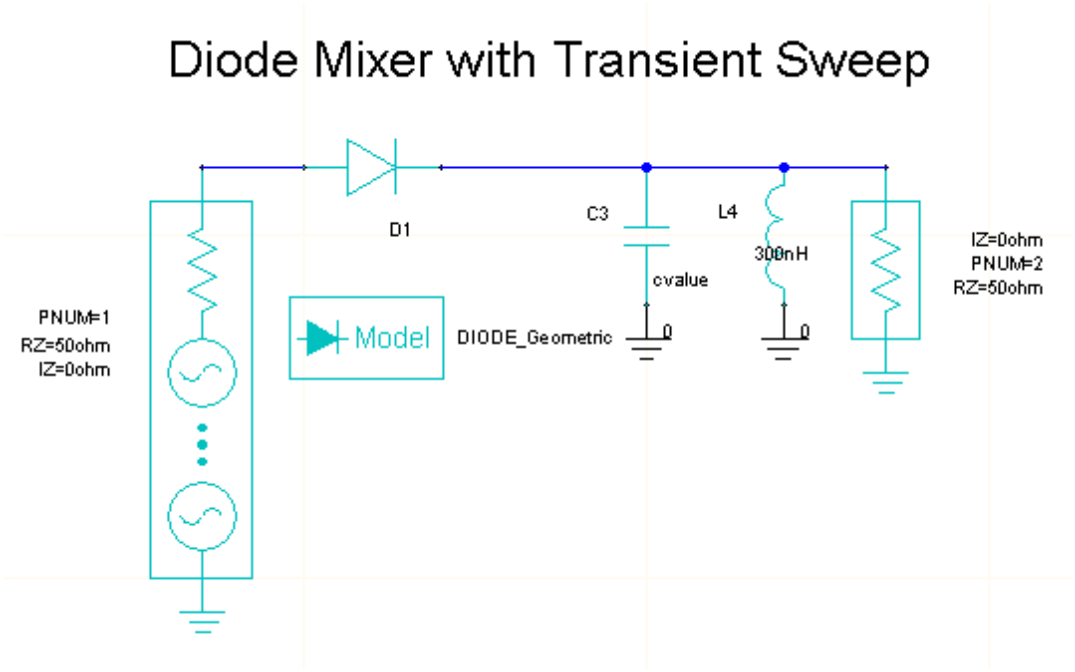
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Open the Example Diode Mixer Project

Open the diode mixer project on the directory of Nexxim example projects.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **RF_Microwave**, the **Mixers** directory, then select the file **SimpleMixerwithSweep.aedt**. Click **Open**.

The **Schematic Editor** window displays the diode mixer circuit.



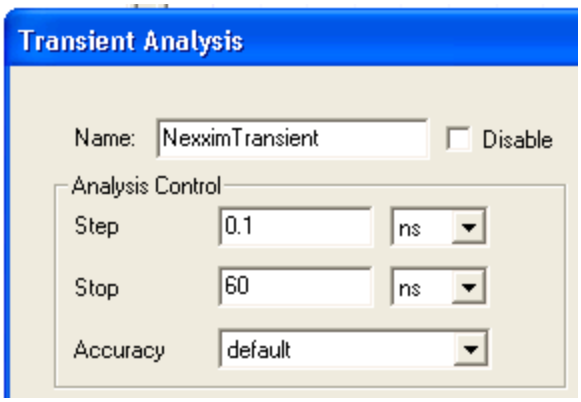
3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

Perform a Transient Analysis of the Mixer

First, let us perform a transient analysis of this netlist to show the time-domain behavior of the mixer. Later, run a sweep of a circuit parameter.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Expand the Analysis icon and double-click the **Nexxim Transient** setup:

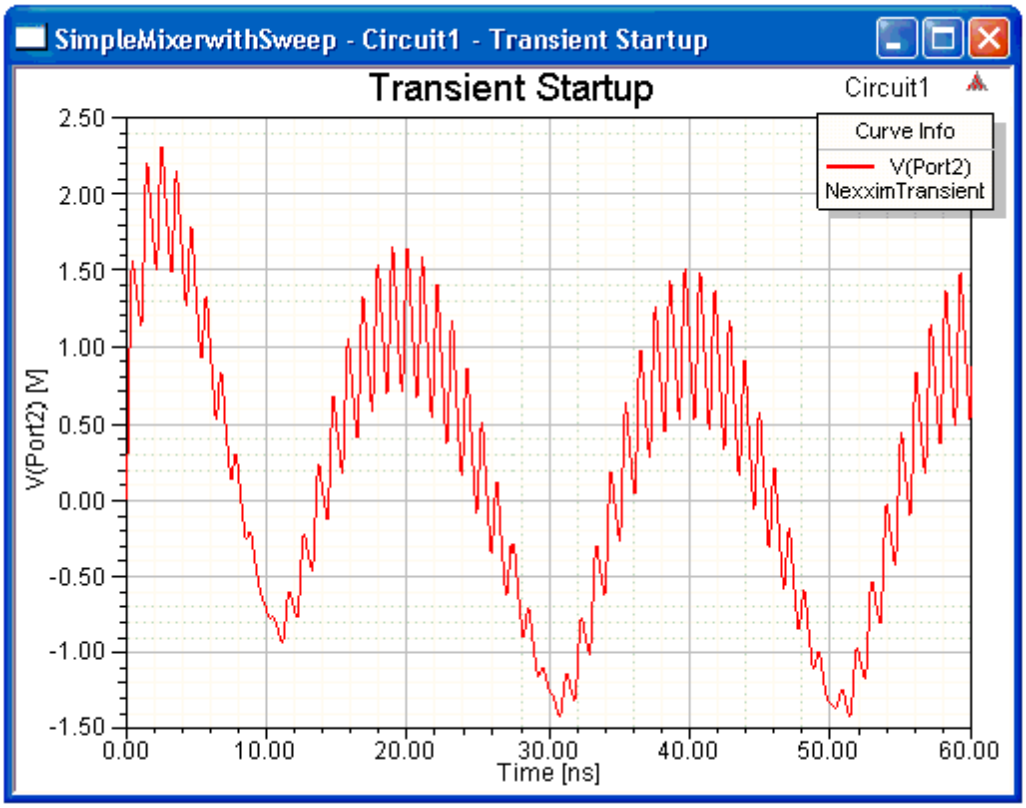


This setup specifies an analysis from time 0 to 60 ns with a maximum timestep of 0.1 ns.

2. To run the transient analysis, right-click the **Nexxim Transient** and select **Analyze**. A progress window briefly appears at the lower-right to indicate that the transient analysis is being performed. When the analysis is completed, the Message Manager window at the lower-left shows the name of the project, errors or warnings if any, and analysis statistics such as CPU time.
3. To view a graph of the results, click the Results icon and select the **Transient Startup** report.

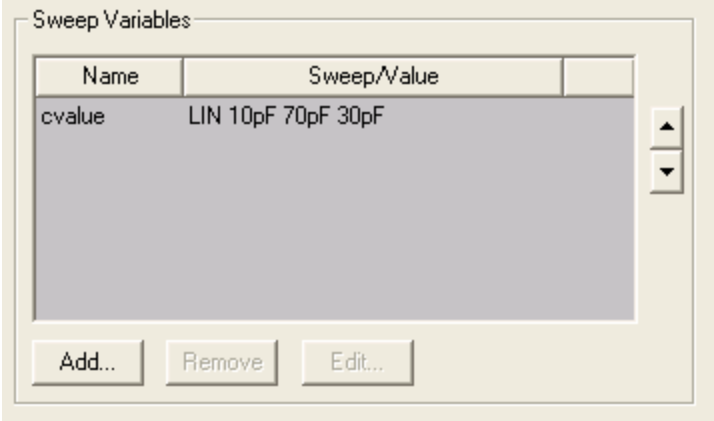
The **Reports** window opens with the graph of the transient analysis:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Perform a Transient Analysis with Parameter Sweep

1. Click the Capacitor and verify that **cvalue** is the value of the **C** property.
2. Expand the Analysis icon and double-click the **Nexxim Transient Sweep** setup. Verify that the setup contains a sweep of **cvalue**:

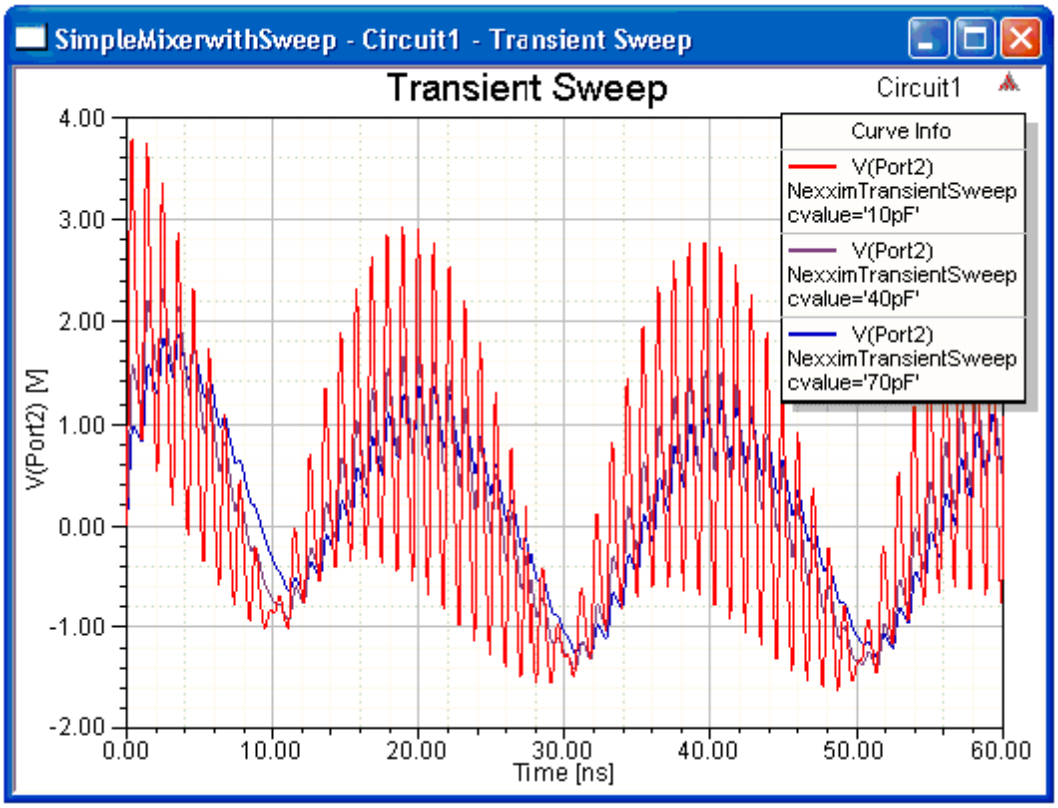


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This setup specifies a linear sweep of **cvalue** from 10pF to 70pF with a step of 30pF. The swept values is 10pF, 40pF, and 70pF.

3. To run the transient sweep, right-click the **Nexxim Transient Sweep** and select **Analyze**. A progress window opens at the lower-right to showeach sweep as transient analysis is being performed. When the analysis is completed, the Message Manager window at the lower-left shows the name of the project, errors or warnings if any, and analysis statistics such as CPU time.
4. To view a graph of the results, click the Results icon and select the **Transient Sweep** report.

The **Reports** window opens with the graph of the transient analysis with all sweep values:



Related Topics:

Nexxim Transient Analysis

Nexxim Variable Sweep

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Transient Analysis Method Option RF

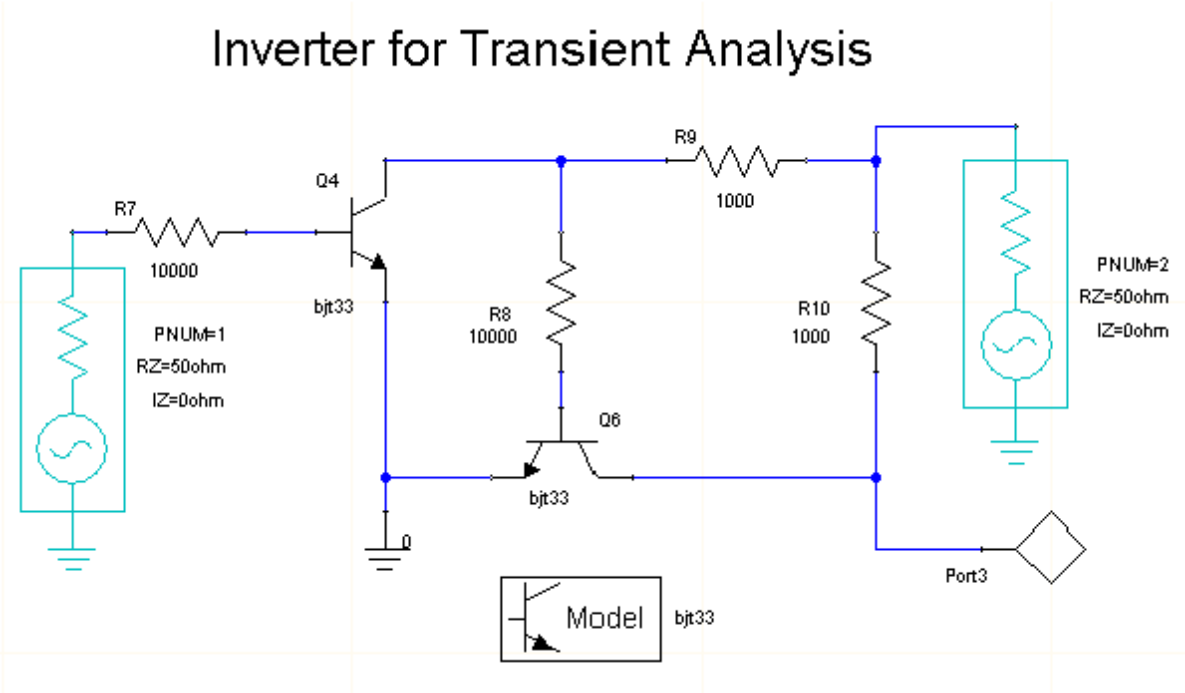
This topic describes the use of the **Method** option to select numerical methods for Transient Analysis. The example used is a BJT inverter circuit. You can open the inverter circuit schematic on the Examples directory.

Open the Example Inverter Project

Load the BJT inverter project on the directory of Nexxim example projects.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **RF_Microwave**, the **Amplifiers** directory, then select the file **BJT_Inverter.aedt**. Click **Open**.

The **Netlist Editor** window opens to open the BJT inverter circuit schematic:



3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project.
4. Click **OK**.

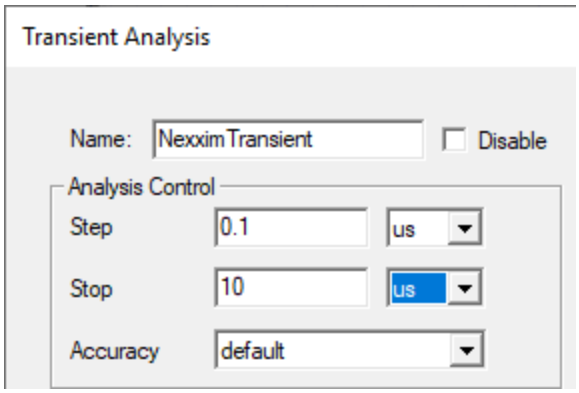
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Perform a Transient Analysis of the Inverter

Add a solution setup before analyzing the inverter circuit.

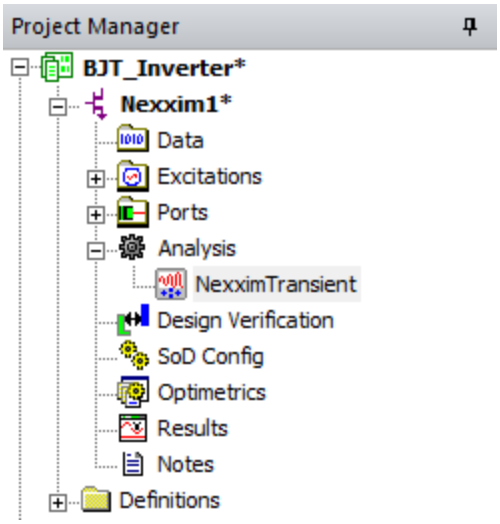
1. From the **Circuit** menu, select **Add Nexxim Solution Setup ...** > **Transient Analysis**. A window opens to specify the parameters for the transient analysis.
2. Set the **Step** value to 0.1 microseconds, using the drop-down menu to select the unit (us). This is the maximum step size.
3. Set the **Stop** value to 10 microseconds (us), to define the length of the simulation. Since the frequency of the input sinusoid is 1 MHz, ten microseconds should contain ten cycles.

The **Analysis Control** group box should look like the following:



4. From the **Transient Analysis** window, click **OK**.
5. Click the **Projects** tab of the **Project Manager** window, and expand the project icon by clicking on the plus sign. Expand the **Nexxim1** icon, the **Analysis** icon. The newly solution setup, named **NexximTransient** if it is the first, or **NexximTransient***n* for the *n*th one you create, is now available.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



6. Click that solution setup to select it, then right-click to display a drop-down. From that drop-down, click **Analyze** (or click the **Analyze** icon on the toolbar).

A progress window briefly appears at the lower right to indicate that the transient analysis is being performed. When the analysis is completed, the Message Manager window at the lower-left shows the name of the project, errors or warnings if any, and analysis statistics such as CPU time.

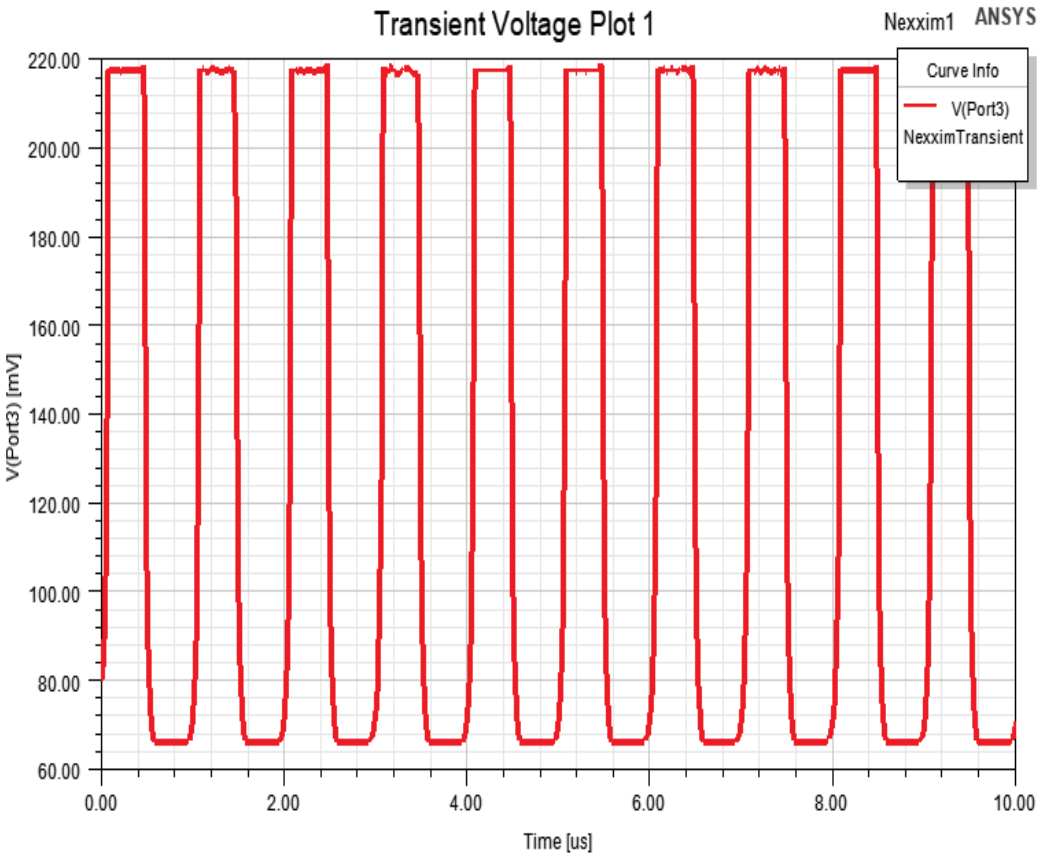
7. From the **Project Manager** window, locate the **Results** icon. Right-click the **Results** icon, then select **Create Standard Report** > **Rectangular Plot**. The **Create Report** window opens with the **Trace** tab selected.

   The X-axis displays the time values. For the Y-axis, select **Voltage** as the Category, **V (Port*n*)** as the Quantity, and **<none>** as the Function.

> **Note:** The Port number (**Port3** in our example) and the other node names (**net_*n***) may have different numbers in your circuit. However, there should be only one port voltage to select.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. Click **New Report**.
9. Click **Close** on the **Report** window. The **Reports** window displays the graph of the result:



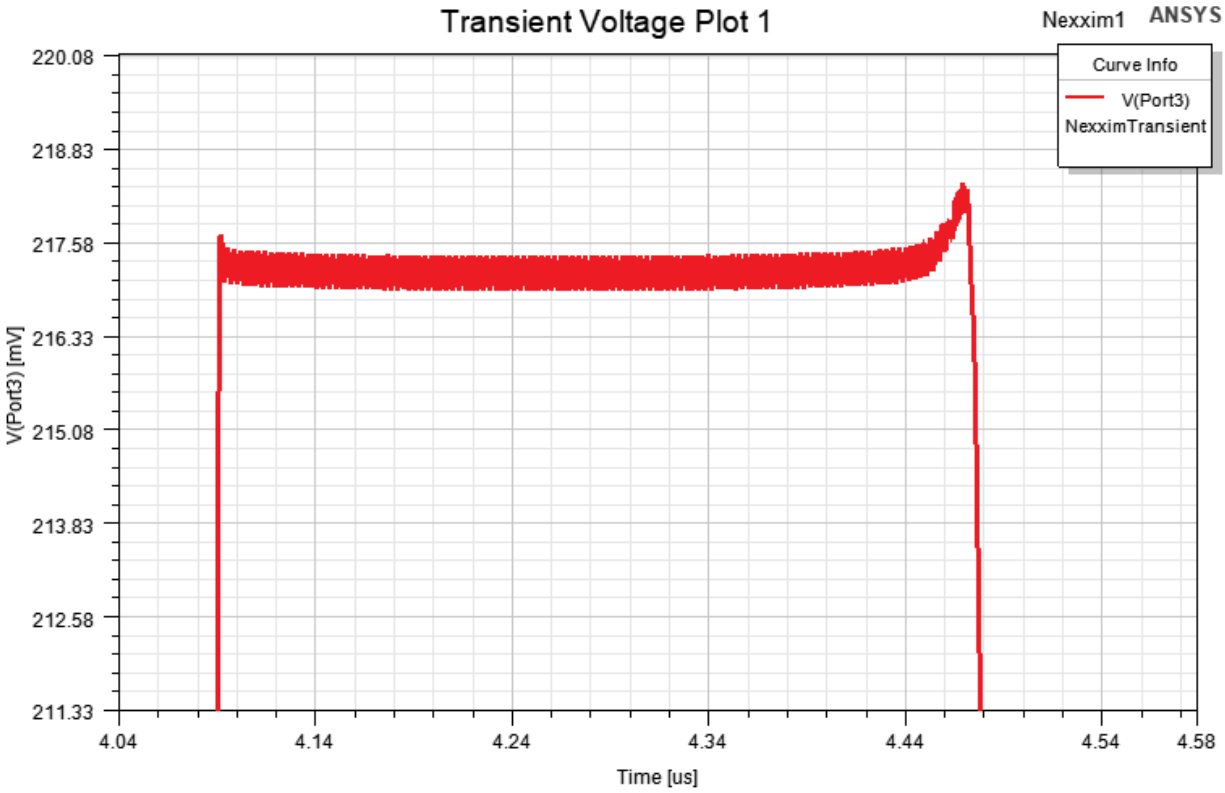
The BJT inverter has converted the sinusoidal input to a square wave output. Note the slightly ragged appearance at the peaks of the wave. Let us look more closely at one of these segments.

10. Right-click in the **Reports** window, then select **View** > **Zoom In**. Click directly above and the left of one of the wavetops, then **click+drag** to include the wavetop. Then release the mouse button. The graph changes to show the zoomed-in view.

> **Note:** To restore the full image (not zoomed in), right-click in the graph and select **Fit All**.

10. You may have to repeat this operation once or twice more until you see an image like the following:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This tiny irregularity (approximately 1.0 mV) is called “trapezoidal ringing.” It is produced by the trapezoidal rule method of numerical integration, and is not the true circuit behavior. The trapezoidal rule is the Nexxim default numerical integration method. Numerical ringing commonly occurs with the trapezoidal rule method at points in a waveform with sharp corners or discontinuities such as this square wave.

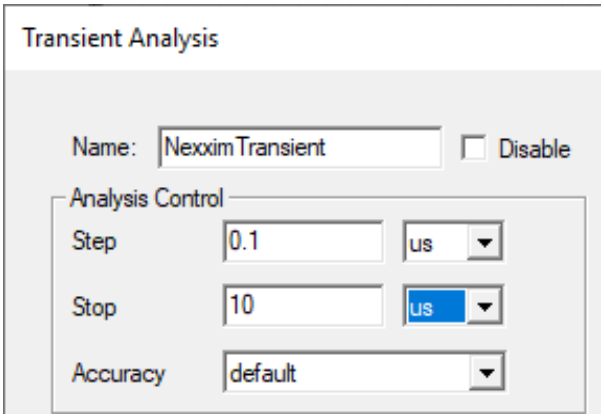
12. Leave the **Reports** window open with the zoomed-in trace.

Use the NDF2 Method Option for Transient Analysis

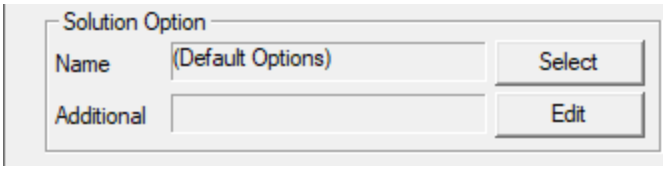
For cases where the exact circuit behavior is important, Nexxim offers an integration method, NDF2, that avoids numerical ringing. Here is how to select the **Method=NDF2** option for Transient Analysis.

1. From the **Project Manager** window, expand the **Project Tree** and **Analysis** folder. Then double-click the Transient analysis setup to reopen the **Transient Analysis** window.
2. To perform the same transient analysis, the **Step** and **Stop** values should be set up the same as before.

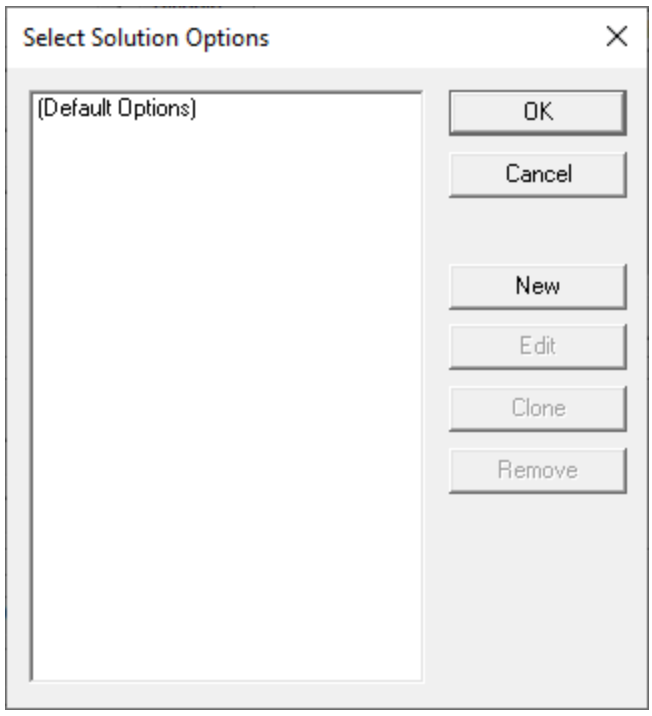
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Click **Select** in the **Solution Options** group box:

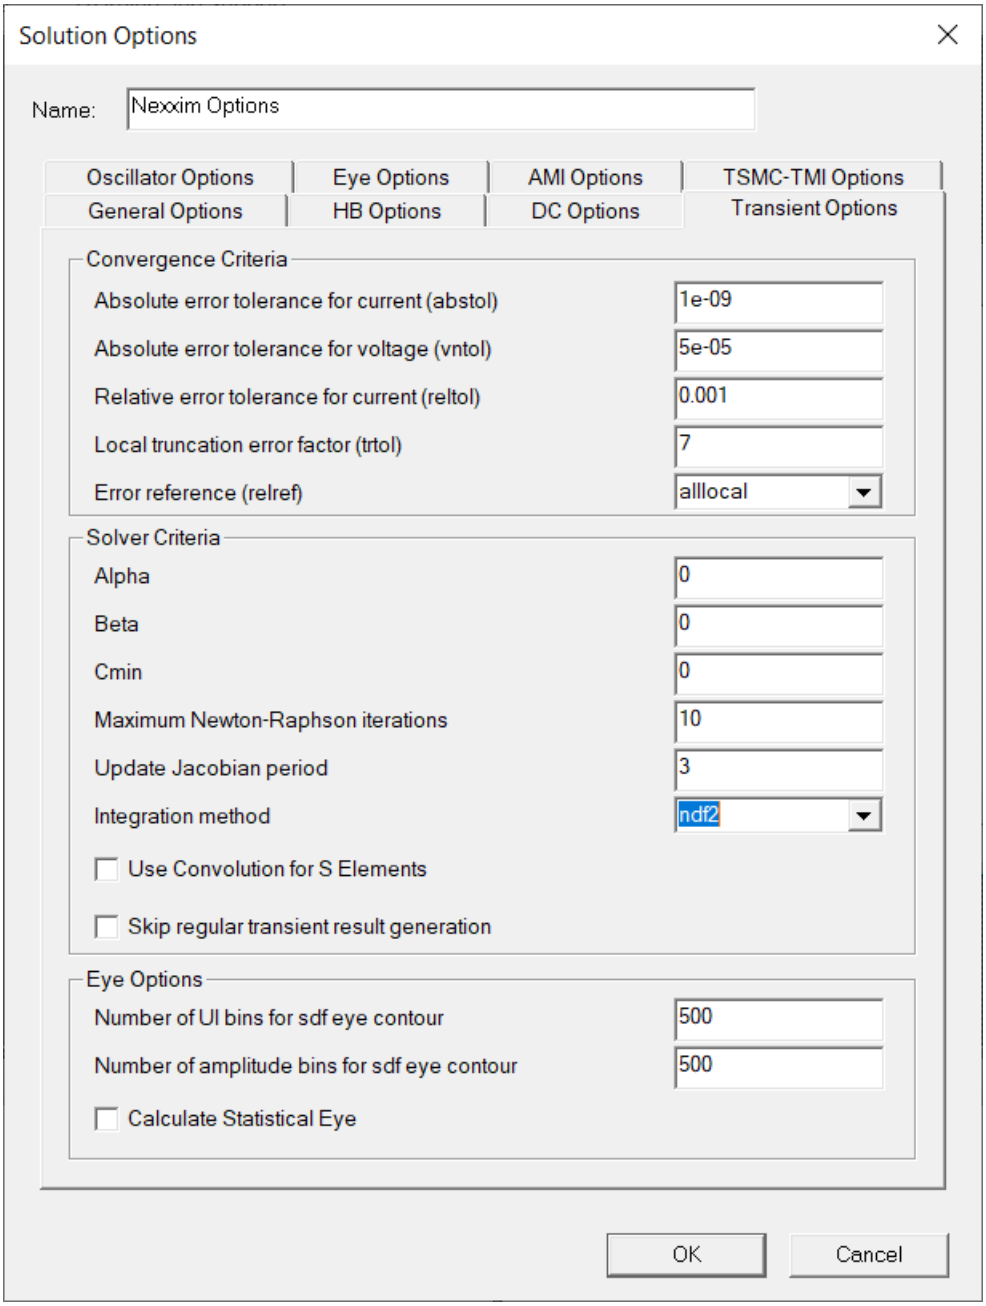


The **Select Solution Options** window opens:



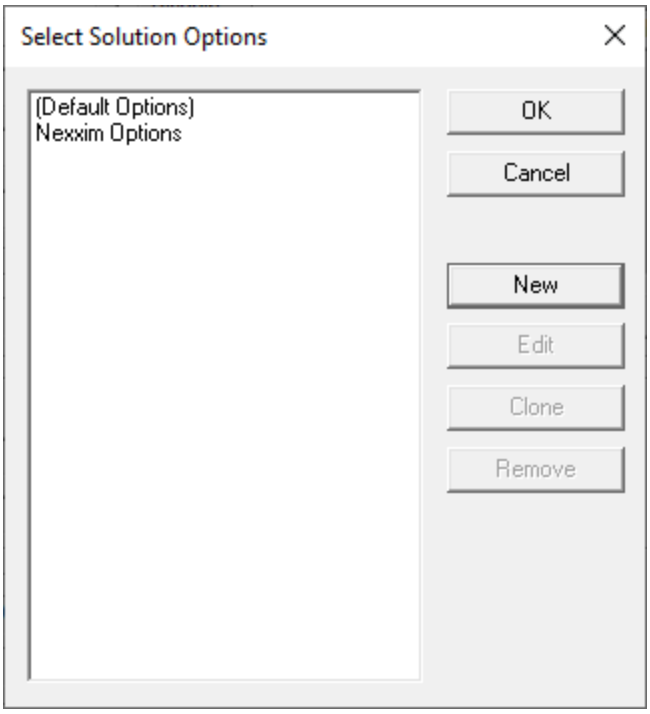
4. Click **New**. The **Solution Options** group box opens, with the **Transient Options** tab already selected.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. The default **Integration method** is **trapezoidal**. From the **Integration method** window, select **ndf2** on the drop-down menu (for more information see Transient Analysis Options).Then click **OK** on the **Solution Options** window to reopen the **Select Solution Options** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



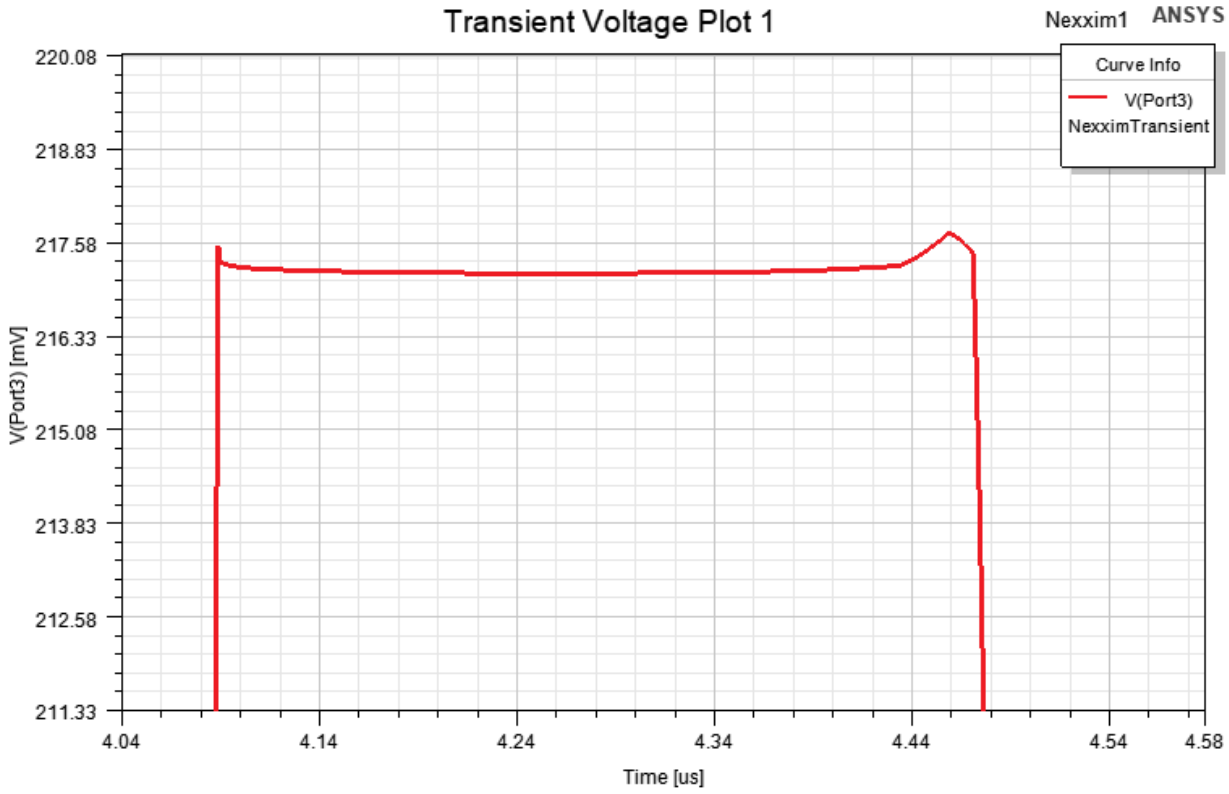
6. Click the name of the new set of options you just defined (**NexximOptions** in our example). Click **OK** to reopen the **Transient Analysis** setup window, now showing the name of the new option ("Nexxim Options" in our example) set in the **Solution Options** group box:

7. Click **OK**.
8. To run the modified transient analysis, open the **Analysis** icons, right-click the solution setup "Transient" you just created, and select **Analyze**. This runs the analysis with the options you have set up.

A progress window briefly appears at the lower right to indicate that the transient analysis is being performed. When the analysis is completed, the Message Manager window at the lower-left shows the name of the project, errors or warnings if any, and analysis statistics such as CPU time.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The transient analysis report is redrawn with the new result:



The simulation response using NDF2 does not exhibit the numerical ringing with the trapezoidal rule.

For more information, see Nexxim Transient Analysis.

Harmonic Balance Analysis Example

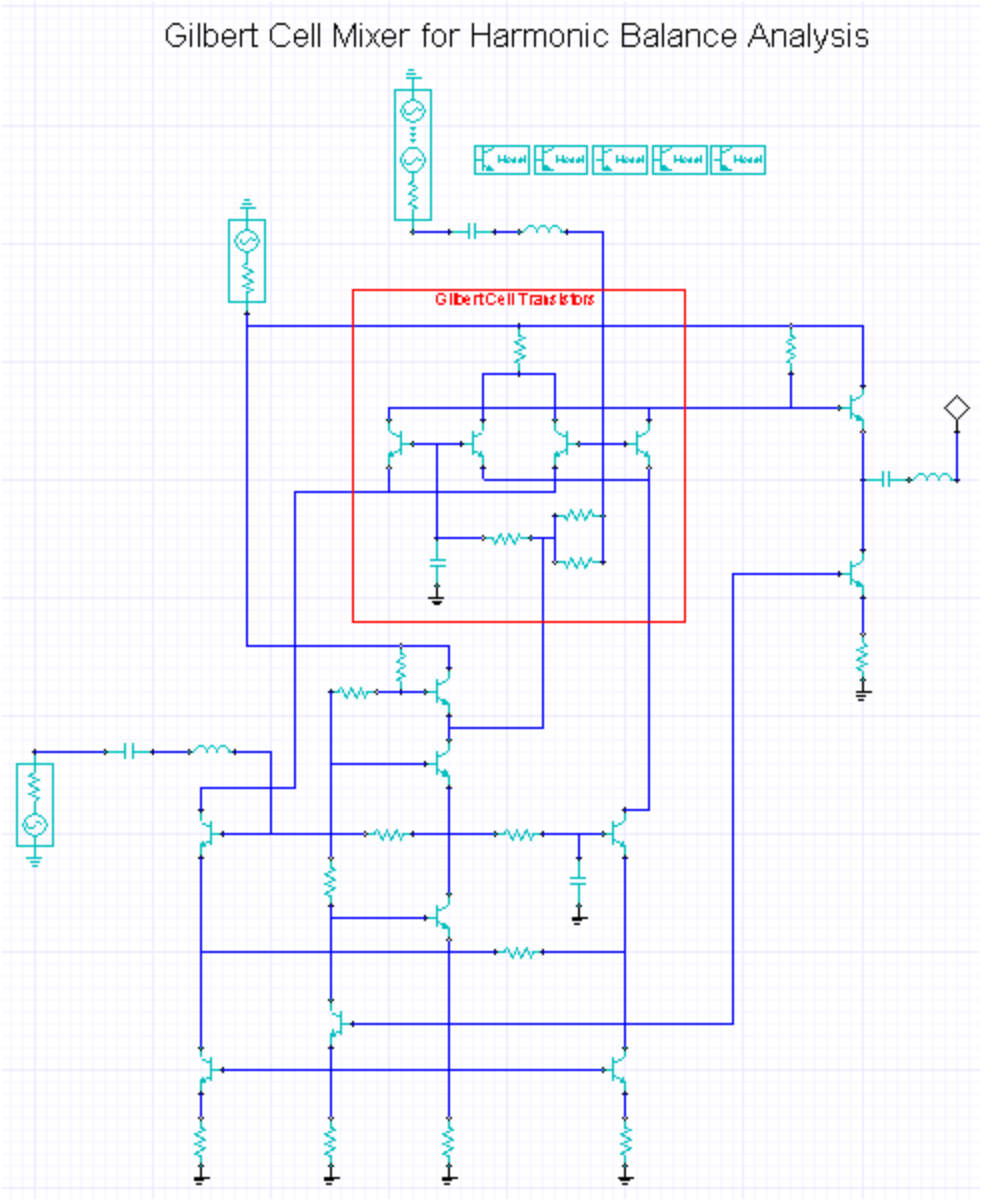
The Gilbert Cell mixer is a well-known design. It is a differential-pair mixer, with low conversion loss when implemented with active nonlinear elements. This example compares Nexxim harmonic balance analysis with transient analysis. In this example, a local oscillator frequency **VLO** is the carrier for one or two RF signals, **VRF1** and **VRF2**.

Open the Gilbert Cell Mixer Schematic

Open the Gilbert Cell Mixer project on the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **RF_Microwave**, the **Mixers** directory, then select the file **GilbertCellMixer.aedt**. Click **Open**.
3. The schematic appears in the design window.

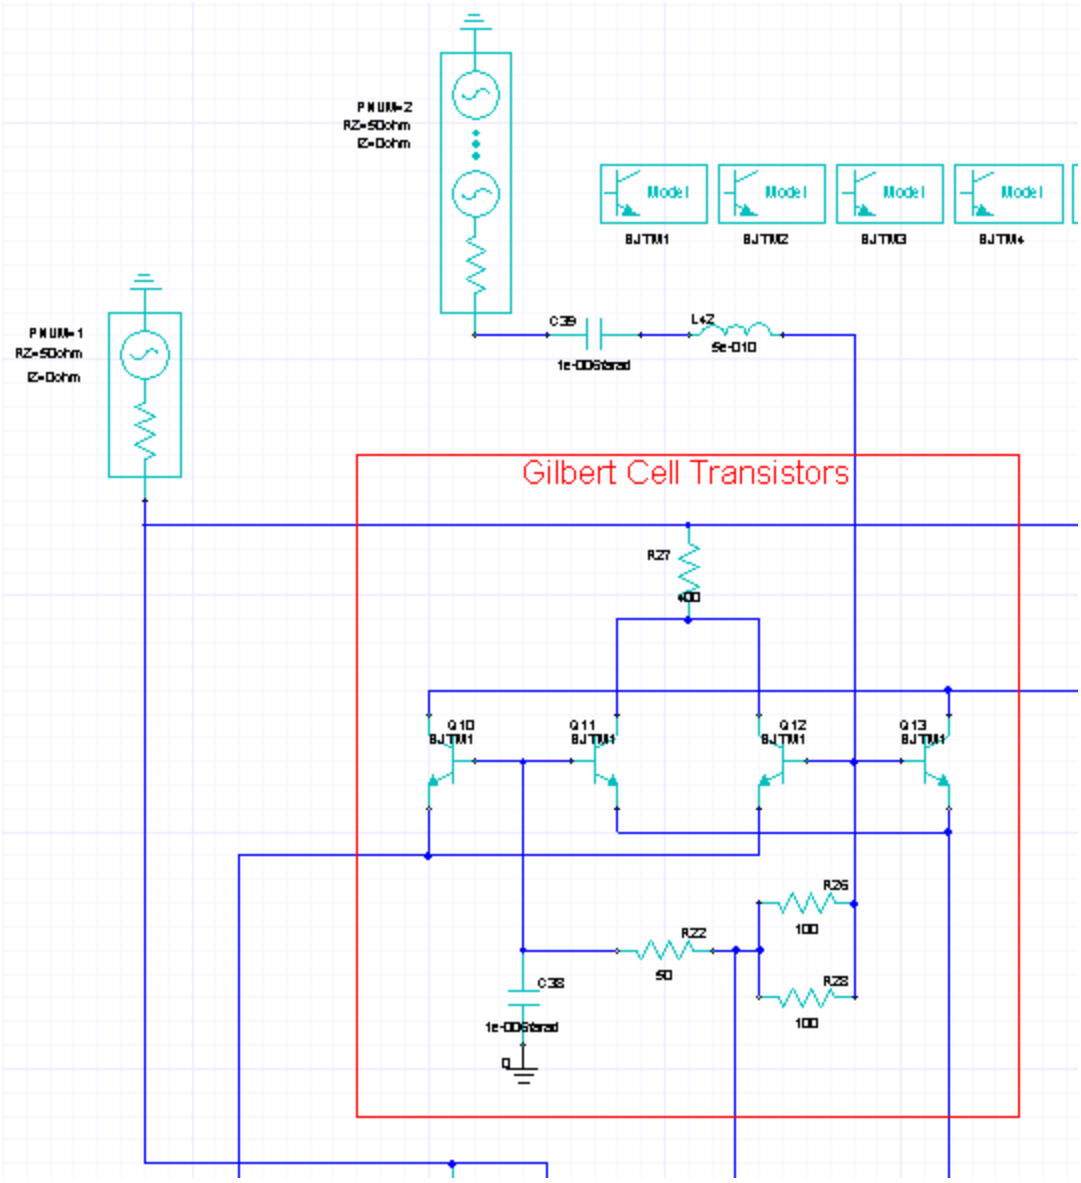
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

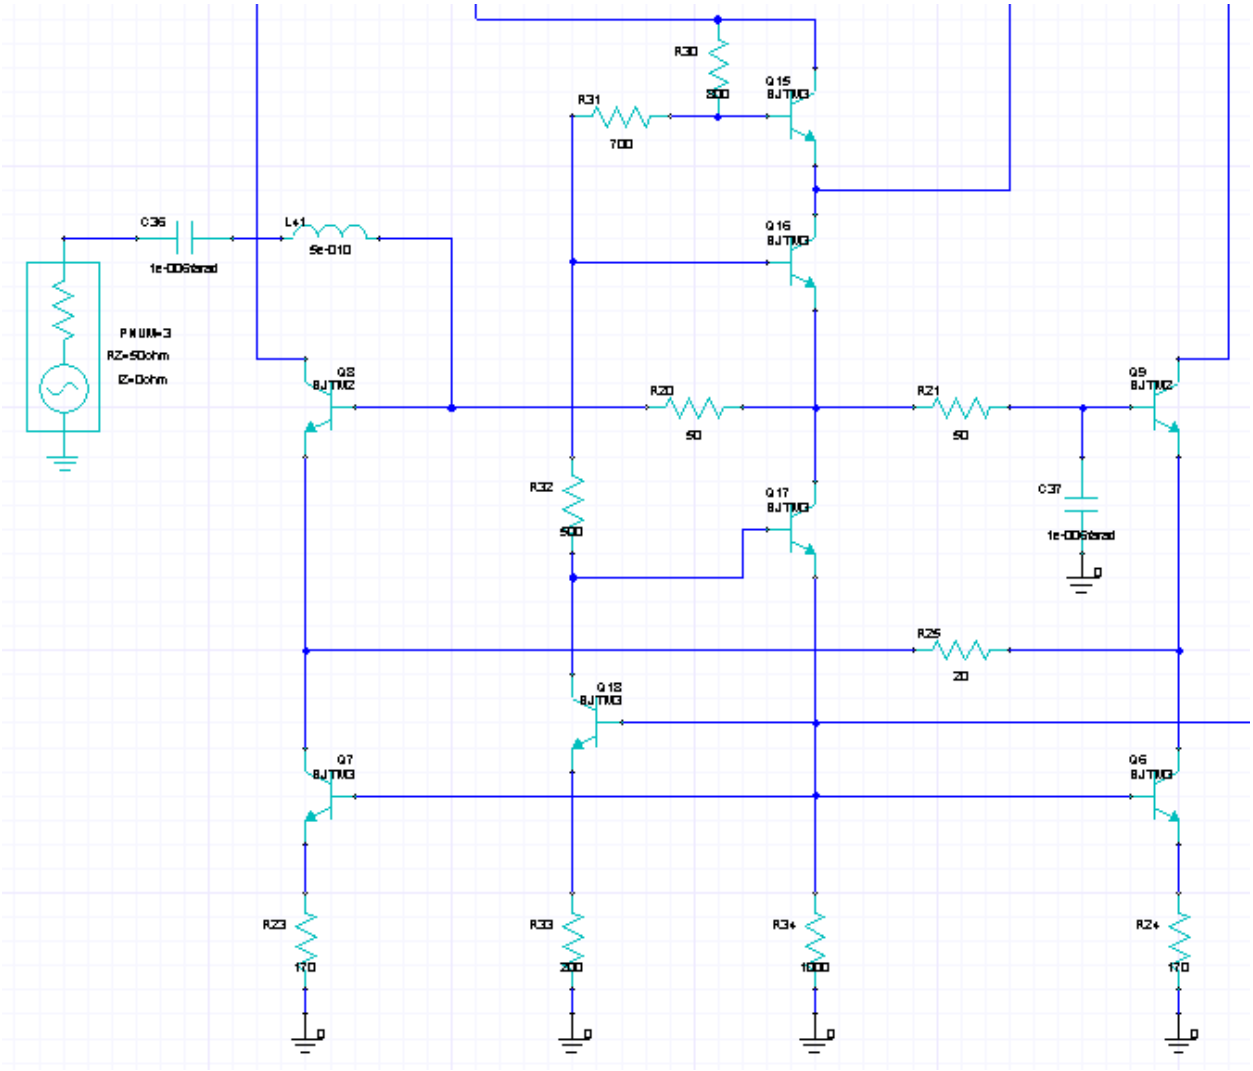
The core Gilbert Cell employs four NPN transistors. This is the portion of the schematic with the Gilbert cell. This block also shows two of the four input ports. Port1 includes a DC voltage source **VSRC1** for all the transistors in the circuit. Port2 includes the two sinusoidal voltage signals **VRF1** and **VRF2**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



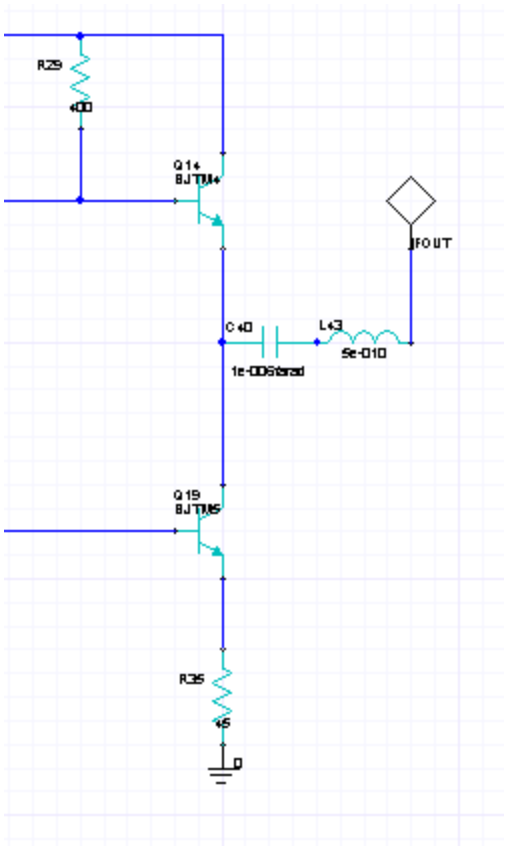
Here is the mixer **VLO** input. Port 3 includes the **VLO** sinusoidal voltage source.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This is the mixer output.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The circuit has three input ports and one output port.

- Port 1 (PNUM=1) contains a 5V DC voltage source **VSRC1** common to all the transistors.
- Port 2 (PNUM=2) contains two sinusoidal voltage sources, the RF inputs **VRF1** and **VRF2**.
- Port 3 (PNUM=3) contains one sinusoidal voltage source, the local oscillator input **VLO**.
- Port 4 is the output port.

Analyze the Gilbert Cell Mixer

1. From the Project group box, expand the **Analysis** icon. Two analyses have been set up, **Nexxim Transient** and **HBnTone**. Sources **VSRC1**, **VLO**, and **VRF1** are enabled for both analyses. Source **VRF2** is enabled for **HBnTone** only.
2. To run both analyses, right-click the **Analysis** icon, and click **Analyze**.

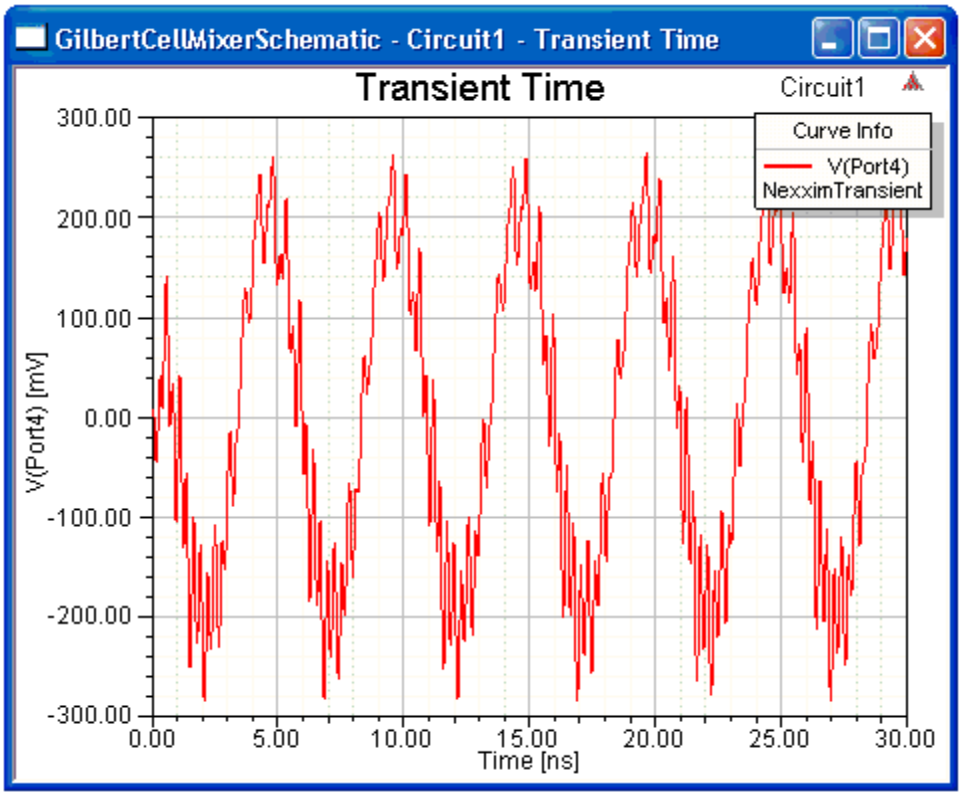
A progress window briefly appears at the lower right to indicate that the transient analysis is being performed. A longer-duration progress window indicates that the harmonic balance analysis is being performed. When both analyses are completed, the Message Manager

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

window at the lower-left shows the name of the project, errors or warnings if any, and analysis statistics such as CPU time.

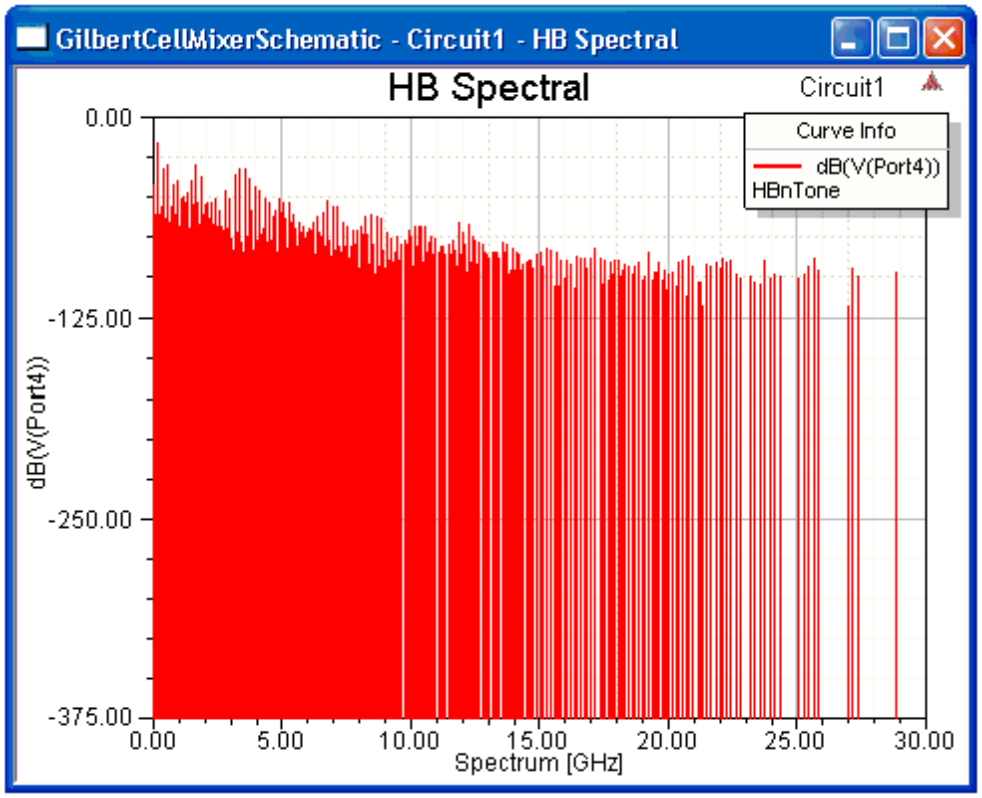
View the Time and Spectral Domain Results

To view the result of transient analysis, expand the reports icon and click the **Transient Time** report. The **Reports** window displays the time domain waveform for the mixer:



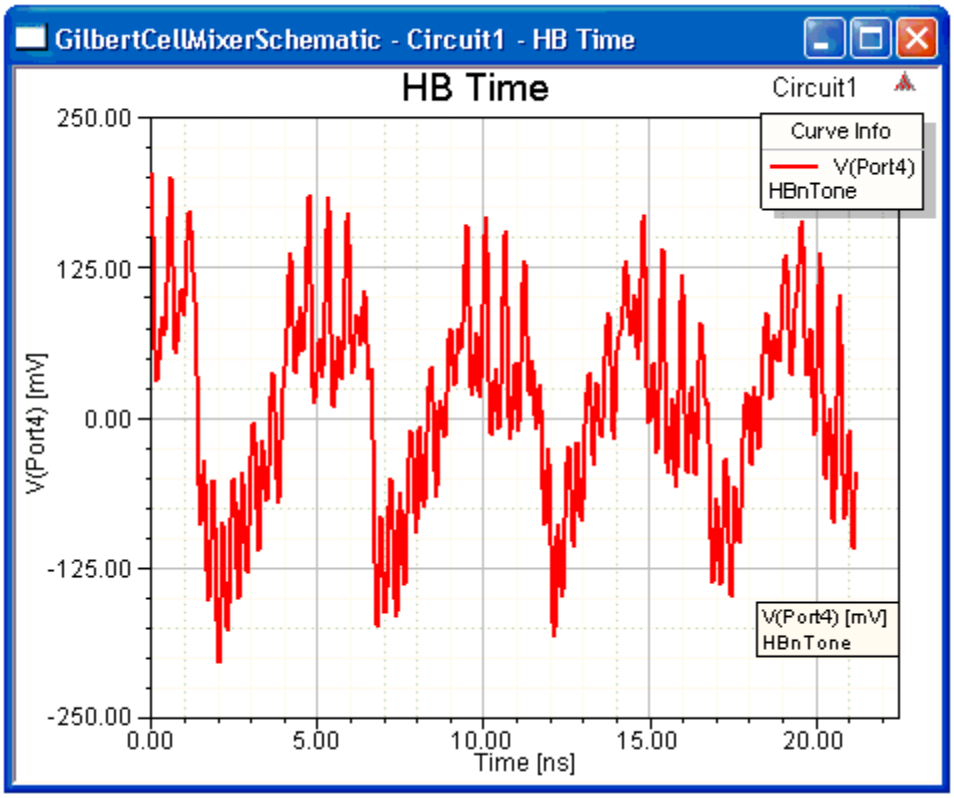
3. Double-click the **Spectral** report. The **Results** window displays the frequency domain data:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. For comparison with the transient analysis result, view the harmonic balance analysis results in the time domain. In the **Results** tree, double-click the **HB Time** report. The **Results** window displays the time domain transformation:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For more information, see Nexxim Harmonic Balance.

Oscillator and Phase Noise Analysis

In this example you run a Nexxim oscillator analysis to find the frequency of a Colpitts oscillator circuit , then verify the initial estimate using a resonant frequency search. Next, you run a phase-noise analysis to determine the behavior of the oscillator around its dominant oscillation point.

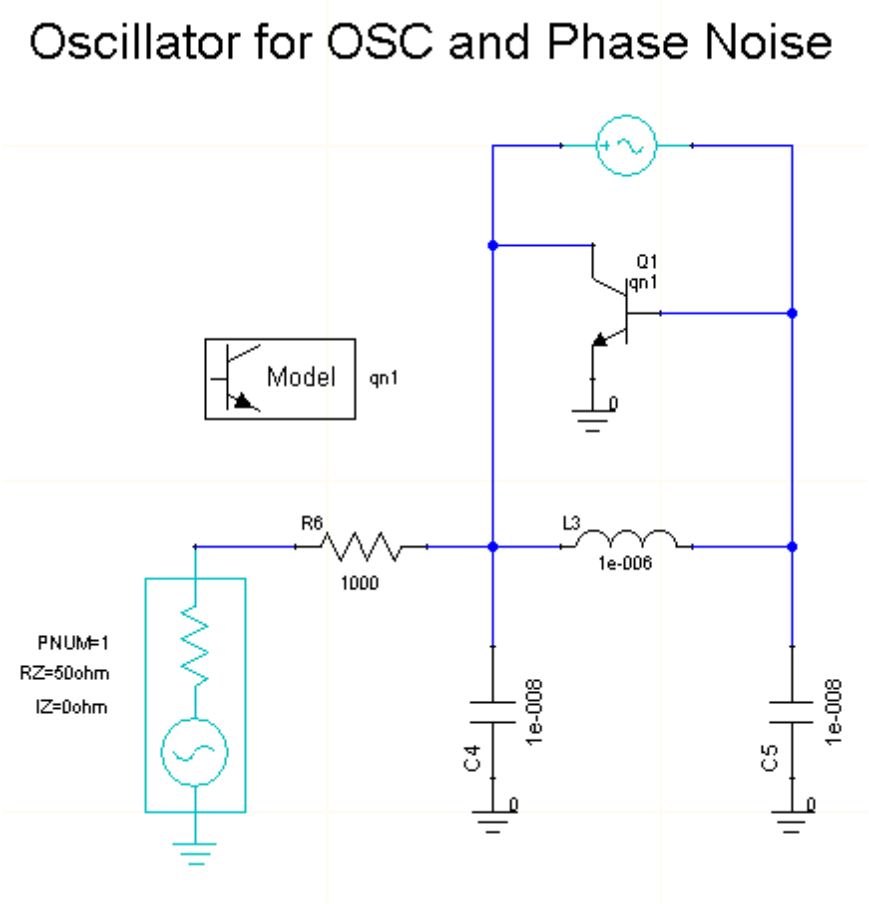
Open the Oscillator Schematic

Open the example Oscillator Schematic project on the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **RF_Microwave**, the **Oscillators** directory, then select the file **ColpittsOscillator.aedt**. Click **Open**.

The oscillator schematic appears in the design window:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

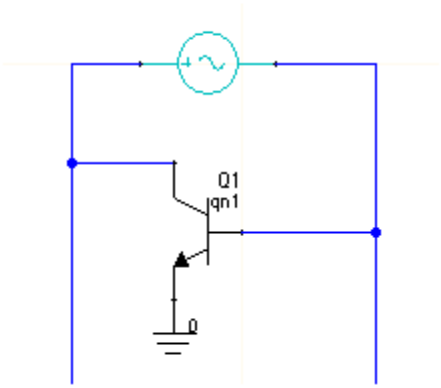


3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

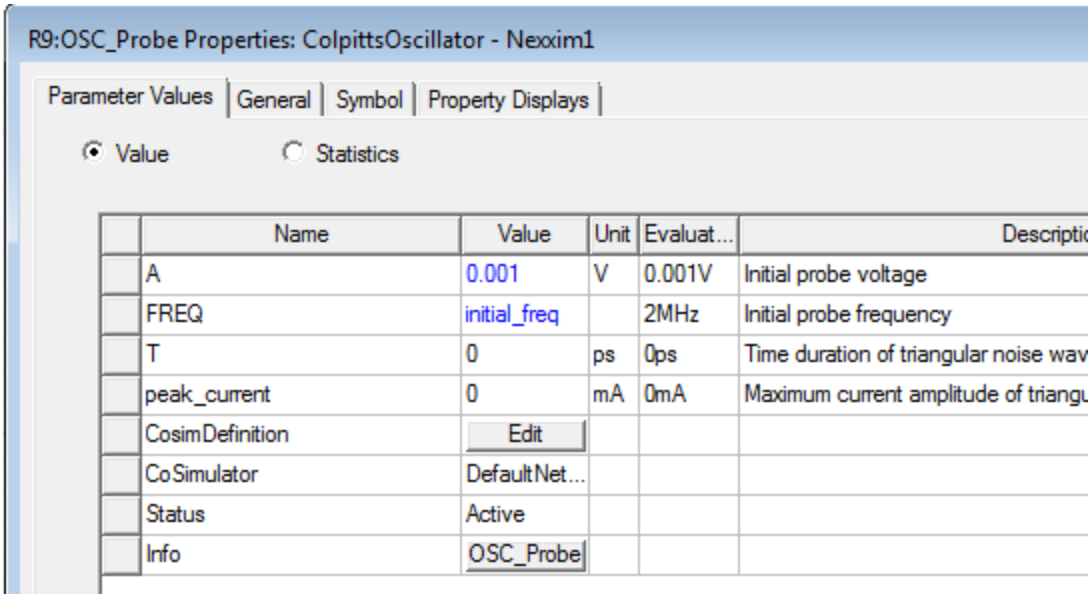
Perform an Oscillator Analysis

1. To enable oscillator analysis, an oscillator probe has been added to the schematic above the bipolar transistor Q1. Here is that portion of the schematic :

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Click the oscillator probe to display its properties on the **Param Values** tab of the **Properties** window.
- The **Param Values** tab for the oscillator probe should have the values shown here:

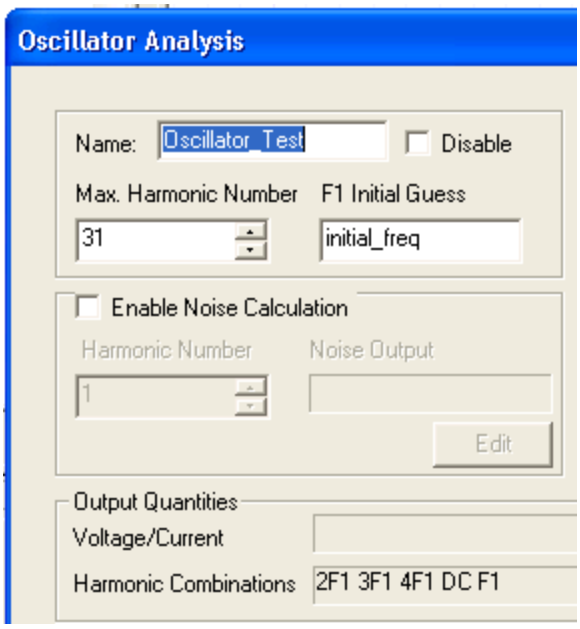


- Parameter **A** is set to 0.001. Parameter **A** is the initial voltage used for the initial guess at the oscillating frequency. Press **Enter** to move to the next parameter.
- Parameter **FREQ** is set to local variable **initial_freq**. The initial value is **2Mhz** as shown above. Click **OK** to close the **Properties** window.
- Parameters **T** and **peak_current** are specific to transient analysis and do not affect oscillator analysis, so they are not set for this example.

2. Select the **Projects** tab in the Project window. Expand the **Analysis** icon in the **Project Manager** window, right-click the **Oscillator_test** solution setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. The **Oscillator Analysis** window opens:



- **Oscillator_test** is the name of the setup.
- **31** is the **Max. Harmonic Number**. This specifies the highest harmonic to use in the harmonic balance calculations that underlie the oscillator analysis.
- Variable **initial_freq** is the **F1 Initial Guess**. The local variable sets the initial frequency estimate for both the oscillator probe and the analysis setup:
- Click **OK** to close the **Oscillator Analysis** window.

4. Expand the **Analysis** icon in the Project window, right-click the **Oscillator_test** solution setup, and select **Analyze** on the menu. The oscillator analysis runs. The **Progress** window displays a red line to show the progress of the analysis.

```
analysis:osc(info): lowest oscillation frequency is 2.28274e+006 Hz
(1:09:46 PM Mar 25, 2017)
```

- The **analysis:osc** message shows the final oscillating frequency, 2.28274 MHz.
- Other messages regarding the initial guess and other analysis operations are written to the log file.

Perform a Resonant Frequency Search

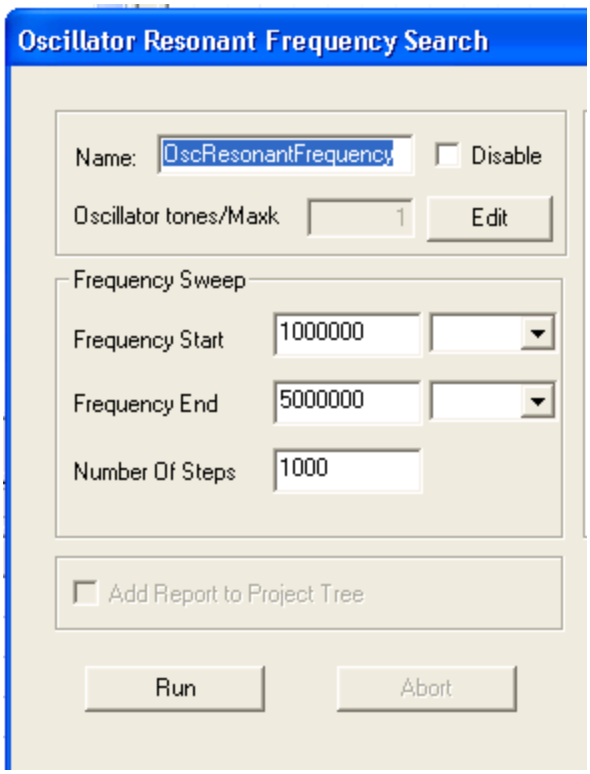
Resonant frequency search performs a limited form of oscillator analysis to obtain a rough estimate of the resonant frequency. With resonant frequency search, only the initial guess phase of oscillator analysis is performed. Resonant frequency search uses the frequency sweep method rather than the transient method used in the full oscillator analysis. The frequency sweep method operates on highly linearized versions of the circuit elements. Compare the result

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

obtained by the resonant frequency search with the result of the fully nonlinear oscillator analysis obtained earlier in this example.

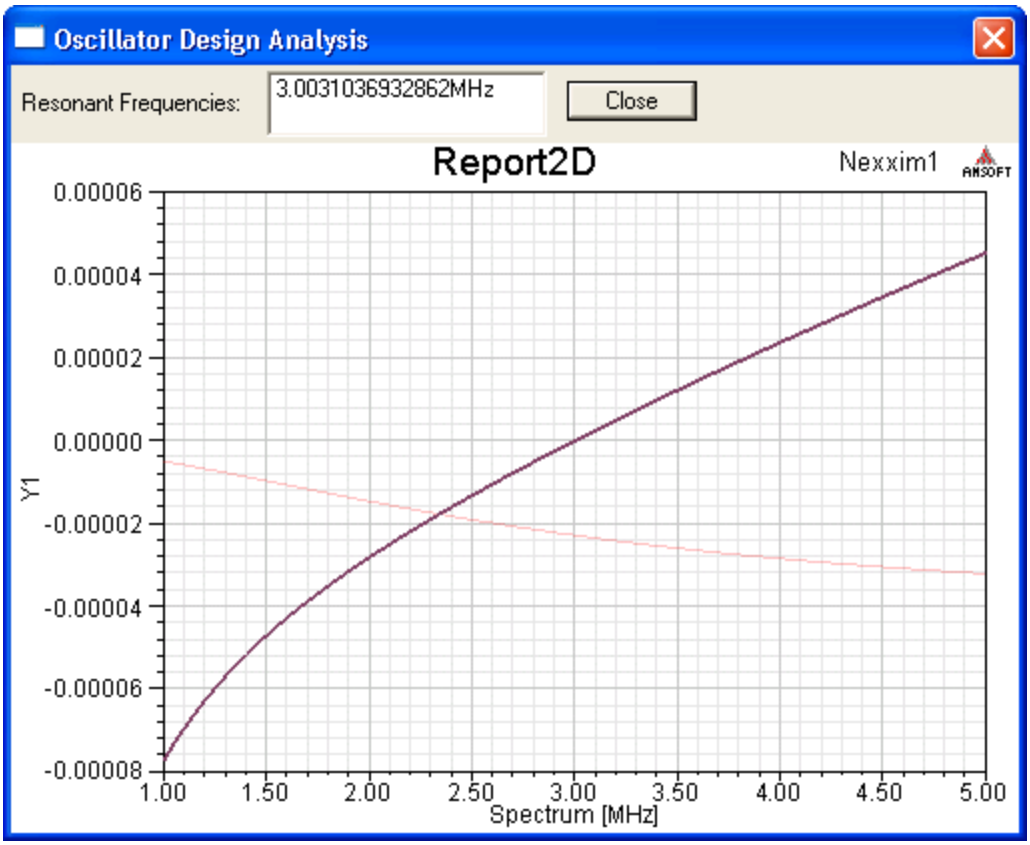
> **Note:**
>
> Resonant frequency search is a separate analysis only in Nexxim running under the Schematic Editor. With netlist designs, the equivalent of resonant frequency search can be set up using oscillator command entries and options. For more information see .OSC Resonant Frequency Search Statement.

1. Right-click the Analysis icon and select **Add Nexxim Solution Setup > Oscillator Resonant Frequency Search** to open the **Oscillator Resonant Frequency Search** setup window.
3. In the **Frequency Sweep** group box, **Frequency Start** is 1MHz, **Frequency End** is 5MHz, and N**umber of Steps** is 1000. The values are displayed in decimal form:



4. Click **Run**. The analysis runs directly on the window window. The Progress window briefly opens to show the progress of the analysis.
5. When the simulation has completed successfully, the **Oscillator Design Analysis** window opens to open the result:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



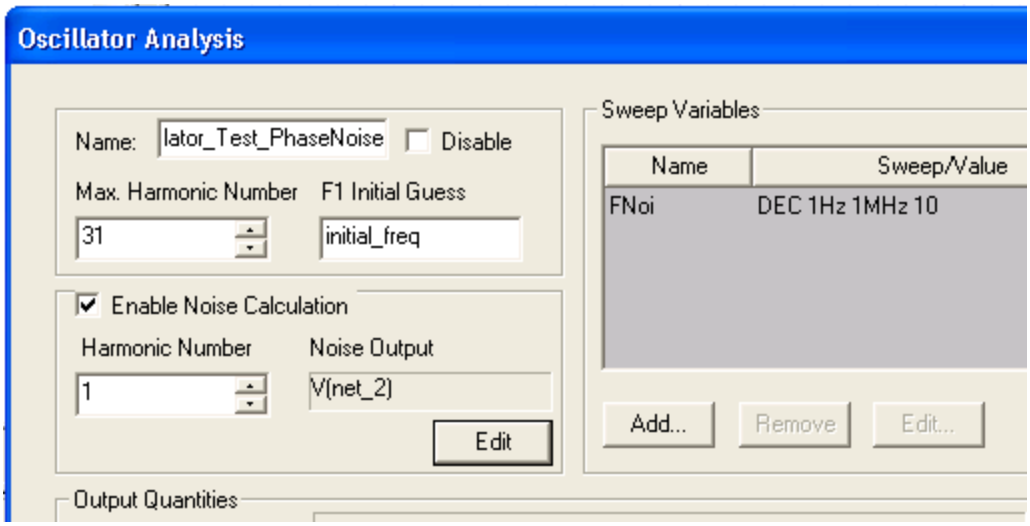
6. The resonant frequency occurs where the imaginary part of the probe current Im[I (Probe1)] (the darker trace) crosses the zero line on the Y-axis. This frequency displays in the **Resonant Frequencies** field at the top of the window. Because of the limitations of resonant frequency search, the estimated resonant frequency is about 30% higher than the frequency calculated by the full oscillator analysis.
7. Click **Close** to close the **Oscillator Design Analysis** window.
8. Click **OK** to close the **Oscillator Resonant Frequency Search** window.

Perform a Phase Noise Analysis

The next exercise is to run phase noise analysis on the oscillator circuit. Nexxim uses the calculated oscillating frequency as the fundamental around which phase noise is computed.

1. Expand the **Analysis** icon in the Project window and double-click the **Oscillator_Test_PhaseNoise** solution setup to open the **Oscillator Analysis** window.

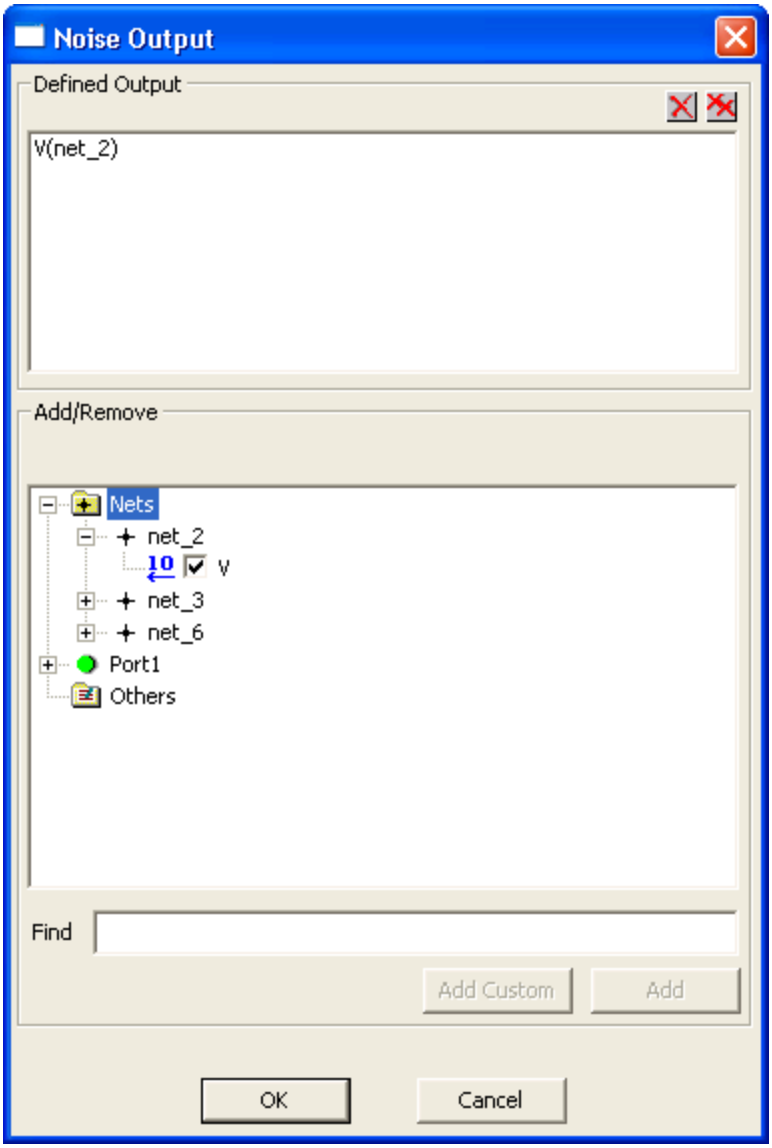
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- The **Enable Noise Calculation** check box is checked.
- The default **Harmonic Number** is 1, the fundamental oscillating frequency.
- In the **Sweep Variables** group box, a sweep of the noise frequency Fnoi has been set up. The sweep is a **Decade count**, from 1 Hz to 1 MHz using a count of 10.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Click **Edit** under the **Noise Output** field. The **Noise Output** window opens:



- Expand the **Nets** icon, and then expand the **net_2** icon. The **V** group box under **net_2** is selected as the output. The **Defined Output** group box shows **V(net_2)**.
- Click **OK** to close the **Noise Output** window and return to the **Oscillator Analysis** window.
- Click **Finish** to close the **Oscillator Analysis** window.

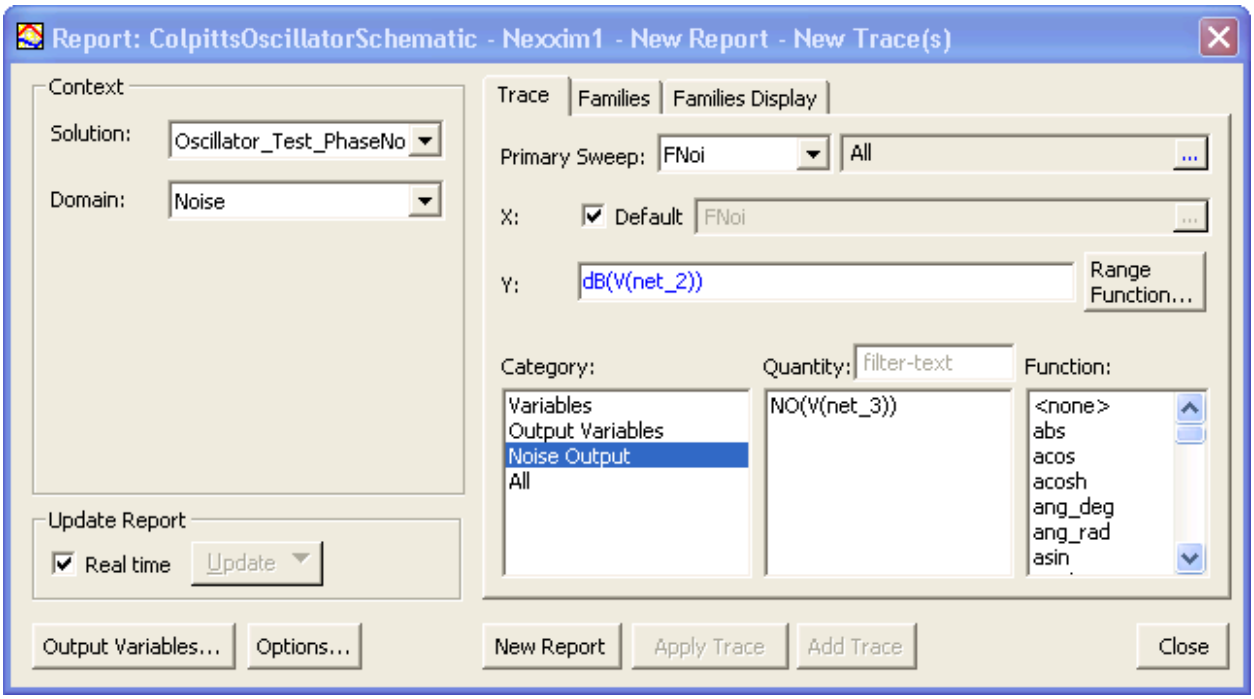
2. Expand the **Analysis** icon in the Project window, right-click the **Oscillator_Test_PhaseNoise** solution setup, and select **Analyze** on the menu. The oscillator analysis runs. The **Progress** window displays a red line to show the progress of the analysis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. When the analysis has completed, the Message window reports the oscillator RMS jitter:

```
analysis:osc(info): Oscillator root mean square jitter is
5.57352e-014 seconds (7.99402e-007 radians) per oscillation
```

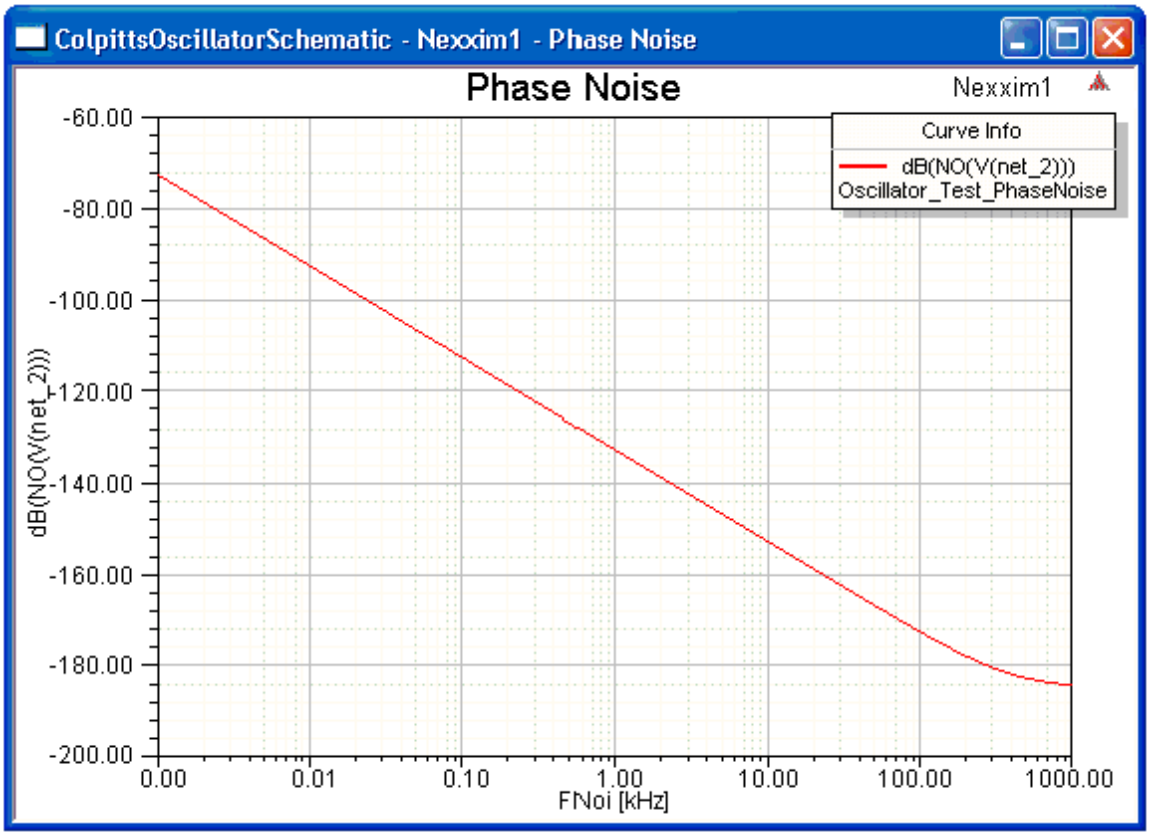
4. Right-click the **Results** icon in the **Project Manager** window and select the **PhaseNoise** report setup. The **Report** window opens:



- The **Solution** is **Oscillator_Test_PhaseNoise**.
- **Noise** is the **Domain**.
- **Noise Output** is the **Category**.
- The X-axis is the sweep of noise frequency **Fnoi**.
- the Y-axis is the noise output **dB(V(net_2))**.
- Click **New Report** to generate the report.
- Click **Close** to close the **Report** window.

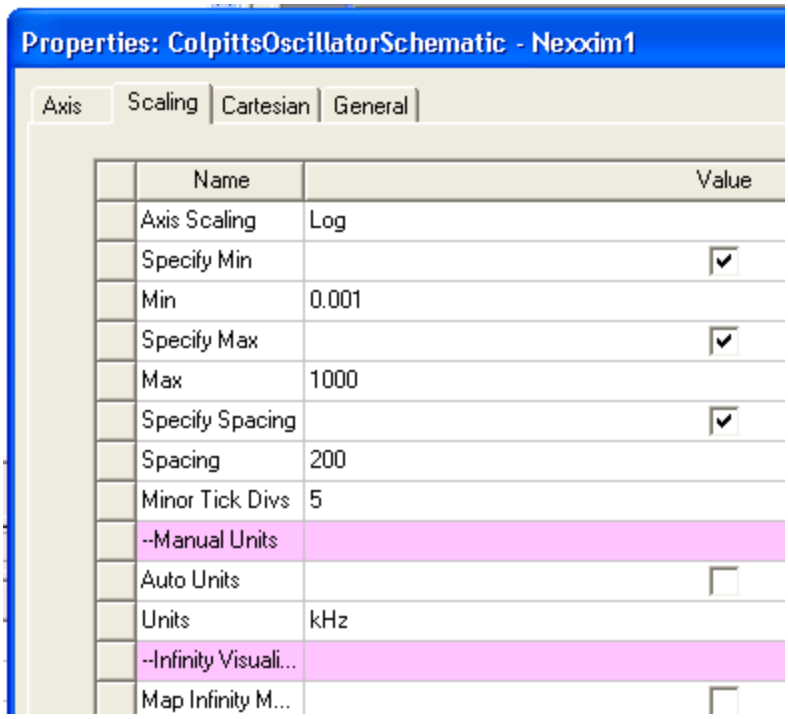
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. The Report window opens with a graph of the result:



6. The X-axis has been modified to show the double-logarithmic form that is commonly used for displaying phase noise. To see the modifications, double-click the X-axis label “Fnoi [MHz]” to open the **X-Axis Properties** window. Select the **Scaling** tab:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- **AxisScaling** is **Log** scaling (default is **Linear**). **Min** is 0.001, **Max** is 1000, and **Minor Tick Divs** to 5. The **Auto Units** option is deselected, and the **Units** are **Khz**.
- Click **OK** to close the **X-Axis Properties** window.

7. Close the Project when you are finished viewing the graph.

For more information, see Nexxim Oscillator Analysis.

TV Noise and PXF Analyses

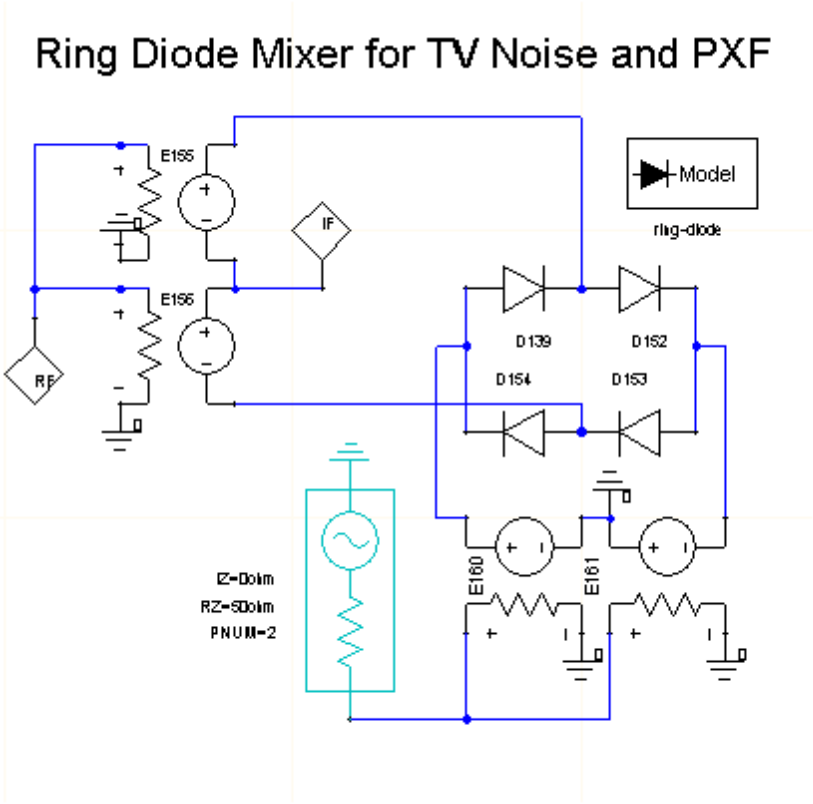
In this example you perform time-varying noise analysis and periodic transfer function analysis on a ring diode mixer circuit.

Open the Ring Diode Mixer Schematic

Open the example on the file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Navigate to **Electronics Desktop** > **Circuit** > **RF_Microwave** > **Mixers** and select **Ring_Diode_Mixer.aedt**. Then click **Open** to open the mixer schematic in the design window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



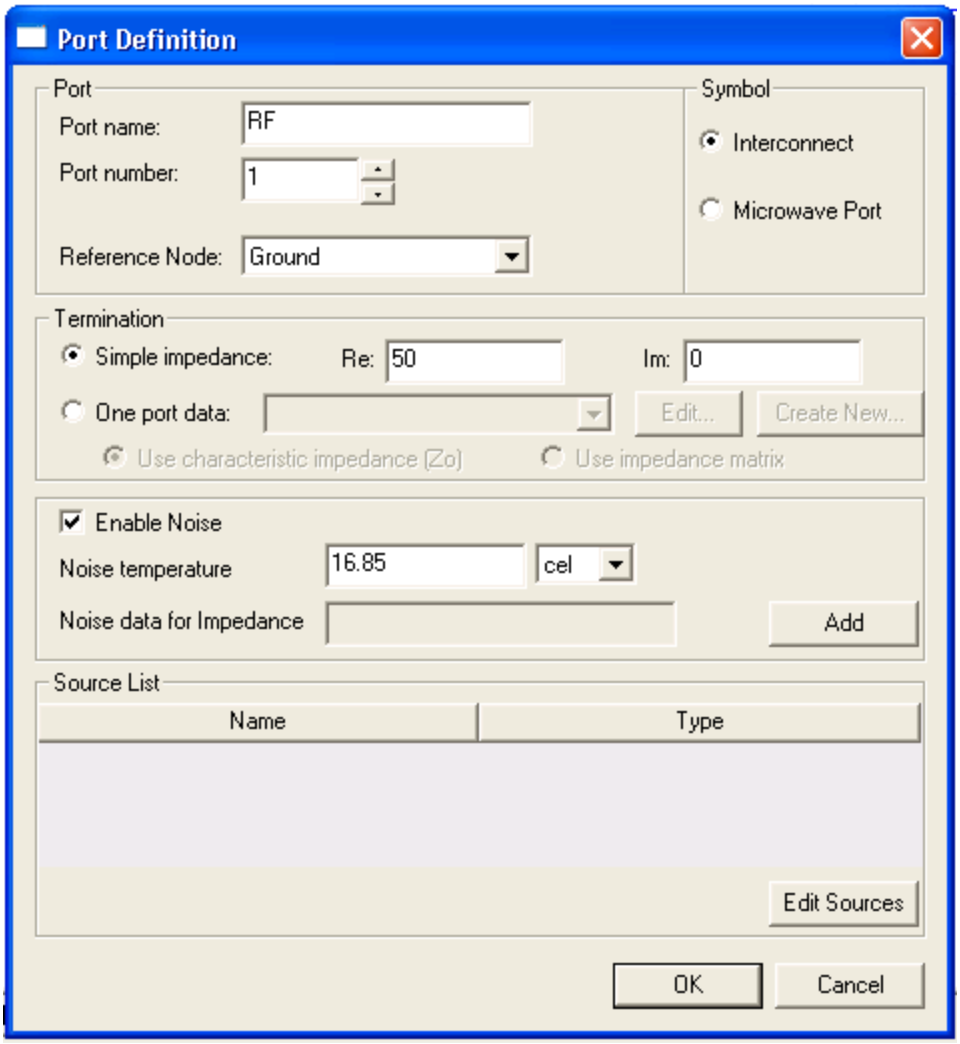
3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

Perform a Time-Varying Noise Analysis

To enable periodic time-varying noise (TV noise) analysis, the input port definition should include noise data.

1. Right-click the **RF** interface port at the left of the schematic and select **Edit Port** on the menu. The **Port Definition** window opens:

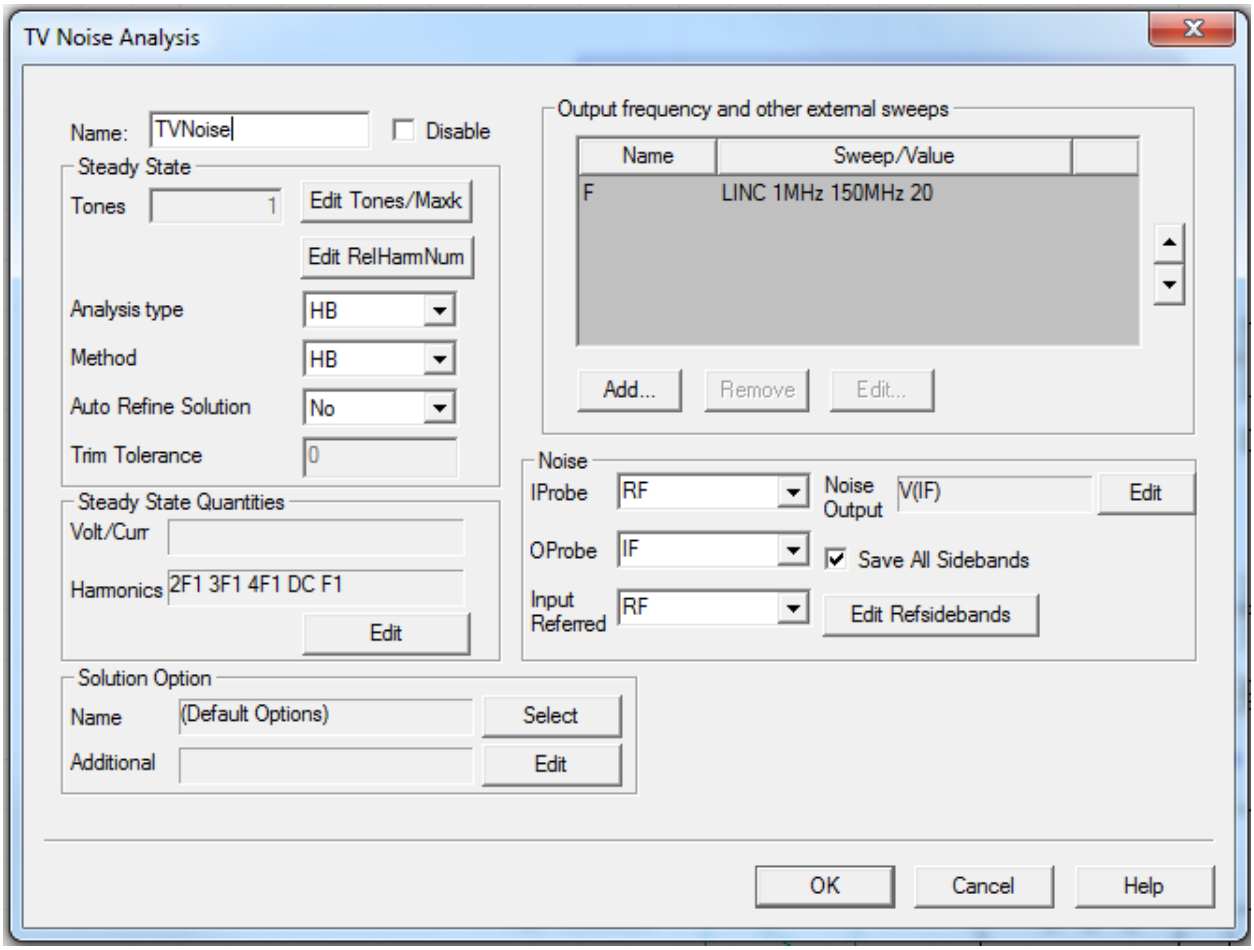
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Verify that the **Enable Noise** check box is checked as shown in the illustration above.
- Click **OK** to close the **Port Definition** window.

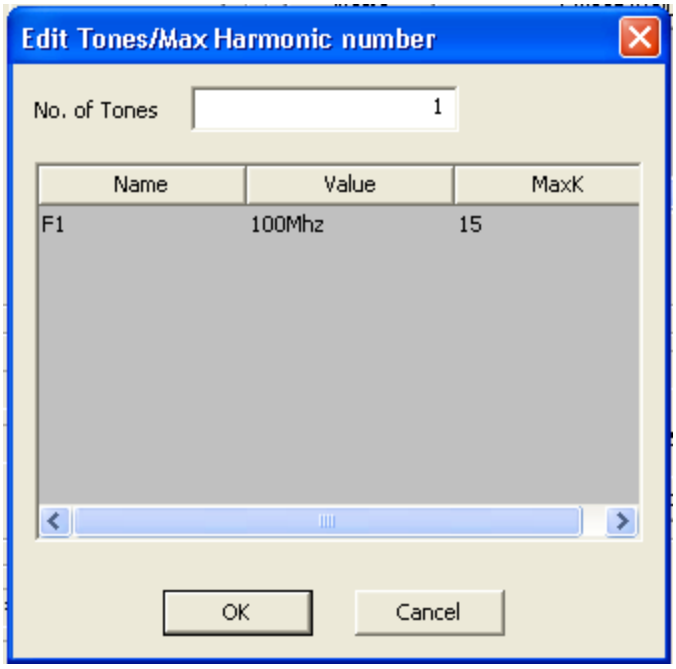
2. Expand the Analysis icon and double-click the **TVNoise** analysis setup. The **TV Noise Analysis** window opens:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



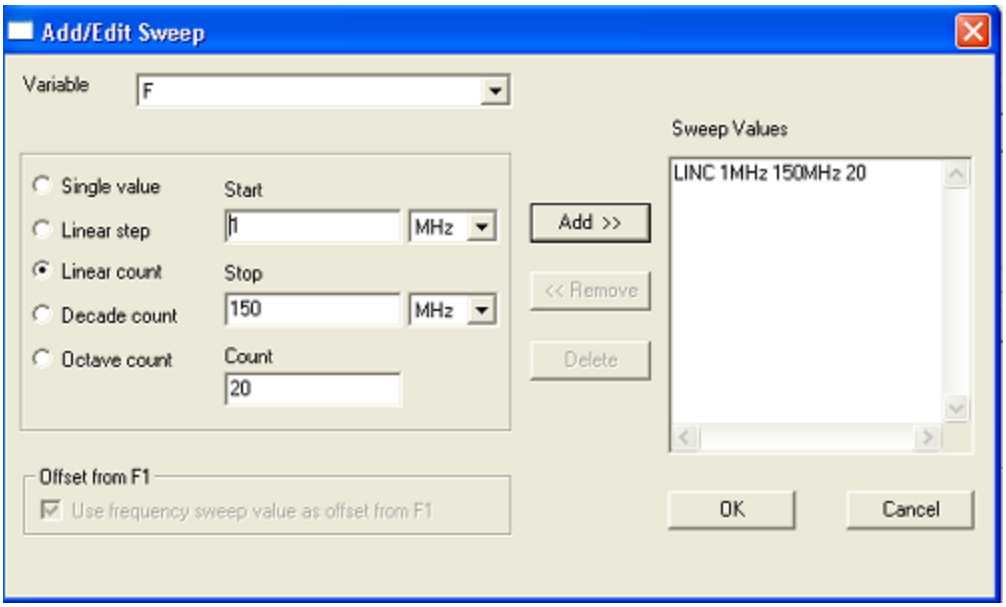
3. Verify that the **Analysis Type** is HB, the **Method** is HB, **Auto Refine Solution** is **No**, and the **Trim Tolerance** field is inactive (0).
4. Click **Edit Tones/Maxk** in the **Steady State** group box.
5. The **Edit Tones/Max Harmonic Number** window opens:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- **T** he **No. of Tones** is **1**.
- F1 is the frequency for the harmonic balance calculations. The **Value** field is **100MHz**.
- **15** is the **MaxK** field. **MaxK** specifies the highest harmonic to use in the harmonic balance calculations that underlie the TV Noise analysis.
- Click **OK** to close the **Edit Tones/Max Harmonic Number** window and return to the **TV Noise Analysis** window.

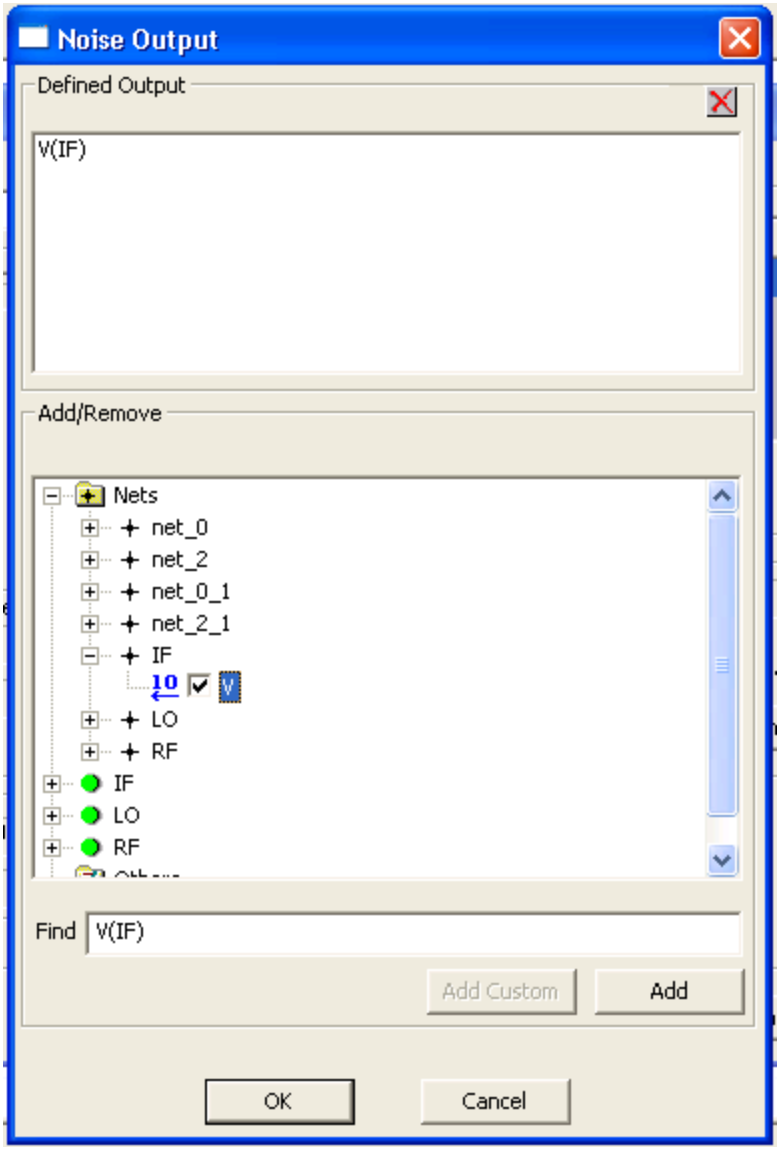
6. In the **Output frequency and other external sweeps** group box, click **Edit** to open the **Add/Edit Sweep** window.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Ensure **F** is showing in the **Variable** field.
- Select **Linear Count**.
- Enter **1** in the **Start** field. Use the drop-down menu to select **MHz** as the unit.
- Enter **150** in the **Stop** field. Use the drop-down menu to select **MHz** at the unit.
- Enter **20** in the **Count** field.
- Click **Add**. The sweep specification appears in the **Sweep Values** display.
- Click **OK** to close the **Add/Edit Sweep** window and return to the **TV Noise Analysis** window.

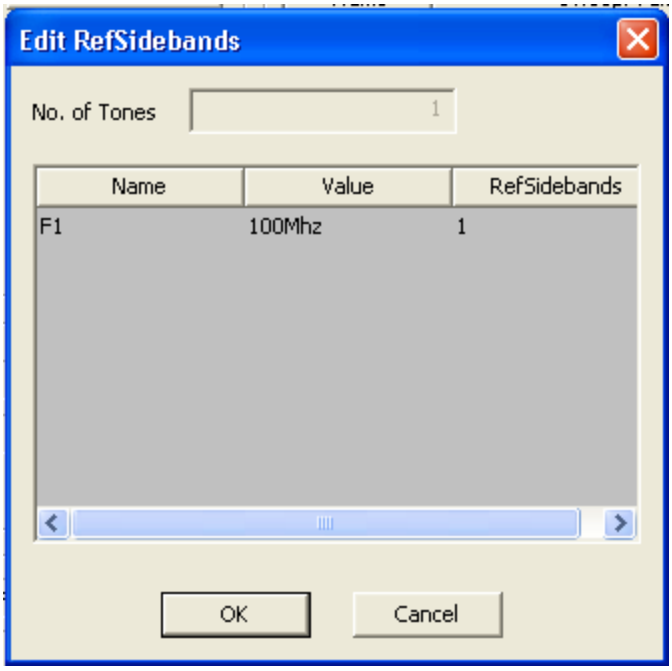
7. In the **Noise** group box, select **RF** aand **IF** on the **IProbe** and **OProbe** drop-down menus.
8. Click **Edit** on the **Noise Output** field to open the **Noise Output** window:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Expand the **Nets** icon, the **IF** icon, then click the **V** group box as shown in the preceding figure. Click **Add**. The entry V(IF) appears in the **Defined Output** field.
- Click **OK** to close the **Noise Output** window and return to the **TV Noise Analysis** window.

9. Selecting a noise output enables the **Input Referred** field. Select **RF** on the drop-down menu.
10. Click the **Save All Sidebands** group box. click **Edit Refsidebands** to view the sidebands settings:



11. Click **OK** to close **EditRefSidebands** window.
12. Click **OK** to close the **TV Noise Analysis** window.
13. Expand the **Analysis** icon in the Project window, right-click the **TVNoise** solution setup, and select **Analyze** on the menu. The TV noise analysis runs. The **Progress** window displays a red line to show the progress of the analysis.

When the analysis has completed, the results are available, including: the Noise Figure (NF) and the Power Conversion Gain (CG).

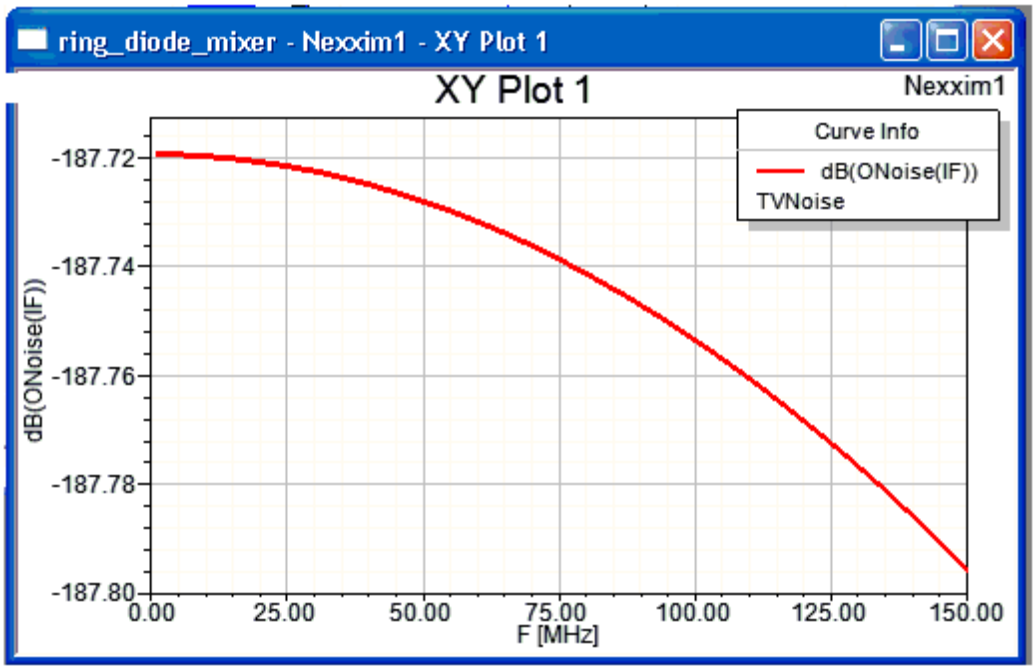
1. Right-click the **Results** icon in the **Project Manager** window and select **Create Standard Report > Rectangular Plot**.
2. The **Report** window opens with the **Trace** tab selected.

- Select **TVNoise** on the **Solution** drop-down.
- Select **Noise** on the **Domain** drop-down.
- Select **Noise** in the **Category** group box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Select **Onoise(IF)** in the **Quantity** list.
- Select **dB** in the **Function** group box.
- Click **New Report**.
- Click **Close** to close the **Report** window.

3. The Report window opens with a graph of the result:

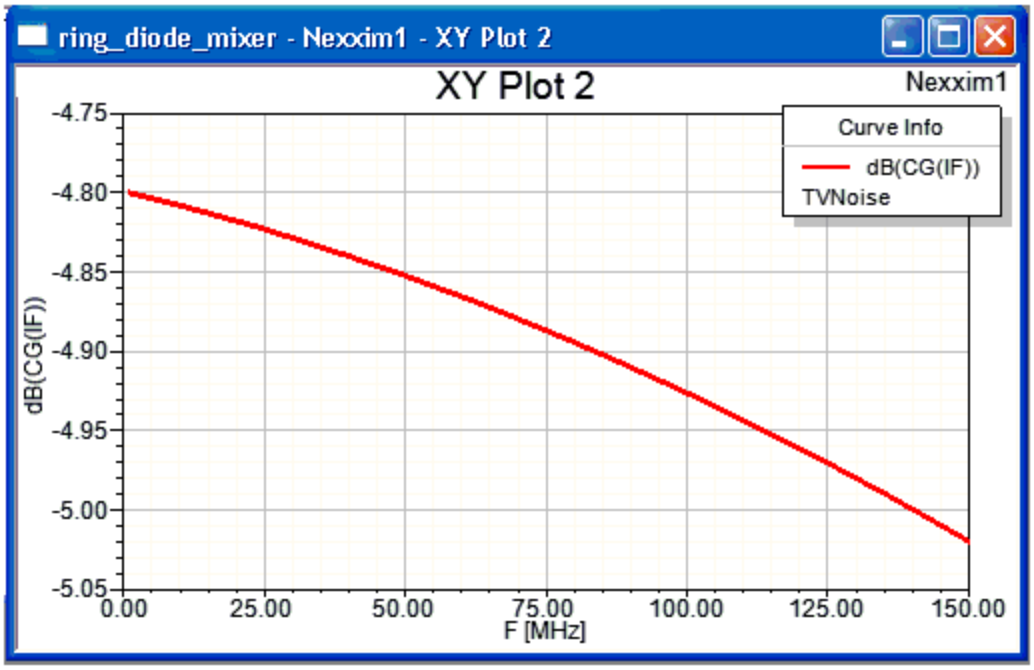


4. Right-clickce more on the **Results** icon in the **Project Manager** window and select **Create Standard Report > Rectangular Plot**.
5. The **Report** window opens with the **Trace** tab selected.

- Select **TVNoise** on the **Solution** drop-down.
- Select **Noise** on the **Domain** drop-down.
- Select **Power Conversion Gain** in the **Category** list.
- Select **CG(V(IF))** in the **Quantity** list.
- Select **dB** in the **Function** group box.
- Click **New Report**.
- Click **Close** to close the **Report** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. The Report window opens with a graph of the result:



Perform a Periodic Transfer Function Analysis

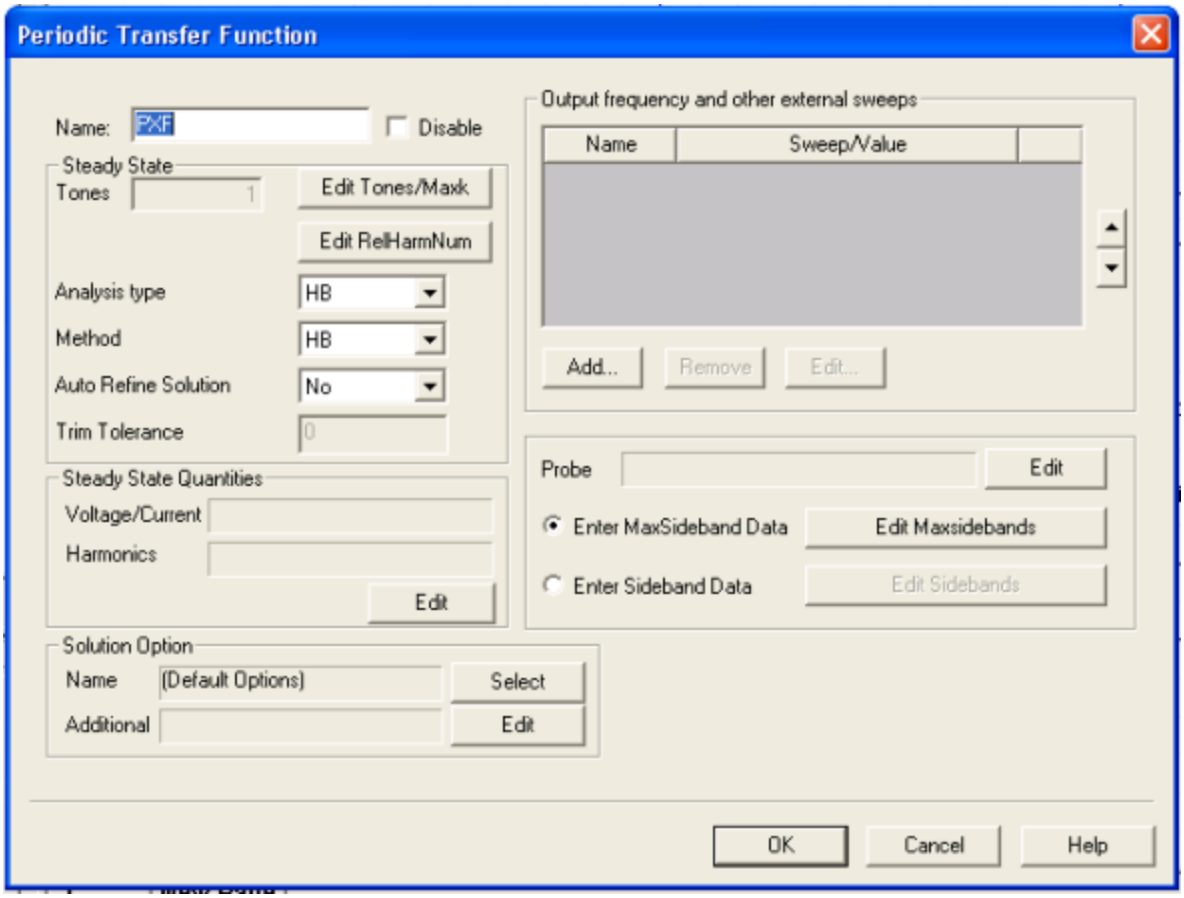
Periodic transfer function (PXF) analysis computes the small-signal transfer function from selected voltage and current sources in the circuit to a specified single output at a frequency that can be swept. A steady-state HB or OSC analysis first computes the periodic or quasi-periodic operating point, on which the small-signal PXF analysis is calculated. In Nexxim, PXF analysis is an extension of time-varying noise analysis.

Use the ring diode mixer to demonstrate periodic transfer function analysis.

1. From the **Circuit** menu, select **Add Nexxim Solution Setup** > **Periodic Transfer Function (PXF)**.

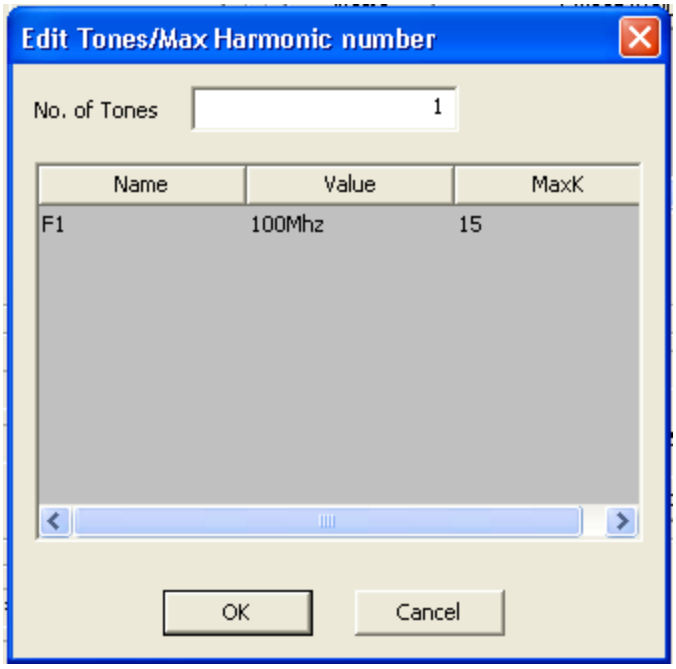
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. The Periodic Transfer Function setup window opens:



3. Verify that the **Analysis Type** is HB, the **Method** is HB, **Auto Refine Solution** is No, and the **Trim Tolerance** field is inactive (0).
4. Click **Edit Tones/Maxk** in the **Steady State** group box.
5. The **Edit Tones/Max Harmonic Number** window opens:

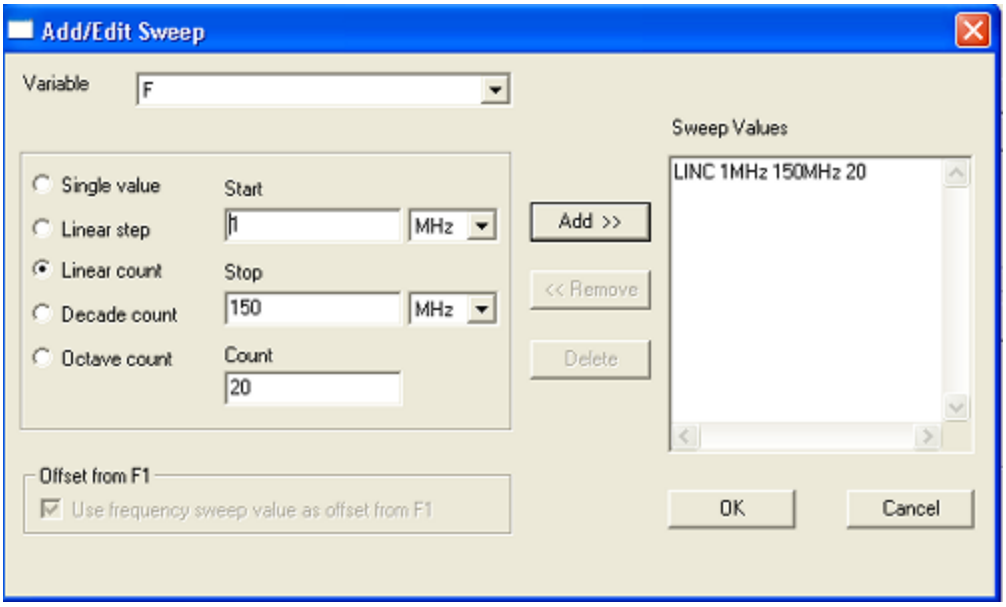
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Leave the default of **1** as the **No. of Tones**.
- Click the F1 line and click again on the **Value** field. Enter **100MHz** in the **Value** field. The value sets the frequency for the harmonic balance calculations.
- Enter **15** in the **MaxK** field. This specifies the highest harmonic to use in the harmonic balance calculations that underlie the Periodic Transfer Function analysis.
- Click **OK** to close the **Edit Tones/Max Harmonic Number** window and return to the **Periodic Transfer Function Analysis** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

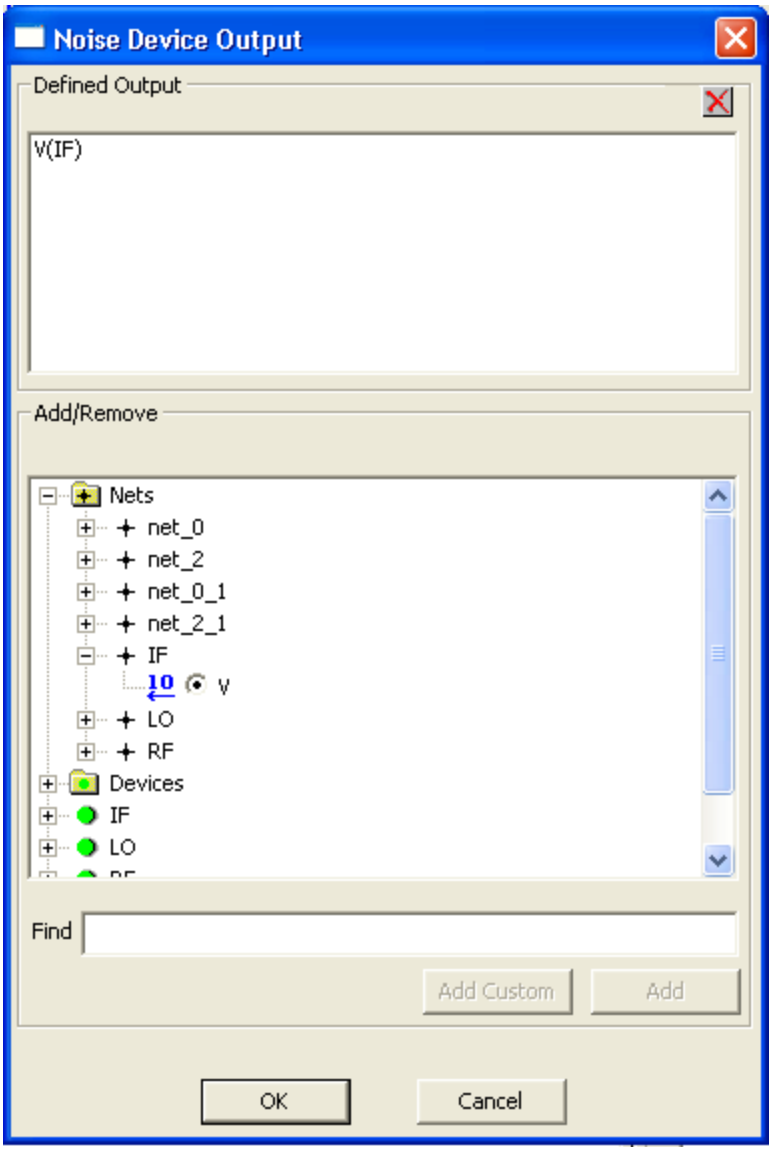
6. In the **Sweep Variables** group box, click **Add** to open the **Add/Edit Sweep** window.



- Ensure **F** is showing in the **Variable** field.
- Select **Linear Count**.
- Enter **1** in the **Start** field. Use the drop-down menu to select **MHz** as the unit.
- Enter **150** in the **Stop** field. Use the drop-down menu to select **MHz** at the unit.
- Enter **20** in the **Count** field.
- Click **Add**. The sweep specification appears in the **Sweep Values** display.
- Click **OK** to close the **Add/Edit Sweep** window and return to the **Periodic Transfer Function Analysis** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

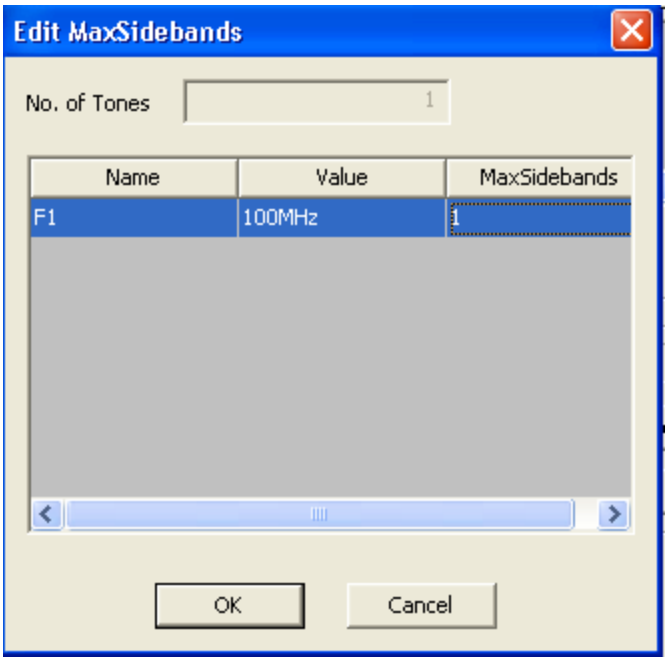
7. Click **Edit** on the **Probe** field to open the **Noise Device Output** window:



- Expand the **Nets** icon, the **IF** icon, then click the **V** group box as shown in the preceding figure. Click **Add**. The entry V(IF) appears in the **Defined Output** field.
- Click **OK** to close the **Noise Device Output** window and return to the **Periodic Transfer Function Analysis** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. Click **Edit Maxsidebands** to open the **Edit MaxSidebands** window:



- The F1 and 100MHz values are automatically inserted in the window.
- Click the **MaxSidebands** field and enter **1**.
- Click **OK** to close the **Edit MaxSidebands** window and return to the **Periodic Transfer Function Analysis** window.
- Click **OK** to close the **Periodic Transfer Function Analysis** window.

9. Select the **Projects** tab in the Project window. Expand the **Analysis** icon and right-click the **Periodic Transfer Function** solution setup. Select **Browse Netlist** from the menu. The Netlist Editor opens to show the netlist that has been created for the circuit and the solution setup. Here is the solution setup:

```
* end toplevel circuit
.TV_NOISE
+ LIN 20 1000000 150000000
+ PROBE=[v(if)]
+ SS_MAXK=[15]
+ SS_TONES=[1000000000]
+ MAXSIDEDAND-[1]
+ SS_ANALYSIS=HB
+ METHOD=HB
+ AUTO_REFINE_SOLUTION=No
+ PXF=1

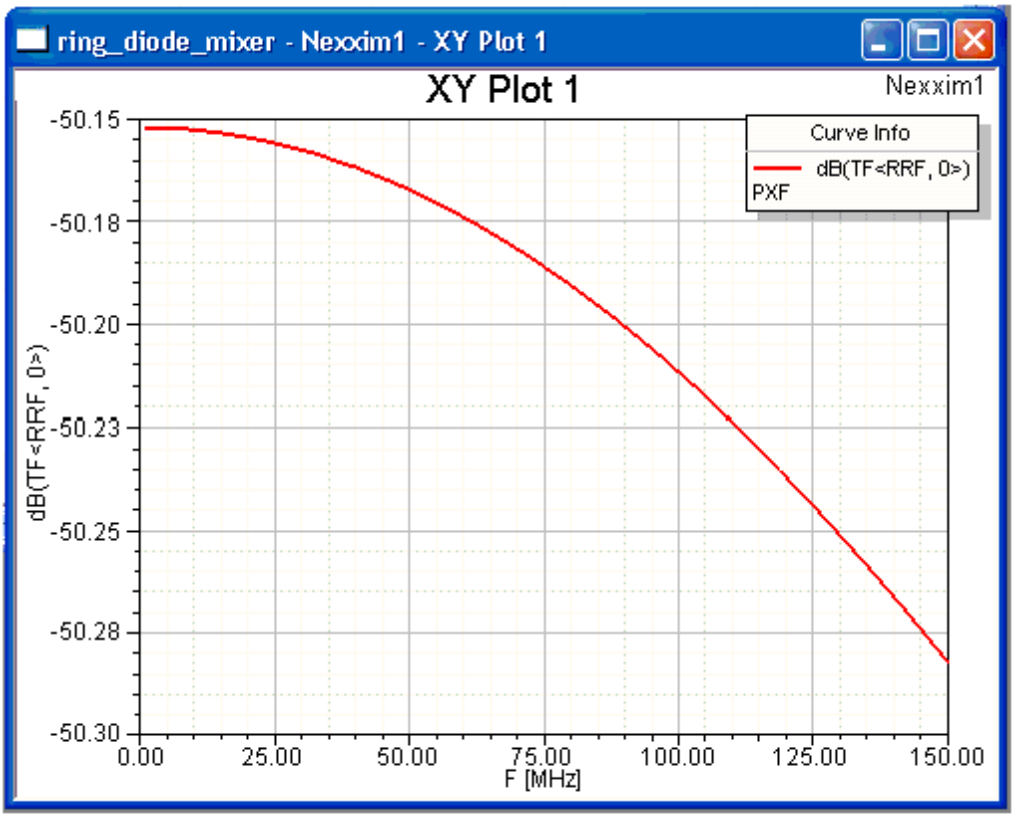
.end
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

10. Right-click the **Periodic Transfer Function** solution setup and select **Analyze** on the menu. The PXF analysis runs. The Progress window displays a red line to show the progress of the analysis.

When the analysis has completed, the results are available. Compare the PXF analysis result to the Power Conversion Gain (CG) on the TV Noise analysis.

11. Right-click the **Results** icon in the **Project Manager** window and select **Create Standard Report > Rectangular Plot**.
12. The **Report** window opens with the **Trace** tab selected.
    - Select **PXF** on the Solution drop-down.
    - Select **Transfer Function** on the **Domain** drop-down.
    - Select **Transfer Function** in the **Category** list.
    - Select **TF(RRF,0)** in the **Quantity** list.
    - Select **dB** in the **Function** group box.
    - Click **New Report**, then click **Close** to close the **Report** window and generate the report.



13. You can verify that this graph is identical to the Conversion Gain graph on the TV Noise analysis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

14. Close the Project when you are finished viewing the graph.
15. Exit **Electronics Desktop** by selecting **Exit** on the **File** drop-down, or by clicking the X at the upper-right of the window.

For more information, see Nexxim Time-Varying Noise Analysis.

Loadpull Analysis Example

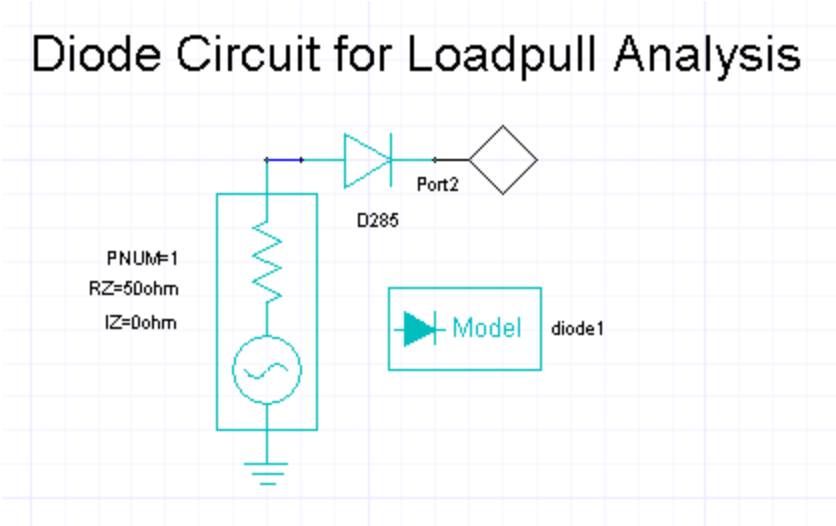
This example demonstrates how to set up and perform a loadpull analysis using a circuit that consists of just a single diode. For more information see Loadpull Analysis.

Open the Loadpull Schematic

Open the Loadpull Schematic project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **RF_Microwave**, the **Amplifiers** directory, then select the file **Nexxim_Load_Pull_Schematic.aedt**. Click **Open**.

The schematic appears in the design window:



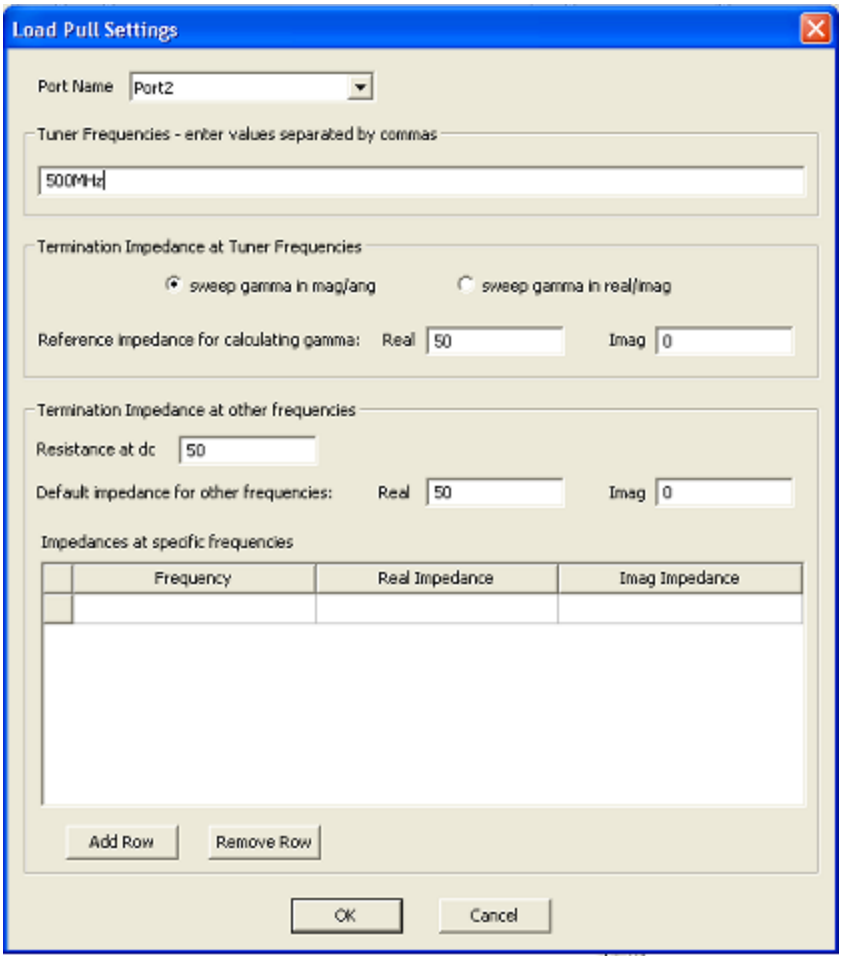
3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Set Up a Loadpull Analysis

1. Click the **Circuit** drop-down menu on the menu and select **Add Nexxim Solution Setup,** then choose **Harmonic Balance(1-Tone**) to open the **Harmonic Balance Analysis, 1-Tone** setup window.

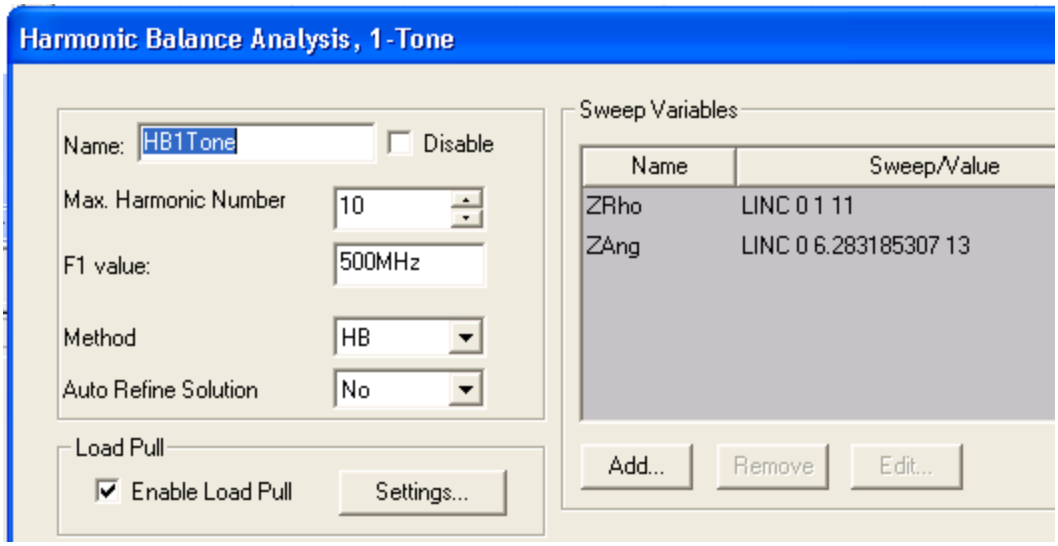
- In the upper-left corner of the window, select **10** as the **Max Harmonic Number**.
- Set the **F1** value to **500MHz**.
- Verify that the **Method** is **HB** and **Auto Refine Solution** is **No**.
- Click **Enable Load Pull**. The **Load Pull Settings** window opens:



- Choose **Port2** on the **Port Name** drop-down menu.
- Enter **500MHz** as the **Tuner Frequency**.
- Verify that the termination impedances at the tuner frequency and at frequencies other than the tuner frequency are the defaults (50 Ohm), and that **sweep gamma in mag/ang** is selected.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Click **OK** to close the **Load Pull Settings** window and return to the **Harmonic Balance Analysis, 1-Tone** setup window. The completed window should look like the following:



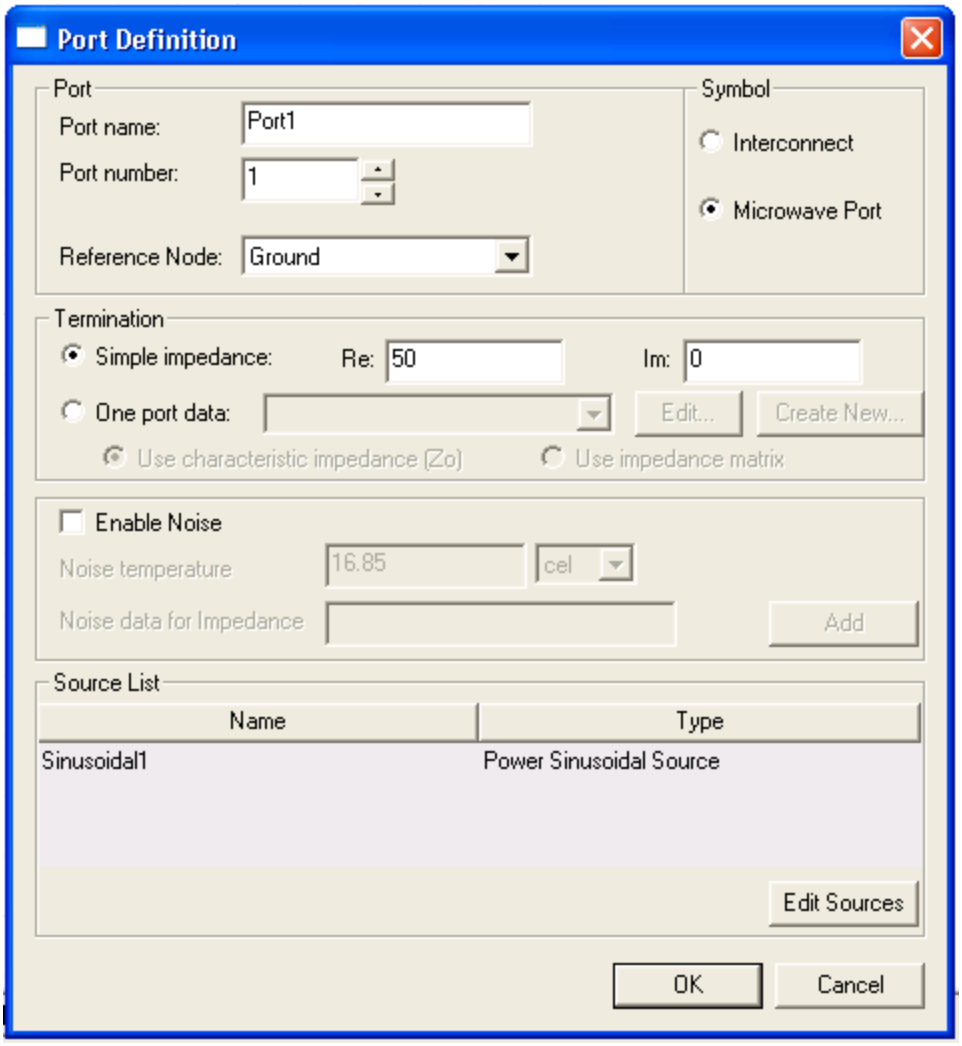
- Note that sweeps have been set up for **ZRho** and **ZAng**. These variables set the output load. Sweeping the output load generates the loadpull data.
- Click **OK** to close the **Harmonic Balance, 1-Tone** setup window.

Check the Port1 Source

Nexxim allows you to configure any number of ports and sources, and associate each source to run only for certain analyses. This example has only one source and only one analysis.

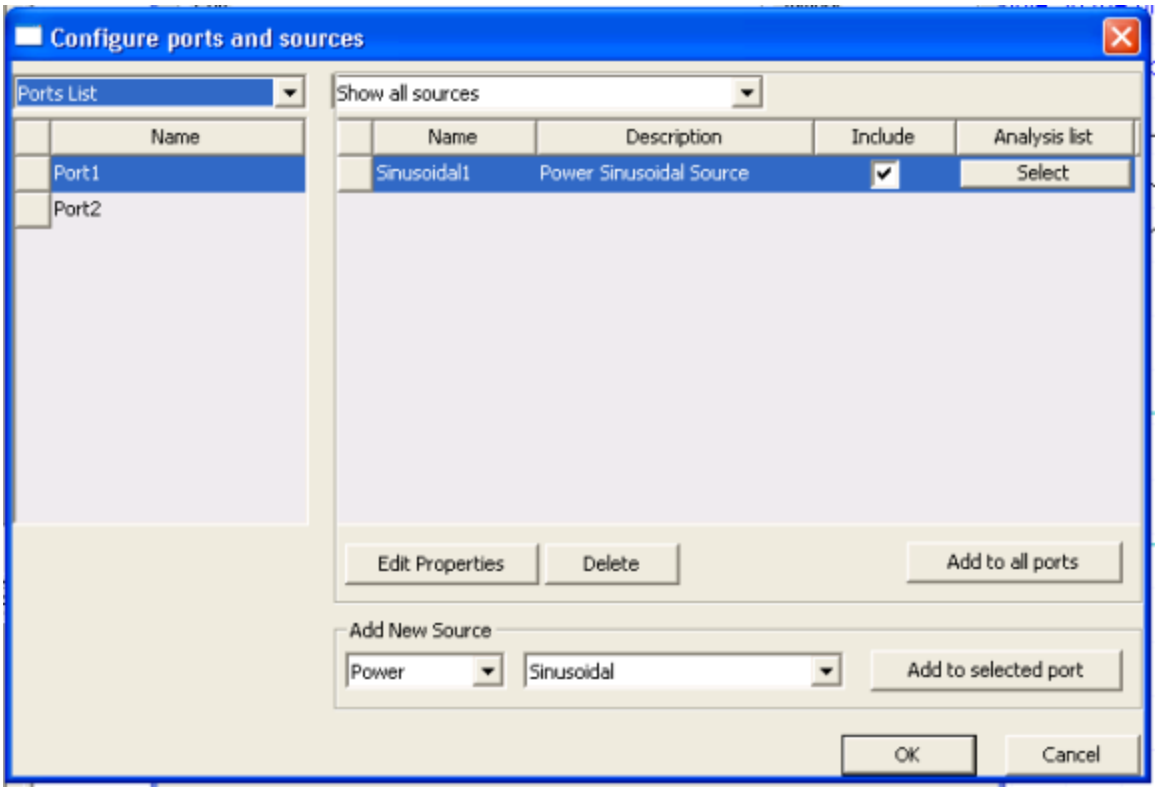
1. Right-click Port 1 (PNUM=1), and select **Edit Port** on the menu. The **Port Definition** window opens:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

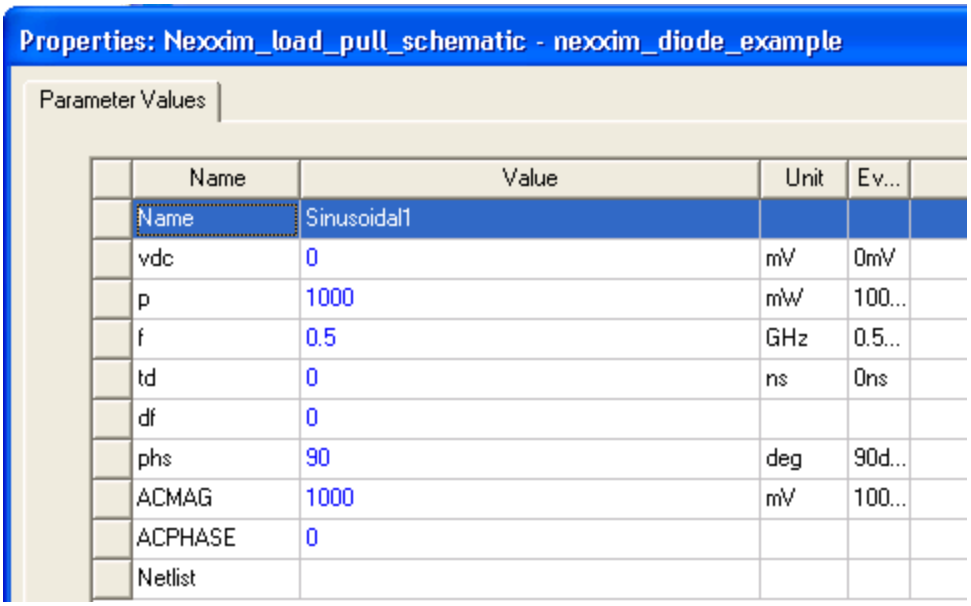


2. Port 1 has been set up as a sinusoidal power source. To review the setup, click **Edit Sources** to open the **Configure ports and sources** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



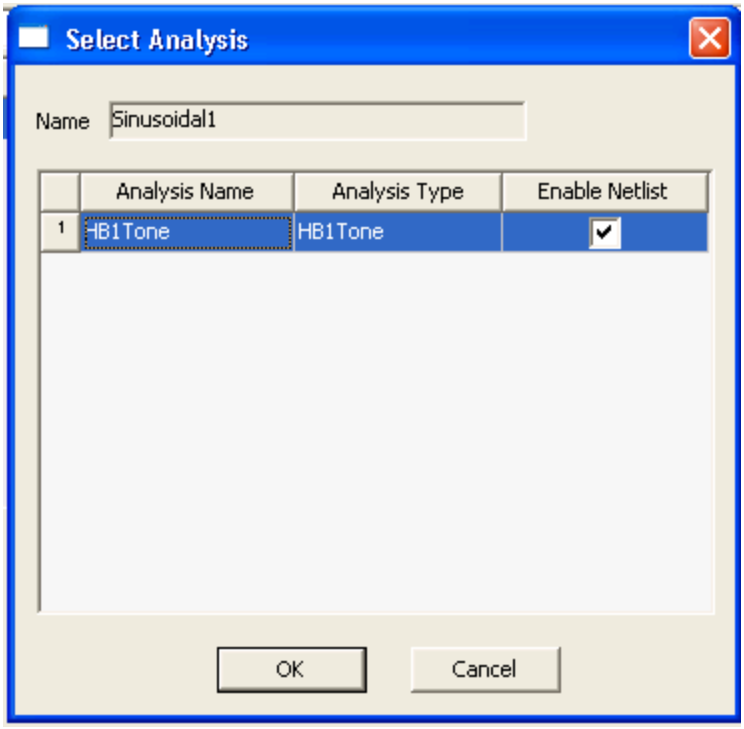
3. To view the source definition, click Edit Properties. The **Properties** window opens:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Verify that the frequency (property **f**) is 0.5 GHZ (500MHz).
- Click **OK** to close the **Source Selection** window and return to the **Port Definition** window.

4. Click **OK** to close the **Properties** window and return to the **Configure ports and sources** window.
5. Click **Select** in the Analysis list column. The **Select Analysis** window opens:



Verify that the source is enabled for the harmonic balance loadpull analysis netlist. Click **OK** to return to the **Configure ports and sources** window. Click **OK** to return to the **Port Definition** window. Click **OK** to close the **Port Definition** window.

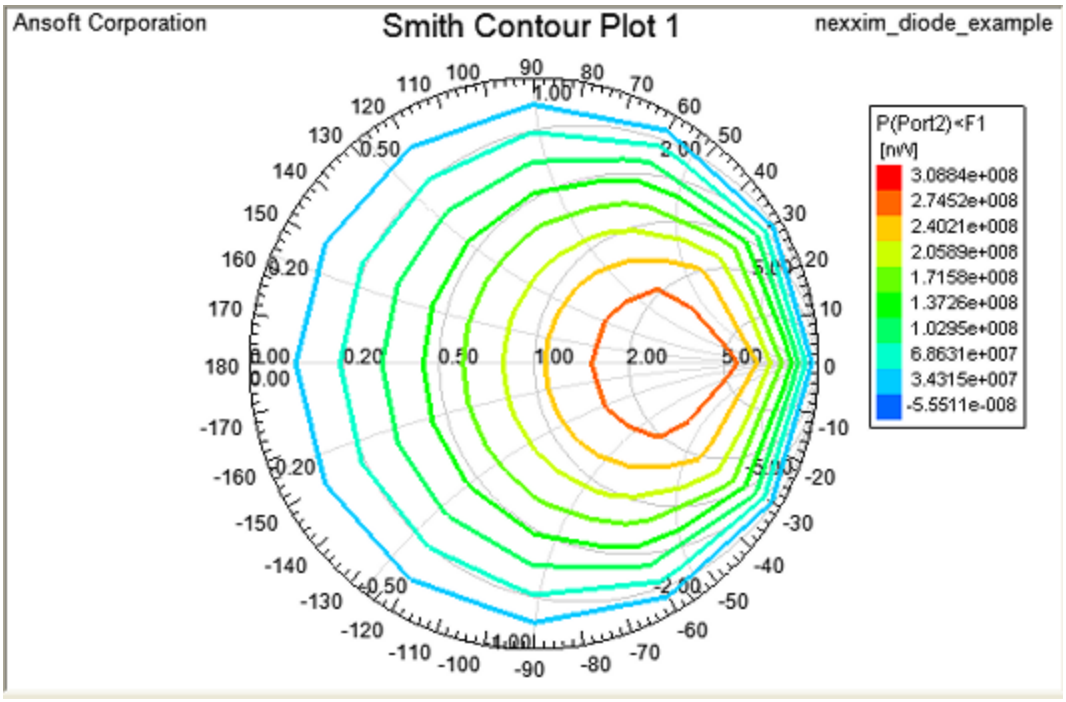
Run the Loadpull Analysis and View the Results

1. Right-click the **HB1Tone** setup icon and select **Analyze**. The Progress window displays a red line to show the analysis as it performs the sweeps.
2. When the analysis is complete, right-click on the **Results** icon in the **Project Manager** window and select **Create LoadPull Report > Smith Contour Chart**.
3. The **Report** window opens with the **Trace** tab selected.

- Verify that **HB1Tone** is the **Solution** and **LoadpullContour** is the **Domain**.
- Select **Power** as the **Category**, **P(Port2)<F1>** as the **Quantity**, and **<None>** as the **Function** (loadpull results are automatically set in watts).
- Click **New Report**, then click **Close**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. The Report window opens with a Smith Chart showing the contour plots of the sweep results:



5. Close the Report window and the Project when you have finished viewing the graph.

Envelope Analysis Example

This example demonstrates how to set up and perform an envelope analysis using an amplifier circuit. For more information see Envelope Analysis.

Open the Amplifier Netlist

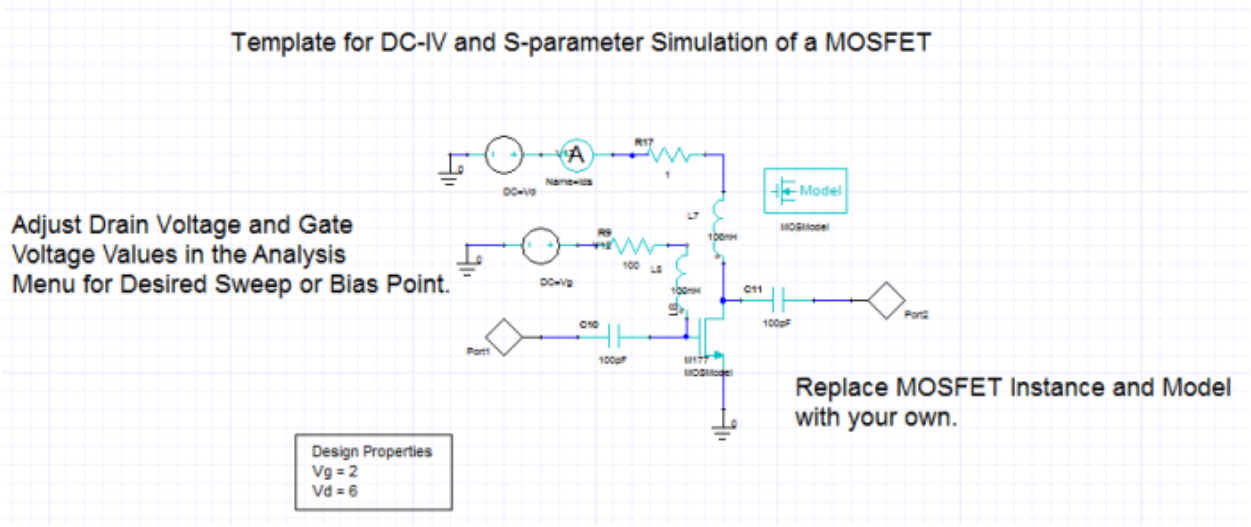
Envelope analysis allows us to evaluate the performance of the amplifier when it is stimulated by the IQ-data source.

Open the Amplifier project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **RF_Microwave**, the **Amplifiers** directory, then select the file **DifferentialAmplifier_Envelope.aedt**. Click **Open**.

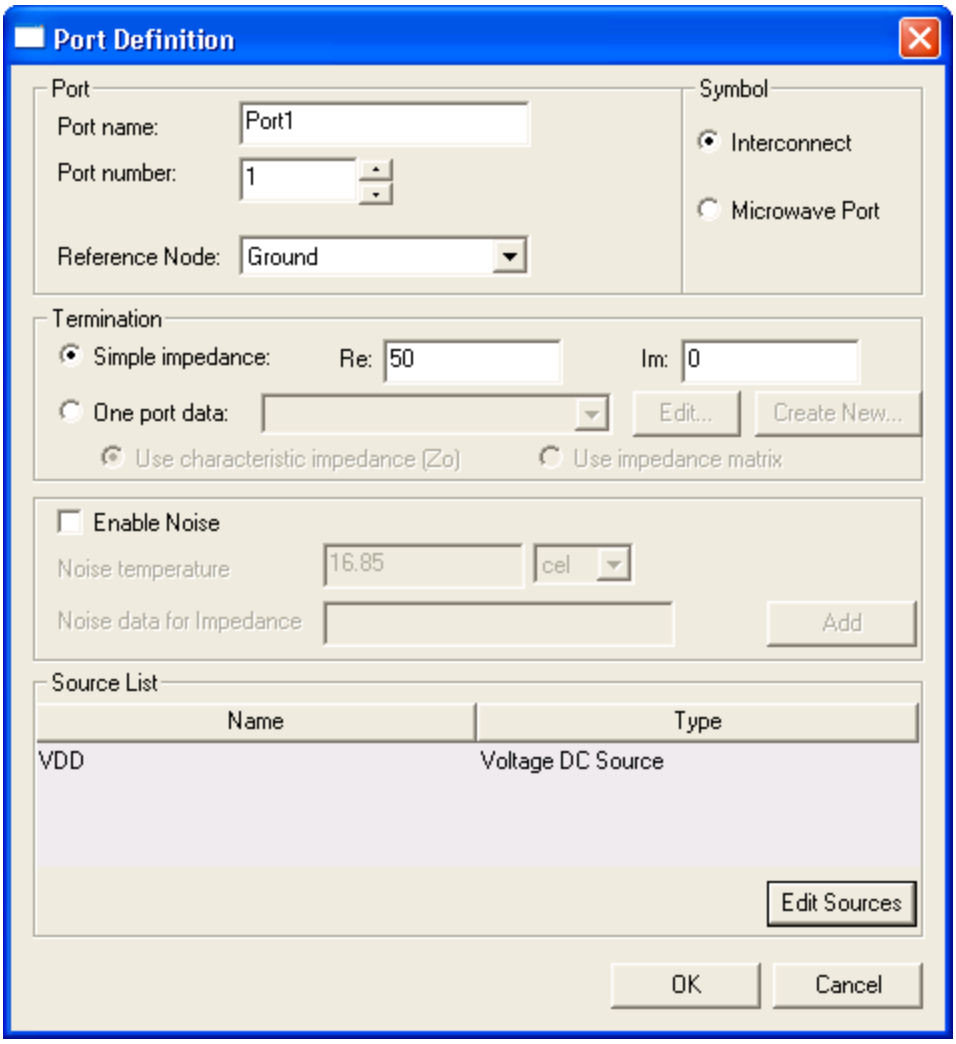
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The circuit opens in the **Schematic Editor** window.



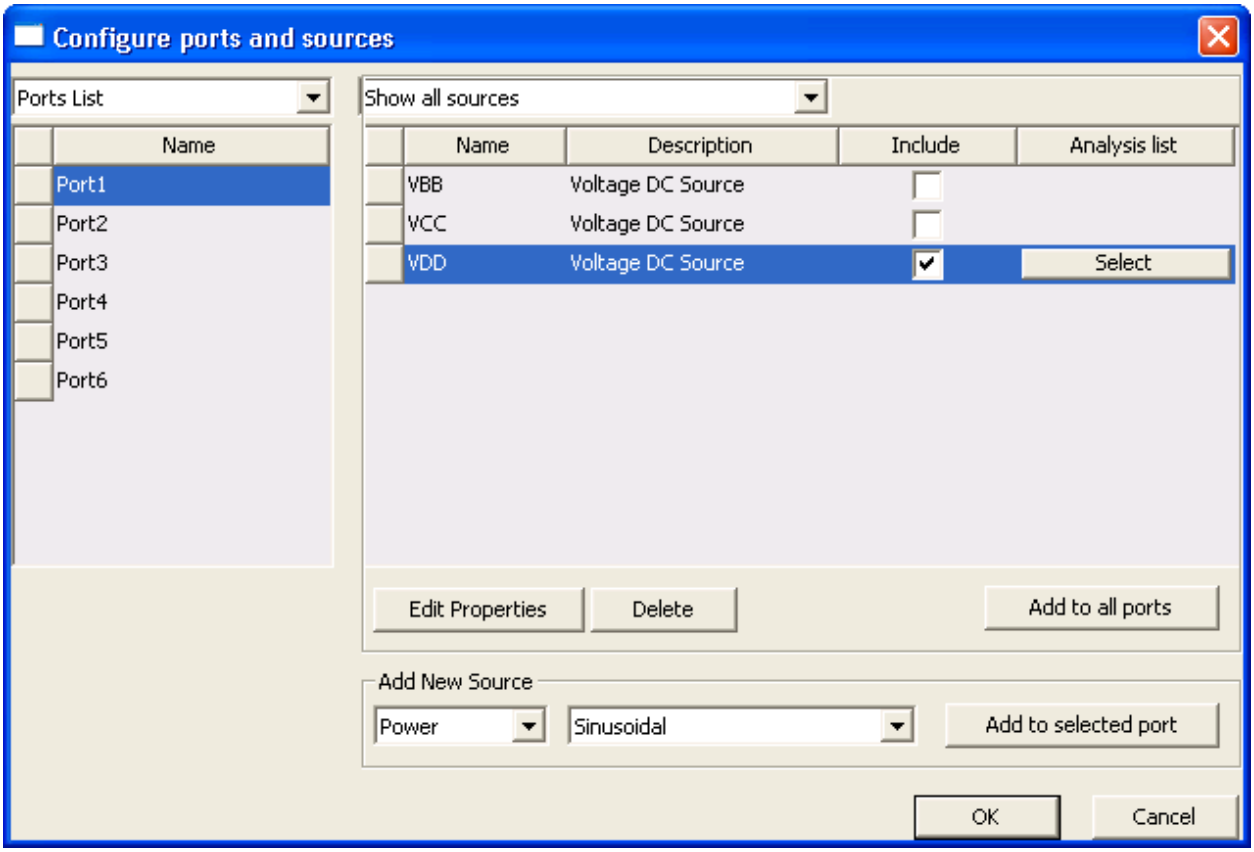
3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.
4. The differential amplifier consists of two transistors and seven resistors. The setup includes two VCVS sources and the IQ data source.
5. Select **Port 1** (or any port), right-click it, and select **Edit Port** to open the Port Definition window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



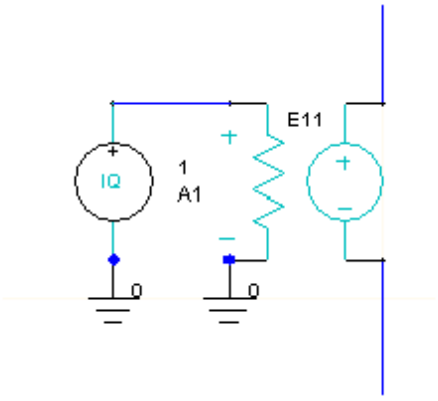
6. The **Source List** shows the voltage source connected to the port. Click **Edit Sources** to view the configuration window:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



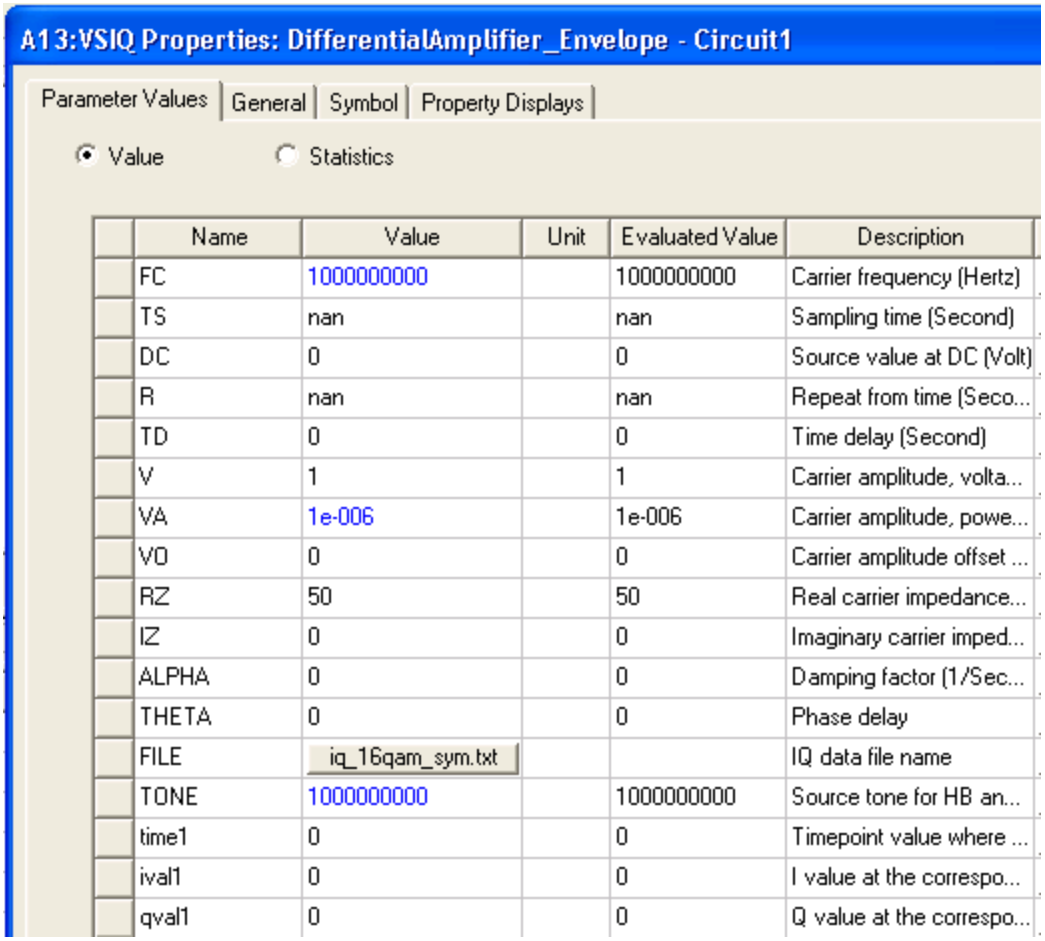
The window shows that six ports and three DC sources are defined. Click the ports to verify that Port 1 receives VDD (-3V), Ports 2 and 3 receive VBB (1.5V), Ports 4 and 5 receive VCC (15V). Port 6 is the output.

7. Here is the input portion of the schematic with the IQ Source:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. Select the IQ source and display its properties:

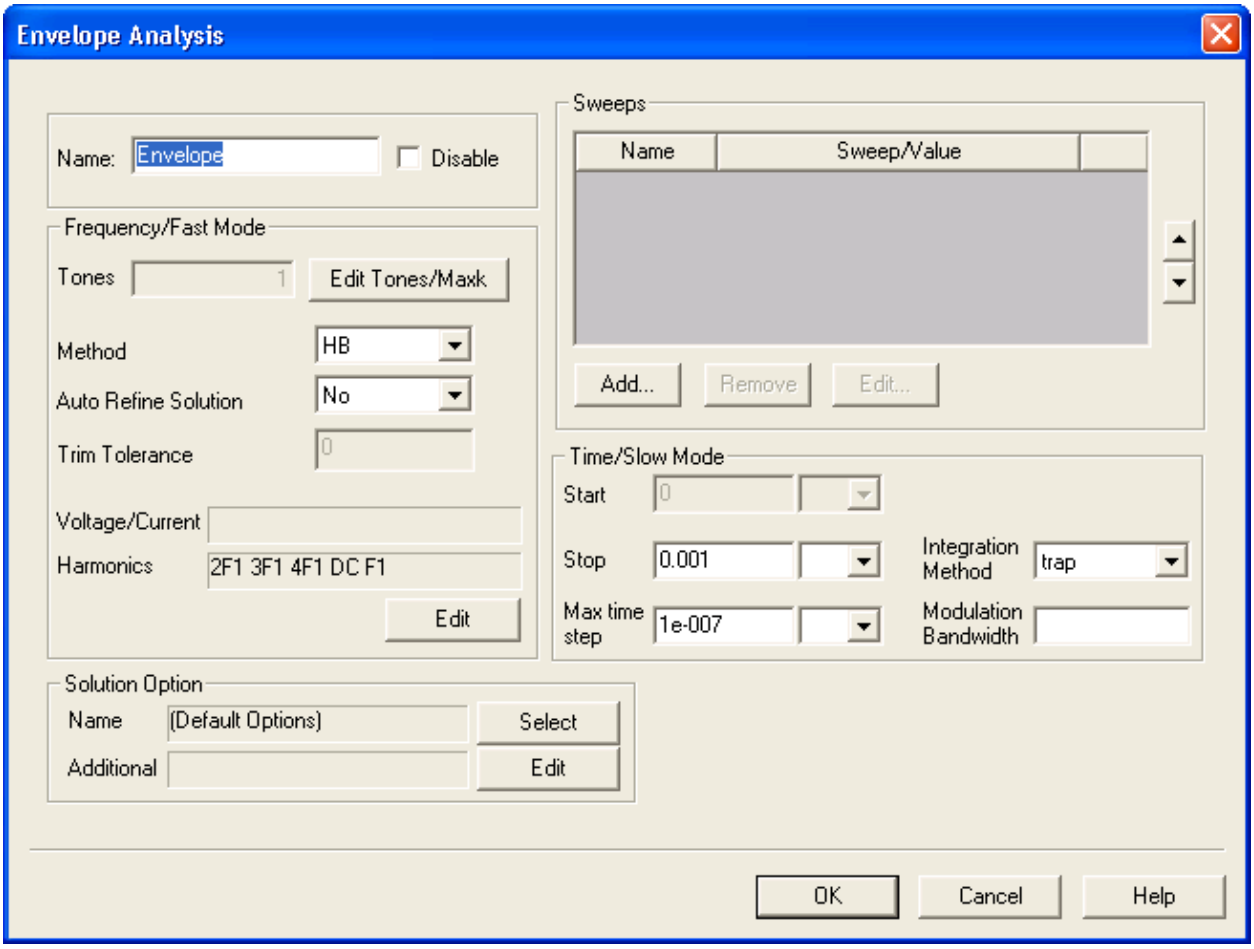


Name	Value	Unit	Evaluated Value	Description
FC	1000000000		1000000000	Carrier frequency (Hertz)
TS	nan		nan	Sampling time (Second)
DC	0		0	Source value at DC (Volt)
R	nan		nan	Repeat from time (Seco...
TD	0		0	Time delay (Second)
V	1		1	Carrier amplitude, volta...
VA	1e-006		1e-006	Carrier amplitude, powe...
VO	0		0	Carrier amplitude offset ...
RZ	50		50	Real carrier impedance...
IZ	0		0	Imaginary carrier imped...
ALPHA	0		0	Damping factor (1/Sec...
THETA	0		0	Phase delay
FILE	iq_16qam_sym.txt			IQ data file name
TONE	1000000000		1000000000	Source tone for HB an...
time1	0		0	Timepoint value where ...
ival1	0		0	I value at the correspo...
qval1	0		0	Q value at the correspo...

The carrier frequency FC is set to 1GHz, and the TONE parameter sets harmonic balance to use this frequency. The FILE parameter references the IQ data file, **iq_16qam_sym.txt**, in the Examples directory. You can open the data file with a text editor to view the time and data points.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9. Expand the Analysis icon and double-click the Envelope analysis:

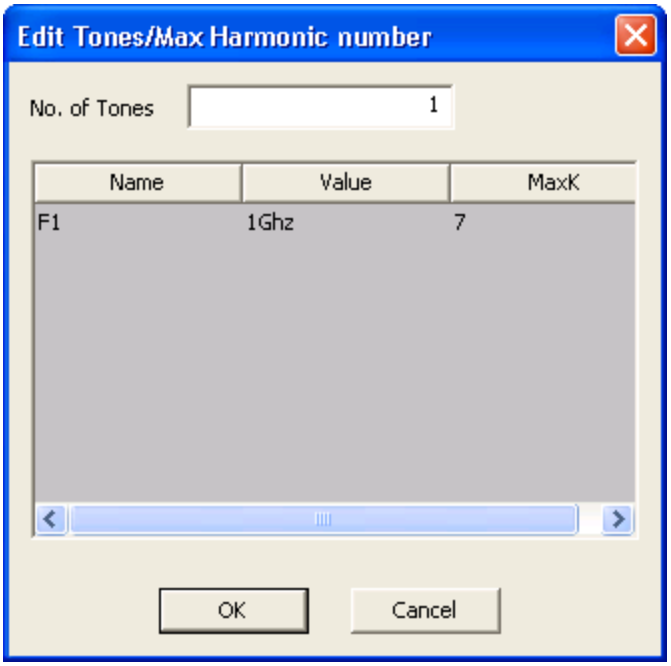


The setup implements the following parameters:

- The Method is **HB** (harmonic balance)
- The **Auto Refine Solution** option is **No**.
- The stop time is **0.001** seconds. This is less than the maximum time point in the IQ data file, **iq_qam_data.txt**.)
- The maximum timestep is set to **1e-007** seconds. This timestep is small enough to capture the envelope waveforms.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

10. Click **Edit Tones/Maxk**:



- The number of tones is **1**, and the **Frequency** is **1GHz**.
- The maximum harmonic number **MaxK** is **7** harmonics

11. Click **OK** to close the **Edit Tones** window, then click **OK** again to close the **Envelope Analysis** window.

Perform an Envelope Analysis

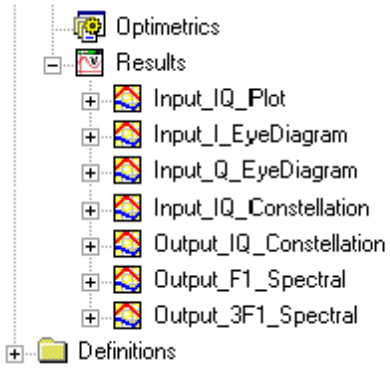
Right-click the **Envelope** analysis and select **Analyze** on the menu. The Progress window shows the progress of the dual simulations: transient analysis for the Time/Slow Mode and harmonic balance for the Frequency/Fast Mode.

View the Results of the Analyses

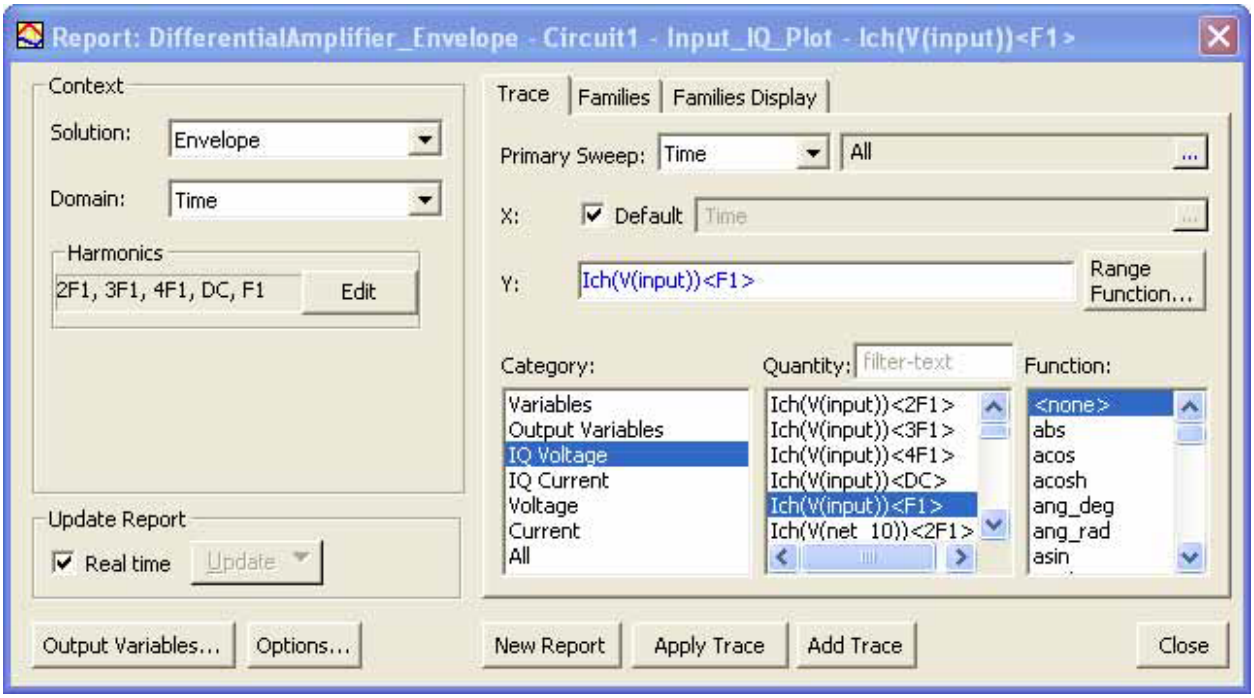
When the analyses have completed, the reports that have been set up become valid.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. From the **Project Manager** window, expand the **Results** icon:



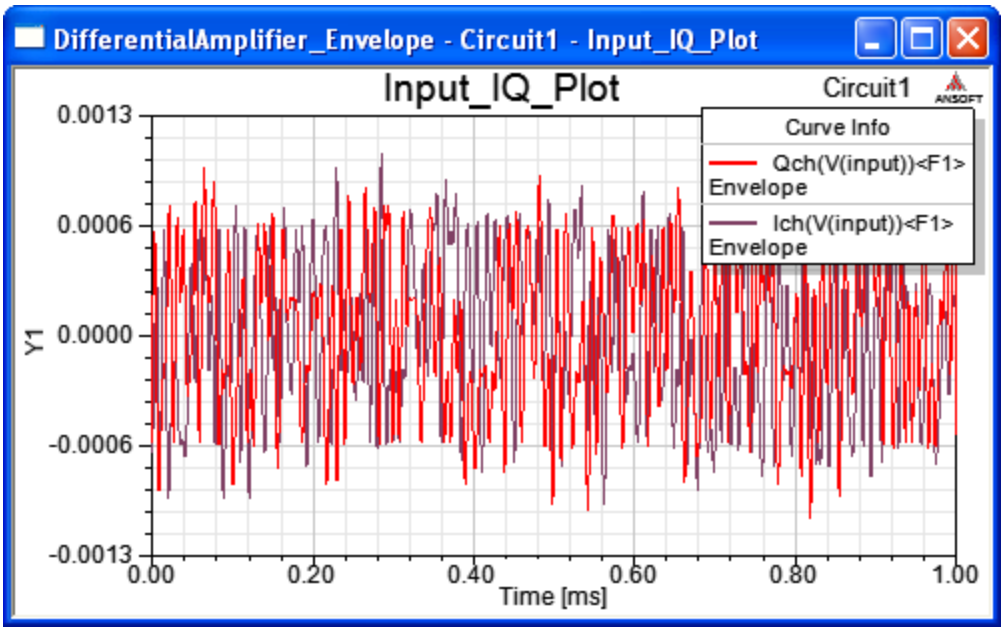
2. Right-click the **Input_IQ_Plot** report and select **Modify Report** to open the setup for the Rectangular Plot report:



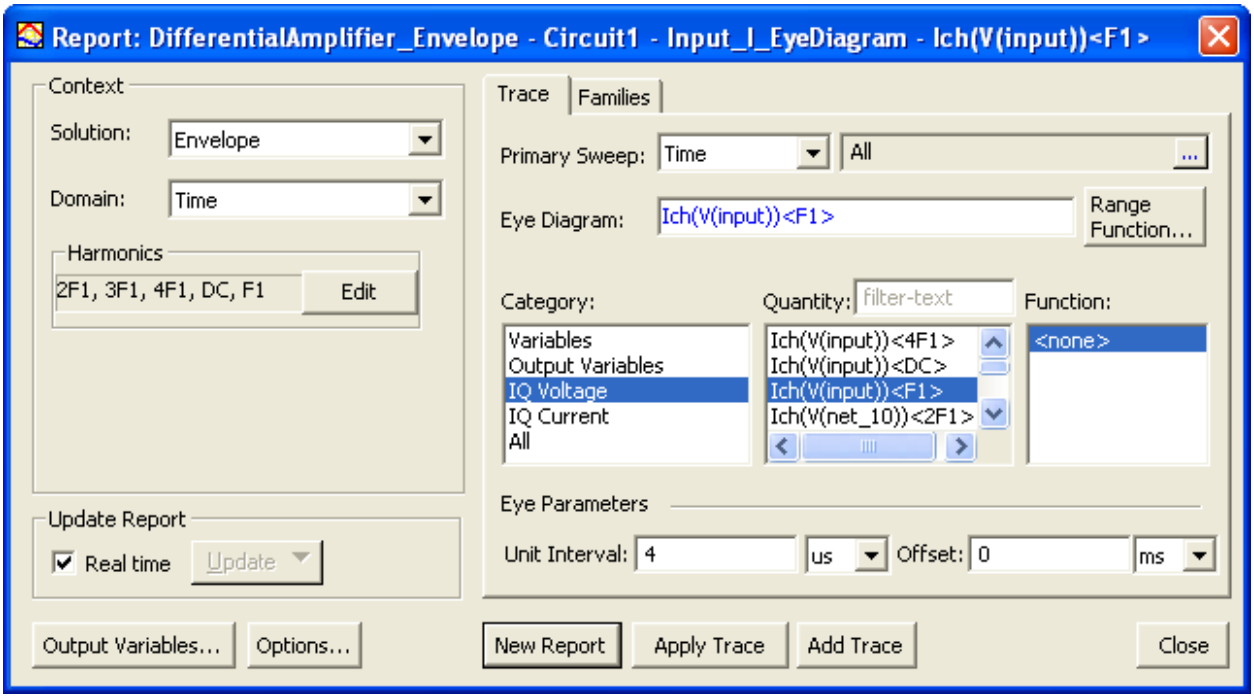
The IQ source drives input node **input** in our circuit. This window shows the setup for the In-quadrature (I) trace. The Q trace has a similar setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Double-click the **Input_IQ_Plot** report to view the input I-Q data against time:



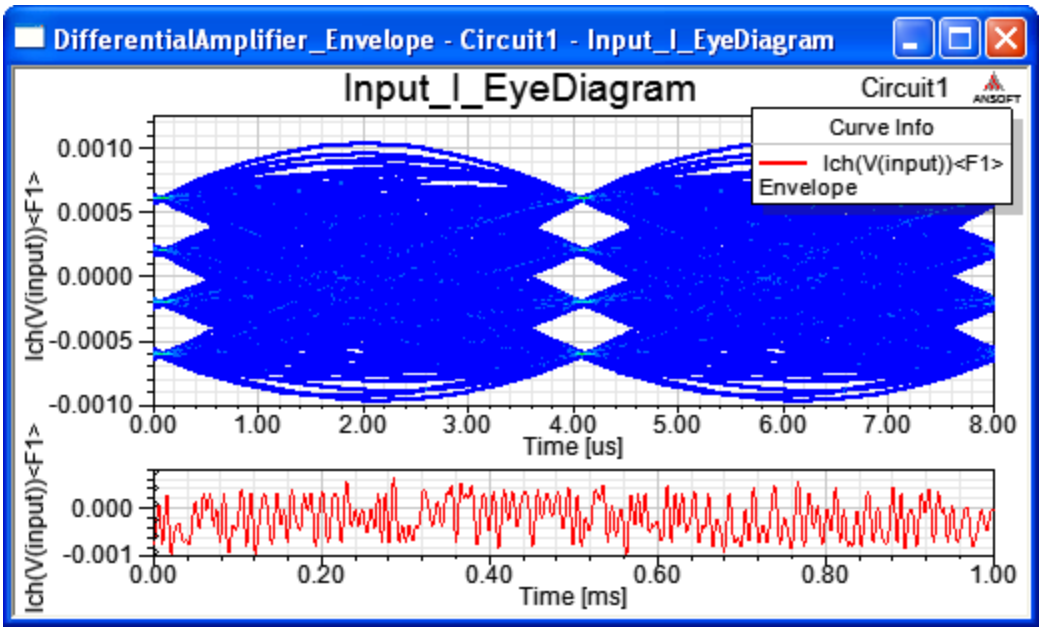
4. Right-click the **Input_I_EyeDiagram** report and select Modify report:



- The Unit Interval is equal to the symbol rate of 4µs.

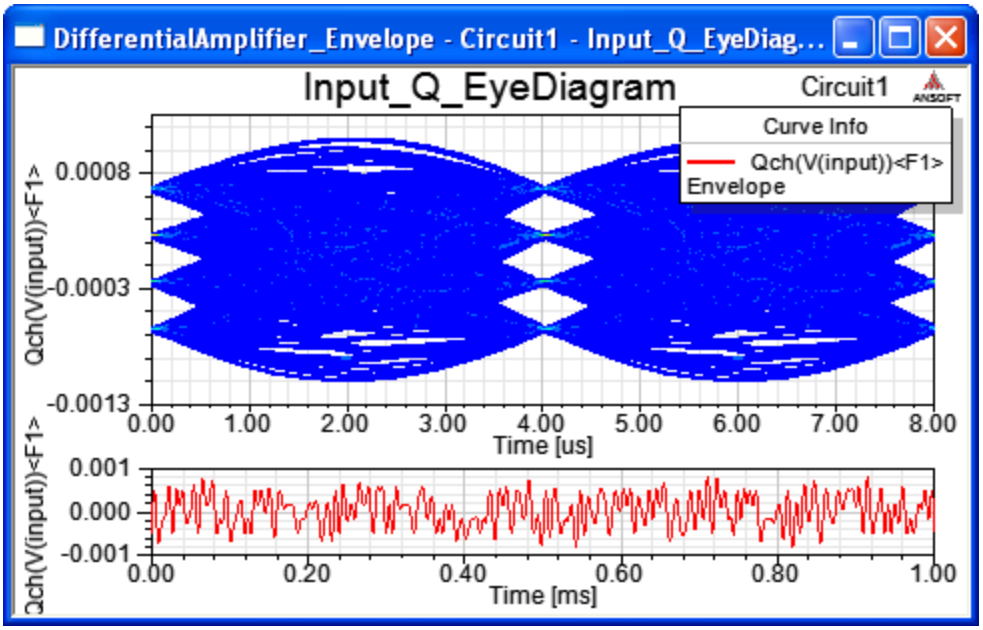
5. Double-click the **Input_I_EyeDiagram** report to view the I (in-quadrature) data as an eye diagram:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- The diagram illustrates the levels of amplitude (0.0006V, 0.0002V, -0.0002V,and -0.0006V) in the I-channel.

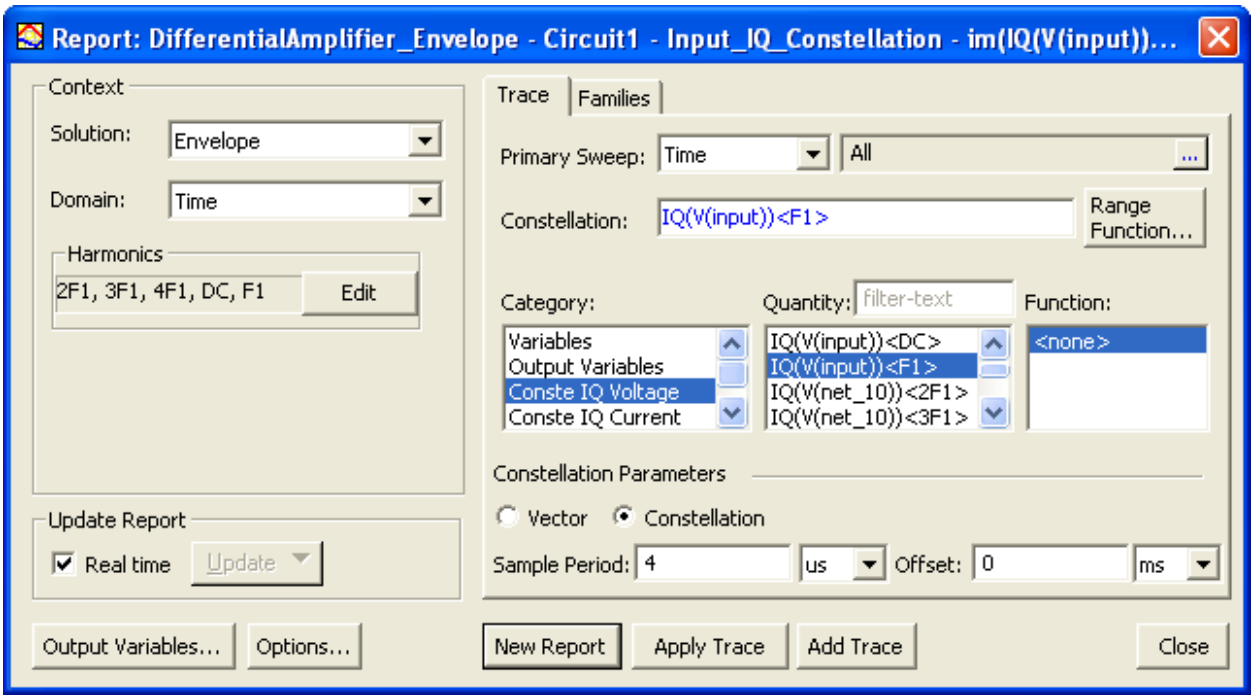
6. Right-click the **Input_Q_EyeDiagram** report to view the Q (quadrature) data as an eye diagram:



- This eye diagram was also created using a Unit Interval of 4µs.
- The diagram illustrates the levels of amplitude in the Q-channel, identical to those for the I-channel (0.0006V, 0.0002V, -0.0002V,and -0.0006V).

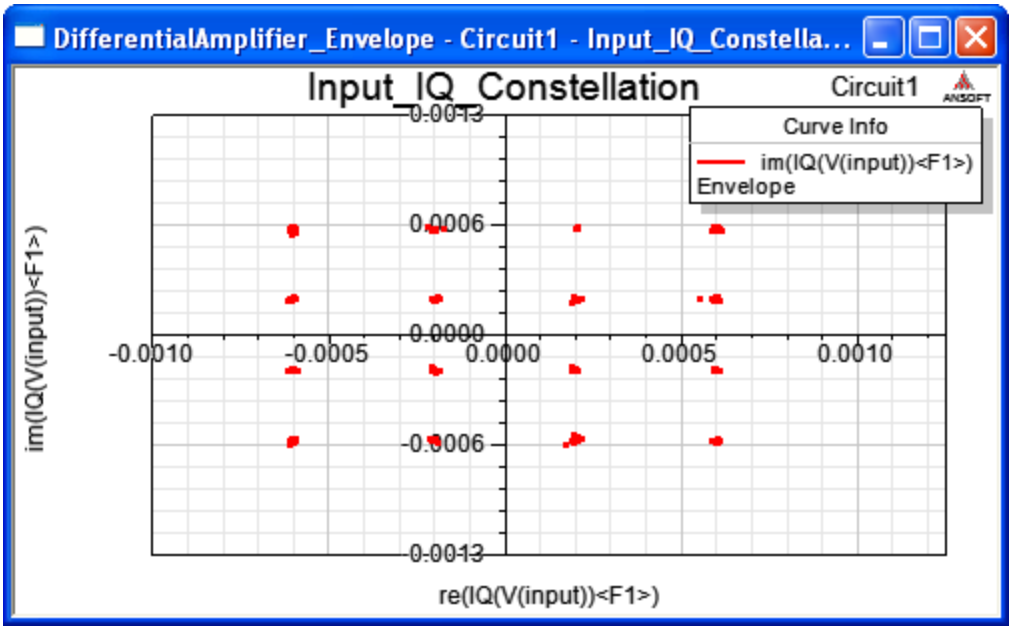
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7. Right-click the **Input IQ Constellation** report:



- In the **Constellation Parameters** group box, **Constellation** has been selected rather than **Vector**. This choice displays just the constellation points and not the transition vectors. The **Sample Period** is the same as the unit interval (4µs)

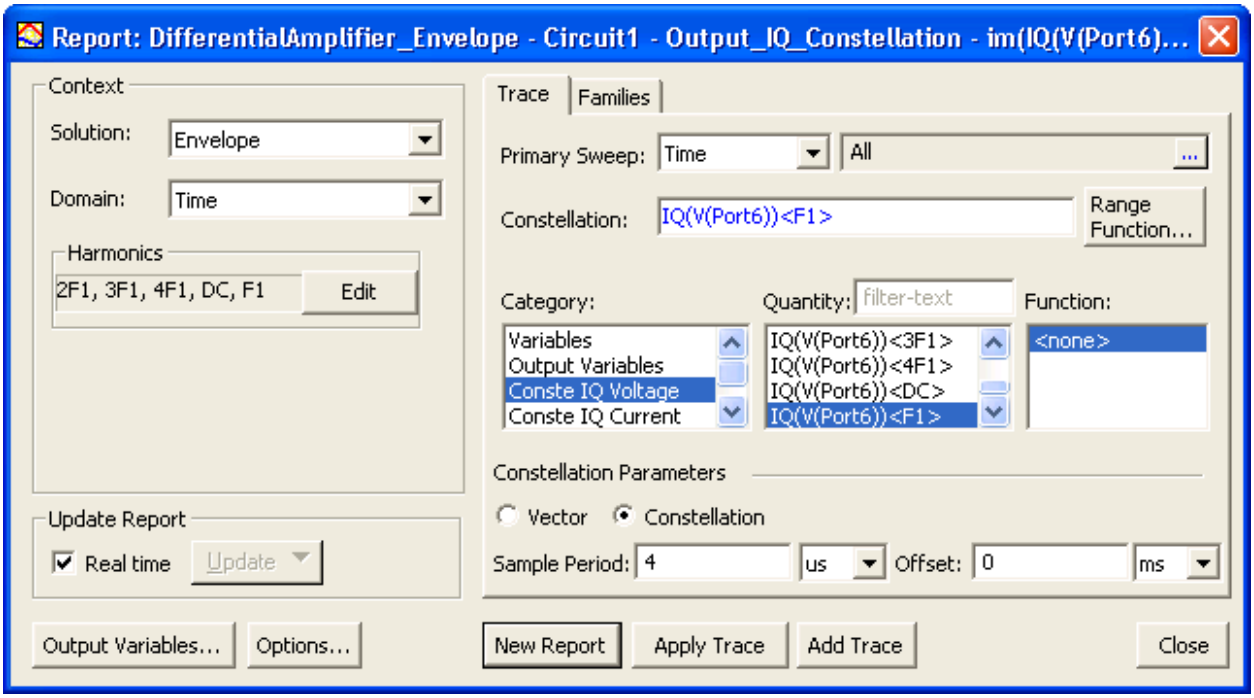
8. Double-click the **Input_IQ_Constellation** report to view the input IQ data plotted as a constellation chart:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The constellation diagram illustrates the clustering of the input I (real) and Q (imaginary) data points.

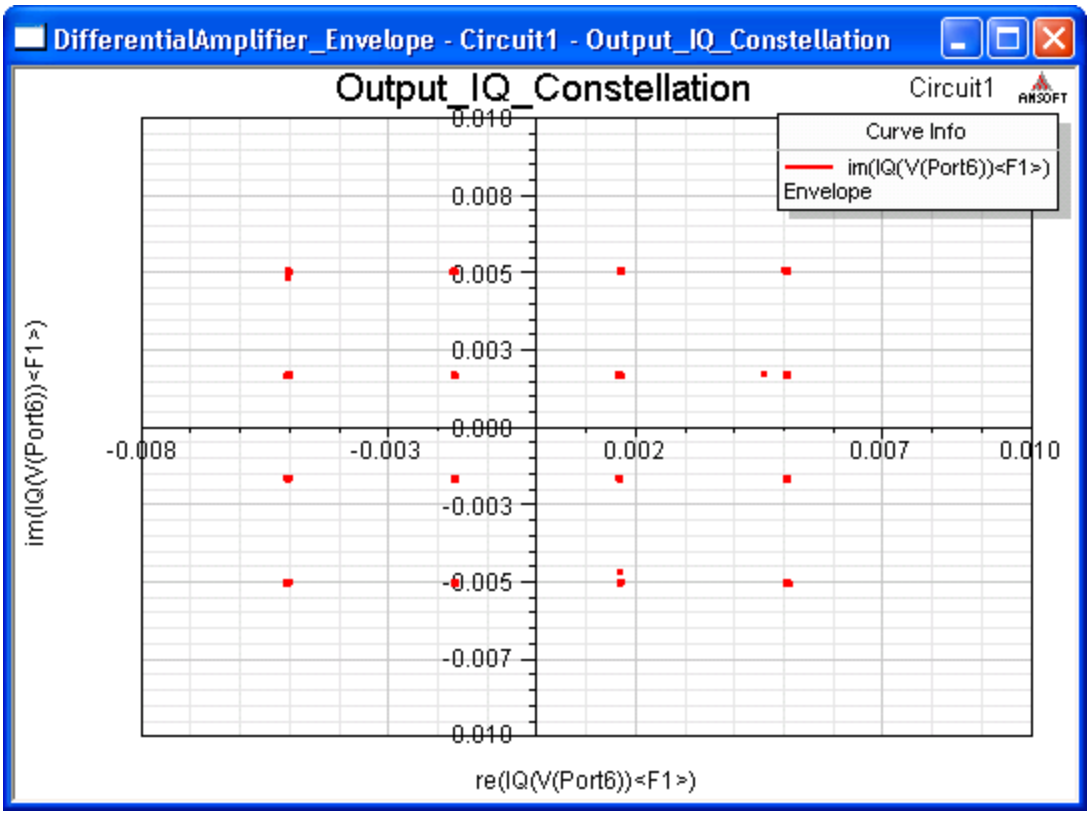
9. Right-click the **Output_Constellation** and select Modify Report to open the definition:



- The output node on our circuit is **Port6**. The sample period is 4µs as before.

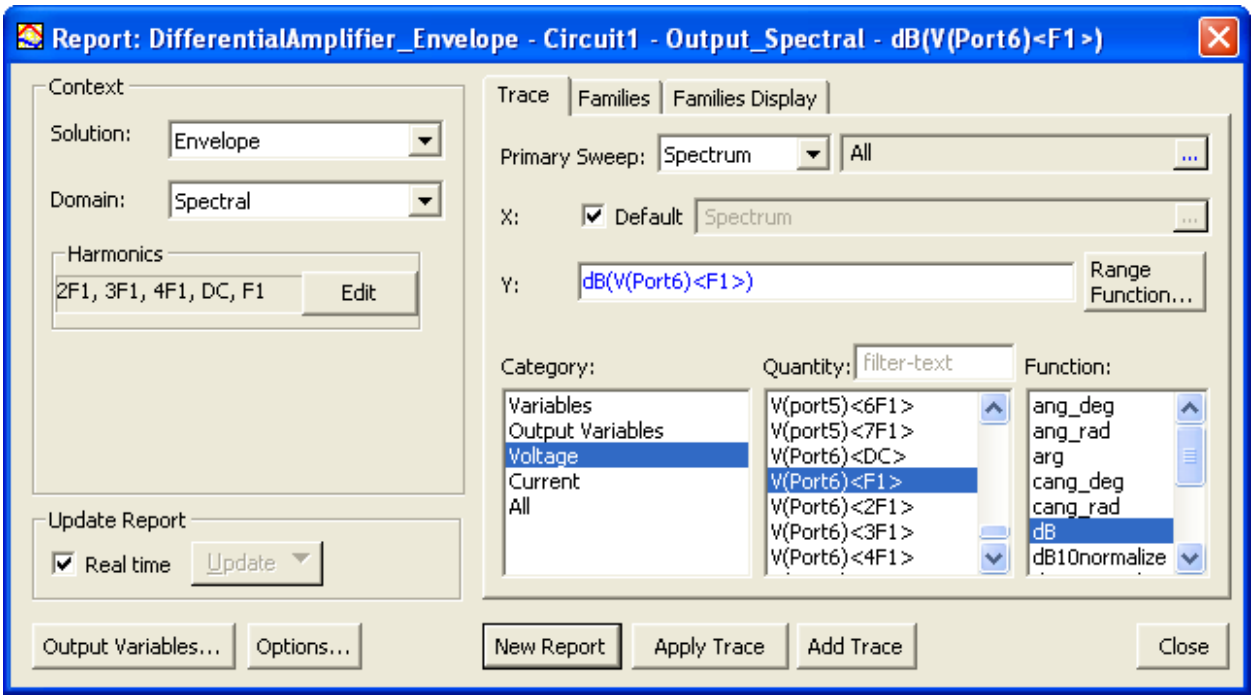
10. Double-click the **Output_IQ_Constellation** report to view the output data as a constellation chart:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- The chart is not rotated, so no phase distortion is present.

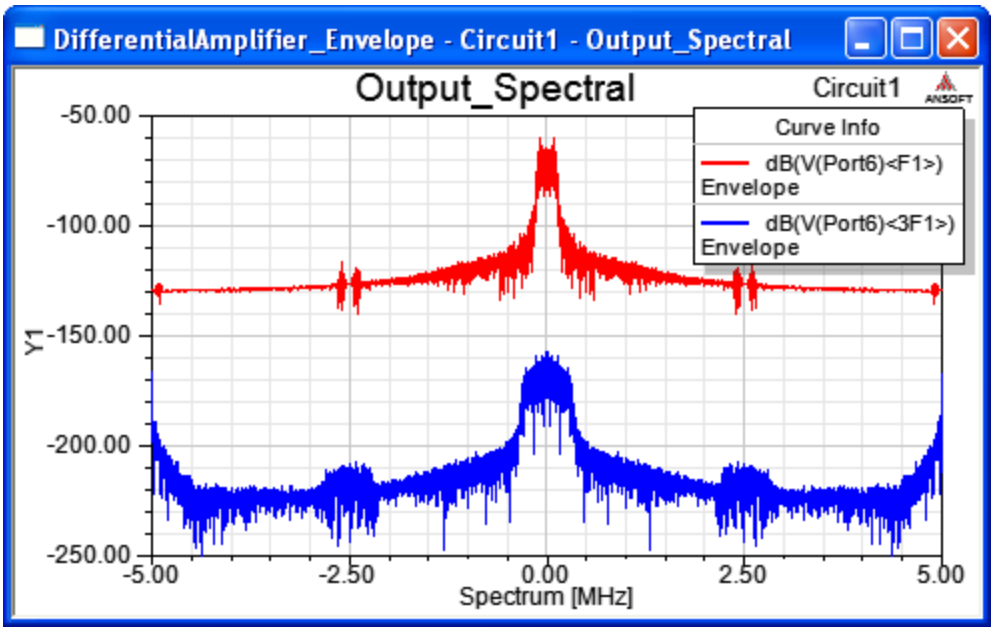
11. Right-click the **Output_Spectral** report:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This window shows the setup for the F1 spectrum. The F3 setup is essentially the same.

12. Right-click the **Output_Spectral** report to view the spectral result for the output at the first harmonic (F1) and the third harmonic (F3):



- This complex baseband representation is centered at 0Hz (DC).
- The spectrum at 3GHz (3F1) is approximately 100dB lower than the spectrum for the fundamental 1Ghz (F1).

Nexsys Timestep Example

This topic presents two versions of a loop filter that combines Nexxim elements with components on the System simulator component library.

The point of this example is to illustrate that timesteps in Nexsys depend on whether the source that is driving the circuit is on the System library or on the Nexxim library.

- When all sources are on the System library, the timestep is fixed and is taken from the sample rates in the System sources, and any timestep set in the transient analysis setup (Step and Stop entries) is ignored.
- When the source is an interface source, the timestep is variable, with a Step and Stop taken on the transient analysis setup.

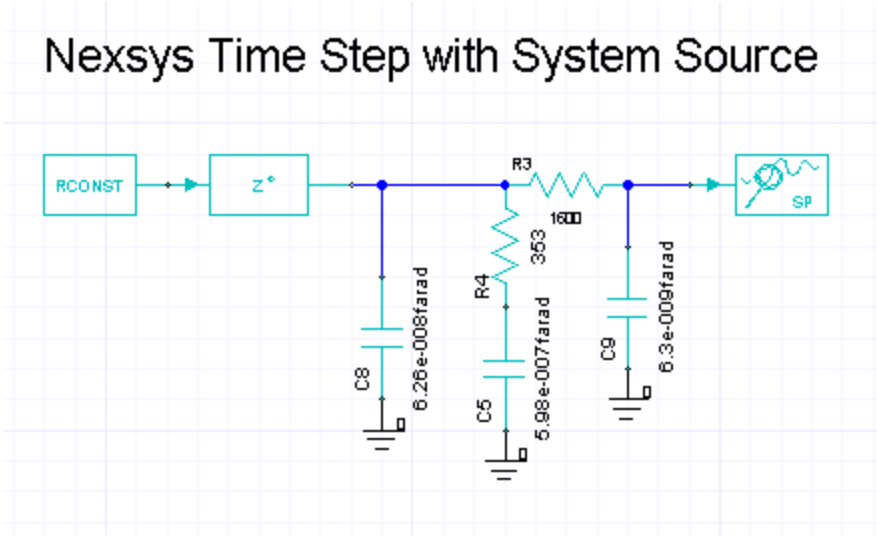
First Loop Filter Schematic Analysis

Open the First Loop Filter Schematic project from its file in the Examples directory.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. From the **Examples** directory, select **Circuit** > **RF Microwave** > **System**. Then double-click **Loopfilter_1_NX.aedt**, or select **Loopfilter_1_NX.aedt** and click **Open**.

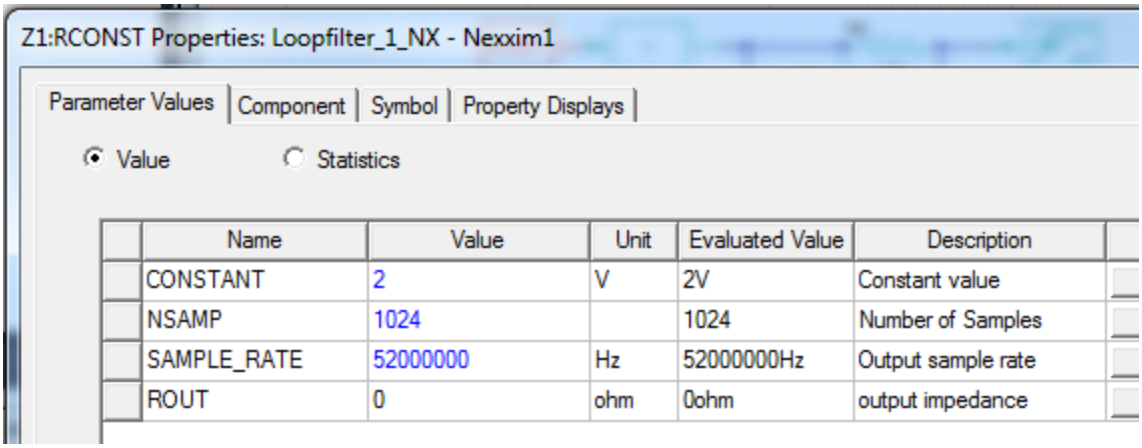
The filter schematic appears in the design window:



3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

The circuit contains a source (RCONST) and a delay element (Z^{-D}) on the System simulator component library and discrete resistors and capacitors on the Nexxim component library. The output probe (SP) is also on the System library.

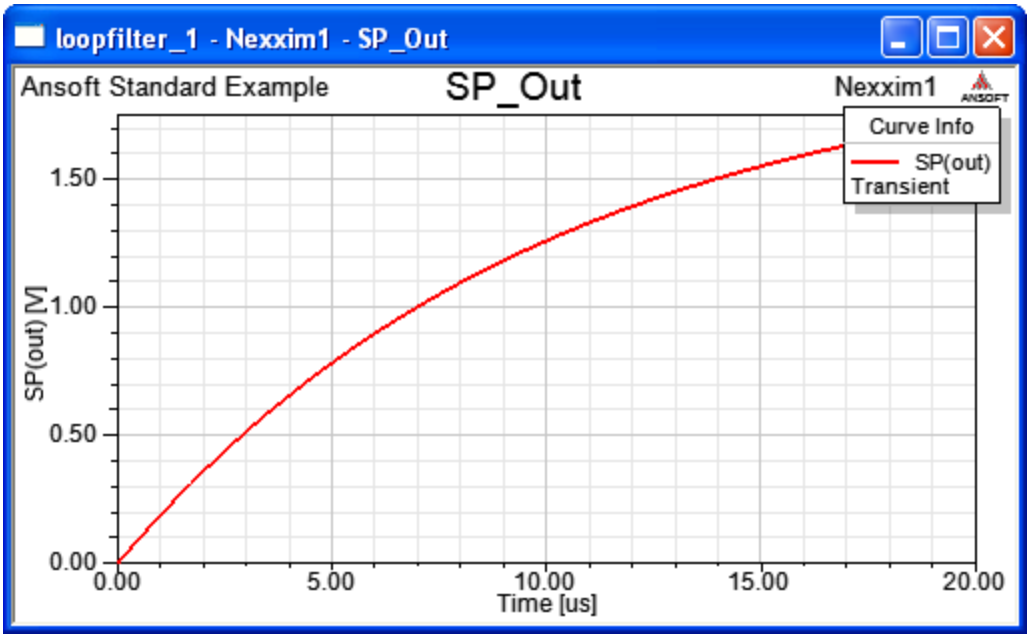
4. Click the RCONST element to display its property settings:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

These parameters control the time-domain simulation in Nexxim, overriding the times specified for the Transient analysis.

5. Expand the **loopfilter_1** project tree, and double-click the Transient analysis icon. The times are Step=0.1ns and Stop=10ns, but *these are overridden by the System source*
6. Right-click the Transient analysis icon and select **Analyze** on the menu. The Progress window displays a red line to show the analysis as it runs.
7. Click the Results icon and double-click on **SP_Out** to see the results:



This graph shows the filtered samples over a time period of 20 microseconds (1024 samples at a sampling rate of 52e6 Hz).

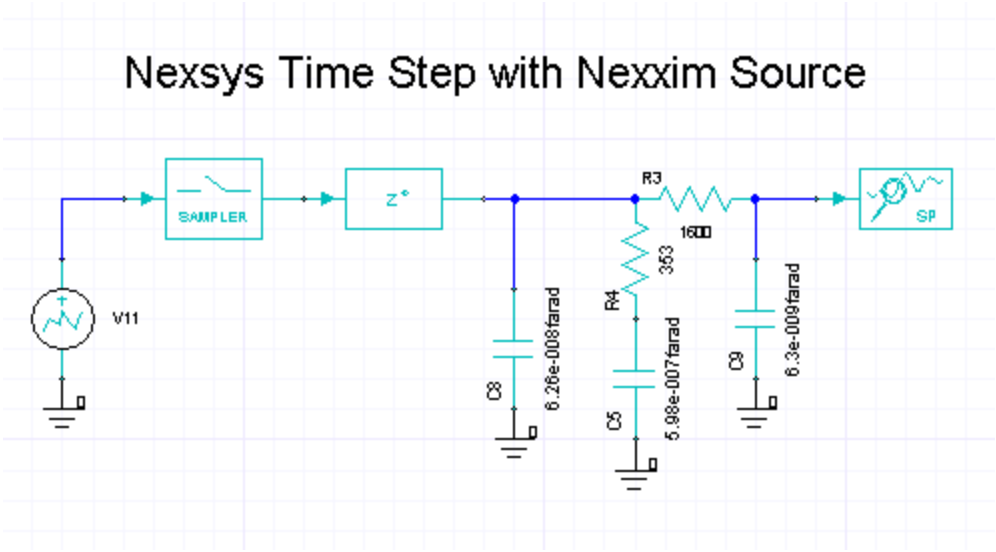
Second Loop Filter Schematic Analysis

Open the second loop filter project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open **Circuit**, then **RF_Microwave**, then **System**, then select the file **Loopfilter_2_NX.aedt**. Click **Open**.

The filter schematic appears in the design window:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

The System **RCONST** sampled source has been replaced with a Nexxim PWL source (V11) and a System Sampler element (SAMPLER). The interface source has been set to provide a constant 2V waveform, and the SAMPLER element samples at the 52MHz sample rate.

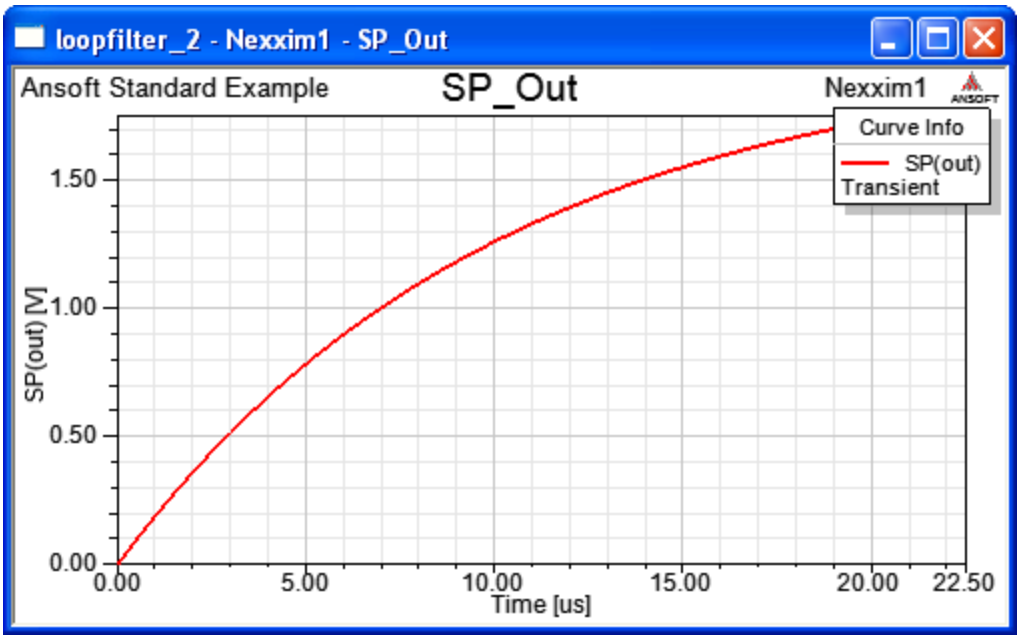
Note:

The SAMPLER element is required for a successful Nexxim simulation of this circuit. Without the sampler, Nexxim reports an error.

4. Expand the **loopfilter_2** project tree, and double-click the Transient analysis icon. Now the times are Step=0.1ns and Stop=20µs, and *these values now affect the simulation*. The Nexxim timesteps vary, with an initial step size of 0.1ns.
5. Right-click the Transient analysis icon and select **Analyze** on the menu. The Progress window displays a red line to show the analysis as it runs.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. Click the Results icon and double-click on **SP_Out** to see the results:



Now the time of 20 microseconds is derived from the Transient analysis setup. The result is the same as the previous one.

Nexsys MPSK Example

This example displays the ability of Nexsys to model the flow in a complete communications design. The circuit consists of baseband and RF transmitters, a noisy channel, and RF and baseband receivers. Probes added to the circuit allow us to view the signal as it proceeds.

Open the project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Navigate to **Electronics Desktop** > **Circuit** > **RF_Microwave** > **System** and select **MPSK_System_NX.aedt**. Then click **Open** to open the schematic in the design window.
3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

The following topics review the operation and function of this design and show some of the results of analysis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

MPSK Netlist Parameters

In the menu, select **Circuit > Browse netlist**. Note the netlist parameters defined near the top of the netlist.

```
* begin toplevel circuit

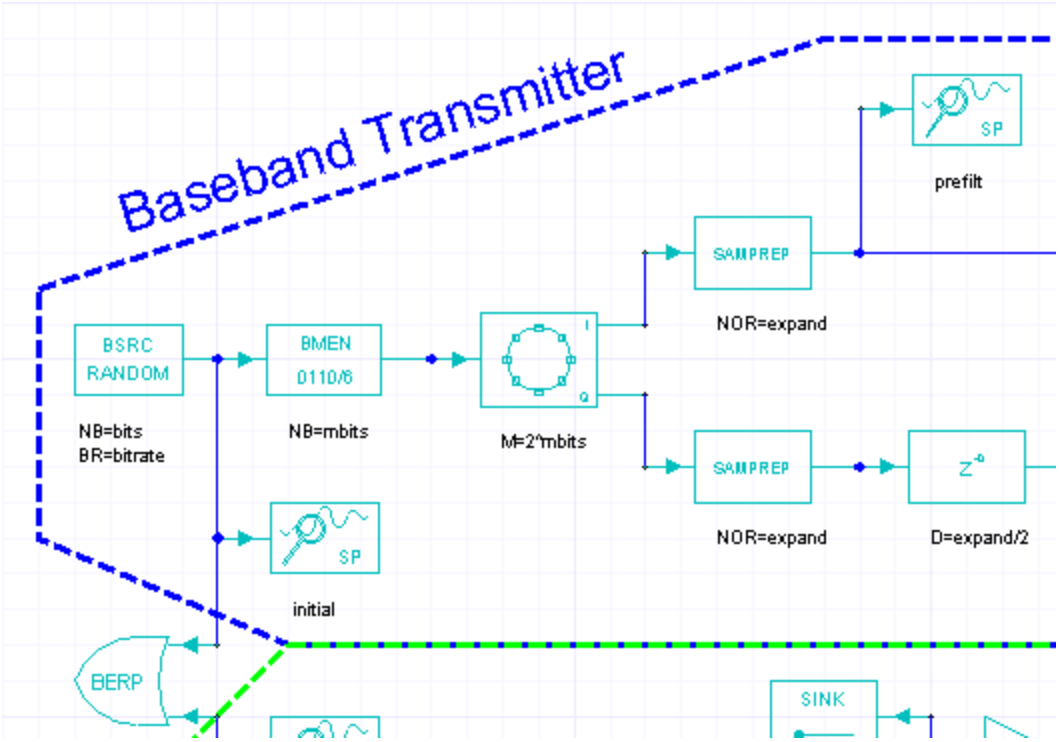
.param bits=1024
.param bitrate=2000000
.param mbits=2
.param expand=8
.param fchannel='bitrate/mbits/2'
.param flength='expand*8'
.param fcutoff='bitrate/mbits*4'
.param fbeta=0.35
.param channel_snr=60
```

The property settings of several components in the design are defined with these netlist parameters, to make it easy to experiment with different values.

Baseband Transmitter Schematic

The baseband transmitter is at the upper-left of the schematic. The baseband transmitter stage takes an input bit stream, encodes it into symbols, converts the symbols using QPSK and I/Q modulation, and outputs the modulated signal upshifted in frequency. Here is the left side of the Baseband transmitter schematic:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

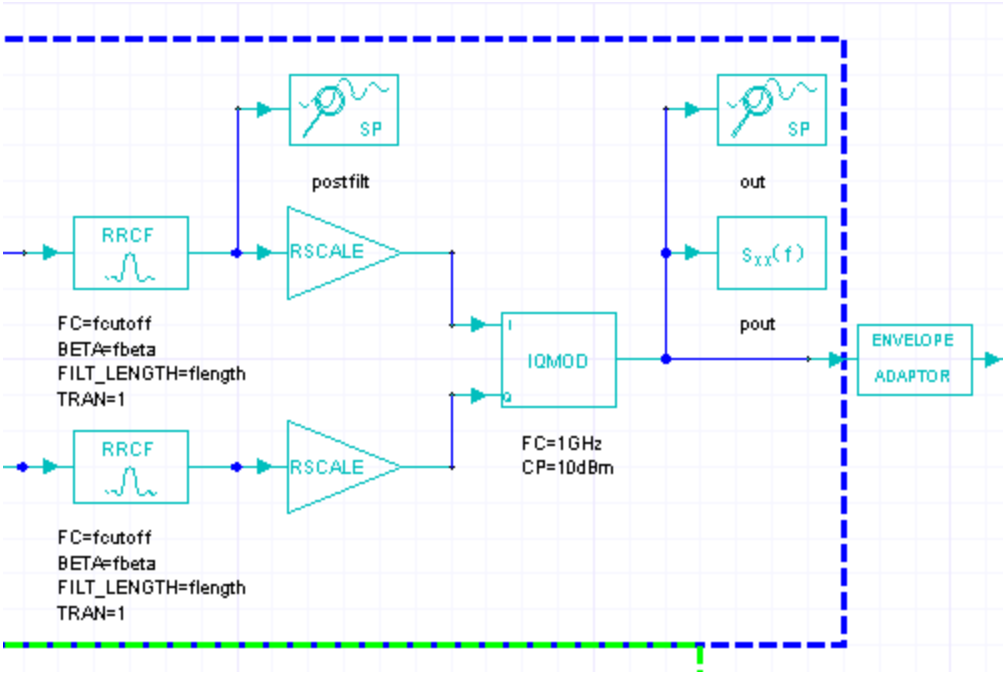


This part of the Baseband transmitter contains the following elements on the System simulator component library:

- A pseudorandom source. The pseudorandom dataset is a good approximation to a compressed set of transmission data. The number of bits to be generated (NB) is set to the parameter **bits** =1024. The bitrate (BR) is set to the parameter **bitrate** =2000000 (2MHz).
- A Binary-to-M-ary encoder. The number of bits to group into one symbol (NB) is set to the parameter **nbits** =2. The bitstream is encoded into four symbols: 0, 1, 2, and 3.
- A phase-shift keying modulator. The order M is set to 2^**nbits** =4, or QPSK. This element divides the signal into its real and imaginary parts, so now there are two parallel signal paths.
- Symbol repeaters on both paths. The number of repeats is set to parameter **expand** =8. The sampling rate is likewise multiplied by 8. Oversampling makes the waveform appear more continuous to the time domain simulator.
- A delay element on the lower path, adding a delay of **expand** /2=4 symbols to the imaginary data.
- A system probe, **prefilt**, is inserted to enable you to view the real part of the signal at this point.

Here is the right side of the Baseband Transmitter schematic:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This part of the Baseband transmitter contains the following elements on the System simulator component library:

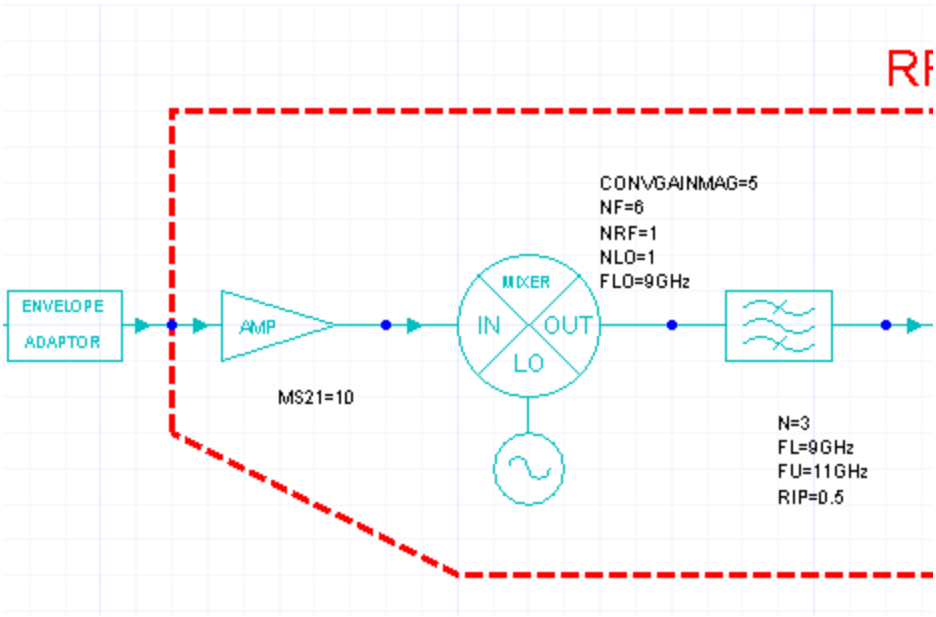
- Root raised cosine filters on both real and imaginary data paths. The cutoff frequency for both filters is set to parameter **fcutoff** =4MHz. The rolloff factor BETA is set to parameter **fbeta** =0.35. The number of filter coefficients FILT_LENGTH is set to parameter **flength** =64.
- A system probe, **postfilt**, is inserted to enable you to view the real part of the signal at this point.
- Real signal scaling elements on both paths. These are provided to enable you to experiment with real and imaginary signals with different gains. The gain on both elements is set to 1.
- An IQ modulator that receives the real part of the signal on input I (In-phase) and the imaginary part on input Q (Quadrature phase). The IQ modulator combines the signals and upshifts the output. The carrier frequency FC is set to 1GHz and the carrier power CP is set to 10dBm.
- A system probe, **out**, is inserted to enable you to view the signal as it leaves the Baseband transmitter.
- A power spectral density probe, **pout**, is inserted to enable you to view the power output of the Baseband transmitter.
- An Envelope adaptor. The adaptor is required to connect the Baseband transmitter stage, with only behavioral components, to the RF transmitter stage which includes electrical components. Behavioral components are unidirectional and time-based; the output is a

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

function only of the input. Electrical components are bidirectional and frequency-based; reflections at both input and output can be characterized with S-parameters. The Envelope adaptor identifies the waveform as an envelope to the Nexxim portion of the simulation. The Nexxim simulation then knows to send on an envelope waveform.

RF Transmitter Schematic

The RF transmitter stage takes the I/Q modulated signal as input and outputs the signal mixed with the carrier wave, amplified and filtered. Here is the left side of the RF Transmitter schematic:

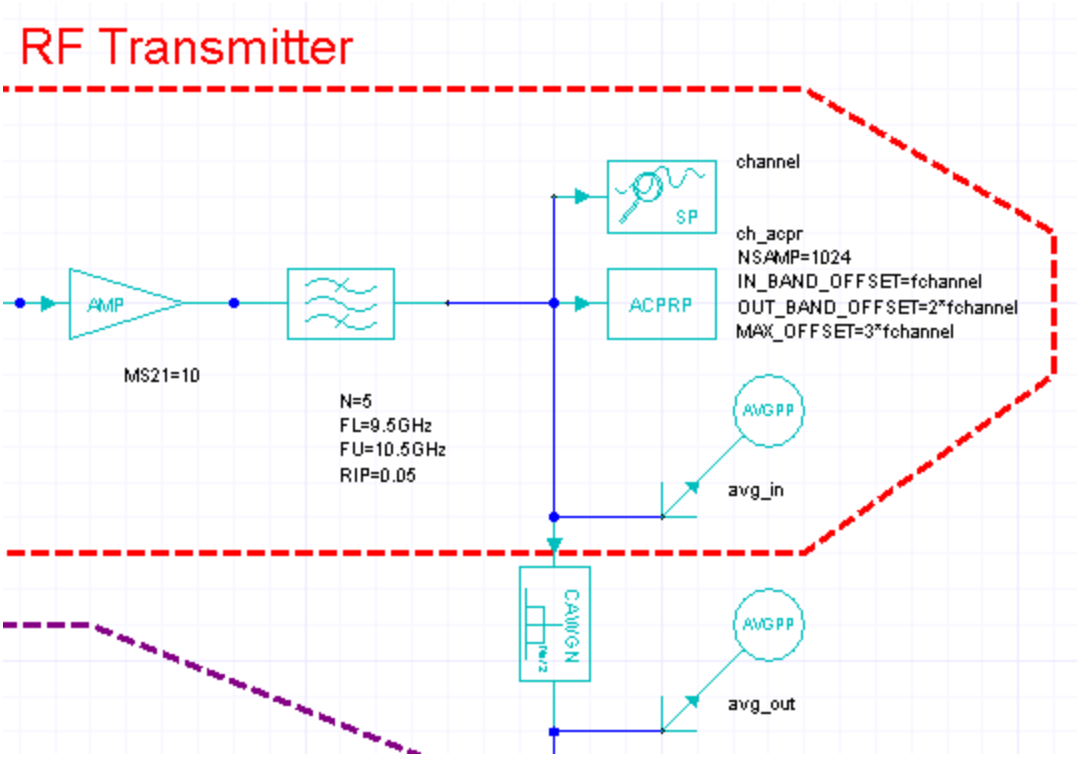


This part of the RF transmitter contains the following elements, two on the System nonlinear RF library and one on the Nexxim component library:

- An amplifier on the System nonlinear RF library provides a 10dB gain.
- A mixer on the System nonlinear RF library mixes the LO frequency (9GHz) with the up-shifted data around 1GHz.The mixer adds a conversion gain from RF (in) to IF(out) of 5dB and a noise figure of 6dB.
- A third-order Chebyshev bandpass filter on the Nexxim component library. The filter is set to pass frequencies between 9GHz and 11GHZ with a maximum inband ripple of 0.5dB.

Here is the right side of the RF Transmitter schematic:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



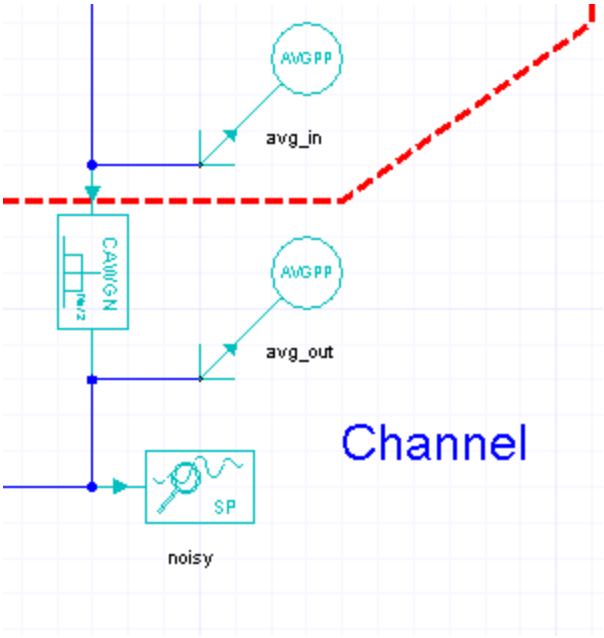
This part of the RF transmitter contains the following elements, one on the System nonlinear RF library and one on the Nexxim component library:

- Another amplifier on the System nonlinear RF library provides a 10dB gain post-filter.
- A fifth-order Chebyshev bandpass filter on the Nexxim component library. The filter is set to pass frequencies between 9.5GHz and 10.5GHZ, this time with a maximum in-band ripple of 0.05dB.
- A system probe, **channel**, is inserted to enable you to view the output of the RF transmitter.
- An adjacent channel power ratio probe, **ch_acpr**, is inserted to enable you to view the in-band and out-of-band power outputs on the RF transmitter.
- An average power probe, **avg_in**, is inserted to enable you to view the average output power on the RF transmitter.

MPSK Channel Schematic

Here is the schematic for the communication channel:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



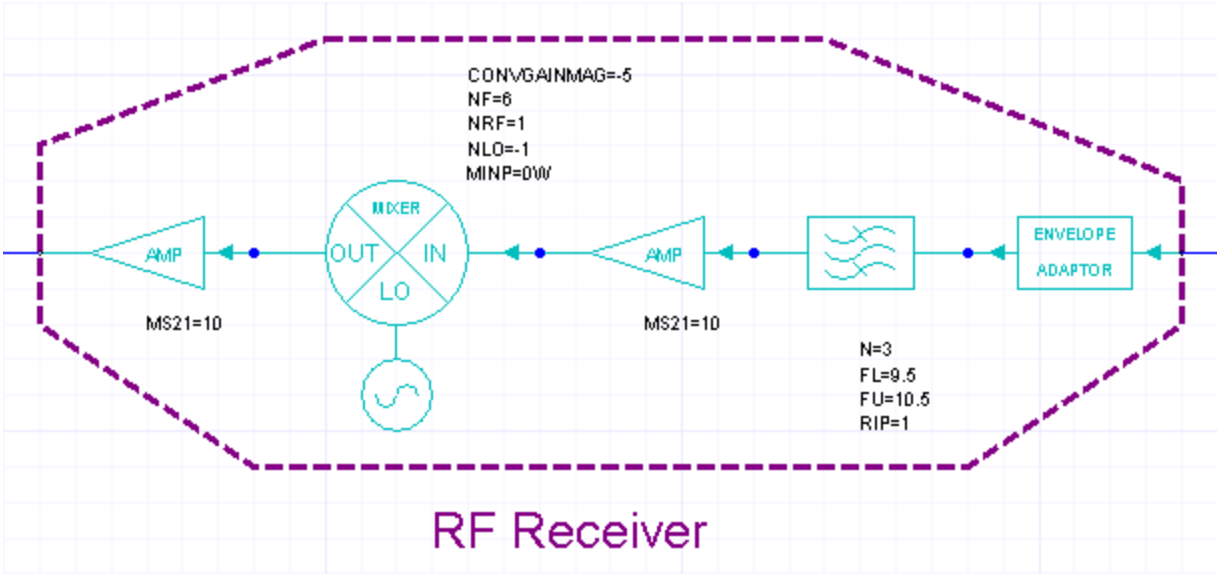
The channel models a noisy transmission line. The channel consists of one element and two probes on the System library.

- A channel element with added complex Gaussian white noise.
- An average power probe, **avg_out**, is inserted to enable you to view the average power after the channel.
- A system probe, **noisy**, is inserted to enable you to view the signal and noise at the receiving end of the channel.

RF Receiver Schematic

The RF transmitter essentially reverses the sequence of operations performed by the RF Transmitter. The Envelope adaptor interfaces the behavioral channel element with the electrical elements in the RF Receiver. The RF Receiver stage takes the signal mixed with the carrier wave as input and outputs the unmixed signal , amplified and filtered. Here is the RF Receiver schematic:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



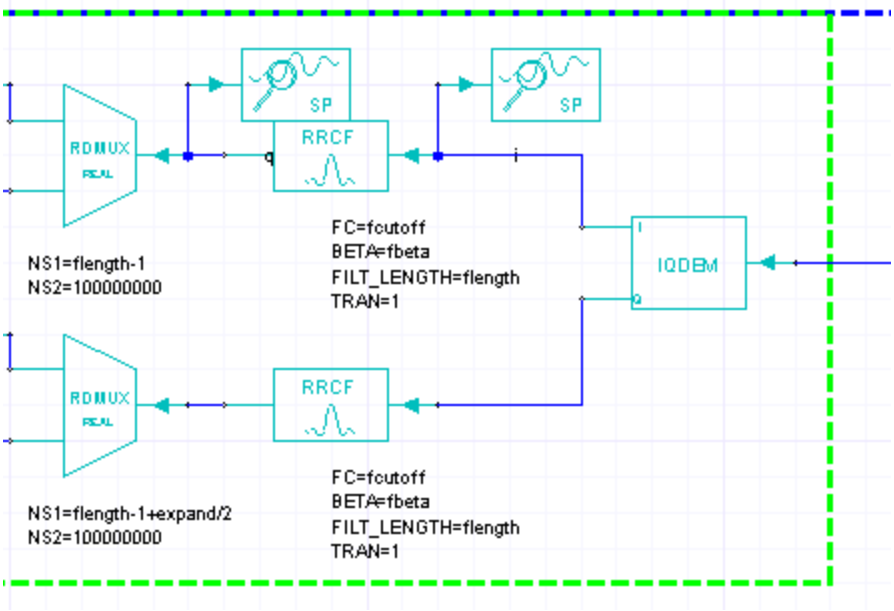
Baseband Receiver Schematic

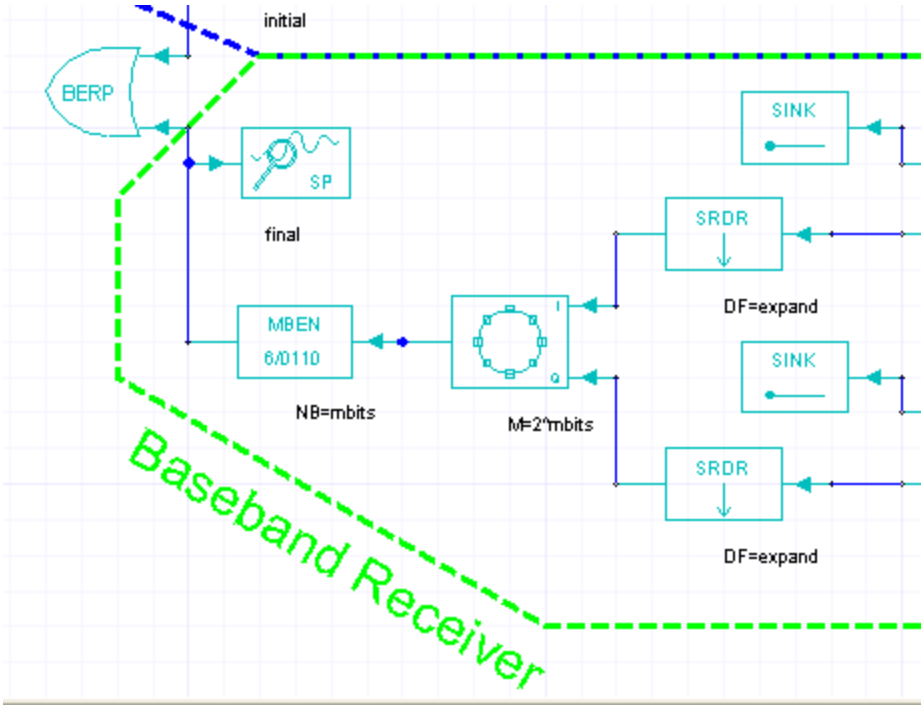
The Baseband receiver essentially reverses the sequence of operations performed by the Baseband transmitter. The receiver inputs a modulated signal, then downshifts, demodulates, and decodes it, and finally outputs the received bit stream.

The output on the pseudorandom bit generator and the bit stream output on the Baseband receiver are both sent to a bit error probe (BERP) for direct comparison and calculation of the bit error rate (BER).

Here are the right and left sides of the Baseband receiver schematic:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



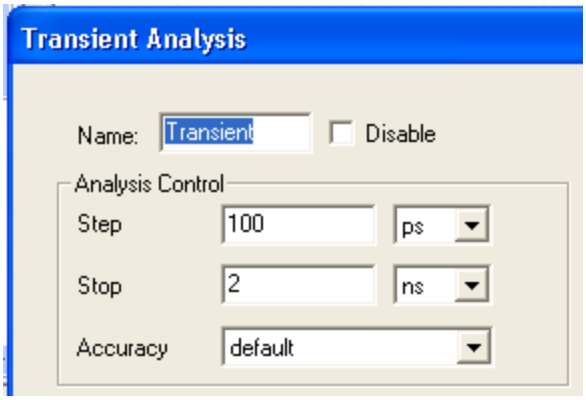


Run All Analyses and View Reports

The main project **MPSK_Nexxim_System** is organized in three sub-projects, **MPSK_ Baseband**, **MPSK_Mixed**, and **MPSK_SweptBER**. All of these sub-projects have the same

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Transient analysis setup:



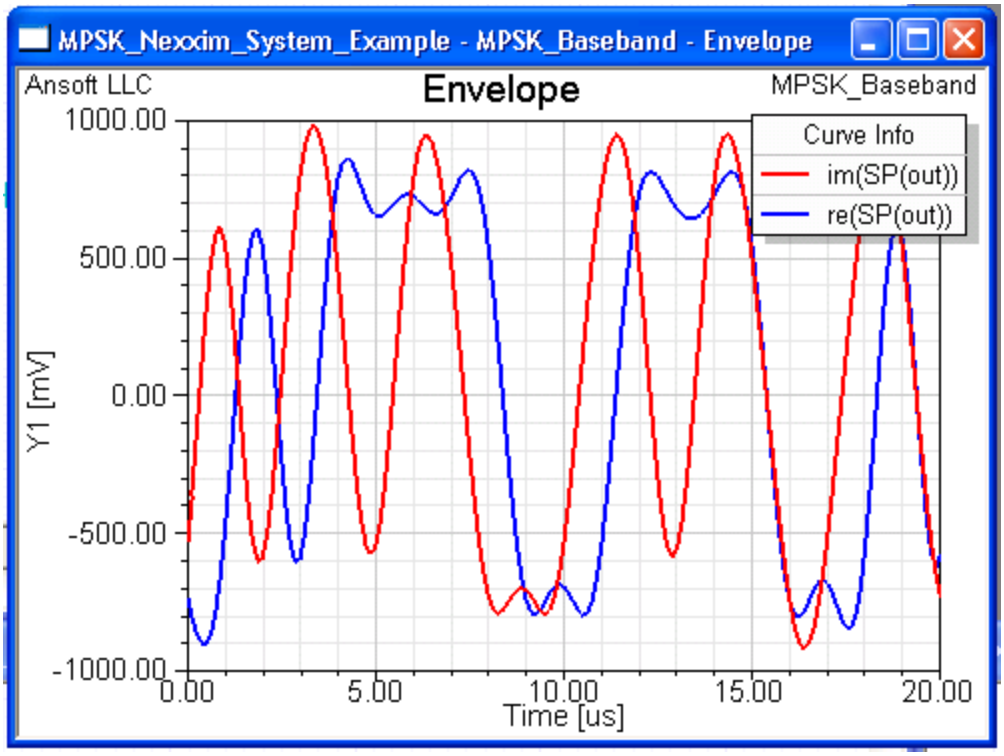
This setup controls the Nexxim library elements. For the System elements, the discrete time domain analysis uses a fixed timestep controlled by the bit rate in the System source.

Each sub-project includes a few typical reports.

1. Click the **MPSK_Nexxim_System** project and select **Analyze All** on the menu. The Progress window displays a red line to show each analysis as it runs. It may take a few moments for all analyses to run to completion.
2. Expand the Results icon under the **MPSK_Baseband** project. The four reports, **Envelope**, **Spectrum**, **Constellation**, and **Eye Diagram** show the output on the Baseband transmitter (system probe **out**) in different ways. Double-click each of the four reports to open it.

Here is the **Envelope** report.

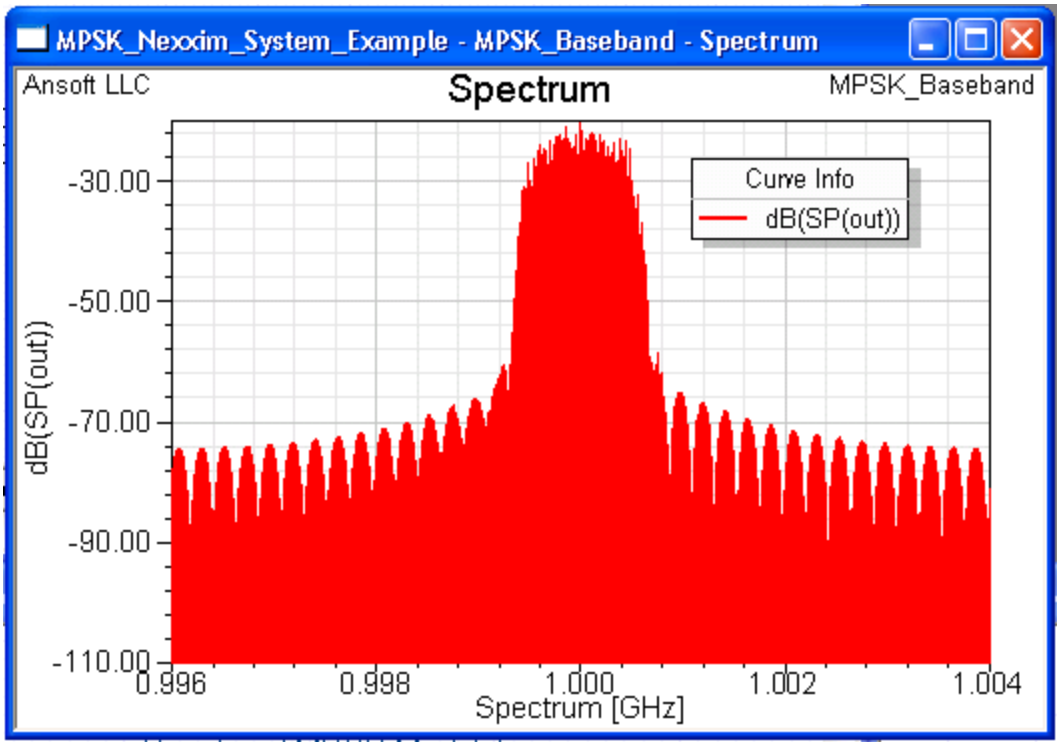
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The System discrete time analysis automatically performs envelope analysis on an I/Q modulated signal. This graph shows the output on the Baseband transmitter [SP(out)] resolved into its In-band (re) and Quadrature-band (im) components.

Here is the **Spectrum** report.

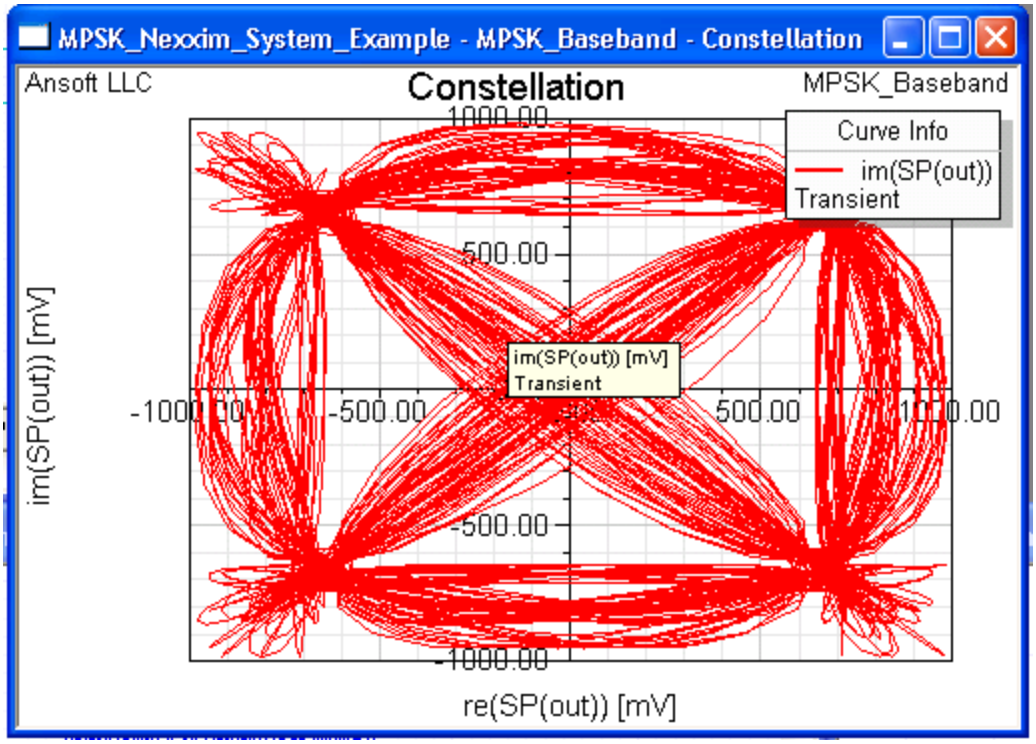
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This graph shows the output from the Baseband transmitter [SP(out)] analyzed in the spectral domain. The energy is centered around 1GHz, the upshifted signal frequency.

Here is the **Constellation** report.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

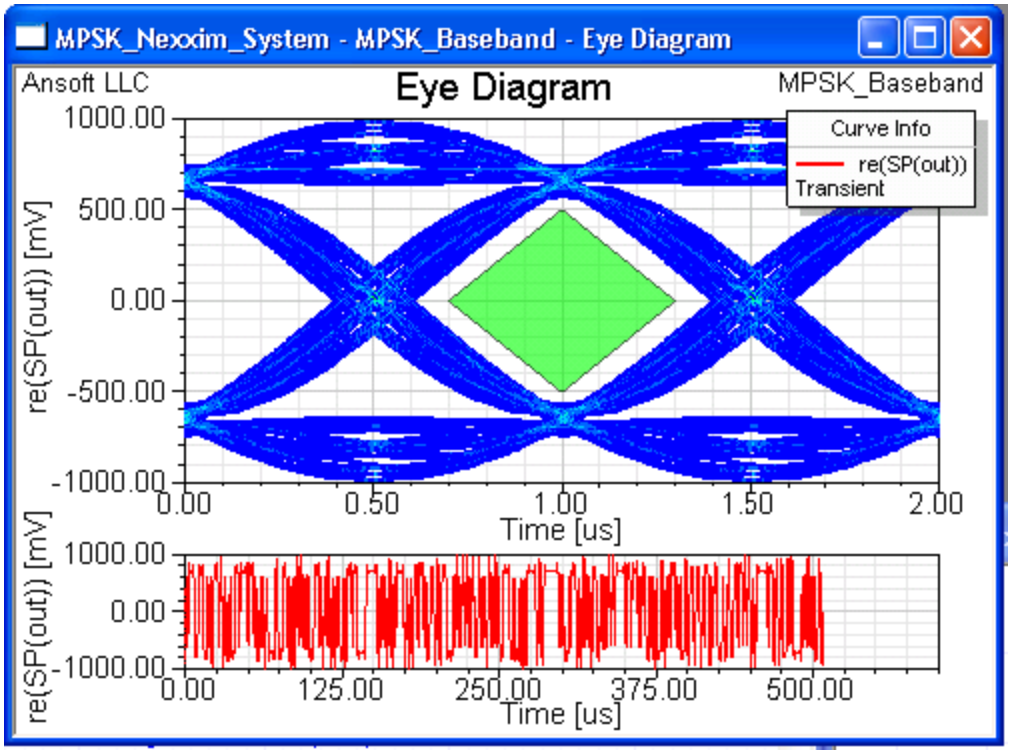


This graph shows the Quadrature-band (im) component of the output on the Baseband transmitter [SP(out)] graphed against the In-band (re) component.

The four nodes about the points (+/-700, +/-700) correspond to the four symbols in the transmission. The distinctness of the constellation indicates a good signal.

Here is the **Eye Diagram** report.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

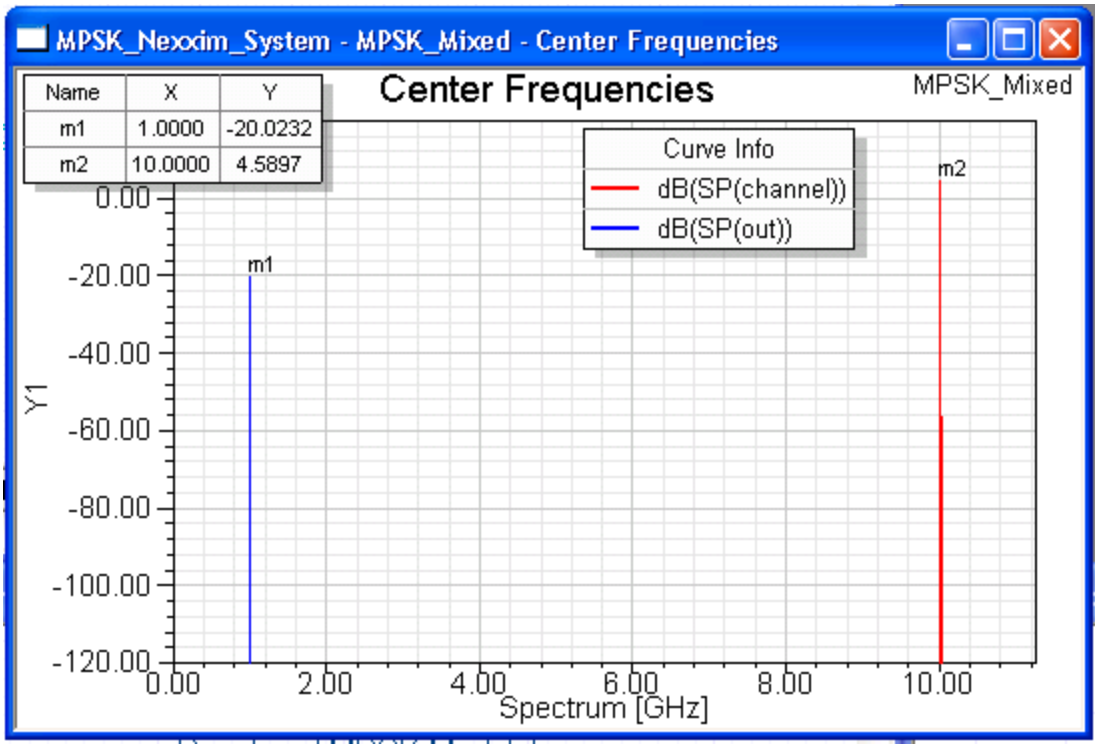


The Eye diagram report confirms the quality of the Baseband transmitter output. The green diamond indicates the portion of the unit interval (UI) that must be open to guarantee the appropriate bit error rate (BER).

3. Expand the Results icon under the **MPSK_Mixed** project. The three reports, **Center Frequencies**, **Signal Noise**, and **Noisy Channel** show the output on the RF transmitter (system probe **channel**) plus the noise contribution on the channel (system probe **noisy**). Double-click each of the three reports to open it.

Here is the **Center Frequencies** report.

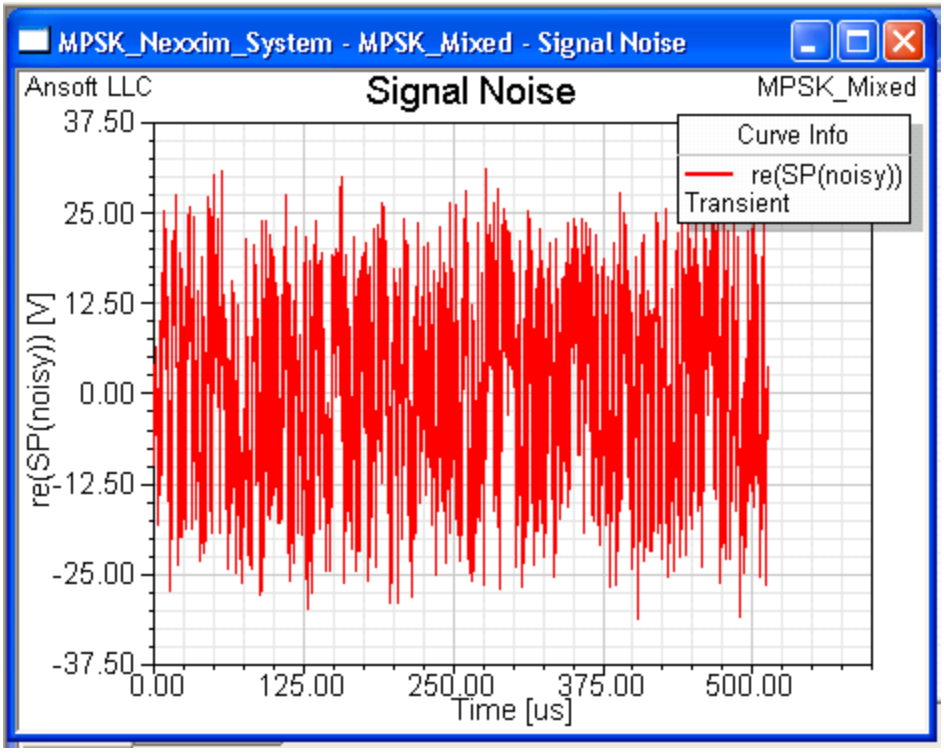
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This graph compares the upshifted spectral output on the Baseband transmitter [SP(out)] at around 1GHz with the combined spectrum of the signal and carrier coming on the RF transmitter [SP(channel)] at around 10GHz.

Here is the **Signal Noise** report.

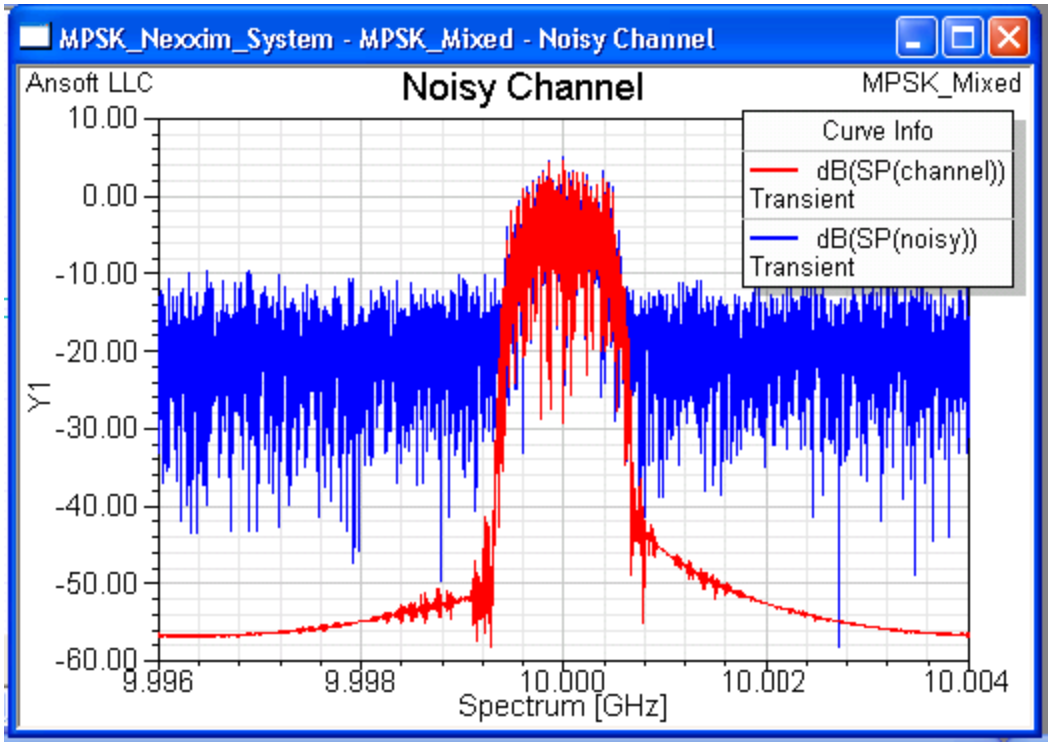
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This graph shows the combined signal and noise output on the channel [SP(noisy)] analyzed in the time domain.

Here is the **Noisy Channel** report.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

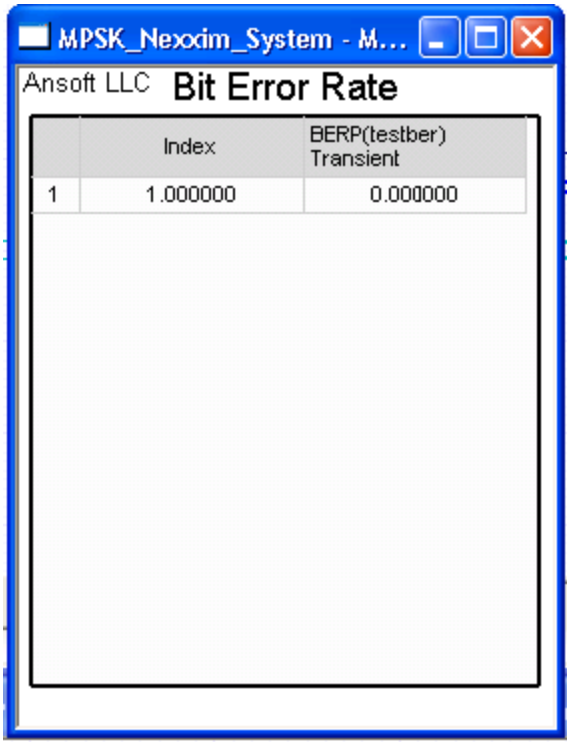


This graph shows the superimposition of the signal [SP(channel) and the Gaussian white noise added by the channel [SP(noisy)].

4. Expand the Results icon under the **MPSK_SweptBER** project. The single report, **Bit Error Rate**, shows the BER calculated by comparing the initial bit stream with the end result.

Here is the **Bit Error Rate** report.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This data table shows that no bit errors are detected.

These examples are just a few of the many possible reports. You can also vary or sweep any of the netlist parameters to investigate the effects.

For additional information, see Nexsys Discrete Time Domain Analysis.

Nonlinear Loadpull Amplifier Example

The nonlinear loadpull amplifier component (NLAMP) uses data-driven loadpull values to generate a behavioral amplifier model. The user supplies the loadpull data in LPD format (from Focus Microwaves, Inc.) The data gives the output power for a range of output impedances at constant input power and at a given frequency. To predict the non-linear behavior of the amplifier, the current version also provides the third-order inter-modulation products. The second-order IMD products are not provided.

The NLAMP component supports one-tone and two-tone harmonic balance simulation, including a sweep of input power. You can use Nexxim loadpull analysis to open the behavioral amplifier model such as a Smith chart.

For more information, see *Nonlinear Loadpull Amplifier*.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

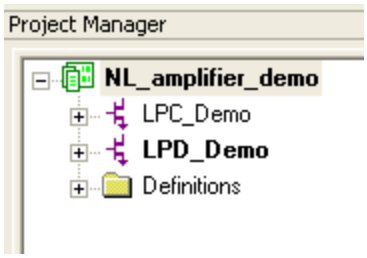
Open the NLAMP Design

The schematic for the demo and an example loadpull data file are available in the Examples directory.

Open the **NL_Amplifer_Demo** Schematic project from its file in the Examples directory.

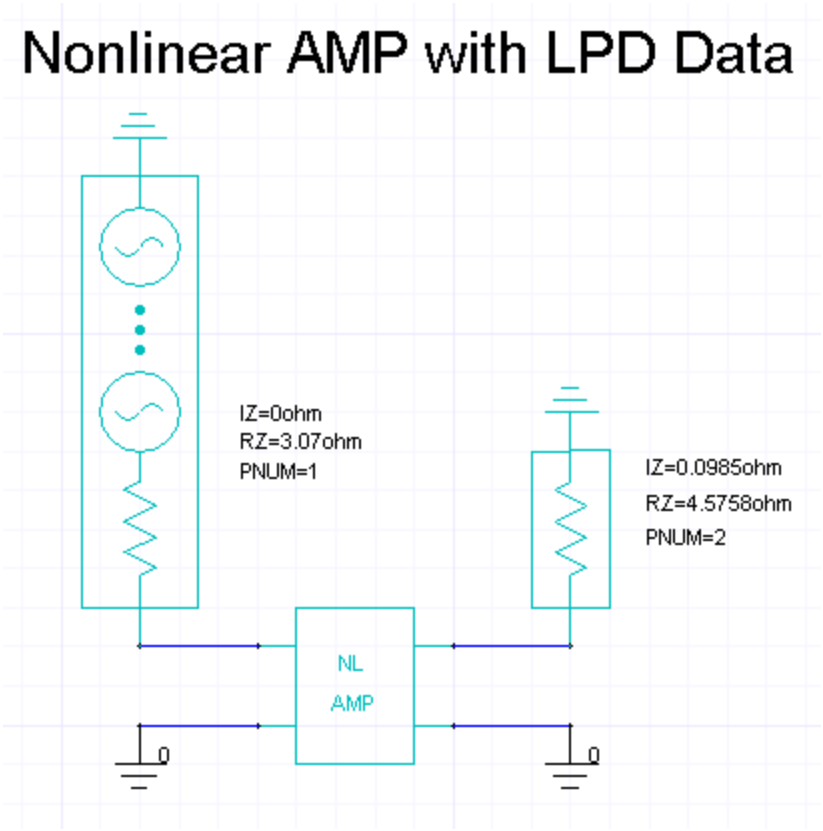
1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then t**Circuit**, then **RF_Microwave**, the **Amplifiers** directory, then select the file **NL_Amplifier_Demo.aedt**. Click **Open**.
3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

The project contains two circuits:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click the **LPD_Demo** circuit. The **LPD_Demo** schematic appears in the design window:



- NLAMP is a four terminal device. In this example, two terminals (one input and one output) are connected to ports while the remaining terminals are grounded. The value of the characteristic source impedance specified in the loadpull data file (3.07) is added as the impedance of port 1 (input port). A load impedance of (4.5758 + j0.0985) is specified as the impedance of port 2 (output port).

5. Click the **NLAMP** element to display its property settings:

Name	Value	Unit	Evalu...	Description
loadpull_file	NLAMP_demo.lpd			Load pull data file
source_frequency1	freq1		1.96G...	Frequency of input source
source_frequency2	freq2		2.06G...	Frequency of second input source for 2-tone a
load_resistance	0	ohm	0ohm	Load resistance 0=calculated
load_reactance	0	ohm	0ohm	Load reactance 0=calculated
model_switch	0			Select implementation 0=freq domain 1=time d
CosimDefinition	Edit			
CoSimulator	DefaultNetlist			
Status	Active			

6.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The loadpull model data file is **NLAMP_demo.lpd**. The source frequency is given by the project variable *freq1*. The frequency value is 1.96 GHz, the frequency for the loadpull data in the file. A second, slightly higher frequency given by project variable *freq2* is used in two-tone harmonic balance analysis.

The model_switch is set to select the frequency domain implementation.

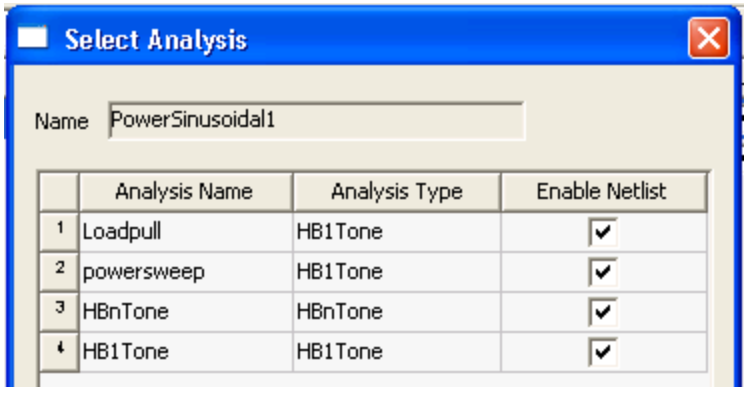
7. Click Port 1 (PNUM=1) and select **Edit Port**. Near the bottom of the Edit Port window, select **Edit Sources**.
8. Select the **PowerSinusoidal1** source and click **Edit Properties**.

	Name	Value	Unit	Evaluate...	Descri
	Name	PowerSinusoidal1			
	ACMAG	nan		nan	AC magnitude for small-signal an
	ACPHASE	0		0	AC phase for small-signal analysi
	DC	0		0	DC voltage (Volts)
	VO	0		0	Voltage offset from zero (Volts)
	POWER	pin		20dBm	Available power of the source
	FREQ	freq1		1.96GHz	Frequency (Hz)
	TD	0		0	Delay to start of sine wave (secc

9.

The **PowerSinusoidal1** source runs at a frequency given by project variable *freq1* at an input power given by project variable *pin*.

With **PowerSinusoidal1** still selected, click **Select** under **Analysis list**:



The **PowerSinusoidal1** source runs on all analyses in the demo. Click **OK** to close the **Select Analysis** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

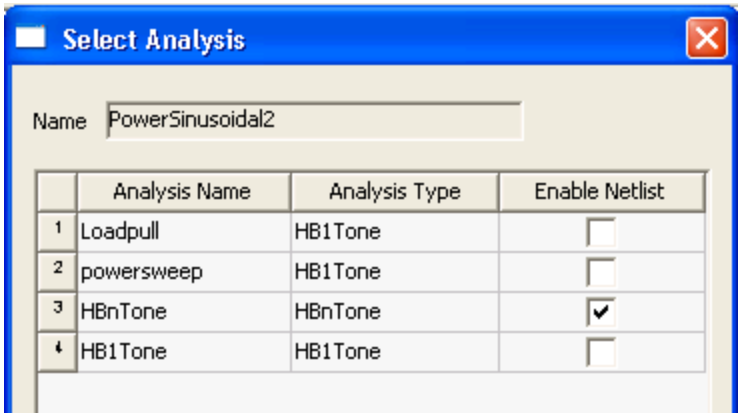
10. Select the **PowerSinusoidal2** source and click **Edit Properties**.

	Name	Value	Unit	Evaluate...	Descri
	Name	PowerSinusoidal2			
	ACMAG	nan		nan	AC magnitude for small-signal an
	ACPHASE	0		0	AC phase for small-signal analysi
	DC	0		0	DC voltage (Volts)
	VO	0		0	Voltage offset from zero (Volts)
	POWER	pin		20dBm	Available power of the source
	FREQ	freq2		2.06GHz	Frequency (Hz)

11.

The **PowerSinusoidal2** source runs at a frequency given by project variable *freq2* at an input power given by project variable *pin*.

With **PowerSinusoidal2** still selected, click **Select** under **Analysis list**:



The **PowerSinusoidal2** source runs only on the **HBnTone** analysis in the demo.

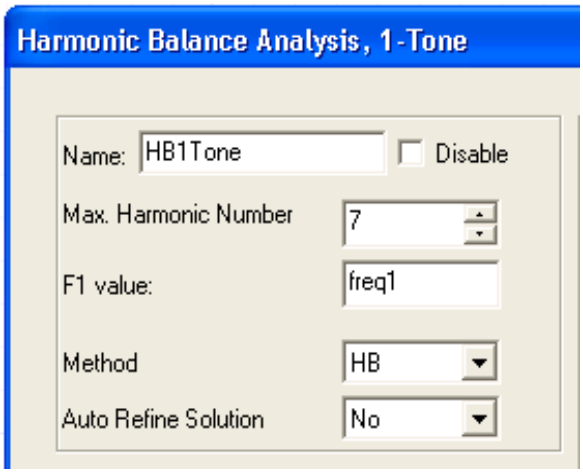
12. Click **OK** to close the **Edit Sources** window, and **OK** again to close the **Edit Ports** window.

One-Tone HB with NLAMP

For the single-tone harmonic balance analysis, a power source **PowerSinusoidal1** is connected to the input port supplying an input power *pin* (initially 20dB) at frequency *freq1* (1.96GHz for this set of loadpull data).

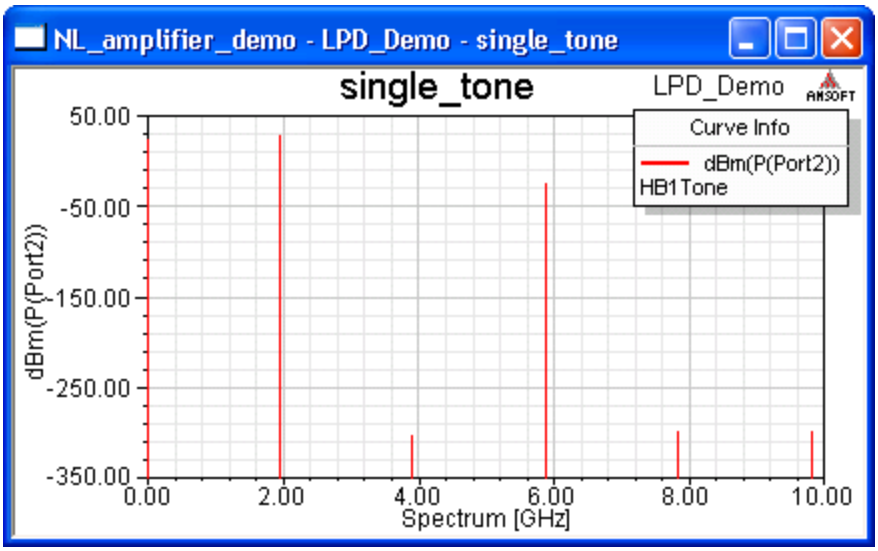
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Expand the **Analyses** icon and double-click on **HB1Tone**.



The **HB1Tone** analysis is set to analyze the first seven harmonics of frequency *freq1*. Click **OK** to close the setup window.

2. With analysis **HB1Tone** still selected, right-click and select **Analyze**. The analysis runs to completion.
3. Click the **Results** icon and double-click **single_tone** to see the results:



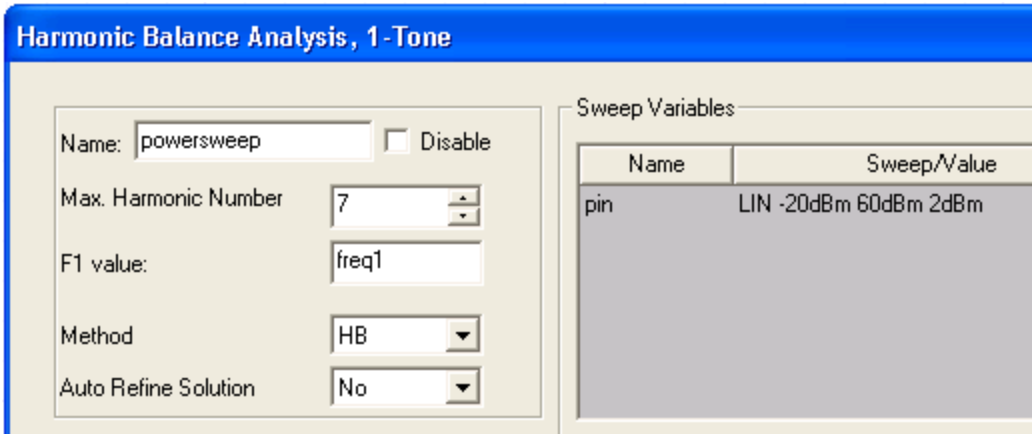
The **single_tone** plot shows the output power (dBm) for all the seven tones (DC and multiples of 1.96 GHz). As expected, the fundamental component is the most dominant followed by the 3rd harmonic. The subsequent odd order terms have lower values. Even-order terms (2nd, 4th etc.) should be considered to be zero, since the second order IMD is not provided.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Power Sweep with NLAMP

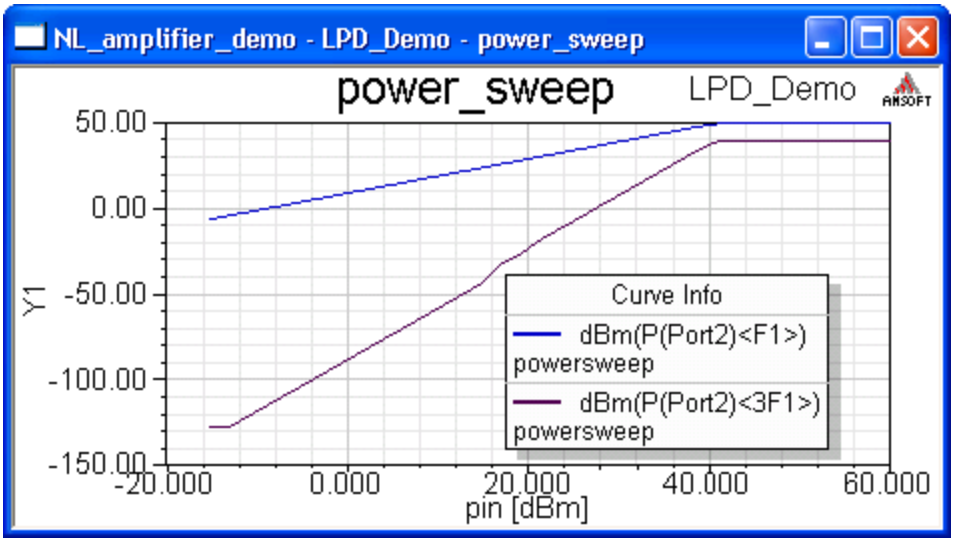
For the power sweep, the input power *pin* is swept over the range -20dBm to 60dBm in steps of 2dBm while performing one-tone harmonic balance.

1. Expand the **Analyses** icon and double-click on **powersweep**.



The **powersweep** analysis is the one-tone HB analysis with the added sweep of input power, given by project variable *pin*. Click **OK** to close the setup window.

2. With analysis **powersweep** still selected, right-click and select **Analyze**. The analysis runs to completion.
3. Click the **Results** icon and double-click **powersweep** to see the results:



The **powersweep** plot shows the fundamental (red) and third harmonic (blue) output power plotted vs. input power **pin**, and the saturation of the amplifier. In the linear region the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

fundamental output power has a slope of 1:1 while the third harmonic has a slope of 3:1 vs. the input power. Both axes are in log scale (dBm).

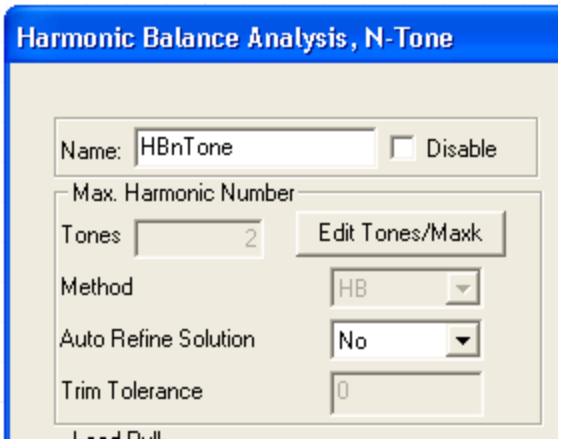
Two-Tone HB with NLAMP

Inter-modulation distortion (IMD) is typically measured with a spectrum analyzer by first injecting a two tone signal into the device , then measuring the resulting inter-modulation product signals. The two tones *freq1* and *freq2* are very close to each other. This ensures that the 3rd order products (2**freq1* – *freq2* and 2**freq2* – *freq1*) are generated very close to the fundamental. Thus their effects can be seen even when the amplifier is operating in a narrow band.

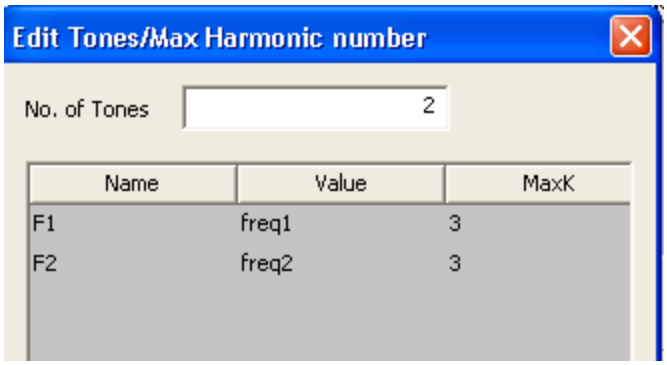
For the two-tone harmonic balance analysis, two simusoidal power sources connect to input Port 1:

- **PowerSinusoidal1** supplies power *pin* (20dB) at frequency *freq1* (1.96GHz).
- **PowerSinusoidal2** supplies power *pin* (20dB) at frequency *freq2* (2.06GHz).

1. Expand the **Analyses** icon and double-click on **HBnTone**.

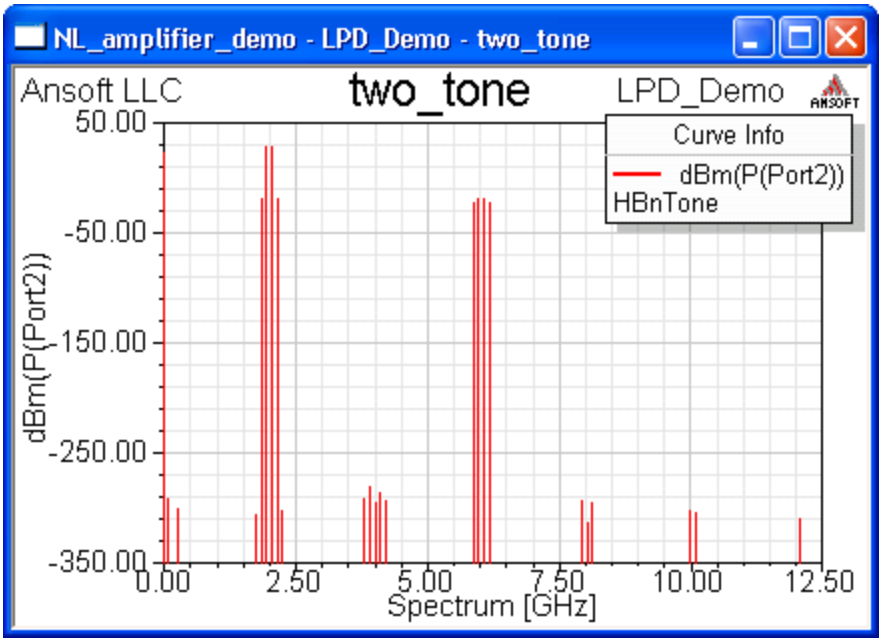


Click **Edit Tones/Maxk** to view the frequency setup, three harmonics each of *freq1* and *freq2*.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. With analysis **HBnTone** still selected, right-click and select **Analyze**. The analysis runs to completion.
3. Click the **Results** icon and double-click **two_tone** to see the results:



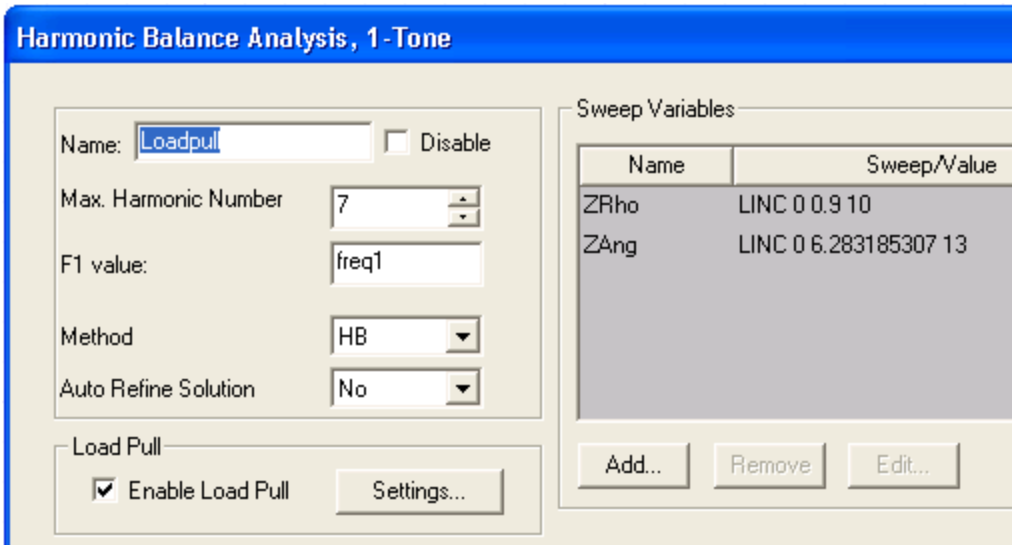
The **two_tone** report shows the two fundamental components corresponding to *freq1* (1.96 GHz) and *freq2* (2.06 GHz) to be dominant, followed by the third order terms 2**freq1* – *freq2* (1.86 GHz) and 2**freq2* – *freq1* (2.16 GHz). Since the input power for both the sources is the same, the amplitudes of the two fundamental and the two third harmonic components are identical.

Loadpull Analysis of NLAMP

For the loadpull analysis, the resistance and reactance of the load at Port 2 is varied to cover the entire Smith chart.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Expand the **Analyses** icon and double-click on **Loadpull**.

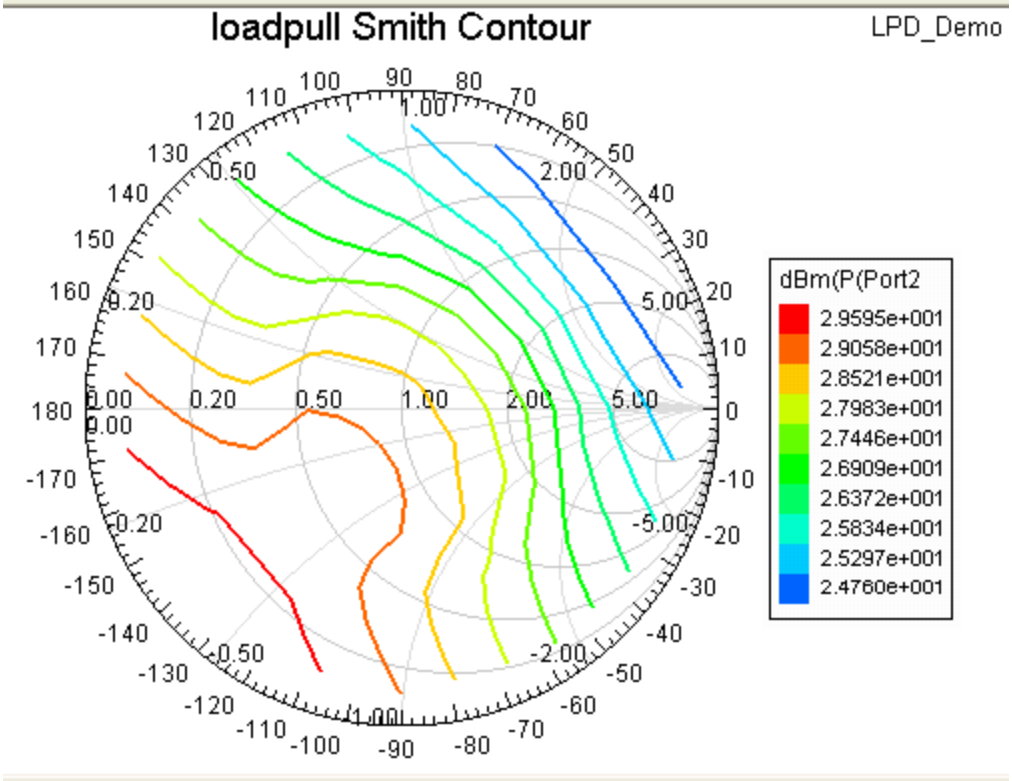


The **Loadpull** analysis is set to analyze the first seven harmonics of frequency *freq1*, with added sweeps of **ZRho** and **ZAng**, the resistance and reactance variables. Click **OK** to close the setup window.

2. With analysis **Loadpull** still selected, right-click and select **Analyze**. The analysis runs to completion.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Click the **Results** icon and double-click **loadpull Smith Contour** to see the results:



The **loadpull Smith Contour** plot shows the output power in dBm over the swept loadings as a Smith Chart contour. The plot shows the Maximum output power generated by the amplifier for a given load impedance.

Power Sweep using Time Domain Implementation

For most analyses, the newer frequency domain implementation produces much the same result as the earlier time domain implementation. In the case of the power sweep, there is a noticeable difference.

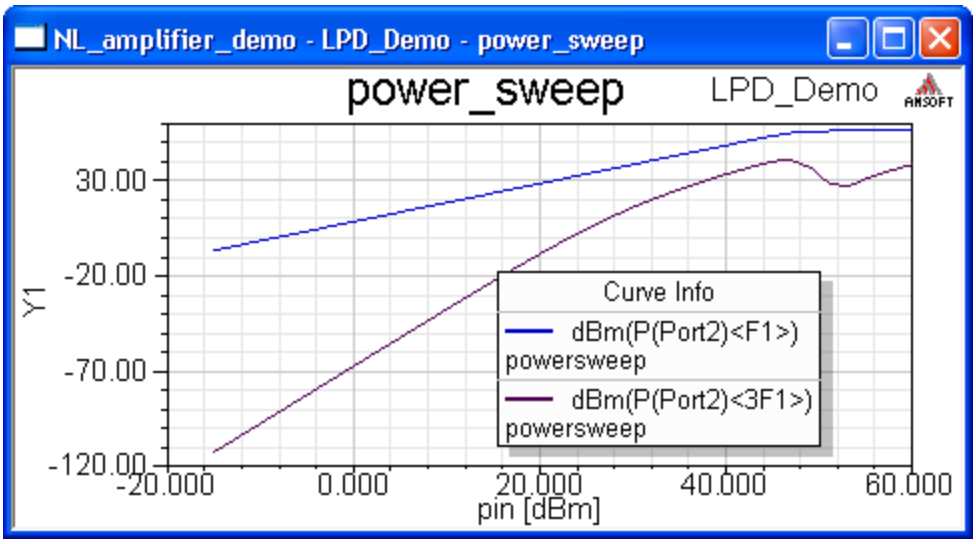
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the **NLAMP** element and open its **Properties**.

	Name	Value	Unit	Evalu...	Description
	loadpull_file	NLAMP_d...			Load pull data file
	source_frequency1	freq1		1.96G...	Frequency of input source
	source_frequency2	freq2		2.06G...	Frequency of second input source for 2-tone analysis
	load_resistance	0	ohm	0ohm	Load resistance 0=calculated
	load_reactance	0	ohm	0ohm	Load reactance 0=calculated
	model_switch	1			Select implementation 0=freq domain 1=time domain
	CosimDefinition	Edit			
	CoSimulator	DefaultNet...			
	Status	Active			

Set the **model_switch** property to 1 to select the time domain implementation. Click **OK** to close the Properties window.

2. With analysis **powersweep** still selected, right-click and select **Analyze**. The analysis runs to completion.
3. Click the **Results** icon and double-click **powersweep** to see the results:



The **powersweep** plot shows the fundamental (red) and third harmonic (blue) output power plotted vs. input power **pin**, and the saturation of the amplifier. In the linear region the fundamental output power has a slope of 1:1 while the third harmonic has a slope of 3:1 vs. the input power. Both scales \are in logarithmic units (dBm). Notice the notch at the upper end of the 3F1 trace. This feature is missing on the frequency domain plot.

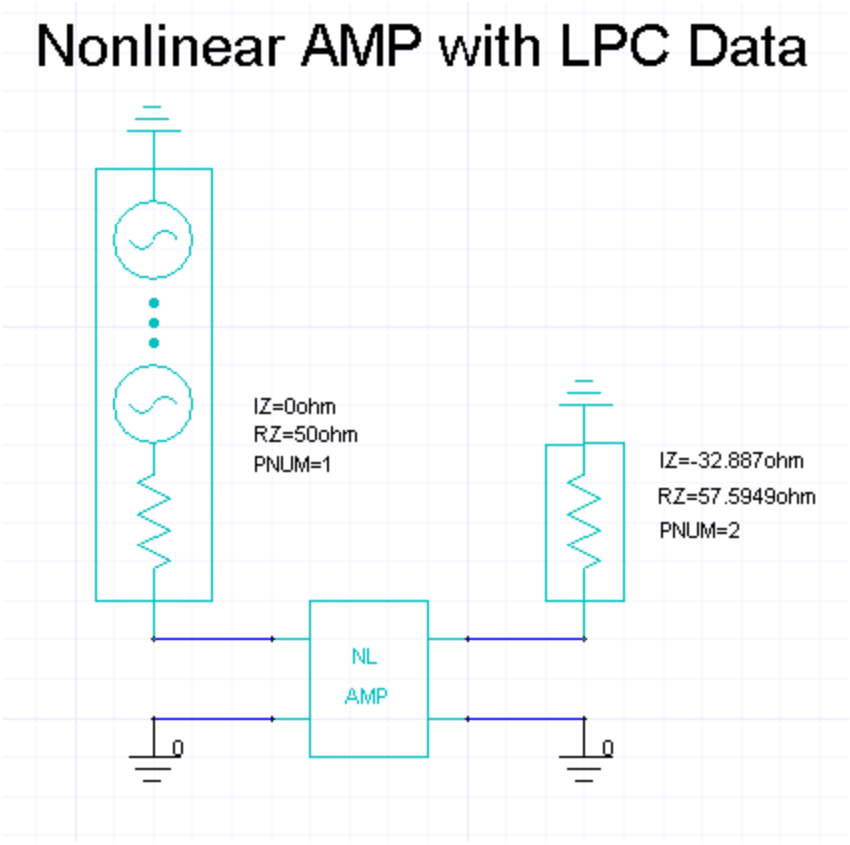
When you have finished viewing the reports, you may save the project.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

NLAMP with the LPC Demo File

The LPC format is an alternative to the LPD format.

1. Select the LPC_Demo circuit. The schematic appears:



The source has a characteristic impedance of 50 ohms, and the output port impedance has been set at (57.5949 - j32.887), matching one of the values in the LPC file.

2. Click the NL AMP element and open its Properties:

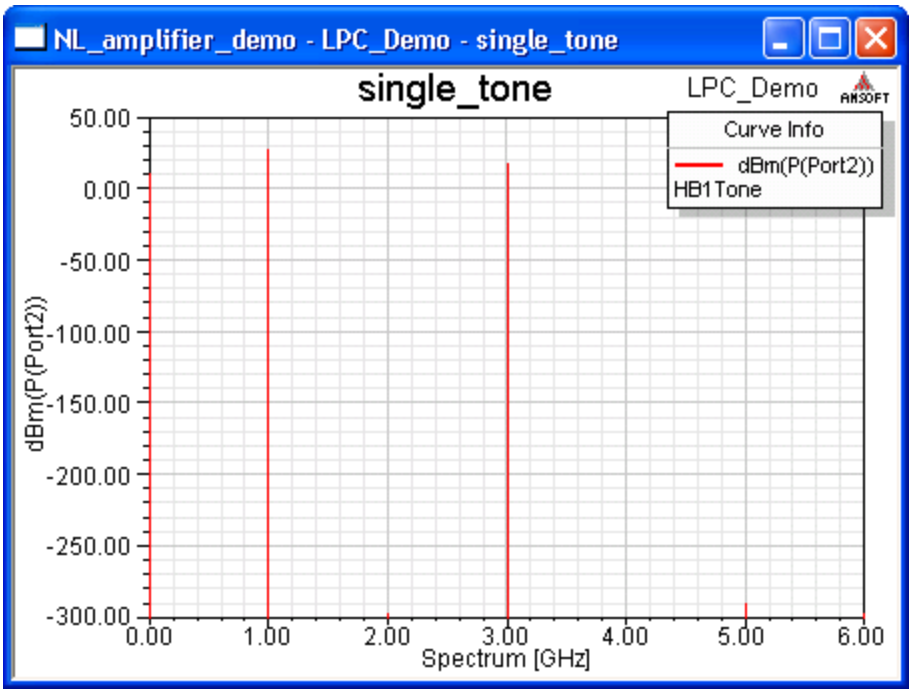
Name	Value	Unit	Evalu...	Description
loadpull_file	NLAMP_demo.lpc			Load pull data file
source_frequency1	freq3		1GHz	Frequency of input source
source_frequency2	freq4		1.03G...	Frequency of second input source for 2-tone
load_resistance	0	ohm	0ohm	Load resistance 0=calculated
load_reactance	0	ohm	0ohm	Load reactance 0=calculated
model_switch	0			Select implementation 0=freq domain 1=time
CosimDefinition	Edit			
CoSimulator	DefaultNetlist			
Status	Active			

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The new loadpull_file is **NLAMP_demo.lpc**. The source frequency given by project variable *freq3* is 1GHz, the frequency at which the file data is derived. A second, nearby frequency given by project variable *freq4* is used in two-tone harmonic balance analysis. The sinusoidal sources and the analysis setups have been modified to use *freq3* and *freq4*.

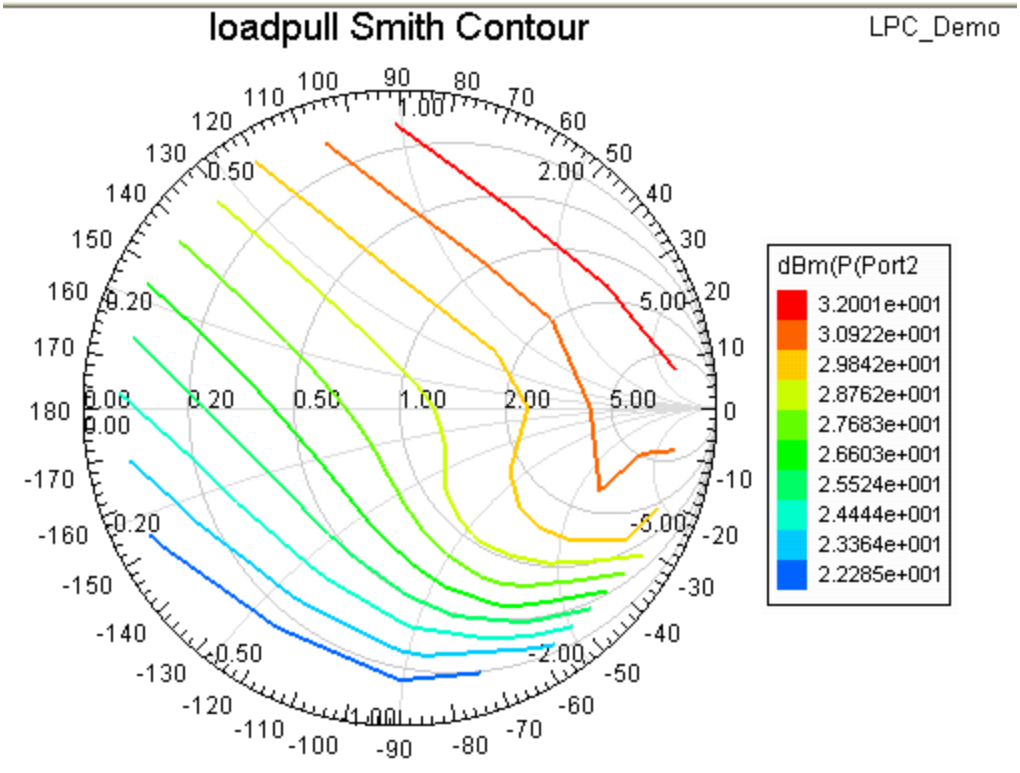
The **model_switch** is set for the frequency domain implementation. The time domain implementation gives the same results for this LPC file.

3. Right-click **Analysis** in the Project window and select **Analyze** on the menu. This runs all four analyses.
4. When all four analyses have completed, click the **one tone** Report:

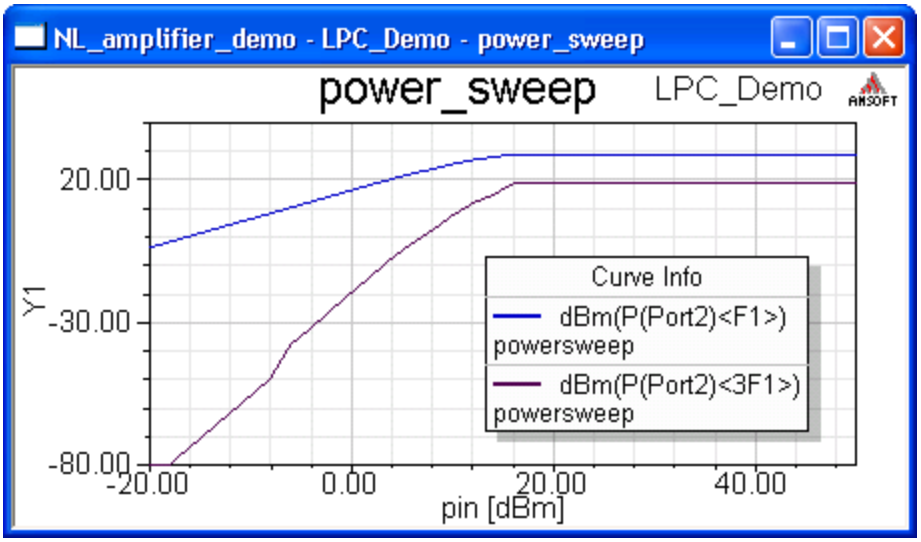


5. Click the **loadpull Smith Contour** Report:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

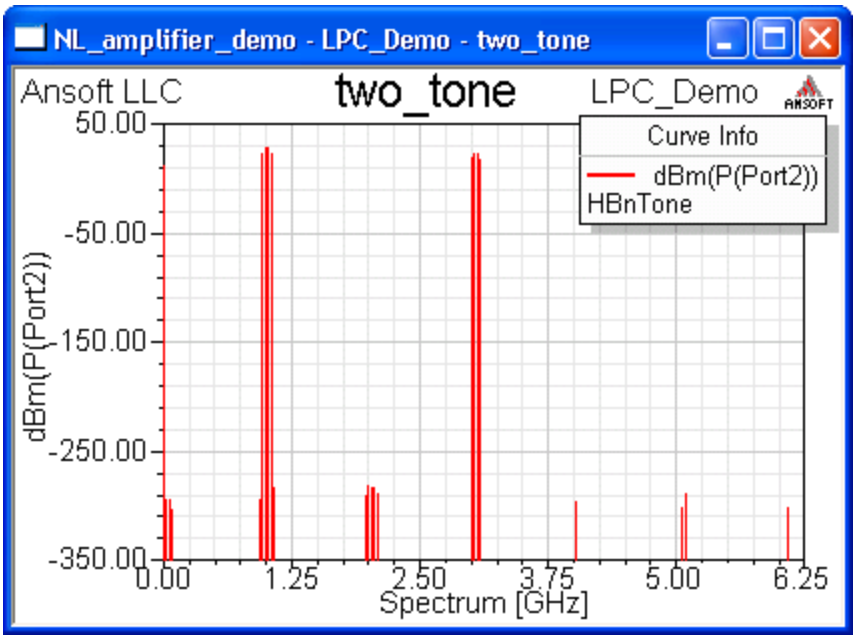


6. Click the **power_sweep** Report:



7. Click the **two tone** Report:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



8. When you are finished with the demo, you may save and close the project.

X-Parameter Example

X-parameters describe the frequency-dependent behavior of non-linear systems. In this example, compare the outputs of an amplifier, modeled using both a conventional transistor model and an X-parameter model.

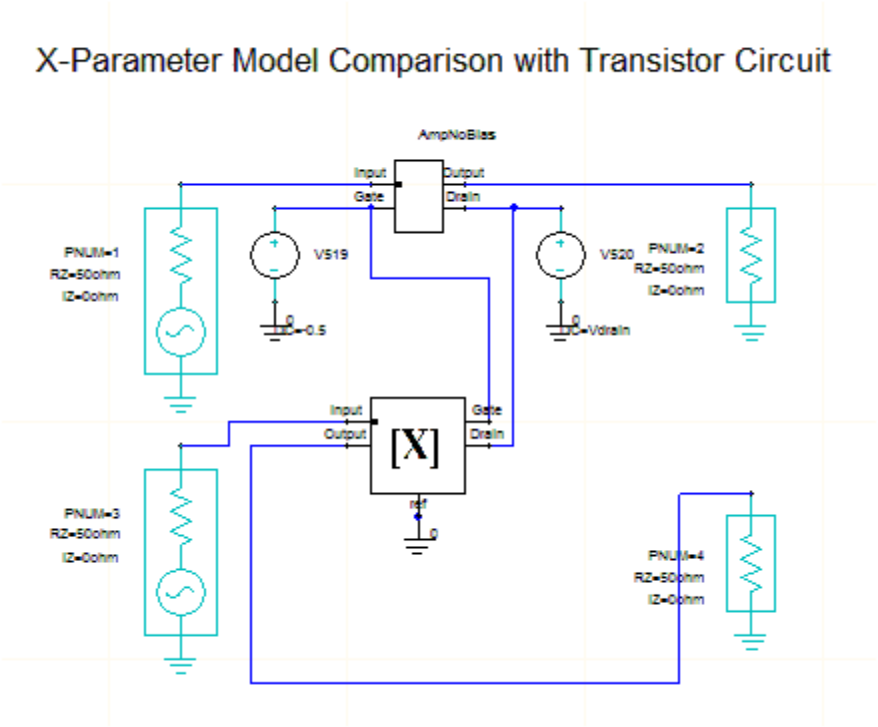
The schematic and data file for the example are available in the Examples directory.

Open the **X_Parameter_Example** Schematic project from its file in the Examples directory.

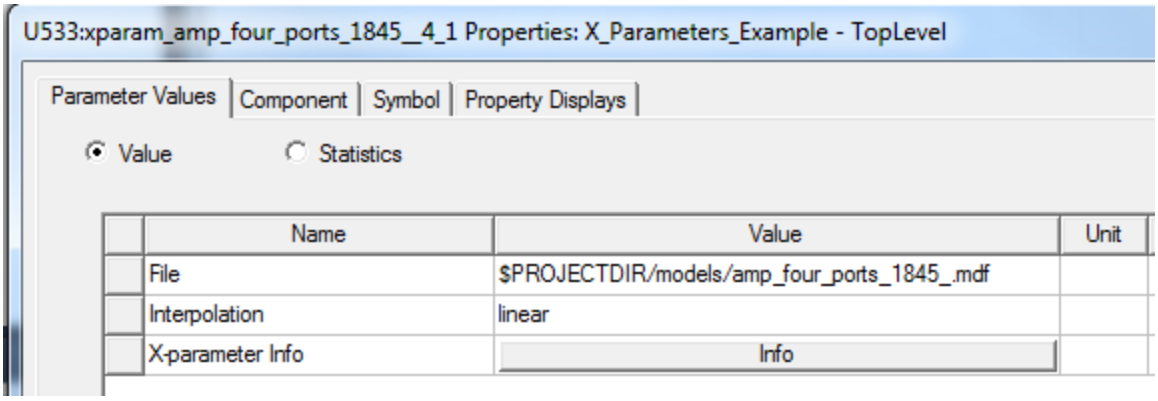
1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **RF_Microwave**, the **Amplifiers** directory, then select the file **X_Parameter_Example.aedt**. Click **Open**.
3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

The Project consists of two designs (circuits), **AmpNoBias** with an amplifier circuit design, and **TopLevel** to instantiate the amplifier circuit and compare it to an X-parameter model. Here is the TopLevel schematic:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

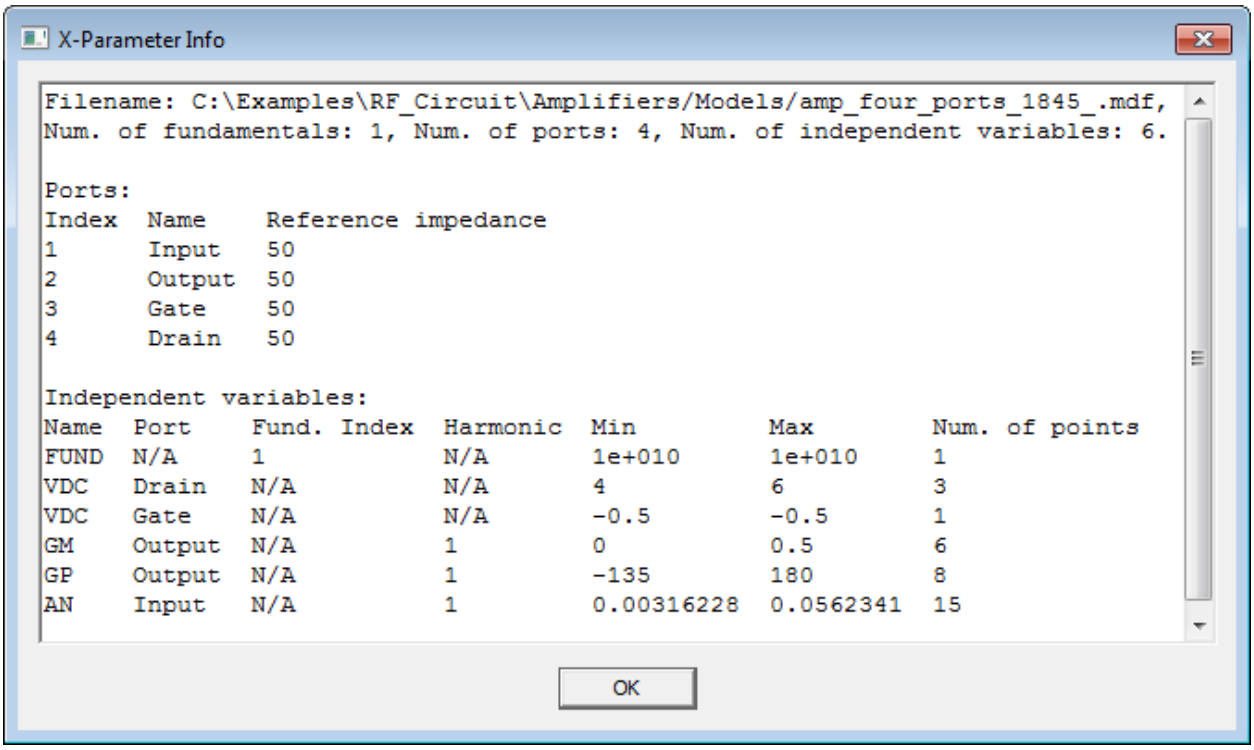


4. Select the X-parameter component and display its Properties:



5. The **File** property points to the file with the X-parameter data.
6. The **Interpolation** should be **linear**.
7. Click **Info** in the X-parameter Info **Value** field to display a summary of the variables in the data file.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The upper lines show the name of the model file and the numbers of fundamentals (1), ports (4), and independent variables (6).

The Ports entries show the name and reference impedance associated with each of the numbered ports.

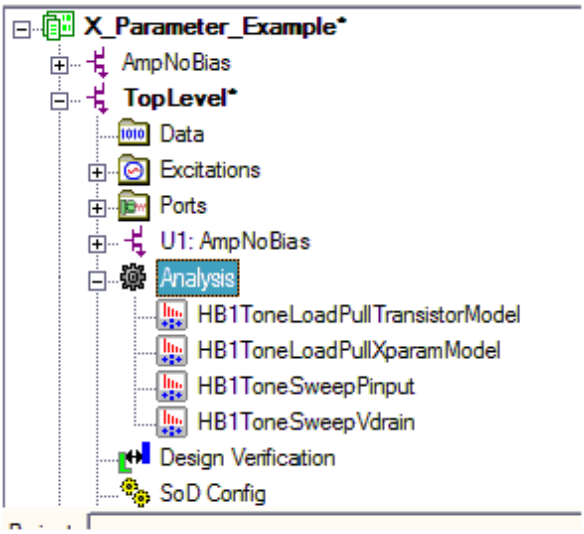
The X-parameter model was derived for the following variable ranges:

- Variable **FUND**: One fundamental frequency, 10GHz.
- Variable **VDC**: Drain voltage 4V to 6V, 3 sample points.
- Variable **VDC**: Gate voltage -0.5V, 1 sample point.
- Variable **GM**: Magnitude of load reflection coefficient 0.5, 6 sample points.
- Variable **GP**: Phase of load reflection coefficient -135 degrees to 180 degrees, 8 sample points.
- Variable **AN**: Input power ranging from -20dBm to 5dBm, 15 sample points.

Click **OK** to close the Info window.

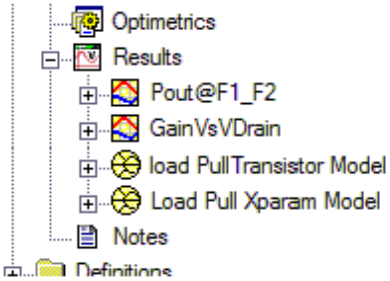
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. Expand the **Analysis** icon in the **TopLevel** project.



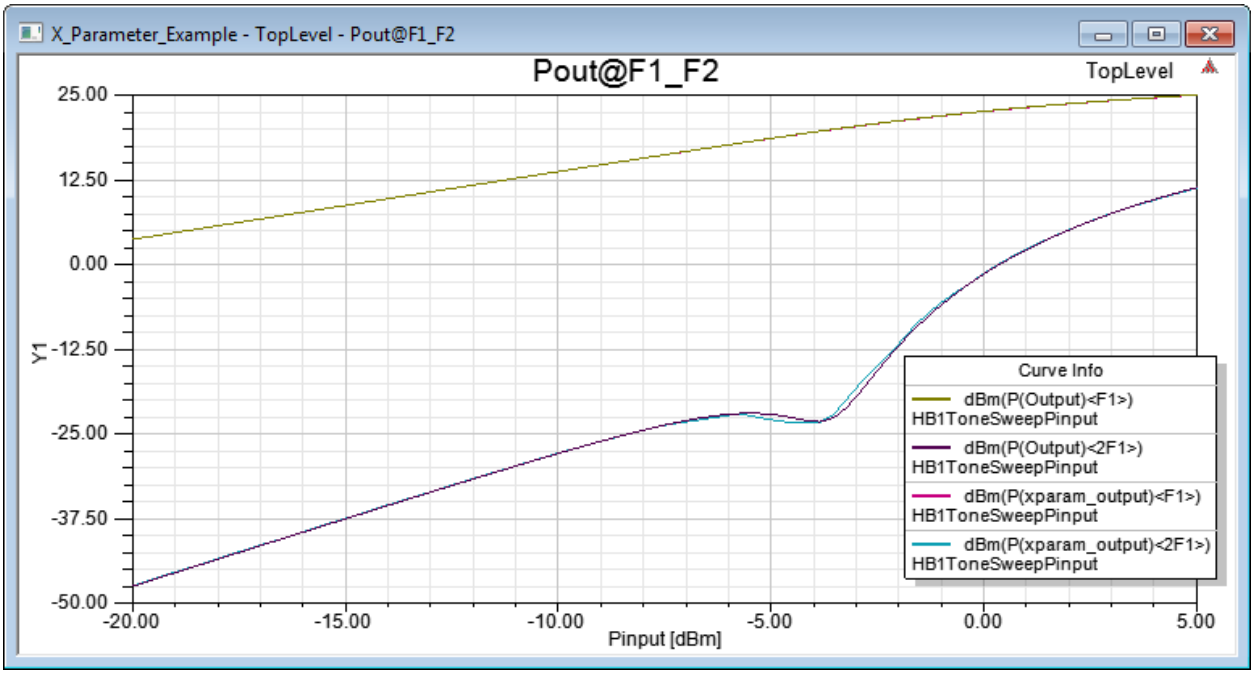
Right-click the Analysis icon and select **Analyze**. (You may need to select **Force Analysis** or change something to get the analysis to run.) All four HB1Tone setups run to completion.

9. Expand the Results icon:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

10. Click the **Pout@F1_F2** report to open it.



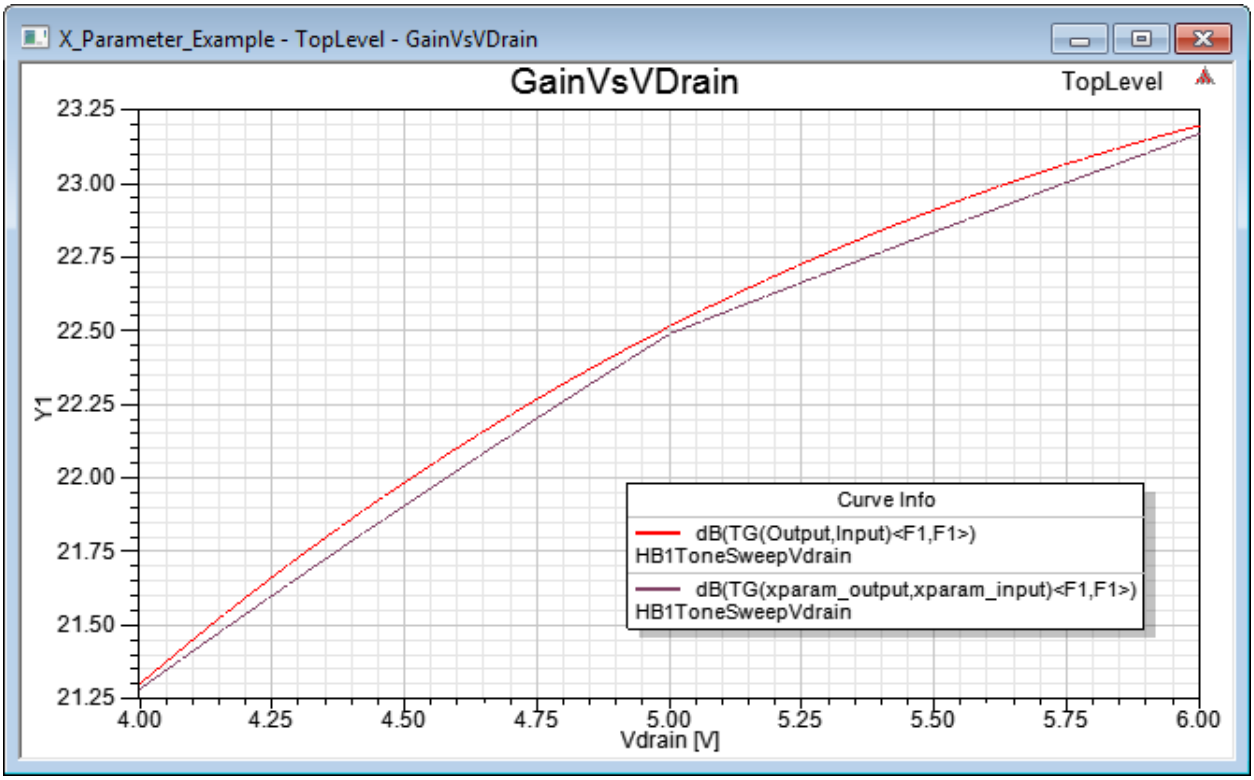
This plot shows the power out versus the power in for the F1 harmonic (the fundamental) and the F2 harmonic (2F1).

The upper line is actually two traces: At the F1 harmonic, the power out vs power in for the transistor model and for the X-parameter model are nearly identical everywhere in this range.

The lower set of traces shows that at the second harmonic, the X-parameter model is very close to the transistor model.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

11. Click the **GainVsVDrain** report to open it.

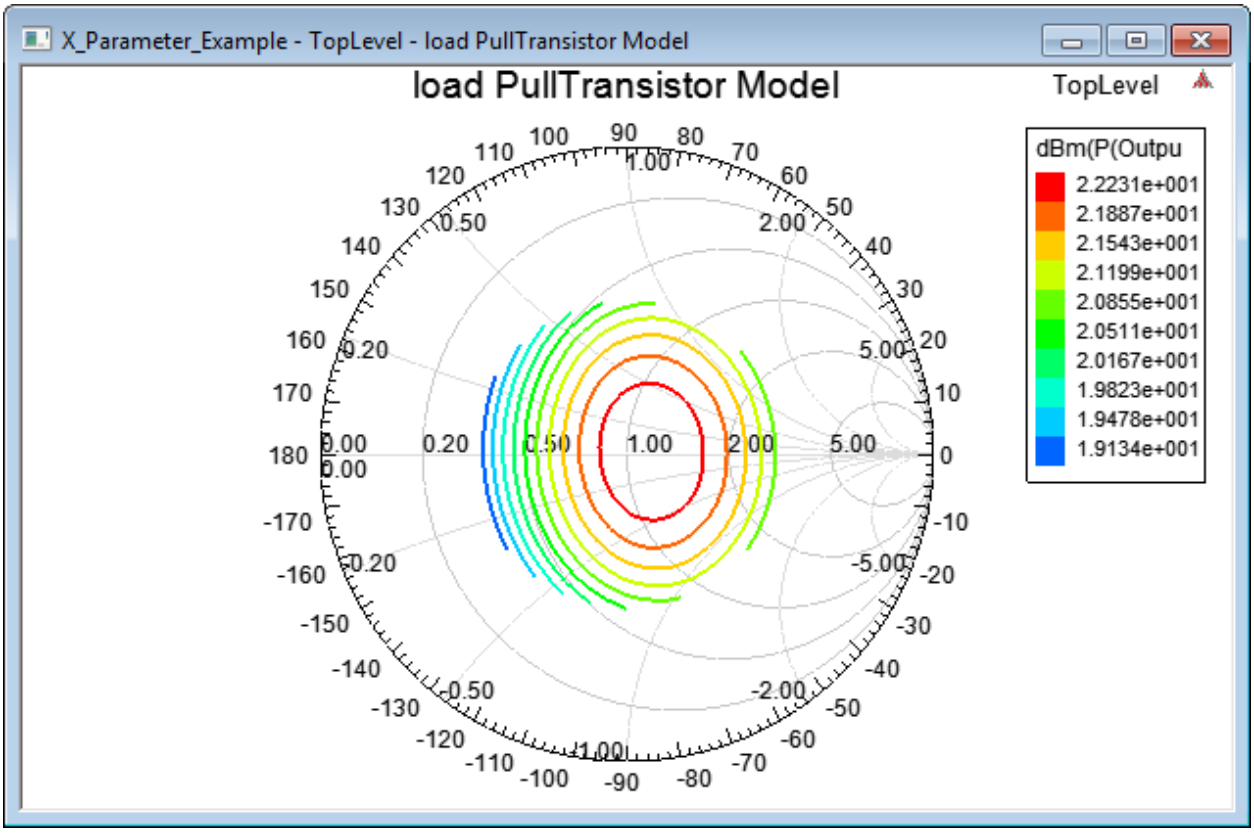


This plot shows the gain as the drain voltage is swept from 4V to 6V.

The set of traces shows that again the X-parameter model is very close to the transistor model.

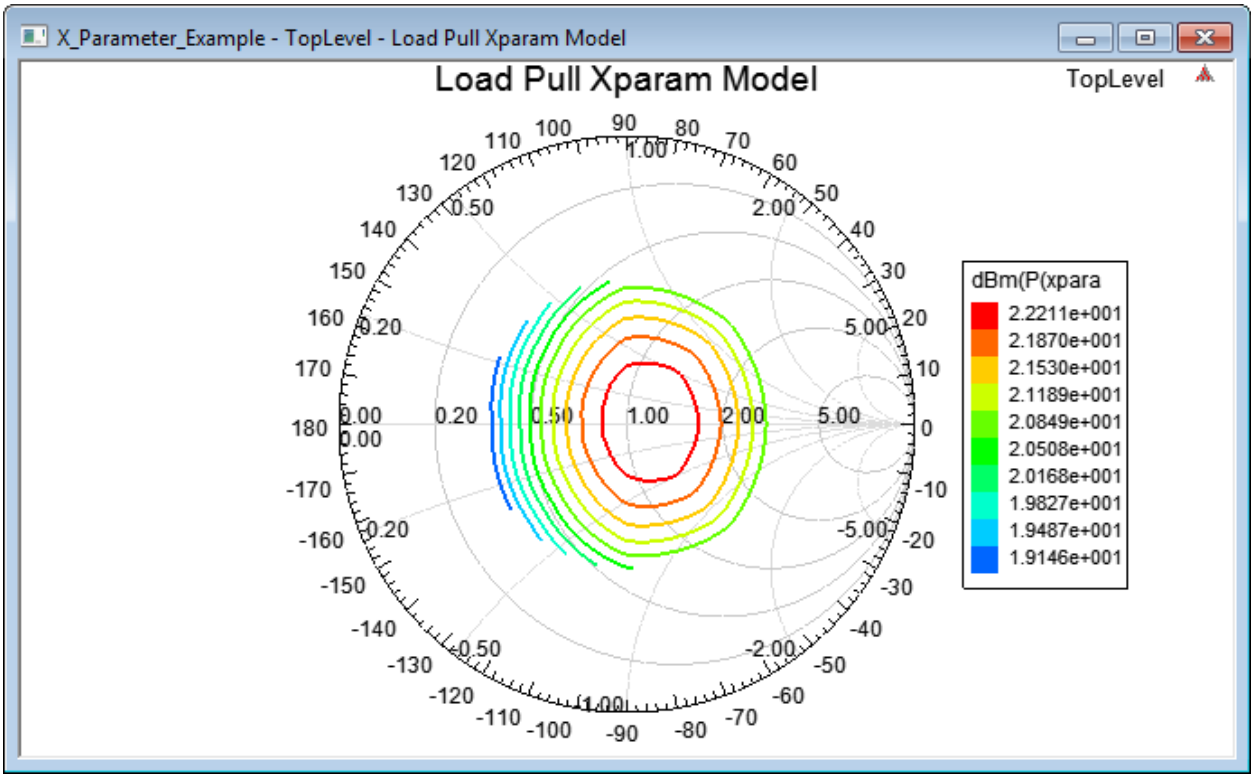
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12. Click the **Load Pull Transistor Model** report to open it.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

13. Click the **Load Pull Xparam Model** report to open it.



A comparison of the two Smith Charts shows that the X-parameter model is very close to the transistor model.

14. Click **File>Save** to save the example.

System Frequency Domain Analysis: Receiver Circuit

This example shows System Frequency Domain (FD) analysis of a receiver circuit consisting of Nexxim filters and transmission lines combined with Nexsys behavioral MIXER and AMP elements.

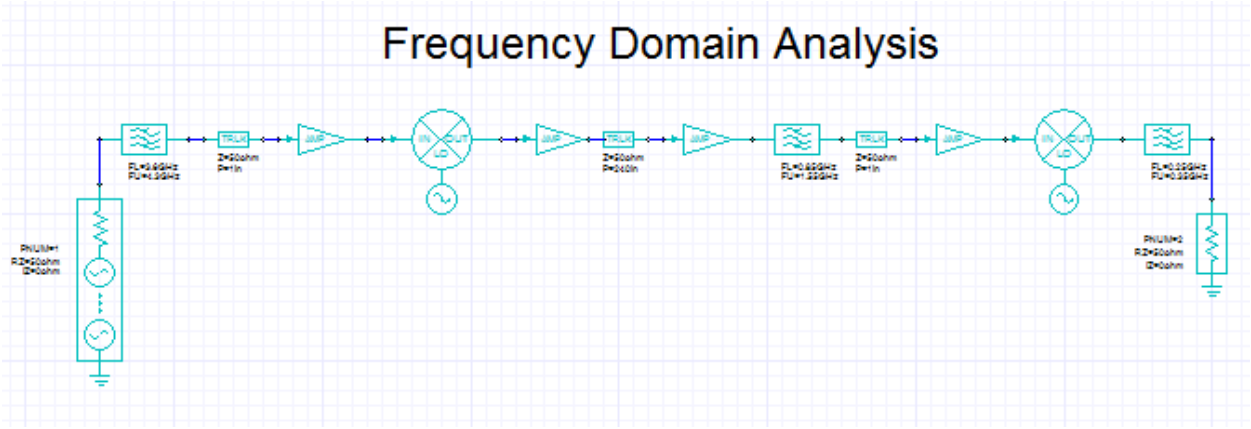
The schematic and data file for the example are available in the Examples directory.

Open the project on the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **RF_Microwave**, the **System** directory, then select the file **System_FD_Receiver_Example.aedt**. Click **Open**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

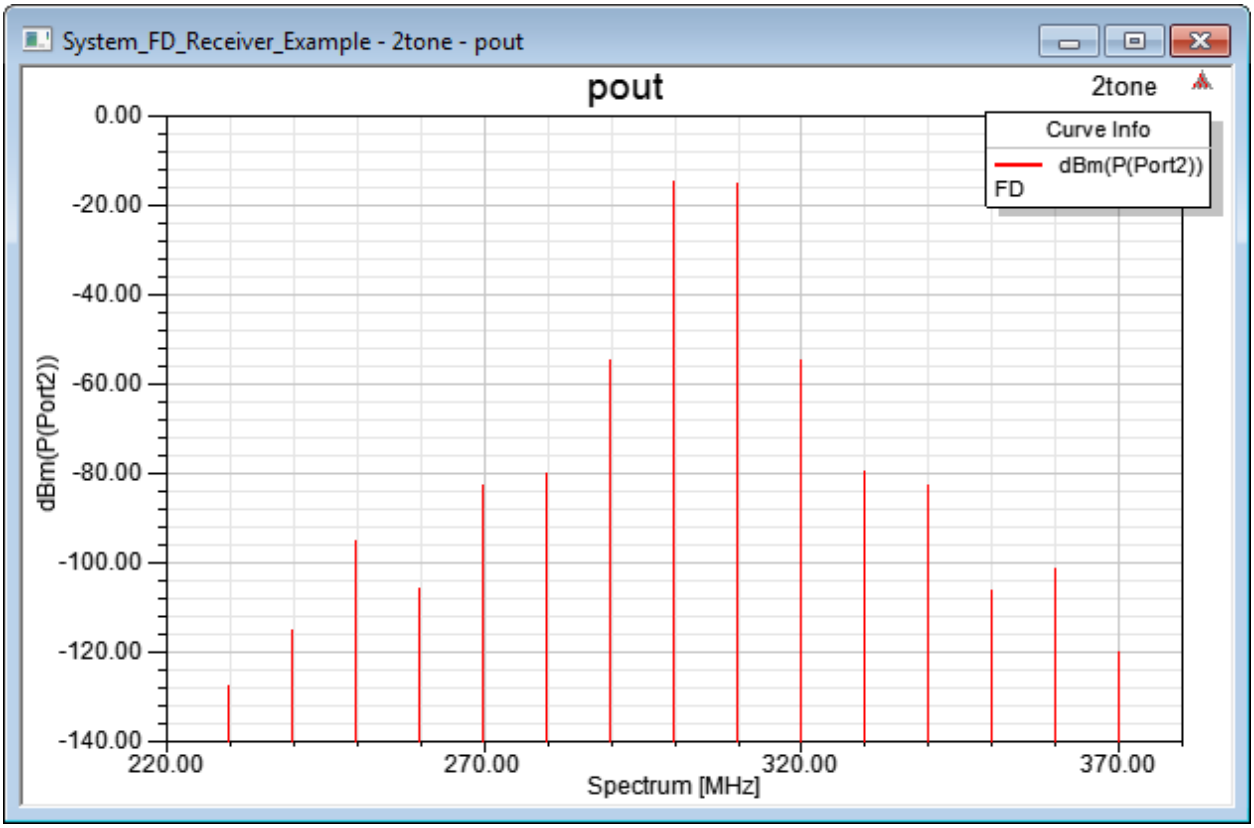
3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.
4. The schematic opens in the design window.



The central transmission line TRLK component is 240 inches (20 feet) in length. The AMP elements on the transmitter and receiver ends of the long TRLK use NMF files for the compression data. The other AMP elements and the MIXER elements have S-parameters specified as component properties.

5. Expand the Analysis folder, right-click and select Analyze (you may need to use Force Analysis).
6. When the analysis is complete, expand the Results folder and click the **pout** report to see the spectral distribution of the output power.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



7. Click **File>Save** to save the project.

For more information, see System Frequency Domain Analysis.

System Frequency Domain Analysis: Mixer Data

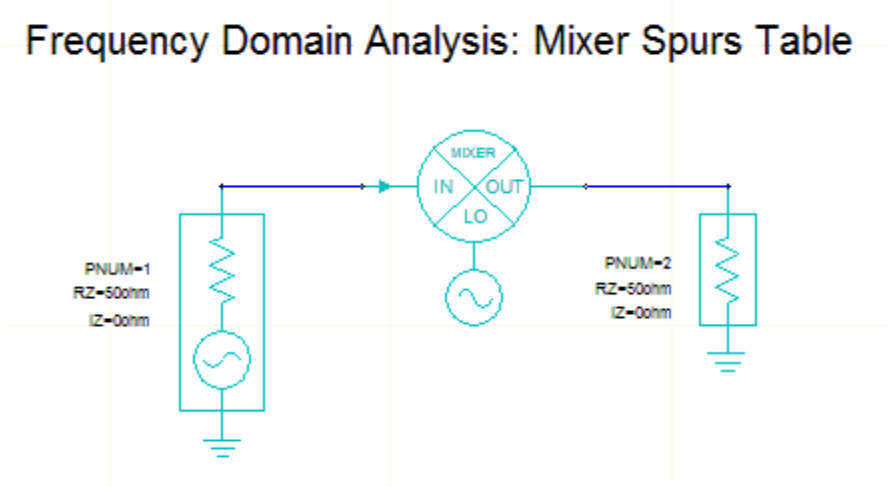
This example demonstrates System Frequency Domain analysis of a behavioral MIXER element with mixer spurs data from a NMF file. The schematic and data file for the example are available in the Examples directory.

Open the project on the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **RF_Microwave**, the **System** directory, then select the file **System_FD_Mixer_Data_Example.aedt**. Click **Open**.
3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

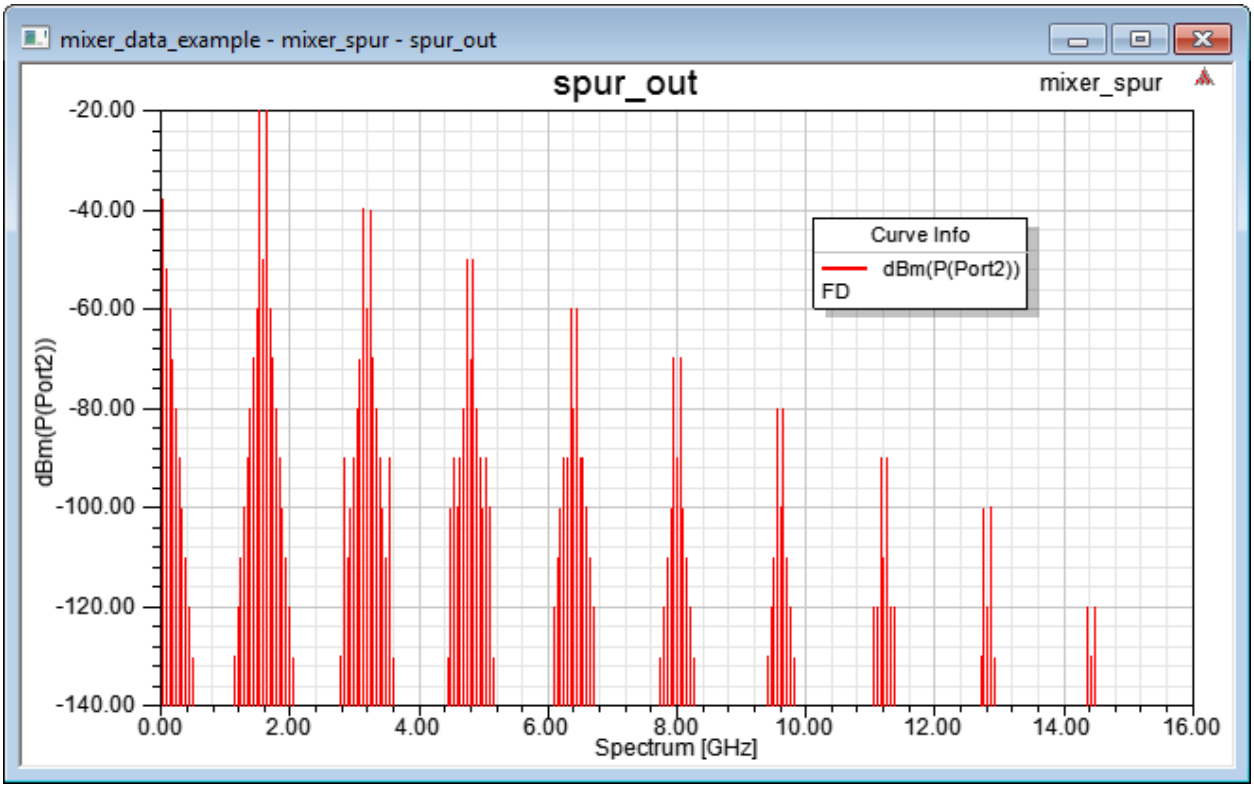
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. The schematic opens in the design window:



5. Select the MIXER component to display its properties. The mixer reads the mixer spurs data from a data file, NMFSpurTable.nmf (**file** property).
6. Expand the Analysis folder, right-click and select Analyze (you may need to use Force Analysis).
7. When the analysis is complete, expand the Results folder and click the **spur_out** report to see the spectral distribution of the mixer spurs output.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



8. Click **File>Save** to save the project.

For more information, see System Frequency Domain Analysis.

DC-IV Characteristics Transistor Example

This example demonstrates how to perform DC-IV characterization and S-parameter sweep for various transistors. The example project can be used as a template to customize the simulation and serve as a starting point for an amplifier design.

Open the DC-IV Example

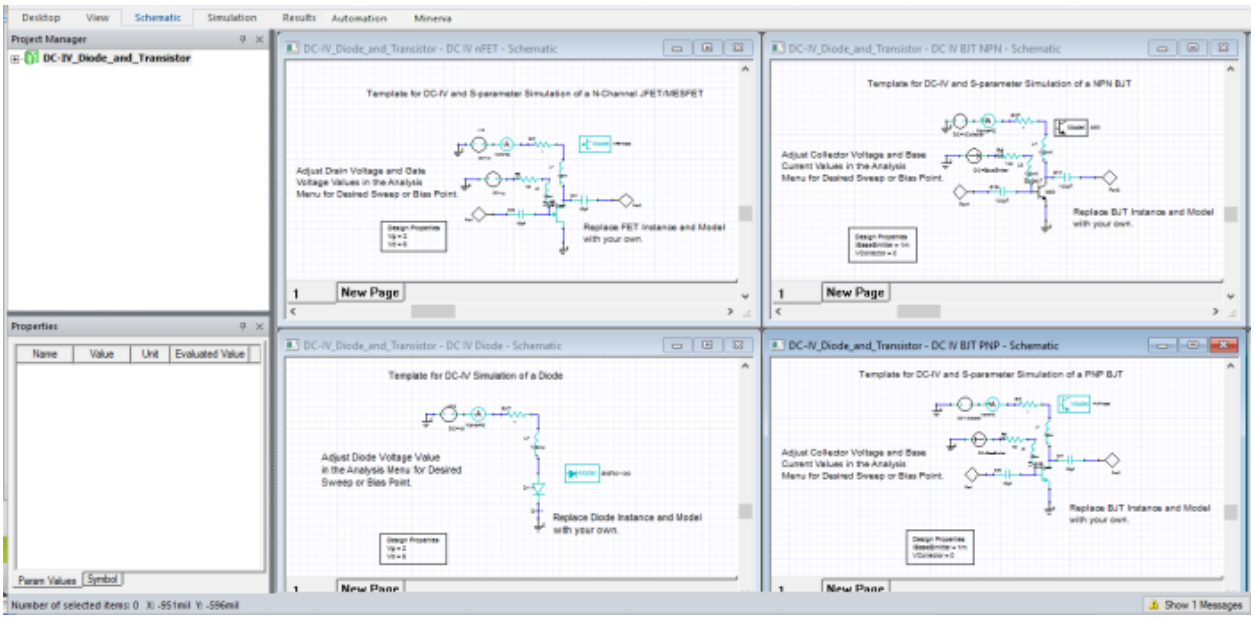
This example demonstrates the I-V Characteristic Curves of an electrical device that show the relationship between the current flowing through the device and the applied voltage across its terminals.

The schematic and data file for the example are available in the Examples directory.

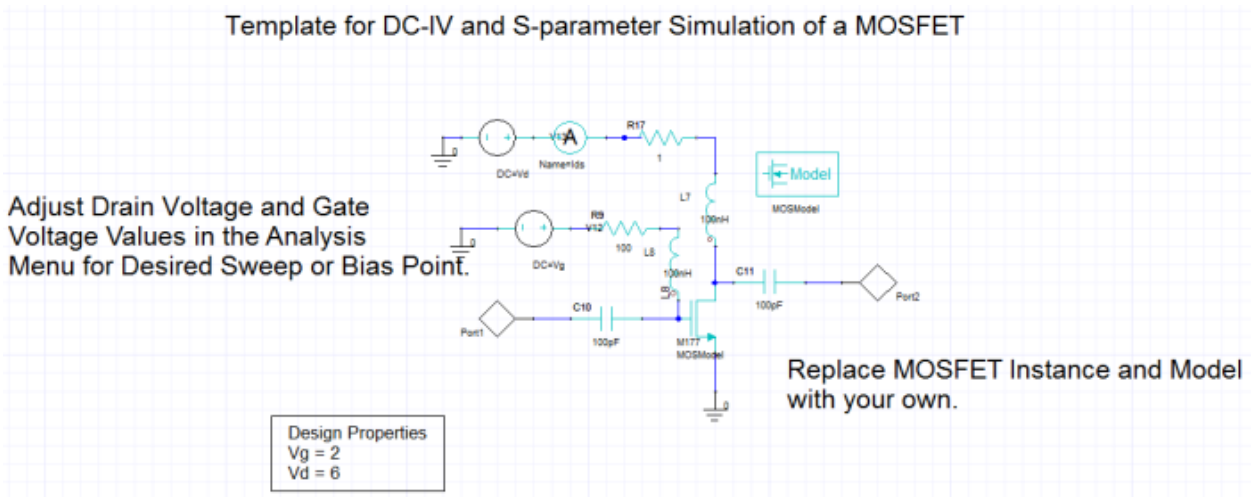
1. From the **File** menu, select **Open Examples** to open an explorer window.
2. In the **File Open** window, open the **Electronics Desktop** directory, then **Circuit**, then **RF_Microwave**, the **DC-IV** directory, then select the file **DC-IV_Diode_and_Transistor.aedt** and click **Open**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission, then click **OK**. The schematics for the **DC-IV_Diode_and_Transistor.aedt** project open in the design window.



4. In the **Project Tree**, open **DC-IV_Diode_and_Transistor** and select the **DC IV MOSFET** design, or any design that is listed. In the design window double-click the design to make it appear full screen.



5. Right-click in the design to open the **Design Properties** window and adjust any of the properties to meet your needs. The transistor model and instance can even be replaced with your own versions. For more information, see Plot I-V Curves of Active Components.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. Double-click an I-V solution beneath **Analysis** to make adjustments to the voltage, frequency sweeps, or the lumped circuit element parameters. For more information, see Plot I-V Curves of Active Components.
7. Click **File>Save** to save the project.

Complete the DC-IV Analysis

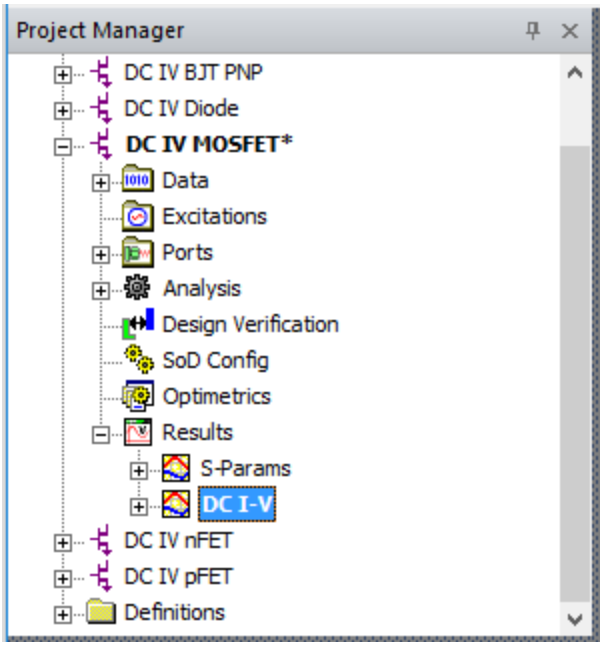
To perform the DC-IV analysis:

1. In the **Project Tree**, right-click a **DC-IV** analysis, such as **DC IV MOSFET**, then select **Analyze** on the menu.

View the Results of the DC-IV Analyses

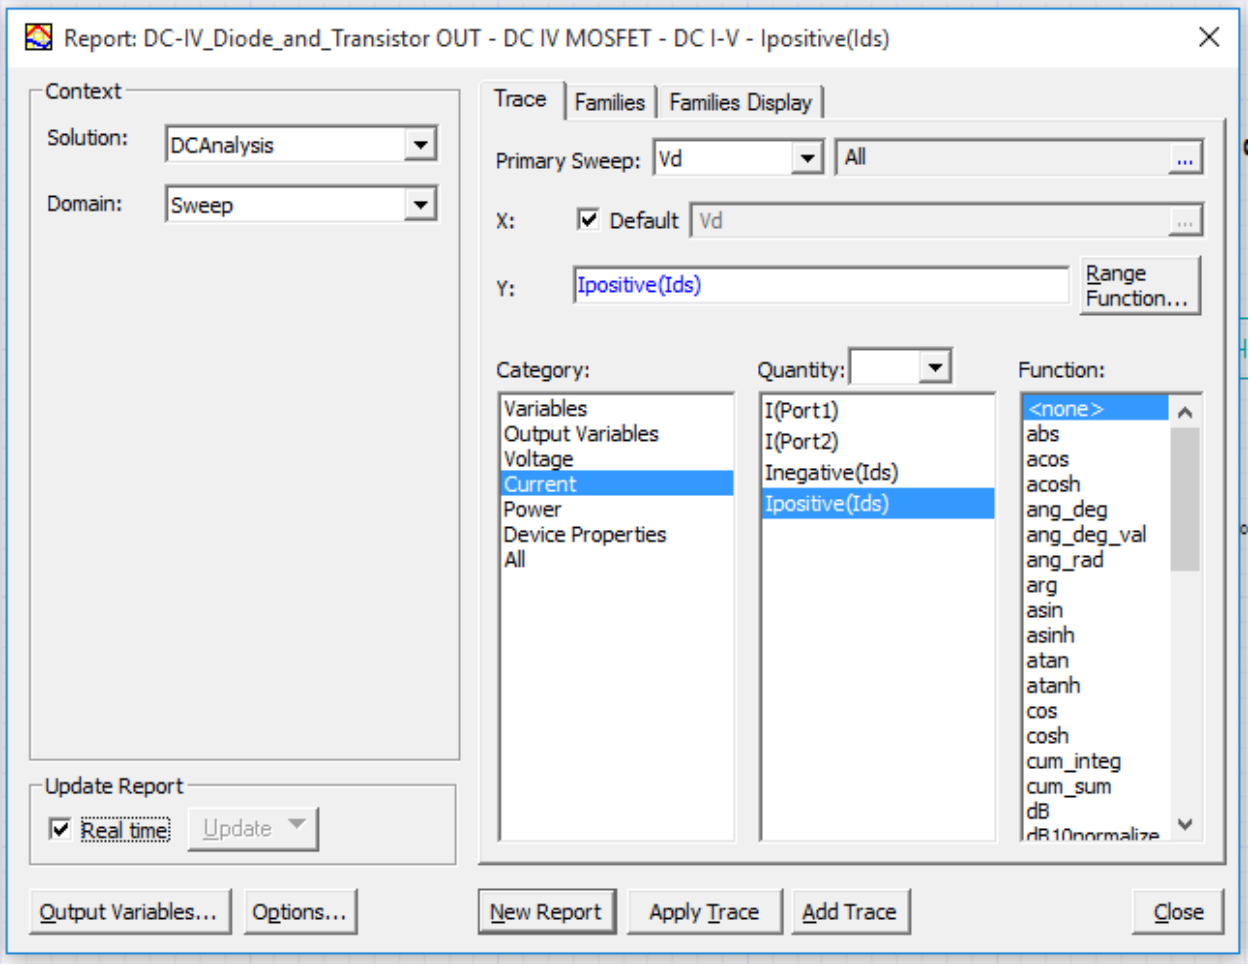
When the analyses have completed, the reports that have been set up become valid.

1. From the **Project Manager** window, expand the **Results** icon:



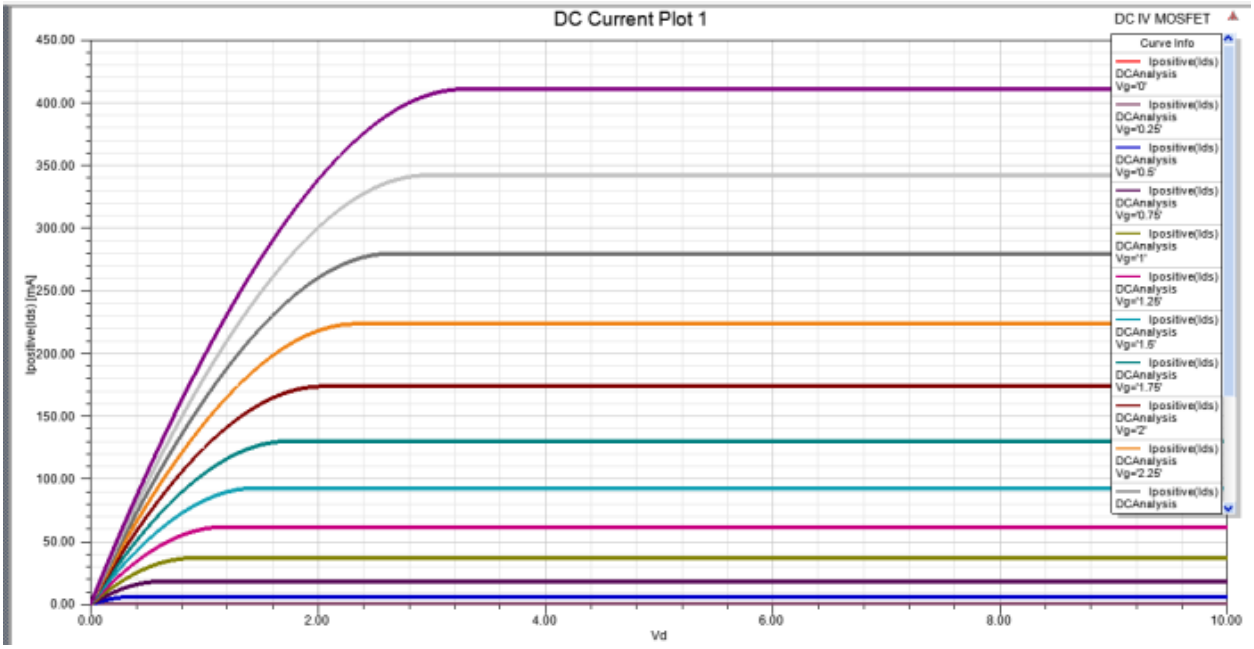
2. Right-click the **DC-IV** report and select **Modify Report** to open the setup for the Rectangular Plot report:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. After making your modifications, click **New Report** ; a new report appears in the **Project Tree** within **Results**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Time Domain Reflectometer Example

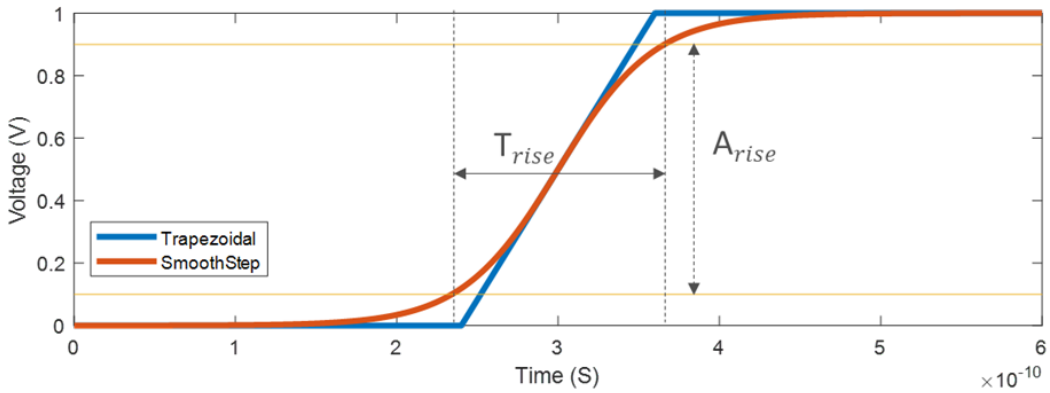
This topic presents differential and single-ended versions of a Time Domain Reflectometer (TDR). The setup demonstrates the process of analyzing both impedance and delay. The schematics are configured to substitute another design for the Device Under test, then run the analysis and view the results. The project includes an example showing how to obtain the equivalent reactance (capacitance or inductance) for a non-uniformity that is detected by the TDR.

Single-Ended TDR

The schematics for all three TDR demonstrations are in one project in the Examples directory.

The following example is for a Single-Ended Time Domain Reflectometer using a Trapezoidal waveform. The TDR probe also provides the option for a Smooth Step waveform, which provides a more realistic step input and allows control of the rise interval. Step 4 is optional; it demonstrates how to choose between the Trapezoidal and SmoothStep waveform for analysis.

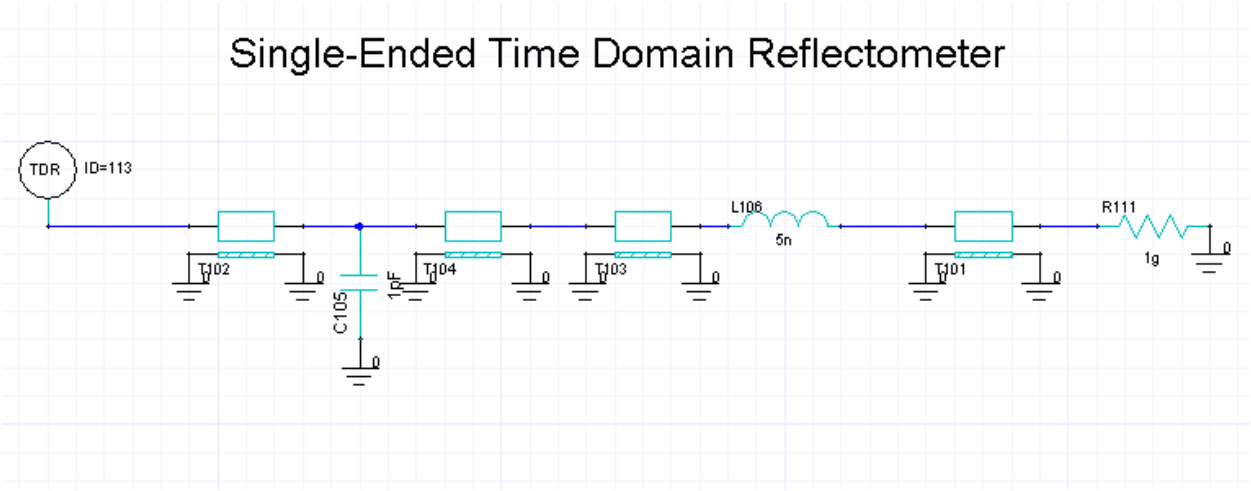
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Open the TDR Schematic project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open a file explorer window.
2. Select **Circuit > Signal Integrity**, scroll to find and select **TDR_Example.aedt**, click **Open**.

   In the Project Tree, Expand the **TDR_Example** icon and the **1_Single Ended** icon. The single-ended TDR schematic appears in the design window:



The single-ended TDR consists of a unit pulse source, an internal impedance of Z0 ohm, a reference length of transmission line (Z0-ohm impedance, 0.5ns delay), and two voltage probes, Vexcited_pos for the step voltage and Vdetected_pos for the reflected voltage. (Z0 is the TDR component parameter.)

The Device Under Test (DUT) is a series of transmission lines and discrete passives to represent the typical TDR problem of finding where impedance changes in a line.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In sequence, the DUT elements are:

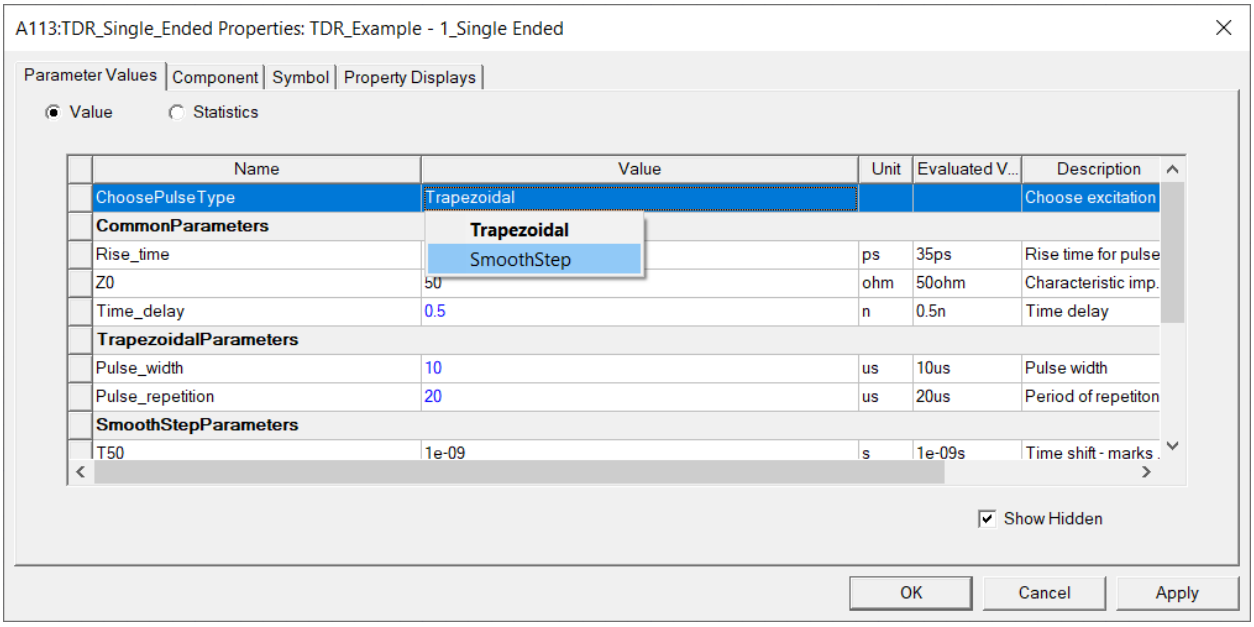
- Transmission line, 50-ohm impedance, 1 ns delay
- Shunt capacitor, 1 pf
- Transmission line, 50-ohm impedance, 3 ns delay
- Transmission line, 55-ohm impedance, 5 ns delay
- Series inductor, 5 nH
- Transmission line, 25-ohm impedance, 2 ns delay
- Series resistor, 1 gigohm
- Terminating ground

3. The Examples directory is write-protected. Use **File** > **Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.
4. (Optional) Choose between Trapezoidal and SmoothStep.
    i. Click **Tools** > **Project Tools** > **Update Definitions**.
    ii. In the **Update Definitions** dialog, select **Show All Items**, **Select All**, then click **Update** . Close the dialog once updates are successful.

    iii. Right-click the TDR model symbol and click **Properties** to open the properties dialog.

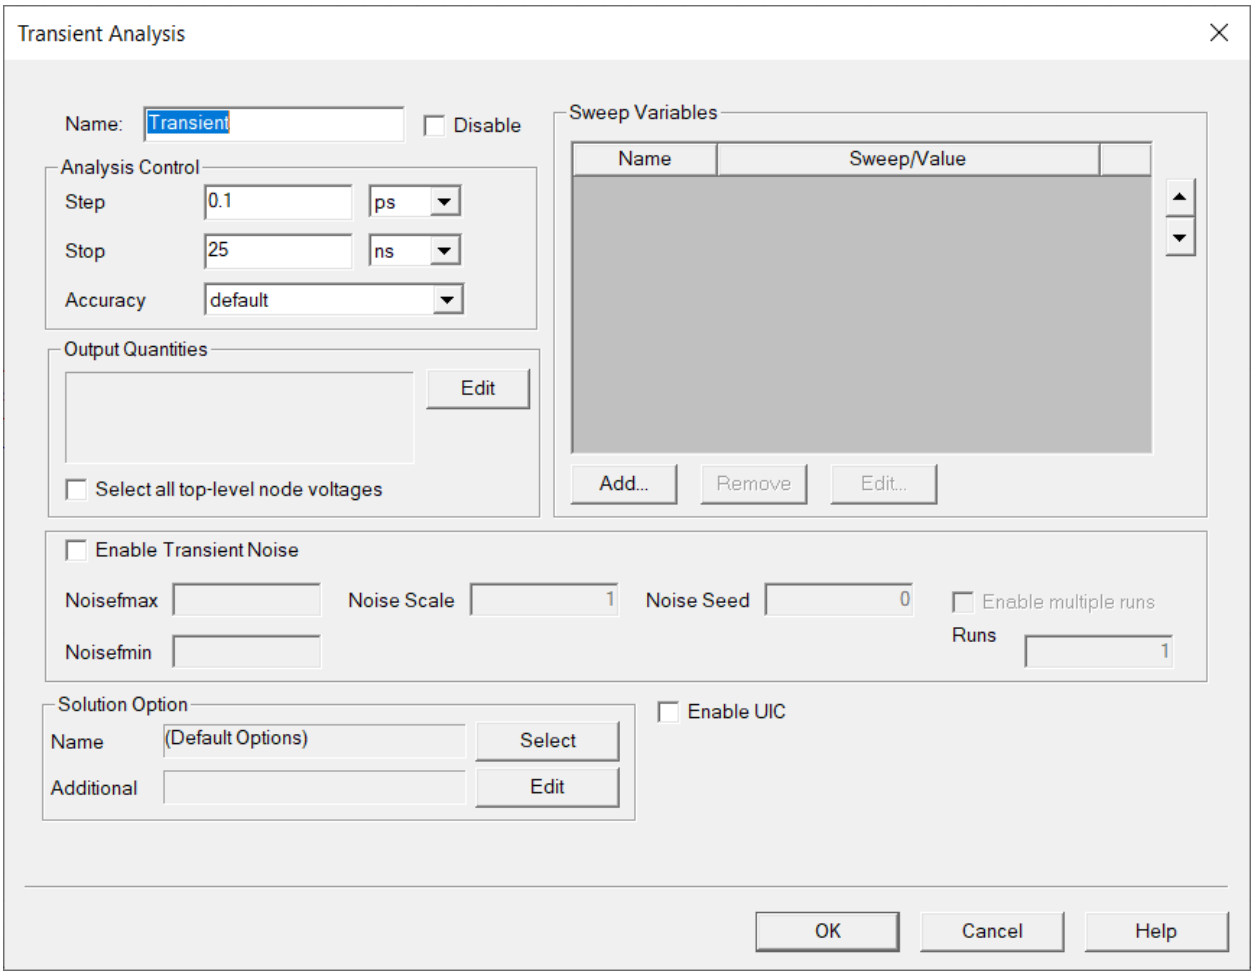
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

iv. Click the **Value** field for **ChoosePulseType** to view the two options. Select **SmoothStep**, click **Apply**, then **OK** to close the dialog.



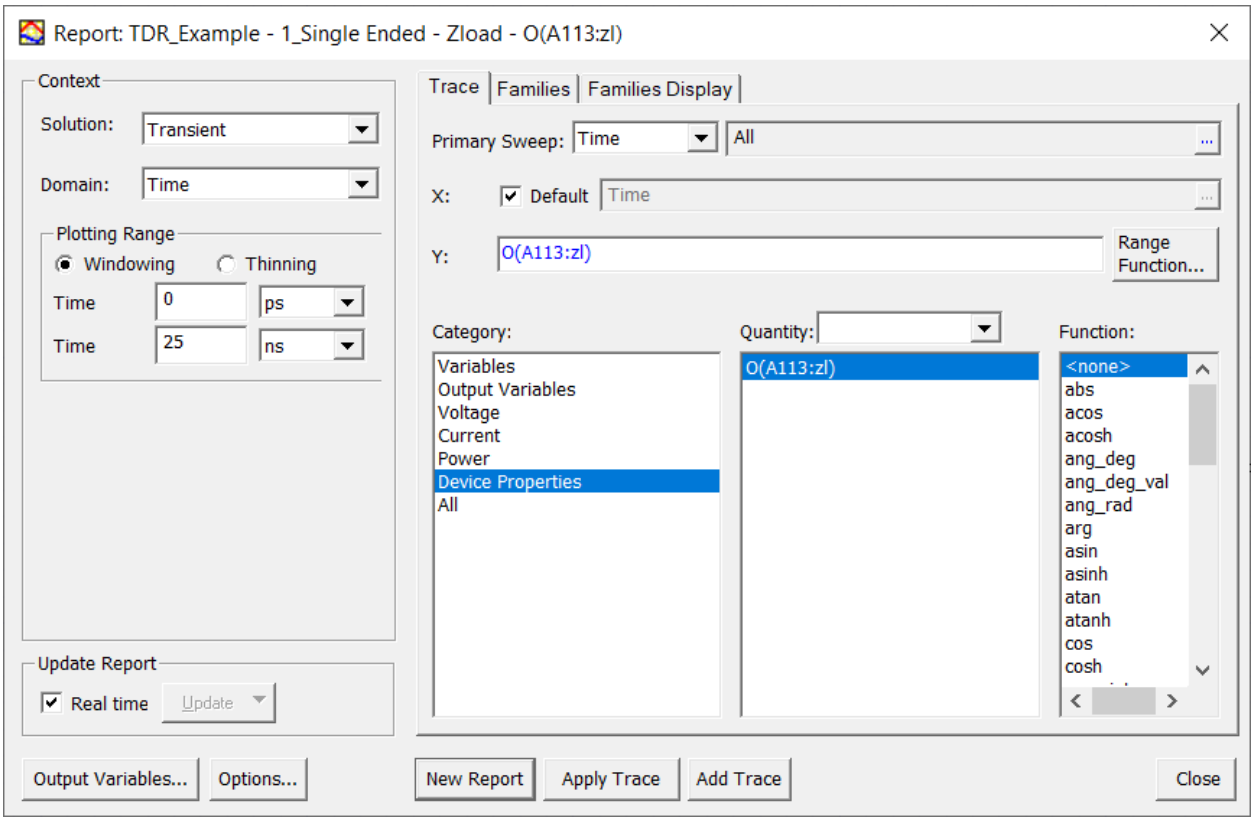
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. In the **Project Tree**, expand the Analysis icon and double-click on **Transient** to view the Transient Analysis setup. Click **OK**.



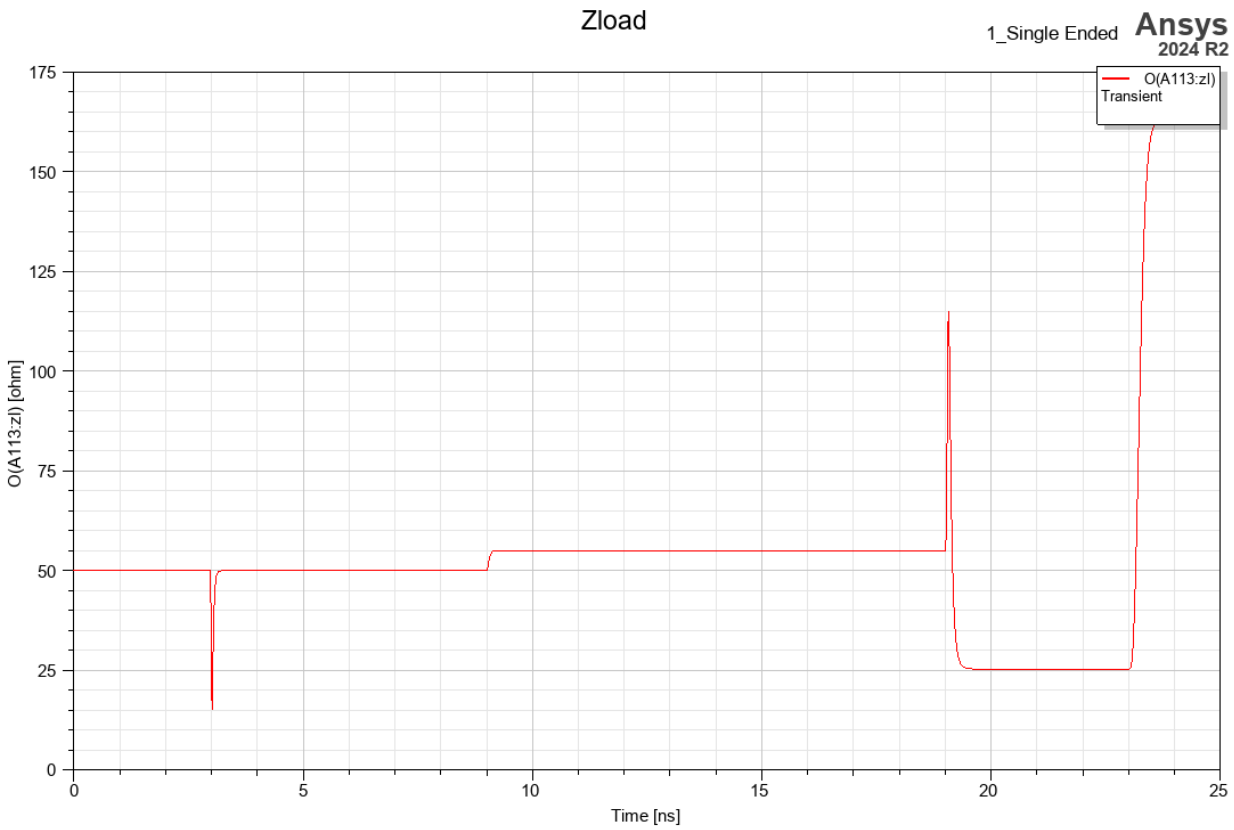
6. In the **Project Tree**, right- click **Transient** and select **Analyze**. The analysis runs to completion.
7. Expand the Reports icon and right-click on the **Zload** report setup. Select **Modify Report** to open the Report Setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. Click **New Report** to generate the report:

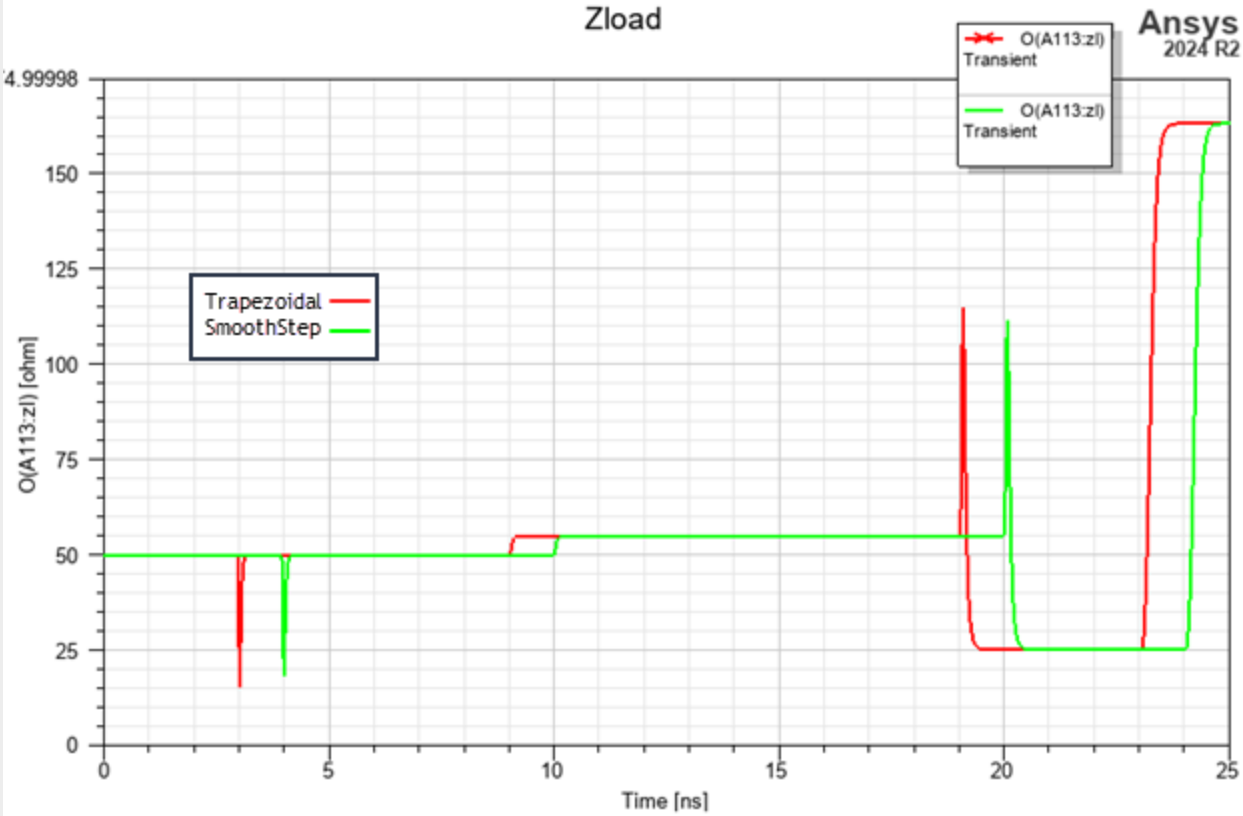


The TDR analysis allows us to identify each of the components of the DUT by their timing and behavior. Using the Trapezoidal waveform, the reflection timings are expected at 2* (Total Delay):

- At 3ns, the impedance drops to indicate the presence of the capacitor. The 3ns delay is the TDR internal delay (0.5ns) plus the first transmission line delay (1ns), times two for the reflection. Both transmission lines are at 50 ohms.
- At 9ns, the impedance increases to 55 ohm at the beginning of the 55-ohm line segment. 9ns=2(0.5+1.0+3.0).
- At 19ns, the impedance jumps to indicate the presence of the inductor, then immediately drops to25 ohm for the resistor. 19ns=2((0.5+1.0+3.0+5.0).
- At 23ns, the impedance goes to infinity at the high final resistor. 23ns=2(0.5+1.0+3.0+5.0+2.0).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: If SmoothStep waveform is selected, the parameter T50 will have an effect on the time-shift of the plot. See **Circuit > Nexxim Components > Probes > Time Domain Reflectometer** for more information about TDR properties, including the T50 SmoothStep parameter.



For a SmoothStep waveform, the reflection timings are expected at T50 + 2*(Total Delay):

- At 4ns, the impedance drops to indicate the presence of the capacitor. The 4ns delay is the TDR internal delay (0.5ns) plus the first transmission line delay (1ns), times two for the reflection, plus 1 ns for the T50 parameter. Both transmission lines are at 50 ohms.
- At 10ns, the impedance increases to 55 ohm at the beginning of the 55-ohm line segment. 10ns= 1 + 2(0.5+1.0+3.0).
- At 20ns, the impedance jumps to indicate the presence of the inductor, then immediately drops to 25 ohm for the resistor. 20ns= 1 + 2((0.5+1.0+3.0+5.0).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- At 24ns, the impedance goes to infinity at the high final resistor. 24ns= 1 + 2(0.5+1.0+3.0+5.0+2.0).

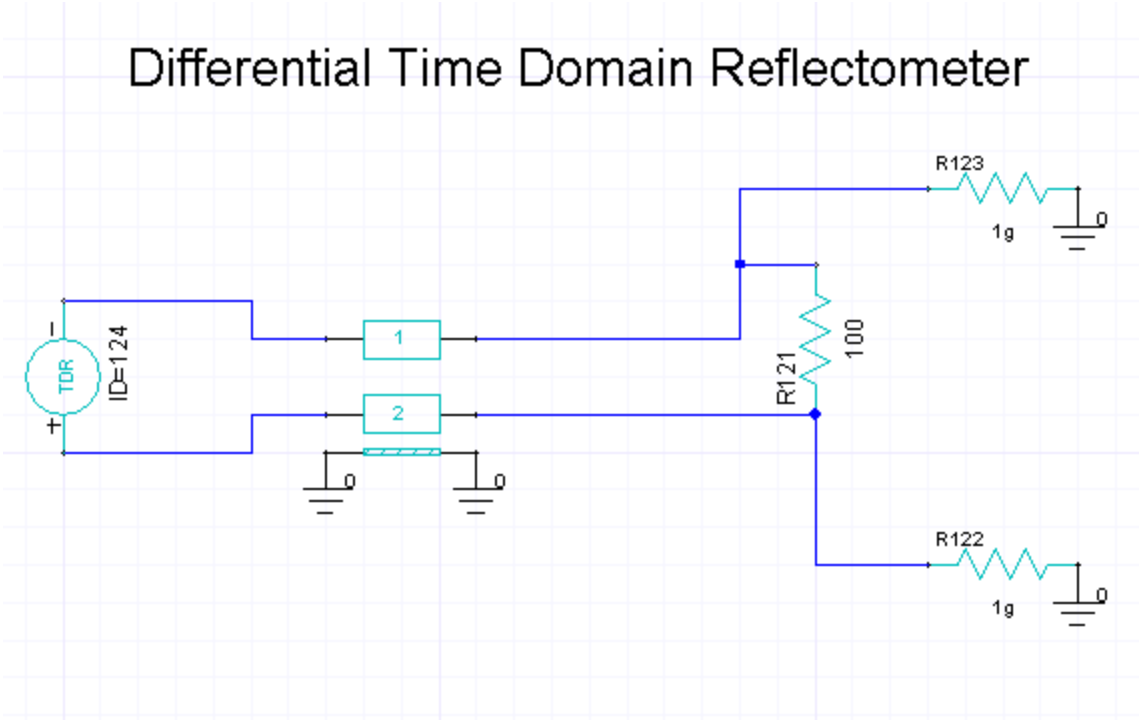
.

Differential TDR

Open the TDR Schematic project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open **Circuit**, then **Signal Integrity**, and select the file **TDR_Example.aedt**. Click **Open**.

   Expand the **TDR_Example** icon and the **2_Differential** icon. The differential TDR schematic appears in the design window:



The differential TDR consists of two channels, each with a pulse source, an internal impedance equal to 0.5Z0 ohm, a transmission line with 0.5Z0-ohm impedance and with 0.5-ns delay, and two voltage probes, Vexcited_pos or Vexcited_neg for the step voltage and Vdetected_pos or Vdetected_neg for the reflected voltage. (Z0 is the TDR component parameter.)

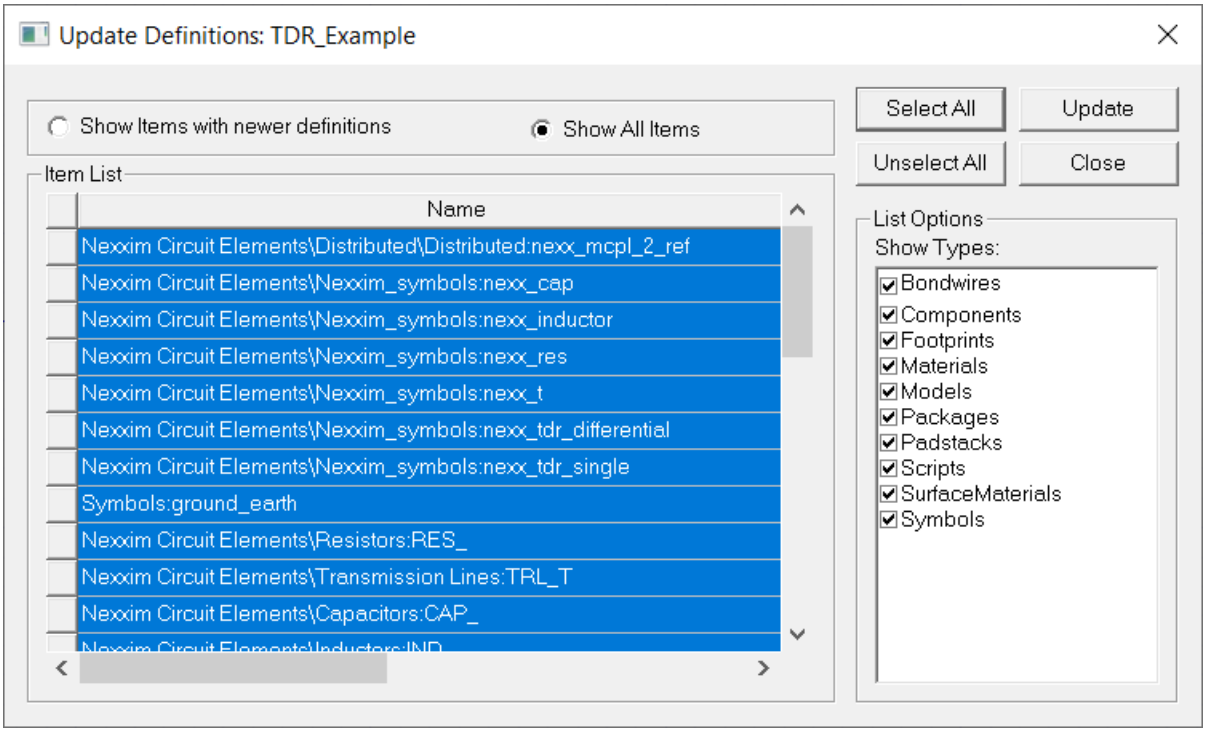
The TDR component provides two options for the pulse type: Trapezoidal and SmoothStep. SmoothStep provides a more realistic step input and allows control of the rise interval.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(Optional) Choose between Trapezoidal and SmoothStep.

i. Click **Tools** > **Project Tools** > **Update Definitions**.

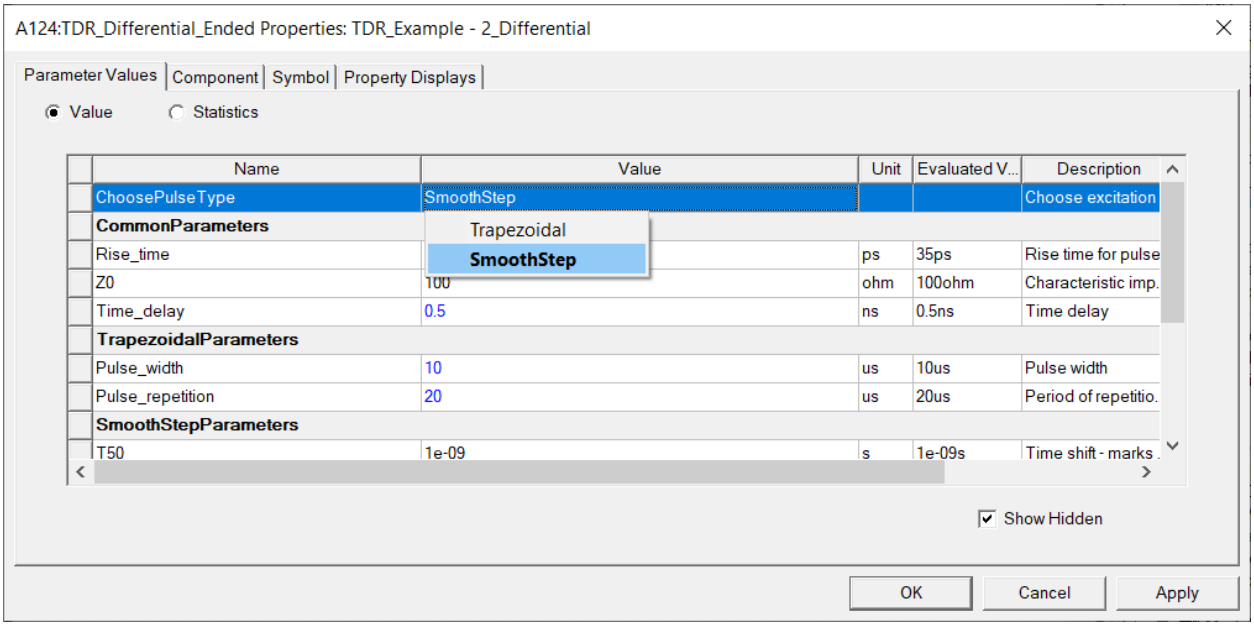
ii. In the **Update Definitions** dialog, select **Show All Items**, **Select All**, then click **Update** . Close the dialog once updates are successful.



iii. Right-click the TDR model symbol and click **Properties** to open the properties dialog.

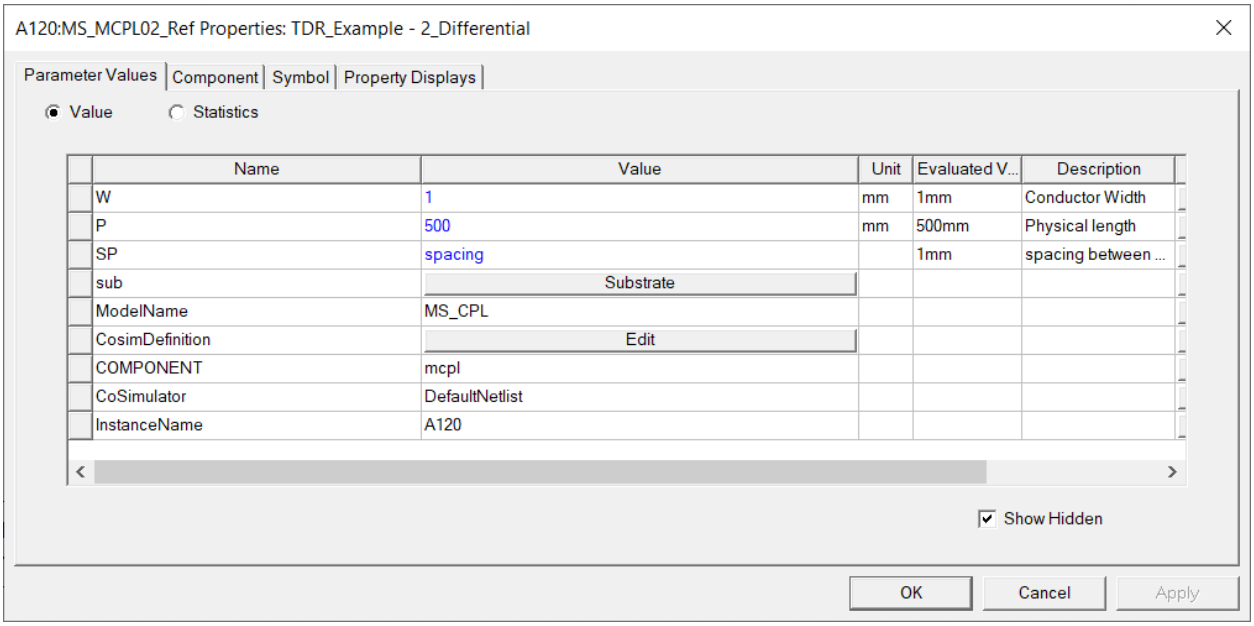
iv. Click the **Value** field for **ChoosePulseType** to view the two options. Select **SmoothStep**, click **Apply**, then **OK** to close the dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



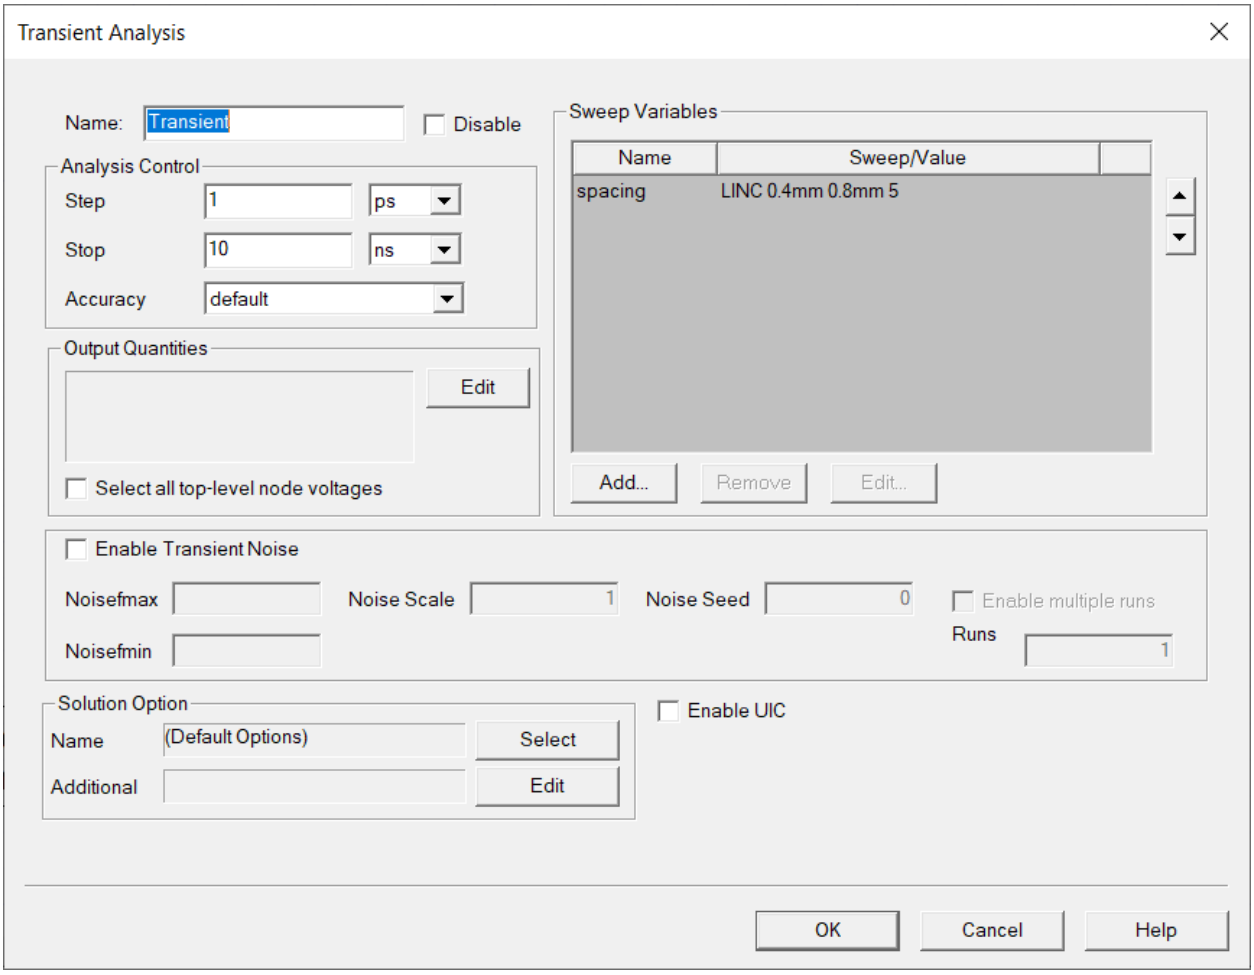
The Device Under Test (DUT) is microstrip coupled line pair and a termination network. The transient analysis sweeps the spacing between the coupled lines, which shows how the spacing affects the differential impedance, Zdiff.

1. Select the coupled lines. The Property window shows that the spacing parameter SP has been defined with a local variable.



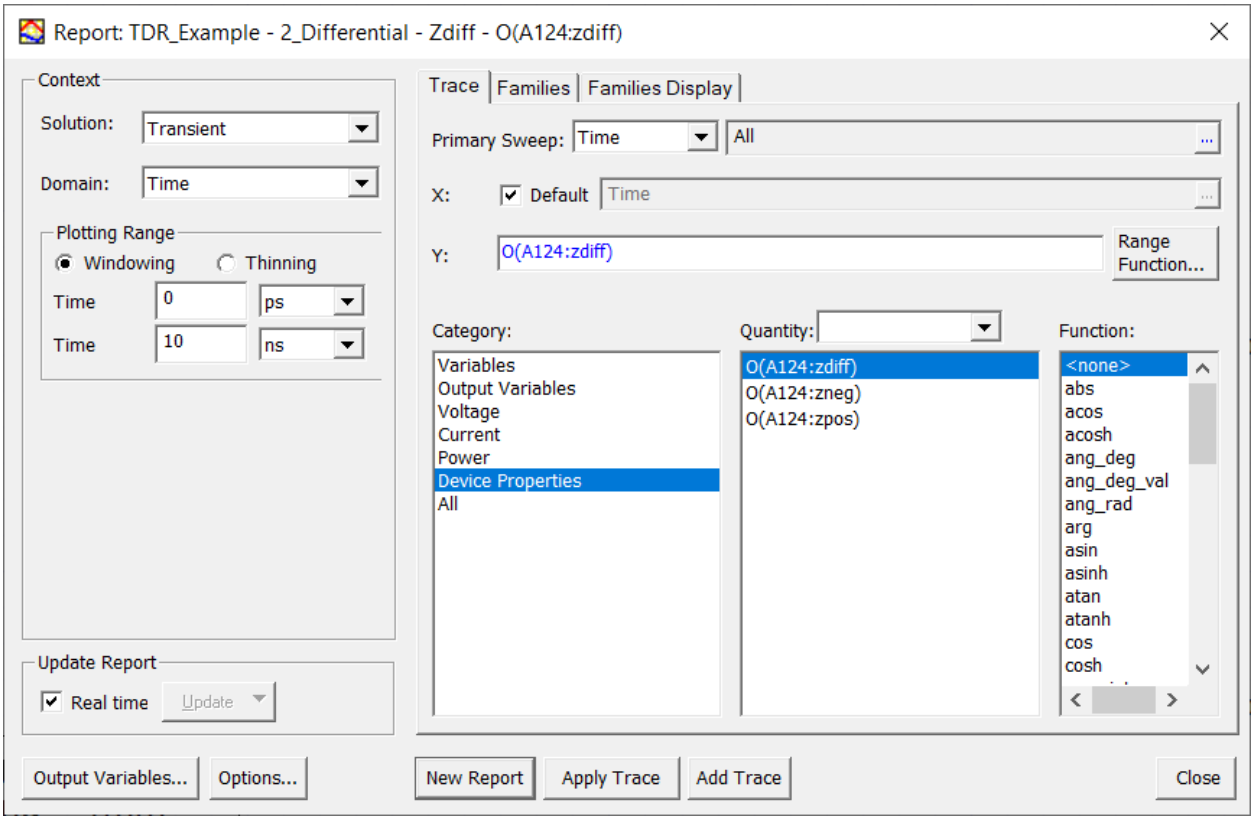
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Expand the Analysis icon, double-click on the Transient analysis setup, and verify the sweep of the spacing variable.



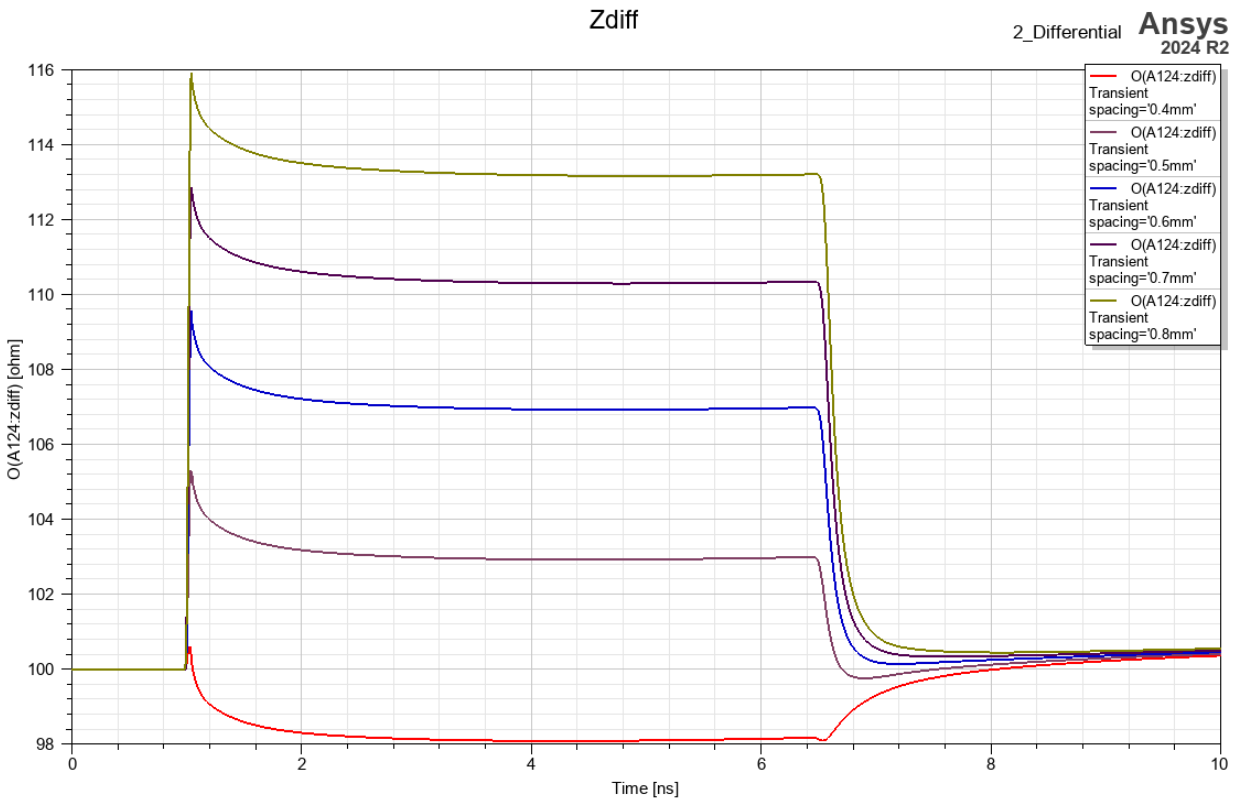
3. In the Project Tree, right-click Transient and select Analyze. The analysis runs to completion.
4. Expand the Reports icon and right-click on the **Zdiff** report setup. Select **Modify Report** to open the Report Setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

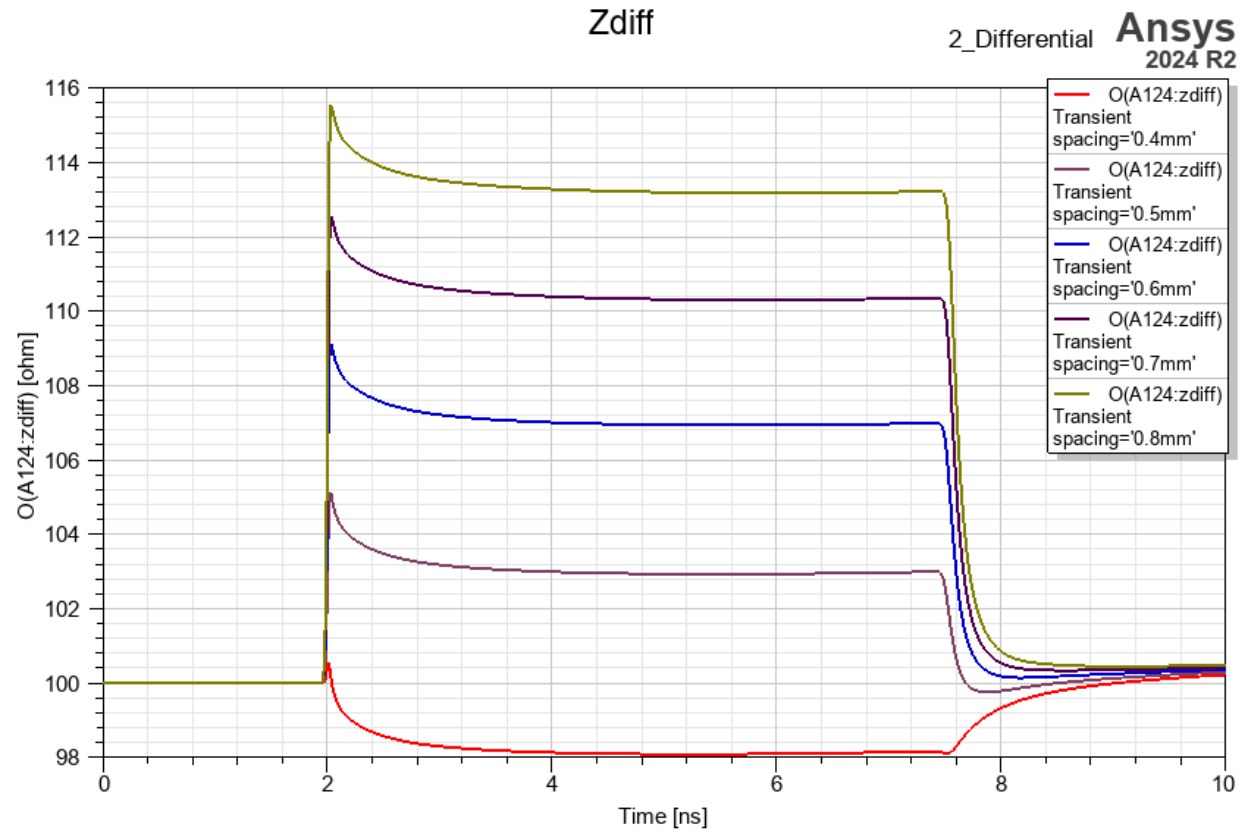
5. Click New Report to generate the report:



The TDR analysis shows how the spacing affects the differential impedance. Using the Trapezoidal waveform, the reflection timings are expected at 2*(Total Delay).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: If SmoothStep pulse type is selected, the reflection timings are expected at T50 + 2*(Total Delay). See **Circuit > Nexxim Components > Probes > Time Domain Reflectometer** for more information about TDR properties, including the T50 SmoothStep parameter.



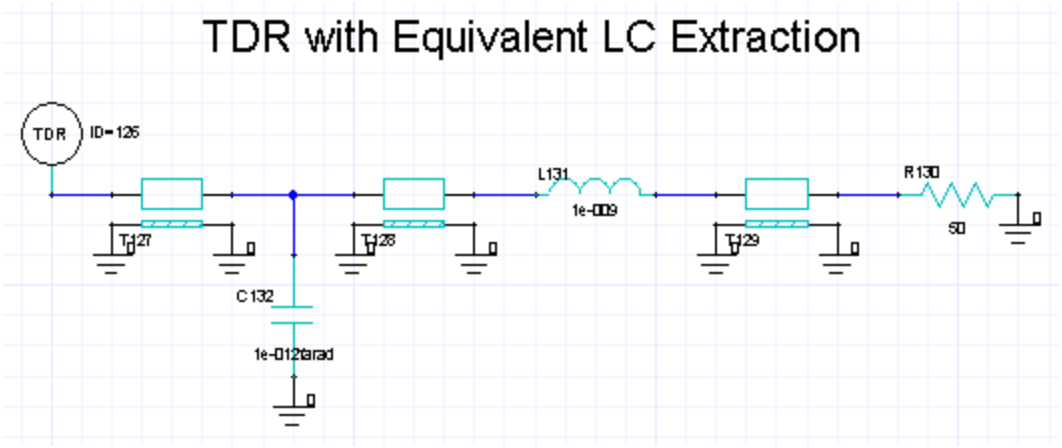
LC Extraction

Open the TDR Schematic project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open **Circuit**, then **Signal Integrity**, and select the file **TDR_Example.aedt**. Click **Open**.

Expand the TDR_Example icon and the **3_LC_Extraction** icon. The LC_Extraction schematic appears in the design window:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This circuit consists of:

- A TDR component with pulse_width = 1sec and pulse_repetition = 1sec, and Time_delay = 0.
- Three time delay elements (TRL_T), each one set for a delay of 1ns (1e-9 sec).
- A shunt capacitance of 1pF (1e-12 farad)
- a series inductance of 1nH (1e-9 henry).
- A terminating impedance. The impedance of all lines and the termination is 50 ohm.

The TDR element can analyze the changes in impedance and calculate the equivalent capacitance for a drop in impedance or inductance for a spike in impedance. For more information see *Time Domain Reflectometer* in the Circuit Components help.

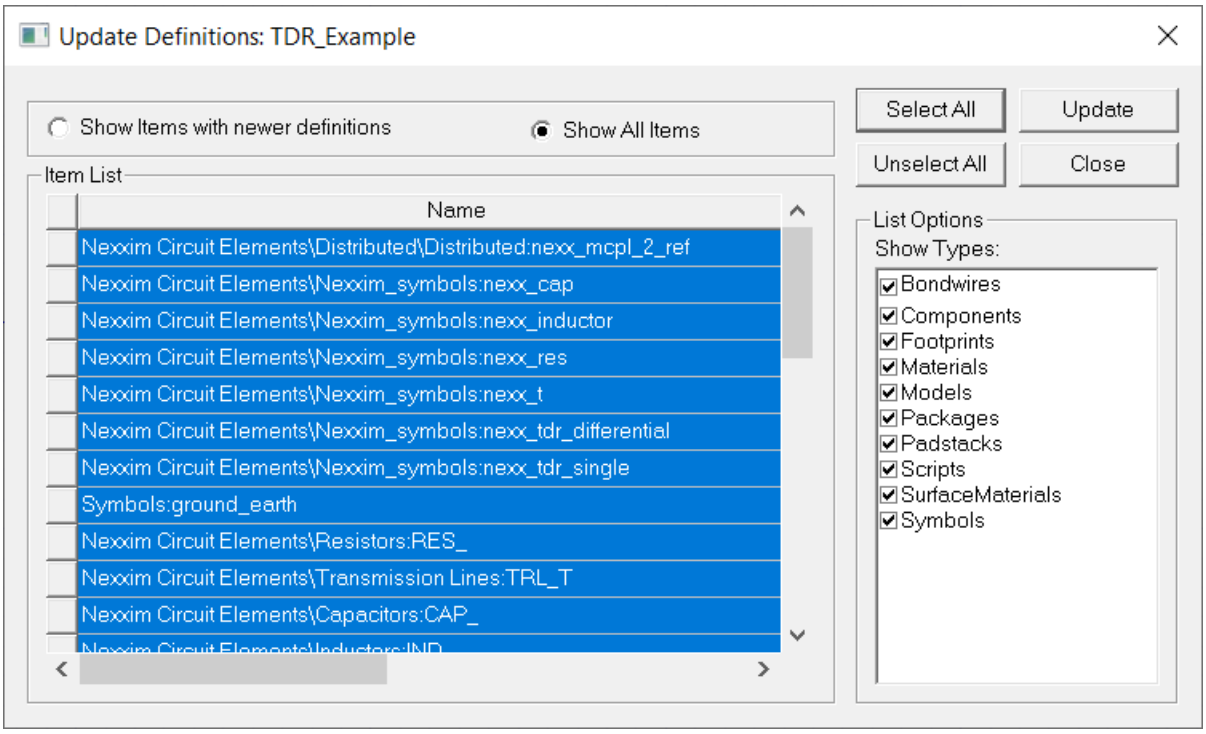
The TDR component provides two options for the pulse type: Trapezoidal and SmoothStep. SmoothStep provides a more realistic step input and allows control of the rise interval.

(Optional) Choose between Trapezoidal and SmoothStep.

i. Click **Tools** > **Project Tools** > **Update Definitions**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

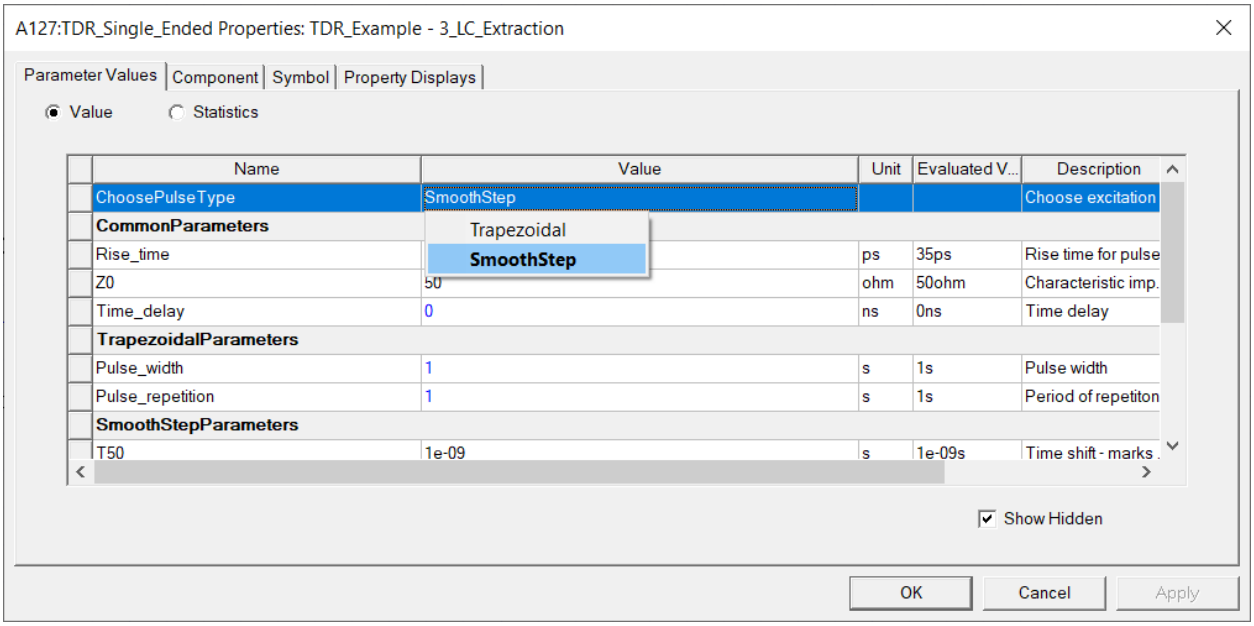
ii. In the **Update Definitions** dialog, select **Show All Items**, **Select All**, then click **Update** . Close the dialog once updates are successful.



iii. Right-click the TDR model symbol and click **Properties** to open the properties dialog.

iv. Click the **Value** field for **ChoosePulseType** to view the two options. Select **SmoothStep**, click **Apply**, then **OK** to close the dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This demonstration includes the Transient setup and an example of a Report with the equivalent reactance values. A routine report setup follows.

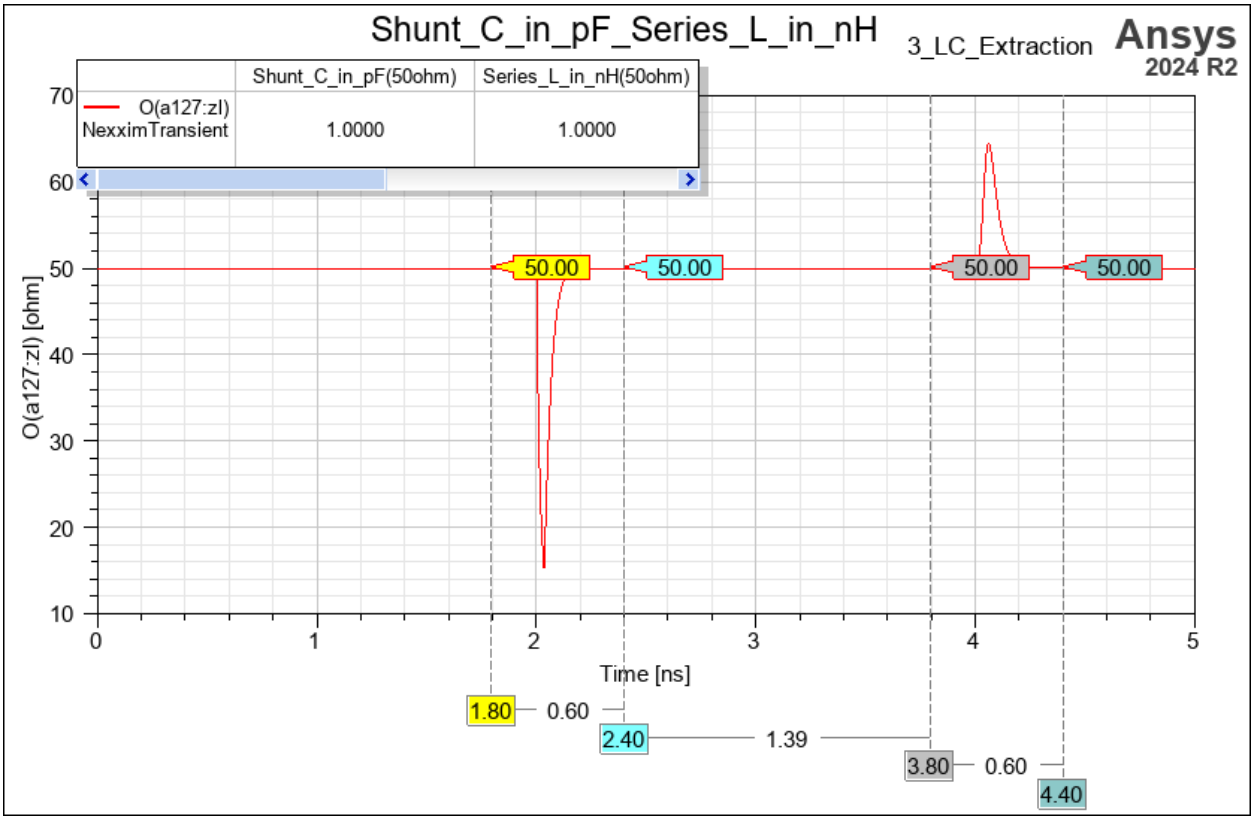
1. Click the three transmission line components and verify the delay (**D** property) is 1e-9 sec.
2. Expand the Analysis folder and double-click on the **NexximTransient** setup. Verify that the Time is set to run from 0 to 5ns, with a Step of 0.1ps. This time period allows us to see the reflected impedance on the capacitor (at 2ns) and the inductor (at 4ns) and omit secondary reflections.
3. Click the **NexximTransient** setup and select **Analyze** (or **Force Analysis** if necessary). The analysis runs to completion.
4. Expand the Results folder, right-click on the **Shunt_C_in_pF_Series_L_in_nH** report, and select **Open Report**.

A display of the report is shown later. Here are the steps used to create it after the analysis runs to completion.

1. Right-click the **Results** folder, then select **Create Standard Report>Create Rectangular Report**.
2. From the **Report** window, set the **Category** to **Device Properties**.
3. Verify that the (only) **Quantity** is **O(a126:z)**.
4. Click **New Report**, then **Close**. The **XY Plot1** report opens with the trace of impedance versus time. The graph has a dip at 2ns and a peak at 4ns.
5. Under **Report 2D** at the top, select **Add X Marker**. The X marker appears at time 0 on the plot.

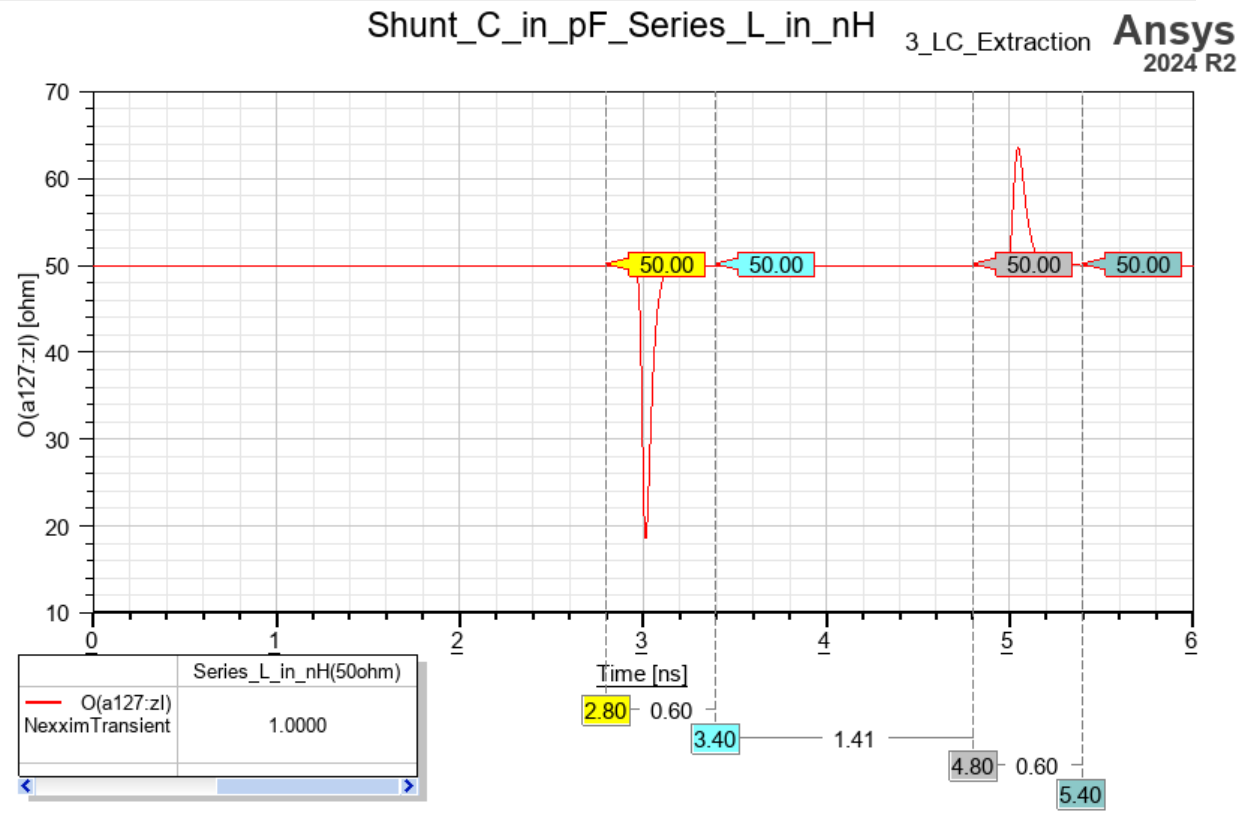
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. Click the tag at the bottom of the X marker and position it just to the left of the dip on the graph, around 1.8ns. The location need not be exact.
7. Repeat the previous step three times more, to locate X markers on both sides of the dip and on both sides of the peak, at approximately 2.4ns, 3.8ns, and 4.4ns, respectively.
8. Under **Report 2D** at the top, select **Trace Characteristics >All** to open the **AddTrace Characteristics** window.
9. For the **Category**, select **TDR** at the very end of the menu.
10. For the **Function**, click the check box to select **Shunt_C_in_pF**.
11. In the table, Row 2 is the **Range**. Click the button in the **Range Value** field, and select **X Markers** on the menu. In the **AddTrace Characteristics** window, table rows 3 and 4 are populated with the first two X-Markers, designated **MX1** and **MX2**.
12. Click **Add**.
13. Uncheck **Shunt_C_in_pF** in the **Function** group box, then check **Series_L_in_nH**.
14. In the **Trace Characteristics** window, table rows 3 and 4 are still populated with the first two X-Markers, designated **MX1** and **MX2**.
15. Click the XMarker1 **Value** field and select **MX3** on the menu.
16. Click the XMarker2 **Value** field and select **MX4** on the menu.
17. Click **Add**, then **Done**.
18. The **Curve Info** group box displays the calculated values, 1.0pF for **Shunt_C_in_pF** and 1.0nh henry for **Series_L_in_nH**.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: If SmoothStep pulse type is selected, the reflection timings are expected at T50 + 2*(Total Delay). See **Circuit > Nexxim Components > Probes > Time Domain Reflectometer** for more information about TDR properties, including the T50 SmoothStep parameter.



Eye Analysis Example

This example of a high-speed serial communications channel allows you to experiment with Nexxim Transient, QuickEye, and VerifEye analyses. It focuses on modeling the effect of equalization on the performance of the channel. The schematic for the channel with complete analysis and report setups is available in the Examples directory.

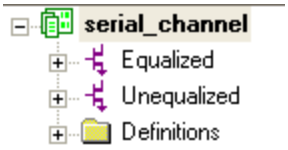
Open and examine a High-Speed Channel Schematic project.

1. From the **File** menu, select **Open Examples**, or click **Open Examples** on the **Desktop** ribbon, to open an explorer window to the **Examples** folder.
2. Select the file **Electronics Desktop** / **Circuit** / **Signal Integrity** / **Serial_Channel.aedt** and click **Open**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

   There are two circuits in the project:



4. Examine the **Unequalized** schematic.

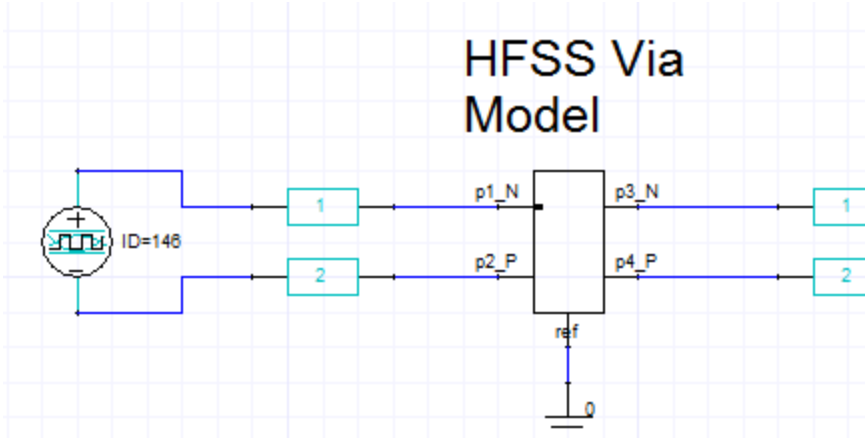
   a. From the **Project Manager** window, double-click **Unequalized**. The **Schematic Editor** displays the schematic:

   This differential communication channel transmits first over surface-level traces, then through via connectors to buried traces, then through a cable connector to a cable, then back through cable connector, buried traces, via connectors, surface traces, and termination on the receiver end.

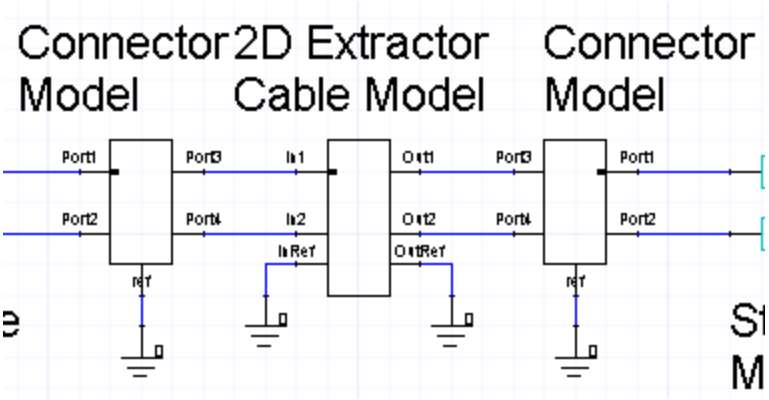
   The Eye Source at the transmitter end provides a controllable bit stream for both Transient and Quick Eye analyses.

   The left side of the circuit consists of the Eye Source, microstrip differential line pair, via connector, and stripline differential line pair.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

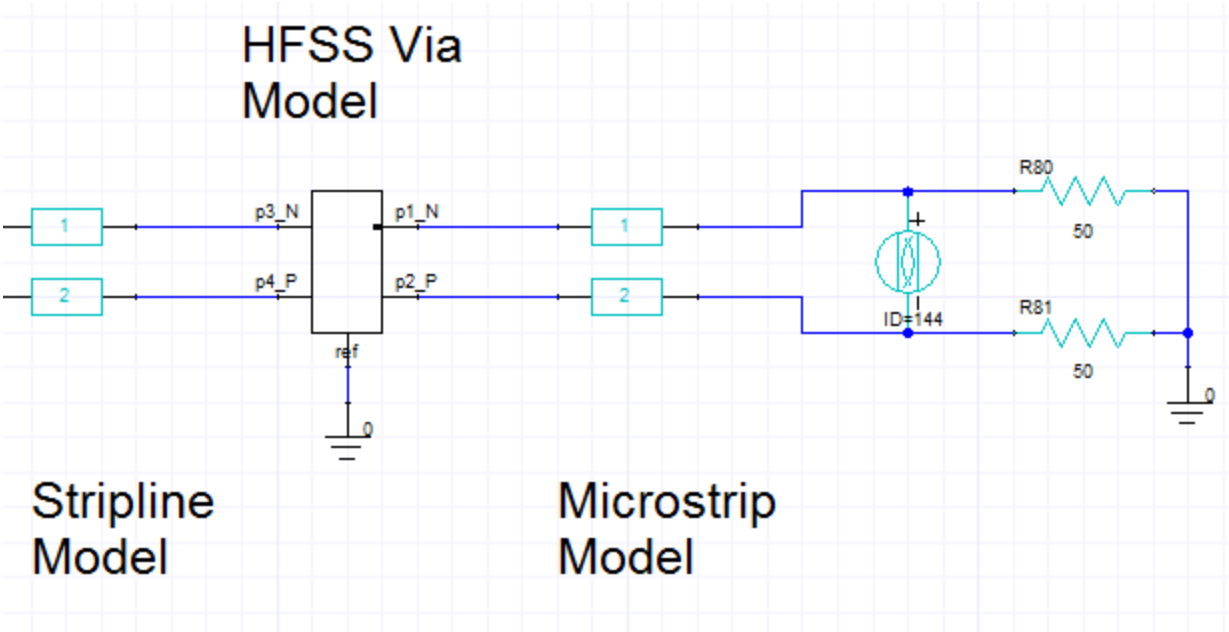


The center components of the circuit includes the left cable connector, the cable modeled as a W-element, and the right cable connector.



The right side of the circuit consists of the stripline differential line pair, via connector, microstrip differential line pair, Eye Probe, and line termination.

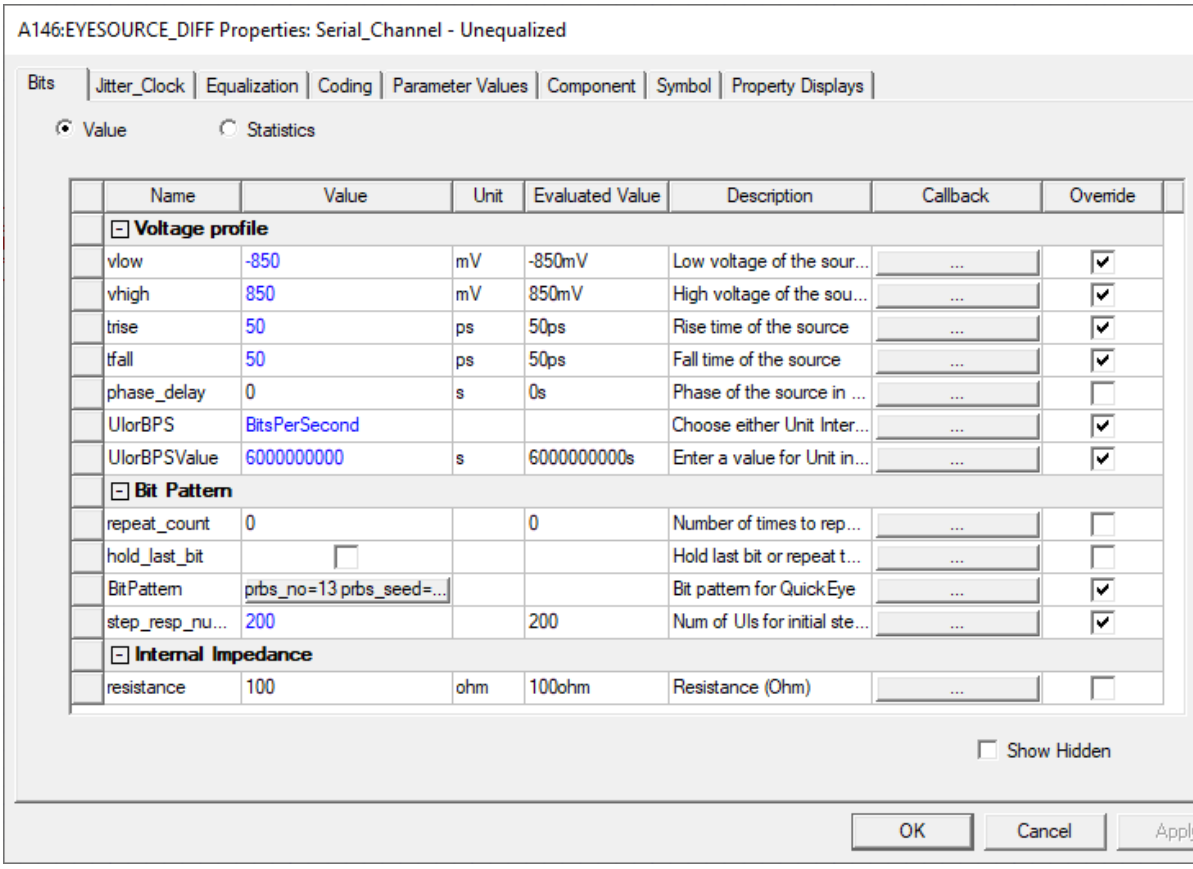
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



b. Double-click the Eye Source at the front (left) end of the channel to open its **Properties** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

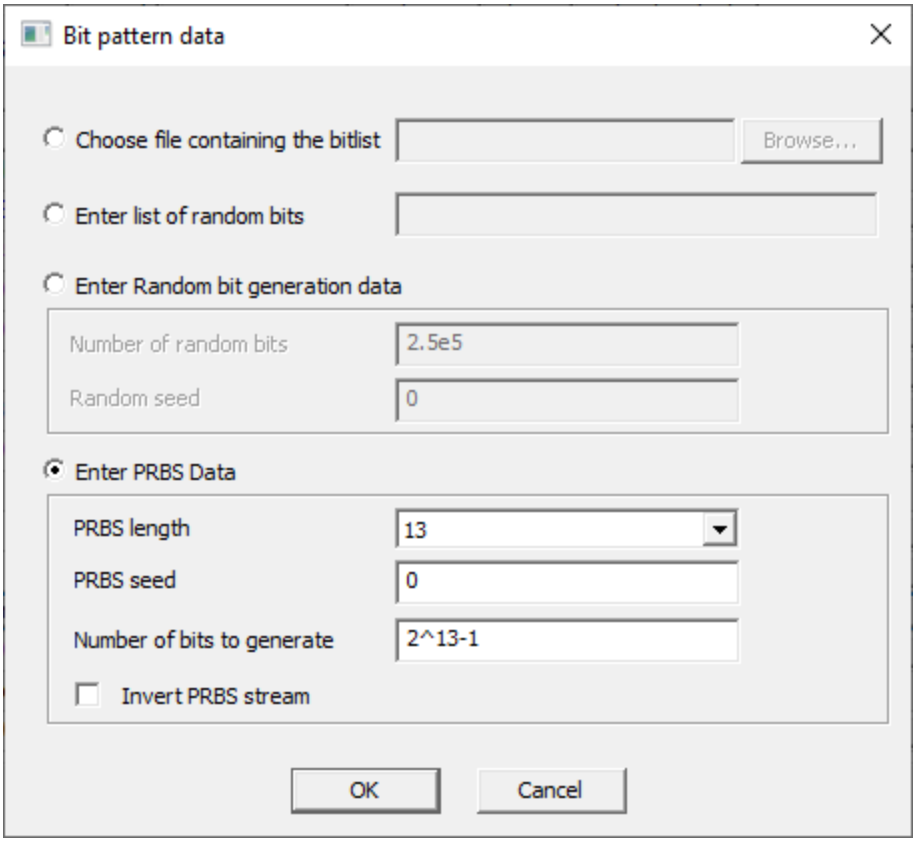
1. Open the **Bits** tab:



The source has a data rate of 6 GBits per second. Rise and fall times are 50 ps.

2. Click the button in the **BitPattern Value** field to open the **Bit Pattern Data** window:

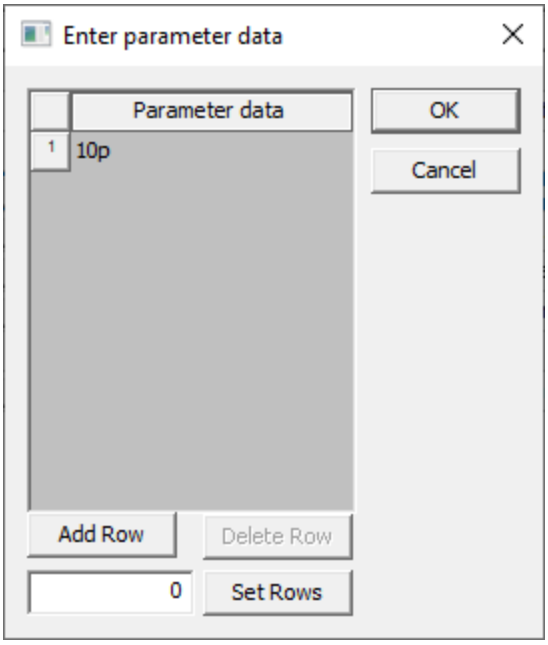
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The Random bit generation data or pseudo random bit sequence (PRBS) data provides the bit stream for both transient and Quick Eye analyses. Click **OK** to close the **Bit Pattern Data** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

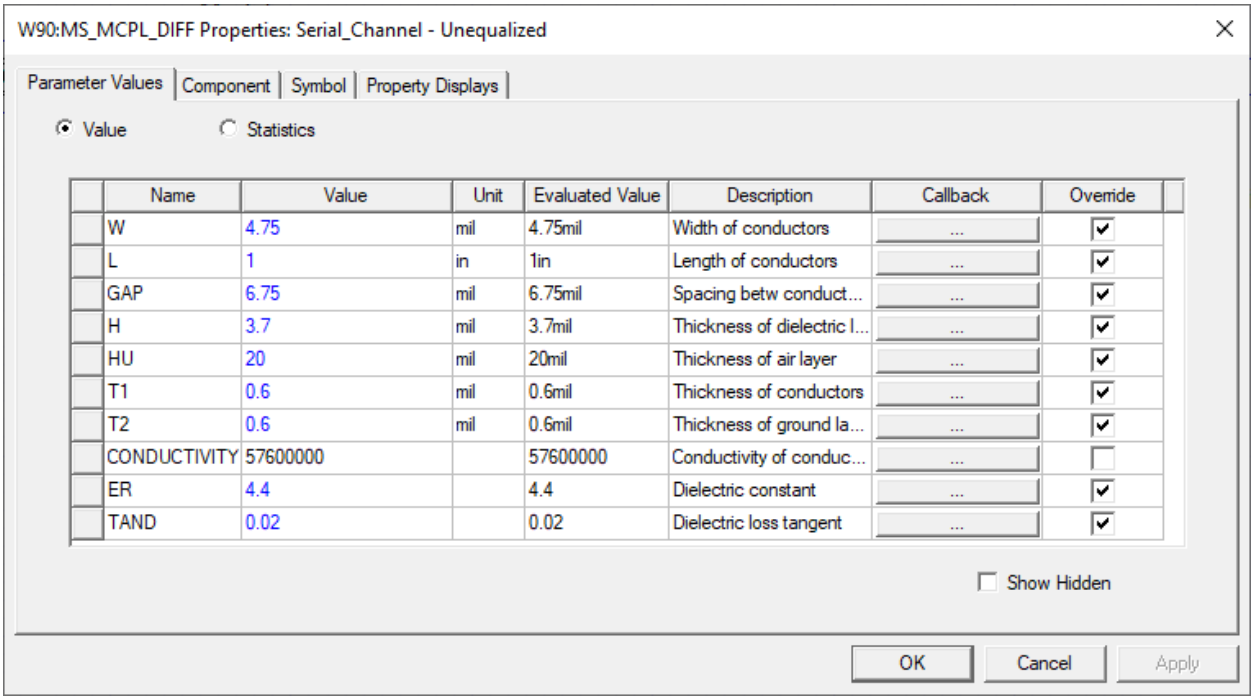
3. Click the **Jitter_Clock** tab. Click **txrj** to open the **ParameterData** window.



A random (Gaussian) transmit jitter distribution with a standard deviation of 10ps is applied to the transmitted signal. The source is set to transmit with a Gaussian jitter source using 10ps as the standard deviation. The jitter appears in all analyses. Click **OK** to close the **ParameterData** window, and **OK** again to close the **Properties** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

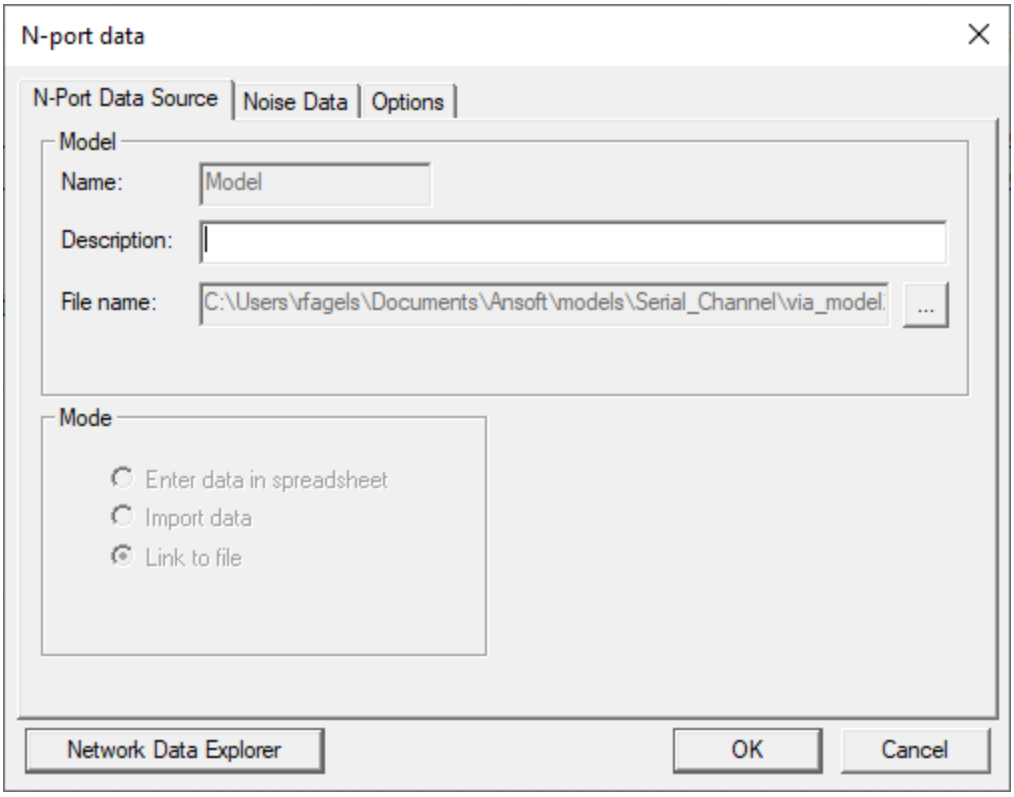
c. Double-click the left Microstrip differential line pair to open its **Properties** window:



The two microstrip portions of the channel have the same parameters. The length of both segments is one inch. Click **Cancel** to close this window.

d. The via connector is modeled with S-parameters. Right-click the **HFSS Via Model** symbol and click **Edit Model** to open the N-port data window:

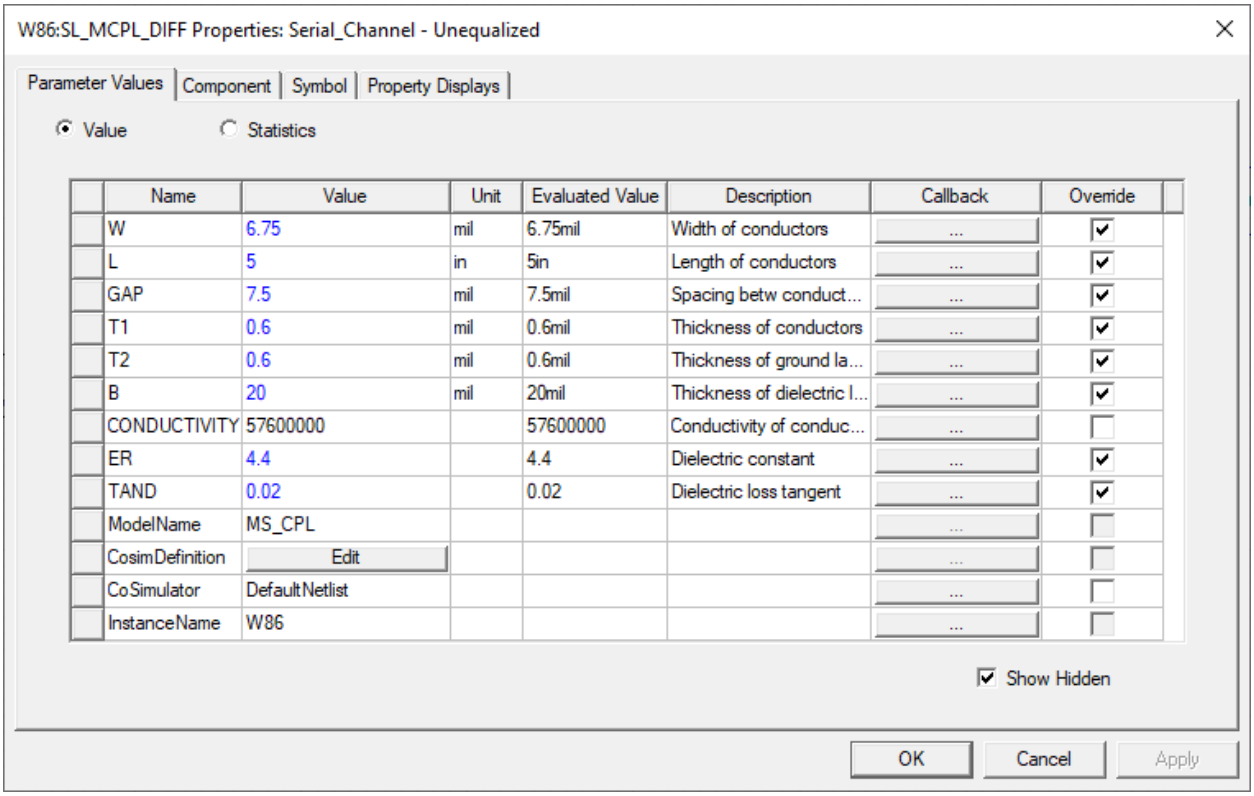
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



File **via_model2.s4p** contains the Touchstone data. Both via connectors use this model. Click **Cancel** to close the window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

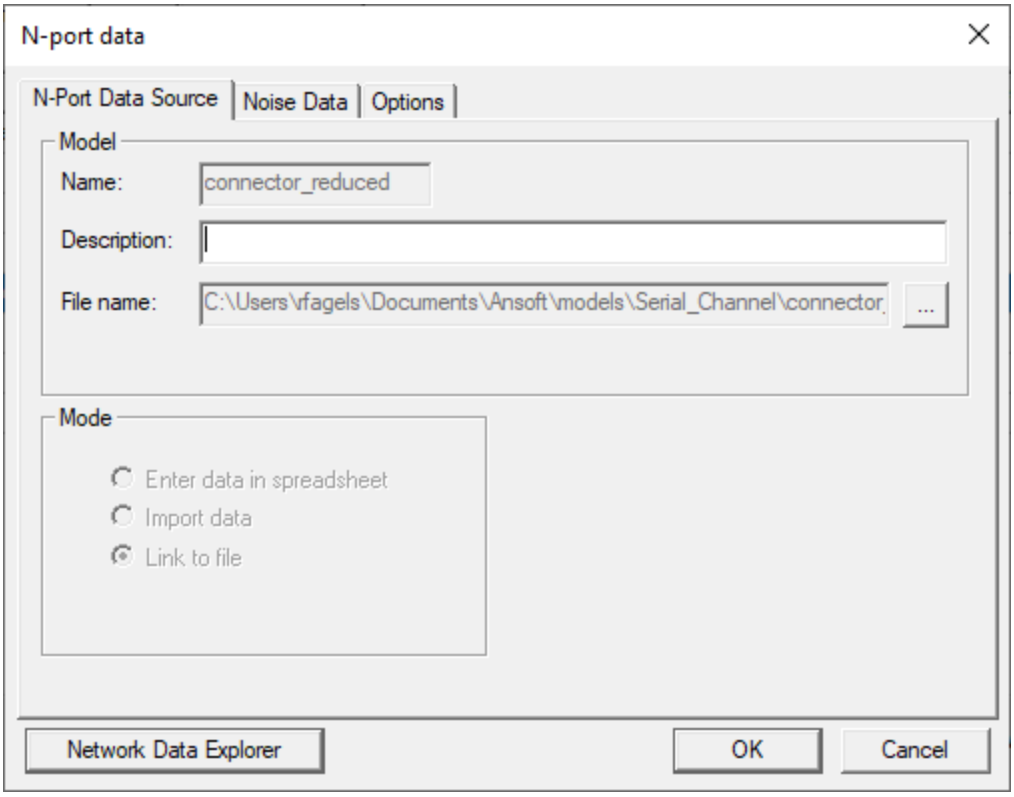
e. Double-click the left Stripline differential pair to open its **Properties** window:



Both stripline segments use the same Parameter values. The length of both segments is five inches. Close this window.

f. The cable connector is modeled with S-parameters. Double-click the **Connector Model** symbol, select the **Components** tab, and click **Edit** for the **Cosim Definition**.

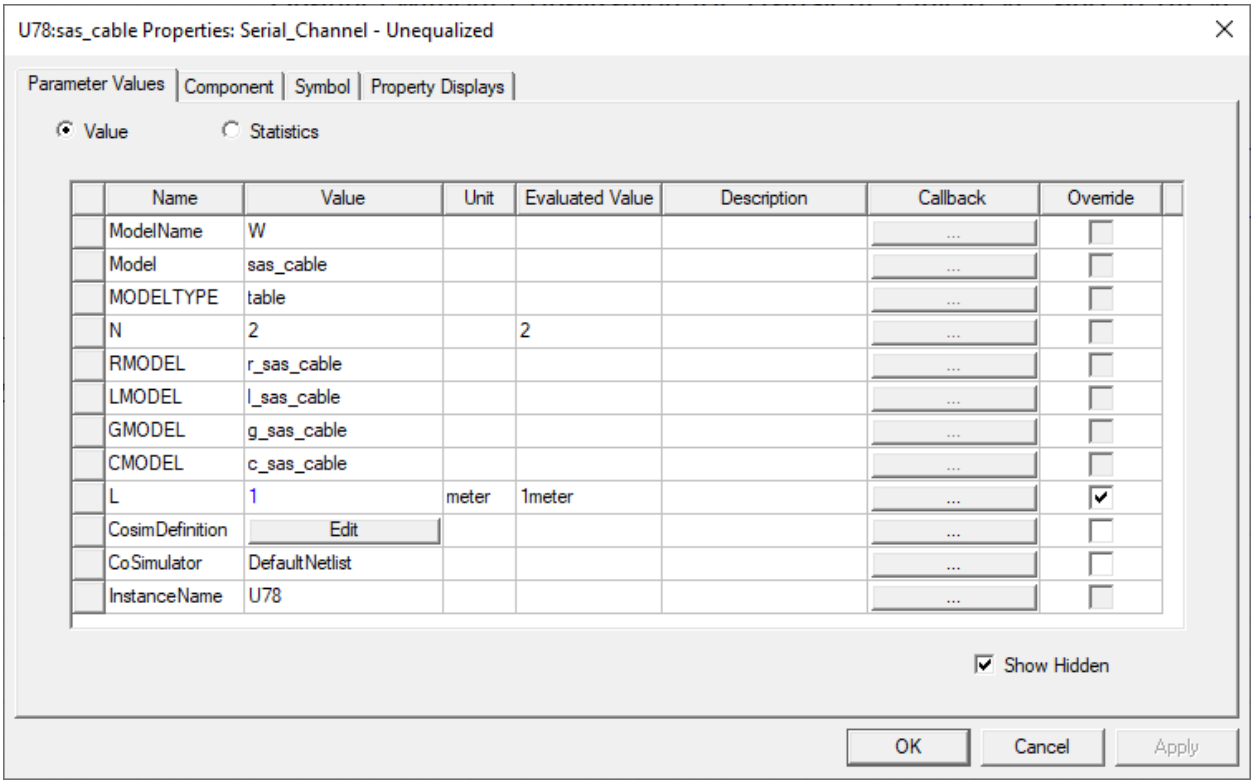
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



File **connector_mode2.s4p** contains the Touchstone data. Both cable connectors use this model. Click **OK** to close both windows.

g. Double-click the **2D Extractor Cable Model** symbol to open its **Properties** window. Open the **Parameter Values** tab.

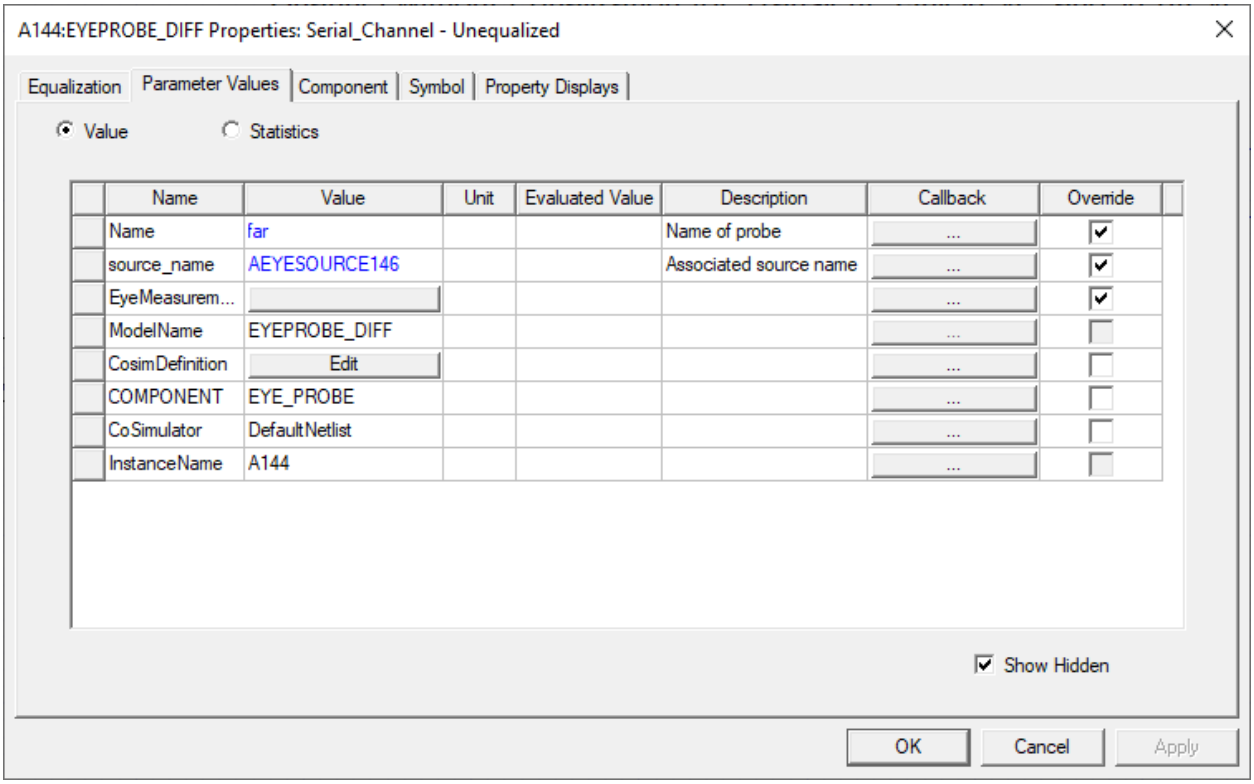
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The cable is modeled with a W-element RLGC table model. Its length is one meter. Both ends of the channel uses the same elements. Click **Cancel** to close the window.

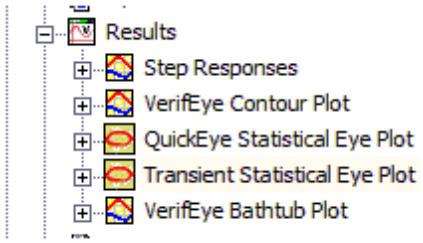
h. Double-click the Eye Probe on the right side to open its **Properties** window. Open the **Parameter Values** tab:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



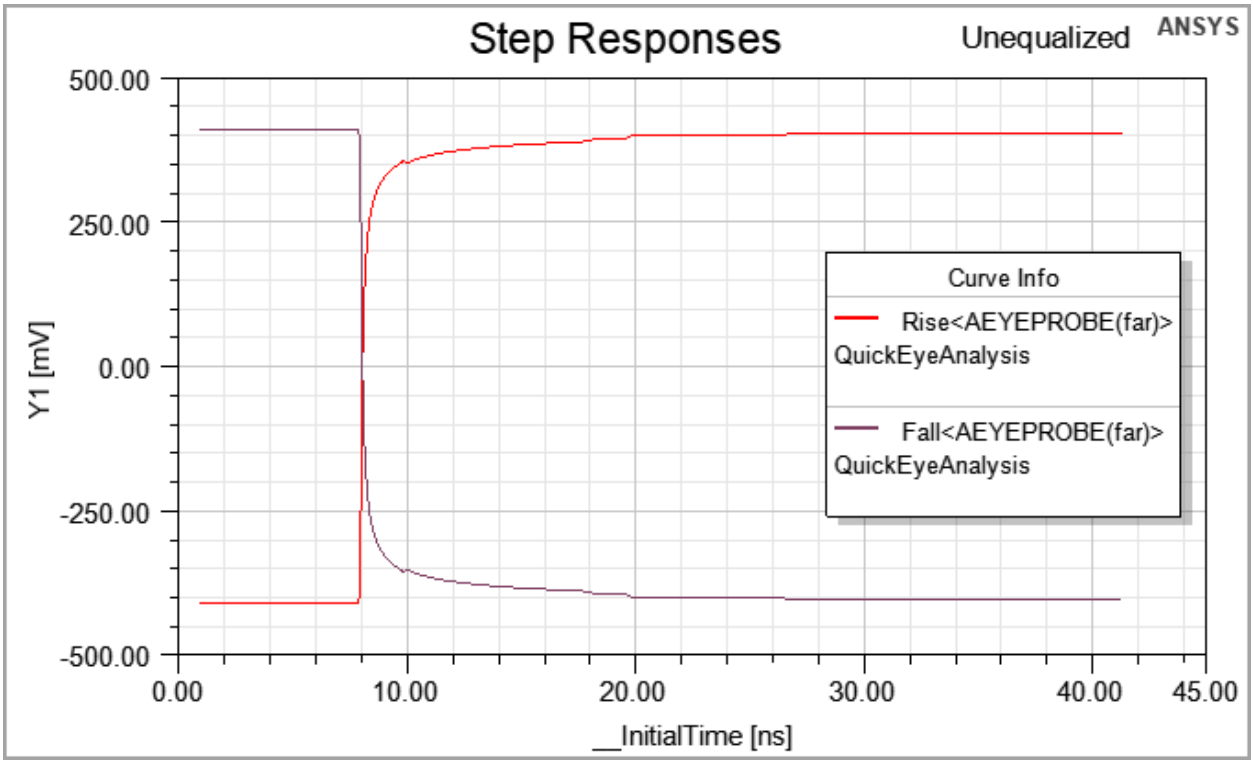
No receive equalization is set up in the probe. The next step is to simulate the circuit without equalization. Click **Cancel** to close the window.

5. Generate and review the project's unequalized Transient, QuickEye, and VerifEye analyses.
    a. From the **Project Manager** window under **Unequalized**, right-click **Analysis** and select **Analyze**. This starts all three analyses, which takes a few minutes to complete.
    b. Expand the **Results** folder. Several reports are set up.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

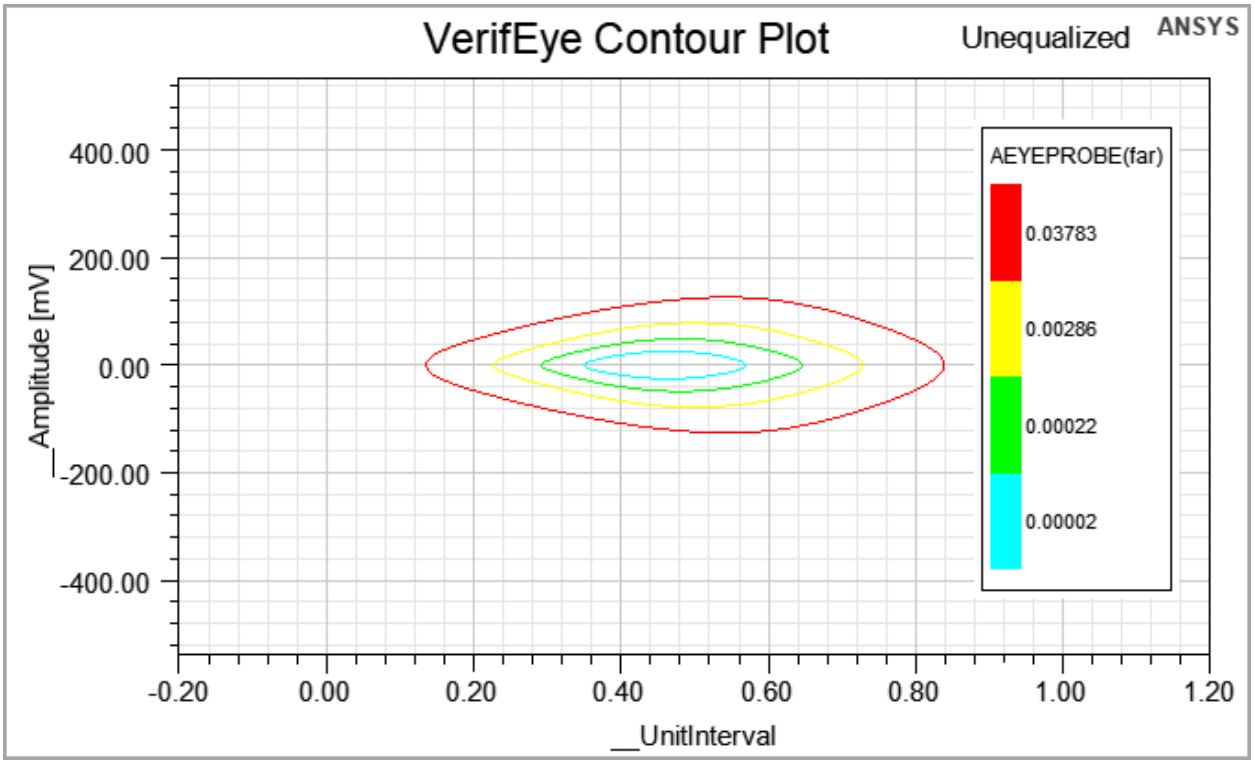
c. Double-click the **Step Responses** report to open it:



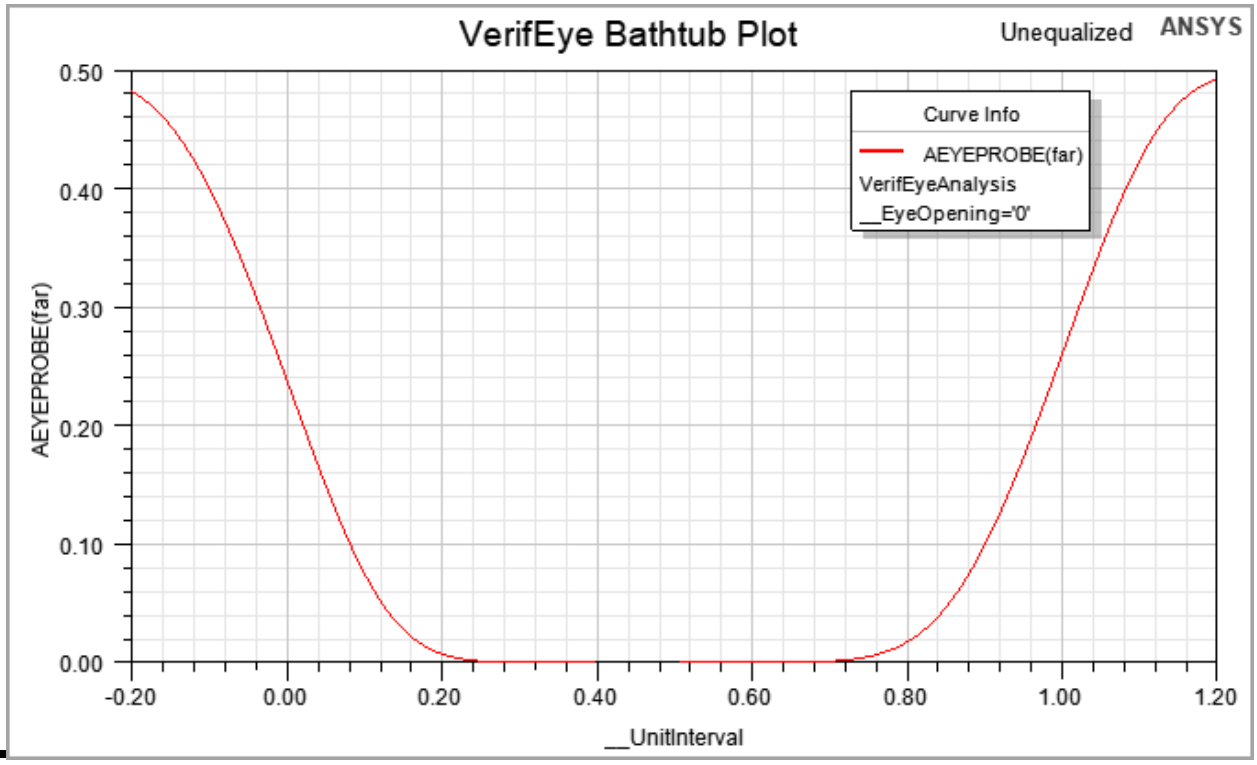
The step responses are symmetrical.

d. VerifEye calculates the channel bit error rate using the channel parameters. Double-click the **VerifEye Contour Plot** report:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



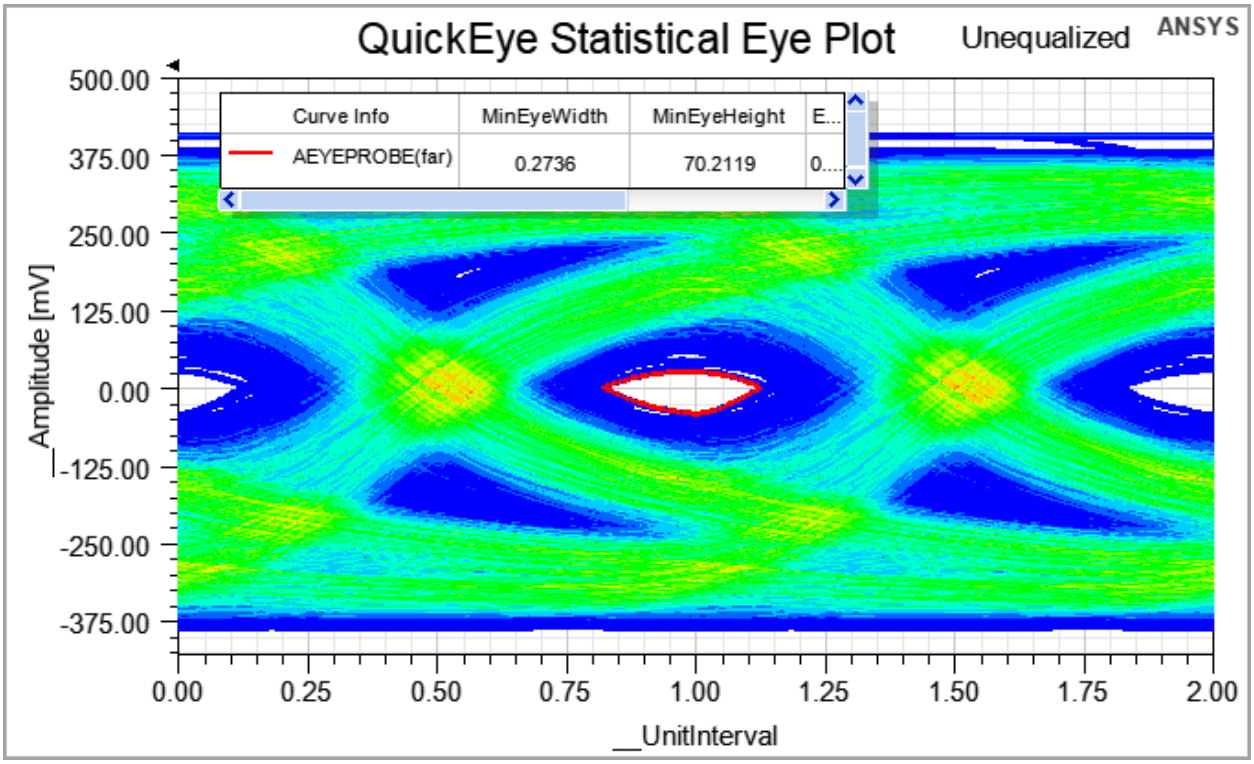
The **VE Bathtub** plot shows the BER curve.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

All the Unequalized plots show the negative effect of jitter on the eye opening.

e. Quick Eye analysis involves the impulse response of the channel with the bit pattern generated by the Eye source. Double-click the **QuickEye Statistical Eye Plot** report:

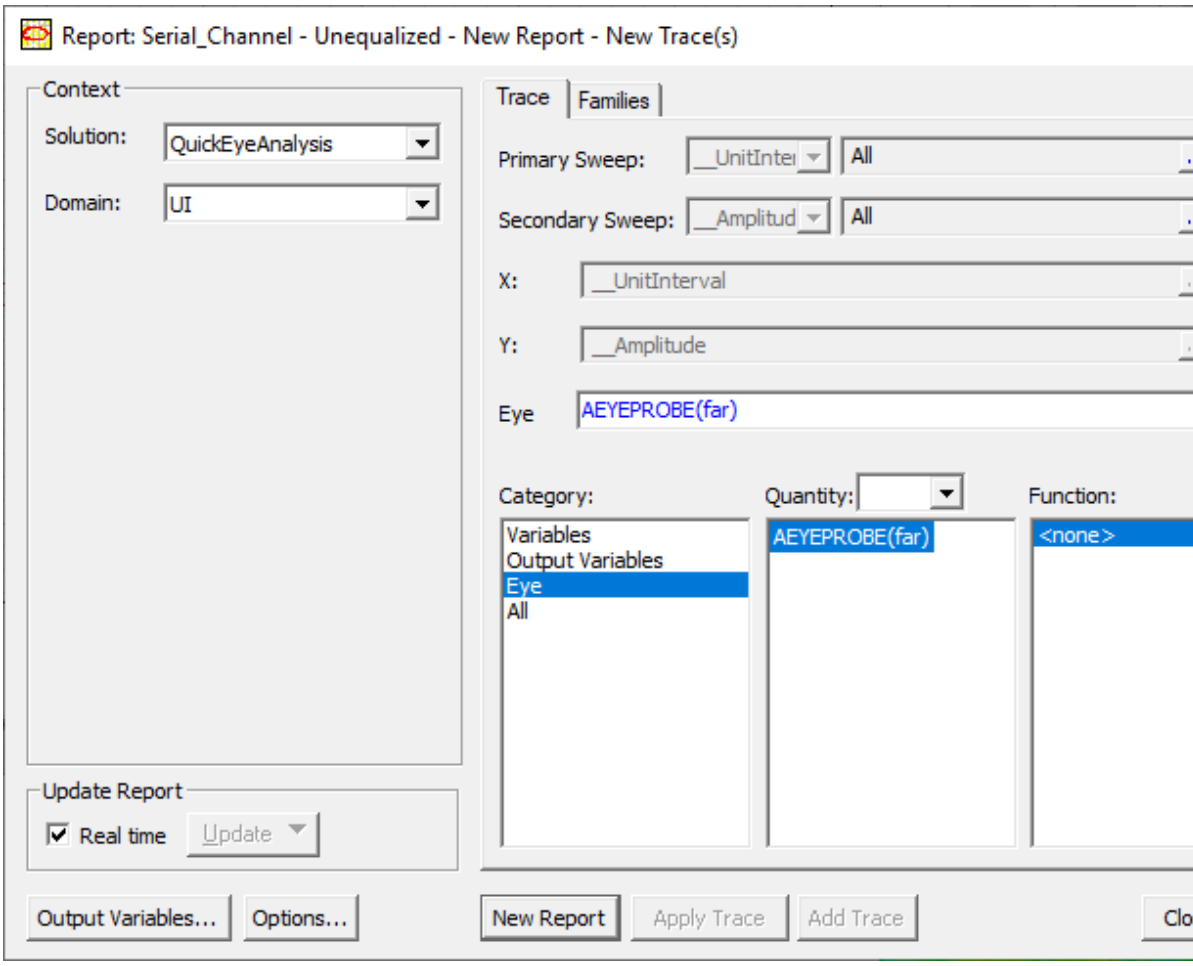


f. A Transient analysis runs the entire bit sequence:

   1. From the **Project Manager** window, right-click **Results** and click **Create Statistical Eye Report** > **Statistical Eye Plot**.

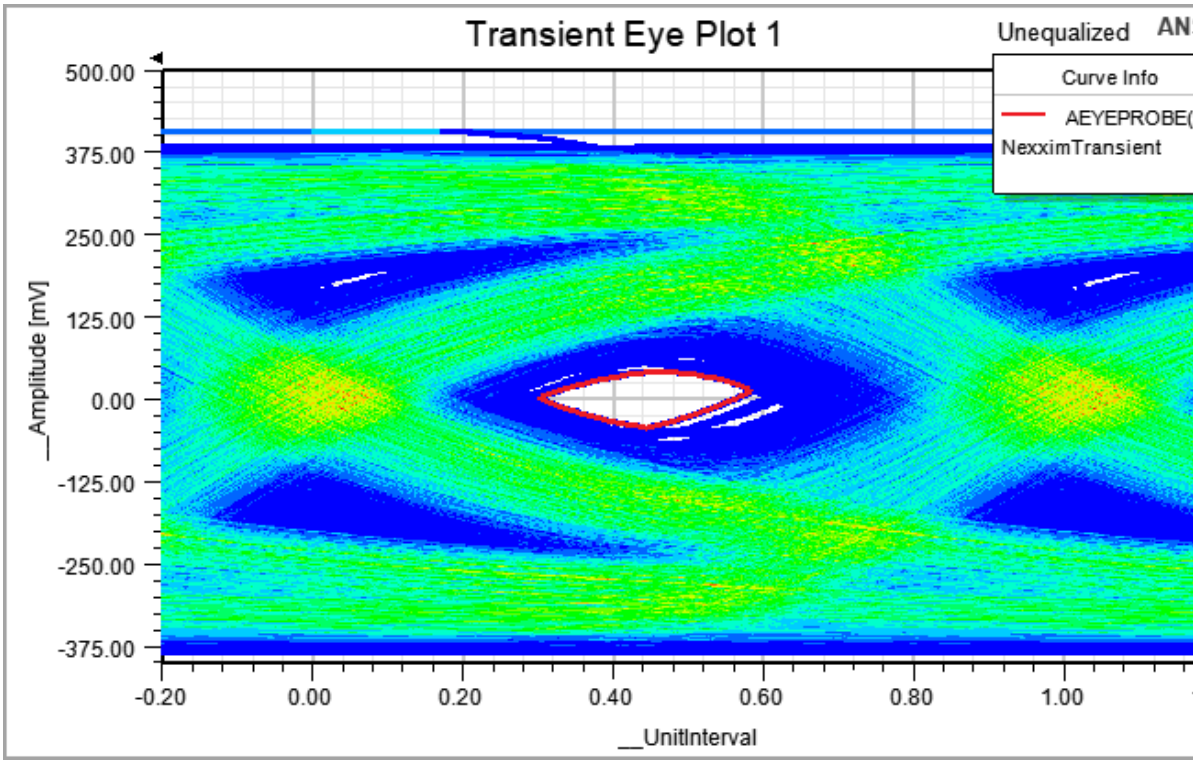
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the **Report** window, set **Solution** to **NexximTransient**.



3. Click **New report** to generate the **Transient Statistical Eye Plot** report and **Close** to close the **Report** window.

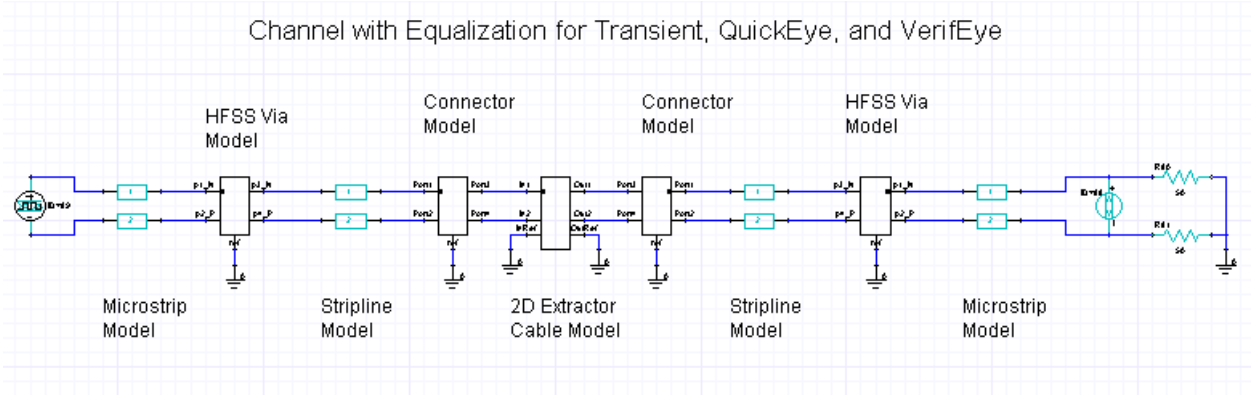
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



g. From the menu bar, click **Window** > **Close All** to close all the schematic and report windows.

6. Examine the **Equalized** schematic.

a. From the **Project Manager** window, double-click **Equalized** to open its schematic.

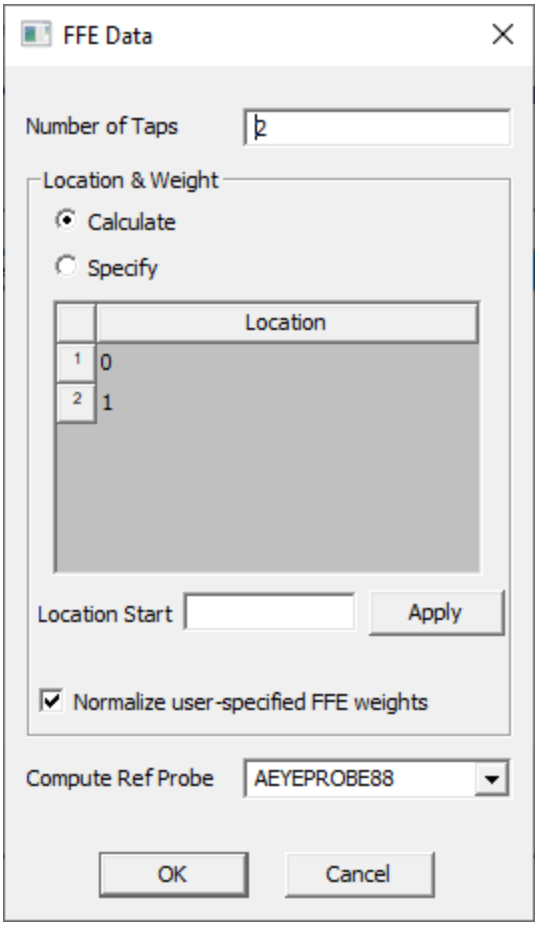


The circuit elements are the same, but the properties of the Eye Source and Eye Probe have been changed to add transmit and receive equalization.

b. Double-click the left Eye Source to open the **Properties** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. From the **Equalization** tab, click in the **FFE_data Value** field to open the **FFE Data** window. Two taps of Feed-Forward Equalization are set up for the source:



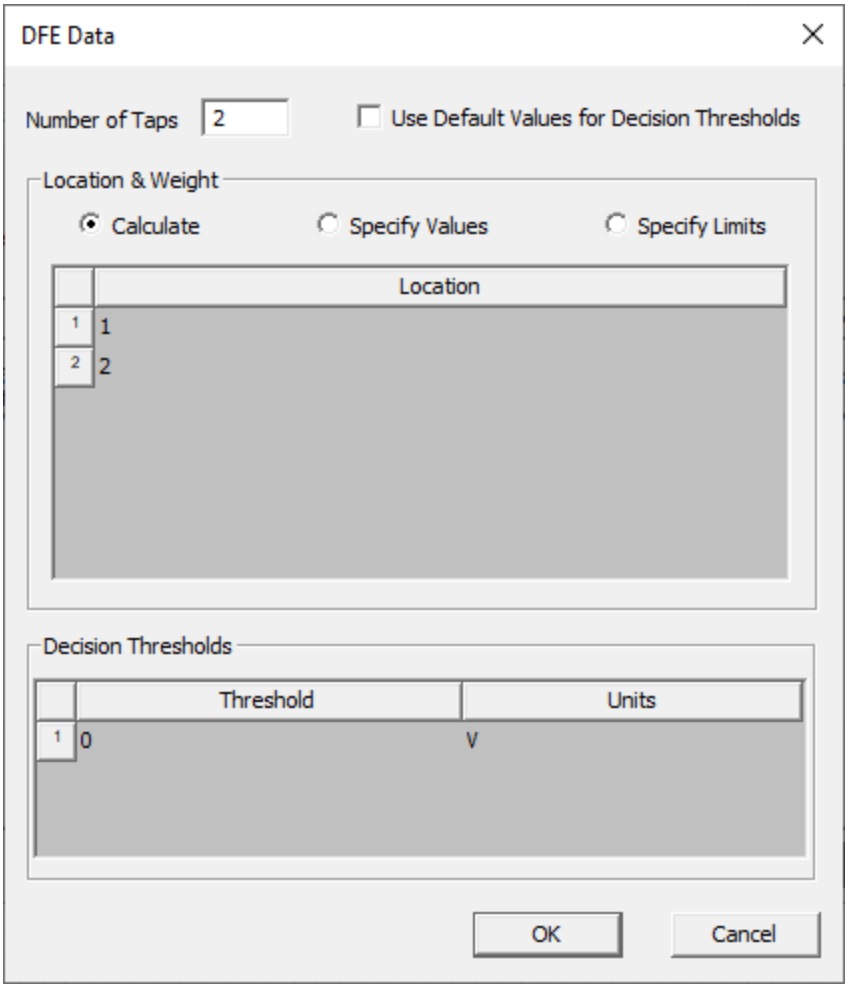
To disable Feed-Forward Equalization, set the number of taps to zero. To enable FFE, set the number of taps to an integer greater than 0.

d. Click **OK** to close the **FEE Data** window and **OK** again to close the **Properties** window.

e. Double-click the right Eye Source to open its **Properties** window.

f. From the **Equalization** tab, click **DFE_Data** to open the **DFE Data** window. Two taps of Decision-Feedback Equalization are set up for the probe:

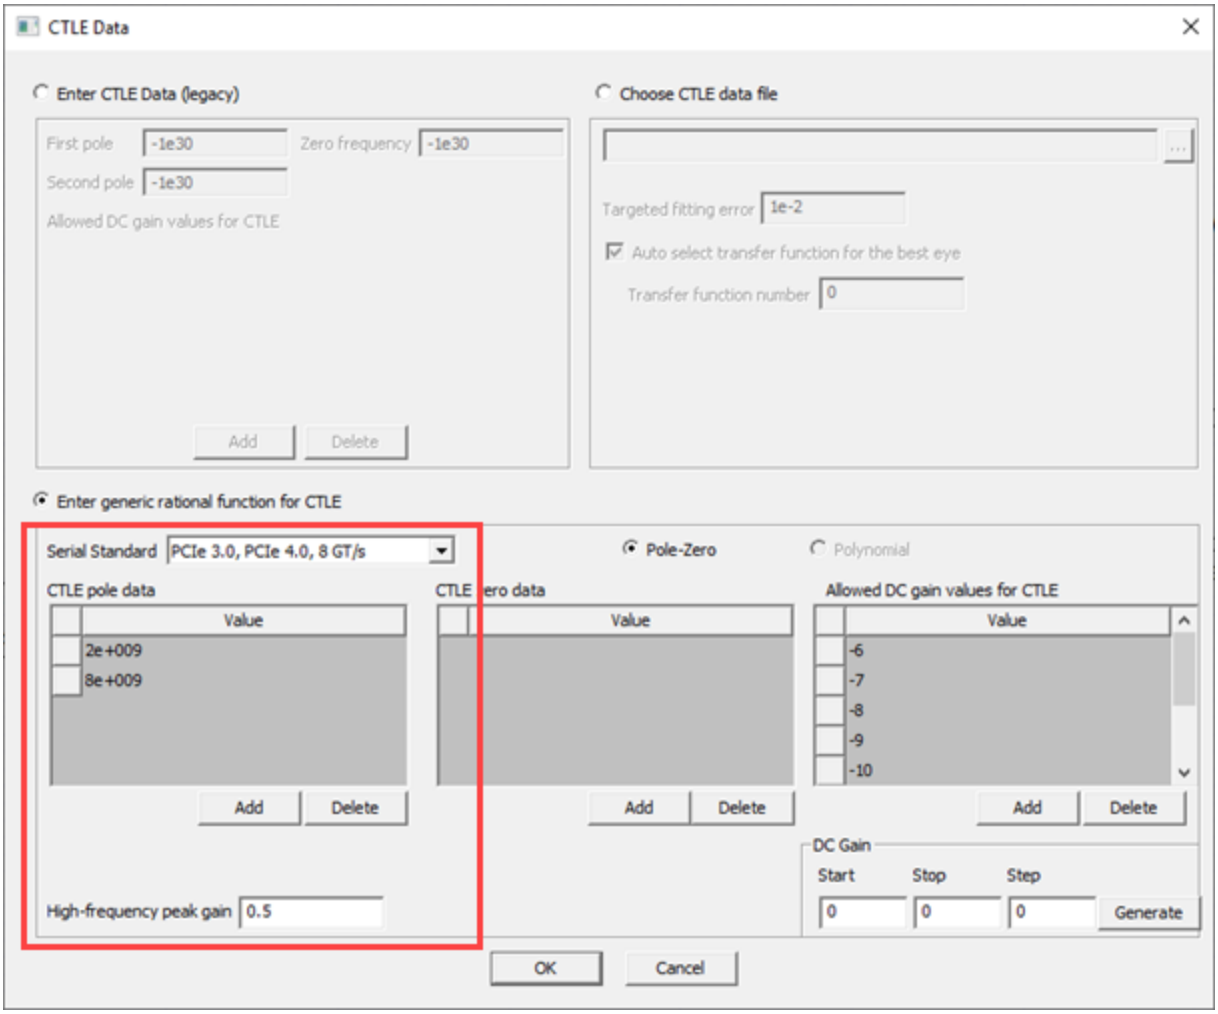
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To disable Decision-Feedback Equalization, set the number of taps to zero. To enable DFE, set the number of taps to an integer greater than 0. Click **OK** to close the **DFE Data** window.

g. From the **Equalization** tab of the same **Properties** window, click **CTLE_Data** to open the **CTLE Data** window. Two pole frequencies for Continuous-Time Linear Equalization are set up for the Eye Probe, using the Serial Standard menu to select the PCIe3.0 pole settings, with the added specification of 0.5 for the High-frequency peak gain (maximum CTLE transfer function value.)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

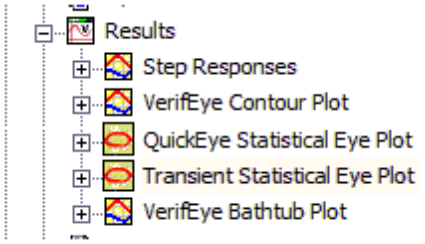


A range of Allowed DC gain values from -6 dB to -12 dB has been specified. Nexxim tries the values in the range and select the one that gives the best eye. Click window and **OK** again to close the **Properties** window.

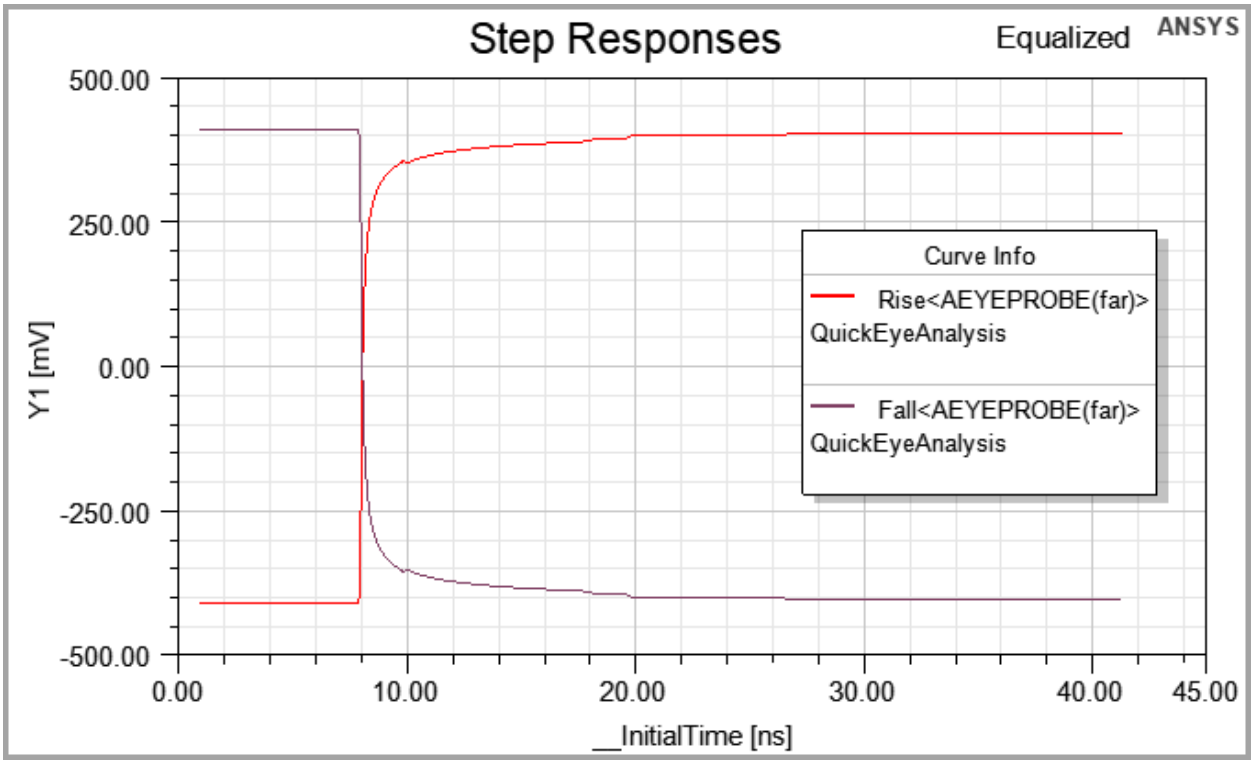
7. The **Equalized** circuit project has setups for Transient, QuickEye, and VerifEye analyses.
   a. From the **Project Manager** window, open **Equalized**, right-click **Analysis**, and select **Analyze**. This starts all three analyses. It takes a few minutes for all analyses to complete.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. The same reports are set up.



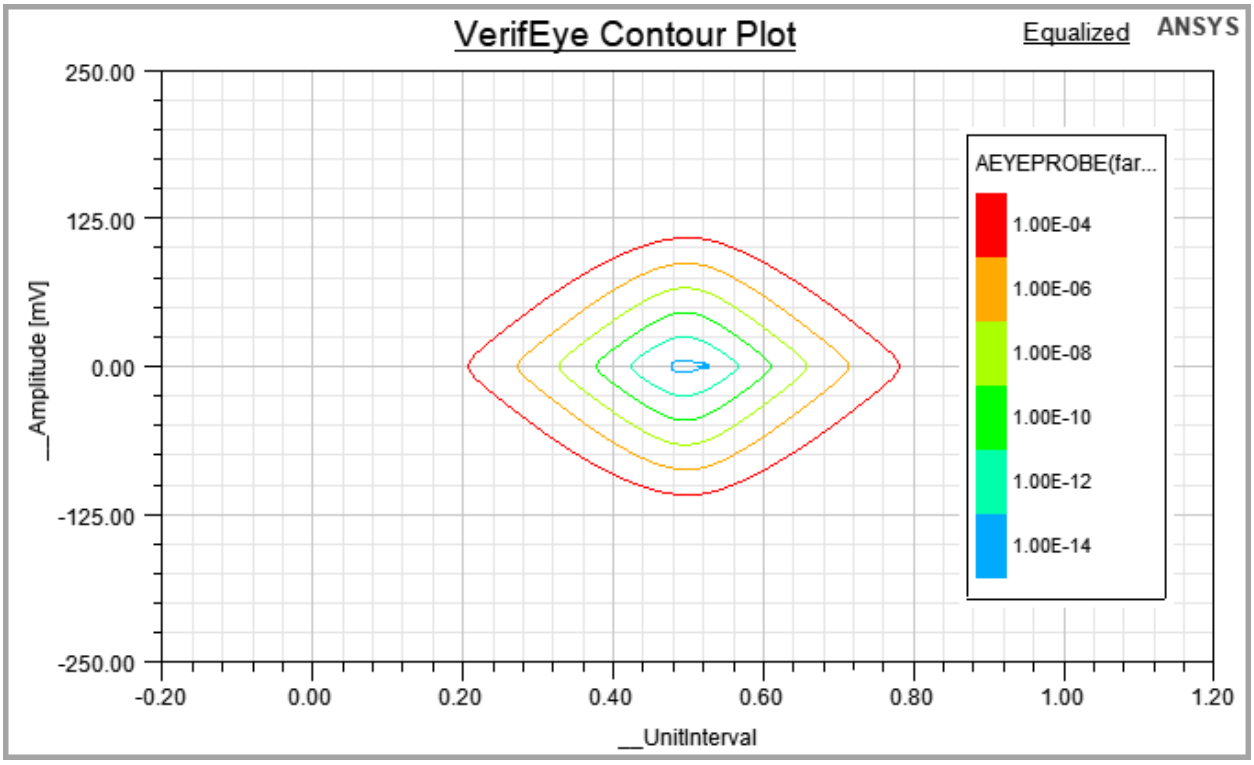
c. Double-click the **Step Responses** report to open it:



The step responses are unchanged by the equalization.

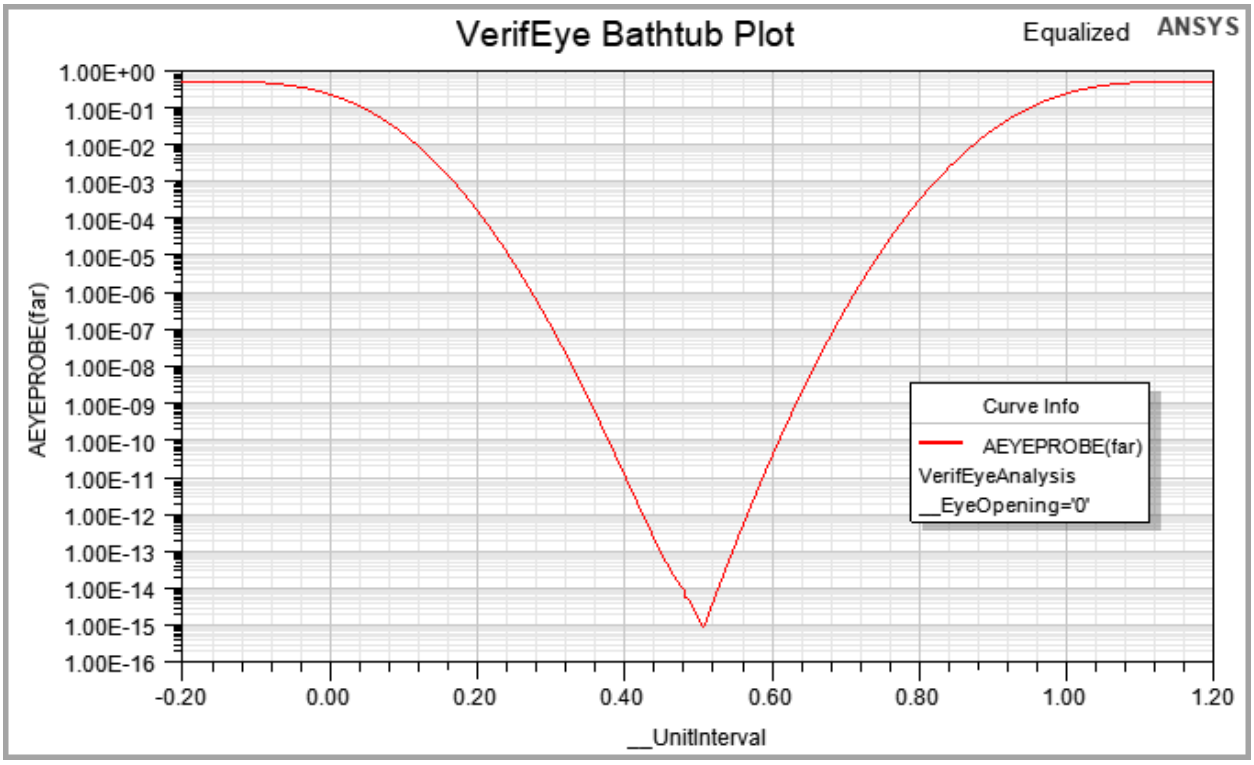
d. Double-click the **VerifEye Contour Plot** report. Equalization has significantly reduced the bit error rate in the center of the eye.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



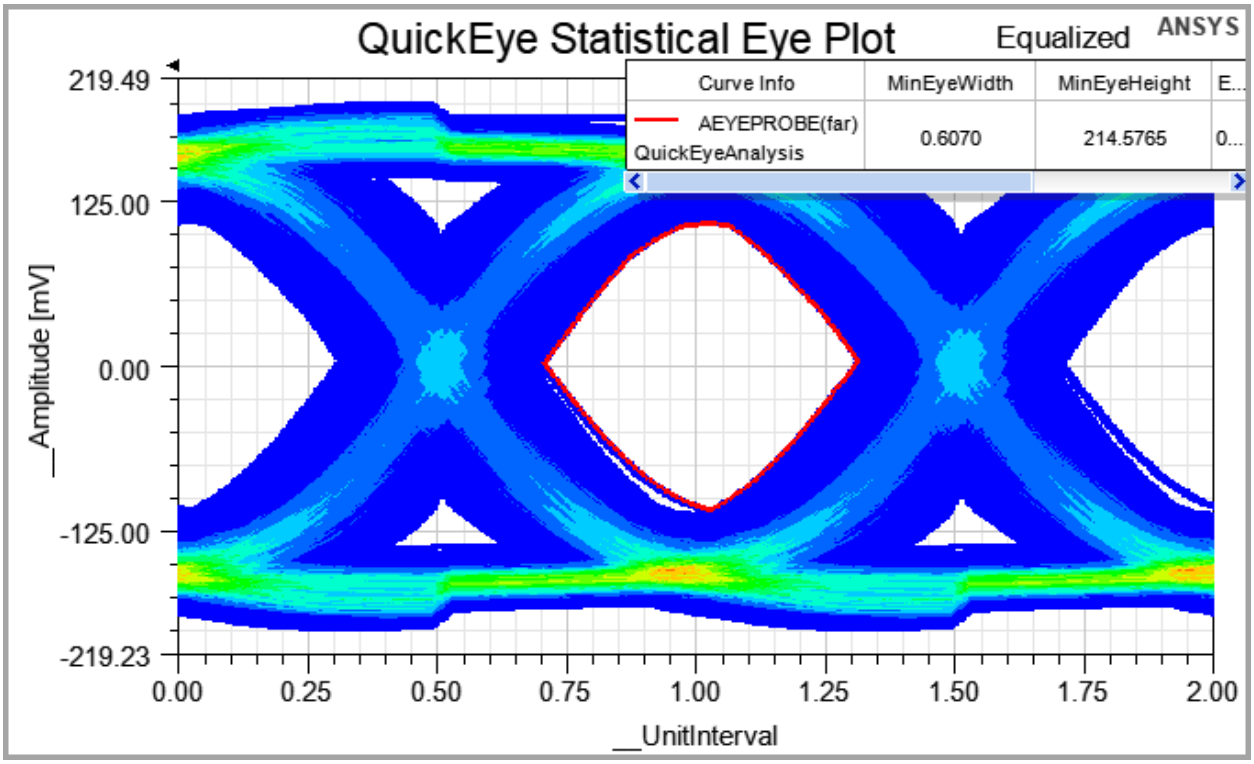
The VerifEye Bathtub Plot shows the corresponding BER curve.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

e. Double-click the **QuickEye Statistical Eye Plot** report:

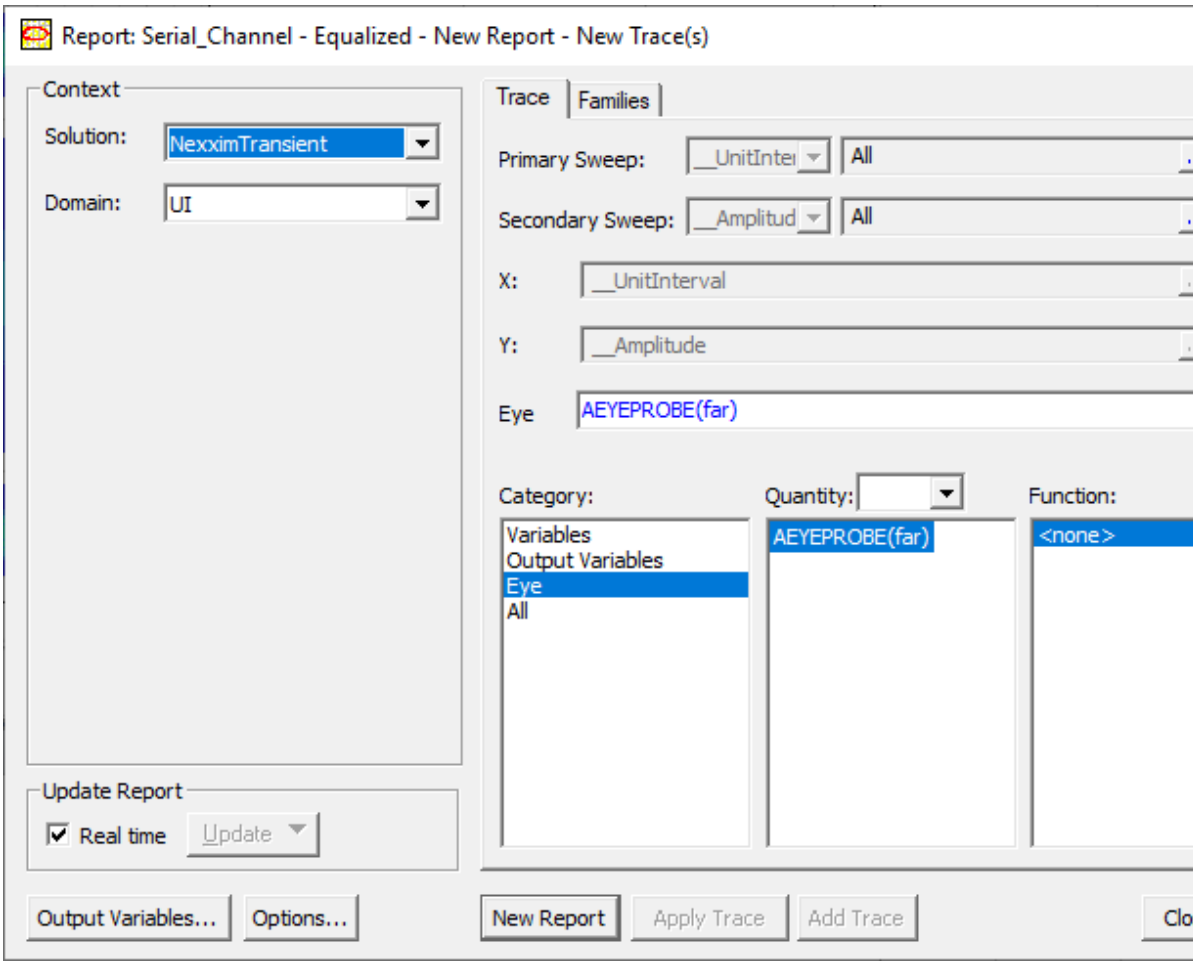


f. Create a Transient analysis report:

1. From the **Project Manager** window, right-click **Results** and click **Create Statistical Eye Report** > **Statistical Eye Plot**.

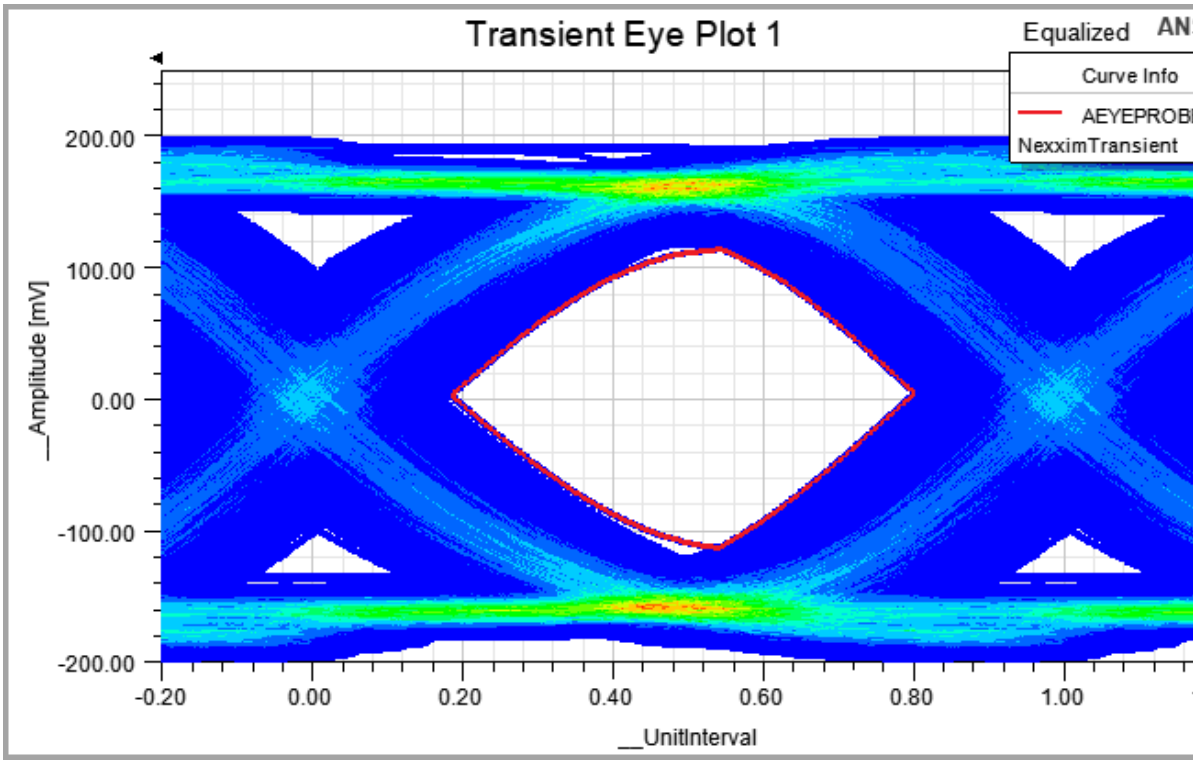
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the **Report** window, set **Solution** t o**NexximTransient**.



3. Click **New report** to generate the **Transient Statistical Eye Plot** report and **Close** to close the **Report** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



g. When you are done, click **Window** > **Close All** to close all the schematic and report windows.

External Step Response Example

This example shows how to use the External Step Response (ESR) element in Circuit schematics to provide the impulse response data for QuickEye and VerifEye. The example demonstrates how to generate an impulse-response file using transient analysis. Once the impulse-response data has been generated and exported to a file, QuickEye and VerifEye can use the file data to calculate the channel response without re-running a transient analysis. This can save time when the channel step-response does not change between analyses.

Generating Impulse Response Data

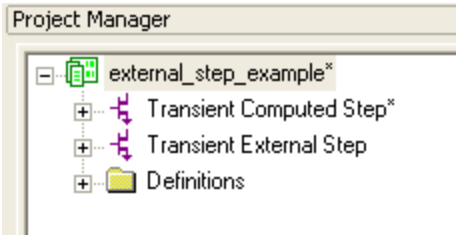
The example design is available in the Examples directory. The design contains both parts of the example as separate projects.

Open the design from its file in the Examples directory.

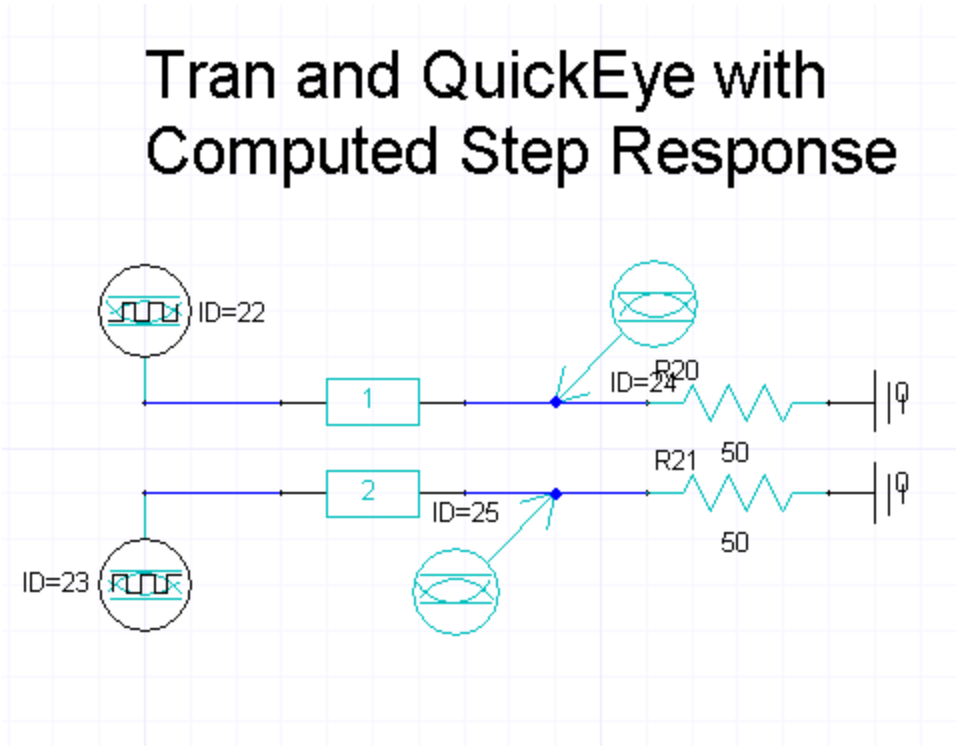
1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **SignalIntegrity**, then select the file **External_Step_Example.aedt**. Click **Open**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The design opens with two projects:



3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.
4. Click the **Transient Computed Step** project to open the schematic.



The circuit contains two Eye Sources and two Eye Probes.

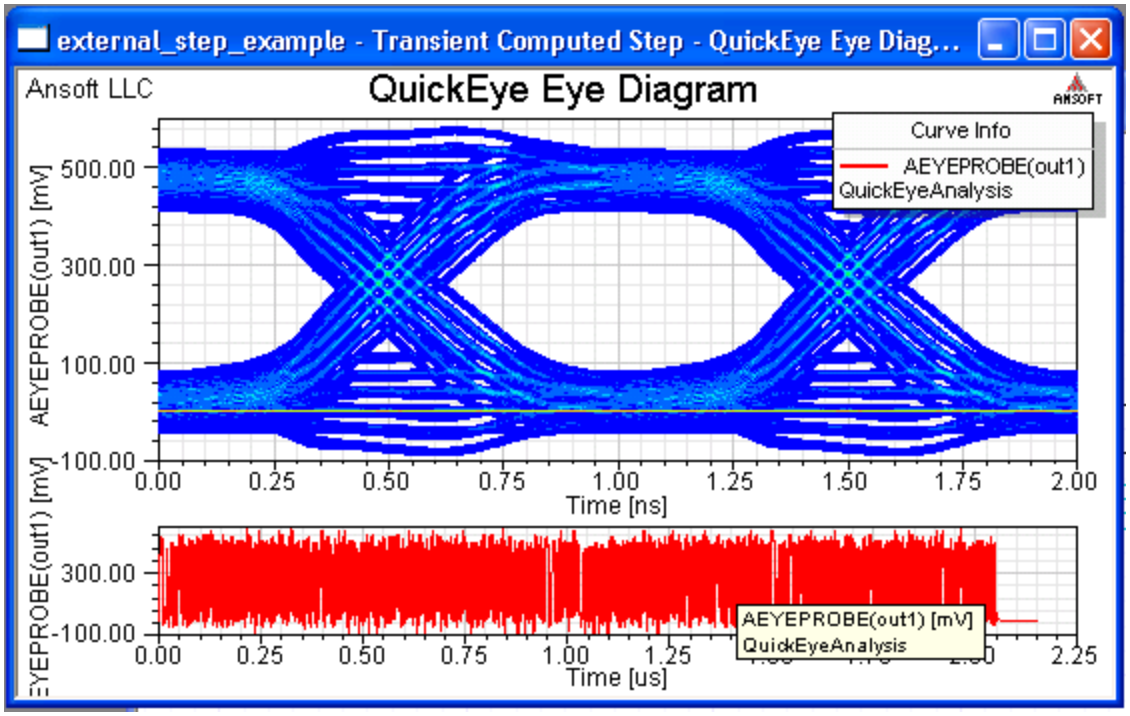
The through path from Eye Source ID=22 to Eye Probe ID=24 (out1) is the main channel. The through path from Eye Source ID=23 to Eye Probe ID=25 (out2) is the secondary (competing) channel). The two sources produce PRBS bit streams with different seeds.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The paths from Eye Source ID=22 to Eye Probe ID=25 (out2) and from Eye Source 23 to Eye Probe ID=24 (out1) generate the crosstalk terms.

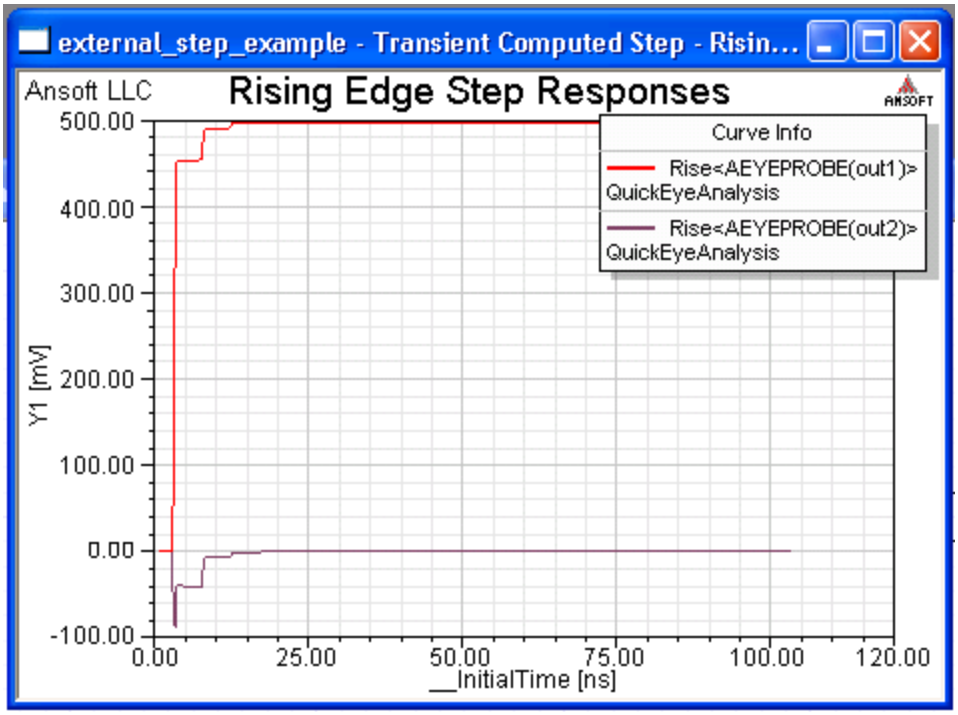
From the **Project Manager** window, expand the **Analysis** icon, right-click **QuickEyeAnalysis**, and select **Analyze**. The analysis runs to completion.

Expand the **Results** icon and double-click on the **QuickEye Eye Diagram** report:



To view the rising step response data, double-click on the **Rising Edge Step Responses** report:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The upper trace is the main channel response. The lower trace is the crosstalk response. To view the step response data in tabular form suitable for exporting, double-click the **Rising Edge Step Through Path** report:

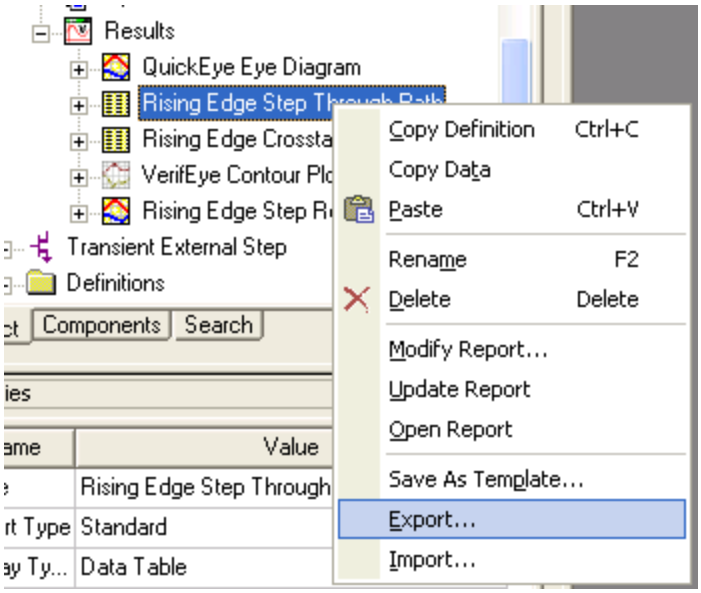
	__InitialTime [s]	Rise<AEYEPROBE(out1)> [V] QuickEyeAnalysis
26	0.000000	0.249523
27	0.000000	0.337940
28	0.000000	0.437192
29	0.000000	0.451466
30	0.000000	0.451855
31	0.000000	0.452059

The data window has been scrolled down to a segment with data.

By default, the data is in units such as nanoseconds and millivolts. The ESR component requires units of **seconds** and **volts**. To change to the units shown above, click the column heading (e.g., **_InitialTime**) and set the **Units** property to the appropriate unit.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The data from this table have been exported to step response files for the second part of this example. To export the data on the data table report, right-click the report and select **Export** to open an explorer window.



Browse to the appropriate directory. Save the data using the **Post-processor format files (*.txt)** format.

The data file **rise_through_path.txt** in the Examples directory was created in this way.

The data table report **Rising Edge Crosstalk Response** contains the response data for one crosstalk path, Eye Source ID=22 to EyeProbe ID=25 (out2). The exported data is in the data file **rise_xtalk_term.txt** in the Examples directory.

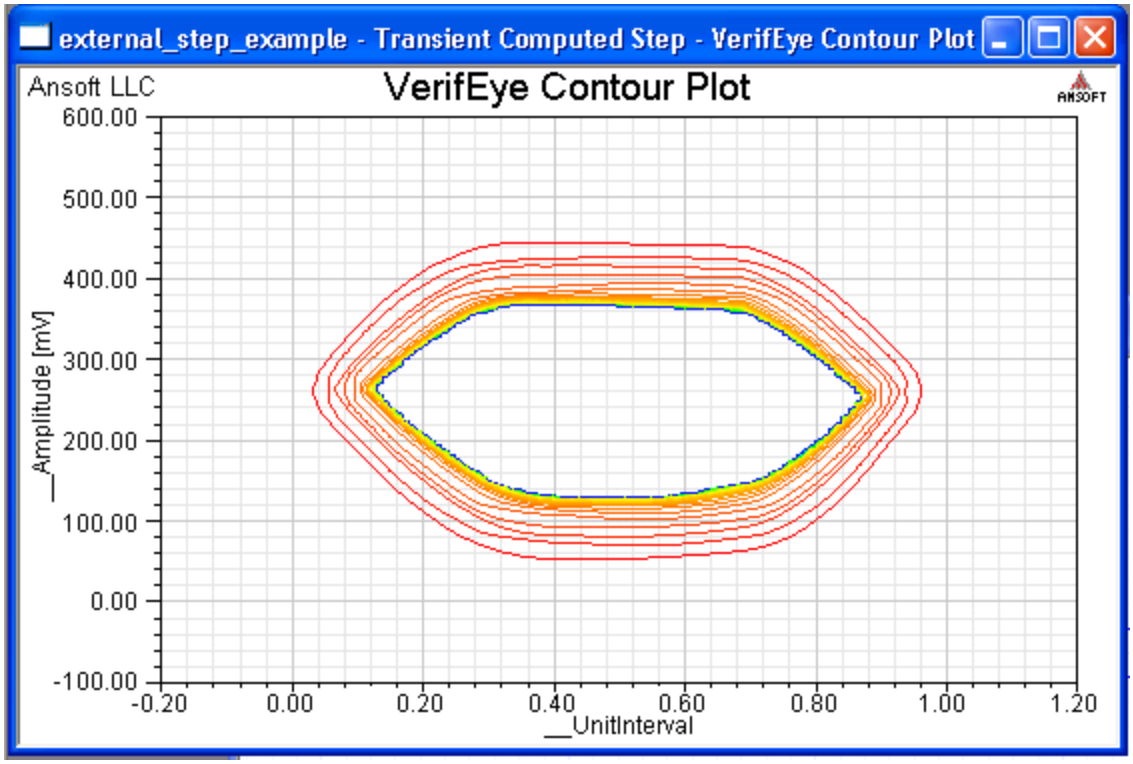
Similar reports are generated and exported to create the data files **fall_through_path.txt** and **fall_xtalk_term.txt** in the Examples directory.

In this simplified example, both through paths use the same rise and fall times, and the crosstalk terms are assumed to be the same in both crosstalk paths.

The same analysis may be run using VerifEye instead of QuickEye. Under the Analysis icon, right-click **VerifEye Analysis** and select **Analyze**. The analysis runs to completion.

To view the results: double-click the **VerifEye Contour Plot** report:

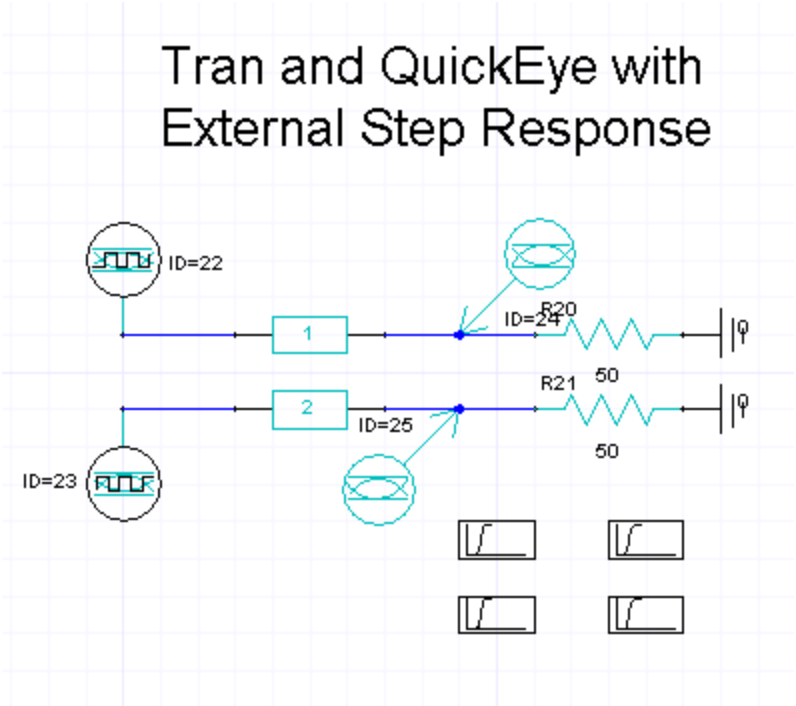
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



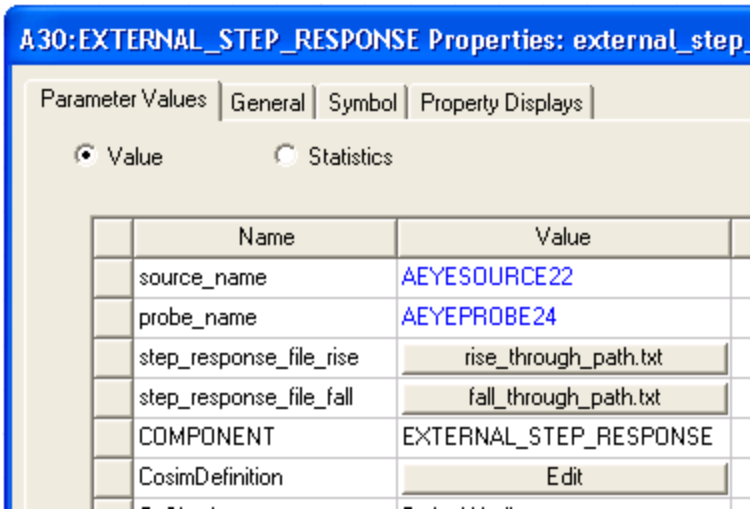
Using External Step Response Data

The second project uses the step response data instead of repeating the transient analysis. Under the Design icon, click the **Transient External Step** project:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The circuit is basically the same, only now the responses is controlled by the four External Step Response ESR) elements in the schematic. Click the upper-left ESR element and display its properties:



The ESR elements do not physically connect to the circuit. Each ESR element specifies a rise time and a fall time for one of the four paths:

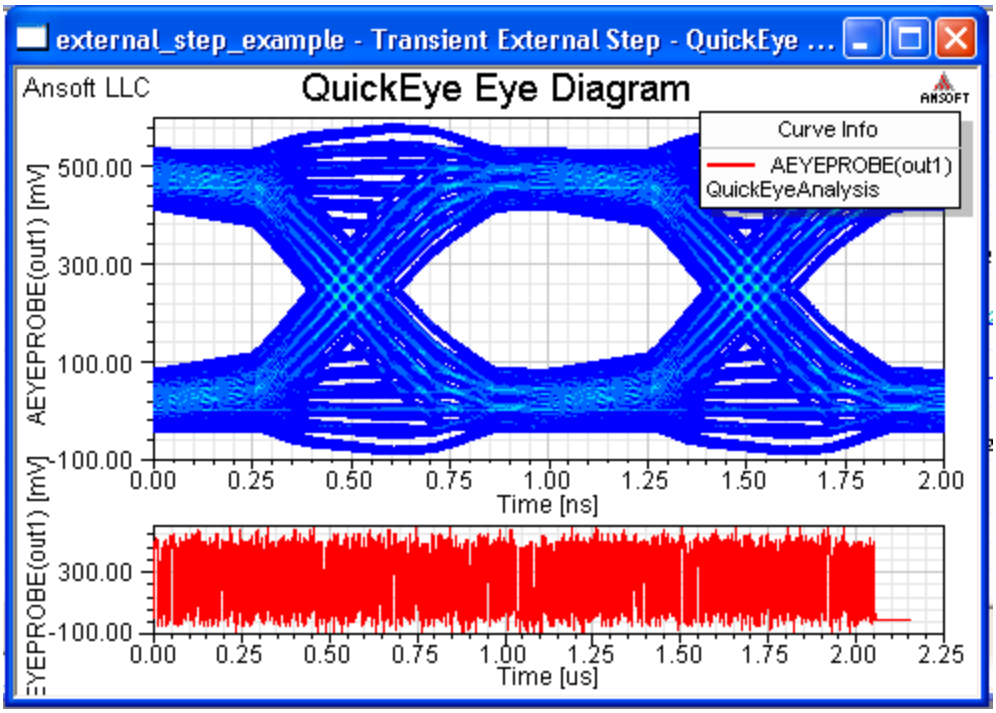
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The main through path from Eye Source 22 to Eye Probe 24 (out1).
- The second through path from Eye Source 23 to Eye Probe 25 (out2).
- The crosstalk path from Eye Source 22 to Eye Probe 25 (out2).
- The crosstalk path from Eye Source 23 to Eye Probe 24 (out1).

The two through paths use the same rise and fall data files. The two crosstalk paths share a different set of rise and fall data files.

From the **Project Manager** window, expand the **Analysis** icon, right-click **QuickEyeAnalysis**, and select **Analyze** on the dropdown menu. The analysis runs to completion very quickly compared to the earlier transient analysis. Because the step data is provided, no transient analysis is run, saving significant time.

Expand the **Results** icon and double-click the **QuickEye Eye Diagram** report:

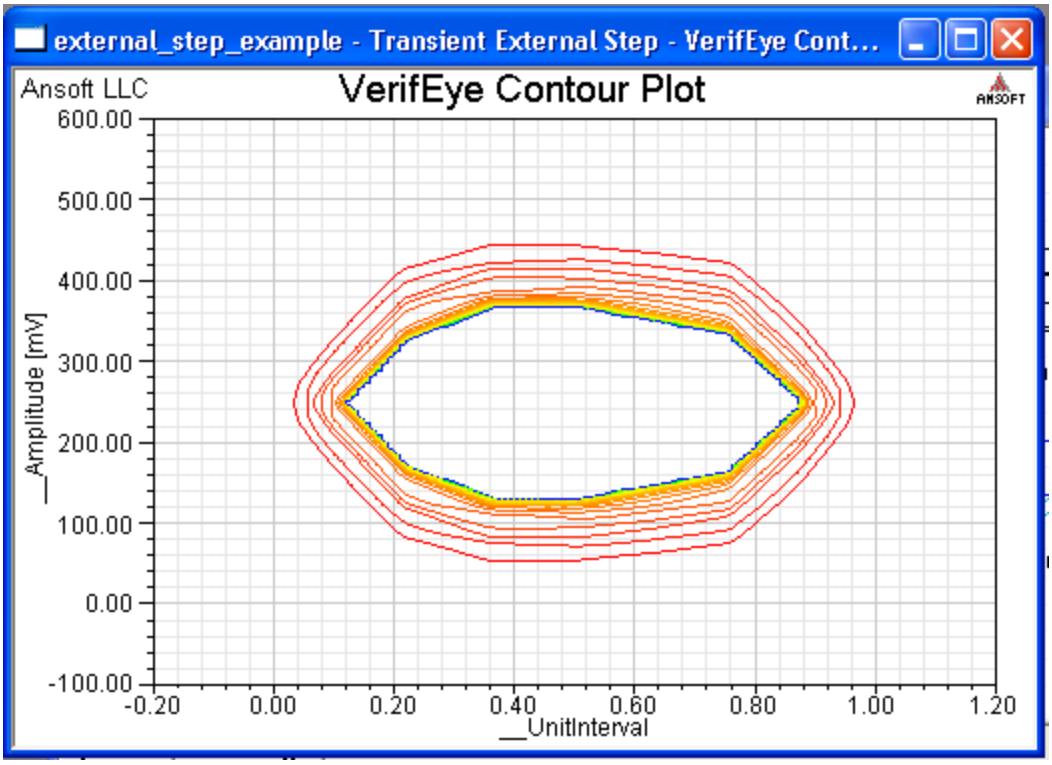


The result is nearly identical to the QuickEye Eye diagram produced by transient analysis.

An equivalent speedup is also available for VerifEye analysis. From the **Project Manager** window, expand the **Analysis** icon, right-click **VerifEyeAnalysis**, and select **Analyze**. This analysis also runs to completion quickly (much of the time is needed to generate the eye diagram). Providing the step data saves VerifEye some processing time.

Expand the **Results** icon and double-click the **VerifEye Contour Plot** report:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The result is identical to the VerifEye Contour diagram produced by transient analysis.

AMI Analysis Example

The Algorithmic Modeling Interface (AMI) allows time-domain simulation of a linear channel using customer-supplied models and parameters for the transmitter and receiver. Reports include eye diagrams and bit-error-rate (BER) contours. The Nexxim implementation allows you to sweep the value of a parameter in an AMI file. VerifEye analysis can then be run with the AMI channel definition in order to give an accurate picture of the channel response.

Channel Example with AMI

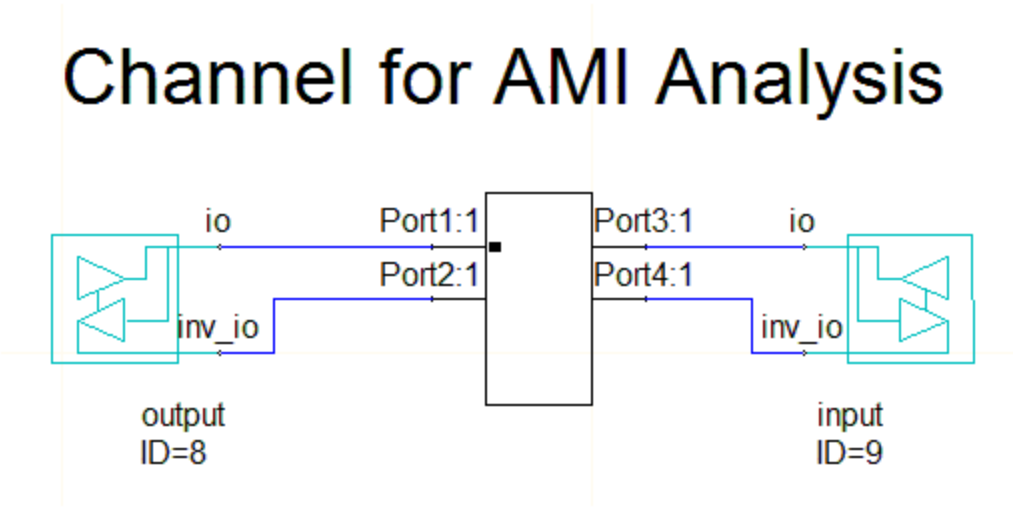
The schematic for the circuit is available in the Examples directory.

Open the project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open the **Examples** directory in an **Open** explorer window.
2. From the **Examples** directory, select **Circuit** > **Signal Integrity**. Then double-click **AIM_Example.aedt**, or select **AIM_Example.aedt** and click **Open**.

The channel schematic appears in the design window:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

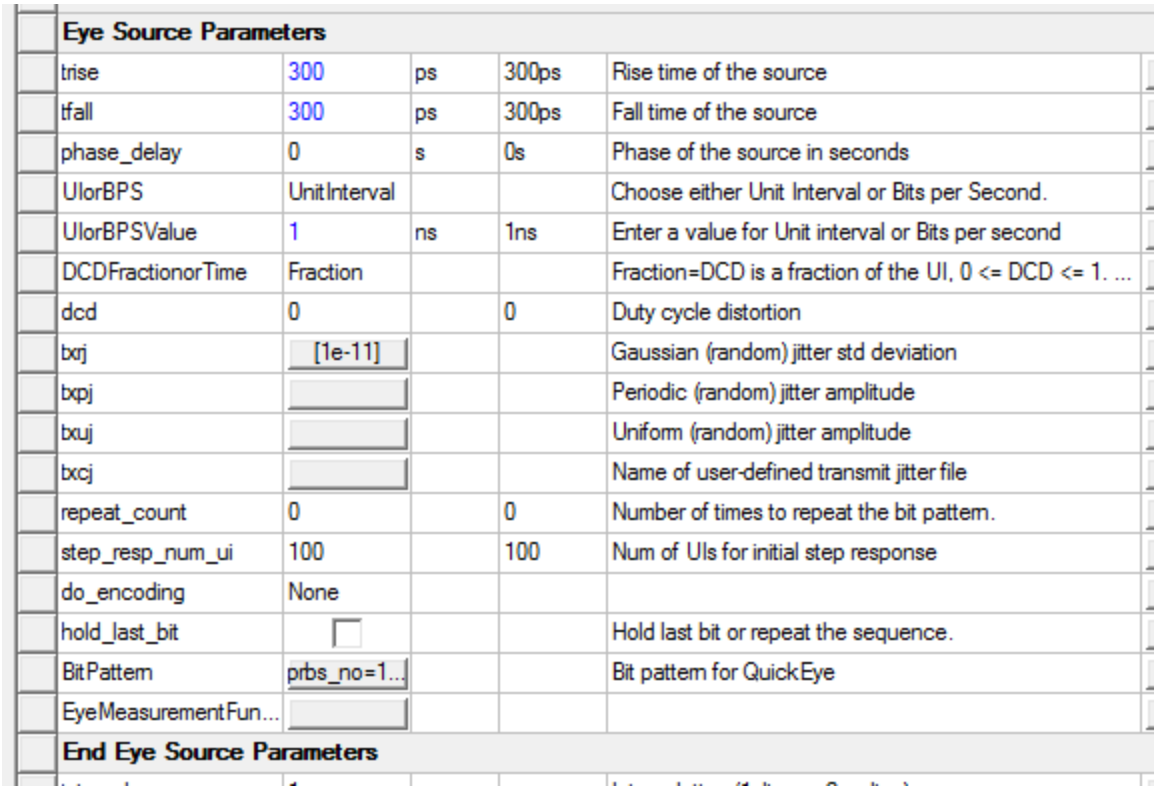


3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.
4. Double-click the IBIS output buffer to display its properties:

Name	Value	Unit	Evaluated...	Description
file	ibis_ami_example_tx.ibs			Name of IBIS file (required)
typ	typ		"typ"	Parameter range (typ, min, max, fast, slow)
power	internal			Power mode (on=internal, off=external)
buffer	output			Buffer type (output)
Model1	example_model_tx		"example...	
Model2	example_model_tx		"example...	
polarity	Non-Inverting			Polarity (Non-Inverting, Inverting, No Polarity,
--Pin Properties				
logic_in	Internal Source			
--End Pin Properties				

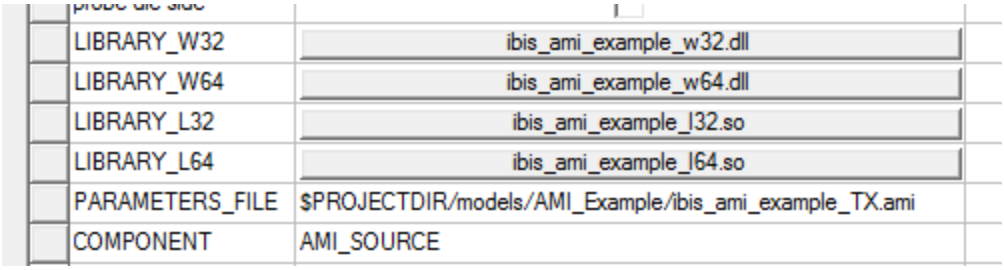
The **file** parameter points to the IBIS transmitter file. The **logic_in** property is set to **Internal Source**, enabling the Eye Source properties.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Eye Source Parameters				
trise	300	ps	300ps	Rise time of the source
tfall	300	ps	300ps	Fall time of the source
phase_delay	0	s	0s	Phase of the source in seconds
UIorBPS	UnitInterval			Choose either Unit Interval or Bits per Second.
UIorBPSValue	1	ns	1ns	Enter a value for Unit interval or Bits per second
DCDFractionorTime	Fraction			Fraction=DCD is a fraction of the UI, 0 <= DCD <= 1. ...
dcd	0		0	Duty cycle distortion
txrj	[1e-11]			Gaussian (random) jitter std deviation
txpj				Periodic (random) jitter amplitude
txuj				Uniform (random) jitter amplitude
txcj				Name of user-defined transmit jitter file
repeat_count	0		0	Number of times to repeat the bit pattern.
step_resp_num_ui	100		100	Num of UIs for initial step response
do_encoding	None			
hold_last_bit	☐			Hold last bit or repeat the sequence.
BitPattern	prbs_no=1...			Bit pattern for QuickEye
EyeMeasurementFun...				
End Eye Source Parameters				

The Eye Source parameters call for rise and fall times of 300ps, with a bit pattern generated via the internal PRBS. A small amount of random jitter has been added at the transmitter.



LIBRARY_W32	ibis_ami_example_w32.dll
LIBRARY_W64	ibis_ami_example_w64.dll
LIBRARY_L32	ibis_ami_example_l32.so
LIBRARY_L64	ibis_ami_example_l64.so
PARAMETERS_FILE	$PROJECTDIR/models/AMI_Example/ibis_ami_example_TX.ami
COMPONENT	AMI_SOURCE

The **library** files contain the AMI code for both transmitter and receiver.

The **parameter_file** contains FFE data for the transmitter:

```
| method = 1 applies the tap weights inside AMI_init to the channel
impulse
| method = 2 applies the tap weights inside AMI_Getwave to the wave
| results of both methods should be nearly identical, but method 1 is
faster.
(method 1) | 1 or 2
(ffe 1 -0.2 0.1 -0.05) | arbitrary number of tap weights
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** Method 1 is required for VerifEye analysis to produce the same result as AMI. VE uses just the impulse data from AMI_Init, and does not use the AMI_Getwave data.

The AMI File Properties display the data on the parameter file:

Properties from AMI file				
Ignore_Bits	4		4	
Max_Init_Aggressors	10		10	
Init_Returns_Impulse	☑			
GetWave_Exists	☑			
Use_Init_Output	☑			
method	2		2	
ffe_weight_1	-0.2		-0.2	
ffe_weight_2	0.1		0.1	
ffe_weight_3	-0.05		-0.05	
End Properties from AMI file				

5. Double-click the AMI Receiver to display its properties:

Name	Value	Unit	Evaluated...	Description
file	ibis_ami_example_rx.ibs			Name of IBIS file (required)
typ	typ		"typ"	Parameter range (typ, min, max, fast, slow)
power	internal			Power mode (on=internal, off=external)
buffer	input			Buffer type (input)
Model1	example_model_rx		"example...	
Model2	example_model_rx		"example...	
polarity	Non-Inverting			Polarity (Non-Inverting, Inverting, No Polarit
--Pin Properties				
Out	Out_pin			
--End Pin Properties				

The **file** parameter points to the IBIS transmitter file.

LIBRARY_W32	ibis_ami_example_w32.dll
LIBRARY_W64	ibis_ami_example_w64.dll
LIBRARY_L32	ibis_ami_example_l32.so
LIBRARY_L64	ibis_ami_example_l64.so
PARAMETERS_FILE	$PROJECTDIR/models/AMI_Example/ibis_ami_example_RX.ami

The **library** files contain the AMI code for both transmitter and receiver.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The parameters file contains FFE and clock data for the receiver:

```
| method = 1 applies the tap weights inside AMI_init to the channel
impulse
| method = 2 applies the tap weights inside AMI_Getwave to the wave
| results of both methods should be nearly identical, but method 1 is
faster
(method 1) | 1 or 2
(ffe 1 -0.1 -0.05) | arbitrary number of tap weights
(clock_threshold 0.4) | threshold for clock tics
```

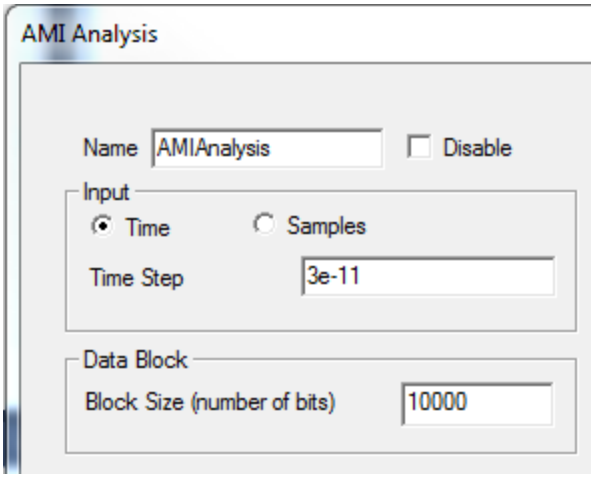
> **Note:** Method 1 is required for VerifEye analysis to produce the same result as AMI. VE uses just the impulse data from AMI_Init, and does not use the AMI_Getwave data.

The AMI File Properties display the data on the parameter file:

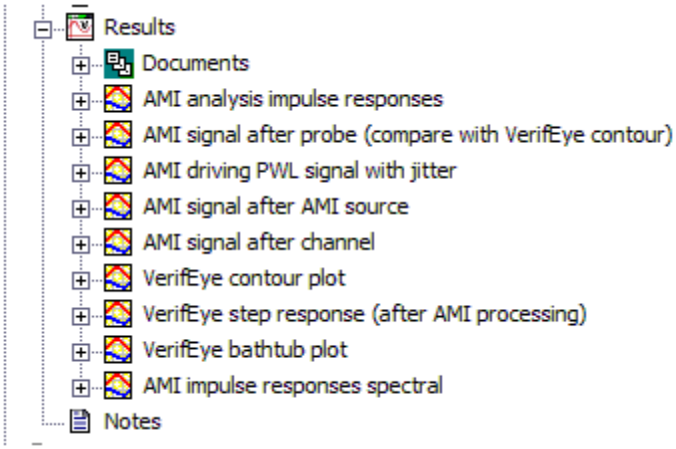
--Properties from AMI file				
Ignore_Bits	4		4	
Max_Init_Aggressors	10		10	
Init_Returns_Impulse	☑			
GetWave_Exists	☑			
Use_Init_Output	☑			
method	1		1	
clock_threshold	0.4		0.4	
ffe_weight_1	rx_ffe1		1.2	
ffe_weight_2	rx_ffe2		-0.1	
ffe_weight_3	rx_ffe3		0.05	
--End Properties from AMI file				

6. Expand the **Project Manager** window to show the Analysis setups, and double-click the **AMI Analysis** setup. The setup specifies the input timestep and data block size:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



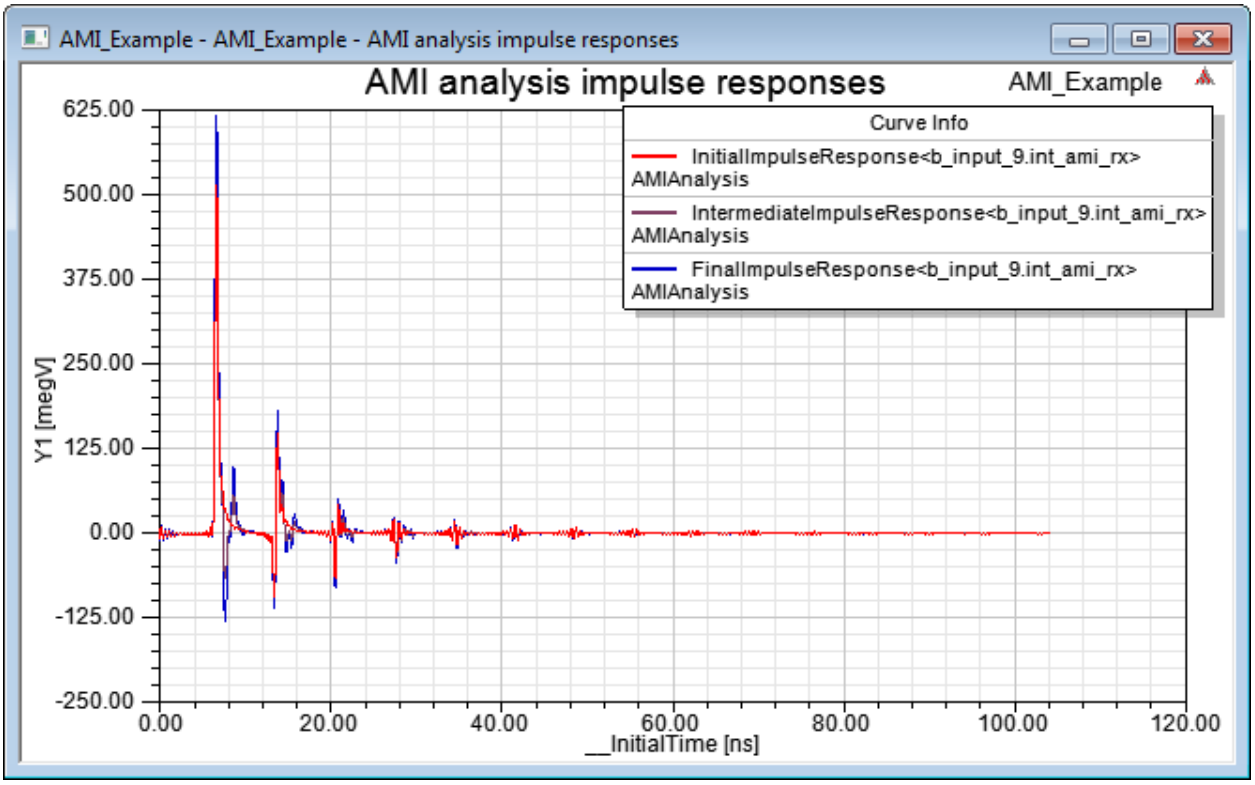
7. Right-click the **AMI Analysis** setup and select **Analyze**. The AMI analysis runs to completion.
8. Expand the **Project Manager** window to show the Reports:



9. Double-click **AMI analysis impulse responses** to open the report showing the impulse responses as initially calculated and as modified by the FFE tap weights in the Source or Probe by FFE method 1 or 2. With method 1 (shown), the FFE taps are applied to the impulse response and are reflected on this graph. With method 2, the equalization is

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

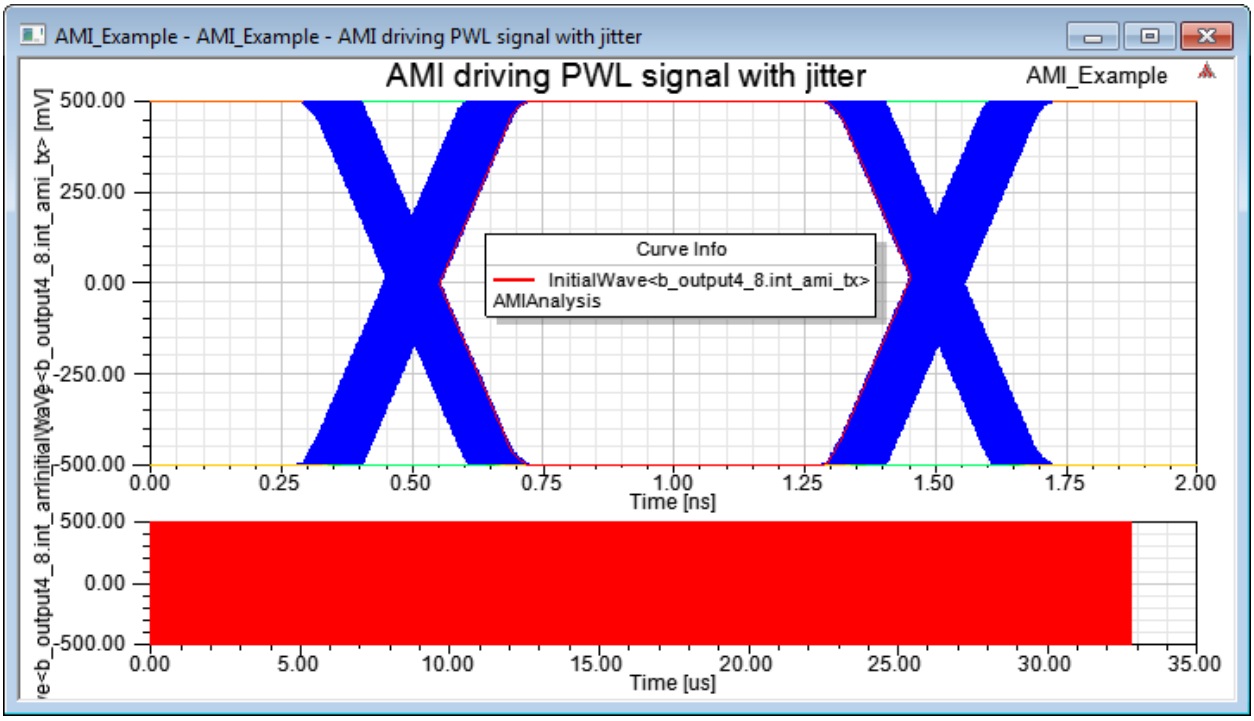
applied internally to the model and has no affect the impulse response.



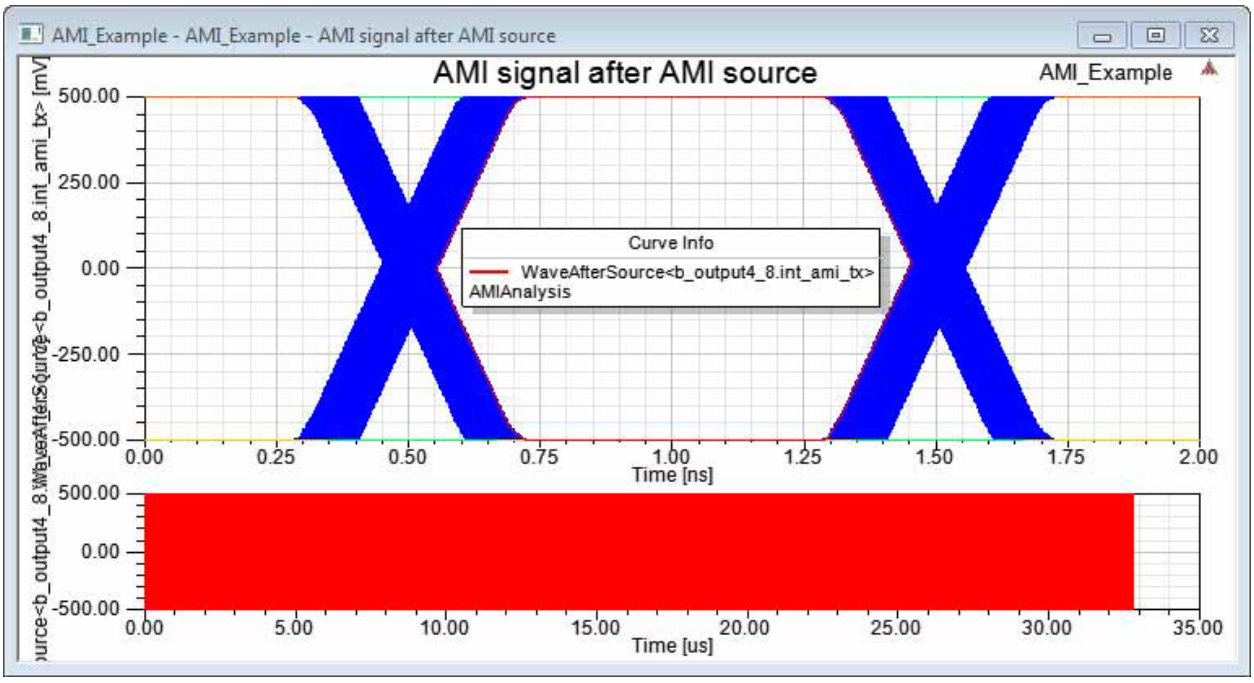
Edit the parameters files to select the method and change the FFE tap numbers and weights.

10. Double-click **AMI driving PWL signal with jitter** to open the report showing the eye diagram of the input signal.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

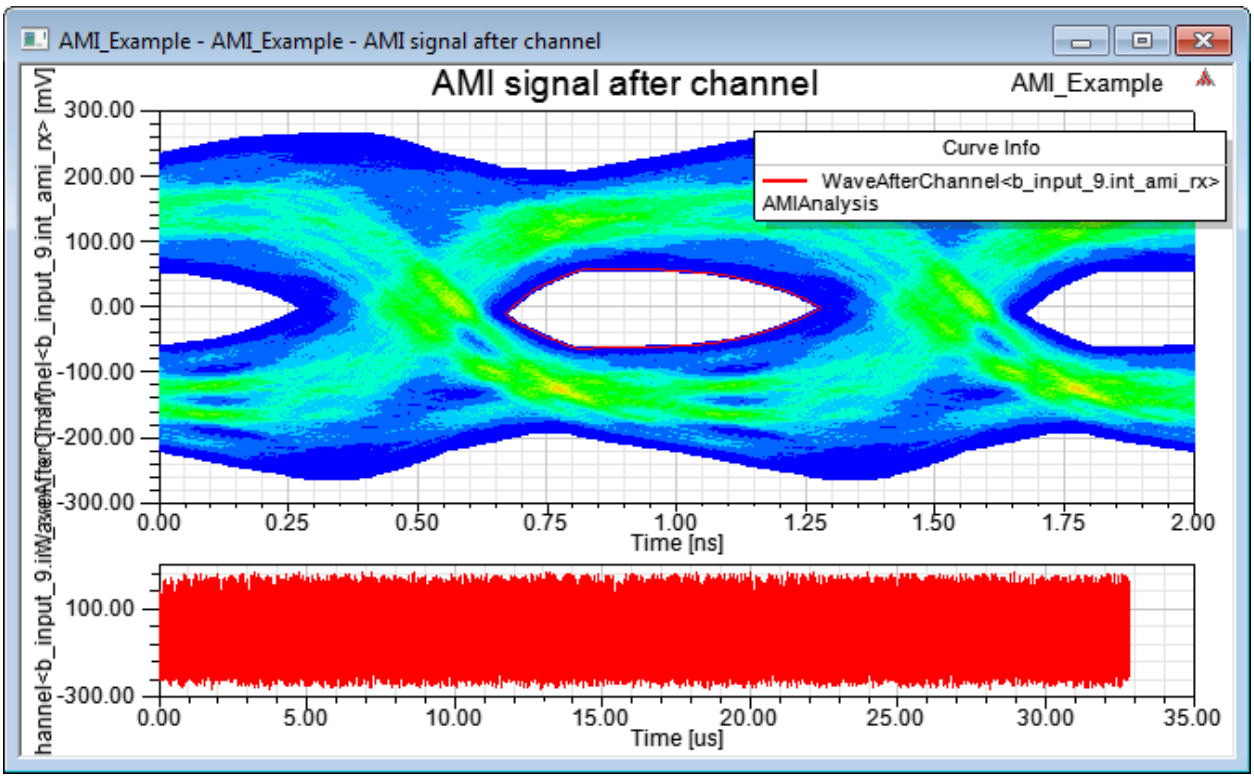


11. Double-click **AMI signal after AMI source** to open the report showing the eye diagram of the output signal on the AMI Source.



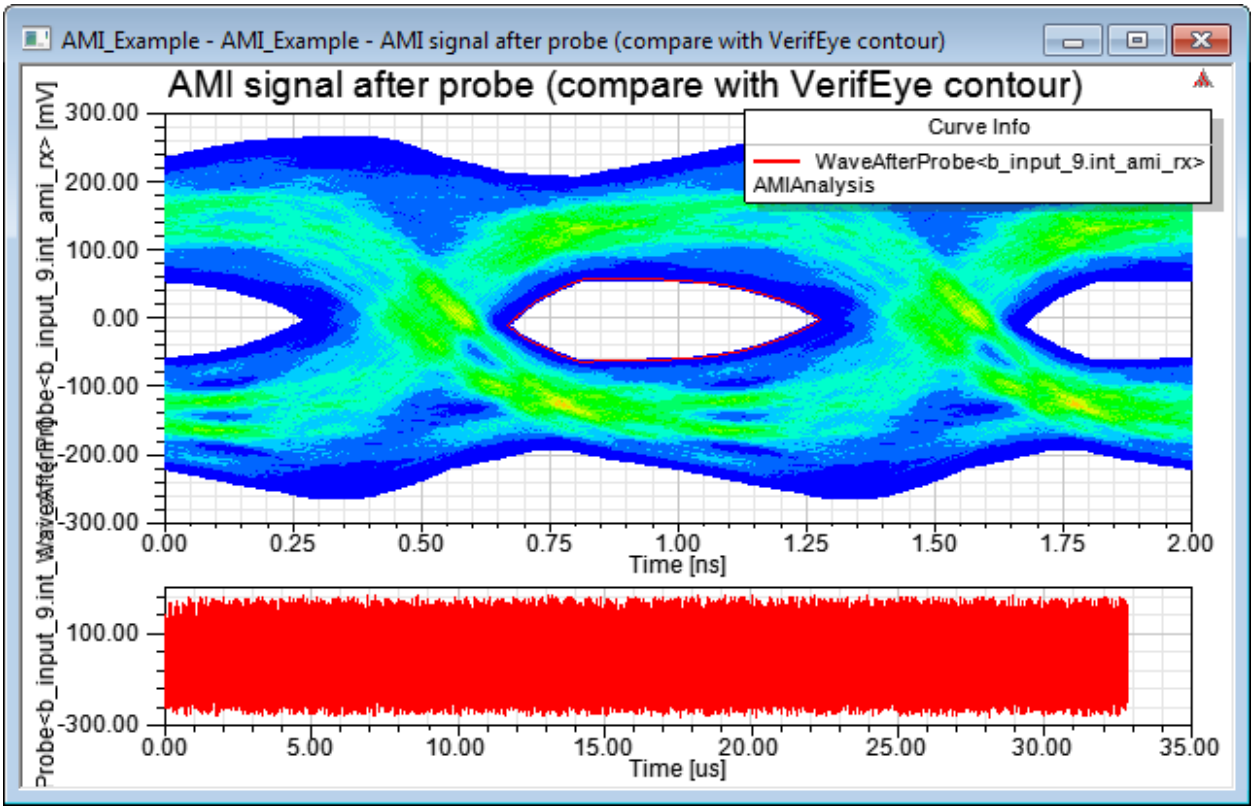
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12. Double-click **AMI signal after channel** to open the report showing the eye diagram of the output signal from the channel.



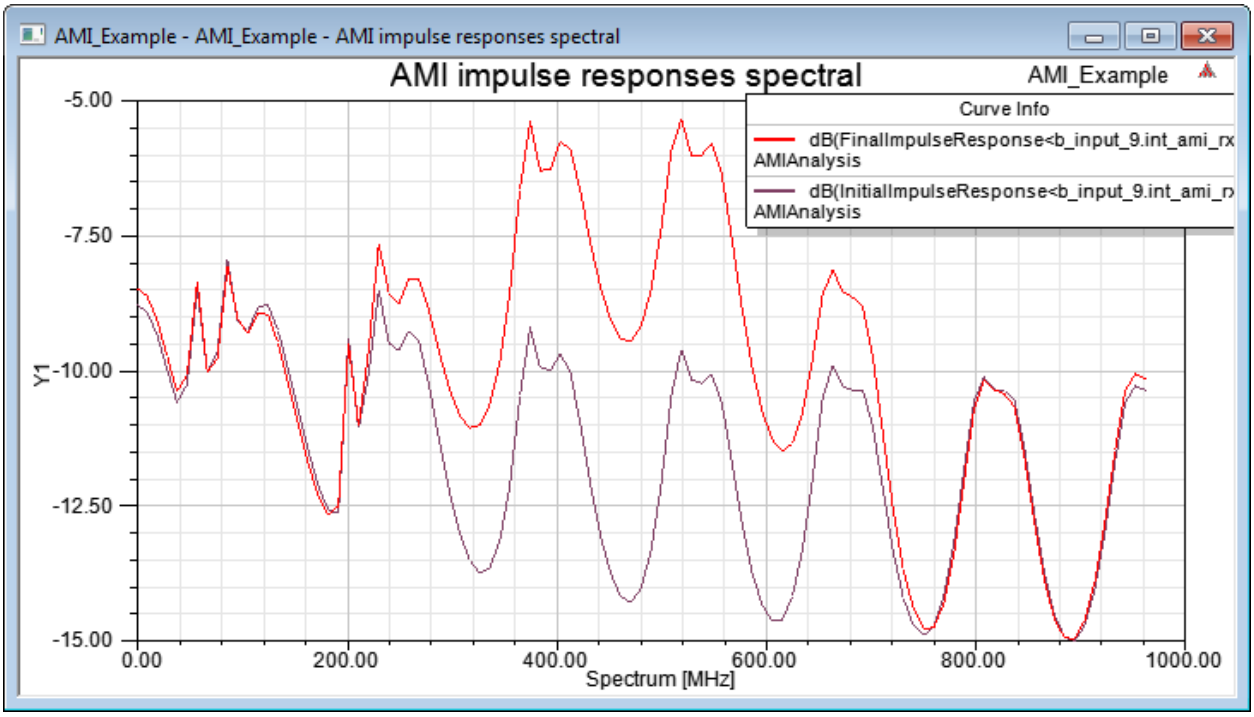
13. Double-click **AMI signal after probe** to open the report showing the eye diagram of the output signal from the AMI Probe.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



1. Double-click **AMI impulse responses spectral** to open the report showing the initial and final impulse responses in the spectral domain.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

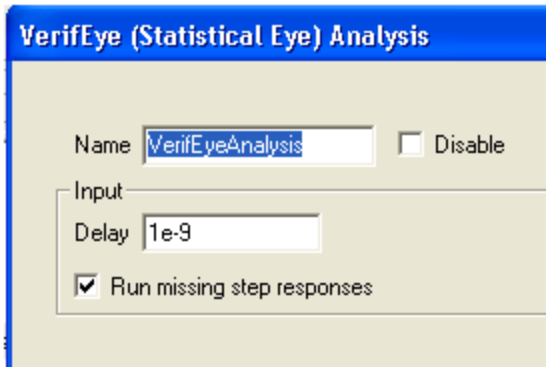


See Plotting Spectral Domain Data in the Reports topic. Although that topic mentions only transient solutions, the Context controls also apply to AMI analyses.

Channel Example with VerifEye

Use the same project, **AMI_Example.aedt**, to compare the AMI analysis with VerifEye analysis using the AMI impulse response definitions.

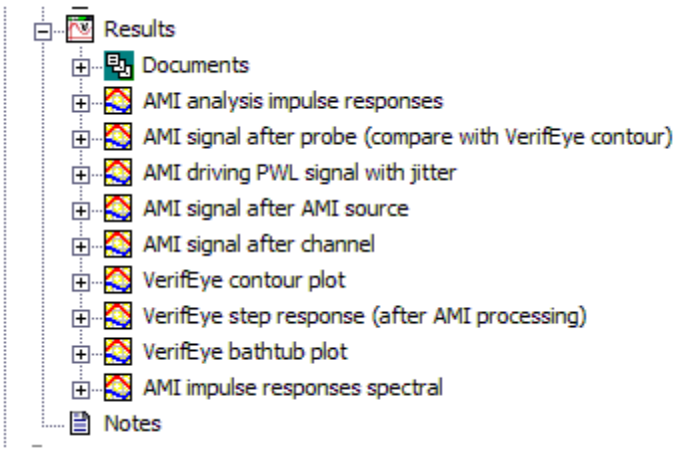
1. Double-click the **VerifEye Analysis** setup:



This is the default setup for VerifEye.

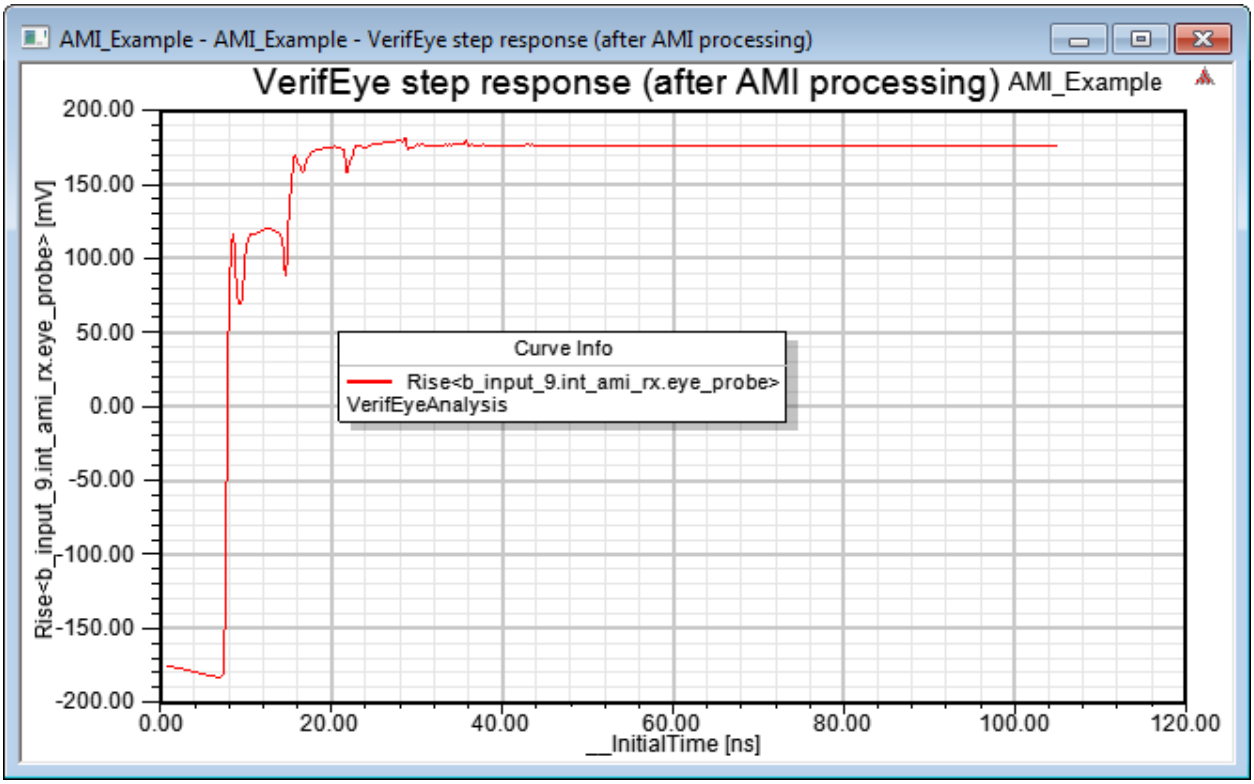
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Right-click the **VerifEye Analysis** setup and select **Analyze**. The VerifEye analysis runs to completion.
3. Expand the **Project Manager** window to show the Reports:



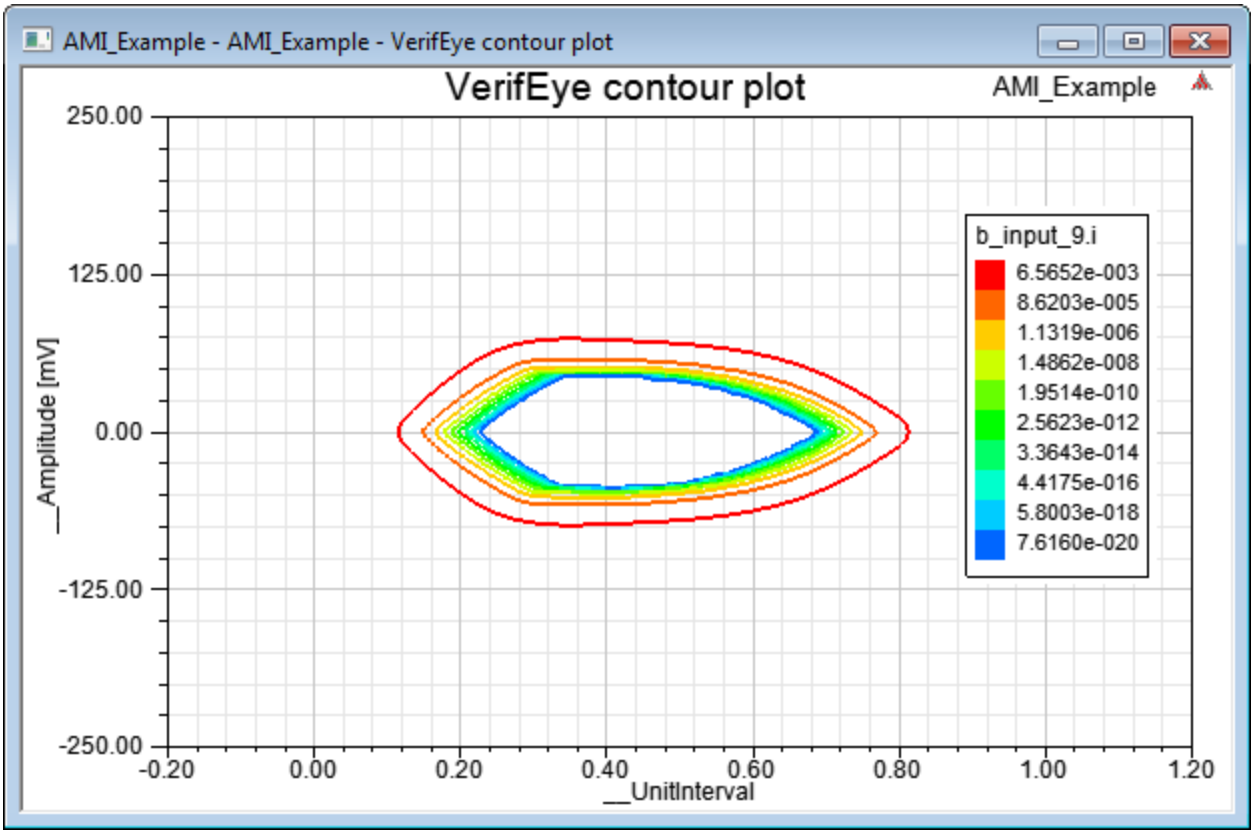
4. Double-click **VerifEye step responses** to open the report showing the rising step response as calculated by VerifEye using the FFE tap weights in the Source or Probe by FFE method 1. With method 1, the FFE taps are applied to the impulse response and are reflected on this graph. Because VerifEye uses only the **AMI_Init** function, only Method 1 guarantees that the results with VE is the same as the results for AMI analysis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



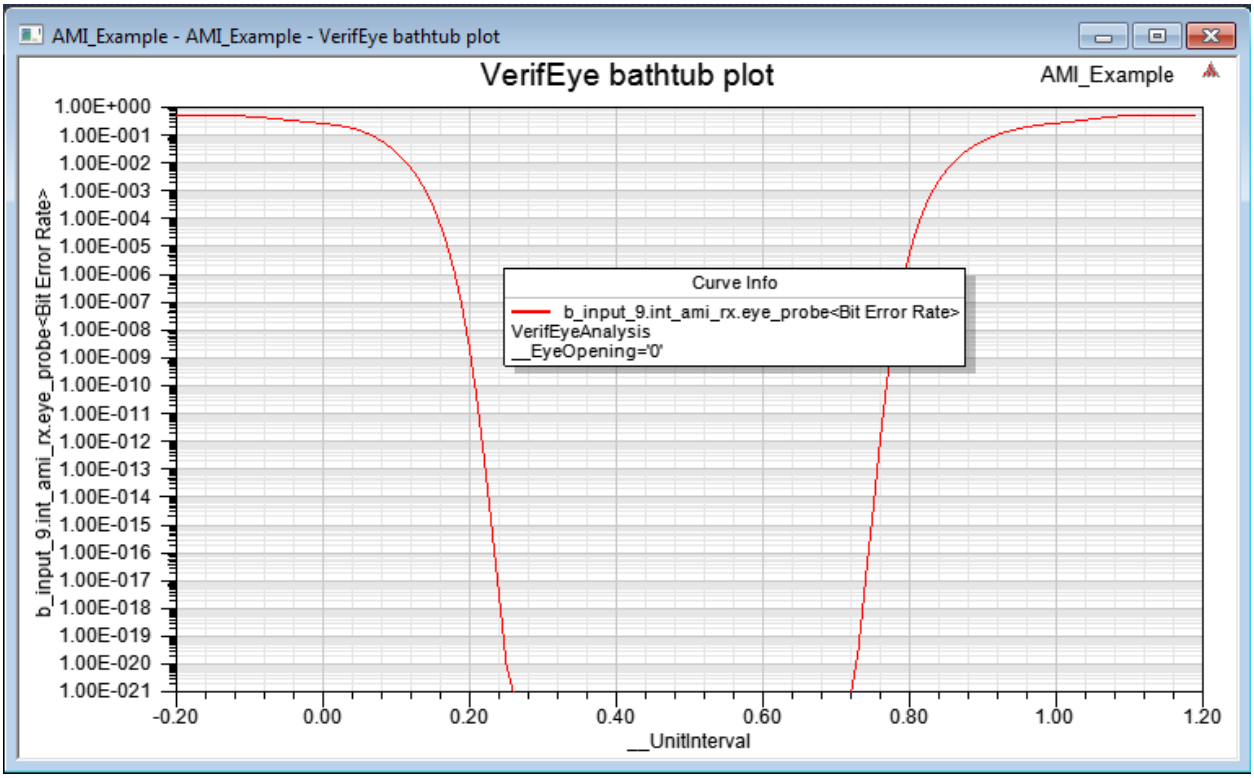
5. Double-click **VerifEye contour plot** to open the report showing the VerifEye contour plot of the of the output signal.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



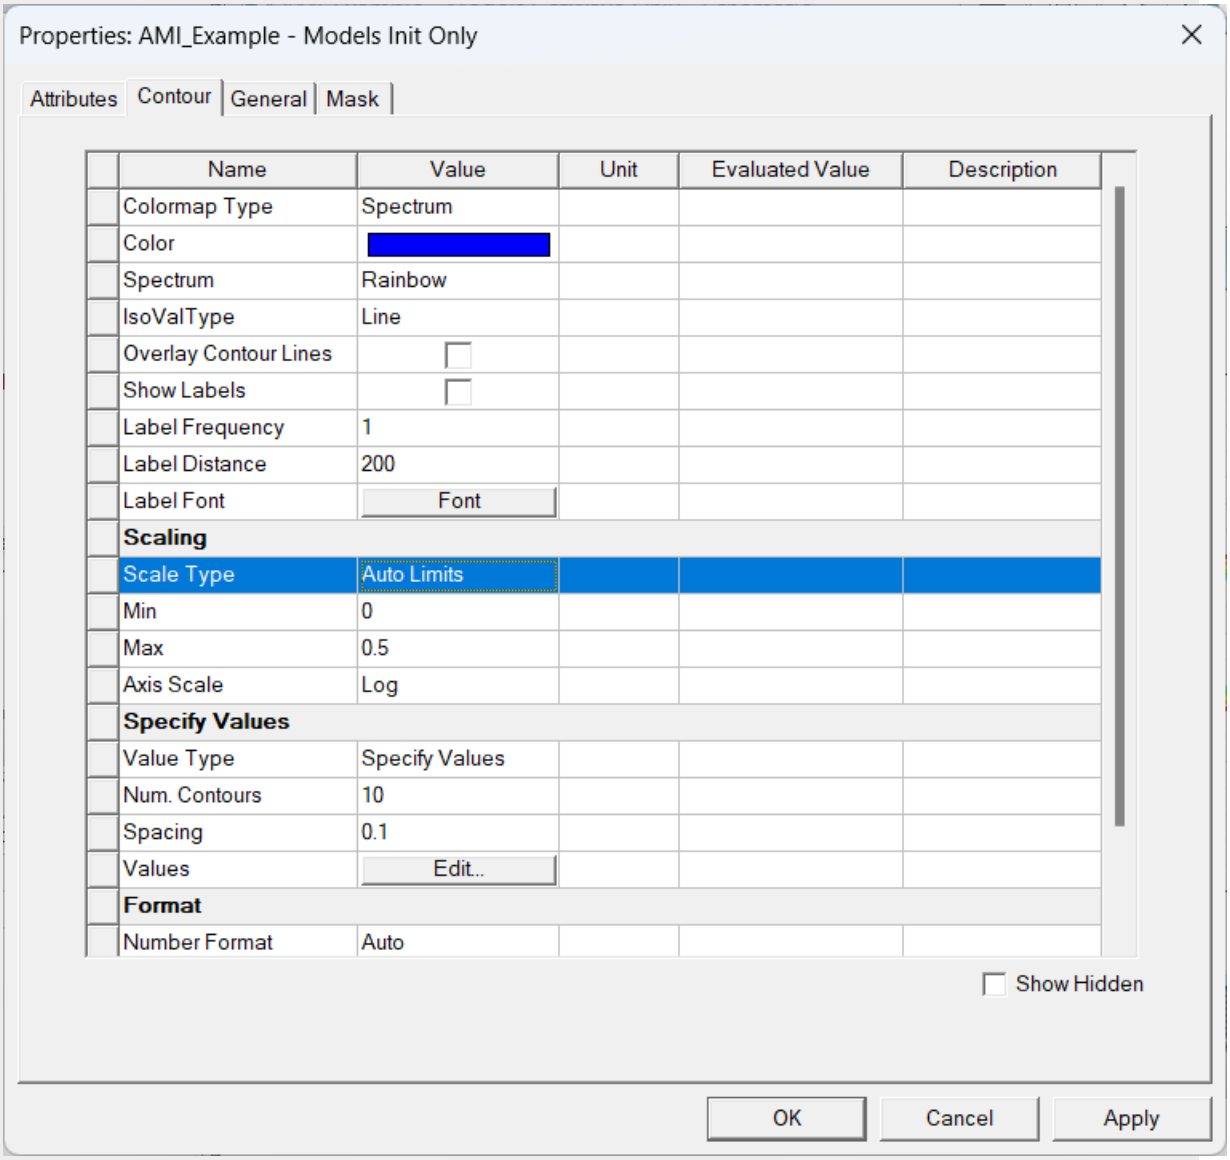
Double-click **VerifEye bathtub plot** to open the report showing the VE data as a bathtub plot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: Double-click the contour plot to open the **Properties** dialog. Editable properties are detailed in the Post Processing and Editing Reports chapter. In the **Contour** tab, **Scaling Type** property, when toggling from **Specify Limits** to **Auto Limits** , estimated auto limit values are displayed. Select **Apply** and **OK** to calculate the exact values and close the dialog. Open the contour plot properties dialog again to view the exact values.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Transmit Jitter Demonstration

Transmit jitter is variation in the timing of edges. Both QuickEye and VerifEye can include jitter distributions when calculating the eye measurements and Bit Error Rate (BER). Several common jitter types—uniform, periodic, random or Gaussian, and duty cycle distortion—can be added in any combination including multiple distributions of the same type. A custom jitter distribution can be read from a file provided by the user. See "Transmit Jitter in QuickEye and VerifEye " on page 26-311 for further information. Following are the examples for this Transmit Jitter Demonstration.

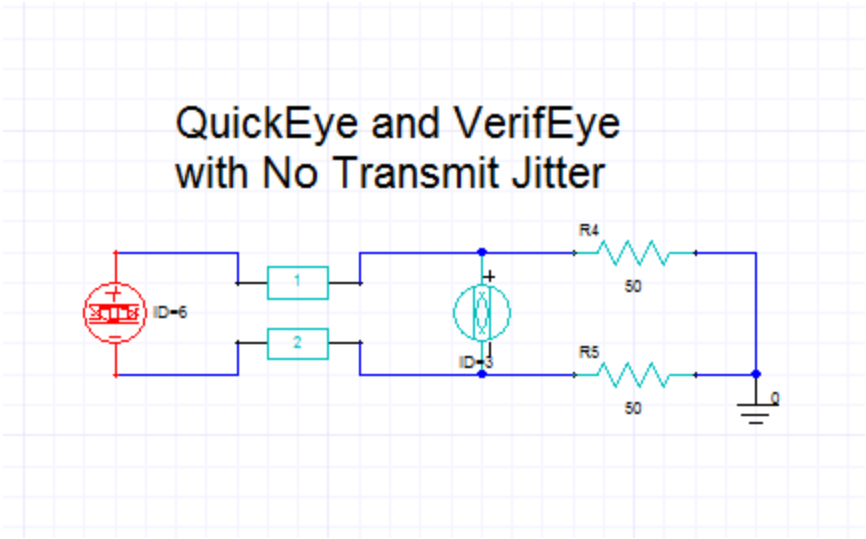
Channel Example with No Transmit Jitter

The schematic for the circuit is available in the Examples directory.

Open the project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. From the **Examples** directory, select **Circuit** > **Signal Integrity**. Then double-click **SimpleChannelTransmitJitterDemo.aedt**, or select **SimpleChannelTransmitJitterDemo.aedt** and click **Open**.

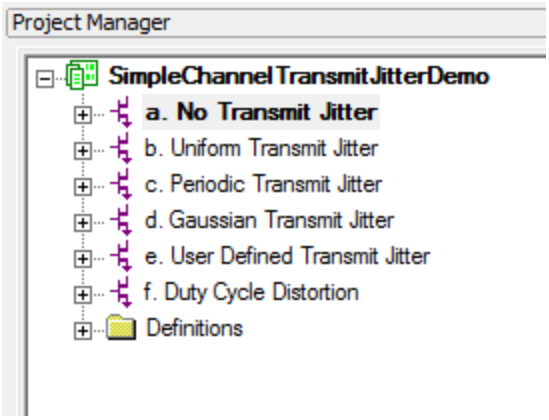
The channel schematic appears in the design window:



3. The Examples directory is write-protected. Use **File>Save As** to save the example project to a directory where you have write permission. A **Handle Project Directory Files** window opens showing you the supporting model files that is copied along with the project. Click **OK**.

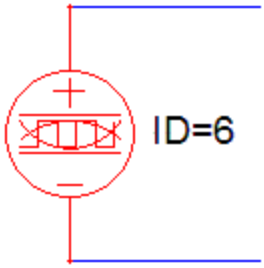
The project contains six designs:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



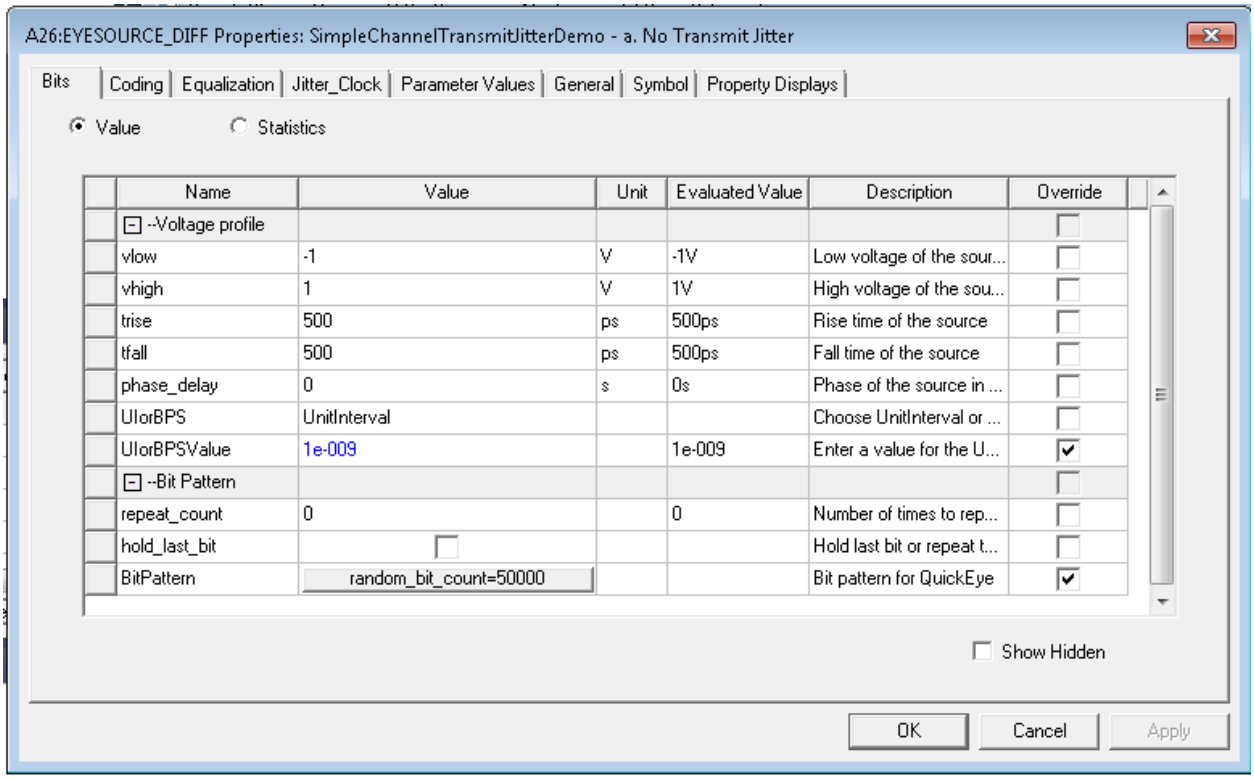
Initially, the **No Transmit Jitter** design is displayed.

Each of these designs uses the same schematic elements, with the same analysis setups and reports. The differences are in the Eye Source:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

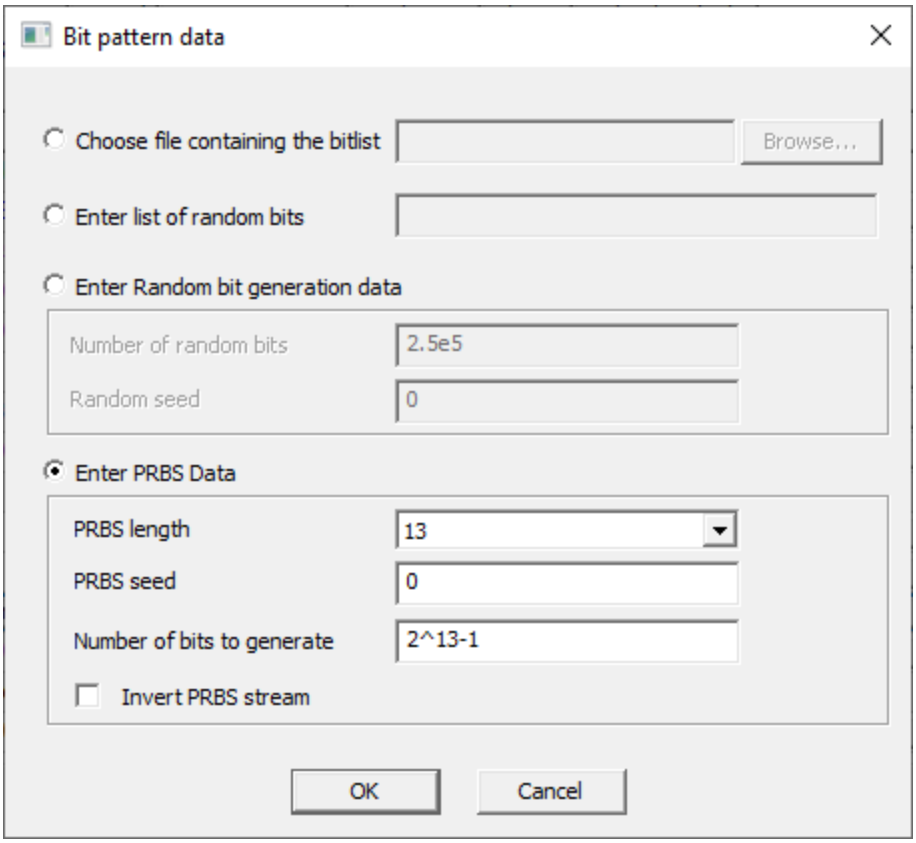
4. Click the Eye Source to open the **Properties** window, **Bits** tab:



All the designs use the same basic transmitter parameters. The voltage swing is from -1V (low) to +1V (high). The Unit Interval (UI) is 1ns.

5. Click the Bit Pattern group box to open the **Bit pattern data** window:

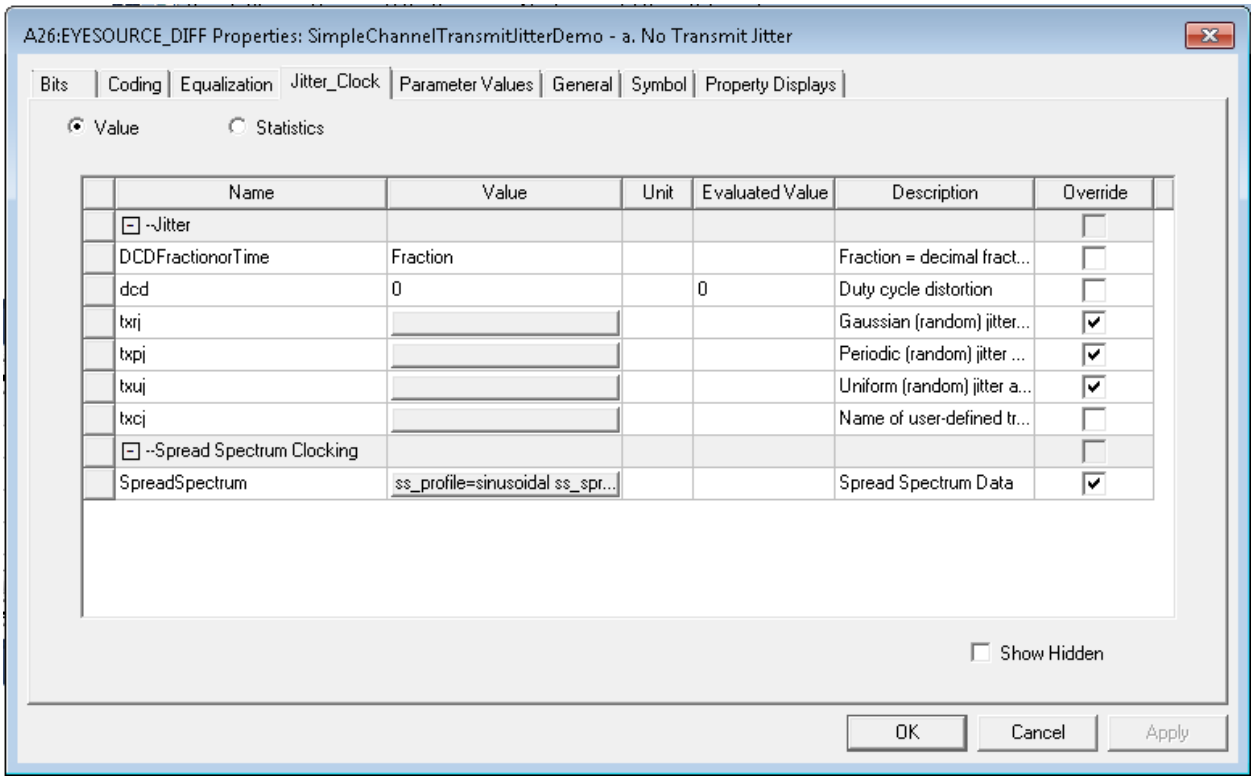
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



All the designs use the same random bit pattern for the Quick Eye analysis.

Click the **Jitter_Clock** tab to verify that no transmit jitter has been specified.

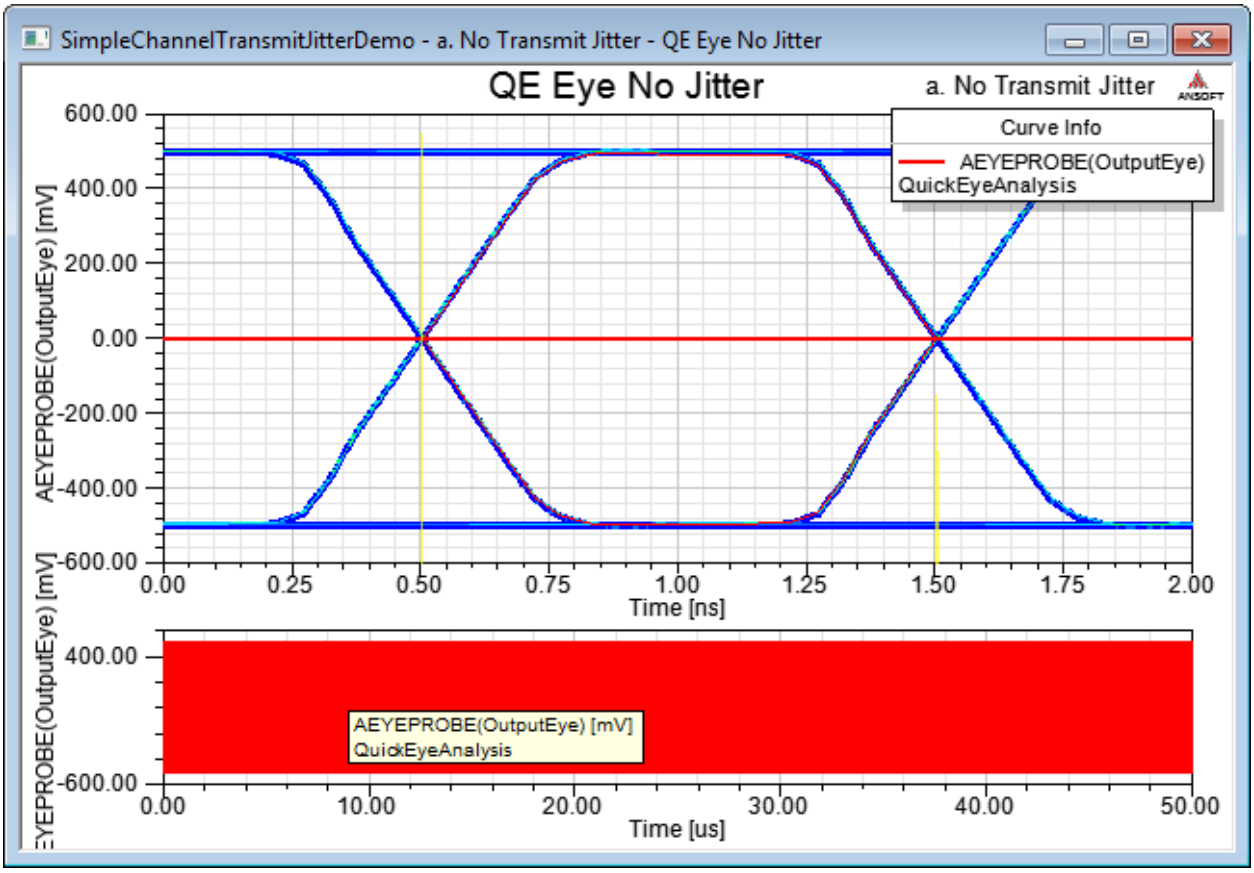
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



6. Click the Analysis icon in the Project window and select Analyze to run the QuickEye and VerifEye analyses.
7. When the analyses have run to completion, expand the Results icon and open the two reports.

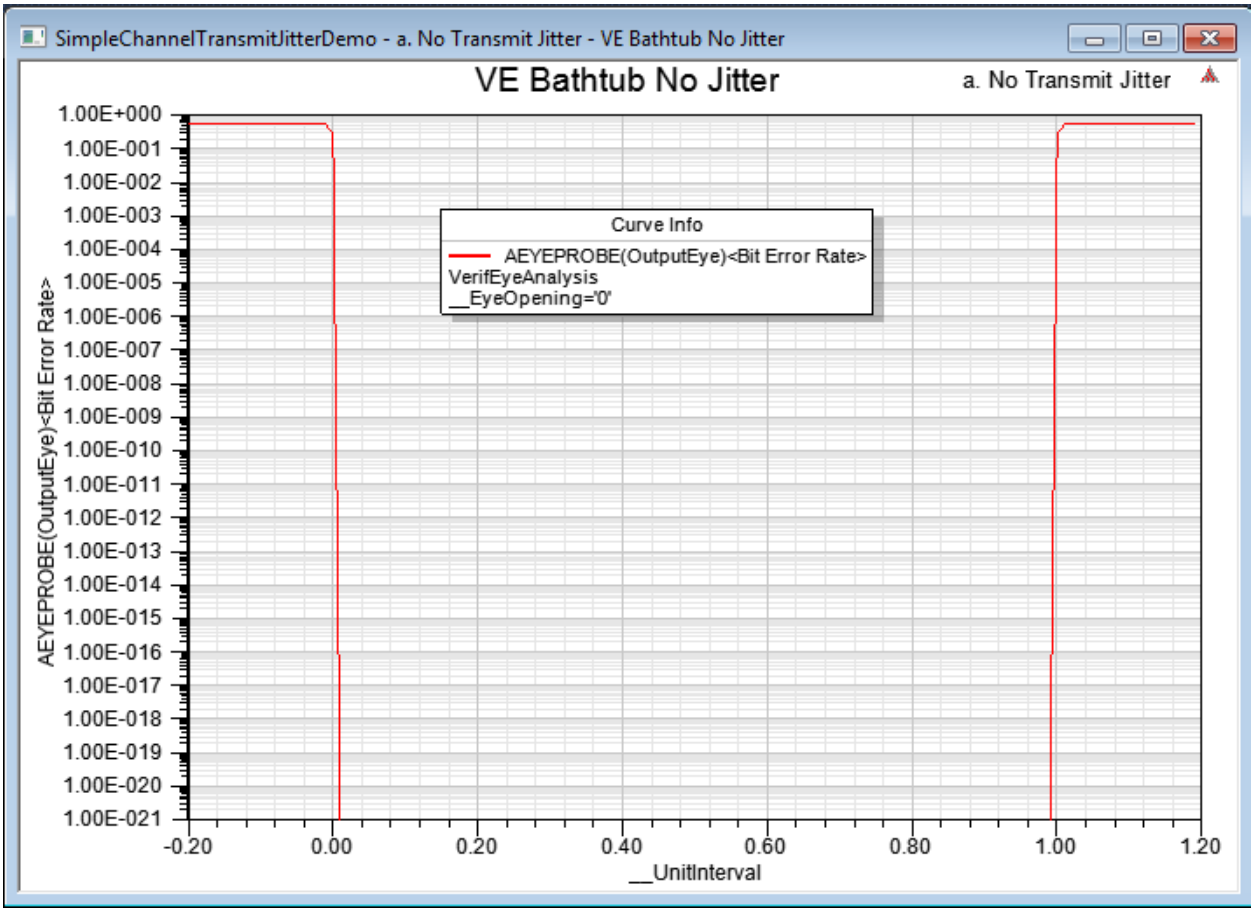
The QuickEye Eye diagram illustrates the channel response with no transmit jitter:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The VerifEye Bathtub diagram illustrates the channel Bit Error Rate (BER) with no transmit jitter:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

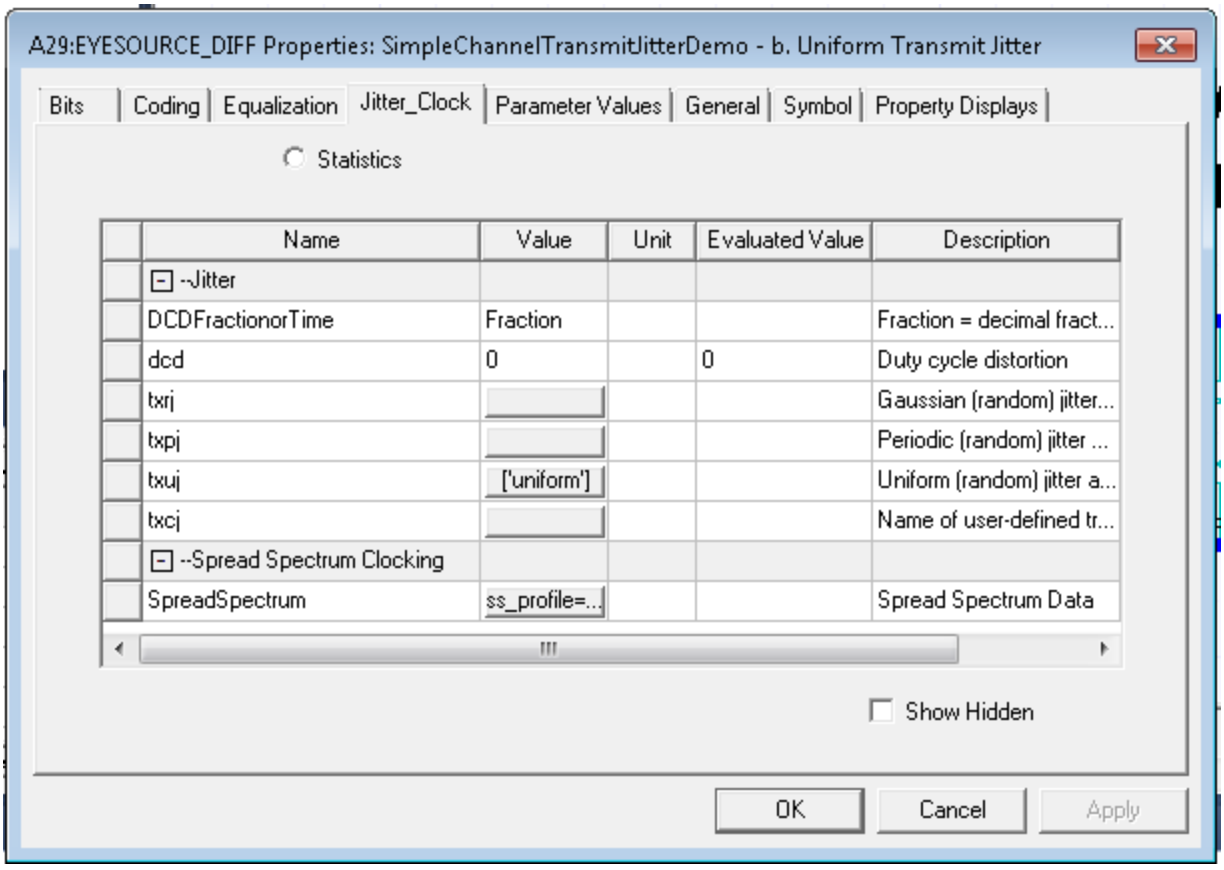


Channel Example with Uniform Transmit Jitter

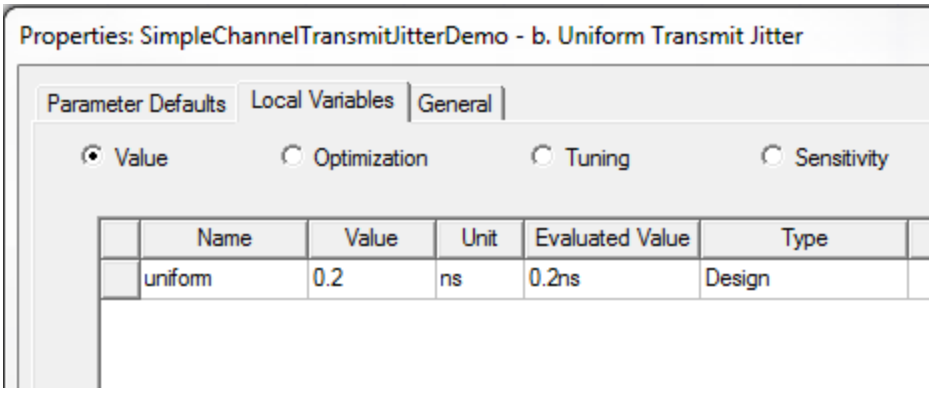
Next, the effect of jitter, starting with uniform jitter.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click the design **Uniform Transmit Jitter** to open the schematic.
2. Click the Eye Source to open the Properties. Click the **Jitter_Clock** tab:



3. The **txuj** parameter sets the bounds of the uniform jitter distribution. A local variable, 'uniform,' has been set up to allow us to change or sweep the parameter:

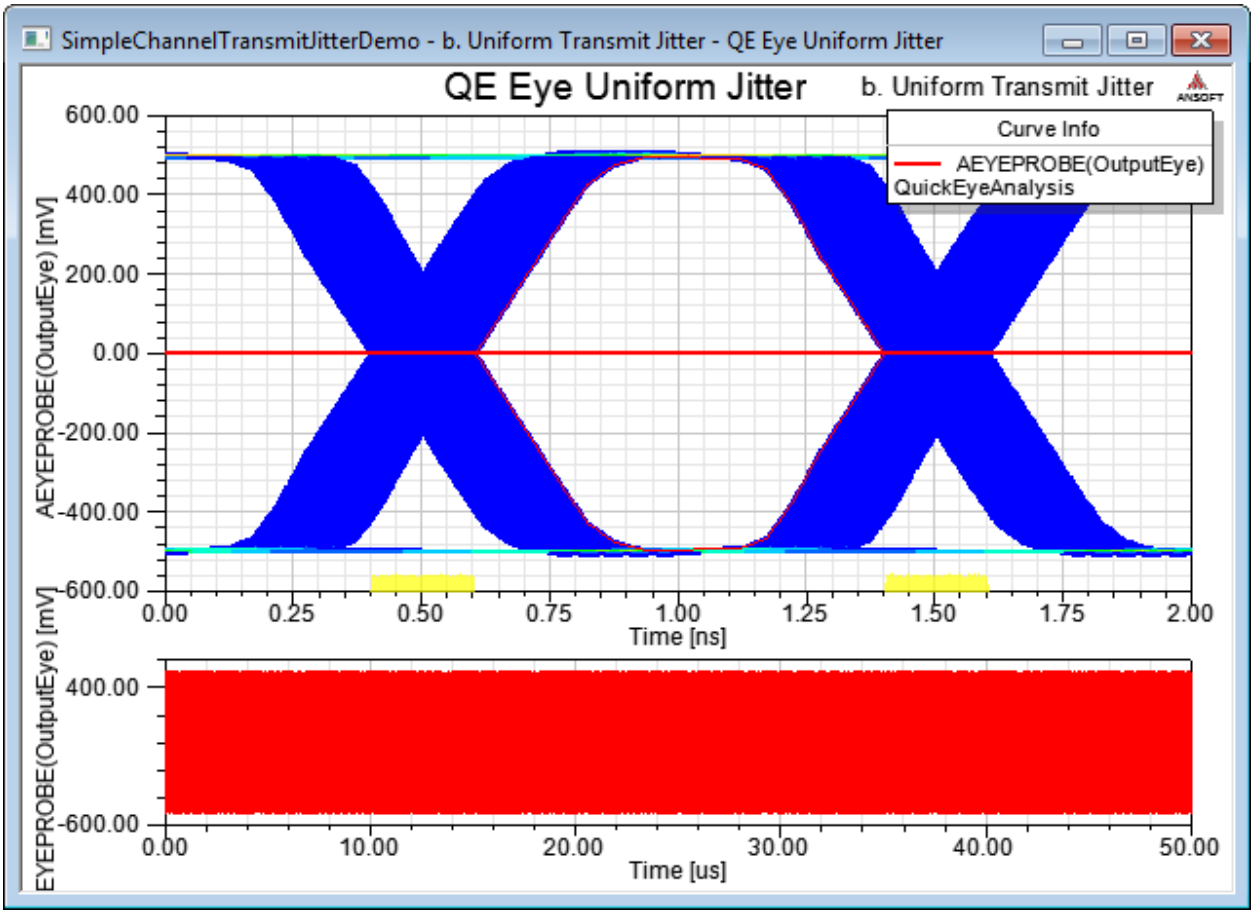


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Quick Eye analysis uses the nominal value of the variable, 0.2ns. The VerifEye analysis has been set up with a sweep of the variable through three values, 0.1ns, 0.2 ns, and 0.3ns.

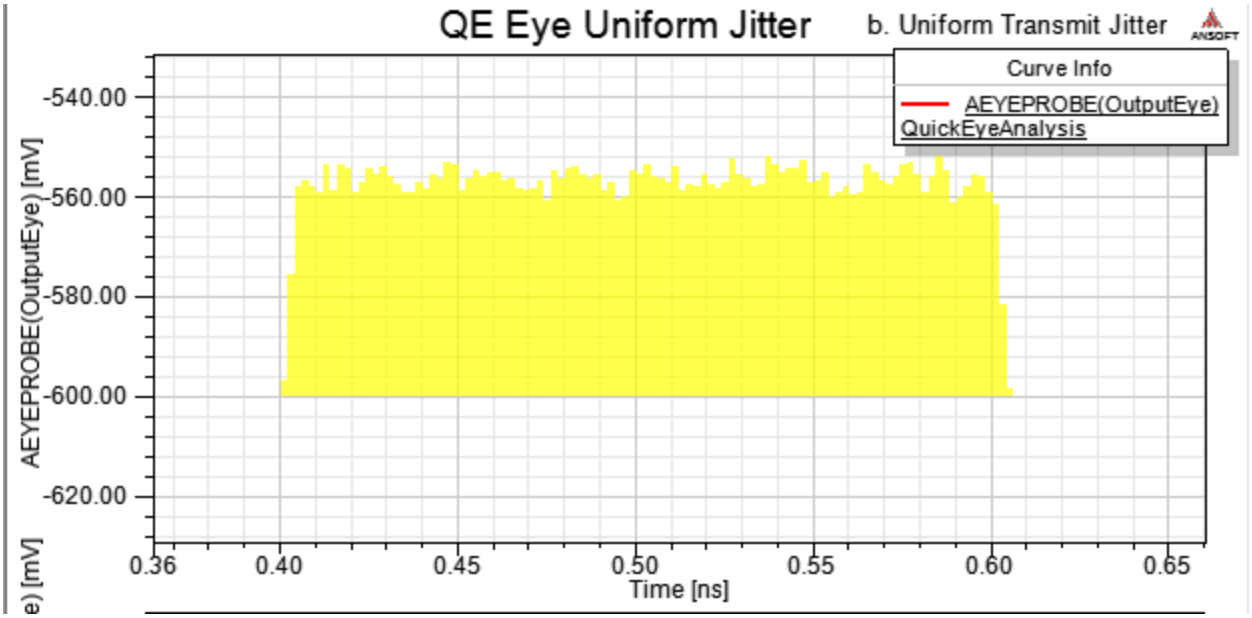
4. Click the Analysis icon in the Project window and select Analyze to run the QuickEye and VerifEye analyses.
5. When the analyses have run to completion, expand the Results icon and open the two reports.

The QuickEye Eye diagram illustrates the channel response with uniform jitter:



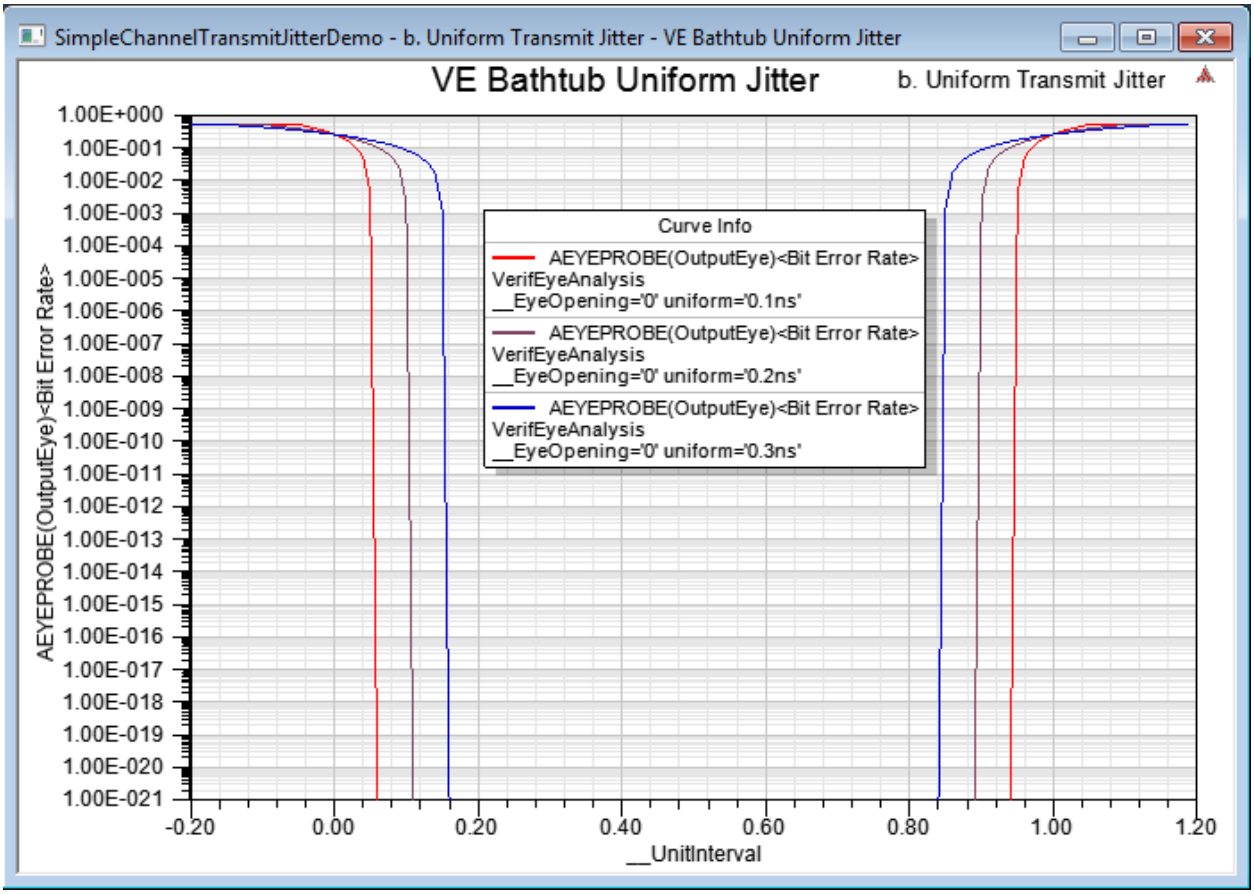
The yellow bars under the eye diagram show the histogram of the jitter distribution. Here is a zoomed-in view:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The VerifEye Bathtub diagram illustrates the channel Bit Error Rate (BER) with three levels of uniform jitter:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

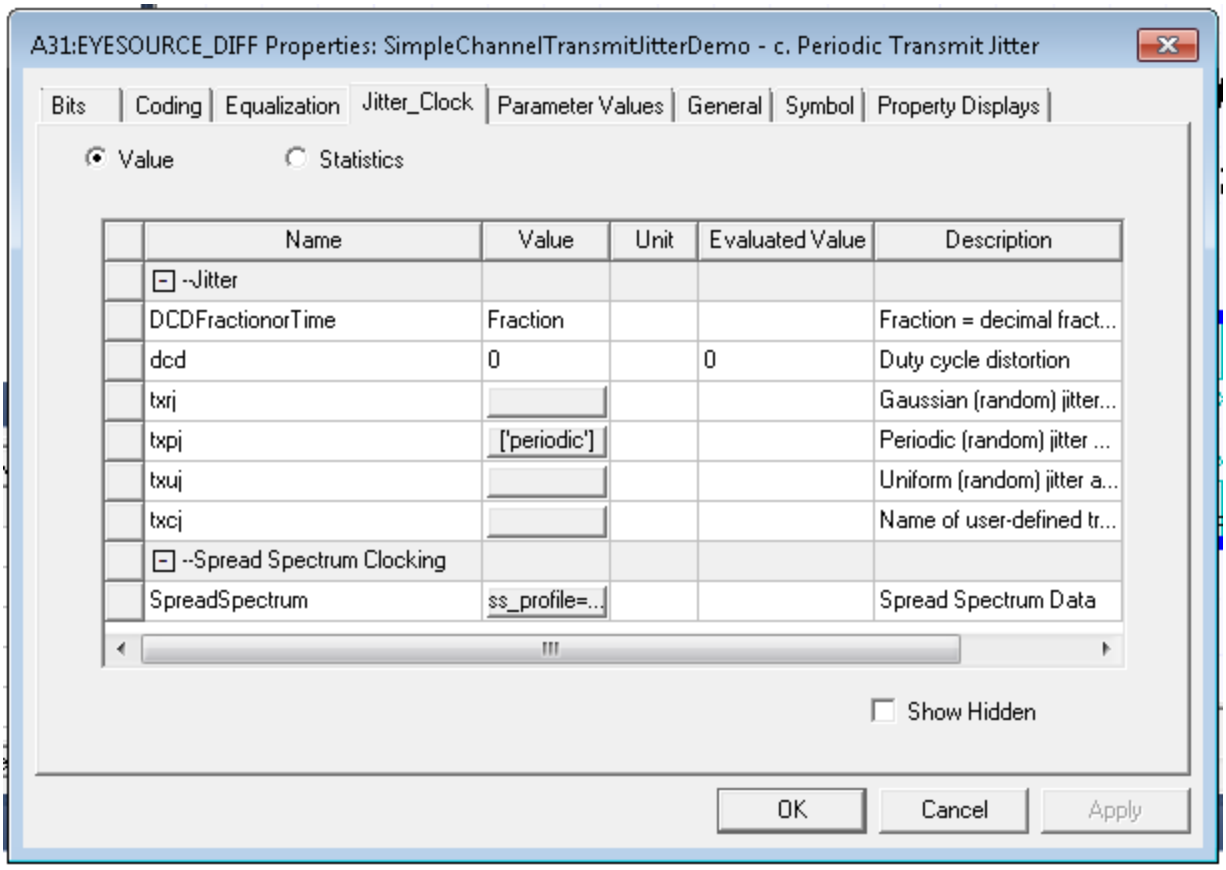


Channel Example with Periodic Transmit Jitter

Next, the effect of periodic transmit jitter.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click the design **Periodic Transmit Jitter** to open the schematic.
2. Click the Eye Source to open the Properties. Click the **Jitter_Clock** tab:



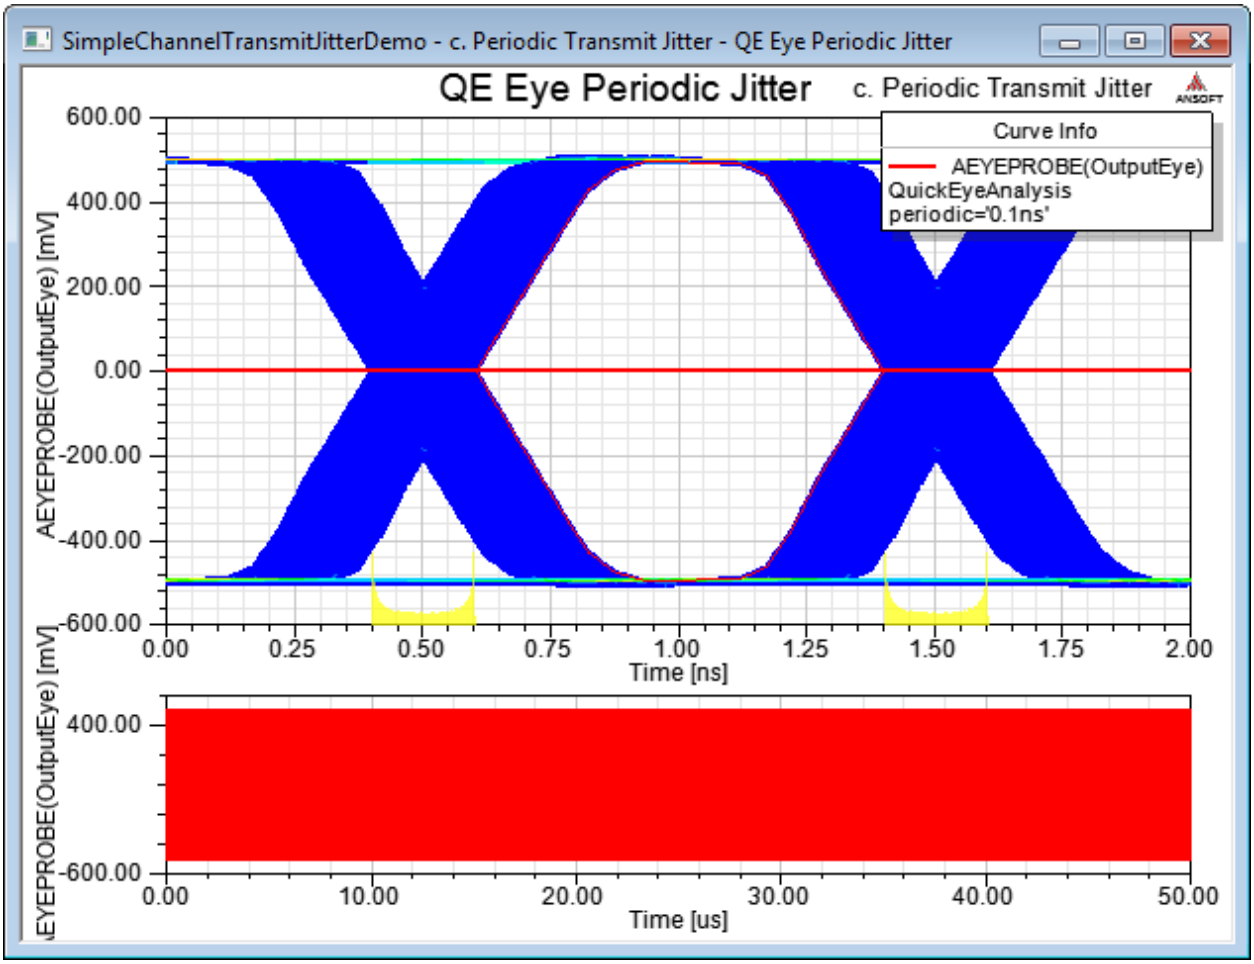
3. The **txpj** parameter sets the bounds of the periodic jitter distribution. A local variable, 'periodic,' has been set up to allow us to change or sweep the parameter.

Quick Eye analysis uses the nominal value of the variable, 0.1ns. The VerifEye analysis has been set up with a sweep of the variable through three values, 0.05ns, 0.1ns, and 0.15ns.

4. Click the Analysis icon in the Project window and select Analyze to run the QuickEye and VerifEye analyses.
5. When the analyses have run to completion, expand the Results icon and open the two reports.

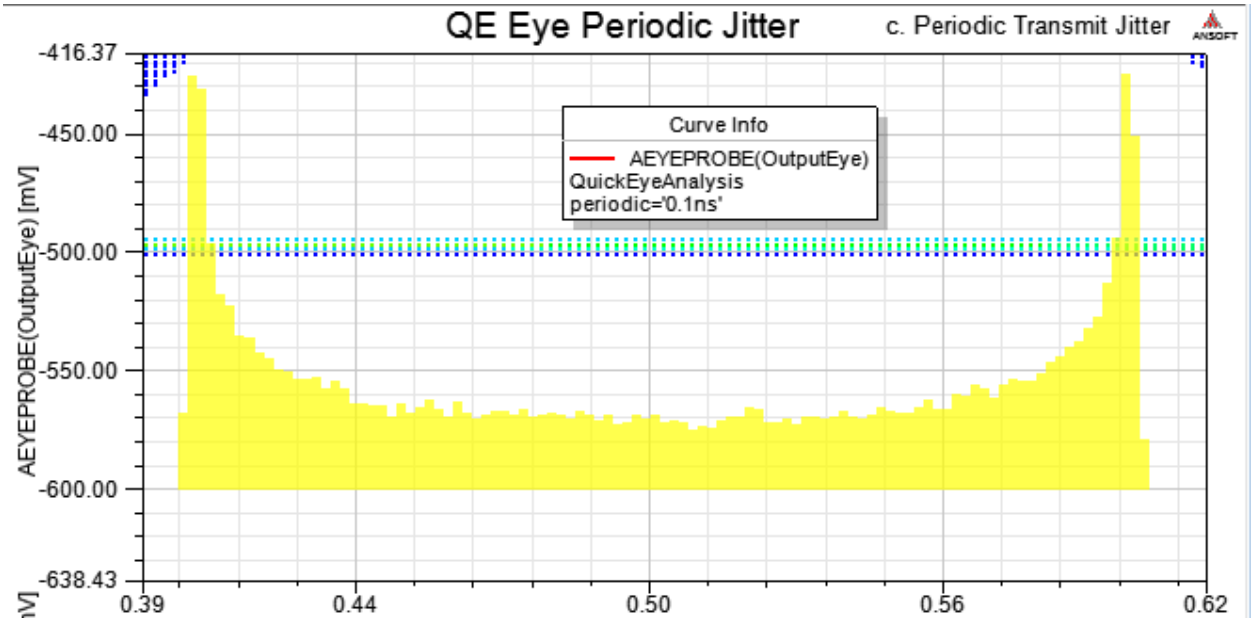
The QuickEye Eye diagram illustrates the channel response with periodic jitter:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



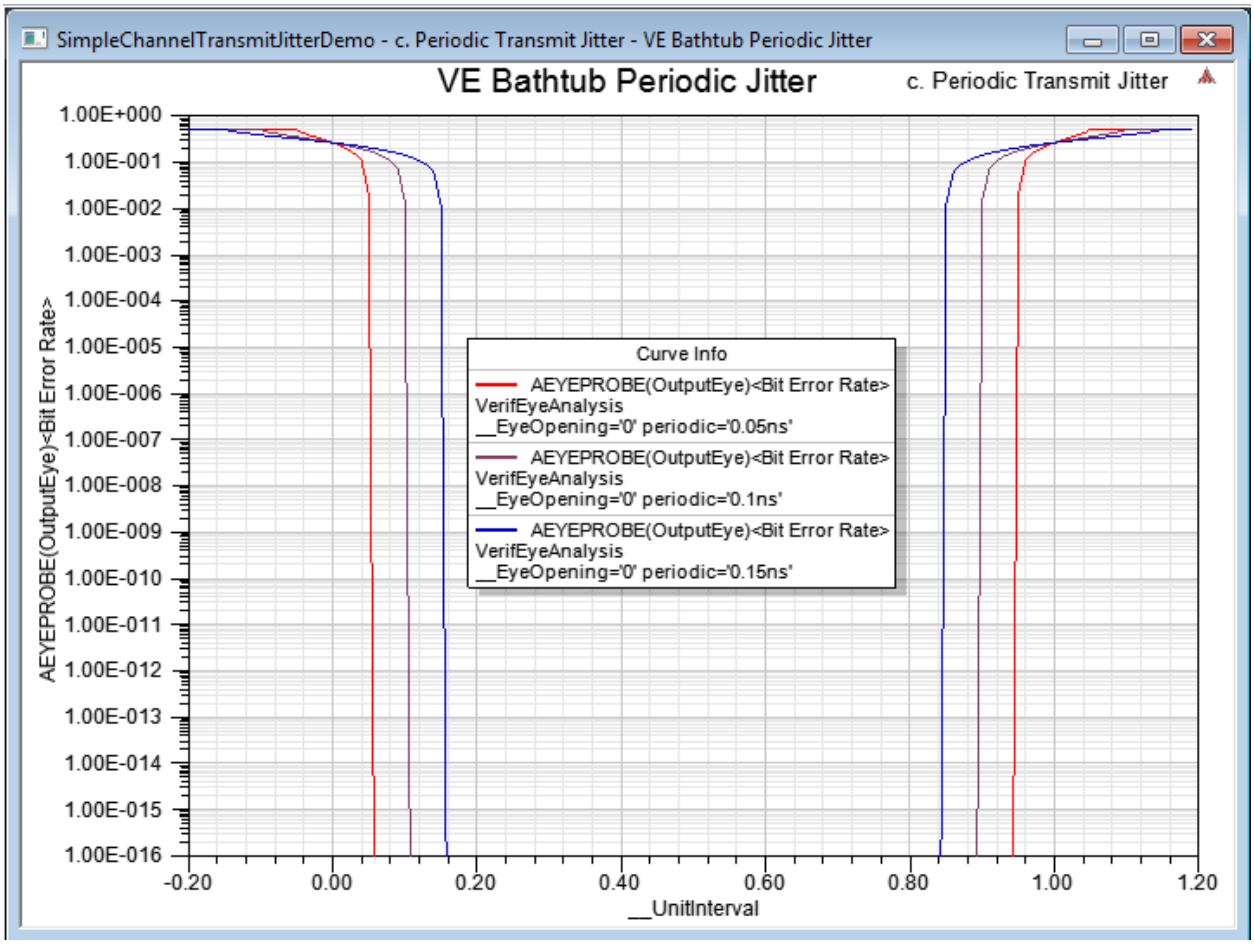
The yellow bars under the eye diagram show the histogram of the jitter distribution. Here is a zoomed-in view:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The VerifEye Bathtub diagram illustrates the channel Bit Error Rate (BER) with three levels of periodic jitter:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

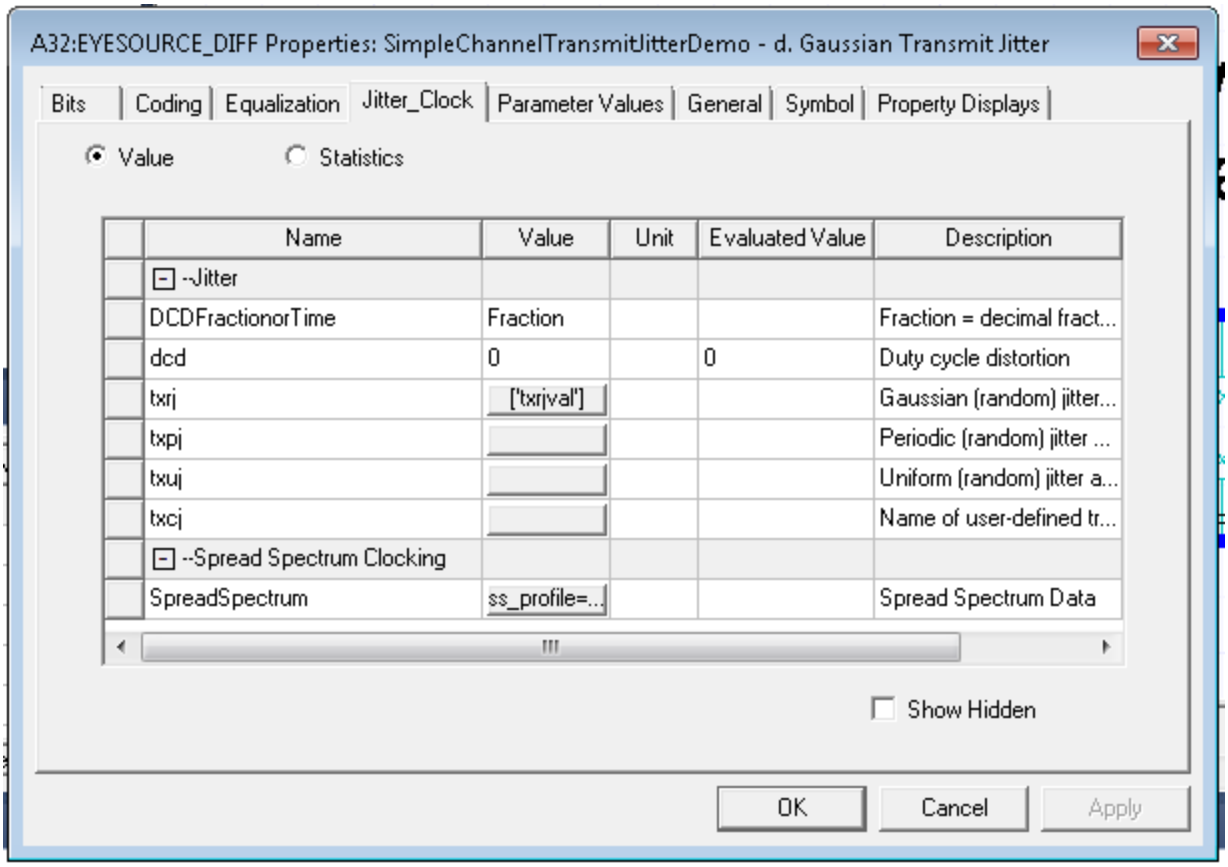


Channel Example with Gaussian Random Transmit Jitter

Next, the effect of Gaussian random transmit jitter.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click the design **Gaussian Transmit Jitter** to open the schematic.
2. Click the Eye Source to open the Properties. Click the **Jitter_Clock** tab:



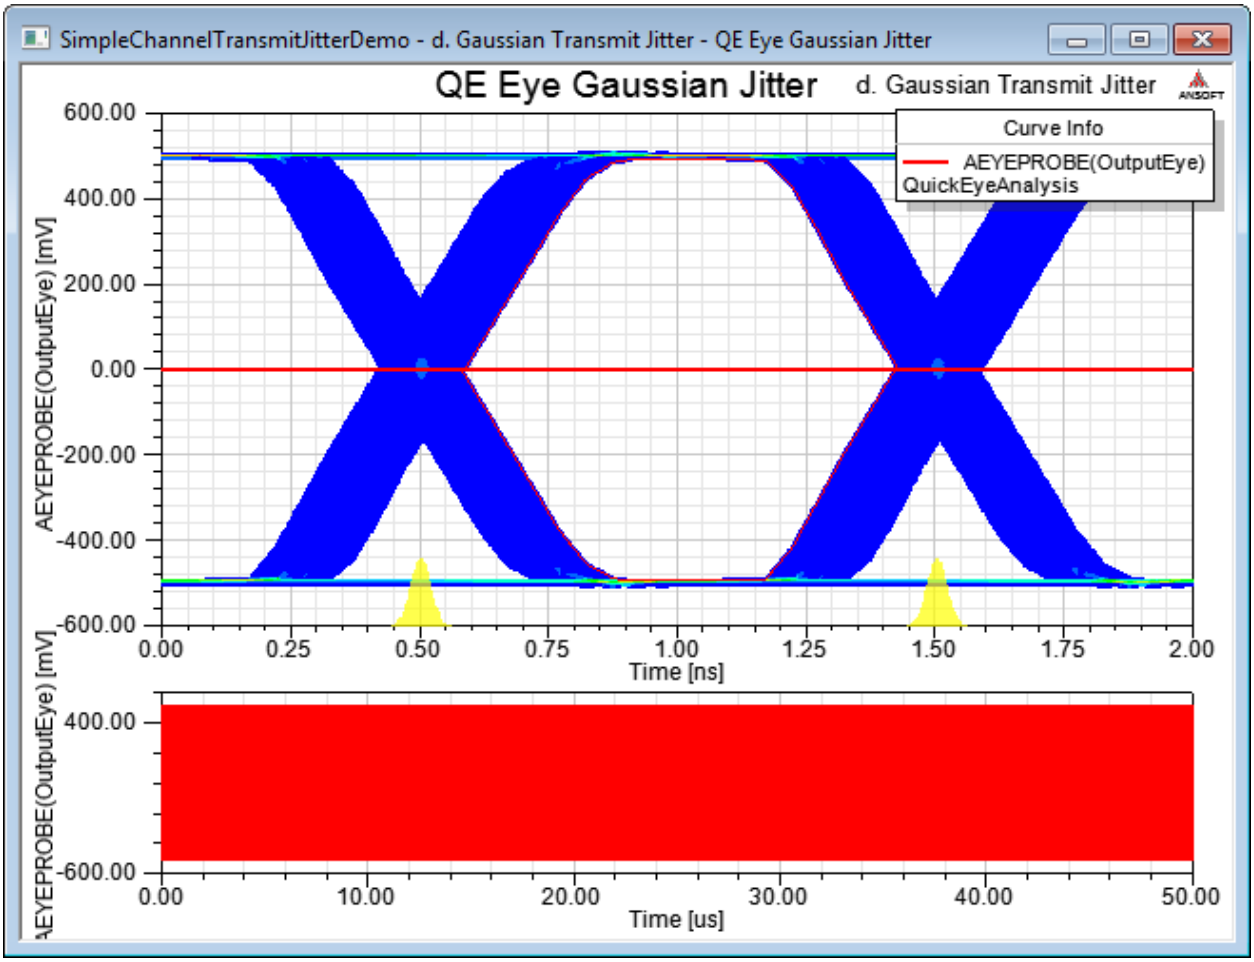
3. The **txrj** parameter sets the standard deviation of the Gaussian jitter distribution. A local variable, 'txrjval,' has been set up to allow us to change or sweep the parameter.

Quick Eye analysis uses the nominal value of the variable, 20ps. The VerifEye analysis has been set up with a sweep of the variable through three values, 10ps, 20ps, and 30ps.

4. Click the Analysis icon in the Project window and select Analyze to run the QuickEye and VerifEye analyses.
5. When the analyses have run to completion, expand the Results icon and open the two reports.

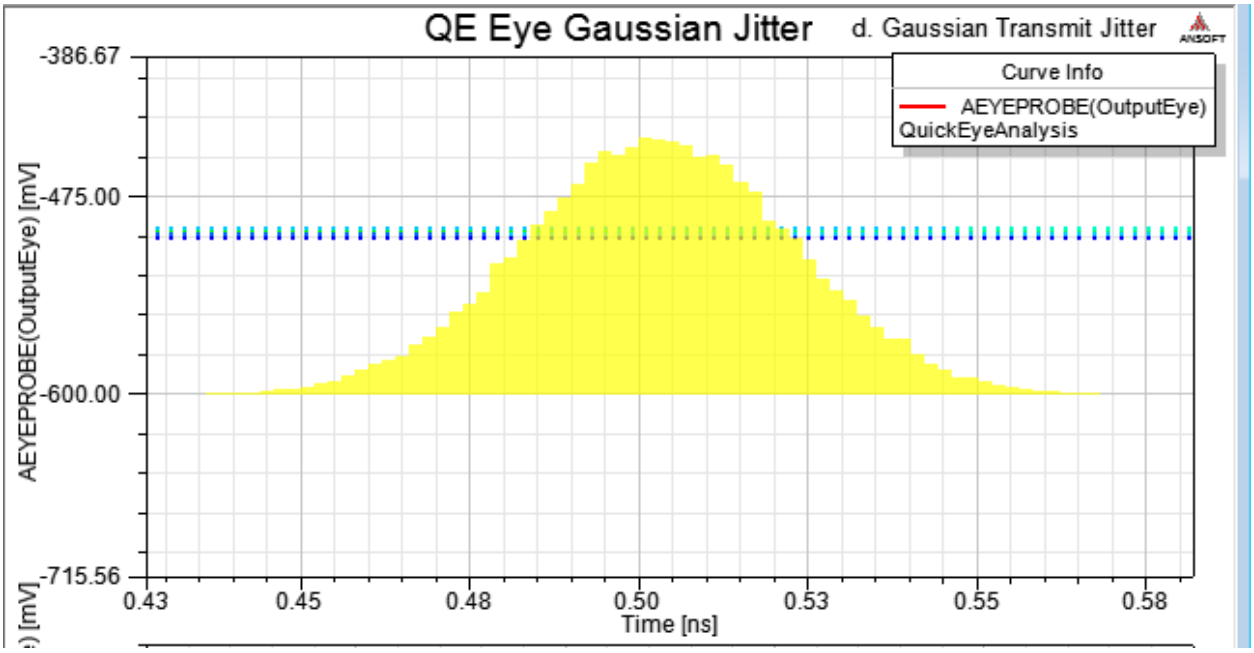
The QuickEye Eye diagram illustrates the channel response with Gaussian random jitter:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



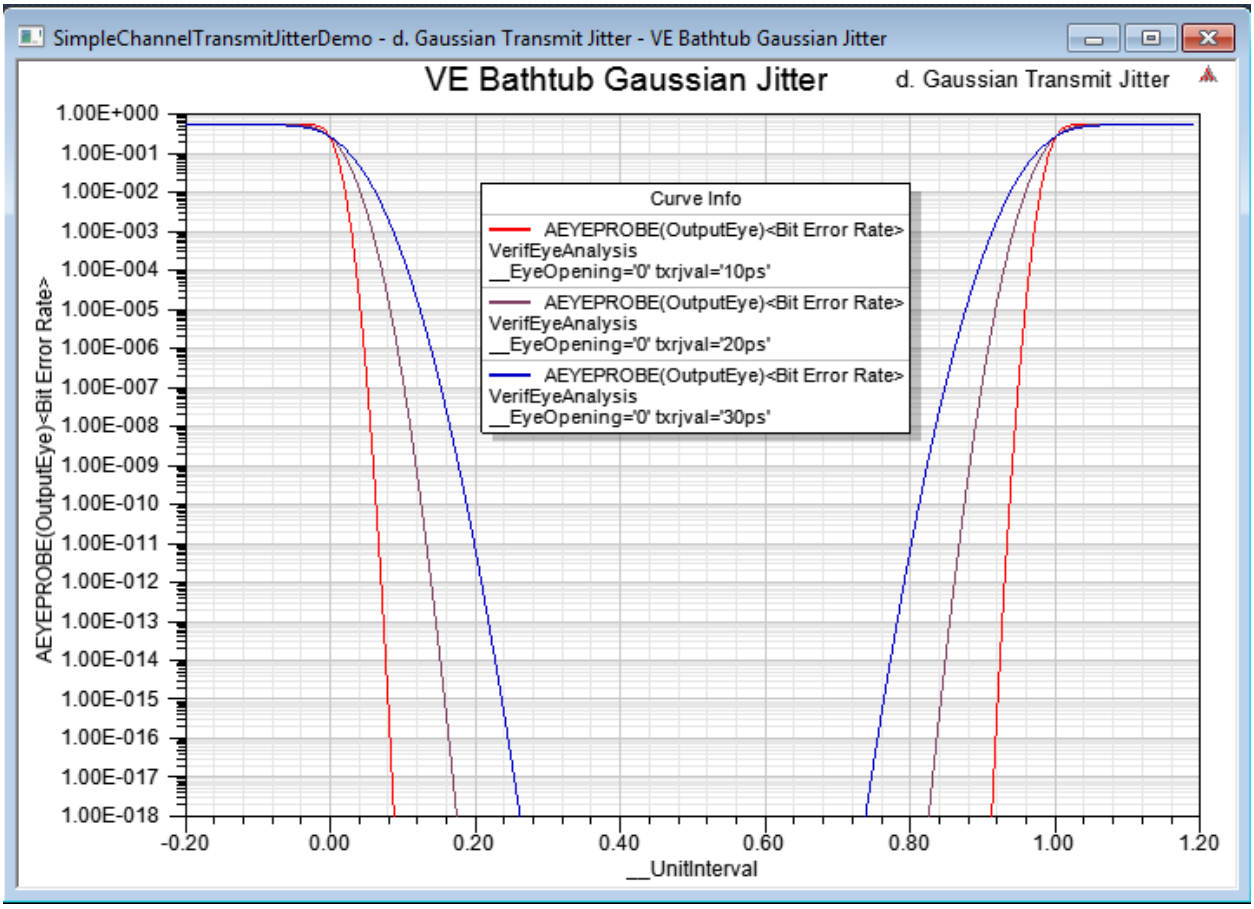
The yellow bars under the eye diagram show the QuickEye Eye diagram. Here is a zoomed-in view:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The VerifEye Bathtub diagram illustrates the channel Bit Error Rate (BER) with three levels of Gaussian random jitter:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

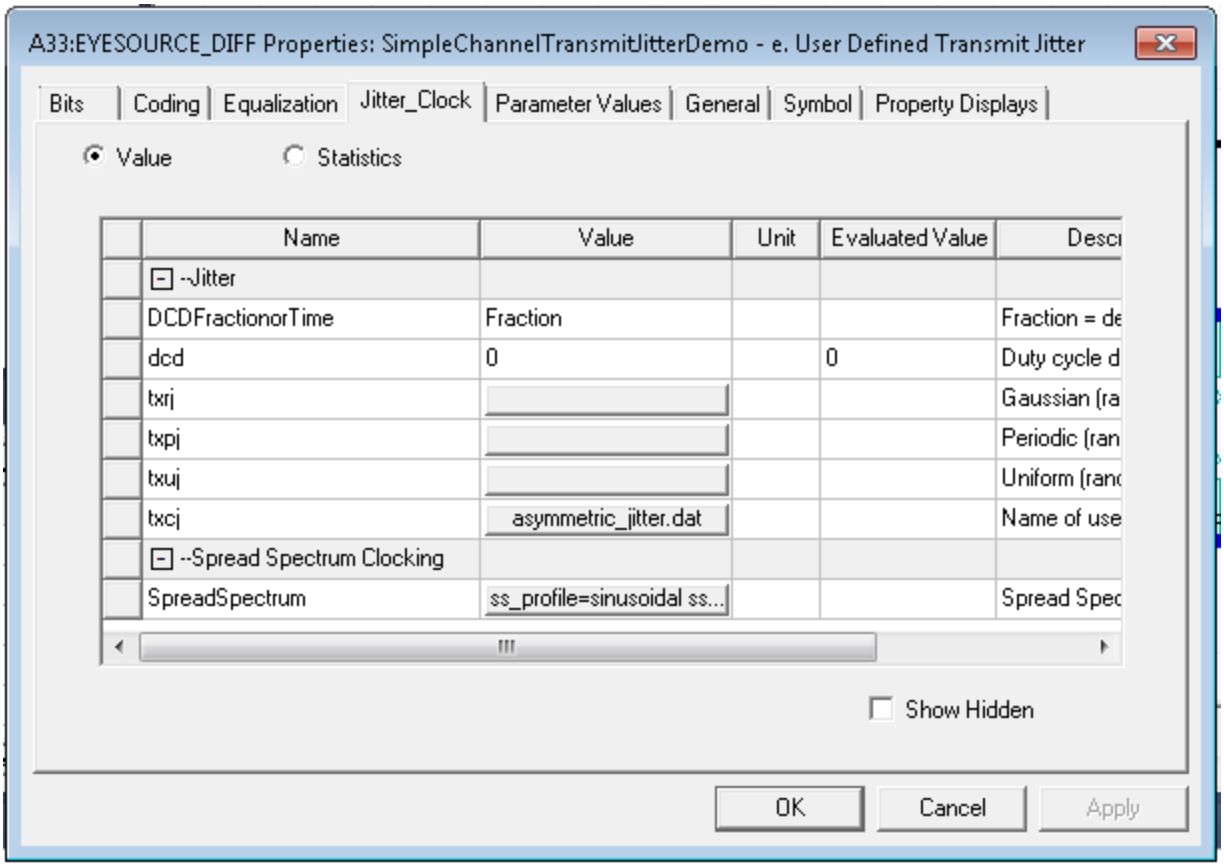


Channel Example with Custom Transmit Jitter

Next, add a custom transmit jitter distribution.

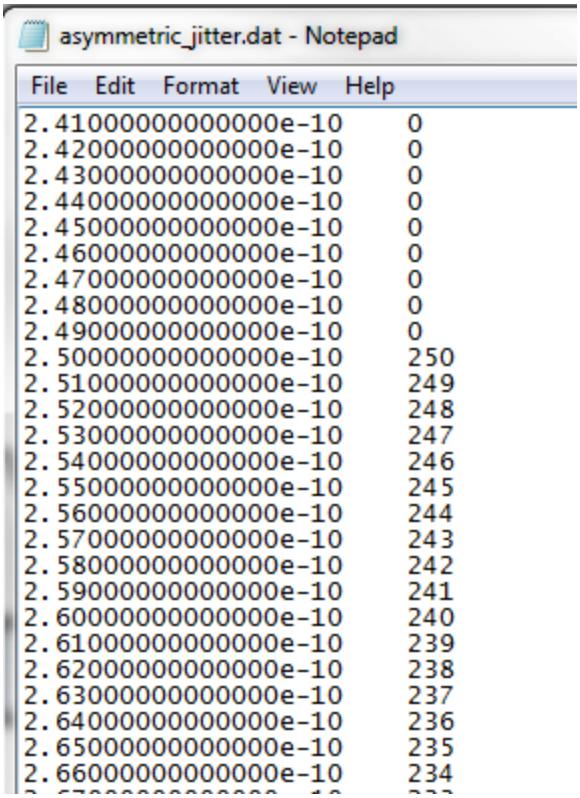
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click the design **user-defined Transmit Jitter** to open the schematic.
2. Click the Eye Source to open the Properties. Click the **Jitter_Clock** tab:



3. The **txcj** parameter specifies a file containing the custom jitter distribution. The Examples directory contains several examples of custom transmit jitter files (Examples/Circuit/SignalIntegrity/models/SimpleChannelTransmitJitterDemo/*.dat). Here is a portion of the file asymmetric_jitter.dat:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

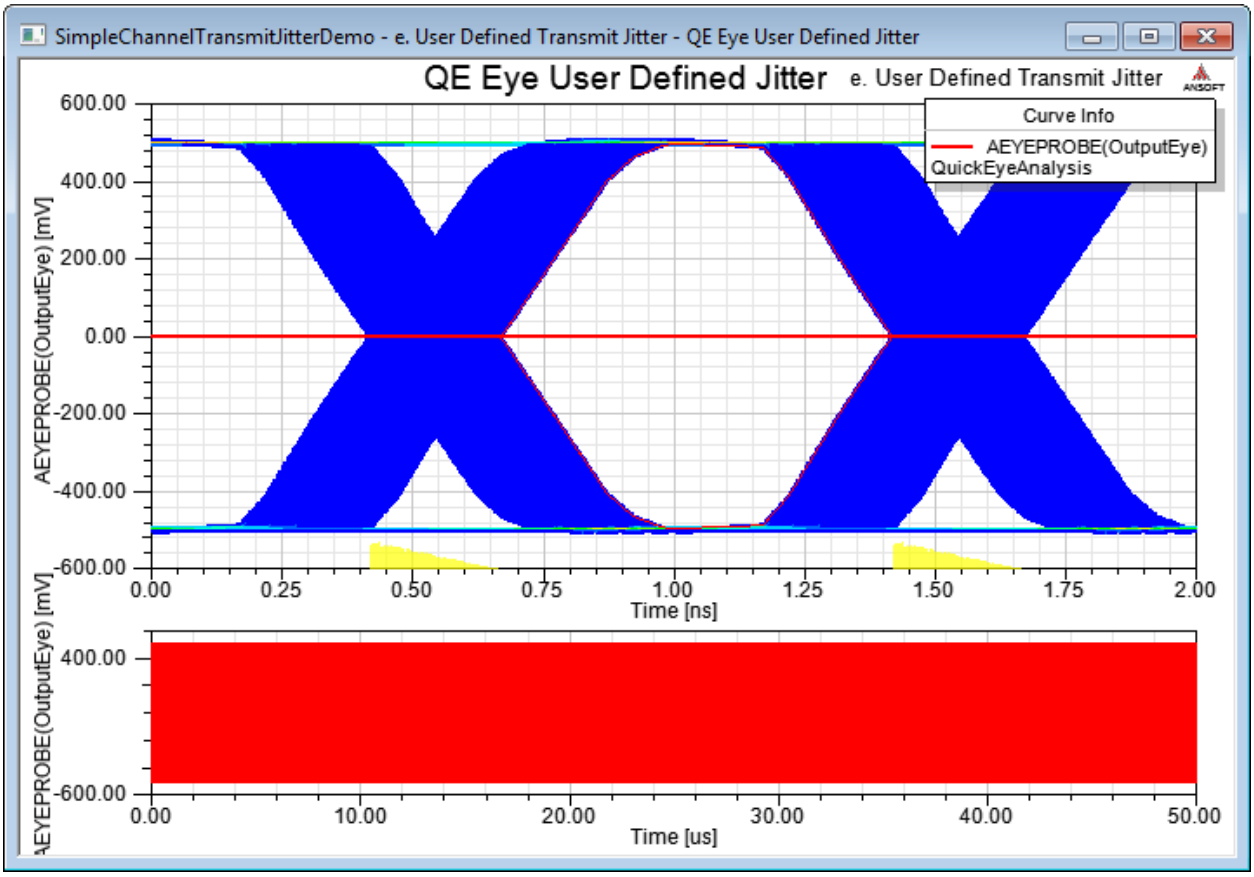


Each line specifies a time and the relative magnitude of the jitter probability distribution function at that time. Nexxim centers the distribution's mean value at the edges of the unit interval.

4. Click the Analysis icon in the Project window and select Analyze to run the QuickEye and VerifEye analyses.
5. When the analyses have run to completion, expand the Results icon and open the two reports.

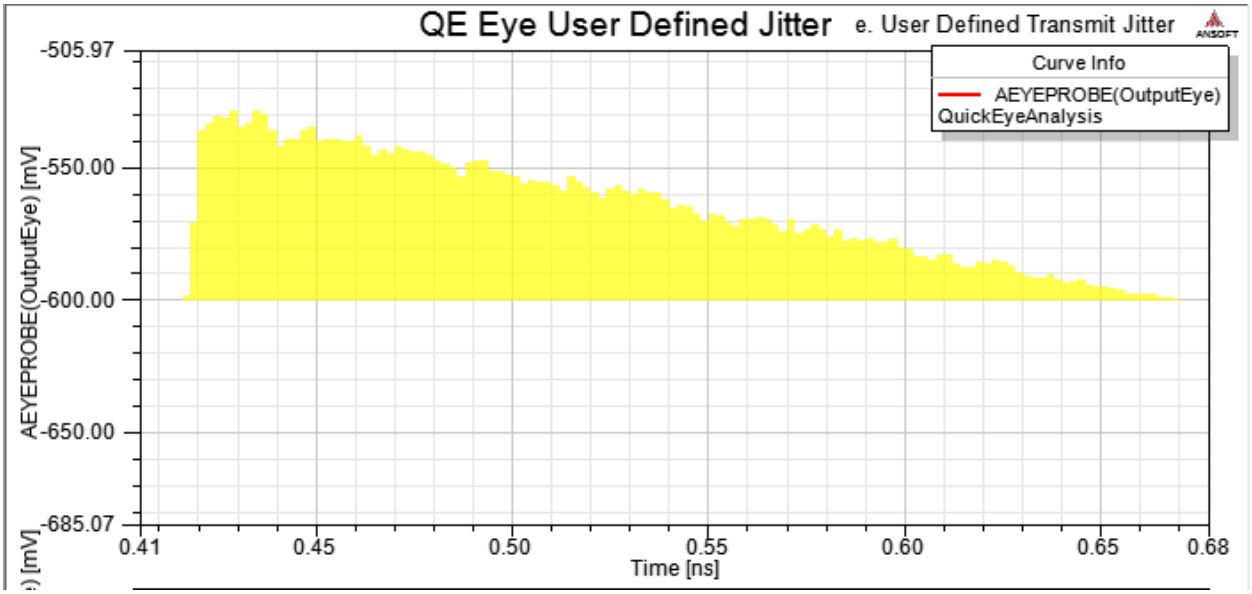
The QuickEye Eye diagram illustrates the channel response with custom jitter:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

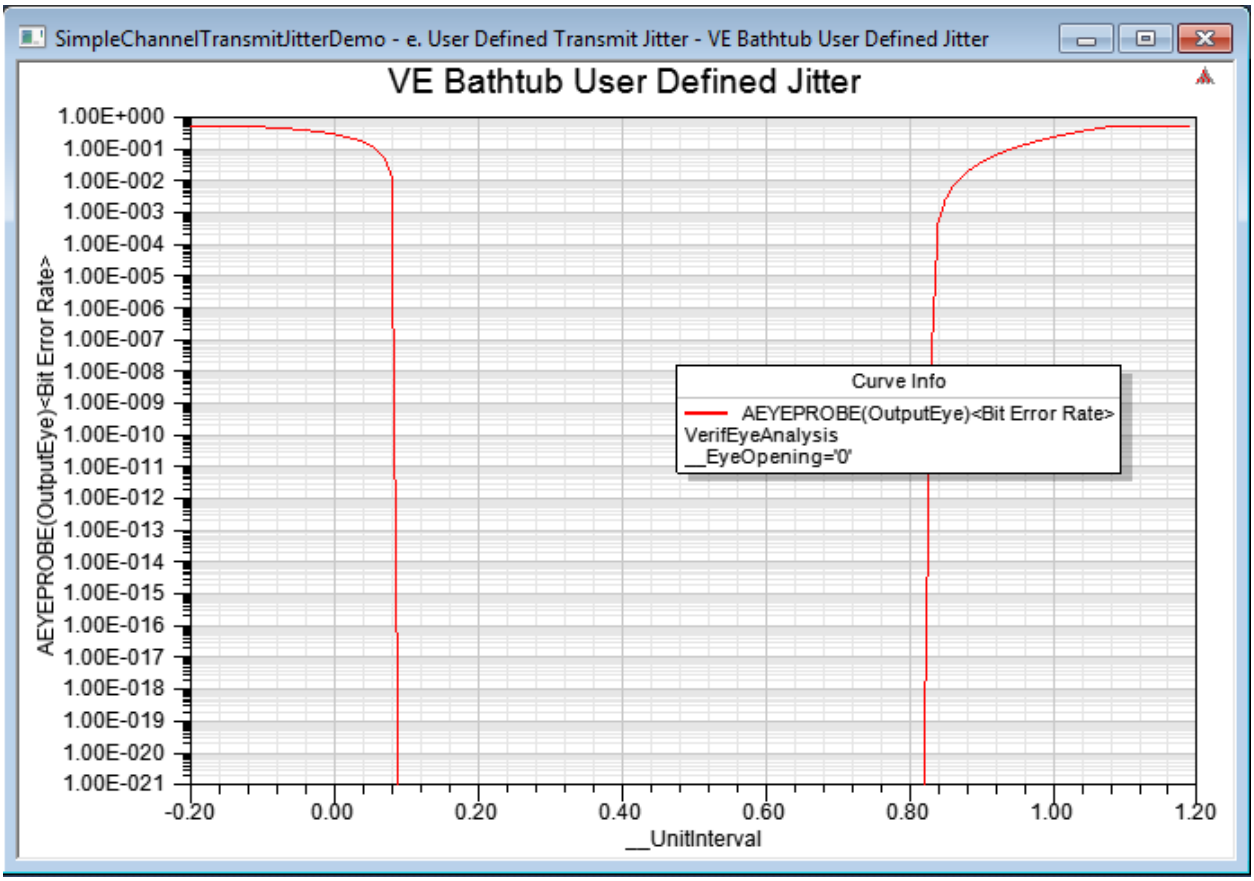


The yellow bars under the eye diagram show the histogram of the jitter distribution. Here is a zoomed-in view:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The VerifEye Bathtub diagram illustrates the channel Bit Error Rate (BER) with custom jitter:

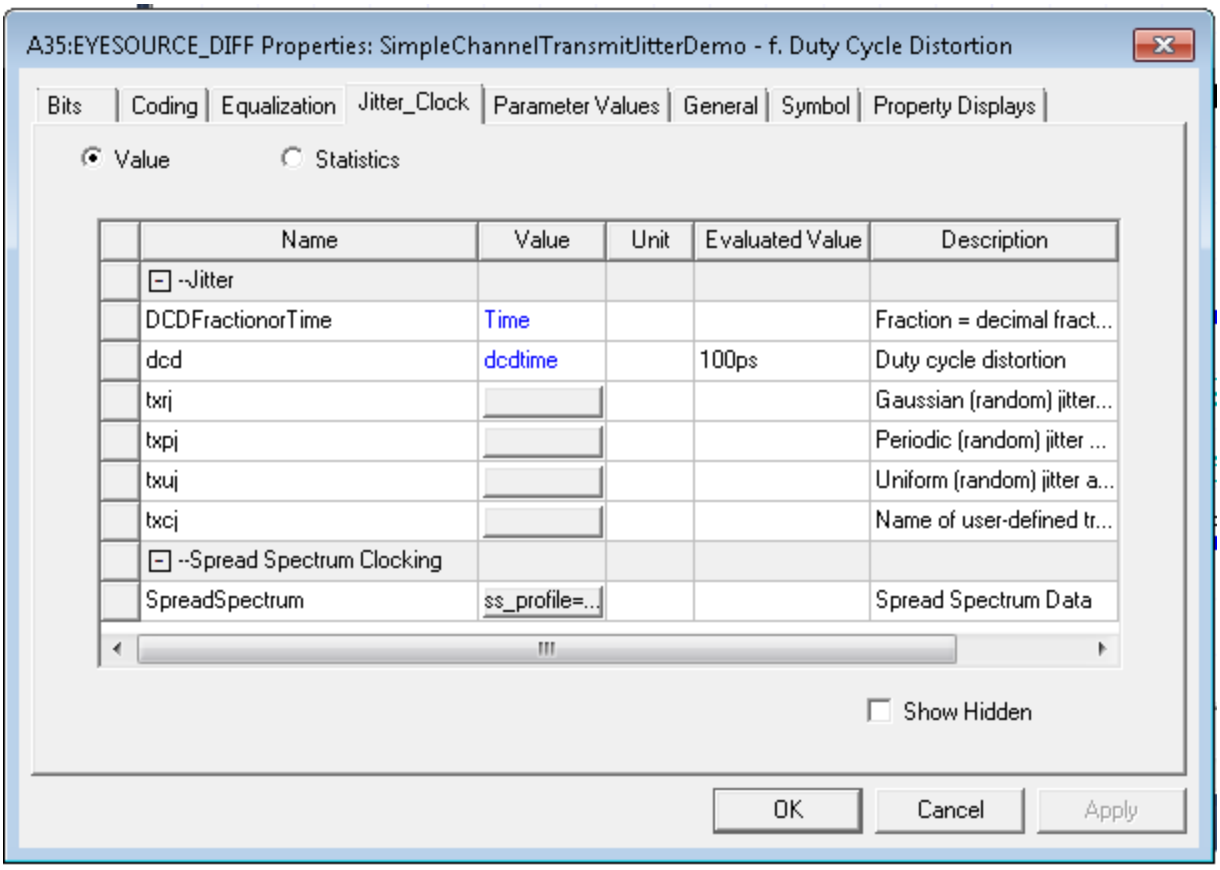


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Channel Example with Duty Cycle Distortion

Next, the effect of duty cycle distortion (asymmetry in the bit timings). The duty cycle distortion can be specified as a fraction of the unit interval (UI) or as an absolute time.

1. Click the design **Duty Cycle Distortion** to open the schematic.
2. Click the Eye Source to open the Properties. Click the **Jitter_Clock** tab:



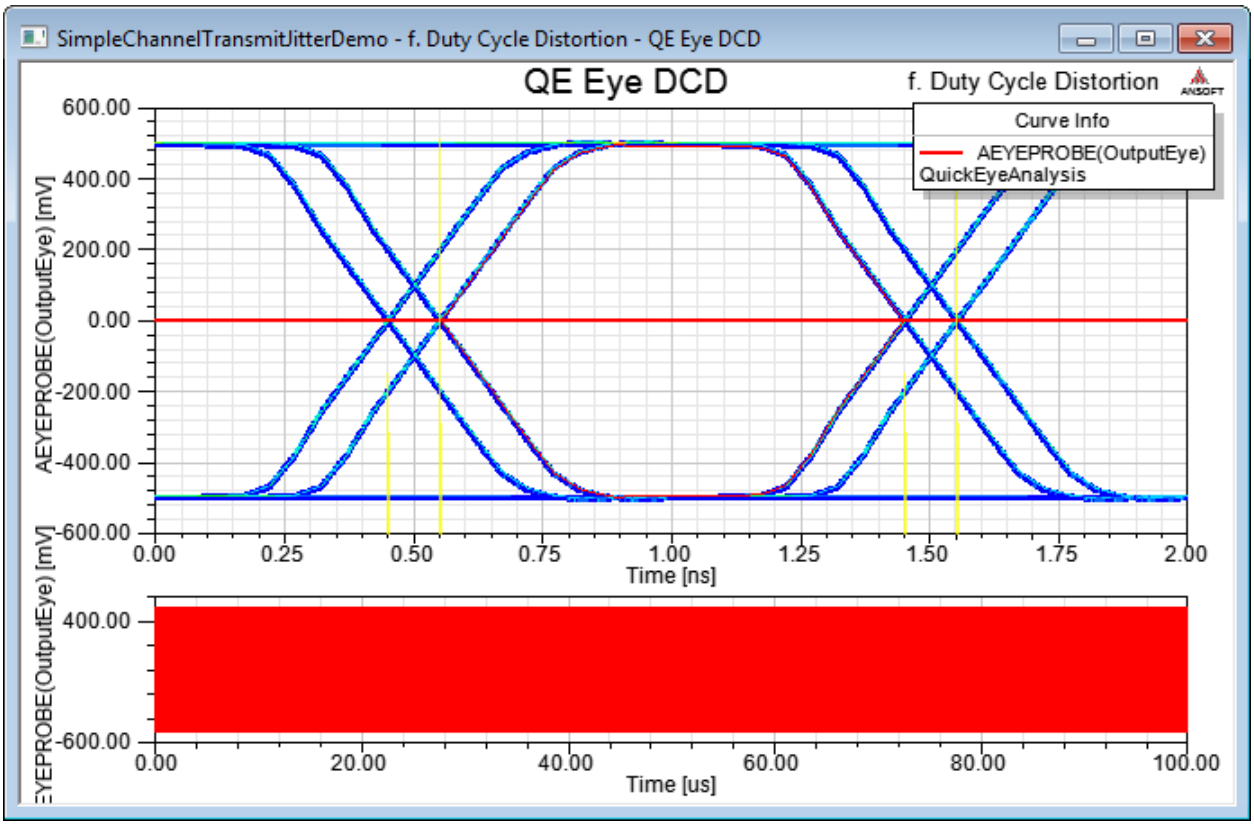
3. The parameter **DCDFractionorTime** selects between the two ways to specify the DCD. The default is **Fraction**. In this mode, the **dcd** parameter sets the bounds of the duty cycle distortion to be a fraction of the UI, 0<=DCD<=1. A local variable, 'dcdval,' has been set up to allow us to change or sweep the DCD Fractional value.

Both QuickEye and VerifEye analyses use the nominal value of the variable, 0.1 or 10% of the UI (1ns).

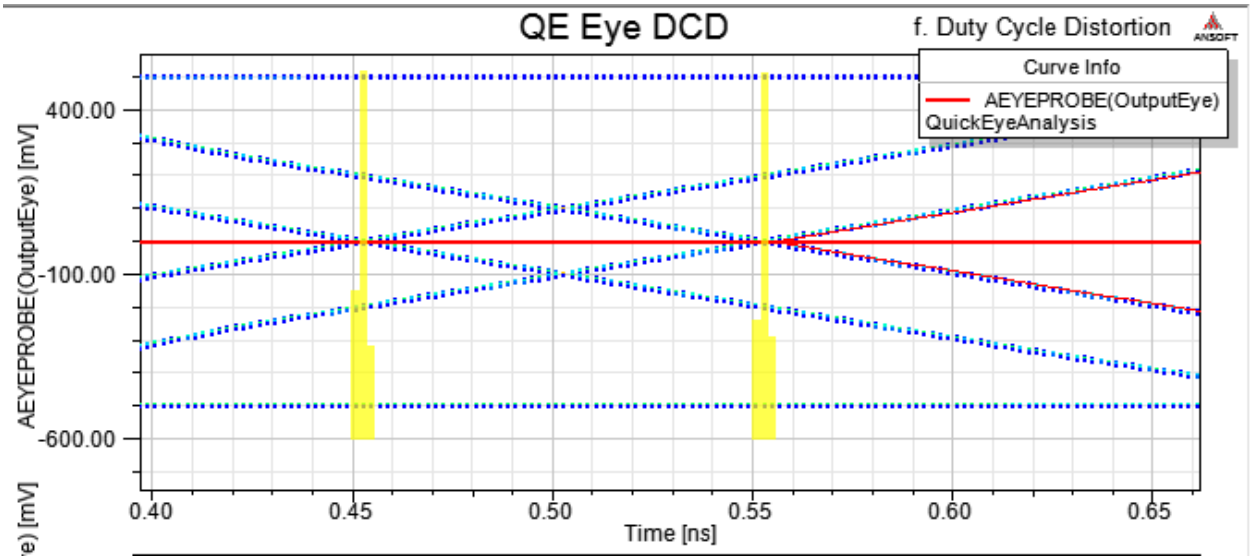
4. Click the Analysis icon in the Project window and select Analyze to run the QuickEye and VerifEye analyses.
5. When the analyses have run to completion, expand the Results icon and open the two reports.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The QuickEye Eye diagram illustrates the channel response with duty cycle distortion:

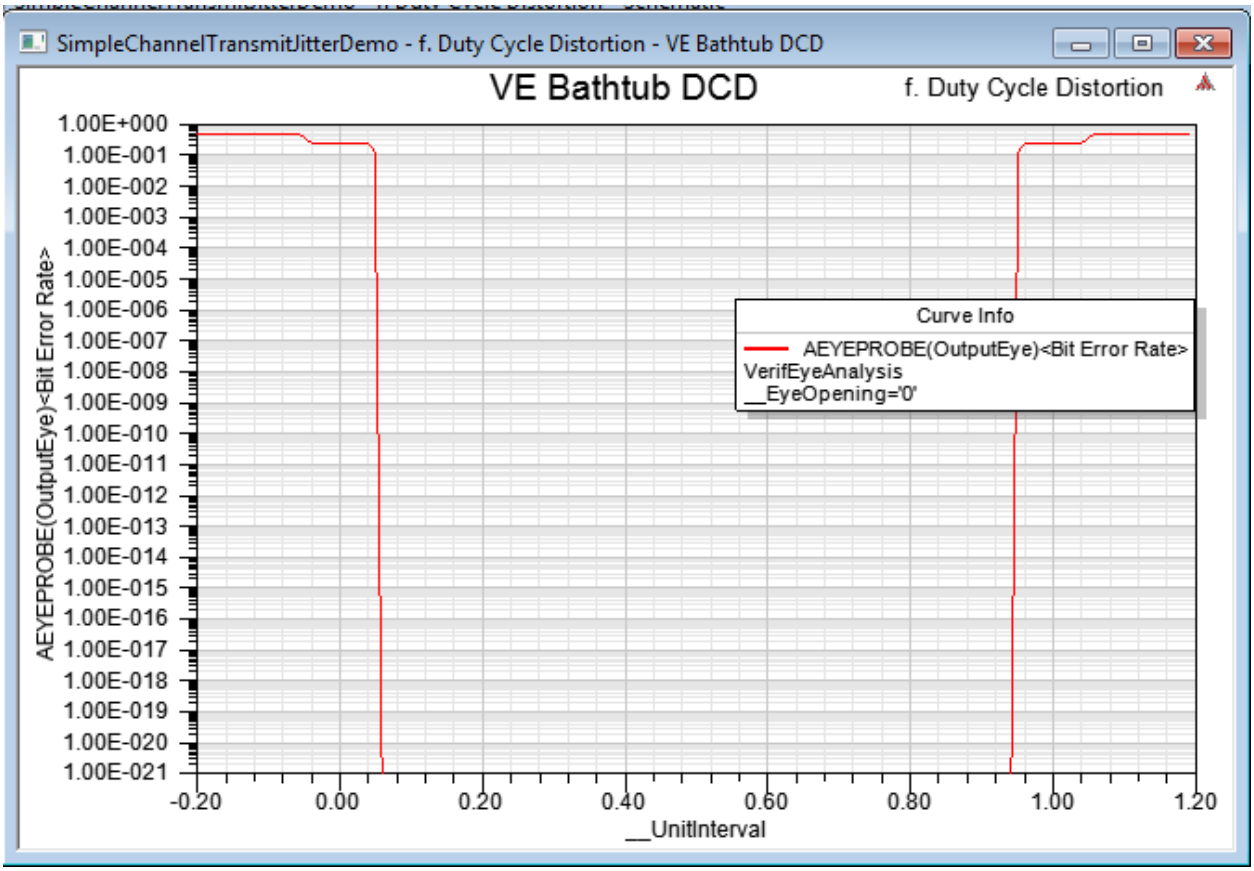


The yellow bars under the eye diagram show the histogram of the DCD distribution. Here is a zoomed-in view:

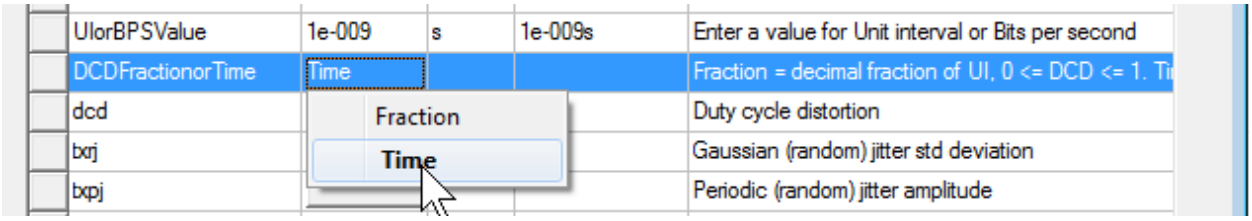


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The VerifEye Bathtub diagram illustrates the channel Bit Error Rate (BER) with duty cycle distortion:

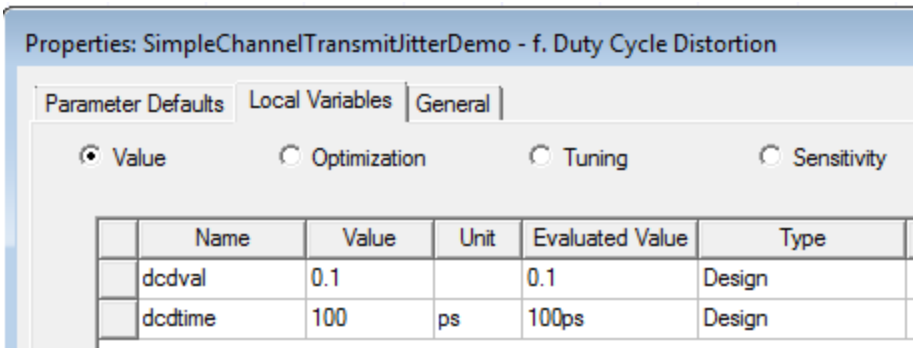


Alternatively, you may wish to specify the DCD as an absolute time between 0 and the size of the UI. Click the **DCDFractionorTimeValue** field and select Time on the menu.



For the **dcd** property value, enter **dcdtime**. This local variable has been defined as 100ps, equivalent to the fraction 0.1 when the UI is 1ns.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Here is the **Properties** window with the **dcdtime** variable specified.

Name	Value	Unit	Evaluated Value	Description
resistance	100	ohm	100ohm	Resistance (Ohm)
vlow	-1	V	-1V	Low voltage of the source
vhigh	1	V	1V	High voltage of the source
trise	5e-010	s	5e-010s	Rise time of the source
tfall	5e-010	s	5e-010s	Fall time of the source
phase_delay	0	s	0s	Phase of the source in seconds
UIorBPS	UnitInterval			Choose either Unit Interval or Bits per Second.
UIorBPSValue	1e-009	s	1e-009s	Enter a value for Unit interval or Bits per second
DCDFractionorTime	Time			Fraction = decimal fraction of UI, 0 <= DCD <= 1. Ti
dcd	dcdtime		100ps	Duty cycle distortion
bxrj				Gaussian (random) jitter std deviation

Run the analyses again and verify that the results are exactly the same.

CTLE Gain with USB3.0 Parameters

This example plots the response of a continuous-time linear equalizer (CTLE) using the *CTLE Visualization* element on the Circuit Component library. The CTLE boosts the high-frequency components of the received data. The CTLE parameters are pole 1 (low bound of HP), pole 2 (high bound of HP), and pole z (start of upslope). The gain can also be specified.

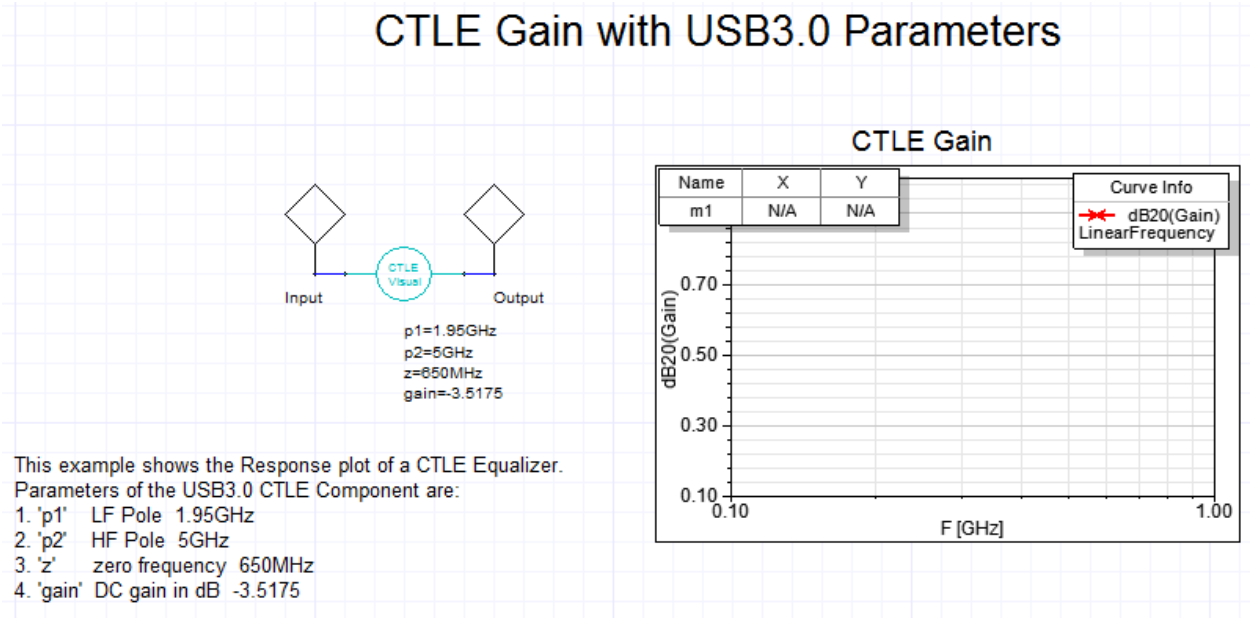
The initial values (p1=1.95GHz, p2=5GHz, z=650MHz, gain=-3.5175), are on the example given in the USB 3 Compliance Standard.

The schematic for the circuit is available in the Examples directory.

Open the project from its file in the Examples directory.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. From the **Examples** directory, select **Circuit** > **Signal Integrity**. Then double-click **CTLE_Gain_USB3.0.aedt**, or select **CTLE_Gain_USB3.0.aedt** and click **Open**.

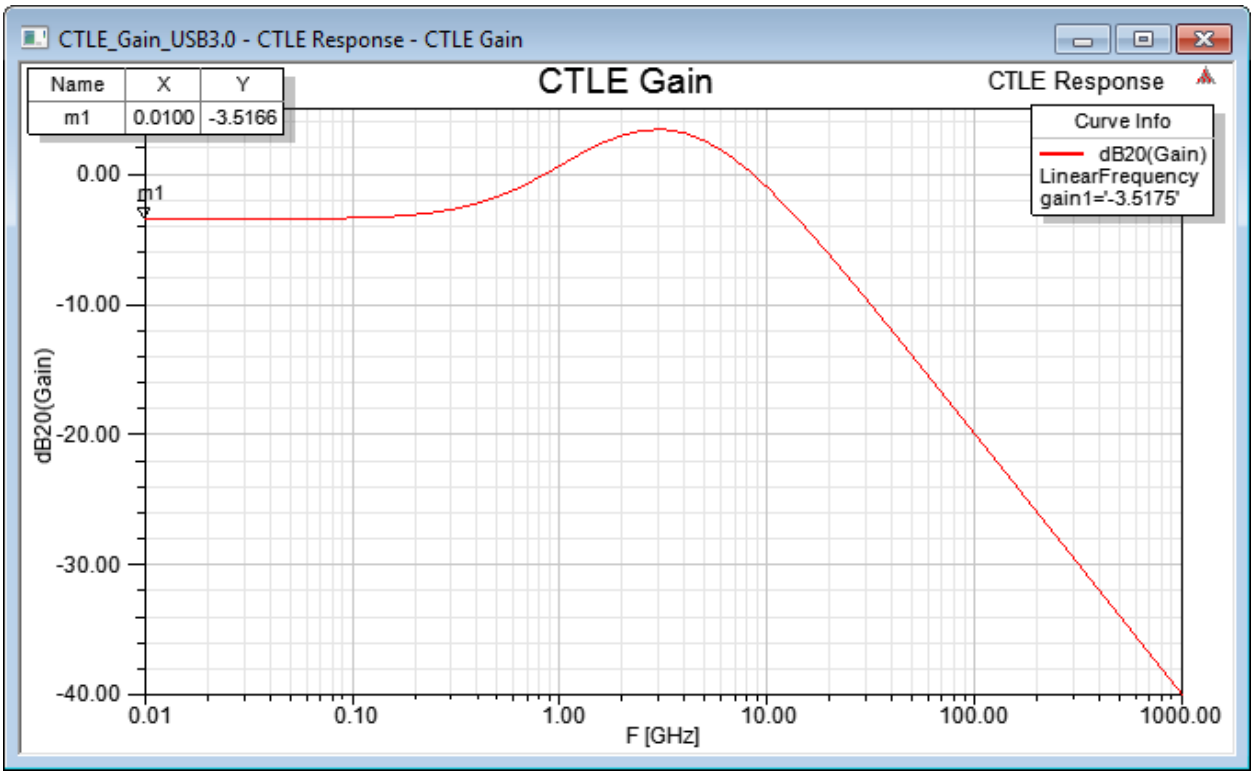


The plot on the schematic is filled in when the analysis is run.

3. Use **File>Save As** to save the project in a directory where you have write permission.
4. Click the CTLE Visual component to verify the parameter settings.
5. The Linear Network analysis is already set up. Expand the **Analysis** icon, double-click the **Linear Frequency** setup, and select **Analyze** (you may need to use **Force Analysis**).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. When the analysis is complete, the schematic plot is filled in. You can view a larger plot by expanding the **Results** icon, then clicking on the **CTLE Gain** report:



The marker shows the gain at the lowest plotted frequency (10MHz), close to the DC gain of -3.5175.

7. Use **File>Save** to save the project, and **File>Close** to close it.

CTLE Gain with USB3.0 Parameters from a File

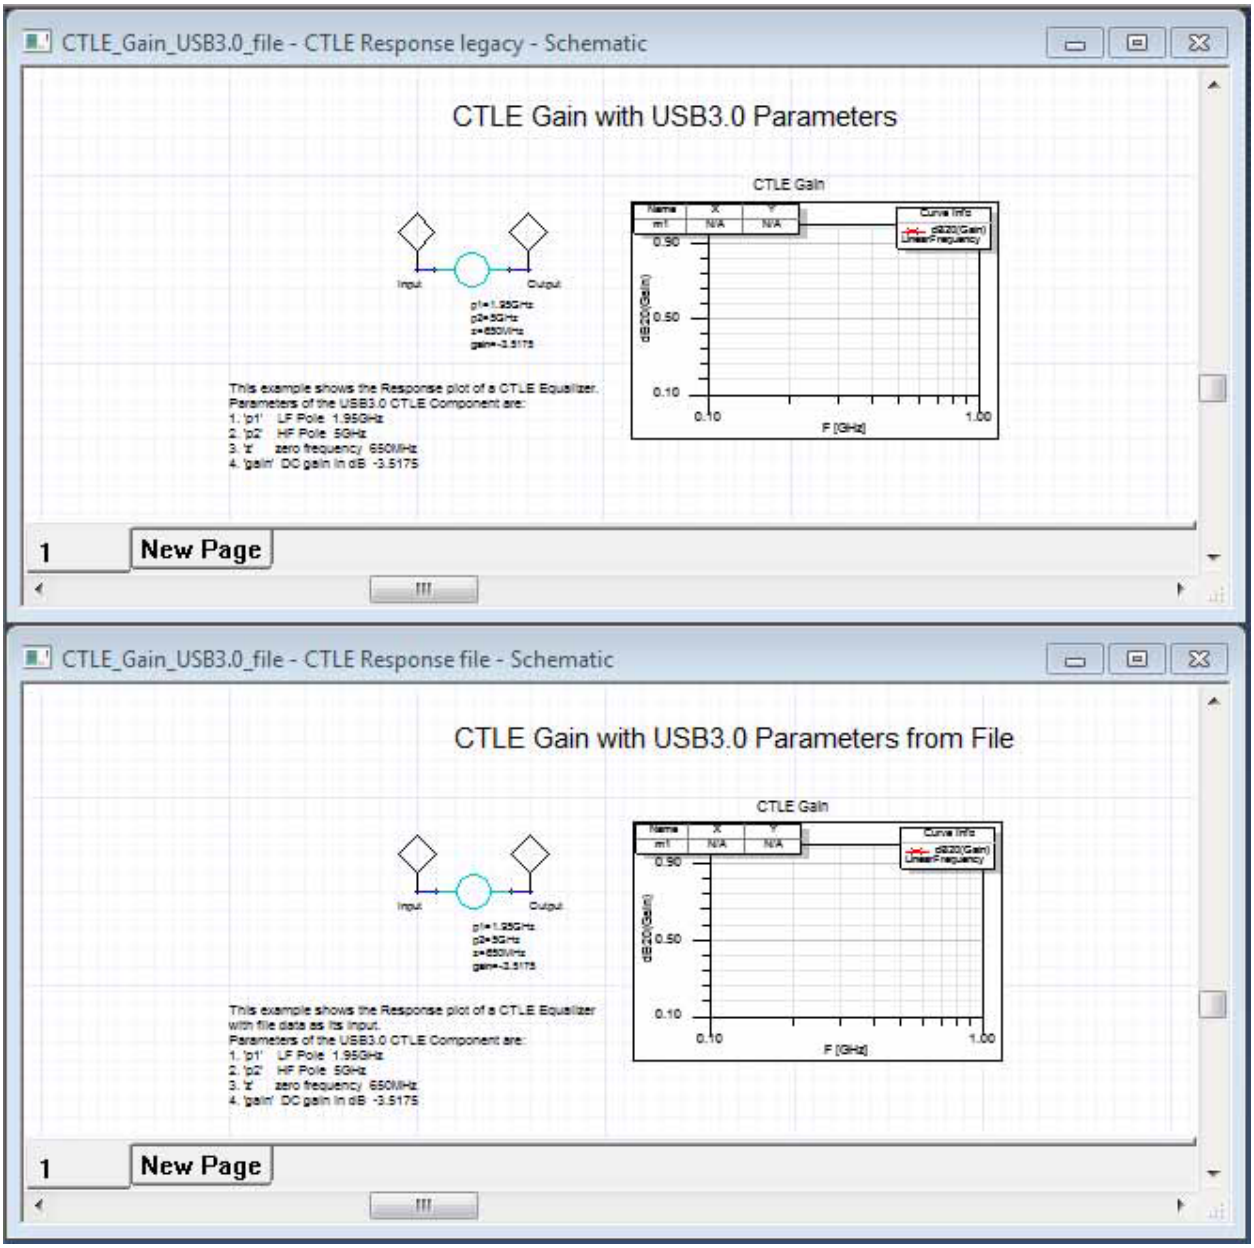
This example compares the response of the CTLE Visualization element with fixed USB3.0 parameters to the response obtained from a file with CTLE data derived on the same USB3.0 specification.

The schematic for the circuit is available in the Examples directory.

Open the project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. From the **Examples** directory, select **Circuit** > **Signal Integrity**. Then double-click **CTLE_Gain_USB3.0_file.aedt**, or select **CTLE_Gain_USB3.0.aedt** and click **Open**.

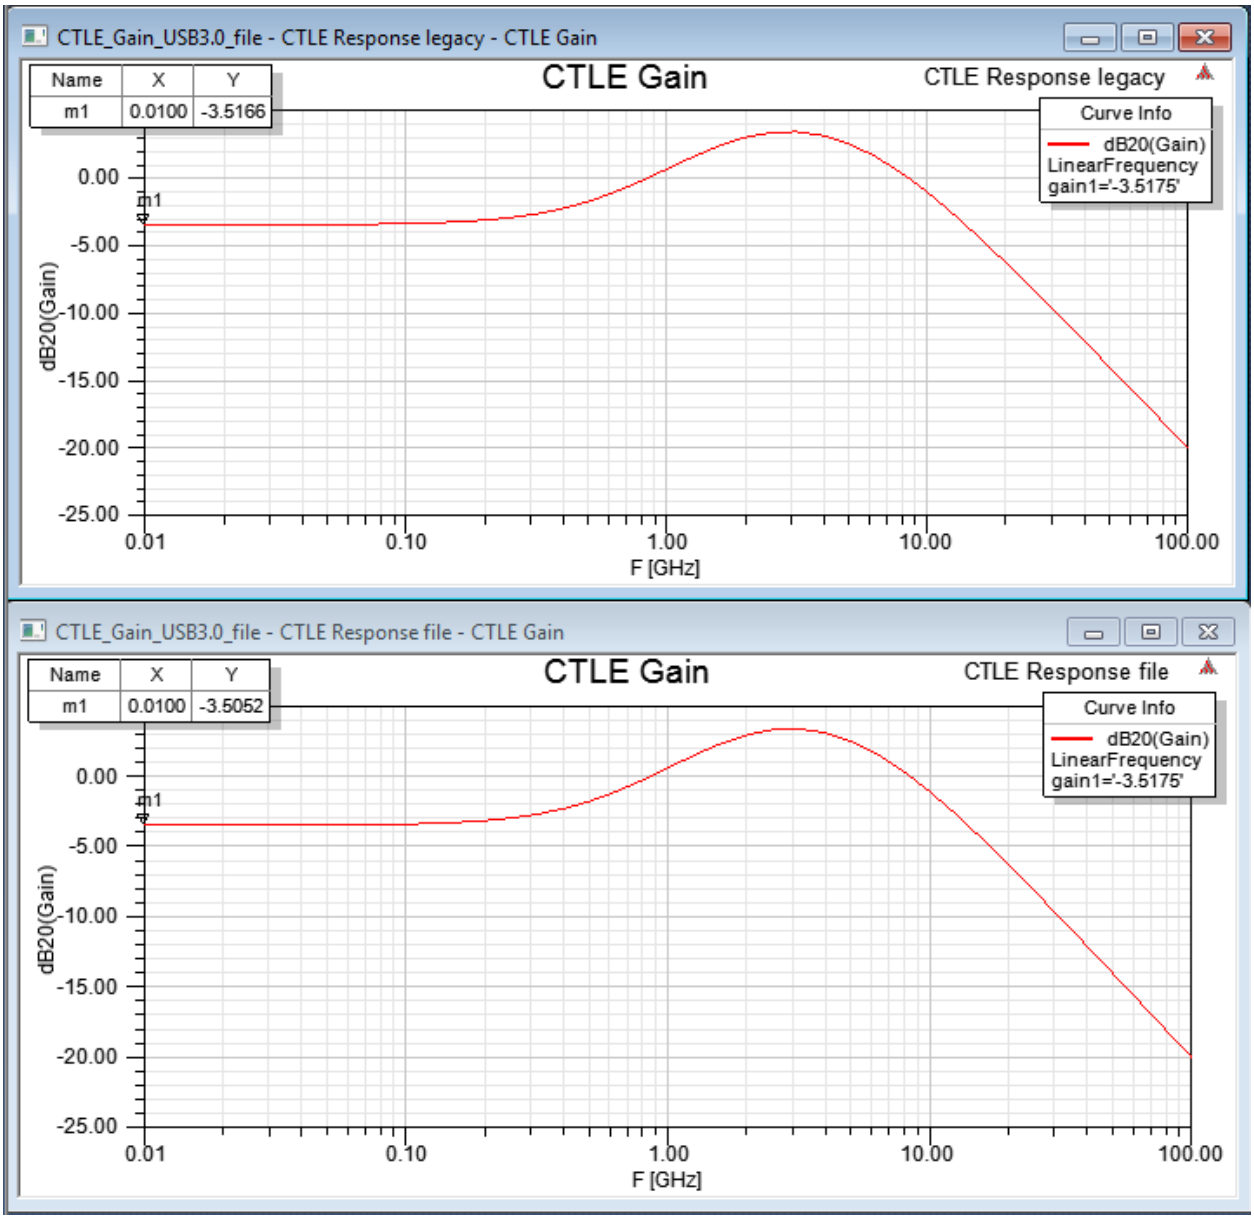
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. In the project **CTLE Response legacy**, view the Eye Source properties and verify that the values (p1=1.95GHz, p2=5GHz, z=650MHz, gain=-3.5175), are the same as in the example given for the USB 3.0 Compliance Standard.
4. Click the **Linear Frequency** analysis, and click Analyze. The **CTLE Gain** plot for that project is displayed.
5. In the project **CTLE Response file**, view the Eye Source properties and verify that the file parameter points to the data file **usb3.ctle** (in a subdirectory of the Examples folder.)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. Click the **Linear Frequency** analysis, and click Analyze. The **CTLE Gain** plot for that project is displayed.
7. Verify that the two plots are identical.



CTLE Gain with PCIe3.0 Parameters

This example plots the response of a continuous-time linear equalizer (CTLE) using the *CTLE Visualization* element on the Circuit Component library. The CTLE boosts the high-frequency components of the received data. The CTLE parameters are pole 1 (low bound of HP), pole 2

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

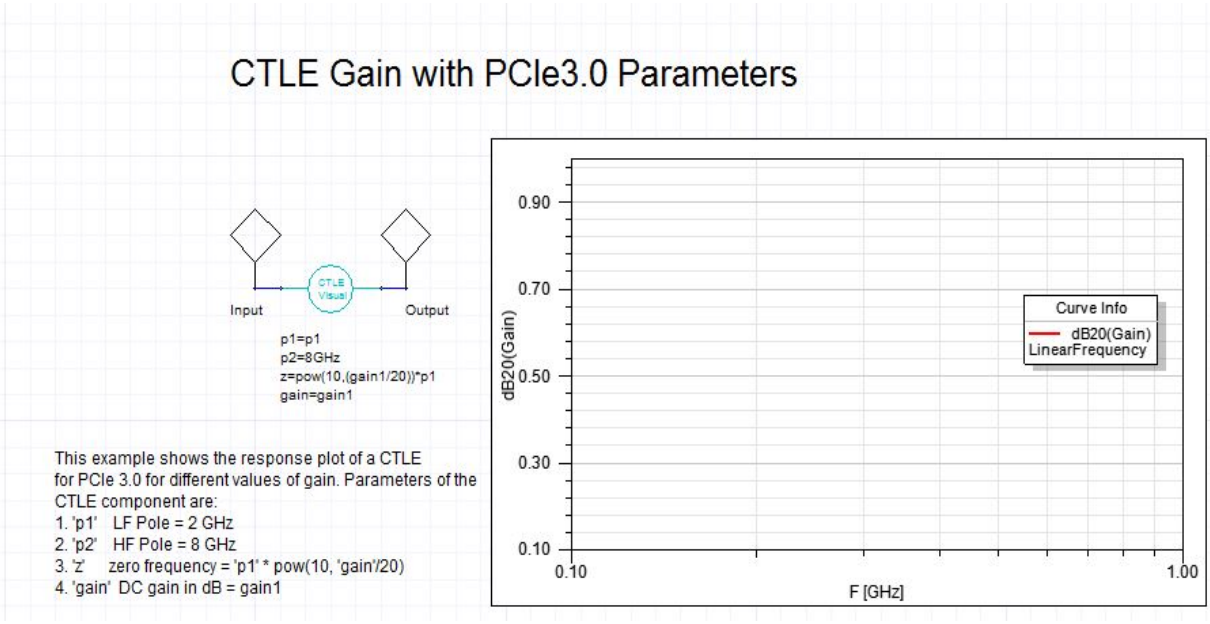
(high bound of HP), and pole z (start of upslope). The gain can also be specified and, to implement the PCIe3.0 values in Nexxim, the frequency for pole z is calculated on the gain.

The initial values are p1=2GHz, p2=8GHz, gain=-6, and z=pow(10,(gain/20))*p1, representing the Nexxim implementation of the PCIe3.0 standard.

The schematic for the circuit is available in the Examples directory.

Open the project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. From the **Examples** directory, select **Circuit** > **Signal Integrity**. Then double-click **CTLE_Gain_PCIe3.0.aedt**, or select **CTLE_Gain_PCIe3.0.aedt** and click **Open**.



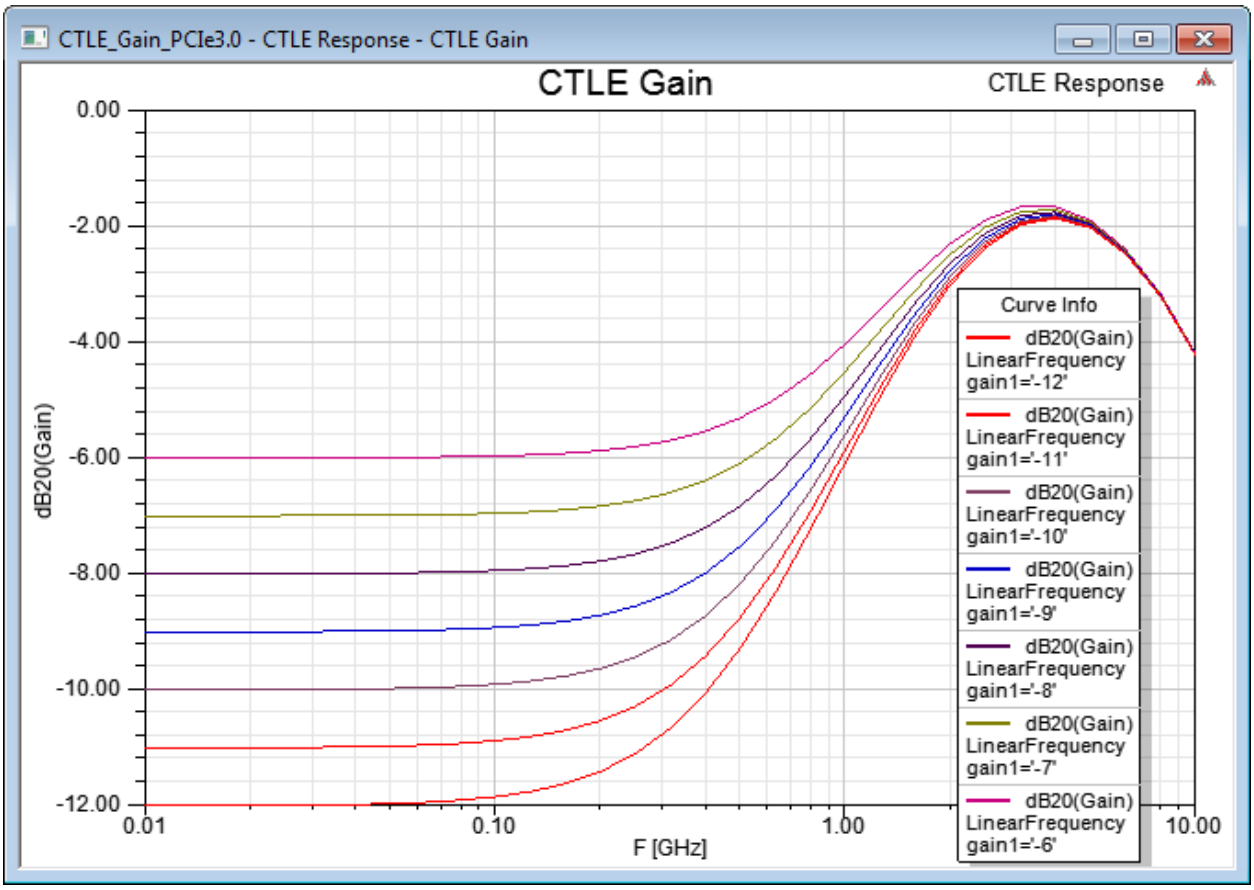
3. Use **File>Save As** to save the project in a directory where you have write permission.

The plot on the schematic is filled in when the analysis is run.

4. Click the CTLE Visual component to verify the parameter settings. The gain parameter is set with a local variable, gain1, that is swept from -6 to -12 dB.
5. The Linear Network analysis is already set up.
6. Expand the **Analysis** icon and double-click the **Linear Frequency** setup. Verify the sweep settings. Click OK to close the setup.
7. Right-click the **Linear Frequency** setup and select **Analyze** (you may need to use **Force Analysis**).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. When the analysis is complete, the plot is generated. You can view a larger plot by expanding the **Results** icon, then clicking on the **CTLE Gain** report:



9. Use **File>Save** to save the project, and **File>Close** to close it.

CTLE Gain with PCIe3.0 Parameters from a File

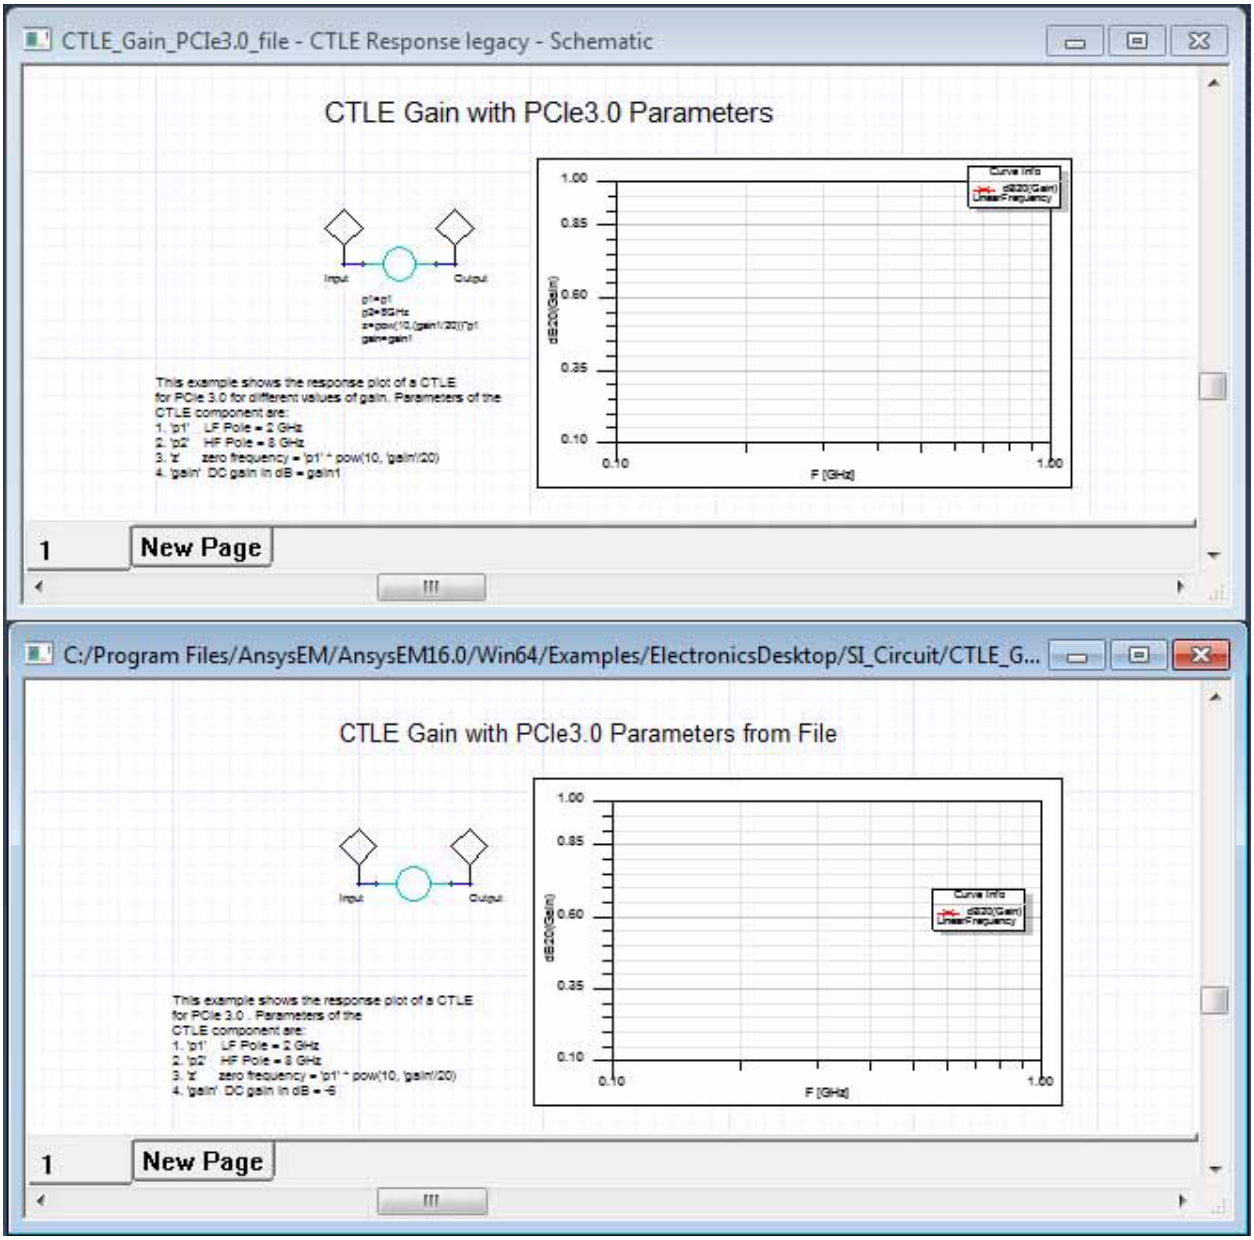
This example compares the response of the CTLE Visualization element with fixed PCIe3.0 parameters to the response obtained from a file with CTLE data derived on the same PCIe3.0 specification.

The schematic for the circuit is available in the Examples directory.

Open the project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. From the **Examples** directory, select **Circuit** > **Signal Integrity**. Then double-click **CTLE_Gain_PCIe3.0.aedt_file**, or select **CTLE_Gain_PCIe3.0.aedt_file** and click **Open**.

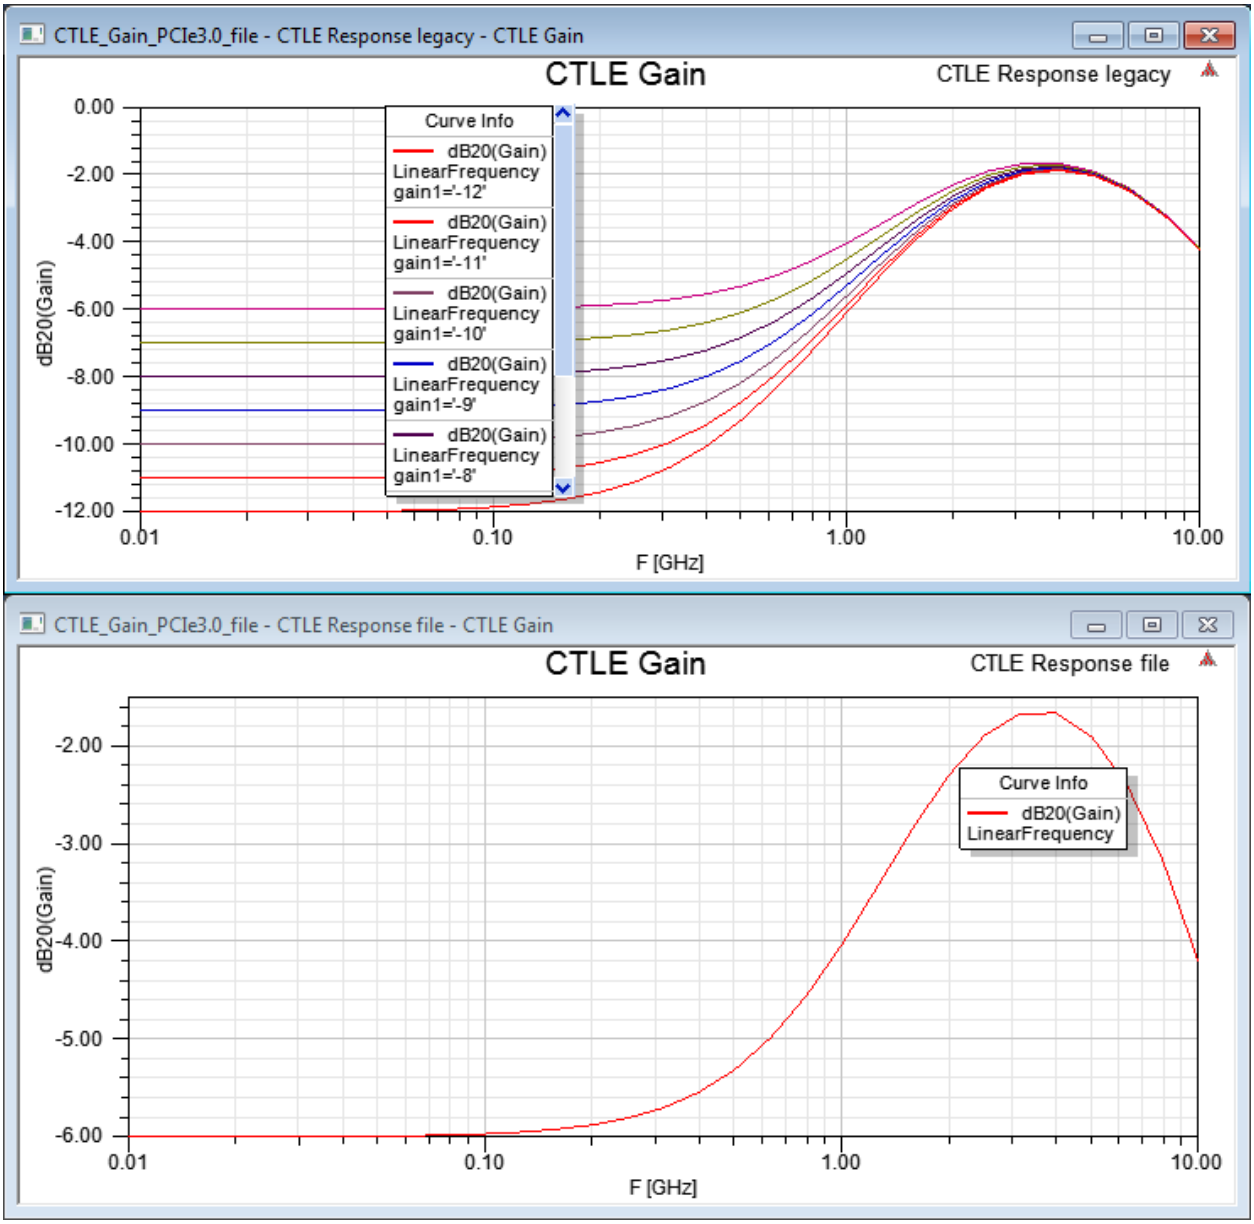
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. In the project **CTLE Response legacy**, view the Eye Source properties and verify that the values (p1=2GHz, p2=8GHz, gain=-6, and z=pow(10,(gain/20))*p1, are the same as for the example given earlier using the PCIe3.0 standard.
4. The Linear Frequency analysis has been set to sweep the variable **gain1** from -6 to -12. Click the **Linear Frequency** analysis, and click Analyze. The **CTLE Gain** plot for that project is displayed.

Verify that the two plots for gain=-6 are identical.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



CTLE Gain using a Generic Rational Function

This example shows how to Click the **Generic rational function** group box on the CTLE data window to specify the transfer function for Continuous Time Linear Equalization (CTLE). Earlier versions of the CTLE data window offered one method, the “legacy” method. These examples show how the newer method can do everything that the legacy method could do, and more.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The CTLE data window also allows you to read the CTLE data from a file. See CTLE Gain with USB3.0 Parameters from a File and CTLE Gain with PCIe3.0 Parameters from a File for examples of the file method.

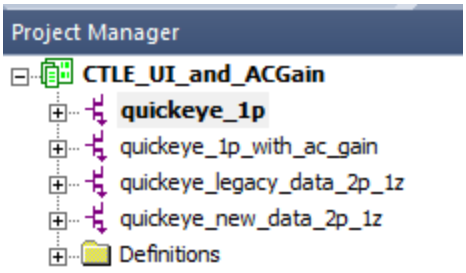
The schematic for the circuit is available in the Examples directory.

Open the project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. From the **Examples** directory, select **Circuit** > **Signal Integrity**. Then double-click **CTLE_UI_and_ACGain.aedt_file**, or select **CTLE_UI_and_ACGain.aedt_file** and click **Open**.

   The circuit is the same as the Serial_Channel used for the Eye Analysis Example.

3. There are four Circuit projects in this example. Each one shows a different way to specify a CTLE filter function:



4. Open the **quickeye_1p** project. View the properties for the Eye Source.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. All the projects use the same Eye Source setup:

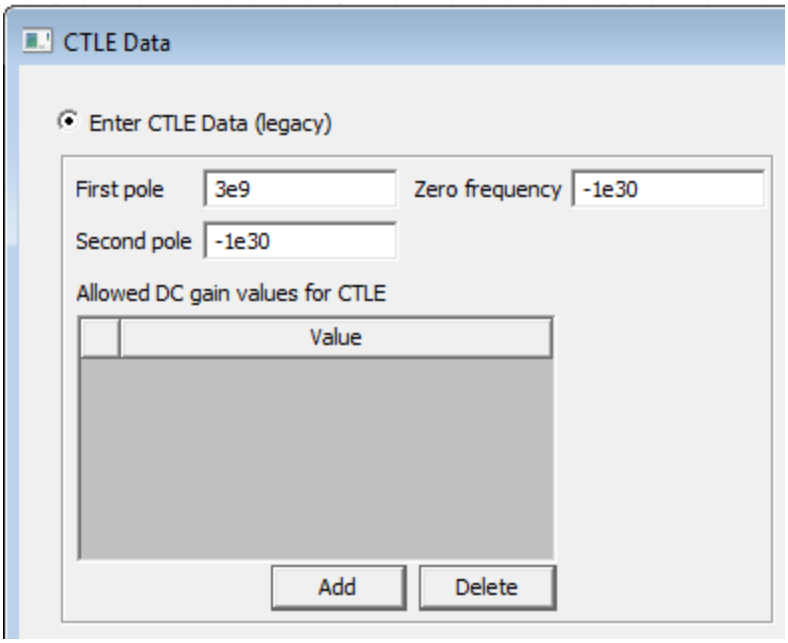
Name	Value	Unit	Evaluated Va...	
resistance	100	ohm	100ohm	Resistance (Ohm)
vlow	-850	mV	-850mV	Low voltage of the source
vhigh	850	mV	850mV	High voltage of the source
trise	50	ps	50ps	Rise time of the source
tfall	50	ps	50ps	Fall time of the source
phase_delay	0	s	0s	Phase of the source in seconds
modulation	NRZ			Serial data modulation, NRZ (two voltage levels, 1 bit p
coding_PAM4_only	Gray			Relevant for PAM-4 only. Coding for mapping low-to-hig
UIorBPS	BitsPerSecond			Choose UnitInterval or BitsPerSecond. UnitInterval is th
UIorBPSValue	6000000000		6000000000	Enter a value for the Unit Interval (time duration of one
DCDFractionorTime	Fraction			Fraction = decimal fraction of UI, 0 <= DCD <= 1. Time
dcd	0		0	Duty cycle distortion
txrj	['10ps']			Gaussian (random) jitter std deviation
txpj				Periodic (random) jitter amplitude
txuj				Uniform (random) jitter amplitude
txcj				Name of user-defined transmit jitter file
repeat_count	0		0	Number of times to repeat the bit pattern.
step_resp_num_ui	100		100	Num of UIs for initial step response
do_encoding	0		0	Encoding type: 0=none; 1=8b10b; 2=64b66b
hold_last_bit				Hold last bit or repeat the sequence.
FFE_data				FFE data
BitPattern	random_bit_count=1000...			Bit pattern for QuickEye
COMPONENT	EYE_SOURCE			

The transmitter includes a Gaussian jitter with a standard deviation of 10ps to be overcome by equalization. The transmitter itself contributes two taps of feed-forward equalization (FFE).

6. View the properties for the Eye Probe. The Eye Probe includes two taps of Decision Feedback Equalization (DFE).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

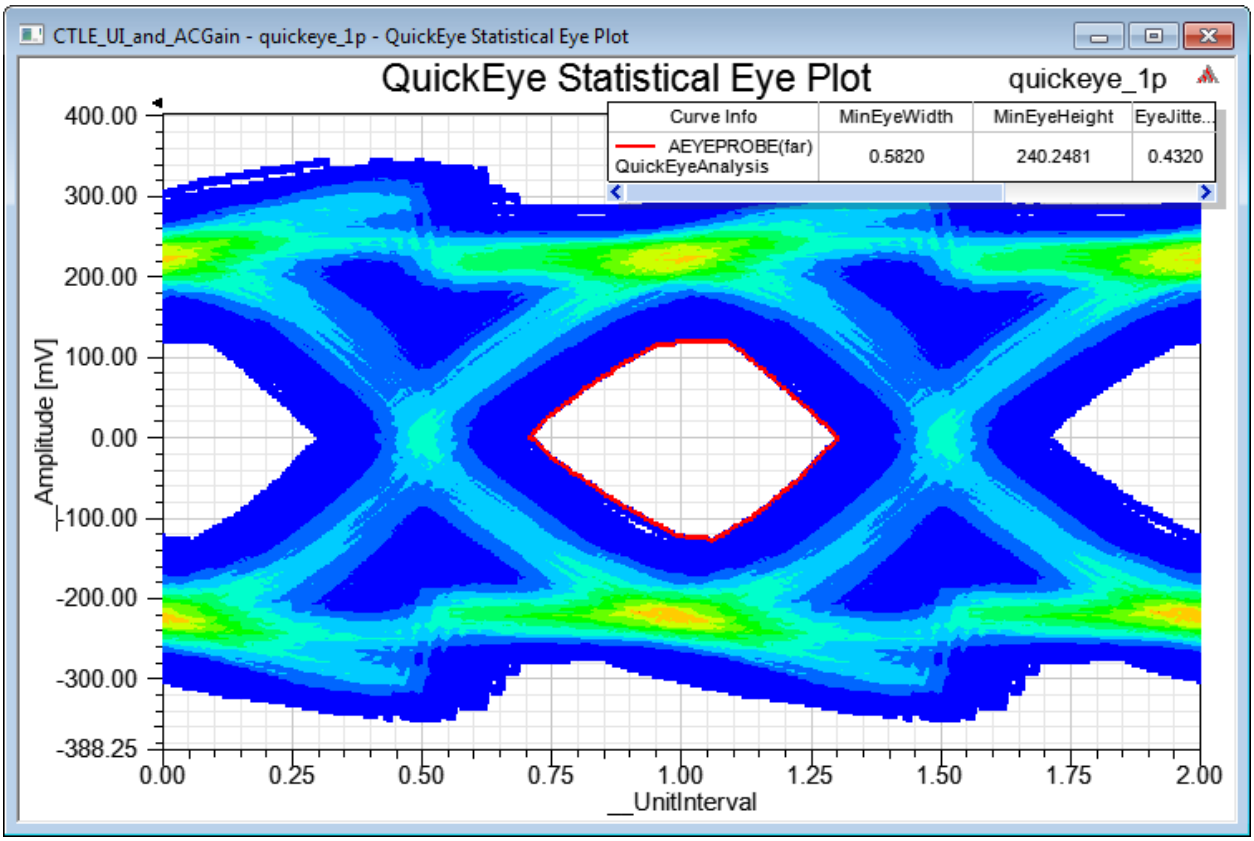
7. Click **CTLE_data**.



With the “legacy” method, you specify one or two pole frequencies and, optionally, a zero frequency. For this example, **Enter CTLE Data (legacy)** is selected, and the **First pole** is set to 3GHz.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

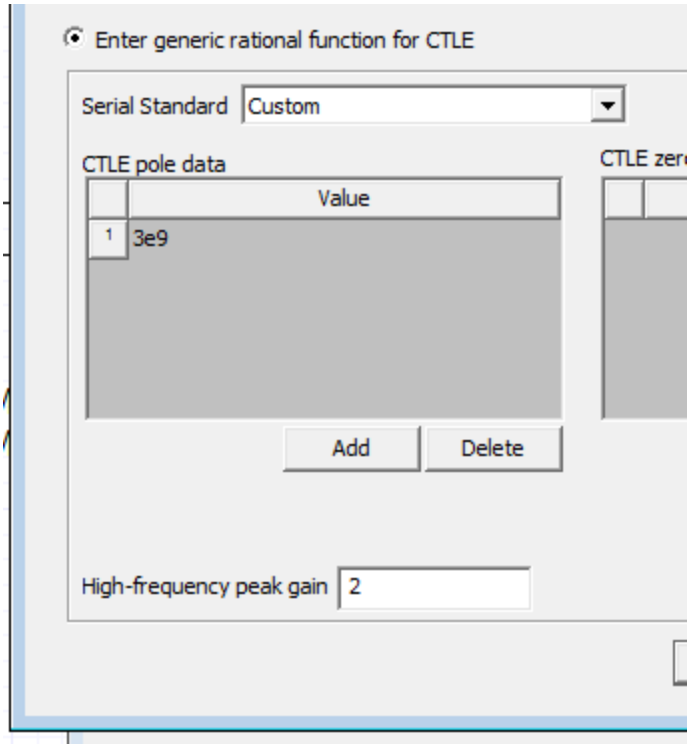
8. Click the **Analysis** icon. A simple Quick Eye analysis has been set up. Click **Analyze**.
9. Under the results, icon, open the **QuickEye Statistical Eye Plot**.



You can see the effect of the random jitter.

10. Close the **quickeye_1p** project and open the **quickeye_1p_with_ac_gain** project. The only change is to the CTLE data window on the Eye Probe:

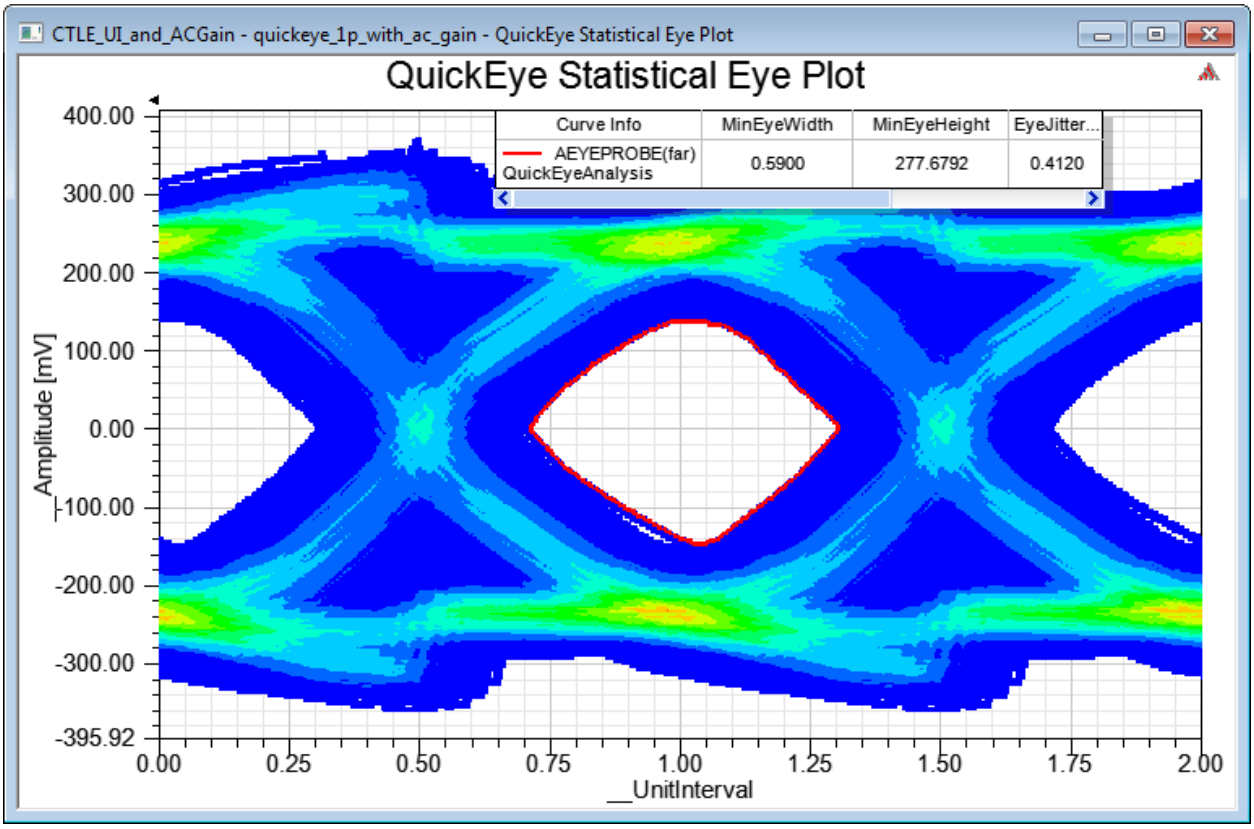
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The setup uses the **Enter generic rational function for CTLE** group box instead of the legacy method, but the setup is for the same single pole at 3GHz as before. Using the generic setup, In this example, the High-frequency peak gain or AC gain value, has been added. This sets the maximum value of the CTLE transfer function. The legacy method does not support AC gain.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

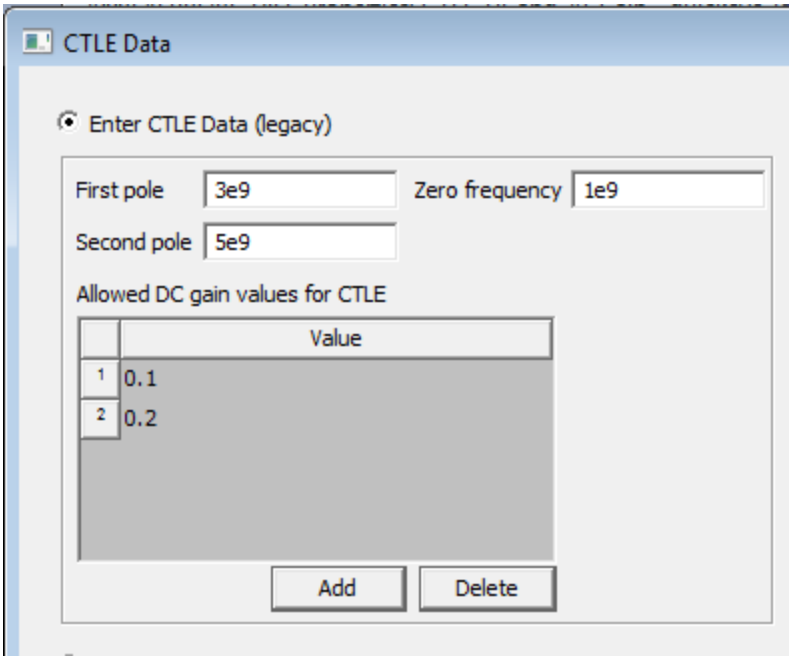
11. Run the QE analysis for this project, and view the result with AC gain added:



Note the slight improvement in the eye height and width. over the plot with no AC gain in the CTLE.

12. Close the **quickeye_1p_with_ac_gain** project and open the **quickeye_legacy_data_2p_1z** project. View the CTLE data window in the Eye Probe properties.

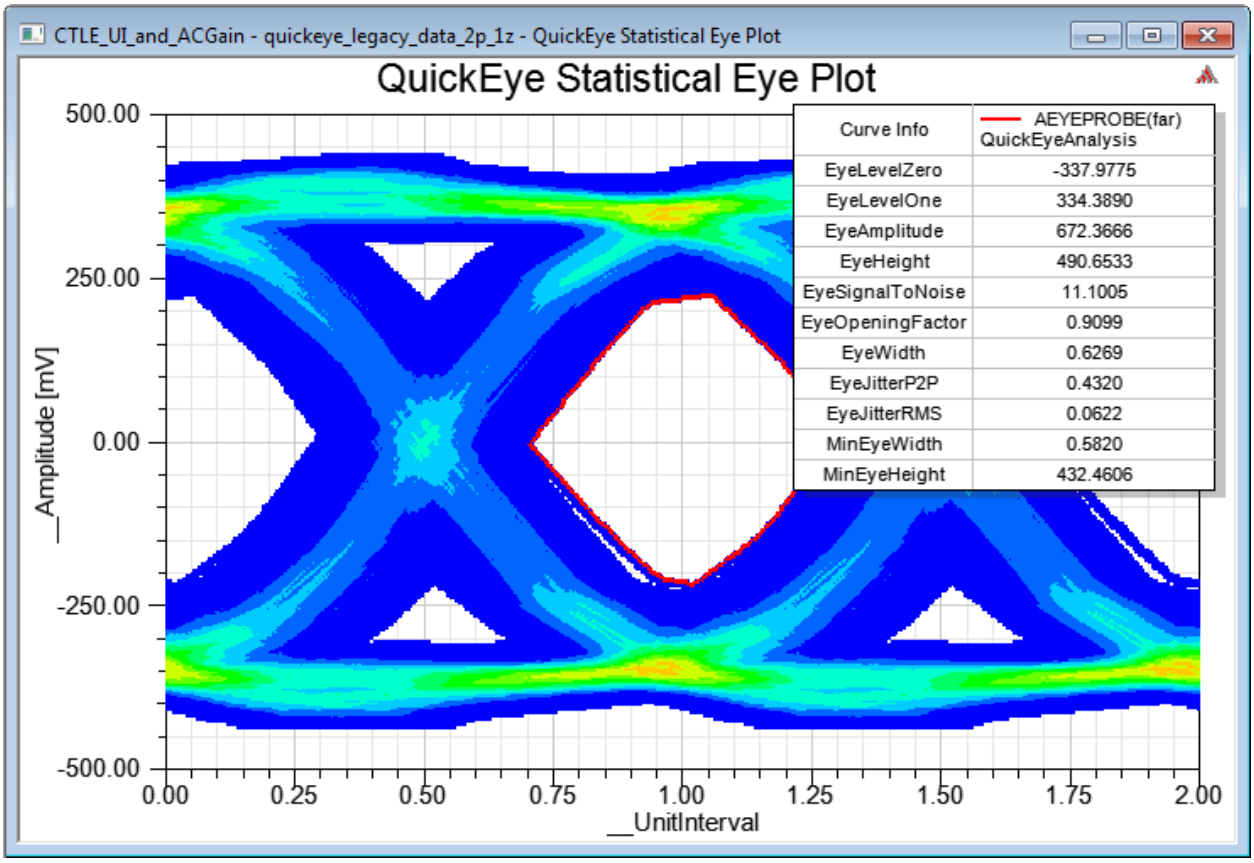
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



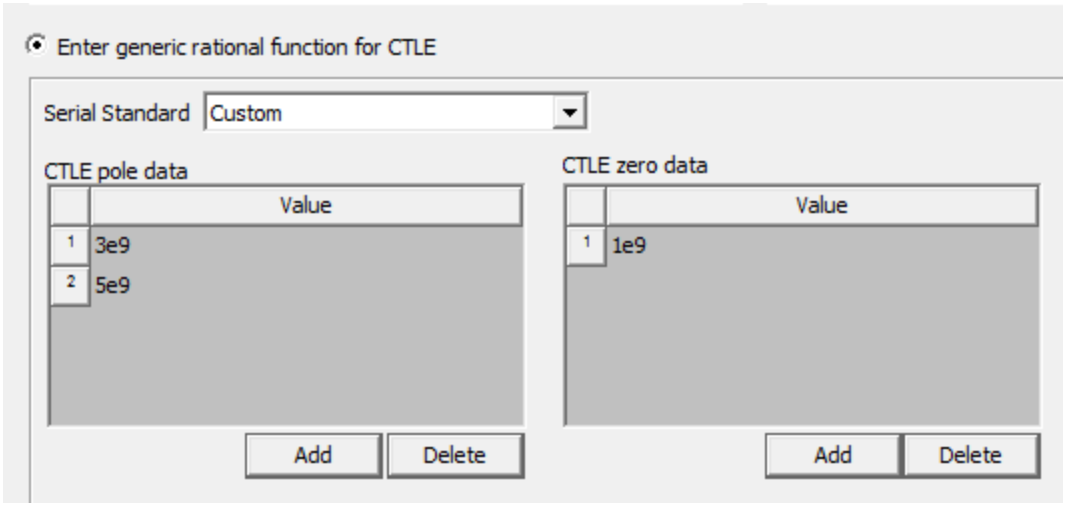
The legacy CTLE data group box has been set with poles at 3gHz and 5gHz, and a zero at 1gHz. The legacy group box also allows you to specify a range of DC gain values. Nexxim tries all the gain values and uses the one that gives the best eye. Here, two DC gain values of 0.1 and 0.2 are specified.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

13. Run the Quick Eye analysis and view the report:

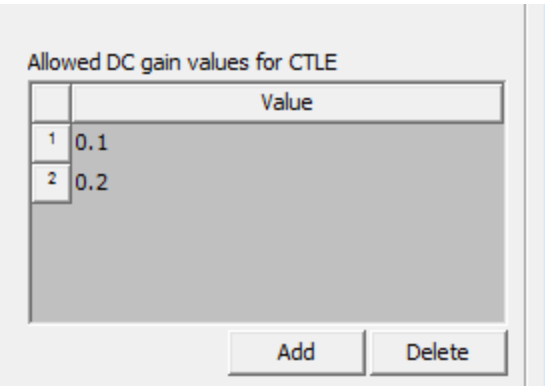


14. Close the quickeye_legacy_data_2p_1z project and open the **quickeye_new_data_2p_1z** project. View the CTLE data window:

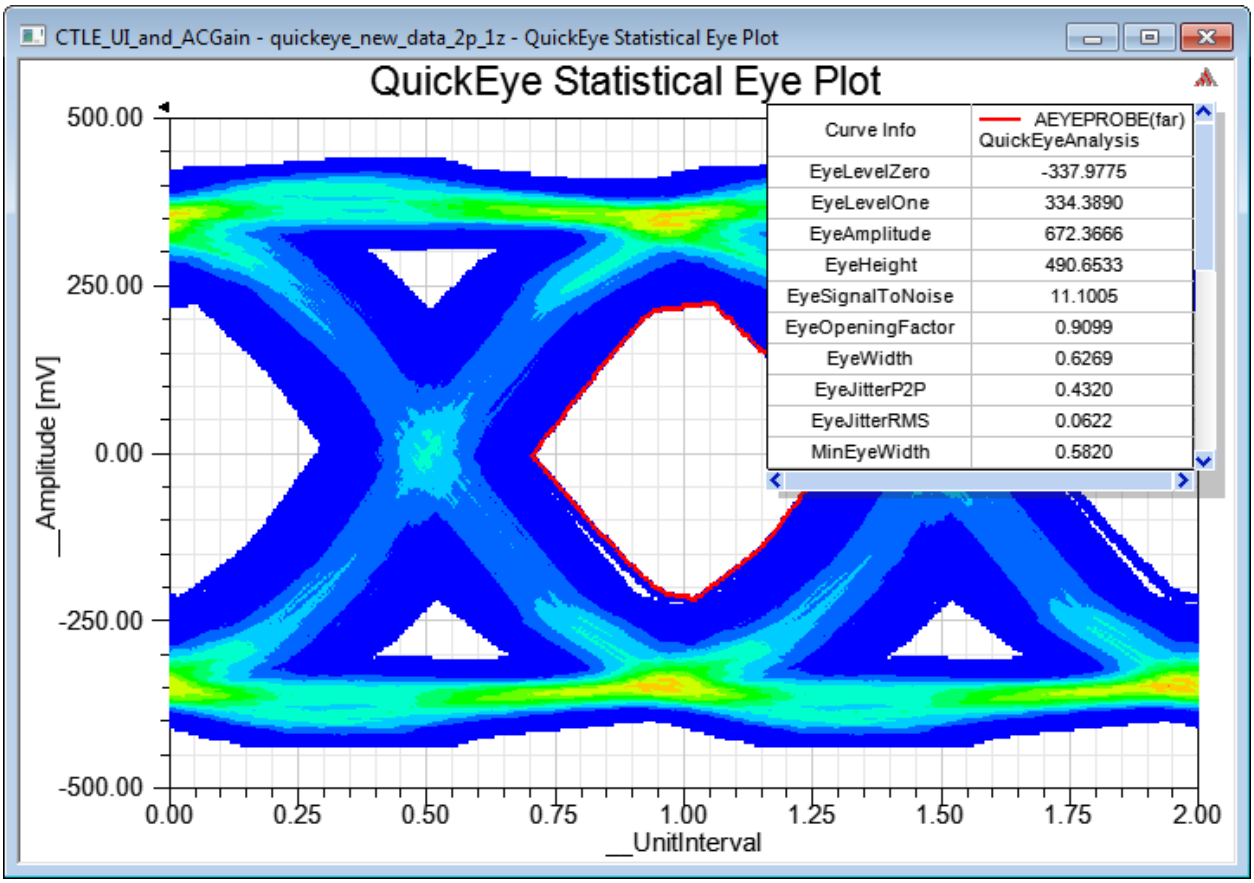


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

15. This setup is identical to the legacy 2pole, 1 zero specification. The same two Allowed DC gain values (0.1 and 0.2 dB) have been added to the specification.



16. Nexxim tries each of these and use the one that gives the best eye.
17. Run the Quick Eye analysis and view the results.



This should be very similar to the two-pole, one-zero legacy setup shown earlier.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

PCI Crosstalk Example

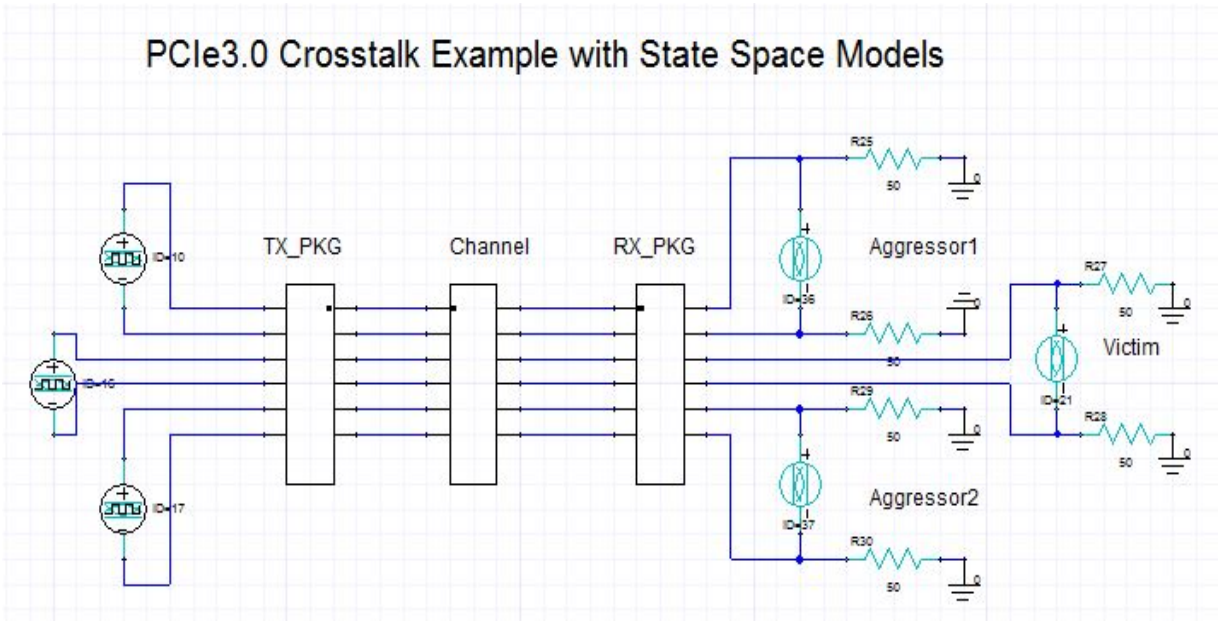
This example analyzes crosstalk on a channel with equalization at both transmitter and receiver. The receiver equalization includes PCIe3.0-specific CTLE. For a simpler example of using PCIe3.0 CTLE see CTLE Gain with PCIe3.0 Parameters.

- The setup uses three differential line pairs so crosstalk between pairs can be evaluated.
- The outer two pairs are the aggressors, and the inner pair is the victim. All three channels use equalization.
- The gain on all channels is swept from (-6dB) to (-12dB), and the reports show how the eye is affected.

The models for this demonstration have been converted on their original S-parameters (.sNp) to state-space fittings (.sss). The complete simulation takes under one minute with state-space models, noticeably faster than the original version with S-parameter models. The original TX and RX Touchstone models are on the PCI-SIG Seasim software package.

The schematic for the circuit is available in the Examples directory. Open the project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **Signal_Integrity**, then select the file **PCIe_StateSpace.aedt**. Click **Open**.



3. Use **File>Save As** to save the project and its subordinate files to a directory where you have write permission.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

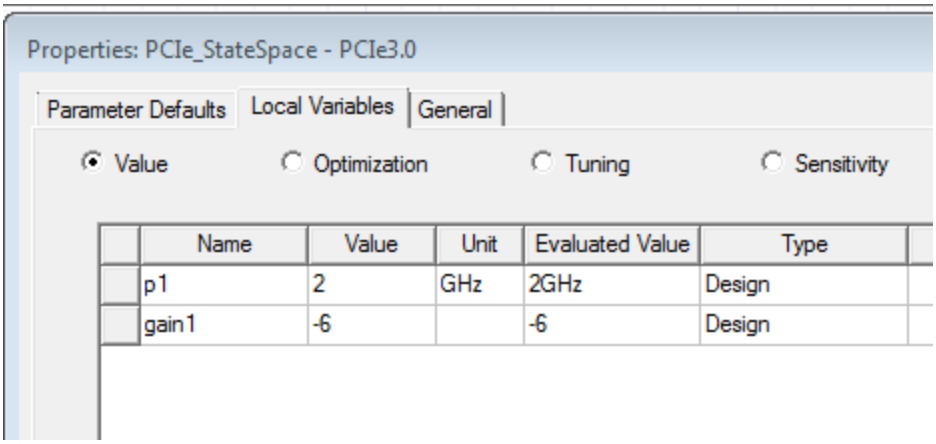
4. Click any of the Eye Sources to view the Properties. All three sources use the same setup:

- Logic levels 0.8V for high, -0.8V for low.
- 125ps unit interval with 10ps rise and fall times.
- Three-tap feed-forward equalization (FFE).
- 7-bit PRBS as the bit pattern.

5. Click any of the Eye Probes to display the Properties. All three probes use the same setup:

- One-tap decision-feedback equalization (DFE).
- Continuous-time linear equalization (CTLE). The CTLE boosts the high-frequency components of the received data. The CTLE parameters are pole 1, pole 2, and pole z. For the Nexxim implementation of the PCIe3.0 standard, the frequency for pole z is calculated from the gain. The initial values, pole 1 (p1) at 2GHz, pole2 at 8GHz, gain (gain1) at -6dB, and pole z=pow(10,(gain/20))*p1, represent the Nexxim implementation of the PCIe3.0 standard.

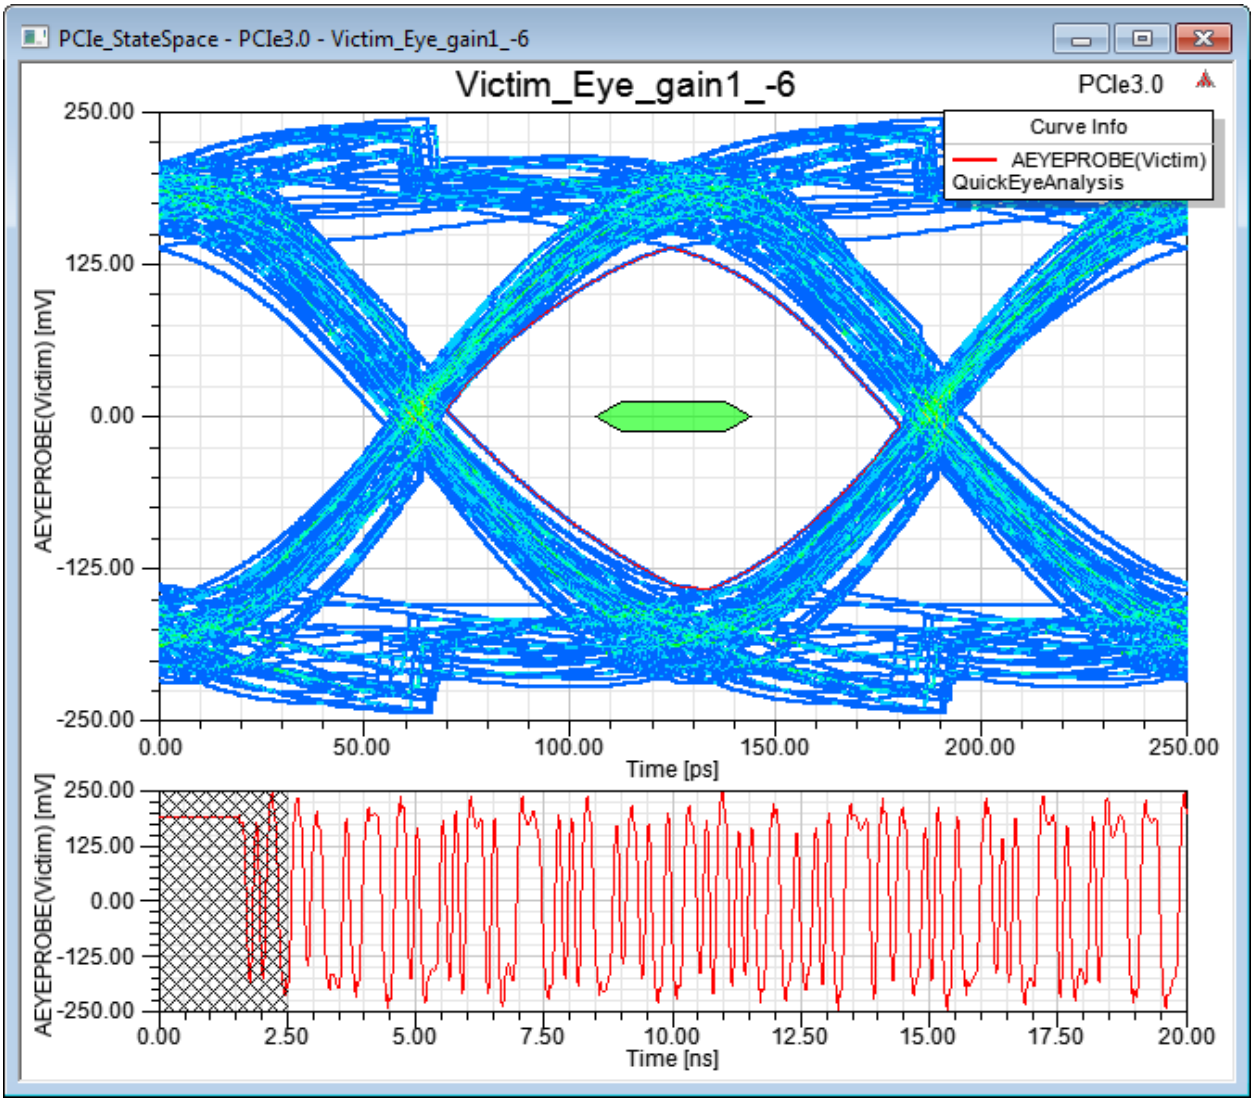
6. The values for pole 1 and gain are set up as local variables, **p1** and **gain1**, so they may be swept. In this example, only the gain is swept. To view the local variables, right-click the **PCI3.0** project, then select **Design Properties**, and click the **Local Variables** tab:



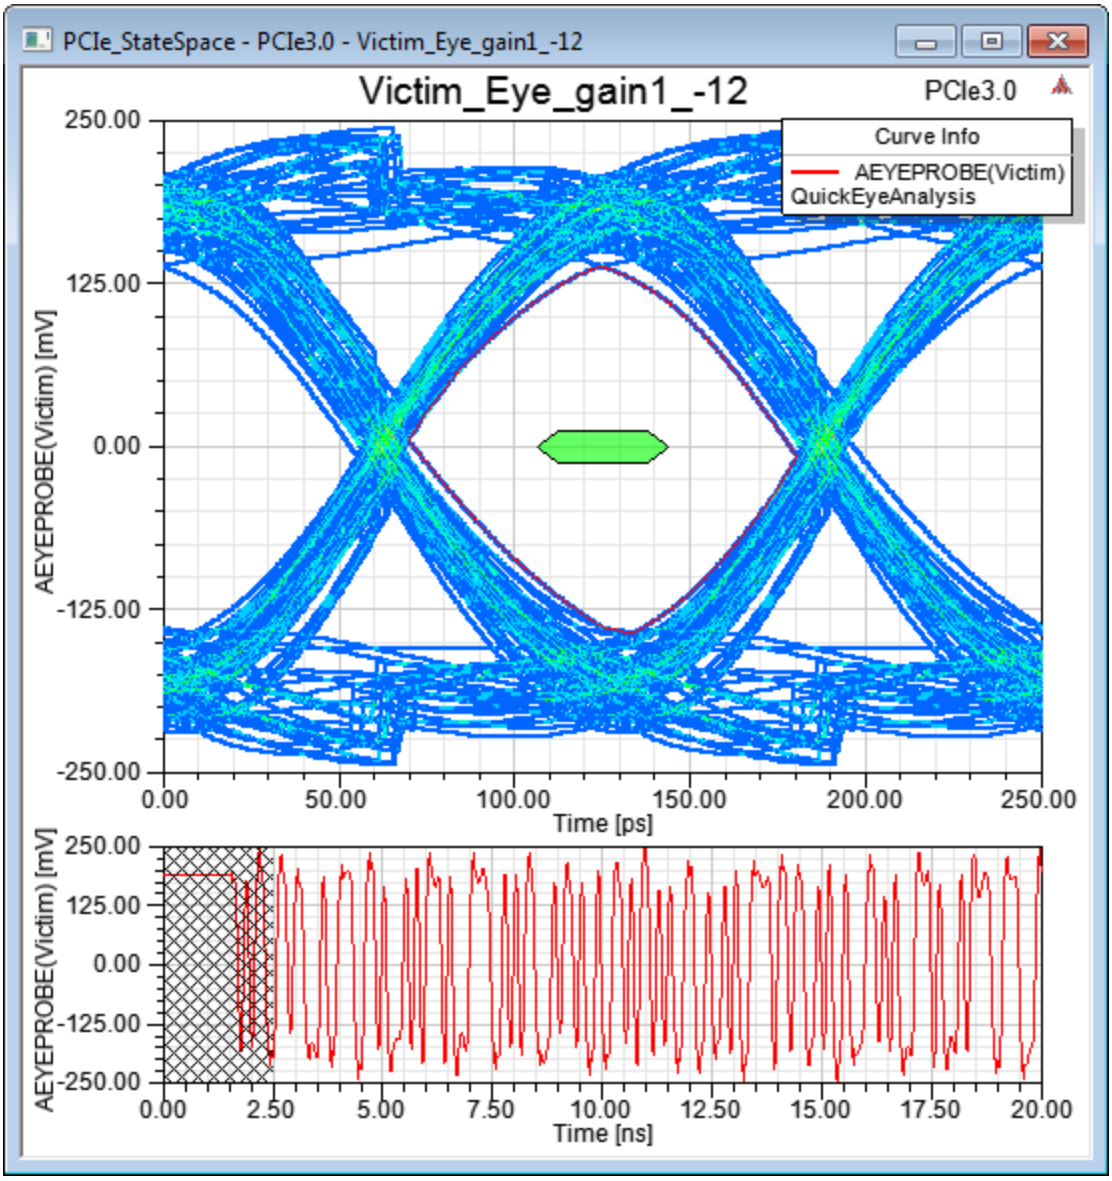
7. The Quick Eye analysis is already set up. The local variable, **gain1**, is swept from -6 to -12 dB.
8. Expand the **Analysis** icon and double-click the **QuickEye** setup. Verify the sweep setting. Click **OK** to close the setup.
9. Right-click the **QuickEye** setup and select **Analyze** (you may need to use **Force Analysis**).
10. When the QE analysis has run to completion, click the reports to see the Eye Diagrams.

The reports show the eye closing as the gain is swept.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

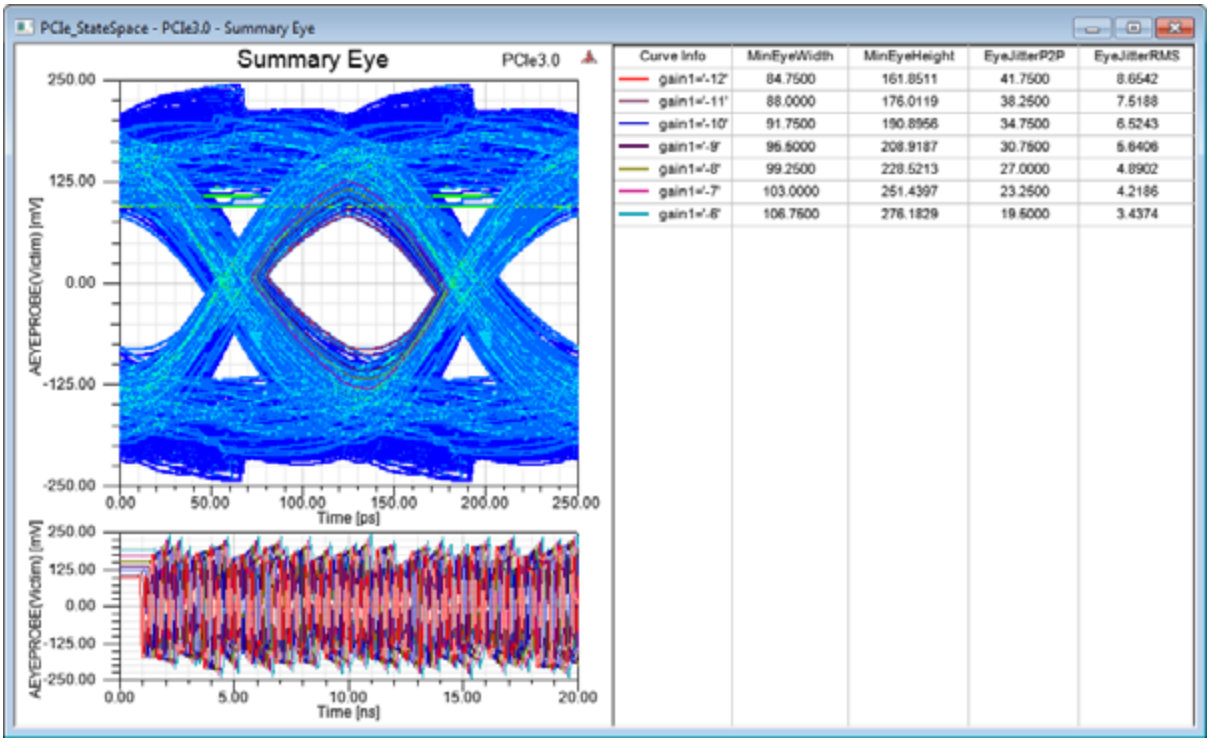


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



11. The Summary Report overlays all the plots, and provides key metrics for the different gains: Min Eye Height, Min Eye Width, P2P Jitter, RMS Jitter.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



12. Use **File>Save** to save the project, and **File>Close** to close it.

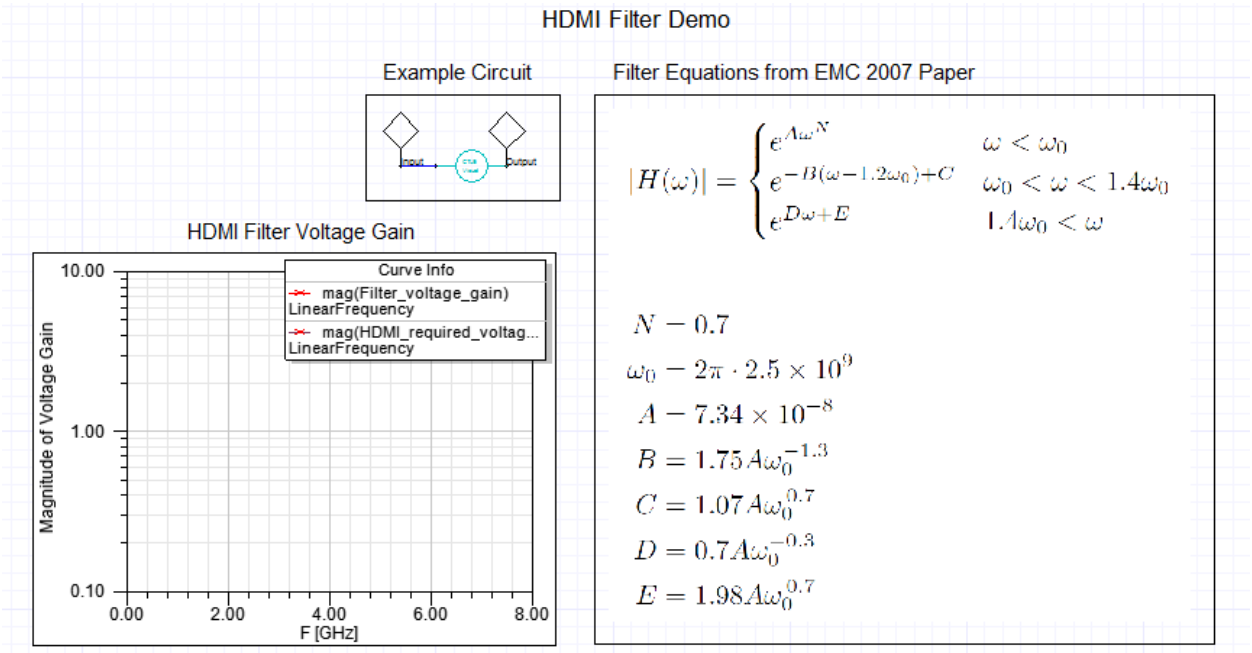
HDMI Filter Demonstration

This example implements a filter for a High-Definition Multimedia Interface (HDMI) cable. The filter equations are from [1]. The *"Causality Enforcement"* paper describes the causality issues that can arise during transient analysis with the HDMI filter.

The schematic for the circuit is available in the Examples directory. Open the project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **Signal_Integrity**, then select the file **HDMI_Filter_Demo.aedt**. Click **Open**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In this example, the filter is realized by fitting a state-space model to a causal transfer function provided in a CTLE data file, HDMI_transfer_function.ctle. The magnitude of this transfer function matches, approximately, the magnitude specified in the equations shown next to the CTLE component.

3. Open on the **Analysis** folder and run the **LinearFrequency** analysis. If needed, use **Force Analysis** to run the LNA.
4. When the LNA has completed, the report in the schematic is updated. The report shows the magnitude of the CTLE component's transfer function and the magnitude specified in the equations, on the same plot. Note that the quantity being compared is the voltage gain.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

[1] Eakhwan Song, Jeonghyeon Cho, Joungho Kim, and Don Gun Kam, "Causality Enforcement in Transient Simulation of HDMI Interconnects with Magnitude Equalization." *IEEE International Symposium on Electromagnetic Compatibility*, 2007.

Transient Parallel Bus Speedup Demonstration

Highly non-linear circuits do not simulate well with QuickEye or VerifEye, so transient analysis must be used. To speed up transient solutions for large non-linear designs that require simulating millions of bits, Nexxim offers the Transient Parallel Bus Speedup (TPBS) option.

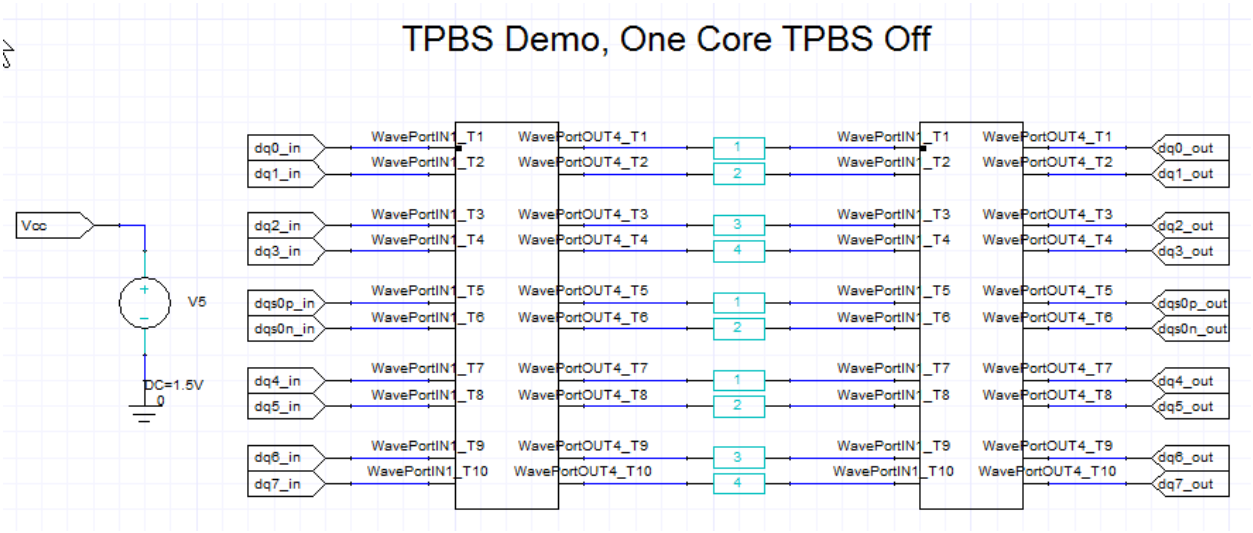
Transient parallel bus speedup operates by dividing the simulation length into equal-length overlapping windows; simulation of windows is performed in parallel. After calculating the response within each window, the overlaps are removed using an iterative error-minimizing algorithm. Due to the overhead required, transient parallel speedup should be used only for bit-pattern problems requiring from a few hundred to millions of bits to determine. As shown in this demonstration, TPBS can achieve a significant speedup of a transient simulation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To run this example, your computer system must have an HPC license and at least four CPU cores. Parallel speedup also requires at least 20GB of free memory, 30GB recommended.

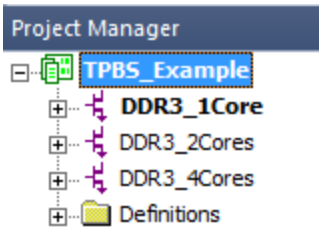
Open the project from its file in the Examples directory.

1. From the **File** menu, select **Open Examples** to open an explorer window.
2. Open the **Electronics Desktop** directory, then **Circuit**, then **Signal_Integrity**, then select the file **TPBS_Example.aedt**. Click **Open**.



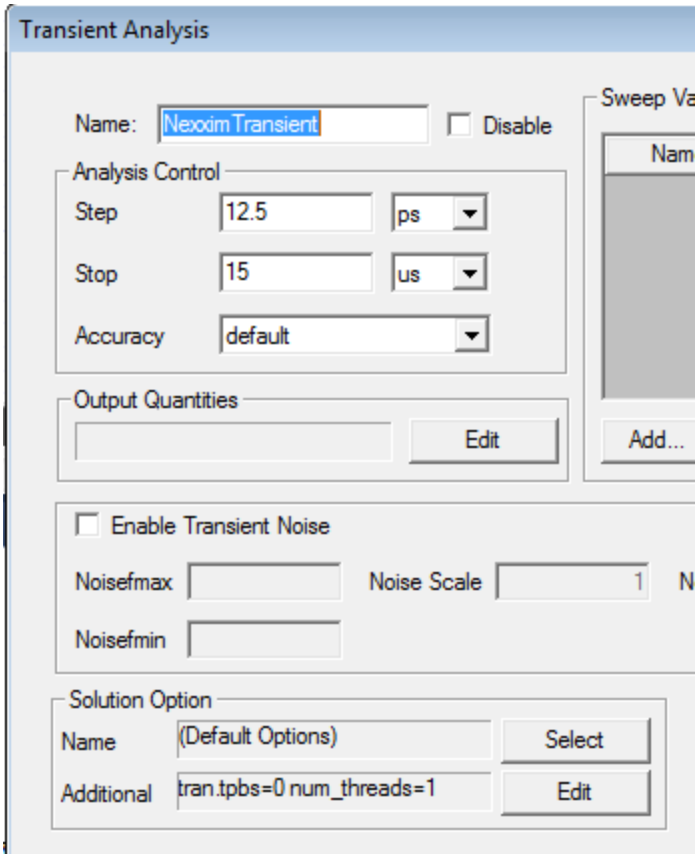
The demonstration uses three identical copies of the DDR3 project to provide a large-scale transient simulation. This does not represent a typical application for TPBS, but it serves as a demonstration.

There are three projects:



3. Expand the **DDR3_1Core** project. Expand the **Analysis** icon and double-click the **NexximTransien** t setup to open it:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The transient analysis runs for 15µs with a maximum step size of 12.5ps.

In the **Solution Options** group box, the **Additional** options have been set to:

```
tran.tpbs=0 num_threads=1
```

This turns TPBS off and sets Nexxim to run with one core, locally to this transient analysis.

4. Click **OK** to close the Transient Analysis window.
5. Right-click the **NexximTransient** setup and select **Force Analysis**. With one core, the analysis takes nearly 20 minutes.
6. When the analysis is complete, scroll the **Message Manager** to locate the entry **TRAN_cpu_time**:

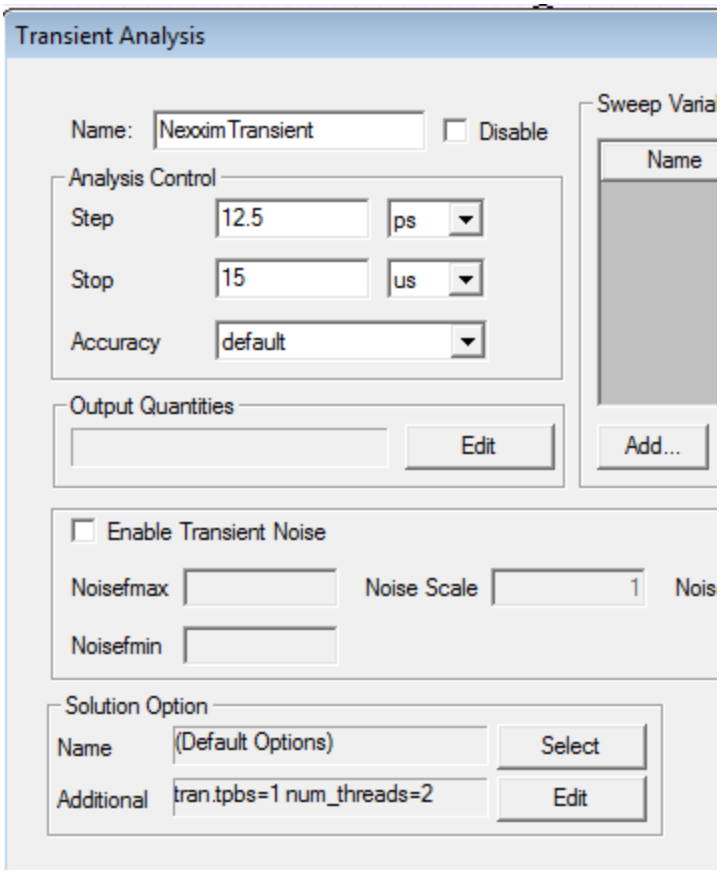
```
(info): Simulation succeeded. Total simulator time: 0:18:39 (11:42:10
AM  Apr 27, 2017)
```

With one core, the transient analysis took 18 minutes, 34 seconds.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Now let us see what TPBS can do for us. (Note: the analysis times you obtain may differ in magnitude from machine to machine, but the relative improvements in time with TPBS should be very similar.)

1. From the **Project Manager** window, open the project **DDR3_2Cores**.
2. The only difference is in the **NexximTransient** setup.
3. Expand the **Analysis** icon and double-click the **NexximTransient** setup to open it:



Now, the option tran.tpbs=1 turns on transient parallel bus speedup, and num_threads=2 requests two cores.

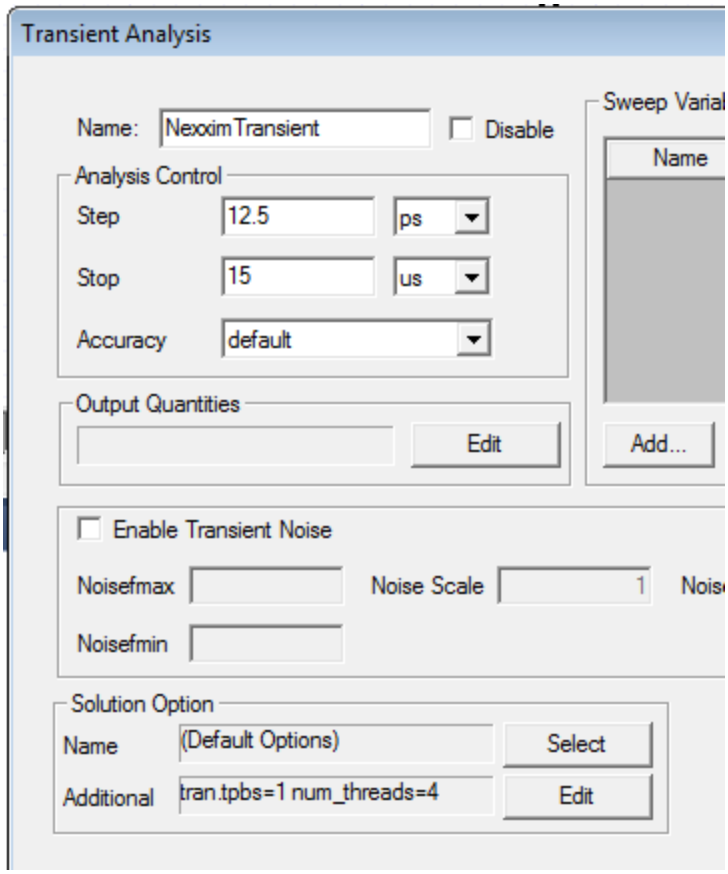
4. Right-click the **NexximTransient** setup and select **Force Analysis**. With two cores, the analysis takes about 10 minutes.
5. When the analysis is complete, scroll the **Message Manager** to locate the entry **TRAN_cpu_time**:

```
(info): Simulation succeeded. Total simulator time: 0:09:47 (11:52:57
AM  Apr 27, 2017)
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The CPU time of 9 minutes, 47 seconds with TPBS and two cores is a speedup of nearly 2x over the one core time. Now let us see what four cores can do.

1. From the **Project Manager** window, open the project **DDR3_4Cores**.
2. The only difference again is in the **NexximTransient** setup.
3. Expand the **Analysis** icon and double-click the **NexximTransient** setup to open it:



Now, the option tran.tpbs=1 turns on transient parallel bus speedup, and num_threads=4 requests four cores.

4. Right-click the **NexximTransient** setup and select **Force Analysis**. With four cores, the analysis takes about 5 minutes.
5. When the analysis is complete, scroll the **Message Manager** to locate the entry **TRAN_cpu_time**:

```
(info): Simulation succeeded. Total simulator time: 0:05:00
(11:58:46 AM  Apr 27, 2017)
```

TPBS with four cores completes in about 5 minutes, nearly twice the performance of two cores, and nearly 4x the speed for one core.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. If appropriate, Click the **File>Save As ...** menu item to save the demonstration.

For this demonstration, TPBS was enabled for each transient simulation setup. More commonly, TPBS is enabled for all transient simulations, using the Global Analysis Options window. For more information, see Transient Parallel Bus Speedup in the Circuit Time Domain topic.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

22 - Circuit and Layout Definition Libraries

This topic describes how to configure and manage **Electronics Desktop** definition libraries. You can use these topics to create and edit circuit and layout library elements.

The typical Electronics Desktop user requires these library tools only rarely. The Desktop automates the creation of many kinds of components. This topic covers only the operations needed to create and maintain components like the built-in Nexxim and EM design components.

- For information on creating component models, see Circuit and Layout Import and Export Operations.
- For information on creating components to be simulated via dynamic links and Solver on Demand, see Co-simulation.
- For information on creating and modifying substrates for use by the layout field solvers, see the *Nexxim Component Models* topics for each kind of distributed element (coplanar waveguide, grounded coplanar waveguide, microstrip, offset stripline, rectangular waveguide, slotline, stripline, and suspended stripline).

Working with Definition Libraries

In Electronics Desktop, a component is a object placed in a design to be solved. Built-in Ansys components contain netlist and footprint information representing the native circuit and EM solver models. Other components can reference external models using frequency-dependent network data or other model formats.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The definition of a built-in component contains parameter data to pass to the solvers. The component definition also references separately stored data for the schematic symbol, fabrication material, layout footprint, and layer stackup definitions. These component dependencies are stored as objects in their own definition libraries.

System, User, and Personal Library Directories

The stock library files that ship with Electronics Desktop are stored under the **syslib** directory. These libraries are intended to be read-only and should not be modified.

In addition to the system libraries, Electronics Desktop recognizes two user-configurable library structures, called the **User Library** and the **Personal Library**. These are used to add foundry support, user-defined models, and any custom or proprietary sets of components or simulation models. Customarily, **userlib** is a network repository for proprietary or corporate definitions available to all seats in an enterprise. **personalLib** contains project and circuit-specific libraries as needed by individual designs.

A root library directory is set up at installation. If none is specified, the default is the root Electronics Desktop directory.

Changing the Locations of Libraries

You can relocate the base library directory to a new valid library location. To specify a new library directory:

1. Click **Tools** > **Options** > **General Options**.
2. In the **Directories** group in the **Project Options** tab, type the new folder location in the **Library Directory** group box, or click **Browse ...** to specify it.
3. Click **OK**.

To return the library directory specification to its default value, click **Reset Library Directory**.

The personal library (**PersonalLib**) folder is located at **<Project Directory>\PersonalLib**, where **<Project Directory>** is the location you specified for your Electronics Desktop projects. To specify a new location for the **PersonalLib** folder, you must specify a new project directory location. To do this:

1. From the **Tools** menu, select **Options** > **General Options...**.
2. In the **Directories** group in the **Project Options** tab, type the new folder location in the **Project Directory** group box, or click **Browse ...** to specify it.
3. Click **OK**.

Library and Project Definitions

In Electronics Desktop, library component definitions are intended to be accessed once per component — when you place the first instance of a component onto a schematic. After it is

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

placed in a schematic, the definition for the component transfers on the library to the project file. Editing and updating a component definition is then controlled on the *project definition*, which is listed in the **Components** folder in the **Project Manager** window. In other words, you do not edit component definitions in the library, but in the project. If you want your edits to be reflected in the library definition (for use in another design) you must export the edited components to a component library.

Once a definition is used, it is transferred to the current project, and remains in the project unless it is explicitly removed. To see the definitions included in a project, expand its **Definition** folders and subfolders in the **Project Manager** window:

Modifying component and dependency definitions in libraries, or installing libraries with modified component and dependency definitions, does not automatically update those definitions in projects that contain them. To update project definitions from library definitions, see Updating Project Definitions from Library Definitions.

Updating Project Definitions from Library Definitions

Once a library component is placed into a design, the parent component definition resides in the project, and the link to the library is broken. To update a project component definition with a definition from a library file, select the project you want to update in the **Project Manager** window, then click **Project Tools** > **Update Definitions** on the **Tools** menu.

The **Update Definitions** window opens, listing any library definitions that have been edited since they are added to the project, and their original library locations. Use the window to select the item to update, and click **Update** to finish.

If you wish to remove project definitions that are unused, choose the **Project Tools** > **Remove Unused Definitions** command on the **Tools** menu which opens the Unused Definitions window.

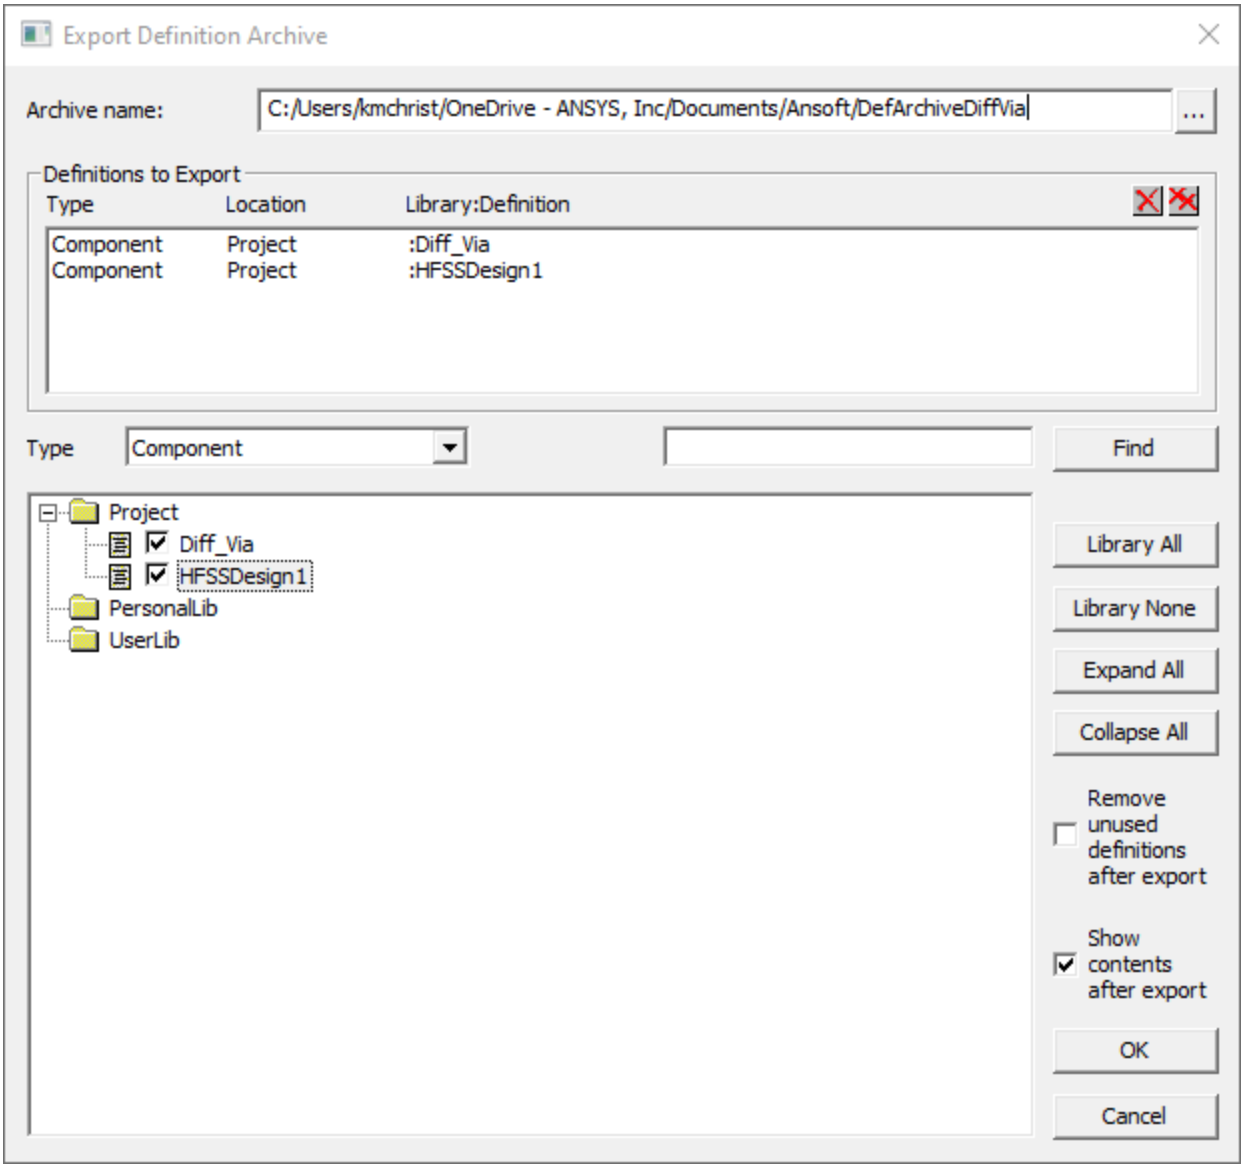
Exporting and Importing Definition Archives

The Import and Export Definition Archive commands allow you to select individual component, model, or other library definitions – or even entire libraries – to package and send to another user. Referenced definitions, data files, and DLLs are included automatically. All selected definitions (either those in an entire library or those selected separately) is written to one set of libraries (e.g., a component library and associated symbol and model libraries).

Exporting Definition Archives

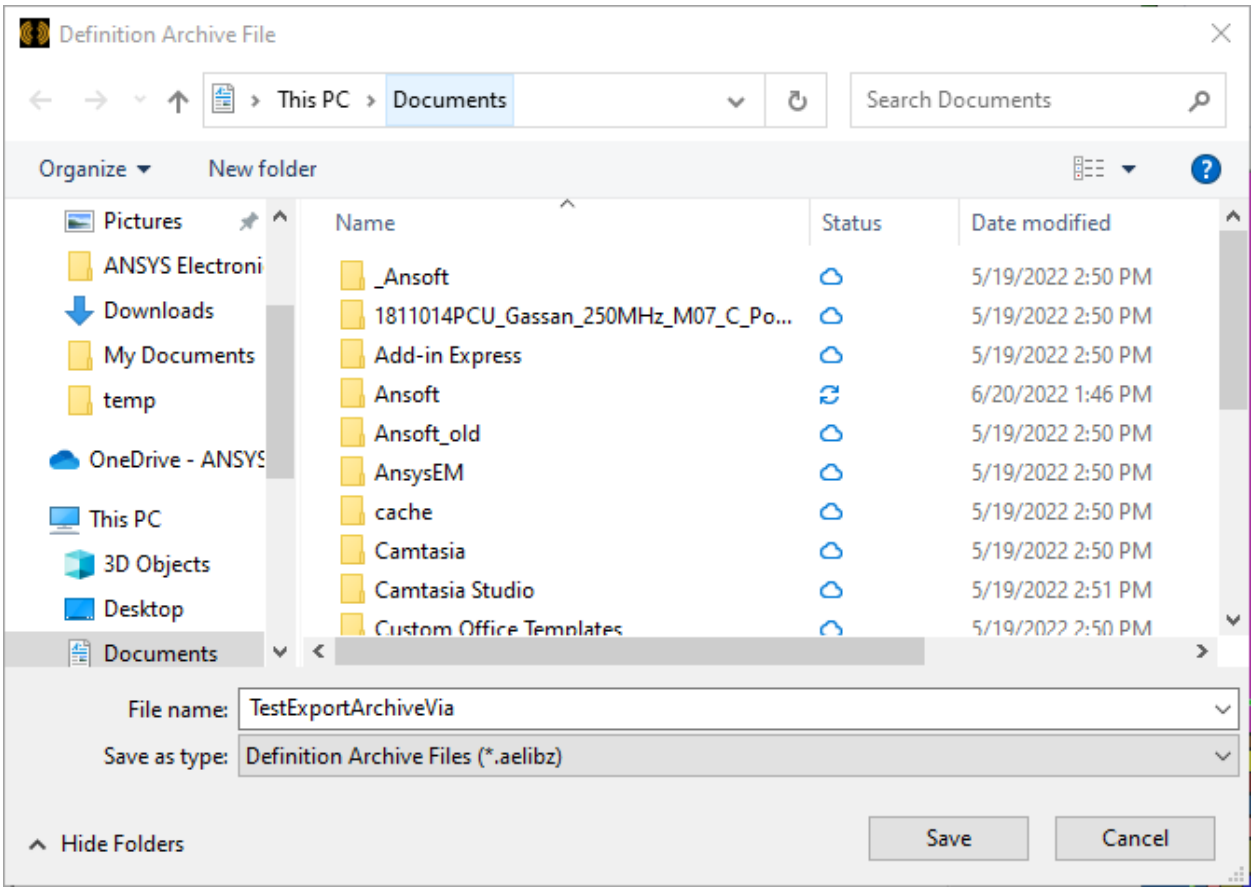
Select **Tools** > **Library Tools** > **Export Definition Archive** to open the **Export Definition Archive** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- To export a definition archive, first choose an archive name, either by typing the full filename in to the **Archive name** edit field, or by using the **[...]** button. This button opens a browser window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- The archive name must have a Definition Archive Files **.aelibz** extension, which is supplied by the window.

Note: An **.aelibz** archive is not readable with utilities such as WinZip®.

- The definitions selected for export are listed in the **Definitions to Export** listbox. Click the and buttons to delete selected entries, or all entries, respectively.
- The **Type** dropdown menu on the left, under the list of **Definitions to Export** controls which libraries are shown in the tree under it. Choices include: **Component**, **Symbol**, **Model**, **Package**, **Material**, and **Script**. In the tree, each leaf element (definition) has an associated check box. Checking the box adds the definition to the export list above. Clearing the box removes the definition on the export list. With a library or library element node highlighted, a user can select all definitions in that library for export by clicking **Library All**. Similarly, the user can unselect all definitions in the selected library by clicking **Library None**. **Expand All** and **Collapse All** expand or collapse the entire tree.
- Typing a string into the field next to the **Find** button allows the user to scroll to the first definition whose name matches the string. Searches are not case-sensitive. You can also use the “wildcard” asterisk character in search strings. For example: entering P* should

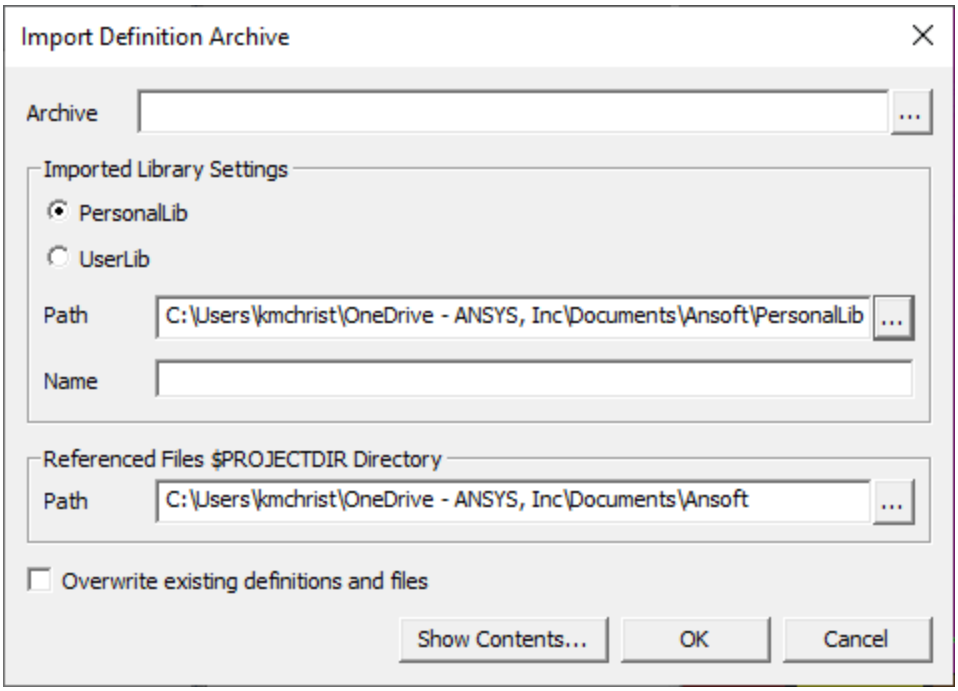
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

find, in succession, every component that starts with P (or p). Use multiple asterisks to further control matches (e.g., type *p* to find any definition with a 'p' in it, including as a first or last character; or *p*p* to find "pipe" and "pump", et cetera).

- The **Remove unused definitions after export** check box allows the user to clean up the current project after export is complete.
- When the **Show contents after export** box is checked, a **Contents** window shows a list of what was saved to the archive. This list may include multiple libraries (due to definition references) or external file references. Save the list to a file by clicking **Save , or** click **Done** when you are finished viewing.
- Click **OK** to complete the process. The selected definitions, libraries, and referenced files are zipped, and given a Definition Archive FIles extension, **.aelibz**. Users can then e-mail or otherwise transfer the archive file to others. The archive file is not encrypted, though models and packages contained in it may be.

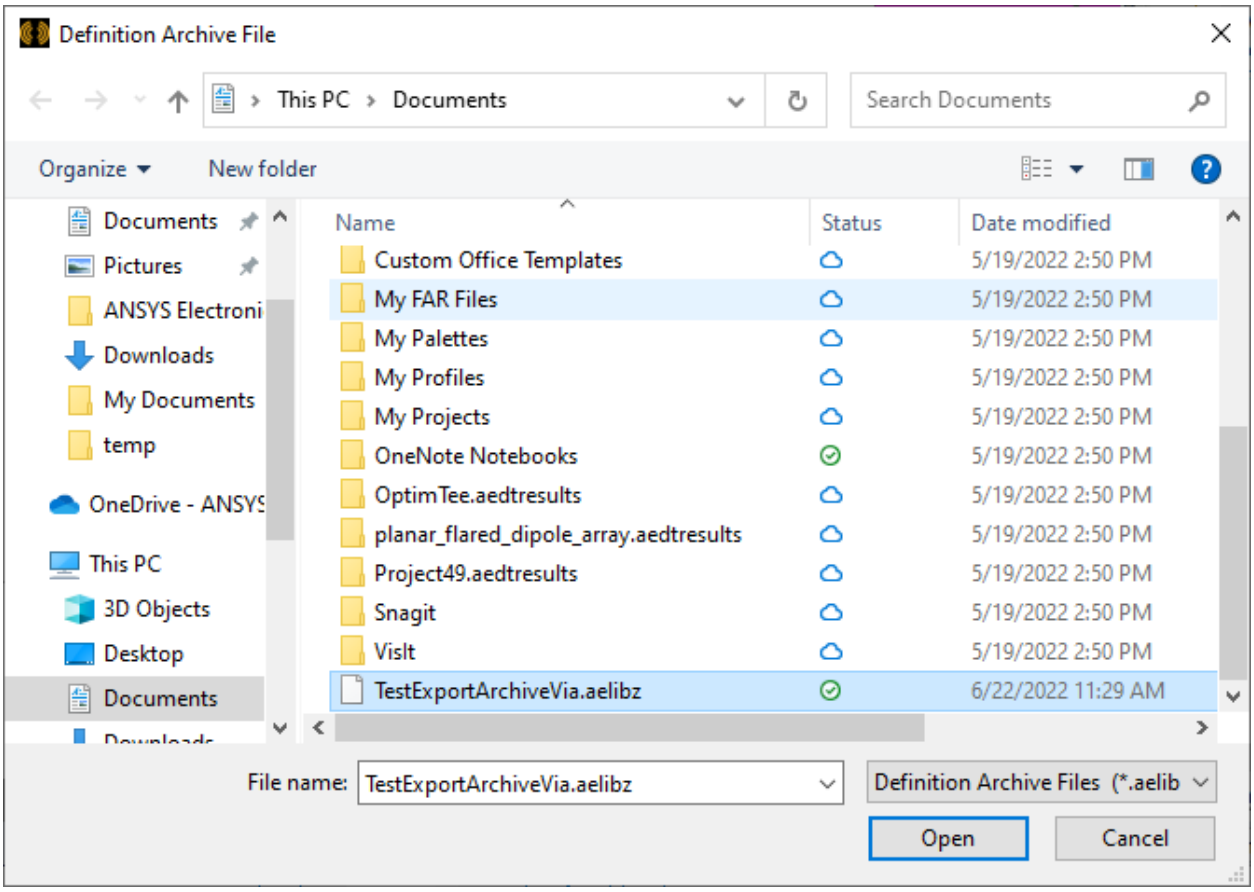
Importing Definition Archives

To import a definition archive, choose **Tools** > **Library Tools** > **Import Definition Archive** to open the **Import Definition Archive** window.



- First select a definition archive either by typing the path and definition archive file name in the **Archive** field, or click **[...]** to browse for the Definition Archive File created using the **Tools** > **Export Definition Archive** command.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- In the **Imported Library Settings** group box, click **PersonalLib** or **UserLib** to choose the basic location for the imported archive. If appropriate, the user can further choose a subdirectory **Path** under **PersonalLib** or **UserLib** as a location for the libraries. The user can also enter a **Name** for the imported libraries. The default name is the base name of the archive file.
- On import, data files is moved to appropriate **bin** and **data** directories. External **Referenced Files** that are not appropriate to **bin** and **data** library directories is referenced using **$PROJECTDIR**. The user can click the **[...]** button to choose the directory for these files. The default is the Project Directory specified in **Tools** > **Options** > **General Options**.
- The **Overwrite existing definitions and files** check box (unchecked by default) allows the user to replace current definitions and files with archive elements, permissions allowing.
- Click **Show contents** to view a window showing a list of what is in the archive. This list may include multiple libraries (due to definition references) or external file references. Save the list to a file by clicking **Save**, or click **Done** when you are finished viewing.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Managing Library Files

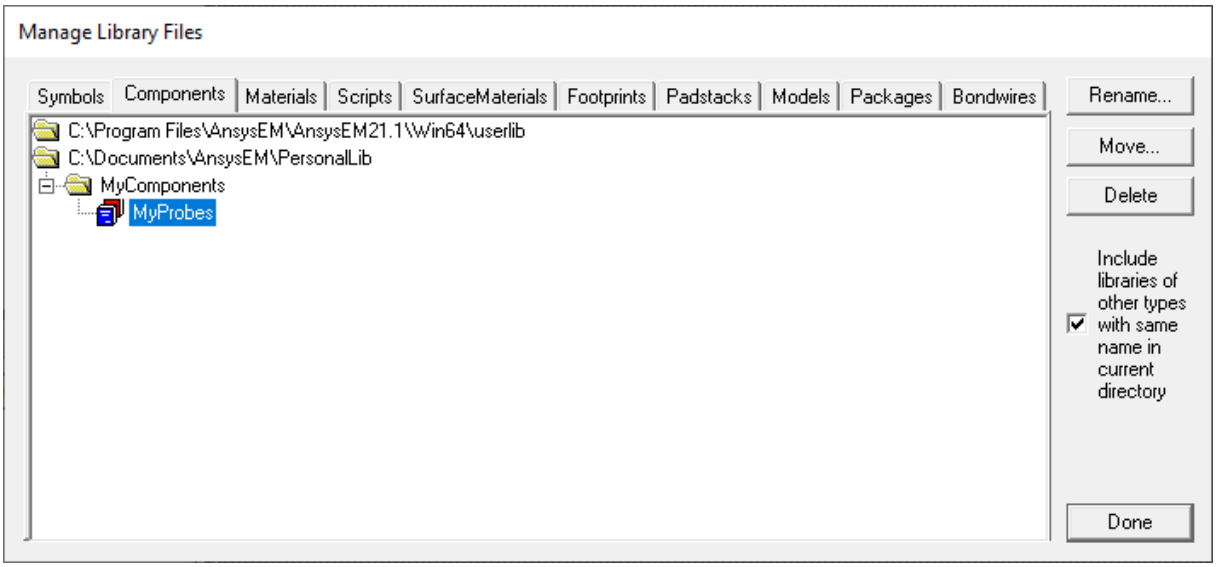
You can use **Manage Files** to change the names of libraries in the UserLib and PersonalLib directories; move libraries to another location in the directories specified for UserLib or PersonalLib, or delete libraries. You can also change the names of sub-directories of the UserLib and PersonalLib directories, move directories to another location in the directories specified for UserLib or PersonalLib, or delete directories.

> **Note:**
>
> - You cannot move libraries out of the UserLib or PersonalLib hierarchies.
> - To move a library or directory to a subfolder, that subfolder must already exist.

Components and other definitions in libraries directly affected by an action which See definitions changing library name or location has those references adjusted. Definitions in libraries indirectly affected– that is, those not having their names or locations modified by an action–with references to definitions in directly affected libraries are updated.

To manage library files:

1. Click **Tools** > **Library Tools** > **Manage Files**. The **Manage Library Files** window opens on the Components tab. The **Manage Library Files** window opens on the Components tab. There is a tab for each library type: Symbols, Components, Materials, Scripts, Surface Materials, Footprints, Padstacks, Models, Packages, and Bondwires.



2. Click the tab you want.
3. Select an individual library or a directory on which you want to perform the action.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click **Rename**, **Move**, and **Delete**, as necessary.
5. Select the **Include libraries of other types with same name in current directory** check box to cause the action to be performed on other types with the same name in the same directory. For example, if you select “MyProbes” on the Components tab, the action is extended to a symbol library called “MyProbes.aslb” in the same directory.
6. Click **Done** when finished managing libraries.

Library Search Precedence

When you place a new component in a design, Electronics Desktop searches in the current project for a definition with the corresponding name. If an appropriate definition exists in the project, that definition is used to satisfy the placement *regardless of whether additional instances, even more recent ones, may exist in external libraries.*

If Electronics Desktop cannot locate the required definitions in the project, it searches in personal (**PersonalLib**), user (**userlib**), and system (**syslib**) library files, *in that order*. Once a definition of the correct name has been located, the search ends, and that definition is used to satisfy the placement request.

Component Creation Sequence

Every component definition uses an associated bitmap (for the **Project Manager** window icon) and a schematic symbol. Many components also require footprints, which in turn depend on material definitions and padstacks to characterize their physical presence in and electrical connections to a layout.

To save time in editing or creating new components, you should identify and modify or create its dependent elements in the following sequence as you define your component. All of the dependencies listed may not be necessary for every component you create or modify.

Materials

Material information defines the physical properties of a substance — such as substrate, metallization, or solder mask layer — for its inclusion in a *stackup*, the physical foundation of a manufacturable layout or model. Material definitions are stored in library files with the extension **.amat**. See Using the Material Editor for how to create and modify materials.

Layers

The substrate technology defines the name and parameters of the layout stackup to use for all distributed elements in the design. You create or define a substrate type by clicking **Circuit>Add Reference Data>Add Substrate Definition**. You can view and modify the current layout stackup by clicking **Schematic>LayourStackup**.

Padstacks

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A padstack defines the physical structure and electrical connectivity of a *pad*, the region where a component pin connects to a copper trace. A padstack must be associated with each pin of a component. Padstack definitions are stored in library files with an extension of **.pslb**. See Using the Padstack Editor for how to create and modify padstacks.

Footprints

A footprint defines the planar space consumption, physical orientation, metal usage, and electrical connectivity of a component in a layout. Footprint definitions are stored in library files with the extension **.aflb**. See Using the Footprint Editor for how to create and modify footprints.

Symbols

A symbol is graphical representation of a component in a schematic. Symbol definitions are stored in library files with the extension **.aslb**. See Using the Symbol Editor for how to create and modify symbols.

Bitmaps

A bitmap is a small picture that is displayed when the ACLB containing the component is opened in the schematic editor. Bitmaps are stored in syslib\Bitmaps*.bmp. To create or modify a bitmap, use a bitmap editor such as MS Paint(r).

Components

The Electronics Desktop **Component Editor** supports the viewing, modification, and saving of information for component elements and graphical primitives. After creating or modifying a component, the information can be saved, used to render a component, or exported. Component definitions are stored in library files with an extension of **.asty**. See Using the Component Editor for how to create and modify components.

Scripts

The Electronics Desktop **Script Editor** supports the viewing, modification, and saving of script file information for footprint elements and graphical primitives. After modifying a script, the information can be saved, used to render a footprint, or exported. Script definitions are stored in library files with an extension of **.dsc**. See Using the Script Editor for how to create and modify scripts.

Using the Library Editor

The Electronics Desktop **Library Editor**, also called the **Edit Libraries** window, allows you to access, manage, save, and control the contents of various development libraries which contain information and properties for the following design entities:

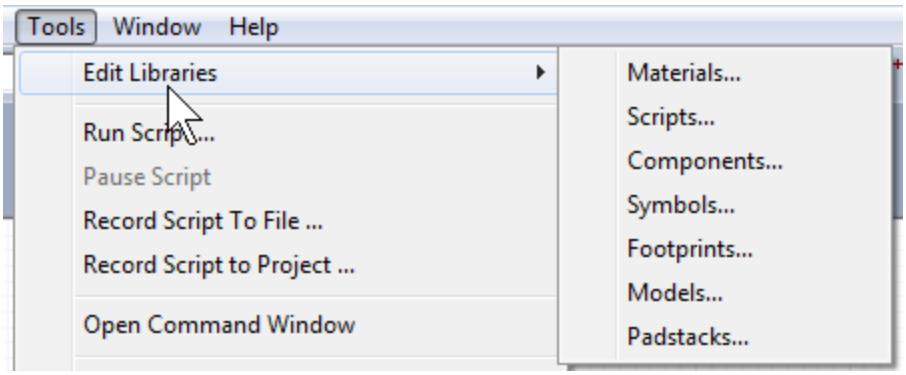
- Materials
- Scripts
- Components

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

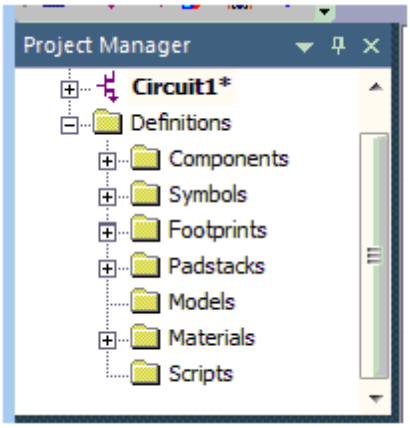
- Symbols
- Footprints
- Models
- Padstacks

Starting the Library Editor

To start the **Library Editor**, select **Tools** > **Edit Libraries**, then select the type of library you wish to access on the following menu:



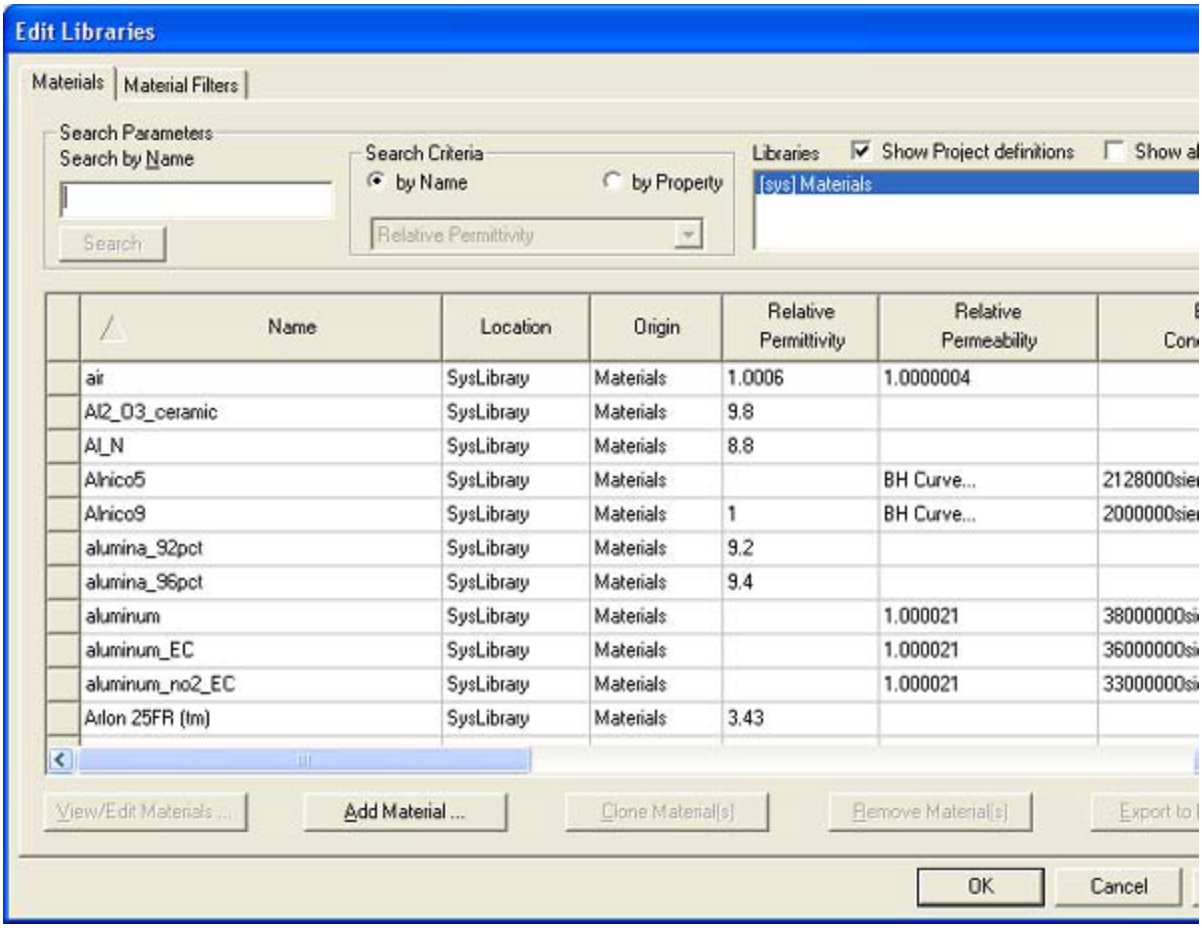
You may also right-click any of the folders listed in the **Definitions** directory of the **Project Tree** in the **Project Manager** window, then select **Edit Library**.



Edit Libraries Window

After choosing a library to edit, the **Edit Libraries** window opens with a tab open to the library you selected, such as the **Materials Browser**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Edit Libraries** browser searches library objects using filters based on a number of attributes:

- Name
- Property
- Model type

You can customize the **Edit Libraries** window by clicking **Show Project definitions** and **Show all libraries** (to override filtering).

The following **Edit Libraries** browser controls are available:

- **Edit** – Edits properties/attributes for the selected object. The resulting object can have the same name as the original, but it is saved to the current project, rather than back to the library. In effect, you have “checked out” the part in order to edit it. If you want to write it back to the library and overwrite the original part, use **Export to Library**.
- **Add** – Creates a new object in the selected library.
- **Clone** – Creates a copy of a selected object with a different name in the selected library.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Remove** – Removes an object on the library
- **Export** – Exports edited objects from a project to a library, or exports selected objects from one library to another. If the component you are exporting is hierarchical, after you click to **Export** and specify a library name in the **Export to user library** window to open the **Export Hierarchy** window. For more information see Exporting Hierarchical Components.

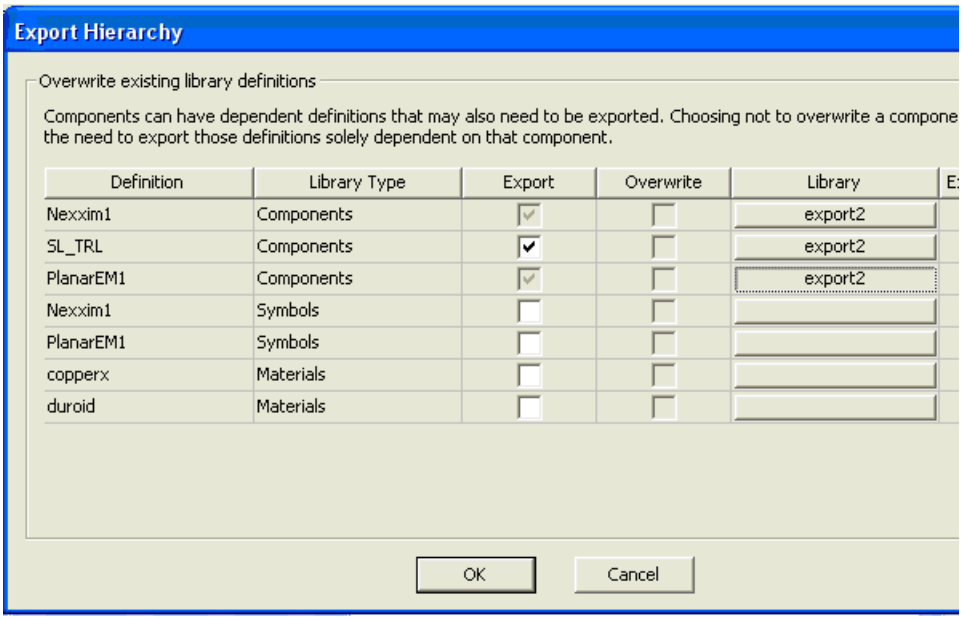
Note:

1. When you modify a library component, the modified definition is automatically transferred to the components available to the current project. In effect, you have "checked out" the component to modify it, and it is now in the project. The original library definition is intact. To update the library definition, you must do the extra step of exporting the modified component on the project to the library.
2. Subcircuits automatically inherit higher-level library configurations.
3. Project variables and project datasets used in designs represented by hierarchical components is saved to the library with the component and restored when the component is used. If the variable or dataset already exists in the project (determined by name), the library version is ignored. When creating project variables or datasets for hierarchical component designs to be saved in a library, ensure the names of the variables and datasets are appropriate and not likely to clash with those of other hierarchical components or common defaults.

Exporting Hierarchical Components

Electronics Desktop allows you to export hierarchical components, along with their solutions. Click **Export** to export a hierarchical component in the Library Editor and specify a library name in the **Export to user library** window to open the **Export Hierarchy** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- The component selected to be exported appears in the top-most row of the window. The library to which it is exported is listed beneath the **Library** column (in this example, “export2”). To select a different library to export to, click the button in the **Library** column (in this example, “export2”).
- Dependent definitions appear underneath the top-most row of the window and may also be exported. Definitions that are mandatory for export has an unavailable **Export** check box.
- You can export a component’s solution by checking its **Export** group box. At import time, the solution is re-associated with the design.
- Symbols need not be exported, they is auto-generated at import time.
- Each definition is exported as a definition in its own right. That is to say, at import time, using the above example, "Planar EM1" is visible in the "export2" library as a component independent of "Nexxim1".
- Components that originated in libraries (e.g., the "SL_TRL" component) need not be exported. At import time, each library component is retrieved from its original library and re-associated with the design.

Using the Material Editor

The Electronics Desktop **Material Editor** supports the viewing, modification, and saving of material information for substrate elements and stackup primitives. After modifying a material, the information can then be saved, used to define a design, or exported.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

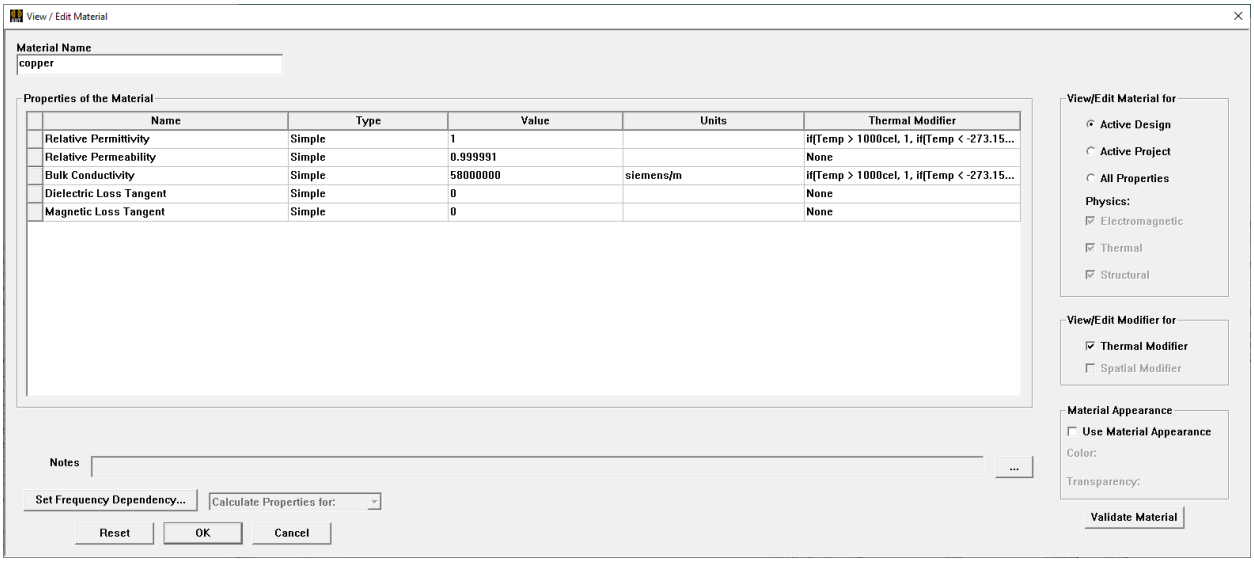
A material is a set of information that defines the physical properties of a substance — such as that used as a substrate, metallization, or solder mask layer — for its inclusion in a *stackup*, the physical foundation of a manufacturable model. Material definitions are stored in library files with an extension of **.amat**. You can access material definitions using the **Edit Material** window, also referred to as the **Material Editor**.

To start the **Material Editor**, select **Tools** > **Edit Libraries** > **Materials**. When the Edit Libraries window opens, use its controls to open the **Material Editor**.

The View / Edit Material Window

From the **View / Edit Material** window, control the property values of materials. Open the **View/Edit Material** window in one of two ways:

- From **Tools**, select **Edit Libraries** > **Materials...** to open the **Edit Libraries** window. Then search for and double-click the name of the appropriate material, or highlight the name and select **View/Edit Materials**.
- From the **Project Manager** window, expand the project tree > **Definitions** > **Materials** folder. Then right-click the appropriate material and select **Edit Material...**.



Material Name — This box sets the material name. To specify or change the name, click in the box, then type the appropriate name.

Property Headings

Name — Displays the property name. The values in this column are not editable.

Type – Displays and sets the property type (**Simple** [the default] or **Anisotropic**). To change a properties Type setting, click in the **Type** cell and select the appropriate type.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Value — Displays and sets the property value. To change a property value, click the value you want to change, then type a value or parameter name.

Units – Displays and, where applicable, sets the unit that applies to the Value entry. (For example, the unit of magnetic saturation can be set to **Gauss**, **uGauss**, **Tesla**, or **uTesla**.) To change a unit, click it, then select the appropriate unit.

Property Names

Relative Permittivity – This box sets the material relative permittivity. To specify or change the value, click in the box, then type the appropriate value.

Relative Permeability – This box sets the material relative permeability. To specify or change the value, click in the box, then type the appropriate value.

Bulk Conductivity – This box sets the material bulk conductivity. To specify or change the value, click in the box, then type the appropriate value.

Dielectric Loss Tangent — This box sets the material dielectric loss tangent. To specify or change the value, click in the box, then type the appropriate value.

Magnetic Loss Tangen t — This box sets the material magnetic loss tangent. To specify or change the value, click in the box, then type the appropriate value.

Magnetic Saturation – This box sets the material magnetic saturation. To specify or change the value, click in the box, then type the appropriate value.

Lande G Factor – This box sets the material Lande G factor. To specify or change the value, click in the box, then type the appropriate value.

Delta H – This box sets the material delta H. To specify or change the value, click in the box, then type the appropriate value.

View/Edit Material For

The check boxes in this group select the Ansys product(s) for which material properties are shown.

- Active Design
- This Product
- All Products

View/Edit Modifier For

The check boxes in this group select the Ansys product(s) for which modifier properties are shown.

- Thermal Modifier

Validate Material

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Click **Validate Material** to validate the current material property values for **Electronics Desktop** product(s) checked. If validation succeeds, a green check mark appears under **Validate Now**. If validation fails, a red X appears instead, and an error message informs you of which parameter value(s) are invalid for which product(s), and why.

Set Frequency Dependency

Click **Set Frequency Dependency** to open a window that allows you to set options for the following:

- Piecewise Linear Input
- Loss Model Input
- Low-Loss Dielectric Model Input
- Enter Frequency Dependent Data Points

After you set options for any of the above, the **Value** column of the **MaterialEditor** indicates that a material's value is set to be frequency dependent, rather than set to a constant.

> **Note:** The **Set Frequency Dependency** option is available only with HFSS 3D Layout. To add a material with frequency dependence, or to edit the frequency dependence of a pre-existing material, you must first ensure that the active design selected in the **Project Tree** is an HFSS 3D Layout, otherwise **Set Frequency Dependency** is not available. For more information see Defining Frequency-Dependent Material Properties.

Material Editor window Controls

- Click **Reset** to restore all changed properties to their values prior to opening the **Material Editor**.
- Click **Cancel** to close the window without committing changes and return to the **MaterialBrowser**.
- Click **OK** to save changes and return to the **MaterialBrowser**.

For more information see Viewing and Modifying Material Attributes.

> **Note:** If you like the changes you have made in a material to be available for use in other projects, you must export the material to a library as described in the Edit Libraries window topic.

Editing an Existing Material

To edit an existing material, display its properties in the Edit Material window by doing either of the following:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Open the **Material Browser** by clicking **Tools > Edit Libraries > Materials**, then search for and select the material you want to edit, and either double-click its name or click **View/Edit Materials**.
- In the **Definitions** /**Materials** subfolder of the **Project Tree**, locate the icon for the material you want to edit, then either double-click the icon or right-click it and select **EditMaterial**.

The Edit Material window opens (also called the **Material Editor**).

Creating a New Material

To create a new material, first open the **Material Browser** by clicking **Tools > Edit Libraries > Materials**, then do either of the following:

- Click **Add Material**. The Edit Material window opens (also called the **Material Editor**).
- Locate and select an existing material definition on which to base the new definition, then click **Clone Material(s)**. The selected definition is copied under a new name. To edit the new material, double-click its name to open the Edit Material window (also called the **Material Editor**).

Using the Models Editor

1. To open the window for a model library, click **Tools** > **Edit Libraries** > **Models**. The **Edit Libraries** window opens on the **Models** tab.
2. From the **Models** tab, Click the **Libraries** scrolling window to select the library file for contents display. Use the buttons described to manage selected library objects:

- **Edit Model** - Edits properties or attributes for a selected model in the corresponding model editor. The resulting model may have the same name as the original, but it is saved to the current project, rather than back to the library. In effect, you have “checked out” the part to the project in order to edit it. If you want to write it back to the library, overwriting the original part, use **Export to Library**.

  (Click the **Show Project Definitions** check box to include current project elements in the **Edit Libraries** window display.)

  Some models - such as those that have been encoded - are not editable (button is unavailable). Encrypted models can be edited after the password has been entered to unlock it.

- **Add Model** – Creates a new model object in the selected library. The **Add Model** window allows you to name the model, and choose the model type you want to add. By default, the model is added via the appropriate model editor.
- **Clone Model(s)** – Creates a copy of selected object(s) with a different name in the selected library. Encoded models cannot be cloned (button is unavailable).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Remove Model(s)** – Removes selected object(s) on the library. System library models cannot be removed (button is unavailable).
- **Export to Library** – Exports a selected object to a different library. (Use also to export edited objects from the project to the library if necessary.) System library models cannot be exported (button is unavailable).

3. When finished, click **OK** to close the **Edit Libraries** window box.

Using the Padstack Editor

A padstack is a set of information that defines the physical structure and electrical connectivity of a pin or via (the region in which a component pin connects to a layout or a connection between layers). A padstack includes information about the layers involved in making the connection, on the size and shape of the layout area to the type and dimensions of the accompanying hole. Padstack definitions are stored in library files with an extension of **.pslb**.

The Electronics Desktop Padstack Editor supports the viewing, modification, and saving of padstack definition information for physical structure and connectivity. After modifying a padstack definition, the information can then be used to define a via or pin. Padstack definitions can be exported to library files.

To open the **Padstack Editor**, load a project and select **Tools** > **Edit Libraries** > **Padstacks**. When the Edit Libraries window opens, use its controls to open the **Padstack Editor**.

Creating a New Padstack

To create a new padstack, do one of the following:

- Select **Tools** > **Edit Libraries** > **Padstacks**, then click **Add Padstack**.

  The **Definition Name** window opens and allows you to specify the name for the new padstack.

  The **Choose Layout Technology** window opens, and you may browse for a technology file to define the original layers of the definition. If no technology file is chosen, the definition is created with initial layers named **Start, Stop, and Default** .

- Select **Tools** > **Edit Libraries** > **Padstacks**, then locate and select an existing padstack definition on which to base a new definition.

  Search for and select a padstack name and then click **Clone Padstack(s)**.

- From the **Project Manager** window, right-click the **Padstack** folder and select **Edit Library** to open the Padstack tab of the **Edit Libraries** window. Click **Add Padstack** or **Clone Padstack(s)** to open the **Edit Padstack Definition** window.
- In the Project Tree, right-click **Padstacks** and select **Add Definition**.

After a padstack is created, edit the padstack.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Editing a Padstack

Edit and define a padstack in the **Edit Padstack Definition** window. Open this window in one of the following ways:

- Select **Tools** > **Edit Libraries** > **Padstacks**. Find and select the padstack you want to edit, then double-click its name or click **Edit Padstack**.
- In the **Definitions** directory of the **Project Manager** window, right-click the **Padstack** folder and select **Edit Library**. Find and select the padstack you want to edit, then double-click its name or click **Edit Padstack**.
- Select a via or pin that uses the padstack. In the **Properties** window, click **Padstack Definition** to open the **Padstack Usage and Definition** window. When opened on the **Properties** window, information related to the padstack definition is highlighted in blue.

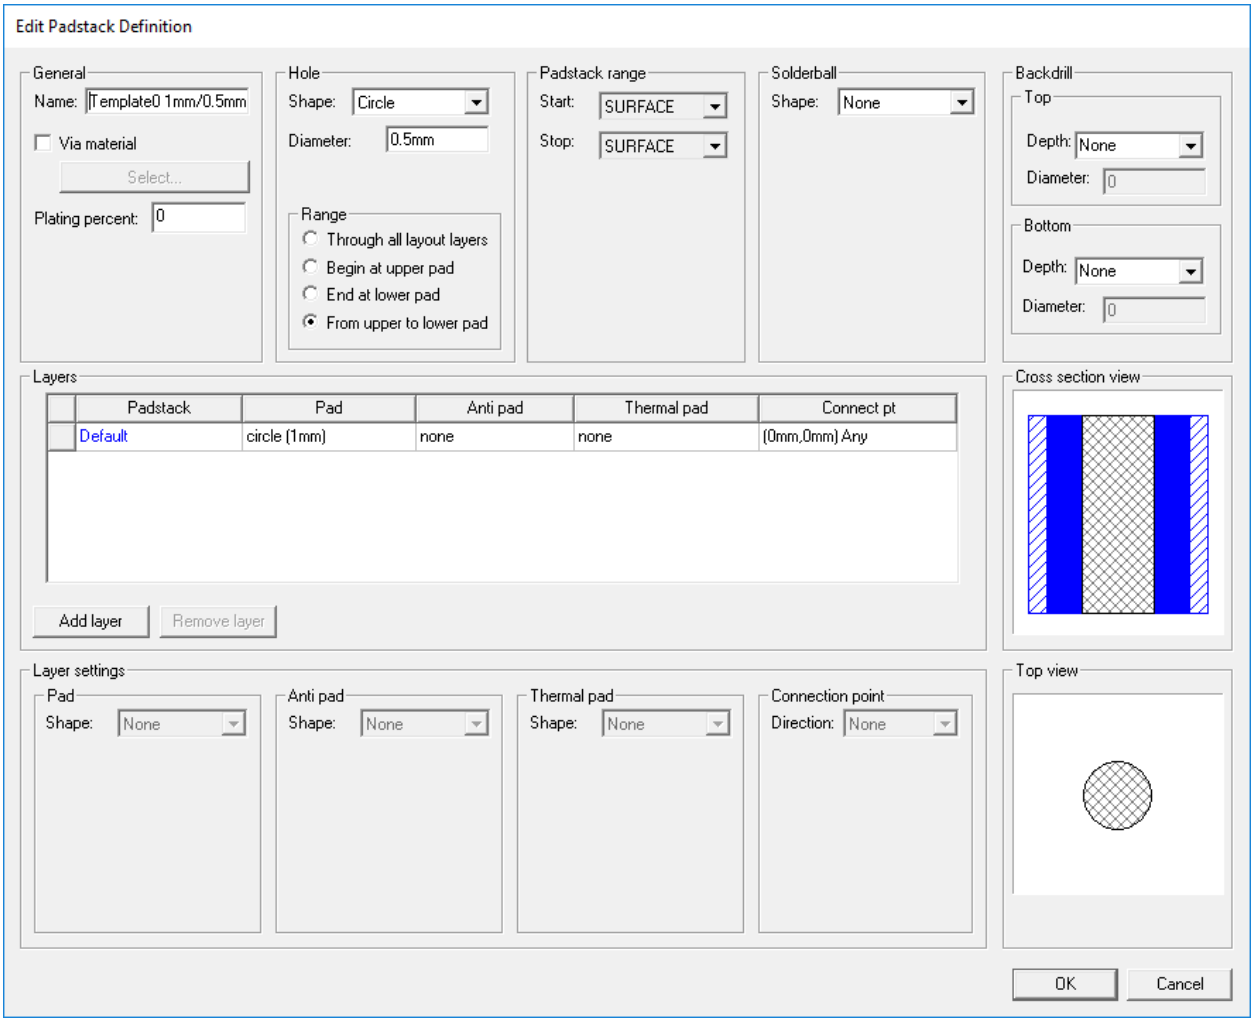


Figure 22-1 The Edit Padstack Definition window

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Important:** Some options may be unavailable or may not appear, depending upon the context and which padstack is being edited.

Options include:

General

- **Name** – the name of the padstack.
- **Via Material** – the material for plating the via or pin hole. Click **Select** to choose from available materials.
- **Plating Percent** – the percent of the hole's radius that is filled by the plating material. At 100%, plating fills the hole. The **Cross section view** and **Top view** areas show the vertical cross-section and top of the layer stackup. This setting is used by SIwave Solvers and Icepak **Electronics Desktop**.

  > **Note:** Zero plating (i.e., 0%) is not recognized and is treated as fully plated.

Hole

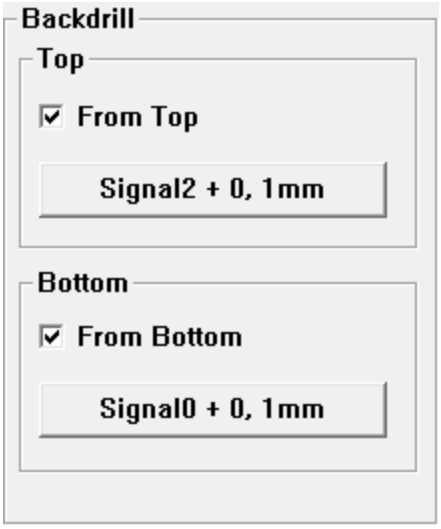
- **Shape** – choices are None, Circle, Square, Rectangle and Polygon. The Polygon choice is currently only supported for padstacks; polygon holes may not be defined through the window. Polygons can be modified by selecting a layer and clicking **Edit Polygon** to open the **Polygon Editor** . Selecting a shape enables additional options:
  - **Size / Diameter / XY Size** – specifies the size of the hole.
  - **Range** – can specify the hole range to be:
    - Through all the layout stackup layers
    - Beginning at the upper pad of the padstack and continuing to the lowest elevation of the layout stackup layers
    - Beginning at the highest elevation of the layout stackup layers and ending at the lowest pad of the padstack
    - Beginning at the upper pad and ending at the lowest pad of the padstack

Padstack Range

This area contains controls to specify the **Start** and **Stop** layers for the padstack.

Backdrill

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Backdrilling creates empty holes on one or both sides of a via. From the **Backdrill** group box, define backdrills from a selected via's top layer, bottom layer, or both. Refer to Backdrilling. Backdrills are rendered in the **Cross section view** and **Top view** group boxes as empty space. In the following script example, the backdrill is recorded as a block:

```
Array("NAME:Backdrill Top Diameter", "MustBeInt:=", false, "Value:=",
"0.4mm").
```

- **From Top** – define a backdrill that starts on the selected via's top layer. Check the adjacent box to activate or remove the check to deactivate. Click the associated button to proceed to the **Backdrill Definition** window.
- **From Bottom** – define a backdrill that starts on the selected via's bottom layer. Check the adjacent box to activate or remove the check to deactivate. Click the associated button to proceed to the **Backdrill Definition** window.

  Refer to Define Backdrill Parameters.

Solderball

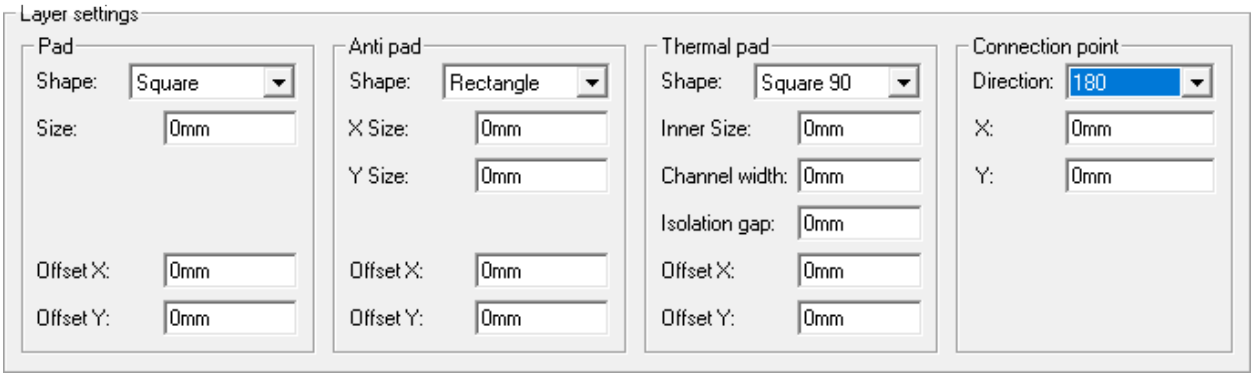
- **Shape** – specifies the shape of the solderball; choices are none, cylinder, and spheroid.
- **Diameter** – specifies the diameter of the solderball.
- **Mid diameter** – for spheroid solderballs, specifies the mid diameter.
- **Solder** – click to open the **Material Editor** for the solderball in order to specify the material used.
- **Connection** – select to specify the location of the solderball either above or below the padstack hole.

Layers

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Layer names are used when a padstack definition is used in a via or pin. A default mapping of padstack definition layers to layout layers occurs based on the layer names.

- None of the **Layers** group box grid control cells are directly editable.
- When one or more rows in the **Layers** group box is selected, the **Layer settings** group box is enabled and can be used to change the pad settings for selected rows.



- **Add Layer** inserts a new layer above the selected row.
- **Remove Layer** removes the selected row(s). You may also rearrange rows to be any order.

Layer Settings

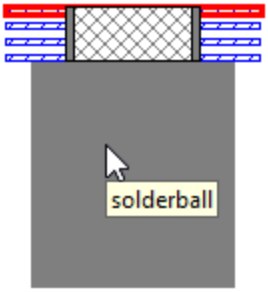
The **Layer settings** area displays pad settings for padstack definition layers. The Polygon choice is currently only supported for imported padstacks; polygon pads, anti pads, and thermal pads may not be defined through the window. Dimension controls appear to support the shape choice for each pad. Controls to specify the pad offset are also available.

- **Pad** and **Antipad** shape choices are None, Circle, Square, Rectangle, Oval, Bullet, N-Sided Polygon, and Polygon. Polygons can be modified by selecting a layer and clicking **Edit Polygon** to open the **Polygon Editor** .
- **Thermalpad** shape choices are None, Polygon, Round45, Round90, Square45, and Square90. Polygons can be modified by selecting a layer and clicking **Edit Polygon** to open the **Polygon Editor** .
- **Connection point** allows you to choose a direction in degrees or specify None. There are also controls to specify the X,Y location of the connection point.

Cross Section View

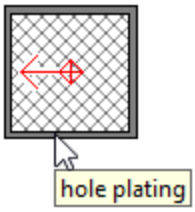
This area displays all definition layers and their pads from a side view. Selected layers are highlighted. Hover the mouse over this area to see tooltips indicating padstack components.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Top View

This area displays the pads of selected layers from a top down perspective. Hover the mouse over this area to see tooltips indicating padstack components.

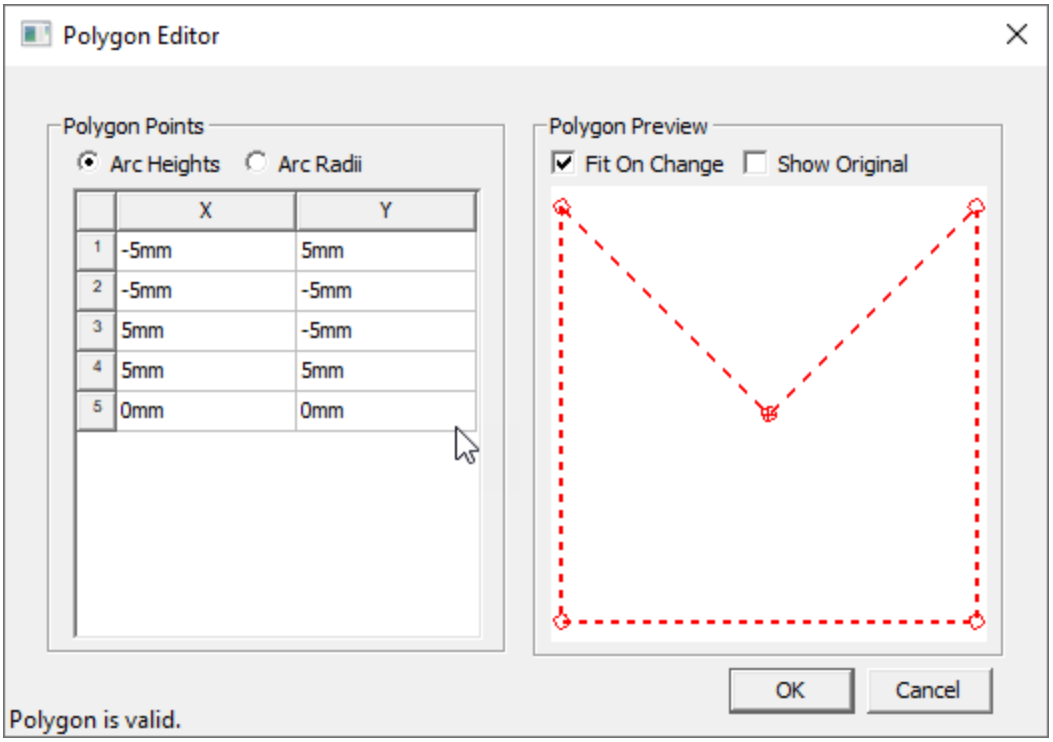


Editing a Polygon Pad

Pads, antipads, thermal pads, and holes can have polygon shapes which can be modified in the **Polygon Editor**. This editor lists the points of the polygon in a grid and displays a diagram of the polygon. The **Polygon Editor** is available on the **Edit Padstack Definition** and the **Padstack**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Usage and Definition windows.



Each row in the grid defines a vertex or an arc segment. Vertices have **X** and **Y** coordinates that are located in relation to the center point of the pad, antipad, thermal pad, or hole. The center point is marked by a plus sign (**+**) on the diagram. Enter a distance on the center point for each coordinate. Select a row to find its corresponding point in the diagram.

Arc segments are curved segments defined by three points: a beginning, end, and apex. Each arc segment must have a vertex before and after it to define its beginning and end. Thus, arc segments cannot be adjacent to one another. Each arc segments has an arc height or arc radius which can be changed in the grid.

The grid has a shortcut menu where you perform the following tasks. Different options appear depending on whether you select a row and whether you Right-click a vertex or arc segment.

- **Append Vertex** adds a new row for a vertex to the grid with the coordinates 0 mm, 0mm.
- **Insert Vertex Before** inserts a point before the current selection.
- **Insert Vertex After** inserts a point after the current selection.
- **Remove Vertex/Segment** removes the row you Right-clicked on.
- **Convert to Arc Segment** converts a vertex to an arc segment.
- **Insert Arc Segment Before** inserts an arc segment before the current selection.
- **Insert Arc Segment After** inserts an arc segment after the current selection.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The diagram displays a rendering of the polygon and the object's center point. Hover over a point to see its coordinates. Click a point to select it in the grid. Right-click the diagram to zoom in or out or to resize it to show the entire polygon. The diagram offers two options:

- **Fit On Change** redraws the diagram to fit the polygon whenever you make a change.
- **Show Original** displays an outline of the original polygon to compare it with any changes.

Edit the Polygon

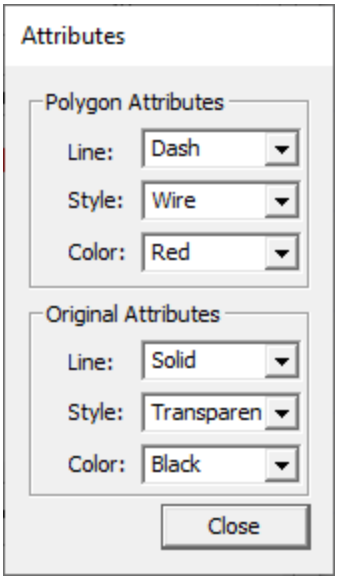
1. Add new vertices as necessary.
    a. Highlight the row of the point just before where you want to add a vertex.
    b. Right-click and choose **Insert Vertex After**. A new row appears in the grid with the coordinates 0 mm, 0mm.
    c. Enter coordinates in the **X** and **Y** columns of the new row.
2. Add new arc segments as necessary.
    a. Highlight the row of the point just before where you want to add an arc segment.
    b. Right-click and choose **Insert Arc Segment After**. A new row appears in the grid.
    c. Above the grid choose whether you want to work with **Arc Heights** or **Arc Radii**.
    d. Enter the arc height or arc radius of the new segment in the new row.
3. Remove unnecessary vertices or segments.
    a. Highlight the row of the unwanted vertex or segment.
    b. Right-click and click **Remove Vertex/Segment**.
4. Check your work in the diagram.
5. Click **OK** to close the **Polygon Editor**. The polygon appears in the **Top view** diagram of the **Edit Padstack Definition** window. The **Cross section view** diagram is unchanged.

Change how the diagram looks

Right-click the diagram and click **Show/hide attributes** to open an **Attributes** window. Here customize the lines, fill, and color of the polygon. Controls are available for both the edited

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

polygon and the original polygon if **Show Original** is enabled.



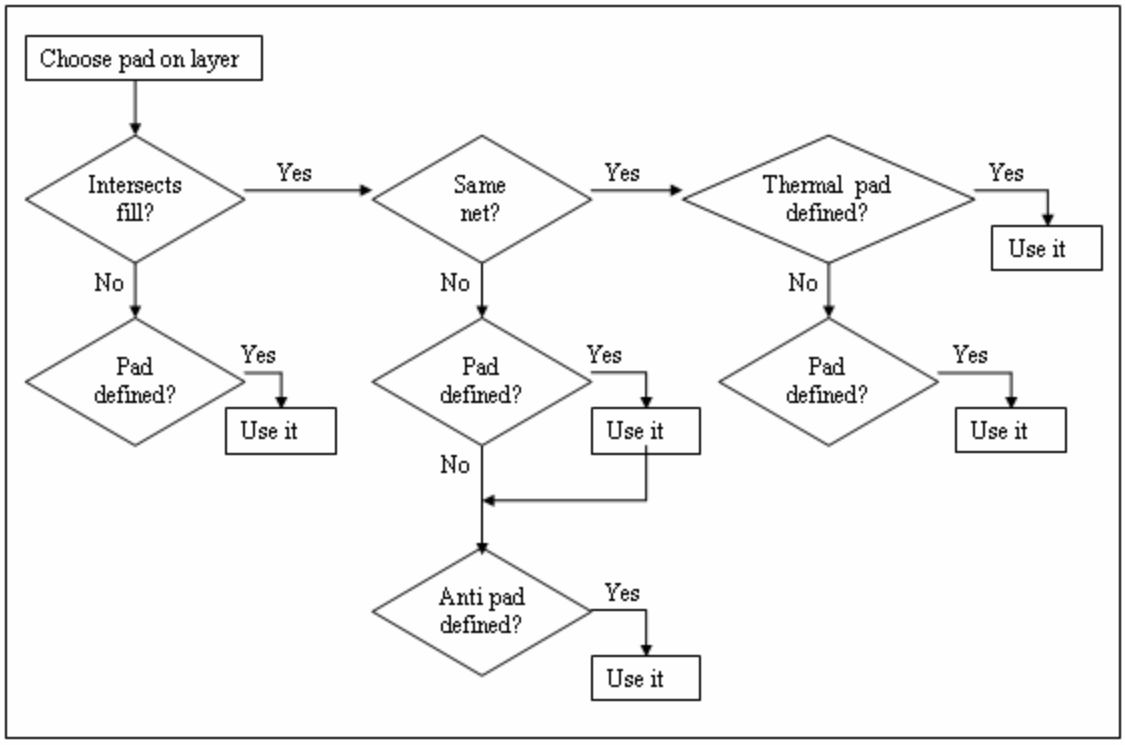
Pad Behavior in Vias and Pins

The pad(s) used in a particular via or pin are determined by the padstack definition and by the intersected primitives in their nets. Multiple pads are sometimes defined for the same layer.

- The intersection point between the central axis of a via or pin and the intersected layers is inspected to determine its metal type (fill, trace, or un-present). By definition, ground layers are fill-metal with primitives defining scratch areas.
- If a fill is intersected, the net of the fill is also taken into consideration.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Based on the intersection of the fill/net/pads that are defined in the padstack definition, the choice of pad that is used is determined using the following algorithm:



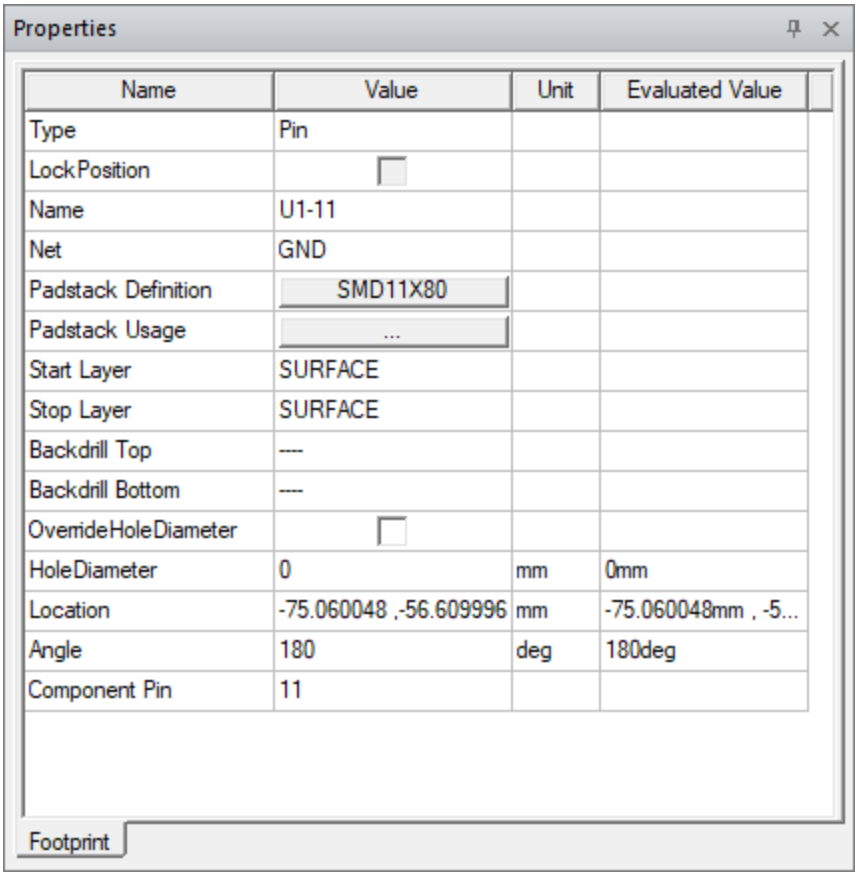
- The pad choice on the algorithm is subject to suppressing of non-functional internal pads as described in Layout Editor Options: Object Panel.

> **Note:**
>
> Anti pads subtract material on the fill area.

Editing Via and Pin Padstacks in Layout

To edit a via or pin padstack, click the via or pin to display its properties in the **Properties** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- **Name** is the name of the object.
- **Net** lists the net to which the object is assigned.
- **Override Hole Diameter** and **Hole Diameter** are used to override the diameter of the padstack definition for this particular via or pin.
- **Padstack Definition** opens the Edit Libraries window, which allows you to switch the padstack definition that is used by the via or pin.
- **Padstack Usage** opens the **Padstack Usage and Definition** window, to edit the padstack. When opened on the Properties window, information related to the padstack definition is highlighted in blue.
- **Type** determines whether the object definition is a via or pin.

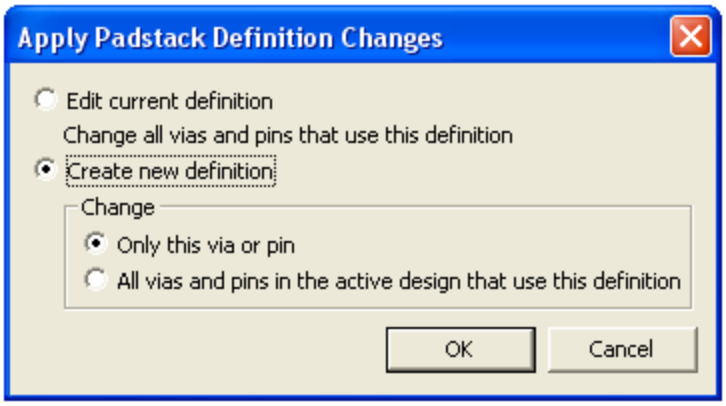
Initial Padstack Definition Layers

Special padstack definition layer names (**Start**, **Stop**, and **Default**) are provided to allow you some control over default mapping of the definition layers to stackup layers when the padstack is placed into a layout as a via or pin. Using these special layer names is optional. When a via or pin is placed, a default mapping occurs in the following order:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Any layout stackup signal layer before the start layer of the padstack or after the stop layer of the padstack does not get mapped to any definition layer.
2. Any layout stackup signal layer whose name matches a definition layer name is mapped to that definition layer.
3. If the start layer of the padstack is not yet mapped, and there is a definition layer named "Start", they are mapped.
4. If the stop layer of the padstack is not yet mapped, and there is a definition layer named "Stop", they are mapped.
5. If there is a definition layer named "Default", any remaining layout stackup signal layers are mapped to it.
6. If there are remaining layout stackup signal layers, they are mapped (in order) to the remaining definition layers.
7. Any layout stackup signal layers that are unmapped, remain that way.

When the **Padstack Usage and Definition** window is closed by clicking **OK**, you are given a choice of how to apply the definition changes that are made; the **Apply Padstack Definition Changes** window opens only if changes are made to the padstack definition (not all changes to the **Padstack Usage and Definition** window change the padstack definition).

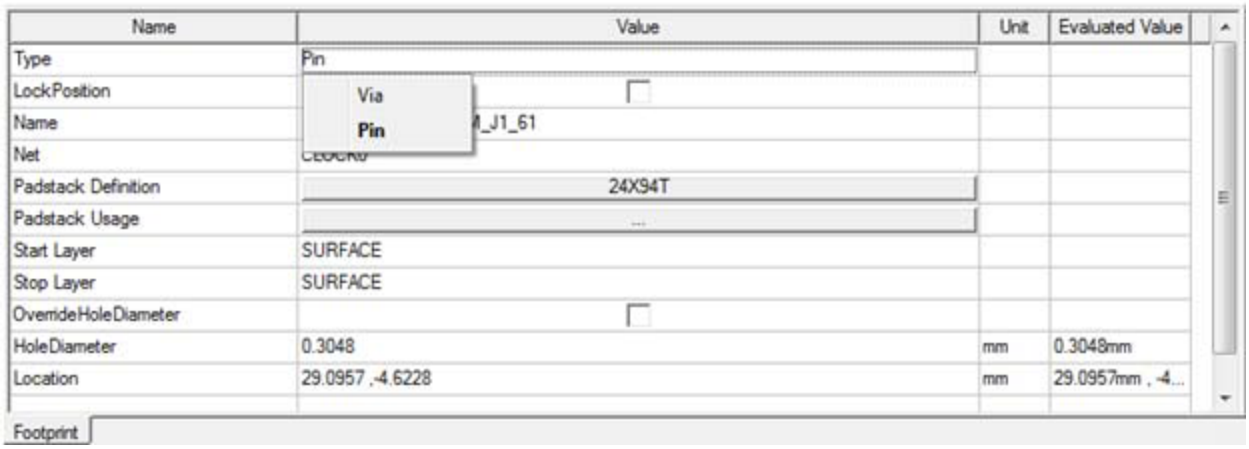


- **Edit current definition** — changes all vias and pins that use this definition
- **Create new definition** – allows you select whether the changes apply to **Only this via or pin** or whether the changes apply to **All vias and pins in the active design that use this definition** of the original padstack.

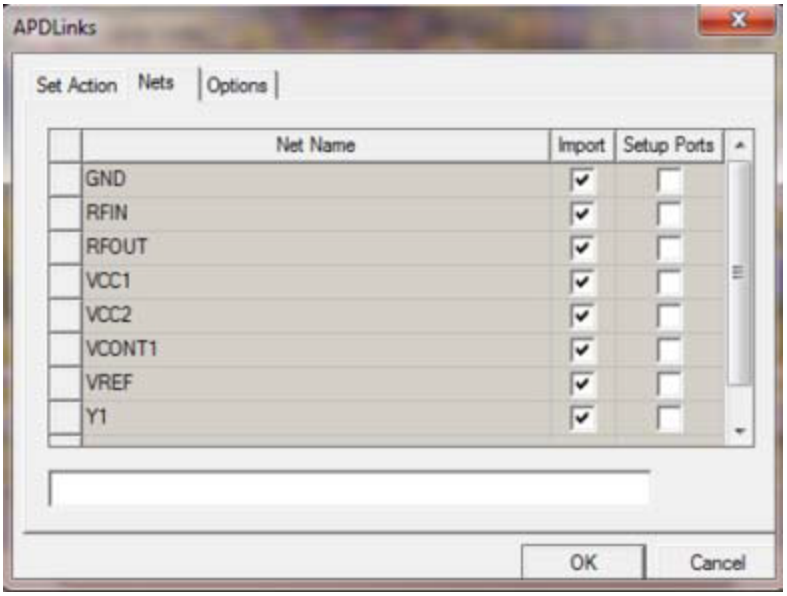
Pin and Net Padstack Operations

Padstack instances are pins or vias; either type may have an associated port. The "pin" designation does not imply that a port must be associated with the padstack. When a port is removed from a pin, the object retains its "pin" type. The type is changed through the "Type" property:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Both APDLinks and ANFV2 imports correctly retain the "pin" and "via" type for padstacks. For APDLinks, only those nets for which "Setup Port" has been selected, has associate ports with the pins.



The following commands act on pins and nets. These are accessed through the shortcut menu on the Layout tab under "Nets" and also on the right-click layout menu. See Pin and Net Padstack Operations for information about the following scripts.

AddPortsToNet

Use:

— Add ports to all the pins on the designated nets.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Command:

— In Layout, **Right-click > Port > Create Ports on Net**

— Layout tab under Nets, **Right-click > Create Ports**

RemovePortsFromNet

Use:

— Removes ports from all the pins on the designated nets.

Command:

— In Layout, **Right-click > Port > Remove Ports from Net**

— Layout tab under Nets, **Right-click > Remove Ports**

AddPortsToAllNets

Use:

— Adds ports to all the pins in all the nets.

Command:

— Layout tab under Nets, **Right-click > Create Ports**

RemovePortsFromAllNets

Use:

— Removes ports from all the pins in all the nets.

Command:

— Layout tab under Nets, **Right-click > Remove Ports**

Using the Footprint Editor

The Desktop **Footprint Editor** supports the viewing, modification, and saving of footprint information for components and layout primitives. After modifying a footprint, the information can be saved, used to define a design, or exported.

A footprint is a set of information that defines the planar space consumption, physical orientation, metal usage, and electrical connectivity of a component. Footprint definitions are stored in library files with an extension of **.aflb**. You can access material definitions using the **Footprint Editor**.

Creating or editing a footprint involves using the footprint editor to:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Draw graphical primitives, such as rectangles, circles, and arcs, using options on the Draw menu
- Add pins using the Pin option on the Draw menu
- Add text labels using the Text option on the Draw menu
- Update the current project with the new or revised footprint definition using the **Update Project** option on the **Footprint** menu

You can export a footprint to a footprint library (**.aflb**) file for use in other projects. For information on how to do this, see the Edit Libraries window topic.

Opening the Footprint Editor

You can create a new footprint definition or edit an existing footprint.

Creating a New Footprint

To create a new footprint, do one of the following:

- Open the **Tools > Edit Libraries > Footprints** window, then click **Add Footprint**.

  — The **Definition Name** window opens and allows you to specify the name for the new footprint.

  — Type a name for the footprint into the **Enter the name for this new Footprint** group box, then click **OK** or press **Enter**. The **Choose Technology** window opens and allows you to specify the original layers of the definition

  — Double-click the entry for the new footprint, or click **Edit Footprint**.

- Select **Add Definition** on the right-click menu in the **Footprints** folder of the **Project Manager** window.

  — The **Definition Name** window opens and allows you to specify the name for the new footprint.

  — Type a name for the footprint into the **Enter the name for this new Footprint** group box, then click **OK** or press **Enter**. The **Choose Technology** window opens and allows you to specify the original layers of the definition

- Open the **Tools > Edit Libraries > Footprints** window, then locate and select an existing footprint on which to base your new footprint.

  — Click **Clone Footprint(s)** to open the **Get Name** window.

  — Type a name for the new footprint into the **Enter the name for this new Footprint** group box, then click **OK** or press **Enter**.

  — Double-click the entry for the new footprint, or click **Edit Footprint** to open the **Footprint Editor**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Editing an Existing Footprint

To edit an existing footprint, do one of the following:

- From the **Project Manager** window, expand the **Definitions** /**Footprints** subfolder for the project that contains the footprint you want to edit. Double-click the entry for the footprint you want to edit, or right-click the entry and select **Edit Footprint**.
- Open the **Tools > Edit Libraries > Footprints** window, then locate and select the Project version of the footprint that you want to edit. Click **Edit Footprint**, or double-click the selected entry.
- Select the footprint you wish to edit and click **Edit Footprint** in the shortcut menu.

The footprint editor runs and opens the selected footprint for editing.

Load a Footprint into the Current Project

To load a footprint into the current project:

1. With a new local project open, select **Tools > Edit Libraries > Footprints**.
   This opens the Edit Libraries window.
2. Select a component in the Name column, for instance, BENDA, and click **Edit Footprint**.
   This loads the component into the local project.

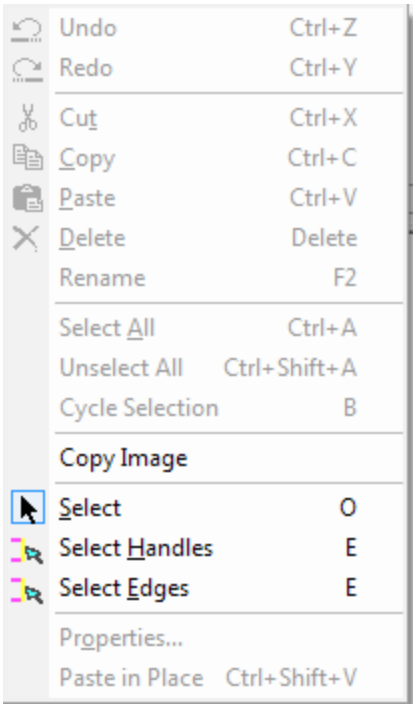
Footprint Editor Operations

The footprint editor opens when a footprint is created or modified. Like the schematic and symbol editors, the footprint editor is a graphical tool that keeps the placement of footprint elements uniform by snapping them to points on a grid.

With the footprint editor, add and manipulate graphical primitives, text labels, pins, vias, and padstacks, and/or adjust the resolution, color, and visibility of the editor grid. Once changes are made, update the current project with any changes to the footprint. Options related to these operations are available on the **Footprint** menu and the Footprint Draw menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Footprint Edit Menu



The fields on this menu become active as appropriate to the type of footprint being edited.

Undo*<last edit operation>* — Undo the last edit operation.

Redo*<last edit operation>* — Redo the last edit operation.

Cut – Delete the selected object, and retain a copy for pasting into a layout in the same application.

Copy – Create a local copy for pasting into a layout in the same application.

Paste – Put the object on the last cut or copy into the layout.

Delete – Delete the selected object without retaining a copy.

Rename – Click to rename the selected object in the layout.

Select All – Select all objects in the layout.

Unselect All – Unselect all objects in the layout.

Cycle Selection – Cycle selection of two or more objects that overlap. Each time you click **Cycle Selection**, a different one of the overlapping objects is selected.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Copy Image — Create a global copy of the selected objects on the clipboard for pasting into a different application.

Select – Sets cursor mode to selection of objects.

Select Handles – Sets cursor mode to selection of object handles.

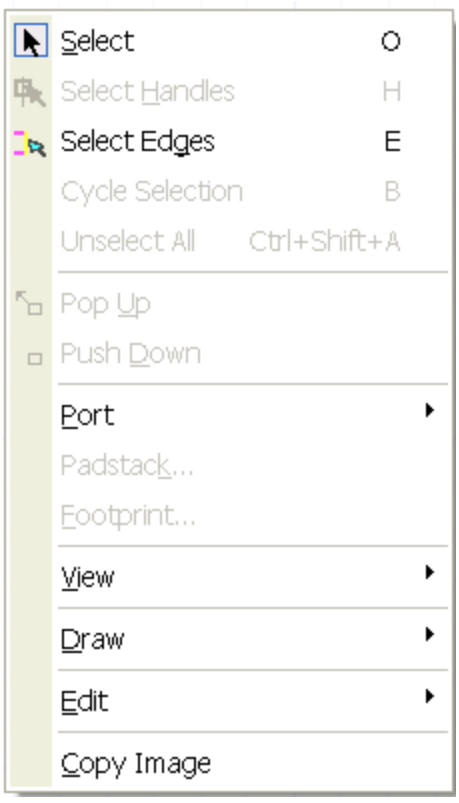
Select Edges – Sets cursor mode to selection of object edges.

Properties – Opens the **Properties** window to view and edit the properties of the selected object.

Paste in Place – Paste object to same location, without any X,Y offset/displacement.

Footprint Shortcut Menu

When a footprint design is active, right-click to open the shortcut menu for the Footprint Editor, similar to the following:

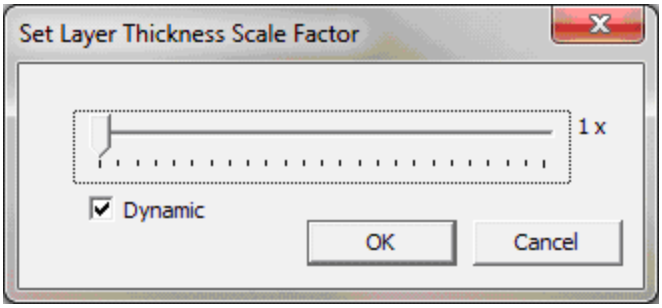


The fields on this menu become active as appropriate to the type of footprint being edited.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Footprint View Menu

- Control the display by selecting the check box of the following: **Status Bar**, **Message Manager, Project Manager window, Properties Window, Progress Window, Component Manager, Layout Window.**
- **Variables**: View the project and design variables with their values in a grid view.
- **Rotate**: **click+drag** to rotate the view; the same double-click options hold true for the alt+drag editor display options.
- Change the zoom display by selecting one of the following: **Zoom In, Zoom Out, Zoom Area, Zoom Previous.**
- Fit or Pan by selecting: **Fit Drawing, Pan.**
- Select **Stretch Z** to open the **Set Layer Thickness Scale Factor** window.



- Dragging the slider applies a Z scaling factor to the current view. If **Dynamic** is selected, the scaling happens in real time otherwise it is applied when **OK** is chosen.

Footprint Draw Menu

The footprint editor **Draw** menu presents options for drawing graphical primitives and text, and manipulating selected objects. The **Draw** menu options include:

Primitive > Arc

This option, also available on the toolbar, initiates creation of an arc. To draw an arc, click the footprint editor grid at the two points that determines the arc's ends, and then drag the arc to the appropriate radius.

Once you have created an arc, adjust its radius or move its endpoints by clicking the arc to select it, and dragging the appropriate handle.

Primitive > Circle

This option, also available on the **Footprint Draw** toolbar, initiates creation of a circle. To draw a circle, click the footprint editor grid to select a center point, then drag the circle to the appropriate diameter.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Click the circle to select it, then drag one of its handles.
- Double-click the circle to open its **Properties** window, type a new value for the **Radius** parameter, and click **OK**.

Primitive > Line

This option, also available on the **Footprint Draw** toolbar, initiates creation of a polyline with one or more segments. To draw a line:

To complete the line, do one of the following after defining its final segment:

- Press the **Spacebar**.
- Right-click and click **Finish**.

After you have completed a line, change the endpoints of its segments as follows:

- Select the line and drag the appropriate handle(s).
- Double-click the line to open its **Properties** window, type new values for the parameters you want to change, and click **OK**.

Primitive > Rectangle

This option, also available on the **Footprint Draw** toolbar, initiates creation of a rectangle. To create a rectangle, click the editor grid to specify the position of one corner, then drag the rectangle to the appropriate size.

Once you have drawn a rectangle, Edit its height and width, the position of its center, and its angle (its rotation, in degrees, relative the handles of its bounding box) as follows:

- Double-click the rectangle, then edit its properties in the **Properties** window.

Primitive > Polygon

This option, also available on the **Footprint Draw** toolbar, initiates creation of a polygon. To create a polygon:

1. Click the footprint editor grid to specify the position of one vertex, then click wherever you want to place additional vertices.
2. To complete a polygon, specify the position of its final vertex, then do either of the following:

Once you have drawn a rectangle, Edit its vertex positions and other properties, including its fill style, as follows:

- Click the rectangle, then edit its properties in the **Properties** window.
- Double-click the rectangle, then edit its properties in the **Properties** window.

Primitive > Text

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This option, also available on the **Footprint Draw** toolbar, adds to the footprint an editable "Default text" label in 12-point Arial. To edit the default text string immediately after placement, type the text you want, then press **Enter** or click elsewhere in the editor grid.

To change just the text of an existing label:

1. Click the label.
2. Click the label again to open its text for editing.
3. Press **Enter** or click elsewhere in the editor grid.

To change other properties of a label, including its font and size:

1. Click the label and view its properties in the **Properties** window, or double-click the label and view its properties in the **Properties** window.
2. Click in the **Value** cell for the property you want to modify.
3. Modify the value.
4. Click **OK**, or click in another **Value** cell to commit the change and keep editing values.

Void > Circle

Create a void, or remove material from an object, in the shape of a circle, rectangle, polygon, or line using the Void > Circle command. One object can have multiple voids, but each void can only be associated with one "parent" object.

Void > Line

Create a void, or remove material from an object, in the shape of a circle, rectangle, polygon, or line using the Void > Line command. One object can have multiple voids, but each void can only be associated with one "parent" object.

Void > Rectangle

Create a void, or remove material from an object, in the shape of a circle, rectangle, polygon, or line using the Void > Rectangle command. One object can have multiple voids, but each void can only be associated with one "parent" object.

Void > Polygon

Create a void, or remove material from an object, in the shape of a circle, rectangle, polygon, or line using the Void > Polygon command. One object can have multiple voids, but each void can only be associated with one "parent" object.

Port > Create

Click the Port > Create command to create a port.

Port > Remove

Click the Port > Remove command to remove a port.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Pin

This option, also available on the **Footprint Draw** toolbar, initiates placement of a footprint pin with a default stem length of 10. You can rotate a pin once you've started to place it by iteratively pressing R until the pin is oriented to your liking. Click in the editor grid to finish placing the pin.

Via

This option, also available on the **Footprint Draw** toolbar, initiates placement of a through hole (via) of the default size (1mm).

Handle

This option, also available on the **Footprint Draw** toolbar, allows you to create an explicit footprint handle that can later be used to resize or reshape the footprint based on the handle's reshaping rules.

3D Structure

Opens a menu that allows you to create and perform operations on a 3D structure in the Drawing Region.

Coordinate System

Opens a menu that allows you to create and perform operations on a coordinate system in the Drawing Region manage. For more information see Coordinate Systems in the **Layout Editor** topic.

Rotate

This option, also available on the **Footprint Draw** menu or by pressing **Ctrl**+**R** on the keyboard, rotates a selected object or group of objects 90° to the left.

Flip Vertical

This option, also available on the **Footprint Draw** menu, flips a selected object about the X axis.

Flip Horizontal

This option, also available on the **Footprint Draw** menu, flips a selected object about the Y axis.

Reverse Line

Reverse selected objects in the Drawing Region.

Align...

Position Relative

When a relative coordinate system (CS) and an object independent of that CS are selected, the "Draw > Position Relative" command positions the CS relative to that object.

Clear Position Relative

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When a relative coordinate system (CS) and an object are selected, the “Draw > Clear Position Relative” command positions the CS unrelative to that object.

Duplicate

Duplicate a selected object in the Drawing Region.

Expand

Expand selected objects in the Drawing Region.

Split Polygon Region

Split selected polygon regions in the Drawing Region.

Geometry Healing

Geometry heal selected objects in the Drawing Region.

Stitch Lines

Stitch together connected/crossing lines into polygons and lines.

Defining Footprint Handles

Handles appear around the perimeter of a selected element as small squares in the selection color. If the cursor is moved over one of these handles, it changes to indicate its proximity to the handle. When clicking on a handle, the user can then resize or reshape the element based on the handle's reshaping rules.

Component footprints can also have handles which can be specified in the footprint editor. These handles can likewise be used to reshape a component footprint, and at the same time altering one or more of its electrical parameters. In other words, the user can use handles to directly manipulate an element's geometry corresponding to electrical parameters.

Defining a Handle

Open the footprint editor for the footprint appropriate. From the **Draw** menu, choose **Handle**. Next, click to place the handle anywhere in the drawing, exact placement does not matter.

Editing Handle Location

Next, open the property window (**Edit > Properties**). There is one property listed: location. For this property, edit the X & Y locations to place the handle in the correct position based on the parameters.

Specifying Parameters to Change

Next, click **Add** in the **Property** window. In the responding window, specify the name of the electrical parameter, and the expression, based on the X & Y location of the handle that sets this parameter. For example:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Edit the footprint for the MSTRL component. Place a handle that is on the top edge of the line. The component has the parameters P for length and W for width. The handle has its location (X,Y) set to: (P/2, W/2). One property is added called "W" and its expression is "abs(Y*2)". The "abs" (absolute value) of "Y*2" ensures that as Y approaches zero, the line width stays positive. The two entries in the window should look like the following:

Location: P/2, W/2

W: abs(Y*2)

How it works

When the user drags the handle, for each new location of the cursor, each of the handles properties are recalculated for that new position. For the TRL example, the y position of the top-side handle is used to set the line's "w", which of course is twice that of y. After the new parameter values are calculated, the handle's own position is recalculated based on the updated parameters and the expressions for its location. Thus, as the cursor goes up, the line gets wider, and the handle tracks with the new width.

Using Scripts to Define Footprints

Footprints in Layout can use scripts and primitives in defining the geometry needed. Scripts can also move and/or create ports. Scripts can be written in any Windows supported languages.

When Layout needs to retrieve footprint geometry, it invokes the script, passing an object called LayoutHost. This object provides the interface to the needed functions within Layout necessary for creating geometry and accessing information within Layout. The script then calls the member functions of this host object to define the footprint appropriate.

Documentation on scripting within Windows can be found at:
http://msdn.microsoft.com/scripting/.

Layout Host Object

LayoutHost is an object within Layout which provides access to necessary Layout functions for use in a script. This topic describes the interface for this function.

LayoutHost Properties

Pars

Returns an ElementPars object. This property is used to set/get the component parameters declared in the footprint.

Example:

var pars = LayoutHost.Pars;

LayoutPars

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Returns an ElementPars object. This property is used to set/get the locally defined parameters in the footprint.

Example:

var layPars = LayoutHost.LayoutPars;

LengthUnits

Returns a string. This property is used to set/get the internal length units in the current script. By default, length units in the script are meters. When this property is changed, any subsequent calls to the LayoutHost are interpreted in the new units.

Example:

LayoutHost.LengthUnits(“mm”);

MID

A constant used to query an edge for its mid point.

Example:

var x = rect.Edge(1).X(LayoutHost.MID);

START

A constant used to query an edge for its start point.

Example:

var x = rect.Edge(1).X(LayoutHost.START);

END

A constant used to query an edge for its end point.

Example:

var x = rect.Edge(1).X(LayoutHost.END);

LayoutHost Methods

The following LayoutHost methods are available for use in **Electronics Desktop**.

LayoutHost General Methods

GetDefinitionType()

Returns an integer which indicates the type of shape used to define a shape-based footprint. This type of footprint allows the user to draw a shape such as a rectangle or polygon , the script

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

uses this definition to create a footprint. The method GetDefinitionPoints is then used to retrieve the points input by the user to define the shape's outline.

Example:

var shapeType = LayoutHost.GetDefinitionType();

Possible shapes are:

0: Single point

1: Rect

2: Polyline

3: Polygon

GetDefinitionPoints()

Returns a PointsObject containing the points defining an outline for a shaped-based footprint. This method is used along with GetDefinitionType to retrieve the information needed regarding the base shape used in order to define the footprint.

Example:

var outline = LayoutHost.GetDefinitionPoints();

GetLastError()

Returns an integer id regarding the last function call which changes the footprint. Functions which change the footprint include those creating geometry, and those altering pins. A non-zero result indicates an error occurred. Zero is returned for success.

Example:

var error = LayoutHost.GetLastError();

GetLayerID(name)

Returns an integer id for the given name. If a layer with "name" is not found, then a -1 is returned. The name is not case-sensitive.

Example:

var layerID = LayoutHost.GetLayerID("Top");

CreatePointsObject()

Creates and returns an empty PointsObject. Points can then be added to this object which in turn is passed as a parameter to certain primitive creation functions.

Example:

var pts = LayoutHost.CreatePointsObject();

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

LayoutHost Shape Creation Methods

These methods create virtual shapes in the footprint. While these shapes mirror actual primitives, they are drawn only and are not selectable or editable. All length values are in the current units of the footprint.

NewArc(layer, cx, cy, r, ang1, ang2, lw)

Creates an arc in the footprint, returns a geometry object.

Parameters:

Layer: In integer id retrieved from GetLayerID

Cx: Center x coordinate

Cy: Center y coordinate

R: Radius of arc centerline

Ang1: Start angle of arc (in degrees)

Ang2: Stop angle of arc going CCW

Lw: Line width of arc

Example:

var geom = LayoutHost.NewArc(layerID, 0, 0, r, 0, 90, w);

NewArcLine(layer, cx, cy, r, ang1, ang2, lw, end)

Creates an arc line in the footprint, returns a geometry object.

Parameters:

Layer: In integer id retrieved from GetLayerID

Cx: Center x coordinate

Cy: Center y coordinate

R: Radius of arc centerline

Ang1: Start angle of arc (in radians)

Ang2: Stop angle of arc going CCW

Lw: Line width of arc

End: End style. Possible end styles are: flat, extended, round.

Example:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

var geom = LayoutHost.NewArcLine(layerID, 0, 0, r, 0, 90, w, “flat”);

NewCircle(layer, cx, cy, r)

Creates a circle in the footprint, returns a geometry object.

Parameters:

Layer: In integer id retrieved from GetLayerID

Cx: Center x coordinate

Cy: Center y coordinate

R: Radius of circle

Example:

var geom = LayoutHost.NewCircle(layerID, 0, 0, r);

NewLine(layer, points, lw, join, end)

Creates a polyline in the footprint, returns a geometry object.

Parameters:

Layer: In integer id retrieved from GetLayerID

Points: A PointsObject populated with the points appropriate

Lw: Linewidth

Join: Join style. Possible join styles are: corner, miter, round.

End: End style. Possible end styles are: flat, extended, round.

(Passing an empty string defaults to round for Join or End style.)

Example:

var geom = LayoutHost.NewLine(layerID, pts, w, “corner”, “flat”);

NewPoly(layer, points)

Creates a polygon in the footprint, returns a geometry object.

Parameters:

Layer: In integer id retrieved from **GetLayerID**.

Points: A PointsObject populated with the points appropriate

Example:

var geom = LayoutHost.NewPoly(layerID, pts);

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

NewRect(layer, cx, cy, width, height, angle)

Creates a rectangle in the footprint, returns a geometry object.

Parameters:

Layer: In integer id retrieved from GetLayerID

Cx: Center x coordinate

Cy: Center y coordinate

Width: Width of rect

Height: Height of rect

Angle: Rotation angle to draw rect (in radians)

Example:

var geom = LayoutHost.NewRect(layerID, 0, 0, w, h, 0);

NewText(layer, text, x, y, font, size, angle, just)

Creates text in the footprint, returns a geometry object.

Parameters:

Layer: An integer id retrieved from GetLayerID

Text: The text string

X: Text x placement position

Y: Text y placement position

Font: Text font; may be left blank. On system layers, a system font must be used. Otherwise, specify a plotter font (e.g., "RomanDuplex").

Size: Text height (in length units for a plotter font; in points for a system font)

Angle: The text angle (in radians)

Just: Text justification relative to the placement position: "LeftTop", "LeftBase", "LeftBottom", "CenterTop", "CenterBase", "CenterBottom", "RightTop", "RightBase", "RightBottom"

Example:

var text = LayoutHost.NewText(layer, "Text", 2, -1, "", 1, 0, "LeftBase");

LayoutHost Relative Shape Placement Methods

These methods place shapes relative to each other

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

SnapEdges(edge, edge_pos, to_edge, to_edge_pos);

Places one geometry object against another so the specified edges are parallel and points touching

Parameters:

Edge: Specifies both the object to be moved and the edge to snap.

Edge_pos: The position on the source edge (the object being moved) that is to be snapped to the target edge; specified as LayoutHost.START, MID, or END (or a value < 0, 0, or > 0).

To_edge: Specifies the target object and edge (this object is not moved)

To_edge_pos: The target snap point. The source edge and position is snapped to this location; specified as LayoutHost.START, MID, or END (or a value < 0, 0, or > 0).

Example:

// Snap 'rect' so as that edge 1 is placed against edge 2 of 'rect2'

LayoutHost.SnapEdges(rect.Edge(1), LayoutHost.MID, rect2.Edge(2), LayoutHost.MID);

SnapEdgesWithOffset(edge, edge_pos, to_edge, to_edge_pos, x_off, y_off, rel_angle);

Same as for SnapEdges but the target snap point is specified by an edge position with an offset and angle. Associated with the target edge position is a normal vector and a tangent vector. The normal vector is perpendicular to the edge and points outwards (to the right in polylines). The tangent vector points in the direction of the edge. These two vectors define the local coordinate system in which x_off, y_off, and angle are specified.

Parameters:

Edge: Specifies both the object to be moved and the edge to snap.

Edge_pos: The position on the source edge (the object being moved) that is to be snapped to the target edge; specified as LayoutHost.START, MID, or END (or a value < 0, 0, or > 0).

To_edge: Specifies the target object and edge (this object is not moved)

To_edge_pos: The target snap point. The source edge and position is snapped to this location; specified as LayoutHost.START, MID, or END (or a value < 0, 0, or > 0).

X_off: An offset along the normal vector for the target edge.

Y_off: An offset along the tangent vector for the target edge.

Rel_angle: An additional rotation (specified as a counter-clockwise rotation in radians) relative to the normal vector for the target edge.

Example:

// Snap 'rect' so as that edge 1 is offset 1 unit from edge 2 of 'rect2'

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

LayoutHost.SnapEdgesWithOffset(rect.Edge(1), LayoutHost.MID, rect2.Edge(2), LayoutHost.MID, 1, 0, 0);

LayoutHost Port and Pin Methods

These methods create and move ports/pins as needed.

MovePort(name, cx, cy, angle)

Moves an existing port of that name. All scripted footprints must call MovePort for every pin in the footprint. This call should be made prior to defining any port geometry.

Parameters:

Name: Name of the port

Cx: Center x coordinate

Cy: Center y coordinate

Angle: Rotation angle to draw port (in radians)

Example:

LayoutHost.MovePort(“1”, x, y, 2*Math.tan(theta));

SnapPort(name, edge, edge_pos, rel_angle)

Moves a port to the specified edge position. The angle is relative to the normal vector (perpendicular to the edge and pointing outwards, or to the right in poly-lines).

Parameters:

Name: Name of an existing port

Edge: The edge on which the port is to be placed

Edge_pos: The position on the edge where the port is to be placed; specified as LayoutHost.START, MID, or END (or a value < 0, 0, or > 0).

Rel_angle: An additional rotation (specified as a counter-clockwise rotation in radians) relative to the normal vector for the edge.

Example:

LayoutHost.SnapPort(“1”, rect1.Edge(1), LayoutHost.MID, 0);

SetPortLayers(name, start_layer, end_layer)

Sets the layer range (and hence placement) for a port

Parameters:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Name: Name of the port

Start_layer: An integer id retrieved from GetLayerID

End_layer: An integer id retrieved from GetLayerID

Example:

var top = LayoutHost.GetLayerId(“top”);

var bottom = LayoutHost.GetLayerId(“bottom”);

LayoutHost.SetPortLayers(“a”, top, bottom);

AddPortEdge (layer, name, points)

Defines the edge of the port to the polyline defined by “points”. Defining the port edge is necessary for co-simulation of a scripted footprint. Note, if you define the port edge, you must also have set the port position via “MovePort” first. Multiple edges may be added by calling this function repeatedly.

The points for the edge should be defined with the port as the origin. For example, if the edge is a vertical line 10 mils long running thru the port, the two points defining the edge is (0, 5) & (0, -5), regardless of the location of the port itself.

Parameters:

Layer: In integer id retrieved from GetLayerID

Name: Name of the port

Points: A PointsObject populated with the points appropriate

Example:

LayoutHost.AddPortEdge(layerID, “n1”, pts));

SetPortWidth (layer, name, w)

Defines the edge of the port to be a single line segment of width “w”, centered on the port position, and rotated to the port angle. This function is an alternate means of defining a port edge. Defining the port edge is necessary for co-simulation of a scripted footprint. Note, if you define the port edge, you must also have set the port position via “MovePort” first.

Parameters:

Layer: An integer id retrieved from GetLayerID

Name: Name of the port

W: Width of the port edge

Example:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

LayoutHost.SetPortWidth(layerID, “n1”, w));

LayoutHost Via and Padstack Methods

NewVia(name, start_layer, end_layer, cx, cy, padstack, diameter)

Creates a via in the footprint and returns it as a via object.

Parameters:

Name: Name of the via

Start_layer: Integer id retrieved from GetLayerID

End_layer: Integer id retrieved from GetLayerID

Cx: Center x coordinate

Cy: Center y coordinate

Padstack: Name of the padstack to use. Passing an empty string (“”) results in “No Pad SMT East” by default.

Diameter: Diameter of the via

Example:

var via = LayoutHost.NewVia(“via_name”, layerID1, layerID2, x, y, “Planar EMVia”, diameter);

SnapVia(via, to_edge, to_edge_pos, x_off, y_off, rel_angle);

Moves a via to the specified edge position. The target snap point is specified by an edge position with an offset and angle. Associated with the target edge position is a normal (perpendicular to the edge and pointing outwards, or to the right in poly-lines) and a tangent vector (pointing in the direction of the edge). These two vectors define the local coordinate system in which x_off, y_off, and angle are specified.

Parameters:

Via: Specifies the via object to be moved

To_edge: Specifies the target object and edge

To_edge_pos: The target snap point. The via position is snapped to this location, specified as LayoutHost.START, MID, or END (or a value < 0, 0, or > 0).

X_off: An offset along the normal vector for the target edge.

Y_off: An offset along the tangent vector for the target edge.

Rel_angle: An additional rotation (specified as a counter-clockwise rotation in radians) relative to the normal vector for the target edge.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Example:

// Place ‘via’ 1 unit inside edge 2 of ‘rect’

LayoutHost.SnapVia(via, rect.Edge(2), LayoutHost.MID, -1, 0, 0);

ElementPars Object

This object permits retrieval of parameters & local variables defined in the footprint for use in a script. Retrieval of this object was discussed under LayoutHost.

Count

Contains the number of parameters in this object. This property is read-only.

Example:

var pars = LayoutHost.Pars;

var numPars = pars.Count;

Item

Contains the given parameter in this object. The item may be retrieved by index (zero based) or name. The name is not case sensitive. This property is read-only.

Example:

var pars = LayoutHost.Pars;

var w = pars.Item(0);

var p = pars.Item(“p”);

ElementPars Methods

There are no methods for the ElementPars object.

Related Topics

ElementPars Properties

ElementPars Methods

Points Object

This object permits retrieval of parameters & local variables defined in the footprint for use in a script. Retrieval of this object was discussed under LayoutHost.

Points Object Properties

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Count

Contains the number of points in this object. This property is read-only.

Example:

```
var pts = LayoutHost.CreatePointsObject();
var numPts = pts.Count; // returns 0 in this case
```

X(index)

Contains the X coordinate for a given index (zero based).

Example:

```
var pts = LayoutHost.CreatePointsObject();
x = 10;
pts.Add(x, y);
x2 = pts.X(0) * 2;
pts.X(0) = x2;
```

Y(index)

Contains the Y coordinate for a given index (zero based).

Example:

```
var pts = LayoutHost.CreatePointsObject();
y = 10;
pts.Add(x, y);
y2 = pts.Y(0) * 2;
pts.Y(0) = y2;
```

Points Object Methods

Add(x,y)

Adds a new point to the end of the object's array.

Example:

```
var pts = LayoutHost.CreatePointsObject();
pts.Add(5, 10);
```

Remove(index)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Removes a point on the object's array, given the (zero-based) index.

Example:

```
var pts = LayoutHost.CreatePointsObject();

pts.Add(5, 10);

pts.Remove(0);
```

Geom Object

Geometry objects are returned by the shape creation methods (NewRect, NewCircle, etc.) Geometry objects may be manipulated in a variety of ways through the methods exposed by their interface. All coordinates and length related values are passed/returned in the current default script units. Unless changed through LayoutHost.LengthUnits, all values are by default assumed to be in meters (SI units).

Example:

```
var rect = LayoutHost.NewRect(layer, 0, 0, l, w, 0);
```

Geom Object Properties

Layer

Get/Set the layer on which a geometry object is placed.

Example:

```
rect.Layer = LayoutHost.GetLayerID('top');
```

Edge(index)

Return the edge object for the edge specified. Edge indexes are zero based and count in a counter-clockwise direction around the object. For rectangles, edge zero is the lower edge. Circles are defined by two arc edges, a lower edge (edge zero) and an upper edge (edge 1); the start/end points of these edges are directly to the left/right of center. Lines and Polygon edges are defined by the user when the object is created. A rotated box giving the text extent is used to define the edges for a text object; edge zero is the line beneath the text.

Example:

```
var len = poly.Edge(5).Length
```

Count

Returns the number of edges in the geometry object.

Example:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

for (var i = 0; i < poly.Count; ++i)

Geom Object Methods

MoveBy(dx, dy)

Translates the geometry object by the specified offset.

Parameters:

Dx: X offset

Dy: Y offset

Example:

rect.MoveBy(10, 20);

MoveTo(x, y)

Moves the geometry object to the specified location; useful for rectangles, circles and arcs (the center point is moved)

Parameters:

X: New X location

Y: New Y location

Example:

rect.MoveTo(10, 20);

Rotate(x, y, angle)

Rotates the geometry object counter-clockwise about the specified location by the angle specified (in radians).

Parameters:

X: X center

Y: Y center

Angle: Rotation angle in radians

Example:

rect.Rotate(0, 0, Math.PI/4);

Scale(x, y, factor)

Scales the geometry object about the specified location by the factor specified.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Parameters:

X: X center

Y: Y center

Factor: Scale factor (2 implies 2 times, 4.5 implies 4 and a half times, etc.)

Example:

rect.Scale(0, 0, 2);

MirrorX(x)

Mirrors the X values of the object (Y values are unchanged) about the specified X value (X values falling on this line are unchanged).

Parameters:

X: Center of reflection (X values on this line are unchanged).

Example:

rect.MirrorX(0);

MirrorY(y)

Mirrors the Y values of the object (X values are unchanged) about the specified Y value (Y values falling on this line are unchanged).

Parameters:

Y: Center of reflection (Y values on this line are unchanged).

Example:

rect.MirrorY(0);

Copy()

Create and return a copy of the geometry object.

Example:

var rect_copy = rect.Copy();

AddVoid(void_geom)

Adds a void object to an existing geometry object.

Example:

Var rect = LayoutHost.NewRect(layer, 0, 0, l, w, 0);

Var void_rect = LayoutHost.NewRect(layer, 0, 0, l/2, w/2, 0);

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

rect.AddVoid(void_rect);

Edge Object

Edge objects are returned by an Edge query on a Geometry object. Note: edges may be arcs or straight segments.

Related Topics

Edge Object Properties

Edge Object Methods

Edge Object Properties

Edge objects are returned by an Edge query on a Geometry object. Note: edges may be arcs or straight segments.

Example:

var edge = geom.Edge(1);

Length

Return the true edge length (if an arc, the curvature is taken into account).

Example:

var len = geom.Edge(1).Length;

Angle(pos)

Return the angle of the tangent (in radians), relative to the standard X axis, of the edge point specified by ‘pos’. Angles are returned using the usual ‘count-clockwise is positive’ convention. Tangents point in the direction of the edge.

Parameters:

Pos: Edge position; usually specified as LayoutHost.START, MID, or END (or a value < 0, 0, or > 0).

Example:

var angle = geom.Edge(1).Angle(LayoutHost.START);

Normal(pos)

Return the angle of the normal (in radians), relative to the standard X axis, of the edge point specified by ‘pos’. Angles are returned using the usual ‘count-clockwise is positive’ convention. Normals are outward facing (or to the right in poly-lines) of the edge.

Parameters:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Pos: Edge position; usually specified as LayoutHost.START, MID, or END (or a value < 0, 0, or > 0).

Example:

var normal = geom.Edge(3).Normal(LayoutHost.END);

X(pos)

Return the X value of the edge point specified by ‘pos’.

Parameters:

Pos: Edge position; usually specified as LayoutHost.START, MID, or END (or a value < 0, 0, or > 0).

Example:

var x = geom.Edge(3).X(LayoutHost.END);

Y(pos)

Return the Y value of the edge point specified by ‘pos’.

Parameters:

Pos: Edge position; usually specified as LayoutHost.START, MID, or END (or a value < 0, 0, or > 0).

Example:

var y = geom.Edge(3).Y(LayoutHost.END);

Edge Object Methods

There are no methods for the Edge object.

Via Object

Via objects are returned by the LayoutHost method NewVia. They may be manipulated in a variety of ways through the methods exposed by their interface. All coordinates and length related values are passed/returned in the current default script units. Unless changed through LayoutHost.LengthUnits, all values are by default assumed to be in meters (SI units).

Example:

var via = LayoutHost.NewVia(“via_name”, layerID1, layerID2, x, y, “EM designVia”, diameter);

Via Object Properties

StartLayer

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Get/Set the start layer of the via.

Example:

via.StartLayer = LayoutHost.GetLayerID('top');

EndLayer

Get/Set the end layer for the via.

Example:

var layer = via.EndLayer;

X

Get/Set the x position for the via.

Example:

v1.X = v2.X;

Y

Get/Set the y position for the via.

Example:

v1.Y = v2.Y;

HoleDiameter

Get/Set the hole diameter for the via. A negative diameter turns off the diameter override and the value on the padstack definition is used.

Example:

v1.HoleDiameter = v2.HoleDiameter;

Rotation

Get/Set the via rotation. The rotation is in radians.

Example:

v1.Rotation = Math.PI/4;

Via Object Methods

ClearLayerMapping(fp_layer)

Clears the mapping between a footprint layer and a layer in the padstack definition.

Parameters:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

fp_layer: An integer id retrieved from GetLayerID

Example:

```
var v1 = LayoutHost.NewVia("via1", layer, bottom, 0, 0, "Round 1mm/0.5mm", 0.2);
v1.ClearLayerMapping(layer);
```

ClearLayerMappings

Clears the mapping between all footprint and padstack definition layers.

Example:

```
var v1 = LayoutHost.NewVia("via1", layer, bottom, 0, 0, "Round 1mm/0.5mm", 0.2);
v1.ClearLayerMappings();
```

Copy()

Create and return a copy of the via.

Example:

```
var via_copy = via.Copy();
```

DefaultLayerMapping

Reset the mapping between all footprint and padstack definition layers to the default mapping.

Example:

```
var v1 = LayoutHost.NewVia("via1", layer, bottom, 0, 0, "Round 1mm/0.5mm", 0.2);
v1.DefaultLayerMapping();
```

MirrorX(x)

Mirrors the via position about the specified X value (Y value is unchanged; an X value falling on this line is unchanged).

Parameters:

X: Center of reflection (X values on this line are unchanged).

Example:

```
via.MirrorX(0);
```

MirrorY(y)

Mirrors the via position about the specified Y value (X values are unchanged; a Y value falling on this line is unchanged).

Parameters:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Y: Center of reflection (Y values on this line are unchanged).

Example:

via.MirrorY(0);

MoveBy(dx, dy)

Translates the via by the specified offset.

Parameters:

Dx: X offset

Dy: Y offset

Example:

via.MoveBy(10, 20);

MoveTo(x, y)

Moves the via to the specified location; useful for rectangles, circles and arcs (the center point is moved)

Parameters:

X: New X location

Y: New Y location

Example:

via.MoveTo(10, 20);

Rotate(x, y, angle)

Rotates the via counter-clockwise about the specified location by the angle specified (in radians).

Parameters:

X: X center

Y: Y center

Angle: Rotation angle in radians

Example:

via.Rotate(0, 0, Math.PI/4);

Scale(x, y, factor)

Scales the via position about the specified location by the factor specified.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Parameters:

X: X center

Y: Y center

Factor: Scale factor (2 implies 2 times, 4.5 implies 4 and a half times, etc.)

Example:

via.Scale(0, 0, 2);

SetLayers(start_layer, end_layer)

Sets the via layer range

Parameters:

Start_layer: An integer id retrieved from GetLayerID

End_layer: An integer id retrieved from GetLayerID

Example:

var top = LayoutHost.GetLayerId(“top”);

var bottom = LayoutHost.GetLayerId(“bottom”);

via.SetLayers(top, bottom);

SetLayerMapping(fp_layer, ps_layer, pad_type);

Creates or adjusts the mapping between a footprint layer and the padstack definition layer.

Parameters:

fp_layer: An integer id retrieved from GetLayerID

ps_layer: The name of the layer in the padstack definition

pad_type: Unused

Example:

var v1 = LayoutHost.NewVia("via1", layer, bottom, 0, 0, "Round 1mm/0.5mm", 0.2);

v1.ClearLayerMappings();

v1.SetLayerMapping(layer, "template", "");

v1.SetLayerMapping(bottom, "template", "");

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Using the Symbol Editor

A symbol is a set of information that defines the graphical representation and electrical connectivity of a component. Symbol definitions are stored in library files with an extension of **.aslb**.

You can access material definitions using the **Symbol Editor**. The Electronics Desktop **Symbol Editor** allows you to view, modify, and save symbol information for components and layout primitives. After modifying a symbol, the information can either be saved, used to define a design, or exported.

When a symbol is used in a project, it is copied to the project. Thus new projects do not list any symbols in the Project Manager. If a change is made to the symbol, it is actually made to the project's copy of the symbol. So each project has its own set of symbols based on AEDT's symbol library. When you open an existing project, the Project Manager displays the symbols in use in the project.

To start the **Symbol Editor**, open a project and select **Tools** > **Edit Libraries** > **Symbols**. When the Edit Libraries window opens, use its controls to open the **Symbol Editor**.

Creating a New Symbol

1. Click **Tools** > **Edit Libraries** > **Symbols**.
2. From the **Symbols** tab of the **Edit Libraries** window, either:
   - Click **Add Symbol** to open the **Get Name** window.
   - Select an existing symbol to base your new symbol and click **Clone Symbol(s)** to open the **Get Name** window.
3. Type a name for the new symbol into the **Enter the name for this new Symbol** field and click **OK**.
4. Then double-click the entry for the new symbol or click **Edit Symbol** to open the symbol editor.
5. Use the symbol editor to:
   - Draw graphical primitives, such as rectangles, circles, and arcs, using options on the Draw menu.
   - Add pins for electrical connections using the Pin option on the **Draw** menu.
   - Modify pin properties in the Pin List dialog box.
   - Add labels. To include component properties or other variables in a label, use the Property Display Setup option on the Symbol menu. For unchanging text, use the text option on the Draw menu. Unusual labels are most likely represent a component property.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Update the current project with the new or revised symbol definition using the Update Project option on the **Symbol** menu

You can also export a symbol to a symbol library (**.aslb**) file for use in other projects. For information on how to do this, see the Edit Libraries.

Editing an Existing Symbol

When a symbol is used in a project, it is copied to the project from a global library. Any changes made to the symbol are made to the project's copy of the symbol and only affect the symbol in the project and not in any other project. To edit an existing symbol, either:

- From the **Project Manager** window, open the project that contains the symbol you want and open **Definitions** > **Symbols**. Either double-click the symbol you want to edit or right-click the symbol and select **Edit Symbol**.
- Open **Tools** > **Edit Libraries** > **Symbols**. From the **Symbols** tab of the **Edit Libraries** window, either double-click the symbol that you want to edit or right-click the symbol and choose **Edit Symbol**.

The symbol editor opens with the selected symbol ready for editing.

Use the symbol editor to:

- Draw graphical primitives, such as rectangles, circles, and arcs, using options on the Draw menu.
- Add pins for electrical connections using the Pin option on the **Draw** menu.
- Modify pin properties in the Pin List dialog box.
- Add labels. To include component properties or other variables in a label, use the Property Display Setup option on the Symbol menu. For unchanging text, use the text option on the Draw menu. Unusual labels are most likely represent a component property.
- Update the current project with the new or revised symbol definition using the Update Project option on the **Symbol** menu

You can also export a symbol to a symbol library (**.aslb**) file for use in other projects. For information on how to do this, see the Edit Libraries.

Symbol Editor Operations

The symbol editor opens when you begin to create or modify a symbol. Like the **Schematic Editor**, the symbol editor is a graphical tool that keeps the placement of symbol elements uniform by snapping them to points on a grid. The window controls are the same as those in the schematic editor: press the arrow keys and **Page Up** and **Page Down** to pan, or **Ctrl** +**D** to fit the view.

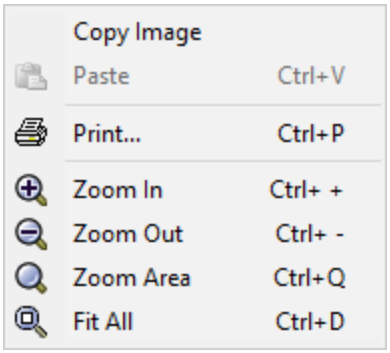
With the symbol editor, add, modify, and manipulate graphical primitives, text labels, pins, and property displays. You can also adjust the resolution, color, and visibility of the editor grid. When

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

you're done, update the current project with any changes you've made to the current symbol. Options related to these operations are available on the Symbol menu and the Symbol Draw menu.

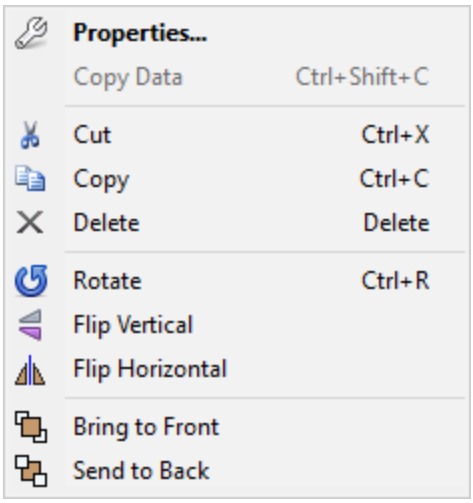
Symbol Editor Shortcut Menus

When you right-click in the symbol editor grid, this shortcut menu appears:



These options are a subset of those available on the **View** menu.

When you right-click an object in the symbol editor, this shortcut menu appears:



Click **Properties** to view the properties of the selected object. The other options are a combination of entries on the **Edit**, **View**, and **Draw** menus.

Symbol Draw Menu

The symbol editor **Draw** menu presents options for drawing graphical primitives and text, and manipulating selected objects. The **Draw** menu options include

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Arc
- Circle
- Line
- Polygon
- Rectangle
- Text
- Image
- Ellipse
- Curve
- Pin
- Rotate
- Align Horizontal
- Align Vertical
- Flip Vertical
- Flip Horizontal
- Bring to Front
- Send to Back

Arc

This option, also available on the **Symbol Draw** toolbar , initiates creation of an arc. To draw an arc, click the symbol editor grid at the two points that determines the arc's ends, then drag the arc to the appropriate radius.

Once you have created an arc, adjust its radius or move its endpoints by clicking the arc to select it, and dragging the appropriate handle.

Circle

This option, also available on the **Symbol Draw** toolbar , initiates creation of a circle. To draw a circle, click the symbol editor grid to select a center point, then drag the circle to the appropriate diameter.

Once you have created a circle, adjust its diameter in either of two ways:

- Click the circle to select it, then drag one of its handles.
- Double-click the circle to open its **Properties** window, type a new value for the **Radius** parameter, then click **OK**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

By default, a new circle is hollow. You can fill a circle with solid color or parallel lines in one of several styles as follows:

a. With the circle's properties displayed, click in the **Value** cell for the **FillStyle** property.
b. Select the appropriate fill style on the list.
c. Click **OK**.

Line

This option, also available on the **Symbol Draw** toolbar , initiates creation of a polyline with one or more segments. To draw a line:

1. Click the symbol editor grid where you want the line to start, then click at one or more points to continue the line.
2. To complete the line, do one of the following after defining its final segment:

- Press the **Spacebar**.
- Right-click, then click **Finish**.

After you have completed a line, change the endpoints of its segments by doing one of the following:

- Select the line and drag the appropriate handle(s).
- Double-click the line to open its **Properties** window, type new position values (in the form X: Y) for the appropriate vertices, and click **OK**.

Alternately, change the endpoints of a selected line by clicking **Layout** > **Line Styles** to open the **Line Styles** window, then click in the Cap Type field to change the cap or line-ending type (Flat, Extended, or Round).

Because a line has nonzero width, its CapType determines how its ends behave:

- **Extended** – Extends the line by its own width past the endpoint you click.
- **Flat** - Cuts the line perpendicularly at the endpoint you click.
- **Round** - Ends the line in a semicircle.

The existing technology files define line/trace styles, including a CapType (typically Flat) for each style. If you select None as the technology type, you'll automatically get a palette of four styles with a variety of widths, BendTypes and CapTypes.

Polygon

This option, also available on the **Symbol Draw** toolbar , initiates creation of a polygon. To create a polygon:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click the symbol editor grid to specify the position of one vertex, then click wherever you want to place additional vertices.
2. To complete a polygon, specify the position of its final vertex, then do either of the following:

- Press the **Spacebar**.
- Right-click, then click **Finish**.

Once you have drawn a rectangle, Edit its vertex positions and other properties, including its fill style, as follows:

- Click the rectangle, then edit its properties in the **Properties** window.
- Double-click the rectangle, then edit its properties in the **Properties** window.

By default, a new polygon is hollow. You can fill a polygon with solid color or parallel lines in one of several styles as follows:

a. With the polygon's properties displayed, click in the **Value** cell for the **FillStyle** property.
b. Select the appropriate fill style on the list.
c. Click **OK**.

Rectangle

This option, also available on the **Symbol Draw** toolbar , initiates creation of a rectangle. To create a rectangle, click the editor grid to specify the position of one corner, then drag the rectangle to the appropriate size.

Once you have drawn a rectangle, Edit its height and width, the position of its center, and its angle (its rotation, in degrees, relative the handles of its bounding box) as follows:

- Click the rectangle, then edit its properties in the **Properties** window.
- Double-click the rectangle, then edit its properties in the **Properties** window.

By default, a new rectangle is hollow. You can fill a rectangle with solid color or parallel lines in one of several styles as follows:

1. With the rectangle's properties displayed, click in the **Value** cell for the **FillStyle** property.
2. Select the appropriate fill style on the list.
3. Click **OK**.

Text

This option, also available on the **Symbol Draw** toolbar , adds to the symbol an editable "Default text" label in 12-point Arial. To edit the default text string immediately after placement, type the text you want, then press **Enter** or click elsewhere in the editor grid.

To change just the text of an existing label:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click the label.
2. Click the label again to open its text for editing.
3. Type the appropriate text.
4. Press **Enter** or click elsewhere in the editor grid.

To change other properties of a label, including its color, font or size:

1. Click the label and view its properties in the **Properties** window, or double-click the label and view its properties in the **Properties** window.
2. Click in the **Value** cell for the property you want to modify.
3. Modify the value.
4. Click **OK**, or click in another **Value** cell to commit the change and keep editing values.

Image

This option, also available on the **Symbol Draw** toolbar , adds an image to the symbol. To add an image, select an image file in the **Select Image** window and click **Open**. Click the editor grid to place the image, then drag the mouse until the image is the appropriate size, and click the mouse again.

Once you have placed an image, Edit its height and width, the position of its center, and its angle (its rotation, in degrees, relative the handles of its bounding box) as follows:

- Click the image to select it, then drag one of its handles.
- Click the image and edit its properties in the **Properties** window.
- Double-click the image and edit its properties in the **Properties** window.

To flip the image horizontally, select the image and in the **Properties** window, click **Mirrored**.

By default, a new image is not linked its original file. To ensure that the image is updated when changes are made to the file, select the image and in the **Properties** window, click **Link to File**.

A new image does not have a border. Add one as follows:

1. With the image's properties displayed in the **Properties** window, click the **Value** cell for the **DisplayBorder** property.
2. Set a **BorderWidth**.
3. Click the **Value** cell for the **BorderColor** property to add a color in the **Color** window.
4. Click **OK** to close the **Color** window.

Ellipse

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This option, also available on the **Symbol Draw** toolbar , initiates creation of an ellipse. To draw a ellipse, click the editor grid to specify the top and left most position of the shape , then drag the ellipse to the appropriate size.

Once you have drawn an ellipse, edit its height and width, the position of its center, and its angle (its rotation in degrees relative the handles of its bounding box) as follows:

- Click the ellipse to select it , then drag one of its handles.
- Click the ellipse and edit its properties in the **Properties** window.
- Double-click the ellipse and edit its properties in the **Properties** window.

By default, a new ellipse is hollow. You can fill an ellipse with solid color or parallel lines in one of several styles as follows:

1. With the ellipse's properties displayed, click in the **Value** cell for the **FillStyle** property.
2. Select the appropriate fill style on the list.
3. Click **OK**.

Curve

This option, also available on the **Symbol Draw** toolbar , initiates creation of a polycurve with one or more segments. To draw a curve:

1. Click the symbol editor grid where you want the curve to start.
2. Clicke or more points to continue the curve.
3. To complete the curve, mark its final segment and do one of the following:
    - double-click.
    - Press the **Spacebar**.
    - Right-click and click **Finish**.

After you have completed a curve, change the endpoints of its segments by doing one of the following:

- Select the curve and drag the appropriate handle(s).
- Double-click the curve to open its **Properties** window, type new position values (in the form X: Y) for the appropriate vertices, and click **OK**.

Pin

This option, also available on the **Symbol Draw** toolbar, initiates placement of a symbol pin with a default stem length of 10. You can rotate a pin once you've started to place it by iteratively pressing R until the pin is oriented to your liking. Click in the editor grid to finish placing the pin.

Rotate

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This option, also available on the **Symbol Draw** menu and by pressing **Ctrl**+**R** on the keyboard, rotates a selected object or group of objects 90° to the left.

Align Horizontal

This option horizontally aligns the uppermost edges of the members of a group of selected objects with the uppermost edge of the first-selected object. To align multiple objects horizontally:

1. Press **Ctrl**, then click the object with which you want to align the others.
2. Still pressing **Ctrl**, click the additional objects in turn to add them to the selection.

   Note that the first-selected object is highlighted in red, and that the subsequently selected objects are highlighted in dark red.

3. From the **Draw** menu, select **Align Horizontal**.

Align Vertical

This option vertically aligns the leftmost edges of the members of a group of selected objects with the leftmost edge of the first-selected object. To align multiple objects vertically:

1. Press Ctrl, then click the object with which you to align the others.
2. Still pressing Ctrl, click the additional objects in turn to add them to the selection.

   Note that the first-selected object is highlighted in red, and that the subsequently selected objects are highlighted in dark red.

3. From the **Draw** menu, select **Align Vertical**.

Flip Vertical

This option, also available on the **Symbol Draw** toolbar, flips a selected object about the X axis.

Flip Horizontal

This option, also available on the **Symbol Draw** toolbar, flips a selected object about the Y axis.

Bring to Front

This option, also available on the **Symbol Draw** toolbar, places a selected object in front of all other elements in the editor, i.e., closest to the user.

Send to Back

This option, also available on the **Symbol Draw** toolbar, places a selected object behind all other elements in the editor, i.e., furthest on the user.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Symbol Menu

The Symbol menu lists options for symbol naming, property displays, and file operations. Its entries include:

Update Project

This option updates the current project with changes made in the current symbol.

> **Note: Update Project** updates your symbol changes to the current project in memory and does not save your changes to disk. To save your changes to disk, you must also click **Save** on the **File** menu. If you like the changes you have made in a symbol to be available for use in other projects, you must export the symbol to a library as described in the Edit Libraries topic.

Set Name

This option opens a **Properties** window to rename the current symbol.

Property Display Setup

This option opens the Properties Display so add or modify display of the names and/or values of properties associated with the component represented by the current symbol.

Pin List

This option gives you access to settings related to pin properties by opening the Pin List window.

Grid Setup

This option gives you access to settings related to the symbol editor grid resolution, color, and visibility by opening the symbol editor Grid Setup window.

Import File

The Import File command allows you to import an existing SVG-formatted symbol into the symbol editor.

Export File

This option saves the current symbol as a Microsoft Enhanced Meta File (**.emf**) graphic.

Edit Component

This option launches the Edit Component window to modify the component associated with the active symbol.

Normalize Symbol on Save

Allows you to normalize the symbol you are editing when you save after making modifications.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

List

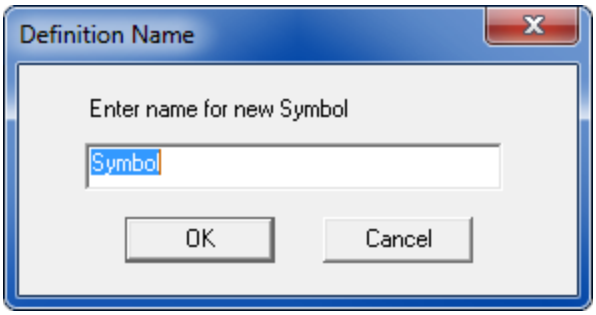
Opens the **Design List** window, which lists the objects in the layout. Each column may be sorted by clicking on the heading. One or more object rows can be selected and operated by clicking **Delete** and **Properties**.

Import File (Symbol)

The **Symbol** > **Import File** command allows you to import an existing SVG-formatted symbol into the symbol editor. The SVG (Scalable Vector Graphics) format is an open, xml-based web standard graphics format supported by many third-party tools.

To import an SVG (**.svg**) file when creating a new symbol definition do the following:

1. From the **Project Manager** window, right-click **Definitions** > **Symbols** in the appropriate project and select **Add Definition**.
2. In the **Definition Name** window, enter a name for the new symbol and click **OK** to open a new blank **Symbol Editor** window.



3. From the main menu bar, select **Symbol** > **Import File** and choose an existing **.svg** symbol file to import it into the symbol editor. A window opens advising that importing the **.svg** file removes any existing symbol graphics in the editor, and asking for confirmation to continue the import.

> **Note:**
>
> - There is no “Undo” for the import operation. Consequently if you make a mistake on import, you must close the project without saving, then reopen it to recover.
> - Currently **.svg** symbols can be imported into any symbol editor window - including those containing pre-existing component symbols in which case the current symbol in the editor is replaced by the imported symbol, so ensure that you import the symbol in the appropriate place.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

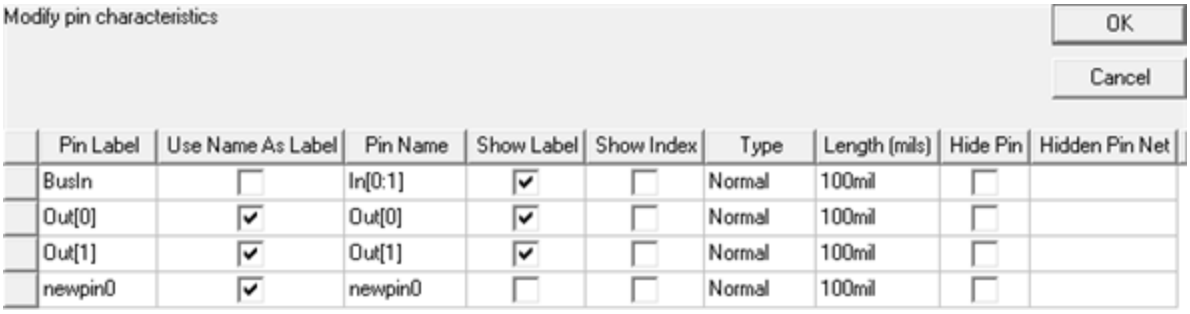
4. Click **OK** to import the **.svg** symbol for further editing, or **Cancel** to abort the operation. Once the new symbol has been created, attach it to a component via the Property Display Setup command.

Editing Pin Properties

To edit a property of a symbol pin, open the symbol editor's **Pin List** window by doing either of the following:

- In the **Symbol** menu, select **Pin List**.
- From the **Symbol** toolbar, click the **Pin list** icon .

The **Pin List** window displays and sets values for the properties of symbol pins.



Pin Label	Use Name As Label	Pin Name	Show Label	Show Index	Type	Length (mils)	Hide Pin	Hidden Pin Net
BusIn	☐	In[0:1]	☑	☐	Normal	100mil	☐	
Out[0]	☑	Out[0]	☑	☐	Normal	100mil	☐	
Out[1]	☑	Out[1]	☑	☐	Normal	100mil	☐	
newpin0	☑	newpin0	☐	☐	Normal	100mil	☐	

Pin properties include:

- **Pin Label** – provides a field to add a user-defined label for the chosen pin on a component symbol without having to change the actual **Pin Name** associated with the chosen pin. Pin labels for pins in a component should be unique.

  To specify or change the label of a pin, click in the **Pin Label** cell for that pin, type the name, and do either of the following:

  - Press **Enter**.
  - Click in another cell.

  The **Pin Label** can be displayed for the chosen pin by unchecking **Use Name As Label**.

- **Use Name As Label** – controls whether the **Pin Name** or **Pin Label** is displayed for the chosen pin when **Show Label** is enabled. For a new pin, **Use Name As Label** is checked by default.
- **Pin Name** – sets the actual pin name. To specify or change the name of a pin, click in the **Pin Name** cell for that pin, type the name, and do either of the following:
  - Press **Enter**.
  - Click in another cell.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Show Label** – controls visibility of the either the **Pin Name** or **Pin Label** text for the pin (as determined by **Use Name As Label**). For a new pin, it is unchecked by default.
- **Show Index** – controls visibility of the pin number in the schematic editor. For a new pin, it is unchecked by default.
- **Type** – drop-down menu sets the pin type. Options include **Normal** (the default), **ANSI In**, **ANSI Out**, and **Zero Length**. To change a pin's type, click in its **Type** cell, then click the appropriate option.
- **Length (mils)** – sets the length of the pin stem (the graphical line associated with the pin port symbol). By default, new pins have a pin stem length of 100 mils. To change the length of a pin, click in its **Length** cell, type a new value, and do either of the following:
  - Press **Enter**.
  - Click in another cell.
- **Hide Pin** – controls whether or not a pin is visible in the schematic editor. For new pins, it is unchecked by default.
- **Hidden Pin Net** – editable when **Hide Pin** is checked, specifies the net (circuit node) to which a pin is connected if it is hidden. To specify a net, click in the **Hidden Pin Net** cell, type a net name, then do either of the following:
  - Press **Enter**.
  - Click in another cell.

Edit Symbol Pin Locations

To edit the location of a symbol pin, open the **Edit Symbol Pins** window by doing one of the following:

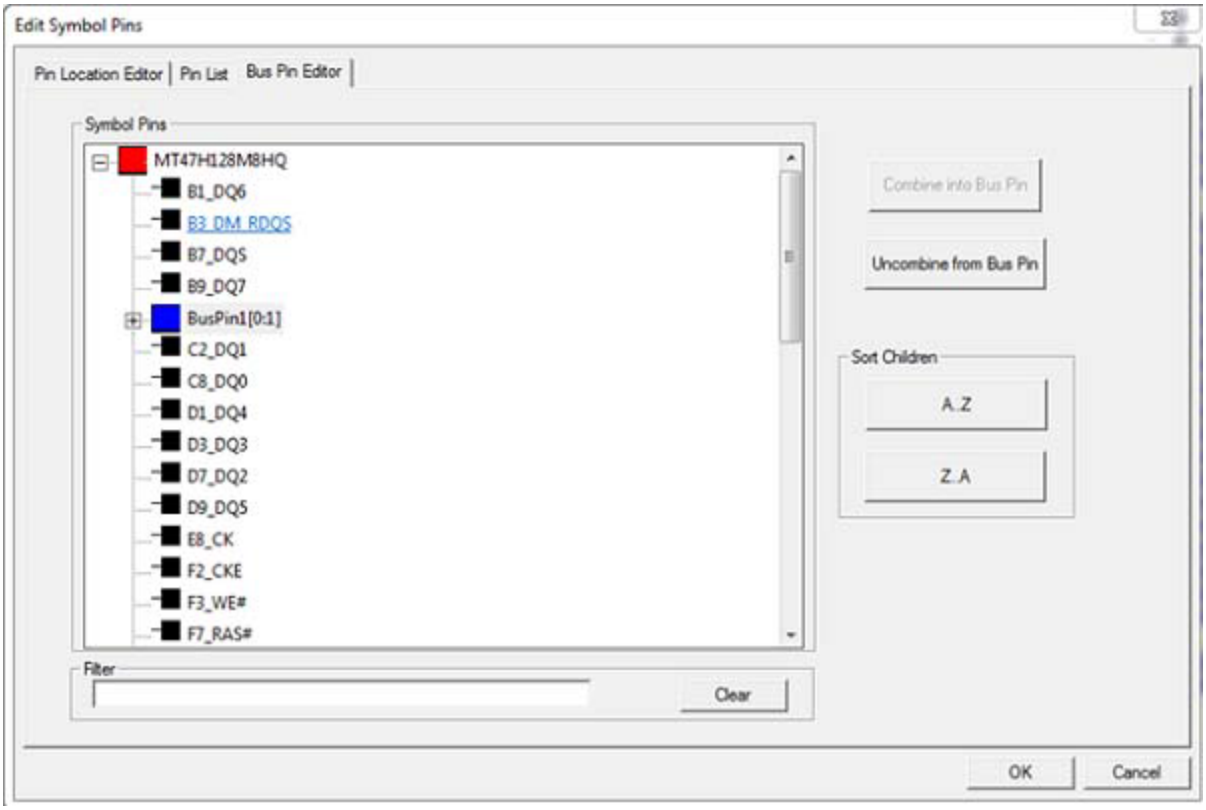
- In the Symbol Editor **Symbol** menu, select **Edit Pins**.
- In the component instance shortcut menu, select **Edit Symbol Pins**.

The window has three tabs: **Bus Pin Editor**, **Pin Location Editor**, and **Pin List**. Bus Pin Editor and Pin Location Editor appear only for symbols that are drawn as a rectangle with pins.

Bus Pin Editor

The **Bus Pin Editor** tab allows you to create, edit, and delete bus pins from regular pins. The pin names are the terminal names associated with the component model and cannot be changed, but the bus pin names can be anything the user wants.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



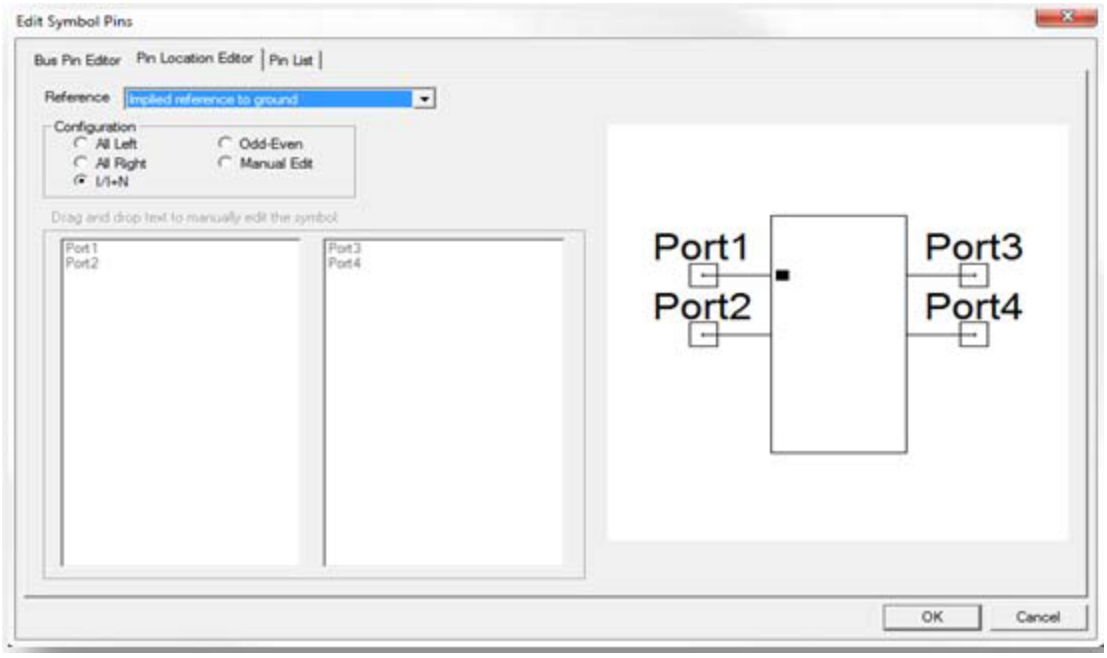
- **To create a new bus pin**
  - Select the pins needed for the bus pin and click **Combine in to Bus Pin**. Both regular pins and bus pins can be combined to create the new bus pin.
  - Pins can be selected with Ctrl + Click or Shift + click.
  - Pins can be dragged and dropped onto an existing bus pin.
- **To remove pins from a bus pin**
  - Select the whole bus pin or individual pins inside the bus pin and click **Uncombine from Bus Pin**.
  - Pins can be dragged out of the bus pin to the root level to remove on the bus pin.
- **Re-ordering Pins**
  - The pins inside a bus pin can be reordered by dragging them to the appropriate location. The order is important since the first pin with index 0 connects to bus[0] when a bus is connected, and so on.
  - When either the root node (red symbol) is selected OR a bus pin is selected, Sort features become available. Click the buttons to order the pins and bus-pins immediately under the selected node by name in either alphanumeric or reverse-alphanumeric order.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Searching the Tree**
  - The tree can be filtered by the pin name by typing in the filter box.
  - The filter text supports wildcard search (e.g., "P*1" should search for everything that begins with a "P" and ends with a "1").
  - Search works for both the root level and leaf level of pins (e.g., if a search matches the pin name under a bus pin, the bus pin is displayed in the search result).

Pin Location Editor

The **Pin Location Editor** allows you to change the locations of the symbol pins to the left or right side according to the settings chosen in the window.



Selecting a new option on the **Reference** drop-down menu changes the symbol displayed to show or hide additional reference pins. The **Reference** list is not shown in the window if the symbol does not support reference pins. The options are:

- **Implied reference to ground**: the global ground is the reference port for each N port connection. Its voltage is always 0V.
- **Common reference port**: an additional reference pin is added that is a common reference for the definition of port voltages. This reference can have any voltage and corresponds to the net for that extra pin.
- **Add individual hidden reference pin per port**: an additional reference pin is added for each port. These reference pins are hidden, set to 0V by default, and can each have their

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

own reference voltage. You can connect each reference pin to its own net. Select this option if you do not want to see the reference pins.

- **Add individual reference pin per port**: an additional reference pin is added for each port. Every reference pin can have its own reference voltage and be connected to its own net.

> **Note:**
>
> See Reference Nodes on S-Parameter Elements in the S-parameter Technical Notes for how the Circuit solver handles reference node configurations.

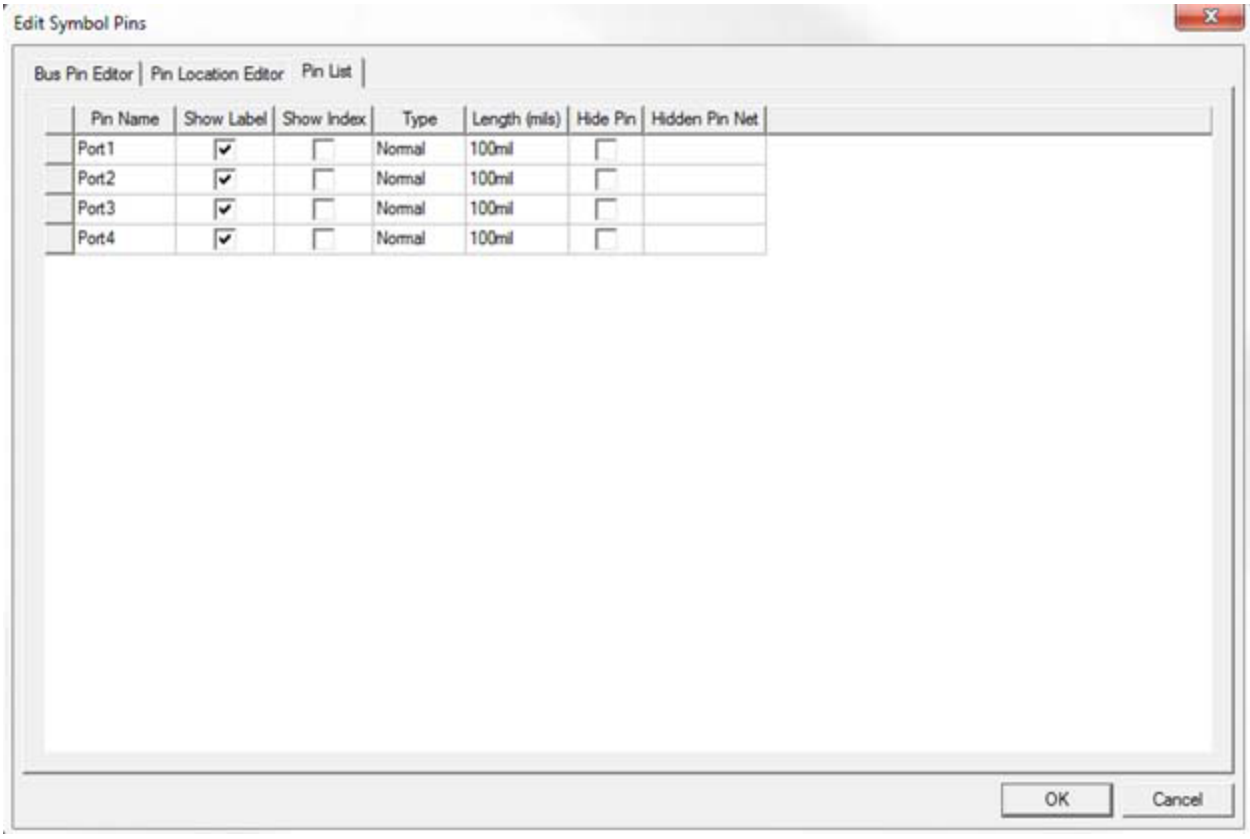
Clicke of the five **PinDirection** options to change the symbol shown to a fixed configuration.

- **All Left** puts all pins on the left side
- **All Right** puts all pins on the right side
- **I/I+N** puts the first half of the pins in order on the left side and the remaining pins on the right side
- **Odd-Even** puts every other pin on the left side and the remaining pins on the right side
- **Manual Edit** enables the two list boxes in the bottom left quadrant. When those boxes are enabled, the user can drag pins from one box to the other to switch sides and drag pins within a box to switch the pin order.

Pin List

The **Pin List** window displays and sets values for the properties of symbol pins.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The available pin properties include:

- **Name** – This editable cell displays and sets the pin name. To specify or change the name of a pin, click in the **Name** cell for that pin, type the name, then press **Enter** or click in another cell.
- **ShowLabel** – This check box controls visibility of the pin name in the schematic editor. For a new pin, it is unchecked by default.
- **ShowIndex** – This check box controls visibility of the pin number in the schematic editor. For a new pin, it is unchecked by default.
- **Type** – This drop-down menu sets the pin type, the options for which include **Normal** (the default), **ANSI In, ANSI Out,** and **Zero Length.** To change a pin's type, click in its **Type** cell, then click the appropriate option.
- **Length** – This editable cell sets the length of the pin stem (the graphical line associated with the pin port symbol). By default, new pins have a pin stem length of 10. To change the length of a pin, click in its **Length** cell, type a new value, then press **Enter** or click in another cell.
- **HidePin** – This check box controls whether or not a pin is visible in the schematic editor. For new pins, it is unchecked by default.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **HiddenPinNet** – This cell, editable when **Hide Pin** is checked, specifies the net (the circuit node) to which a pin is connected if it is hidden. To specify a net, click in the **Hidden Pin Net** cell, type a net name, then press **Enter** or click in another cell.

Changing Pin Properties

To change a pin property, either:

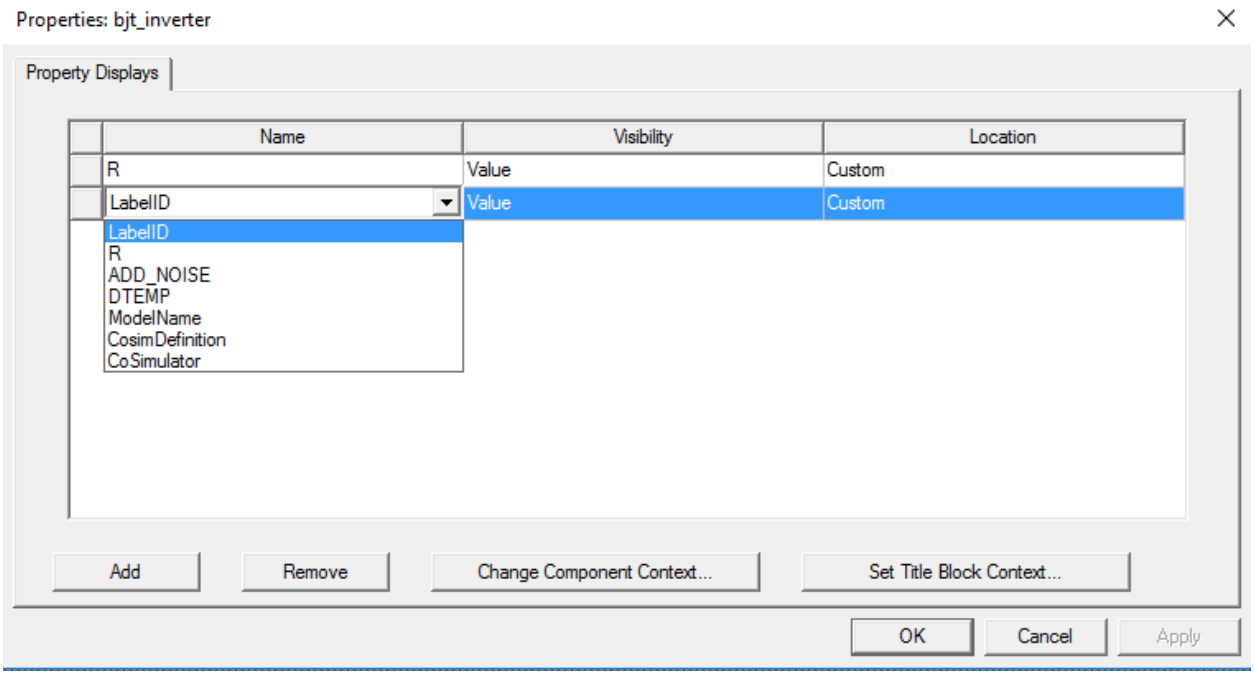
- Click the cell that displays the pin property value that you want to change and modify the property value appropriate to its type as described above.
- To commit the new value and continue editing pin properties, click another property value.

Committing Changes

Clicking **OK** in the window commits changes to the component symbol made in all three tabs.

Symbol Property Display Setup

The **Symbol** > **Property Display Setup** command opens a **Properties** window in which you can add or modify how the names, values, and locations of properties associated with the component or object (such as a title block) are represented by the current symbol.



The Symbol Property Displays Window

This window lists symbol display properties and controls their presence, visibility, and position. Every entry in this window corresponds to a property on a component associated with the symbol in question. Whoever creates or edits a component determines which property to add.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Some properties such as [LabelID] can appear in multiple components. The component is set automatically if you are editing an existing symbol. To change the reference component, click **Change Component Context**.

> **Note:** [LabelID] may display as **[InstanceName]** or *** in the Symbol editor.

Columns in the grid are:

- **Name** – Click in this cell to type a property display name, or to select an existing property display from a list. The component selected via **Change Component Context** determines which property displays are listed for selection.
- **Visibility** – Click in this cell to set the visibility (**None**, **Name**, **Value**, or **Both**) of a property display.
- **Location** – Click in this cell to set the location (**Left**, **Top**, **Right**, **Bottom**, **Center**) of the property display relative to the symbol center.

> **Note:** You can further position a property display by rotating it (**Ctrl**+**R**), or by dragging it to another location. When you do this for a given property display, its Location value is set to **Custom**.

The actions available in this window are:

- Click **Add** to add a new property display entry to the list.
- Click **Remove** to remove the selected property display.
- Click **Change Component Context** to open the **Select Definition** window, to select the component definition on which property displays are based. The properties of the selected component are then available in the **Name** cell properties list.

> **Note:** Because a symbol can be used by multiple components with differing properties, any property name can be entered by the user. If a component using the symbol does not have a property with that name, the symbol property isn't used in that component.

- Click **Set Title Block Context** to make the list of default page properties, and others as specified, available for display. Default properties include: ProjectPath, Project, Design, Title, Author and Date. This context is selected by default if the symbol has three or more propdisplays for default page properties.

Symbol Grid Setup window

The **Symbol** > **Grid Setup** window sets visibility, colors, resolution, and snapping for the Symbol Editor’s alignment grid. It contains the following controls.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Major** — Specifies the spacing of the major grid lines (default in mils). To change the color of the major grid lines, click the **Major** color button, specify a color in the **Color** window, then click **OK**.
- **Minor** — Specifies the spacing of the minor grid lines (default in mils). To change the color of the minor grid lines, click the **Minor** color button, specify a color in the **Color** window, then click **OK**.
- **Show Grid** — Toggles grid line visibility.
- **Snap to Grid** — Controls whether graphics and text placed on the grid automatically snap to the nearest grid intersection.
- **Background Color** — To set the background color used for symbol editing, click the color box to open its window, specify a color, then click **OK**.
- **Save as Default** — Save the current **Grid Setup** values as defaults for future Electronics Desktop sessions.
- **Defaults** — Restore all **Grid Setup** settings to their defaults.
- **OK** — Commit changes and close the window.
- **Cancel** — Close the window without committing changes.

Note:

- To ensure electrical connectivity among schematic elements, placed symbol pins snap to a 100-mil grid (2.54-millimeter) regardless of the graphical Major and Minor grid line settings. This snapping cannot be deactivated, and the spacing of the connectivity grid cannot be adjusted.
- The units used for grid line spacings are controlled by the **Tools** > **Options** > **General Options** window.
- Use of the **Minor** grid setting varies depending upon the active editor. In the Layout Editor, the minor grid-line setting specifies the number of units between each minor grid division. However in the Schematic and Symbol Editors, the **Minor** grid-line setting specifies the number of minor grid lines that appear between major grid lines.

Using the Component Editor

The Electronics Desktop **Component Editor** supports the viewing, modification, and saving of component information for use in the development of circuit designs. You can create new components, edit existing components within a project file, and manage components within external libraries. After modifying a component, the information can be saved, used to define a design, or exported. Component definitions are stored in library files with an extension of **.aclb**. You can access component definitions using the **Component Editor**.

To start the **Component Editor**, open a project and select **Tools** > **Edit Libraries** > **Components**. When the Edit Libraries window opens, use its controls to open the Edit

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Component window, then create a new component, or select an existing one, and click **Edit** to open the **Component Editor**.

Creating and Editing Components

Use the Edit Component window to:

- Specify or change the component name, description, associated bitmap, and default property values, including those necessary for netlisting, co-simulation, and **Solver-on-Demand** operation, as appropriate
- Specify or respecify a graphical symbol to represent the component in the schematic editor
- Specify or change the component terminal properties
- Specify or respecify a footprint to represent the component in the layout editor

The changes you make when creating or editing a library component become part of the current project. The newly edited component is saved to the project, not back to the library. If the edited component is used in any schematics in the project, all default values of any modified parameters are updated immediately.

- To make a new or modified component available for use in other projects, save it to a component library (**.aclb**) file using the **Export** command in the Edit Libraries window.
- To update another project with your updated component(s), select its icon in the **Project Manager** window, then click **Project Tools** > **Update Definitions** on the **Tools** menu.

> **Note:** If you are creating a new component, it is useful to first identify and, if necessary, create the necessary dependencies before defining your component. See Component Creation Process in the introduction for further information.

Related Topics

Editing an Existing Component

Creating a New Component

Editing an Existing Component

To edit an existing component, do either of the following:

- From the **Project Manager** window, expand the **Definitions** /**Components** subfolder for the project that contains the component you want to edit. Double-click the entry for the component you want to edit, or right-click the entry and select **Edit Component**.
- Open the **Tools** > **Edit Libraries** > **Components** window, then locate and select the component that you want to edit. Click **Edit Component**, or double-click the selected entry.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Edit Component window opens, displaying the definition of the selected component for editing.

Creating a New Component

To create a new component, do either of the following:

- Select **Tools** > **Edit Libraries** > **Components**, and click **Add Component** to open the **Edit Component** window.
- Open the **Tools** > **Edit Libraries** > **Components** window, then locate and select an existing component on which to base your new component. Click **Clone Component**. and a renamed copy of the selected component is added to the list. Double-click the entry for the new component, or click **Edit Component** to open the **Edit Component** window.

The Edit Component Window

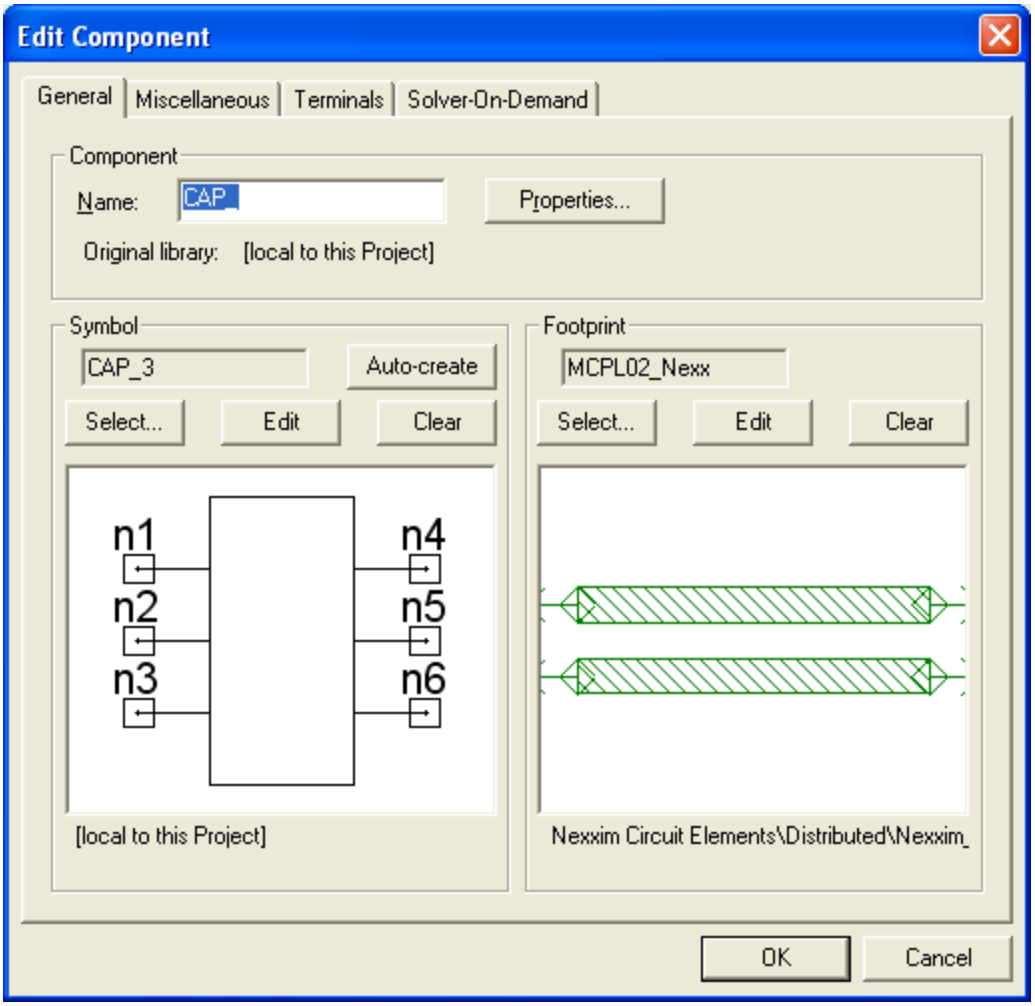
The **Edit Component** window is used to create new components, or edit existing components, in a project file. To show the **Edit Component** window, do either of the following:

- Double-click a component definition in the project tree, or double-click a component listed in the **Edit Library** window.
- Open a project and select **Tools** > **Edit Libraries** > **Components**. When the Edit Libraries window opens, use its controls to open the **Edit Component** window.

Components General Tab

Click the **General** tab to specify all parameter values for the component and assign symbols and footprints on their respective libraries. You can also start the symbol and footprint editors on the window, however, you must exit the component editor to complete the symbol or footprint edits. The symbol and footprint preview windows at the bottom of the window are automatically updated to reflect whatever changes you make to the symbols and footprints you modify.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Component Panel

The Component group box of the General Tab window displays the component Name. The Original Library name is displayed if found. To access and edit the component properties, click **Properties** next to the **Name** text window. In the Properties window, add, edit or remove default or local properties and values.

Symbol Panel

The Symbol group box of the General Tab window allows you to search by symbol name, and also displays a picture of the symbol. Choose any symbol which has an equal or greater number of pins than the component specified in the Component Name field. You can then choose to **Auto-create** the component.

The library of origin of the component is displayed beneath the component display in the **Symbol** area; if the component is **local to this Project**, that message is displayed. When you

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

click **Select** (**...**), the Select Definition window opens and allows you to choose a definition for the symbol from a list that is displayed. Click **Edit** to modify the symbol. A confirmation message is displayed with a reminder that the Component and Definition editors is closed (if open) and that all changes are saved if you choose to continue. Click **Clear** to clear all selections and displays in the Symbol area.

Footprint Panel

The Footprint group box of the General Tab window allows you to search by footprint name, and is used to display a picture of the footprint. Choose any footprint which has an equal or greater number of pins than the component specified in the Component Name field.

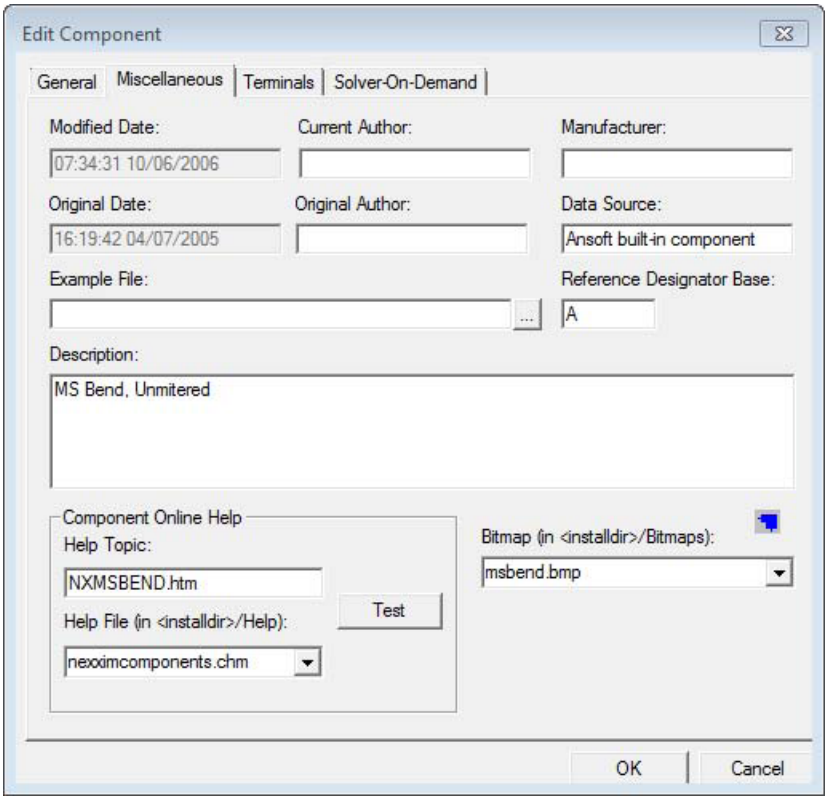
The library of origin of the footprint is displayed beneath the component display in the Footprint area; if the component is **local to this Project**, that message is displayed. When you click **Select**, (**...**) the Select Definition window opens and allows you to choose a definition for the footprint from a list that is displayed. Click **Edit** to modify the footprint. A confirmation message is displayed with a reminder that the Component and Definition editors is closed (if open) and that all changes are saved if choose to continue. Click **Clear** to clear all selections and displays in the Footprint area.

Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

Components Miscellaneous Tab

Use the miscellaneous fields to enter component information such as the name, manufacturer, description, ref des, etc. You can also specify a bitmap for the **Project Tree** and an associated help description (if you use your own documentation). Help files must be located in **<Installation Directory>\Electronics Desktop\help**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



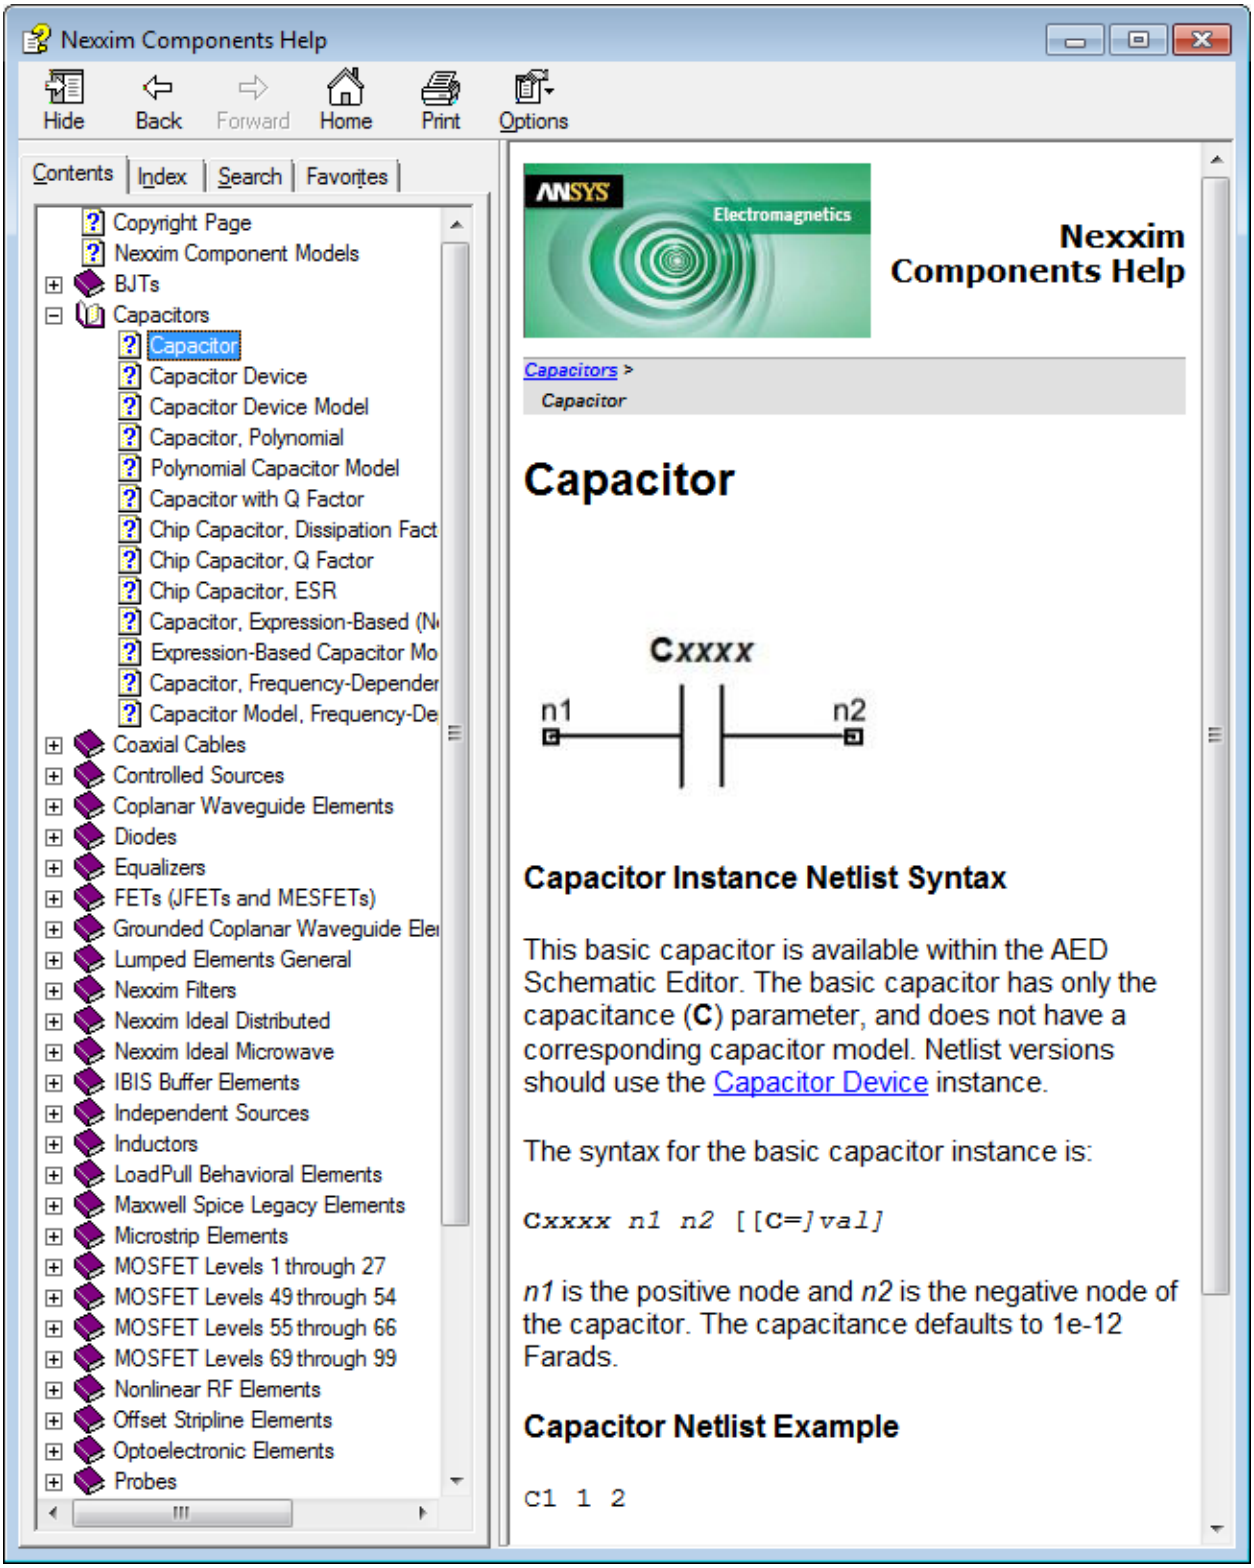
The top two rows of the **Miscellaneous** tab window displays the **Modified Date** and **Original Date** of the component, and allows you to specify the following:

- Current Author
- Manufacturer
- Original Author
- Data Source

You may also specify an **Example File** directory for the component, browse for the directory if necessary (...) and specify its **Reference Designator**, or enter a text **Description** for the component. The default **Bitmap** of the component is displayed at lower-right, and you may use the adjacent drop-down menu to specify a different bitmap file.

The **Component Help** area displays the default HTML help file associated with the component, and allows you to specify an alternative help file of your own. You may also **Test** the specified help file, which displays the component's HTML help page.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

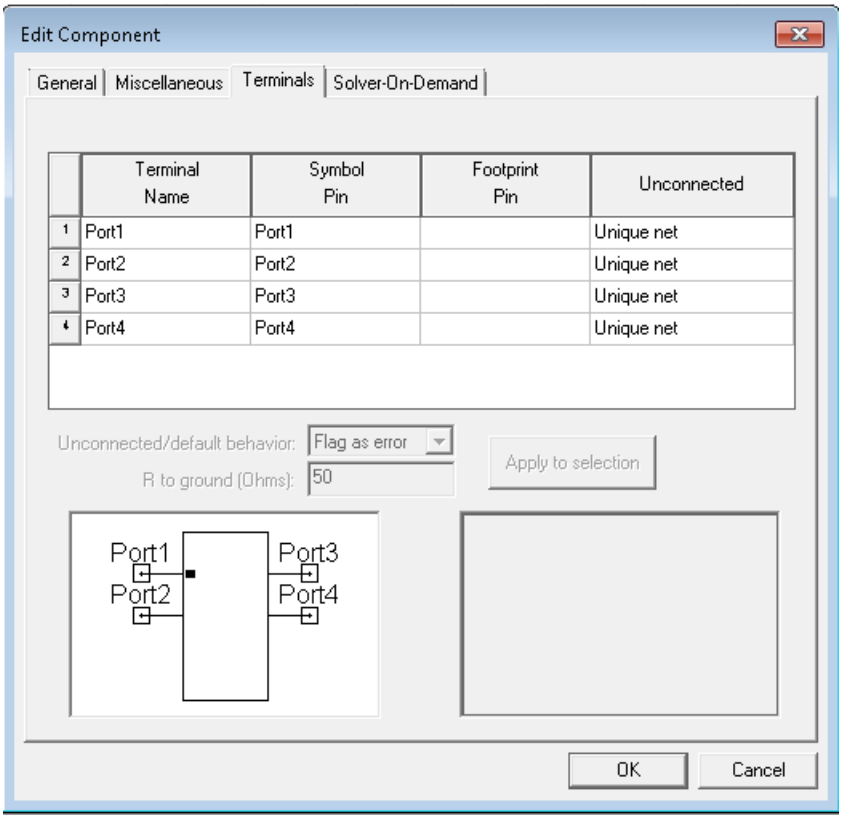


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

Components Terminals Tab

To line up component terminals in an envisioned order, Click the **Terminals** tab to associate each symbol pin with the proper terminal by first ordering the symbol pins, then selecting the corresponding symbol. This allows you to visually associate the symbol pins with the netlist properties for the simulation model. The symbol and footprint preview windows at the bottom of the window are automatically updated to reflect whatever changes you make to the symbols and footprints you modify.



The following controls are available:

In the **Terminals** display window, click one or more terminals directly, which then enables the following window options:

Unconnected/default behavior – Used to specify the response when a pin is not connected to a wire or port in a schematic. Choose between the following drop-down menu actions: **No action** (default), **Flag as error**, and **Grounded**. Click **Applytoselection** to apply your changes to the selected terminals.

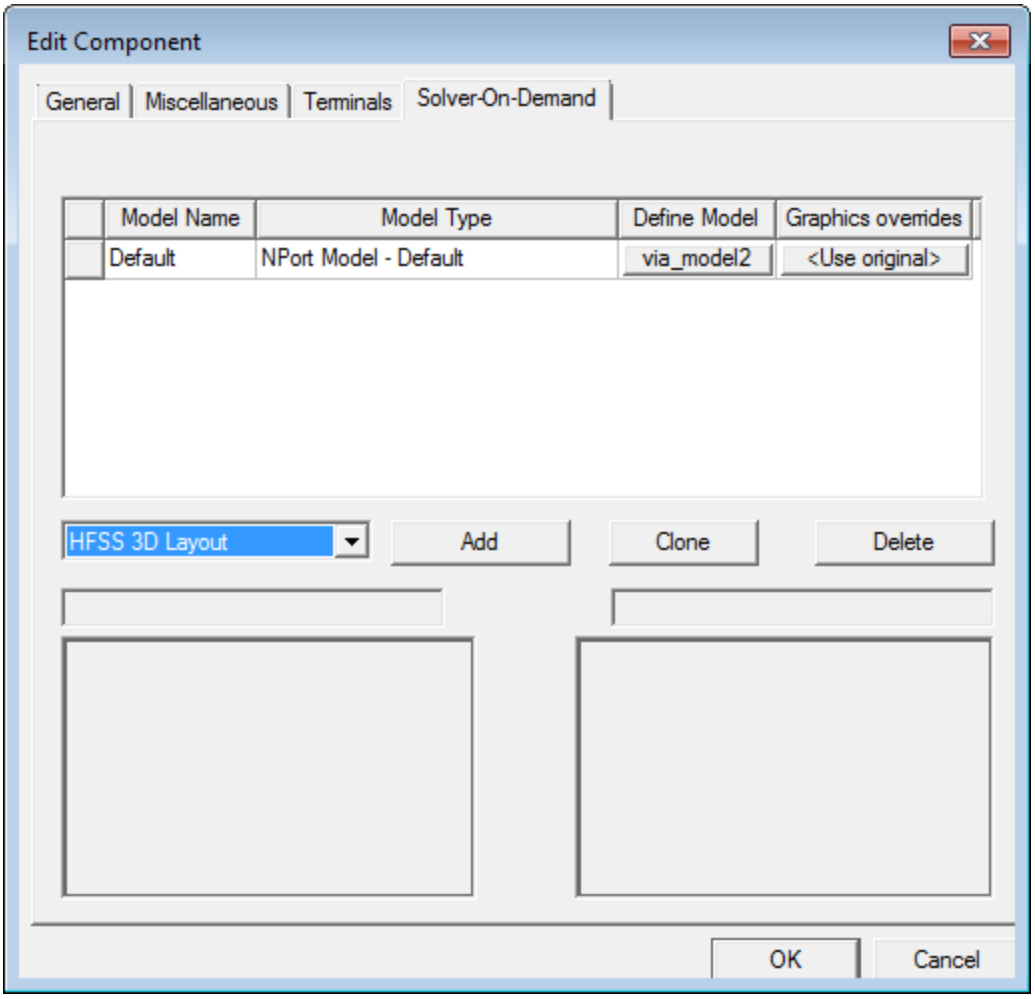
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

R to Ground – If you select **Grounded** for the **Unconnected/default** behavior, then specify the resistance to ground in the **R to Ground** entry window. Click **Applytoselection** to apply your changes to the selected terminals.

Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

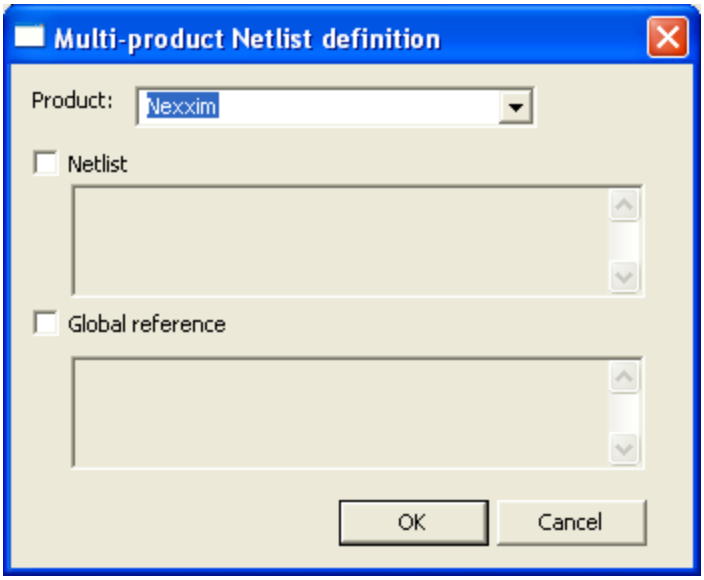
Components Solver On Demand Tab

Solver-on-Demand is a specialized routine to set up co-simulation using multiple products. When you first open the **Solver-on Demand** tab of the **Edit Component** window for a particular component, the only **Model Name** listed is the default multi-product type, **DefaultNetlist**.



DefaultNetlist is a default co-simulation definition type, provided automatically for each component, that allows you to define a different netlist for each Electronics Desktop product. Click the button in the **DefaultNetlist** row to open the **Multi-product Netlist definition** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Click the drop-down menu **Product** menu to choose which Electronics Desktop product netlist to define.
- Click **Netlist** to define a netlist.
- Click **Global reference** to define a global reference.
- Click **OK** to implement your changes, close the window, and return to the **Edit Component** window.

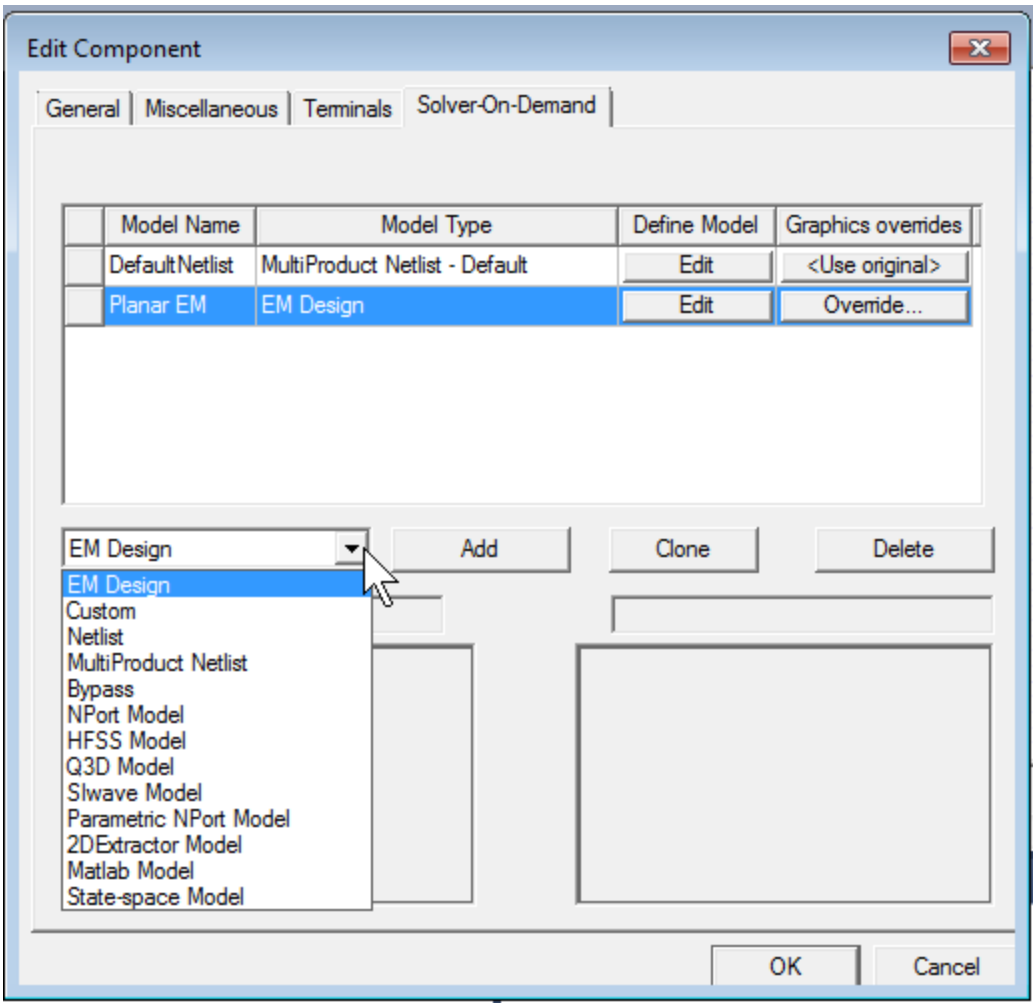
Multiple Co-simulation Models

Electronics Desktop allows for multiple representations of models that can be cosimulated. In the **Solver-on-Demand** tab of the **Edit Component** window, click in the drop-down menu to choose from a list of models to add to the list of **ModelNames**.

To add a model for Solver On Demand:

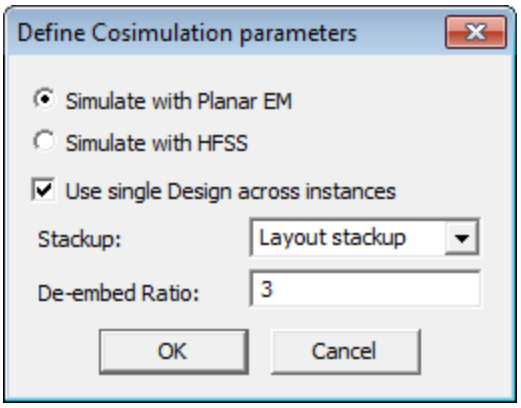
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Make a selection on the model type drop-down menu.



2. Click **Add**. A new model of the selected type is added to the list. The symbol and footprint preview windows at the bottom of the window are automatically updated to reflect whatever changes you make to a component's symbol/footprint definitions.
3. Click in the **ModelName** field for the new model and type the name you want to use for this model (or accept the default in the **ModelName** field). Note that when you highlight a **Model Name**, its symbol and footprint (if defined) are automatically previewed in the windows at the bottom of the window. These preview windows are automatically updated to reflect whatever changes you make to the component's symbol/footprint definitions.
4. Click **Edit** in the **Define Model** field (or with a **Custom** model name) to open a **Cosim** or **Netlist** definition window that is specific to the model type. Here is the window for the EM design model shown in the MSBEND component:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



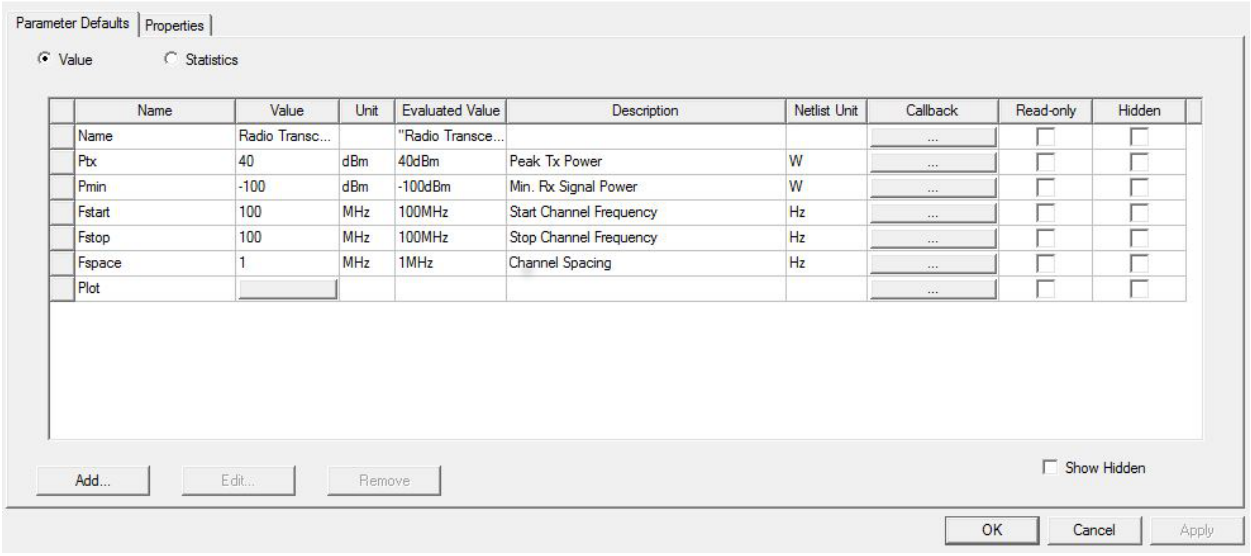
5. Repeat steps 1 through 3 to create all the models you wish to use for this type of component.
6. Click **OK** when you have defined all the models for this component type.

Repeat the above procedure to specify models for all components that is simulated using **Solver-on-Demand**.

For a complete description of the Solver On Demand tab and how to define model types, see Co-simulation.

Edit Component Properties window

To open the **Properties** window for a selected component, double-click the component definition in the **Project Manager** window to open the **Edit Components** window. Then, in the **Edit Components** window, click **Properties** to open the window.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

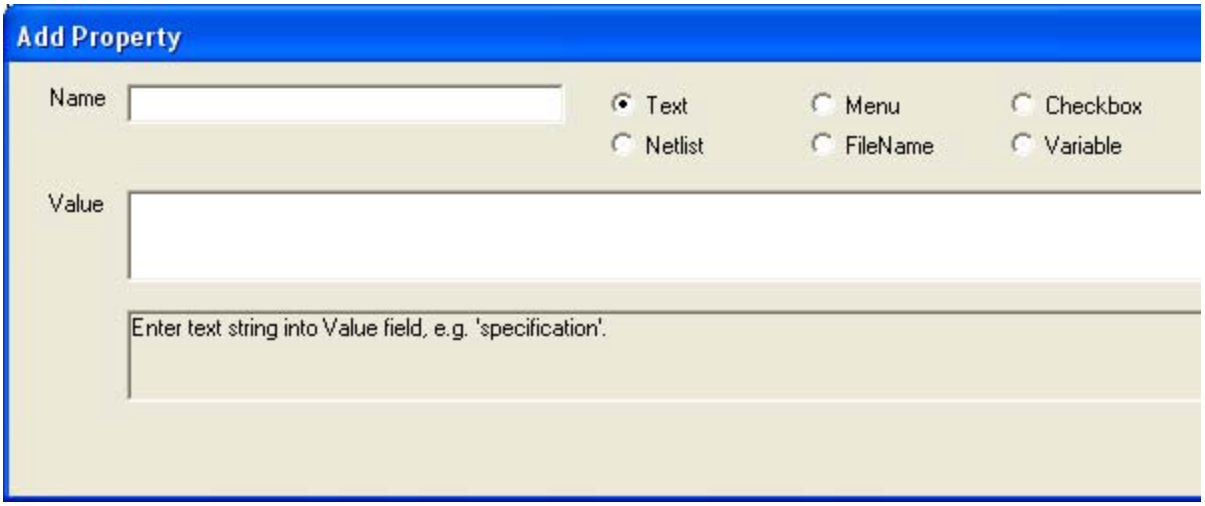
Parameter Defaults Tab

This tab displays and sets the default values for component parameters for general analysis (Value display) or statistical analysis (Statistics display).

When this option is selected, the **Parameter Defaults** tab lists, displays, and sets the default values for component parameters during general analysis.

Adding Parameters

Use **Add** to add a parameter to the definition. You are prompted to define the parameter name, value, and value type (text input, menu, check box, etc.). You may **not** add reserved system parameters to the definition.



Removing Properties

To remove a property on a component, select the property and click **Remove**. The property is deleted on the component definition (model) and from all instances in the design.

> **Warning:**
>
> Removing a property from a component from an Electronics Desktop component library may produce undesirable results when the component is simulated.

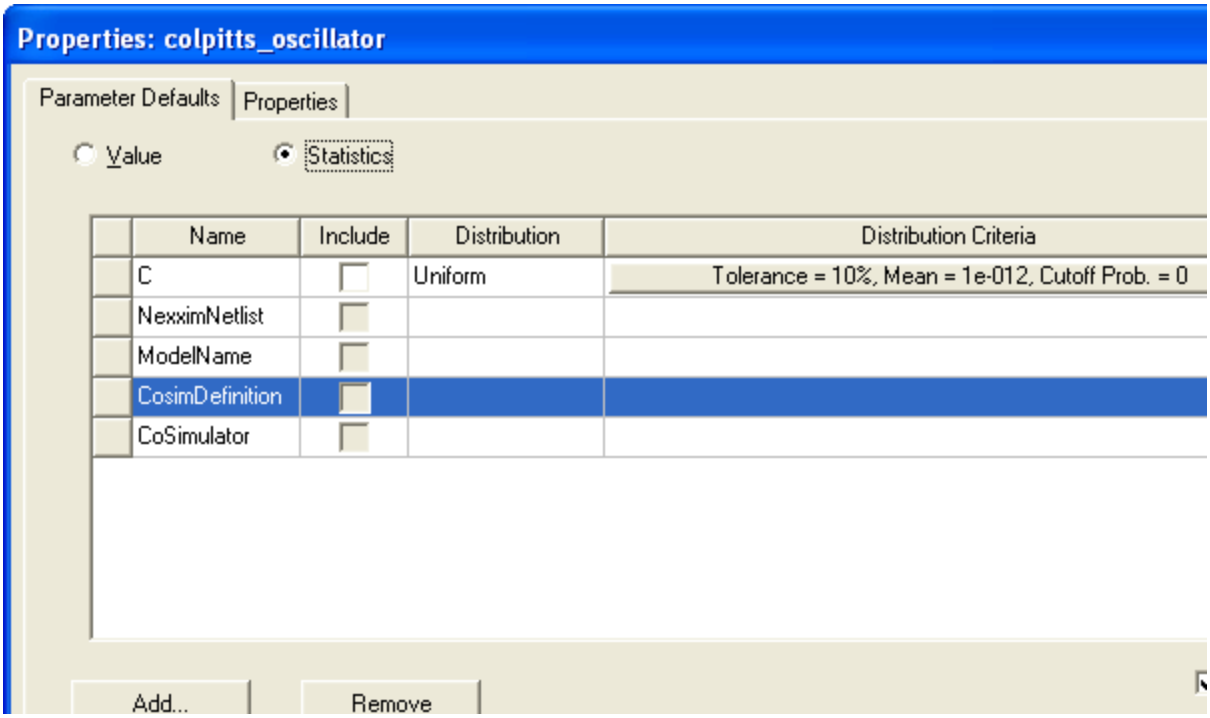
Parameter Statistics Display

Reserved Component Parameters

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Parameter Statistics Display

When this option is selected, the **Parameter Defaults** tab lists, displays, and sets the default statistics for component parameters during general analysis.



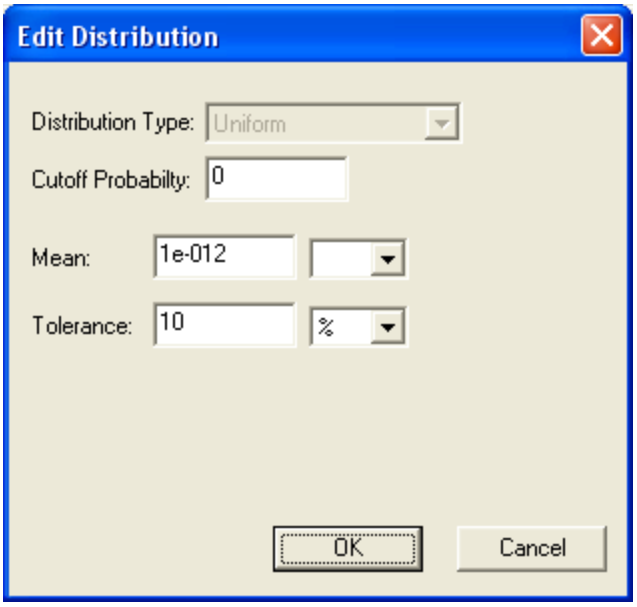
Name —Displays the names of component parameters.

Include —Controls whether or not the associated component parameter is varied during statistical analysis. Check **Include** for each parameter you want Electronics Desktop to vary during statistical analysis.

Distribution —Displays and controls whether the parameter value distribution is Uniform or Gaussian. To change the Distribution setting, click in the cell to open the options, then click the option you want.

Distribution Criteria —Click the display bar to open the **Edit Distribution** window. The **Distribution Type** drop-down menu displays whether the distribution is Uniform or Gaussian, and you can specify values for **Cutoff Probability**, **Mean**, and **Tolerance**. Units for **Mean** and **Tolerance** can be set using their adjacent dropdown menus.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

Reserved Component Parameters

When using **Add** to add a parameter to the component definition in the **Properties** window, you are prompted to define the parameter name, value, and value type (text input, menu, check box, etc.). You may **not** add the following reserved system parameters to the definition:

"Id"

"Status"

"AnalysisSetup"

Component CosimDefinition Property

A netlist is a textual representation of a circuit. The Electronics Desktop simulators extract a netlist on the schematic and perform the simulation on the netlist. The Nexxim simulator uses the Nexxim netlist format. Nexsys components within a Nexxim design use a legacy Ansys netlist format for components.

When an analysis is requested for a modified design, or when **Browse Netlist** is invoked, Electronics Desktop writes the corresponding netlist to the project results folder. The netlist conveys to the simulation engine the connectivity, parameter values, analysis specifications, and other characteristics of the design(s) under analysis. To support this process, every Electronics Desktop component must include a valid definition for the **CosimDefinition** property.

To view the **CosimDefinition** for a component:

1. Open its **Properties** window.
2. Select the **Parameter Values** tab.
3. Click **Edit** for **CosimDefinition**.

The **Multi-product Netlist definition** window opens, displaying the netlist string. Use the window to edit the string if appropriate.

Related Topics

Netlist String Syntax

Netlist String Syntax

The general form for a netlist string is:

<Simulator>Netlist=[netlist_string]

where

<Simulator> is Nexxim | Q3D | etc.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The netlist string may contain the following netlist property syntax:

%<terminal index, 0-based>

Which specifies the name of the net connected to terminal index. A syntax error results if the terminal index is not a positive number, within range. Example:

%0, %1

%_<internal node index, 0-based>

Create a unique net for an internal node. Used when a component has nodes that are not associated with symbol terminals and are not tied to a global node. Syntax error if node index is not a positive number, within range. Example:

%_0, %_1

@<propname> | @(<propname>)

Value of property named propname. Syntax error if propname is empty or contains spaces. Example:

@R, @IDSS

?<propname>(<expr1>)[:(<expr2>)]

If property named propname exists, substitute expr1, else expr2. Also, expr1 and expr2 may contain additional substitutions. Syntax error if propname is empty or contains spaces. Example:

?IDSS(IDSS = @IDSS):(IDSS = 0.05)

~<propname>(<expr1>)[:(<expr2>)]

If property named propname doesn't exist, substitute expr1, else expr2. Syntax error if propname is empty or contains spaces. Example:

~SUB(SUB = MS)

?(<propname>==<value>)(<expr1>)[:(<expr2>)]

?(<propname>!=<value>)(<expr1>)[:(<expr2>)]

~(<propname>==<value>)(<expr1>)[:(<expr2>)]

~(<propname>!=<value>)(<expr1>)[:(<expr2>)]

Same as "?" and "~" above except the first term is evaluated for equal to (==) or not equal to (!=) and if true, substitute expr1 else expr2. Example:

?(sim==fullwave)(NSUM=@NSUM):(F0=@F0)

***<propname>(<expr1>)**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If property named propname has changed from default definition value, then substitute expr1. Syntax error if propname is empty or contains spaces. Example:

*IDSS(IDSS = @IDSS)

&(<expr>)[^(pname1,pname2, . . .)]

Add all properties that have changed from default definition value, except those in the optional exclusion list. In expr, “$” can be used to represent the property name, and “#” the property value. Example:

&($=#)^(Model)

netlists all properties that changed on their default value except the Model property.

\n

A new line marker to inform the netlister to insert a new line. Example:

R@ID %0 %_0 @R \n C@ID %_0 %1 @C

****

The backslash is used as an escape character. The character following the backslash is not processed but added to the netlist string as is. To add a single “\”, use “\\”. Example:

R:@ID %0 %1 R=\{\2*@R\}

Defined Variables

- $SYSLIB is expanded to **<InstallationDirectory>/syslib** upon netlisting, where **<Installation Directory>** is the directory into which Electronics Desktop was installed during setup.
- $USERLIB is expanded to **<InstallationDirectory>/userlib** upon netlisting.
- $PERSONALLIB is expanded to **<ProjectDirectory>/PersonalLib** upon netlisting, where **<ProjectDirectory>** is the location you specified for your Electronics Desktop projects.

Global Reference String in Electronics Desktop

A global reference property processes its value the same way as the netlist string and places the result in the top-level (global) part of the circuit file.

<Simulator>GlobalRef=[string]

where

<Simulator> is Nexxim | Q3D | etc.

Additional Examples

The following additional examples help to demonstrate netlist string syntax.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

NexximNetlist= CPLE@ID %0 %1 %2 %3 ?Z(Z=@Z) ?E(E=@E) ?F(F=@F) *A(A=@A)

“Z”, “E”, and “F” use the "?" conditional because the component definition values assigned to these parameters are different from those in the engine and should always be netlisted if they are present even if the user has not changed them. The “A” parameter uses the "*" conditional because its component definition value matches that of the engine and it needs to be netlisted if the user changes the instance value.

NexximNetlist= R@ID %0 %1 @R ?TC1(TC1=@TC1 ?TC2(tc2=@TC2)) ?TJ(TJ=@TJ) ?TNOM(TNOM=@TNOM)

In this example, TC1 is netlisted only if TC1 exists, and TC2 is netlisted only if TC1 and TC2 exist.

NexximNetlist= MSBENDO@ID %0 %1 w=@Length sub=@Substrate

“w” and “sub” is netlisted.

NexximNetlist= MOSFET@ID %0 %1 %2 %3 MODEL=@Model &($=#)^(Model)

Model is netlisted. The “&($=#)^(Model)” argument designates that all parameters should be netlisted as “name=value”, except for “Model”.

NexximNetlist = D@ID %0 %1 1N914

NexximGlobalRef = .LIB $SYSLIB/Vendor/D.lib

which may netlist to:

D22 net_3 net_4 1N914

< rest of design netlists ...>

.LIB $SYSLIB/Vendor/D.lib

NexximNetlist= R@ID %0 %1 R=\{\2*@R\}

If ID is 1 and R is 100, the netlist is:

R1 net_0 net_1 R={2*100}

Using Vendor Components

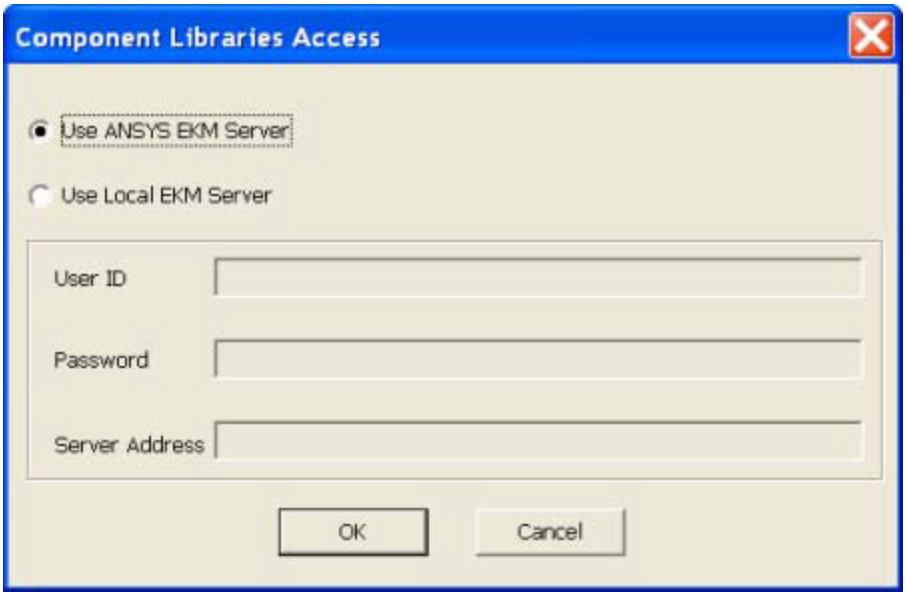
Electronics Desktop allows you to download vendor components from a server. After being downloaded, libraries are automatically configured so these components can be used in Electronics Desktop.

Some installations of Electronics Desktop include a set of RF Vendor Library components. To use these elements, you unzip the files into the **syslib/Vendor Elements** directory in **Electronics Desktop** installation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

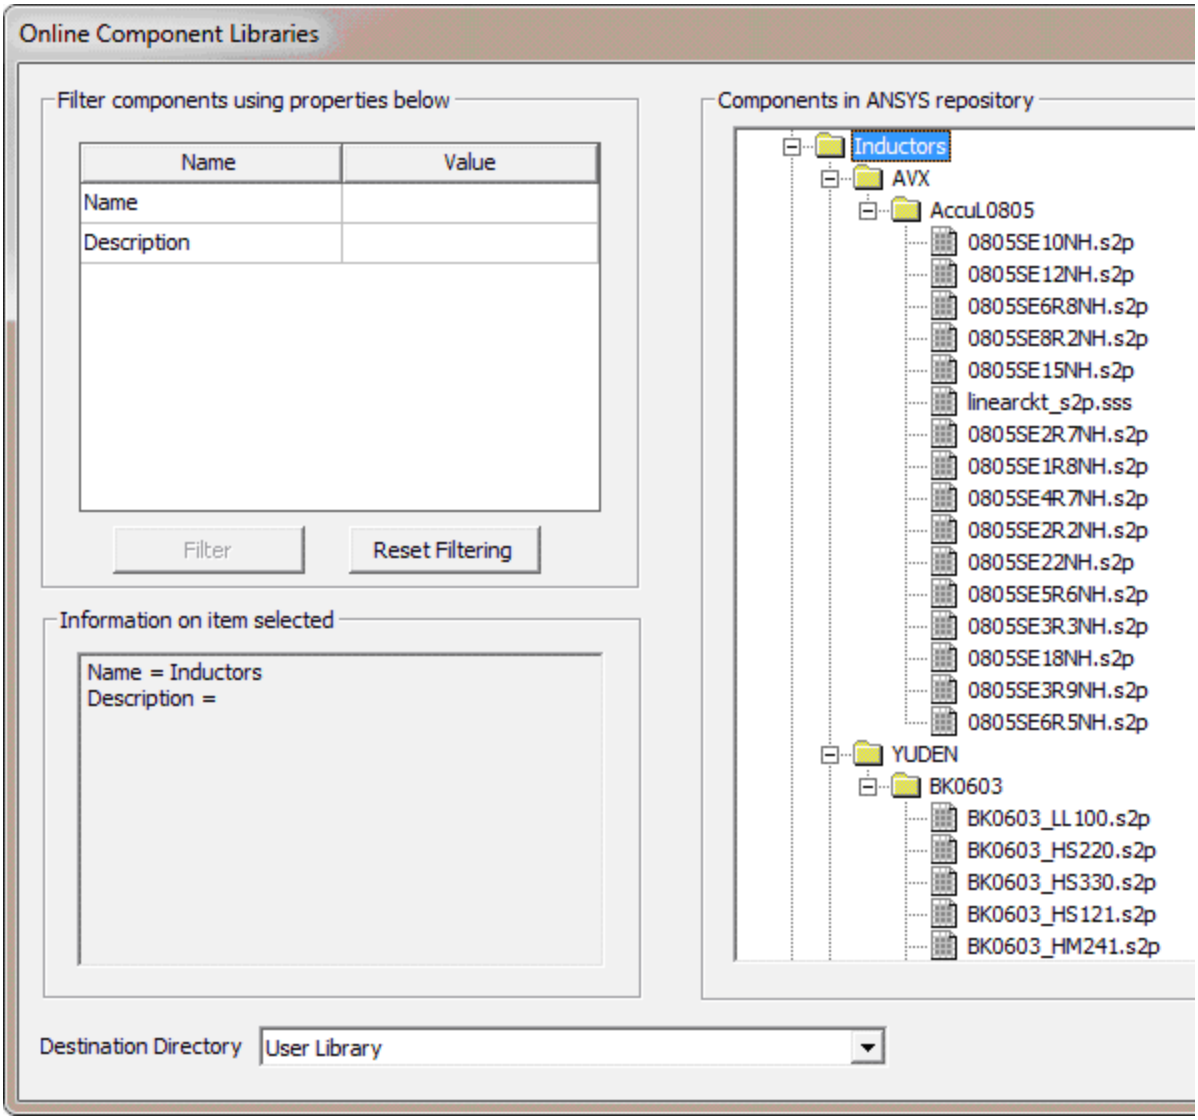
Downloading Vendor Components

Electronics Desktop allows you to download vendor components from a server. After being downloaded, libraries are configured so these components can be used in Electronics Desktop. Server files to be downloaded must be set up in a predefined manner with certain property values. When a Electronics Desktop circuit is active, click **Tools > Library Tools > Download Vendor Components** to open the **Component Libraries Access** window.



Select a server, then enter the User ID, Password, and Server Address. Then click **OK** to open the **Online Component Libraries** window:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The web library window displays files as well; click on '+' next to folders for expansion.

Filter components using properties

- Shows filter criteria, and is used for choosing values for file properties, such as Vendor, Type, and NumPorts.
- Users can search for files and folders using the 'Filter' option.
- The Series property allows you to enter text, including regular expression values with wild card characters, such as "NEC202*".
- Click **Reset Filtering** to set all properties to their most inclusive values ("Any" or "All"). When you choose a new value in the **Filter components** pane, only folders satisfying the filter values are shown in the center pane.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Information on item selected

- Displays 'Name' and 'Description' property of the files and folders as the user navigates through the files in the center pane.

Components in Ansys repository

- The center pane of the window shows all the folders that satisfy the filter criteria.
- Folders are organized into a tree control, so that they can be identified correctly (you must have the full path to uniquely identify a series folder). If you move a cursor over a series folder and hover, text will appear with helpful information about that folder.
- Drag and drop any folder on the center-tree control to the right pane to copy the folder and display it in the right pane.

Components selected for download

- The right pane shows the component folders you have chosen for downloading and behaves the same as the center pane (tree control, hover information).
- If you drag something outside of the right pane and release it, the dragged folder is removed on the pane and cannot be downloaded.

Destination Directory

- For 'Vendor Components', the "Destination Directory" dropdown menu has two choices: User Library and Personal Library.
- For 'Other Files' and 'Project Archives', the drop down has three choices: User Library, Personal Library and a 'Browse…' option. 'Browse…' option allows users to download selection to a directory of their choice.
- When you are happy with the contents of the right pane, click **Download Selected** and all files in the selected folders are downloaded to the Destination.

Using RF Vendor Library Components

The RF Vendor library contains vendor-specific components for Electronics Desktop RF installations. The library is delivered as a compressed file, **Vendor_Libraries.zip**, in the **syslib/Vendor Elements** folder under your Electronics Desktop installation directory.

Here are the steps to follow to enable and place these elements.

Unzip the library directory:

1. Browse to the **syslib** folder in your Electronics Desktop RF installation. The directory path should be something like the following:
   `C:\Program Files\AnsysEM\v`*`xxx`*`\`*`Win64`*`\syslib`

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The entry, *xxx*, is the Ansys EM release number. The operating system field (*Win64* in the example, for the Windows OS) is *Linux64* for the Linux OS.

2. Ensure you have write permission in the **syslib** folder.
3. Open the folder **Vendor Elements**.
4. Locate the file **Vendor_Libraries.zip**.
5. Using any compression tool, extract the contents of the zip file to the **Vendor Elements** folder.

   The folder **Vendor_Libraries** should appear in the **Vendor Elements** directory.

> **Note:**
>
> Since configuration happens automatically at Ansys Electronics Desktop startup, if you unzip the archive while **Electronics Desktop** is open, you may need to save work, close, and restart **Electronics Desktop**.

Place the Component, select Vendor, Series, and Part.

1. In the **Component Manager** group box of Electronics Desktop, you should see a **Vendor Elements** directory with the **Vendor_Libraries** folder. Expand the folder, the **vendors** folder, to display a listing of the component types in the library (Amplifier, Capacitor, etc). Each component type represents a number of components from different vendors.
2. Double-click the icon for the type of part you want to place, then drag the symbol into the design area.
3. Right-click the component, and edit the **Properties**.
4. Select a **Vendor** on the listing of available vendors for the component type.
5. Select a **Series** on the listing available series on the selected **Vendor**.
6. Verify that the **Part** property has the part you wish to use. If the **Part** menu is not populated, or if the part you want is not in the list, change the **Data Type** property (**S-parameter**, **State-Space**, or **subcircuit**) until the part appears on the Part property menu.
7. Select a **Part** on the listing of available parts in the selected **Series**.
8. Optionally, use the **Sweep** window to select a text array variable containing part names to sweep while simulating the component. The text array variable must have been defined previously. See: Adding a Project Variable Array.
9. Click **OK** to close the **Properties** window.
10. Connect the component to the circuit.

Optionally, browse through the folders under **Vendor_Libraries** in the **syslib/Vendor Elements** directory. You can see what Vendors, Series, and Parts are available for each component type. The file extensions on the Part files indicate the **Data Type**:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- S-Parameter data types use the **.sNp** file extension.
- State-Space data types use the **.sss** file extension.
- Subcircuit data types use either the **.ckt** file extension or the **.lib** file extension.

Encrypted Libraries

Electronics Desktop lets users create personal, encrypted files of design information (typically in SPICE format) that they may be added to other designs via *.lib*, *.va*, or *.inc* statements. Encrypted library files are password-protected. If the user references an imported encrypted *.lib* or *.va* file with a user-defined password, the first time a component from the file is used, **Electronics Desktop** prompts the user for the encryption password. The library file and password are then added to the list of password definitions in the **Tools** > **Password Manager** window.

> **Note:** For security reasons, encrypted components are not saved in the **Most Recently Used** list or the **Favorites** list.

Creating and Managing Encrypted Libraries

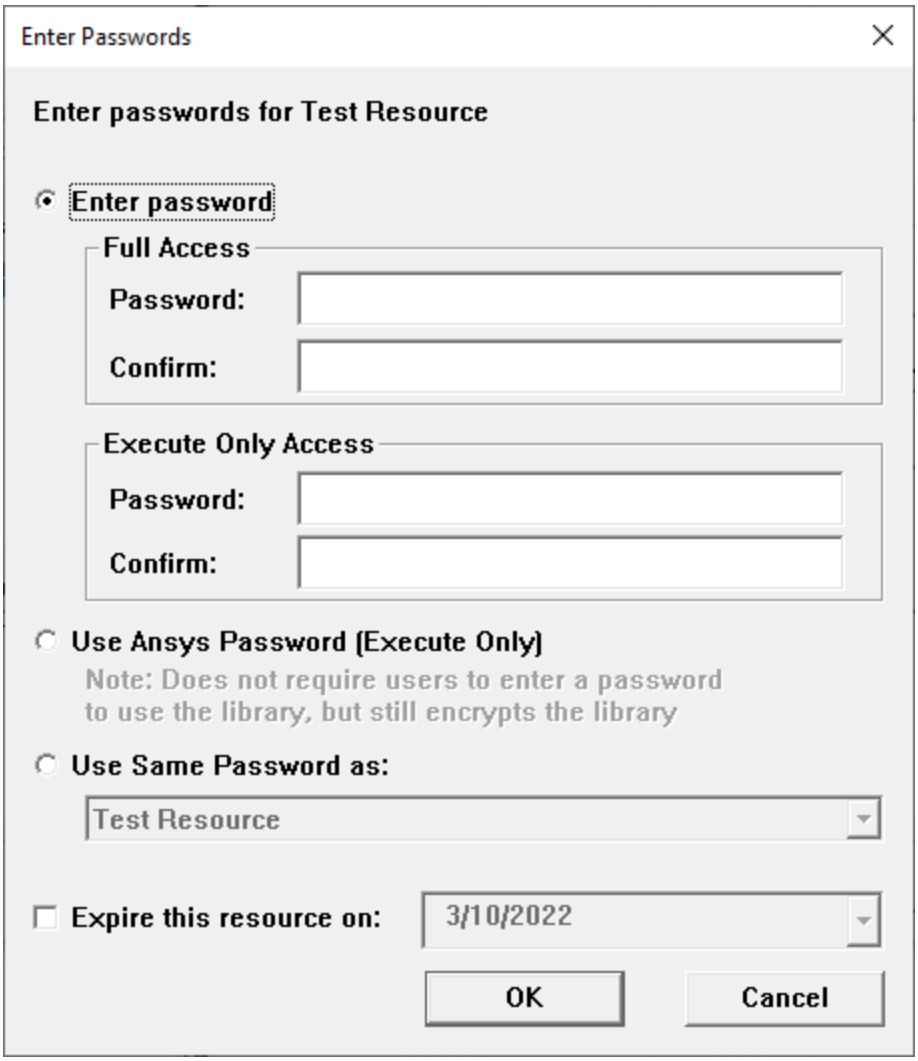
Electronics Desktop lets users create encrypted password-protected files (typically in SPICE format) that may be added to other designs via *.lib*, *.va*, or *.inc* statements. Access the encryption tools through the **Tools** > **Password Manager** window.

Password Assignment Types

From the **Enter Passwords** window, accessible on the **Password Manager** > **New...** option, an encrypted file may be assigned a choice of password types:

- **Enter password**: User-defined passwords for an encrypted library file. Entering and confirming **Full Access** passwords grants users simulation, read, and edit permissions, while **Execute Only Access** permits users to add components and simulate a design, but they cannot read or edit the contents.
- **Use Ansys Password (Execute Only)**: A generic, hard-coded execute-only password shared across all Ansys products. Any Ansys product may read an applicable file encrypted in any other Ansys tool using the **Ansys Password**, making it the easiest way to share encrypted library files among Ansys applications if the files are not expected to be viewed or editable.
- **Use Same Password as**: Choose an existing resource on the drop-down menu to use the same password settings and synchronize passwords across multiple library files.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

1. Passwords are not saved between sessions and must be re-entered each time **Electronics Desktop** is started. Passwords *are* available after one project is closed and another is opened, if the application is not restarted.
2. **Electronics Desktop** and Nexxim use the Advanced Encryption Standard (AES) to encrypt libraries and models. **Electronics Desktop** and Nexxim use a 128 bit block cipher with a 256 bit key.
3. You can encrypt selected parts of a file by enclosing them within a protected “block”. You can set up multiple .protect/.unprotect blocks in the same file, but you cannot nest them.

   e.g.,

   .protect

   This block is encrypted.

   .unprotect

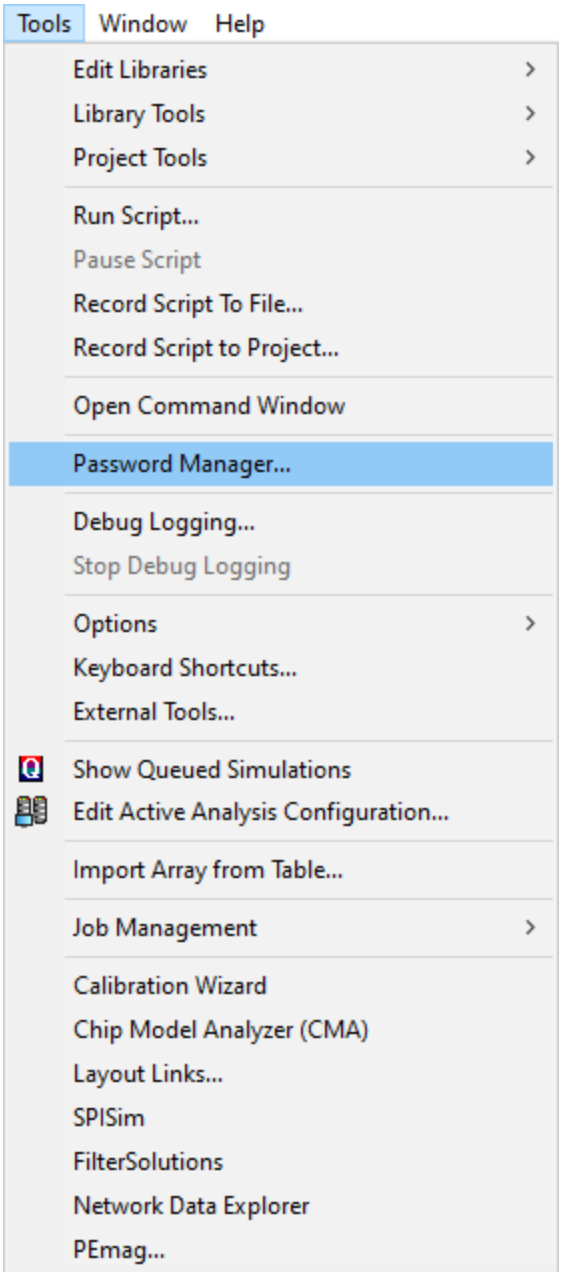
Setting Up Passwords and Encrypted Libraries

Because an encrypted library requires a password, encryption is done through the **Password Manager** window. The **Password Manager** windows lets users create a password or password set as a "password protected resource", which is a group of encrypted files which use the same password. Once the resource and its password type is defined, select it as the password for one or more newly encrypted libraries.

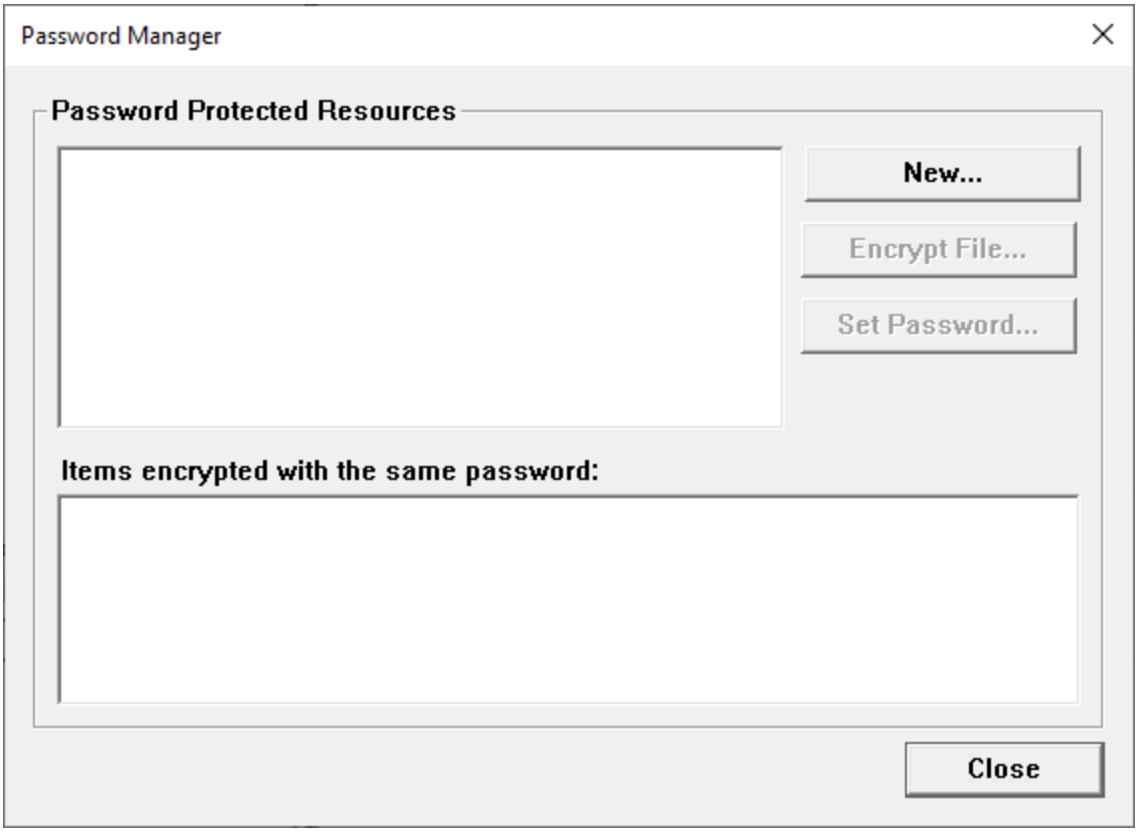
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Generate a New Password Protected Resource

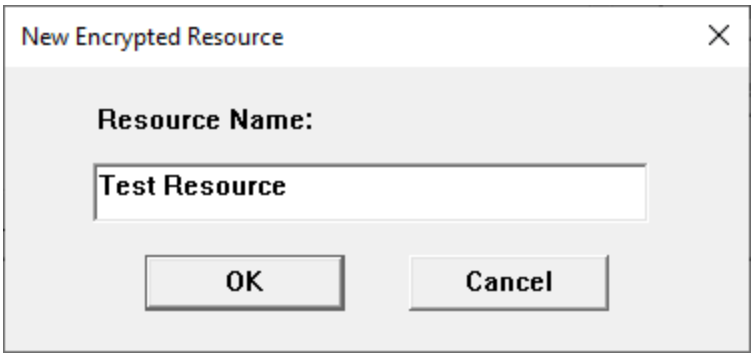
1. From **Tools**, select **Password Manager...** to open the **Password Manager** window.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

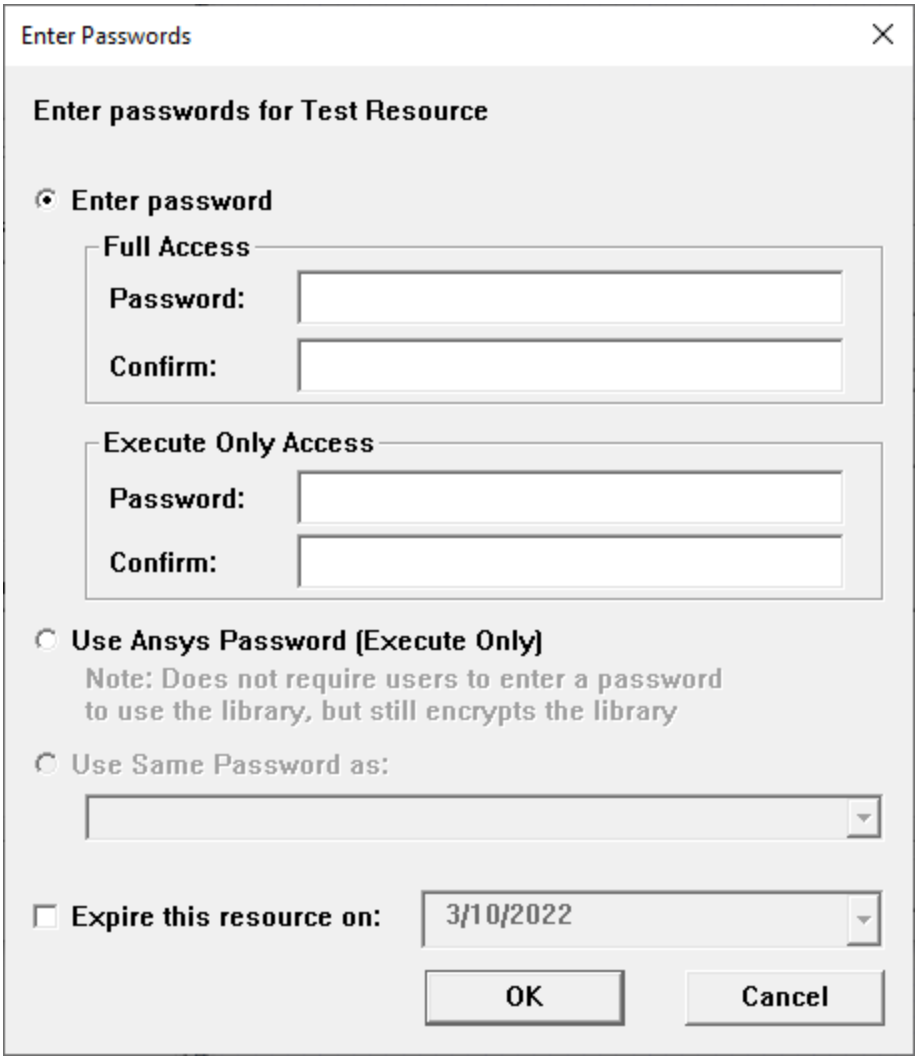


2. Click **New...** to open the **New Encrypted Resource** window.



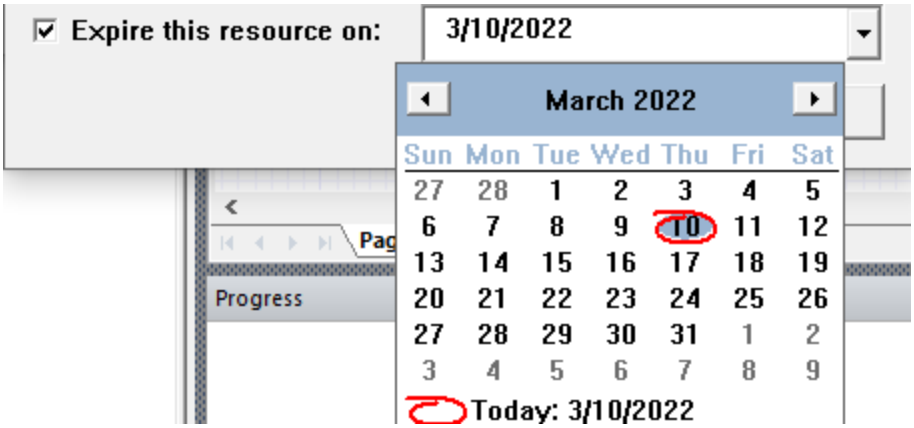
3. Type a name for the resource into the field. Then click **OK** to simultaneously close the **New Encrypted Resource** window and open the **Enter Passwords** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

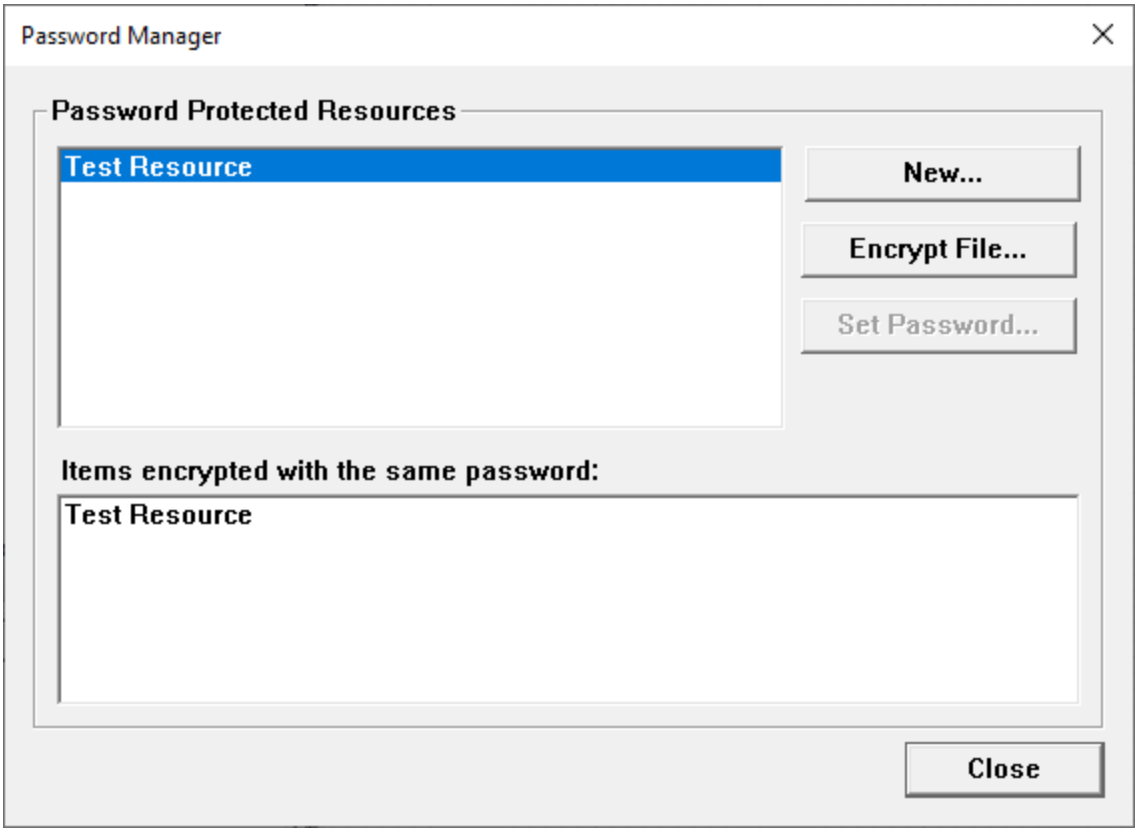


4. Choose on the following:
    - **Enter password**: choose between **Full Access** and **Execute Only Access**, then enter and confirm the new password in the given text fields.
    - **Use Ansys Password (Execute Only)**: as stated, this choice does not require users to enter a password to use the library, but still encrypts the library.
5. Optionally, assign an expiration date for the encrypted library by checking the **Expire this resource on** box and selecting a date on the drop-down calendar. If an expiration date is assigned to a library during encryption, the library cannot be used after the assigned date.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

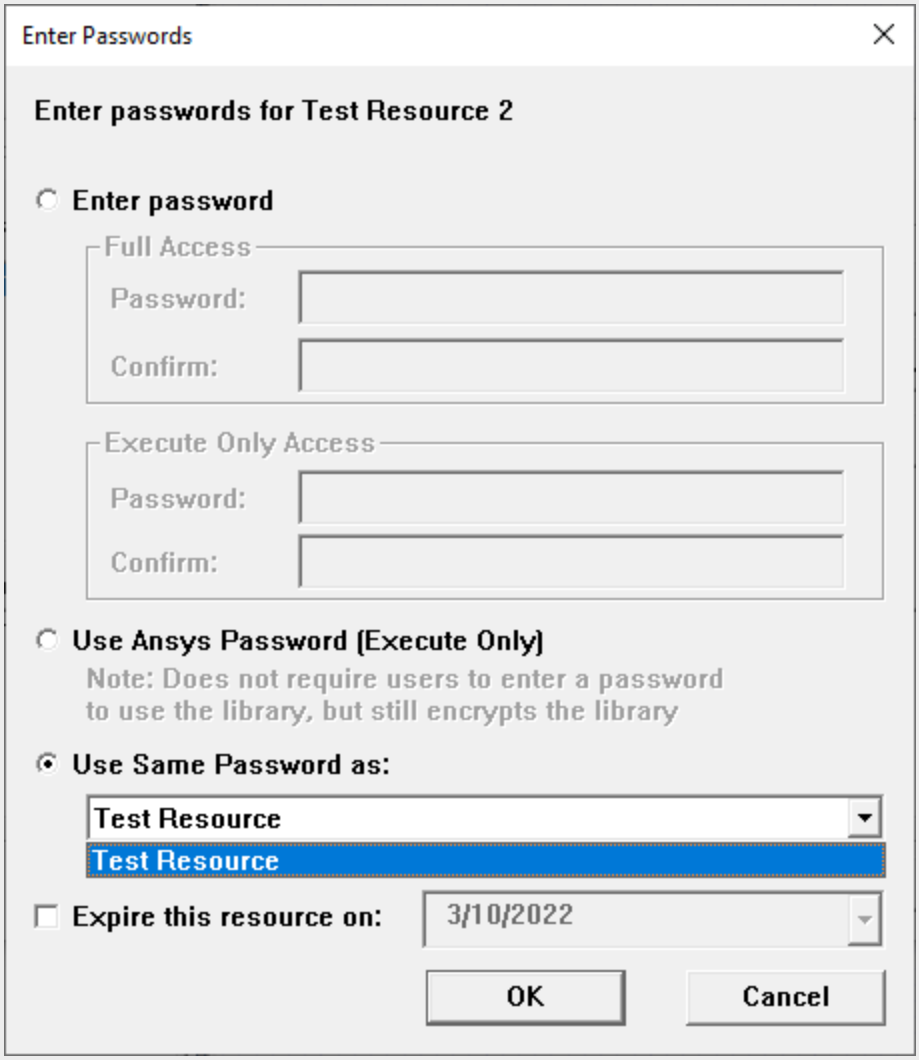


6. Click **OK** to add the new resource to the **Password Manager** list and simultaneously close the **Enter Passwords** window. Any number of libraries may be assigned to the new resource.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: Once one or more resources have been added to the **Password Protected Resources** list on the **Password Manager** window, **New** resources can use the same password profile. From the **Enter Passwords** window, select **Use Same Password as**, which was previously unavailable, and choose the existing resource on the drop-down menu.

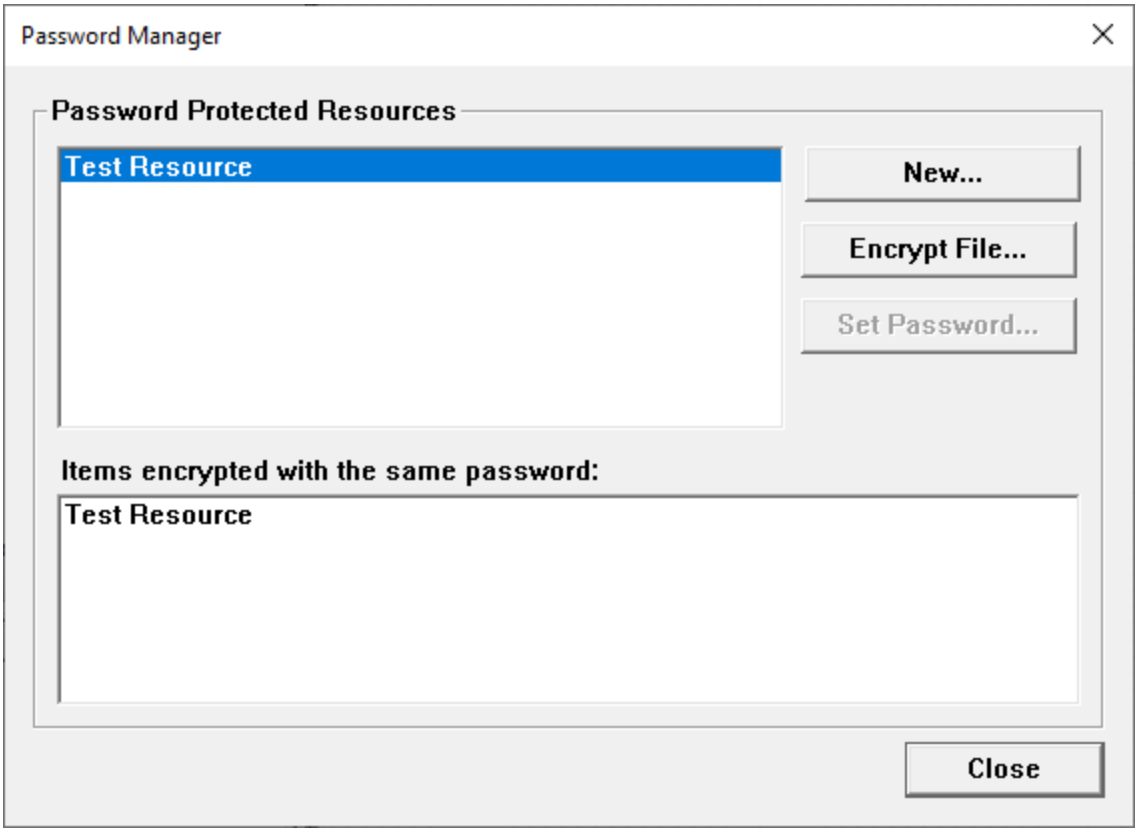


Generate a New Encrypted Library

When a library file is encrypted, the user can choose to overwrite the existing target library with the encrypted one, or save the encrypted library file with a new name and/or to a new location. During encryption, the user is prompted to choose whether the process respects .prot[ect] statements or ignores them. To generate a new encrypted library, complete the following steps.

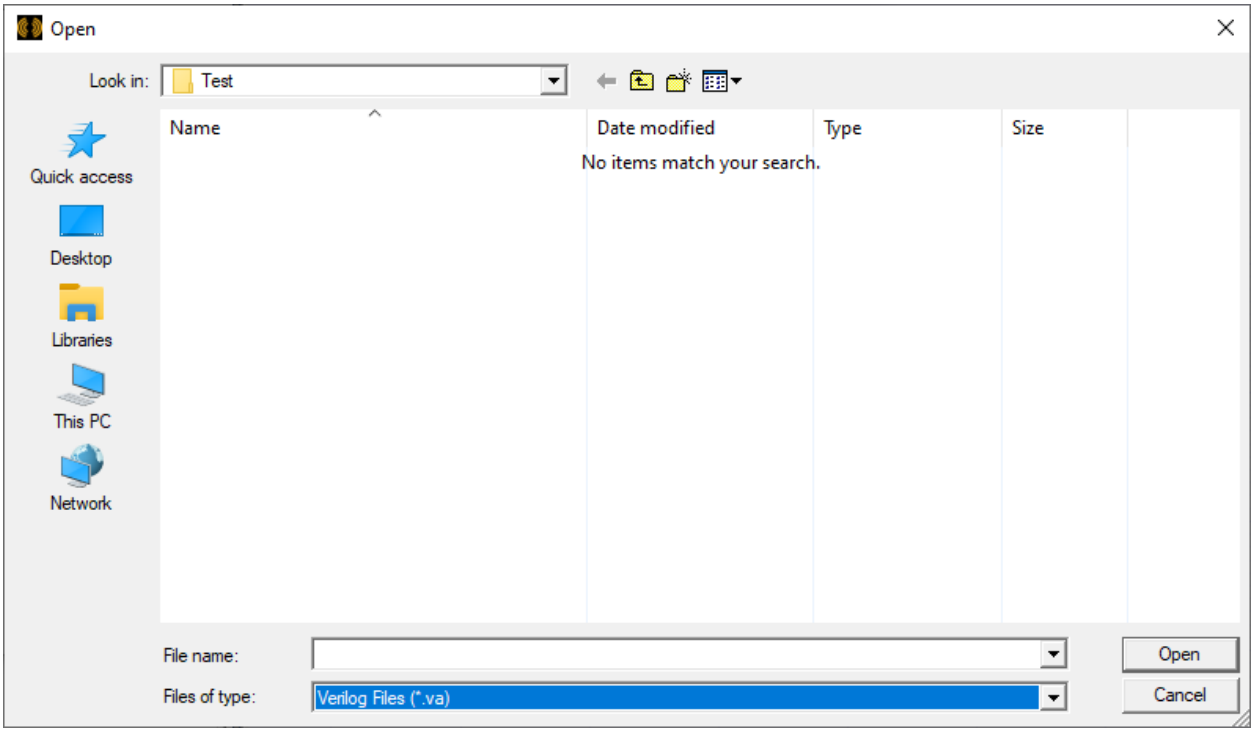
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. From the **Password Manager** window, select a resource on the **Password Protected Resources** list to enable the **Encrypt File...** button.



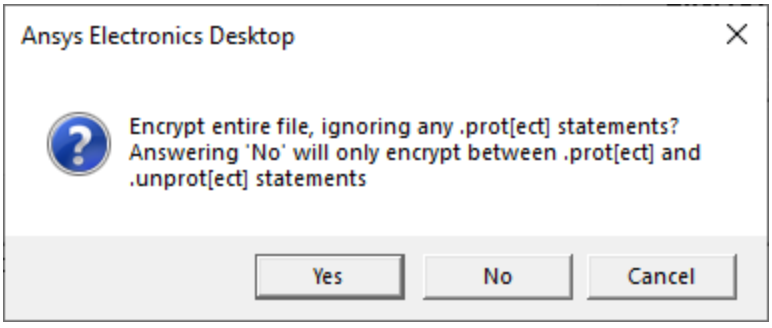
2. Click **Encrypt File...** to open an explorer window. Navigate to the appropriate library file.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



> **Note:** Only library files with **Circuit (.*lib)** and **Verilog (.va)** file extensions are valid.

3. Select a library file, or first narrow the available choices by selecting **Circuit Files (.*lib)** or **Verilog Files (.va)** on the **Files of type** drop-down menu. Then click **Open** to immediately open the prompt: **Encrypt entire file, ignoring any .prot[ect] statements?**



4. As stated in the prompt, choose on the following:
   - Click **Yes** to permanently encrypt the entire library file.
   - Click **No** to recognize any **.prot[ect]** statements and encrypt only the remaining

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

aspect.

- Click **Cancel** to exit out of the prompt and return to the previous explorer window.

5. After the library file is encrypted, an explorer window will appear. Navigate to an appropriate location to save and/or rename the file, if appropriate. If the encrypted library file is saved to the same location and with the same file name as the original unencrypted library file, the unecrypted file is overwritten permanently.
6. Click **Save** to close the explorer window and create the encrypted library file.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

23 - Dynamic Links and Solver On Demand

Co-simulation is a feature of Ansys Electronics Desktop that allows you to simulate a design using multiple simulators. Two co-simulation mechanisms are available: Dynamic Links to subcircuits and Solver On Demand.

- Dynamic Link co-simulation occurs whenever a schematic design contains a dynamic link subcircuit. A dynamic link subcircuit links to a project that was created using a simulator different from the top-level simulator. The dynamically linked project generates simulation results using its native simulator in parallel with the top-level simulator.
- Solver On Demand allows selection of among Circuit or Nexsys co-simulation using a component netlist or HFSS 3D Layout simulation using a layout or footprint, and simulation by a one of a variety of solvers accessed by connecting to a previously defined model.

Dynamic Links

Dynamic linking a subcircuit to a project allows the simulation of the subcircuit with the project native simulator in parallel to the Circuit simulator. The dynamic link subcircuit can provide simulation results on demand using its native simulator in parallel with the Circuit simulator.

The Circuit project can also import *static* subcircuits derived from external simulators. A static subcircuit is a component with a fixed set of solution data, such as Touchstone N-port data. No co-simulation is involved in the simulation of a static subcircuit. See Importing Circuit Models.

The following dynamic link project types are supported from a Circuit (Nexxim) top circuit:

- HFSS
- Q3D
- 2D Extractor
- SIwave

At simulation time, the top-level circuit receives solution data from its subcircuit in order to perform its own simulation. The top-level circuit uses a callback mechanism to wait for subcircuit data while simulating. Since co-simulation circuits are from different products, the type of data being sent back and forth varies. In co-simulation, voltages and currents are usually sent back and forth.

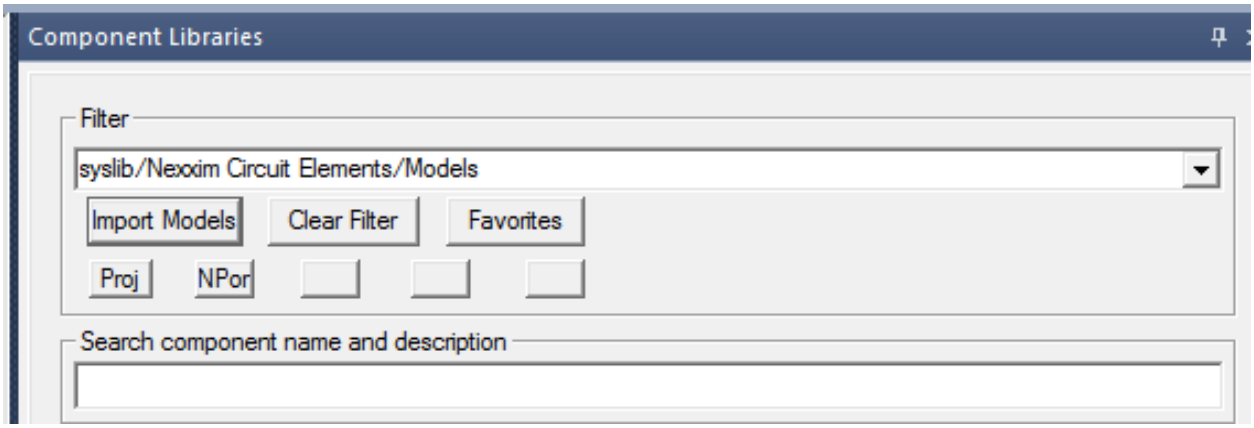
Selecting a Dynamic Link Project

The Models Library is a library of templates to import and place components that represent dynamic links to HFSS, Q3D, 2D Extractor, and SIwave projects. There are several ways to create a dynamic link.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

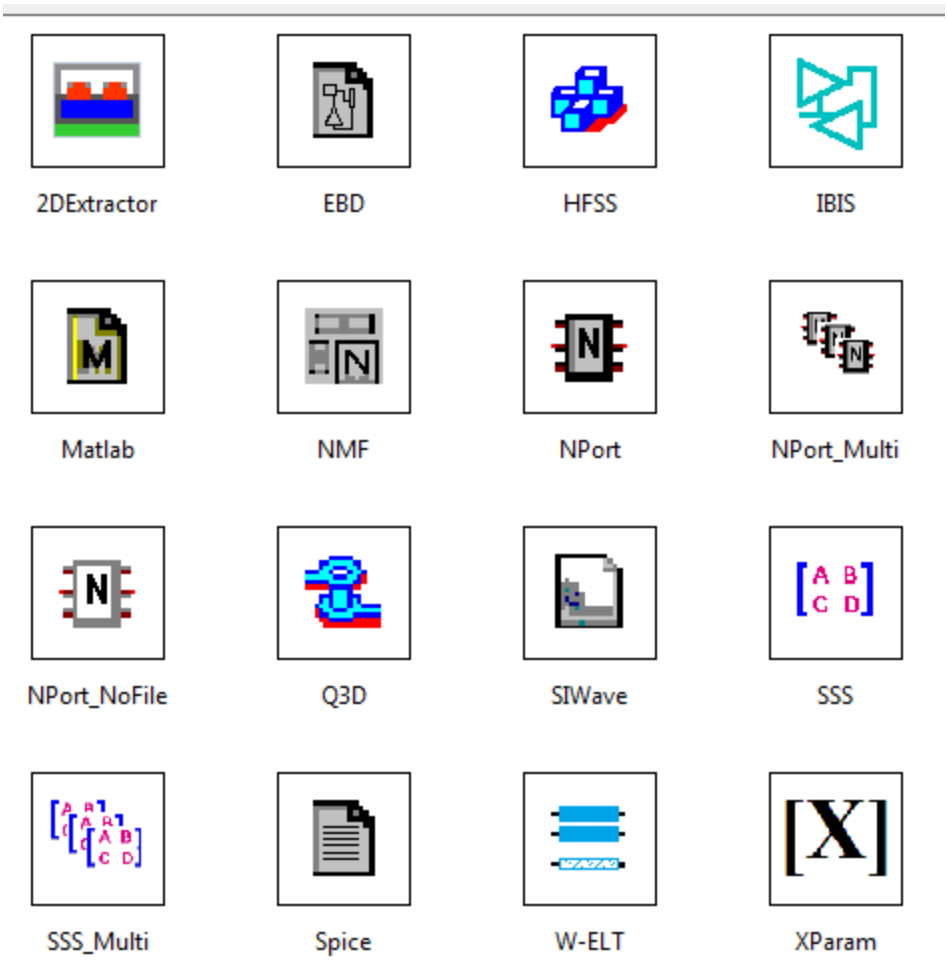
Dynamic Links on the Symbols Tab of the Component Libraries Panel

You can invoke the Models on the **Symbols** tab of the Component Libraries group box, by selecting **Import Models.** .



The **Symbols** group box displays the templates available for creating static and dynamic link models and components.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The dynamic link icons are **2DExtractor**, **HFSS**, **Q3D**, and **SIwave**. Clicking on one of these icons opens a window to choose the project file. When the file is open, if necessary, a second window opens to retrieve additional information. Once you click **OK**, clicking in the schematic places the new component.

Dynamic Links on the Add Subcircuits Menu

To create a dynamic link on the **Project Manager** window, right click a project and select **Add Subcircuit** to open a submenu. Clicking on one of the **Add Link** selections opens a window that allows you to choose a project file. When the file is opened, if necessary, a second window opens to retrieve additional information. Once you click **OK**, clicking in the schematic places the new component.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Drag and Drop or Copy and Paste to Create a Dynamic Link

You can drag and drop, or copy and paste, a project from an open folder, or on the **Project Manager** window, into an open schematic project.

- Dragging and dropping an .aedt project opens the project.
- Dragging and dropping an HFSS, Q3D, 2D Extractor, or SIwave project in the same **Project Tree** creates a new dynamic link.

> **Note:**
>
> If you hold **Ctrl** down while dropping or pasting, the appropriate Dynamic Link window opens, which allows you to make choices such as using an HFSS dynamic link in Transmission Line Model mode.

Using the Model Filter

Once a component of a given type has been created, you can use the filter to display all the models of a given type. For example, after placing several NPort components, view the **Symbols** tab, and type "NP" into the **Filter** group box and choose "type: NPort". This filters to show only NPort components.

For more information, see Using the Component Libraries Window.

Adding a Dynamic Link from HFSS

To create a dynamic link from HFSS to Ansys Electronics Desktop, either import the HFSS data as an N-port device or drag and drop an HFSS design on the **Project Manager** window into an HFSS 3D Layout design to create a link, or use copy and paste on the **Project Manager** window to create a dynamic link.

Add an HFSS dynamic link in the same ways to a Nexxim design as to an HFSS 3D Layout design.

> **Note:**
>
> 1. When you add an HFSS subcircuit, **Electronics Desktop** opens **Electronics Desktop** version of the HFSS project. You must close the HFSS project and the Circuit project separately.
> 2. In HFSS, differential terminal data is transferred to **Electronics Desktop** as underlying terminal data — which is not differential. For this reason, differential data plotted in HFSS may not agree with raw terminal data plotted in Ansys Electronics Desktop.

Add an HFSS N-Port Model

Renormalize Ports Based on HFSS Data

Transmission Lines Based on HFSS Data

Access to HFSS Output Variables from Nexxim

Add an HFSS N-Port Model

1. Open the HFSS design you want to link.
2. Open the Circuit design.
3. In the **Component Libraries** group box, open the **Symbols** tab.
4. Click **Models**.
5. Click the **HFSS** tile. The **HFSS Dynamic Link** window opens:
    a. The **Name** fields displays the HFSS design name.
    b. Enter a **Description** if appropriate.
    c. Select a design on the **Project Manager** window. If the design you want is not present, click **Open Project** to find and open that design.
    d. Enable **Transmission Line Model** to use the dynamic link port impedance. The drop-down menu shows the port name of the HFSS design that is used for the transmission line. To change it, select a different port on the list.
    e. The **Link Information** group box at the bottom of the window shows the selected frequency points and number of pins.

> **Note:** The **HFSS Dynamic Link** window only opens if a project with an HFSS design is already opened. If no open projects have an HFSS design, an explorer window opens. In which case:
>
> 1. Browse to the directory that contains the HFSS project for the dynamic link.
> 2. Select the HFSS project file.
> 3. Click **Open**. **Electronics Desktop** pauses for a few seconds while HFSS starts up. The **HFSS Dynamic Link** window then opens then be displayed with this project displayed in the **Project Manager** window.

6. Click **OK**. An instance of the component is attached to the cursor. Drag and drop it into the schematic.

HFSS Component Menu

Right-click the instance to view the menu. These are the visible commands:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Edit Link Definition** – See the following description.
- **Refresh Dynamic Link** – Reads data from linked design (properties, solutions, ports, geometry) and updates the link component.
- **Recapture Link Image** – Reads the image on the linked design and updates the symbol in schematic to show the new image.
- **Convert to Parametric Snapshot** – Converts a dynamic link to a parametric snapshot which saves a static copy of the solution data and uses that instead of going back to the linked design for solution data.
- **Clear Solution Cache** – Deletes any solution data for the dynamic link; the next analysis requires obtaining new solution data on the linked design.

Edit HFSS Component Properties

Click the **Properties** item to open the **Properties** window for the element. Modify the values of any of the model parameters. For a description of the parameters see ***Edit HFSS Link Definition***. After modifying parameter values, click **OK** to close the **Properties** window.

Edit HFSS Definitions

1. To view or modify the component definition that was created for the linked project, right-click the component instance and click **Edit Component**. See Using the Component Editor for further information.
2. To view or modify the schematic symbol that was created for the linked project, right-click the component instance and click **Edit Symbol**. See Using the Symbol Editor for further information.
3. To view or modify the assignment of pins to signals on the device, right-click the component instance and click **Edit Symbol Bus Pins**. See Editing All N-Port Symbol Bus Pins for further information.

Edit HFSS Link Definition

1. To view the parameters of the dynamic link, right-click the component instance and select **Edit Link Definition** to open the **Properties** window.

The following controls are available:

- The **Name** field shows the dynamic link component name.
- The **File** field displays the HFSS design that is the source for the dynamic link.
- Enter a **Model Description** if appropriate.
- The **Design** field displays the name of the selected design.
- The **Solution** drop-down menu property lists the Solutions available on the linked design. The displayed menu choice is the Solution that supplies the matrix data during analysis. For HFSS linked designs more than one solution can be selected. In this case "-multiple-" is the menu choice. Choosing a different choice in the menu sets the active solution to the new choice.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The **Transmission Line Port** property only shows for HFSS dynamic links that are set up as Transmission Line models. It shows the port name of the HFSS design that is being used for the transmission line.
- **Save project after simulate** specifies that the project is saved and closed once its data is accessed and the simulation is complete.
- **Unload project after use** specifies that the project is unloaded once its data is accessed and the window box is closed.
- **Simulation option** allows selection of the method for dealing with missing frequency points in the solution (Interpolate or Simulate).
- **Interpolation algorithm** field to select an interpolation algorithm option:

  Automatic – Linear interpolation is used if a full grid of solutions is present, otherwise Inverse Least Squares with Shadowing and Hyperplanes is used.

  Linear – When a full grid of solutions is available, the cube of solutions which surrounds the solution to be interpolated is located. The corners of this cube are linearly averaged to determine the interpolated solution. If a full grid is not available, an error is reported and the interpolation fails.

  Inverse Least Squares with Shadowing and Hyperplanes – Least squares interpolation with shadowing and hyperplanes.

  Inverse Least Squares with Shadowing, no Hyperplanes – Least squares interpolation with shadowing, but no hyperplanes.

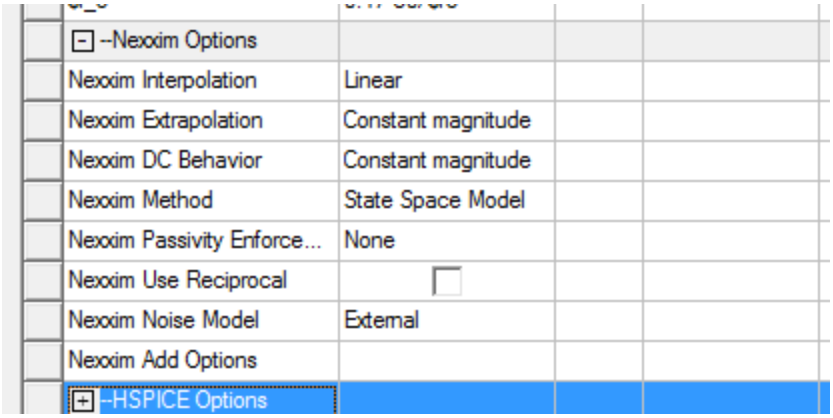
Note: The main difference between **Linear** interpolation and **Inverse Least Squares with Shadowing** (ILSS) is as follows:

- Linear only works with a full grid of solutions — ILSS works with arbitrary data.
- Linear only considers nearest data — ILSS considers data that could possibly be distant, although shadowing mitigates this effect.
- Linear is not first-order continuous — ILSS is first-order continuous.

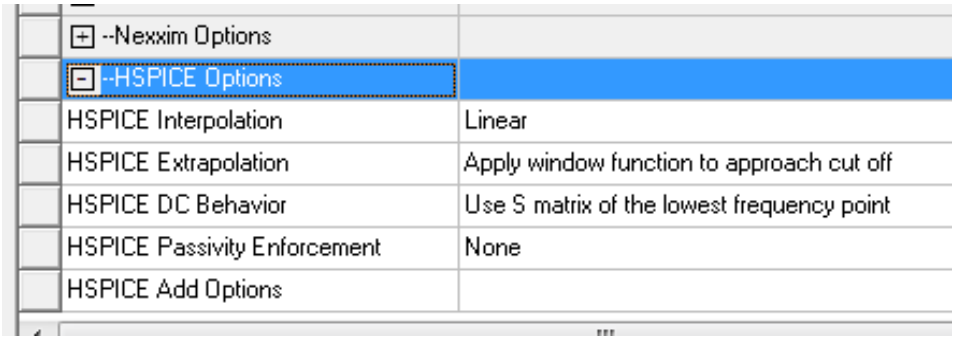
- **Interpolate Y matrix** uses the Y matrix as the basis for interpolation. When **Interpolate Y matrix** is not selected, the S matrix is used as the basis. **Interpolate Y matrix** is selected by default. Circuit particulars determine which basis (S or Y) yields better results, and it is not possible to decide beforehand which one works best.
- **Only use independent variables during interpolation** suppresses the calculation of dependent variable values during interpolation.
- **Renormalize** – If selected, the Scattering parameter Data (S-data) received on the dynamic link are re-normalized with a reference impedance value specified in **Renorm Impedance** before passing the original dynamic link S-data to the Nexxim Circuit solver. If not selected, re-normalization does not take place and the original dynamic link S-data is passed to the Nexxim Circuit solver.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Renorm Impedance** refers to the reference impedance used for renormalization of S-data. The default is 50 Ohms.
- **Nominal Values** displays the value of parameters on the linked project.
- **Nexxim Options** allows you to view or set the following Nexxim simulator options:



- HSPICE options allows you to view or set the following HSPICE simulator options:



Click **OK** to close the Link **Properties** window.

Refresh Dynamic Link

- **Refresh Dynamic Link** on the HFSS Component menu retrieves ALL data on the linked design, including changes to connectivity, solutions, and properties. Choose this command after making any edits to the linked design.

Recapture HFSS Link Image

- **Recapture Link Image** on the HFSS Component menu recaptures an image of the design to use in the schematic symbol. See Capturing or Recapturing Bitmap Symbols for Dynamic Link Models.

Convert HFSS Dynamic Link to Parametric Snapshot

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Convert to Parametric Snapshot** on the HFSS Component menu changes the dynamic link to a static parametric snapshot. After this option has been selected, the menu item toggles to **Convert to Dynamic Link**, which allows you to restore the dynamic linkage.

Clear HFSS Solution Cache

- **Clear Solution Cache** on the HFSS Component menu when clicked immediately clears the solution cache memory.

HFSS Project Link Menu and Setup Menu

When the dynamic link project has been added to the design, click the subcircuit icon in the **Project Manager** window to display a brief menu. Use the menu items to create a copy of the dynamic link project, edit the link definition, recapture the link image, convert the dynamic link to a static parametric snapshot, clear the solution cache, or to display the simulation results in Network Data Explorer. The **Show Network Data Explorer** item is activated only when there are simulation results to display.

You can right-click any one of the dynamic link sweep icons to display a menu. Use the menu to select the sweep to be in the co-simulation, select ONLY this sweep, or display simulation results in Network Data Explorer. The **Show Network Data Explorer** item is activated only when there are simulation results to display.

Renormalize Ports Based on HFSS Data

If there are HFSS designs within your Ansys Electronics Desktop design, renormalize the characteristic impedance of the circuit ports to the port impedance of one of the HFSS ports. To do so:

1. Double-click the port you want to renormalize in the schematic to open the **Port Definition** window.
2. Click **One port data** to enable a drop-down menu that displays the HFSS ports in the active design.
4. Select the appropriate HFSS design and port.
5. Select **Use characteristic impedance (Zo)** or **Use impedance matrix**.
6. Click **OK**.

The circuit ports are renormalized to the characteristic impedance of the HFSS port as a function of frequency and design parameters. For more information, see Editing an Interface Port Definition.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Transmission Lines Based on HFSS Data

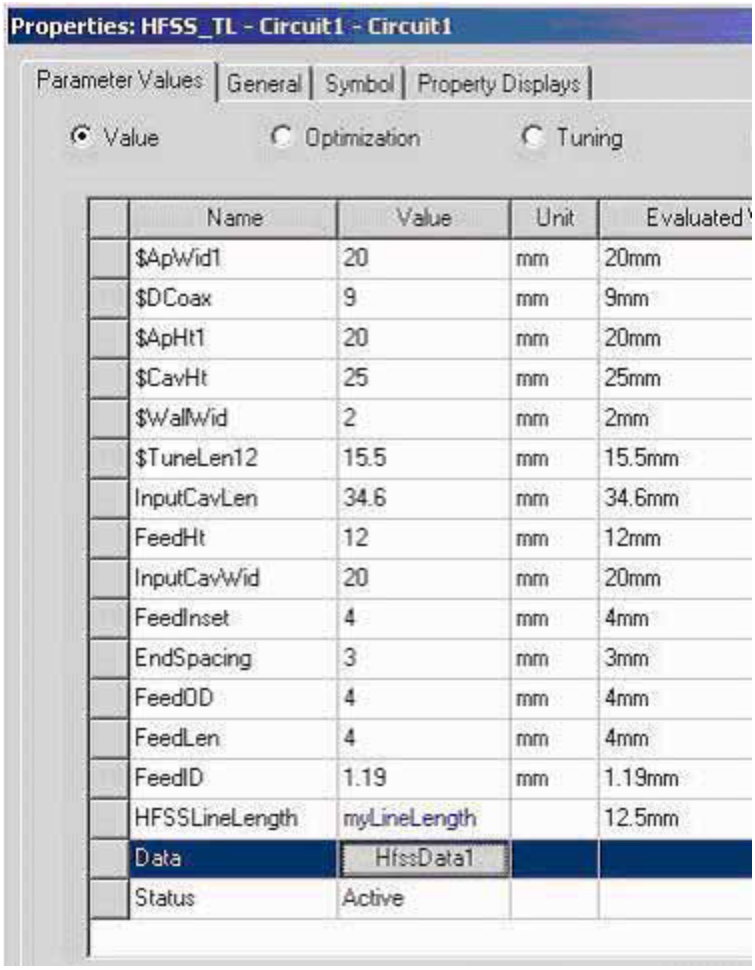
A parameterized two port transmission line can be created in **Electronics Desktop** based on an HFSS port solution. The characteristic impedance and propagation constant from a port in an HFSS design is used along with a user input length to generate an S parameter matrix in **Electronics Desktop** for a single mode transmission line. The resulting transmission line can be used like any other Ansys Electronics Desktop component in the schematic editor.

> **Note:** In HFSS, differential terminal data is transferred to **Electronics Desktop** as underlying terminal data — which is not differential. For this reason, differential data plotted in HFSS may not agree with raw terminal data plotted in Ansys Electronics Desktop.

To create a W-element transmission line model instead of a standard N-port, check the **Transmission Line Model** check box on the HFSS Dynamic Link window. See Add an HFSS Dynamic Link Model.

The properties of this component includes all the properties on the HFSS model plus one called “TLineLength”:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The variable “myLineLength” was created in **Electronics Desktop** to vary the length of the transmission line.

Ansys Electronics Desktop creates a single mode transmission line using the characteristic impedance and propagation constant from the HFSS design. The length of the line is “TLineLength.” Port solution data from HFSS as a function of design parameters is either interpolated or solved automatically depending on the status of the “Interpolate missing solutions/Simulate missing solutions” button.

> **Note:** Calculations of Z_{IN} and Z_{OUT} depend on the correct terminations and propagation constants. These results may not match the results in HFSS.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

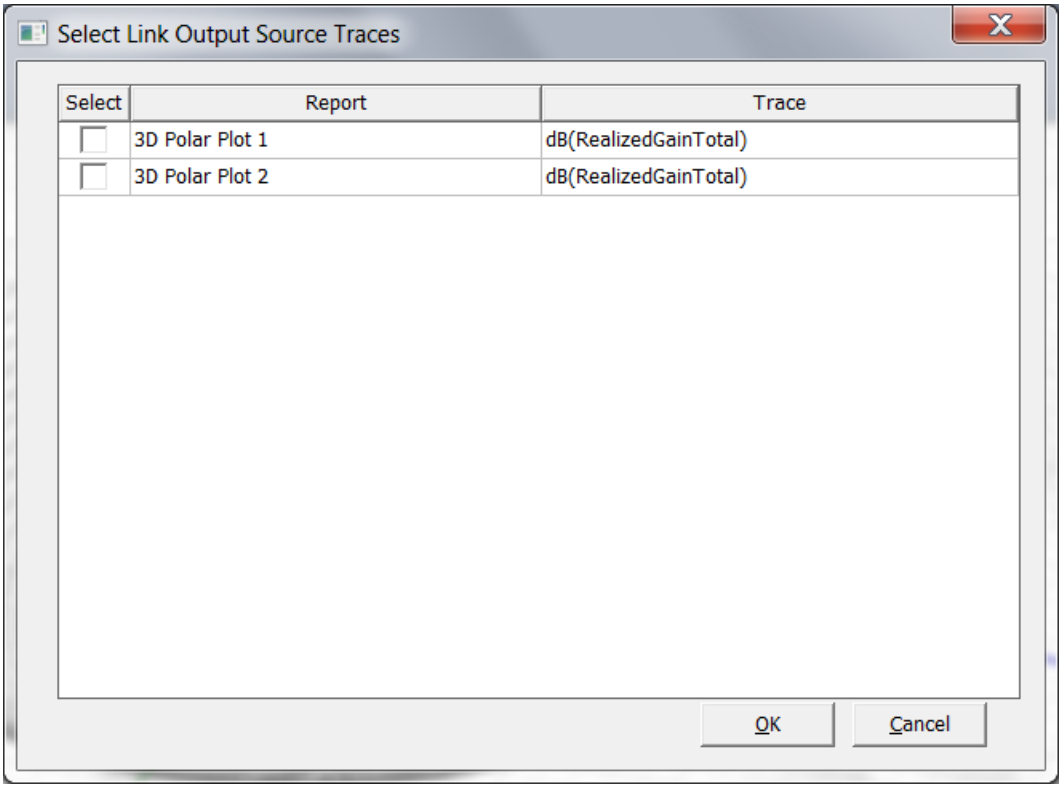
Access to HFSS Output Variables from Nexxim

HFSS dynamic link projects allow you to specify the plot traces to be made available for reporting in the upper-level Circuit project. You select the traces in the HFSS project, then use the outputs in a report in the Circuit Project.

Specifying Dynamic Link Output Traces

To select the traces to be included in dynamic link outputs:

1. Open the HFSS project and right-click the **Results** folder.
2. Select **Link Output ...** on the menu. The **Select Link Output Source Traces** window opens:



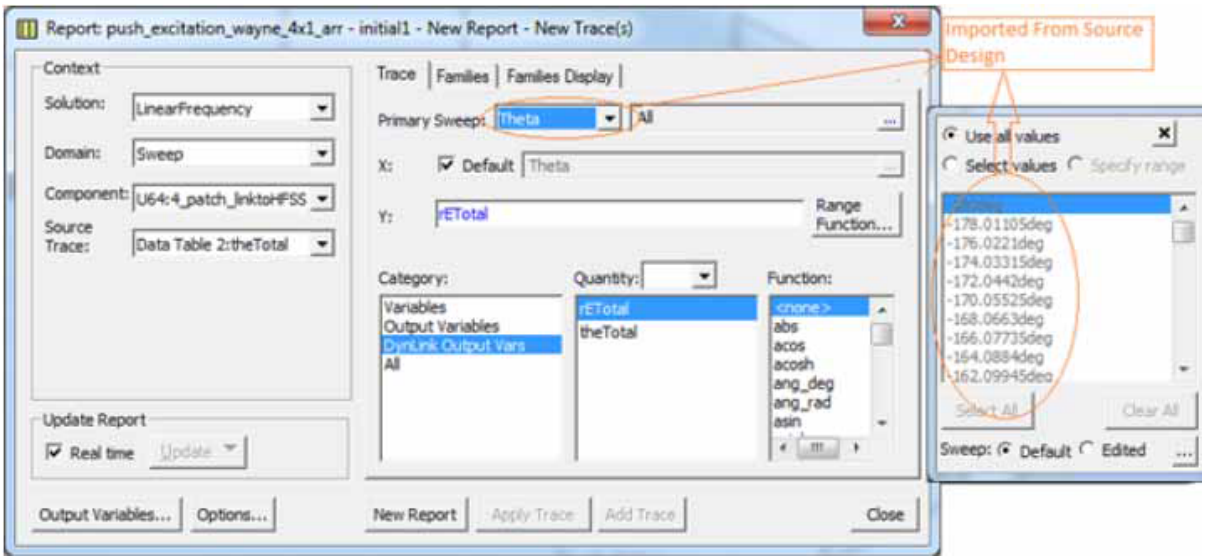
3. Select one or more traces with the check boxes. For each selected trace, the quantity and output variable used in its highest-dimension expression is exposed o the Circuit design.

HFSS Dynamic Link Outputs in Circuit Reports

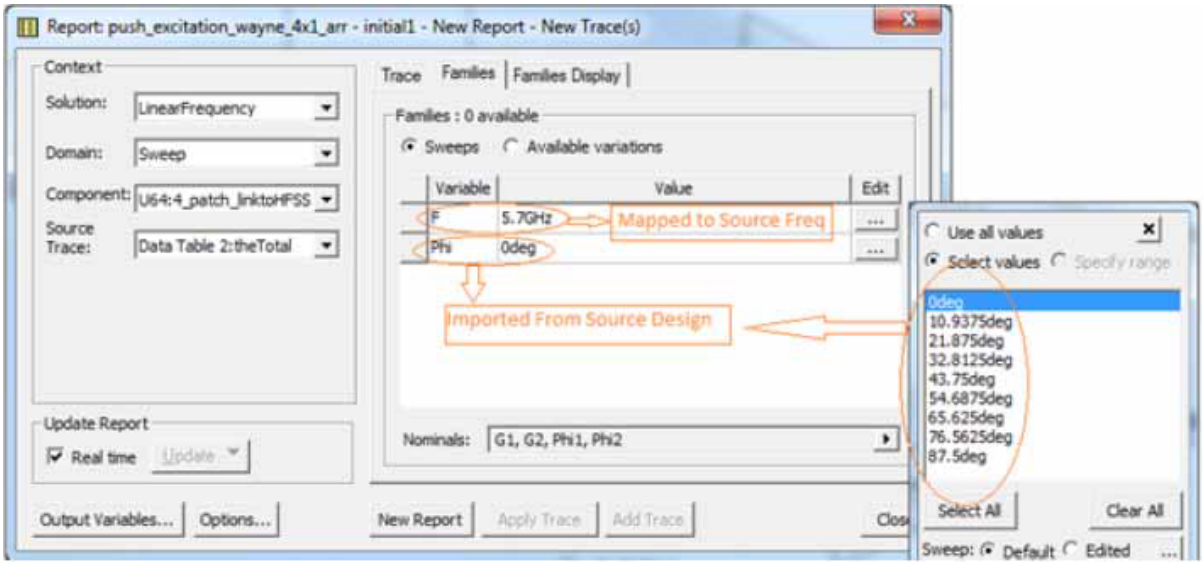
1. Select **Reports>Create Link Output Report,** then select a display type, such as **Rectangular Plot**, to open the **Create Report** window.
2. For **Solution**, select the Circuit solution. Select the Solution Domain.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. The **Component** field lists the available HFSS dynamic link objects.
4. The **Source** trace field lists the traces selected to be exposed by HFSS.
5. From the **Trace** tab, select the HFSS sweep that is to be the primary sweep.



6. The **Category** is selected as **DynLink Output Var**.
7. The **Quantities** field lists the X, Y, or Z expression with its quantity and output variables. (1D trace: X expression; 2D trace: Y expression; 3D trace: Z expression.)
8. From the **Families** tab, there are a list of Circuit solution variables with HFSS variable mappings, and unmapped HFSS solution intrinsic variables.

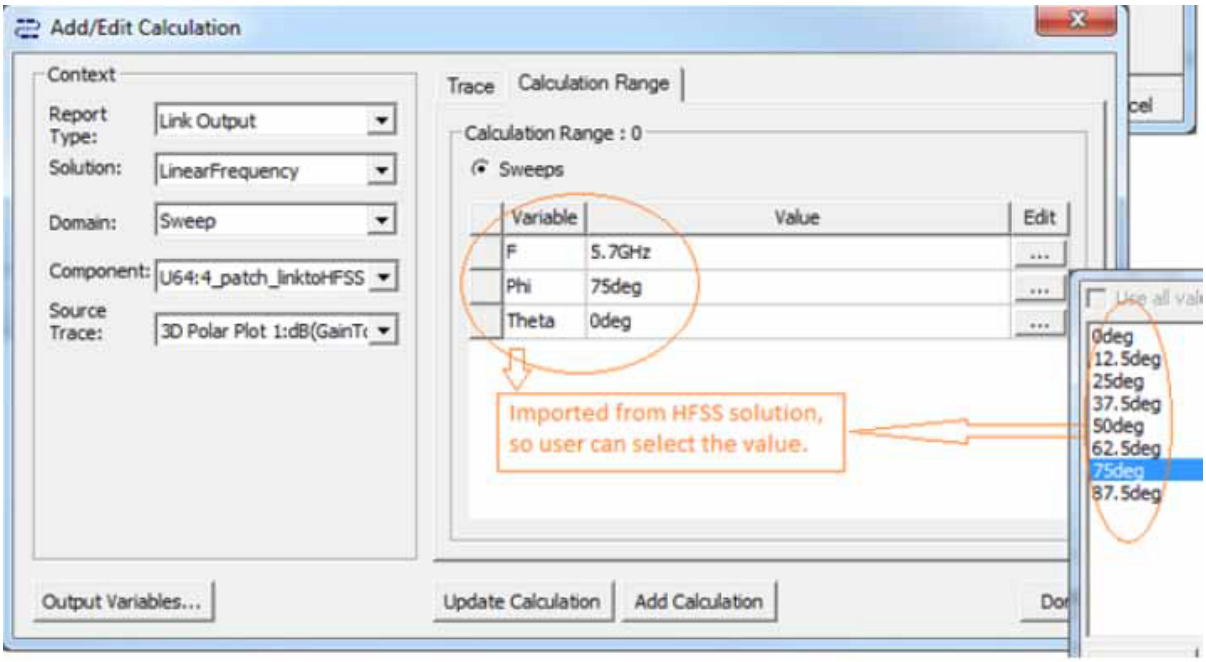


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9. The Circuit **F** intrinsic variable is automatically mapped to the HFSS **Freq** variable. Unmapped HFSS intrinsic variables values is imported on the HFSS solution. Unmapped Circuit variables get values on the Circuit solution only.

HFSS Variables in Optimetric Sweeps

Click **Setup Calculations** to open the **Add/Edit Calculation** window. Select **Link Output** as the **Report Type**.



The HFSS variables have been imported on the HFSS project.

Adding a Dynamic Link from Q3D

To create a dynamic link from Q3D to Ansys Electronics Desktop, you import the Q3D data as an N-port device.

> **Note:** When you add a Q3D subcircuit, **Electronics Desktop** opens the Q3D project. The Electronics Desktop version of Q3D is opened. You must close the Q3D project and the Circuit project separately.

Add a Q3D design as a dynamic-link subcircuit

1. Open the Circuit design to which you want to add a subcircuit.
2. In the **Component Libraries** group box, open the **Symbols** tab.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Click **Models**.
4. Click the **Q3D** tile. The **Q3D Dynamic Link** window opens:
    a. The **Name** fields displays the HFSS design name.
    b. Enter a **Description** if appropriate.
    c. Select a design on the **Project Manager** window. If the design you want is not present, click **Open Project** to find and open that design.
    d. **Reduce Matrix** sets the type of matrix reduction available in the project.
    e. The **Link Information** group box at the bottom of the window shows the selected frequency points and number of pins.

> **Note:** The **Q3D Dynamic Link** window only opens if a project with a Q3D design is already opened. If no open projects have a Q3D design, an explorer window opens. In which case:
>
> A. Browse to the directory that contains the Q3D project for the dynamic link.
> B. Select the Q3D project file.
> C. Click **Open**. **Electronics Desktop** pauses for a few seconds while Q3D starts up. The **Q3D Dynamic Link** window then opens then be displayed with this project displayed in the **Project Manager** window.

5. Click **OK**. A copy of the symbol is attached to the cursor. Drag and drop it into the schematic.

Q3D Component Menu

Right-click the instance to view the menu. These are the visible commands:

- **Edit Link Definition** – See the following description.
- **Refresh Dynamic Link** – Reads data from linked design (properties, solutions, ports, geometry) and updates the link component.
- **Recapture Link Image** – Reads the image on the linked design and updates the symbol in schematic to show the new image.
- **Convert to Parametric Snapshot** – Converts a dynamic link to a parametric snapshot which saves a static copy of the solution data and uses that instead of going back to the linked design for solution data.
- **Clear Solution Cache** – Deletes any solution data for the dynamic link; the next analysis requires obtaining new solution data on the linked design.

Edit Q3D Component Properties

- Click the **Properties** item to open the **Properties** window for the element. Modify the values of any of the model parameters. For a description of the parameters see ***Edit Q3D Link Definition***. After modifying parameter values, click **OK** to close the **Properties** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Edit Q3D Definitions

1. To view or modify the component definition that was created for the linked project, right-click the component instance and click **Edit Component**. See Using the Component Editor for further information.
2. To view or modify the schematic symbol that was created for the linked project, right-click the component instance and click **Edit Symbol**. See Using the Symbol Editor for further information.
3. To view or modify the assignment of pins to signals on the device, right-click the component instance and click **Edit Symbol Bus Pins**. See Editing All N-Port Symbol Bus Pins for further information.

Edit Q3D Link Definition

1. To view the parameters of the dynamic link, right-click the component instance and select **Edit Link Definition** to open the **Properties** window.

The following controls are available:

- The **Name** field shows the dynamic link component name.
- The **File** field displays the Q3D design that is the source for the dynamic link.
- Enter a **Model Description** if appropriate.
- The **Design** field displays the name of the selected design.
- The **Solution** drop-down menu property lists the Solutions available on the linked design. The displayed menu choice is the Solution that supplies the matrix data during analysis. Choosing a different choice in the menu sets the active solution to the new choice.
- **Reduce Matrix** selects the type of matrix reduction available in the project.
- **Save project after simulate** specifies that the project is saved and closed once its data is accessed and the simulation is complete.
- **Unload project after use** specifies that the project is unloaded once its data is accessed and the window box is closed.
- **Simulation option** allows selection of the method for dealing with missing frequency points in the solution (Interpolate or Simulate).
- **Interpolation algorithm** field to select an interpolation algorithm option:

  Automatic – Linear interpolation is used if a full grid of solutions is present, otherwise Inverse Least Squares with Shadowing and Hyperplanes is used.

  Linear – When a full grid of solutions is available, the cube of solutions which surrounds the solution to be interpolated is located. The corners of this cube are linearly averaged to determine the interpolated solution. If a full grid is not available, an error is reported and the interpolation fails.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

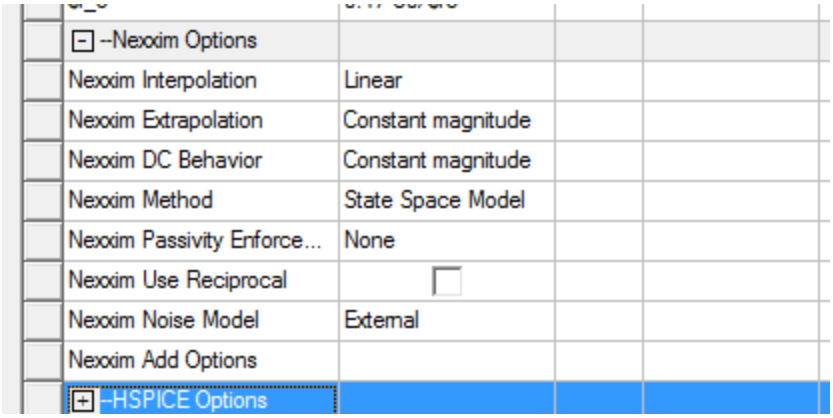
Inverse Least Squares with Shadowing and Hyperplanes – Least squares interpolation with shadowing and hyperplanes.

Inverse Least Squares with Shadowing, no Hyperplanes – Least squares interpolation with shadowing, but no hyperplanes.

Note: The main difference between **Linear** interpolation and **Inverse Least Squares with Shadowing** (ILSS) is as follows:

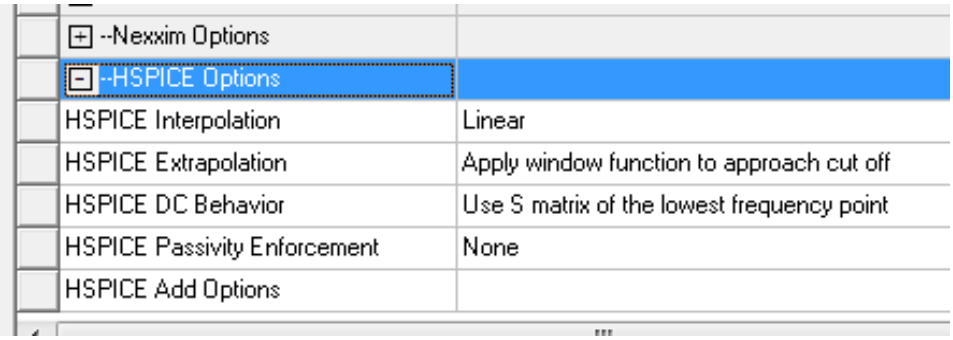
- Linear only works with a full grid of solutions — ILSS works with arbitrary data.
- Linear only considers nearest data — ILSS considers data that could possibly be distant, although shadowing mitigates this effect.
- Linear is not first-order continuous — ILSS is first-order continuous.

- **Interpolate Y matrix** uses the Y matrix as the basis for interpolation. When **Interpolate Y matrix** is not selected, the S matrix is used as the basis. **Interpolate Y matrix** is selected by default. Circuit particulars determine which basis (S or Y) yields better results, and it is not possible to decide beforehand which one works best.
- **Only use independent variables during interpolation** suppresses the calculation of dependent variable values during interpolation.
- **Renormalize** – If selected, the Scattering parameter Data (S-data) received on the dynamic link are re-normalized with a reference impedance value specified in **Renorm Impedance** before passing the original dynamic link S-data to the Nexxim Circuit solver. If not selected, re-normalization does not take place and the original dynamic link S-data is passed to the Nexxim Circuit solver.
- **Renorm Impedance** refers to the reference impedance used for renormalization of S-data. The default is 50 Ohms.
- **Nominal Values** displays the value of parameters on the linked project.
- **Nexxim Options** allows you to view or set the following Nexxim simulator options:



- HSPICE options allows you to view or set the following HSPICE simulator options:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Click **OK** to close the Link **Properties** window.

Refresh Dynamic Link

- **Refresh Dynamic Link** on the Q3D Component menu retrieves ALL data on the linked design, including changes to connectivity, solutions, and properties. Choose this command after making any edits to the linked design.

Recapture Q3D Link Image

- **Recapture Link Image** on the Q3D Component menu recaptures an image of the design to use in the schematic symbol. See Capturing or Recapturing Bitmap Symbols for Dynamic Link Models.

Clear Q3D Solution Cache

- **Clear Solution Cache** on the Q3D Component menu, when clicked, immediately clears the solution cache memory.

Q3D Project Link Menu and Setup Menu

When the dynamic link project has been added to the design, click the subcircuit icon in the **Project Manager** window to display a brief menu. Use the menu items to create a copy of the dynamic link project, edit the link definition, recapture the link image, clear the solution cache, or to display simulation results in Network Data Explorer. The **Show Network Data Explorer** item is activated only when there are simulation results to display.

Click any one of the dynamic link sweep icons to display a menu. Use the menu to open the simulation results in Network Data Explorer. The **Show Network Data Explorer** item is activated only when there are simulation results to display.

Adding a Dynamic Link from 2D Extractor

To create a dynamic link from 2D Extractor to Ansys Electronics Desktop, you import the 2D Extractor data as an N-port device.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** When you add a 2D Extractor subcircuit, **Electronics Desktop** opens the 2D Extractor project. The Electronics Desktop version of 2D Extractor is opened. You must close the 2D Extractor project and the Circuit project separately.

Add a 2D Extractor n-port as a dynamic-link subcircuit to a design

1. Open the Circuit design to which you want to add a subcircuit.
2. In the **Component Libraries** group box, open the **Symbols** tab.
3. Click **Models**.
4. Click the **2DExtractor** tile. The **2DExtractor Dynamic Link** window opens:
    a. The **Name** fields displays the 2DExtractor design name.
    b. Enter a **Description** if appropriate.
    c. Select a design on the **Project Tree**. If the design you want is not present, click **Open Project** to find and open that design.
    d. **Reduce Matrix** selects the type of matrix reduction available in the project.
    e. The **Link Information** group box at the bottom of the window shows the selected frequency points and number of pins.

> **Note:** The **2DExtractor Dynamic Link** window only opens if a project with a 2DExtractor design is already opened. If no open projects have a 2DExtractor design, an explorer window opens. In which case:
>
> 1. Browse to the directory that contains the 2DExtractor project for the dynamic link.
> 2. Select the 2DExtractor project file.
> 3. Click **Open**. **Electronics Desktop** pauses for a few seconds while 2DExtractor starts up. The **2DExtractor Dynamic Link** window then opens then be displayed with this project displayed in the **Project Manager** window.

5. Click **OK**. A copy of the symbol is attached to the cursor. Drag and drop it into the schematic.

2D Extractor Component Menu

Right-click the instance to view the menu. These are the visible commands:

- **Edit Link Definition** – See the following description.
- **Refresh Dynamic Link** – Reads data from linked design (properties, solutions, ports, geometry) and updates the link component.
- **Recapture Link Image** – Reads the image on the linked design and updates the symbol in schematic to show the new image.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Convert to Parametric Snapshot** – Converts a dynamic link to a parametric snapshot which saves a static copy of the solution data and uses that instead of going back to the linked design for solution data.
- **Clear Solution Cache** – Deletes any solution data for the dynamic link; the next analysis requires obtaining new solution data on the linked design.

Edit 2D Extractor Component Properties

- Click the **Properties** item to open the **Properties** window for the element. Modify the values of any of the model parameters. For a description of the parameters see ***Edit 2D Extractor Link Definition***. After modifying parameter values, click **OK** to close the **Properties** window.

Edit 2D Extractor Definitions

1. To view or modify the component definition that was created for the linked project, right-click the component instance and click **Edit Component**. See Using the Component Editor for further information.
2. To view or modify the schematic symbol that was created for the linked project, right-click the component instance and click **Edit Symbol**. See Using the Symbol Editor for further information.
3. To view or modify the assignment of pins to signals on the device, right-click the component instance and click **Edit Symbol Bus Pins**. See Editing All N-Port Symbol Bus Pins for further information.

Edit 2D Extractor Link Definition

1. To view the parameters of the dynamic link, right-click the component instance and select **Edit Link Definition** to open the **Properties** window.

The following controls are available:

- The **Name** field shows the dynamic link component name.
- The **File** field displays the 2DExtractor design that is the source for the dynamic link.
- Enter a **Model Description** if appropriate.
- The **Design** field displays the name of the selected design.
- The **Solution** drop-down menu property lists the Solutions available on the linked design. The displayed menu choice is the Solution that supplies the matrix data during analysis. Choosing a different choice in the menu sets the active solution to the new choice.
- **Reduce Matrix** selects the type of matrix reduction available in the project.
- **Save project after simulate** specifies that the project is saved and closed once its data is accessed and the simulation is complete.
- **Unload project after use** specifies that the project is unloaded once its data is accessed and the window box is closed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Simulation option** allows selection of the method for dealing with missing frequency points in the solution (Interpolate or Simulate).
- **Interpolation algorithm** field to select an interpolation algorithm option:

  Automatic – Linear interpolation is used if a full grid of solutions is present, otherwise Inverse Least Squares with Shadowing and Hyperplanes is used.

  Linear – When a full grid of solutions is available, the cube of solutions which surrounds the solution to be interpolated is located. The corners of this cube are linearly averaged to determine the interpolated solution. If a full grid is not available, an error is reported and the interpolation fails.

  Inverse Least Squares with Shadowing and Hyperplanes – Least squares interpolation with shadowing and hyperplanes.

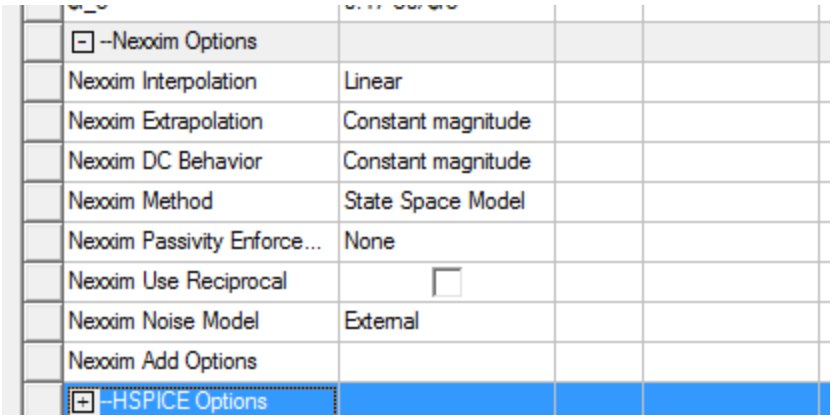
  Inverse Least Squares with Shadowing, no Hyperplanes – Least squares interpolation with shadowing, but no hyperplanes.

> **Note:**
>
> The main difference between **Linear** interpolation and **Inverse Least Squares with Shadowing** (ILSS) is as follows:
>
> - Linear only works with a full grid of solutions — ILSS works with arbitrary data.
> - Linear only considers nearest data — ILSS considers data that could possibly be distant, although shadowing mitigates this effect.
> - Linear is not first-order continuous — ILSS is first-order continuous.

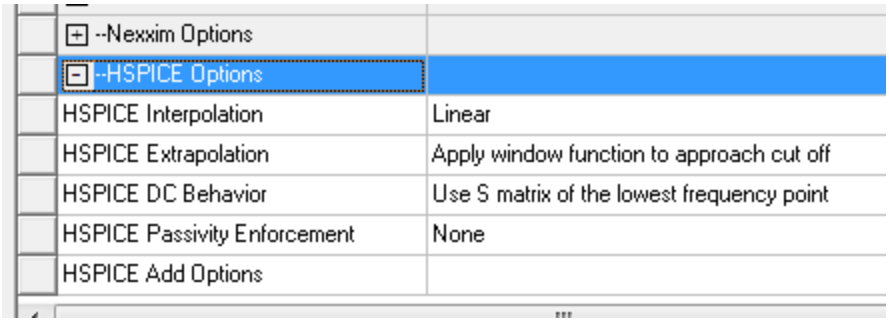
- **Interpolate Y matrix** uses the Y matrix as the basis for interpolation. When **Interpolate Y matrix** is not selected, the S matrix is used as the basis. **Interpolate Y matrix** is selected by default. Circuit particulars determine which basis (S or Y) yields better results, and it is not possible to decide beforehand which one works best.
- **Only use independent variables during interpolation** suppresses the calculation of dependent variable values during interpolation.
- **Nominal Values** displays the value of parameters on the linked project.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Nexxim Options** allows you to view or set the following Nexxim simulator options.



- HSPICE options allows you to view or set the following HSPICE simulator options.



Click **OK** to close the Link **Properties** window.

Refresh Dynamic Link

- **Refresh Dynamic Link** on the 2D Component menu retrieves ALL data on the linked design, including changes to connectivity, solutions, and properties. Choose this command after making any edits to the linked design.

Recapture 2D Extractor Link Image

- **Recapture Link Image** on the 2D Extractor component menu recaptures an image of the design to use in the schematic symbol. See Capturing or Recapturing Bitmap Symbols for Dynamic Link Models.

Clear 2D Extractor Solution Cache

- **Clear Solution Cache** on the 2D Extractor component menu immediately clears the solution cache memory.

2D Extractor Project Link Menu and Setup Menu

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When the dynamic link project has been added to the design, click the subcircuit icon in the **Project Manager** window to display a brief menu. Use the menu items to create a copy of the dynamic link project, edit the link definition, recapture the link image, clear the solution cache, or to open the simulation results in Network Data Explorer. The **Show Network Data Explorer** item is activated only when there are simulation results to display.

Click any one of the dynamic link sweep icons to display a menu. Use the menu to select the sweep to be in the co-simulation.

Adding a Dynamic Link from SIwave

To create a dynamic link from SIwave to Ansys Electronics Desktop, you import the SIwave data as an N-port device.

> **Note:** When you add an SIwave subcircuit, **Electronics Desktop** opens the SIwave project. By default, the latest version of SIwave is opened. You must close the SIwave project and the Circuit project separately.

Add an SIwave design as a dynamic-link subcircuit

1. Open the Circuit design to which you want to add a subcircuit.
2. From the **Component Libraries** menu, open the **Symbols** tab then click **Models**. Select the **SIwave** icon on the group box of icons to open the **Import Components** window.
3. Browse to the directory containing the SIwave project for the dynamic link. Select the project and click **Open** to open the **SIwave Dynamic Link** menu.
4. Make any appropriate changes, then click **OK**. An instance of the component is attached to the cursor. Drag and drop in into the schematic

SIwave Component Menu

Right-click the instance to view the menu. These are the visible commands:

- **Edit Link Definition** – See description.
- **Refresh Dynamic Link** – Reads data from linked design (properties, solutions, ports, geometry) and updates the link component.
- **Recapture Link Image** – Reads the image on the linked design and updates the symbol in schematic to show the new image.
- **Convert to Parametric Snapshot** – Converts a dynamic link to a parametric snapshot which saves a static copy of the solution data and uses that instead of going back to the linked design for solution data.
- **Clear Solution Cache** – Deletes any solution data for the dynamic link; the next analysis requires obtaining new solution data on the linked design.

Edit SIwave Definitions

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. To view or modify the component definition that was created for the linked project, right-click the component instance and click **Edit Component**. See Using the Component Editor for further information.
2. To view or modify the schematic symbol that was created for the linked project, right-click the component instance and click **Edit Symbol**. See Using the Symbol Editor for further information.
3. To view or modify the assignment of pins to signals on the device, right-click the component instance and click **Edit Symbol Bus Pins**. See Editing All N-Port Symbol Bus Pins for further information.

Edit SIwave Link Definition

1. To view the parameters of the dynamic link, right-click the component instance and select **Edit Link Definition** to open the **Properties** window.

The following controls are available:

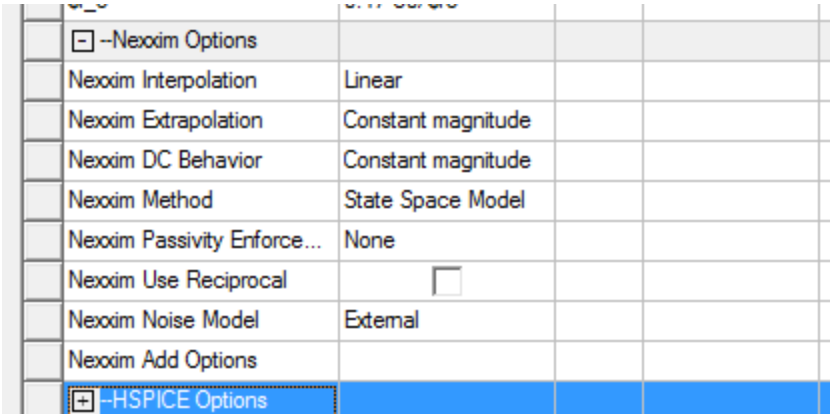
- The **Name** field shows the dynamic link component name
- The **File** field displays the SIwave design that is the source for the dynamic link.
- Enter a **Model Description** if appropriate.
- The **Design** field displays the name of the selected design.
- The **Solution** field displays the solution name.
- **Save project after simulate** specifies that the project is saved and closed once its data is accessed and the simulation is complete.
- **Unload project after use** specifies that the project is unloaded once its data is accessed and the window is closed.
- **Simulation option** allows selection of the dynamic link simulation method:
    - Cache solution (no dynamic simulation)
    - Dynamic simulation (reloads project and simulates as needed)
- **Interpolation algorithm** field to select an interpolation algorithm option:
    - **Automatic** – Linear interpolation is used if a full grid of solutions is present, otherwise Inverse Least Squares with Shadowing and Hyperplanes is used.
    - **Linear** – When a full grid of solutions is available, the cube of solutions which surrounds the solution to be interpolated is located. The corners of this cube are linearly averaged to determine the interpolated solution. If a full grid is not available, an error is reported and the interpolation fails.
    - **Inverse Least Squares with Shadowing and Hyperplanes** – Least squares interpolation with shadowing and hyperplanes.
    - **Inverse Least Squares with Shadowing, no Hyperplanes** – Least squares interpolation with shadowing, but no hyperplanes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: The main difference between **Linear** interpolation and **Inverse Least Squares with Shadowing** (ILSS) is as follows:

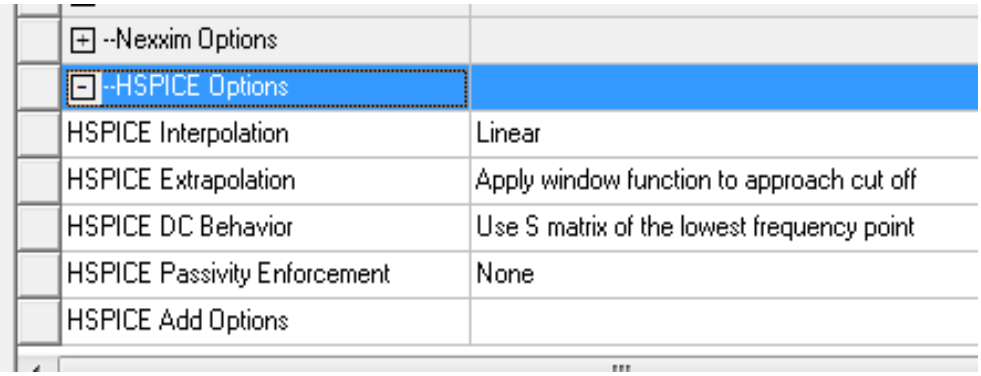
- Linear only works with a full grid of solutions — ILSS works with arbitrary data.
- Linear only considers nearest data — ILSS considers data that could possibly be distant, although shadowing mitigates this effect.
- Linear is not first-order continuous — ILSS is first-order continuous.

- **Interpolate Y matrix** uses the Y matrix as the basis for interpolation. When **Interpolate Y matrix** is not selected, the S matrix is used as the basis. **Interpolate Y matrix** is selected by default. Circuit particulars determine which basis (S or Y) yields better results, and it is not possible to decide beforehand which one works best.
- **Only use independent variables during interpolation** suppresses the calculation of dependent variable values during interpolation.
- **Renormalize** – If selected, the Scattering parameter Data (S-data) received on the dynamic link are re-normalized with a reference impedance value specified in **Renorm Impedance** before passing the original dynamic link S-data to the Nexxim Circuit solver. If not selected, re-normalization does not take place and the original dynamic link S-data is passed to the Nexxim Circuit solver.
- **Renorm Impedance** refers to the reference impedance used for renormalization of S-data. The default is 50 Ohms.
- **Nominal Values** displays the value of parameters on the linked project.
- **Nexxim Options** allows you to view or set the following Nexxim simulator options:



- HSPICE options allows you to view or set the following HSPICE simulator options:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Click **OK** to close the Link **Properties** window.

Refresh Dynamic Link

- **Refresh Dynamic Link** on the SIwave Component menu retrieves ALL data on the linked design, including changes to connectivity, solutions, and properties. Choose this command after making any edits to the linked design.

Recapture SIwave Link Image

- **Recapture Link Image** on the SIwave Component menu recaptures an image of the design to use in the schematic symbol. See Capturing or Recapturing Bitmap Symbols for Dynamic Link Models.

Convert SIwave Dynamic Link to Parametric Snapshot

- **Convert to Parametric Snapshot** on the SIwave Component menu changes the dynamic link to a static parametric snapshot. After this option has been selected, the menu item toggles to **Convert to Dynamic Link**, which allows you to restore the dynamic linkage.

Clear SIwave Solution Cache

- **Clear Solution Cache** on the SIwave Component menu when clicked immediately clears the solution cache memory.

SIwave Project Link Menu

When the dynamic link project has been added to the design, click the subcircuit icon in the **Project Manager** window to display a brief menu. Use the menu items to create a copy of the dynamic link project, edit the link definition, recapture the link image, convert the dynamic link to a static parametric snapshot, clear the solution cache, or to display simulation results in Network Data Explorer. The **Show Network Data Explorer** item is activated only when there are simulation results to display.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Running a Dynamic Link Co-simulation

To run a co-simulation involving a dynamic link subcircuit, right-click **Analysis** in the **Project Manager** window for the top-level circuit and select **Add Solution Setup**. Set up the top-level analysis as appropriate. An icon for the solution is added to the **Analysis** group box.

Right-click the top-level solution icon and select **Analyze**. The **Progress** window displays simulation updates for the top-level circuit and subcircuit simultaneously.

When simulation is successfully completed, view the results for the top-level circuit. See Generating Reports and Post Processing for further information.

> **Note:**
>
> You can create one or more solution setups local to a subcircuit by expanding the subcircuit icon, clicking on its local **Analysis** icon, and selecting **Add Solution Setup**. When you execute a local setup, it solves just the subcircuit.
>
> However, these local solution setups are not used in the co-simulation; any local setup information and options are ignored during co-simulation. The co-simulation parameters are set up as described in the topics on HFSS, Q3d, 2D Extractor and SIwave dynamic links.

Adding a Design Variable for Dynamic Links

Design variables from an HFSS, Q3D, 2D Extractor, Icepak, or Mechanical design can be imported though a dynamic link to a Circuit or 3D Layout design. New design variables are created in the Circuit or 3D Layout design and correspond to the dynamic link variables. When the new design variables are created, the dynamic link variables are set to the Circuit or 3D Layout design variables.

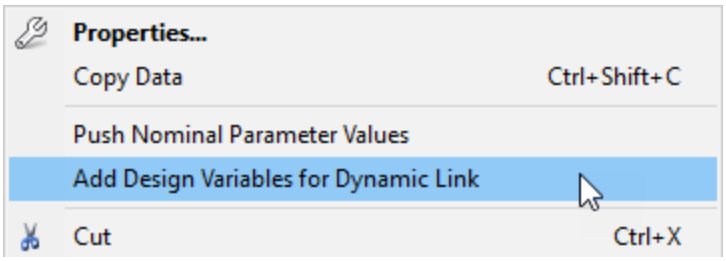
For example, imagine an HFSS design with a variable wire_rad of 3mm. If a dynamic link is created for this design in a Circuit design, then a design variable “d_wire_rad” is created in the Circuit design and the component instance of the HFSS design has a parameter wire_rad set to d_wire_rad.

Design variables can be created from existing or newly added variables in the dynamic link design.

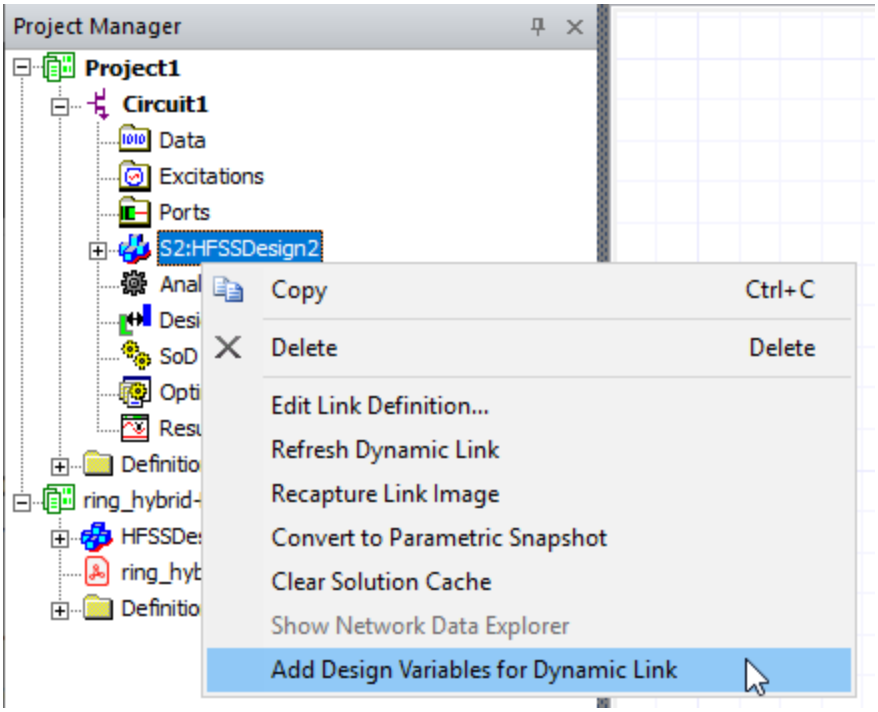
To create design variables based on pre-existing variables in a dynamic link design:

1. In the Circuit or 3D Layout design, create a dynamic link to the target design.
2. Either:
    a. In the Schematic or Layout editor, right-click the new instance of the linked design and click **Add Design Variables for Dynamic Link**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



b. From the **Project Manager** window, right-click **Project Name** > **Design Name** > **Dynamic Link Design** and select **Add Design Variables for Dynamic Link**.

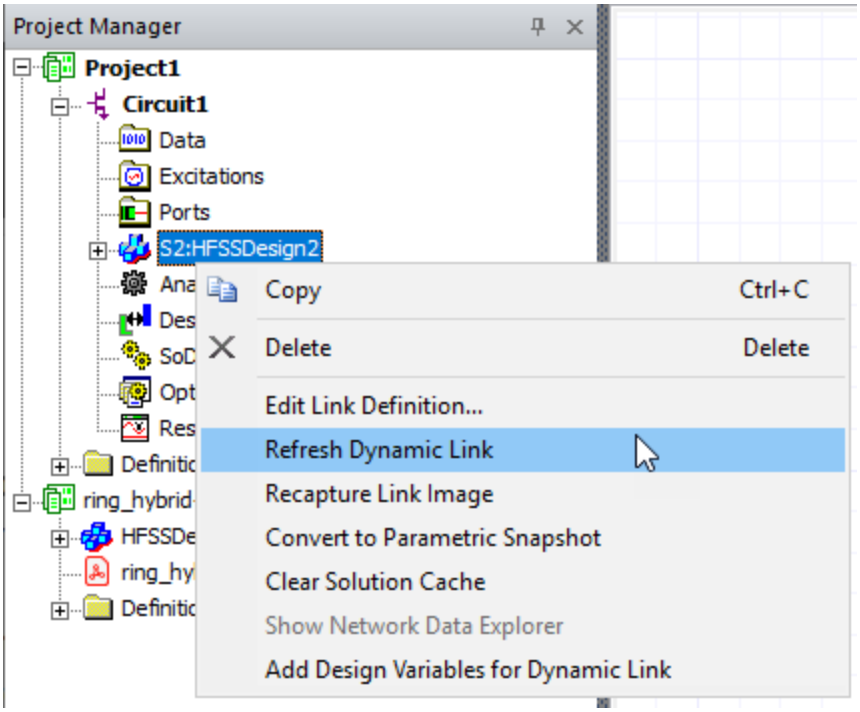


To create design variables based on variables added to a dynamic link design after it was linked:

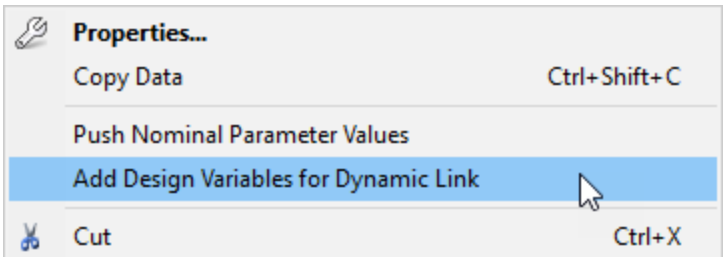
1. Create a new design variable in the dynamic link project.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the Project Manager of the Circuit or 3D Layout design, Right-click *Project Name* > *Design Name* > *Dynamic Link Design* and click **Refresh Dynamic Link**.

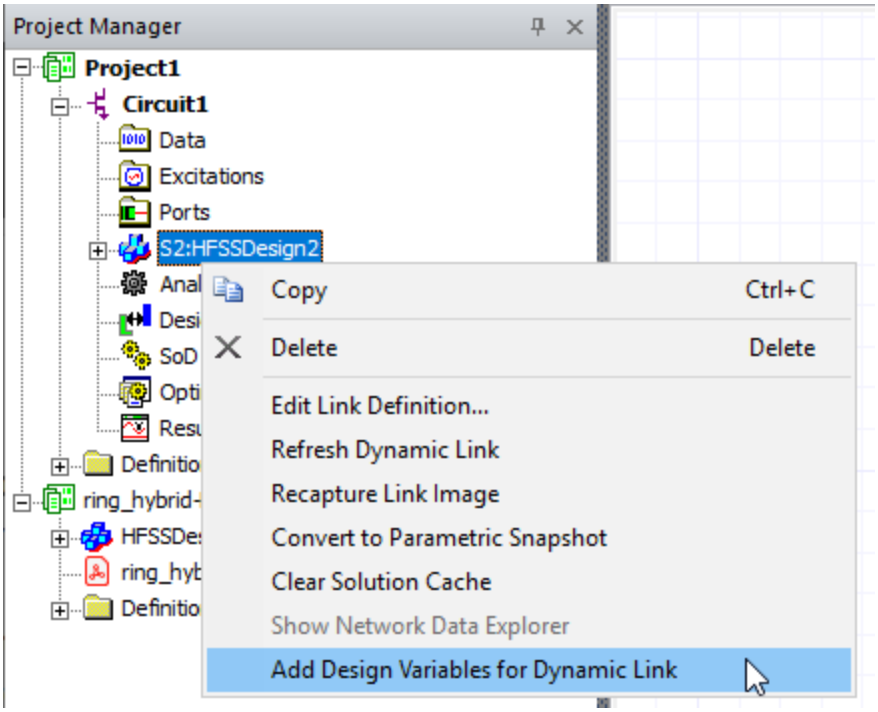


3. Either:
   a. In the Schematic or Layout editor, right-click the new instance of the linked design and select **Add Design Variables for Dynamic Link**.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. From the **Project Manager** window>, right-click **Project Name** > **Design Name** > **Dynamic Link Design** and select **Add Design Variables for Dynamic Link**.



Pushing Variable Values back to a Dynamic Link Design

If you have changed a parameter for a dynamic link component in the Ansys Electronics Desktop, right-clicking the component and choosing the **Push Nominal Parameter Values** command changes the corresponding design parameter in the linked design to have the changed value. This works for all link types except SIwave. Pushing variable values may be needed to enable the **Push Excitations** option to work correctly. See Pushing Excitations for details.

Managing Dynamic Link Simulation Setups

When the dynamic link project has been added to the design, click the subcircuit icon in the **Project Manager** window to display a brief menu. Use the menu items to create a copy of the dynamic link project, or to display simulation results in Network Data Explorer. The **Show Network Data Explorer** item is activated only when there are simulation results to display.

Click any one of the dynamic link simulation setups to display a menu. Use the menu to select the sweep to be in the co-simulation, select ONLY this sweep, or display simulation results in Network Data Explorer. The **Show Network Data Explorer** item is activated only when there are simulation results to display.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Viewing Dynamic Link Geometry in the Layout Editor and a 3D View

Geometry from dynamically linked HFSS and Q3D models can be viewed in the **Electronics Desktop Layout Editor** and the 3D viewer. To do this, open the **Layout Editor** after inserting the HFSS or Q3D model into Ansys Electronics Desktop, double-click the model to open the **Properties** window and check the “Model Graphics” check box on the Footprint tab. When you close the **Properties** window Ansys Electronics Desktop copies a snapshot of the HFSS or Q3D model into Ansys Electronics Desktop that can be viewed in the layout or 3D editors. Note that if you change the model in HFSS or Q3D you must reload the model geometry into **Electronics Desktop** by clicking **Reload Graphics** on the Footprint tab of the Properties window.

Ansys Electronics Desktop respects the location and dimensions of the model and places it accordingly in Ansys Electronics Desktop’s layout. You can manipulate the view of the model in Ansys Electronics Desktop by setting certain properties in the **Properties** window: shift the model in X & Y with the Location property; rotate the model with the Angle property; flip the model with the Flipped check box; and scale the model with the Scaling property. Colors and transparency used to display the dynamically linked model are those set in HFSS or Q3D.

> **Note:** The top-down and 3D views of dynamically linked models is available only if the layout contains at least one stackup layer.

Capturing or Recapturing Bitmap Symbols for Dynamic Link Models

The automatically generated symbols for HFSS, Q3D, and 2D extractor models normally include a bitmap image of the model. The image may fail to render under certain circumstances, or may not show the appropriate view. You can update the bitmap image of the model. Right-click on the component symbol in the schematic and click **Recapture Link Image** to update the bitmap image associated with the model.

The symbols for components that have been placed in the schematic editor are not updated with the new bitmap view, however, new components that are generated by dragging and dropping the model onto the schematic window show the new bitmap image embedded in the symbol.

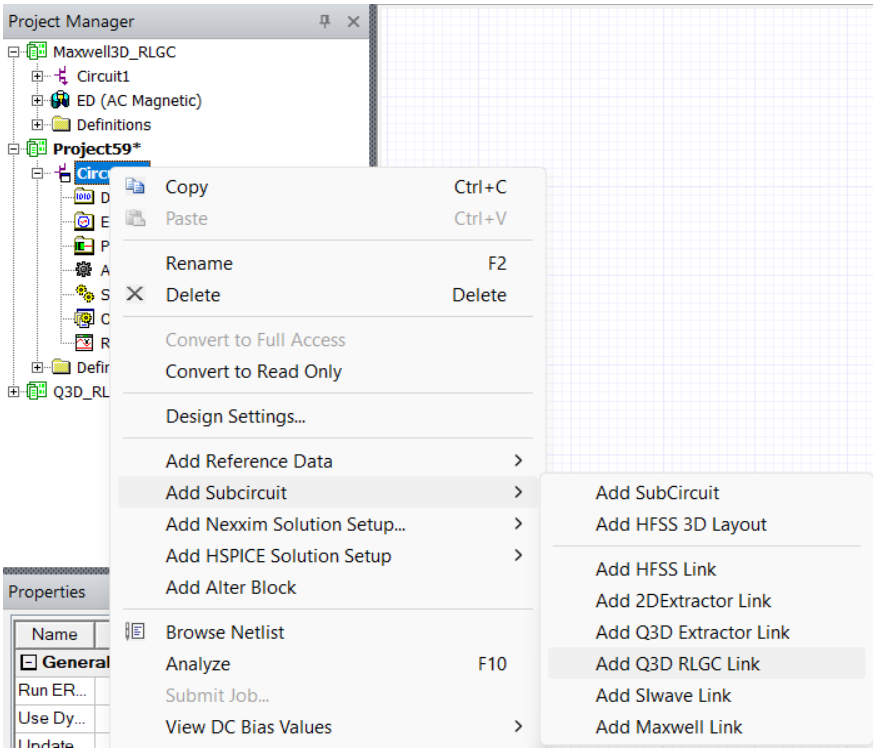
RLGC Dynamic links

RLGC Dynamic links can be created from Q3D or Maxwell 2D/3D designs.

To create a Q3D RLGC Dynamic Link:

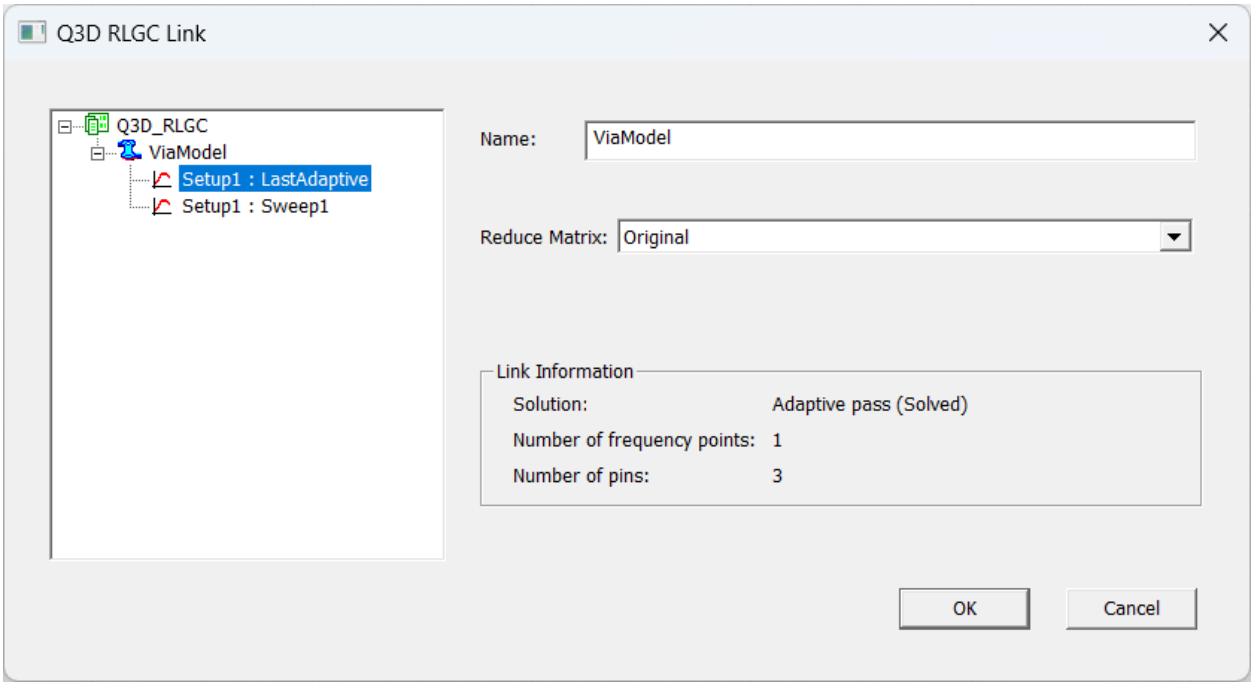
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Open the Circuit design to which you want to add the Q3D subcircuit.
2. From the **Project Tree**, right-click the active Circuit design and expand the **Add Subcircuit** option. Select Add Q3D RLGC dynamic link.



3. The **Q3D RLGC Link** dialog will pop up. Select the design, enter a desired name, and then select the **Reduce Matrix** using the drop down menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

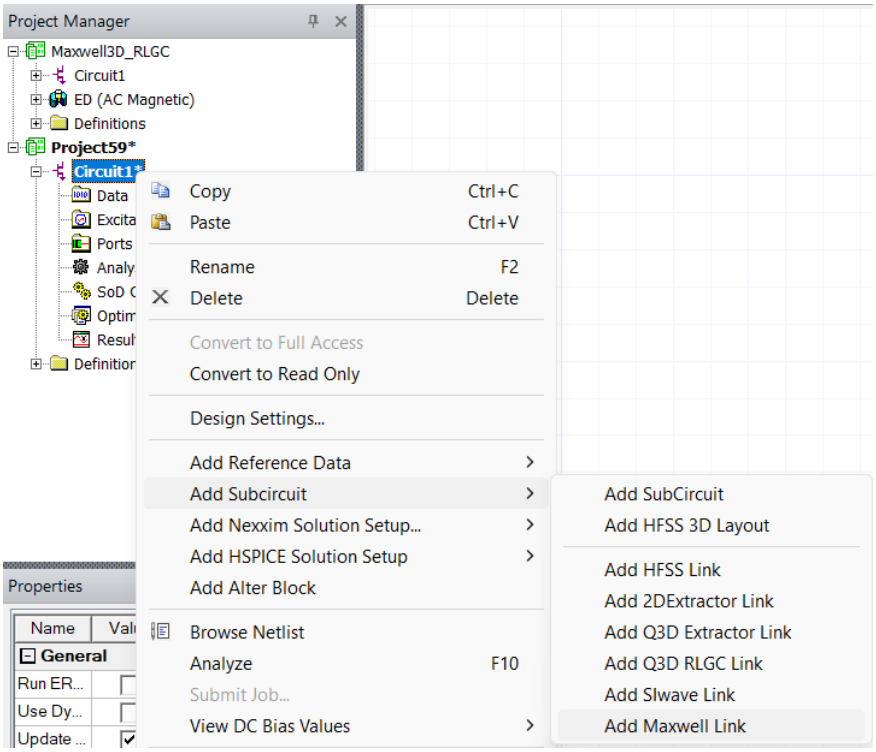


4. The component will be placed in the Circuit design.

To create Maxwell RLGC dynamic link:

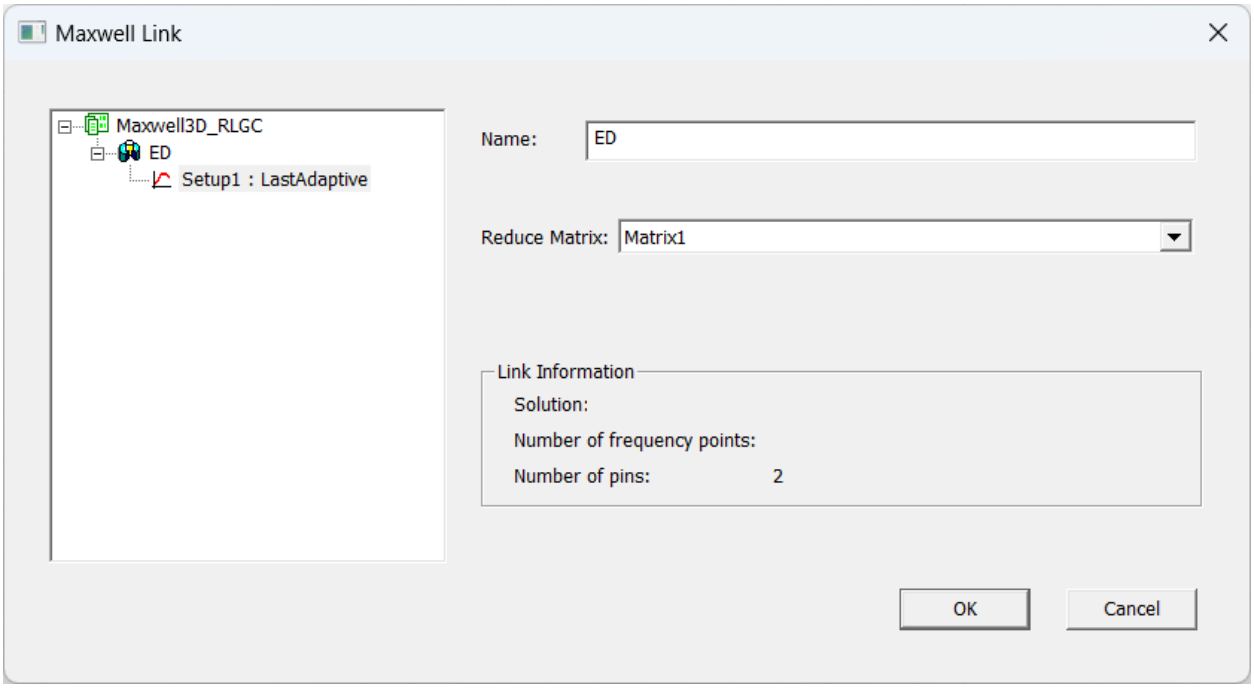
1. Open the Circuit design to which you want to add the Maxwell subcircuit
2. From the **Project Tree**, right-click the active Circuit design and expand the **Add Subcircuit** option. Select **Add Maxwell Link**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. The **Maxwell Link** dialog will pop up. Select the design, enter a desired name, and then select the **Reduce Matrix** using the drop down menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. The component will be placed in the Circuit design.

To edit RLGC Dynamic Link Definition:

Right-click the component and select **Properties**. The following controls are available:

Property	Description
SolveLinkedDesign	If the linked design is not solved, enable the checkbox to allow for the linked solver to be used when generating the .sp file
PSPICE	Enable the check box to use PSPICE formatting
FittingError	Specify the fitting error level for the .sp file
ModelName	Edit the model name

Pushing Excitations from Circuit Designs

You can set the excitations in dynamically linked field solver elements from a parent circuit so true electromagnetic field levels can be calculated by the electromagnetic solver (HFSS, SIwave, HFSS 3D Layout, Q3D). This means the field values calculated by the electromagnetic solver element approximate the true field values when the circuit is active. These calculations

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

are useful for active and passive antenna simulations, EMI/EMC simulations, and signal integrity applications. Ansys calls this "pushing excitations" from a circuit to a field solver.

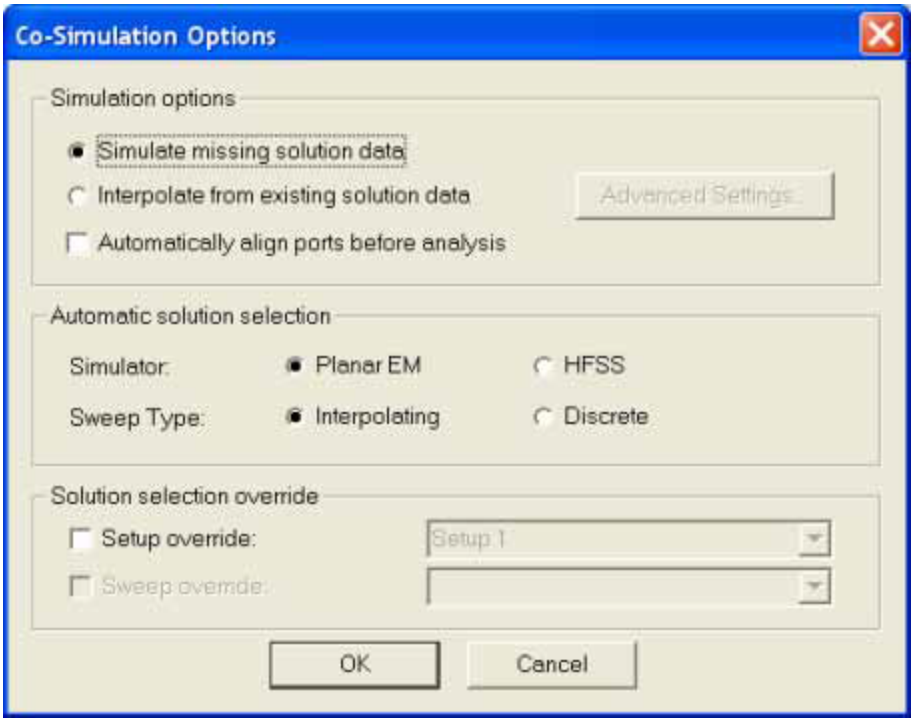
The procedure used to push excitations differs slightly depending on whether the electromagnetic simulator is in the Ansys Electronics Desktop, as is the case with the HFSS 3D Layout, Planar EM, HFSS, Q3D, and 2D Extractor simulators, or external to the Ansys Electronics Desktop, as is the case with SIwave.

To begin, insert a HFSS 3D Layout, HFSS, Q3D, or SIwave model into a circuit using the techniques described in previous topics. While the circuit/field-solver combination can be simulated immediately and S-parameters can be extracted, some additional setup is required to view field values in the field solver element.

Pushing Excitations to an EM Design

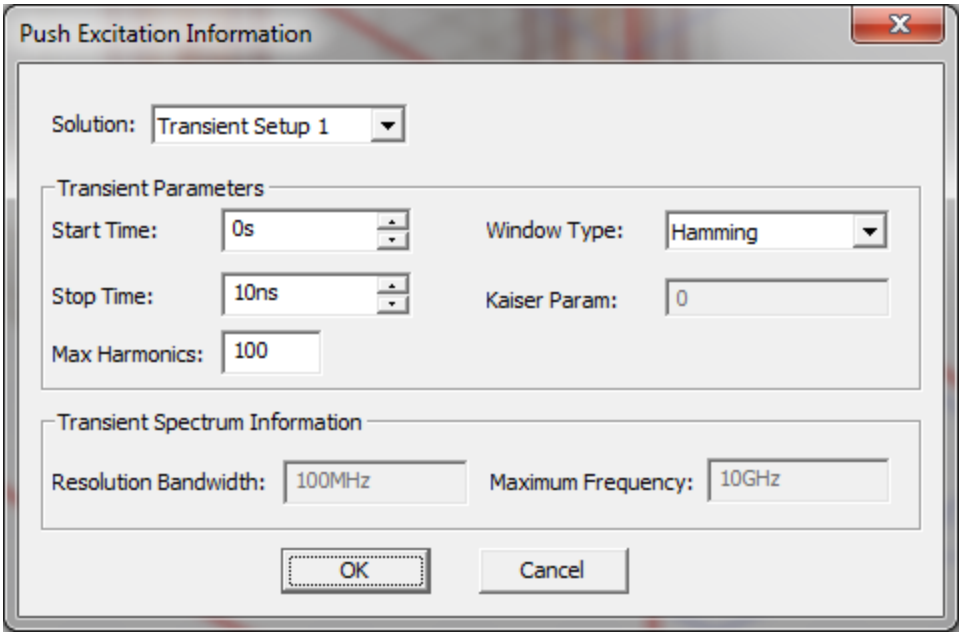
In order to view fields and currents in an EM Design you must force the simulation engine to compute and save currents. To do this, navigate to the EM Design in the Ansys Electronics Desktop **Project Tree** and insert a simulation setup and discrete frequency sweep into the model. Be sure to select **Generate surface currents** in the EM Design model.

Override the default co-simulation options so the simulator uses this setup and sweep. Select the EM Design model in the **Project Manager** window, then click **EM Design > Solution Setup > Co-Simulation Options**. Then select the setup and sweep that save the EM Design currents.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When you simulate the top level circuit, the EM Design subcircuit is automatically simulated using the setup and sweep defined in the Co-Simulation Options window. After simulating the circuit/field-solver combination, right-click the field solver element in the **Schematic Editor** and choose which solution to use to populate the field solver excitation values.



- The **ResolutionBandwidth** and **MaximumFrequency** of the data (that is sent or "pushed" to the dynamically linked project) are calculated based on the transient parameter settings: **StartTime**, **StopTime**, and **Max Harmonics**. The start and stop times must lie in the transient simulation time limits.
- Select the appropriate **Window Type**. When non-rectangular windows are used, the window automatically changes the power level of the signal. This is known as the "coherent gain" or "processing loss" of the window. The coherent gain is always adjusted to account for the processing loss of the window when pushing excitations to dynamically linked projects.

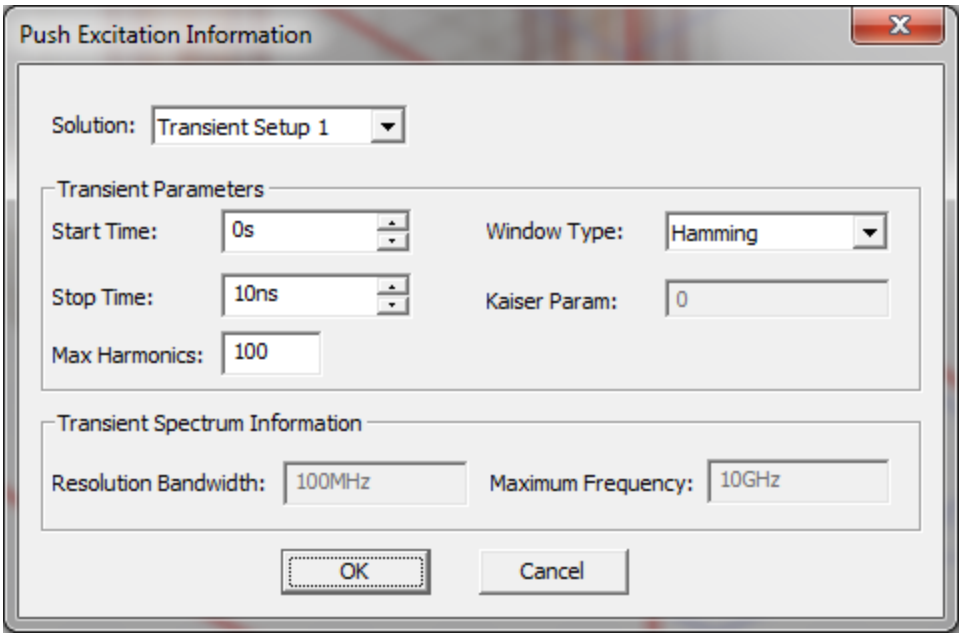
Pushing Excitations to an HFSS, SIwave, or Q3D Dynamic Link Model

The procedures for pushing excitations to dynamically linked models are all similar. You must first set up the field solver element so the fields and currents are saved during simulations (See the HFSS, SIwave, or Q3D documentation). After simulating the circuit/field-solver combination, right-click the field solver element in the **Schematic Editor**, select **Push Excitations** to launch the **Push Excitation Information** dialog, and choose which solution to use to populate the field solver excitation values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: When working with a Q3D Dynamic Link Model, the **Push Excitations** option will only be available if the beta option is enabled. Additionally, the **Push Excitations** option will only become available after simulating the circuit/field-solver combination.

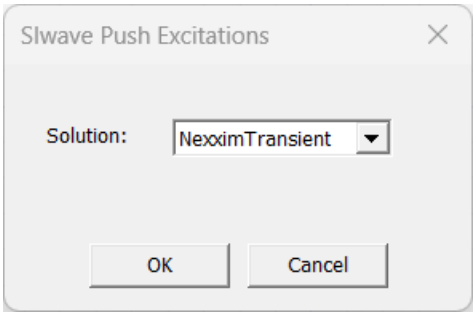
Push excitation dialog for HFSS and Q3D:



- The **ResolutionBandwidth** and **MaximumFrequency** of the data (that is sent or “pushed” to the dynamically linked project) are calculated based on the transient parameter settings: **StartTime**, **StopTime**, and **Max Harmonics**. The start and stop times must lie in the transient simulation time limits.
- Select the appropriate **Window Type**. When non-rectangular windows are used, the window automatically changes the power level of the signal. This is known as the “coherent gain” or “processing loss” of the window. The coherent gain is always adjusted to account for the processing loss of the window when pushing excitations to dynamically linked projects.

Push excitation dialog for SIwave:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note:

- Current quantities, rather than voltage quantities, are pushed to SIwave or Q3D.
- For SIwave or Q3D, push excitations is available for Transient solution only.
- When pushing excitations to SIwave, Transient Parameters are disabled as FFT is not available from this dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

1. The most common reason Push Excitations fails is that one or more terminals of the dynamically linked model are left unconnected. Nexxim does not compute voltages on unconnected terminals so no excitations can be determined. Adding short unconnected wires to the unconnected terminals of the model causes Ansys Electronics Desktop to assign unique net names to the terminals and allow Nexxim to compute voltages. Once Nexxim has computed voltages excitations can normally be pushed to the dynamically linked design.
2. If there is no voltage source in the design, an error appears. You can either cancel the push or add a 1V voltage source, resimulate the design, and push the excitations.
3. Excitations cannot be pushed to HFSS or SIwave if parameter values are swept in the Ansys Electronics Desktop setup.
4. For SIwave simulations, when **Enforce Causality** is selected, if the frequency step is too big it can result in an inconclusive test for causality enforcement. In this case, the causality checker automatically retries the simulation using rational interpolation and analytical integration.
5. For HFSS dynamic links, Push Excitations also pushes available-power to the HFSS Design. The amount of the power pushed is the sum of the available powers calculated at each Circuit Design port connected to the dynamic link — directly or indirectly — with the following caveats:
   - The port has either an associated voltage or power source (current sources are not supported).
   - The solution data being pushed is for a Linear Frequency Network simulation (no restrictions on port impedance values).
   - The solution data is for an HB or Transient simulation AND the port impedance is a constant value (e.g., 50 ohms).

   The pushed available-power shows up in the linked HFSS Design in its **Edit post-process sources** window that is accessible on the Field Overlays or Excitations icon shortcut menu. In HFSS, this power is called System Power and is used only for calculating 'System Gain' in the reporter and 'Total Realized System Gain' in antenna calculations.

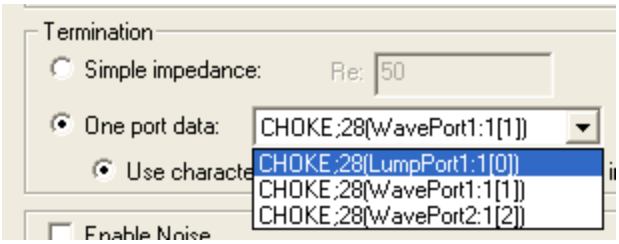
Dynamic Port Termination with a Dynamic Link Model

Nexxim can use port impedances set dynamically on the field solver cosimulator. The port impedances can be frequency-dependent. The Nexxim setup specifies the frequency range of interest to the Nexxim design, say f1 to f3. The field solver tool is set to run over a range of frequencies, f3 to f4, and can provide impedance data for that range. If the frequency range for which port impedance data is dynamically determined (f3, f4) is a subset of the frequency range

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

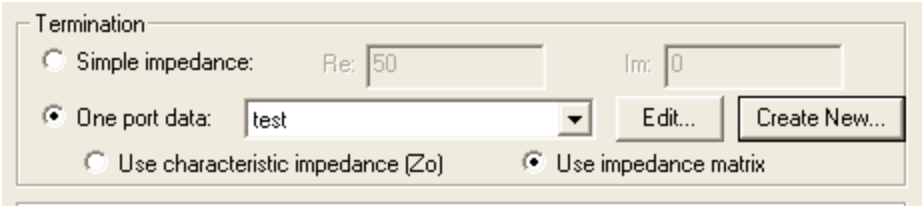
of interest (f1, f2), then the non-overlapping frequencies have the same impedances as the end frequencies.

To specify a dynamic impedance, double-click the port and select **Edit Port**. In the Termination group box of the Edit Port window, select **One port data** and **Use characteristic impedance**. From the drop-down menu, select the field solver port which is to supply the impedance data for this Interface port.



Users can specify a static list of frequencies and corresponding impedance in the following ways:

- In the **Termination** group box, select **One port data** and **Use impedance matrix**. Click **Create New** to open the **N-port data** window. Select a file with 1 port s-parameter data. Click **OK** to create a model. Back in the **Port Definition** window, click this model on the **One port data** menu.
- To enter data manually, first create a NPort_NoFile model with 1 port following these instructions. Place the component in the schematic for this model. In the **Termination** group box of the **Port Definition** window, click **One port data**, this model on the **One port data** menu, and **Use impedance matrix**.

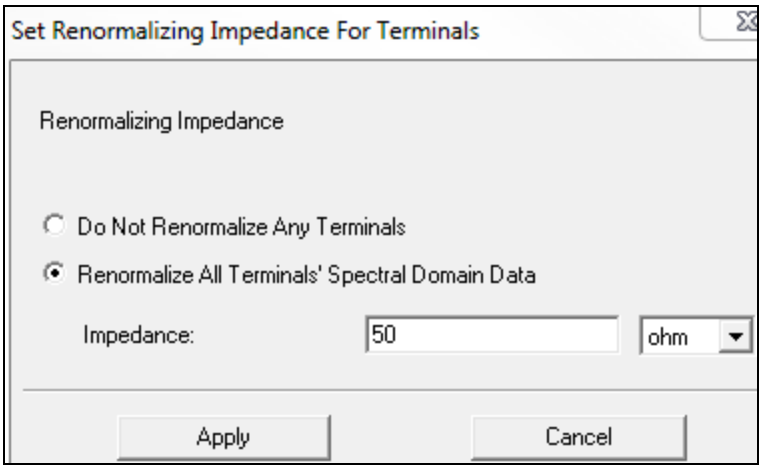


The impedances are interpolated for frequencies intermediate between given points. Impedances for frequencies outside the range given take the end values.

Set Renormalizing Impedance for Terminals

The setup panel for each terminal includes its post processing renormalizing impedance. You can set this value either for all excitations, or for a specific port. If a design includes at least one wave port, the setup panel also includes the radio buttons **Do Not Renormalize Any Terminals**, or **Renormalize All Terminals' Spectral Domain Data** .

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To set the renormalizing impedance for **all excitations**:

1. Right-click **Excitations** in the Project tree and select **Set Terminal Renormalizing Impedances**.

   The **Set Renormalizing Impedance for Terminals** dialog box appears.

2. In the field for **Impedance**, set the value, and select the units from the pull down.

   The format is "<real_part> + <complex_part>*i ohm", for example 50ohm + (-5ohm) * 1i

   > **Note:**
   >
   > The reference impedance is meant to represent the component modeled by the lumped port. You can assign a variable to these values, (for example " resistance + (reactance) * 1i"). This variable can be dependent on the frequency, which allows use of a dataset for frequency dependent impedance, (for example, pwl (ds1,freq) + (pwl(ds2,freq)) * 1i).

3. Click the **Apply** button to close the dialog and apply the change.

To Set the Reference for All terminals on a Port:

1. Right-click the port icon in the Project tree and click **Set Terminal Renormalizing Impedances**.

   The **Set Renormalizing Impedance for Terminals** dialog appears. It differs from the related command for all excitations by specifying that the **Renormalizing Impedance** is for terminals on the selected port.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the field for **Impedance**, set the value, and select the units from the pull down.

   This value can be a variable. This variable can be dependent on the frequency, which allows use of a dataset for frequency dependent impedance.

3. Click the **Apply** button to assign the impedance value.

> **Note:**
>
> For more information, see Scaling a Source Magnitude and Phase.

You can also set the Terminal Reference Impedance on a port by selecting the port and editing the value in the **Properties** dialog.

In designs with at least one wave port, where you want to view un-renormalized Zo impedance and/or the corresponding S parameters in either the Matrix data or in a report, you can select the **Do Not Renormalize Any Terminals** radio button.

Solver On Demand

Solver-on-Demand allows you to specify the simulator model to use for each component in a design. The simulator model for a given component can be switched between simulations.

Setting Up Models for a Component Type

The first step is setting up for **Solver-on-Demand** is to define the models that is available for each component *type*. All instances of that component type inherits the defined set of Solver On Demand models.

1. Open the **Definitions** folder on the **Project Manager** window, then open the **Components** subfolder.
2. Double-click the component in the list to open the Edit Component window. This window sets parameters that affect all components of the given type.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

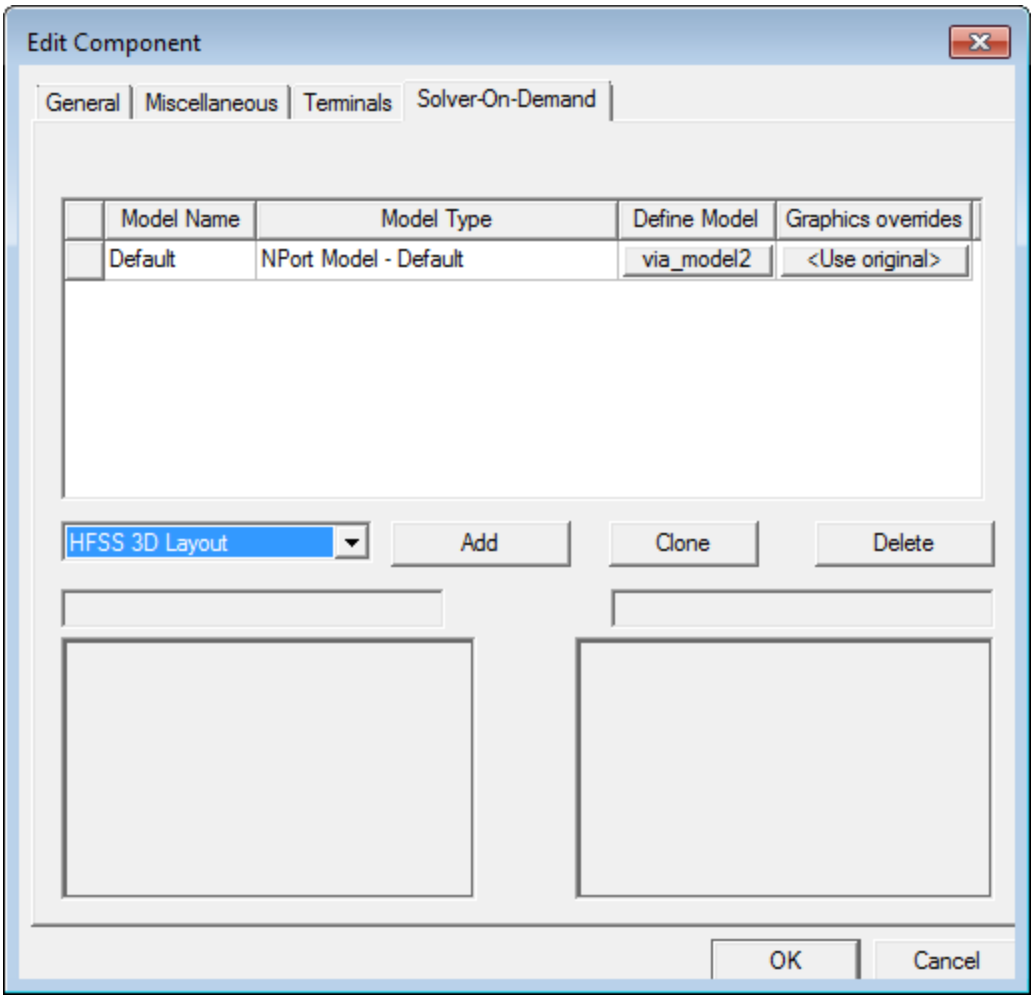
Note:

Alternative ways to open the **Edit Component** window are:

- Right-click a component instance that has already been placed in the schematic and choose **Edit Component**.
- From the **Component Libraries** docking window, right-click the component and choose **Edit Component** in either the *Components* or **Symbols** tabs.

See Using the Component Editor for further information.

3. Select the **Solver-on-Demand** tab:



To add a model for Solver On Demand:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Make a selection on the model type drop-down menu. Then click **Add**. A new model of the selected type is added to the list. The symbol and footprint preview windows at the bottom of the window are automatically updated to reflect whatever changes you make to a component's symbol/footprint definitions.
2. Click in the **ModelName** field for the new model and type the name you want to use for this model (or accept the default which already appears in the **ModelName** field). Note that when you highlight a **Model Name**, its symbol and footprint (if defined) are automatically previewed in the windows at the bottom of the window. These preview windows are automatically updated to reflect whatever changes you make to the component's symbol/footprint definitions.
3. Click the button in the appropriate **Define Model** field to open a **Cosim** or **Netlist** definition window that is specific to the model type.
4. Click the button in the appropriate **Graphics overrides** field to open an **Edit overrides** window to modify **Symbol/Footprint** settings or **Terminals** settings. For more information see General Tab, Terminals Tab, and Solver On Demand Symbol and Footprint Override.
5. Repeat steps 1 through 4 to create all the models you wish to use for this type of component.
6. Click **OK** when you have defined all the models for this component type.

Repeat the above procedure to specify models for all components that is simulated using Solver On Demand, Dynamic Links, or static models.

> **Note:**
>
> After a component type has been created, Edit the definition. Two common ways to edit a Component Type are:
>
> - Right-click a component instance that has already been placed in the schematic and choose **Edit Component**.
> - From the **Component Libraries** docking window, right-click the component and choose **Edit Component** in either the **Components** tab or the **Symbols** tab.
>
> See Using the Component Editor for further information.

Solver-on-Demand components are solved from internal model data: netlists for Nexxim, Nexsys, and HSPICE, or stackups (layout, substrate, footprint) for HFSS 3D Layout.

Select on the following to define a Solver On Demand component model type:

- HFSS 3D Layout
- MultiProduct Netlist
- Netlist

Dynamic Link components link to active HFSS, Q3D, 2D Extractor, or SIwave projects. Select on the following to define a Dynamic Link component model type:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- HFSS Model
- Q3D Model
- 2D Extractor Model
- SIwave Model

Static models contain a single set of solution data such as SYZ-parameters. Select on the following to define a static component model type:

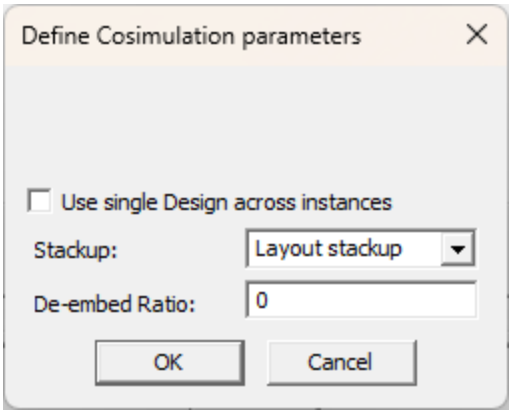
- NPort Model
- Parametric NPort Model
- Matlab Model
- State-Space Model

The Custom and Bypass model types are available for special needs:

- Custom
- Bypass

HFSS 3D Layout as Solver On Demand

HFSS 3D Layout is the available field solves that simulates from a layout, substrate, or footprint defined in the component itself. From the **Solver-on-Demand** tab of the **Edit Component** window, select **HFSS 3D Layout** from the drop-down menu and click **Add** to open the co-simulation definition window.



- **Stackup** – Set to one of three values (Layout, Substrate, or Footprint) to determine which stackup definition are used to model the component when it is simulated by the selected solver. For more information see Stackup Definitions.

Solver-on-Demand with the HFSS 3D Layout tool requires the component possess a physical definition, in the form of a footprint. Many components in the Ansys Electronics Desktop® library have footprints defined so they can be simulated using HFSS 3D Layout as

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

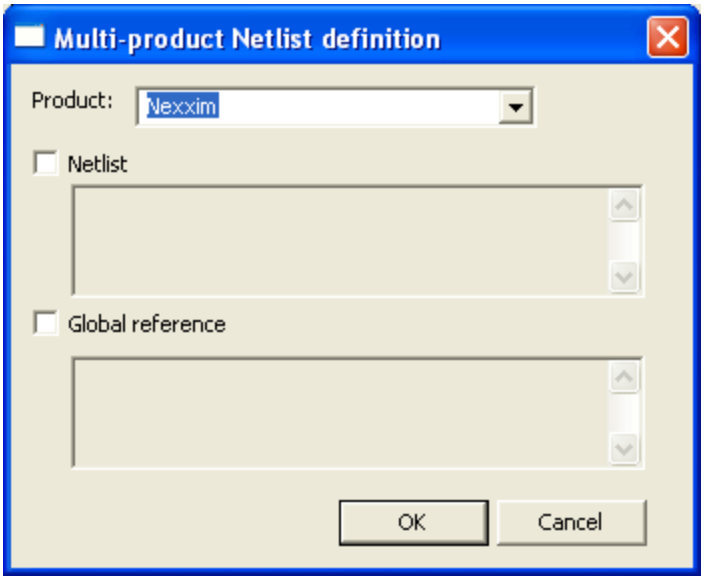
the **Solver-on-Demand**. When you define a component, it can be simulated using **Solver-on-Demand** as long as the component possesses a physical definition. For more information see Physical Definition.

- **De-embed Ratio** – Determines the manner in which excitation sign als are fed to the component via transmission lines during EM simulation. Short sections of transmission line are automatically added to the ports of the **Solver-on-Demand** component to allow discontinuities near the ports to decay in the EM simulation. The length of these transmission lines is equal to the De-embed Ratio times the width of the **Solver-on-Demand** port. That is, Length = De-embed Ratio * W (port connection). The solution data is automatically de-embedded back to the initial **Solver-on-Demand** component geometry to remove the effects of the additional transmission lines.
- **Use single Design across instances** enables the same design to be used for all instances of the component type, eliminating the need to specify the **Solver-on-Demand** model individually.

Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

Multiproduct Netlist in Solver On Demand

Nexxim/Nexsys and HSPICE are available circuit solvers that simulate from netlists defined in the component itself. In the **Solver-on-Demand** tab of the **Edit Component** window, when choose **MultiProduct Netlist** on the model drop-down menu and click **Add** to open the netlist definition window.



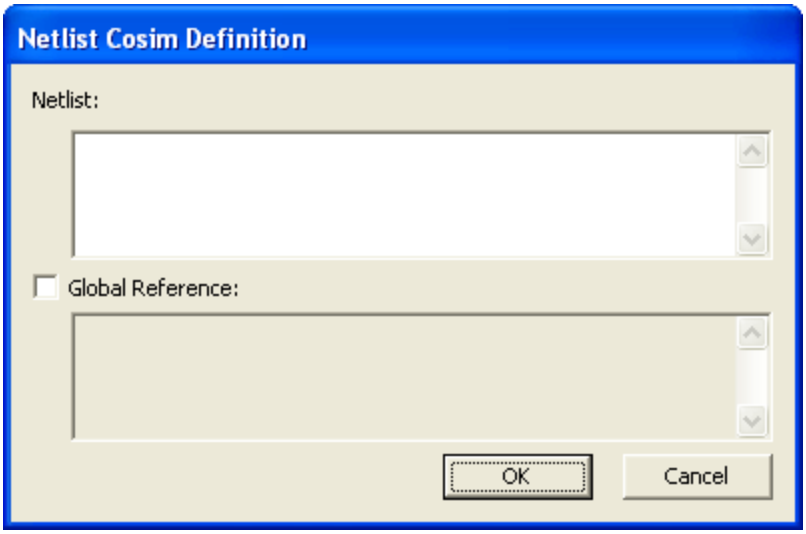
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Click the drop-down menu **Product** menu to choose which **Electronics Desktop** product netlist to define. The choices are Nexxim (which includes Nexsys) and HSPICE.
- Click in the **Netlist** field to define a new netlist.
- Click **Global reference** to define a global reference. The Global Reference group box is for any text that is to appear in the netlist outside of the circuit block, including substrate definitions, model definitions, references to external files, parameters, and comments to document the design.

Click **OK** to implement your changes, close the window, and return to the **Edit Component** window.

Netlist in Solver On Demand

The simple Netlist model is invoked for whatever circuit-level simulator is running. In the **Solver-on-Demand** tab of the **Edit Component** window, when choose **Netlist** from the model drop-down menu and click **Add** to open the co-simulation definition window. (The same window opens when you click **Edit** with a previously added **Netlist** model name selected).



- Click in the **Netlist** field to define a new netlist or make changes to an existing netlist
- Click **Global reference** to define a global reference. The Global Reference group box is for any text that is to appear in the netlist outside of the circuit block, including substrate definitions, model definitions, references to external files, parameters, and comments to document the design.
- Click **OK** to implement your changes, close the window, and return to the **Edit Component** window

Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

HFSS Dynamic Link Model in Solver On Demand

Click the **Add** Model menu in Solver On Demand to set up a dynamic link to an HFSS project.

1. From the **Solver-on-Demand** tab of the **Edit Component** window, select **HFSS Model** > **Add** to open an explorer window.
2. Browse (...) to select an HFSS project for the dynamic link.
3. Click **Open**. Ansys Electronics Desktop pauses for a few seconds while HFSS starts up. The **HFSS Dynamic Link** window are displayed

See Adding a Dynamic Link from HFSS for further information.

Click **OK** to save your changes and close the Edit Component window, or click **Cancel** to close the window without saving any changes.

Q3D Dynamic Link Model in Solver On Demand

Click the **Add** Model menu in Solver On Demand to set up a dynamic link to a Q3D project.

1. In the **Solver-on-Demand** tab of the **Edit Component** window, choose **Q3D Model** on the model drop-down menu and click **Add** to open an explorer window.
2. Browse (...) to select a Q3D project for the dynamic link.
3. Click **Open**. Ansys Electronics Desktop pauses for a few seconds while Q3D starts up. The **Q3D Dynamic Link** window are displayed

See Adding a Dynamic Link from Q3D for further information.

Click **OK** to save your changes and close the Edit Component window, or click **Cancel** to close the window without saving any changes.

2D Extractor Model in Solver On Demand

Click the **Add** Model menu in Solver On Demand to set up a dynamic link to a 2D Extractor project.

1. In the **Solver-on-Demand** tab of the **Edit Component** window, choose **2D Extractor Model** from the model drop-down menu and click **Add** to open the **File Open** window.
2. Browse (...) to select a Q3D project for the dynamic link.
3. Click **Open**. Ansys Electronics Desktop pauses for a few seconds while Q3D starts up. The **2D Extractor Dynamic Link** window then appears

See Adding a Dynamic Link from 2DExtractor for further information.

Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

SIwave Dynamic Link Model in Solver On Demand

Click the **Add** Model menu in Solver On Demand to set up a dynamic link to an SIwave project.

1. From the **Solver-on-Demand** tab of the **Edit Component** window, select **SIwave Model** on the model drop-down menu and click **Add** to open an explorer window.
2. Browse (...) to select an SIwave project for the dynamic link.
3. Click **Open**. Ansys Electronics Desktop pauses for a few seconds while SIwave starts up.

See Adding a Dynamic Link from SIwave for further information.

Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

NPort Model in Solver On Demand

Click the **Add** Model menu in Solver On Demand to set up a link to a file with static solution data such as SYZ-parameters.

1. In the **Solver-on-Demand** tab of the **Edit Component** window, choose **NPort Model** on the model drop-down menu and click **Add** to open an explorer window.
2. Browse (...) to select an appropriate solution data file for the component.
3. Click **Open**.

See Creating an N-Port Model for further information.

Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

Parametric NPort Model in Solver On Demand

Click the **Add** Model menu in Solver On Demand to set up a link to a file with static parametric solution data.

1. In the **Solver-on-Demand** tab of the **Edit Component** window, choose **Parametric NPort Model** from the model drop-down menu and click **Add** to open an explorer window.
2. Browse (...) to select an appropriate solution data file for the component.
3. Click **Open**.

See Creating a Parametric N-Port Model for further information.

Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Matlab Model in Solver On Demand

Click the **Add** Model menu in Solver On Demand to set up a static link to a file with static model data such as a Nexsys Matlab model.

1. In the **Solver-on-Demand** tab of the **Edit Component** window, choose **Matlab Model** on the model drop-down menu and click **Add** to open an explorer window.
2. Browse (...) to select an appropriate Matlab model file for the component.
3. Click **Open**.

See Creating a MATLAB UDM Schematic Component for further information.

Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

State-Space Model in Solver On Demand

Click the **Add** Model menu in Solver On Demand to set up a static link to a file with static solution data such as SYZ-parameters.

1. In the **Solver-on-Demand** tab of the **Edit Component** window, choose **State-space Model** from the model drop-down menu and click **Add** to open an explorer window.
2. Browse (...) to select an appropriate solution data file for the component.
3. Click **Open**.

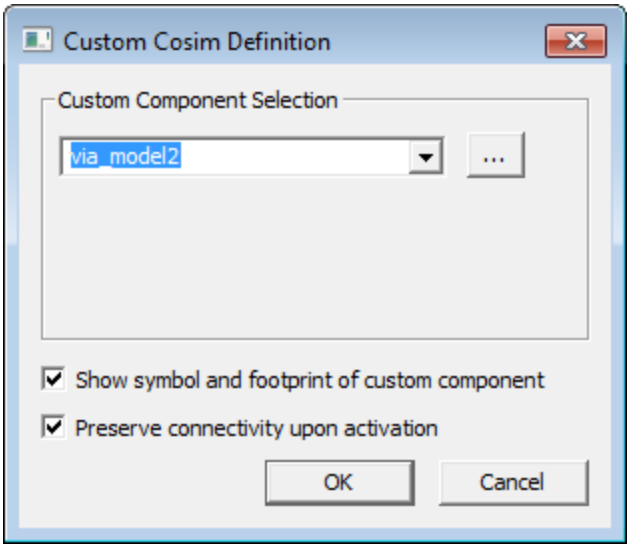
See State-Space Model Support for further information.

Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

Custom Model in Solver On Demand

Add a new component that references an existing component definition. In the **Solver-on-Demand** tab of the **Edit Component** window, choose **Custom** on the model drop-down menu and click **Add** to open the co-simulation definition window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Click the drop-down menu to alter the choice of **Custom Component Selection**, or browse for the selection (...). The menu lists the components already placed in the design that have the same number of terminals as the Custom component.
- If appropriate, uncheck **Show symbol and footprint of custom component** (on by default).
- If appropriate, uncheck **Preserve connectivity upon activation** (on by default).

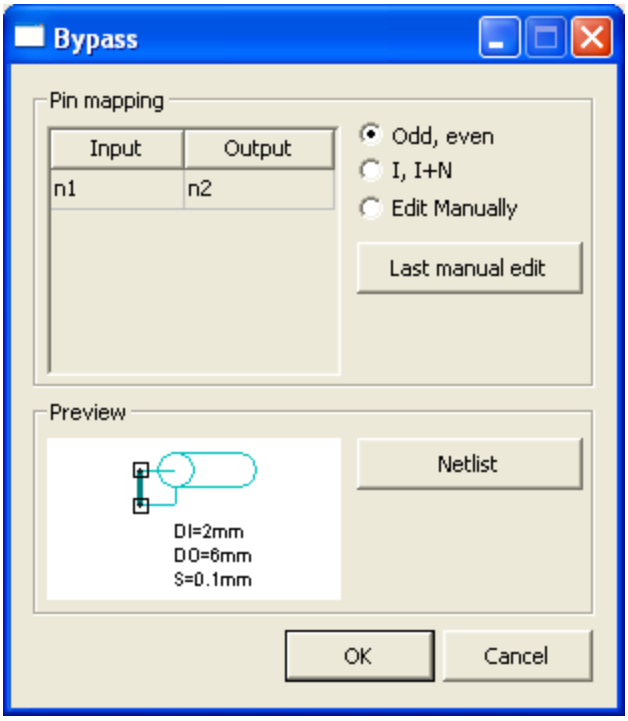
Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

Bypass in Solver On Demand

The **Bypass** Solver-on-Demand model allows you to auto-generate netlists to bypass a component through .CONNECT expressions. Using the **Bypass** definition window, customize the pin connections of a component. For two-port components, a **Bypass** model is created automatically. For components with more than two ports, it is necessary to define the **Bypass** pin mapping.

In the **Solver-on-Demand** tab of the **Edit Component** window, choose **Bypass** on the model drop-down menu and click **Add** to open the **Bypass** window. Alternately, If a **Bypass** model is already listed in the **Edit Component** window, click in the **Define Model Value** field to open the **Bypass** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- The **Bypass** window displays the current pin mappings.
- Select **Odd, even** or **I, I+N** to use a predefined pin combination.
- Click **Edit** to manually define connections. To define a connection, in the **pin mapping** grid, first select on the **Input** drop-down menu, then select from the **Output** drop-down menu.
- Select **Last manual edit** to cancel any changes you have made and return to the last saved pin combination.
- Select **Reset** to reset the pin combinations to their preset defaults.
- Click **Netlist** to see the **Bypass** netlist.
- Once the pin combination is defined, a preview of the component's design is displayed in the **Preview** window.

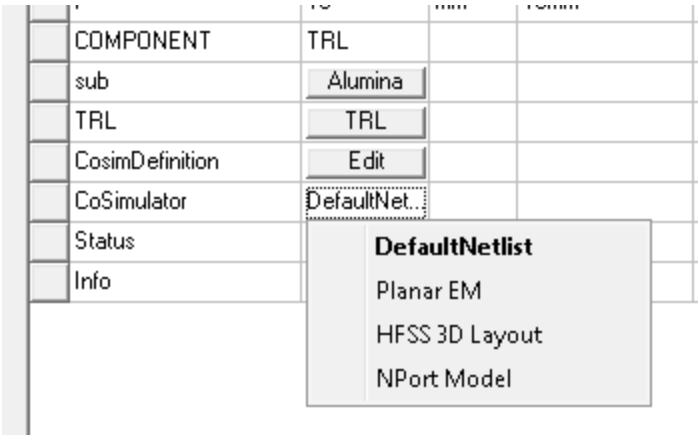
Click **OK** to save your changes and close the window, or click **Cancel** to close the window without saving any changes.

Selecting a Model for an Individual Component

The **Solver-on-Demand** model type can be defined for each individual component in the schematic. Initially, the default solver, **DefaultNetlist**, applies to all components. To specify a different solver for a component, select the component in the Schematic Editor. The properties

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

for that component are then displayed in the Property window. Scroll down to the CoSimulator property:



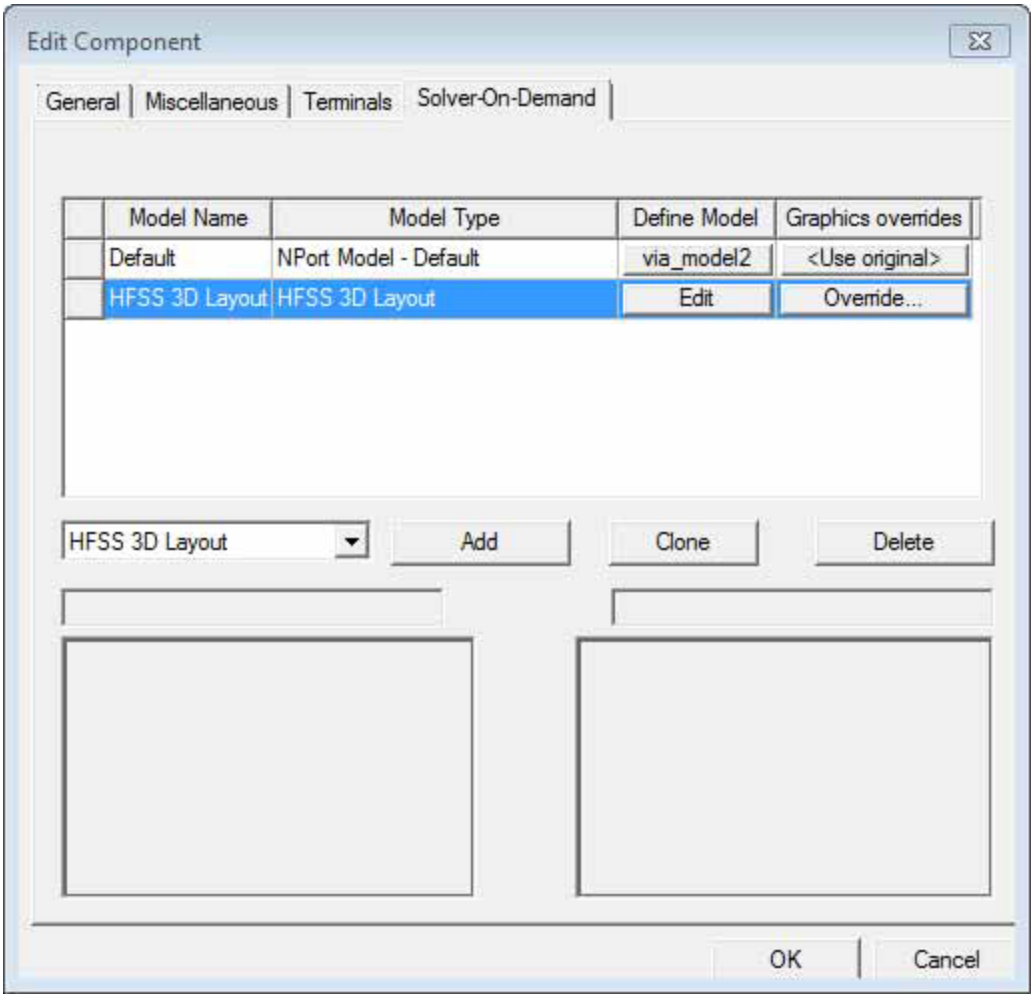
Click in the **Value** field to open the dropdown menu. The drop-down menu shows all the models that have been defined for this type of component. Click a model to select it and close the drop-down. Repeat this process for all components that uses **Solver On Demand** models other than the **DefaultNetlist**.

For more information about selecting and editing component properties, see Using the Component Editor.

Solver on Demand Symbol and Footprint Override

The **Solver-on-Demand** tab in the Edit Component window has symbol and footprint image previews which show the symbol/footprint that is displayed in the Schematic/Layout. The symbol and footprint images can be overridden when you define each model **Cosim Definition**.

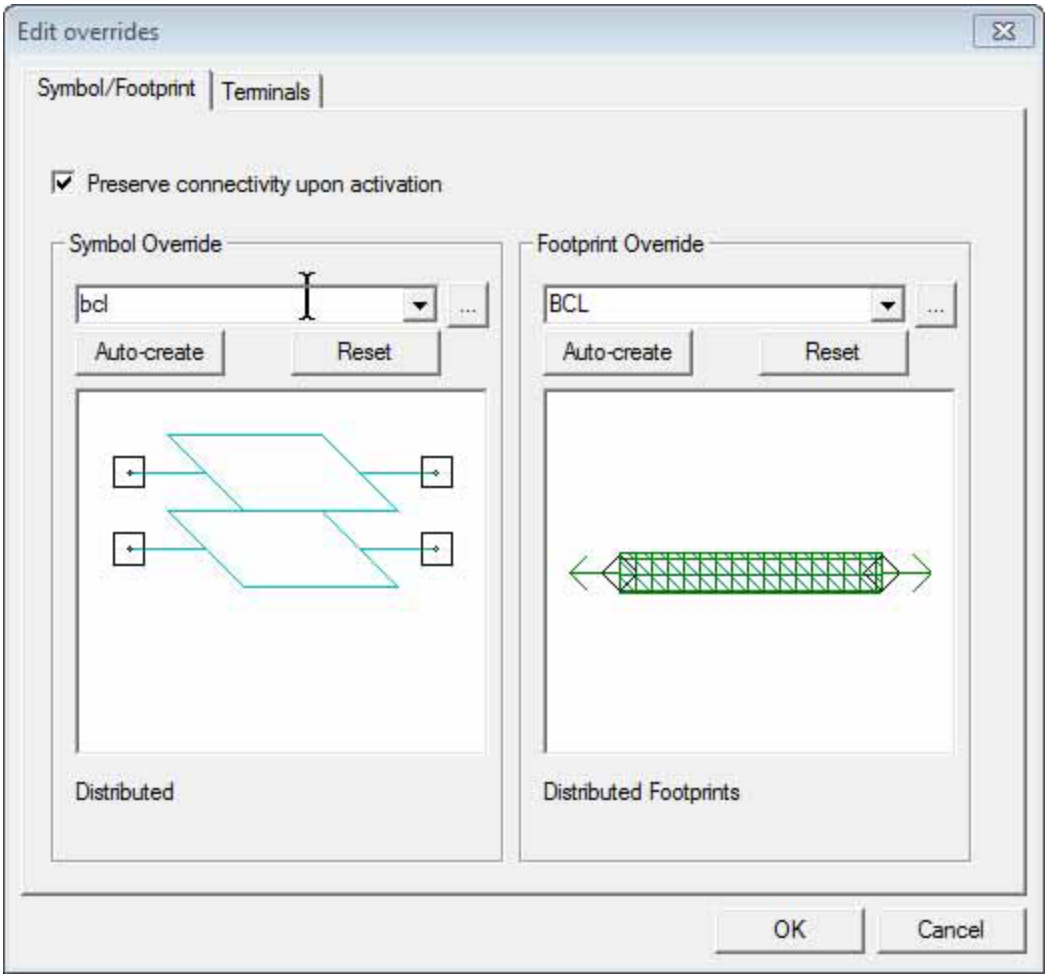
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Click **Override** in the **Graphics overrides** column to open the **Edit overrides** window. You can then override the symbol/footprint using the **Symbol** and **Footprint** drop-down menus of the window.

In the following figure, the override symbol and footprint (in this case, **bcle** and **BCL**) are displayed in the symbol/footprint preview windows at the bottom of the window. These are the same symbol/footprint that is displayed in Schematic/Layout when the component is selected.

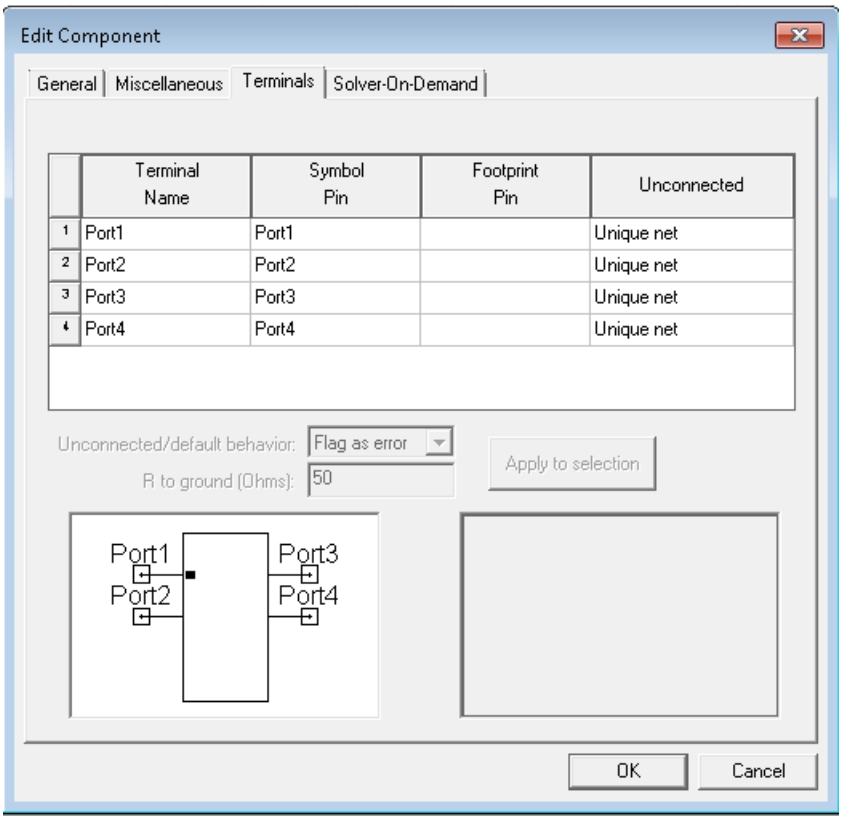
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- If appropriate, click **Preserve connectivity upon activation.**
- **Auto-create** a symbol, or instead **Reset** the symbol/footprint.
- Or **Browse** to choose a symbol/footprint from an existing library.
- Once finished, click **OK** to commit changes.

The chosen symbol and footprint are displayed in Schematic/Layout when the component is selected. You can modify terminal assignments to the symbol or footprint by clicking the **Terminals** tab and editing its contents.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For more information see Components Terminals Tab.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24 - Ansys Workbench Integration Overview

Ansys Workbench combines the strength of its core product solvers with the project management tools necessary to manage project workflow. In Ansys Workbench, analyses are built as *systems*, which can then be combined into a *project*. The project is driven by a schematic workflow that manages the connections between the systems.

From the schematic, you can interact with applications (called workspaces) that are native to Ansys Workbench and that display within the Ansys Workbench interface. Native workspaces include: Project Schematic, Engineering Data, and Design Exploration (Parameters and Design Points).

You can also launch applications that are data-integrated with Ansys Workbench, meaning the application's interface remains separate, but the data from the application communicates with the native Ansys Workbench data. Thus, data can be passed back and forth between any Ansys Electromagnetics product on a Workbench Project Schematic and any supported Ansys or Ansys Electromagnetics desktop product. Depending on the application, data integration can include basic actions such as saving projects, as well as more complex actions such as the coupling of Ansys Electromagnetics product variables to Workbench Design Exploration parameters.

Data-integrated applications include the following Ansys Electromagnetics products:

Circuit, HFSS, Icepak, Maxwell/RMxprt, Mechanical, Q3D Extractor, and Twin Builder.

> **Note:**
>
> For detailed information on working with Ansys Workbench, please refer to the Workbench documentation.

Integrating Ansys EM Suite with Ansys Workbench

You can integrate the Ansys Electromagnetics Suite with the Ansys Workbench application after both have been installed on your system. For successful integration, both preinstalled applications must be of the same version. A single operation completes the integration process for all supported design types.

The same procedure is used to integrate the applications or to decouple them (if they had previously been integrated). The procedure is as follows:

1. From the Windows Start Menu, select **All Programs** > **Ansys EM Suite 20*yy* R*n*** > **Modify Integration with Ansys 20*yy* R*n***.

   A *Modify Integration with Ansys 20yy Rn* command window appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

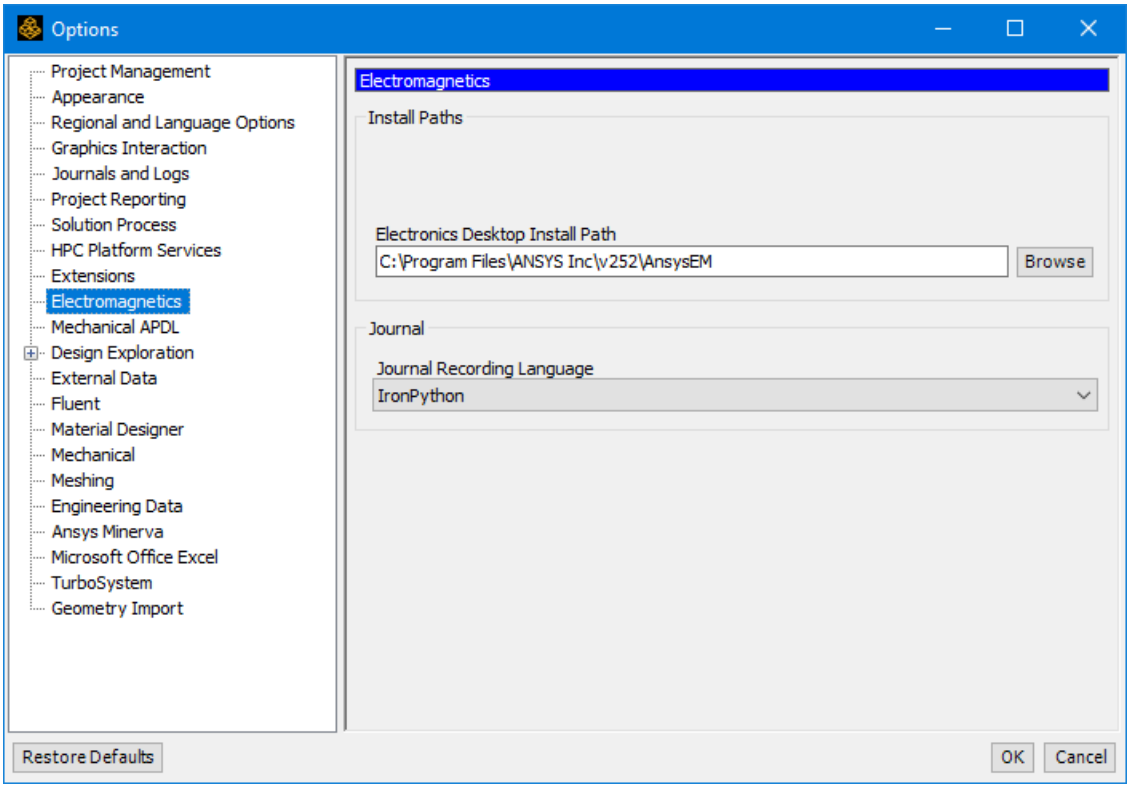
- If both applications are present on the system, their installation paths will be reported, and you will be asked if you wish to integrate them.
- Alternatively, if integration has already been performed, you will be asked if you wish to decouple them.

2. Type **yes** to perform the prompted action or **no** to abort the operation without making any changes. Then press **Enter**
   - If you enter *"yes,"* a confirmation line appears in the command window indicating that integration (or decoupling) has been completed, and the window remains open.

     Press **Enter** again to close the command window.
   - If you enter *"no,"* the operation aborts and the command window closes immediately.

Note:

You can confirm that the Ansys 20*yy* R*n* application is “aware” of the integrated application via the *Options* dialog box in Workbench. The path to the integrated Electronics Desktop application is listed in the *Electromagnetics* group of settings.



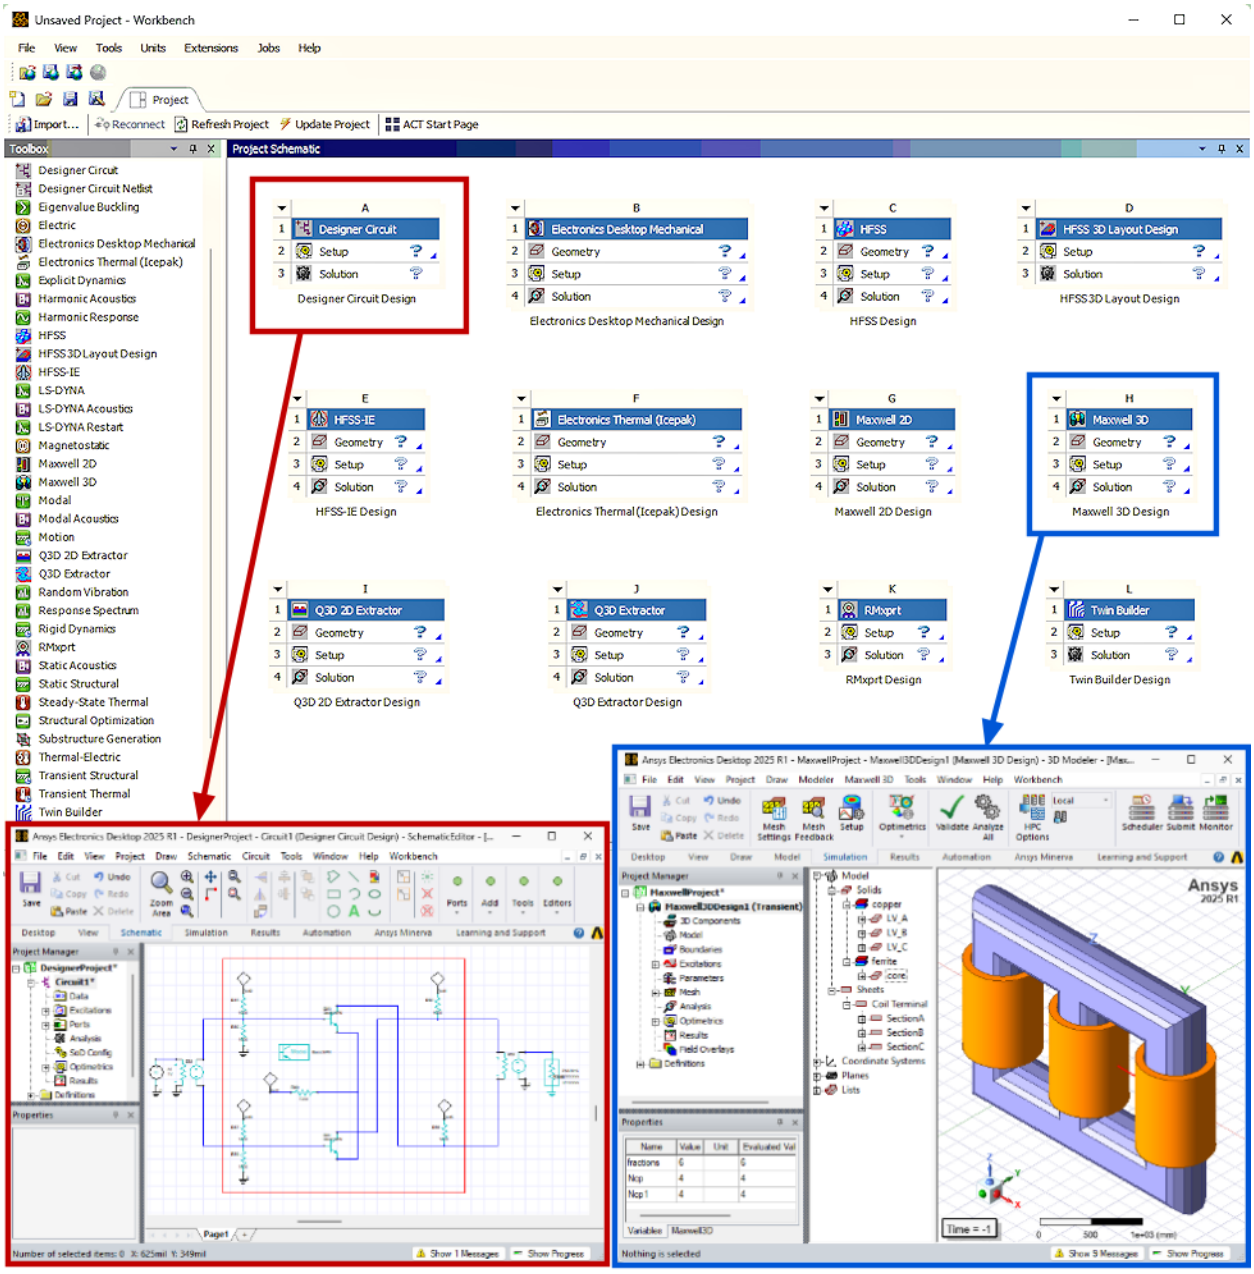
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In this group of options, you can also specify Workbench's default **Journal Recording Language** for use when interoperating with the Ansys Electromagnetics products. **Iron Python** is the default language, and the alternative choice is **Visual Basic** (VB). Changes applied here affect any new Workbench or Ansys Electronics Desktop session launched after the change. Any open instance will continue recording in the language that was in effect when the program was launched.

Workbench Data Integration Overview

Ansys EM data-integrated applications can reside on a Workbench **Project Schematic**, as shown.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



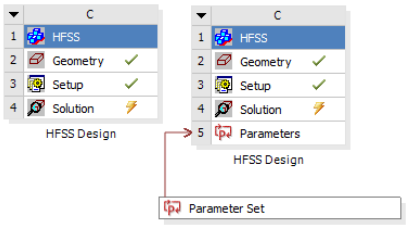
Objects placed on a Workbench Project Schematic (such as instances of Ansys Electromagnetics projects) are referred to as *systems*. The number of cells in the system depend on the desigh type, as follows:

- **RMxprt, Circuit, HFSS 3D Layout,** and **Twin Builder:** Appear on the Workbench Project Schematic as systems with three cells: **<*System_Type_Name*>, Setup,** and **Solution**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **HFSS, Maxwell, Q3D Extractor, Icepak,** and **Mechanical:** Include an additional **Geometry** cell along with the **<*System_Type_Name*>, Setup,** and **Solution** cells, for a total of four cells.

If you invoke Ansys **DesignXplorer** to use variables for refining a design, a **Parameters** cell is added, with a link to the associated Workbench **Parameter Set**. Refer to the Ansys Workbench help for details on working with systems, cells, and parameter sets.



All supported Ansys Electromagnetics Suite products integrate with Workbench commands, services, and DesignXplorer in a similar manner. Some capabilities include:

- Adding New Analysis Systems
- Importing Existing Ansys EM Projects into Workbench
- Editing Ansys EM Models in Workbench
- Ansys EM to Workbench Geometry Transfer
- Ansys EM to Workbench Material Data Transfer
- Analyzing Ansys EM Models in Workbench
- Performing Parameter Studies in Workbench
- Scripting in Workbench

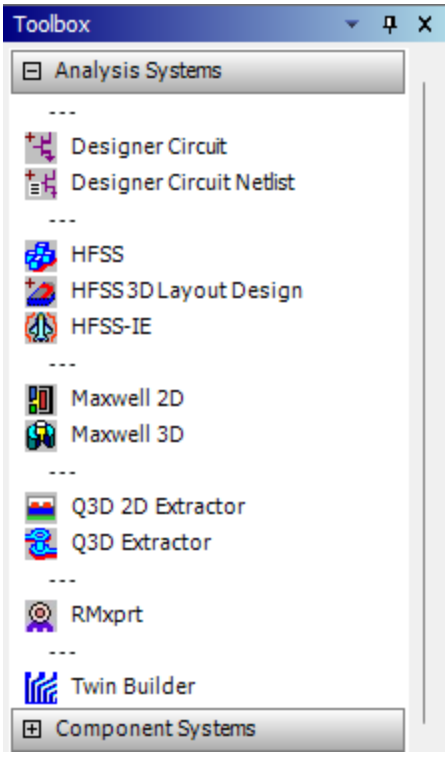
In addition to these major features, Workbench can archive, save, back up, duplicate, and delete Ansys Electromagnetics projects used in a Workbench project. Progress information and messages from integrated Ansys EM projects are also displayed in Workbench.

> **Note:**
>
> Look in the *Ansys Workbench Help* to find detailed information about performing the above-listed operations.

Adding New Analysis Systems

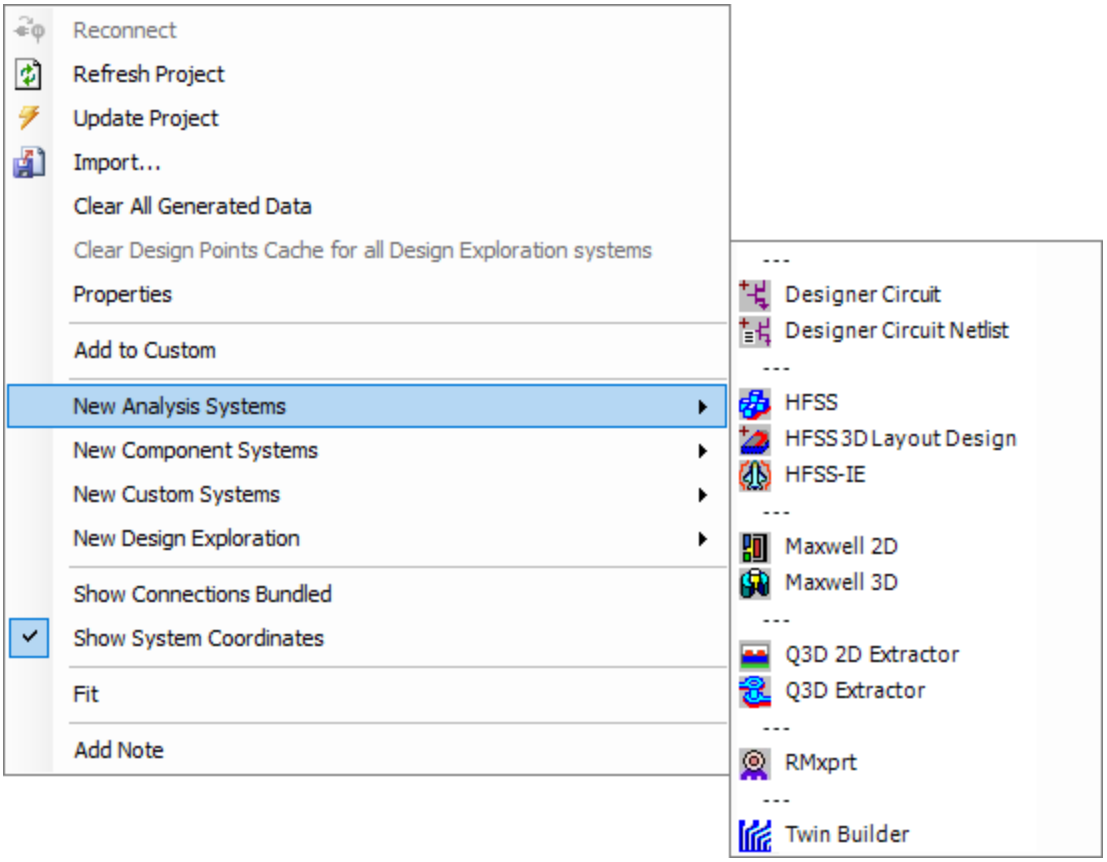
A new Ansys Electromagnetics Analysis System can be added to a Workbench Project Schematic by dragging and dropping it from the Toolbox:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Alternately, you can add a system by right-clicking in the Workbench Project Schematic area and selecting **New Analysis Systems** > **[System Type]**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

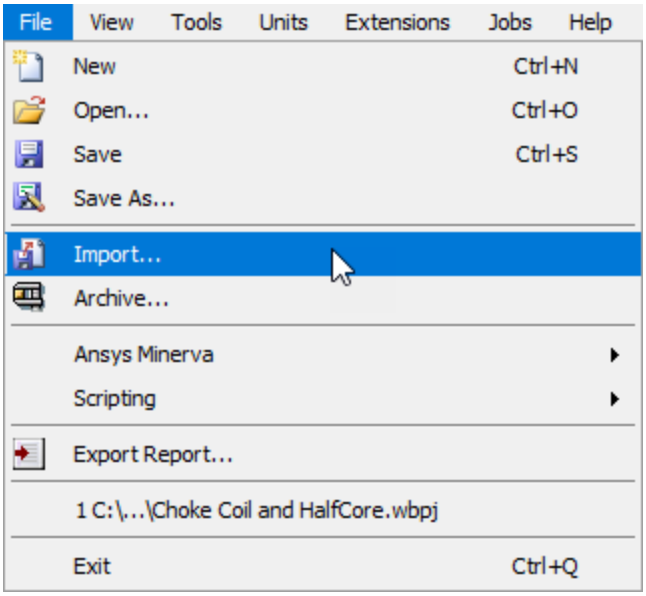


Importing Existing Ansys EM Projects into Workbench

You can import existing Ansys Electromagnetics Suite projects into a Workbench project schematic using **File** > **Import**. When you do, a copy of the Ansys Electromagnetics project is placed in the Workbench project folder. The original Ansys Electromagnetics project remains intact.

> **Note:**
>
> Object, material, and parameter names with non-ASCII characters are not allowed for data transfer. Such transfers fail and produce an error message.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

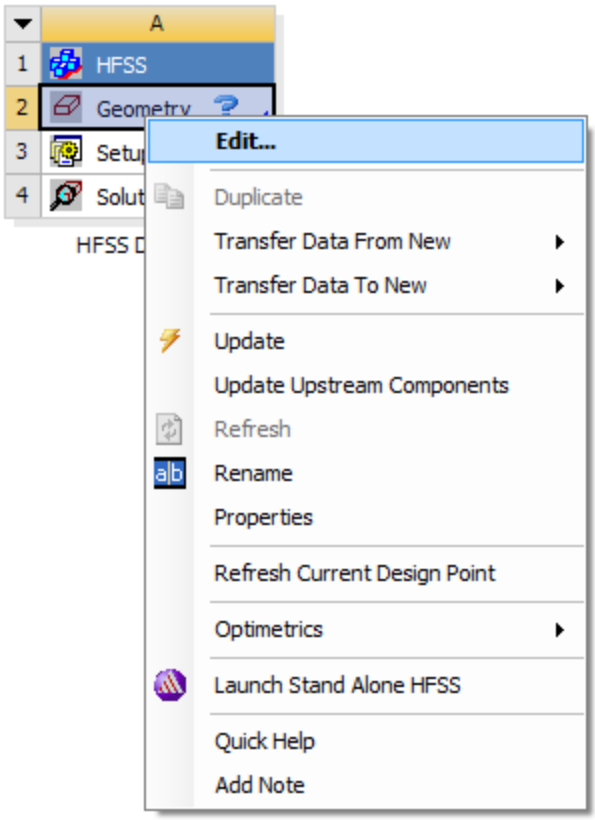


Editing Ansys EM Models in Workbench

You can edit various properties and parameters of the Ansys Electromagnetics project (geometry, setup, solution, etc.) either by right-clicking the project in Workbench and selecting **Edit**, or by double-clicking the project.

Doing so launches the Ansys Electromagnetics desktop application and loads the project so that you can set up your project in a familiar desktop environment. Changes made to the Ansys Electromagnetics project are saved to the project instance in the Workbench project folder.

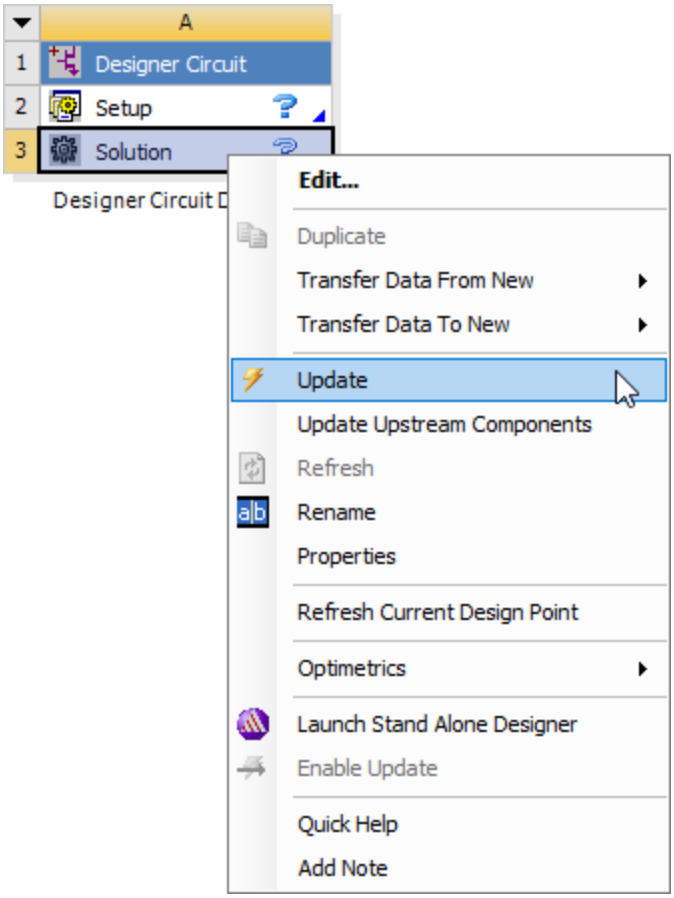
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



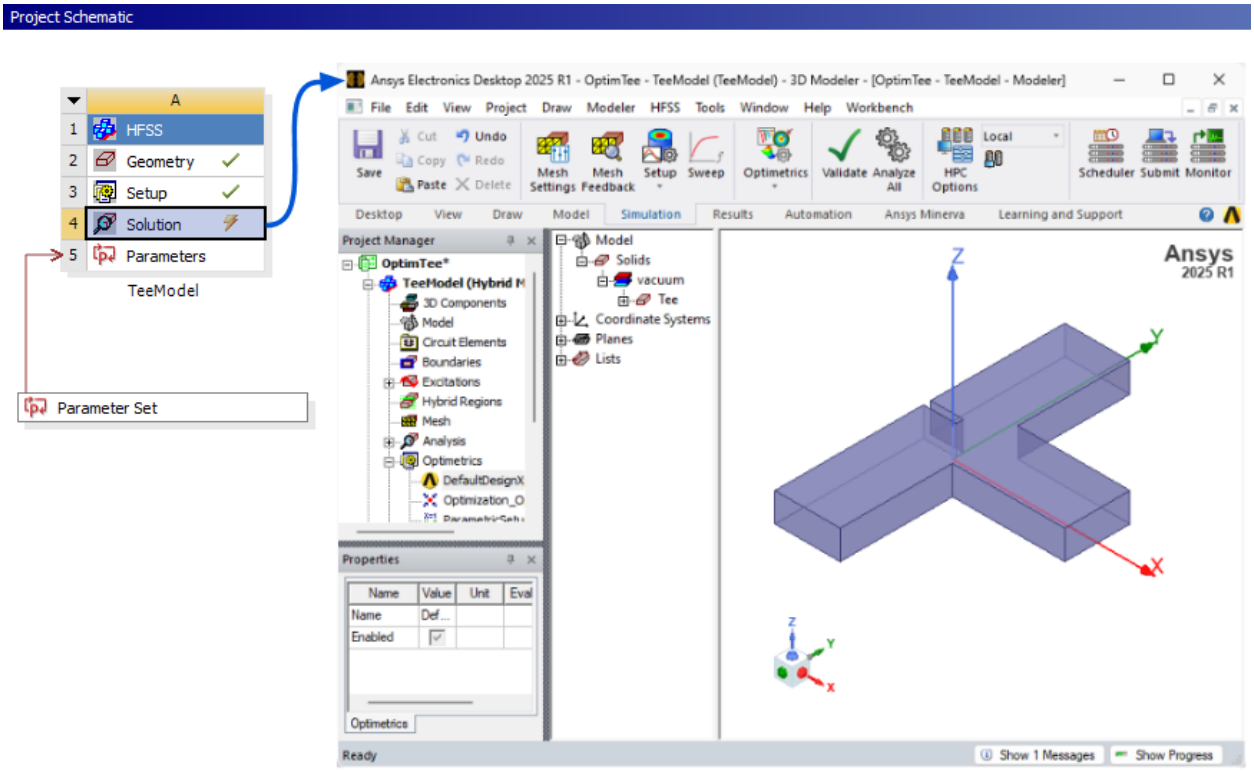
Analyzing Ansys EM Models in Workbench

You can use Workbench's **Update** command to run analyses in the integrated Ansys Electromagnetics project. Progress information is also shown in Workbench.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



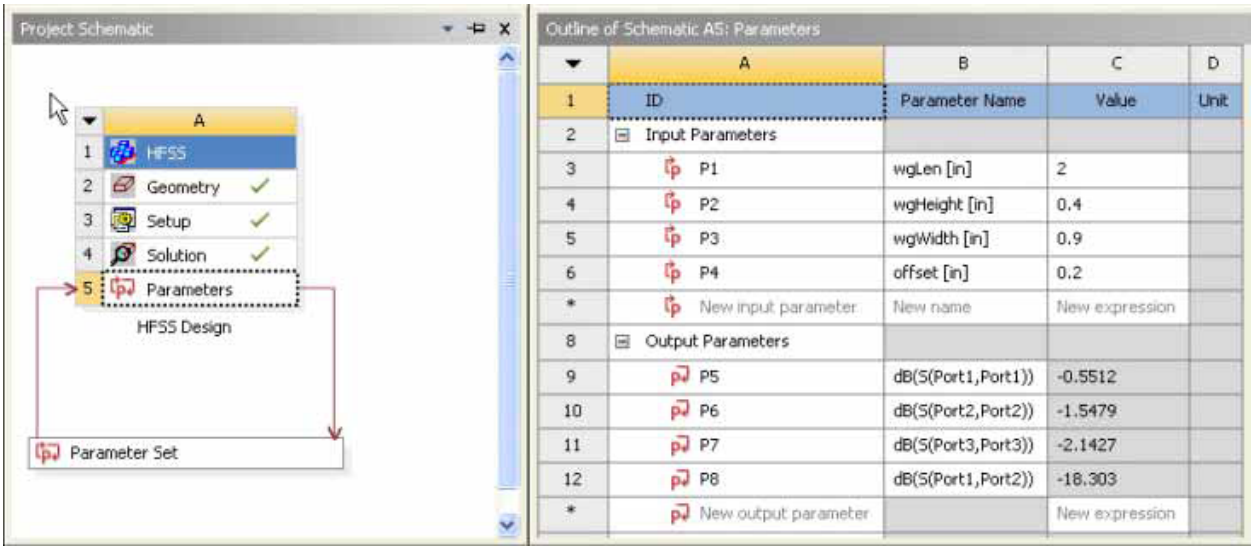
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Performing Parameter Studies in Workbench

Workbench **Parameter Sets** allow you to change parameter values and units of measure, or add new parameters. Parameter data is passed back to the Ansys Electromagnetics application for updated analyses. After analysis, the Workbench Parameter table should be updated correctly for all design points.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

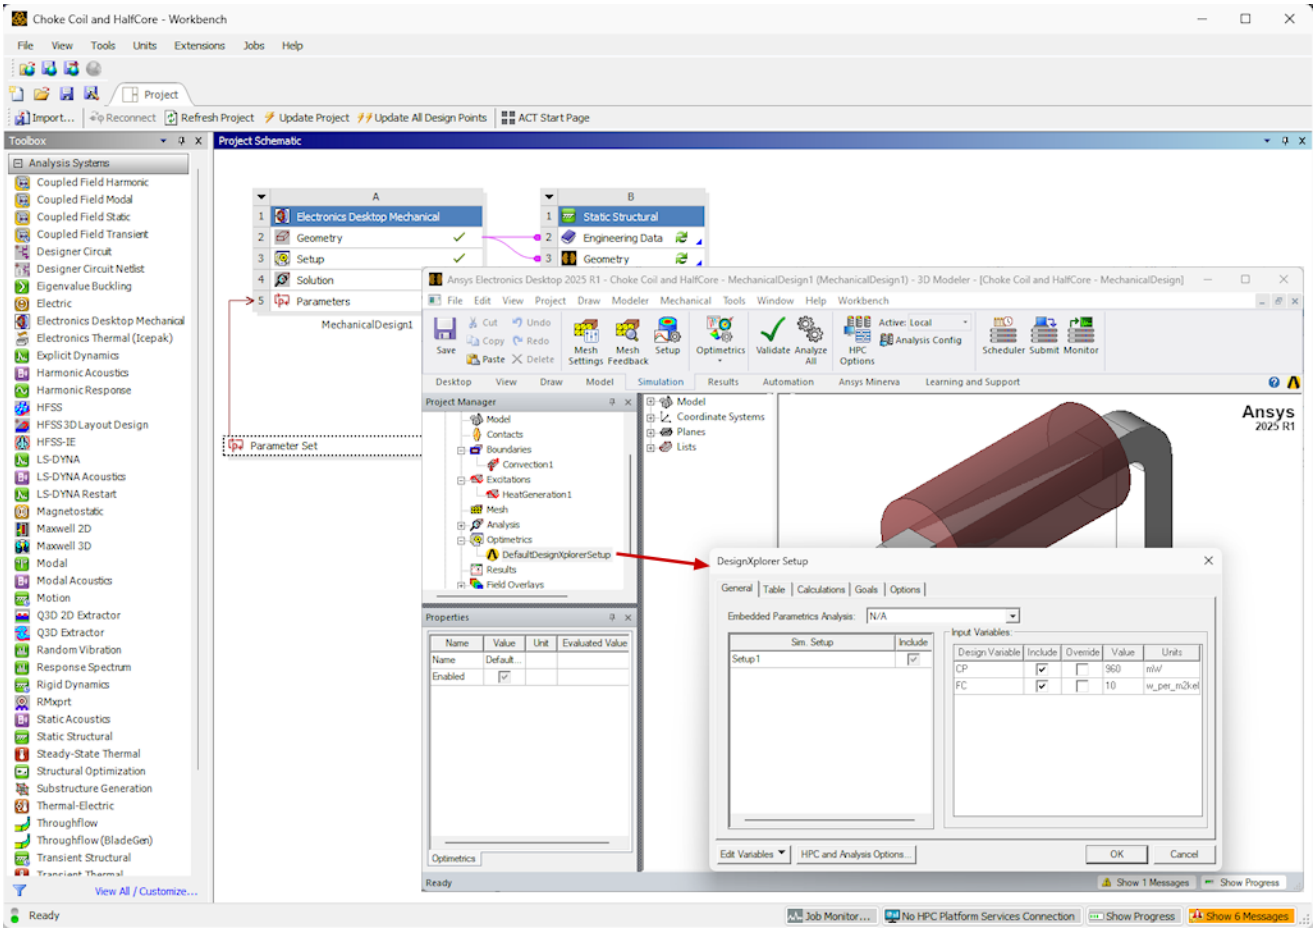


Note:

Because Workbench and Ansys Electromagnetics Desktop have different unit systems, units defined in Desktop are Dimensionless in the Workbench Parameters table and thus cannot be changed. Refer to the *Ansys Design Modeler User's Guide* > *Project Schematic Operations* > *Parameters in Project Schematic* > *Parameter Units* topic for additional information.

Parameters from the Ansys Electromagnetics project are exposed to Workbench through the **DesignXplorer** setup. The Ansys Electromagnetics system's cell status on the Workbench project is updated as changes are made in the Ansys Electromagnetics application. The following example is a Mechanical, Steady-State Thermal design in which two variables have been defined. One variable (CP) is the coil power (960 mW heat generation) and the other (FC) is the film coefficient of the assigned convection boundary:

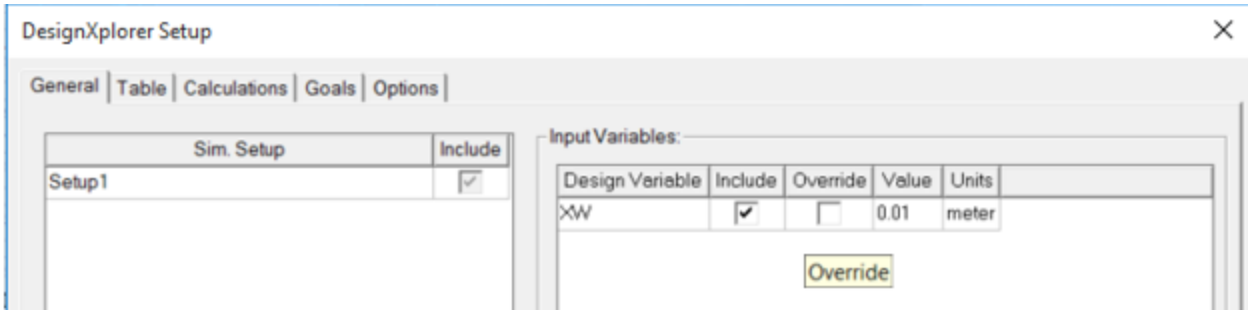
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



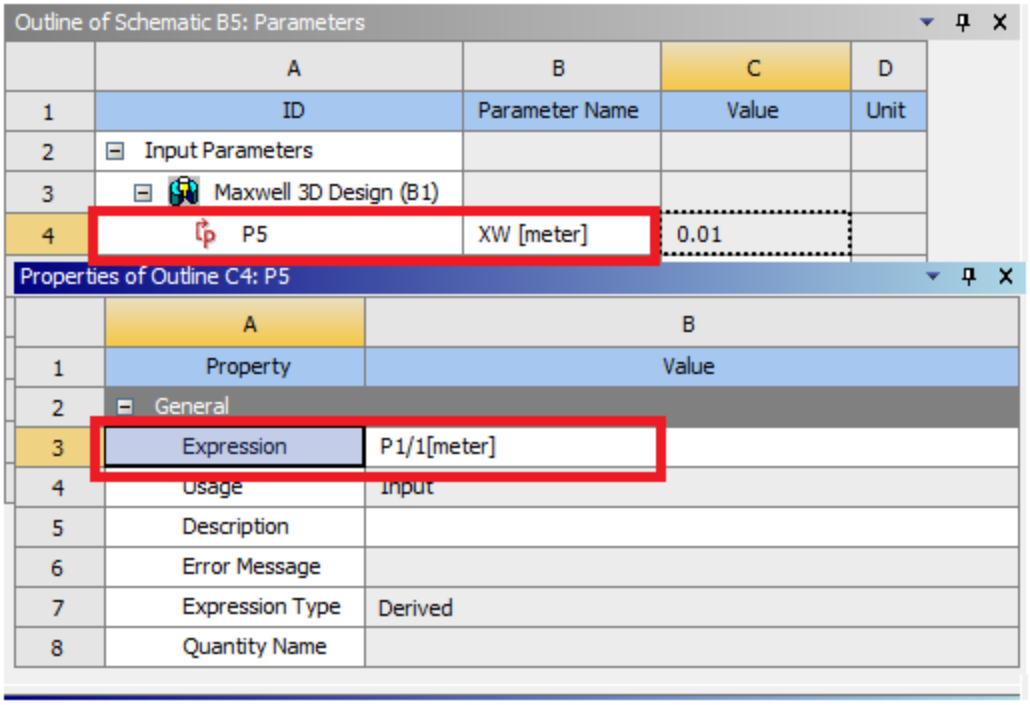
The workflow for using Electronics Desktop systems with the Workbench to take advantage of Distributed Analysis is as follows:

1. In the Ansys Electronics Desktop, specify a variable an as input parameter. The following figure shows a DesignXplorer Setup that includes a geometry variable called XW This variable is mapped to a variable in the corresponding Workbench Design, in this example, P5.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

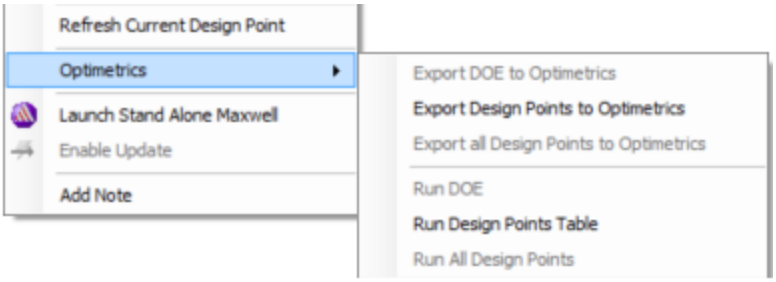


2. In the Workbench Design, change the P5 expression to a new value (in this example figure, the P5 parameter is assigned an expression of P1/1[meter] to tie it to the geometry system's variable.



In Workbench, the **Export Design Points to Optimetrics** and **Run Design Points Table** commands are enabled.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

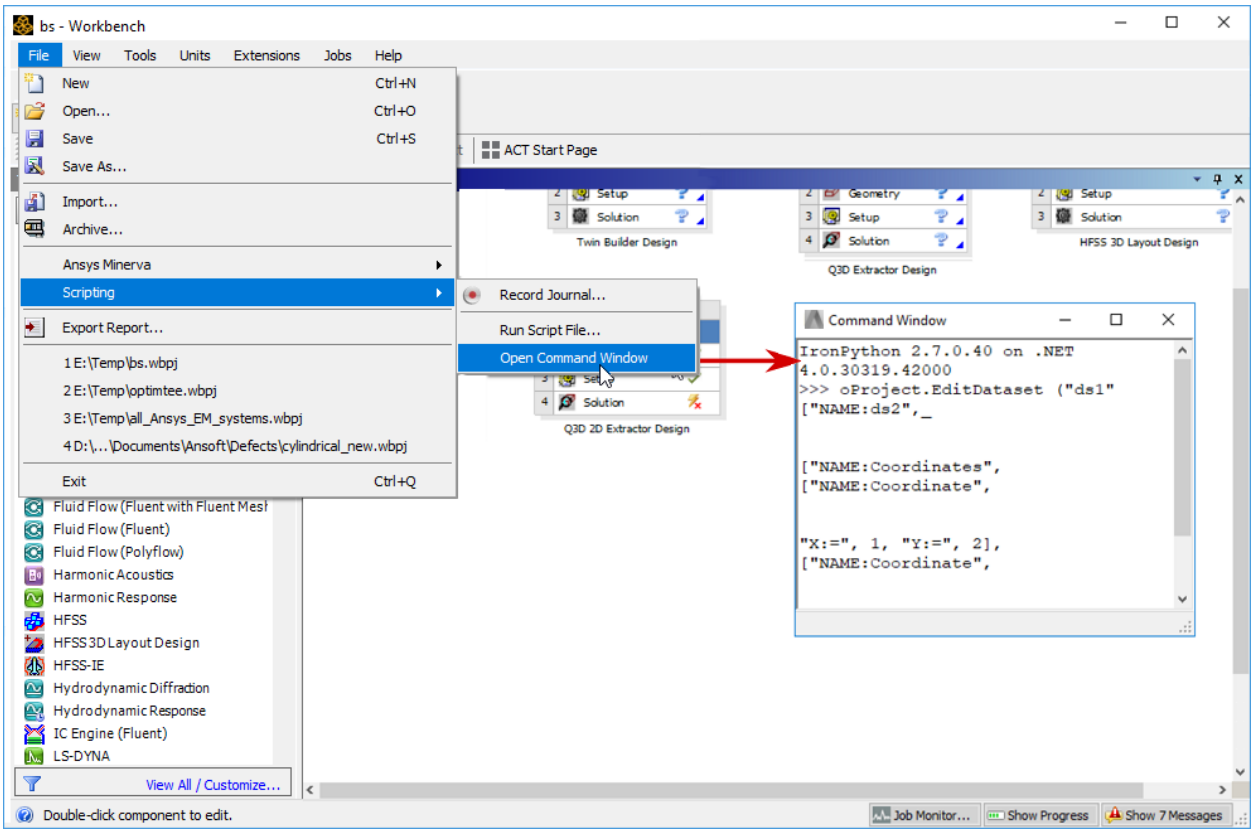


3. In Electronics Desktop, you can click on the default DesignXplorer Setup, and choose **Generate Variation Data**.

If you have configured your Analysis Configuration for multiple machines, the Project is ready for Distributed Analysis. After analysis, the Workbench Parameter table should be updated correctly for all design points.

Scripting in Workbench

Scripts that include Ansys Electromagnetics projects can be recorded and run in Workbench.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When a Workbench journal is run from the command line, Electronics Desktop allows the Ansys EDT portion to also run in batch mode (that is, when using RunWB2 -b).

Example: From a Windows Command prompt, enter the following command to replay the journal named "myReplayJournal.wbjn":

```
RunWB2 -b -r myReplayJournal.wbjn
```

Ansys EM - Ansys Multiphysics Coupling

Data integration provides an improved multiphysics workflow between Ansys Electromagnetics designs and Ansys applications such as Mechanical and Thermal. Coupling is provided through project schematic links. Heat losses and force data are automatically transferred to Ansys Mechanical, and there is no need to export or import transfer XML files. Edits made in Ansys Electromagnetics applications are automatically transferred to the Ansys application through the Workbench **Refresh** command. Workbench commands also enable easier automation of iterative coupling of thermal feedback.

The following sections provide some examples of multiphysics coupling.

Multiphysics Coupling on Workbench with Ansys Thermal

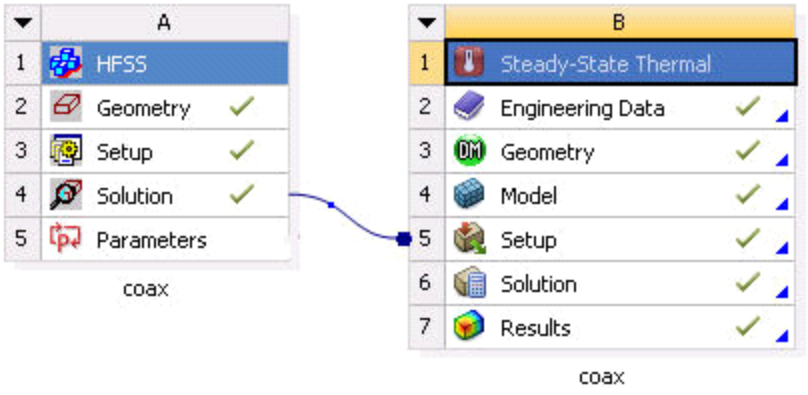
Multiphysics Coupling on Workbench with Ansys Structural

Multiphysics Coupling between Ansys EM Field Systems on Workbench

Multiphysics Coupling on Workbench with Ansys Thermal

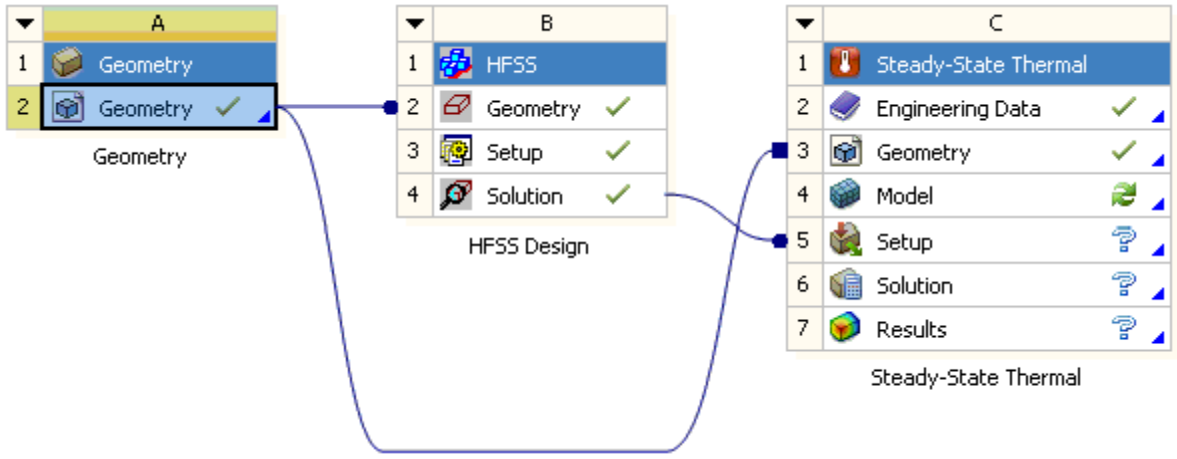
Using data integration, HFSS, Maxwell, and Q3D Extractor provide heat losses (heat generation and heat flux) to Ansys Thermal. In HFSS, both Driven and Eigenmode projects can be coupled for multiphysics. You first need to enable feedback as described in Setting the Temperature of Objects.

Note how the HFSS design is linked visually to Ansys Thermal on the Workbench project schematic.

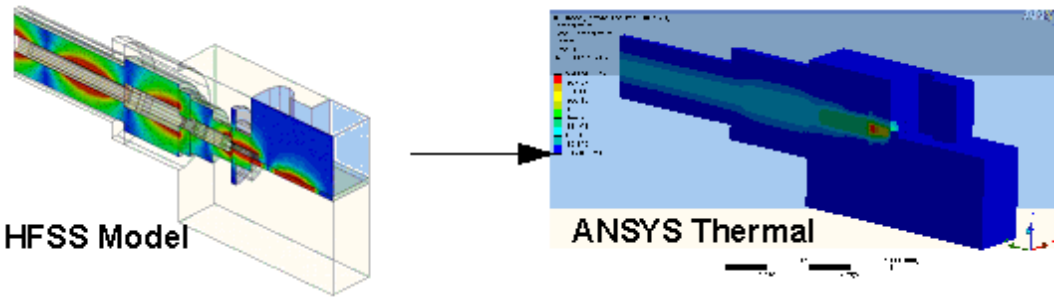


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Geometry sharing is possible, provided you activate Beta Options in Workbench. A geometry from the Component Systems in the Toolbox in Workbench Schematic can be shared as shown in the image below.



In this example, HFSS coax model Solution provides heat loss data as a thermal load to the Ansys Thermal Setup. The resulting analysis shows a thermal "hotspot", providing the user with the information needed to adjust the design's material to fix the problem.

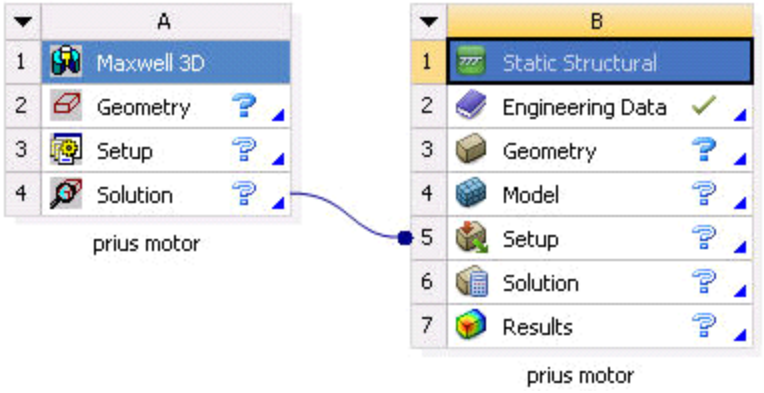


You enable this feature by checking Enable Feedback in the dialog for Setting the Temperature of Objects.

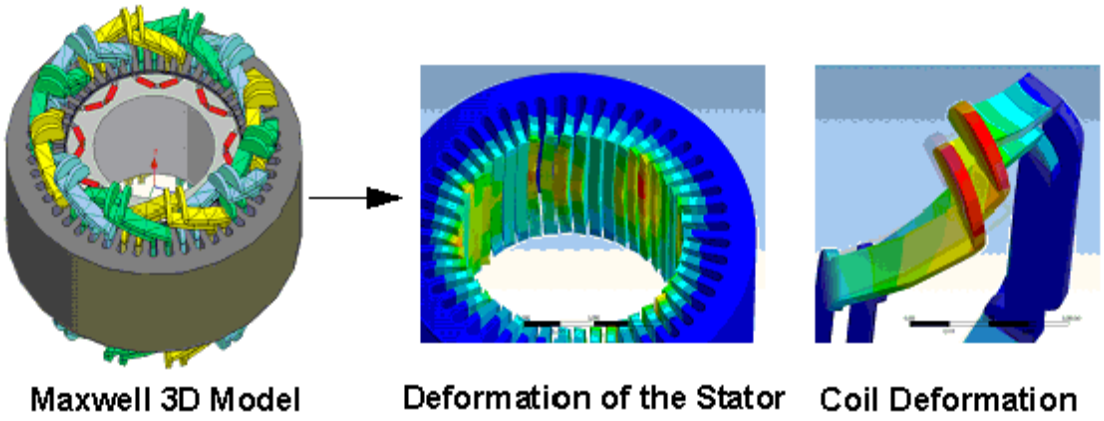
Multiphysics Coupling on Workbench with Ansys Structural

Using data integration, Maxwell 2D and Maxwell 3D can provide forces to Ansys Structural.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In this example, the Maxwell 3D electromagnetic force density **Solution** is used as the load in Ansys Structural to determine how these forces deform the motor's stator and coils.

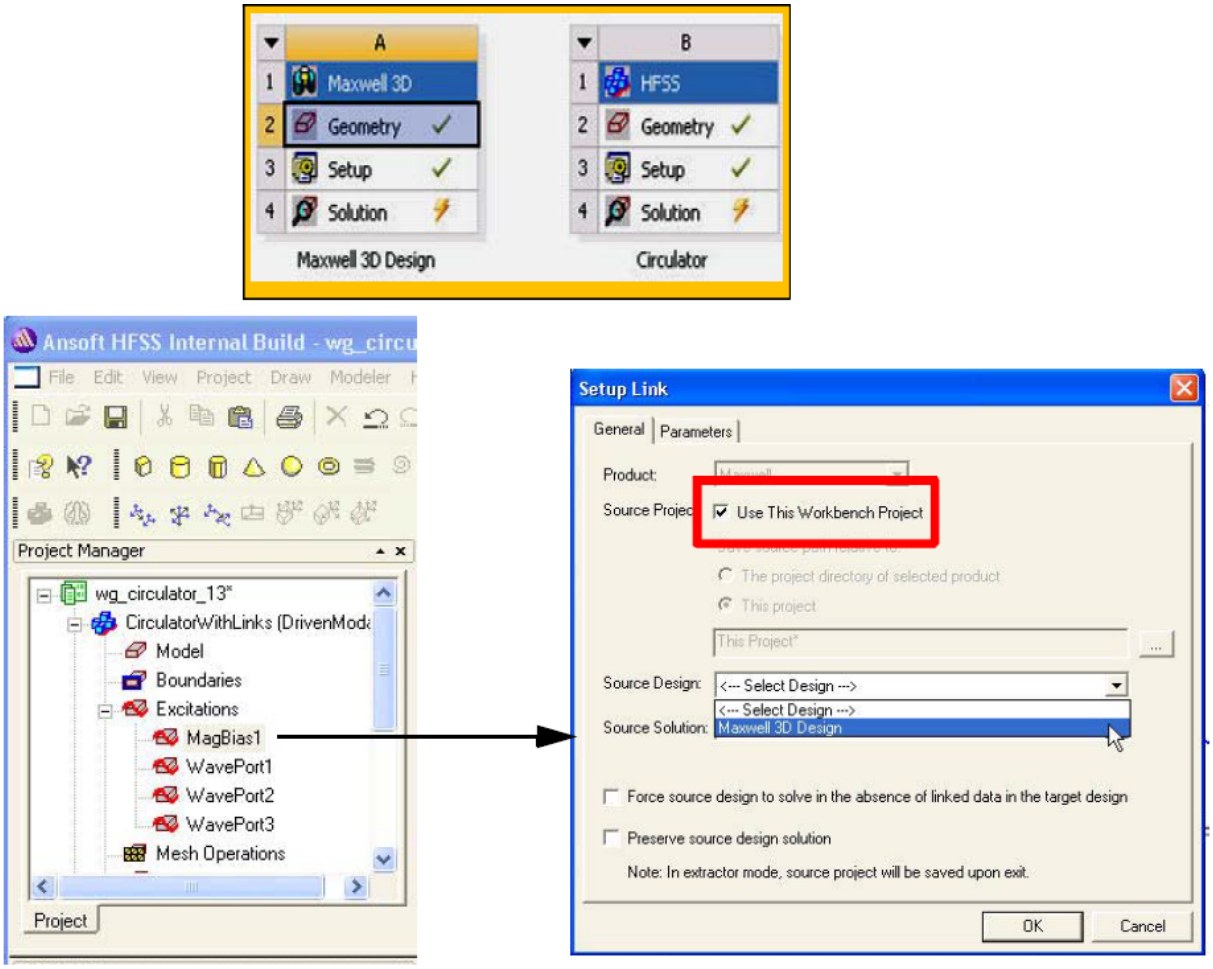


Multiphysics Coupling between Ansys EM Field Systems on Workbench

You can set up links between Ansys Electromagnetics field systems that reside on a Workbench project schematic. Linking is set up in the Ansys Electromagnetics application as shown in the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

following example.

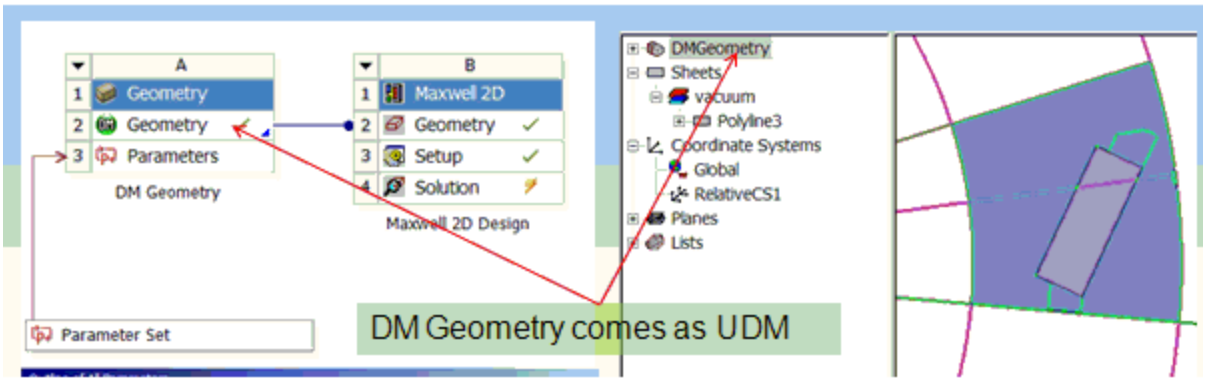


Ansys EM CAD Integration through Workbench

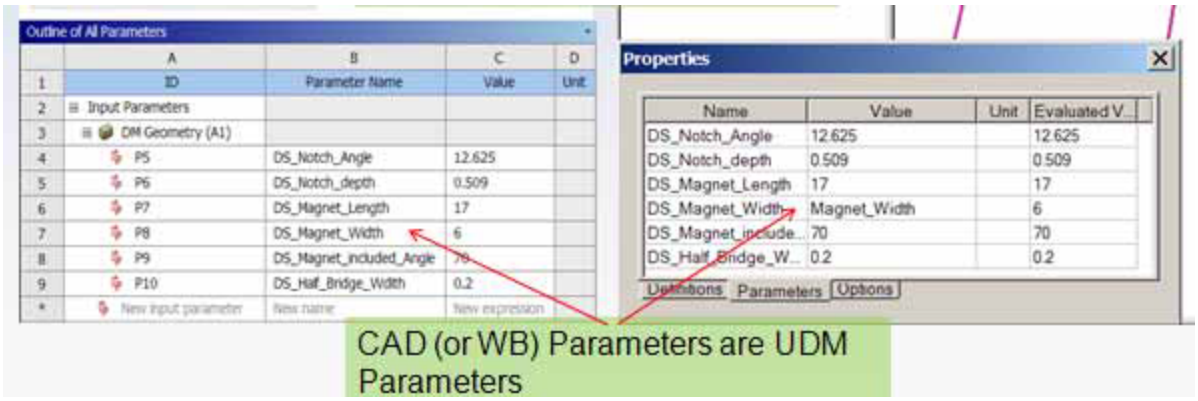
Ansys Electromagnetics CAD integration is a Workbench feature available for Ansys Electromagnetics 3D Products - HFSS, Maxwell, Q3D, Icepak, and Mechanical, as the Ansys Framework. The feature is available only through Workbench, and is not available via standalone Ansys Electromagnetics products.

Ansys CAD integration provides a bi-directional dynamic link through Workbench. This makes it possible to get updated geometry from CAD, modify CAD parameters in Ansys Electromagnetics products, and return an updated geometry. The feature is non-associative due to a need to reassign boundaries if a modified CAD model is used. The process creates a User Defined Model (UDM) for each geometry source.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



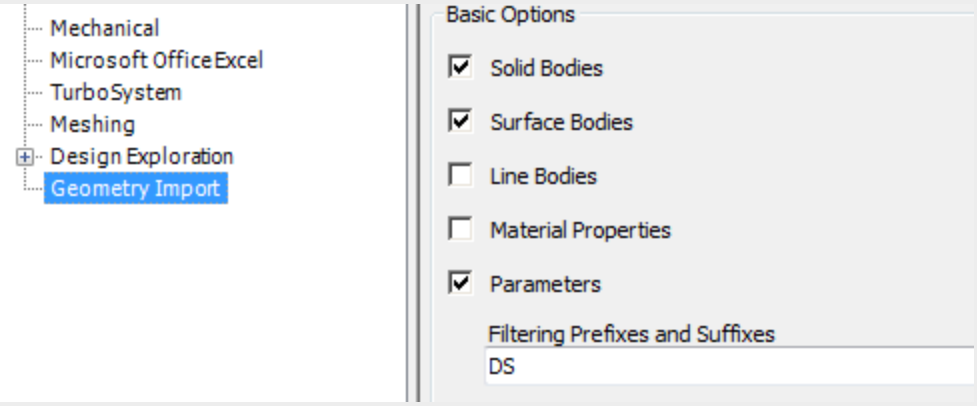
The UDM format makes it possible to exchange parameters. Ansys online help contains further description of the UDM feature and function.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

The parameters shown in the previous example all have a DS prefix. This is the default for the Workbench **Tools>Options** for **Geometry Import**. To import parameters with different prefixes or names, assign an appropriate prefix or clear the **Filtering Prefixes and Suffixes** field.



Ansys Electromagnetics CAD integration makes it possible to consume geometry from multiple upstream sources (any CAD or Ansys Electromagnetics product).

This feature supports direct interfaces with major CAD systems, including

- Creo Parametric
- UG NX
- CATIA V5
- SOLIDWORKS
- Autodesk Inventor
- Ansys Design Modeler (DM)
- Discovery UDM model

Note:

The CAD software must be installed on the user machine (not required for solve nodes).

The following sections contain additional information:

CAD Integration Functionality

CAD Integration and Geometry Sharing

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Bi-Directional CAD Integration

CAD Integration Model Edits

Multiple Geometry Links for CAD Integration

Creating Dynamic Links to EDT Designs

Adding a Design Variable for Dynamic Links

CAD Integration Functionality

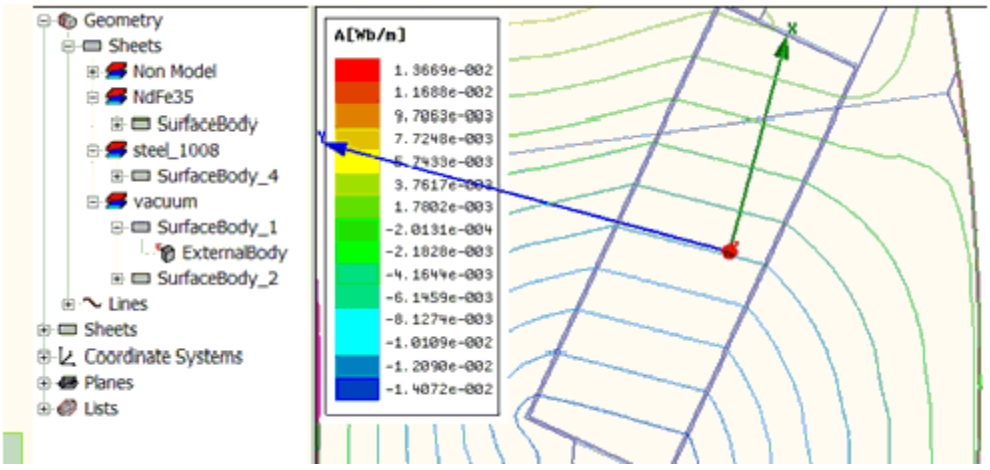
Healing with CAD Integration

Important Geometry Options for CAD Integration

CAD Integration Functionality

CAD Integration includes the following functionality:

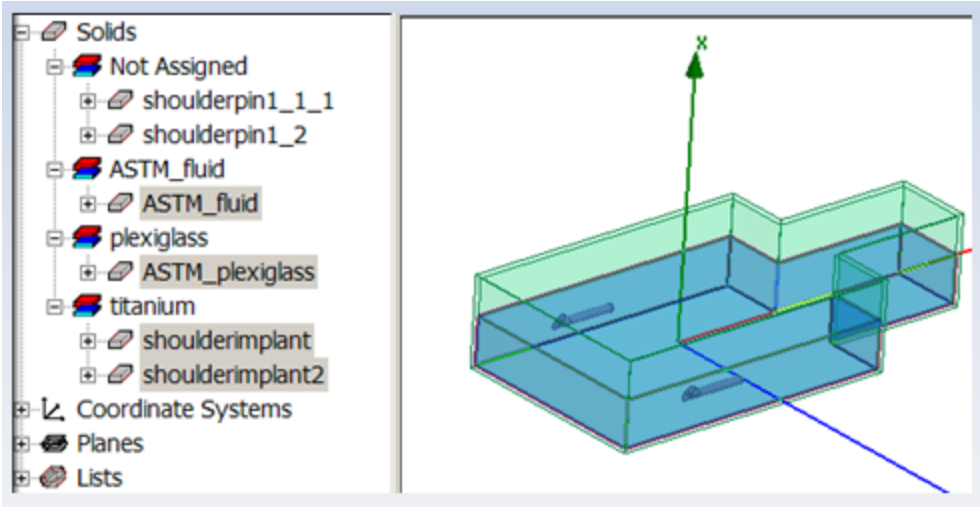
- DX analysis
- WB Update Project
- WB Update All Design Points
    - Parametric analysis with DSO
    - Animation
    - Geometry
    - Field plots



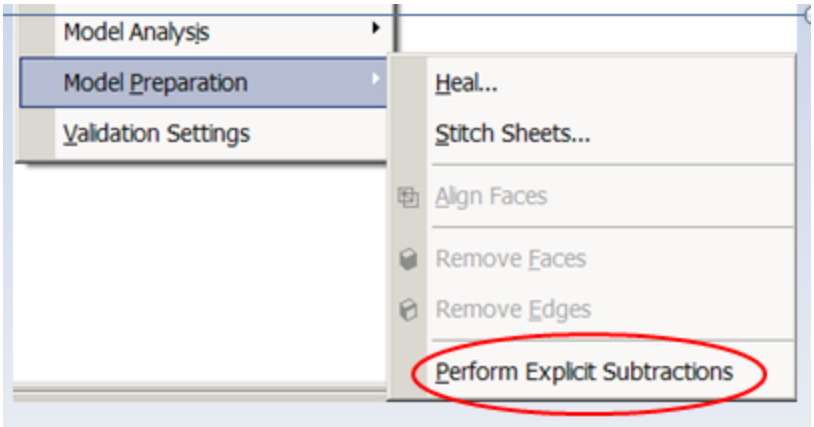
Ansys Mechanical does not do implicit subtraction. Ansys Electromagnetics products can do explicit subtractions before sending geometry to Ansys using **Modeler > Model Preparation > Perform Explicit Subtraction**.

For example, consider the following model.

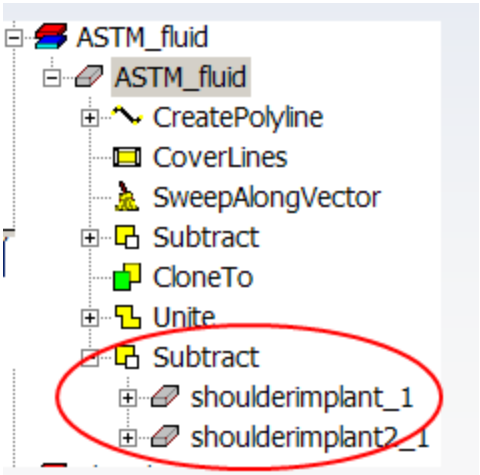
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Perform Explicit Subtractions can be performed.

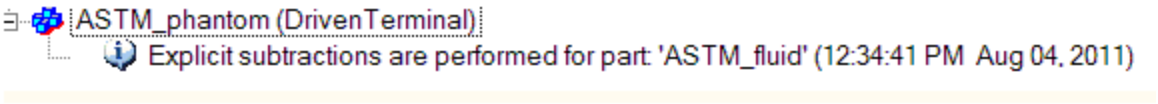


Results appear in the History tree, as shown:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Messages** window reports this action.

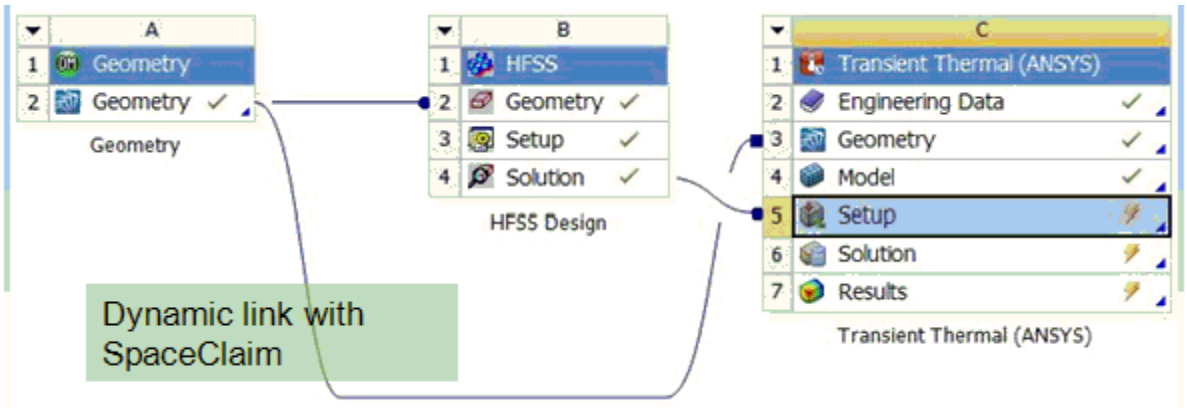


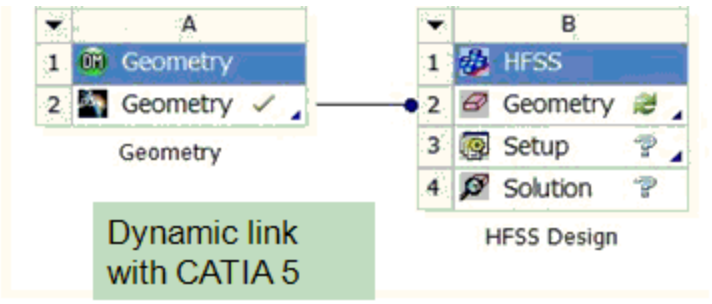
CAD Integration and Geometry Sharing

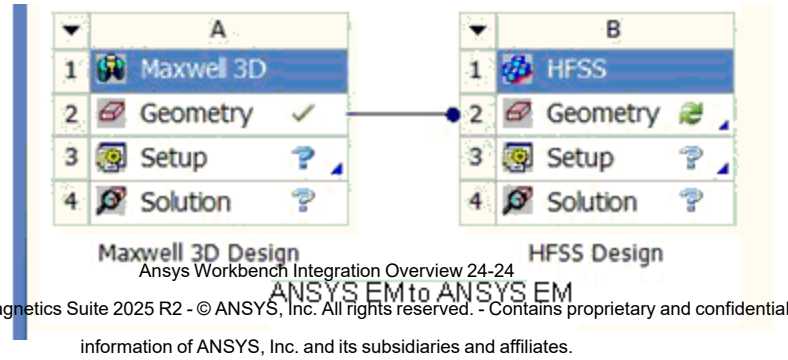
A CAD model comes into Ansys Electromagnetics as a User Defined Model (UDM).

The inputs to Ansys Electromagnetics from CAD are

- Geometry/Topology with persistent IDs
- CAD parameters
- Material assignment
- Attributes, such as name and color

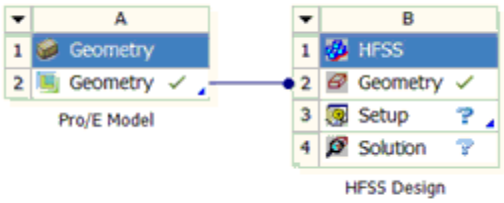




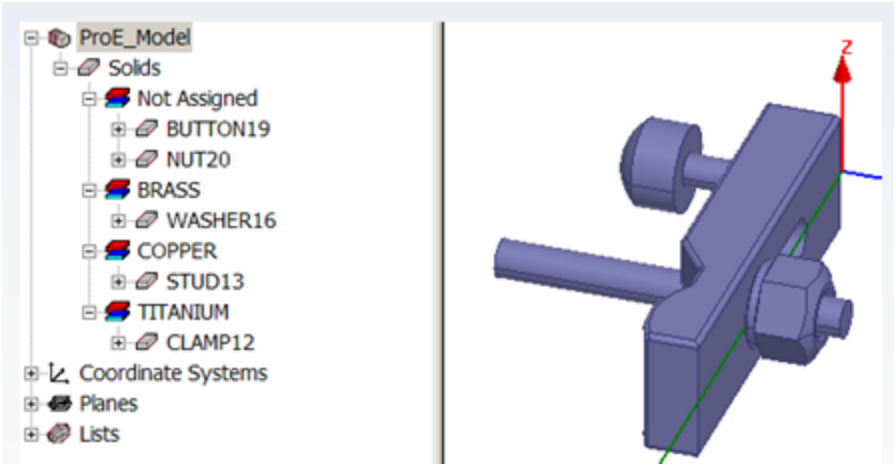


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For example, in Workbench, a Pro/E Model can be linked to Ansys:



The geometry can then be viewed as a UDM.



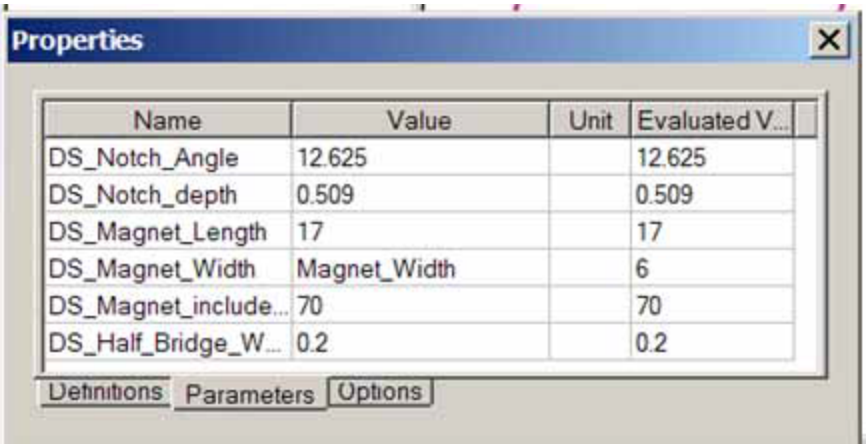
The CAD or WB model parameters appear in the Workbench:

Outline of All Parameters

	A	B	C	D
1	ID	Parameter Name	Value	Unit
2	Input Parameters			
3	DM Geometry (A1)			
4	P5	DS_Notch_Angle	12.625	
5	P6	DS_Notch_depth	0.509	
6	P7	DS_Magnet_Length	17	
7	P8	DS_Magnet_Width	6	
8	P9	DS_Magnet_included_Angle	70	
9	P10	DS_Half_Bridge_Width	0.2	
*	New input parameter	New name	New expression	

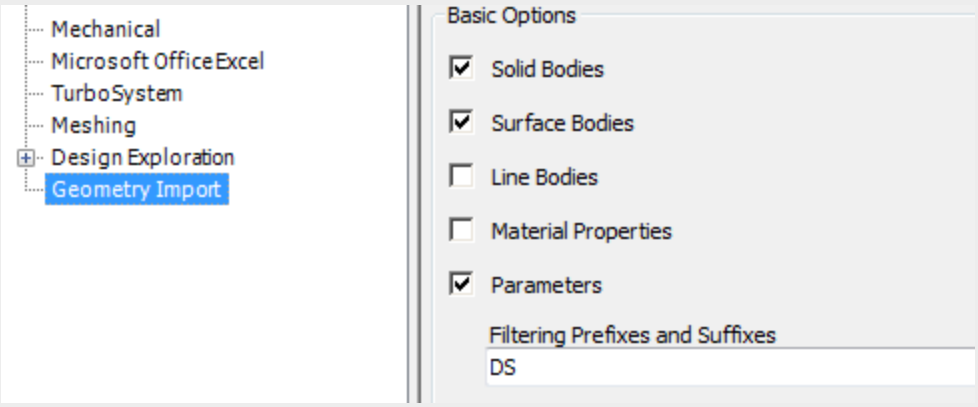
Through the Ansys Electromagnetics CAD integration, the linked UDM includes the same parameters.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



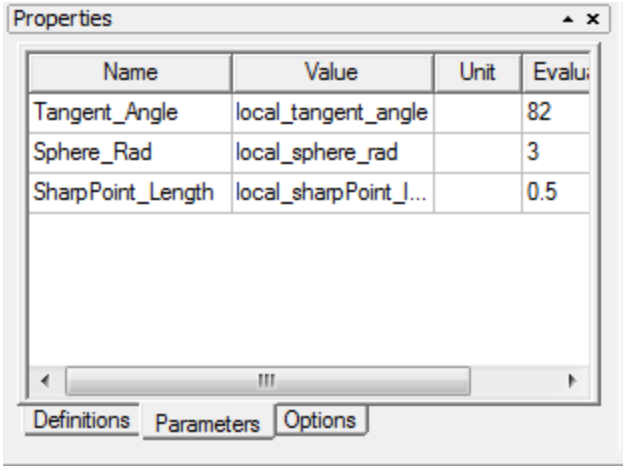
Note:

The parameters shown in these examples all have a DS prefix. This is the default for the Workbench **Tools** > **Options** for **Geometry Import**. To import parameters with different prefixes or names, assign an appropriate prefix or clear the **Filtering Prefixes and Suffixes** field.



Once you import a geometry with parameters to an Electromagnetics application in the desktop, you need to map to local variables. In the target Electromagnetics application, select the geometry associated with the parameters. Update the geometry and view the **Parameters** tab in the **Properties** window. The **Value** column shows the values of the imported parameters. Type names for local variables in the **Name** column.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Once you have local variables for the imported Design Modeler parameters, you are ready to use Design Xplorer for multiple design parameters.

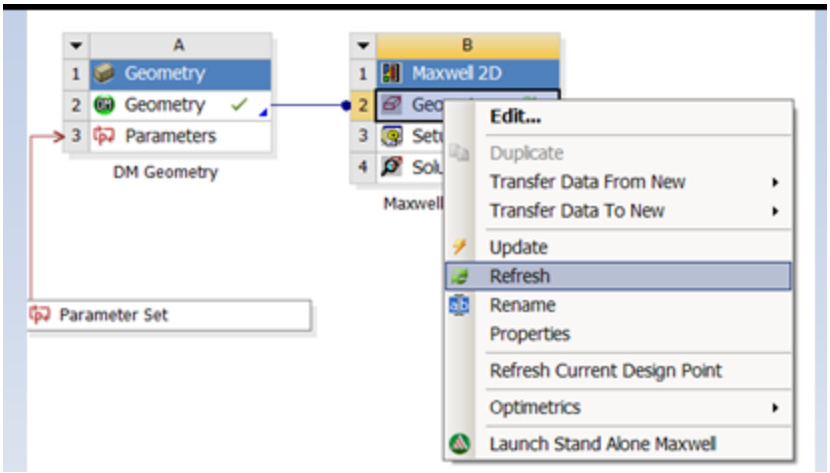
Table of Schematic D2: Design of Experiments (Custom)

	A	B	C
1	Name	P3 - Tangent_Angle (degree)	P4 - Sphere_Rad (in)
2	1	80	3
3	2	75	3
4	3	85	3
5	4	80	2.7

Bi-Directional CAD Integration

Ansys Electromagnetics CAD Integrations uses **Refresh** or **Generate** to pass updates.

You make an edit in a CAD application and run **Refresh** on an Ansys Electromagnetics Geometry Cell.

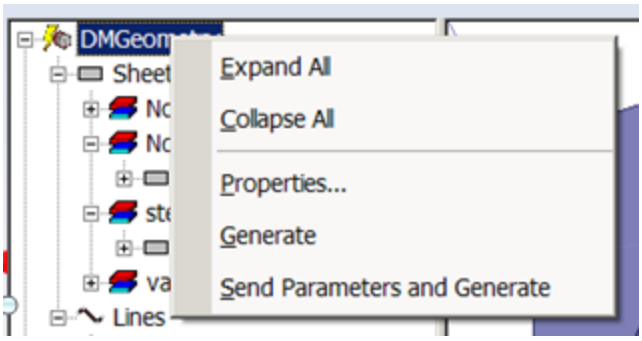


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refresh pulls the current state of CAD model (geometry, parameters, materials etc) and updates the corresponding data in the Ansys Electromagnetics application.

Alternatively, you can run **Generate** on the UDM in the Ansys Electromagnetics window.

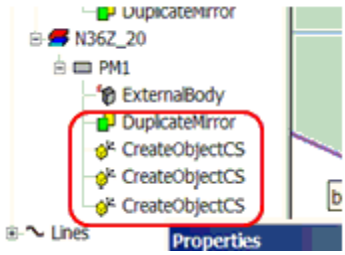
If you edit UDM (CAD) parameters in the Ansys Electromagnetics modeler window you can run the **Send Parameters and Generate** command.



The command passes the edited parameters to the linked CAD application and then pulls corresponding CAD geometry.

CAD Integration Model Edits

Several modeling operations are allowed on a CAD model in the Ansys Electromagnetics Modeler window. Operations are included in the History tree and retained during model **Refresh**.

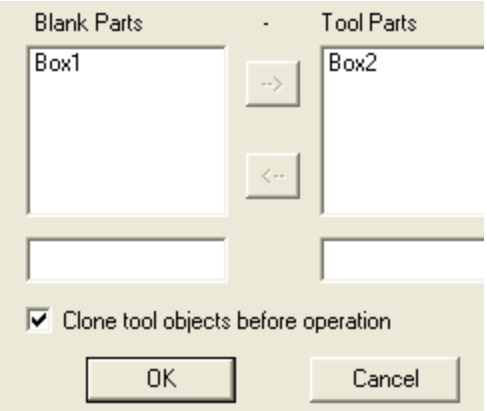


The following operations are not allowed:

- Non-history tree operations like Heal or defeature.
- Operations that use UDM parts as tools, such as Sweep

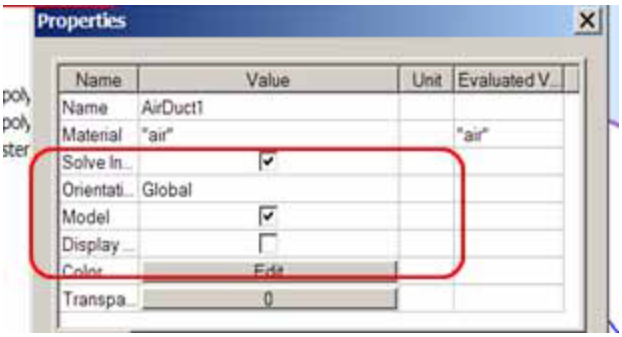
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Boolean operations like Split or Unite (allowed when you select the clone tool option)



The following part attributes can be modified for UDM parts:

- Model/Non Model flag
- Part orientation
- Color
- Display Wireframe



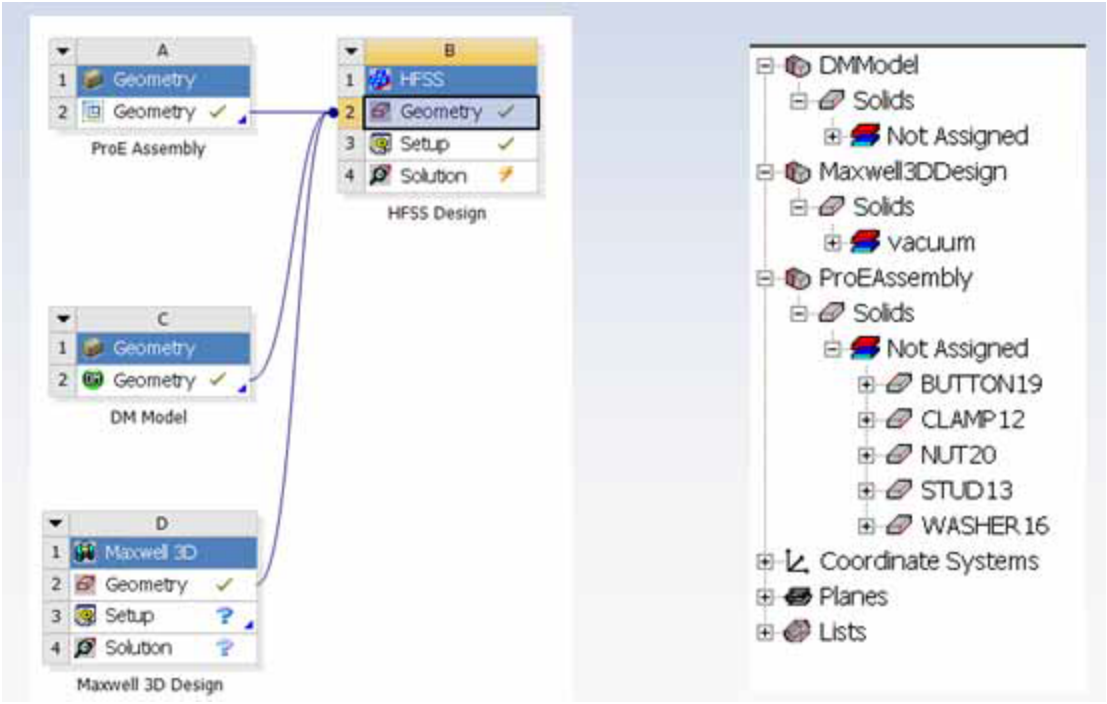
It is not possible to delete individual parts of UDM.

Multiple Geometry Links for CAD Integration

With CAD Integration you can consume geometry from multiple upstream sources. The source can be any of supported CAD or Ansys Electromagnetics products. This creates a UDM for each geometry source.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

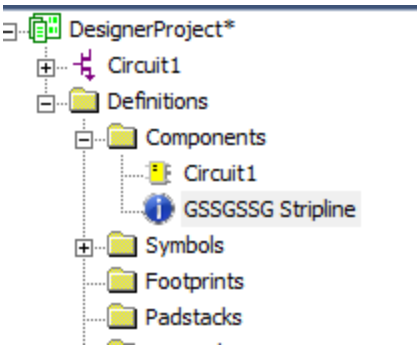
For example, the following figure shows a DM Model, a Maxwell model, and ProE model linked to HFSS in Workbench, and displayed in the HFSS History tree as three UDMs.



Creating Dynamic Links to EDT Designs

If you have a Circuit Design and one or more HFSS, 2D Extractor, Q3D, Icepak, or Mechanical designs open in a Workbench project, you can create dynamic links to those designs.

Update the Circuit Design to open the Electronics Desktop. In the menu bar, select **Workbench** > **Update Dynamic Link Components**. This command will create components in the project tree for each design in the Workbench project.

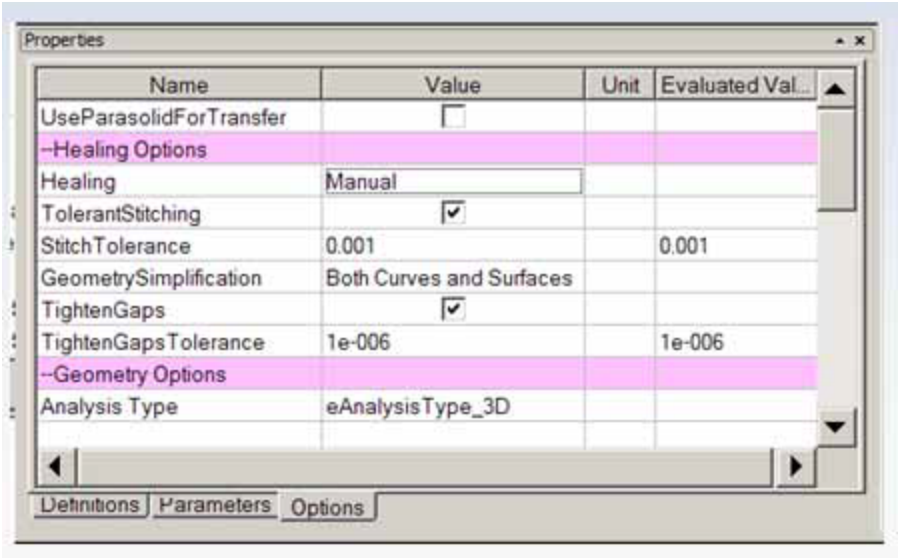


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that in this example, a GSSGSSG Stripline component was created corresponding to the GSSGSSG Stripline design in WorkBench. Once created, you can drag the component into a schematic to place it.

Healing with CAD Integration

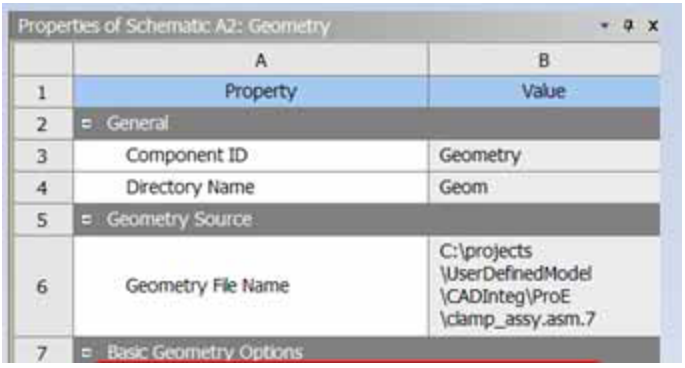
It is not possible to use the Heal command in Ansys Electromagnetics Modeler. Instead similar healing options are available under UDM properties option tab.



Healing options are None, Auto and Manual. By default, healing is off (None) and should be turned on only if required.

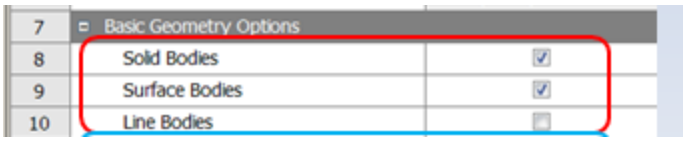
Important Geometry Options for CAD Integration

Select a Geometry Cell in Workbench to see options in the Properties window.



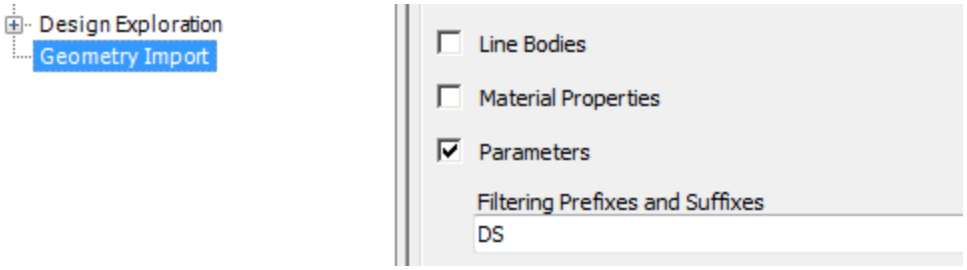
Control dimension of bodies coming from CAD

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Make sure **Parameters** is checked and that the parameter key (filter) is appropriate for CAD parameters.

The default parameter key filtering means that only parameters whose names start with DS will come through. This is the default for the Workbench **Tools>Options** for **Geometry Import**. To import parameters with different prefixes or names, assign an appropriate prefix or clear the **Filtering Prefixes and Suffixes** field.



The **Attribute Key** should be empty or "Color" to bring in CAD colors.

Material Properties must be checked to bring in the material assignment.

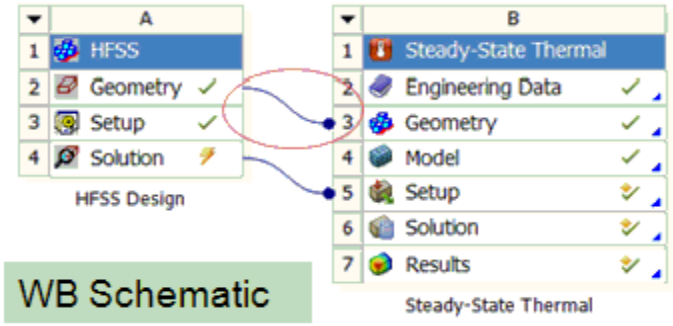
The **Mixed Import Resolution** option is used to resolve parts with mixed dimension (typically from Pro/E)

Refer to Ansys Help for details.

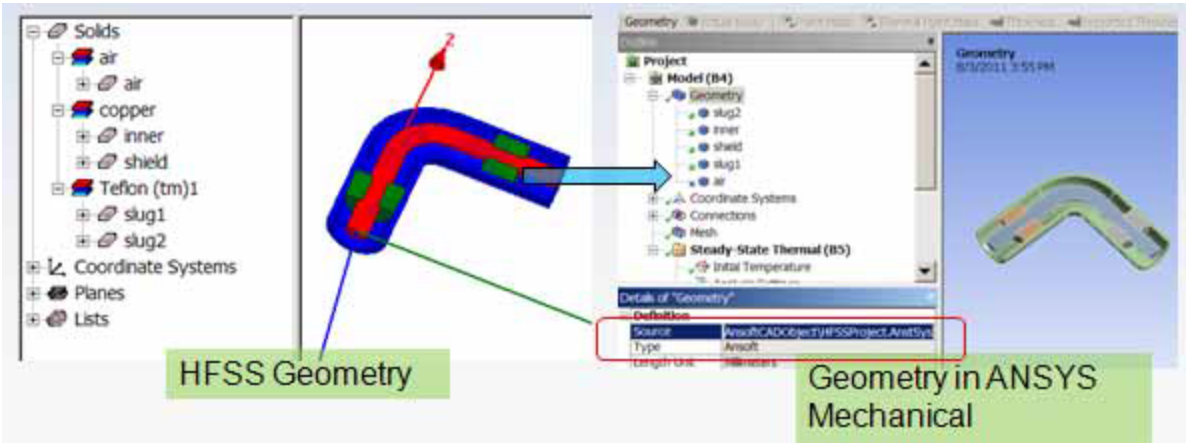
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys EM to Ansys Geometry Transfer

Ansys Electromagnetics CAD Integration transfers model information based on Workbench links.

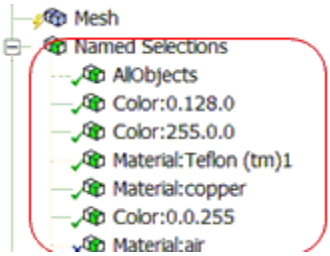


The following figure shows how the information is transferred between simulators.



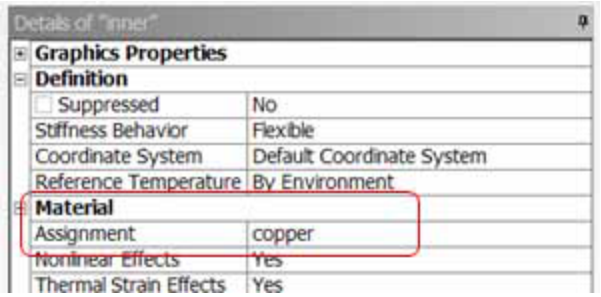
Information transferred includes

- Geometry
- Ansys Electromagnetics lists and material assignment as Named Selection



- Material assignment

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The CAD Integration geometry link is dynamic (you can get updated geometry from Ansys Electromagnetics) and associative (IDs persist between Ansys Electromagnetics model and Ansys model during model refresh).

Boundary conditions in Ansys are preserved. Object, material, and parameter names with non-ASCII characters are not allowed for data transfer. Such transfers fail and produce an error message.

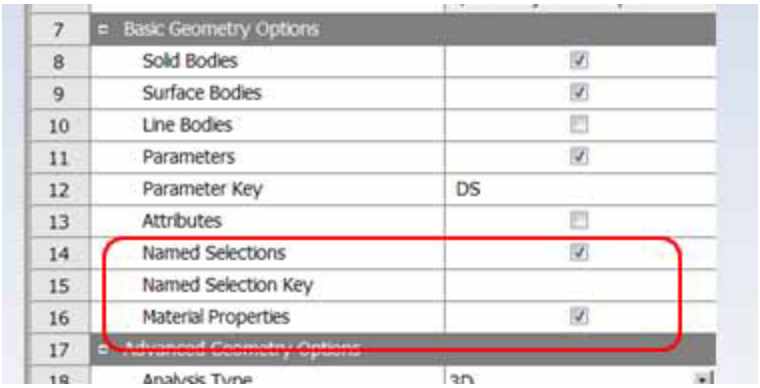
Material Assignment Transfer

There are two prerequisites for material assignment transfer:

- Engineering Data should have materials used in Ansys Electromagnetics model and material names should match (including case)
- Material Properties in Geometry Options must be checked

Before transferring as a named selection, **Named Selections** must be checked in **Basic Geometry Options**.

The Named Selection Key should either be empty or contain "Material."

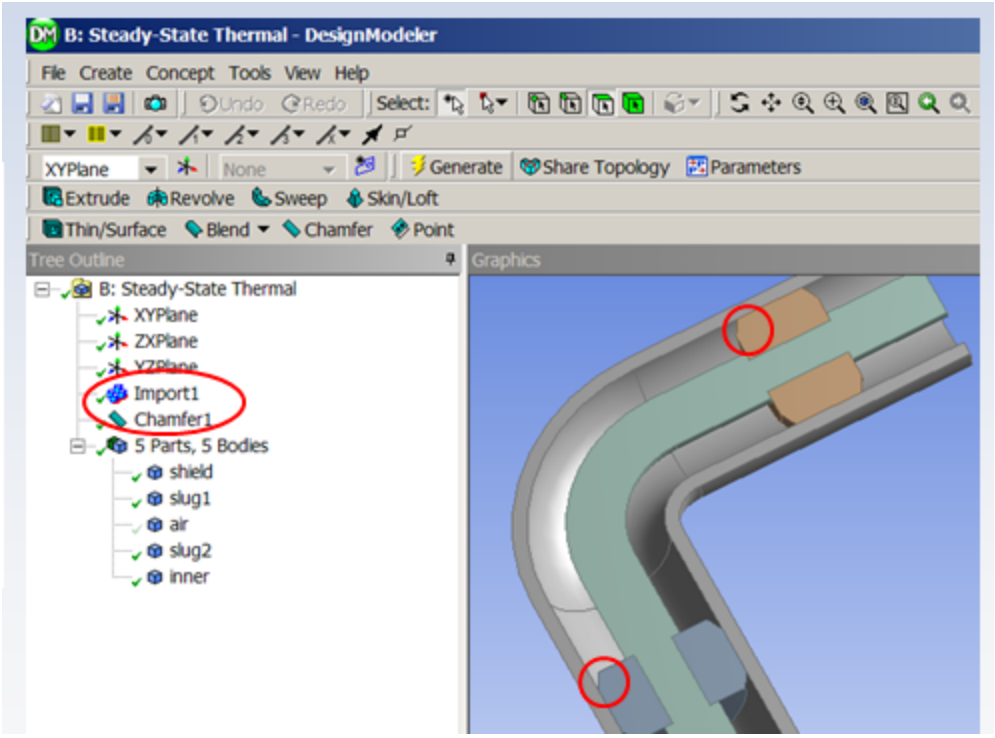


Geometry Transfer through Ansys DesignModeler (DM)

It is possible to edit geometry in Ansys DesignModeler (DM) before consuming it in Mechanical. This is useful when geometry requires preprocessing for Ansys simulation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

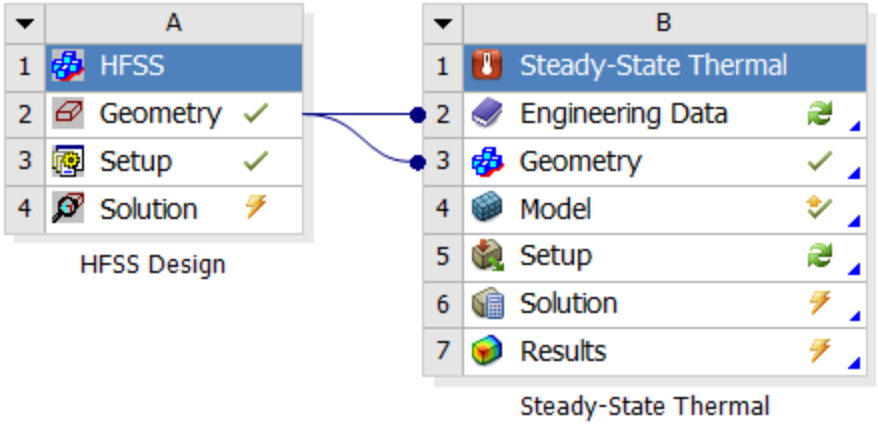
Consider an HFSS model linked to DM through the Workbench. In the following example, a chamfer operation on geometries is being imported.



Workbench Material Data Transfer

A link can be created from an Ansys Electromagnetics Desktop system (e.g., HFSS) geometry cell to a downstream Engineering Data (ED) cell. When the downstream ED cell is refreshed, it updates with materials (names and properties) used by the upstream project. This ensures that the geometry-to-geometry link connecting the same two systems, which specifies the material assignments for various parts, refers to the correct materials and their properties.

Detailed Behavior



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The geometry-to-ED link can be created by dragging the Ansys Electromagnetics Desktop system geometry cell to the ED cell of a downstream system. When the downstream system's ED cell refreshes, the upstream system generates a MatML format XML file, which is consumed by Workbench to update the downstream system. This file is stored in the workbench project files according to design point. Note that Workbench ED cell material names are case-sensitive, as are material names within Ansys Electromagnetics Desktop products.

For material assignments to work with the ED in the downstream model, the downstream geometry cell must have the **Material Properties** check box selected. A convenient way to do this is to have this property checked by default, by setting this in **Tools** > **Options** > **Geometry Import**. Systems created after this default option is set will have **Material Properties** automatically checked for the geometry cell.

When the downstream model cell is refreshed or updated, material properties from the ED in the same system are used in the model's materials, based on material assignments set during the geometry cell refresh. Note that if material assignment fails, the Workbench default material (Structural Steel) is used.

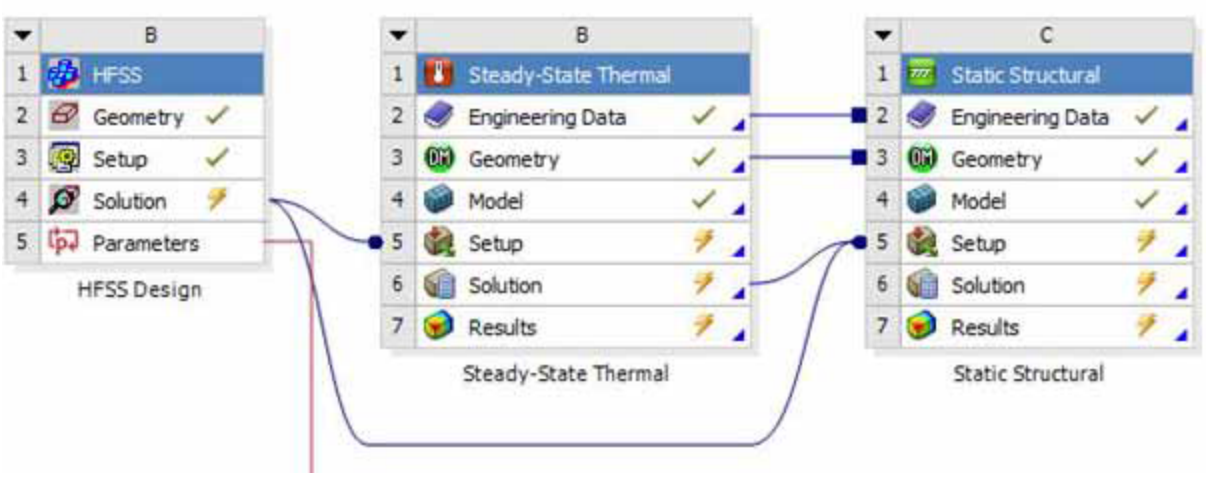
Workbench resolves name conflicts by changing the name of any materials being transferred over from the upstream system. For example, if the upstream Ansys Electromagnetics Desktop system uses a material named "Structural Steel", this will conflict with the existing downstream default material of the same name. The update will result in the Ansys Electromagnetics Desktop material being named "Structural Steel 2" in the downstream ED, but the downstream model will still use the properties supplied by Ansys Electromagnetics Desktop for the material.

Note that some materials may not satisfy all requirements for downstream system physics. For example, vacuum has no thermal conductivity, but downstream steady state thermal systems require a non-zero value for this property. Material properties in the workbench ED cell of the downstream system can be modified after refresh to ensure that validity criteria can be met. Any property added to a material in the downstream ED is preserved in subsequent ED cell updates. However, any existing property that is edited in the downstream ED will be overwritten by a subsequent ED cell update.

Stress Feedback to HFSS using Workbench

Including stress feedback to HFSS involves coupling an HFSS system with both thermal and stress systems. The thermal system serves as an upstream system to the stress system and simulates the effect of heat induced displacement. And through the Workbench link between the Solution cell of HFSS and the setup cell of Mechanical, the displacement can feedback into HFSS. The HFSS project can be Driven or Eigenmode.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You use a dialog to select one or more objects (geometry) in HFSS upon which displacement data from Mechanical applies. This feature lets you avoid applying displacement to the whole model where only certain parts are sensitive to stress. You must select the same objects in the thermal and stress system to apply the respective imported loads.

The results of the process include deformation feedback applied to selected objects. The Solution Profile includes a report of Solve with thermal/displacement feedback, including information Maximum Delta T and Maximum Delta Displacement. You can create field plots with based on Displacement and Mag_Displacement, and you can scale the deformation displayed. The Fields Calculator also includes these input quantities.

Interface Changes for Stress Feedback from Mechanical to HFSS

Process Flow for Stress Feedback to HFSS

Interface Changes for Stress Feedback from Ansys Mechanical to HFSS

When used through the Workbench for stress feedback projects, the HFSS interface contains some commands and information that do not appear in standalone HFSS.

Deformation of Objects dialog

Solution Profile information for Solve with Displacement Feedback

Plot Fields Menu with Displacement and Mag_Displacement

Deformation Scale tab for Modify Plot Attributes

Revert to Zero Displacement command under the **Solve Setup** menus

Fields Calculator Field Quantities for Stress Feedback Projects

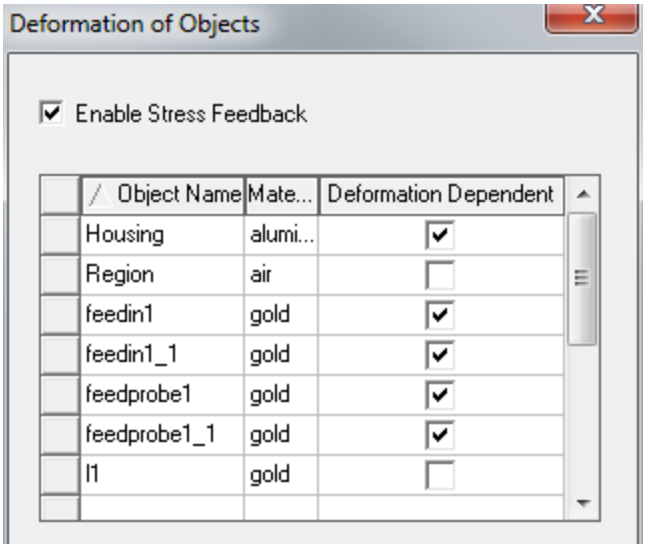
Plot Fields Context Menu for Stress Feedback Projects

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modify Plot Attributes Dialog for Stress Feedback Projects

Deformation of Objects Dialog

When working with HFSS through Ansys Workbench, the HFSS menu for Driven and Eigenmode projects includes a Deformation of Objects command that opens this dialog for specifying which objects shall be deformation dependent.



The Enable Stress Feedback check box enables object selection. All selections are disabled when this is unchecked. Changing the setting invalidates any existing solutions.

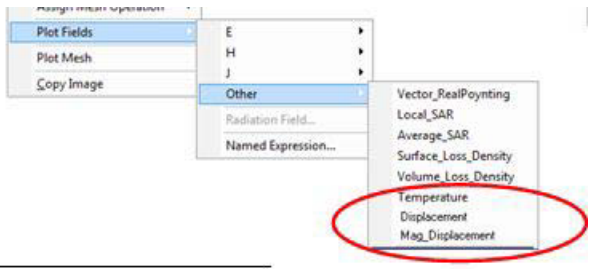
The objects listed do not include objects without materials assigned, non-model objects, or non-3D objects. Objects assigned materials such as air or vacuum are not deformed and don't apply to stress feedback.

Solution Profile with Displacement Feedback

The Solution Profile includes a report of Solve with thermal/displacement feedback, including information Maximum Delta T and Maximum Delta Displacement.

Plot Fields Menu with Displacement and Mag_Displacement

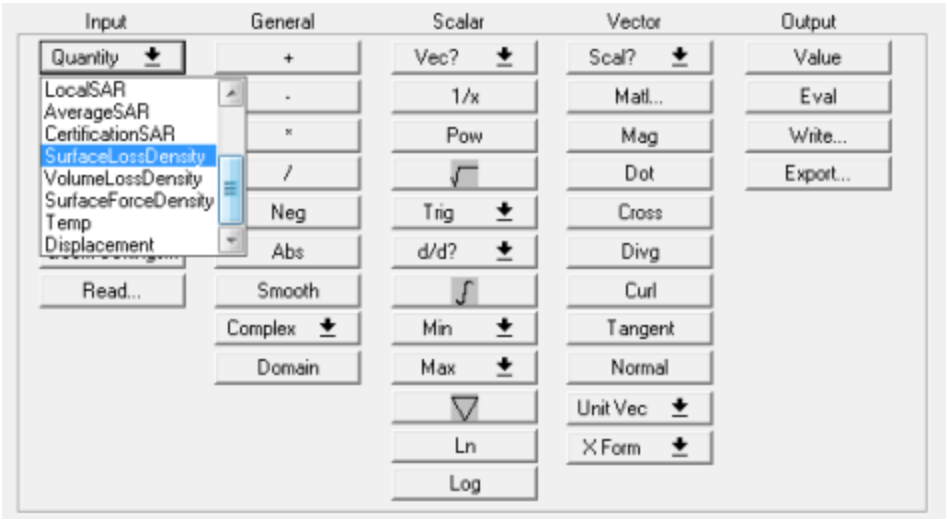
The Plot Fields menu includes entries for displacement and mag_displacement.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

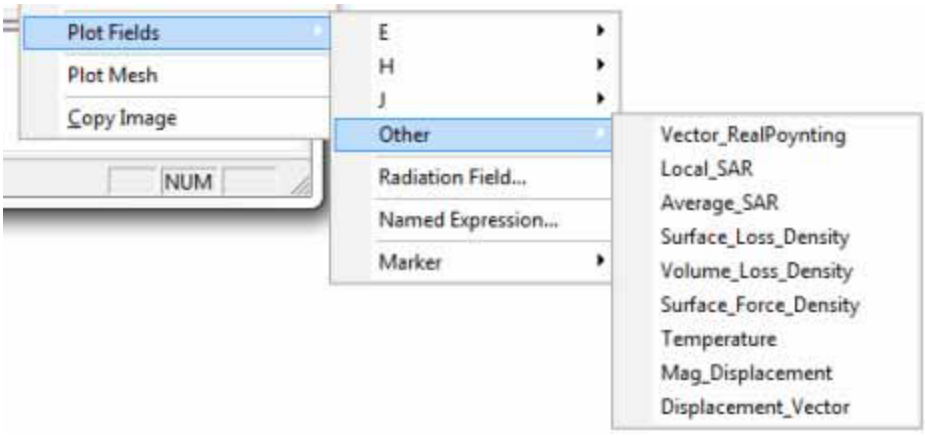
Fields Calculator Field Quantities for Stress Feedback Projects

The Quantity menu for the Fields Calculator lists Displacement for Stress Feedback projects.



Plot Fields Context Menu for Stress Feedback Projects

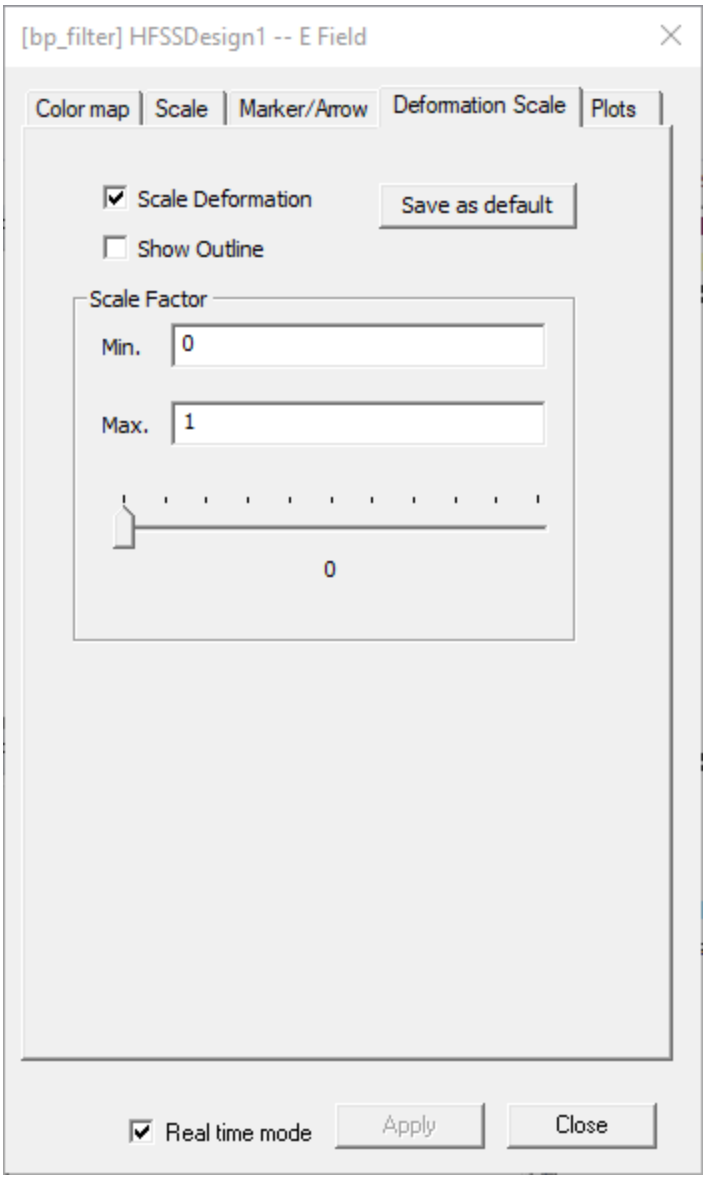
The **Plot Fields>Other** menu includes Displacement_vector and Mag_Displacement, a scalar. A field plot remains empty until the displacement data applies to the HFSS solution.



Modify Plot Attributes Dialog for Stress Feedback Projects

When an HFSS plot includes deformation, the **HFSS>Fields>Modify Plot Attributes** dialog includes a tab for scaling the deformation. If you check Scale Deformation, you can also select Show Outline.

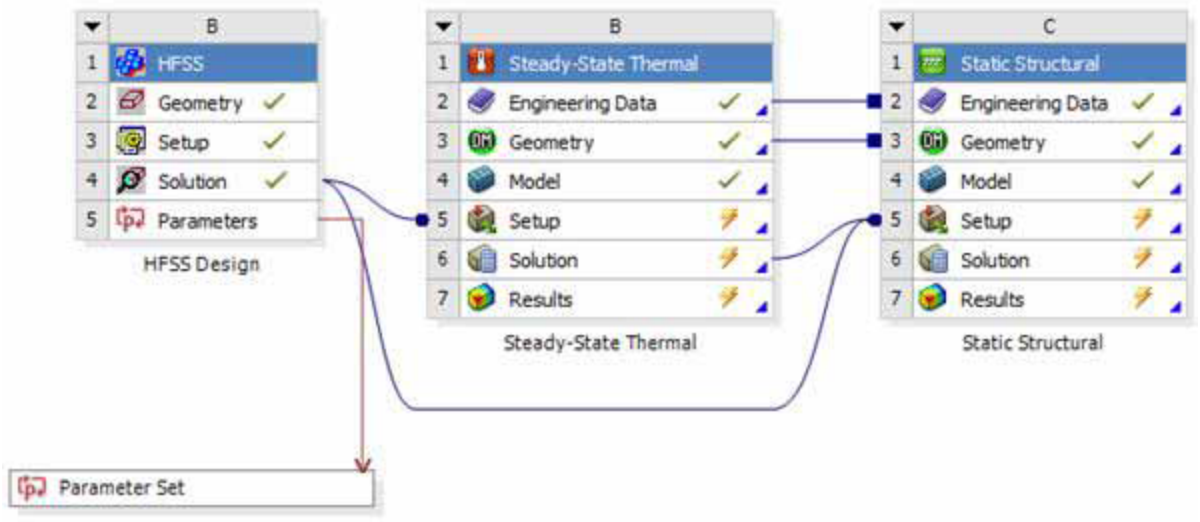
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Process Flow for HFSS Workbench for Stress Feedback

to set up the coupling, drag the "Solution" cell of the HFSS system and drop it at the "Setup" cell of a Thermal and Stress system. You also need to also couple the Thermal and Stress system to capture the effect of thermal force. The following image illustrates a coupling setup where both the Thermal and Stress system are ready to be "Updated". The HFSS adaptive solution has converged in 3 passes. The HFSS system has both thermal and stress feedback enabled.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



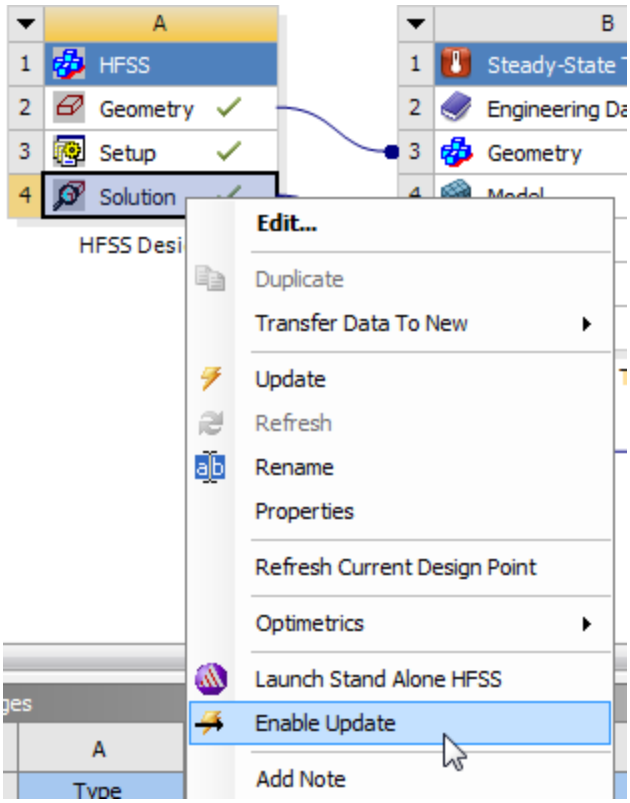
1. Right-click the Solution cell of Stress and select "Update"

   a. The Setup of Thermal will be "Updated" with em loss from HFSS
   b. The Solution of Thermal will be "Updated" and temperature will be exported to HFSS

   c. The Setup of Stress will be "Updated" with thermal force from Thermal and force density (just zeros) from HFSS
   d. Displacement will be exported to HFSS after Stress finishes simulation

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Right-click the Solution cell of HFSS and select "Enable Update"



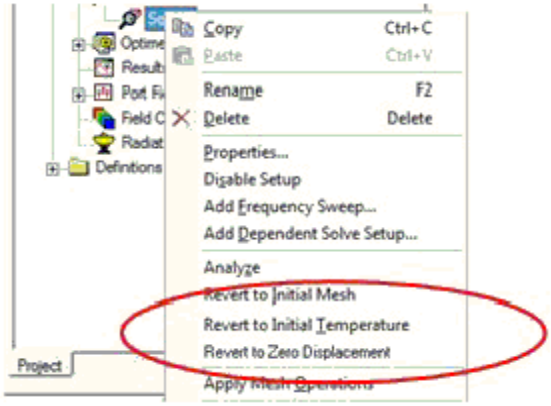
The Solution cell icon changes from a green checkmark to the Update lighting icon.

3. Right-click the Solution cell of HFSS and select "Update"

   a. HFSS re-simulate the 3rd pass with its mesh and the temperature/displacement feedback
   b. The profile will show information about the feedback

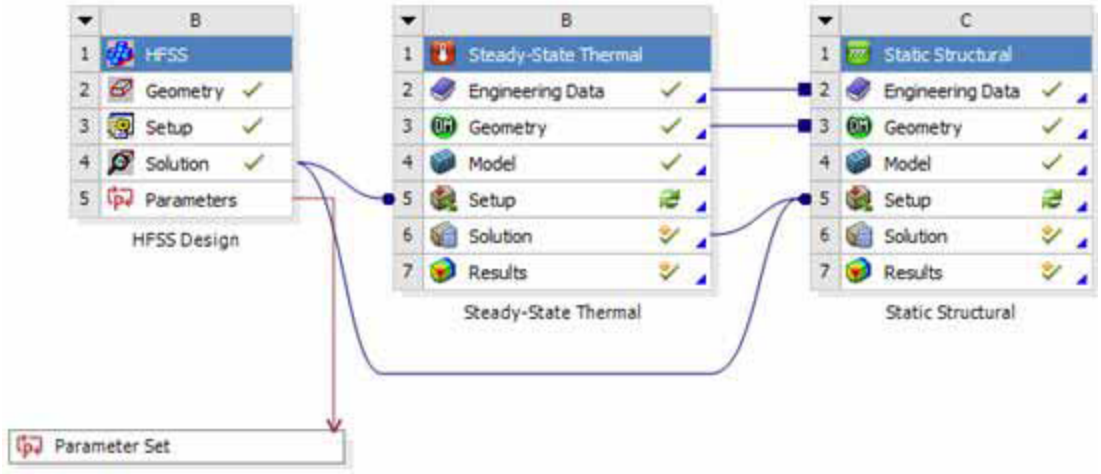
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. Both "Revert" menus will be available at the right mouse click menu of the solve setup item.



Manual Iteration After First Iteration Completes

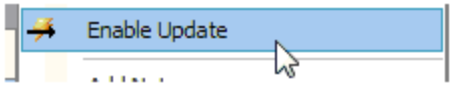
The following image illustrates the WB schematic after the previous situation, after the 1st iteration has completed. Notice the changed icons for the status for Setup for Thermal and Structural.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Right-click the Solution cell of Stress and select "Update"

   a. The Setup of Thermal will be "Refreshed" and "Updated" with EM loss from HFSS
   b. The Solution of Thermal will be "Updated" and temperature will be exported to HFSS
   c. The Setup of Stress will be "Refreshed" and "Updated" with thermal force from Thermal and force density from HFSS
   d. Displacement will be exported to HFSS after Stress finishes simulation
2. Right-click the Solution cell of HFSS and select "Enable Update"



3. Right-click the Solution cell of HFSS and select "Update"

   a. HFSS re-simulates the 3rd pass with its mesh and NEW temperature/displacement feedback
   b. The profile will show information about the feedback

Note that the delta temperature and displacement is being reported in the profile

Revert the HFSS Solution For Temperature and Displacement

You can revert the temperature and displacement in HFSS solution separately.

1. Select "Revert to Initial Temperature" in HFSS.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A warning message notifies you about the invalidation of solution

2. Right-click HFSS solve setup and select "Analyze"

HFSS re-simulates the 3rd pass with its mesh and displacement that was previously exported from Mechanical, but without temperature.

3. Select "Revert to Zero Displacement" in HFSS, and followed by "Analyze"

HFSS re-simulates the 3rd pass with its mesh without neither temperature nor displacement

Only Stress Feedback

The coupling setup is the same as in Use Case 1, with either one of the following differences

- The HFSS system is not enabled for thermal feedback. Since HFSS is not enabled to support feedback, the "Export Result" properties will be missing in the thermal system's property window.
- The HFSS system is enabled for thermal feedback, but users select not to "Export Result" in the thermal system. This is to disable the "automatic" feedback after Mechanical finishes its simulation.

1. Right-click the Solution cell of Stress and select "Update"
    a. The Setup of Thermal will be "Updated" with em loss from HFSS
    b. The Solution of Thermal will be "Updated"
    c. The Setup of Stress will be "Updated" with thermal force from Thermal and force density from HFSS
    d. Displacement will be exported to HFSS after Stress finishes simulation
2. Right-click the Solution cell of HFSS and select "Enable Update"
3. Right-click the Solution cell of HFSS and select "Update"
    a. HFSS re-simulate the 3rd pass with its mesh and the displacement feedback
    b. The profile will show information about the feedback and "Revert to Zero Displacement" will be enabled at the RMC menu of the solve setup item

Feedback Iterator

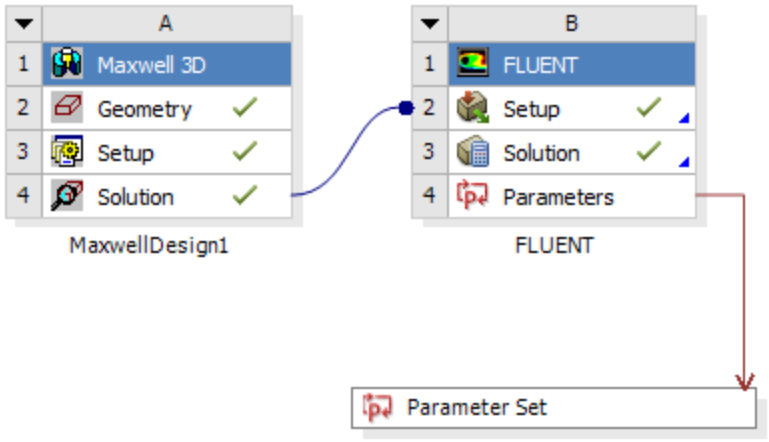
Background Information

Prior to the introduction of the Feedback Iterator, Ansys Workbench supported a two-way loose-coupling protocol with Ansys Electromagnetics products.

System Coupling already uses the word coupling to mean low-level solver coupling. Existing electromagnetics product coupling is loose compared to system coupling and is limited to file transfers at the end of a complete solve in a standalone system/product. No communication occurs during a solve. The coupling is two-way.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The one way portion (Upstream source component to Downstream target component) is handled via existing Workbench data/transfer connection mechanism.

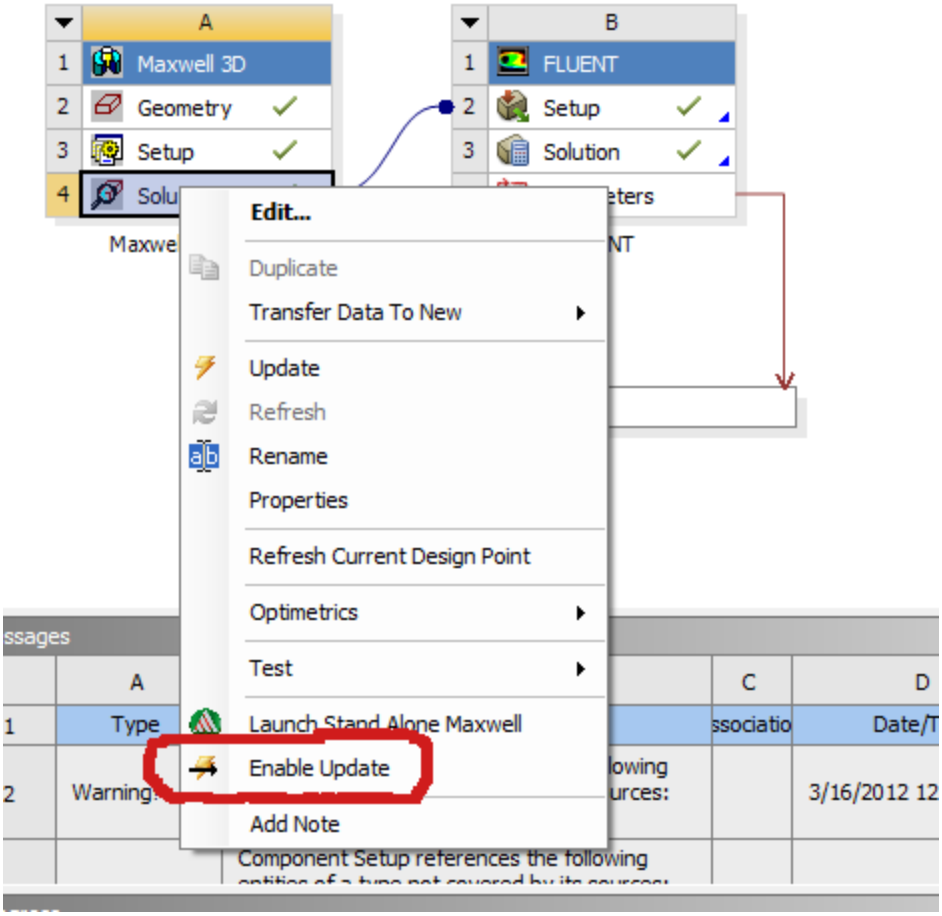


The round trip is handled by a separate protocol, agreed upon by the participating systems, whereby the downstream system exports a set of files to a location specified by the upstream system via its one-way transfer. This exported data is then incorporated by the upstream system in its next update.

To run the next coupled solve iteration, invoke the **Enable Update** operation, as shown below, which updates all systems involved.

These steps (**Enable Update**, **Update Project**) are continued as long as needed.

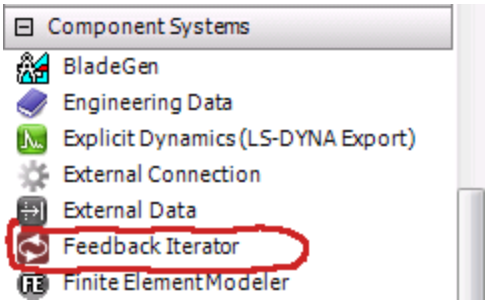
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The Feedback Iterator System

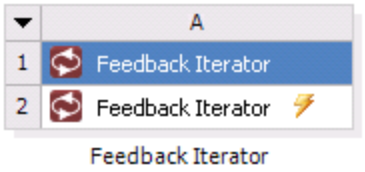
Ansys Electromagnetics Suite provides the Feedback Iterator system for automating the manual steps needed for driving a feedback utilizing system-pair to convergence. In addition to automating feedback incorporation over a user-specified number of iterations, the Feedback Iterator also allows control over the number of iterations (iteration termination criteria), target temperature, and displacement convergence criteria.

The **Feedback Iterator** appears in the Workbench Toolbox user interface under **Component Systems**.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

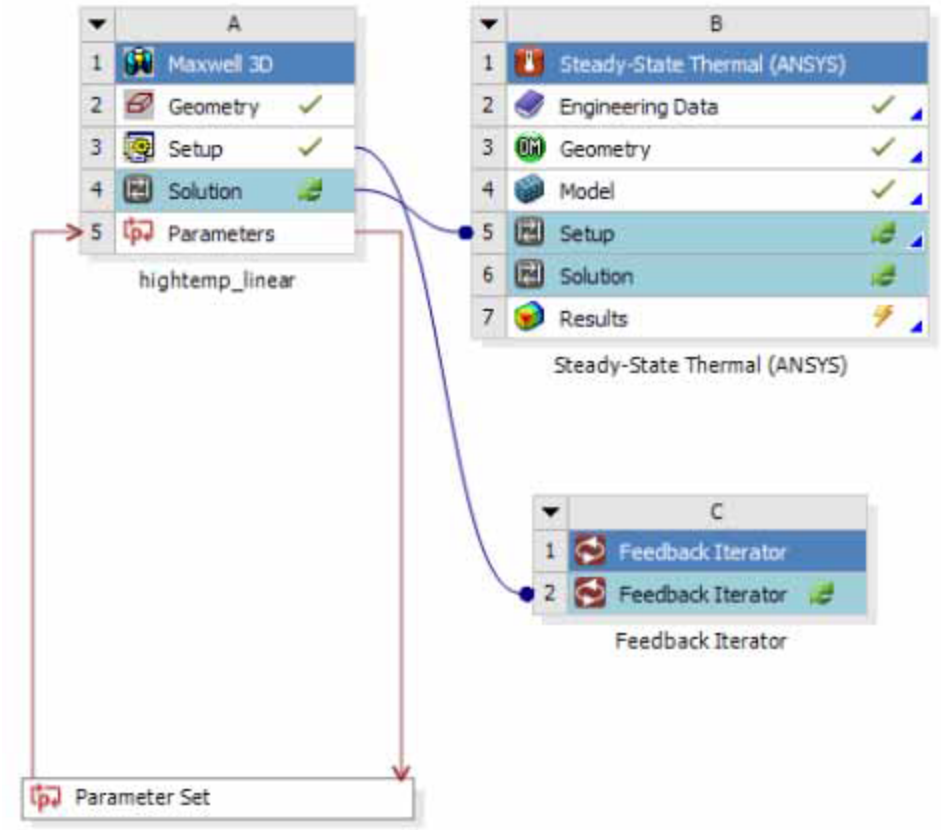
If you drag and drop an instance of the Feedback Iterator into a Workbench schematic, the default system name is Feedback Iterator:



Feedback Iterator in Use

The Feedback Iterator system attaches to the Workbench schematic like any other system.

In the following example, a Maxwell system provides heat loss data to aFluent system. Dropping the Maxwell setup cell onto the Feedback Iterator component results in the links shown:



The Feedback Iterator add-in functions the same way with all systems that participate in the Electromagnetics product two-way loose coupling (Maxwell and HFSS for sources and Fluent, Thermal, and Structural for targets).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Feedback Iterator Component Properties

The Feedback Iterator's primary role is to control iterative solves and its properties target this end.

For Maxwell and HFSS, the Feedback Iterator properties are

- **Iterations Completed** – a read-only property that displays the number of iterations completed.
- **Max Iterations** – sets the maximum number of iterative solve loops to perform before terminating iterations in case the *Target Delta Temperature %* or *Target Delta Displacement %* is not achieved. The default value is 100.
- **Target Delta Temperature %** – specifies the maximum *Target Delta Temperature %* that signifies convergence. The default value is 5%, and the value must be 0.01 or greater.

  > **Note:**
  >
  > • The delta temperature error is calculated in Kelvin.
  >
  > • The Maxwell and HFSS design **Profile** tab displays absolute/relative delta data, while the delta temperate in Workbench means the relative delta (expressed as %).

- **Target Delta Displacement %** – specifies the maximum *Target Delta Displacement %* that signifies convergence. The default value is 5%, and the value must be 0.01 or greater.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	A	B
1	Property	Value
2	⊟ General	
3	Component ID	FeedbackIterator
4	Directory Name	FeedbackIteratorComponent
5	⊞ Notes	
7	⊞ Used Licenses	
9	⊟ Iterations	
10	Iterations Completed	0
11	Max Iterations	100
12	⊞ Callback	
14	⊟ Temperature Convergence	
15	Target Delta Temperature %	5
16	Latest Delta Temperature %	Not Available
17	⊟ Displacement Convergence	
18	Target Delta Displacement %	5
19	Latest Delta Displacement %	Not Available

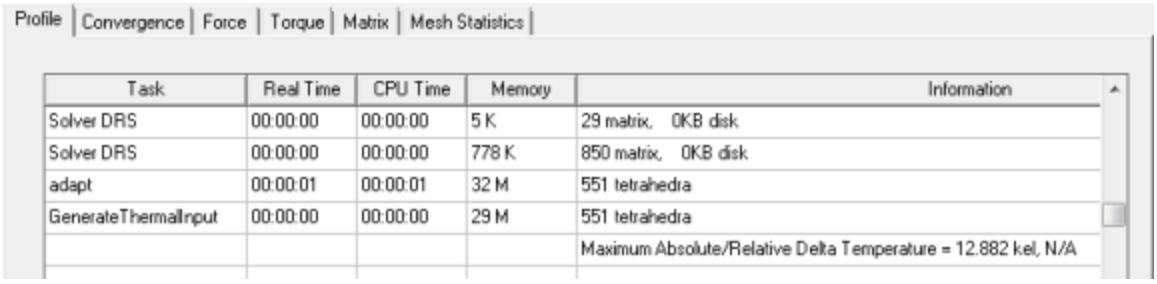
The Feedback Iterator properties also display the most recently achieved *Latest Delta Temperature %* and *Latest Delta Displacement %* values, allowing the user to manually abort when satisfied with the achieved deltas.

> **Note:**
>
> Both the Temperature and Displacement Convergence properties sections are always shown irrespective of which feedback types are enabled for the project.

Running a two-way feedback simulation from the Workbench application while keeping the Maxwell or HFSS **Profile** tab open shows that the 3D solver keeps track of two feedback related quantities:

- Maximum Absolute/Relative Delta Temperature (if temperature feedback is enabled)
- Maximum Absolute/Relative Delta Displacement (if displacement feedback is enabled)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

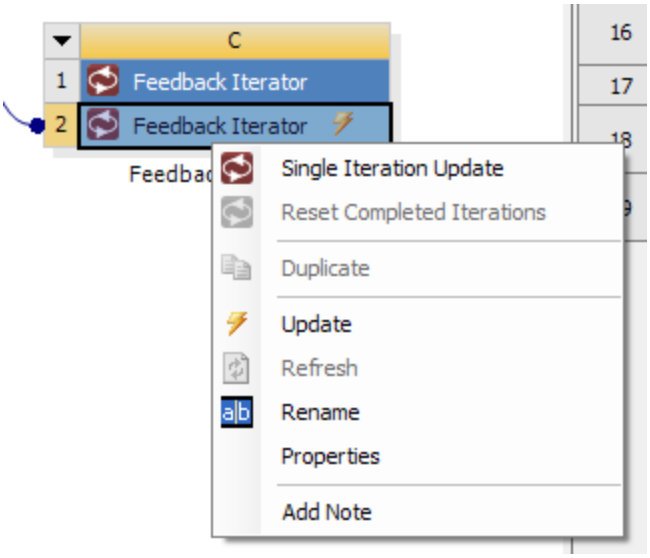


These signify the maximum difference on the solution mesh of the quantity in question from one feedback iteration to the next (thus the value is only available from the second iteration onward). This data forms the basis for the convergence controls in the Feedback Iterator. These controls allow the user to base the termination of feedback iterations on a target max delta T and/or max delta displacement. The target max delta forms the convergence condition.

Feedback Iterator GUI Operations

The **Single Iteration Update** action allows you to run a single iteration worth of updates, as follows:

1. Updates the Electromagnetics product system, which will incorporate any previous feedback from the downstream system.
2. Updates the downstream system.
3. All coupled systems (Electromagnetics product, Electromagnetics product Downstream, and Iterator) are in the UpToDate state.
4. Iterator's “Iterations Completed” property increments by 1.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Right-clicking the Feedback Iterator component and selecting **Update** allows you to run iterations automatically. Iterations continue to run either until convergence criteria are met, or until the Max Iterations value is reached.

Callback Interface

The callback interface allows you to react to each step of the iteration process as implemented by the Feedback Iterator component. This is useful for implementing special iterations or solving transient simulations with a limited scope.

There are four main API features provided:

- Callback functions, which the Feedback Iterator calls at various points in each iteration
- Utility functions, which the Callback functions can use to extra properties of the containers being processed
- Output functions, which allow script debugging and supply additional messages
- Limited state management, which allows the script to store and retrieve state across callback functions and iterations

Callback and State API

State is managed in a limited fashion. All the API methods take a final dictionary argument. This dictionary is limited to using **string keys** and **number or string values**. Within this limitation, add new keys, read old keys, clear the dictionary, etc., and it will be persisted across functions calls and even across Updates. When the **Iterations Completed** property is **rest**, the dictionary is also cleared out.

It is advisable for the callback script to initialize the dictionary at Iteration 1.

All the API methods use a subset of the following arguments:

`iterationNumber`	An integer representing the current iteration. This always starts from 1.
`ContainerList`	A Python list of containers (DataContainerReference). This is the entire list of the coupled containers managed by the Feedback Iterator. You typically loop through them and using the utility methods listed below, identities them.
`Container`	A single container that is being processed. This is a DataContainerReference.
`State`	A read/write Python dictionary that is used to maintain state across function calls and iterations.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Only return values from `BeforeIterationEx` are processed. Returns from all other functions are discarded.

1. `BeforeIteration(IterationNumber, ContainerList, State)`: This method is called before each iteration. Ideally used to initialize the state dictionary, open editors as required, or initialize setups as needed for each iteration.
2. `BeforeIterationEx(IterationNumber, ContainerList, State)`: Similar to the `BeforeIteration` method except that this allows you to control the number of iterations via the return value.
   - Return: `"more"` to request one more iteration
   - Return `"last"` to indicate that this is the last iteration
   - Any other return (including none) will be treated as a return of `"last"` and terminate iterations.
3. `AfterIteration(IterationNumber, ContainerList, State)`: This method is called after each iteration. This can be used to copy result files over, check results, implement any possible convergence calculations, logging of results, *etc*.
4. `BeforeContainerRefresh(IterationNumber, Container, ContainerList, State)`: Is called before each of the coupled containers is refreshed. The `Container` argument represents the container about to be refreshed.
5. `AfterContainerRefresh(IterationNumber, Container, ContainerList, State)`: Is called after each of the coupled containers is refreshed. The `Container` argument represents the container just refreshed.
6. `BeforeContainerUpdate(IterationNumber, Container, ContainerList, State)`: Is called before each of the coupled containers is Update (after a refresh). The `Container` argument represents the container about to be updated.
7. `AfterContainerUpdate(IterationNumber, Container, ContainerList, State)`: Is called after each of the coupled containers is updated. The `Container` argument represents the container just updated.

If the callback scripts uses other files to send commands to various containers (vb, js, apdl, python, etc.), all of those files are best saved under the user_files directory. This allows you to use the `FBGetUserFilePath(str)` to get the absolute path of the file and allows the files to be packaged with any created archive.

Utility Functions

`FBSystemForContainer` (container)	system	Given a container, returns the system it belongs to
`FBSystemDisplayName` (system)	string	Given a system, returns its display name on the schematic
`FBSystemID`(system)	string	Given a system, returns its ID. This is the same as the `UniqueDIrectory` for the system

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`FBGetUserFilesPath` (relativePath)	Given a relative path located under the user_files directory, say "hello.py", this returns the absolute path of the file

Output/Debugging Functions

`FBAddInfoMessage (string)`	Adds an info message to the WB message window
`FBAddWarningMessage (string)`	Adds a warning message to the WB message window
`FBAddErrorMessage (string)`	Adds an error message to the WB message window
`FBMessageBox (string)`	Pops up a dialog box with the supplied string with an **OK** button

Example Scenarios for Feedback Iterator

This section describes several scenarios for using the Feedback Iterator:

Setting up Iteration with Feedback Iterator

Breaking Iteration Control

Starting an Iterative Update

Running a Single Iteration

Interrupting an Iterative Loop

Resuming an Interrupted Iterative Loop

Modifying any of the Systems Involved in Iteration (coupled clients)

Iterating to Convergence

Setting up Iteration with Feedback Iterator

Scenario	Steps to execute	Outcome
Electromagnetics product solution provides solution data to a single downstream setup	• Drop Feedback Iterator system on the setup component of Electromagnetics product	Electromagnetics product setup component is connected to the Iterator. Electromagnetics product solution and downstream setup and solution components are coupled as clients to the iterator. The iterator component is the coupled master and

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scenario	Steps to execute	Outcome
	OR • Create Feedback iterator system and connect Electromagnetics product setup component to the TwoWay iterator component AND User clicks on the Iterator component and sets the desired Feedback Iterator properties.	the rest are coupled clients. Any coupling changes schematic visuals: • Coupled cells including coupling master are colored differently from normal cells • Coupled cell icons change to reflect the icon of the coupling master • Coupled client cells no longer display the **Update** context menu item and cannot be updated via script commands • The cell states of all coupled cells (master and clients) are synchronized to be the most pessimistic state among any of them (e.g., after an update, any modification will set all of them to the "Modified" state).
Electromagnetics product solution provides to multiple downstream setup cells	same as above	All the downstream components (setup and solution in each downstream system) are coupled as clients. The update order in this case depends on any additional data-flow connections between the systems that consume the upstream Electromagnetics product solution data.
Electromagnetics product solution cell does not have any downstream targets	same as above	No changes occur beyond what is expected when you create a new connection (no coupling). Coupling only occurs when Electromagnetics product solution cell has a downstream connection. If a downstream connection is added after the link to the iterator, coupling will be performed as described in the first row.

Breaking Iteration Control

Scenario	Steps to execute	Outcome
Iterator coupled to Electromagnetics product solution cell and downstream setup/solution cells	• Break Electromagnetics product solution cell's provides link	In addition to what is normally expected from the user actions, all coupled clients are de-coupled (their icons and colors

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

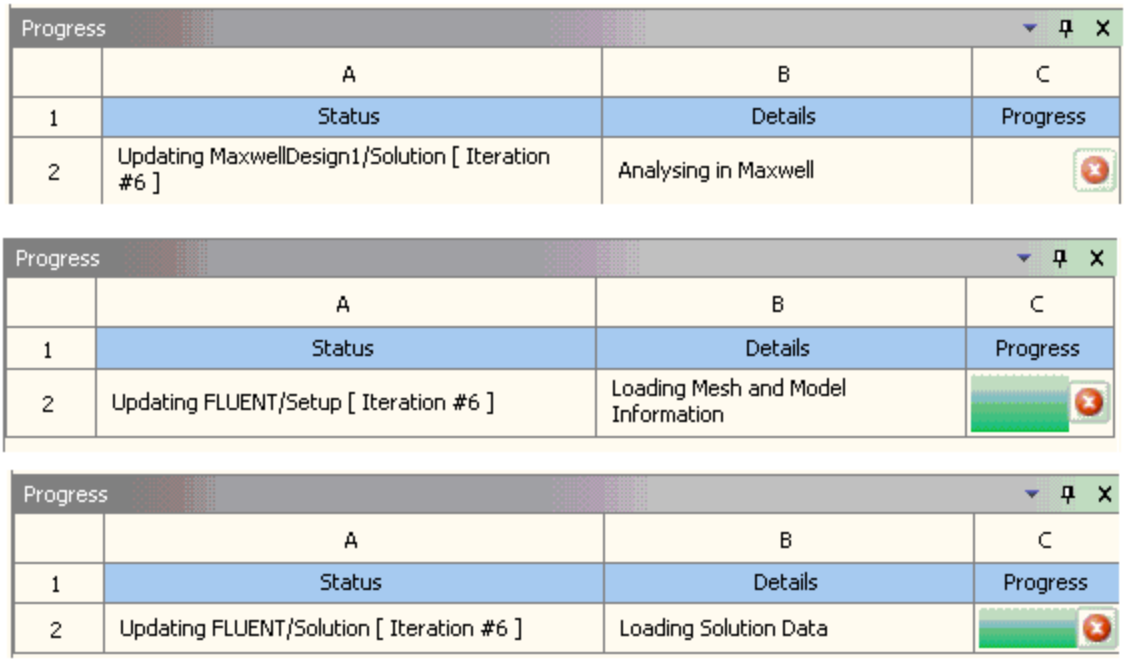
Scenario	Steps to execute	Outcome
	OR • Break Electromagnetics product setup link to iterator OR • Delete Electromagnetics product solution consumer system OR • Delete Iterator system	on UI are restored)
Electromagnetics product setup cell is connected to iterator but Electromagnetics product solution does not provide anything. No components are coupled to the iterator	• Break Electromagnetics product setup link to iterator • Delete Iterator system	No coupling exists in this scenario so nothing visible changes beyond what is expected from the user actions

Starting an Iterative Update

Scenario	Steps to execute	Outcome
Standard update scenario	• RMB on iterator component and select Update GUI operation OR • Update Project OR • Update all design points OR	For each iteration, the Electromagnetics product solution is updated followed by the downstream setup and the downstream solution. Each of the client component updates display their progress monitor and can be aborted (resulting in aborting the current iteration)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scenario	Steps to execute	Outcome
	• DX Update	



Running a Single Iteration

Scenario	Steps to execute	Outcome
NumCompleted < NumIterations	RMB on iterator component and select Single Iteration Update	One iteration is run. "Completed Iterations" property is incremented.
NumCompleted ≥ NumIterations	same as above	same as above

Interrupting an Iterative Loop

Currently, there is no special progress or interruption control. The progress monitor for individual components displays as they are updated and any control they choose to provide (interrupt, abort or both) is available. Choosing to abort any of the client component updates aborts the current iteration, and the Completed Iterations property remains unchanged from the previous iteration.

Resuming an Interrupted Iterative Loop

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scenario	Steps to execute	Outcome
Single step	RMB on iterator component and select Single Iteration Update	One iteration is always run and the Completed iterations property is incremented.
Run until completion	• RMB on iterator component and select Update OR • Select the Project Update menu option from the toolbar, etc.	If the user specified number of operations are already completed, nothing is done. Otherwise, the remaining iterations are run.

Modifying any of the Systems Involved in Iteration (Coupled Clients)

When any coupled client components are modified (either in Workbench or in an external editor), the coupled clients and master are marked as modified. The Completed Iterations property is set to 0.

Iterating to Convergence

Scenario	Steps to execute	Outcome
Standard update scenario	• Right-click on the Feedback Iterator component and select Update OR • Update Project OR • Update all design points OR • DX Update	For each iteration, the Electromagnetics product solution is updated, followed by the downstream setup and the downstream solution. Each of the client component updates display their progress monitor and can be aborted (resulting in aborting the current iteration)

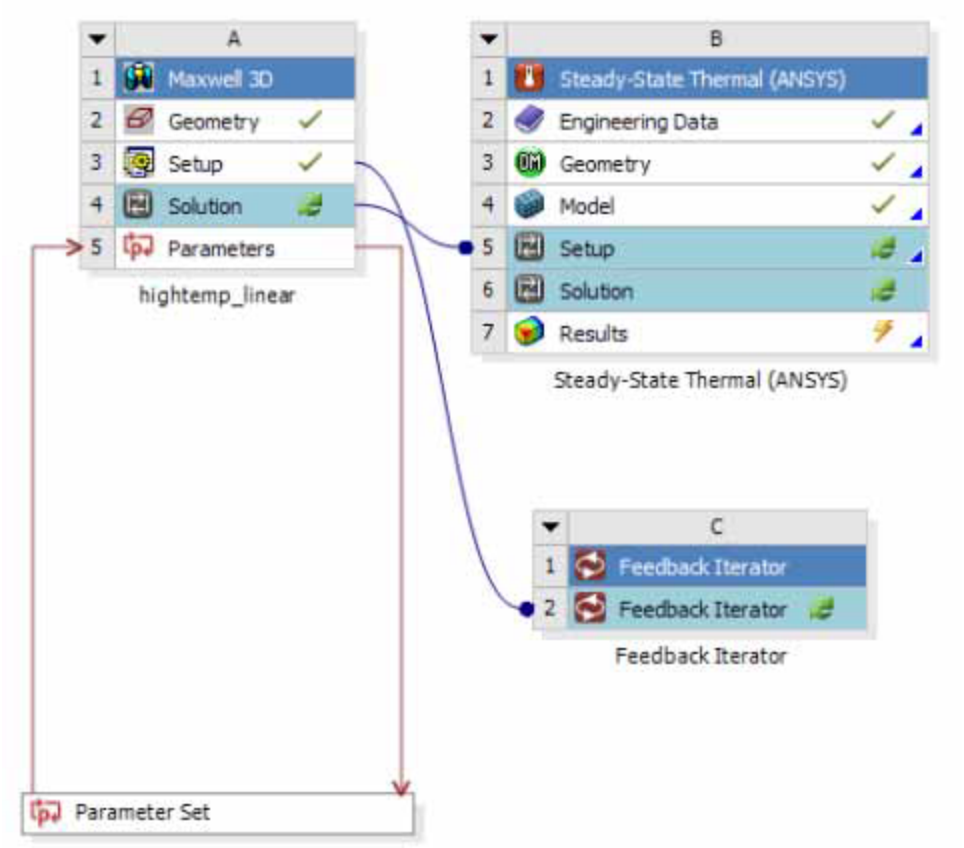
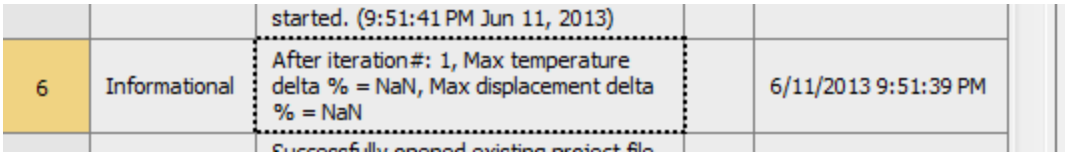
The following temperature convergence example uses Feedback Iterator with a Maxwell design, coupled with a Steady-State Thermal component. Iterating to convergence operates similarly for HFSS projects.



The example uses defaults of 5% for the convergence targets and a value of 100 max iterations. Recall that the max iterations value is set as a safety measure to ensure that iterations do not continue indefinitely if the solution does not converge. As we progress through the iterations, we observe the following:

End of Iteration #1

The first iteration, because it has no previous iteration, cannot return a meaningful delta value.



At the end of this iteration, the Latest Delta value is listed as Not Available.

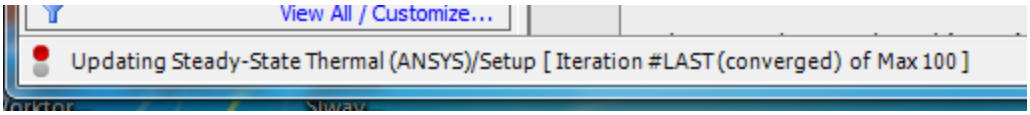
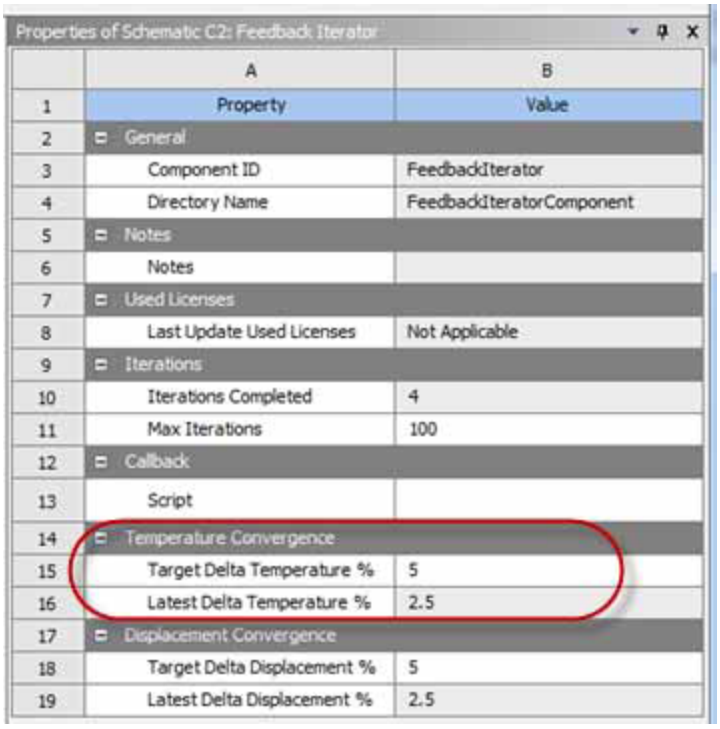
Convergence Achieved

In this example, convergence has been achieved by the third iteration.

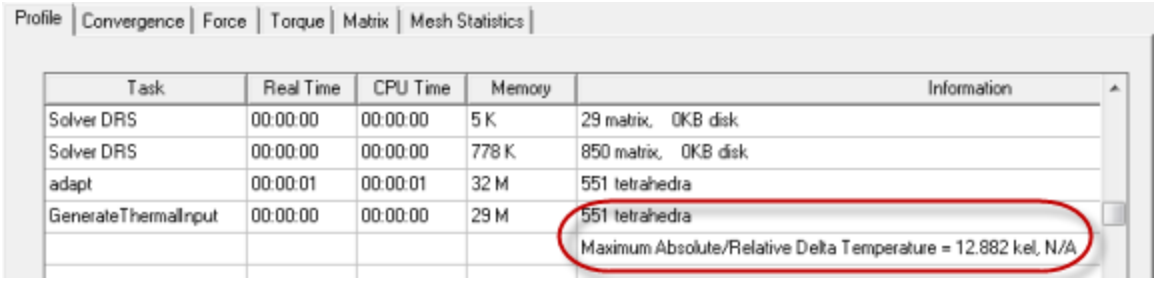


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



When convergence criteria are met, the simulation stops. If you attempt to update after convergence has been achieved, the simulation will not be launched since the current solutions satisfy the convergence criteria.

You can monitor the iteration progress by opening the Maxwell editor and selecting **Results** > **Solution data**. Choose the **Profile** tab and keep the window open. As you solve each iteration, you can observe the reported Delta-T (with thermal feedback) and/or delta-displacement (with displacement feedback) and abort the iterations (or stop single iteration updates) when the values reach acceptable convergence levels.



Surface Force Density in HFSS

HFSS can calculate surface force density for Work Bench coupling and for post processing within HFSS. The whole approach resembles Maxwell except that HFSS must calculate the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

surface force density at the post processing stage while solver provide the surface force density in Maxwell.

The surface force density formulation is provided in a technical note here. Surface forces may exist on surfaces where one side is conductor but the other is not, or finite conductivity and layered impedance boundary. The computation of surface force density will be performed at field geometry instance level.

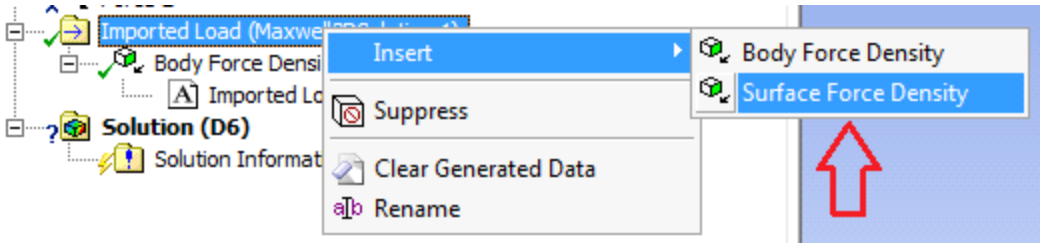
This feature is mainly for the purpose of mapping surface force density in HFSS to Work Bench Mechanical. We will also provide it for post processing within HFSS. This feature should work regardless of HFSS solution types as long as surface forces exist. Surface forces may exist when one side is conductor but the other is not, or finite conductivity and layered impedance boundary.

If an old coupling project happens to request surface force and is solved again, then the surface forces (likely nonzero) will be passed to mechanical side.

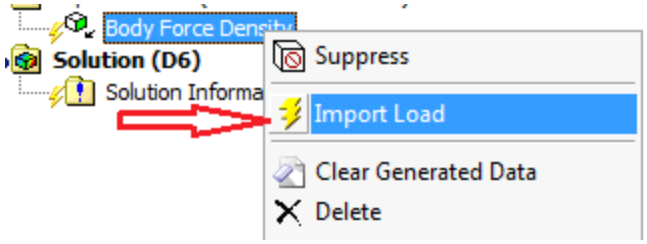
Mapping surface force density from HFSS to Work Bench Mechanical

The behavior is the same as all current couplings.

1. From the Mechanical side set up a surface force coupling to an HFSS design similar to Maxwell.



2. Import the load.



Behind the scenes Mechanical will pass necessary information to HFSS, points on surface to request surface forces and auxiliary files, HFSS will then calculate the surface force densities and pass them back to Mechanical.

3. Post process surface density within HFSS over any surfaces where surface forces exist.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Surface Force Density will appear in the context menu in the Other category under Fields menu.

In the fields calculator Surface Force Density appears in the Named Expression list and the Quantity drop-down menu. So the user can use it the same way as other vector quantities.

State-Space Fitting Guide

State-space fitting is a technique for generating time-domain models of systems on their frequency-domain responses at a set of frequencies. The term state-space refers to the following representation of a linear system,

$$\dot{\boldsymbol{x}} = \boldsymbol{A}\boldsymbol{x} + \boldsymbol{B}\boldsymbol{u}$$
$$\boldsymbol{y} = \boldsymbol{C}\boldsymbol{x} + \boldsymbol{D}\boldsymbol{u}$$

in which *u* is a vector of inputs, and y is a vector of outputs. The input/output relation is mediated by a *state vector, x*. All of these vectors depend on time, and in particular, the time-derivative of *x*, denoted $\dot{\boldsymbol{x}}$ is governed by the first of these equations. The matrices A, B, C, and D are constant, and hence the first of these equations is a system of linear, first-order differential equations in the state vector. The second equation gives the output as a linear function of the state vector and the input. This is a general representation of a linear system, and one which is very convenient for integration in a time-domain solver, such as a circuit simulator. Moreover, in

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

most cases, this representation is more compact than say, a representation by the impulse response, and this compactness leads to faster time-domain simulations.

The task of state-space fitting involves the determination of A, B, C, and D, such that the frequency-domain response of state-space model matches some frequency-domain data, typically given at a set of frequencies. The frequency-domain transfer function matrix associated with a state-space model can be obtained using the Laplace transform. The result is,

$$H(s) = C(sI - A)^{-1}B + D$$

where I is the identity matrix, and *s* is the Laplace transform variable, which is related to frequency f by

$$s = 2\pi jf$$

with

$$j = \sqrt{-1}$$

So, given a set of frequency-domain data, say

$$S(s_i) \text{ for } i = 1, 2, \ldots, N$$

the aim of a fitting algorithm is to find A, B, C, D, such that

$$H(s_i) \approx S(s_i)$$

for all *i*. One possible mathematical formulation for the state-space fitting problem is as a minimax problem,

$$\min_{A,B,C,D} \max_{i} |C(s_i\, I - A)^{-1}B + D - S(s_i)|$$

It is easy to show that H(s) is a rational function in s, so essentially, this is a problem of fitting a rational function to a set of data. There are several well-established algorithms for fitting rational functions, and the theory behind them is the foundation upon which Ansys's state-space fitting algorithms are built. However, in order for the models to be useful in a time-domain simulation, the condition

$$H(s_i) \approx S(s_i)$$

is not enough. The state-space model must satisfy several other conditions and this is what complicates the algorithms, and indeed even their use.

To be useful in a time-domain simulation, a state-space model must usually satisfy the following conditions:

- Stability
- Passivity

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Smoothness and low-order
- Good fit at DC

Let us explain what each of these mean.

Stability

The relevant notion of stability is Bounded-Input Bounded-Output (BIBO) stability. In general, for any set of frequency-domain data, it is possible to generate both stable and unstable state-space models which fit the data perfectly.

$$H(s_i) = S(s_i)$$

but unstable models are useless in a time-domain simulation because they result in diverging time-domain signals. In the frequency domain, the condition of stability for a state-space model is that the poles of the system, which are the eigenvalues of A, must have negative real parts. All state-space models generated by Ansys's tools are stable.

Passivity

A device is passive if it does not generate energy. This is a stronger condition than stability: not all stable models are passive. In the context of electromagnetic/circuit simulations, the quantities typically modeled are scattering (or S) parameters. These parameters are arranged in a square matrix that maps the incident wave amplitudes to the scattered wave amplitudes. For a passive device, the total power scattered by the device must be no greater than the power incident on it. Mathematically, this condition implies that the 2-norm, or equivalently, the maximum singular value, of the S-parameter matrix must be ≤1, for all frequencies.

$$\| H(s) \|_2 \leq 1 \; for \; all \; s \; = \; 2\pi jf$$

Note that a model must be passive even outside the band of frequencies for which data is available. When a non-passive device is introduced into a circuit simulation, the simulation results may diverge for a bounded input, even if the device is stable. A typical case in which this occurs is when the non-passive device is part of a feedback loop. When modeling passive devices, it is important to ensure that the model is passive. Enforcing the passivity constraint is done in a separate step, after a state-space model has been generated. If the model is found to be non-passive, it is perturbed so as to make it passive. This is a complicated and quite computationally demanding step. Ansys has developed several algorithms for enforcing passivity. At the time of writing, passivity enforcement is not on by default. In many cases, a passive fit is obtained even if passivity is not enforced. Moreover, even if the fit is slightly non-passive, the time-domain simulation may still run fine. So the current logic is that, by default, the fits are initially done without passivity enforcement, the time-domain simulation is run, and if the results diverge, then passivity is enforced and the simulation is run again.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Smoothness and Low-order

The order of a state-space model is the number of poles, which equals the size of the matrix *A*. All other things being equal, a low-order model is to be preferred over a higher-order one. Not only would the time-domain simulation run faster with a lower-order model, but a higher-order might match the data at the sample frequencies but behave erratically in between the sample points, or outside the band of given frequency points. Such erratic behaviour can lead to significant artifacts in the time-domain simulation. Keeping the order as low as possible while still meeting the other criteria *usually* leads to models that are smooth between sampling frequencies, and this is relied upon in common fitting algorithms. In the latest version of Ansys's state-space fitter, FastFit, the smoothness between sampling points and out of band are explicitly enforced. In the Tsuk-White Algorithm (TWA), the smoothness is controlled by searching for the lowest order that meets the tolerance, and by limiting the Q-factor of the poles.

Good Fit at DC

The quality of the fit at DC is particularly important, not least because it determines the operating point in a circuit simulation. In fact, the accuracy of the fit to the S-parameters often needs to be extremely high, especially in signal integrity applications. Consider, for example, a signal bus. The elements of the impedance matrix (the Z-parameters) of a bus tend to have a 1/f dependence, diverging at DC. This happens when the dielectric separating the signal and ground planes is assumed to have zero conductivity, which is often a valid assumption. Or, if the dielectric is not considered perfect, the DC impedances are still very large. However, the S-parameters must remain ≤1. This means that the mapping between S and Z,

$$Z = z_0\,(I + S)(I - S)^{-1}$$

where z_0 is the characteristic impedance, amplifies the tiniest errors in S to large errors in Z (following figure). So, a state-space model must either match the DC point data with extremely high accuracy, or, if there is no DC point, the fit to S must be such that the corresponding Z diverges at DC. Otherwise, there is a small leakage current between the signal and ground planes. The FastFit algorithm ensures that Z matches the DC point if one is available. If not, it checks whether it is possible to make Z diverge without affecting the quality of the fit at non-zero frequencies, and if so perturbs the model slightly so as to ensure this.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

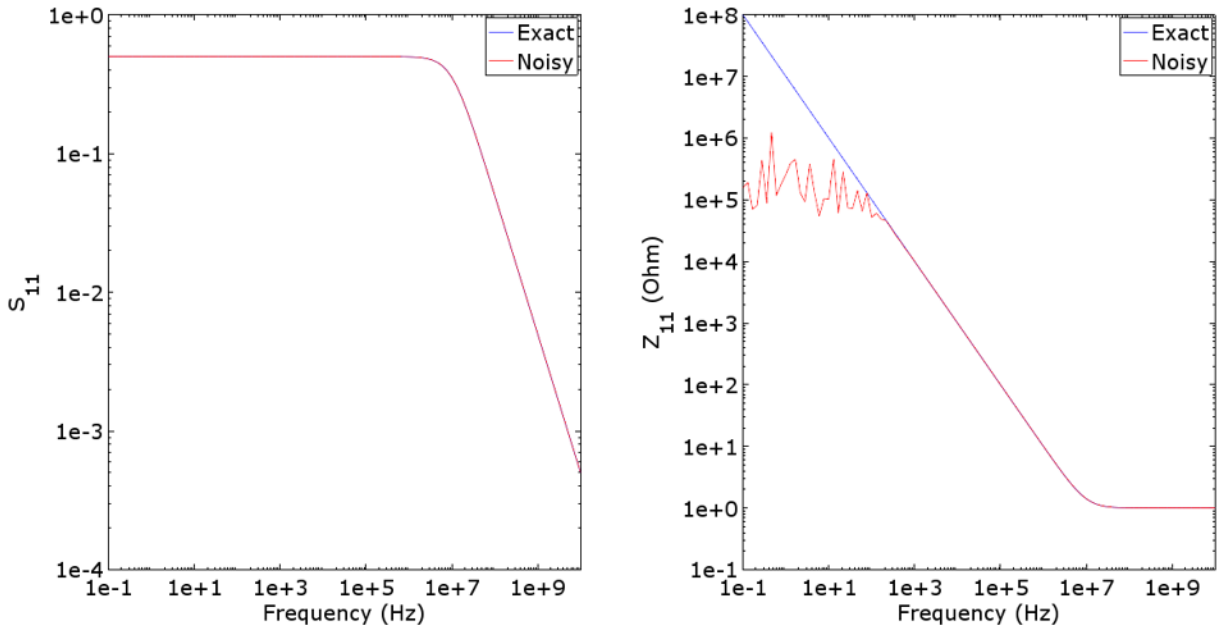

Figure 26-1 S_{11} and Z_{11} of a simple T-network, exact and noisy. Very small noise has been added to the exact S- matrix. This noise is amplified when the noisy S is converted to Z

TWA also tries to ensure a good fit a lower frequencies, though it does not match the DC point, nor ensure divergence if there is no DC point.

When passivity is enforced, the fit is perturbed and this may lead to a poor low-frequency fit. This problem has been recently resolved, however, with a fitting method called IFPVLF.

The various conditions mentioned above make state-space fitting a difficult computational problem, for which there is no known closed-form mathematical solution. Ansys has developed increasingly sophisticated algorithms for state-space fitting over the years. For the sake of backward compatibility, and because an older algorithm might, in rare cases, yield better results than the latest algorithm, nearly all algorithms and their options are still accessible. The main goal of this technical note is to guide the user through this maze.

Algorithms

There are three algorithms available for state-space fitting in Ansys' tools.

- Iterated rational fitting
- TWA
- FastFit

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Iterated rational fitting is a fairly old method, which is not recommended. The TWA is a more recent algorithm, which generally yields good results, but it is somewhat slow. FastFit is the latest and fastest algorithm. It explicitly incorporates all the fitting conditions described above, and generally yields results similar to those of TWA. FastFit it is the default algorithm.

These algorithms try to avoid non-passive fits, but passivity is not enforced nor guaranteed. Passivity enforcement is a separate step, in which a non-passive model is perturbed so as to make it passive.

There are four algorithms for enforcing passivity:

- Convex optimization algorithm
- Passivity-by-perturbation algorithm
- Iterated fitting of passivity violations (IFPV)
- Iterated fitting of passivity violations, low frequency (IFPVLF)

The first two of these are quite old, and though theoretically superior in some respects, they tend to be extremely slow and are generally not recommended. IFPV is the default method, and it usually yields good results, except that it tends to perturb the fit at DC. When the accuracy of the fit at DC is important, the next algorithm IFPVLF is recommended.

Data Quality

The default algorithms and option settings generally yield good results, with the possible exception of IFPV destroying the accuracy near DC. When results are not satisfactory, check the data before trying to change any of the default options. Examples of several common problems with frequency-domain data follow.

- Data causality
- Data passivity
- Guidelines for sampling frequency responses
- DC data should be real

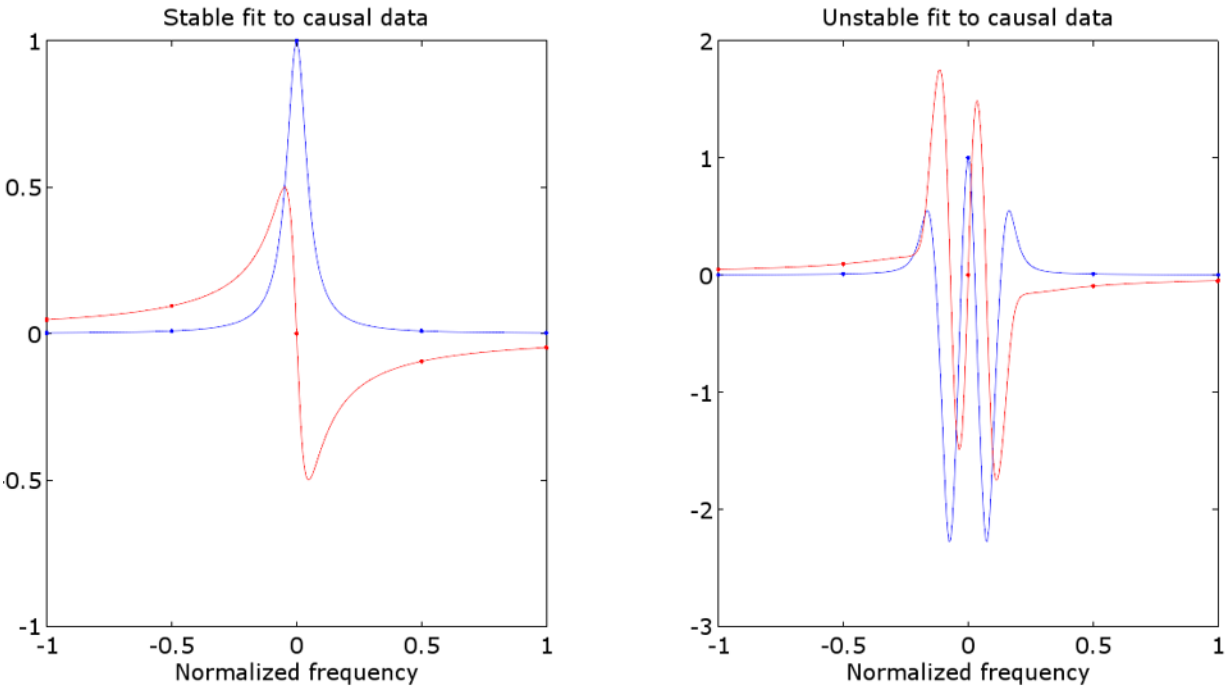
Data Causality

All physical devices should have causal transfer functions. If the frequency-domain transfer function is Fourier-transformed, the result, which is the impulse response, should be zero for t < 0. Causality, which can be ascertained by inspection in the time-domain, is much more difficult to ascertain in the frequency-domain. The real and imaginary parts of a causal transfer function must be related by the Kramers-Kronig relations, which are difficult to use in practice, because they require knowledge of the frequency domain data for all frequencies from zero to infinity. The frequency-domain data is only given at a finite set of frequencies, and therefore it is impossible to determine whether they are samples of a purely causal system. Indeed, for any such dataset, it is possible to find both causal and non-causal systems from which they could have been sampled (following figure). Nonetheless, if the data come from a causal system, the non-causal

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

fit is bound to be of high order, non-smooth and non-passive. So, although in a sense there is no such thing as causal or non-causal data. A good fit to it can be found that is of low-order (compared to the number of samples), smooth, and passive.

Non-causal data can occur in many ways. If the data come from measurements, then incorrect de-embedding can make them non-causal. If they come from a simulation, then numerical inaccuracies, or non-causal modeling of physical properties such as permittivity can result in non-causal data. Lastly, any manipulation of the causal data which does not take care to preserve causality is bound to destroy it.



All state-space models are causal, so fitting fails if the data is non-causal. Indeed, the fact that the fitting fails is a strong indication that the data may be non-causal. However, Ansys also has a causality checker, which attempts to ascertain the causality of the data, and which should be used whenever the fitting has failed.

Data Passivity

Ascertaining passivity of the data is much more straightforward than ascertaining causality. For each frequency in the dataset, the 2-norm of the S-parameter matrix should be computed, and it should be verified that

$$\|S\|_2 \leq 1$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If this is not the case and passivity is enforced, fitting fails. Of course, if passivity is not enforced, a non-passive model is practically certain to be obtained.

A matrix whose 2-norm is greater than 1 can be perturbed so its 2-norm is one, and the minimal perturbation that achieves this can be computed using the Singular Value Decomposition (SVD). However unless the original norms are extremely close to 1, doing this manipulation is bound to make the data non-causal and should therefore be avoided.

Guidelines for Sampling Frequency Responses

State-space fitting can deal with quite significant gaps between samples, especially if each of the given samples can be predicted very accurately by a low-order (compared to the number of samples) model. But if the samples are somewhat noisy or are sampled from a system that has a large number of poles, a fitting algorithm might not produce an accurate, passive, and smooth fit. Ideally, samples should be such that no resonance is missed, and the data should vary fairly smoothly from one sample to the next. One rule of thumb is that the difference between a spline interpolation of the data and a linear interpolation of the data should be fairly small, say no more than 0.1-0.2 for S-parameters.

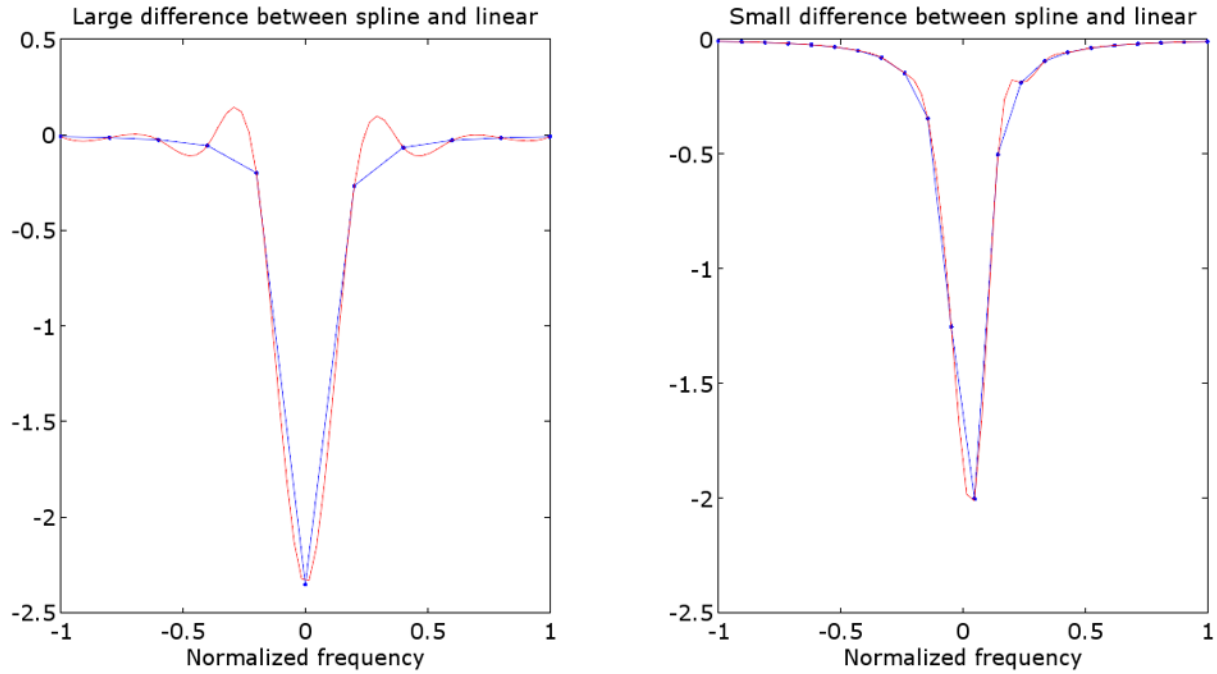


Figure 26-2 Adequate and inadequate sampling of a resonance, judged by the difference between linear and spline interpolations.

The sample frequencies should start as low as possible, preferably at DC, and end only once high-frequency losses become apparent, so the 2-norm of the S-parameter matrix begins to

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

taper off. For systems with very small losses, this might be too high for practical simulations or measurements. The fitter should be able to handle such cases, in which the losses are very small throughout the sampling band, but they are challenging. The reason these cases are difficult is that the state-space model can in principle assume any values in these gaps or out of band. While the FastFit algorithm controls the magnitude of the fit in these gaps (and out of band), significant passivity violations may still occur. Then, when passivity is enforced, removing these passivity violations entails a significant perturbation of the fit, which results in significant errors w.r.t to the data. If it is not practical to sample up to a frequency in which losses become apparent, then at the very least the highest frequency should be above the highest frequency of the excitations that is used in the time-domain simulation.

DC Data Should Be Real

In order for the impulse response to be real, the transfer function must have a zero imaginary part at DC. Perhaps through the result of some manipulation of the data or numerical errors, complex DC data may occur. A state-space fitter cannot fit such data.

Options and Troubleshooting

If the data appears to be causal, passive, and adequately sampled, there are a handful of algorithm options that are worth experimenting with.

- If fitting fails
- If fitting succeeds, but time-domain simulation does not
- If fitting takes very long
- Fitting sensitivity to small changes

If Fitting Fails

By default, a fit with an error > 0.1 is considered to have failed. If this occurs, try:

- Turning off passivity enforcement. If the error is reduced significantly, the data is not quite passive, there are large gaps between frequency samples, or the highest frequency sample is not high enough.
- Experiment doubling and halving the appropriate fitting error. All fitting algorithms use complicated heuristics for determining the best tradeoff between accuracy, passivity, and order. In very rare cases, these heuristics may fail and changing the error tolerance might yield a better tradeoff.
- Try TWA instead of FastFit. TWA has different heuristics than FastFit. In particular, if it cannot find a fit that yields a good fit at low-frequencies, it defaults to finding a fit that ignores the quality of the low-frequency fit.

If all these experiments fail to yield a fit with error < 0.1, then most probably the data is non-causal. When running a circuit simulation, the solver halts if the error > 0.1. If the data cannot be

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

improved upon, the solver's behavior can be deactivated with the option s_element.errorif = 0, so the simulation proceeds. Of course, the accuracy of the results cannot be trusted, but they might be good enough for ball-park estimates.

If Fitting Succeeds, But Time-domain Simulation Does Not

If the error of the fit is reasonable, say < 0.01, problems might still be encountered in the time-domain simulation. If this happens and the state-space model is suspect, try:

- Turning on passivity enforcement, especially if the results seem to diverge in the time-domain. Note that by default, if the transient engine fails to converge and passivity was not enforced, the fit is redone automatically with passivity enforced. This behavior is controlled with the option auto_enforce_passivity.
- Assuming passivity was on, use IFPVLF, especially when the results do not diverge but seem wrong. This can result from an incorrect fit to DC.

If Fitting Takes Very Long

In rare situations or very large problems, fitting may take a long time. This can be because:

- The port-count is very large (several hundreds or more), and passivity is enforced. Enforcing passivity for large port-count problems can be a difficult computational task. At the moment, IFPV is the fastest passivity enforcer Ansys has and, to our knowledge, it is the fastest algorithm there is at the time of writing.
- The data is sampled from a device with a large delay. Delays are not easily represented with a state-space models (they require numerous poles). If the device has a single delay, such as in a single cable, it is possible to extract the delay and fit only what is left over after the delay has been factored out of the transfer function. This has to be done manually by the user, at the time of writing. Another option is to use a convolution-based model, using the option s_element.convolution=1. Except for data representing delays, this option should be avoided, particularly because there is no control over the errors it may introduce.
- The data is very noisy, there are many samples, and the noise is large compared to the fitting tolerance. TWA attempts to recognize such situations and lowers the error tolerance, so it might be faster than FastFit in such a case. Of course, the tolerance can be reduced by the user, in which case FastFit usually is much faster than TWA.

Fitting Sensitivity to Small Changes

In mathematics, well-posed problems are defined as ones that always have a solution, which is unique and which depends continuously on the parameters defining the problem. The state-space fitting problem can be viewed as an inverse problem, of deducing a hidden model from some measurements and like other inverse problems, it is not well-posed. For example, if the data is not passive, there is no solution. If there is a solution, it need not be unique. Since the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

data is only defined in a finite frequency band, there may be several solutions that differ only outside of the frequency band. Lastly, the solution does not depend continuously on the data.

Consider the following scenario: a fit has been found that meets all requirements and the error tolerance. Now add a small delay to the data. As long as the delay is small enough, the new data can be fit to tolerance without changing the number of poles. If the tolerance begins to increase, there comes a point where new poles must be added to meet the error tolerance. At once, all the matrices of the state-space model must change. So do not expect that a small change to the data always leads to small changes in the model. This sensitivity is a characteristic of the fitting problem, not of any algorithm that is used to solve the problem. Hence, one should not be surprised if a small change in the data, such as roundoff error introduced in generating the data, should have a significant effect on the model.

Lastly, the S-to-Z parameter mapping amplifies small differences immensely. A difference in the 7th digit in the S-parameters can translate to MegaOhms of difference in the Z-parameters. As a result, very small changes in the data can lead to different results in the time-domain. When passivity is not enforced, the DC behaviour should always match the DC-point data (or be an open-circuit at DC if there is none).

When passivity is enforced with IFPVLF, this match should be preserved, although in rare cases, a small deviation still exists. In such cases, the DC behavior may change as a result of small changes in the data.

Summary of State-Space Fitting

State-space models are the preferred models for integrating linear systems in circuit solvers. Algorithms for their generation from frequency-domain data is quite mature and most of the time, require no user intervention. However, state-space fitting is a complicated mathematical problem. In particular, user intervention may be required when the data is inaccurate, non-causal, non-passive, or when the transfer function has not been adequately sampled. In such cases, different algorithms may select different trade-offs and obtain quite different results, so some experimentation with different methods is warranted. However when fitting fails, it is best to carefully examine the data because more often than not, that is where the problem lies.

Circuit S-Parameter Technical Notes

S-parameter elements or N-ports are generic components whose characteristics are defined by user-supplied network-parameter data. They are *black box* elements because no information regarding their function is provided except for their network parameters. S-parameter elements can introduce measured data into the simulation for comparison or modeling, or represent a part of a circuit for which modeling is difficult or undesired.

The network parameters are frequency-dependent and must be specified at many frequency points. The network parameters may be supplied as complex scattering parameters (S parameters), complex admittances (Y parameters), complex impedances (Z parameters),

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

complex propagation constants (gamma parameters), or complex terminal characteristic impedances (Z_0 parameters). The data may be given in either polar form or in rectangular form.

Network parameter data may be entered in spreadsheet form in the N-port import window, but is more commonly read from external files. This data then may be extracted on the data files and used in the simulation. Several data file formats are supported:

- **Touchstone/EESof Data** — This format uses the **.s*p, .y*p**, or **.z*p** filename extension. Only one dataset may be present in each **.s*p, .y*p**, or **.z*p** data file. See "Touchstone Data Format" on page 26-132.
- **HFSS V6.0+ (Z_0-Gamma)** – This format uses the **.szg** file extension, and contains gamma or Z_0 parameter data.
- **Circuit (Compact FLP)** – This format uses the **.flp** filename extension, and may contain several data groups, each of which is preceded by a header. The data group header identifies the group by means of a label, which is used as a reference name. See "Compact FLP Data File" on page 26-132.
- **CITIfile** – This format uses the **.cit** filename extension, and contains S-parameter data in a proprietary format. See "CITIfile Format" on page 26-139.
- **SSS file** – This format uses the **.sss** filename extension, and contains data in a proprietary state-space format. See "State-Space Method " on page 26-18.

The same set of methods for handling frequency-dependent data is applied throughout Circuit designs. Most data is processed using a state-space method. Convolution is also available.

Since network data may come from any source, they may contain violations of causality and passivity that prevent simulation from succeeding. Topics in the following list describe the methods for identifying violations and correcting for them.

Troubleshooting S-Parameter Issues

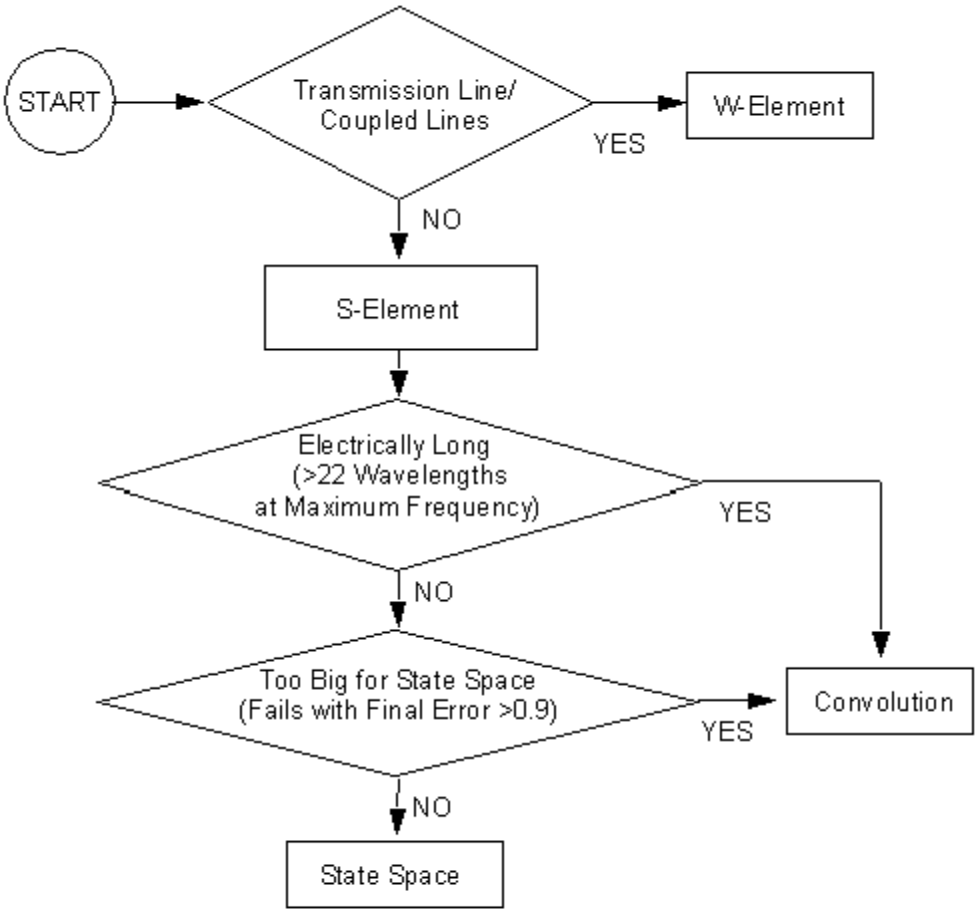
These topics show how to select the correct S-parameter representation for your design and how to identify passivity and causality issues with state-space models of frequency-dependent data.

Selecting the Correct Element and Method

The following flow chart outlines the process of selecting the correct implementation for an element defined by S-parameters. The two main choices are between the S-element and the W-element, then, for the S-element, between the default state-space representation and the convolution method.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Selecting Implementation and Method for S-Parameter Elements

Selecting W-Element or S-Element

The first decision is whether to use a W-Element or an S-Element. W-Element modeling exhibits fewer stability issues than S-element modeling.

- When the S-parameter component to be simulated is a transmission line or a set of coupled lines, use a W-Element that points to an S-model. The S-parameter data must be well de-embedded. The S-model computes the unit RLGC or TABLE model for the W-element from the S-parameters. See *Transmission Lines* in the Nexxim Components help for details on the W-Element.
- When the element has many ports, has a short electrical length, or is not a transmission line despite a long electrical length, use an S-Element to model the component in Nexxim.

For processing S-elements, Nexxim uses one of two methods—state space or convolution.

Selecting State-Space or Convolution Method

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Nexxim must convert the frequency-dependent scattering parameters in the data to a numerical model that is suitable for time-domain simulation. The default representation, a state-space model calculated by fitting methods, is the best method for most applications. The alternative convolution method calculates the impulse response for the element and convolves the impulse response with the data during transient simulation. Convolution should be selected when:

- The circuit is electrically long (greater than 22 wavelengths at the maximum frequency).
- The circuit is too big for the state-space representation. State-space fitting fails with a message such as "Final Error ε, unable to achieve acceptable error." The final error ε, is larger than 0.9 (ε can exceed 1.0 in rare cases, but can never exceed 2.0).

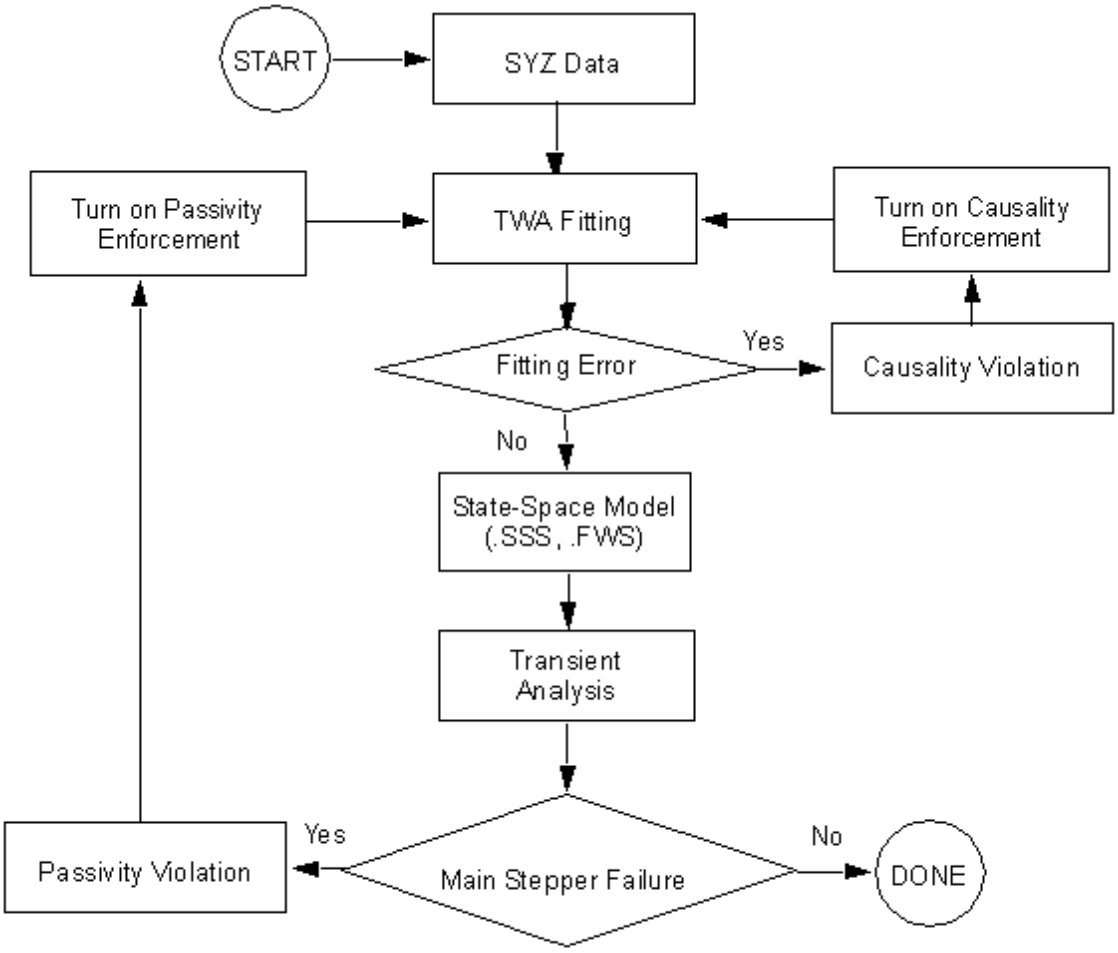
See Convolution Method for details on setting the convolution options.

See the State-Space Method for more on the State-Space representation.

Troubleshooting State-Space Issues

State-space models can exhibit passivity violations and causality violations. These stability issues may be present in the original S-parameter data or introduced by the numerical fitting methods. The following figure illustrates the process for diagnosing these two sources of error.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Identifying Causality and Passivity Issues

Identifying Causality Problems

Causality violations can lead to errors during the calculation of the rational fit to the S-parameter data. The final error indicates the magnitude of the fitting error.

Before starting transient simulation, Nexxim calculates a causal macromodel that approximates the original data in the frequency domain. If the original data is noncausal, the approximation by the macromodel may not be accurate. The more severe the noncausality, the higher is the fitting error of the approximation. If the fitting error is greater than 10%, transient analysis does not even begin. Even when transient runs, a fitting error greater than 1% can give results that are inaccurate, often to a degree that is unacceptable.

See Causality Checking and Enforcement for further information.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Identifying Passivity Problems

Passivity violations can be detected in the original S-parameter data and rejected if they are serious. Mild passivity errors in the data may persist in the state-space realization, and more serious passivity errors may be introduced by the fitting algorithms. State-space passivity violations may result in errors during Transient analysis such as exponential growth of the voltages at the ports of the S-parameter block or timesteps below minimum.

See "Passivity Checking and Enforcement " on page 26-35for details

Passivity Issues with SPICE Format S-Parameter Macromodels

A SPICE format S-parameter macromodel can be generated by broadband export from HFSS or SIwave analysis data, or from another tool such as Twin Builder. The macromodel can be placed as an S-parameter element in the schematic. If transient simulation of the circuit fails to converge, while issuing one of the following errors:

```
Starting stepper failed. Unable to proceed.
```

```
Main stepper failed. Unable to proceed.
```

A likely reason for this failure is a passivity violation in the SPICE format macromodel. However, the solver cannot automatically enforce passivity using the SPICE format. To remedy the situation, you should re-export the SPICE model with passivity enforcement activated , then replace the SPICE format sub-circuit.

Generally, the Touchstone format is the recommended format for passing an S-element to the circuit solver.

See Passivity Checking and Enforcement for more details.

S-Parameter Basic Definitions

Scattering parameters (S-parameters) represent the element behavior in matrix form. The S matrix indicates what fraction of an incident voltage wave is transmitted or reflected at each port. The voltage wave is normalized with respect to the square root of the characteristic impedance of the port, for example, $a = V*Z_0^{-0.5}$. If the characteristic impedance is completely real, the elements of the S matrix are equivalent to the square root of the fraction of power transmitted or reflected. An S-matrix for a three-port structure is:

$$\begin{bmatrix} b_1 \\ b_2 \\ b_3 \end{bmatrix} = \begin{bmatrix} S_{11} & S_{12} & S_{13} \\ S_{21} & S_{22} & S_{23} \\ S_{31} & S_{32} & S_{33} \end{bmatrix} \begin{bmatrix} a_1 \\ a_2 \\ a_3 \end{bmatrix}$$

where:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- All quantities are complex numbers.
- a_i represents the incident voltage wave at port i.
- b_i represents the transmitted or reflected voltage wave at port i.
- The phase of a_i and b_i is the phase of the incident and of the transmitted or reflected voltage wave at t = 0:

  Za$_i$is the phase angle of the excitation voltage wave on port i at t = 0 (by default, it is zero).

  Zb$_i$is the phase angle of the transmitted or reflected voltage wave with respect to the excitation voltage wave.

- S_{ij} is the S-parameter describing how much of the incident voltage wave at port j is reflected back or transmitted to port i. Thus, S_{31} is the amount of power on the port 1 excitation that is transmitted to port 3. The phase of S_{31} specifies the phase shift that occurs as the voltage wave travels from port 1 to port 3.

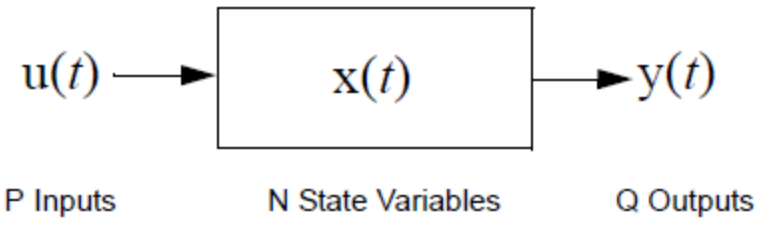
State-Space Method

S-parameters describe a system in terms of its frequency-dependent responses. The Nexxim state-space model assumes a linear time-invariant (LTI) system with a vector of inputs **u(*t*)** of length *P* and a vector of outputs **y(*t*)** of length *Q*:



Model of Linear Time-Invariant System

The state-space model represents the data as a vector of N state variables **x(*t*)** representing the responses of the system for all inputs in the specified range, and four state-space matrices, **A**, **B**, **C**, and **D**. See Reference [1] in State-Space References for an introduction to state-space modeling.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

State Equations and Output Equations

The vector of state equations gives the rate of change of the state variables (responses), computed as a weighted sum of the current state vector and the input vector:

$$\dot{\boldsymbol{x}}(t) = \boldsymbol{A}\boldsymbol{x}(t) + \boldsymbol{B}\boldsymbol{u}(t)$$

where:

$$\dot{\boldsymbol{x}} = \frac{\mathrm{d}}{\mathrm{d}t}\boldsymbol{x}(t)$$

Matrix **A**, the state matrix, contains the frequency-dependent poles of the system. Matrix **A** has dimension N by N. Matrix **B**, the input matrix, contains the weights applied to the input vector. Matrix **B** has dimension P by N.

From the time derivatives of the state variables *x(t)* one may calculate the values of $x(t + \Delta t)$ using the vector of output equations:

$$\boldsymbol{y}(t) = \boldsymbol{C}\boldsymbol{x}(t) + \boldsymbol{D}\boldsymbol{u}(t)$$

The output vector is a weighted sum of the current state vector and the input vector. Matrix **C**, the output matrix, contains the weights applied to the state vector. Matrix **C** has dimension Q by N. Matrix **D**, the feed-forward matrix, contains weights applied to the input vector. Matrix **D** has dimensions Q by P.

State-Space Transfer Function

The transfer function is the ratio of the output to the input. Using the Laplace transform to convert from time domain to complex frequency domain *s*, the transfer function can be expressed in terms of the state-space matrices:

$$\boldsymbol{H}(s) = \boldsymbol{C}(s\boldsymbol{I} - \boldsymbol{A})^{-1}\boldsymbol{B} + \boldsymbol{D}$$

where *sI* is an N by N matrix with *s* on the diagonal and zeros elsewhere.

H(s) is a matrix of frequency-dependent transfer functions with dimension Q by P.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Impulse Response and Stability

The impulse response *h(t)* is the response of the system to the Dirac delta function, a pulse of vanishingly narrow width. The impulse response is the inverse Laplace transform of the transfer function, and can be expressed in terms of the poles of the system $\mathbf{p}_i$ (the entries of matrix **A**).

$$h(t) = \sum_{t>0} e^{p_i t} u(t)$$

Bounded-In, Bounded-Out (BIBO) stability specifies that as long as the input is bounded, the output must be bounded. For BIBO stability, the exponential factor e^{pt} must decay rather than increase. Thus, all the poles $\mathbf{p}_i$ must have negative real parts.

For BIBO stability, the norm of the impulse response must always be finite:

$$\|h(t)\| < \infty \quad \forall t$$

State-Space Fitting Methods

By default, Nexxim uses a proprietary fitting method — FastFit — for calculating the state-space matrices on the network data. The FastFit algorithm for state-space fitting is an alternative to the Tsuk-White algorithm (TWA) and Iterated Rational Fitting (IRF). FastFit is generally as accurate as TWA, but is significantly faster than both TWA and IRF. Also, FastFit aims to fit the lower frequencies with higher fidelity.

The Tsuk-White algorithm (TWA) is an alternative proprietary fitting method. TWA generates the poles of the state-space fit on the singular value decomposition of Loewner matrices derived on the input data [State-Space Reference 2]. Unlike rational fitting, TWA is not an iterative procedure. Thus, TWA can produce high-quality state-space fits in much less time than rational fitting.

The TWA algorithm may succeed where rational fitting produces a bad fit or gives a fit that is good but non-passive on a problem too big for passivity enforcement.

The option

```
s_element.disable_fastfit=0|1
```

can be used to toggle between the FastFit algorithm (0) and the method selected by the option s_element.twa (1). The default is 0 (FastFit is enabled).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When **s_element.disable_fastfit** =1, the option:

```
s_element.twa=1|0
```

can be used to toggle between the TWA algorithm (1) and the rational fitting method (0). The default is 1 (TWA is selected).

Causality Checking and Enforcement

This topic explains how Nexxim handles causality checking and causality enforcement with S-parameter data.

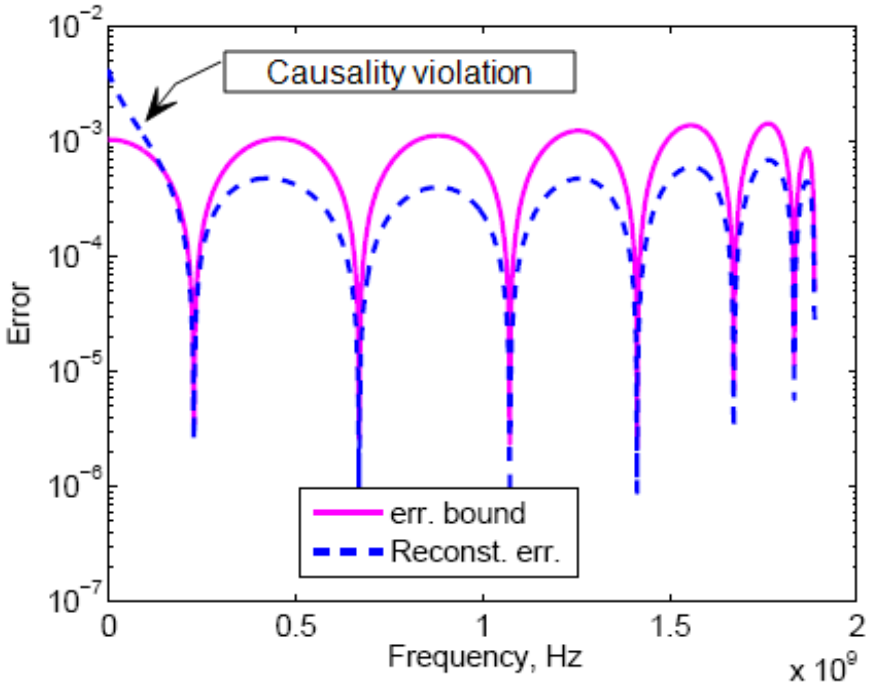
Any physical, realizable system must be *causal*, that is, the time of its response cannot precede the excitation that produces the response. Although causality is a consideration in a simulation of any physical system, the focus for signal and power integrity simulations is on linear, time-invariant (LTI) systems, a category that includes transmission lines, interconnects, packages, connectors, and board-level systems. LTI systems are typically simulated from frequency response data, so ensuring the causality of frequency response data is a key issue.

Nexxim can check for causality violations and can correct causality problems. The basic strategy for causality checking is to compute a causal reconstruction of the data, calculate the difference between the reconstruction and the original data, and compare the reconstruction error to a known error bound or threshold for noncausality over all frequencies. The causal reconstruction can be used in place of the faulty original if necessary to correct the problem. Following are links to the causality checking and enforcement topics.

An Example of a Noncausal System

The following figure shows the internal results of the Nexxim causality checker with a transmission line.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The solid (magenta) line is the error bound for noncausality. The maximum value for the error bound has been set to $2x10^{-3}$. The dashed (blue) line is the reconstruction error, the difference between the known-causal reconstructed data and the original. At the lowest frequencies, the reconstruction error exceeds the threshold or maximum error bound, indicating a causality violation in the original data.

Symptoms of Noncausality

Problems with causality of frequency response data shows up as errors in the accuracy and stability of the simulation.

Causality and Accuracy

Before starting transient simulation, Nexxim calculates a causal macromodel that approximates the original data in the frequency domain. If the original data is noncausal, the approximation by the macromodel may not be accurate. The more severe the noncausality, the higher is the fitting error of the approximation. If the fitting error is greater than 10%, transient analysis does not even begin. Even when transient runs, a fitting error greater than 1% can give results that are inaccurate, often to a degree that is unacceptable.

Causality and Stability

$[-\infty, \infty]$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Unstable results can be avoided if the macromodel is passive, or can be made passive. Thus, one possible solution for instability issues is to try passivity enforcement on the macromodel before running transient again. However, passivity enforcement increases the runtime, and any degree of noncausality adds to the problem. To obtain an acceptable fit with noncausal data, the macromodel may require a large model order (number of poles > 200). Model order has a direct effect on the passivity correction runtime.

A second, related issue is memory usage. Passivity correction encounters memory problems for systems with large numbers of I/O ports (>400). When the model order is also high due to noncausality, passivity enforcement is at high risk of running out of memory, which causes transient to terminate without simulating anything. Memory problems during passivity enforcement are common with package models for memory subsystems.

Passivity enforcement also affects the accuracy of the result. If the calculated passive macromodel has a fitting error (to the original data) of more than 10%, transient simulation does not begin. The higher the non-passivity (as measured by the maximum singular value), the greater chance that the macromodel is inaccurate. Hence, strong causality problems typically lead to poorly fitting passivity-enforced macromodels.

Sources of Noncausality

Touchstone data come from three different sources: from measurements, from field solvers (2-D, 3-D, or 2.5-D), and from circuit solvers. Any of these sources can introduce noncausality into data. This technical note analyzes causality issues in data from field solvers and circuit solvers.

Causality Issues with Field Solvers

There are many sources of noncausality in data from field solvers.

- Subsystems in field solvers can have noncausal models.
- Discontinuity of the field solutions can produce noncausal data. Field solvers typically use a special formulation for low-frequency solutions (near DC), which can be discontinuous with the solutions obtained at higher frequencies with the standard formulations.
- Noncausal interpolating functions during interpolation sweep are a frequent source of problems.
- Constant loss-tangent models for modeling frequency-dependent dielectric behavior often contributed to noncausality in the data. Fortunately, the Debye and Djordevic-Sarkar models for dielectric constants have eliminated this source of noncausality.

Causality Issues with Circuit Solvers

Circuit solvers can introduce noncausality into Touchstone data. Most of the noncausality comes from components meant to work at radio or microwave frequencies. A typical example of such a component is the coaxial cable transmission line model. The dielectric loss of the lines is still modeled by constant loss-tangent models (conductance is made to vary linearly with frequency,

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

while capacitance is held constant), and the conductor loss is modeled by varying the square root of the frequency while making the inductance constant with frequency.

Testing for Causality

The basis for causality checking and enforcement is the *dispersion relation*:

A causal frequency response is equal to its own generalized Hilbert transform.

The following topics briefly show how this method for causality checking S-parameter data follows from constraints on the impulse response and on the frequency response of an LTI system.

Enforcing Causality of Touchstone Data

Nexxim can also perform causality enforcement on frequency response data that have been flagged as noncausal. The enforcement method employs fact that the real and imaginary parts of a causal frequency response are Hilbert transforms of each other [see equation (8)].

The reconstruction obtained by combining the real and imaginary parts is guaranteed causal. However, accuracy may suffer. Hence, causality enforcement is not recommended unless there are no alternative fixes.

Understanding the Causality Options

Three options control Nexxim causality checking and enforcement. Here are technical details for the causality options.

causality_check

Setting **.option s_element.causality_check=1** activates a causality test to check for non-causality in the (sampled) frequency data. Causality checking uses a formula based on the generalized Hilbert transform of equation (28).

A signal is declared causal if it meets the following two constraints:

$$\left| E_n^{tot}(\omega_k) \right| \le \delta_{nc} \quad \forall \omega_k$$

(39)

$$\left| \tilde{\Delta}_n(j\omega_k) \right| \le \delta_{nc} \quad \forall \omega_k$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(40)

A signal is declared noncausal if any value exceeds the threshold:

$$\exists k: \left|\tilde{\Delta}_n(j\omega_k)\right| > \delta_{nc}$$

(41)

The causality check is inconclusive when:

$$\left| E_n^{tot}(\omega_k)\right| > \delta_{nc} \quad \exists \omega_k$$

By default, **s_element.causality_check=0**, and no causality checking is performed.

enforce_causality

Setting **.option s_element.enforce_causality=** 1 runs the causality check and attempts to compensate for any noncausality. Compensation replaces the original frequency data with the causal reconstruction estimate. Any cached S-parameter solution is updated with new corresponding causal estimates. Since causality enforcement affects accuracy, fixing the original non-causal data is always a better solution.

By default, **s_element.enforce_causality=0**, and no causality enforcement is performed.

causality_checker_tolerance

The **.option s_element.causality_checker_tolerance=***val* sets δ_{nc}, the maximum magnitude of error that still satisfies the causality checker. Nexxim sets the default causality tolerance to the overall tolerance for fitting errors. The default for the fitting error is 1% (0.001).

interpolation_typecc

The **.option s_element.interpolation_typecc=1** sets the causality checker to use cubic spline interpolations. 2 selects interpolation by rational functions. Cubic spline interpolation is the default.

integration_typecc

The **.option s_element.interpolation_typecc=1** sets the causality checker to use numerical integration. 2 selects analytical integration. Numerical integration is the default.

enable_cc_continuation

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **.option s_element.enable_cc_continuation=1** enables the causality checker to continue automatically when the default interpolation and integration types lead to an inconclusive causality check. A test is inconclusive when the causality checker cannot determine that the data is definitely causal or definitely noncausal. The causality checker starts with **interpolation_typecc=1** (cubic splines) and **integration_typecc=1** (numerical). If the test is inconclusive, the causality checker continues with **interpolation_typecc=2** (rational functions) and **integration_typecc=2** (analytical). The default is **enable_cc_continuation=1**, automatic continuation is enabled. To disable automatic continuation, set **enable_cc_continuation=0**.

Table 2 compares the performance of the four combinations of interpolation and integration types.

Table 2: Combinations of Interpolation and Integration Types

interpolation_typecc	integration_typecc	False Positives	Resolution	Accuracy	Runtime	Bounded Result
1	1	High	Low	Low	Good	Yes
1	2	High	Low	Low	Good	Not Always
2	1	Medium	Medium	Medium	Worst	Yes
2	2	Low	High	High	Bad	Yes

False positives: A false positive occurs when the checker reports a causality violation for data that are causal. Interpolation via cubic splines (**interpolation_typecc=1**) can yield a high percentage of false positives with either type of integration (first and second rows of Table 2). Interpolation via rational functions (**interpolation_typecc=2**) produces a lower incidence of false positives, especially in combination with analytical integration (**integration_typecc=2**) (third and fourth rows of Table 2).

Resolution: The higher the resolution of the causality checker, the smaller the true causality violations that can be detected reliably. Interpolation via cubic splines (**interpolation_typecc=1**) achieves only low resolution with either type of integration. Interpolation via rational functions (**interpolation_typecc=2**) achieves higher resolution, especially in combination with analytical integration (**integration_typecc=2**).

Accuracy: The accuracy of the computation is measured by comparing the reconstructed data to the original. A highly accurate causality check avoids false positives and inconclusive results. Spline interpolation yields low accuracy while rational function interpolation achieves high accuracy, especially with analytical integration.

Runtime: The runtime is the denominator in the equation for the efficiency of the causality check. Here, interpolation via cubic splines (**interpolation_typecc=1**) has a relatively short runtime with either type of integration (first and second rows of Table 2). Interpolation via rational

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

functions (**interpolation_typecc=2**) uses more computer time in general. The combination of rational function interpolation with numerical integration (**integration_typecc=1**) yields the worst runtime of all the combinations.

Bounded Result: The combination of spline interpolation (**interpolation_typecc=1**) and analytical integration (**integration_typecc=2**) can lead to an unbounded result.

The automatic continuation strategy employed by **enable_cc_continuation=1** starts with low resolution/accuracy and fast runtime (first row in Table 2). If this setup does not yield a conclusive test, causality checking continues with high resolution/accuracy and slower runtime (fourth row in Table 2). The other combinations are not useful due to the runtime and stability issues noted above.

Examples of Causality Checking and Enforcement

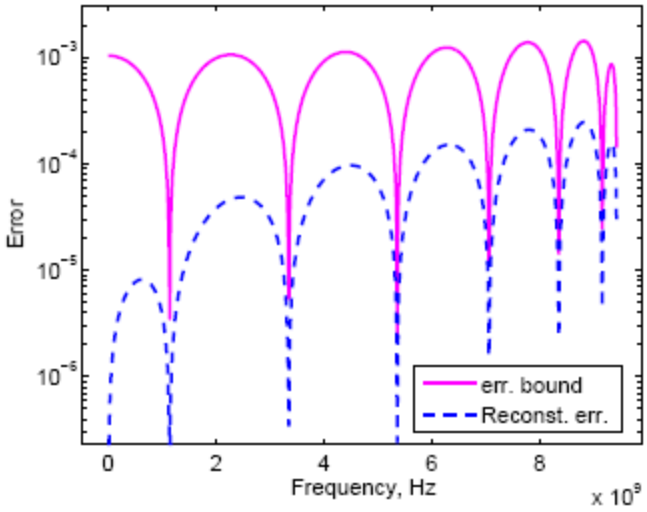
This topic show the results of causality checking on a simple resistor, a lossy transmission line, and a known-causal W-element.

Causality Check of a Resistor

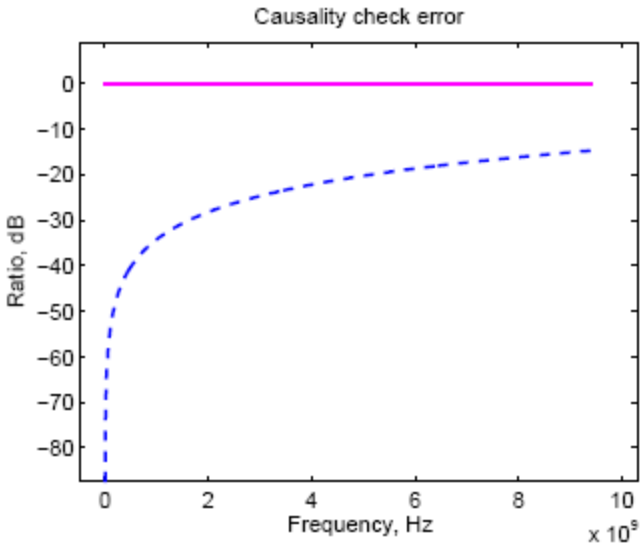
The first example is a resistor with resistance R (Figure 3a, 3b). Such a resistor is known to be causal: the impulse response is an impulse at *t*=0, hence causal. However, confirming this fact in the frequency domain with just the Hilbert transform is problematic due to the non-square-integrable nature of the resistance. Hence, the causality of a resistor is confirmed with the generalized Hilbert transform. Here, the resistance R is fixed as 75Ω and is converted to the corresponding one-port S-parameter. With a 50-Ω reference impedance, the S-parameter S(jω) is computed to be 0.2 at all frequencies. Tabulated values of this S-parameter are created for frequencies in the range [0, 10GHz] in steps of 10 MHz. The parameter ε is chosen as approximately 0.05. So from (19), $\Omega' \approx 2\pi[-9.5GHz, 9.5GHz]$. The causality checker tolerance δ_{nc} is chosen as 0.002. The quantity *n* was found to be 14 for $T_n(\omega)$ to satisfy (31). Because the S-parameter is constant with frequency, the bound $\tilde{D}_n(\omega) \approx 0$. Therefore, $\tilde{E}_n^{tot}(\omega)$ satisfies (33).

In Fig. 3, causality reports of the resistor are shown. In Fig. 3a, the computed $|\tilde{A}_n(j\omega)|$ is compared against $\tilde{E}_n^{tot}(\omega)$. From the figure, it is clear that $|\tilde{A}_n(j\omega)|$ is smaller than $\tilde{E}_n^{tot}(\omega)$ for all frequencies in Ω'except near the subtraction frequencies (minima in the plot). To get a clear picture even at the subtraction frequencies, the ratio of two quantities is computed. In Fig. 3(b), the ratio of the two quantities is shown as a function of frequency. If the ratio is more than 0 dB at any frequency, the frequency response has a possible noncausality at that frequency. From Fig. 3(b), it can be concluded that the frequency response satisfies (29) and, hence, is causal.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



(a) Comparison of $|\widetilde{\Delta}_n(j\omega)|$ ("Reconst. Err.") versus $E_n^{tot}(\omega)$ ("err. bound").



(b) Plot of the ratio $20\log\left(\frac{|\widetilde{\Delta}_n(j\omega)|}{E_n^{tot}(\omega)}\right)$ versus frequency (dashed line). The solid line (0 dB) shows the maximum value the ratio can take for the frequency response to be declared causal.

Figure 3. Causality reports on the frequency response of a resistor, δ_{nc} = 0.002, *n*=14.

Causality Check of a Lossy Transmission Line

The S-parameters of a lossy transmission line are computed on the closed-form expressions of the frequency-dependent per-unit-length (p.u.l.) parameters R (resistance), L (inductance), G (conductance), and C (capacitance). See Figures 4, 5, 6, and 7.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Let R_{dc} and G_{dc} be the p.u.l. resistance and conductance, respectively, at DC. Further, let R_s and G_d be real-values constants such that $R(f) = R_{dc} + R_s\sqrt{f}$ and $G(f) = G_{dc} + G_d f$. Let the inductance
$L(f) = L_{ext}$, where L_{ext} is the p.u.l. external inductance at $f = \infty$, and let $C(f) = C_0$, where C_0 is the constant p.u.l. capacitance.

S-parameters computed from such p.u.l. parameters are expected to be noncausal, since the corresponding p.u.l. impedance ($R + j\omega L$) and admittance ($G + j\omega C$) are not causal frequency responses. However, when $R_s = 0$ and $G_d = 0$, the S-parameters are expected to be causal.

Cases 1 through 4 (Figures 4, 5, 6, and 7, respectively) illustrate how causality results depend on the values of R_s and G_d.

1. $R_s = 0$ and $G_d = 0$. See Figure 4. The transmission line still has loss due to the nonzero R_{dc} and G_{dc}. S-parameters are computed from tabulated frequencies in the range [0, 2GHz]. The causality checker tolerance δ_{nc} is 0.002 and n is 14, as in the resistor example. Figures 4a and 4b indicate that the transmission line is causal under these conditions.
2. $R_s = 0$ and $G_d \neq 0$. See Figure 5. The simulation parameters are the same as Case 1, except that G_d is made nonzero. Figures 5a and 5b show the resulting causality violation at low frequencies.
3. $R_s \neq 0$ and $G_d = 0$. See Figure 6. The parameters are the same as in Case 1, except that R_s is made nonzero. Figures 6a and 6b show the resulting causality violation over half the frequencies.
4. $R_s \neq 0$ and $G_d \neq 0$. See Figure 7. The parameters are the same as in Case 1, except that both G_d and R_s are made nonzero. Figures 7a and 7b show the resulting causality violation, similar to the result in Case 3.

Causality Check of a Causal Model W-Element Transmission Line

Compare the causality check results of the lossy transmission line S-parameters with those obtained using the Nexxim causal W-element RLGC model. In this example, the RLGC values are comparable to the ones used for the lossy transmission line. The causality reports are shown in Figures 8a and 8b. As can be seen on the figure, the new S-parameters are causal.

Passivity Checking and Enforcement

A passive system does not contain any energy sources. Frequency-dependent data may nevertheless exhibit non-passive behavior. Nexxim offers four methods for passivity checking and enforcement: an iterated fitting method, an iterated fitting method for better Z-fit at DC and low frequencies, a convex programming method, and a perturbation method.

Iterated Fitting Method of Passivity Violations

Iterated Fitting of Passivity Violations (IFPV) is the default passivity enforcement algorithm provided by Nexxim (**s_element.enforce_passivity=7**). IFPV requires relatively little memory to run, and runs significantly faster than either convex optimization or passivity by perturbation. However, IFPV does not guarantee goodness-of-fit as does the convex optimization method. The IFPV algorithm works by taking the results of the original state-space fit, selecting those areas that have passivity violations, and fitting just the excess values, with the original poles. The fitted residues are then subtracted on the original state-space fit. This step is iterated, balancing between goodness of fit and passivity, until a passive model is achieved.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Iterated Fitting of Passivity Violations Low Frequency

Iterated Fitting of Passivity Violations Low Frequency (IFPVLF) is the latest passivity enforcement algorithm (**s_element.enforce_passivity=8**). It builds upon the default passivity enforcement algorithm (Iterated Fitting of Passivity Violation) by providing a better fit to “Z” at DC and low frequencies.

In a dynamic link simulation, Circuit receives the calculated Scattering Parameter data (S-data) on the field solver. Circuit performs state-space fitting, which generates a macromodel that represents the input/output behavior of the structure modeled in the field solver, and performs time or frequency domain simulations. In many applications such as power delivery networks, Circuit must fit the S-data while also preserving its fit of the corresponding Z-data. This fitting process is called “Z-fitting”.

Often, the generated macromodel is not passive. When passivity enforcement is invoked using the default Iterated Fitting of Passivity Violation (IFPV) method, there is no guarantee that the Z-fit to DC and low frequencies are preserved. Preserving the fit to Z-data at DC and low-frequency can be very important. For example, due to inaccuracies of the fit to Z-data at DC and low frequencies, a DC-DC buck converter may not converge to a correct steady state voltage regulated value. To remedy this issue, Circuit offers a DC/low frequency Z-fitting passivity enforcement called Iterated Fitting of Passivity Violation at Low Frequency. IFPVLF provides advanced passivity protection to preserve Z-fit at the DC point, or a better fit to Z-data at DC and low frequencies, while remaining passive. Ideally, IFPVLF provides a significant improvement when the S-data is casual and passive, and the DC data point should be preserved. Use IFPVLF for passivity enforcement when a better Z-fit at DC and low frequencies are appropriate.

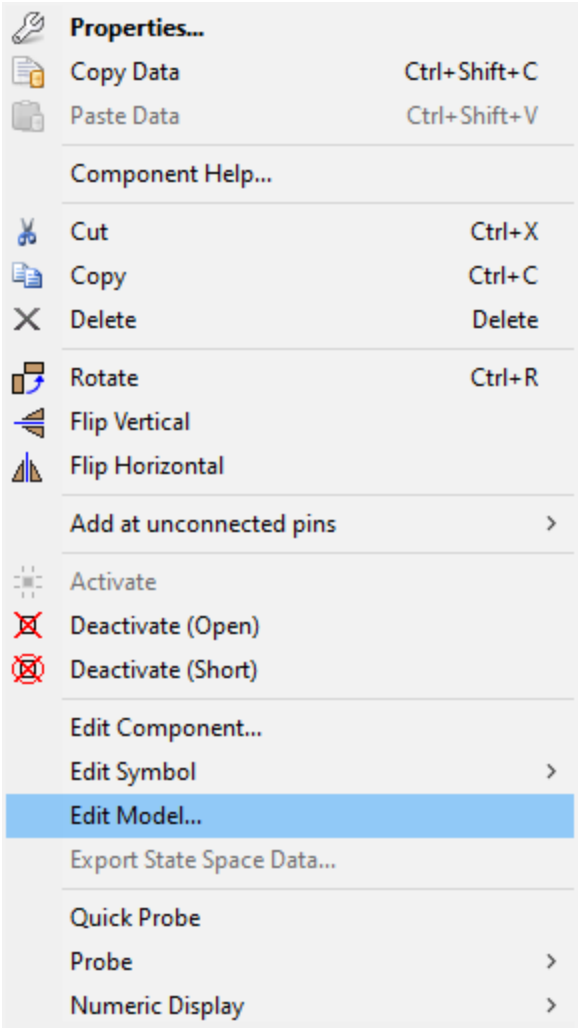
Selecting IFPVLF

To select the IFPVLF algorithm, complete the following steps for either a static or dynamic project.

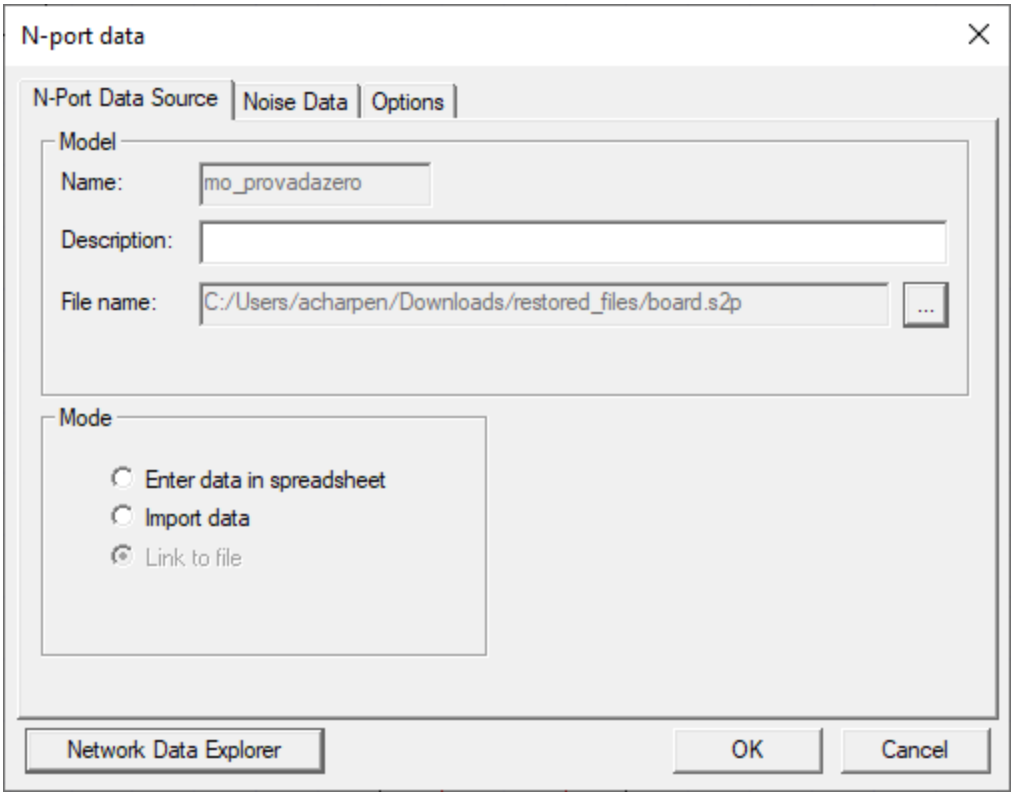
Static Project

1. From the **Schematic Editor**, right-click the model and select **Edit Model...** to open the **N-port data** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

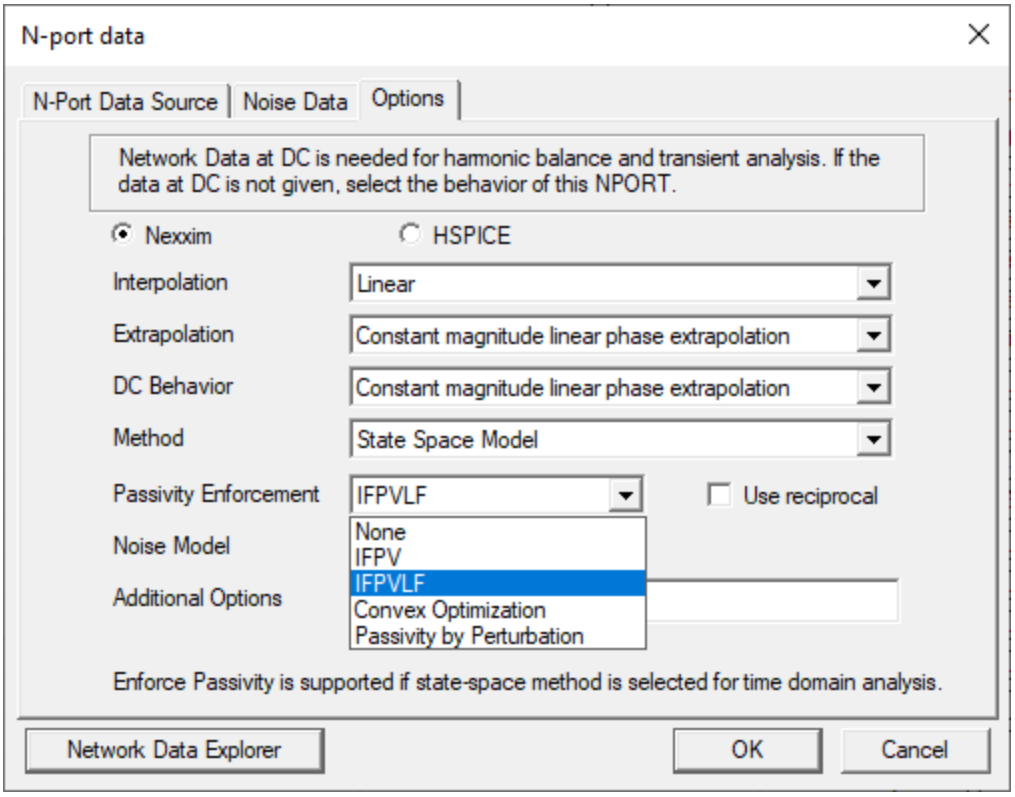


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Click the **Options** tab.
3. From the **Passivity Enforcement** drop-down menu, select **IFPVLF**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



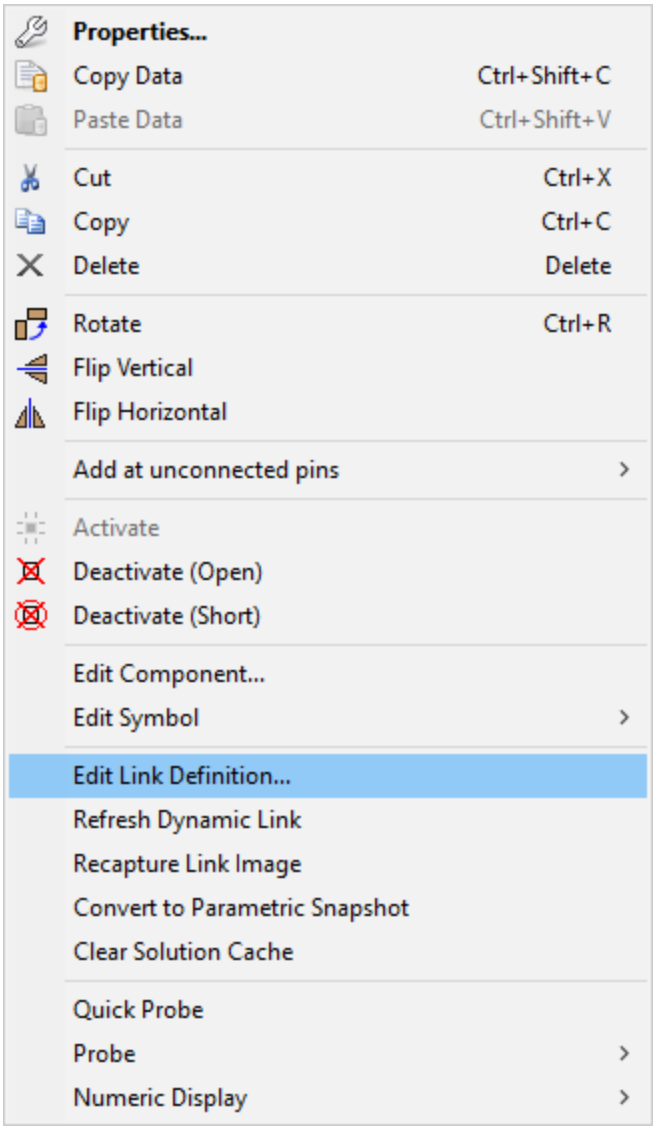
4. Click **OK**.

The procedure is complete.

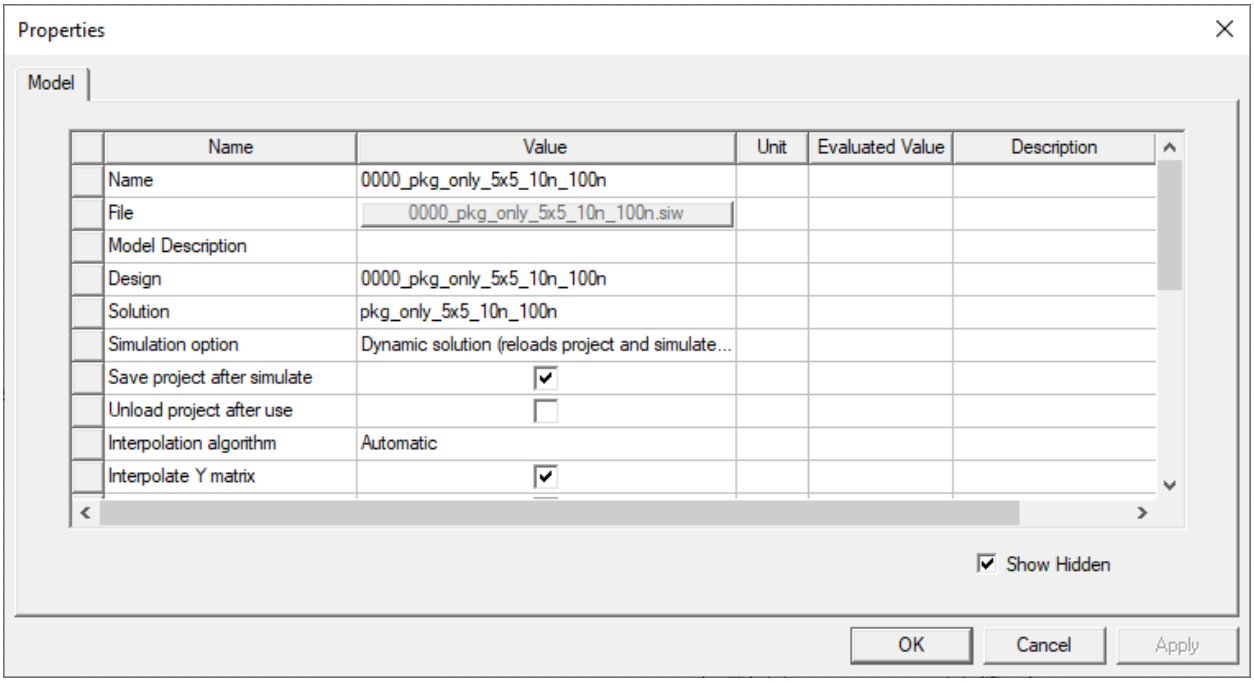
Dynamic Project

1. From the **Schematic Editor**, right-click in the model and select **Edit Link Definition...** to open the **Properties** window.

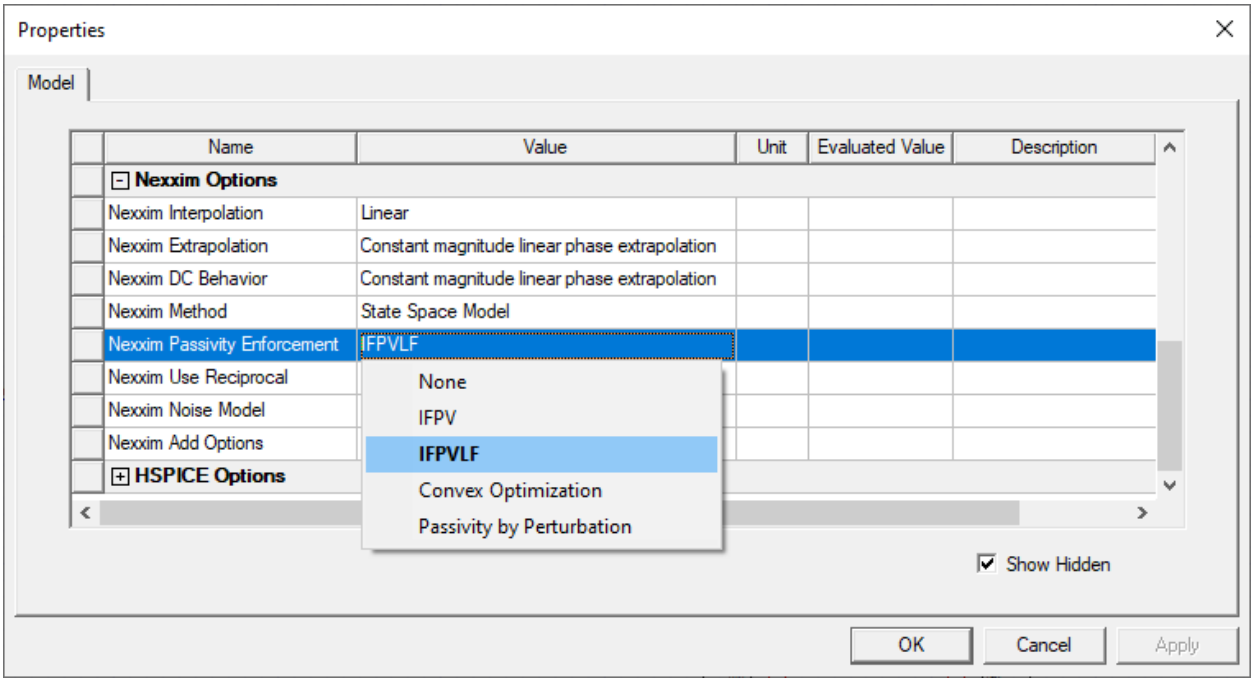
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Scroll down and expand **Nexxim Options**.
3. Click in the **Nexxim Passivity Enforcement Value** field and select **IFPVLF** on the drop-down menu.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click **OK**.

The procedure is complete.

Viewing IFPVLF Algorithm Status

Once analysis has begun, view the status of the advanced DC passivity protection on the log file. From the **Project Manager** window, expand the **Project Tree** > [*active design folder*] > **Analysis**. Then right-click the transient analysis icon and select **Browse log file** to open the log file in the operating system's default text editor.

Advanced DC Passivity Protection in Action

Advanced DC Passivity Protection preserves DC fit in scenarios where the fit is destroyed during enforced passivity. A sequence of alternate projections is performed between the sets of all state-space fits. The accurate DC fits and passive fits finally converge to a fit that is both accurate and passive (i.e., fixed point). Advanced DC Passivity Protection utilizes the Anderson Acceleration (AA) Algorithm for fixed-point iterations to quickly reach the intersection of the best DC and passive fit. The resulting macromodel should possess an accurate DC fit that is several magnitudes better than the initial fit, and is also passive.

> **Note:** The AA Algorithm is used to speed up the iterative process of alternating projections between the sets of accurate DC fits and passive fits. The overall fit is not constrained during this process. In some rare situations, the overall fit worsens beyond tolerance. In such scenarios, IFPVLF automatically deactivates the algorithm and chooses the best fitting that meets the error tolerance before launching the DC fit preservation algorithm.

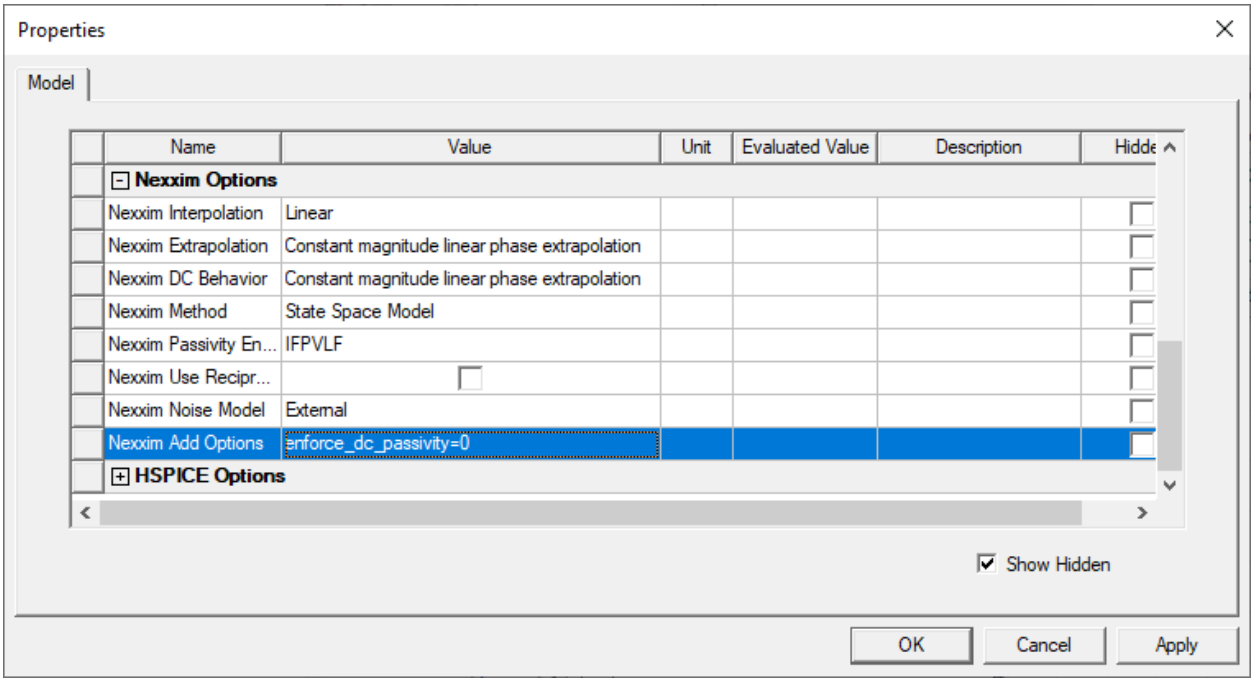
2. Scroll down and expand **Nexxim Options**.
3. Click in the **Nexxim Add Options** field and type [**enforce_dc_passivity=0**].



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click **OK**.

The procedure is complete.

Augmented Data Passivity Enforcement (Beta Feature)

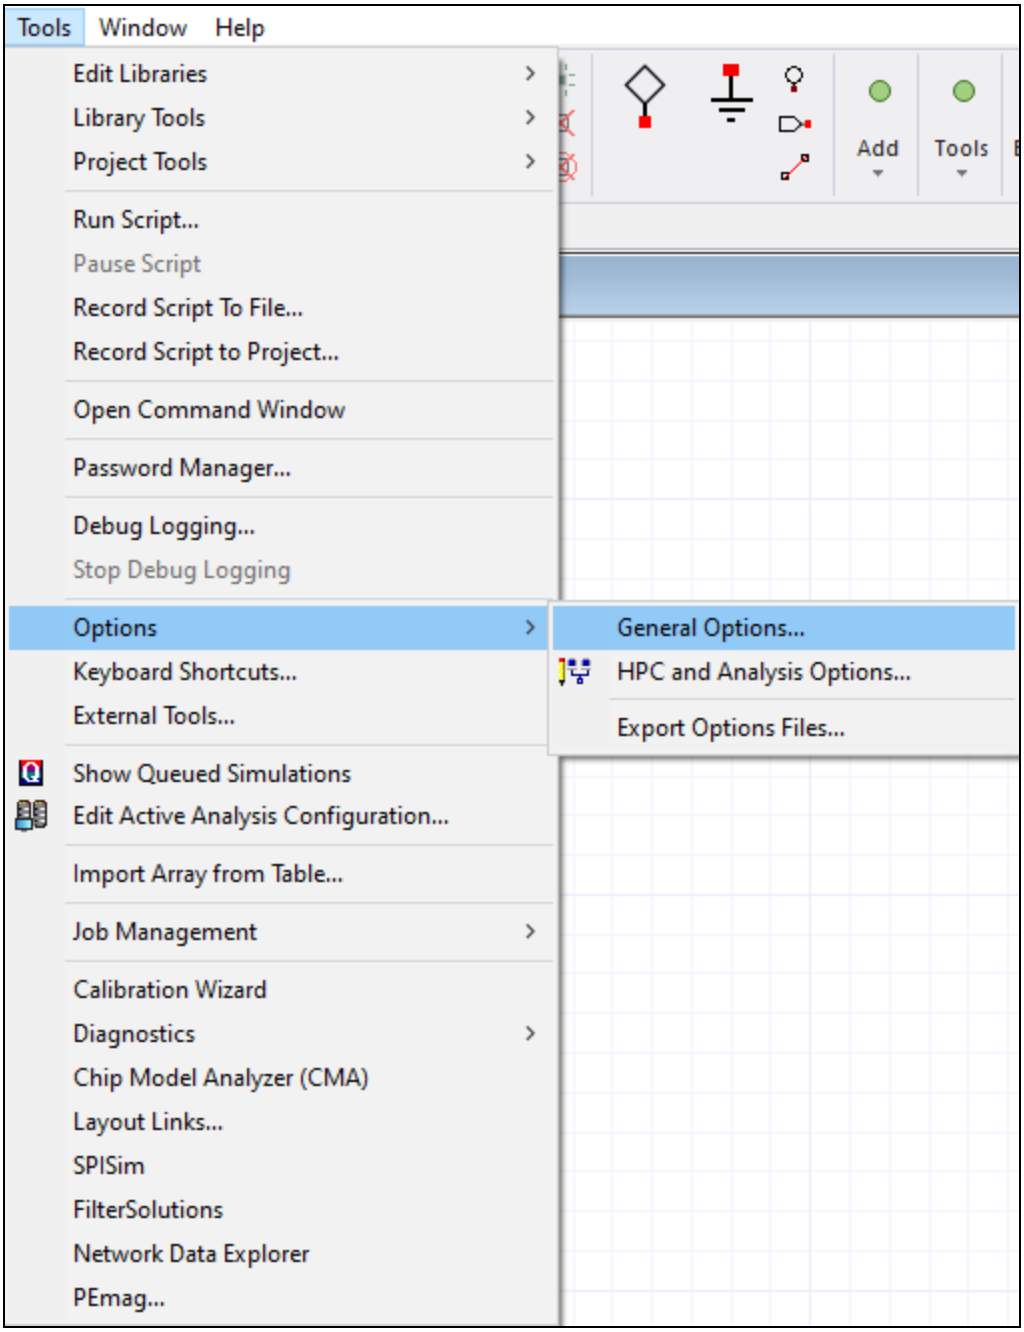
The **Augmented Data Passivity Enforcement (ADPE)** feature improves the fitting error of a passive macromodel. After performing state-space fitting on S-Parameter data (S-data), ADPE augments the original S-data with new causal and passive data to improve the fitting experience. If the fitting error is improved, the macromodel created from the augmented S-data is reported to the user. If not, **the fit to the** original S-data is reported instead. ADPE is only accessible if Nexxim's default state-space fitting method is utilized (i.e., **FastFit**) and either Iterated Fitting of Passivity Violations (IFPV) or Iterated Fitting of Passivity Violations Low Frequency (IFPVLF) is selected as the passivity enforcement algorithm.

Activating the Augmented Data Passivity Enforcement Feature

Complete these steps to activate the **Augmented Data Passivity Enforcement** beta feature.

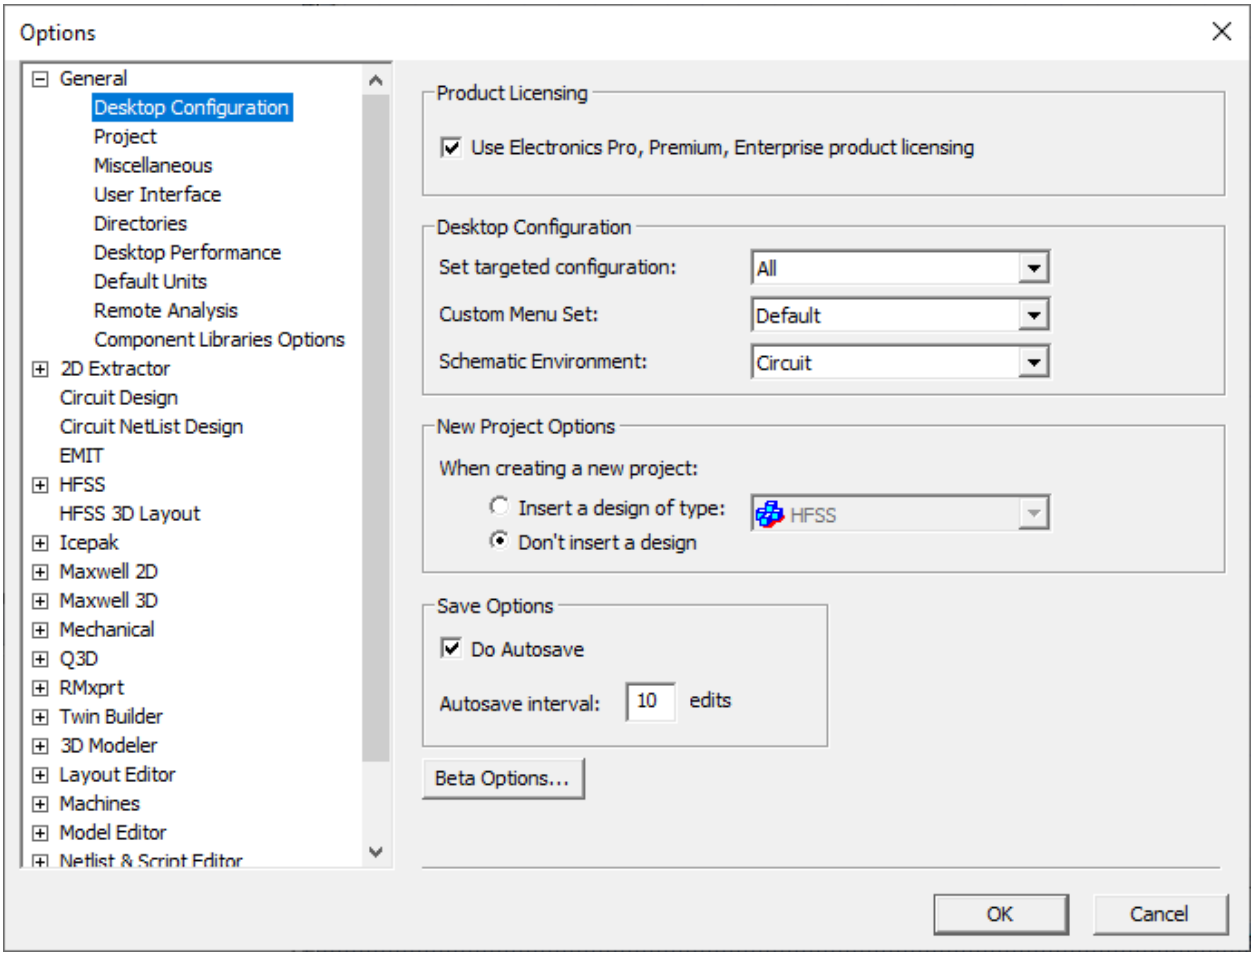
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. From **Tools**, select **Options** > **General Options...** to open the **Options** window.



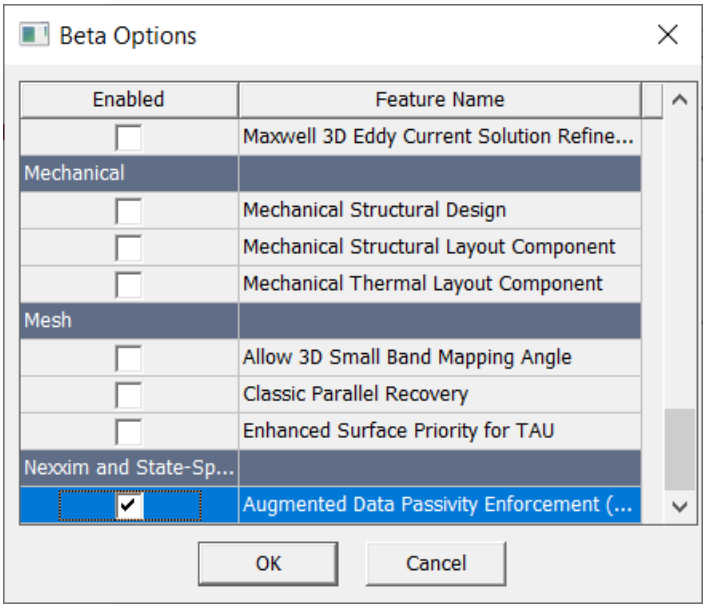
2. From the **Options** window, select **General** > **Desktop Configuration** from the navigation tree. Then click **Beta Options...** to open the **Beta Options** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. From the **Beta Options** window, check the box adjacent to **Augmented Data Passivity Enforcement**. Then select **OK** to close the **Beta Options** window and activate **Augmented Data Passivity Enforcement**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. Select **OK** to close the **Options** window.

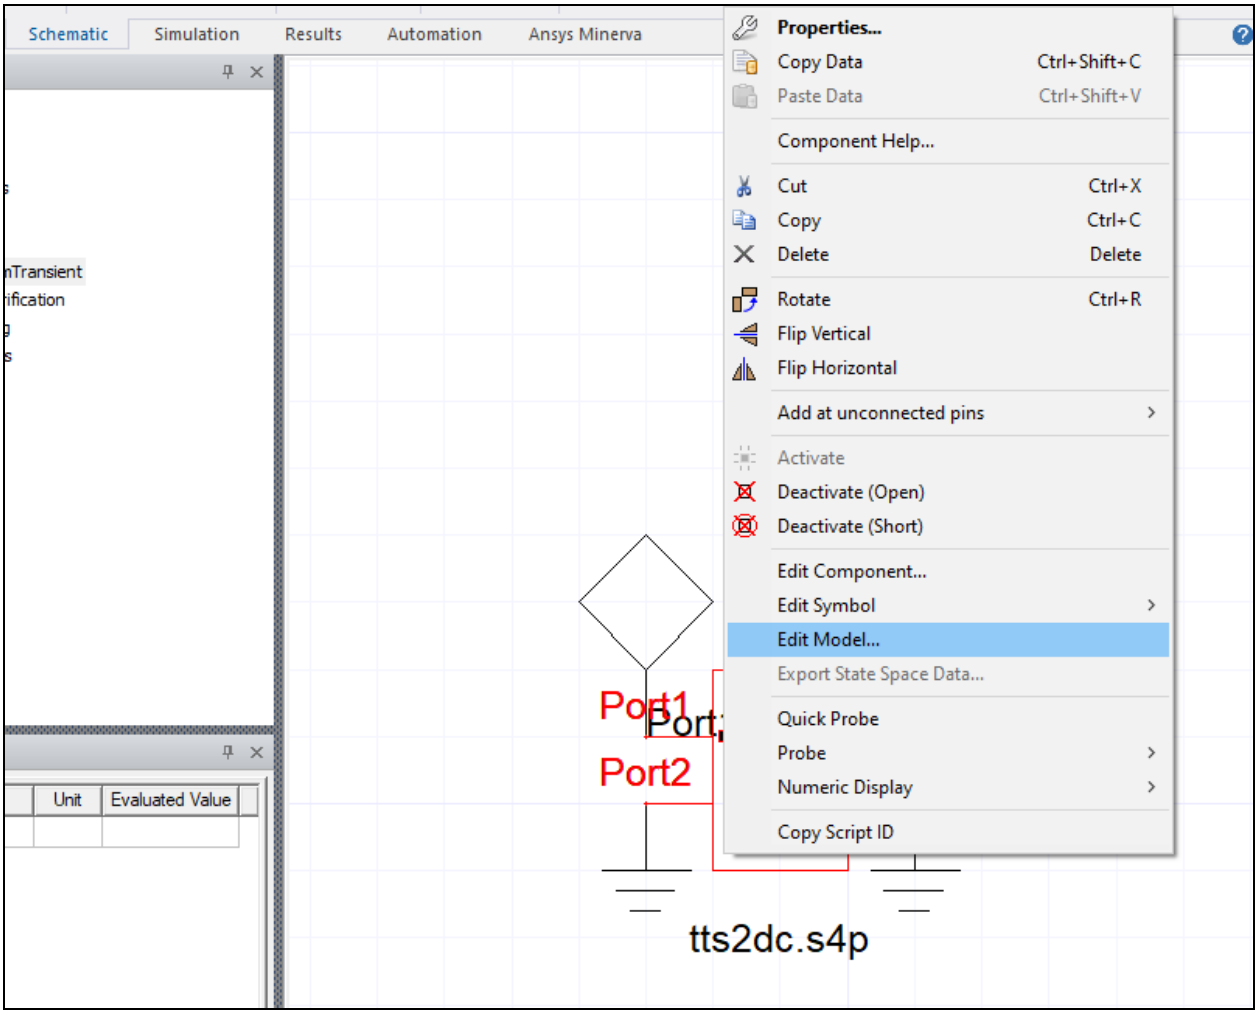
The procedure is complete.

Configuring N-Port Data for ADPE

Complete these steps to configure **N-Port Data** settings so the **Augmented Data Passivity Enforcement** feature functions.

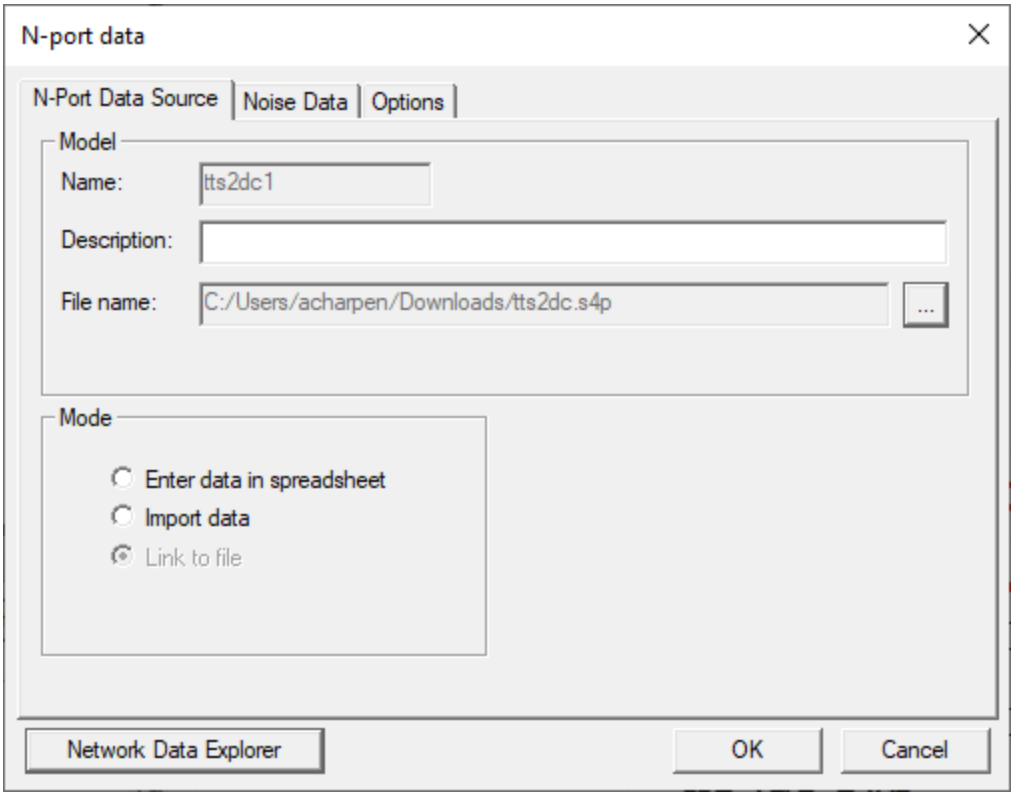
1. From the **Schematic** tab, right-click the model and select **Edit Model...** to open **N-port data** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



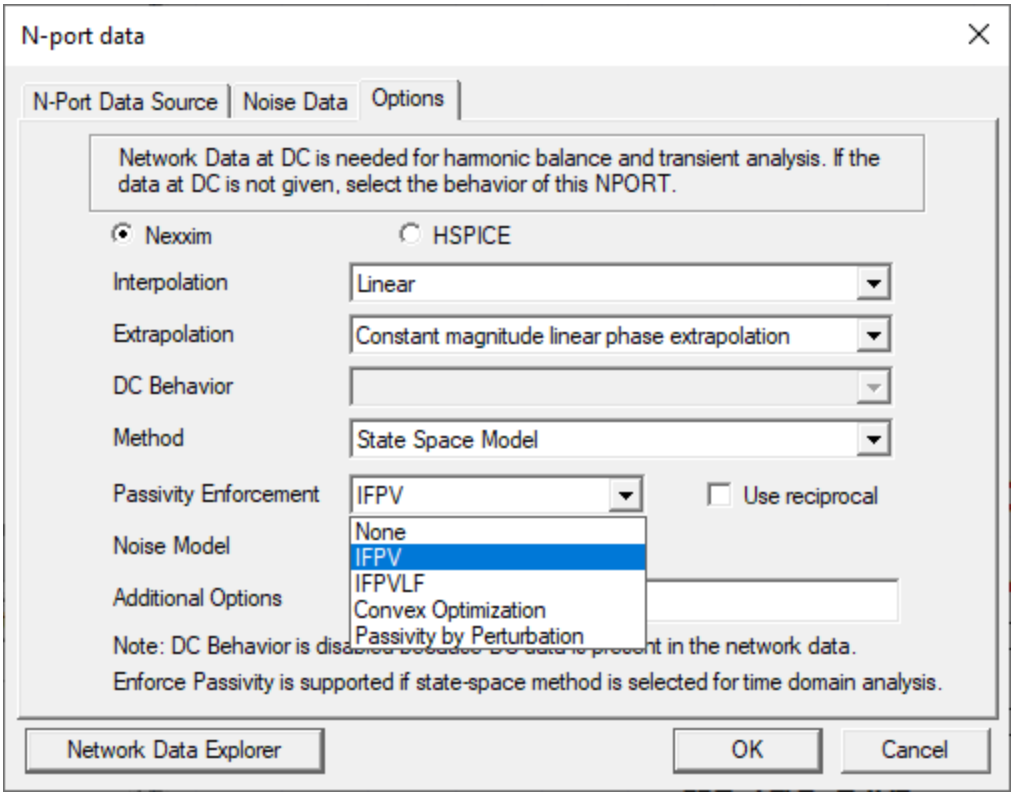
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Navigate to the **Options** tab.



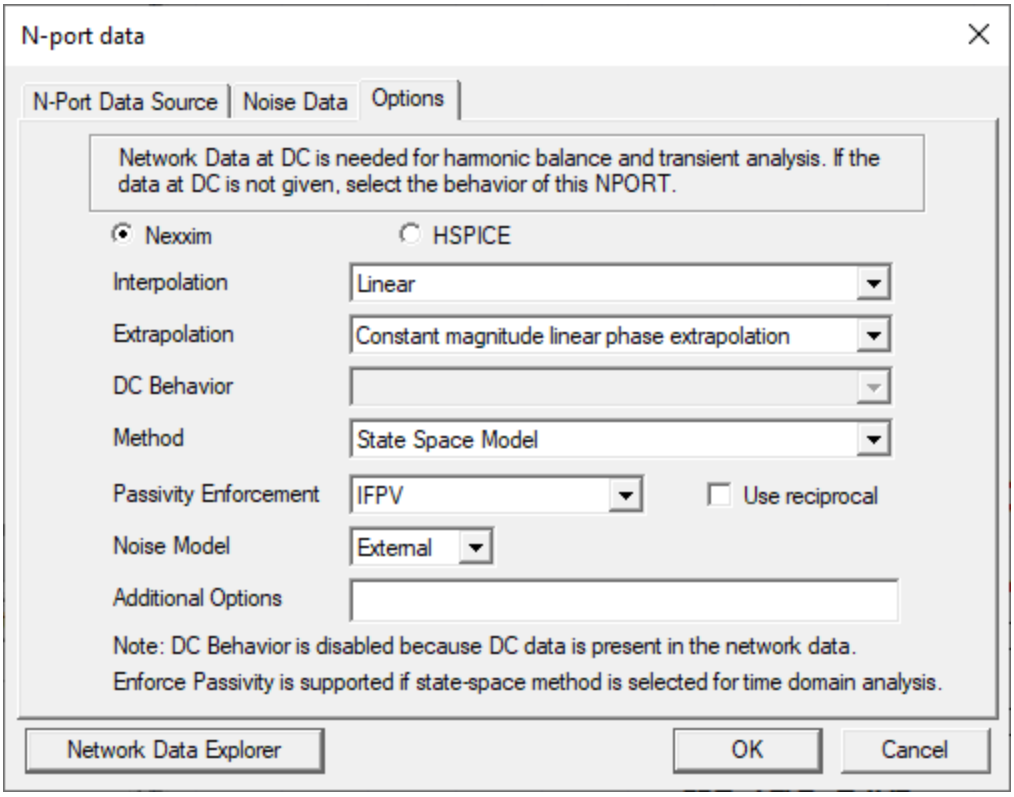
3. From the **Options** tab, select either **IFPV** (i.e., Iterated Fitting of Passivity Violations) or **IFPVLF** (i.e., Iterated Fitting of Passivity Violations Low Frequency) from the **Passivity Enforcement** drop-down menu. ADPE **only** functions with **IFPV** or **IFPVLF** selected.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



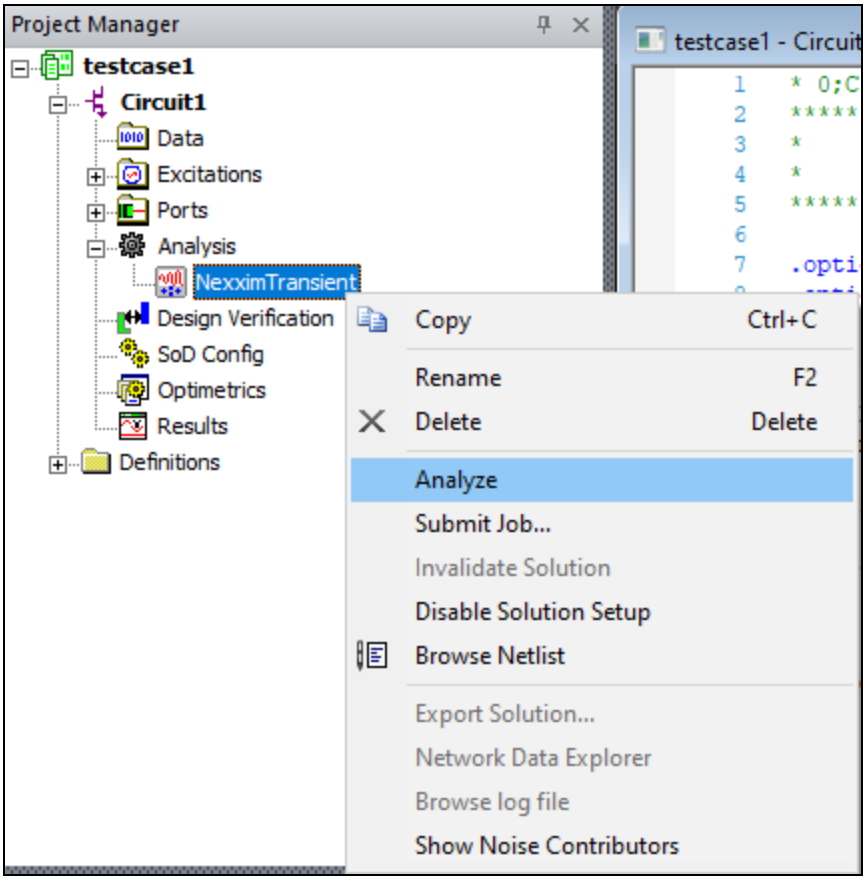
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click **OK** to close the **N-port data** window.



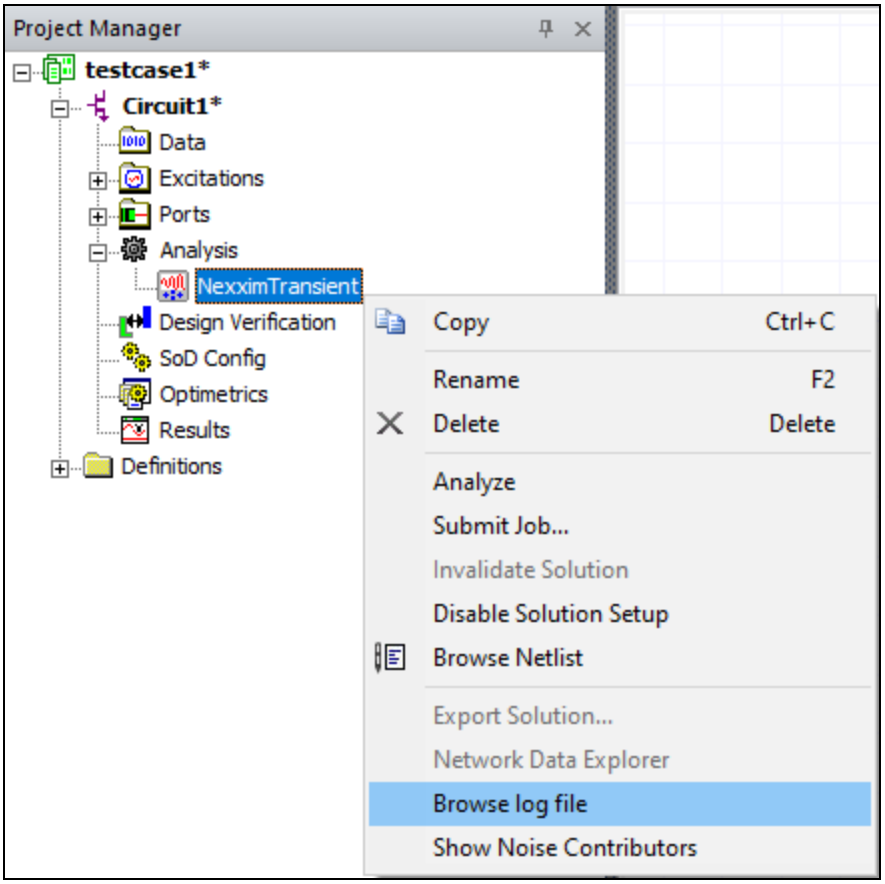
5. From the **Project Manager** window, right click the **NexximTransient analysis** and select **Analyze** to solve the analysis with the **Augmented Data Passivity Enforcement** feature assisting.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



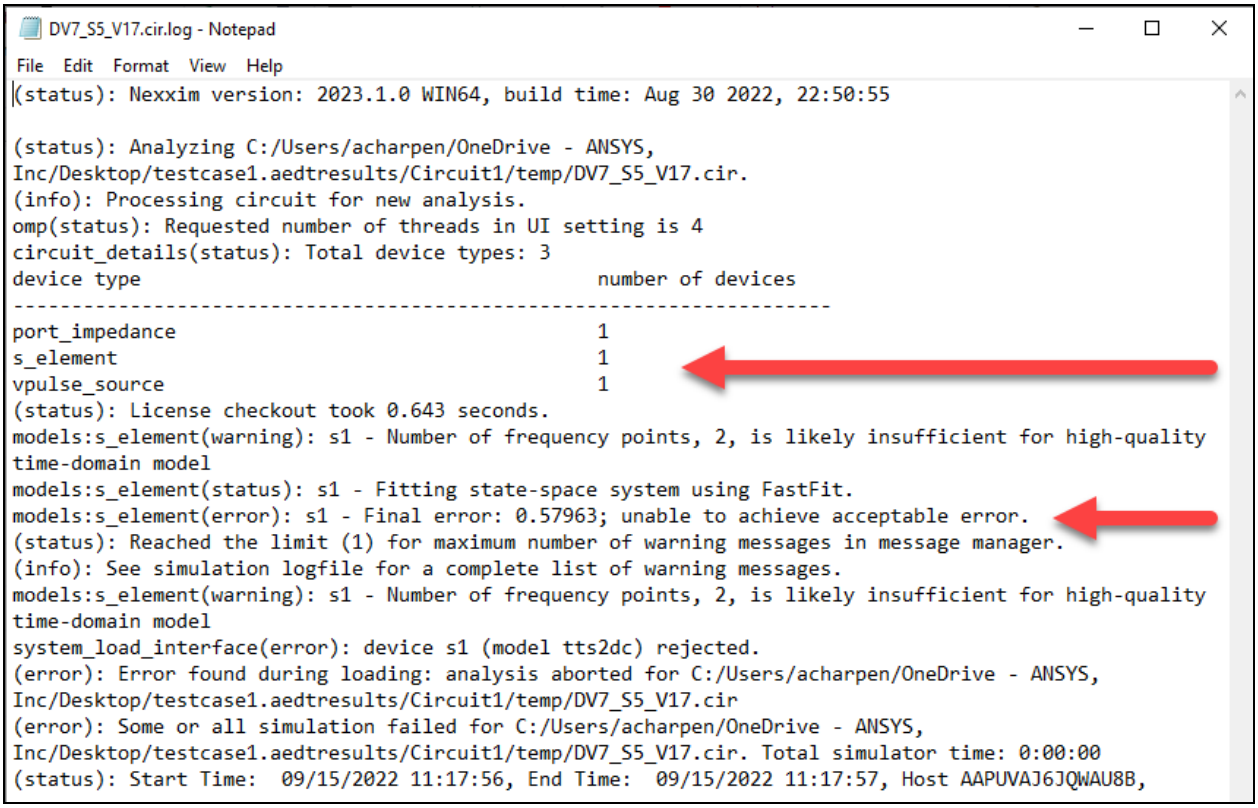
6. After analysis completes, right-click the **Nexxim Transient** analysis and select **Browse log file** to open the log file (e.g., **DV7_S5_V17.cir.log**).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



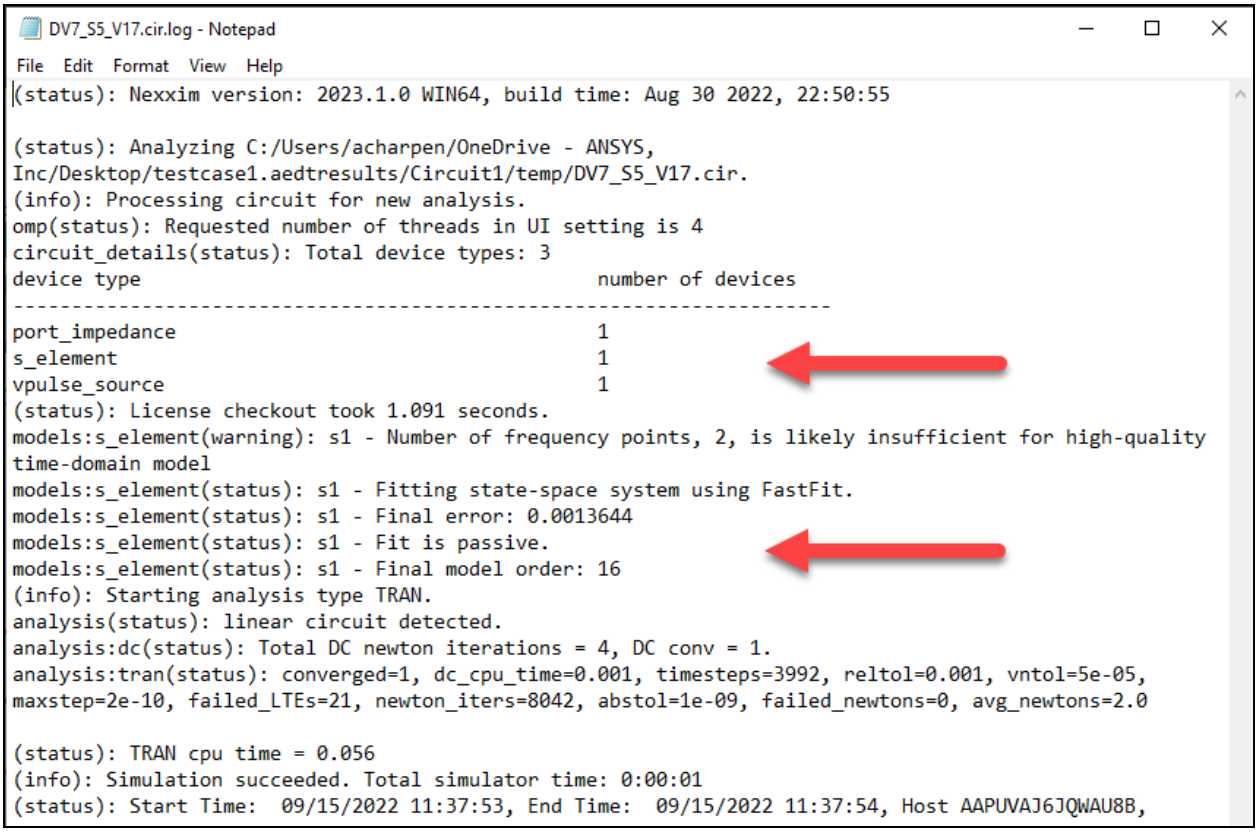
In the following example, the ADPE feature is inactive. As a result, the fitting error is unacceptable.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In the next example, the ADPE feature is active and the same design is analyzed using the same parameters. As a result of the ADPE feature augmenting the S-data, the fitting error is acceptable.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



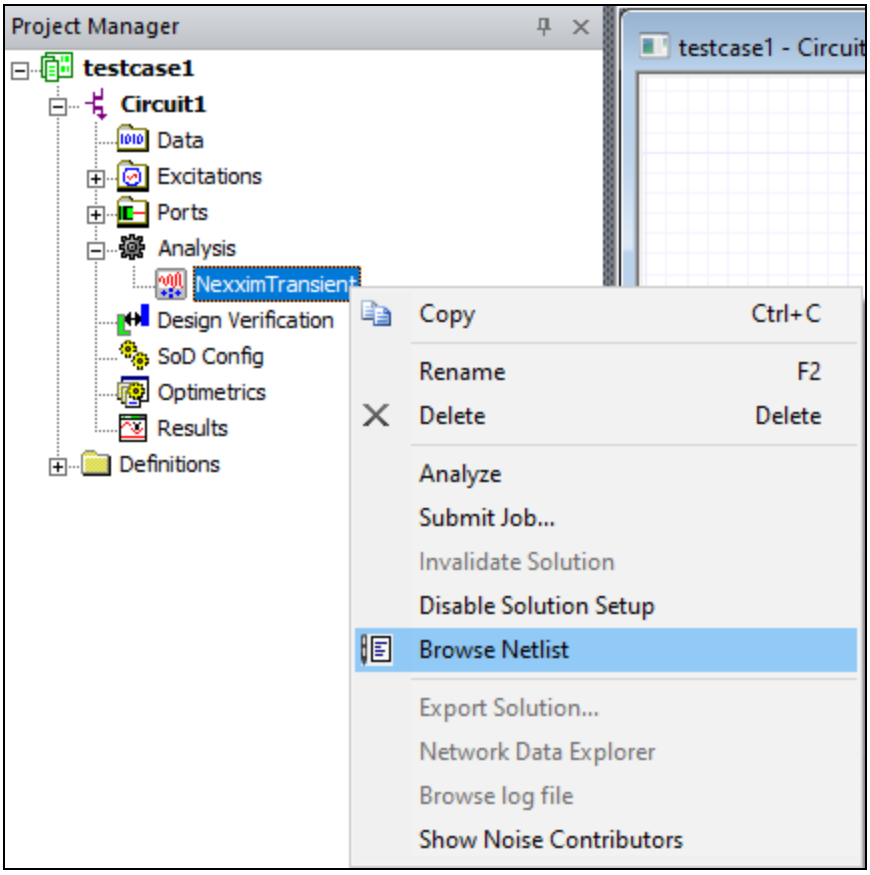
The procedure is complete.

Confirming ADPE is Active

Complete these steps to confirm the **Augmented Data Passivity Enforcement** feature is active.

1. Assuming a **Nexxim Transient analysis** has been added to the design, from the **Project Manager** window, expand the **Project Tree** > [*active design folder*] > **Analysis**. Then right-click **NexximTransient** and select **Browse Netlist** to open the **Netlist** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. From the **Netlist** window, search for **enforce_adpe=1**, which indicates that the ADPE feature is active.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Convex Programming Method for Passivity Enforcement

The convex programming method (**s_element.passivity_enforcement=1**) enforces passivity by constraining the transfer function to be positive real (Passivity Reference [1]).

By the Bounded Real Lemma, the state-space system ABCD is passive if a positive definite matrix **K** >0 exists such that:

$$\begin{bmatrix} -KA - A^T K & -KB & -C^T \\ -B^T K & I & -D^T \\ -C & -D & I \end{bmatrix} > 0$$

The convex programming method preserves the poles from the original state formulation (state matrix **A**). The formulation is such that the estimate of matrix **B** is not needed. For a fixed matrix **A**, the method recomputes matrices **C** and **D** to minimize errors while observing the Bounded Real Lemma.

The convex method of passivity enforcement is guaranteed to produce a passive state-space realization, but is very slow and memory-intensive. Convex optimization requires computing the Hessian or second derivative matrix, with dimension $(P+Q)^2$ by $(P+Q)^2$, where P+Q is the total

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

number of input and output ports. The total memory requirement for the matrices is $(P+Q)^4$. The compute time to solve the matrices is $(P+Q)^6$. In practice, the exponential growth of the solution size limits the convex programming method to systems with the total number of ports (P+Q) less than or equal to 10.

Perturbation Method for Passivity Enforcement

The passivity by perturbation method is selected with (**s_element.passivity_enforcement=6**). With this method, passivity enforcement of scattering parameter data with larger numbers of ports is achieved by the perturbation of the singular values of the transfer function matrix.

The frequency-domain transfer function matrix **H** (jω):

$$\boldsymbol{H}(j\omega) = \boldsymbol{C}(j\omega\boldsymbol{I} - \boldsymbol{A})^{-1}\boldsymbol{B} + \boldsymbol{D}$$

is obtained on the transfer matrix fit to the S-parameter data *S(jω).*

The singular values of the transfer matrix σ[**H** (jω)] are the square roots of the eigenvalues of [**H** ^{H}(jω)**H** (jω)], where **H** ^{H}(jω) denotes the complex conjugate transpose of **H** (jω).

For passivity, the singular values of the transfer matrix must be less than or equal to 1 for all frequencies.

$$max(\sigma_i[H(j\omega)]) \leq 1 \qquad \forall\omega$$

The perturbation method is derived on the eigenvalue (modal) perturbation of [**H** ^{H}(jω)**H** (jω)], equivalent to the perturbation of the singular values of **H** (jω). Higher order terms are ignored. As a first step, the **D** matrix is passified to guarantee asymptotic passivity. Next, linear perturbation is applied iteratively to the **C** matrix, minimizing the norm of the perturbation and the transfer matrix deviation at each iteration.

Generally, a nonpassive singular value exceeds the threshold only over a range of frequencies. The method uses the slope of the curve at the points where the singular value crosses the threshold to determine the direction of the perturbation to be applied.

The perturbation method generates matrices of approximate size *k* * N* (P+Q), where N is the number of states and *k* is the number of singular values that are greater than 1. Thus, this method is applicable to systems with large numbers of ports.

Passivity Enforcement Actions for S-Elements and W-Elements

Special actions are taken for an S-element or a W-element when **enforce_passivity** is set to a nonzero value, in an instance statement, an **.option** statement, or a **.model** statement.

Actions for S-Elements

a. If **enforce_passivity** is set to a non-zero value in a frequency-domain analysis (LNA or HB analysis) and time domain modeling was not enabled a priori (i.e., there is no **.option** statement for **time_domain_s_model=1**), then Nexxim enables time-domain modeling and switches to state-space modeling. The following warning message is issued:

```
Passivity enforcement requested for one or more S-elements during a
frequency-domain analysis. Switching to state-space modeling.
```

b. If passivity is enforced (**enforce_passivity** is set to non-zero) but the **convolution** option is 1,2, or 3, then the request for passivity enforcement is ignored and convolution proceeds. The following warning message is issued:

```
Passivity enforcement not supported for convolution models.
Proceeding without passivity enforcement.
```

c. If **enforce_passivity** is zero and a frequency-domain analysis is run with **convolution** option 1, 2, or 3, the convolution options is ignored. Note that the option **time_domain_s_model=1** has no effect on the analysis in this case, since that option is valid only for state-space models, not for convolution models. The warning is:

```
Convolution modeling (convolution options 1, 2, and 3) ignored during
frequency-domain analysis.
```

Actions for W-Elements

a. If **enforce_passivity** is set to a non-zero value, and the default value of the **dc_only** option is not over-ridden, and a frequency-domain analysis (LNA or HB analysis) is chosen, then Nexxim enables time-domain modeling and switches to state-space modeling. The following warning message is displayed:

```
Passivity enforcement requested for one or more W-elements
during frequency-domain analysis. Enabling time-domain model.
```

b. If **enforce_passivity** is set to a non-zero value and the default value of the **dc_only** option is over-ridden, then Nexxim ignores the **enforce_passivity** option. The following warning message is displayed:

```
Request for passivity enforcement for W-elements ignored
when only DC solution is needed.
```

c. If passivity is not enforced, time-domain modeling is enabled, and the **dc_only** option is set to 1, then time-domain modeling is deactivated. The following warning message is displayed:

Definitions

What is Causality?

Causality is a property of a system which ensures that output does not come before input (i.e., the output from the system at any instance depends on present and past inputs, not on future inputs).

What is Passivity?

Passivity is a property of a (causal) system which ensures that maximum singular value of each S - parameter is less than 1. Thus, the system is lossy and is not generating power on its own.

What is a fitting error?

When performing transient simulations with S-parameter data extracted in frequency domain, the transient solver must convert the S-parameter data into a suitable quality macromodel (i.e., a Nexxim state space model). The resulting state space model is fitted to the extracted S-parameter data. The extent of error between the S-parameter data and the fitted state space model is called the fitting error.

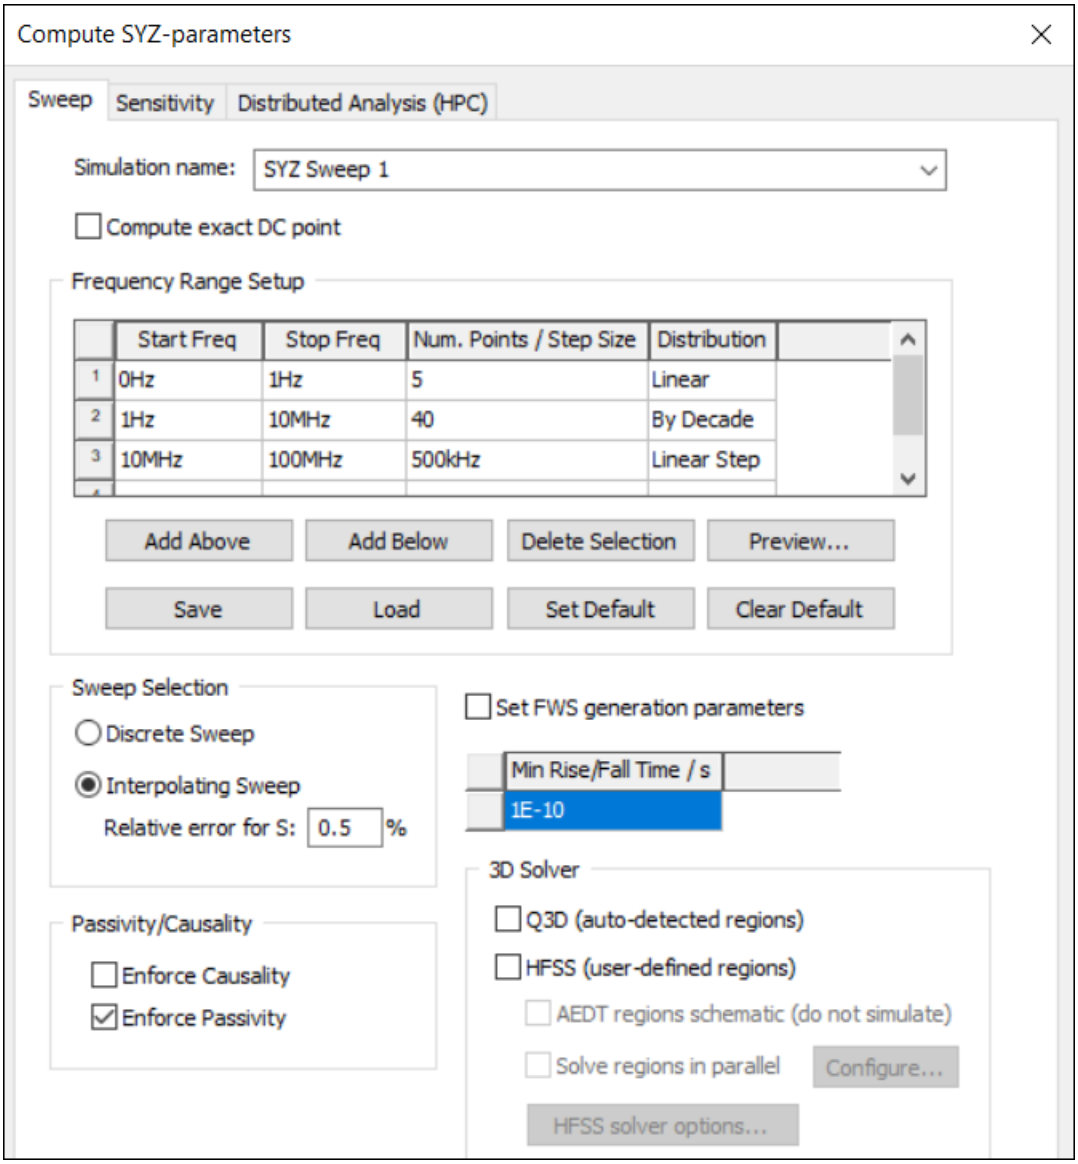
Introduction

Passivity and Causality are two critical properties that decide the quality of an S-parameter data extracted from any field solver (e.g., SIwave, HFSS, Q3D etc.). They are necessary conditions (but might not be sufficient) for expecting a good fitting experience (i.e., low fitting error) when generating a broadband macromodel for a transient simulation. While the notion of causality and passivity is valid for the entire frequency range from -infinity to +infinity, the user will typically sample bandlimited data (e.g., from 0 Hz to 1 GHz, with a certain step size or distribution). Trying to make bandlimited data causal and passive can result in the fitting error worsening when trying to convert the data into a state space model for transient simulations. The following sections will explain some of the scenarios and fitting experiences the user may encounter.

Impact of Type of Frequency Sweep

Assume there is a PCB inside SIwave for which the user is trying to extract S -parameter data using SYZ analysis. Some of the settings inside SYZ analysis play a major role in the quality of the exported S-parameter data.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



A discrete sweep solves the structure for the field solution at all the frequency sweep points given. An interpolating sweep solves selective points in the sweep based on an adaptive frequency sampling (AFS) algorithm. Then, based on the smaller number of solved points (i.e., basis points), the sweep interpolates the S-parameter data values of the remaining unsolved points in the sweep until the desired interpolation error is achieved. An Interpolating sweep is more suitable when the frequency range is wide, and the frequency response is smooth aside for a few resonances (i.e., most EMI/EMC applications). In those circumstances, an interpolating sweep will extract a reasonable matrix in a reasonable simulation time.

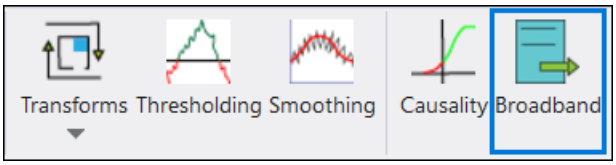
An interpolation sweep is performed in two ways: one that goes through every basis point and then interpolates out to the set of unsolved points (default, when the “Enforce Causality”

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

checkbox is unchecked), and does not guarantee causality or passivity, and the other, which does a casual rational fit to the set of basis points and then interpolates (activate by checking the box for “Enforce Causality”), which also does not guarantee passivity. By checking the “Enforce Passivity” option within an interpolating sweep, the user is guaranteed that the field solver will generate causal and passive S-parameter data.

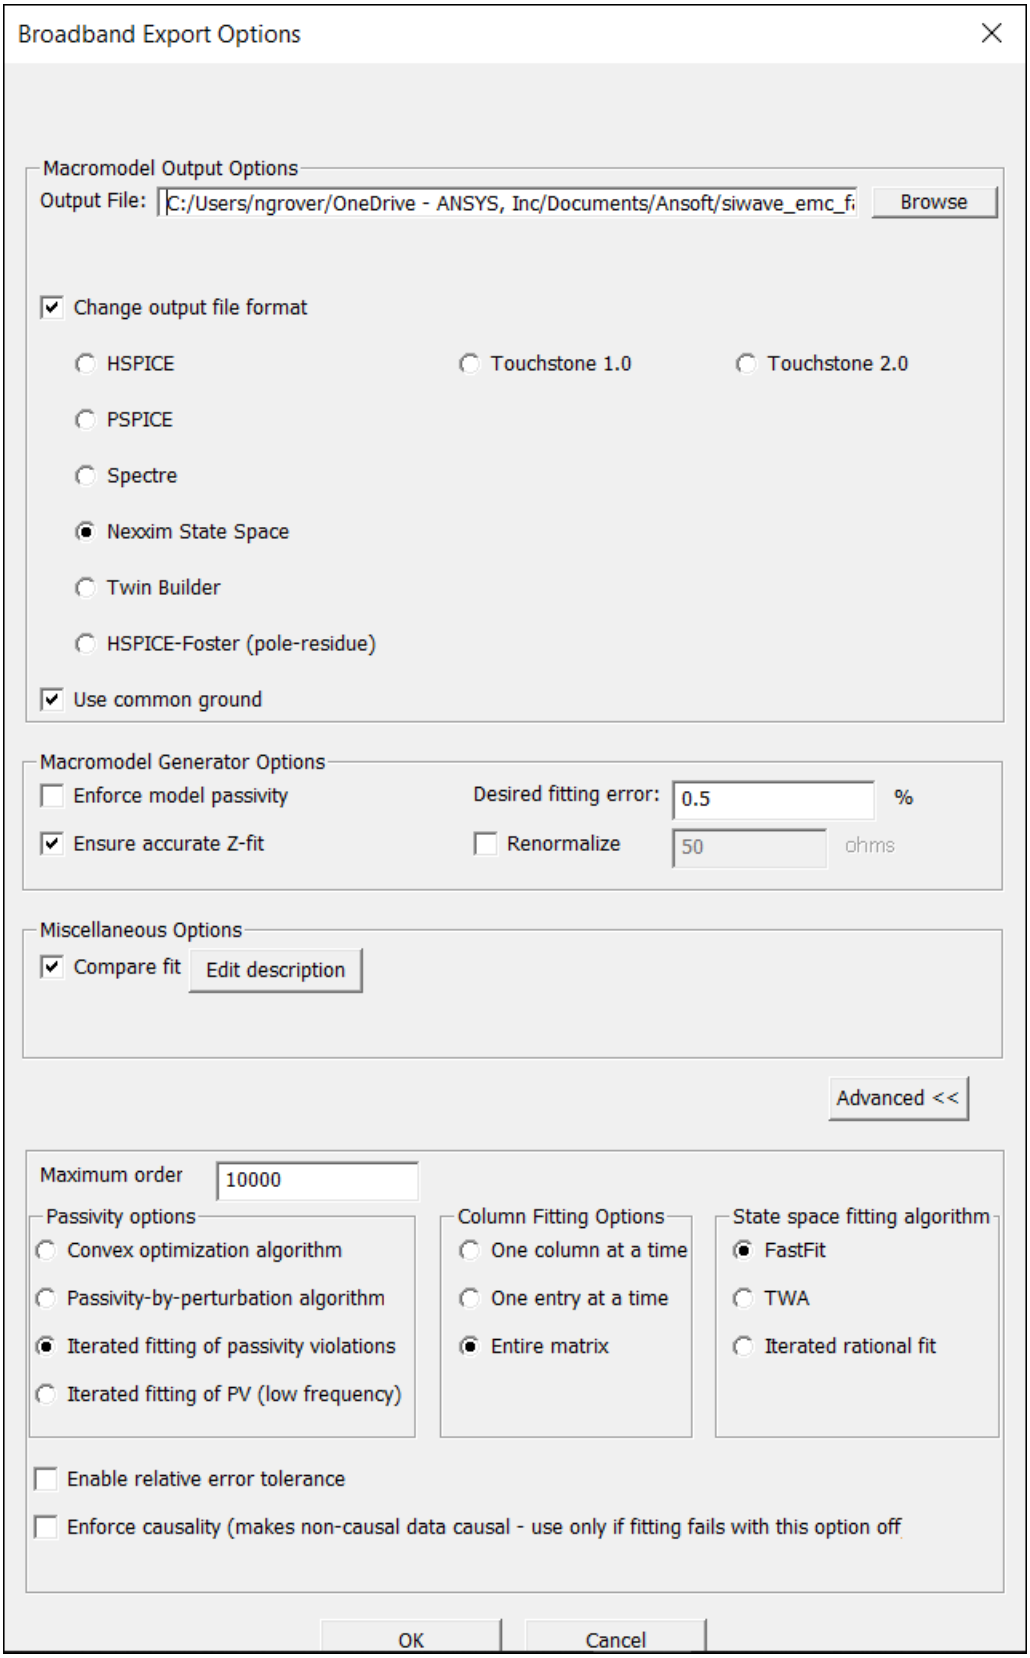
How to Check Causality, Passivity & Fitting Error

Use **Network Data Explorer** (NDE) to view the aspects described in Section III., such as the quality of data fitting. Upon reviewing the exported S-parameter data in NDE, review the causality of the data when it is exported into a macromodel (i.e., state space model) by clicking Broadband in the top ribbon of NDE (shown in the following screenshot).



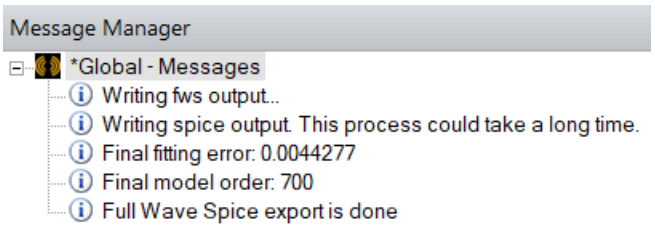
Once the default settings and format are selected for a Nexxim state space model, generate the macromodel via the **Broadband Export Options** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



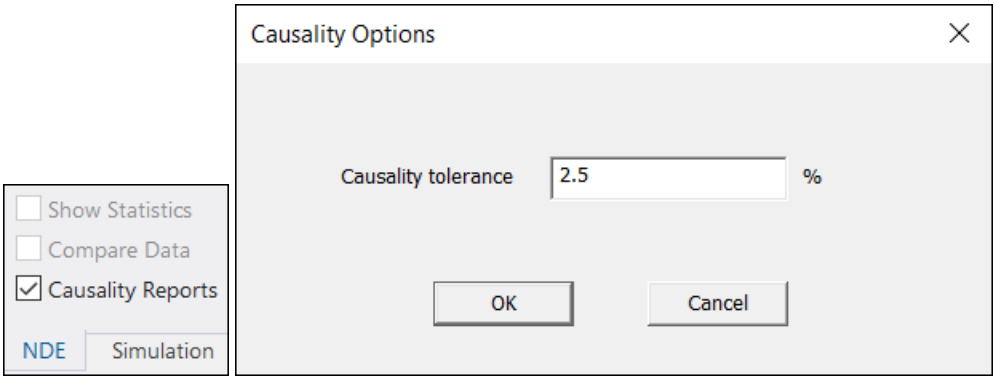
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once the macromodel is generated, the final fitting error will be displayed in the **Message Manager** window (shown in the following screenshot).



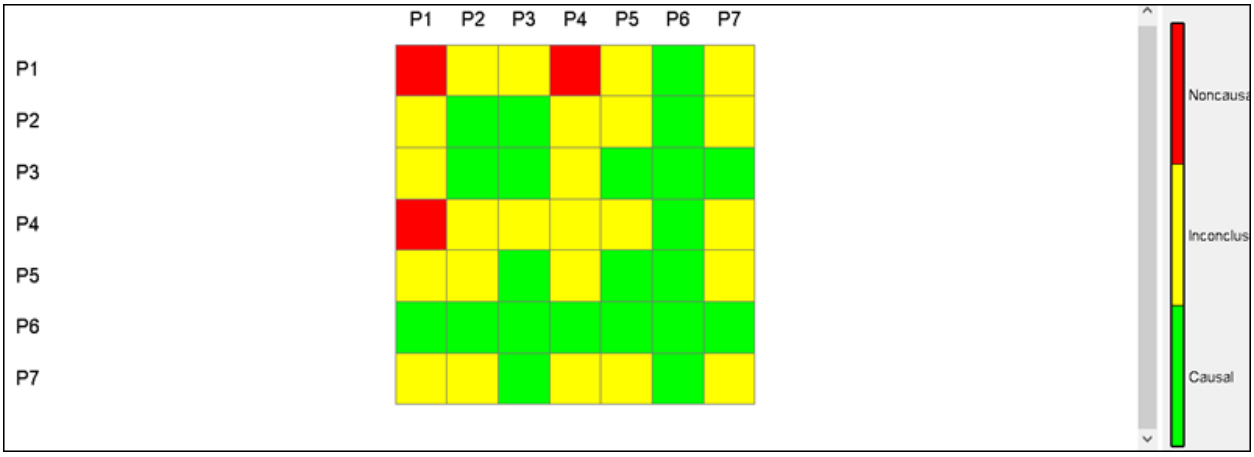
In this example, the final fitting error is 0.0044277 or approximately 0.44%. The macromodel is causal with respect to the fitting error tolerance of 0.5% set during export. The final fitting error could potentially exceed 0.5% which would mean, with a threshold of 0.5%, that the macromodel is not causal. The tolerance could also be altered (e.g., set to 0.1%, 1%, etc.) for double-checking the causality of a macromodel with tolerances lower and higher than the default 0.5%. Sometimes, tightening or loosening the tolerance gives a better fit. The latter works because a lower (i.e., tighter) fitting tolerance, the software may try to over fit the data and, in the process, destroy the fitting quality of the macromodel. This could result in, for example, many (out of band) passivity violations.

The following screenshot demonstrates one method for checking causality.



This method yields a colored plot (following). The data is causal, non – causal, or inconclusive.

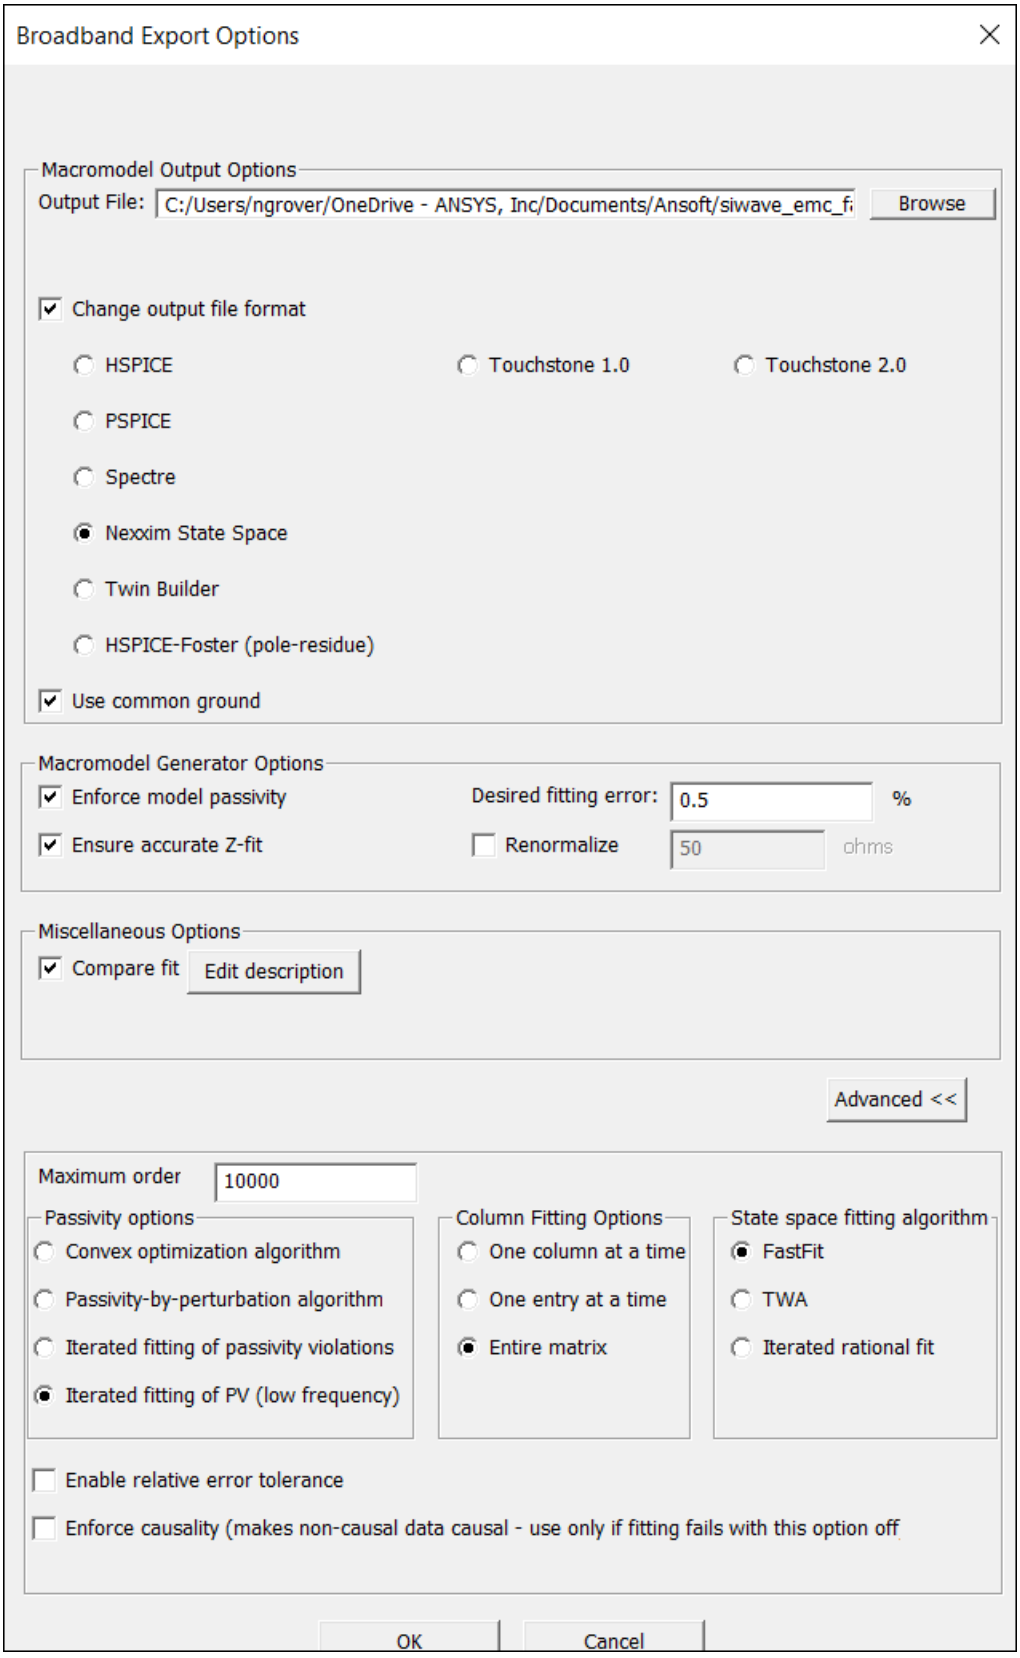
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note that the colored plot is also generated with respect to the tolerance set by the user (in this case, the default fitting error is 2.5%). There is no direct correlation between the tolerance of 2.5% here and 0.5% fitting error set in the Broadband Export Options window. Use this example for guidance, to see where the data is not meeting causality once the fitting error check returns a bad result. This example should not be used as a final basis to check for causality. Once the macromodel is created and returns a satisfactory causality check result, it returns to the Broadband Export Options window.

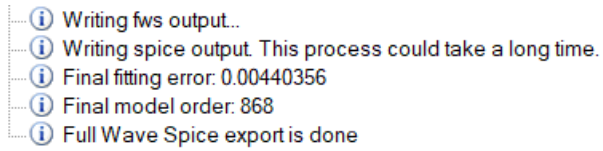
This time, check the **Enforce model passivity** box and select **Iterated fitting of PV (low frequency)** from the Passivity options group box (i.e., IFPVLF), as shown in the following screenshot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

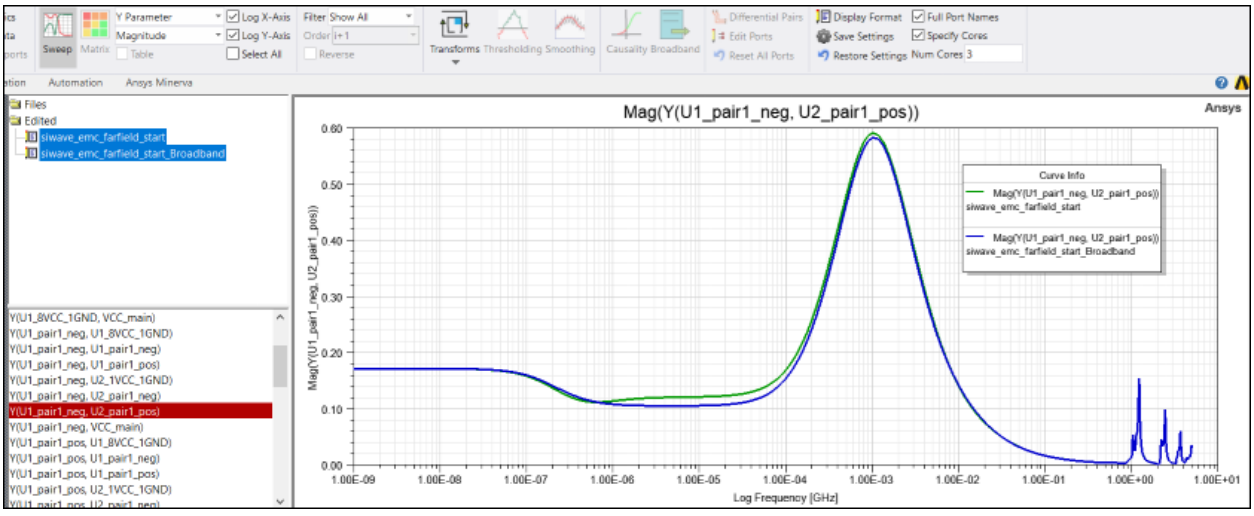
Once the new macromodel is generated, the final fitting error will appear again in the Message Manager window. Fitting error (with IFPVLF considered) will be displayed as in the following screenshot.



If the error is below the fitting tolerance of 0.5%, the generated macromodel is causal and passive. Subsequently, the macromodel can be utilized for the next step of transient simulation. A final fitting error below the fitting tolerance is a necessary condition for a good fitting experience but may not be sufficient when generating a broadband macromodel for a transient simulation. It must be ensured that the transient simulation functional output makes sense.

Consider that though the original S-parameter data may be causal and passive, there is no guarantee that the resultant macromodel is going to remain passive. For example, assuming the user has the following data: 1.0, 1.0, 0.9999, 0.9999 and so on, at several frequency samples, and a rational fit is applied to this data, given that the data is causal and passive, and the target fitting error is 0.5% or 0.005. The resulting fit would be: 1.0049, 1.0049, 1.00001, 1.000001 and so on. Though the fitting error is better than 0.5%, the maximum singular value is 1.0049, which exceeds one. Hence, the result is non-passive. Though the data is causal and passive, the fit may not be.

What is important is what the macromodel fitting tool does with respect to the original S - parameter data. This can be done in NDE, using a “Y” parameter plot in magnitude (with log – log axis), as shown in the following screenshot. The green line is the original data, and the blue line is the fitted data:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Why IFPVLF?

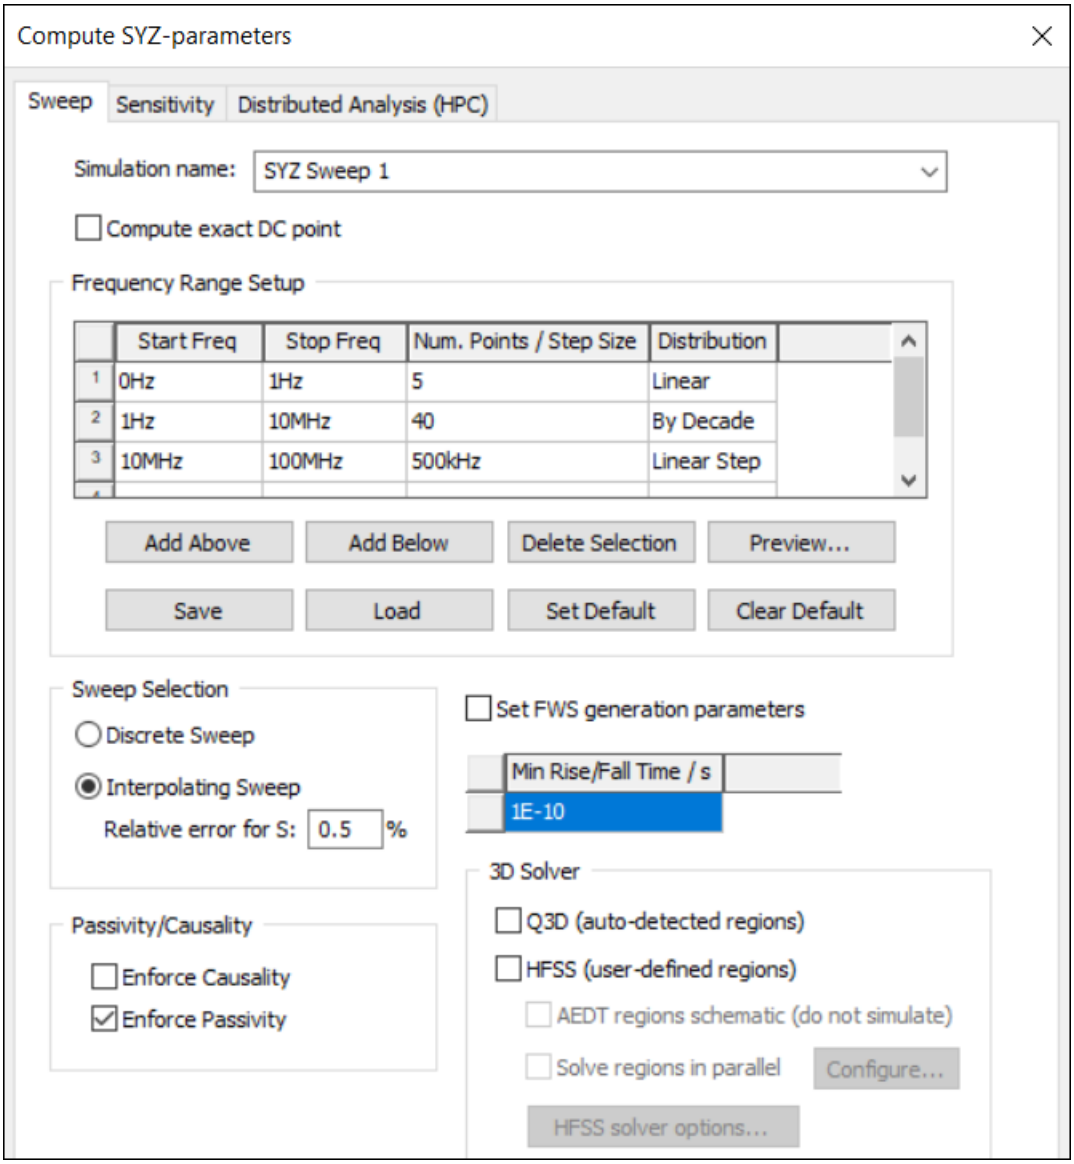
For many applications (e.g., EMI, EMC, etc.), the desire is to fit to S-parameter data while preserving the fit corresponding to “Z” or “Y” at DC and low frequency to minimize the inaccuracies in steady state results from transient simulations. IFPVLF increases the likelihood of optimal DC and low frequency fit. However, a weighting function (of frequency) to control the fit to low frequency is utilized, and the final fitting error to mid and higher frequency ranges may be less accurate.

Recommendations to Improve Causality, Passivity & Fitting Error

If the final fitting error is unsatisfactory for any tolerance the user sets. (e.g., anywhere between 0.1% and 3%), it is prudent to return to the field solver to incorporate some additional settings that may improve the fitting experience. The following are just some of the additional settings that should be considered:

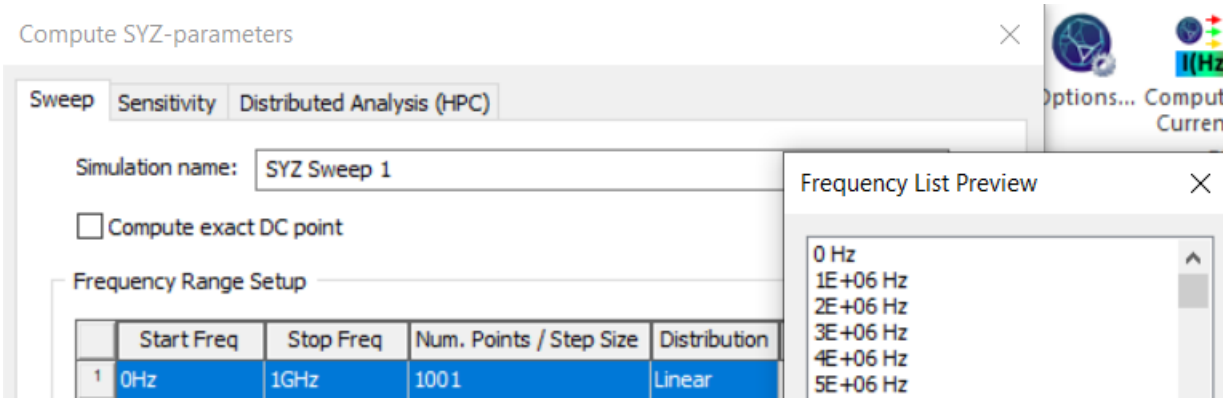
- Use of causal material properties in a PCB stackup, in which the extracted data is also expected to be causal.
- Use the **Enforce Passivity** checkbox. For example, in SIwave, check the **Enforce Passivity** box and the solver will try and make data at the remaining unsolved points (in case of interpolating sweep) passive if they were not already. Then the user only needs to enforce passivity for the interpolation sweep.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

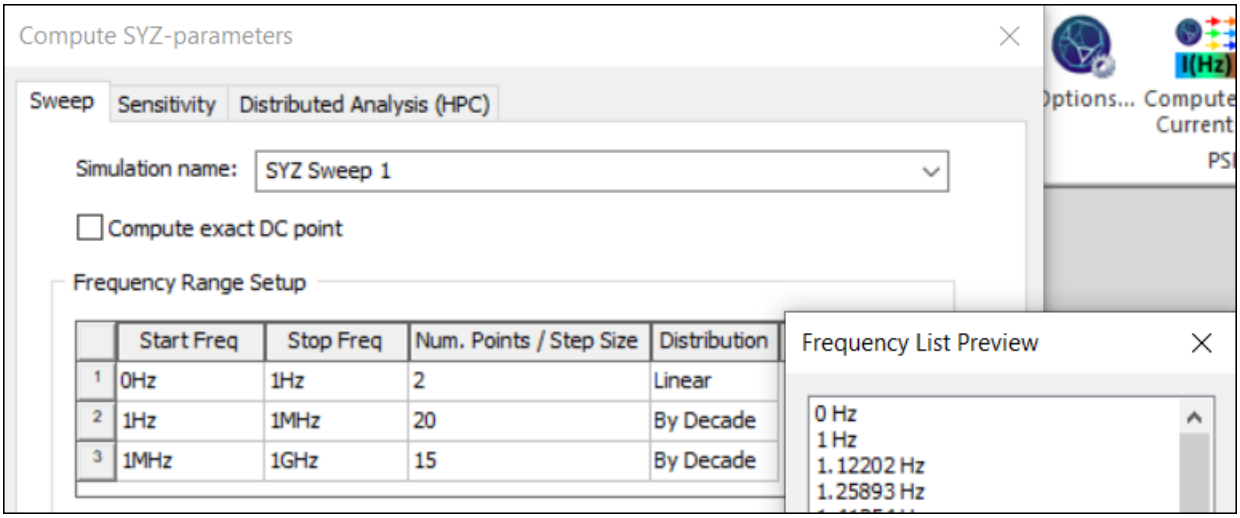


- Lower the interpolation error percentage tolerance. In SIwave analysis settings, the default interpolation error is 0.5%. Lower the interpolation error percentage to improve the S-parameter data. Lowering this tolerance will force the solver to solve a greater number of (basis) points. Reducing the relative interpolation error percentage tolerance is more effective if the number of steps is increased. However, increasing the number of steps will also raise the run time of the field solver.
- Refine and distribute the frequency range to properly cover the low frequency range instead of defining one single range up to the highest frequency. For example, one could define frequency range as shown in the following screenshot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Using this sweep, consider that passed the DC point of 0Hz, the next point is in a higher range (in this example, 1 MHz). There is low-frequency data missing, which could negatively impact the fitting later. The following screenshot demonstrates a sweep will result in a more even distribution.



- Increase the highest frequency of solving. Increasing the max frequency is potentially helpful depending upon the application.

  For example, running a transient simulation with a pulse and small rise time typically requires first ensuring the frequency data covers a bandwidth equal to a factor (e.g., two times one over the rise time).

  The robustness of the test in place (i.e., NDE) on causality of the scattering parameter data can potentially be improved by covering more of the data, since much of the uncertainty happens out of the band. The notion of causality and passivity should be understood on the whole real line.

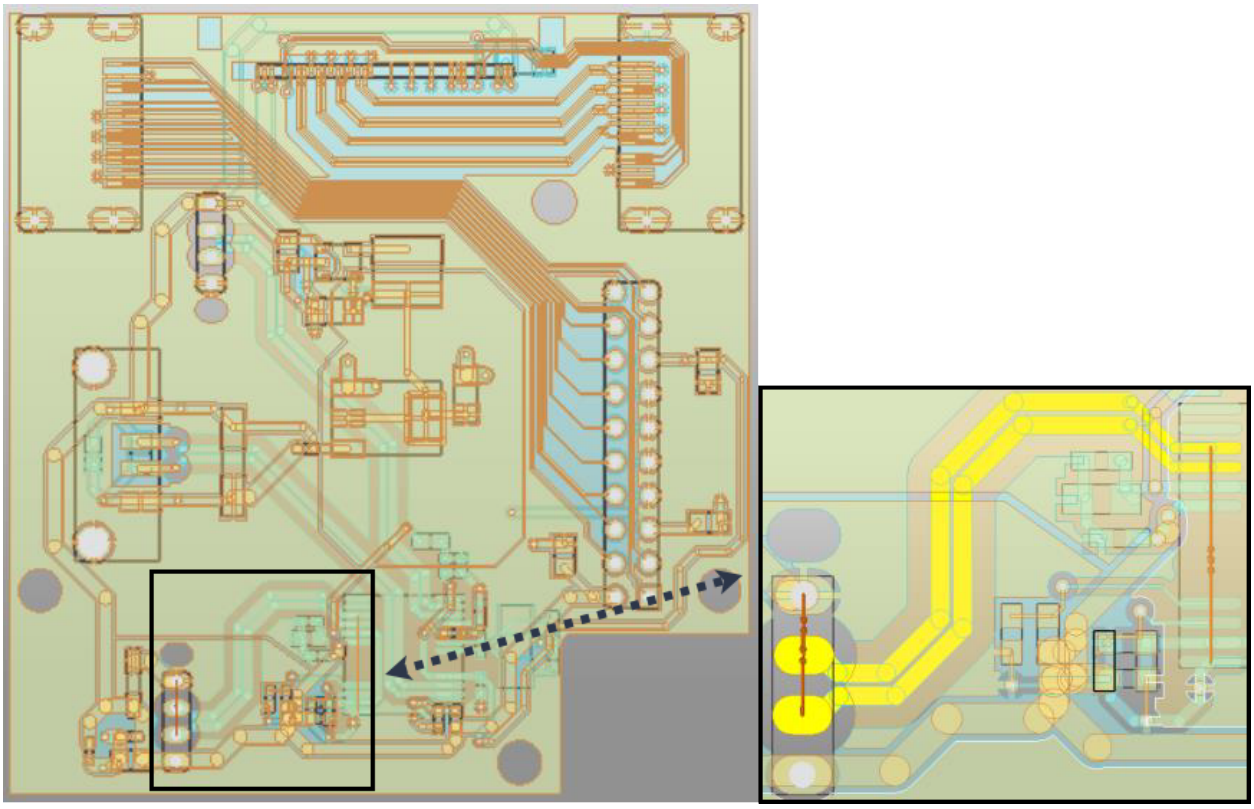
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For example, consider increasing the highest frequency of a sweep to 3 GHz, if it is currently 1 GHz.

What is important is what the software has done with respect to the original S-parameter data. This result can also be achieved in NDE first, for exploration, by making sure the fit is adequate before running the project in a Circuit design for transient analysis.

PCB Example

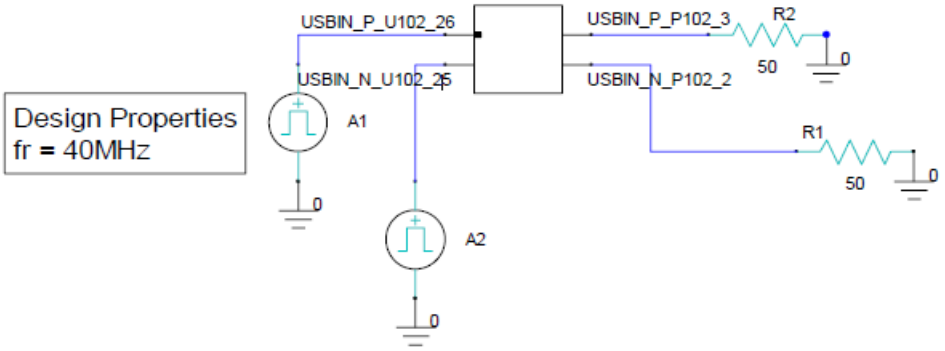
The following screenshots are of a simple PCB with four ports (on the two traces considered) for which the S-parameter model is extracted using SIwave.



When the user creates a Circuit simulation for transient analysis, they feed the two traces with a pulse source each of switching frequency 40 MHz and terminate the other end of the traces with 50 Ohms.

Apart from the touchstone model and the macromodel quality, different settings of extraction and broadband model generation affect the transient analysis output.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



After field solver (in this case SIwave) extraction, use Network Data Explorer (NDE) to check the model quality in terms of causality, passivity, and fitting error.

Tabulated below are some examples with different settings in SIwave (when exporting S-parameter data) and NDE (when exporting a broadband macromodel):

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

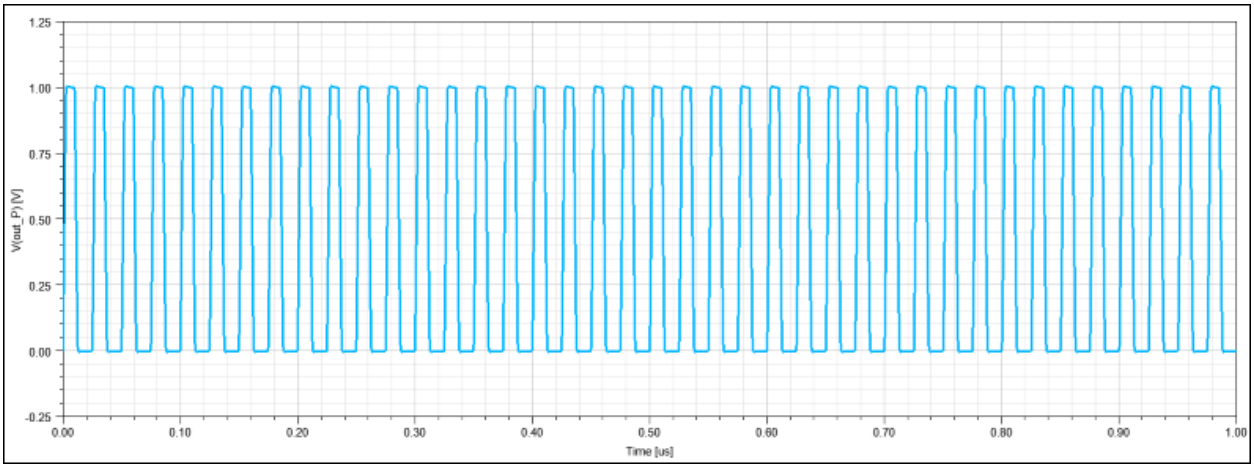
	SIWave				Network Data Explorer (NDE)		
S. No.	Interpolation Error Tolerance (%)	Causality/Passivity Enabled in Siwave	Highest Frequency in Siwave Sweep	Sweep Distribution	IFPVLF Yes or No	Fitting Error Tolerance (%)	Final Fitting Error (%)
1.	1	No	100MHz	0Hz-100MHz 51 Points (Linear)	No	0.5	1.46
2.	1	No	100MHz		Yes	0.5	1.38
3.	0.001	Yes	100MHz		Yes	0.5	0.46
4.	0.001	Yes	2GHz	0Hz – 1Hz: 5 points (Linear) 1Hz – 100MHz: 30 points (Decade) 100MHz – 2GHz: 1.5MHz (Linear step)	Yes	0.5	0.17
5.	0.001	Yes	5GHz	0Hz – 1Hz: 5 points (Linear) 1Hz – 100MHz: 30 points (Decade) 100MHz – 5GHz: 1.5MHz (Linear step)	Yes	0.5	0.19
6.	0.001	Yes	10GHz	0Hz – 1Hz: 5 points (Linear) 1Hz – 100MHz: 30 points (Decade) 100MHz – 10GHz: 1.5MHz (Linear step)	Yes	0.5	0.17

Consider the final fitting error of the models in S. No. 1 without passivity (IFPVLF) imposed, which is above the threshold of 0.5%. The model is not causal with respect to the threshold set.

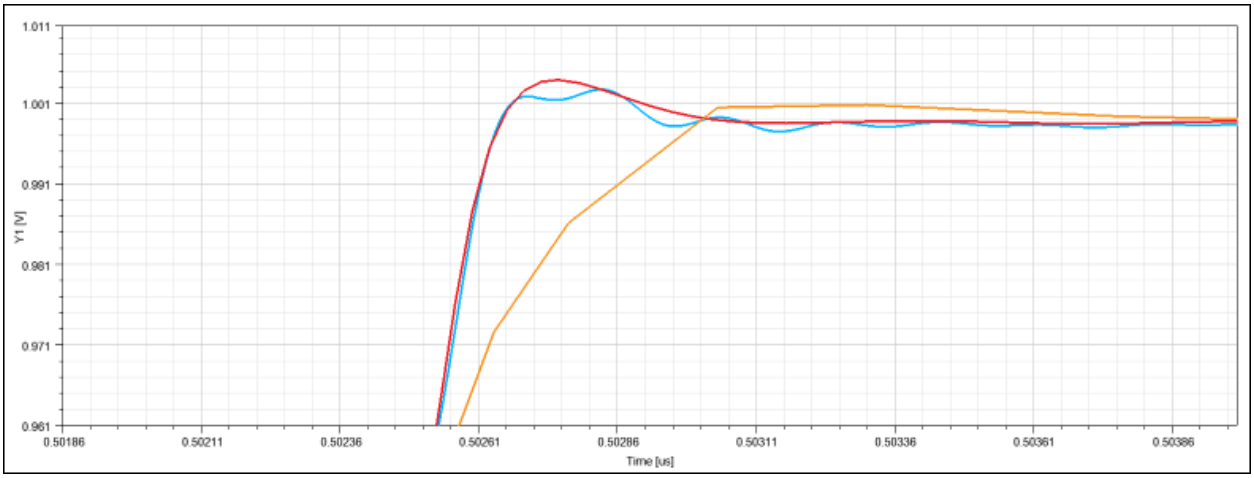
Consider models S. No. 2 through S. No. 6. Models S. No. 2 through S. No. 6. have final fitting errors with passivity (IFPVLF) imposed, but only models S. No. 3 through 6 are causal and passive. Subsequently, model S. No. 2 should not be used for transient simulation.

To confirm the transient simulation behavior from these models, monitor the voltage across the 50 Ohms load on the USBIN_P trace. A typical output waveform is shown in the following screenshot, but the section that follows focuses on one of the rising edges of the waveform.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



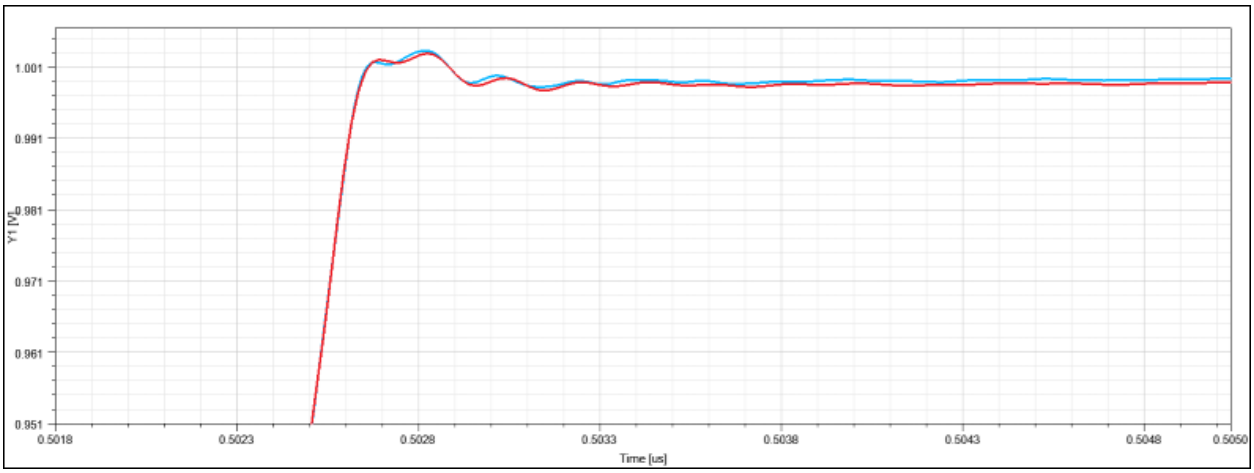
Between models S. Nos. 3, 4, and 5, the maximum frequency extracted in SIwave has been modified to 100 MHz (i.e., the orange line shown in the following screenshot), 2GHz (i.e., the red line), and 5GHz (i.e., the blue line) respectively. The change happening between the transient results of these three models is also shown. The blue line (i.e., 5GHz model) captures the high frequency content (i.e., the ripples) in the rising and falling edges of the voltage waveform more accurately. Thus, increasing the maximum frequency in SIwave extraction corrects the functional voltage output waveform, even though all three models were causal and passive (having final fitting errors below 0.5% threshold).



The only difference between models S. No. 5 and 6 is in the maximum frequency extracted in SIwave, 5GHz (i.e., the blue line in the following example) and 10GHz (i.e., the red line), respectively. Since the transient results of these two models are a trivial difference, it is unnecessary to increase the maximum frequency of extraction beyond 5 GHz. The functional output voltage has started to converge to the correct waveform even with the 5 GHz model.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

With a 40 MHz switching source, as shown in the previous screenshot, the maximum frequency of 100 MHz may be insufficient to capture all the switching dynamics. Depending on the application and switching frequencies, the impact of choosing the maximum frequency in the sweep is shown in the following screenshot.



Conclusion

Depending on the model and the desired frequency range, one or a combination of the above recommendations may be required to improve the fitting experience and/or the transient functional outputs. A fundamental understanding of these concepts is important for appropriate analysis.

FAQs

Q1. Is it guaranteed that the discrete sweep in our field solvers will always generate causal and passive S-parameter data?

Answer: This is more expected than guaranteed. For example, if a frequency dependent dielectric (loss) material is not provided by the user, then the calculated discrete sweep S - parameter data could end up being non - causal. However, using the Debye or Djordjevic-Sarkar models will ensure that does not happen, resulting in causal S-parameter data. There have not been any cases reported of non - causality of S - parameter data with discrete sweep using our field solvers. However, as the causality property will depend upon the frequency range and number of points in the sweep giving rise to bandlimited discretized S - parameter data, the above answer is subjective.

Q2. How is the causality check used if the check shows the data is not causal within the tolerance specified? Does this indicate that the S-parameter data is unsuitable?

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Answer: Causality and passivity should be considered in the whole real line, from -infinity to +infinity in continuous domain. For example, if the S-parameter data received is discrete bandlimited and the user needs to know whether the sampled bandlimited S-parameter data is causal, then causality is here understood with respect to a prescribed threshold. This threshold should have a correlation to the state space fitting error which uses a causal rational function to fit to the same S-parameter data. Therefore, the best measure of causality relative to a target fitting error (default is 0.5%) is whether the solver produces a better fit than the target fitting error. Meanwhile, the causality checker considers the contributions of discretization error (i.e., the error between samples) as well as the unavailable S -parameter data (i.e., the data outside of the band), by using a tight (upper) bound accounting for the missing data.

Q3. Does a low fitting error below the set threshold guarantee a better macromodel for transient simulation?

Answer: Even models with 100 MHz (i.e., S. No. 3 in the Section VII table) or 2 GHz (i.e., S. No. 4 in the table) - maximum extracted frequency were causal and passive and had a fitting error below the set threshold of 0.5% were not guaranteed the most accurate transient output. Low fitting error is only an indication of how well the solver is working to produce a macromodel that fits the original S-parameter data. Whether the original S-parameter data is of optimum quality (in terms of frequency points, maximum frequency, etc.) needs to be considered.

Convolution Method

By default, Nexxim transient analysis of S-parameter elements uses a state-space formulation.

Setting option **s_element.convolution** to 1, 2, or 3 sets Nexxim to use convolution rather than state-space matrices to model the behavior of S-parameter elements during transient analysis.

The convolution method converts the frequency-domain parameters into time-domain impulse responses. The impulse responses are directly applied in transient simulation via the convolution integral. See Convolution References for further information.

Upon completion, Nexxim reports the error in the least-squares convolution fit. Errors greater than 0.1 suggest non-causality in the S-parameter data. Convolution may also yield inaccurate results without any warning. Several modifications to the data may improve the quality of the convolution response:

- Provide linearly spaced frequency points in the S-parameter file.
- Include DC in the S-parameter file.
- Provide as large a frequency range as possible.
- Avoid sharper-than-necessary input waveforms in the netlist.

The **convolution** options control the generation of the impulse response. **Convolution=1** is recommended. **Convolution=2** and **3** are for advanced users.

- **convolution=1**: The impulse response is a piecewise linear waveform, with breakpoints chosen to exactly match the given frequency-domain data. This setting gives the most accurate response, but may have passivity violations just above the frequency band of interest.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When **convolution=1** has been enabled, setting the S-element parameter **DELAYHANDLE=1** enables convolution to incorporate propagation delay for that element.

> **Note:**
>
> The HSPICE S-Model parameter **DELAYHANDLE=1** has the same effect as option **convolution =1**.

- **convolution=2**: The impulse response is a train of impulses in the time domain, given by the inverse Fast Fourier Transform. This setting yields an impulse response that is accurate in-band and usually passive. However, the transient waveforms may have discontinuity effects.
- **convolution=3**: The impulse response is the linear interpolation of the inverse FFT results. This setting yields an impulse response with a low probability of passivity violations, but there is significant filtering toward the top of the frequency range of the input data.

The **convolution=1**, **2**, **3** options apply the convolution method globally to all S-parameter models in the design. The **convolution** option can be overridden in a particular model by setting model parameter **CONVOLUTION**. The setting of a **CONVOLUTION** model parameter overrides the global option **convolution** setting for S-element instances that reference the given model.

Reference Nodes on S-Parameter Elements

When an S-parameter element is inserted into a schematic, the import window allows you to specify a reference node. You may choose:

- **Implied reference to ground**: the global ground is the reference port for each N port connection. Its voltage is always 0V.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Common reference port**: an additional reference pin is added that is a common reference for the definition of port voltages. This reference can have any voltage and corresponds to the net for that extra pin.
- **Add individual hidden reference pin per port**: an additional reference pin is added for each port. These reference pins are hidden, set to 0V by default, and can each have their own reference voltage. You can connect each reference pin to its own net. Select this option if you do not want to see the reference pins.
- **Add individual reference pin per port**: an additional reference pin is added for each port. Every reference pin can have its own reference voltage and be connected to its own net.

Nexxim does not make any adjustments to the S-parameter matrix when **Implied reference to ground** is selected or when **Common reference port** is chosen , then connected or shorted directly to ground in the schematic.

When a **Common reference port** is unconnected or is connected to ground through a resistor, Nexxim uses matrix operations to adjust the S-parameters. When a **Common reference port** is left unconnected, Nexxim connects the port to ground through a resistor with value 10^{12} ohms. If there are individual reference pins, Nexxim adjusts the S-parameter matrix to be twice the size to accommodate the connections to these reference pins.

The following formulas are for the frequency domain at a single frequency.

It is convenient to convert from S-parameters to the equivalent Z parameters. The Z-matrix takes the vector of input currents into the vector of terminal voltages: V = Z x I.

Suppose that the S-parameters all have a common reference impedance Zref and that the resistor inserted between the reference node of the S-parameter block and ground is of value R>0.

Let matrix **A** be the 2x2 matrix with the value R/Z_{ref} in each of the four locations. The effective Z-matrix of the structure with the resistor $V_{eff} = Z + A$.

Put in the form of matrix manipulations for the S-parameters:

$$S_{\text{eff}} = \frac{\frac{I+S}{I-S} + A - I}{\frac{I+S}{I-S} + A + I}$$

where ***I*** is the 2x2 identity matrix.

Noise in S-Parameter Elements

By default, DC and frequency-domain analyses of S-parameter models look in the Touchstone file for noise data. If the file does not supply external noise data, an internal noise model generates the noise data. The S-Element option and instance parameter **NOISEMODEL** selects the noise data source:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Use external data if present, or the internal noise model when no external data is present.
- Use only the internal noise model.
- Turn off all noise calculation.

Nexxim Internal Noise Model

In Nexxim, a noisy electronic circuit is modeled as a noiseless circuit plus external noise sources for which certain noise characteristics are known. The noise sources are represented as current sources, which are defined in terms of a so-called $\mathbf{S}_{xx}$ matrix. The $\mathbf{S}_{xx}$ matrix for a two-port device states the noise behavior at a frequency point as:

$$S_{xx} = \begin{bmatrix} \overline{i_{n_1}^2} & \overline{i_{n_2} i^*_{n_1}} \\ \overline{i_{n_2} i^*_{n_1}} & \overline{i_{n_2}^2} \end{bmatrix}$$

where $i_{ni}i_{nj}$ is a noise correlation factor between currents i and j.

The TouchStone format allows for noise specification of circuit devices of up to two ports. The noise characteristics are :

- Minimum noise figure (F_{min}) in dB.
- Source reflection coefficient to realize F_{min} (Γ_{opt}), specified in the Touchstone file as two values, magnitude and phase.
- Normalized effective noise resistance (r_n).

dru

All of these parameters are specified against frequency. The parameter Γ_{opt} is a complex VALUE, . The noise characteristics are specified as a noise block appended after the S-parameter block in a TouchStone file, formatted according to the TouchStone standard. Nexxim performs a transformation on the noise parameters found in the TouchStone file to the noise matrix S_{xx}, as explained in Gonzales [1984] (Reference [1] in the S-Parameter General References).

In the Nexxim internal noise model, circuit noise is inferred on the S-parameters.

Noise Example

Here is a shortened example of a two-port Touchstone file with noise data:

```
!2-port S-parameter file with noise data
# GHZ S RI R 50.0
```

8 2.7 0.46 -33 0.40
```

Interpolation and Extrapolation of Frequency-Dependent Data

Data may not be available at each frequency point of the simulation. Consequently, the data may require interpolation or extrapolation to produce information at the necessary frequencies.

When the S-parameter data have a low top frequency compared to the frequency content of the input signal, Nexxim extrapolates the data. The Nexxim standard transient solution for S-parameters incorporates a state-space formulation, which is guaranteed causal. This state-space formulation gives a natural extrapolation function, which is also causal. However, The Nexxim extrapolation function can differ on the functions provided by other simulators. Convolution-based simulators generally provide simple constant, linear, or windowing extrapolation functions. Such simple extrapolation functions are not causal, and therefore can give erroneous transient results.

- The designer can avoid the issue of extrapolation by extending the frequency range of the input S-parameter data well above the traditional signal integrity bandwidth of 0.35/risetime.
- The HIGHPASS and LOWPASS parameters on the S-element model control the extrapolation method. See *S-Model* in the Nexxim Components help.
- For interpolation, the S-element model in Nexxim has parameters for selection between LINEAR and STEP interpolation. STEP interpolation takes the interpolated value on the closest table entry that is lower in frequency that the current entry. LINEAR is the default. See *S-Model* in the Nexxim Components help.

Traveling Wave and Power Wave Formulas

There are two common definitions of the scattering matrix, *S*. One definition is based on traveling waves while the other is based on power waves. Traveling waves correspond to the inward and outward propagating solutions to the telegrapher equations (See References [1]). Power waves relate the power transfer in the inward and outward directions (See References [2,3]). The two definitions are equivalent if the characteristic impedances are real. However if the characteristic impedance is complex, important differences arise.

Both *S* parameter formulations define the relation between the outgoing waves **b** and the incoming waves **a**, or more specifically:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$b = Sa$$

The difference is whether to choose traveling waves or power waves for **a** and **b**. For this derivation, consider voltage traveling waves. There are also current traveling waves and many different normalized voltage waves; however, the most common is the voltage wave:

$$V(z) = V^{+}e^{-j\beta z} + V^{-}e^{j\beta z}$$

Use the subscripts *v* and *p* to denote voltage and power waves respectively. If voltage waves are chosen, which is typical for high frequency (HF) applications, $\mathbf{a}_V$ and $\mathbf{b}_V$ are:

$$a_v = V^{+} = \frac{V + Z_c I}{2}$$

$$b_v = V^{-} = \frac{V - Z_c I}{2}$$

where Z_C is a diagonal matrix of comprising the characteristic impedance of each port. The inverse transformation is:

$$\mathbf{V} = \mathbf{a}_v + \mathbf{b}_v$$
$$\mathbf{I} = Z_c^{-1}(\mathbf{a}_v - \mathbf{b}_v)$$

And if power waves are chosen, which is typical for circuit applications, $\mathbf{a}_p$ and $\mathbf{b}_p$ are:

$$\mathbf{a}_p = \frac{\mathbf{V} + Z_c \mathbf{I}}{2\sqrt{R_c}}$$
$$\mathbf{b}_p = \frac{\mathbf{V} - Z_c^H \mathbf{I}}{2\sqrt{R_c}}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where $R_c$is the real part of characteristic impedance, R_c= Re (Z_c) and where the superscript *H* denotes the Hermitian, or conjugate transpose. The inverse transformation of the power waves is:

$$\mathbf{V} = \frac{Z_c^H \mathbf{a}_p + Z_c \mathbf{b}_p}{\sqrt{R_c}}$$

$$\mathbf{I} = \frac{\mathbf{a}_p - \mathbf{b}_p}{\sqrt{R_c}}$$

The voltage based definitions yield the following familiar relationships between the network parameters:

$$S_v = (\overline{Z}_v - I)^{-1}(\overline{Z}_v + I)$$

$$\overline{Z} = (I - S_v)^{-1}(S_v + I)$$

$$\overline{Y} = (I + S_v)^{-1}(S_v - I)$$

where $\overline{Y}$ and $\overline{Z}$ are the normalized *Y* and *I* matrices and where *I* is the identity matrix. The power based definition yields more complicated expressions for network relationships:

$$S_p = R_c(Z - Z_c^H)(Z + Z_c)^{-1}R_c^{-1}$$

$$S_p = R_c(I - Z_c^H Y)(I + Z_c Y)^{-1}R_c^{-1}$$

$$Z = R_c^{-1}(I - S_p)^{-1}(S_p Z_c + Z_c^H)R_c$$

If the characteristic impedance is completely real (Z_c= $Z^H{}_c$ = R_c), there is no difference between the two definitions. Only a significant imaginary part to the characteristic impedance can cause a noticable difference. If there is an imaginary part to the characteristic impedance, the voltage based definition can yield S parameters greater than unity. This occurs if the reactance of the load has the opposite sign of the line (e.g., the load is inductive and the line is capacitive). It is important to note that this is not wrong, just counter-intuitive. Connect the device to other components within a circuit simulator to get the correct answer.

There are two significant drawbacks to the power based S parameters [" Traveling Wave and Power Wave References" on the next page 4,5]. A waveguide in cutoff has a characteristic impedance that is completely imaginary (R_c= 0); hence the S parameters are undefined. The concepts of normalized impedance and normalized admittance are not applicable to the power

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

based S parameters; in the numerator, normalize with respect to Z^H_c , but in the denominator, normalize to Z_c. This means that the Smith chart cannot be used to convert power based S parameters to the network parameters *Y* and *Z*. The Smith chart only works with voltage wave or traveling wave S parameters.

Running State-Space Fitting on the Command Line

You can operate the Ansys state-space fitter on the command line. Use the executable `genequiv.exe` which is available in the **Electronics Desktop** installation directory, most commonly `"C:\Program Files\ANSYS Inc\v252\AnsysEM"`.

Command Line Syntax:

```
genequiv [options] "<input_file>" -o "<output_file>" -s
<subcircuit_name>
```

Input file:

Input_file is the file name of input Touchstone S-parameter file. Put quotation marks around the path to accommodate any spaces in the path or file name.

Output file:

Output_file is the name of the model output file that is written to the same directory as the input file. A model_name must always be specified but is overridden if the **-o** option is used. Put quotation marks around the path to accommodate any spaces in the path or file name.

Sub-circuit name:

Subcircuit_name is required when generating SPICE-type equivalent circuits. It is not required for passivity and causality checking operations.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

General Options:

All options can be specified with either a single leading dash (-help) or two dashes (--help).

- **-built**

  Display the version, build date, and time. A synonym for **-v** and **-version**.

- **-h**

  Lists the flags that genequiv accepts and their descriptions. A synonym for **-help**.

- **-help**

  Lists the flags that genequiv accepts and their descriptions. A synonym for **-h**.

- **-v**

  Display the version, build date, and time. A synonym for **-built** and **-version**.

- **-version**

  Display the version, build date, and time. A synonym for **-built** and **-v**.

State-Space Fitting Options:

- **-colfit**

  Fits the entire S-matrix using a common set of poles. **-matfit** by default.

- **-entryfit**

  Fits a unique set of poles for each entry of the S matrix.

- **-matfit**

  Fits the entire S-matrix using a common set of poles. See **-colfit**.

- **-maxp** <integer>

  Sets the maximum number of poles to use per matrix entry. 10000 by default.

- **-method** <integer>

  Sets the method to be used for the state-space fitting. Acceptable values are:

  0 for old iterated rational fitting, depricated.

  1 for TWA

  2 for FastFit. This is the default value.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **-mp** <integer>

  Specifies the number of threads to use for multiprocessing. The default is half of the total number of cores available in your computer.

- **-relerr**

  Enforces per-entry relative error tolerance when performing a state-space fitting. False by default.

- **-tol** <double>

  Specifies the error tolerance for the state-space fitter. Set a double value and is 0.005 by default.

- **-zfit** <integer>

  Improves fitting accuracy for Z-parameters. Acceptable values are:

  0 for deactivate.

  1 for activate. This is the default value.

Passivity Enforcement and Checking Options:

- **-checkpassivity**

  Performs a passivity check on the input data and can be combined with **-checkcausality**. False by default.

- **-passive**

  Enables passivity enforcement via convex optimization. False by default.

- **-passive_ifpv**

  Enables passivity enforcement via Iterated Fitting of Passivity Violations (IFPV). False by default.

- **-passive_ifpvlf**

  Enables IFPV with enforcement of low-frequency fit. False by default.

- **-passive_pert**

  Enables passivity enforcement via Passivity-by-Perturbation (PBP). False by default.

- **-passive_rlfit**

  Enforce passivity on RL (GC) fitting (Pspice export only). False by default.

Causality Enforcement and Checking Options:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **-autorenormcc**

  Deprecated: activates automatic renormalization of S-parameters for causality check. False by default.

- **-causal**

  Enforce causality on the input data before performing state-space fitting. False by default.

- **-causality_plots**

  Forces the causality checker to write necessary data (into Touchstone files) to get causality plots in Network Data Explorer. False by default.

- **-causality_tol** <double>

  Specifies the error tolerance for the causality checker. This is 0.01 by default.

- **-cccontinuation** <integer>

  Controls whether the causality checker continues automatically when the default interpolation and integration types lead to an inconclusive causality check. Accepted values are:

  0 to deactivate continuation.

  1 to activate. This is the default value.

- **-ccintegration** <integer>

  Controls the integration method applied in the evaluation of the in-band data and the calculation of the discretization error bound. Accepted values are:

  1 for numerical integration. This is the default value.

  2 for analytic integration.

- **-ccinterp** <integer>

  Controls the interpolation method applied in the evaluation of the in-band data and the calculation of the discretization error bound. Accepted values are:

  1 for cubic spline interpolation. This is the default value.

  2 for rational interpolation.

- **-checkcausality**

  Performs a causality check on the input data and can be combined with **-checkpassivity**. False by default.

- **-causality_thresh**

  Error threshold for causality correction on RL model.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Output and Formatting Options:

- **-foster**

  Generates an HSPICE model in Foster (pole-residue) format. It must be paired with the **-hspice** option and is false by default.

- **-gndopt** <integer>

  Sets the ground reference type for ports. Accepted values are:

  0 for common (suppressed) ground. This is the default behavior. (Previously **-cg**)

  2 for one negative reference terminal per port. This was the old default behavior.

- **-hspice**

  Generates HSPICE-compatible circuit model (*.sp file). False by default.

- **-hspice_rfm**

  Experimental: Generates a state-space model in HSPICE rational function matrix format (*.rfm file). False by default.

- **-o** <string>

  Sets the output file name.

- **-printlog**

  Activates more verbose message printing on the state-space fitter. False by default.

- **-prof** <string>

  Specifies an output file for runtime statistics profile.

- **-pspice**

  Generates a PSPICE-compatible circuit model (*.lib file). False by default.

- **-s** <string>

  Sets the subcircuit name in the output file.

- **-simplorer_s** and **-simplorer_hfss**

  Generates a Simplorer S-element circuit model (*.sml file). False by default.

- **-spectre**

  Generates a Spectre-compatible circuit model (*.cir file). False by default.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **-sss**

  Generates a state-space model in Nexxim/Designer format file (*.sss). False by default.

- **-tstone** <string>

  Generates Touchstone V1 or V2 output file. You must specify a formatting control input file name.

- **-vrfy**

  Produces a Touchstone file and passivity report from fitted state-space model. False by default.

- **-vrfy_sss**

  Produces an additional Nexxim/Designer format file (*.sss) for comparing the fitted results with the original data. This SSS file is generated alongside the primary output file and is read by Network Data Explorer when it generates comparison plots.

Input Options:

- **-designname** <string>

  Sets the design name in the comment block if called from a desktop environment.

- **-i** <string>

  Sets the input file name.

- **-pnames** <string>

  Specifies a text input file containing the port names with one name per line.

- **-projname** <string>

  Sets the project name in the comment block if called from a desktop environment.

- **-projpath** "<string>"

  Sets the path to the project file that created the model. Place the path in quotes.

- **-reducename** <string>

  Sets the reduce matrix name for Q3D/2D Extractor projects.

- **-setupname** <string>

  Sets the solution setup name for desktop projects.

- **-sweepname** <string>

  Sets the frequency sweep name for desktop projects.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **-zrefs** <string>

  Specifies a text input file containing the port reference impedances with one per line.

Circuit Design File Formats

This topic contains descriptions of the file formats used by Ansys tools.

Related Topics

Circuit Netlist Format

Touchstone Data Format

Compact FLP Format

CITIfile Format

Ansys Neutral File (ANF) Format

Circuit Netlist Format

The circuit simulator reads the circuit description and the simulation controls from a netlist, which must be in ASCII format. The netlist can be created with a text editor and saved in a text file, which can be imported into the schematic for simulation. A Circuit Netlist Design can also be entered directly using the built-in Netlist Editor. A netlist is automatically generated from a Circuit design entered with the **Schematic Editor**.

Options and Controls

External Files

Netlist File Structure

A Circuit netlist specifies both the topology of a single circuit and the Circuit analysis to be run on the circuit, The netlist is parsed line by line. This topic describes the structural features of a Circuit netlist.

Input Lines

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The netlist file consists of one or more input lines. Each line starts with a non-blank character and ends with a standard (non-continued) carriage return/line feed (CR/LF). An input line can occupy as many physical lines as needed.

> **Note:**
>
> Except for external filenames, entries in the netlist are not case-sensitive.

Statements

The meaningful lines in a netlist file are called statements. Each kind of statement is interpreted according to its predefined syntax or format. (Statements are sometimes also called cards, a terminology recalling the time when a netlist consisted of a physical 'deck' of punched Hollerith cards.)

All statements except device instance statements begin with a period (**.**) followed by a keyword that identifies the type of statement.

TITLE and END Statements

The first input line in a netlist file is treated as the title of the netlist. The title appears at the top of all output files generated by the netlist.

The netlist can use a TITLE statement to identify the title:

.TITLE*title_text*

The title line can be a comment:

title_text

The title line can be a string enclosed in quotes:

'*title_text*'

The title line can be a normal input line without any special identification:

title_text

A netlist file ends when the physical end of file is reached. The netlist can use a END statement to delimit the end of the netlist.

.END

Any characters or lines in a source file after the END statement are ignored. However, an END statement in an INCLUDE or LIB file (See External Files) does not end the netlist. Only the END in the main source file terminates the parsing of the netlist.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

- The first line in a netlist file is always used as the title and any other meaning is ignored.
- A netlist file for the Circuit solver can contain only one circuit description. Multiple circuits in one netlist file are not supported.

MEASURE Statements

The MEASURE statement generates a value which measures a quantity in the simulation data. The MEASURE statement is supported in externally generated netlists. This topic describes the categories of available MEASURE statements, along with a description of the syntax that is supported.

Delay Measurements (OPDelay)

The syntax for delay measurements (time between events) is:

```
.MEASURE [DC|AC|TRAN] result trigger_spec target_spec
```

Where *trigger_spec* can be either:

```
+ TRIGoutput_varVAL=trigger_value|'expression'
 + [TD=delay|'expression']
+ [CROSS=crosses|LAST] | [RISE=rises|LAST] | [FALL=falls|LAST]
```

or

```
+ TRIGAT=begin_time
```

And *target_spec* can be either:

```
+ TARGoutput_varVAL=target_value|'expression'
 + [TD=delay|'expression'|TRIG]
+ [CROSS=crosses|LAST] | [RISE=rises|LAST] | [FALL=falls|LAST]
```

or

```
+ TARG AT=end_time
```

Functions Across Two Events

The syntax for measurements across two events is:

```
.MEASURE [DC|AC|TRAN] result
+ FUNCTIONoutput_varFROM=begin_timeTO=end_time
```

Where *FUNCTION* is **MIN**, **MAX**, **PP**, **AVG**, **RMS**, or **INTEG**

Derivative Function

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The syntax for the derivative of a quantity at an event is:

```
.MEASURE [DC|AC|TRAN] result
+ DERIVATIVEoutput_var|'expression' AT=at_value
.MEASURE [DC|AC|TRAN] result
+ DERIVATIVEoutput_var|'expression' AT=at_value
+ WHENoutput_var=value|output_var|PAR('expression')
 + [TD=delay|'expression']
+ [CROSS=crosses|LAST] | [RISE=rises|LAST] | [FALL=falls|LAST]
```

Where *at_value* is time for TRAN, frequency for AC, and a parameter value for DC analysis.

Locating Points in the Data

The syntax for locating single points in the data is:

```
.MEASURE [DC|AC|TRAN] result
+ WHENoutput_var=value|output_var|PAR('expression')
 + [TD=delay|'expression']
+ [CROSS=crosses|LAST] | [RISE=rises|LAST] | [FALL=falls|LAST]
.MEASURE [DC|AC|TRAN] result
+ FINDoutput_var|PAR('expr') AT=at_value
+ [TD=delay|'expression']
+ [CROSS=crosses|LAST] | [RISE=rises|LAST] | [FALL=falls|LAST]
```

Where *at_value* is time for TRAN, frequency for AC, and a parameter value for DC analysis.

```
.MEASURE [DC|AC|TRAN] result
+ FINDoutput_var|PAR('expr')
+ WHENoutput_var=value|output_var|PAR('expression')
 + [TD=delay|'expression']
+ [CROSS=crosses|LAST] | [RISE=rises|LAST] | [FALL=falls|LAST]
```

Delay Measurements (OPDelay)

Setting MEASURE Output Variables to Expressions

The syntax for setting a MEASURE output variable using an expression is:

```
.MEASUREoutput_var PARAM= 'expression'
```

The *expression* can reference other MEASURE *output_vars*. The calculated *output_var* may be used in subsequent MEASURE statements.

CONNECT Statement

A CONNECT statement connects two nodes in the netlist. A CONNECT statement that appears inside a subcircuit definition is local to that subcircuit. The CONNECT statement syntax is:

```
.CONNECTvisible_node invisible_node
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

After the CONNECT statement, only the first node, termed *visible_node* in the syntax above, is evaluated in the simulation. The second node, termed *invisible_node* in the syntax, is no longer recognized as a node name in netlist statements. For example:

```
.CONNECT n22 50
```

After this statement, references to node n22 also apply to node 50, while references to node 50 are no longer valid.

Multiple CONNECT statements can connect several nodes to one visible node. For example:

```
.CONNECT n22 50
.CONNECT 50 100
```

After these statements, references to node N22 also apply to nodes 50 and 100, while references to either node 50 or node 100 are no longer valid.

PRINT Statements

A netlist can use one or more PRINT statements to specify the outputs from particular types of analysis. The netlist syntax is:

.PRINT [*analysis*] *output1* [*output2*] ...

> **Warning:**
>
> By default, the Circuit solver stores all intermediate values for all nodes. If you do not use a PRINT statement, all node voltages and branch currents are retained so they can be output to the results file. With large circuits or analyses, the amount of data to be stored can cause the simulation to slow down, or even to exceed memory limits (usually a fatal error). PRINT statements specify which nodes and values can be retained, allowing the Circuit solver to discard all other values when they are no longer needed. Use of PRINT statements can significantly reduce memory usage. Although the range of output values may be limited, in those cases where memory is an issue a PRINT statement may be required to allow the computation to complete successfully.

> **Note:**
>
> PROBE statements in imported netlists are internally converted to PRINT statements.

ALTER Statements

The ALTER statement directs the Circuit solver to re-simulate a netlist using changed values for parameters. The netlist may contain any number of ALTER statements.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** Library and include files cannot contain ALTER statements.

The syntax is:

```
$ Rest of netlist
.ALTER [title1]
$ ALTER block statements
[.ALTER title2
$ ALTER block statements]
...
.END
```

The ALTER statements should come after all other statements in the netlist except for the END statement. An ALTER block can contain the following kinds of statements:

- .DEL LIB
- .INCLUDE
- .IC
- .LIB
- .MODEL
- .NODESET
- .OPTIONS
- .PARAM
- .PRINT
- .SUBCKT
- .ENDS
- .TEMP
- Analysis statements (See Analysis Controls for a list)
- Device instances, including subcircuits.

In the ALTER block, assign a new value to any device instance name, model name, netlist parameter name, or option name on the main netlist. You can also define new device instances, models, subcircuits, netlist parameters, and options. In the simplest case, the netlist contains just one ALTER statement. The Circuit solver first simulates the netlist on the beginning up to the first ALTER statement. The Circuit solver then reanalyzes the netlist, using any changes made in the ALTER statement, up to the END statement. The simulation includes the analyses specified in the original netlist, plus any analyses added in the ALTER block. All the analyses use the values of parameters, etc. set in the ALTER block.

When more than one ALTER block is present, the Circuit solver first simulates the netlist on the beginning up to the first ALTER statement, as before. The Circuit solver then reanalyzes the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

netlist, using any changes made in the first ALTER block, up to the second ALTER statement. The simulation includes the analyses specified in the original netlist, plus any analyses added in the first ALTER block. All the analyses use the values of parameters, etc. set in the first ALTER block.

The Circuit solver next re-analyzes the netlist, using any changes made in the second ALTER block, up to the next ALTER statement (or up to the END statement, if there are just two ALTER blocks). The simulation includes the analyses specified in the original netlist, plus any analyses added in the first ALTER block, plus any analyses added in the second ALTER block. All the analyses use the values of parameters, etc. set in the second ALTER block.

The Circuit solver continues re-simulating the circuit until the last ALTER statement has been processed. Following is an example:

```
* Test of ALTER blocks

.param myval=1000

V1 1 0 sin(0 1 myval)
R1 1 2 1000
C1 1 2 0.001
R2 2 0 1000

.TRAN 1e-6 2e-3
.PRINT TRAN V(2)

.ALTER first_one
.param myval=2000
.HB TONES=2000 MAXk=3
.PRINT HB V(2)

.ALTER second_one
.param myval=3000
.LNA POI 3 1000 3000
.PRINT LNA V(2)

.END
```

For this example, the Circuit solver runs a transient analysis with netlist parameter **myval** equal to 1000. After reading ALTER block **first_one**, the Circuit solver runs a transient analysis and a harmonic balance analysis, both with **myval** equal to 2000. Finally, after reading ALTER block **second_one**, the Circuit solver runs a transient analysis, a harmonic balance analysis, and a linear network analysis, all with **myval** equal to 3000.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The .DEL LIB and LIB statements allow an ALTER block to control which library files are active for each variation on the netlist. Using these statements, avoid rerunning any previous analyses and only run the analyses specified within specific ALTER blocks. Put all the affected simulation commands into a library file referenced with a LIB statement, either in the outer netlist or in an ALTER block. Then an ALTER block uses DEL LIB to delete the unwanted statements.

Suppose the library file **analyses.lib** contains the following blocks:

```
*analyses.lib
.LIB T1
.TRAN 1e-6 2e-3
.PRINT TRAN V(2)
.ENDL
.LIB H1
.HB TONES=2000 MAXk=3
.PRINT HB V(2)
.ENDL
.LIB L1
.LNA POI 3 1000 3000
.PRINT LNA V(2)
.ENDL
```

The netlist on the previous example could be modified as follows:

```
* Test of ALTER blocks with Library file

.param myval=1000

V1 1 0 sin(0 1 myval)
R1 1 2 1000
C1 1 2 0.001
R2 2 0 1000

.LIB 'analyses.lib' T1

.ALTER first_one
.param myval=2000
.DEL LIB 'analyses.lib' T1
.LIB 'analyses.lib' H1

.ALTER second_one
.param myval=3000
.DEL LIB 'analyses.lib' H1
.LIB 'analyses.lib' L1

.END
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

With this netlist, the Circuit solver first runs the transient analysis specified in the library block T1, using netlist parameter **myval** equal to 1000. Next, after reading ALTER block **first_one**, the Circuit solver deletes the transient analysis library block T1 and executes the harmonic balance analysis specified in library block H1, using netlist parameter **myval** equal to 2000. Last, after reading ALTER block second_one, the Circuit solver deletes the harmonic balance analysis library block H1 and executes the linear network analysis specified in library block L1, using netlist parameter **myval** equal to 3000.

Continuation Lines

To improve readability, an input line can contain intermediate carriage return/line feeds. The intermediate line breaks must be continued or 'escaped' using one of the following character combinations.

- A backslash (\) before a CR/LF suppresses the interpretation of the CR/LF as the end of the input line. Any whitespace (blanks or tabs) before the slash is retained, and any whitespace at the beginning of the continuation line is also retained. A valid comment can appear on the line after the backslash.

```
   M25 nd ng ns nb model_1 L=1.1e-3 W=2.2e-3 \
M=2 DTEMP=25 OFF
```

- A double backslash (\\) before a CR/LF also suppresses the interpretation of the CR/LF as the end of the input line. Any whitespace before the double slash is ignored. Any whitespace on the same line after the double slash is ignored. Any whitespace at the beginning of the continuation line is ignored. A valid comment can appear on the line after the double backslash. This form is useful when a path must be broken over a line without any intervening spaces.

```
   .INCLUDE './long_directory_name/long_subdirectory_name\\
/file_name'
```

- A plus sign (+) as the first character in a line (after a CR/LF at the end of the previous line) indicates that the new line is a continuation of the previous line. Blank lines and valid comment lines between the previous line and the continuation line are ignored.

```
   M25 nd ng ns nb model_1 L=1.1e-3 W=2.2e-3
+ M=2 DTEMP=25 OFF
```

A line continued with a plus sign is interpreted as part of the statement, even if the previous line ended with a comment. For example:

```
R1 1 2 ; comment
+ 1000
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Is the same as:

```
R1 1 2 1000
```

Comments

A comment is text that is not part of any statement.

A semicolon (;) anywhere outside of quotes makes the rest of the line a comment.

```
; This is a comment
M1 1 2 3 4 model_1; This is a comment
```

A line that begins with an asterisk (*), a dollar sign ($), or a double slash (//) is treated as a comment and is not interpreted.

```
* This is a comment
$ This is a comment
// This is a comment
```

Characters in a line become comments when they follow an asterisk (*), a dollar sign ($), or a double slash (//) that is both outside of quotes and directly preceded by one or more blanks or tabs (“whitespace”).

```
M2 5 6 7 8 model_1 $ This is a comment
M3 9 10 11 12 model_1 * This is a comment
M4 13 14 15 16 model_1 // This is a comment
```

> **Note:**
>
> The asterisk also serves as the sign for multiplication in expressions. When an expression includes the asterisk character, the expression *must* be enclosed in single or double quotes, otherwise any part of the expression that follows the asterisk is treated as a comment.

Characters in a comment are not interpreted in any way. A single or double backslash (\ or \\) in a comment is not interpreted as a continuation character. Also, a plus sign (+) at the beginning of a continuation line does not continue a comment on the previous line, but instead continues the interpreted statement on the previous line. To continue a comment, the netlist must use one of the comment characters on the continuation line. Here are some examples.

The next two examples of device instance statements show invalid uses of continuation characters for a comment. The second line in each example causes a syntax error.

```
V1 1 2 0.5V ; This is an \\
invalid continued comment
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
V2 3 4 1.5V ; This is another
+ invalid continued comment
```

The simplest way to continue a comment is just to begin the next line with a comment character:

```
V1 1 2 0.5V ; This is one way
* to continue a comment
```

You can also continue the command itself, then add the rest of the comment:

```
V2 3 4 // This is another
+ 1.5V // way to continue a comment
```

Names, Numbers, Constructs, and Expressions

A name is a user-defined token for a node, device instance, model, parameter, or other object in the netlist. The rules for names are presented here for comparison.

Node Names

A node name can contain any number of alphanumeric characters, and the following special characters:

```
! # $ % ^ * - + _ [ ] < > /
```

However, a node name containing a special character that also represents an arithmetic operator (- + * /) or a relational operator (< >) cannot be used in expressions, with or without quotes.

Node names can begin with one of the special characters

```
! # % _
```

Net names entered in the **Schematic Editor** may not contain spaces ( ), ampersands (&), or asterisks(*).

> **Note:**
>
> All node names in the Circuit solver are treated as strings, even when they appear as integers such as “12”. No numeric conversion is performed. For example, some simulators treat node “001” as node “1”. The Circuit solver treats these as two different node names.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Device Instance Names

The name for a circuit device instance begins with a predefined character representing the device type.

Element-Identity Characters

Character	Element Type
A	Distributed element or Ansys-developed element
B	Nonlinear dependent voltage source
C	Capacitor
D	Diode
E	Voltage-controlled voltage source (VCVS)
F	Current-controlled current source (CCCS)
G	Voltage-controlled current source (VCCS)
H	Current-controlled voltage source (CCVS)
I	Independent current source
J	JFET or MESFET
K	Coupled inductor
L	Inductor
M	MOSFET
N	Maxwell SPICELink N element
P	Piecewise linear dependent current source
Q	BJT
R	Resistor
S	S-parameter element (N-port) or Voltage-controlled switch
T	Lossless transmission line
U	Lossy transmission line
V	Independent voltage source
W	Lossy transmission line
X	Subcircuit

For example, a resistor instance name must begin with the letter R, a capacitor name must begin with the letter C, a MOSFET name must begin with the letter M. Characters after the first can be alphanumerics or the special characters:

```
! # $ % * - + _ [ ] < > / :
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that the period character (“.”) is NOT valid in device instance names.

Model Names

The name for a device model begins with any alphabetic character. Characters after the first can be alphanumerics or the special characters:

```
! # $ % * - + _ [ ] < > / :
```

Netlist Parameter Names

The name for a netlist parameter defined in a .PARAM statement begins with any alphabetic character. Characters after the first can be alphanumerics or the special characters:

```
! # $ % _ [ ] : .
```

> **Note:**
>
> For compatibility with existing netlist formats, the Circuit solver accepts parameters whose names include symbols for arithmetic and relational operations, such as (+, -, *, /, <, >, =). However, parameter names that include such symbols cannot be used in quoted expressions.

Device Instance Parameter and Model Parameter Names

Device instance parameters and model parameters have names defined in the Circuit models. They must be spelled as documented, but are case-insensitive.

Delimiters

Delimiters separate names and other tokens in an input line. Delimiters are the blank, tab, comma, equal sign (=), and parentheses ( ). A name may not contain any of these delimiters.

The period (.) character also indicates subcircuit hierarchy (See Subcircuits), and thus becomes another kind of delimiter. The period may not be used in device instance names.

Numbers

Real numbers in the netlist file can be represented as decimal, exponential, or scaled numbers, or as decibels (exponentially scaled numbers).

A decimal number consists of the numerals 0 through 9, with or without a decimal point, and with or without a leading unary plus or minus: 123, 12.30, +5.0, -20.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

An exponential number consists of a decimal number mantissa, the letter **e** (for “exponent”) and a decimal number exponent. The decimal equivalent is the mantissa multiplied by 10 to the power of the exponent.

Exponential Number Examples

Exponential Number	Interpretation	Decimal Equivalent
1e5 or 1e+5	1×10^{5}	100000
1.0e-5	1.0×10^{-5} ($1/10^{5}$)	.00001
-5e4	-5×10^{4}	-50000
-2.05e-4	-2.05×10^{-4} ($-2.05/10^{4}$)	-.000205

A scaled number consists of a decimal number and an alphabetic token representing a scale factor: 20K, 1.5P, -7.25MEG. The following table lists the scale factor tokens and their exponential equivalents.

Numeric Scale Factors

Factor	Interpretation	Exponential Multiplier
ATTO	atto	1e-18
F	femto	1e-15
P	pico	1e-12
N	nano	1e-9
U	micro	1e-6
M	milli	1e-3
K	kilo	1e+3
MEG	mega	1e+6
X	mega	1e+6
G	giga	1e+9
T	tera	1e+12

Note: By default, the single-letter token “A” as a numeric suffix represents amperes (AMP). If the netlist contains the statement **.OPTIONS UNIT_ATTO**, the single-letter suffix “A” represents 1e-18 (ATTO). In either case, the token AMP (with or without any trailing characters) is interpreted as amperes, and the token ATTO (with or without any trailing characters) is interpreted as 1e-18.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A decibel number uses one of the units DB or DBM. A number (*nn* in the following examples) with one of these units scales exponentially:

*nn*DB is scaled as 10 ^ (*nn* * 0.1).

*nn*DBM is scaled as 10 ^ (*nn* * 0.1 – 3).

In both of these examples, the ^ sign denotes exponentiation and the * sign denotes multiplication.

Note: Any extra letters after the DB or DBM prevent a match for DB or DBM (unlike other units, where additional letters are ignored). Here are some examples:

5K = 5000

5KOHM = 5000

5KAPPLES = 5000

5DB = 3.1622777

5DBW = 5

5DBM = 0.0031622777

5DBMW = 5

Netlist Parameters

The netlist can define parameters or variables to represent temporary values. Netlist parameter names follow the rules for names given earlier. Netlist parameters can be global or local, depending on where in the netlist they are defined. Global netlist parameters are defined with a .PARAM statement in the main body of the netlist, as discussed in this topic. Local netlist parameters are defined within a subcircuit definition, see Subcircuits.

The .PARAM statement has the following syntax:

.PARAM*param_name* **=***expression* [*param_name* **=***expression ...*]

Each .PARAM statement can define one or more netlist parameters. A netlist parameter can be referenced as a value or in an expression anywhere in the netlist, including subcircuit definitions. Global netlist parameter definitions can appear anywhere in the netlist. The same parameter-name can appear in two or more definitions. However, the last value assigned to any parameter is used everywhere in the netlist.

A reference to a global parameter anywhere in the netlist returns the value of the corresponding expression. A global parameter reference can precede or follow the statement that assigns the parameter a value (variable substitution occurs after the entire netlist has been parsed). A reference to a global netlist parameter that has not been given a value somewhere in the netlist results in an error.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Here is an example of a netlist parameter used to sweep the value of a resistor device:

```
.PARAM A=1
R10 10 0 R=A*1000
.TRAN 1e-3 1e-2 SWEEP A POI 3 1 3 5
```

The SWEEP specification generates three simulations. In the first simulation, A is equal to 1 so R10 has resistance 1000 ohms. In the second simulation, A is equal to 3 so R10 has resistance 3000 ohms. In the third simulation, A is equal to 5 so R10 has resistance 5000 ohms.

A parameter name cannot be a keyword such as TEMP.

Distribution Functions

A distribution function (**UNIF**, **AUNIF**, **GAUSS**, **AGAUSS**, **LIMIT**) specifies a statistical distribution of values around a nominal value. See Netlist Parameters for details on defining netlist parameters.

Instances of Circuit Devices

A circuit is described by specifying one or more circuit devices. Each instance of a device is specified with an instance statement.

A device instance statement has the general syntax:

instance_name nodes [*model_name*] [*instance_parameters*]

Models of Devices

A simulator model contains the physical and mathematical description for one type of circuit device. .MODEL statements in the netlist reference the simulator models. The general syntax for a .MODEL statement is:

.MODEL*modelname type* [*model_parameters*]

Each .MODEL statement provides a unique model name to be referenced by the instance statements for devices that use the given model. The *type* entry tells the kind of element, for example, D for diode model or NMOS for N-MOSFET model. The .MODEL statement can also specify values for physical and electrical parameters that then apply to all instances that reference that model name. Many device models have several different implementations identified via LEVEL and VERSION model parameters.

```
.MODEL MOS903 NMOS LEVEL=50 LER=1.92e-007 WER=1.00028e-005
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Expressions

An expression is a combination of operands, operators, and built-in functions that evaluates to a numeric or Boolean value. An expression should be delimited with single or double quotes to distinguish it from other entry types.

> **Note:**
>
> All expressions evaluate to double precision numeric constants.

A quoted expression can contain blanks separating the operands and operators. Without the quotes, blanks are token delimiters. For example, 'A + B + 1' is interpreted as an expression, while
A + B + 1 represents five separate tokens, whose interpretation depends on the context (most likely generating an error).

> **Note:**
>
> Identifiers (names) containing the characters for arithmetic or relational operators cannot be used in expressions, with or without quotes.

Operands

An operand can be one of the following:

A decimal, exponential, scaled, or exponential scaled (decibel) number.

A voltage or current source (e.g., V2, I34).

A node voltage or branch current (V(23), V(10,12), I(R1))

A user-defined parameter or variable (myparam) [See Netlist Parameters for details on user-defined parameters.]

A valid sub-expression enclosed in parentheses.

> **Note:** Complex numbers are not valid as operands or as arguments to built-in functions in expressions in Circuit netlists. Expressions with this limitation include component parameter expressions, expressions in **.param** statements, and sweep variable expressions.

An expression can consist of just a single operand. However, because a name can include the special characters +, -, and *, even a single-token expression should be enclosed in single or

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

double quotes. For example, node-1 is interpreted as a node name, while ‘node-1’ is evaluated as an expression.

Operators

The Circuit solver supports arithmetic and relational operators.

Arithmetic operators include unary and binary operators.

The supported unary operators are listed in The following table:

Unary Operators

Operator	Description
-	Unary minus or negation.
!	Logical “NOT.” !0 = 1, !1 = 0, !a = 0 for a<>0

The unary operators can precede any operand, for example, –1, !(A<B).

A binary operator appears between its two operands. The supported binary arithmetic operators are the character combinations listed in the following table:

Binary Arithmetic Operators

Operator	Operation
+	Add
–	Subtract
*	Multiply
/	Divide
**	Power
^	Power (synonym for **)

The supported relational operators are the character combinations listed in the following table:

Relational Operators

Operator	Operation
>	Is greater than
<	Is less than
= or ==	Is equal to
<> or !=	Is not equal to

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Operator	Operation
>=	Is greater than or equal to
<=	Is less than or equal to

The relational operators are binary, that is, they require two operands. The relational operators return a value of 1 if the relation between the two operands is true, or a value of 0 if the relation is false.

Built-In Functions

A built-in function has the format:

function_name(*arguments*)

Each function has a specified number of arguments and format for entering its arguments. The built-in functions return arithmetic, trigonometric, or Boolean values. The following tables list the built-in functions valid in Circuit netlist expressions. In the tables, arguments *x* and *y* can themselves be any expressions.

Built-In Arithmetic Functions

Function	Return Value
ABS(*x*)	Absolute value of *x*.
CEIL(*x*)	Returns the smallest integer greater than or equal to *x (r*ounds *x* toward positive infinity)
DB(*x*)	(sign of *x*)*20*$\log_{10}$(abs(*x*)) [*x* expressed in deciBels, with the sign of x]
DB_ NONINVERTING (*x*)	20*$\log_{10}$(abs(*x*)) [*x* expressed in deciBels]
DDT(*x*)	Time derivative of x.
EXP(*x*)	e^x
FLOOR(*x*)	Returns the largest integer less than or equal to *x* (rounds *x* toward negative infinity)
FMOD(*x*,*y*)	*x* -*i* **y* for some integer *i*, such that if *y* is non-zero the result has the same sign as *x* and magnitude less than *y*.
INT(*x*)	Integer portion of *x*
LOG(*x*)	$\log_e(x)$, -300.0*$\log_e$(10) if x≤0
LOG10(*x*)	$\log_{10}(x)$, -300 if x≤0
MAX(*x*,*y*)	x if x > y, y if y ≥ x
MIN(*x*,*y*)	x if x < y, y if y ≤ x
NINT(*x*)	Rounds *x* up or down to nearest integer. A fractional part of .5 is rounded

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Function	Return Value
	UP to the nearest integer. NINT(-1.5) is -1 and NINT(1.5) is 2.
POW(*x*,*y*)	x^y
PWR(*x*,*y*)	SGN(*x*)$\|x\|^y$
SIGN(*x*,*y*)	abs(*x*) if y ≥ 0 -abs(*x*) if y < 0
SGN(*x*)	-1 if *x* < 0, 0 if *x* = 0, 1 if *x* > 0
SQRT(*x*)	Positive square root of *x*

Built-In Trigonometric Functions

Function	Return Value
ACOS(*x*)	Inverse cosine of *x* in radians
ASIN(*x*)	Inverse sine of *x* in radians
ATAN(*x*)	Inverse tangent of *x* in radians
ATAN2 (*x,y*)	For any real arguments (*x*, *y*) not both zero, the angle in radians between the positive X-axis and the point (*x*, *y*). The angle is positive for *y* > 0 and negative for *y* < 0.
COS(*x*)	Cosine of *x* in radians
COSH(*x*)	Hyperbolic cosine of *x* in radians
HYPOT (*x*,*y*)	SQRT(*x***2 + *y***2)
SIN(*x*)	Sine of *x* in radians
SINH(*x*)	Hyperbolic sine of *x* in radians
TAN(*x*)	Tangent of *x* in radians
TANH(*x*)	Hyperbolic tangent of *x* in radians

Built-In Boolean Functions

Function	Return Value
IS_EQUAL(*x*,*y*)	1 if *x* is equal to *y*, 0 otherwise
IS_NOT_EQUAL(*x*,*y*)	1 if *x* is not equal to *y*, 0 otherwise
IS_GREATER(*x*,*y*)	1 if *x* is greater than *y*, 0 otherwise
IS_GREATER_EQUAL (*x*,*y*)	1 if *x* is greater than or equal to *y*, 0 otherwise
IS_LESS(*x*,*y*)	1 if *x* is less than *y*, 0 otherwise
IS_LESS_EQUAL(*x*,*y*)	1 if *x* is less than or equal to *y*, 0 otherwise

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Conditional Expressions

A conditional expression is an expression that returns a Boolean value (1 when the condition is true, 0 when the condition is false). The relational operators in Table 6 return Boolean values (using the format X *relop* Y). The built-in Boolean functions in Table 9 also return Boolean values.

Conditional Assignments

A conditional assignment uses one of the following formats:

```
variable = '(cond_expr)?true_value:false_value'
variable = 'if(cond_expr,true_value,false_value)'
```

The quotes are optional, but are recommended for clarity. The conditional expression *cond_expr* is any expression that evaluates to a Boolean value. When the conditional expression is true, the variable is assigned the *true_value*. When the condition is false, the variable is assigned the *false_value*.

Examples:

```
A = '(X>Y) ? 0 : 1'
A = 'if(X>Y,0,1)'
```

In both examples, when the conditional expression X>Y is true, variable A is set to 0, and when the conditional expression is false, A is set to 1.

Operator Precedence in Circuit Expressions

Expressions are evaluated using the following order of operator precedence.

1. Parentheses may be used to group operations. Operations in the innermost pair of parentheses are evaluated first. The result of the operations within a set of parentheses becomes an operand for the next level of evaluation.
2. The arguments to functions can be expressions. An expression that is used as the argument to a function is evaluated before the function is called.
3. Functions have higher precedence than operators outside of functions. When functions are nested, the innermost function is evaluated first.
4. Unary minus (-) and unary NOT (!) operators are applied to their operands before binary operators are applied. If parentheses are not used, a unary operator applies only to the very next operand.
   - For example, if A=2 and B=4, '-A+B' is evaluated as '(-A)+(B)' with value 2, while '-(A+B)' is evaluated as '(-A)+(-B)' with value -6.
   - Similarly, if A=2 and B=4, the expression '!A<B' is evaluated as '(!2)< 4', with value 1 or true, while '!(A<B)' is evaluated as '!(1)', with value 0 or false.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Power (**) is the highest binary operator. When two exponentiation operations are present without parentheses to control the precedence, evaluation is left to right.
   - For example, 'A**B**C' is evaluated as '(A**B)**C)'.
6. Multiply (*) and divide (/) have equal precedence. When two multiplies or divides are present without parentheses to control the precedence, evaluation is left to right.
   - For example, '-A/B/C' is evaluated as '((-A)/B)/C'.
7. Add (+) and subtract (-) have equal precedence. When two additions or subtractions are present without parentheses to control the precedence, evaluation is left to right.
   - For example, 'A+B-C' is evaluated as '(A+B)-C'.
8. Relational operators (>, <, =, ==, <>, >=, <=) have equal precedence. When two relational operators are present without parentheses to control the precedence, evaluation is left to right.
   - For example, 'A>B=C' is evaluated as '(A>B)=C'.

Evaluation of Expressions

With two exceptions, an expression is evaluated once at the beginning of simulation and the resulting value is used thereafter. The two exceptions are expressions in sweep specifications and expressions in the instance statements for behavioral devices.

An expression in a sweep specification (See Variable Sweeps) is evaluated once on every sweep step. Note that an expression in one level of a multi-level sweep cannot depend either on a sweep value that is set in another level of the same sweep, or on a value that is set in any level of another sweep statement.

An expression that determines the value of a behavioral device such as an expression-based resistor or behavioral voltage source is evaluated continuously, that is, on every Newton-Raphson iteration and every step of a discrete-time simulation.

A **.OPTION** statement cannot contain an expression.

Divisors

Division operations in most contexts are subject to the **minimum_divisor** option. This option is provided to improve compatibility with HSPICE®.

This option can be set in the netlist:

.option minimum_divisor=*val*

Alternatively, it can be set in the Circuit configuration file, **cirsim.cfg**:

`minimum_divisor=`*val*

or on the command line:

`-minimum_divisor=`*val*

(See Command Line Controls for details on the command line and configuration file.)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If **minimum_divisor** is not set, it defaults to 0. The value to match HSPICE^{tm} is 1e-28.

During expansion of subcircuits any divisor anywhere in the netlist whose absolute value is too small is replaced by the (signed) minimum_divisor. A divisors in the range (-minimum_divisor < divisor < > 0) is replaced by (-minimum_divisor) and a divisor in the range (0 <= divisor < minimum_divisor) is replaced by (minimum_divisor).

Replacement can happen when the entire expression is sweep-dependent or voltage-dependent. But it does not happen if just the divisor is sweep-dependent or voltage-dependent. Expression-based components such as the expression-based resistor are not affected by minimum_divisor.

A parallel option, **behavioral_minimum_divisor**, prevents division by zero during the evaluation of behavioral or functional components.

To prevent division by zero, the option must be set when set to a nonzero value in the netlist:

.option behavioral_minimum_divisor=*val*

Subcircuits

A subcircuit is a named set of elements and other circuitry that can be used multiple times in a netlist. The subcircuit definition can include local parameters. Different instances of the subcircuit can have different element values.

Subcircuit Definition

A subcircuit is defined in a block. The syntax of a subcircuit block is:

.SUBCKT*sub_name* [*boundary_nodes*] [*local_params*]
subcircuit_statements
.ENDS

> **Note:**
>
> .MACRO is a synonym for .SUBCKT and .EOM is a synonym for .ENDS.

Subcircuit Statements

The body of the subcircuit definition can contain device instance statements, model definitions, and the definitions and instances of nested subcircuits, all of which are local to the subcircuit. Node names are generally local to the subcircuit, but can be made global, as discussed in later topics.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

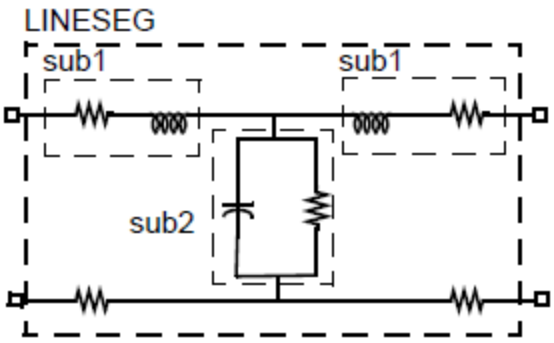
Note:

- Global control statements such as .TEMP and analysis statements such as .DC, .TRAN, and .PRINT that occur within .SUBCKT definitions are treated as if they are in the top-level circuit. .IC and .NODESET statements inside subcircuit definitions apply only to nodes in the subcircuit (See Scope of Initialization Controls).
- Subcircuits automatically inherit higher-level library configurations.

Example with Subcircuits

As an example for use in later discussions, Figure 1 diagrams the circuit topology of a segment of lossy transmission line. Netlist examples to follow shows how this circuit can be implemented with subcircuits:

Lossy Transmission Line Segment with Subcircuits



Here are example netlist definitions for the two internal subcircuits. Later netlist examples shows how to combine the subcircuits into a multi-segment transmission line and illustrate how to modify these definitions to incorporate additional features of subcircuits.

```
.SUBCKT sub1 sub1in sub1out
R1 sub1in sub1local ser_res
L1 sub1local sub1out ser_ind
.ENDS
.SUBCKT sub2 sub2in sub2out
C3 sub2in sub2out par_cap
R3 sub2in sub2out par_res
.ENDS
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

This example is just for demonstration purposes, not to be used in an actual circuit. The U transmission line model in the Circuit device library allows you to specify both the overall line length and the number of lumped line segments to be used to simulate the transmission line, so you do not have to construct the line segment by segment.

Boundary Nodes

The nodes in the list of *boundary_nodes* on the subcircuit definition line represent points of connection to the external circuit. In subcircuit sub1 above, the nodes sub1in and sub1out are the boundary nodes.

Note:

A subcircuit can be defined without any boundary nodes, in which case it can connect only to nodes defined as **GLOBAL** nodes. See Global Nodes in Subcircuits for further information.

The boundary nodes can have any names except 0, GROUND, GND, and GND!, which stand for the global reference node. The boundary node names do not represent actual nodes in the circuit, they are just dummy names used in the subcircuit.

When a node name inside the subcircuit definition is in the list of *boundary_nodes*, the element node is connected to the corresponding external circuit node when the subcircuit is instantiated.

In this subcircuit example, sub1, nodes sub1in and sub1out are the boundary nodes. Naming nodes sub1in in the R1 instance statement and sub1out in the L1 instance statement create connections to the external circuit nodes:

```
.SUBCKT sub1 sub1in sub1out
R1 sub1in sub1local ser_res
L1 sub1local sub1out ser_ind
.ENDS
```

Local Nodes

Node names in the subcircuit definition that are NOT in the list of boundary nodes are local nodes whose names are valid only inside the subcircuit. In subcircuit sub1 above, the node sub1local is a local node. A local node requires a hierarchical node name to be referenced outside of the subcircuit definition, as described in Hierarchical Names.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

CONNECT statements in subcircuit definitions are local to the subcircuit. See CONNECT Statement for further information.

Global Nodes in Subcircuits

The names for the global reference node (0, GROUND, GND, or GND!) are global. These names used anywhere See the single global reference node. A device instance node with one of the global reference node names is connected directly to the global reference node from any level of subcircuit nesting.

A subcircuit local node also becomes global when the node name is specified in a .GLOBAL statement either inside or outside a subcircuit definition, in the main module or in a module imported with an .INCLUDE or .LIB statement.

.GLOBAL*nodename1* [*nodename2* ...]

All nodes with a .GLOBAL node name are connected to that signal at every level of the netlist.

```
.SUBCKT sub4 N1 N2 $ Series resistors
R1 INPUT N1 R=0.05
R2 N2 0 R=0.1
.ENDS
.GLOBAL INPUT $ R1 in subcircuit sub4 connects to this node.
```

Note:

1. The .GLOBAL statement should appear in the top-level netlist. If a .GLOBAL statement occurs in a .SUBCKT definition, it is treated as if it appeared in the top-level circuit.
2. Use the .GLOBAL statement sparingly. Special attention should be paid to .GLOBAL definitions appearing inside a subcircuit library. Common names defined as .GLOBAL inside a circuit library may unintentionally affect the overall circuit that references the library.
3. In the **Schematic Editor**, adding a Global port to a schematic node inserts a .GLOBAL statement into the netlist that represents the circuit.

Local Device Instances

Device instance names that appear within a subcircuit definition are local to the subcircuit. Local device names can duplicate names in the outer circuit and in other subcircuits. A local device instance requires a hierarchical device name to be referenced outside of the subcircuit definition, as described in Hierarchical Names.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Subcircuit Instance Statement

To create an instance of a subcircuit, the netlist adds an X-element statement:

X*xxxcircuit_nodessub_name* [*local_params*] [**M=** val]

The subcircuit instance name must begin with the letter **X** (or **x**), followed by any number of valid device name characters. See Device Instance Names for the list of valid characters.

The circuit nodes in the X-element statement are the nodes in the actual circuit that connect to the *boundary_nodes* in the order given by the subcircuit definition.

The *sub_name* is the name of the subcircuit definition to instantiate.

The optional **M** parameter on a subcircuit instance statement specifies a value that multiplies the value of the **M** model parameter in every Circuit device instance referenced in the subcircuit. For example, suppose the netlist contains the following statements:

```
.SUB MTEST 1 2 3 4
M1 x1 x2 x3 x4 mos1
M2 x5 x6 x7 x8 mos1 M=3
...
.ENDS
...
X1 101 102 103 104 MTEST M=2
```

When subcircuit X1 is instantiated, its parameter setting **M=2** causes the instance of MOSFET M1 to have an effective instance parameter **M=2**, since by default the MOSFET instance parameter **M** has value 1. MOSFET M2 has an effective instance parameter **M=6** (3 times 2).

Here is the basic definition for the subcircuit LINESEG that combines the two subcircuits to make one segment of a lossy transmission line:

```
.SUBCKT LINESEG insig inref outsig outref
Xleft insig local1 sub1
Xright outsig local1 sub1
Xmid local1 local2 sub2
Rleft inref local2 ser_res
Rright local2 outref ser_res
.ENDS
```

Here is a circuit fragment that builds a multi-segment transmission line by connecting together two instances of subcircuit LINESEG.

```
* Lossy transmission line fragment
Xtrans1 send1 GND 10 20 LINESEG
Xtrans2 10 20 rcv1 GND LINESEG
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Subcircuit Parameters

The subcircuit definition can reference global netlist parameters defined with .PARAM statements external to the subcircuit block. The subcircuit definition can also define one or more local subcircuit parameters for use in the subcircuit statements. The names and values of subcircuit parameters are valid only inside the subcircuit. A subcircuit parameter can be created, or the value of an existing subcircuit parameter can be changed, by the X-element subcircuit instance statement.

The subcircuit statements can contain references to global and local parameters. A reference to a global parameter returns the value set in the external netlist. A reference to a local parameter returns the value set by the subcircuit definition or by the subcircuit instance. If both the subcircuit definition and the subcircuit instance assign values to the same local parameter, the value assigned in the subcircuit instance takes precedence. A subcircuit parameter value assigned in a subcircuit instance statement affects all references to that parameter in all subcircuits that are instantiated as a result of the called subcircuit.

> **Note:**
>
> A subcircuit may define a parameter named **M** using the **.param** statement, but this subcircuit parameter does not affect the value of the **M** parameter on subcircuit instance statements or on Circuit device instances in the subcircuit.

The example subcircuits given earlier reference the following parameters: ser_res and par_res for the serial and parallel resistors, ser_ind for the serial inductors, and par_cap for the parallel capacitor. The earlier examples do not show where the parameters get their values. Here is a more complete netlist fragment which gives definitions for all the parameters.

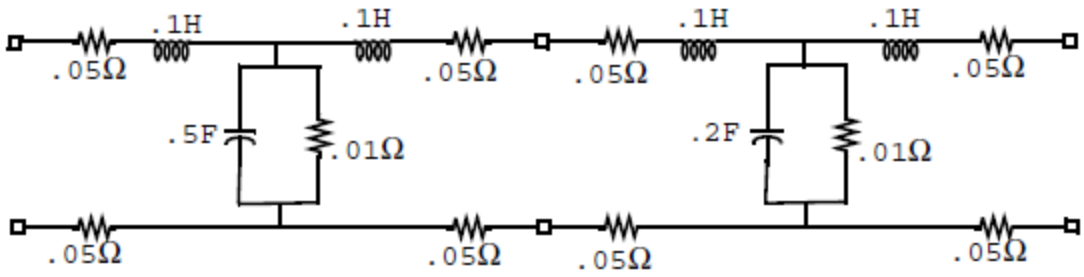
```
* Lossy transmission line fragment with parameters
.PARAM ser_res=.05
Xtrans1 send1 GND 10 20 LINESEG
Xtrans2 11 21 rcv1 GND LINESEG par_cap=.2
.SUBCKT LINESEG insig inref outsig outref ser_ind=.1
Xleft insig local1 sub1
Xright outsig local1 sub1
Xmid local1 local2 sub3
Rleft inref local2 ser_res
Rright local2 outref ser_res
.ENDS $ End of LINESEG
.SUBCKT sub1 sub1in sub1out
R1 sub1in sub1local ser_res
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
L1 sub1local sub1out ser_ind
.ENDS $ End of sub1
.SUBCKT sub2 sub2in sub2out par_cap=.5 par_res=.01
C3 sub2in sub2out par_cap
R3 sub2in sub2out par_res
.ENDS $ End of sub2
.END $ End of Netlist
```

Here is the resulting circuit fragment, with device values:

Lossy Transmission Line Segment with Device Values



- The parallel resistors in subcircuits sub1 and LINESEG all reference the global parameter ser_res, which is set in the .PARAM statement to 0.05 Ohm.
- The serial inductors in subcircuit sub1 reference local parameter ser_ind, which is given the value 0.1 Henry in the definition of subcircuit LINESEG, which instantiates sub1.
- The parallel capacitor in subcircuit sub2 references local parameter par_cap. Parameter par_cap is given a default value 0.5 Farad in the definition of subcircuit sub2, and this value is applied in the instance of sub2 that results on the subcircuit instance Xtrans1. However, the subcircuit instance Xtrans2 sets the value of par_cap to 0.2 Farad. The subcircuit instance Xtrans2 instantiates subcircuit LINESEG, which in turn instantiates subcircuit sub2, so the subcircuit instance value of par_cap, 0.2 Farad, overrides the default.
- The parallel resistor in subcircuit sub3 references local parameter par_res. Parameter par_res is given the value 0.01 Ohm in the definition of subcircuit sub2, and this value is applied in both instances of sub2 that are created.

Overriding the Precedence of Subcircuit Parameters

A subcircuit parameter can be given a value at different levels of nesting. There are two orders of precedence, global and local. Here is an example; consider the definitions of parameter foo.

```
.PARAM foo=1
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
X1 10 20 SUBA foo=2
.SUBCKT SUBA n1 n2 foo=3
X2 n1 n2 SUBB foo=4
.ENDS $ End of SUBA
.SUBCKT SUBB n3 n4 foo=5
R1 n3 n4 R=foo
.ENDS $ End of SUBB
.END
```

Global Precedence

With global precedence, the outermost assignment of subcircuit parameter foo has highest precedence. In the example above, the precedence of these assignment statements is as follows:

- The .PARAM statement has the highest precedence.
- The assignment in statement X1 has next highest precedence.
- The assignment in .SUBCKT SUBA has next highest precedence.
- The assignment in statement X2 has next highest precedence.
- The assignment in .SUBCKT SUBB has lowest precedence.

Thus, resistor R1 in subcircuit SUBB is instantiated with resistance R = 1 Ohm.

Local Precedence

Setting the global option PARHIER=LOCAL invokes local precedence, the reverse of global precedence. With PARHIER=LOCAL in effect, the precedence in the example above is:

- The assignment in .SUBCKT SUBB has highest precedence.
- The assignment in statement X2 has next highest precedence.
- The assignment in .SUBCKT SUBA has next highest precedence.
- The assignment in statement X1 has next highest precedence.
- The .PARAM statement has the lowest precedence.

With PARHIER=LOCAL in effect, resistor R1 in subcircuit SUBB has resistance 5 Ohm.

> **Note:**
>
> Setting PARHIER to any value starting with the letter L enables local precedence. Omitting PARHIER or setting it to any value not starting with the letter L leaves the precedence global.

Overriding the Default

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Circuit netlists generated from schematics insert PARHIER=LOCAL by default. To override this default, uncheck the **Use local parameter scoping** group box on the Nexxim Circuit Design Global Options or Nexxim Circuit Design-Level Options window. See Circuit Design Settings Reference for further information.

Hierarchical Names

subcircuit_element[.*subcircuit_element ...*].*name*

The subcircuit element is the X-element that instantiates the subcircuit (See Subcircuit Instance Statement). For example, to reference resistor Rleft in the instance of subcircuit LINESEG that was instantiated by subcircuit instance Xtrans1, the netlist has:

```
Xtrans1.Rleft
```

The hierarchical device name can include any number of lower level subcircuit calls, separating them with periods. For example, to reference node n25 in the instance of subcircuit sub3 that was instantiated indirectly by subcircuit instance Xtrans2, the netlist has:

```
Xtrans2.Xmid.n25
```

Subcircuit element Xtrans2 calls subcircuit LINESEG, which in turn uses subcircuit element Xmid to reference subcircuit sub3 containing the appropriate node.

Nested Subcircuits

A subcircuit definition can contain the definitions of other “nested” subcircuits. A .SUBCKT definition that is nested within another .SUBCKT definition is local to the enclosing subcircuit. Instances of the nested subcircuit can appear only in the scope of the enclosing subcircuit definition. Here is a skeletal example:

```
.SUBCKT Outer 1 2
* Definition of subcircuit Outer
.SUBCKT Inner 1 2
* Definition of nested subcircuit Inner
.ENDS Inner
X1 3 4 Inner $ Valid subcircuit instance
.ENDS Outer
* Start of top-level circuit
X2 10 20 Outer $ Valid subcircuit instance
X3 30 40 Inner $ Invalid subcircuit instance
.END top-level circuit
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In this example, the definition of subcircuit Inner is nested in the definition of subcircuit Outer. Instance X1 is valid since subcircuit Inner is known inside the definition of subcircuit Outer. However, instance X3 is not valid, since subcircuit Inner is not recognized outside of subcircuit Outer.

Note that instances of non-nested subcircuits are valid both inside and outside of subcircuit definitions, as shown in the transmission line example given earlier.

Options and Controls

The following options and controls are available for working with Circuit netlist formatting.

Analysis Controls

To perform simulations, the netlist uses one or more of the analysis control statements:

Analysis Controls

Statement	Analysis
.DC	DC operating point analysis
.HB	Harmonic balance
.LNA	Linear network analysis
.OSC	Oscillator analysis
.TRAN	Transient analysis
.TV_NOISE	Time-varying noise analysis

A **SWEEP** specification can be added to any of these analysis statements to perform a series of analyses using a parameter sweep.

Separate help topics explain the complete syntax for each of the analysis statements.

> **Note:**
>
> .AC analysis statements are processed correctly in netlists imported from other simulator environments. Linear Network Analysis (.LNA) matches their functionality.

Netlist Options

The netlist can include one or more .OPTIONS statements to specify controls that apply to the entire netlist.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Simulator options are used by one or more simulation tools. See the chapters on the individual tools for further information.

Model options are used to create instances of particular kinds of device models. See the Circuit Component Models help topics for further information.

A **.OPTIONS** statement cannot contain an expression.

Initialization Controls

The netlist also contains initialization controls: NODESET statements for DC operating point and IC statements for transient analyses.

NODESETs

The netlist can include one or more .NODESET statements. Voltages assigned with .NODESET are applied at the start of the DC operating point analysis, to provide the initial values for the first Newton-Raphson iteration. Any node voltages not specified with NODESET are initialized to zero.

The syntax is:

.NODESET V(*node1***)=***value1* [**V(***node2***)=***value2* **...**]

For example, to initialize node 12 to 4.5 volts and node in2 to 2.23 volts:

```
.NODESET V(12)=4.5 V(in2)=2.23
```

Initial Conditions Statements

The netlist can include one or more .IC statements to force nodes to particular voltages. Voltages set with .IC are applied throughout the DC operating point analysis. Any node voltages not specified with .IC are computed.

The syntax is:

.IC V(*node1***)=***value1* [**V(***node2***)=***value2* **...**]

For example, to force node 12 to 4.5 volts and node in2 to 2.23 volts:

```
.IC V(12)=4.5 V(in2)=2.23
```

Scope of Initialization Controls

.NODESET and .IC statements at the outer level of the netlist can reference nodes that are defined in the top-level circuit directly, as in the examples above.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

.NODESET and .IC statements at the outer level of the netlist can also use hierarchical names to reference nodes within subcircuit instances. For example:

```
.SUBCKT test in out
R1 in middle 100
R2 middle out 200
.ENDS test
Xtest 1 2 test
.NODESET V(Xtest.middle)=5
```

.NODESET and .IC statements inside a subcircuit definition apply only to those nodes that appear in the subcircuit definition. For example:

```
.SUBCKT test in out
R1 in middle 100
R2 middle out 200
.NODESET V(middle)=6
.ENDS test
```

In this subcircuit definition, the voltage on node middle is initialized at 6 volts in all instances of the subcircuit. Since the .NODESET is internal to the subcircuit definition, the node it references is treated as a subcircuit internal node.

External Files

The Circuit solver allows input lines to be copied into the netlist from three types of external files: include files, library files, and vector files. External files can also be referenced in netlist statements defining the N-element, a frequency-dependent S-parameter element compatible with Ansys Maxwell Spice, and the SP frequency-dependent model for S-elements and W-element transmission lines.

File References

A reference to an external file in a Circuit netlist can use one of the following formats:

filename

"*filename*"

'*filename*'

"*path/filename*"

'*path/filename*'

"**$***environment_variable/path/filename*"

'**$***environment_variable/path/filename*'

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A *filename* that contains only characters valid for node names can be entered without quotation marks. If the *filename* contains any special characters not valid for node names, it must be enclosed in single or double quotation marks.

The *path* specifies the directory where the *filename* is to be found. When *path* is given, the combined *path* and *filename* must be enclosed in single or double quotes. Pathnames must See subdirectories using a syntax that is compatible with the platform operating system. Some operating systems use a forward slash (/) as a path separator, while others use a backslash (\). The examples above use a forward slash, but a backslash is the valid separator used in Windows™ systems. The system ensures the consistent and compatible use of slash designators in netlist file paths for each of the following platforms: Windows and Linux™.

> **Note:**
>
> The forward slash (/) is a valid separator for file path resolution in Circuit netlists under the Windows operating system.

A *filename* with a *path* that contains a fully rooted path (identifying the drive and all intermediate directories) is called an *absolute* file reference. An absolute file reference is searched for along the specified path. Absolute file references that include the drive are valid only in Windows systems.

The value of an environment variable can be used to supply the leading part of the *path*. For example, if an environment variable MyLibrary has been defined as ‘C:\Project5\Models’, the file reference ‘$MyLibrary\Model5’ is expanded to ‘C:\Project5\Models\Model5’.

A *filename* without a *path*, or with a *path* that is not fully rooted, is called a *relative* file reference. The search for a relative file reference depends on the location of the netlist file that is the source for the file reference. Linux systems should use relative paths.

- If the source netlist file is a top-level netlist that is referenced by a Circuit .ADSN or a netlist .NDSN file, the relative-referenced *filename* is searched for first in the directory where the .ADSN or .NDSN file resides, then in the directory where the application was started.
- If the source netlist file is not a top-level netlist, or the Circuit solver is being run as a standalone process, the relative-referenced *filename* is searched for starting in the directory where the source netlist file resides, then in the directory where the Circuit solver was started.

Include Files

The **.INCLUDE** statement identifies a file that is to be inserted in its entirety into the netlist at the point of the **.INCLUDE** statement:

```
.INCLUDE file_reference
```

The file-reference has the form discussed in the previous topic. For example:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
.INCLUDE 'diode_model_statements'
.INCLUDE 'models\diode_models'
.INCLUDE 'C:\simulator\model_statements\diode_model_statements'
```

The complete contents of the include file are added to the calling netlist. The included file can contain further **.INCLUDE** files to be processed.

> **Note:**
>
> None of the included files can See any other file in the sequence of included files. A loop of included files causes an unrecoverable error condition. However, the Circuit solver cannot detect this error in advance, so no warning message is given.
>
> Include files cannot contain ALTER statements.

Library Files

Library files contain one or more blocks of netlist statements. Each block in the library file has the format:

.LIB*block_name*
lib_block_statements
.ENDL

The library file block can contain any valid netlist statements. LIB blocks are processed after all the other statements in the netlist have been processed, and the order of execution of LIB block statements cannot be predetermined.

To read and process the statements from a library file block, the netlist uses a library call the form:

.LIB*file_referenceblock_name*

The rules for *file_reference* are the ones given in the module on File References.

A **.LIB** block in a given library file can contain calls to blocks in the same library file or in other library files, but a **.LIB** block may not call a block with its own block name in its own file (that is, a **.LIB** block cannot call itself).

> **Note:**
>
> Library files cannot contain ALTER statements.

To delete a library file on the netlist, use the DEL LIB statement:

.DEL LIB*file_referenceblock_name*

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Vector Files

Digital vector files contain vector pattern definitions to be used as input stimuli to the circuit.

To read and process the statements from a vector file, the netlist uses a vector file statement of the form:

.VEC*file_reference*

The rules for *file_reference* are the ones given in the module on File References.

> **Note:**
>
> The Circuit solver supports vector files containing only input vector types. Output and bidirectional vector types are not processed.

Touchstone Data Format

Touchstone data files contain S-, Y-, Z-, H-, or G-parameter data for a single device. The data file typically contains information about the device type and measurement conditions followed by sequential data lines. Touchstone® is a registered trademark of Agilent Technologies, Inc.

The Circuit solver supports both Version 1.1 and Version 2.0 of the Touchstone specification.

- *Touchstone® File Format Specification*, Rev 1.1, Copyright© 2002 by the EIA/IBIS Open Forum.
- *Touchstone® File Format Specification*, Version 2.0, Copyright© 2009 by TechAmerica.

> **Note:**
>
> The Circuit solver does not support the Mixed-Mode N-Port Parameters in the Touchstone 2.0 Specification.

See Circuit S-Parameter Technical Notes for details on how the Circuit solver handles Touchstone files.

Compact FLP Data File

Compact FLP files contain network parameter data for one or more devices. Each device's data is entered on sequential lines to form a dataset. Each such dataset begins with a mandatory header line that is used to identify the set followed by a mandatory description line. The header format is the same for all *N*-port data sets. Two-port network data sets may contain a subsequent secondary header for associated noise data. When multiple data sets are stored in a data bank file, they must be uniquely named.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

FLP data bank files may contain multiple data sets, but they must all be of the same port size—that is, all two-port, all three-port, et cetera —but not mixed.

> **Note:**
>
> Ansys tools can read and import, but not write and export, data in the FLP format. The FLP format is documented to support backward compatibility only.

FLP Data Header Form

This header form is used in the following forms:

DEVname Min_Freq Max_Freq N_Freq R0 Data_Code
Mandatory_description_line

where:

Table 37:

DEVname	An alphanumeric device name beginning with a letter character
Min_Freq	Lowest frequency for which measured data is provided
Max_Freq	Highest frequency for which measured data is provided
N_Freq	Number of frequencies for which measured data is provided
R0	Reference resistance of *S*-parameter data
Data_Code	A numeric code identifying the type of signal parameters data: • 1 or S identifies S-parameter data in magnitude phase format • 2 or Y identifies Y-parameter data in real imaginary format • 3 or Z identifies Z-parameter data in real imaginary format

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	• 31 or DB identifies S-parameter data where magnitudes are in [dB] • –1 or RI identifies S-parameter data in real imaginary format
Mandatory_description_line	Data set description text line must not begin with ! or *
Comment lines	Must begin with *

One-Port Data

Form

```
header
f1 a1 b1
f2 a1 b1:
```

where **header** is the FLP data bank header.

The entries **f1, f2, . .** represent frequencies, and the data pairs **a1, b1** represent real values identifying the data for each dataset. The actual numbers that replace **a1** and **b1** for each frequency are either the magnitude and angle (in degrees) or real and imaginary parts of the complex reflection coefficient, admittance or impedance.

Example

```
DIODE2 6GHZ 8GHZ 3 50 1
PIN diode in 'ON' state with 20mA in pill package
* From the HP device library
 6GHZ 0.073 6.3
 7GHZ 0.09 9.9
 8GHZ 0.103 10.4
```

In this example, S-parameter data is given for three frequency points. The name of the dataset is **DIODE2**.

Two-Port Data

Form

```
header
[f1] a11 b11 a21 b21 a12 b12 a22 b22
[f2] a11 b11 a21 b21 a12 b12 a22 b22
 :
```

where **header** is the FLP data bank header.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The entries **f1, f2, ...** represent frequencies. The indexing system in the form above identifies the 11, 21, 12 and 22 matrix elements of the network parameters at each sweep point. Depending on the format used, the matrix coefficients **a** and **b** are magnitude and phase (in degrees) or real and imaginary components of the data type that is specified by the code.

Three-Port Data

Form

```
header
* Data for first frequency
[f1] a11 b11 a12 b12 a13 b13
 a21 b21 a22 b22 a23 b23
 a31 b31 a32 b32 a33 b33
* Data for second frequency
[f2] a11 b11 a12 b12 a13 b13
 a21 b21 a22 b22 a23 b23
 a31 b31 a32 b32 a33 b33
.
.
.
```

where **header** is the FLP data bank header.

The entries **f1, f2, ...** represent frequencies. The indexing system in the form above identifies the matrix elements of the network parameters at each sweep point. Depending on the format that is used, the matrix coefficients **a** and **b** are magnitude and phase (in degrees) or real and imaginary components of the data type that is specified by the code.

Example

```
MY_DIPLEXER 2GHZ 6GHZ 3 50 1

FLP Noise Data

Noise data may also be supplied using a header line that follows the network data:

Form

```
NOI { RN | NC } [x]
[f1] fmin g1 g2 r1
[f2] fmin g1 g2 r1
 :
```

where

RN signifies that the normalized equivalent noise resistance is given as r1
NC signifies that the noise figure in dB is given as r1
x is an optional reference normalization impedance whose default value is 50 ohms.

Each data line that follows begins with the frequency and is a separate dataset, where

fmin = minimum noise figure in dB
g1 and **g2** = magnitude and phase in degrees of the optimum noise input reflection coefficient
r1 = normalized equivalent noise resistance when the RN option is used or the noise figure in dB when the NC option is used.

The noise data does not require the same number of data sets as those given for the preceding network parameters data, however, the dataset entries follow the same rules as the other data types.

Example

The dataset in this example is identified by the set name **HPM02**. The header indicates the frequency range of the S-parameter data and seven data points and reference termination of 50 ohms. The second header line explains that the data is for a transistor with parasitic lead inductances attached to the three terminals. The seven S-parameter data lines follow the header. Three noise data lines are appended to the end of the S-parameter data following an appropriate noise data header.

Conventions for Compact FLP File Formats

In the Compact FLP file format topic, optional entries such as [f1], [f2] may be used to represent frequencies that must be included if interpolation is required or necessary. They need not be included if a set of data for each simulation frequency is given.

When two or more data sets are supplied in a single data file, they must all follow the same form. If a frequency is included, it is the first entry in each dataset and all the data sets that belong to the same data group must also have a frequency entry. The frequency entry may include a unit code (e.g., 100MHz) or be a number with an optional exponent (e.g., 1E8) in which case the unit code (Hz) is assumed. When frequencies are supplied as part of the data sets, the order of data sets is unimportant within each group; the data sets are automatically sorted internally.

CITIfile Format

CITIfile (“Common Instrumentation Transfer and Interchange”) is an ASCII-based format originally developed by Hewlett-Packard (now Agilent Technologies). CITIfile format files containing frequency-dependent data can be both imported into and exported. A CITIfile file contains a single “package” consisting of a header followed by one or more arrays of data.

> **Note:**
>
> The CITIfile format is case-insensitive. In these help topics, CITIfile keywords are shown in upper case, but that is not required.
>
> A CITIfile file can contain only a single package (header plus data). Packages after the first one in a file is ignored.

Related Topics

CITIfile File Header

CITIfile Data Arrays

CITIfile Example

CITIfile File Header

A CITIfile package must begin with a header. The header consists of the following entries, each occupying one or more lines.

CITIfile Version

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The first line in the file identifies the version of the CITIfile format supported by Ansys. This line must be the following:

CITIFILE A.01.00

> **Note:**
>
> CITIfile revision A.01.01 defines the statement type “CONSTANT” with or without an accompanying “COMMENT.” The import facility silently ignores all such lines.

Package Name

The second line gives a name for the package. This line is optional. The format is:

NAME*name*

For example:

```
NAME BJTInverter
```

> **Note:**
>
> The CITIfile reference defines several keywords for the NAME statement (such as DATA for error-corrected data). The netlist parser does not interpret the NAME entry.

Frequency Information

The next line in the file identifies the data as dependent on frequency magnitude, and specifies the number of frequencies. The format for this line is:

VAR FREQ MAG*number_of_freqs*

For example, if the data is for ten frequencies, the VAR line is:

```
VAR FREQ MAG 10
```

Data Types

The next line or lines in the file define the types of the data. Each data type is defined in a line with the format:

DATA*type format*

The following DATA types are supported by Ansys:

- **S** or **S[***port***,***port***]** (Scattering parameter data. **S** with no port identification is interpreted as **S[1,1]**. Explicit port identification such as **S[1,2]** is required for any other multi-port combination.)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Y** or **Y[***port*,*port***]** (Admittance parameter data. **Y** with no port identification is interpreted as **Y[1,1]**. Explicit port identification such as **Y[1,2]** is required for any other multi-port combination.)
- **Z** or **Z[***port*,*port***]** (Impedance parameter data. **Z** with no port identification is interpreted as **Z[1,1]**. Explicit port identification such as **Z[1,2]** is required for any other multi-port combination.)
- **Zo** or **Zo[***port***]** (Terminal characteristic impedance. **Zo** with no port identification is interpreted as **Zo[1]**. Explicit port identification such as **Zo[2]** is required for any port.)
- **Zpi** or **Zpi[***port***]** (Terminal characteristic impedance, power/current. **Zpi** with no port identification is interpreted as **Zpi[1]**. Explicit port identification such as **Zpi[2]** is required for any other port.)
- **Gamma** or **Gamma[***port***]** (Propagation constant parameters. **Gamma** with no port identification is interpreted as **Gamma[1]**. Explicit port identification such as **Gamma[2]** is required for any other port.)

> **Note:**
>
> Zpi is identical to Zo in Circuit designs, and upon import, Zpi becomes Zo. The CITIfile should not specify both Zpi and Zo. If both Zo and Zpi are specified with different values, the values of Zpi take precedence.

The only DATA format supported is **RI** (real/imaginary).

There can be multiple DATA lines in the package. For example:

```
DATA S[1,1] RI
DATA Gamma[1] RI
DATA Zo[1] RI
```

Frequency List

The file header should contain a list of the frequencies at which the data is generated. The number of frequencies in the list should correspond to the number given in the VAR line described earlier. Two formats are supported for frequency listings: VAR_LISTs and SEG_ LISTs.

The VAR_LIST explicitly lists all the frequencies in Hz. The format is:

VAR_LIST_BEGIN
frequency_1
...
frequency_n
VAR_LIST_END

Here is an example with ten frequencies:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
VAR_LIST_BEGIN
1000000000
2000000000
3000000000
4000000000
5000000000
6000000000
7000000000
8000000000
9000000000
10000000000
VAR_LIST_END
```

Instead of a VAR_LIST, the CITIfile can use a SEG_LIST. The SEG_LIST specifies a start frequency, stop frequency, and number of frequency points. The format is:

SEG_LIST_BEGIN

SEG*start_freq stop_freq number_of_freqs*

SEG_LIST_END

Ansys tools convert the SEG_LIST into individual frequencies using the following formula:

F_n = *start_freq* + {(*n*-1) × [(*stop_freq* -*start_freq*) / (*number_of_freqs* -1)]}

The index *n* goes from 1 to *number_of_frequencies*. For example, to produce the same set of frequencies as the VAR_LIST given above, the SEG_LIST is:

```
SEG_LIST_BEGIN
SEG 1000000000 10000000000 10
SEG_LIST_END
```

The VAR_LIST or SEG_LIST is the last item in the header.

> **Note:**
>
> A CITIfile header may contain only a single VAR_LIST or SEG_LIST. Ansys does not support the use of multiple VAR_LISTS.

CITIfile Data Arrays

The CITIfile package should contain one data array for each DATA line in the header. The first array is the data whose type and format was specified in the first DATA line, the second array is for the second DATA line, et cetera. Each array contains one line of data for each frequency in the VAR_LIST block in the header, described earlier.

Here is a data array for the DATA S[1,1] RI line given earlier:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
BEGIN
-8.515589E-001, -2.006537E-001
-9.498286E-001, -1.361623E-001
-9.761472E-001, -9.717214E-002
-9.862472E-001, -7.472031E-002
-9.910952E-001, -6.048325E-002
-9.937765E-001, -5.072857E-002
-9.954099E-001, -4.365178E-002
-9.964769E-001, -3.829255E-002
-9.972115E-001, -3.409734E-002
-9.977385E-001, -3.072603E-002
END
```

Each Real/Imaginary pair of data points corresponds to one of the ten frequencies in the VAR_ LIST given earlier.

> **Note:**
>
> Multiple, indexed data arrays are not supported.

CITIfile Example

Here is a brief CITIfile example:

```
CITIFILE A.01.00
NAME BJTInverter

```

Ansys Neutral File Format

ANF is a public, neutral file format that allows third party tools to exchange design data with Ansys products. Ansys Neutral File (ANF) formatted files are generated either by third party tools, by the “ALinks” program that translates third-party designs, or by Ansys tools when exporting schematic or layout data. An ANF file can contain schematic data, 2D geometry (layout), 3D geometry, and component data. None of the data is required. A given ANF file may contain just schematic data with no layout data, or may contain just layout data with no schematic data.

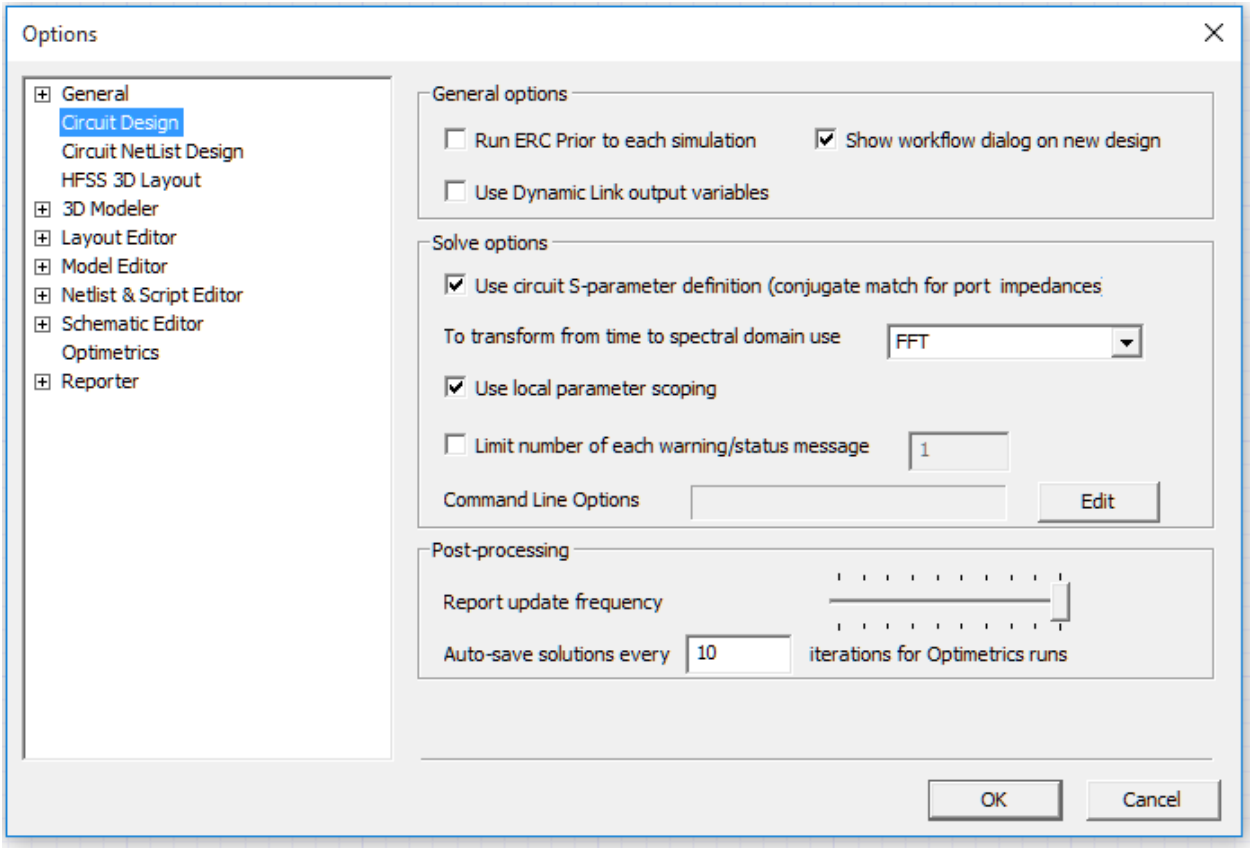
Circuit Design Settings

Nexxim options specify settings or values that control Nexxim analyses. Nexxim options can apply globally to all designs, to analyses in a specific design, to specific types of analysis, or to the treatment of S-elements and W-elements.

Nexxim Circuit Design — Global Options

To set option defaults that affect all designs, click **Tools>Options>General** to open the **Options** window, then select **Circuit Design** on the left group box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



General Options

Run ERC Prior to each simulation — Runs electrical rules checking for nets or nodes that are electrically connected but not physically connected. The ERC results display in the message window. The simulation proceeds regardless of the results of ERC.

Show Workflow window on new design — Controls the display of the Workflow window when a new circuit design is inserted. When a new design is inserted, a window opens that allows you to associate the new design with a workflow template. For more information, see Workflow Projects.

Use Dynamic Link output variables — Enables the Nexxim simulation to use output variables from dynamically linked HFSS designs. Using the HFSS output variables gives Nexxim access to nearly all types of HFSS data instead of just S-parameters. However, accessing the HFSS output variables can slow down the analysis. See Access to HFSS Output Variables for further information.

Solve Options

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Use circuit S-parameter definition — Controls the definition for port impedances. For Nexxim, this option should typically be selected (check box checked). The definition of a “matched port” depends on the application. In applications that deal mostly with circuit quantities (including the Nexxim simulator), a “matched port” has a characteristic impedance that maximizes the power transfer. This is also called a “conjugate match.” In applications that deal mostly with electromagnetic quantities (including HFSS and HFSS 3D Layout), a “matched port” has a characteristic impedance that maximizes the transfer of the voltage wave. The two definitions differ only by the conjugate of the characteristic impedance of the port. For real port impedances, there is no difference.

To transform from time to spectral domain — Allows you to select the method used to transform on the time domain to the spectral domain for all projects.

- Fourier Integration is very accurate but may be time-consuming for large data sets. The Fourier Integration method computes the projection of the signal on each of the requested harmonics via integration of the inner-product integral.
- FFT (Fast Fourier Transform, the default) achieves faster conversion with a slight reduction in accuracy. The FFT method samples the signal at 2*(maximum harmonic number) points, and outputs the FFT of the sampled signal. The FFT method may not be robust enough to avoid aliasing while converting some time-domain signals to the frequency domain.

Use local parameter scoping – Controls the precedence of parameter handling in subcircuits. By default, option PARHIER=local is inserted in the Nexxim netlist. Uncheck the box to restore global parameter scoping. See Overriding the Precedence of Subcircuit Parameters for further information.

Limit number of each warning message – Lets you specify a maximum number for multiple instances of the same warning message (all error messages are always displayed). Click the check box and enter a whole number, 0 or greater. If the Nexxim solver generates multiple warning messages for the same issue, the number of messages displayed is limited to the value specified. The default is one (1) warning. The logfile includes all status messages, info messages, warning messages, and error messages regardless of this option.

Command Line Options — Additional options that the user can pass to the HPSICE solver during an HSPICE analysis.

Post-processing

Report update frequency — When dynamic probes (DYNIPROBE or DYNVPROBE) are used in circuit designs, the user can set up plots in schematic. These plots are updated as the simulation progresses. "Report update frequency" controls the frequency at which these reports are updated.

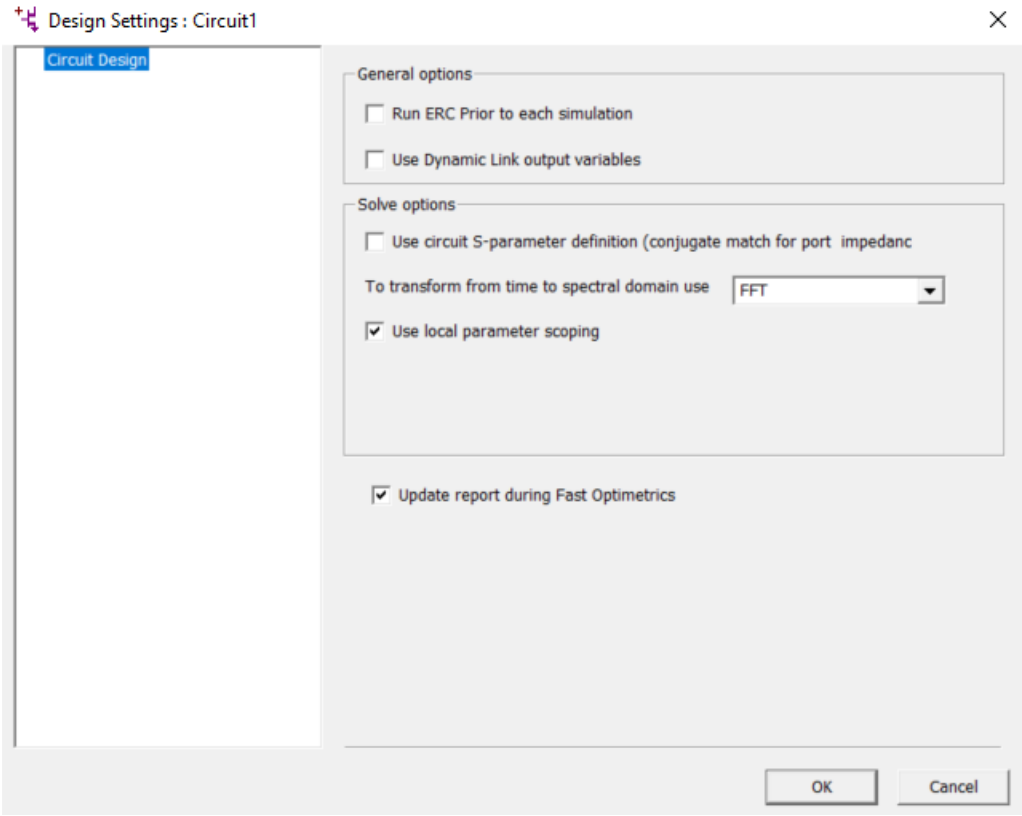
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** Dynamic probes (DYNIPROBE or DYNVPROBE) have been deprecated, and the **Report update frequency** option is only provided for use with projects created in earlier releases that contain dynamic probes.

Auto-save solutions every — Used to set **Iterations for Optimetrics runs**, which is the number of iterations after which to do an auto save during an optimetrics analysis.

Nexxim Circuit Design — Local Options

To set option defaults that affect a particular circuit netlist design, on the **Project Manager** window, expand the **Project Tree**. Then right-click the active design and select **Design Settings ...** to open the **Design Settings** window.



General Options

Run ERC Prior to each simulation — Runs electrical rules checking for nets or nodes that are electrically connected but not physically connected. The ERC results display in the message window. The simulation proceeds regardless of the results of ERC.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Use Dynamic Link output variables — Enables the Nexxim simulation to use output variables from dynamically linked HFSS designs. Using the HFSS output variables gives Nexxim access to nearly all types of HFSS data instead of just S-parameters. However, accessing the HFSS output variables can slow down the analysis. See Access to HFSS Output Variables for further information.

Solve Options

Use circuit S-parameter definition — Controls the definition for port impedances. For Nexxim, this option should typically be selected (check box checked). The definition of a “matched port” depends on the application. In applications that deal mostly with circuit quantities (including the Nexxim simulator), a “matched port” has a characteristic impedance that maximizes the power transfer. This is also called a “conjugate match.” In applications that deal mostly with electromagnetic quantities (including HFSS and HFSS 3D Layout), a “matched port” has a characteristic impedance that maximizes the transfer of the voltage wave. The two definitions differ only by the conjugate of the characteristic impedance of the port. For real port impedances, there is no difference.

To transform from time to spectral domain use — Allows you to select the method used to transform on the time domain to the spectral domain for all projects.

- Fourier Integration is very accurate but may be time-consuming for large data sets. The Fourier Integration method computes the projection of the signal on each of the requested harmonics via integration of the inner-product integral.
- FFT (Fast Fourier Transform, the default) achieves faster conversion with a slight reduction in accuracy. The FFT method samples the signal at 2*(maximum harmonic number) points, and outputs the FFT of the sampled signal. The FFT method may not be robust enough to avoid aliasing while converting some time-domain signals to the frequency domain.

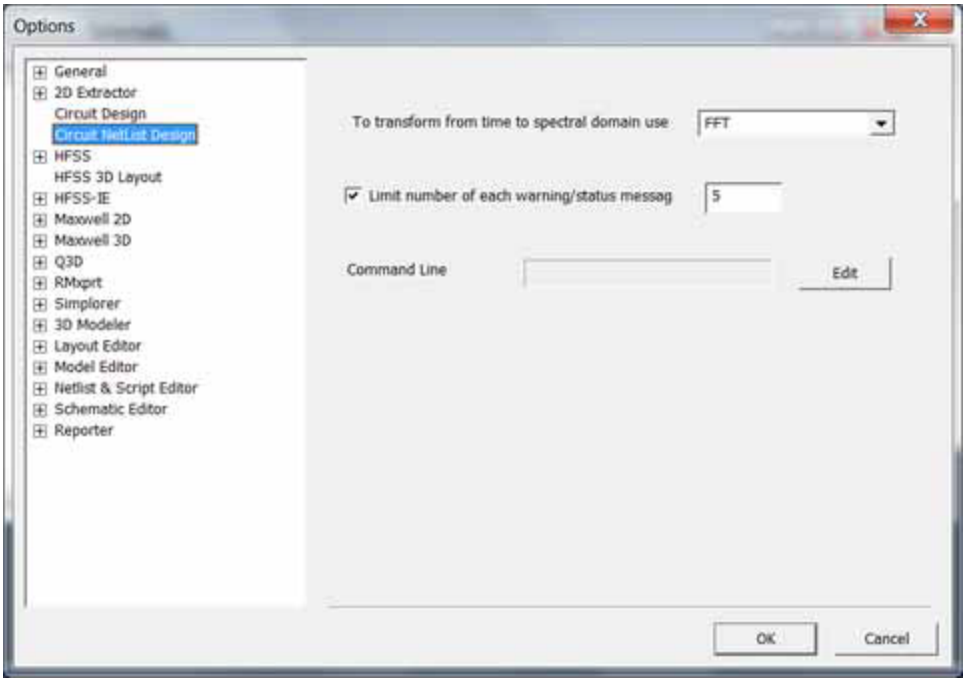
Use local parameter scoping – Controls the precedence of parameter handling in subcircuits. By default, option PARHIER=local is inserted in the Nexxim netlist. Uncheck the box to restore global parameter scoping. See Overriding the Precedence of Subcircuit Parameters for further information.

Update report during Fast Optimetrics – If a report has all variables set to "nominal", the report is updated during fast-optimetrics if this option is checked.

Nexxim Circuit Netlist Design — Global Options

Selecting **Netlist format** on the **Circuit** menu allows you to set the format for netlists opened with **File>Open**. The choices are **HSPICE** and **Spectre**. The initial setting is **HSPICE**. The format is reset automatically to correspond to the format of the file being opened. To set option defaults that affect all circuit netlist designs, click **Tools>Options >General** to open the **Options** window, then select **Netlist Design** from the left group box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To transform on the time domain to the spectral domain for the selected netlist design. The default method, Fourier Integration, is very accurate but may be time-consuming for large data sets. The alternative method uses the Fast Fourier Transform to achieve faster conversion with a slight reduction in accuracy.

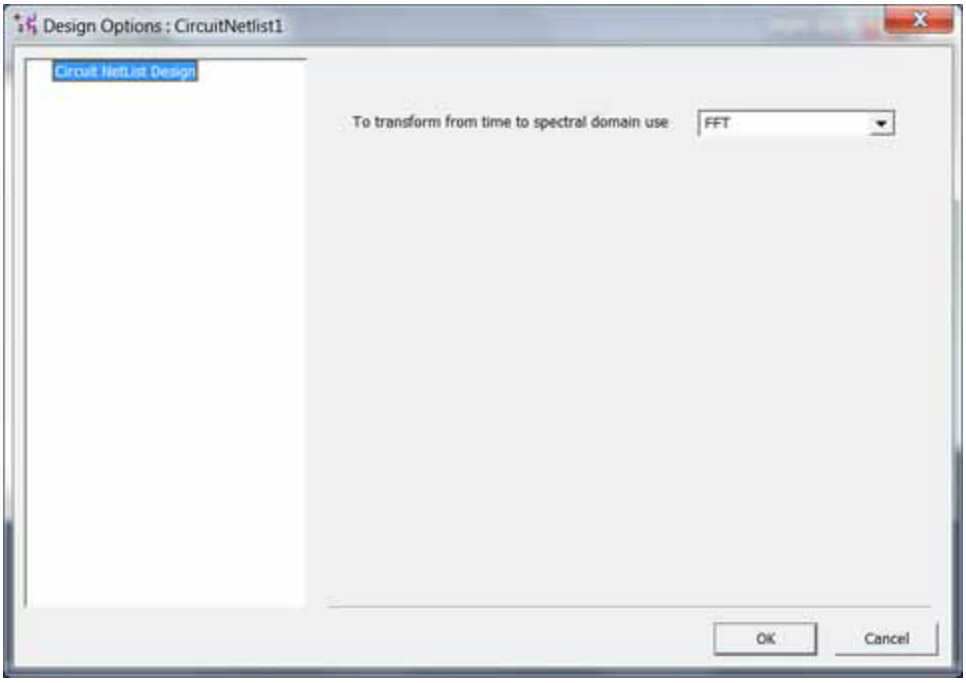
Limit number of each warning message – Lets you specify a maximum number for multiple instances of the same warning message (all error messages are always displayed). Click the check box and enter a whole number, 0 or greater. If the Nexxim solver generates multiple warning messages for the same issue, the number of messages displayed is limited to the value specified. The default is one (1) warning. The logfile includes all status messages, info messages, warning messages, and error messages regardless of this option.

Command Line — Additional options that the user can pass to the HPSICE solver during an HSPICE analysis.

Nexxim Circuit Netlist Design — Local Options

To set option defaults that affect a particular circuit netlist design, select the design in the **Project Manager** window, then select **Design Options** to open the **Nexxim Options** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To transform on the time domain to the spectral domain allows selection of the method used to transform on the time domain to the spectral domain for the selected netlist design.

- The default method, Fourier Integration, is very accurate but may be time-consuming for large data sets.
- The alternative method, Fast Fourier Transform, uses the FFT to achieve faster conversion with a slight reduction in accuracy.

Analysis-Specific Options

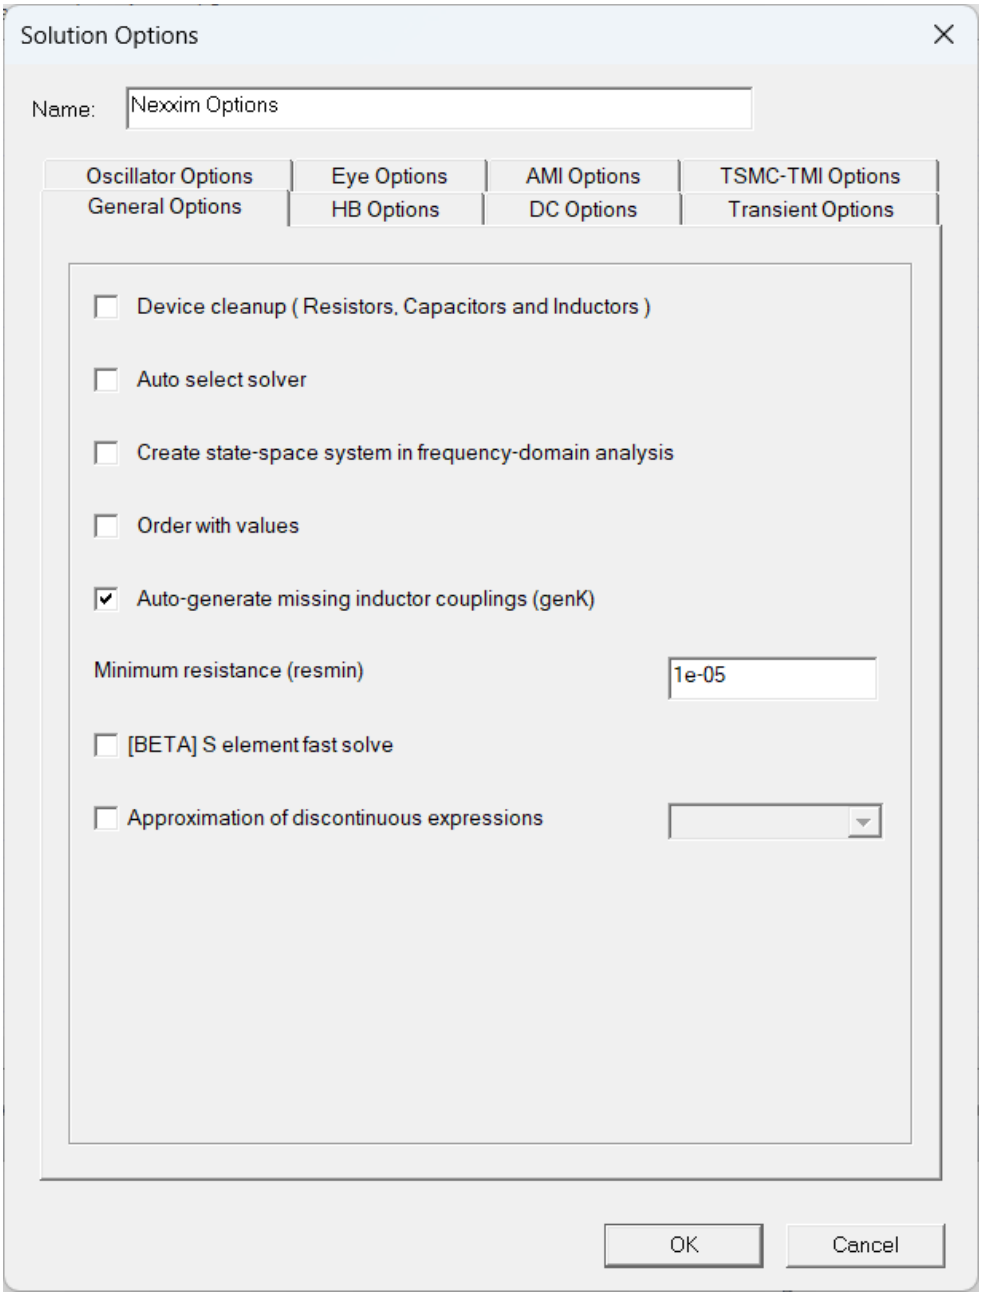
In a schematic, define sets of analysis-specific options with the **Add Nexxim Solution Options ...** selection. Then select a defined option set when creating or editing a solution setup. Using this mechanism, use the same option set in multiple analysis setups, or use different option sets in the same solution setup by editing the setup.

There are multiple ways to create an option set:

- From the **Circuit** menu, select **Add Nexxim Solution Options ...**.
- From the **Project Manager** window, expand the **Project Tree** and [*active design folder*]. Then right-click **Analysis** and select **Add Nexxim Solution Options ...** to open the **Solution Setup** window.
- Click **Select** in the **Solution Options** group box in a **Solution Setup** window.

Any of these actions opens the **Solution Options** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Click the **Name** field in the **Solution Options** window to assign a unique name to the set of options you are defining, or accept the default name.
- The **Solution Options** window has a tab for each of the Circuit analysis types: General Options, HB Options, DC Options, Transient Options, Oscillator Options, Eye Options, AMI Options, and TSMC-TMI Options.

General Options Tab

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The **General Options** tab sets options that apply to all Nexxim analyses. See Global Analysis Options and Global Device Options for more information on these options.
- **Device Cleanup** enables Nexxim to delete unused passive elements (sets **device_cleanup=1**).
- **Auto select solver** enables Nexxim to automatically select the sparse linear solver (sets **auto_select_solver=yes**). The default for **auto_select_solver** is No. When **auto_select_solver** is set to Yes, Nexxim selects the sparse linear solver that gives the best performance for all simulations specified in the netlist. Setting **auto_select_solver** can improve performance. However, for large circuits with a short simulation time (e.g., with a short-time transient analysis), **auto_select_solve** r may incur a time penalty due to the initialization.
- **Create state-space system in frequency-domain analysis** controls the treatment of S-parameter elements (sets **time_domain_s_model=1**).
- **Order with values** controls the matrix ordering algorithm (sets **order_with_values**). By default, **order_with_values=0**, selecting the default sparse matrix solver. Setting **order_with_values=1** selects an earlier solver.
- **Minimum Resistance** sets a minimum resistance for floating nodes (sets **RESMIN**).
- **[BETA] S element fast solve** enables the s element solving strategy to shorten simulation time for circuits with significant S, Y, or Z state space model presence. (Sets s_element.fast_solve=1).
- **Approximation of Discontinuous expressions** enables a smooth approximation of discontinuous expressions that arise from IF(t,x,y), LIMIT(x,min,max), MIN(x,y), MAX(x,y), SGN(x), and STP(x) netlist statements (sets the options: **conditional_sigmoid**, **soft_limit**, **soft_min**, **soft_max**, **step_sigmoid**, and **sgn_tanh**) . Once the approximation is enabled, the smoothness of the approximation is determined by the settings in the dropdown menu. The settings are **smooth**, **moderate**, and **accurate**. The **smooth** setting provides the most efficient simulation by trading off some accuracy, while the **accurate** setting trades off some efficiency and smoothness for the sake of accuracy. The **moderate** setting balances smoothness with accuracy.

HB Options Tab

- The **HB Options** tab sets options that apply only to Nexxim harmonic balance analyses. See Harmonic Balance Options for details on the HB analysis options.

DC Options Tab

- The **DC Options** tab sets options that apply only to Nexxim DC operating point analyses. See DC Analysis Options for details on the DC analysis options.

Transient Options Tab

- The **Transient Options** tab sets options that apply only to Nexxim transient analyses. See Transient Analysis Options for details on the transient analysis options.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Oscillator Options Tab

- The **Oscillator Options** tab sets options that apply only to Nexxim oscillator analyses. See Oscillator Analysis Options for details.

Eye Options Tab

- The **Eye Options** tab sets options that apply only to Nexxim VerifEye and Quick Eye analyses. See VerifEye and Quick Eye Analysis Options for details on the Eye analysis options.

AMI Options Tab

- The **AMI Options** tab sets options that apply only to Nexxim AMI analyses. See AMI Analysis Options for details on the AMI analysis options.

TSMC-TMI Options Tab

- The **TSMC-TMI Options** tab contains settings that apply only to Nexxim simulation using TMI models. Your installation must include DLLs from TSMC to use these options. Click the **Enable** check box to enable the Circuit solver to access the TSMC-TMI DLLs and activate the fields in the **TSMC-TMI Options** tab. See TSMC-TMI Options for details on the TSMC-TMI analysis options.

When you have completed setting options, click **OK** to exit the window. The named set of options is added to the **Analysis** icon in the **Project Manager** window.

Editing Solution Options

To edit a set of Solution options that has previously been defined:

- Click the icon for the option set under the Analysis group in the **Project Manager** window to open the **Solution Options** window. Edit the options, then click **OK** to exit.
- Alternatively, click **Select** in the **Solution Options** group box in a **Solution Setup** window to open the **Select Solution Options** window . Click the option set you wish to edit, and click **Edit** to open the **Solution Options** window. Edit the options, then click **OK** to exit the **Solution Options** window.

> **Note:** To apply a set of options in a Nexxim analysis, you must add the options in the **Solution Setup** window for a particular analysis. Click **Select** in the **Solution Options** group box of the **Solution Setup** window to open the **Select Solution Options** window. Click the name of the option set you want to use, then click **OK** on the **Select Solution Options** window. The name of the selected option appears in the **Name** field in the **Solution Options** group box. Complete the **Solution Setup** window as described in the topics on the individual analyses.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setting Options in a Netlist

In a netlist, both device and analysis-specific options are set with the **.OPTIONS** statement. The syntax is:

.OPTIONS [*qualifier.*]*option*[**=***val*][[*analysis.*]*option*[**=***val*] ...]

The **.OPTIONS** statement can contain multiple option settings, separated by spaces.

The *qualifier* makes its option specific to one analysis type:

dc for DC analysis

tran for transient analysis

hb for harmonic balance analysis

hb.env for harmonic balance envelope analysis

lna for linear network analysis

osc for oscillator analysis

osc.phase_noise for oscillator phase noise analysis

tv_noise for time-varying noise analysis

eye for VerifEye and Quick Eye analyses

ami for Algorithmic Modeling Interface (AMI) analysis

s_element for S-element calculations

w_element for W-element calculations

Nexxim also allows statement parameters that set options for just one particular analysis. For example, here is a partial syntax for the TRAN statement:

.TRAN*stepstoptime*
+**ERRPRESET=relaxed**|**moderate**|**strict**
+**RELREF=pointlocal**|**allocal**|**sigglobal**|**allglobal**

ERRPRESET and **RELREF** are statement parameters that set the corresponding options.

An analysis-specific option setting takes precedence over a non-specific setting of the same option, for the given analysis. For example, during a harmonic balance analysis, the option setting:

hb.abstol=4e-12

takes precedence over a setting of **abstol=2e-12** set elsewhere in the netlist. When you set an option with the **AddSolution Options** selection on the **Circuit** drop-down, or from in the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

individual **Solution Setup** windows, Ansys Electronics Desktop automatically puts the correct prefix on the option in the netlist.

See the help topics on the individual analyses for examples and discussions of the analysis-specific options.

Some options are flags that do not have a value. They are enabled when they are present in the **.OPTIONS** statement and unavailable otherwise. An example is WL, which reverses the order of the width and length model parameters in a MOSFET instance or element statement. Other options take a value, in which case the statement adds an equals sign after the name of the option.

When the same option has been set both inside and outside of the netlist, the following precedence is applied:

Command line options > netlist options > default (configuration file) options.

Within a netlist, options on the **.OPTIONS** statement can be overridden by model and instance parameters. The order of precedence is: instance parameter > model parameter > option.

If the netlist contains multiple **.OPTIONS** statements that set the same option, the last setting overrides any earlier settings.

Circuit Temperature Options

Properties of circuit elements may be a function of the element's temperature. The TC1 and TC2 parameters of a resistor, for example, relate the resistance to the resistor's temperature.

A Nexxim circuit includes two representations of temperature: the *actual* temperature and the *nominal* temperature.

The nominal temperature is the temperature at which the elements' baseline parameters are valid. The actual temperature is the temperature at which the circuit is being simulated. Temperature dependency equations deal with the difference between the element's actual and nominal temperature. Therefore, each element's actual and nominal temperature must be known.

By default, the global nominal temperature is 25 degrees Celsius. The global nominal temperature can be set in the netlist with the statement:

.OPTIONS TNOM=*val*

The value on the last **.OPTIONS TNOM** statement in the netlist becomes the global nominal temperature for all devices in the netlist that do not have another nominal temperature specification. The use of **TNOM** as a global option is available only via the netlist. There is currently no way to set **TNOM** globally from in the **Schematic Editor**.

Many device models include a **TNOM** or **TREF** model parameter. A **TNOM=***val* or **TREF=***val* entry in a **.MODEL** statement sets the nominal temperature for all device instances that

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

reference that model. The **TNOM** or **TREF** parameter can be set in the netlist, or on the Properties window of individual models in the **Schematic Editor**. A **TNOM** or **TREF** parameter overrides the value of the **TNOM** option, when both are present.

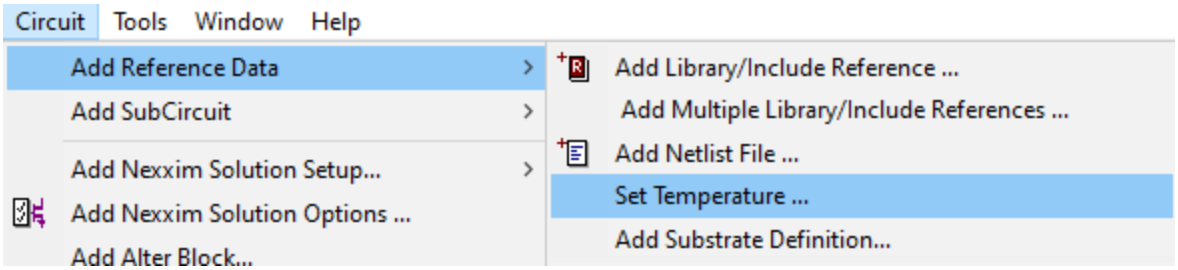
Note that it is also legal to give the value of the **TNOM** or **TREF** model parameter in the netlist statement defining a device instance. This overrides the value of the **TNOM** or **TREF** parameter in the model.

By default, the global circuit temperature is equal to the global nominal temperature. The global circuit temperature can be set in a netlist with the statement:

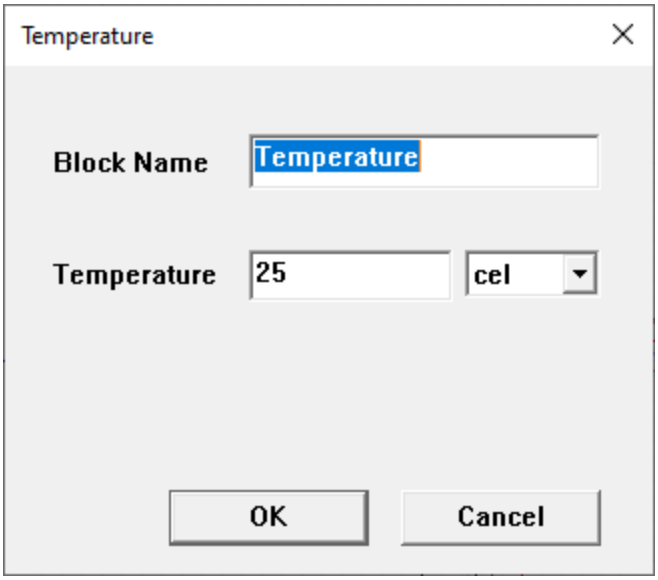
```
.TEMP temperature [temperature ...]
```

When more than one temperature is specified, Nexxim analyses perform a sweep of the multiple temperature points (unless the individual analysis statement already includes a temperature sweep). See Variable Sweep for further information. If the netlist contains multiple **.TEMP** statements, the last temperature overrides any earlier settings.

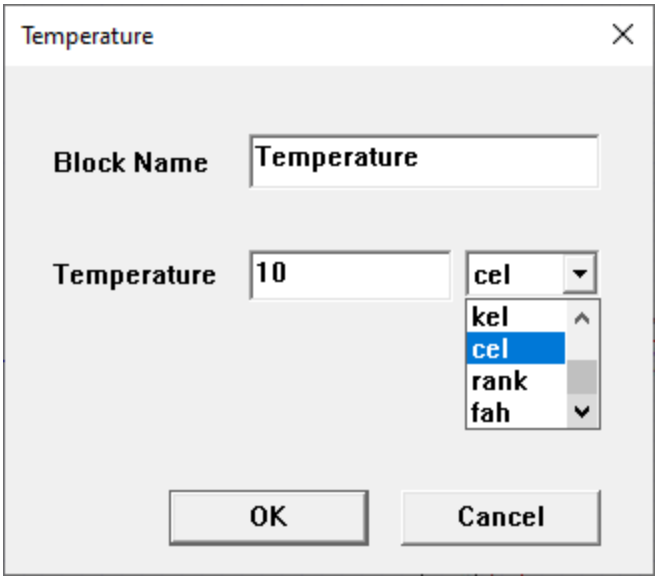
1. Set the global temperature by completing the following steps.
2. From the **Circuit** menu, select **Add Reference Data** >**Set Temperature ...** to open the **Temperature** window.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Choose the appropriate scale (i.e., **mkel**, **ckel**, **dkel**, **kel**, **cel**, **rank** or **fah**) and type the appropriate temperature into the field.



4. Click **OK**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** A device instance statement can include the entry **DTEMP=***val*. The value *val* is added to the global circuit temperature to determine the actual temperature of the device instance.

Setting Options or Temperature in External Files

.OPTIONS and **.TEMP** statements can be supplied from external **.INCLUDE** and **.LIB** files (See External Files in the Netlist Format help topic).

A file imported with **.INCLUDE** is copied into the netlist at the point of the **.INCLUDE** statement. Thus, a setting made with **.OPTIONS** or **.TEMP** statements in a **.INCLUDE** file overrides settings made in earlier statements, and is overridden by later statements.

A portion of a file imported with **.LIB** is processed after all other statements in the netlist have been processed, and the order of processing of statements in .LIB files versus the main file cannot be determined in advance. Thus, if a **.LIB** block contains a **.OPTIONS** statement for a particular option, it should be the only setting for that option in the entire netlist. If a **.LIB** block contains a **.TEMP** statement, it should be the only **.TEMP** statement in the entire netlist.

If a **.OPTIONS** statement is deprecated, it generates a warning and be ignored.

Nexxim Circuit Netlist Design — Options Reference

This topic contains tables for all the customer-accessible Nexxim Circuit netlist design-level options.

Global Analysis Options Reference

Global analysis options apply to multiple Nexxim analyses.

Global Analysis Options

Option	Default Value	Description
abstol	1e-9	Absolute error tolerance for currents (Amps)
alpha	0.0	Minimum conductance of the resistor placed in parallel with each branch (mho)
auto_enforce_passivity	1	1=Enable auto_enforce_passivity for all W-elements and S-elements. Passivity enforcement should be enabled or deactivated globally for both S-elements and W-elements. Use of the local auto_enforce_passivity options to selectively deactivate passivity

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
		enforcement for 0=Turns off passivity enforcement for all w-elements and s-elements in the circuit. When the Global option is deactivated (set to 0), the **auto_enforce_passivity** option set in a W-element or S-element is ignored. **auto_enforce_passivity** is valid only in a transient simulation and is ignored in a frequency-domain analysis (HB or LNA).
auto_select_ solver	No	When Yes, Nexxim selects the sparse linear solver that gives the best performance for all simulations in the netlist
autoconverge	1	1 = Enable automatic cyclic progression through convergence methods upon convergence failure. 0 = Turns off automatic cycling of methods.
behavioral_ minimum_ divisor	0	Minimum divisor to use for behavioral components. Set to nonzero value to prevent division by zero.
beta	0.0	Minimum conductance of the resistor placed between each node and ground (mho)
dcic	1	Flag to ignore initial conditions
delmax, tmax, maxstep	min (*stoptime*/100, 15**tstep*)	Maximum step size
foster_ bundling	1 if the number of Foster elements in the design is 25 or more and AMI, EYE or Tran analysis is requested — otherwise 0.	1=Detect port-to-port transfer functions (of type VCCS or VCVS) of an N-port macromodel in pole-residue format (also known as the Foster format) that share the same poles, and eliminate redundant calculations. This is the default setting. Macromodels are usually constructed with port-to-port transfer functions that share the same set of poles. In these cases, the **foster_bundling** option significantly reduces the run time and memory consumption of the simulation,

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
		especially for macromodels with large numbers of ports and/or large numbers of poles. This option does not affect the accuracy of the simulation. 0=Treat each port-to-port transfer function independently. When this option is set to 1 (bundling enabled), error messages on the simulator due to some errors in the macromodel (e.g., a complex pole-pair with only real values for the residues) does not pinpoint the Foster element that is causing the problem; instead, they is more generic. If this kind of limitation is a concern, then set this option to 0. This option is ignored for LNA, OSC, HB and TV analyses.
gmax	1e2	Maximum conductance of the resistor placed in parallel with each branch (mho)
gmindc	0.0	Minimum conductance of the resistor placed in parallel with each branch (mho)
gshunt	0.0	Minimum conductance of the resistor placed between each node and ground (mho)
iabstol	1e-9	Absolute error tolerance for currents (Amps)
limiting	1	1=allow limiting on Newton steps
limiting_step	0.3 for nonlinear circuits. Very large (unavailable) for linear circuits.	Maximum absolute voltage update allowed per N-R iteration (Volts)
ltratio	7.0	Ratio of transient analysis tolerance to Newton-Raphson tolerance, for timestep calculation
macmod	0	1=Use subckt definition for *modelname* in MOSFET/BJT/Diode instance when no .MODEL reference exists.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
		2=Use .MODEL definition for *subckt_name* in X-element instance when no subckt exists. 3=Both 1 and 2. When **TMIFLAG** is set, **macmod=2** is automatically set.
max_continuation_iterations	500	Maximum number of continuation steps allowed per strategy
max_newton_iterations	10 (TRAN) 200 (DC) 20 (HB)	Maximum number of Newton-Raphson (N-R) iterations per continuation step
maxiters	10 (TRAN)	Maximum number of Newton-Raphson iterations for each timestep
max_messages	1	Maximum number of warning messages of the same type to be displayed in the **Message Manager** window. All error messages are always displayed. If **max_messages** is not present, no message filtering is done. The logfile includes all messages, warnings, and errors regardless of this option.
method	trap	Integration method (parentheses show synonyms for methods): **trap** (**trapezoidal**) **gear** (**bdf2**) **ndf2**
minimum_divisor	0	Minimum divisor. Use 1e-28 for HSPICE compatibility.
num_threads	1	Maximum number of independent processor threads to use during analyses. To prevent a scenario where parallel simulation is slower than serial simulation, Nexxim may use fewer threads than requested by the user.
order_with_values	0	0=default sparse matrix solver 1=earlier solver, uses values in Jacobian in computing the fill reduction ordering
parhier	None	PARHIER=L reverses the precedence of parameter assignment in subcircuits

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
password	None	To access encrypted password-protected external files.
reltol	1e-3	Relative error tolerance for currents and voltages
result_as_initial_guess	1	1=Use of the result from each step in a sweep as the initial guess for the next sweep step.
rmax	5	Factor for calculating maximum first stage timestep
seed	None	Used by random-value generator to initialize the sequence of pseudorandom values. Using the same seed generates the same sequence of values.
skip_dc	no	yes = Field solvers need not solve for DC. Use this option only for circuits with linear devices and no non-zero-valued sources except AC sources. no = Solve for DC.
time_domain_s_model	0	1=Create state-space system in a frequency-domain analysis like LNA where one is not usually generated. The state-space system may not be passive unless passivity enforcement is enabled. (**s_element.enforce_passivity** =non-zero). **time_domain_s_model** is processed only in a frequency-domain analysis (HB or LNA) that is run WITHOUT passivity enforcement activated. If passivity is enforced in a frequency-domain analysis, then time-domain modeling is automatically enabled, eliminating the need for the **time_domain_s_model** option. If this option is specified in a netlist along with passivity enforcement and LNA, then this option is silently ignored.
time_domain_w_model	0	1=create state-space system, even in a frequency-domain analysis like LNA where one is not usually generated. The state-space system may not be passive

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
		unless passivity enforcement is enabled. (**w_element.enforce_passivity** =non-zero). **time_domain_w_model** is processed only in a frequency-domain analysis (HB or LNA) that is run WITHOUT passivity enforcement activated. If passivity is enforced in a frequency-domain analysis, then time-domain modeling is automatically enabled, eliminating the need for the **time_domain_w_model** option. If this option is specified in a netlist along with passivity enforcement and LNA, then this option is silently ignored.
trtol	7.0	Ratio of transient analysis tolerance to Newton-Raphson tolerance, for timestep calculation
unit_atto	None	When set, A as a numeric suffix means e-18 (atto) rather than Ampere.
vabstol	50e-6	Absolute error tolerance for voltages (Volts)
vntol	50e-6	Absolute error tolerance for voltages (Volts)

Global Device Options Reference

Global device options affect all devices of a given type unless overridden by model and instance parameters.

Global Device Options

Option	Description	Used By	Default
DEVICE_CLEANUP	1 = delete zero-valued resistors, capacitors, and inductors 0 = do not delete (default)	Resistor, Capacitor, Inductor	0
DAMPINDUCTORS	Damping of inductors	Power electronics simulations	1e12
DIODECJO	Specify minimum value of parameter CJO for simulation of PSPICE diode	PSPICE diodes	5e-17

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Description	Used By	Default
	models.		
	Enable/disable computing of missing mutual inductances (for HSPICE compatibility).	Mutual inductor	1
GENK	• **1** =compute • **0** =do not compute. When GENK=0, all missing mutual inductance coupling coefficients are set to 1e-10 (no coupling).		
GFARAD	Conductivity leakage of capacitors.	Power electronics simulations	1e-12
GMAX	Maximum conductance used in NODESET calculations	Resistor	1.0
MOSFETCJO	Supply a minimum capacitance for MOSFET source/drain junctions.	Power electronics simulations.	5e-12
PARHIER	PARHIER=L reverses the precedence of parameter assignment in subcircuits	Subcircuits	Not set (default precedence)
RESMIN	Minimum resistance (positive or negative)	Resistor	If GMAX is defined, calculated from GMAX Else: 1.0e-5
SCALE	Scaling multiplier for instance parameters. The parameters affected vary across model implementations.	Device Instances	1.0
SCALM	Multiplier for model parameter values. The parameters affected vary across model implementations.	MOSFETs	1.0
SKIP_PWL_DIODE	Determines whether to keep the original model. Possible values are: • **0** - Replace idealized semiconductor diode models (n < 0.5) with an equivalent piece-wise linear model to improve convergence in Power Electronics simulations. Active only for PSPICE model import.	Diodes	0

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Description	Used By	Default
	• **1** - Override replacement (keep original models).		
THEV_INDUC	Turns a default 1 mOhm series resistance on or off for inductors.	Power electronics simulations	1(on)
WL	Reverses the default order of width and length parameters on MOSFET instances	MOSFETs	Not set (default parameter order)

DC Analysis Options Reference

These options apply to Nexxim DC operating point analyses. See DC Analysis Options for an explanation of these options in the **Schematic Editor** and netlist editor.

Nexxim DC Analysis Options

Option	Default Value	Description
abstol	1e-9	Absolute current tolerance (Amps). The DC simulator starts with this options at an initial value.
alpha	1e-13	Minimum conductance of the resistor placed in parallel with each branch (mho, equivalent to GMINDC)
autoconverge	1	1 = Enable automatic cyclic progression through convergence methods starting with **conv** setting, upon convergence failure. 0 = Turns off automatic cycling of methods.
beta	1e-12	Minimum conductance of the resistor placed between each node and ground (mho, equivalent to GSHUNT)
conv	1	1 = Beta and device continuation 2 = Device continuation 3 = Pseudotransient 4 = Modified beta/device continuation 5 = Alpha, beta, and device continuation
create_ic_file	0	1=Create initial conditions (.ic) file from DC operating point.
dcic	1	Flag to ignore initial conditions
gmax	1e2	Maximum conductance of the resistor placed in parallel with each branch (mho). Used for HSPICE compatibility in NODESETs and initial conditions

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
limiting	1	1=allow limiting on Newton steps
limiting_ method	Standard Limiting	Standard Limiting = Damped Newton-Raphson. Modified Limiting = Newton-Raphson with enhanced limiting algorithm. Faster convergence rate for moderately nonlinear circuits.
limiting_step	0.3 for nonlinear circuits. Very large (unavailable) for linear circuits	Maximum absolute voltage update allowed per N-R iteration (Volts). The DC simulator starts with this options at an initial value.
max_ continuation_ iterations	500	Maximum number of continuation steps allowed per strategy
max_newton_ iterations	200	Maximum number of Newton-Raphson (N-R) iterations per continuation step. The DC simulator starts with this options at an initial value.
max_newton_ iterations_limit	None	Maximum post-lambda pseudo-transient continuation
max_pt_ continuation_ iterations (Used only when **conv=3** has been specified.)	5000	Maximum iterations of pseudotransient continuation
min_lambda_ step	1e-4	Minimum lambda step allowed in continuation
output_ic_file_ name	None	Name of the initial condition file
reltol	1e-3	Relative current and voltage tolerance. The DC simulator starts with this options at an initial value.
result_as_ initial_guess	1	Turned off, when set to 0, otherwise the use of the result from each step in a sweep as the initial guess for the next sweep step.
vntol	50e-6	Absolute voltage tolerance (Volts). The DC simulator starts with this options at an initial value.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Transient Analysis Options Reference

These options apply to Nexxim transient analysis.

Nexxim Transient Analysis Options

Option	Default Value	Description
abstol	1e-9	Absolute error tolerance for currents (Amps)
accurate_ points.num	0	Force transient analysis to place time points at N equidistant points (simulate N events)
accurate_ points.start	0.0	First accurate point
accurate_ points.stop	0.0	Last accurate point
alpha	0.0	Minimum conductance of the resistor placed in parallel with each branch (mho)
auto_conv_ enhancement	0	To enable, set to 1. Increases the chance of convergence, balance performance, and accuracy. The following initial solver settings are modified if enabled: **step** = **step**/100 **maxiters** = 100 **update_jacobian_period** = 2 **method** = ndf2 **maxstep** = 100*step **alpha** = **beta** = 1e-5 **relref** = **alllocal** if it was **pointlocal** **relref** = **allglobal** if it was **alllocal** The value of **alpha** and **beta** are dynamic during simulation. Aggressive time stepping algorithm is applied.
beta	0.0	Minimum conductance of the resistor placed between each node and the ground (mho)
CMIN	0.0	Minimum capacitance placed between each node and the ground (F).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
		The CMIN option should be used when transient analyses fail to converge despite the step size becoming very small. The minimum capacitance specified should be in the range of 1e-18 to 1e-14 F for the most accurate results. If CMIN is set to a value larger than 1e-12 F, the CMIN value is automatically reset to 1e-12 F.
convergence_ enhancement	0	To enable, set to 1. Increases the chance of convergence for some designs. The following solver settings are modified if enabled: **step** = **step**/100 **maxiters** = 100 **update_jacobian_period** = 1 **method** = ndf2 **maxstep** = 25*step **alpha** = **beta** = 1e-5 **relref** = **alllocal** if it was **pointlocal** **relref** = **allglobal** if it was **alllocal**
delmax, tmax, maxstep	min (*stoptime* /100, 15**tstep*)	Maximum step size
errpreset	None	Overrides parameter defaults for speed/accuracy trade-off. See Table 4 in this topic.
freq_ restriction	1	Ensure at least 8 time points in one period.
limiting	1	1=allow limiting on Newton steps
limiting_step	0.3 for nonlinear circuits. Very large (unavailable) for linear circuits.	Maximum absolute voltage update allowed per N-R iteration (Volts)
max_damp	0	Nonlinearity-based time stepping decreasing factor controller. Must be no greater than 1.
max_ frequency	50e9	Maximum frequency resolved by transient; used for S-parameters
maxiters	10	Maximum number of Newton-Raphson iterations for each

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
		timestep
max_mem_ size	200e6	Maximum size in bytes for internal storage of unknowns. With 64-bit solvers, max_mem_size may be set to 500e6 or higher to handle circuits with large numbers of nodes and branches, or circuits with W-elements that have long delays.
max_stretch	0	Nonlinearity-based time stepping increasing factor controller. Must be no greater than 2.
method	trap	Integration method (parentheses show synonyms for methods): **trap** (**trapezoidal**) **gear** (**bdf2**) **ndf2**
NOISEFMAX	0	The highest frequency to analyze for pseudorandom noise. Must be non-zero to enable transient noise analysis. Maximum transient timestep is set to 1/NOISEFMAX.
NOISEFMIN		Lowest frequency to analyze for noise. Under NOISEFMIN, noise power density is constant. 1/NOISEFMIN must be less than the transient analysis stoptime. **Not used currently.**
NOISESCALE	1	Scale factor
NOISESEED	0	Random number seed. Using the same seed generates the same set of random values
NOISESTART	0	Noise start time
NOISETMIN	0	Noise minimum transient step. **Not used currently.**
num_ frequencies	500	Number of frequencies resolved by transient plus DC; used for S-parameters
outputstart	0.0	Time to start saving results to a file
relref	alllocal	The **RELREF** argument controls how the norms are computed for the delta check, function check, and LTE checks. *Point-local* means the norm is local to the signal and to the timestep. *Local* means the norm is local to the signal but considers the maximums over all time-steps. *Global* means the norm is global for the entire circuit over all time-steps. The settings for **relref** are: **pointlocal** = Point-local for delta, function, and LTE **alllocal** = Local for delta, function, and LTE

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
		sigglobal = Local for function, global for delta & LTE **allglobal** = Global for delta, function, and LTE
reltol	1e-3	Relative error tolerance for currents and voltages
read_state	None	Read initial state on the specified file
result_as_ initial_guess	1	1=Use of the result from each step in a sweep as the initial guess for the next sweep step.
rmax	5	Factor for calculating maximum first stage timestep
sig_storage_ off	0	1=Skip time domain probe data storage
skipResult	0	By default, transient results are stored into the SDF file. For the Eye Scope, setting skipResult to 1 allows the user to see the eye without storing all the data. WARNING: Nexxim does not check that there is an Eye Scope present, risking loss of data.
step	None	Suggested transient step size
stop	None	Stop time
stop_pwl_ times	1	0=Transient does not stop at the data points in any PWL source 1=Transient stops and starts backward Euler at every point specified in all PWL sources 2=Transient stops at every data point in all PWL sources, but maintains the current integration order 3=Transient stops only at data points that deviate on the extrapolation using the previous two points by more than the reltol and abstol specified for transient
tpbs	0	1=Enable transient parallel bus speedup
tpbs.maxiters	Depends on num_threads	Number of parallel iterations
tpbs.overlap	Depends on num_threads	Length of parallel overlap in seconds
tpbs.reltol	0.005	Relative error tolerance for voltages and currents within parallel iterations
tran.calc_stat_ eye	0	Enables statistical eye plots for Transient setups when there is an eyeprobe or eyescope present in the design
trtol	7.0	Ratio of transient analysis tolerance to Newton-Raphson tolerance, for timestep calculation
update_ jacobian_	3	Number of Newton steps per Jacobian update

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
period		
write_final_state		Write the final values of node voltages to specified file
write_initial_state		Write the initial (DC) values of node voltages to specified file
vntol	50e-6	Absolute error tolerance for voltages (Volts)

Nexxim Transient Analysis Accpreset Option

Option	accpreset			
	None	**relaxed**	**moderate**	**strict**
reltol	x1	x10	x1	/10
trtol	7	7	7	10
relref	alllocal	sigglobal	sigglobal	alllocal
method	trap	trap	trap	ndf2
maxstep	stoptime/100	stoptime/12	stoptime/50	stoptime/100
update_jacobian_period	3	3	3	1

Nexxim Transient Analysis: Specific Solver Settings for Power Electronics

	Description	Specified Options Values
Power Electronics	Default settings for power electronics designs.	Integration method=ndf2 Update Jacobian period=1 Maximum Newton-Raphson iterations = 30
Power Electronics-	Use when the magnitudes of the voltages and currents in the circuit approach >100V or >100 A or when the default power	Integration method=ndf2

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	Description	Specified Options Values
HV (High Voltage)	electronics settings fail to converge.	Update Jacobian period=1 Maximum Newton-Raphson iterations=100 Absolute error tolerance for current (abstol) = 0.001 Absolute error tolerance for voltage (vntol) = 0.001 Relative error tolerance (reltol) = 0.01 Local truncation error factor (trtol) =5 Alpha = 1e-10 Beta = 1e-10
Power Electronics-Speed Up	Apply to circuits that already converge and are fairly well behaved. This setting can result in an approximately 2x speed-up.	Integration method=ndf2 Update Jacobian period=3 Maximum Newton-Raphson iterations=30

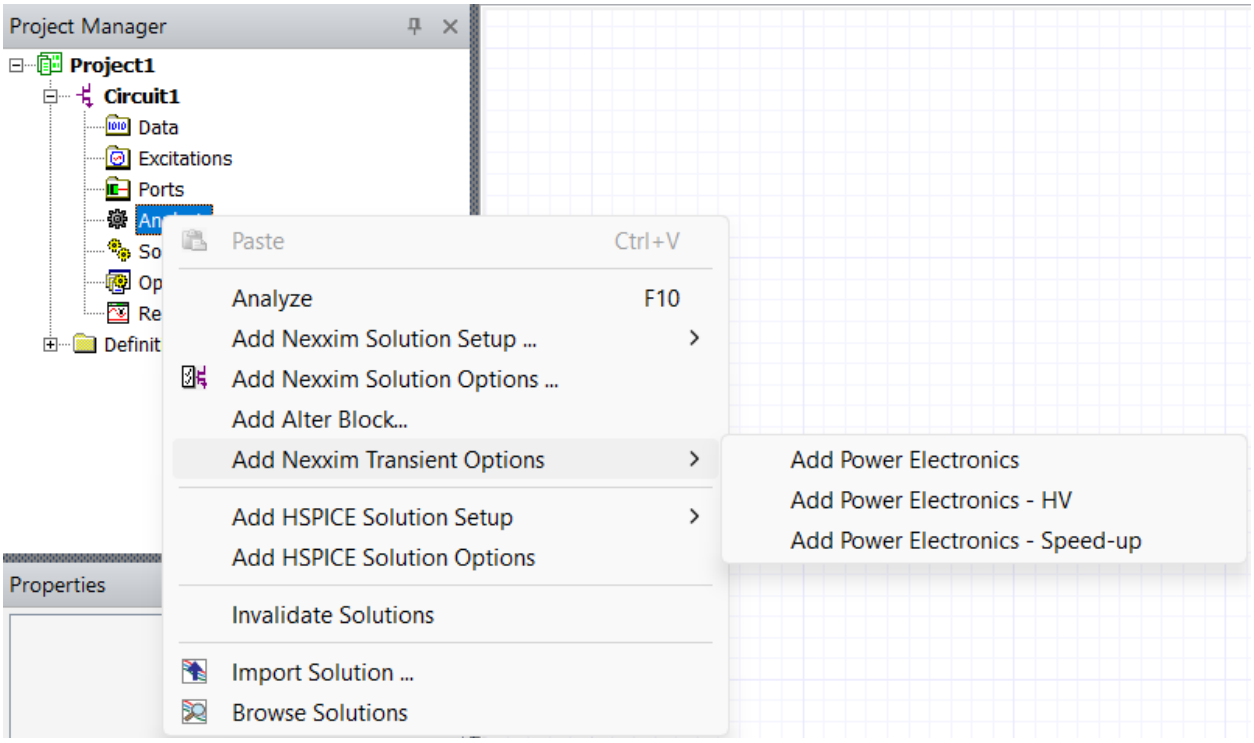
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	Description	Specified Options Values
		Relative error tolerance (reltol) = 0. 0025

UI Access to Specific Solver Settings for Power Electronics

To access these settings via the UI:

From the **Project Manager** window, expand the **Project Tree** and [*active design folder*]. Right-click **Analysis** and expand **Add Nexxim Transient Options** to select a power electronics solver setting option.



Harmonic Balance Options Reference

These options apply to Nexxim harmonic balance analyses.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Nexxim Harmonic Balance Analysis Options

Option	Default Value	Description
abstol	1e-12	Absolute error tolerance for currents for the nonlinear equation solver (Amp)
alpha	1e-12	Conductance in parallel with each branch (mho, equivalent to G_{MIN})
auto_refine_solution	no	For power sweeps, yes = increase number of harmonics as power increases
beta	0.0	Conductance between each node and ground (mho, equivalent to G_{SHUNT})
cmin	0.0	Capacitance between each node and ground (Farad)
cluster_tol	1e-2	Multitone frequencies within this tolerance are clustered to save memory (Hz)
continuation	**source_ stepping_ last_tone**	Continuation strategy **source_stepping_last_tone** (solve low-voltage case for last tone in **TONES** group box, then increase voltages until true circuit is solved.) **pseudo_transient** (use additive transient term)
continuation.pseudo_ transient.max_h Used only when **continuation=pseudo_ transient** is in effect	5e3	Initial value of internal pseudotransient variable
continuation.pseudo_ transient.pt_reltol_scale Used only when **continuation=pseudo_ transient** is in effect	0.8	Relative tolerance of pseudotransient reltol to standard HB
continuation.pseudo_ transient.step_reltol_ scale Used only when **continuation=pseudo_ transient** is in effect	0.8	Relative tolerance of pseudotransient continuation to standard HB
initial_guess	**dc** for single-tone, **fewer_ tones** for	Source for initial guess at voltages and currents **dc** (Run DC)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
	multi-tone	**fewer_tones** (iterative guesses) **fewer_tones_transient** (iterative guesses starting with result of transient analysis) **file** (read from HB file) **transient** (Run transient analysis) **zero** (Zero)
initial_guess.fewer_tones_transient.num_cycles (Used only when **fewer_tones_transient** is selected for the **initial_guess** option.)	20	Number of cycles of 1st tone period to run initial transient analysis
initial_guess.fewer_tones_transient.tmax (Used only when **fewer_tones_transient** is selected for the **initial_guess** option.)	None	Suggested maximum step size for transient analysis
initial_guess.fewer_tones_transient.tstop (Used only when **fewer_tones_transient** is selected for the **initial_guess** option.)	None	Stop time for transient analysis
initial_guess.transient.num_cycles (Used only when **transient** is selected for the **initial_guess** option.)	20	Number of cycles of 1st tone period to run initial transient analysis
initial_guess.transient.tmax (Used only when **transient** is selected for the **initial_guess** option.)	None	Suggested maximum step size for transient analysis
initial_guess.transient.tstop (Used only when **transient**	None	Stop time for transient analysis

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
is selected for the **initial_ guess** option.)		
initial_guess_file (Used only when **file** is selected for the **initial_ guess** option.)	None	Pathname and filename of SDF-format file with HB results to use as initial guess
limiting_step	0.3	Maximum absolute voltage update allowed per iteration for the nonlinear equation solver
linearsolver_reltol	1e-2	Reltol for linear solver
linearsolver_restarts	1	Maximum linear solver restarts
limiting_step	0.3 for nonlinear circuits. Very large (unavailable) for linear circuits.	Maximum absolute voltage update allowed per N-R iteration (Volts)
maxk	None	Maximum number of harmonics at each frequency
max_linearsolver_ iterations	100	Maximum number of iterations for linear equation solver
max_newton_iterations	20	Maximum number of iterations for the nonlinear equation solver
memory_over_speed	0	0 = Run to maximize speed, memory use may be excessive 1 = Run to conserve memory
method	hb	**hb** = standard HB calculation. **shooting** = HB method for strongly nonlinear circuits
power_of_two_ expansion	1 for single-tone, 0 for multi-tone	Expand MAXK to
preconditioner	0	Select preconditioner (1=time_ frequency, 0=bdf)
read_state	None	Read initial state on the specified file
reltol	1e-3	Relative error tolerance for currents and voltages (dimensionless)
result_as_initial_guess	1	Turned off, when set to 0, otherwise the use of the result from each step in a sweep as the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
		initial guess for the next sweep step.
strongly_nonlinear	0	0=linear/mild, 1=strongly nonlinear/shooting
td_preconditioner	1	1=use td preconditioner. **Mainly for internal use.**
tones	None	List of frequencies to analyze
trim_tol	0	Harmonics voltage tolerance. Harmonics less than trim_tol after the initial guess are pruned. 0=no pruning. **Mainly for internal use.**
trtol	7	Ratio of transient analysis tolerance to Newton-Raphson tolerance, for timestep calculation
tstab	None	Initial stabilization time. Can be used to change the starting phase of the HB algorithm
vntol	1e-7	Absolute error tolerance for voltages for the nonlinear equation solver (Volt)
write_final_state		Write the final values of node voltages to specified file.
write_initial_state		Write the initial (DC) values of node voltages to specified file.
zero_freq_at_end	1	Return to DC at end of simulation. Only for single-tone HB

Linear Network Analysis Options Reference

These options apply to Nexxim linear network analyses.

Nexxim Linear Network Analysis Options

Option	Default Value	Description
flag	LNA	LNA = simple AC analysis NOISE_DC = noise analysis LNAN=AC and noise LNAG=AC and group delay LNANG=AC, noise, and group delay
group_ delay_	None	Perturbation (percentage of the test frequency) to be applied in group delay calculation

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
pert		
input_referred_noise	None	Node voltage, branch, or current to be used as the source for an input-referred noise calculation
result_as_initial_guess	1	Use LNA solution as initial guess in sweep
noise_output	None	Output nodes where noise should be computed in noise analysis. No noise factor or conversion gain is computed for these outputs
skip_dc	no	yes = Field solvers need not solve for DC. Use this option only for circuits with linear devices and no non-zero-valued sources except AC sources. no = Solve for DC.
small_signal_beta	1e-12	Minimum conductance from node to ground in small-signal analysis
ZERO_PORT_VALUES	TRUE	Enable use of port impedance resistors **Note:** **May be obsolete.**

Oscillator and Phase Noise Analysis Options Reference

These options apply to Nexxim oscillator and oscillator phase noise analyses.

Nexxim Oscillator and Phase Noise Analysis Options

Option	Default Value	Description
freq_abstol	10	Relative tolerance for oscillation frequency
harmonic_number	None	Oscillator harmonic to compute phase noise for (Phase noise analysis only)
initial_guess	**transient**	Select method for initial guess at probe frequency **dc** = use **FREQ** parameter on the oscillator probe.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
		freq_sweep = run frequency sweep **transient** = run transient analysis
initial_guess.freq_sweep.method	linear	Linear or nonlinear solution type for frequency sweep initial guess
initial_guess.freq_sweep.num_steps	50	Number of steps for frequency sweep
initial_guess.freq_sweep.start	1e9 Hz	Start frequency for frequency sweep
initial_guess.freq_sweep.stop	5e9 Hz	End frequency for frequency sweep
initial_guess.transient.num_cycles	Calculated	Number of periods for transient initial guess (like stop time)
initial_guess.transient.output_start	0	Initial time during transient analysis that is ignored by initial guess
initial_guess.transient.tmax	Calculated	Maximum step size for transient analysis
initial_guess.transient.tstep	Calculated	Maximum step size for transient analysis
initial_guess.transient.tstop	Calculated	Stop time for transient analysis initial guess
iprobe_abstol	1e-11	abstol for probe current
maxk	None	Maximum number of harmonics at each frequency (Phase noise analysis only)
noise_output	None	Node or branch to compute the phase noise on (Phase noise analysis only)
nonlinear_method	**newton**	Newton-Raphson iteration strategy **newton** = standard Newton-Raphson **damped_newton** = use ΔV damping **descent** = follow slope of derivative
nonlinear_method.descent.num_iterations	100	Maximum number of steps in descent initial guess. **Mainly for internal use.**
nonlinear_method.descent.param.f_tolerance	1e-4	Function reltol in descent **Mainly for internal use.**
nonlinear_method.descent.param.max_step	0.01	Maximum normalized step size in descent **Mainly for internal use.**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
nonlinear_ method.descent.param.step	1e-4	Normalized step size in descent **Mainly for internal use.**
nonlinear_ method.descent.param.tolerance	0.01	reltol in descent **Mainly for internal use.**
nonlinear_ method.descent.param.	1e-4	Function reltol in descent **Mainly for internal use.**
nonlinear_method.newton.barrier	2	Power of the barrier that prevents probe from zero voltage. **Mainly for internal use.**
phase_noise.method	**stochastic**	Select stochastic or time_varying method for phase noise computation
reltol	1e-4	Relative voltage tolerance for NR iterations
result_as_initial_guess	**false**	When set to **true**, result from previous sweep step is used as the initial guess for the current sweep
tones	None	Approximate oscillator frequency
vprobe_abstol	1e-5	abstol for voltage probe

Envelope Analysis Options Reference

These options apply to Nexxim envelope analyses.

Nexxim Envelope Analysis Options

Option	Default Value	Description
clockname	None	Name of the device providing the clock fundamental. Nexxim determines the clock period by searching the sources with this name. (Mutually exclusive with period and fund)
envmethod	trap	Integration method for transient analysis. trap=trapezoidal rule, bdf2=second-order backward difference formula (Gear)
fund	None	Clock or carrier frequency (mutually exclusive with period and clockname)
maxk	None	Maximum number of harmonics at each frequency (Phase noise analysis only)
modulationbw	None	Estimate of the bandwidth of the nonperiodic RF modulation input signal

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
period	None	Period of clock fundamental (mutually exclusive with fund and clockname)
step	None	Used in maximum timestep calculation for transient
stop	None	Stop time for transient. Required to distinguish envelope analysis from ordinary HB
tones	None	Estimated frequencies of the periodic inputs for HB
hb.auto_ refine_ solution	no	For power sweeps, yes=increase number of harmonics as power increases
hb.env.fixed_ step	0	If >0 envelope analysis uses this as a fixed step. **Mainly for internal use.**
hb.method	hb	**hb** =standard HB calculation. **shooting** =HB method for strongly nonlinear circuits
hb.trim_tol	0	Harmonics voltage tolerance. Harmonics less than trim_tol after the initial guess are pruned. 0=no pruning. **Mainly for internal use.**

TV Noise and PXF Analysis Options Reference

These options apply to Nexxim time-varying (TV) noise and periodic transfer function (PXF) analyses.

Nexxim TV Noise and PXF Analysis Options

Option	Default Value	Description
abstol	1e-12	Absolute error tolerance for currents (Amp)
freqaxis	absin	Output results versus the input frequency, the output frequency, or the absolute value of the input frequency. Only for PXF.
fund	None	Steady state analysis fundamental frequency (or estimate for autonomous circuits).
iprobe	None	Input RF port, current source, or voltage source for small-signal input. For a port, Nexxim computes the noise figure and conversion gain in Volts (in the sense of available power)
linearsolver_ restarts	1	Maximum linear solver restarts
max_	20	Maximum number of iterations for linear equation solver

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
linearsolver_ iterations		
maxsideband	None	Maximum sideband for PXF
noise_output		Output nodes where noise should be computed in noise analysis. No noise factor or conversion gain is computed for these outputs
oprobe	None	Output port, current source, voltage source, resistor, or current probe for small-signal output.
probe	None	PXF computes every transfer function to the specified probe component
pxf	false	Enable PXF analysis
refsideband	None	Coefficients for calculation of the input frequency
relharmnum	None	Specify a single relative harmonic number
relharmvec	None	Specify a list of relative harmonic numbers
saveallsidebands	no	yes=save all sideband results
sidebands	None	List of relevant sidebands
ss_analysis	hb	Select hb or osc to compute the steady-state values
ss_maxk	None	Maximum number of harmonics at each frequency in the steady-state calculations
ss_tones	None	List of frequencies to use in the steady-state HB calculations
reltol	1e-3	Relative error tolerance for currents and voltages (dimensionless)
tstab	None	Initial stabilization time. Can be used to change the starting phase of the HB algorithm
hb.auto_refine_ solution	no	For power sweeps, yes=increase number of harmonics as power increases
hb.method	hb	**hb** =standard HB calculation. **shooting** =HB method for strongly nonlinear circuits
hb.trim_tol	0	Harmonics voltage tolerance. Harmonics less than trim_tol after the initial guess are pruned. 0=no pruning. **Mainly for internal use.**

VerifEye and Quick Eye Analysis Options Reference

These options apply to both VerifEye and Quick Eye analyses. All statistical eye analysis options use the prefix **eye**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Nexxim VerifEye and Quick Eye Analysis Options

Option	Default Value	Description
eye.ampl_bins	500	Number of histogram bins to use for generating the 3D and contour data
eye.auto_ extend_step_ response	0	By default, the step response is extended only to the end of simulation time. To extend the step response beyond the simulation time, set this option to 1.
eye.eye_start_ time	0	For statistical plots of eye diagrams, discard all data from time 0 to **eye_start_time** in seconds.
eye.maxstep	0.25xUI	Maximum second-stage timestep size for the transient step response calculation. See Note.
eye.normalize_ ffe_weights	1	1=Normalize user-supplied tap weights (Sum of absolute values of all weights equals one) 0=no normalization
eye.num_ initial_ui	100	Number of unit intervals (UI) over which the initial transient step response should run after any channel or source delay. For example, with num_initial_ui set to 100 and a UI of 1ns, the initial transient analysis should run for at least 100ns + source delay + channel delay. There are additional constraints on the values this parameter can take. Please see **eye.resp_tmax** for additional information.
eye.q_scale_ extrap	1	Q-scale extrapolation: 0=never extrapolate 1=extrapolate only when transmit jitter is present 2=always extrapolate. This setting can minimize noise at the bottom of a VerifEye bathtub curve when no transmit jitter is present.
eye.qe_only_ cmf	0	By default, QuickEye stores the eye diagram and the transient-like result. Setting qe_only_cmf=1 turns off the storage of the transient-like result.
eye.resp_tmax	1e-6	Maximum stop time for the transient simulation needed to calculate the step response. If the step response calculation does not settle to a stable state value before the time in **resp_ tmax**, simulation stops at this time. To have transient simulation run until the step response settles, increase the value of **resp_tmax**. NOTE: QuickEye and VerifEye use the minimum of (**num_initial_ui** x UI) and **resp_tmax** to set the transient stop time for the step response calculation.
eye.rmax	5	Factor for calculating maximum first-stage timestep for the transient step response calculation. See Note.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
eye.sym_step_reponse	0	By default, QuickEye and VerifEye use different rise and fall times. To use the rise time as the fall time, set this option to 1.
eye.ui_bins	500	Number of histogram bins to use for generating the 3D and contour data
eye.verifeye_correlated_crosstalk	1	zero=enables VE uncorrelated crosstalk calculation

Warning:

QuickEye and VerifEye use transient analysis to calculate the step response. The transient analysis uses the two-stage timestep control (See"Timestep Control " on page 26-270). Additional accuracy can be achieved by reducing the maximum step size in both stages. For best performance, start by reducing the first-stage time maximum timestep **eye.rmax** from 5 gradually to 1. Then, if additional accuracy is appropriate, reduce the second-stage maximum timestep **eye.maxstep**.

AMI Analysis Options Reference

These options apply to AMI analyses. All these options use the prefix **ami**.

AMI Analysis Options

Option	Default Value	Description
ami.ampl_bins	500	Number of histogram bins to use for generating the 3D and contour data
ami.delay	1	Delay before computing impulse response
ami.eye_start_time	0	Start time for recording eye data
ami.resp_tmax	1e-6	Maximum time for the transient impulse response calculation
ami.skip_tran_result	0	0=Save transient data for AMI 1=Skip transient result generation for AMI (useful for long runs of data that need not be saved)
ami.ui_bins	500	Number of histogram bins to use for generating the 3D and contour data
ami.use_clock_times	1	1=Turn on sampling of the eye diagram based on the clock time values produced by the AMI receiver model.

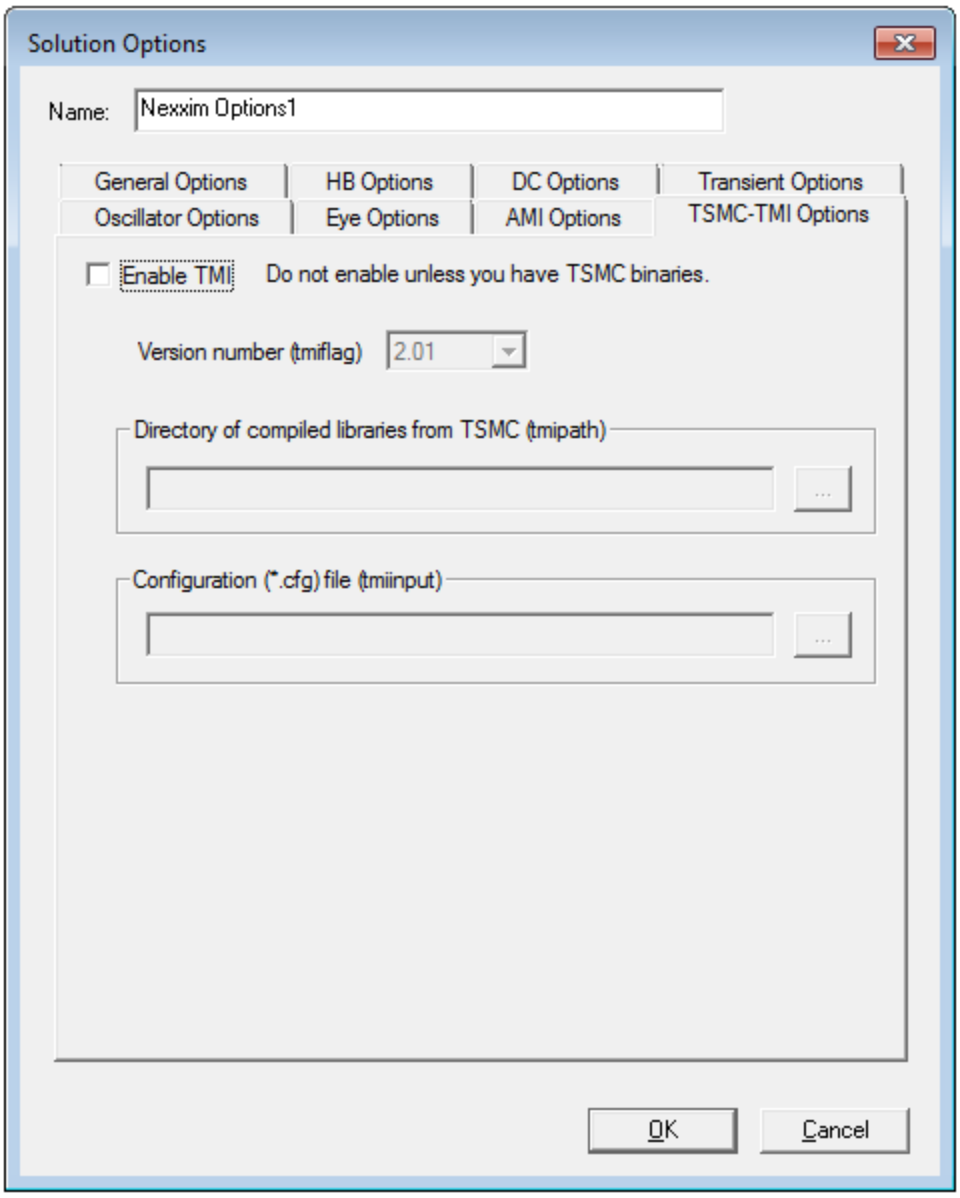
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
		0=Do not use clock times on the AMI receiver. The eye diagram is sampled at even UI intervals. The results of clock time sampling can be observed only in the Statistical Eye Plot for the "EyeAfterProbe" quantity.

TSMC-TMI Options Reference

These options apply to the Circuit simulation of MOSFETs using your TSMC Modeling Interface (TMI) model files and DLLs from TSMC. From the **Solution Options** window, click the **TSMC-TMI Options** tab:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Click the **Enable TMI** check box to enable Circuit simulation of MOSFET components with TSMC-TMI models. The fields in the tab are activated.

Table 15: TMI Options

Option	Default Value	Description
tmiflag	2.01	TMI specification version (1.00, 2.00, or 2.01)
tmipath	None	Path and directory containing the TMI compiled library

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Default Value	Description
tmiinput	None	Path and name of TMI configuration file.

The current release of the Circuit solver supports additional TSMC-TMI options not listed on the tab or table only with their default values: **tmiage** =0 (off), **tmisave** =0 (off), and **modmonte** =0 (off).

Layout Editor Layer Colors

The Electronics Desktop supports layer mapping files (.tech) with the following format:

- A forward slash, “/”, is the comment character.
- Units may be specified with a “UNITS <string>” entry that precedes the layer information t entries, where “<string>” is any of the allowed desktop length units; the default is “nm”.
- Each layer information entry is specified by a line that contains the following:

  <import layer> — Name of the DXF layer

  <destination layer> — The layout layer in the **Layout Editor** (i.e., the name to map the DXF layer to)

  <layer color> — A color string choice from those listed

  <layer elevation> — Double

  <layer height> — Double

  The follow list shows the various color string choices with corresponding RGB values:

  snow RGB = { 255, 250, 250},

  ghost white RGB = { 248, 248, 255},

  GhostWhite RGB = { 248, 248, 255},

  white smoke RGB = { 245, 245, 245},

  WhiteSmoke RGB = { 245, 245, 245},

  gainsboro RGB = { 220, 220, 220},

  floral white RGB = { 255, 250, 240},

  FloralWhite RGB = { 255, 250, 240},

  old lace RGB = { 253, 245, 230},

  OldLace RGB = { 253, 245, 230},

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

linen RGB = { 250, 240, 230},

antique white RGB = { 250, 235, 215},

AntiqueWhite RGB = { 250, 235, 215},

papaya whip RGB = { 255, 239, 213},

PapayaWhip RGB = { 255, 239, 213},

blanched almond RGB = { 255, 235, 205},

BlanchedAlmond RGB = { 255, 235, 205},

Circuit and Layout Unit Types

The Electronics Desktop supports a subset of the unit types shown in this list. To confirm that a particular unit is supported, consult the default-value drop-down-menus for the various unit specifications listed in the Default Units Tab of the **General Options** window.

Unit Type	String Representation	Description
Angle	deg	
Angle	rad	
AngularSpeed	deg_per_sec	
AngularSpeed	deg_per_min	
AngularSpeed	deg_per_hr	
AngularSpeed	rad_per_sec	
AngularSpeed	rad_per_min	
AngularSpeed	rad_per_hr	
AngularSpeed	rpm	
Capacitance	farad

AreaPerVoltage	Am2_per_kW	Ampere-square-meter per Kilo-Watt
AreaPerVoltage	m2_per_kV	Square-meter per Kilo-volt
AreaPerVoltageTemperature	m2_per_Vkel	Square-meter per Volt and Kelvin
AreaPerVoltageTemperature	Am2_per_Wkel	Ampere-square-meter per Watt-Kelvin
Attentuation	dB_per_km	Decibel per kilometer
Attentuation	dB_per_dm	Decibel per decimeter
Attentuation	dB_per_m	Decibel per meter
Attentuation	dB_per_cm	Decibel per centimeter
Attentuation	dB_per_mi	Decibel per mile
Attentuation	dB_per_ft	Decibel per foot
Attentuation	Np_per_km	Neper per kilometer
Attentuation	Np_per_dm	Neper per decimeter
Attentuation	Np_per_m	Neper per meter
Attentuation	Np_per_cm	Neper per centimeter
Attentuation	Np_per_mi	Neper per mile
Attentuation	Np_per_ft	Neper per foot
BIGB	F_per_ghalfs_per_Vm	(Farad per gram) root second per Volt-meter
BIGB	Fs2_per_ghalf_per_Vm	(Farad second squared per gram) root per Volt-meter
CapacitancePerArea	F_per_m2	Farad per square-meter
CapacitancePerArea	nF_per_m2	Nano-Farad per square-meter
CapacitancePerArea	uF_per_m2	Micro-Farad per square-meter
CapacitancePerArea	F_per_cm2	Farad per square-cent-meter
CapacitancePerArea	mF_per_m2	Milli-Farad per square-meter
CapacitancePerAreaPerVoltage	F_per_Vm2	Farad per Volt and square-meter
CapacitancePerAreaPerVoltage	mF_per_Vm2	Milli-Farad per Volt and square-meter
CapacitancePerAreaPerVoltage	pF_per_Vm2	Pico-Farad per Volt and square-meter
CapacitancePerAreaPerVoltage	nF_per_Vm2	Nano-Farad per Volt and square-meter
CapacitancePerAreaPerVoltage	uF_per_Vm2	Micro-Farad per Volt and square-meter
CapacitancePerLength	F_per_m	Farad per meter

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

CapacitancePerLength	pF_per_m	Pico-Farad per meter
CapacitancePerLength	nF_per_m	Nano-Farad per meter
CapacitancePerLength	mF_per_m	Milli-Farad per meter
CapacitancePerLength	uF_per_m	Micro-Farad per meter
CapacitanceTemperatureCoeff	F_per_Kel	Farad per Kelvin
CapacitanceTemperatureCoeff	pF_per_Cel	Pico-Farad per degree Celsius
CapacitanceTemperatureCoeff	pF_per_Kel	Pico-Farad per Kelvin
CapacitanceTemperatureCoeff	mF_per_Cel	Milli-Farad per degree Celsius
CapacitanceTemperatureCoeff	pF_per_Fah	Pico=Farad per degree Farenheit
CapacitanceTemperatureCoeff	nF_per_Kel	Nano-Farad per Kelvin
CapacitanceTemperatureCoeff	mF_per_Kel	Milli-Farad per Kelvin
CapacitanceTemperatureCoeff	F_per_Cel	Farad per degree Celsius
CapacitanceTemperatureCoeff	mF_per_Fah	Milli-Farad per degree Farenheit
CapacitanceTemperatureCoeff	nF_per_Cel	Nano-Farad per degree Celsius
CapacitanceTemperatureCoeff	F_per_Fah	Farad per degree Farenheit
CapacitanceTemperatureCoeff	uF_per_Kel	Micro-Farad per Kelvin
CapacitanceTemperatureCoeff	nF_per_Fah	Nano-Farad per degree Farenheit
CapacitanceTemperatureCoeff	uF_per_Cel	Micro-Farad per degree Celsius
CapacitanceTemperatureCoeff	uF_per_Fah	Micro-Farad per degree Farenheit
Charge	Charge	Coulomb
Charge	Ahour	Ampere hour
Charge	uC	Micro-Coulomb
Charge	mC	Milli-Coulomb
Charge	nC	Nano-Coulomb
Charge	kC	Kilo-Coulomb
Charge	As	Ampere second
Compliance	m_per_N	Meter per Newton
Compliance	in_per_lbf	Inch per pound-force
Compliance	cm_per_N	Centi-meter per Newton
ConductancePerLength	S_per_m	Siemens per meter
ConductancePerLength	mS_per_m	Milli-Siemens per meter
ConductancePerLength	kS_per_m	Kilo-Siemens per meter
ConductancePerLength	uS_per_m	Micro-Siemens per meter
ConductancePerLength	cS_per_m	Centi-Siemens per meter
CurrentChangeRate	A_per_s	Ampere per second
CurrentChangeRate	A_per_hour	Ampere per hour

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

CurrentChangeRate	mA_per_s	Milli-Ampere per second
CurrentChangeRate	kA_per_s	Kilo-Ampere per second
CurrentChangeRate	uA_per_s	Micro-Ampere per second
CurrentChangeRate	A_per_min	Ampere per minute
CurrentDensity	A_per_m2	Ampere per square-meter
CurrentDensity	uA_per_m2	Micro-Ampere per square-meter
CurrentDensity	mA_per_cm2	Milli-Ampere per square-centi-meter
CurrentDensity	mA_per_m2	Milli-Ampere per square-meter
CurrentDensity	A_per_cm2	Ampere per square-centi-meter
CurrentDensity	uA_per_cm2	Micro-Ampere per square-centi-meter
CurrentGain	A_per_A	Ampere per Ampere
CurrentGain	A_per_mA	Ampere per Milli-Ampere
CurrentGain	mA_per_A	Milli-Ampere per Ampere
CurrentLengthPerVoltage	Am_per_V	Ampere-meter per Volt
CurrentLengthPerVoltage	mAm_per_V	Milli-Ampere-meter per Volt
CurrentLengthPerVoltage	uAm_per_V	Micro-Ampere-meter per Volt
CurrentPerCharge	A_per_C	Ampere per Coulomb
CurrentPerCharge	A_per_Ahour	Ampere per Ampere-hour
CurrentPerCharge	A_per_As	Ampere per Ampere-second
CurrentPerIrradiance	A_per_W_per_m2	Ampere per Watt per meter-squared
CurrentPerIrradiance	kA_per_W_per_m2	Kilo-Ampere per Watt per meter-squared
CurrentPerIrradiance	uA_per_W_per_m2	Micro-Ampere per Watt per meter-squared
CurrentPerIrradiance	mA_per_W_per_m2	Milli-Ampere per Watt per meter-squared
CurrentPerLength	A_per_m	Ampere per meter
CurrentPerLength	mA_per_m	Milli-Ampere per meter
CurrentPerLength	kA_per_m	Kilo-Ampere per meter
CurrentPerLength	uA_per_m	Micro-Ampere per meter
CurrentPerTemperature2_half	A_per_Kel2half	Ampere per Kelvin to the power of 2.5
CurrentPerTemperatureCubed	A_per_Kel3	Ampere per Kelvin-cubed
CurrentPerTemperatureDiffCubed	A_per_diff_Kel3	Ampere per Kelvin-cubed
CurrentPerTemperatureDiffCubed	A_per_Cel3	Ampere per degree Celsius

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

		cubed
CurrentSquaredTime	A2s	Ampere-squared second
CurrentSquaredTime	mA2s	Milli-Ampere-squared second
CurrentTemperatureCoeff	A_per_Kel	Ampere per Kelvin
CurrentTemperatureCoeff	A_per_Cel	Ampere per degree Celsius
CurrentTemperatureCoeff	mA_per_Kel	Milli-Ampere per Kelvin
CurrentTemperatureCoeff	mA_per_Fah	Milli-Ampere per degree Farenheit
CurrentTemperatureCoeff	kA_per_Kel	Kilo-Ampere per Kelvin
CurrentTemperatureCoeff	A_per_Fah	Ampere per degree Farenheit
CurrentTemperatureCoeff	uA_per_Kel	Micro-Ampere per Kelvin
CurrentTemperatureCoeff	uA_per_Cel	Micro-Ampere per degree Celsius
CurrentTemperatureCoeff	mA_per_Cel	Milli-Ampere per degree Celsius
Damping	Ns_per_m	Newton second per meter
Damping	kNs_per_m	Kilo-Newton second per meter
Damping	mNs_per_m	Milli-Newton second per meter
Damping	cNs_per_m	Centi-Newton second per meter
Damping	dNs_per_m	Deci-Newton second per meter
Density	kg_per_m3	Kilogram per Cubic-Meter
Density	g_per_cm3	Gram per Cubic-Centimeter
Density	kg_per_l	Kilo-Gram per Liter

InductancePerLength	uH_per_m	Micro-Henry per meter
Inertance	Pas2_per_m3	Pascal square-second per cubic-meter
Inertance	Ns2_per_m5	Newton square second per meter to power 5
Inertance	kg_per_m4	Kilo-gram per meter to the power of 4
Irradiance	irrad_W_per_m2	Watt per meter-squared
Irradiance	megW_per_m2	Mega-Watt per meter-squared
Irradiance	mW_per_m2	Milli-Watt per meter-squared
Irradiance	irrad_W_per_cm2	Watt per cent-meter-squared
Irradiance	kW_per_m2	Kilo-Watt per meter-squared
Irradiance	uW_per_m2	Micro-Watt per meter-squared
Irradiance	W_per_in2	Watt per inch-squared
Jerk	m_per_s3	Meter per second cubed
Jerk	cm_per_s3	Centi-Meter per second cubed
Jerk	nm_per_s3	Nano-Meter per second cubed
Jerk	in_per_s3	Inch per second-cubed
Jerk	um_per_s3	Micro-Meter per second cubed
Jerk	mm_per_s3	Milli-Meter per second cubed
Length2PerVoltage2	m2_per_V2	Meter-squared per Volt-squared
LengthCoefficient	per_m	Per meter
LengthCoefficient	V_per_V_per_m	Volt per Volt per meter
LengthCoefficient	per_km	Per kilo-meter
LengthCoefficient	per_um	Per micro-meter
LengthCoefficient	per_in	Per inch

LengthCoefficient	per_cm	Per centi-meter
LengthCoefficient	V_per_V_per_in	Volt per Volt per inch
LengthCoefficient	per_mm	Per milli-meter
LengthPerVoltage	m_per_V	Meter per Volt
LengthPerVoltage	mm_per_V	Milli-Meter per Volt
LengthPerVoltage	km_per_V	Kilo-Meter per Volt
LengthPerVoltage	um_per_V	Micro-Meter per Volt
LengthPerVoltage	dm_per_V	Deci-Meter per Volt
LengthPerVoltage	cm_per_V	Centi-Meter per Volt
LengthPerVoltageRoot	m_per_Vhalf	Meter per Volt-root
LengthPerVoltageRoot	dm_per_Vhalf	Deci-Meter per Volt-root
LengthPerVoltageRoot	mm_per_Vhalf	Milli-Meter per Volt-root
LengthPerVoltageRoot	um_per_Vhalf	Micro-Meter per Volt-root
LengthPerVoltageRoot	km_per_Vhalf	Kilo-Meter per Volt-root
LengthPerVoltageRoot	cm_per_Vhalf	Centi-Meter per Volt-root
LuminousFlux	lm	Lumen
LuminousFlux	gm2_per_s3	Kilo-gram meter-squared per second-cubed
LuminousFlux	klm	Kilo-Lumen
LuminousFlux	mlm	Milli-Lumen
LuminousFlux	meglm	Mega-Lumen
LuminousIntensity	Cd	Candela
LuminousIntensity	GCd	Giga-Candela
LuminousIntensity	kCd	Kilo-Candela
LuminousIntensity	mCd	Milli-Candela
LuminousIntensity	megCd	Mega-Candela
MagneticReluctance	A_per_Wb	Ampere per Weber
MagneticReluctance	A_per_Vs	Ampere per Volt-second
MassFlowRate	kg_per_s	Kilogram per second
MassFlowRate	g_per_s	Gram per second
MMF	a	Ampere
MMF	ua	Micro-Ampere
MMF	na	Nano-Ampere
MMF	ma	Milli-Ampere
MMF	ka	Kilo-Ampere
MolarDensity	mol_per_m3	Mol per cubic-meter

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

MolarDensity	mol_per_dm3	Mol per cubic-deci-meter
MolarDensity	mol_per_cm3	Mol per cubic-centi-meter
MolarDensity	mol_per_l	Mol per liter
MolarEnergy	J_per_mol	Joule per mole
MolarEnergy	megJ_per_mol	Mega-Joule per mole
MolarEnergy	mJ_per_mol	Milli-Joule per mole
MolarEnergy	uJ_per_mol	Micro-Joule per mole
MolarEnergy	kJ_per_mol	Kilo-Joule per mole
MolarEnergy	gJ_per_mol	Giga-Joule per mole
MolarVelocity	mol_per_s	Mole per second
MolarVelocity	cmol_per_s	Centi-Mole per second
MolarVelocity	mmol_per_s	Milli-Mole per second
MolarVelocity	kmol_per_s	Kilo-Mole per second
MolarVelocity	umol_per_s	Micro-Mole per second
MolarViscosity	Pas_per_mol	Pascal second per Mol
MomentInertia	kgm2	Kilo-gram square-meter
MomentInertia	lbin2	Pound inch-squared
MomentInertia	lbft2	Pound foot-squared
Momentum	kgm_per_s	Kilo-gram meter per second
Momentum	gm_per_s	Gram meter per second
Percentage	percent	Per cent
PercentagePerTime	percent_per_s	Percent per second
PercentagePerTime	per_day	Per day
PercentagePerTime	percent_per_min	Percent per minute
PercentagePerTime	per_hour	Per hour
PercentagePerTime	percent_per_day	Percent per day
PercentagePerTime	percent_per_hour	Percent per hour
PercentagePerTime	per_min	Per minute
PercentagePerTime	per_s	Per second
Permeance	Vs_per_A	Volt-second per Ampere
Permeance	Wb_per_A	Weber per Ampere
PressureChangeRate	Pa_per_s	Pascal per second
PressureChangeRate	torr_per_hour	Torr per hour
PressureChangeRate	mmH2O_per_s	Milli-meter water column per second
PressureChangeRate	psi_per_s	PSI per second

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

PressureChangeRate	techatm_per_hour	Technical atmosphere per hour
PressureChangeRate	bar_per_hour	Bar per hour
PressureChangeRate	statm_per_s	Standard atmosphere per second
PressureChangeRate	mbar_per_s	Milli-Bar per second
PressureChangeRate	mmH2O_per_hour	Milli-meter water column per hour
PressureChangeRate	Pa_per_hour	Pascal per hour
PressureChangeRate	psi_per_hour	PSI per hour
PressureChangeRate	mmH2O_per_min	Milli-meter water column per minute
PressureChangeRate	techatm_per_min	Technical atmosphere per minute
PressureChangeRate	statm_per_hour	Standard atmosphere per hour
PressureChangeRate	torr_per_s	Torr per second
PressureChangeRate	mbar_per_hour	Milli-bar per hour
PressureChangeRate	techatm_per_s	Technical atmosphere per second
PressureChangeRate	bar_per_s	Bar per second
PressureChangeRate	statm_per_min	Standard atmosphere per minute
PressureChangeRate	torr_per_min	Torr per Minute
PressureChangeRate	Pa_per_min	Pascal per minute
PressureChangeRate	bar_per_min	Bar per minute
PressureChangeRate	mbar_per_min	Milli-bar per minute
PressureChangeRate	psi_per_min	PSI per minute
PressureCoefficient	per_Pa	Per Pascal
PressureCoefficient	per_statm	Per standard atmosphere
PressureCoefficient	per_psi	Per PSI
PressureCoefficient	per_mmH2O	Per Milli-meter water column
PressureCoefficient	per_mbar	Per Milli-bar
PressureCoefficient	V_per_Vper_Pa	Volt per Volt per Pascal
PressureCoefficient	per_mmHg	Per Milli-meter mercury
PressureCoefficient	per_techatm	Per technical atmosphere
PressureCoefficient	per_bar	Per bar
Ratio	db	Decibel
Ratio	bel	Bel
ReciprocalPower	per_W	One over Watt
ReciprocalPower	per_megW	One over Mega-Watt
ReciprocalPower	per_Js	One over Joule-second

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ReciprocalPower	per_mW	One over Milli-Watt
ReciprocalPower	per_kW	One over Kilo-Watt
ReciprocalPower	per_gW	One over Giga-Watt
ReciprocalResistanceCharge	per_OhmC	One over Ohm-coulomb
ReciprocalResistanceCharge	per_OhmAs	One over Ohm-Ampere-second
ReciprocalResistanceCharge	per_OhmAhour	One over Ohm-Ampere-hour
ReciprocalResistanceTime	per_Ohms	One over Ohm-second
ReciprocalResistanceTime	per_Ohmmin	One over Ohm-minute
ReciprocalResistanceTime	per_Ohmhour	One over Ohm-hour
ResistancePerCharge	Ohm_per_C	Ohm per Coulomb
ResistancePerCharge	Ohm_per_Ahour	Ohm per Ampere-hour
ResistancePerCharge	megOhm_per_C	Mega-Ohm per Coulomb
ResistancePerCharge	nOhm_per_C	Nano-Ohm per Coulomb
ResistancePerCharge	mOhm_per_C	Milli-Ohm per Coulomb
ResistancePerCharge	uOhm_per_C	Micro-Ohm per Coulomb
ResistancePerCharge	kOhm_per_C	Kilo-Ohm per Coulomb
ResistancePerCharge	Ohm_per_As	Ohm per Ampere-second
ResistancePerCharge	gOhm_per_C	Giga-Ohm per Coulomb
ResistancePerLength	Ohm_per_m	Ohm per meter
ResistancePerLength	megOhm_per_m	Mega-Ohm per meter
ResistancePerLength	mOhm_per_m	Milli-Ohm per meter
ResistancePerLength	uOhm_per_m	Micro-Ohm per meter
ResistancePerLength	kOhm_per_m	Kilo-Ohm per meter
ResistancePerLength	Ohm_per_um	Ohm per micro-meter
ResistanceTemperatureCoeff	Ohm_per_Kel	Ohm per Kelvin
ResistanceTemperatureCoeff	mOhm_per_Kel	Milli-Ohm per Kelvin
ResistanceTemperatureCoeff	kOhm_per_Kel	Kilo-Ohm per Kelvin
ResistanceTemperatureCoeff	Ohm_per_Cel	Ohm per degree Celsius
Resistivity	Ohmm	Ohm Meter
Resistivity	Ohmcm	Ohm Centi-Meter
Resistivity	Ohmum	Ohm micro-meter
Resistivity	Ohmmm2_per_mm	Ohm Square-Milli-Meter per Meter
SpecificHeatCapacity	J_per_Kelkg	Joule per Kelvin and Kilo-gram
SpecificHeatCapacity	mJ_per_Kelkg	Milli-Joule per Kelvin and Kilo-gram
SpecificHeatCapacity	kJ_per_Kelkg	Kilo-Joule per Kelvin and Kilo-

EnergyDensity	kJ_per_m3	kilo joules per meter cubed

Controlling Nexxim Output

For large circuits, significant memory space can be saved by specifying a set of values to output, rather than the default method of storing values for every node.

Schematic Design Output Control

In the **Schematic Editor**, Click the **Edit Output Quantities** feature in the **Solution Setup** window to specify particular outputs. Ports and probes in the schematic are automatically added as outputs

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Warning:

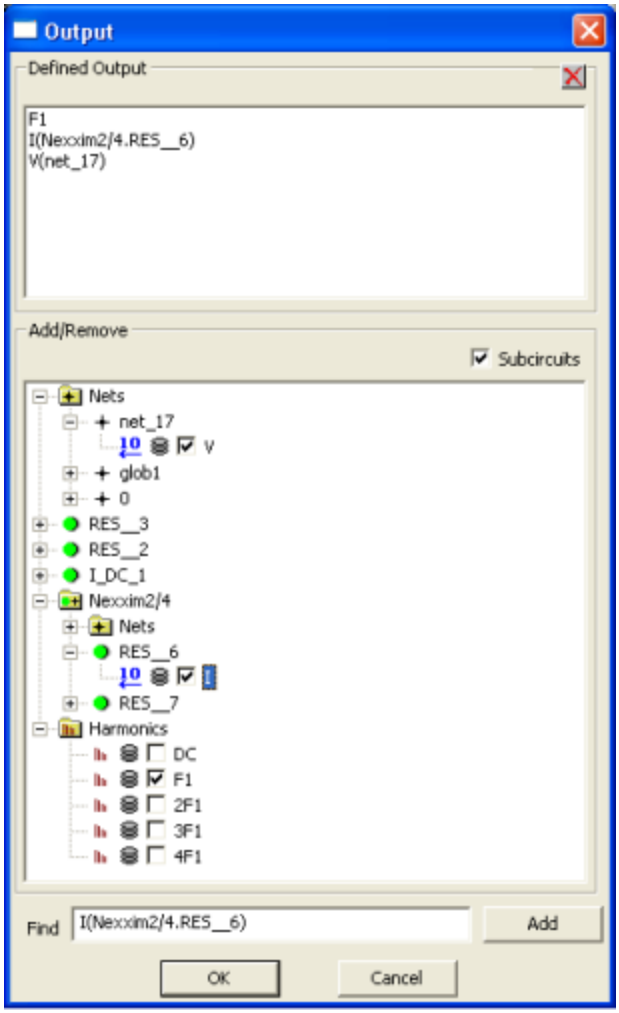
By default, Nexxim stores all intermediate values for all nodes. If you do not specify any output quantities at setup, all node voltages and branch currents are retained so they can be output to the results file. With large circuits or analyses, the amount of data to be stored can cause the simulation to slow down, or even to exceed memory limits (usually a fatal error for Ansys Electronics Desktop/Nexxim). The Edit Output Quantities window specifies which nodes/values can be retained, allowing Nexxim to discard all other values when they are no longer needed. Use of the window can significantly reduce memory usage. Although the range of output values may be limited, in those cases where memory is an issue, use of the Edit Output Quantities facility may be required to allow the computation to complete successfully.

Edit Output Quantities

1. In the **Circuit** drop-down, select **Add Solution Setup**.
2. In the **Solution Setup** window, select the type of analysis to be run. Click **Next** to open a setup window for the selected analysis.
3. In the window, click **Edit Quantities** in the **Output Quantities** group box. (This facility is not available for Linear Network Analysis).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. The **Output** window opens:



For all analysis types, the **Output** window identifies the nets available for voltage outputs. After running an analysis, voltage values are available for these nodes. Expand the **Nets** icon to see the individual nodes. Expand each node to select its voltage as an output.

For all analysis types, the **Output** window identifies devices available for current outputs. After running an analysis, current values are available for all nodes of the requested devices. For example, if you request the current through a resistor **R1**, the current outputs includes the values **Iterminals_0(R1)** and **Iterminals_1(R1)**.

For Harmonic Balance, Time-Varying Noise, and Oscillator analyses, the **Output** window identifies harmonics available for output analysis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If the circuit contains a subcircuit, the **Output** window displays its nets and devices for selection as outputs when you expand the icon for the subcircuit.

5. Click its check box to select an output quantity. The selected quantities are listed in the **Defined Output** field.
6. Click **OK** to close the **Output** window and return to the window for the selected analysis. The output quantities you selected are listed in the **Output Quantities** group box of the analysis window. Complete the solution setup as described in the topics for the individual analyses.

Ports in Schematics

In schematic circuit designs, add hierarchical ports to nodes that represent the circuit outputs. The nodes with attached ports are automatically added to the list of output quantities available for reports of simulation results.

Probes in Schematics

In schematic circuit designs, add voltage and current probes to nodes whose values are of interest. The nodes with attached probes are automatically added to the list of output quantities available for reports of simulation results.

.MEASURE Quantities in Schematics

A Nexxim netlist may set up a MEASURE variable to contain a value calculated during simulation. After simulation has run successfully, all variables defined in .MEASURE statements are available in the **MeasureCategory** listing of the Report window. See .MEASURE Statements in the File Formats topic for further information.

Netlist Design Output Control

Several types of output controls are available in Nexxim netlists.

Netlist PRINT Statements

A netlist can use one or more **.PRINT** statements to specify the outputs from particular types of analysis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Warning:

By default, Nexxim stores all intermediate values for all nodes. If you do not use a .PRINT statement, all node voltages and branch currents are retained so they can be output to the results file. With large circuits or analyses, the amount of data to be stored can cause the simulation to slow down, or even to exceed memory limits (usually a fatal error for Ansys Electronics Desktop/Nexxim). .PRINT statements specify which nodes/values are to be retained, allowing Nexxim to discard all other values when they are no longer needed. Use of .PRINT statements can significantly reduce memory usage. Although the range of output values may be limited, in those cases where memory is an issue a .PRINT statement may be required to allow the computation to complete successfully.

Note:

.PROBE statements in imported netlists are internally converted to .PRINT statements.

There are three forms of the .PRINT statement, one for simple circuit values, one for expressions involving circuit values, and one for the output of values calculated internally by selected device models. The output specification for all three PRINT statement types can use wild card characters.

PRINT Statements with Simple Values

The netlist syntax for simple outputs is:

.PRINT [*analysis*] *output1* [*output2*] ...

The following topics explain the analysis type and the output specifications.

Analysis Type

The *analysis* is one of:

dc for DC analysis

tran for transient analysis

hb for harmonic balance analysis

lna for linear network analysis

ac for AC analysis (when linear network analysis has been performed)

osc for oscillator analysis

tv_noise for periodic time-varying noise analysis

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A **.PRINT** statement that does not have an explicit *analysis* is automatically supplied with one using the following rules:

- A **.PRINT** that occurs before ANY analysis is filled in as "**.PRINT dc**."
- Any other **.PRINT** statement is filled in with the name of the analysis specified most recently above it.
- All **.PRINT** statements that apply to a given analysis type are then applied to that analysis.

So, for example, a netlist that specifies a circuit and the following:

```
.print V(1)
.tran 1e-2 1
.print V(2)
.dc sweep R1 100 200 10
.print V(3)
.dc sweep R2 100 200 50
.print V(4)
```

is interpreted as

```
.print dc V(1)
.tran 1e-2 1
.print tran V(2)
.dc sweep R1 100 200 10
.print dc V(3)
.dc sweep R2 100 200 50
.print dc V(4)
```

and performs three analyses:

1. The transient analysis, in which only V(2) is saved.
2. A DC analysis sweeping the value of R1, in which only V(1), V(3), and V(4) are saved.
3. A DC analysis sweeping the value of R2, in which only V(1), V(3), and V(4) are saved.

Output Quantities

The output quantities can be node voltages or currents through individual elements. For a node voltage, the syntax is:

V(*n1***)**

The simulator outputs the voltage difference between the specified node name (*n1*) and ground.

The output can specify a differential voltage between nodes, using the syntax:

V(n1, n2**)**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The output is the differential voltage for the node pair V(n1) - V(n2). If n1 and n2 are the same node, the output evaluates to zero volts.

For a current through a branch containing any single device, the syntax is:

I(*device_name***)**

The output includes the current entering the device through each node.

The following **.PRINT** statement outputs the current through resistor R10 in a harmonic balance analysis:

```
.PRINT HB I(R10)
```

The outputs includes the current values **Iterminals_0(R1)** and **Iterminals_1(R1)** (See the following illustration).

The following statement outputs the current through voltage source VSRC in a transient analysis:

```
.PRINT TRAN I(VSRC)
```

The outputs includes the current values **Ipositive(VSRC)** and **Inegative(VSRC)** (See the following illustration).

To obtain voltage and current output variables within one or more subcircuit levels, use the following syntax:

V (*subcircuit1*. [*subcircuit2*.]...[*subcircuitn*.]*element*)

I (*subcircuit1*. [*subcircuit2*.]...[*subcircuitn*.]*element*)

For example, if subcircuit instance XSUB1 contains voltage source V6, the **.PRINT** statement to output the current through V6 in transient analysis is:

```
.PRINT TRAN I(XSUB1.V6)
```

If XSUB1 is an instance of a subcircuit whose definition includes a node N25, the **.PRINT** statement to output the voltage through node N25 in transient analysis is:

```
.PRINT TRAN V(XSUB1.N25)
```

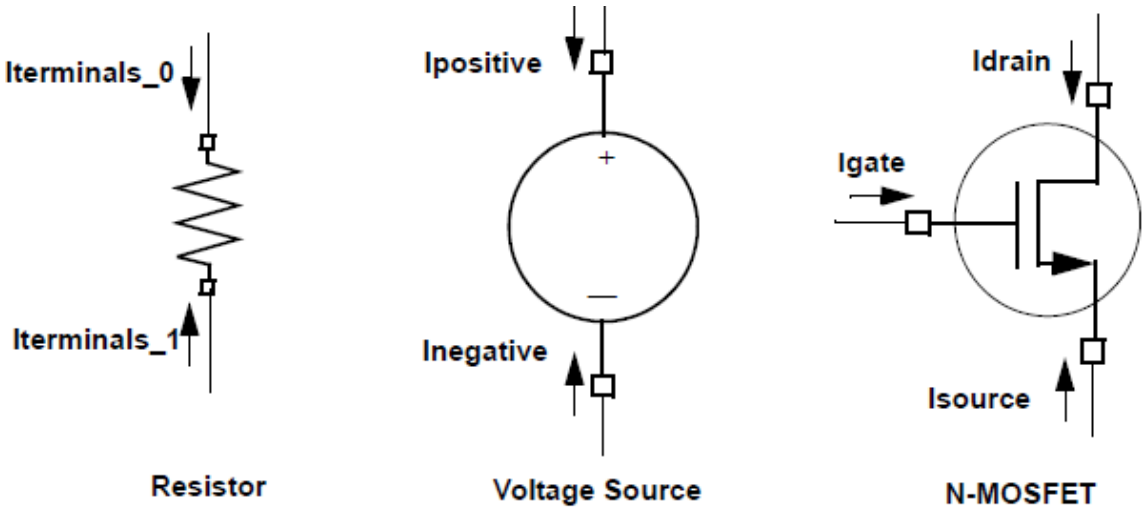
If subcircuit instance XSUB1 contains a nested subcircuit instance XSUB2 which in turn includes NMOS MOSFET M23, the **.PRINT** statement to output the current through D23 is:

```
.PRINT TRAN I(XSUB1.XSUB2.M23)
```

The outputs includes the current values **Isource(M23)**, **Igate(M23)**, and **Idrain(M23)**.

The following diagram illustrates the directions of the current values for the resistor, voltage source, and MOSFET examples given earlier.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



PRINT Statements with Expressions

Output can be specified with an expression, with or without a label. The syntax is a variation on the **.PRINT** statement:

.PRINT [*analysis*] [*label*=] **PAR(***expression***)**

The types for *analysis* are the ones given above for simple outputs (See "PRINT Statements with Simple Values " on page 26-246).

The *expression* can reference node voltages, branch currents, and parameter values. Nexxim stores the expression and the values in the results file, along with the *label* specified in the **.PRINT** statement.

Examples:

```
.PRINT PAR(V(1) + V(2))
.PARAM Y = 42
.PRINT X=PAR(Y + V(12)/V(13))
```

Calculated Model Outputs

Certain device models have been set up to provide calculated quantities as outputs. To enable the output quantities, the netlist uses a variation of the .PRINT statement:

.PRINT*analysis***O(***instance_name***)**

The *analysis* is one of the Nexxim analysis types listed above. The *instance_name* is the name of a device instance defined elsewhere in the netlist. The outputs are calculated values particular to the device model referenced by the instance statement.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Here is a netlist fragment:

```
.MODEL bsim_model NMOS LEVEL=53 // Device model
M101 1 2 3 bsim_model // Device instance

.TRAN 1us 100us // Analysis
.PRINT tran O(M101) // Outputs model internal values
// Rest of netlist is not shown in this example
```

The output quantities are listed in the documentation for the individual devices. Since the >PRINT statement references the instance name, the output quantities are documented under the instance statement for the device types. See the documentation for the *MOSFET instance, Level 49 or 53* for an example.

To open the calculated quantities in a Report window:

1. Select **Create Report** on the **Results** icon in the **Project Manager** window. Click **OK** to accept the defaults on the **Create Report** window and open the **Report** window.
2. Select **Device Properties** as the **Category** in the **Report** window. Select one or more of the outputs in the **Quantity** listing, along with the corresponding **Functions**. Click **Add Trace** and **Done** to close the **Report** window and display the outputs.

Wildcard Characters in Output Values

The output specification can contain the wildcard characters asterisk (*****) and question mark (**?**):

***** means “match zero or more characters.” For example “V(net*)” outputs the voltage of any node whose name begins with the characters **net**, such as **net**, **net55**, or **net_whatever**.

? means “match any single character.” For example “V(net?)” outputs the voltage of any node whose name consists of the characters **net** followed by one more character, such as **net1** or **netA**.

> **Note:**
>
> Instances of “V(*,*)” or “V(?,?) that produce “V(x,x),” the differential voltage between two identical nodes, are not normally included in the output.
>
> However, if a wildcard pattern of two nodes matches one or more “V(x,x)” outputs, just one of those matches is included in the result. This guarantees that a statement such as .PRINT PAR(‘V(x) + V(?,?)’) has a value when a valid result exists.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Output of Small-Signal AC Transfer Functions

When linear network analysis is being performed, the netlist can include a **.PRINT AC** statement. Nexxim LNA computes AC transfer functions for any outputs listed in the **.PRINT AC** statement. If the **.PRINT AC** statement is omitted, no AC transfer functions are output. See the Nexxim Linear Network Analysis help topic for further information.

Port Impedance Resistors in LNA

In Nexxim linear network analysis of netlist circuit designs, you add Port Impedance resistors to the netlist to specify outputs. See the Nexxim Linear Network Analysis help topic for details on the use of Port Impedance resistors to control simulation output.

> **Note:**
>
> Port impedance resistors are not required for a linear network analysis that consists only of Noise calculations or only of AC small-signal analyses.

Nexxim Command Line Controls

This topic describes how to control the Nexxim simulator on the operating system command line. Nexxim allows many options to be entered on the command line. All command-line options and arguments are case-insensitive.

> **Note:**
>
> On MS Windows™ systems, the command-line version of **nexxim.exe** is supported only for the Windows MS-DOS™ command prompt. Other shells such as Cygwin™ may not successfully run **nexxim.exe**.

Invoking the Nexxim Simulator

To run the Nexxim simulator, type the following command line at the prompt:

nexxim [**-o***output_file*] [*options*] *input_file*

The input netlist file contains the circuit description, simulator controls, and options.

Valid formats and filename extensions for the input netlist file are:

- **.cir** —Nexxim internal netlist format
- **.sp** —HSPICE netlist format
- **.scs** —Spectre® netlist format.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See Netlist Format for a description of the Nexxim internal netlist syntax.

The **–o***output_file* entry outputs the quantities specified by the **.PRINT** statements in the input *netlist_file* to a file called *output_file***.sdf**, located by default in the simulator directory. To output the file under a different directory, include the directory path with the filename. If the **–o** entry is omitted, the simulation results are output to a file called *input_file***.sdf** in the directory containing the netlist file. The output file is written in the Nexxim SDF (Simulation Data File) format. See Viewing Results for information on viewing SDF-format files in **Electronics Desktop**.

Configuration File

Simulation options can be provided in a configuration file (*filename***.cfg**) specified in a **-config_file** option to the command line:

nexxim [**-config_file=***filename***.cfg**] [**-o***outputfile*] *input_file*

If no **config_file** option is provided, the simulator looks for a file named **cirsim.cfg** in the directory where **Electronics Desktop** is installed. If the configuration *filename* is not located in the install directory, its path must be provided with the filename. Within the configuration file, each option should be on a separate line, and can start with a prefix to identify the simulation tool or device category to which it applies:

option
Option for all analyses

dc.*option*
Option for dc analysis

tran.*option*
Option for transient analysis

hb.*option*
Option for harmonic balance analysis

lna.*option*
Option for linear network analysis

osc.*option*
Option for oscillator analysis

tvnoise.*option*
Option for time-varying noise analysis

s_element.*option*
Option for analysis of s-parameter element

When the same option has been set more than once, the following precedence is applied:

- Command line options > netlist options > default (configuration file) options.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See Invoking the Nexxim Simulator for details on the other command line entries. See the individual help topics for details on the options recognized by each of the simulation tools.

HPC Options

The Nexxim solver ignores any High Performance Computing (HPC) options in a netlist. Instead, they must be provided on the command line in this form:

nexxim *input_file* [**num_threads***workgroup*] [**-hpc_type***#*] [**-use_gpu***#*] [**-enable_tpbs***#*]

HPC Options

Option	Description	Acceptable Values	Default
-enable_tpbs	Enables Transient Parallel Bus Speedup to speed up transient solutions for large non-linear designs	**0** = False **1** = True	1
-hpc_type	Determines which license to use.	**0** = One HPC workgroup license enables one unit of HPC. **1** = One HPC pack license enables eight units of HPC. Additional packs multiply by four, enabling 32, 128, 512, etc., in the context of a single simulation.	1
num_threads	Specifies the number of cores to use for the project. Place no dash before this option.	Integer	4

Log File

By default, error and status messages on the netlist parser and on the simulation tools are displayed on the standard output. Messages can be directed to a logfile specified in a **-logfile** option to the command line:

nexxim [-logfile*messagefile*] [-o*outputfile*] *input_file*

The **–logfile***messagefile* option outputs any messages into a file called *messagefile*.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Message Controls

By default, status, error, and warning messages from the netlist processor, the simulation tools, and the device models are output to standard out or to a specified logfile. You can control the type of error logging with the following options.

All Messages

The **–error.filter** option controls all messages:

nexxim -error.filter=*level* [**-o***outputfile*] *input_file*

The *level*is an integer characterizing errors based on their severity:

0 Trace messages

1 Status

2 Info

3 Warnings

4 Errors

The option **–error.filter=***level* allows errors with severity *level* or higher to go through and be posted. For example, **-error.filter=3** allows warnings and errors to be displayed, suppressing all trace, status, and info messages.

> **Note:** Nexxim issues a warning message if the circuit contains floating nodes or nodes with single connections. Only nodes with a single branch connection that is both conservative and constitutive are flagged. For example, the controlling nodes in a VCVS have a constitutive/behavioral/relational connection to the controlled nodes, but not a physical/structural/conservative connection, and therefore are not flagged.

Messages from Analysis Tools

The option **-error.filter.analysis** allows messages from all analysis tools with severity *level* or higher to go through:

nexxim -error.filter.analysis=*level* [**-o***outputfile*] *input_file***.cir**

For example, **–error.filter.analysis=0** provides screen output on the convergence of the DC and transient simulations.

You can specify a filter for messages from individual analysis tools:

-error.filter.analysis:dc=*level*

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Allows DC analysis errors with severity *level* or higher to go through.

-error.filter.analysis:tran=*level*

Allows transient analysis errors with severity *level* or higher to go through.

-error.filter.analysis:hb=*level*

Allows harmonic balance analysis errors with severity *level* or higher to go through.

Messages from Device Models

The option **-error.filter.models=***level* controls error and warning messages on the device models. More specifically:

-error.filter.models=*level*

Allows all model errors with severity *level* or higher to go through.

-error.filter.models:*modelname=level*

Allows errors related to the model called *modelname* and with severity *level* or higher to go through. For example:

-error.filter.models:resistor=0

Device Listing

The **–print_inventory** option generates a listing of device types and instance count:

nexxim -print_inventory=1 [**-o***outputfile*] *input_file*

Here is an example listing:

```
device type_______________number of devices
-----------------------------------------
s_element_________________1
port_impedance____________2
s_element_core_fdomain____1
```

Viewing Results in the GUI

The result of a Nexxim simulation is written out to a file in Simulation Data File (SDF) format, an Ansys-proprietary binary format. To view the results of a simulation that has been run on the command line, start **Electronics Desktop**.

1. From the **File** menu, select **Open** to open an explorer window.
2. In the **Look in** field, browse to the directory containing the SDF file you want to display.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. In the **Files of type** drop-down, select **Ansoft Nexxim Solution (*.sdf)** or **All Ansoft Nexxim Files (*.adsn, *.cir, *.sdf, *.sp)**.
4. Select the SDF file you want to display, then click **Open**.
5. A Project icon appears in the Projects window of **Electronics Desktop**. Click the + sign for the project, then on the + sign for the circuit. A **Results** icon appears. Right-click on the **Results** icon, and select one of the Report types to open the **Report** window. Select the Y-data on the group box on the right, then click **New Report** to open the graphic display of the trace.
6. Repeat steps 5 through 8 as often as appropriate to display all the simulation data in the results file.
7. From the **File** menu, select **Save as**, then save your settings as a **Electronics Desktop .aedt** file.

Viewing the Nexxim Solution Log File

After a simulation has completed, Nexxim prints messages about the success or failure of the analysis to the Ansys Electronics Desktop Message Manager window.

Nexxim writes details regarding the simulation to a solution log file. The log file information may be useful for diagnosing why a particular analysis failed.

- From a schematic design, right-click the analysis setup under the Analysis icon in the **Project Manager** window and select **Browse Solution Log File**.
- From a netlist design, right-click the circuit icon in the **Project Manager** window and select **Browse Solution Log File**.

The log file opens in a standard Notepad window.

DC Analysis Technical Notes

The following topics provide technical details on Nexxim Direct Current (DC) analysis.

Nexxim DC Analysis Overall Flow

Figure 1 shows the sequence of operations performed in Nexxim DC analysis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

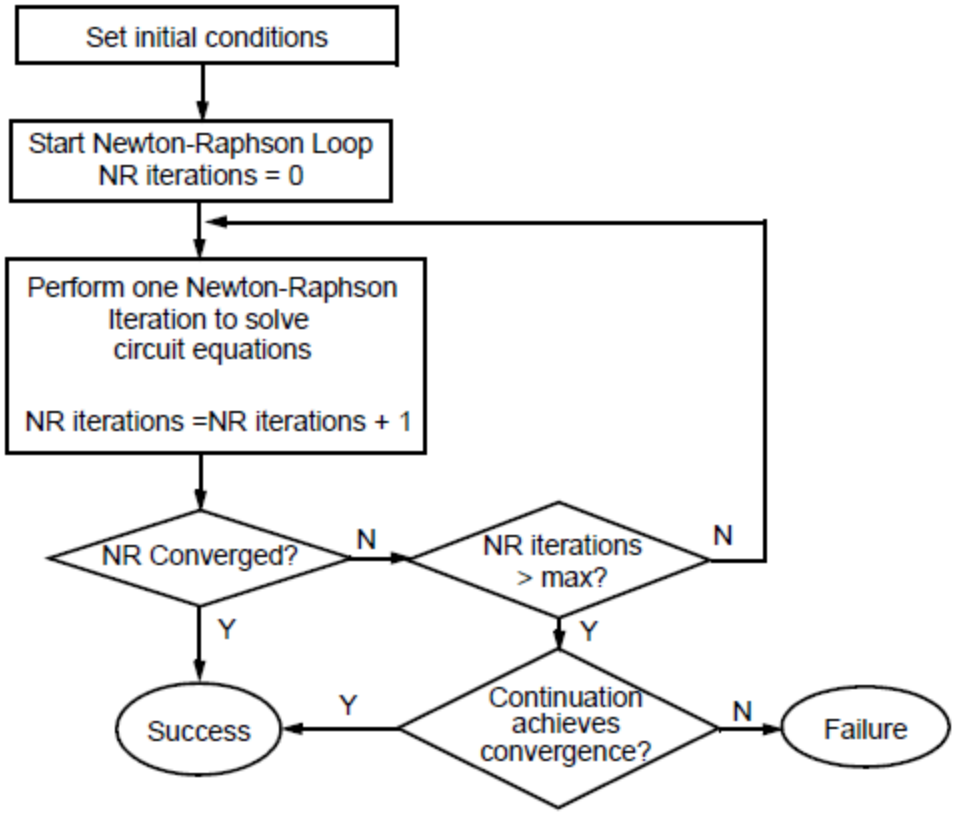


Figure 1. DC Analysis—Overall Flow

Initialization of Nexxim DC Circuit Parameters

DC analysis begins by initializing the circuit to a known state.

- Capacitors are modeled as open circuits.
- Inductors are modeled as short circuits.
- Voltage sources are set to zero and held constant (dv(t)/dt = 0).
- Current sources are set to zero and held constant (di(t)/dt = 0)
- Initial voltages from .NODESET are applied to the specified nodes. See NODESET Statements.
- Non-floating nodes are set to zero volts for the first Newton-Raphson iteration.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Floating nodes that are not specified with .NODESET are undefined.

> **Note:**
>
> Nexxim issues a warning message if the circuit contains floating nodes or nodes with single connections. Only nodes with a single branch connection that is both conservative and constitutive are flagged. For example, the controlling nodes in a VCVS have a constitutive/behavioral/relational connection to the controlled nodes, but not a physical/structural/conservative connection, and therefore are not flagged.

- Conductances with value **alpha** (G_{MIN}) are added between all branches.
- Conductances with value **beta** (G_{SHUNT}) are added between each node and the ground reference node (node 0).
- The nominal circuit temperature is set to **TEMP**.

NODESET Statements

The netlist can include one or more .NODESET statements. Voltages assigned with .NODESET are applied at the start of the DC operating point analysis, to provide the initial values for the first Newton-Raphson iteration. Any node voltages not specified with NODESET are initialized to zero.

The syntax is:

.NODESET V(*node1***)=***value1* [**V(***node2***)=***value2* **...**]

For example, to initialize node 12 to 4.5 volts and node in2 to 2.23 volts:

```
.NODESET V(12)=4.5 V(in2)=2.23
```

IC Statements

The netlist can include one or more .IC statements to force nodes to particular voltages. Voltages set with .IC are applied throughout the DC operating point analysis. Any node voltages not specified with .IC are computed.

The syntax is:

.IC V(*node1***)=***value1* [**V(***node2***)=***value2* **...**]

For example, to force node 12 to 4.5 volts and node in2 to 2.23 volts:

```
.IC V(12)=4.5 V(in2)=2.23
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> Nexxim recognizes .IC statements during .OP analysis. Other simulators may not.

Initialization of Nexxim DC Simulation Parameters

The DC simulator starts with a set of simulation parameters at initial values:

- The maximum number of Newton-Raphson iterations is set to **max_newton_iterations**, and the maximum voltage change between NR iterations is set to **limiting_step**.
- Tolerance values are set to the values of **abstol** (absolute current tolerance in amperes), **vntol** (absolute voltage tolerance in volts), and **reltol** (relative current and voltage tolerance, dimensionless), as appropriate.

DC Diagnostics

- If DC analysis fails, Nexxim checks the solution and finds the component that violates tolerance. The device information corresponding to the problematic node or branch is printed in the log file.
- DC analysis starts with DC continuation. If DC continuation fails, diagnostic information of Device continuation is provided.

Solving the Circuit Equations in Nexxim DC Analysis

In general, the equations for a system with a large number of nonlinear elements cannot be solved directly. The DC solver uses the Newton-Raphson (NR) method, a well-known iterative method.

The Newton-Raphson loop begins with vectors of initial values for the node voltages and branch currents. In each NR iteration, the simulator linearizes the circuit around the solution calculated in the previous iteration, and calculates the Jacobian matrix associated with the linearization point. The linear circuit models are represented in matrix/vector form. The simulator then uses a matrix solver to calculate a new vector of unknowns. At the end of each iteration, the Newton-Raphson method updates the solution and checks to see if the new solution satisfies the specified tolerances. If the result is within tolerance, the loop terminates. Otherwise, the loop uses the new result to start the next iteration.

Convergence is a critical issue with the Newton-Raphson method. Convergence to a correct solution is guaranteed by NR only when the initial starting point is sufficiently close to the final solution. Initial voltages set with .NODESET can help, but in many cases the DC solver starts with zero values, which may be too far on the correct values. Thus, convergence is often a serious problem that causes the DC solver to fail, which in turn prevents any further analysis such as transient analysis to be performed. In the Nexxim circuit simulator, the basic Newton-

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Raphson method is combined with sophisticated continuation schemes to ensure robust convergence without loss of simulation speed and accuracy.

Linearization of Nonlinear Device Equations

The current through a device is typically expressed as a function of the voltages at its nodes. Linear device currents are linear functions of node voltages. For example, the current through a resistor is described by:

$$f(v) = i = \frac{v_2 - v_1}{r}$$

For nonlinear devices, the relationships between current and voltage are expressed by one or more nonlinear functions of voltage. The Newton-Raphson method linearizes each nonlinear function $f(v)$ using the following iterative matrix/vector form, where on the kth iteration:

$$\Delta v_k = v_{k+1} - v_k = \frac{-f(v_k)}{\partial f(v_k)/\partial v_k}$$

Newton-Raphson Initial Values

The Newton-Raphson method starts with initial guesses for each of the unknown voltages. Some voltages are preset by .NODESETs and by the input voltages and currents. Voltages for connected nodes that are not preset default to zero.

Circuit Matrix Solver

On each NR iteration, the matrix solver computes the linearized solution using the formula:

$$\Delta v_k \times \frac{\partial f(v_k)}{\partial v_k} = -f(v_k)$$

and updates the solution at the end of each NR iteration with:

$$v_{k+1} = v_k + \Delta v_k$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The functions and derivative formulas are specific to the device models. The simulator uses either a direct solver or a Krylov subspace solver.

Nexxim DC Analysis Convergence Criteria

After each Newton-Raphson iteration, the simulator uses two criteria, the delta check and the function check, to determine whether the solution meets required tolerances. The delta check guarantees that the solution converges in the voltage tolerances set by options **reltol** (relative voltage and current tolerance) and **vntol** (absolute voltage tolerance). The function check guarantees that the solution satisfies the nonlinear equations in the current tolerances set by options **reltol** and **abstol** (absolute current tolerance).

Solving nonlinear circuits may also require limiting the size of voltage changes at each Newton-Raphson iteration.

Delta Check

The delta check is also known as the update criterion. As the solution of the Newton-Raphson solver gets close to the correct values, the norm of the voltage vector Δv_k should approach zero. The norm of Δv_k is the square root of the sum of the squares of the vector elements, represented by $||\Delta v_k||$. The delta check is satisfied when:

$$\left\|\Delta v_k\right\| < \left|(reltol \times \left|\Delta v_k\right| + vntol)\right|$$

The default value for **reltol** is 0.001 (dimensionless). The default for **vntol** is 50μV (50e-6 Volts).

Function Check

$$F(v_k) = B$$

The norm of the residue of this equation is:

$$\|r\| = \left\|F(v_k) - B\right\|$$

The norm of the residue should approach zero as the solution converges. The function check ensures that NR has converged to a correct solution, not just to a local minimum. The function check is satisfied when:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\|r\| < \left|(reltol \times \left|F(v_k)\right| + abstol)\right|$$

The default value for **reltol** is 0.001 (dimensionless). The default for **abstol** is 1nA (1e-9 Amperes).

Limiting Step and Limiting Method

Nexxim automatically identifies circuits that contain nonlinear elements. For large circuits with many nonlinear devices such as BJTs and MOSFETs, it is necessary to reduce the magnitude of the Δv_k update to aid in obtaining convergence. The DC solver limits the size of voltage updates to a maximum value given by the **limiting_step** option. The default **limiting_step** for circuits with nonlinear devices is 0.3 Volts.

For circuits that contain only linear devices, Nexxim sets the default for **limiting_step** to a large number, effectively disabling it. A large **limiting_step** speeds the convergence of circuits that are mostly linear, while a smaller value may help nonlinear circuits to converge more reliably.

The default method, **Standard Limiting**, reduces the magnitude of the Δv_k update that corresponds to all nonlinear elements and thus slows down convergence. The **Modified Limiting** method aims to avoid unnecessary limiting of moderately nonlinear elements, thus improving the DC convergence rate.

Nexxim DC Continuation Strategies

The Newton-Raphson method guarantees convergence only when its initial guess is close enough to the final solution. Without specific information about the circuit, the DC solver starts from an initial guess of zero. For many nonlinear circuits, zero is too far from the final solution, and Newton-Raphson fails to converge. In these cases, continuation methods can be applied to achieve convergence.

Nexxim uses a fixed sequence of continuation strategies to help achieve convergence. Each strategy uses a set of optimal parameters and a combination of several basic methods—device continuation, alpha (G_{min}) continuation, beta (G_{shunt}) continuation, and pseudotransient continuation. The **conv** option selects the initial combination of methods to use (See DC Analysis Options for details). By default, when one strategy fails to converge, the simulator cycles through the available combinations, and analysis fails only after all continuation strategies fail. You can deactivate the automatic cycling, in which case analysis fails when the first combination of methods fails to converge.

Alpha Continuation

Alpha continuation (also called G_{min} stepping) improves the robustness of the DC simulator. Some circuits may have floating nodes due to open devices. A floating node does not have a

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

unique voltage solution, so the circuit is a singular system that does not have a unique solution. Alpha continuation is one way to reach a solution that is unique and meaningful.

For the alpha continuation method, the simulator inserts a small conductance G_{min} (equivalent to a large resistor) in parallel with every branch. The value of the conductances is equal to the value of the **alpha** option, which defaults to 1e-13 mho. This conductance is small enough that the effect of the conductances on the circuit is typically negligible.

If the Newton-Raphson method fails to converge with the initial small conductance value, alpha stepping attempts to reach convergence by setting the conductances to a relatively large value, so the circuit is affected by the conductances and becomes more “linear.” The solver then attempts to solve this more “linear” circuit. The solution of the modified circuit is not the same as that of the original. However, if the modified circuit converges, the solution should be close to the solution of the original circuit. The solver uses the solution for the modified circuit as the input to the next NR loop, and decreases the value of the alpha conductances to decrease their effect on the circuit.

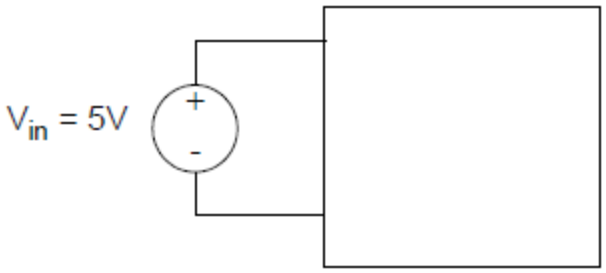
Alpha stepping progresses through smaller and smaller conductance values until convergence is achieved with the minimum value, unless an intermediate value of conductance fails to achieve convergence. The solution is accepted when the conductance equals the **alpha** option, which defaults to 1e-13 mho. If the behavior of the circuit is strongly affected by the G_{min} conductances, reduce **alpha** or even set it to zero.

Device Continuation

Device continuation (also called source stepping) attempts to reach convergence by initializing all voltage and current sources to values close to zero. In this condition, the initial guess of zero for all circuit values is a “correct” solution. Device continuation then attempts to reach convergence on the true solution by solving a sequence of circuits with progressively increasing source values.

For example, Figure 2 diagrams a circuit block diagram excited by a single 5V source, V_{in}.

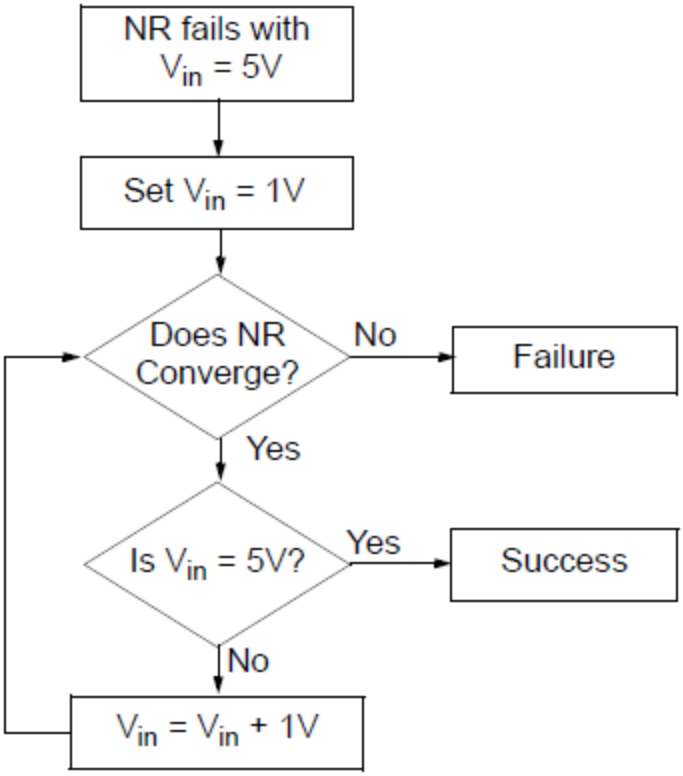
Figure 2. Device Continuation Example



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If NR fails to converge when V_{in} = 5V, source stepping may begin by trying to solve the circuit with V_{in} set to 1V. If that attempt converges, the solver uses that solution as the initial guess to a new circuit with V_{in} set to 2V, and tries NR again. This process repeats with V_{in} = 3V, V_{in} = 4V, and finally V_{in} = 5V. If each step converges, the fifth step with V_{in} = 5V is the correct solution and source stepping succeeds. If any step fails to converge, the device continuation fails. The device continuation algorithm for this example is illustrated in Figure 3.

Figure 3. Device Continuation Algorithm for Example in Figure 2



Beta Continuation

Beta continuation (also called G_{shunt} stepping) is similar to alpha continuation. With beta continuation, a small conductance (large resistor) G_{shunt} is added between each node and ground. The conductance is equal to the value of the **beta** option, which defaults to 1e-12 mho. If Newton-Raphson fails with the initial small beta conductances, the DC solver attempts to continue by setting the conductances to a relatively large value and executing Newton-Raphson on this more “linear” circuit. If this step succeeds, the solution to the modified solution is used to start the next NR loop with a decreased value for the conductances. Stepping continues until convergence is attained with the conductance equal to the **beta** option, which defaults to 1e-12 mho.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Pseudotransient Continuation

Direct DC analysis sometimes fails to solve a circuit. For such circuits, transient analysis can be employed. The transient problem is solved over a long enough time to reach the DC steady state. This continuation method is called pseudotransient continuation.

Convergence, Speed, and Accuracy

DC operating point simulation provides the large-signal bias point that is important for small-signal analyses such as AC analysis, transfer function analysis, noise analysis, and linear network analysis. These small-signal simulations cannot be performed without a DC solution. Because the duration of the DC analysis is added to the small-signal simulations, it is important to achieve fast DC convergence with high accuracy.

The DC analysis must of course converge in order to obtain a usable result. Once convergence is achieved, the trade-off between solution accuracy and convergence speed can be considered. The options in the following topics affect the convergence, accuracy, or speed.

Options that Affect Nexxim DC Convergence Only

The options in the following categories control the ability of the simulator to achieve convergence.

DC Convergence Algorithms

The option **conv** sets the DC convergence algorithm.

- **conv=1** is the default algorithm, a combination of beta and device continuation which is both aggressive and robust.
- **conv=2** uses only device continuation, and is usually not as robust as **conv=1**.
- **conv=3** uses the more robust pseudotransient algorithm, but is not as fast as **conv=1** when the circuit is linear.
- **conv=4** is a slight modification of the **conv=1** beta and device continuation algorithm.
- **conv=5** combines alpha, beta, and device continuation.

When **conv=3** (pseudotransient continuation) has been specified, the option **max_pt_continuation_iterations** controls the maximum iterations to use (default is 5000 iterations).

The Boolean option **autoconverge** enables and disables automatic cycling through the convergence strategies.

- **autoconverge=1** is the default. Suppose **conv=1** is the current selection. If DC analysis fails with **conv=1**, the simulator automatically tries **conv=2**, **3**, **4**, and **5** until convergence is achieved. If **conv** has been set to a value other than 1, autoconvergence cycles from that method through the remaining methods. For example, if **conv=3** has been selected

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

then fails, autoconvergence cycles through **conv=4**, **5**, **1**, and **2** until convergence is achieved. If no method achieves convergence, analysis halts.

- **autoconverge=0** disables autoconvergence cycling. If the chosen strategy fails, analysis halts.

Initial Guess in Sweeps

By default, DC sweeps use the result on the previous sweep step as the initial guess for the current step. The option **result_as_initial_guess** controls this behavior.

- **result_as_initial_guess=0** turns off the use of previous results.
- **result_as_initial_guess=1** enables the use of previous results. However, the use of previous results is the default, so this option setting is never needed.

Maximum NR Iterations

The option **max_newton_iterations** determines how many iterations is attempted before the Newton-Raphson loop exits without achieving convergence. The default is 200 iterations. Increasing the number of iterations allows the DC simulator to try more iterations per continuation step. As a result, each continuation step takes a longer time. However, this may help large nonlinear circuits to converge with fewer continuation steps.

NR Limiting Step

The option **limiting_step** sets the maximum size for changes in node voltages at each step in the Newton-Raphson loop. The default is 0.3 Volts. Use of a limiting step is referred to as “damped Newton-Raphson.” This option trades off the ability to converge and the speed of the simulation. Making the limiting step smaller improves the chance of convergence, but usually increases the number of NR iterations needed to reach convergence. For circuits with nearly linear functions, increasing the limiting step can speed up the simulation.

Maximum Continuation Iterations

The option **max_continuation_iterations** determines the maximum number of incremental steps to be used for G_{min}, G_{shunt}, and source stepping. This option thus takes effect only when the circuit has failed to converge normally. Increasing the maximum number of continuation iterations might improve the chance that the circuit converges. However, the default number, 500, should be large enough for all cases. If the circuit does not converge with the default continuation parameters, increasing **max_continuation_iterations** is unlikely to succeed.

Options that Affect Convergence, Speed, and Accuracy

The options in the next categories trade off the guarantee of convergence, the speed of the simulation, and the accuracy of the solution.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Relative Voltage and Current Tolerance

The **reltol** option controls the relative tolerance used for both the delta voltage check and the current function check (See "Nexxim DC Analysis Convergence Criteria" on page 26-261). The default **reltol** is 0.001 (0.1%).

Both the delta check and the function check have two parts, a relative part and an absolute part. The relative part is a function of **reltol** and some reference value, typically calculated voltage or current. When the reference values are large, the relative part of the criterion is much larger than the absolute part, and **reltol** in effect controls the convergence. In these cases, making **reltol** larger ("loosening" **reltol**) allows the circuit to converge in fewer iterations (and shorter simulation time), but with reduced accuracy.

Conversely, decreasing (or "tightening") **reltol** increases the accuracy of the result, but may require more Newton-Raphson iterations to reach convergence. Thus, if **reltol** is tightened, the **max_newton_iterations** option may need to be increased.

Absolute Voltage Tolerance

The **vntol** option controls the absolute part of the delta voltage convergence criterion. The default is 50e-6 Volts or 50μV. When the reference values are close to zero volts, the absolute part of the criterion controls the convergence. **vntol** should be a value that is reasonable given the smallest voltage that is expected. One possibility is to set **vntol** equal to the smallest expected voltage times **reltol**.

Like **reltol**, tightening **vntol** increases accuracy but may require more NR iterations.

Absolute Current Tolerance

The **abstol** option controls the absolute part of the current function convergence criterion. The default is 1e-9 Amps or 1nA. When the current values in the circuit are close to zero amperes, the absolute part of the criterion controls the convergence. **abstol** should be a value that is reasonable given the smallest current that is expected. One possibility is to set **abstol** equal to the smallest expected current times **reltol**.

Like **reltol**, tightening **abstol** increases accuracy but may require more NR iterations.

Alpha Initial Value

The **alpha** option sets the initial value for the G_{min} conductances inserted across all branches in the circuit. The default value is 1e-13 mho (0.1 picoSiemens). The default value is usually too small to affect the operation of most circuits. The user may reduce G_{min} or even set it to zero to avoid affecting the circuit. Changing alpha can affect the convergence.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Beta Initial Value

The **beta** option sets the initial value for the G_{shunt} conductances inserted from all nodes to ground. The default value is 1e-12 mho (1 picoSiemens). The default value is normally small enough, but the user may change it. Changing beta can affect the convergence.

Summary of Effects of DC Options

The following table summarizes the options that affect the convergence, speed, and accuracy of the DC operating point simulation.

	Effect of Options on DC Operating Point Simulation	
Simulation Result	**Effect of Option**	
	Improve	**Worsen**
Convergence	Increase **max_newton_iterations**	Decrease **max_newton_iterations**
	Decrease **limiting_step**	Increase **limiting_step**
	Increase **max_continuation_ iterations**	Decrease **max_continuation_ iterations**
	Increase **reltol**, **vntol**, **abstol**	Decrease **reltol**, **vntol**, **abstol**
	Increase **alpha**, **beta**	Decrease **alpha**, **beta**
	Set **conv** =3, 4, or 5	Set **conv** =2
		Set **autoconverge** =0
Speed	Increase **limiting_step**	Decrease **limiting_step**
	Increase **reltol**, **vntol**, **abstol**	Decrease **reltol**, **vntol**, **abstol**
	Set **conv** =2	Set **conv** =3, 4, or 5
Accuracy	Decrease **reltol**, **vntol**, **abstol**	Increase **reltol**, **vntol**, **abstol**
	Decrease **alpha**, **beta**	Increase **alpha**, **beta**

Transient Analysis Technical Notes

The following topics provide technical information on Nexxim transient analysis.

Initial Conditions for Transient Analysis

Transient analysis obtains a set of initial conditions (at time = 0) by performing a DC operating point analysis as described in Nexxim DC Analysis. As in DC analysis, .NODESET and .IC statements may be used to affect the computation of initial conditions.

Any options specified for DC analysis affects the DC calculation done to obtain the initial conditions for transient analysis. See DC Analysis Options.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Some options (in particular, **abstol** and **reltol**) can affect both DC analysis and transient analysis. See "Circuit Transient Analysis Options" on page 12-32 for further information.

Floating Node Warning

Nexxim issues a warning message if the circuit contains floating nodes or nodes with single connections. Only nodes with a single branch connection that is both conservative and constitutive are flagged. For example, the controlling nodes in a VCVS have a constitutive/behavioral/relational connection to the controlled nodes, but not a physical/structural/conservative connection, and therefore are not flagged.

Numerical Integration Methods

Transient analysis computes the time-domain response of a circuit by numerically integrating a system of differential/algebraic equations derived on the circuit topology and the circuit device models. Transient analysis uses Newton-Raphson iteration with the following numerical integration methods to solve the circuit equations at each discretized timestep.

Backward Euler

The Nexxim transient analysis engine always uses the backward Euler method when automatically starting or restarting integration.

Trapezoidal Rule

The trapezoidal rule is the Nexxim circuit simulator's default method for transient analysis.

The trapezoidal rule is an accurate integration method that does not produce numerical damping. It can produce "trapezoidal ringing," an oscillation in calculated values that is not the true circuit behavior. If ringing is observed, switch to BDF2 or NDF2.

See Transient Analysis Method Option RF in the Nexxim Design Examples help topic for an example of trapezoidal ringing and the use of the NDF2 integration method.

Second Order Backward Difference Formula

The Second Order Backward Difference Formula or BDF2 is also called the Gear method.

BDF2 is not quite as accurate as the trapezoidal rule, but is an A-stable numerical method. This means that BDF2 does not produce ringing, but instead produces numerical damping (the calculated circuit output eventually decays to zero although the true behavior does not). If BDF2 exhibits severe damping, use TRAP or NDF2.

Numerical Differentiation Formula

The Nexxim simulator offers a proprietary variable-step integration method called the Numerical Differentiation Formula (NDF2). NDF2 offers nearly the accuracy of the trapezoidal method. It

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

creates less numerical damping than BDF2, but like BDF2 it is an A-stable method.

Selecting the Integration Method

The integration method can be specified with the .OPTIONS statement.

.OPTIONS method=*selection*

The default is **TRAP** (the Trapezoidal rule). You can also specify **GEAR** (**BDF2**) or **NDF2**.

Newton-Raphson Iterations

At each timestep, the simulator solves the discrete time approximation equations using the Newton-Raphson (NR) iterative method. Because the solution on the previous timestep is close to the solution for the current step, the number of Newton-Raphson iterations required to reach convergence at each time point is typically much less than the number of iterations needed for the initial DC operating point calculations.

You can set the maximum number of iterations to use with the **maxiters** option on the .OPTIONS statement. The default for transient analysis is 10 iterations.

The option **limiting_step** sets the maximum size for changes in node voltages at each step in the Newton-Raphson loop. Nexxim automatically identifies circuits that contain nonlinear elements. For large circuits with many nonlinear devices such as BJTs and MOSFETs, it is necessary to reduce the magnitude of the Δv_k update to aid in obtaining convergence. The Transient solver limits the size of voltage updates to a maximum value given by the **limiting_step** option. The default **limiting_step** for circuits with nonlinear devices is 0.3 Volts.

For circuits that contain only linear devices, Nexxim sets the default for **limiting_step** to a large number, effectively disabling it. A large **limiting_step** speeds the convergence of circuits that are mostly linear, while a smaller value may help nonlinear circuits to converge more reliably.

The maximum change in voltage per timestep is given by **maxiters** times **limiting_step**. In general, it is safer to change **maxiters** to adjust the size of the allowed voltage change per timestep, rather than changing the **limiting_step**.

The **update_jacobian_period** option can affect the overall speed of the Newton-Raphson process. By default, the Jacobian matrix is updated after every third iteration. Increasing the number of NR iterations per Jacobian update can speed up the simulation, but is risky when the circuit contains nonlinear elements. Reducing the **update_jacobian_period** option to 2 or 1 slows the simulation but may be necessary for highly nonlinear circuits. The Jacobian update period is sometimes called the Šamanskii step size.

Timestep Control

Transient analysis (including the transient analysis used to calculate the step response for QuickEye and VerifEye) uses a variable timestep that depends on several factors:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Failure of the Newton-Raphson iterations to converge. If the Newton-Raphson iterations on any timestep fail to converge, the simulator decreases the size of the timestep and tries again.
- The Local Truncation Error and the Local Error. If the Local Error (which is calculated based on the Local Truncation Error) on any timestep is too large, the simulator decreases the size of the timestep and tries again.
- The **rmax** and **delmax** options, which control the maximum timestep size. Options **maxstep** (**eye.maxstep** in QuickEye and VerifEye options) and **tmax** are equivalent to **delmax** and can be used interchangeably. A two-stage timestep control algorithm is used to control the step size. The first stage is controlled by **rmax** (**eye.rmax** in QuickEye and VerifEye options). The maximum step size for the first stage is calculated by multiplying the value of the **rmax** option times the *tstep* argument from the .**TRAN** statement. The second stage limit uses the value of **delmax** and incorporates circuit information such as input frequencies. **delmax** should be greater than or equal to **rmax** times the *tstep*. The step size control algorithm behaves more liberally in the first stage, where the actual step size is smaller than **rmax** times the *tstep*, and more conservatively in the second stage, where the step size is larger than **rmax** times the *tstep* yet smaller than **delmax**. The two-stage algorithm allows a good trade-off between simulation time and accuracy.
- The two-stage timestep control algorithm increases/decreases the timestep based on the Local Truncation Error (LTE) and the number of Newton iterations (an indicator of nonlinearity). A small/large LTE leads to increase/decrease the timestep. **max_stretch** and **max_damp** determine the weight of nonlinearity-based factor of timestep control. Nonzero **max_stretch** is expected to reduce simulation time for circuits of weak/moderate nonlinearity. Nonzero **max_damp** increase the change of convergence for circuits of strong nonlinearity. By default, time stepping adaptivity will be triggered, that is a nonzero **max_stretch** will be generated automatically, if time step size is too small.
- The **trtol** option, which controls the relative solution tolerance. The **trtol** option specifies the (dimensionless) ratio between the tolerance of the overall transient analysis solution and the tolerance used in the Newton-Raphson iterations. The default of seven (7) means that tolerance used for the transient analysis solution is seven times looser than the tolerance used for the Newton-Raphson iterations. Increasing **trtol** has the effect of decreasing solution accuracy and increasing the timesteps.

Note:

Nexxim does not use the HSPICE “NPDELAY” parameter when it is present in imported netlists. The Nexxim timestep methodology is more advanced than the HSPICE NPDELAY method.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Controlling Output from Transient Analysis

By default, the output shows all node voltage values at the timesteps produced by the numerical integration. From the Schematic Editor, limit the output to specific variables with the Output Quantities window. From the netlist, specify a list of particular values with a .PRINT statement. For example, if the netlist input contains the following statements:

```
.TRAN 10ns 1us
.PRINT TRAN V(12), V(15)
```

Nexxim outputs just the voltages on nodes 12 and 15 at the internal timesteps. Without the .PRINT statement, the output includes voltages at all nodes in the circuit.

Nexxim performs quadratic interpolation between time steps. Unlike some Spice simulators, the output is not automatically interpolated to (uniform) TSTEP increments.

Stable Undershoot and Numerical Beating

When a periodic signal such as a sinusoidal or piecewise linear waveform is analyzed, the timesteps are selected to give an accurate representation of the periodic signal. Chance differences in the location of timepoints can lead to apparent errors when the wave is plotted.

Undershoot. In some cases, no timestep falls at the exact high or low point of the waveform. When this happens, interpolation may cause the maximum and minimum values as plotted to appear less than the known high and low values. Quadratic interpolation used by Nexxim helps with this “stable undershoot” problem, but cannot fully resolve it.

Beating. Nexxim tries to set constant time points to sample at the same places in each period of the waveform. When the period of the signal is not an integral multiple of the timestep, the apparent frequency implied by the timesteps can be slightly different on the frequency of the signal. This frequency difference generates a “numerical beating” which appears in the plotted waveform. Decreasing the timestep improves the plots, but uses more analysis time.

Transient Continuation

If transient analysis fails, Nexxim checks to see whether a nonpassive S-parameter element could be the cause. If a suspicious element is detected, Nexxim sets option **s_element.enforce_passivity=7** to enable passivity checking and enforcement by the IFPV method, and then retries the transient analysis. To disable automatic transient continuation for S-elements, set option **s_element.auto_enforce_passivity=0**. For W-elements, the option to disable automatic transient continuation is **w_element.auto_enforce_passivity=0**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> The global option **auto_enforce_passivity=0** overrides any passivity enforcement set for s_element or w_element.

See Circuit S-Parameter Technical Notes for more details.

Transient Convergence

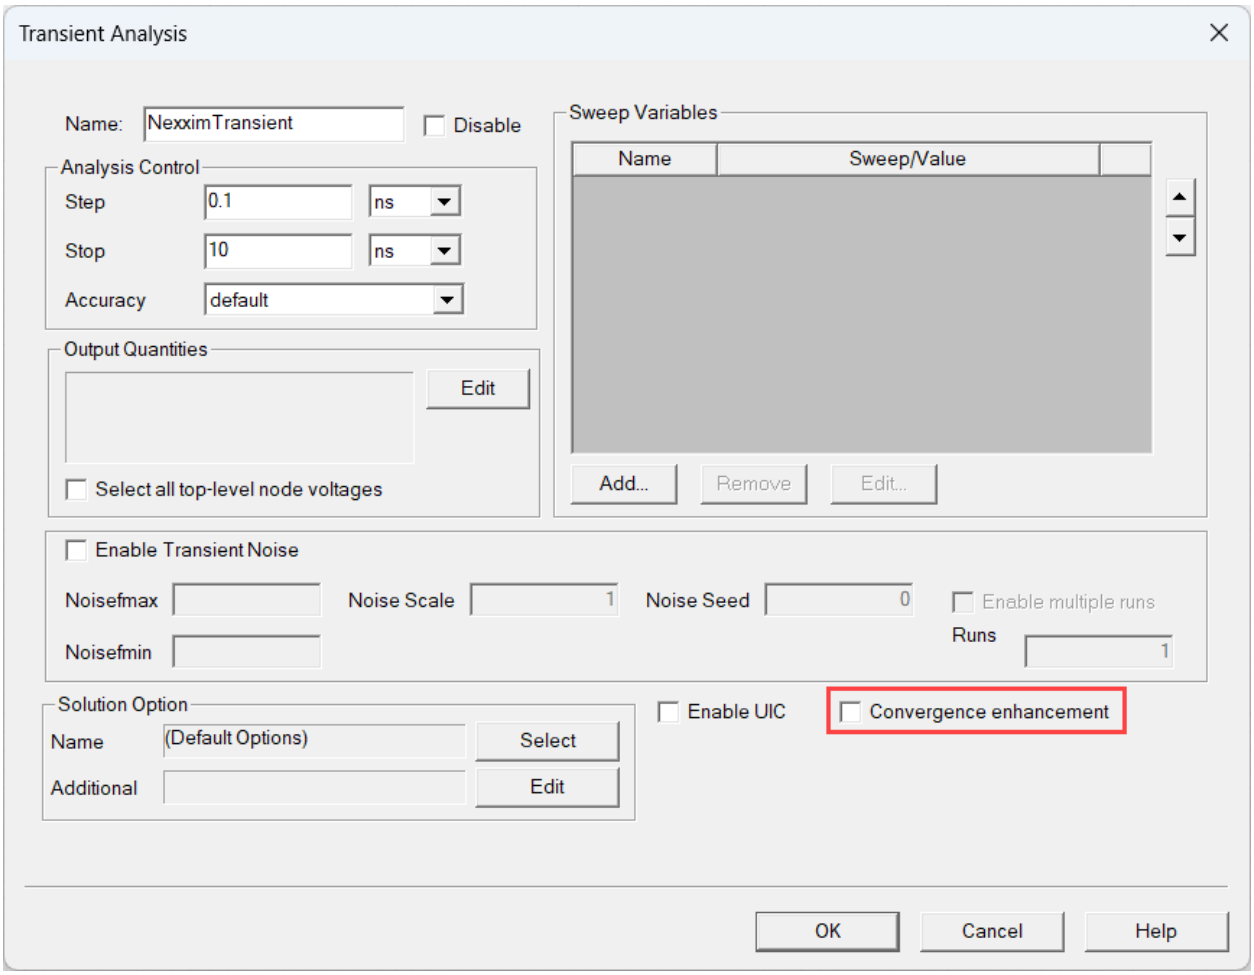
The result of transient analysis depends on three factors: convergence, accuracy, and speed. In practice, one of the three factors must be traded off. For example, without loss of convergence, a fast simulation implies that the accuracy must be low. Conversely, solver settings of high accuracy and high performance can lead to a convergence failure or require a long simulation time. Nevertheless, convergence is the top priority and cannot be traded off.

For cases that are difficult to converge with the default method, Nexxim provides two alternative convergence enhancement methods: **Max convergence enhancement** and **Balanced convergence enhancement**.

- **Max convergence enhancement** applies fixed values on some parameters to maximize the chance of convergence. See Transient Analysis options reference for details. This method can be enabled by setting `tran.convergence_enhancement=1`. If Nexxim still fails to converge with this method, use Transient Diagnostics to locate problematic device information.
- **Balanced convergence enhancement** applies dynamic values on parameters to balance performance, convergence, and accuracy. The method can be enabled by the checkbox in the **Transient Analysis** set up window or by setting `tran.auto_conv_enhancement = 1`. This method has high accuracy and better performance compared to Max convergence enhancement, but may fail to solve extreme cases like highly nonlinear circuits. If Nexxim fails to converge with Balanced convergence enhancement,

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

please retry Max convergence enhancement.



Transient Diagnostics

- If Transient analysis fails, Nexxim checks the solution and finds the component that violates tolerance. The device information corresponding to the problematic component is printed in the log file.
- The ratio of the max node voltage and the min node voltage is tracked. If the ratio is large, a suggestion on relref is included in the log file.
- The first *N* largest/smallest time steps that lead to convergence are collected. Such information can be printed in the log file if setting the message controller to

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`error.filter=0`. The value of *N* for largest and smallest time steps can be modified by **`tran.num_large_h_record`** and **`tran.num_small_h_record`**, respectively.

Virtual EMI Receiver Probe

This FFT-based (i.e., Fast Fourier Transform) virtual EMI receiver (i.e., Time Domain Scan) probe reduces EMI/EMC compliance test time, allowing users to verify their designs with shorter bench and chamber time.

> **Note:** The EMI receiver probe enables post-processing of a signal available after completion of the transient analysis of a circuit. Refer to the Circuit Help for instructions.

The virtual EMI receiver functions with the following major steps for EMI/EMC compliance tests:

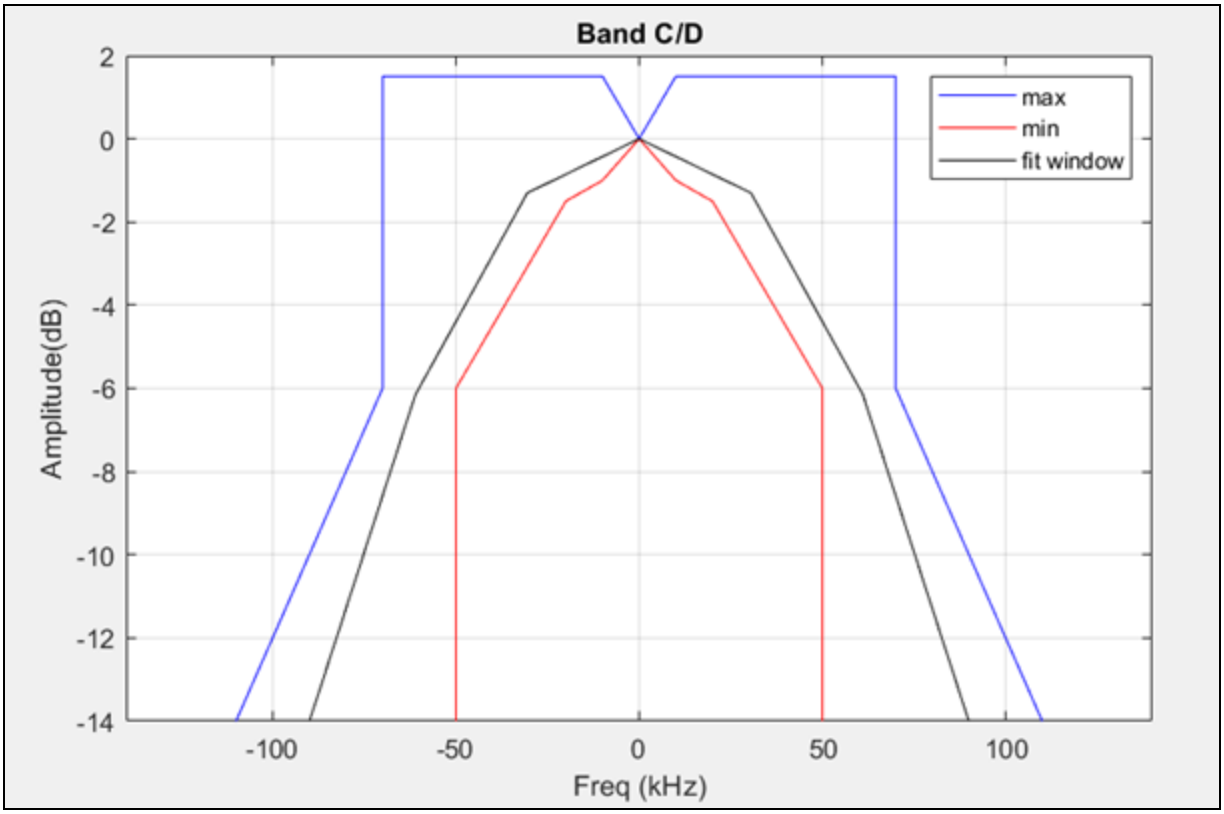
Transient signal mixed with EMI noise of DUT (Device Under Test) first undergoes Short-Time-Fourier-Transform (STFT) analysis with Gaussian Window ( ) to output 3D Spectrogram data which shows frequency component change in the signal with respect to time. Then the Spectrogram data is passed through the desired EMI detectors to obtain signal strength (e.g., dBmV) in the selected frequency range. Users can apply limit lines defined according to various standards (e.g., CISPR25 for automobile tests, IEC 61967 for IC circuits), to analyze if the DUT data passes EMC testing.

The accuracy of the virtual EMI receiver is dependent upon the length of signal (time duration), of Gaussian window, window length, size of FFT, and the overlap rate of windows during calculation of STFT. CISPR 16-1-1 defines the band pass selectivity requirement of the Gaussian window for each band. Resolution bandwidth (RBW) is the bandpass width at 6dB below peak of a Gaussian window.

Characteristics	Frequency Band		
	Band A (9 kHz to 150 kHz)	Band B (0.15 MHz to 30 MHz)	Band C and D (30 MHz to 1,000 MHz)
Bandwidth at the -6 dB points (kHz)	0.20	9	120
Detector electrical charge time constant (ms)	45	1	1
Detector electrical discharge time constant (ms)	500	160	550

The following figure demonstrates a Gaussian window that successfully fits within the tolerance defined in CISPR 16-1-1 for Band C and D.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

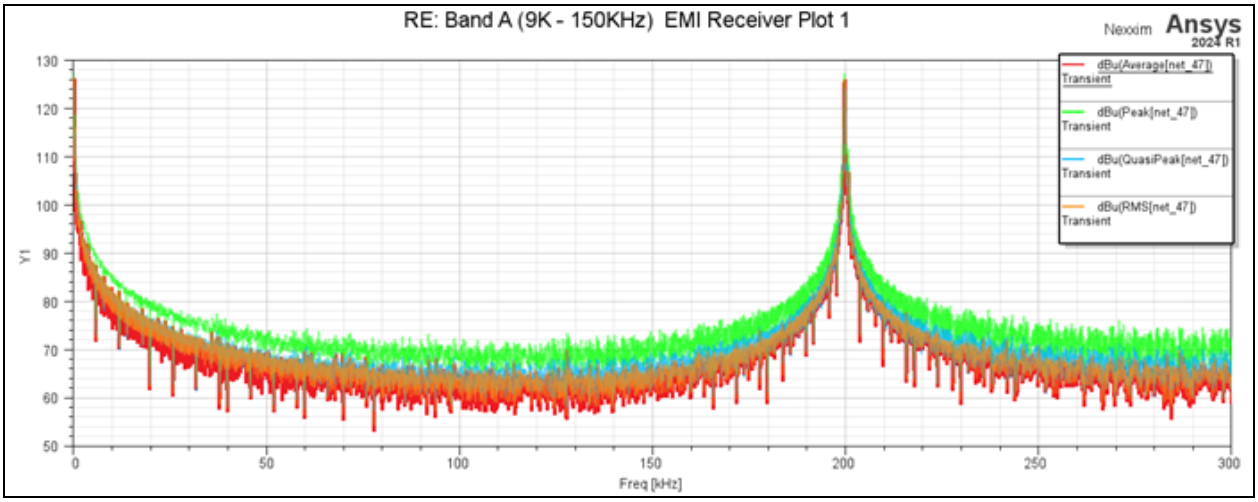


RBW affects EMI receiver's ability to resolve closely spaced signals. Two narrow signals can only be separated, if the resolution bandwidth is smaller than the distance between these two signals. RBW also determines the noise floor of the detected spectrum. Larger RBW results in higher measured noise floor because more frequency components can pass through a wider RBW filter for various detectors.

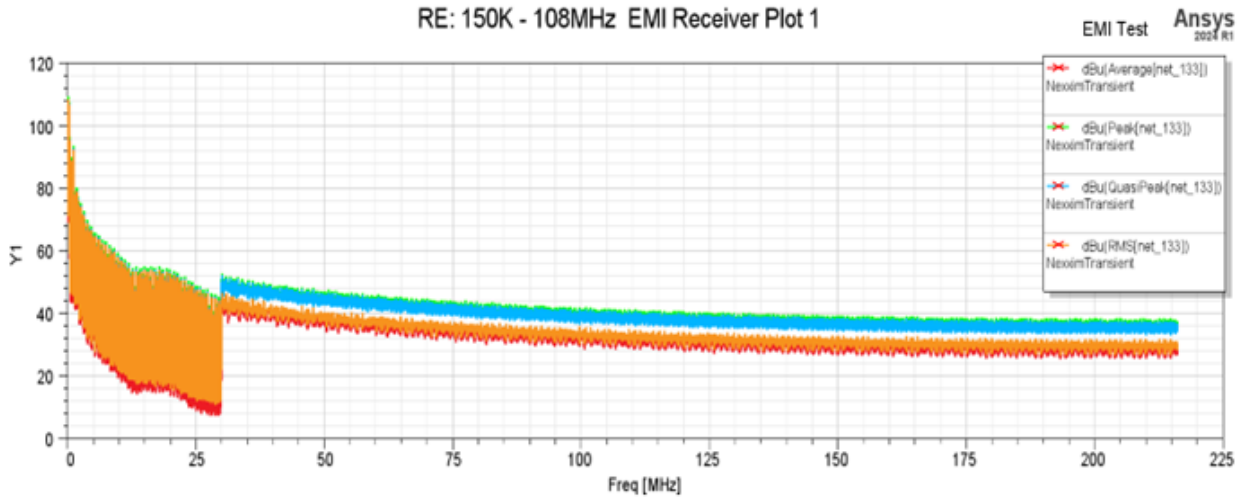
RBW Factor is added to provide choices for number of frequency samples per RBW. The number of frequency samples per RBW = 1/'RBW Factor', i.e., 4 samples per RBW when RBW Factor = 0.25. Frequency step size of the EMI receiver is equal to 'RBW' * 'RBW Factor'. Similar to smaller RBW, more samples per RBW lead to a more accurate representation of the signal and lower detection noise floor. It's common practice to have 2 to 4 samples per RBW in EMI receivers to ensure adequate sampling and resolution of the signal.

Examples of detected EMI signals are shown below with P, QP, RMS and Ave detectors.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



When a Band includes multiple CISPR16 Bands and mixed RBW values are used, detected EMI signals show steps in noise level due to RBW value change. The following is an example plot for Band 150K-108MHz(RBW = 9KHz is applied for frequency range from 150K to 30M, and RBW=120K is used for 30M-108MHz):



By default, Gassian parameter sigma, the size of the FFT, and the window size is automatically set to meet the band pass selectivity requirements defined in CISPR 16-1-1. When the signal length is less than the window size appropriate for the chosen RBW and RBW Factor, only single FFT can be applied to the available signal. In such case, EMI receiver results for all detection methods would be on top of each other based on the single FFT. Smaller RBW or RBW factor requires larger window size, hence longer transient signal for effective EMI analysis. The following table provides reference signal length for each CISPR16 band to accommodate

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

available RBW factor settings. Note that these signal lengths do not take into account the QP detection time constants for each band, which demand much longer signals.

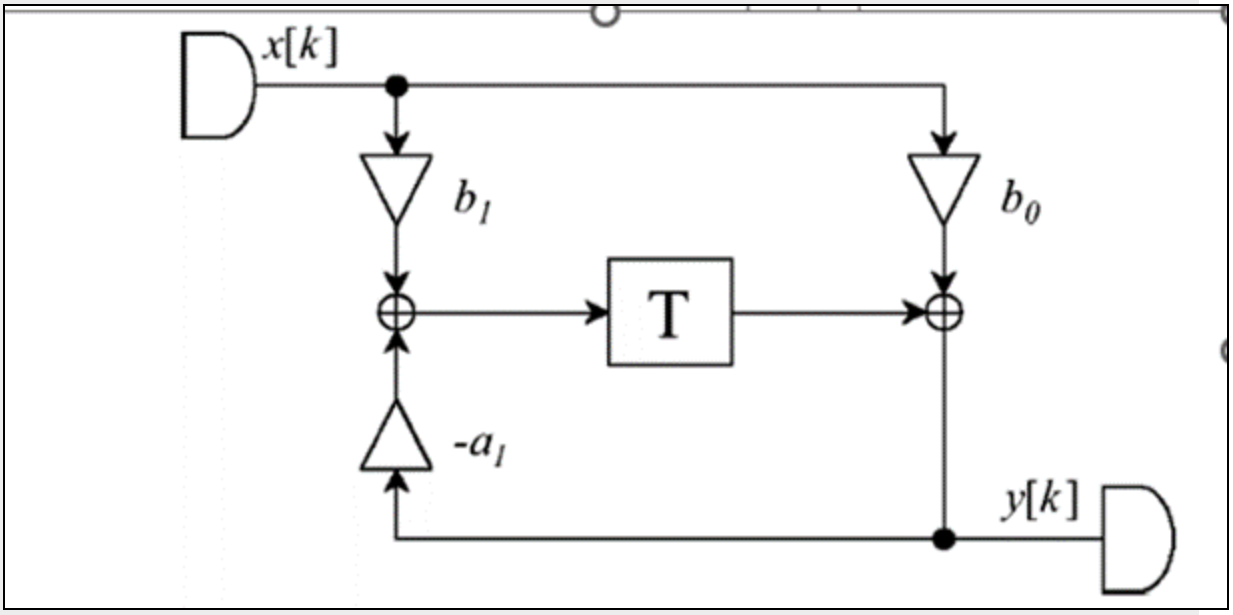
	RBW	**Signal Length**
Band A	200Hz	> 25ms
Band B	9KHz	> 555us
Band C/D	120KHz	> 42us
Band E and above	1MHz	> 5.3us

The virtual EMI receiver supports four types of detectors defined in CISPR 16-1-1 (i.e., Average, Peak, Quasi-Peak (QP) and RMS).

- Average computes the average signal over time
- Peak saves the maximum signal value over time at each frequency point
- QP provides weighted signal magnitude at each frequency point; component signals with a high repetition rate are weighted more than rarer signals
- RMS computes root-mean-square signals over time at each frequency point.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note: There are two time-constants associated with the QP detector for each band. Such a detector can be implemented as an IIR filter.



To achieve accurate QP results with large time constants, about 1 second of simulated signal is required. To overcome this limitation, as long as the signal length is 2.2 x charge time (rise to 90% of signal strength), the IIR filter structure is used to compute QP. Otherwise, a simplified estimate of QP detection is applied. Due to these assumptions, QP results should be used with consideration unless the signal is long enough to support the required time constants. The result of Peak and RMS detections provides upper and lower bounds for QP detection.

QuickEye and VerifEye Technical Notes

These topics provides background information and technical details about QuickEye and VerifEye. The formulas and relationships in these topics are conceptual, and do not describe the actual algorithms used by the solver.

The Bit Error Rate

The bit error rate (BER) is the figure of merit for signal integrity issues. The transmitter sends a sequence of bits through a channel to the receiver. In a perfect channel, every received bit value (0 or 1) is equal to the transmitted value. In the typical channel, some bit errors occur. The BER is the ratio of bits incorrectly received to the total number of bits transmitted.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Inter-symbol interference (ISI) is the major cause of bit errors. ISI occurs when the response of the channel to a change in bit value (from 0 to 1 or from 1 to 0) is longer than the unit interval (UI) or bit time. When a transition takes more than one UI to settle, the values of previous bits affect the waveform for the current bit.

Here is a simple example. Suppose the channel to analyze is a 100-ohm differential driver feeding into an R-C load with R=100 ohms and C=40 pF. Figure 1 shows the input bit sequence to the channel. 1V represents a logic “1”, while -1V represents a logic “0”. The unit interval (UI) is 1ns.

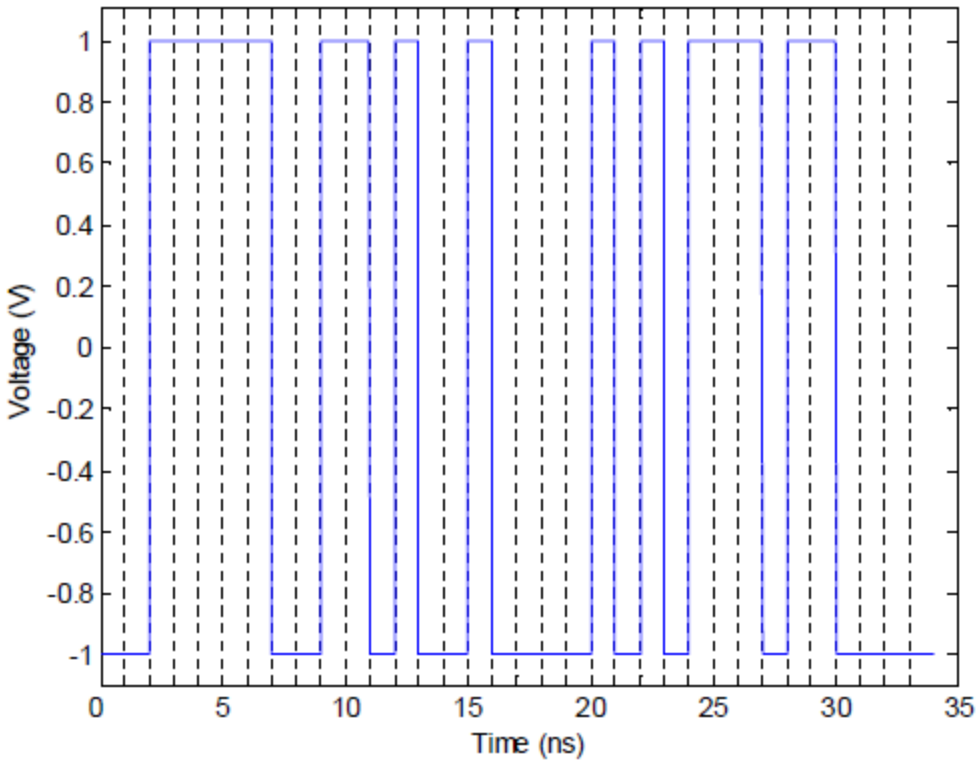


Figure 1: Input to Simple R-C Channel.

Figure 2 graphs the measured output at the receiver end of the channel, showing the degradation of the original stream of bits as it goes through the channel.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

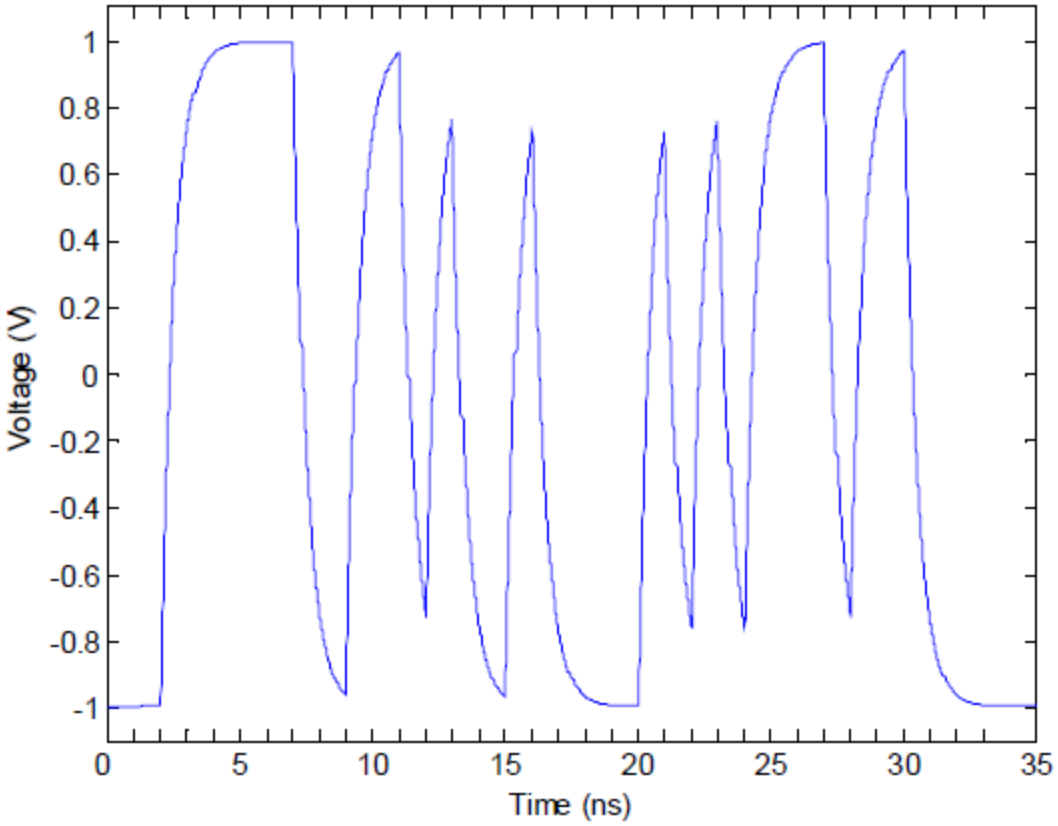

Figure 2: The output of the simple R-C channel.

The waveform in Figure 2 shows the effects of intersymbol interference (ISI). With this channel, the waveform for an isolated 1 surrounded by zeros never gets close to the nominal +1V value, and an isolated 0 surrounded by ones does not fall to -1V. Clearly, this channel has a non-zero bit error rate.

The eye diagram is a convenient tool for estimating the BER given the waveform. Copies of the waveform generated at the receiver end of the channel are overlaid at a spacing of one unit interval (UI). The eye diagram illustrates the allowable window for distinguishing bits from each other at the receiver end. The width and height of the eye opening are the dimensions of the window. The minimum allowable width of the eye depends on the jitter budget. The required height of the window is given by the noise margin of the receivers. Given the required width and height, how often does the waveform violate this window? This is the Bit-Error Rate, or BER.

Figure 3 shows the eye diagram created by shifting and overlaying the waveform of Figure 2. The area of white space in the center is the eye. (More bits is needed to obtain a better “eye.”)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

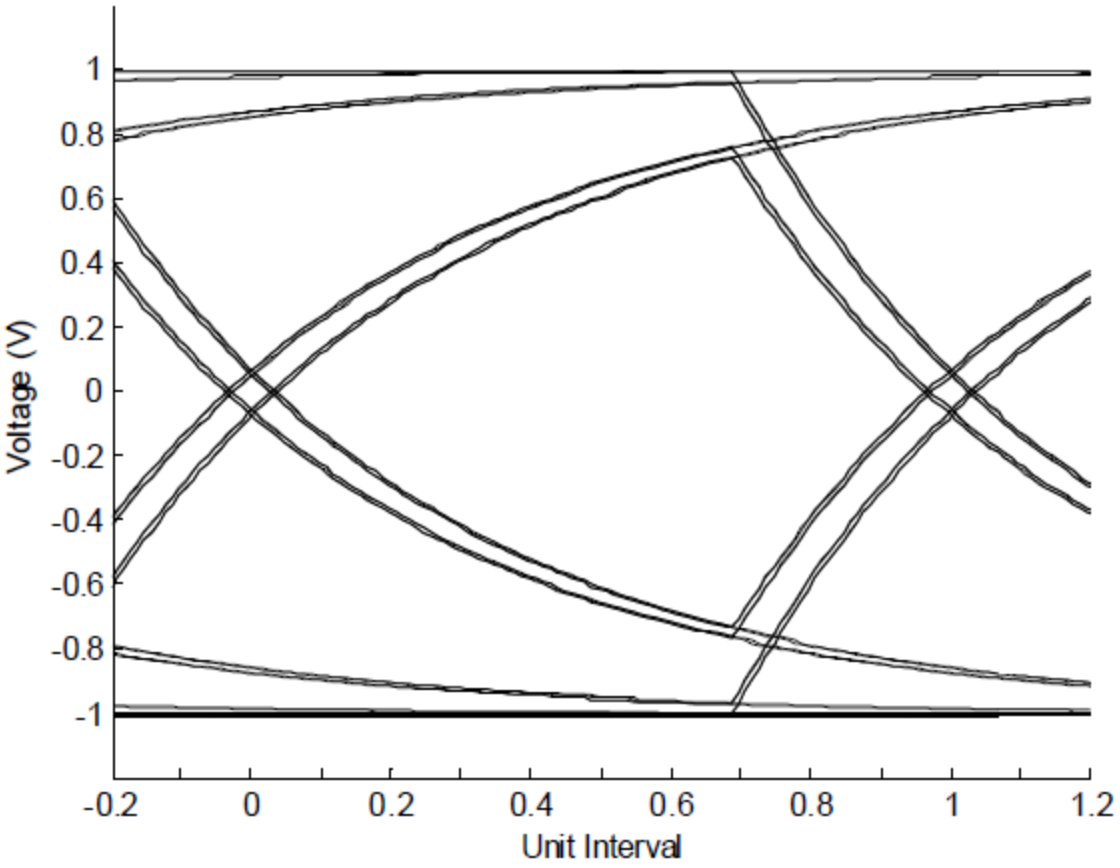

Figure 3: Eye Diagram for Simple R-C Channel

Traditionally, eye diagrams have been measured in the lab or simulated with transient analysis. However, with increasing data rates, particularly in the case of high-speed serial links, the required BER has decreased significantly. The need to predict very low BERs leads to a corresponding increase in the number of bits to be simulated, and thus to a search for alternatives.

The *probability* that a waveform violates the eye window can be measured from test data or calculated from channel parameters. Both transient analysis and QuickEye measure the BER probability by running sufficient data and counting errors. Quick Eye analysis uses simplifying assumptions to speed up the simulation, but requires the same large data sets to measure low BERs. VerifEye analysis uses a fully statistical approach to calculate the BER without requiring any test data.

The LTI Channel Model

A fundamental assumption for both QuickEye and VerifEye is the channel can be treated as a linear time-invariant (LTI) system characterized by a step response. QuickEye and VerifEye are

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

based on the principle of superposition, which makes use of this assumption. Forcing an LTI approximation allows a convolution-based approach to solving the time domain problem. The following topics show how the step response (and the related edge response) can be understood in terms of LTI systems theory.

The LTI Criteria

A system is linear and time-invariant if it meets two criteria:

Linearity: If input $x_1(t)$ produces output $y_1(t)$ and input $x_2(t)$ produces output $y_2(t)$, the linear combination $a_1x_1(t) + a_2x_2(t)$ generates output $a_1y_1(t) + a_2y_2(t)$.

Time invariance: If input x(t) produces output y(t), input $x(t+t_0)$ produces output $y(t+t_0)$, where the offset t_0 can be positive or negative.

The Impulse Response

As a direct consequence of the LTI criteria, an LTI system can be characterized completely by its impulse response. The impulse response *h(t)* is the output of an LTI system when the input is a Dirac delta function δ(t). The Dirac delta function is a distribution that is 0 everywhere except at the origin, where it is of infinite magnitude (Figure 1).

$$\delta(t) = \begin{cases} \infty, & t = 0 \\ 0, & t \neq 0 \end{cases}$$

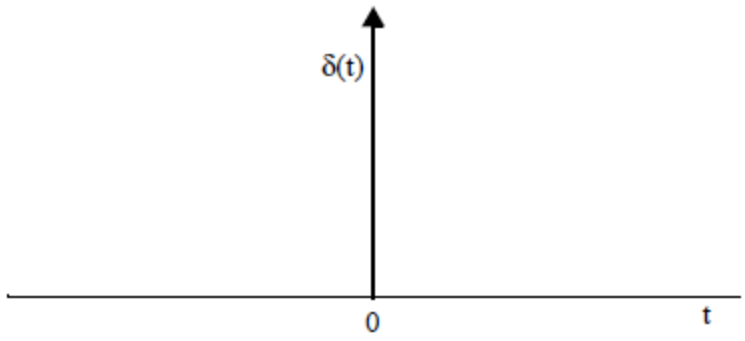

Figure 1. The Dirac Delta Function δ(t)

In time-domain formulas, the Dirac delta function is the unit impulse.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

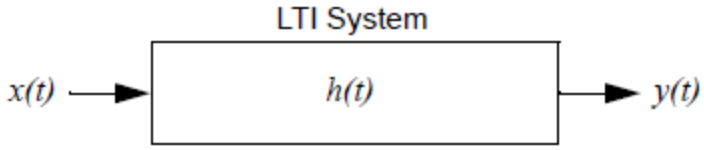

Figure 2. LTI System

For the overall LTI system, the output *y(t)* is the convolution (*) of the input signal *x(t)* and the impulse response *h(t)*:

$$y(t) = x(t)*h(t) = \int_{-\infty}^{\infty} x(\tau)h(t-\tau)d\tau$$

The Ideal Step Response

The step response *u(t)* is the response of the LTI system when the input is a pure step function. The unit step function (*D(t)* in this topic) is the cumulative distribution function (CDF) of the Dirac delta function:

$$D(t) = \begin{cases} 1, & t >= 0 \\ 0, & t < 0 \end{cases}$$

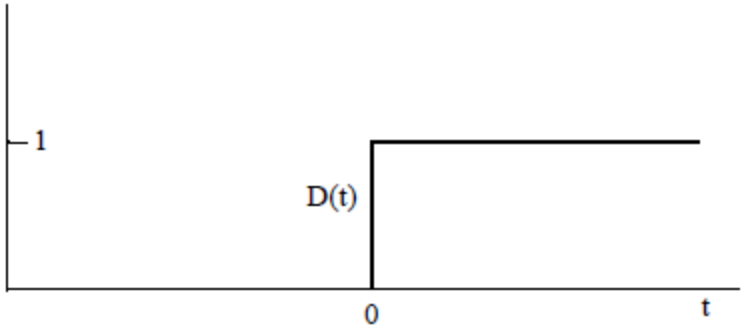

Figure 3. The Step Function D(t)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Edge Response

Physical transmitters cannot produce a pure step function. The input to the channel on the transmitter is not a true step function but an edge function, rising or falling. The edge functions $E_R(t)$ and $E_F(t)$ incorporate the rise time and fall time specified in the eye source. These transition times cannot be zero.

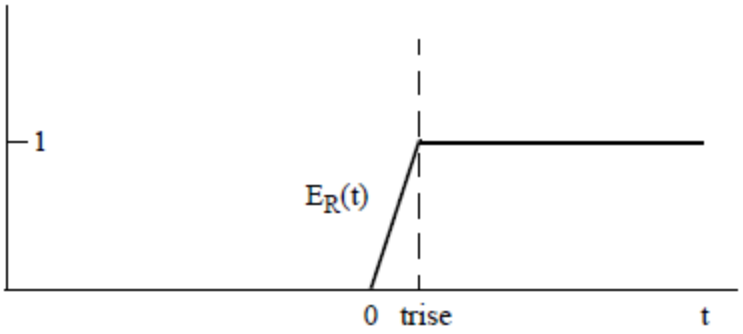

Figure 4. Rising Edge Function $E_R(t)$

By default, the rise and fall times are the same. The eye source can set the rise and fall times to different values.

The edge response *w(t)* is the response of the LTI system when the input is an edge function.

Both QuickEye and VerifEye run transient analysis to calculate the rising and falling edge responses of the channel.

By default, the solver simulates over a time period of 100 UIs to calculate the edge response. The **STEP_RESP_NUM_UI** parameter on the Eye Source sets the number of unit intervals needed to allow the response to reach a steady state (high or low).

Despite the formula differences, the term *step response* is used in the GUI window and in the text of the help topics to represent either the step or edge response.

Figure 5 shows typical rising and falling step responses.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

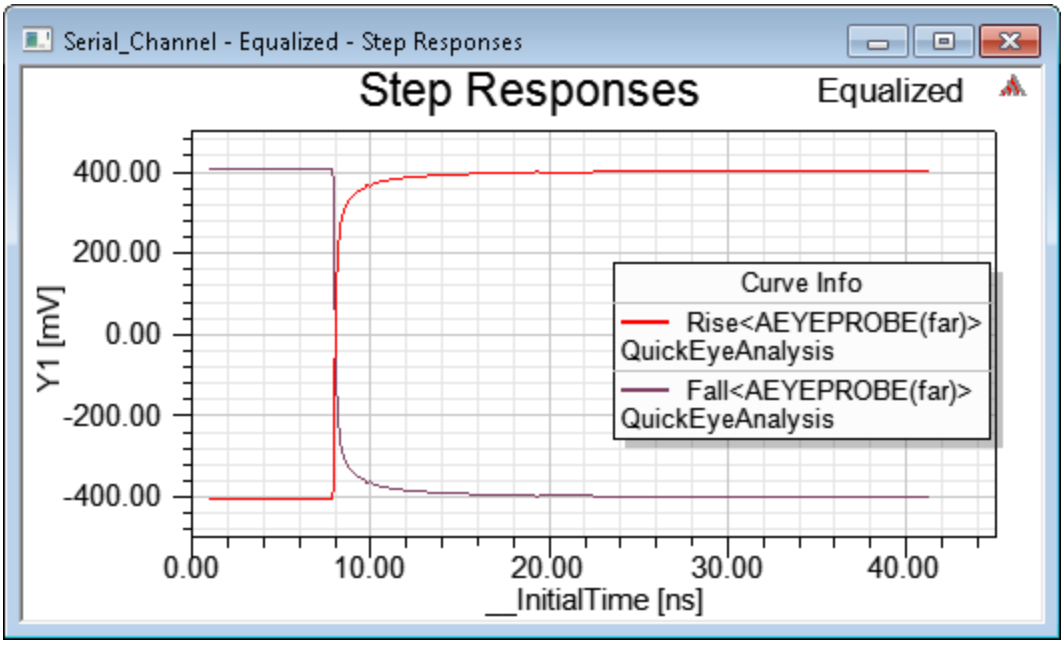

Figure 5. Typical Rising and Falling Step Responses *u(t)* or Edge Responses *w(t)*

QuickEye Technical Notes

Quick Eye analysis employs pattern-dependent convolution. The step responses are simulated with transient analysis for a single rising edge and a single falling edge. The step responses are then combined with the data stream to create an intermediate waveform that approximates the behavior of the fully simulated channel. With QuickEye, inter-symbol interference (ISI) is easy to calculate, but random transmit jitter is more difficult to handle.

QuickEye convolves the step responses for rising and falling edges with the time derivative of the input waveform to calculate the output. Here is a brief derivation.

The output of the LTI channel on the input and the impulse response once more:

$$y(t) = x(t) * h(t)$$

From the assumption of superposition, the impulse response *h(t)* is the time derivative of the step response *u(t).* This allows the following substitution:

$$y(t) = x(t) * \frac{\mathrm{d}}{\mathrm{d}t} u(t)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

We can transform this formula into the complex frequency **s** domain by applying the Laplace transform to both sides:

$$Y(s) = X(s)sU(s)$$

Where *Y(s)* and *X(s)* are the Laplace transforms of *y(t)* and *x(t)*, and *sU(s)* is the Laplace transform of *du(t)/dt*. Rearranging the product terms, to get:

$$Y(s) = sX(s)U(s)$$

Take the inverse Laplace transform of both sides to obtain the formula used by QuickEye:

$$y(t) = \frac{\mathrm{d}}{\mathrm{d}t}x(t)*u(t)$$

This formulation captures the edge-based nature of the calculation, since the derivative *dx(t)/dt* is non-zero only during the transitions.

QuickEye creates an intermediate waveform by applying the rising and falling step responses to the transitions in the input data. Figure 1 shows the intermediate QuickEye waveform for the RC example. Rising edges are solid, falling edges are dashed. Summing these transitions creates the waveform in Figure 2.

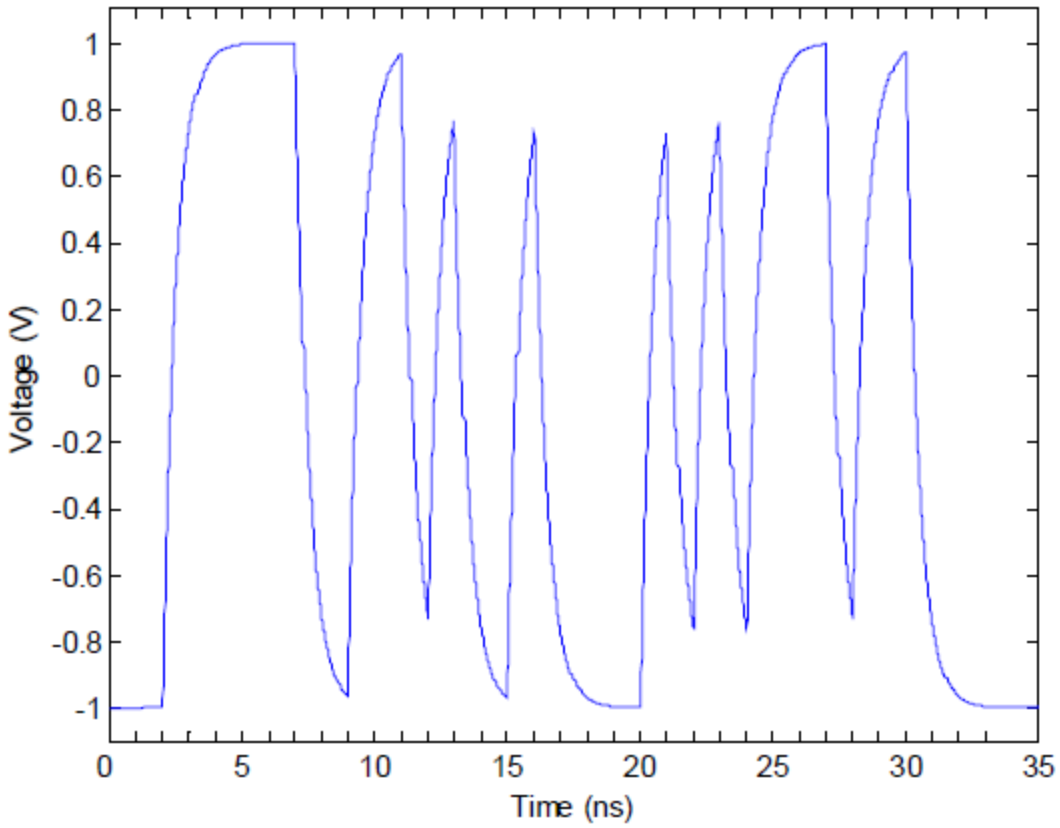

Figure 2: The RC Waveform as Simulated with Transient Analysis

QuickEye overlays the unit intervals on the intermediate waveform to generate the eye diagram. The input bit pattern can be a literal bit list specified in the netlist, a sequence of random bits, a bit pattern read from a file, a pseudo-random selection of bit patterns, or the worst-case bit pattern calculated by peak distortion analysis. (See Eye Source Bit Data and Peak Distortion Analysis).

QuickEye calculates the bit error rate by comparing the data received to the data sent, and counting the number of errors. For a given set of data, the QuickEye convolution algorithm is faster than full transient analysis. Like transient analysis, however, QuickEye requires gigabit run sizes to determine BER values in the 10^{-12} range. This practical limitation is the reason for VerifEye.

VerifEye Technical Notes

VerifEye analysis is a statistical eye-analysis algorithm, similar to the public domain Stat Eye (See QuickEye and VerifEye References for a citation). VerifEye calculates the bit error rate from an analysis of the probability density function for the receiver voltage. VerifEye incorporates

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the effects of intersymbol interference (ISI) by considering how transitions that preceded the current bit could affect the receiver voltage, given the step response.

For example, suppose the current receiver bit is a 1. This can happen in two ways: either the previous bit was a 1, in which case there was no transition, or the previous bit was a 0, in which case there was a low-to-high transition. In the first case, the receiver voltage is very near to V_{HI}, the voltage representing a “1” bit. In the second case, the voltage does not reach V_{HI} due to the slow rise time of the step response at the end of the channel. If the bits are independent, the probability of a transition here is 0.5. Statistically, therefore, the waveform has a 50% chance of having no deviation, and a 50% chance of having a negative deviation.

Chain this process forward and backward, considering each possible transition in turn. However, even if the bits are independent, the transitions are not. A high-to-low transition must be followed by a low-to-high transition and vice versa. VerifEye calculates conditional probabilities including all the possible cases.

The results are probability distribution functions (PDFs) for the voltage value of the rising and falling waveforms. The probability density function $p_V(v)$ gives the probability of obtaining a particular voltage at the receiver at some sample time tau (τ). Figure 1 shows an artificial example.

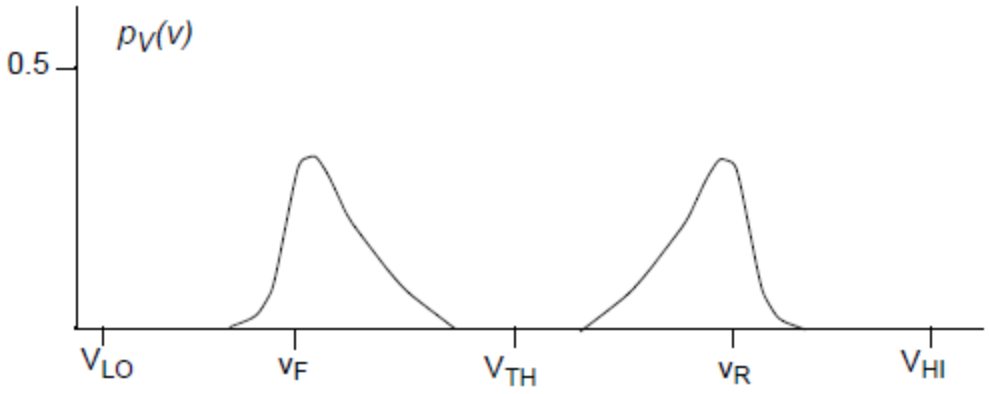

Figure 1. Probability Density Function for Receiver Voltage at Sample Time τ

The distribution of $p_V(v)$ is bimodal. The lobe on the left is the PDF for the falling waveform at the given sample time. The lobe on the right is the PDF for the rising waveform at the sample time.

If the channel are purely lossless, the two lobes is narrow peaks. The preceding figure,shows some spreading of the distributions due to intersymbol interference (ISI), jitter, and other factors that causes the voltage to vary around the ideal values. The effect of ISI is to spread the distribution toward the threshold voltage.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Represent the receiver voltage PDF with formulas. Let B_{TX} be the logic value (0 or 1) of the transmitted bit, and let B_{RX} be the logic value (0 or 1) of the received bit. The left lobe Figure 1 is the PDF of the receiver voltage when the transmitted bit was a 0, or in probability notation:

$$p_V(v)\big|_{B_{TX}=0}$$

The right lobe is the receiver voltage PDF when the transmitted bit was a 1, or:

$$p_V(v)\big|_{B_{TX}=1}$$

Since B_{TX} must be either 0 or 1, the total area under the PDF is unity:

$$p_V(v)\big|_{B_{TX}=0} + p_V(v)\big|_{B_{TX}=1} = 1$$

If the bit values are independent, the two lobes are equal in area.

The bit error rate (BER) depends on the threshold voltage. Let V_{TH} be the threshold voltage that determines whether the receiver bit B_{RX} is a 1 or a 0. The bit error rate at sample time τ is the area under the PDF that is above V_{TH} when the transmitted bit B_{TX} is a 0, plus the area of the PDF that is under V_{TH} when B_{TX} is a 1, all divided by the total area under both lobes. Since the total area under the PDF is unity, the area of the overlapping regions equals the bit error rate.

Consider just the left lobe of the PDF, the voltage lobe when the transmitted bit is a zero. Figure 2 shows a PDF for B_{TX}=0, with a tail that overlaps the threshold (the area of overlap is exaggerated for effect).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

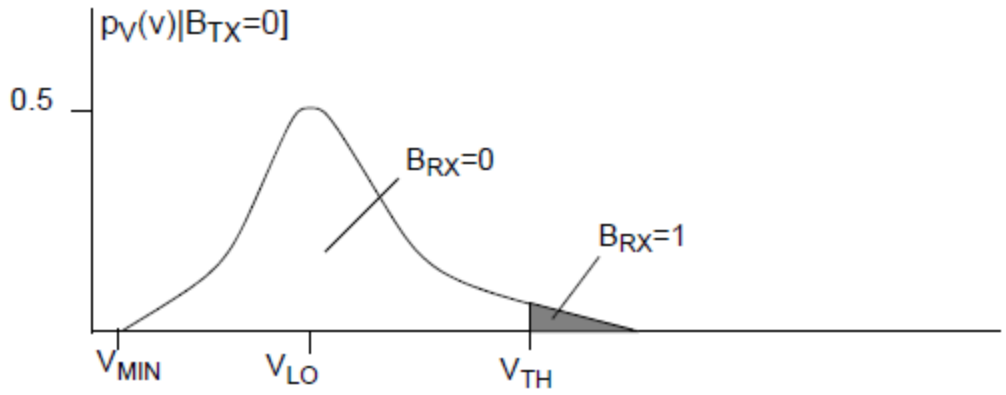

Figure 2. PDF with Bit Error Rate.

The area under the curve that lies under the threshold V_{TH} is the probability that the received bit is correctly received as a 0. The shaded region in Figure 2 represents the probability that the received bit is incorrectly read as a 1 when the transmitted bit is a 0.

The area of the shaded region represents the probability:

$$P\left(B_{RX}=1\Big|_{B_{TX}=0}\right) = P\left(v(\tau)>V_{TH}\Big|_{B_{TX}=0}\right)$$

Where *P()* signifies a simple probability rather than a density function.

If the PDF lobe for B_{TX}=1 also has a tail that falls under the threshold, the area of the error region represents the following probability:

$$P\left(B_{RX}=0\Big|_{B_{TX}=1}\right) = P\left(v(\tau)<V_{TH}\Big|_{B_{TX}=1}\right)$$

The sum of the two probabilities is the bit error rate at the specified threshold voltage V_{TH} and at the specified sample time τ.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$BER_{\tau} = P\left(v(\tau) > V_{TH}\Big|_{B_{TX}=0}\right) + P\left(v(\tau) < V_{TH}\Big|_{B_{TX}=1}\right)$$

When BER_{τ} is plotted over all values of sample time τ from 0 to 1UI, the result is the familiar bathtub curve (Figure 3). Each point on the curve shows the probability that the received bit B_{RX} fails to equal the transmitted bit B_{TX} for some value of the threshold voltage V_{TH}, at sample time τ. In Figure 3, the Y-axis uses logarithmic scaling.

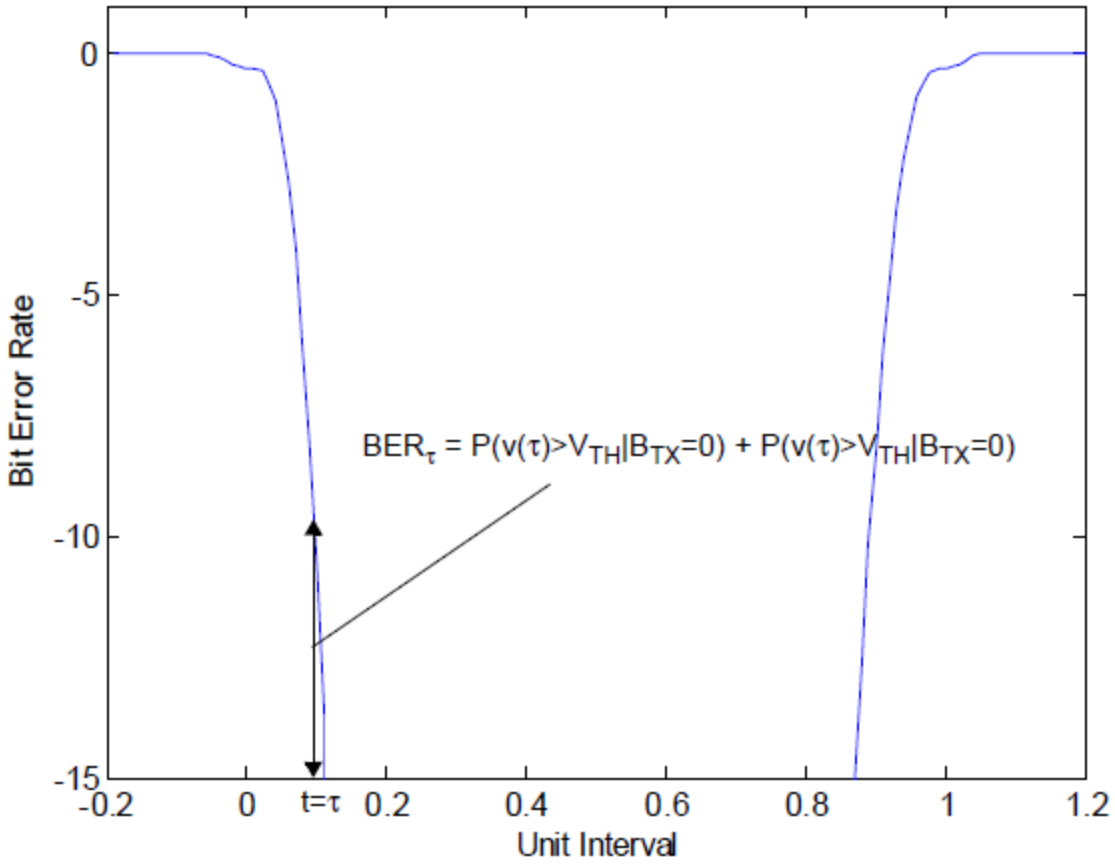

Figure 3. A Bathtub Curve of Bit Error Rate (BER) at Threshold Voltage V_{TH}.

The integral of the BER curve over threshold voltages ($V_{MIN} < V_{TH} < V_{MAX}$) produces the cumulative distribution function (CDF) of the receiver voltage. A plot of the CDF is the 3D bathtub or contour plot.

Feed-Forward Equalization

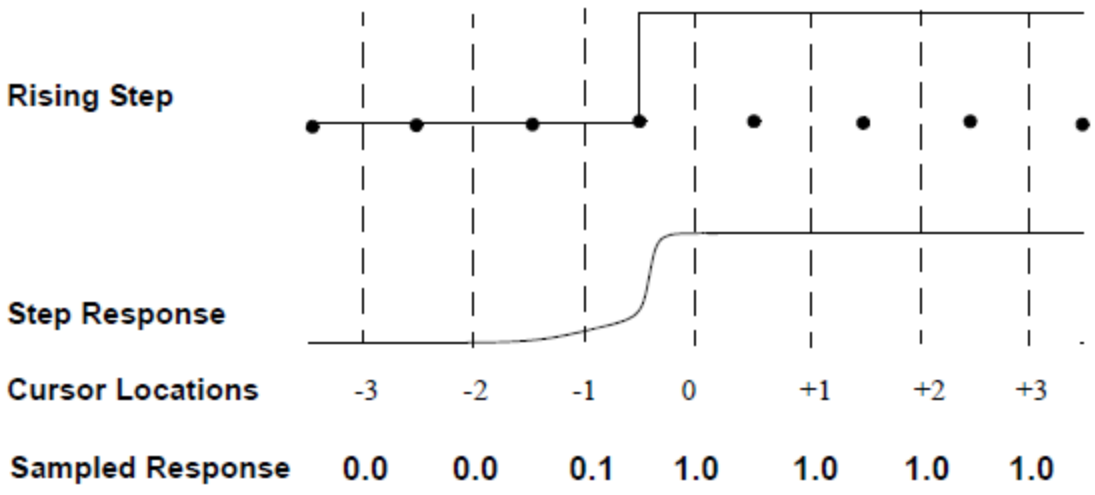
Equalization is one of the principal methods for improving the signal integrity of a channel. Equalization can be applied at the transmitter (Eye Source), the receiver (Eye Probe), or both. The Eye Source provides Feed-Forward Equalization (FFE). The Eye Probe provides Decision-Feedback Equalization (DFE) and Continuous-Time Linear Equalization (CTLE). This topic describes how Nexxim performs driver-side FFE. See Decision Feedback Equalization for details on DFE. See Continuous-Time Linear Equalization for details on CTLE.

Feed-forward equalization (FFE) is an extended form of frequency enhancement. Channels typically attenuate high-frequencies more than low frequencies. FFE adjusts the waveform being injected into the channel to compensate for frequency-dependent losses suffered during propagation.

The basic idea of FFE is to replace a single driver with a series of drivers, each one delayed by a set amount on the previous one. The delay in Nexxim is the unit interval (UI). These drivers are called *taps*. Each tap drives with a given strength, called the *tap weight*. The tap weights are set so as to reduce intersymbol interference (ISI).

Calculating the FFE Tap Weights

The algorithm for automatically calculating the tap weights in QuickEye and VerifEye is the Zero-Forcing Equalizer (ZFE). The ZFE algorithm is invoked when the FFE weights are not given but a non-zero number of taps is specified. The algorithm starts with the response to the channel of a rising step function.



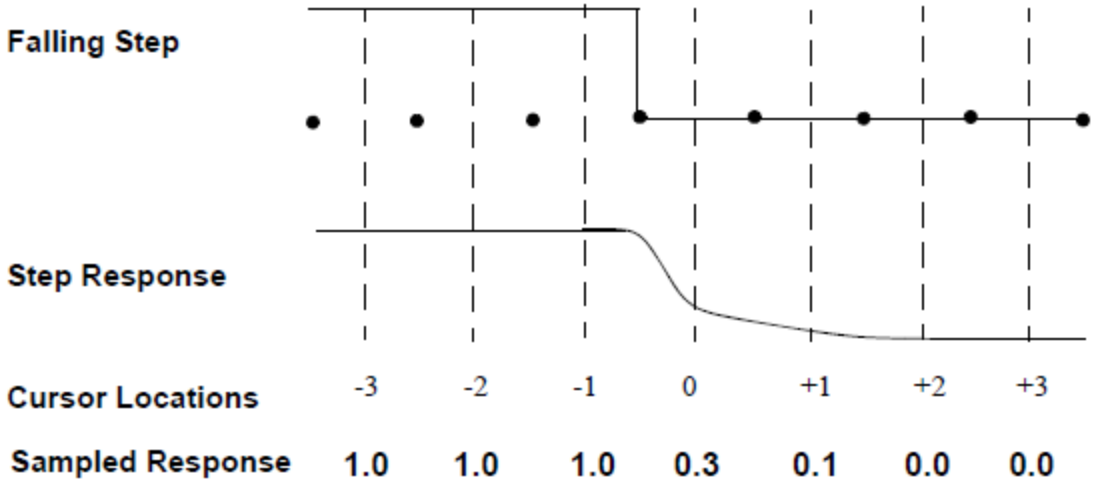
In the preceding figure, the dots on the Rising Step function plot delimit the unit intervals (UIs).

The dotted lines show the time locations of the *cursors* or sample points for the Step Response. The cursors are at the midpoint of each UI in this example. The numbers under the cursor lines

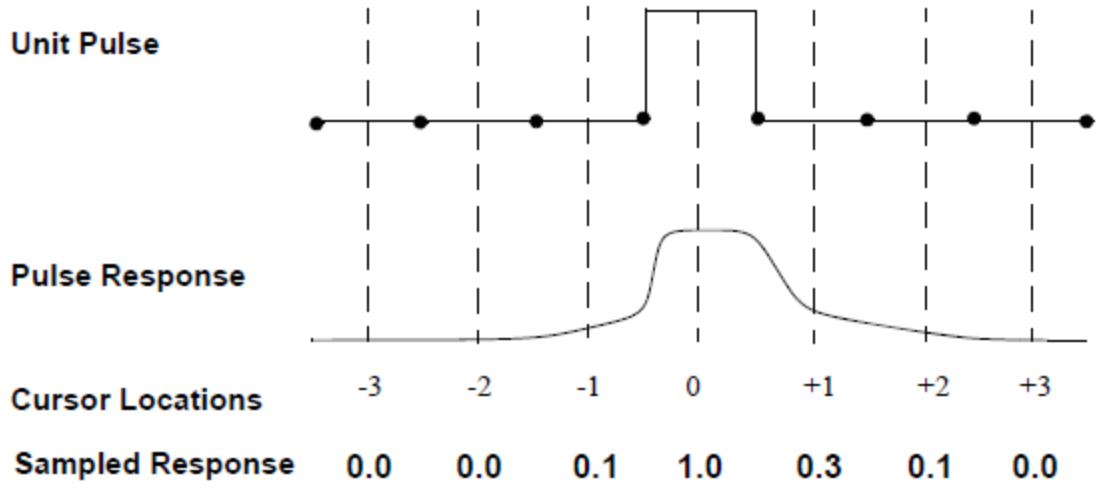
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

are cursor *locations*. Location 0 is the *main cursor*, sampling the response at the center of the pulse. Cursors at locations -1, -2, -3, etc. are *precursors*, sampling the values of bits that occur earlier in time than the main cursor. Cursors at locations +1, +2, +3, etc. are *postcursors*, sampling the values of bits that occur later in time than the main cursor. The lowest line in the preceding figure,shows the value of the sampled step response at each cursor.

Inverting the rising step response produces the falling step response.



Adding the rising step response to the falling step response shifted one UI simulates the response of the channel to a unit pulse.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The goal is to make the total response zero at the time points corresponding to the center of the eye for ISI for a number of cursors in the pulse response equal to the number of FFE taps specified. The FFE setup window lets you specify how many taps to use and which cursor locations to equalize. Each sampled response is replaced by a weighted sum of the neighboring responses.

For example, a three-tap FFE with starting location -1 equalizes the main cursor, one precursor, and one postcursor. The equation for the weighted sum looks something like Equation 1:

$$E_C = w_1 R_{C-1} + w_2 R_C + w_3 R_{C+1}$$

(1)

Where:

E_C is the equalized value of the response at cursor *C*.

w_1, w_2, and w_3 are the weights associated with the three taps.

R_X is the sampled value of the response at the cursor locations *X* = *C-1*, *C*, and *C+1*.

Applying this formula over a number of cursors and setting each weighted sum to the corresponding value in the unit pulse produces a system of equations. Using the pulse response in the preceding figure, here are the equations for a three-tap FFE with one precursor (*C* = -1), the main cursor (*C* = 0) and one postcursor (*C* = +1).

$$E_{-1} = 0.0w_1 + 0.1w_2 + 1.0w_3 = 0$$

(2)

$$E_0 = 0.1w_1 + 1.0w_2 + 0.3w_3 = 1$$

(3)

$$E_1 = 1.0w_1 + 0.3w_2 + 0.1w_3 = 0$$

(4)

The sampled responses are known, and all other cursor values are forced to be zero. Solving for the tap weights yields w_1 = -0.308, w_2 = 1.063, and w_3 = -0.106.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

1. QuickEye and VerifEye normalize the automatically calculated tap weights such that the sum of all weights is 1.0. No calculation is done in this example.
2. The cursor locations in principle extend infinitely in both directions, and always exceed the number of taps. The response of cursors outside the tapped region can limit the accuracy of the tap weight calculations. Nexxim applies an error-minimizing algorithm to correct for this source of error. This calculation is not shown in this example.

Applying the FFE Tap Weights to Generate the Output Voltages

To generate the output, QuickEye and VerifEye apply the tap weights are applied to the step response $V_s(t)$ calculated using the transient analysis engine of the Circuit solver.

Begin with the default operation, no equalization. QuickEye and VerifEye apply the step response to the rising and falling edges in the bit pattern.

Here are some terms to be used in the formulas:

The step response is $V_s(t)$.

The subscript i references the cursor locations where bits are evaluated, $-\infty \le i \le \infty$.

b_i is the value (0 or 1) of the bit at cursor location i.

The step response is applied only at transitions. Function is defined α to be the exclusive-OR of the current bit and its immediate predecessor:

$$\alpha(b_i) = b_i \otimes b_{i-1}$$

Function α is 1 when the bits differ, indicating that a transition has occurred. Function α is 0 for non-transitions.

When the current bit is a one, the transition is a rising edge and the sign of the step response is positive. When the current bit is a zero, the transition is a falling edge and the sign of the step response is negative. Function is defined $\beta(b_i)$ to set the sign of the adjustment based on the bit value (0 or 1) of b_i.

$\beta(0) = -1$, $\beta(1) = +1$

With this notation, the formula for the unequalized output voltage is expressed at time t as follows:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$V_{out}(t) = \sum_{i=-\infty}^{\infty} \alpha(b_i) \cdot \beta(b_i) \cdot V_s(t - i \times UI)$$

(5)

Now add *N* taps of FFE, indexed with variable *j*, which is swept on the Starting Location specified in the GUI, $1 - N \le Start \le 0$, to the Ending Location, $End = Start + N - 1$. The series of tap locations must always include location 0.

The tap weights W_j are the ones calculated earlier.

Using this notation, express the formula for the voltage output adjusted by FFE as follows:

$$V_{FFE}(t) = \sum_{i=-\infty}^{\infty} \sum_{j=Start}^{End} \alpha(b_{i-j}) \cdot \beta(b_{i-j}) \cdot W_j \cdot V[t - (i-j) \times UI]$$

(6)

FFE in the Frequency Domain

Channel attenuation is equivalent to adding a low-pass filter. To compensate, the FFE acts as a high-pass filter in the frequency domain.

The frequency response *H(s)* is the Laplace transform of the time domain pulse response *R(t)*. The frequency response of an N-tap equalized signal $H(s)_{FFE}$ can be calculated on the unequalized frequency response *H(s)*, the tap weights W_j, and the time delays T_j.

$$H_{FFE}(s) = H(s) \cdot \sum_{j=1}^{N} W_j \cdot e^{-j\omega T_j}$$

(7)

The frequency response on the typical FFE is that of a high-pass filter.

FFE Examples

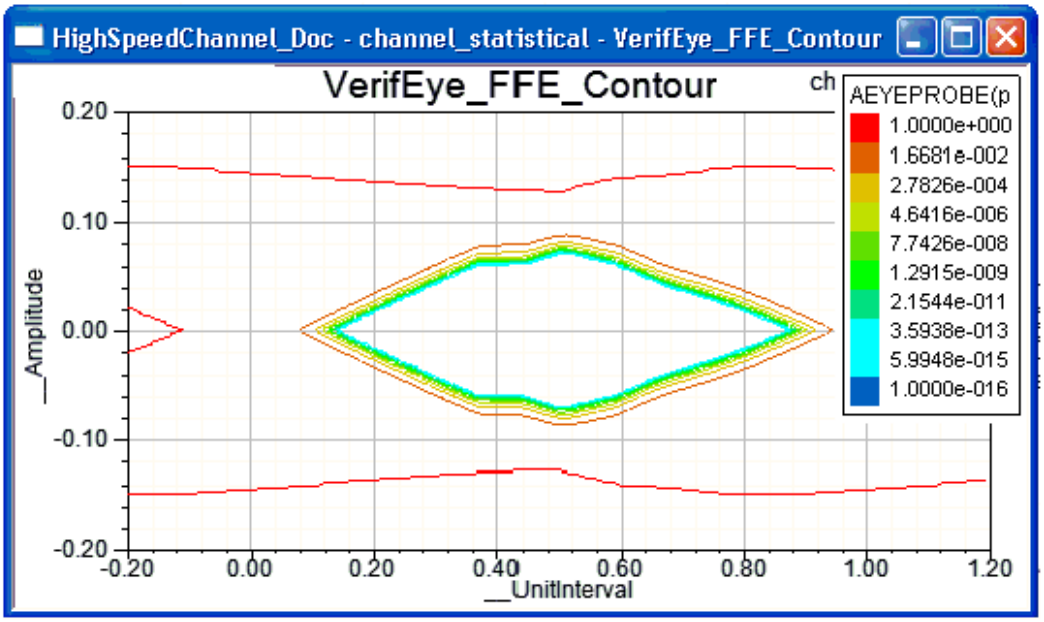

Figure 4. VerifEye analysis of the high-speed channel with 4-tap FFE. The tap coefficients automatically calculated by the Circuit solver are (0.59792, -0.3481, 0.03863, and -0.03355).

Feed-forward equalization is set up in the Eye Source, using the FFE_TAPS, FFE_LOCS, FFE_WEIGHTS, NORMALIZE_FFE_WEIGHTS, and FFE_COMPUTE_PROBE parameters.

Decision-Feedback Equalization

Decision-Feedback Equalization (DFE) is set up in the Eye Probe. Receiver DFE corrects for inter-symbol interference (ISI) from previous bits on the interpretation of the current bit.

Eye Probe parameters specify values for logic 1, logic 0, and the default threshold voltage. The decision-feedback equalizer applies the threshold to determine the logic value (0 or 1) of each incoming bit. The DFE keeps the results of the decision on the state of previous bits, and applies a set of tap weights to compensate for ISI at rising and falling transitions.

As in FFE, the number of DFE taps determines the number of unit intervals over which equalization is to operate. The DFE knows what the transmitted voltage level of a 0 or 1 should be. For each decoded bit, the DFE can calculate the deviation of each received bit voltage on the ideal voltage. The DFE weights are applied to compensate for the deviations. In a classical DFE, the sum of the tap weights multiplied by the corresponding bit errors is added to the received voltage of the current bit before it is sent to the decoder. Instead, the Circuit solver applies the sum of the weighted tap values to the threshold voltage.

The DFE weights can be automatically calculated using an algorithm similar to the algorithm used for FFE. Alternatively, supply the DFE weights directly. No normalization is applied to the DFE weights in either case.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Formula for DFE Output

While the FFE taps work toward canceling ISI both before the UI (precursors) and after the UI (post-cursors), DFE taps are limited to canceling post-cursors, because of the need to make a decision on a bit before its effect can be dealt with.

Like FFE, DFE is applied only at transitions (rising and falling edges). Using the notation introduced earlier for FFE, function α is 1 for transitions and 0 for non-transitions, while function β is +1 for rising edges and -1 for falling edges. DFE tap locations start at location 0, the current bit. The formula for the output voltage with *M* taps of DFE is as follows.

$$V_{DFE}(t) = \sum_{i=-\infty}^{\infty} \sum_{j=0}^{M} \alpha(b_{i-j}) \cdot \beta(b_{i-j}) \cdot W_j$$

(8)

DFE Examples

Figure 1 shows the Quick Eye analysis of the same high-speed serial channel shown in Figure 8, but with 4 taps of DFE. The abrupt edges are produced when the DFE adjusts the decision threshold.

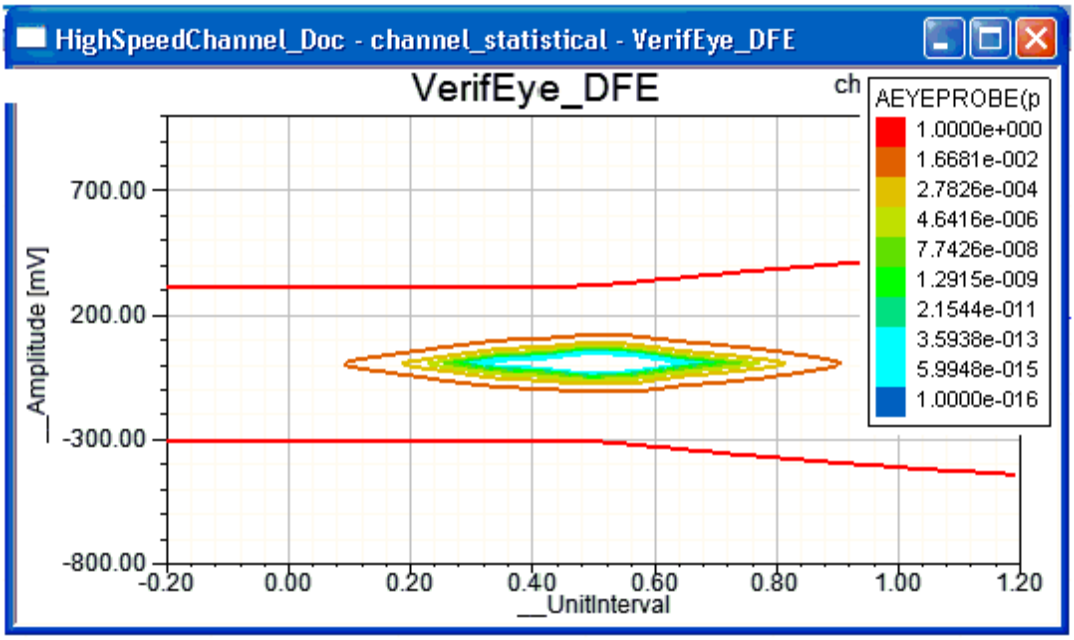
Weights automatically calculated for DFE by the Circuit solver are (0.10439, 0.05148, 0.03139, and 0.02215)

Figure 2 shows the VerifEye analysis of the same high-speed serial channel shown in Figure 10, but with 4 taps of DFE.



Weights automatically calculated for DFE by the Circuit solver are (0.10439, 0.05148, 0.03139, and 0.02215)

Decision-feedback equalization is set up in the Eye Probe, using the DFE_TAPS, DFE_LOCS, DFE_WEIGHTS (or DFE_WEIGHT_LBS and DFE_WEIGHT_UBS), DECISION_HIGH, DECISION_LOW, and DECISION_THRESHOLD parameters.

Decision-Feedback Equalization with PAM4

When PAM4 modulation is used, the eye diagram report shows three eyes, bounded by the four voltage levels. DFE can be applied to all three eyes in PAM4 transmissions, using a vector of three voltage thresholds to control the decision portion of the algorithm.

Continuous Time Linear Equalization

Communication channels typically attenuate the high-frequency components of the signal more than the low-frequency components. High-frequency roll-off degrades rise and fall times. Continuous-Time Linear Equalization (CTLE) compensates for this loss by inserting a high-pass filter at the receiver.

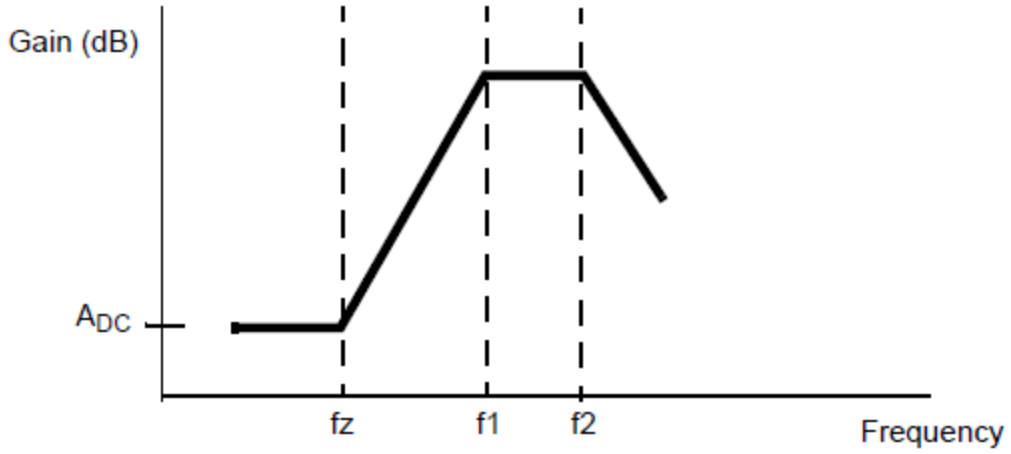
Nexxim offers four ways to specify the CTLE transfer function:

1. By specifying one or two poles and, optionally, one zero and the DC gain of the high-pass filter.
2. By specifying the tabulated values of the frequency-dependent transfer function directly with a data file.
3. By specifying any number of poles and zeros, the range of DC gain values, and the high-frequency gain, representing a generic rational function.
4. By specifying the coefficients of the numerator and denominator of a polynomial representing a generic rational function.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

CTLE Data Parameters

The default, "legacy" implementation uses a first- or second-order filter model, depending on whether one or two poles (respectively) are specified. To enable CTLE, the user gives the linear frequency corresponding to the first pole (*f1*). Optionally, the user can supply a linear frequency corresponding to the second pole (*f2*), a zero frequency for the response curve, and a list of allowable DC *Gain* values. The first pole frequency *f1* typically is the lower bound of the high passband. The optional second pole frequency *f2* typically is the upper bound. The optional zero frequency *fz* typically is the beginning of the upslope in the response curve. Here is a simplified diagram:



The Circuit solver varies the *Gain* to find the optimum equalization (maximum eye height) for the channel. The list of gain values can contain one value or several (-infinity dB to 0 dB). If no list of *Gain* values is supplied, the Circuit solver calculates the optimum CTLE gain between the corresponding linear values, from 0 (equivalent to -infinity dB) to 1 (equivalent to 0 dB). For the legacy transfer function formulas, there are only two poles and one zero. Let:

$$\omega_1 = 2\pi f_1$$

$$\omega_2 = 2\pi f_2$$

$$\omega_z = 2\pi f_z$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$A_{DC} = 10^{(DCGain/20)}$$

The legacy transfer function with one pole frequency is:

$$H(s) = \frac{s + \omega_1 \cdot A_{DC}}{(s + \omega_1)}$$

(1)

The legacy transfer function with two poles but no zero is:

$$H(s) = \omega_2 \cdot \frac{s + \omega_1 \cdot A_{DC}}{(s + \omega_1) \cdot (s + \omega_2)}$$

(2)

The legacy transfer function with two poles and a zero is:

$$H(s) = \frac{\omega_1 \cdot \omega_2}{\omega_z} \cdot \frac{A_{DC} \cdot (s + \omega_z)}{(s + \omega_1) \cdot (s + \omega_2)}$$

(3)

CTLE Transfer Function from a File

Alternatively, define the CTLE transfer function over a appropriate range of frequencies, then put the tabulated data in a file. The format of the CTLE data file is described later in this topic.

Nexxim reads the data on the file specified by the **file** parameter in the Eye probe, and fits a rational function to the data. The **reltol** option allows you to specify the fitting error. The resulting rational function is applied in the simulation (QuickEye, VerifEye, Transient, or LNA).

The transfer function with a rational function has the following form. Let:

P = Number of poles Z = Number of zeros, Z < P $\omega_p = 2\pi f_p$ $\omega_z = 2\pi f_z$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$H(s) = \frac{\prod_{j=1}^{Z} (s + \omega_{z_j})}{\prod_{i=1}^{P} (s + \omega_{p_i})}$$

(4)

A rational function generally provides the best fit to CTLE data: the CTLE transfer function data may represent a lumped RC implementation with known poles and/or zeros. If the data is from a rational function originally, a pure rational function finds the poles and zeros exactly.

The data file can contain multiple transfer functions for the same set of frequencies, controlled by the Eye probe **tf_num** parameter. Transfer functions in the file are numbered from 1 to N. By default (**tf_num** =0), Nexxim tries each transfer function in turn, finally using the one that produces the maximum eye height. Setting parameter **tf_num** to an integer from 1 to N directs Nexxim to use only that one transfer function in the analysis. If the **tf_num** is less than zero or greater than the number of transfer functions in the file, an error occurs.

Here is a summary of the format for the CTLE transfer function data. The format is similar to the Touchstone 2.0 file format.

- The file must be in text format, and the file name must have a **.ctle** extension.
- A comment is any text after an exclamation point (!). Whitespace and blank lines are ignored.
- A line beginning with **[Complex format]***may* be included to specify the data format. Options are **RI** (Real/Imaginary) and **MA** (Magnitude/Angle in degrees). If no **[Complex format]** line is present in the file, **RI** is the default interpretation. All transfer functions in a given file must use the same data format (**RI or MA**).
- A line beginning with **[Number of frequencies]** must be present to specify the number of frequency points in the file.
- A line beginning with **[Number of transfer functions]** must be present to specify the number of transfer functions given for each frequency point in the file.
- A line with **[Data]** alone introduces the lines of data.
- Each line of data has the frequency in Hz as the first entry. The frequencies must be in ascending sequence, but do not need to be evenly spaced. There must be no repeated frequencies (same convention as Touchstone 2.0).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- After each frequency, the transfer function values appear, separated by commas, tabs, or spaces. For Real/Imaginary and Magnitude/Angle data formats, each transfer function uses two entries.

> **Note:**
>
> To guarantee that high frequencies remain unique after rounding, use high precision (e.g., for frequencies in the 10GHz range, a precision of 10 digits is recommended).
>
> For Magnitude/Angle data, angles are in *degrees* (as in Touchstone 2.0).

Here is an example:

```

Specifying a Generic Equalizer Transfer Function, Pole-Zero Format

A generic equalizer transfer function can be specified using either the pole-zero format or the polynomial format.

With the pole-zero format, you specify the poles and zero frequencies for the generic equalizer rational function, as well as the allowable DC Gain values and a value for the high-frequency peak gain (maximum amplitude of the high-pass filter). As with the legacy CTLE, Nexxim varies the DC Gain to find the value that gives the maximum eye height given the other parameters.

P = Number of poles Z = Number of zeros, Z < P $\omega_p = 2\pi f_p$ $\omega_z = 2\pi f_z$

$$A_{DC} = 10^{(DCGain/20)} \quad A_{AC} = 10^{(ACGain/20)}$$

Case 1: The data includes one or more zero frequencies, Z>0. The rational function for this case has the form:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$H(s) = A_{DC}\left[\frac{\prod_{j=1}^{Z}(s+\omega_{z_j})}{\prod_{i=1}^{P}(s+\omega_{p_i})}\right]$$

(5)

When P=2 and Z=1, Equation (5) reduces to the legacy case of Equation (3). This case generalizes the legacy formulation of Equation (3) from P=2 and Z=1 to any P>1 and any Z<P. This allows Nexxim to match industry-standard CTLE specifications such as VESA.

Case 2: The data does not have any zero frequencies explicitly specified, Z=0. The rational function has the form:

$$H(s) = A_{AC}\cdot\prod_{i=2}^{P}\omega_{p_i}\cdot\left[\frac{s+\frac{A_{DC}}{A_{AC}}\cdot\omega_{p_1}}{\prod_{i=1}^{P}(s+\omega_{p_i})}\right]$$

(6)

When P=2, Z=0, and A_{AC}=1, Equation (6) reduces to the legacy case of Equation (2). This case generalizes the legacy formulation of Equation (2) from P=2, Z=0, and A_{AC}=1 to any P>1 and any A_{AC}<1. This allows Nexxim to match industry-standard CTLE specifications such as USB3.1 Gen2.

Note that at DC (s=0, A_{AC}=1), $H(s) = A_{DC}$ as expected.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Specifying a Generic Equalizer Transfer Function, Polynomial Format

A generic equalizer transfer function can be specified using either the pole-zero format or the polynomial format. Standards such as MIPI use a polynomial format for the transfer function. Use the GUI entry fields to enter the coefficients for the numerator and denominator of the function.

For a polynomial with N+1 degrees in the numerator (coefficients a_0, a_1, ... $a_{N)}$, and M+1 degrees in the denominator (coefficients b_0, b_1, ... b_M), M >= N, the transfer function is:

$$H(s) = \frac{\sum_{i=0}^{N} a_i s^i}{\sum_{j=0}^{M} b_j s^j}$$

Transmit Jitter in QuickEye and VerifEye

Transmit jitter is variation in the location of edges. QuickEye and VerifEye can add the effects of transmit jitter, in combinations of Random (Gaussian), Uniform, Periodic, and Custom (user-defined) jitter.

QuickEye Jitter Calculation

QuickEye employs a Monte-Carlo method: each transition is displaced a random amount on the nominal time using a probability distribution that combines all specified Gaussian, Uniform, Periodic, and Custom jitter distributions. The Monte Carlo approach requires significant simulation time, since there is a different set of jittered transitions for each bit in the original stream.

VerifEye Jitter Calculation

The VerifEye method involves calculating the probability distribution function (PDF) for receiver voltage. VerifEye calculates a second probability distribution function that combines all specified Random (RJ), Uniform (UJ), Periodic (PJ), and Custom (user-defined, CJ) jitter distributions. The total jitter PDF (p_{TJ}) is the convolution of the individual PDFs:

$$p_{TJ}(tj) = p_{RJ}(rj) * p_{UJ}(uj) * p_{PJ}(pj) * p_{CJ}(cj)$$

VerifEye translates the total jitter probability distribution function to the corresponding voltage PDF at each sample time. The voltage PDF has the same distribution as the jitter PDF. The mean of the voltage PDF is offset on the mean of the jitter distribution (always 0) by the value of

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the rising or falling step response. The width of the voltage PDF is the width of the jitter PDF scaled by the rate of change of the response at the sample time.

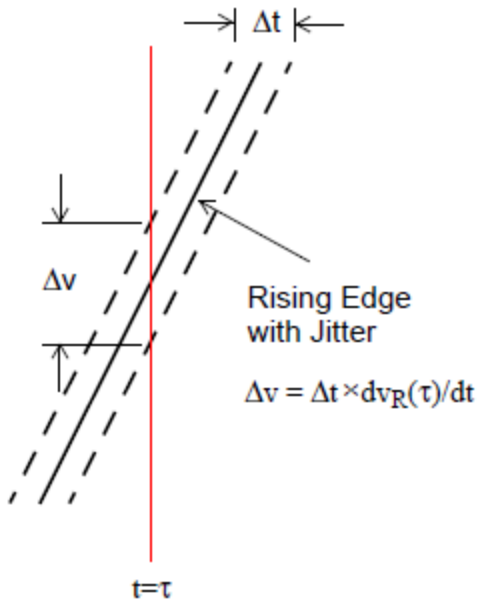

Figure 1. Transmit Jitter PDF Translated to Voltage PDF.

Figure 1 diagrams an arbitrary segment of a rising waveform, sampled at time τ. The dotted lines indicate the maximum displacement of the waveform on the time axis due to transmit jitter, Δt. The exact shape of the jitter distribution is not shown. The corresponding spread in the voltage PDF due to jitter is shown as Δv. The slope of the rising wave at sample time τ is:

$$\frac{d}{dt}v_R(\tau)$$

The spread in the voltage PDF due to the spread in the jitter PDF is:

$$\Delta v = \Delta t \times \frac{d}{dt}v_R(\tau)$$

The next topics provide details on the PDFs for random (Gaussian), uniform, periodic, and custom (user-defined) transmit jitter.

Random Transmit Jitter

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Gaussian probability distribution function for variable *x* with mean μ and standard deviation σ is:

$$\frac{1}{\sqrt{2\pi\sigma^2}} e^{\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)}$$

For QuickEye and VerifEye, the variable is the time value of the random jitter (*t*), the mean μ is zero, and the standard deviation σ is set to Eye Source entry TXRJ. The resulting PDF for random jitter is:

$$p_{RJ}(rj) = \frac{e^{-(rj^2/2\times TXRJ^2)}}{\sqrt{2\pi\times TXRJ^2}}$$

This PDF has the familiar normal curve, as shown in Figure 2:

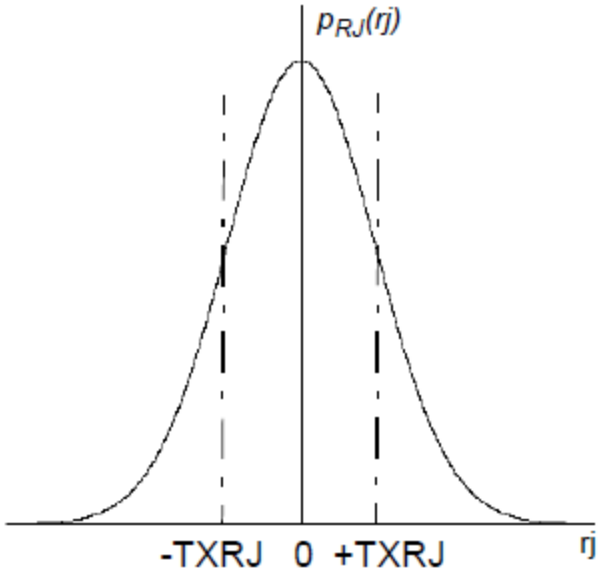

Figure 2. Random Jitter PDF.

Uniform Transmit Jitter

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Uniform random jitter represents a distribution of offsets in time on the nominal edge location. The uniform distribution is centered on time *uj*=0 with bounds -0.5*TXUJ to +0.5*TXUJ, where TXUJ is the entry on the Eye Source (Figure 3).

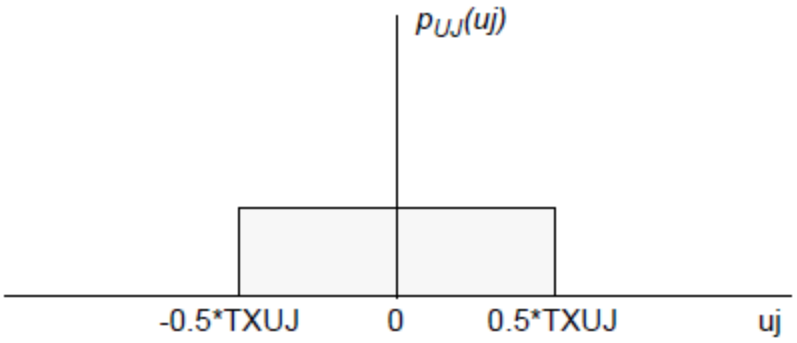

Figure 3. Uniform Jitter PDF.

Uniform jitter is not common by itself, but can be used in combination with the other jitter distributions to more closely match measured values.

Periodic Transmit Jitter

Periodic jitter simulates the effect of variations in voltage such as those produced by sinusoidal noise. The periodic variation in voltage translates into a periodic variation in the location of the edges of the signals generated.

In the QuickEye and VerifEye implementation of periodic jitter, the frequency of the periodicity is ignored. The noise frequency is assumed to be uncorrelated to the clock frequency, and the phase of the periodic noise is basically a uniform random variable. The noise voltage is the sine of this variable, giving the following probability distribution (TXPJ is the Eye Source entry):

$$p_{PJ}(pj) = \frac{1}{\pi\sqrt{1-\left(\frac{pj}{TXPJ}\right)^2}}$$

for |*pj*| < TXPJ, zero otherwise.

Figure 4 shows the shape of the periodic jitter PDF. This probability distribution has peaks at |*pj*| = TXPJ, and is sometimes approximated as a bimodal or dual-Dirac distribution (but not by QuickEye or VerifEye).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

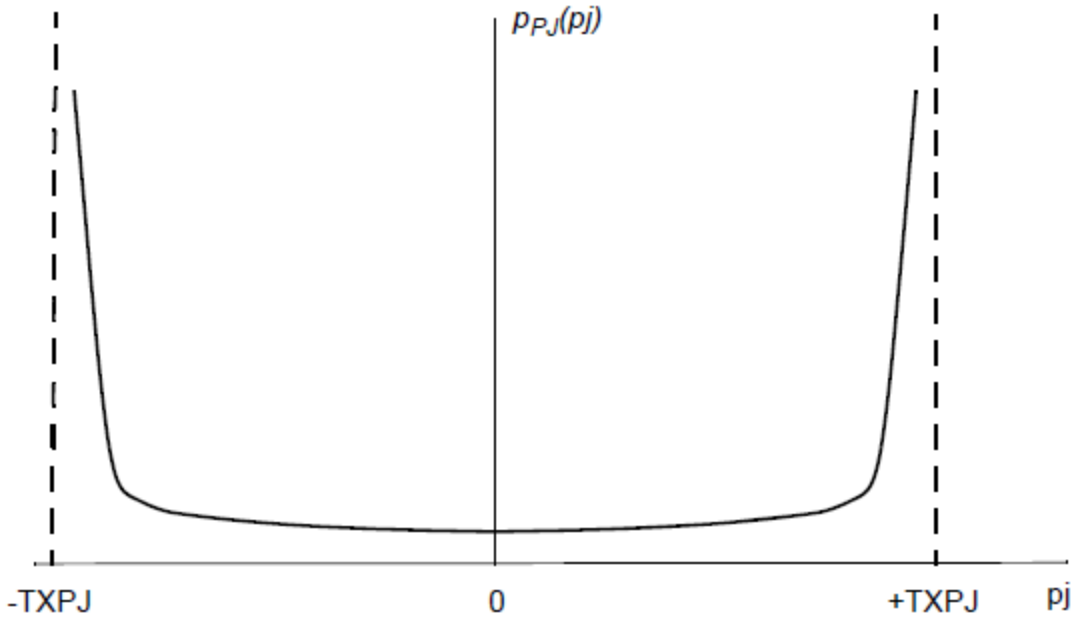

Figure 4. Periodic Jitter PDF

Custom or User-Defined Transmit Jitter

The user can specify a probability density function (PDF) for transmit jitter, to be combined with any other forms of jitter specified in the Eye source for both QuickEye and VerifEye. The PDF data is read on the file indicated by the **TXCJ** parameter on the Eye source.

The data in the jitter file are in two columns. The first column is the time in seconds. The time values may be positive or negative, and need not be centered around t=0. The Circuit solver automatically centers the mean value of the data at t=0 before doing the jitter calculation. The second column is the PDF value for each time. The PDF values must be greater than or equal to zero.

The Circuit solver automatically scales the PDF data such that the area underneath is unity, so no manual scaling is required.

The Circuit solver performs linear interpolation between the data points. Best results are obtained when the number of data points is large enough to minimize discontinuities of slope. The time axis should extend far enough to allow the PDF to drop to negligible values at both ends.

Duty Cycle Distortion

Duty cycle distortion or DCD is a systematic variation in the duty cycle of the transmitter clock, the proportion of time that the clock is high. By default, the duty cycle is 50% (upper waveform in

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 1). The DCD parameter on the Eye source specifies the duty cycle distortion as a fraction of the unit interval (UI). The transmitted bits can be numbered from 1 to N; bit numbers 1, 3, 5, etc. are odd bit positions, numbers 2, 4, 6, etc, are even bit positions. (Note that the odd and even positions do not in general correspond to particular bit values (0 or 1), except when the signal is a pure clock.)

For both QuickEye and VerifEye, the Circuit solver reads the DCD parameter (DCD as a fraction of the UI) or the DCD_TIME parameter (DCD as an absolute time in seconds.) A DCD_TIME parameter value is converted to DCD as a fraction of the UI. The solver computes the offset value (0.5×DCD×UI). The offset value is then subtracted from all even bit positions and added to all odd bit positions (lower waveform in Figure 1).

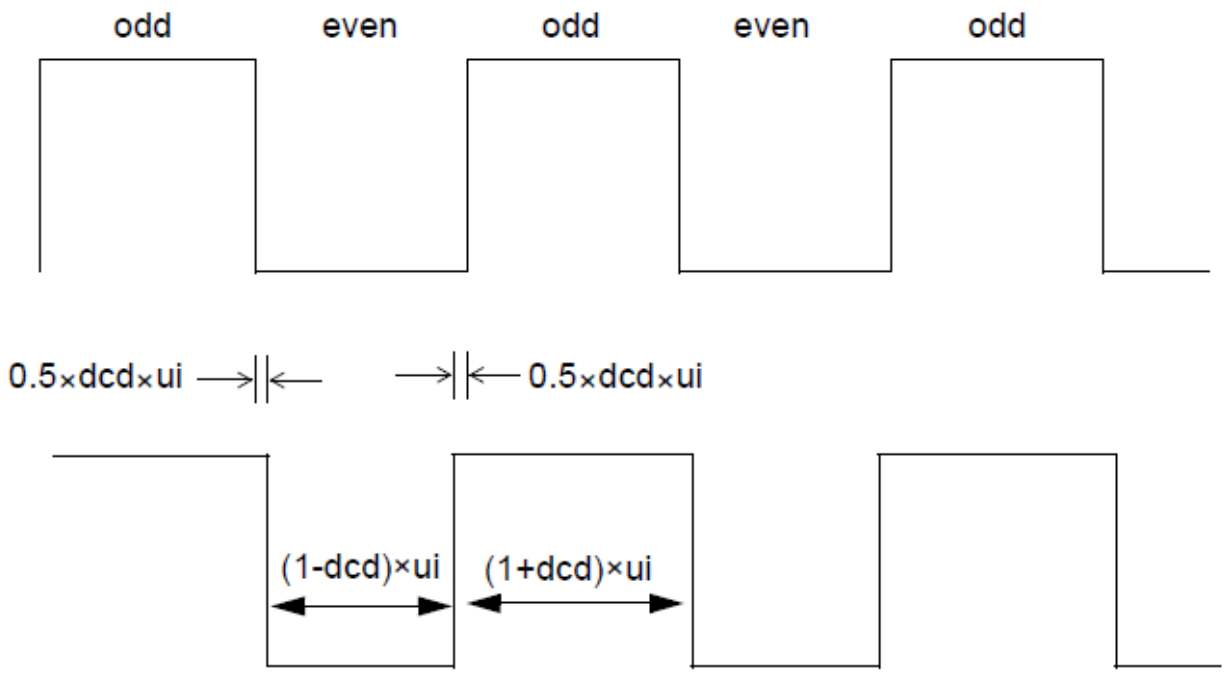

Figure 1. Clock Waveforms. The Lower Trace shows Duty Cycle Distortion.

Peak Distortion Analysis

Peak distortion analysis (PDA) calculates the worst case bit pattern on the step responses of the channel, for both VerifEye and Quick Eye analyses. Peak distortion analysis is calculated for each combination of Eye Source and Eye Probe.

For Quick Eye analyses, the worst case bit patterns can be pushed to all Eye Sources and repeated by setting the **PD_COUNT** parameter in the Quick Eye analysis setup. When the PDA data is enabled, any bit patterns set in the Eye Sources are ignored. Figure 1 shows an example

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

of the eye diagram from Quick Eye resulting from one iteration of the worst-case bits (no repeats).

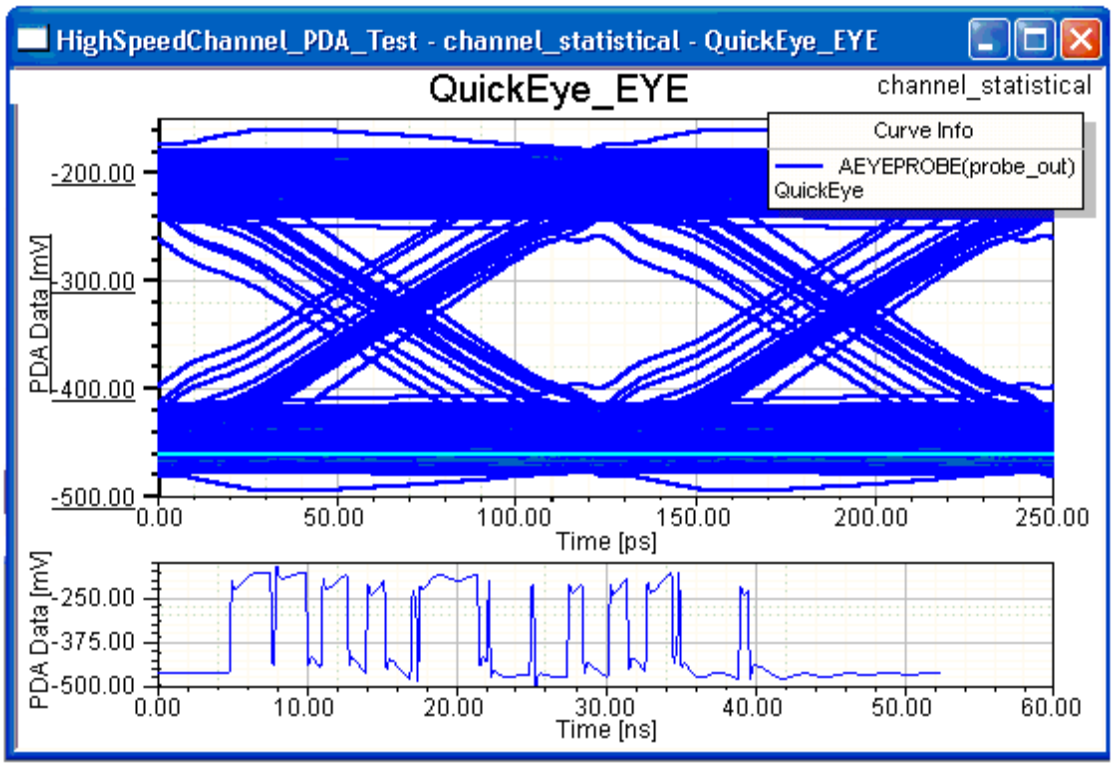

Figure 1. QuickEye Result using Worst-Case Bit Pattern from Peak Distortion Analysis

For both QuickEye and VerifEye analyses, the Peak Distortion domain data (bit list, error contribution) can be reported as a standard 2D plot or in a data table. Figures 2 and 3 show the 2D plot and data table for the bit pattern above. The data table shows just a portion of the data.

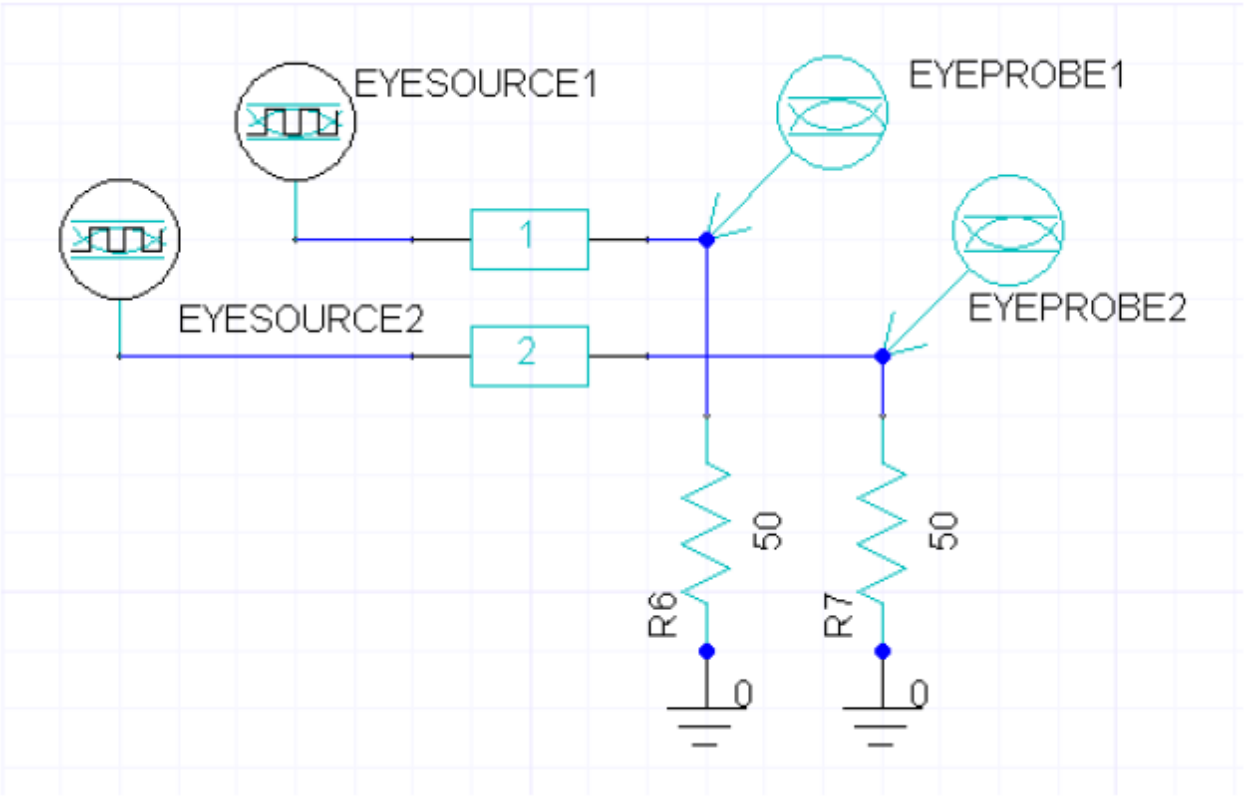
Figure 3. Data Table for Worst-Case Bit Pattern from Peak Distortion Analysis

NOTE: Peak Distortion Analysis (PDA) considers any 8b10b or 64b66b encoding when generating the worst-case bit pattern.

The PROBE parameter in the PDA setup determines the target for worst-case analysis. Here is a reference diagram:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



When PD_COUNT=-1, PDA calculates the worst-case bit pattern for EYESOURCE1 to EYEPROBE1 and from EYESOURCE2 to EYEPROBE2, but no bits are sent.

When PD_COUNT=0 or greater, the target PROBE must be specified. If PROBE=EYEPROBE1 in the example above, PDA calculates the worst case bit patterns from EYESOURCE1 and EYESOURCE2 to EYEPROBE1, and those bit patterns are sent to the analysis.

Encoding 8b10b 64b66b 128b130b 128b132b

8b10b, 64b66b, 128b130b, and 128b132b encoding are common methods for reducing errors caused by long strings of 1s with embedded isolated 0s, and long strings of 0s with embedded isolated 1s. By default, no encoding is performed (Eye Source option **do_encoding** =0). The VerifEye, QuickEye, AMI, or Transient Source can be enabled to do encoding on the transmitted data (**do_encoding** =1 for 8b10b, 2 for 64b66b, 3 for 128b130b, and 4 for 128b132b).

Notes:

1. Option **do_encoding** is valid only when **modulation=NRZ** on the Eye Source. **do_encoding** is ignored when **modulation=PAM4**.
2. Peak Distortion Analysis (PDA) considers the encoding when generating the worst-case bit pattern.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Eye Source Bit Data

The Eye source can generate bit data for both QuickEye and transient analyses, using one of four methods.

- The source can link to a file that contains the data, using the BITFILE parameter. See QuickEye Bit Files for further information.
- The source can contain the sequence of 0 and 1 bits, using the BITLIST parameter. See QuickEye Bit Lists for further information.
- The source can generate a sequence of random bits, controlled by the RANDOM_BIT_COUNT and RANDOM_SEED parameters. See QuickEye Random Bit Data for further information.
- The source can generate a pseudorandom sequence of bit patterns, controlled by the PRBS_NO, PRBS_COUNT, PRBS_SEED, and PRBS_INVERT parameters. See "QuickEye Pseudorandom Bit Data" on page 26-323 for further information.

If both the BITFILE and the BITLIST parameters are set, the BITFILE is used.

Any of these bit sources can be repeated using the REPEAT_COUNT parameter. The default is one time through the list (REPEAT_COUNT=0).

- The bit stream can be the worst-case pattern from Peak Distortion Analysis (PDA). When the PD_COUNT parameter is set to 1 or higher in the Quick Eye analysis setup, the Eye Source uses the worst-case bit pattern with REPEAT_COUNT set to (PD_COUNT). See Peak Distortion Analysis for further information.

QuickEye Bit Files

The BITFILE parameter on the Eye Source contains the path to the file containing the test bits. The bit file for QuickEye can be a simple text file (**.txt** extension) containing a list of 0s and 1s without separators.

A QuickEye bit file can also use a Coded Bit Pattern (**.cbp** extension). A coded bit pattern file has two entries on each line: a *tag* and the number of *repeats*. The *tag* entry specifies the type of bit pattern to generate:

Tag	Bit Representation
Zero	0
One	1
Lonely_0	101
Lonely_1	010

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Tag	Bit Representation
Random	Random 0s and 1s

The *repeats* entry tells how many instances of the given bit representation to generate. A line beginning with an exclamation point is a comment.

Here is an example of a Coded Bit Pattern file:

```
! example coded bit pattern file
zero 10
random 100
one 1
zero 42
lonely_1 3
```

QuickEye Bit Lists

The BITLIST parameter on the Eye Source specifies the sequence of 0s and 1s without separators. The bit list is preceded in the netlist by a pound sign (**#**) to indicate that it is binary data.

QuickEye Random Bit Data

The RANDOM_BIT_COUNT parameter on the Eye Source specifies the number of random bits to generate.

The RANDOM_SEED parameter controls the repeatability and uniqueness of the random sequence. The default RANDOM_SEED is 1000.

Repeatability. A positive RANDOM_SEED value generates the same sequence of random bits on every simulation.

Uniqueness. When two or more Eye Sources use the same positive RANDOM_SEED value, the random bit sequences is the same for all such sources, and each source generates the same sequence of bits on every run.

Negative values of RANDOM_SEED guarantee uniqueness among multiple random bit sources, with or without repeatability.

- Multiple sources with RANDOM_SEED set to **-1** receive unique seeds 1000, 1001, ... 1000+(N-1), and these seeds stay the same on every simulation. (The order in which multiple sources receive seeds is indeterminate, but is the same on every simulation.)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Multiple sources with RANDOM_SEED set to **-2** receive unique seeds derived on the system clock, and these seeds is different on every simulation.

QuickEye Pseudorandom Bit Data

Setting the PRBS_NO parameter to an integer value between 2 and 31 specifies the length of the pseudorandom bit patterns. The Circuit solver randomly selects from bit pattens of the given length to generate the total number of bits requested.

The PRBS_BITLENGTH parameter specifies the total number of bits to be generated. The default is $(2^{PRBS_NO} - 1)$.

The PRBS_SEED parameter controls the starting value for the pseudorandom bit sequence. The default is 0 (zero).

The PRBS_INVERT parameter, when set to 1, inverts the bit values as they are generated. The default is 0 (no inversion).

QE and VE Crosstalk Analysis

For crosstalk analysis, the design incorporates multiple combinations of Eye Sources and Eye Probes. The typical crosstalk situation has one victim channel (the one whose integrity is being assessed) and one or more aggressor channels creating the crosstalk. Each channel has an Eye Source on the transmit end and an Eye Probe at the receive end; these two components link to each other via parameters. (A channel may have multiple Eye Probes, but only the probe at the receiver should be linked to the source.) To make the analysis meaningful, the design should use coupled transmission lines.

The basic idea of crosstalk analysis is to run the victim channel alone to obtain the victim's eye diagram with no crosstalk. Then run both the victim and the aggressor channels, compute the victim's eye diagram again, and compare the two eyes to assess the effect of the crosstalk.

Quick Eye and VerifEye treat correlation differently, affecting the treatment of crosstalk.

QuickEye is similar to transient in the way it deals with correlation. The algorithm inherently takes into consideration the time behavior at the output due to each source given by the step response. When convolving the step responses from various sources, the factors that contribute to correlation (bit sequence, phase delays, bps/UI) are taken into consideration.

By default, the VerifEye statistical methodology computes correlated crosstalk, but uncorrelated crosstalk can also be computed.

Uncorrelated Crosstalk

If the two lines (i.e., the victim and the aggressor channels) have the same UI, the crosstalk pulse occurs in the same place in each bit time. QE shows the pulse, but VE does not. However, if the two UIs differ, the crosstalk pulse is out of phase with the intended signal, and its effect

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

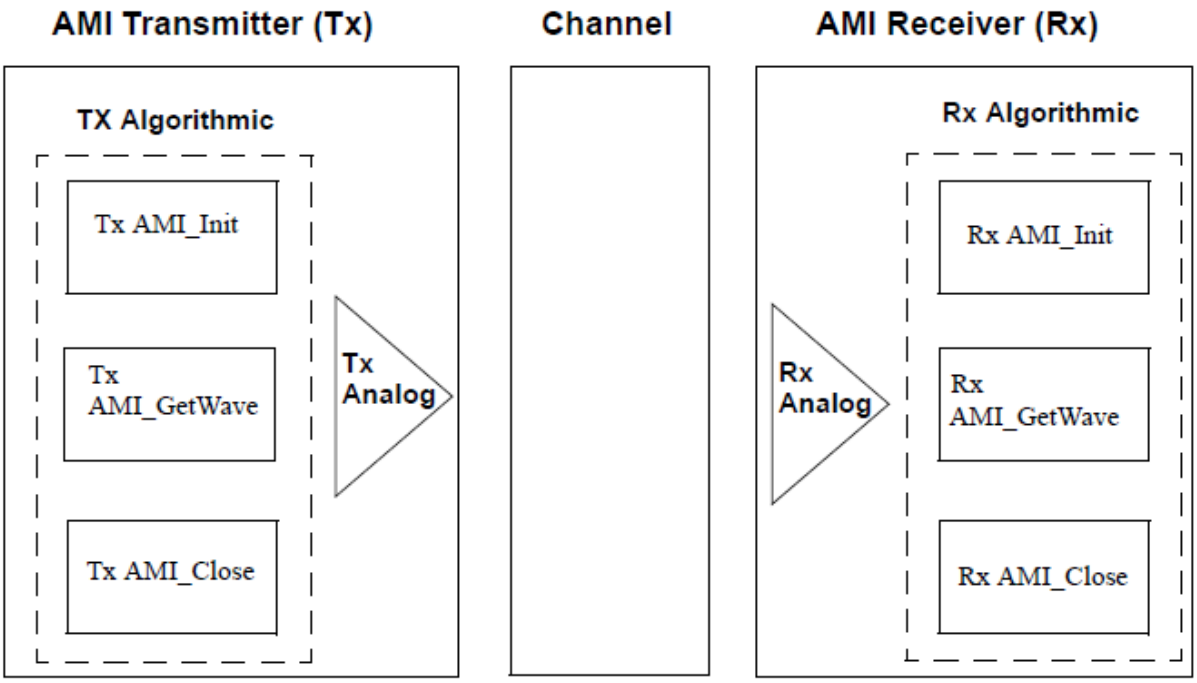
shows up equally at any location in the eye. This circumstance is “uncorrelated crosstalk". To compute uncorrelated crosstalk, uncheck the **Calculated correlated crosstalk** box in the **VerifEye (Statistical Eye) Analysis** window, or set the solver option **eye.verifeye_correlated_crosstalk** to zero. Refer to "Set Up the VerifEye Analysis" on page 12-57 and "VerifEye and Quick Eye Analysis Options Reference" on page 26-182.

AMI Analysis Technical Notes

The IBIS Algorithmic Modeling Interface simulates user-specified transmitter and receiver models, furnished as C-interface compiled libraries, over a linear channel. The AMI Specification is published in the IBIS Specification (See AMI Analysis References).

AMI Analysis Components

Here is a diagram showing the internal structure of the AMI transmitter and receiver.



The following topics describe the options for the AMI transmitter, the Channel Impulse Response, and the AMI Receiver.

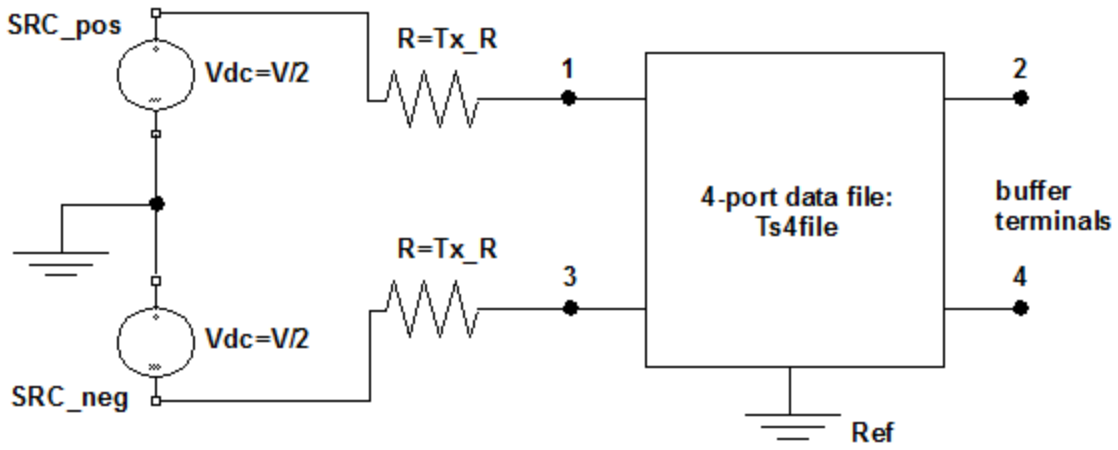
The AMI Transmitter Model

The AMI transmitter consists of an Analog output model and three Algorithmic processing functions, Tx **AMI_Init**, Tx **AMI_GetWave**, and Tx **AMI_Close** that model equalization behavior

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

and are provided in a .dll or .so. The IBIS specification allows the transmitter to omit the TX **AMI_GetWave** function.

The Analog output model can be specified using traditional IBIS methods (including linearized I/V tables and voltage ramps), or with 4-port frequency-dependent data from a Touchstone-format file containing the transmitter behavior.



When the transmitter model uses 4-port data, the reserved parameters **Ts4file** (name of Touchstone file), **TX_V** (transmitter voltage swing), and **Tx_R** (series resistances) control the transmitter operation.

- The voltages of the voltage sources correspond to **V=Tx_V** for logic level 1 and **V=-Tx_V** for logic level 0.
- The series resistors have resistance **R=Tx_R**.

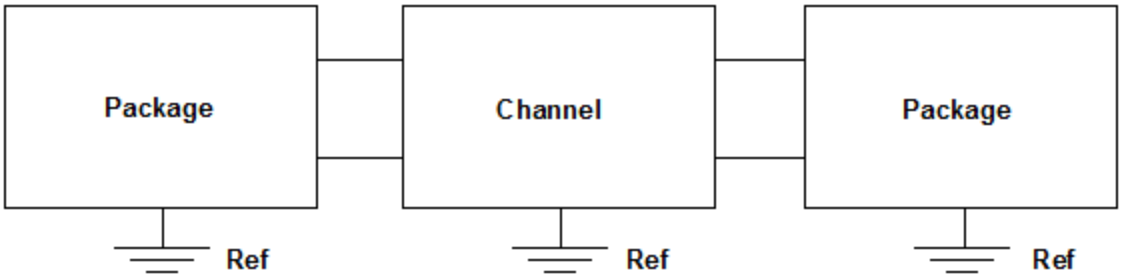
See "AMI Ts4 Analog Buffer Model Parameters " on page 12-150"AMI Ts4 Analog Buffer Model Parameters " on page 12-150 for details on these parameters.

The Channel Impulse Response

AMI Analysis assumes a linear channel. The channel is characterized by its impulse response function.

When 4-port Touchstone files are referenced for the AMI transmitter and receiver, the channel is assumed to include the package behavior in the impulse response:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

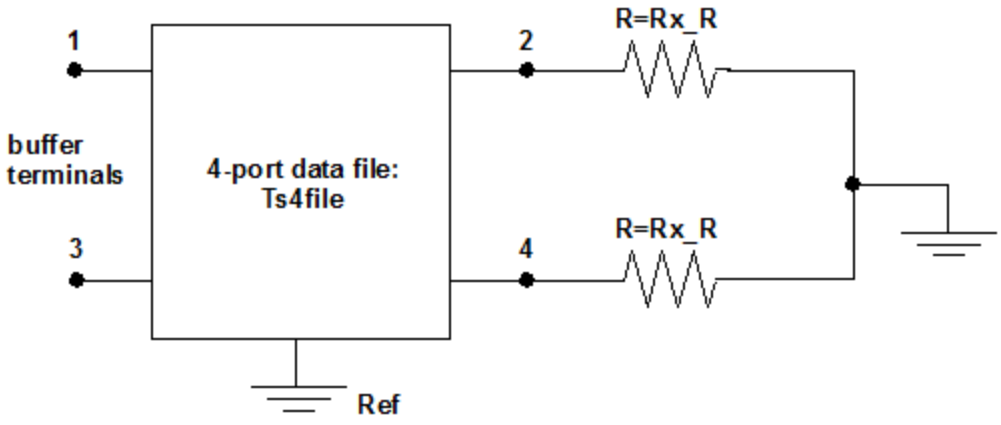


The AMI Receiver Model

The AMI receiver consists of an Analog input model and three Algorithmic processing functions that model equalization behavior and are provided in a .dll or .so: Rx **AMI_Init**, Rx **AMI_GetWave**, and Rx **AMI_Close**. The IBIS specification allows the receiver to omit the Rx **AMI_GetWave** function, unless it is part of an AMI retimer link (See AMI Repeaters).

The RX **AMI_GetWave** function in the receiver model can generate clock times internally, and return the clock ticks as parameters to the solver for post-processing. For AMI channel simulation, the results of clock tick sampling can be observed in the Statistical Eye Plot for the EyeAfterProbe quantity. For an AMI Retimer link, the clock times are used to generate a new digital waveform (See AMI Repeaters).

The Analog Receiver model can be specified using traditional IBIS methods or with 4-port frequency-dependent data from a Touchstone-format file containing the receiver behavior.



When the receiver model uses 4-port data, the reserved parameters **Ts4file** (name of Touchstone file), and **Rx_R** (terminating resistances) control the Receiver analog section

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

operation. The terminating resistors have resistance **R=Rx_R**. See "AMI Ts4 Analog Buffer Model Parameters " on page 12-150 for details on these parameters.

AMI Time Domain Simulation

Ansys supports both Time Domain and Statistical types of AMI simulation as described in the IBIS specification. In **Electronics Desktop**, AMI Time Domain simulation is called AMI Analysis which models signal propagation through a transmitter, interconnect, and receiver. The AMI transmitter generates a waveform representing a stream of bit values and sends the waveform through the transmitter model to the channel. The wave on the transmitter is convolved with the impulse response of the channel to generate the input to the receiver.

AMI analysis is more resource intense than AMI Statistical simulation, which is called VerifEye Analysis in **Electronics Desktop**. VerifEye depends solely on statistical analysis based on impulse responses (IR) modified by the AMI models, which allows them to only return linear approximations. In contrast, AMI analysis allows AMI models to provide nonlinear, time varying algorithms that allow for more flexible simulations.

AMI Time Domain Simulation Phases

AMI Analysis proceeds in three phases: Initialization, Data Generation, and Close. The transmitter (Tx) and receiver (Rx) models must contain the functions **AMI_Init()** and **AMI_Close()**. The transmitter and receiver models may contain **AMI_GetWave()** functions. Each of these functions is called during the appropriate phase.

At Initialization, the files are opened and checked for the presence or absence of the Tx **AMI_GetWave()** and Rx **AMI_GetWave()** functions. The simulator calls the **AMI_Init()** functions to compute the impulse responses (IRs). The **AMI_Init()** functions are only called during the Initialization phase. The Intermediate and Final IRs are not used during AMI simulation if the Tx and Rx **AMI_GetWave()** functions exists, respectively.

The presence of the **AMI_GetWave()** functions determines the sequence of events during the Data Generation phase. If the AMI Tx or Rx model contains an **AMI_GetWave()** function, the **AMI_GetWave()** function processes the waveform. When no Tx **AMI_Getwave()** function is supplied, the simulator convolves the initial waveform with the Intermediate IR. The simulator then calls the Rx **AMI_GetWave()** function to equalize the effects of the channel on the modified waveform and determine the final waveform ($WAVE_{rxout}$). Because the transmitter has no **AMI_Getwave()** function, the simulator uses deconvolution to determine any effects on the transmitter. The simulator uses these effects to create a pseudo-GetWave function which is then applied to the initial waveform to determine what comes out of the transmitter. The receiver's input is independent on the results of the pseudo-GetWave function.

All AMI analyses produce the same overall sequence of waveforms, all of which may be displayed as reports:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The **Initial Wave**: The Piecewise Linear waveform generated by the bit source in the AMI transmitter and passed into the AMI transmitter algorithmic model ($WAVE_{txin}$ in the diagram).
- The **Wave After Transmitter**: The waveform that is output on the AMI transmitter model ($WAVE_{txout}$).
- The **Wave After Channel**: The waveform output by the channel and passed into the AMI receiver model ($WAVE_{rxin}$).
- The **Wave After Probe**: The waveform output by the AMI receiver model ($WAVE_{rxout}$).

Eye diagrams can be created for each of these 4 steps. See AMI Analysis for details.

AMI GetWave Functions

In a typical AMI analysis, the application provides an **AMI_GetWave()** function in both transmitter and receiver models. A detailed description follows of what happens when both, one, or neither **AMI_GetWave()** function is provided. See the IBIS Specification for more information on the cases where one or both of these functions are not present. (See AMI Analysis References.)

At Initialization:

The simulator opens the files and notes whether there are Tx **AMI_GetWave()** and Rx **AMI_GetWave()** functions.

The simulator computes the initial impulse response (IR) of the main channel. This includes the Tx's analog output, the channel, and the Rx's analog front end. Signals are sampled using a constant timestep, which is set in the UI. The simulator also computes the IRs of any aggressor channels. At the end of this phase, the simulator has the Initial IR, Intermediate IR returned by the Tx **AMI_Init()**, and Final IR returned by the Rx **AMI_Init()**.

> **Note:** When the Tx and Rx **AMI_GetWave()** functions exist, they modify the waveform to account for their effects, and the Intermediate and Final IRs are not used in the simulation. They are stored for post-processing.

During Data Generation:

The simulator processes each block of transmit data in this order:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. The AMI Source generates a user-specified sequence of bits using one of several methods.
2. The AMI transmitter converts the stream of bits into a Piecewise Linear (PWL) waveform. The PWL waveform includes any transmit jitter specified in the AMI Source. This Initial Wave, $WAVE_{txin}$, is the input to the AMI transmitter.
3. If there is a Tx **AMI_Getwave()** function:
    a. The simulator calls Tx **AMI_GetWave()** to modify $WAVE_{txin}$ and create $WAVE_{txout}$, the Wave After Transmitter.
    b. The simulator convolves $WAVE_{txout}$ with the Initial IR to create $WAVE_{rxin}$. Contributions from aggressors are added linearly.
4. If there is no Tx **AMI_GetWave()** function:
    a. The simulator creates $WAVE_{txout}$ using information extracted on the Intermediate IR:
        1. The Intermediate IR is deconvolved with the Initial IR to determine what effects a waveform experiences on the transmitter.
        2. The simulator uses the deconvolution results to create a pseudo-GetWave function for the transmitter.
        3. This pseudo-GetWave function is applied to $WAVE_{txin}$ to simulate $WAVE_{txout}$.
    b. The simulator convolves $WAVE_{txin}$ with the Intermediate IR to create $WAVE_{rxin}$. Contributions from aggressors are added linearly.

    > **Note:** $WAVE_{txout}$ is not involved in creating $WAVE_{rxin}$.

5. If there is a Rx **AMI_Getwave()** function, $WAVE_{rxin}$ is passed to the receiver model's **AMI_Getwave()** function to create $WAVE_{rxout}$.
6. If there is no Rx **AMI_Getwave()** function and:
    a. There is no Tx **AMI_GetWave()** and there are no crosstalk aggressors, the Final IR contains the combined effects of the entire system. The simulator convolves $WAVE_{txin}$ with the Final IR to produce $WAVE_{rxout}$.
    b. There is a Tx **AMI_GetWave()** and/or crosstalk contributions must be accumulated in the $WAVE_{rxin}$, then deconvolution is required. The simulator creates $WAVE_{rxout}$ using information extracted on the Final IR:
        1. The Final IR is deconvolved with the Intermediate IR to determine what effects a waveform experiences on the receiver.
        2. The simulator uses the deconvolution results to create a pseudo-GetWave function for the receiver.
        3. This pseudo-GetWave function is applied to $WAVE_{rxin}$ to simulate $WAVE_{rxout}$.
7. The simulator saves clock times that receiver model internally generates for post-processing.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. The data for each block on the receiver model's **AMI_GetWave()** function are formatted for post-processing.

At the Close:

Once all the blocks have been processed, the Circuit simulator calls the **AMI_Close()** functions in the transmitter and receiver models to close files and release memory.

AMI Statistical Simulation

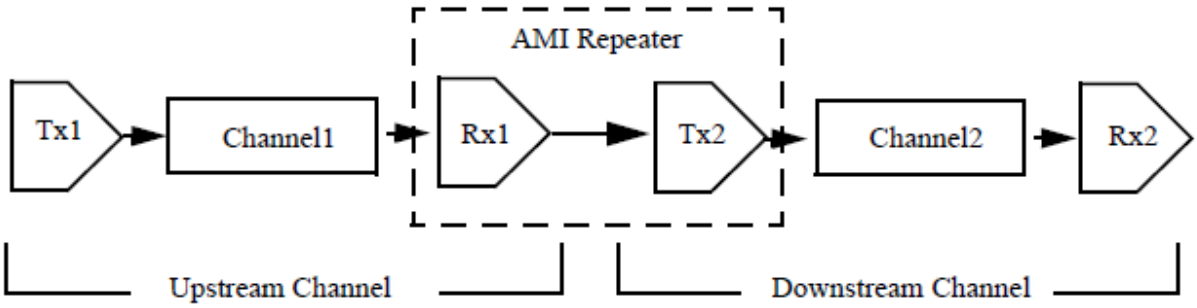
AMI statistical simulation calculates the impulse responses at various points in the channel. In **Electronics Desktop**, AMI statistical simulation is performed using the VerifEye simulator.

In AMI statistical simulation, the solver performs the following sequence:

1. Reads the IBIS model file and the AMI parameters file.
2. Calls the AMI_Init functions in the transmitter and receiver, and generates an impulse response which combines the channel impulse response with any filtering steps present in the AMI_Init functions.
3. Generates the impulse response at three stages: Initial (before any AMI_Init functions are applied), Intermediate, (after the transmitter AMI_Init is applied) and Final (after both AMI_Init functions are applied).

AMI Repeaters

A repeater is a device placed in the middle of a channel to compensate for loss. An AMI repeater model consists of a Receiver (Rx) model on one AMI channel setup and a Transmitter (Tx) model on a second channel setup. The pins on the Rx and Tx are paired to define the repeater. The repeater compensates for channel loss, reducing the bit error rate of the system.



In the preceding figure, the upstream channel of the repeater consists of:

- The upstream Transmitter model, both algorithmic and analog portions (Tx1).
- The physical channel (Channel1).
- The upstream Receiver model, both algorithmic and analog portions (Rx1).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A single impulse response characterizes the incoming (upstream) analog channel of the repeater, which includes the upstream Tx analog model, the physical channel, and the upstream Rx analog model.

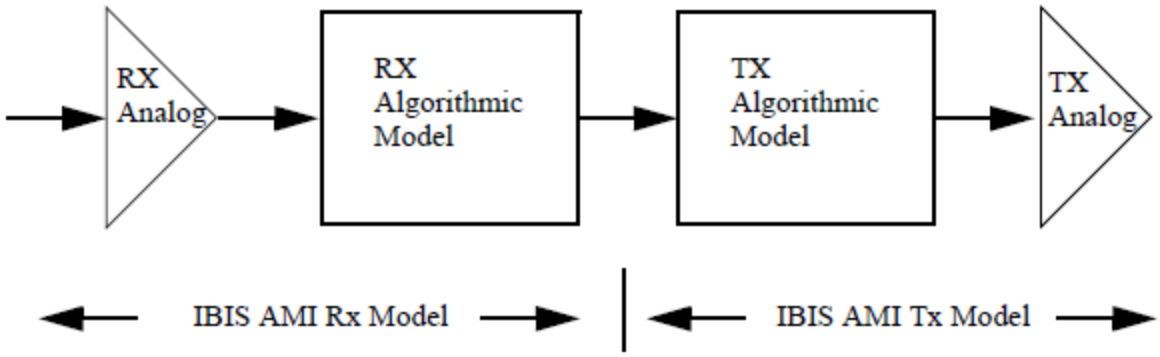
In the preceding figure, the downstream channel of the repeater consists of:

- The downstream Transmitter model, both algorithmic and analog portions (Tx2).
- The physical channel (Channel2).
- The upstream Receiver model, both algorithmic and analog portions (Rx2).

A second impulse response characterizes the outgoing (downstream) channel, including the downstream Tx analog model, the physical channel, and the downstream Rx analog model.

A repeater model is specified in a single IBIS library (.ibs) file that includes both the input and output models. The .ibs file identifies the pins on the Rx and Tx that are paired to define the repeater. See AMI Repeater Properties for information on setting the AMI Repeater properties.

Here are some details about the AMI repeater components:



The signal flow in a repeater model is from Rx Analog to Rx algorithmic to Tx algorithmic to Tx Analog.

The Rx and Tx algorithmic models represent equalizers, clock data recovery (CDR) circuits, or pre-emphasis inside the devices.

The analog part of the Rx model represents the input termination at the device input. Looking on the Rx analog portion, the Rx algorithmic block is assumed to have an infinite input impedance. The analog part of the Tx model represents the output impedance at the device output. Looking on the Tx analog portion, the Tx algorithmic block is assumed to have the output characteristics of an ideal voltage source. In AMI repeater simulations, both Rx and Tx analog models are assumed linear and time-invariant.

A Repeater can be either a Redriver or a Retimer.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

AMI Redrivers

A redriver equalizes the upstream channel and retransmits it to the downstream channel. The output signal is continuously driven by the input signal and no retiming is performed when the redriver retransmits the signal. The redriver Rx passes its equalized output waveform directly to the Tx half of the repeater. The redriver boosts the signal, improving the quality of the signal at the link and at the output of the final receiver.

In a redriver, both algorithmic models can also implement the AMI_GetWave function.

See also:

AMI Retimers

AMI Time Domain Simulation with AMI Redriver or Retimer

AMI Statistical Simulation with AMI Redriver or Retimer

AMI Retimers

A retimer contains both a CDR and a generator for clock times in its AMI_GetWave function. The retimer CDR uses the clock times to sample the Rx equalized waveform and generate a digital stimulus for the Tx half of the repeater. The use of a retimer significantly improves the signal quality at each repeater stage.

In a retimer, the Rx algorithmic model must implement AMI_GetWave and the function must return clock times. The retimer Tx Algorithmic model can also implement AMI_GetWave.

For a retimer, the simulator generates a digital input to the retimer Tx by sampling the Rx AMI_GetWave output at each (tick + UI/2). the digital stimulus has **vlow** of -0.5V and **vhigh** of +0.5V.

AMI Time Domain Simulation with AMI Redriver or Retimer

In time domain simulation, the waveform from upstream channel 1 is propagated to downstream channel 2.

AMI Redriver Time Domain Simulation

Here is the sequence of operations for an AMI redriver link.

1. The solver obtains the impulse response of the upstream analog channel 1.
2. The impulse response is sent through the AMI_Init functions of the upstream transmitter Tx1 and receiver Rx1.
3. The solver obtains the impulse response of the downstream analog channel 2.
4. The impulse response is sent through the AMI_Init functions of the downstream transmitter Tx2 and receiver Rx2.
5. The solver performs AMI time domain simulation of upstream channel.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. The simulator uses the output on the upstream receiver (Rx1out) as the input to the downstream transmitter (Tx2in). Any AMI_GetWave function in Rx1 or Tx2 is ignored.
7. The solver performs AMI time domain simulation of the downstream channel.

AMI Retimer Time Domain Simulation

Here is the sequence of operations for an AMI retimer link.

1. The solver obtains the impulse response of the upstream analog channel 1.
2. The impulse response is sent through the AMI_Init functions of the upstream transmitter Tx1 and receiver Rx1.
3. The solver obtains the impulse response of the downstream analog channel 2.
4. The impulse response is sent through the AMI_Init functions of the downstream transmitter Tx2 and receiver Rx2.
5. The solver performs AMI time domain simulation of upstream channel.
6. The solver samples the waveform output by upstream receiver Rx1 AMI_GetWave function at 0.5UI after each clock tick returned by the function. The parameter **Rx_ Receiver_Sensitivity** controls the interpretation of a sampled bit as logic 1 or logic 0; see the IBIS Specification (AMI Analysis References) for further information.
7. The sampled waveform is used to generate a new digital waveform as input to the downstream transmitter Tx1. Any AMI_GetWave function in the downstream transmitter Tx2 is ignored. The digital waveform has values of -0.5V for logic 0 and +0.5V for logic 1.
8. The solver performs AMI time domain simulation of the downstream channel.

AMI Statistical Simulation with AMI Redriver or Retimer

AMI statistical simulation calculates the impulse response of a channel. When the system includes one or more AMI Repeater links, statistical simulation differs between redrivers and retimers.

If the Repeater is a redriver, the output of the final **AMI_Init()** at the Receiver (Rx) end of the downstream channel must incorporate the impulse responses of both channels.

1. The solver calculates the Initial, Intermediate, and Final impulse responses of the upstream channel.
2. The solver calculates the Initial and Intermediate impulse responses of the downstream channel.
3. The solver convolves the Final impulse response of the upstream channel with the Intermediate impulse response of the downstream channel to calculate the impulse response input to the Rx **AMI_Init()** function in the downstream channel.
4. The final impulse response output by the downstream Rx **AMI_Init()** function is used to perform statistical simulation of the combined channels.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When multiple redrivers are chained, the final impulse response of any given downstream channel includes the effects of all previous upstream channels and redriver pairs. The solver treats the combination of all previously analyzed channels as the upstream channel.

1. The solver calculates the Initial and Intermediate impulse responses of the next channel in the chain, the downstream channel in the analysis.
2. The solver convolves the final impulse response output by the last Rx **AMI_Init()** function of the previously analyzed channels with the Intermediate impulse response of the downstream channel to calculate the impulse response input to the Rx **AMI_Init()** function in the downstream channel.
3. The final impulse response output by the downstream Rx **AMI_Init()** function is used to perform statistical simulation of the combined channels.

If the Repeater is a retimer, the two channels are independent.

1. The solver calculates the Initial, Intermediate, and Final impulse responses of the upstream channel.
2. The solver calculates the Initial, Intermediate, and Final impulse responses of the downstream channel.
3. The solver uses the Final impulse response for the upstream channel to perform a statistical simulation of channel 1.
4. The solver then uses the Final impulse response of the downstream channel to perform a statistical simulation of channel 2.

Harmonic Balance Technical Notes

The following topics provide technical information about Nexxim Harmonic Balance analysis.

Nonlinear and Linear Solvers

Harmonic balance applies Kirchhoff's Current Law (KCL) at each node for each independent frequency, then solves the nodal equations supplied by the device models in the frequency domain, yielding the steady state frequency spectrum at every node and every branch. In this way the frequency spectrum for all the currents at each node is "balanced". The algorithm combines a nonlinear solver with a linear solver. As illustrated in Figure 1, the nonlinear solver is an outer loop that arranges the equations so they can be solved with a linear solver in an inner loop.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

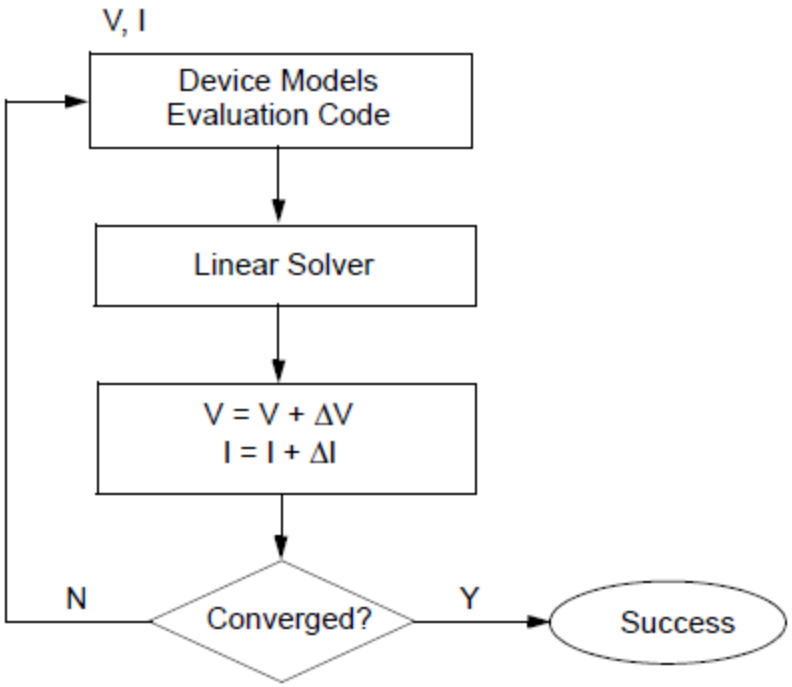


Figure 1. Nonlinear Solver Loop

Nexxim One-Tone Harmonic Balance Analysis

Single-tone or periodic harmonic balance computes the periodic steady-state response of a circuit. A time-dependent response *x(t)* is periodic with period T when *x(t) = x(t + T)* for all *t*, in response to a sinusoidal input with frequency *f* = 1/(*nT)*, where *n* is an integer.

A one-tone harmonic balance analysis uses a single tone frequency *f* with a specified number of harmonics, *M*.

> **Note:**
>
> When the option **hb.power_of_two_expansion=1** is set, the single-tone harmonic balance algorithm adjusts the maximum harmonic number MAXK so that (2*MAXK + 2) is always a power of 2 (i.e., MAXK = {1, 3, 7, 15, 31, 63, ...}). Power of two expansion is always off for multi-tone analysis.

Nexxim N-Tone Harmonic Balance Analysis

Multi-tone or N-tone harmonic balance analysis computes the steady-state response of a circuit to two or more input sinusoids. The output yields a spectrum with all the elements of the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

harmonic series of the two fundamental inputs and their intermodulation (sum and difference) frequencies. The Fourier coefficients in multi-tone harmonic balance represent harmonic and intermodulation distortion.

An N-tone mixer harmonic balance analysis uses one or more tone frequencies, f_1 through f_N, each with a specified number of harmonics M_1 through M_N to be used in the analysis. In the typical N-tone mixer analysis, one of the tones has greater power than the others and is analyzed over a greater number of harmonics. The harmonic series for tone $f_1$contains harmonic numbers k_1 = 1, 2, ... M_1. The series for tone $f_N$contains harmonic numbers k_N = 1, 2, ... M_N.

The harmonic balance analysis yields the Discrete Fourier coefficients of the output at the frequencies

$k_1f_1 + k_2f_2 + ... k_Nf_N, | k_i | \leq M_i$

If the frequency content at harmonic k is [V, I], the frequency content at harmonic $-k$ is the complex conjugate [V*, I*].

Controlling Nexxim Harmonic Balance Analysis

The following topics describe options and statement parameters that control the harmonic balance analysis.

Controlling Nexxim Harmonic Balance Analysis

MAXK Expansion

Each **MAXK** entry M_i specifies the maximum harmonic number to use for the corresponding tone f_i. The analysis is performed at DC and with harmonics 1 through M_1 of tone f_1 (frequency f_1 itself is harmonic 1), the harmonics 1 through M_2 of tone f_2, up to harmonics 1 through M_N of tone f_N, plus their combinations (sums and differences of the harmonics).

> **Note:** The prefix **hb.** before an option specifies that the value of the option applies only to harmonic balance. Without the prefix, the value applies to all analyses that use the option.

For a two-tone mixer analysis the total number of output frequencies is:

$M_1 + 2*M_1*M_2 + M_2$

In a two-tone analysis with two frequencies f_1=1 MHz, M_1=4 and f_2=27 kHz, M_2=2, harmonic balance computes the Fourier coefficient for each of the frequencies listed in the following table at each node in the circuit. The total number of frequencies in the output is 4 + 2*4*2 + 2 = 22.

When the option **power_of_two_expansion=1** is set, the single-tone harmonic balance algorithm adjusts the maximum harmonic number MAXK so (2*MAXK + 2) is always a power of

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2 (i.e., MAXK = {1, 3, 7, 15, 31, 63, ...}). Set the option to 0 to disable expansion. Power of two expansion is not used for multi-tone analysis. The default for single-tone analysis is 1 (on).

Output Frequencies for Two-Tone Harmonic Balance Example

Formula	Frequency (Hz)	Formula	Frequency (Hz)
f_1	1.0e+6	$3f_1 + 2f_2$	3.054e+6
$2f_1$	2.0e+6	$4f_1 + f_2$	4.027e+6
$3f_1$	3.0e+6	$4f_1 + 2f_2$	4.054e+6
$4f_1$	4.0e+6	$f_1 - f_2$	0.973e+6
f_2	27e+3	$f_1 - 2f_2$	0.946e+6
$2f_2$	54e+3	$2f_1 - f_2$	1.973e+6
$f_1 + f_2$	1.027e+6	$2f_1 - 2f_2$	1.946e+6
$f_1 + 2f_2$	1.054e+6	$3f_1 - f_2$	2.973e+6
$2f_1 + f_2$	2.027e+6	$3f_1 - 2f_2$	2.946e+6
$2f_1 + 2f_2$	2.054e+6	$4f_1 - f_2$	3.973e+6
$3f_1 + f_2$	3.027e+6	$4f_1 - 2f_2$	3.946e+6

Initial Guess for Vector of Node Voltages

The option **hb.initial_guess** can be used to control the initial guess for the vectors of node voltages and currents used in the harmonic balance calculation.

> **Note:**
>
> The prefix **hb.** before an option specifies that the value of the option applies only to harmonic balance. Without the prefix, the value applies to all analyses that use the option.

Fewer Tones Initial Guess

initial_guess=fewer_tones is the default for multi-tone analysis. For single-tone analysis, **fewer_tones** has the same effect as **initial_guess=dc** (performs a DC analysis, then starts harmonic balance with the DC values as the initial guess). For multitone analyses, **fewer_tones** starts with the DC operating point as the initial guess and solves the circuit with only the first tone enabled. The values with the 1-tone analysis are used as the initial guess for the analysis of the circuit with the first two tones enabled, et cetera until the circuit has been solved with all tones enabled. For example, if the netlist contains:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
.OPTIONS hb.initial_guess=fewer_tones
.HB tones=(1e6, 1.1e7, 2.1e7) maxk=(3,4,5)
```

The simulator first calculates the DC operating point, then uses those values as the initial guess in solving the single-tone analysis using tone 1e6Hz. The values on the 1-tone analysis then become the initial guess for the two-tone analysis using tones 1e6Hz and 1.1e7Hz. The result on the two-tone analysis then become the initial guess for the full analysis using all three tones.

Fewer Tones Transient Initial Guess

initial_guess=fewer_tones_transient solves the 1-tone problem using transient analysis, then proceeds to solve the multitone problems with the **fewer_tones** algorithm described above. This option has two subordinate options.

- **initial_guess.fewer_tones_transient.tmax=***val* sets the maximum step size. There is no default.
- **initial_guess.fewer_tones_transient.tstop=***val* specifies the stop time.

DC Initial Guess

initial_guess=dc performs a DC analysis, then starts harmonic balance with the DC values as the initial guess. **DC** is the default for single-tone analysis.

Zero Initial Guess

initial_guess=zero starts harmonic balance with vectors of zero voltages and currents as the initial guess.

File Initial Guess

initial_guess=file uses vectors of node voltages and currents saved from a previous harmonic balance simulation. When **file** is the source for the initial guess, the netlist option statement must also include an **initial_guess_file=** [*path*]*filename* option to identify the file. The *filename* specifies the name of an SDF-format file generated by a previous run of HB. The *path* can be omitted if the file is in the directory where the netlist resides. The *path* can specify a subdirectory in the current directory; otherwise, the path must provide the full directory path.

See External Files in the Netlist File Format help topic for further information.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> The path and filename of the initial guess file from a previous run of HB must not be the same as the path and filename of the output file to be generated by the current run of HB. That is, HB cannot read old values from and write new values to the same file.

Transient Initial Guess

initial_guess=transient performs a transient analysis, then uses the final values as the initial guess for the harmonic balance analysis. When **transient** is the source for the initial guess, the netlist option statement can also include two additional options to control the transient analysis.

- **initial_guess.transient.tmax=***val* suggests a maximum step size to use.
- **initial_guess.transient.tstop=***val* sets the stop time.

Initial Guess in Sweeps

By default, harmonic balance applies the initial guess strategy at the beginning of each iteration of a sweep. A separate option, **result_as_initial_guess**, controls this behavior.

- **result_as_initial_guess=0** turns off the use of previous results.
- **result_as_initial_guess=1** enables the use of previous results. However, the use of previous results is the default, so this option setting is never needed.

Nonlinear Solver Controls

The following options control the convergence of the outer, nonlinear solver loop.

> **Note:**
>
> The prefix **hb.** before an option specifies that the value of the option applies only to harmonic balance. Without the prefix, the value applies to all analyses that use the option.

hb.abstol=*val* sets the absolute error tolerance for currents to be used by harmonic balance. Increase (loosen) to aid convergence with less accuracy. The default is 1e-12 Amp.

hb.vntol=*val* sets the absolute error tolerance for voltages to be used by harmonic balance. Increase (loosen) to aid convergence with less accuracy. The default is 1e-7 Volt.

hb.reltol=*val* sets the relative error tolerance for both currents and voltages to be used by harmonic balance. Increase (loosen) to aid convergence with less accuracy. The default is 1e-3 (dimensionless).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

max_newton_iterations=*val* sets the maximum number of tries before the nonlinear iterative method gives up trying to converge. Increase if necessary to aid convergence.

limiting_step=*val* sets the maximum absolute update in voltage that can occur from one iteration to the next. Decrease if necessary to aid convergence.

memory_over_speed=*val* controls the use of memory resources. With the default of 0, the simulation emphasizes speed over memory, but switches to a memory-conserving scheme if too many memory resources are being consumed. With **memory_over_speed** set to 1, simulation emphasizes memory over speed. **memory_over_speed** cancels automatic adjustments such as the adjustment of MAXK.

cluster_tol=*val* clusters frequencies that are within a certain tolerance of each other, in order to conserve memory. The final solution is not affected, but the simulation speed may be slowed for certain nonlinear circuits. This option is applied for multitone problems in circuits with no frequency-dependent devices. The default value is 1e-2 Hz.

When **cluster_tol** is in effect, Nexxim saves a message such as the following to the log file:

```
analysis:hb(status): frequency compression = 7.14286
```

This message indicates the percentage reduction in the number of frequencies that results from clustering (about 7% in the example above).

> **Note:**
>
> Frequency-domain elements in the circuit prevent the application of clustering in the harmonic balance analysis. When one or more frequency-domain elements are present, Nexxim saves the following message to the log file:
>
> ```
> analysis:hb(status): presence
> of frequency domain elements: frequency clustering NOT utilized
> ```
>
> In particular, a port element contains a complex impedance, so the port element acts as a frequency-domain device. When clustering is appropriate in harmonic balance analysis, it may be possible to use a simple resistor in place of a port element.

Linear Solver Controls

The following options control the linear equation solver inside the nonlinear solver.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> The prefix **hb.** before an option specifies that the value of the option applies only to harmonic balance. Without the prefix, the value applies to all analyses that use the option.

max_linearsolver_iterations =*val* sets the maximum number of iterations for the solution of the system of linear equations at each Newton step.

linearsolver_restarts sets the maximum number of times the linear solver is restarted until a satisfactory step solution is obtained. The default is 1. (Most users do not need to adjust this option.)

HB Convergence Aids

The **alpha**, **beta**, and **cmin** options aid in harmonic balance convergence by adding conductances and capacitances to the circuit. The values can be increased to aid the convergence of circuits with rapidly changing circuit values.

> **Note:** The prefix **hb.** before an option specifies that the value of the option applies only to harmonic balance. Without the prefix, the value applies to all analyses that use the option.

- **hb.alpha=***val* sets a conductance across all branches. The default value is 1e-12 mho.
- **hb.beta=***val* sets a conductance between every node and ground. The default value is 0.0 mho.
- **hb.cmin=***val* sets a capacitance between every node and ground. The default value is 0.0 Farad.

> **Note:** If floating nodes are present in the circuit, a non-zero **beta** conductance value is automatically added to those nodes. If a value of **beta** has been specified in an **.options** statement in the netlist, that value is used. Otherwise, if **alpha** is greater than zero, the added **beta** conductances have the value **alpha** /10. If **alpha** is not greater than zero, the added **beta** conductances have the value 1e-13 mho.
>
> Nexxim issues a warning message if the circuit contains floating nodes or nodes with single connections. Only nodes with a single branch connection that is both conservative and constitutive are flagged. For example, the controlling nodes in a VCVS have a constitutive/behavioral/relational connection to the controlled nodes, but not a physical/structural/conservative connection, and therefore are not flagged.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **continuation** option controls the strategy to be used when convergence is not achieved with normal methods.

- **continuation=source_stepping_last_tone**

  Source stepping solves the last tone in the **TONES** argument to the **.HB** statement by reducing the input voltages and currents and adding resistances between all nodes and ground, solving this low-voltage case, then gradually increasing the inputs until a solution is found that uses the original input values. Source stepping is the default continuation strategy.

- **continuation=pseudo_transient**

  In the pseudotransient continuation strategy, harmonic balance is run with an additive transient term. Pseudotransient continuation is very useful for problems that are not strongly nonlinear but that have high memory requirements because of the size of the problem or of singularities in the circuit. If source-stepping does not provide a solution or if memory bounds are reached, continuation automatically switches to pseudotransient. This option has two subordinate options:

- **continuation.pseudo_transient.step_reltol_scale=***val*

  The harmonic balance pseudotransient continuation solver relies on the HB solver as the inner solver. This option specifies the relative tolerance of the HB solver with respect to the pseudotransient tolerance. The default for **step_reltol_scale** is 0.8.

- **continuation.pseudo_transient.pt_reltol_scale=***val*

  The harmonic balance pseudotransient continuation solver relies on the HB solver as the inner solver. This option specifies the relative tolerance of the HB solver with respect to the pseudotransient tolerance. Because HB is called repeatedly, this scale factor tightens the tolerances. The default for **pt_reltol_scale** is 0.8. If pseudotransient continuation does not converge in a reasonable number of iterations or shows convergence problems toward the end of the simulation, lowering **pt_reltol_scale** to 0.5 might help. (Most users do not need to adjust this option.)

- **continuation.pseudo_transient.max_h=***val*

  HB pseudotransient continuation has a time-stepping scheme with an internal variable, **h**, that can be thought of as a resistance value. The variable **h** is manipulated internally, but it cannot exceed a maximum value. This option sets the maximum value for **h**. Larger values of **h** cause HB pseudotransient continuation to more closely resemble standard HB. Smaller values of **h** lead to quicker and more accurate solutions, typically with lower memory overhead but with increased simulation time. The default is 5e3.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Handling Strongly Nonlinear Circuits

The **method** parameter in the .HB statement selects between the standard harmonic balance calculation and a shooting method that facilitates single-tone analysis of circuits with strongly nonlinear behavior. The **tstab** parameter in the .HB statement assists HB in finding a solution for difficult circuits, especially when the shooting method is in effect.

> **Note:**
>
> The prefix **hb.** before an option specifies that the value of the option applies only to harmonic balance. Without the prefix, the value applies to all analyses that use the option.

method=hb, standard harmonic balance, is the default for single-tone analysis and is always used for multi-tone harmonic balance analysis.

method=shooting is available for single-tone analyses only. When **method** is set to **shooting**, single-tone harmonic balance uses a time-domain shooting method that is efficient for nonlinear circuits. The **method** option is ignored for multi-tone harmonic balance.

If single-tone harmonic balance fails or takes a long time to complete with the default, try setting **method=shooting** for subsequent runs. Example:

```
.HB TONES=(2.7e6) MAXK=(7) METHOD=SHOOTING
```

The **tstab** parameter in the .HB statement represents additional time needed for transient to settle before HB tries to use the result. A large **tstab** may be used to aid convergence for circuits that have initial nonlinearities, or to allow HB to find one out of several possible solutions. **Tstab** can be applied in both one-tone and multi-tone harmonic balance.

Increasing Accuracy or Speed

The HB statement parameters **auto_refine_solution** and **trim_tol** direct the simulator to automatically adjust the number of harmonics during the simulation to provide either increased accuracy (more harmonics) or faster simulation (fewer harmonics).

> **Note:**
>
> The prefix **hb.** before an option specifies that the value of the option applies only to harmonic balance. Without the prefix, the value applies to all analyses that use the option.

The auto_refine_solution Statement Parameter

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When the simulation includes a sweep of power, accuracy can be improved by increasing the number of harmonics as power increases. The **auto_refine_solution** parameter increases the harmonics as needed. The syntax for this statement parameter is:

auto_refine_solution=no|**yes**

The default is **no**, specifying that no automatic increase is to be done.

With **auto_refine_solution=yes**, Nexxim examines the result at each sweep iteration to determine if the solution is sufficiently resolved. If it is not, Nexxim doubles the number of harmonics and repeats the iteration. Start the sweep with MAXK set to a low number, and have Nexxim automatically increase MAXK as needed to maintain accuracy. Example:

```
.HB TONES=(1.01e6,2.7e6) MAXK=(3,7) AUTO_REFINE_SOLUTION=YES
+ SWEEP pwr_val START=1.5 STOP=2.5 STEP=0.5
```

The trim_tol Statement Parameter

IP3 analyses and similar N-tone problems with N>2 may not require the full tensor product using all the harmonics of all the tones. To increase the speed of the analysis, it is useful to “prune” harmonics that have minimal contribution. The **trim_tol** parameter in the HB statement causes Nexxim to prune harmonics automatically after the initial guess calculation. The syntax is:

trim_tol=*val*

The default value is 0.0, specifying that no pruning is to be done.

The parameter **trim_tol** is a voltage tolerance like **vntol**. The tolerance is applied to the harmonics calculated in the two-tone initial guess. Setting **trim_tol** to a value such as 1e-6 directs Nexxim to eliminate any harmonic whose coefficient has magnitude less than 1e-6. The pruning is then symmetrically applied to higher tones so the result has fewer frequencies than the full tensor product.

With the **trim_tol** parameter, start out with large MAXK values for each of the HB TONES frequencies. This is equivalent to oversampling the frequencies. The **trim_tol** parameter directs Nexxim to prune the harmonics in a way that depends on the circuit specifics. Use this parameter to avoid trying to determine the optimal MAXK values in advance. Example:

```
.HB TONES=(1.01e6,2.7e6,3.221e6) MAXK=(21,21,21) TRIM_TOL=1e-6
```

TONE Parameter on Sources

To ensure that the appropriate harmonic balance frequency is used with a SIN, PWL, or PULSE source, qualify the source instance statement by adding a **TONE** =*tone_value* parameter at the end of the source instance statement in the netlist. The *tone_value* is then used in a subsequent HB statement.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **TONE** parameter is needed with a SIN voltage or current source only when the driving frequency of the source differs on the frequency at which the harmonic balance is to run. For example, to analyze a circuit driven by a single 1-KHz AC voltage source using harmonic balance at a test tone of 1 KHz over the first 31 harmonics, the netlist is:

```
V1 1 0 SIN(0 1v 1000)
.HB TONES=1000 MAXK=31
```

However, to specify a 1000-Hz tone for harmonic balance while driving the circuit with a 2000-Hz sinusoidal voltage, the voltage source statement should include the **TONE** parameter:

```
V1 1 0 SIN(0 1v 2000) TONE=1000
.HB TONES=1000 MAXK=31
```

The **TONE** parameter is *required* with any PWL or PULSE source. For example, to analyze a mixer driven by sources at 1 MHz and 27 kHz over the first four harmonics of a PWL source and the first two harmonics of a PULSE source, the netlist syntax is:

```
V23 20 0 PWL(0 0 0.1e-6 2.0 0.5e-6 5.0 1.0e-6 0 R) TONE=1.0e6
V1 1 0 PULSE (0 5 0 5e-3 5e-3 27e-3 27.0e3) TONE=27.0e3
.HB TONES=(1.0e+6, 27.0e+3) MAXK=(4, 2)
```

Restriction on Sources with Time Delay

Several voltage and current sources can specify a time delay parameter. However, such a time delay prevents harmonic balance analysis from correctly calculating the steady-state period. Therefore, sources with time delays should not be used in circuits for Nexxim harmonic balance analysis.

HB Output Notes

By default, all node voltages are output to the results file. For large circuits, simulation time can be significantly reduced by specifying a set of values to output, rather than the default of outputting values for every node.

In the **Schematic Editor**, Click the **Edit Output Quantities** feature in the **Solution Setup** window to specify particular outputs.

The netlist can use one or more .PRINT statements to specify the outputs from harmonic balance analysis. If you do not add a .PRINT statement, only node voltages are output. The netlist syntax is:

.PRINT HB*output1* [*output2*] ...

See Controlling Nexxim Output for further information.

General Conversion Parameters

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Nexxim can also use the results of HB to compute complex general conversion (GC) transfer parameters. General conversion parameters are also called nonlinear S-parameters, since they are the large-signal analogy to small-signal S-parameters. A GC parameter is the ratio:

$$GC_{ij}\langle m,n\rangle = \frac{B_i\langle m\rangle}{A_j\langle n\rangle}$$

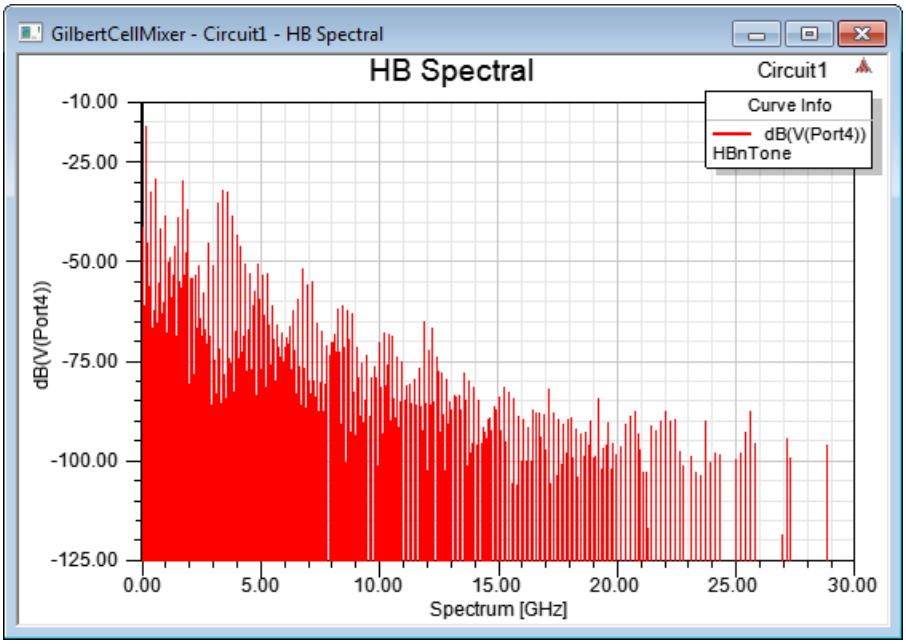
Where:

- *i* is the name of the output port.
- *j* is the name of the input port.
- <*m*> is the number of the harmonic of interest at the output port (+/-*m*)
- <*n*> is the number of the harmonic of interest at the input port (+/-*n*)
- A_j is the magnitude of the incident traveling wave at input port *j*.
- B_i is the magnitude of the incident traveling wave at output port *i*.

To display general conversion parameters in the Reporter window, select the Sweep domain, under category **General Conversion**. The responses are of the format GC(*output_port*,*input_port*)<*output_harmonic*,*input_harmonic*>.

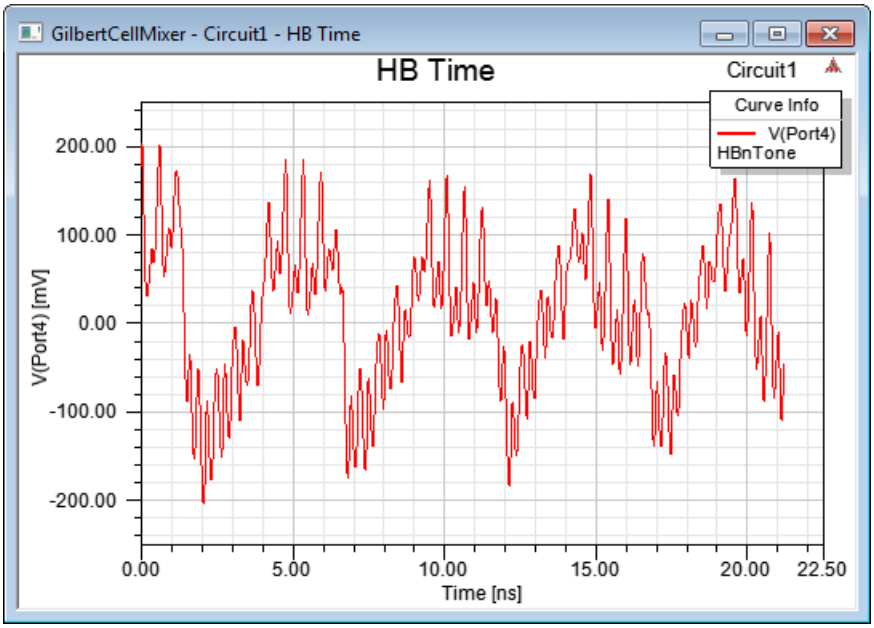
Time Domain and Frequency Domain Response Formulas

As shown earlier, spectral domain results look like the following graph:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Time domain results look like the following graph:



This topic describes the relationship between the responses in the time and spectral (frequency) domains.

The lines in the spectral domain plot above represent the absolute value, in dB, of the phasors $\underline{V}_n$, corresponding to the response at the harmonic frequencies of the HB analysis, f_n. The complex values of the $\underline{V}_n$can be obtained by creating a data table report.

Each phasor is associated with a time-domain waveform:

$$V_n(t) = \mathrm{Re}\left\{\underline{V}_n e^{j2\pi f_n t}\right\}$$

$$= V_n^R \cos(2\pi f_n t) - V_n^I \sin(2\pi f_n t)$$

$$= \left|\underline{V}_n\right| \cos(2\pi f_n t + \phi_n),$$

where the rectangular and polar representations of the $\underline{V}_n$ are related by:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\underline{V}_n = V_n^R + j\, V_n^I = \left|\underline{V}_n\right| e^{j\phi_n}.$$

For example, a purely real phasor $\underline{V}_n$=5V represents the time-domain waveform:

$$V_n(t) = 5\cos(2\pi f_n t) \quad (\mathrm{V}),$$

and a purely imaginary phasor $\underline{V}_n$=-5*j*V represents the time-domain waveform:

$$V_n(t) = 5\sin(2\pi f_n t) \quad (\mathrm{V}).$$

The complete time-domain waveform is a superposition of the waveforms for all harmonics:

$$V(t) = \sum_n V_n(t) = \sum_n \left|\underline{V}_n\right| \cos(2\pi f_n t + \phi_n).$$

HB Load-Pull Analysis Notes

Nexxim load-pull analysis computes the frequency-dependent input impedance Z of an ideal tuner, using harmonic balance analysis. The harmonic balance analysis is computed over a spectrum of frequencies specified with the **TONES** and **MAXK** entries in the HB statement. The load-pull analysis setup matches the frequencies analyzed by HB to the frequencies of interest specified in the ideal tuner definition.

Impedances at Tuner Frequencies

The frequencies used to compute the tuner impedance are specified in the **TUNER_FREQS** entry in the HB statement. The impedances at these frequencies are calculated on the following formula:

$$Z = Z_r \times \frac{(1+\Gamma)}{(1-\Gamma)}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Where Γ (Gamma) is the reflection coefficient of the tuner, and Z_r is a reference impedance. The ideal tuner instance parameters define Γ and Z_r:

```
Rxxxn1 n2PORTNUM=val
+ GAMMA_MAG=val // Magnitude of Gamma
+ GAMMA_ANG=val // Angle of Gamma
+ REF_REAL=val // Real part of reference impedance
+ REF_IMAG=val // Imaginary part of reference impedance
```

The impedance calculation is performed over a combined sweep of **GAMMA_MAG** and **GAMMA_ANG**. **GAMMA_MAG** is swept over a range from zero to one, and **GAMMA_ANG** is swept over a range of zero to 2π (6.283185307) radians. At each sweep point, a harmonic balance is performed to solve for the circuit responses at the calculated tuner impedance.

A tuner frequency can be any appropriate value. If no tuner frequency matches the current HB frequency (or when no tuner frequency is specified), the default impedance parameters **RDEF** and **XDEF** are used as the tuner impedance.

Impedances at Cluster Frequencies

The analysis can incorporate tuner impedances at frequencies of interest other than the actual tuner frequencies. These “cluster” frequencies typically represent harmonics of the tuner frequencies and intermodulation products for multi-tone analyses, but can be any frequencies of interest. The cluster frequencies are specified in the **Z_FREQS** parameter in the tuner definition. The impedances at these frequencies are specified in the corresponding **Z_REAL** and **Z_IMAG** entries. If no cluster frequencies are specified, only the tuner frequencies are analyzed.

Default Impedances

The default tuner impedances are specified in the **RDC**, **RDEF** and **XDEF** entries in the tuner definition. The **RDC** entry specifies the resistance of the tuner at DC (frequency = 0). The **RDEF** entry specifies the default resistance of the tuner. The **XDEF** entry specifies the default reactance of the tuner. The default impedances are used at any frequency not specified in the **TUNER_FREQS** or **Z_FREQS** entries, and when no tuner frequency is supplied.

See *Ideal Tuner* in the Nexxim Components help topics for details on the netlist format for the ideal tuner element.

See Nexxim Load-Pull Analysis Netlist Syntax for an example of the ideal tuner netlist format.

Oscillator Analysis Technical Notes

The following topics provide technical details on Nexxim oscillator analysis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Using the Oscillator Probe

The oscillator probe identifies a resonance to be analyzed, and provides initial values used in the frequency calculation. The oscillator probe represents an oscillating voltage source with amplitude given by the parameter **A** at the frequency given by the parameter **FREQ**. At all other frequencies, the probe current is zero. The oscillator probe is a frequency domain element; in the time domain (e.g., in transient and DC analyses) the oscillator probe behaves like an open circuit.

The oscillator probe applies a small voltage at a known frequency. Nexxim starts with the frequency specified in the **TONES** entry in the **.OSC** statement and also in the **FREQ** parameter on the oscillator probe, and applies one of several methods to calculate an initial guess at the oscillating frequency. The method used to calculate an initial guess at the circuit oscillating frequency is controlled by the **initial_guess** option (See Initial Guess for Oscillator Frequency). The voltage given by probe parameter **A** is always used as the initial probe voltage. The simulator adjusts the frequency and voltage of the probe until both the real and imaginary components of the probe current (I_{probe}) are zero, that is, $Re(I_{probe}) = 0$ and $Im(I_{probe}) = 0$. The frequency where this occurs is the oscillating frequency.

Placement of a probe is circuit-dependent. If the focus of the oscillation in the circuit is known in advance, place the probe accordingly. If not, try placing the probe across two nodes in the circuit that exhibits a voltage difference when the circuit is oscillating.

> **Note:**
>
> As analysis progresses, oscillator analysis may save messages like the following to the log file:
>
> analysis:osc(status): Probe 0: selecting (*node_name1*,*node_name2*) as alternative location 1.
>
> analysis:osc(status): Probe 0: selecting (*node_name3*, *node_name4*) as alternative location 2.
>
> The *node_name*s are circuit-specific. If oscillator analysis fails, Nexxim automatically reruns the analysis after moving the probe to alternative location 1. If that analysis fails, Nexxim retries using alternative location 2.

Controlling Nexxim Oscillator Analysis

The options described in the following topics allow you to fine-tune the oscillator analysis.

Initial Guess for Oscillator Frequency

The initial guess for the resonant frequency can be controlled by the **initial_guess** option and its subordinate options. Settings for the **initial_guess** option are **transient**, **fewer_tones_**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

transient, **freq_sweep**, and **dc**. For single-tone oscillator analysis (with no driven frequency), **transient** is the default (listed as **transient** on the Oscillator Options window in the schematic editor). For the two-tone oscillator analysis that includes a driven oscillation, **fewer_tones_transient** is the default method (two-tone oscillator analysis is available only in netlists).

Another option, **osc.result_as_initial_guess**, allows Nexxim to use the result on the previous oscillator sweep step as the initial guess for the current step.

Transient Initial Guess

osc.initial_guess=transient obtains an initial guess for the resonant frequency by running a transient analysis.

- The subordinate option **osc.initial_guess.transient.num_cycles** specifies the number of cycles to use in the transient analysis (default is calculated).
- The subordinate option **osc.initial_guess.transient.tmax** specifies the maximum timestep to use in the transient analysis (default is calculated).
- The subordinate option **osc.initial_guess.transient.tstop** specifies the stop time to use in the transient analysis (default is calculated).
- The subordinate option **osc.initial_guess.transient.tstep** specifies the stop time to use in the transient analysis (default is calculated).
- The subordinate option **osc.initial_guess.transient.output_start** specifies an initial period of transient analysis to be ignored in the initial guess.

Fewer Tones Transient Initial Guess

initial_guess=fewer_tones_transient solves for the oscillator frequency using transient analysis, then proceeds to solve the full two-tone circuit. This option has two subordinate options.

- **initial_guess.fewer_tones_transient.tstop=***val* specifies the stop time. There is no default.
- **initial_guess.fewer_tones_transient.tmax=***val* sets the maximum step size. There is no default.

Frequency Sweep Initial Guess

osc.initial_guess=freq_sweep sweeps the frequency of the probe looking for a frequency where the real component of the probe current [Re(Iprobe)] crosses zero from positive to negative. If a zero-crossing is not observed in the sweep range, the initial frequency guess is the frequency at which the minimum value min{abs[Re(Iprobe)]} is obtained. The **osc.initial_guess=freq_sweep** option has four subordinate options

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Subordinate option **osc.initial_guess.freq_sweep.start** sets the starting frequency. The default is 1e9 Hz.
- Subordinate option **osc.initial_guess.freq_sweep.stop** sets the ending frequency. The default is 5e9 Hz.
- Subordinate option **osc.initial_guess.freq_sweep.num_steps** sets the number of sweep frequencies to be swept. **num_steps** defaults to 50.
- Subordinate option **osc.initial_guess_freq_sweep.method** sets the sweep type. At present, the only method is **linear**.

> **Note:**
>
> The value of probe parameter **A** is always used as the initial probe voltage.

DC Initial Guess

osc.initial_guess=dc uses the value of the **FREQ** parameter on the oscillator probe as the initial guess for the resonant frequency. It also uses DC analysis to calculate initial voltage and current values.

Previous Result as Initial Guess

By default, oscillator analysis uses the initial guess strategy at the beginning of each iteration of a sweep. The option **osc.result_as_initial_guess** allows Nexxim to use the result on the previous oscillator sweep step as the initial guess for the current step. Use of this option can avoid repeated analysis runs.

The default for **osc.result_as_initial_guess** is false (0). Set this option to true (1) to enable the analysis to use the result from each previous step as the initial guess for each new step.

> **Note:**
>
> For **result_as_initial_guess** to be effective, the increments in the variable being swept must be closely spaced or in a region where the frequency does not vary much with each sweep step.
>
> If an analysis step fails while this option is in effect, Nexxim defaults to the normal guess based on transient analysis.

Controlling Convergence of Oscillator Analysis

Oscillator analysis involves circuits that may be highly nonlinear. The **nonlinear_method** option is provided to allow the user to select an alternative strategy if standard Newton-Raphson

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

iteration fails to converge. Settings for the **nonlinear_method** option are **newton**, **damped_newton**, and **descent**.

- **osc.nonlinear_method=newton** uses the standard algorithm, controlled by harmonic balance options. **Default** (standard Newton-Raphson) is the fastest and least robust (lowest probability of convergence)
- **osc.nonlinear_method=damped_newton** checks the ΔV value at each step. If ΔV exceeds an internally derived maximum, the iteration is rerun. The **damped_newton** method is intermediate in speed and robustness between the default and descent methods.
- **osc.nonlinear_method=descent** uses the slope of the derivative as a guide to the direction for the next iteration. **Descent** is the slowest and most robust of the three methods.

Setting Tolerances for Oscillator Analysis

Two options are provided to control the tolerances for oscillator analysis.

- **.osc.reltol** is the standard relative voltage tolerance used in Newton-Raphson. Specifying **osc.reltol** allows the user to tighten or loosen the voltage tolerance for accuracy vs. convergence, as applied just to oscillator analysis. The default is 1e-4.
- **osc.freq_abstol** is the relative frequency tolerance to be applied to the resonant frequency calculation. The default is 10.

Setting Tolerances for Oscillator Analysis

Two options are provided to control the tolerances for oscillator analysis.

- **.osc.reltol** is the standard relative voltage tolerance used in Newton-Raphson. Specifying osc.reltol allows the user to tighten or loosen the voltage tolerance for accuracy vs. convergence, as applied just to oscillator analysis. The default is 1e-4.
- **osc.freq_abstol** is the relative frequency tolerance to be applied to the resonant frequency calculation. The default is 10.

Floating Nodes Warning

Nexxim issues a warning message if the circuit contains floating nodes or nodes with single connections. Only nodes with a single branch connection that is both conservative and constitutive are flagged. For example, the controlling nodes in a VCVS have a constitutive/behavioral/relational connection to the controlled nodes, but not a physical/structural/conservative connection, and therefore are not flagged.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

LNA Technical Notes

Linear network analysis performs a frequency-domain analysis of the circuit linearized around the DC operating point. You can also run DC noise analysis, group delay analysis, and AC transfer function analysis.

Linear network analysis can be used with all passive circuits, and with active circuits that operate under small-signal conditions. In linear analysis the signal level and termination values do not cancel the small-signal conditions, and the superposition principle holds.

After a successful linear-circuit analysis, the results reflect the electrical characteristics of the circuit under small-signal conditions. The results of the analysis are linear network parameters such as scattering (S), admittance (Y), hybrid (H), and impedance (Z) parameters, port parameters such as RHO and VSWR, and noise parameters such as NF and FMIN.

> **Note:**
>
> Nexxim issues a warning message if the circuit contains floating nodes or nodes with single connections. Only nodes with a single branch connection that is both conservative and constitutive are flagged. For example, the controlling nodes in a VCVS have a constitutive/behavioral/relational connection to the controlled nodes, but not a physical/structural/conservative connection, and therefore are not flagged.

The results also include transfer functions of each output current over each input voltage at each of the test frequencies. Transfer functions are typically complex values.

LNA Netlist Inputs and Outputs

In a netlist, inputs and outputs for LNA are identified by adding port impedance resistors. Additional inputs and outputs for LNA analyses can be specified by adding AC specifications, as discussed later.

Port impedance resistors include a **PORTNUM** parameter to specify the port number and additional parameters to specify the impedance. All resistors with **PORTNUM** values are included as inputs and outputs. LNA calculates the network parameters (S, Y, Z, etc.) and the noise parameters.

See *Resistor, Port Impedance* in the Nexxim Components help for further information.

ZERO_PORT_VALUES Option

Port impedance resistors specify the port impedances with their **PORTNUM** parameters. LNA needs to treat these impedances as external to the circuit. The option **ZERO_PORT_VALUES=1** is therefore required for LNA.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **ZERO_PORT_VALUES** option is automatically enabled with any design entered through the **Schematic Editor**. It does not appear on the list of **Solution Options**. For designs entered with the Netlist Editor, the **ZERO_PORT_VALUES** option must be entered explicitly with a **.OPTIONS** statement.

See *Resistor, Port Impedance* in the Nexxim Components help for further information.

Nexxim Group Delay Analysis

Optionally, LNA can include group delay analysis. Group delay analysis determines the delay of the propagation of energy at a given frequency point, defined as the derivative of the phase of a network parameter with respect to frequency. The calculation is $GD_{ij} = d\phi_{ij} / d\omega$, where ϕ_{ij} is the phase of S_{ij}.

To compute group delay, numerical perturbation is used to compute the derivative. At each frequency, two analyses are performed, one at the nominal frequency *F*, and a second at the perturbed frequency *F'*. The perturbed frequency is:

$F' = F \times (1.0 + GROUP_DELAY_PERT)$

The default for GROUP_DELAY_PERT is 0.001 (0.1%) which is acceptable for most circuits. The typical range is 0.1 to 1.0e-7. However, smaller values may yield more accurate results for circuits with high-Q components, or those with sharp passbands-stopbands. Larger values may yield more accurate results for large circuits that use numerically complex models, where truncation errors can accumulate. Negative values for PERT use a perturbed frequency less than the nominal frequency.

Nexxim DC Noise Analysis

Optionally, LNA can include DC noise analysis.

- *DC noise analysis* calculates the noise spectral density at designated outputs due to thermal, flicker, and shot noise sources in a circuit that has been linearized around the DC bias operating point.
- *Thermal noise* is a variation in current due to random thermal motion of the electrons in physical resistors and bulk materials. Thermal noise is directly proportional to the absolute temperature.
- *Flicker noise* is a random variation in current associated with contamination and crystal defects in semiconductors. Flicker noise is associated with a flow of direct current. Flicker noise generates a noise signal with energy concentrated at low frequencies; because of this $1/f$ frequency dependence, flicker noise is also called $1/f$ noise.
- *Shot noise* is a fluctuation in the current across P-N junctions in diodes and transistors due to random barrier crossings by electrons and holes in the vicinity of the junction. Like flicker noise, shot noise is associated with a direct current flow.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Results of noise simulation include the Output Noise (Onoise) matrix and the Input-Referred (Inoise) matrix. The entries in the Onoise and Inoise matrices have units of Volt/$Hz^{½}$ or Amp/$Hz^{½}$.

DC Output Noise Matrix

Noise analysis generates a matrix Syy of transfer functions that show the noise power spectral density (noise power at each output at each frequency), in units of $Volt^2$/Hz or Amp^2/Hz.

$$Syy = [TF(\omega) \times Sxx(\omega) \times TF(\omega)^H]$$

Where:

- Syy is the power spectral density at the output. The size of Syy is (number_of_outputs × number of outputs).
- Sxx is the power spectral density of the noise sources at frequency ω radians per second. Typically, Sxx is a diagonal matrix.
- TF is the transfer function matrix at the output due to the noise sources. TF^H is the Hermitian transpose of the TF-matrix.

The output noise (Onoise) matrix is calculated from Syy with the formula:

$$Onoise = \sqrt{Syy}$$

The interpretation of the output noise matrix depends on the numbers of outputs, and on the presence and numbers of input reference nodes.

- When there is just one output, the result is the square root of spectrum of noise power at that output over the specified range of frequencies.
- When there are N>1 outputs, the result is an N×N matrix. The diagonal elements of the matrix are the square root of the self-noise spectrum for each output port (Onoise_*n*_*n*). The off-diagonal elements are the square roots of the cross-noise spectrum between each pair of output ports (Onoise_*n1*_*n2*). Each element is actually a vector showing the transfer functions at all the test frequencies.

DC Input Noise Matrix

When there are one or more inputs, the result includes the input referred noise transfer functions for the noise power at each output referred to each specified voltage or current input. The input-referred noise matrix (Inoise matrix) is calculated on the power spectral density equation:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$Inoise(out, in) = \frac{Onoise(out, out)}{\sqrt{TF(out, in) \times (TF(out, in))^*}}$$

Where Onoise is the output noise matrix and TF* is the complex conjugate of the transfer function matrix TF.

LNA-Associated AC Analysis

Additionally, the netlist can include voltage or current sources with an **.AC** entry to specify the magnitude and phase to be applied to the AC value. (See LNA Circuit Configuration for an example.) With a corresponding **.PRINT AC** statement, LNA computes AC transfer functions for any outputs listed in the **.PRINT AC** statement. If the **.PRINT AC** statement is omitted, no AC transfer functions are output.

TV Noise Technical Notes

The following topics describe the technical considerations regarding various TV noise issues such as sources, spectrum, and computations.

Sources of Noise

The noise output Onoise is a combination of thermal, shot, and flicker noise.

- *Thermal noise* is a variation in current due to random thermal motion of the electrons in physical resistors and bulk materials. Thermal noise is directly proportional to the absolute temperature.
- *Shot noise* is a fluctuation in the current across P-N junctions in diodes and transistors due to random barrier crossings by electrons and holes in the vicinity of the junction. Shot noise is associated with a direct current flow.
- *Flicker noise* is a random variation in current associated with contamination and crystal defects in semiconductors. Like shot noise, flicker noise is associated with a flow of direct current. Flicker noise generates a noise signal with energy concentrated at low frequencies; because of this 1/*f* frequency dependence, flicker noise is also called 1/*f* noise.

Noise Spectrum

The noise spectrum consists of the power spectrum of the coefficients for the harmonic frequencies.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The large-signal periodic steady-state of a circuit can be represented by the Fourier equation derived in harmonic balance. In a single large-signal circuit, the one-tone periodic steady state transfer function can be represented by the equation:

$$\sum_k C_k e^{j2\pi k f_1 t}$$

Where k is the harmonic number $-\infty < k < \infty$, f_1 is the large-signal steady-state frequency, and C_k is the coefficient giving the magnitude of the function at harmonic k.

The small-signal AC perturbation can be represented by the equation:

$$A e^{j2\pi f_i t}$$

Where A is a constant and f_i is the small-signal frequency.

The output response of the circuit is the product of the small-signal perturbation and the large-signal transfer function. The response can be represented by the equation:

$$\sum_k A C_k e^{-j2\pi t(k f_1 + f_i)}$$

The frequency of the response has been shifted by f_i. When constant A is normalized to 1 (one), the coefficient C_k gives the magnitude of the response at harmonic k.

In a circuit with two large-signal tones f_1 and f_2, the periodic steady state can be represented by the equation:

$$\sum_k \sum_l C_{k,l} e^{j2\pi t(k f_1 + l f_2)}$$

Where k is the harmonic number for frequency f_1 and l is the harmonic number for frequency f_2. The response of this circuit to the small-signal perturbation above can be represented by the equation:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\sum_{k}\sum_{l} AC_{k,l} e^{-j2\pi t(kf_1 + lf_2 + f_i)}$$

The frequency of the response has again been shifted by f_i. When constant A is normalized to 1 (one), the coefficient $C_{k,l}$ gives the magnitude of the response at the frequency that combines harmonic *k* of f_1 and harmonic *l* (letter *l*) of f_2.

Noise Computation Formulas

The calculation of the noise frequencies is a multiple-step procedure.

First, a set of output frequencies is generated from the swept output frequencies by applying the offsets on the **RELHARMVEC** list to the (*n*) corresponding frequencies on the **SS_TONES** list.

$$F_{output} = F_{swept} + \sum_{t=1}^{n} (relharmvec[t] \times SSTONES[t])$$

Here is an example that shows how the offsets work.

Suppose the appropriate output frequencies are 1001Hz, 1010Hz, and 1100Hz. This sequence could be specified using the **POI** sweep specification. However, this example uses the **RELHARMVEC** offset to calculate the appropriate frequencies. (Since only one offset is required, the example could use **RELHARMNUM** instead of **RELHARMVEC**.)

```
.TV_NOISE
+ DEC 1 1 100
+ SS_TONES=[1000]
+ RELHARMVEC=[1]
...
```

The decade (DEC) sweep generates F_{swept} values of 1, 10, and 100. An input frequency is calculated for each swept value. In this example with one **SS_TONES** frequency, there is only one product:

$(relharmvec[1] \times SS_TONES[1]) = (1 \times 1000) = 1000.$

Then:

$F_{output}[1] = 1 + 1000 = 1001$

$F_{output}[2] = 10 + 1000 = 1010$

$F_{output}[3] = 100 + 1000 = 1100$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The default for **RELHARMVEC** is a vector of zeros; with this value, the output frequencies are just the swept frequencies.

For the gain calculation, Nexxim TV Noise computes the input frequency F_{input} at each of the values of the output frequency F_{output} by adding sum of the products of each of the (*n*) steady-state frequencies F_{SS_TONES} multiplied by the corresponding **REFSIDEBAND** coefficient:

$$F_{input} = F_{output} + \sum_{t=1}^{n} (refsideband[t] \times SSTONES[t])$$

> **Note:**
>
> When an **IPROBE** device is specified, the netlist must also have the **REFSIDEBAND** list of coefficients for the **SS_TONES** frequencies in order to perform the conversion gain calculation. When no **IPROBE** device is specified, the **REFSIDEBAND** entry is optional; the default coefficient value is 1.

Here is a simplified example. This example uses a single output frequency.

```
.TV_NOISE
+ POI 1 1000000 // Single frequency for the sweep
+ SS_TONES=[1000, 2000, 3000]
+ RELHARMVEC=[0, 0, 0] // This is the default
+ REFSIDEBAND=[-1, 1, 2]
```

The resulting calculation is:

$SUM1 = (0 \times 1000) + (0 \times 2000) + (0 \times 3000) = 0$

$F_{output} = F_{swept} + SUM1 = 1000000 + 0 = 1000000$

$SUM2 = (-1 \times 1000) + (1 \times 2000) + (2 \times 3000) = 7000$

$F_{input} = F_{output} + SUM2 = 1000000 + 7000 = 107000$

Typically, the sweep specification generates several output frequencies, perhaps using **RELHARMVEC** coefficients other than zero.

The Onoise output vector is calculated for the specified output devices at the output frequencies. Nexxim combines the harmonic frequencies (from -SS_MAXK to +SS_MAXK, plus 0) of each of the steady-state tones (specified by **SS_TONES**) with the output frequencies to calculate a vector of internal noise frequencies that can contribute to the Onoise output.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

If any of these internal noise frequencies is zero, the flicker noise (1/*f*) component is set to 0.0, and a warning message is displayed.

The formula is too complicated to write explicitly. Here is a numerical example.

```
.TV_NOISE
+ POI 1 1000000 // Single frequency for the sweep
+ SS_TONES=[1001, 20000]
+ RELHARMVEC=[0, 0] // This is the default
+ SS_MAXK=[1, 2]+
```

Using the default for **RELHARMVEC**, F_{output} is just the swept frequency, one megahertz.

The F_{onoise} vector is calculated for every combination of harmonics (-1, 0, +1) for the 1001-Hz steady-state tone and harmonics (-2, -1, 0, +1, +2) for the 20000-Hz steady state tone. The resulting vector has $(3 \times 5) = 15$ elements:

```
1000000 + (0 × 20000) + (0 × 1001) = 1000000
1000000 + (0 × 1001) + (1 × 20000) = 1020000
1000000 + (0 × 1001) + (2 × 20000) = 1040000
1000000 + (0 × 1001) + (-2 × 20000) = 960000
1000000 + (0 × 1001) + (-1 × 20000)= 980000
1000000 + (1 × 1001) + (0 × 20000) = 1001001
1000000 + (1 × 1001) + (1 × 20000) = 1021001
1000000 + (1 × 1001) + (2 × 20000) = 1041001
1000000 + (1 × 1001) + (-2 × 20000) = 961001
1000000 + (1 × 1001) + (-1 × 20000) = 981001
1000000 + (-1 × 1001) + (0 × 20000) = 998999
1000000 + (-1 × 1001) + (1 × 20000) = 1018999
1000000 + (-1 × 1001) + (2 × 20000) = 1038999
1000000 + (-1 × 1001) + (-2 × 20000) = 958999
1000000 + (-1 × 1001) + (-1 × 20000) = 978999
```

Nexxim then calculates the noise output at these frequencies.

Periodic Transfer Function Computation Formulas

The netlist must specify the combination of harmonics of the steady state **SS_TONES** frequencies, using either **MAXSIDEBAND** or **SIDEBAND**.

When the **SS_TONES** group box has only one frequency, click the **MAXSIDEBAND** entry to specify the maximum harmonic of that frequency. The input frequencies is calculated using the formula:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$F_{input} = F_{output} + \{-K \times f1 \text{ to } K \times f1\}$

Where F_{output} is the output frequency (possibly swept), K is the value specified for **MAXSIDEBANDS**, and *f1* is the frequency specified in the **SS_TONES** entry.

Alternatively, specify a set of specific sidebands to use for the single output frequency, using the SIDEBAND entry. For example, if the SS_TONES frequency is *f1*, the entry

```
SIDEBAND=[1,3,-5]
```

specifies a calculation of the input frequencies using the following set of frequencies:

$F_{input} = F_{output} + \{(1 \times f1), (3 \times f1), (-5 \times f1)\}$

When the **SS_TONES** group box specifies more than one frequency, you must Click the **SIDEBAND** entry to specify the combinations of harmonics that are of interest as input frequencies (**MAXSIDEBANDS** is not valid with multiple **SS_TONES** frequencies). Each combination of harmonic numbers (positive integers, negative integers, or zero) contains one value for each of the frequencies in the **SS_TONES** group box. For example, if the **SS_TONES** group box contains two frequencies *f1* and *f2*, the entry

```
SIDEBAND=[1,0,2,-1,1,1]
```

specifies three combinations of harmonics of the two SS_TONES frequencies, and the input frequencies is calculated using the formula:

$F_{input} = F_{output} + \{(1 \times f1 + 0 \times f2), (2 \times f1 - 1 \times f2), (1 \times f1 + 1 \times f2)\}$

Floating Node Warning

Nexxim issues a warning message if the circuit contains floating nodes or nodes with single connections. Only nodes with a single branch connection that is both conservative and constitutive are flagged. For example, the controlling nodes in a VCVS have a constitutive/behavioral/relational connection to the controlled nodes, but not a physical/structural/conservative connection, and therefore are not flagged.

Floating Node Warning

Nexxim issues a warning message if the circuit contains floating nodes or nodes with single connections. Only nodes with a single branch connection that is both conservative and constitutive are flagged. For example, the controlling nodes in a VCVS have a constitutive/behavioral/relational connection to the controlled nodes, but not a physical/structural/conservative connection, and therefore are not flagged.

27 - Glossary

This section defines the terminology used in the Ansys desktop help topics. Terms are listed in alphabetical order.

A **B** **C**
D **E** **F**
G **H** **I**
J **K** **L**
M **N** **O**
P **Q** **R**
S **T** **U**
V **W** **X**
Y **Z**

Glossary: A

A/D

See Analog-to-Digital.

ACPR

Adjacent channel power ratio.

Active Substrate

A hybrid or multichip module substrate formed from a semiconductor. Termed active because components such as transistors can be fabricated directly into the substrate.

Active Trimming

The process of trimming components such as resistors while the circuit is under power. Such components are fabricated directly onto the substrate of a hybrid or multichip module, and the trimming is usually performed using a laser beam.

Active-High

A signal whose active state is considered to be a logic 1.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Active-Low

A signal whose active state is considered to be a logic 0.

Actuator

A transducer that converts an electronic signal into a physical equivalent. For example, a loudspeaker is an actuator which converts electronic signals into corresponding sounds.

Adaptive Hardware

Refers to devices which allow new design variations to be "compiles" in real-time, which may be thought of as dynamically creating subroutines in hardware (see also Virtual Hardware and Cache Logic).

Additive Process

A process in which conducting material is added to specific areas of a substrate. Groups of tracks, individual tracks, or portions of tracks can be built up to precise thicknesses by iterating the process multiple times with selective masking.

Address Bus

A unidirectional set of signals used by a computer to point to memory locations in which it is interested.

Analog

A continuous value that most closely resembles the real world and can be as precise as the measuring technique allows.

Analog Circuit

A collection of components used to generate or process analog signals.

Analog-to-Digital (A/D)

The process of converting an analog value into its digital equivalent.

Anisotropic Adhesive

Special adhesives which contain minute particles of conductive material. These adhesives find particular application with the flipped-chip techniques used to mount bare die on the substrates of hybrids, multichip modules, or circuit boards. The conducting particles are only brought in contact with each other at the sites where the raised pads on the die are pressed down over their corresponding pads on the substrate, thereby forming good electrical connections between the pads.

Anti-Fuse Technology

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A programmable logic device technology in which conducting paths (anti-fuses) are grown by applying signals of relatively high voltage and current to the device's inputs.

Anti-Pad

The area of copper etched away around a via or a plated through-hole on a power or negative signal plane, thereby preventing an electrical connection being made to that plane.

Application-Specific Integrated Circuit (ASIC)

A device whose function is determined for a particular application or group of applications.

Application-Specific Standard Part (ASSP)

Refers to an integrated circuit created by a device manufacturer using ASIC technologies, and for these components to be sold as standard parts to anybody who wants to buy them.

ASIC

See Application-Specific Integrated Circuit.

ASIC Cell

A logic function in the cell library defined by the manufacturer of an application-specific integrated circuit.

Assertion-Level Logic

Special symbols which are used to more precisely indicate the function of gates with active-low inputs.

ASSP

See Application-Specific Standard Part.

Asynchronous

A signal whose data is acknowledged or acted upon immediately, irrespective of any clock signal.

Atto

Unit qualifier (symbol = a) representing one millionth of one millionth of one millionth, or 10-18. For example, 3aS stands for 3 x 10-18 seconds.

Attenuator

A passive device used to reduce signal strength while maintaining proper input and output impedance.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Glossary: B

Backplane

The medium used to interconnect a number of circuit boards. Typically refers to a special, heavy-duty printed or discrete wired circuit board.

Ball Grid Array (BGA)

A packaging technology similar to a pad grid array, in which a device's external connections are arranged as an array of conducting pads on the base of the package. However, in the case of a ball grid array, small balls of solder are attached to the conducting pads.

Bandpass

The frequency limits between half-power points of a signal or filter.

Bare Die

An unpackaged integrated circuit.

Base

Refers to the number of digits in a numbering system. For example, the decimal numbering system is said to be base-10. May also be referred to as the "radix".

Basic Cell

A pre-defined group of unconnected components that is replicated across the surface of a gate array.

BER

Bit error rate.

BGA

See Ball Grid Array.

BiCMOS

A technology in which the function of each logic gate is implemented using low-power CMOS, while the output stage is implemented using high-drive bipolar transistors

Binary Encoding

A form of state assignment for state machines that requires the minimum number of state variables.

BiNMOS

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A relatively new low-voltage integrated circuit technology in which complex combinations of bipolar and NMOS transistors are used to form sophisticated output stages providing both high speed and low static power dissipation.

Bi-quinary

A system which utilizes two bases, base-2 and base-5, to represent decimal numbers. Each decimal digit is represented by the sum of two parts, one of which has the value of decimal zero or five, and the other the values of zero through four. The abacus is one practical example of the use of a bi-quinary system.

Bit

Abbreviation of binary digit.

Bipolar Junction Transistor (BJT)

A family of transistors.

Blackbox

Same as N-Port.

Blind Via

A via that is only visible from one side of the substrate.

Bobble

A small circle used on the inputs to a logic gate symbol to indicate an active-low input or control, or on the outputs to indicate a negation (inversion) or a complementary signal. Some engineers prefer to use the term bubble.

Bounce Pad

A special pattern etched onto the power or negative signal plane of a microwire circuit board to be used in conjunction with a laser beam which is employed to create blind vias. The laser beam evaporates the epoxy forming the outer layers of the board and continues down to the bounce pad which reflects, or bounces, it back up, thereby terminating the via.

Braze

To unite or fuse two pieces of metal by heating, or with a hard solder with a high melting point.

Bulk Storage

Refers to some form of media, typically magnetic, such as tape or a disk drive which can be used to store large quantities of information relatively inexpensively.

Buried Via

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A via used to link conducting layers internal to a substrate. Such a via is not visible from either side of the substrate.

Bundle

A set of signals related in some way that makes it appropriate to group them together for ease of representation or manipulation. May contain both scalar and vector elements; for example, {a,b,c,d[5:0]}.

Bus

A set of signals performing a common function and carrying similar data. Typically represented using vector notation; for example, address[7:0].

Byte

A group of eight binary digits, or bits.

Glossary: C

Capacitance

A measure of the ability of two adjacent conductors separated by an insulator to hold a charge when a voltage differential is applied between them. Capacitance is measured in units of Farads.

CDMA

Code division multiple access.

Cell Library

The collective name for the set of logic functions defined by the manufacturer of an application-specific integrated circuit. The designer decides which types of cells should be realized and connected together to make the device perform its desired function.

Ceramic

An inorganic, nonmetallic material, such as alumina, beryllia, steatite, or forsterite, which is fired at a high temperature and is often used in electronics as a substrate or to create component packages.

CGA

See Column Grid Array.

Channel

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(1)The area between two arrays of basic cells in a channeled gate array.

(2)The gap between the source and drain regions in a MOS transistor.

Channeled Gate Array

Application-specific integrated circuit organized as arrays of basic cells. The areas between the arrays are known as channels.

Channel-Less Gate Array

Application-specific integrated circuit organized as a single large array of basic cells. May also be referred to as a "sea of cells" or a "sea of gates" device.

Checksum

The final cyclic-redundancy-check value stored in a linear feedback shift register (or software equivalent). Also known as a "signature" in the guided-probe variant of functional test.

Chip

Popular name for an integrated circuit.

Chip-On-Board (COB)

A process in which unpackaged integrated circuits are physically and electrically attached to a circuit board, and are then encapsulated with a "glob" of protective material such as epoxy.

Chip-On-Chip (COC)

A process in which unpackaged integrated circuits are mounted on top of each other. Each die is very thin and it is possible to have over a hundred dies forming a 3D cube.

Chip-On-Flex (COF)

Similar to chip-on-board (COC), except that the unpackaged integrated circuits are attached to a flexible printed circuit.

Circuit Board

The generic name for a wide variety of interconnection techniques, which include rigid, flexible, and rigid-flex boards in single-sided, double-sided, multilayer, and discrete wired configurations.

CMOS

Logic gates constructed using both NMOS and PMOS transistors connected in a complementary manner.

Coaxial Cable

A conductor in the form of a central wire surrounded first by a dielectric (insulating) layer, and then by a conducting tube which serves to shield the central wire from external interference.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Coefficient of Thermal Expansion

Defines the amount a material expands and contracts due to changes in temperature. If materials with different coefficients of thermal expansion are bonded together, changes in temperature will cause shear forces at the interface between them.

Cofired Ceramic

A substrate formed from multiple layers of "green" ceramic that are bonded together and fired at the same time.

Column Grid Array (CGA)

A packaging technology similar to a pad grid array, in which a device's external connections are arranged as an array of conducting pads on the base of the package. However, in the case of a column grid array, small columns of solder are attached to the conducting pads.

Combinatorial

A digital function whose output value is directly related to the current combination of values on its inputs. Also known as combinational.

Compiled Cell Technology

A technique used to create portions of a standard cell application-specific integrated circuit. The masks used to create components and interconnections are directly generated from Boolean representations using a silicon compiler. May also be used to create data-path functions and memory functions.

Complementary Output

Refers to a function with two outputs carrying complementary logical values. One output is referred to as the true output and the other as the complementary output.

Complex Programmable Logic Device (CPLD)

A device that contains a number of PLA or PAL functions sharing a common programmable interconnection matrix.

Component

Components are items placed on schematics and layouts to represent electrical elements and sub circuits. The component information defines a signal-processing function or source, or secondarily a data source, data channel, or similar entity. Components have pins for connections, bitmaps in the project tree, and properties for simulation. The information that constitutes a component includes its component chooser bitmap, schematic symbol, layout footprint, pin properties, parameters and parameter values, and netlist string definition. A component can be associated with more than one simulation if it can be analyzed in more than one simulator.

Computer-Generated Hologram (CGH)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refers to a slice of quartz or similar material into which three-dimensional patterns are cut using a laser. The angles of the patterns cut into the quartz are precisely calculated for use in the optical communication strategy known as holographic interconnect. All of these calculations are performed by a computer, and the laser used to cut the three-dimensional patterns into the quartz is also controlled by a computer. Thus, the slice of quartz is referred to a computer-generated hologram.

Conductive Ink Technology

A technique in which tracks are screen printed directly onto the surface of a circuit board using a conductive ink.

Configurable Hardware

A product whose function may be customized once or a very few times (see also Reconfigurable Hardware, Remotely Reconfigurable Hardware, Dynamically Reconfigurable Hardware, and Virtual Hardware).

Conjunction

Propositions combined with an AND operator; for example, "You have a parrot on your head AND you have a fish in your ear." The result of a conjunction is true if all the propositions comprising that conjunction are true.

Conversion Loss

The ratio in dB of the IF output of a mixer to the RF input power. All conversion loss measurements and specification are normally based on the mixer being terminated on all ports and a stated LO signal power level being applied.

Cost Function

In an optimization setup, a cost function is based on goal values specified for at least one solution quantity. Optimetrics changes the design parameter values to fulfill the cost function.

CPLD

See Complex Programmable Logic Device.

CRC

See Cyclic Redundancy Check.

CSIC

See Customer-Specific Integrated Circuit.

Customer-Specific Integrated Circuit (CSIC)

An alternative and possibly more accurate name for an ASIC, but this term is rarely used in the industry and shows little indication of finding favor with the masses.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chemical Vapor Deposition (CVD)

A process for growing thin films on a substrate, in which a gas containing the required molecules is converted into a plasma by heating it to extremely high temperatures using microwaves. The plasma carries atoms to the surface of the substrate where they are attracted to the crystalline structure of the substrate. This underlying structure acts as a template. The new atoms continue to develop the structure to build up a layer on the substrate's surface.

Chemical Vapor Infiltration (CVI)

A process similar to chemical vapor deposition (CVD) but, in this case, the process commences by placing a crystalline powder of the required substance in a mold. Additionally, thin posts, or columns, can be pre-formed in the mold, and the powder can be deposited around them. When exposed to the same plasma as used in the CVD technique, the powder coalesces into a polycrystalline mass. After the CVI process has been performed, the posts can be dissolved leaving holes through the crystal for use in creating vias. CVI processes can produce layers twice the thickness of those obtained using CVD techniques at a fraction of the cost.

CW

Continuous wave; refers to an unmodulated sine-wave signal.

Cyclic Redundancy Check (CRC)

A calculation used to detect errors in data communications, typically performed using a linear feedback shift register. Similar calculations may be used for a variety of other purposes such as data compression.

Glossary: D

D/A

See Digital-to-Analog.

Data Bus

A bi-directional set of signals used by a computer to convey information from a memory location to the central processing unit and vice versa. More generally, a set of signals used to convey data between digital functions.

Data-Path Function

A well-defined function such as an adder, counter, or multiplier used to process digital data.

dBm

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Power level relative to 1mV rms.

DC Balance

Stream of data encoded to ensure an equal balance of 1 or 0 . 8b10b encoding has been developed to ensure DC balancing.

DC Coupling

A method of coupling two different circuits together, allowing them to share both the static DC and varying AC characteristics of a signal.

Decoder (digital)

A logic function that uses a binary value, or address, to select between a number of outputs and to assert the selected output by placing it in its active state.

Deep Sub-Micron

Typically taken to refer to integrated circuits containing structures which are smaller than 0.5 microns.

DeMorgan Transformation

The transformation of a Boolean expression into an alternate, and often more convenient, form.

Design

Designs are the building blocks of projects, and can be Circuit designs or 3D models. Designs consist of schematics or geometrical models, model data, solution setup information, output graphs and tables, and other pieces of information that go into describing simulation of electrical circuits. A design is the largest single simulatable entity in a project.

Design Variation

A single combination of variable values that is solved during a parametric or optimization setup.

Device

A discrete, separate electrical entity such as a diode, a capacitor or a packaged transistor.

Die

(1)An unpackaged integrated circuit. In this case, the plural of die is also die (in much the same way that "a shoal of herring" is the plural of "herring"). (2)A piece of metal with a design engraved or embossed on it for stamping onto another material, upon which the design appears in relief.

Die Separation

The process of separating individual die from the wafer by marking the wafer with a diamond scribe and fracturing it along the scribed lines.

Die Stacking

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A technique used in specialist applications in which several bare die are stacked on top of each other to form a sandwich. The die are connected together and then packaged as a single entity.

Dielectric Layer

(1) An insulating layer used to separate two signal layers.

(2) An insulating layer used to modify the electrical characteristics of an MCM-D substrate.

Diffusion Layer

The surface layer of a piece of semiconductor into which impurities are diffused to form P-type and N-type material. In addition to forming components, the diffusion layer may also be used to create embedded traces.

Digital

A value represented as being in one of a finite number of discrete states called quanta. The accuracy of a digital value is dependent on the number of quanta used to represent it.

Digital Circuit

A collection of logic gates used to process or generate digital signals.

Digital Signal Processor (DSP)

A primarily digital component used to process either digital or analog signals. In the case of the latter, the signal may first be conditioned, then converted into a digital equivalent using an analog-to-digital (A/D) converter function. The signal conditioning and A/D functions may either be external to the DSP or resident in the device. A typical DSP application might be the compression/decompression of video data.

Digital-to-Analog (D/A)

The process of converting a digital value into its analog equivalent.

Diode

A two-terminal device that only conducts electricity in one direction; in the other direction it behaves like an open switch. The term diode is typically taken to refer to a semiconductor device, although alternative implementations such as vacuum tubes are available.

Diode-Transistor Logic (DTL)

Logic gates implemented using particular configurations of diodes and bipolar junction transistors. For the majority of today's designers, diode-transistor logic is of historical interest only.

Discrete Device

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Typically taken to refer to an electronic component such as a resistor, capacitor, diode, or transistor that is presented in an individual package. More rarely, the term may be used in connection with a simple integrated circuit containing a small number of primitive gates.

Discrete Wire Board (DWB)

A form of circuit board in which a special computer-controlled wiring machine ultrasonically bonds extremely fine insulated wires into the surface layer of the board. This discipline has enjoyed only limited recognition, but may be poised to emerge as the technology-of-choice for high-speed designers.

Discrete Wire Technology

The technology used to fabricate discrete wire boards.

Doping

The process of inserting selected impurities into a semiconductor to create P-type or N-type material.

Double-Sided

A printed circuit board with tracks on both sides

DPSK

Differential phase-shift keying.

DQPSK

Differential quadrature phase-shift keying.

DRAM

See Dynamic RAM.

DSP

See Digital Signal Processor.

DTL

See Diode-Transistor Logic.

DUT

Device under test.

Dynamic Flex

A type of flexible printed circuit which is used in applications that are required to undergo constant flexing such as ribbon cables in printers.

Dynamic RAM (DRAM)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A memory device in which each cell is formed from a transistor-capacitor pair. Called dynamic because the capacitor loses its charge over time, and each cell must be periodically recharged if it is to retain its data.

Glossary: E

E2PROM

See electrically Erasable Programmable Read-Only Memory.

EBE

See Electron Beam Epitaxy.

ECL

See Emitter-Coupled Logic.

Edge port

A place in a layout or footprint geometry through which excitation signals enter and leave the structure.

Edge-Sensitive

An input that only affects a function when it transitions from one logic value to another.

EEPROM

See electrically Erasable Programmable Read-Only Memory.

electrically Erasable Programmable Read-Only Memory (EEPROM or E2PROM)

A memory device whose contents can be electrically programmed by the designer. Additionally, the contents can be electrically erased allowing the device to be reprogrammed. Also known as EEPROM and E2PROM.

Electromigration

(1)A process in which structures on an integrated circuit's substrate are eroded by the flow of electrons in much the same way as land is eroded by a river (also known as subatomic erosion). (2)The process of forming transistor-like regions in a semiconductor using an intense magnetic field.

Electron Beam Epitaxy (EBE)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A technique for creating thin films on substrates in precise patterns, in which the substrate is first coated with a layer of dopant material before being placed in a high vacuum. A guided beam of electrons is fired at the substrate causing the dopant to be driven into it, effectively allowing molecular-thin layers to be "painted" onto the substrate where required.

Electron Beam Lithography

An integrated circuit fabrication process in which fine beams of electrons are used to draw extremely high-resolution patterns directly into the resist without the use of a mask.

Electro-Static Discharge (ESD)

The process of moving around can generate static electricity. The term electro-static discharge refers to a charged person, or object, discharging static electricity. Although the current associated with such a static charge is low, the electric potential can be in the millions of volts and can severely damage electronic components. CMOS devices are particularly prone to damage from static electricity.

EM

Electromagnetic.

Emitter-Coupled Logic (ECL)

Logic gates implemented using particular configurations of bipolar junction transistors.

Enzyme

One of numerous complex proteins which are produced by living cells and catalyze biochemical reactions at body temperatures.

EPROM

See Erasable Programmable Read-Only Memory.

Equivalent Gate

A concept in which each type of logic function is assigned an equivalent gate value for the purposes of comparing functions and devices. However, the definition of an equivalent gate varies depending on who you're talking to.

Equivalent Integrated Circuit

A concept used to compare the component density supported by diverse interconnection technologies such as circuit boards, hybrids, and multichip modules

Erasable Programmable Read-Only Memory (EPROM)

A memory device whose contents can be electrically programmed by the designer. Additionally, the contents can be erased by exposing the die to ultraviolet light through a quartz window mounted in the top of the component's package.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ESD

See Electro-Static Discharge.

Etching

The process of selectively removing any material not protected by a resist using an appropriate solvent or acid. In some cases the unwanted material is removed using an electrolytic process.

Eutectic Bond

A bond formed when two pieces of metal, or metal-coated materials, are pressed together and vibrated at ultrasonic frequencies.

Euler Angles

Euler angles are used in Ansoft software to carry out a coordinate transformation from one coordinate system to another. The Swiss mathematician and physicist Leonhard Euler first developed the classical rotation theorem to describe rotations in 3D space. The angles used are Euler angles and can be used to describe any 3D rotation. These angles, given by (ö, è, ø) represent a series of sequential rotations about two axis of the coordinate system. The first rotation (ö) represents a rotation about the Z-axis of the source coordinate system (X, Y, Z) which results in an intermediate coordinate system denoted by (X'', Y'', Z''). The second rotation (è) represents a rotation of the intermediate coordinate system about the X''-axis, again resulting in an intermediate coordinate system denoted by (X', Y', Z'). The third and final rotation (ø) represents a rotation about the Z'-axis of the intermediate coordinate system. The final rotation completes the rotation and results in the "target" coordinate system denoted (X, Y, Z).

For further information see, Eric W. Weisstein, "Euler Angles." From *MathWorld* - A Wolfram Web Resource.

http://mathworld.wolfram.com/EulerAngles.html .

Eye Diagram

Eye diagrams are commonly used to analyze signal integrity issues with communications channels. The bits are superimposed at unit intervals representing the duration of each bit.

Eye Mask

The size of the eye opening in the center of an eye diagram indicates the amount of voltage and timing margin available to sample this signal. Thus, for a particular electrical interface, a fixed reticule or window could be placed over the eye diagram showing how the actual signal compares to minimum criteria window, know as the eye mask. If a margin rectangle with width equal to the required timing margin and height equal to the required voltage margin fits into the opening, then the signal has adequate margins. Voltage margin can often be traded off for timing margin.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Glossary: F

Fan-Out Via

In the case of surface mount devices attached to double-sided or multilayer boards, each component pad is usually connected by a short length of track to a via which forms a link to other conducting layers, and this via is known as a fan-out via. The term fan-out via is generally also taken to include any vias that fall inside the device's footprint (under the body of the device). Some designers attempt to differentiate these vias from those that fall outside the device's footprint by referring to them as fan-in vias, but this is not an industry-standard term.

Falling-Edge

A transition from a logic 1 to a logic 0. Also known as a negative edge.

Falltime

The time it takes for a waveform to transition from the high logic state to the low logic state. Falltime is usually measured from 90% of the total signal swing to 10% of the signal swing.

Fan-In and Fan-Out Vias

In the case of surface mount devices attached to double-sided or multilayer boards, each component pad is usually connected by a short length of track to a via which forms a link to other conducting layers, and this via is known as a fan-out via. The term fan-out via is generally also taken to include any vias that fall inside the device’s footprint (under the body of the device). Some designers attempt to differentiate these vias from those that fall outside the device’s footprint by referring to them as fan-in vias, but this is not an industry-standard term.

Femto

Unit qualifier (symbol = f) representing one thousandth of one millionth of one millionth, or 10-15. For example, 3fS stands for 3 x 10-15 seconds.

FET

See Field-Effect Transistor.

Field-Effect Transistor (FET)

A transistor whose control, or gate, signal creates an electro-magnetic field which turns the transistor ON or OFF.

Field-Programmable Gate Array (FPGA)

A programmable logic device which is more versatile than traditional programmable devices such as PALs and PLAs, but less versatile than an application-specific integrated circuit. Some

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

field-programmable gate arrays use fuses such as those found in programmable logic devices, but others are based on SRAM equivalents.

Field-Programmable Interconnect Chip (FPIC)

An alternative, proprietary name for a field-programmable interconnect device (FPID).

Field-Programmable Interconnect Device (FPID)

A device which is used to connect logic devices together, and which can be dynamically reconfigured in the same way as standard SRAM-based FPGAs. Because each FPID may have around 1,000 pins, only a few such devices are typically required on a circuit board.

Filter

Filters are used to block out undesired frequencies. There are two types of filters: band pass and rejection. A band pass filter permits only the desired range to pass through, while the rejection filter attenuates an undesired range of frequencies.

Firmware

Refers to programs, or sequences of instructions, that are hard-coded into non-volatile memory devices.

First-In First Out (FIFO)

A memory device in which data is read out in the same order that it was written in.

Flash (e.g., Gold Flash)

An extremely thin layer of gold with a thickness measured on the molecular level which is either electroplated or chemically plated onto a surface.

FLASH Memory

An evolutionary technology that combines the best features of the EPROM and E2PROM technologies. The name FLASH is derived from the technology's fast reprogramming time compared to EPROM.

Flex

See Flexible Printed Circuit.

Flexible Printed Circuit (FPC or Flex)

A specialist circuit board technology, often abbreviated to "flex", in which tracks are printed onto flexible materials. There are a number of flavors of flex, including static flex, dynamic flex, and rigid flex.

Flipped Chip

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A generic name for processes in which unpackaged integrated circuits are mounted directly onto a substrate with their component-sides facing the substrate.

Flipped TAB

A combination of flipped chip and tape automated bonding.

Footprint

The area occupied by a device mounted on a substrate.

Fourier Analysis

A mathematical procedure used to determine the collection of sine waves (differing in frequency and amplitude) that is necessary to make up the square-wave pattern under consideration.

FPC

See Flexible Printed Circuit.

FPGA

See Field-Programmable Gate Array.

FPIC

See Field-Programmable Interconnect Chip.

FPID

See Field-Programmable Interconnect Device.

FR4

The most commonly used insulating base material for circuit boards. FR4 is made from woven glass fibers which are bonded together with an epoxy. The board is cured using a combination of temperature and pressure which causes the glass fibers to melt and bond together, thereby giving the board strength and rigidity. The first two characters stand for "Flame Retardant". FR4 is technically a form of fiberglass, and some people do refer to these composites as fiberglass boards or fiberglass substrates, but not often.

Free-Space Optical Interconnect

A form of optical interconnect in which laser-diode transmitters communicate directly with photo-transistor receivers without employing optical fibers or optical waveguides.

Full Custom

An application-specific integrated circuit in which the designer has complete control over every mask layer used to fabricate the device. The manufacturer does not provide a cell library or pre-fabricate any components on the substrate.

Functional Latency

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refers to the fact that, at any given time, only a portion of the logic functions in a device or system are typically active (doing anything useful).

Functional Test

A test strategy in which signals are applied to a circuit's inputs, and the resulting signals which are observed on the circuit's outputs are compared to known good values.

Fuse

See Fusible-Link Technology.

Fusible-Link Technology (Fuse)

A programmable logic device technology which employs links called fuses. Individual fuses can be removed by applying pulses of relatively high voltage and current to the device's inputs.

Fuzz-Button

A small ball of fibrous gold used in one technique for attaching components such as multichip modules to circuit boards. Fuzz-buttons are inserted between the pads on the base of the package and their corresponding pads on the board. When the package is forced against the board, the fuzz-buttons compress to form good electrical connections. Even when the pressure is removed, the fuzz-buttons act in a similar manner to Velcro and continue to hold the component in place. One of the main advantages of the fuzz-button approach is that it allows broken devices to be quickly removed and replaced. Even though fuzz-button technology would appear to be inherently unreliable, it is used in such devices as missiles, so one can only assume that it is fairly robust.

Glossary: G

Gain

The ratio of the power output to the power input of the amplifier in dB. The gain is specified in the linear operating range of the amplifier where a 1 dB increase in input power gives rise to a 1 dB increase in output power. Gain = 20*log(S21)

Gate Array

An application-specific integrated circuit in which the manufacturer pre-fabricates devices containing arrays of unconnected components organized in groups called basic cells. The designer specifies the function of the device in terms of cells from the cell library and the connections between them, and the manufacturer then generates the masks used to create the metallization layers.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Glue Logic

Simple logic gates used to interface more complex functions together.

Gold Flash

An extremely thin layer of gold with a thickness measured on the molecular level which is either electroplated or chemically plated onto a surface.

Goal

In an optimization setup, a goal is the value of a solution quantity that you want to be achieved during the optimization. A goal is represented as one row in the cost function table. Each cost function defined in an optimization setup must include at least one goal.

Gray Code

A sequence of binary values in which each pair of adjacent values differs by only a single bit; for example, 00, 01, 11, 10.

Green Ceramic

Unfired, malleable ceramic.

Ground Bounce

Momentary noise on the device negative signal plane causing a 0 signal to erroneously be seen as a 1. Ground bounce is caused by simultaneously switching outputs (SSO).

Guard Condition

A Boolean expression associated with a state transition in a state diagram or state table. The expression must be satisfied for that state transition to be executed.

Guided Probe

A form of functional test in which the operator is guided in the probing of a circuit to isolate a faulty component or track.

Guided-Wave

A form of optical interconnect, in which optical waveguides are fabricated directly on the substrate of a multichip module. These waveguides can be created using variations on standard opto-lithographic thin-film processes.

Glossary: H

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Hard Macro (Macro Cell)

A logic function defined by the manufacturer of an application-specific integrated circuit. The function is described in terms of the simple functions provided in the cell library and the connections between them. The manufacturer also defines how the cells forming the macro will be assigned to basic cells and the routing of tracks between the basic cells.

Hardware

Generally understood to refer to any of the physical portions constituting an electronic system, including components, circuit boards, power supplies, cabinets, and monitors.

Harmonic

Integer multiples of the fundamental frequency of interest commonly produced by a non-linear amplifier.

Harmonic Balance

A frequency domain analysis technique for simulating nonlinear circuits and systems. This method assumes the input stimulus consists of a relatively few steady state sinusoids. Therefore the solution can be expressed as a sum of steady state sinusoids that includes the input frequencies in addition to any significant harmonics or mixing terms. A circuit with a single input source will require a single tone HB simulation. The harmonic balance simulation is ideal for situations where transient simulation methods are problematic, such as:

- Components modeled in frequency domain, for instance (dispersive) transmission lines
- Circuit time constants large compared to period of simulation frequency
- Circuits with lots of reactive components

Harmonic balance methods, therefore, are the best choice for most microwave circuits excited with sinusoidal signals (e.g., mixers, power amplifiers).

Harmonic Tuning

Impedance-matching at the harmonic frequencies for enhanced performance and efficiency.

Hertz (Hz)

Unit of frequency. One Hertz equals one cycle, or one oscillation, per second.

Heterojunction

The interface between two regions of dissimilar semiconductor materials. The interface of a hetrojunction has naturally occurring electric fields which can be used to accelerate electrons, and transistors created using hetrojunctions can switch much faster than their counterparts of the same size.

Hexadecimal

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Base-16 numbering system. Each hexadecimal digit can be directly mapped onto four binary digits, or bits.

High Impedance State

The state on a signal that is not being driven by any value. A high-impedance state is indicated by the character Z.

Holographic Interconnect

A form of optical interconnect based on a thin slice of quartz, into which three-dimensional images are cut using a laser beam. Thus, the quartz is referred to as a computer-generated hologram, and this interconnection strategy is referred to as holographic.

Homojunction

An interface between two regions of semiconductor having the same basic composition but opposing types of doping. Homojunctions dominate current processes because they are easier to fabricate than heterojunctions.

Hybrid

An electronic sub-system in which a number of integrated circuits (packaged and/or unpackaged) and discrete components are attached directly to a common substrate. Connections between the components are formed on the surface of the substrate, and some components such as resistors and inductors may be fabricated directly onto the substrate.

Hydrogen Bond

The electrons in a water molecule are not distributed equally, because the oxygen atom is a bigger, more robust fellow which grabs more than its fair share. The end result is that the oxygen atom has an overall negative charge, while the two hydrogen atoms are left feeling somewhat on the positive side. This unequal distribution of charge means that the hydrogen atoms are attracted to anything with a negative bias; for example, the oxygen atom of another water molecule. The resulting bond is known as a hydrogen bond.

Hz

See Hertz.

Glossary: I

IBIS

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

IBIS (I/O Buffer Information Specification) is a standard for electronic behavioral specifications of integrated circuit input/output analog characteristics. The core of an IBIS model is a table of current versus voltage and I/O switching timing information. Xilinx IBIS models contain tables for typical, slow/MIN (weak transistors, high temperature, low voltage) and fast/MAX (strong transistors, low temperature, high voltage) process corners. IBIS models are derived from SPICE simulation results and/or lab measurements. The benefit for IBIS model user is fast and accurate simulation while preserving IC vendors intellectual property (information about circuit and process details).

IC

See Integrated Circuit.

ICR

See In-Circuit Reconfigurable.

Impedance

The resistance to the flow of current caused by resistive, capacitive, or inductive devices (or undesired elements) in a circuit.

Impedance Matching

Function of ensuring that the impedance of the transmitter, the receiver, and the transmission line are identical. Mismatched impedances could result in signal reflections, ringing, overshoot, undershoot, and stairstep waveforms.

Incident Voltage

The user specified voltage at an input.

In-Circuit Reconfigurable (ICR)

An SRAM-based, or similar component which can be dynamically reprogrammed on-the-fly while remaining resident in the system.

Inductance

A property of a conductor that allows is to store energy in a magnetic field which is induced by a current flowing through it. Inductance is measured in units of Henries (the base unit is a Henry).

Insertion Loss

Insertion Loss (dB) is defined as the drop in power as a signal enters an RF component. This value not only includes the reflected incoming signal, but also the attenuation of the component.

In-System Programmable (ISP)

An E2-based, FLASH-based, or similar component which can be reprogrammed while remaining resident on the circuit board.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Integrated Circuit (IC)

A device in which components such as resistors, capacitors, diodes, and transistors are formed on the surface of a single piece of semiconductor.

Ion

A particle formed when an electron is added to, or subtracted from, a neutral atom or group of atoms.

Ion Implantation

A process in which beams of ions are directed at a semiconductor to alter its type and conductivity in certain regions.

Isolation

The ratio (expressed in dB) of the power level at one port compared to the resulting power level of the output port.

ISP

See In-System Programmable.

Glossary: J

JEDEC

See Joint Electronic Device Engineering Council.

Jitter

The jitter of a periodic signal is the delay between the expected transition of the signal and the actual transition. Jitter is a zero mean random variable. When worst case analysis is undertaken the maximum value of this random variable is used.

Jitter Tolerance

Jitter tolerance is defined as the peak-to-peak amplitude of sinusoidal jitter applied on the input that causes a predefined, acceptable loss at the output. For example jitter applied to the input of an OC-N equipment interface that causes an equivalent 1dB optical power penalty.

Jitter Transfer

Jitter transfer is defined as the ratio of jitter on the output of a device to the jitter applied on the input of the device, versus frequency. Jitter transfer is important in applications where the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

system is utilized in a loop-timed mode, where the recovered clock is used as the source of the transmit clock.

Joint Electronic Device Engineering Council (JEDEC)

A council which creates, approves, arbitrates, and oversees industry standards for electronic devices. In programmable logic, the term JEDEC refers to a textual file containing information used to program a device. The file format is a JEDEC approved standard and is commonly referred to as a JEDEC file.

Jumper

A small piece of wire used to link two tracks on a circuit board.

Glossary: K

Karnaugh Map

A graphical technique for representing a logical function. Karnaugh maps are often useful for the purposes of minimization.

Kelvin Scale of Temperature

A scale of temperature which was invented by the British mathematician and physicist William Thomas, first Baron of Kelvin. Under the Kelvin, or absolute, scale of temperature, 0 K (corresponding to -273oC) is the coldest possible temperature and is known as absolute zero.

Kilo

Unit qualifier (symbol = K) representing one thousand, or 103. For example, 3KHz stands for 3 x 103 Hertz.

Kirchhoff's current law

The sum of all currents entering a node is equal to the sum of all currents leaving the node.

Kirchhoff's voltage law

The directed sum of the electrical potential differences around a circuit must be zero.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Glossary: L

Laminate

A material constructed from thin layers or sheets. Often used in the substrate of circuit boards.

Large-Scale Integration (LSI)

Refers to the number of logic gates in a device. By one convention, large-scale integration represents a device containing 100 to 999 gates.

Laser Diode

A special semiconductor diode which emits a beam of coherent light.

Last-In First-Out (LIFO)

A memory device in which data is read out in the reverse order to which it was written in.

Latch-Up Condition

A condition in which a circuit draws uncontrolled amounts of current, and certain voltages are forced, or "latched-up", to some level. Particularly relevant in the case of CMOS devices which can latch-up if their operating conditions are violated.

Lateral Thermal Conductivity

Good lateral thermal conductivity means that the heat generated by components mounted on a substrate can be conducted horizontally across the substrate and out through its leads.

Layers (and Stackup)

Layers are used in the layout editor to organize and isolate sets of geometry or other visual indicators. Signal, Negative Signal, and Dielectric are common physical layers, while Symbol (to show component symbols in layout), Error, and Ratsnest (to show connectivity) are non-physical layers. The stackup contains additional properties of the physical layers, such as material, thickness, and elevation. Geometrical information on these layers is used to generate masks for manufacturing.

LDMOS

Laterally diffused metal oxide semiconductor.

Lead

(1) A metallic element (chemical symbol Pb).

(2) A metal conductor used to provide a connection from the inside of a device package to the outside world for soldering or other mounting techniques. Leads are also commonly called pins.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Lead Frame

A metallic frame containing leads and a base to which an unpackaged integrated circuit is attached. After encapsulation, the outer part of the frame is cut away and the leads are bent into the required shapes.

Lead Through-Hole (LTH)

A technique for populating circuit boards in which component leads are inserted into plated through-holes. Often abbreviated to "through-hole" or "thru-hole". When all of the components have been inserted, they are soldered to the board, usually using a wave soldering technique.

Level-Sensitive

An input whose effect on a function depends only on its current logic value or level, and is not directly related to it transitioning from one logic value to another.

LFSR

See Linear Feedback Shift Register.

Library

A library is a collection of one or more components or component dependencies (materials, symbols, footprints, or padstacks) stored in a container file. A library must be configured to a circuit before use, either by the user (manually) or by loading technology files (automatically). User libraries and Personal libraries are used to add foundry support, user defined models, and any custom set of components or simulation models. See the Library Overview topic for more information.

LIFO

See Last-In First-Out.

Limiting Level

The input power level when the output power is goes into compression and no longer becomes linear.

Line

Used to refer to the width of a track; for example, "This track has a line-width of 0.12mm."

Linear Feedback Shift Register (LFSR)

A shift register whose data input is generated as an XOR or XNOR of two or more elements in the register chain.

Linearity

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Describes how closely an output signal is to a perfectly scaled multiple of a corresponding input signal.

Load Pull

Automated measurement of RF performance of a device under test (at a constant frequency) by varying the source and load impedance presented to the device

Logic Function

A mathematical function that performs a digital operation on digital data and returns a digital value.

Logic Gate

The physical implementation of a logic function.

Logic Synthesis

A process in which a program is used to optimize the logic used to implement a design.

Low-Fired Cofired

Similar in principle to standard cofired ceramic substrate techniques. However, low-fired cofired uses modern ceramic materials with compositions that allow them to be fired at temperatures as low as 650oC to 750oC. Firing at these temperatures in an inert atmosphere such as nitrogen allows non-refractory metals such as copper to be used to create tracks.

LSI

See Large-Scale Integration.

LTH

See Lead Through-Hole.

Glossary: M

Mask Programmable

A device such as a read-only memory which is programmed during its construction using a unique set of masks.

Maximal Displacement

A linear feedback shift register whose taps are selected such that changing a single bit in the input data stream will cause the maximum possible disruption to the register's contents.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Maximal Length

A linear feedback shift register that sequences through (2n - 1) states before returning to its original value.

Maxterm

The logical OR of the inverted variables associated with an input combination to a logical function.

MBE

See Molecular Beam Epitaxy.

MCM

See Multichip Module.

Medium-Scale Integration (MSI)

Refers to the number of logic gates in a device. By one convention, medium-scale integration represents a device containing 13 to 99 gates.

Meg

Unit qualifier (symbol = M) representing one million, or 106. For example, 3MHz stands for 3 x 106 Hertz.

Metallization Layer

A layer of conducting material on an integrated circuit that is selectively deposited or etched to form connections between logic gates. There may be several metallization layers separated by dielectric (insulating) layers.

Metal-Oxide Semiconductor (MOS)

A family of transistors where the controlling terminal is connected to a plate that is separated from the semiconduxtor by an insulating layer. This plate was originally made out metal (we now use polysilicon, or poly) and the insulator is an oxide -- hence the "metal-oxide" appellation.

Meta-Stable

A condition where the outputs of a logic function are oscillating uncontrollably between undefined values.

Micro

Unit qualifier (symbol = u) representing one millionth, or 10-6. For example, 3uS stands for 3 x 10-6 Seconds.

Microwave

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The range in the electromagnetic spectrum from 300 MHz to 30 GHz (with corresponding wavelengths from 100 cm to 1 cm).

Microwire

A trade name for one incarnation of discrete wire technology. Microwire augments the main attributes of multiwire with laser-drilled blind vias, allowing these boards to support the maximum number of tracks and components.

Millman's method

The voltage on the ends of branches in parallel is equal to the sum of the currents flowing in every branch divided by the total equivalent conductance.

Minterm

The logical AND of the variables associated with an input combination to a logical function.

MMIC

Monolithic Microwave Integrated Circuit

Mod or Modulus

Refers to the number of states that a function such as a counter will pass through before returning to its original value. For example, a function that counts from 00002 to 11112 has a modulus of 16 and would be called a modulo-16 or mod-16 counter.

Molecular Beam Epitaxy (MBE)

A technique for creating thin films on substrates in precise patterns, in which the substrate is placed in a high vacuum, and a guided beam of ionized molecules is fired at it, effectively allowing molecular-thin layers to be "painted" onto the substrate where required.

MOS

See Metal-Oxide Semiconductor.

MOSFET

Metal-oxide semiconductor field-effect transistor.

MSI

See Medium-Scale Integration.

Multichip Module (MCM)

A generic name for a group of advanced interconnection and packaging technologies featuring unpackaged integrated circuits mounted directly onto a common substrate.

Multilayer

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A printed circuit board constructed from a number of very thin single-sided and/or double-sided boards which are bonded together using a combination of temperature and pressure.

Multiplexer (digital)

A logic function that uses a binary value, or address, to select between a number of inputs and conveys the data from the selected input to the output.

Multiwire

A trade name for one incarnation of discrete wire technology.

Multizone

A stackup that contains zones or areas, each of which contains a subset of the layers in the stackup.

Mutual Capacitance

The capacitance between two conductors (one considered aggressor, the other victim) when all other conductors are connected together and then regarded as an ignored ground. It describes the amount of coupling due to the electric field. The mutual capacitance will inject an often undesired current into the victim line proportional to the rate of change of voltage on the aggressor line. Mutual Capacitance it a cause of crosstalk.

Mutual Inductance

The inductance between two conductors (one considered aggressor, the other victim) placed close enough that the magnetic field induced by a current flowing into the aggressor line encompasses the victim. The mutual inductance will inject an often undesired voltage noise onto the victim proportional to the rate of change of the current on the aggressor line.

Glossary: N

Nano

Unit qualifier (symbol = n) representing one thousandth of one millionth, or 10^{-9}. For example, 3nS stands for 3 x 10^{-9} Seconds.

Nanobot

A molecular-sized robot (see Nanotechnology below)

Nanophase Materials

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A form of matter which was only recently discovered, in which small clusters of atoms form the building blocks of a larger structure. These structures differ from those of naturally occurring crystals, in which individual atoms arrange themselves into a lattice.

Nanotechnology

Nanotechnology is an elusive term that is used by different research-and-development teams to refer to whatever it is that they're working on at the time. However, irrespective of their particular area of interest, nanotechnology always refers to something extremely small. One of the more exciting branches of nanotechnology that has been suggested as having potential in the future is that of micro-miniature electronic products that assemble themselves.

N-channel MOS (NMOS)

Refers to the order in which the semiconductor is doped in a MOS device. That is, which structures are constructed as N-type versus P-type material.

Negative-Edge

A transition from a logic 1 to a logic 0. Also known as a falling edge.

Negative Ion

An atom or group of atoms with an extra electron.

Negative Logic

A convention which dictates the relationship between logical values and the physical voltages used to represent them. The more negative potential is considered to represent TRUE and the more positive potential is considered to represent FALSE. Also known as negative true logic.

Negative Resist

A process where ultraviolet radiation passing through the transparent areas of a mask causes the resist to be cured. The uncured areas are then removed using an appropriate solvent.

Negative Signal Plane

A conducting layer in, or on, a substrate providing a grounding, or reference, point for components. There may be several negative signal planes separated by insulating layers.

Negative-True

A convention which dictates the relationship between logical values and the physical voltages used to represent them. The more negative potential is considered to represent TRUE and the more positive potential is considered to represent FALSE. Also known as negative logic.

Nibble

See Nybble.

NMOS

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See N-channel MOS.

Noise Figure / Noise Factor

The Noise Factor of a transducer at a specified input frequency is the ratio of (a/b) where “a and b” are:

(a) the available Signal to Noise Ratio (SNR) at the signal generator terminals per unit bandwidth when the temperature of the input termination (generator or source) is 290 K and the bandwidth is limited by the transducer, to

(b) the available SNR per unit bandwidth at the output terminals of the transducer.

Traditionally:

Noise Figure NF = 10 log(noise factor F)

Noise Temperature (T_e) = T_o(F - 1)

Where:

- T_e is the noise temperature
- T_o is standard temperature 290 K
- F is noise factor

Noise Floor

This is defined as the lowest possible input to a chain or a component, that will produce a detectable output.

Noise Temperature

This is the amount of thermal noise in a chain or a component. Noise Factor and Noise Temperature (T_e) are related as follows:

Noise Temperature (T_e) = (F - 1)T_o

Where:

- T_e is the noise temperature
- T_o is standard temperature 290 K
- F is noise factor

For example, a noise figure of 2.0 dB is equivalent to a Noise Temperature of 170 K.

Nominal Design

The original model on which Optimetrics analyses are based.

Non-Volatile

A memory device which does not lose its data when power is removed from the system.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Non-Volatile RAM

A device which is generally formed from an SRAM die mounted in a package with a very small battery, or as a mixture of SRAM and EEPROM cells fabricated on the same die.

Norton's theorem

Any two-terminal collection of voltage sources and resistors is electrically equivalent to an ideal current source in parallel with a single resistor.

NPN (N-type - P-type - N-type)

Refers to the order in which the semiconductor is doped in a bipolar junction transistor.

N-Port

An N-port component is typically characterized by network parameter data contained in the N-port itself in spreadsheet form or (more usually) by network parameter data contained in an external file.

N-type

A piece of semiconductor doped with impurities that make it amenable to donating electrons.

Nybble

A group of four binary digits, or bits (also called a nibble).

Glossary: O

Octal

Base-8 numbering system. Each octal digit can be directly mapped onto three binary digits, or bits.

Ohm

Unit of resistance. The Greek letter omega, *, is often used to represent ohms; for example, 1M* indicates one million ohms.

Ohm's law

The voltage across a resistor is the product of its resistance and the current flowing through it.

One-Hot Encoding

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A form of state assignment for state machines in which each state is represented by an individual state variable.

One-Time Programmable

A device such as a PAL, PLA, or PROM that can only be programmed a single time and whose contents cannot be subsequently erased.

Optical Interconnect

The generic name for interconnection strategies based on opto-electronic systems, including fiber-optics, free-space, guided-wave, and holographic techniques.

Optical Lithography

A process in which radiation at optical wavelengths (usually in the ultraviolet range) is passed through a mask, and the resulting patterns are projected onto a layer of resist coating the substrate material.

Optical Mask

A sheet of material carrying patterns that are either transparent or opaque to the wavelengths used in an optical-lithographic process. Such a mask can carry hundreds of thousands of fine lines and geometric shapes.

Opto-Electronic

Refers to a system which combines optical and electronic components.

Organic Resist

A material which is used to coat a substrate and is then selectively cured to form an impervious layer. These materials are called organic because they are based on carbon compounds as are living creatures.

Organic Solvent

A solvent for organic materials such as those used to form organic resists.

Organic Substrate

Substrate materials such as FR4, in which woven glass fibers are bonded together with an epoxy. These materials are called organic because epoxies are based on carbon compounds as are living creatures.

Overglassing

One of the final stages in the integrated circuit fabrication process in which the entire surface of the wafer is coated with a layer of silicon dioxide or silicon nitride. This layer may also be referred to as the barrier layer or the passivation layer. An additional lithographic step is required to pattern holes in this layer to allow connections to be made to the pads.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Glossary: P

Package

Leaded assembly (inside of which one or more dies are mounted and connected) for use in larger circuits.

Pad

An area of metallization on a substrate used for probing or to connect to a via, plated through-hole, or an external interconnect.

Pad Grid Array (PGA)

A packaging technology in which a device's external connections are arranged as an array of conducting pads on the base of the package.

Padstack

Refers to any pads, anti-pads, and thermal relief pads associated with a via or a plated through-hole as it passes through the layers forming the substrate.

Padcap

A special flavor of circuit board used for high-reliability military applications. Distinguished by the fact that the outer surfaces of the board have pads but no tracks. Signal layers are only created on the inner planes, and tracks are connected to the surface pads by vias.

Parallel-In Serial-Out (PISO)

Refers to a shift register in which the data is loaded in parallel and read out serially.

Parasitic Effects

The effects caused by undesired resistance, capacitance, or inductance inherent in the material or topology of a track or component.

Passive Trimming

A process in which a laser beam is used to trim components such as thick-film and thin-film resistors on an otherwise unpopulated and unpowered hybrid or multichip module substrate. Probes are placed at each end of a component to monitor its value while the laser evaporates some of the material forming the component.

Pass-Transistor Logic

A technique for connecting MOS transistors such that data signals pass between their source and drain terminals. Pass-transistor logic minimizes the number of transistors required to

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

implement a function, and is typically employed by designers of cell libraries or full-custom integrated circuits.

PGA

See either Pad Grid Array or Pin Grid Array.

Photo-Transistor

A special transistor which converts an optical input in the form of light into an equivalent electronic signal in the form of a voltage or current.

Pico

Unit qualifier (symbol = p) representing one millionth of one millionth, or 10^{-12}. For example, 3pS stands for 3 x 10^{-12} Seconds.

PIN Diode

A diode where a thin layer exists between the N and P regions. Rectification with pin diodes is limited. They actually behave more like a variable resistor that changes based upon the DC bias.

Pin Grid Array (PGA)

A packaging technology in which a device's external connections are arranged as an array of conducting leads, or pins, on the base of the package.

PISO

See Parallel-In Serial-Out.

Place-Value

Refers to a numbering system in which the value of a particular digit depends both on the digit itself and its position in the number.

PlasmA gaseous state in which the atoms or molecules are dissociated to form ions.

Plated Through-Hole (PTH)

(1) A hole in a double-sided or multilayer board that is used to accommodate a through-hole component lead and is plated with copper.

(2) An alternative name for the lead through-hole technique for populating circuit boards in which component leads are inserted into plated through-holes.

PMOS (P-channel MOS)

Refers to the order in which the semiconductor is doped in a MOS device. That is, which structures are constructed as P-type versus N-type material.

PNP (P-type - N-type - P-type)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refers to the order in which the semiconductor is doped in a bipolar junction transistor.

Polysilicon Layer

An internal layer in an integrated circuit used to create the gate electrodes of MOS transistors. In addition to forming gate electrodes, the polysilicon layer can also be used to interconnect components. There may be several polysilicon layers separated by dielectric (insulating) layers.

Populating

The act of attaching components to a substrate.

Positive Logic

A convention which dictates the relationship between logical values and the physical voltages used to represent them. The more positive potential is considered to represent TRUE and the more negative potential is considered to represent FALSE. Also known as positive true logic.

Positive Resist

A process where radiation passing through the transparent areas of a mask causes previously cured resist to be degraded. The degraded areas are then removed using an appropriate solvent.

Positive-Edge

A transition from a logic 0 to a logic 1. Also known as a rising edge.

Positive-True

A convention which dictates the relationship between logical values and the physical voltages used to represent them. The more positive potential is considered to represent TRUE and the more negative potential is considered to represent FALSE. Also known as positive logic.

Power Amplifier

A class of amplifier with the primary purpose of delivering high output power (usually accompanied by significant dissipated power).

Power Plane

A conducting layer in or on the substrate providing power to the components. There may be several power planes separated by insulating layers.

Prepreg

Non-conducting semi-cured layers of FR4 used to separate conducting layers in a multilayer circuit board.

Primitives

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Simple logic functions such as BUF, NOT, AND, NAND, OR, NOR, XOR, and XNOR may be referred to as primitive logic gates or primitives.

Product Term

A set of literals linked by an AND operator.

Programmable Array Logic (PAL)

A programmable logic device in which the AND array is programmable but the OR array is pre-defined.

Programmable Logic Array (PLA)

The most user-configurable of the traditional programmable logic devices, because both the AND and OR arrays are programmable.

Programmable Logic Device (PLD)

The generic name for a device constructed in such a way that the designer can configure, or "program" it to perform a specific function.

Programmable Read-Only Memory (PROM)

A programmable logic device in which the OR array is programmable but the AND array is pre-defined. Usually considered to be a memory device whose contents can be electrically programmed (once) by the designer.

Project

A container that groups designs and their associated settings, including report definitions, in a file with a .adsn extension. To the fullest extent possible, projects are portable in that they include, rather than merely refer to, the library elements (graphical symbols, materials, footprints, and so on) of the components and models they contain. Multiple projects can be open simultaneously.

PROM

See Programmable Read-Only Memory.

Pseudo-Random

An artificial sequence of values that give the appearance of being random.

PTH

See Plated Through-Hole.

P-type

A piece of semiconductor doped with impurities that make it amenable to accepting electrons.

Pulling

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The difference between the maximum frequency of a VCO when the phase angle of the load impedance reflection coefficient varies through 360 degrees.

Pulsed Radar

A transmit and receive system used for ranging and detection that transmits a train of short bursts of high microwave signals and receives return signals reflected from a target.

Pushing

The change in frequency when the supply voltage changes, expressed in MHz/V.

Glossary: Q

Q

Quality factor; a measure of stored energy/dissipated energy. Also a measure of bandwidth.

QAM

Quadrature amplitude modulation.

QFP

See Quad Flat Pack.

QPSK

Quadrature phase-shift keying.

Quad Flat Pack (QFP)

The most commonly used package in surface mount technology to achieve a high lead count in a small area. Leads are presented on all four sides of a thin square package.

Quinary

Base-5 numbering system.

Glossary: R

Radio Frequency (RF)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The range in the electromagnetic spectrum loosely defined from 30 MHz to 3 GHz (with corresponding wavelengths from 1000 cm to 10 cm).

Radix

Refers to the number of digits in a numbering system. For example, the decimal numbering system is said to be radix-10. May also be referred to as the "base".

Rats Layer

A non-physical, default layer in the stackup that displays a drawing of logical connections between different components, circuit elements, and net connections. A single connection is called a rat and all of the connections on a rat layers is a rat's nest.

Reed-Müller Logic

Logic functions implemented using only XOR and XNOR gates.

Refractory Metal

Metals such as tungsten, titanium, and molybdenum which are capable of withstanding extremely high, or refractory, temperatures.

Remotely Reconfigurable Hardware

A product whose function may be customized remotely, by telephone or radio, while remaining resident in the system (see also Configurable Hardware, Reconfigurable Hardware, Dynamically Reconfigurable Hardware, and Virtual Hardware).

Reflection

The appearance of a previously transmitted signal on the transmission line causing interference with the current signal. Reflections are caused by a poorly terminated or discontinuous transmission line, where the signal energy is not fully absorbed within the receiver and is therefore transmitted back toward the transmitter.

Resist

A material which is used to coat the substrate and is then selectively cured to form an impervious layer.

Resistor-Transistor Logic (RTL)

Logic gates implemented using particular configurations of resistors and bipolar junction transistors. For the majority of today's designers, resistor-transistor logic is of historical interest only.

Return Loss

Return Loss (dB) is defined as a ratio of the incoming signal to the same reflected signal as it enters a component.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Return Loss (dB) = 10 * LOG10(Reflected Power/Incident Power)

RF

See Radio Frequency.

RF Power

A class of engineering. Circuits and signals primarily concerned with power levels ranging from a few watts to tens of thousands of watts in the RF spectrum.

RF Power Transmitter

A discrete packaged transistor used in the amplification of RF power.

Rigid Flex

Hybrid constructions which combine standard rigid circuit boards with flexible printed circuits, thereby reducing the component count, weight, and susceptibility to vibration of the circuit, and greatly increasing its reliability.

Ringing

Common name for the waveform that is seen when a transmission line ends at a high impedance discontinuity. The signal first overshoots, then dips down below the target value, and continues this with decreasing amplitude until it converges on the target voltage.

Risetime

The time it takes for a signal to rise from 10% of its total logic swing to 90% of its total logic swing.

Rising-Edge

A transition from a logic 0 to a logic 1. Also known as a positive edge.

RTL

See Resistor-Transistor Logic.

Glossary: S

Sample Rate

Time increment of analysis. Sometimes referred to as sampling rate.

Sampling

The process of converting an analog signal into a series of digital values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scalar Notation

A notation in which each signal is assigned a unique name; for example, a3, a2, a1, and a0.

Scaling

A technique for making transistors switch faster by reducing their size. This strategy is known as scaling, because all of the transistors features are typically reduced by the same proportion.

Schematic

Common name for a circuit diagram.

Scrubbing

The process of vibrating two pieces of metal, or metal coated materials, at ultrasonic frequencies to create a friction weld.

Seed Value

An initial value loaded into a linear feedback shift register or random number generator.

Sensor

A transducer that detects a physical quantity and converts it into a form suitable for processing. For example, a microphone is a sensor which detects sound and converts it into a corresponding voltage or current.

Sequential

A function whose output value depends not only on its current input values, but also on previous input values. That is, the output value depends on a sequence of input values.

Side-Emitting Laser Diode

A laser diode constricted at the edge of an integrated circuit's substrate such that, when power is applied, the resulting laser beam is emitted horizontally; that is, parallel to the surface of the substrate.

Sign Bit

The most significant binary digit, or bit, of a signed binary number. If set to a logic 1, this bit represents a negative quantity.

Signal Conditioning

Amplifying, filtering, or otherwise processing a signal.

Signal Layer

A layer carrying tracks in a circuit board, hybrid, or multichip module. See also wiring layer.

Signature

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refers to the checksum value from a cyclic-redundancy-check when used in the guided-probe form of functional test.

Signature Analysis

A guided-probe functional-test technique based on signatures.

Signed Binary Number

A binary number in which the most-significant bit is used to represent a negative quantity. Thus, a signed binary number can be used to represent both positive and negative values.

Sign-Magnitude

Negative numbers in standard arithmetic are typically represented in sign-magnitude form by prefixing the value with a minus sign; for example, -27. For reasons of efficiency, computers rarely employ the sign-magnitude form. Instead, they use signed binary numbers to represent negative values.

Silicon Bumping

The process of depositing additional metallization on a die's pads to raise them fractionally above the level of the Barrier Layer.

Silicon Chip

Although a variety of semiconductor materials are available, the most commonly used is silicon and integrated circuits are popularly known as silicon chips, or simply chips.

Silicon Compiler

The program used in compiled cell technology to generate the masks used to create components and interconnections. May also be used to create data-path functions and memory functions.

Single-Sided

A printed circuit board with tracks on only one side.

Sintering

A process in which ultra-fine metal powders weld together at temperatures much lower than those required for larger pieces of the same materials.

SIPO (Serial-In Parallel-Out)

Refers to a shift register in which the data is loaded in serially and read out in parallel.

SISO (Serial-In Serial-Out)

Refers to a shift register in which the data is both loaded in and read out serially.

Skew

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Time delay between different bits transmitted at the same time, measured at the receiver.

Skin Effect

In the case of high frequency signals, electrons are only conducted on the outer surface, or skin, of a conductor. This phenomenon is known as the skin effect.

Small-Scale Integration (SSI)

Refers to the number of logic gates in a device. By one convention, small-scale integration represents a device containing 1 to 12 gates.

SMD

See Surface Mount Device.

SMOBC

See Solder Mask Over Bare Copper.

SMT

See Surface Mount Technology.

SNR

Signal-to-noise ratio.

Soft Macro (Macro Function)

A logic function defined by the manufacturer of an application-specific integrated circuit. The function is described in terms of the simple functions provided in the cell library and connections between them. The assignment of cells to basic cells and the routing of the tracks is determined at the same time, and using the same tools, as for the other cells specified by the designer.

Solder Bumping

A flipped chip technique in which spheres of solder are formed on the die's pads. The die is flipped and the solder bumps are brought into contact with corresponding pads on the substrate. When all the chips have been mounted on the substrate, the solder bumps are melted using reflow soldering or vapor-phase soldering.

Solder Mask

A layer applied to the surface of the substrate that prevents solder from sticking to any metallization except where holes are patterned into the mask.

Solder Mask Over Bare Copper (SMOBC)

A technique in which the solder mask is applied in advance of the tin-lead plating. This results in lighter circuit boards because the tin-lead alloy is only used to plate the pads.

Solution

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A solution is the successful result of an analysis, or imported results available for plotting.

Space

Used to refer to the width of the gap between adjacent tracks.

SPICE

Simulated Program for Integrated Circuit Emulation

SRAM

See Static RAM.

SS-CDMA

Spread-spectrum code-division multiple access.

SSI

See Small-Scale Integration.

Stackup

An arrangement of physical signal and dielectric layers that is used in the design of circuit boards. In Circuit, the stackup editor lists conceptual non-stackup layers with the physical stackup layers.

Standard Cell

An application-specific integrated circuit which, unlike a gate array, does not use the concept of a basic cell and does not have any pre-fabricated components. The manufacturer creates custom masks for every stage of the device's fabrication allowing each logic function to be created using the minimum number of transistors.

State Assignment

The process by which the states in a state machine are assigned to the binary patterns that are to be stored in the state variables.

State Diagram

A graphical representation of the operation of a state machine.

State Machine

The actual implementation (in hardware or software) of a function that can be considered to consist of a set of states through which it sequences.

State Table

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A tabular representation of the operation of a state machine. Similar to a truth table, but also includes the current state as an input and the next state as an output.

State Transition

An arc connecting two states in a state diagram.

State Variable

One of a set of registers whose values represent the current state occupied by a state Static Flex.

Statement

A sentence that asserts or denies an attribute about an object or group of objects.

Static Flex

A type of flexible printed circuit which can be manipulated into permanent three-dimensional shapes for applications such as calculators and high-tech cameras which require efficient use of volume and not just area.

Static RAM (SRAM)

A memory device in which each cell is formed from four or six transistors configured as a latch or a flip-flop. The term static is used because, once a value has been loaded into an SRAM cell, it will remain unchanged until it is explicitly altered or until power is removed from the device.

Steady State

A condition in which nothing is changing or happening.

Subatomic Erosion

A process in which structures on an integrated circuit's substrate are eroded by the flow of electrons in much the same way as land is eroded by a river (also known as electromigration)

Substrate

Generic name for the base layer of an integrated circuit, hybrid, multichip module, or circuit board. Substrates may be formed from a wide variety of materials, including semiconductors, ceramics, FR4 (fiberglass), glass, sapphire, or diamond depending on the application. Note that the term substrate has traditionally not been widely used in the circuit board world, at least not by the people who manufacture the boards. However, there is an increasing tendency to refer to a circuit board as a substrate by the people who populate the boards. The main reason for this is that circuit boards are often used as substrates in hybrids and multichip modules, and there is a trend toward a standard terminology across all forms of interconnection technology.

Subtractive Process

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A process in which a substrate is first covered with conducting material, then any unwanted material is subsequently removed, or subtracted.

Superconductor

A material with zero resistance to the flow of electric current.

Surface Mount Device (SMD)

A component whose packaging is designed for use with surface mount technology.

Surface Mount Technology (SMT)

A technique for populating hybrids, multichip modules, and circuit boards, in which packaged components are mounted directly onto the surface of the substrate. A layer of solder paste is screen printed onto the pads and the components are attached by pushing their leads into the paste. When all of the components have been attached, the solder paste is melted using either reflow soldering or vapor-phase soldering.

Surface-Emitting Laser Diode

A laser diode constricted on an integrated circuit's substrate such that, when power is applied, the resulting laser beam is emitted directly away from the surface of the substrate.

Sweep Definition

Also called *variable sweep definition*. A set of variable values within a range that Optimetrics drives the Electronics Desktop to solve when a parametric setup is analyzed. A parametric setup can include one or more sweep definitions.

Synchronous

(1)A signal whose data is not acknowledged or acted upon until the next active edge of a clock signal. (2)A system whose operation is synchronized by a clock signal.

System Gain

The net loss of a system as a measure of reliability with respect to system parameters. It measures the difference between the output power and minimum input power required for satisfactory performance. It represents a system net loss, and is represented as a negative dB value that is larger than or equal to the summed gains and losses of a signal propagating in a system from transmitter to receiver.

Glossary: T

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Tap

A register output which is used to generate the next data input to a linear feedback shift register.

Tape Automated Bonding (TAB)

A process in which transparent flexible tape has tracks created on its surface. The pads on unpackaged integrated circuits are attached to corresponding pads on the tape which is then stored in a reel. Silver-loaded epoxy is screen printed on the substrate at the site where the device is to be located and onto the pads to which the device's leads are to be connected. The reel of TAB tape is fed through an automatic machine which pushes the device and the TAB leads into the epoxy. When the silver-loaded epoxy is cured using reflow soldering or vapor-phase soldering, it forms electrical connections between the TAB leads and the pads on the substrate.

TDM

Time-division multiplexing.

TDMA

Time-division multiple access.

Technology File

A technology file is a collection of information, specifiable by name at design-creation time using the Choose Layout Technology dialog box, that specifies material stackup properties for layout, substrates for simulation, and component libraries for design creation. A technology (.asty) file may be saved from the current project via the File menu. A technology file initializes a design with a set of data to avoid repeated entry of commonly used data. This data can consist of layers and stackup information for layout, configured libraries of components, and substrate definition (s) for circuit analysis. Users and foundries can customize Technology files for their own manufacturing process and simulation models.

Tertiary Logic

An experimental technology in which logic gates are based on three distinct voltage levels. The three voltages are used to represent the tertiary digits 0, 1, and 2, and their logical equivalents FALSE, TRUE, and MAYBE.

Thermal Impedance

Relates the temperature rise for a given dissipated power (which employs an analogy to the voltage-current relationship of impedance).

Thermal Relief Pad

A special pattern etched around a via or a plated through-hole to connect it into a power or ground plane. A thermal relief pad is necessary to prevent too much heat being absorbed into the power or ground plane when the board is being soldered.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Thermal Tracking

Typically used to refer to the problems associated with optical interconnection systems whose alignment may be disturbed by changes in temperature.

Thevenin's theorem

Any two-terminal combination of voltage sources and resistors is electrically equivalent to a single voltage source in series with a single resistor.

Thick-Film Process

A process used in the manufacture of hybrids and, to a lesser extent, multichip modules in which signal and dielectric (insulating) layers are screen-printed onto the substrate.

Thin-Film Process

A process used in the manufacture of hybrids and multichip modules in which signal layers and dielectric (insulating) layers are created using opto-lithographic techniques.

Time-Of-Flight

The time taken for a signal to propagate from one logic gate or opto-electronic component to another.

Tin-Lead Plating

An electroless plating process in which exposed areas of copper on a circuit board are coated with a layer of tin-lead alloy. The alloy is used to prevent the copper from oxidizing and provides protection against contamination.

Tinning

An abbreviation of tin-lead plating, which is an electroless plating process in which exposed areas of copper on a circuit board are coated with a layer of tin-lead alloy. The alloy is used to prevent the copper from oxidizing and provides protection against contamination.

Toggle

Refers to the contents or outputs of a logic function switching to the inverse of their previous logic values.

TOI

Third-order intercept point.

Total Voltage

Total voltage = Incident voltage + reflected voltage, that is $V^T = V^a + V^b$.

Trace

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A conducting connection between electronic components. May also be called a track or a signal. In the case of integrated circuits, such interconnections are often referred to collectively as metallization.

Tracks

A conducting connection between electronic components. May also be called a trace or a signal. In the case of integrated circuits, such interconnections are often referred to collectively as metallization.

Transducer

A device that converts input energy of one form into output energy of another.

Transistor

A three-terminal semiconductor device that, in the digital world, can be considered to operate like a switch.

Tri-State Function

A function whose output can adopt three states: 0, 1, and Z (high-impedance) The function does not drive any value in the Z state and, in many respects, may be considered to be disconnected from the rest of the circuit.

Truth Table

A convenient way to represent the operation of a digital circuit as columns of input values and their corresponding output responses.

TTL (Transistor-Transistor Logic)

Logic gates implemented using particular configurations of bipolar junction transistors.

Glossary: U

ULA

See Uncommitted Logic Array.

Ultra-Large-Scale Integration (ULSI)

Refers to the number of logic gates in a device. By one convention, ultra-large-scale integration represents a device containing a million or more gates.

ULSI

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See Ultra-Large-Scale Integration.

Uncommitted Logic Array (ULA)

One of the original names used to refer to gate array devices. This term has largely fallen into disuse.

Unsigned Binary Number

A binary number in which all the bits are used to represent positive quantities. Thus, an unsigned binary number can only be used to represent positive values.

Undershoot

The percentage a waveform falls below its lowest determined value before setting at the correct value.

Glossary: V

Vapor-Phase Soldering

A surface mount process in which a substrate carrying components attached by solder paste is lowered into the vapor-cloud of a tank containing boiling hydrocarbons. This melts the solder paste thereby forming good electrical connections. However, vapor-phase soldering is becoming increasingly less popular due to environmental concerns.

Vaporware

Refers to either hardware or software that exist only in the minds of the people who are trying to sell them to you.

Variable Sweep Definition

Also called *sweep definition*. A set of variable values within a range that Optimetrics drives HFSS or Q3D to solve when a parametric setup is analyzed. A parametric setup can include one or more sweep definitions.

Vector Notation

A notation used in logic simulation and synthesis in which a single name is used to reference a group of signals, and individual signals within the group are referenced by means of an index; for example, a[3:0] = a[3], a[2], a[1], and a[0].

Very-Large-Scale Integration (VLSI)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refers to the number of logic gates in a device. By one convention, very-large-scale integration represents a device containing 1,000 to 999,999 gates.

Via

A hole filled or lined with a conducting material which is used to link two or more conducting layers in a substrate.

Virtual Hardware or Virtual Logic

An extension of dynamically configurable hardware based on a new generation of FPGAs which were introduced around the beginning of 1994. In addition to supporting the dynamic reconfiguration of selected portions of the internal logic, these devices also feature: no disruption to the device's inputs and outputs; no disruption to the system-level clocking; the continued operation of any portions of the device that are not undergoing reconfiguration; and no disruption to the contents of internal registers during reconfiguration, even in the area being reconfigured (see also Configurable Hardware, Reconfigurable Hardware, Remotely Reconfigurable Hardware, and Dynamically Reconfigurable Hardware).

Virtual Memory

A trick used by a computer's operating system to pretend that it has access to more memory than is actually available. For example, a program running on the computer may require ten mega-bytes to store its data, but the computer may have only five mega-bytes of memory available. To get around this problem, whenever the program attempts to access a memory location that does not physically exist, the operating system performs a slight-of-hand and exchanges some of the contents in the memory with data on the hard disk.

VLSI

See Very-Large-Scale Integration.

Volatile

Refers to a memory device which loses any data it contains when power is removed from the system; for example, random-access memory in the form of SRAM or DRAM

Glossary: W

Wafer Probing

The process of testing individual integrated circuits while they still form part of a wafer. An automated tester places probes on the device's pads, applies power to the power pads, injects a

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

series of signals into the input pads, and monitors the corresponding signals returned from the output pads.

Wave Soldering

A process used to solder circuit boards populated with through-hole components. A wave generating mechanism maintains a wave of hot, liquid solder traveling back and forth across the surface of a tank. The populated circuit boards are passed over the wave soldering machine on a conveyor belt. The velocity of the convener belt is carefully controlled and synchronized such that the solder wave brushes across the bottom of the board only once.

Waveguide

A transparent path bounded by non-transparent, reflective areas, which is fabricated directly onto the surface of a substrate. Used in the optical interconnection strategy known as guided-wave.

W-CDMA

Wideband code-division multiple access. Typically defined with 5 MHz channels and 3.84 MHz carrier signals.

Wire Bonding

The process of connecting the pads on an unpackaged integrated circuit to corresponding pads on a substrate using wires that are finer than a human hair. Wire bonding may also be used to connect the pads on an unpackaged integrated circuit, hybrid, or multichip module to the leads of the component package.

Wiring Layer

A layer carrying wires in a discrete wired board. See also signal layer.

Word

A group of signals or logic functions performing a common task and carrying or storing similar data; for example, a value on the data bus could be referred to as a data word.

Glossary: X

X-Ray Lithography

Similar in principle to optical lithography, but capable of constructing much finer features due to the shorter wavelengths involved. However, X-ray lithography requires an intense source of X-rays, is more difficult to use, and is considerably more expensive than optical lithography.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Glossary: Y

Yield

The number of devices that work as planned, specified as a percentage of the total number actually fabricated.

Glossary: Z

Zepto (z)

The symbol used to represent the high-impedance state in tri-state logic.

Zone

A spatial area on a printed circuit board that may contain a subset or all of the layers in the board’s stackup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

VerifEye analysis 12-64
VerifEye analysis, add an eye probe 12-42
VerifEye analysis, add external step response 12-56
VerifEye analysis, copying 12-115
VerifEye analysis, netlist format 12-62
VerifEye analysis, options 12-64
VerifEye analysis, schematic editor 12-35
VerifEye analysis, setup 12-57
VerifEye and Quick Eye analyses 12-34
VerifEye and Quick Eye analyses, options reference 26-182
VerifEye and Quick Eye analyses, options reference | Primary.Circuit | [12] 12-108
VerifEye channel example 21-180
VerifEye probe, netlist syntax 12-61
VerifEye source, netlist syntax 12-61
VerifEye, add an eye source 12-35
VerifEye, analyze AMI models 5-123, 12-173
VerifEye, external step response netlist syntax 12-62
VerifEye, technical notes 26-289
VerifEye, transmit jitter 26-311
verify analysis, netlist editor 12-61
VerifyEye, plotting bathtub curves 19-440
verilog component, creating 5-170
Verilog features supported 5-175
Verilog library support 5-166
verilog symbol, creating 5-167
via object 22-58
methods 22-59
properties 22-58
vias
and pin padstacks
edit in layout 22-28
vias and pins, pad behavior 22-27
