Index	Index-1

1 - Digital Elements

The Digital Elements Library has been developed in VHDL to support users with the common basic functionality used for simple digital circuits. The models have been developed according to the IEEE 1076 (VHDL standard).

The digital components operate with digital signals and can be characterized with rise time/fall time/propagation delays. They do not have any conservative nodes but can be connected with analog quantities using omnicastrs.

Digital VHDL components appear in the **Digital** tab. The components are subdivided into **ADC/DAC, Counters, Digital Sources, Flip-Flops, Latches, Logic Blocks, and Logic Gates**. Click the **Digital** folder, choose one of the groups, click on a name, drag the component onto the sheet, and release the mouse button.

The models provided are open source and can be used to derive more advanced models. This may be done by copying the element in the user library and editing the VHDL text to modify the model.

You can view the inputs and outputs of VHDL models using a 2D Digital Graph display element. You can also view the internal values used within the architecture of a model in a 2D Digital Graph and use them as variables between models. However, if the VHDL design needs to be exported to other simulators, then internal values of the model should not be referenced outside the model.

Description

The Analog-Digital Converter can be used in simple mixed signal circuit simulations. The component accepts an analog value input of type real and translates it to a four bit digital value according to specified minimum and maximum thresholds. A clock signal input is specified to sample the analog signal value.

Counters

The counters can be used in simple sequential digital circuit simulations with propagation delays. The models operate on digital signals of type BIT and provide a vector output of the count value. Delays are specified in terms of propagation delays (**t_prop**).

The model is positive-edge triggered and has the capability of having the outputs cleared to LOW through an asynchronous **CLR** input.

Component Dialog Settings

The following Parameters are set in the Component Dialog for the **Digital Stimulus Component**:

Name:

Specify the Name of the component instance. Select the **Show Name** checkbox to display the name on the schematic.

Parameters:

Base Clock: The base clock is represented in the dialog along with a time scale. To edit the **Base Clock** definition, click the button in the dialog to return to the Parameters Wizard. Create or delete entries of input signals with the symbols placed on the upper right side. Available signals are **Bit**, **Bit Vector**, **Std Logic**, or **Std Logic Vector**.

Base Clock Parameter Wizard: By default, you must first specify the Base Clock cycle for the Stimulus source. Note that the number of clock cycles that can be displayed is limited to 1000. A message is displayed informing you when the limiting is applied.

Time Resolution: Select the time resolution units for the pull-down list.

Stimulus End Time: Enter a numerical value (non-negative integer) in the text box. Please note: You cannot define a variable or expression in this case. Only a positive integer is accepted.

Clock High Time:/Clock Low Time: Type a numerical value (non-negative integer) in the text box to define the portion of time to remain at the high/low output value. Please note: You cannot define a variable or expression in this case. Only a number is accepted.

Start with Low Time: Select the checkbox to have the simulator start the stimulus source with the low time portion of the cycle.

BIT/Std Logic signal: Select the Wizard checkbox to enable the Parameters Wizard for the **BIT** source type or **Std Logic** source type. Leaving the Wizard checkbox unselected allows you to change the data for the signal manually for each time step. The **Bit** signal and the **Std Logic** are equivalent with the exception of allowable states. The **BIT** source can accept a logic "0" or logic "1" state only. The **Std Logic** source can have "U", "X", "0", "1", "Z", "W", "L", "H", and "-" states.

BIT/Std Logic Signal Parameter Wizard:

Signal Name: Enter a name for the signal.

Pattern Type: Three pattern types are supported for the bit signal, **Toggle**, **Pulse**, and **Random**. The selected pattern type and representation of the Properties is shown in the preview

window of the dialog.

The **Toggle** type switches between the two states on the clock signal trailing edge. The frequency of the switch is set by the Toggle Period parameter.

The **Pulse** type switches between two states with a user definable initial delay and pulse width.

The **Random** signal type uses a random number generator to select either a high or low value for the next random period specified by the user.

Pattern Repetition Number: Enter the number of times the pattern should repeat.

Initial Value: The value the signal takes at the beginning of the simulation. This is set to a logic "0" or "1".

Other Value/Pulse Value: The value the signal will switch to during clocking. This is set to a logic "0" or "1" and should be set to the opposite of the Initial Value setting.

Toggle Period/Pulse Width: The Toggle Period/Pulse Width defines how many clock cycles the pulse remains "ON" for the Toggle/Pulse pattern types respectively.

Initial Delay: In Pulse mode, this parameter defines the delay from the end of the last pulse, to the leading edge of the next pulse in clock cycles.

Random Seed: The random seed is a parameter used to seed a random number generator and is used to randomize the switching pattern of the signal. The random number generator returns only one number and all random signals in all stimulus components in the circuit will get the same value when determining whether to switch states.

Random Period: The random period is the length of the pulse before another switch is possible. Switching may or may not occur due to the random nature of the signal.

BIT/Std Logic Vector: The Bit Vector source is set up via the Bit Vector Parameter Wizard and cannot be manually modified.

BIT/Std Logic Vector Parameter Wizard:

Signal Name: Enter a name for the signal.

Pattern Type: Six pattern types are supported for the bit vector signal, **Alternate**, **Count Up**, **Count Down**, **Shift Left**, **Shift Right**, and **Random**. The selected pattern type and representation of the Properties is shown in the preview window of the dialog.

The **Alternate** type switches between two states on the clock signal trailing edge. The frequency of the switch is set by the toggle Period parameter.

The **Count Up/Count Down** performs a binary count between the initial and final values specified.

The **Shift Left/Shift Right** performs a standard binary shift operation, shifting the bits set in the initial value left or right and shifting in the value specified in the **Input Value**.

The **Random** signal type uses a random number generator to select either a high or low value

for the next random period specified by the user.

Pattern Repetition Number: Enter the number of times the pattern should repeat.

Vector Length: Enter the number of signals in the vector.

Value1/Pulse Width Value 1: For each **Index**, corresponding to the **Vector Length**, select the quantity for Value 1 and the associated **Pulse Width** as shown in the preview window.

Value2/Pulse Width Value 2: For each **Index**, corresponding to the **Vector Length**, select the quantity for Value 2 and the associated **Pulse Width** as shown in the preview window. Generally, Value 2 should be set to the opposite of Value 1 for each index entry.

Initial Value: When the **Pattern Type** is either **Count Up**, **Count Down**, **Shift Left**, or **Shift Right**, specify the bit values for the initial vector.

Final Value: When the **Pattern Type** is either **Count Up** or **Count Down**, specify the bit values for the final vector.

Increment/Decrement Value: Specify the increment for each count in the **Count Up** or **Count Down** sequence. An **Increment Value** of 1 will provide a standard binary count sequence.

Count: Specify the number of clock cycles per count. A **Count** of one will increment or decrement the vector with each clock cycle.

Input Value: When using the **Shift Left** or **Shift Right** type, the **Input Value** indicates what data value is to be shifted into the vector.

Random Seed: The random seed is a parameter used to seed a random number generator and is used to randomize the switching pattern of the signal. The random number generator returns only one number and all random signals in all stimulus components in the circuit will get the same value when determining whether to switch states.

Random Period: The random period is the length of the pulse before another switch is possible. Switching may or may not occur due to the random nature of the signal.

Random Value: The random value allows you to choose between randomly setting the vector with "0", "1" states only, or using all possible logic states.

Outputs/Display

For information regarding displaying parameter pins, see *Output/Display Tab* in the main Twin Builder help.

Two-bit Vector Source

Flip Flops

The flip-flop models can be used in simple sequential digital circuit simulations with propagation delays. The models operate on digital signals of type **BIT**. Delays are specified in terms of propagation delays (**t_{prop}**).

All models are positive edge triggered and some have the capability of having the outputs preset to '1' or cleared to '0' through asynchronous **PST** and **CLR** inputs. If both **PST** and **CLR** inputs are active at the same time, priority is given to the **PST** input. The following three types of flip-flop models are provided:

- [D Flip-Flop](#)
- [JK Flip-Flop](#)
- [T Flip-Flop](#)

D-Flip Flops

- Basic D Flip-Flop (ffd)
- D Flip-Flop with asynchronous preset and clear (ffdcp)
- D Flip-Flop with asynchronous active-low preset and clear (ffdcpal)

Latches

The latches can be used in simple sequential digital circuit simulations with propagation delays. The models operate on digital signals of type **BIT**. Delays are specified in terms of propagation delays (**t_prop**).

All models are positive edge triggered and some have the capability of having the outputs preset to '1' or cleared to '0' through asynchronous **PST** and **CLR** inputs. If both **PST** and **CLR** inputs are active at the same time, priority is given to the **PST** input.

Description

The component represents a two-bit comparator. The comparator operates on digital signals of type **BIT**. It compares the two input two-bit vector values and indicates the result with a '1' on one of the three outputs, *greater than*, *less than*, or *equal to* lines. Delays are specified in terms of propagation delays (**t_prop**).

Description

The component represents a two-to-four line decoder. The decoder operates on digital signals of type **BIT**. Depending on the coded value available in the two-bit input line, the decoder model indicates a result of '1' in one of the four output lines. Delays are specified in terms of propagation delays (**t_{prop}**).

Four Bit Bidirectional Serial Shift Register

Library: Digital	Modeling Language: VHDL	Version Number: Twin Builder 2025.2
------------------	-------------------------	-------------------------------------

Figure 1. Component symbol

- [Description](#)
- [Assumptions and Limitations](#)
- [Mathematical Description](#)
- [Netlist Syntax](#)
- [Parameters](#)
- [Input/Output Quantities](#)
- [Example](#)
- [References](#)

Description

This component represents a 4-bit bidirectional serial shift register with asynchronous clear (positive edge triggered) with parallel load. The register operates on digital signals of type **BIT**. Delays are specified in terms of propagation delays (**t_{prop}**). The model can shift four bits of data serially, either to the right (right input = '1') or to the left (right input = '0'). All four bits of data can be loaded in the model in parallel (pll = '1', use d_in input) or in serial (pll = '0', use s_in input). It is also possible to clear the data in the model using the asynchronous, active-high clear input.

Parameters

Table 2

Name	Description	Data Type	Default Value [Unit]
x1	Input Signal X1	bit	'0'
x2	Input Signal X2	bit	'0'
x3	Input Signal X3	bit	'0'
tp_lh	Rise Time Delay	real	0.0 [s]
tp_hl	Fall Time Delay	real	0.0 [s]

Logic Gates Example: AND & NAND

This example illustrates the use of the AND and NAND Logic Gates.

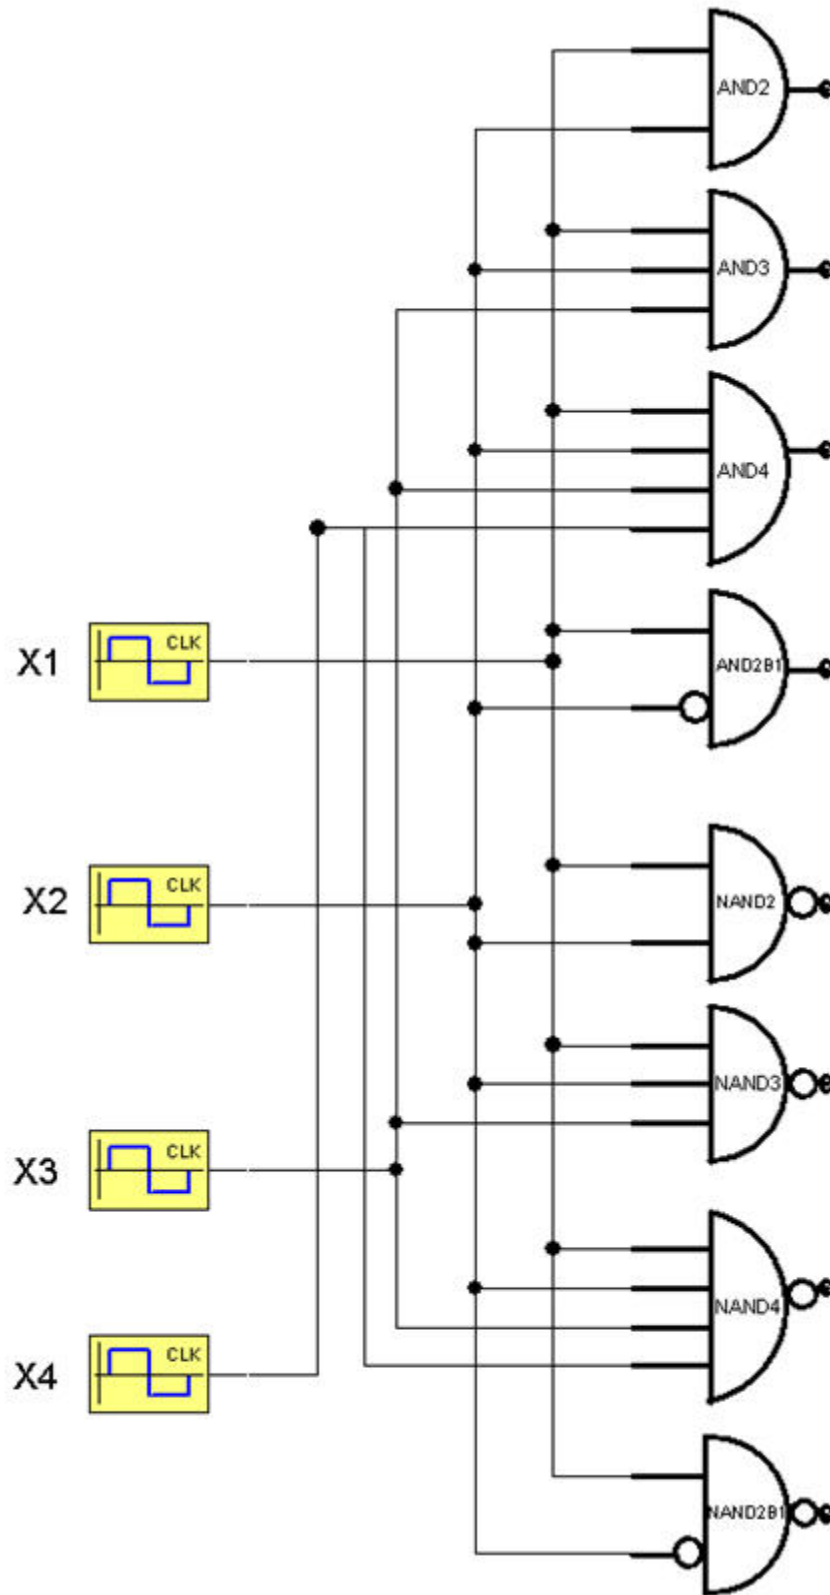

Figure 1. Application example of the AND and NAND Logic Gates

Table 1. System Parameters

Component	Parameter	Value [unit]
Clock Source X1	ped	2m [S]
	del	0 [S]
	periodical	1.0
Clock Source X2	ped	4m [S]
	del	0 [S]
	periodical	1.0
Clock Source X3	ped	8m [S]
	del	0 [S]
	periodical	1.0
Clock Source X4	ped	16m [S]
	del	0 [S]
	periodical	1.0
2-input AND Gate and21	tp_lh	0.0 [S]
	tp_hl	0.0 [S]
	x1	X1.val
	x2	X2.val
3-input AND Gate and31	tp_lh	0.0 [S]
	tp_hl	0.0 [S]
