
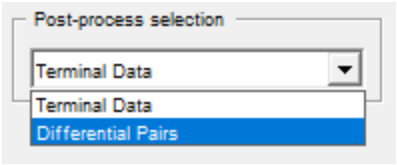
4. Select a pair from the list on the left and click **Add Pairs**.
5. Click **OK**.
6. To disable all differential pairs, click the **Enabled** column header in the **Differential Pairs** dialog to deselect all pairs.

For HFSS Driven Terminal designs, selecting the solution data will disable this ribbon button. The user must make port/differential pair changes directly in the HFSS Design and re-import the solution. When the HFSS Driven Terminal Design has differential pairs defined, NDE shows this drop down menu and you can change between showing reports for Terminals or Differential Pairs.Select **Differential Pairs** from the **Post-process selection** field to view mixed-mode

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

parameters.



Note:

The Network Data Explorer **Edit** menu option **Reset All Port Properties** deactivates all pairs, but it does not clear the differential pair settings. And since **Reset All Port Properties** also clears reference impedances and terminations, it should not be used when the user simply wishes to disable all differential pairs.

Reset All Port Properties

Reset All Ports resets all changes in the **Edit Ports** window. It also deactivates all differential pairs defined in the **Differential Pairs** window but does not remove the definitions.

Note: For HFSS Driven Terminal designs, selecting the solution data will disable this ribbon button. The user must make port/differential pair changes directly in the HFSS Design and re-import the solution.

Data View Pane Context Menus

The Data View pane presents different right-click menu options, depending on the context. Some commands are the same as those on the NDE ribbon. Others appear only in the context menus.

Network Data Explorer commands unique to the context menus are:

- Multiple Frequency Statistics
- Highlight Min/Max
- Select Transpose
- Color Legend Attributes
- Matrix Entries Plot Menu

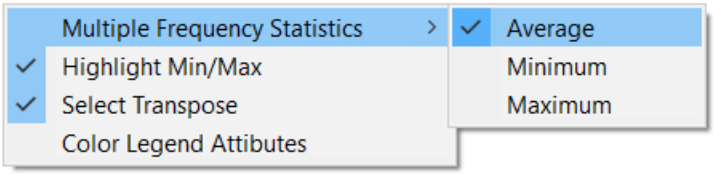
Multiple Frequency Statistics

The **Multiple Frequency Statistics** menu option determines the statistical composite to display when multiple frequencies have been selected for the matrix display. The statistical data is

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

always the first matrix displayed, followed by matrices for each individual frequency. The **Multiple Frequency Statistics** option also indicates the data used in the colored matrix plot when multiple frequencies have been selected.

This right click menu option appears in the **Matrix** plot, regardless of whether you are in Table or Plot view.



The menu options are:

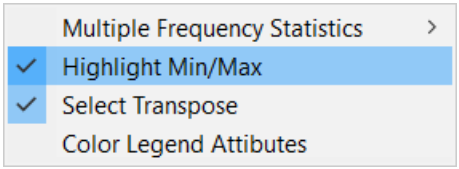
- **Average** – display the average of the matrix values across selected frequencies.
- **Minimum** – display the minimum matrix values across selected frequencies.
- **Maximum** – display the maximum matrix values across selected frequencies.

The selected information also appears in a tool-tip when you hover the cursor over a cell.

Highlight Min/Max

The **Highlight Min/Max** menu option determines whether the minimum and maximum matrix entries should be highlighted in the matrix table and color plot view.

This right click menu option appears in the **Matrix** plot, regardless of whether you are in Table or Plot view.

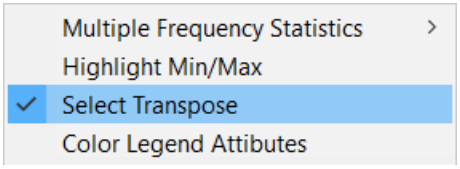


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Select Transpose

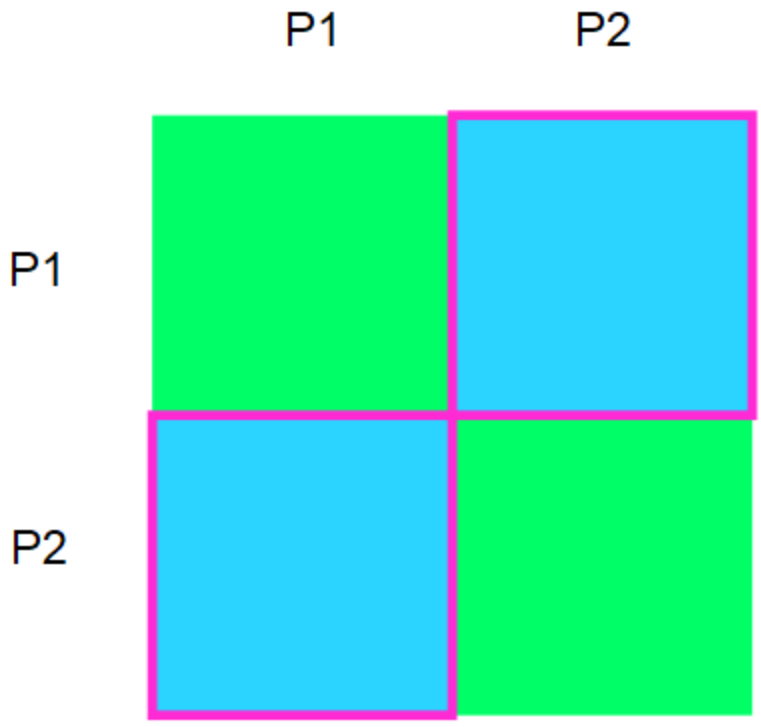
The **Select Transpose** menu option determines whether transpose cells are highlighted along with selected cells.

This right click menu option appears in the **Matrix** plot, regardless of whether you are in Table or Plot view.



Transpose cells are highlighted in Table or Plot view, as shown below.

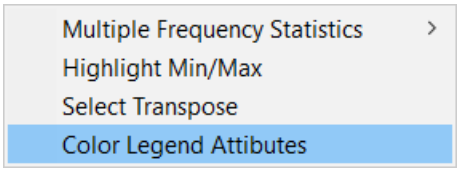
0.01000GHz	P1	-57.10340, -81.97841	-57.72581, 85.70836	-0.00213, -0.18916
	P2	-57.72582, 85.70825	-57.09556, -81.98749	-66.27113, 99.16916
	P3	-0.00213, -0.18916	-66.27110, 99.16941	-57.10246, -81.95892
	P4	-66.27112, 99.16942	-0.00213, -0.18929	-57.72556, 85.71465



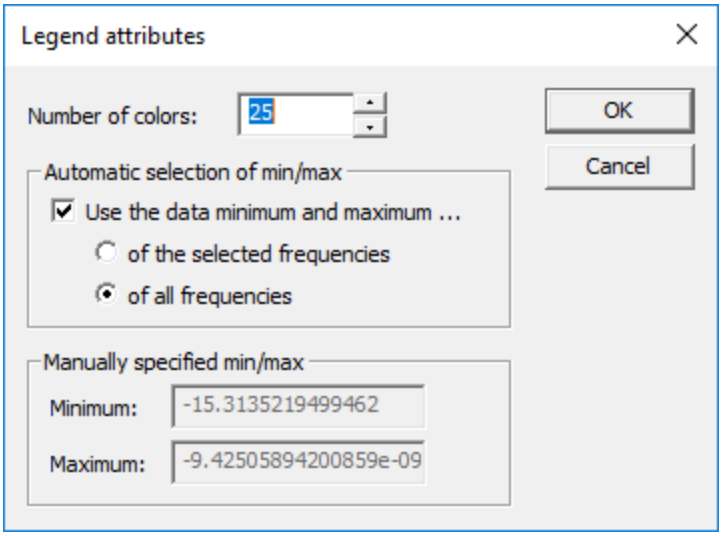
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Color Legend Attributes

The **Color Legend Attributes** menu option allows you to change the granularity of the color scheme and the value range for plots. This right click menu option appears in the **Matrix** plot.



Alternatively, double-click the matrix plot's legend to open the **Legend Attributes** window.



Options include:

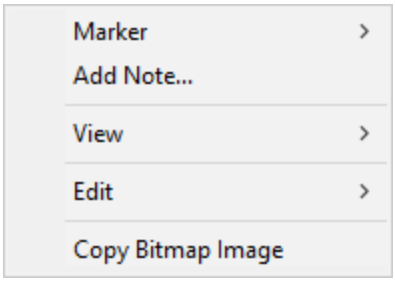
- **Number of colors** – allows you to select number of color entries in the legend (the number of divisions between the start/end of the data range). This can be set to any discrete number between 1 and 50.
- **Automatic selection of min/max** – check the **Use the data minimum and maximum** check box to automatically select the data range using the minimum and maximum values from either selected frequencies or all frequencies in the data set.
- **Manually specified min/max** – when the when the range is not automatically determined, these fields permit the user to manually enter hard values. For example, for S parameter data magnitude data, you could enter a minimum of 0 and a maximum of 1.

Using a standard range across all frequencies permits you to quantitatively compare plots, and ndExplorer remembers legend settings for each data-type and display-format pair.

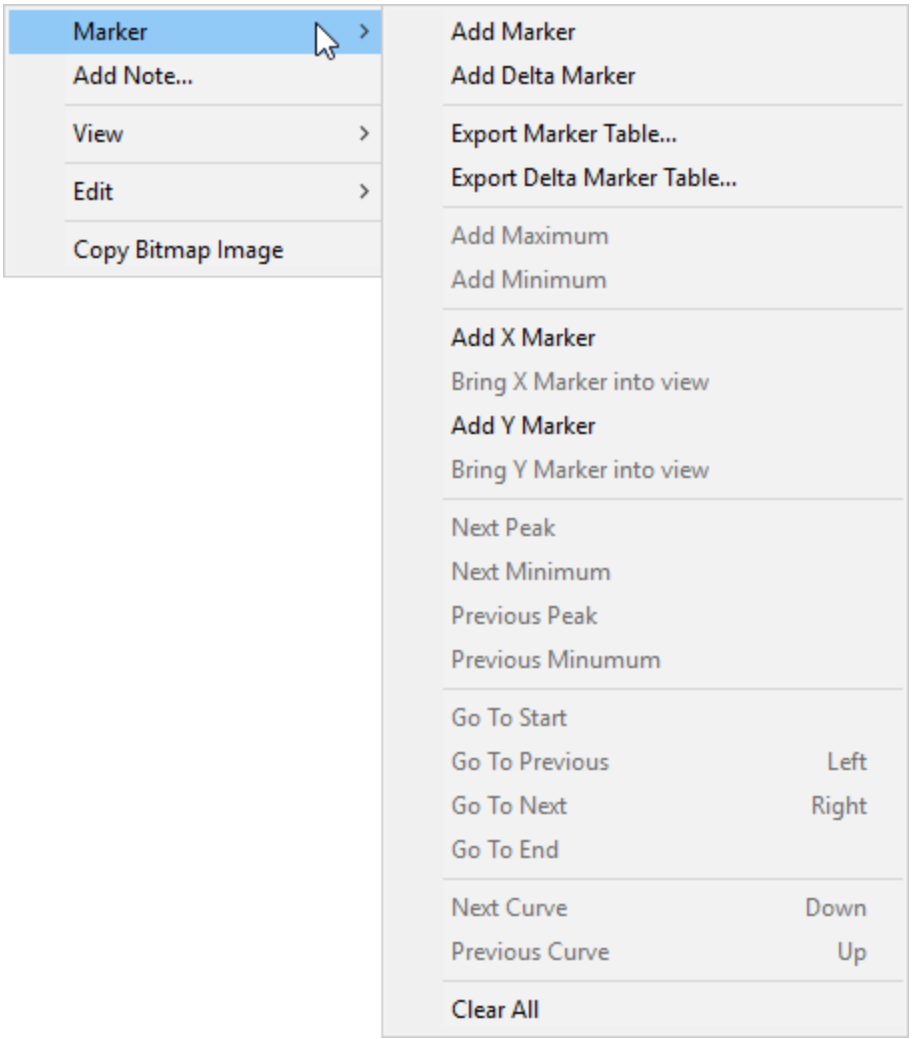
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Matrix Entries Plot Menu

On the **Matrix** plot, several new right-click menu options appear.

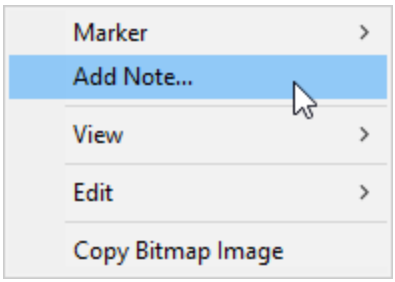


The **Marker** sub-menu provides commands for adding markers to plots.

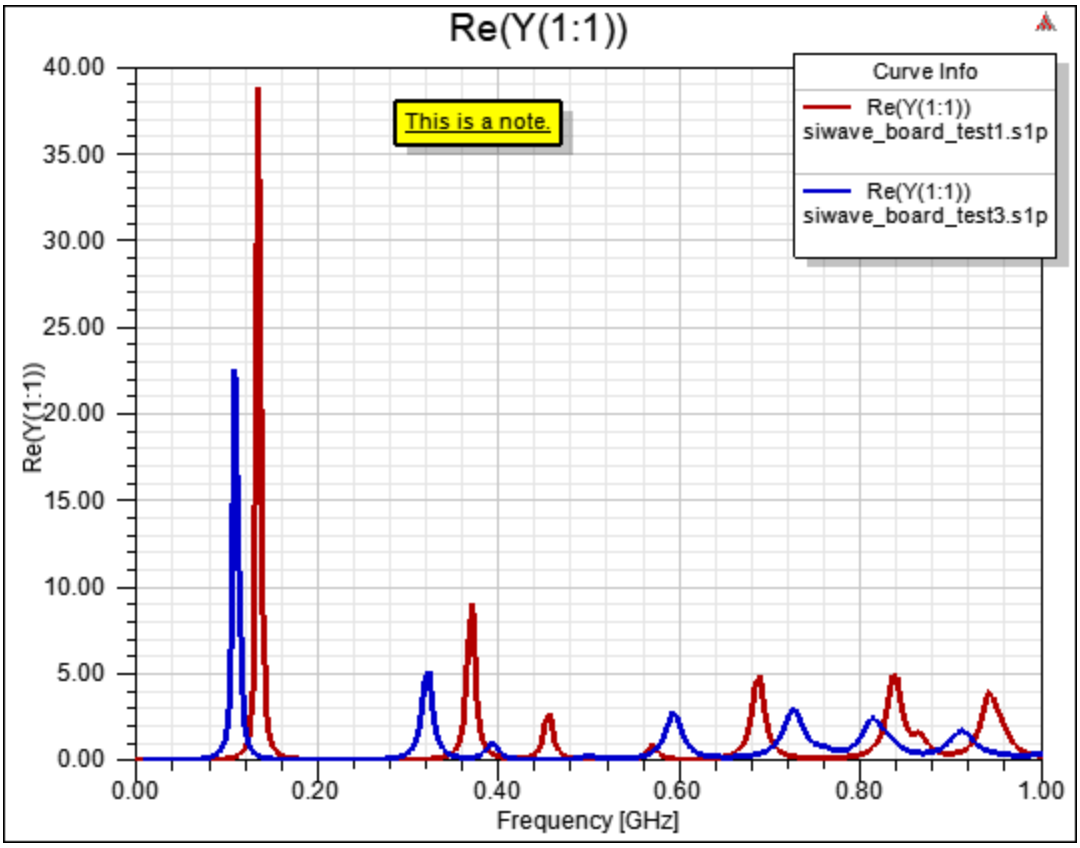


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Add Note** menu option allows you to add a note to the plot.

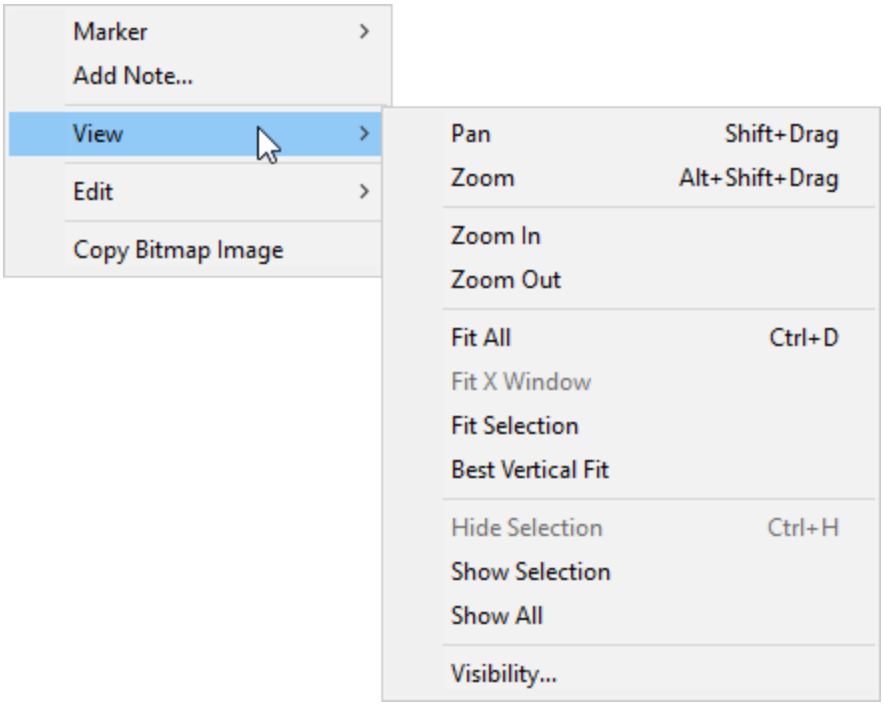


The note appears at the location you right-clicked. You can click and drag the note to a new location, or double-click the note to change its color and font.



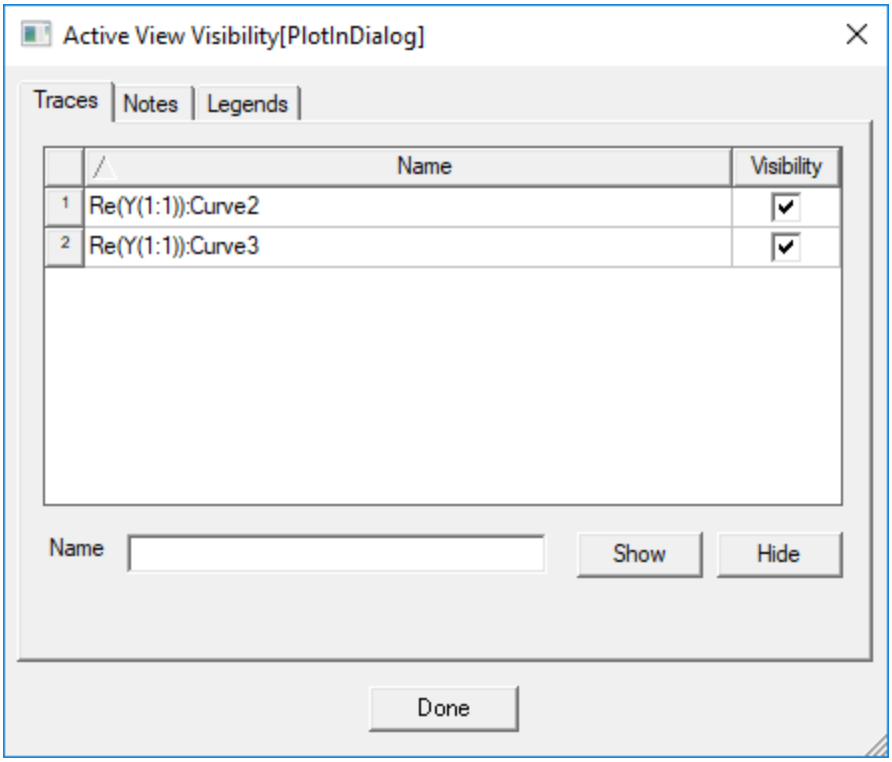
The **View** sub-menu provides commands for viewing, panning, zooming, and fitting elements to your plot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

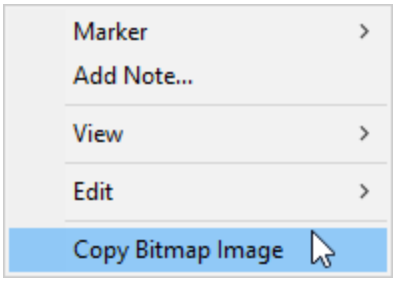


Click **Visibility** to open the **Active View Visibility** window, where you can select the visibility of traces, notes and legends.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Copy Bitmap Image** menu option copies the plot to your clipboard. You can then paste it into a graphics editor.



Exploring Network Data and Modifying the Display

Network Data Explorer allows you to view data and modify various aspects of the display, including color plots, color coding, viewing across frequencies, and displaying individual statistics. This section provides examples of Network Data Explorer capabilities:

- Viewing the S, Y, or Z Matrix for a Frequency
- Viewing a Color-coded Matrix Plot
- Displaying a Cell Graph Across All Frequencies

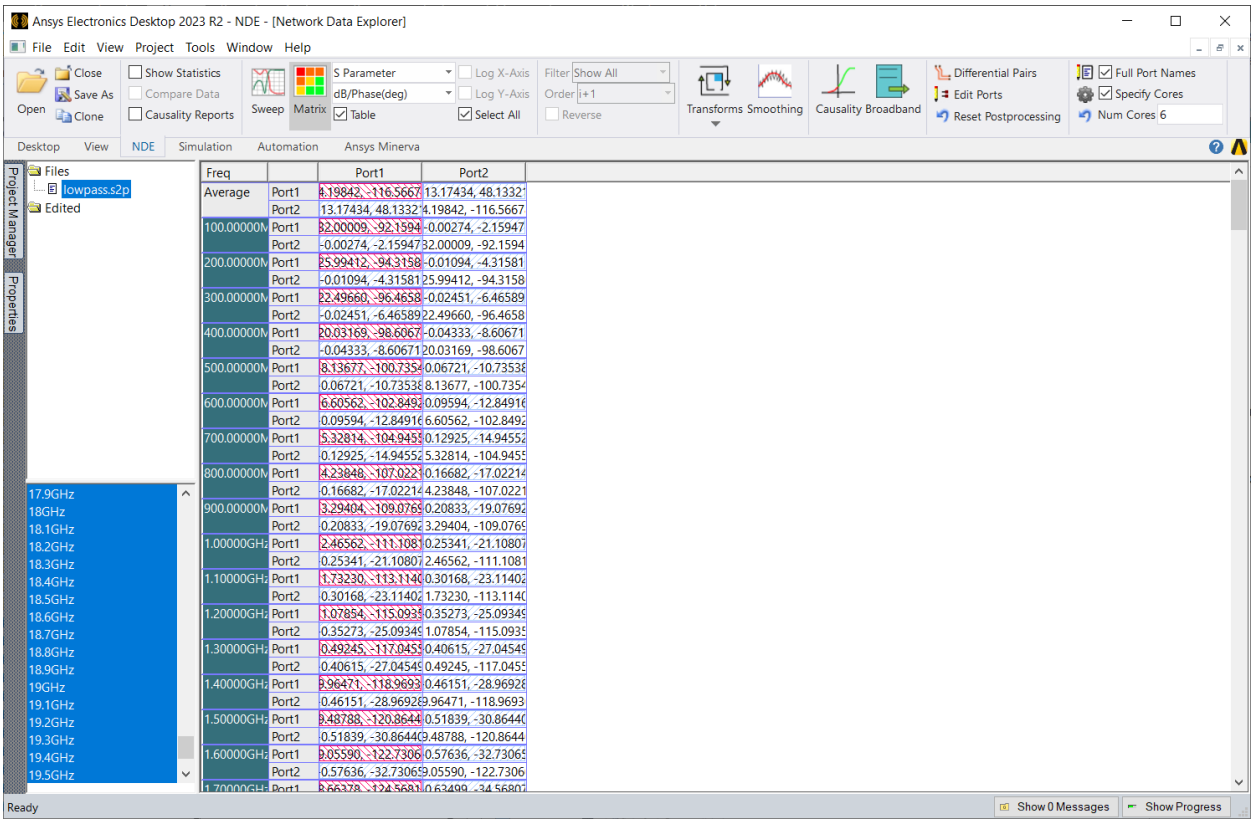
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Displaying Matrix Statistics by Frequency
- Displaying Individual Statistics for All Frequencies
- Creating a Statistics Plot
- Comparing Variations

Viewing a Matrix Table

To view the S, Y or Z matrix:

1. On the **NDE** ribbon, click **Matrix**.
2. Click the **Table** check box.
3. Use the **Parameter** type drop-down menu to select **S parameter**, **Y parameter**, **Z parameter**, or another choice.
4. Choose a format from the drop-down menu, for example dB or Mag.
5. In the Cell and Frequency Selection pane, select frequencies to display or click the **Select All** check box on the **NDE** ribbon to select all frequencies. The S, Y, or Z matrix displays.



6. Hover over a cell to see more information in a tool tip.
7. Right click to see a right click menu with other commands.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Maximum values are highlighted in red stripes. If Select Transpose is enabled, transposes are highlighted in red stripes as well.

Minimum values are highlighted in blue stripes.

Selected cells appear in solid blue. If Select Transpose is enabled, the transpose is highlighted in blue as well.

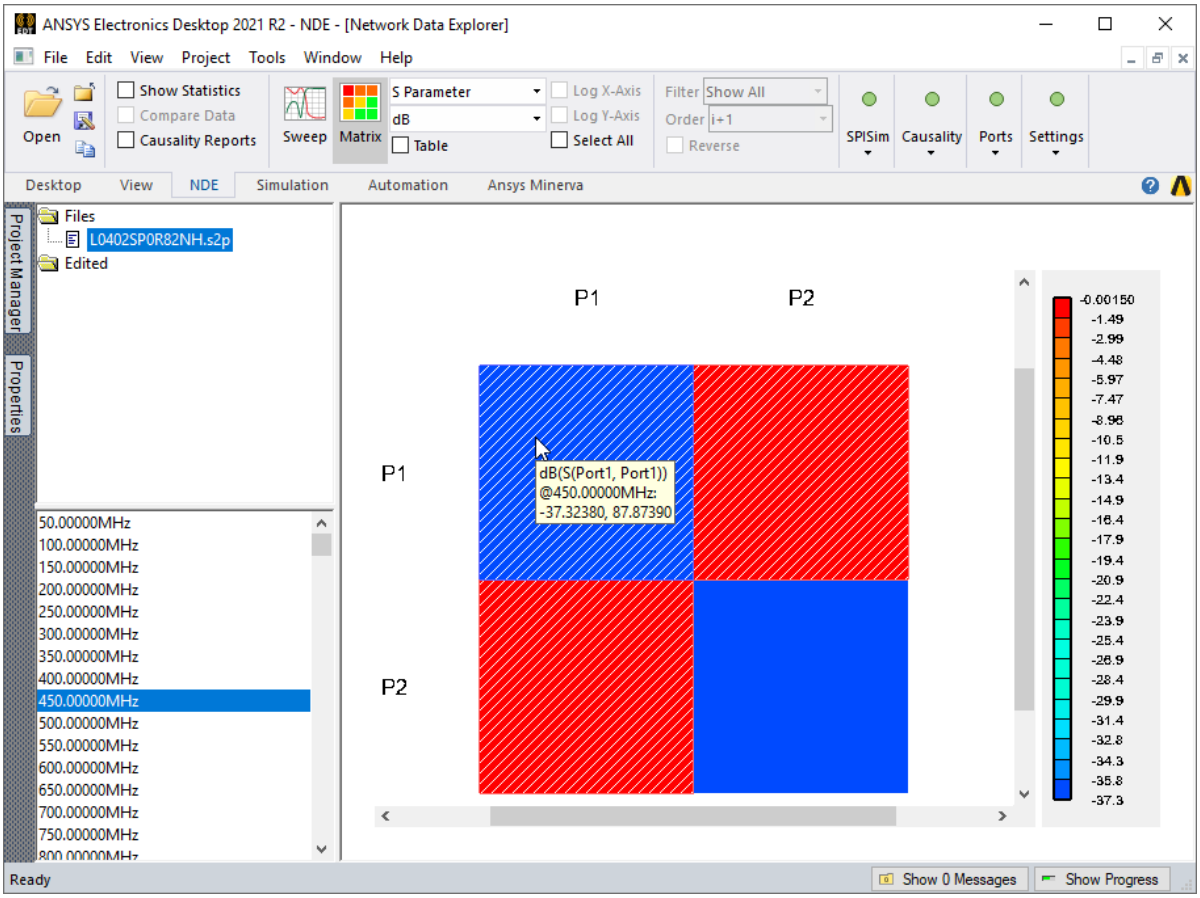
Double-clicking a cell switches to a matrix cell view, in which values for all frequencies for that cell are displayed. The double-clicked frequency is highlighted with solid red shading

Complex values are compared using their modulus. When multiple frequencies are selected, the data display depends on the Multiple Frequency Statistics setting.

Viewing a Color-Coded Matrix Plot

1. On the **NDE** ribbon, click **Matrix**.
2. Use the **Parameter** type drop-down menu to select **S parameter**, **Y parameter**, **Z parameter**, or another choice.
3. In the Cell and Frequency Selection pane, select the frequencies you want to plot or click the **Select All** check box on the **NDE** ribbon to select all frequencies.
4. Hover over a cell to see more information in a tool tip.
5. Right click to see a right click menu with other commands.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Matrix values display in a color-coded grid. If the selected **Format** is a complex value, only the real component is used to determine the display color. When multiple frequencies or variations are selected, the data display depends on the Multiple Frequency Statistics setting. Maximum values are highlighted in red. Minimum values are highlighted in dark blue.

Hover the cursor over any cell to view information about it.

Click any cell to select it. Selected cells appear with a pink outline. If Select Transpose is enabled, the transpose is selected in pink as well.

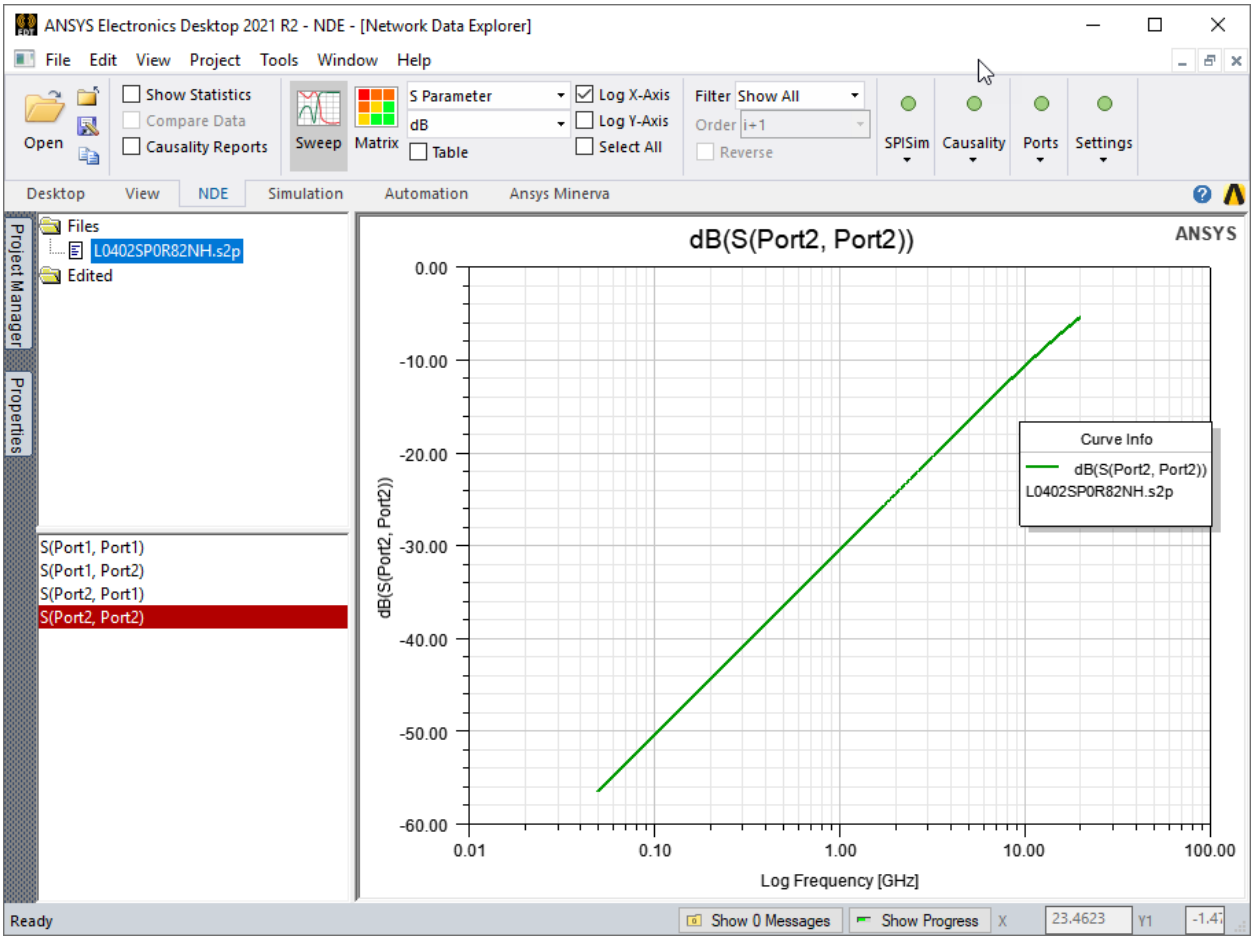
Double-click any cell to view a matrix cell plot in which all frequency values for that matrix cell are displayed as a graph.

Displaying a Cell Graph Across All Frequencies

Network Data Explorer can plot a cell across all frequencies.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. On the **NDE** ribbon, click **Sweep**. The Data View Pane updates if necessary.
2. Use the **Parameter** type drop-down menu to select **S parameter**, **Y parameter**, or **Z parameter**.
3. In the Cell and Frequency Selection pane, select cells to display or click the **Select All** check box on the **NDE** ribbon to select all cells.
4. To add a log scale to the X-axis, click **Log X-Axis** on the **NDE** ribbon.



5. To add a log scale to the Y-axis, click **Log Y-Axis** on the **NDE** ribbon.
6. Right click to see a right click menu with other commands.

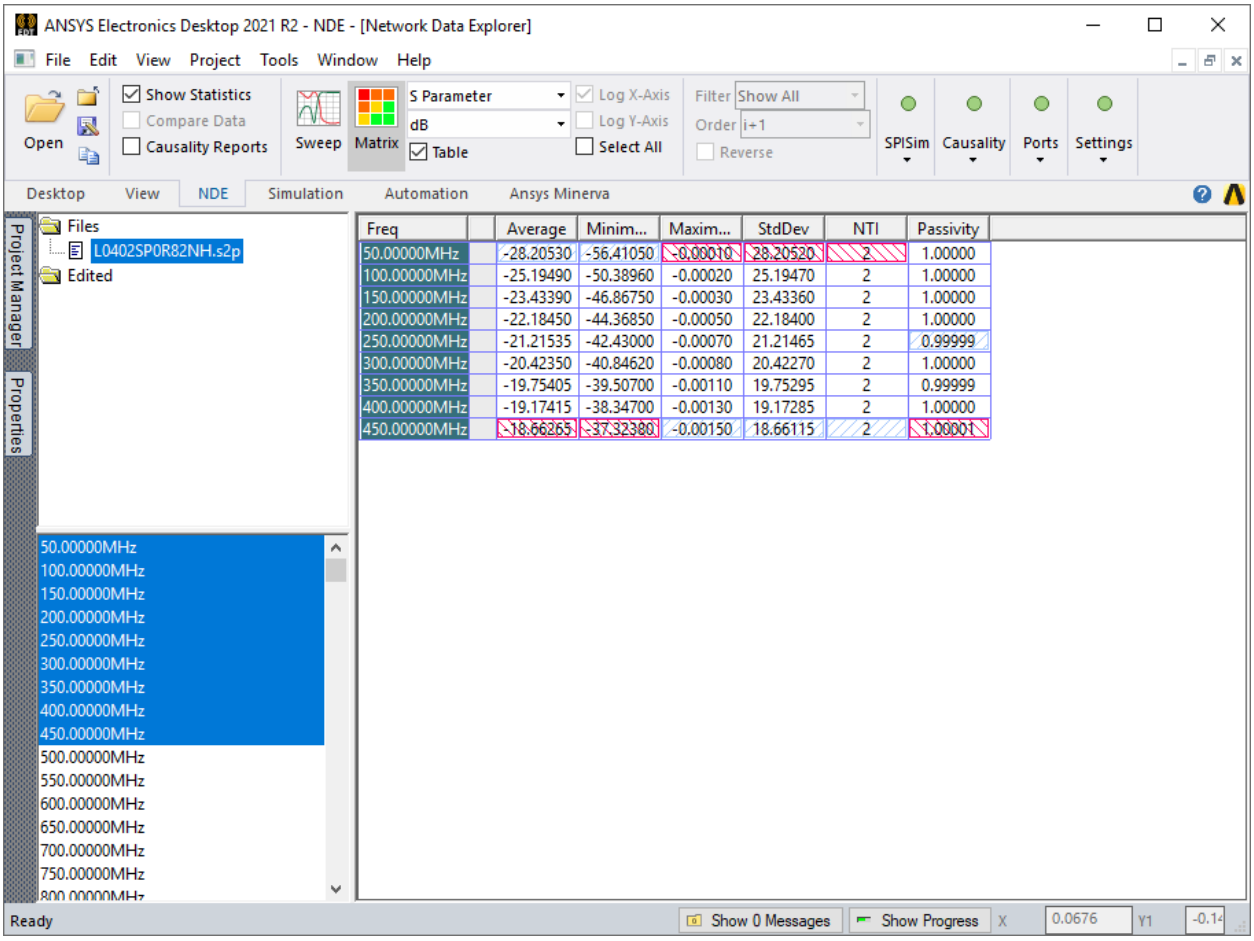
Displaying Matrix Statistics by Frequency

Network Data Explorer can display various statistical measurements.

1. On the **NDE** ribbon:
   a. Click **Matrix**.
   b. Click **Table**.
   c. Click **Show Statistics**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the Cell and Frequency Selection pane, select frequencies to display.



3. Click a column header to sort data by that column.
4. Hover the cursor over a cell to view information about it.

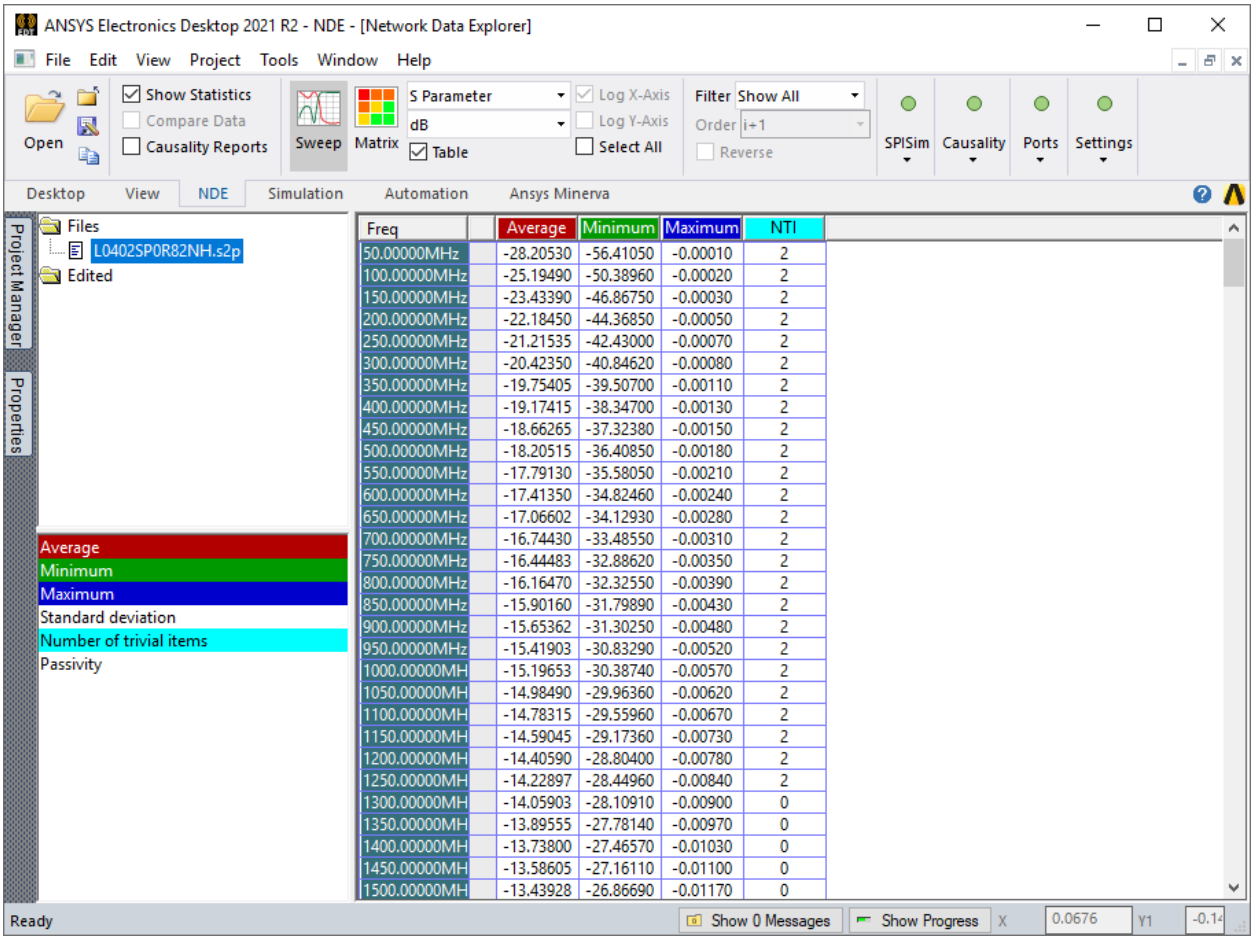
Only real (not complex) data formats are offered for statistical analysis. **Passivity** is only available for S-parameter data (comparisons inactive). **NTI** refers to the number of trivial items; for S-parameters, this includes all zeros and ones; for all other data (and data comparisons), only zeros are counted as trivial. The minimum value for each column is highlighted in blue; the maximum is highlighted in red.

Displaying Individual Statistics for All Frequencies

1. On the **NDE** ribbon:
    a. Click **Sweep**.
    b. Click **Table**.
    c. Click **Show Statistics**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the Cell and Frequency Selection pane, select statistics to display. The information displays in a table in the Data View pane.



Selected statistics are displayed for all frequencies.

Passivity is only available for S-parameters (comparisons inactive).

For S-parameters, the **Number of Trivial Items (NTI)** includes all values of 0 and 1. For other data and data comparisons, only values of 0 are counted as trivial.

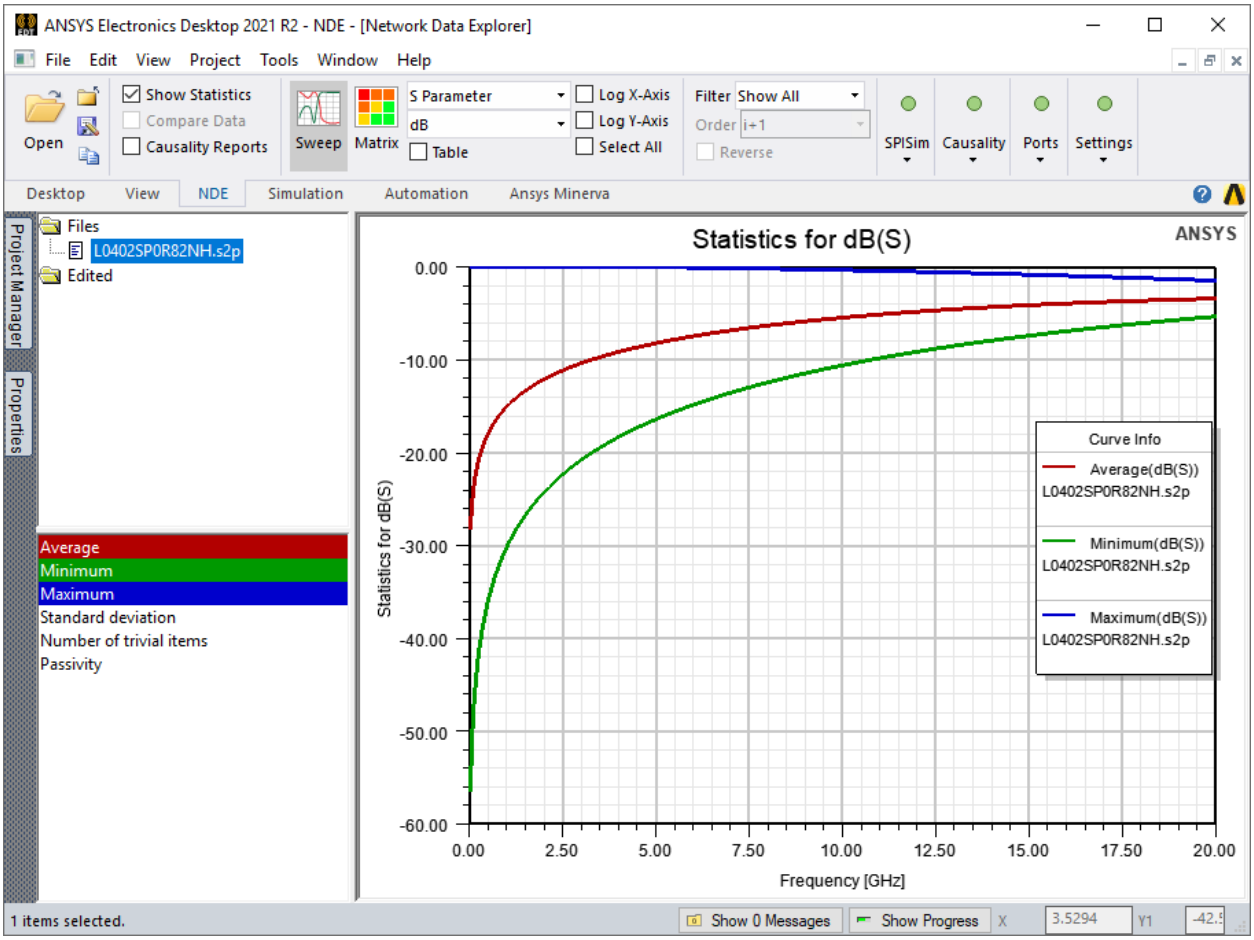
Creating a Statistics Plot

Network Data Explorer can display a graph of selected statistical measures across all frequencies.

1. On the **NDE** ribbon:
    a. Click **Sweep**.
    b. Click **Show Statistics**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the Cell and Frequency Selection pane, select statistics to display. The selected statistics are plotted.



3. Hover the cursor over a statistic to view more information about it.

Passivity is only available for S-parameters (comparisons inactive).

For S-parameters, the **Number of Trivial Items (NTI)** includes all values of 0 and 1. For other data and data comparisons, only values of 0 are counted as trivial.

Comparing Network Data

Network Data Explorer can compare variations for two network data sets that are the same size.

1. On the **NDE** ribbon, click **Sweep**.
2. In the Network Data Selection pane, select exactly two data sets.
3. On the **NDE** ribbon, click **Compare Data**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. In the Cell and Frequency Selection pane, select which cells you want to compare . For each value along the X-axis, the Y-axis values are subtracted, one from the other, to create the comparison plot. The second selected data is subtracted from the first selected data.
5. Optionally, check **Show Statistics** to show values applied to all cells and all frequencies

It is not possible to compare a data set against itself *unless the data set has been cloned.* Then, you can compare the original data set to the clone.

Traces for a given cell or statistical measure are displayed for all data sets; you can use tool tips to distinguish between them.

If a single cell or statistical measure is displayed, different colors are used for each data trace. If multiple cells or statistical measures are selected, a single color is used for all data traces for each cell or statistical measure.

In a data comparison, traces are shown for all selected data sets. This is true for both cell and statistical traces.

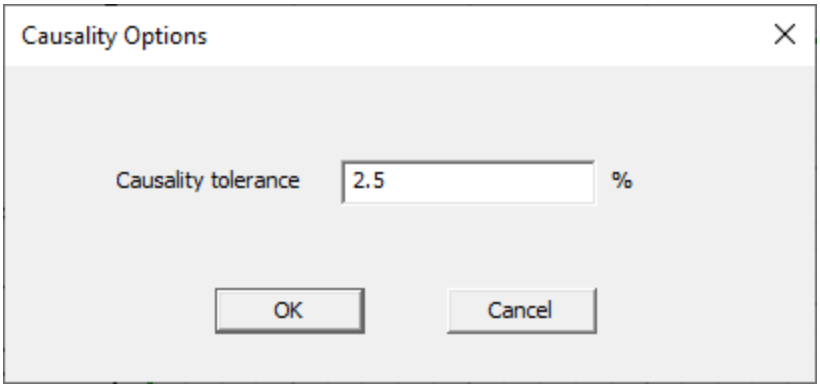
If **dB** format is shown, you can either subtract values before or after applying the dB function. See Display Format to make this choice.

Causality Checking and Plots

Network Data Explorer can perform a causality check on S-parameter data from any source (solution or file), and provide plots of the results in various formats.

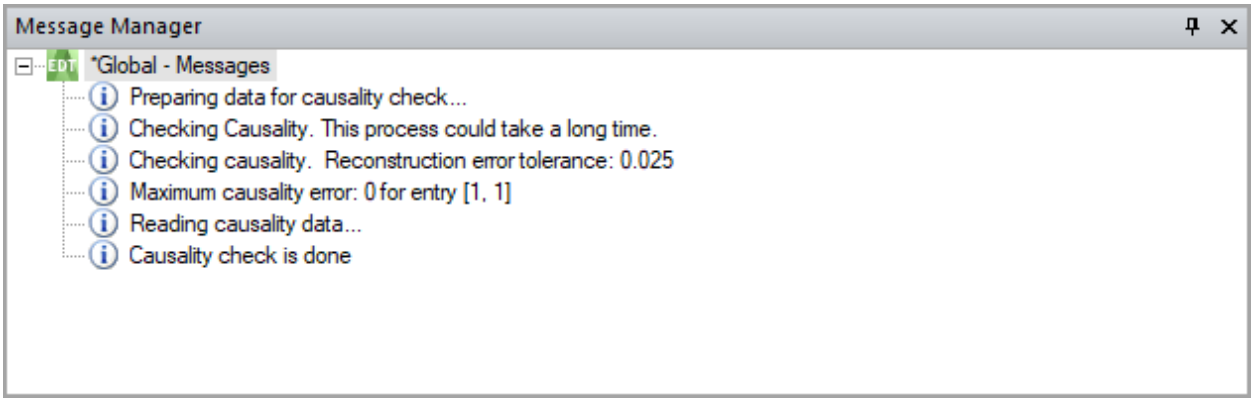
When S-parameter data is loaded into Network Data Explorer, the **Causality** button is enabled.

1. On the **NDE** ribbon, click **Causality**. The **Causality Options** dialog opens.



2. Enter a **Causality tolerance** and click **OK** to start the causality check. Depending on the size of the S-parameter data, the causality check may take several minutes to complete. The check's status displays in the Message Manager.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

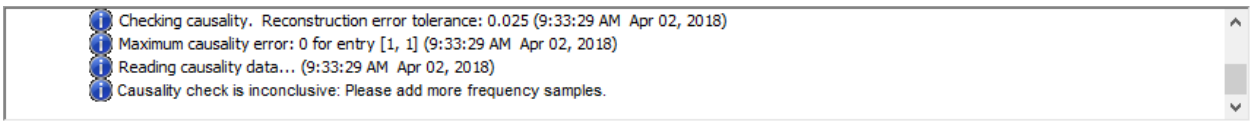


When the check completes, the Message Manager updates to display a summary of results.

Reconstruction Error Tolerance – Causality of a frequency response is determined by calculating the generalized Hilbert transform of the data at all frequencies. A causal frequency response is equal to its generalized Hilbert transform. The reconstruction error is the difference between the tabulated data and its transform at a given frequency. The message shows the maximum reconstruction error tolerance for a causal frequency response. The default tolerance of 0.01 is equal to the state-space fitting tolerance.

Maximum Causality Error – The maximum causality error for all port pairs and all frequencies, along with the matrix indices (port numbers) where the maximum noncausality occurs. A noncausal response is one where all matrix entries can be conclusively analyzed, and at least one entry exceeds the causality tolerance. The maximum reconstruction appears first, followed by port numbers in brackets (e.g., [port number, port number]). When all results are conclusive but no matrix reconstruction error exceeds the tolerance, the maximum causality error is reported as zero, and no matrix entry is listed.

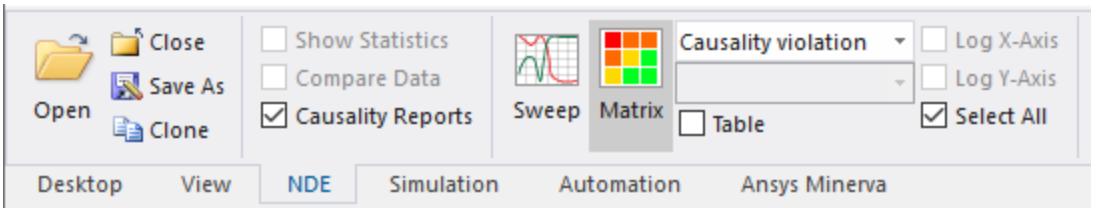
If the data does not contain enough frequency points to determine whether the data is or is not causal, the Messages Pane will note an inconclusive result. Network Data Explorer will also report the data set as inconclusive if any cells are inconclusive, even if other entries exhibit causality violations.



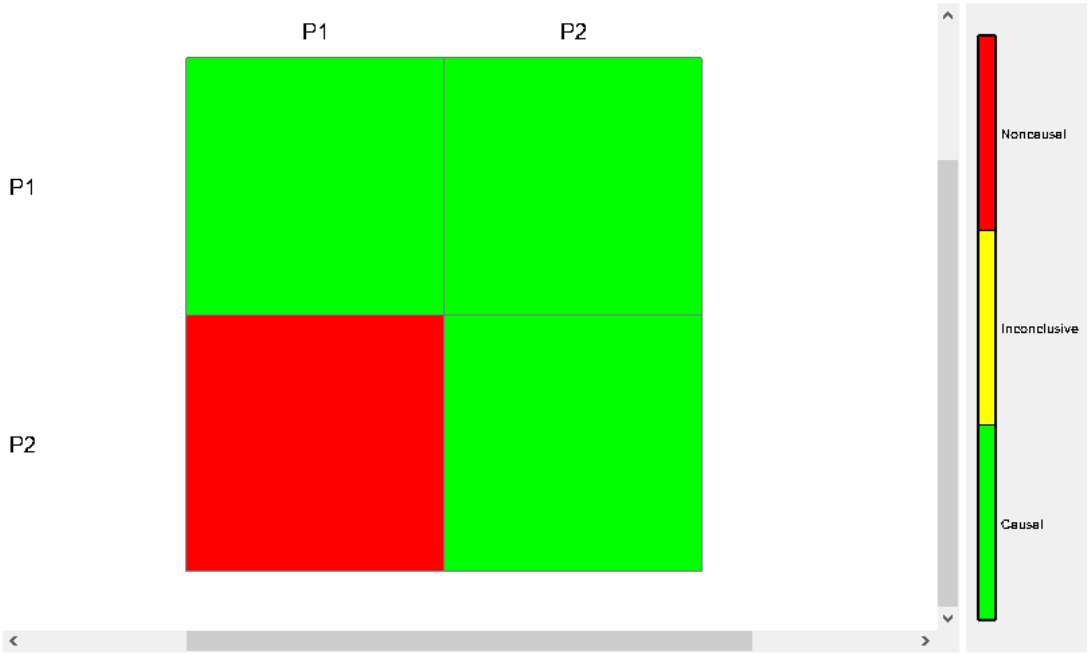
To see the plotted results of the causality check:

1. On the **NDE** ribbon, click **Causality Reports**.
2. Either click the **Matrix** icon or select **Causality violation** in the **Parameter** type drop-down menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



A rectangular plot displays, with dimension N x N and color-coding to indicate the causality status of each port pairing.



In this plot, the cells go from (Port 1, Port 1) at the upper-left area to (Port N, Port N) at the lower-right corner. The result shows the causality over all frequencies in the data. In this example, the matrix is asymmetric, so that S12 is noncausal, while S11, S21, and S22 are causal.

To see the details for each frequency, click the **Table** check button on the **NDE** ribbon.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

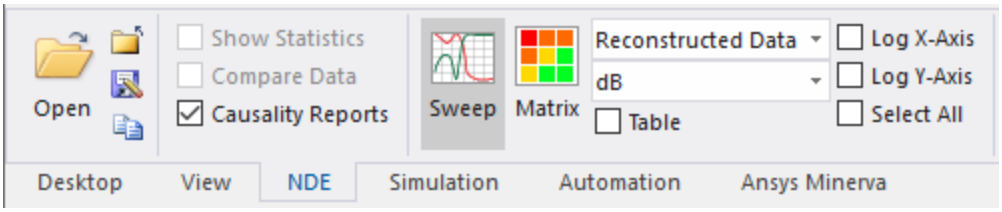
	Port2	0.06069, 0.00000	0.00152, 0.00000	0.00101, 0.00000	0.00021, 0.00000

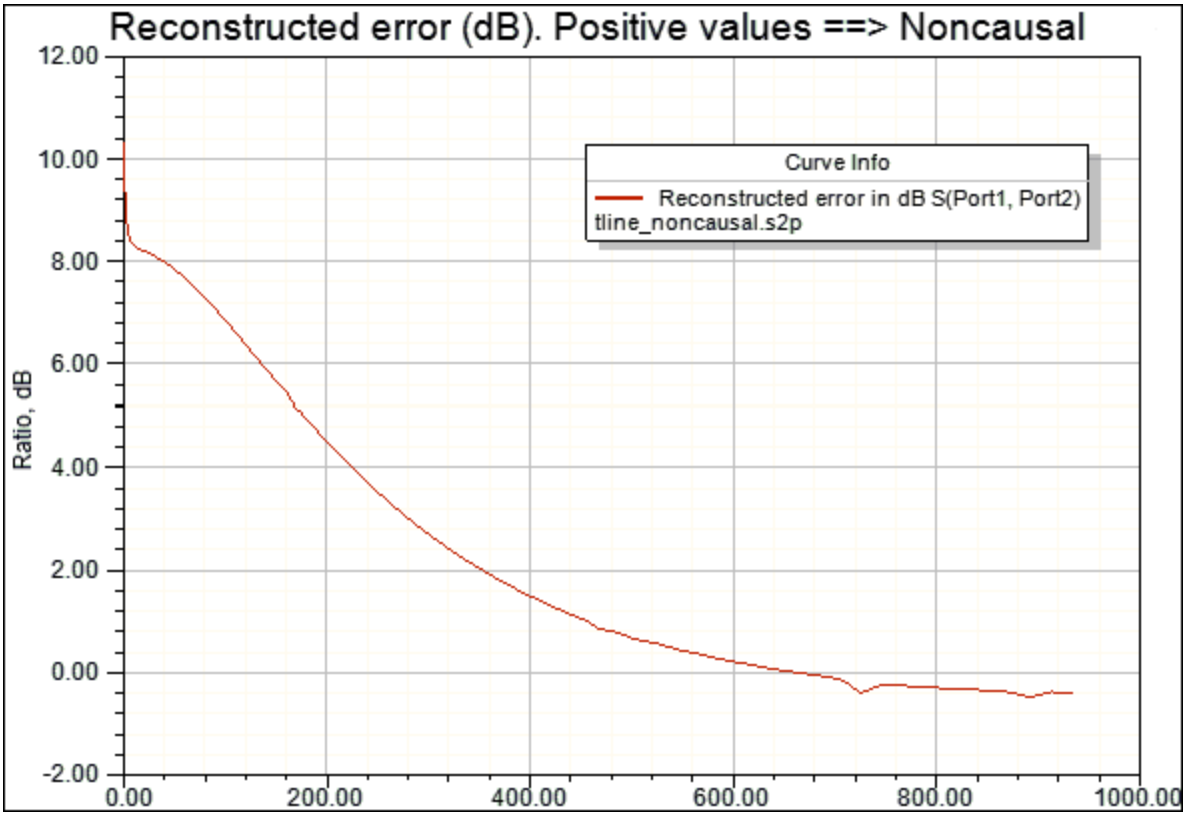
To plot the reconstructed frequency response generated by the causality checker:

1. On the **NDE** ribbon, click **Causality Reports**.
2. Either click the **Sweep** icon or select **Reconstructed Data** in the **Parameter** type drop-down menu.
3. In the **Format** drop-down menu, select the desired format. **dB** is selected by default.



The plot appears, showing the reconstruction error at each frequency divided by the tolerance.

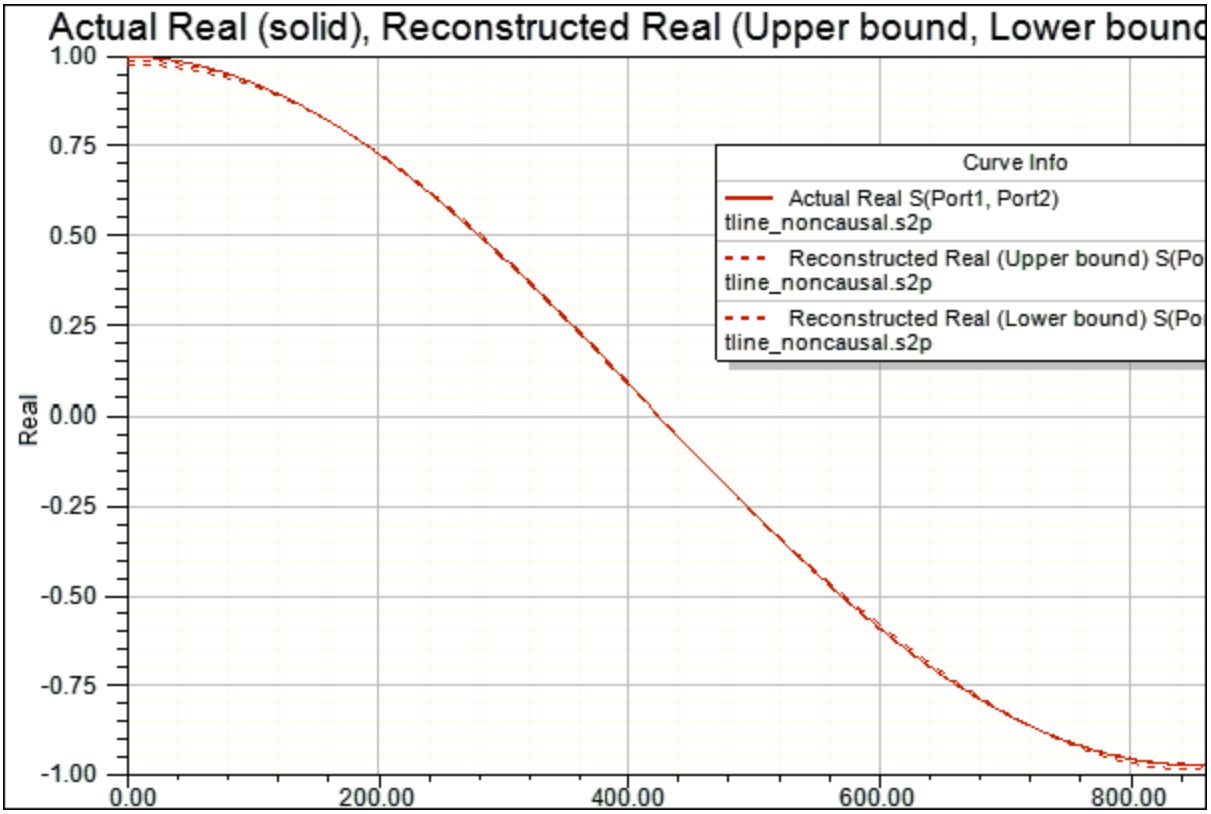
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The reconstruction error ratio for parameter S12 is positive for frequencies less than about 680MHz, indicating a broad range of noncausal behavior.

4. To compare the real part of the reconstructed data to the real part of the actual data, set the **Format** to **Real**.

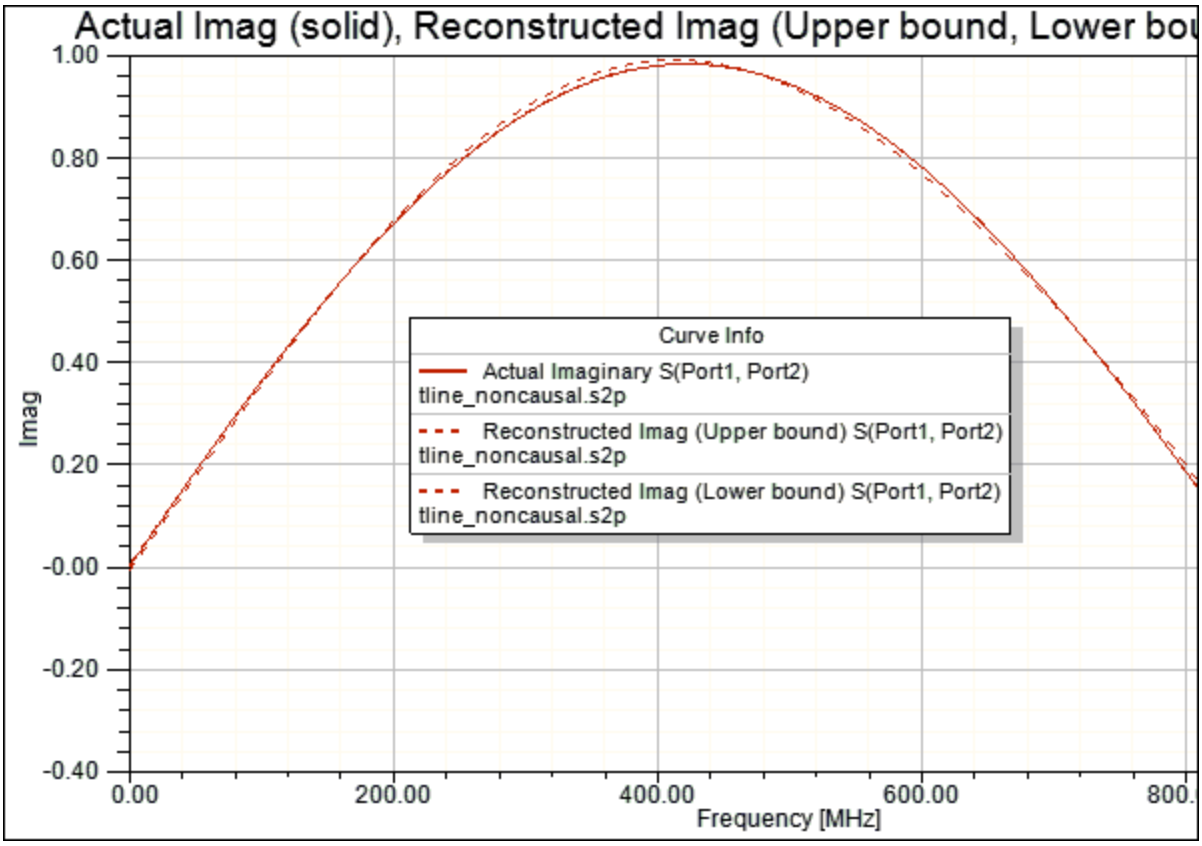
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For a causal frequency response, the actual data (solid line) will be within the upper and lower bounds of the reconstruction (dotted lines) at all frequencies.

5. To compare the imaginary part of the reconstructed data to the imaginary part of the actual data, set the **Format** to **Imaginary**.

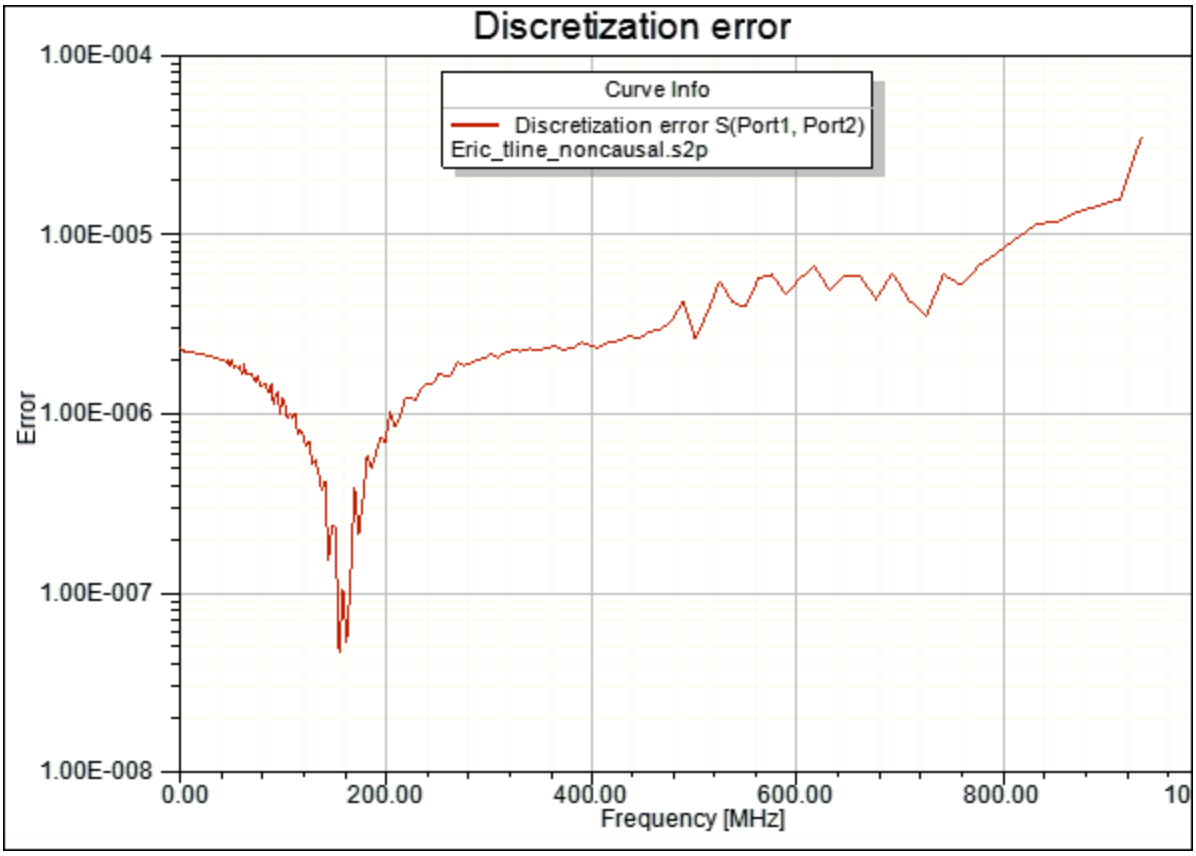
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For a causal frequency response, the actual data (solid line) will be within the upper and lower bounds of the reconstruction (dotted lines) at all frequencies.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. To view the frequency-dependent discretization error, set the **Format** to **Discretization**.



The discretization error is the error that is due to the fact that the data are available only at discrete frequencies rather than for a continuous spectrum. A discretization error near or greater than the causality tolerance renders the causality check inconclusive. Data at more frequencies could reduce the discretization error and render the analysis conclusive. This set of data exhibits low discretization errors (<<0.01) at all frequencies, and the causality check is conclusive (conclusively noncausal in this example).

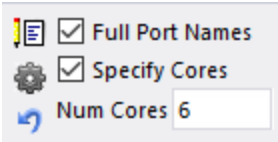
Multithreading

By default, multithreading (execution on multiple cores) is enabled for Causality Checking and Macro Model export. Multithreading saves significant time in the Causality Check calculation, and improves the time for other state-space fitting operations. See Technical Notes.

The **Cores** field in the Network Data Explorer Control Pane defaults to half the number of cores detected on your computer.

For best performance, disable hyper-threading on your computer. When hyper-threading is enabled, the number of cores includes the physical cores and an equal number of logical cores. With hyper-threading disabled, the display shows only half the number of physical cores.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To disable multithreading, uncheck the check box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

25 - Scripting

Information about creating, editing, and using IronPython scripts is in the product's scripting guide in the help. You can also access PDF versions of the scripting guide from the help system.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

26 - Ansys Workbench Integration Overview

Ansys Workbench combines the strength of its core product solvers with the project management tools necessary to manage project workflow. In Ansys Workbench, analyses are built as *systems*, which can then be combined into a *project*. The project is driven by a schematic workflow that manages the connections between the systems.

From the schematic, you can interact with applications (called workspaces) that are native to Ansys Workbench and that display within the Ansys Workbench interface. Native workspaces include: Project Schematic, Engineering Data, and Design Exploration (Parameters and Design Points).

You can also launch applications that are data-integrated with Ansys Workbench, meaning the application's interface remains separate, but the data from the application communicates with the native Ansys Workbench data. Thus, data can be passed back and forth between any Ansys Electromagnetics product on a Workbench Project Schematic and any supported Ansys or Ansys Electromagnetics desktop product. Depending on the application, data integration can include basic actions such as saving projects, as well as more complex actions such as the coupling of Ansys Electromagnetics product variables to Workbench Design Exploration parameters.

Data-integrated applications include the following Ansys Electromagnetics products:

Circuit, HFSS, Icepak, Maxwell/RMxprt, Mechanical, Q3D Extractor, and Twin Builder.

> **Note:**
>
> For detailed information on working with Ansys Workbench, please refer to the Workbench documentation.

Integrating Ansys EM Suite with Ansys Workbench

You can integrate the Ansys Electromagnetics Suite with the Ansys Workbench application after both have been installed on your system. For successful integration, both preinstalled applications must be of the same version. A single operation completes the integration process for all supported design types.

The same procedure is used to integrate the applications or to decouple them (if they had previously been integrated). The procedure is as follows:

1. From the Windows Start Menu, select **All Programs** > **Ansys EM Suite 20*yy* R*n*** > **Modify Integration with Ansys 20*yy* R*n***.

   A *Modify Integration with Ansys 20yy Rn* command window appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

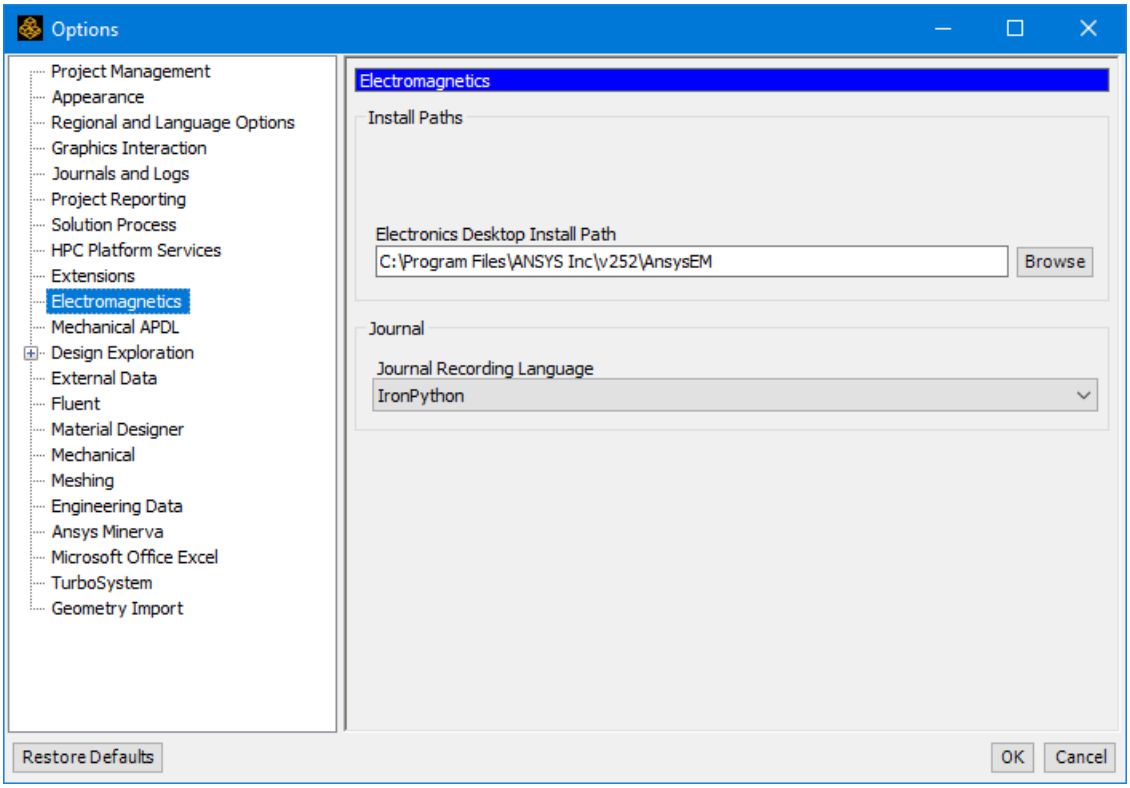
- If both applications are present on the system, their installation paths will be reported, and you will be asked if you wish to integrate them.
- Alternatively, if integration has already been performed, you will be asked if you wish to decouple them.

2. Type **yes** to perform the prompted action or **no** to abort the operation without making any changes. Then press **Enter**
   - If you enter *"yes,"* a confirmation line appears in the command window indicating that integration (or decoupling) has been completed, and the window remains open.

     Press **Enter** again to close the command window.
   - If you enter *"no,"* the operation aborts and the command window closes immediately.

Note:

You can confirm that the Ansys 20*yy* R*n* application is “aware” of the integrated application via the *Options* dialog box in Workbench. The path to the integrated Electronics Desktop application is listed in the *Electromagnetics* group of settings.



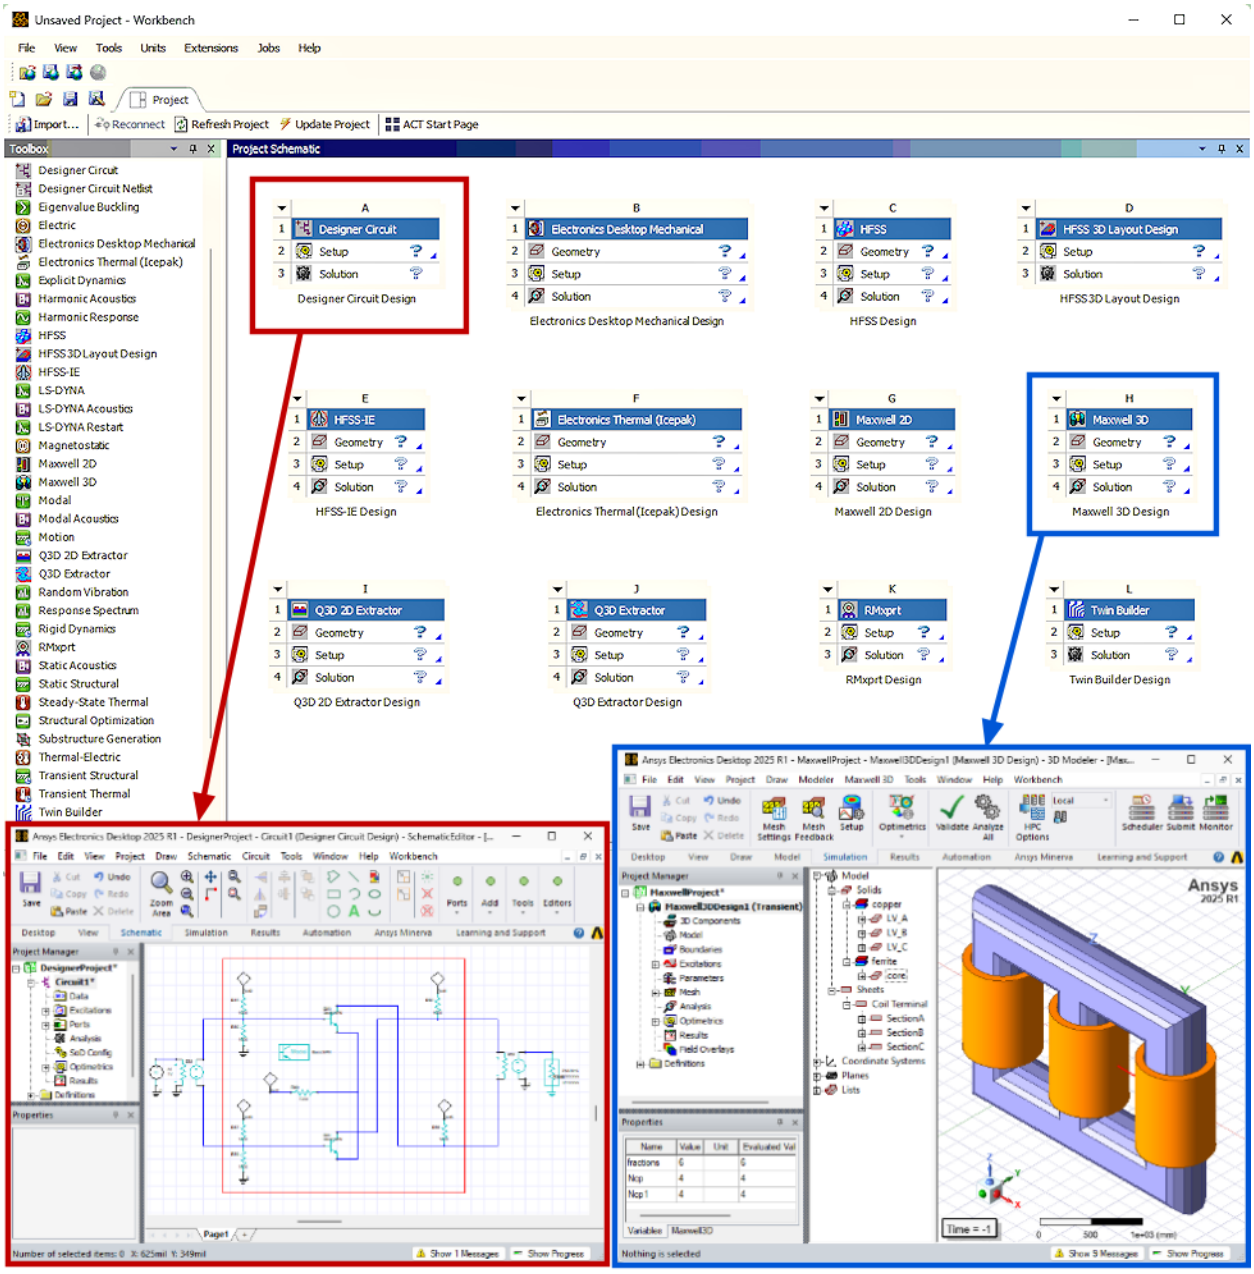
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In this group of options, you can also specify Workbench's default **Journal Recording Language** for use when interoperating with the Ansys Electromagnetics products. **Iron Python** is the default language, and the alternative choice is **Visual Basic** (VB). Changes applied here affect any new Workbench or Ansys Electronics Desktop session launched after the change. Any open instance will continue recording in the language that was in effect when the program was launched.

Workbench Data Integration Overview

Ansys EM data-integrated applications can reside on a Workbench **Project Schematic**, as shown.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



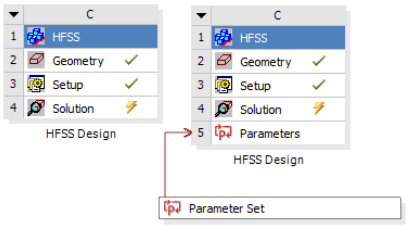
Objects placed on a Workbench Project Schematic (such as instances of Ansys Electromagnetics projects) are referred to as *systems*. The number of cells in the system depend on the desigh type, as follows:

- **RMxprt, Circuit, HFSS 3D Layout,** and **Twin Builder:** Appear on the Workbench Project Schematic as systems with three cells: **<*System_Type_Name*>, Setup,** and **Solution**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **HFSS, Maxwell, Q3D Extractor, Icepak,** and **Mechanical:** Include an additional **Geometry** cell along with the **<*System_Type_Name*>, Setup,** and **Solution** cells, for a total of four cells.

If you invoke Ansys **DesignXplorer** to use variables for refining a design, a **Parameters** cell is added, with a link to the associated Workbench **Parameter Set**. Refer to the Ansys Workbench help for details on working with systems, cells, and parameter sets.



All supported Ansys Electromagnetics Suite products integrate with Workbench commands, services, and DesignXplorer in a similar manner. Some capabilities include:

- Adding New Analysis Systems
- Importing Existing Ansys EM Projects into Workbench
- Editing Ansys EM Models in Workbench
- Ansys EM to Workbench Geometry Transfer
- Ansys EM to Workbench Material Data Transfer
- Analyzing Ansys EM Models in Workbench
- Performing Parameter Studies in Workbench
- Scripting in Workbench

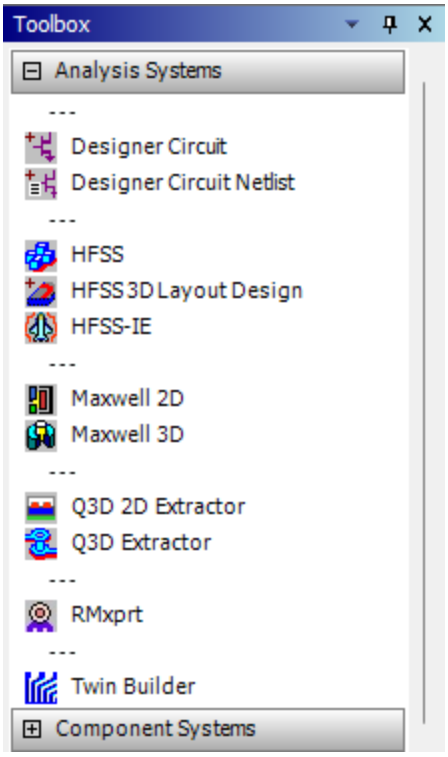
In addition to these major features, Workbench can archive, save, back up, duplicate, and delete Ansys Electromagnetics projects used in a Workbench project. Progress information and messages from integrated Ansys EM projects are also displayed in Workbench.

> **Note:**
>
> Look in the *Ansys Workbench Help* to find detailed information about performing the above-listed operations.

Adding New Analysis Systems

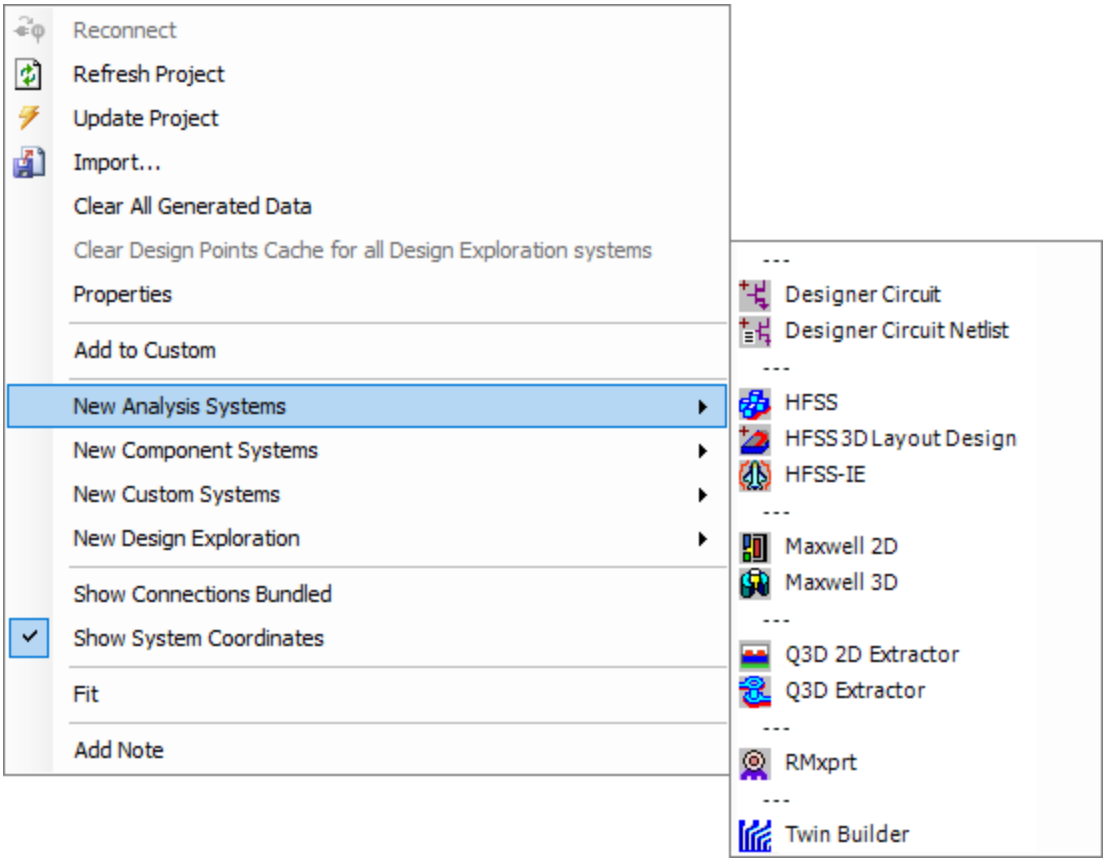
A new Ansys Electromagnetics Analysis System can be added to a Workbench Project Schematic by dragging and dropping it from the Toolbox:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Alternately, you can add a system by right-clicking in the Workbench Project Schematic area and selecting **New Analysis Systems** > **[System Type]**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

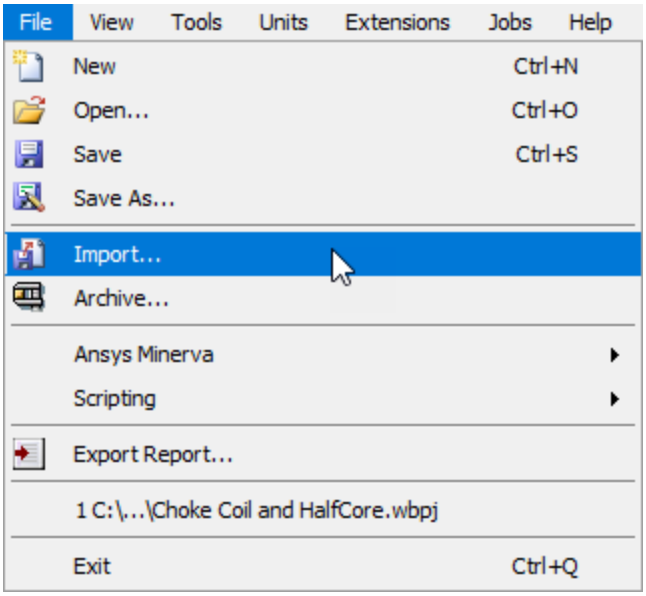


Importing Existing Ansys EM Projects into Workbench

You can import existing Ansys Electromagnetics Suite projects into a Workbench project schematic using **File** > **Import**. When you do, a copy of the Ansys Electromagnetics project is placed in the Workbench project folder. The original Ansys Electromagnetics project remains intact.

> **Note:**
>
> Object, material, and parameter names with non-ASCII characters are not allowed for data transfer. Such transfers fail and produce an error message.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

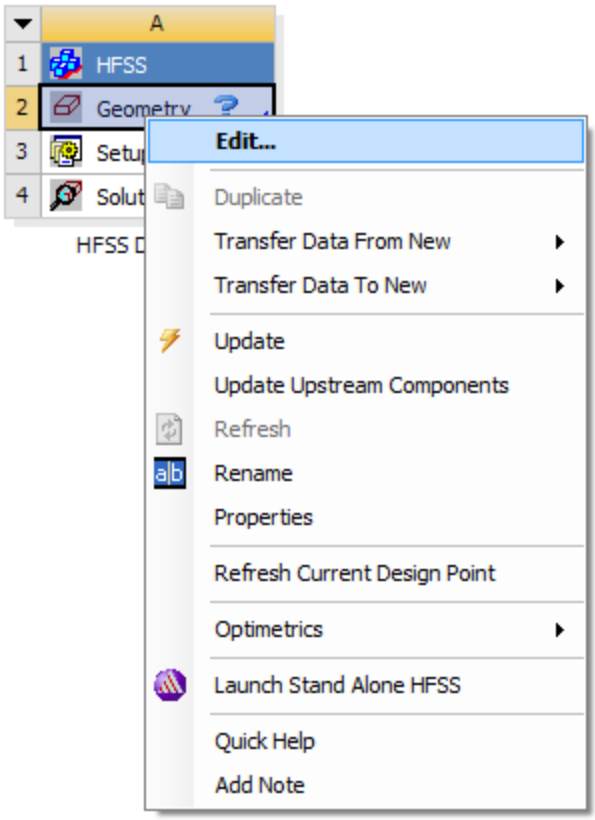


Editing Ansys EM Models in Workbench

You can edit various properties and parameters of the Ansys Electromagnetics project (geometry, setup, solution, etc.) either by right-clicking the project in Workbench and selecting **Edit**, or by double-clicking the project.

Doing so launches the Ansys Electromagnetics desktop application and loads the project so that you can set up your project in a familiar desktop environment. Changes made to the Ansys Electromagnetics project are saved to the project instance in the Workbench project folder.

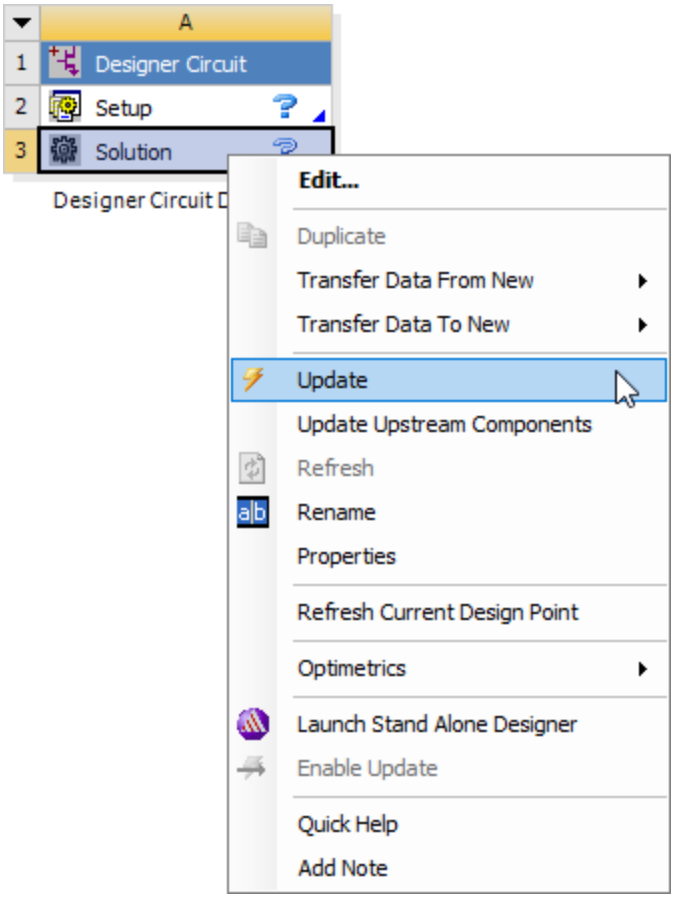
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



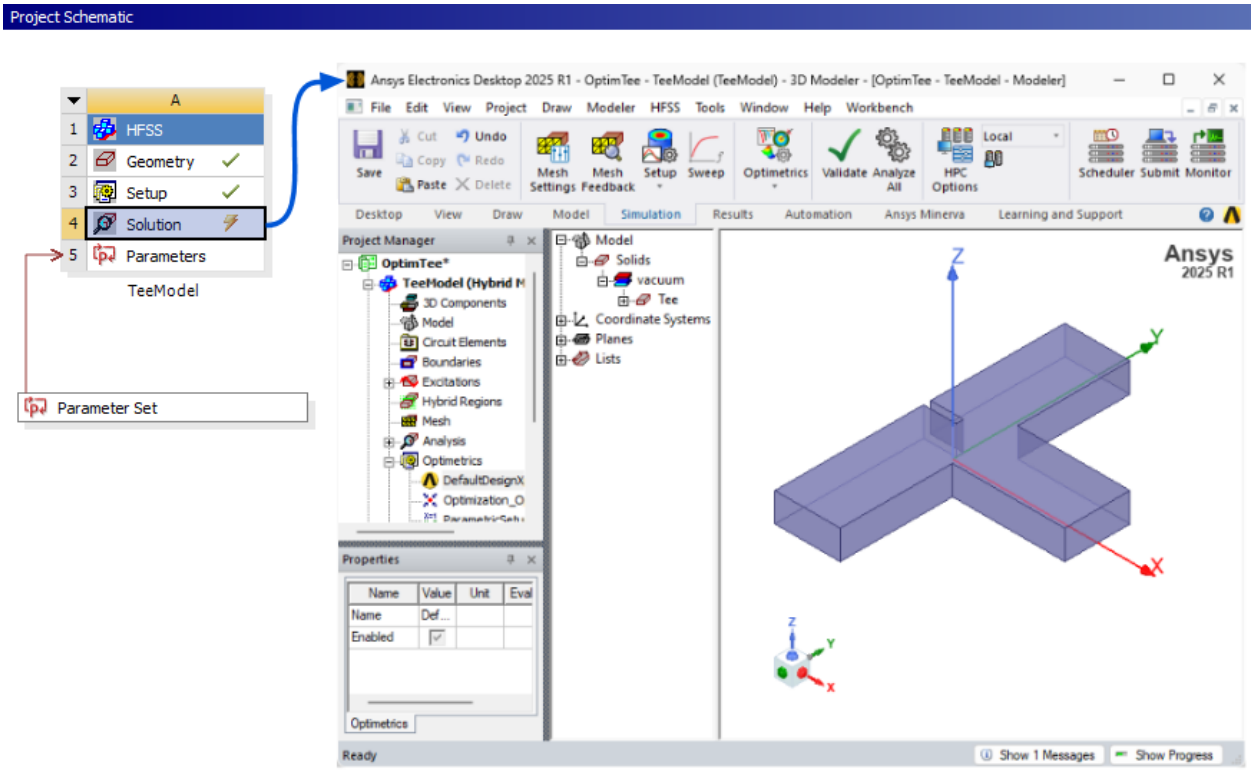
Analyzing Ansys EM Models in Workbench

You can use Workbench's **Update** command to run analyses in the integrated Ansys Electromagnetics project. Progress information is also shown in Workbench.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



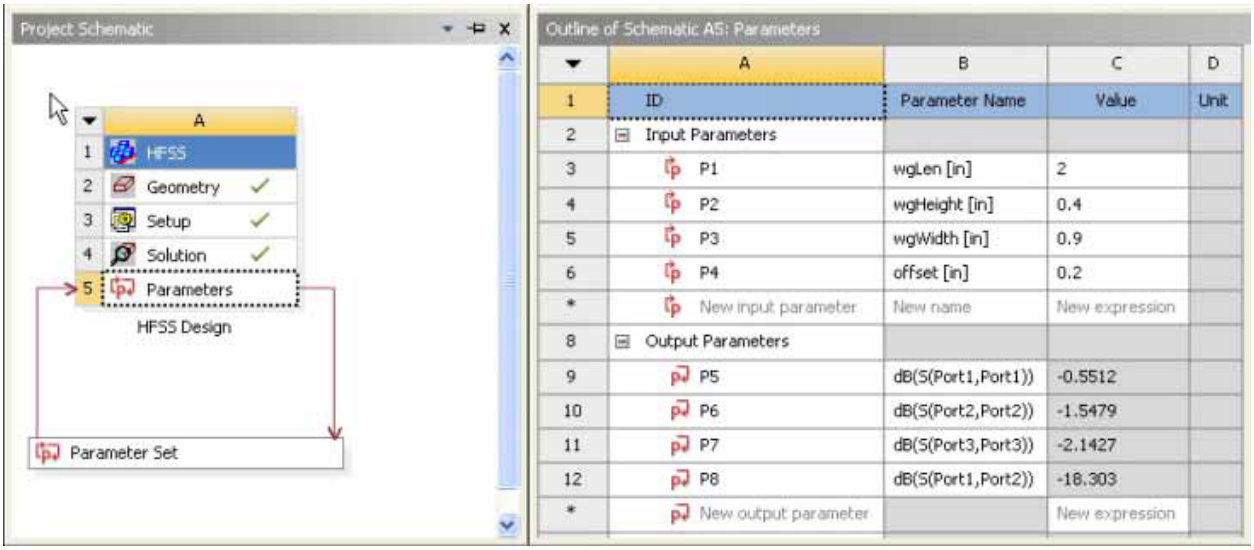
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Performing Parameter Studies in Workbench

Workbench **Parameter Sets** allow you to change parameter values and units of measure, or add new parameters. Parameter data is passed back to the Ansys Electromagnetics application for updated analyses. After analysis, the Workbench Parameter table should be updated correctly for all design points.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

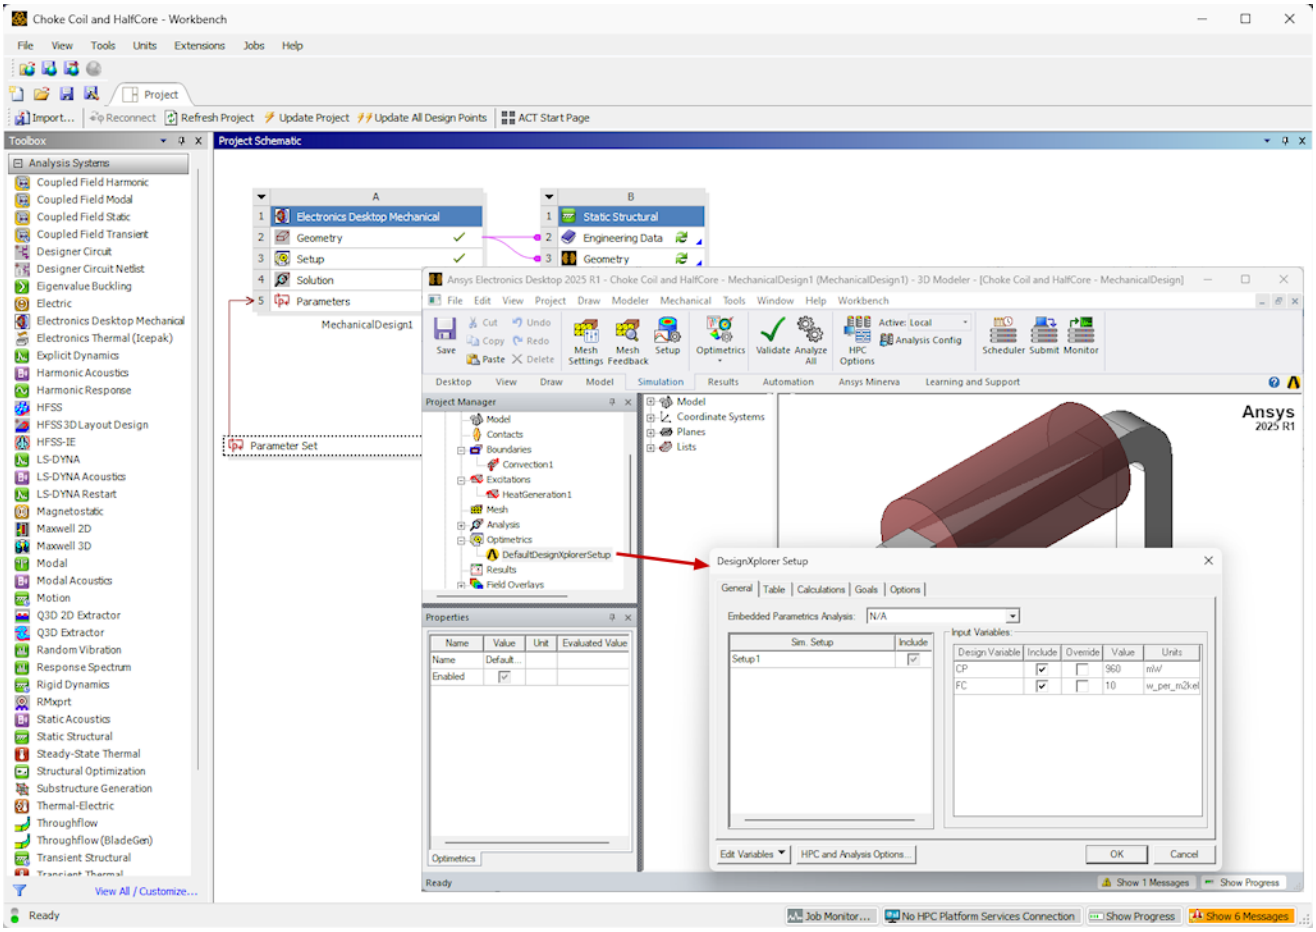


Note:

Because Workbench and Ansys Electromagnetics Desktop have different unit systems, units defined in Desktop are Dimensionless in the Workbench Parameters table and thus cannot be changed. Refer to the *Ansys Design Modeler User's Guide* > *Project Schematic Operations* > *Parameters in Project Schematic* > *Parameter Units* topic for additional information.

Parameters from the Ansys Electromagnetics project are exposed to Workbench through the **DesignXplorer** setup. The Ansys Electromagnetics system's cell status on the Workbench project is updated as changes are made in the Ansys Electromagnetics application. The following example is a Mechanical, Steady-State Thermal design in which two variables have been defined. One variable (CP) is the coil power (960 mW heat generation) and the other (FC) is the film coefficient of the assigned convection boundary:

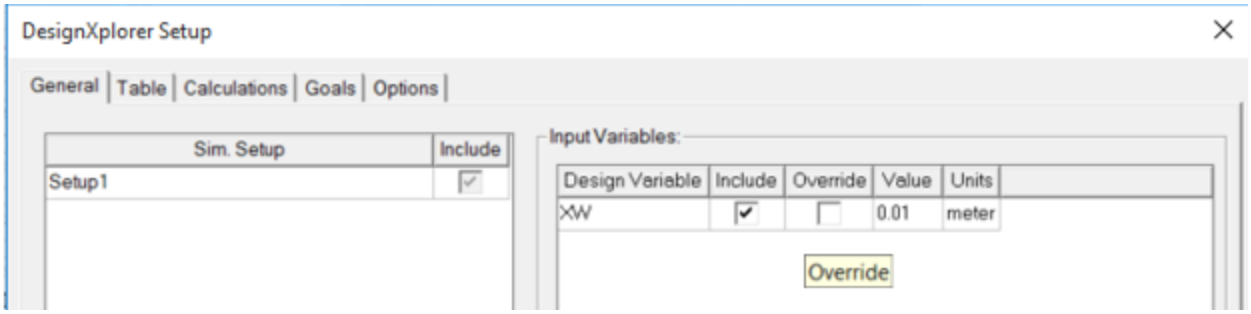
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



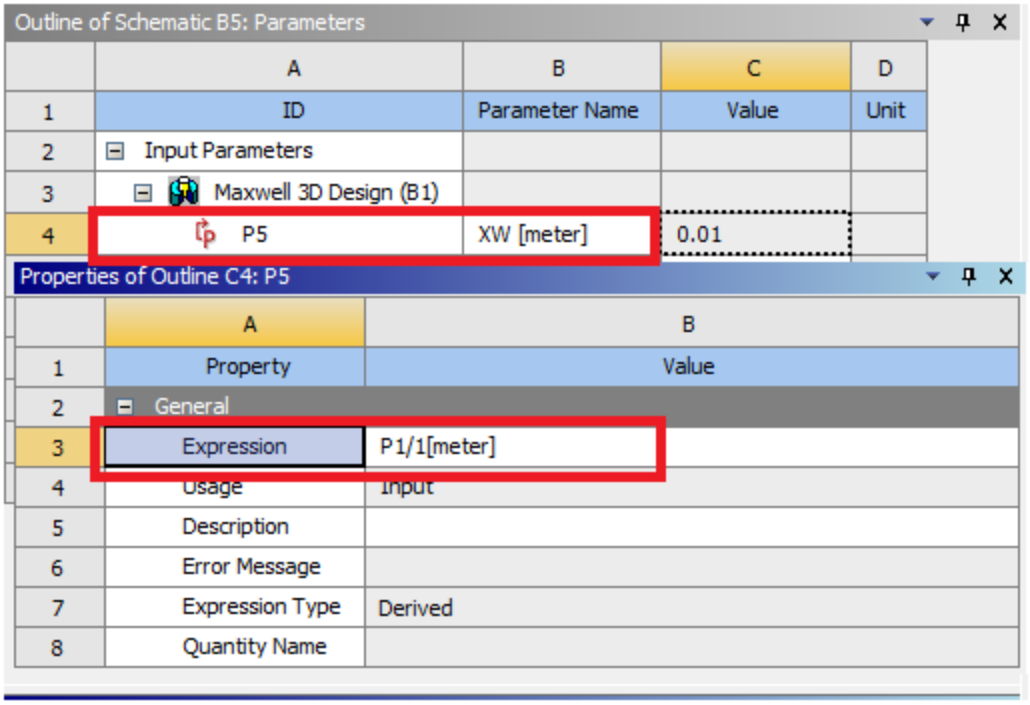
The workflow for using Electronics Desktop systems with the Workbench to take advantage of Distributed Analysis is as follows:

1. In the Ansys Electronics Desktop, specify a variable an as input parameter. The following figure shows a DesignXplorer Setup that includes a geometry variable called XW This variable is mapped to a variable in the corresponding Workbench Design, in this example, P5.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

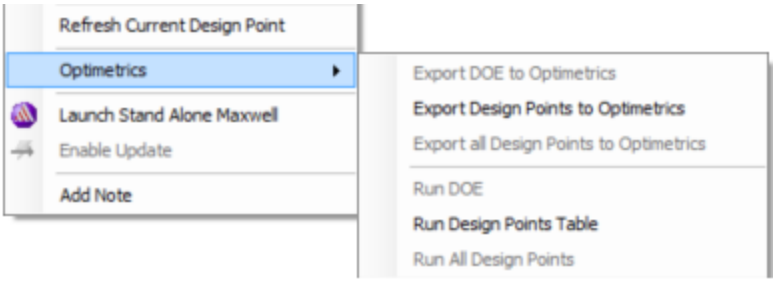


2. In the Workbench Design, change the P5 expression to a new value (in this example figure, the P5 parameter is assigned an expression of P1/1[meter] to tie it to the geometry system's variable.



In Workbench, the **Export Design Points to Optimetrics** and **Run Design Points Table** commands are enabled.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

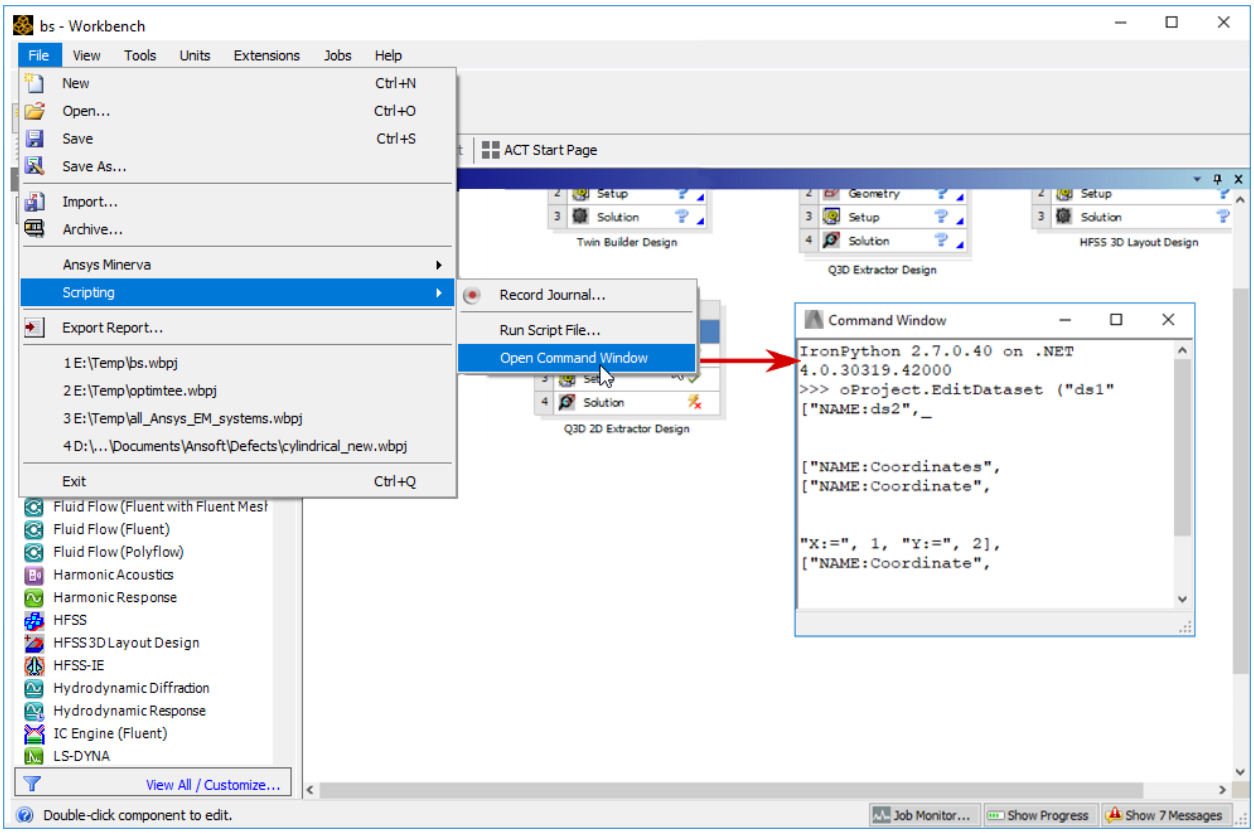


3. In Electronics Desktop, you can click on the default DesignXplorer Setup, and choose **Generate Variation Data**.

If you have configured your Analysis Configuration for multiple machines, the Project is ready for Distributed Analysis. After analysis, the Workbench Parameter table should be updated correctly for all design points.

Scripting in Workbench

Scripts that include Ansys Electromagnetics projects can be recorded and run in Workbench.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When a Workbench journal is run from the command line, Electronics Desktop allows the Ansys EDT portion to also run in batch mode (that is, when using RunWB2 -b).

Example: From a Windows Command prompt, enter the following command to replay the journal named "myReplayJournal.wbjn":

```
RunWB2 -b -r myReplayJournal.wbjn
```

Ansys EM - Ansys Multiphysics Coupling

Data integration provides an improved multiphysics workflow between Ansys Electromagnetics designs and Ansys applications such as Mechanical and Thermal. Coupling is provided through project schematic links. Heat losses and force data are automatically transferred to Ansys Mechanical, and there is no need to export or import transfer XML files. Edits made in Ansys Electromagnetics applications are automatically transferred to the Ansys application through the Workbench **Refresh** command. Workbench commands also enable easier automation of iterative coupling of thermal feedback.

The following sections provide some examples of multiphysics coupling.

Multiphysics Coupling on Workbench with Ansys Thermal

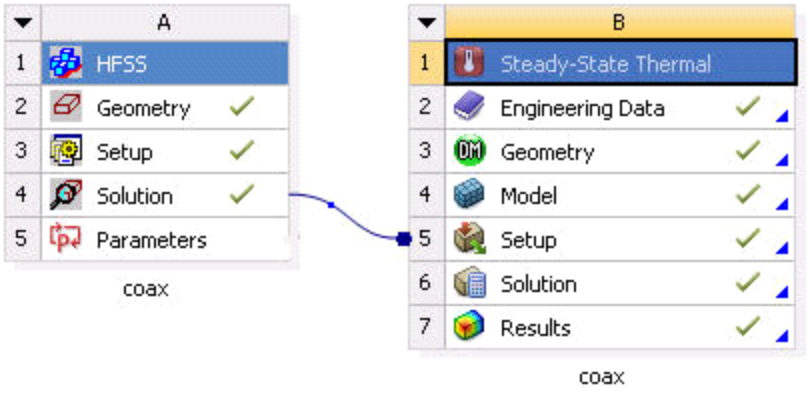
Multiphysics Coupling on Workbench with Ansys Structural

Multiphysics Coupling between Ansys EM Field Systems on Workbench

Multiphysics Coupling on Workbench with Ansys Thermal

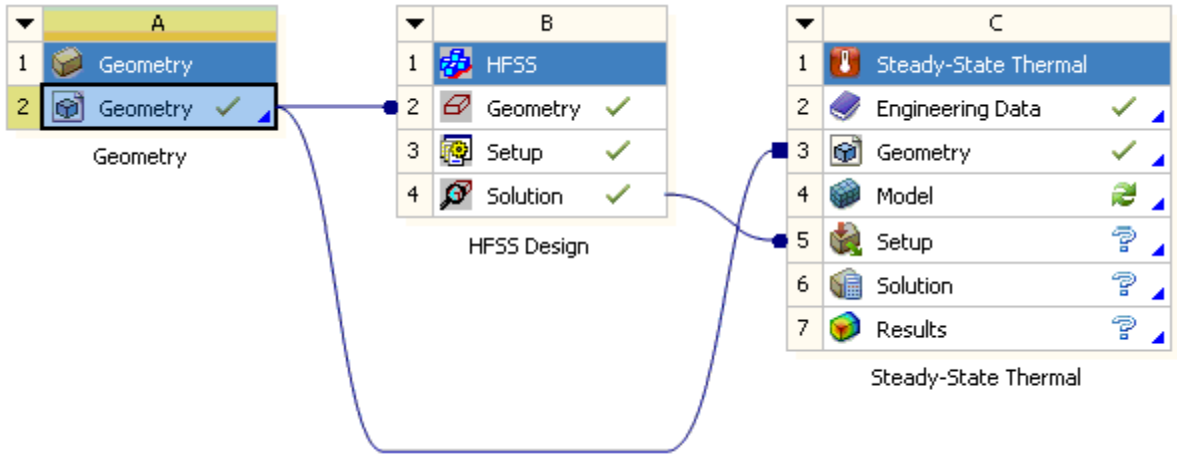
Using data integration, HFSS, Maxwell, and Q3D Extractor provide heat losses (heat generation and heat flux) to Ansys Thermal. In HFSS, both Driven and Eigenmode projects can be coupled for multiphysics. You first need to enable feedback as described in Setting the Temperature of Objects.

Note how the HFSS design is linked visually to Ansys Thermal on the Workbench project schematic.

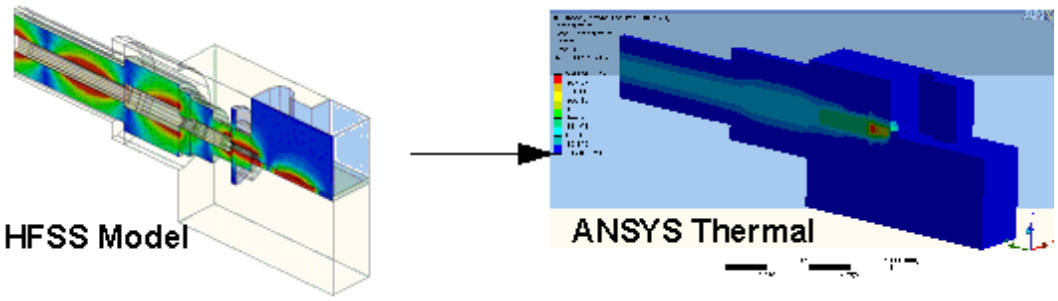


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Geometry sharing is possible, provided you activate Beta Options in Workbench. A geometry from the Component Systems in the Toolbox in Workbench Schematic can be shared as shown in the image below.



In this example, HFSS coax model Solution provides heat loss data as a thermal load to the Ansys Thermal Setup. The resulting analysis shows a thermal "hotspot", providing the user with the information needed to adjust the design's material to fix the problem.

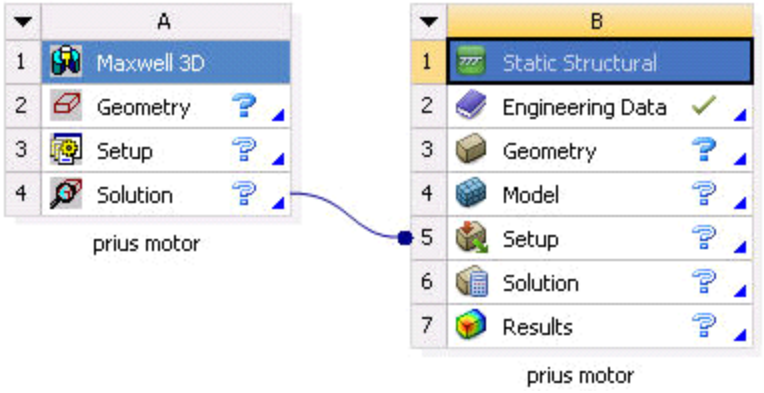


You enable this feature by checking Enable Feedback in the dialog for Setting the Temperature of Objects.

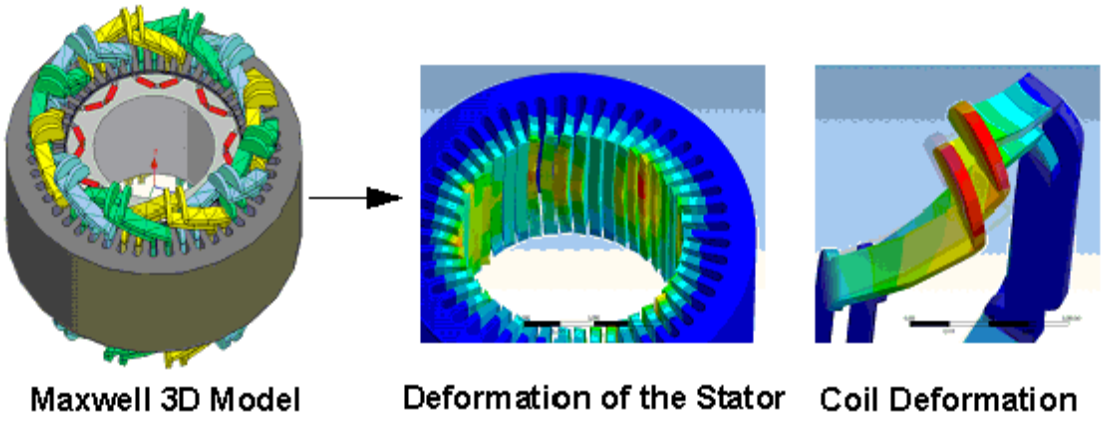
Multiphysics Coupling on Workbench with Ansys Structural

Using data integration, Maxwell 2D and Maxwell 3D can provide forces to Ansys Structural.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In this example, the Maxwell 3D electromagnetic force density **Solution** is used as the load in Ansys Structural to determine how these forces deform the motor's stator and coils.

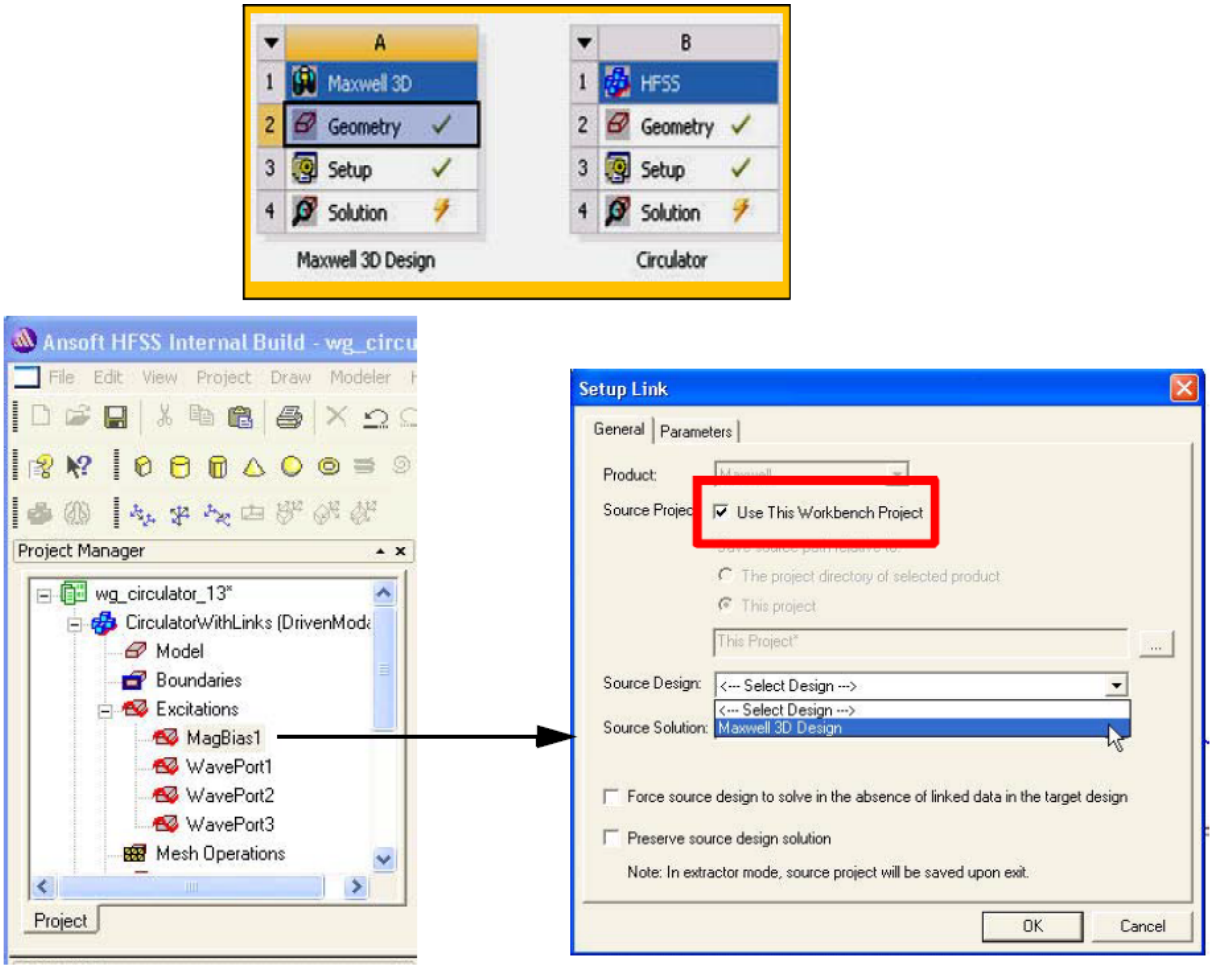


Multiphysics Coupling between Ansys EM Field Systems on Workbench

You can set up links between Ansys Electromagnetics field systems that reside on a Workbench project schematic. Linking is set up in the Ansys Electromagnetics application as shown in the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

following example.

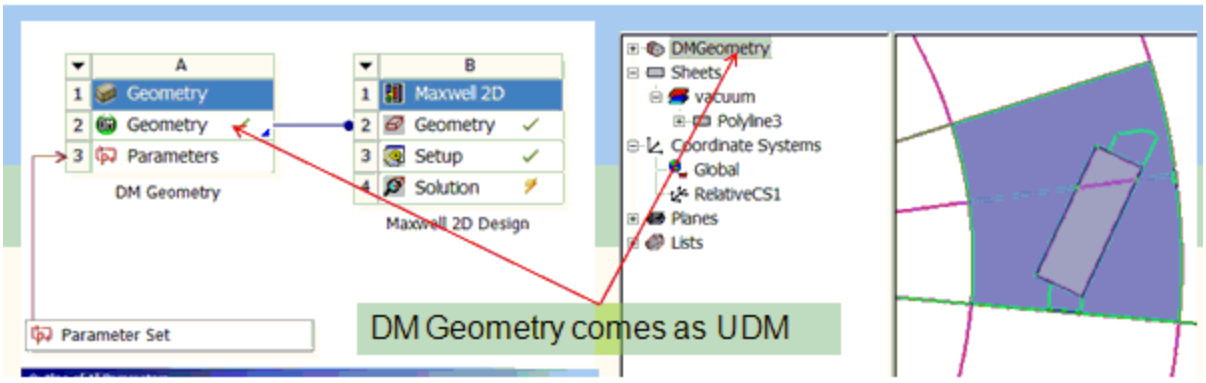


Ansys EM CAD Integration through Workbench

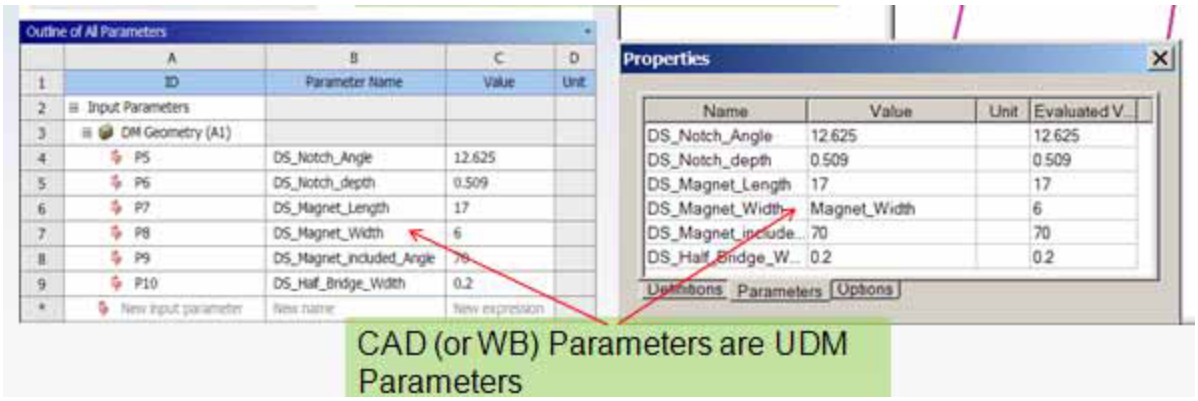
Ansys Electromagnetics CAD integration is a Workbench feature available for Ansys Electromagnetics 3D Products - HFSS, Maxwell, Q3D, Icepak, and Mechanical, as the Ansys Framework. The feature is available only through Workbench, and is not available via standalone Ansys Electromagnetics products.

Ansys CAD integration provides a bi-directional dynamic link through Workbench. This makes it possible to get updated geometry from CAD, modify CAD parameters in Ansys Electromagnetics products, and return an updated geometry. The feature is non-associative due to a need to reassign boundaries if a modified CAD model is used. The process creates a User Defined Model (UDM) for each geometry source.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



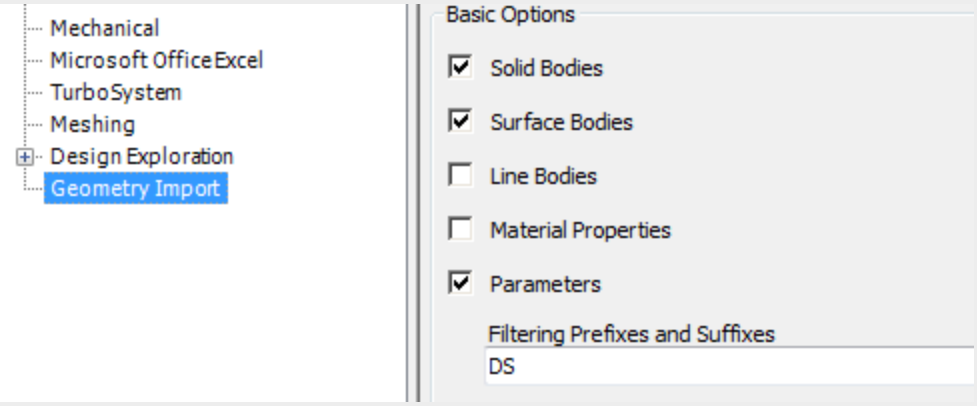
The UDM format makes it possible to exchange parameters. Ansys online help contains further description of the UDM feature and function.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

The parameters shown in the previous example all have a DS prefix. This is the default for the Workbench **Tools>Options** for **Geometry Import**. To import parameters with different prefixes or names, assign an appropriate prefix or clear the **Filtering Prefixes and Suffixes** field.



Ansys Electromagnetics CAD integration makes it possible to consume geometry from multiple upstream sources (any CAD or Ansys Electromagnetics product).

This feature supports direct interfaces with major CAD systems, including

- Creo Parametric
- UG NX
- CATIA V5
- SOLIDWORKS
- Autodesk Inventor
- Ansys Design Modeler (DM)
- Discovery UDM model

Note:

The CAD software must be installed on the user machine (not required for solve nodes).

The following sections contain additional information:

CAD Integration Functionality

CAD Integration and Geometry Sharing

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Bi-Directional CAD Integration

CAD Integration Model Edits

Multiple Geometry Links for CAD Integration

Creating Dynamic Links to EDT Designs

Adding a Design Variable for Dynamic Links

CAD Integration Functionality

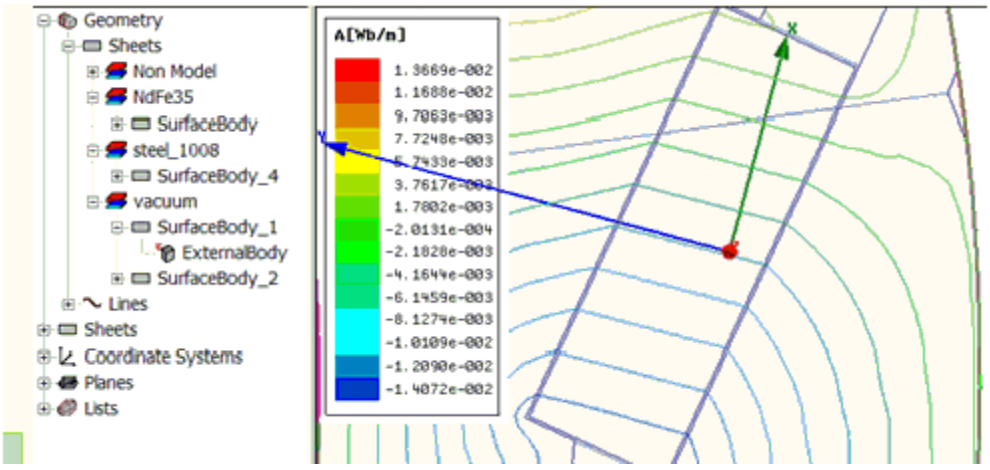
Healing with CAD Integration

Important Geometry Options for CAD Integration

CAD Integration Functionality

CAD Integration includes the following functionality:

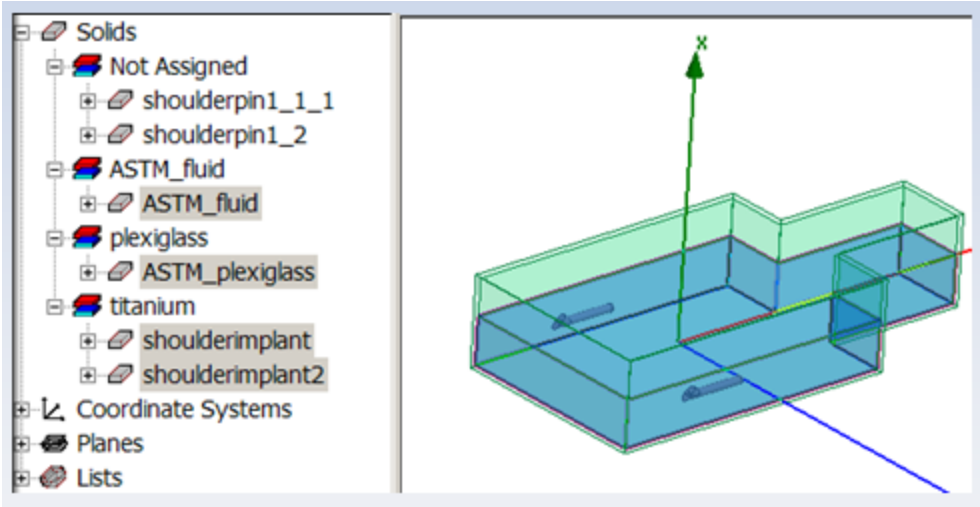
- DX analysis
- WB Update Project
- WB Update All Design Points
    - Parametric analysis with DSO
    - Animation
    - Geometry
    - Field plots



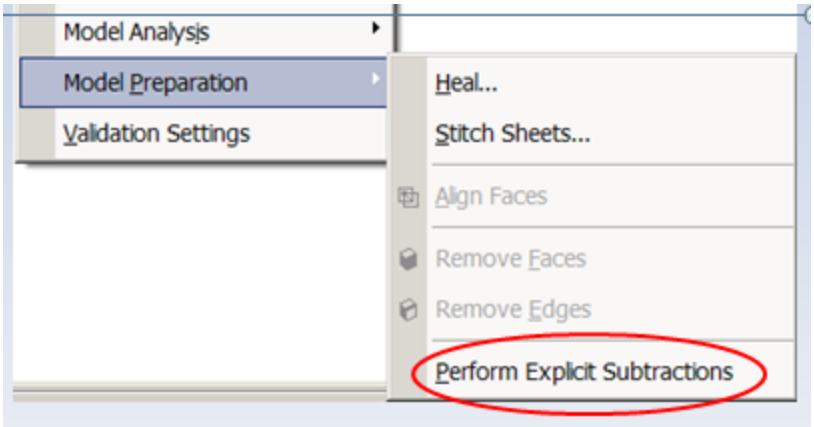
Ansys Mechanical does not do implicit subtraction. Ansys Electromagnetics products can do explicit subtractions before sending geometry to Ansys using **Modeler > Model Preparation > Perform Explicit Subtraction**.

For example, consider the following model.

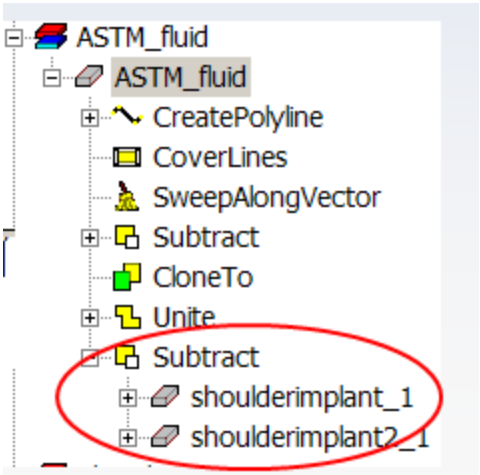
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Perform Explicit Subtractions can be performed.

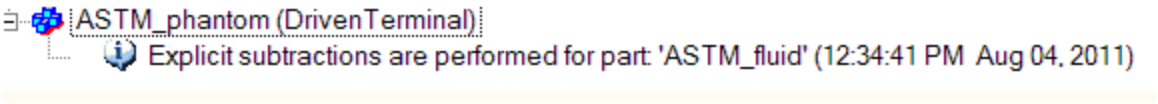


Results appear in the History tree, as shown:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Messages** window reports this action.

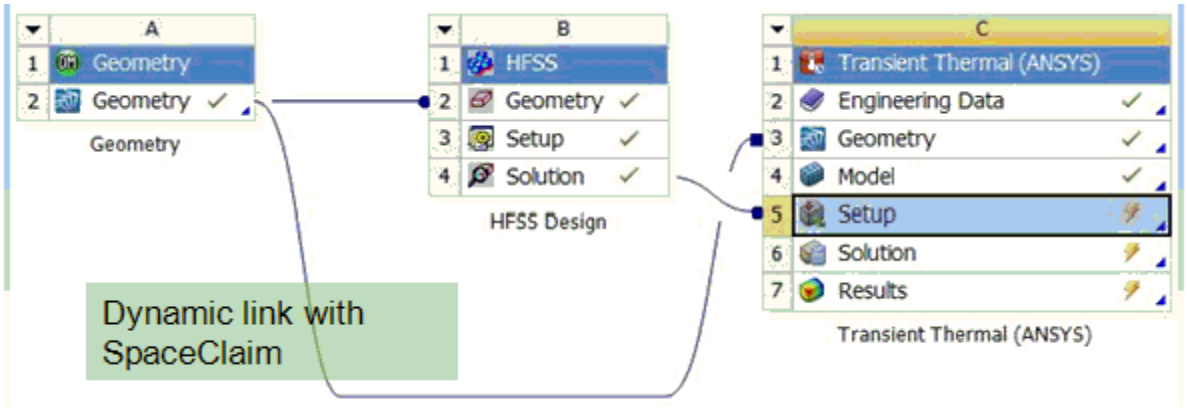


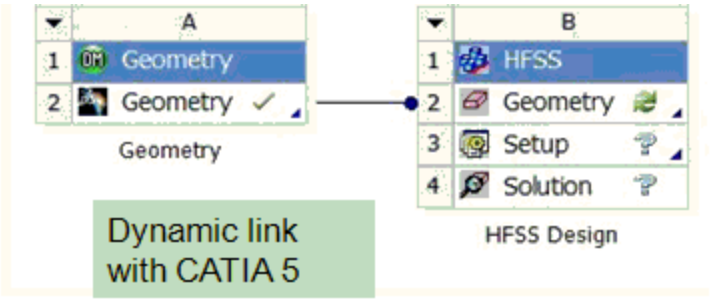
CAD Integration and Geometry Sharing

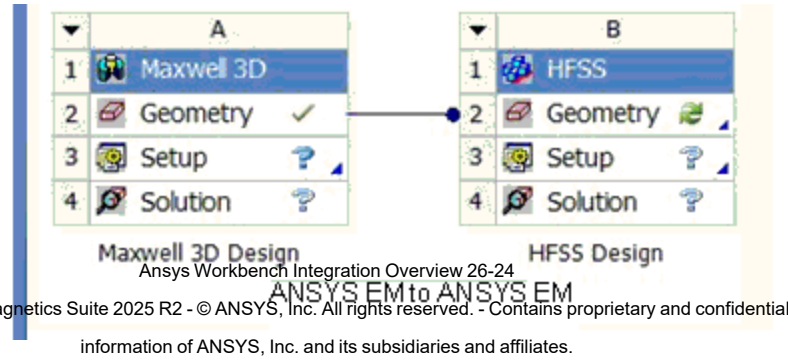
A CAD model comes into Ansys Electromagnetics as a User Defined Model (UDM).

The inputs to Ansys Electromagnetics from CAD are

- Geometry/Topology with persistent IDs
- CAD parameters
- Material assignment
- Attributes, such as name and color

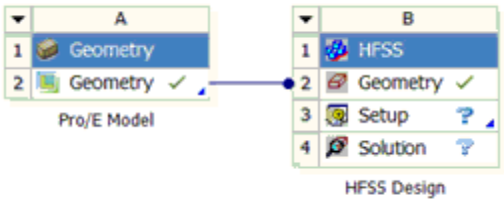




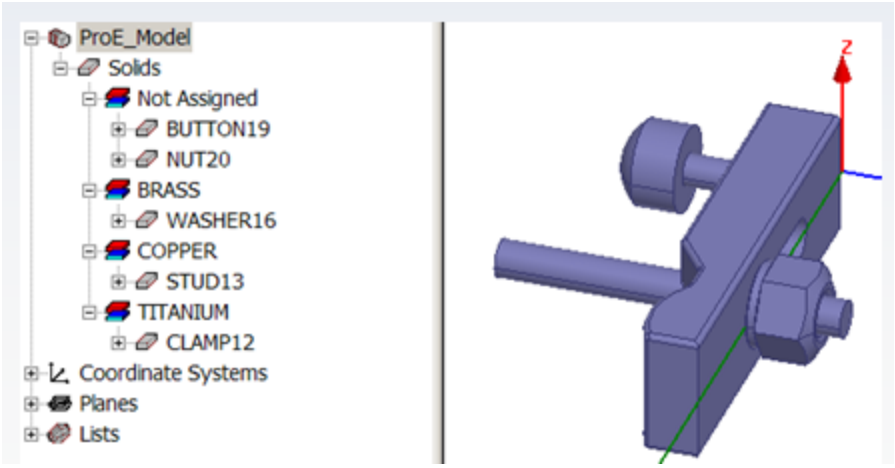


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For example, in Workbench, a Pro/E Model can be linked to Ansys:



The geometry can then be viewed in HFSS as a UDM.



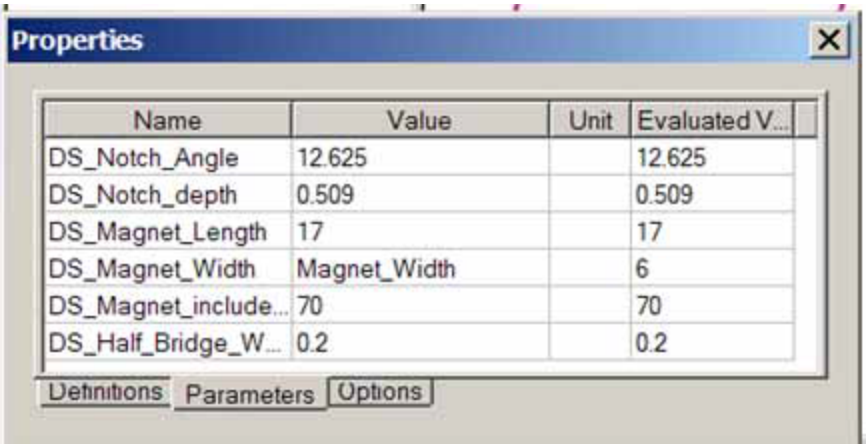
The CAD or WB model parameters appear in the Workbench:

Outline of All Parameters

	A	B	C	D
1	ID	Parameter Name	Value	Unit
2	Input Parameters			
3	DM Geometry (A1)			
4	P5	DS_Notch_Angle	12.625	
5	P6	DS_Notch_depth	0.509	
6	P7	DS_Magnet_Length	17	
7	P8	DS_Magnet_Width	6	
8	P9	DS_Magnet_included_Angle	70	
9	P10	DS_Half_Bridge_Width	0.2	
*	New input parameter	New name	New expression	

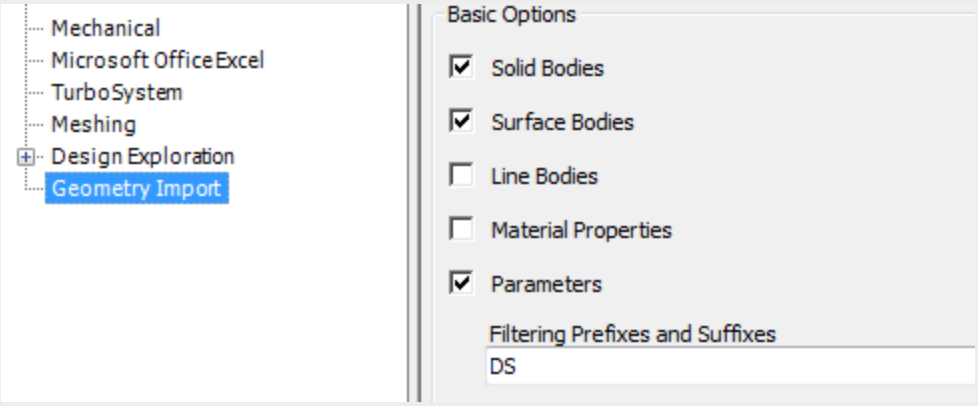
Through the Ansys Electromagnetics CAD integration, the linked UDM includes the same parameters.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



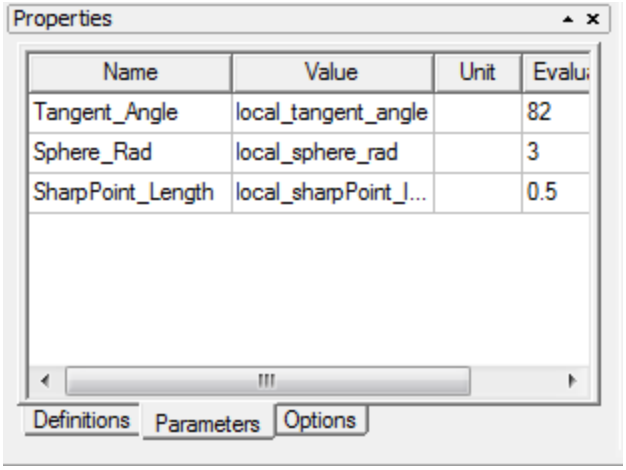
Note:

The parameters shown in these examples all have a DS prefix. This is the default for the Workbench **Tools** > **Options** for **Geometry Import**. To import parameters with different prefixes or names, assign an appropriate prefix or clear the **Filtering Prefixes and Suffixes** field.



Once you import a geometry with parameters to an Electromagnetics application in the desktop, you need to map to local variables. In the target Electromagnetics application, select the geometry associated with the parameters. Update the geometry and view the **Parameters** tab in the **Properties** window. The **Value** column shows the values of the imported parameters. Type names for local variables in the **Name** column.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Once you have local variables for the imported Design Modeler parameters, you are ready to use Design Xplorer for multiple design parameters.

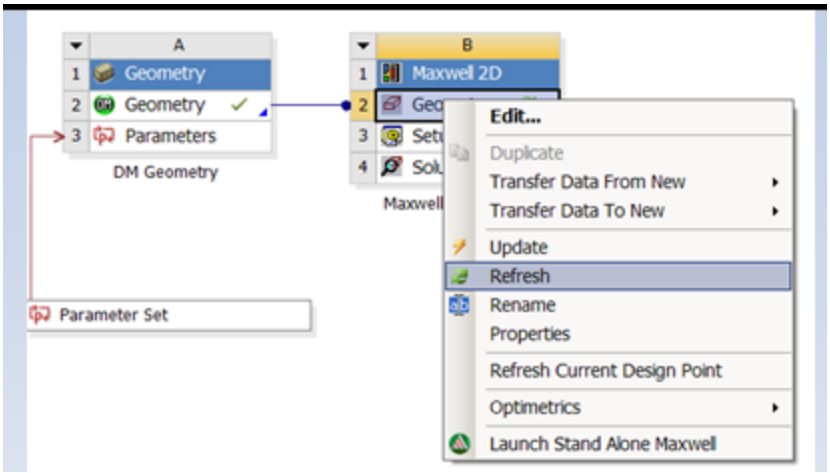
Table of Schematic D2: Design of Experiments (Custom)

	A	B	C
1	Name	P3 - Tangent_Angle (degree)	P4 - Sphere_Rad (in)
2	1	80	3
3	2	75	3
4	3	85	3
5	4	80	2.7

Bi-Directional CAD Integration

Ansys Electromagnetics CAD Integrations uses **Refresh** or **Generate** to pass updates.

You make an edit in a CAD application and run **Refresh** on an Ansys Electromagnetics Geometry Cell.

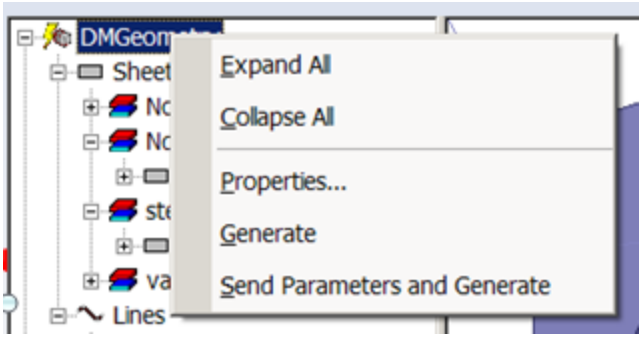


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refresh pulls the current state of CAD model (geometry, parameters, materials etc) and updates the corresponding data in the Ansys Electromagnetics application.

Alternatively, you can run **Generate** on the UDM in the Ansys Electromagnetics window.

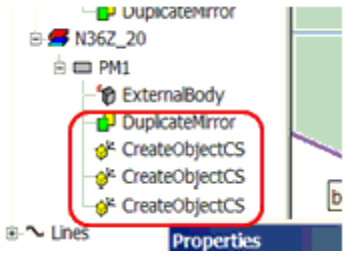
If you edit UDM (CAD) parameters in the Ansys Electromagnetics modeler window you can run the **Send Parameters and Generate** command.



The command passes the edited parameters to the linked CAD application and then pulls corresponding CAD geometry.

CAD Integration Model Edits

Several modeling operations are allowed on a CAD model in the Ansys Electromagnetics Modeler window. Operations are included in the History tree and retained during model **Refresh**.

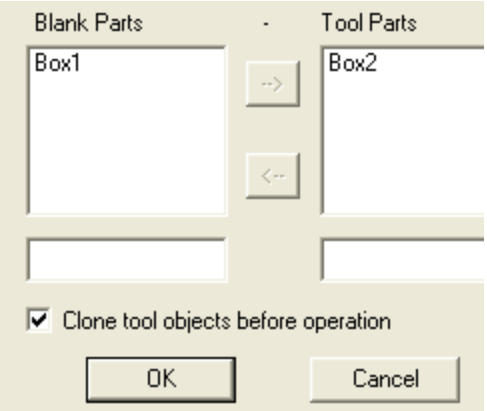


The following operations are not allowed:

- Non-history tree operations like Heal or defeature.
- Operations that use UDM parts as tools, such as Sweep

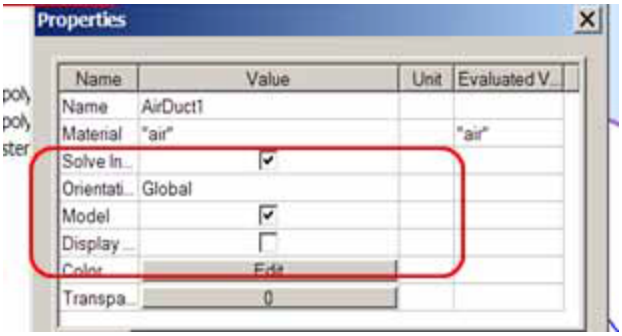
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Boolean operations like Split or Unite (allowed when you select the clone tool option)



The following part attributes can be modified for UDM parts:

- Model/Non Model flag
- Solve Inside flag
- Part orientation
- Color
- Display Wireframe



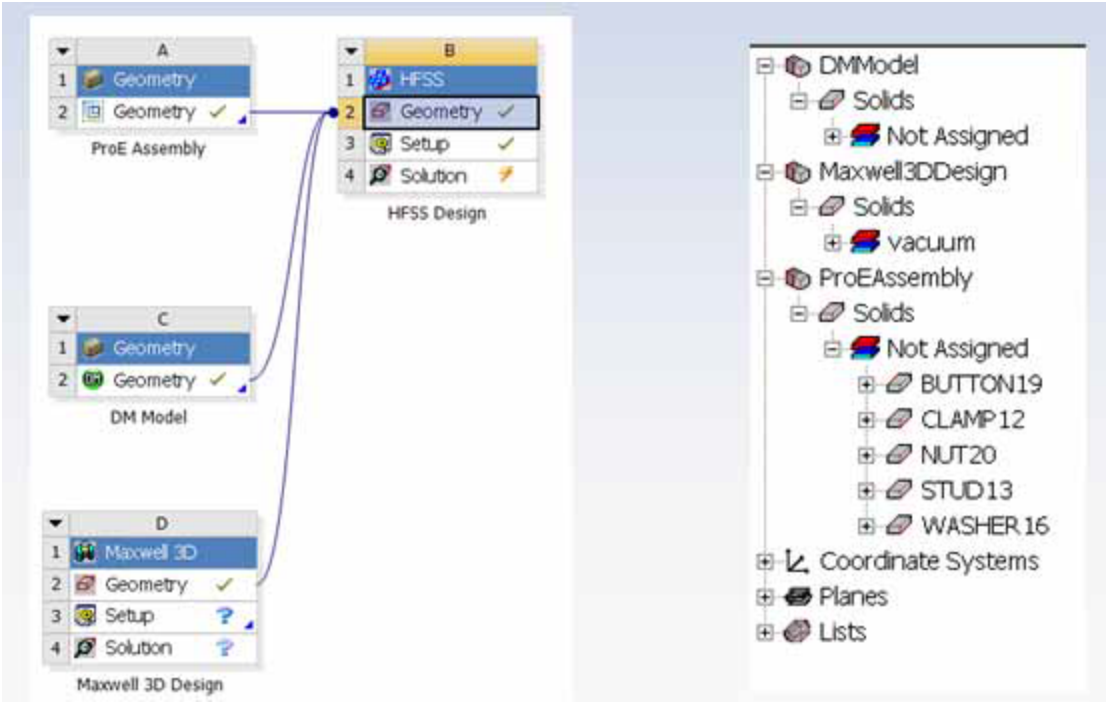
It is not possible to delete individual parts of UDM.

Multiple Geometry Links for CAD Integration

With CAD Integration you can consume geometry from multiple upstream sources. The source can be any of supported CAD or Ansys Electromagnetics products. This creates a UDM for each geometry source.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

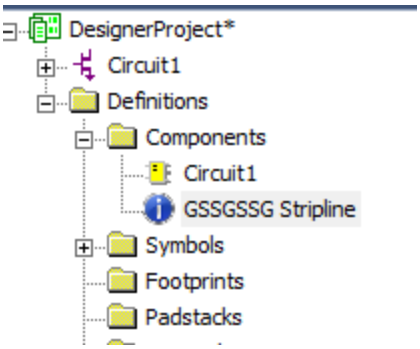
For example, the following figure shows a DM Model, a Maxwell model, and ProE model linked to HFSS in Workbench, and displayed in the HFSS History tree as three UDMs.



Creating Dynamic Links to EDT Designs

If you have a Circuit Design and one or more HFSS, 2D Extractor, Q3D, Icepak, or Mechanical designs open in a Workbench project, you can create dynamic links to those designs.

Update the Circuit Design to open the Electronics Desktop. In the menu bar, select **Workbench > Update Dynamic Link Components**. This command will create components in the project tree for each design in the Workbench project.

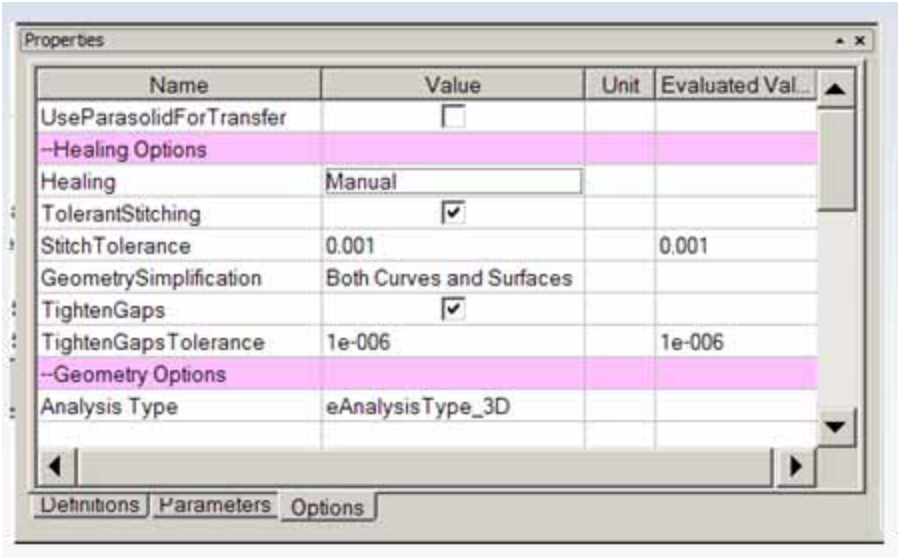


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that in this example, a GSSGSSG Stripline component was created corresponding to the GSSGSSG Stripline design in WorkBench. Once created, you can drag the component into a schematic to place it.

Healing with CAD Integration

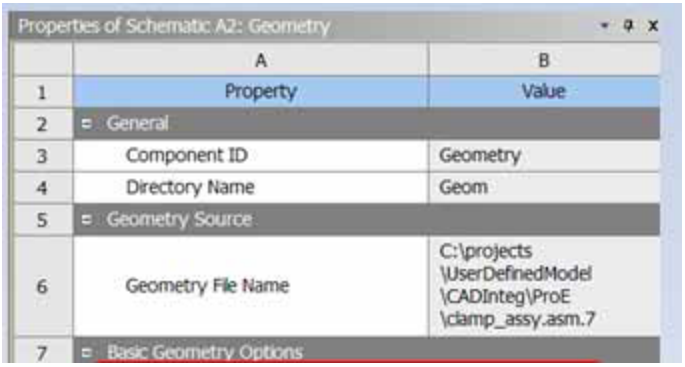
It is not possible to use the Heal command in Ansys Electromagnetics Modeler. Instead similar healing options are available under UDM properties option tab.



Healing options are None, Auto and Manual. By default, healing is off (None) and should be turned on only if required.

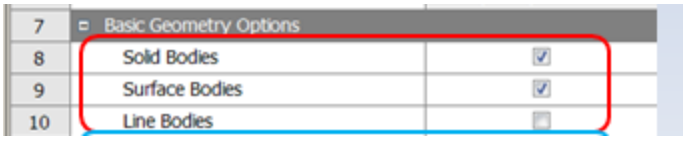
Important Geometry Options for CAD Integration

Select a Geometry Cell in Workbench to see options in the Properties window.



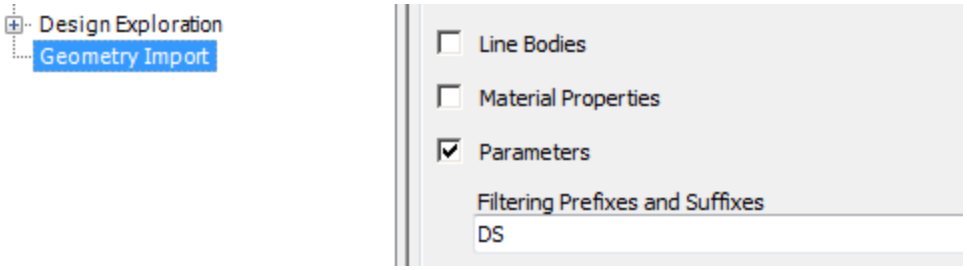
Control dimension of bodies coming from CAD

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Make sure **Parameters** is checked and that the parameter key (filter) is appropriate for CAD parameters.

The default parameter key filtering means that only parameters whose names start with DS will come through. This is the default for the Workbench **Tools>Options** for **Geometry Import**. To import parameters with different prefixes or names, assign an appropriate prefix or clear the **Filtering Prefixes and Suffixes** field.



The **Attribute Key** should be empty or "Color" to bring in CAD colors.

Material Properties must be checked to bring in the material assignment.

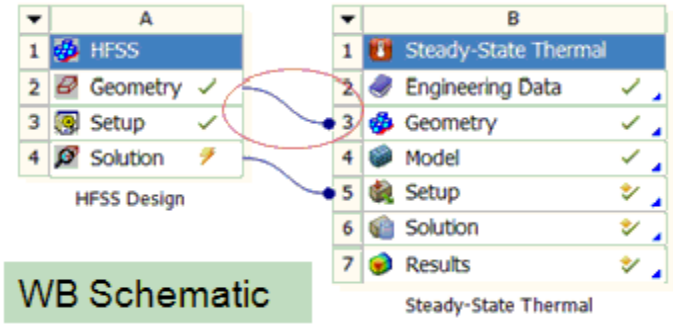
The **Mixed Import Resolution** option is used to resolve parts with mixed dimension (typically from Pro/E)

Refer to Ansys Help for details.

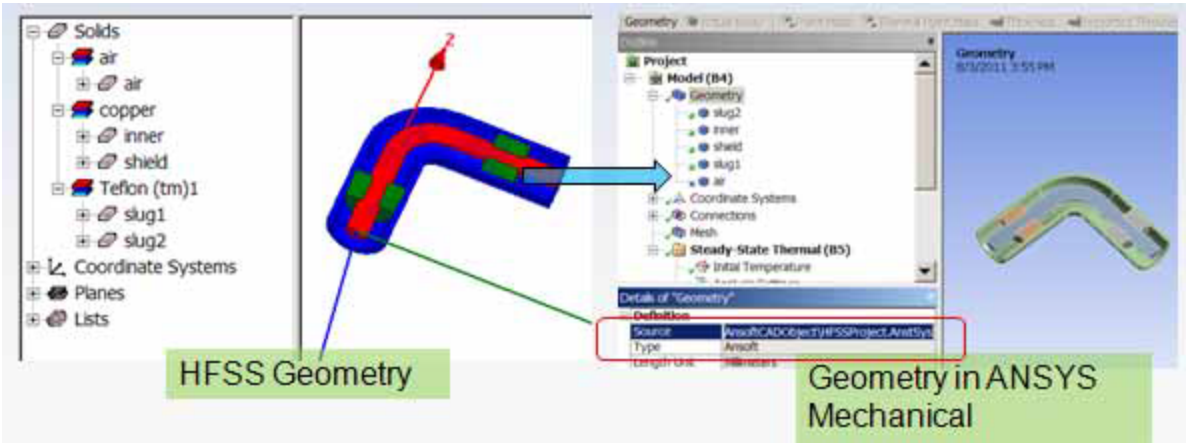
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys EM to Ansys Geometry Transfer

Ansys Electromagnetics CAD Integration transfers model information based on Workbench links.

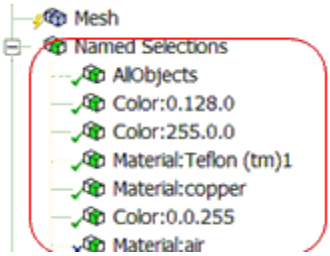


The following figure shows how the information is transferred between simulators.



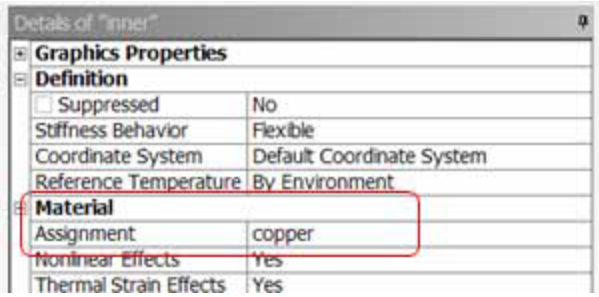
Information transferred includes

- Geometry
- Ansys Electromagnetics lists and material assignment as Named Selection



- Material assignment

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The CAD Integration geometry link is dynamic (you can get updated geometry from Ansys Electromagnetics) and associative (IDs persist between Ansys Electromagnetics model and Ansys model during model refresh).

Boundary conditions in Ansys are preserved. Object, material, and parameter names with non-ASCII characters are not allowed for data transfer. Such transfers fail and produce an error message.

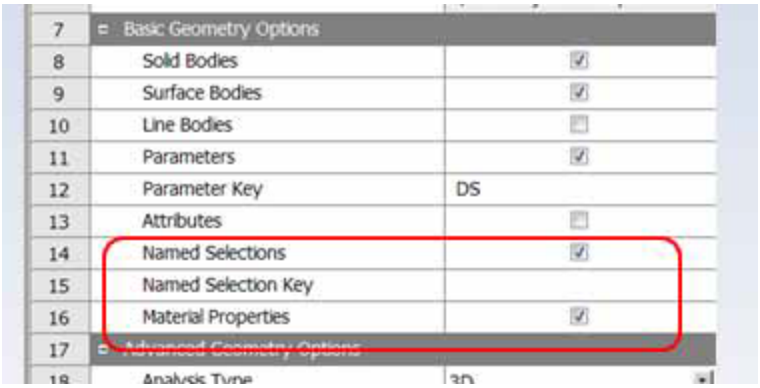
Material Assignment Transfer

There are two prerequisites for material assignment transfer:

- Engineering Data should have materials used in Ansys Electromagnetics model and material names should match (including case)
- Material Properties in Geometry Options must be checked

Before transferring as a named selection, **Named Selections** must be checked in **Basic Geometry Options**.

The Named Selection Key should either be empty or contain "Material."

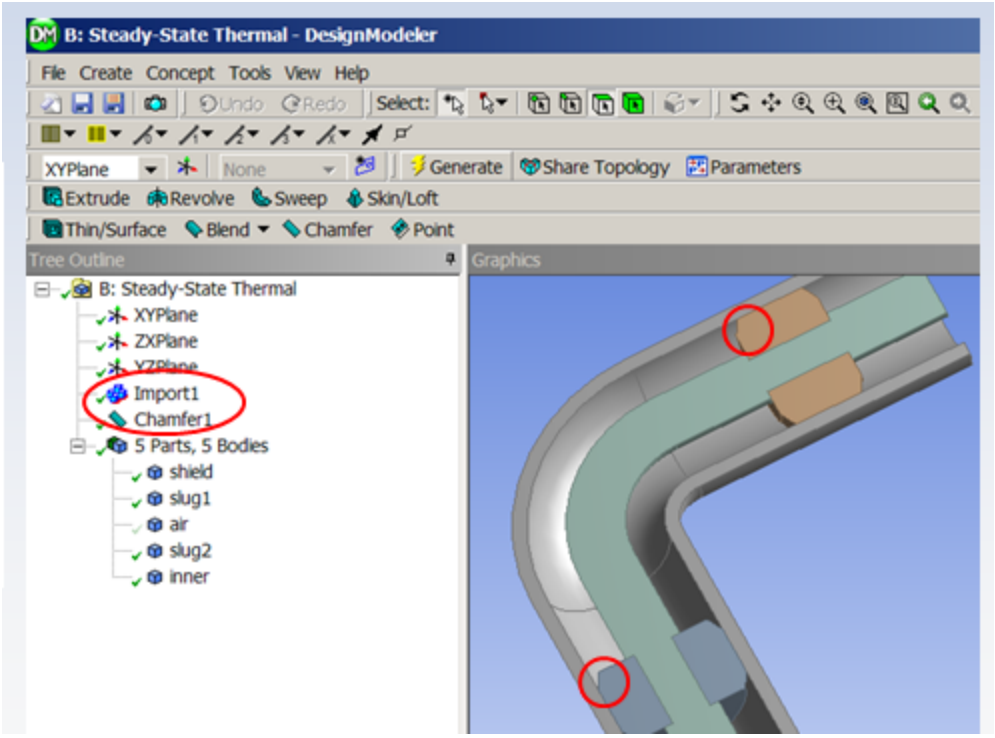


Geometry Transfer through Ansys DesignModeler (DM)

It is possible to edit geometry in Ansys DesignModeler (DM) before consuming it in Mechanical. This is useful when geometry requires preprocessing for Ansys simulation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

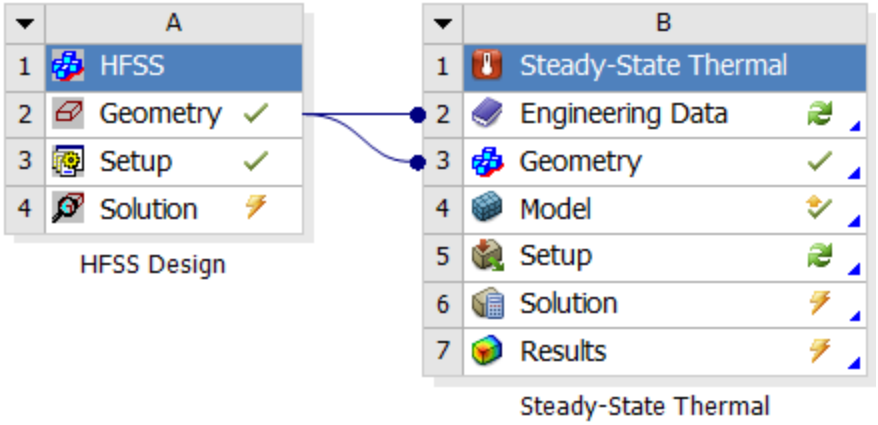
Consider an HFSS model linked to DM through the Workbench. In the following example, a chamfer operation on geometries is being imported.



Workbench Material Data Transfer

A link can be created from an Ansys Electromagnetics Desktop system (e.g., HFSS) geometry cell to a downstream Engineering Data (ED) cell. When the downstream ED cell is refreshed, it updates with materials (names and properties) used by the upstream project. This ensures that the geometry-to-geometry link connecting the same two systems, which specifies the material assignments for various parts, refers to the correct materials and their properties.

Detailed Behavior



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The geometry-to-ED link can be created by dragging the Ansys Electromagnetics Desktop system geometry cell to the ED cell of a downstream system. When the downstream system's ED cell refreshes, the upstream system generates a MatML format XML file, which is consumed by Workbench to update the downstream system. This file is stored in the workbench project files according to design point. Note that Workbench ED cell material names are case-sensitive, as are material names within Ansys Electromagnetics Desktop products.

For material assignments to work with the ED in the downstream model, the downstream geometry cell must have the **Material Properties** check box selected. A convenient way to do this is to have this property checked by default, by setting this in **Tools** > **Options** > **Geometry Import**. Systems created after this default option is set will have **Material Properties** automatically checked for the geometry cell.

When the downstream model cell is refreshed or updated, material properties from the ED in the same system are used in the model's materials, based on material assignments set during the geometry cell refresh. Note that if material assignment fails, the Workbench default material (Structural Steel) is used.

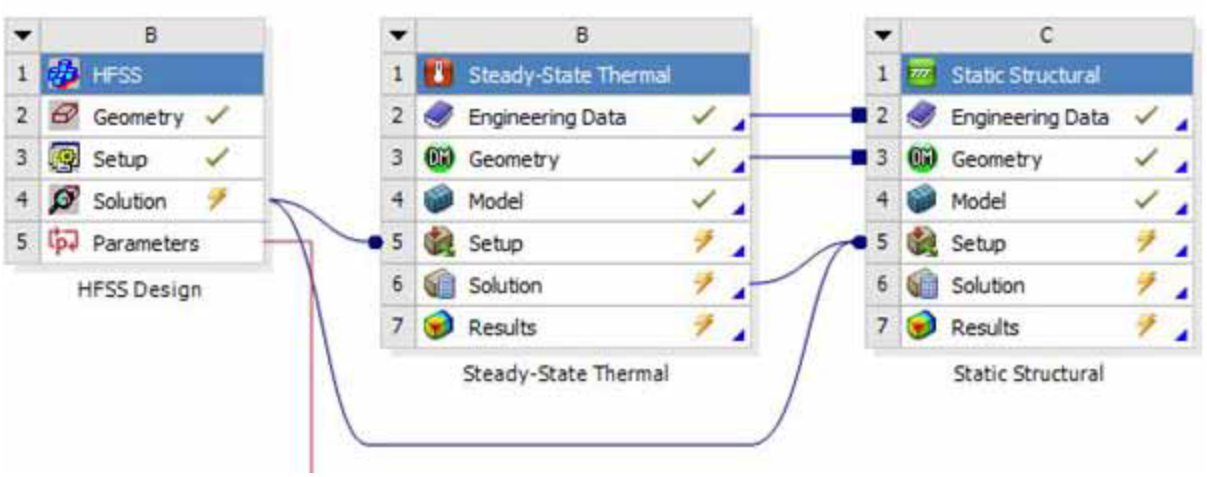
Workbench resolves name conflicts by changing the name of any materials being transferred over from the upstream system. For example, if the upstream Ansys Electromagnetics Desktop system uses a material named "Structural Steel", this will conflict with the existing downstream default material of the same name. The update will result in the Ansys Electromagnetics Desktop material being named "Structural Steel 2" in the downstream ED, but the downstream model will still use the properties supplied by Ansys Electromagnetics Desktop for the material.

Note that some materials may not satisfy all requirements for downstream system physics. For example, vacuum has no thermal conductivity, but downstream steady state thermal systems require a non-zero value for this property. Material properties in the workbench ED cell of the downstream system can be modified after refresh to ensure that validity criteria can be met. Any property added to a material in the downstream ED is preserved in subsequent ED cell updates. However, any existing property that is edited in the downstream ED will be overwritten by a subsequent ED cell update.

Stress Feedback to HFSS using Workbench

Including stress feedback to HFSS involves coupling an HFSS system with both thermal and stress systems. The thermal system serves as an upstream system to the stress system and simulates the effect of heat induced displacement. And through the Workbench link between the Solution cell of HFSS and the setup cell of Mechanical, the displacement can feedback into HFSS. The HFSS project can be Driven or Eigenmode.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You use a dialog to select one or more objects (geometry) in HFSS upon which displacement data from Mechanical applies. This feature lets you avoid applying displacement to the whole model where only certain parts are sensitive to stress. You must select the same objects in the thermal and stress system to apply the respective imported loads.

The results of the process include deformation feedback applied to selected objects. The Solution Profile includes a report of Solve with thermal/displacement feedback, including information Maximum Delta T and Maximum Delta Displacement. You can create field plots with based on Displacement and Mag_Displacement, and you can scale the deformation displayed. The Fields Calculator also includes these input quantities.

Interface Changes for Stress Feedback from Mechanical to HFSS

Process Flow for Stress Feedback to HFSS

Interface Changes for Stress Feedback from Ansys Mechanical to HFSS

When used through the Workbench for stress feedback projects, the HFSS interface contains some commands and information that do not appear in standalone HFSS.

Deformation of Objects dialog

Solution Profile information for Solve with Displacement Feedback

Plot Fields Menu with Displacement and Mag_Displacement

Deformation Scale tab for Modify Plot Attributes

Revert to Zero Displacement command under the **Solve Setup** menus

Fields Calculator Field Quantities for Stress Feedback Projects

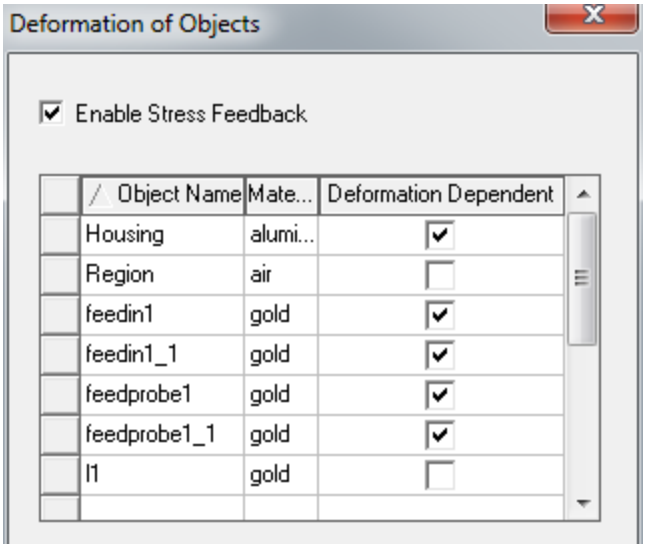
Plot Fields Context Menu for Stress Feedback Projects

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modify Plot Attributes Dialog for Stress Feedback Projects

Deformation of Objects Dialog

When working with HFSS through Ansys Workbench, the HFSS menu for Driven and Eigenmode projects includes a Deformation of Objects command that opens this dialog for specifying which objects shall be deformation dependent.



The Enable Stress Feedback check box enables object selection. All selections are disabled when this is unchecked. Changing the setting invalidates any existing solutions.

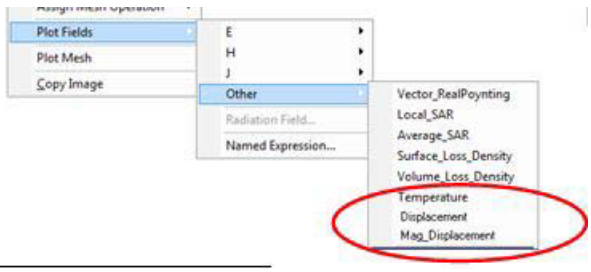
The objects listed do not include objects without materials assigned, non-model objects, or non-3D objects. Objects assigned materials such as air or vacuum are not deformed and don't apply to stress feedback.

Solution Profile with Displacement Feedback

The Solution Profile includes a report of Solve with thermal/displacement feedback, including information Maximum Delta T and Maximum Delta Displacement.

Plot Fields Menu with Displacement and Mag_Displacement

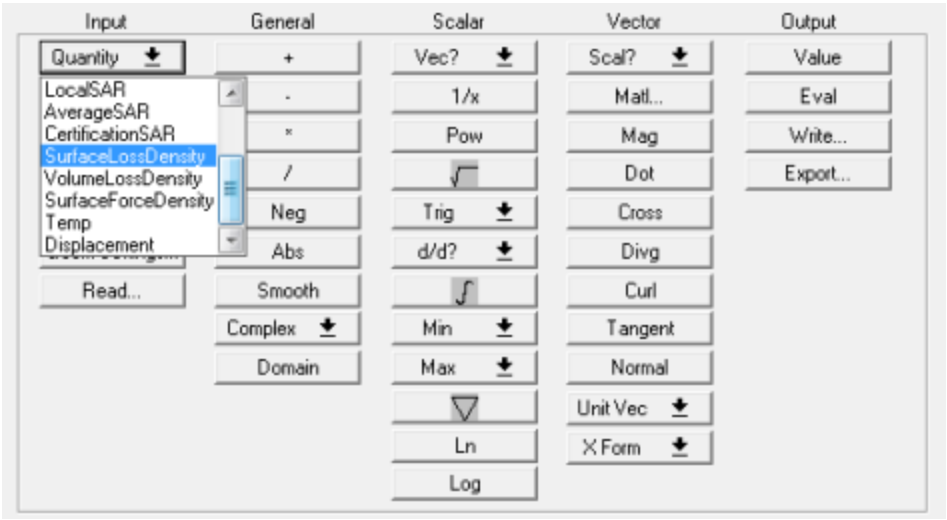
The Plot Fields menu includes entries for displacement and mag_displacement.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

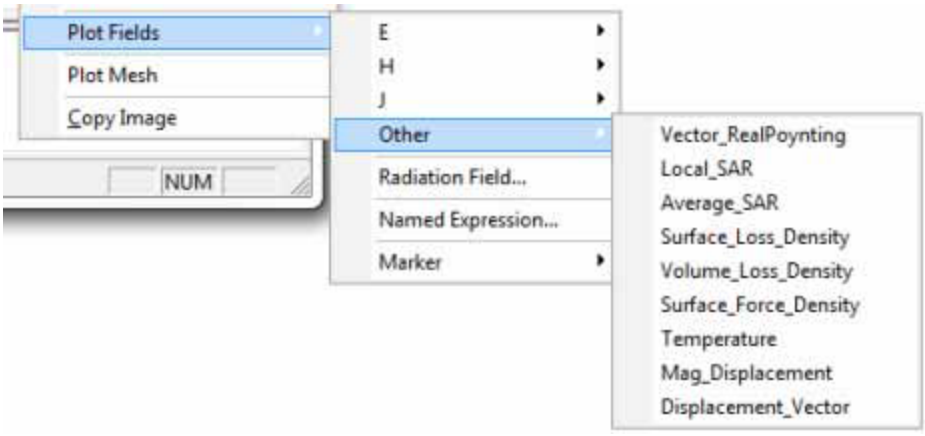
Fields Calculator Field Quantities for Stress Feedback Projects

The Quantity menu for the Fields Calculator lists Displacement for Stress Feedback projects.



Plot Fields Context Menu for Stress Feedback Projects

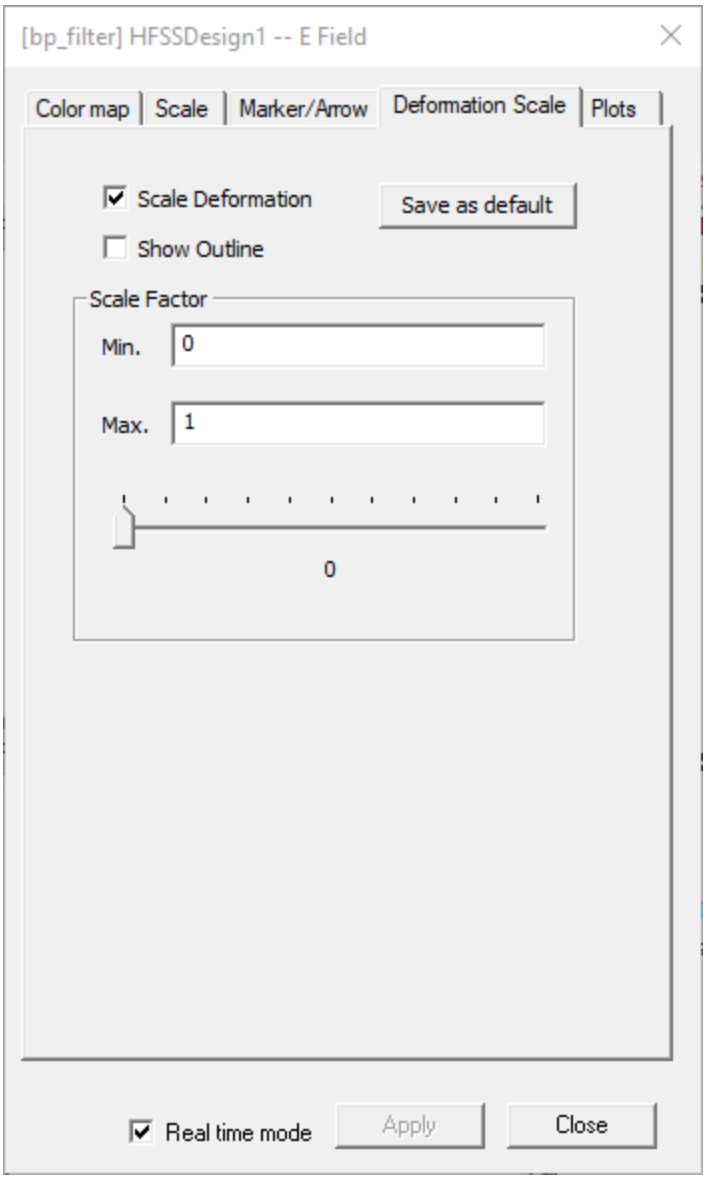
The **Plot Fields>Other** menu includes Displacement_vector and Mag_Displacement, a scalar. A field plot remains empty until the displacement data applies to the HFSS solution.



Modify Plot Attributes Dialog for Stress Feedback Projects

When an HFSS plot includes deformation, the **HFSS>Fields>Modify Plot Attributes** dialog includes a tab for scaling the deformation. If you check Scale Deformation, you can also select Show Outline.

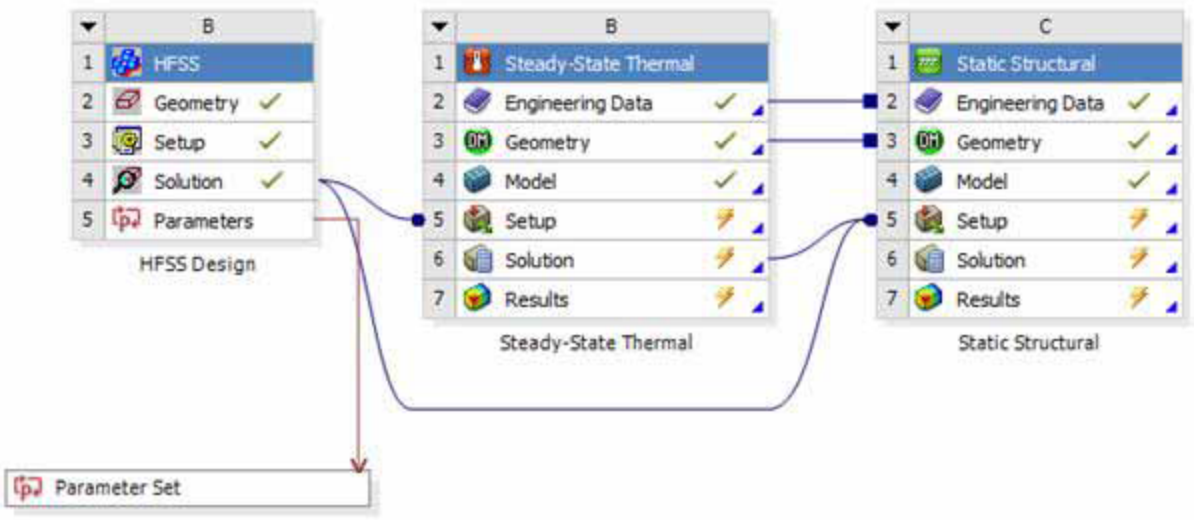
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Process Flow for HFSS Workbench for Stress Feedback

to set up the coupling, drag the "Solution" cell of the HFSS system and drop it at the "Setup" cell of a Thermal and Stress system. You also need to also couple the Thermal and Stress system to capture the effect of thermal force. The following image illustrates a coupling setup where both the Thermal and Stress system are ready to be "Updated". The HFSS adaptive solution has converged in 3 passes. The HFSS system has both thermal and stress feedback enabled.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

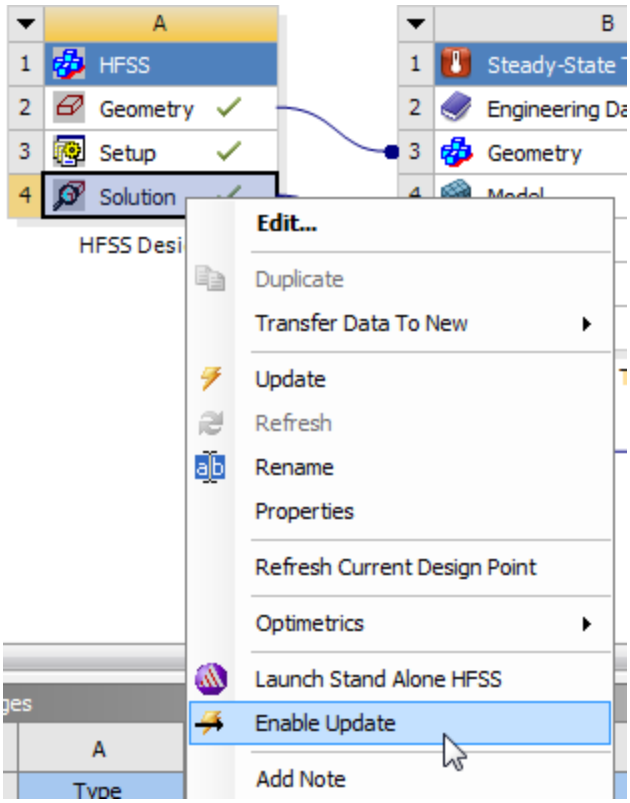


1. Right-click the Solution cell of Stress and select "Update"

   a. The Setup of Thermal will be "Updated" with em loss from HFSS
   b. The Solution of Thermal will be "Updated" and temperature will be exported to HFSS
   c. The Setup of Stress will be "Updated" with thermal force from Thermal and force density (just zeros) from HFSS
   d. Displacement will be exported to HFSS after Stress finishes simulation

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Right-click the Solution cell of HFSS and select "Enable Update"



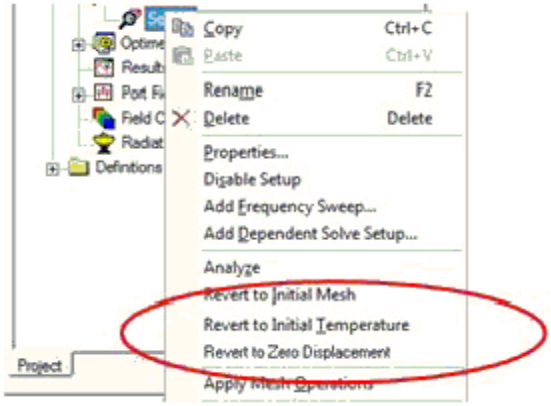
The Solution cell icon changes from a green checkmark to the Update lighting icon.

3. Right-click the Solution cell of HFSS and select "Update"

   a. HFSS re-simulate the 3rd pass with its mesh and the temperature/displacement feedback
   b. The profile will show information about the feedback

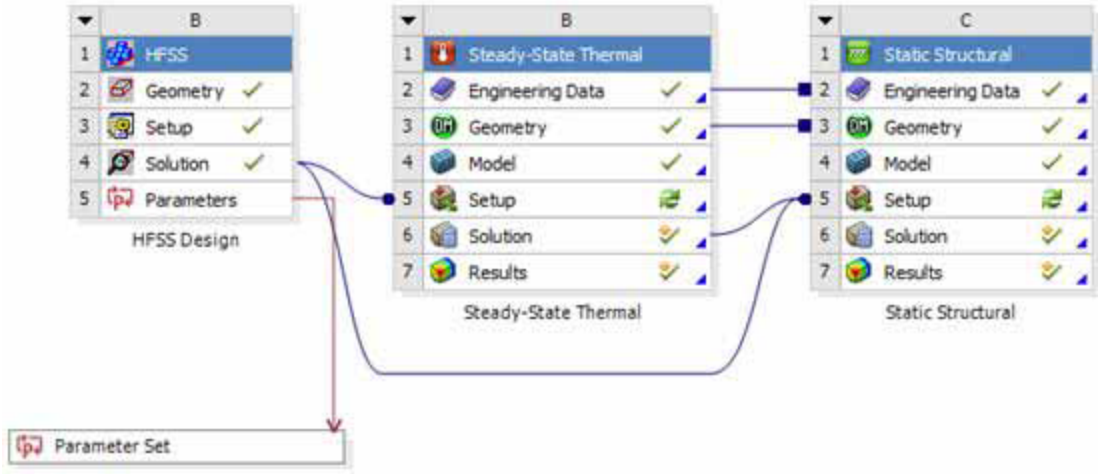
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. Both "Revert" menus will be available at the right mouse click menu of the solve setup item.



Manual Iteration After First Iteration Completes

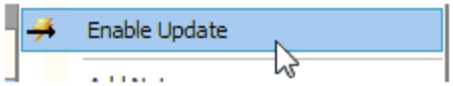
The following image illustrates the WB schematic after the previous situation, after the 1st iteration has completed. Notice the changed icons for the status for Setup for Thermal and Structural.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Right-click the Solution cell of Stress and select "Update"

   a. The Setup of Thermal will be "Refreshed" and "Updated" with EM loss from HFSS
   b. The Solution of Thermal will be "Updated" and temperature will be exported to HFSS
   c. The Setup of Stress will be "Refreshed" and "Updated" with thermal force from Thermal and force density from HFSS
   d. Displacement will be exported to HFSS after Stress finishes simulation
2. Right-click the Solution cell of HFSS and select "Enable Update"



3. Right-click the Solution cell of HFSS and select "Update"

   a. HFSS re-simulates the 3rd pass with its mesh and NEW temperature/displacement feedback
   b. The profile will show information about the feedback

Note that the delta temperature and displacement is being reported in the profile

Revert the HFSS Solution For Temperature and Displacement

You can revert the temperature and displacement in HFSS solution separately.

1. Select "Revert to Initial Temperature" in HFSS.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A warning message notifies you about the invalidation of solution

2. Right-click HFSS solve setup and select "Analyze"

HFSS re-simulates the 3rd pass with its mesh and displacement that was previously exported from Mechanical, but without temperature.

3. Select "Revert to Zero Displacement" in HFSS, and followed by "Analyze"

HFSS re-simulates the 3rd pass with its mesh without neither temperature nor displacement

Only Stress Feedback

The coupling setup is the same as in Use Case 1, with either one of the following differences

- The HFSS system is not enabled for thermal feedback. Since HFSS is not enabled to support feedback, the "Export Result" properties will be missing in the thermal system's property window.
- The HFSS system is enabled for thermal feedback, but users select not to "Export Result" in the thermal system. This is to disable the "automatic" feedback after Mechanical finishes its simulation.

1. Right-click the Solution cell of Stress and select "Update"
    a. The Setup of Thermal will be "Updated" with em loss from HFSS
    b. The Solution of Thermal will be "Updated"
    c. The Setup of Stress will be "Updated" with thermal force from Thermal and force density from HFSS
    d. Displacement will be exported to HFSS after Stress finishes simulation
2. Right-click the Solution cell of HFSS and select "Enable Update"
3. Right-click the Solution cell of HFSS and select "Update"
    a. HFSS re-simulate the 3rd pass with its mesh and the displacement feedback
    b. The profile will show information about the feedback and "Revert to Zero Displacement" will be enabled at the RMC menu of the solve setup item

Feedback Iterator

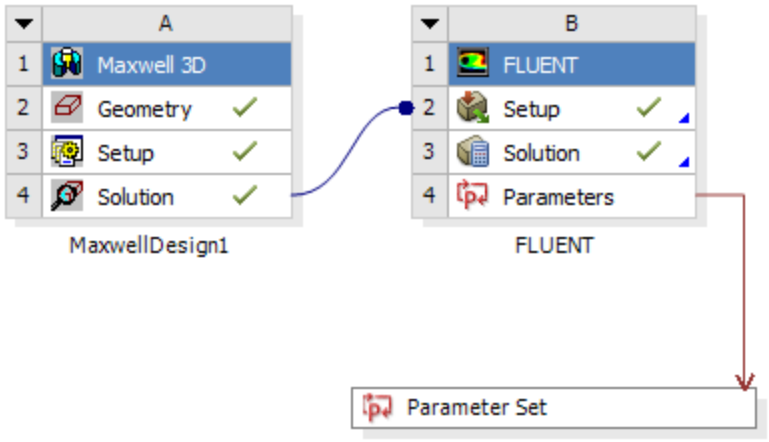
Background Information

Prior to the introduction of the Feedback Iterator, Ansys Workbench supported a two-way loose-coupling protocol with Ansys Electromagnetics products.

System Coupling already uses the word coupling to mean low-level solver coupling. Existing electromagnetics product coupling is loose compared to system coupling and is limited to file transfers at the end of a complete solve in a standalone system/product. No communication occurs during a solve. The coupling is two-way.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The one way portion (Upstream source component to Downstream target component) is handled via existing Workbench data/transfer connection mechanism.

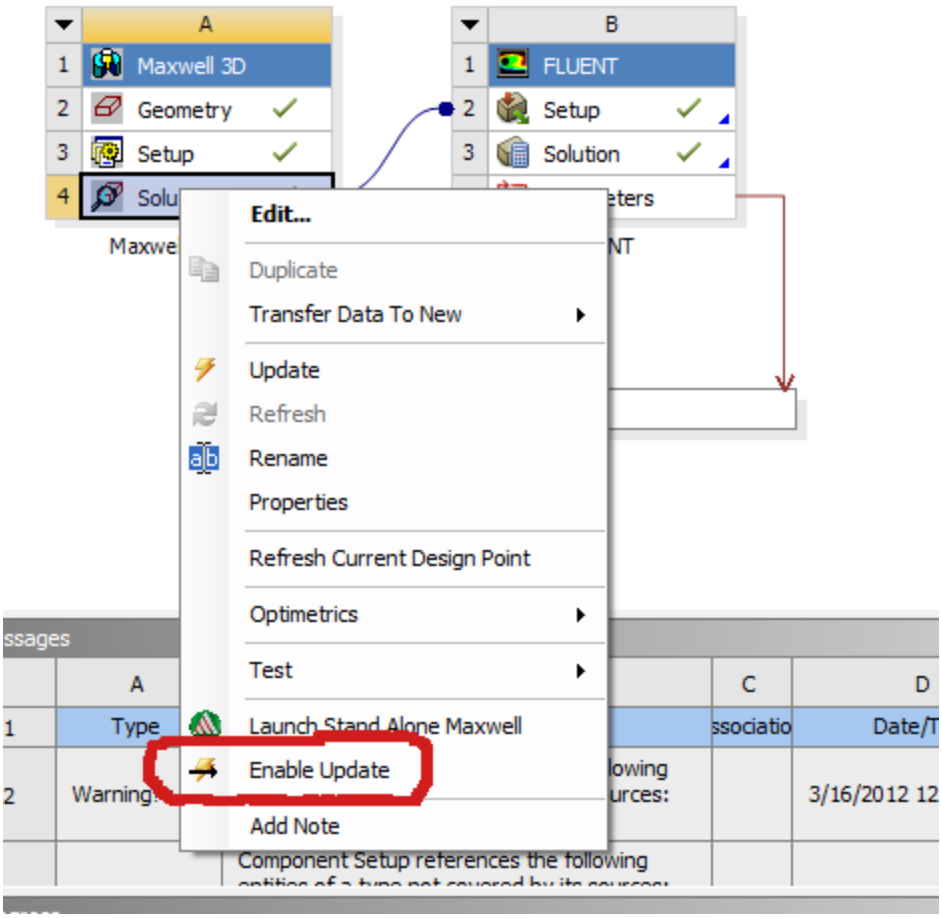


The round trip is handled by a separate protocol, agreed upon by the participating systems, whereby the downstream system exports a set of files to a location specified by the upstream system via its one-way transfer. This exported data is then incorporated by the upstream system in its next update.

To run the next coupled solve iteration, invoke the **Enable Update** operation, as shown below, which updates all systems involved.

These steps (**Enable Update**, **Update Project**) are continued as long as needed.

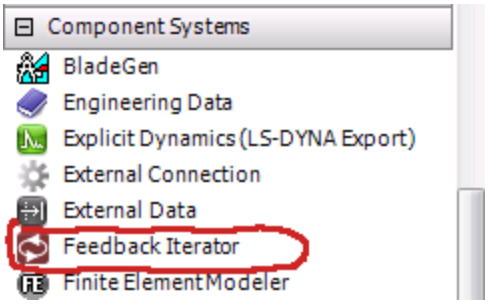
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The Feedback Iterator System

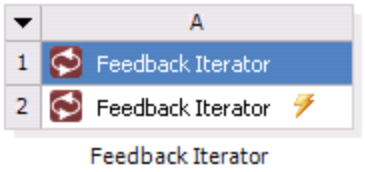
Ansys Electromagnetics Suite provides the Feedback Iterator system for automating the manual steps needed for driving a feedback utilizing system-pair to convergence. In addition to automating feedback incorporation over a user-specified number of iterations, the Feedback Iterator also allows control over the number of iterations (iteration termination criteria), target temperature, and displacement convergence criteria.

The **Feedback Iterator** appears in the Workbench Toolbox user interface under **Component Systems**.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

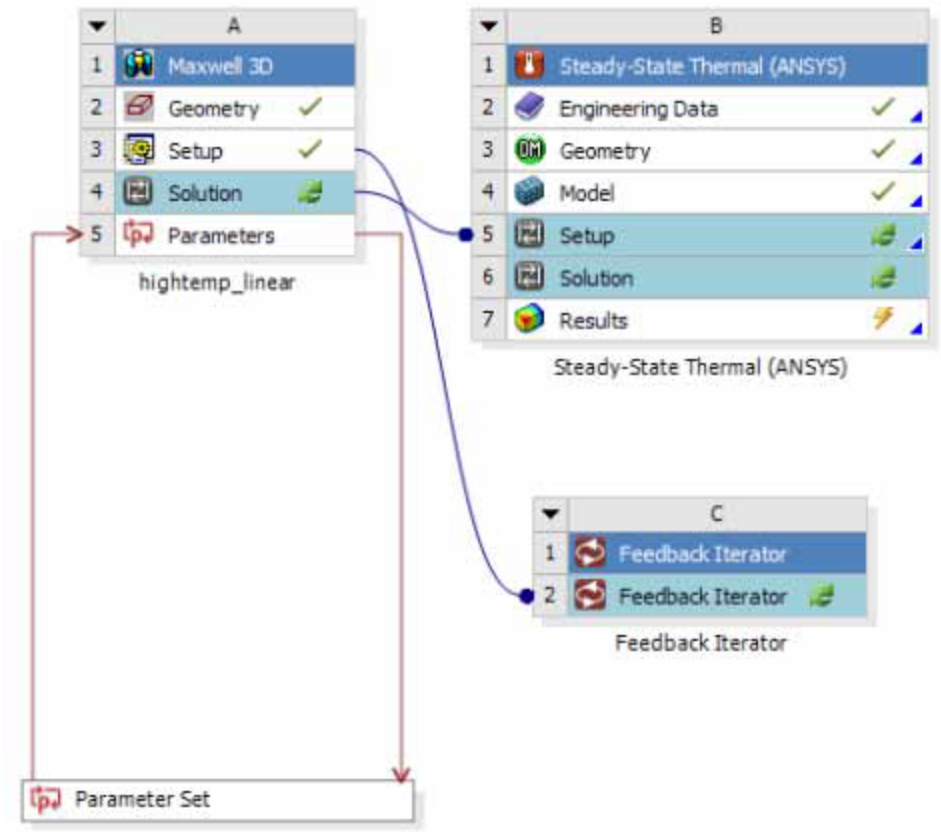
If you drag and drop an instance of the Feedback Iterator into a Workbench schematic, the default system name is Feedback Iterator:



Feedback Iterator in Use

The Feedback Iterator system attaches to the Workbench schematic like any other system.

In the following example, a Maxwell system provides heat loss data to aFluent system. Dropping the Maxwell setup cell onto the Feedback Iterator component results in the links shown:



The Feedback Iterator add-in functions the same way with all systems that participate in the Electromagnetics product two-way loose coupling (Maxwell and HFSS for sources and Fluent, Thermal, and Structural for targets).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Feedback Iterator Component Properties

The Feedback Iterator's primary role is to control iterative solves and its properties target this end.

For Maxwell and HFSS, the Feedback Iterator properties are

- **Iterations Completed** – a read-only property that displays the number of iterations completed.
- **Max Iterations** – sets the maximum number of iterative solve loops to perform before terminating iterations in case the *Target Delta Temperature %* or *Target Delta Displacement %* is not achieved. The default value is 100.
- **Target Delta Temperature %** – specifies the maximum *Target Delta Temperature %* that signifies convergence. The default value is 5%, and the value must be 0.01 or greater.

  > **Note:**
  >
  > • The delta temperature error is calculated in Kelvin.
  >
  > • The Maxwell and HFSS design **Profile** tab displays absolute/relative delta data, while the delta temperate in Workbench means the relative delta (expressed as %).

- **Target Delta Displacement %** – specifies the maximum *Target Delta Displacement %* that signifies convergence. The default value is 5%, and the value must be 0.01 or greater.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	A	B
1	Property	Value
2	⊟ General	
3	Component ID	FeedbackIterator
4	Directory Name	FeedbackIteratorComponent
5	⊞ Notes	
7	⊞ Used Licenses	
9	⊟ Iterations	
10	Iterations Completed	0
11	Max Iterations	100
12	⊞ Callback	
14	⊟ Temperature Convergence	
15	Target Delta Temperature %	5
16	Latest Delta Temperature %	Not Available
17	⊟ Displacement Convergence	
18	Target Delta Displacement %	5
19	Latest Delta Displacement %	Not Available

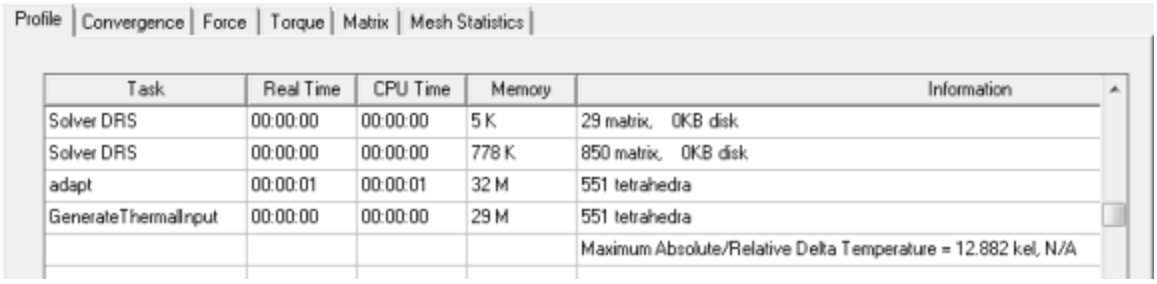
The Feedback Iterator properties also display the most recently achieved *Latest Delta Temperature %* and *Latest Delta Displacement %* values, allowing the user to manually abort when satisfied with the achieved deltas.

> **Note:**
>
> Both the Temperature and Displacement Convergence properties sections are always shown irrespective of which feedback types are enabled for the project.

Running a two-way feedback simulation from the Workbench application while keeping the Maxwell or HFSS **Profile** tab open shows that the 3D solver keeps track of two feedback related quantities:

- Maximum Absolute/Relative Delta Temperature (if temperature feedback is enabled)
- Maximum Absolute/Relative Delta Displacement (if displacement feedback is enabled)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

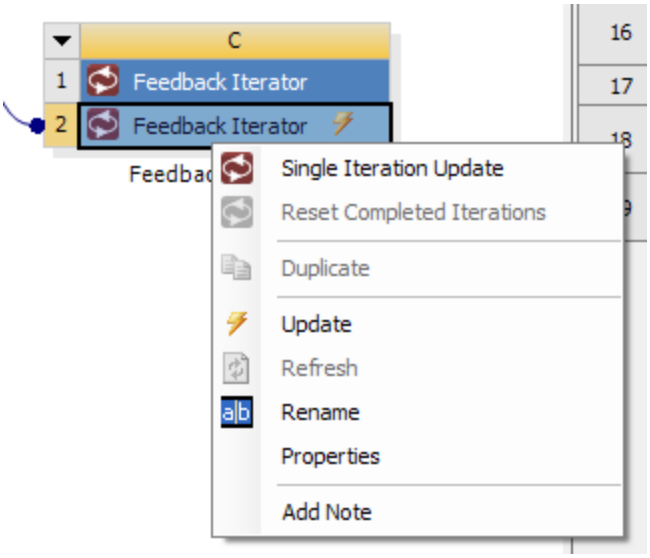


These signify the maximum difference on the solution mesh of the quantity in question from one feedback iteration to the next (thus the value is only available from the second iteration onward). This data forms the basis for the convergence controls in the Feedback Iterator. These controls allow the user to base the termination of feedback iterations on a target max delta T and/or max delta displacement. The target max delta forms the convergence condition.

Feedback Iterator GUI Operations

The **Single Iteration Update** action allows you to run a single iteration worth of updates, as follows:

1. Updates the Electromagnetics product system, which will incorporate any previous feedback from the downstream system.
2. Updates the downstream system.
3. All coupled systems (Electromagnetics product, Electromagnetics product Downstream, and Iterator) are in the UpToDate state.
4. Iterator's “Iterations Completed” property increments by 1.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Right-clicking the Feedback Iterator component and selecting **Update** allows you to run iterations automatically. Iterations continue to run either until convergence criteria are met, or until the Max Iterations value is reached.

Resetting the Feedback Iterator

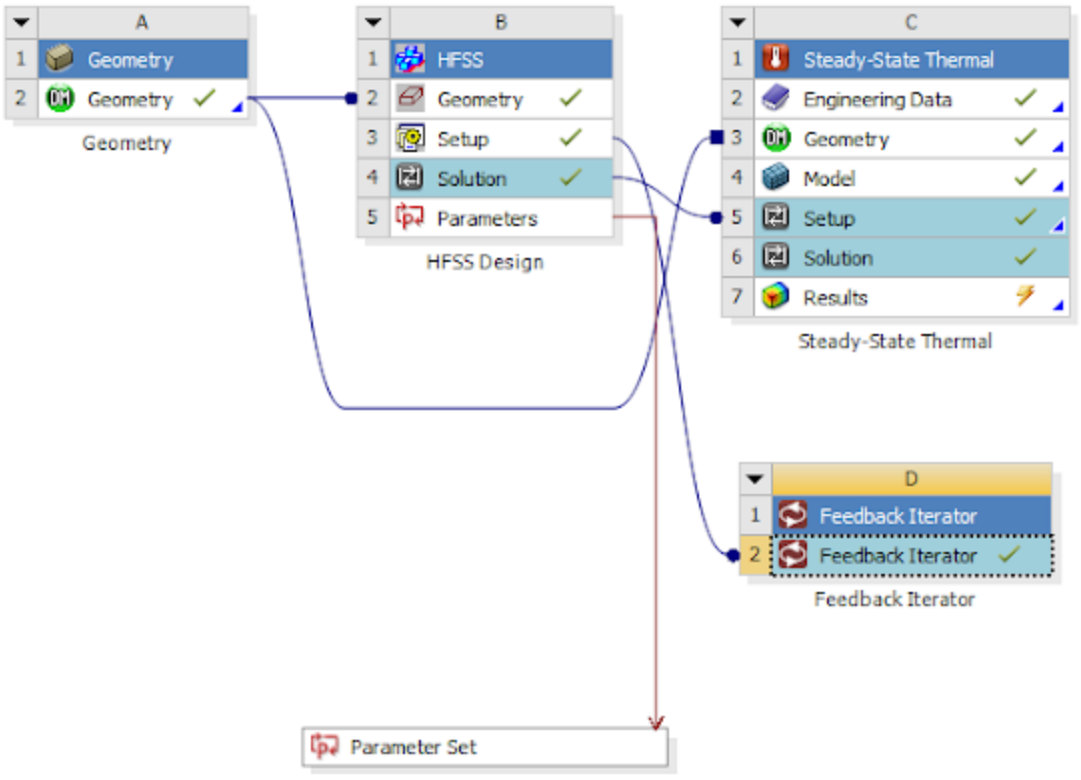
Resetting the iterator essentially means starting from iteration-0 conditions, that is:

- No Displacement or Temperature feedback from another system is incorporated.
- The first iteration solution will be purely an Ansys EM analysis solution.

Resetting the Feedback Iterator cannot easily be done entirely within the Workbench application. However, the following two processes can be used:

- Resetting via the Ansys EM user interface
- Resetting via a Workbench journal script

The following example uses an HFSS/Thermal project. (This same approach applies to the other Ansys EM design types.)



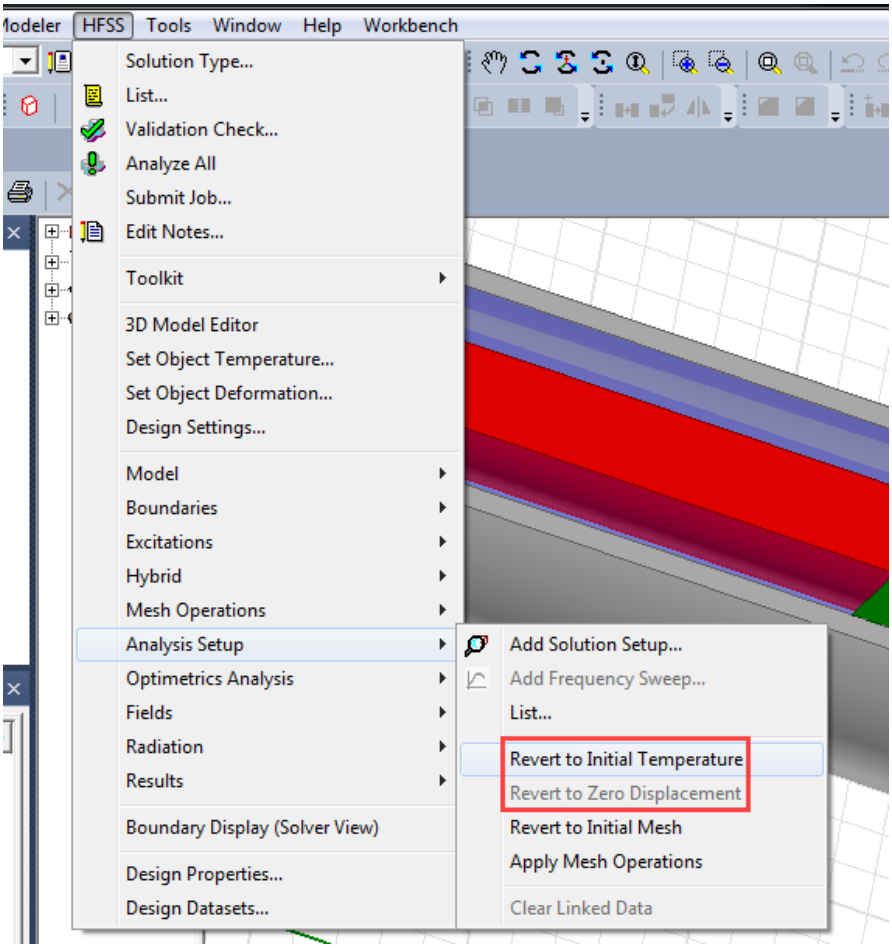
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Resetting via the Ansys EM User Interface

Depending on the type(s) of feedback involved, this typically means reverting to initial conditions for one or both of the following settings:

- **Revert to Initial Temperature**
- **Revert to Zero Displacement**

You can find these under the respective design type menu, such as the **HFSS** menu shown below.



Resetting via a Workbench Journal Script

> **Note:** The above Ansys EM user interface actions can be recorded into a Workbench journal script and played back for the easiest approach.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You also can build a script from scratch using the following as the template – simply update the system name as appropriate, include the appropriate "Revert..." commands, and either save as a script or enter into the Workbench Command window.

```
oDesign = Ansoft.GetDesign(GetSystem(Name="HFSS"))

oDesign.GetModule("AnalysisSetup").RevertAllToInitialTemperature()

oDesign.GetModule("AnalysisSetup").RevertAllToZeroDisplacement()
```

Callback Interface

The callback interface allows you to react to each step of the iteration process as implemented by the Feedback Iterator component. This is useful for implementing special iterations or solving transient simulations with a limited scope.

There are four main API features provided:

- Callback functions, which the Feedback Iterator calls at various points in each iteration
- Utility functions, which the Callback functions can use to extra properties of the containers being processed
- Output functions, which allow script debugging and supply additional messages
- Limited state management, which allows the script to store and retrieve state across callback functions and iterations

Callback and State API

State is managed in a limited fashion. All the API methods take a final dictionary argument. This dictionary is limited to using **string keys** and **number or string values**. Within this limitation, add new keys, read old keys, clear the dictionary, etc., and it will be persisted across functions calls and even across Updates. When the **Iterations Completed** property is **rest**, the dictionary is also cleared out.

It is advisable for the callback script to initialize the dictionary at Iteration 1.

All the API methods use a subset of the following arguments:

`iterationNumber`	An integer representing the current iteration. This always starts from 1.
`ContainerList`	A Python list of containers (DataContainerReference). This is the entire list of the coupled containers managed by the Feedback Iterator. You typically loop through them and using the utility methods listed below, identities them.
`Container`	A single container that is being processed. This is a DataContainerReference.
`State`	A read/write Python dictionary that is used to maintain state across

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

function calls and iterations.

Only return values from `BeforeIterationEx` are processed. Returns from all other functions are discarded.

1. `BeforeIteration(IterationNumber, ContainerList, State)`: This method is called before each iteration. Ideally used to initialize the state dictionary, open editors as required, or initialize setups as needed for each iteration.
2. `BeforeIterationEx(IterationNumber, ContainerList, State)`: Similar to the `BeforeIteration` method except that this allows you to control the number of iterations via the return value.
   - Return: `"more"` to request one more iteration
   - Return `"last"` to indicate that this is the last iteration
   - Any other return (including none) will be treated as a return of `"last"` and terminate iterations.
3. `AfterIteration(IterationNumber, ContainerList, State)`: This method is called after each iteration. This can be used to copy result files over, check results, implement any possible convergence calculations, logging of results, *etc*.
4. `BeforeContainerRefresh(IterationNumber, Container, ContainerList, State)`: Is called before each of the coupled containers is refreshed. The `Container` argument represents the container about to be refreshed.
5. `AfterContainerRefresh(IterationNumber, Container, ContainerList, State)`: Is called after each of the coupled containers is refreshed. The `Container` argument represents the container just refreshed.
6. `BeforeContainerUpdate(IterationNumber, Container, ContainerList, State)`: Is called before each of the coupled containers is Update (after a refresh). The `Container` argument represents the container about to be updated.
7. `AfterContainerUpdate(IterationNumber, Container, ContainerList, State)`: Is called after each of the coupled containers is updated. The `Container` argument represents the container just updated.

If the callback scripts uses other files to send commands to various containers (vb, js, apdl, python, etc.), all of those files are best saved under the user_files directory. This allows you to use the `FBGetUserFilePath(str)` to get the absolute path of the file and allows the files to be packaged with any created archive.

Utility Functions

`FBSystemForContainer (container)`	system	Given a container, returns the system it belongs to
`FBSystemDisplayName (system)`	string	Given a system, returns its display name on the schematic

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`FBSystemID`(system)	string	Given a system, returns its ID. This is the same as the `UniqueDIrectory` for the system
`FBGetUserFilesPath` (relativePath)		Given a relative path located under the user_files directory, say "hello.py", this returns the absolute path of the file

Output/Debugging Functions

`FBAddInfoMessage (string)`	Adds an info message to the WB message window
`FBAddWarningMessage (string)`	Adds a warning message to the WB message window
`FBAddErrorMessage (string)`	Adds an error message to the WB message window
`FBMessageBox (string)`	Pops up a dialog box with the supplied string with an **OK** button

Example Scenarios for Feedback Iterator

This section describes several scenarios for using the Feedback Iterator:

Setting up Iteration with Feedback Iterator

Breaking Iteration Control

Starting an Iterative Update

Running a Single Iteration

Interrupting an Iterative Loop

Resuming an Interrupted Iterative Loop

Modifying any of the Systems Involved in Iteration (coupled clients)

Iterating to Convergence

Setting up Iteration with Feedback Iterator

Scenario	Steps to execute	Outcome
Electromagnetics product solution provides solution data to a single	• Drop Feedback Iterator system on the setup component of	Electromagnetics product setup component is connected to the Iterator. Electromagnetics product solution and downstream setup and solution components

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scenario	Steps to execute	Outcome
downstream setup	Electromagnetics product OR • Create Feedback iterator system and connect Electromagnetics product setup component to the TwoWay iterator component AND User clicks on the Iterator component and sets the desired Feedback Iterator properties.	are coupled as clients to the iterator. The iterator component is the coupled master and the rest are coupled clients. Any coupling changes schematic visuals: • Coupled cells including coupling master are colored differently from normal cells • Coupled cell icons change to reflect the icon of the coupling master • Coupled client cells no longer display the **Update** context menu item and cannot be updated via script commands • The cell states of all coupled cells (master and clients) are synchronized to be the most pessimistic state among any of them (e.g., after an update, any modification will set all of them to the "Modified" state).
Electromagnetics product solution provides to multiple downstream setup cells	same as above	All the downstream components (setup and solution in each downstream system) are coupled as clients. The update order in this case depends on any additional data-flow connections between the systems that consume the upstream Electromagnetics product solution data.
Electromagnetics product solution cell does not have any downstream targets	same as above	No changes occur beyond what is expected when you create a new connection (no coupling). Coupling only occurs when Electromagnetics product solution cell has a downstream connection. If a downstream connection is added after the link to the iterator, coupling will be performed as described in the first row.

Breaking Iteration Control

Scenario	Steps to execute	Outcome
Iterator coupled to Electromagnetics product	• Break Electromagnetics	In addition to what is normally expected from the user actions,

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

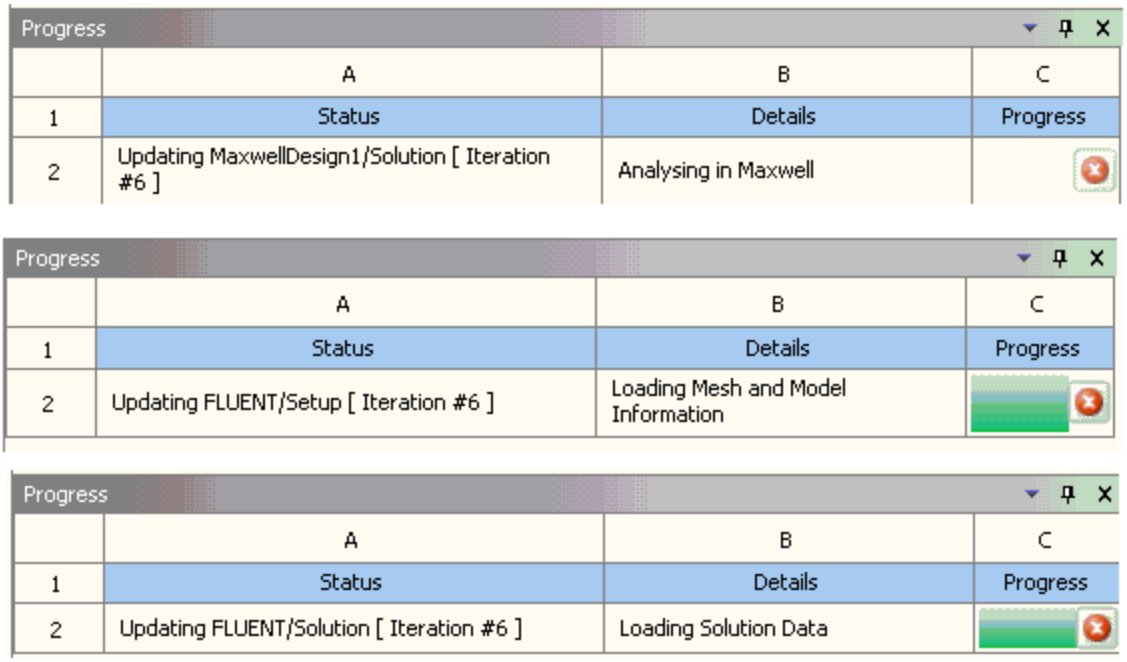
Scenario	Steps to execute	Outcome
solution cell and downstream setup/solution cells	product solution cell's provides link OR • Break Electromagnetics product setup link to iterator OR • Delete Electromagnetics product solution consumer system OR • Delete Iterator system	all coupled clients are de-coupled (their icons and colors on UI are restored)
Electromagnetics product setup cell is connected to iterator but Electromagnetics product solution does not provide anything. No components are coupled to the iterator	• Break Electromagnetics product setup link to iterator • Delete Iterator system	No coupling exists in this scenario so nothing visible changes beyond what is expected from the user actions

Starting an Iterative Update

Scenario	Steps to execute	Outcome
Standard update scenario	• RMB on iterator component and select Update GUI operation OR • Update Project OR • Update all design points	For each iteration, the Electromagnetics product solution is updated followed by the downstream setup and the downstream solution. Each of the client component updates display their progress monitor and can be aborted (resulting in aborting the current iteration)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scenario	Steps to execute	Outcome
	OR • DX Update	



Running a Single Iteration

Scenario	Steps to execute	Outcome
NumCompleted < NumIterations	RMB on iterator component and select Single Iteration Update	One iteration is run. "Completed Iterations" property is incremented.
NumCompleted ≥ NumIterations	same as above	same as above

Interrupting an Iterative Loop

Currently, there is no special progress or interruption control. The progress monitor for individual components displays as they are updated and any control they choose to provide (interrupt, abort or both) is available. Choosing to abort any of the client component updates aborts the current iteration, and the Completed Iterations property remains unchanged from the previous iteration.

Resuming an Interrupted Iterative Loop

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scenario	Steps to execute	Outcome
Single step	RMB on iterator component and select Single Iteration Update	One iteration is always run and the Completed iterations property is incremented.
Run until completion	• RMB on iterator component and select Update OR • Select the Project Update menu option from the toolbar, etc.	If the user specified number of operations are already completed, nothing is done. Otherwise, the remaining iterations are run.

Modifying any of the Systems Involved in Iteration (Coupled Clients)

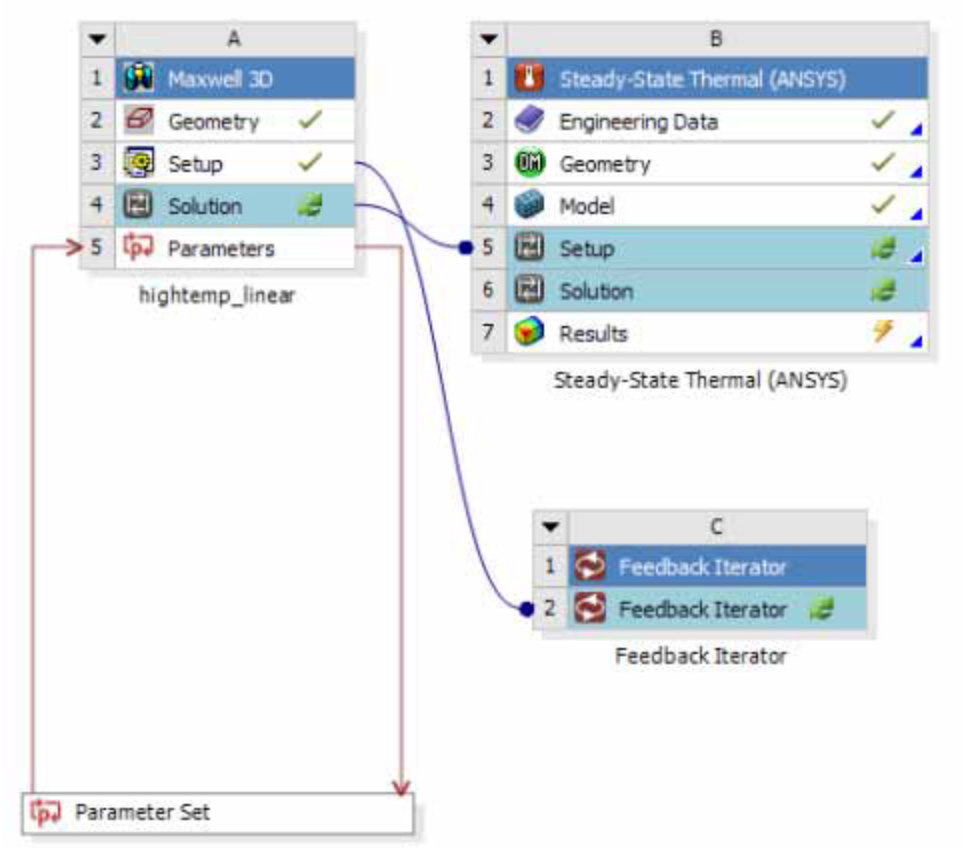
When any coupled client components are modified (either in Workbench or in an external editor), the coupled clients and master are marked as modified. The Completed Iterations property is set to 0.

Iterating to Convergence

Scenario	Steps to execute	Outcome
Standard update scenario	• Right-click on the Feedback Iterator component and select Update OR • Update Project OR • Update all design points OR • DX Update	For each iteration, the Electromagnetics product solution is updated, followed by the downstream setup and the downstream solution. Each of the client component updates display their progress monitor and can be aborted (resulting in aborting the current iteration)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

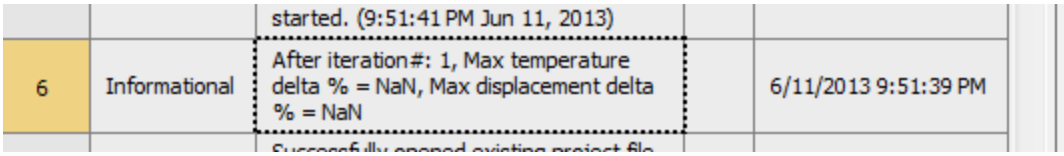
The following temperature convergence example uses Feedback Iterator with a Maxwell design, coupled with a Steady-State Thermal component. Iterating to convergence operates similarly for HFSS projects.



The example uses defaults of 5% for the convergence targets and a value of 100 max iterations. Recall that the max iterations value is set as a safety measure to ensure that iterations do not continue indefinitely if the solution does not converge. As we progress through the iterations, we observe the following:

End of Iteration #1

The first iteration, because it has no previous iteration, cannot return a meaningful delta value.



At the end of this iteration, the Latest Delta value is listed as Not Available.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

15	Target Delta Temperature %	5
16	Latest Delta Temperature %	2.5
17	Displacement Convergence	
18	Target Delta Displacement %	5
19	Latest Delta Displacement %	2.5

When convergence criteria are met, the simulation stops. If you attempt to update after convergence has been achieved, the simulation will not be launched since the current solutions satisfy the convergence criteria.

You can monitor the iteration progress by opening the Maxwell editor and selecting **Results** > **Solution data**. Choose the **Profile** tab and keep the window open. As you solve each iteration, you can observe the reported Delta-T (with thermal feedback) and/or delta-displacement (with displacement feedback) and abort the iterations (or stop single iteration updates) when the values reach acceptable convergence levels.

Surface Force Density in HFSS

HFSS can calculate surface force density for Work Bench coupling and for post processing within HFSS. The whole approach resembles Maxwell except that HFSS must calculate the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

surface force density at the post processing stage while solver provide the surface force density in Maxwell.

The surface force density formulation is provided in a technical note here. Surface forces may exist on surfaces where one side is conductor but the other is not, or finite conductivity and layered impedance boundary. The computation of surface force density will be performed at field geometry instance level.

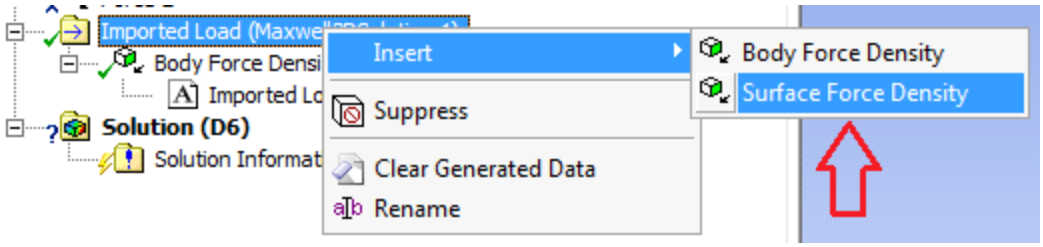
This feature is mainly for the purpose of mapping surface force density in HFSS to Work Bench Mechanical. We will also provide it for post processing within HFSS. This feature should work regardless of HFSS solution types as long as surface forces exist. Surface forces may exist when one side is conductor but the other is not, or finite conductivity and layered impedance boundary.

If an old coupling project happens to request surface force and is solved again, then the surface forces (likely nonzero) will be passed to mechanical side.

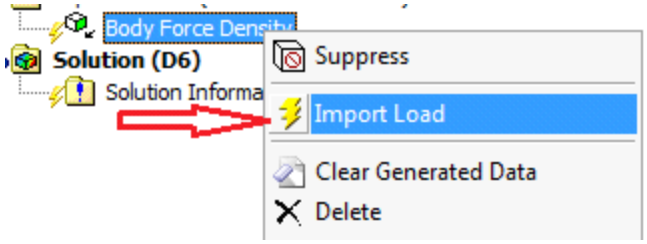
Mapping surface force density from HFSS to Work Bench Mechanical

The behavior is the same as all current couplings.

1. From the Mechanical side set up a surface force coupling to an HFSS design similar to Maxwell.



2. Import the load.



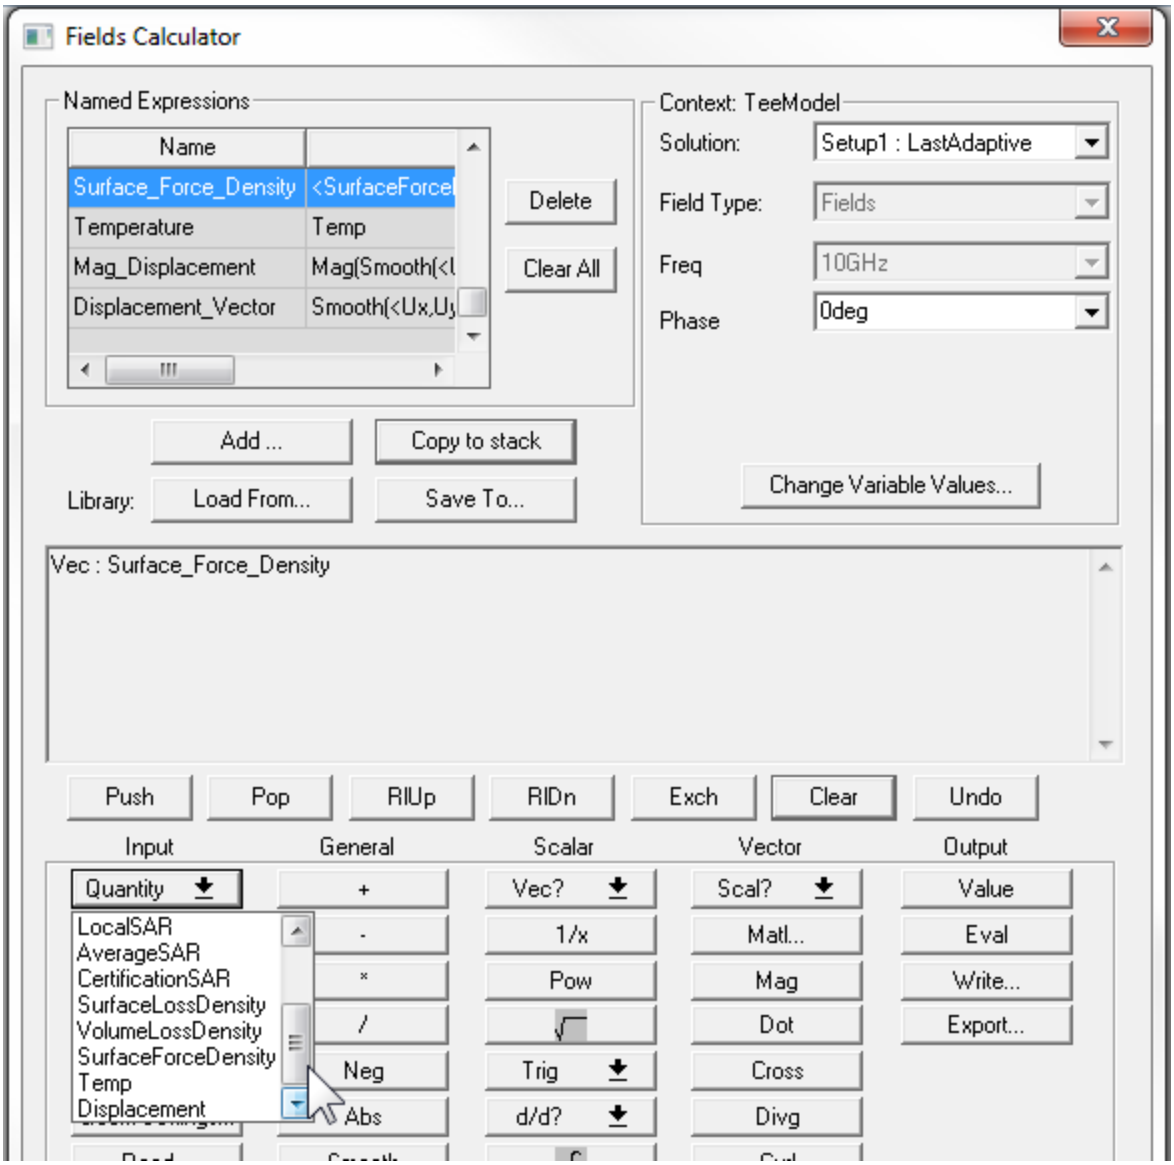
Behind the scenes Mechanical will pass necessary information to HFSS, points on surface to request surface forces and auxiliary files, HFSS will then calculate the surface force densities and pass them back to Mechanical.

3. Post process surface density within HFSS over any surfaces where surface forces exist.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Surface Force Density will appear in the context menu in the Other category under Fields menu.

In the fields calculator Surface Force Density appears in the Named Expression list and the Quantity drop-down menu. So the user can use it the same way as other vector quantities.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

27 - Meshing In HFSS

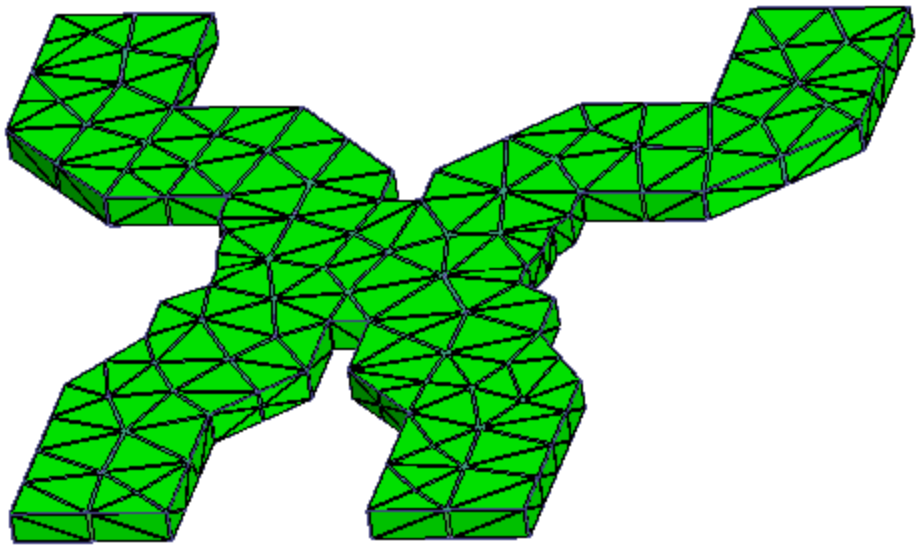
Automatic adaptive meshing is an essential and integral part of the simulation process. An appropriate mesh that supports electromagnetic FEM calculations is essential for obtaining accurate results. Meshes are produced automatically, ensuring efficient simulations in generating highly accurate results. During the simulation process, the initial mesh is created and then the adaptive refinement process begins in which Maxwell's Equations are solved and the mesh is intelligently refined. This adaptive refinement process continues until the solution is converged and accurate.

Introduction to Meshing in HFSS

The geometric model is automatically divided into a number of tetrahedra. The collection of tetrahedra forms the finite element mesh.

The partial differential equations that govern the behavior of the electromagnetic fields form an accurate mathematical model. The partial differential equations are Maxwell's Equations, valid everywhere in the three-dimensional space. The finite element formulation uses sophisticated mathematical techniques to satisfy the partial differential equations in the geometrical model, which represents some device or system of interest.

Collection of tetrahedra forming a finite element mesh that represents a waveguide combiner



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

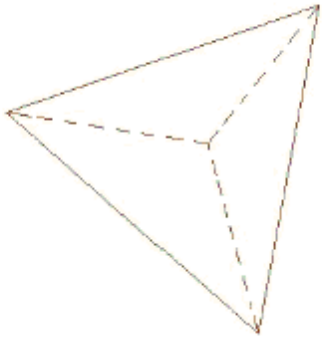
Mesh Generation

Mesh generation is the process by which space-discretization is implemented. During mesh generation, a geometric domain is divided into a number of elements.

The type of the mesh is defined by the shape of the element, which can be tetrahedral, hexahedral, polyhedral, pyramidal, prismatic etc.

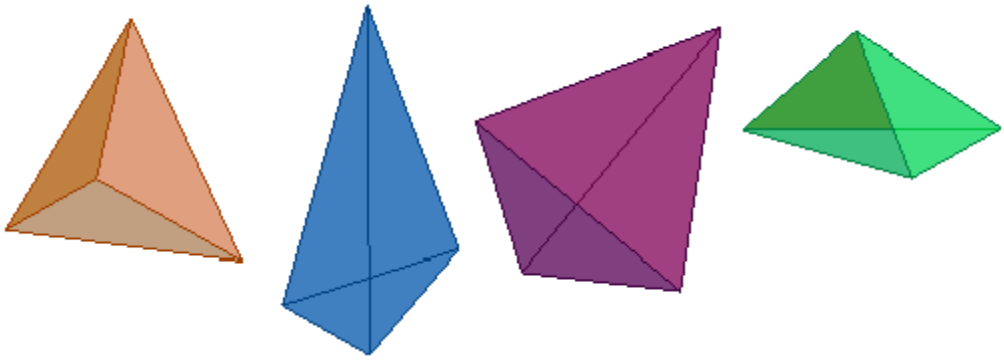
In HFSS, a mesh is a discretization of a continuous domain (geometry) into small three-dimensional tetrahedral and two-dimensional triangular elements. The following figure shows a tetrahedron, which is a solid composed of four triangular faces.

A tetrahedron



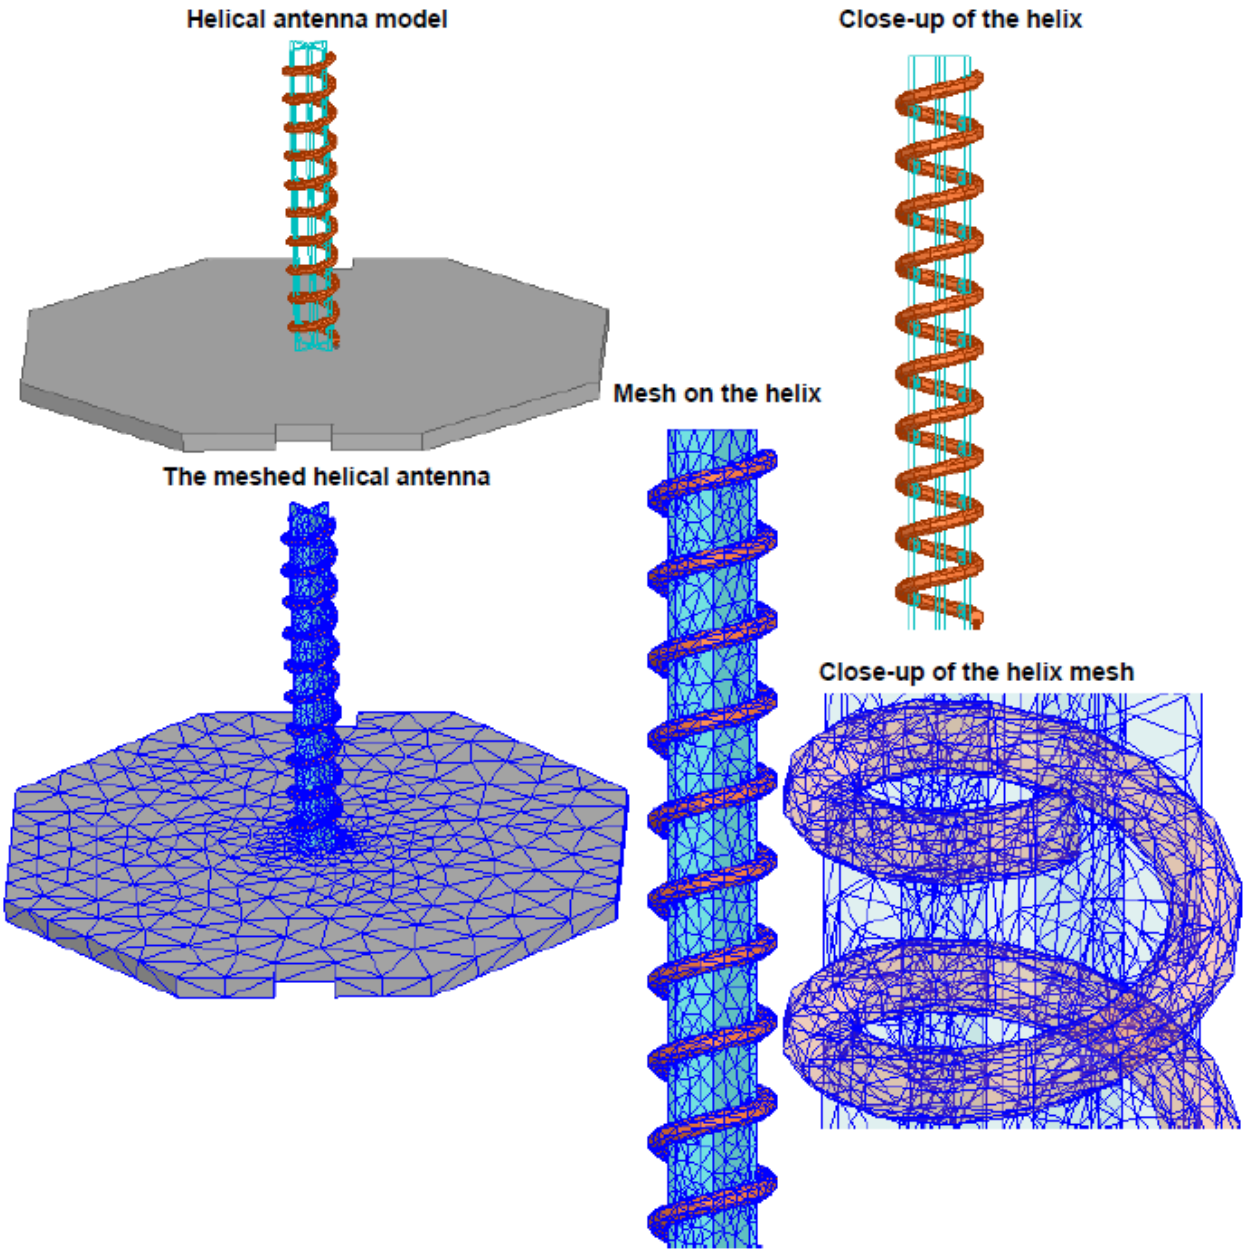
Tetrahedra are the simplex for R3 space, which means that any 3D shape can be decomposed into tetrahedra. Since the process of mesh generation is automatic in HFSS, this mathematical guarantee is necessary for successful mesh generation of arbitrary domains. Therefore tetrahedra (and triangles for two-dimensional surfaces) are used. Tetrahedra can be stretched and pulled (see the figure below), which allows them to fit any arbitrary 3D geometry; so any 3D shape can be decomposed into a number of tetrahedra.

Different kinds of tetrahedra



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The following figures illustrate HFSS designs of a helical antenna before and after the mesh is created. Notice that the helical antenna model is well-represented by the mesh.



Adaptive Mesh Refinement

Adaptive mesh refinement automatically generates accurate solutions. This meshing technique helps you focus on setting up your design efficiently rather than spending time in determining and creating the best mesh. To set up the design, you need only to create the geometry and specify material properties, boundary conditions, excitations, and the solution frequency.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This automatic adaptive mesh refinement technique differentiates HFSS from most electromagnetic simulators, which typically require extensive user controls to ensure that the generated mesh is suitable for simulation. Without the correct mesh, results from such simulators may be erroneous.

In HFSS, however, the automatically generated mesh accurately represents the electromagnetic characteristics of the design. HFSS determines the size and density of tetrahedra for optimal efficiency and accuracy. An initial mesh is generated and solved to produce error estimates of the solution. These error estimates are used to refine the mesh in high-error regions. Using this refined mesh, HFSS generates another solution and recomputes the error. This adaptive refinement process continues until HFSS converges to an accurate solution. Convergence is determined by monitoring a parameter from one adaptive pass to the next. The most common convergence criterion is to ensure that the difference in the S-parameter value between two consecutive solves is less than the specified magnitude. If you need to increase the accuracy, you can easily tighten the convergence criteria, and HFSS further refines the mesh.

Adaptive refinement ensures that the mesh elements are sufficiently fine in those areas where strong electromagnetic fields exist and/or the field gradients are high. The mesh is coarser in the remaining areas. This process makes the mesh size appropriate and suitable for efficient simulations leading to highly accurate solutions.

To illustrate, an aperture coupled microstrip filter design with three traces is shown below. One of the traces is located on one side of the ground plane, while the other two traces are located on the opposite side. The figures also show the resulting electric fields that develop for the design after the simulation is completed. The plots show the traces of the microstrip on both sides of the ground plane illuminated by the electromagnetic fields.

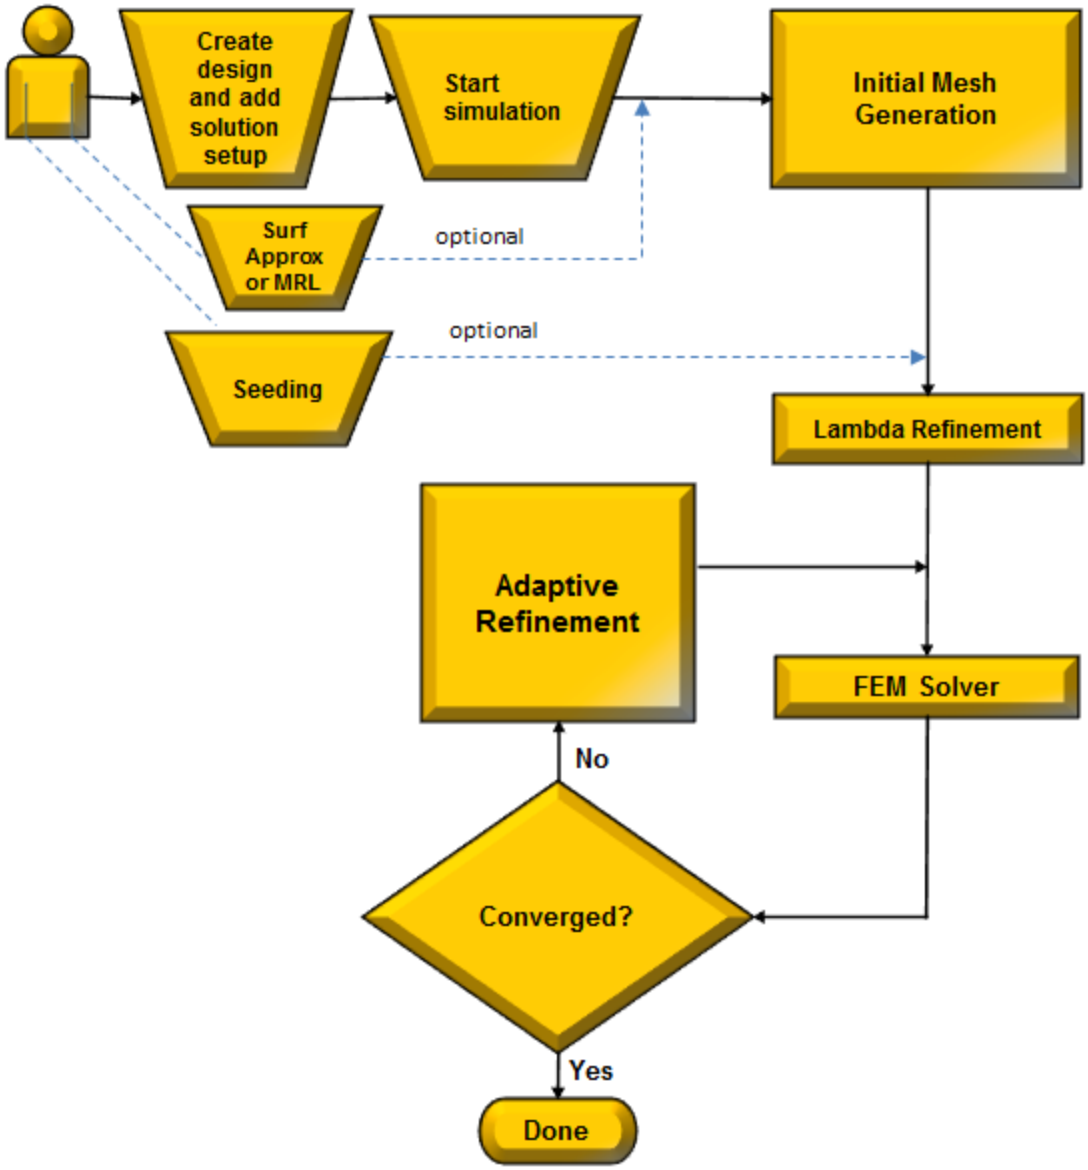
Adaptive Mesh Refinement Process Flow

HFSS uses the adaptive mesh refinement technique and generates accurate solutions with minimal use of computational resources. The following diagram shows the adaptive mesh refinement process flow that can deliver accurate results with least user involvement.



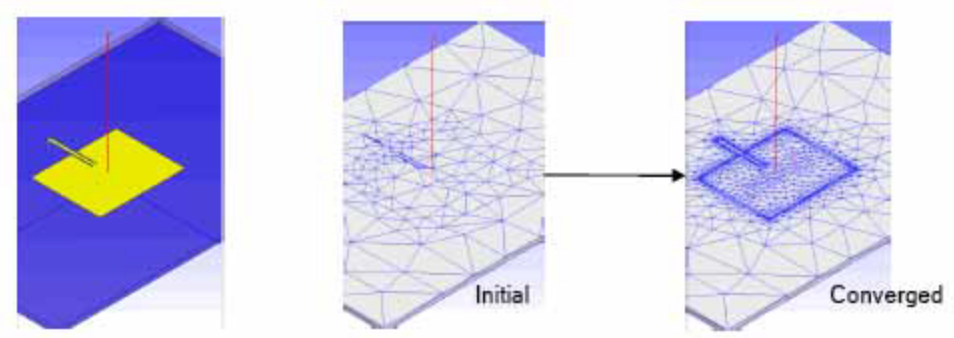
For mesh operations, defining surface approximation, model resolution length, and seeding are optional steps in the solution process, as shown in the flow diagram. This is because the automatic adaptive refinement process is adequate to produce accurate results. Only on rare occasions, adaptive refinement is used with mesh operations. For more information, see Optional Mesh Refinement Settings.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The process depicted by the flow diagram can be summarized as follows:

1. HFSS generates an initial mesh that can be controlled by surface approximation settings.
2. Seed refinement (if assigned) and Lambda refinement occur on the initial mesh.
3. Using the resulting mesh, HFSS computes the electromagnetic fields in the structure.
4. From the current solution, HFSS produces error estimates and refines the mesh in regions of high error and uses the refined mesh to generate another solution.
5. HFSS performs the iterative process of solve, error analyses, and adaptive refinement until the convergence criteria are satisfied or the maximum number of adaptive passes is completed.

The following figure illustrates that the initial mesh is refined until convergence criteria are satisfied and a suitable final mesh is generated.



Stages of Meshing

During mesh generation, HFSS divides the geometric domain into tetrahedra. The collection of tetrahedra forms the finite element mesh. The different stages of meshing are described as follows:

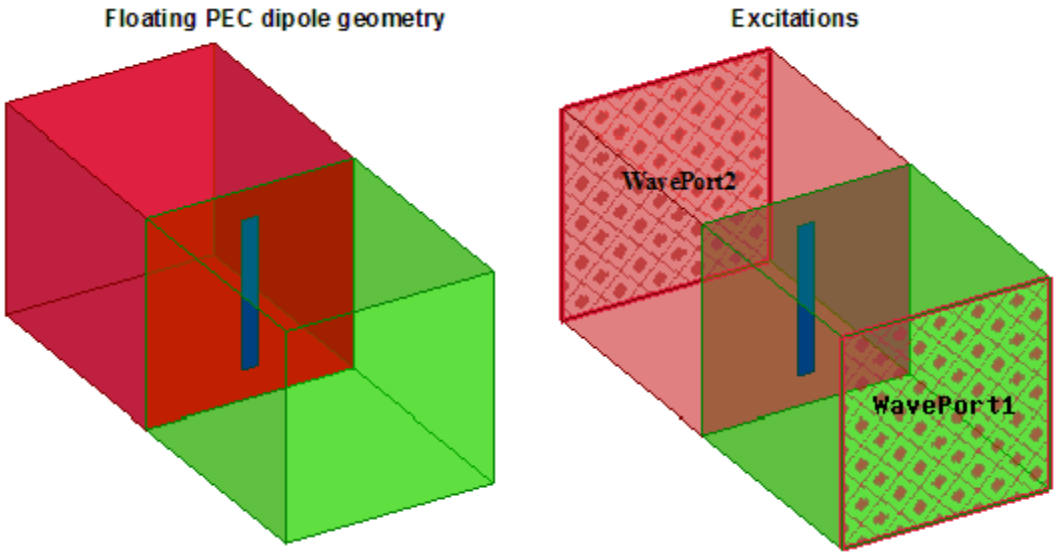
1. HFSS creates an initial mesh that can be controlled by the surface approximation settings.
2. The initial mesh is refined based on the material-dependent wavelength lambda refinement and any mesh operations that are defined.
3. HFSS iteratively refines the 2D mesh at any ports in the model.
4. The electromagnetic fields are computed inside the structure.
5. The current solution is used to estimate the tetrahedra where the solution has large error and those tetrahedra are refined. This results in a refined mesh.
6. The refined mesh is used to generate another solution.

HFSS continues with the iterative process (steps 4and 6) until the convergence criteria are satisfied and then generates accurate results.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Example: Floating PEC Dipole

The following figures show a floating PEC dipole enclosed in a parallel plate waveguide excited at both ends by wave ports.



Although floating PEC dipole appears to be a simple design to solve, it is a canonical project for testing adaptive meshing algorithms. In this problem, the challenge is to efficiently refine the mesh for capturing the electromagnetic field singularities around the dipole.

The following figures illustrate how adaptive refinement addresses this challenge. First HFSS generates an initial mesh as shown in Figure 1. This initial mesh serves as a good starting point for adaptive refinement. Figure 2 shows the mesh plot after Adaptive Pass 1. This automatic adaptive refinement process continues until the convergence criterion is satisfied. Figure 3 shows an intermediate mesh during a later stage of the simulation. Figure 4 shows the final mesh that is produced after the solution converges.

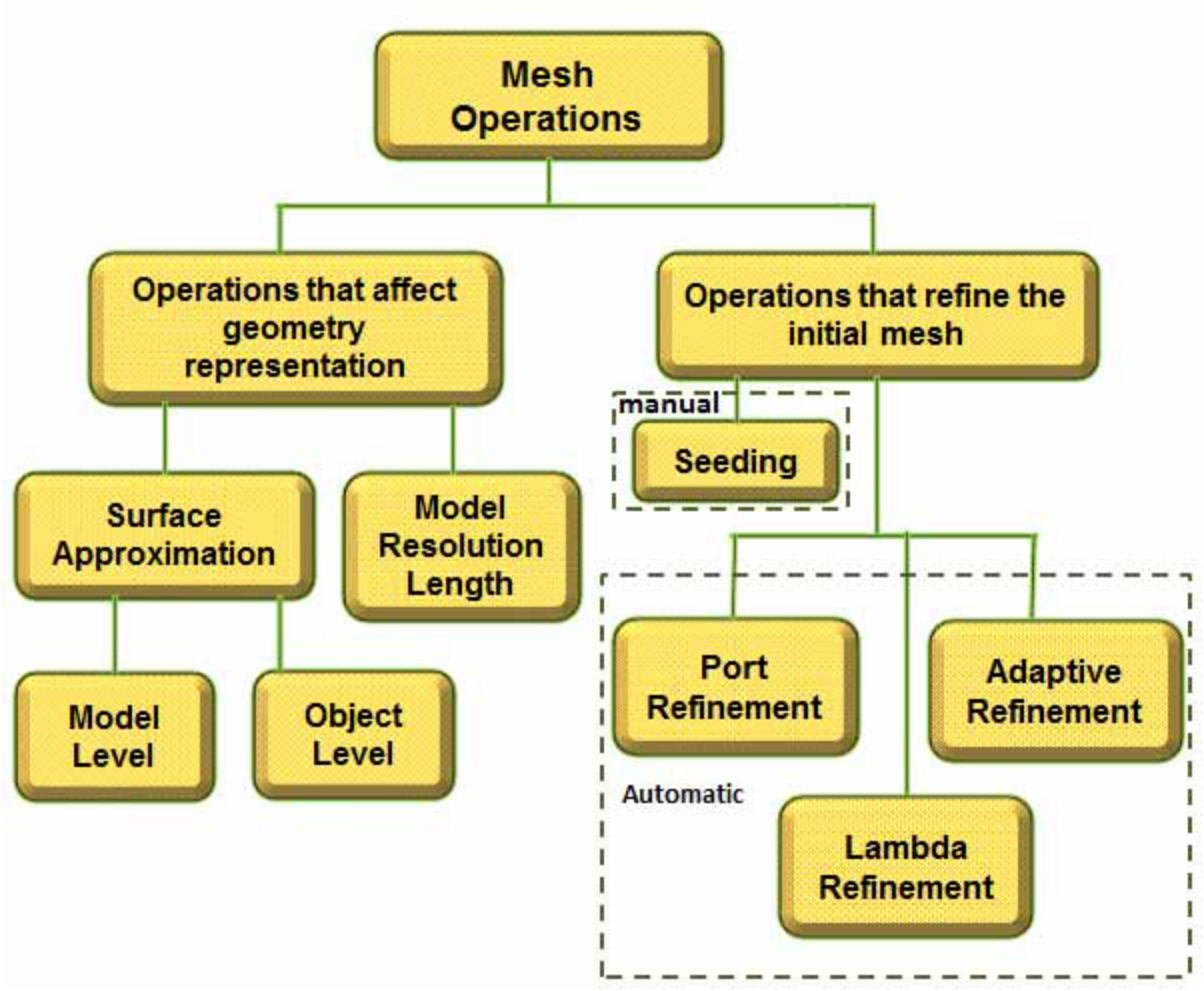
Assign Mesh Operations

Mesh Operation settings are optional. The following figure provides a synopsis of the different mesh operations available in HFSS. The figure shows a classification only; it does not show the solution process flow. For more information about the solution process, see Stages of Meshing and Adaptive Refinement Process Flow.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The next sections describe these mesh operations.

Operations Affecting Geometry Representation

Surface Approximation and **Model Resolution Length** operations affect the initial mesh. If you modify any of the options on the **Surface Approximation** or the **Model Resolution Length** panels, the initial mesh is invalidated, and HFSS regenerates the initial mesh. The plausible reasons for controlling the initial mesh are:

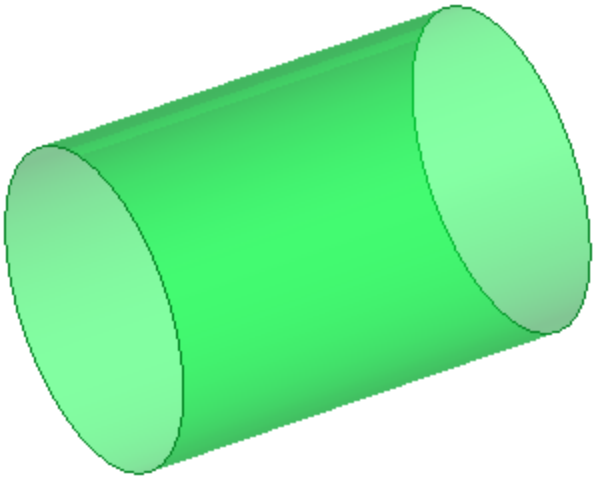
- if improved representation of curved surfaces is required.
- if initial mesh failures require workarounds.

> **Note:**
>
> See **Troubleshooting Mesh Failures** for more information.

Example: Improved Representation of Curved Surfaces

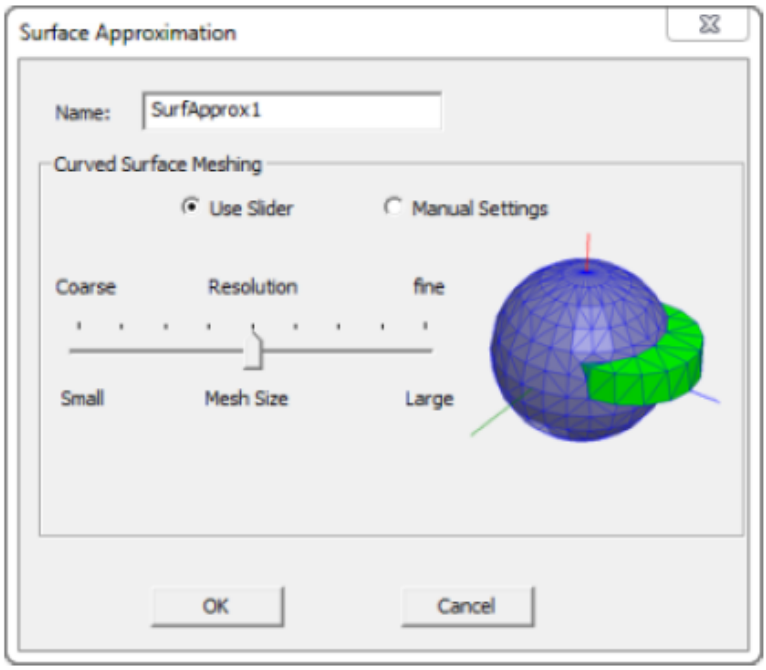
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Consider a cylinder shown in the following figure. The mesh representing the geometry of the cylinder can be modified by changing the surface approximation settings. HFSS uses these settings only during initial mesh generation.

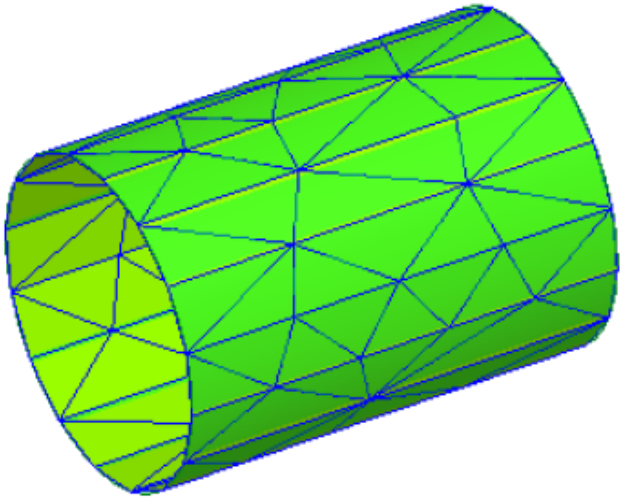


If you do not define any mesh operation, HFSS automatically uses default settings to create the initial mesh. If you define or modify a **Surface Approximation** setting, the current initial mesh is discarded and a new initial mesh is generated. The following figures illustrate the initial mesh for the default, and for a user-defined setting where maximum surface normal deviation angle is changed. Due to the reduced value of the maximum normal deviation angle, the initial mesh has more triangulations to represent the curved surface of the cylinder.

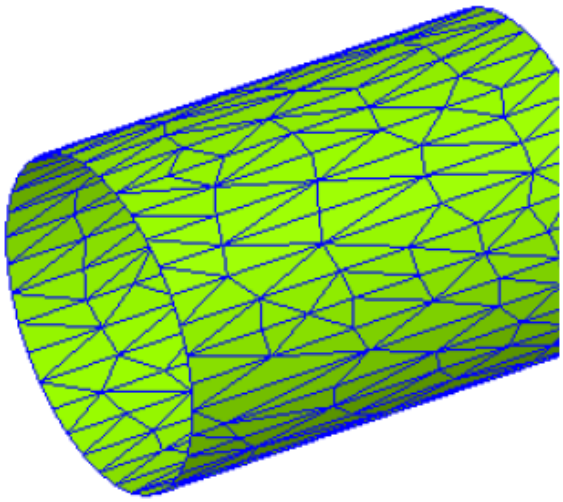
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Default SA settings



User-defined SA settings

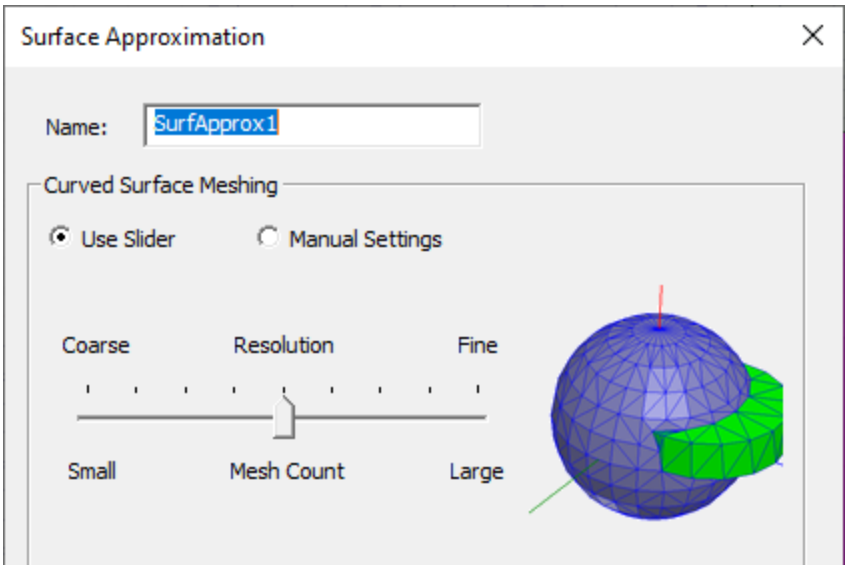


Surface Approximation

Surface Approximation is a mesh operation that controls the initial mesh generation. If you modify the default **surface approximation** settings, the initial mesh is invalidated. They are used for models with curved surfaces. In HFSS, you can access these settings in two places. When you select a curved surface, right-click and choose **Assign Mesh Operation** > **Surface Approximation** from the short-cut menu, you can define the settings for the current selection of

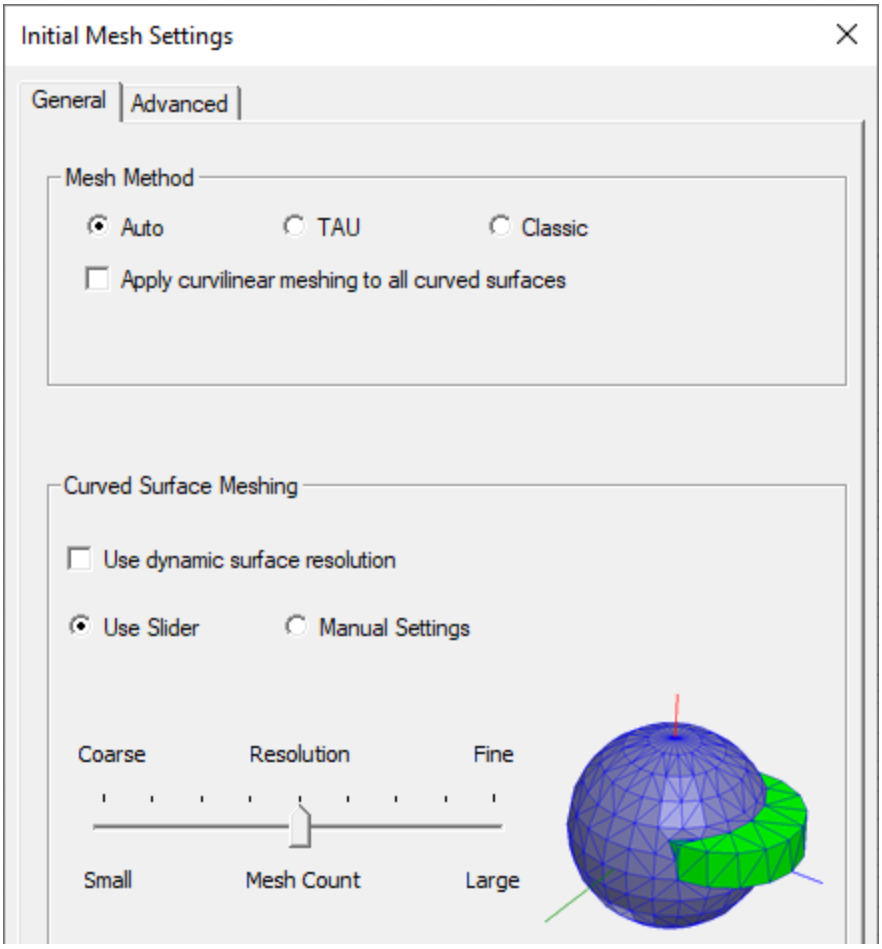
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the object. The slider permits you to set surface approximation in convenient way. The actual slider bar values applied can be interpreted differently by different solvers as is suitable in each case (for instance, it is more refined for IE Regions or SBR+ Regions than for FEM).



However, when you right-click **Mesh** in the project tree and select **Initial Mesh Settings**, you can define the settings at a global level. Additional options in this panel include **Mesh Method** and **Apply curvilinear elements** check box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

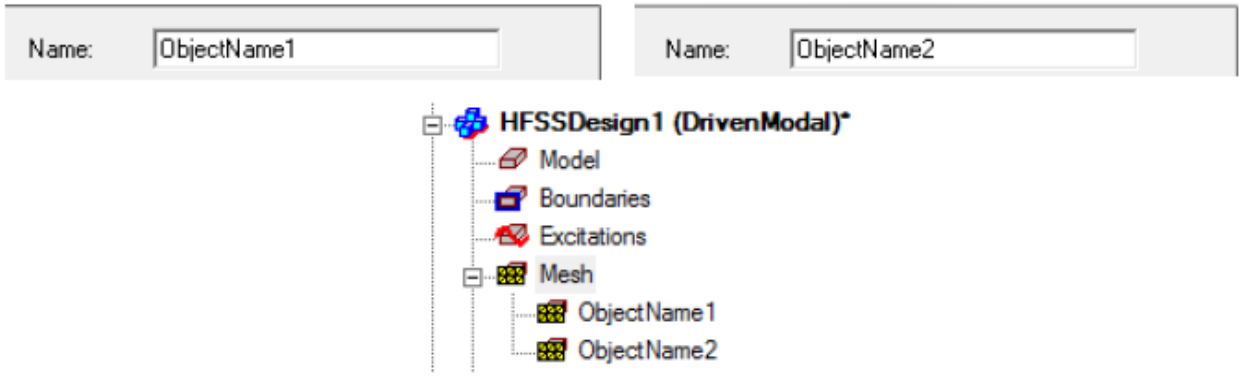


Note: Apply Curvilinear elements is only supported for the entire model whereas **Surface Representation Priority for Tau Mesh** is only supported for the selected object.

Name

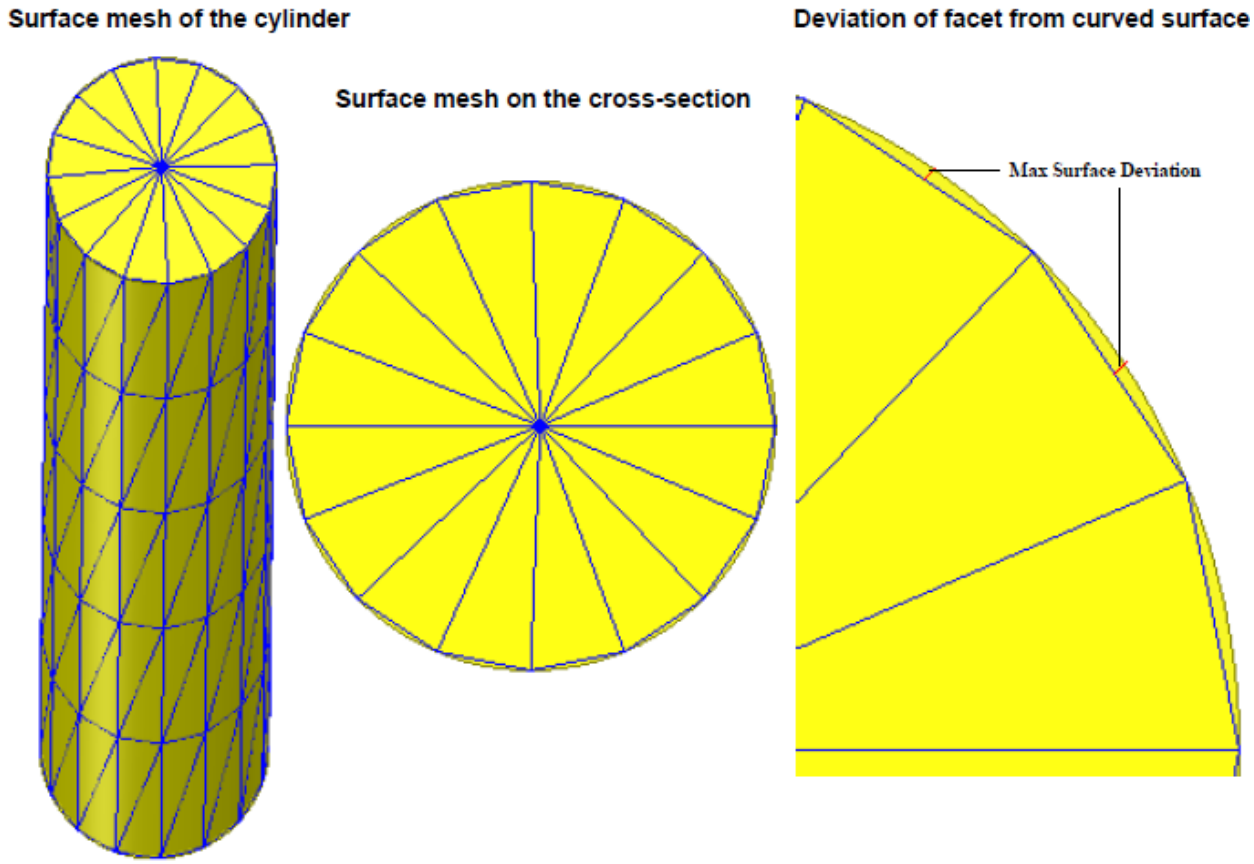
In this field, use the default or enter the name for the group of settings. Assign meaningful names so that you can easily distinguish between the different surface approximation assignments for the corresponding objects in the model. Accordingly, **Mesh** on the **Project Manager** window is populated as shown in the following figure.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



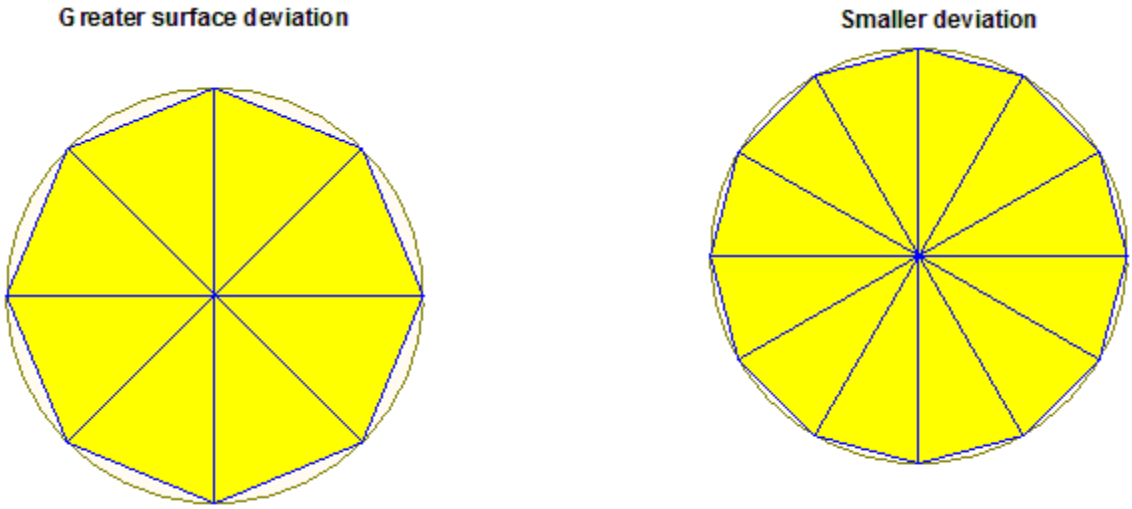
Maximum Surface Deviation (Length)

All curved surfaces are faceted during the meshing process. A facet is a collection of triangles. There is a small distance between the faceted surface and the curved surface, which is called surface deviation. **Maximum Surface Deviation** is the maximum value of this distance. The following figures show a meshed cylinder in HFSS, the cylinder cross-section, and the **maximum surface deviation** that occurs near the center of each faceted triangle. When you use an appropriate value for **Maximum Surface Deviation** (length), the curved surfaces are well-represented to realize the original surface.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

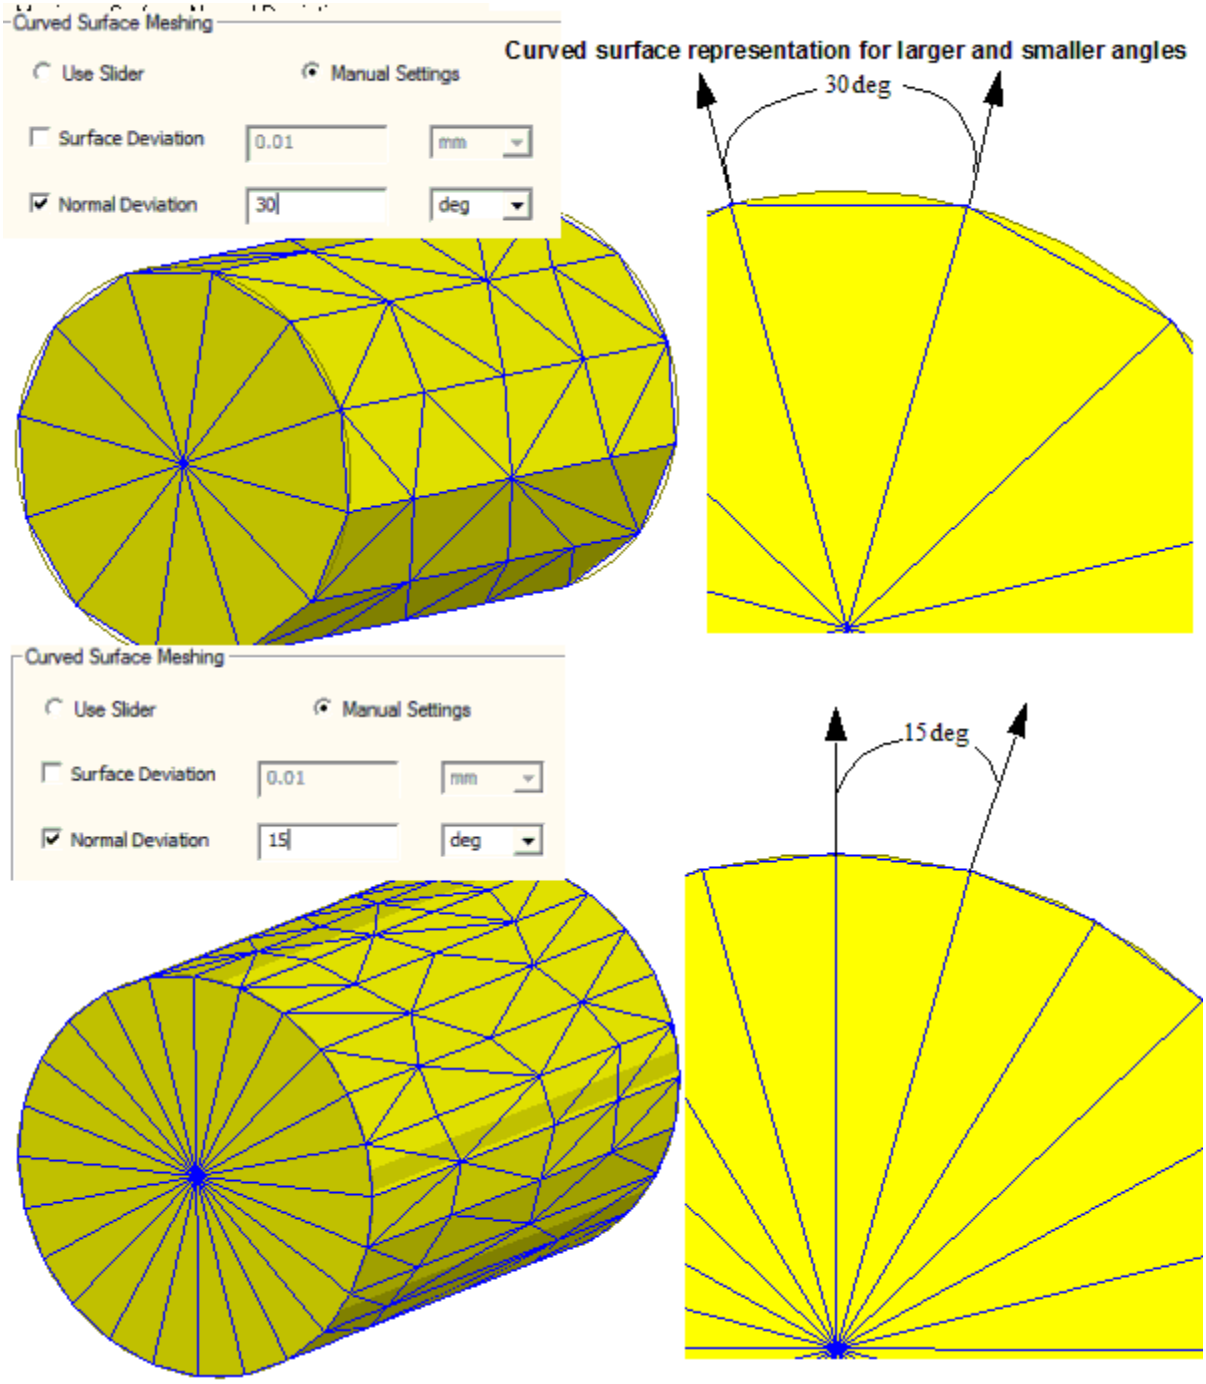
The following figures illustrate how the representation of a curved surface changes when different values of maximum surface deviation (length) are used. Smaller values of maximum surface deviation can result in greater number of faceted triangulations, for more accurate approximation of the curved surface. However, increasing the number of triangles causes more CPU time and memory consumption during simulation. For this reason, use the default settings, since they are adequate for most circumstances. In the following figure, the cylinder radius is 0.5 mm, height is 1.5 mm, and the normal deviation angle is kept constant at 45 degrees to illustrate the effects of different maximum surface deviation lengths.



Maximum Normal Deviation (Angle)

Maximum Normal Deviation is the maximum angular deviation between any two normals on a curved surface approximated by a faceted triangulation. The following figures illustrate the effect of using different maximum normal deviation angles on a cylindrical surface. In the following figure, the cylinder radius is 0.5 mm and its height is 1.5 mm.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



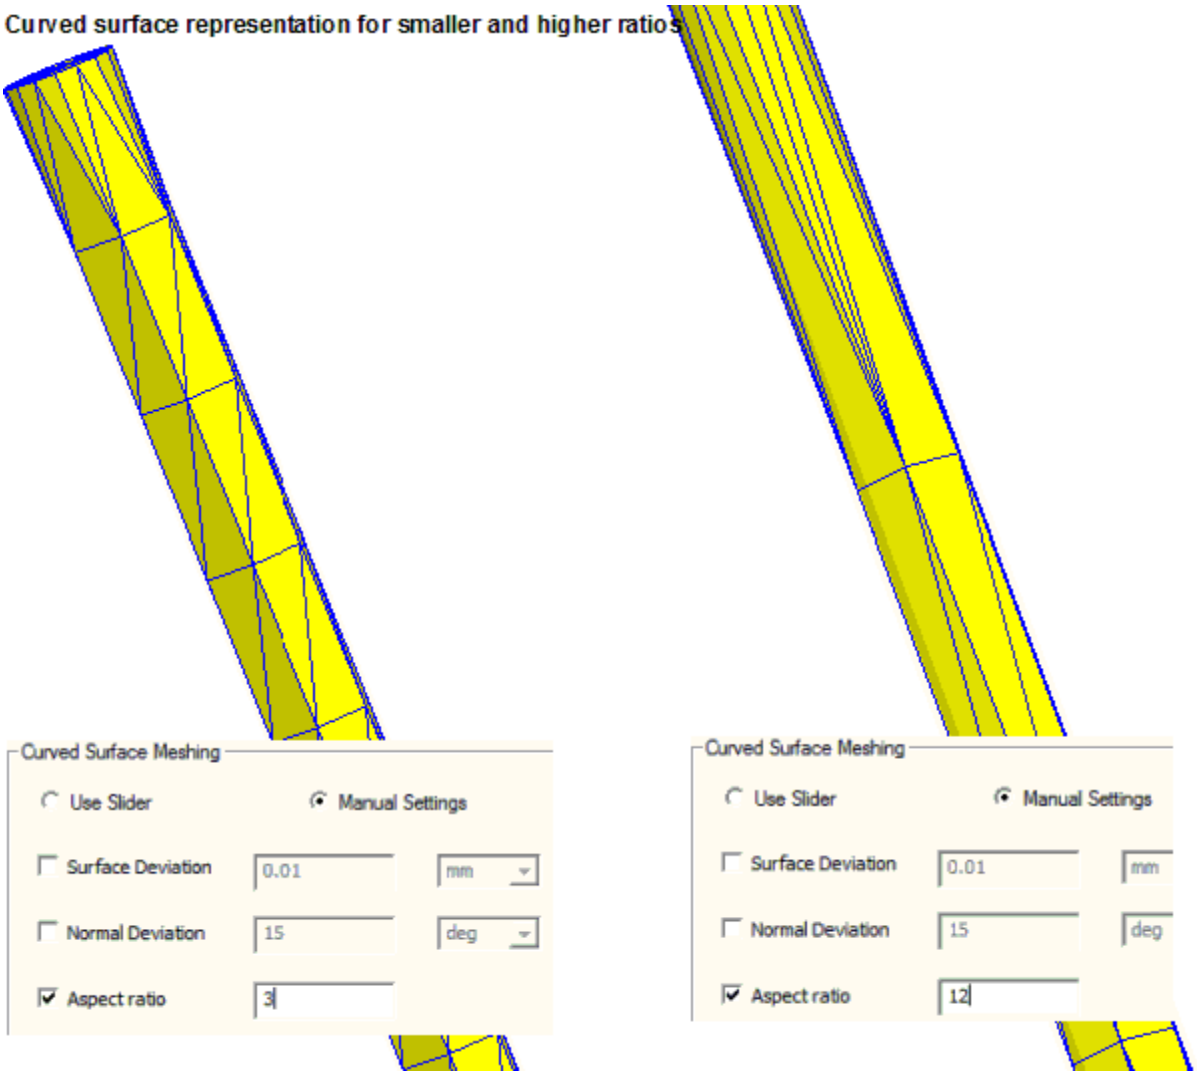
Maximum Aspect Ratio

Maximum Aspect Ratio controls the ratio of the longest side to shortest side in a triangular mesh. It is a type of mesh operation occurring at the object level, and it directly controls the surface representation of the object. Aspect ratio and the shape of the triangulated facet

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

representing the surface of the object, are related. As aspect ratio increases, the triangles become narrower. Setting aspect ratio to 1 does not guarantee equilateral triangles but produces triangles similar to isosceles right-angled triangles.

> **Note:**
>
> Default value for **Maximum Aspect Ratio** setting is recommended. Values in the range of 2 to 20 can produce suitable meshes.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

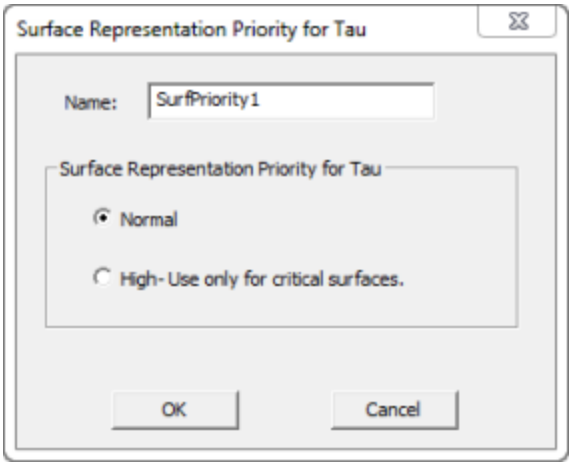
Surface Representation Priority for Tau Mesh (effective only for Tau Tolerant Mesh)

If a particular surface is very small in size and located close to large surfaces and/or this object is very important or has critical boundary conditions, you can set the Mesh Operation **Surface Representation Priority for Tau Mesh** to preserve it accurately. For example, a small antenna on the body of an aircraft may need high surface representation priority.

Tau mesh uses the dimension of the model as reference to specify the mesh tolerance. Generally, mesh tolerance is 1e-5 of the model dimension. In some designs, the dimension of the model is large while some critical objects are small, such as the framed antenna on a windshield embedded on a car or a small antenna on a huge aircraft.

In such designs, sometimes the small objects are assigned boundary conditions or they are critical to the simulation. Using global tolerance might not produce a highly accurate mesh on these small objects. Therefore for such designs when **Surface Representation Priority for Tau Mesh** is specified as high on the small objects, the mesher preserves every detail and by strict verification ensures that the mesh properly represents these objects. This mesh operation is effective only for the TAU (Tolerant) mesher. TAU (strict) follows the same rules as Classic mesh, which ensures a very accurate representation of the surface as defined by the surface approximation settings.

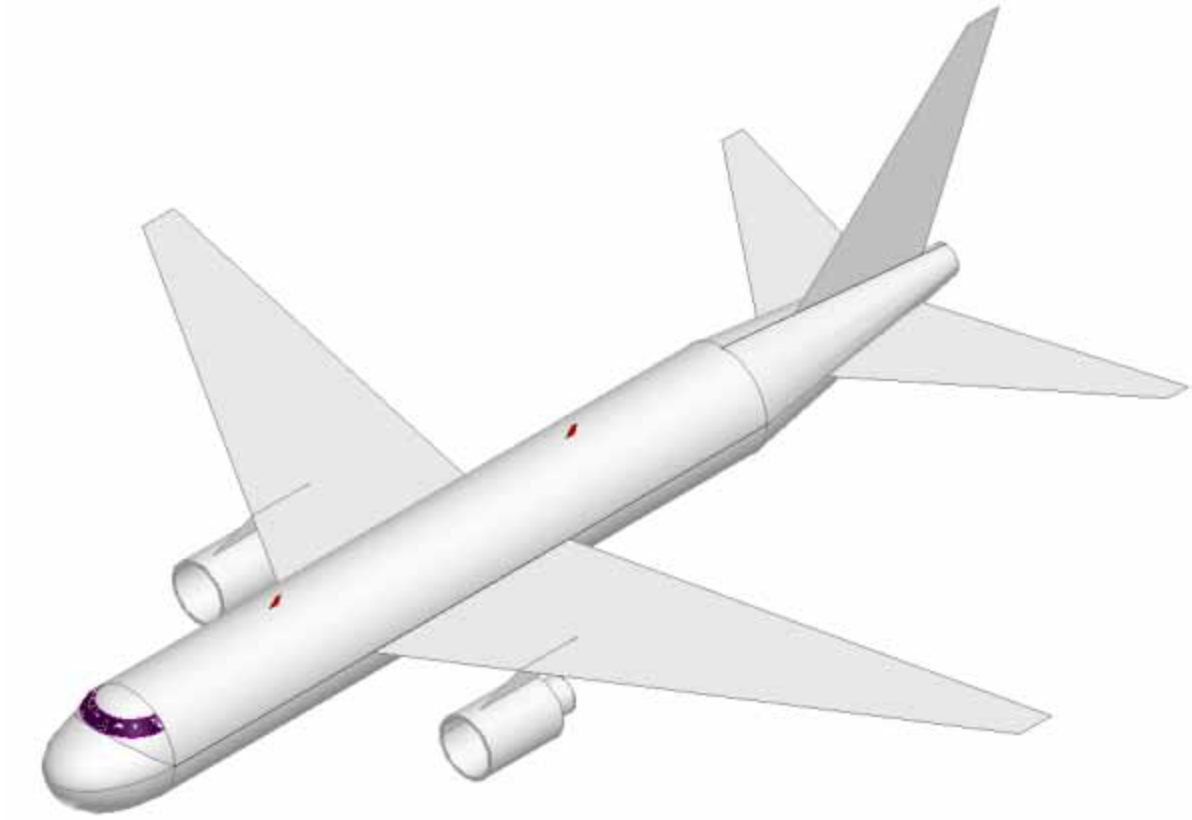
> **Important:**
>
> The consolidation of surfaces into a conformal mesh is skipped for dynamic and tolerant meshing, including for light weight geometries. This can lead to overlapping surfaces in SBR+ simulations. The user should carefully avoid overlapping surfaces or objects as SBR+ can produce unexpected results.

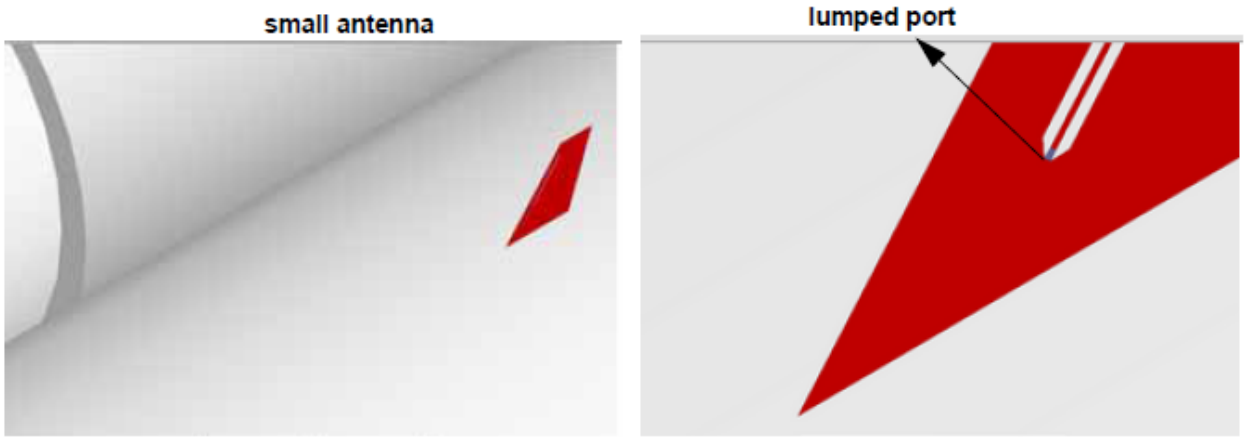


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Important:

Use this mesh operation with caution. Use this option only if the model has tiny elements or critical boundary conditions since performs several additional strict mesh verification steps on the selected objects.

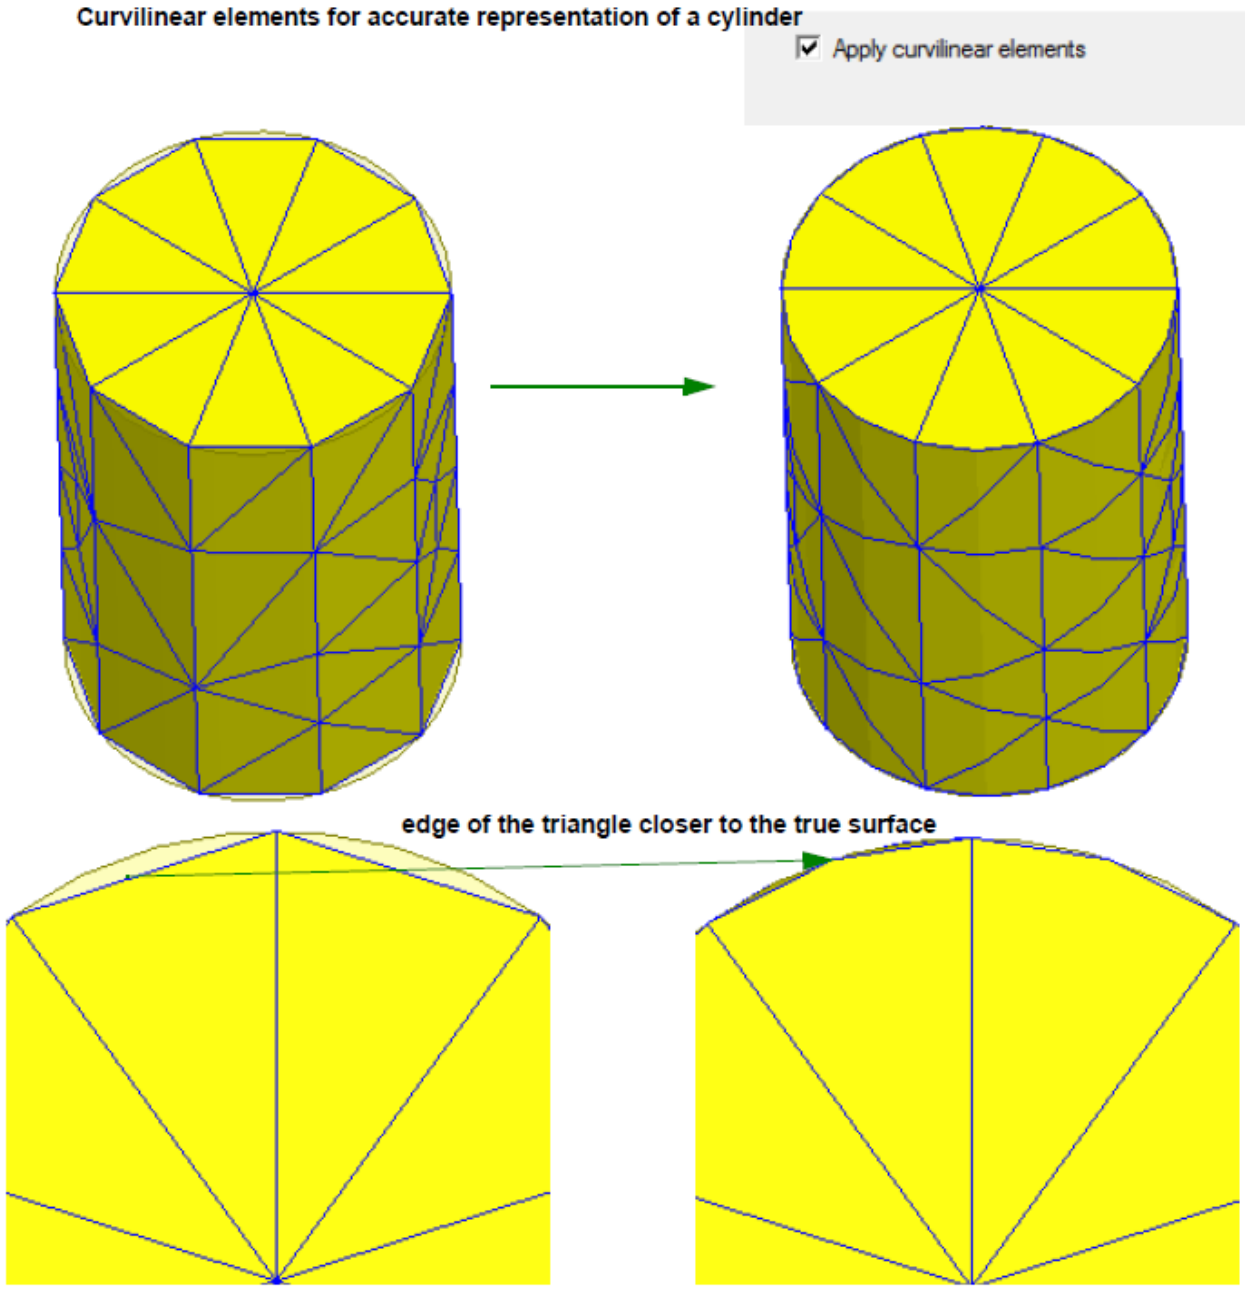




Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Apply Curvilinear Elements Discussion

This Mesh Operation is a global surface approximation setting, and it is used to enable curvilinear elements for all true surfaces in the model. If you select this Mesh Operation command, higher order or curvilinear elements are used to represent the geometry. The midpoints of the surfaces of the tetrahedra are pulled to the true surface ensuring better representation of the geometry as illustrated in the following figures.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Default surface approximation settings with curvilinear elements yield accurate results in an efficient way. The application of curvilinear elements allows you to maintain a relatively low facetation and therefore save on computational resources.

> **Note:**
>
> Curvilinear elements can be used on FE-BI, IE Region and SBR+ surfaces.

Meshing for Curved Surfaces

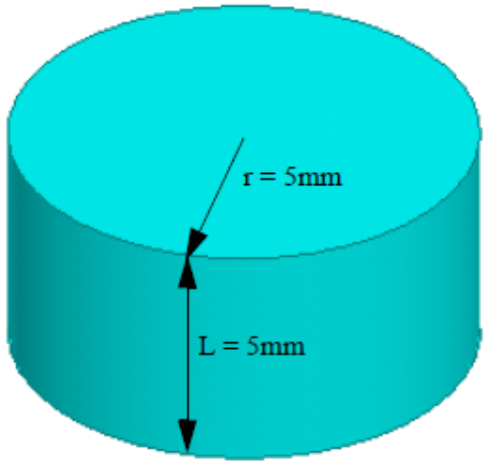
For curved surfaces, the initial mesh obtained on the surface of a geometry is the same initial mesh generated in accordance with the surface approximation settings. During the meshing process of curved surfaces, first the volumetric mesh is created based on Parasolid triangulation. For Classic and Tau (Strict), the surface triangulations on the volume mesh are very close to the Parasolid triangulation. The approximation can be further improved by modifying surface approximation settings. As the mesh is adapted and refined, new mesh points are added to the surface mesh. If the solution is rectilinear, these points are added to the faceted representation of the curved surfaces. On the other hand, if the solution is curvilinear, then newly added points are used to improve the curved surface representation in the mesh. The process of applying curvilinear elements is often referred to as “pulling points to the true surface,” which essentially means that edges of the triangulated facets are moved closer to the true surface, resulting in accurate representation of the curved surface.

Effective Surface Approximation For a Pillbox Resonator

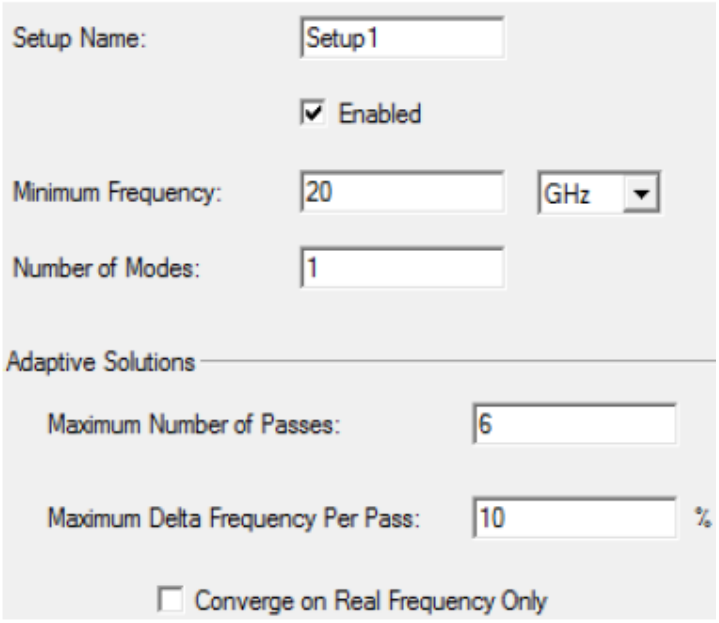
This section describes different surface approximation settings for meshing true surfaces and how they impact the accuracy of the solutions. To demonstrate these settings, a pillbox resonator is described whose dominant mode is estimated to be above 20 GHz. The eigensolver finds the specified number of modes that exist above the minimum frequency. In this example, the eigensolver finds the first mode above this frequency. The analytical resonant frequency is 22.9502 GHz.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Pillbox Resonator design



Eigen solution setup options



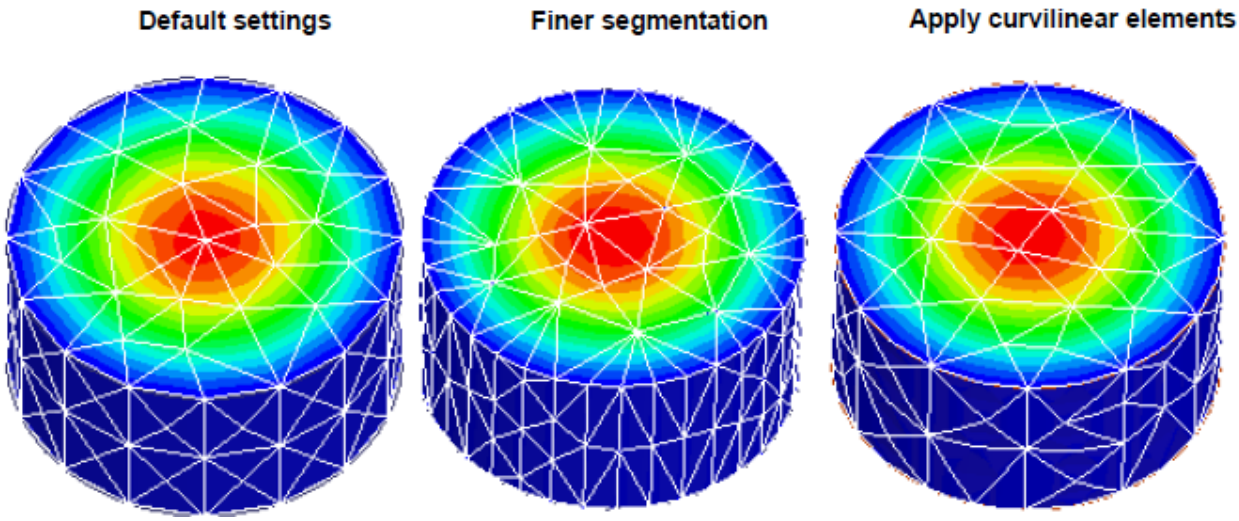
The pillbox resonator is solved using each of the following surface approximation settings:

- Default.
- Finer segmentation.
- Curvilinear elements.

For default settings, the calculated frequency is 23.2685 GHz. This frequency is higher than the analytical frequency (22.9502 GHz) because the effective volume that is being computed is smaller than the actual volume of the pillbox due to rectilinear elements. Default settings provide reasonable approximation, with relative error of 1.38%, and the degrees of freedom (matrix size) are 6024. To improve the accuracy, finer segmentation of the cylindrical surface is attempted by decreasing the maximum normal deviation angle to 10 degrees. In this case, the calculated frequency is 23.0121 GHz and the relative error is 0.026%. The accuracy is much better; the DOFs increase to 6140. In the third case, curvilinear elements are applied on a relatively coarse mesh with a maximum surface deviation angle of 30 deg, and the other default settings are retained. The calculated frequency is 22.9500 GHz, the relative error is 0.0008%, and the DOFs is only 4966. These results show that curvilinear elements on a coarse mesh ensure extremely accurate values in an efficient manner. This example showed that one way to approximate the curved surface better than the default is to decrease the maximum normal deviation angle, which results in more facets. Another method is to apply curvilinear elements, which performs surface approximation automatically and is also better than other improvement methods. For this reason, you can even start with a large normal deviation angle that will produce a coarse mesh; however, by applying curvilinear elements, the geometry is represented better and simulation yields more accurate results.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The field and the mesh plots for all the three cases are shown below.



Model Resolution Length

Model Resolution Length sets the threshold for the mesh maker to ignore features smaller than the default or user-specified length and captures major features in the model that are important for the simulation. Models that are imported from other sources may have extraneous details that do not contribute toward the electrical characteristics in the simulation process. If you specify an appropriate value for model resolution length, the mesh maker can selectively remove even tiny unneeded features. When you define the model resolution length for one or more objects, the mesh maker removes the triangulations for these objects.

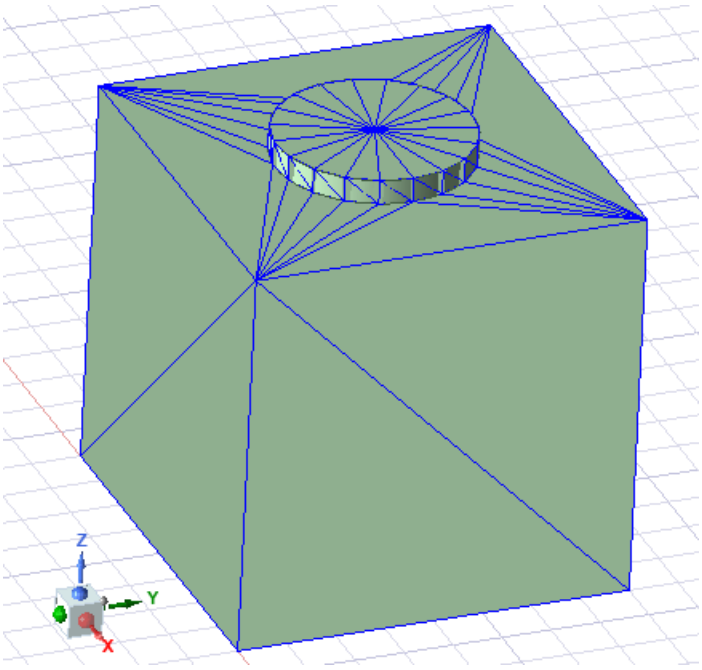
For objects with uniform thickness or with constant cross-sections, the value specified for **Model Resolution Length** can be less than 40% of the thickness. The default **Model Resolution Length** value is 10e-4 user units. For example, if the model is drawn in mm, all gaps, stubs, holes and other features smaller than 0.0001 mm can be removed by HFSS during the creation of the mesh. It is important that you choose units and values in such a manner that all important and critical features of the model are strictly greater than 0.0001 model units.

> **Note:**
>
> If you modify the model resolution length operation, the initial mesh is invalidated and HFSS triggers regeneration of the initial mesh.

Use Model Resolution Length

To illustrate how the model resolution length can be used, a meshed model of a box that has a small cylindrical feature on the top surface is shown in the following figure.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

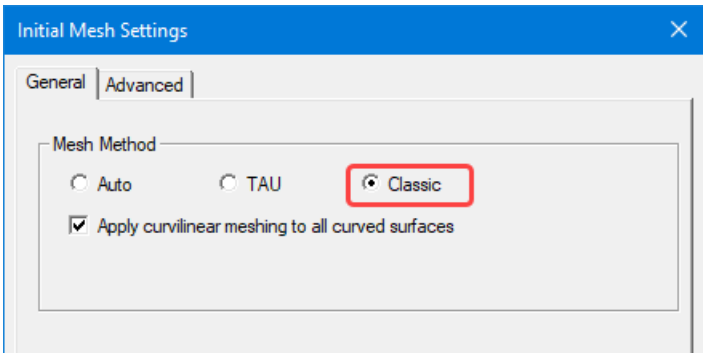


If you want to exclude the cylinder from meshing, specify an appropriate value for **Model Resolution Length** such that it is smaller than the cylinder diameter, but bigger than the cylinder height.

> **Warning:** The Model Resolution Length function is not supported for the Phi mesher or fully supported for the TAU mesher.

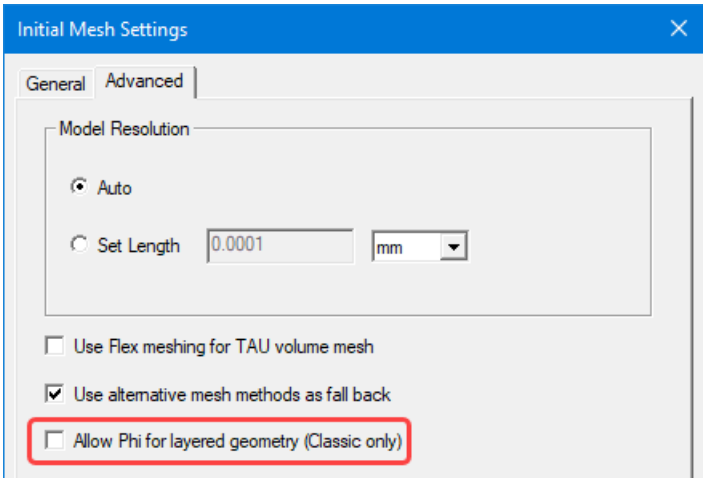
To assign **Model Resolution**, follow these steps:

1. Press **Ctrl+A** to select the whole model.
2. Right-click **Mesh** and select **Initial Mesh Settings**.
3. From the **General** tab, select **Classic**.

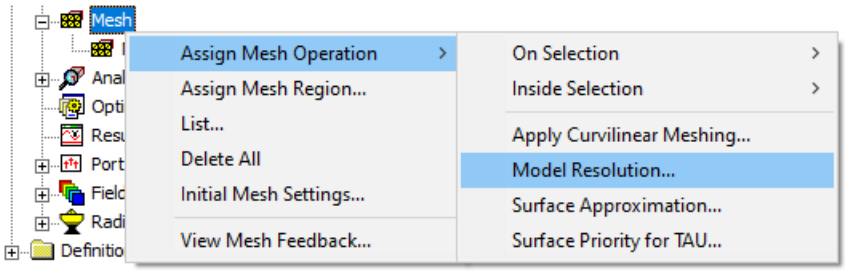


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click the **Advanced** tab, and make sure that **Allow Phi for layered geometry (Classic only)** is **unchecked**.



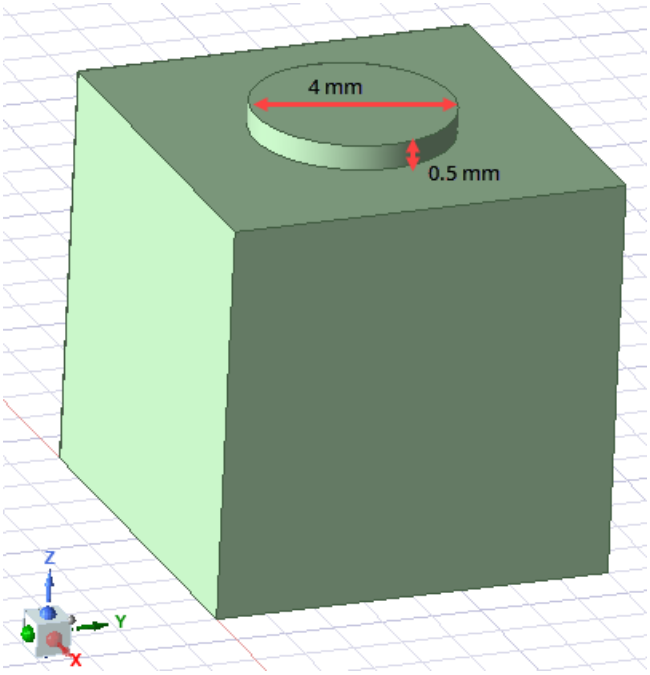
5. If you know the desired Model Resolution Length, you can set it in the **Advanced** tab of the Initial Mesh Settings window before generating the mesh.
6. If you have already generated the mesh and need to modify the Model Resolution Length, right-click **Mesh** and select **Assign Mesh Operation** > **Model Resolution**.

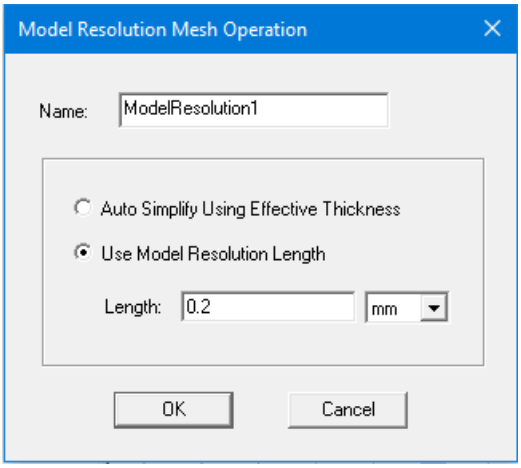


The **Model Resolution Mesh Operation** dialog box appears.

7. Set the value of the length smaller than the cylinder diameter, but bigger than the cylinder height, and click **OK**. In this case, we set it to 0.2 mm.

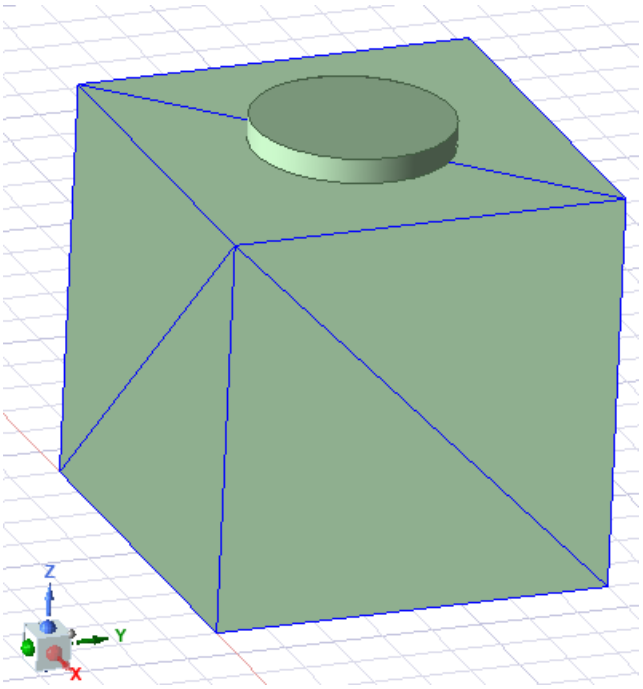
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





The meshed model excluding the cylinder looks as shown in the following figure.

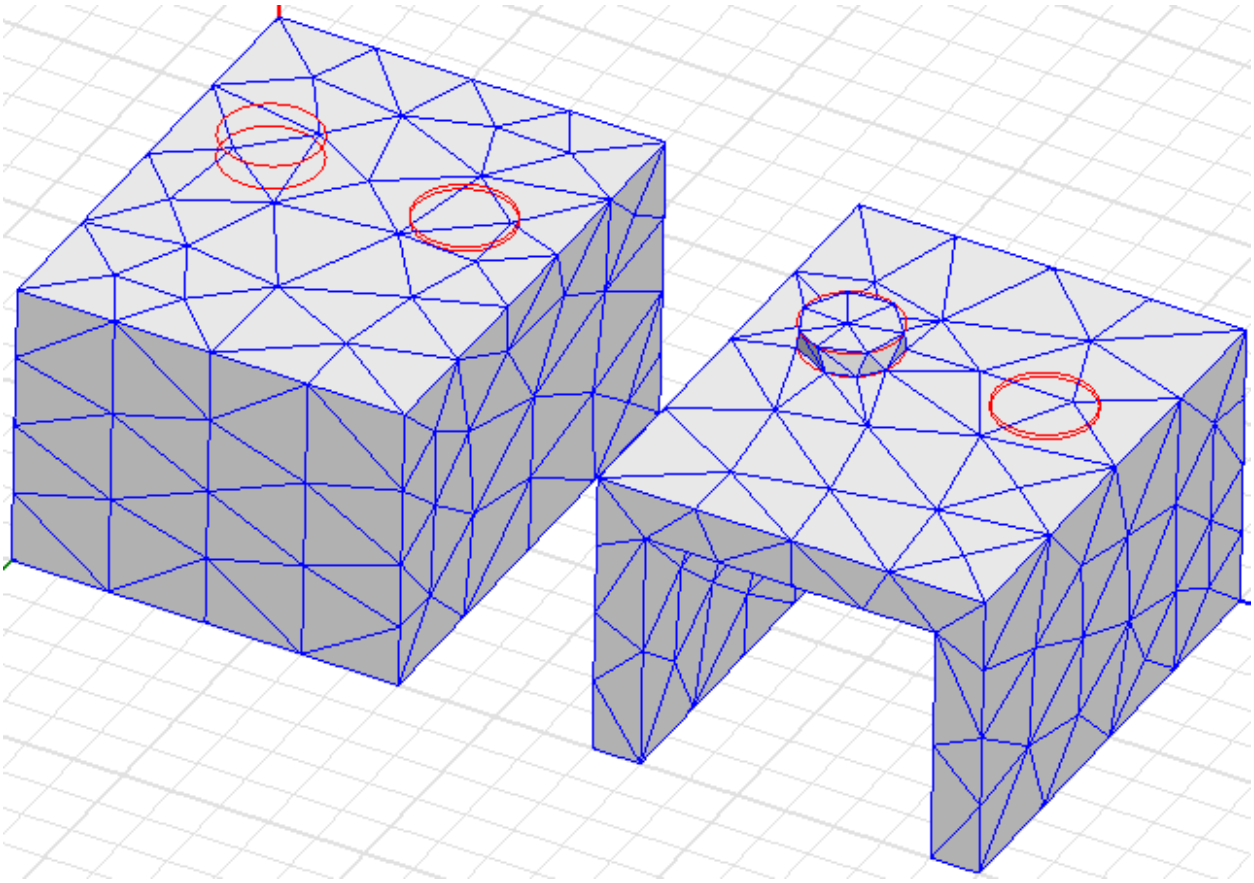
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Auto Simplify Using Effective Thickness

The following figures show the results of using the **Auto Simplify Using Effective Thickness** option on a model containing a box united with two cylindrical objects. The **Auto Simplify Using Effective Thickness** option appears in the **Model Resolution Length Mesh Operation** dialog box. The effective thickness of the body in the left is very high. Therefore applying automatic MRL defeatures both the cylinders out. The effective thickness of the body on the right is smaller so it defeatures the smaller stub and leaves the bigger stub.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

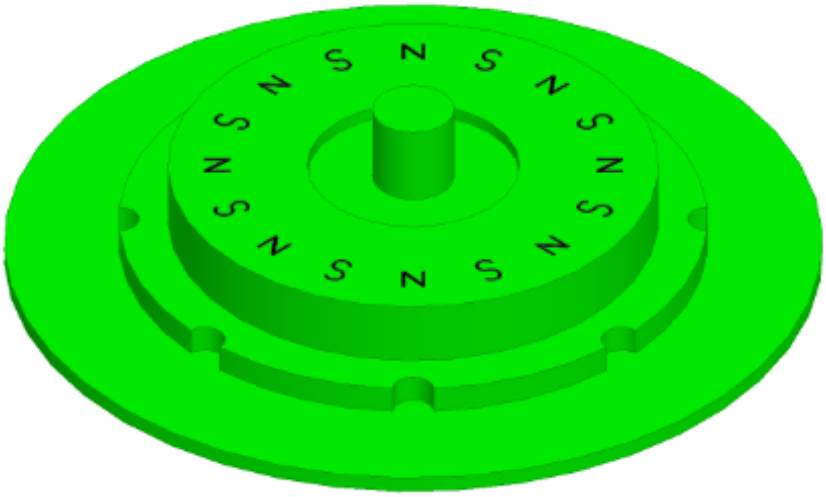


An MRL Scenario

When you define a **Model Resolution LengthOperation,** only major portions of the model are retained in the mesh. An MRL example is shown in the following figure: 3 D symbols S and N are stamped on the top surface of the original geometry.

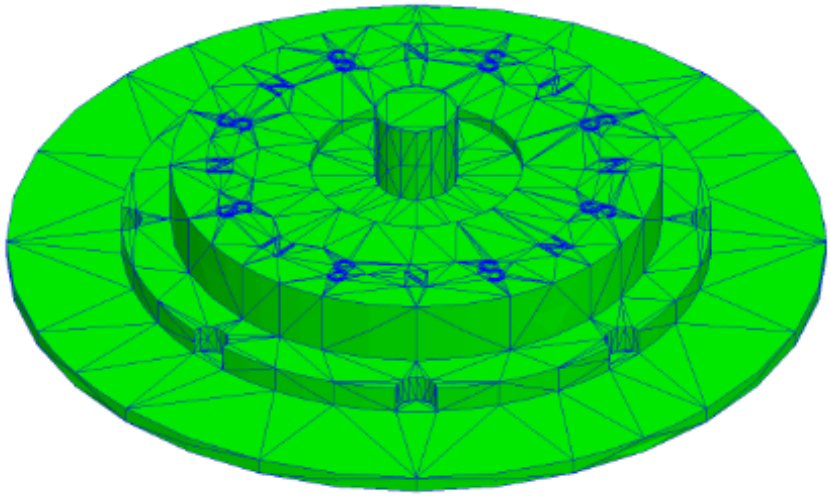
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Original Geometry

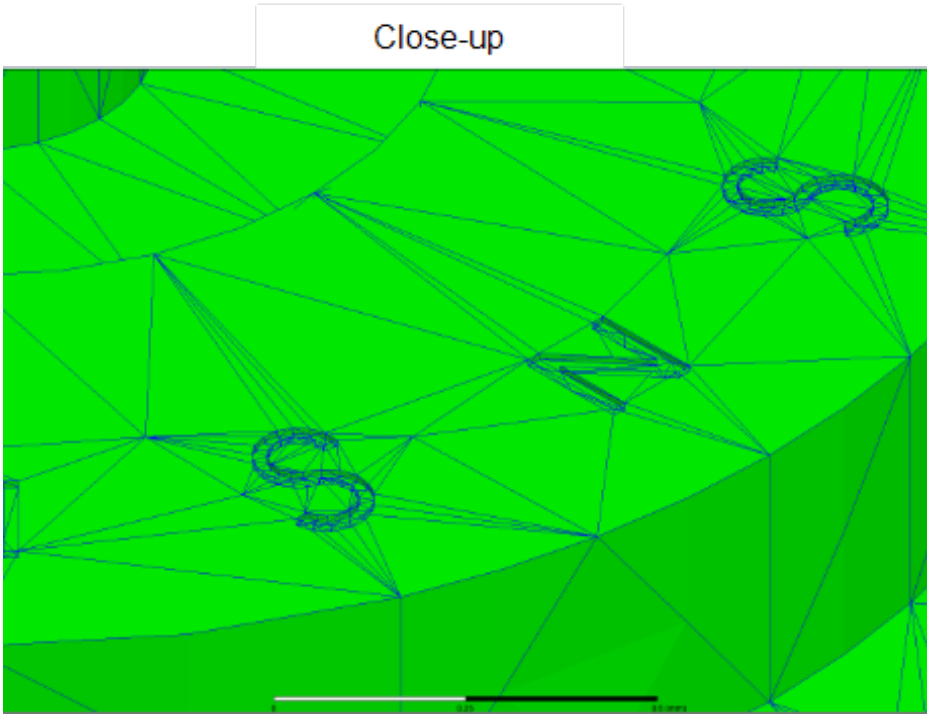


The following figures show the mesh plot without using **Model Resolution Length Operation**. The symbols S and N are magnified to show the mesh's appearance when no **model resolution lengthoperation**is applied. These tiny indentations on the top surface are actually not significant for the simulation. Their presence results in a denser and bigger mesh of the model, especially in the tiny regions as shown below.

Mesh with no MRL



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

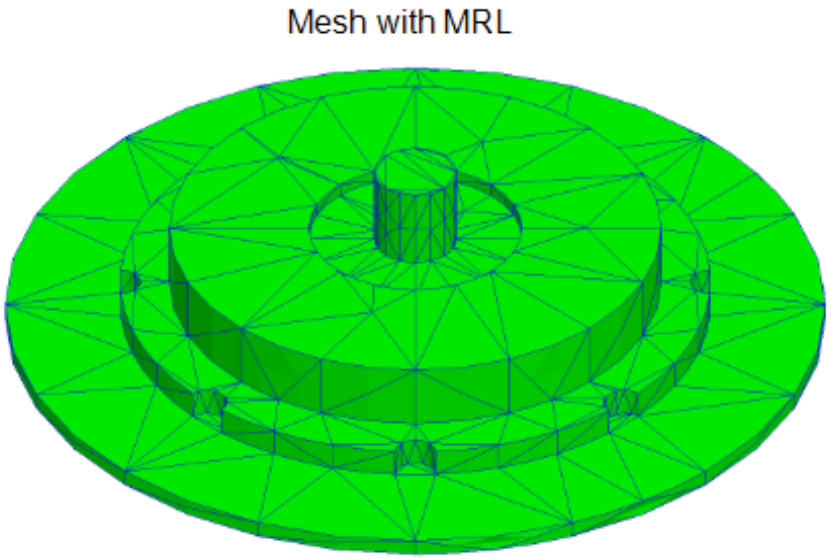


By defining a **model resolution length operation**, these tiny features or indentations can be removed from the mesh.

The following figure shows the mesh of the same model looks when you specify **model resolution length**. The mesh is coarse when compared to the previous mesh. Due to the **model resolution length operation,** the tetrahedrons representing the symbols for north pole and south pole have been removed.

Compare the figures and observe the difference between the meshes before and after the **model resolution length operation**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The removal of extraneous features improves mesh quality and simulation efficiency and requires fewer computational resources.

Operations Refining Initial Mesh

Seeding, port, lambda, and adaptive refinement modify the initial mesh. If you modify seed refinement, the changes are applied to the initial mesh saved by HFSS.

> **Note:**
>
> For more information see Mesh Refinement Settings (Optional)

Notwithstanding the availability of **Assign Mesh Operations**, use the automatic adaptive refinement technique of solving problems in most cases since it is sufficient to yield accurate results.

Mesh Refinement Settings (Optional)

Mesh operations are optional mesh refinement settings that provide HFSS with mesh construction guidance. They can give adaptive refinement a head-start and may accelerate the convergence of the solution. Although assigning mesh operations like seeding can further refine the mesh and may help in generating rapidly convergent results, for most practical purposes, the adaptive meshing technique alone is sufficient to produce accurate results. You must know beforehand where mesh operations apply; otherwise the mesh will be needlessly refined.

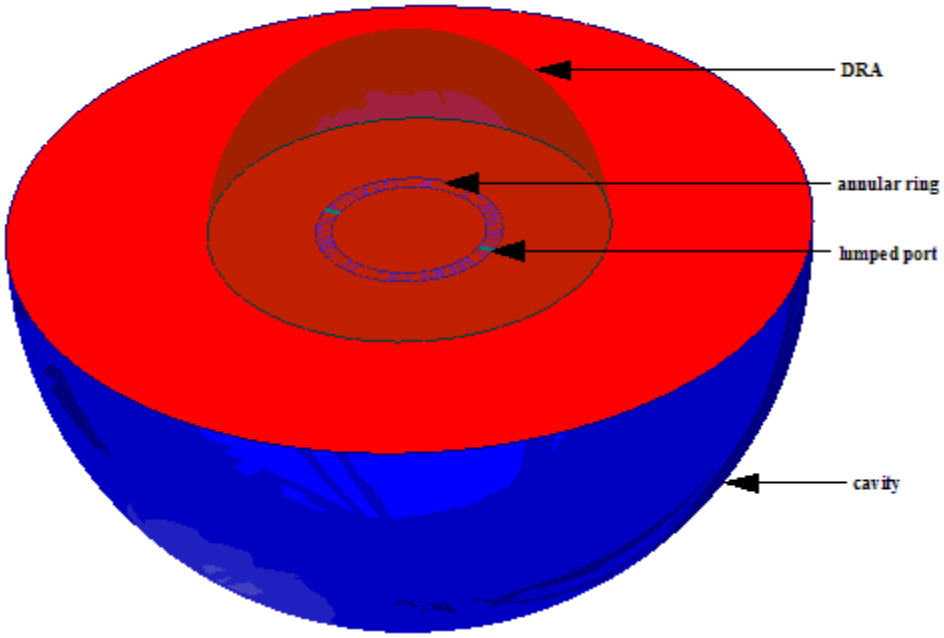
The following examples demonstrate adaptive mesh refinement occurring with mesh seeding.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Example 1: Dielectric Resonator Antenna

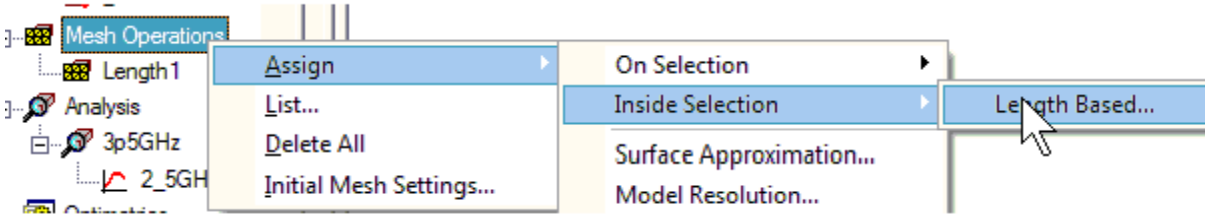
The following figure shows a dielectric antenna resonator. The antenna is cavity-backed with an annular-slot-fed dielectric resonator. The model is fed with lumped port across the annular slot. The design's operating frequency is 3.5 GHz.

Dielectric resonator antenna design

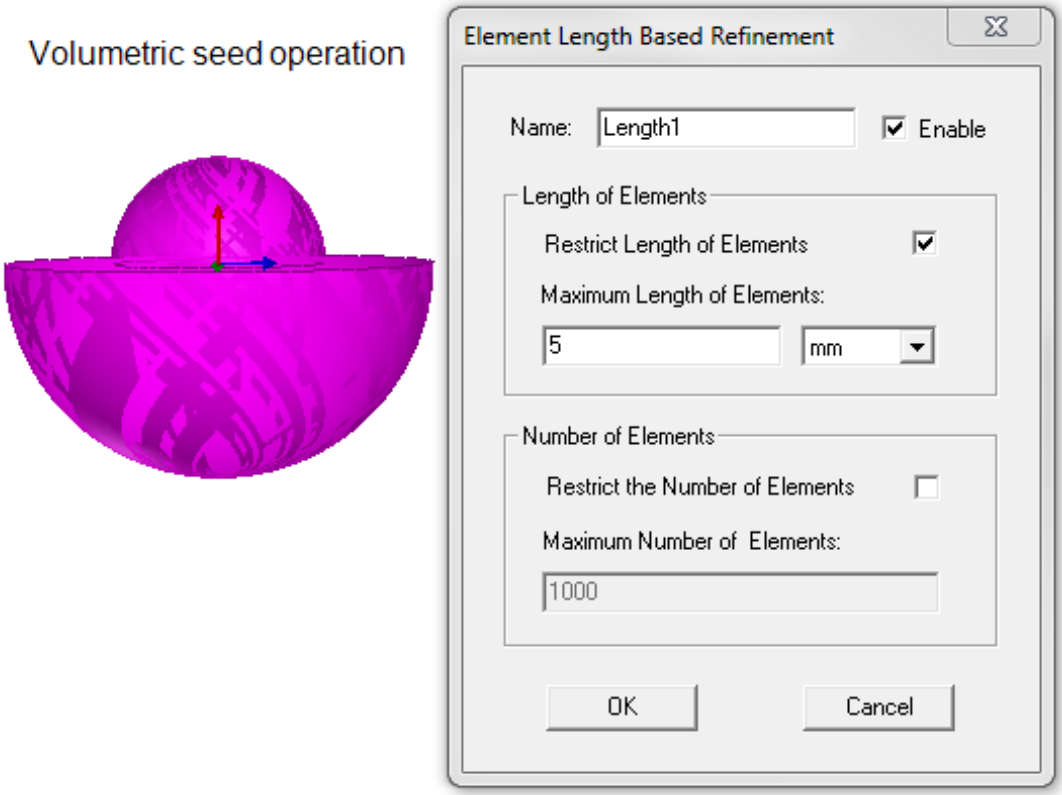


Seeding this model can improve the appearance of the field plots in the desired areas. For this design, mesh seeding operations for the model are assigned as shown below.

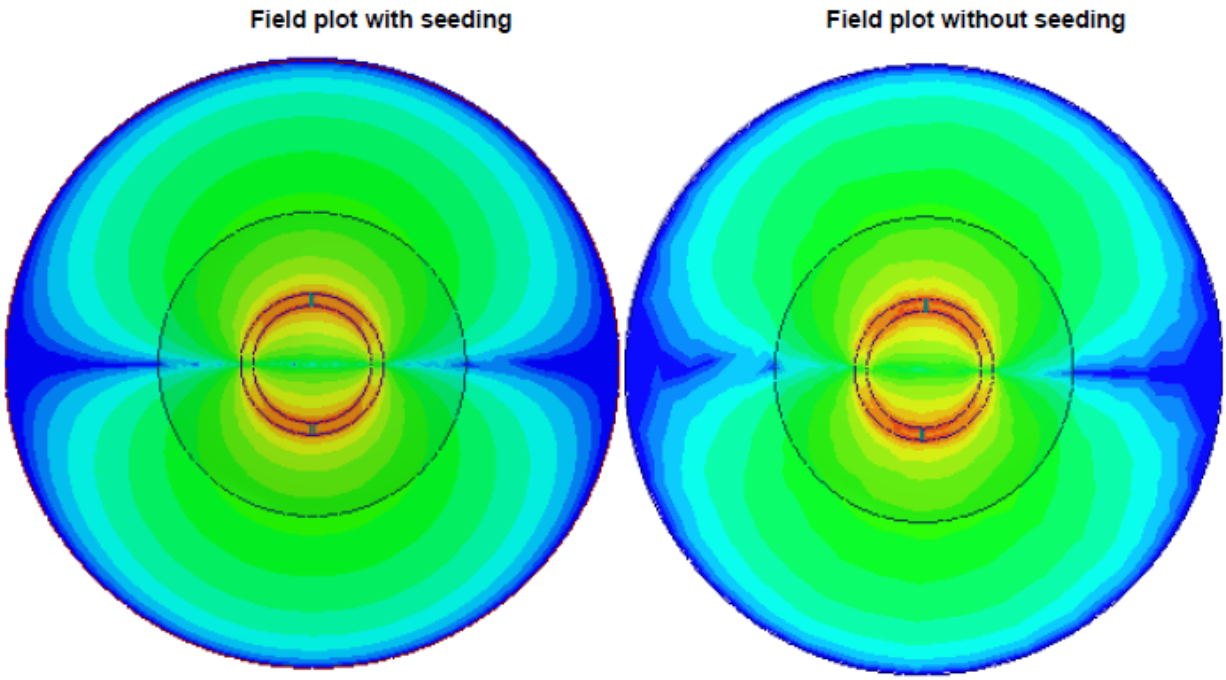
UI controls for assigning seed operation



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



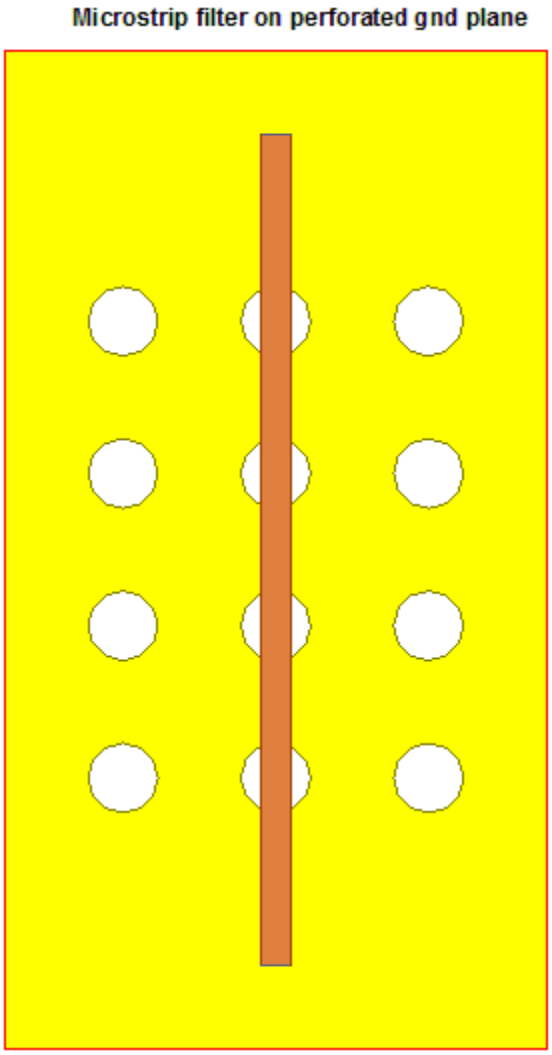
After HFSS solves the design, the resulting field plots on the ground plane are shown in the following figures. In this case, seeding the mesh ensures a high resolution plot.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Example 2: Microstrip Filter on a Perforated Ground Plane

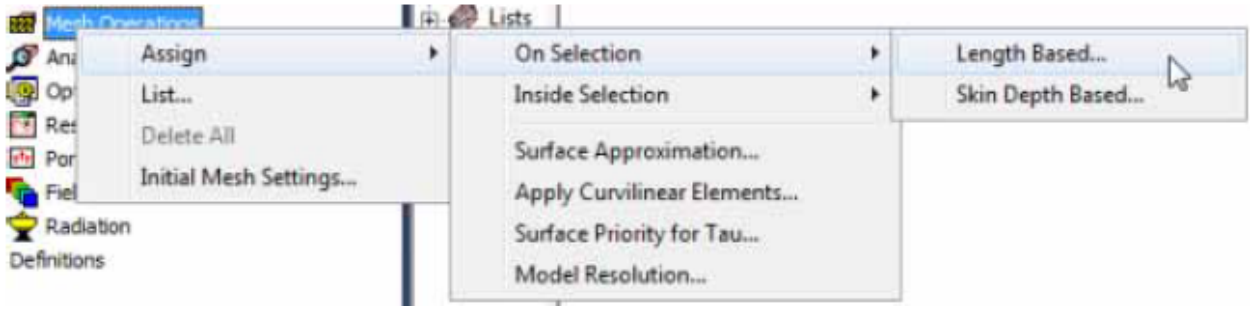
Consider a microstrip filter with a single trace and perforations in the ground plane as shown in the following figure. The design is set up to run at an adapt frequency of 14 GHz. Using the default adaptive refinement process, the mesh consists of 64681 solved elements and the matrix size is 556699. The simulation uses 3.85 GB of memory. The solution converges in 4 minutes, 7 seconds after running 9 adaptive passes using a 12 core machine. The total time taken to solve the problem including the interpolating sweep, is 26 minutes, 44 seconds.

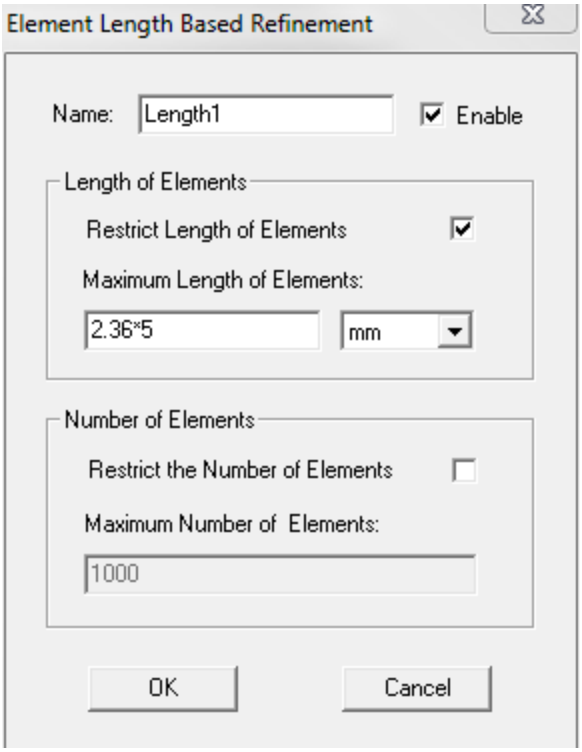


For this design, the trace seeding target length used is five times the width of the trace (see the following figure).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

UI controls for assigning seed operation on the trace





Adaptive refinement with seed operation generates a mesh of 49300 solved elements and a matrix size of 422017. The solution converges in 3 minutes after running 8 adaptive passes and the simulation uses 2.79 GB of memory. The total time taken to solve the problem including the interpolating sweep is 17 minutes, 7 seconds.

For this project, seed refinement ensures that the solution converges faster with fewer adaptive passes, uses less memory, and creates smaller matrix size than when using adaptive refinement without any seed operation.

The following figures show the resulting mesh plots and field plots.

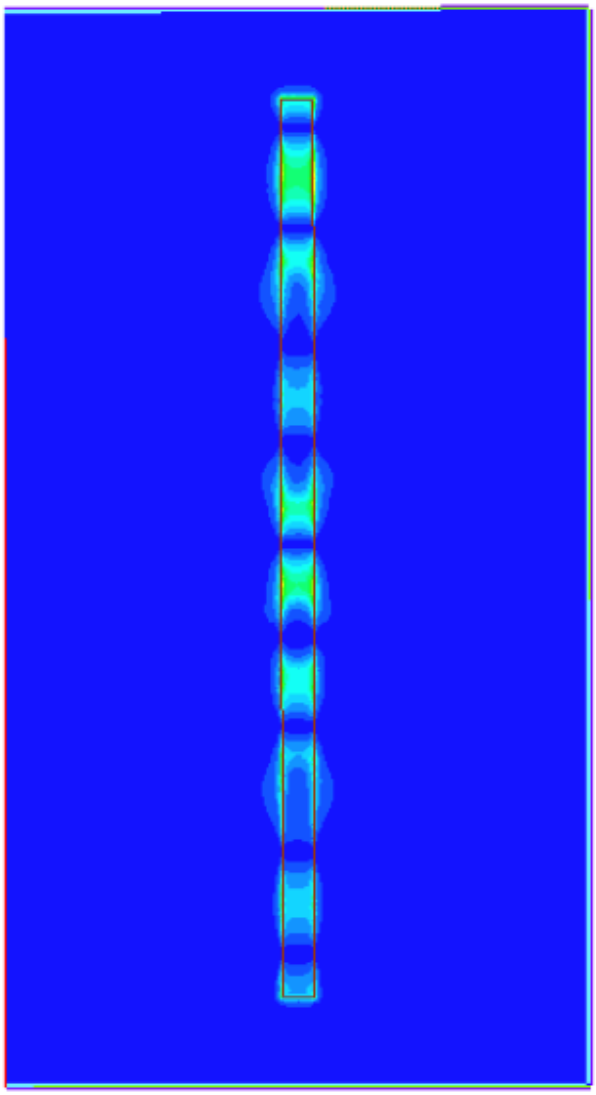
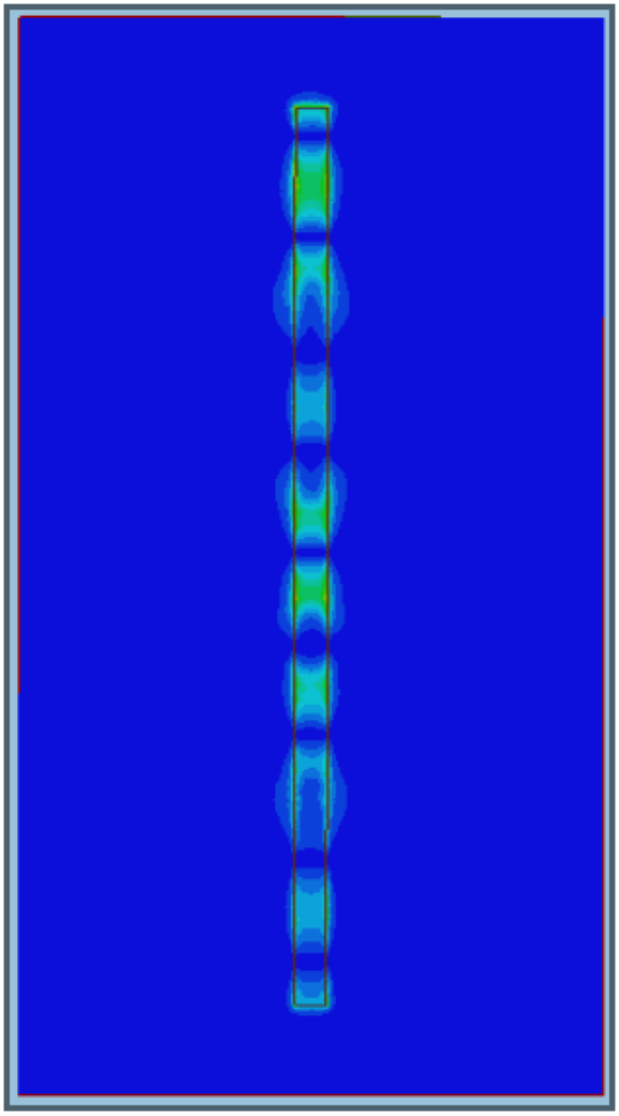
E-field plot without specifying seed operation.

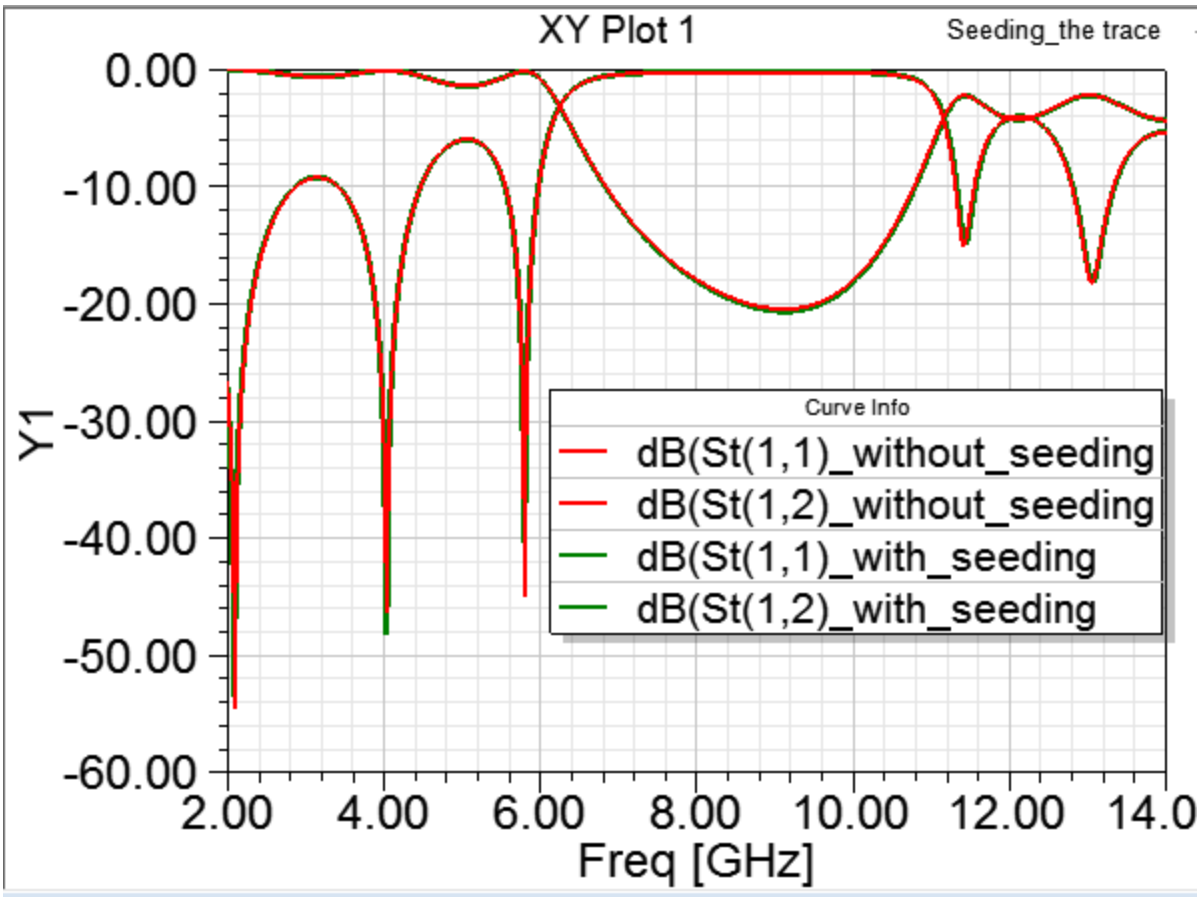


E-field plot after seeding the trace.



The S-parameter plots for both cases are shown below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



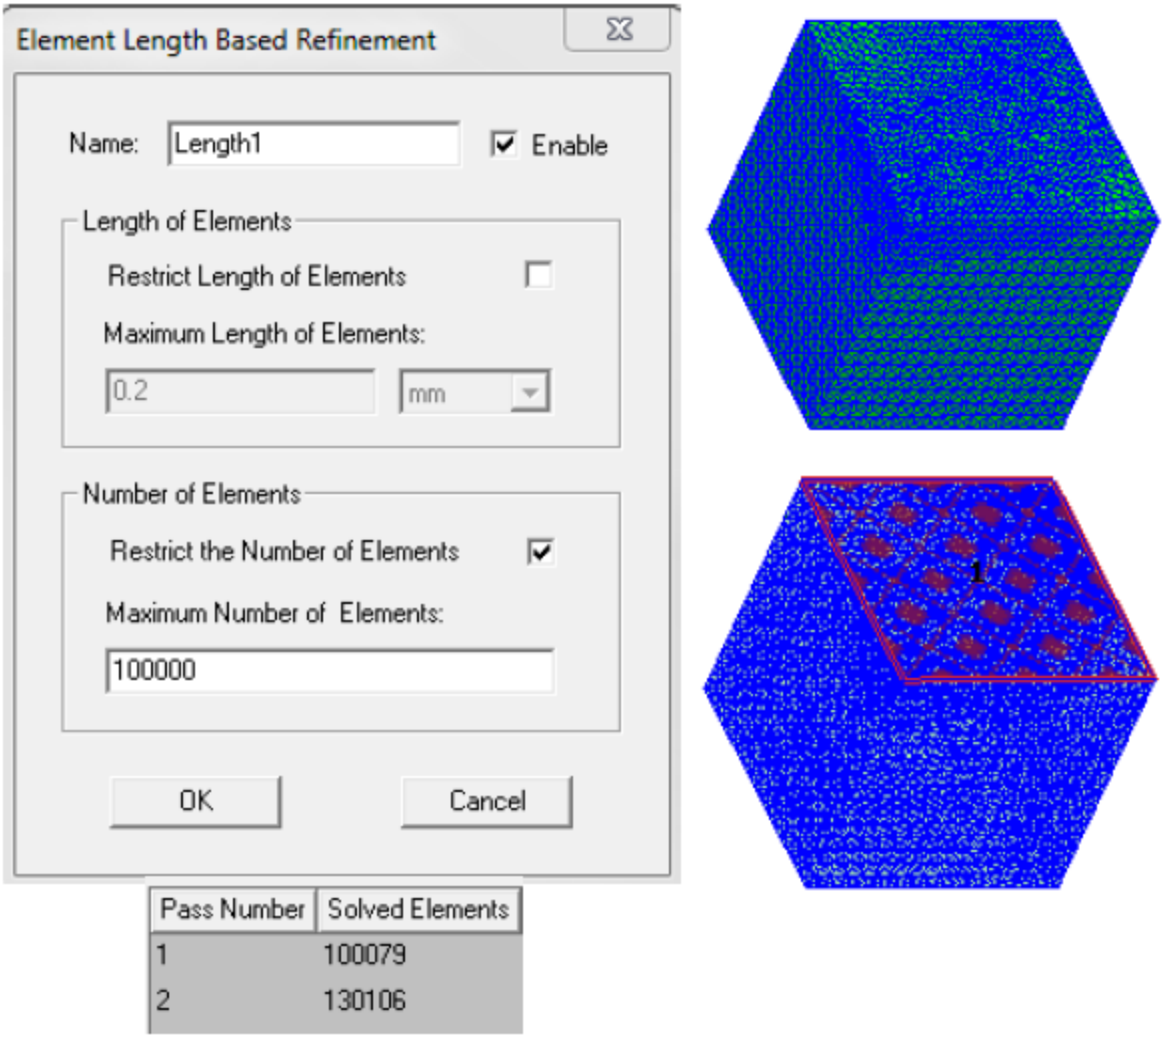
The results from the two simulations (with and without seeding) agree. The automatic meshing feature of adaptive refinement is effective and produces accurate results. The advantage obtained by seeding is not significant enough to warrant the time and effort needed to determine the seed values and define the seed operation. It is extremely challenging to improve the efficiency by defining a seed operation.

Mesh Seeding Controls

Seeding is the technique of guiding HFSS through the construction of the mesh. HFSS starts with an initial mesh and by adaptive refinement refines the mesh. However, if you know before starting the simulation where such refinement is needed in your model, seeding can provide a more refined starting mesh for the adaptive refinement process, which may result in obtaining the converged mesh faster. The following figure shows a type of mesh seeding called element based refinement.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

empirical example showing a heavily seeded mesh representing a cube

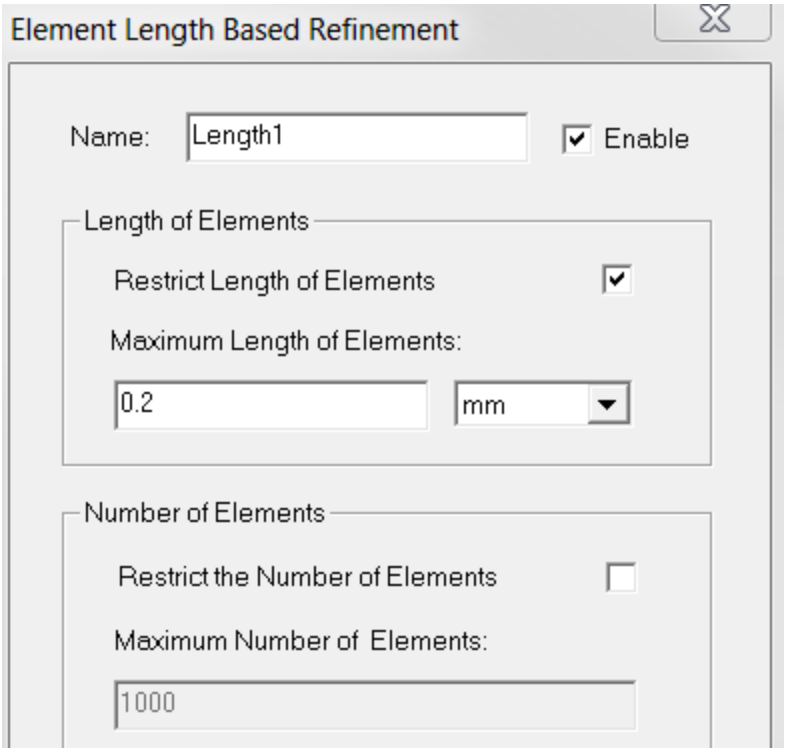


Since the value of Maximum Number of Elements is restricted to 100000, the number of solved elements is in excess of 100000.

Length-Based Mesh Refinement

Length-based mesh refinement controls the length of the tetrahedral elements and the growth of the whole mesh. You can set a ceiling on the mesh growth with the option **Restrict the Number of Elements** to ensure a mesh of reasonable size after the length refinement.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



When you define a mesh operation on a selection of objects (more than one) and set a maximum length, the operation occurs on the whole mesh. If you select just one object, when you refine its boundary, elements are added both inside and outside of that object.

When there are no more elements to refine or when no more elements can be added, the refinement process stops because it has either met the growth limit or the element length target. However, there are more quality improvement swaps, smoothing, and matching boundary issues, performed at the finishing stage that might slightly alter the mesh size.

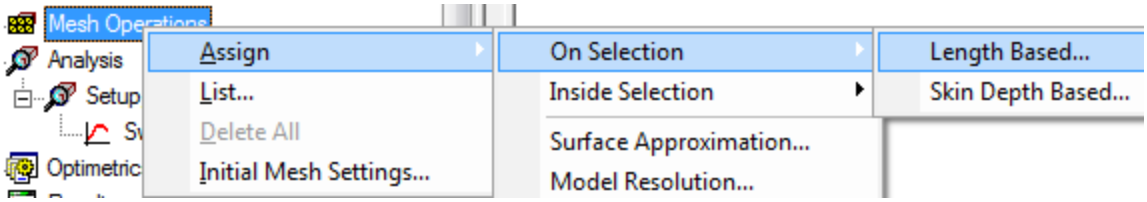
> **Important:**
>
> Be careful about specifying length targets for voluminous structures. This is because element count and target length have a cubic relationship. The relationship between length target and element count is inversely proportional, to the order of n^3 (that is length target = $1/n^3$) where ***n*** is the element count.

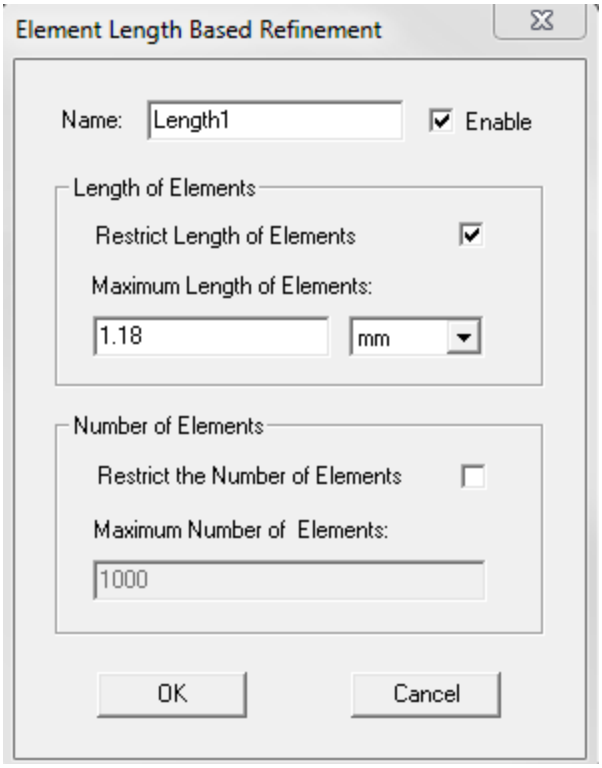
Seed Refinement for Mesh Growth

Seed refinement for mesh growth is performed by defining either the **Number of Elements** and/or the **Length of Elements** option. When either one of these specified criteria on the **Element Length Based Refinement** window is met, seed refinement stops. To access the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

settings for seed refinement, . Depending upon your selection, you can either seed inside the object or on the object surface.





Mesh Refinement Scenarios

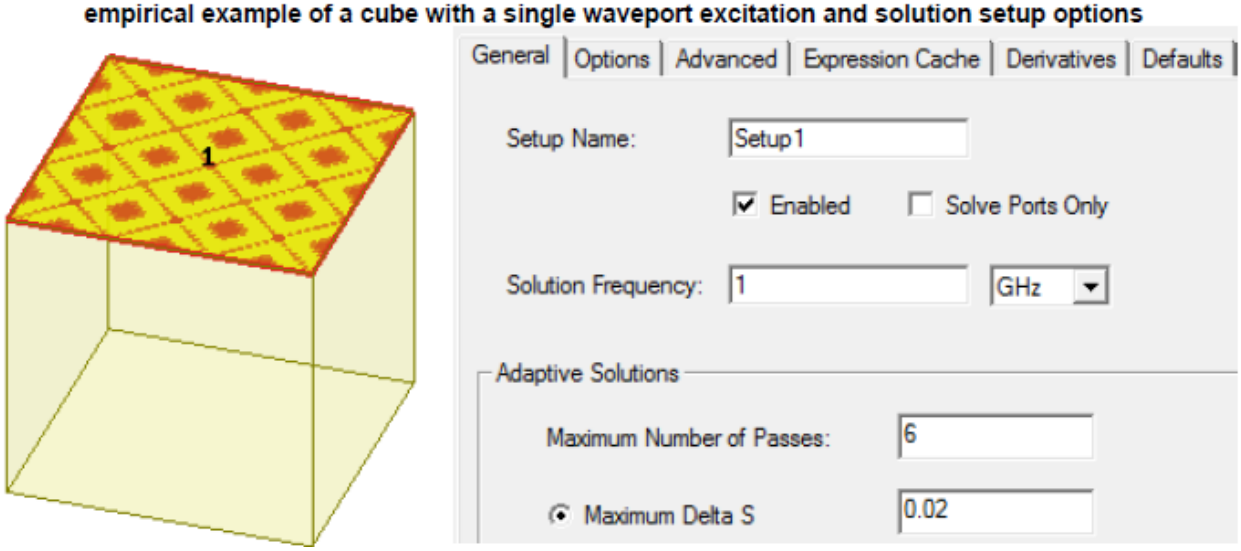
This section describes how mesh refinement settings affect your simulation. You can refine a mesh at any stage and then solve from there.

Scenario 1: Assign Mesh Operations after the First Pass

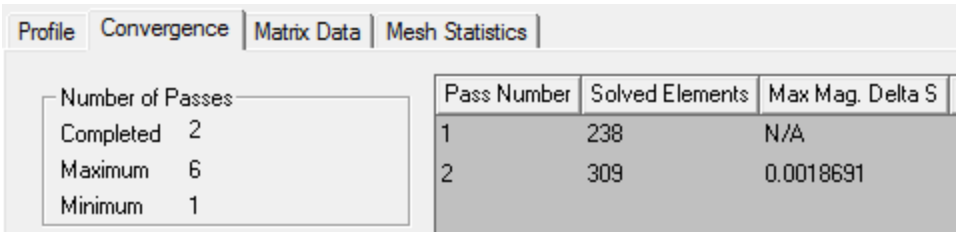
The following figure shows a cube with vacuum as the material assigned. The cube is 1 mm in size with a wave port defined on a face. Default options in the solution setup dialog box are used with **Maximum Number of Passes** =***6***.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

empirical example of a cube with a single waveport excitation and solution setup options

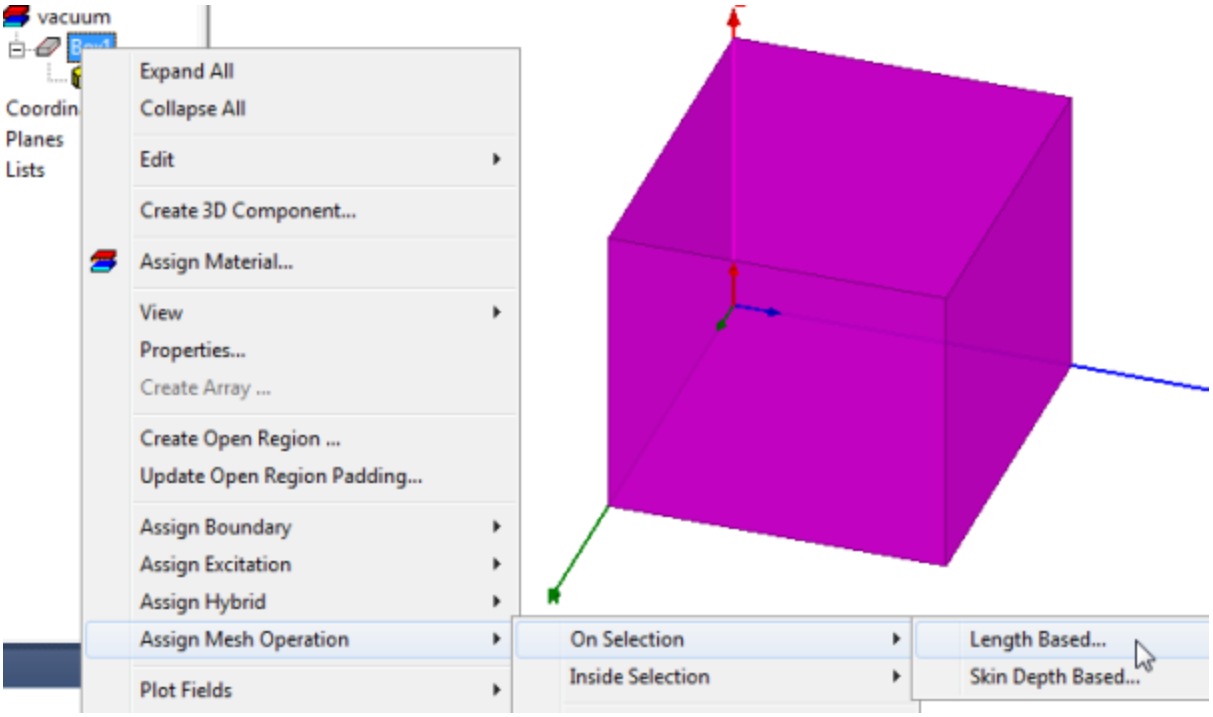


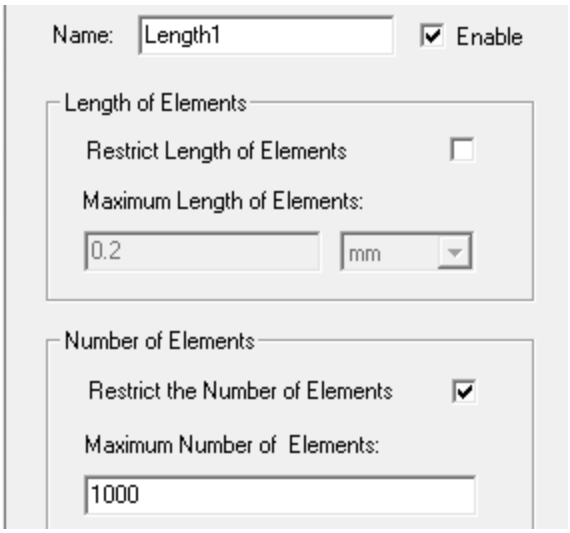
When you solve this design, it runs 2 passes and creates over 300 solved elements on the second pass as shown below.



At this stage, suppose mesh operations are applied as shown in the following figures.

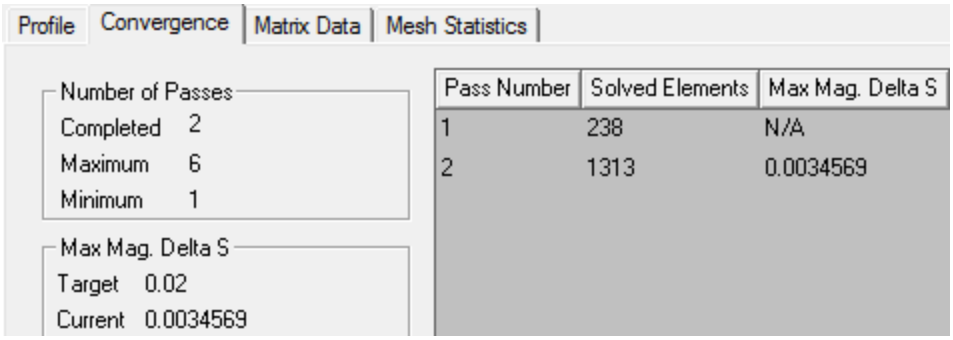
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



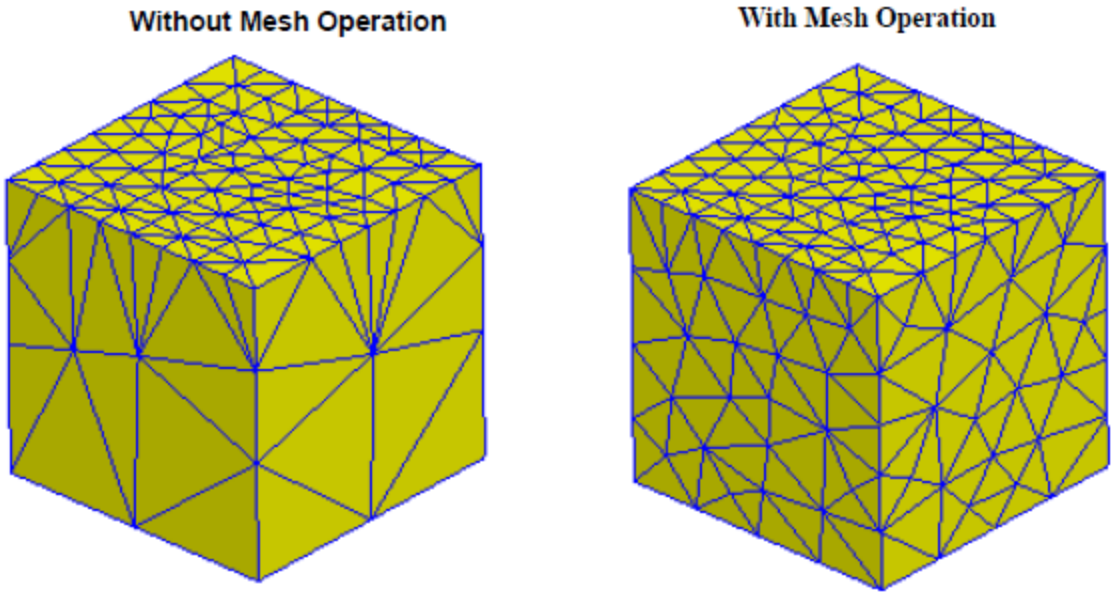


If you solve the design with **Maximum Number of Elements** = 1000, approximately 1000 elements are added in Pass 2 as shown by the column **Solved Elements** on the **Convergence** panel in the figure below. Since the mesh operation was defined after the first pass, the specified value for the maximum number of elements that is 1000 is added to the second pass.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

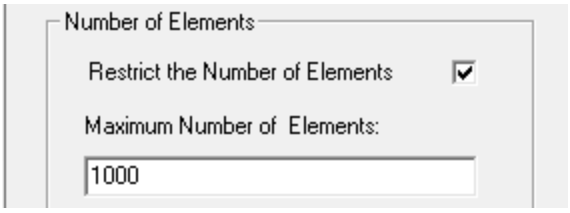


The corresponding mesh plots are given below.



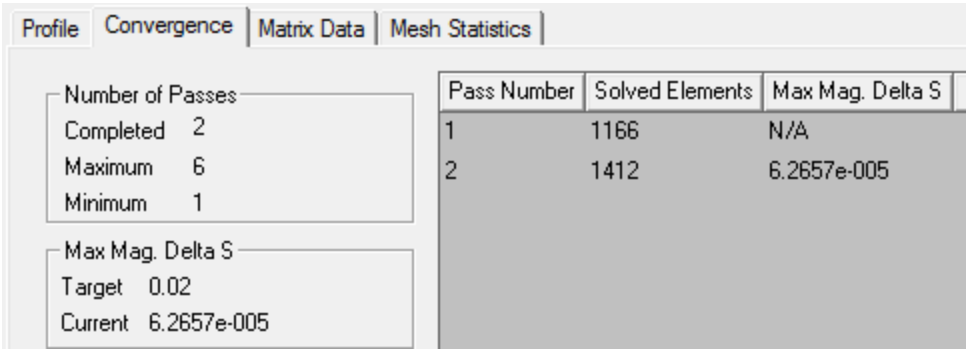
Scenario 2: Assign Mesh Operations Upfront

In this scenario for the same cube, the mesh operation is performed upfront.

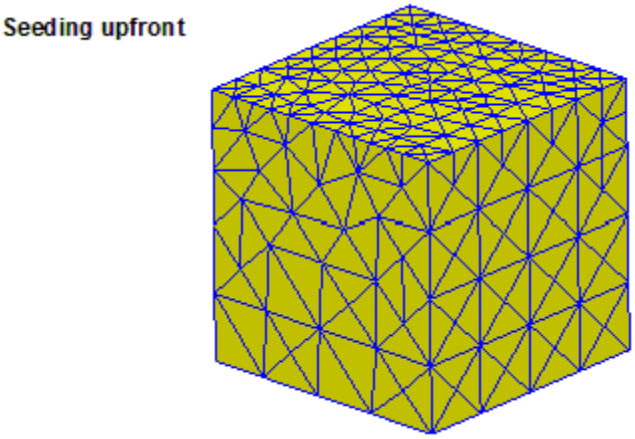


Therefore the assigned mesh operation is applicable for the first pass and 1000 elements are added in the initial mesh as shown in the following figure.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The mesh plot for this operation is shown in the following figure.



Note:

The number of solved elements is directly affected only for that pass where seed operation begins. For example, when seeding is performed upfront, only the first pass gets affected and elements are added according to the value defined in the mesh for the first pass only, and subsequent passes are solved but they remain unaffected directly by the seed operation. Similarly, if you seed from the nth pass, the operation affects only the nth pass and the subsequent passes from n+1 are solved from there without being affected directly by the seed operation. For example, if you set **Maximum Number of Elements** = M for a particular pass N, M elements are added on the Nth pass only. In the (N+1)th pass, again M extra elements are not added.

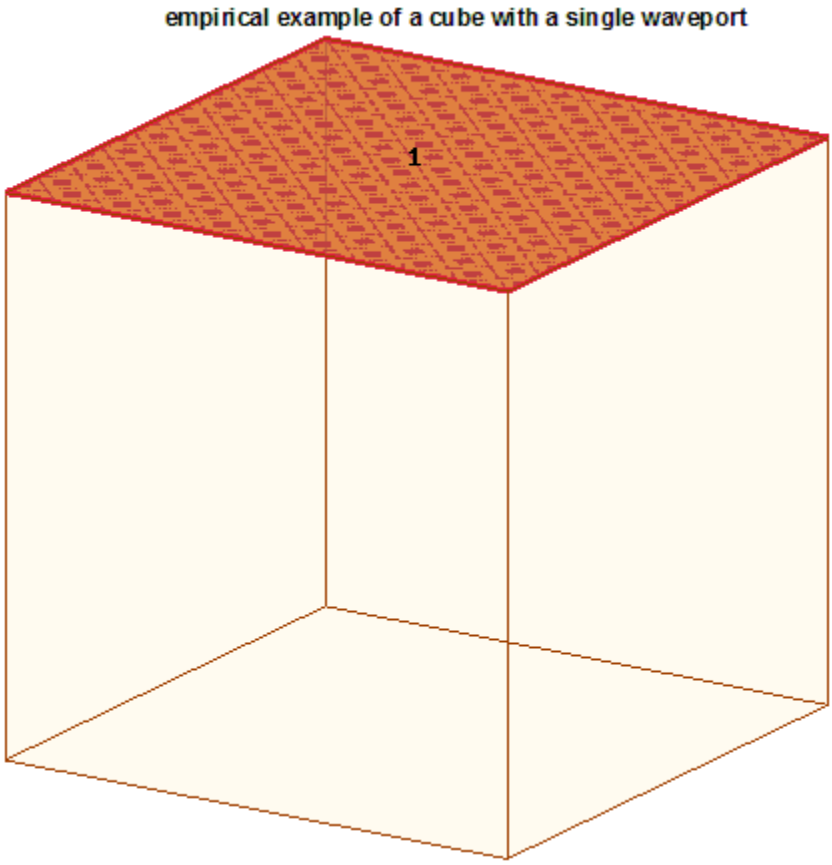
Restrict Length of Elements

Selecting the **Restrict Length of Elements** check box enables you to set the stopping criteria for seed refinement. When the longest edge of a tetrahedral element under the specified value

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

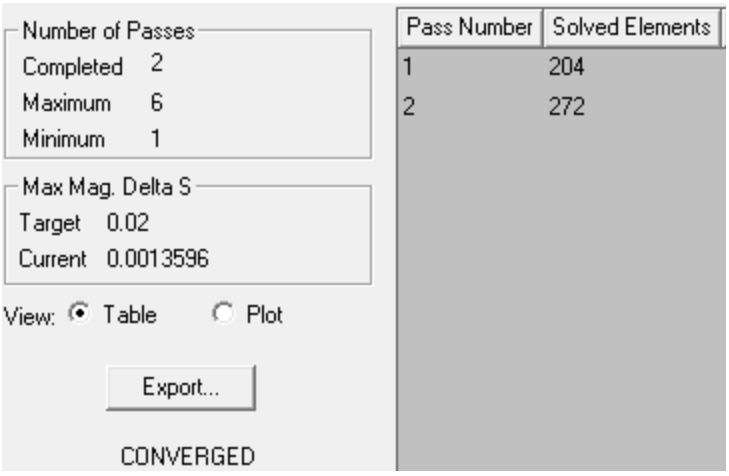
of **Maximum Length of the Tetrahedral Element** is reached, seed refinement stops.

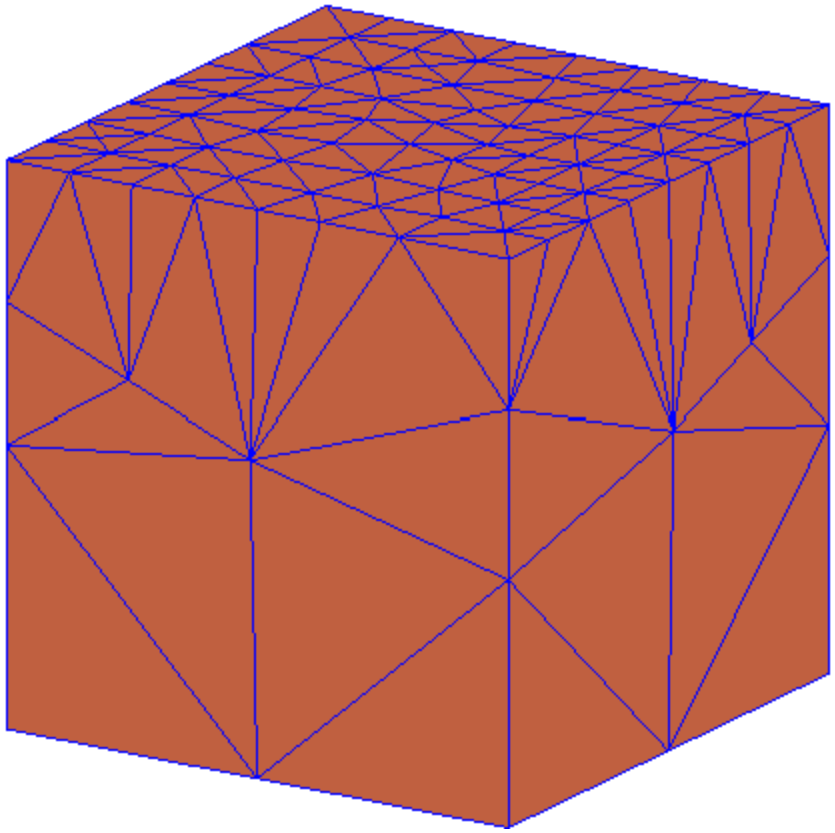
The following example of a cube 1000 mm in size and material vacuum illustrates seed refinement when it is specified by a value of the **Maximum Length of The Tetrahedral Element** as the stopping criteria. The cube has a wave port assigned on one of its faces and the adaptive frequency is 0.25 GHz.



First the design is solved with no seed refinement. The mesh plot on the cube after convergence is shown in the following figures.

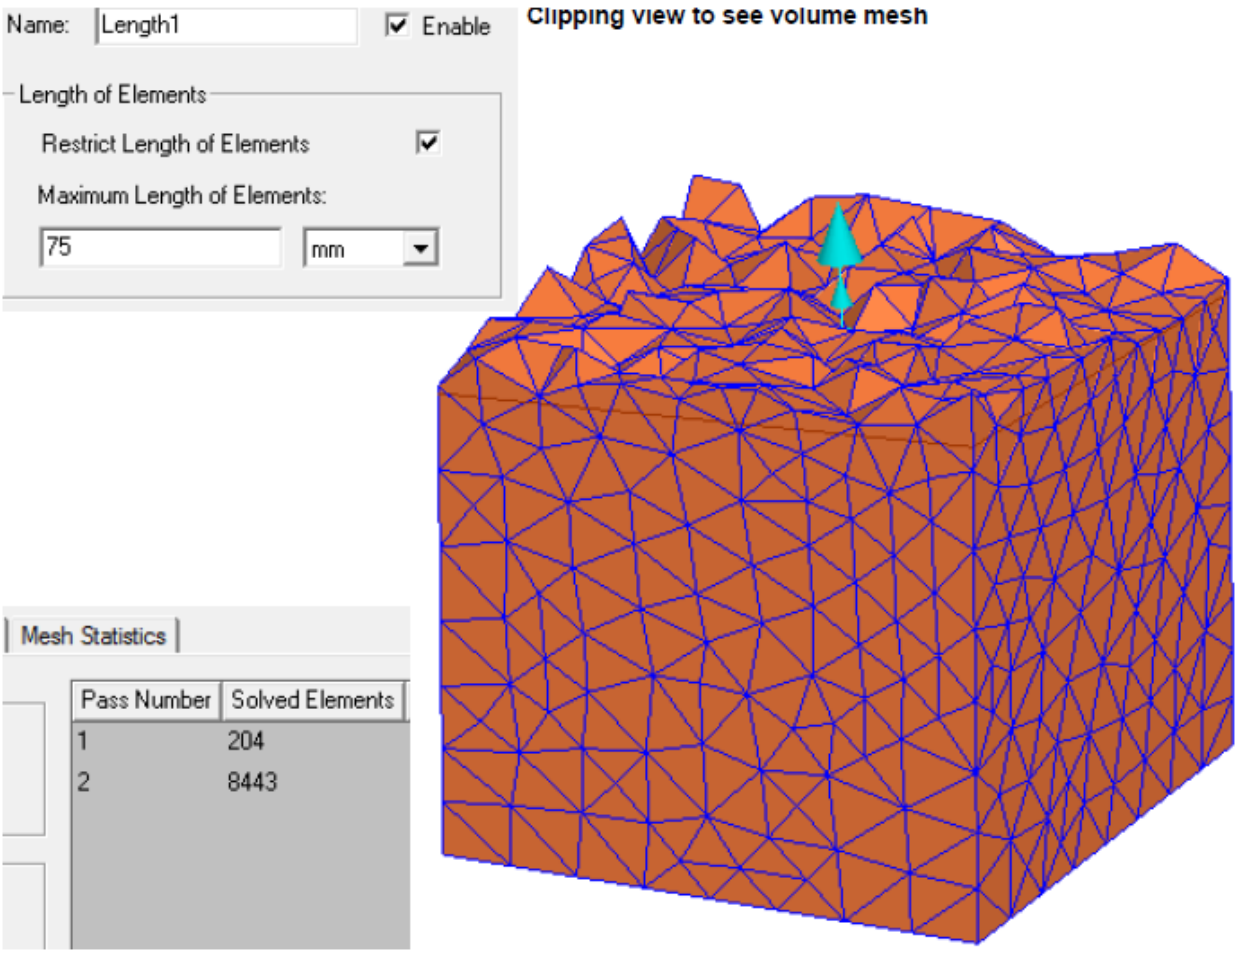
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





A plane is drawn at the center of the cube and the normal to the plane is along the Z axis. Using the **Clipping** view feature, the cube is virtually clipped along the normal. After seed refinement, the mesh plot of the cube along the normal is shown in the following figure.

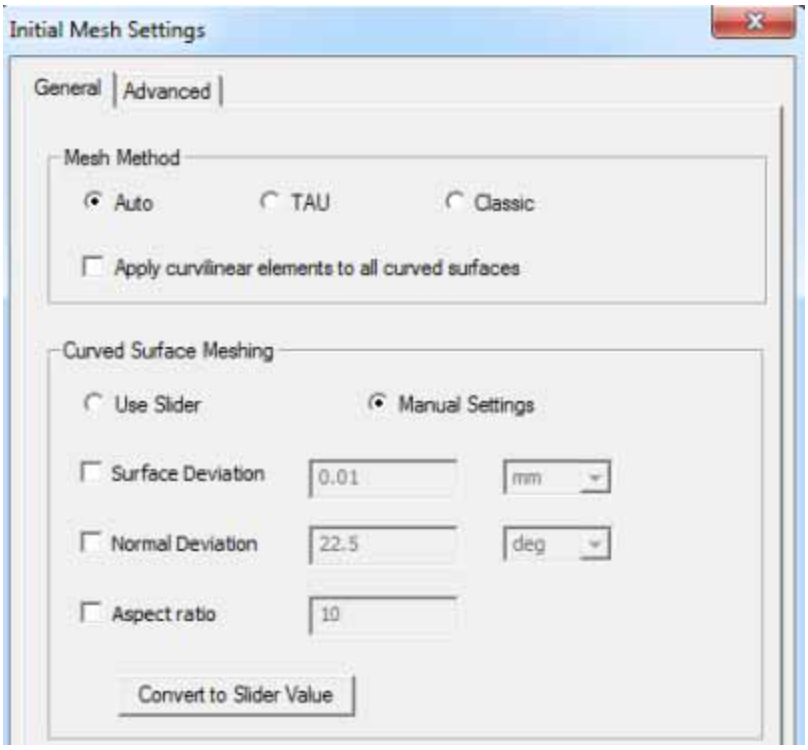
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Defining a Model-Level Mesh Operation

A model-level mesh operation is applied to all objects in the model. To illustrate, a model that has two cylindrical objects is used. For model-level mesh operation, the two important controls for the Manual settings are **Normal Deviation** and **Surface Deviation**. Model-level operations with respect to these **Manual Setting** controls are described below.

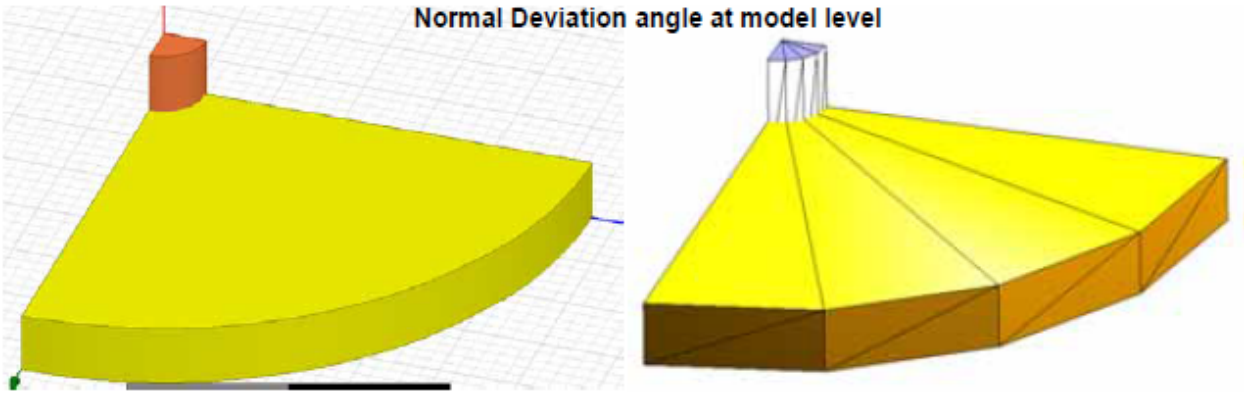
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Normal Deviation Angle

By default, **Normal Deviation** is 22.5 degrees in HFSS. When specifying model-level mesh operation, consider the sizes and shapes of all curved objects to obtain the desired faceted triangulation model for the mesh.

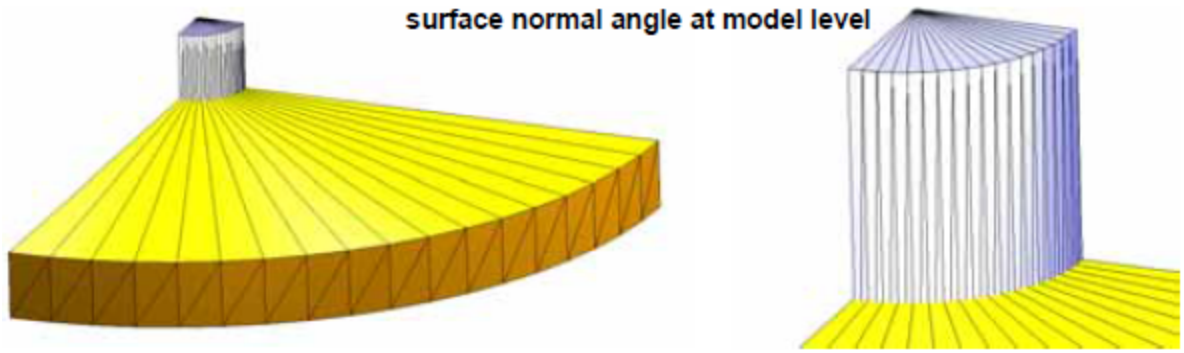
The following illustrations show a model that has two cylindrical objects.



In HFSS, the 90 degree sweeping curves are faceted as 4 segments since **Normal Deviation** is 22.5 degrees by default. If you specify the surface normal angle as 5 degrees at the model level, there are 18 segments on both cylindrical curved surfaces as illustrated in the following figures.

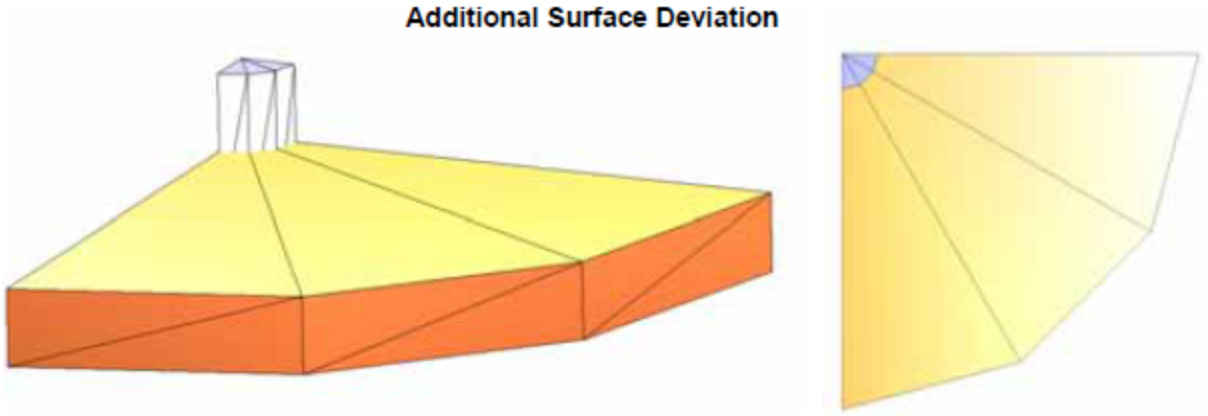
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Such a level of granularity is useful for large curved surfaces, but for small curved surfaces, it creates an extremely dense mesh. Therefore, use caution to assign a model-level mesh operation with small **Normal Deviation** unless all the curved objects in the model have equivalent curvatures and sizes.



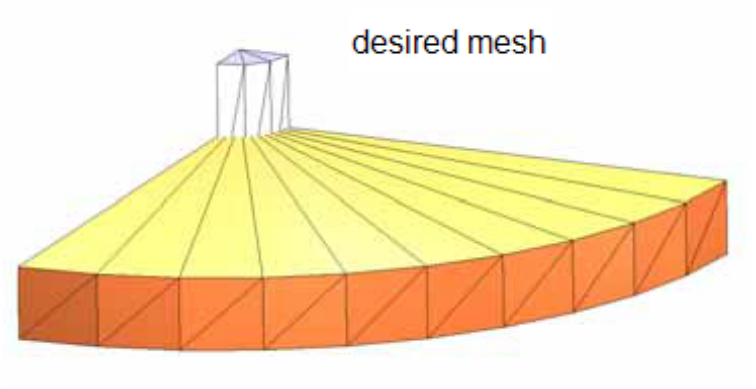
Maximum Surface Deviation Length

An appropriate value of **Surface Deviation** supplements the **Normal Deviation** setting. When you set **Surface Deviation** in addition to the **Normal Deviation** setting, it can further improve the geometry representation. By specifying **Surface Deviation** you can control the difference between the faceted face and the real curved face. **Surface Deviation** is defined in user unit. Consider the same model with two cylindrical objects. In this mode, if you specify 30 degrees as the **Normal Deviation**, there are 3 segments on both cylindrical surfaces as expected.



Since the radius of the large cylindrical surface is 6mm, set 0.06mm as the **Surface Deviation** in the model-level mesh operation. This ensures we have the desired faceting geometric model.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To summarize, the **Surface Normal Angle** of 30 degrees provides one facetation of the geometry, and the **Surface Deviation** of 0.06 mm controls the difference from the real curvatures. Since the small faceted cylindrical surface already has the difference smaller than 0.06 mm, the surface is maintained as is. However, since the large cylindrical surface has a gap greater than 0.06mm, the facetation is made finer to adhere to the specified length.

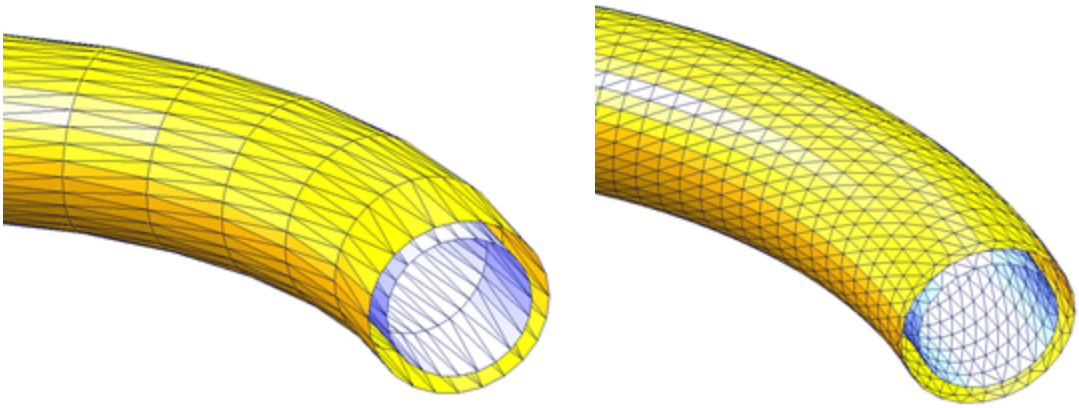
As a rule of thumb, large surface normal angle can control the small curved objects while small Surface Deviation can control the large curved objects in the model-level mesh operation. **Surface Normal Angle** is effective for skewed curved surfaces.

Aspect Ratio

Aspect Ratio *is the ratio of the longest length of an element to its shortest length.* **Aspect ratio** controls the faceting triangle ratio. It is needed only when you want a highly uniform mesh on the curved surfaces or when the curved object is either thin or has a narrow gap. By default, **Classic** mesher uses 20.0 as the **Aspect Ratio** whereas **TAU** mesher uses 8.0 as the **Aspect Ratio**.

When there is a narrow gap between two curved surfaces, a small value of aspect ratio ensures the gap to be uniform. The figures below illustrate a geometric model with the aspect ratio of 20 and 2. Smaller aspect ratio ensures better representation of the curvature for skewed curved surfaces, especially in thin curved layers.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



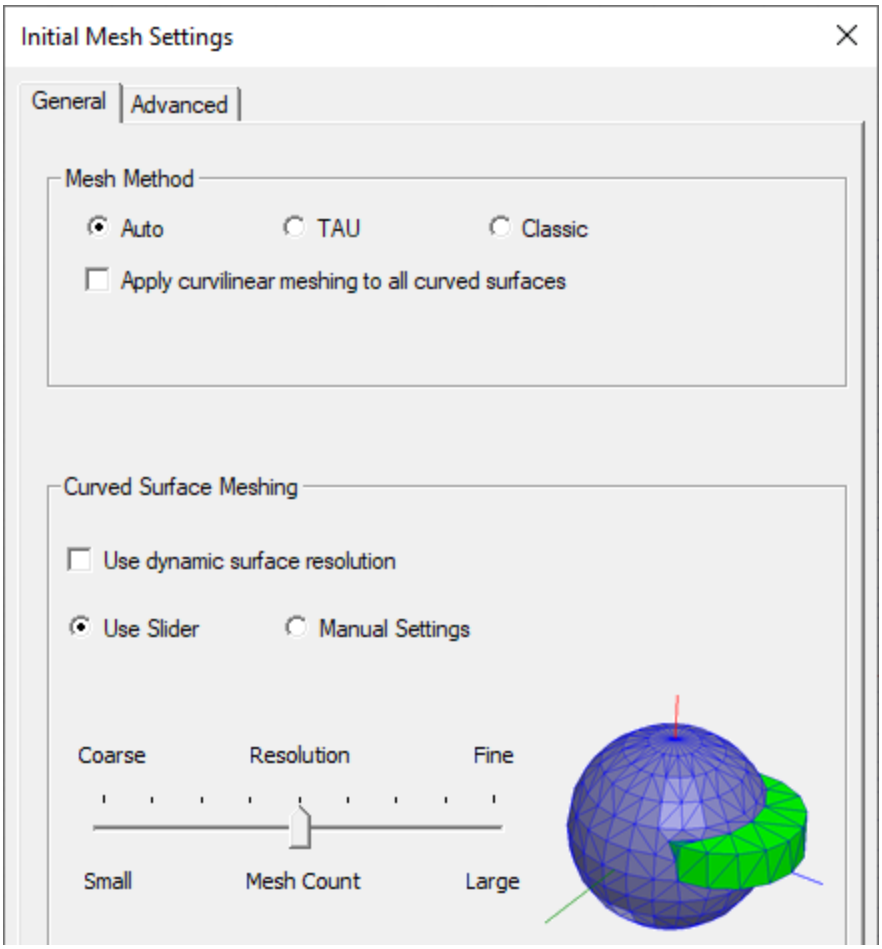
Use caution when assigning a small aspect ratio, since it will produce a dense mesh at many other curved surfaces which may not require the denseness.

Initial Mesh Settings

The initial mesh settings dialog box has the following panels:

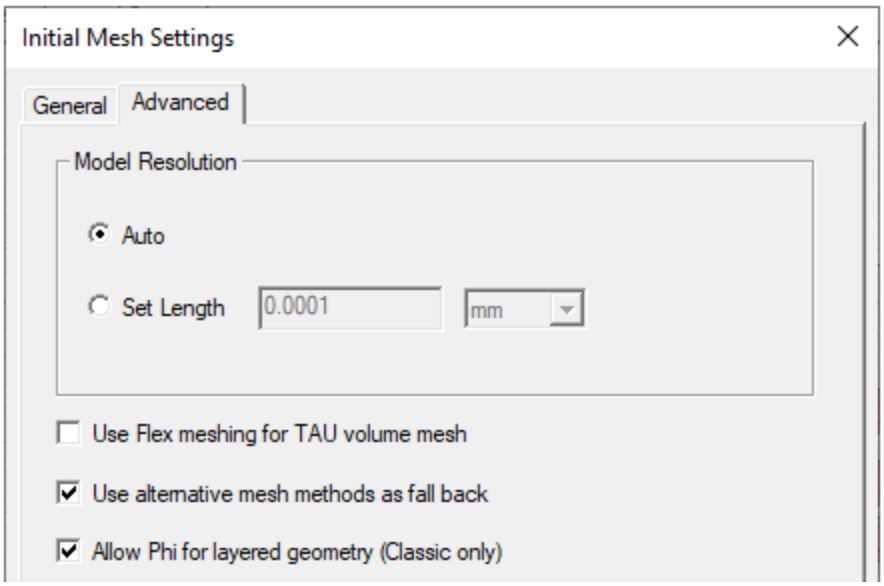
- Curved Surface Meshing
- Meshing Method

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Advanced** tab lets you optionally specify a **Set Length** for **Model Resolution**. This is for experienced users who have a good understanding of how particular values will affect their models. In general, the **Auto** setting provides good results.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For details, on using these features, see Specifying Initial Mesh Settings.

Meshing Method

HFSS has four meshers available to generate the initial mesh: the **Auto**, **Tau**, **Classic**, and **Phi Plus** meshers.

The **Auto** selection automatically chooses a suitable mesh method for the design based on geometry characteristics (e.g., if the design contains bondwires, **Phi Plus** is selected).

The **Classic** mesher uses a Bowyer algorithm to create compact meshes for the model with very large length scales. It represents the model very accurately.

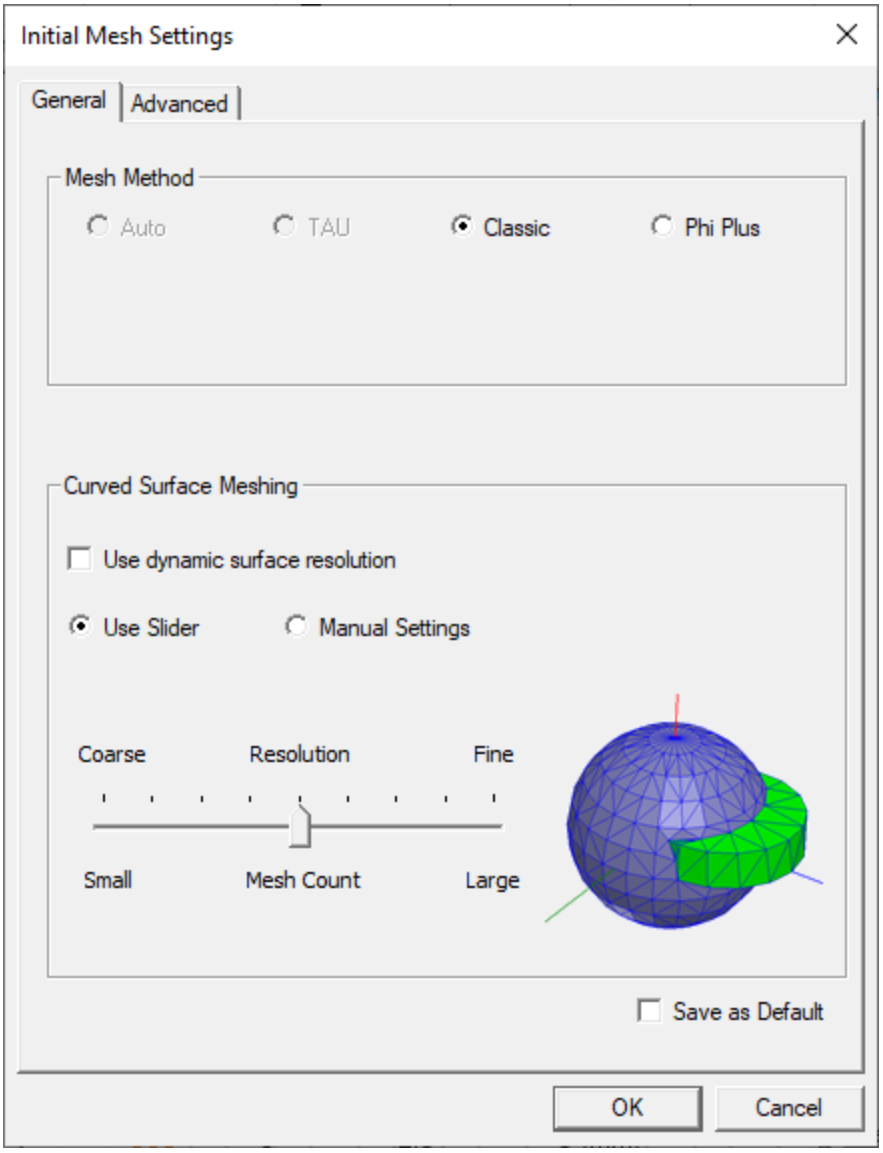
The **Tau** mesher produces very high quality meshes. It uses a volume decomposition method to create the initial mesh and coarsens it to achieve small element count. It has the ability to adaptively relax the tolerance to overcome the inaccuracies and misalignments in the input model. This mode of operation is called the **Tau** tolerant. The other version is called **Tau** strict.

Both meshers are designed to handle all geometries. However, if you select **Auto**, HFSS picks either the **Classic** or **Tau** mesher based on the analysis of the geometry. You can override the selection and choose either **Classic** or **Tau** to make the initial mesh. Depending on the model, sometimes **Classic** converges with fewer resources whereas **Tau**may converge faster. Whichever mesh is selected, the converged results are accurate. Ansys recommends selecting **Auto** since HFSS automatically determines the correct choice of the mesher for a given geometry.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Important:

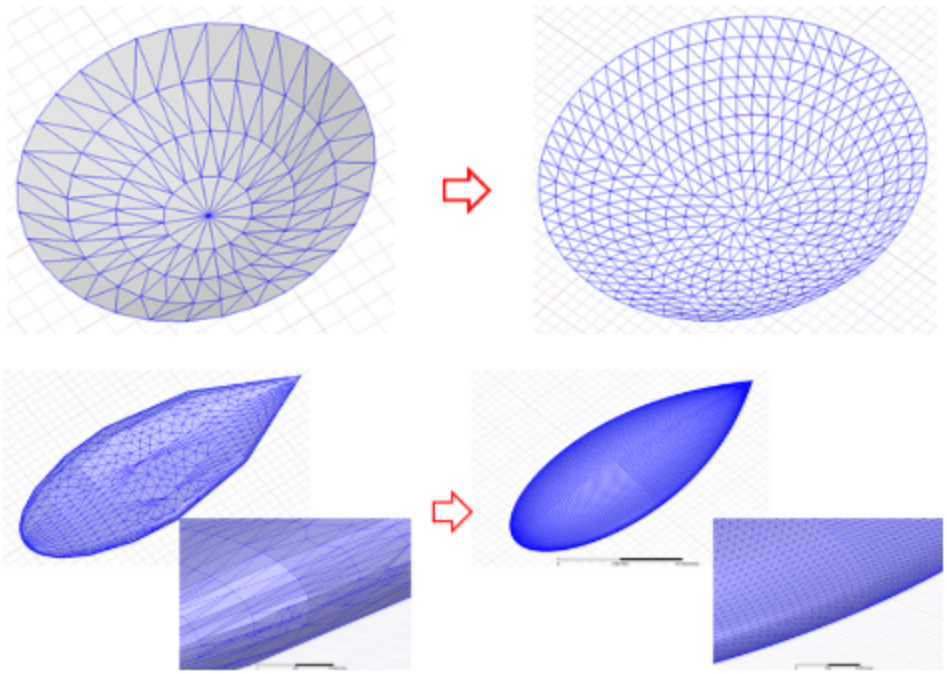
The consolidation of surfaces into a conformal mesh is skipped for dynamic and tolerant meshing, including for light weight geometries. This can lead to overlapping surfaces in SBR+ simulations. The user should carefully avoid overlapping surfaces or objects as SBR+ can produce unexpected results.



If the model contains IE Regions, the Tau mesher uses a surface mesh routine to detect which curve faces should be remeshed, rather than using the faceting triangles. This produces a high quality mesh, uniform, including the top, sides and bottom. (See the following figure for

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

examples of the benefit.) Other faces that cannot be remeshed still get faceting triangles. In the final output, the remeshed surface mesh and faceting surface mesh are coupled to ensure the mesh is watertight and conformal.

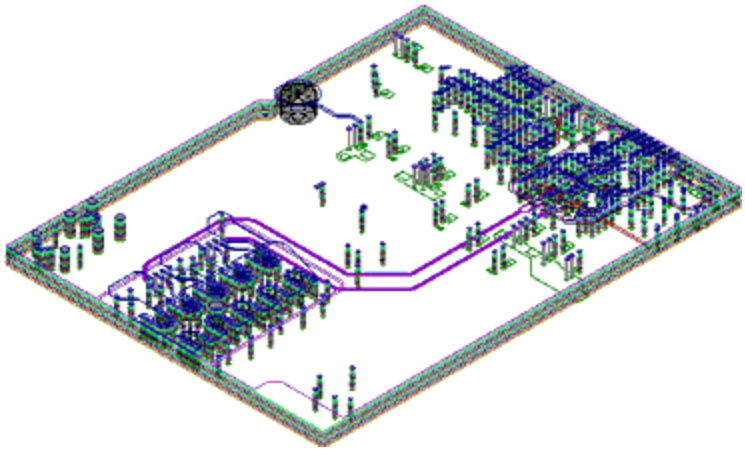


The Phi Mesher

The Phi mesher is a layout-based meshing technology, available in the HFSS 3D Layout interface. This advanced meshing technology is capable of rapidly generating an initial mesh ensuring faster simulations that can be further accelerated and enhanced by using high performance computing.

While the traditional Classic mesher is suitable for HFSS 3D MCAD and for certain geometries solved in HFSS 3D Layout, the Phi Mesher works on the HFSS 3D layout interface where principally 2.5D geometry is comprised of z-extruded layers that have no oblique facets. Therefore package models, for example, containing bondwires cannot take advantage of this meshing technology. Phi mesher uses a unique method to generate the initial mesh from the a priori knowledge of the layered nature of the geometry. It generates a volume mesh directly from the layout data saving tremendous amount of time, requires less user clean up, and eliminates several situations that might cause potential kernel errors in the traditional 3D modeler flow. A typical complex layout package is shown below.

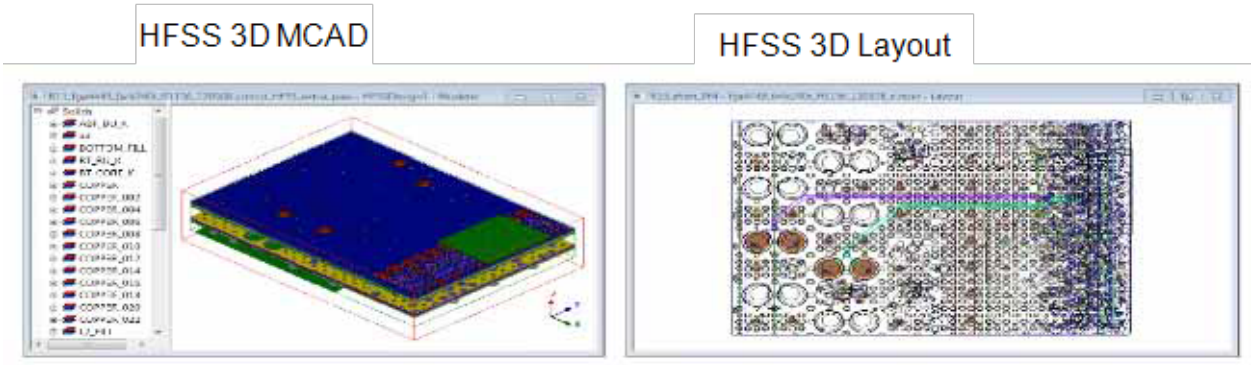
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



When compared to the traditional Classic mesh, the Phi mesher is several orders of magnitude faster, including from the initial meshes the adaptive meshing algorithm produces to the final convergence. Another advantage of the Phi mesher is its ability to mesh larger and more complex designs previously unmeshable from the traditional 3D interface or with the Classic mesher in the 3D layout interface. In cases where Phi produces large meshes, you can use the HPCsolver feature to leverage more cores and distributed memory to neutralize the time that would have been otherwise required for the simulation to complete.

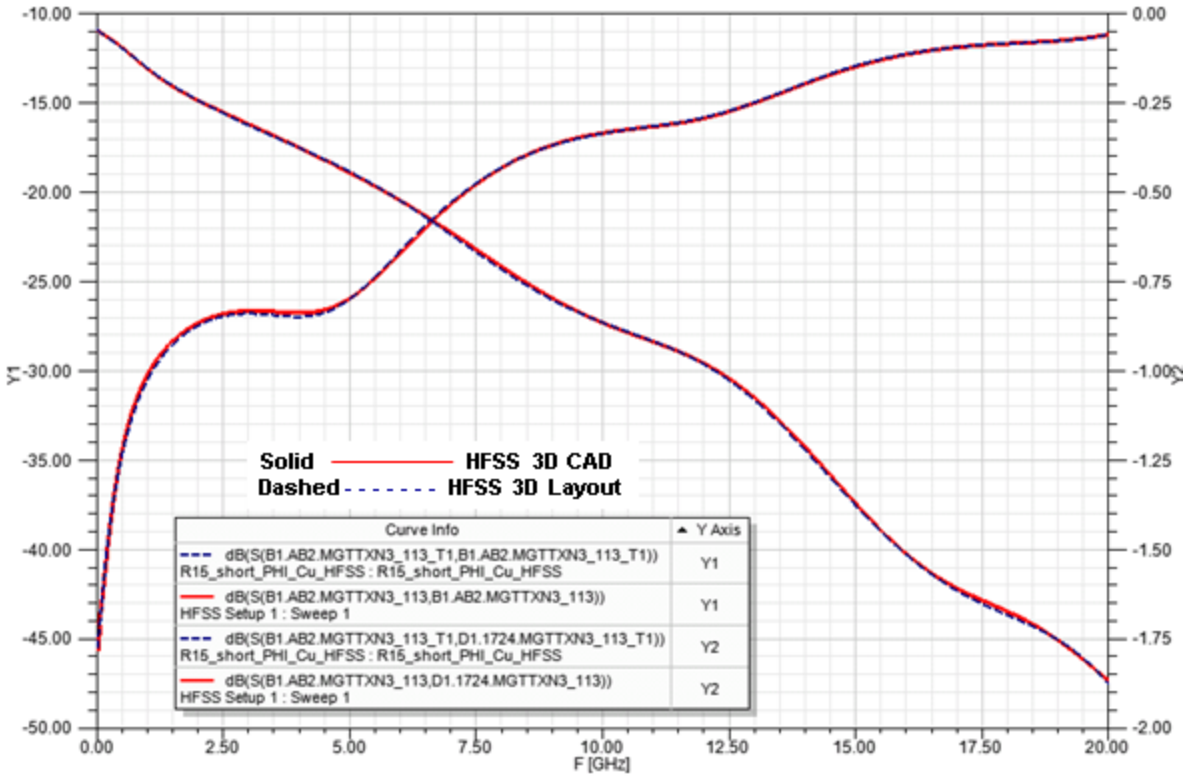
Phi Mesher for Multilayer Complex Package Layout

In this section, the simulation of a multilayer complex package layout is used to demonstrate the feature of the Phi mesher in HFSS 3D layout. To illustrate the advantages of a Phi mesher, a task-based comparison is performed between a regular HFSS 3D MCAD and the same geometry which is imported, set up, and solved through the HFSS 3D Layout GUI.



The same HFSS solver engine is used to solve both the geometries.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The HFSS MCAD results marked in red agree with the HFSS 3D Layout results in dashed blue.

The comparison of the two solutions is shown in the following table.

	HFSS 3D CAD	HFSS 3D Layout
Initial Mesher	Classic	Phi
Initial Mesh Size (tets)	763, 953	712, 536
Initial Mesh Time	1hr 20min	4min
Number of Adaptive Passes	6	7
Number of Tets - Final	1, 617, 954	1, 620, 969
Adaptive Passes Run Time	4hrs 1min	1hr 5min
RAM	47.6 GB	49.6 GB
HFSS Model number of Ports	8	8

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Initial mesher in the HFSS 3D CAD interface takes 1 hour and 20 minutes to generate the initial mesh. The entire simulation takes just over 4 hours to complete in 6 adaptive passes, and the total number of tetrahedra generated in the final mesh is 1.6 million.

On the other hand, the Phi initial mesher creates a very comparable initial mesh size of 712000 tetrahedra in only 4 minutes. The entire simulation takes one extra pass to solve; however, for the same number of solved tetrahedra, 1.6 million, it required only 1 hour and 5 minutes. This example shows the benefits of using the HFSS 3D layout and its ability to leverage the Phi mesher to mesh an extremely complex geometry. Typically, the Phi mesher requires a small amount of time ranging from only 5 to 10 minutes to create the initial mesh. The Phi mesher provides a great advantage for solving any arbitrary package or PCB layout structures.

Troubleshooting Mesh Failures

Common causes of mesh failures are improper geometry, incorrect design, or mesh settings. The following checklist can be used to address mesh failures and ensure that a suitable mesh is created to solve the problem:

1. Select the model units in such a way that the smallest critical features in a design are at least 0.001 units long. Critical features include traces, gaps, vias, and contacts between objects.
2. Override the **Auto** option on the **Initial Mesh Settings** panel to see if that helps. For example, set **Classic Mesh** as the initial mesh if the **TAU Mesh** fails and vice versa.
3. Specify an appropriate value for the option **Surface deviation (length)** on the **Surface Approximation** panel (Manual Settings), if spline surfaces are present in the geometry. Typically, five percent of the thickness of the bounding box of the surface is a good choice.
4. Either tighten or loosen the settings on the **Surface Approximation** dialog box to check if that helps.
5. Select the **Mesh Feedback** tab on the **Model Analysis** dialog box to view the error log reported by the mesher. Go to **Modeler > Model Analysis > Show Analysis Dialog > View Mesh Feedback** to access this tab.

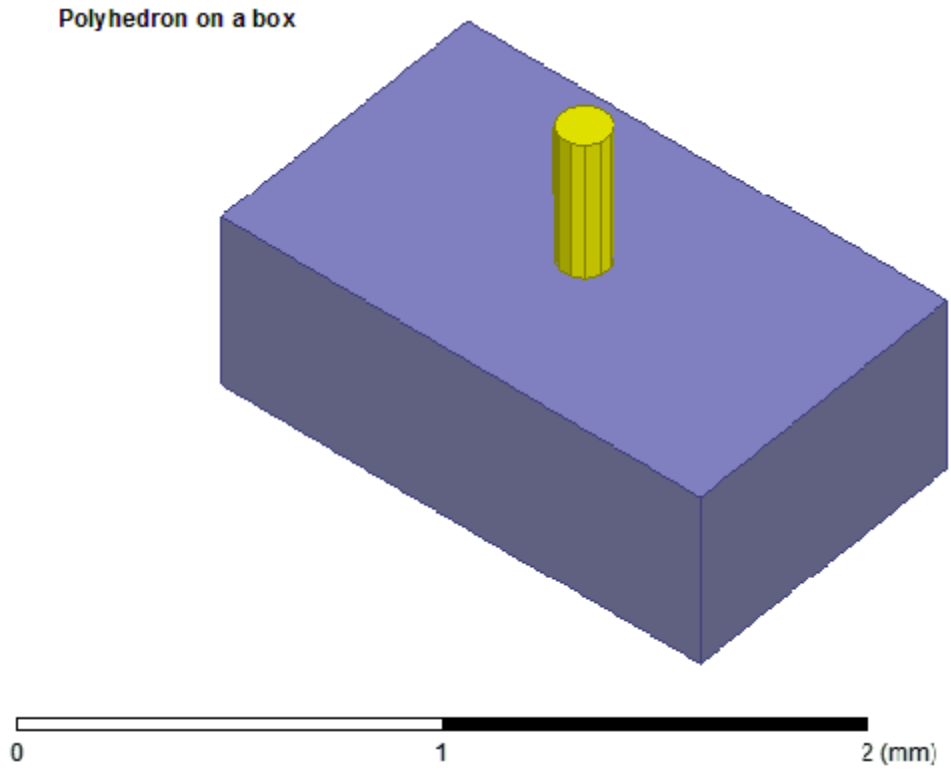
The HFSS mesher can automatically repair and correct a poorly translated and healed model to generate a reliable mesh. You can adjust the surface approximation settings if you want to further modify the corrections. The **Profile** reports when mesh repairs are made and the results of these repairs are displayed for every object in the mesh statistics panel.

The following sections provide troubleshooting tips to correct potential mesh failures on simple geometries:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

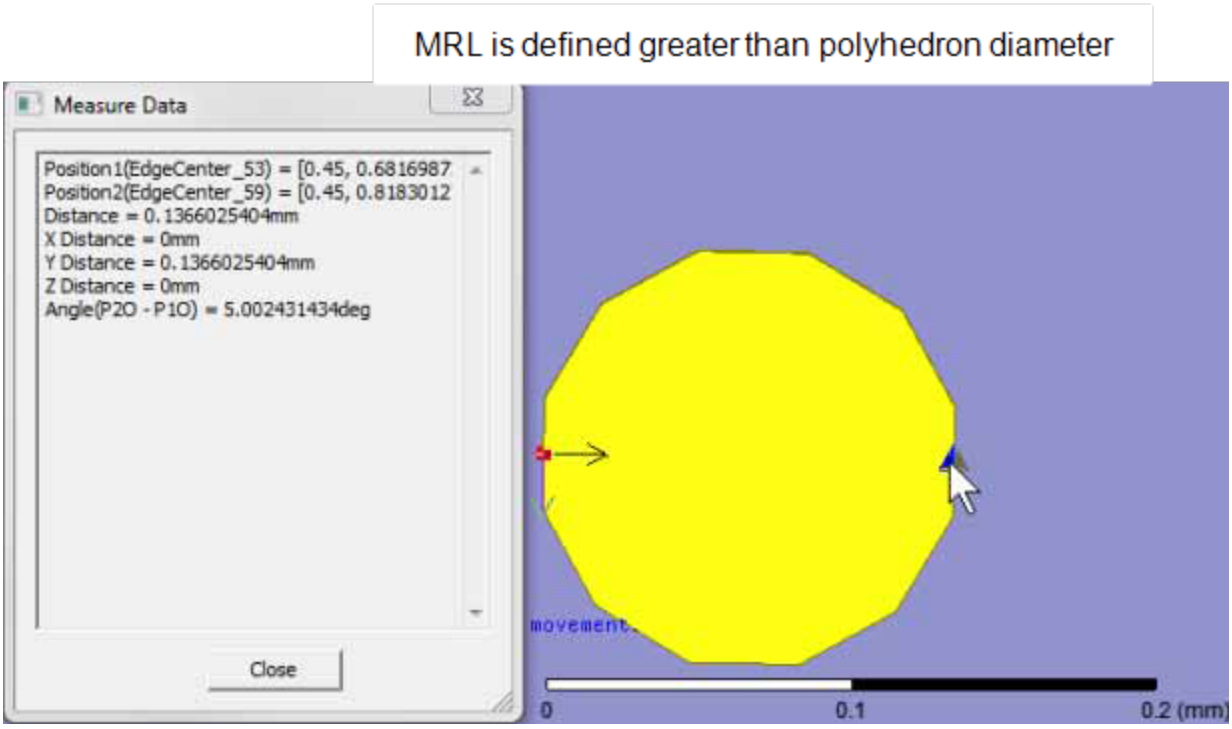
Scenario 1:Model Resolution has Caused Significant Changes in Object Dimensions

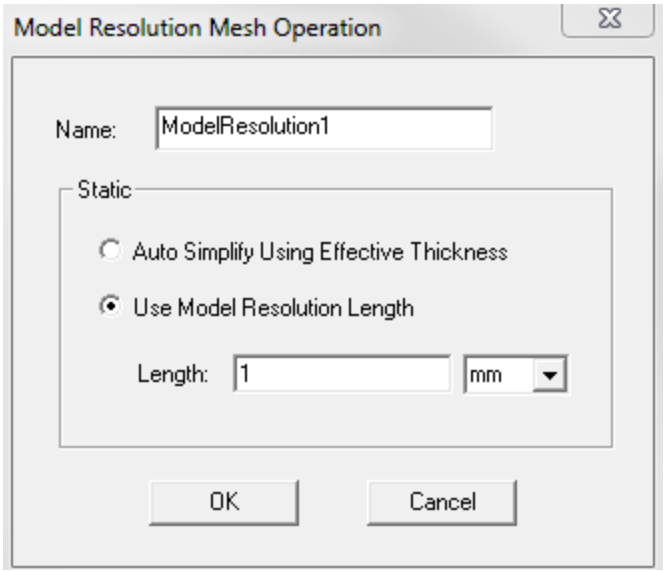
The following figure illustrates a scenario where improper MRL length can cause mesh failures. The geometry consists of a regular polyhedron on the top of a box.



The diameter of the polyhedron is 0.136 mm and the **Model Resolution Length** defined for the polyhedron is larger than the diameter itself as shown in the following figure.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





HFSS generates the following warning messages:

Model Resolution has caused significant changes in object dimensions or contact between objects. Please compare the MRL set on the bodies with the dimensions of the bodies. Please ensure the unites selected such that the smallest critical features of the model are at least 0.001

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

units long. Specific details may be found in Modeler > Model Analysis > Show Analysis Dialog > View Mesh Feedback.

Geometry stitch failed. Failing back to backup process.

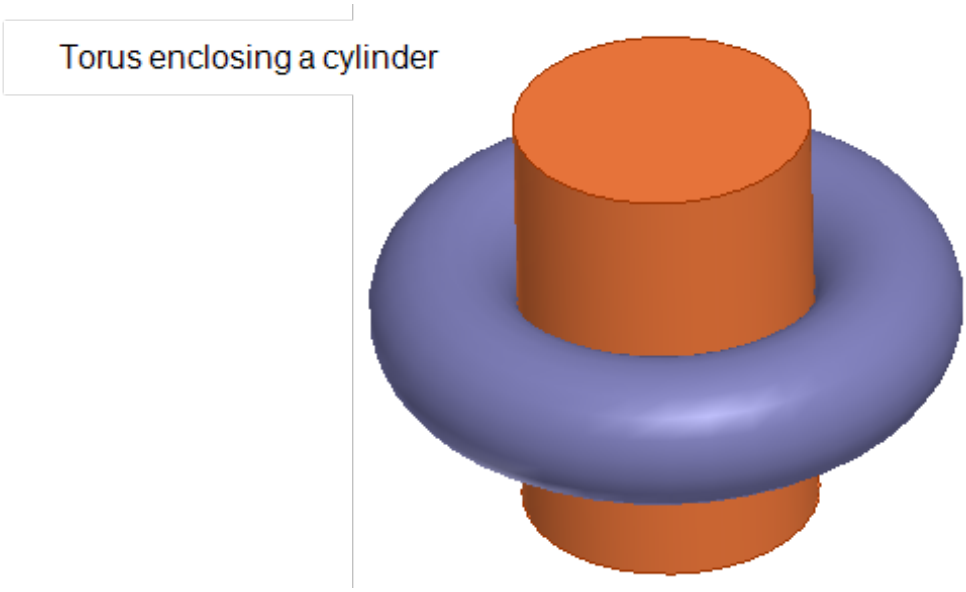
To diagnose the problem, first see the **Model Analysis** dialog box. For more details of the error type, select the **Display Mesh Error Log** check box.

For this particular geometry, a model resolution length of 0.045mm (one-third of the diameter of the polyhedron) created the correct mesh.

In general, select the model units such that the smallest critical features are at a minimum 0.0001 units long to address such warning messages. For a circuit board with a 1-micron trace width and vias, solder balls, bondwires, and gaps, each greater than 1 micron, the smallest critical feature is the trace; if the model is drawn in mm, the smallest critical feature can be 0.001 mm. However, if the model is drawn in centimeters, the smallest critical feature is 0.0001cm, which is way below the minimum permissible value 0.001. Such improper unit selections can cause mesh failures. Choose the units such that the entire solution domain is less than 1000 units.

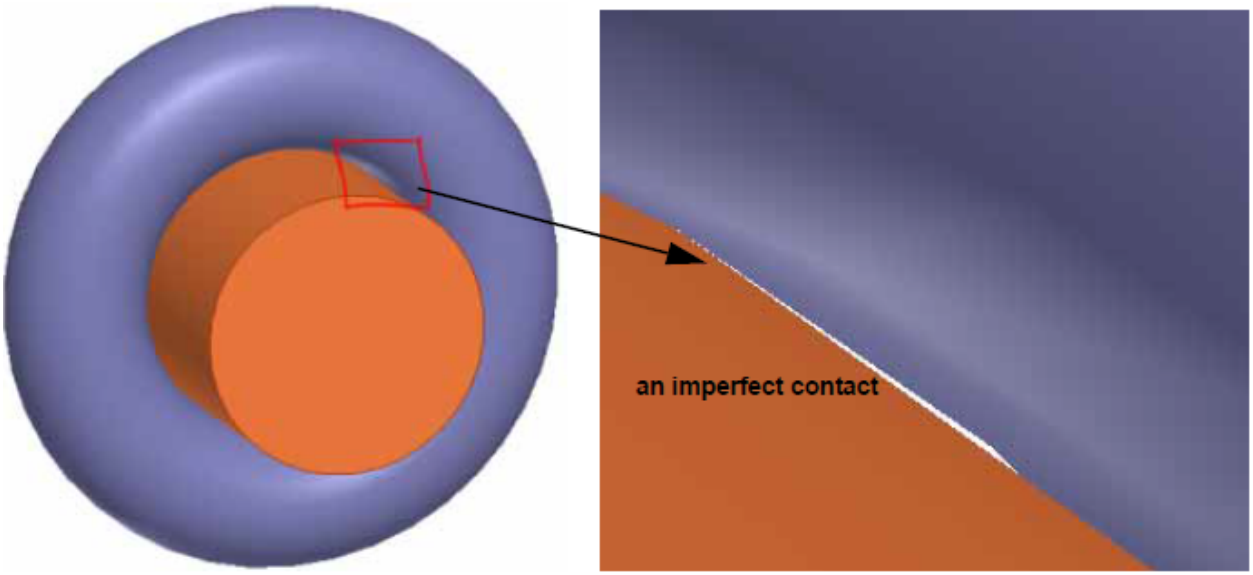
Scenario 2: Contact Area Change Too Large

Imperfect tangential contacts between curved surfaces can cause mesh failures. In the following figure, the radius of the cylinder is 0.1 mm, the major radius of the torus is 0.15 mm, and the minor radius is 0.05mm.

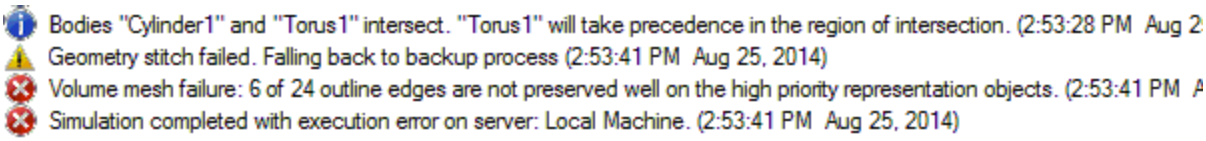


The axis of the cylinder is slightly tilted relative to the axis of the torus causing significant change in contact between objects.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

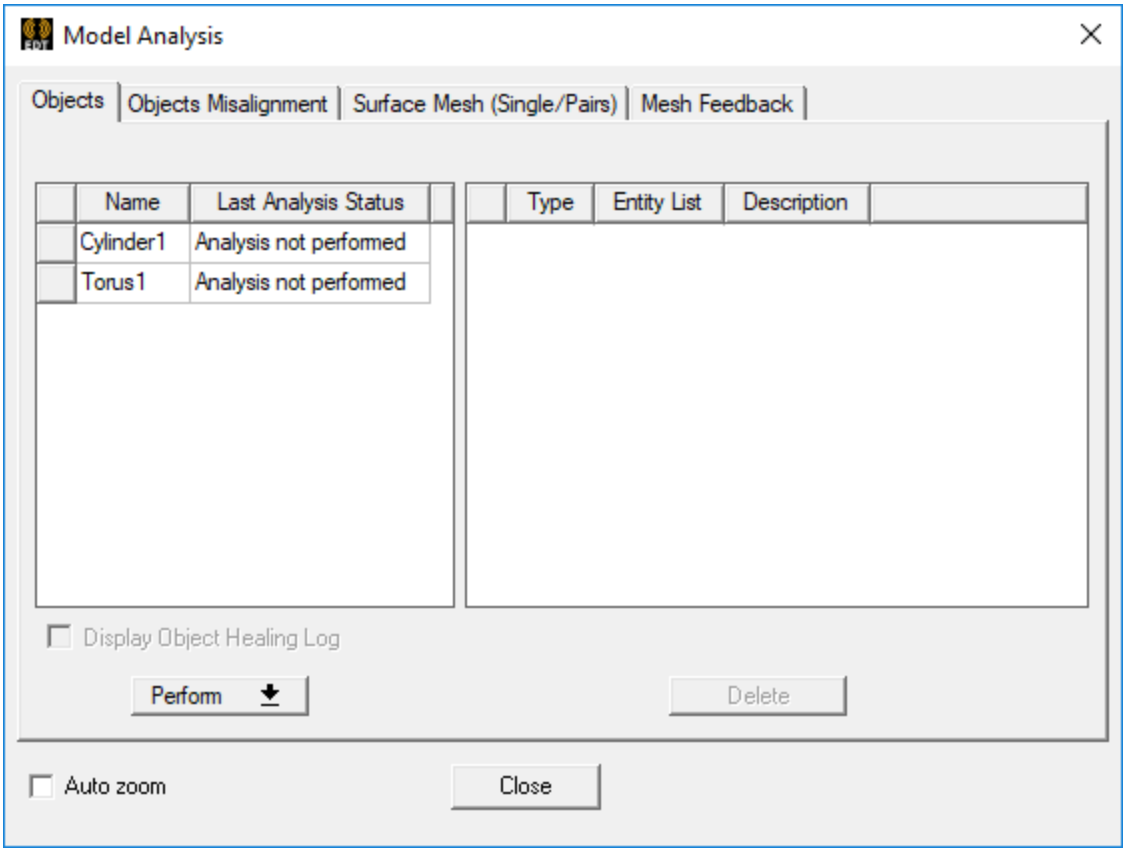


A mesh cannot be generated for this incorrect geometry. When analysis of this design is attempted, the following informational, warning, and error messages are reported in the Message Manager window.



On the **Model Analysis** dialog box, the last analysis status for each of the objects is listed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For the simulation to complete successfully, the axis of the cylinder relative to that of the torus must be aligned properly.

UI Controls for Mesh Operations

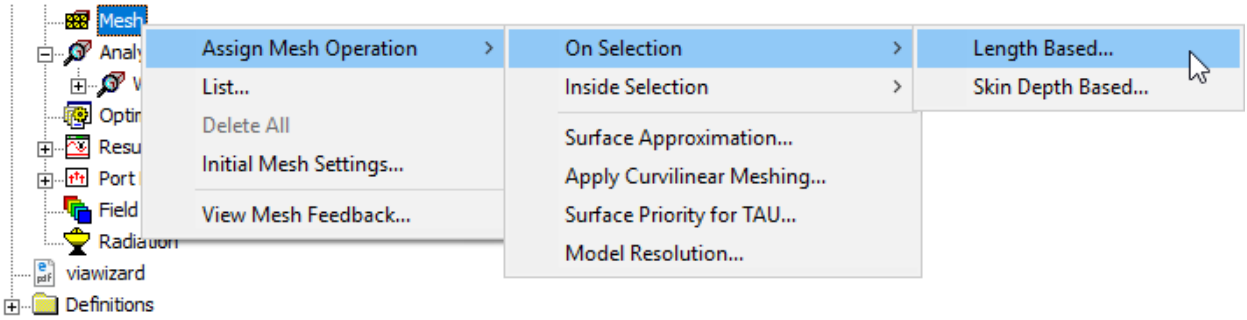
This section describes the various UI controls to access and define mesh operations. Each of these controls is described below.

Mesh Operations

You can define **Mesh Operations** from various places. From the Project Manager window, define mesh operations as follows.

1. Press F to enter face-selection mode, and select the surface of interest.
2. In the **Project Manager** window, right-click **Mesh** to access all the controls.

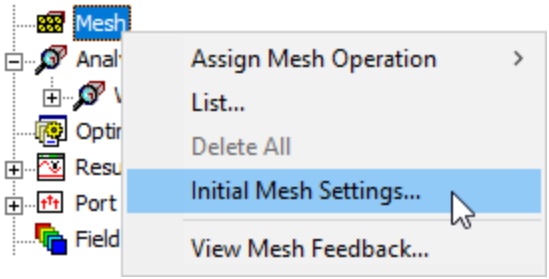
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Mesh Operations are also available on the **HFSS** menu item.

Assign Curvilinear Elements

To apply curvilinear elements on a surface, right-click **Mesh** and select **Initial Mesh Settings** from the short-cut menu as shown in the following figure.



The **Initial Mesh Settings** dialog box has the controls for **Surface Approximation**.

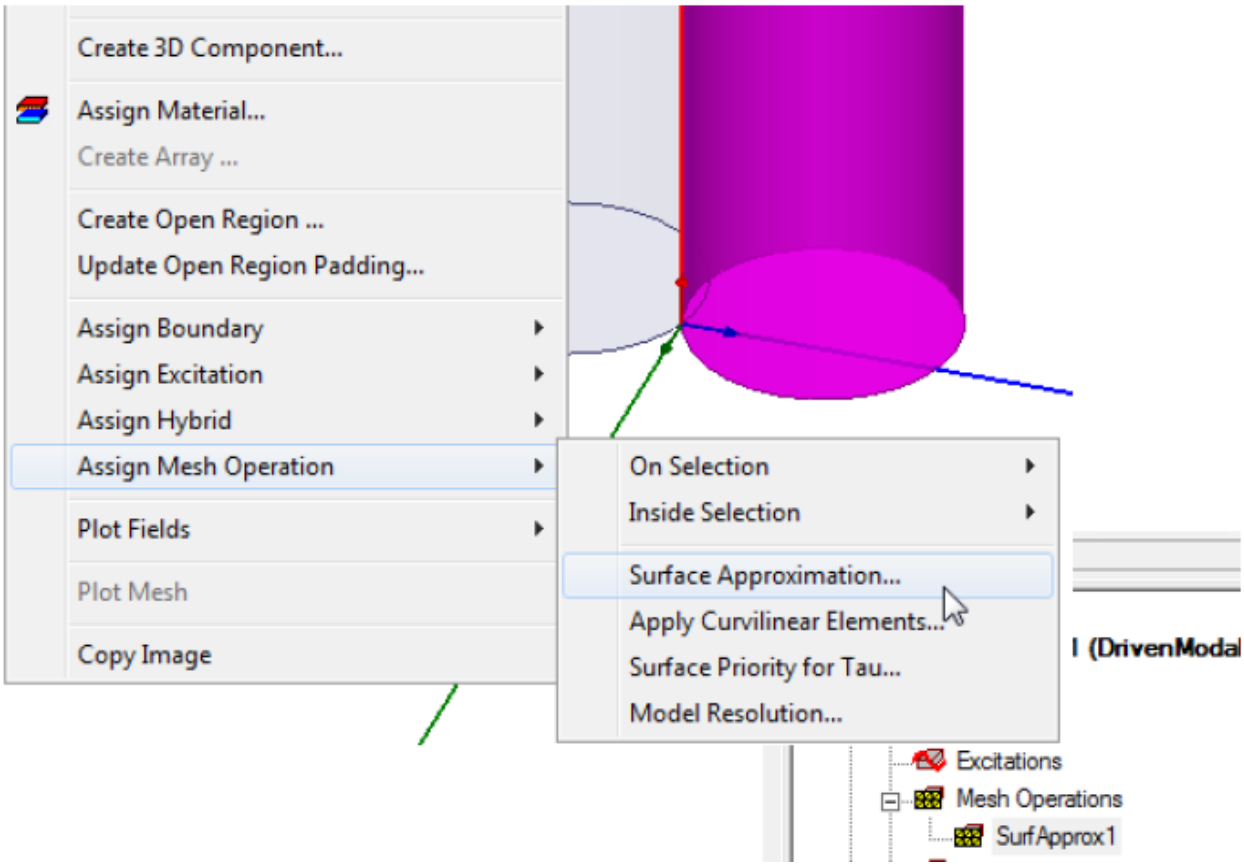
Access Surface Approximation (Object Level)

To access **Surface Approximation** at the object level, follow these steps:

1. Click **Edit** > **Selection Mode** > **Object** to enter object-selection mode.
2. Select the objects for which you want to apply **Surface Approximation**.
3. Right-click in the modeler field and select **Assign Mesh Operation**>**Surface Approximation**

   The **Surface Approximation** dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

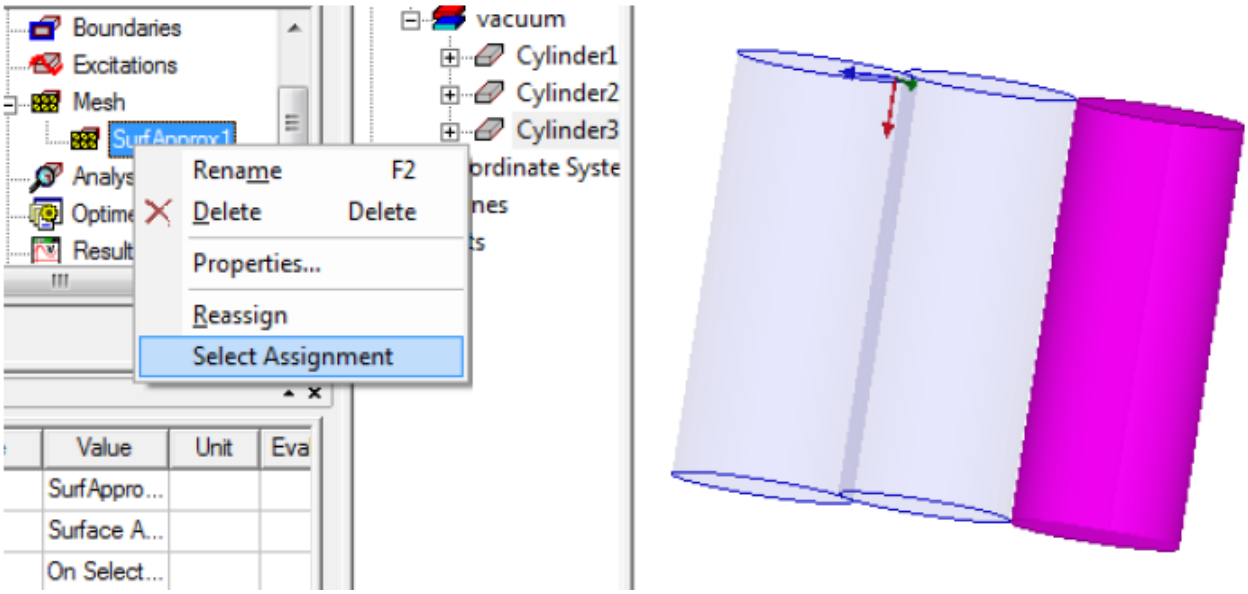


Note:

Surface Approximation performed at the object level overrides Surface Approximation performed at the model level. Also, once you define Surface Approximation at the object level, the setting name appears under **Mesh** in the Project Manager window. In the figure it is the default name SurfApprox1. If you want to apply Surface Approximation on specific surfaces of the object, you must be in Face Selection mode.

To determine where in the geometry Surface Approximation setting was applied, right-click the particular surface approximation setting of interest from the project tree and choose Select Assignment from the short-cut menu as shown in the following figure. This feature is especially useful when there are several surfaces that are assigned these approximation settings and you want to see which setting corresponds to which surface in the geometry.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Mesh Assembly

With mesh assembly you can specify that multiple design modal FE-BI or IE/PO, SBR+ or FEM components and native regions are meshed independently to ensure very robust and rapid meshing. If a design contains multiple instances of a component, that component need only be meshed once. Parametric variations for one or more instances only affects the mesh of those instances.

The solver supports the following types of mesh assembly components.

- Volume component containing FEBI boundary
- Surface component (IE/PO)
- SBR+ component
- Volume components without FEBI.

Some of the benefits of mesh assembly are as follows:

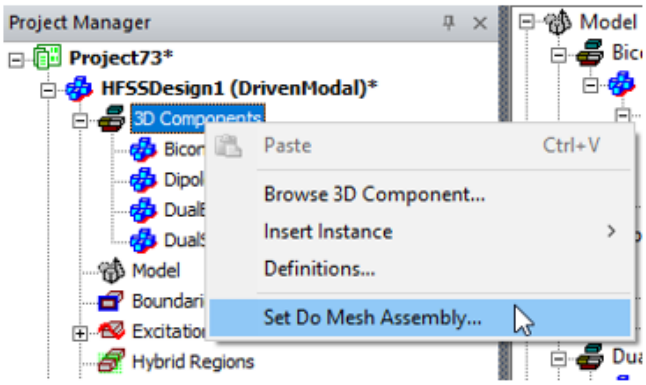
- Systems with large variation in length scales can be successfully meshed. For example, in the case of a small 3D antenna touching an aircraft, you can mesh both the bodies separately and ensure a conformal mesh between them. That is, the triangulations in the contact area between the volume mesh of the 3D antenna component and the surface mesh of the aircraft are aligned resulting in a conformal mesh.
- You can select different meshers for each component via the **Component Meshing** properties. That is, you can pick the Tau mesher for a given component and the Classic mesher for another component, in order to ensure system meshing is successful.

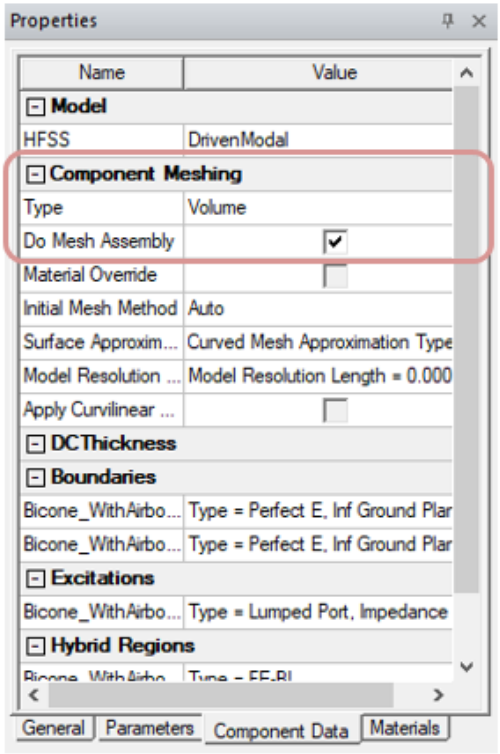
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Faster meshing for multiple instances of the same component is possible: only one initial mesh is created. For instance, when multiple identical antennas appear in a design, only one needs to be meshed.
- Mesh resuse enables fast placement studies. If you move a component, no re-meshing needs to be done. Also only the last adaptive mesh is used and no adaptive meshing of the component needs to done.
- Reused initial meshes are not impacted by any parametric variation. Suppose there are multiple components that are independently meshed and you make a parametric variation in one component, the remaining components are not remeshed. In this situation, the last adaptive mesh cannot be reused. Some examples of parametric variation can include increasing or decreasing the dimension of a geometry or changing the material properties.

- Mesh Assembly can be distributed.

You can access the **Do Mesh Assembly** feature through the **Project** tree shortcut menu for **3D Components**, through the **Advanced** tab of the Solution Setup, or through **Component Meshing** properties.

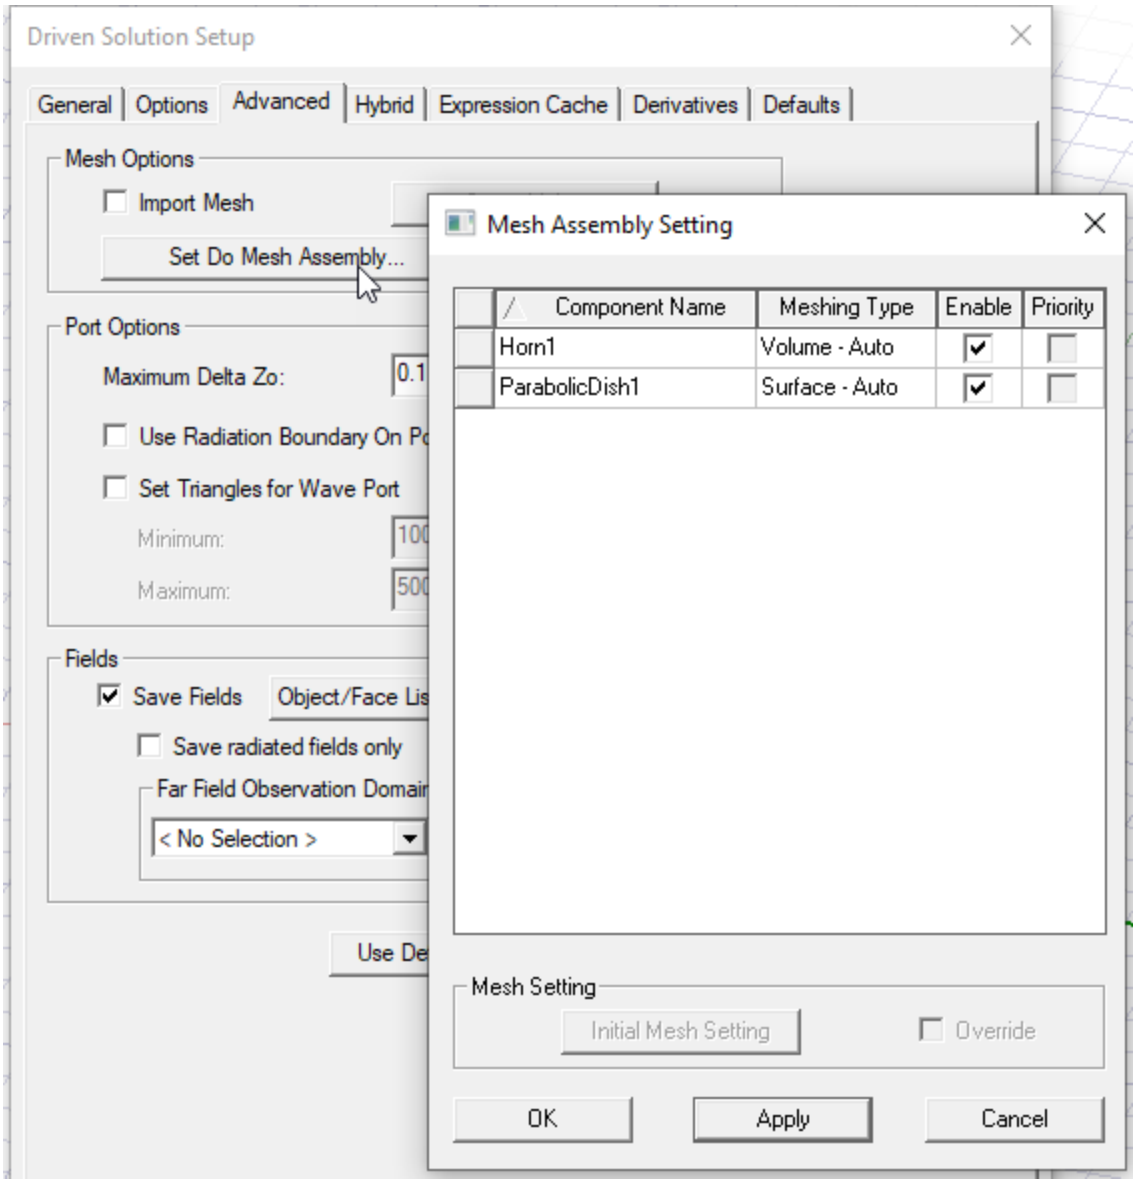




Selecting **Set Do Mesh Assembly...** opens a dialog which lists eligible components. Selecting a component enables the fields.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can also access the **Do Mesh Assembly Setting** dialog through the **Advanced** tab of the Solution Setup.



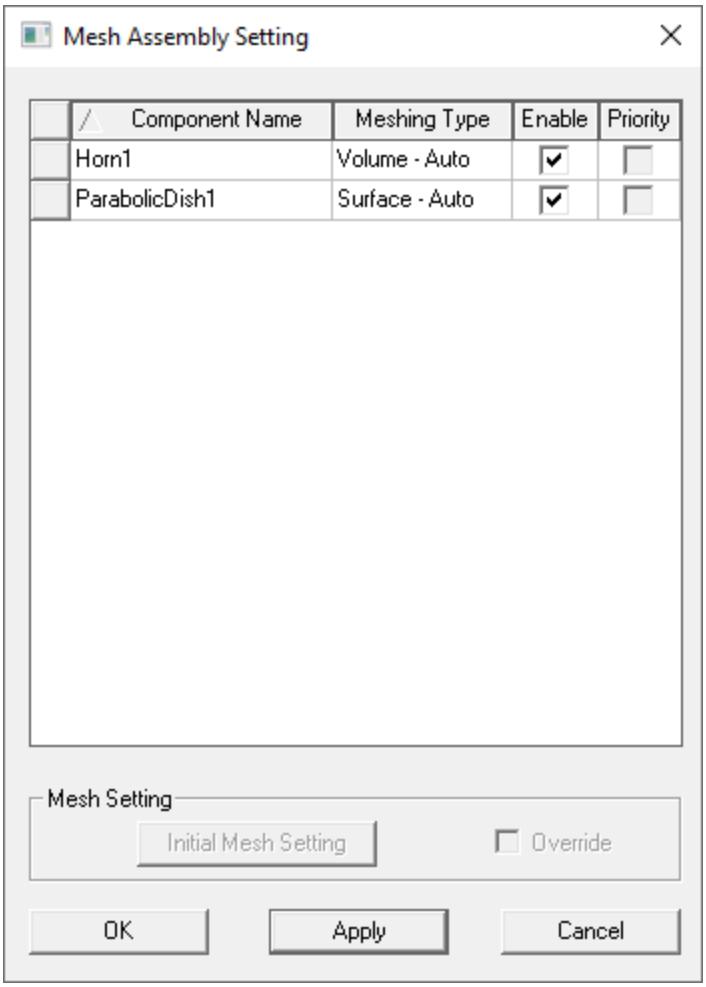
If a component does not meet the requirement for mesh assembly, the feature is disabled in the **Do Assembly Setting** dialog and the **Component Meshing** properties.

Mesh Method Override

You can override the mesh method from the component definition in the **Do Mesh Assembly Setting** dialog box, accessed either through the 3D Component shortcut menu in the **Project** tree, **3D Components>Set Do Mesh Assembly**, or the **Advanced** tab of the an Advanced

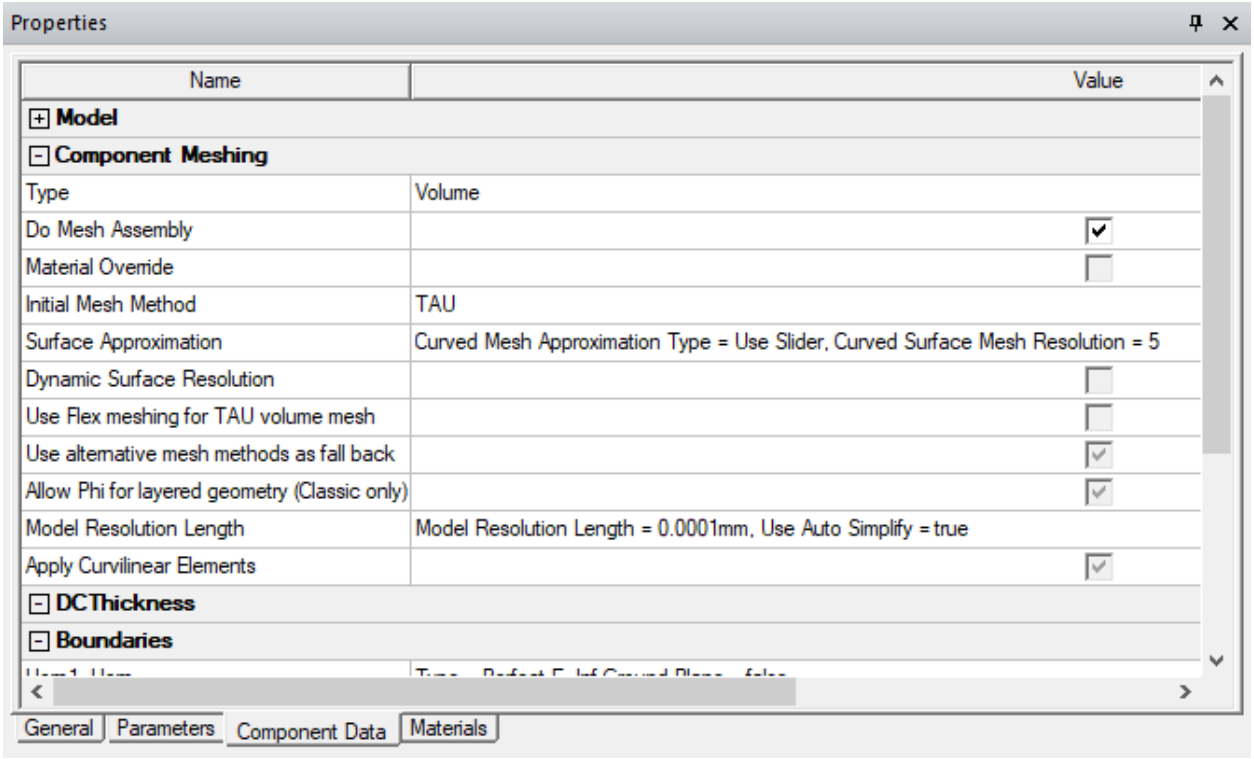
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solution Setup. This lets you deal with potential mesh failure based one specific mesh method when doing assembly meshing. If a failure happens using one method, you can easily switch the mesh method and try again. Selecting a component in the **Do Mesh Assembly Setting** dialog enables Override checkbox. Checking the box enables the **Intial Mesh Setting** button, which opens the **Initial Mesh Settings** dialog box, where you can select and Apply, Auto, TAU, or Classic. For convenience, the dialog also displays each component's meshing method in its Meshing Type column. The Component Priority checkboxes will be enabled if the components are valid for that feature.



The overriding Component Mesh settings are shown in the Component **Properties** window, Component Data tab.

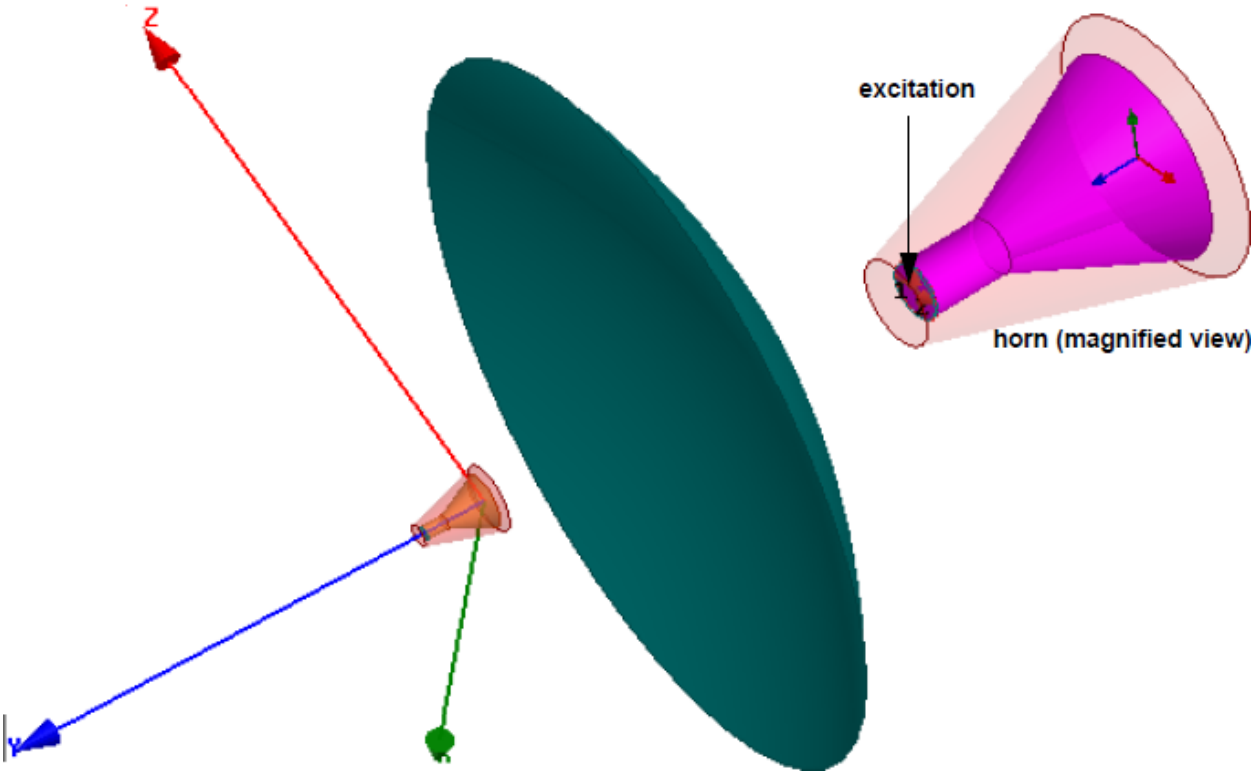
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



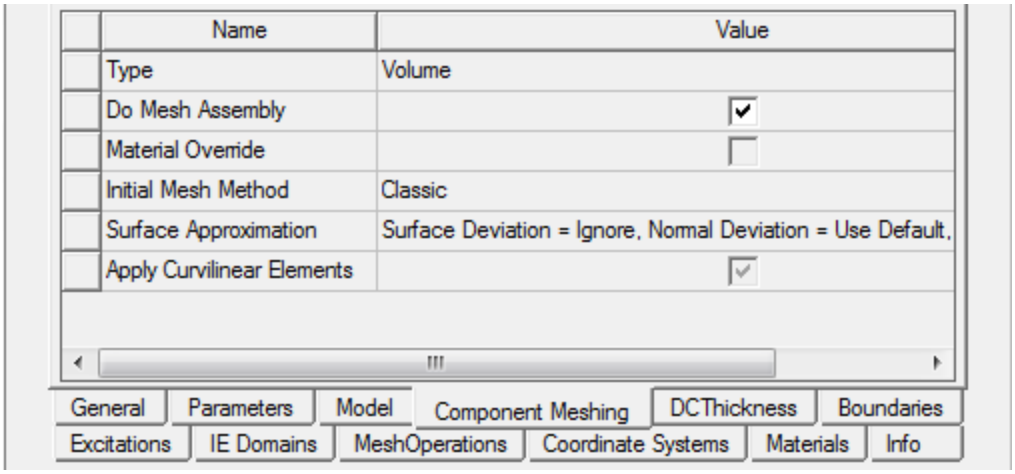
Example: Horn Antenna and a Dish

This example shows an electrically large problem for the placement study of a horn antenna illuminating a dish, when the antenna is moved along the y-axis. For such designs, meshing the horn and the dish separately makes the simulation faster since only the currents on the dish and on the radiation boundary of the horn need to be modeled. Meshing the volume of the region between the horn and the dish to model coupling occurring due to the currents on the dish and the radiation volume bounding the horn is not required. With mesh assembly, you can reuse the meshes of the individual components for performing placement studies. The diameter of the reflector is 2000 mm and the adapt frequency is defined to be 5 GHz. A design variable offset is defined to vary the placement of the horn along the y axis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To use the mesh assembly feature, select the **Do Mesh Assembly** option for the individual components of the design as shown in the following figures:

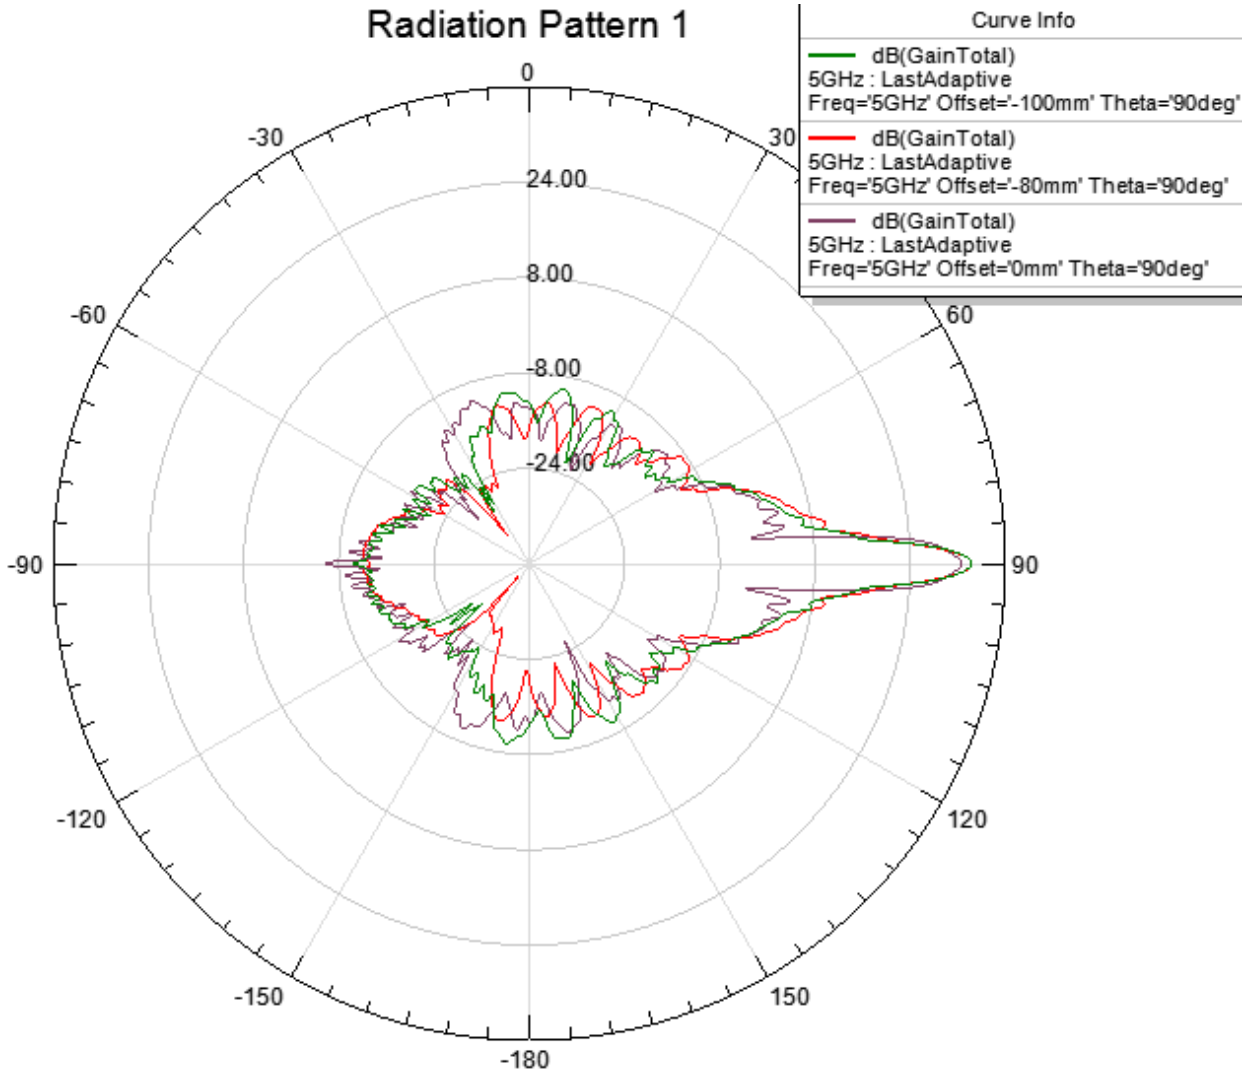


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

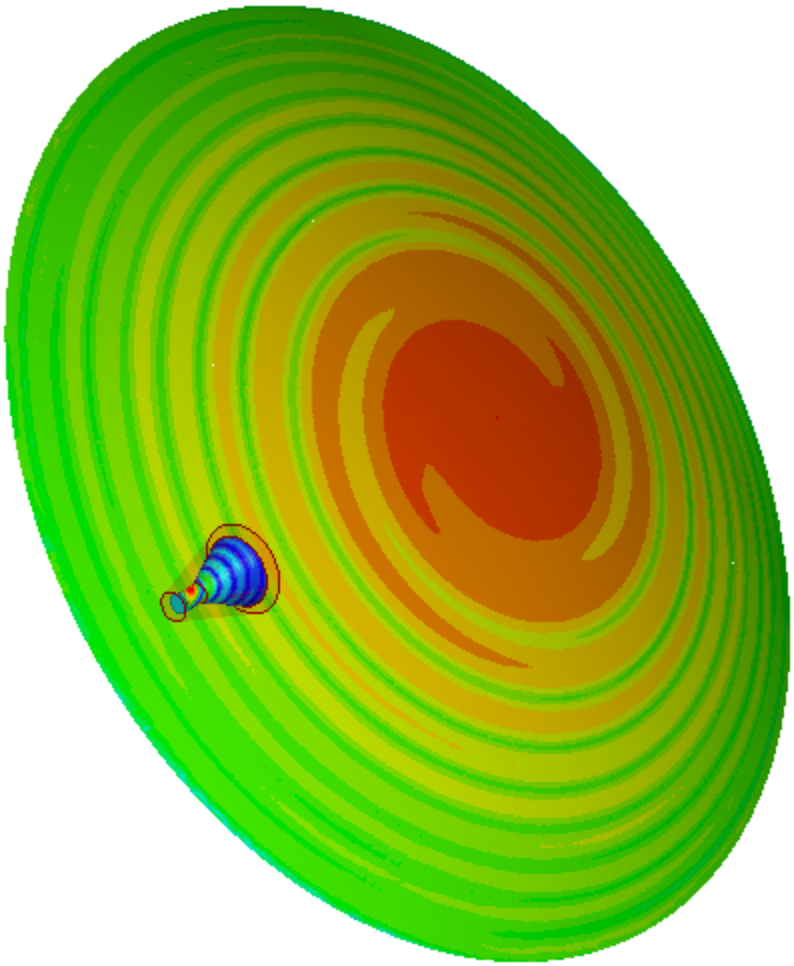
To access this feature, select component in the Project tree and select the **Component Meshing** tab in the **Properties** window. You can also view and set mesh assembly for all valid components in a design by using **Set Do Mesh Assembly** to open the **Do Mesh Assembly** dialog box, as shown above.

The radiation pattern for the three design variations is shown below.



The plot for one such design variation, offset at 0 mm, is shown in the following figure.

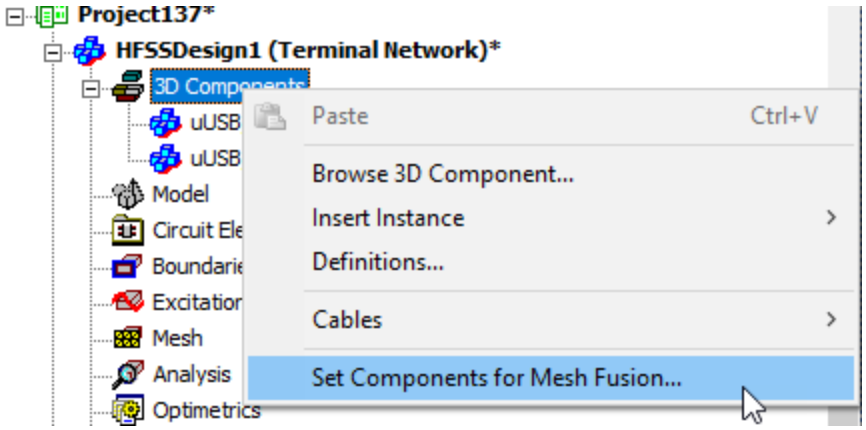
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



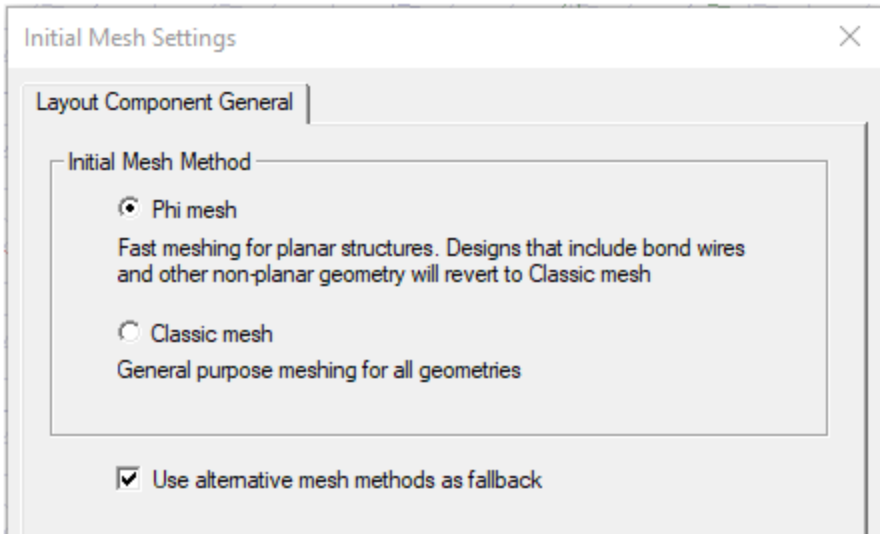
Mesh Fusion

With mesh fusion you can specify that multiple design modal FEM components and native regions are meshed independently to ensure very robust and rapid meshing. If a design contains multiple instances of a component, that component need only be meshed once. Parametric variations for one or more instances only affects the mesh of those instances. You can access the **Do Mesh Fusion** dialog through the **Project** tree shortcut menu for 3D Components, using the **Set Components for Mesh Fusion...** command. You can use the dialog to manage settings for all components in the project.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

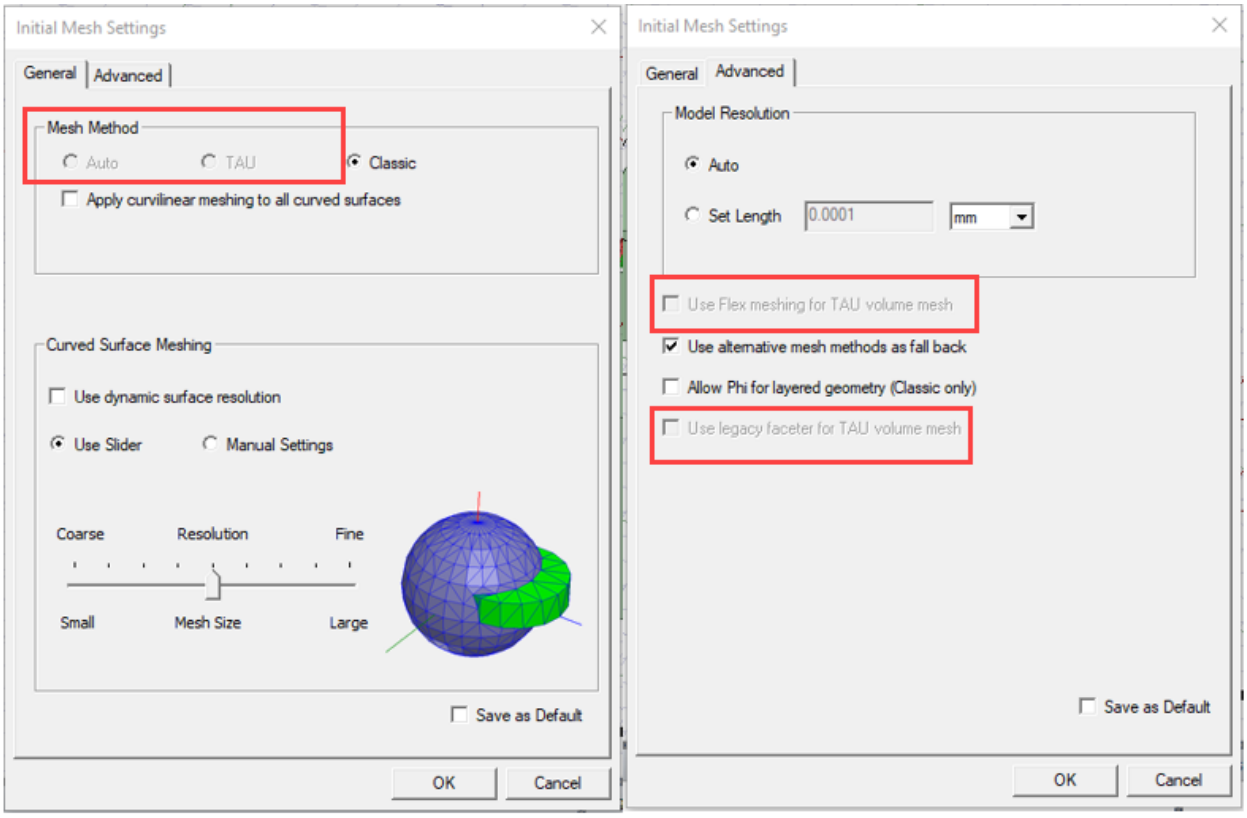


The solver supports mesh fusion for FEM volume and HFSS 3D Layout components in HFSS design type. This type of volume component cannot coexist with any FEBI, and/or surface and/or SBR+ components. Similar to 3D components, HFSS 3D layout components, when marked as mesh fusion, also support mesh envelope padding and mesh setting override. The mesh setting override dialog for layout components are different from that for 3D components and can be seen in the figure below.



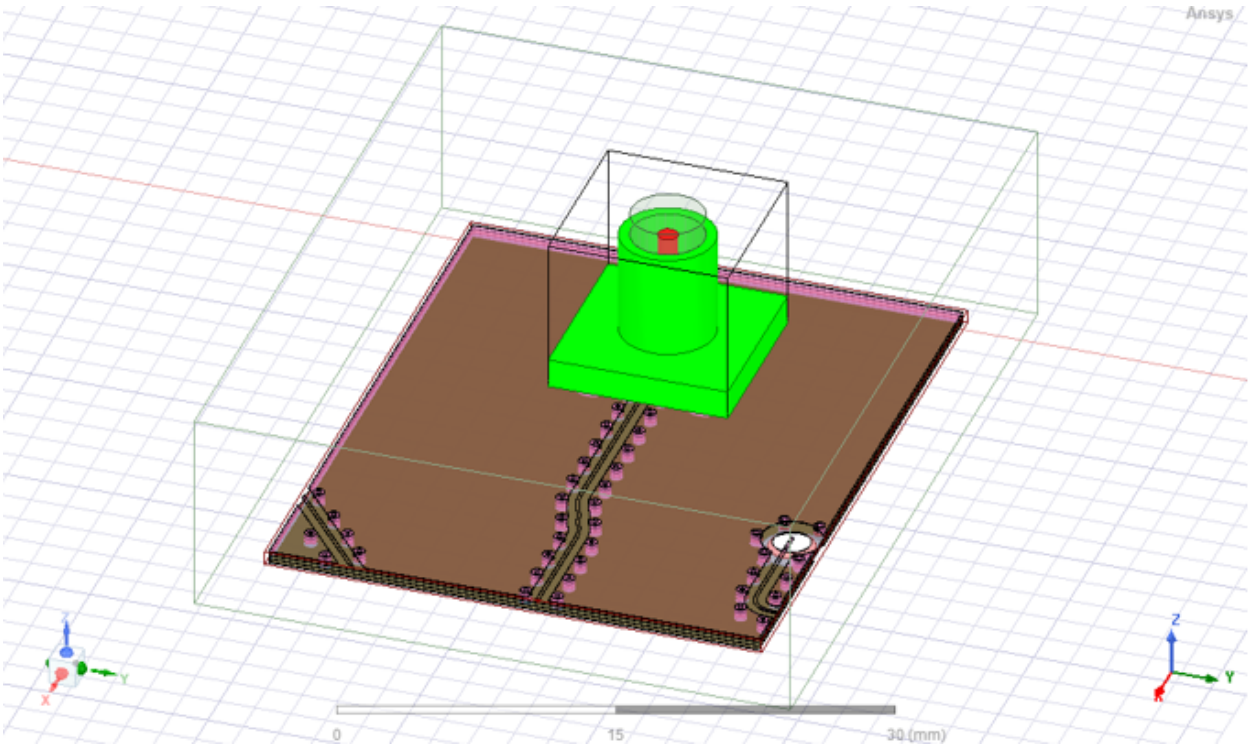
In this dialog, you can choose different mesh methods specific to layout components. This dialog is fully modeless, which loads different pages when you select layout or 3D components. In addition to this dialog, the **Initial Mesh Setting** dialog for the native design is also modified. If there are layout components meshed in native, the **Initial Mesh Setting** dialog will disable the Auto and TAU mesh method. The options related to TAU in the advanced setting page are also disabled.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



With the proper setting, the design can be meshed and solved. Layout components marked as mesh fusion will have full interaction with other layout components, 3D components and native geometry.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

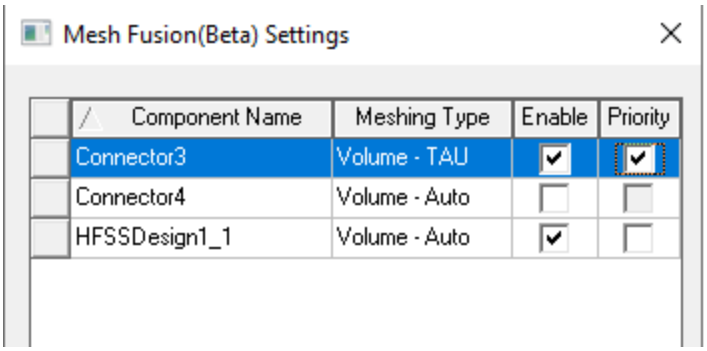


Some of the benefits of Mesh Fusion are as follows:

- Systems with large variation in length scales can be successfully meshed. For example, in the case of a small 3D antenna touching an aircraft, you can mesh both the bodies separately and ensure a conformal mesh between them. That is, the triangulations in the contact area between the volume mesh of the 3D antenna component and the surface mesh of the aircraft are aligned resulting in a conformal mesh.
- You can select different meshers for each component via the Component Meshing properties, or directly . That is, you can pick the Tau mesher for a given component and the Classic mesher for another component, in order to ensure system meshing is successful.
- The iterative solver option is available for mesh fusion projects as an Advanced Solution Setup option, except for 3D component array in both 3D layout and MCAD. The Iterative solver uses 1.e-6 as the default.
- Faster meshing for multiple instances of the same component is possible: only one initial mesh is created. For instance, when multiple identical antennas appear in a design, only one needs to be meshed.
- Mesh resuse enables fast placement studies. If you move a component, no re-meshing needs to be done. Also only the last adaptive mesh is used and no adaptive meshing of the component needs to done.

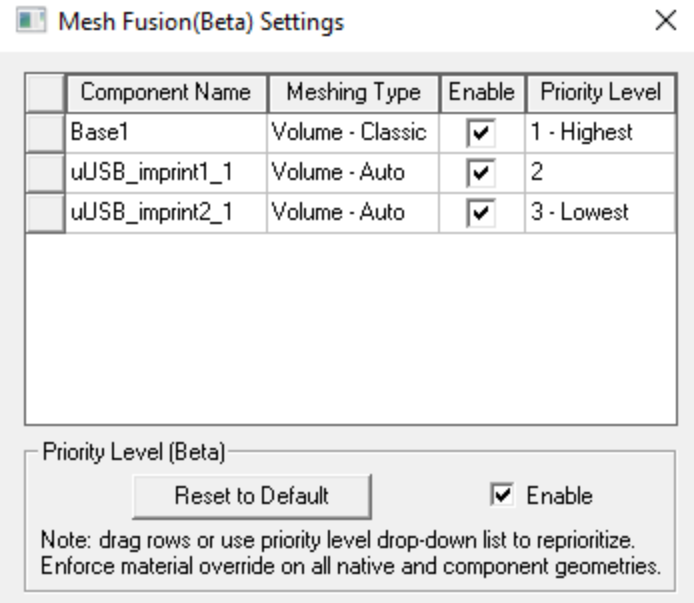
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Reused initial meshes are not impacted by any parametric variation. Suppose there are multiple components that are independently meshed and you make a parametric variation in one component, the remaining components are not remeshed. In this situation, the last adaptive mesh cannot be reused. Some examples of parametric variation can include increasing or decreasing the dimension of a geometry or changing the material properties.
- Mesh fusion can be distributed, including support for distributing Iterative Solver Excitations.
- Mesh Fusion components can be marked as Priority in the **Mesh Fusion Settings** dialog box. It is common for a large project to have some native objects intersect with mesh fusion components due to user error or modeling issue. These intersections are usually small and would not affect simulation result if ignored, but they can stop simulations and cost much time to fix. To improve this problem, you can mark any mesh fusion components as priority.



The dialog also contains a section to enable Priority Level ranked from Highest to Lowest for each component in the design. This feature aims to develop a better intersection resolution mechanism that could help you resolve most of the intersections with ease and customization for both regular and mesh fusion applications.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

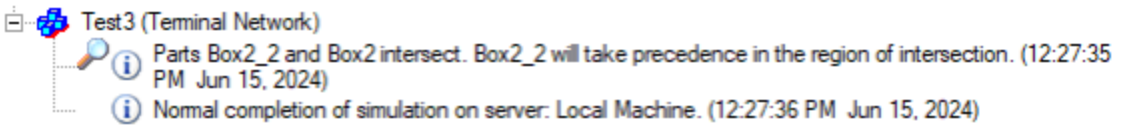


Once the Priority Level is enabled, a column named “Priority Level” replaces the “Priority” column. In this setting, all the components in the design are ranked from highest priority to the lowest based on rules for default priority. You can drag a row to change the priority level of a component. Alternatively, you can also click the cell in the Priority Level column for a row to open a drop-down list. You can then pick a level in the list and assign it to that component.

Additionally, you can click the **Reset to Default** button to assign a default priority level to all components. For details on how the default priority is calculated, refer to the **Rules for Default Priority** section below.

Most of the intersections will be resolved automatically during simulation according to the priority levels. All the resolutions will happen behind the scenes, and you will not notice any difference due to objects being cut-off in the post processing. This priority levels setting is only used for resolving intersections and not for containment. This priority levels setting will enforce the material setting to turn on.

Once you enable Priority Level, the design validation reports the intersection resolution result.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If the priority levels setting is not enabled, HFSS uses the old behavior to handle any intersections.

Rules for Ranked Priority Level

If you enable Priority level and use the default rankings the rules for Default Priority Level apply.

Rules for Default Priority Level

Default Priority level uses the following rules.

1. Starting from the first rule, the dialog applies each rule to compare the priority levels of two components until the winner can be determined.
2. Components that are checked for mesh fusion have higher priority than those that are not.
3. Layout/encrypted 3D components have higher priority than regular 3D components.
4. If both components are checked for mesh fusion, the component with smaller mesh envelop has higher priority.
5. If both components are not checked for mesh fusion, the component that is inserted later has higher priority.
6. Geometries that do not belong to a component have the lowest priority.

Rules for Resolving Intersection between Two Objects

If two objects intersect, and the priority level is enabled, HFSS tries to resolve the intersection using the following rules. Starting from the first rule, HFSS applies each rule until the winner can be determined.

1. If one object is conductor and the other object is dielectrics, conductor wins in the region of intersection.
2. If both objects are conductors or dielectrics, the object that belongs to the component with higher priority wins.
3. If both objects are conductors or dielectrics and have the same component priority level, but their material is different, it is not valid. The code will return validation error.
4. For the rest of the case, the object with the smaller volume wins. If their volumes are equal, the object with smaller ID wins.

For example:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Two objects, red and blue, intersect. Both are conductors. The program determines that the red object has higher priority according to the rules.

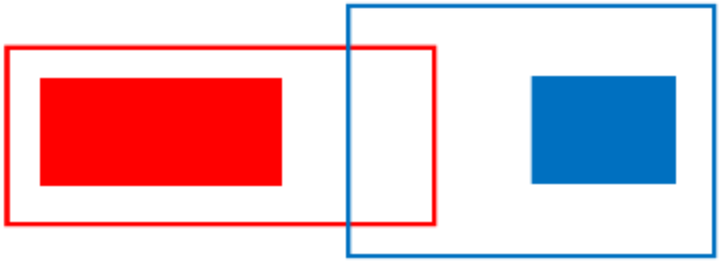
The red object will take precedence in the region of intersection.

Rules for Resolving Intersection between Two Components' Mesh Fusion Envelope

If two components are marked as mesh fusion, and their mesh envelopes intersect, the envelope that belongs to the component with higher priority level takes precedence in the region of intersection. The intersecting portion is subtracted from the envelope with lower priority. The mesh fusion envelope includes both the user defined mesh region and auto-generated mesh envelope.

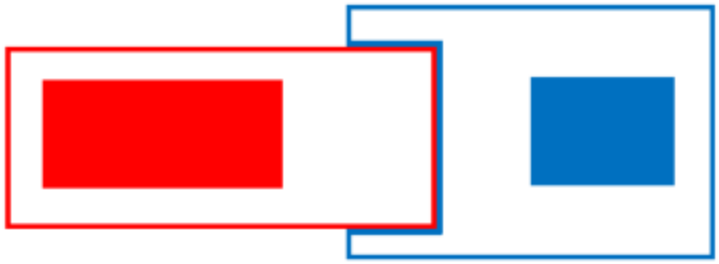
For example:

There are 2 components in red and blue. The rectangular outline represents the mesh fusion envelop of each component, and the solid rectangle represents the actual geometry of that component. The two components' mesh fusion envelopes intersect, and the red component has a higher priority level.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

HFSS resolves such intersection by subtracting the intersecting portion from the blue component's mesh fusion envelope.



Rules for Resolving Intersection between an Object and Another Component's Mesh Fusion Envelope

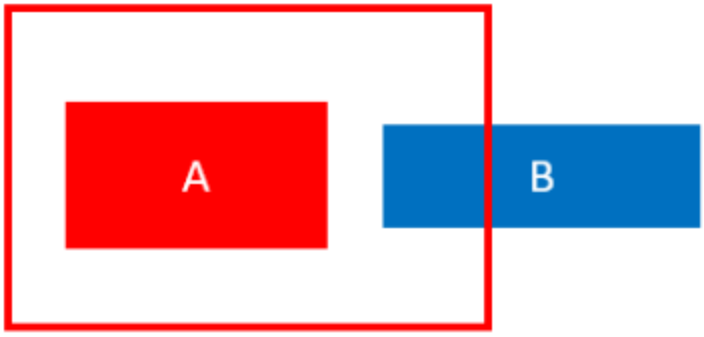
If one object intersects another component's mesh fusion envelope, the intersecting portion is cut off from the object and included with the other component. This cutout portion is meshed with that component.

If there are any boundaries or mesh operations assigned on the object, they are shared to the cutout portion. However, the following case is not valid and will cause a validation error.

- The object belongs to a layout component or an encrypted 3D component
- The cutout portion is assigned with circuit elements or excitations

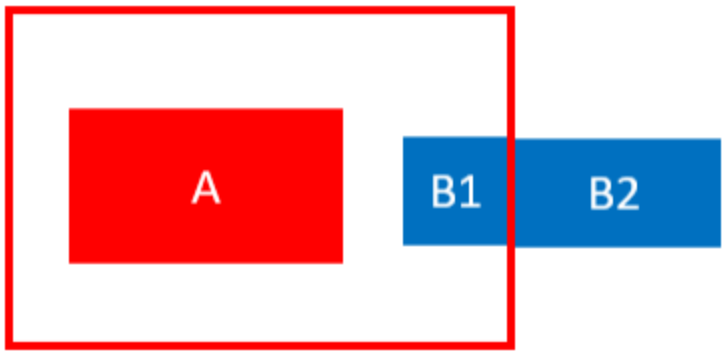
For example:

There is a component A whose mesh fusion envelope intersects with object B.



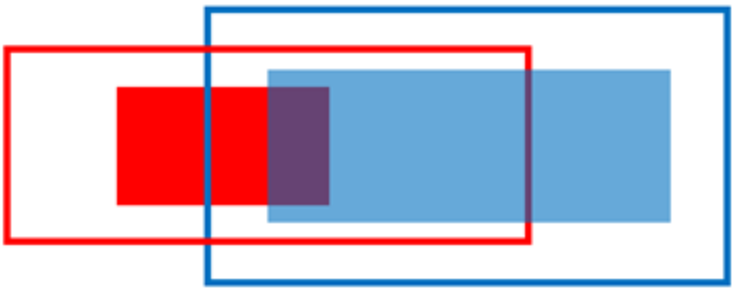
The intersecting portion is cut off from Object B. Object B is now split into 2 parts, B1 and B2. B1 is meshed with component A.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



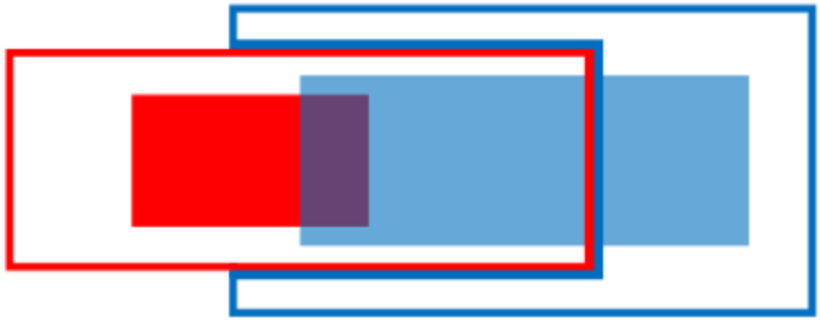
Putting it all together:

In the below example, there are 2 components in red and blue. The rectangular outline represents the mesh fusion envelop of each component, and the solid rectangle represents the actual geometry of that component. The two components' mesh fusion envelopes intersect, so do their actual objects. The red component has a higher priority level.

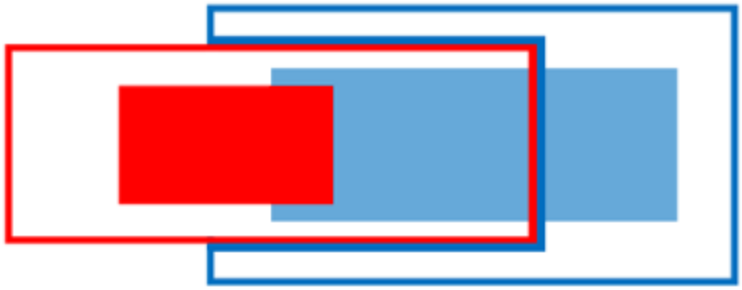


The envelope-envelope intersection is resolved by subtracting the blue component's envelope. After this, the blue component's envelope no longer intersects with the red component's actual object. However, the red component's envelope still intersects with the blue component's actual object. This intersection is resolved by cutting off the intersecting portion from the blue object and including it with the red component.

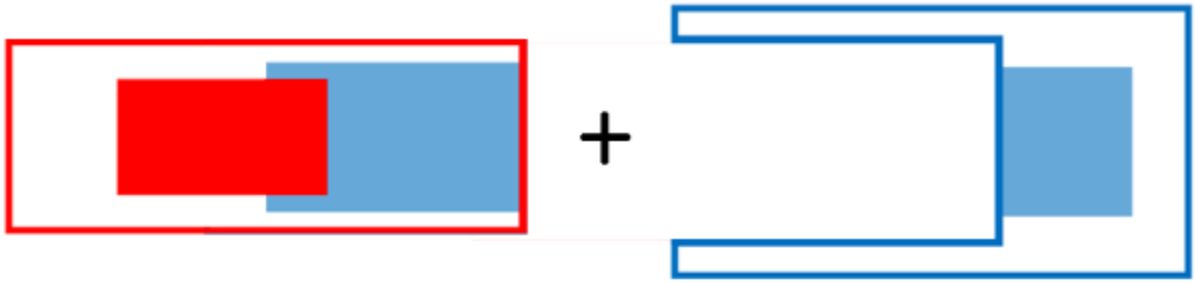
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The cutout portion from the blue object still intersects with the red component's actual object. This intersection is resolved by letting the red object take precedence in the region of intersection.

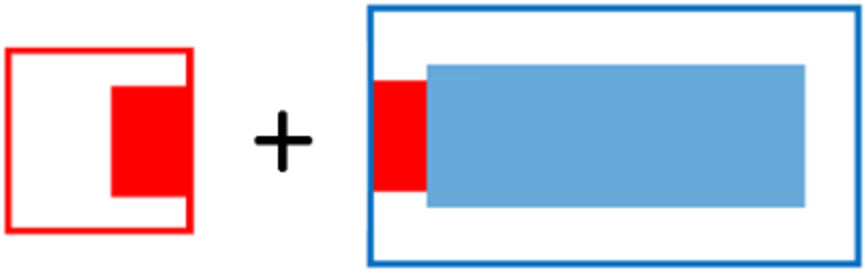


With all the intersection resolved, the two components are processed and split into two new groups of geometries that are meshed separately using mesh fusion.



On the other hand, if the blue component has higher priority instead, the two components will become the following after intersection resolution.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

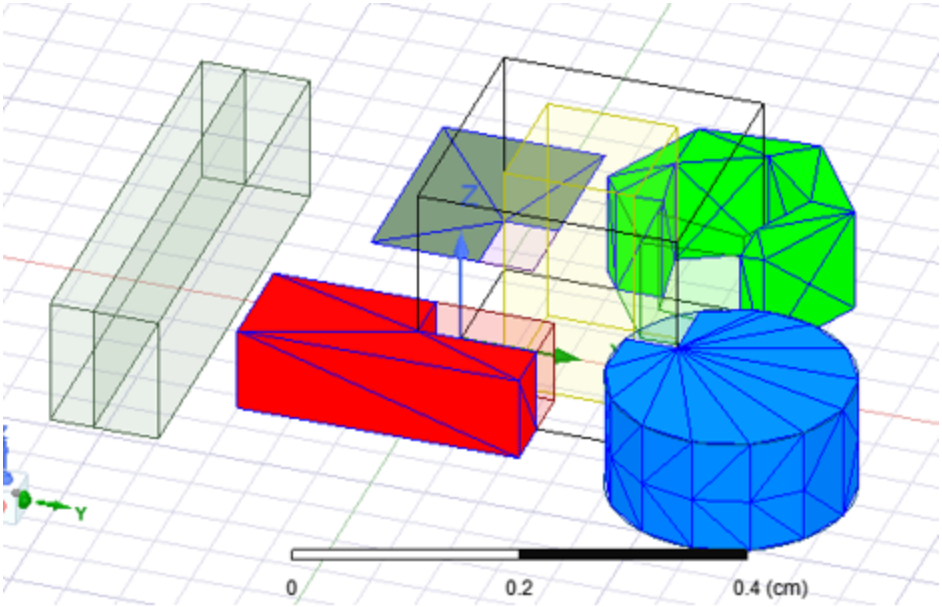


Rules to Resolve Containments

The Priority Level feature does not introduce any new rules to resolve the case in which one object contains another object. HFSS follows the old behavior for resolving such containment or reporting error. However, the Priority Level feature resolves a special containment case in which one component's mesh fusion envelope contains another component's mesh fusion envelope. This case was invalid in prior releases but can now be supported by letting the smaller envelope subtract the larger envelope. This leaves a cavity on the larger envelope, and the smaller envelope resides in the cavity.

Rules for Simple Priority

Using Simple Priority, if a priority mesh fusion component intersects a native object, the intersecting portion is subtracted from the native object, so that the simulation continues.

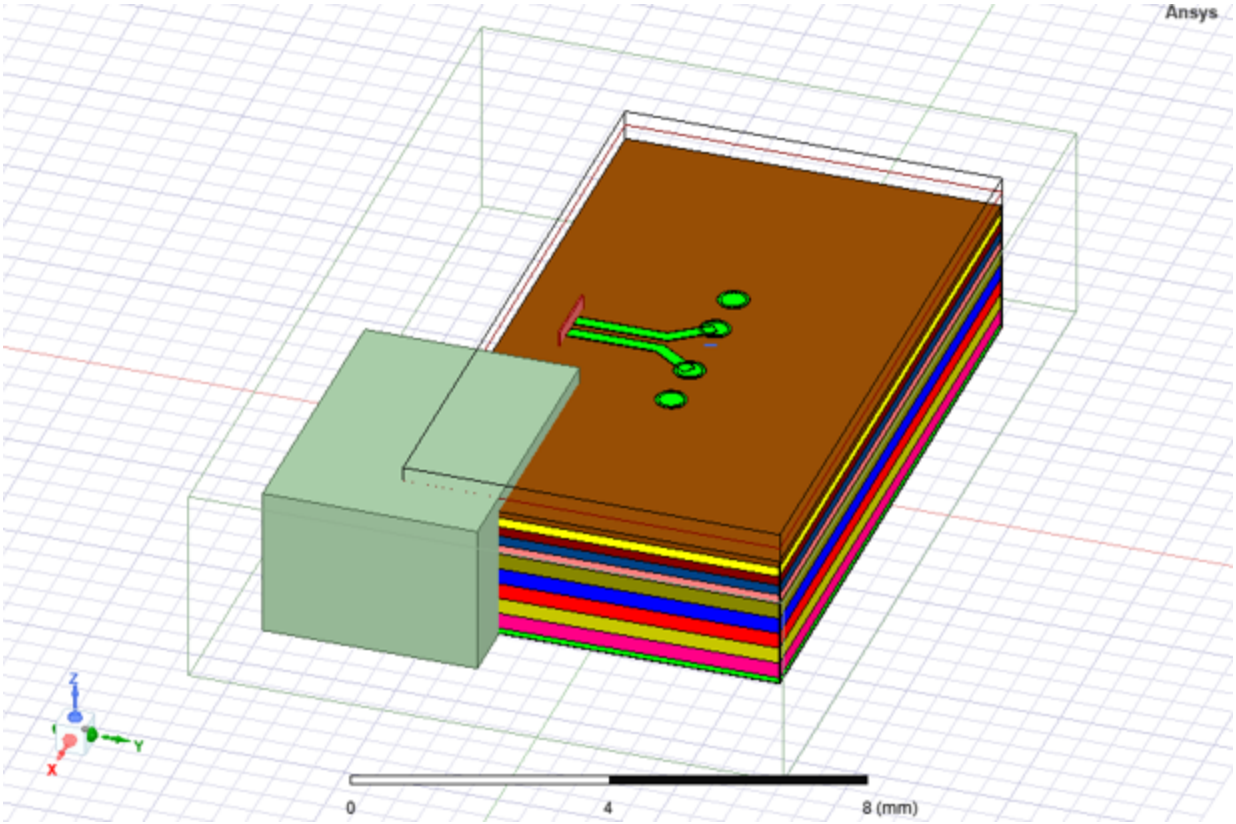


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

    - If the intersection portion has boundary assignment, the simulation will still report error
    - If two mesh fusion components intersect each other, the simulation will still report error
- Any overriding mesh setting appears in each component's property window.
- Mesh Fusion can share surface approximation operation between imprint face pairs that have curved outlines. Take surface approximations assigned on face, on body, and on the component level for both faces of the imprint pair and combine them to create the operation that results in finest mesh. This will only be done for face pairs that have classic mesh method on both sides. (TAU mesher does not support assigning surf approximation on planar faces, even if they have curved edges.) You can automatically assign 15 degrees normal angle to all shared mesh operations by env var ASSIGN_15_DEG_NORMAL_DEV_TO_CURVE_IMPRINT. This approach does not support array in native.
- You can generate field plots using data from either side of the boundary surfaces, using the "Adjacent side" check box on the Field Plot dialog, despite the sides belonging to different meshes and domains.

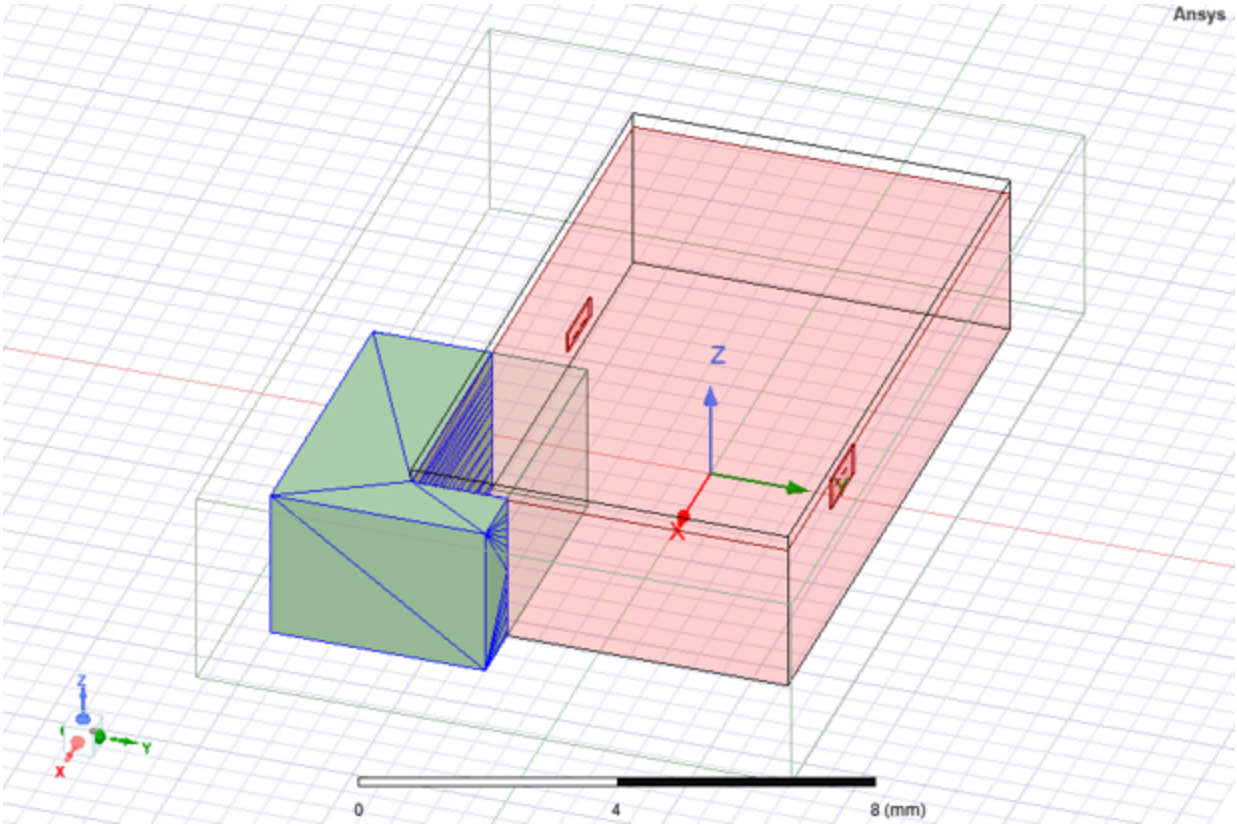
Layout components that are marked as Mesh Fusion also support the priority option. The priority option provides a way to resolve component intersection conflicts with native objects. If such intersection appears, the intersecting portion will be subtracted from the native object, so that the components marked as priority stay intact and the simulation could continue. For example, consider a design with layout component being intersected by a native box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If the priority option is not marked for this layout component, the simulation reports error. If the component is marked as priority, then the intersecting portion is subtracted from the native object, and the simulation can complete. You can plot mesh on the native objects to confirm that the subtraction is applied, and the mesh for the layout component marked as priority is intact.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

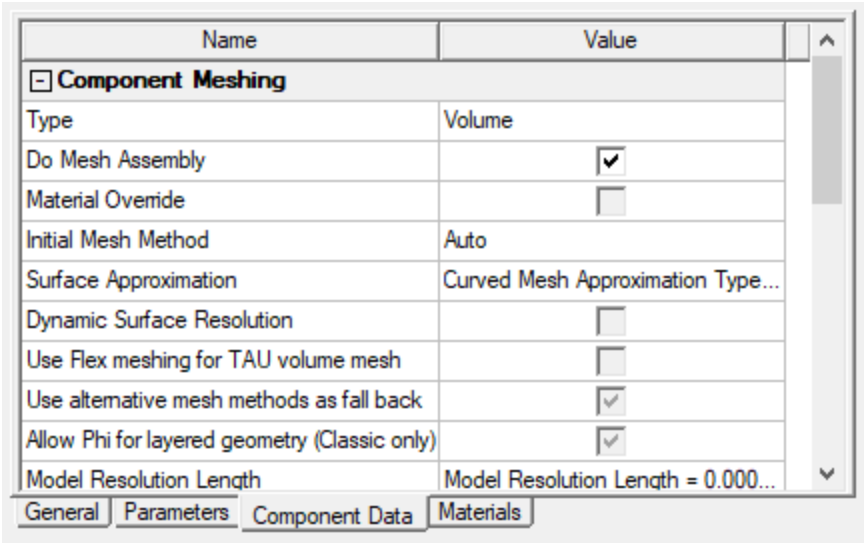


Some limitations of mesh regions include:

- Unless marked as Priority, Mesh region cannot intersect with each other or any non-assembly geometries.
- Mesh region cannot contain each other or any non-assembly geometries.
- Mesh region must have all planar faces.
- Any face of a mesh region cannot contact following boundaries:
  - port
  - boundaries with shell element enabled
  - boundaries containing spatial or temperature dependent material

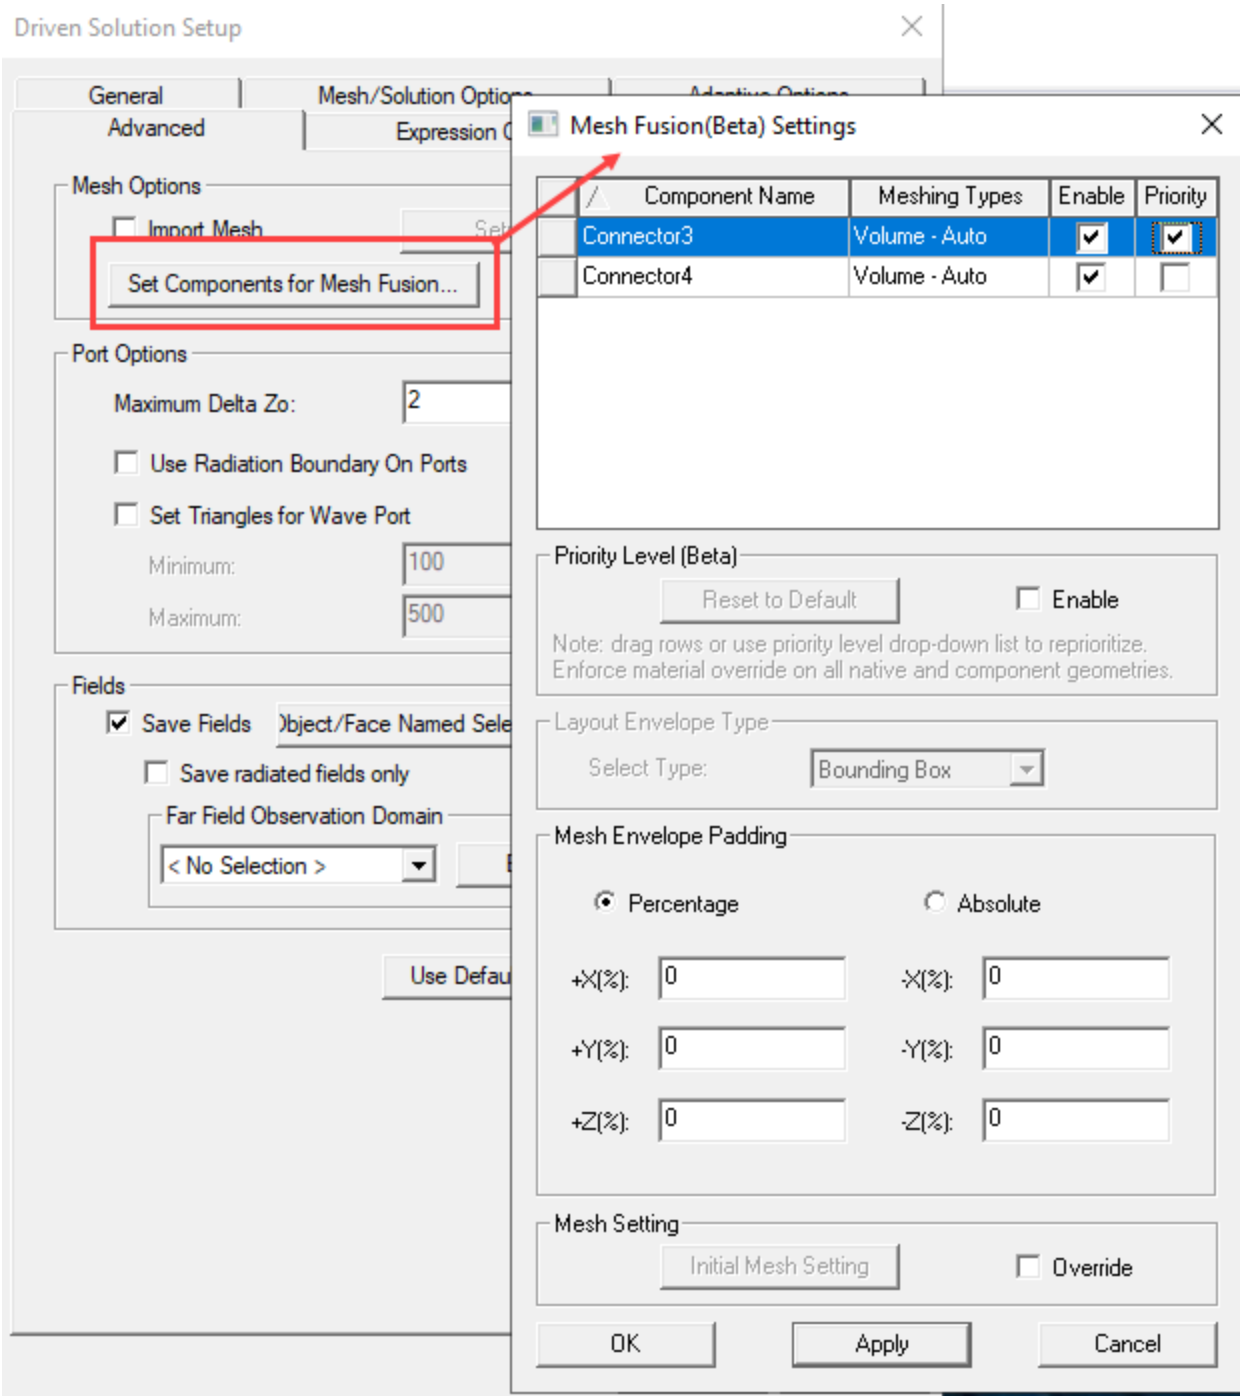
You can access the setting through **Component Meshing** properties.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can also access Mesh Fusion through the **Advanced** tab of the Solution Setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

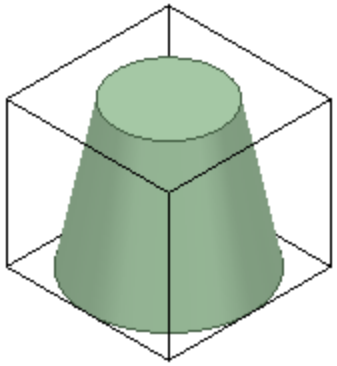


If a component does not meet the requirements for **Mesh Fusion**, the feature is disabled in the **Do Mesh Fusion** dialog and the **Component Meshing** properties.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mesh Envelope Padding for Components without a User-defined Mesh Envelope

For each component used in mesh fusion, a tight bounding box is automatically created in the component's target coordinate system. This tight region box is referred as 'mesh envelope'. You can visualize such mesh envelope from the modeler window. See the example below.



To override this automation, users can manually assign mesh region to a single solid solve-inside model object which must contain all geometries in the design. Manual mesh region is needed in following scenarios:

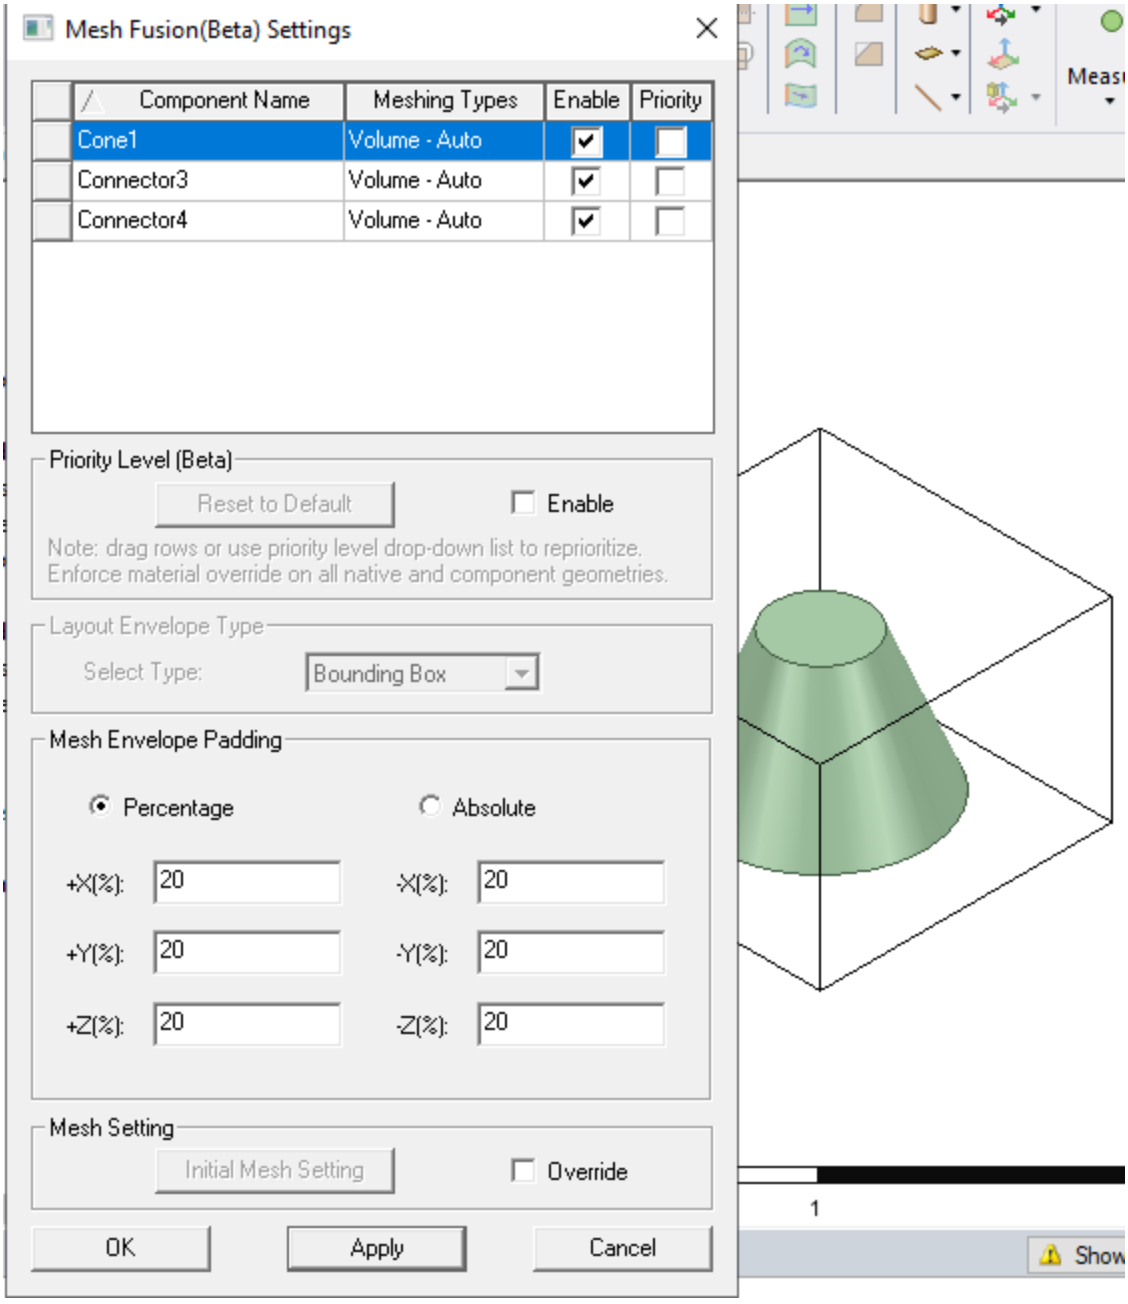
- To avoid overlap with native geometry or another component
- To avoid contact with internal faces when possible. This will improve mesh quality leading to better solver performance.

For each component without a manually assigned mesh envelope, users can add padding to its mesh envelope in all 6 directions.

Note: The Mesh Envelope padding is applied in the component reference coordinate system. That is, think of the padding as applied in layout before bringing the component into HFSS.

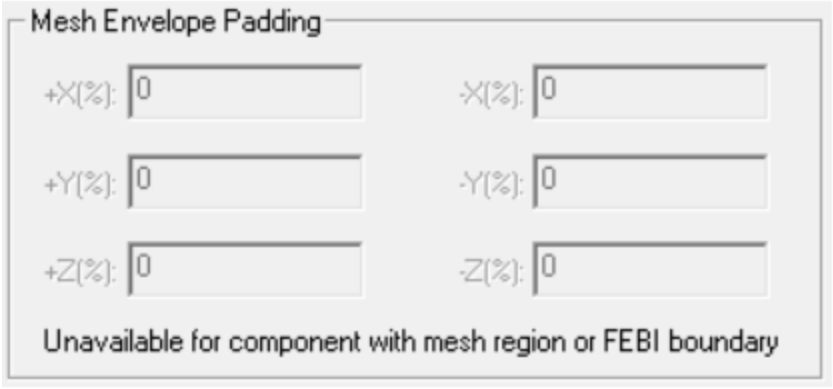
The example below shows the same component discussed above with 20% padding added to all directions of its mesh envelope.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If a component has user-defined mesh envelope or is not a FEM volume component, the mesh envelop padding is disabled with a warning message.

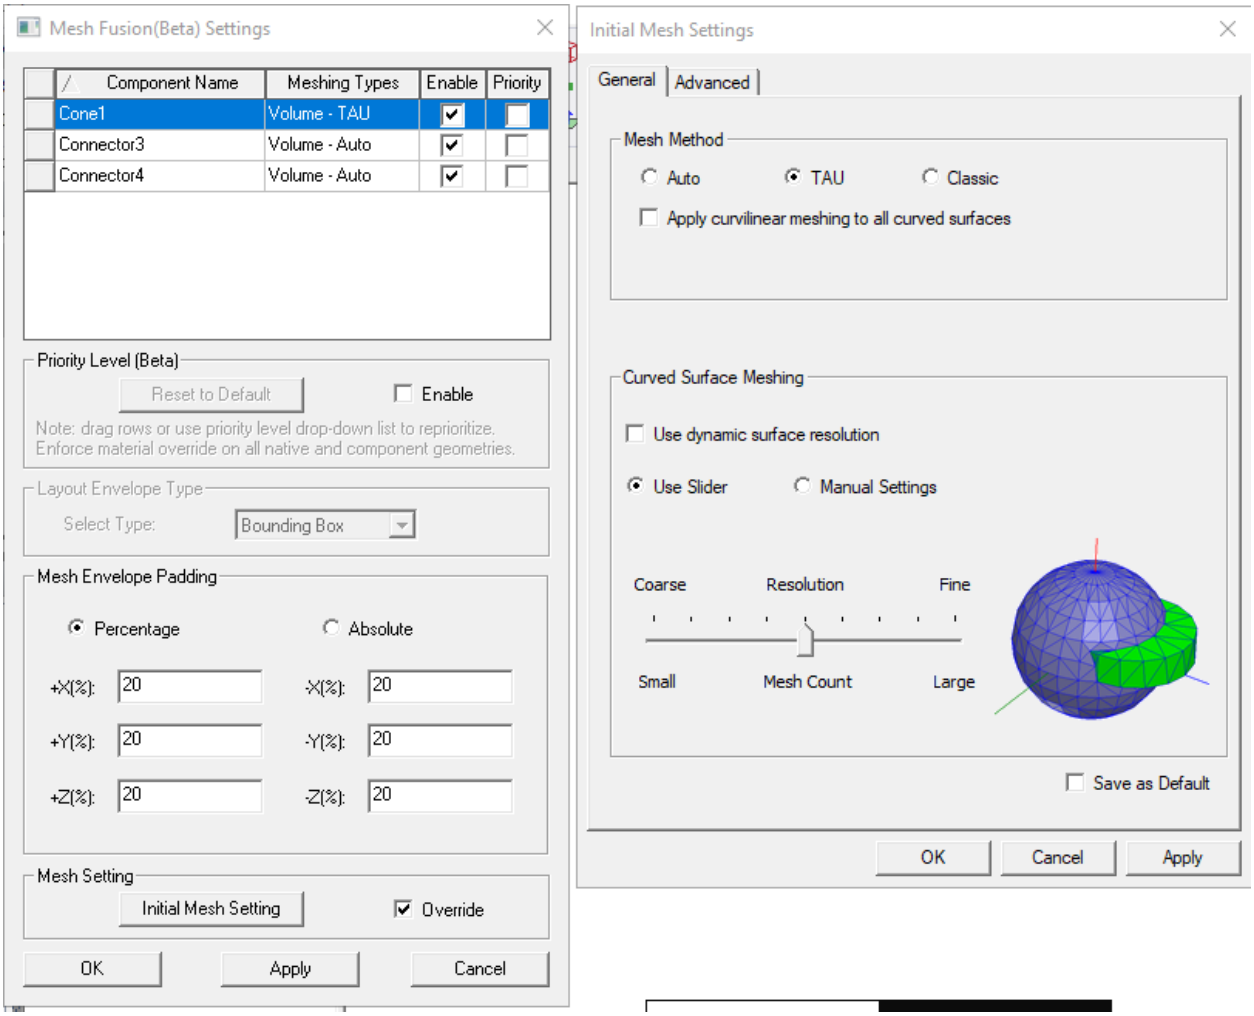
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Mesh Method Override

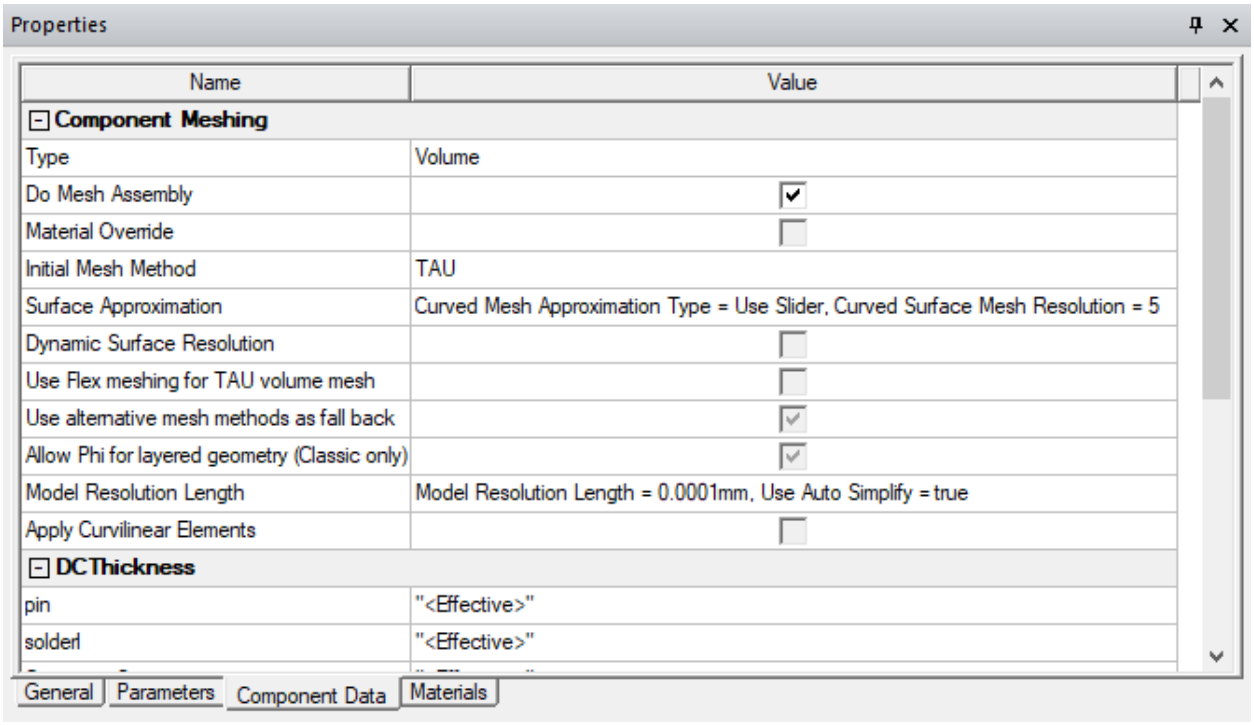
You can override the mesh method from the component definition in the **Mesh Fusion Setting** dialog box, accessed either through the **3D Component** shortcut menu in the **Project** tree, or the Advanced tab of the an **Advanced Solution Setup**. This lets you deal with potential mesh failure based one specific mesh method when doing assembly meshing. If a failure happens using one method, you can easily switch the mesh method and try again. Selecting a component in the **Mesh Fusion Setting** dialog enables the region, where can check Override, and then select, Auto, TAU, or Classic. For convenience, the dialog also displays each component's meshing method in its Meshing Type column.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



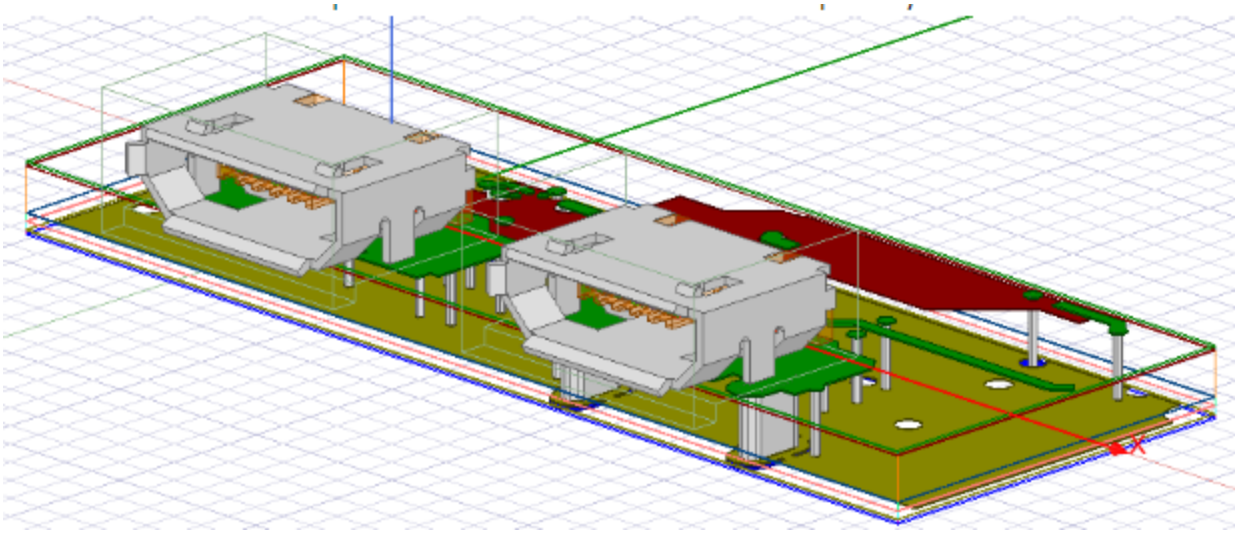
The Component Mesh settings will appear in the Component **Properties** window, **Component Data** tab.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



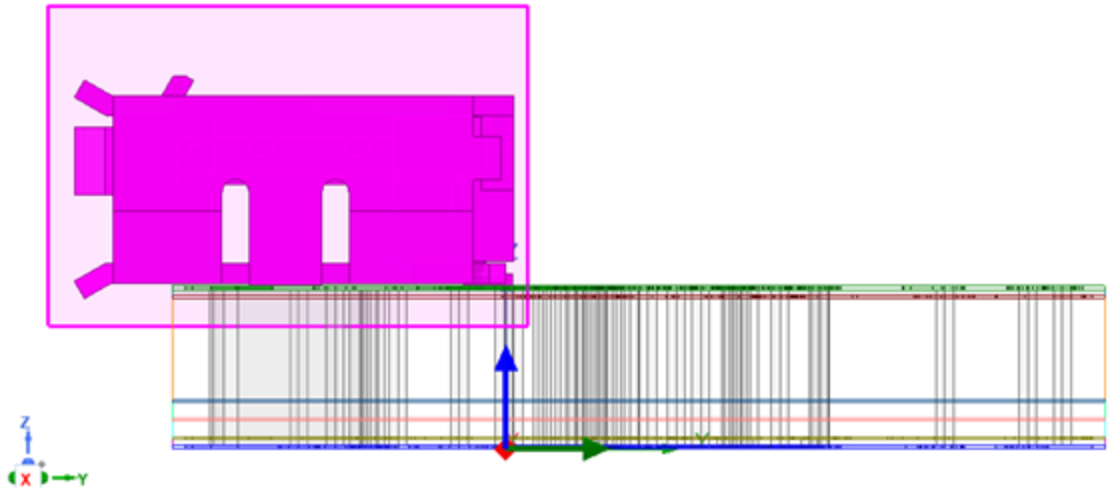
Example 1: USB Socket using Priority Level

In the following example design, there are two micro-USB's mounted on a mother board. The 2 USB's are from two 3D components, and the mother board is from a third 3D component. Users would like to mark each of the three components as mesh fusion to mesh them separately.

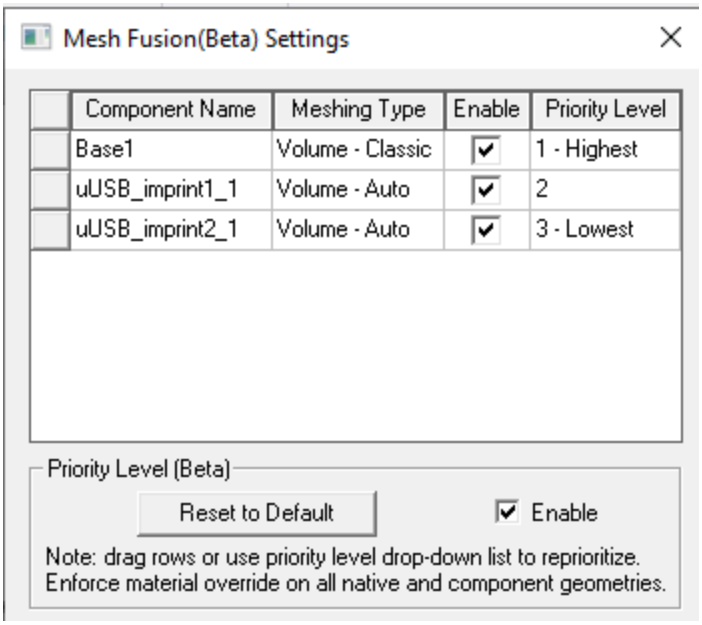


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

However, there are intersections in the design that must be resolved to use the mesh fusion technology. The below figure shows the right-side view of the design. The USB components have mesh fusion envelopes that intersect with the mother board. To resolve such intersections, the old way would be to manually cut out some bottom portion of the USB's mesh fusion envelope.

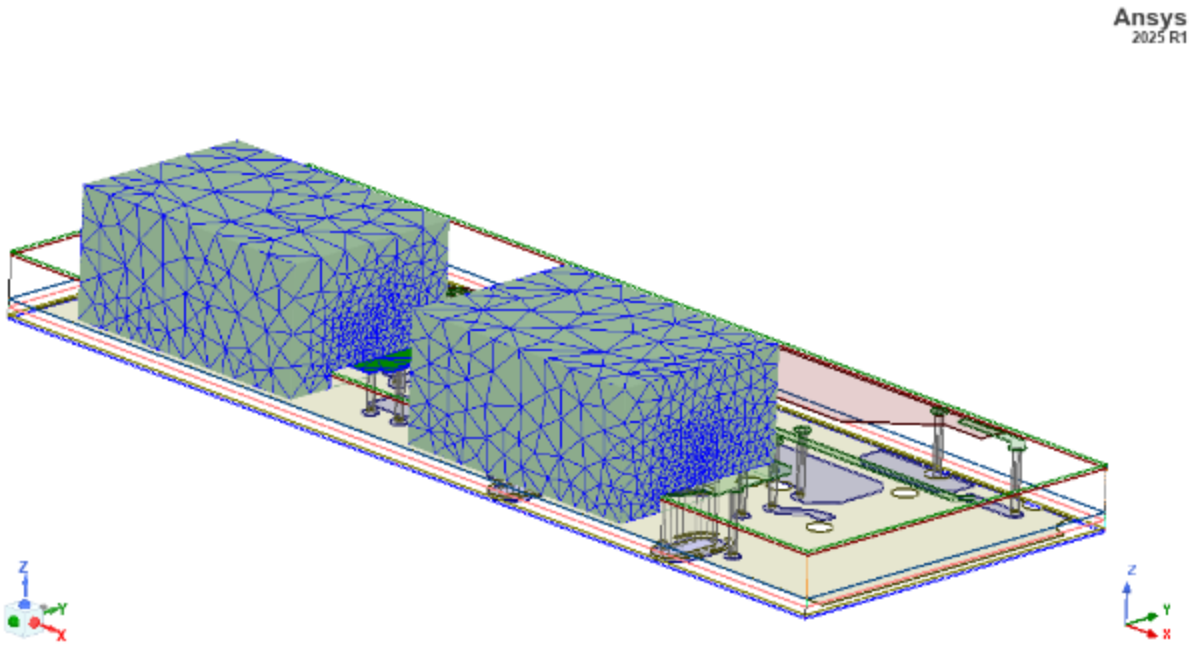


Using Priority Level, resolving such intersections is made easy. You can open the **Set Do Mesh Assembly** dialog and enable the component priority level. Then, you can assign the mother board component with the highest priority level as follows.



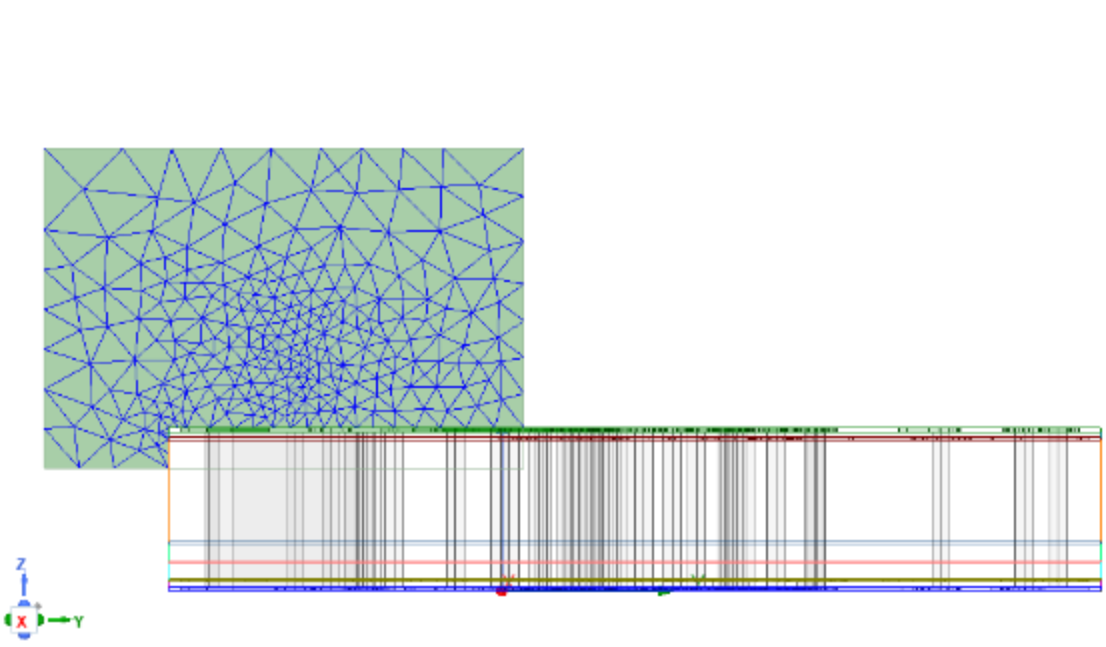
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

By doing so, the intersection is automatically resolved during simulation. According to the rules discussed in the earlier section, the mesh fusion envelope of the mother board component will cut off the mesh fusion envelopes of the USB components. The mesh plot of the USB components; envelopes is shown as follows.

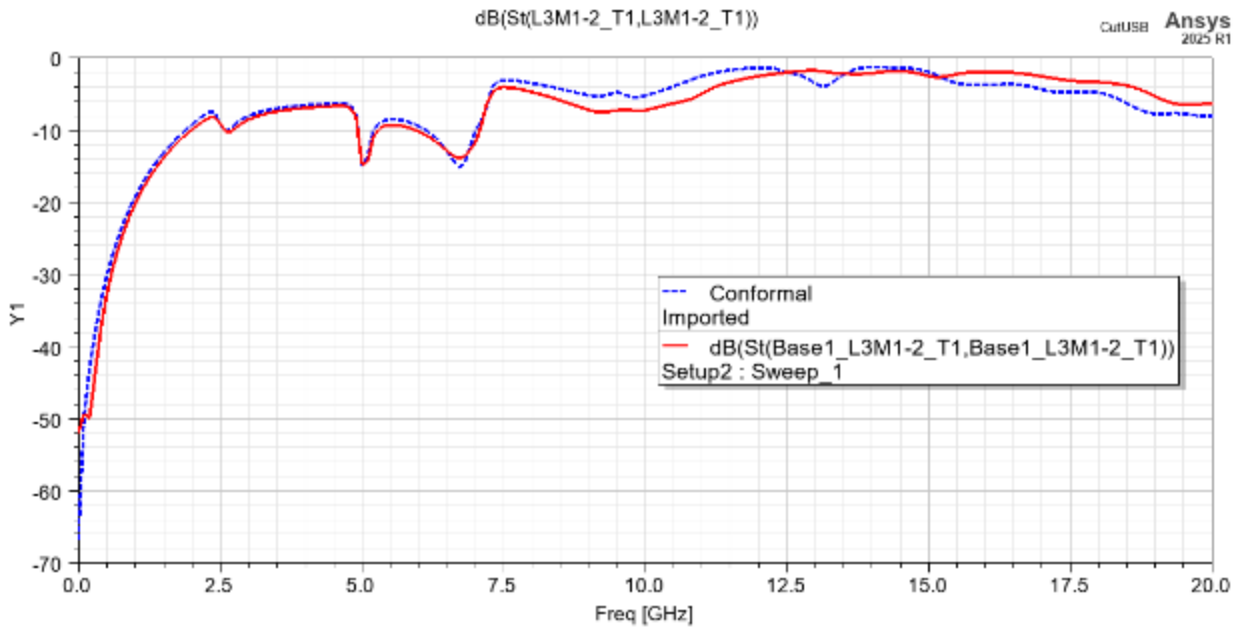


It is clear that the intersection is resolved by cutting the intersecting portion off the USB components' envelopes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



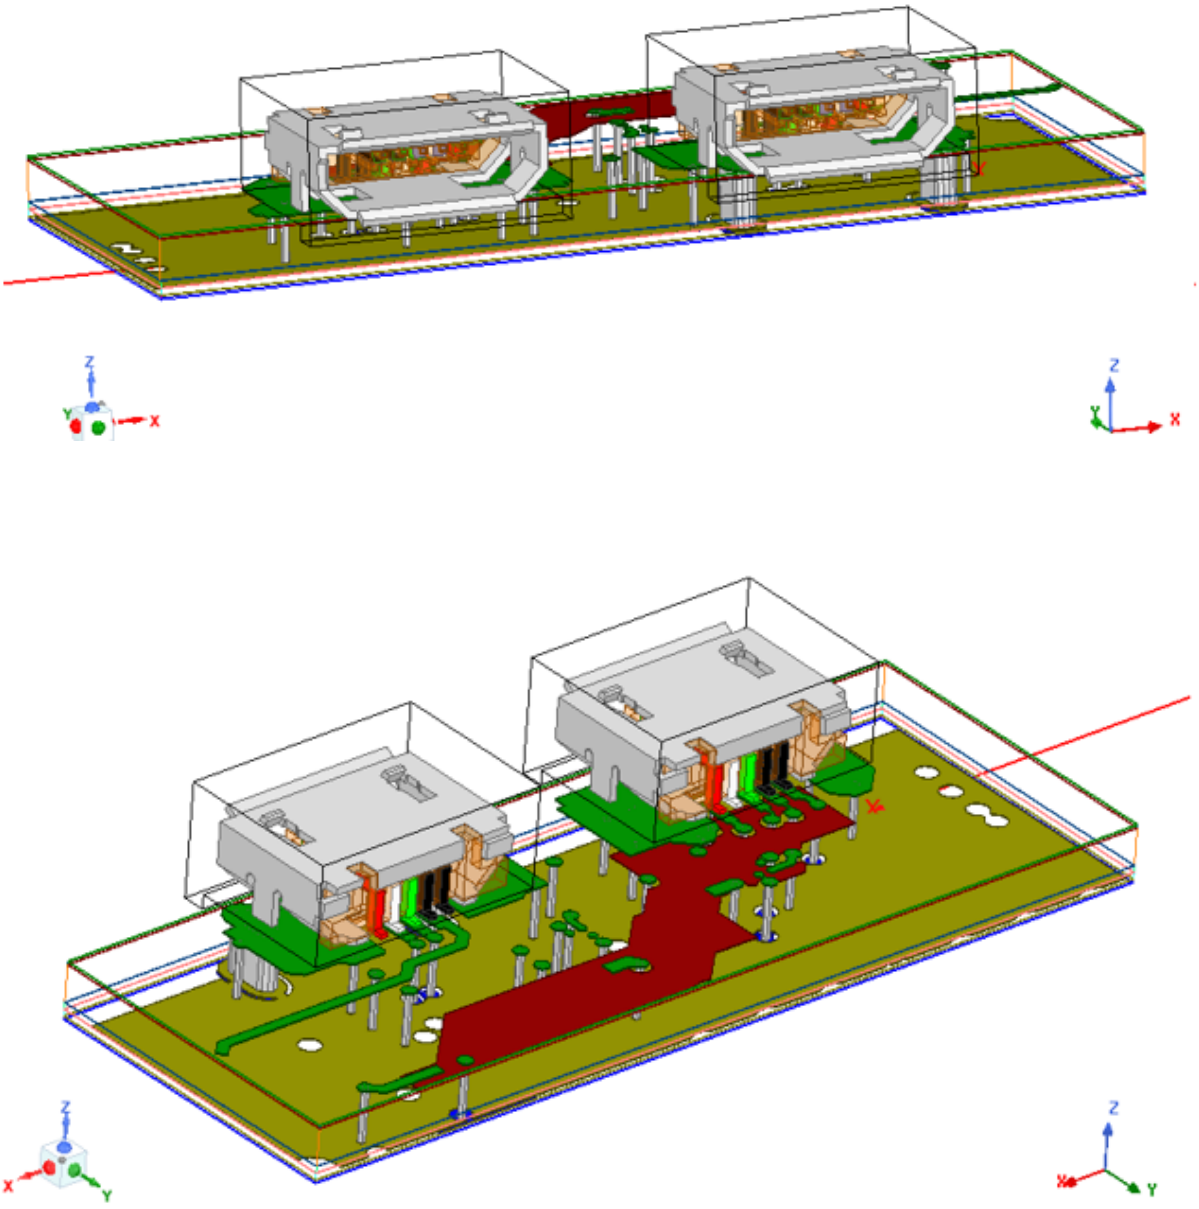
The simulation result of this case highly agrees with the result where all mesh fusion is turned off.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

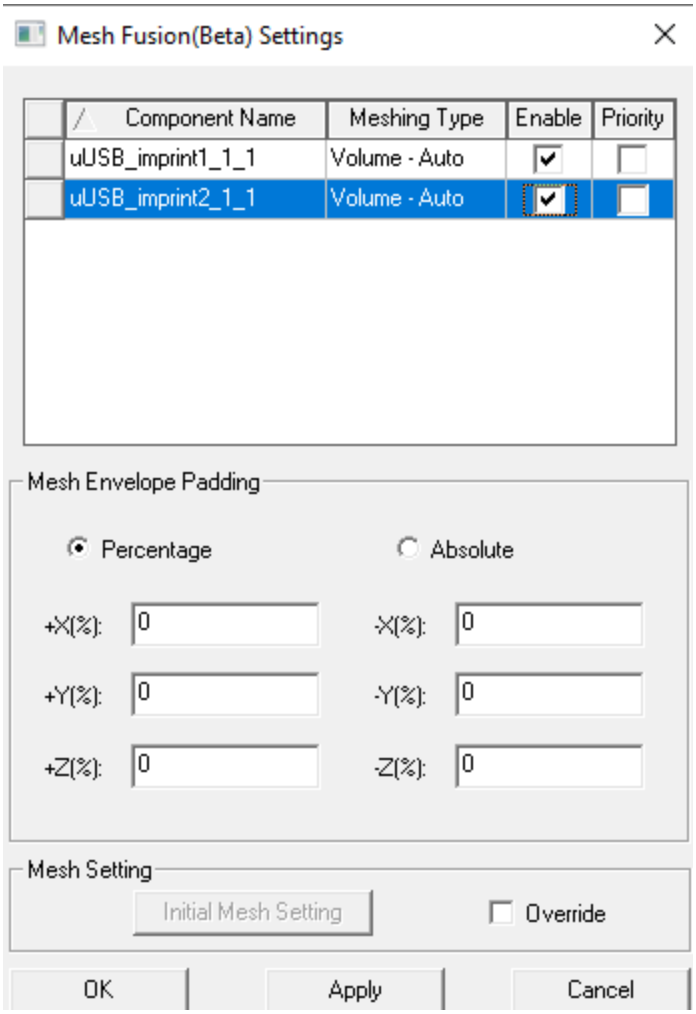
Example 2: USB Socket using Simple Priority

This example shows a circuit board with two USB sockets. The USB sockets are FEM components with custom defined air box as mesh regions.



You can set the **Do Mesh Fusion** property of each components by accessing the **Do Mesh Fusion** dialog through the **Project** tree shortcut menu for 3D Components.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The plots below show the comparison of terminal S parameters between designs in which the components are set for mesh fusion (solid line) or not (dashed line).

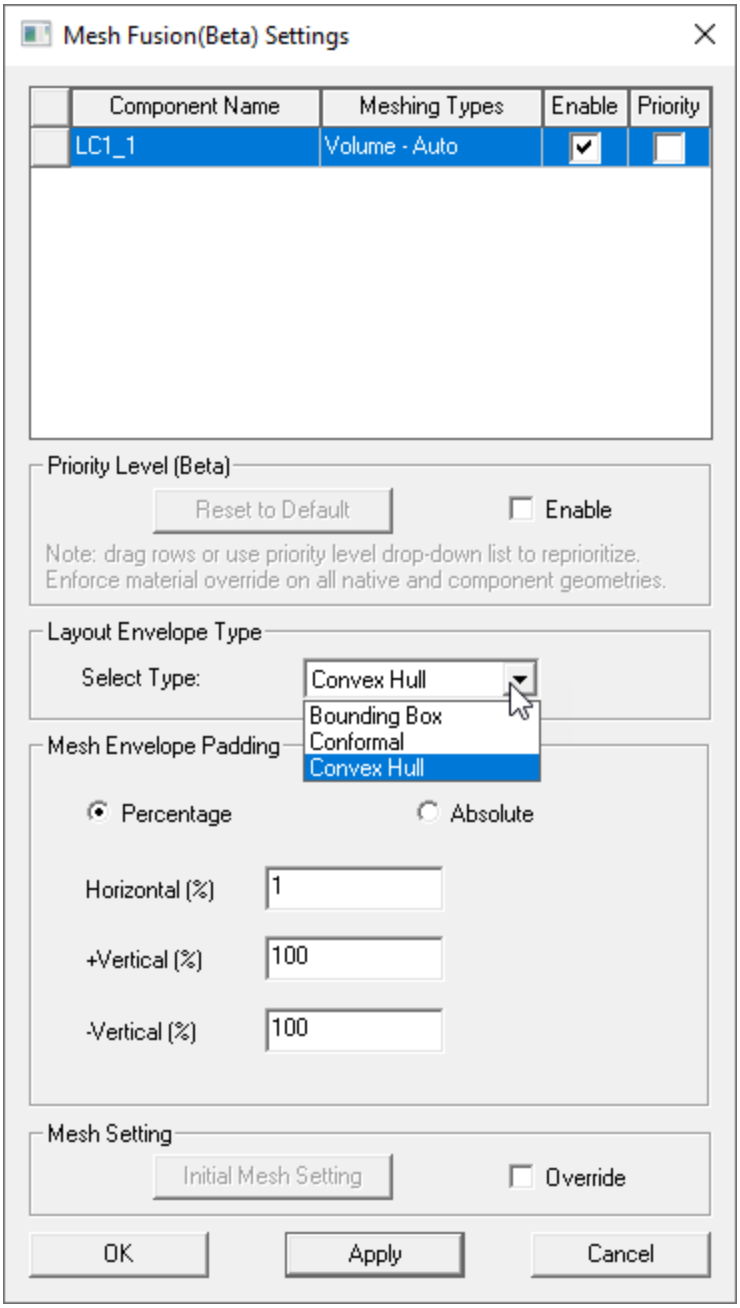
Mesh Region Options for Layout Component

When you select a component for Mesh Fusion a mesh region is required to define the meshing boundaries between this component and native geometries. The choice of the mesh region directly affects the quality of the resulting mesh. Layout Component includes envelope options that allow flexibility in handling Layout Component meshing including Bounding Box, Conformal, and Convex Hull.

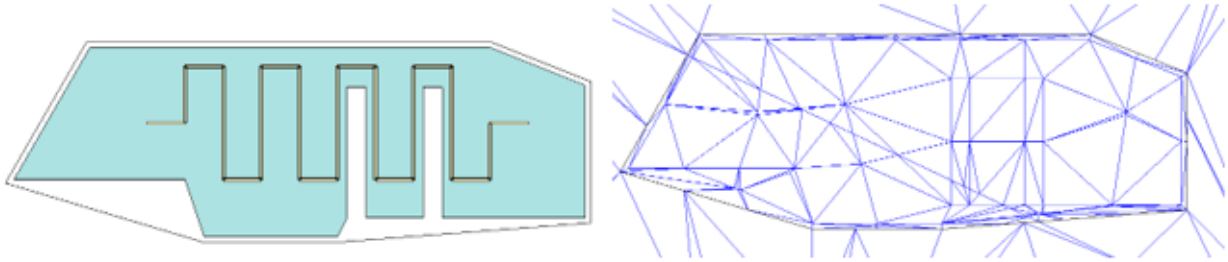
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



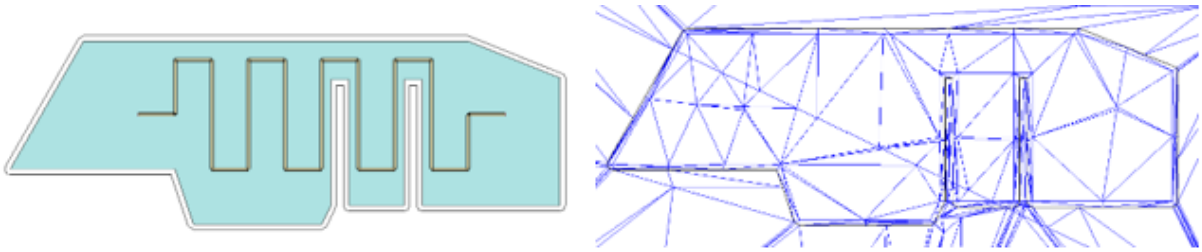
The shape of the envelope respects the dielectric extent chosen for a layout component. To better demonstrate the envelopes, the following layout component has conformal dielectric extent defined.

Convex Hull Envelope Example

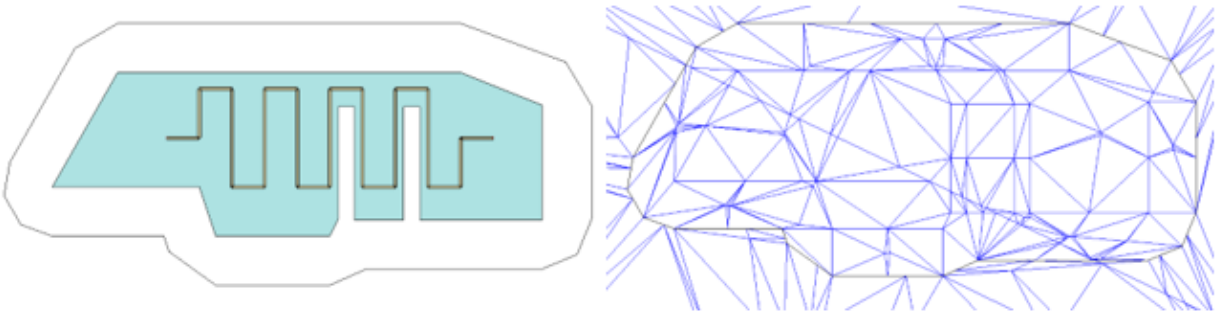
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Conformal Envelope Example



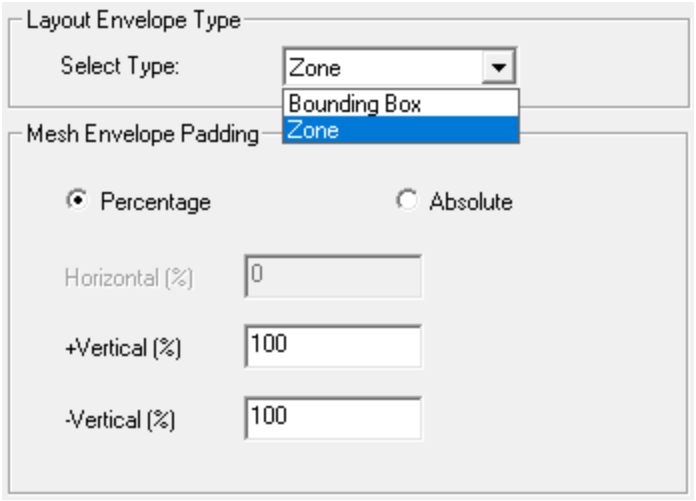
Conformal envelopes may cause meshing issues, especially for a geometry with small gaps, as shown above. In such cases, you can specify a larger padding as shown in the following example. Note that the gaps in the middle disappear in this case.



Options for Layout Component with Multizone stack up type

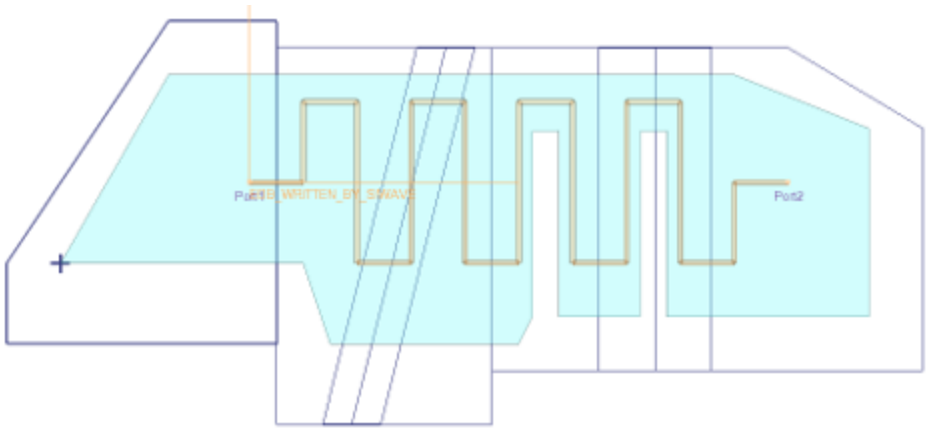
Mesh envelope options and padding choices for component with multizone stack up type include Bounding Box and Zone.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



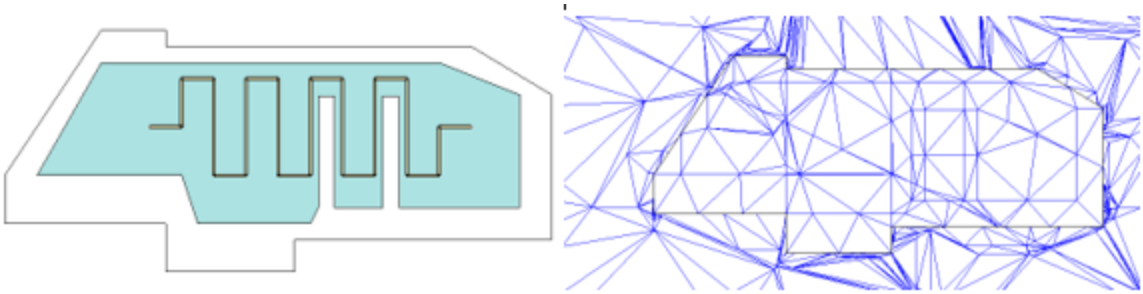
For Mesh Fusion, the Mesh Envelope can be specified as a percentage or as an absolute. If necessary, conversion from relative to absolute is done for Layout Component in HFSS when doing mesh assembly. For multizone stack up envelope padding, the conversion is based on the largest layer thickness across all zones.

The Zone envelope type respects the user-defined zone outlines in a layout component.

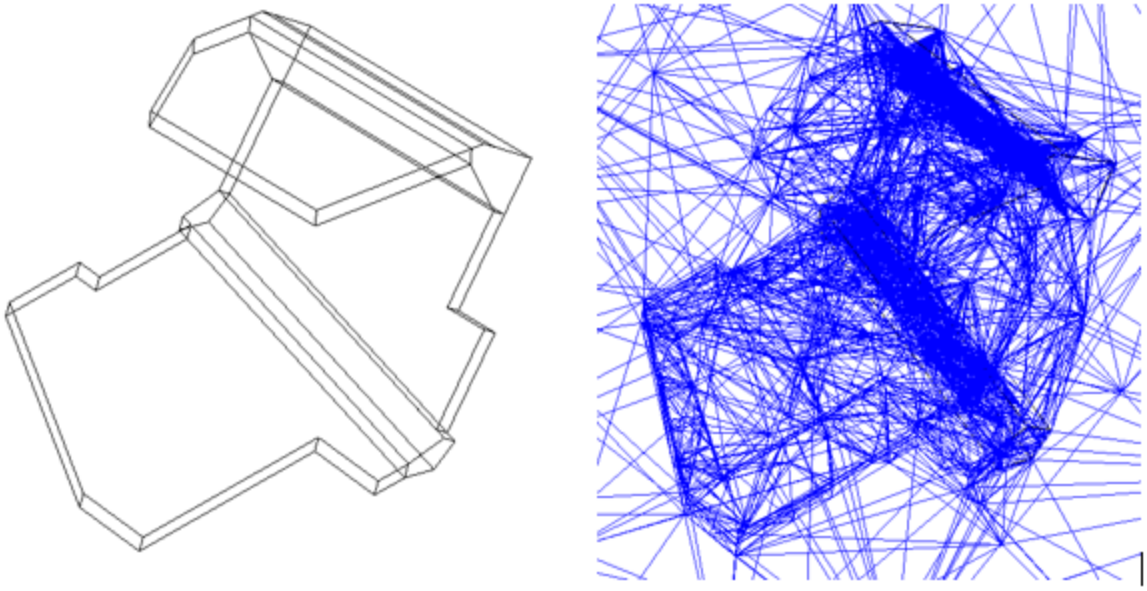


Layout component user-defined zone boundaries as well as flex bend definitions. The following Layout component shows Zone envelope type for an unbent configuration:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



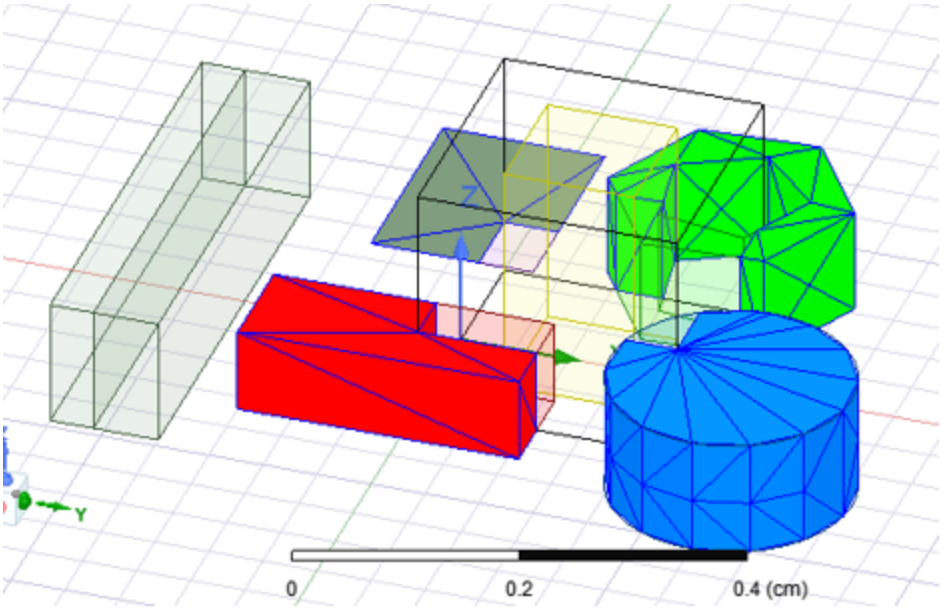
The next example shows layout component with a Zone envelope in for a bent configuration:



Component Priority

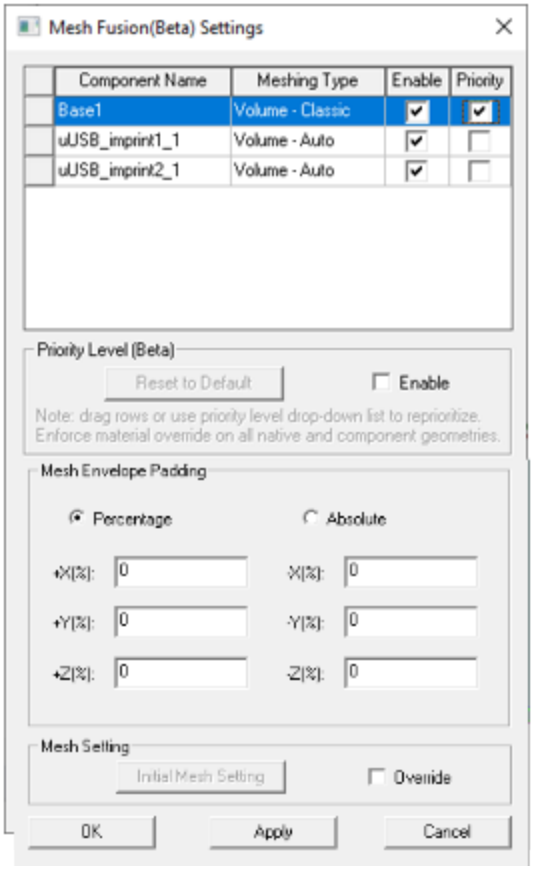
Component Priority provides a way to resolve component intersection conflicts with native objects. It is common for a large project to have some native objects intersect with mesh fusion/mesh assembly, or encrypted 3D components, that is components with a defined mesh region, due to user errors or modeling issues. Such intersections are usually small and would not affect simulation result if ignored, but they can stop simulations and cost much time to fix. To improve this problem, you can mark any of these components as priority. If such intersection appears, the intersecting portion will be subtracted from the native object, so that the components marked as priority stay intact and the simulation could continue.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



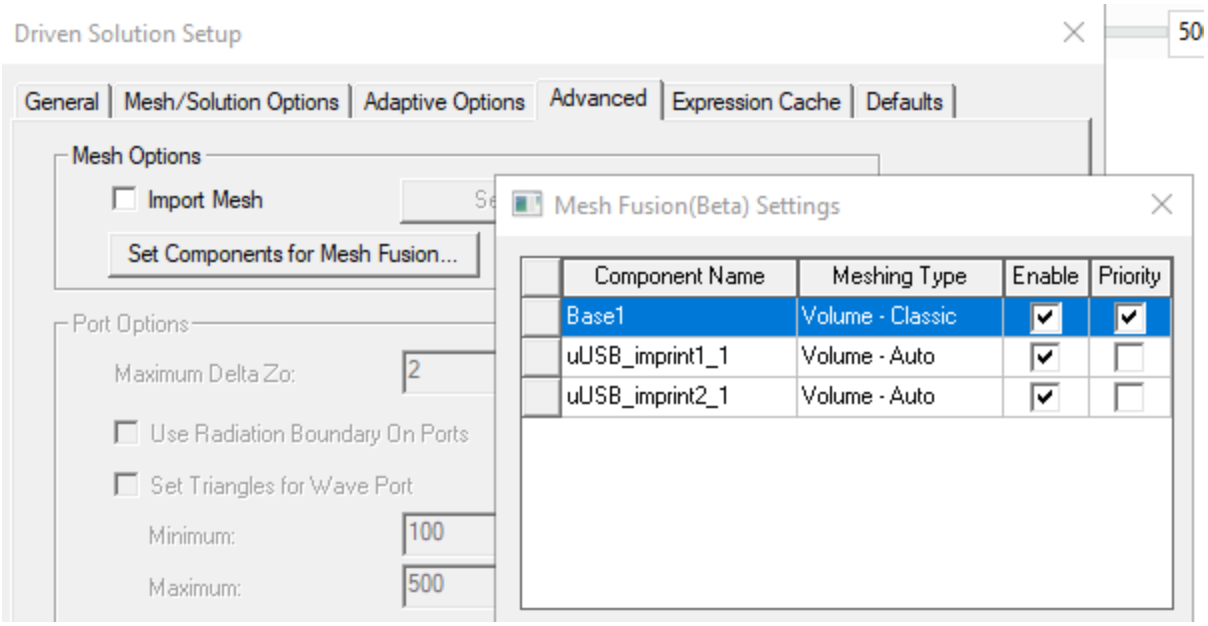
You can mark any component as priority as long as it has defined mesh region. This feature does not support array or SBR+ solution type. You access the feature through either the dialogs for the Set Components for Mesh Assembly... command or the Set Components for Mesh Fusion... commands.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can also access these dialogs through the **Advanced** tab of the Solution Setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The components for which you can set priority include:

- Components with mesh region manually assigned. This feature also supports encrypted components because the subtraction will not expose any of their internal data.
- Components marked as mesh fusion (They will have mesh envelopes automatically generated).
- Layout components in 3D if they are marked as mesh fusion.

The subtraction only works on normal native objects.

- If the priority component is intersecting with an object from a component marked with priority as well, or from a component marked as mesh fusion/mesh assembly, or from an encrypted component, then the setup is invalid, and the simulation reports an error.
- If the intersection portion has boundary assignment, the setup is invalid, and the simulation reports an error
- When one component's Mesh Fusion envelope contains another component's Mesh Fusion envelope, the smaller envelope subtracts the larger envelope. This leaves a cavity in the larger envelope, and the smaller envelope resides in the cavity. Both components can mesh using Mesh Fusion technology and assembled back to the overall mesh. Component Priority supports nested containment
- When a layout component having lower priority is intersected by other components with higher priority, the intersection portion from the layout component is cut out and meshed

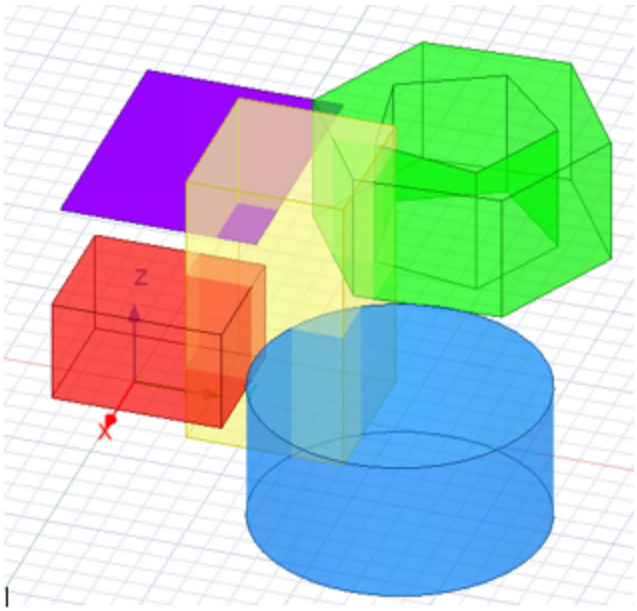
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

together with the other component. The non-intersection portion of the layout component is meshed separately.

- Cutting the layout component must be in a direction parallel to the layout component's local z-axis, and the cut must have all straight edges.
- Does not support encrypted layout component and Flex PCBs
- This feature does not support array or SBR+ solution type.

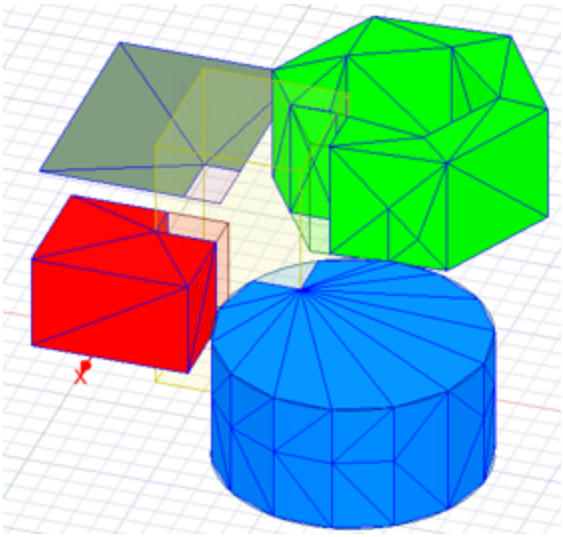
The steps to process priority components will be saved to a file in the initial mesh folder and the current mesh folder, together with steps to generate mesh fusion imprints (if any). This file will be used to generate identical mesh in the future.

For example, consider a simple design with a component (yellow box) being intersected by many native objects.

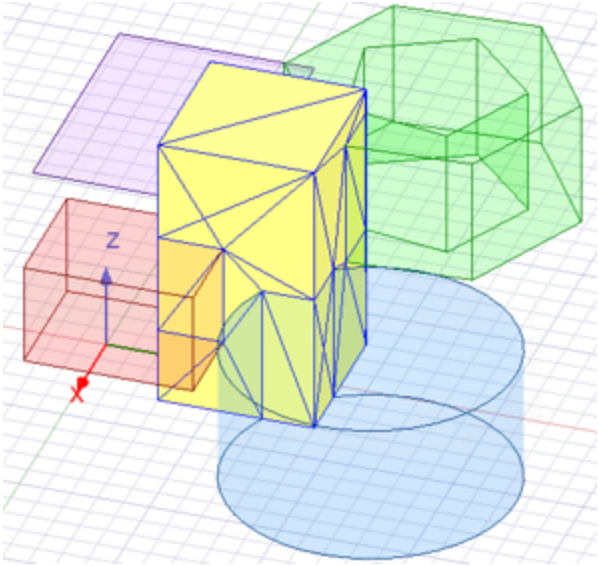


If the priority is not marked for this component, and that component intersects native object, the simulation will report error. If the component is marked as priority. Then the intersecting portion will be subtracted from the native object, and the simulation could complete. Users can plot mesh on the native objects to confirm that the subtraction is applied.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The mesh for the component marked as priority is intact.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28 - HFSS Technical Notes

The simulation technique used to calculate the full 3D electromagnetic field inside a structure is based on the finite element method. Although its implementation is largely transparent, a general understanding of the method is useful in making the most effective use of HFSS.

The HFSS Technical Notes provide an overview of the finite element method and its implementation in HFSS. They also describe how modal S-parameters are computed from the simulated electric and magnetic fields and how they can be converted to "nodal" or "voltage" based pseudo-S-parameters used in circuit theory.

Information is included on the following:

- The Finite Element Method
- The HFSS Solution Process
- Domain Decomposition
- S-Parameters
- Radiated Fields
- Geometric Objects
- Boundaries
- Derivatives
- Integral Equation Method Used in IE Regions
- HFSS SBR+ Technical Overview
- Transient Solution Theory
- Excitations
- Materials
- Best Practices for Accurate and Causal Broad Band Frequency Sweeps
- Parametric Analysis
- Sensitivity Analysis
- Tuning Analysis
- Modes to Terminals Conversion
- Large Scale DSO Theory

The Finite Element Method

In order to generate an electromagnetic field solution, HFSS employs the finite element method. In general, the finite element method divides the full problem space into thousands of smaller regions and represents the field in each sub-region (element) with a local function.

In HFSS, the geometric model is automatically divided into a large number of tetrahedra, where a single tetrahedron is a four-sided pyramid. This collection of tetrahedra is referred to as the finite element mesh.

Representation of a Field Quantity

Rectilinear Elements and Curvilinear Elements

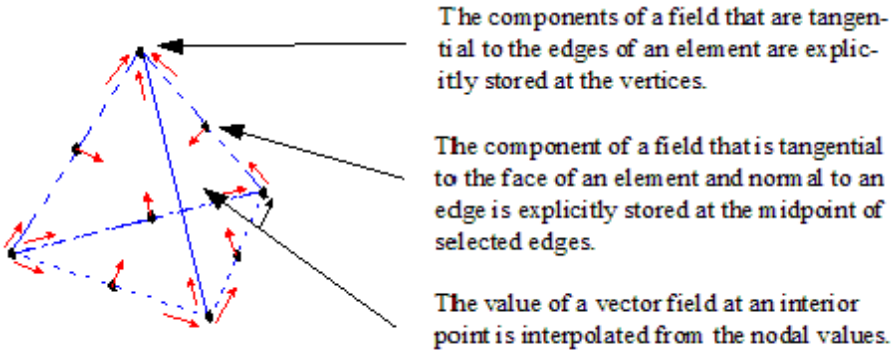
Basis Functions

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Size of Mesh Vs. Accuracy

Representation of a Field Quantity

The value of a vector field quantity (such as the H-field or E-field) at points inside each tetrahedron is interpolated from the vertices of the tetrahedron. At each vertex, HFSS stores the components of the field that are tangential to the three edges of the tetrahedron. In addition, HFSS can store the component of the vector field at the midpoint of selected edges that is tangential to a face and normal to the edge (as shown below). The field inside each tetrahedron is interpolated from these nodal values.



By representing field quantities in this way, the system can transform Maxwell's equations into matrix equations that are solved using traditional numerical methods.

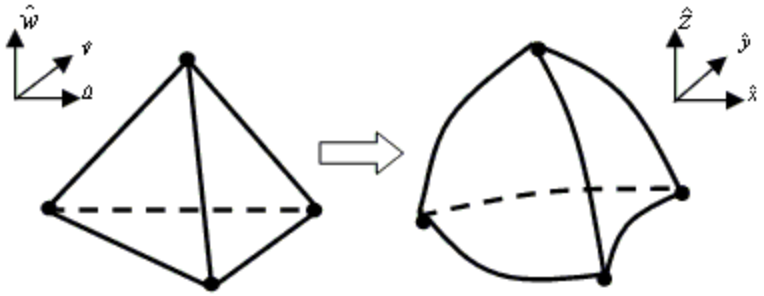
Rectilinear Elements and Curvilinear Elements

In the Finite Element Method (FEM), the physical domain is subdivided into many small elements. In the global coordinates (x, y, z), the field quantities to be solved are expanded by a set of basis functions. Since the basis functions are associated with each element, it is more convenient to write them in the local coordinates (u, v, w), which are independent of the shape of the element. The local coordinates and the global coordinates are linked by a transformation through a so-called Jocobian.

If the transformation is linear, the elements are called rectilinear elements, with straight edges and planar faces; if the transformation is non-linear, such as quadratic or cubic, the elements are called curvilinear elements, with curved edges and/or curved faces. So the curvilinear elements are a more general type of elements than their rectilinear counterparts. While they may not always conform exactly to the curved boundaries, the curvilinear elements conform better with less number of elements than the rectilinear ones. As a result, they generate more accurate and usually faster FEM solutions.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$J = \begin{bmatrix} \frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} & \frac{\partial z}{\partial u} \\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} & \frac{\partial z}{\partial v} \\ \frac{\partial x}{\partial w} & \frac{\partial y}{\partial w} & \frac{\partial z}{\partial w} \end{bmatrix}$$



Basis Functions in HFSS

Various interpolation schemes, or basis functions, can be used to interpolate field values from nodal values.

- A first order tangential element basis function interpolates field values from both nodal values at vertices and on edges.

First order tangential elements have 20 unknowns per tetrahedron.

- A zero order basis function makes use of nodal values at vertices only — and therefore assumes that the field varies linearly inside each tetrahedron.

Zero order tangential elements have six unknowns per tetrahedron.

- A second order tangential element interpolates field values from nodal values at vertices, on edges and on faces.

Second order tangential elements have 45 unknowns per tetrahedron.

- Mixed order assigns basis function elements based on the need for higher accuracy in different parts of the model.

Size of Mesh Vs. Accuracy in HFSS

There is a trade-off among the size of the mesh, the desired level of accuracy, and the amount of available computing resources.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The accuracy of the solution depends on the size of each of the individual elements (tetrahedra). Generally speaking, solutions based on meshes using thousands of elements are more accurate than solutions based on coarse meshes using relatively few elements. To generate a precise description of a field quantity, each element must occupy a region that is small enough for the field to be adequately interpolated from the nodal values.

However, generating a field solution involves inverting a matrix with approximately as many elements as there are tetrahedra nodes. For meshes with a large number of elements, such an inversion requires a significant amount of computing power and memory. Therefore, it is desirable to use a mesh fine enough to obtain an accurate field solution but not so fine that it overwhelms the available computer memory and processing power.

To produce the optimal mesh, HFSS uses an iterative process, called an adaptive analysis, in which the mesh is automatically refined in critical regions. First, it generates a solution based on a coarse initial mesh. Then, it refines the mesh in areas of high error density and generates a new solution. When selected parameters converge to within a desired limit, HFSS breaks out of the loop.

The HFSS Solution Process

To calculate the S-matrix associated with a structure with ports, HFSS does the following:

- Divides the structure into a finite element mesh.
- Computes the modes on each port of the structure that are supported by a transmission line having the same cross-section as the port.
- Computes the full electromagnetic field pattern inside the structure, assuming that one mode is excited at a time.
- Computes the generalized S-matrix from the amount of reflection and transmission that occurs.

The resulting S-matrix allows the magnitude of transmitted and reflected signals to be computed directly from a given set of input signals, reducing the full 3D electromagnetic behavior of a structure to a set of high frequency circuit parameters.

The Mesh Generation Process

Reverting to the Initial Mesh

Seeding the Mesh

Guidelines for Modifying Surface Approximation Settings

Meshing Region Vs. Problem Region

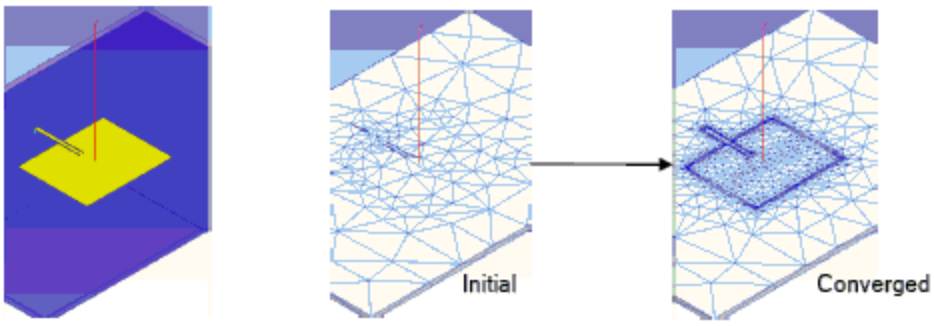
Mesh Refinement on Ports

Model Resolution

The Mesh Generation Process

Following is the general mesh generation process:

1. An initial mesh is generated and includes surface approximation settings. If necessary, the mesher will automatically perform any repairs needed to recover an accurate mesh representation of a model. The solution profile will indicate when mesh repairs have been made, and the results of these repairs will be displayed per object in the mesh statistics panel.
2. If lambda refinement was requested, the initial mesh is refined based on the material-dependent wavelength.
3. Any mesh operations that were defined are used to refine the mesh.
4. If ports were defined, the 2D mesh is refined iteratively.
5. Using the resulting mesh, the electromagnetic fields are computed that exist inside the structure when it is excited at the solution frequency.
6. If you are performing an adaptive analysis, the current finite element solution is used to estimate the regions of the problem domain where the exact solution has strong error. Tetrahedra in these regions are refined.
7. Another solution is generated using the refined mesh.
8. The error is recomputed, and the iterative process (solve — error analysis — adaptive refinement) repeats until the convergence criteria are satisfied or the maximum number of adaptive passes is completed.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9. If a frequency sweep is being performed, then the problem is solved at the other frequency points without further refining the mesh. An adaptive solution is performed only at the specified solution frequency.

> **Note:**
>
> An initial mesh is not generated each time it starts the solution process. The initial mesh is generated only if a current mesh is unavailable.

Seeding the Mesh

In HFSS, mesh operations are optional mesh refinement settings that enable you to provide HFSS with engineering guidance based on your knowledge of the parts of the model geometry that are critical to the structure's electromagnetic performance. Providing such guidance prior to beginning the adaptive analysis process can reduce (sometimes extensively) the number of passes necessary to converge upon a field solution as well as the final number of tetrahedra in the mesh for that solution. Although adaptive analysis convergence targets areas where field behavior is found, refining the mesh using more than the standard criteria, such as material characteristics, can result in finding areas of critical field behavior as soon as the first few passes are solved.

The technique of guiding the mesh construction is referred to as "seeding" the mesh. Seeding is performed using the **Mesh** commands on the **HFSS** menu.

You can instruct HFSS to refine the length of tetrahedral elements on a surface or within a volume until they are below a certain value (length-based mesh refinement) or you can refine the surface triangle length of all tetrahedral elements on a surface or volume to within a specified value (skin depth-based mesh refinement.) These types of mesh operations can be defined at any time. If you apply them before the adaptive solution process, they are used to refine the initial mesh after it has been generated. You can also choose to generate a mesh without solving, in which case mesh operations are applied to the current mesh.

In a few circumstances, you may also want to define a mesh operation that modifies the surface approximation settings for one or more faces. Surface approximation settings are only applied to the initial mesh.

Guidelines for Seeding the Mesh

While seeding the mesh is not required, it is useful in the following conditions:

- Seeding the mesh inside a volume in the model geometry where regions of strong electric or magnetic fields (with strong capacitive or inductive loading) are expected. Examples include a capacitively loaded gap in a resonant structure, sharp waveguide angles or corners, or gaps between multi-coupled lines in filter structures.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Seeding the mesh on every face of higher aspect ratio boundaries, such as long PCB traces or on the surfaces of long wires. Spacing the mesh points roughly equal to the trace width of the wire diameter enables you to more accurately capture the behavior of the high-aspect structure from the first adaptive pass.

Length-Based Mesh Refinement Process

When you request length-based mesh refinement, you instruct HFSS to refine the length of tetrahedral elements until they are below a specified value. The length of a tetrahedron is defined as the length of its longest edge.

You can specify the maximum length of tetrahedra on faces or inside of objects. You can also specify the maximum number of elements that are added during the refinement. When the initial mesh has been generated, the refinement criteria you specified will be used to refine the initial mesh.

Skin Depth-Based Mesh Refinement

When you request skin depth-based mesh refinement, you instruct HFSS to refine the surface triangle length of all tetrahedral elements on a face to within a specified value. A layered mesh is created based on the surface mesh. The layers are graded based on the skin depth and number of layers you specify.

During skin depth-based mesh refinement, HFSS creates a series of layers that are planes parallel to the object face, and that are spaced within the specified skin depth. For each point on the surface of the face, a series of points (P0, P1, P2, ..., Pn) are added to the mesh, where n is the number of layers. P0 is the point on the surface and the distance from P0 to Pn is the skin depth. The points are spaced in a non-uniform manner, with the distance between them decreasing in a geometric progression, as you move from Pn to P0.

For example, if

Skin Depth:	12 mm
Number of Layers of Elements:	4

then

Distance [P0,P1]:	0.8 mm
Distance [P1,P2]:	1.6 mm
Distance [P2,P3]:	3.2 mm

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Distance [P3,P4]:	6.4 mm
Distance [P0,P4]:	0.8 + 1.6 + 3.2 + 6.4 = 12 mm

The skin depth-based refinement first satisfies the surface triangle edge length criterion, then introduces the series of points to each additional layer. If a limit has been placed on mesh growth, one of the following happens:

- The limit is set high enough to complete the skin depth refinement.
- The limit is set high enough to satisfy the surface triangle edge length criterion, but not high enough to complete the depth seeding.
- The limit is not set high enough to satisfy even the surface triangle edge length criterion.

Because refining by skin depth can add many seeding points, you should first refine the surface of the object using length-based mesh refinement to obtain an accurate count of the number of points HFSS will add when refining by skin depth. This allows you to reach the surface edge length criterion and approximate the number of elements in the mesh and the number of points on the surfaces before proceeding to skin depth seeding.

The refinement criteria you specified are used to refine the current mesh.

Surface Approximation Settings

Object surfaces in HFSS may be planar, cylindrical or conical, toroidal, spherical, or splines. The original model surfaces are called *true surfaces*. To create a finite element mesh, HFSS first divides all true surfaces into triangles. These triangulated surfaces are called faceted surfaces because a series of straight line segments represents each curved or planar surface.

For planar surfaces, the triangles lie exactly on the model faces; there is no difference in the location or the normal of the true surface and the meshed surface. When an object's surface is non-planar, the faceted triangle faces lie a small distance from the object's true surface. This distance is called the *surface deviation*, and it is measured in the model's units. The surface deviation is greater near the triangle centers and less near the triangle vertices.

The normal of a curved surface is different depending on its location, but it is constant for each triangle. (In this context, "normal" is defined as a line perpendicular to the surface.) The angular difference between the normal of the curved surface and the corresponding mesh surface is called the *normal deviation* and is measured in degrees.

The *aspect ratio* of triangles used in planar surfaces is based on the ratio of circumscribed radius to the in-radius of the triangle. It is unity for an equilateral triangle and approaches infinity as the triangle becomes thinner.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can modify the surface deviation, the maximum permitted normal deviation, and the maximum aspect ratio of triangles settings on one or more faces at a time in the **Surface Approximation** dialog box. (Click **HFSS** > **Mesh Operations** > **Assign** > **Surface Approximation**.)

The surface approximation settings are applied to the initial mesh.

> **Note:**
>
> For the initial mesh, all the vertices of the triangles lie on the true surfaces. During mesh refinement all the points are first added to the faceted surface for all products, not to the true surfaces. Then, for all Maxwell projects and for curvilinear meshing enabled HFSS projects , the points on the faceted surfaces will be moved to the curved surface locations when such movement does not degrade the quality of the mesh.

Guidelines for Modifying Surface Approximation Settings

If you intend to modify the surface approximation settings for an object face or faces, keep the following guidelines in mind:

- When necessary, override the default surface approximation settings to represent curved surfaces more accurately. More accurate representation will increase the mesh size and consume more CPU time and memory. The default settings are adequate for most circumstances.
- If you want to obtain a faster solution by using a cruder representation of curved surfaces, set the coarser setting for the whole object, not just a single face.
- It is difficult to satisfy aspect ratio demands if the aspect ratio value is set close to 1 because an arbitrary shape cannot be filled with only equilateral triangles. Therefore, setting the aspect ratio to 1 can lead to unreasonably large meshes. The aspect ratio is limited to 4 for planar objects and 1.2 for curved objects.

Meshing Region Vs. Problem Region

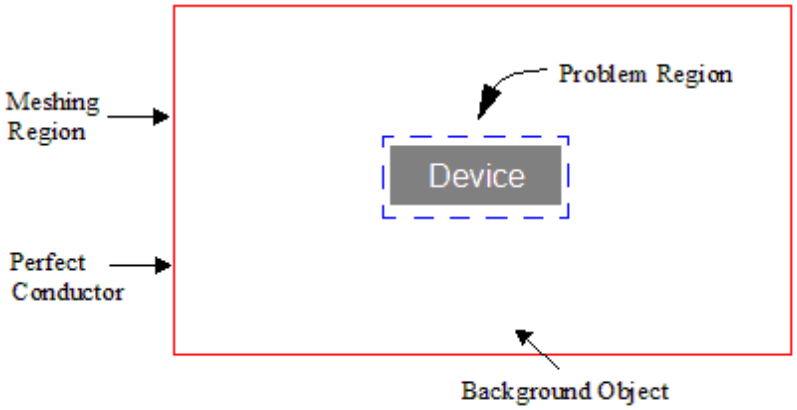
HFSS distinguishes between the problem region and the meshing region. The *problem region* is the region in which the solution is generated and the mesh is refined. The *meshing region*, which includes the problem region, is the area in which an initial mesh is generated. After an initial mesh is generated, the mesh is refined only in the problem region.

The problem region encompasses an area that is just large enough to include the entire design, but no larger. HFSS automatically defines the problem region during the solution process. If you are interested in effects outside of the structure, such as radiated effects, then you can create a virtual object to expand the size of the problem region to include these areas.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The meshing region, like the problem region, is a box that completely encloses the structure. However, the meshing region must be at least 10 times larger than the model. The part of the meshing region not occupied by objects is considered to be the *background* object. The background extends to the boundaries of the meshing region and fills in any voids not occupied by objects. Because the background object is defined as a perfect conductor, no solution is generated inside the background even though an initial mesh is generated for it. HFSS automatically defines the meshing region during the solution process.

The problem region and the meshing region are illustrated below.



Model Resolution

Model Resolution is a setting that determines the smallest details of a model that the mesher should capture and represent in the mesh.

Many times the analysis starts with the geometry already drawn in a different tool for different purpose. Some tools are designed for manufacturing and the resulting models contain lots of extra details not needed for electromagnetic analysis. If the user removes such details in the original tool the results will be better. But if the user does not have access to the original drawing tool or redrawing the model without these details is not possible, **Model Resolution** is another way to remove the details from analysis.

When the user sets the model resolution length to be L, the mesher will start with a surface representation of the model accurate to the modeler's tolerance limit. Then it will progressively remove edges, move points, merge points etc., within the allowable model resolution limit and simplify the surface mesh. During this process, tiny fillets, rounds, and chamfer protrusions are removed.

Other common model translation anomalies are also handled using **Model Resolution**. For example, some geometry engines will blindly export all of the surfaces as splines. When a user imports such a model for analysis, it would result in very large number of triangles. If the surface

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

can be represented by a smaller set of triangles using Model Resolution, this procedure would reduce the number of triangles in the surface mesh.

The user can start with a model resolution length around 0.1*wavelength. If the model resolution length chosen by the user is too large, the mesher will detect it and report it as an error. The model resolution length is specified in the user units of the modeler. It can be set on selected bodies only. The default value is 100* the tolerance limit of the modeler.

Port Solutions

The excitation field pattern at each port must be calculated before the full 3D electromagnetic field inside a structure can be calculated. HFSS calculates the natural field patterns (or modes) that can exist inside a transmission structure with the same cross-section as the port. The resulting 2D field patterns serve as boundary conditions for the full 3D problem.

- Excitation Fields
- Wave Equation
- Mesh Refinement on Ports
- Modes
- Multiple Ports on the Same Face
- Port Accuracy
- Calculating Characteristic Impedance
- Complex Propagation Constant

Excitation Fields

HFSS assumes that each port is connected to a uniform waveguide that has the same cross-section as the port. A waveguide supports an infinite number of modes with a given field pattern and propagation constant.

Therefore, the excitation field is one of the modes specified for a port where mode *m* can be expressed by:

$$\boldsymbol{E}_m(x,y,z,t) = \Re\left[\boldsymbol{E}_m(x,y)e^{j\omega t-\gamma_m z}\right] \quad (1)$$

where

- $\Re$ is the real part of a complex number or function.
- **Em**(x,y) is the electric field mode pattern of mode *m*.
- $\gamma_m=\alpha_m + j\beta_m$ is the complex propagation constant of mode *m*, where
- α_m is the attenuation constant of mode m.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- β_m is the propagation constant of mode m that determines, at a given time *t*, how the phase angle varies with z.
- $\omega = 2\pi f$ is angular frequency of oscillation,
- *j* >is the imaginary unit, $\sqrt{-1}$.

In this context, the x- and y-axes are assumed to lie in the cross-section of the port; the z-axis lies along the direction of propagation.

Wave Equation

The field pattern of a traveling wave inside a waveguide can be determined by solving Maxwell's equations. For each mode m, the port solver solves the following equation obtained from Maxwell's equation.

$$\nabla\times\left(\frac{1}{\mu_r}\nabla\times\boldsymbol{E}_m(x,y)e^{-\gamma_m z}\right)-k_0{}^2\varepsilon_r\boldsymbol{E}_m(x,y)e^{-\gamma_m z}=0 \qquad (1)$$

where

- $k_0 = \omega/c$ is the wave number of free-space
- $\mu_r(x,y)$ is the complex relative permeability.
- $\varepsilon_r(x,y)$ is the complex relative permittivity.

By solving the equation, the electric field mode pattern $E_m(x,y)$ and the propagation constant γ_m are both obtained for all the modes specified for a given port. For the current based impedance calculations, the port solver also solves independently for $H_m(x,y)$ using a corresponding equation for the magnetic field.

Also note that the excitation field pattern computed by the port solver is valid only at a given frequency. A different excitation field pattern is computed for each frequency point of interest.

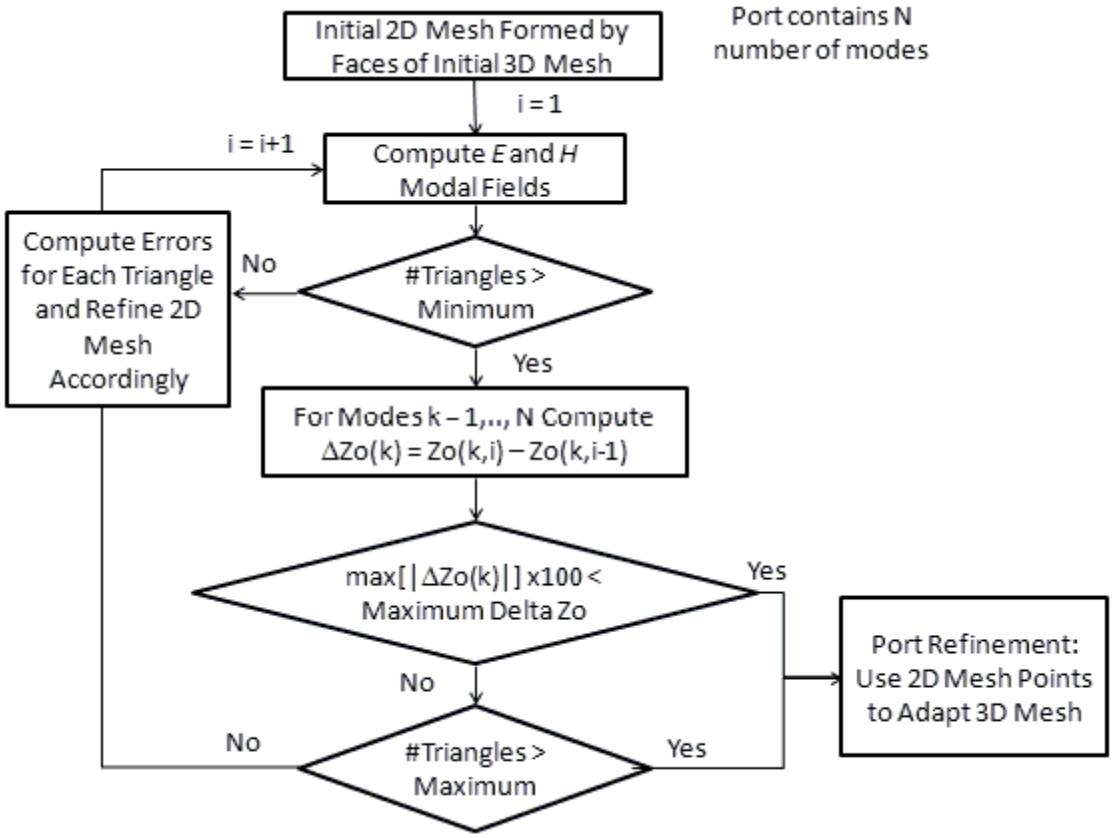
Mesh Refinement on Ports

The port solver computes mode patterns and propagation constants based on solutions of a finite element system of equations. The finite element mesh associated with each port is a 2D mesh of triangles corresponding to the faces of the tetrahedra that lie on the planar port surface. The port solver performs an iterative refinement of the triangular mesh.

User settings for the iterative refinement can be found under Port Options in the **Advanced** tab of the **Solution Setup** window. Those settings are reflected in the flow chart below that describe the refinement procedure where #Triangles refer to the number of triangles of the current mesh in the refinement process. The numerical implementation of $\Delta Zo(k)$ in the flow chart is actually based on relative difference when $|Zo(k)| > 1.0$. Moreover, for terminal projects the comparison

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

is done for each entry of the terminal characteristic impedance matrix rather than the modal impedances such that the worst entry in the impedance matrix satisfies the user specified value.



For a good technical discussion of the port solution procedure, refer to the following:

Jin-Fa Lee, Din-Kow Sun, and Zoltan J. Cendes, "Full-Wave Analysis of Dielectric Waveguides Using Tangential Vector Finite Elements," *IEEE Transactions on Microwave Theory and Techniques*, vol. 39, No 8, August 1991.

Modes

For a waveguide or transmission line with a given cross-section, there is a series of basic field patterns, or modes, that satisfy Maxwell's equations at a specific frequency. Any linear combination of these modes can exist in the waveguide. A user is responsible to specify the number of modes to be included in a wave port but not for lumped ports since they are restricted to contain only one mode. In general, in order to obtain accurate S-parameters the number of modes defined for a given port should be the same or greater than the number of propagating modes at the highest frequency of interest. Note that the port solver automatically determines what modes should be included based on the specified number of modes. The modes included in a port are based on a sorting criteria to extract the dominant set of modes out of the infinite set

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

of possible modes. If there is no prior knowledge to the number of propagating modes, the user can do a ports only solution while specifying a reasonably large number of modes and view the 'Gamma' values in the Matrix Data panel to determine what modes are propagating.

If a port is defined on a surface where there is a geometrical discontinuity in the normal direction of the port, it may not be enough to include only the propagating modes for accurate S-parameters. If possible, it is recommended to avoid this case by modeling a short section of the port transmission line such that all the higher order modes have decayed and do not contribute to the field on the port surface. The length of the constant cross-section segment that has to be included in the model depends on the value of the mode's attenuation constant, α.

Degenerate Modes

Degenerate modes refer to the case when a set of modes have the same complex propagation constant which means that any linear combination of those modes is still a valid set of natural (or eigen) modes. When you become aware that a wave port contains degenerate modes as a part of the requested modes, you should use the Mode Alignment feature in HFSS.

Multiple Ports on the Same Face

Visualize a port face on a microstrip that contains two conducting strips side by side as two separate ports. If the two ports are defined as being separate, the system simulates the case in which the two ports are connected to uncoupled transmission structures. It is as if a conductive wall separates the excitation waves. However, in actuality, there will be electromagnetic coupling between the two strips.

To model this coupling accurately, analyze the two ports as a single port with multiple modes. In general, if there are N disconnected conductors in the port cross-section, at least N - 1 modes are required for an accurate solution. For example, if the port consists of two adjacent microstrip lines surrounded by a conducting enclosure, N = 3; therefore at least two modes should be defined on the port. Assign an equal number of terminals as modes. Refer to Assigning Wave Ports for Terminal Solutions for more information.

If the multi-conductor port plane is near discontinuities within the 3D model, additional modes beyond *N* - 1 may be necessary. However, if you define terminals on a multi-conductor port, the presence of non-quasi transverse electromagnetic (TEM) modes will adversely affect the entries of any computed terminal matrices. Therefore, rather than increase the number of modes beyond the required *N* - 1, extend the port outward until any higher-order modes have sufficient attenuation to be omitted from consideration.

Port Accuracy

Generally, the port accuracy defaults**,** specified under the Port Options in the Advanced tab of the **Solution Setup** window, are adequate. You may want improved port accuracy under the following conditions:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- You are interested primarily in the port impedances. Port impedances are computed as part of the port solution.
- You need to lower the noise floor to catch S-parameters that are expected to be in the –70 dB range.

The port accuracy settings are only used for port adapt. If those settings are modified after port adapt nothing will happen. Therefore, to specify new port accuracy settings, add another solution setup and generate a new solution.

Refining the mesh at the ports causes HFSS to refine the mesh for the entire structure as well. This occurs because it uses the port field solutions as boundary conditions when computing the full 3D solution. Therefore, specifying too small a port field accuracy can result in an unnecessarily complex finite element mesh.

Calculating Characteristic Impedance

Each port in a structure being analyzed can be viewed as a cross-section of a transmission line. HFSS computes the characteristic impedance of each port in three ways — as Zpi, Zpv, and Zvi impedances. You have the option of specifying which impedance will be used in the renormalization calculations.

- For TEM waves, the Zvi impedance converges on the port's actual impedance and should be used.
- When modeling microstrips, it is sometimes more appropriate to use the Zpi impedance.
- For slot-type structures (such as inline or coplanar waveguides), Zpv impedance is the most appropriate.

HFSS will always calculate Zpi impedance, the impedance calculation using power and current, which are well-defined for a port because they are computed over the area of the port. Zpv and Zvi are not calculated by default. This is because V is computed by integrating along a user-defined integration line. To renormalize the solution to a Zpv or Zvi characteristic impedance, you must have defined an impedance line.

Under the **Matrix Data** tab of the **Solution Data** dialog box, the characteristic impedance can be displayed as magnitude/ phase, real/ imaginary, magnitude, phase, real, or imaginary.

For more information on the computation of impedances, refer to the following:

Bruno Bianco, Luigi Panini, Mauro Parodi, and Sandro Ridella, "Some Considerations about the Frequency Dependence of the Characteristic Impedance of Uniform Microstrips," *IEEE Transactions on Microwave Theory and Techniques*, vol. MTT-26 No. 3, March 1978.

Edward F. Kuester, David C. Chang, and Leonard Lewin, "Frequency-Dependent Definitions of Microstrip Characteristic Impedance," *International URSI Symposium on Electromagnetic Waves*, Munich, 26-29 August 1980, pp. 335 B/1-3.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Calculating the PI Impedance

The Z_{pi} impedance is the impedance calculated from values of power (P) and current (I):

$$Z_{pi} = \frac{P}{I \cdot I} \quad (1)$$

The power and current are computed directly from the simulated fields. The power passing through a port is equal to the following:

$$P = \oint_s E \times H ds \quad (2)$$

where the surface integral is over the surface of the port.

The current is computed by applying Ampere's law to a path around the port:

$$I = \oint_l H \bullet dl \quad (3)$$

While the net current computed in this way will be near zero, the current of interest is that flowing into the structure, I^-, or that flowing out of the structure, I^+. In integrating around the port, HFSS keeps a running total of the contributions to each and uses the average of the two in the computation of impedances.

> **Note:**
>
> Zpi calculation is modified when a symmetry E plane touches a port. The current on the symmetry E plane is included in the Zpi calculation for a port with more than one conductor, where as for a single conductor port, such as a waveguide, the current on the symmetry E plane is not included in the Zpi calculation.

Calculating the PV Impedance

The Z_{pv} impedance is the impedance calculated from values of power (P) and voltage (V):

$$Z_{pv} = \frac{V \bullet V}{P} \quad (1)$$

where the power and voltage are computed directly from the simulated fields.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The power is computed in the same way as the Z_{pi} impedance. The voltage is computed as follows:

$$V = \int_l E \bullet dl \quad (2)$$

The result over which HFSS integrates is referred to as the impedance line — which is defined when the ports are set up. To define the impedance line for a port, select the two points across which the maximum voltage difference occurs. You must define an integration line to specify where the maximum voltage difference will be.

Calculating the VI Impedance

The Z_{vi} impedance is given by:

$$Z_{vi} = \sqrt{Z_{pi} Z_{pv}}$$

For TEM waves, the Z_{pi} and Z_{pv} impedances form upper and lower boundaries to a port's actual characteristic impedance. Therefore, the value of Z_{vi} approaches a port's actual impedance for TEM waves.

Impedance Multipliers

If a symmetry plane has been defined (allowing the model of a structure to be cut in half), the impedance computations must be adjusted by specifying an impedance multiplier. The need for this multiplier can be understood by looking at how the use of symmetry affects the computation of Z_{pv}.

In cases where a perfect E plane of symmetry splits a structure in two, only one-half of the voltage differential and one-half of the power flow can be computed by the system. Therefore, since the Z_{pv} impedance is given by:

$$Z_{pv} = \frac{V \bullet V}{P}$$

the computed value is one-half the desired value. An impedance multiplier of 2 must be specified in such cases.

In cases where a perfect H plane of symmetry splits a structure in two, only one-half of the power flow is seen by the system but the full voltage differential is present. Therefore, structures split in half with perfect H symmetry planes result in computed impedances that are twice those for the full structure. An impedance multiplier of 0.5 must be specified in such cases.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If multiple symmetry planes are used or if only a wedge of a structure is modeled, you must adjust the impedance multiplier accordingly.

It is important to be careful with the impedance multiplier when using symmetry planes in order to get the right answer. In general, there does not exist a simple rule for a multiplier and it is problem dependent. However, in most cases the following values can be used for the impedance multiplier:

- If the structure has a perfect E plane of symmetry, use 2. Such models have one-half of the voltage differential and one-half of the power flow of the full structure, resulting in impedances that are one-half of those for the full structure.
- If the structure has a perfect H plane of symmetry, enter 0.5. Such models have the same voltage differential but half the power flow of the full structure, resulting in impedances that are twice those for the full structure.
- If the structure has a combination of perfect H and perfect E boundaries, adjust accordingly. For example, you do not have to enter an impedance multiplier for a structure with both a perfect E and perfect H boundary since you would be multiplying by 2 and 0.5.

Calculating Terminal Characteristic Impedance Matrix

See Modes to Terminals Conversion.

Complex Propagation Constant

Each port is assumed to be connected to a transmission structure that has the same cross-section as the port. The complex propagation constant, γ, of these transmission lines is computed by HFSS, and is given by $\gamma = \alpha + j\beta$, where:

- α is the attenuation constant of a signal in the transmission structure. It is the real component of the propagation constant and has units of nepers per meter.
- β is the phase constant associated with the wave. It is the imaginary component of the propagation constant and has units of radians per meter.

Under the **Matrix Data** tab of the **Display Items Dialog**, gamma can be displayed as magnitude/ phase, real/ imaginary, magnitude, phase, real, or imaginary.

Calculating the Effective Wavelength (Lambda)

The effective wavelength, λ_{eff}, is calculated from

$$\lambda_{eff} = \frac{2\pi}{\beta} \quad (1)$$

where β is the phase constant associated with the wave.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Under the **Matrix Data** tab of the **Solution Data** dialog box, lambda is displayed when **Gamma** is selected as the matrix type.
s

Calculating the Relative Permittivity (Epsilon)

The relative permittivity, ε_r, is calculated using

$$\lambda_{eff} = \frac{c}{\sqrt{\varepsilon_r} f} \quad (1)$$

where

- λ_{eff} is the effective wavelength given in meters.
- *c* is the speed of light.
- *f* is the frequency of the wave.

Under the **Matrix Data** tab of the **Solution Data** dialog box, epsilon is displayed when **Gamma** is selected as the matrix type.

Maximum Delta S

For designs with ports.

The delta S is the change in the magnitude of the S-parameters between two consecutive passes. If the magnitude and phase of all S-parameters change by an amount less than the **Maximum Delta S Per Pass** value from one iteration to the next, the adaptive analysis stops. Otherwise, it continues until the requested number of passes is completed.

For example, if you specify **0.1** as the **Maximum Delta S Per Pass**, HFSS continues to refine the mesh until the number of requested passes is completed or until the magnitude of the complex delta of all S-parameters changes by less than **0.1**.

The maximum delta S is defined as

$$Max_{ij}\left|S_{ij}^{N} - S_{ij}^{N-1}\right| \quad (1)$$

where:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- *i* and *j* cover all matrix entries.
- *N* represents the pass number.

> **Note:**
>
> Delta S is computed on the appropriate S-parameters - modal or terminal - after the S-parameters have been de-embedded and renormalized.

Maximum Delta E

For designs with voltage sources, current sources, or incident waves.
Not applicable to designs with ports.

The delta E is the difference in the relative energy error from one adaptive solution to the next. It is a measure of the stability of the computed field values from pass to pass. As the solution converges, delta E approaches zero.

The **Maximum Delta E Per Pass** value is a stopping criterion for the adaptive solution. If the delta E falls below this value, the adaptive analysis stops. Otherwise, it continues until the convergence criteria are reached.

The data represents the delta E for all tetrahedra.

Percent of Tetrahedra Refined Per Pass

The value you set for **Percent Refinement Per Pass** determines how many tetrahedra are added at each iteration of the adaptive refinement process. For instance, entering **30** causes the mesh to increase approximately 30 percent each pass. The tetrahedra with the highest error will be refined. If your mesh consisted of 1000 elements, the tetrahedra would be refined so that 300 new elements are added to the mesh. Generally, you can accept the default value.

Magnitude Margin

For solutions in which convergence criteria for specific S-matrix entries were specified.

For each element in the S-matrix, the magnitude margin is the difference between the S-parameter delta magnitude and the target delta magnitude, as specified in the **Matrix Convergence** dialog box. The magnitude margin reported under the **Convergence** tab is the maximum of these values over the entire matrix. The magnitude margin is defined as

$$Max_{ij}\left[\left|S_{ij}^{N}-S_{ij}^{N-1}\right|-\left|M_{ij}\right|\right] \quad (1)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where M_{ij} is the matrix convergence entry. It indicates the solution's proximity to the target delta magnitude. If the solution has converged within the target delta magnitude, a value of zero will be reported for the pass.

Phase Margin

For solutions in which convergence criteria for specific S-matrix entries were specified.

For each element in the matrix, the phase margin is the difference between the S-parameter delta phase and the target delta phase, which was specified in the **Matrix Convergence** dialog box. The phase margin reported under the **Convergence** tab is the maximum of these values over the entire matrix. The phase margin is defined as

$$Max_{ij}\left[\left|phaseS_{ij}^{N} - phaseS_{ij}^{N-1}\right| - phaseM_{ij}\right] \quad (1)$$

where M_{ij} is the matrix convergence entry. The phase margin indicates the solution's proximity to the target delta phase. If the solution has converged within the target delta phase, a value of zero will be reported for the pass.

> **Note:**
>
> When the Mag S becomes small (near to zero) its phase becomes indefinite and insignificance due to mathematical issue so that Phase Margin will be discarded.

Maximum Delta Frequency

For Eigenmode solutions.

At any time during the solution process, you can view the percent difference in the resonant frequencies from one adaptive solution to the next, or the maximum delta frequency. This is a measure of the stability of the computed frequencies from pass to pass and is available only two or more adaptive passes are completed.

For lossless problems, the maximum delta frequency is the largest percent change in the real part of the frequency for any of the calculated modes. For lossy problems, the maximum delta frequency is the greater of two quantities: the largest percent change in the real part of the frequency over all the modes, and the largest percent change in the imaginary part of the frequency.

Max Delta (Mag S)

For solutions in which convergence criteria for specific S-matrix entries were specified.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Max delta(Mag S) is the maximum difference of S-Matrix magnitudes between two consecutive passes. If the difference in magnitudes of the S matrices change by an amount less than the **Maximum Delta Mag S** value from one pass to the next, this satisfies the part of the convergence criteria.

$$Max\left|S_{ij}^{N} - S_{ij}^{N-1}\right| \quad (1)$$

Max Delta (Phase S)

For solutions in which convergence criteria for specific S-matrix entries were specified.

The Max delta(Phase S) is the maximum difference of S-Matrix phase between two consecutive passes. If the difference in phase of the S matrices change by an amount less than the **Maximum Delta Phase S** value from one pass to the next, this satisfies this part of the convergence criteria.

$$Max(PhaseS_{n} - PhaseS_{n-1}) \quad (1)$$

Matrix Solvers

HFSS includes two solvers. The default solver and the Iterative Matrix Solver. See Enable Iterative Solver for a discussion of when to use the Iterative Matrix solver. For details on the default solver see Direct Matrix Solver. For details on the Iterative Matrix solver see *Technical Notes*: Iterative Matrix Solver.

Direct Matrix Solver

Direct methods obtain an exact solution to the following linear system of equation

$$Ax = b \quad (1)$$

where A is a matrix, b a right hand side and x the solution. A matrix solver using a direct method is called a direct matrix solver.

The most widely known direct method is Gaussian elimination, which uses elementary matrix operations to compute the solution. Most other direct solution techniques are either a variant of Gaussian elimination or are based upon a particular factorization of the equations that will allow an exact computation. One of the most commonly used such techniques is the LU decomposition, which is introduced below.

LU decomposition is both a factorization approach and closely related to Gaussian elimination. It is based upon the assumption that A can be decomposed into a product of two matrices or factors.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$A = LU \quad (2)$$

where L is a lower triangular matrix (has elements only on the diagonal and below) and U is an upper triangular matrix (has elements only on the diagonal and above).

With the help of (2), we can equivalently solve (1) by first solving for y such that

$$Ly = b \quad (3)$$

then solving for x such that

$$Ux = y \quad (4)$$

The advantage of decomposition (2) is that the solution of triangular set of equations (3) and (4) is quite trivial. Namely, they can be solved directly by forward substitution and by backward substitution respectively. Furthermore, the factors in (2) are computed only once and can be reused in (3) and (4) for different right hand sides.

In LU decomposition, the major storage is for matrix A, factor L and factor U. The major operation is the decomposition (2), which is roughly equivalent to a matrix-matrix multiplication; while the operation in (3) and (4) combined, is equivalent to a matrix-vector multiplication. The total computational cost is S+mT with S>>T in general, where S is the number of operations for decomposition (2), m the number of right hand sides, and T the number of operations for both forward substitution and for backward substitution.

Direct methods are best used for solving system matrix equations with moderate size or with a large number of right hand sides. As the system to be solved becomes larger, the overhead associated with the more complicated iterative methods becomes less of an issue, and the iterative methods should outperform the direct methods. For sparse systems, the use of direct methods is complicated by the possible introduction of more nonzero entries (fill-in) such that the L and U factors become much denser than the original matrix A.

Both the distributed and non-distributed direct solvers automatically trade speed for memory when that is necessary.

Iterative Matrix Solver

This section contains information on the Iterative Matrix Solver.

- Guidelines for Using the Iterative Solver
- Multiprocessing and the Iterative Solver
- Iterative Solver Technical Details

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Guidelines for Using the Iterative Solver

1. The iterative solver works most efficiently when it is enabled for designs that do not contain many excitations. (For example, the number of excitations is less than twice the number of processors.)
2. If you choose to take advantage of the iterative solver, and your analysis includes interpolating sweeps or discrete sweeps, the adaptive solution should be well converged at the higher end of the frequency band.
3. The **Relative Residual** provides a stopping criteria. The residual measures the convergence of the iterative solver to the solution of the matrix equation. Its value affects the performance of the iterative solver as follows:

- Default is 1E-6. This gives accurate S-parameters and fields, indistinguishable from those generated by the direct solver. Ansys recommends this residual.
- With a larger residual, for example, 1E-3 or 1E-2, the iterative process will stop with fewer iterations and the solution will be less converged. S-parameters won't differ much from those of a direct solution, for example, a difference in third or second digit. Fields and antenna patterns are visually the same.
- A residual of 0.1 can be used for quick adaptive mesh refinement early in the adaptive process, but S-parameters will be noticeably different.
- A residual of 1 should never be used. The interface will not allow a residual above 0.1.

Multiprocessing and the Iterative Solver

In computing the pre-conditioner, the iterative solver uses multiple processors, if set under **Tools>Options>HFSS Options**, just like the multi-frontal solver does. The operations involved are very similar. After that, there is one iterative process per excitation. Each iterative process can only use one processor. If you have one excitation and multiple processors, you will see that HF3D.exe uses only one processor at this stage. If you have multiple excitations and multiple processors, HF3D.exe will use multiple processors at this stage. For example, with four processors and eight excitations, HF3D will perform the iterative processes for four excitations first, and for the other set of four excitations next.

Iterative Matrix Solver Technical Details

The iterative solver always saves significant memory - easily a factor two with simulations of intermediate size, and more with larger simulations. It is also faster than the multi-frontal solver with large simulations.

The following table shows asymptotic behavior with large simulations. N = number of unknowns. This shows that the iterative solver has a better asymptotic behavior both in RAM and in time.

	Time	RAM
Multi-frontal	$N^{1.7}$	$N^{1.3}$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solver		
Iterative Solver	N $^{1.2}$	N $^{1.0}$

The iterative solver uses a preconditioner that is based on the next-lower order. Therefore, there is no iterative solver option when you solve with zeroth order.

Consider the matrix equation

$$Ax = b \quad (1)$$

where *A* is a matrix, *b* a right hand side and *x* the solution.

When $A^{-1}$is computationally expensive or the exact solution *x* is impossible, an alternative is to seek an approximation $\bar{x}$ to *x*, with an error $e = x - \bar{x}$. The exact solution can therefore be rewritten as

$$x = \bar{x} + e \quad (2)$$

Substituting (2) into (1) results in the so called residual equation

$$Ae = r \quad (3)$$

where *r* is the residual defined by

$$r = r - A\bar{x} \quad (4)$$

As aforementioned, the exact solution for *e* in (3) is impossible since it requires A^{-1}. However, if an approximation $M \approx A$ is available, the error *e* can be approximated in (3) by

$$\bar{e} = M^{-1}r \quad (5)$$

$\bar{x}$

$$\bar{x} \leftarrow \bar{x} + \bar{e} \quad (6)$$

It is (4)-(6) that form the foundation of the iterative solution method. A matrix solver using the iterative solution method is called an iterative matrix solver. The method starts with an initial guess $\bar{x} = x_0$ and repeats (4)-(6) until the approximation $\bar{x}$ to *x* is within tolerance, or the number of iterations exceeds a given number. In the former case, it is said the solution converges; while in the latter, it doesn't.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The residual *r* is used for measuring the closeness of $\bar{x}$ to *x*. Since *A* and *b* in (1) can be scaled by the same factor without altering *x*, so does the residual *r* in (4). It typically makes more sense to replace ||*r*|| as the stopping criterion with the **relative residual**:

$$res = \frac{\|r\|}{\|b\|} \quad (7)$$

$\| \|$

M in (5) is called a preconditioner of *A*. A good preconditioner greatly reduces the number of iterations. The following makes *M* a good preconditioner: *M* is very similar to *A* in eigen spectrum and M^{-1} is computationally cheap. Some of the classic iterative matrix methods include: the Jacobi method where *M* is the diagonal of *A,* the Gauss-Seidel method where *M* is the lower triangular or upper triangular matrix of *A* and the successive over-relaxation method (SOR) where *M* is a weighted combination of the lower triangular and upper triangular matrix of *A.*

In the iterative method, the major storage is for matrix *A* and for preconditioner *M.* The major operation is a matrix-vector multiplication in (4). The computational cost is *S*+*mnT,* where *S* is the number of operations for setting up the preconditioner*,m* the number of right hand sides, *n* the average number of iterations per right hand side and *T* the number of operations for each iteration*.*

Details of the iterative solver in HFSS are given in:

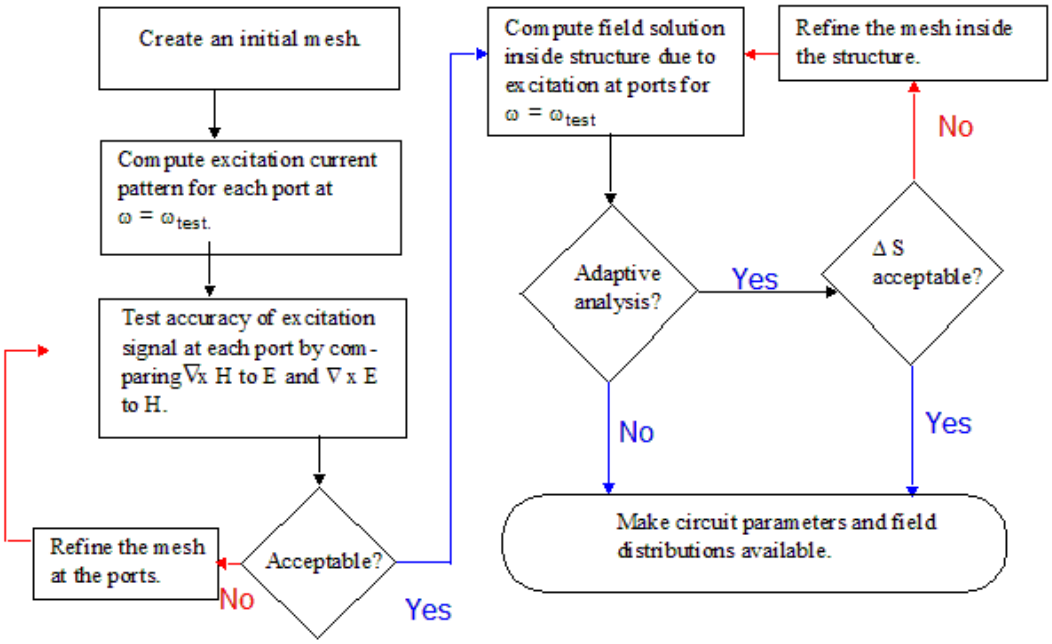
D. K. Sun, J. F. Lee and Z. J. Cendes, "Construction of nearly orthogonal Nedelec bases for rapid convergence with multilevel preconditioned solvers", *SIAM Journal on Scientific Computing*, Vol. 23, No. 4, pp. 1053-1076, 2001.

I. Bardi, G. Peng and Z.J. Cendes, "Improvements in Adaptive Mesh Refinement and Multi-level methods in High Frequency Electromagnetics", ACES Symposium, 2002.

Single Frequency Solution

A single frequency solution generates an adaptive or non-adaptive solution at a single frequency, the solution frequency specified in the **Solution Setup** dialog box, and is often the first step in performing a frequency sweep. An adaptive solution is one in which a finite element mesh is created and automatically refined in the areas of highest error — increasing the accuracy of succeeding adaptive solutions. The procedure for performing a single frequency solution is shown below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Frequency Sweeps in HFSS

Perform a frequency sweep when you want to generate a solution across a range of frequencies. You may choose one of the following sweep types:

Fast	Generates a unique full-field solution for each division within a frequency range. Best for models that will abruptly resonate or change operation in the frequency band. A Fast sweep will obtain an accurate representation of the behavior near the resonance.
Discrete	Generates field solutions at specific frequency points in a frequency range. Best when only a few frequency points are necessary to accurately represent the results in a frequency range.
Interpolating	Estimates a solution for an entire frequency range. Best when the frequency range is wide and the frequency response is smooth, or if the memory requirements of a Fast sweep exceed your resources.

Fast Frequency Sweeps

A Fast sweep generates a unique full-field solution for each division within a frequency range. Choose a Fast sweep if the model will abruptly resonate or change operation in the frequency band. A Fast sweep will obtain an accurate representation of the behavior near the resonance.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

HFSS uses the center frequency of the frequency range to select an appropriate eigenvalue problem with which to generate a solution for the entire Fast sweep. It then uses an Adaptive Lanczos-Padé Sweep (ALPS)- based solver to extrapolate the field solution across the requested frequency range from the center frequency field solution.

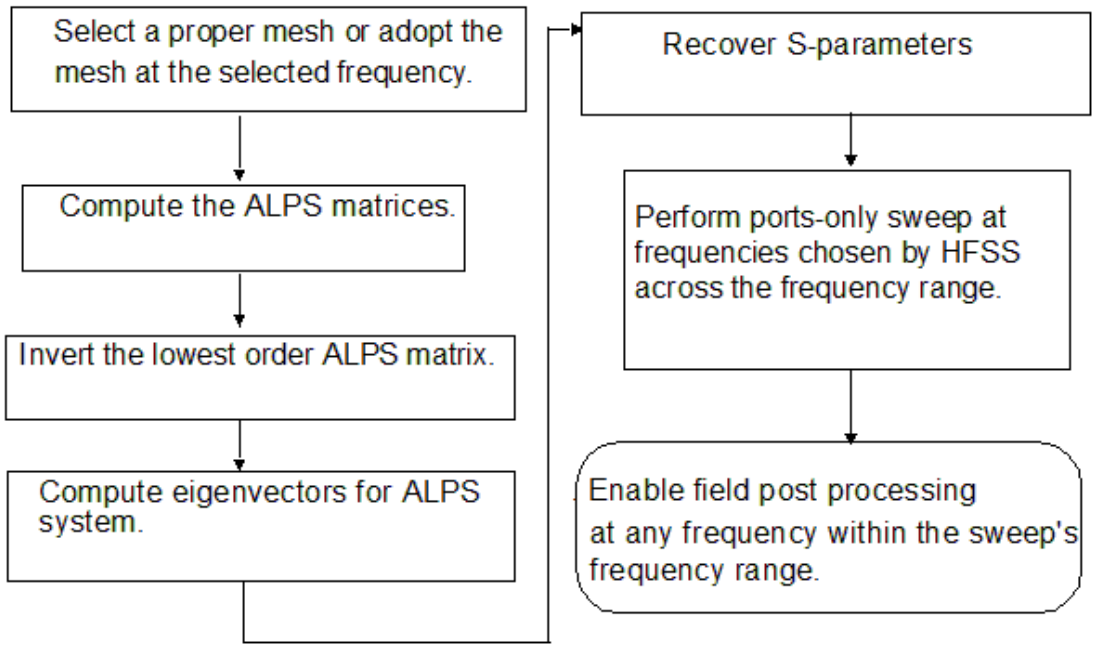
HFSS always uses the middle of the frequency range and the center frequency.

Be aware that HFSS uses the finite element mesh refined during an adaptive solution at the solution frequency or, if you did not request an adaptive solution, the initial mesh generated for the problem. It uses this mesh without further refinement. Also, the field solution at the center frequency is the most accurate. Depending upon the desired level of accuracy you require throughout the frequency range, you may wish to perform additional Fast sweeps at other center frequencies.

The full-field solution is saved only at the center frequency, while the S-parameters are saved for every frequency point; however, the Fast sweep allows the you to post process fields for any frequency entries to the sweep range.

The time and memory required for a Fast sweep may be significantly greater than the time and memory required for a single frequency solution.

The procedure for a Fast frequency sweep is shown below.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Discrete Frequency Sweeps in HFSS

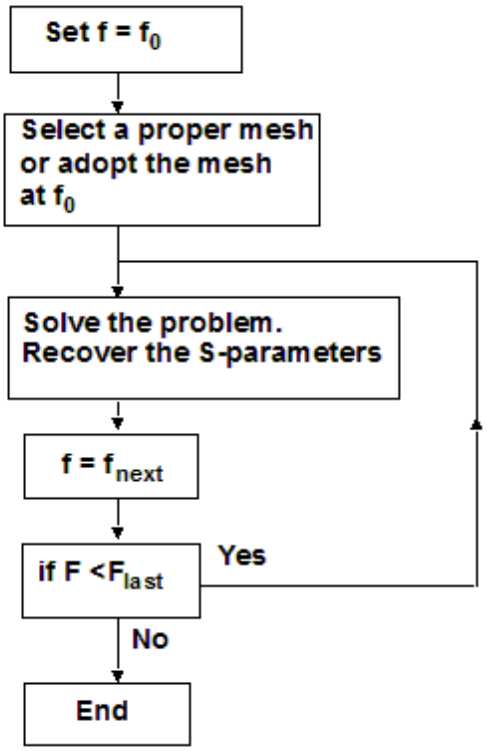
A Discrete sweep generates field solutions at specific frequency points in a frequency range. For example, if you specify a range of 1000 MHz to 2000 MHz, then a Step Size of 2.5, the result would be solutions at 1000, 1250, 1500, 1750, and 2000 MHz. By default, the field solution is only saved for the final frequency point computed, which would be at 2000 MHz in this case. Select the **Save Fields** option when setting up the points to solve if you want to save the field solution for a specific point. The S-parameters are saved for every frequency point. The more steps you request, the longer it takes to complete the frequency sweep.

Choose a Discrete sweep if only a few frequency points are necessary to accurately represent the results in a frequency range.

Be aware that HFSS uses the finite element mesh refined during an adaptive solution at the solution frequency or, if you did not request an adaptive solution, the initial mesh generated for the problem. It uses this mesh without further refinement. Because the mesh for the adaptive solution is optimized only for the solution frequency, it is possible that the accuracy of the results could vary at frequencies significantly far away from this frequency. If you wish to minimize the variance, you can opt to use the center of the frequency range as the solution frequency. Then, after inspecting the results, run additional solutions with the solution frequency set to the critical frequencies.

The procedure for a Discrete frequency sweep is shown below, where *n* equally spaced frequencies are included in the sweep.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Interpolating Frequency Sweeps in HFSS

An Interpolating sweep estimates a solution for an entire frequency range. HFSS chooses the frequency points at which to solve the field solution so that the entire interpolated solution lies within a specified error tolerance. The sweep is complete when the solution meets the error tolerance criterion or generates the maximum number of solutions. To view more information about the solution, increase the number of steps and perform the sweep again.

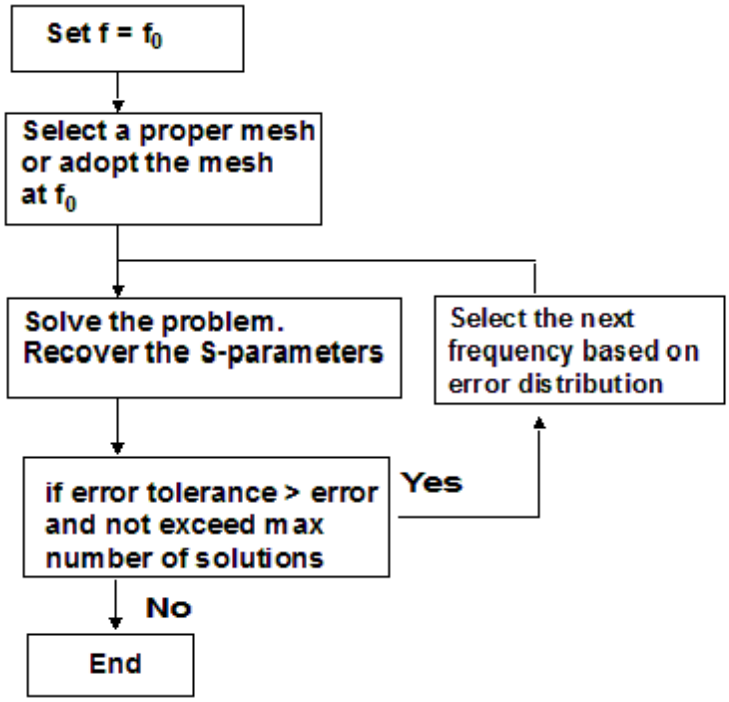
The field solution for each point is deleted so that a new field solution can be generated for the next point. The full-field solution is only saved for the final frequency point computed. The S-parameters are saved for every solved frequency point.

Choose an Interpolating sweep if the frequency range is wide and the frequency response is smooth with the exception of a few resonances, or if the memory requirements of a Fast sweep exceed your resources. An Interpolating sweep's time requirement may be much less than a Discrete sweep's because a solution for the entire frequency range is interpolated based on solutions for a minimal number of frequency points. The maximum time required for an Interpolating sweep is the time required for a single frequency solution multiplied by the maximum number of solutions.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Be aware that HFSS uses the finite element mesh refined during an adaptive solution at the solution frequency or, if you did not request an adaptive solution, the initial mesh generated for the problem. It uses this mesh without further refinement.

The procedure for an Interpolating sweep is shown below, where *n* frequencies determined by the system are included in the sweep.



Solution Types in HFSS

Solution Types	
HFSS	This enables the Driven Options Modal and Terminal. **HFSS** selection enables Mesh Fusion for FEM components. You can add padding to the mesh bounding volume. The finite array is disabled, and the Hybrid folder is removed from the project tree. The FEBI boundary becomes a regular boundary instead of hybrid region. When there are components set up for mesh fusion, the solution setup only allows direct solver and no derivatives.
HFSS with Hybrid	This enables the Driven Options Modal and

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

and Arrays	Terminal. **HFSS with Hybrid and Arrays** selection enables mesh assembly for hybrid components. You cannot add padding to the mesh assembly bounding volume. The finite array is enabled, and the Hybrid folder is added to the project tree, along with the tab for Hybrid in the solution setup.
HFSS Transient	**Transient** - For calculating problems in the time domain. It employs a time-domain ("transient") solver. For **Transient** your choice of **Composite Excitation** or **Network Analysis** affects the options for the setup. If you select **Network Analysis** the setup includes an Input Signal tab for the simulation. Typical transient applications include, but are not limited to: • Simulations with pulsed excitations, such as ultra-wideband antennas, lightning strikes, electro-static discharge; • field visualization employing short-duration excitations; • time-domain reflectometry.
HFSS SBR+	This option simplifies design creation for SBR+ users. HFSS can use EMA3D shooting and bouncing ray (SBR) technology to calculate the far field from current sources and defined geometry via a one-way coupling. With this solution type, you do not need to specify explicit SBR+ Hybrid Regions. The Driven option for this solutions is Network Analysis only, with no Auto-Open Region. For details, see Design Flow for SBR+ Solution Type. You can also use parametric antennas in SBR+ solutions. For SBR+ solutions, you see an option in Initial Mesh Settings to **Allow tolerant meshing in SBR+ regions**. For HFSS SBR+solutions, you can also choose to import STL files as Lightweight Geometry.
HFSS Eigenmode	For calculating the eigenmodes, or resonances, of a structure. The Eigenmode solver finds the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	resonant frequencies of the structure and the fields at those resonant frequencies. Eigenmode designs cannot contain design parameters that depend on frequency, for example a frequency-dependent impedance boundary condition.
HFSS Characteristic Mode	This option is used for calculating the characteristic modes of a structure. The structure can be metal or dielectric. The solution reports the Number of Modes, the characteristic angle and current (amp/meter), the modal significance and quality factor, and the voltage per port based in edit sources weighting. The Selecting Characteristic Modes changes the Solution Setup criteria and dialog. You specify the minimum modal significance (default 0.02). Convergence is based on Max E rather than Max S (default (0.02). Only discrete sweeps are supported. Only the CMA solver is supported. Only lossless boundaries are allowed. Finite conductivity boundaries are allowed but are converted to lossless. The half-space boundary is not allowed.

Driven Modal

Choose the **Driven Modal** option for HFSS Driven when you want HFSS to calculate the modal-based S-parameters of passive, high-frequency structures such as microstrips, waveguides, and transmission lines. The S-matrix solutions will be expressed in terms of the incident and reflected powers of waveguide modes. **Network Analysis** is the default and functions as before.

Composite Excitation provides a method for solving fields in a large frequency domain problem.

Driven Terminal

Choose the **Driven Terminal** option for HFSS Driven when you want HFSS to calculate the terminal-based S-parameters of single and multi-conductor transmission line ports. The S-matrix solutions will be expressed in terms of voltages and currents on the terminals. **Network Analysis** is the default and functions as before.

Composite Excitation provides a method for solving fields in a large frequency domain problem.

Auto-Open Region

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For open region problems (typically antennas), you can choose **Auto-Open Region**. The option is available for HFSS Driven modal, terminal and transient solutions. This automatically creates an open region and a predefined Analysis setup for the project. You can select whether the region is Radiation, FE-BI, or PML. This simplifies the design process. If you do not choose **Auto-Open Region**, you must create an airbox and then assign a radiation boundary, either manually, or using the Create Open Region command. For more information on this Solution setting, see Using Auto-Open Region for the Solution Type for Antenna Designs.

Eigenmode Solutions

The Eigenmode solver can find the Eigenmodes of lossy as well as lossless structures, and can calculate the unloaded Q of a cavity. Q is the quality factor, and is a measure of how much energy is lost in the system. Unloaded Q is the energy lost due to lossy materials and boundary conditions. Because ports and other sources are restricted for eigenmode problems, the Q calculated does not include losses due to those sources.

The following restrictions apply to Eigenmode solution designs:

- No excitations may be defined.
- Radiation boundaries may not be defined.
- Frequency sweeps are not available.
- You may not view or plot the S-matrix data.
- Designs cannot include ferrite materials.

If a material or boundary condition, other than finite conductivity, varies with frequency, the eigenmode solution procedure will evaluate the frequency dependent property at the user specified minimum frequency and use that value during the S and T matrix assembly. This may limit the accuracy of the solved Eigenmodes depending on how significant the property varies from the minimum frequency to the eigen frequency.

Calculating the Resonant Frequency

Eigenmodes are the resonances of the structure. The eigenmode solver finds the resonant frequencies of the structure and the fields at those resonant frequencies. For a Driven Solution, HFSS solves the following matrix equation (for a lossless case):

$$Sx + k_o^2 Tx = b \quad (1)$$

where

- S and T are matrices that depend on the geometry, the materials, and the mesh.
- $\boldsymbol{x}$ is the electric field solution.
- k_o is the free-space wave number.
- b is the value of the source defined for the problem.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

However, in order to find the resonances of the structure, the eigenmode solver sets *b* to zero, and solves the equation

$$Sx + k_o^2 Tx = 0 \quad (2)$$

for sets of (*ko*,***x***), one *ko* for every ***x***. The variable *x* is still the electric field solution, and *ko* is the free space wave number corresponding to that mode. The resonant frequency of the eigenmode can be found using:

$$f = \frac{k_o c}{2\pi} \quad (3)$$

where

- *c* is the speed of light.

Calculating the Quality Factor

Q is the unloaded quality factor, and is a measure of how much energy is lost in the structure due to lossy materials. Because ports and other sources are restricted for Eigenmode solutions, the Q calculated does not include losses due to those sources.

HFSS uses the following equation to calculate the approximate quality factor:

$$Q = \left| \frac{Mag(freq)}{2 \cdot Im(freq)} \right| \quad (1)$$

The Fields Calculator can also be used to calculate Q. In general, the equation for Q is

$$Q = (2\pi)(freq)\frac{U}{P} \quad (2)$$

where:

- *U* is the total energy stored in the cavity.
- *P* is the power lost, from resistive losses, for example.

Q Factor of Resonant Cavities

Basic Definition

$$Q = \frac{\omega W}{P_{loss}} \qquad \omega = |\omega| \quad (1)$$

In complex case (see examples in textbooks)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Since P_{loss} comes form W

$$Q_{min} = \frac{1}{2} \quad (2)$$

Calculating from complex resonance Frequency

$$\omega = \omega_r + j\omega_i \quad (3)$$

Definition 1 (Correct)

$$Q = \frac{|\omega|}{2\omega_i} \quad (4)$$

Definition 2 (Incorrect)

$$Q = \frac{\omega_r}{2\omega_i} \quad (5)$$

Arguments for using Definition 1

- Collin always uses the right frequency
- Gardiole [1] always uses definition1.
- IEEE papers [2], [3], and [5] use Definition 1.

Example R,L,C Circuit

$$R + j\omega L + \frac{1}{j\omega C} = 0 \quad (6)$$

$$\omega_{res} = \frac{1}{2}\left(j\frac{R}{L} + \sqrt{\frac{4}{LC} - \left(\frac{R}{L}\right)^2}\right) \quad (7)$$

Definition 1 (Correct)

$$Q = \frac{\omega_o L}{R} \qquad \omega_o = \frac{1}{\sqrt{LC}} \quad (8)$$

Definition 2 (Incorrect)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$Q = \frac{\sqrt{\frac{4}{LC} - \left(\frac{R}{L}\right)^2}}{2\frac{R}{L}} \quad (9)$$

Example Cube Resonator

$$f_{res} = \frac{1}{2\pi} j\frac{\sigma}{2\varepsilon} + \sqrt{-\left(\frac{\sigma}{2\varepsilon}\right)^2 + \frac{1}{\mu\varepsilon}k^2} \quad (10)$$

Definition 1 (Correct)

$$Q = \frac{\omega_o \varepsilon}{\sigma} \qquad \omega_o = \frac{k}{\sqrt{\mu\varepsilon}} \quad (11)$$

Definition 2 (Incorrect)

$$Q = 0.5\frac{\sqrt{\frac{1}{\mu\varepsilon}k^2 - \left(\frac{\sigma}{2\varepsilon}\right)^2}}{\frac{\sigma}{2\varepsilon}} \quad (12)$$

- Both definitions give almost the same answer at low losses
- Definition 2 gives nonphysical values at high losses, so Definition 1 is the correct one

Theory of Characteristic Modes

Characteristic modes or characteristic currents can be represented quantitatively as eigenfunctions of the following generalized eigenvalue problem:

$$XJ_n = \lambda_n RJ_n$$

where

λ_n = eigenvalue

J_n= eigenvector

R and X are the real and imaginary parts of the impedance operator.

The total power exiting a surface is:

$$P = \langle E, J \rangle$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Where E is the electric field on the surface and J is the surface current. We can use the electric field integral equation to relate these two quantities to obtain

$$P = \langle ZJ, J \rangle = \langle (R + jX)J, J \rangle$$

Where R and X are the real and imaginary parts of the EFIE impedance matrix, Z = R + jX. The real part of P is the power radiated and the imaginary part is the power stored in the near field. For antenna design, we want to maximize the power radiated, or equivalently, minimize the power stored in the near field. The solution to this minimization problem is the generalized eigenvalue problem given above.

Qualitatively, characteristic modes are equiphase current modes, which can be computed for metallic and dielectric structures of arbitrary shapes and sizes and are independent of any excitation. Characteristic modes not only allow modal analyses of conductors but they are also useful for antenna design and placement, and the properties of the characteristic modes provide insight and valuable information for designing antennas. In fact, these quantities provide a physical interpretation of the radiating characteristics of an antenna. Therefore, understanding them can be very useful in problems involving syntheses, analyses, and optimization of antennas and scatterers. These quantities, known as characteristic value and characteristic current, are obtained by solving the above generalized eigenvalue problem. Together they define a characteristic mode. In addition to characteristic value and characteristic current, HFSS also depicts these quantities in the form of characteristic angle and modal significance to provide a practical insight into the behavior of the modes.

Using the standard Galerkin discretization of the EFIE, the characteristic values and characteristic currents in a lossless system are purely real. When the characteristic value is 0, no power is stored in the near field--all the power is radiated. From the characteristic value, you can make the following inferences:

- when $\lambda_n = 0$, the mode is externally resonant.
- when $\lambda_n > 0$, the mode is inductive (the energy is stored in a magnetic field).
- when $\lambda_n < 0$, the mode is capacitive (the energy is stored in an electric field).

Since the characteristic values can range from -infinity to +infinity, it’s more convenient to represent this quantity in terms of characteristic angle.

Characteristic Angle

Characteristic angle represents the phase lag between the electric field and surface current on a conductor. Mathematically, characteristic angle is defined as:

$\alpha_n = 180° - \tan^{-1}\lambda_n$

Characteristic Angle can range from 90 deg to 270 deg leading to the following possibilities:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- when α_n= 180 deg, the mode is externally resonant.
- when 90 deg < α_n < 180 deg, the mode is inductive.
- when 180 deg < α_n < 270 deg, the mode is capacitive.

Modal Significance

Modal Significance, as the term indicates is a measure of how significant a mode is for solving the EFIE at a given frequency. It also determines how hard or how easy it is to excite a mode. Mathematically, Modal Significance is defined as:

$$MS = \frac{1}{|1+j\lambda_n|}$$

Since the characteristic current diagonalizes both the real and imaginary parts of the impedance matrix, we can define

v_n=1+ $j\lambda_n$

which is an eigenvalue of the EFIE impedance matrix, Z = R+ jX. The eigenvalue is significant since its magnitude provides information about how well the corresponding mode radiates. Using the impedance matrix, eigenvalues, as well as the characteristic currents, the EFIE is analytically solved and the modal excitation coefficients are obtained as follows--

$$c_n = \frac{\langle E_{tan}^{inc}, J_n \rangle}{1+j\lambda_n}$$

Thus, we write that the magnitude of the coefficient must be

$$|c_n| \leq MS * |\langle E_{tan}^{inc}, J_n \rangle| \Big|$$

where MS is the modal significance. The maximum value of modal significance is 1. This happens when the mode is externally resonant. Modal significance can decay to zero when the mode is not resonant.

Depending upon the electrical size of the antenna, when you perform a characteristic mode analysis, a large number of modes can be computed. From a practical standpoint, when an object is not electrically large, most of the modes are difficult to excite since their characteristic values are far from 0. While one can generate plots of the characteristic value (λ_n) as a function of frequency, it's often more convenient to plot a quantity like Modal Significance as a function of frequency. This is because one is interested mostly in the characteristic values close to 0, in other words, MS =1 where the mode is externally resonant. A graph depicting modal significance

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

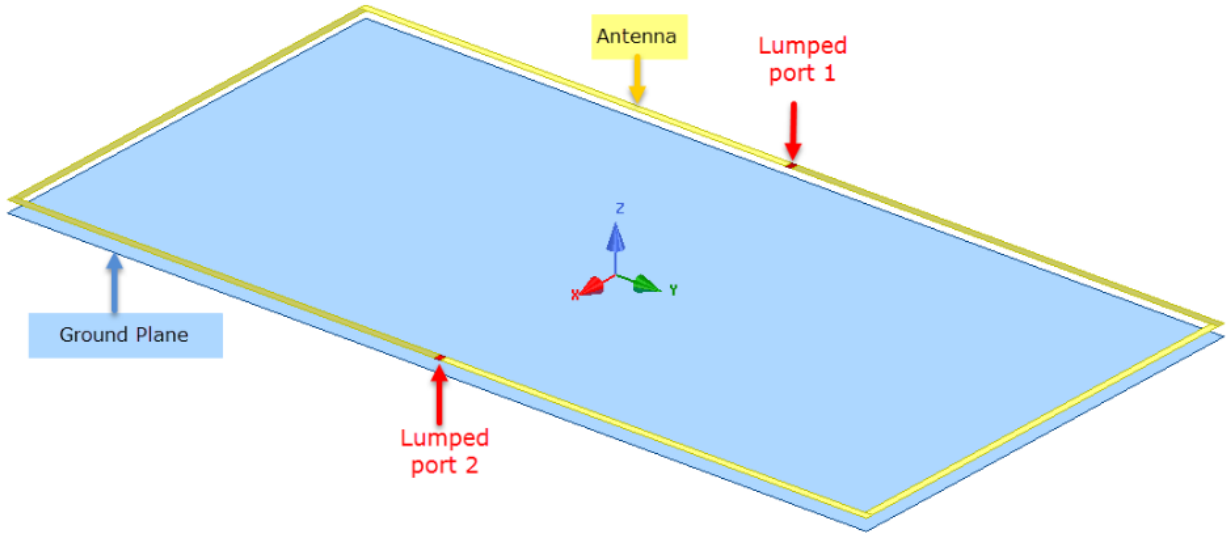
as a function of frequency can be very useful because such a graph lets you easily examine the importance of the modes and understand which of the modes contribute significantly to the radiated power (MS = 1), and the ones that are decaying (MS = 0).

Characteristic mode analyses give physical insight of the current pattern that can exist on an antenna and the platform upon which it operates. This insight can be valuable to a design engineer and help as a first step toward achieving correct antenna placement on electrically medium-sized structures.

The following designs are practical applications of characteristic mode analysis in HFSS.

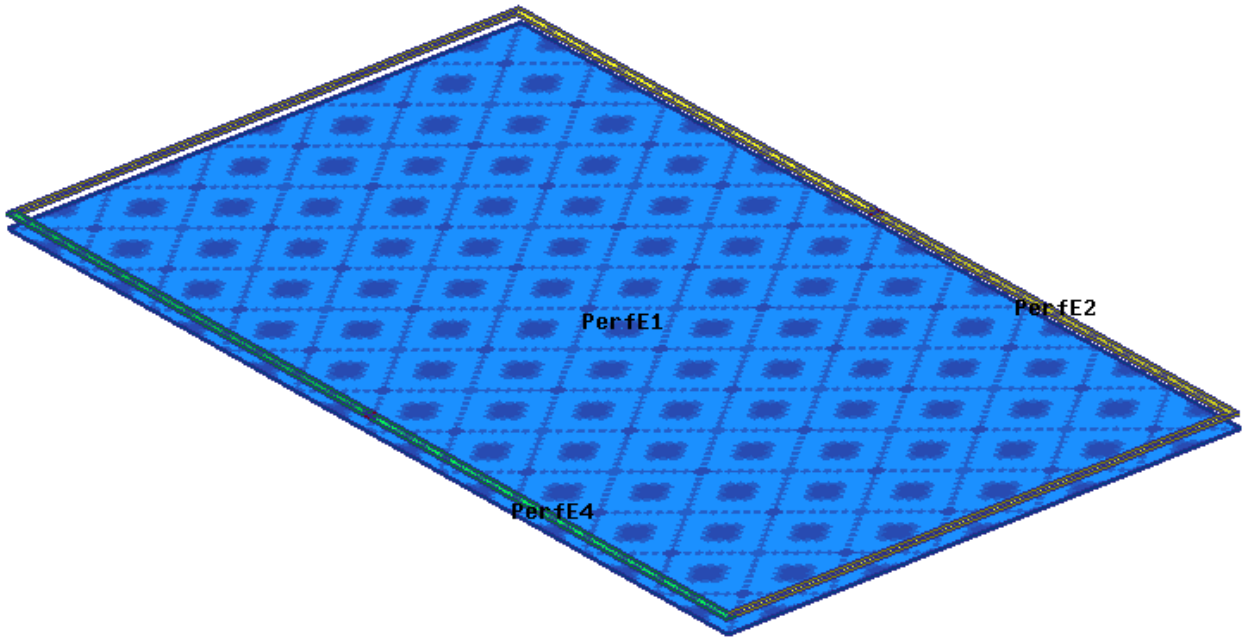
Loop Antenna of a Cell Phone Chassis

The following figure shows a cell phone chassis, which contains a simple plate representing its backplane. It also has a loop antenna.

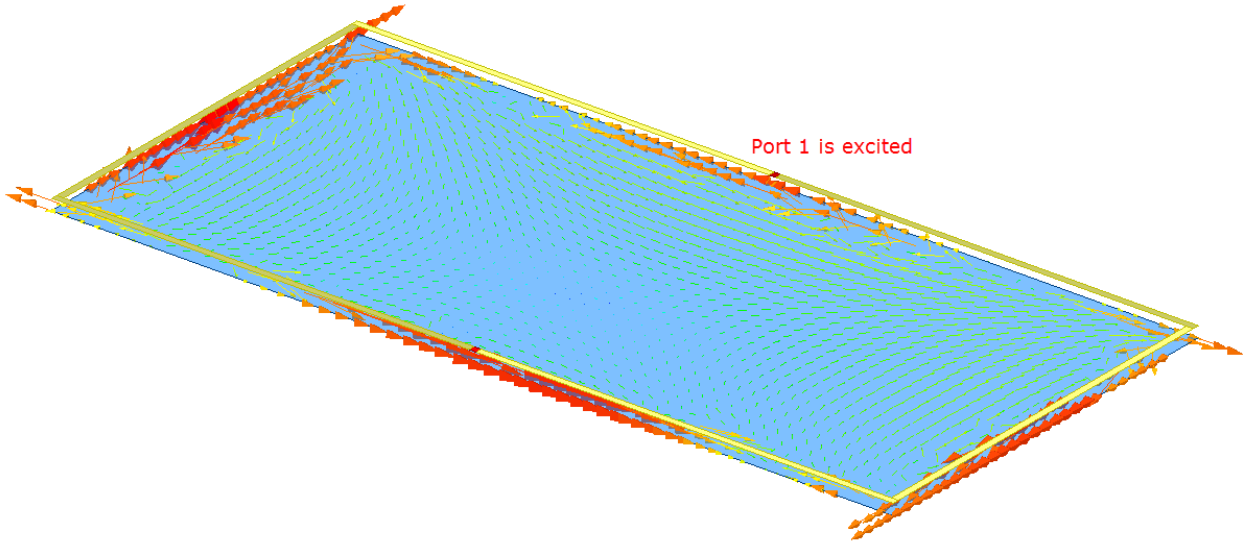


The boundary conditions are shown below. The plate and the antenna are assigned Perfect E boundaries. Also, the antenna modes are excited by assigning lumped ports. The simple plate acts as the antenna's ground plane, and its shape and size affect the performance of the antenna significantly. Therefore, if you perform a characteristic modal analysis of this design in HFSS, you can obtain critical information about the current modes and their pattern for this structure. Characteristic Mode Analysis solution type is chosen for this design. The design is analyzed at solution frequency of 1.6 GHz. Minimum Modal Significance is 0.02 so all modes above this threshold are calculated by HFSS. On the Edit Sources panel, you can configure the type of CMA Excitations as Port or Modes.

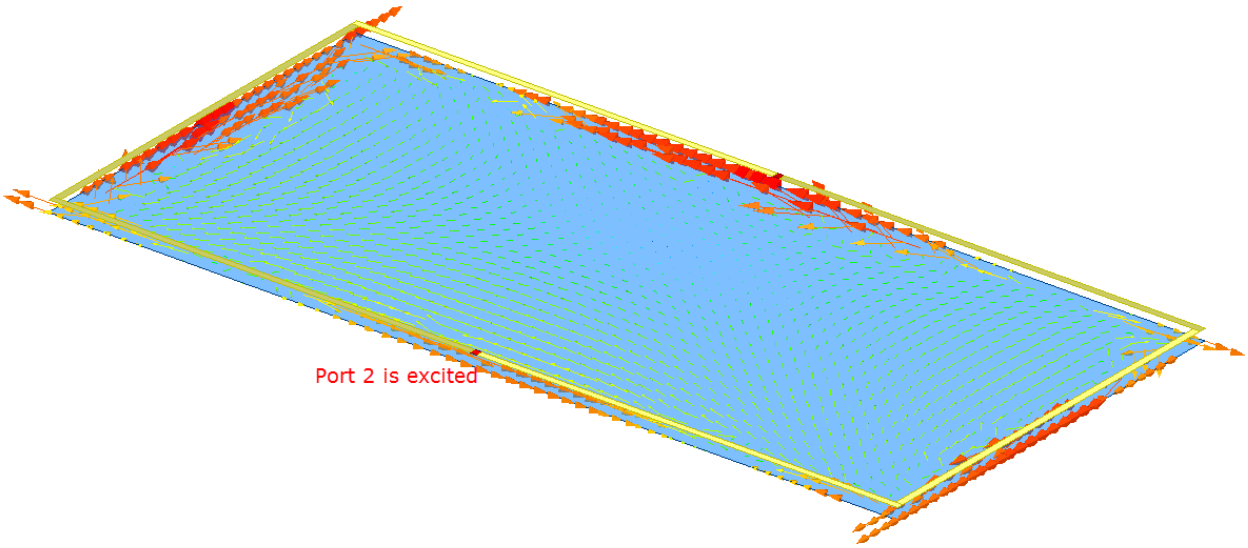
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

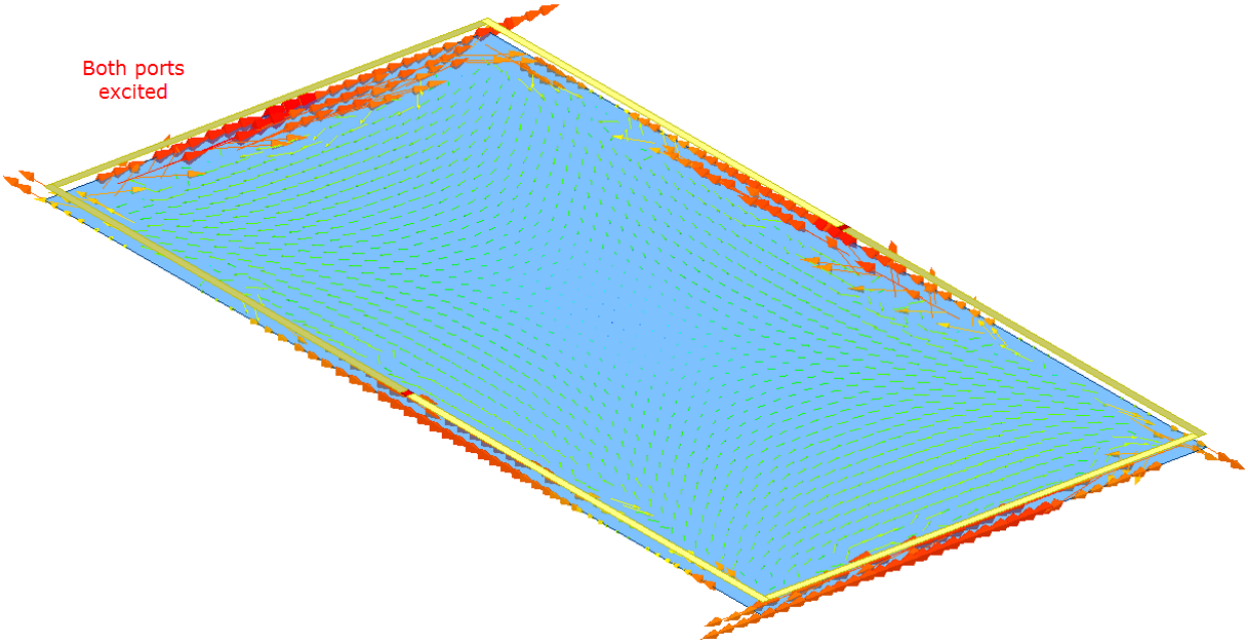


Settings in the Edit Sources panel can help you understand the impact of the CMA excitations on the behavior of modes and their current patterns.



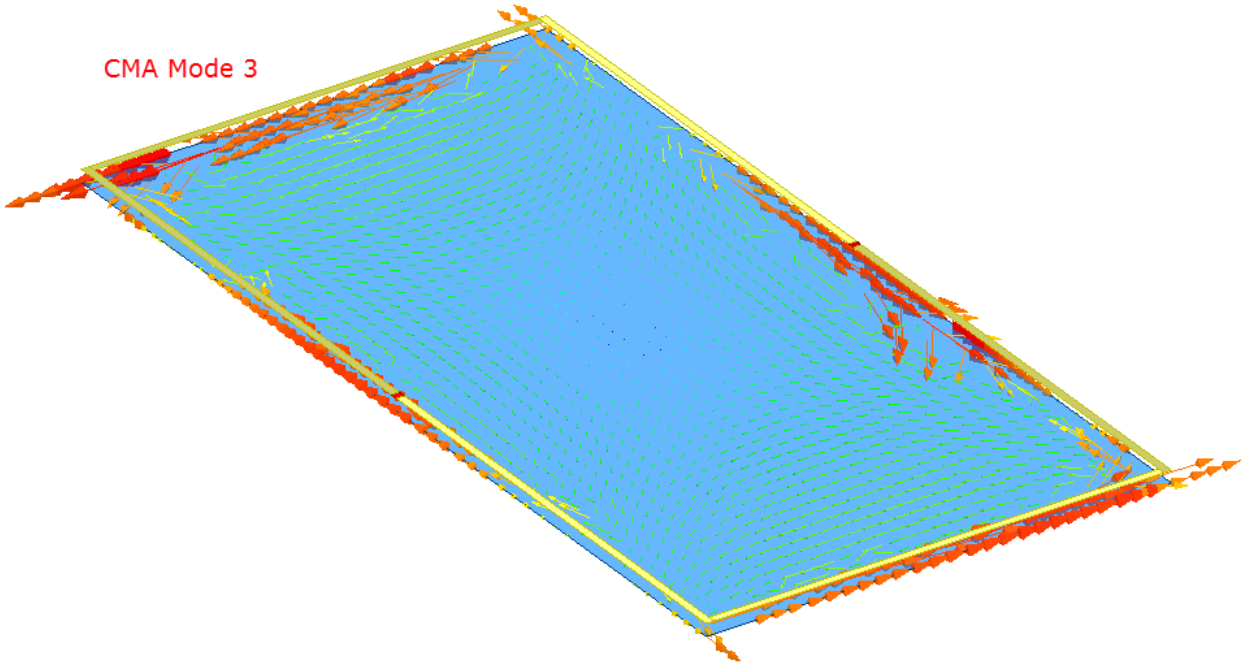
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

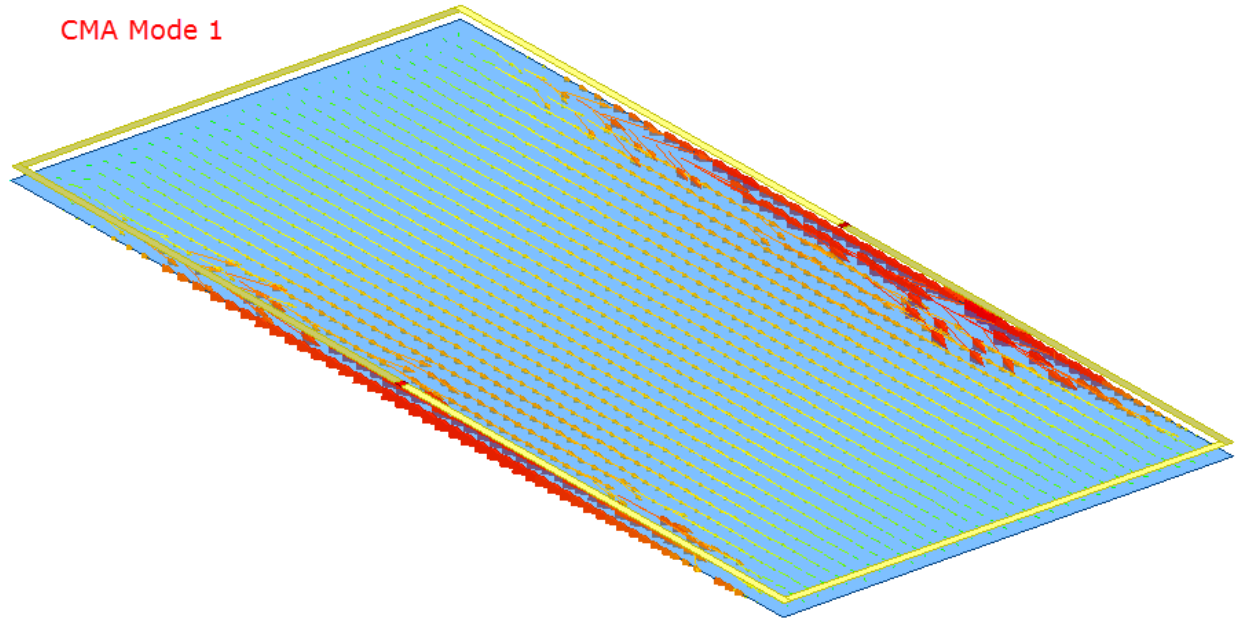




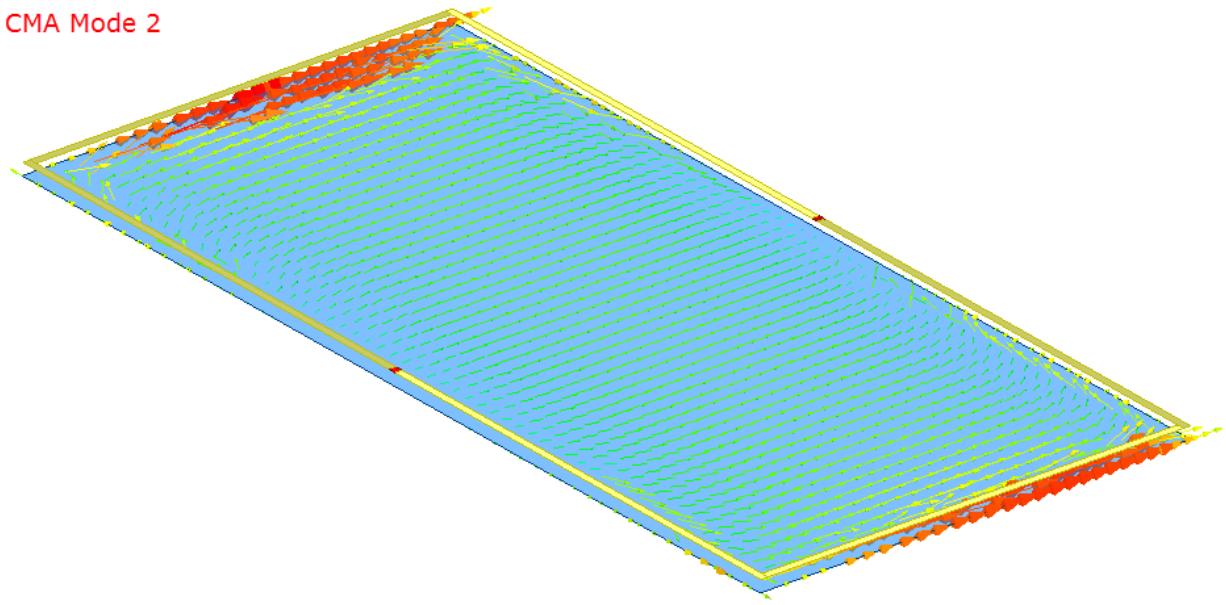
To illustrate, you can plot the characteristic currents in this design and understand how the mode behavior is affected by the port excitations. Depending upon how you define the CMA Port excitations, different modes are excited accordingly on the plane. For example, if you define lumped port 1 as the excitation for this structure, the current pattern mostly consist of mode 3. However, the other modes do have some contribution to the field pattern. Similarly, when lumped port 2 is excited the current pattern mostly consists of mode 3. If both ports are excited the pattern is identical to mode 3.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



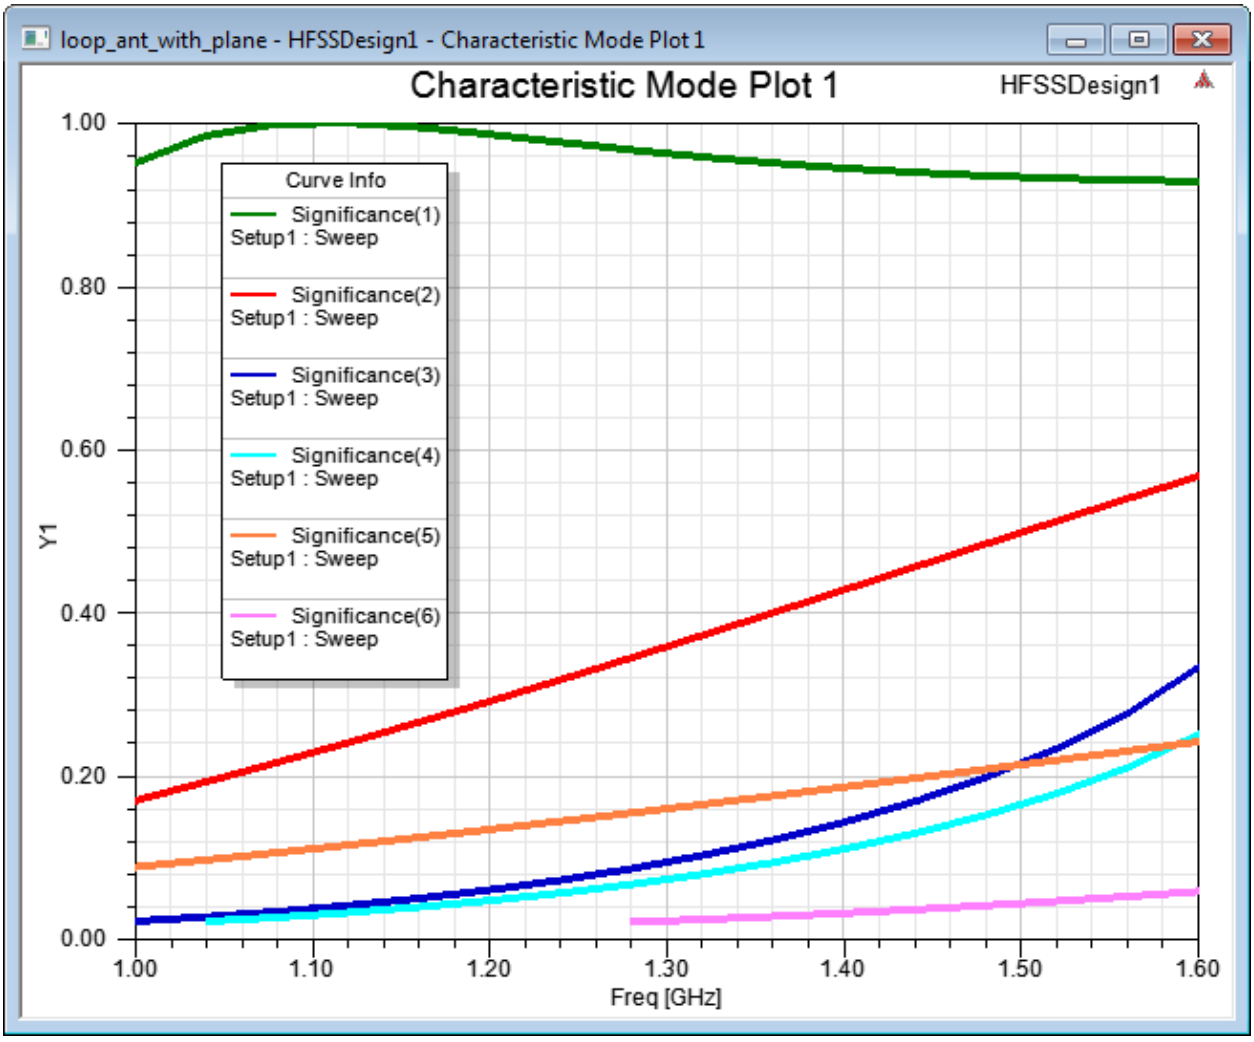


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The above images illustrate the mode currents when the CMA Excitations are configured to be modes 1, 2, or 3. Mode 3 is the dominant mode. Characteristic angles associated with the current modes can be plotted as a function of frequency.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Once you have completed the modal analysis of your design, you can make modifications to your design as needed to excite the desired modes. This characteristic mode analysis example demonstrates how by viewing the current patterns you can excite only those modes of interest and maximize radiated power. Design modifications depending upon the modes you want to excite can improve antenna performance.

Field Solutions

During the iterative, adaptive solution process, the S-parameters typically stabilize before the full Electric field solution. Therefore, when you are interested in analyzing the field solution or quantities computed from the field solutions associated with a structure, it is advisable to use tighter convergence criteria.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In addition, for any given number of adaptive iterations, the magnetic field (H-field) is less accurate than the solution for the electric field (E-field) because the H-field is computed from the E-field using the relationship: .

$$H = \frac{\nabla \times E}{-j\omega\mu}$$

Field Overlay Plots

In HFSS, field overlays are representations of basic or derived field quantities on surfaces or objects. The objects on which you plot the fields may be pre-existing parts of the model geometry or they may be objects that you draw in post-processing mode.

If you select a surface, HFSS will plot the field quantities on the surface. If you select an object, HFSS will plot the field quantities within the volume of the object.

You can choose to create a scalar plot or a vector plot of the fields. A scalar plot can use several user selectable plot types to illustrate the magnitude of field quantities on surfaces or volumes. A vector plot uses arrows to illustrate the magnitudes of the x-, y-, and z-components of field quantities.

Field Quantities

The default field quantities that can be plotted, their definitions, and associated units are as follows (see the following note for issues in HFSS-IE for plotting magnetic and electric current):

Field Quantity	Definition	Units
CG Fields		
Q		
E		
Vector_E	The electric field, E(x,y,z,t).	V/m
Mag_E	The magnitude of the electric field, |E|(x,y,z,t).	V/m
DC R/L Fields		
Phidc	Voltage (electrostatic potential) from the DC solution, referenced to the sink terminal of the net.	V/m
VolumeJdc	DC current density vector in the conductor.	$Amps/m^2$
Mag_VolumeJdc	Magnitude of VolumeJdc.	$Amps/m^2$
Volume_Loss_DensityDc	The resistive (ohmic) power loss density from the DC solution, and is	W/m^3

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	defined as: $\frac{1}{\sigma}\left\|f_{\mathrm{dc}}\right\|^2$ Where conductivity of the metal.	
DC R/L Thin Conductor Fields		
JdcThinCond	DC surface current density vector in a thin conductor.	Amps/m
Mag_JdcThinCond	Magnitude of JdcThinCond.	V/m
PhidcThinCond	Electrostatic potential in a thin conductor.	V/m
AC R/L Fields		
J		
SurfaceJac	Surface current density vector from AC RL solution.	Amps/m
Mag_SurfaceJac	Magnitude of SurfaceJac vector.	V/m
H		
Mag_H	The magnitude of the magnetic field, |H|(x,y,z,t).	Amps/m
Vector_H	The magnetic field, H(x,y,z,t).	Amps/m

Field Quantity	Definition	Units
HFSS Fields		
E		
Mag_E	The magnitude of the electric field, |E|(x,y,z,t).	V/m
Complex Mag E	The complex magnitude of the electric field, |E|(x,y,z).	V/m
Vector_E	The electric field, E(x,y,z,t).	V/m
H		
Mag_H	The magnitude of the magnetic field, |H|(x,y,z,t).	Amps/m
Complex Mag H	The complex magnitude of the magnetic field, |H|(x,y,z).	Amps/m
Vector_H	The magnetic field, H(x,y,z,t).	Amps/m
J		
Mag Jsurf	The magnitude of the current density, |J|(x,y,z,t), on the surface.	Amps/m
Complex Mag Jsurf	The complex magnitude of the current density, |J|(x,y,z), on the surface.	Amps/m
Vector Jsurf	The current density, J(x,y,z), on the surface.	Amps/m
Mag Jvol	The magnitude of the current density, |J|(x,y,z,t), over the	Amps/m

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	volume.	^{2}
Complex Mag Jvol	The complex magnitude of the current density, |J|(x,y,z), over the volume.	Amps/m^2
Vector Jvol	The current density, J(x,y,z), over the volume.	Amps/m^2
Other		
Vector Real Poynting	The Poynting vector, defined as E x H*.	W/m^2
Surface_Loss_ Density	Resistive power loss density from the AC RL solution.	W/m
Volume_Loss_ Density	Resistive power loss volume from the AC RL solution.	W/m^3
Local SAR	The specific absorption rate.	W/kg
Average SAR	The average specific absorption rate.	W/kg
Certification SAR	The IEEE specific absorption rate certification number.	W/kg

Note: Plotting Magnetic current in HFSS-IE is relatively simple. It is M = Exn on an interface between two non-conducting materials. This is an equivalent current. Plotting Electric current in HFSS-IE involves three cases:

1. J = nxH on a surface of solid conductor (H is zero inside the conductor). This is a TRUE physical current.
2. J = nx(H1-H2) on a conducting sheet which is inside a region/background (or it is not an interface between two regions). This is a TRUE physical current.
3. J = nxH1 on a conducting boundary between two regions (it doesn't matter if the two regions have the same material). H1 is the field on the positive side of the surface. However, if region 2 is the background, we will display J = nxH2. This is an equivalent current.

Specifying the Phase Angle

Specifying the phase angle at which the field quantity is calculated enables you to compute the real part of the field's magnitude at different points in its cycle. These quantities can be represented in the form

$$A(x, y, z, t) = A(x, y, z)\cos(\omega t + \theta)$$

where

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- ω is the angular frequency specified during the solution.
- θ is the phase angle (the offset from a cosine wave that peaks).

Peak Versus RMS Phasors

This section concerns how field quantities are represented within HFSS. Some users will not need this information, such as those who wish to know port S-parameters or relative amplitudes of field solutions. Those that wish to find absolute field values, for example, will need to review the difference between the two types of field representation, peak and RMS.

HFSS solves in the frequency domain and obtains a phasor representation of the steady-state finite element field solution. Physical quantities such as the instantaneous (time domain) electric field are then obtained as derived quantities from the phasor representation.

If *Ex* is the x-component of a "peak" phasor quantity representing a time-harmonic electric field, the physical electric field x-component at time *t*, denoted $E_x(t)$, is computed from

$$\boldsymbol{E}_x(t) = \Re\left[E_x e^{j\omega t}\right] \quad (1)$$

where

- $\Re$ is the real part of a complex number or function.
- ω is angular frequency, $2\pi f$.
- *j* is the imaginary unit, $\sqrt{-1}$.
- *t* is the time.

On the other hand, if $\mathbf{E}_x$ is an "RMS" phasor, an additional factor of $\sqrt{2}$ is required as follows:

$$\boldsymbol{E}_x(t) = \Re\left[\sqrt{2}E_x e^{j\omega t}\right] \quad (2)$$

As a consequence of these equations, the peak physical field, max ($E_x(t)$) observed over a full time cycle is $max(\boldsymbol{E_x}(t)) = |E_x|$ for peak phasors and $max(\boldsymbol{E_x}(t)) = \sqrt{2}\,|E_x|$ for RMS phasors.

Additionally, given field phasors E and H, to compute the time-averaged power flow through a surface, the normal component of the real part of the complex Poynting vector is integrated over the surface. The correct form of the complex Poynting vector *S* depends on which phasor representation is used.

For peak phasors, $S = \frac{1}{2}E \times H^*$.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For RMS phasors, $E = E \times H^*$.

The conventions used by HFSS are as follows:

- Each propagating mode incident on a port contains 1 watt of time-averaged power.
- Circuit gap sources are specified in a peak sense. That is, if a voltage gap source magnitude is 5 volts, then the time domain circuit source behaves as $v(t) = 5\cos\omega t$. Likewise for a current gap source.
- Plane wave sources are specified in a peak sense. That is, if the plane wave magnitude is 5 V/m, then the plane wave incident field magnitude is $E(t) = 5\cos(\boldsymbol{k} \cdot \boldsymbol{r} + \omega t)$.
- Radiated power, as computed by the fields post processor, is a time-averaged quantity computed using the complex Poynting vector.
- Phasors in the Fields Calculator are peak phasors. The Poynting vector button in the calculator
  therefore implements the Poynting vector for peak phasors,

$$S = \frac{1}{2} E \times H^*$$

Calculations that compute either average or instantaneous time domain quantities must adhere to the peak phasor conventions.

Calculating the SAR

The specific absorption rate (SAR) is a measure of the amount of electromagnetic energy absorbed in a lossy dielectric material. The SAR is a basic scalar field quantity that can be plotted on surfaces or within objects in HFSS. The **HFSS>Fields>SAR Setting...** command lets you specify the SAR setting. You have a choice ofIEC/IEEE 62704-4 Draft and Gridless.

For the IEEE/IEC STD 62704-4 we subdivide the model space into a grid of voxels properly aligned along the global coordinate system. The density and local SAR values are then mapped over the grid of voxels. Afterwards the two-pass average SAR algorithm is applied to the voxels. Since this two pass algorithm is very time consuming we try to use parallel processing as much as possible. The algorithm is divided into two phases so that the results of the time consuming phase can be reused when fields change.

For more details, see IEC "Determining the Peak Spatial Average Specific Absorption Rate (SAR) in the Human Body from Wireless Communications Devices, 30 MHz - 6 GHz: Requirements for Using the Finite-Element Method for SAR Calculations, specifically involving Vehicle Mounted Antennas and Personal Wireless Devices."

For Gridless, HFSS uses the following equation to calculate the SAR: $\sigma * E^2/(2\rho)$.

where

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- σ = the material's conductivity. This is defined as: $\sigma_{bulk}+\omega\varepsilon_0\varepsilon_r tg\delta$
- ρ = the mass density of the dielectric material in mass/unit volume.

There are two types of SAR Field Overlay plots available in HFSS: local SAR, and average SAR. When calculating the local SAR, HFSS uses the equation above to calculate the SAR at each mesh point on an overlay plot. HFSS interpolates the values between the mesh points across the plot.

When plotting the average SAR, for each mesh point on the plot, HFSS reports the SAR averaged over a volume that surrounds that point. The volume is determined by the settings for the material's mass density and mass of the material surrounding each mesh point set in the **Specific Absorption Rate Setting** dialog box. When you use the Gridless method, the volume will not cross object boundaries. The IEEE/IEC method performs averaging over all tissues.

The Certification SAR quantity provided in the Fields Calculator is an efficient way to determine the peak spatial-average SAR. When computing the certification SAR using the Gridless method, HFSS assumes the peak spatial-average SAR is located on an object surface. HFSS therefore searches for the peak local SAR on the surfaces, and creates an averaging volume around that location, completely inside the object with an axis normal to the surface at the location of the peak value of the local SAR.

If the Average SAR method is IEC/IEEE 62704-4 Draft, then the IEC/IEEE 62704-4 Draft standard is followed. Voxel meshes are used, E fields, mass density and conductivity values are resampled onto the voxels first. Then the algorithm for IEC/IEEE 62704-1 is applied to calculate the psSAR. In order to reduce the computation time for the iterative resampling and SAR averaging, subregions with SAR hot spots are identified in a pre-scan. In these subregions, the psSAR is then calculated according to IEC/IEEE 62704-1. The maximum psSAR of all subregions is reported as the psSAR maximum. The psSAR is calculated on an initial voxel mesh according to the procedure defined in IEC/IEEE 62704-1. Then the computational domain shall be resampled with on a voxel mesh of half grid size. This procedure is repeated until the differences in psSAR from the previous iteration to the current iteration are less than 1%.

Average SAR Through Voxelization

To calculate the Average SAR, HFSS first subdivides the model space into a grid of voxels properly aligned along the global coordinate system. The density and local SAR values are then mapped over the grid of voxels. Afterwards, HFSS applies the two-pass average SAR algorithm to the voxels. Finally HFSS distributes the average SAR from the voxels back to the FEM mesh. Because this two pass algorithm is very time consuming, HFSS uses parallel processing as much as possible. The algorithm is divided into two phases so that the results of the time consuming phase can be cached and reused while fields change due to new combinations from edit sources.

HFSS progress messages are included here in parentheses and in red color.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Build the grid of voxels.
    a. If we have cached data, load the data. (2nd phase: Reading voxel data) Go to 3.
    b. Otherwise subdivide the model space into a grid of voxels and map density to voxels. See below for details on mapping. (1st phase: Mapping density to voxels...)
2. Collect information for all valid and unused voxels.
    a. Traverse all voxels to collect all valid voxels. For each valid voxel store the extends in one direction and the used ratio of the exterior voxels. See below for requirement for valid voxels. See Figures 1 and 2. (1st phase: 1st pass …)
    b. Traverse all valid voxels to collect all used voxels. (1st phase: 2nd pass ...)
    c. For the unused voxels find possible extends in the 6 directions, see Figure 3. For each unused voxel store an array of directions, extends and ratio of exteriors.
    d. Cache data from a and c.
3. Collect voxels needed for field plot and calculation (field geometry instance).
    a. Get overall elements for field geometry instance.
    b. Get all voxels that cover the nodes of these elements. (2nd phase: Collecting voxels containing elements)
    c. Classify these voxels as valid, used and unused. For each used voxel add all the valid voxels using it to the valid set.
    d. Collect all elements needed to get the data for all the voxels above. (2nd phase: Collecting involved elements)
    e. Map FEM local SAR to voxels. (2nd phase: Mapping data to voxels)
4. Calculate average SAR.
    a. Traverse all valid voxels. For each valid voxel collect average SAR and mark used voxels and propagate average SAR to used voxels. (2nd phase: 1st pass)
    b. Traverse all unused voxels. For each calculate the average SAR on possible directions and take the maximum. (2nd phase: 2nd pass)
5. Distribute average SAR to the FEM mesh from the voxels. For each element node take the SAR value from the voxel which contains this node. (2nd phase: Distributing fields)

This section describes how HFSS maps general data (mass density and conductivity) from FEM mesh to voxels. For each voxel:

1. Collect all intersecting tetrahedra and calculate data over these tetrahedra.
2. Cut each intersecting tetrahedron by this voxel. This gives a series of new smaller tetrahedra.
    a. For each new tetrahedron get data by interpolating over its parent (the original tetrahedron that it is cut from). Integrate the data to get the total over it.
    b. Add the contributions to get the total over the intersection of this voxel and this tetrahedron.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Now add the total from above for all intersecting tetrahedra. This gives the total over this voxel. Now take the average by dividing this total by the voxel volume.

A voxel is counted as tissue if its centroid lies in an FEM element with nonzero conductivity and the field value at this location is used for this voxel. The density at each voxel is the total tissue mass divided by voxel volume.

A voxel is valid if the following holds:

1. Expand a cubic volume centered at the voxel evenly in the six directions aligned along the global axis so that the enclosed tissue mass is within 0.0001% of the prescribed mass.
2. Less than or equal to 10% of the cube contains background material in volume.
3. None of the six faces is completely filled with background material.

Transient Solution Theory

An important advantage of the Finite-Element Method (FEM) is its ability to solve Maxwell's equations on an unstructured mesh [1]. In such a mesh, the elements have a range of sizes and orientations such that, rather than forming a regular grid, they conform to the geometry of the model, respecting all its details. The use of unstructured meshes, combined with automatic mesh adaptation in HFSS Frequency Domain, has been instrumental in delivering accurate results for complicated geometries.

So far, commercially available solvers based on time-domain methods have relied on the Finite Difference Time Domain method (FDTD) [2] or on the closely related Finite Integration Technique (FIT). The use of unstructured meshes for both schemes presents technical difficulties that have yet to be overcome, and thus both FDTD and FIT continue to rely on brick-based space partitioning.

Time-domain methods developed for unstructured meshes such as the Finite Volume Time Domain (FVTD) [3, 4] or the Finite Element Time Domain (FETD) [5] methods do not offer an acceptable trade-off between accuracy, speed and memory usage. However, recent advances in finite-element techniques have led to a new scheme based on the Discontinuous Galerkin [6] family of numerical methods. This scheme retains the flexibility, accuracy and reliability of unstructured-mesh finite-element methods but avoids the solution of a large matrix equation at each time step. Instead, in the Discontinuous Galerkin Time Domain (DGTD) method, each mesh element advances in time using its own time step in a synchronous manner. This results in a significant speed-up on unstructured meshes as the largest mesh elements typically take time steps that are two to five orders of magnitude larger than those of the smallest mesh elements.

This chapter provides an explanation of how the DGTD method has been implemented in HFSS Transient. as the Hybrid Solver. It also describes the Implicit Solver for efficient simulation of electrically small structures.

Discontinuous Galerkin Finite Element Method

The DGTD solver provides the time-domain solution of Maxwell's Equations.

$$\frac{\partial \vec{D}}{\partial t} + \vec{J} = curl(\vec{H}) \quad \frac{\partial \vec{B}}{\partial t} = -curl(\vec{E}) \tag{1}$$

$$div(\vec{D}) = \rho \qquad div(\vec{B}) = 0$$

The mathematical framework of the Discontinuous Galerkin family of numerical methods for Maxwell's equations has been presented by Jan Hesthaven and Tim Warburton [7, 8]. To apply the DG method, we choose basis and test functions local to each mesh element *T*, in a similar way to the Finite Element Method:

$$\int_T \frac{\partial \vec{D}}{\partial t} \cdot \vec{\varphi} = \int_T curl(\vec{H}) \cdot \vec{\varphi} - \int_T \vec{J} \cdot \vec{\varphi} = \int_T curl(\vec{\varphi}) \cdot \vec{H} - \int_T div(\vec{\varphi} \times \vec{H}) - \int_T \vec{J} \cdot \vec{\varphi} \tag{2}$$

$$\int_T \frac{\partial \vec{B}}{\partial t} \cdot \vec{\varphi} = \int_T -curl(\vec{E}) \cdot \vec{\varphi} - \int_T curl(\vec{\varphi}) \cdot \vec{E} + \int_T div(\vec{\varphi} \times \vec{E})$$

As is the case with the frequency-domain finite-element solver, the DGTD method is free of spurious solutions [9] and supports higher-order basis functions. In the time domain, the use of high orders minimizes dispersion errors occurring during the simulation of electrically large problems. The DGTD solver not only employs high-order elements but allows mixed element orders in the same mesh, known as hp-adaptivity, to optimize accuracy and solution times.

Following the same approach as in the Finite Volume Method, the divergence term containing volume integrals is transformed into surface integrals:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\int_T \frac{\partial \vec{D}}{\partial t} \cdot \vec{\phi} = \int_T curl(\vec{\phi}) \cdot \vec{H} + \int_{\partial T} (\vec{n} \times \vec{H}) \cdot \vec{\phi} - \int_T \vec{J} \cdot \vec{\phi} \quad (3)$$

$$\int_T \frac{\partial \vec{B}}{\partial t} \cdot \vec{\phi} = -\int_T curl(\vec{\phi}) \cdot \vec{E} - \int_{\partial T} (\vec{n} \times \vec{E}) \cdot \vec{\phi}$$

The tangential fields $\vec{n} \times \vec{E}$ and $\vec{n} \times \vec{H}$ are then evaluated as upwind fluxes at the surface of *T* by using a Riemann solver [10]. Separating the treatment inside the element from its surface provides a robust and flexible framework to take into account boundary conditions. This separation also enables various combinations of locally implicit and locally explicit time-integration schemes for instance to achieve an optimum trade-off between speed and memory, without compromising accuracy and stability.

Local Time Stepping

A prime benefit of satisfying Maxwell's equations in a way analogous to the Finite Volume Method is greatly reduced RAM usage. Since the DGTD solver avoids solving the large matrix equation that represents the entire computational domain at each time step, no large matrix needs to be stored.

One of the key features of the DGTD solver is an innovative local time-stepping scheme that advances in time each mesh element independently from its neighbors. This feature efficiently exploits the use of highly unstructured meshes and hp-adaptivity: in the DGTD solver, each mesh element has its own energy-based stability criterion [11], calculated from its size, material properties and basis-function type and order.

Figure 1 illustrates the process. This figure shows a cut-plane through an unstructured mesh model of a ground-penetrating radar. Each element of the mesh is colored according to the time-step values used to locally advance the fields in time. Large elements are colored yellow and use larger time-steps than the smaller elements colored green and or even smaller elements in blue. This results in fewer iterations for most mesh elements and reduced overall simulation times.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

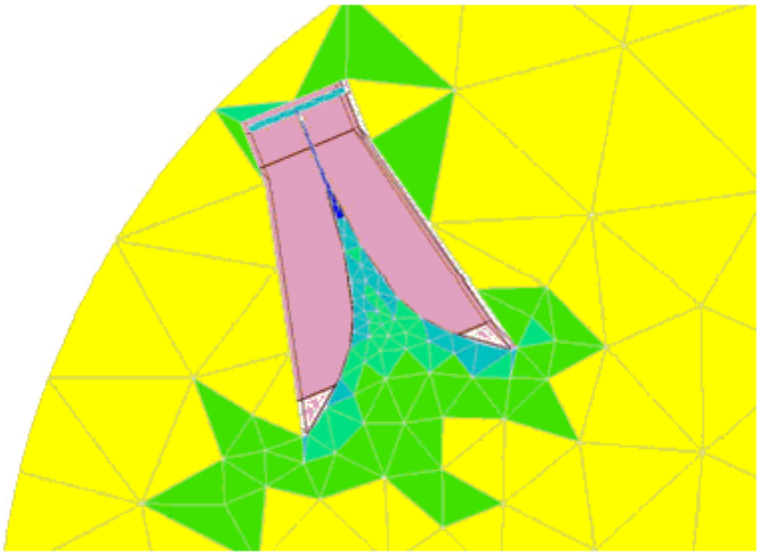

Fig. 1 Local time stepping

The time step of any mesh element is chosen such that at the largest time steps the entire simulation is "in sync." From a user point of view however, the local time-stepping scheme is transparent and all time-domain data are provided or rendered synchronously "on the fly" as needed. In contrast to FIT or FDTD, the DGTD solver doesn't advance in time uniformly using the smallest time step but uses an optimal range of time steps that minimize simulation times, ensures stability and minimizes the dispersion error.

One last important feature of DGTD solver is its affinity for parallel computations. This is a direct consequence of the local nature of its formulation that yields a spatially compact numerical scheme. Parallelism is naturally exploited with this scheme by partitioning the computational domain into sub-domains and solving each sub-domain concurrently on multi-core or many-core systems.

Materials in Time Domain

In any time-domain method, handling frequency-dependent material parameters is not straightforward. Two important cases, frequently encountered in electromagnetic simulations, are (1) non-perfectly conducting metals and (2) lossy dielectric materials.

In most high-frequency applications, one does not solve for fields inside non-perfectly conducting metals. Rather, the skin effect is expressed with a boundary condition on the surfaces of the metal. Since the skin impedance is frequency dependent, containing a factor Ö (frequency), a suitable way has to be found to approximate this in the time domain. In HFSS Transient, the Padé approximation [ ] is used. With this approximation one can expect accurate

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

results over a very wide band which includes the highest frequency of interest. Near DC, a modest reduction in accuracy is to be expected.

Lossy dielectric materials can be described by a bulk conductivity s or by a loss tangent tan(d). If the conductivity is the only loss mechanism, the relation between the two is tan(d) = s/(2p×frequency ×e_0e_r). In any case, the loss tangent of a material is frequency dependent, and a suitable way has to be found to approximate it in the time domain. In HFSS Transient, when a lossy dielectric is specified with a certain loss tangent at the highest frequency of interest, the Debye model is used to describe the material for all frequencies. The Debye model is more realistic than the assumption of a constant loss tangent.

Excitations in Time Domain

Excitations available in HFSS Transient are wave ports, lumped ports, voltage sources, current sources and incident waves. In the case of ports, the modal port solution is provided by the same 2D port solver as is used in HFSS Frequency Domain. If a lossy dielectric or a non-perfectly conducting metal touches the port, the port impedance will be frequency dependent. A frequency-dependent excitation poses a problem to any time-domain solver. HFSS Transient, as well as some competing time-domain codes, uses the mode belonging to the lossless case as an excitation in the port.

In order to deal with higher-order modes or with frequency-dependent (lossless) modes, HFSS Transient takes advantage of the trans-finite element method, which has always been an important technique in HFSS Frequency Domain. In HFSS Transient, elements touching the ports are set aside in an implicit time-stepping scheme that is close to the FETD method. Since this is a small fraction of the total number of elements, the penalty for solving the matrix equation is negligible, while the implicit method allows large time steps. The upshot is that higher-order modes and frequency-dependent (lossless) modes are handled accurately.

In a standard HFSS simulation a port excitation is the equivalent of an excited infinite transmission line connected to the port face. For a modal project this is easy to visualize but in a terminal project the user defines the input voltage. This raises the question of how this input voltage is applied to the port for terminal designs. While the following discussion is directed to transient simulations, it is also applicable to HFSS terminal designs where the Incident Voltage option in Edit Sources is used.

To derive the correct model for a terminal port, first consider the transmission line section shown in Figure 1. The port is at the point 0-0 and to the left is the equivalent infinitely long feed line.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

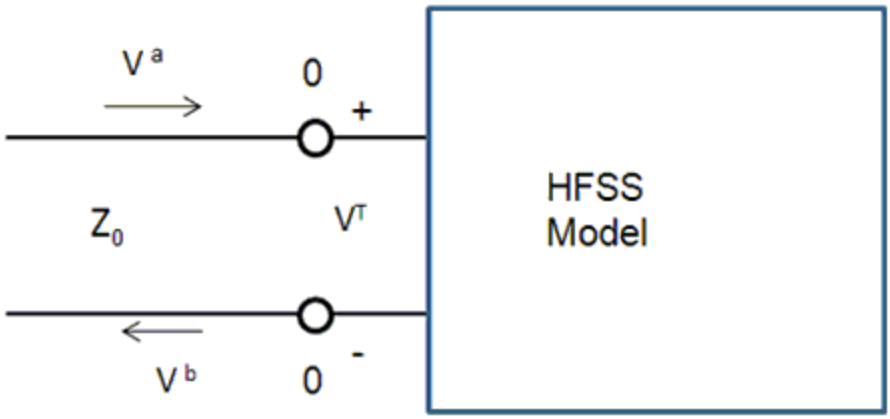

Figure 1

For this model then V^a is the incident voltage and V^b is the reflected voltage seen at the port. We know from the definition of voltage and current on a transmission line that for the total voltage, V^T, the following is true:

$$V^T = V^a + V^b \quad (1)$$

If the characteristic impedance of the line is equal to Z0 then we also know:

$$Z_0 I = V^a - V^b \quad (2)$$

If we add equations (1) and (2) we find that at point 0-0:

$$V^T + Z_0 I = 2V^a \quad (3)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If we apply Kicrchkoff's voltage law to the equivalent circuit shown in Figure 2 we see it yields the result shown in (3). This is the port model for a terminal port in HFSS.

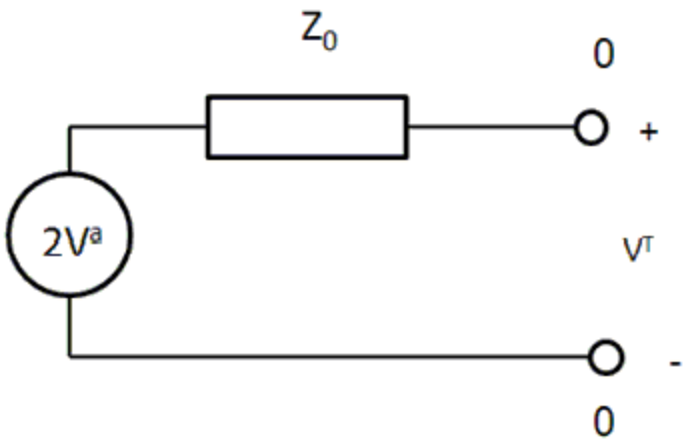

Figure 2

To be consistent then the same terminal port excitation is used in HFSS Transient. Therefore if you define an incident voltage signal in the transient setup that signal is applied to the 3D model as a voltage source of twice the user defined amplitude in series with the terminal impedance.

> **Note:**
>
> As a consequence of the above discussion, one needs to be careful when comparing results with a circuit tool or textbooks using the voltage source shown in Figure 2. If one volt is used for the voltage source in the circuit simulator, this should be compared with an HFSS transient simulation with edit sources set to 0.5 volt.

Before considering an example one more point needs to be made. In the reporter for HFSS Transient when plotting the voltage at a given port the options are Input( ) and Output( ). Input is the user defined incident voltage (Va in the Figure 2) and Output is the reflected voltage (Vb = VT - Va). We can see then that to view the total voltage at the port terminals one needs to create an output variable that is the sum of Input ( ) and Output( ). We will consider two examples to illustrate this.

Consider the HFSS Transient model of a simple coax shown in the Figure 3. It is an air filled 50Ω line that has a center section with a smaller inner radius that results in an impedance of 91.5 ohm in that part of the line. Each section of this air filled coax (the two 50 Ω and the one 91.5 ohm sections) has a length of 100mm. This length has a time delay of 1/3 nS. This was simulated in HFSS Transient using the incident voltage signal shown in the inset for Figure 3.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

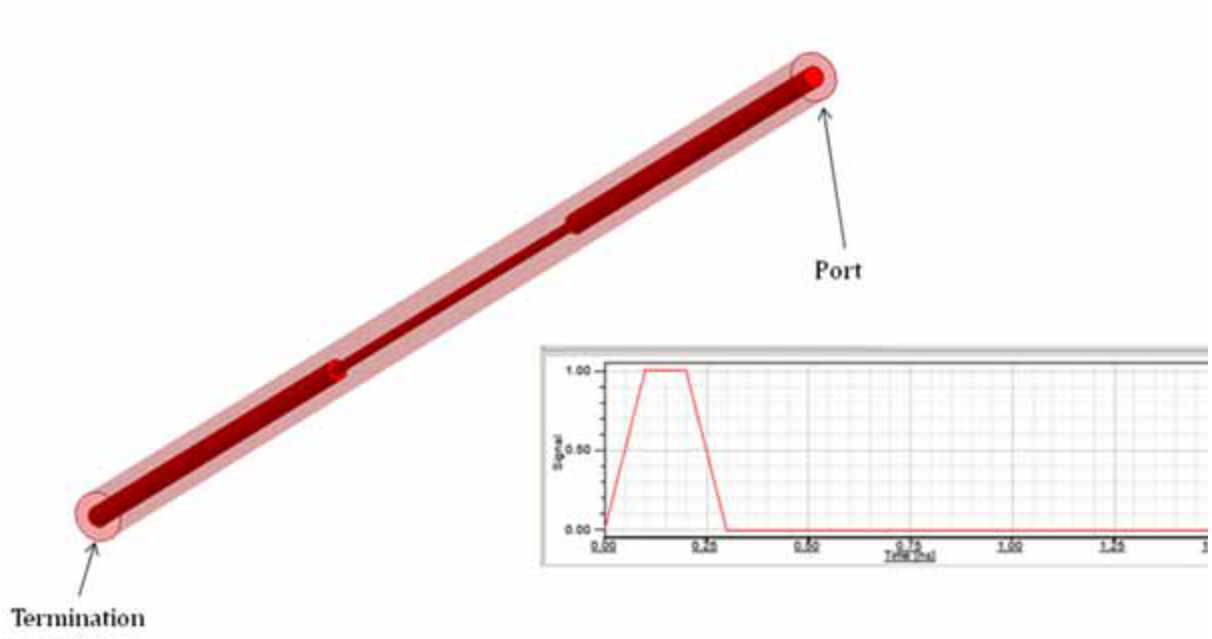

Figure 3

This model was simulated with a single 50 Ω terminal port on one end and a matched termination on the opposite end. The response seen at the port is shown below in Figure 4.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

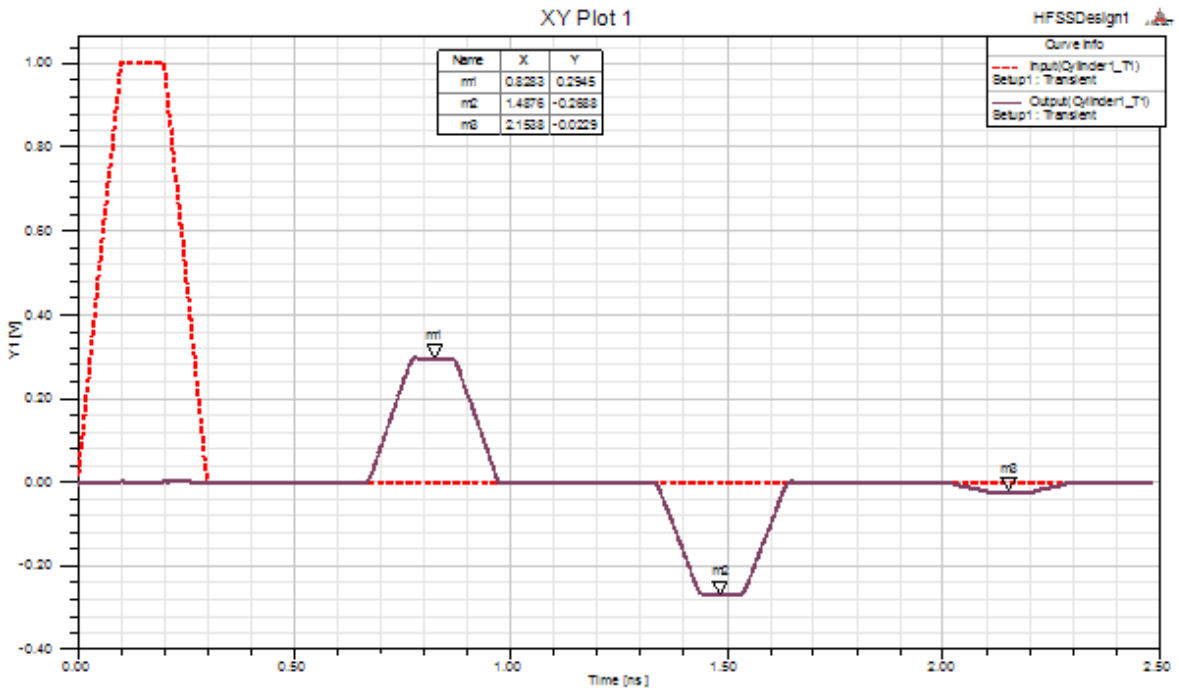

Figure 4

Figure 4 shows the Input and Output signals at the port terminal (Cylinder1_T1). Remember that Input( ) is the incident signal as shown in Figure 3. If one uses the equations for reflection and transmission to compute the amplitude of the signal at the 3 points shown in the figure these textbook equations would give 0.29, -0.27,-.02 respectively. We can see that the reflected voltage is accurately computed for the applied signal.

For an example where one might be more interested in the total voltage a second case was considered. The same HFSS Transient model was simulated with the same incident signal, but this time the port terminal impedance was set to 30 Ω. The HFSS Transient response for this simulation is shown in the Figure 5.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

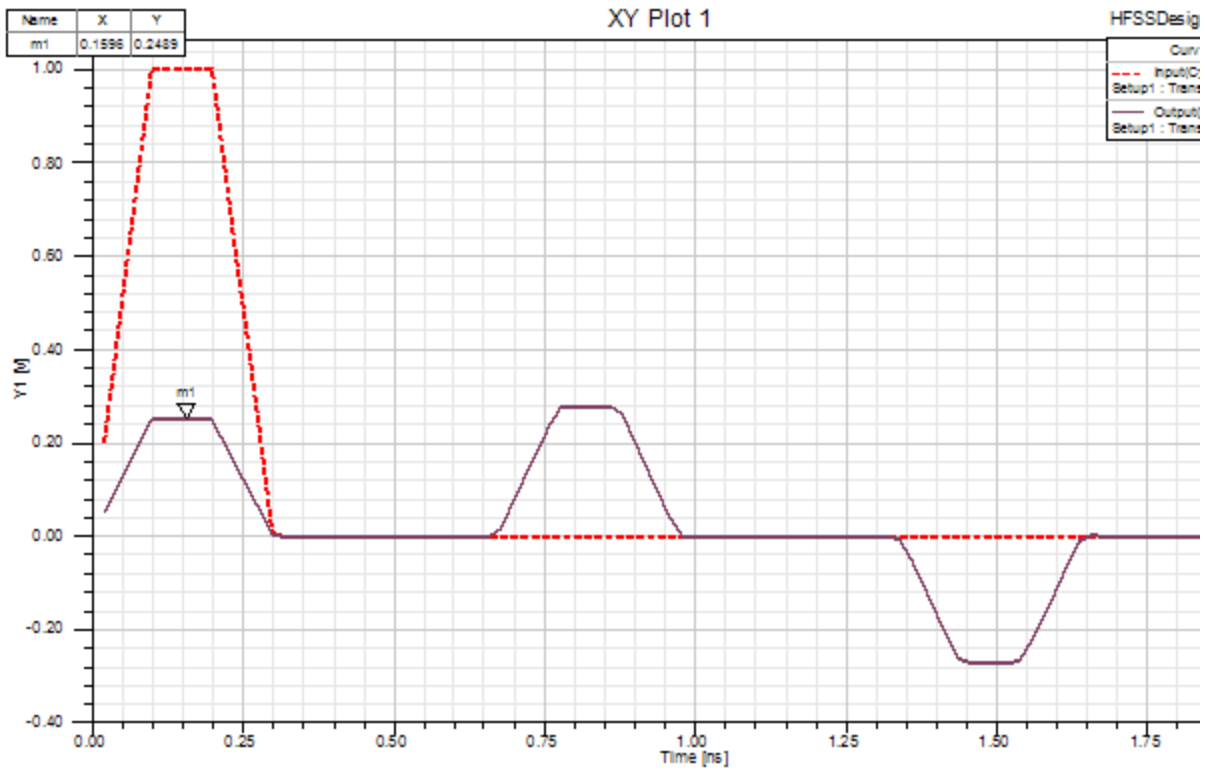

Figure 5

For the time between 0.1 - 0.2 nS the textbook response says that V^T should be 1.25V. Again that is the total voltage and if you add together the 2 curves shown in the plot you would get the correct response of 1.25V in that range.

Analysis Setup in Time Domain

Two classes of analyses exist: those focused on device characterization, and more general analyses. In the case of device characterization, one is interested in quantities like S-parameters and/or time-domain output at ports due to excitation of a specific port. This requires that excitations be "on" one at a time. For each active port and mode, a separate simulation is done. These simulations are independent and can be distributed over a network, to be executed in parallel. Each active port and mode will employ an excitation with the same time profile.

In the more general analysis type, all active ports and modes are "on" simultaneously. Each one can have an excitation with a different time profile. This type of analysis gives you more freedom, but S-parameters cannot be extracted.

In both classes of simulations, fields can be saved and visualized.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Target Residual for Transient Analysis Duration

The residual is defined to be the ratio of the global RMS value of the electric field at time *t* to the maximum RMS value in the time range zero to time *t*:

$$E_{rms}(t) = \sqrt{\frac{\sum_{i=1}^{N} \left|\vec{E}_i t\right|^2}{N}} \quad (1)$$

$$Residual(t) = \frac{E_{rms}(t)}{max\{E_{rms}(\tau): 0 \le \tau \le t\}} \quad (2)$$

where $\vec{E}_i$ is the electric field at the ith interpolation point in the mesh which contains a total of *N* interpolation points. Note that the number of interpolation points is typically much larger than the number of mesh vertices. The time duration of a simulation can be controlled by specifying a target residual in db20 located in the Duration tab of the solution setup.

Transient Implicit Solver

The implicit solver is based on the finite element time domain (FETD) method with an implicit time stepping [13-14]. The Implicit Solver is unconditional stable and is not limited by any Courant-Friedrichs-Lewy (CFL) type condition as the Hybrid Solver. Therefore the Implicit Solver can have much larger time step compared to the Hybrid Solver. To satisfy Nyquist sampling theory, the time step for the Implicit Solver is such that resolves the spectral content of the input signal (time-step = 1/(20*fmax)). On the other hand, the implicit solver solves a large sparse system matrix during time stepping. Therefore, each step of the implicit solver takes much longer than that of the hybrid solver. Both the memory usage and simulation time can increase rapidly as the problem size becomes larger. This renders the implicit solver less efficient for solving electrically large problems. Finally, the implicit solver does not support GPU acceleration. A warning message will be shown in the user interface when the GPU is enabled for an implicit simulation.

The hybrid solver is based on the explicit-implicit discontinuous Galerkin time domain method [15]. When the GPU is enabled, only the explicit part of the hybrid solver is running and being accelerated by GPUs. More information about the hybrid solver can be found in Transient Solution Theory.

Domain Decomposition Method

HFSS solves a linear matrix equation of the form:

$$\mathbf{Ax} = \mathbf{b} \quad (1)$$

where the excitation vector **b** is commonly called the right-hand-side or RHS. The number of RHS vectors depends on the total number of modes used to excite the problem.

HFSS provides three distinct solution methods. By default, a direct solver is used and is the preferred method for small to medium size problems and/or problems with a large number of modes. A major strength of the direct solver is the ability to provide a solution for a large number of modes with relatively small computational overhead for the multiple RHS. However, if the problem size is too large for the machine memory, the second option is to use the iterative solver which can handle larger problems but requires a complete solution for each RHS. The iterative solver modifies the matrix equation (1) by multiplying both sides with a pre-conditioner, M, in order to enable a faster solution:

$$\mathbf{MAx} = \mathbf{Mb} \quad (2)$$

Both the direct solver and the iterative solver work only with a single machine's shared memory. This limitation is addressed in HFSS with the introduction of an advanced solving technique called the Domain Decomposition Method (DDM) which enables the use of distributed memory across many different machines to solve very large problems.

- Basic DDM Theory
- Computational Memory
- Computational Time

Basic DDM Theory

DDM has emerged as a powerful and attractive technique due to its inherent parallelism which enables the use of distributed memory. DDM is based on a divide-and-conquer philosophy where instead of solving a large and complex problem directly, the original problem as defined by the mesh is partitioned into smaller, possibly repetitive, and easier to solve sub meshes or sub-domains. In this approach it is critical to enforce continuity of electromagnetic fields at the interfaces between adjacent sub-domains through some suitable boundary conditions.

To illustrate the basic idea of DDM, we solve (1) by decomposing the original problem into two domains. Subsequently, we have:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\begin{bmatrix} \mathbf{A}_{11} & \mathbf{A}_{12} \\ \mathbf{A}_{21} & \mathbf{A}_{22} \end{bmatrix} \begin{bmatrix} \mathbf{x}_1 \\ \mathbf{x}_2 \end{bmatrix} = \begin{bmatrix} \mathbf{b}_1 \\ \mathbf{b}_2 \end{bmatrix} \quad (3)$$

where $\mathbf{A}_{ii}$, $\mathbf{x}_i$ and $\mathbf{b}_i$, i=1,2 are system matrix, solution vector and RHS for domain *i*, respectively and $\mathbf{A}_{12}$, $\mathbf{A}_{21}$ are the coupling matrices between the two domains. To solve in parallel sub-domain problems, one popular domain decomposition algorithm is of Jacobi type:

$$\begin{bmatrix} \mathbf{A}_{11} & \mathbf{A}_{12} \\ \mathbf{A}_{21} & \mathbf{A}_{22} \end{bmatrix} = \begin{bmatrix} \mathbf{A}_{11} & \mathbf{0} \\ \mathbf{0} & \mathbf{A}_{22} \end{bmatrix} + \begin{bmatrix} \mathbf{0} & \mathbf{A}_{12} \\ \mathbf{A}_{21} & \mathbf{0} \end{bmatrix}. \quad (4)$$

Using (4) and applying iteration, (3) can be solved as

$$\begin{bmatrix} \mathbf{A}_{11} & \mathbf{0} \\ \mathbf{0} & \mathbf{A}_{22} \end{bmatrix} \begin{bmatrix} \mathbf{x}_1 \\ \mathbf{x}_2 \end{bmatrix}^{(n)} = \begin{bmatrix} \mathbf{b}_1 \\ \mathbf{b}_2 \end{bmatrix} - \begin{bmatrix} \mathbf{0} & \mathbf{A}_{12} \\ \mathbf{A}_{21} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \mathbf{x}_1 \\ \mathbf{x}_2 \end{bmatrix}^{(n-1)}. \quad (5)$$

Through some simple algebra, equation (5) leads to two coupled systems:

$$\mathbf{A}_{11}\mathbf{x}_1^{(n)} = \mathbf{b}_1 - \mathbf{A}_{12}\mathbf{x}_2^{(n-1)} \qquad \mathbf{A}_{22}\mathbf{x}_2^{(n)} = \mathbf{b}_2 - \mathbf{A}_{21}\mathbf{x}_1^{(n-1)} \quad (6)$$

By setting $\mathbf{x}_1^{(0)} = 0$ and $\mathbf{x}_2^{(0)} = 0$ and, we have initial guess $\mathbf{x}_i^{(1)} = \mathbf{A}_{ii}^{-1}\mathbf{b}_i$ which is the local solution of each sub-domain problem. These initial solutions are then refined through coupling matrices $\mathbf{A}_{12}$ and $\mathbf{A}_{21}$ until equilibrium is reached.

The approach (5) is known as a stationary Jacobi solution of (3) which unfortunately converges rather slowly. A more advanced approach is to apply as a preconditioner

leading to:

$$\begin{bmatrix} \mathbf{A}_{11} & \mathbf{0} \\ \mathbf{0} & \mathbf{A}_{22} \end{bmatrix}^{-1} \begin{bmatrix} \mathbf{A}_{11} & \mathbf{A}_{12} \\ \mathbf{A}_{21} & \mathbf{A}_{22} \end{bmatrix} \begin{bmatrix} \mathbf{x}_1 \\ \mathbf{x}_2 \end{bmatrix} = \begin{bmatrix} \mathbf{A}_{11} & \mathbf{0} \\ \mathbf{0} & \mathbf{A}_{22} \end{bmatrix}^{-1} \begin{bmatrix} \mathbf{b}_1 \\ \mathbf{b}_2 \end{bmatrix}, \quad (7)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\begin{bmatrix} \mathbf{I} & \mathbf{A}_{11}^{-1}\mathbf{A}_{12} \\ \mathbf{A}_{22}^{-1}\mathbf{A}_{21} & \mathbf{I} \end{bmatrix} \begin{bmatrix} \mathbf{x}_1 \\ \mathbf{x}_2 \end{bmatrix} = \begin{bmatrix} \mathbf{A}_{11}^{-1}\mathbf{b}_1 \\ \mathbf{A}_{22}^{-1}\mathbf{b}_2 \end{bmatrix}. \quad (8)$$

Computational Memory

Using domain decomposition we need to solve (factorize) $\mathbf{A}_{11}$, $\mathbf{A}_{22}$ compared to solving **A** using the standard method. When a direct solver is used, DDM is inherently more memory efficient since a series of smaller matrices are needed to be solved compared to a large matrix. This is evident by assuming that domains are equally partitioned so that $N_1 = N_2 = N/2$ where N_1, N_2, and N are numbers of unknown for the sub-domains and the original problem respectively. Memory requirement for original problem typically scales as C_1N^a where C_1 is a constant and $\alpha > 1$. For an M domain decomposition solve, the total memory requirement is

$$MC_1\left(\frac{N}{M}\right)^{\alpha} = M^{1-\alpha}C_1N^{\alpha}$$

For example, if $\alpha = 1.5$, using 2-domains we save about 30% of total memory. Also keep in mind that the memory can be distributed across different machines enabling a problem to be solved which is not possible on a single machine.

Computational Time

A domain decomposition solution consists of three steps:

1. Mesh partitioning, a relatively fast process. HFSS will automatically partition the mesh into roughly equivalent sized mesh sub-domains to balance memory and solution times for the domains.
2. Matrix-assembly/solve where both **A** and **M** are solved in parallel
3. Domain iteration where we solve **MAx=Mb** via an iterative solver.

The solution time for solving the entire system (1) without DDM requires C_2N^{β} operations with a direct solver where $C_2$is a constant and $\beta > 1$ (and typically larger than α). For an M domain DDM solve, the factorization time of step 2 above is dominated by the most time consuming (i.e., largest) domains, given as:

$$C_2\left(\frac{N}{M}\right)^{\beta} = M^{-\beta}C_2N^{\beta}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Therefore, given $\beta > 1$, this stage exhibits a super-linear speed-up. This type of speed-up is commonly referred to as "scalable".

For step 3 the major computation is on the matrix-vector multiplication (**MA**)**x** which can be parallelized. In each iteration, the master node produces a new solution vector **x** and then sends its appropriate components to each domain (cpu/node/machine). Each domain then sends back to the master the vector **y=MAx** which is used by the master to produce a new solution vector **x**. This process goes on until **x** converges. In this step, the cost of matrix-vector multiplication per iteration is also scalable with respect to number of domains. Therefore if the iteration number remains relatively unchanged as number of domains increases, the domain decomposition solver can exhibit overall scalable performance.

HFSS SBR+ Technical Overview

HFSS SBR+ is a shooting-and-bouncing ray (SBR) method and solver for efficient prediction of installed far-field antenna patterns, coupling (S-parameters) between antennas, and Radar Cross Section (RCS) in the presence of electrically large scattering geometries. These sections provide technical details for working with SBR+.

- Shooting and Bouncing Rays (SBR)
- Excitations for SBR+
- Geometries and Boundaries in SBR+
- Meshing Operations for SBR+
- Physical Theory of Diffraction (PTD) and Uniform Theory of Diffraction (UTD)
- GO Blockage Technical Note
- Creeping Waves
- Visual Ray Tracing (VRT)
- Current Conformance and Array Conformance in SBR+
- Ray Statistics for SBR+ Analysis

Shooting and Bouncing Rays (SBR)

SBR+ uses a high-frequency (asymptotic) ray-tracing approximation that efficiently computes scattering from electrically large geometries. SBR+ can be thought of as a hybridization of geometrical optics (GO) and physical optics (PO). Many GO rays are launched from a radiation source (e.g., Tx antenna) toward the visible surfaces of the scattering geometry. The launched GO rays are vector-field weighted by the source antenna pattern or current distribution and represent diverging volumetric ray tubes. When a ray hits a surface, the ray "paints" a PO current on the geometry according to the GO boundary condition. These currents are radiated to the analysis observation domain for determination of far-field radiation or antenna coupling.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Then, the ray is reflected and traced, possibly to a second bounce. Its vector fields are updated according to GO and the material properties of the reflecting surface. When the reflected ray hits a surface again, it paints a second-bounce current and progresses to third bounce and so on. The process continues until the ray escapes from the scene without hitting another surface or reaches a maximum bounce number. If a penetrable surface is encountered by the ray, then a transmission ray is also generated in addition to the reflection ray.

The SBR methodology is intended to predict scattering from large-scale geometry, such as an antenna installation environment or platform. In general, it is not suitable for detailed simulation of the antennas, themselves, excepting cases where the antenna proper includes electrically large scattering geometry (e.g., reflector antenna). For this reason, HFSS SBR+ simulation requires some electromagnetic description of the source that launches and weights the rays. Conceptually, this source description can come in one of several supported forms when using HFSS SBR+:

- FEBI and/or IE simulation of antenna, resulting in distributed current sources or a far-field pattern excitation
- Idealized antenna source models (e.g., dipoles, monopoles, slots, horns, etc.)
- Imported far-field antenna patterns
- Plane-wave source (RCS application)

The first three are antenna characterizations that can also serve as receivers in an SBR antenna-coupling simulation. In the case a plane-wave source for determining RCS, the rays are launched in parallel from a plane outside the scattering geometry, being given equal initial weight. In this case, the represented volumetric ray tubes are initially neither diverging nor converging.

SBR workflow

The algorithm implemented in HFSS SBR+ is summarized in the following steps:

1. SBR sources may be introduced through Parametric Antennas in the SBR+ Solution Type, Linked Source designs, or an antenna design (with FE-BI or Radiation boundaries) within the same Driven Modal or Driven Terminal solution type. Also, Incident Plane Wave may be used for Radar Cross Section (RCS).
2. Launch many rays from the source toward the scattering geometry. The rest of the steps are the same for each ray.
3. Assign each ray a vector field weight according to the source field distribution.
4. For each launched ray:
    a. If the ray escapes from scene without hitting any surface, ignore it.
    b. If the ray hits a surface, generate a reflected ray. The reflected ray propagates GO reflected fields modified to account for surface curvature at the hit point and the surface material interface.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. If the ray hits a penetrable surface, also generate a transmitted ray, heading in the same direction as the incident ray. The transmitted ray propagates GO transmitted fields modified to account for the surface material interface.

5. At the ray hit-point, compute the incident, reflected, and if penetrable transmitted, field based on material properties of the surface. Use these and the PO approximation to determine equivalent surface currents.
6. Radiate the equivalent currents to observation angles/points. If the observation point represents an Rx antenna, compute the coupling of the radiated fields into the receiver according to the Rx gain or current distribution.
7. Continue tracing the reflected and transmitted rays generated in step 3 and repeat from there. The process continues until either the ray escapes from scene or the maximum bounce limit is reached.

Step 6 is implemented with the following equation:

$$\overline{\boldsymbol{E}}_s = \frac{1}{4\pi}\int_{s'} d\boldsymbol{S}' \left[(\hat{\boldsymbol{n}}' \cdot \overline{\boldsymbol{E}})\nabla' \frac{e^{-jkR}}{R} + (\hat{\boldsymbol{n}}' \times \overline{\boldsymbol{E}})\nabla' \frac{e^{-jkR}}{R} - j\omega\mu_0(\hat{\boldsymbol{n}}' \times \overline{\boldsymbol{H}})\nabla' \frac{e^{-jkR}}{R}\right] \quad (1)$$

where $\overline{\boldsymbol{E}}_{\boldsymbol{S}}$ is the scattered electric field at the observation point, *S'* is the domain of the ray tube at the hit point and projected onto the surface, $\overline{\boldsymbol{E}}$ and $\overline{\boldsymbol{H}}$ are the total electric and magnetic fields at the surface when considering the incident, reflected ray and transmitted *R* is the distance from the source to the observer ($R = |\bar{\boldsymbol{r}} - \boldsymbol{r}'|$, which depends on the integration point within ***S'***), ***r'*** is the position vector to the equivalent current density in the ray footprint, $\hat{\boldsymbol{n}}'$ is the surface normal, $\bar{\boldsymbol{r}}$ is the position vector to the observer, μ_0 is the free-space magnetic permeability. The equivalent currents mentioned in Step 5 are those obtained by the cross product or dot-product of $\hat{\boldsymbol{n}}'$ with $\overline{\boldsymbol{E}}$ or $\overline{\boldsymbol{H}}$, as indicated in Eq. (1).

The above expression can be used to compute the scattered field contribution in near- or far-field observations. For far-field observation angles, the factor exp(*-jkR*)/*R* in Eq. (1) is replaced with a phase factor corresponding to the chosen phase reference point, yielding a result in units of volts instead of volts-per-meter.

For Tx/Rx antenna coupling, $\overline{\boldsymbol{E}}_{\boldsymbol{S}}$ is converted into the scattered field contribution to an S-parameter (i.e., coupling ratio) by computing received signal, *b*, at the Rx port using the Rx antenna gain or current distribution. The S-parameter is the ratio of the received signal to the incident signal, *a*, at the Tx port:

$S = b/a$.

When an Rx antenna is characterized to SBR in a far-field representation, the received signal *b* is given by

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$b = \frac{-j\lambda}{\sqrt{4\pi\eta_0}} \overline{E} \cdot \overline{g}_{Rx} \ , \qquad (2)$$

where $\overline{g}_{Rx}$ is the field-scale (complex), far-field, polarized (vector) gain of the Rx antenna. Here, gain differs from antenna directivity by incorporating the effects of mismatch between the Rx antenna and its port and also ohmic losses in the Rx antenna. $\overline{E}$ is the total electric field at the Rx antenna, and η_0 is the free-space impedance. The obtained quantity, b, is the complex amplitude of the received signal delivered to the port. Since antenna gain has angular dependence and cannot be reduced to single number (or vector) for a given antenna, a subtle point of Eq. (2) in this context is that it is actually a summation over all contributing “ray paths”. Each term in that summation has an associated electric-field contribution ($\overline{E}$), and the direction of the incoming ray path to the Rx antenna resolves the angular dependence in the Rx antenna gain to a concrete vector, allowing the dot-product to be evaluated. These contributions comprise the incident-field contribution from the Tx antenna and the scattered-field contributions (see Eq. (1)) from each ray footprint, thus yielding the total-field contribution to the received signal. “Ray paths” as used here should not be confused with SBR GO rays that, for the most part, travel nowhere near a given Rx antenna. Here, “ray path” merely means the vector from the Tx antenna (incident-field) or SBR ray footprint (scattered-field) to the Rx antenna.

For an Rx antenna described by a current distribution, Eq. (2) generalizes to a more accurate one where the incident and scattered electric- and magnetic-fields are multiplied by the amplitude vectors of the Rx antenna current distribution through a vector dot product. That is, the incident or scattered field is computed separately at each current "source" of the Rx antenna and the vector dot products are then coherently summed.

Although the current sources and gain pattern represent the Rx antenna as a radiator, they serve to also characterize the Rx antenna as a receiver according to the reciprocity theorem. For example, reciprocity is the basis for using Eq. (2) to determine the received signal of an Rx antenna characterized by its far-field radiation gain pattern.

Additional capabilities in SBR+

In HFSS SBR+, the baseline SBR solution described above can be improved with ray-based physics additions. Physical Theory of Diffraction (PTD) corrects surface currents near wedges. Uniform Theory of Diffraction (UTD) shoots additional diffracted rays from wedges. Creeping Waves shoots rays propagating along smoothly curved surfaces.

Excitations for SBR+

Antenna and SBR+ Hybrid Region with Hybrid and Arrays Solution Type

Within the Hybrid and Arrays Driven Modal and Driven Terminal solution types, HFSS can use SBR+ to compute the scattered field contribution from a platform geometry. More information can be found in Assigning SBR+ Hybrid Regions.

When an antenna is simulated via FEM, the antenna must be enclosed by a Radiation boundary or FE-BI Hybrid Region. Instructions may be found in Assigning Radiation Boundary and Assigning FE-BI Hybrid Region. First, the antenna is solved by HFSS in the absence of the SBR region. The bounding surface of the Radiation Boundary or FE-BI Hybrid Region is also used as the exterior Huygens surface whose field samples (equivalent currents) yield current sources or far-field radiation patterns to drive the SBR+ simulation or serve (via reciprocity) as a receiving antenna in an SBR+ simulation. When Near Field is selected for Field Type, currents are computed on the Huygens surface using

$$\boldsymbol{J} = \boldsymbol{n} \times \boldsymbol{H},$$

$$\boldsymbol{M} = -\boldsymbol{n} \times \boldsymbol{E},$$

where $\boldsymbol{J}$ and $\boldsymbol{M}$ are the equivalent electric and magnetic current sources, n is the outward normal of the Huygens surface, $\boldsymbol{H}$ and $\boldsymbol{E}$ are Electric Fields and Magnetic Fields computed by FEM solver.

A Perfect E Boundary may be assigned to some faces of the exterior Huygens surface, but at least one face must be assigned to Radiation Boundary or FE-BI region. When Perfect E is assigned on a face, no currents for SBR+ simulations are generated on that face. More instructions are found in Assign a Perfect E Boundary. Also, the presence of Perfect E indicates that the antenna has a ground plane, and the antenna can be properly installed on a metallic platform surface. When Current Conformance is set to Enable, current conformance is only performed on antennas where at least one face is assigned to Perfect E. When Current Conformance is set to Auto, current conformance is only performed on antennas placed with a small tolerance separation from the nearest SBR+ region surface, this tolerance being determined as one-twentieth (1/20) of the diagonal displacement of source's bounding box. In addition, if none of the faces is assigned a Perfect E infinite ground plane, Auto will automatically insert one on the face nearest the SBR+ region.

When SBR and IE hybrid regions are assigned to different objects, the FEM with IE regions must first be solved together via two-way coupling. The instructions are found in Set Current Source Option. When two-way coupling is configured, current sources are also generated on the IE region to launch rays in an SBR+ simulation.

Antenna introduced via Linked Source

The antenna may be introduced via linked sources for SBR+ simulations. When a designed antenna is already analyzed, a linked source is a convenient way to introduce the antenna into SBR+ simulations without analyzing the antenna again. Instructions for configuring a linked source are found in Link from a Driven Modal or Driven Terminal Antenna to an SBR+ design for SBR+ solution type, and Far Field or Near Field representations for Driven Modal or Driven Terminal solution type.

When a near field linked source is introduced for SBR+ simulation, fields and current sources are also generated on the exterior Huygens surface.

A far-field linked source is converted to a pattern-weighted point-source for the SBR+ simulation. It is therefore handled with much greater efficiency by SBR+ than a near-field linked source, which presents SBR+ with a distribution of current sources, each of which launches its own ray set. *However, the far-field representation is only valid if the SBR+ scattering geometry is in far-field of the source*. More discussion on this crucial point is found in the later section, Near Field vs Far Field Source Representation. Moreover, the phase reference of the far-field representation must be manually specified to be as close as possible to the physical antenna phase center by selecting **Excitations>Set Far Field Phase Center...** in the source design of the antenna. More instructions are found in Link from Driven Modal or Driven Terminal Antenna to SBR+ Design.

Incident Plane Wave

A plane wave is a wave that propagates along a fixed direction where the electric and magnetic fields are in the transverse plane and perpendicular to each other. For SBR+, Incident Plane Wave is required to compute Radar Cross Section (RCS). More instructions are found in Incident Plane Wave.

The phase reference of the incident plane wave may be set as the Zero Phase Position in the Incident Wave panel. For monostatic RCS simulation, this serves as the phase reference for both illumination and observation. For bistatic RCS simulation, the Far Field Radiation Sphere Setup allows one to set the phase reference for observation, which can be set up via a relative coordinate system.

Parametric Antennas

The SBR+ Solution Type provides a suite of parametric antennas that are very convenient for system analyses. Parametric antennas are sources that either have no physical structure definition or have a highly idealized physical structure. No model parts are constructed or used in the simulation. Parametric antennas are intended to be very quick to define and place, copy and duplicate, and are thus intended for systems studies where the specific antenna structure is either unknown or where a simple, topologically representative antenna type is sufficient. The

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

editable parameters depend on the antenna type. More detailed instructions are found in Parametric Antennas for SBR+ Solution Type.

Parametric Antennas create far-field pattern sources that can provide S-parameter outputs and composite far-field radiation patterns. Some Parametric antennas also provide a current-source representation option. In general, a current-source representation yields more accurate results than its far-field counterparts, especially when placed nearby platform scattering geometry within 2 or 3 wavelengths. This is because it provides a near-field description of the antenna that is physical everywhere, whereas the far-field description is only physical beyond a critical distance from the antenna where it's far-field has converged. In particular, current-source antennas with implicit ground-planes (e.g., Wire Monopole, Parametric Slot, Horizontal Dipole, and Cross-Dipole over Ground Plane) are intended to be placed directly on a highly conductive surface of the platform (SBR+ scattering region). In these situations, using the same antenna's far-field counterpart is not recommended. For example, if you place the far-field version of the Wire Monopole on a supporting platform that provides the grounding function to the wire monopole, the half-donut *far-field* pattern of the Wire Monopole will only interact with structures in the upper half-space of the placement surface. In contrast, when using the current-source representation of the Wire Monopole, the axial current sources radiate in all directions, and SBR can correctly predict the interaction with the placement structure directly underneath because of the higher-order fields imbedded in the current-source representation.

By File Antenna

User defined far-field data in .ffd format may be imported into the SBR+ solution type. The SBR+ solver will automatically interpolate the source fields from the file-based antenna in order to represent the antenna at all frequencies of the user defined frequency sweep in the solution setup. The file-based antenna must be defined with at least two frequencies, and the min/max frequencies of the simulation sweep should fall within the frequency band of the file-based antenna. In the model window, the antennas display as a scaled far-field pattern at the antenna origin. Instructions are found in Parametric Antennas for SBR+ Solution Type. The file formats for .ffd are found in Frequency Independent Far Fields or Frequency Dependent Far Fields.

Current Conformance

The instructions for activating current conformance are found in Set SBR+ Source Region. It is only available for antennas represented by Near Field and parametric antennas that allow an Antenna Representation set to Current Sources. This capability is primarily intended for antennas requiring a ground plane to operate (e.g., monopole, blade, microstrip patch, slot, etc.) and that will be placed on a flat or slightly curved metallic section of the platform that conceptually provides this grounding function. It is typically used to make small positional adjustments to current-source positions that will improve simulation accuracy. There are a couple of reasons why one should consider using the current conformance feature.

- The unadjusted sources may otherwise be too close or possibly even slightly underneath the platform placement surface due to small positioning errors in placing the antenna on

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the platform. In general, placing sources that are conceptually intended to be directly on the surface closer than λ/40 above the surface harms run time with little or no accuracy benefit, as in the case of horizontal magnetic sources representing a slot cut in the placement surface.

- The platform placement surface is slightly curved, the shape of the actual antenna will conform to this curvature, yet the antenna might not exhibit this intended curvature (it is flat).

These situations are fairly common, so the current conformance feature is a valuable capability. When the antenna structure is to be placed directly on the platform, such that it touches the platform, conformance is often beneficial.

Current Reduction

For SBR+ simulations where the Tx and/or Rx antennas are defined by an equivalent currents on a large Huygens surface (e.g., FEBI sources), the current-source reduction feature can significantly improve run time by removing a large number of very weak sources. The instructions for setting up the current reduction are given in Set Current Source Option.

When antennas are represented by current sources, run time generally grows with the number of current sources. When applied to both the Tx and Rx antenna in an antenna coupling simulation, this effect is multiplicative, not additive. Antennas are sometimes represented by hundreds or thousands of current sources, and this can result in excessive SBR+ run times. The SBR+ solver will dynamically aggregate current sources when illuminating far-away surfaces to mitigate this run-time impact. While quite effective, it only applies to Tx antennas, not Rx antennas. At the same time, many of the current sources may be very weak, with the dominant ones just a small fraction of the total. One way to reduce run time without significant compromise of accuracy is to thin the current sources according to their relative powers, and this is the function of the Current Reduction option. Current reduction (optional) and dynamic aggregation (always on) can operate simultaneously, and current reduction has the further advantage of also speeding up computations involving Rx antennas.

When Thin Sources is enabled, for each SBR+ source defined by current sources, HFSS will first remove the weakest current sources during a pre-processing stage of the SBR+ region analysis. The Power Fraction to Keep can be set between 0 and 1, but settings less than 0.9 are not recommended due to the potential for excessive lost accuracy. During pre-processing, the current sources of each SBR+ source are sorted from weakest to strongest on a power scale. Their individual power contributions are summed to establish a reference composite power. If, for example, the Power Fraction to Keep is set to 0.95, then the partial sum of the strongest current sources that contribute 95% of this reference level are retained, and all the weaker current sources that contribute the remaining 5% are discarded. For sources defined by a large number of current sources, it will typically be the case that the fraction discarded will far exceed their fractional power contribution. This is why current-source thinning can be an effective means of reducing SBR+ simulation burden without significant sacrifice of accuracy.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

One side effect of current-source thinning in HFSS Hybrid designs (but not in the SBR+ solution type) is that field and S-parameter results may show variability depending on HPC settings and how frequency samples of the analysis are dynamically divided among several processes to be solved in parallel. To achieve maximum efficiency, the weakest-to-strongest sorting by the thinning algorithm considers the power weight of each source averaged across all analysis frequencies. In the context of an HPC parallelization by frequency decomposition, this average can only be performed for the subset frequency samples known to each process. For example, if the analysis is divided into two separate processes, the frequency decomposition may assign N1 frequencies to the first process and N2 to the second, where N1 + N2 is the total number of frequencies configured for the analysis. The first process will be unaware of the N2 frequencies of the second process, and the current-source weights for the second process may not yet even be determined by the time the first process proceeds with the SBR+ stage of its analysis. In general, owing to the frequency dependence of the current source weights, the weakest current sources discarded by the first process will be different than the those discarded by the second process, which in turn will be different from the weakest current sources discarded if all N1 + N2 frequencies had been considered together. This impact is typically small in terms of final results, but to the extent that consistency is paramount, one should either avoid Current Reduction or switch to using a near-field link in the SBR+ Solution Type; the SBR+ Solution Type relies exclusively on ray-based decomposition for parallelization and does not use frequency decomposition.

Near Field vs Far Field Source Representation

Representing an antenna by its near-fields on a Huygens surface is always more accurate than representing it by a far-field pattern. This is because the current distribution produced on the Huygens surface captures both the near-field and far-field radiation fields of the antenna, whereas the far-field pattern sacrifices near-field information. By reciprocity, the same is true when an antenna is used as a receiver in antenna coupling simulations.

If there are surfaces in the SBR+ scattering geometry in the near-field of the antenna, then it ***is not suitable*** *to represent the antenna in SBR+ by its far-field antenna pattern*. Thus, when representing an antenna directly mounted on a grounding surface, such as a fuselage, the antenna should always be specified according to its current distribution, not its far-field pattern. Otherwise, one cannot expect accurate results, especially in the shadow region under the mounting surface.

As a practical matter, installed antennas always require some sort of mounting structure, and since the part of this structure attaching to the antenna must be in its near-field, using the far-field antenna pattern representation might never seem justified. *This would be the wrong conclusion.* For example, consider the case of a reflector antenna with a feed horn at its focal point. Suppose we wish to model this case in SBR+, where the horn is the source antenna and the reflector is the SBR+ scattering geometry described by the CAD model. The feed horn is attached to a mounting plate that is supported by thin rods extending from the outer rim of the reflector and converging on the sides of the mounting plate. As a very good approximation, we

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

can model this by specifying in SBR+ the far-field pattern of the feed horn. Now, technically speaking, the sections of supporting rods near the mounting plate are in the near-field of the horn. However, depending on the details, these are not significant scatterers in the context of determining the radiation pattern of the reflector.

We may even choose to include the supporting rods in the CAD model, recognizing that the scattering from the rod sections near the horn is not accurately captured since they are illuminated by a far-field pattern that has not yet had sufficient radius to form. However, since scattering from these nearby portions of the support rods is small compared to the overall scattering of the reflector, this problem can possibly be ignored.

Another example would be an input antenna mounted on the front of a wing pod. If the antenna is self-contained and predominantly radiates in the forward direction (such as a cavity-backed spiral), a reasonable approach is to model this antenna according to its forward half-space antenna pattern (or perhaps an even larger conical section), setting the fields in the backward half-space (or conical section) to zero. That way, one does not illuminate the mounting pod with far-field data that are not relevant to the mounting conditions and that have, at any rate, not yet had sufficient distance to be valid. Alternatively, we may remove the mounting pod from the CAD model.

With a current-source representation, run time grows in proportion to the number of current sources in the Huygens surface, although this behavior is substantially mitigated by the *SBR*+dynamic aggregation feature (described below). This is because a separate set of rays must be launched from each current source and then processed. Thus, the run time for a Tx antenna described by a single current source is roughly the same as that for a Tx antenna (placed in the same environment) represented by a far-field antenna pattern. However, if the antenna is instead represented by N current sources, the run time will be up to N times as long. For this reason, if accurate results can be obtained using the far-field pattern representation, and run time is a consideration, this is the approach that should actually be used.

There is an important caveat to the above point about run time. Many antennas need to be characterized by a large number of current sources, numbering in the hundreds or thousands. With a brute force simulation, the SBR+ run times could then be excessive. However, SBR+ invokes an important feature known as dynamic zoning that greatly mitigates the run-time impact of having a large number of current sources with negligible loss of accuracy.

Given the above guidance, it is important to understand what is meant here by the complementary terms, "near-field" and "far-field". The far-field region of an antenna extends from some minimum distance R_{min} to infinity, where R is the radius measured from the center of the antenna. That is, we require $R > R_{min}$ for an observer at R to be in the far-field of the antenna. For a transmitting antenna, R_{min} is the distance beyond which the radiated fields decay as $1/R$ and are transverse (perpendicular) to the observation direction. If one of these conditions is not satisfied, then one is in the near-field of the antenna.

Owing to the continuous nature of fields, there is no precise way to quantify R_{min} for a particular antenna. That is, the far-field conditions identified above are only precisely satisfied in the limit

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

as *R* goes to infinity. However, there are well established formulas for specifying R_{min} beyond which these conditions are satisfied to an excellent approximation. Specifically, we require

$$R > \frac{2D^2}{\lambda}$$

and

$$R > 3\lambda$$

The first criterion is the parallax far-field criterion. Here, *D* is the largest linear dimension of the antenna. It is generally relevant for large aperture antennas and antenna arrays. The second criterion is based on the distance beyond which only the propagating field components remain and field components associated with stored energy and charge contributions have decayed to negligible levels. Here, *R* must be measured conservatively (i.e., measured between the observation point and the nearest point on the antenna). The second criterion is more relevant to small, single element antennas, such as a dipole or monopole. Regardless, if either of these criteria is violated, then one is in the near-field of the antenna, whether it is serving as a Tx or Rx antenna. If there are *significant* scattering surfaces in the CAD model within either of these distances, then a current-source distribution representation should be used.

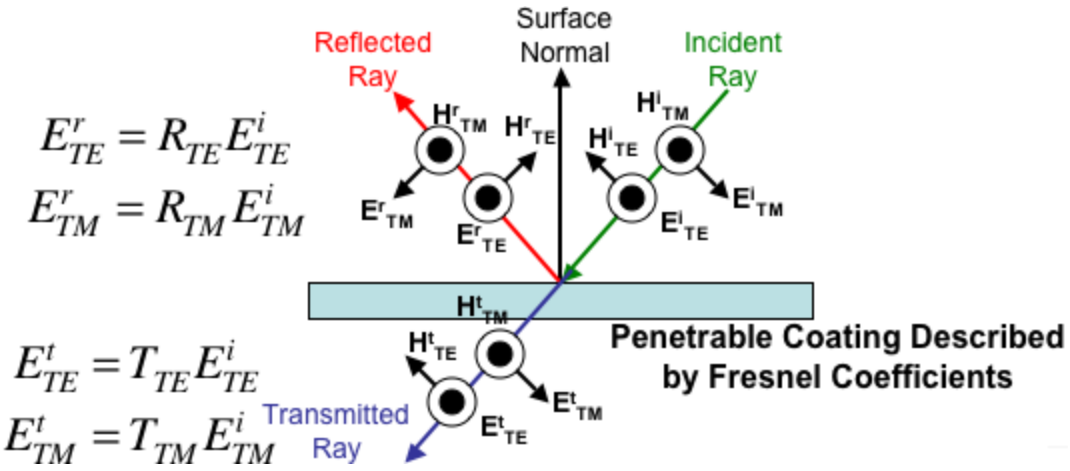
Geometry, Boundaries, and Dielectric Region Support in SBR+

Boundaries Concept in SBR+

In SBR+ simulations, all geometries other than dielectric regions (discussed in Assigning a Dielectric or Conducting Material to Volumetric Region) are introduced as surfaces based on Fresnel reflection and transmission coefficients. Tables of these coefficients are either developed internally or they can be read from a user-provided file.

When a ray hits a surface, its Geometrical Optics (GO) ray fields are decomposed into surface-local transverse-electric (TE) and transverse-magnetic (TM) polarizations. Then, based on the boundary assigned to the surface and the incidence angle relative to the surface normal, the Fresnel TE and TM coefficients are obtained from the table. These are applied to the incident field to determine the GO fields of the reflected ray. If the boundary is penetrable, then Fresnel transmission coefficients are also developed from the same table and applied to determine the fields of the transmitted ray. Because the equivalent currents are developed from the total GO field at the surface, the Fresnel coefficients not only influence fields of the GO reflected and transmitted rays but also the scattered field results.

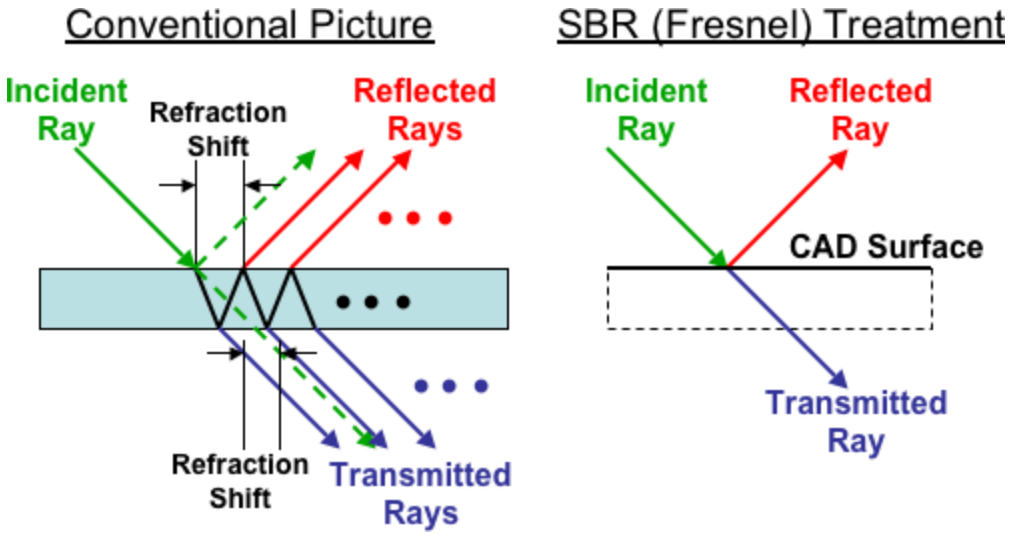
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The Fresnel coefficients are defined assuming an infinitely extended plane wave and a layered planar surface that is laterally uniform and unbounded. Since, these assumptions are never satisfied - the scattering geometry is finite, rarely flat, and the boundaries change from region to region - the question arises about the suitability of Fresnel coefficients. The same objection can be made of the Physical Optics (PO) approximation applied to metallic surfaces, yet PO is a well-established approximation. This approach to handling layers is essentially a generalization of traditional PO. Provided the surface does not curve too rapidly and spans a moderate number of wavelengths, using Fresnel coefficients to determine the GO ray fields and the equivalent currents that produce the scattered field is a good approximation of the actual fields that would be measured.

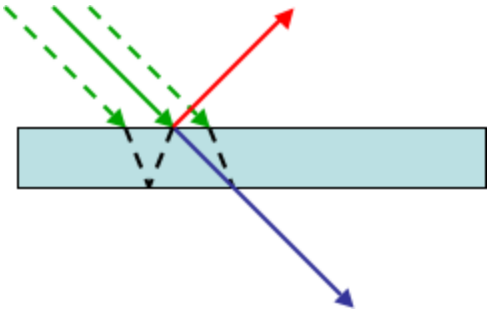
The question often arises as to whether this boundary model includes the effects of refraction, especially if the dielectric layers are electrically thick. Consider a single dielectric layer. The common picture from ray optics is that a ray enters a dielectric layer from free-space, bends due to the change in refractive index, travels through the layer, and then bends back upon leaving the layer. Hence, the exiting ray travels in the same direction as the entering ray, but it is shifted over. The reflected ray is also shifted. Moreover, there are many reflecting and transmitting rays escaping due to internal reflection within the layer. This complex picture, shown on the left in the figure below, is in sharp contrast to the simple diagram on the right that shows the rays as they are actually traced in SBR. Note that the finite thickness layer is only manifested in the reflection and transmission coefficients applied to the GO rays, not in the thin-surface CAD model itself.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In SBR, there is no spatial shift in the transmitted or reflected ray, and multiple exiting rays are not generated due to internal reflections within the layer. Again, the question arises as to whether the implementation is missing something important. The answer is that nothing is missing. The Fresnel coefficients entirely capture the impact of refraction and internal reflections, but not in the way we are used to thinking about it.

To see why, it is important to understand that while rays are traced individually, an individual ray with no neighbors has little physical meaning. In SBR+, and in GO more generally, each ray is a sampling of a larger wavefront. Individual, isolated rays do not really refract because individual, isolated rays do not even exist. The more complete picture for SBR is shown in the figure below. To preserve the refraction picture as commonly understood, one can think of the reflected or transmitted ray as continuing not the original incident ray but one of its neighbors. Likewise, the multiply reflected and transmitted rays are just continuations of other ray neighbors. The entire effect is built into the magnitudes and phases of the Fresnel coefficients. Moreover, if the simulation is applied to very thick materials and conducted over a wide frequency band, with the incident field Fourier-transformed into a narrow time-domain pulse, then the Fourier-transformed scattered fields will manifest multiple internal reflections that occur in the dielectric layer.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Perfect E Boundary

A Perfect E boundary represents a Perfect Electric Conductor (PEC) coated surface for SBR+ simulations. The configuration instructions are found in Assigning Perfect E Boundaries. In SBR+ simulations, Perfect E is a reasonable assignment for surfaces that are highly conductive at the simulation frequency, such as Copper, Aluminum, and many other high-conductivity metals at radio or microwave frequencies. Alternatively, users may consider to use a Finite Conductivity boundary in for improved accuracy.

When a ray hits a Perfect E boundary, the reflected ray field has the same magnitude as the incident ray field. The total field at the reflecting surface (incident plus reflected ray fields) has zero electric field tangent to the surface and double the incident electric field normal to surface. The opposite is true of the magnetic field (i.e., no normal component and double tangential components). Based on these constraints, and following the polarization conventions for TE and TM illustrated earlier, one can show that R_{TE} = -1 and R_{TM} = +1 at all incidence angles for a Perfect E boundary.

When an antenna excitation is introduced in SBR+ simulations via Huygens box, Perfect E may be assigned on its faces. When Perfect E is assigned on a face, no currents for SBR+ simulations are generated on that face. Also, presence of Perfect E indicates that the antenna has a ground plane, and the antenna can be properly installed on a platform. When Current Conformance is set to Auto, current conformance is performed only on Huygens surface at least a surface assigned to Perfect E.

Perfect H Boundary

A Perfect H boundary represents Perfect Magnetic Conductor (PMC) coated surface for SBR+ simulations. The configuration instructions are found in Assigning Perfect H Boundaries. Unlike Perfect E, Perfect H does not approximate a typical condition at a physical boundary, so it's use is much more specialized.

When a ray hits a Perfect H boundary, the reflected ray field has the same magnitude as the incident ray field. The total field at the reflecting surface (incident plus reflected ray fields) has zero magnetic field tangent to the surface and double the incident magnetic field normal to surface. The opposite is true of the electric field (i.e., no normal component and double tangential components). Based on these constraints, and following the polarization conventions for TE and TM illustrated earlier, one can show that R_{TE} = +1 and R_{TM} = -1 at all incidence angles for a Perfect H boundary.

Finite Conductivity Boundary

The finite conductivity boundary is valid only if a material is classified as a PEC-like conductor. See section of PEC-like State of a Boundary below. Transmitted rays are not generated. Further instructions are found in Assigning Finite Conductivity Boundaries.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Layered Impedance Boundary

A Layered Impedance Boundary is used to model a stack of uniform layers with dielectric or conductive materials. Further instructions are found in Assigning Layered Impedance Boundaries.

The top surface of the top layer is conformal with the mesh surface, and the implied thickness of the layer is built up under the surface with respect to the incident ray. Thus, when a ray hits the boundary from above, the layers are built up below the boundary. Likewise, when a ray hits the boundary from below, the layers are built up (in the opposite direction) above the boundary.

While this is an inconsistent structural arrangement, it is convenient from a modeling perspective. The implications for users are that some thought must be given to how best to place the boundary surface in the CAD model, and this depends on which side of the surface will be predominantly illuminated by rays.

For example, consider a platform with a radome that is to be modeled with one or more dielectric layers (and no backing material). Physically, the radome has an interior surface and an exterior surface. When one is interested to predict the radiation characteristics of an antenna located behind the radome, then it is best to define the radome surfaces in the CAD model according to its interior surface. On the other hand, when one is interested to model the scattering contribution of the radome due to some source outside the radome, then it is best to define the radome surface in the CAD model according to its exterior surface. In situations where the radome is expected to be significantly illuminated by rays from both sides, the best approach is to compromise by placing the radome CAD model surface half-way between the actual radome's interior and exterior surfaces.

Layered Impedance Boundary may be configured as one- or two-sided. When configured as one-sided, the finite-thickness layers stack on top of a backing material with infinite thickness (e.g., half space). One-sided Layered Impedance is not penetrable and transmitted rays are not generated. On the other hand, when configured as two-sided, the surface is penetrable and transmitted rays are generated (see diagram above), weighted by the Fresnel transmission coefficients derived from the material and thickness properties of the layers.

Impedance Boundaries

An Impedance Boundary (IB) represents a surface with resistive and/or reactive properties. The behavior of the field at the surface and the losses generated by the currents flowing inside the surface are computed using analytical formulae. SBR+ does not actually simulate any fields inside the surface, and transmitted rays are not generated. The instructions are found in Assign Impedance Boundaries.

For an IB characterized by a surface impedance Z_S, the boundary condition at the surface is $E_{tan} = Z_S H_{tan}$, where E_{tan} and H_{tan} are the surface-tangent components of the total (incident +

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

reflected) electric and magnetic field, respectively. Angular and frequency dependent Fresnel reflection coefficients are internally developed by the SBR+ solver from this relationship.

Fresnel (SBR+) Boundaries

Fresnel (SBR+) boundary introduces Perfect Absorber Boundary and imported Reflection – Transmission Table for SBR+ simulations. The instructions are found in Assigning (SBR+) Perfect Absorber Boundaries and Assigning (SBR+) Fresnel Table Boundaries.

Perfect Absorber

Any ray hitting a face with Perfect Absorber gets terminated, thus creating no further reflections or transmissions. *However, this does not imply that there is no radiation from surface currents on perfectly absorbing surfaces*. The perfect absorber still generates very strong forward scattering. This scattering is associated with the incident GO ray fields at the surface. These ray fields are converted into equivalent currents at the surface that are radiated to observation angles/points in any direction (including the backward direction); the scattered field tends to be strongest in the forward direction relative to the incident ray. At the same time, since the reflected ray has zero field strength (and therefore no reflected ray is traced), the equivalent surface currents associated with the reflected ray are also zero, so scattering in the backward half-space (relative to the incident ray) is weak.

Since we properly expect an absorbing surface to cast a shadow behind it, the strong forward scattering of the Perfect Absorber may seem unintuitive. The intuitive expectation is recovered by considering the impact on the total field rather than the scattered field. For example, consider the simplified case an antenna illuminating flat plate configured as Perfect Absorber. Behind the plate, the incident field from the antenna is strong because, by definition, *the incident field is the radiation of the source in the absence of any scatterers*. During SBR ray-tracing, the antenna also illuminates the perfectly absorbing plate with rays, creating a strong incident field on the plate surface. This results in a strong scattered field behind the plate relative to antenna. However, in this region behind the plate, the scattered field is 180^{o} out-of-phase relative to the incident field of the antenna. Hence, in the “shadow” region behind the plate, the incident and scattered field destructively interfere, leaving a very weak total field. Moreover, the non-zero total field in this shadow region corresponds to fields diffracting around the edges of the perfectly absorbing plate.

Reflection-Transmission Table (.rttbl)

A Reflection – Transmission Table directly specifies Fresnel coefficients of the boundary through a reflection/transmission coefficients table file. Fresnel coefficients are based on the assumption of plane-wave incidence and reflection and represent the ratio of the reflected field to the incident field. Ray bundles can represent complex wavefronts, and each ray represents a sample of that wavefront that is assumed to be locally planar. Provided the wavefront is not too irregular, and the layers are not too thick compared to their lateral extent, the Fresnel coefficients

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

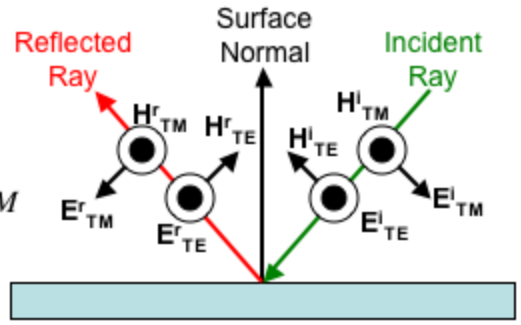
applied in conjunction with individual rays provide a good approximation of the reflection of an arbitrary wavefront off a surface.

There are two types of the tables supported by SBR+.

- reflection coefficients
- reflection + transmission coefficients

Fresnel coefficients depend on the polarization of the incident plane wave. There are two unique, orthogonal polarizations: transverse electric (TE) and transverse magnetic (TM). SBR+ adopts the convention given in the diagrams below. In this convention, PEC metal has a TE reflection coefficient of -1 and a TM reflection coefficient of +1. In general, reflection coefficients are complex quantities that depend on incident angle and frequency.

$$E^r_{TE} = R_{TE} E^i_{TE}$$
$$E^r_{TM} = R_{TM} E^i_{TM}$$



Reflective Coating Described by Fresnel Reflection Coefficients

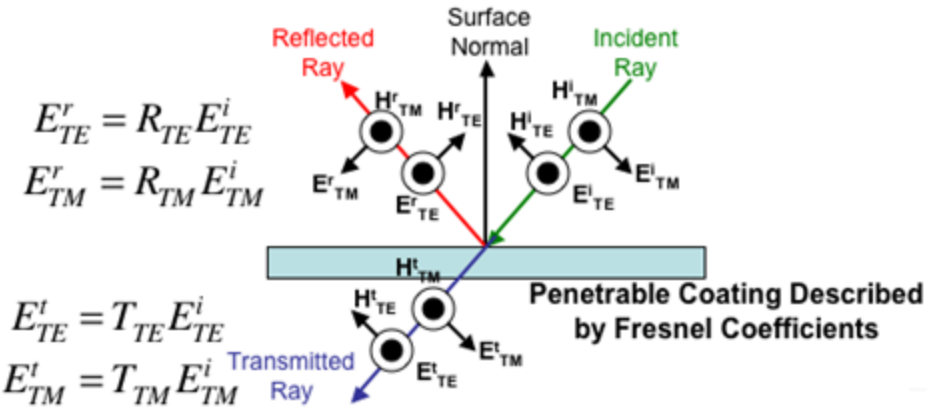
When developing tables of Fresnel coefficients for import into HFSS SBR+, it is vital to observe these polarization conventions. If the tables are generated by existing software that exports Fresnel coefficient data, then when converting the exported data into the file format expected by HFSS, special care should be taken in noting the polarization convention of that software and making sign corrections as applicable.

When a ray hits a surface, the SBR+ solver determines its incidence angle relative to the surface normal. The incident ray tube fields are decomposed into TE and TM components. SBR+ then looks up the TE and TM reflection coefficients for that angle, whether internally generated or provided by an external table as described here. These are applied to the respective incident ray field components to determine the TE and TM components of the reflected ray field.

On the other hand, penetrable boundaries, as are encountered in the case of canopies and radomes, should be described by both reflection and transmission coefficients. When creating *a Layered Impedance Boundary in SBR+*, if one specifies *Two sided*, then the solver will treat this as a penetrable and internally generate both reflection and transmission coefficients. Likewise, arbitrary boundaries that are penetrable can be entered as a table of reflection and transmission in SBR+.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When a ray hits a penetrable boundary, it generates both a reflected ray and a transmitted ray, as shown in the diagram below, which also extends the polarization convention of the previous diagram. In the diagram below, it is intentional that the transmitted ray is shown as starting from the top of the surface, rather than the bottom. In SBR+, CAD models represent infinitely thin surfaces. The effect of layer thickness is entirely captured in the reflection and transmission coefficients. *Hence, in creating a reflection + transmission table input for SBR+, it is critical to do so such that the phase reference of the transmission coefficient is the surface nearest the incident ray*. That way, the transmitted ray will include the correct phase delay given that it is launched from exactly the same point as where the incident ray hit the surface.



PEC-like State of a Boundary

The PTD, UTD, and Creeping Wave enhancements in SBR+ are developed from formulations that assume perfectly conducting boundaries. However, their results remain valid for highly conducting boundaries provided they are sufficiently “PEC-like”. In addition to the Perfect E boundary, HFSS SBR+ permits deployment of these enhancements on Layered Impedance and Finite Conductivity boundaries provided their behavior is PEC-like, as determined from details of their configuration.

In the case of a Layered Impedance boundary, whether it is considered PEC-like by SBR+ depends upon the simulation frequency and the material properties of its exposed layer (the first layer in the stack.) The following table illustrates the frequency dependence for several typical metals. For example, if the exposed boundary layer is Copper and 30-μm thick, then the entire Layered Impedance boundary stack will be considered PEC-like between f_{min} = 192 MHz and f_{max}= 735 GHz. The 192-MHz lower bound is not explicitly shown in the table but is consistent with the Minimum Thickness columns for 10 MHz and 1 GHz. For simulation frequency sweeps residing within this band, wedges with this top-layer will be considered PEC-like and therefore eligible for deployment of PTD and UTD. However, if the frequency sweep partially or completely falls outside of this band, then the same wedge will ineligible. To prevent discontinuous sweep results, HFSS SBR+ will not switch on PTD, UTD, or Creeping Wave mid-sweep if the sweep crosses one of these frequency boundaries.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Material	Conductivity [S/m]	Dielectric Constant	Rel. Magnetic Permeability	Minimum Thickness [um] @ 10 MHz	Minimum Thickness [um] @ 1 GHz	Minimum Thickness [um] @ 100 GHz	Maximum Frequency [GHz]
Silver	6.10E+07	1	0.99998	128.04	12.80	1.28	772.589

Iron	1.03E+07	1	4000	4.93	NA	NA	0.033

For a top-layer coating to be PEC-like, several conditions must be met, and the above table is developed from these conditions. The top layer must have free-space electric permittivity ($\varepsilon_r = 1$) and lossless magnetic permeability ($\mathrm{Im}\{\mu_r\} = 0$). In addition, the dielectric layer must possess the very high conductivity (σ) of a metal. Furthermore, the thickness of the top-layer coating must be greater than 2π skin depths $\delta = 1/\sqrt{(\pi f \sigma \mu)}$ as computed at the lower bound of the frequency sweep. Increasing the layer thickness or its conductivity lowers the minimum frequency (f_{min}) at which the layer exhibits good PEC properties. Because of this skin depth requirement, additional layers do not change the PEC-like status of a Layered Impedance boundary. Likewise, whether the Layered Impedance boundary is One-sided or Two-sided makes no difference.

The maximum frequency f_{max} at which the coating is deemed PEC-like increases with the top layer's conductivity σ and decreases with its relative magnetic permeability μ_r. In HFSS SBR+, f_{max} is computed as

$$f_{max} = (0.1\ \mathrm{Ohm}^2)\ \sigma/(2\pi\mu_0\mu_r)$$

Assigning a Dielectric or Conducting Material to a Volumetric Region

For a discussion, see Assigning a Dielectric or Conducting Material to Volumetric Region.

Meshing Operations for SBR+

Surface Curvature Information, Curvilinear Meshing, and Curvature Extraction

When faceted formats such as STL are imported into HFSS, each triangle of the faceted model is flat. Faceted models lack intrinsic curvature information. In order to support methodology features of SBR+ that depend on surface curvature information, such as the ray-tube divergence correction and creeping wave enhancement, local curvature is automatically synthesized

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(estimated) during SBR+ simulation according to spatial orientation relationships among the immediate neighbors of each flat facet, a process known as curvature extraction.

Unless disabled by the user, curvature extraction is applied to all faceted surfaces. Smooth curvature will be extracted under the assumption of smooth curved surfaces extending across the facet edges. For this extraction process to work well, clean imported STL models satisfying the following criteria are required:

- Two adjacent facets share two common vertices across an edge.
- Highly curved surfaces must be meshed with small faces to eliminate large changes in surface slope between neighboring facets.

Since 2019 R2, Curvilinear Meshing in SBR+ is supported for a) curved-surface geometries built within HFSS and b) imported geometries that retain explicit surface curvature information, such as SAT and IGES format models. With curvilinear meshing, accurate curvature information from the objects is directly used by the SBR+ solver. With curvature extraction, an algorithm is deployed to recover or infer information that was either lost at some point prior to synthesis and import of the faceted model, or that was never available to begin with, so it is necessarily an approximation. Curvilinear meshing is therefore preferred over curvature extraction in those situations where it is available for use with SBR+.

Since 2019 R2, explicitly flat surfaces can be specified to the SBR+ solution by selecting Disable Curvature Extraction for Faceted Surfaces. Users may disable curvature extraction for specific flat surfaces and introduce polygonal surfaces with flat curvatures. When SBR rays reflect off explicitly flat surfaces, the divergence/convergence rate of their associated ray-tube is not modified as it would be with a curved reflecting surface. Also, the creeping wave rays will not propagate over explicitly flat surfaces, as the creeping wave formulation assumes surfaces have finite (non-zero) convex curvature.

Ray-tube Divergence Correction

In SBR+, the one-dimensional rays traced on the CAD model actually represent volumetric ray tubes whose cross-sections are precisely maintained through multiple reflections and transmissions. The 1-D rays shown in the visual ray tracer reside in the centers of these ray tubes.

When rays are launched from a point and represent a spherical wavefront, as with rays launched from antenna sources, their cross-sectional area grows in proportion to R^2, where R is the propagation distance. Correspondingly, GO fields of the ray tubes decrease as $1/R$. This is known as ray-tube divergence. When a ray (tube) reflects off of a flat surface, the rate of ray-tube divergence is unchanged, where R is taken as the total path distance of the ray when starting from the Tx antenna.

Reflection off a curved surface is more complicated. When a ray tube reflects off a convex surface, its rate of divergence increases. When reflecting off a concave surface, its rate of divergence decreases. If the surface has enough concavity, the ray tube will actually start to

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

converge and pass through one or two caustics (focus points) before diverging again. In this process, the shape of the ray tube changes as it propagates. With CAD models described by curved surfaces, SBR+ accounts for this effect precisely, considering both the non-spherical curvature of the incident wavefront (if the ray already reflected off another curved surface) and also localized curvature conditions of the CAD model at the ray hit point. It is important to capture this effect, as it influences the distribution and strength of currents painted on surfaces after the reflection, and these are the currents that determine the scattered field.

In the case of an incident plane-wave source, as when using SBR+ to compute RCS, a set of rays is launched in parallel toward the scattering geometry. In consequence, the associated ray-tubes initially have zero rate of divergence, and this condition will be preserved after the rays reflect off flat surfaces. However, upon encountering curved surfaces of the scattering geometry, the reflecting ray tubes will start to converge or diverge, depending on details of the surface curvature and the angle of incidence relative to the surface perpendicular at the ray hit point.

Dynamic meshing, Tolerant Meshing, Lightweight geometry

Unlike FEM or IE, the ray-tracing methodology of SBR+ does not require sub-wavelength meshing of the scattering geometry. Rather, it is sufficient that the mesh accurately represents the shape of the scattering geometry. For large CAD models when interactive 3D visualization manipulations, geometry meshing, or post-meshing SBR+ simulation becomes too time consuming, one may consider using the relaxed import and meshing options described below.

Note that all of these relaxed meshing options skip the automated process of identifying and eliminating overlapping (coplanar) surfaces. When overlapping surfaces are passed to the SBR+ solver, this can confuse its ray-tracing engine, leading to unexpected and inaccurate results. For example, coplanar surfaces create ambiguity as to which surface was actually hit first, and this can lead to trapped rays bouncing between them. Therefore, when using these relaxed import/meshing options, there is greater responsibility upon the user to avoid the introduction of overlapping surfaces.

Lightweight geometry

Importing large STL files into Ansys Electronics Desktop can be time consuming. STL files contain triangle surface meshes. Importing them to the modeler creates one face entity for each STL triangle and one edge entity for each triangle edge. This can result in a large number of faces and edges, leading to sluggish interactive behavior with 3D visualization. The lightweight geometry import option for STL models bypasses this overhead and associated meshing operations, passing the original STL mesh directly to the SBR+ simulation engine. This results in more responsive UI operations and faster SBR+ simulations.

Dynamic meshing

Dynamic Meshing eliminates mesh generation during SBR+ simulations, which can significantly reduce simulation time. When importing STL models with the Lightweight Geometry option,

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Dynamic Meshing is automatically engaged (and it cannot be switched off). However, even when Lightweight Geometry has not been engaged, Dynamic Meshing can be switched on in the Initial Mesh Settings dialog in order to receive the benefits of bypassing potentially expensive meshing operations prior to engaging the SBR+ solver.

Tolerant Meshing

If the design contains an SBR+ Region, the Initial Mesh Settings window will include a Tolerant Meshing option. This is because the SBR+ ray-tracing solver has relaxed surface meshing requirements relative to other HFSS solvers. If an imported scattering geometry for the SBR+ region contains anomalies that make it too time-consuming or impossible to use Auto (default) meshing, the tolerant meshing option should be attempted, as it will often result in a successful meshing of the geometry in cases where Auto does not. On the other hand, if the imported geometry is clean and Auto meshing works well, Tolerant Meshing can sometimes result in an excessive number of surface mesh triangles that increase SBR+ solution time. The best meshing option for SBR+ is very dependent on the quality of the imported geometry, so users need to consider both approaches and choose the one that works best for their particular scattering geometry.

HFSS SBR+ Technical Overview

Physical Theory of Diffraction (PTD) and Uniform Theory of Diffraction (UTD)

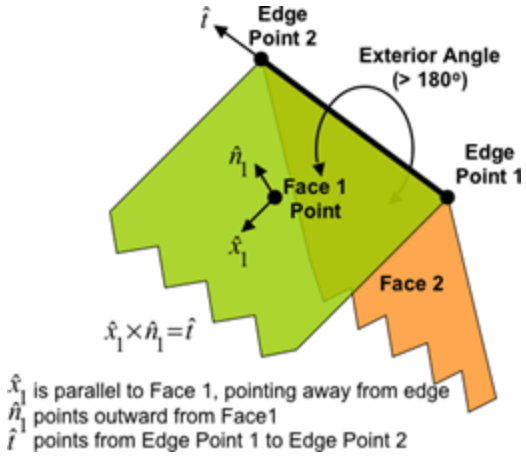
For SBR+ simulations, the Physical Theory of Diffraction (PTD) and Uniform Theory of Diffraction (UTD) physics enhancements can account for additional phenomenology not predicted by ordinary SBR due to truncation of uniform Physical Optics (PO) currents at sharp angular discontinuities (“wedges”) on metallic surfaces and blockage of SBR’s Geometrical Optics (GO) rays. PTD is a numeric correction to the scattered fields radiated by incorrect PO currents near wedges. UTD launches bundles of edge-diffraction rays from directly illuminated portions of each wedge along the Keller cone. Once launched, the UTD rays behave exactly like regular SBR rays, propagating according to GO and painting PO currents at each bounce that contribute to the scattered field. The UTD rays often illuminate portions of the SBR scattering geometry that are never reached by SBR GO rays launched directly from the field source.

The PTD and UTD wedge features are only deployed for metallic wedges with line-of-sight visibility from the source (Tx) location. If either adjacent surface of the wedge is non-PEC and not within the tolerance for PEC-like, or if the *entire* edge segment is invisible to the source, the wedge will be ignored in the SBR+ simulation and for visual ray tracing (VRT).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

SBR+ Wedges

SBR+ wedges are required to enable PTD/UTD corrections. Wedges are extracted from metal surfaces if their exterior *angle* is larger than the **Maximum Wedge Angle** specified in SBR+ Wedge Settings or Wedge Settings. The default Maximum Wedge Angle is 225 degrees. Also, toggle on *Include Sheet Edges* to extract knife edges from open-ended sheets. When many wedges are extracted, PTD/UTD computations may be time consuming. The SBR+ wedges can be selectively filtered out using **Apply Source Distance filter** or **Apply Box Filter**, and PTD/UTD corrections are then applied only to the wedges that remain.



Physical Theory of Diffraction (PTD)

When SBR+ wedges are extracted from metal surfaces, SBR+ can apply a PTD wedge correction to improve the accuracy of the baseline SBR solution. Recall that SBR uses GO to extend PO to multiple bounces. The first-bounce solution of SBR is therefore traditional PO, with ray tracing used to determine which surfaces are lit. A limitation of this approximation is that it does not account for the distortion of surface currents in the vicinity of discontinuities in the geometry, such as sharp edges.

For example, consider a metal plate of moderate size in wavelengths. In the middle region, PO does a good job of approximating the currents. However, near the plate edges, PO assumes uniform currents up to the edge boundary. In reality, approaching the edge, current components perpendicular to the edges smoothly drop to zero while components parallel to the edges become very large. This localized PO inaccuracy is of little importance near specular scattering regions (i.e., near GO inter-bounce or exit ray paths in the near- or far-field) since the field results are dominated by the influence of the large area of currents over the plate interior where PO is accurate. However, the currents near the plate edges have a strong influence on diffraction in the shadow region and other regions far removed from specular scattering angles. Hence, while PO (and SBR) alone predicts diffraction in the shadow regions, it cannot be expected to consistently yield accurate levels of diffraction.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

PTD theory was originally developed to address this very problem. The PTD wedge treatment is an asymptotic, coherently additive correction to PO that is designed to account for localized non-uniformity of currents near metal wedges and edges. It is somewhat analogous to the UTD correction to GO in this sense, except that the PTD correction to PO is milder than the UTD correction to GO; GO yields zero fields in the shadow region while PO always yields finite fields and already partially accounts for diffraction.

PTD was originally formulated as a correction term in the scattered fields rather than as a correction to the currents near edges that give rise to these correction fields. From the perspective of practical computation, the methodology was subsequently improved by casting PTD in terms of equivalent (artificial) edge currents running along the edges. These are sometimes referred to as incremental length diffraction coefficients (ILDCs) in the literature. One integrates these 1-D edge-axial currents along the actual path of the platform edges. For curved wedges, the equivalent currents are only based on local conditions that vary along the edge according to the changing incident and scattered field angles relative to the wedge geometry. From the standpoint of practical computation, the key benefit of using ILDCs is that they allow PTD to be applied to complex geometrical shapes encoded in 3-D CAD models. The implementation of the PTD wedge correction in SBR+ is based on this approach of equivalent, filamentary edge currents.

Users should be aware of a several limitations of the PTD wedge correction in SBR+. First, it can only be applied to metallic (PEC or PEC-like) wedges. There is no PTD correction formulation for dielectric wedges. SBR+ takes steps to ensure that the correction is not applied to wedges with one or two non-metal faces; the PTD correction is automatically skipped during the simulation when encountering wedges with non-conductive boundaries. Second, the correction is only applied to wedges that are directly illuminated by the Tx antenna, not edges indirectly illuminated via GO multi-bounce. Third, the PTD correction is only valid for field observation points on the order of a wavelength or more from the edge scattering point. This is because the correction is formulated in terms of 1-D equivalent (artificial) currents instead of a distribution of 2-D physical surface currents in the vicinity of the edge. This limitation has no impact on far-field results, but it can matter for near-field results when the observation points and Rx antennas get too close to a wedge in the CAD model. In fact, left to itself, the PTD correction based on equivalent currents becomes singular approaching the edge. To prevent this from happening, SBR+ automatically tapers the correction field generated by the equivalent currents at small distances from the edge. For example, at 1.0, 0.5, 0.2, and 0.1 wavelengths distance from a given edge, only 98%, 90%, 60%, and 28% of the correction is applied.

When a wedge consists of two flat faces meeting to from a common edge, the edge has finite axial extent. However, the faces are assumed by the PTD formulation to extend away from the edge without ending. This assumption limits accuracy when a source, wedge face, and observation angle/point are aligned.

Uniform Theory of Diffraction (UTD)

When SBR+ wedges are extracted from metal surfaces, the traditional GO rays can be augmented by another class of rays that are created by diffraction at these wedges. These rays are called UTD rays in SBR+, since they are governed by the uniform theory of diffraction at metallic wedges. UTD, formulated by Kouyoumjian and Pathak in 1974, is an extension of Keller's geometrical theory of diffraction (GTD). The coefficients of the diffracted rays in Keller's GTD exhibited singularities at the incident and reflection shadow boundaries. These singularities were removed by UTD, yielding a description of diffracted rays that is uniformly valid at all angles.

The UTD rays are an augmentation of GO rays, much like the PTD Wedge Correction is an augmentation of PO radiation. Without the UTD rays, only the regions of the CAD model that have a line-of-sight (LOS) or multi-bounce GO path from the transmitter are illuminated. This direct and indirect illumination is effected by the GO rays launched from the transmitter. With the addition of UTD rays, portions of the CAD model that do not have a LOS or multi-bounce GO paths to the transmitter can also be illuminated, improving the ray coverage on the CAD model. This type of indirect illumination is achieved when rays leaving the transmitter diffract at wedges (which are required to be in direct LOS of the transmitter, as they are for PTD wedge correction) in accordance with the uniform theory of diffraction. The resulting UTD rays reach previously shadowed points on the CAD model. It should be noted that the UTD illumination mechanism is not limited to shadow regions: UTD rays can also hit portions of the CAD model that are in the LOS of the transmitter.

The existence of a UTD ray is not guaranteed for every point on the CAD model. The defining property of a UTD ray is the minimum distance principle, as it is for a GO ray. An equivalent expression of this property is that a UTD ray leaving a wedge lies on the Keller cone at the diffraction point. The angle formed between the incident ray and the edge line at the diffraction point defines the characteristic half-angle of the Keller cone, whose cone axis is aligned with the edge. There may be portions of the CAD model that do not intersect any of the Keller cones defined by the transmitter and the existing wedges. There may also be blockage effects preventing the propagation of UTD rays to some regions. Conversely, some points on the CAD model may be illuminated by multiple UTD rays if there are valid UTD paths to those points through multiple wedges.

Once a UTD ray is launched from a wedge, it behaves in exactly the same way as other GO rays in the SBR algorithm. It gets reflected, transmitted, and absorbed at subsequent bounces, and either reaches the maximum number of bounces or escapes to infinity. However, the initial state of the UTD ray upon leaving the wedge depends heavily on the diffraction geometry.

Creeping Waves

Traditional SBR is limited by its reliance on straight-line geometrical optics (GO) ray tracing for the electromagnetic interaction with the scattering geometry. The Creeping Wave (CW) option is

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

an additive physics enhancement to SBR (and part of HFSS SBR+) that addresses this limitation. The CW scattering mechanism complements both the field-transport and the current radiation aspects of SBR.

In a similar way as SBR rays, CW rays paint currents on the scattering geometry that are then radiated to field observers and receiving antennas. The main difference is that creeping rays are traced on the scattering surface in geodesic paths rather than through space in straight-line paths. As with SBR's GO rays, the CW rays are never used to directly transport energy to field observers, and they comply with Fermat's principle of least time.

The currents painted by SBR on the CAD geometry via the physical optics (PO) approximation are abruptly truncated at the so-called shadow boundary, the mathematical border between directly illuminated and shadowed surface regions. This non-physical truncation of the surface current leads both to a false diffraction effect (which is particularly a problem in Radar Cross Section (RCS) predictions) and to missing progressive surface diffraction beyond the shadow boundary (which is particularly a problem in cosite antenna coupling predictions). The introduction of CW rays provides a current-based correction to the SBR-PO currents that addresses both problems by painting currents beyond the shadow boundary, smoothly blending SBR and CW currents across the shadow boundary.

Creeping wave propagation follows a minimum path distance rule (i.e., Fermat's least-time principle), resulting in a geodesic path on a curved surface. Creeping waves decay quickly in the shadow region as they propagate since they progressively shed energy to space along their direction of travel. Even if creeping rays can indefinitely propagate on an uninterrupted smooth surface, such as a sphere, the currents they paint on a surface are important only up to a certain travel distance. Ray Decay Threshold [dB] controls how far the creeping rays are allowed to propagate by terminating each ray once its power density decays below a threshold, defined as dB down from its power density at the shadow boundary.

The SBR+ Creeping Wave implementation is entirely consistent with its baseline SBR solution as a coherently additive correction component to the scattered field. That is, both can concurrently contribute to the scattered field, and in a manner that improves accuracy over the baseline SBR solution alone. In areas of the lit region where SBR first-bounce rays and CW rays would both paint currents, care is taken in the implementation to prevent double-counting of scattering mechanisms.

For RCS simulations, the shadow boundary is identified via SBR first-bounce rays from plane wave incidence. The CW rays are then launched into the shadow region from many points along the shadow boundary, initially advancing in the same the direction of the incident plane wave. CW currents are painted as the CW rays advance along geodesic paths that adhere to the curved surface. The formulation for first-bounce SBR currents is also modified so that surface currents across the shadow boundary transition smoothly between the lit and shadow regions. This has the important benefit of eliminating a spurious diffraction from the shadow boundary that arises in the SBR-only solution due to abrupt truncation of PO currents there.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For simulations involving transmitting antennas, CW analysis can only be performed from either 1) a near-field link to an HFSS source such as a FEBI or IE region, or 2) one of the current source based parametric antennas, which are available in the SBR+ solution type. In either case, the antenna must also have an infinite PEC ground plane, and part of the antenna must be located close (distance less than λ/2) to the nearest PEC or PEC-like surface.

The latter requirement is why only near-field sources are supported. With transmitting antennas, creeping waves launch from the closest point on the surface below each current source.

The creeping wave in SBR+ is limited to specific conditions:

- The creeping wave rays will only be launched and continue propagating on metal (PEC-like) surfaces
- The creeping wave will only advance on convex surfaces

The implementation does not require that the scattering geometry to be globally convex, such as a sphere or ellipsoid. However, the creeping-wave rays will terminate upon encountering local regions of surface concavity or saddle-shaped curvature (convex along one principal direction, concave along the other). This a requirement of the implemented CW formulation, but it can also be understood in terms of the of the minimum-path-distance rule. Where the surface becomes concave, the shortest path between the surface crests bounding the concavity no longer resides on the surface but, instead, is a straight line through space. When a local concavity is small and should be ignored, a relaxed value of Irregular Surface Tolerance allows CW rays to propagate over it.

Irregular Surface Tolerance is a single control for a collection of tolerances that determine creeping rays' sensitivities to local surface irregularities that theoretically should block their further propagation. Moving the slider toward Relaxed allows creeping rays to propagate through small surface irregularities that may arise through defects in the input geometry or due to limitations of curvature extraction accuracy. However, setting this tolerance too relaxed may allow creeping waves to pass through concave surfaces, saddle surfaces, or wedges, which are not supported by creeping wave physics. Therefore, users are strongly encouraged to perform a creeping-wave visual ray trace (VRT) to determine an acceptable setting for this tolerance, which will differ from model to model. The intention is that creeping rays only propagate over the convex portions of surfaces, and some user judgment is required in correctly setting the Irregular Surface Tolerance for each situation.

When a CW ray is shot, each CW ray stops propagating when it triggers a termination condition. The CW ray termination type for VRT with Creeping Wave may be found as render and filter parameters appearing in Properties of the parent Visual Ray Trace CW folder. Use the Render tab to set the color for each termination type. The configurable filters help in identifying issues for a specific termination type. Termination types include:

- **Natural Decay**: Decayed normally according to Ray Decay Threshold [dB]
- **Curvature Not Supported**: Encountered explicitly flat surface or where curvature could not be extracted

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Non-PEC Surface**: Encountered non-metallic surface (creeping wave formulation is limited to PEC-like surfaces)
- **Non-Smooth Crossing**: Encountered excessive slope discontinuity upon attempted crossing to next surface patch
- **Saddle Point**: Encountered section of surface with non-negligible saddle curvature (creeping wave formulation is limited to convex surfaces)
- **Double-Concave Point**: Encountered section of surface with non-negligible concave curvature (creeping wave formulation is limited to convex surfaces)
- **Unknown Creeping-Ray Error**: Creeping-ray algorithm encountered an unexpected condition
- **Geodesic Hit an Edge**: Encountered a surface edge (i.e., no continuing patch detected)
- **Geodesic Width Too Large**: Creeping ray footprint grew too wide
- **Unknown Geodesic Error**: Geodesic ray-trace algorithm encountered an unexpected condition
- **Natural Decay**: Decayed normally according to Ray Decay Threshold [dB]
- **Curvature Not Supported**: Encountered a surface where curvature could not be extracted
- **Non-Metallic Surface**: Encountered non-metallic surface (creeping wave formulation is limited to PEC-like surfaces)
- **Non-Smooth Crossing**: Encountered excessive slope discontinuity upon attempted crossing to next surface patch
- **Saddle Point**: Encountered section of surface with non-negligible saddle curvature (creeping wave formulation is limited to convex surfaces)
- **Double-Concave Point**: Encountered section of surface with non-negligible concave curvature (creeping wave formulation is limited to convex surfaces)
- **Unknown Creeping-Ray Error**: Creeping-ray algorithm encountered an unexpected condition
- **Geodesic Hit an Edge**: Encountered a surface edge (i.e., no continuing patch detected)
- **Geodesic Width Too Large**: Creeping ray footprint grew too wide
- **Geodesic Hit an Invalid Surface**: Encountered finding an incorrect neighboring surface.
- **Geodesic Blocked by Surface**: Creeping ray is blocked by another surface
- **Unknown Geodesic Error**: Geodesic ray-trace algorithm encountered an unexpected condition
- **Rough Surface**: Encountered section of surface where rough surface is defined

GO Blockage Technical Note

In SBR+, rays are used to transport fields from the source to the scattering geometry (first bounce) and between different surfaces of the scattering geometry (multi-bounce). However, rays are not used to propagate incident or scattered fields to field observers, whether far-field, near-field, or receiving antennas. Rays are only used to paint equivalent currents on the scattering geometry. Once these currents are determined, SBR+ rays serve no further purpose and are discarded. The painted currents are then radiated in free space to all field observers to establish the scattered field contribution. The scattered field coherently combined with the incident field from the source, also propagated in free space, yields the total (i.e., measurable) field at all defined field observers.

Since propagating the source incident field and radiating the scattered fields to field observers is performed in free space, these operations of the SBR+ algorithm are not mediated by rays. This means that SBR+ applies a physical optics (PO) blockage model: total-field shadows cast by the scattering geometry relative to the field source emerge through destructive interference of the incident and scattered fields. PO blockage not only occurs in connection with the incident field from the source, but also within the scattered field itself. Scattered fields from the previous bounce are diminished behind a blocking surface via destructive interference when the reflecting or transmitting rays from the previous bounce hit that surface and the equivalent currents painted by the incident ray fields at the current bounce are radiated as part of the scattered field contribution.

Because the PO blockage model depends on destructive interference to recover the total-field shadow cast by an obstruction, the PO blockage model requires accurate currents over the extent of the obstruction. This can be hard to achieve in the Geometrical Optics (GO) approximation inherent in a ray propagation model. For example, the obstruction may not be well illuminated by direct rays from the field source or indirect multi-bounce rays after an earlier reflection or transmission. Even small inaccuracies in the painted equivalent currents can spoil the coherent cancellation mechanism needed to yield a robust shadow. An alternative is to invoke the SBR+ GO blockage model. In this model, the scattering contribution of a painted equivalent current to a field observer is included after passing a line-of-sight (LoS) check. This check is performed using the same geometric ray tracing engine that deploys the SBR+ rays. The GO blockage model can be more accurate than the default PO blockage formulation.

In the GO blockage model, it is ambiguous whether a field observer on the opposite side of a thin surface relative to the reflected/transmitted ray, but otherwise having line-of-sight path to the hit point, is blocked. The SBR+ GO blockage model provides an option to resolve this ambiguity. If Surface Self-Block is switched on (true), then any observation points in the opposite half-space of the hit surface with respect to the reflected/transmitted ray will be blocked. If Self-Block is switched off (false), then only a different surface (or different part of the same surface if the surface is curved) can cause blockage.

When GO blockage is used, blockage of the incident field from the field source by directly illuminated surfaces of the scattering geometry is computed by the PO cancellation method, but

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

scattered fields arising from interacting with the geometry are added subject to a line-of-sight blockage check to the field observers. When GO blockage is enabled, PTD, UTD and Creeping Wave radiation are also subject to a line-of-sight blockage check. It is recommended to use the GO blockage feature for SBR-only simulations, as the GO blockage effects for other diffraction mechanisms might not produce accurate results.

The GO blockage model has a non-trivial computational cost relative to the default PO blockage model. This is because many LoS test rays must be shot: one from each ray hit point to each field observer. However, when the GPU is enabled for the analysis, this additional cost is substantially mitigated since the ray tracing operations of these LoS blockage checks are performed very efficiently on the GPU.

Visual Ray Tracing (VRT)

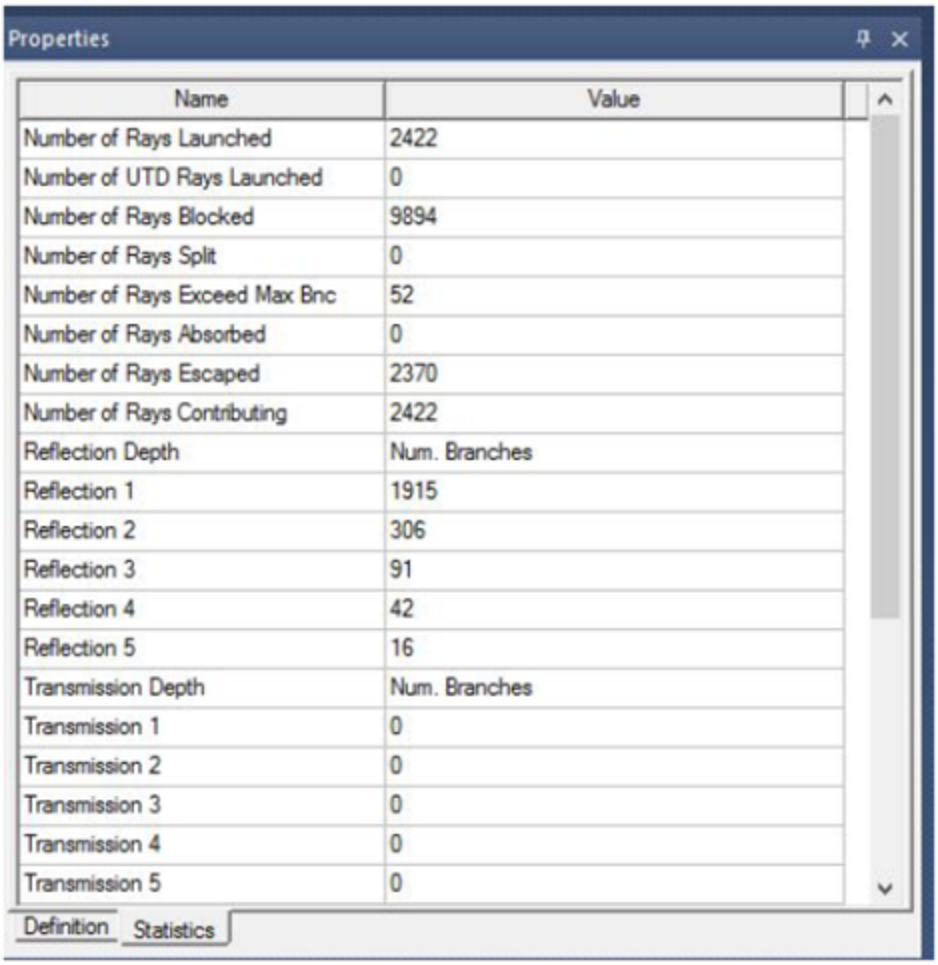
Visual Ray Trace (VRT) is a powerful feature available in HFSS for visualizing the ray geometry and interactions for an SBR+ simulation. Since SBR+ relies on “painting” physical optics (PO) currents on the geometry, VRT can provide valuable insight for analyzing these PO contributions from the direct illumination first-bounce rays and the multi-bounce GO rays. VRT can selectively display:

- ray hit (bounce) points on the scattering geometry,
- ray paths (lines) between each bounce, and
- triangular ray “footprints” that are used to integrate the PO currents.

The VRT feature includes a number of rendering controls and options to filter whole ray tracks or individual ray bounces, visualize ray scattering directions, and color ray point/lines/footprints according to different criteria.

When SBR rays are shot in VRT, SBR ray statistics are collated and displayed within the Statistics tab of the Properties window for the SBR Plot node of the Visual Ray Trace SBR plot folder:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

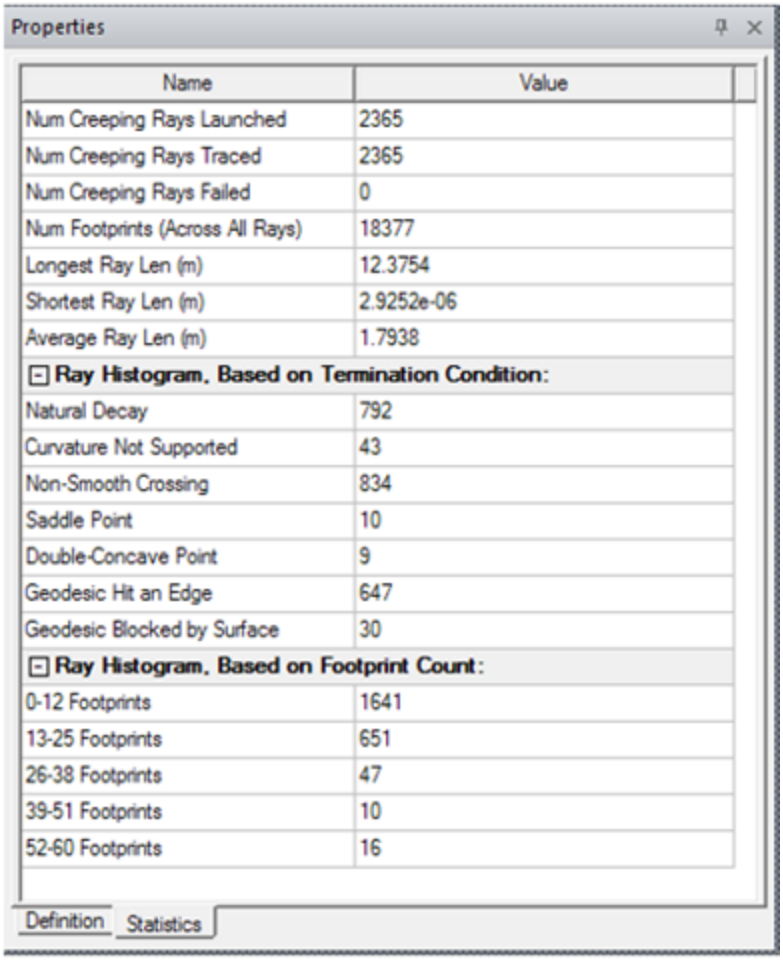


- Number of Rays Launched: Number of GO (non-UTD) rays illuminating the CAD model from the antenna or source, not including those blocked by other surfaces
- Number of UTD Rays Launched: Number of UTD rays illuminating the CAD model, not including those blocked by other surfaces
- Number of Rays Blocked: Number of potentially launched rays whose line-of-sight path was blocked by part of the CAD model
- Number of Rays Split: Number of rays that hit a penetrable surface (e.g., 2-sided Layered Impedance Boundary). These rays are split to form both a transmitted and reflected ray
- Number of Rays Exceed Max Bnc: Number of rays that would have continued propagating through the model, but were terminated because they reached the Max Number of Bounces limit set in the plot Definition
- Number of Rays Absorbed: Number of rays that hit a surface with a Perfect Absorber boundary. Ray track branches terminate on such surfaces.
- Number of Rays Escaped: Number of ray track branches whose final ray escapes the scene

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Number of Rays Contributing: Number of ray track branches that would contribute to the scattered field result in a corresponding simulation
- Reflection <N> under Reflection Depth: Number of branches that terminate/escape after <N> reflections
- Transmission <N> under Transmission Depth: Number of branches that terminate/escape after <N> transmissions

When Creeping Wave (CW) rays are shot in VRT, CW ray statistics are collated and similarly displayed:



- Num Creeping Rays Launched: Total number of creeping rays launched
- Num Creeping Ray Traced: Number of launched creeping rays that were successfully traced
- Num Creeping Ray Failed: Number of launched creeping rays that failed to trace
- Num Footprints (Across All Rays): Total number of ray footprints generated across all traced creeping rays

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Longest Ray Len (m): Length of longest creeping ray (in meters)
- Shortest Ray Len (m): Length of shortest creeping ray (in meters)
- Average Ray Len (m): Average length among all creeping rays (in meters)
- Ray Histogram Based on Termination Condition: Breakout of number of rays terminated due to each termination type (e.g., Natural Decay, Non-smooth Crossing)
- Ray Histogram Based on Footprint Count: Number of creeping rays with a footprint count residing within a particular min/max range of footprint counts

Current Conformance and Array Conformance in SBR+

Activate Current Conformance to shift the heights of the current sources to better accommodate to the underlying platform structure with which they will be interacting. This capability is primarily intended for antennas requiring a ground plane and that will be placed on a flat or slightly curved metallic section of the platform that will provide this grounding function. It is typically used to make slight adjustments that will improve simulation accuracy and speed. There are a couple of reasons why one should consider using the adjust/conform antenna feature.

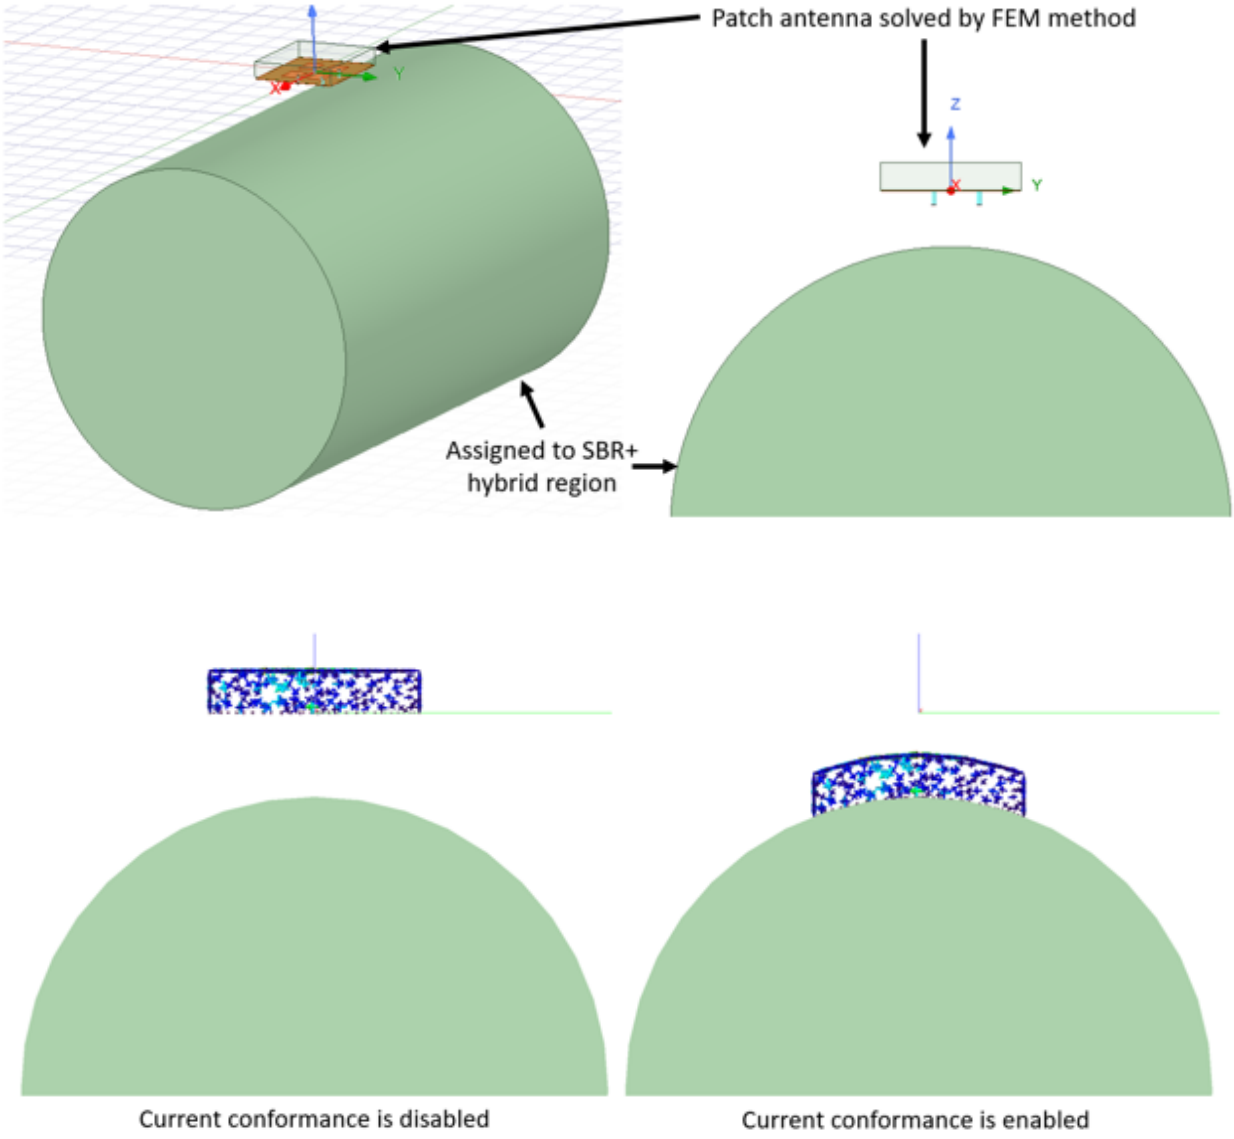
- The unadjusted sources may otherwise be too close or possibly even slightly underneath the platform placement surface. In general, placing sources that are conceptually intended to be directly on the surface closer than λ/20 above the surface harms run time with little or no accuracy benefit, as in the case of horizontal magnetic sources representing a slot cut in the placement surface.
- The platform placement surface is slightly curved, the shape of the actual antenna will conform to this curvature, yet the antenna might not exhibit this intended curvature (it's flat)

These situations are common, so the Current Conformance feature is an important capability. When the antenna structure is to be placed directly on the platform, such that it touches the platform, a small source adjustment will often be beneficial.

Example of Current Conformance

The following driven terminal hybrid design has a patch antenna surrounded by a FEBI region with a Perfect E infinite ground plane, and a PEC cylinder assigned to an SBR+ hybrid region. The fields on the FEBI surface are converted to current sources in the SBR+ simulation. The patch antenna is placed too high relative to the cylinder, as evidenced by the gap between its ground plane and the cylinder. If Current conformance is enabled, the current sources will be shifted parallel to the antenna’s z-axis toward the placement surface, such that their heights above the curved PEC placement surface will match their original heights above the ground plane .

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Conformance in SBR+ Parametric Array

Parametric array conformance is processed in two stages, array element conformance, and current conformance if the element antenna is based on current sources.

Array conformance (Conform to Geometry) for Parametric Array

Array conformance may be selected from **Conform to Geometry** which is found in first page of **Create Parametric Array: General** dialog. Select **Perpendicular to Plane** or **Along Normal** to shift the heights of the elements to better accommodate the underlying platform structure with which they will be interacting. This capability is primarily intended to conform an antenna array

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

that will be placed on a flat or slightly curved metallic section of the platform. See Create and Use Parametric Array in SBR+.

Element Offset specifies the offset as a 3-D Cartesian vector. The elements will be shifted by the fixed offset specified in the local coordinate system of the parametric array. The z-directed offset is also maintained after conformance above the underlying platform structure when **Along Normal** or **Perpendicular to Plane** are chosen. Pay attention to sources of element antenna that are not too close to the platform surface. Placing sources directly on the platform surface closer than λ/20 above the surface harms run time with little or no accuracy benefit. Use **Element Offset** to shift the heights of the elements such that the sources are λ/20 away from platform, in particular, when the element antenna is far-field source. On the other hand, **Current Conformance** is recommended when element antenna is current source or Near-field link which is explained in later section.

The array conformance is applied after the **Element Offset** is applied to each array element in antenna local coordinates. There are three options:

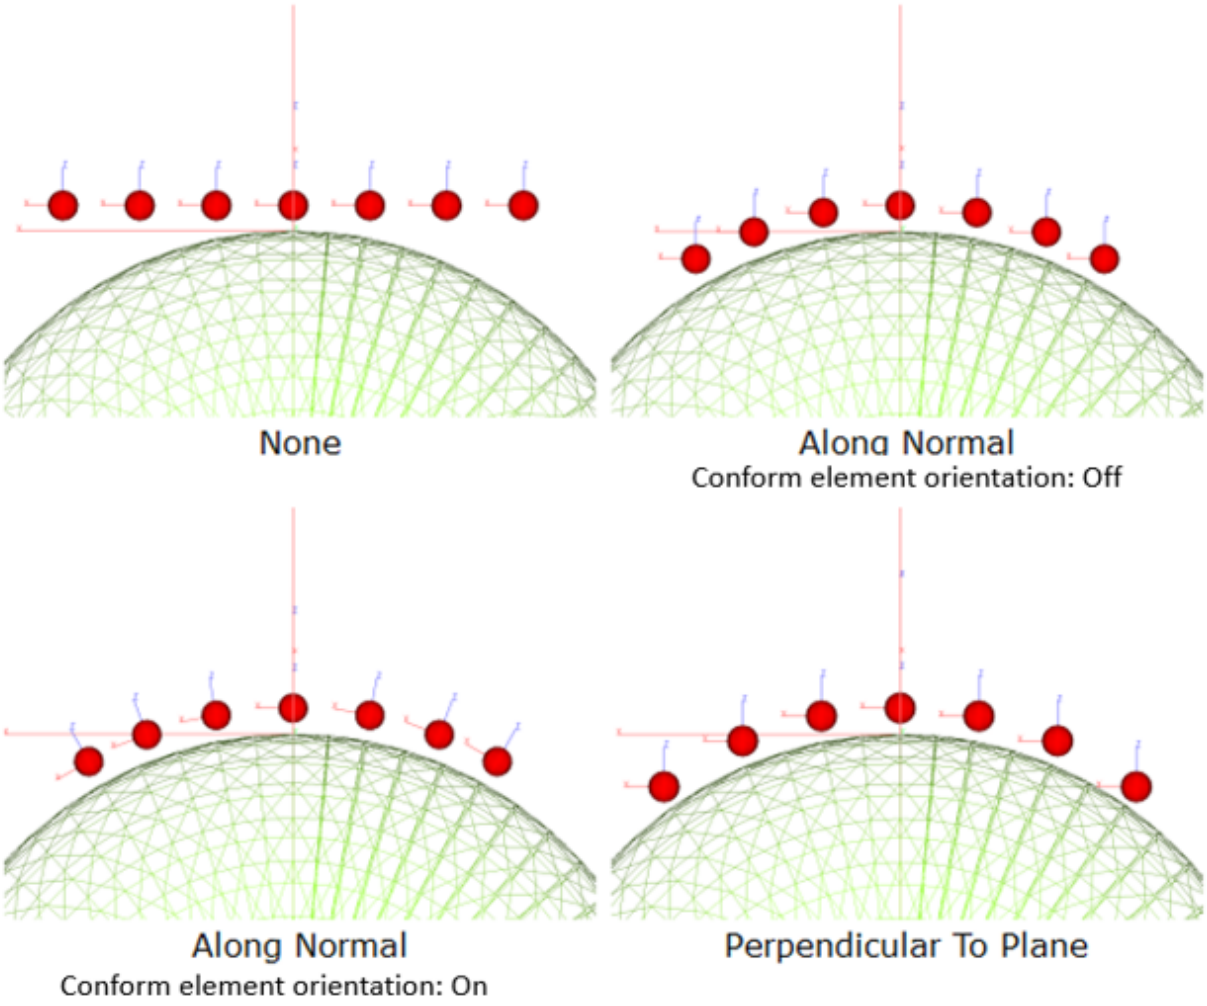
None - No further adjustment after **Element Offset** is applied.

Along Normal: Element positions are further modified according to the position and perpendicular of the platform surface point *Pn* closest to each array element. If **Conform Element Orientation** is also switched on, then the element orientations are similarly modified according to the surface perpendicular at *Pn*.

Perpendicular to Plane: Element positions are further modified according to the position of the platform surface point *Pu* directly under each array element.

The behavior of these three options is summarized in the illustration below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The concept behind array conformance is to shift the array element positions so that their height with respect to the array platform on the XY plane is maintained with respect to the SBR CAD platform placement surface. If the platform placement surface is uniformly flat over the extents of the array elements, the elements will be shifted downward to maintain their heights above flat platform surface. If the platform curves away, then the elements will be shifted downward to maintain their heights above the actual curved surface.

One intended use of array conformance is to simplify the modeling task for antennas conforming to the platform surface. Many antennas are not engineered with a particular platform in mind, and their shape is fixed independent of the shape of the placement surface. However, there are applications requiring the antenna to be shaped according to the intended placement surface. For example, this occurs with conformal arrays placed on a fuselage, wing, or some other curved surface.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In these situations, one would ideally capture this curvature in the geometry definition of the array antenna. However, it may not be convenient to do so, as it entails greater effort in developing the model.

The difference between Array Conformance **Along Normal** and **Perpendicular to Plane** is the determination of the surface points *Pn* and *Pu* relative to which the array elements are repositioned, and also the direction in which these adjustments are applied.

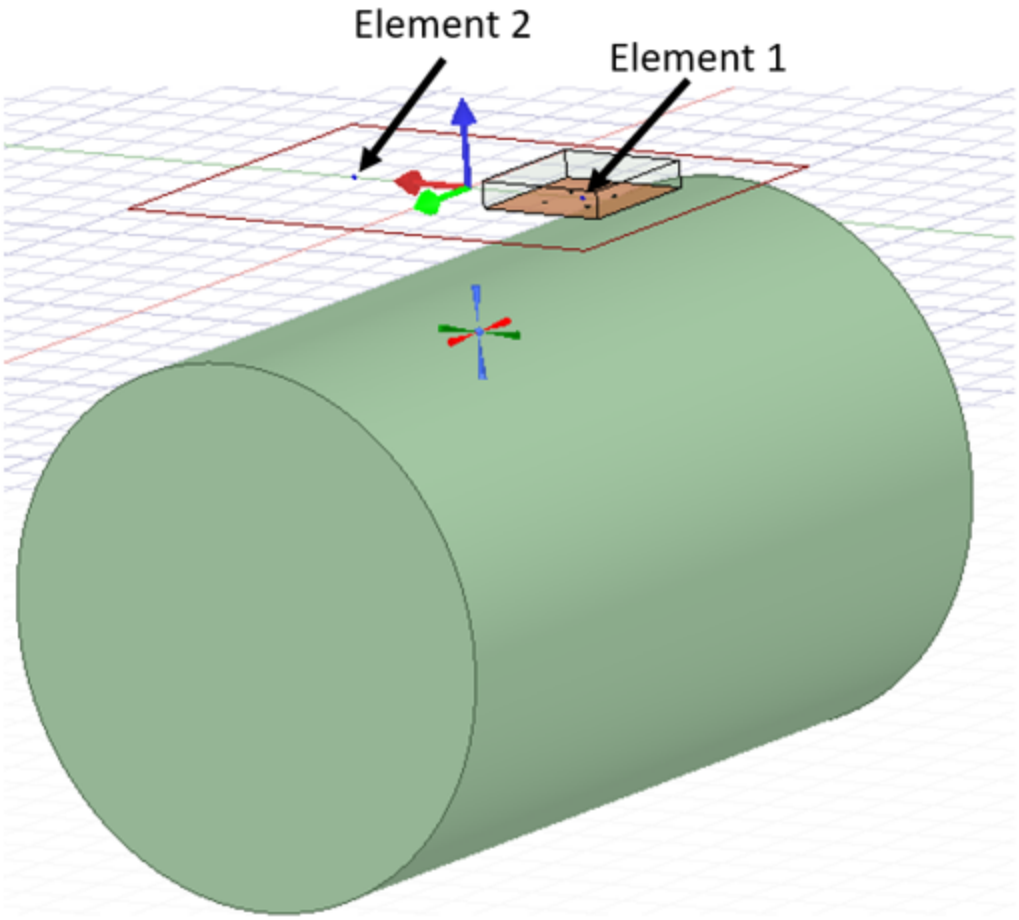
If Array Conformance is **Along Normal**, then *Pn* is the surface point nearest the n^{th} array element (after application of **Element Offset**). The array element is then repositioned at distance *h* from *Pn* along the surface perpendicular at that point.

If **Conform Element Orientation** is switched on (True), then each array element is also rotated to maintain the same orientation relative to the surface tangent plane at each *Pn* as it had relative to the Reference XY-Plane of the array coordinate. Specifically, if the rotation matrix *R* would rotate the Reference Plane to the tangent plane at *Pn*, then the same rotation matrix *R* is applied to the orientation of the n^{th} array element. It is only available when **Conform to Geometry** is set to **Along Normal**.

If Array conformance is **Perpendicular to Plane**, the surface point *Pu* is determined by extending a line from each array element (after application of **Element Offset**) toward the Reference XY-Plane and perpendicular to the same. The first platform surface point intersecting this line is designated as the surface point *Pu* "under" the array element. The array element is then repositioned along this line to maintain the same distance relative to *Pu* as its original height *h*. For this adjustment option, the array elements are never re-oriented; only their positions are shifted.

An example of two element linear array of a patch antenna is shown below. Each element is assigned the same FEBI box source. The first of these two elements is indicated by the element-positioned FEBI box. The second element is depicted as a simple point, but it is important to understand that it also has the same FEBI box centered on it during simulation. In general, with Parametric Array rendering in Desktop, the FEBI box is only drawn for the first element of a parametric ray. This is done to reduce clutter in the visualization and keep the focus on the arrangement of array elements.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



When the parametric array is conformed with Array Conformance “None”, all elements are located on XY-plane of the antenna coordinate. On the other hand, when **Along Normal** or **Perpendicular to Plane** are selected, elements and element antennas are moved toward the underlying platform structure. Also, when **Along Normal** and **Conform Element Orientation** are selected, elements are rotated such that the rotated to maintain the same orientation relative to the surface tangent plane as it had relative to the Reference XY-Plane of the array coordinate.

Elements of the array might intersect the placement surface after array conformance. One way to avoid this problem, is to adjust the element offset Z used as the height of the elements above the underlying platform structure. However, this should only be done if it makes physical sense given the actual array being simulated. The alternative resolution, and often the superior one, is to use **Current Conformance**, which is explained in next section.

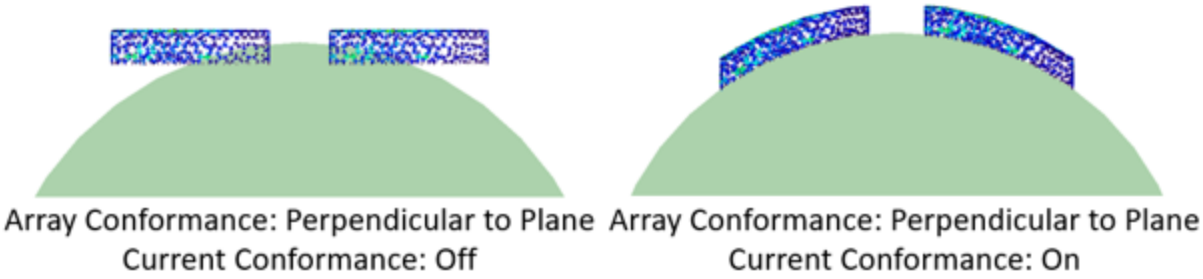
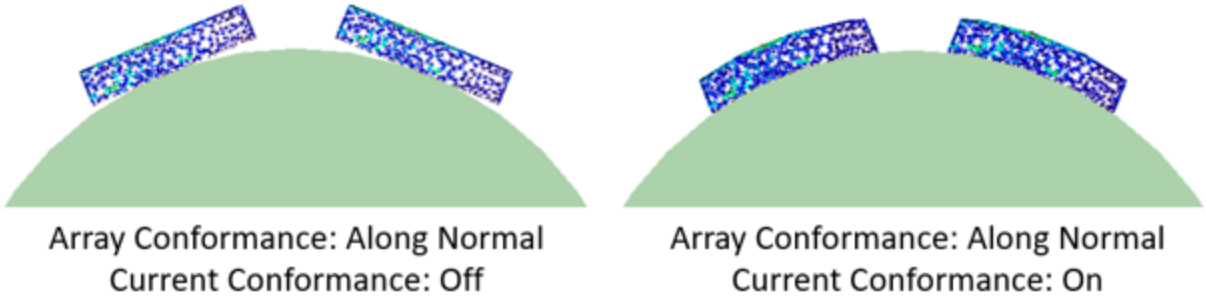
Current Conformance for Parametric Array

In addition to Array conformance, Current Conformance is recommended for Parametric Arrays whose elements are parametric antennas with current sources or Near-Field linked antenna.

In previous example, Array Conformance **Perpendicular to Plane** without offset resulted in array elements intersecting the underlying platform structure. When current conformance is off, some current sources intersect the platform structure or end up under the platform structure. When current conformance is enabled, the element current sources are conformed to the platform structure.



In general, it is recommended to enable current conformance, even in cases where no intersection occurs between the array elements and the platform. This feature helps in detecting if any current source results in being positioned below the platform after conformance, in which case the simulation is aborted with an error message.

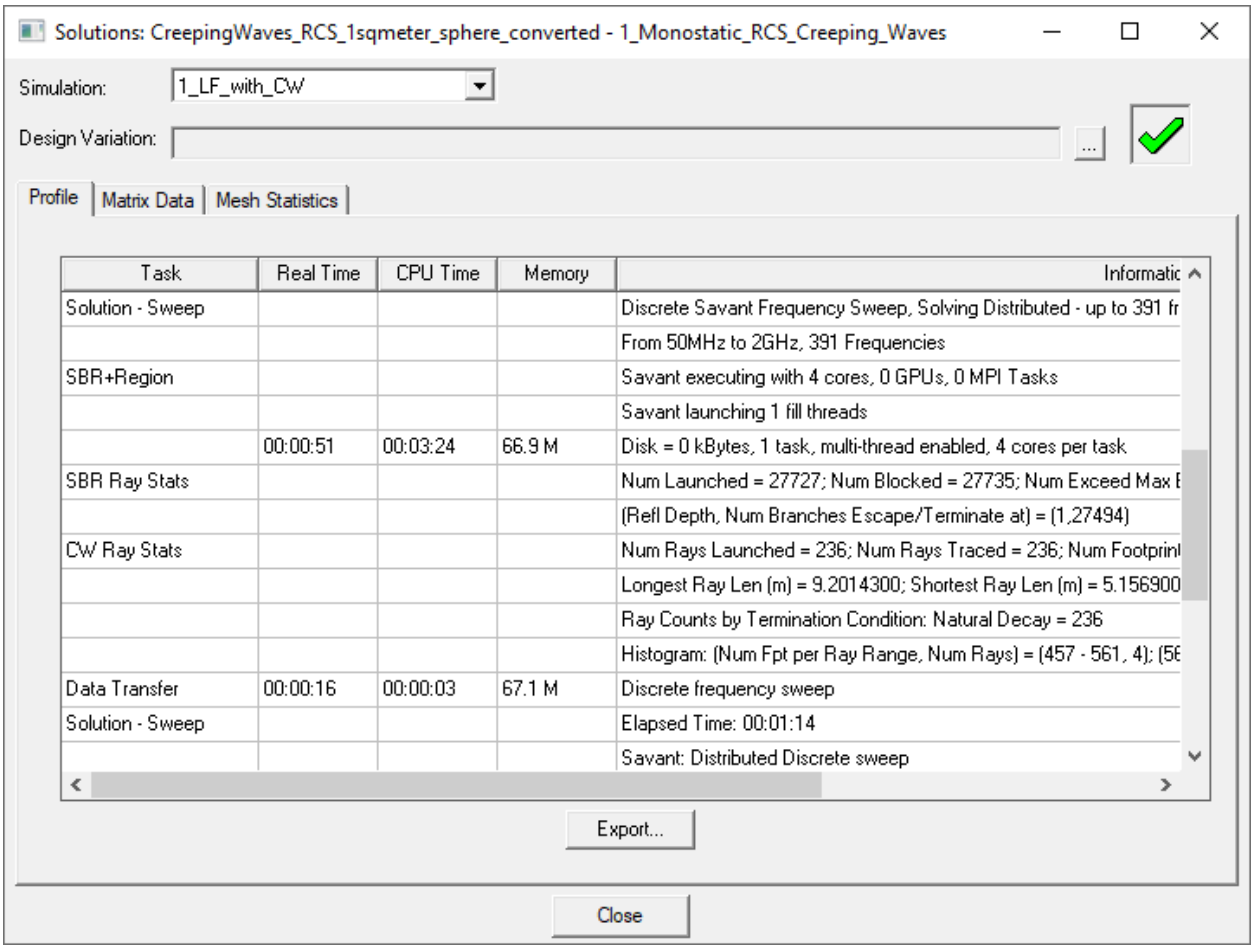


Ray Statistics for SBR+ Analysis

Ray statistics summarize the ray tracing performed during the SBR+ simulation. Ray statistics are primarily useful for understanding the role of multi-bounce, UTD, creeping-wave, and other geometrical-optics mechanisms in the simulation. They are also useful for understanding the run time of SBR+ simulations, especially in the context of penetrable surfaces that lead to many split rays.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ray statistics are found in the profile after an SBR+ run. Ray statistics are reported cumulatively for all Tx antennas in the simulation. Ray statistics appear under two different task names, with “SBR Ray Stats” reserved for SBR+ and "CW Ray Stats” reserved for Creeping Wave.



In the following, SBR and creeping-wave ray statistics are explained separately in more detail.

SBR Ray Stats

An SBR ray track is a sequence of connected ray segments (bounces). When a ray hits a surface, a reflected ray is generated, extending the track. If the surface is penetrable on a two-sided Layered Impedance Boundary or a face on dielectric solid object, a transmitted ray is also generated. This is called a split, leading to a new branch of the original ray track. On models with no penetrable surfaces, each ray track has only a single branch. On models with penetrable surfaces, each track may consist of 1 - N branches. If UTD rays are enabled for the simulation, the number of UTD rays are also listed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Num Launched:** Number of (non-UTD) rays illuminating the CAD model from the antenna, not including those blocked by other surfaces
- **Num Launched (UTD):** Number of UTD rays illuminating the CAD model, not including those blocked by other surfaces
- **Num Blocked:** Number of potentially launched rays whose line-of-sight path was blocked by part of the CAD model
- **Num Split:** Number of rays that hit a penetrable surface. These rays are split to form both a transmitted and reflected ray
- **Num Exceed Max Bnc:** Number of rays that would have continued propagating through the model, but were terminated because they reached the Max Number of Bounces limit set in the project
- **Num Absorbed:** Number of rays that hit a surface coated with a perfect absorber. Ray track branches terminate on such surfaces.
- **Num Escaped:** Number of ray track branches whose final ray escapes the scene
- **Num Contributed:** Number of ray track branches that contributed to the scattered field
- **Num Invalid Interface:** Number of rays that encounter volume interface inconsistency.

SBR ray histograms on the SBR ray track are also reported. The histograms are reported as pairs of number, with the first number being the Reflection or Transmission Depth followed by the number of branches that are terminated or escaped at that depth. For example,

```
(Refl Depth, Num Branches Escape/Terminate at) = (1,18353)
```

means 18353 branches are terminated or escaped after 1 reflection.

CW Ray Stats

If Creeping Rays are enabled, creeping rays are launched and traced on curved surfaces. Like SBR rays, creeping rays have footprints that cover finite areas on the curved surface. If the creeping rays are launched densely enough, they collectively cover the surface on which they propagate without overlap. The creeping-wave ray statistics provide information on the number and distribution of footprints across all creeping rays. More details can be found in Creeping Wave.

Typically, all these rays are traced successfully, and they contribute to the scattered field. If a ray encounters a critical error because of an unhandled contingency in the formulation, it gets discarded and its contribution to the scattered field is not computed. The number of these rays is given in the Num Failed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Num Launched:** Total number of creeping rays launched during simulation
- **Num Traced:** Number of creeping rays successfully traced and radiated
- **Num Failed:** Number of creeping rays failed and discarded without being radiated
- **Num Footprints (Across All Rays):** Total number of footprints across all creeping rays
- **Longest Ray Len (m):** Length of longest creeping ray (in meters)
- **Shortest Ray Len (m):** Length of shortest creeping ray (in meters)
- **Average Ray Len (m):** Average length among all creeping rays (in meters)

Creeping-wave ray statistics also provide a break-down of the ray counts with respect to how the rays are terminated.

- **Natural Decay:** Decayed normally according to Ray Decay Threshold [dB]
- **Curvature Not Supported:** Encountered a surface where curvature could not be extracted
- **Non-Metallic Surface:** Encountered non-metallic surface (creeping wave formulation is limited to PEC-like surfaces)
- **Non-Smooth Crossing:** Encountered excessive slope discontinuity upon attempted crossing to next surface patch
- **Saddle Point:** Encountered section of surface with non-negligible saddle curvature (creeping wave formulation is limited to convex surfaces)
- **Double-Concave Point:** Encountered section of surface with non-negligible concave curvature (creeping wave formulation is limited to convex surfaces)
- **Unknown Creeping-Ray Error:** Creeping-ray algorithm encountered an unexpected condition
- **Geodesic Hit an Edge:** Encountered a surface edge (i.e., no continuing patch detected)
- **Geodesic Width Too Large:** Creeping ray footprint grew too wide
- **Geodesic Hit an Invalid Surface:** Encountered finding an incorrect neighboring surface.
- **Geodesic Blocked by Surface:** Creeping ray is blocked by another surface
- **Unknown Geodesic Error:** Geodesic ray-trace algorithm encountered an unexpected condition
- **Rough Surface:** Encountered section of surface where rough surface is defined

Occasionally creeping rays cannot be launched because of problems related to the source.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Far-Field Antenna:** Far-field antennas do not support CW
- **Antenna Too Far From Platform:** The entire antenna is too far from the platform
- **No Ground Plane:** The antenna has no ground plane
- **No Closest Point:** No closest point could be found on the surface
- **Closest Point Failure:** The vector connecting the closest point to the source is not perpendicular to the surface
- **Current Source Too Close to Platform:** The current source is too close to the platform
- **Current Source between Original and Fitted Surface:** When an original (flat) surface was fitted with a curved surface based on its curvature information, the current source ended up between these two surfaces.
- **Curvature Not Supported:** The closest point is on a surface that does not have curvature information
- **Closest Point Not Metal:** The closest point is not located on a metallic surface
- **Closest Point On Concave Surface:** The closest point is on a surface with concave curvature
- **Point On Saddle Surface:** The closest point is on a surface with saddle curvature
- **Closest Point On Rough Surface:** The closest point is located on a surface that has a surface roughness model defined

Similarly to SBR ray statistics, CW ray statistics include a footprint histogram,

```
(Num Fpt per Ray Range, Num Rays) = (39 - 51, 285)
```

means 285 creeping rays are terminated in a range between 39 and 51 footprint counts.

Integral Equation Method Used in for IE Regions

The most commonly used electromagnetic integral equation is the Electric Field Integral Equation, or more commonly referred to by its acronym, EFIE. Consider a perfect conductor that is illuminated by a plane wave or any other source. On the surface of a perfect conductor the total tangential electric field must be zero. The total electric field comprises the incident electric field and the scattered electric field; hence, on the conducting surface.

$$\hat{n} \times (\vec{E}^{inc} + \vec{E}^{scat}) = 0 \quad (1)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The above relation only specifies the scattered field on the surface of the conductor. To fully understand the system, we need to be able to calculate the scattered field everywhere; one way to do this is to calculate the induced current which generates the scattered electric field.

The field generated by a current is

$$\vec{E}(\vec{r}) = \frac{1}{j\omega\varepsilon}\left(\nabla\nabla\bullet + k^2\right)\int J(\vec{r}')\,G\left(\left|\vec{r}-\vec{r}'\right|\right)d\vec{r}' \quad (2)$$

where G is the Green's function defined as

$$G(r) = \frac{1}{4\pi}\frac{e^{-jkr}}{r} \quad (3)$$

and J is the surface current density. Combining the relationship between current and scattered field with the boundary condition yields the EFIE

$$G(r) = \frac{1}{4\pi}\frac{e^{-jkr}}{r} \quad (4)$$

$$\hat{n}\times\vec{E}^{inc} = \hat{n}\times\left[\frac{1}{j\omega\varepsilon}(\nabla\nabla\bullet + k^2)\int J(\vec{r}')G(|\vec{r}-\vec{r}'|)d\vec{r}'\right] \quad (5)$$

The unknown current density is within the integral operator; these types of equations are known as integral equations. Also note the integral is a convolution. Electromagnetic integral equations are convolutions, and this allows us to make an analogy to system theory. The Green's function is the transfer function, or the impulse response of the system, and the incident electric field is the output. Our task is to find the input, or the current density, from the output knowing the transfer function.

Solving the EFIE is typically done through a finite element technique. We divide the surface of the conductor into many, many triangles, and on each triangle we assume a current distribution. This converts EFIE into a matrix equation, and in the electromagnetics literature this technique is called the method of moments (MoM).

The EFIE is just one of many different integral equations used in electromagnetics. We can vary the boundary conditions we enforce, or the method we use to specify the field everywhere. For example, if on the surface of the conductor, we enforce the continuity of the magnetic field, following a similar procedure yields the magnetic field integral equation (HFIE). All of them are similar in form to the EFIE and are solved in a similar manner. We use EFIE and CFIE formulations in our IE solver for standalone IE region applications. We don't use MFIE alone.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

However, CFIE is a linear combination of EFIE and MFIE. We use EFIE on open surfaces and small closed surfaces, and use CFIE on large closed surfaces.

S-Parameters

One of the most important features of HFSS is the capability to categorize an electromagnetic structure in a compact manner using the concept of S-parameters. S-parameters are available for projects that contain ports and this document focuses on the case when the S-parameters are related to the eigen modes of the ports. The use of S-parameters for terminals are described in Modes to Terminals Conversion.

At each port, the modal representations of the electric and magnetic fields assuming *K* modes are:

$$\mathbf{E} = \sum_{m=1}^{K} (a_m + b_m)\mathbf{e}_m \quad (1)$$

$$\mathbf{H} = \sum_{m=1}^{K} (a_m - b_m)\mathbf{h}_m \quad (2)$$

where a_m and b_m are unitless complex amplitudes of the incident and reflected modal fields, respectively. Given a particular electromagnetic structure, it can be categorized in terms of the incident and reflected/transmitted modal amplitudes using the *NxN* generalized S-matrix, *S*:

$$\mathbf{b} = S\mathbf{a} \quad (3)$$

where **a** and **b** are unitless complex modal coefficient vectors. The size of these vectors, *N*, is the total number of modes obtained by adding up the number of the modes on all ports.

An entry of the S-matrix, S_{ij}, specifies the multiplication factor to be applied to the incident modal amplitude a_j to get the reflected/transmitted modal amplitude b_i given that all the other incident modes are turned off. This can be described mathematically as:

$$S_{ij} = \left.\frac{b_i}{a_j}\right|_{a_k = 0,\ k \neq j} \quad (4)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

HFSS automatically provides an S-matrix when a project contains ports. The following links contain information on various topics related to S-matrices.

- Post Processed S-Matrices
- Passivity
- Alternative Matrix Characterizations

Post Processed S-Matrices

HFSS automatically computes the generalized S-matrix during the solve time when a project contains ports. The S-matrix can be modified after solution time by applying post processing transformations. The following post processing transformations are supported by HFSS:

- Renormalized S-Matrices in HFSS
- De-embedded S-Matrices in HFSS

Renormalized S-Matrices in HFSS

Before a structure's generalized S-matrix can be used in a high frequency circuit simulator to compute the reflection and transmission of signals, it must be normalized to the appropriate impedance. For example, if a generalized S-matrix has been normalized to 50 ohms, it can be used to compute reflection and transmission directly from signals that are normalized to 50 ohms.

To renormalize a generalized S-matrix to a specific impedance, HFSS first calculates a unique impedance matrix Z, associated with the structure defined as follows:

$$Z = \sqrt{Z_0}\,(I - S)^{-1}\left(I + S\right)\sqrt{Z_0} \qquad (1)$$

where

- S is the n x n generalized S-matrix.
- I is an n x n identity matrix.
- Z0is a diagonal matrix having the characteristic impedance (*Z0*) of each port as a diagonal value.

The renormalized S-matrix is then calculated from the unique impedance matrix using this relationship:

$$S_\Omega = \sqrt{Y_\Omega}\left(Z - Z_\Omega\right)(Z + Z_\Omega)^{-1}\sqrt{Z_\Omega} \qquad (2)$$

where

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Z is the structure's unique impedance matrix.
- $Z\Omega$ and $Y\Omega$ are diagonal matrices with the desired impedance and admittance as diagonal values. For example, if the matrix is being renormalized to 50 ohms, then $Z\Omega$ would have diagonal values of 50.

Visualize the generalized S-matrix as an S-matrix that has been renormalized to the characteristic impedances of the structure. Therefore, if a diagonal matrix containing the characteristic impedances of the structure is used as $Z\Omega$ in the above equation, the result would be the generalized S-matrix again.

HFSS needs to calculate the characteristic impedance of each port in order to compute a renormalized S-matrix.

The S-matrices initially calculated by HFSS are generalized S-matrices that have been normalized to the impedances of each port; however, you can compute S-matrices that are normalized to specific impedances, such as 50 ohms.

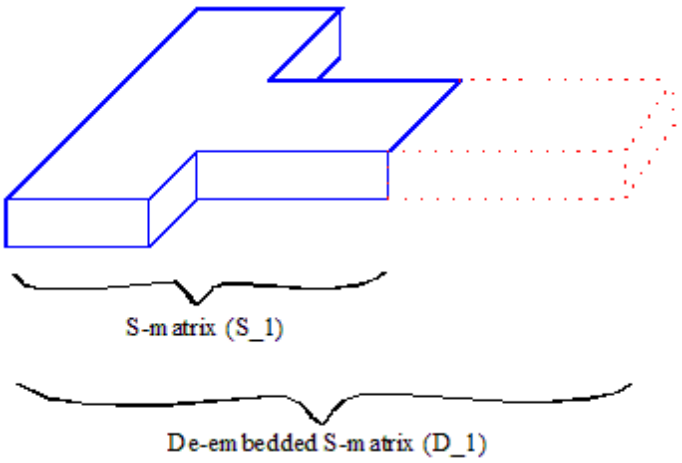
To convert a generalized modal S-matrix to a renormalized modal S-matrix, HFSS first needs to compute the characteristic impedance at each port. There are several ways to compute characteristic impedance. Two methods — the Zpv and Zvi methods — require an impedance, or *integration*, line.

HFSS will always calculate Zpi impedance, the impedance calculation using power and current, which are well-defined for a port because they are computed over the area of the port. Zpv and Zvi are not calculated by default. This is because v is computed by integrating along a user-defined integration line. If Zpi is very small (less than 10^-14) HFSS uses Zpv (if it is non-zero). In this case, a warning says that the design has too few conductors touching the lumped port. To renormalize the solution to a Zpv or Zvi characteristic impedance, you must define an integration line.

De-embedded S-Matrices in HFSS

De-embedding allows you to shift the reference plane of the S-matrix for any port by adding (or subtracting) a length of lossless transmission line to (or from) a port. The figure shown below illustrates such a case.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The S-matrix, S_1, describes the behavior of the structure that was modeled.

The de-embedded S-matrix, D_1, describes the behavior of a structure created by subtracting or adding a length of lossless transmission line to the structure that was modeled. It is computed by phase rotating the S-matrix inward toward or outward away from the structure by the specified length at each port.

To shift the reference plane of the structure, the S-matrix of the modified structure can be calculated using the following relationship:

$$[S'] = [e^{\gamma l}][S][e^{\gamma l}]$$

- where:

  $[e^{\gamma l}]$ is a diagonal matrix with the following entries:

$$\begin{bmatrix} e^{\gamma_1 l_1} & 0 & 0 \\ 0 & e^{\gamma_2 l_2} & 0 \\ 0 & 0 & e^{\gamma_3 l_3} \end{bmatrix}$$

- $\gamma = \alpha + j\beta$ is the complex propagation constant, where α is the attenuation constant of the current and β is the phase constant associated with the uniform transmission line at port i.
- l_i is the length of the reference plane shift. A positive value indicates a shift toward the structure by a length l.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Alternative Matrix Characterizations

- Calculating the Z-Matrix
- Calculating the Y-Matrix

Calculating the Z-Matrix

The impedance matrix, *Z*, is calculated from the S-matrix as follows:

$$Z = \sqrt{Z_0}(I-S)^{-1}(I+S)\sqrt{Z_0} \quad (1)$$

where

- *S* is the *n x n* generalized S-matrix.
- *I* is an *n x n* identity matrix.
- Z_0 is a diagonal matrix having the characteristic impedance (Z_0) of each port as a diagonal value.

Under the **Matrix Data** tab of the **Display Items Dialog**, the Z-matrix can be displayed as magnitude/ phase, real/ imaginary, magnitude, phase, real, or imaginary.

Calculating the Y-Matrix

The admittance matrix, *Y*, is simply the inverse of the impedance matrix, *Z*.

Under the **Matrix Data** tab of the **Solution Data** dialog box, the Y-matrix can be displayed as magnitude/ phase, real/ imaginary, magnitude, phase, real, or imaginary.

Passivity

Passive devices can only dissipate or temporarily store energy, but never generate it. The mathematical definition of passivity is based upon the following condition:

Q = I - conjugate(transpose(S)) * S must be a positive semidefinite matrix.

where:

- S is the S-parameter matrix
- I is an identity matrix.

A positive semidefinite matrix has only non-negative eigenvalues. The passivity test computes the eigenvalues of the matrix Q above at each frequency in the sweep. If any of the eigenvalues is negative, and larger (in magnitude) than the specified passivity tolerance, then a violation of passivity is reported to the user. The default value for passivity tolerance is .0001 tolerance above 1.0 magnitude.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Radiated Fields

When HFSS calculates radiation fields, the values of the fields over the radiation surface are used to compute the fields in the space surrounding the device. This space is typically split into two regions — the near-field region and the far-field region. The near-field region is the region closest to the source. In general, the electric field **E**(x,y,z) external to the region bounded by a closed surface may be written as

$$\boldsymbol{E}(x,y,z) = \int_s (\langle j\omega\mu_0 \boldsymbol{H}_{tan}\rangle G + \langle \boldsymbol{E}_{tan} \times \nabla G\rangle + \langle \boldsymbol{E}_{normal} \nabla G\rangle) ds \quad (1)$$

where

- *s* represents the radiation boundary surfaces.
- *j* is the imaginary unit, $\sqrt{-1}$.
- ω is the angular frequency, $2\pi f$.
- μ_0 is the relative permeability of the free space, $4\pi\times10^{-7}$ Wb/Am.
- $\boldsymbol{H}_{tan}$ is the component of the magnetic field that is tangential to the surface.
- $\boldsymbol{E}_{normal}$ is the component of the electric field that is normal to the surface.
- $\boldsymbol{E}_{tan}$ is the component of the electric field that is tangential to the surface.
- *G* is the free space Green's function, given by

$$G = \frac{e^{-jk_0|\boldsymbol{r}-\boldsymbol{r}'|\sqrt{\mu_r\varepsilon_r}}}{|\boldsymbol{r}-\boldsymbol{r}'|} \quad (2)$$

where

- k_0 is the free space wave number,
  $k_o = \omega\sqrt{\mu_o\varepsilon_o} = \omega/c$
- $\boldsymbol{r}$ and $\boldsymbol{r}'$ represent field points and source points on the surface, respectively.
- ε_0 is the permittivity of free space, $1/(c^2\mu_0)$
- ε_r is the relative permittivity of a dielectric.
- μ_r is the relative permeability of a dielectric.

This *r* dependence is characteristic of a spherical wave, a key feature of far fields. The far field is a spherical TEM wave with the following equation:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\boldsymbol{E} = \eta_o \sqrt{\frac{\mu_r}{\varepsilon_r}} \boldsymbol{H} \times \hat{\boldsymbol{r}} \quad (3)$$

where η_0 is the intrinsic impedance of free space, $\eta_o = \sqrt{\frac{\mu_o}{\varepsilon_o}}$.

You can select the material in which the objects are embedded (the default is vacuum). In that case, the Green's function and the intrinsic impedance of that material will be used, so the far field will be correct. See Global Material Environment.

When calculating the near fields, HFSS uses the general expressions given in (**eq. 1**). You must specify the radial coordinate *r*. Because it can be used to compute fields at an arbitrary radius from the radiating structure, this command can be useful in EMC applications.

> **Note:**
>
> If HFSS calculates the near fields in a problem containing an incident wave, the radius at which the fields are calculated is very important. If the radius is within the solution region, then the fields calculated are either the total fields or the scattered fields depending upon which is selected. If the radius is outside the solution region, then the fields calculated are only the scattered fields.

When calculating the far fields, the previously discussed far-field approximations are used, and the result is valid only for field points in the far-field region.

> **Warning:**
>
> A radiation or PML boundary or Floquet port must have been defined in the design for HFSS to calculate radiated fields.

Spherical Cross-Sections

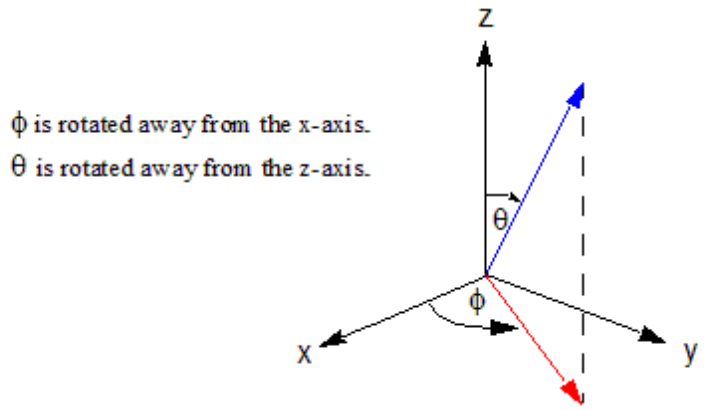
When you set up a spherical surface over which to analyze near or far fields, you specify a range and step size for phi and theta, or for far fields, also Azimuth over Elevation. These indicate the spherical direction in which you want to evaluate the radiated fields. For every value of phi there is a corresponding range of values for theta, and vice versa. This creates a spherical grid. Each grid point indicates a unique direction along a line that extends from the center of the sphere through the grid point. The radiated field is evaluated in this direction. The number of grid points is determined by the step size for phi and theta.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The sphere can be defined according to any defined coordinate system and before or after a solution has been generated.

> **Note:**
>
> For parts of the sphere outside of the model region, near-field approximation is calculated. However, if parts of the sphere are inside the model region, the model fields are used to compute interpolated values. A section of the sphere is considered to overlap the model if it lies in the enlarged model region after accounting for symmetry planes.

The relationship between phi and theta is shown below.



Antenna pattern measurements are calculated in a spherical coordinate system using the following basis vectors:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\hat{r} = \begin{bmatrix} \cos(\emptyset)\sin(\theta) \\ \sin(\emptyset)\sin(\theta) \\ \cos(\theta) \end{bmatrix}$$

$$\hat{\theta} = \begin{bmatrix} \cos(\emptyset)\sin(\theta) \\ \sin(\emptyset)\sin(\theta) \\ -\sin(\theta) \end{bmatrix}$$

$$\hat{\emptyset} = \begin{bmatrix} -\sin(\emptyset) \\ cos(\theta)] \\ 0 \end{bmatrix}$$

When HFSS evaluates the radiated fields, it needs at least two directions along which to plot the fields. Therefore, if the step size for phi is zero, then the step size for theta must be greater than zero, and vice versa. This ensures that the fields are plotted in at least two directions.

When setting up the sphere, phi and theta angles must be specified between -360 degrees (**deg**) and 360 degrees (**deg**), or the equivalents in radians (**rad**). If **deg** nor **rad** is specified, HFSS assumes the value to be in degrees.

Following are additional guidelines for specifying **Phi** in the **Near Field Radiation Sphere Setup** window or the **Far Field Radiation Sphere Setup** window:

Start	The point where the rotation of phi begins. The **Start** value must be equal to or greater than one.
Stop	The point where the rotation of phi ends. The **Stop** value must be greater than the **Start** value and less than 360. If the **Stop** value is equal to the **Start** value, then HFSS assumes that only one angle should be used and the **Step Size** value will be ignored.
Step Size	The number of degrees or radians (spherical grid points) between the sweep of phi. For example, to divide a sweep from 0° to 180° into 10° increments, you would enter **10**. Entering zero for the **Step Size** causes the sweep to consist of one point, the start value. If the **Step Size** value is zero, then HFSS assumes that only one angle should be used.

Following are additional guidelines for specifying **Theta**:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Start	The point where the rotation of theta begins. The **Start** value must be greater than -90 degrees, or the equivalent in radians.
Stop	The point where the rotation of theta ends. In classic definition the **Stop** value must be greater than the **Start** value and less than or equal to 180 degrees, or the equivalent in radians. In HFSS, you can input 360 degrees. If the **Stop** value is equal to the **Start** value, HFSS assumes that only one angle should be used and the **Step Size** value will be ignored.
Step Size	The number of degrees or radians (spherical grid points) between the sweep of theta. For example, to divide a sweep from -60 degrees to 60 degrees into 10-degree increments, you would enter **10deg**. Entering zero for the number of steps causes the sweep to consist of one point, the **Start** value. If the **Step Size** value is zero, then HFSS assumes that only one angle should be used.

For a discussion of using Azimuth and Elevation, see Setting up a Far Field Infinite Sphere.

Maximum Near-Field Data

The parameters listed in the **Max Field Data** window remain the same regardless of the geometry over which they were calculated. However, the coordinates displayed change depending on the geometry.

On a sphere, the coordinates — phi and theta — of the maximum value are listed under **Phi** and **Theta**. The values are given in volts per meter. Along a line, the coordinates — x, y, and z — of the maximum values are listed under **X**, **Y**, and **Z**. The values are given in volts per meter, and the coordinates are given in meters.

The following parameters are listed:

Total	The maximum of the total E-field.
X	The maximum E-field in the x-direction.
Y	The maximum E-field in the y-direction.
Z	The maximum E-field in the z-direction.
Phi	The maximum E-field in the ϕ-direction.
Theta	The maximum E-field in the θ-direction.
LHCP	The maximum left-hand circularly polarized component, which is equal to $\left\lvert\frac{1}{\sqrt{2}}(E_\theta - jE_\phi)\right\rvert$.
RHCP	The maximum right-hand circularly polarized component, which is equal to

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	$\left\|\frac{1}{\sqrt{2}}(E_\theta + jE_\phi)\right\|$.
Ludwig 3/X dominant	The maximum of the dominant component, *Vmain*, for an x-polarized aperture using Ludwig's third definition of cross polarization. This is equal to $\|E_\theta cos\phi - E_\phi sin\phi\|$.
Ludwig 3/Y dominant	The maximum of the dominant component, *Vmain*, for a y-polarized aperture using Ludwig's third definition of cross polarization. This is equal to $\|E_\theta sin\phi + E_\phi cos\phi\|$.

Maximum Far-Field Data

When HFSS calculates antenna parameters, the following maximum field data is calculated:

Total	The maximum of the total rE-field.
X	The maximum rE-field in the x-direction.
Y	The maximum rE-field in the y-direction.
Z	The maximum rE-field in the z-direction.
Phi	If you specified Phi-Theta coordinate system in the Far Field Sphere, the maximum rE-field in the ϕ-direction.
Theta	If specified Phi-Theta coordinate system in the Far Field Sphere, the maximum rE-field in the θ-direction.
Azimuth	If you specified Azimuth over Elevation or Elevation over Azimuth in the Far Field Sphere, the maximum rE for Azimuth.
Elevation	If you specified Azimuth over Elevation or Elevation over Azimuth in the Far Field Sphere, the maximum rE for Elevation.
LHCP	The maximum left-hand circularly polarized component, which is equal to $\left\|\frac{1}{\sqrt{2}}(E_\theta - jE_\phi)\right\|$.
RHCP	The maximum right-hand circularly polarized component, which is equal to $\left\|\frac{1}{\sqrt{2}}(E_\theta + jE_\phi)\right\|$.
Ludwig 3/X dominant	The maximum of the dominant component, *Vmain*, for an x-polarized aperture using Ludwig's third definition of cross polarization. This is equal to $\|E_\theta cos\phi - E_\phi sin\phi\|$.
Ludwig 3/Y dominant	The maximum of the dominant component, *Vmain*, for a y-polarized aperture using Ludwig's third definition of cross polarization. This is equal to $\|E_\theta sin\phi + E_\phi cos\phi\|$.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When calculating the maximum far field values, the distance *r* is factored out of the E-field. Therefore, the units for the maximum field data values are given in volts.

Array Factor Calculation

HFSS enables you to compute antenna array radiation patterns and antenna parameters for designs that have analyzed a single array element. You can define array geometry and excitation. HFSS models the array radiation pattern by applying an "array factor" to the single element's pattern.

Two array geometry types are supported. The "regular uniform array" geometry defines a finite 2D array of uniformly spaced, equal-amplitude elements. This is a natural specification after analyzing a single-unit cell of an infinite array. The regular array type may be scanned to a user-specified direction. Scan direction can be specified in terms of spherical coordinate angles in the radiation coordinate system. The regular array geometry type also allows scan specification in terms of differential phase shifts between elements.

The "custom array" geometry allows for greater flexibility. It defines an arbitrary array of identical elements distributed in 3D space with individual user-specified complex weights.

Cautionary Note for Array Factor Use

The field factorization (eq. 1) and consequent use of an array factor are useful tools for analyzing the radiated fields of antenna arrays; however, the analysis can yield incorrect results if used improperly. An HFSS single array element solution does not generally take into account the effects of the element's hypothetical neighbors.

For closely spaced array elements, these proximity effects (mutual coupling) may be significant. Consequently the patterns of the array elements vary with their position in the array and may depart significantly from the isolated element pattern. In such cases, the primary assumption in the use of the array factor is violated and the results will be inaccurate.

Note in particular that the array power expressions (eq. 13) and (eq. 14) neglect mutual coupling between elements of the finite array. Unless mutual coupling effects are negligible or have been implicitly included in the single element solution, the normalizations (eq. 13) and (eq. 14) gain and directivity are incorrect.

Theory of the Array Factor Calculation

The composite far-field pattern, $\boldsymbol{E}_{array}(\phi, \theta)$ from an array of *N* identical radiating sources, each with far-field pattern $\boldsymbol{E}_{element}(\phi, \theta)$, may be factored into the form

$$\boldsymbol{E}_{array}(\phi,\theta) = AF(\phi,\theta)\boldsymbol{E}_{element}(\phi,\theta) \quad (1)$$

where the "array factor" AF (ϕ, θ) is defined as

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$AF(\phi,\theta) = \sum_{n=1}^{N} W_n e^{jk\mathbf{r}_n \cdot \hat{\mathbf{r}}} \quad (2)$$

and where

- (ϕ, θ) are the field-point spherical angles.
- W_n is the complex weight assigned to element *n*.
- *j* is $\sqrt{-1}$.
- *k* is $2\pi/\lambda$., whereλ is the wave length in the global material environment.
- $\mathbf{r}_n$ is the position vector of element *n*, <*xn*, *yn*, *zn*>.
- $\hat{\mathbf{r}}$ is the pattern angle unit vector, <sinθcosϕ, sinθsinϕ, cosθ>.

The complex weights W_n in (eq. 2) may be written in terms of a (real) voltage amplitude A_n and (real) phase Ψ_n as:

$$W_n = A_n e^{j\Psi n} \quad (3)$$

To scan a regular array in the direction (ϕ_0, θ_0), the element phases Ψ_n are set to

$$\Psi_n = -k\mathbf{r}_n \cdot \hat{\mathbf{r}}_o \quad (4)$$

where

$$\hat{\mathbf{r}}_0 = <\sin\theta_0\cos\phi_0,\ \sin\theta_0\sin\phi_0,\ \cos\theta_0> \quad (5)$$

is the scan-angle unit vector.

Regular Uniform Arrays

Let us define a uniform array as an array with unity amplitude weights for all elements ($A_n = 1$ for all *n*). For the case in which a uniform array is scanned to direction $\hat{\mathbf{r}}_0$, the array factor (eq. 2) becomes

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$AF(\phi, \theta) = \sum_{n=1}^{N} e^{jk\mathbf{r}_n \cdot (\hat{\mathbf{r}} - \hat{\mathbf{r}}_0)} \quad (6)$$

For a "regular" uniform array with element spacing defined by lattice vectors ***u*** and ***v***, the element position vectors $\mathbf{r}_n$ may be written in the doubly indexed form

$$\mathbf{r}_{mn} = (m-1)\mathbf{u} + (n-1)\mathbf{v} \quad (7)$$

with *m* = 1, 2, ..., *Nu* and *n* = 1, 2, ..., *Nv*. The total number of elements in the array is given by *N* = *NuNv*.

The array factor (eq. 6) for the *Nu*x*Nv* array becomes

$$AF(\phi, \theta) = \sum_{m=1}^{N_u} \sum_{n=1}^{N_v} e^{jk\mathbf{r}_{mn} \cdot (\hat{\mathbf{r}} - \hat{\mathbf{r}}_0)} \quad (8)$$

Scan Specification for Regular Uniform Arrays

$\hat{\mathbf{r}}_0$

To develop this alternate scanning phase description, (eq. 7) is used to rewrite the expression (eq. 4) in doubly indexed form as follows:

$$\Psi_{mn} = -k\mathbf{r}_{mn} \cdot \hat{\mathbf{r}}_0 = -k(m-1)\mathbf{u} \cdot \hat{\mathbf{r}}_0 - k(n-1)\mathbf{v} \cdot \hat{\mathbf{r}}_0 \quad (9)$$

(Let us define ψ_u as the differential phase between adjacent elements in the **u** direction. Similarly, let us define ψ_v as the differential phase between adjacent elements in the **v** direction. Then

$$\Psi_u \equiv \Psi_{m+1,n} - \Psi_{m,n} = -k\mathbf{u} \cdot \hat{\mathbf{r}}_0 \quad (10)$$

and

$$\Psi_v \equiv \Psi_{m,n+1} - \Psi_{m,n} = -k\mathbf{v} \cdot \hat{\mathbf{r}}_0 \quad (11)$$

The scanning phase (eq. 4) may now be rewritten in terms of ψ_u and ψ_v as

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\psi_{mn} = (m-1)\psi_u + (n-1)\psi_v \quad (12)$$

Thus in the case of a regular uniform array, the angle pair (ψ_u, ψ_V) may act as a substitute scan definition for the more general (ϕ_0, θ_0).

Custom Arrays

Once you have imported the array factor information from a text file, HFSS uses (eq. 8) to compute the array factor. When a custom array is defined, no scan direction is set and the array factor phase weights are those specified on an element-by-element basis in the geometry file.

The text file must have the following format. Coordinate values are assumed to be model units, and phase and amplitude are in SI units (radians and volts respectively):

```
N
x_1 y_1 z_1 A_1 P_1
x_2 y_2 z_2 A_2 P_2
...
 ...
 x_N y_N z_N A_N P_N
```

where

- x_1 is the x-coordinate position of the first element.
- y_1 is the y-coordinate position of the first element.
- z_1 is the y-coordinate position of the first element.
- A_1 is the amplitude weight of the first element. Amplitude references voltage.
- P_1 is the phase weight for the first element. Phase references radians.

Following is an example of a square 3 x 3 custom array geometry defined in a text file. The array elements are uniformly weighted and separated from one another in the x- and y-directions by 0.6729 user units.

```
! first line is a count of cells
9

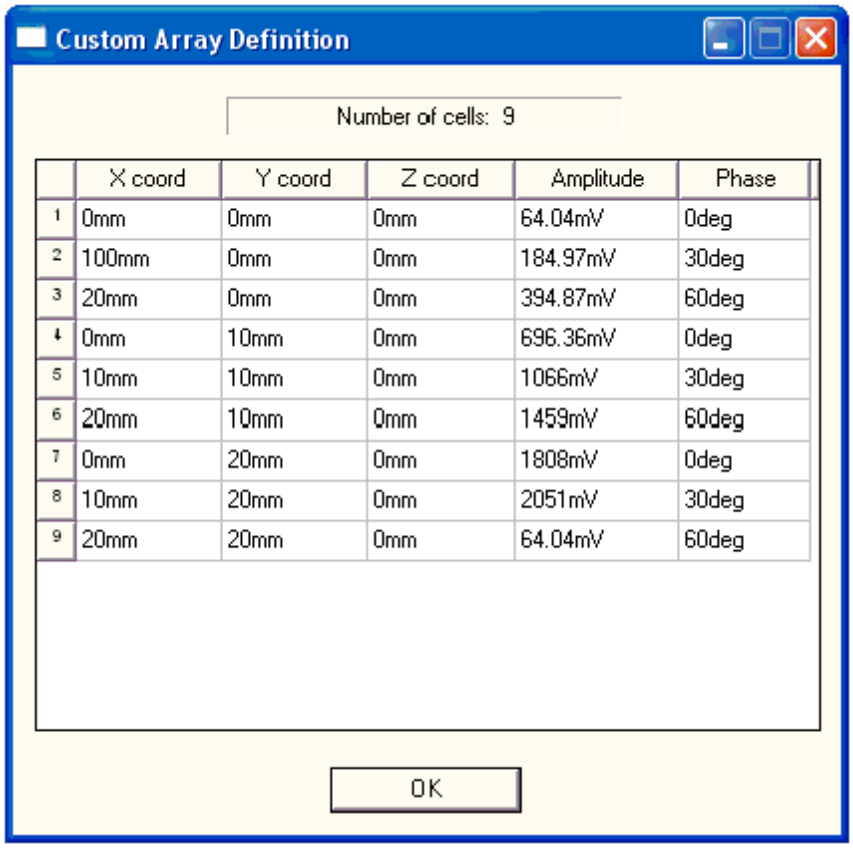
! then [x,y,z] position of each cell
! and amplitude and phase
! default units for position are model units
! default units for amplitude is Volts
! default units for phase is radians

0 0 0 64.04mV 0
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
10cm 0 0 184.97mv 30deg
20 0 0 394.87mv 60deg
0 10 0 696.36mv 0
10 10 0 1.066 30deg
20 10 0 1.459 60deg
0 20 0 1.808 0
10 20 0 2.051 30deg
20 20 0 64.04mv 60deg
```

The information will appear as follows in the **Custom Array Definition** window:



Power Normalizations

When the array factor feature is in use, the power normalization used to compute realized gain, gain, and directivity are modified as follows.

Let $P^{inc}_{element}$, $P^{acc}_{element}$, and $P^{rad}_{element}$ denote the incident, accepted, and radiated power of the single array element. When the array factor feature is invoked for an array of N elements, the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

array incident power, array accepted power, and the array radiated power will be computed simply as the sums of the corresponding element powers. Symbolically

$$P_{array}^{inc} = N \bullet P_{element}^{inc} \quad (13)$$

$$P_{array}^{acc} = N \bullet P_{element}^{acc} \quad (14)$$

$$P_{array}^{rad} = N \bullet P_{element}^{rad} \quad (15)$$

Caution: The above power array formulas are applicable to uniform excitation of large planar arrays analyzed using a unit cell with linked boundaries. For array elements that have been analyzed in isolation, only the incident power formula is rigorous, and the accepted and radiated power normalizations are generally not accurate.

Antenna Parameters

Generally, when dealing with radiated fields, you are also interested in the antenna properties of the radiated bodies. You can right click on an Antenna Parameters Overlay to open a Properties dialog that lets you select a set of the available parameters.

HFSS 3D Layout can calculate the following antenna properties:

- Maximum intensity (Max U)
- Peak directivity
- Peak gain
- Peak realized gain
- Radiated power
- Accepted power
- Incident power
- System Gain (see Scaling Sources of HFSS)
- System Power (see Scaling Sources for HFSS)
- Radiation efficiency
- Total efficiency
- System efficiency
- Front to Back Ratio
- Decay Factor

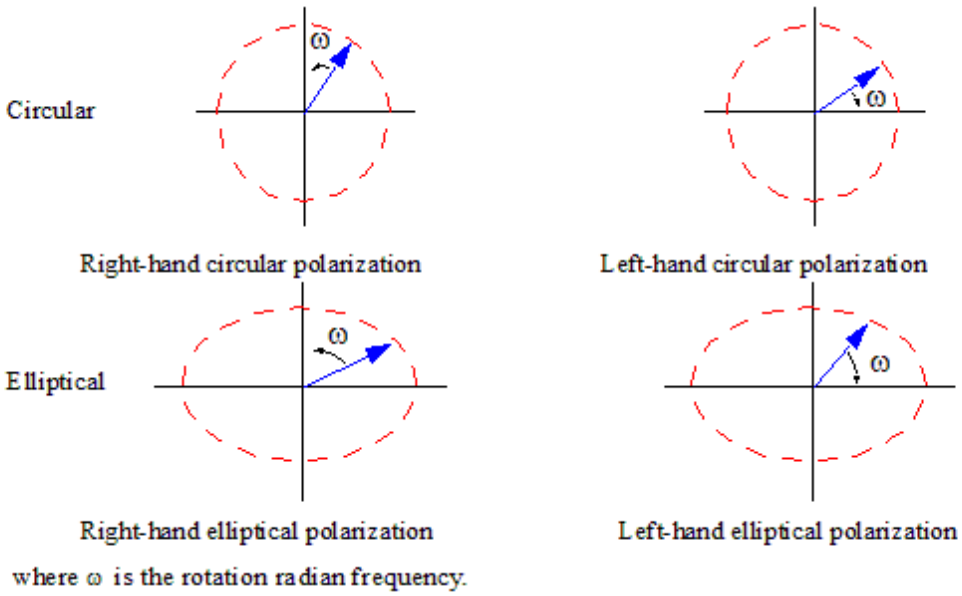
> **Warning:**
>
> A radiation or PML boundary must have been defined in the design for HFSS to calculate radiated fields.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Polarization of the Electric Field

At each aspect angle in the far field of a radiating source, the electric and magnetic field vectors lie in a fixed plane. Over time, the instantaneous electric field vector traces out a figure or shape in this plane. This figure defines the polarization state of the field.

In general, this figure is an ellipse and is called the *polarization ellipse*. The wave is said to be *elliptically polarized* when the instantaneous electric field traces out an ellipse. As a special case, the polarization ellipse may be a circle, in which case the wave is *circularly polarized*. Elliptical and circular polarization have two different states, *left* and *right*, distinguished by the sense of rotation of the electric field vector. Some of these figures, or states, are shown below. In each case the direction of propagation is off the screen.



A second special case occurs when the polarization ellipse degenerates to a straight line. In this case the wave is *linearly polarized*.

To completely describe the polarization state of a radiated field, two independent components are required. HFSS supports three types of descriptions:

- Spherical polar
- Ludwig-3
- Circular

Spherical Polar

$$E = (E_\theta, E_\phi)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The polarization ratio for a predominantly ϕ-polarized antenna is equal to

$$\left|\frac{E_\phi}{E_\theta}\right| \quad (1)$$

The polarization ratio for a predominantly θ-polarized antenna is equal to

$$\left|\frac{E_\theta}{E_\phi}\right| \quad (2)$$

Ludwig-3 Polarization

Arthur C. Ludwig wrote a classic paper [Ref. 1]on the definition of cross polarization. In particular, his third definition is often used since it describes the field components that are typically measured on a far-field antenna test range. Using his definition, the radiated field may be written as $E = E_x, E_y$ where

$$E_x = E_\theta \cos\phi - E_\phi \sin\phi \quad (1)$$

$$E_y = E_\theta \sin\phi + E_\phi \cos\phi \quad (2)$$

and phi is the usual azimuthal angle in the reference spherical coordinate system.

[1] Arthur C. Ludwig, The Definition of Cross Polarization, IEEE Transactions on Antennas and Propagation, vol. AP-21 num. 1, pp. 116 -119, Jan. 1973.

Circular Polarization

For antennas designed to receive or transmit circularly polarized fields, a meaningful description is in terms of pure left and right circular states. In this description, the field may be written as $E = E_R, E_L$ where

$$E_R = \frac{1}{\sqrt{2}}(E_\theta + jE_\phi) \quad (1)$$

$$E_L = \frac{1}{\sqrt{2}}(E_\theta - jE_\phi) \quad (2)$$

Axial Ratio

Axial ratio is defined as the ratio of the major to the minor axis of the polarization ellipse.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. E_x and E_y are orthogonal complex-valued field components. If either is zero, HFSS treats the field as linearly polarized. However, if neither E_x and E_y is zero:
2. Compute circular components E_- and E_+ from:

   $E_- = E_x - jE_y$ (1)

   $E_+ = E_x + jE_y$ (2)

3. If $E_+ = 0$ or $E_- = 0$ HFSS understands the field as perfectly circular, the axial ratio is 1. Otherwise, for the elliptical polarization case, HFSS determines the tilt angle τ from:

   $\text{phase}(E_-/E_+) = 2\tau$ (3)

4. Rotate the original data to coincide with the axes of the polarization ellipse.

   $$E'_x = E_x \cos\tau - E_y \sin\tau \quad (4)$$

   $$E'_y = E_x \sin\tau + E_y \cos\tau \quad (5)$$

5. The Axial Ratio AR is given by:

   $$AR = \left|\frac{E'_y}{E'_x}\right| \quad (6)$$

   Because the above definition does not discriminate between major and minor ellipse axes, to enforce the convention that $AR \leq 1$, it is necessary to check this condition and if necessary invert the value obtained.

Polarization Ratio

The IEEE defines the (complex) polarization ratio as, "For a given field vector at a point in space, the (magnitude of the) ratio of the complex amplitudes of two specified orthogonally polarized field vectors into which the given field vector has been resolved." [Ref. 2] HFSS computes the following six polarization ratios at each selected aspect angle:

$$Circular/LHCP = \left|\frac{E_L}{E_R}\right| \quad (1)$$

$$Circular/RHCP = \left|\frac{E_R}{E_L}\right| \quad (2)$$

$$Spherical/Phi = \left|\frac{E_\phi}{E_\theta}\right| \quad (3)$$

$$Spherical/Theta = \left|\frac{E_\theta}{E_\phi}\right| \quad (4)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$Ludwig \qquad 3/X = \left|\frac{E_x}{E_y}\right| \quad (5)$$

$$Ludwig \qquad 3/Y = \left|\frac{E_y}{E_x}\right| \quad (6)$$

[2] IEEE Standard Definitions of Terms for Antennas, IEEE Transactions on Antennas and Propagation, vol. AP-31 num. 6, Nov. 1983.

Front to Back Ratio

Front-to-back-ratio is one value for the entire far field setup (and is an unambiguous single quantity for a given setup) and is maximum rETotal (equivalently directivity) as the front value, then the rETotal from the opposite direction and use the ratio of front to back values, without log.

Max U

The radiation intensity, *U*, is the power radiated from an antenna per unit solid angle. HFSS calculates the radiation intensity in the direction in which it has the maximum value. The maximum intensity of the radiation is measured in watts per steradian and is calculated by

$$U(\theta,\phi) = \frac{1}{2}\frac{|E|^2}{\eta_0}r^2 \quad (1)$$

where

- $U(\theta,\phi)$ is the radiation intensity in watts per steradian.
- $|E|$ is the magnitude of the E-field.
- η_0 is the intrinsic impedance of free space — 376.7 ohms.
- r is the distance from the antenna, in meters.

Peak Directivity

Directivity is defined as the ratio of an antenna's radiation intensity in a given direction to the radiation intensity averaged over all directions. Peak directivity, in turn, is the maximum directivity over all the user-specified directions of the far-field infinite sphere.

Directivity is a dimensionless quantity represented by
where

$$directivity = \frac{4\pi U}{P_{rad}} \quad (1)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- U is the radiation intensity in watts per steradian in the direction specified.
- P_{rad} is the radiated power in watts.

> **Note:**
>
> The peak directivity displayed in the **Antenna Parameters** window is the directivity in the direction of maximum radiation intensity, U_{max}.

- For a lossless antenna, the directivity will be equal to the gain. However, if the antenna has inherent losses, the directivity is related to the gain by the radiation efficiency of the antenna.

Peak Gain

Gain is four pi times the ratio of an antenna's radiation intensity in a given direction to the total power accepted by the antenna. Peak gain, in turn, is the maximum gain over all the user-specified directions of the far-field infinite sphere.

The following equation is used to calculate gain in HFSS:

$$gain = 4\pi\frac{U}{P_{acc}} \quad (1)$$

where

- U is the radiation intensity in watts per steradian in the direction specified.
- P_{acc} is the accepted power in watts entering the antenna.

Gain can be confused with directivity, since they are equivalent for lossless antennas. Gain is related to directivity by the radiation efficiency of the antenna. If the radiation efficiency is 100%, they are equal.

> **Note:**
>
> Because the gain is calculated from the input signal at the port, a port must be defined for this quantity to be displayed.

Peak Realized Gain

Realized gain is four pi times the ratio of an antenna's radiation intensity in a given direction to the total power incident upon the antenna port(s). Peak realized gain, in turn, is the maximum realized gain over all the user-specified directions of the far-field infinite sphere. Time-average power of the incident wave is referenced for realized gain. This quantity can be small for the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

case when the imaginary part of port impedance is much larger than real part. In fact, it can be significantly smaller than accepted power which means that realized gain can be larger than gain.

The following equation is used to calculate realized gain in HFSS:

$$\text{realized gain} = 4\pi\frac{U}{P_{incident}} \quad (1)$$

where

- U is the radiation intensity in watts per steradian in the direction specified.
- $P_{incident}$ is the incident power in watts.

> **Note:**
>
> Because the gain is calculated from the input signal at the port, a port must be defined for this quantity to be displayed.

Radiated Power

Radiated power is the amount of time-averaged power (in watts) exiting a radiating antenna structure through a radiation boundary.

For a general radiating structure in HFSS, radiated power is computed as

$$P_{rad} = \Re\int_s \boldsymbol{E} \times \boldsymbol{H}^* \cdot d\boldsymbol{s} \quad (1)$$

where

- P_{rad} is the radiated power in watts.
- $\Re$ is the real part of a complex number.
- s represents the radiation boundary surfaces.
- E is the electric field.
- H^* is the conjugate of **the magnetic field**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- *ds* is the local radiation-boundary unit normal directed out of the 3D model.

> **Note:**
>
> The accuracy of the computed radiated power depends on the accuracy of ***E*** and ***H***. In some cases it is possible that the computed radiated power may deviate slightly from the actual radiated power.

The accuracy of the computed radiated power depends on the accuracy of E and H on the absorbing boundary. In some cases it is possible that the computed radiated power may deviate slightly from the actual radiated power. To increase the accuracy of the radiated power, seed the mesh on the absorbing boundary.

As a default behavior for SBR+ design and SBR+ hybrid design, an additional SBR+ power loss is subtracted from the total radiated power. For each source *i*, the SBR+ power loss $L_i$over all other sources *j* is computed as

$$L_i = 0.5 \sum_j \Re(b_j P_i b_j^*), b_j = S_{ji} a_i$$

where

- $\Re$ is the real part of a complex number
- S_{ji} is the S parameter from SBR+. When source *i* and *j* come from the same component instance, S_{ji} includes only scatter component. Otherwise,S_{ji} includes both scatter and incident components.
- a_i is the scaling factors specified in Edit Source.
- b_j^* is the conjugate of b_j.
- P_i is port characteristic matrix

Accepted Power

The accepted power is the time-averaged power (in watts) entering a radiating antenna structure through one or more ports.

Fundamentally in HFSS, accepted power is computed as

$$P_{acc} = Re \int_A \boldsymbol{E} \times \boldsymbol{H}^* \cdot d\boldsymbol{S} \quad (1)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where

- P_{acc} is the accepted power in watts.
- *Re* is the real part of a complex number.
- *A* is the union of all port boundaries in the model, including Wave and Lumped Ports, but excluding Floquet ports.
- *E* is the electric field.
- H^* is the conjugate of the magnetic field.
- *dS* is the local port-boundary unit normal directed into the 3D HFSS model.

Example: Consider the simple case of a single port antenna with zero imaginary port impedance modeled in a modal project. Then the general expression for accepted power reduces to

$$P_{acc} = |a|^2(1 - |s_{11}|^2) \quad (2)$$

where

- $|a|$ is the complex modal excitation specified in the **Edit Sources** window.
- s_{11} is the single-entry generalized scattering matrix.

> **Note:**
>
> Because the accepted power is calculated from the input signal at the port, a port must be defined for this quantity to be displayed.

Thus when $|s_{11}|$ approaches 1 (total reflection), P_{acc} approaches zero. When $|s_{11}|$ approaches 0 (perfect match), $P_{acc} = |a|^2$, the total power carried by the incident mode.

In the multiport case the physical interpretation of accepted power can sometimes be confusing. By the fundamental definition, energy that leaves the antenna structure through a port reduces accepted power. This, in a multiport antenna, energy cross coupled from an excited port to a different port reduces accepted power. Therefore in such cases, even if an excited port is well-matched, P_{acc} may be small.

In the Edit Sources window of a terminal project, you specify total voltage V instead of model incident power. Using the underlying model S-matrix, HFSS converts the terminal excitation to total fields at the ports, and then applies the general definition.

Incident Power

Incident power for an antenna structure is defined as the time-averaged power incident on the port(s) of the antenna:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$P_{inc} = Re\int_A \boldsymbol{E_{inc}} \times \boldsymbol{H^*_{inc}} \cdot \boldsymbol{dS} \quad (1)$$

where

- P_{inc} is the incident power in watts.
- *Re* is the real part of a complex number.
- *A* is the union of all port boundaries in the model, including Wave and Lumped Ports, but excluding Floquet ports.
- $\boldsymbol{E}_{inc}$ is the incident electric field.
- $\boldsymbol{H}^*_{inc}$ is the conjugate of the incident magnetic field.
- ***dS*** is the local port-boundary unit normal directed into the 3D HFSS model.

In the Edit Sources window of a modal project, you specify the power as the magnitude of the Poynting vector along with the a phase specification for the complex modal excitation. The magnitude of the Poynting vector is computed from:

$$Q_{inc} = Mag\int_A \boldsymbol{E_{inc}} \times \boldsymbol{H_{inc}} \cdot \boldsymbol{dS} \quad (2)$$

For a lossless port the incident power is the same as what is specified in edit sources. However, for lossy ports this is not true and therefore the incident power can be different from what is specified in edit sources.

In the **Edit Sources** window of a terminal project, you specify total voltage V instead of the modal incident power. Using the underlying modal S-matrix, HFSS converts the terminal excitation to total fields at the ports, and then applies the general definition. As a result of this procedure, the incident power in a terminal project depends on both the user-specified stimulation as well as the model itself.

Radiation Efficiency

The radiation efficiency is the ratio of the radiated power to the accepted power given by

$$e = \frac{P_{rad}}{P_{acc}} \quad (1)$$

where

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- P_{rad} is the radiated power in watts.
- P_{acc} is the accepted power in watts.

> **Note:**
>
> Because the radiation efficiency is calculated from the accepted power, a port must be defined for radiation efficiency to be displayed.

Total Efficiency

The total efficiency is Radiated Power over Incident Power.

System Efficiency

The system efficiency is Radiated Power over System Power.

Decay Factor

When Global Environment Material is lossy, strictly speaking, the far field is zero, since the Green's function is:

$$|g| = \frac{1}{r} e^{-kr} = \frac{1}{r} e^{-(\alpha + j\beta)r} \quad (1)$$

where

$$k = j\omega\mu(\sigma + j\omega\varepsilon) = \alpha + j\beta \quad (2)$$

Against that fact, HFSS calculates the far field using the imaginary part of vector ***k***.

You can then modify the magnitude of the field pattern by using the real part (α) of the propagation constant, which is displayed as "Decay Factor).

Ansys Near Field Description File Format Specification

The purpose of the Ansys Near Field Description (AND) File is to facilitate the auto-generation of HFSS design for any Near Field Data the user may wish to use for an HFSS simulation. These Near Field Data files could be in a variety of different formats and files, so the AND Format was designed to be as flexible as possible to accommodate them.

Overview

- Recognized by the ".and" extension
- 'NearFieldHeader' Block - Provides format, field type, and geometry information.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- 'NearFieldData' Block - Links the user's near field data files to particular solve frequencies.

Blocks are defined with opening ($begin 'block_name') and closing ($end 'block_name') block tags that contain either key/value pairs, or function/argument calls described below.

```
$begin 'BlockName'
  key=value
  func(arg1, arg2)
$end 'BlockName'
```

NearFieldHeader Block

Every AND File requires a NearFieldHeader block shown below. This header is used to provide information to HFSS about the Near Field Data that may not be present in the Data Files themselves. Depending on the Near Field Data Format, some of this information may be redundant and merely used for verification purposes.

Key	Value Format	Description
type	*'format type*'	[Required] Format Type of the of the User's Near Field Data files.
fields	*'field type*'	[Optional] Field Type of the User's Near Field Data. Defaults to "EH" when not present.
geometry	*'primitive type*'	[Required] Primitive describing Near Field Source Geometry.
center	'10mm, 10mm, 10mm'	[Based on Geometry] Center of geometric primitive.
size	'10mm, 10mm, 10mm' '20mm, 20mm	[Based on Geometry] xSize, ySize, zSize of primitive. Only two dimensions (XY, YZ or XZ) required for Plane Geometry.
axis	'0, 0, 1'	[Based on Geometry] Primary axis of primitive.
normal	'0, 1, 0'	[Based on Geometry] Normal axis of primitive.
radius	'20mm'	[Based on Geometry] Radius
height	'20mm'	[Based on Geometry] Height
fsweep	'1GHz, 2GHz, … 5.6 GHz'	[Required] The frequency band of the analysis.
fcoords	*'fcoords type'*	[Optional] Coordinate System used to describe data points

Valid Dimension Units:

Standard SI and Imperial Length Units are supported in Geometry Dimensions including:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

'nm', 'mm', 'meter', 'cm', 'ft', 'in', 'mil', 'uin'

Standard SI Frequency Units are supported in 'fsweep' including:

'Hz, 'kHz, 'MHz, 'GHz, 'THz

Supported '*format type*':

- "nfd" - HFSS External Near Field Data File generated by exporting Fields.

Supported '*field type*':

- "EH" - Both E and H incident fields are provided. (Default)
- "E" - Only E Fields are provided.
- "H" - Only H Fields are provided.
- "JM" - Both J and M Tangential Currents are provided.
- "J" - Only J Current is provided.
- "M" - Only M Current is provided.

Supported '*primitive type*':

- ""sphere" - Spherical Geometry requiring center, radius.
- ""box" - Cube Geometry requiring center, size. Must be axis aligned.
- ""cylinder" - Cylinder Geometry requiring center, axis, radius, height. Must be axis aligned.
- ""plane" - Pseudo-Plane Geometry requiring center, normal, size. Must be axis aligned. Plane data is really treated as a Rectangle so a two dimensional size must be specified.

Supported '*fcoords type*':

- "cartesian" - Data Points are described using cartesian coordinates.
- "spherical" - Data Points are formatted using spherical coordinates.
- "cylindrical" - Data Points are formatted using cylindrical coordinates.

The Coordinate System Type is optional and will default to the corresponding system for that primitive type

("spherical" for Spheres, "cylindrical" for Cylinders, "cartesian" for Box/Plane).

Example NearFieldHeader Blocks

Box

```
$begin 'NearFieldHeader'
  type='nfd'
  fcoords='cartesian'
  fields='JM'
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
  geometry='box'
  center='0mm,0mm,0mm'
  size='20mm,20mm,20mm'
  fsweep='1GHz, 3GHz'
$end 'NearFieldHeader '
```

Sphere

```
$begin 'NearFieldHeader'
  type='nfd'
  fcoords='spherical'
  fields='EH'
  geometry='sphere'
  center='0mm,0mm,0mm'
  radius='150mm'
  fsweep='1GHz, 3GHz'
$end 'NearFieldHeader'
```

Plane

```
$begin 'NearFieldHeader'
  type='nfd'
  fields='E'
  geometry='plane'
  center='0mm,0mm,0mm'
  size='20mm,20mm'
  normal='0,1,0'
  fsweep='1GHz, 3GHz'
$end 'NearFieldHeader '
```

Cylinder

```
$begin 'NearFieldHeader'
  type='nfd'
  geometry='cylinder'
  center='0mm,0mm,0mm'
  axis='0,0,1'
  radius='20mm'
  height='258mm'
  fsweep='1GHz, 3GHz'
$end 'NearFieldHeader'
```

NearFieldData Block

The NearFieldData Block is used to specify which external data files to use for which frequencies. External Near Field Data can be spread across multiple files and multiple frequencies. This block provides a means of organizing these data files.

To bind a single Near Field Data file to a particular frequency, use:

```
FreqData("1GHz", "path/to/data.nfd")
```

To split Near Field Data files (one contains E Fields, one contains H Fields), use:

```
FreqData("1GHz", "path/to/efields.nfd", "path/to/hfields.nfd")
```

To bind a default Near Field Data file to all frequencies not explicitly defined, use:

```
FreqData("0", "path/to/data.nfd")
```

Example NearFieldData Blocks

```
$begin 'NearFieldData'
  FreqData("0", "exportfields.nfd")
$end 'NearFieldData'
$begin 'NearFieldData'
  FreqData("1GHz", "exportfields.nfd")
  FreqData("2GHz", "exportfields2.nfd")
  FreqData("3GHz", "exportfields3.nfd")
  FreqData("4GHz", "exportfields4.nfd")
  FreqData("5GHz", "exportfields5.nfd")
$end 'NearFieldData'

$begin 'NearFieldData'
  FreqData("0", "efields0.nfd", "hfields0.nfd")
  FreqData("2GHz", "efields1.nfd", "hfields1.nfd")
  FreqData("4GHz", "efields2.nfd", "hfields2.nfd")
$end 'NearFieldData'
```

Example .and Files

```
$begin 'NearFieldHeader'
  type='nfd'
  geometry='box'
  center='0mm,0mm,0mm'
  size='20mm,20mm,20mm'
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
  fsweep='1GHz, 3GHz'
  $end 'NearFieldHeader'
  $begin 'NearFieldData'
  FreqData("0", "exportfields.nfd")

Emission Test

The Emission Test in HFSS is intended for EMC analysis. EMC regulations specify the maximum radiated emissions as a function of frequency. The Emission Test in HFSS produces a plot that can be compared with these regulations. Assuming that the HFSS simulation contained a frequency sweep in which all the fields were saved (a fast frequency sweep is very suited for this), the Emission Test does the following:

1. It steps through the frequencies of your sweep;
2. At each frequency, it determines the maximum value of |E| on a sphere around the radiating device, regardless of direction;
3. It plots this $|E_{max}|$ as a function of frequency. Optionally, $|E_{max}|$ is scaled to account for the spectral density of a pseudo-random digital signal.

Geometry, S-parameters and antenna pattern

Let's start with a small model that solves quickly. Figure 1 shows an open-ended rectangular waveguide of which two side walls are perfect-H walls. Symmetry has been exploited twice, so we end up with a quarter of the geometry.

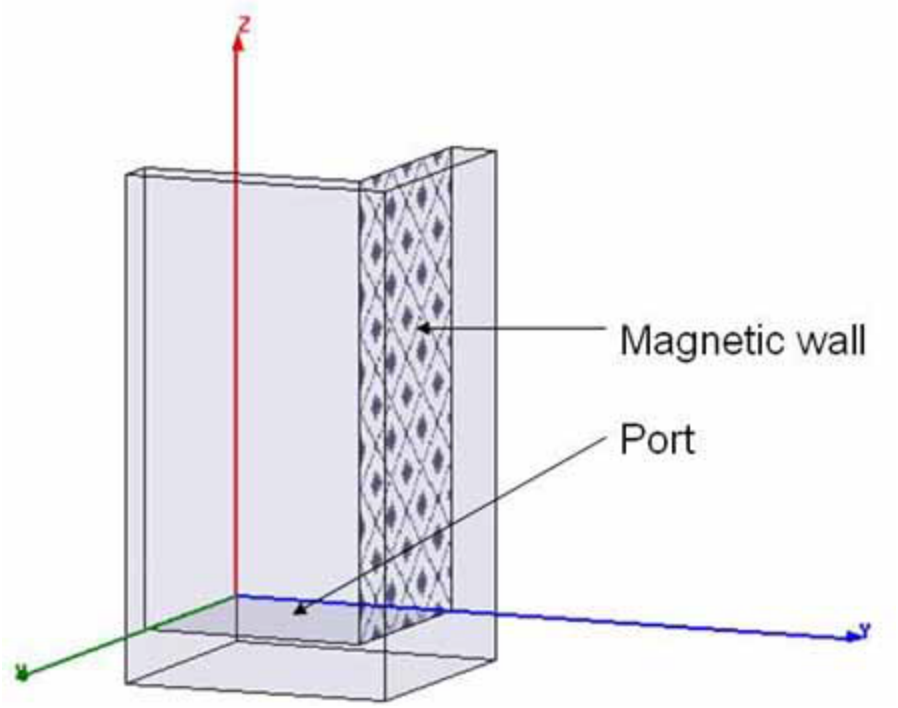

Fig. 1 The geometry: waveguide without cut-off

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Around the waveguide is a larger volume of air with a radiation boundary. The model has been solved from DC to 12 GHz. Figure 2 shows the S parameters.

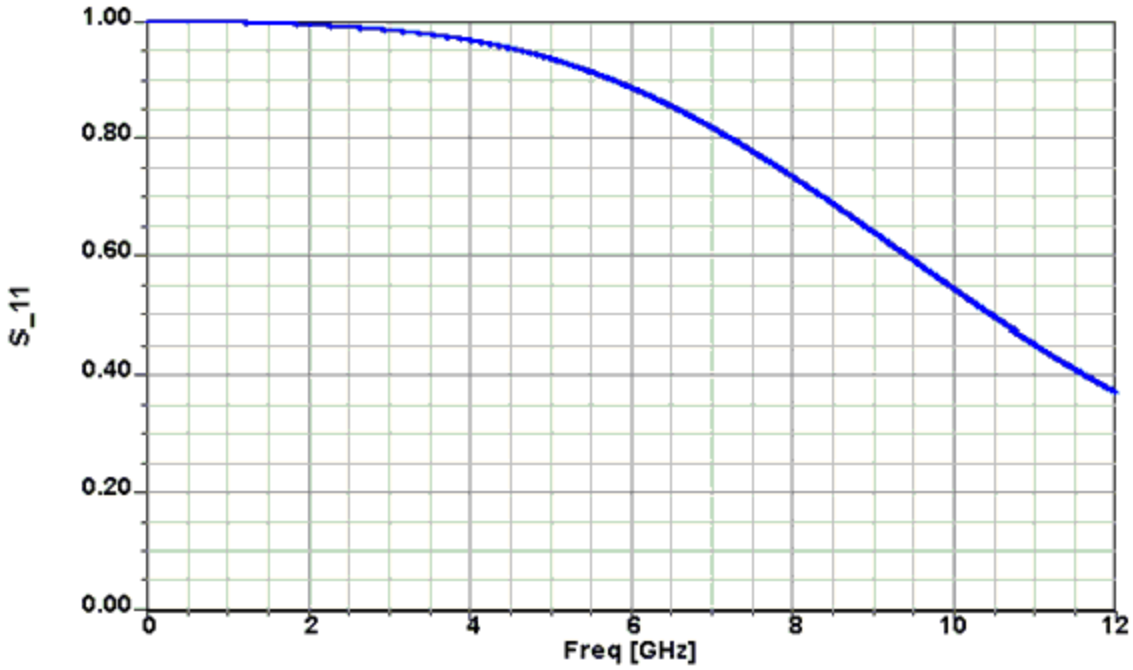

Fig. 2 S11 of the open-ended waveguide with two magnetic walls

Figure 3 shows a plot of the electric field at 12 GHz on a sphere with a radius of one meter. In this case, this is already way in the far field, so we are really dealing with radiated fields. Note that the electric field has a maximum of 28.8 V/m.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

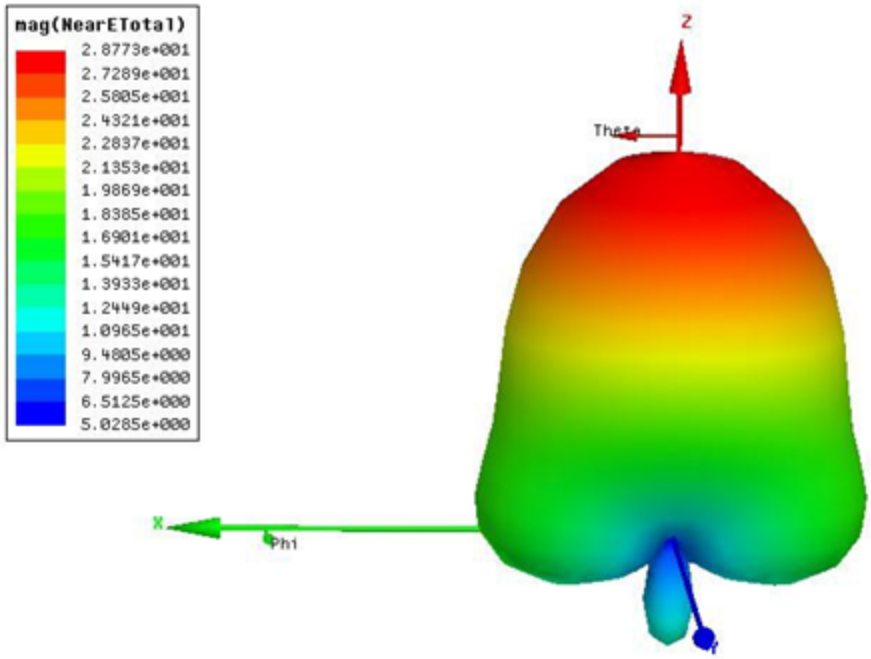

Fig. 3 Radiated electric field on a sphere with radius one meter

The average value in figure 3 is roughly 14 V/m. This corresponds to a power flux of $0.5|\underline{\mathbf{E}}\times\underline{\mathbf{H}}| = 0.5|E|^2/Z = 0.5\times196/377$ W/m^2 = 0.26 W/m^2. Over the sphere, area 4π m^2, this gives a power of 3.3 W. This value makes sense: the power into a quarter model is 1 W, so the total

power is 4 W, of which a small fraction is reflected back to the source.

Emission Test: Set Up and Results

To perform an Emission Test, right-click Results and select Create Report. For Report Type, select Emission Test (Fig. 4). It is not necessary to define a Radiation Near Field Setup in advance - the software will do this automatically for you.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

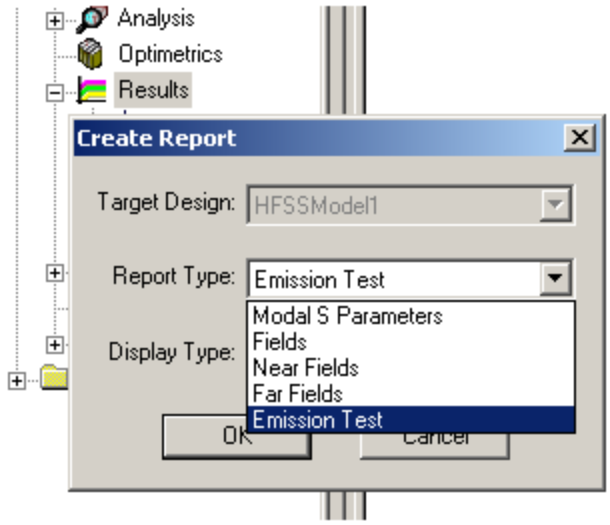

Fig. 4 Preparing an Emission Test

The simplest form of the Emission Test does not take the actual spectrum of your digital signal into account. This is the case for the first four spheres under Quantity (Fig. 5). For every frequency, the source excitation is the same power or voltage (depending on your model and your settings under Fields/Edit Sources), and the maximum |E| on the sphere is reported (Fig. 6).

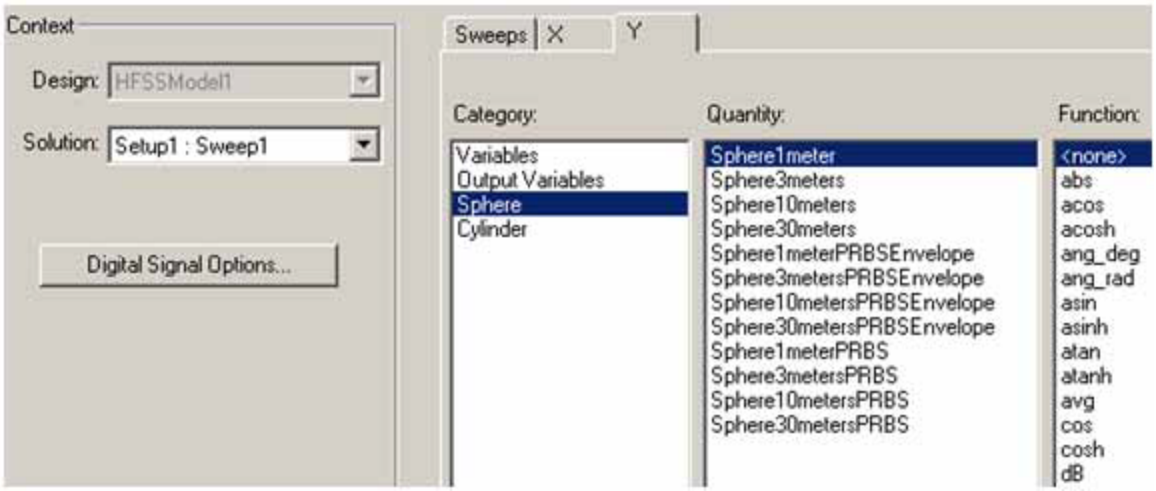

Fig. 5 Selecting an Emission Test at one meter distance from the origin, without scaling for the spectrum of the actual signal

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fig. 6 Result of the Emission Test of Fig. 5

In principle, the data in Fig. 6 can be compared with EMC regulations. However, in practical situations one wants to scale these data by taking the spectrum of the actual digital signal into account. To do this, specify your rise time and hold time under Digital Signal Options (Fig. 5) and select one of the spheres with PRBS in the name under Quantity (Fig. 5). PBRS stands for Pseudo-Random Binary Sequence.

In this example, we look at a digital signal with a rise time of 200 ps and a hold time of 800 ps (Fig. 7). We plot the maximum |E| on a one-meter sphere around the origin with two weighting functions: the exact one, which has many zeroes, and "envelope", which shows the envelope. Figure 8 shows the result.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

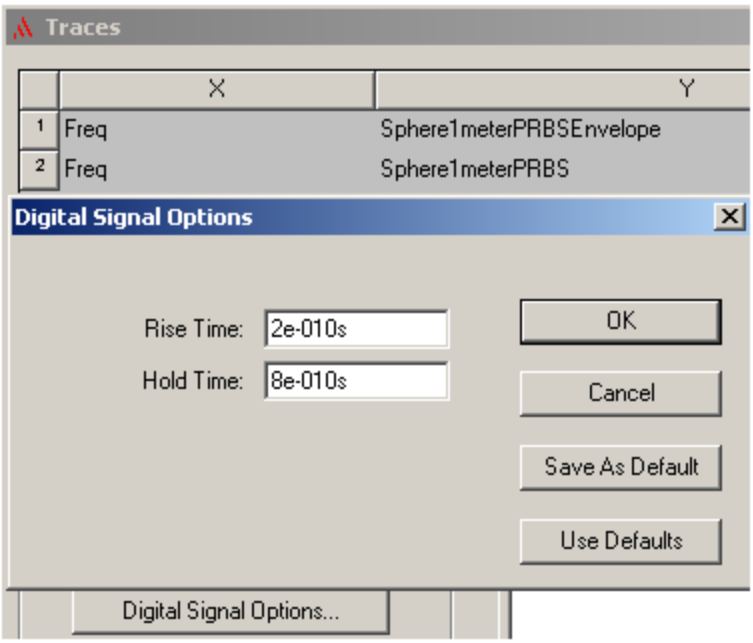

Fig. 7 Setting up an Emission Test with scaling for the spectrum of the digital signal

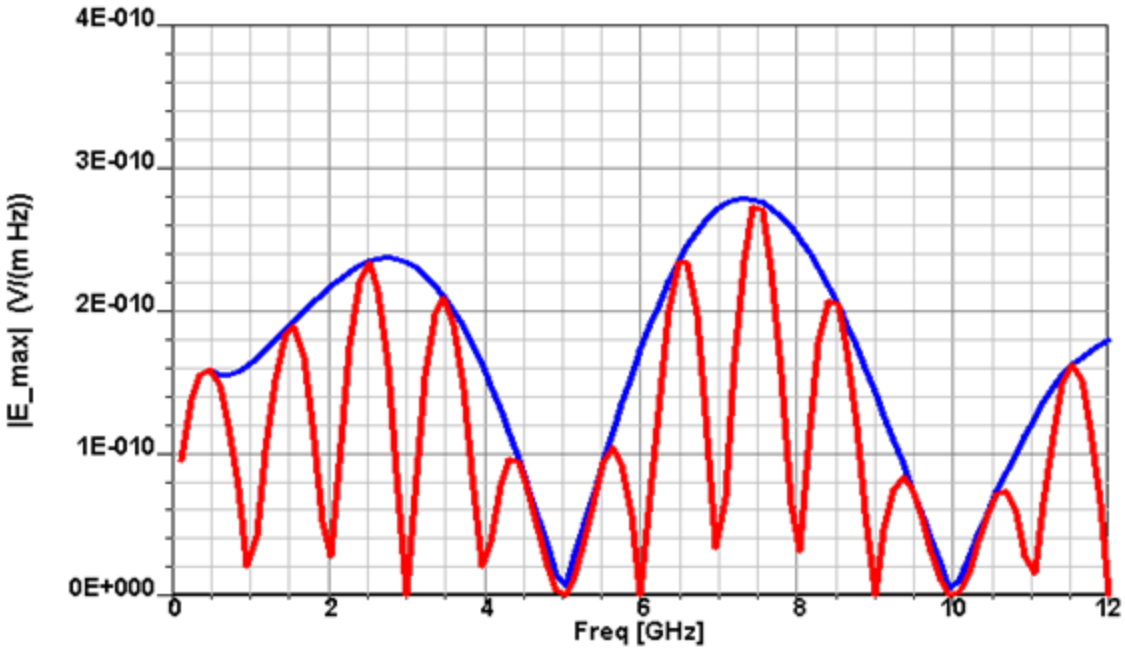

Fig. 8 Emission Test for a pseudo-random digital signal.
Red: exact scaling; blue: envelope scaling.

Scaling factor

The red line in figure 8 is the result of multiplying figure 6 by

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$2(T+T_r)\frac{\sin(\pi T_r f)\sin(\pi(T+T_r)f)}{(\pi T_r f)(\pi(T+T_r)f)} \quad (1)$$

where T is the hold time, T_r is the rise time, and *f* is the frequency. If figure 6 corresponds to a situation where the source produces an AC signal with an amplitude V_0 (peak-to-peak swing $2V_0$) at every frequency, then figure 8 corresponds to a situation where the source produces a PRBS with levels $\pm V_0$ (a swing of $2V_0$) and the given hold and rise times. Let's make a sanity check at 7.5 GHz. For our digital signal, at this frequency, the factor becomes

$$E-9)\frac{\sin(1.5\pi)\sin(7.5\pi)}{(1.5\pi)(7.5\pi)}s = \frac{2E-9}{11.25\pi^2}s = (1.8E-11)Hz^{-1} \quad (2)$$

Indeed, |Emax| in Fig. 6 is 16 V/m at 7.5 GHz, and in Fig. 8 the value is 280 pV/(m Hz).

Comparison with regulations

How does this level relate to EMC regulations? First of all, one has to take into account that EMC regulations specify a bandwidth of the measurement equipment of at least 100 kHz. The level of 2.8E-10 V/(m Hz) would register 28 µV/m when measured with equipment of which the bandwidth is 100 kHz (or a little over 100 kHz with roll-off at the edges). Typical MIL-STD EMC limits are on the order of several hundred µV/m at 1m. Hence, this simple, admittedly unrealistic example stays well within the limits. One reason is that its considerable power is spread out over a very broad range of frequencies. A regular clock pulse transmitted by this device would have its power concentrated in narrow bands and would certainly violate regulations. Another reason why the spectral density is low is that 7.5 GHz is well beyond the knee frequency of 0.35/Tr = 1.8 GHz.

Why is the envelope function provided?

Note that the red line in Fig. 8 has many zeroes in the frequency spectrum. There are two reasons for providing the envelope function.

1. If you would produce a frequency sweep and/or a plot with a small number of points, many points would be likely to lie in the valleys and you might not distinguish the peaks anymore. This would give you a false impression.
2. The red line is based on the assumption of bits with perfect trapezoidal shapes. In reality, your signal would not have been perfectly trapezoidal when it was generated, and may have suffered some additional distortions due to interactions in your device. This reduces the value of the fine structure in the spectrum.

Result for a regular clock pulse

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The spectrum of a repetitive clock signal is very different from the spectrum of a pseudo- random binary sequence: it consists of narrow spikes. The Emission Test in Fig. 6 can be used to produce the radiated spectrum of a clock pulse. For example, if we have a clock pulse with zero rise time and f_c=1GHz, we would take the points at 1 GHz, 3 GHz, 5 GHz, 7 GHz, etc., and multiply those fields by $2/\pi$, $2/(3\pi)$, $2/(5\pi)$, $2/(7\pi)$, etc. It would look like the following figure.

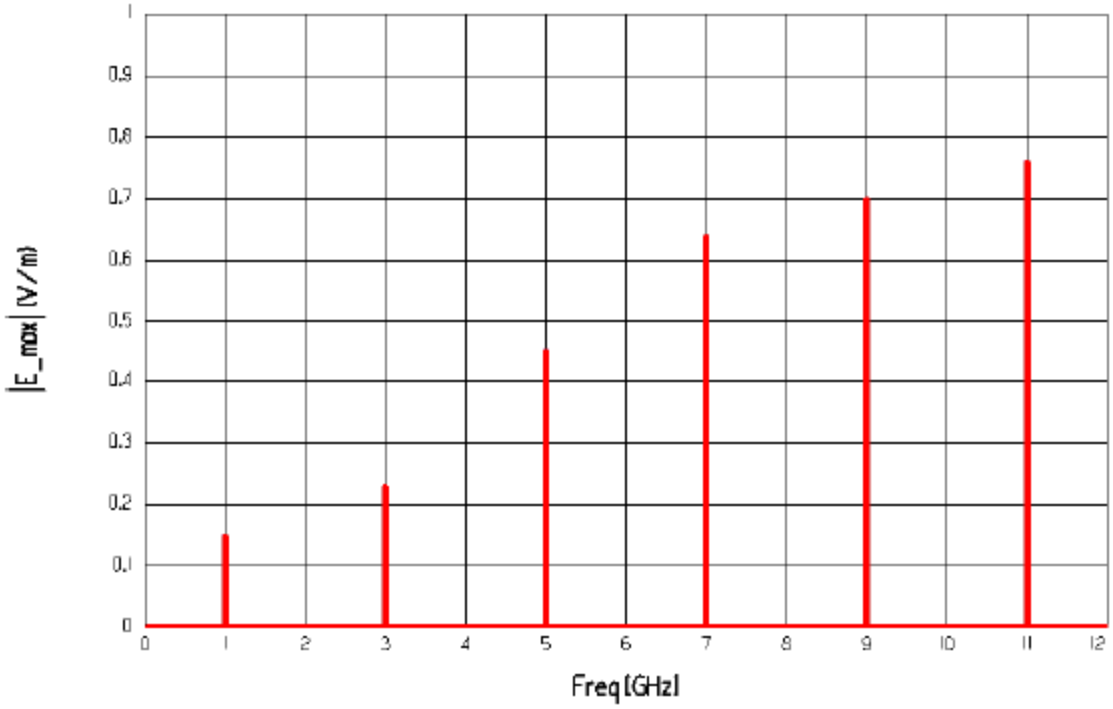

Fig. 9 Emission Test for a clock pulse with a clock frequency of 1 GHz

Whereas the PBRS satisfied strict military standards, the clock pulse violates them by several orders of magnitude. This is because the spectrum of a clock pulse is concentrated in narrow high spikes.

Mathematical Background: Spectra of Digital Signals

In the remainder of this note we derive the spectra of different digital signals of interest. These signals can be divided into two categories: the first is deterministic signals and the second is stochastic (random) signals.

Deterministic Signals

To characterize deterministic signals, we employ the Fourier transform. Let the input signal be $x(t)$, typically measured in Volts. We seek the Fourier transform $X(j\omega)$, typically measured in Volts/Hz. This is given by

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$X(j\omega) = \int_{-\infty}^{\infty} x(t)e^{-j\omega t}dt \quad (1)$$

Here $\omega=2\pi f$ is the angular frequency (radians/sec) and *f* is the frequency in Hz. Also, $j^2 = -1$. There is also an inverse Fourier transform defined by

$$x(t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} X(j\omega)e^{j\omega t}d\omega \quad (2)$$

First let's consider a simple digital pulse with zero rise time. We will then extend the result to a pulse with finite rise and fall time, and then to the case of periodically repeating pulses.

Zero Rise Time Pulse

The input signal is held at the value 1 Volt for T seconds, and is zero at all other times. It looks like this:

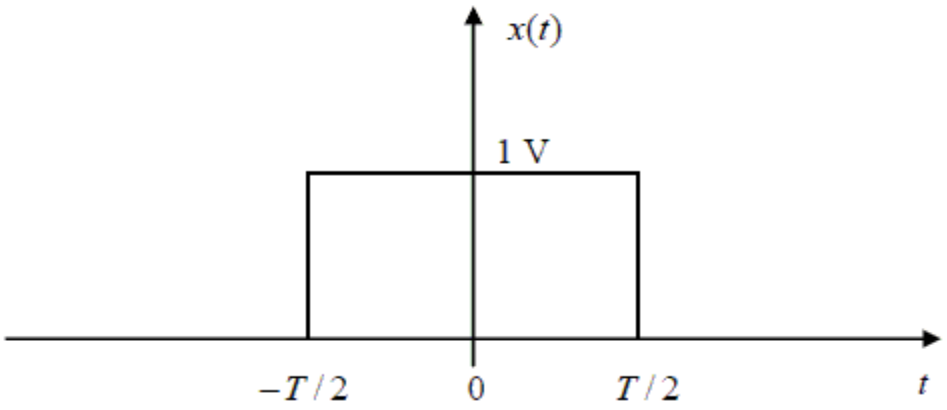

Fig. 10 A zero-rise time pulse

Applying the Fourier transform (1), we get

$$X(j\omega) = \int_{-T/2}^{T/2} 1 \cdot e^{-j\omega t}dt = \frac{e^{-j\omega T/2} - e^{j\omega T/2}}{-j\omega} = \frac{2\sin(\omega T/2)}{\omega} \quad (3)$$

Converting this to frequency units of Hertz yields

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$X(f) = T\frac{\sin(\pi fT)}{\pi fT} \quad (4)$$

The Fourier transform for the zero-rise time signal looks like this:

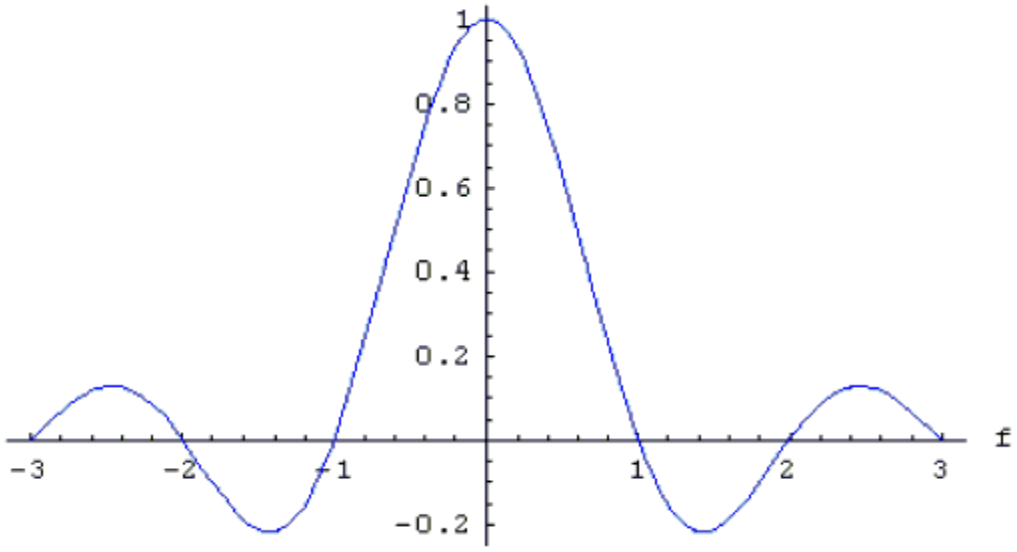

Fig. 11 Fourier transform of the zero-rise time pulse on a normalized scale

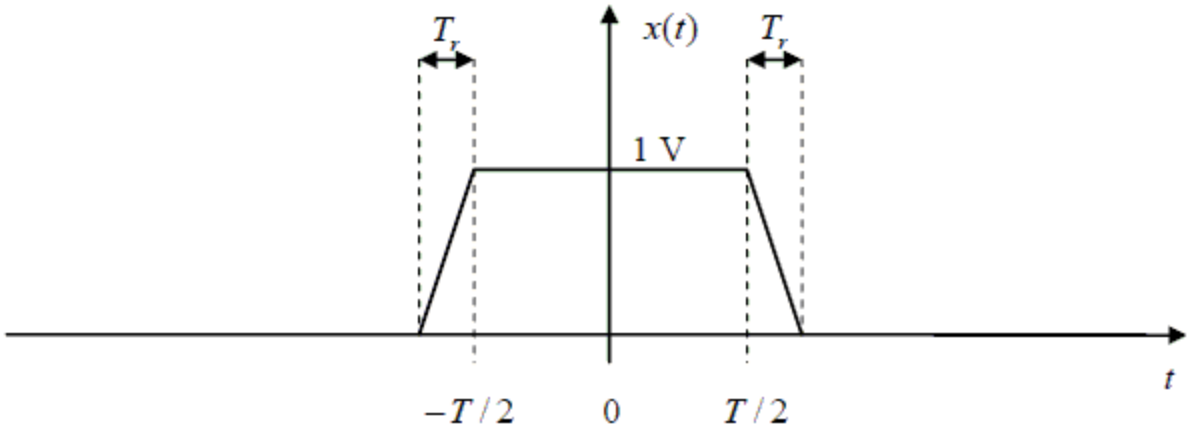
Notice that the maximum value of the function in (3) is *T*, attained at *f* = 0 . Evaluation of this function will require special care in the limit as *f*g0 to avoid dividing by zero.

Finite Rise Time Pulse

In this case, the input signal has the appearance shown in the following figure. The maximum value is 1 Volt. The total width of the pulse is $T + 2T_r$.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fig. 12 A finite rise-time pulse

The waveform may be expressed analytically as

(5)

$$x(t)=\begin{cases} 0 & , \quad t<-T/2-T_r \\ \dfrac{T/2+T_r+t}{T_r} & , \quad -T/2-T_r\le t<-T/2 \\ 1 & , \quad -T/2\le t<T/2 \\ \dfrac{T/2+T_r-t}{T_r} & , \quad T/2\le t<T/2+T_r \\ 0 & , \quad t\ge T/2+T_r \end{cases}$$

Now the Fourier transform becomes

(6)

$$X(j\omega)=\frac{1}{T_r}\int_{-T/2-T_r}^{-T/2}(\frac{T}{2}+T_r+t)e^{-j\omega t}dt+\int_{-T/2}^{T/2}e^{-j\omega t}dt+\frac{1}{T_r}\int_{T/2}^{T/2+T_r}(\frac{T}{2}+T_r-t)e^{-j\omega t}dt$$

After some manipulation this can be simplified to

(7)

$$X(j\omega)\;=\;\frac{4\sin\left(\dfrac{\omega T_r}{2}\right)\cdot\sin\left(\dfrac{\omega(T+T_r)}{2}\right)}{\omega^2 T_r}$$

If we convert this to frequency in Hertz, we have

(8)

$$X(f)\;=\;(T+T_r)\frac{\sin(\pi f T_r)\cdot\sin[\pi f(T+T_r)]}{(\pi f T_r)\pi f(T+T_r)}$$

The maximum value of this function is $T + T_r$, approached in the low-frequency limit. A normalized plot of this frequency response for $T = 0.6$, $T_r = 0.4$ is given below:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

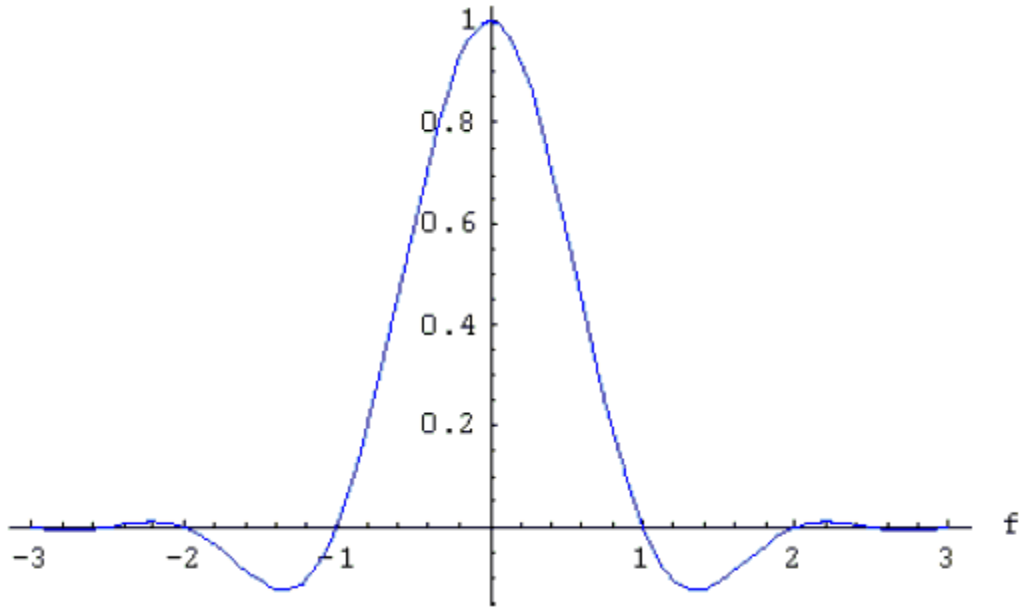


Fig. 13 Frequency response for a finite rise-time signal with T=0.6, T_r = 0.4

Notice that figures 11 and 13 look fairly similar. At higher frequencies, the amplitude of the frequency response falls off more quickly for the signal with finite rise time.

Periodically Repeating Pulse

Now we consider a digital pulse that repeats regularly with a period T_0. This signal is shown in figure 14 below.

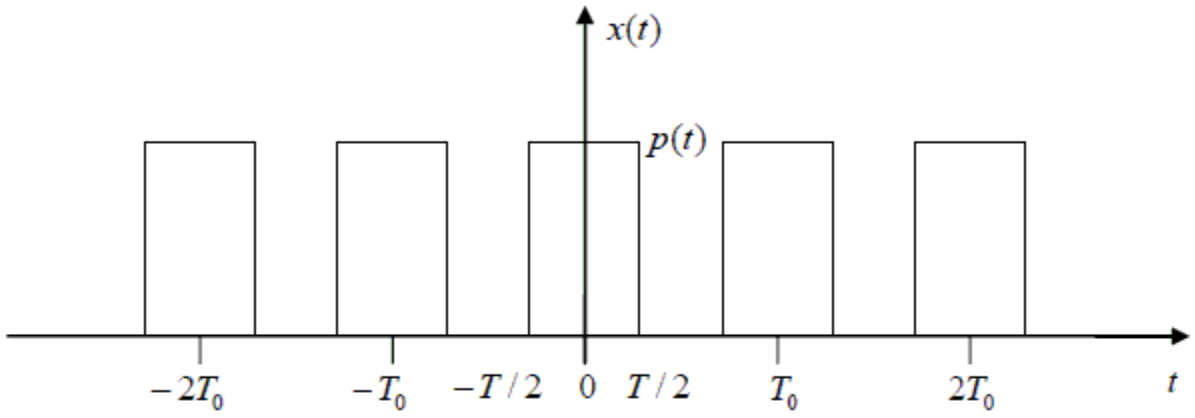

Fig. 14 Example of a periodically repeating digital pulse.
In this example, the basic pulse shape is a zero-rise time pulse.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The basic pulse shape for a single period is given by the function $p(t)$, which is nonzero only for $-T_0/2 < t \leq T_0/2$. The complete periodic signal can be expressed as an infinite summation of delayed pulses:

$$x(t) = \sum_{n=-\infty}^{\infty} p(t - nT_0) \tag{9}$$

An alternative representation for a periodic signal is its *Fourier* series

$$x(t) = \sum_{k=-\infty}^{\infty} a_k e^{-jk\omega_0 t} \tag{10}$$

Here $\omega_0 = 2\pi/T_0$ is the fundamental frequency of the periodic signal, and the complex Fourier series coefficients a_k can be computed with the following integral:

$$a_k = \frac{1}{T_0} \int_{-T_0/2}^{T_0/2} p(t) e^{-jk\omega_0 t} dt \tag{11}$$

The similarities of this integral to the Fourier transform in equation (1) are obvious. In the case of the Fourier series, the integral is carried out over a single period, while the Fourier transform integral in (1) is taken over all time. Another difference is that the Fourier series requires only the discrete set of frequencies $k\omega_0$, whereas the Fourier transform integral deals with a continuous spectrum of frequencies from.

$$-\infty < \omega < \infty$$

Another difference is the leading factor of $1/T_0$ in the Fourier series integral. This leads to a coefficient a_k with units of Volts, not Volts/Hz.

Let us compute the Fourier transform $P(j\omega)$ of the basic pulse shape function $p(t)$. Thanks to the time-limited nature of $p(t)$, this is:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$P(j\omega) = \int_{-\infty}^{\infty} p(t)e^{-j\omega t}dt = \int_{-T_0/2}^{T_0/2} p(t)e^{-j\omega t}dt \quad (12)$$

Comparing with equation (11), we see that

$$a_k = \frac{1}{T_0}P(jk\omega_0) \quad (13)$$

Thus we can rewrite the Fourier series (10) for the periodic signal as

$$x(t) = \sum_{k=-\infty}^{\infty} \frac{1}{T_0}P(jk\omega_0)e^{-j\omega t}dt \quad (14)$$

It is easy to show (by using the inverse Fourier transform in (2)) that the Fourier transform of the complex exponential signal $e^{jk\omega_0 t}$ is a Dirac delta function, $2\pi\delta(\omega\text{-}k\omega_0$. Using this fact, we can now find the Fourier transform of the repeating pulse signal in (14):

$$X(j\omega) = \sum_{k=-\infty}^{\infty} \frac{2\pi}{T_0}P(jk\omega_0)\delta(\omega - k\omega_0) = P(j\omega)\sum_{k=-\infty}^{\infty} \frac{2\pi}{T_0}\delta(\omega - k\omega_0) \quad (15)$$

If we convert this to frequency in Hertz, we get

$$X(f) = \frac{1}{T_0}P(f)\sum_{k=-\infty}^{\infty} \delta(f - kf_0) \quad (16)$$

Here $f_0=1/T_0$ is the fundamental frequency in Hz.

Thus we have shown that the Fourier transform of a repeating pulse is an infinite series of delta functions, scaled by $1/T_0$ times the Fourier transform of the basic pulse shape. Such a signal is impossible to plot, because the delta function is an infinitely high, infinitely narrow spike. It is, however, possible to plot the closely related Fourier series coefficients. For a zero-rise time pulse with $T = 1$ and a period $T_0 = 4$ we get the following plot:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

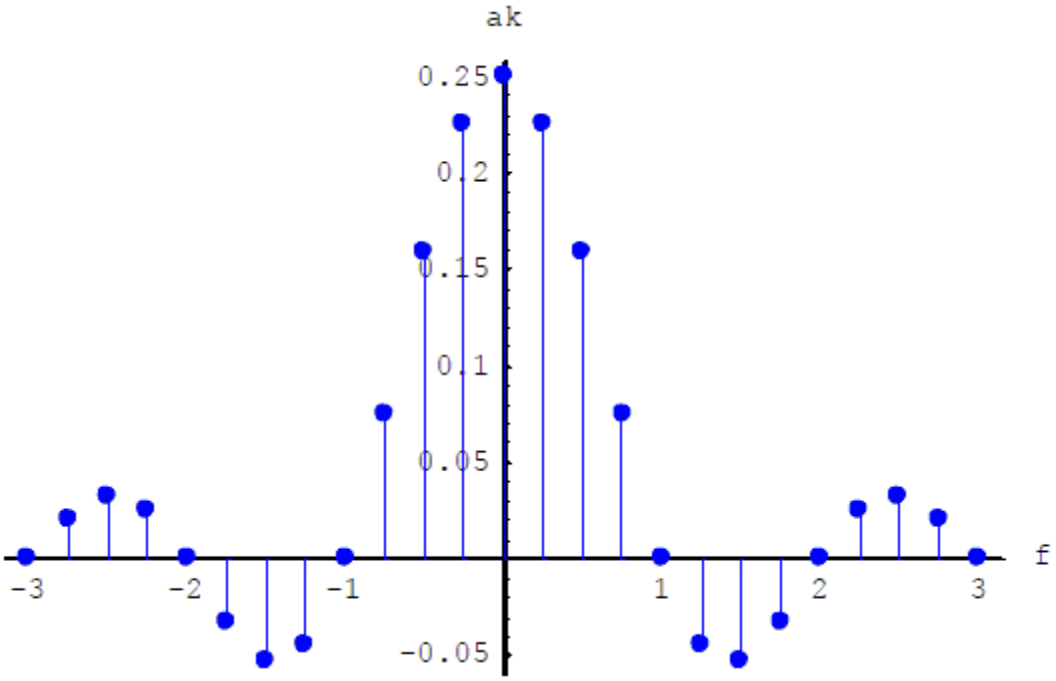

Fig. 15 The Fourier coefficients for a periodic repeating zero rise-time pulse Compare this with figure 11 for a single pulse.

Special case: clock pulse with $T_0=T_{clock}=1/f_{clock}$ and $T+T_r=T_0/2$

In this case we have from (16)

$$X(f) = \frac{1}{T_{clock}} P(f) \sum_{k=-\infty}^{\infty} \delta(f - kf_{clock})$$

and we substitute from (8)

$$P(f) = \left(\frac{T_{clock}}{2}\right) \frac{\sin(\pi f T_r) \cdot \sin[(\pi f T_{clock})/2]}{(\pi f T_r)(\pi f T_{clock}/?)}$$

This gives

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$X(f) = \frac{1}{2}\delta(f) + \sum_{k=1}^{\infty} \frac{\sin(\pi f T_r)}{(\pi f T_r)} \frac{\sin(\pi f T_{clock})}{(\pi f T_{clock})} \delta(f - k f_{clock})$$

The first term on the right-hand side, 1/2δ(*f*) , is the DC term which comes from k=0.

Indeed, in this case the average value of the signal is ½.

In the summation, by combining the positive and negative values of k, we implicitly limited the observations to positive frequencies and inserted a factor of two. See the practical note later in this document.

The product $\sin(\pi f T_{\text{clock}} / 2)\ \delta(f - k f_{clock})$ is zero for even values of k and is $\pm\delta(f - k f_{clock})$ for odd values of k. We therefore find

$$|X(f)| = \frac{1}{2}\delta(f) + \sum_{k = 1, 3, 5, 7, \ldots} \frac{\left|\sin(\pi f T_r)\right|}{(\pi f T_r)} \frac{1}{k\pi/2} \delta(f - k f_{clock})$$

The unit is V/Hz if the clock signal is a voltage. Thus, the spectrum consists of a DC term of 0.5 V plus AC terms of

$$\frac{2}{k\pi} \frac{\sin(\pi f T_r)}{\pi f T_r} \text{Volt}$$

at frequencies f=kfclock, k=1,3,5,7,…

If the rise time is zero, the sinc function is one and we simply have AC terms of at frequencies f=kfclock, k=1,3,5,7,… This is confirmed by Eric Bogatin in [1].

[1] Eric Bogatin, *Signal Integrity - Simplified*, ISBN 0-13-066946-6, published by Prentice Hall, Chapter 2: Time and Frequency Domains.

Using the Envelope Function for Radiated Field Computations

In any single-input linear time-invariant system, the Fourier transform *Y*(*j*ω) of the output is related to that of the input signal by a transfer function *H*(*j*ω):

$$Y(j\omega) = H(j\omega)X(j\omega) \quad (17)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If there are *N* inputs, with Fourier transforms $X_1(j\omega)$, $X_2(j\omega)$,...$X_N(j\omega)$, output is characterized by *N* different transfer functions:

$$Y(j\omega) = \sum_{k=1}^{N} H_k(j\omega)X_k(j\omega) \tag{18}$$

The input signals in an HFSS project are typically incident modal waves or terminal voltages. The output signals could be reflected waves (if we are dealing with S-parameters) or the vector components of near or far electromagnetic fields. HFSS computes the transfer functions from the inputs to the outputs of interest.

The Edit Sources function in the fields postprocessor takes care of forming the following linear combination:

$$Y(j\omega) = \sum_{k=1}^{N} H_k(j\omega)XC_k \tag{19}$$

where the C_k are complex-valued constants (specified by their magnitude and phase.)

If all of the input signals are deterministic digital signals *with the same shape* (aside from a constant scaling factor C_k), then we can write $X_k(j\omega)=C_kX_0(j\omega)$ where $X_0(j\omega)$ ισ the Fourier transform of the common signal shape. In this case, equation (18) reduces to

$$Y(j\omega) = X_0(j\omega)\sum_{k=1}^{N} H_k(j\omega)C_k \tag{20}$$

Therefore we can simply multiply the Edit Sources result in equation (19) by the Fourier transform $X_0(j\omega)$ of the (common) digital signal shape. If, at some future point, we want to consider inputs that carry *different* digital signals, then modifications would be needed to Edit Sources to implement equation (18) in its full generality.

If we are dealing only with the magnitude of the response $Y(j\omega)$, then we have

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$|Y(j\omega)| = X_0(j\omega)\left|\sum_{k=1}^{N} H_k(j\omega)C_k\right| \quad (21)$$

A Note about the Signal Scale Factors

Strictly speaking, only real-valued (positive or negative) signal scale factors C_k should be allowed when we are dealing with digital signals. If an arbitrary complex number is used, then the resulting scaled time-domain signal will not be real-valued. This is non- physical.

It would be more reasonable to interpret the phase as being the phase lag (modulo 2π) *at a certain frequency*; then an equivalent delay T_d could be computed. This could be used to compute a frequency dependent scale factor $\exp(-j\omega T_d)$ for the input signal.

A Practical Note about Measurement Equipment

Most frequency domain measurement equipment (spectrum analyzers and vector network analyzers) will display signal amplitude, not the Fourier transform amplitude. If the input signal is a cosine function with amplitude 1, its Fourier transform is

$$x(t) = \cos(2\pi f_0 t) = \frac{1}{2}e^{j2\pi f_0 t} + \frac{1}{2}e^{-j2\pi f_0 t} \rightarrow X(f) = \frac{1}{2}\delta(f - f_0) + \frac{1}{2}\delta(f + f_0) \quad (22)$$

This would suggest that a spike of amplitude ½ should appear at the frequency f_0. Most measurement equipment is calibrated with exactly this sort of reference signal, but usually the persons performing the calibration adjust the equipment to display a value of 1 as the output. Therefore, if one wishes to duplicate what is shown on the measurement equipment, the Fourier transform of the output signal should be multiplied by a factor of 2.

Stochastic Signals: Random Bit Streams

Now we consider random bit streams. The signal is a continuous function of time, and consists of pulses with a fixed basic pulse shape $p(t)$. Each delayed pulse is modulated by a random variable $\mathbf{x}_n$. We represent the complete random bit stream as

$$\mathbf{x}(t) = \sum_{n=-\infty}^{\infty} \mathbf{x}_n p(t - nT_0) \quad (23)$$

For a digital random process, the discrete random variables $\mathbf{x}_n$ can take on only two distinct real values, representing a logic 1 or 0. We make some assumptions about the statistics of these

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

discrete random variables. First, we assume that the mean (expected) value of $\mathbf{x}_n$ is independent of time:

$$E\{\mathbf{x}_n\} = E\{\mathbf{x}_m\} \qquad \text{for all } m, n \quad (24)$$

Here $E(.)$ denotes the expected value of a random variable. Secondly, we assume that the discrete *autocorrelation* function of the bit values $E\{\mathbf{x}_m\mathbf{x}_n\}$ depends only on the time difference m-n, and not upon the absolute values of m and n :

$$E\{\mathbf{x}_m\mathbf{x}_n\} = R_{m-n} \quad (25)$$

To use the formal language of random processes, we are assuming that the discrete random sequence $\{\mathbf{x}_n\}$ is *wide-sense stationary*.

For a real-valued random process $\mathbf{x}(t)$ that is a function of a continuous time variable t, we define the *autocorrelation function* $R_{xx}(t, \tau)$ as

$$R_{xx}(t, \tau) = E\{\mathbf{x}(t)\mathbf{x}(t+\tau)\} \quad (26)$$

In this note, we are dealing with random processes of the form shown in equation (23). Such a process is *cyclostationary*. In this case, the autocorrelation is a periodic function of time:

$$R_{xx}(t + nT_0, \tau) = R_{xx}(t, \tau) \quad (27)$$

For a cyclostationary signal, we can introduce a time-averaged autocorrelation, where the time averaging is over a single period. In this case the autocorrelation depends only upon the time shift τ:

$$R_{xx}(\tau) = \frac{1}{T_0}\int_{-T_0/2}^{T_0/2} E\{\mathbf{x}(t)\mathbf{x}(t+\tau)\}\,dt \quad (28)$$

The *power spectral density* (or PSD) of a random process is the Fourier transform of its autocorrelation function:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$S_{xx}(j\omega) = \int_{-\infty}^{\infty} R_{xx}(\tau) e^{-j\omega\tau} d\tau \quad (29)$$

Typically we use the power spectral density to characterize random processes in the frequency domain.

Deterministic Signals with Finite Energy

The autocorrelation and PSD are also defined for deterministic signals, but the definition of the autocorrelation is somewhat different. For a real-valued deterministic signal $x(t)$ with finite energy (i.e., non-periodic), we define the autocorrelation as

$$R_{xx}(\tau) = \int_{-\infty}^{\infty} x(t)x(t+\tau)dt \quad (30)$$

The PSD is still defined as the Fourier transform of the autocorrelation. We can show that the PSD is the magnitude squared of the Fourier transform X j of the deterministic signal:

$$S_{xx}(j\omega) = |X(j\omega)|^2 \quad (31)$$

Deterministic Periodic Signals

For a deterministic signal that is periodic and real-valued, the autocorrelation is defined using an integral over a single period:

$$R_{xx}(\tau) = \frac{1}{T_0} \int_{-T_0/2}^{T_0/2} x(t)x(t+\tau)dt \quad (32)$$

(Notice the similarity to equation (28), which applies to cyclostationary random signals.) If $x(t)$ has the Fourier series coefficients a_k, then we can show that its autocorrelation function is also periodic, and has a Fourier series with the coefficients $|a_k|^2$.

Here again the PSD is the Fourier transform of the autocorrelation. Because the autocorrelation is periodic, the PSD is a set of impulses in frequency:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$S_{xx}(j\omega) = \sum_{k=-\infty}^{\infty} 2\pi |a_k|^2 \delta(\omega - k\omega_0) \quad (33)$$

or in units of Hz,

$$S_{xx}(f) = |a_k|^2 \delta(f - kf_0) \quad (34)$$

Finding the Power Spectrum of a Random Bit Stream

We are now ready to attempt to find the power spectral density (PSD) of the random bit stream in equation (23). The procedure will be to compute its autocorrelation $R_{xx}(\tau)$ using equation (28), and then to take the Fourier transform of this to get the PSD.

Substituting (23) into (28), we find that the autocorrelation is

$$R_{xx}(\tau) = \frac{1}{T_0} \int_{-T_0/2}^{T_0/2} E\{\mathbf{x}(t)\mathbf{x}(t+\tau)\} dt \quad (35)$$

$$= \sum_{m=-\infty}^{\infty} \sum_{n=-\infty}^{\infty} E\{x_m x_n\} \frac{1}{T_0} \int_{-T_0/2}^{T_0/2} p(t - mT_0) p(t + \tau - nT_o) dt$$

$$= \sum_{m=-\infty}^{\infty} \sum_{n=-\infty}^{\infty} R_{n-m} \frac{1}{T_0} \int_{-T_0/2}^{T_0/2} p(t - mT_0) p(t + \tau - nT_o) dt$$

Here again we are using $R_k = E\{\mathbf{x}_n \mathbf{x}_{n+k}$ to denote the autocorrelation of the discrete random bit values xn . Now let us define $k = n - m$ and eliminate n from the above expression. We rewrite the summation as

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$R_{xx}(\tau) = \sum_{k=-\infty}^{\infty} R_k \sum_{m=-\infty}^{\infty} \frac{1}{T_0} \int_{T_0/2}^{T_0/2} p(t - mT_0)p(t + \tau - (m+k)T_0)dt \tag{36}$$

$$= \sum_{k=-\infty}^{\infty} R_k \sum_{m=-\infty}^{\infty} \frac{1}{T_0} \int_{T_0/2}^{T_0/2} p(u)p(u + \tau - kT_0)dt$$

where we have introduced $u = t - mT_0$. Notice now that the integrals being summed up over non-overlapping intervals of length T_0, when taken together, actually constitute a single integral over the entire time axis. Thus we can write

$$R_{xx}(\tau) = \sum_{k=-\infty}^{\infty} R_k \frac{1}{T_0} \int_{-\infty}^{\infty} p(u)p(u + \tau - kT_0)dt \tag{37}$$

$$= \frac{1}{T_0} \sum_{k=-\infty}^{\infty} R_k R_{pp}(\tau - kT_0)$$

where $R_{pp}(\tau)$ is the autocorrelation of the basic pulse shape $p(t)$:

$$R_{pp}(\tau) = \int_{-\infty}^{\infty} p(t)p(t + \tau)dt \tag{38}$$

To get the PSD of the random bit stream, we now need to take the Fourier transform of the autocorrelation in (37). Making use of standard Fourier transform properties, this is

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$S_{xx}(j\omega) = \frac{1}{T_0}|P(j\omega)|^2 \sum_{k=-\infty}^{\infty} R_k e^{-jk\omega T_0} \quad (39)$$

Here $P(j\omega)$ is the Fourier transform of the basic pulse shape; thus $|P(j\omega)|^2$ is the PSD of the basic pulse.

The power spectrum expression in (39) is fairly general. We can now consider some important special cases.

A Random Bit Stream with Bipolar Modulation

In this case, the random variables $\mathbf{x}_n$ take on the values +1 or -1 with equal probability (1/2), and we assume that the values of any two different bits are independent of one another. The signal is illustrated below in figure 16.

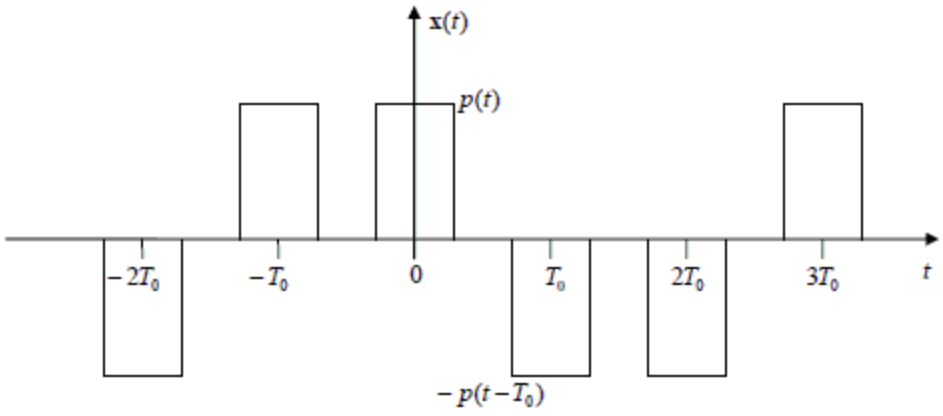

Fig. 16 A sample of an ideal random digital bit stream with bipolar modulation It is modulated by a sequence of random variables that assume the values +1 or -1 in each interval.

Thanks to the assumed statistics, we have

$$R_k = E\{\mathbf{x}_n \mathbf{x}_{n+k}\} = \begin{cases} 1, & k = 0 \\ 0, & k \neq 0 \end{cases} \quad (40)$$

Therefore (39) immediately simplifies to

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$S_{xx}(j\omega) = \frac{1}{T_0}|P(j\omega)|^2 \quad (41)$$

This derivation does not depend upon the particular pulse shape $p(t)$. Therefore it applies equally well to zero rise time pulses and to finite rise time pulses. An illustration for a zero-rise time pulse ($T = 1$) and a pulse period $T_0 = 4$ is shown below in figure 17:

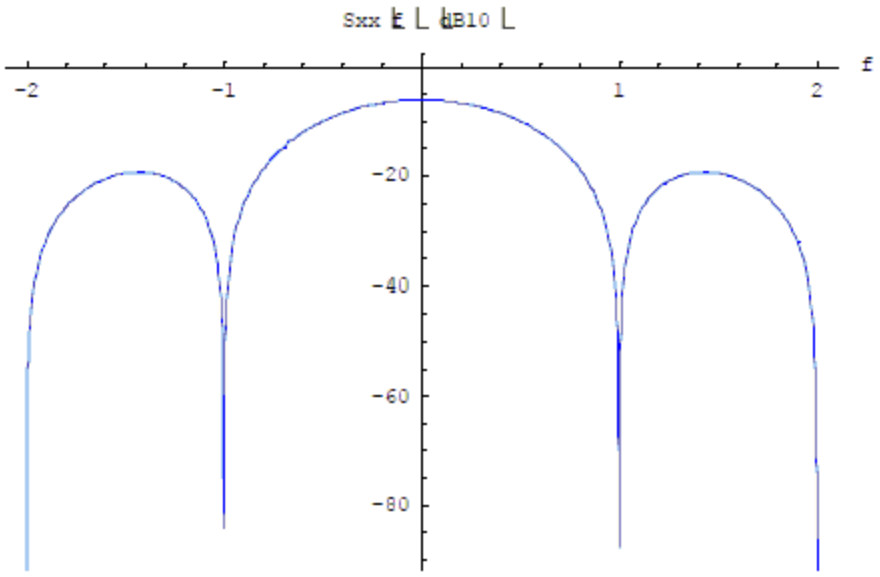

Fig. 17 Power spectral density for a random bit stream with bipolar modulation and a pulse shape corresponding to a zero rise time pulse. A logarithmic dB10 scale has been used for clarity.

Special case with bipolar modulation

Let's consider the special case where $T+2T_r=T_0$. This means that the signal x(t) in figure 16 never stays at zero for any length of time. From (41) we have

$$S_{xx}(j\omega) = \frac{1}{T_0}|P(j\omega)|^2$$

and from (8) we have

$$P(f) = (T + T_r)\frac{\sin(\pi f T_r) \cdot \sin[\pi f(T + T_r)]}{(\pi f T_r)\pi f(T + T_r)}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This leads to

$$S_{xx}(f) = \frac{(T+T_r)^2}{T+2T_r}\frac{\sin^2(\pi f T_r)}{(\pi f T_r)^2}\frac{\sin^2[\pi f(T+T_r)]}{(\pi f(T+T_r))^2}$$

For zero rise time, this equation simplifies considerably:

$$S_{xx}(f) = T\frac{\sin^2(\pi f T)}{(\pi f T)^2}$$

The field- or voltage based spectral density is simply given by (8)

$$P(f) = (T+T_r)\frac{\sin(\pi f T_r)\cdot\sin[\pi f(T+T_r)]}{(\pi f T_r)\pi f(T+T_r)}$$

which for zero rise time simplifies to

$$P(f) = T\frac{\sin(\pi f T)}{\pi f T}$$

To see that P(f) indeed accounts correctly for the field- or voltage based spectral density, consider the following situation. The signal x(t) is a voltage that is applied to a one-Ohm resistor. If we have a sequence of N bits, -1V or 1V, with zero rise time, and with a total duration of NT seconds, how much **energy** would this signal dissipate in the 1-Ω resistor?

The energy deposited in the resistor will be

(VI in the frequency domain) × number_of_bits.

Both V and I will now be given by P(f), one being in V/Hz and the other in A/Hz.

$$T^2\frac{\sin^2(\pi f T)}{(\pi f T)^2}\times N$$

This results in a power dissipation (energy/time = energy/(NT)) of

$$T\frac{\sin^2(\pi f T)}{(\pi f T)^2} \qquad W/(Hz)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

in which we recognize the expression for $S_{xx}(f)$.

At this stage, both positive and negative frequencies are allowed. Because of the practical note elsewhere in this document we can limit ourselves to positive frequencies, add a factor of two, and state that the voltage- or field based spectral density is given by

$$P(f) = 2(T + T_r)\frac{\sin(\pi f T_r) \cdot \sin[\pi f(T + T_r)]}{(\pi f T_r)(\pi f(T + T_r))} \qquad f > 0$$

A Random Bit Stream with Unipolar Modulation

Now we will consider the case where the modulating random process $\mathbf{x}_n$ takes on the values +1 or 0 (with equal probability of 1/2) in each interval. We refer to this as unipolar modulation. The signal is illustrated below:

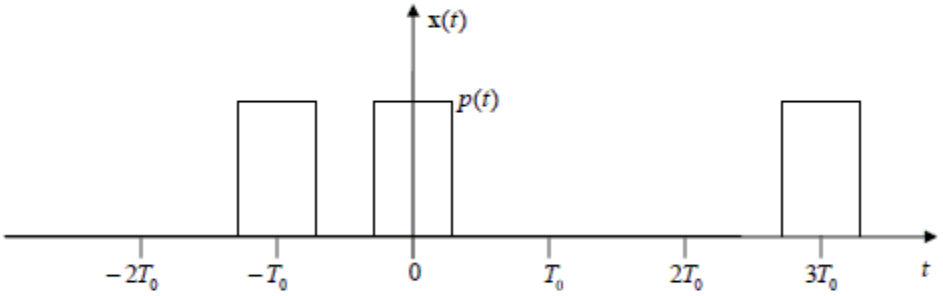

Fig. 18 Random bit stream with unipolar modulation

Again we assume that the values of two different bits are independent. Here the autocorrelation function values are different. For $m = n$, the two possible values of $\mathbf{x}_m\mathbf{x}_n$ are 1 and 0, and each occurs with probability ½. For mm n, the possible values of $\mathbf{x}_m\mathbf{x}_n$ are also 1 and 0, but because the two random variables are independent, a value of 1 occurs only ¼ of the time. Thus we have

$$R_k = E\{\mathbf{x}_n\mathbf{x}_{n+k}\} = \begin{cases}(1/2), & k = 0\\ (1/4), & k \neq 0\end{cases} \qquad (42)$$

Inserting this into (39) gives

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$S_{xx}(j\omega) = \frac{1}{T_0}|P(j\omega)|^2\left[\frac{1}{2} + \sum_{\substack{k=-\infty \\ k\neq 0}}^{\infty} e^{-jk\omega T_0}\right] \tag{43}$$

$$= \frac{1}{T_0}|P(j\omega)|^2\left[\frac{1}{4} + \frac{1}{4}\sum_{k=-\infty}^{\infty} e^{-jk\omega T_0}\right]$$

The infinite sum can be recognized as a Fourier series with the coefficients a_k =1. Thus it represents a periodic signal. As we show in the appendix, the signal with this particular set of Fourier series coefficients is an infinite train of impulses. Replacing the Fourier series with the periodic impulse train, we obtain

$$S_{xx}(j\omega) = \frac{1}{T_0}|P(j\omega)|^2\left\{\frac{1}{4} + \frac{1}{4}\sum_{k=-\infty}^{\infty}\frac{2\pi}{T_0}\delta(\omega - k\varpi_0)\right\} \tag{44}$$

If we prefer to work in frequency units of Hz, this becomes

$$S_{xx}(f) = \frac{1}{4T_0}|P(f)|^2\left[1 + \frac{1}{T_0}\sum_{n=-\infty}^{\infty}\delta(f - nf_0)\right] \tag{45}$$

Once again, the derivation applies to any pulse shape, with zero or finite rise time. The above result for a unipolar bit stream is distinctly different from the result for a bipolar stream, thanks to the train of impulses represented by the second term. The power spectrum contains a continuous part, exactly ¼ as large as the spectrum of a bipolar signal, plus a set of narrow spikes at discrete frequencies (multiples of 1/ T_0). It can be shown that one half of the total signal power is in the discrete part of the spectrum, and one half is in the continuous part.

Obtaining a plot of this function is difficult, because it contains both infinite impulses and a finite continuous part. If we assume that the frequency response is run through a detector with finite frequency sensitivity Δf, then the apparent amplitude of the spikes will be finite and scaled by the factor $1/\Delta f$. The amplitude of the continuous part of the spectrum will be almost unaffected.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Taking, for example, $T_0 = 4$, a zero rise time pulse shape with $T = 1$, and $\Delta f = 10^{-4}$, we arrive at the following plot:

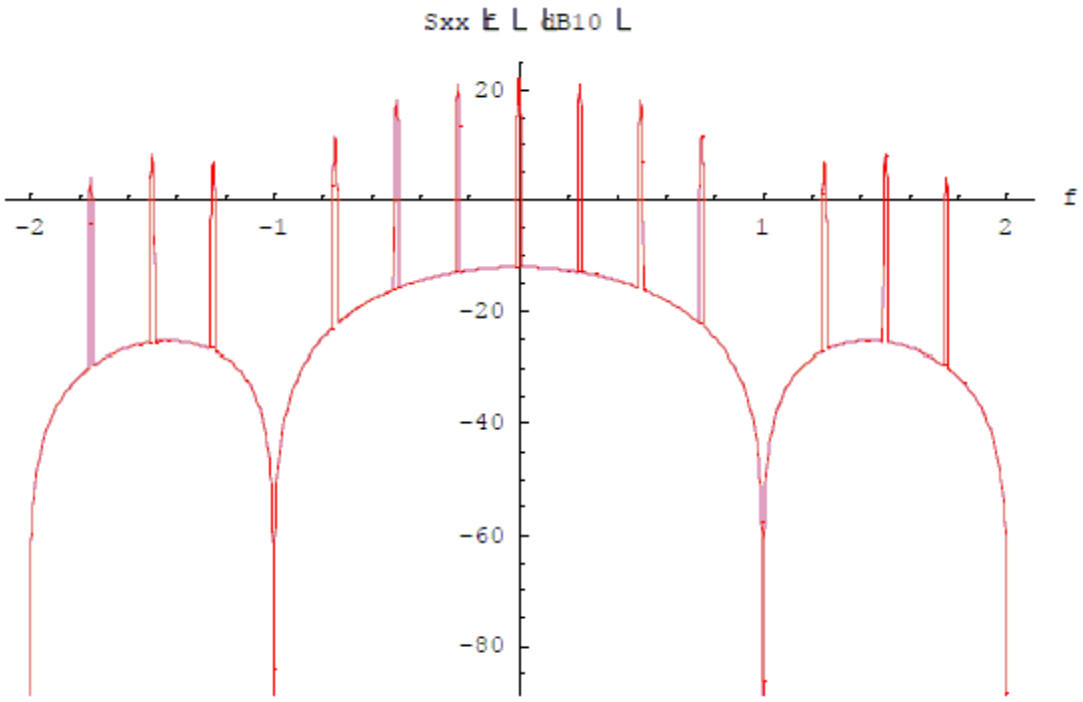

Fig. 19 Power spectrum for the random bit stream with unipolar modulation, showing the periodic spikes. A dB10 logarithmic scale has been used for clarity.

Special case with unipolar modulation

Let's consider the special case where T+Tr=T0. This means that the random signal spends equal amounts of time at level zero and at level one. We repeat (45) for convenience:

$$S_{xx}(f) = \frac{1}{4T_0}|P(f)|^2\left[1 + \frac{1}{T_0}\sum_{n=-\infty}^{\infty}\delta(f - nf_0)\right]$$

In this equation P(f) is given by (8)

$$P(f) = (T + T_r)\frac{\sin(\pi f T_r)\cdot \sin[\pi f(T + T_r)]}{(\pi f T_r)\pi f(T + T_r)}$$

which can now be written as

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$P(f) = T_0 \frac{\sin(\pi f T_r) \cdot \sin[\pi f T_0]}{(\pi f T_r)(\pi f T_0)}$$

This leads to

$$S_{xx}(f) = \frac{T_0}{4} \frac{\sin^2(\pi f T_r)}{(\pi f T_r)^2} \frac{\sin^2(\pi f T_0)}{(\pi f T_0)^2} \left[1 + \frac{1}{T_0} \delta(f) + \frac{1}{T_0} \sum_{n \neq 0} \delta(f - n f_0) \right]$$

Note that, for *n*m0,

$$\frac{\sin(n \pi f_0 T_0)}{(n \pi f_0 T_0)} = 0$$

so the summation with delta functions over nonzero values of *n* disappears. What remains is

$$S_{xx}(f) = \frac{1}{4} \delta(f) \frac{T_0}{4} \frac{\sin^2(\pi f T_r)}{(\pi f T_r)^2} \frac{\sin^2(\pi f T_0)}{(\pi f T_0)^2}$$

This can be recognized as a DC term of 0.25 W plus a spectrum for all nonzero frequencies. The DC term of 0.25 W makes sense since the average value of the signal x(t) is 0.5 V in this case.

The field- or voltage based spectral density is simply given by (8)

$$P(f) = \frac{T_0}{2} \frac{\sin(\pi f T_r) \cdot \sin[\pi f T_0]}{(\pi f T_r)(\pi f T_0)}$$

which for zero rise time simplifies to

$$P(f) = \frac{T_0}{2} \frac{\sin(\pi f T_0)}{\pi f T_0}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To see that P(f) indeed accounts correctly for the field- or voltage based spectral density, consider the following situation. The signal x(t) is a voltage that is applied to a one-Ohm resistor. If we have a sequence of N bits, 0V or 1V, with zero rise time, and with a total duration of NT seconds, how much energy would this signal dissipate in a 1-Ω resistor?

We can expect a DC level of 0.5V with a DC current of 0.5A, plus bits with the given spectrum for an additional voltage swing of ±0.5V with a corresponding additional current of ±0.5A. If there are N bits for a total duration of the stream of NT seconds, the energy deposited in the resistor will be

DCterm × time + ACterm × number_of_bits

$$\frac{1}{4}NT + \frac{1}{4}T^2\frac{\sin^2(\pi fT)}{(\pi fT)^2} \times N$$

This results in a power dissipation (energy/time = energy/(NT)) of 0.25 W for the DC term plus a power dissipation of

$$\frac{T}{4}\frac{\sin^2(\pi fT)}{(\pi fT)^2} \qquad W/(Hz)$$

to account for the pseudo-random voltage swing of ±0.5 V around the DC level. Here, we recognize the result we had earlier.

This expression corresponds to the expression given for power spectral density by Clayton Paul [2].

[2] Clayton R. Paul, "Introduction to Electromagnetic Compatibility", ISBN 0-471- 54927-4, published by John Wiley and Sons, 1992, section 7.6: Signal Spectra, Representation of Random Signals.

Finally, because of the practical observation elsewhere in this note, we can limit ourselves to non-negative frequencies and include a factor of two:

$$P(f) = T_0\frac{\sin(\pi fT_r)\cdot\sin[\pi fT_0]}{(\pi fT_r)(\pi fT_0)} \qquad f>0$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Using the Power Spectrum for Radiated Field Computations

Suppose we have a single-input linear time-invariant system, and let the input be a random process with power spectral density $S_{xx}(j\omega)$. Let the transfer function of the linear system be $H(j\omega)$. Then we can show that the power spectrum $S_{yy}(j\omega)$ of the output is related to that of the input signal as follows:

$$S_{yy}(j\omega) = |H(j\omega)|^2 S_{xx}(j\omega) \tag{46}$$

If there are N inputs to the system, then it becomes considerably more challenging to compute the power spectrum of the output. In general, the input signals may be correlated to one another. Then the output power spectrum is given by

$$S_{yy}(j\omega) = \sum_{m=1}^{N} \sum_{n=1}^{N} H_m^*(j\omega) S_{x_m x_n}(j\omega) H_n(j\omega) \tag{47}$$

Here x^* denotes the complex conjugate of x, and $Sx_mx_n(j\omega)$ is the *cross-power spectral density* of the two random signals $\mathbf{x}_m(t)$ and $\mathbf{x}_n(t)$. This is the Fourier transform of the *cross-correlation* function Rx_mx_n. For our cyclostationary, real-valued random digital signals the cross-correlation is defined as

$$R_{x_m x_n}(\tau) = \frac{1}{T_0} \int_{-T_0/2}^{T_0/2} E\{\mathbf{x}_m(t)\mathbf{x}_n(t+\tau)\}\, dt \tag{48}$$

Another way of expressing (47) is as a matrix inner product:

$$S_{yy}(j\omega) = \begin{bmatrix} H_1(j\omega) & \cdots & H_N(j\omega) \end{bmatrix}^* \begin{bmatrix} S_{x_1x_2}(j\omega) & \cdots & S_{x_1x_N}(j\omega) \\ \vdots & \ddots & \vdots \\ S_{x_Nx_1}(j\omega) & \cdots & S_{x_Nx_N}(j\omega) \end{bmatrix} \begin{bmatrix} H_1(j\omega) \\ \vdots \\ H_N(j\omega) \end{bmatrix} \tag{49}$$

Bipolar Modulation (Statistically Independent Signals)

If the input signals are all *uncorrelated* then (by definition) $Rx_mx_n(\tau)=0$ and $Sx_mx_n(j\omega)=0$ for all $m \neq n$. Then the expression for the output power spectrum will simplify to

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(50)

$$S_{yy}(j\omega) = \sum_{n=1}^{N} |H_n(j\omega)|^2 S_{x_n x_n}(j\omega) \qquad \text{(uncorrolated input signals)}$$

Equivalently, we could say that the power spectrum matrix in equation (49) becomes diagonal in this case.

The input signals will be uncorrelated if they are statistically independent of one another and we are using bipolar modulation. This is a result of the fact that the expected value of the product of any two bits from different signals is 0.

Unipolar Modulation (Statistically Independent Signals)

If we use unipolar modulation, then the input signals will be correlated, even if the bit patterns for two random digital bit streams are statistically independent of one another. For unipolar modulation, we can show that a cross-correlation between independent bit streams of $R^k = 1/4$ (for all k) will result. This will produce the cross power spectral density $Sx_m x_n(j\omega)$.

(51)

$$S_{x_m x_n}(j\omega) = \frac{1}{4T_0} |P(j\omega)|^2 \left[\frac{2\pi}{T_0} \sum_{n=-\infty}^{\infty} \delta(\omega - n\omega_0) \right]$$

The derivation of this result is very similar to that for equation (44). Here we have assumed that the two bit streams have the same basic pulse shape. With this result in hand, the power spectrum of the output signal can be computed using equation (47). We can simplify the expression to

(52)

$$S_{yy}(f) = \frac{1}{4T_0} |P(f)|^2 \left[A + \frac{B}{T_0} \sum_{n=-\infty}^{\infty} \delta(f - nf_0) \right]$$

In the above expression

(53)

$$A = \sum_{n=1}^{N} |H_n(j\omega)|^2 \qquad \text{and}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$B = A + 2\sum_{m=1}^{N}\sum_{n=m+1}^{N} \mathrm{Re}[H_m^*(j\omega)H_n(j\omega)]$$

Inputs that Are Not Independent: Differential Signals

Differential signals represent an important special case where two input signals are not at all independent of one another. In the case of bipolar modulation, we can simply write one member of the pair as the negative of the other. The cross-correlation between bits will be -1 for $k = 0$ and 0 for k m 0. Therefore the cross-power spectral density for the pair will be nonzero. We can show that it will be equal to the negative of equation (41).

Suppose that the two signals of the differential pair are the only inputs to the system and bipolar modulation is used. Then we can use equation (49) to show

(54)

$$S_{yy}(j\omega) = \frac{1}{T_0}|P(j\omega)|^2[H_1(j\omega)H_2(j\omega)]^*\begin{bmatrix}1 & -1\\ -1 & 1\end{bmatrix}\begin{bmatrix}H_1(j\omega)\\ H_2(j\varpi)\end{bmatrix}$$

$$= \frac{1}{T_0}|P(j\omega)|^2\left\{|H_1(j\omega)|^2 - 2\mathrm{Re}[H_1^*(j\omega)H_2(j\omega)] + |H_2(j\omega)|^2\right\}$$

For a typical differential pair, the two transfer functions will be nearly equal, and so this expression shows that the output power will be substantially reduced when compared to single-ended signaling.

If we use unipolar modulation for our differential pair, then a bit of value $\mathbf{x}_m$ (0 or 1) in one signal becomes 1- $\mathbf{x}_m$ (1 or 0, respectively) in the other signal. For two bits in the same period (k =0) the product is always zero, so $R_k = 0$ for k =0. For two bits in different periods the expected value is ¼ (just as it was for independent unipolar signals), so R_k = 1/ 4 for km0. Plugging this into (48) and simplifying will result in

(55)

$$S_{x_1x_2}(j\omega) = \frac{1}{T_0}|P(j\omega)|^2\left\{-\frac{1}{4} + \frac{1}{4}\sum_{k=-\infty}^{\infty}\frac{2\pi}{T_0}\delta(\omega - k\omega_0)\right\}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Thus the impulse train part of the cross power spectrum is unchanged (as compared to equation (51) for independent unipolar signals), but now a continuous component has been added. The continuous component of the cross power spectrum is the negative of the continuous component of a self-power spectrum (compare equation (44)).

If we now suppose that the signals of the differential pair are the only inputs to the system, then the output power spectrum has the same form as equation (52), but now the coefficients will be

$$A = \left|H_1(j\omega)\right|^2 - 2\mathrm{Re}[H_1{}^*(j\omega)H_2(j\omega)] + \left|H_2(j\omega)\right|^2 \quad (56)$$

$$B = \left|H_1(j\omega)\right|^2 + 2\mathrm{Re}[H_1{}^*(j\omega)H_2(j\omega)] + \left|H_2(j\omega)\right|^2 \quad (57)$$

Conclusions and Discussion

This note has dealt with the output responses of linear systems with deterministic (finite energy as well as periodic) and stochastic (random) inputs.

When the signals are deterministic, and have the same time-domain waveforms (apart from constant scaling factors) it is fairly straightforward to consider multiple inputs and compute the Fourier transform of the output signal. The Fourier transform could be a continuous function of frequency (for finite energy signals) or a set of sharp lines (for periodic signals.)

If the signals are random, the process of combining multiple inputs is more complex. In addition to the power spectrum for each input, we must also know the cross power spectrum for every pair of inputs. The cross power spectrum depends on whether the inputs are statistically independent or not. We saw that differential signals are an important special case where signals are strongly dependent on one another. Despite all of these complications, it is still possible to compute the output signal power, and the procedure is sufficiently mechanical for it to be reduced to a computer program.

In this note we have focused our attention on random binary-valued logic signals. These are the sorts of signals we expect to see on the internal buses of a digital system. There are other random signal types (not considered here) that could be of interest. One class that is worthy of mention is digital communication signals, such as PAM, CPM, CPFSK, QPSK, etc.

Appendix A: Handy Delta Function Facts

Definition of the Dirac Delta Function

The Dirac delta function $\delta(x)$ is defined by the following relations:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. $\delta(x) = 0 \quad \text{for} \quad x \neq 0$
2. $\delta(x) \quad \text{is undefined (infinite) at} \quad x = 0$
3. $$\int_{-\infty}^{\infty} g(x)\delta(x)dx = g(0)$$

Delayed Delta Functions

Using Property 3 above, and a change of variables, we can show that if the delta function is shifted:

$$\int_{-\infty}^{\infty} g(x)\delta(x - x_0)dx = g(0)$$

Time Reversal of a Delta Function

$$\int_{-\infty}^{\infty} g(x)\delta(-x)dx = g(0) = \int_{-\infty}^{\infty} g(-u)\delta(u)d(-u) = \int_{-\infty}^{\infty} g(-u)\delta(u)du = g(0)$$

Thus a time reversal has no effect on the basic properties of the delta function.

Products of Delta Functions with Regular Functions

It is easy to see that

$$\int_{-\infty}^{\infty} g(x)\delta(x - x_0)dx = g(0) = \int_{-\infty}^{\infty} g(x_0)\delta(x)dx$$

Thus we are free to replace $g(x)\delta(x-x_0)$ by $g(x_0)\delta(x-x_0)$, or vice versa.

Scaling the Argument for Delta Functions

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This often occurs when converting from angular frequency (radians/s) to Hertz. Let *A* be a positive, constant scale factor and define $u = Ax$. Then we can show

$$\int_{-\infty}^{\infty} g(x)\delta(x-x_0)dx = \frac{1}{A}\int_{-\infty}^{\infty} g\left(\frac{u}{A}\right)\delta(u-Ax_0)du = \frac{1}{A}g(x_0)$$

Therefore, we can replace

$$\delta(A(x-x_0)) = \frac{1}{A}\delta(x-x_0)$$

When $A = 2\pi$, we have the common case of converting from ω to *f*.

The above discussion can also be used to explain the units associated with a delta function. The definition of the delta function requires that its argument should be dimensionless. Nonetheless we often write expression like $\delta(t - t_0)$ where the argument is a variable (for example, time) with physical dimensions (seconds in this case.) To reconcile this with the definition, we must introduce a scaling factor. Suppose we introduce a dimensionless time variable τ such that $t = (1s)\tau$. Then the scaling factor A = 1s (1 second) and we have

$$\delta(t-t_0) = \delta\left((1s)\left(\tau - \frac{t_0}{1s}\right)\right) = \frac{1}{1s}\delta\left(\tau - \frac{t_0}{1s}\right)$$

Thus a delta function implicitly carries units of 1/[units of its argument.]

Fourier Transform of a Delta Function in Time

Using the definition of the Fourier transform and the definition of the delta function, we get

$$\int_{-\infty}^{\infty} \delta(t-t_0)e^{-\omega}dt = e^{j\omega_0 t}$$

Inverse Fourier Transform of a Delta Function in Frequency

Using the definition of the inverse Fourier transform, we have

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} 2\pi\delta(\omega-\omega_0)e^{j\omega t}dw = e^{j\omega_0 t}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fourier Transform of an Infinite Train of Impulses

Suppose we have an infinitely long "train" of time-domain impulses:

$$x(t) = \sum_{n=-\infty}^{\infty} \delta(t - nT_0)$$

This is a periodic signal. Its Fourier coefficients are

$$a_k = \frac{1}{T_0} \int_{-T_0/2}^{T_0/2} \delta(t) e^{-j\omega t} dt = \frac{1}{T_0}$$

Therefore we can represent the signal as its Fourier series

$$x(t) = \sum_{k=-\infty}^{\infty} \frac{1}{T_0} e^{jk\omega_0 t}$$

The Fourier transform is then easily found from one of the above relationships:

$$X(j\omega) = \sum_{k=-\infty}^{\infty} \frac{2\pi}{T_0} \delta(\omega - k\omega_0)$$

where $\omega_0 = 2\pi / T_0$. If we prefer to measure frequency in units of Hz, this becomes

$$X(f) = \sum_{k=-\infty}^{\infty} \frac{1}{T_0} \delta(f - kf_0)$$

where $f_0 = 1/T_0$. Thus we have shown that the Fourier transform of an infinite impulse train is another infinite impulse train.

The same thing works for a frequency-domain train of impulses. We have

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$X(j\omega) = \sum_{k=-\infty}^{\infty} \delta(\omega - k\omega_0) = \sum_{n=-\infty}^{\infty} a_n e^{-jn\omega T_0}$$

The Fourier series coefficients are

$$a_n = \frac{1}{\omega_0} \int_{-\omega_0/2}^{\omega_0/2} \delta(\omega) e^{jn\omega T_0} d\omega = \frac{1}{\omega_0} = \frac{T_0}{2\pi}$$

Thus

$$X(j\omega) = \sum_{k=-\infty}^{\infty} \delta(\omega - k\omega_0) = \sum_{n=-\infty}^{\infty} \frac{T_0}{2\pi} e^{-jn\omega T_0}$$

This can be used to prove the useful fact that

$$\sum_{n=-\infty}^{\infty} e^{-jn\omega T_0} = \sum_{k=-\infty}^{\infty} \frac{2\pi}{T_0} \delta(\omega - k\omega_0)$$

Calculating Finite Thickness Impedance

The **Assign DC Thickness** option on the **HFSS** menu is enabled if at least one object contains a good conducting isotropic material (such as copper), and the **Solve Inside property** is not selected. If the object meets these conditions, you can assign a DC thickness. If the thickness of the layer is finite, the surface impedance is calculated as:

$$Z = R + jX \quad (1)$$

$$R = \frac{1}{\sigma\delta} \frac{sh(2v) + \sin(2v)}{ch(2v) - \cos(2v)} \quad (2)$$

$$X = \frac{1}{\sigma\delta} \frac{sh(2v) - \sin(2v)}{ch(2v) - \cos(2v)} \quad (3)$$

where

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\delta = \sqrt{\frac{2}{\omega \mu \sigma}} \quad (4)$$

$$\nu = \frac{h}{\delta} \quad (5)$$

where *h* is the layer thickness.

Similar surface impedance is assigned to surfaces of 3D objects of good conductors, which are of NoSolveInside and Thickness for DC Resistance is set.

Modes to Terminals Conversion

This section describes the conversion of modal S-parameters, computed using HFSS's full-wave field solver, into terminal or voltage-based pseudo-S-parameters used in circuit theory.

The S-matrix solutions in HFSS are expressed in terms of incident and reflected complex amplitudes of waveguide modes. This description is mathematically and physically rigorous, but for the case of multi-conductor lines where multiples modes are propagating simultaneously it is convenient to convert the modes to physical quantities directly related to conductors such as currents. Examples of such situations include coupled transmission lines on printed circuit boards, multi-conductor cables, and many common types of electrical connectors. For these types of structures, which generally support multiple, quasi-transverse electromagnetic (TEM) modes of propagation, it is difficult to excite and measure a single mode. In any practical, or laboratory-like, measurement situation:

- measurements (e.g., voltage) contain contributions from several modes
- the applied stimuli excite several modes simultaneously

Terminal support was added to HFSS to enable the simulation of terminal currents and voltages directly, without requiring engineers to determine the needed linear combinations of waveguide modes.

Background

Recall from electromagnetic field theory that the solutions for the transverse components of the electric and magnetic fields in a waveguide with a uniform cross-section can be written as

$$\vec{E}_t = \sum_n a_n \vec{e}_n(x,y) e^{-\gamma z} + \sum_n b_n \vec{e}_n(x,y) e^{\gamma z} \quad (1)$$

$$\vec{H}_t = \sum_n a_n \vec{h}_n(x,y) e^{-\gamma z} - \sum_n b_n \vec{h}_n(x,y) e^{\gamma z} \quad (2)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Here the a_n and b_n are the intensities of the forward and backward traveling modal waves $\vec{e}_n$ and $\vec{h}_n$ are the transverse electric and magnetic field patterns. Note that the a_n and b_n are considered to be dimensionless quantities here, while $\vec{e}_n$ and $\vec{h}_n$ have the normal units for electric and magnetic fields. For this discussion's purpose, assume that each port is defined at z = 0; this permits the removal of exponential terms in the above equations.

Terminal Voltages and Currents

It is possible to define a set of voltages for a port by establishing a number of different integration paths across the port. If a port supports *N* quasi-TEM modes of propagation, one can set up *N* different open contours of integration, C_1, C_2, ... C_N, and define *N* different voltages, v_1, v_2, ... v_N, according to the integral formulas

Alternatively, you can define a set of currents **{**i_k**}**using a set of closed contours of integration **{**D_k**}**:

$$v_k = -\int_{C_k} \vec{E}_t \cdot \vec{dl} \quad (3)$$

$$i_k = \oint_{D_k} \vec{H}_t \cdot \vec{dl} \quad (4)$$

These closed contour paths are set when you define the terminals on a port. HFSS does not require you to set up the voltage integration paths separately. The software automatically infers the voltage paths from the chosen current contours using a power conservation relationship.

Each definition produces a set of relationships between the modal intensities and the voltages or currents. Since the total transverse fields can be expanded as a linear combination of modes, we can rewrite the previous equations as

$$v_k = -\sum_n a_n \int_{C_k} \vec{e}_n(x,y) \cdot \vec{dl} - \sum_n b_n \int_{C_k} \vec{e}_n(x,y) \cdot \vec{dl} \quad (5)$$

$$i_k = \sum_n a_n \int_{D_k} \vec{h}_n(x,y) \cdot \vec{dl} - \sum_n b_n \int_{D_k} \vec{h}_n(x,y) \cdot \vec{dl} \quad (6)$$

To simplify, introduce the following terms:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$t_{kn} = -\int_{C_k} \vec{e}_n(x,y) \cdot \vec{dl} \quad (7)$$

$$u_{kn} = \int_{D_k} \vec{h}_n(x,y) \cdot \vec{dl}. \quad (8)$$

Now v_k and i_k become

$$v_k = \sum_n a_n t_{kn} + \sum_n b_n t_{kn} \quad (9)$$

$$i_k = \sum_n a_n u_{kn} - \sum_n b_n u_{kn} \quad (10)$$

Since there are *N* possible voltage definitions and *N* quasi-TEM modes, there are *N*x*N* matrices that relate the terminal voltages and currents to the following modal intensities:

$$[i_k] = [u_{kn}]([a_n] - [b_n]) \quad (11)$$

$$[v_k] = [t_{kn}]([a_n] + [b_n]) \quad (12)$$

Now introduce the matrices $T = [t_{kn}]$ and $U = [u_{kn}]$ to represent these transformations. Note that the units of *T* are volts, while the units of *U* are amperes.

In summary, the **3D Post Processor** could be used to load different modal field patterns and manually perform the integrals defined previously over each terminal contour line. This would be a tedious and error-prone process, which HFSS's modes-to-terminals conversion feature eliminates.

Calculating the W-Elements

W-elements are a distributed model for transmission lines used in certain HSPICE-compatible circuit simulators. The W-element models in HFSS are computed from the 2D port solutions.

$$Z = R + j\omega L = \gamma * Z_0 \quad (1)$$

$$Y = G + j\omega C = \gamma * \text{inverse}(Z_0) \quad (2)$$

Extensions to the multi conductor case are possible but are beyond the scope of this discussion.

There are two flavors of W-element export in HFSS: Tabular and RLGC. (You see them in the Equivalent Circuit Export Options panel.) The more basic "RLGC" format fits the computed RLGC data to the model equations repeated below. For RLGC format RG parameters are frequency dependent such that HSPICE computes them as

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

R(f) = Ro + Rs * sqrt(f) (3)

G(f) = Go + Gd * f (4)

where Ro is the low frequency resistance and Go is the low frequency conductance. Rs and Gd represent the high-frequency asymptotes due to skin effect and loss tangent, respectively. L and C are assumed to be fixed over the frequency band.

Thus the "RLGC" format uses four matrices (Ro, Rs, Go, Gd) to model frequency dependence for R(f) and G(f), and it neglects the frequency dependence of L and C.

In contrast the "Tabular" format is not fitting the data to this simplified model: it is printing out the actual RLGC values at each frequency as computed by HFSS from the port solution.

Under some conditions, during W-Element export, HFSS may issue a warning that "One or more of the diagonal terms in the W-element <designated> matrix for some frequency are negative for a <specified port>." There may also be warnings if there are insufficient low-frequency points for the W- element data.

This signifies a non-physical result. A negative diagonal entry in the RLGC matrices indicates that the model is non-passive at that frequency (i.e., can produce energy, which is probably not realistic for a metal interconnect).

This can be caused by a number of things:

- Interpolating sweeps.
- Non-causal dielectric material models, such as the traditional constant loss tangent, constant permittivity dielectric model. The Djordjevic or Debye models in HFSS would be the preferred ones to use here.
- Allowing radiation boundaries on the ports.
- Solving to a very low frequency (one so low that the field solution from the full-wave solver contains significant numerical errors.) For frequencies under 10 MHz, you must have at least 10 sampling points per decade.

Terminal-Based Models for Circuit Analysis

It is possible to use the transformations developed above to compute terminal-based admittance (Y), impedance (Z) and pseudo-S-matrices (S_p). First consider the admittance case. A relationship of the form $i = Yv$ is needed that gives the vector of terminal currents $i = [i_k]$ as a function of the vector of terminal voltages $v = [v_k]$. It is known that

$$v = T(a + b) \quad (1)$$

and

$$i = U(a - b) \quad (2)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

It is also known that the incident and scattered modal amplitudes are related by $b = Sa$, where S is the modal S-matrix computed by HFSS. Therefore:

$$v = T(a + Sa) = T(I + S)a \quad (3)$$

$$i = U(a - Sa) = U(I - S)a \quad (4)$$

Here I denotes an identity matrix of the same size as S. i can then be solved for in terms of v by eliminating the incident wave variable a.

$$a = (I + S)^{-1} T^{-1} v \quad (5)$$

$$i = U(I - S)(I + S)^{-1} T^{-1} v \quad (6)$$

The terminal-based admittance matrix Y is identified from the above expression as:

$$Y = U(I - S)(I + S)^{-1} T^{-1} \quad (7)$$

A similar relationship can be developed for the terminal-based impedance matrix:

$$Z = T(I + S)(I - S)^{-1} U^{-1} \quad (8)$$

It is also possible to convert the terminal-based admittance and impedance matrices into a terminal-based "pseudo-S-matrix" S_p. To do this, a reference impedance matrix must be specified. Then standard formulas are used to convert the terminal impedance matrix Z into the terminal S-matrix

$$S_p = Z_{\text{ref}}^{1/2} (Z + Z_{\text{ref}})^{-1} (Z - Z_{\text{ref}}) Z_{\text{ref}}^{-1/2} \quad (9)$$

Z_{ref} can be either a user defined diagonal reference impedance matrix or the terminal characteristic impedance matrix, Zo, which is the matched case for terminal-based models.

The terminal S-matrix S_p relates the intensities of the incident and reflected pseudo-waves at the terminals.

$$\beta = S_p \alpha \quad (10)$$

These pseudo-waves are defined by:

$$\alpha = \frac{1}{2} Z_{ref}^{-1/2} (v + Z_{ref} i) \quad (11)$$

$$\beta = \frac{1}{2} Z_{ref}^{-1/2} (v - Z_{ref} i) \quad (12)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that the units of α and β are watts$^{1/2}$. The terminal voltages and currents can also be written in terms of the pseudo-waves.

$$v = Z^{1/2}(\alpha + \beta) \quad (13)$$

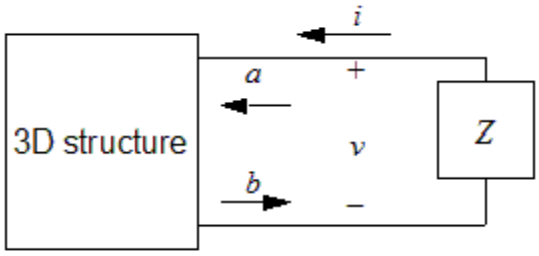
$$i = Z^{-1/2}(\alpha - \beta) \quad (14)$$

Unlike true waveguide modes, the pseudo-waves α and β have no associated propagation constant. The pseudo-waves represent linear combinations of several modes, which may all have differing propagation constants. HFSS is still capable of performing de-embedding on the terminal-based S-matrix, but this is accomplished by first de-embedding the modal S-matrix and then performing the transformation back to a terminal-based S-matrix.

For the normalization of terminal voltages in the Fields Post Processor, see **Scaling a Source's Magnitude and Phase**.

Terminal Characteristic Impedance Matrix

Consider the situation illustrated below. A 3D structure with one multi-mode waveguide port is loaded by an *N*-port matrix impedance *Z*. The structure contains internal sources, which generate outgoing waves that exit through the waveguide port and strike the impedance *Z*. If *Z* does not match the impedance of the waveguide in some sense, a reflection will occur from this load and will return to the 3D structure, where it is interpreted as an incident wave.



An optimal choice of *Z* will prevent any reflections from the load returning as an incident wave *a*. Note that the circuit equations at the load are $v = -Zi$ (the minus sign is due to the sense of the current *i*). By replacing the voltages and currents with their modal expansions, the voltage becomes

$$v = T(a + b) = -ZU(a - b) \quad (1)$$

Rearranging this to isolate *a* and *b*, it is determined that:

$$(T + ZU)a + (T - ZU)b = 0 \quad (2)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Now notice that if we select $T = ZU$; the incident wave a vanishes. Corresponding to this condition is an "optimal" choice Z_0 for the impedance Z:

$$Z_0 = TU^{-1} \quad (3)$$

Z_0 is the terminal characteristic impedance matrix for the multi-mode waveguide port. This value of impedance will completely absorb any linear combination of modal waves leaving the port. As such, it should be of interest to circuit designers wishing to control reflections. In the important, special case of a lossless waveguide, it can be shown that $Z_0 = TT^T$ is a real-valued, symmetric impedance matrix. It is then easy to synthesize a network of resistors with the specified matrix impedance.

Overview of the Technical Approach for Derivatives in HFSS

HFSS can compute the derivatives of S-parameters and related matrix quantities with respect to design parameters you have defined. The variables of differentiation could be geometric parameters, such as the length of a waveguide, or material parameters, such as the relative permittivity of a dielectric.

To make use of this feature, you must first create design or project variables and use them in the definition of an object or a material. You must also enable derivative calculation in the solution setup. After HFSS solves for the nominal value of an output quantity, for example S_{12}, it will also compute its derivative $\partial S_{12}/\partial p$ with respect to the parameter you defined.

There are several possible applications of derivatives. One use is to estimate how much the quantity of interest will change if the parameter is varied: $\Delta S_{12} \cong ((\partial S_{12})/\partial p)\Delta p$. Such an estimate can provide guidance on how to best choose a parameter value, or can help to decide which parameters require tighter control of tolerance. Another possible use is to compute the derivatives with respect to several design parameters to see which parameters are more effective in controlling the quantity of interest.

The basic approach in HFSS can be described as follows. For the nominal solution of a problem, HFSS forms a finite element matrix A and computes a solution vector x (containing fields and S-parameters) for a given excitation vector b. If the problem is parameterized, then the entries of the matrix depend on the design parameter p. The nominal problem is therefore a linear system of the form

$$A(p)x(p)=b$$

Now if we are interested in the derivatives of the solution quantities with respect to p, we can differentiate the original equation:

$$\partial A/\partial p \; x(p)+A(p)\; \partial x/\partial p=0$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

We have assumed here that the excitation vector b is independent of the design parameter. The derivative of the solution vector is then obtained by solving

$$A(p)\,\partial x/\partial p = -\partial A/\partial p\; x(p)$$

In practice, many problems in HFSS are analyzed with a direct matrix solver which computes an *LU* factorization of the matrix *A*. Once the *LU* factors have been obtained, it is very efficient to solve additional right-hand side vectors, such as the one produced in the derivative calculation above. We already have the solution $x(p)$ for the nominal problem, so to form the right-hand side vector the only additional requirement is the derivatives of the matrix entries with respect to p. In HFSS this is done analytically for the most part. Thus a matrix assembly algorithm has been crafted that fills $\partial A/\partial p$ in a manner similar to how *A* itself is filled.

It is worth mentioning that the derivatives of the matrix entries $\partial A/\partial p$ are computed analytically for the most part in HFSS. Therefore the computed derivatives of the output quantities are nearly exact. This should be contrasted with the alternative approach where the design parameter is perturbed from p to $p+\Delta p$ and a new solution $x+\Delta x$ is calculated by solving a new finite element system $A(p+\Delta p)$. That approach is computationally more expensive, because a new finite element system must be formed and factorized, and it is less accurate because $\Delta x/\Delta p$ is not a true partial derivative.

Some technical details on the implementation of derivatives in HFSS may be found in: "Sensitivity Analysis of S-parameters Including Port Variations Using the Transfinite Element Method", L. Vardapetyan, J. Manges, Z. Cendes, 2008 *IEEE International Microwave Symposium*, Atlanta, Georgia, June 2008.

Units for Calculated Derivatives

Note: The derivatives calculated by HFSS are dependent on the units of the design parameters. For example, if the design parameter p is originally defined with units of millimeters, then the value of the derivative gives the (linearized) change in the output quantity when p is varied by one unit (1 mm). If the units of p are changed to an equivalent value in micrometers, and the derivative is recomputed, then it will appear to drop in magnitude by a factor of 1000 because it now represents how much the output changes when p is varied by one unit (now 1 micrometer.) Therefore, when reporting derivative values it is necessary to record the units of the output quantity as well as the units for the variable of differentiation.

Best Practices for Accurate and Causal Broad Band Frequency Sweeps

This section presents practices applied in the Finite Element Method in order to extract accurate and causal broad band frequency sweeps when simulating Printed Circuit Boards (PCBs) and interconnects. The importance and treatment of metal traces of finite thickness, accurate DC

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

point, causal material models, causal surface roughness models and deembedding parasitic effects will be discussed and demonstrated by simulating real life problems.

Introduction to Causality Issues for Simulations

Signal integrity (SI) engineers are challenged to efficiently design and verify high-speed PCBs and interconnects by simulation. When working in the multi-GHz frequency range, simulation typically requires full-wave electromagnetic analysis. The Finite Element method (FEM) is the most common way to rigorously and accurately simulate 3D structures in a broad frequency range and extract the S parameters, which will then be used in a transient SPICE simulation as black boxes to predict the signals in the overall system. A critical consideration for these is the causality behavior of the resulting S-parameter models. Causality means that an output signal cannot start to change before the input signal changes. A necessary and sufficient condition for the causality is that the frequency domain transfer functions (S parameters) have to satisfy the Kramers - Kronig relations [1]. This technical note presents the best practices for getting accurate and causal solutions and not how to enforce causality of existing broad band S parameters. The Kramers - Kronig relationship will just be applied as a causality checker.

Physical Parameters Compared to Simulation

There might be two sources of the discrepancies between the physical parameters and the results of the simulation: one is the improper mathematical model used for the FEM calculations and the other is the numerical solution itself. Both discrepancies can result in causality violation. The paper focuses on the proper mathematical models. It is supposed that the adaptive mesh refinement has converged for the finite element solution, so the mesh is fine enough to approximate the exact solution well.

Modeling Issue: Solve Inside and Surface Impedance Boundaries

One of the most important modeling issues is how the solution should be treated in metals when the frequency range is broad. It is well known that the skin depth varies between infinity and very small value. A large skin depth typically necessitates solving the field inside the metal objects. This solve inside option is impractical for very small skin depths (high frequency), because a large mesh is needed to model the very strong decay of the field. A widely used method is to apply the infinite half space skin impedance as a Surface Impedance Boundary Condition (SIBC), replacing the solution inside the metal objects. It is accurate for high frequencies, MHz to GHz for typical interconnect and PCB geometries, but very inaccurate/unphysical for low frequencies when the finite thickness of the object approaches the skin depth δ, because the real part of the impedance goes to zero with decreasing the frequency instead of going to an appropriate finite DC value. An obvious option would be to combine two methods; apply solve inside at low frequencies and use SIBC at high frequencies. However problems would arise in the transition region, strongly violating causality by introducing jumps or non-physical smoothing. The paper presents a method, which uses the analytical impedances of the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

conductors with finite thickness in the whole frequency region. The method doesn't violate the causality, since the analytical formulas satisfy the Maxwell's equations and the DC point can also be approximated with arbitrary accuracy.

Modeling Material Properties

A common dielectric material model is to assume constant properties across the frequency range. However this is not a physical model of the loss mechanism in dielectrics and violates the causality of the results. Fitting a Debye or Djordjevic - Sarkar material model [3] to the input data will provide a causal model definition.

Modeling Surface Roughness

Another issue is how to take the loss mechanism of surface roughness into account. Two methods for obtaining causal surface roughness models will be presented and discussed in the paper.

When extracting S parameters of the system, ports are inserted into the simulation model. Ports won't introduce any error when they model perfect transmission line terminations, which is possible in FEM codes, unlike Method of Moment (MoM) codes, where so called port calibration is always necessary. In geometries where a transmission line port is not possible, the FEM method allows for non-transmission line terminations (e.g., lumped gap ports). Such a situation most often occurs when there is not even room for a complete transmission port in the design. The user is still interested in extracting S parameters as if the model was terminated by perfect transmission line wave ports. A method will be presented to deembed the parasitic effects introduced by using lumped gap ports.

If all the above mentioned techniques are used in a FEM extraction and the adaptive meshing procedures have converged within a reasonably small tolerance, the S parameters will be accurate and causal. Real-life problems will be presented to demonstrate this using Ansys HFSS, where all the techniques are implemented.

Surface Impedance Boundary Condition (SIBC) for Metal Traces of Finite Thickness

Surface Impedance Boundary Condition (SIBC) for Metal Traces of Finite Thickness

As previously noted, it is not recommended to solve inside of conductive objects in the whole frequency range. The task is to apply equivalent SIBC on the surface which result in the right circuit impedance in the whole frequency range. The derivations will be detailed for internal objects only.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

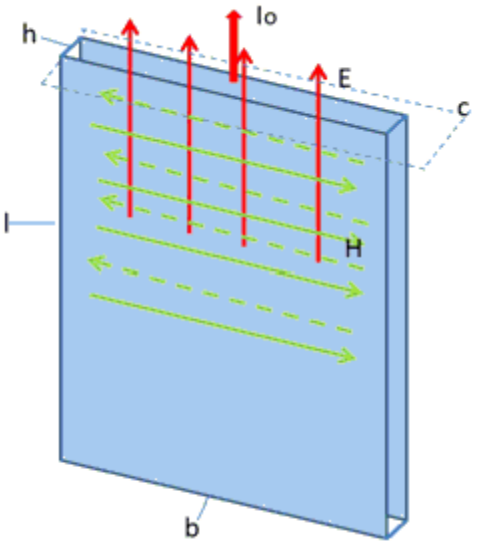

Figure 1: A conductor of finite thickness

Using the notations of Figure. 1 and applying Ampere's law, we get:

$$\oint_c H dc = I_o \qquad 2Hb = I_o \quad (1)$$

Integrating the Poynting vector over both sides of the object:

$$P = 2EHlb = I_o^2 Z_{circuit} \quad (2)$$

Then we get:

$$Z_{field} = \frac{E}{H} = 2Z_{circuit}\frac{b}{l} \quad (3)$$

Using the circuit impedance analytical formula from [5], the real and imaginary parts of the field impedance for the SIBC are:

$$R_{field} = \frac{1}{\sigma\delta c}\frac{sh(v) + \sin(v)}{h(v) - \cos(v)} \quad (4)$$

$$X_{field} = \frac{1}{\sigma\delta c}\frac{sh(v) - \sin(v)}{h(v) - \cos(v)} \quad (5)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Here $v=h/\delta$ and δ is the skin depth. The formulas satisfy the asymptotic conditions, namely at low frequencies and

$$R_{circuit_DC} = \frac{1}{\sigma h} \text{ at low frequencies and } R_{field_high_freq} = X_{field_high_freq} = \frac{1}{\sigma\delta} \quad (6)$$

at high frequencies. For outer surfaces, where the SIBC is applied to the outer boundary of the computational domain,

$$Z_{field} = \frac{E}{H} = Z_{circuit}\frac{b}{1} \quad (7)$$

$$R_{field} = \frac{1}{\sigma\delta}\frac{sh(2v)+\sin(2v)}{ch(2v)-\cos(2v)} \quad (8)$$

$$X_{field} = \frac{1}{\sigma\delta}\frac{sh(2v)-\sin(2v)}{ch(2v)-\cos(2v)} \quad (9)$$

Using SIBC, the solution, including the extrapolated DC point, will be more accurate because the DC behavior is modeled accurately. Also the causality is not violated because the analytical formulas satisfy the Maxwell's equations. Experimental data shows that FEM with low frequency treatment can cope with structures when the ratio of the average mesh size and the wave length is 10-10. Assuming a PCB with 1um average mesh size. It allows us to solve down to 300 Hz.

Using Causal Material Models

Using Causal Material Models

Using causal dielectric material models is one of the most important considerations to extract causal S parameter models. Causal material model means that the real and imaginary parts of the permittivity should satisfy the causality relationship (causal magnetic materials are not discussed here).

The most general material model is the multipole Debye model [3]:

$$\varepsilon_r(\omega) = \varepsilon'_\infty + \sum_{i=1}^{N}\frac{\Delta\varepsilon_i}{1+j\frac{\omega}{\omega_1}} - j\frac{\sigma}{\omega\varepsilon_o} \quad (10)$$

It is applicable when we have information about the permittivity and the loss tangent of the material in the frequency range, such as when measured material data are available. Single pole

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Debye model is also a good approximation when just polarization losses are present and the polarization frequency is known:

$$\varepsilon_r(\omega) = \varepsilon_{r_optical} + \frac{\varepsilon_{r_static} - \varepsilon_{r_optical}}{1 + j\frac{\omega}{\omega_{pol}}} \quad (11)$$

In other cases, especially when the permittivity and loss tangent are known at only one or two frequencies, the broad band Djordjevic - Sarkar (D-S) material model can be used:

$$\varepsilon_r(\omega) = \varepsilon_{r_optical} + \frac{\varepsilon_{r_static} - \varepsilon_{r_optical}}{m_2 - m_1}\frac{\ln\frac{\omega_2 + j\omega}{\omega_1 + j\omega}}{\ln 10} - j\frac{\sigma}{\omega\varepsilon_o} \quad 12$$

where

$$\omega_1 = 10^{m_1} \qquad \omega_2 = 10^{m_2}$$

are the limits of the frequency range. The D-S model can also be viewed as a multipole Debye model with an infinite continuum of poles.

Using causal material models leads to frequency dependent complex materials, which is standard in most finite element codes.

Surface Roughness Modeling

Surface Roughness Modeling

Surface roughness plays an important role in accurately modeling radio frequency components (RFC), such as resonators and signal integrity projects (e.g., microstrips, printed circuit boards (PCBs)). The increase of the surface resistance due to surface roughness results in lower quality factor (Q) in resonators and higher insertion losses for microstrips and PCBs. The scale of the roughness is different in the different application areas so different surface roughness models are used. The common theme in the different models is that an effective frequency dependent conductivity is defined depending on the type and magnitude of the roughness, which shows the increase of the surface resistance compared to the smooth surface resistance.

For HFSS and HFSS 3D Layout designs, Groiss [6] or Huray [2] surface roughness models may be employed, the latter being a complex-value-based causal modification of the original real-

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

value-based model. For SIwave and 2D Xtractor designs, the original Hammerstad-Jensen [4] or modified Huray [2] model may be employed.

Impedance at a rough surface is higher than the impedance at a smooth surface by a factor $\boldsymbol{fact_R}$ as shown in the general equation below:

$$Z_{rough} = Z_{smooth} * fact_R \quad (13)$$

where Z_{rough} is the impedance at the rough surface and Z_{smooth} is the impedance at the smooth surface.

For the **Groiss** model, the surface roughness factor is given by the equation:

$$fact_R = 1 + e^{-\left(\frac{\delta}{2s}\right)^{1.6}} \quad (14)$$

where δ is the skin depth and s is the surface roughness.

> **Note:**
>
> The Groiss surface roughness model is not causal, and therefore, it is only suitable for frequency-domain computations, not for the time-domain.
>
> Additionally, you can see, from equation (14), that the maximal roughness factor is 2. So this model is only applicable to RFC problems when the surfaces are highly polished to avoid lower Q. A surface roughness model of higher losses is necessary to model the fabrication effects in PCBs, where the roughness of the deposited metal is considerably higher.

The alternative modified **Huray** [2] surface roughness model, available in the Ansys Electronics Desktop software, is a complex-value-based causal model that is suitable for both frequency-domain and time-domain computations. It also overcomes the factor of 2 limitation of the Groiss model, as it supports rougher surfaces with factors greater than 2:

Refer to the Technical Note: Huray Surface Roughness Model for the equations and definitions that are applicable to this model.

The Huray roughness factor adjusts the surface impedance in the same manner as shown in equation (13) except that the roughness factor variable is referred to as $\boldsymbol{H_c}$ instead of $\boldsymbol{fact_R}$. (15)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

All SIBCs depend on the material conductivity too, because the skin depth varies with conductivity.

Deembedding Parasitic Port Effects

Deembedding Parasitic Port Effects

Figure 4 shows a strip line that is fed by internal lumped ports instead of perfect wave ports. The FEM simulation was performed using these excitations and resulted in the entire scattering matrix, *S**. The goal is to calculate scattering matrix *S* (scattering matrix of the DUT), as if the structure were fed by perfect virtual ports. It can be done if S matrices of the transition or error boxes are known ($S^{(1)}$and $S^{(2)}$ in Fig.2). When **b* =S*a*** is known and **b=Sa** is sought, we get:

$$\mathbf{S} = [\langle \mathbf{C}_{bb} \rangle + \mathbf{S}^* \langle \mathbf{C}_{ab} \rangle]^{-1} [\mathbf{S}^* \langle \mathbf{C}_{aa} \rangle - \langle \mathbf{C}_{ba} \rangle] \tag{16}$$

where

$$\langle \mathbf{C}_{aa} \rangle, \langle \mathbf{C}_{ab} \rangle, \langle \mathbf{C}_{ba} \rangle, \text{and } \langle \mathbf{C}_{bb} \rangle$$

are diagonal matrices:

$$\mathbf{C}^i{}_{aa} = \frac{1}{S_{21}{}^{(i)}}; \quad \mathbf{C}^i{}_{ab} = \frac{S_{22}{}^{(i)}}{S_{21}{}^{(i)}}; \quad \mathbf{C}^i{}_{ba} = \frac{S_{11}{}^{(i)}}{S_{21}{}^{(i)}}; \quad \mathbf{C}^i{}_{bb} = S_{12}{}^{(i)} - \frac{S_{11}{}^{(i)} S_{22}{}^{(i)}}{S_{21}{}^{(i)}} \tag{17}$$

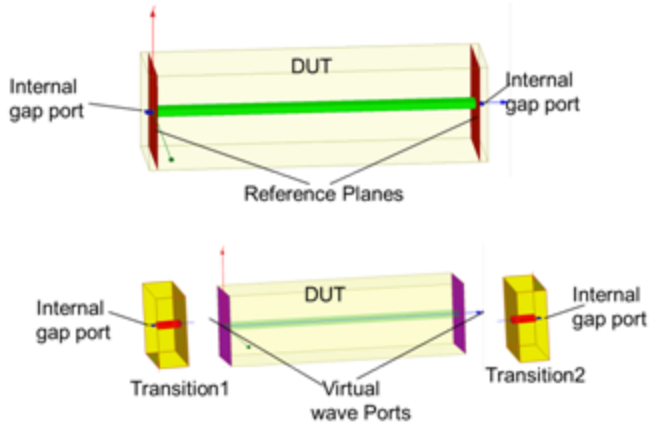

Figure 4: Strip line (DUT) fed by two internal lumped ports

Using Circuit Ports Does Not Change the Deembedding Analysis

Figure 4 shows a strip line, which is fed by internal lumped ports instead of perfect wave ports. Using circuit ports would not change the deembedding analysis.

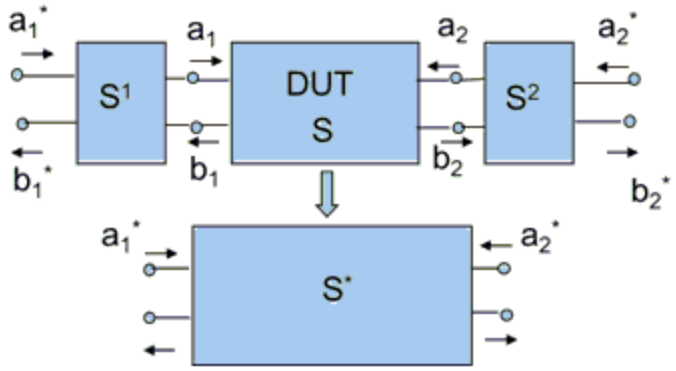

Figure 5: Black boxes of a strip line fed by two internal lumped ports

Usually, the device under test (DUT) is very large and complex. It is not possible to create perfect wave ports inside the complex geometry. However, it is not necessary to do that, when using the proposed method. The transition boxes can be independently created and solved as very small, 3D projects with two ports. In that case, the method is exact, within computational errors. In simple cases, *S* matrices of the transition boxes can be estimated, (for example, by a series impedance). The simplest case is when a lumped gap port is represented by a "parasitic" inductance. Applying experimental approximations for the calculation of the partial inductance of a lumped gap port ([7], [8]):

(18)

$$L = \frac{\mu_0 len}{2\pi}\left[\ln\left(u+\sqrt{u^2+1}\right)+u\ln\left(\frac{1}{u}+\sqrt{\frac{1}{u^2}+1}\right)+\frac{1}{3}\left(u^2+\frac{1}{u}-\frac{(u^2+1)^{3/2}}{u}\right)\right]$$

Where:

Input: w = width of the lumped port [m]

len = length of the lumped port[m]

u = len/w

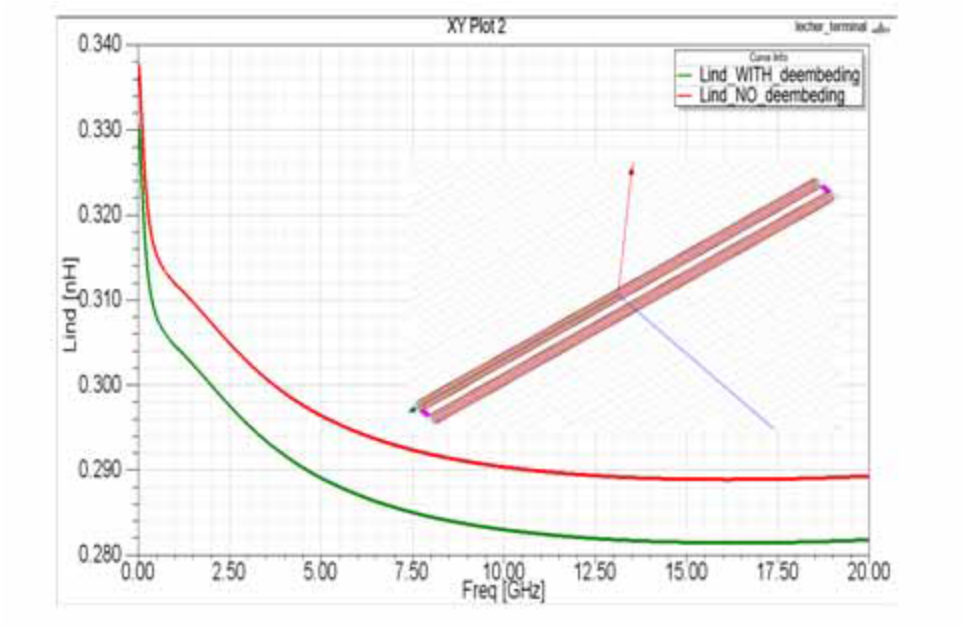

Figure 6: Loop inductance of a pair of cylindrical wires with and without deembedding the parasitic gap port inductance

Conclusions

New numerical constructs are developed for the causal modeling of transient signals in PCBs and interconnects. By introducing the correct treatment of metal traces of finite thickness, accurate DC point solution, causal material models, causal surface roughness models and deembedding parasitic effects of lumped ports, result in accurate and causal broad band frequency sweeps of S parameters. Using these techniques in a finite element code generates accurate and causal simulations provided the mesh is converged to reasonably small tolerance. The techniques described here are implemented in Ansys HFSS. Real-life problems were solved to demonstrate the efficacy of the methods.

Determining PCB Material Properties: Q2D and Nexxim Measurements for HFSS Simulation

This technical note describes how to determine Printed Circuit Board Material Properties (PCB) by using Ansys Electronics Desktop Q2D and Nexxim measurements for accurate simulation with HFSS. The necessary PCB properties are:

- Dielectric Constant (ε_r)
- Loss Tangent ($\tan\delta$)
- Metal Conductivity (σ)
- Surface Roughness Parameters (Hall-Huray Parameters)

In order to obtain the proper values for HFSS Simulation:

- Use the Beatty Standard to characterize loss
- Use proper calibration, or de-embedding to get to actual structure

Use Ansys Q2D and Nexxim to match the measured data.

- Use the properly de-embedded Device Under Test (DUT)
- Use Ansys Q2D to quickly vary the material properties
- Use Nexxim to cascade different line sections together to build the DUT

Validate the Extracted Parameters with HFSS Simulation

The Beatty Standard and its Use

What is the Beatty Standard? as drawn from Reference [1]

- A series resonator between two lines of characteristic impedance Z_0.

- Z_0 length of line is 0.25 inches. Z_B length of line is 1 inch.

How it performs:

- The resonator will have a periodic response because of transmission line effects
- S_{11} maximums (and S_{21} minimums) will also be λ/2 apart
- S_{11} minimum to maximum (and S_{21} maximum to minimum) will be λ/4 apart

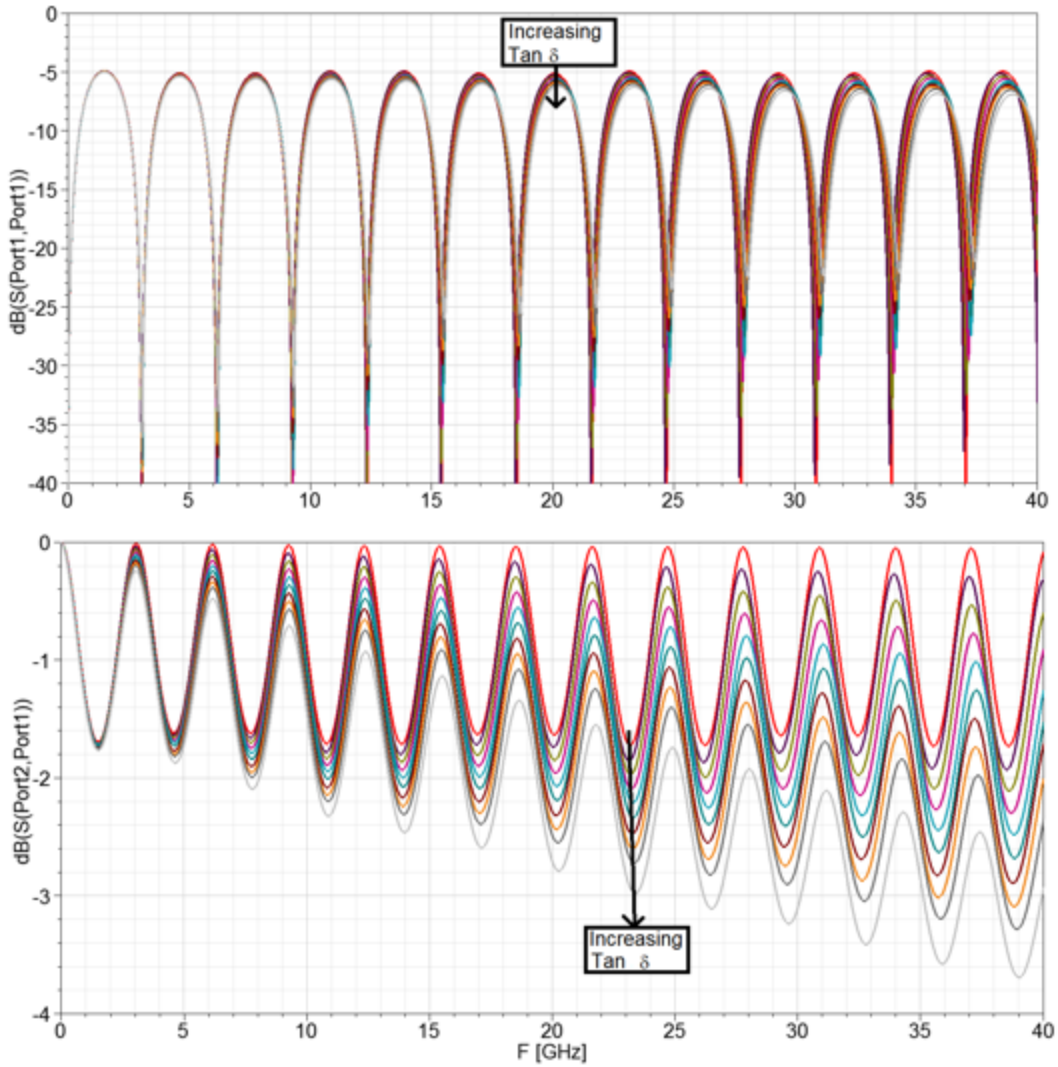
$5.7x10^7$	0.068127
$5.8x10^7$	0.067817
$5.9x10^7$	0.067518
$6.0x10^7$	0.067228

What about Loss Tangent?

The plots shows a change in shape due to substrate loss.

- We know metal conductivity from DC value, so change tan to get loss to match. Sweep from 0.001 to 0.01.
- Less change at “low frequency” and more “high-frequency” loss with tanδ

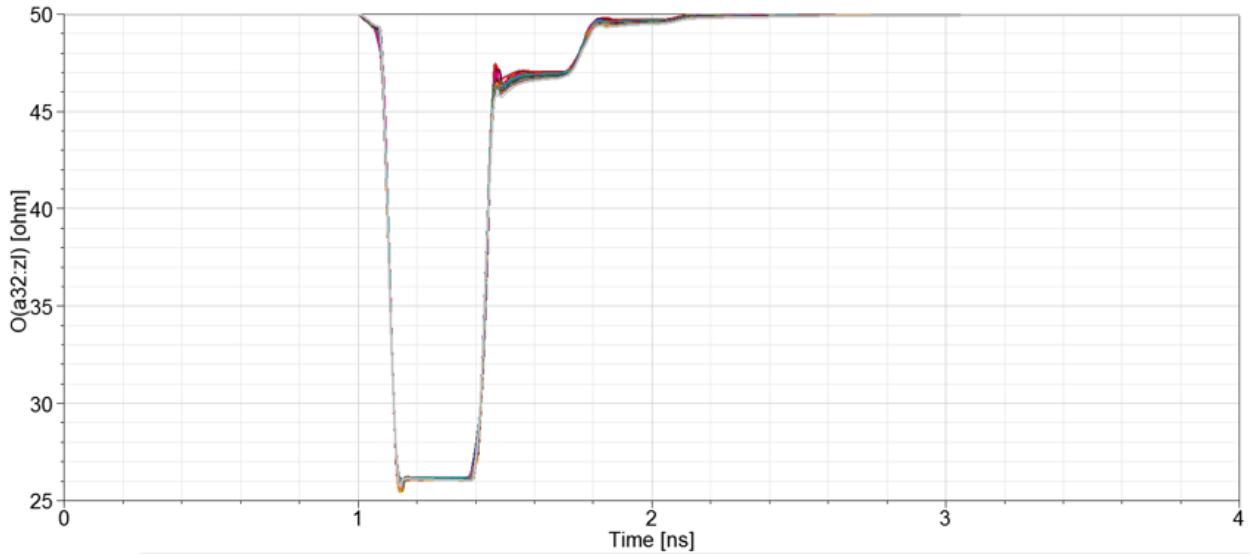
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Now Look at TDR for Loss Tangent

This shows a change in shape due to substrate loss, with little change in TDR.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

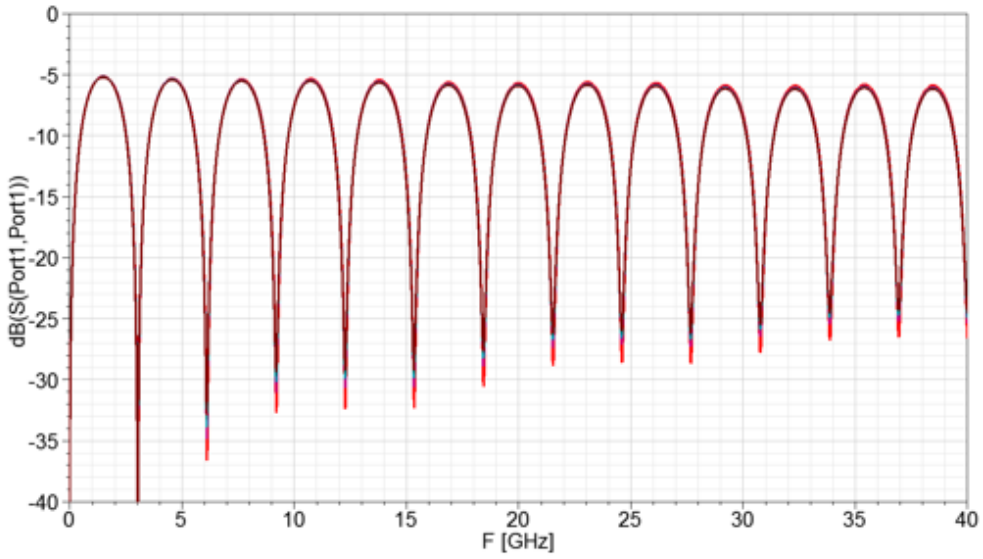


What about Surface Roughness?

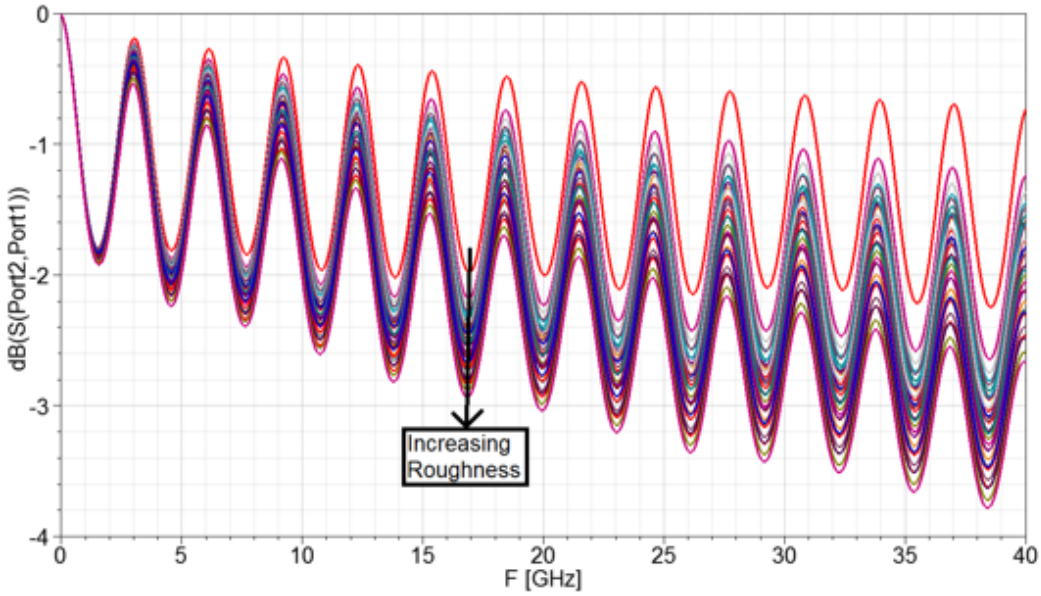
This plot shows a change in shape due to roughness.

- Similar loss as loss tangent at high-frequency.
- More loss at low frequency. Match low frequency first with surface roughness.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



S_{11}



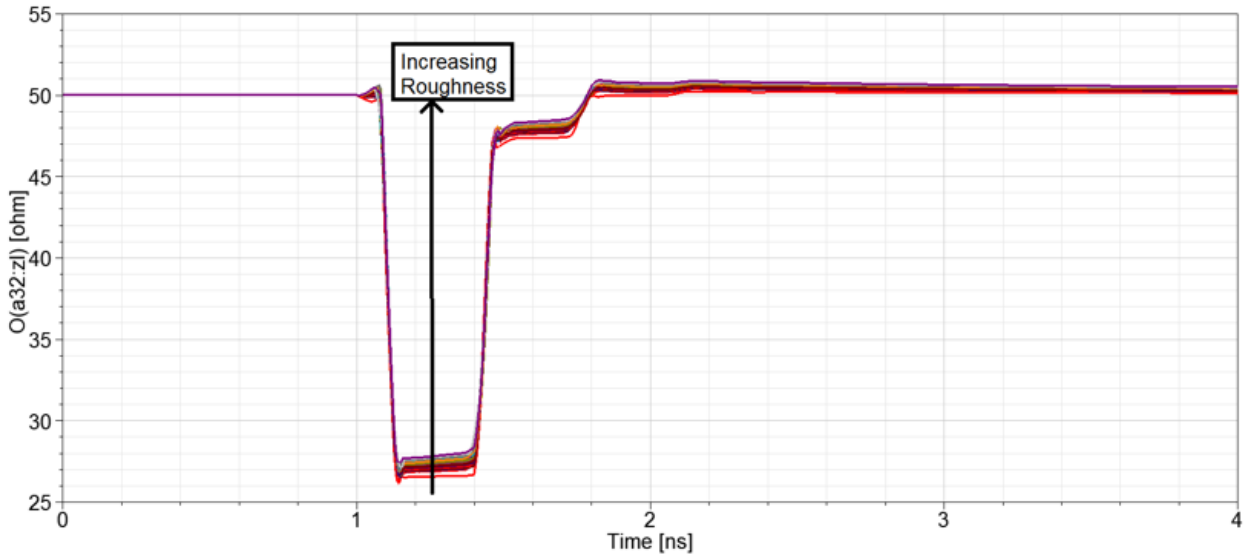
S_{21}

Now Look at TDR for Surface Roughness

The plot shows change in shape due to roughness.

- More change in impedance compared to changing loss tangent.
- May be important to separate roughness from substrate loss.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Observations so Far

- Change ε_r to match spacing between maxima and minima.
- Look at very low frequency (ideally DC) to match conductivity
- Look at “low frequency” to match Surface Roughness
- Look at “high frequency” loss to match Loss Tangent after Surface Roughness is matched.
    - Look at TDR plot to help separate loss if not obvious from Frequency Domain data

Not Looking at:

- Changing line and substrate dimensions
    - Restricting variables to tune for loss
    - Need to verify all the thickness, widths, and any etch with cross-section
- Phase Information and Group Delay
    - To verify propagation time if needed for fine tuning

What Have We Haven’t Looked At

- Changing line and substrate dimensions
    - Restricting variables to tune for loss
    - Need to verify all the thickness, widths, and any etch with cross-section
- Phase Information and Group Delay
    - To verify propagation time

Next

De-embedding of the Design Under Test from Test Fixture

De-embedding of Design Under Test from Test Fixture

This section describes de-embedding, that is the impact of the test fixture on the measurement result is removed from the measurement data thereby allowing characterization of the device under test (DUT). This is accomplished by means of:

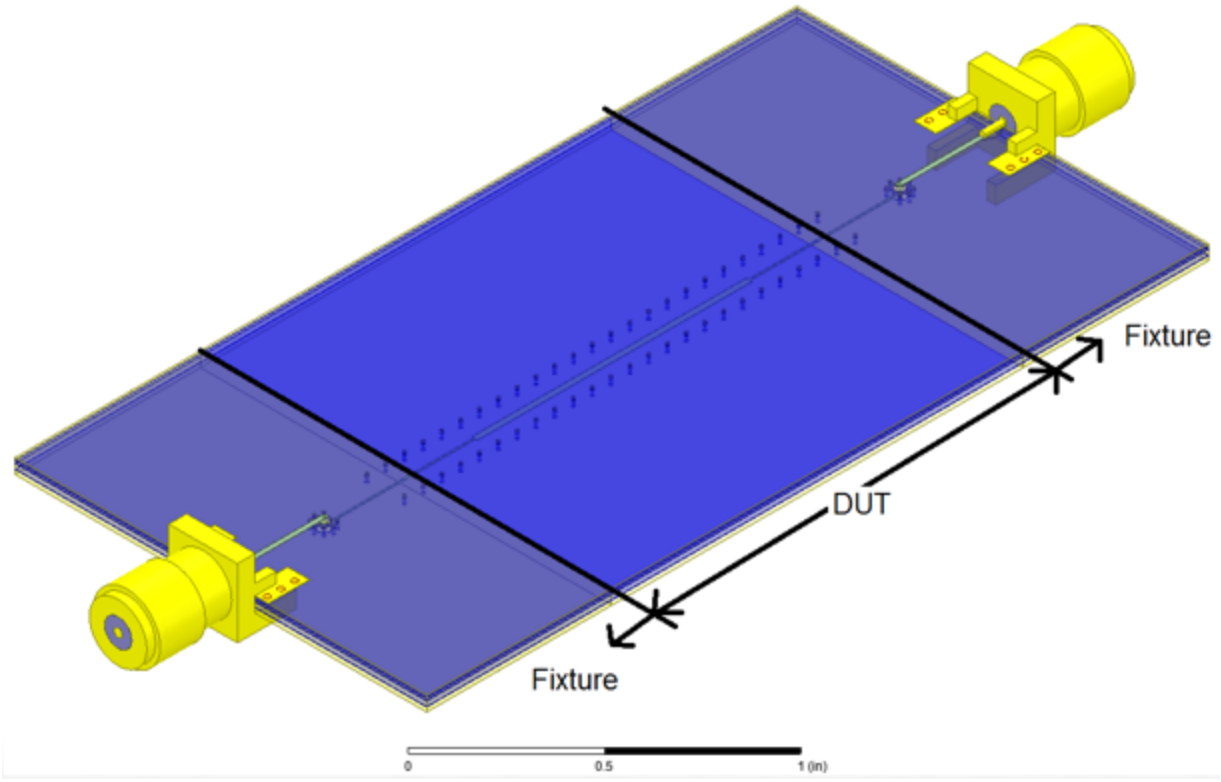
- Custom Calibration Kit
- YZ De-embedding
- Modeling and Simulation
- Automatic Fixture Removal (AFR)

Illustration of Fixture and Device Under Test (DUT)

The total structure includes the following:

- CAD drawing of the Fixtures and Device Under Test (DUT)
- We want the response of just the DUT, but we can only measure at coaxial connectors.
- Notice that the Fixtures are identical. While not necessary, this makes the de-embedding a little easier.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



De-embedding: Custom Calibration

This section describes how you can make a calibration kit on your PCB. In this case, we use Short-Open-Load-Thru (SOLT). You can also use a variant called Short-Open-Load-Reciprocal (SOLR), sometimes called Short, Open, Load, Unknown Thru. The process needs well-defined standards which can be difficult to get at high frequency.

We also use a technique called Use Multiline Thru-Reflect-Line (TRL) described in Reference [3].

- Use multiple Lines to get required bandwidth as each line can only cover a line whose electrical length is between 200 and 1600
- Used by National Institute of Standards and Technology (NIST)
- Can take a lot of space to get lines long enough for low frequency measurements

While there are many other calibration methods, with well defined standards, this is an excellent choice. It can be difficult to make, and characterize, standards at a necessary reference plane.

De-Embedding: YZ De-embedding Described in Reference [4]

This approach is used mainly for on-die (i.e. on-wafer) measurements.

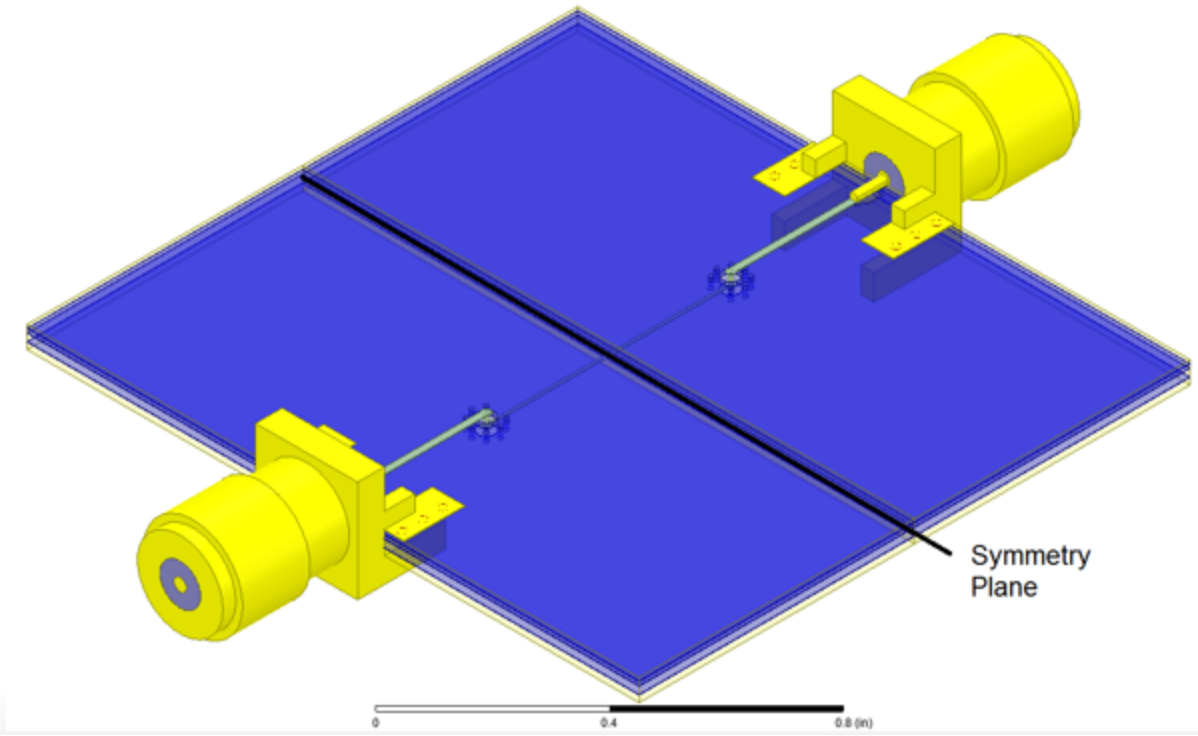
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Measure an Open Standard (i.e. the Y-standard)
- Measure a Short Standard (i.e. the Z-standard)
- Convert the measured device, with fixture, to Y-parameters and subtract Y-parameters of Open. Call this $Y_{Yremove}$. Also, remove the open standard from the Z-standard.
- Convert $Y_{Yremove}$ to Z-parameters and subtract the Z-parameters of the Y-corrected Short Standard. The result is the de-embedded DUT.
- Assumes that the Fixture is electrically small.
- Easy to have electrically small structure on-die, but harder to do on PCB.

De-embedding: Modeling and Simulation

To perform the de-embeding for Automatic Fixture Removal (AFR as described in Reference [5]):

1. Concatenate the Fixture.
2. Make symmetric (as this is much easier).
3. Measure 2X Thru. Use this structure



4. Create circuit model of each fixture half and concatenate as well

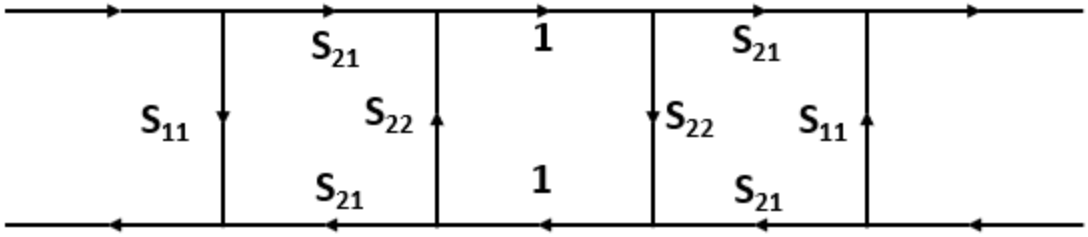
- Use Lumped Element
- Or Distributed
- Match of model to measurement must be excellent, or you will introduce error

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Simulate with full-wave solver like HFSS.
   - You need to know surface roughness, dielectric properties, etc.
   - Match in S-parameters needs to be excellent, or you will introduce error.

Using Signal Flow Graphs (see References [6, 7]), we can model the 2X Thru.

- Notice the S-parameters in each half.
- 2X Thru has symmetry. Also, S_{21}=S_{12} since they are reciprocal.



These are the S-parameters we are looking for, but we are measuring the 2X Thru, so we only know:

- $S_{11,2X_THRU}$=$S_{22,2X_THRU}$=S_{11} since symmetric
- $S_{12,2X_THRU}$=$S_{21,2X_THRU}$=S21 since reciprocal

So, solve these equations

$$S_{11,2X_THRU} = S_{11} + \frac{S_{22}S_{21}^2}{1 - S_{22}^2} \qquad S_{21,2X_THRU} = \frac{S_{21}^2}{1 - S_{22}^2}$$

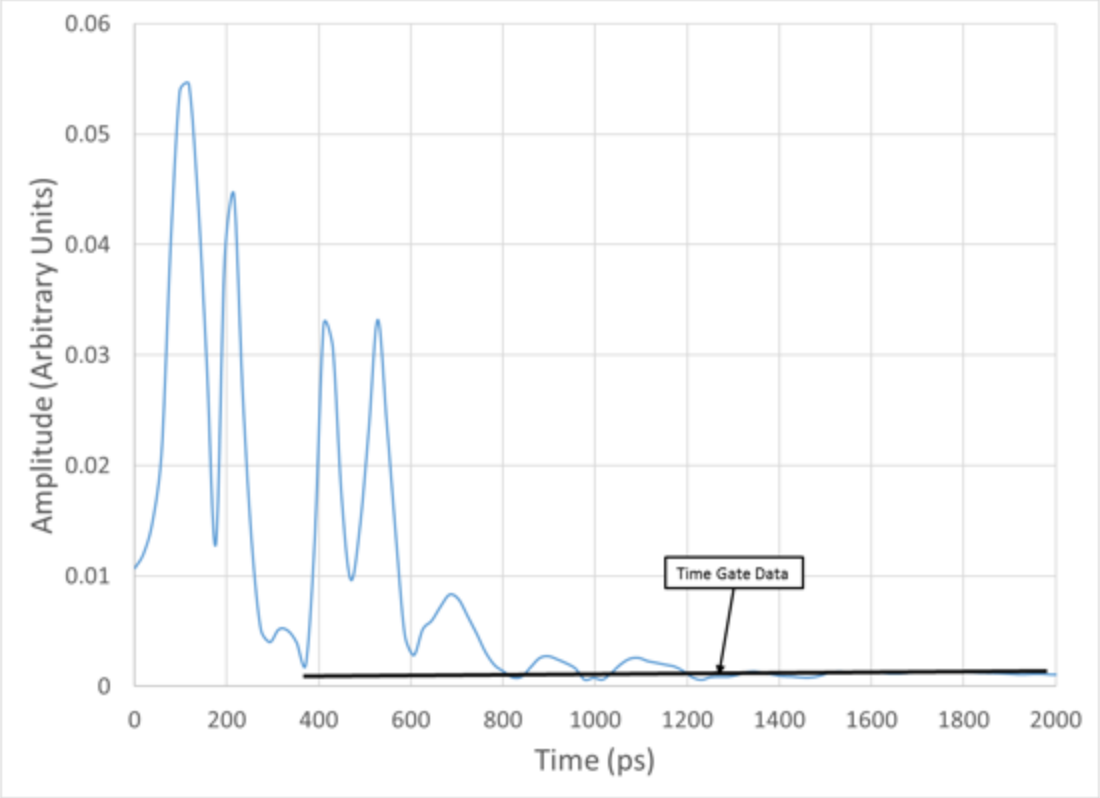
This gives us two equations with three unknowns.

Use time gating to learn S_{11}.

- Take inverse Fourier Transform of $S_{11,2X_THRU}$
- At half-way point in time, set level to that of a matched termination.
- Take Fourier Transform of gated data
  - This is S_{11} of the Signal Flow Graph
  - Now you have two equations and two unknowns to find S_{21} and S_{22}
  - Recall square root of complex number is (in mag/ang format):
  - $\sqrt{Magnitude}\angle\ \theta/2$

Solving is outside the scope of this chapter, but once solved you have the fixtures.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



With S-parameters of the fixture

- Use ABCD parameters described in *Reference [6]* to remove fixture effects from measured data to get DUT
- Can use T-parameters described in *Reference [7]* as well.
- Or, use Nexxim with Reciprocal option to de-embed the data for you.

Next

Example of Determining PCB Material Properties: Q2D and Nexxim to HFSS

Example Determining PCB Material Properties: Q2D and Nexxim to HFSS

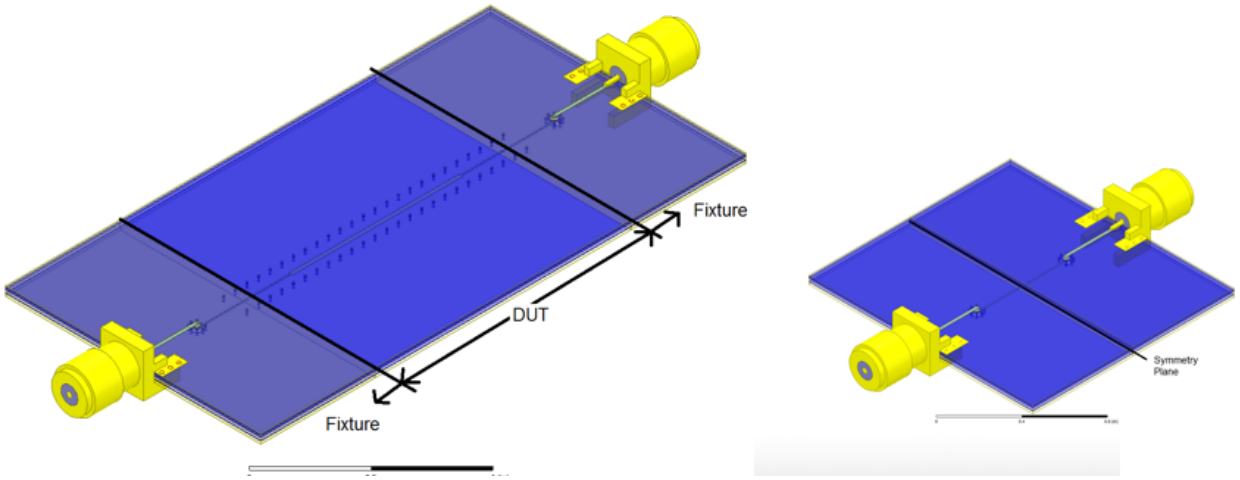
This section describes the procedure for determining the PCB material properties that will be used for an HFSS simulation of a PCB.

Beatty Structure

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- 7 mil wide, 0.25in long 50 ohm line, with 1.4 mil thick trace and 8 mil dielectric above and below. A stripline
- 21 mil wide, 1 inch long line, with 1.4 mil thick trace and 8 mil dielectric above and below. A stripline.

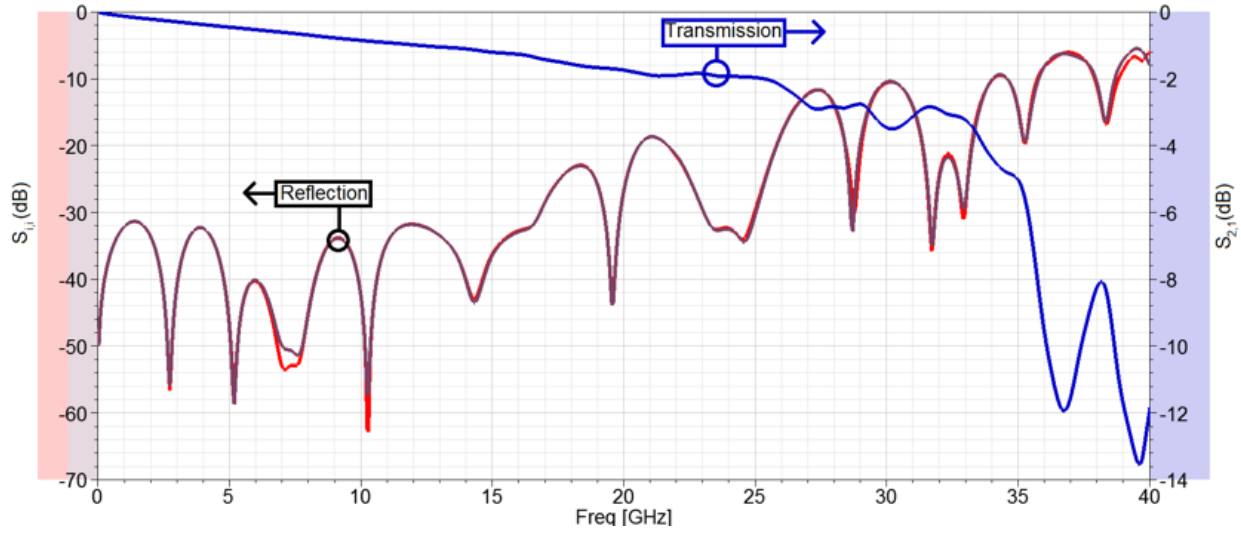
Fixture is a coaxial connector with a via transition down to the stripline.



Note: The Full structure is simulated in HFSS. It is called “Measured” to illustrate that this will typically be measured data

Look at 2X Thru S-parameters. There is a Good response until ~35 GHz.

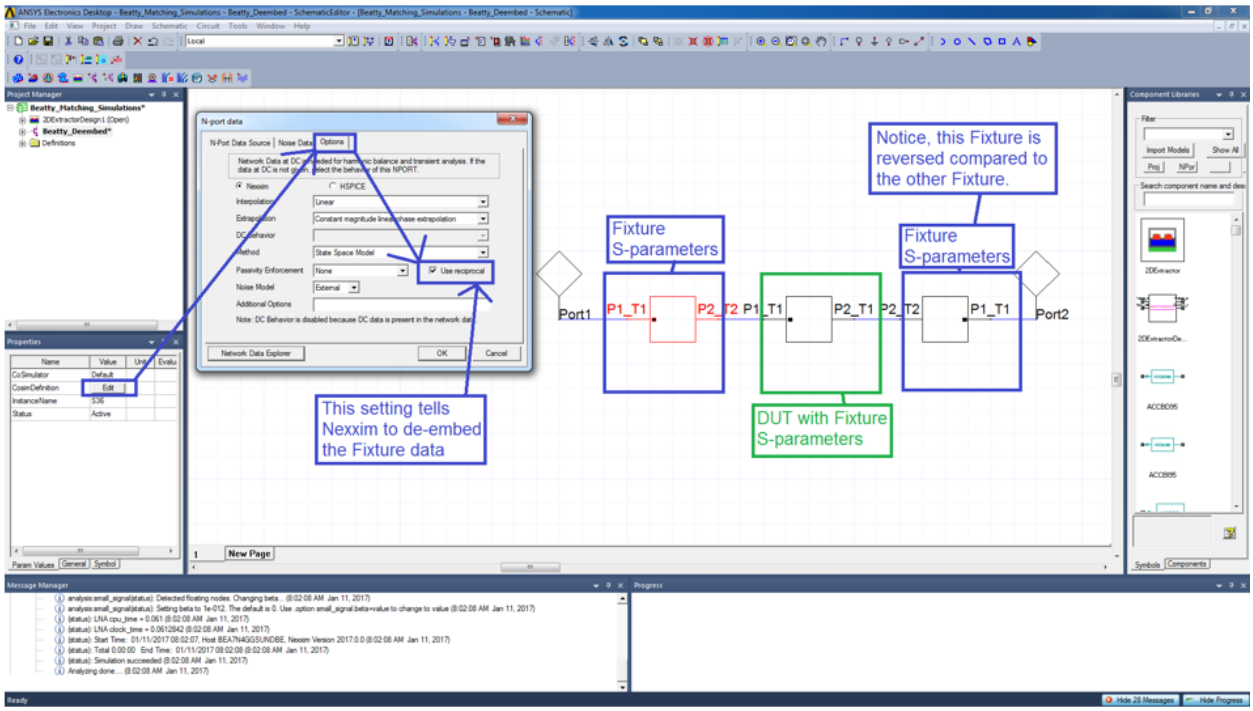
- De-embedding will be questionable above this frequency
- Still good for the “lower” frequency data.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

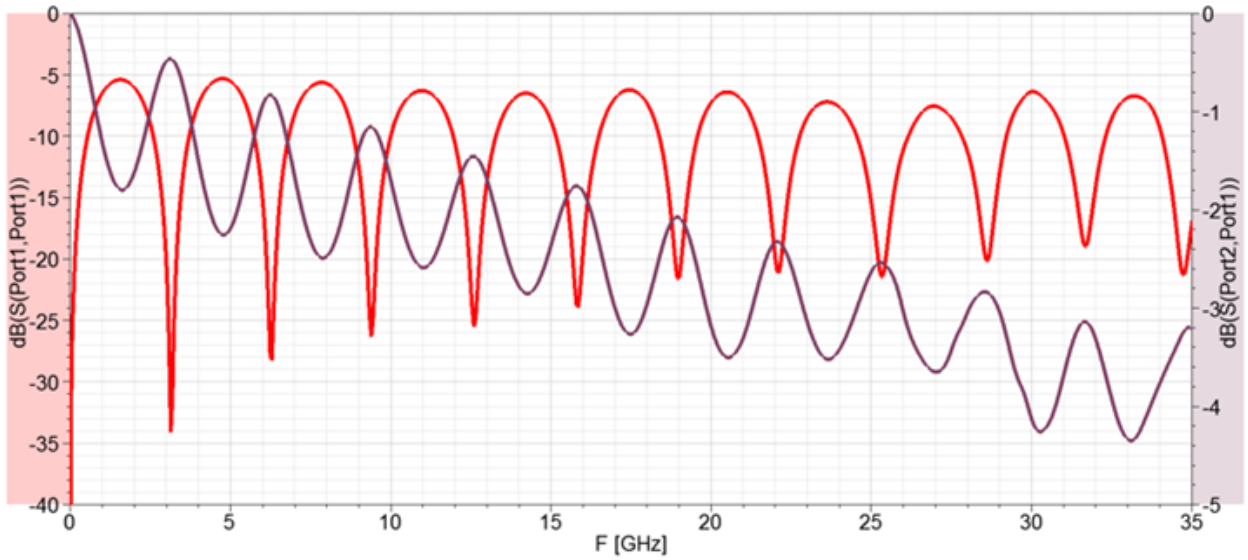
De-embed in Nexxim

- Get Fixture S-parameters using Automatic Fixture Removal (AFR as described in Reference [5]).
- Cascade Fixture S-parameter block (with reciprocal turned on) with measured data to get just the Design Under Test (DUT).



De-embedded Results in Nexxim. We clearly see the resonances

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Q2D Model

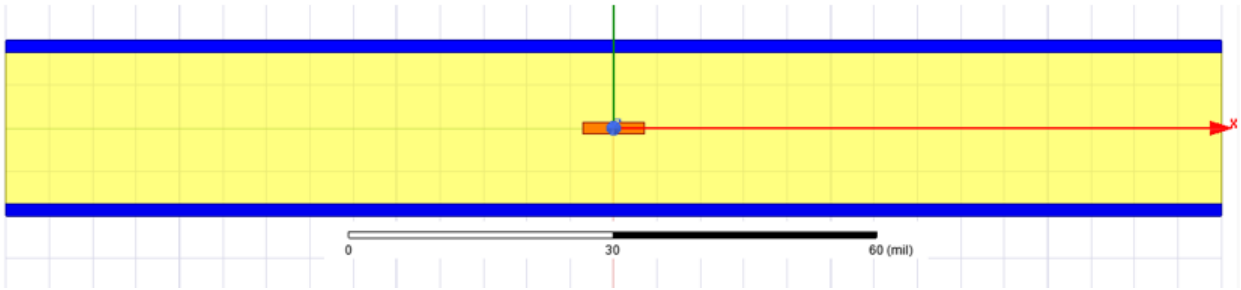
Now make Q2D model of the transmission lines and perform circuit simulations with Nexxim

Fully Parameterized so we can optimize response to extract material properties.

- Width, thickness
- Metal conductivity and surface roughness: Roughness assumed the same on top/bottom of trace and on two GND planes
- Dielectric constant and loss tangent.

Fix the following because they were measured:

- Line width is 7 mils (for 50 Ω sections) and 21 mils for Beatty Section
- Metals are all 1.4 mils thick
- Total substrate thickness (from Top GND to Bottom GND) is 17.4 mils.

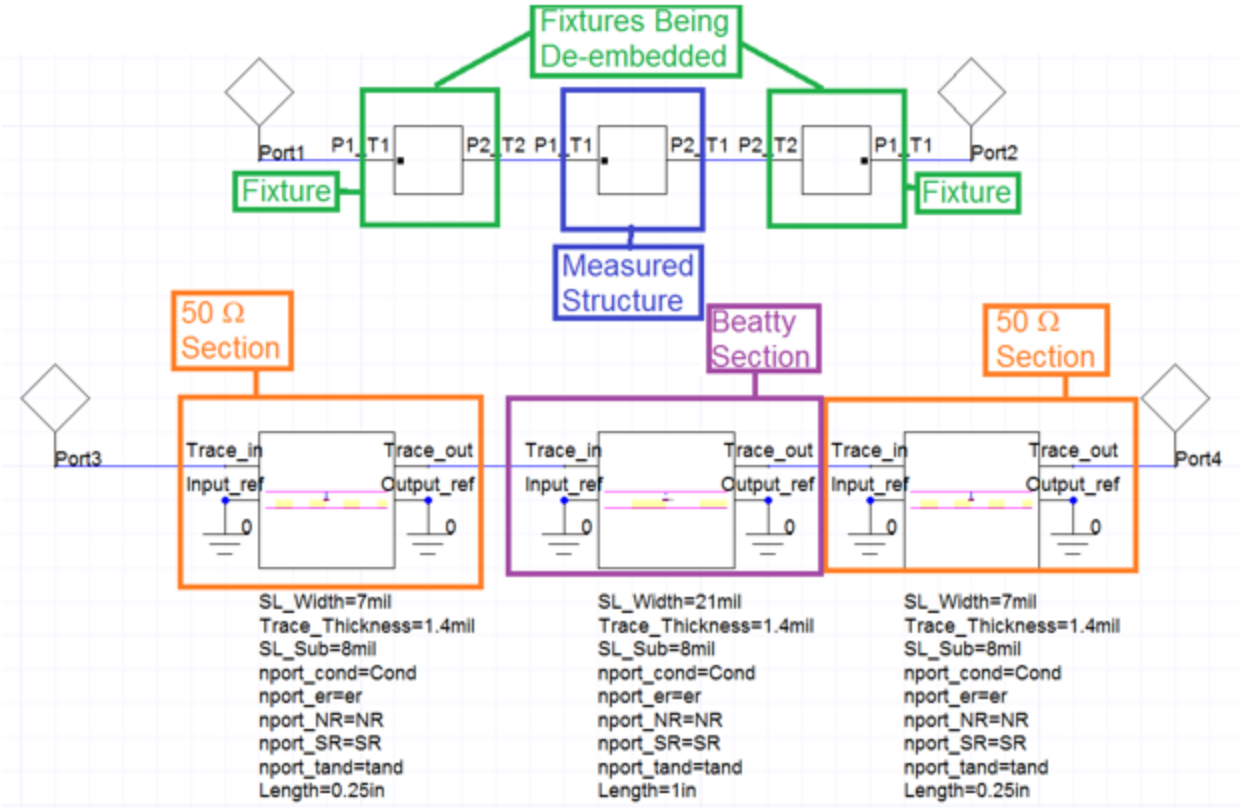


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Nexxim with Q2D Model

Run the Q2D model in Nexxim with the following to compare to our measured results.

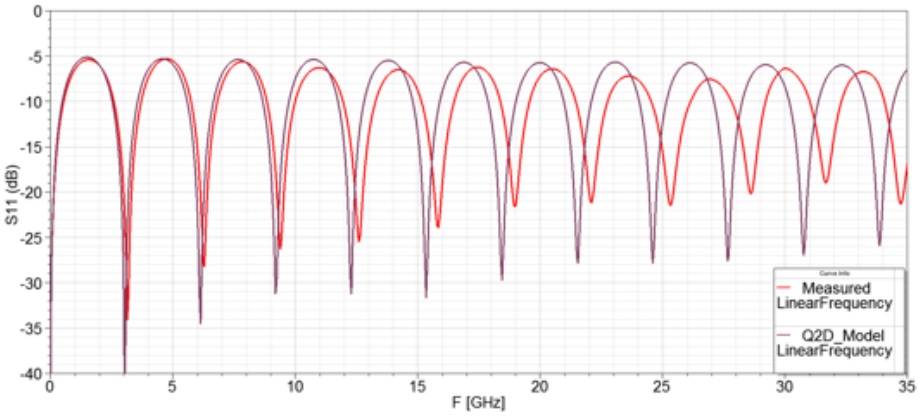
- Copper Conductivity = 5.8×10^7 S/m
- Dielectric Constant = 3.66
- Loss Tangent = 0.004
- Hall-Huray Nodule Radius = 0.4 um
- Hall-Huray Surface Ratio = 1.9



Nexxim Model Results

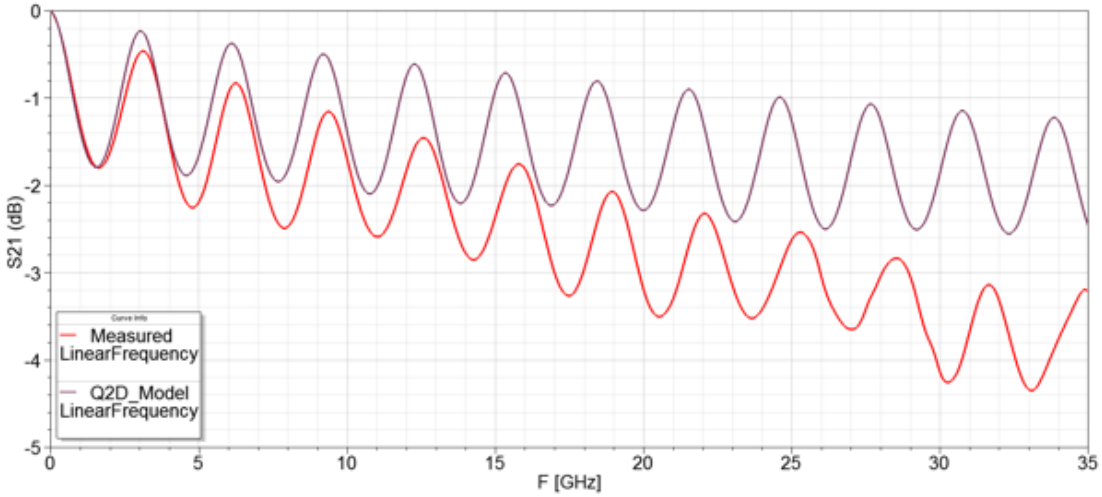
Notice the Q2D model does not match

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



S_{11}

Measured is "Red"



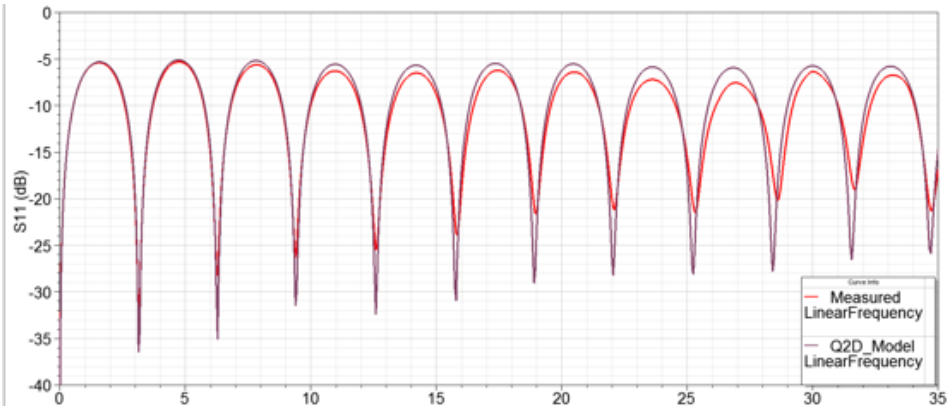
S_{21}

In Nexxim, you need to make ε_r lower so that the maxima/minima are further apart

Nexxim Model with Changed ε_r

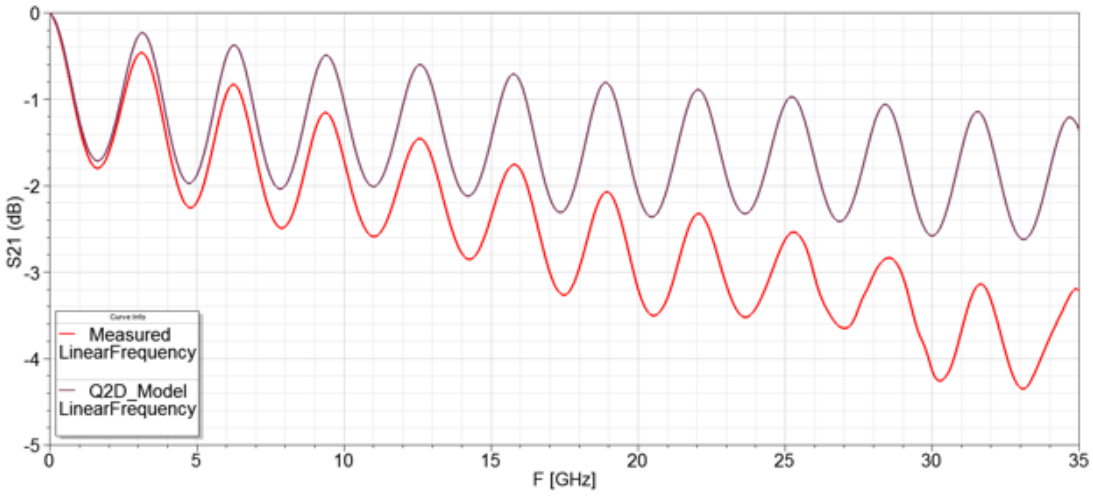
Use Optimetrics to automatically sweep ε_r. Notice ε_r =3.48 is best.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



S_{11}

Measured is "Red"



S_{21}

Now look at DC Resistance

Nexxim Model, Changing Conductivity

Use Optimetrics to automatically sweep Conductivity.

Notice is closest $5.0x10^7$ S/m. This has very little impact on results.

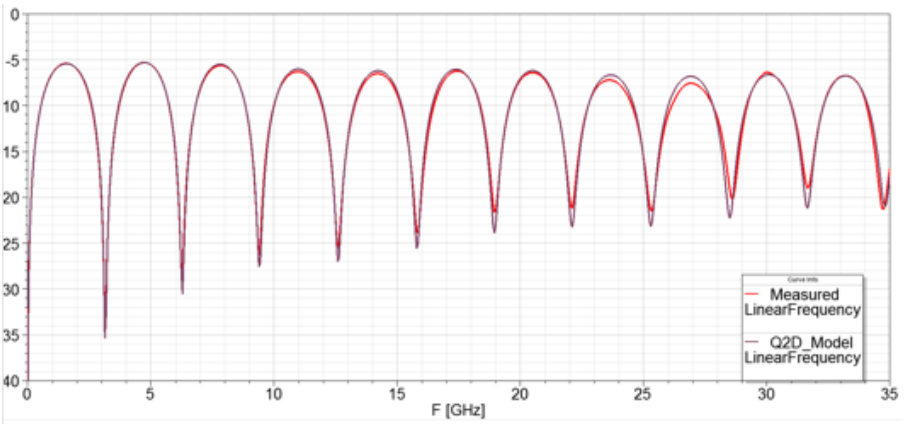
Conductivity (S/m)	DC Resistance (Ω)	Measured Resistance (Ω)
$5.0x10^7$	0.070643	0.070691
$5.1x10^7$	0.070241	
$5.2x10^7$	0.069855	
$5.3x10^7$	0.069483	
$5.4x10^7$	0.069125	
$5.5x10^7$	0.068780	
$5.6x10^7$	0.068448	

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Conductivity (S/m)	DC Resistance (Ω)	Measured Resistance (Ω)
$5.7x10^7$	0.068127	
$5.8x10^7$	0.067817	
$5.9x10^7$	0.097518	
$5.10x10^7$	0.067228	

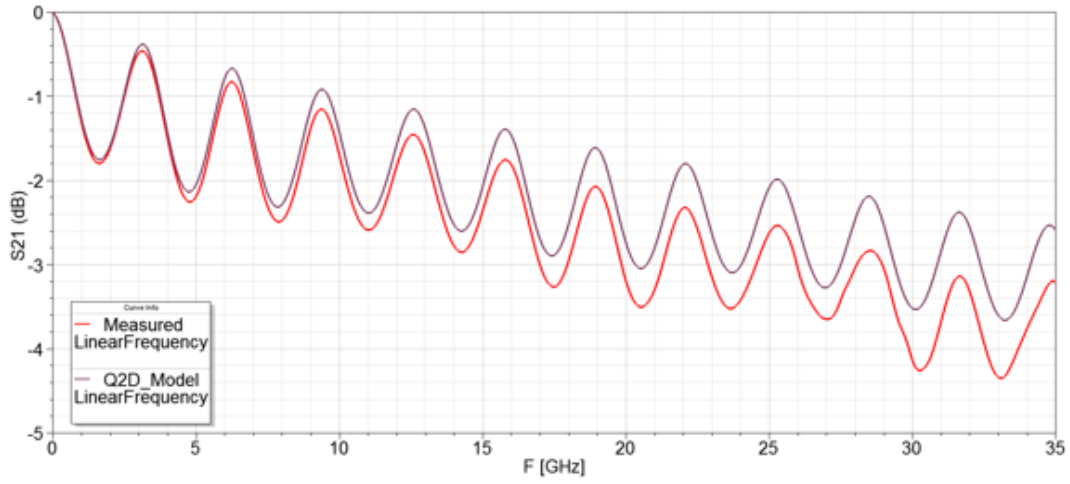
Observations So Far

- We have determined ε_r =3.48 and conductivity of the metal is $5.0x10^7$ S/m
- Add more roughness to make loss match in lower part of band.
- Use Optimetrics to automatically sweep Nodule Radius and Surface Ratio
- Nodule Radius = 0.5um and Surface Ratio = 2.9 appears to be best fit.



S_{11}

Measured is "Red"



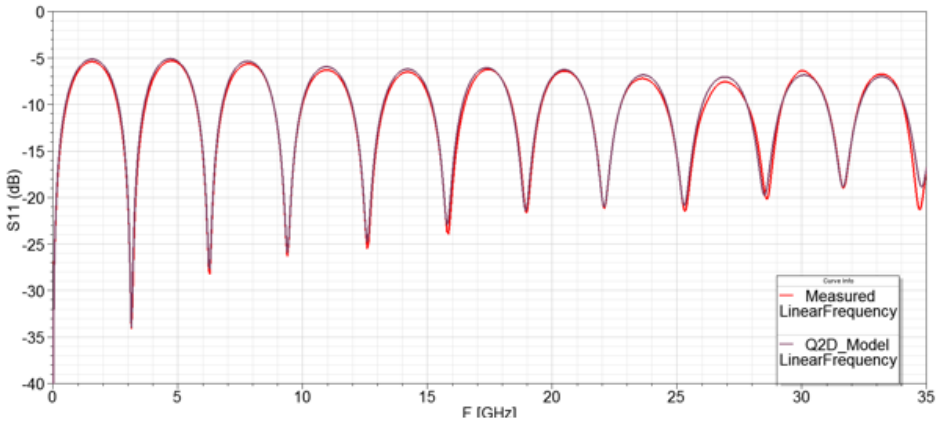
S_{21}

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Change Loss Tangent

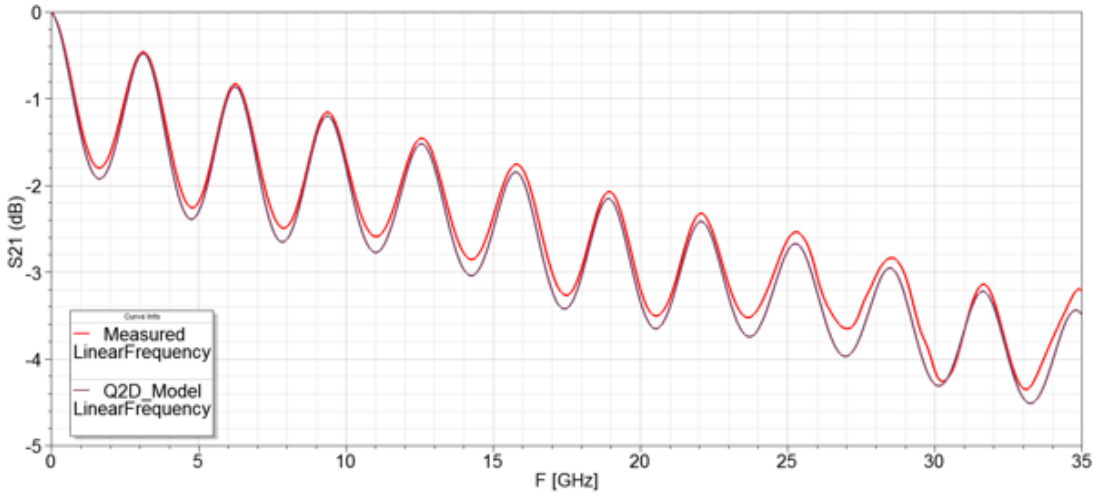
Use Optimetrics to automatically sweep Loss Tangent.

Loss Tangent = 0.008 appears to be best fit at high frequency.



S_{11}

Measured is "Red"



S_{21}

Final Values from Nexxim and Q2D

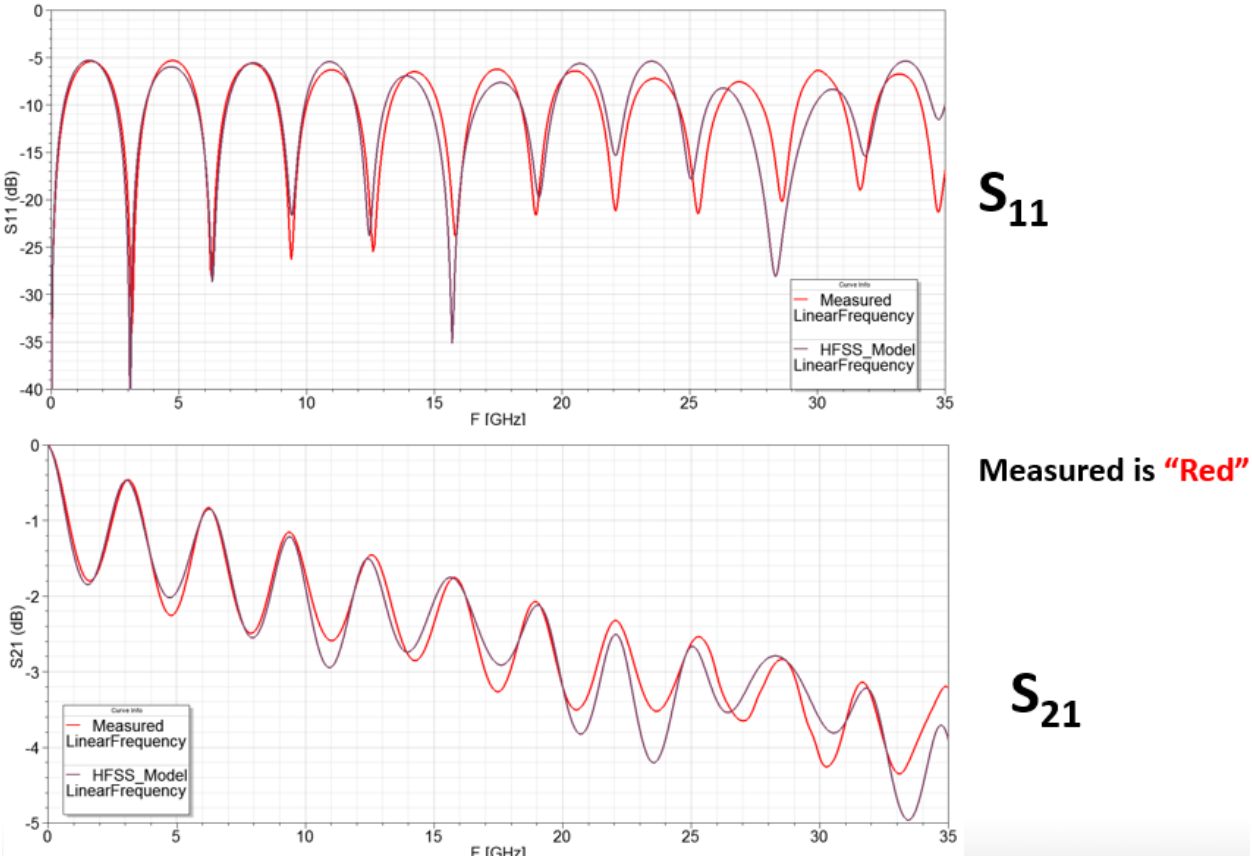
The final tuning gives:

- Copper Conductivity = 5.0×10^7 S/m
- Dielectric Constant = 3.48
- Loss Tangent = 0.008
- Hall-Huray Nodule Radius = 0.5 um
- Hall-Huray Surface Ratio = 2.9

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can use Optimizer to match S-parameters as well. The goal of this example is show how each parameter changes the response in order to build your intuition in using them.

Compare HFSS Simulation with Extracted Parameters



Final Tuning Values

- Copper Conductivity = 5.0×10^7 S/m
- Dielectric Constant = 3.48
- Loss Tangent = 0.008
- Hall-Huray Nodule Radius = 0.5 um
- Hall-Huray Surface Ratio = 2.9

Summary of the Method for using Nexxim and Q2D to Determine PCB Parameters for HFSS

- Use the Beatty Standard to characterize loss
- Use proper calibration, or de-embedding, to get to actual structure.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Use Q2D with Nexxim
    - Deembed using Nexxim
    - Quickly (in seconds) simulate variations of line to match measured data
- Validate extraction with HFSS simulations
    - Ideally have multiple structures to measure and simulate to verify parameters.

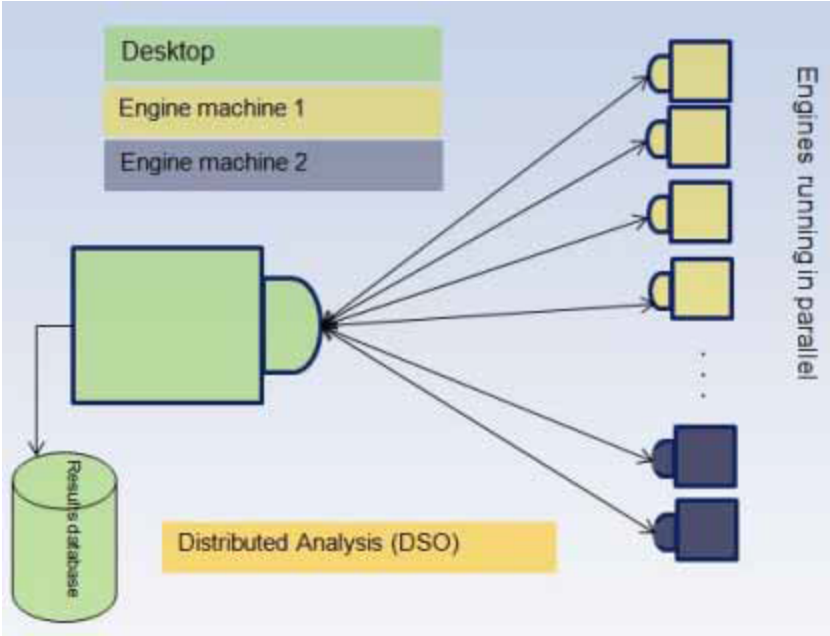
Large Scale DSO Theory

The parametric analysis command in Desktop computes simulation results as a function of model parameters, such as geometry dimensions, material properties and excitations. The parametric analysis is either performed on a local machine, where each variation is analyzed serially by a single engine, or distributed across machines through a DSO license. Desktop's DSO analysis runs multiple engines in parallel, thus generating results in a shorter time. In the Regular DSO algorithm, the parametric analysis job (Desktop) runs on master node, which in turn launches one or more distributed-parallel engines on each machine allocated to the job. Desktop distributes parametric variations among these engines running in parallel. As variations are solved, the progress/messages and variation results are sent back to Desktop, where they are persisted into the common results database on master node, as illustrated below:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



A single engine can now span multiple machines with auto multi-level DSO.

Regular DSO Bottleneck

As per above illustration, Regular DSO's speedup is limited by the resources of the centralized 'Desktop' bottleneck. It's been observed that DSO becomes unreliable at a certain point, as the number of engines and number of variations is increased. The term 'large scale parallel' can be used to define this tipping point. For a given model, a 'large-scale parallel' job denotes scenarios, in terms of the number of distributed-parallel engines and the number of parametric variations, where the Regular DSO runs into centralized bottlenecks that result in one or both of: progressively smaller speedups, unreliability.

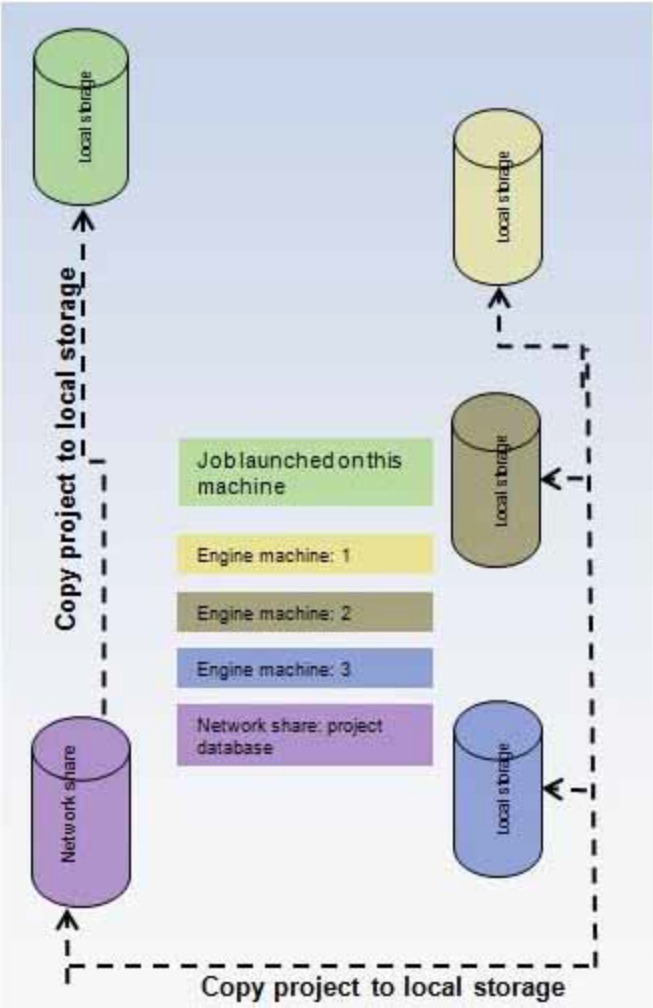
With the advent of economical availability and timely provisioning of compute resources, product designers have access to large compute clusters to run their simulations. And they are throwing larger and larger number of compute resources at simulation jobs, in order to obtain results faster. The parametric DSO needs to meet this challenge and target linear speedup for 'large-scale parallel' jobs. The Large Scale DSO feature is targeted toward 100% reliability and linear speedup of large-scale parallel DSO jobs.

Key Algorithms/Concepts for Large Scale DSO

- **Embarrassingly Parallel algorithm**: Large Scale DSO exploits the embarrassingly parallel nature of parametric runs. The solve of each variation is made fully independent of another variation, by replacing Regular DSO's centralized database with per-engine distributed databases
- **Distributed databases**: For each distributed-parallel engine, the database of the input model is cloned to local storage of engine's compute node (as illustrated in the following

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

picture). Parallel analysis is performed on these cloned models and the analysis results also go the corresponding location on local storage. As each engine has it's own database, there is no 'shared database' contention between any two engines. There is negligible network traffic as analysis/computations are contained in a single machine and use just the 'local resources'.



- **Hierarchical activation of engines**: In the Large Scale DSO algorithm, engine activation is done hierarchically, where the overhead of launching of engines is also shared across the nodes. Such hierarchical activation improves reliability of the activation phase of large-scale parallel jobs. A new 'desktopjob' program encapsulates hierarchical activation, as illustrated in the following pictures. In this approach, the 'root' desktopjob (Root DJ) activates a 'level-one' child desktopjob (DJ(L1)) for each unique node allocated to the DSO job. Each level-one desktopjob activates one or more 'leaf' desktopjobs (DJ(L2)) equal to the number of distributed engines per node. A leaf desktopjob in turn runs Desktop in batch mode, to perform local-machine parametric analysis to solve the variations assigned to this engine.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Decentralized Load balancing:** A parametric table is divided into regions of equal number of variations, with the number of regions equal to the number of engines. In the following illustration, the analysis of 30 parametric variations is distributed among 5 engines. Each engine solves it's assigned region as a 'local machine' parametric analysis. Large Scale DSO job is considered done once all engines are done with their assigned variations.
- **Distributed results postprocessing**: As engine is done with the solve of a variation, it extracts results for the solved variation before progressing to the analysis of next variation. The extracted results are saved to the local storage. When the engine is done with analysis of all variations, the extracted results are transferred from local storage to the results folder of the input project.

Redistribution Feature

Large Scale Distributed Solve Operation could submit a parametric setup to be solved in multiple machines, each machine may launch multiple EM-Desktop processes to solve the assigned variations(Design Points). Variations are distributed to each task(EM-Desktop process) equally, regardless of the machine hardware and each variation's complexity. That may resultin some tasks finishing earlier than others, in some extreme case some tasks may hours behind fastest task.

Now, redistribution occurs when a task finished its own assignment, it calls back to the L2 to ask for new assignment, L2 forward the request to L1, L1 forward it to L0, L0 may pick one of the slow task to remove some variations or return with no more assignment. When a task is picked to remove unsolved variation, L0 calls L1(may be different L1), L1 forward it to the selected L2, L2 makes a request to the EM-Desktop to remove some variations from its queue. EM-Desktop returns the removed variation indexes, or error code if it fails. In L0 if error is returned, it marks the selected task failed to respond the remove request, to void picking it again. L0 returns the result through L1-L2 back the EM-Desktop.

The Ansys Electronics Desktop will enqueue the new assignment and then start solving those new variations. If the return data indicates error, it makes another call to L2 to get new assignment. If no more variations return, the Ansys Electronics Desktop finishs the simulation and exit.

Geometric Objects

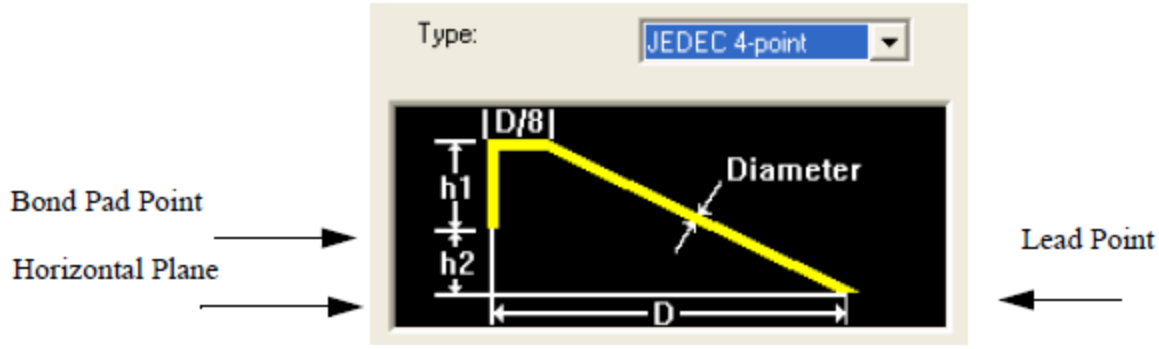
Following are supplemental technical details about working with geometric objects and complicated models:

- Bondwires
- Braided Shield Models for Cable Modeling
- Detecting and Addressing Model Problems to Improve Meshing
- Handling Complicated Models

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Bondwires

A bondwire is a thin metal wire that connects a metal signal trace with a chip. You can choose to draw a standard **JEDEC 4-point** bondwire, as shown below:



where

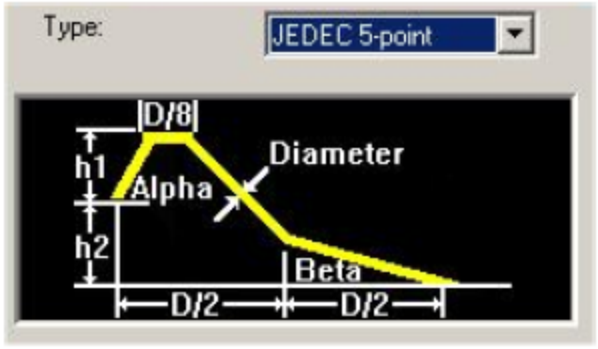
h1 = the height between the bond pad point and the top of the loop.

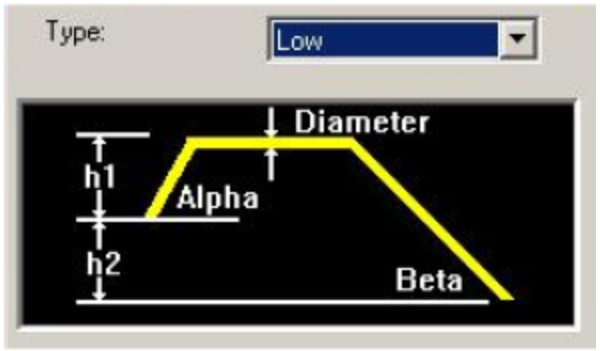
h2 = the height between the lead point and the bond pad point.

diameter = thickness of the wire.

D = the distance between the start and end points, and D/8 is the distance divided by 8.

Or you can choose to draw a **JEDEC 5-point** or **Low** bondwire, as shown below:





where

α = the angle between the horizontal plane and the wire at the bond pad point.

β = the angle between the horizontal plane and the wire at the lead point.

D = the distance between the start and end points, D/2 is the distance divided by 2, and D/8 is the distance divided by 8.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When drawing the bondwire, you first select the bond pad point, a point in 3D space that defines the bond pad position in a horizontal plane. Then you select the lead point, which indicates the distance the wire covers in the horizontal plane. HFSS will use the distance between the bond pad and lead points to calculate the height between the bond pad and the lead point, or *h2*, a value that you can modify in the **Bondwires** dialog box.

For the JEDEC types, notice that the horizontal distance on the wire is calculated as the total length divided by 8. (This horizontal distance is shown in the JEDEC 4 and 5-point figure as "D/8.") For the Low type, the horizontal distance is affected by the Alpha and Beta values as well as the length.

Braided Shield Models in Cable Modeling

The Cable Modeling feature includes an option for braided shields. This section provides technical details on the Kley model used in Cable Modeling.

Definitions

The following definitions are used throughout:

N	number of wires per carrier
C	number of carriers (belts) in the braid
α	weave angle of the braid
d	diameter of individual wires
D_0	diameter under the braid
P	number of “picks” (carrier crossings) per unit length
σ	conductivity of the braid
f	frequency in Hz
$\omega=2\pi f$	frequency in rad/sec

Kley’s Model

Kley further defines

$D_m=D_0+2.5d$	average braid diameter
$G_0=NCd/(2\pi D_m$	“minimal” fill factor
$F=G_0/\cos\alpha$	fill factor (Kley uses G for this)
$B=F(2-F)$	optical coverage
$d_R=0.67d/\sqrt{\cos\alpha}$	“equivalent” wire thickness for DC resistance
$\delta=1/\sqrt{\pi f \mu_0 \sigma}$	skin depth

Kley then derives the transfer impedance of the braid as

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$Z_{T,Kley} = Z_D + j\omega L_T + (1+j)\omega L_s$$

Here Z_D is the diffusion component of the transfer impedance, given by

$$\gamma = \frac{1+j}{\delta}$$

$$Z_D = \frac{4}{\pi d^2 \sigma N C \cos\alpha} \cdot \frac{\gamma d_R}{\sinh \gamma d_R}$$

L_T is the combined hole and braid component of the transfer impedance, given by

$$L_T = \frac{\mu_0}{C}\left[0.875\frac{\pi}{6}(2-\cos\alpha)\cdot(1-F)^3 e^{-\tau_H} - \frac{0.11}{N}\cos(2k_1\alpha)\right]$$

Where

$$\tau_H = 9.6F\sqrt[8]{B^2 d/D_m}$$

$$k_1 = \frac{\pi}{4}\left(\frac{2}{3}G_0 + \frac{\pi}{10}\right)^{-1}$$

$(1+j)\omega L_s$ is the skin impedance of the holes, given by

$$(1+j)\omega L_s = \frac{1+j}{\pi\sigma\delta D_m}\left[10\pi G_0^2 \cos\alpha\cdot(1-F)e^{-\tau_E} - \frac{3.3}{2\pi G_0}\cos(2k_2\alpha)\right]$$

Where

$$\tau_E = 12F\sqrt[8]{B^2 d/D_m}$$

$$k_2 = \frac{\pi}{4}\left(\frac{2}{3}G_0 + \frac{3}{8}\right)^{-1}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Geometric Relations

Figure 2 below shows a braided shield, along with some of the parameters that define it. The shield has been flattened, as if it were cut down one side and smoothed out. Defining parameters are *P*, the number of "picks" (holes) per unit length, and the shield's average diameter D_m. The number of carriers (belts of wire) is *C*, and the number of wires per carrier is *N*. Another key parameter is the weave angle, α.

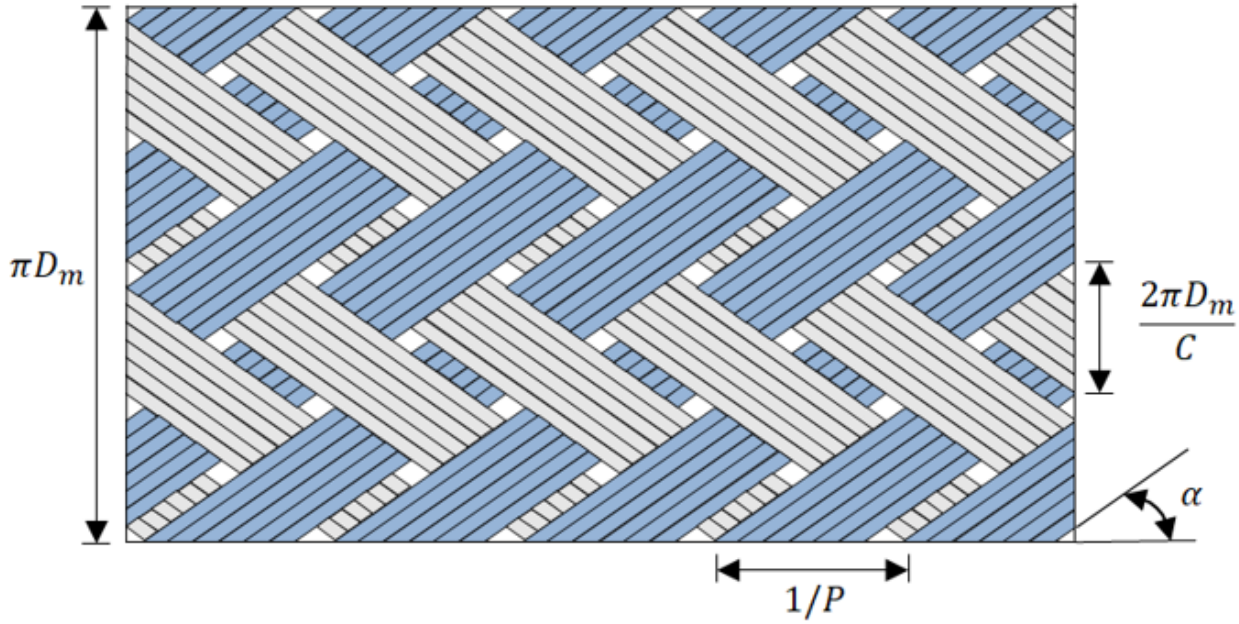


Figure 2. Portion of a braided shield (adapted from Vance).

The value of *P* can be determined by measuring the horizontal distance along the braid from one corner of the diamond-shaped holes to the next corresponding corner, and then taking the reciprocal. The number of carriers *C* can be determined by counting the carriers crossing the left or right edge of the figure. (It is 8 in this example.)

From the figure, the weave angle is related to the other parameters by

$$\alpha = \tan^{-1}\left(\frac{2\pi D_m P}{C}\right)$$

Therefore, if we know three of the parameters $\{\alpha, P, C, D_m\}$ we can always compute the fourth.

Referring now to Fig 3 below, we can derive several more parameters of the braid model. First, the width *W* of the carrier plus the hole is

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$W = \frac{1}{P} \sin \alpha$$

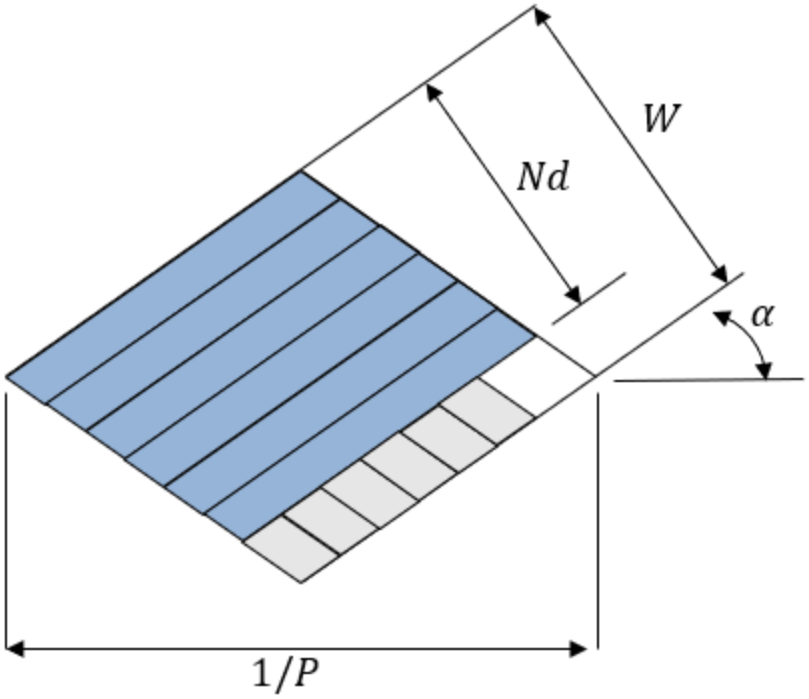

Figure 3. Close-up of one diamond of the braid (adapted from Vance).

Therefore the fractional coverage of the carrier is

$$F = \frac{Nd}{W} = \frac{PNd}{\sin \alpha} = \frac{NCd}{2\pi D_m \cos \alpha}$$

The carrier coverage *F* is different from the optical coverage *B* (the fraction of the braid's surface area covered by carriers) due to the crossing carriers. It can be seen from Figure 3 that the hole and the diamond are similar polygons, and thus the area of the hole is $(1\text{-}F)^2$ times smaller than the area of the diamond. Therefore, the optical coverage is

$$B = 1 - (1 - F)^2 = (2 - F)F$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cable manufacturers often quote the optical coverage of their braided shields. Given **B**, we can solve for *F*, as follows:

$$F = 1 - \sqrt{1 - B}$$

If the weave angle α is not known, but *B*, *N*, *C*, *d* and D_m are given, then we can find *F* as above, and then compute α as

$$\alpha = \cos^{-1}\left(\frac{NCd}{2\pi D_m F}\right)$$

Detecting and Addressing Model Problems to Improve Meshing

The following sections describe a systematic procedure to detect and address model problems that can interfere with the meshing process.

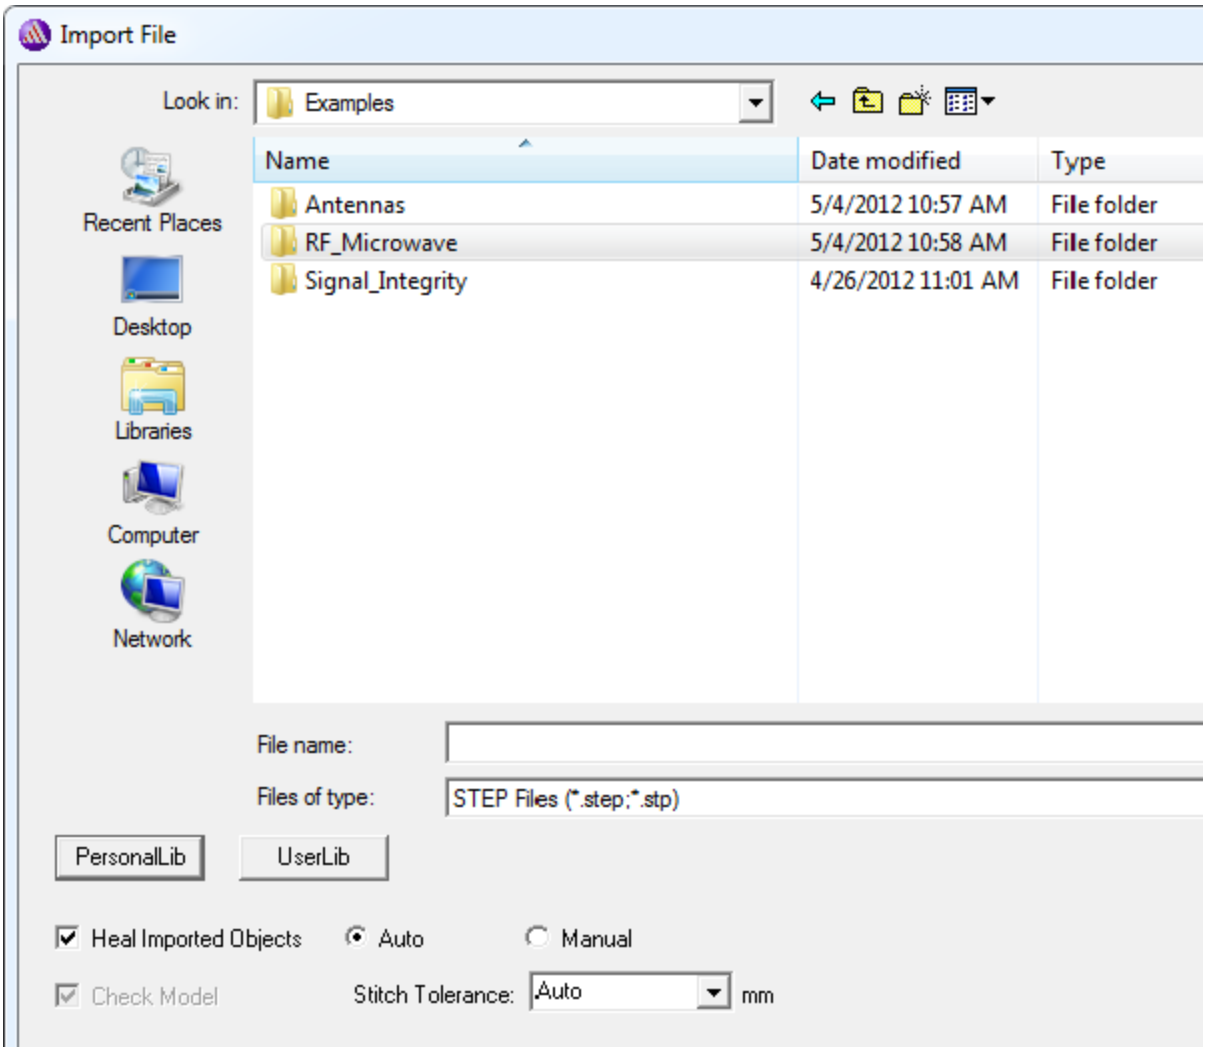
- Technical Notes: Healing After Geometry Import
- Technical Notes: Removing Object Intersections
- Technical Notes: Removing Small Features
- Technical Notes: Aligning Objects
- Technical Notes: Troubleshooting if Meshing Still Fails

One: Healing During Geometry Import

In case you don't draw your entire geometry in the Ansys EM environment but wish to import (part of) it, in the **Import File** window you select which geometry file to import. Some formats permit healing during import (See: Healing). Selecting these formats enables a check box at the bottom of this window, "**Heal Imported Objects**." For these supported formats (except for 3D Modeler files), two modes exist, "auto" and "manual". Auto Healing will try to address kernel errors and non-manifold errors, the first two classes of potential problems listed earlier. It will also fix surface normals in the body and updating orientation of body, to avoid having a body with negative volume.

Manual healing adds tolerant stitching, geometry simplification (such as small-feature removal) and tight en gaps settings to this. You can remove small features at this stage if you wish. However, the usual approach is to apply auto-healing at this stage and leave small-feature removal until later.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Two: Healing after geometry import

Healing can only be performed on objects that have no drawing history other than "import". If necessary, object history will be automatically deleted through **Modeler>Purge History**. If that causes a warning that another object will be deleted, you may need to purge the history of that other object first, or purge the histories of several objects simultaneously. If you need to preserve the object history, you should save a separate copy before purging the history.

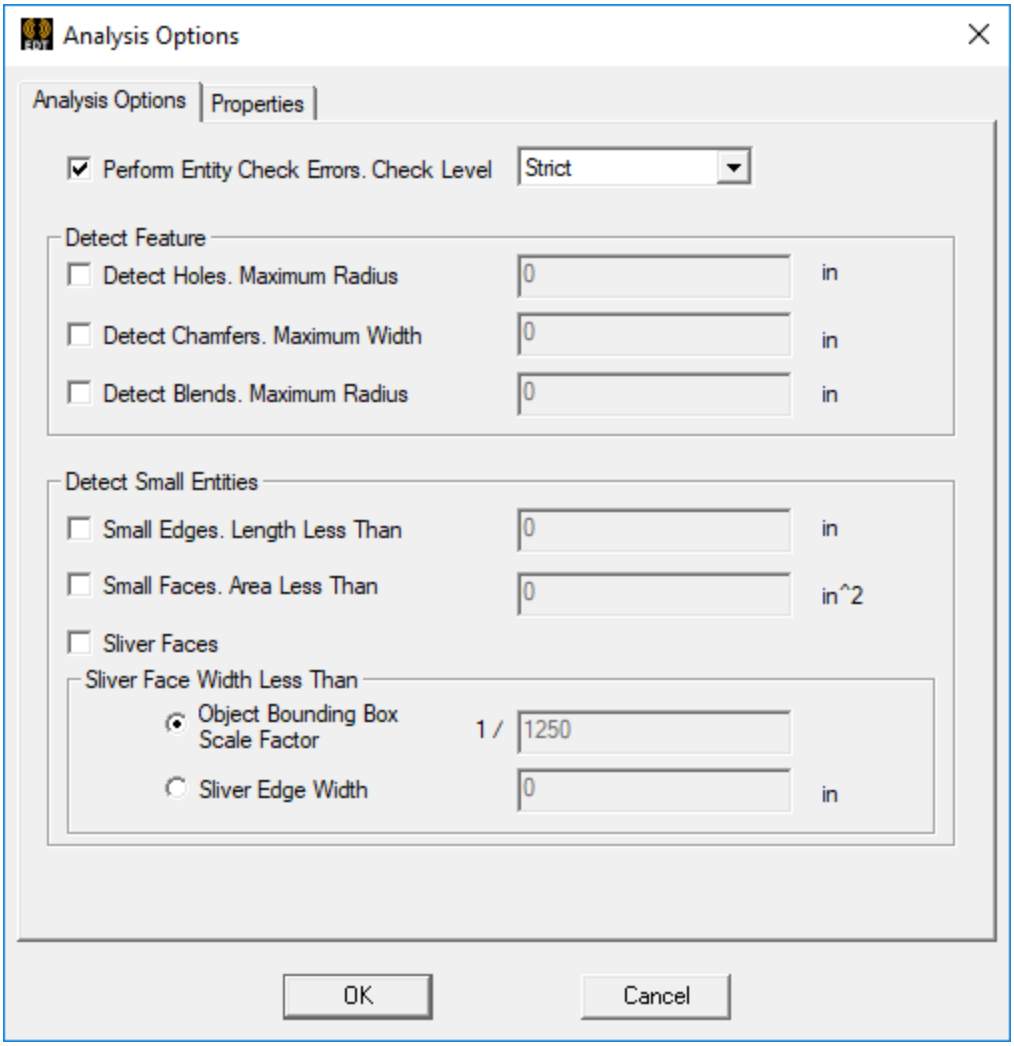
At any time after import, you can perform a Validation Check: **HFSS** > **Validation Check**. This will enable you to focus on bodies and body pairs that need attention before a mesh can be created. Note that you can set the Modeler Validation settings for Warning Only, Basic, and Strong.

1. Select the objects that have kernel errors, such as failing api_check_entity(), and the objects that have non-manifold features (See: Mixed Dimensionality).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Invoke **Modeler->Model Analysis->Analyze Objects**.

This will bring up an Analysis Options dialog where you set the strictness of the entity check, detection and thresholds for holes, chamfers and blends, thresholds for small feature detection.



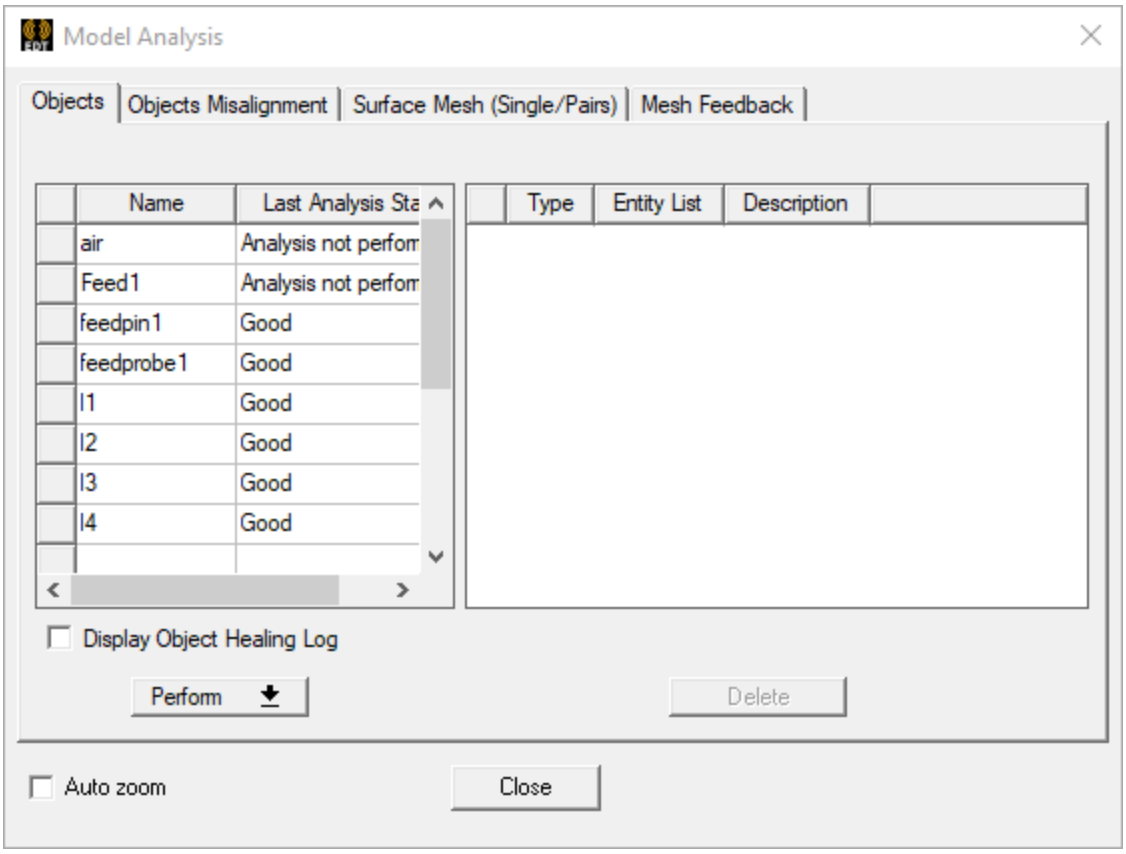
3. When you have made selections, click **OK** to start the analysis.

On completion, the **Model Analysis** dialog is displayed. All bodies in the model are shown in the objects grid along with their status. Bodies can have the following status:

1. Good
2. Null Body
3. Analysis not performed
4. Invalid entities found

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Small-entity errors.



Invalid-entity errors are kernel errors and non-manifold errors. Small-entity errors are small faces, sliver faces and small edges that are optionally detected based on user-defined parameters.

> **Note:**
>
> Invalid-entity errors must be fixed before a mesh can be generated.

To fix invalid entity errors:

1. Choose the bodies that have "Invalid Entities Found."
2. In the same **Model Analysis** window, choose **Perform>Heal Objects**, with or without an optional setting for small-feature removal.

   In most cases, the bodies will be healed and the errors fixed.

3. If errors still persist, choose "offending" faces and edges and click on **Delete**.

   This will replace the selected face/edge entity by a tolerant edge/vertex respectively.

In order to avoid unintended changes, it is good practice to do the following:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

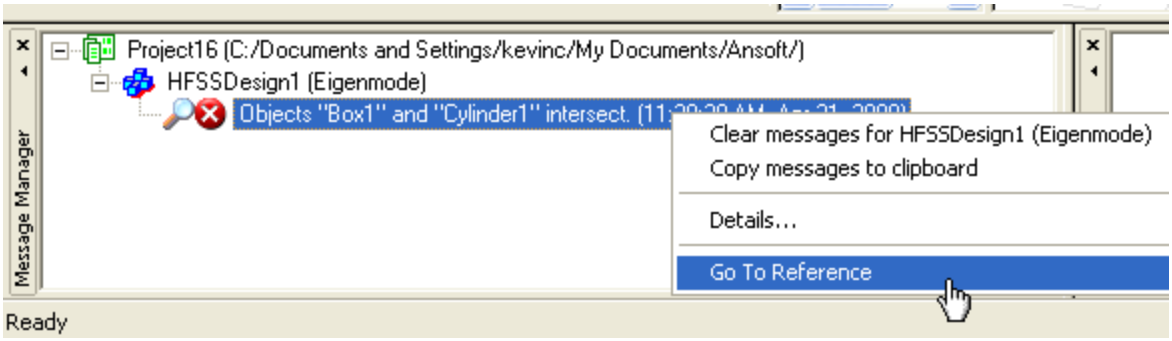
1. At the bottom of the **Model Analysis** window, check the box "Auto Zoom to Selection."
2. Select one face or edge at a time
3. Decide for each face and edge whether you want to delete it.

> **Note:**
>
> Healing causes changes to the geometry and topology of the body being healed. Validation check has to be re-run after healing is done to identify body pairs that intersect. It is possible that after healing, bodies that were disjoint before now overlap.

In some cases the replacement of the face/edge by tolerant edge/vertex will fail. If the object remains invalid, you know at this point what parts of the object are invalid. You will need to change that part of the object manually, either in Ansys EM's drawing environment or in the original CAD tool, to make it pass. Often, the invalid entities are in small details that can be changed without noticeably affecting the results of the electromagnetic analysis. For example, it may be possible to create a small object, well placed in the "offending" region, and to unite it with or subtract it from the problematic object, such that the "offending" details don't exist anymore.

Three: Removing Object Intersections

If there are any intersecting objects, a Validation Check will list them. You must eliminate object intersections before a mesh can be created. After you run a validation check, you can right-click on an intersection error message in the Message window, and select **Go to reference** from the shortcut menu. This selects the intersecting objects.



In complicated models, before making changes, it is good practice to inspect the overlap visually. A way to do this is to:

1. Duplicate both objects and place the copies outside the model.
2. Perform **Boolean Intersect** on the copies.

   This will show you what causes the intersection and will help you decide how to remove it.
3. Delete the copies.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The easiest way to eliminate object overlap is to subtract one object from the other, in the order that leaves the desired material in the region of overlap. If the overlap is very small and you can choose the order of subtraction, choose one that does not create coincident true surfaces, if possible.

Caveat: if as a result of a subtraction the model has pairs of true surfaces that are coincident, that is, smooth curved surfaces that fit exactly one inside the other, you will make it harder for the mesh generator to create a mesh. This is because Parasolid will create segmentations on each of these surfaces, and these segmentations are not guaranteed to fit. Setting a small value for **Surface Deviation** under **Mesh** > **Assign Mesh Operations** > **Surface Approximation** increases your chance of success in such a case, but it is better to avoid such situations if you can.

A way to eliminate object intersections without subtraction is to split one object in parts, in such a way that some parts are completely enclosed in the other object, and some parts are completely outside the other object. Even for complicated objects, this is possible through a sequence of Boolean operations on the objects and copies of the objects.

At this point, the geometry has no kernel errors, no non-manifold objects and no partial object intersections. A mesh can be created for the electromagnetic analysis.

The procedure for fixing face improper intersections is similar. When it occurs, the error report lists a pair of faces intersecting.

1. You can detach those faces (using **Modeler** > **Surface** > **Detach Faces**), and others if necessary.
2. Select the faces and invoke either the **Modeler** > **Model Healing** > **Stitch Sheets** command (see Stitch Sheets) or **Modeler** > **Boolean** > **Unite** (see Uniting Objects).
3. Once the improper intersections have been corrected, you can stitch the set of faces back to the original model.

Four: Removing Small Features

Even though, in principle, the geometry may be ready for a mesh to be created, it is possible that small features in the geometry lead to a mesh that is unnecessarily large and contains long and thin tetrahedra that make the simulation converge slower. Small features may even cause the mesh generation to fail. By small, we mean details on an object that are thousands of times smaller than the main features of the object, and that, in most cases, are unintended consequences of the drawing history in another CAD tool. Therefore, it is advantageous to remove small features.

You may have noticed that you could have invoked small-feature removal at several earlier stages. There is no objection to doing it earlier. See Object Overlap Settings for Complicated Models. The reason why it is presented here as stage four is that the previous stages were necessary while this one is optional.

To start the small-feature removal:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click HFSS>Modeler>Analysis Options and specify the Entity Check level, make selections for holes, chamfers, and blends, their thresholds, as well as for edges, faces and slivers.
2. Select objects and invoke object analysis through **Modeler>Model Analysis>Analyze Objects**.

Alternatively, without objects selected, use **Modeler>Model Analysis>Show Analysis Dialog>Objects** and select objects from the list. In the **Model Analysis window**, invoke **Perform>Analyze Objects**.

The software will report according to the **Analysis Options** settings, such as holes smaller than a given radius, the smallest edge length and the smallest face area.

3. Upon clicking OK, the analysis is performed.

As a result of the analysis, the software presents a list of all holes, chamfers, blends, faces and edges that don't meet the thresholds set by you in the Analysis Options.

4. Check the box "Auto-Zoom to Selection" at the bottom of the **Model Analysis** window and click on items in the list.

Inspect them visually and decide whether they can be deleted. It is good practice to delete them one by one rather than deleting many at once in order to prevent unintended changes.

Sometimes, an edge or face cannot be deleted, and you get a message notifying you. In that case, either ignore it, or revisit it after deleting some other details first, or revisit it later manually in the 3D drawing environment.

At this point, the geometry has no errors, no non-manifold objects and no partial object intersections. Furthermore, there are fewer small features that were unintended or unimportant for the electromagnetic analysis, so the quality of the model has improved.

Five: Aligning Objects

Objects that touch each other in imported geometries don't always have well-aligned faces. Often, this is a consequence of the limited level of precision in the imported file. Misaligned faces can cause tiny object intersections or tiny gaps between objects, which in turn can lead to an inefficient mesh or even a failure to create the mesh.

To repair such occurrences in an automated way, you can select groups of objects and invoke **Modeler>Model Analysis>Analyze Interobject Misalignment**. This will yield face pairs from different bodies that are slightly misaligned with respect to each other.

In the window that shows this list, check the box "**Auto-Zoom to Selection**" and select face pairs from the list. When you decide that faces should be aligned, click Align Faces. In some cases, face alignment will fail if the topology of the body would change by a large amount after alignment. In that case, you can decide to ignore it, as it may not be a problem, or revisit it later manually in the Modeler environment.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

In complicated models, the **Interobject Misalignment** analysis can take a long time if you select all objects before launching the analysis. If you don't know which pairs of objects to analyze, just let the mesh generator try to make a mesh. If the mesh fails, a list will be presented to you of misalignments that the mesh generator finds suspicious but didn't want to adjust without permission. Not every misalignment in the list is always a problem: this is a list of features that might need your attention.

Note:

As face misalignments between touching objects can cause small object intersections, this alignment capability can already serve a useful role in stage three.

Six: Troubleshooting if Meshing Still Fails

If mesh generation fails, information about the reasons for the failure is presented under **Modeler** > **Model Analysis** > **Show Analysis Dialog** > **Mesh Feedback**.

Again, check the box **Auto Zoom to Selection**, and click on the errors in the list. This can give you hints about which parts of the model are causing difficulties.

For instance, there may be self-intersecting bodies or faces. Such errors can have a variety of causes, such as a face that is supposed to be planar, but of which the vertices don't quite lie in the same plane. When you zoom and search, you are likely to see what causes the problem.

Also, there may be face misalignments. Once you know they exist, you can inspect them and decide whether to align them under the Objects Misalignment tab.

One of the tabs of the **Model Analysis** window is the **Surface Mesh** tab. Under that tab, you can try to create surface meshes for objects and pairs of objects. Since a surface mesh on selected objects is easier to create than a volume mesh for the whole model, this can help you to identify quickly which objects are causing difficulties and why.

Also, in order to determine which objects are causing difficulties, you can exclude objects temporarily from the model. If the mesh succeeds without them, this helps to identify the reason for failure. To exclude an object temporarily, select it and uncheck "Model" in its properties window. Then try to create the mesh again.

Once you know which objects make the mesh fail, you can try to make small changes to them that don't affect the electrical properties noticeably but help the mesh maker succeed. For example:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Zoom in on details and consider removing details;
- Find coincident true surfaces and move one of the faces over a very short distance so the pair of faces is not coincident anymore;
- Split very complicated objects into multiple less-complicated objects;
- Delete a complicated 3D ground object and create a 2D ground through a boundary condition on the appropriate faces of a dielectric;
- Replace imported objects by objects drawn in Ansys EM's 3D modeling environment. For instance, some CAD tools produce cylinders that consist of two half cylinders that have a seam where they join. The fit is not always perfect.

Finally, for coincident true surfaces, set a very small value for **Surface Deviation** under **Mesh** > **Assign Mesh Operation** > **Surface Approximation**. Parasolid will give them more segments, but you can compensate for that with **Model Resolution**. In a parametric sweep, you can experiment with settings for **Surface Deviation** and **Model Resolution**.

Handling Complicated Models

Complicated models, often imported from a CAD tool or layout tool, may slow down the interface, use a lot of RAM during file I/O and other operations, contain imperfections and object overlaps. After analysis, post processing of such models may be time consuming. The modeler has several options and features that address these problems.

- Interface Options for Complicated Models
- Geometry Imperfections and Complicated Models
- Object Overlap Settings for Complicated Models
- Post Processing Settings for Complicated Models

> **Note:**
>
> Remember that Healing always purges the history. If you heal an object for which you need to recover the history, use the Undo command. If you want to heal an object for which you want to keep the history, you should make a copy of the object for that purpose.

Interface Options for Complicated Models

To improve the speed of the interface when dealing with complicated geometries, do the following:

Under **Tools>Options>Modeler Options**, on the **Display** tab...

- Set "Default View Render" to "Wire Frame". Wire-frame rendering is faster than shaded rendering.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Turn off "Display UV Isolines". For models with curved faces, this will simplify the wire-frame display, so the rendering will be faster.
- Turn off "Visualize History of Objects". This will remove visualization of objects that are part of the model history. For large models, this is faster and uses less memory.

Under **Tools>Options>HFSS Options**, on the **General** tab...

- Turn off "Visualize Boundaries on Geometry". When a boundary or excitation is selected, it will not be shown with a "pattern". This will prevent large delays when selecting.

Under **View>Visualization Settings**

- Use larger deviations to view curved objects in less detail.

Under **Modeler>Import**

- Un-check "Check Model" and "Heal Imported Objects." This helps for complicated models: Validation and healing take considerable time for such models. Use this option to defer checking to a later stage (especially in cases where you know that you want to mesh the model as is).

Under **Tools>Options>General Options**, on the **Project Options** tab

- Turn off "Do Autosave" or set the autosave interval to a larger value (e.g., 50). Auto-save can be time consuming.

Geometry Imperfections and Complicated Models

Modeler>Import

Many formats can be handled. It is recommended to import a version of the geometry that is as close as possible to its source, rather than geometries that have been translated before from one format to another, or that have been imported into another computational tool and later exported from it.

Modeler>Validation Settings

Geometry imperfections are listed as kernel errors when executing **HFSS>Validation Check** and when starting an analysis. It is recommended to attempt to heal objects with such errors. However, HFSS enables you to bypass the errors (not the check itself) by choosing a setting under **Modeler>Validation Settings**. "Warning Only" enables you to ignore all errors. "Basic" enables you to bypass all but the most severe errors. The HFSS mesh generator has been enhanced to handle many geometry errors.

Object Overlap Settings for Complicated Models

HFSS>Set Material Override

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Complicated geometries often have small object overlaps. This option allows some intersections to be resolved automatically in the mesh. If metal intersects dielectric, the metal will override the dielectric in the region of the overlap. If objects with the same material intersect, the smaller object will override the larger. All other intersections will still be treated as errors.

Post Processing for Complicated Models

Under **Tools>Options>General Options**, on the **Miscellaneous Options** tab...

- Turn off "Dynamically update postprocessing data during edits". This will disable expensive updating of existing reports and plots.
- Turn off "Update reports on file open". This will disable expensive updating of reports and plots when opening a project.

Under **HFSS>Fields>Modify Plot Attributes**, on the Plots tab…

- Set Plot Quality to Coarse, and save as default. This will make field plots much faster. The fields will not be as smoothly approximated within each tetrahedron, but this should not be noticeable on very large meshes.

Boundaries Technical Notes

Boundary conditions specify the field behavior on the surfaces of the problem region and object interfaces. This area of the technical notes includes information about the following boundary types:

- Perfect E
- Impedance
- Radiation
- PML
- Finite Conductivity
- Symmetry
- Primary and Secondady (Lattice Pair)
- Lumped RLC
- Anisotropic Impedance
- Layered Impedance
- Infinite Ground Planes

and the following subjects:

- Frequency-Dependent Boundaries
- Default Boundary Assignments

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Perfect E Boundaries

In HFSS, perfect E boundaries represent perfectly conducting surfaces in a structure.

By default, all HFSS model surfaces exposed to the background are assumed to have perfect E boundaries; HFSS assumes that the entire structure is surrounded by perfectly conducting walls. The electric field is assumed to be normal to these surfaces. The final field solution must match the case in which the tangential component of the electric field goes to zero at perfect E boundaries.

The surfaces of all model objects that have been assigned perfectly conducting materials are automatically assigned perfect E boundaries.

> **Note:**
>
> Currents from a Symmetric E boundary will not be included in the ZPI calculation when there is only 1 conductor on the port. Otherwise, the currents will be included in ZPI calculations.

Impedance Boundaries

In HFSS, impedance boundaries represent surfaces of known impedance. The behavior of the field at the surface and the losses generated by the currents flowing on the surface are computed using analytical formulas; HFSS does not actually simulate any fields inside the resistor.

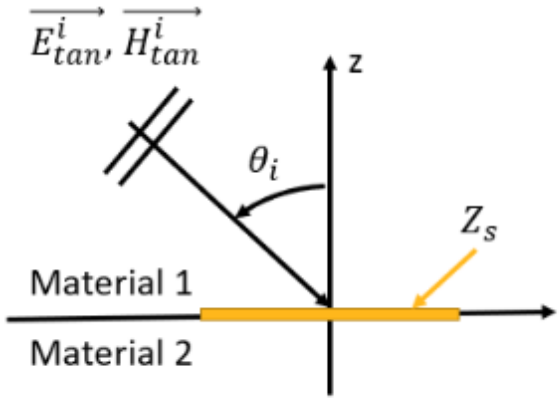
Similar to finite conductivity boundaries, the following condition applies at impedance boundaries:

$$\boldsymbol{E}_{tan} = Z_s(\hat{n} \times \boldsymbol{H}_{tan}) \quad (1)$$

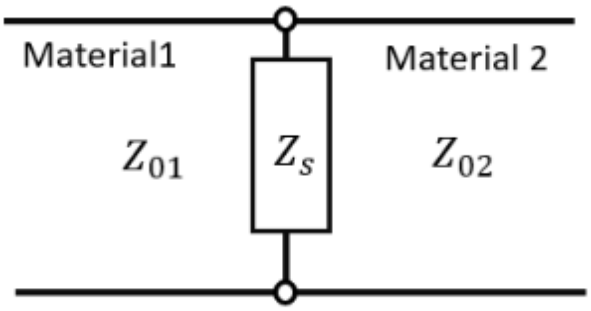
- $\hat{n}$ is the is the unit vector that is normal to the surface.
- E_{tan} is the component of the E-field that is tangential to the surface.
- H_{tan} is the component of the H-field that is tangential to the surface.
- Z_s is the surface impedance of the boundary, $Rs + jXs$, where
- Rs is the resistance in ohms/square.
- Xs is the reactance in ohms/square.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For example, consider a structure containing two dielectrics separated by a thin-film resistor. This resistor can be represented by an impedance boundary at the surface between the two objects. In the transmission-line equivalent model, the resistor acts as shunt impedance.

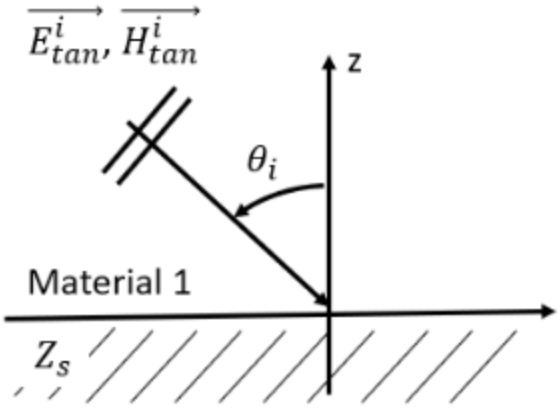


Geometry

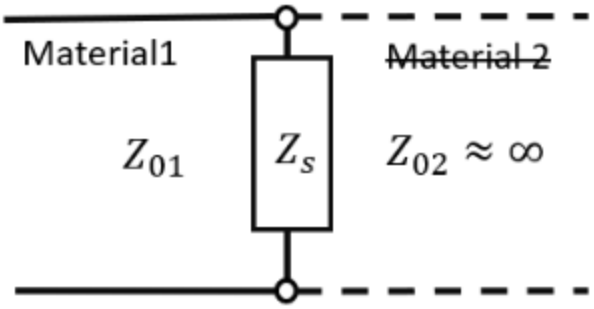


Transmission line equivalent model

Note that the boundary for that geometry is modified when the Solve Inside flag for an object is set to false. When Solve Inside is false, the boundary is replaced by a half-space material with the surface impedance. This means that the object is treated as perfect magnetic conductor.



Geometry



Transmission line equivalent model

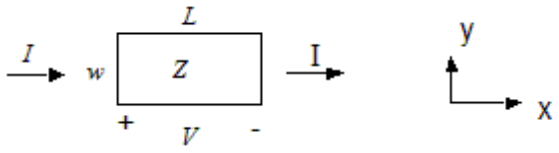
In general, for full-wave solvers, the Solve Inside flag is set automatically based on the material conductivity. The Solve Inside is set to false when the conductivity is greater than Solve Inside Threshold (100000 S/m by default), otherwise it is set to true. Users may override this behavior manually. SBR+ regions do not expose the Solve Inside flag, and such manual override is not available. The only way to modify the behavior of the Solve Inside flag in SBR+ is to modify the global Solve Inside Threshold.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Units of Impedance Boundaries

Impedance on the surface of objects, Z_S, has units of ohms per square. The units *ohms per square* indicate that the impedance, Z_S, is equal to the equivalent circuit impedance, Z, measured between the edges of a square sheet of the material.

For example, a rectangle of length *L* and width *w* has a uniform current, *I*, applied to it. It has a voltage drop, *V*, across it and an equivalent circuit impedance of *Z* ohms.



If the current density, *J*, is uniform over the rectangle then the equation (1)

$$\hat{n} \times \vec{E} = Z_s \hat{n} \times \vec{J} \quad (1)$$

becomes equation (2)

$$E = Z_s J \quad (2)$$

where

- $E = |\vec{E}|$ on the rectangle, and
- $J = |\vec{J}|$ on the rectangle.

The circuit quantities and fields are related as follows:

$$V = \int_{x=0}^{L} \vec{E} \cdot \overrightarrow{dL} = EL \quad (3)$$

$$I = \int_{y=0}^{w} \vec{J} \cdot \hat{x} dy = Jw \quad (4)$$

$$Z = \frac{V}{I} = \frac{EL}{Jw} \quad (5)$$

Substituting equation (1) into equation (5) results in the following equation:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$Z = Z_s \frac{L}{w} \quad (6)$$

Thus, when $L = w$, the equivalent circuit impedance is equal to the impedance on one square. Hence the units *ohms per square*.

If in this example $L = 2w$, the impedance would be equal to one-half of the circuit equivalent impedance for the rectangle, or the circuit equivalent impedance of one "square" of the rectangle is equal to the impedance of that square. Therefore, when entering the surface impedance for an object, you must enter the impedance per square.

Radiation Boundaries

When solving radiating and scattering structures in an unbounded, infinite domain, HFSS truncates the problem into a bounded domain and prescribes the appropriate truncation condition. This is generally known as the "radiation boundary condition". Theoretically, the radiation boundary condition should be a "transparent" condition. In other words it should not produce any unphysical reflection as a result of the artificial truncation. HFSS offers three types of radiation boundaries: first-order absorbing boundary condition (ABC), perfectly matched layers (PML), and boundary integral equations (IE).

ABC and PML Boundaries

Both the ABC and PML boundaries attempt to minimize reflections by absorbing all outgoing waves at the truncation boundary. Because of this, they can only be prescribed at convex surfaces. This is because for concave surfaces, outgoing waves will re-enter the problem domain and should therefore not be completely eliminated. While PMLs absorb any kind of waves including guided waves, ABC imitates radiation to homogeneous background space.

ABCs only absorbs normal or near normal incident waves. Thus in order to produce accurate results, it must be placed sufficiently far away from structures. The typical recommendation is at least a quarter wavelength from the radiating source, although in some cases the radiation boundary may be located closer than one-quarter wavelength, such as portions of the radiation boundary where little radiated energy is expected. ABC is a local condition and thus preserving the sparse nature of the FEM formulation.

PMLs absorb all outgoing waves by adding artificial material layers that are designed such that all of the incident waves impinging upon them are completely transmitted with minimal reflections. Thus PMLs can be placed closer than ABCs. Furthermore, the PML absorbs a much wider range of waves in terms of frequency and direction whereas ABC absorbs only normally incident waves accurately. However, PMLs in general makes it more difficult for the iterative solver to reach convergence compared to ABCs. PMLs also preserves the sparse nature of the FEM formulation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

Radiating BCs and PMLs are local boundary conditions and inherit the Global Environment Material from the computational domain. They work as if the material of the computational domain were continued to infinity. FE-BI uses the user defined Global Environment material which may or may not be the same as the material of the computational domain. If they are the same, PMLs and FE-BI give the same results. If the materials are different, there is a jump in the materials which can be modeled by FE-BI, but not by PMLs.

Boundary Integral Equations

The boundary integral equations (IE) is an exact transparent condition. The Sommerfeld radiation condition at infinity as required by physics is enforced exactly through the employment of appropriate Green's functions via an integral equation method. This hybridization is commonly known as the finite element-boundary integral (FE-BI) method. Unlike ABC and PML, the IE hybrid region can be of arbitrary shape, both concave and convex thus in some cases allowing the size of the finite element solution domain to be significantly reduced. It can be placed very close to the structures and produce accurate results and from a performance point of view a minimum distance of 0.125 wavelengths is recommended. Since analytic Green's functions are known only for a few specific situations, the IE hybrid region is not allowed to touch any other boundary except an infinite ground plane. In addition the IE hybrid region does not work with symmetry planes. The IE condition is a non-local condition, producing a partial sparse and partial dense system matrix. For this reason when simulating electrically large structures, the IE condition typically requires more RAM and CPU than either ABC or PML assuming all are placed on the same geometry. However by taking advantage of conformal radiation volumes to reduce the overall finite element solution domain utilization of the IE hybrid region will result in more efficient simulation for electrically large open boundary problems.

PML Boundaries

Perfectly matched layers (PMLs) are fictitious materials that fully absorb the electromagnetic fields impinging upon them. These materials are complex anisotropic.

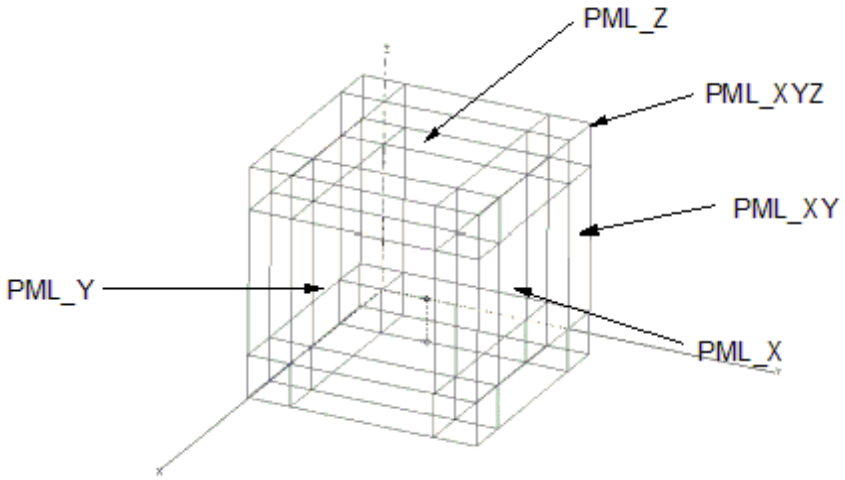
There are two types of PML applications: free space termination and guided wave termination. With free space termination, PMLs are associated with a surface that radiates into free space equally in every direction. PMLs are more appropriate than radiation boundaries in this case because PMLs enable radiation surfaces to be located closer to radiating objects, reducing the problem domain. Any homogeneous isotropic material, including lossy materials like ocean water, can surround the design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

With reflection-free termination of guided waves, the structure continues uniformly to infinity. Its termination surface radiates in the direction in which the wave is guided. Reflection-free PMLs are appropriate for simulating phased array antennas because the antenna radiates in a certain direction.

Material Tensors Applied at PML Boundaries

PMLs materials are complex anisotropic. An example is shown below.



To ensure that there will not be any reflection at the PML/air interface, the bi-axial diagonal material tensors for x-, y- and z-directed PMLs (PML_X, PML_Y, and PML_Z) are as follows.

For PML_X:

$$\frac{[\varepsilon]}{\varepsilon_0} = \begin{bmatrix} \frac{1}{C} & C & C \end{bmatrix} \qquad \frac{[\mu]}{\mu_0} = \begin{bmatrix} \frac{1}{C} & C & C \end{bmatrix} \tag{1}$$

For PML_Y:

$$\frac{[\varepsilon]}{\varepsilon_0} = \begin{bmatrix} C & \frac{1}{C} & C \end{bmatrix} \qquad \frac{[\mu]}{\mu_0} = \begin{bmatrix} C & \frac{1}{C} & C \end{bmatrix} \tag{2}$$

For PML_Z:

$$\frac{[\varepsilon]}{\varepsilon_0} = \begin{bmatrix} C & C & \frac{1}{C} \end{bmatrix} \qquad \frac{[\mu]}{\mu_0} = \begin{bmatrix} C & C & \frac{1}{C} \end{bmatrix} \tag{3}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where $C = a - jb$.

The tensors designated as PML_X characterize an x-directed PML corresponding to a PML wall in the yz plane. Similarly, PML_Y and PML_Z are designated tensors for y- and z-directed PMLs.

PMLs of different directions must be joined in order to construct a box with PML walls. To ensure complete coverage where the edges and corners of two PMLs meet, create edge and corner PML objects. The tensors of an edge object joining PML_X and PML_Y are as follows for PML_XY:

$$\frac{[\varepsilon]}{\varepsilon_0} = \begin{bmatrix} 1 & 1 & C^2 \end{bmatrix} \qquad \frac{[\mu]}{\mu_0} = \begin{bmatrix} 1 & 1 & C^2 \end{bmatrix} \quad (4)$$

A similar tensor construction rule is valid for joining x- and z-directed and y- and z-directed PMLs. The tensor for a corner object is a follows for PML_XYZ:

$$\frac{[\varepsilon]}{\varepsilon_0} = \begin{bmatrix} C & C & C \end{bmatrix} \qquad \frac{[\mu]}{\mu_0} = \begin{bmatrix} C & C & C \end{bmatrix} \quad (5)$$

> **Note:**
>
> This example in shows the material in GLOBAL coordinate system, while the Material Manager shows the materials in LOCAL coordinate system assigned to the object, which are then rotated to the global coordinate system by the solver.

Tensor Entries

Entering the matrices of the anisotropic materials doesn't require a special procedure. The usual anisotropic material definitions can be used for any PML structure. However, keep in mind that the efficiency of the PMLs depends on the material values assigned to them.

Setting the complex parameter C ensures that the electromagnetic field decays strongly in the PMLs. Back reflections from the bounding PECs are then kept below a prescribed bound. To accomplish this, the following inequalities have to be satisfied:

$$e \geq \frac{-\ln \rho}{2D_{min}H} = e_{min} \quad (1)$$

$$e \leq \frac{-\ln d}{2D_{max}h} = e_{max} \quad (2)$$

where

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$D_{min} = \alpha_{min} + \beta_{min} = \frac{1}{r_{max}} + \frac{\omega_{min}}{c} \quad (3)$$

$$D_{max} = \alpha_{max} + \beta_{max} = \frac{1}{r_{min}} + \frac{\omega_{max}}{c} \quad (4)$$

- $e = a = b$
- $a$and b are the real and imaginary parts of C.
- $H$is the thickness of the PML object.
- ω_{max} and ω_{min} are the minimum and maximum angular frequencies.
- r_{max} and r_{min} are the minimum and maximum distance of a radiating object to the PML surface.
- ρis the bound for back reflection.
- $d$is the maximum decay characterizing the element. ($d$is approximately $3^* 10^{-3}$.)
- $h$is the thickness of one finite element.
- $c$is the velocity of light in vacuum.

Boundaries at PML Surfaces

After embedding a structure in PMLs, the next step is to specify boundaries on the outer surface of the box. The simplest way is to bound the box either with perfect electric conductors (PECs) or perfect magnetic conductors (PMCs.) In general, use PECs because they reduce the problem size.

Finite Conductivity Boundaries

In HFSS, finite conductivity boundaries represent imperfect conductors.

At such boundaries, the following equation holds:

$$\boldsymbol{E_{tan}} = \boldsymbol{Z}\left(\hat{\boldsymbol{n}} \times \boldsymbol{H_{tan}}\right)$$

where:

- E_{tan} is the component of the E-field that is tangential to the surface.
- H_{tan} is the component of the H-field that is tangential to the surface.
- Z_s is the surface impedance of the boundary. When the thickness is much larger than the skin depth, $(1+j)/(\delta\sigma)$ can be used. When not, Z_s can be calculated from the transmission line model used at a layer impedance boundary condition.
- δ is the skin depth $\sqrt{2/(\omega\sigma\mu)}$ of the conductor being modeled.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- ω is the frequency of the excitation wave in radians/second.
- σ is the conductivity of the conductor.
- μ is the permeability of the conductor.

The fact that the E-field has a tangential component at the surface of imperfect conductors simulates the case in which the surface is lossy.

The surfaces of any objects defined to be non-perfect conductors are automatically set to finite conductivity boundaries.

> **Note:**
>
> HFSS does not attempt to compute the field inside these objects; the finite conductivity boundary approximates the behavior of the field at the surfaces of the objects.

The finite conductivity boundary condition is valid only if the conductor being modeled is a good conductor; that is, if the conductor's thickness is much larger than the skin depth in the given frequency range. If the conductor's thickness is in the range or larger than the skin depth in the given frequency range *and has been defined*, HFSS takes the thickness into account.

Huray Surface Roughness Model

Surface roughness can increase conductor power losses by more than two times the loss associated with smooth conductors. In Ansys Electronics Desktop, a modification of the standard real-valued Huray surface roughness model is implemented to accurately account for these losses in both the frequency and time domains.

This modification fixes a causality problem with the original Huray model by adding some frequency-dependent reactance to the roughness-enhanced surface impedance. The purpose is to provide a complex-valued causal analytic model that exactly matches the loss results of the original model but is also suitable for time domain computations.

The original Huray model was limited to calculations in the frequency domain and did not account for the effects of roughness on the phase of the transmitted signal. These limitations have been eliminated. The enhanced causal model not only provides accurate broadband modeling of the losses in very rough copper foils (typically used in PCB manufacturing) but also accurately predicts increased phase delay due to the surface roughness.

Essentially, the smooth surface impedance (Z_{smooth}) is increased by a complex “Huray” factor (H_c), a function of frequency, given by the following equation (1):

$$H_c\left(j\omega\right) = 1 + \frac{K}{1+\left(\frac{j2\omega}{\omega_0}\right)^{-1/2}}$$

where:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- ω is the frequency in radians/second
- ω_0 is a corner frequency represented by the equation (2):

$$\omega_0 = \frac{2}{a^2 \mu_r \mu_0 \sigma}$$

- K is a derived constant used to simplify the equation (3):

$$K = \frac{3}{2} \cdot SR = \frac{6\pi a^2 N}{A_f}$$

in which:

- *SR* is the Hall-Huray surface ratio:

$$\frac{4\pi a^2 N}{A_f}$$

- *a* is the radius of a spherical nodule
- μ_r is the relative permeability of the conductor
- μ_0 is the permeability of free space

$$\mu_0 = 4\pi \cdot 10^{-7}\ \mathrm{H/m}$$

- σ is the electrical conductivity in Siemens/m
- *N* is the number of nodules
- A_f is a unit cell area

Note:

a and *SR* are the two parameters you must enter in the **Finite Conductivity Boundary** dialog box when you select the Huray surface roughness model:

For more information about this complex causal Huray model (its necessity, background, derivation, proof of accuracy, and consistency with the original real-valued model), see Reference 6 below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once the Huray surface roughness factor is determined, the rough surface impedance (Z_{rough}) is determined by the equation (4):

$$Z_{rough} = H_c \cdot Z_{smooth}$$

Groiss Surface Roughness Model

The Groiss surface roughness model is a simple function of the surface roughness and skin depth of the conductor.

The smooth surface impedance (Z_{smooth}) is increased by a factor ($fact_R$), given by the equation (1):

$$fact_R = 1 + e^{-\left(\frac{\delta}{2s}\right)^{1.6}}$$

where:

- s is the surface roughness (in length units)
- δ is the skin depth, which is defined as (2):

  $$\delta = \frac{1}{\sqrt{\pi f \mu_r \mu_0 \sigma}}$$

  in which:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- f is the frequency in Hz
- μ_r is the relative permeability of the conductor
- μ_0 is the permeability of free space

$$\mu_0 = 4\pi \cdot 10^{-7}\ \mathrm{H/m}$$

- σ is the electrical conductivity in Siemens/m

Once the Groiss surface roughness factor is determined, the rough surface impedance (Z_{rough}) is determined as (3):

$$Z_{rough} = fact_R \cdot Z_{smooth}$$

Limitations of the Groiss Model:

The Groiss surface roughness model is non-causal and is therefore limited to the frequency-domain (not suitable for time-domain computations). The Groiss roughness factor is bound by the following limits:

$0 < fact_R \leq 2$

Therefore, it is suitable for relatively highly polished conductors and not suitable for the much rougher copper conducting traces that are typical of manufactured PCBs.

For roughness factors greater than 2 and for time-domain computations, use the Huray Surface Roughness Model.

Modified Hammerstad Model

In Ansys Electronics Desktop, the Hammerstad-Jensen surface roughness model is only implemented for metal layers in SIwave designs and for Finite Conductivity boundaries assigned to applicable edges in 2D Extractor designs. For HFSS and HFSS 3D Layout designs, you can map Hammerstad surface roughness to the Huray model when assigning Finite Conductivity boundaries.

This section describes a modified Hammerstad model and how it is expressed as a function of frequency. The Hammerstad model is strictly mathematical. As mentioned above, it is possible to map the Hammerstad surface roughness data to a physics-based Huray model.

The modified Hammerstad model is described by two parameters, the RMS surface roughness Δ and the scale factor *SF*. In the original Hammerstad-Jensen model, the value of *SF* = 2.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The model equation (1) is as follows:

$$\mathrm{H_{HJ}}\left(f\right) = 1 + \left(\frac{2}{\pi}\right)\left(SF - 1\right)arc\tan\left[1.4\left(\frac{\Delta}{\delta(f)}\right)^2\right]$$

$\delta\left(f\right)$ is given by

$$\delta\left(f\right) = \frac{1}{\sqrt{\pi f \mu \sigma}}$$

Therefore, the model equation reduces to (2):

$$\mathrm{H_{HJ}}\left(f\right) = 1 + \left(\frac{2}{\pi}\right)\left(SF - 1\right)arc\tan\left[1.4\pi\Delta^2\mu\delta f\right]$$

Define the model's corner frequency, f_{HJ} using the formula (3):

$$f_{HJ} = \frac{1}{1.4\pi\Delta^2\mu\sigma}$$

Therefore, the modified Hammerstad model can be written as (4):

$$\mathrm{H_{HJ}}\left(f\right) = 1 + \left(\frac{2}{\pi}\right)\left(SF - 1\right)arc\tan\left[\frac{f}{f_{HJ}}\right]$$

> **Note:**
>
> At low frequencies, the value of $H_{HJ}(f)$ approaches 1. At high frequencies, the value approaches *SF*.

Obtaining Broadband Matching between Huray and Hammerstad Models

This topic contains the procedure for obtaining broadband matching between Huray and Hammerstad models.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

Before reading this topic, see the sections Huray Surface Roughness Model and Modified Hammerstad Model for the definitions of Scale Factor (SF) and to see how each of these models is expressed as a function of frequency.

The simplest way to create a Hammerstad model that is in some sense close to a Huray model is to ensure the maximum values of the models are the same.

$$SF = 1 + \frac{3}{2}(SR)$$

$$SR = \frac{2}{3}(SF - 1)$$

Then, try to line up the models at their 50% crossing points. For the Hammerstad model, that occurs when (1):

$$1 + \left(\frac{2}{\pi}\right)(SF - 1) arc\tan\left(\frac{f}{f_{HJ}}\right) = \frac{1+SF}{2}$$

$$f = f_{HJ}$$

For the Huray model, the 50% point is reached when (2):

$$\frac{\frac{f}{f_{HH}}}{\frac{f}{f_{HH}} + \sqrt{\frac{f}{f_{HH}}} + \frac{1}{2}} = \frac{1}{2}$$

By solving for *f*, the equation reduces to the following (3):

$$f = f_{HH}\left(1 + \frac{\sqrt{3}}{2}\right)$$

Therefore, for 50% of points to agree, the following condition must be realized (4):

$$f_{HJ} = f_{HH}\left(1 + \frac{\sqrt{3}}{2}\right) \cong 1.866 f_{HH}$$

Using equation 4 and relating back to the model parameters, the following is obtained (5):

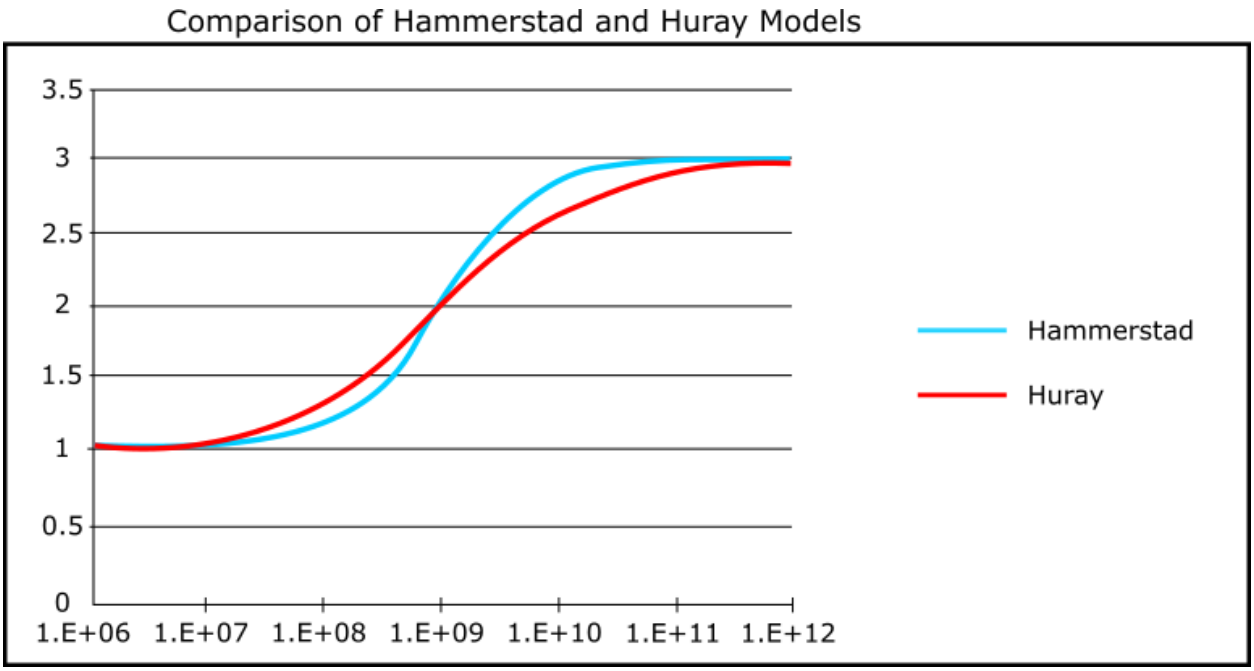
$$\frac{1}{1.4\pi\Delta^2\mu\delta} = \frac{1.866}{\pi a^2 \mu\sigma}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Compare the two models. For the Hammerstad model, set *SF*=3 and Δ=1.766m and let the material be copper. This conveniently yields f_{HJ} = 1 GHz.

Using the preceding relations, the corresponding Huray model has *SR*=4/3 and *a*=2.854μm.

Plots of $H_{HJ}(f)$ and $H_{HH}(f)$ are shown in the following figure.



The figure demonstrates the expected match between the two curves at the 50% point (1 GHz), and the expected match at the low and high frequency extremes. It is also clear the Hammerstad model transitions between low and high frequency more rapidly than the Huray model. This is inherent to the mathematical functions used in the model. Since the Huray model is based on the physics of the underlying loss mechanism while the Hammerstad model is a curve fit, it is reasonable to expect the Huray model to be more realistic.

The preceding model-matching procedure potentially may be critiqued as follows:

- The matching is exact at some (three) points and is decent across the entire frequency range.
- The computed snowball radius is actually greater than the RMS surface roughness value. This does not seem realistic.

An alternative procedure is to try matching the two models at low frequencies. The rationale for doing this is the loss measurements used to derive a Hammerstad model are likely to be taken mainly at frequencies well beneath the 50% point. Therefore, the higher frequency values might not be given as much weight in the matching process. This approach is described below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Obtaining Better Low Frequency Matching

The low frequency match could be improved by shifting the Huray model curve to the right. Such a shift can be accomplished by reducing the value of the snowball radius; this increases the Huray corner frequency f_{HH}.

No unique method exists to do this since there are many different frequency ranges and error metrics that could be used. Results obtained from some trial and error experiments reveal that a good starting point is using the broadband parameter values:

$$SR = \frac{2}{3}(SF - 1)$$

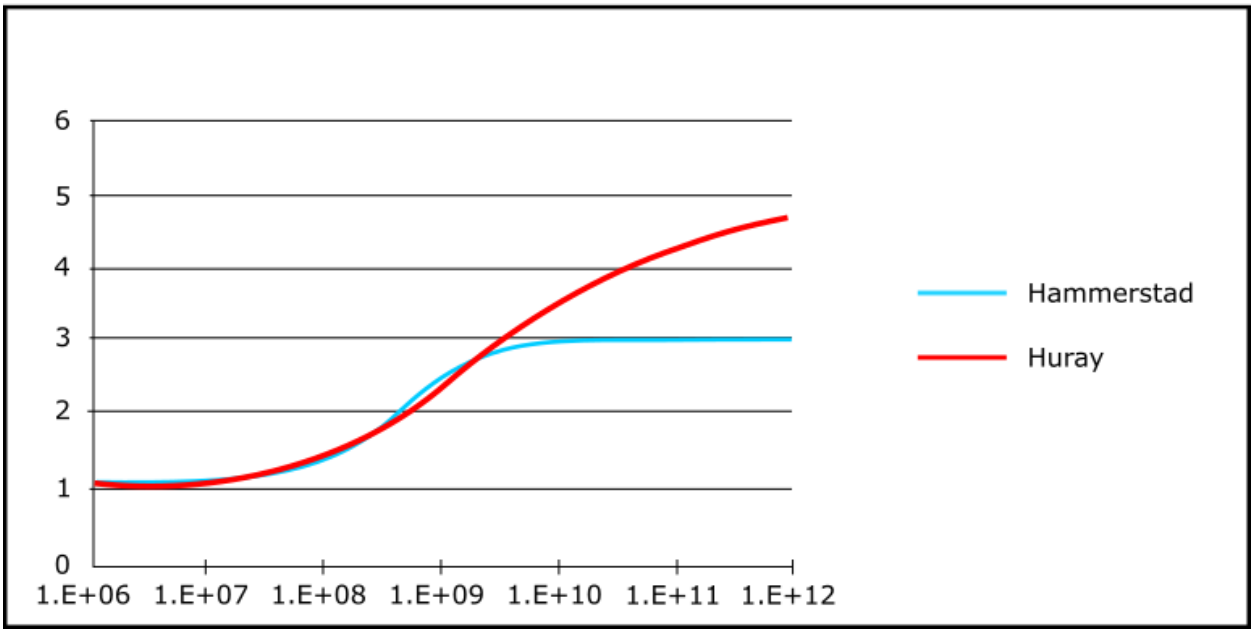
A match qualitatively similar to that shown in the following figure is obtained by choosing:

$$a = 0.65\Delta \quad SR = \frac{4}{3}(SF - 1)$$

For more information, see references below.

Setting a = 1.148μm and SR = 2.667 results in the following comparison:

Comparison of Hammerstad and Huray Models with Low-Frequency Matching Emphasized at the Expense of High-Frequency



The match between the two is very good up to about 4 GHz, well beyond the 50% crossing point of the Hammerstad model at 1 GHz. Beyond this frequency, the fitted Huray model predicts significantly higher losses (66% greater) than the Hammerstad model. This is the price paid for

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the improved low frequency match. Of course it was assumed the Hammerstad model may not be accurate in this higher frequency range anyway.

To summarize, the Hammerstad model is fundamentally different from the Huray model. Since Hammerstad is strictly a mathematical model and the Huray model is a physics-based model, *the conversion between the two is not exact*. An approximate conversion is indeed possible, as shown, and the choice of conversion process depends on whether a broadband or a low-pass match is selected. Two conversion schemes have been described here, but a continuum of different choices is available.

Expect that any usable conversion scheme has Huray model parameters that satisfy the following bounds:

$$0.65\Delta \leq a \leq 2\Delta$$

and

$$\frac{2}{3}\left(SF-1\right) \leq SR \leq \frac{3}{2}\left(SF-1\right)$$

Symmetry Boundaries

In HFSS, symmetry boundaries represent perfect E or perfect H planes of symmetry. Symmetry boundaries enable you to model only part of a structure, which reduces the size or complexity of your design, thereby shortening the solution time.

When you are defining a symmetry plane, keep the following requirements in mind:

- A plane of symmetry must be exposed to the background.
- A plane of symmetry must not cut through an object drawn in the **3D Modeler** window.
- A plane of symmetry must be defined on a planar surface.
- Only three orthogonal symmetry planes can be defined in a problem.

Perfect E Vs. Perfect H Symmetry Boundaries

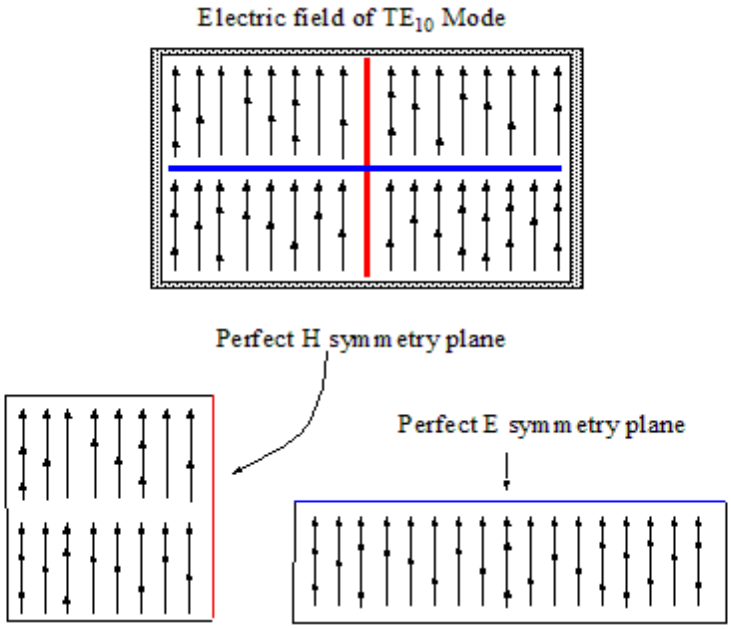
In general, use the following guidelines to decide which type of symmetry boundary to use, a perfect E or a perfect H:

- If the symmetry is such that the E-field is normal to the symmetry plane, use a perfect E symmetry plane.
- If the symmetry is such that the E-field is tangential to the symmetry plane, use a perfect H symmetry plane.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The simple rectangular waveguide shown below illustrates the differences between the two types of boundaries. The E-field of the dominant mode signal (TE_{10}) is shown. The waveguide has two planes of symmetry, one vertically through the center and one horizontally.

The horizontal plane of symmetry is a perfect E surface. The E-field is normal and the H-field is tangential to that surface. The vertical plane of symmetry is a perfect H surface. The E-field is tangential and H-field is normal to that surface.



For common problems, you can usually decide which symmetry boundary to use by reviewing the geometry. For example, if the structure is a microstrip, the flux lines of the E-field run between the ground plane and the conductive strip; therefore, the E-field is tangential to any vertical symmetry plane that slices a microstrip in half.

Symmetry and Port Impedance

If a symmetry plane has been defined, the computed port impedances will not match the port impedance of the full structure unless an impedance multiplier is specified.

> **Note:**
>
> Port impedance is only calculated when a port has been defined. If you are solving a problem without ports, you do not need to specify an impedance multiplier.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Symmetry and Multiple Modes

If you are solving for multiple modes, keep in mind that the orientation of the E- and H-fields may differ from mode to mode. A perfect H symmetry boundary for the dominant mode may be a perfect E symmetry for another mode.

Primary and Secondary Boundaries

Primary and secondary boundaries (Lattice Pairs) enable you to model planes of periodicity where the E-field on one surface matches the E-field on another to within a phase difference. They force the E-field at each point on the secondary boundary match the E-field to within a phase difference at each corresponding point on the primary boundary. They are useful for simulating devices such as infinite arrays.

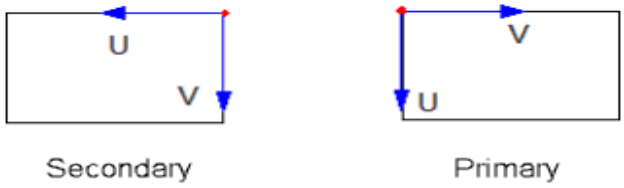
Unlike symmetry boundaries, **E** does not have to be tangential or normal to these boundaries. The only condition is that the fields on the two boundaries must have the same magnitude and direction (or the same magnitude and opposite directions).

When creating matching boundaries, keep the following points in mind:

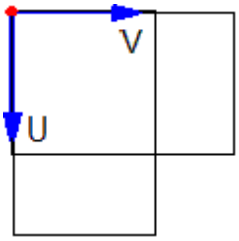
- Primary and secondary boundaries can only be assigned to planar surfaces. These may be the faces of 2D or 3D objects.
- The geometry of the surface on one boundary must match the geometry on the surface of the other boundary. For example, if the primary is a rectangular surface, the secondary must be a rectangular surface of the same size.
- If the mesh on the primary boundary does not match the mesh on the secondary boundary exactly, the solution will fail. Normally HFSS automatically forces the mesh to match on each boundary; however, in some cases, the mesh cannot be forced to match. To prevent the solution from failing, create a virtual object on the secondary boundary that exactly matches any extra object on the primary boundary, or create a virtual object on the primary boundary that exactly matches any extra object on the secondary boundary.
- To make a surface a primary or secondary boundary, you must specify a coordinate system that defines the plane on which the selected surface exists. When HFSS attempts to match the two boundaries, the two coordinate systems must also match each other. If they do not, HFSS will transpose the secondary boundary to match the primary boundary. When doing this, the surface to which the secondary boundary is assigned is also transposed. If, after doing this, the two surfaces do not occupy the same position relative to their combined defined coordinate system, an error message appears.

For example, consider the following figure:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To match the coordinate system of the primary boundary, the coordinate system on the secondary boundary must rotate 90 degrees counterclockwise; however, when this is done, you get the following:



The two surfaces do not correspond and thus the mesh will not match, causing an error message.

- The angle between the axes defined by the u point and v point must be identical for the primary and secondary boundary.

Calculating the E-Field on the Secondary Boundary

The E-field on the secondary boundary is forced to match the E-field on the primary boundary. The magnitude of the E-field on both boundaries is the same; however, the fields may be out of phase with each other.

The function relating the electric field on the secondary boundary, E_S, to the electric field on the primary boundary, E_M, depends on the type of problem you are solving. For example, consider an infinite array simulation for a rectangular array. If the array excited to radiate in the direction (θ, ϕ) in spherical coordinates. The fields above the array experience a phase delay of

$$\Psi = k(\hat{r}_o \bullet \boldsymbol{v}) \quad (1)$$

where

- $\hat{r}_0$ is the unit vector in the direction of scan.
- $\boldsymbol{v}$ is the vector from the secondary boundary to the primary boundary.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To simulate this in the finite element solution, HFSS incorporates phase shifts in the relation between the matching boundaries. That is, the electric field values on the primary boundary will be related to the electric field values on the corresponding points on the secondary boundary. This equation would be the following:

$$E_S = e^{j\Psi} E_M \quad (2)$$

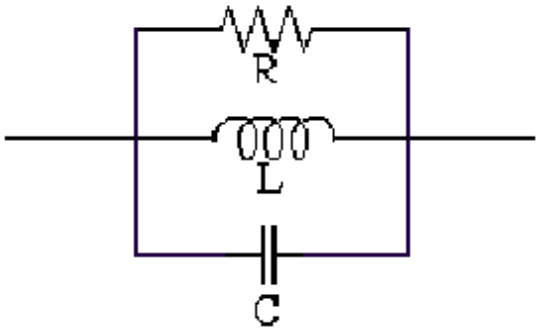
HFSS gives you the option of entering the scan angles, ϕ and θ, when relating E_S to E_M. The phase delay is calculated from the scan angles. However, if you know the phase delay, you may enter that directly.

Anisotropic Impedance Boundaries

Planar screens or grids of large extent with periodic geometry can be replaced by an Anisotropic impedance boundary. The boundary applies a homogeneous characteristic impedance to the surface in an effort to create an equivalent electrical representation of the geometric grid pattern.

Lumped RLC Boundaries

To model any combination of lumped resistor, inductor, and/or capacitor in parallel on a surface, create a lumped RLC boundary. A lumped RLC boundary represents R, L, and C in parallel:



Similar to impedance boundaries, the following condition holds at lumped RLC boundaries:

$$Loss = 0.5 \times Real\left((\vec{E} \times \overrightarrow{normal}) \cdot \overline{(\vec{E} \times \overrightarrow{normal}) \div \overline{Impedance}}\right)$$

Unlike impedance boundaries, you are not required to supply the impedance per square, but you must supply the actual values for R, L, and C. HFSS then determines the impedance per square of the lumped RLC boundary at any frequency.

A Fast frequency sweep is supported for this boundary condition.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Layered Impedance Boundaries

A layered impedance boundary is used to model multiple layers in a structure as one impedance surface. The effect is the same as an impedance boundary condition, except that HFSS calculates the reactance and resistance values for the surface based on data you enter for the layered structure. Surface roughness is also taken into account.

The reactance and resistance values are calculated differently for internal and external layered impedance boundaries. For external layered impedance boundaries, HFSS calculates the impedance for the side of the surface in contact with the computational domain and assigns this value to the boundary. For internal layered impedance boundaries, HFSS calculates the average impedance value for the two sides of the surface that are in contact with the computational domain and assigns this value to the boundary.

The layered impedance boundary is supported for single-frequency solutions and Discrete and Interpolating frequency sweeps.

Impedance Calculation for Layered Impedance Boundary

The impedance of the layered structure is calculated recursively. First the impedance of the lowest layer is calculated, and then the impedance of the layer above is computed from transmission line theory as follows:

$$Z_{input,k} = Z_{wk}\frac{Z_{input,k+1}\cosh(\gamma_k d_k) + Z_{wk}\sinh(\gamma_k d_k)}{Z_{input,k+1}\sinh(\gamma_k d_k) + Z_{wk}\cosh(\gamma_k d_k)}$$

The process is completed when the uppermost layer is reached.

Here, for the k^{th} layer:

- d_k is the layer thickness.
- Z_{wk} is the wave impedance:

$$Z_{wk} = \sqrt{\frac{\mu_0\mu_{rk}}{\epsilon_0\epsilon_{rk}}}$$

- γ_k is the propagation constant:

$$\gamma_k = jk_0\sqrt{\epsilon_{rk}\mu_{rk}}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- $k_0=\omega\sqrt{\mu 0\,\epsilon 0}$ is the free space wave number, where $\omega=2\pi f$ is the angular frequency.
- ϵ_{rk} the complex relative permittivity.
- μ_{rk} is the complex relative permeability.

ϵ_{rk} and μ_{rk} are given by the following formulas:

$$\epsilon_{rk} = \epsilon'_{rk} - j\epsilon''_{rk}$$

$$\mu_{rk} = \mu'_{rk} - j\mu''_{rk}$$

The real parts ϵ'_{rk} and μ'_{rk} are entered directly. The imaginary parts of the complex relative permeability and permittivity may be entered directly, or derived from the conductivity and loss tangents of the materials as follows:

$$\epsilon''_{rk} = \frac{\sigma_k}{\omega\epsilon_0} + \epsilon'_{rk}\tan\delta_{ek}$$

$$\mu''_{rk} = \mu'_{rk}\tan\delta_{mk}$$

Here, for the k^{th} layer:

- σ_k is the bulk electrical conductivity.
- $\tan\delta_{ek}$ is the electric loss tangent.
- $\tan\delta_{mk}$ is the magnetic loss tangent.

Surface Roughness Calculation for Impedance Boundary

The surface roughness is measured as the RMS deviation of the conductor surface from a plane. Surface roughness increases conduction losses. HFSS calculates surface roughness by modifying the conductivity as follows:

$$\sigma_c = \frac{\sigma}{K_w^2} \quad (1)$$

where

σis the material's conductivity.

$$K_w = 1 + \exp\left(-\left(\frac{s}{2h}\right)^{1.6}\right) \quad (2)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where, further:

- *h* is the surface roughness.
- *s* is the skin depth.

Shell Elements Theory

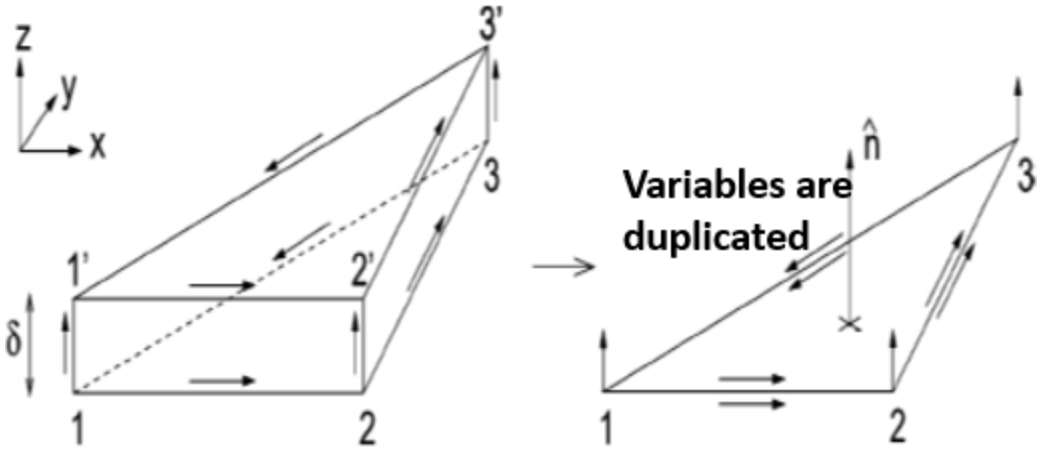
Layered Impedance Boundaries include an option to designate two-sided boundaries as shell elements. For Finite Conductivity boundaries, if DC thickness is set and the user selects two-sided, they can also designate that the boundary be treated as a shell element. If the layered structure is within a 3D model, meshing thin layers and solving inside may be inefficient, so replace the highly conductive thin layer with a shell element. The Shell Element option only applies to HFSS Driven solution types and does not apply to HFSS Eigenmode and Transient solution types. Shell elements are useful for both shielding and radome applications. They can touch or intersect other boundary conditions or materials. They must be valid across a broad frequency range. Example uses include simulation of an antenna inside a car chassis or an antenna inside a dielectric radome, when the chassis and/or radome is modeled using sheets. Shell elements maintain two sets of unknown coefficients for the top and bottom surface.

> **Note:**
>
> The shell element option is applicable for all frequencies and can therefore be used for broadband simulations without the need to modify boundary options depending on the simulation frequency. A sheet can also be a face of a solve inside object.

HFSS uses non-classical shell elements. Classical shell elements appear as prism elements created by doubling tangential components of the electrical field on both sides of a layer. This assumes constant linear or higher order variation in the normal direction. This classical approach is limited in application when the layer is not thin enough to the degree that the field has significant variation in the normal direction or if the field has strong decay in the layer despite it being thin.

Conventional Shell Elements (First Order)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



$$\vec{N}_{12} = \beta \vec{N}_1^t \quad \vec{N}_{23} = \beta \vec{N}_2^t \quad \vec{N}_{31} = \beta \vec{N}_3^t$$
$$\vec{N}_{1'2'} = \beta' \vec{N}_1^t \quad \vec{N}_{2'3'} = \beta' \vec{N}_2^t \quad \vec{N}_{3'1'} = \beta' \vec{N}_3^t$$
$$\vec{N}_{11'} = -L_1^t \nabla\beta \quad \vec{N}_{22'} = -L_2^t \nabla\beta \quad \vec{N}_{33'} = -L_3^t \nabla\beta \quad (1)$$

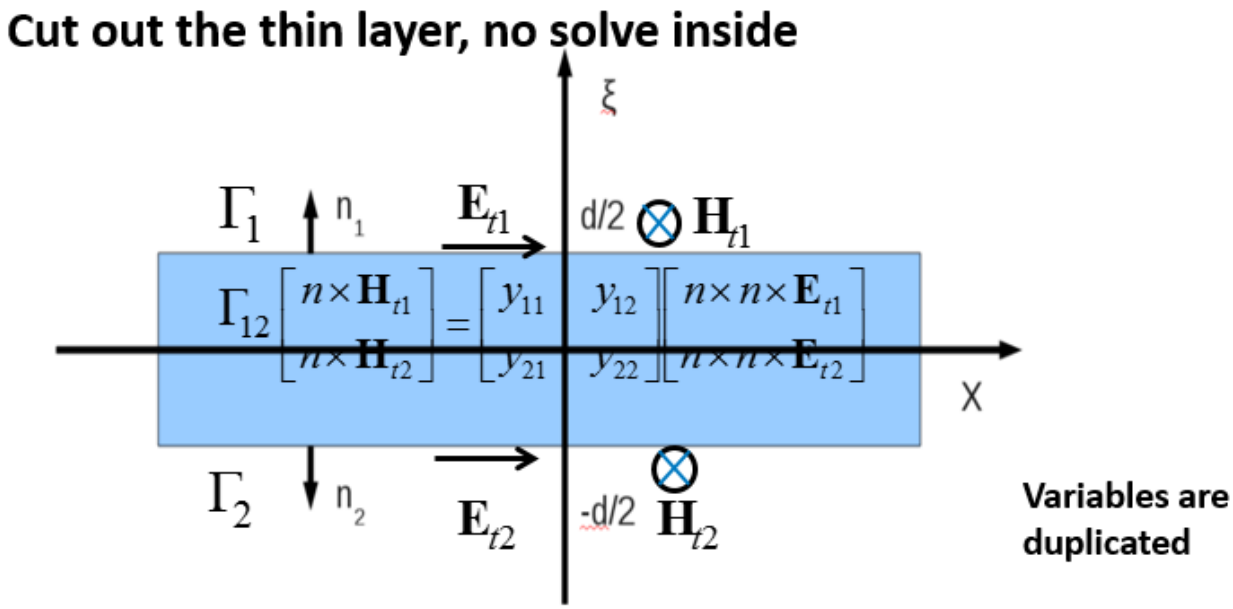
where $\beta' = 1 - \beta$ and $\vec{N}_{12}$ denotes the basis function associated with the edge between node 1 and node 2.

This depicts a degenerated prism element with no 3D mesh assembled on the fly.

Non-Conventional Shell Elements

For non-classical shell elements, we assume that we know the tangential electric and magnetic field on the two sides of the sheet. Rather than evaluate the finite element matrices in the thin prism, we apply a Neuman boundary condition to both sides of the sheet using the circuit ***Y*** matrix of the layers. Due to cases where the structure ***Y*** matrix cannot be characterized by closed analytical formulas, HFSS uses a two stage method which does not require analytical coupling formulas to replace Frequency Select Surfaces (FSS) by a sheet with shell elements. First, we extract a ***Y*** matrix for the FSS by solving a unit cell model of the layer(s). Then we use the ***Y*** matrix to couple the two sides of the layer in the FEM. This approach provides accurate and efficient modeling for an arbitrary thin or thick FSS. This is valid for any broad band frequency and material. (See References).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This uses:

- Use a 1D local transmission line model inside
- No Solve Inside, no 3D mesh
- Neumann/natural boundary condition
- Skin effect - copes with strong decay

Conventional versus Non-Conventional Shell Elements

Conventional shell elements:

- accurate
- good for the mesh maker
- can’t cope with strong decay
- higher order is difficult

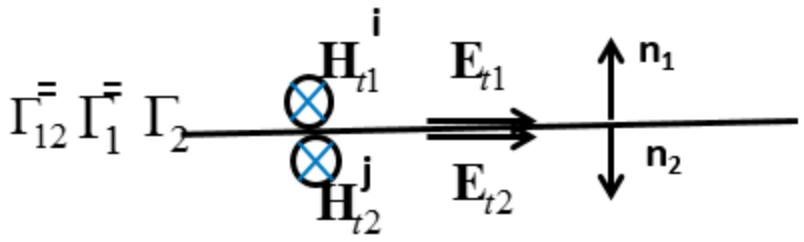
Non-Conventional shell elements

- approximated by a 1D local model
- good for the mesh maker
- copes with strong decay
- no need for higher order

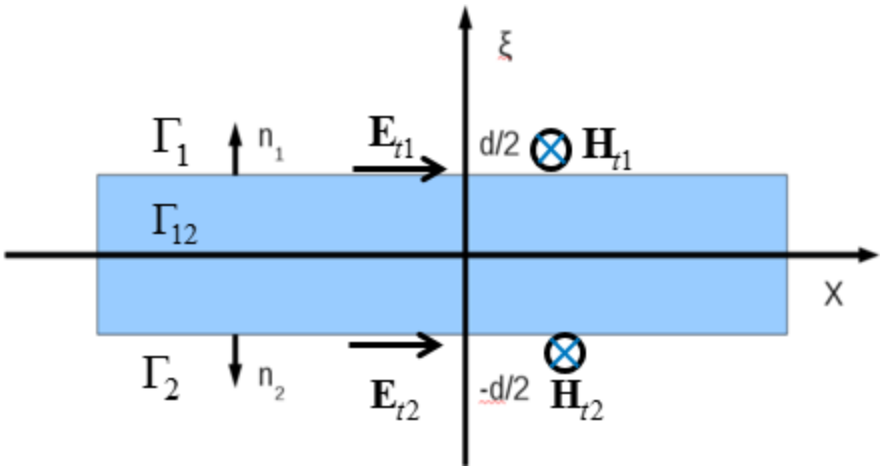
Finite Element Discretization

For sheet shell elements, 3D objects are replaced by a sheet:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For volumetric shell elements, keep the layer of thickness *d*, no solve inside.



Finite Element Discretization

Sheet shell elements:

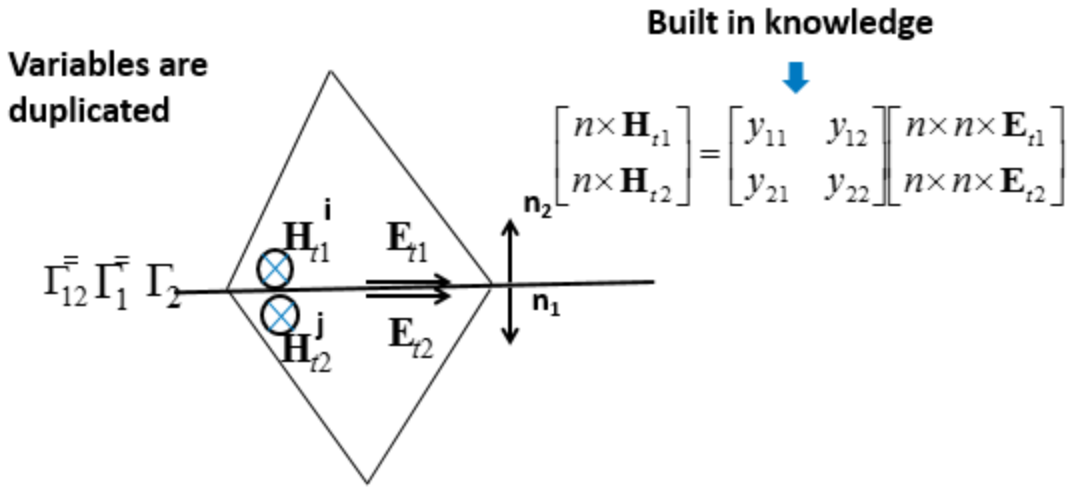
- no mesh inside
- good for the mesh maker
- manual work to get rid of 3D objects

Volumetric shell elements

- good for automation and ease of use
- background mesh inside
- overall mesh quality might be worse

Sheet Shell Elements

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- 3D layer replaced by a sheet
- E DoFs have to be duplicated
- Edges and vertices also can touch the surface

Finite Element Implementation

$$\int_{\Gamma_1} \mathbf{E}_1^* \bullet (\mathbf{n}_1 \times \nu_r curl\mathbf{E}_1) d\Gamma = -j\omega\mu_o \int_{\Gamma_1} (\mathbf{E}_1^* \bullet \mathbf{n}_1 \times \mathbf{H}_1) d\Gamma$$

$$\int_{\Gamma_1} \mathbf{E}_1^* \bullet (\mathbf{n}_1 \times \nu_r curl\mathbf{E}_1) d\Gamma = -j\omega\mu_o \int_{\Gamma_1} (\mathbf{E}_1^* \bullet (\mathbf{n}_1 \times (y_{11}\mathbf{n}_1 \times \mathbf{E}_1) + (y_{12}\mathbf{n}_1 \times \mathbf{E}_2)) d\Gamma$$

$$\int_{\Gamma_2} \mathbf{E}_2^* \bullet (\mathbf{n}_2 \times \nu_r curl\mathbf{E}_2) d\Gamma = -j\omega\mu_o \int_{\Gamma_2} (\mathbf{E}_2^* \bullet (\mathbf{n}_1 \times (y_{22}\mathbf{n}_2 \times \mathbf{E}_2) + (y_{21}\mathbf{n}_2 \times \mathbf{E}_1)) d\Gamma$$

Here $\mathbf{E}^*$ denotes weighting functions in the FEM Galerkin method. In this way, a shell element resembles an outer impedance boundary condition. Notice that the field coupling from one side to the other is captured by the term $y_{ij}\mathbf{n}_i \times \mathbf{E}_j$ in the surface integrals. Furthermore, when assembling a tetrahedron on one side of the sheet, the solver does not include n regular coupling from a tetrahedron on the opposite side except the surface integration contribution just described.

Implementation Issues: Sheet Shell Element Considerations

- Mesh is not modified
- Mesh maker provides the solver with list of shell tets

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

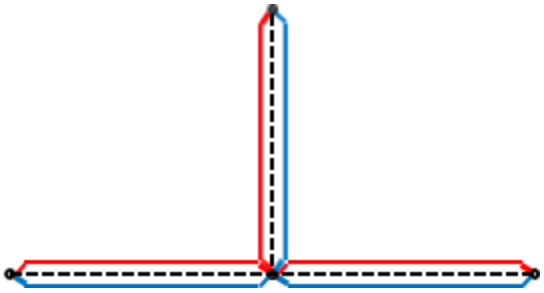
Implementation Issues: FEM and Sheet Shell Elements

Broad frequency range: Singlar matrix at low frequencies when E tangential components are continuous.

Boundary edges always have impedance:

Intersecting edges:

- Impedance on dielectrics
- PEC on metals



Accuracy

Conclusions

- Shell elements are applicable both for conductive and dielectric layers.
- Broad band frequency sweep
- For dielectric layers, the accuracy deteriorates in relation to the how off normal the angle of incident is from the boundary. If the layered impedance boundary or shell element contains at least one high conductivity layer, then the accuracy maintains for a significant extent off normal.
- This dependence is much less when using layers with high conductivity.
- Numerical shell elements work well by using Unit Cell Data Link.
- Volumetric shell elements are accurate even with non-conformal mesh.

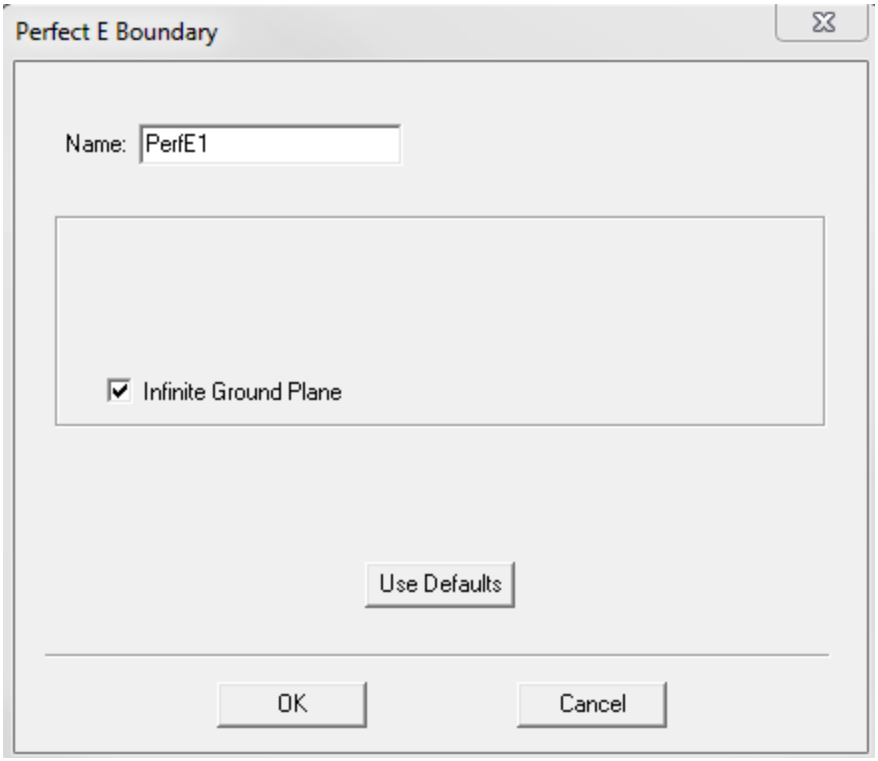
Infinite Ground Planes

When defining **Perfect E Boundary**, **Impedance Boundary**, or **Finite Conductivity Boundary**, select the **Infinite Ground Plane** check box to model its effects in the simulation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The following figure shows the **Perfect E Boundary** dialog box with this option selected.



For designs with port excitations but no FE-BI boundary and metallic IE region defined, selecting **Infinite Ground Plane** affects only the calculation of near field and far field radiation during post processing; otherwise, the design has to be re-simulated to model the effects of infinite ground plane.

The boundary condition infinite ground plane divides the problem region into two halves. The entire model resides in the half above the boundary, and the radiated fields are set to zero in the half below the boundary. Antenna parameters involving radiated power are consistent with these properties.

Lossy ground planes can be approximated by selecting the **Infinite Ground Plane** check box when defining **Finite Conductivity Boundary** or **Impedance Boundary**. The effects of these boundary conditions are incorporated in the field solution and in the radiated fields accordingly.

Remember the following requirements when defining an infinite ground plane:

- It must be defined on a planar surface.
- All infinite ground planes and symmetry planes must be mutually orthogonal.
- For impedance, layered impedance, or finite conductivity boundaries, only one infinite ground plane can exist in a design. For perfect E boundary conditions, multiple infinite ground planes are supported and they must be co-planar.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> When PML or a standard radiation boundary is used, the FEM model must contain the ground plane on the bottom surface and the PML or radiation boundary on the other surfaces. To achieve accurate results, this restriction must be followed. This restriction does not apply in the following cases:

- When a FE-BI is used for the radiation boundary and the infinite ground plane is modeled as metallic IE region.
- Finite arrays are analyzed using a Finite Array DDM model.

Frequency-Dependent Boundaries and Excitations

In general, boundary and excitation parameters cannot depend on intrinsic functions. An exception is when a parameter depends on the variable *Freq*, which represents the solution frequency. The following boundary parameters can be assigned an expression that includes *Freq*:

- Impedance boundary - the Resistance and Reactance parameters.
- Finite conductivity boundary - the Conductivity parameter. If a material is specified, the conductivity of the material can be frequency dependent.
- Secondary boundary - the Phase parameter.
- Lumped RLC boundary - Resistance, Inductance, and Capacitance parameters.
- Layered impedance boundary - materials assigned on layers can be frequency dependent.
- Anisotropic Impedance boundary - Resistance and Reactance parameters.

> **Note:**
>
> Dependence on *Freq* is supported for single-frequency solutions and for Discrete and Interpolating frequency sweeps. If a Fast sweep is requested, the solution will be valid for the center frequency, but may not be valid at other frequencies.

Implicit Boundary Assignments

If a boundary has not been assigned to a model surface, one of the following default boundaries will be assigned to the surface:

smetal	A single perfect E boundary is assigned to all objects that do not have **Solve Inside** selected in the **Properties** window and that are perfect conductors.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

i_<*object name*>	A finite conductivity boundary is assigned to each object that does not have **Solve Inside** selected in the **Properties** window and that is not a perfect conductor. <*object name*> is the name of the object on which the boundary is assigned.
outer	A default boundary applied on the outermost surfaces of the model.

These boundary assignments are intrinsic and not displayed in the modeler.

Gradient Model for Surface Roughness

The gradient model was proposed by G. Gold and K. Helmreich in reference [1] below. In their approach, random variations in a rough metal surface are modeled by an assumed *probability density function* (PDF). The PDF describes how likely it is that the surface will be perturbed by some distance above or below its mean height (see Figure 1). Provided that these perturbations are small compared to the wavelength, their effects on a propagating signal can be averaged out. This averaging results in a spatially varying conductivity that is a function of the distance from the mean surface (see Figure 2). This conductivity can be plugged into a one-dimensional version of Maxwell's equations which can then be solved to yield the effective surface impedance.

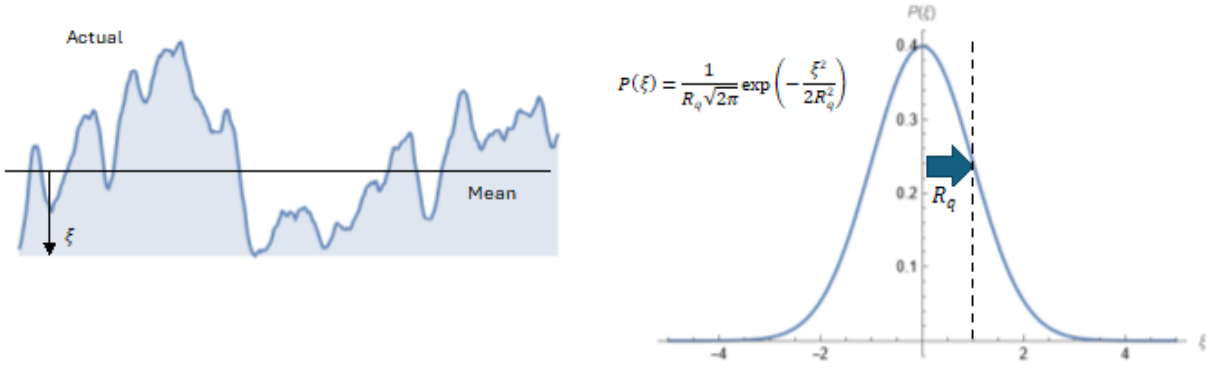


Figure 1: A Rough Suface described with a Gaussian Probability Density Function

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

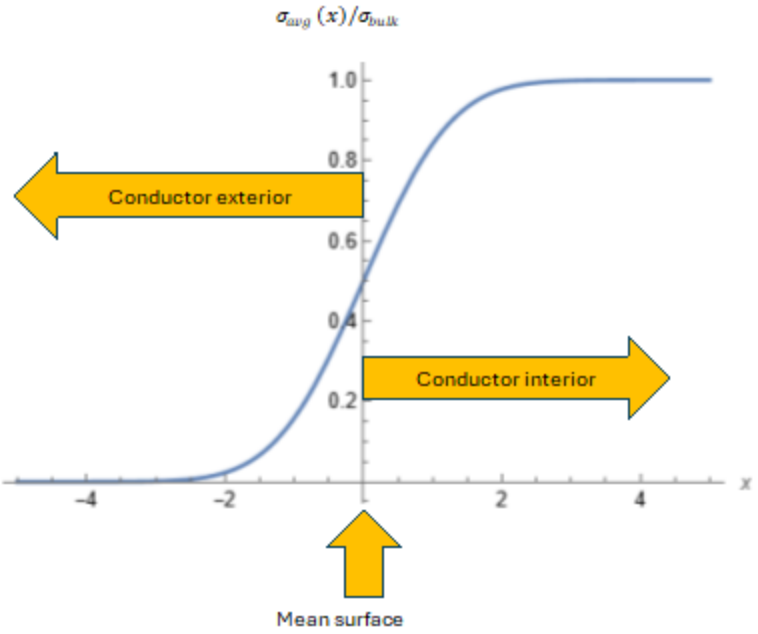

Figure 2: The Spatially Varying Conductivity, $\sigma(x)$ obtained by averaging the PDF.

An advantage of this approach is that the PDF can usually be characterized by a single parameter, the RMS roughness. This is convenient because the RMS roughness is typically measured by manufacturers and reported on their data sheets.

The gradient model in HFSS supports two types of PDF: Gaussian and Rayleigh. The Gaussian PDF is suitable for a low-profile conductor. The Rayleigh model produces somewhat higher losses and may be more appropriate for a high-profile conductor (see reference [2] below).

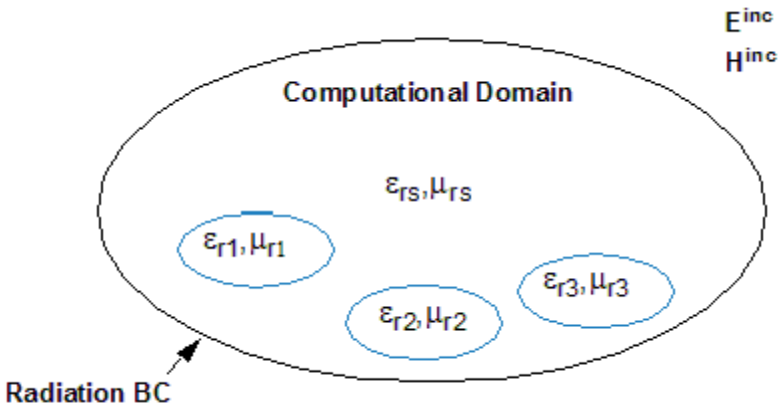
General Approach for Scattered and Total Field Decomposition

Given our compositional domain:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Incident field is known in absence of our computational domain
- Physical (total) field is sought in presence of our computational domain
- Radiation BC applies to the field generated by the objects of our computational domain (scattered field)
- Incident field might be known in the whole domain (scattered field description) or just on the surface ("space ports," total field description)
- HFSS Transient provides the total field. The fair comparison is to use a single frequency in the frequency domain and apply a harmonic excitation in the time domain with the same frequency.

Scattered and total field formulation pros and cons

Scattered field formulation

- Mostly for plane waves and analytical waves
- Cancellation errors when total field is weak
- Problems arise at infinite scatterers (slot in an infinite conducting plate)
- Near/far incident waves are not known in the whole region

Total field formulation

- Applicable for any incident pattern
- Cancellation errors when scattered field is weak
- Infinite scatterers can be treated
- Applicable to near/far field, too, since excitations have to be known on surfaces
- New, space port concept (decomposition differs from the literature).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Where the Solvers Apply Scattered or Total Field Formulations

Scattered Field Formulation

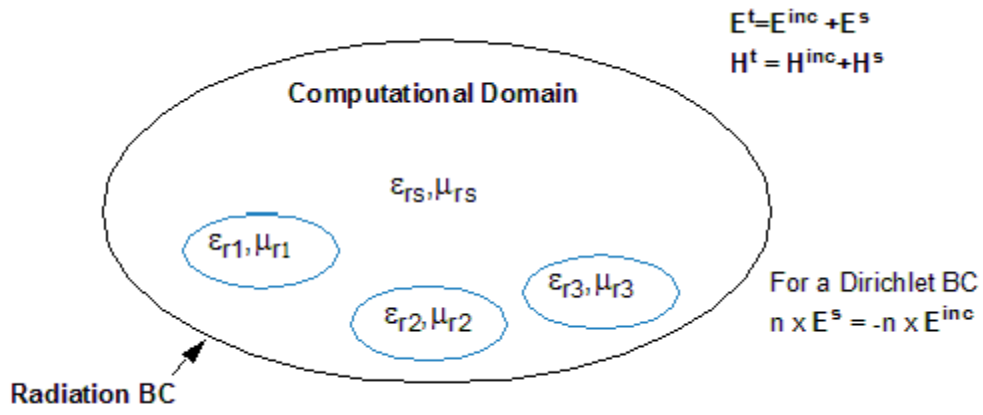
- Monostatic/bistatic RCS of finite scatterers
- Frequency Selective Surfaces (FSSs)

Total Field Formulation

- Monostatic/bistatic RCS of infinite scatterers
- Frequency Selective Surfaces (FSSs)
- When near/far field Link is involved
- EMC/EMI problems

For Scattered Field Decomposition

It is known in the whole domain.



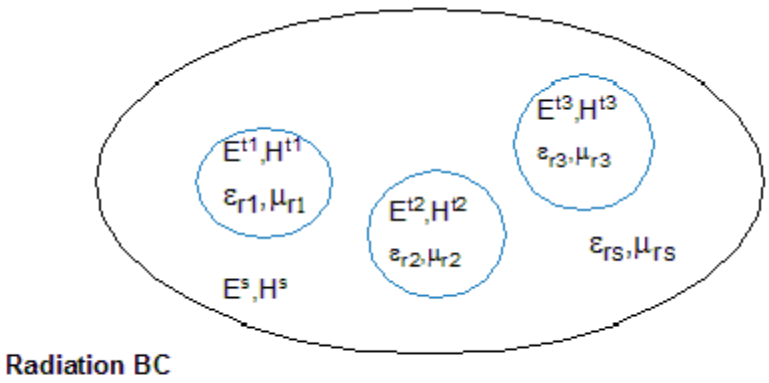
In summary, scattered field descriptions apply:

- Environment material other than vacuum
- Inhomogeneous magnetic material
- Special treatments on
- Ports
- Impedance BCs
- PMC

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

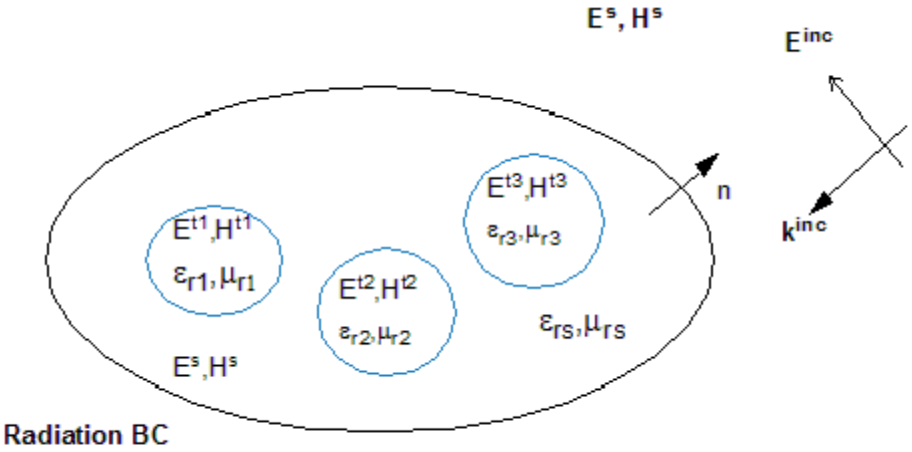
Total Field Description: Usual Approach

When the incident field is known, everywhere, the solvers take the usual approach. Both E and H jump with n x E^{inc} and n x H^{inc} on the interfaces, respectively.



Total Field Description: Unusual Approach

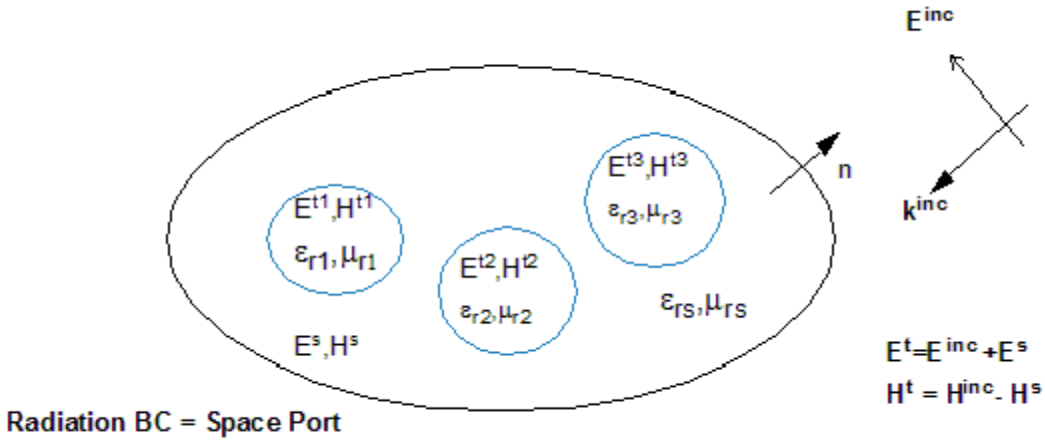
In this case, the incident wave is just on known on the surface. Both E and H jump with n x E^{inc} and n x H^{inc} on the outer surface respectively.



Total Field Description: Space Port Concept

The Radiation Boundary Condition is treated as a space port. The field is decomposed just on the surface of the space port.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Summary for Total and Scattered Fields

- Enhanced scattered field formulation
- Scattered field formulation for classical RCS problems
- Total field formulation with space ports is necessary for numerical incident waves (near/far)
- Total field formulation is necessary to analyze infinite scatterers (infinite plane, iris, etc)
- Total field formulation improves the accuracy in many cases

Excitations

Assigning excitations to an HFSS design enables you to specify the sources of electromagnetic fields and charges, currents, or voltages on objects or surfaces. This area of the Technical Notes includes information on the following topics:

- Wave Ports Theory
- Lumped Ports Theory
- Terminals Theory
- Floquet Ports Theory
- Incident Waves
- Simulating Circuits Containing N-Port Models from a Full-Wave Solver
- Voltage Sources
- Current Sources

- Magnetic Bias Sources
- Dembedding

Wave Ports Theory

By default, the interface between all 3D objects and the background is a perfect E boundary through which no energy may enter or exit. Wave ports are typically placed on this interface to provide a window that couples the model device to the external world.

HFSS assumes that each wave port you define is connected to a semi-infinitely long waveguide that has the same cross-section and material properties as the port. When solving for the S-parameters, HFSS assumes that the structure is excited by the natural field patterns (modes) associated with these cross-sections. The 2D field solutions generated for each wave port serve as boundary conditions at those ports for the 3D problem. In addition to serving as a boundary condition, a wave port also supplies port impedances and propagation constants that are useful in describing waveguides or transmission lines.

A wave port is restricted to reside at an external boundary of a 3D problem. In some instances, it makes sense to get around this restriction by defining a wave port in the interior of a 3D domain by capping the wave port surface with a PEC object. In doing this, in effect the wave port is viewed as residing at the external boundary of a 3D problem. However, in general lumped ports should be used when defining ports in the interior of a 3D domain.

Often there is a need to have a particular field direction of a mode pattern for consistent results. There are two different methods in HFSS to accomplish this task. The most basic method is where, in the presence of an integration line, HFSS resolves 180 degree ambiguity by enforcing the electric field mode pattern to have a positive line integral along the integration line for that mode (Mode Polarity). The second more advanced option is where HFSS aligns electric field mode patterns, when appropriate, in specific directions (Mode Alignment). This second option consists of a manual but general approach and an automated approach for a few port types. For more in-depth discussions refer to the following topics:

- Mode Polarity
- Mode Alignment

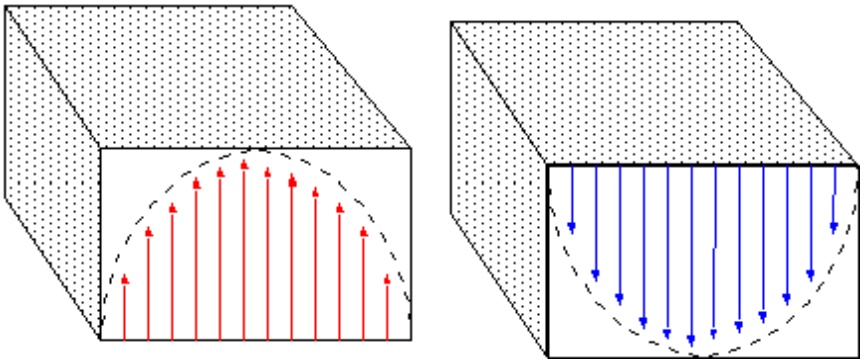
Mode Polarity

When HFSS computes an excitation mode pattern, the direction of the field at $\omega t = 0$ is arbitrary; the field can point in one of at least two directions. This document addresses how to remove the ambiguity of the field direction when a mode is not part of a set of degenerate modes. For the case of degenerate modes, there is no unique mode alignment and this topic is addressed in Mode Alignment.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In the following figure, at $\omega t = 0$ the electric field pattern of the mode can point either up (left image) or down (right image). Either direction is correct - unless a preferred direction is specified. This issue becomes of concern when inspecting the phase angle of S-parameters.

For example, consider a 3D model containing two single-mode ports of the type shown in the figure. The phase of the computed S-parameters linking the two ports will flip by 180 degrees if the polarity of the mode at either port is reversed. Therefore when transmission S-parameter phase is of interest in models such as this, the user has the responsibility to properly set the mode polarity at each port.



To specify the polarity of a mode, a mode calibration must be performed by creating an appropriate integration line. For instance, if the preferred direction is up then the integration line should be drawn at the center of the waveguide starting at the bottom and ending at the top. In general, a mode calibration is automatically performed if an integration line has been defined for a mode where HFSS ensures that the real part of the line integral of the electric field of that mode is positive.

Mode Alignment

In some cases the requested set of modes to be used with a wave port contains degenerate modes. For that case, the modes that are degenerate need special care in obtaining a unique orientation of the mode patterns which is important, for example, when a specific orientation for a given mode is intended to excite the structure.

For example, in the case of a square waveguide the first two dominant modes form a degenerate mode set. Therefore, in order to guarantee that the typically desired orientation of the modes (TE_{01} and TE_{10}) are used for an HFSS simulation, the user needs to enable one of the two supported mode alignment options. The first option is general but manual and requires detailed user knowledge of the mode patterns while the other is restricted to a few basic port types where HFSS automatically aligns the modes.

The general mode alignment option is enabled by defining appropriate integration lines for the modes that should be aligned and selecting **Align modes using integration lines** in the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modes tab of the Wave Port setup window. Note that not all modes requested for a wave port need to have an integration line defined - only the ones for which mode alignment is desired. It is important that you draw integration lines that make sense for the modes to be aligned along and that all the modes that form a set of degenerate modes have a line defined. For example, if the first two modes of a square waveguide should be TE_{10} and TE_{01}, you should draw two lines through the center of the waveguide where one line starts at the bottom and ends at the top while the other line starts on the left side and ends on the right side.

You enable the automated mode alignment option by selecting **Align modes analytically using coordinate system** in the **Modes** tab of the Wave Port setup window. By selecting this option, the user will be asked to draw a local coordinate system which is used to automatically align the modes in pre-defined directions. This option is only available for a select few port types discussed in Analytic Port Types.

In order to get intended outcome of either alignment option, it is necessary to include all modes in a set of degenerate modes. For example, assume that modes 3, 4, 5, and 6 are degenerate. You should either include all of them by specifying at least 6 modes or none of them by specifying at most 2 modes.

Analytic Port Types

Analytic mode alignment is available for certain port types by selecting **Align modes analytically using coordinate system** in the **Modes** tab in the Wave Port setup window. If analytic mode alignment is selected for a port that is not supported, the port setup becomes invalid. Here is a summary of the validation for analytic mode alignment:

- The port geometry must correspond to a known analytic type, as follows:
- Rectangular. The port must have four linear edges which meet at right angles. Square ports are a special case of rectangular.
- Circular. The port must have all curved edges. The radius, perimeter, and area of the face must be consistent with those of an ideal circle.
- Faceted Circular. The port must have at least 16 edges, all linear and of equal length. The radius, perimeter, and area of the face must be consistent with those of an ideal polygon.
- Circular or Faceted Coax.

  Explicit. The port face must have one set of inner and one set of outer edges. The inner radius, outer radius, face area and perimeter must be consistent with an ideal coaxial circle or polygon.

  Implicit. The port face itself must be circular or faceted circular, and it must have a circular or faceted circular conducting object touching it and aligned with the face center.

- The port must be assigned to a single face of a 3D object whose material is isotropic. Assignment to sheets is not allowed, as this makes it difficult to determine the object

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

material.

- No other material can contact the port, except for the inner conductor of a coax.
- Only Perfect E and Finite Conductivity boundaries can contact the port.

When reading legacy projects prior to v12, HFSS automatically tests ports with the "Polarize E Field" option enabled. If they qualify for analytic alignment, that option will be selected, and U-V lines will be set from the first two modal integration lines.

Alignment Groups for Wave Ports with Multiple Modes

When assigning wave ports for modal solutions, alignment groups can be used only for a consecutive block of degenerate modes with each block of modes identified by a unique group number. There may be modes at the end of the modes table which have no assigned alignment group, but no unassigned modes in the middle of a block of degenerate modes containing an alignment group definition. Finally, each mode with an alignment group must have an integration line.

Alignment groups allow the solver to collect the modes within a group and ensure that each mode has non-zero voltage on its own integration line and zero voltage on every other integration line in the group. If the modes in a group are not degenerate or its defined integration lines are not appropriately defined, hf3d will terminate with an error message.

Any change in the mode groups will cause invalidation of solutions but not of the mesh.

Lumped Ports Theory

Lumped ports resemble wave ports, but can be located internally and have a complex user-defined reference impedance. Lumped ports are restricted to single mode ports and the S-parameters are always based on the user defined reference impedance. This mainly because no transmission line is being modeled in the interior domain which suggests an interpretation of the lumped port as a measurement probe being connected to the surface of the lumped port with the reference impedance specified by the user.

When a lumped port is used internal to a 3D problem, it makes sense to place the lumped port at a location where the field distribution would approximately be the same as the dominant mode of the port definition in the absence of the lumped port. A typical example of this is when a rectangular port is drawn between a conductor trace and a ground plane with the face oriented perpendicular to both conductors. The port mode resulting from this case is a parallel plate mode which will often closely resemble the field distribution at that location in the absence of the port. Lumped ports must be planar but can have any arbitrary shape within the plane.

A perhaps unsuspected result of using a complex reference impedance is that the S-parameters can be greater than one even for a passive device.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

When a lumped port is used as an internal port, the conducting cap required for a traditional wave port must be removed to prevent short-circuiting the source.

Terminals Theory

HFSS can categorize microwave structures in terms of a black-box that relates voltages and currents flowing in and out of a given structure. The black-box has several terminals, each with an associated voltage/current pair. In HFSS, these terminals reside inside wave ports that enable post processing of a modal representation of the black-box into the terminal representation.

When a terminal project is solved using HFSS, the number of modes for a port is determined by the number of terminals touching the port. If N+1 distinct conductors touch the port, there are N terminals and one reference conductor usually referred to as ground. The modal port representations of the electric and magnetic fields are:

$$\mathrm{E} = \sum_{n=1}^{N} (a_n + b_n)\mathrm{e}_n \quad (1)$$

$$\mathrm{H} = \sum_{n=1}^{N} (a_n - b_n)\mathrm{h}_n \quad (2)$$

where a_n and b_n are unitless complex amplitudes of the ingoing and outgoing modal fields, respectively. The modal black-box representation of a given structure is given by HFSS in terms of the generalized scattering matrix, *S*,

$$\mathrm{b} = S\mathrm{a} \quad (3)$$

where a and b are the unitless complex modal coefficient vectors. In order to obtain a terminal representation of the black-box, N integration paths Ci and N integration loops Li are used to define N voltages and N currents, respectively,

$$= \int_{C_i} (\vec{\mathbf{E}} \cdot \vec{\mathbf{dl}}) = \sum_{n=1}^{N} (a_n + b_n) \int_{C_i} \vec{\mathbf{e}_n} \cdot \vec{\mathbf{dl}} \quad (4)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$= \sum_{n=1}^{N} (a_n + b_n) T_{in} \quad i = 1,2...,N$$

$$i_i = \oint_{C_i} (\mathrm{H} \cdot \mathrm{dl}) = \sum_{n=1}^{N} (a_n - b_n) \oint_{C_i} \mathrm{h}_n \cdot \mathrm{dl} \qquad (5)$$

$$= \sum_{n=1}^{N} (a_n - b_n) U_{in} \quad i = 1,2...,N$$

In matrix notation, the equations become

$$\mathrm{v} = T(\mathrm{a} + \mathrm{b}) \quad (6)$$

$$\mathrm{i} = U(\mathrm{a} - \mathrm{b}) \quad (7)$$

Combining these equations with (3), yields the following circuit or terminal description of the black-box representation of the structure

$$\mathrm{i} = Y\mathrm{v} \quad (8)$$

where the terminal admittance matrix Y is given by

$$Y = U(I - S)(I + S)^{-1} T^{-1} \qquad (9)$$

In HFSS, a generalized terminal scattering matrix S_t is supplied to the user..

$$\beta = s_t \alpha \quad (10)$$

where α and β are ingoing and outgoing pseudo waves, respectively. The S_t matrix is obtained by assuming that the voltages and currents are measured by some device with a given renormalizing impedance. This assumption leads to the following relations.

$$\mathrm{v} = Z_{ref}^{1/2} \quad (\alpha + \beta) \qquad (11)$$

$$\mathrm{i} = Z_{ref}^{-1/2} \quad (\alpha - \beta) \qquad (12)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where Zref is a renormalizing impedance matrix representing the measuring device. In HFSS, the user has the option to use the terminal characteristic impedance matrix, *Zo*, as the renormalizing impedance matrix by using the 'Do Not Renormalize' option in the port post processing tab. This means that the measuring device is perfectly matched to the transmission line. By default, all the terminals are individually renormalized which results in Zref being a diagonal renormalizing impedance matrix. An expression for St is obtained by using equations (8) - (12)

$$S_t = (I + Z_{ref}^{1/2} \quad YZ_{ref}^{1/2} \quad)^{-1} (I - Z_{ref}^{1/2} \quad YZ_{ref}^{1/2} \quad) \quad (13)$$

Terminals in HFSS can also be used to create differential pairs as discussed in the Differential Pairs section.

Differential Pairs

A differential pair signal resides on two conducting traces in the presence of a ground plane. To form the differential pair, the transmitter launches a wave that carries equal but opposite voltages on the two traces (e.g., one trace is +1 volt and the other -1 volt). When two traces are routed in close proximity to each other, the waves traveling on those traces exhibits similar amounts of system noise. A differential pair is an effective way to remove noise from a signal because when a receiver processes a differential signal it subtracts the voltages on the two traces. This can dramatically reduce the amount of noise in the differential signal compared to if the traces are driven individually (single-ended signals). In HFSS, a differential pair can be defined for two terminals residing in the same wave port or for terminals that reside in two different wave ports or lumped ports. From the case of wave ports, matched differential pairs can be defined by not renormalizing the wave ports involved in the differential pair definitions.

Computing Differential Pairs

To obtain various differential pair quantities, we first define differential and common voltages v_d and v_c in terms of the singled-ended terminal voltage pairs $v_1$and v_2, (see Setting up Differential Pairs).

The differential and common voltages v_d and v_c are defined by

$$v_d = v_1 - v_2 \quad (1)$$

$$v_c = \frac{v_1 + v_2}{2}$$

Consistent with power conservation, the corresponding differential and common currents, represented as i_d and i_c respectively, are defined by

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$i_d = \frac{i_1 - i_2}{2} \quad (2)$$

$$i_c = i_1 + i_2$$

Equations (1) and (2) can be concisely represented as

$v = Qe$ (3)
$i = Q^{-T}u$

where

$$v = \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} \quad i = \begin{bmatrix} i_1 \\ i_2 \end{bmatrix} \quad e = \begin{bmatrix} v_d \\ v_c \end{bmatrix} \quad u = \begin{bmatrix} i_d \\ i_c \end{bmatrix}$$

- Q is the real, non-singular matrix defined by

$$Q = \begin{bmatrix} \frac{1}{2} & 1 \\ -\frac{1}{2} & 1 \end{bmatrix} \quad (4)$$

- Q^{-T} is the inverse transpose of Q defined by

$$Q^{-T} = \begin{bmatrix} 1 & \frac{1}{2} \\ -1 & \frac{1}{2} \end{bmatrix} \quad (5)$$

Using eq. (3), we may easily transform between single-ended and differential quantities.

Differential Admittance and Impedance Matrices

The terminal admittance (Y) and impedance (Z) matrices discussed in the previous topics in the *Technical Notes* relate single-ended voltages and currents as $i = Yv$ and $v = Zi$, respectively. By first making differential voltage and current definitions, e and u eq. (3) can be used to derive Y_d and Z_d matrices that relate those qualities.

For example, if $i = Yv$, then substituting eq. (3) yields

$Q^{-T}u = YQe$.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solving for u yields

$$u = Q^T Y Q e$$

and the matrix Y_d relating differential quantities e and u is defined by

$$Y_d = Q^T Y Q \quad (6)$$

A similar procedure applies to the terminal Z_d.

Differential S-Matrices

It is clear that an S-matrix can be computed for differential signals because it is possible to compute admittance and impedance matrices for differential signals. The differential S-matrix can be envisioned as relating in-going and out-going waves on imaginary transmission lines attached to the differential ports. Characteristic impedances must be specified for these lines unless they are considered to be matched loaded which is automatically the case when the wave port(s) that contain the single-ended terminals used to define the differential pair is not renormalized.

In the single-ended case, the characteristic impedance for a pair of transmission lines may be written in the form of a matrix relating the voltages and currents on the two (uncoupled) lines,

$$\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} Z^{(1)}_{ref} & 0 \\ 0 & Z^{(2)}_{ref} \end{bmatrix} \begin{bmatrix} i_1 \\ i_2 \end{bmatrix} \quad (7)$$

where $Z^{(1)}ref$ and $Z^{(2)}ref$ are the user-specified renormalizing impedances. In the differential case, the matrix equation relating differential and common currents and voltages is written as:

$$\begin{bmatrix} v_d \\ v_c \end{bmatrix} = \begin{bmatrix} Z^{(d)}_{ref} & 0 \\ 0 & Z^{(c)}_{ref} \end{bmatrix} \begin{bmatrix} i_d \\ i_c \end{bmatrix} \quad (8)$$

In this case, $Z^{(d)}ref$ and $Z^{(c)}ref$ denote the user-specified differential and common renormalizing impedances, respectively.

Floquet Ports Theory

The Floquet port in HFSS is used exclusively with planar-periodic structures. Chief examples are planar phased arrays and frequency selective surfaces when these may be idealized as infinitely large. The analysis of the infinite structure is then accomplished by analyzing a unit cell. Linked boundaries most often form the side walls of a unit cell, but in addition, at least one "open"

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

boundary condition representing the boundary to infinite space is needed. The Floquet port is a specialized boundary condition to handle this case.

The Floquet port is closely related to a wave port in that a set of modes, here "Floquet modes", is used to represent the fields on the port boundary. Fundamentally, Floquet modes are plane waves with propagation direction set by the frequency and geometry of the periodic structure. Just like Wave modes, Floquet modes have propagation constants and experience cut-off at a sufficiently low frequency.

When a Floquet port is present, HFSS performs a modal decomposition that gives additional information on the performance of the radiating structure. As in the case of a wave port, this information is cast in the form of an S-matrix interrelating the Floquet modes. In fact, if Floquet ports and wave ports are simultaneously present, the S-matrix will interrelate all wave modes and all Floquet modes in the model. Floquet ports can be combined with lumped ports, but not with terminal ports.

Formula Summary for HFSS Floquet Modes

- Planar array lattice is specified by lattice vectors **a** and **b**.
- Lattice angle α defined by $a * b = ab\cos\alpha$
- Unit cell area A
- Global material is lossless, isotropic, and homogeneous, and specified by real ε_r and μ_r.
- Frequency is specified in the form of free-space wave number $k_0 = \frac{2\pi f}{c}$ where f is frequency and c is the speed of light in a vacuum.
- Local coordinate system (LCS) unit vectors $\hat{x}$ and $\hat{y}$ are related to lattice vectors by:

$$\hat{\mathbf{x}} = \hat{\mathbf{a}} \quad (1)$$

$$\mathbf{c} = \mathbf{b} - (\mathbf{b} \cdot \hat{\mathbf{a}})\hat{\mathbf{a}} \quad (2)$$

$$\hat{\mathbf{y}} = \frac{\mathbf{c}}{c} \quad (3)$$

$$\hat{\mathbf{a}} = \frac{\mathbf{a}}{a}$$

Unit vector $\hat{r}_s$ denotes scan direction. In the global coordinate system (GCS) the components of $\hat{r}_s$ are given by ($\sin\theta_s\cos\phi_s$, $\sin\theta_s\sin\theta\phi_s$, $\cos\theta_s$) where scan angles θ_s and ϕ_s are specified as spherical angles in the GCS.

$$\psi_a = \sqrt{\mu_r \varepsilon_r} k_s \hat{\mathbf{r}} \cdot \mathbf{a} \quad (4)$$

$$\psi_b = \sqrt{\mu_r \varepsilon_r} k_0 \hat{\mathbf{r}}_s \cdot \mathbf{b} \quad (5)$$

$$m,n \varepsilon \{\ldots,-2,-1,0,1,2,\ldots\} \quad (6)$$

If $k_z \neq 0$ (7)

$$k_a = \frac{2\pi m}{a} + \frac{\psi_a}{a} \quad (8)$$

$$k_b = \frac{2\pi n}{b} + \frac{\psi_b}{ab} \quad (9)$$

$$k_x = k_a \quad (10)$$

$$k_y = \frac{k_b}{\sin\alpha} - k_a \cot\alpha \quad (11)$$

$$k_c^2 = k_x^2 + k_y^2 \quad (12)$$

$$k_z = \sqrt{\mu_r \varepsilon_r k_0^2 - k_c^2} \quad (13)$$

$$\psi_{mn}(x,y) = \sqrt{\frac{1}{A}} e^{-jk_x x} e^{-jk_y y} \quad (14)$$

$$\Psi_{mn}^{(1)} = \left[\frac{k_y \hat{\mathbf{x}} - k_x \hat{\mathbf{y}}}{k_c}\right] \psi_{mn}(x,y) \qquad (k_c \neq 0) \quad (15)$$

$$\Psi_{mn}^{(2)} = \left[\frac{k_x \hat{\mathbf{x}} + k_y \hat{\mathbf{y}}}{k_c}\right] \psi_{mn}(x,y) \qquad (k_c \neq 0) \quad (16)$$

$$\tilde{\Psi}_{mn}^{(1)} = \sqrt{\frac{1}{A}} (\sin\theta_s \hat{\mathbf{x}} - \cos\theta_s \hat{\mathbf{y}}) \qquad (k_c \neq 0) \quad (17)$$

$$\tilde{\Psi}_{mn}^{(2)} = \sqrt{\frac{1}{A}} (\sin\theta_s \hat{\mathbf{x}} + \cos\theta_s \hat{\mathbf{y}}) \qquad (k_c \neq 0) \quad (18)$$

$$\vec{\mathbf{e}}_{mn}^{TE} = N_{mn}^{TE} \Psi_{mn}^{(1)}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\vec{\mathbf{h}}_{mn}^{TE} = Y_{mn}^{TE}\hat{\mathbf{z}} \times \vec{\mathbf{e}}_{mn}^{TE} \tag{19}$$

$$Y_{mn}^{TE} = \frac{k_z}{\mu_0 k_0}\frac{1}{\eta_0} \tag{20}$$

$$N_{mn}^{TE} = \sqrt{\mu_r k_0}\frac{1}{\sqrt{|k_z|}}\sqrt{\eta_0} \tag{21}$$

$$\hat{\mathbf{z}} e_{mn}^{TE} = 0 \tag{22}$$

$$\hat{\mathbf{z}} h_{mn}^{TE} = -\hat{\mathbf{z}} Y_{mn}^{TE} \quad N_{mn}^{TE} \quad \left(\frac{k_c}{k_z}\right)\Psi_{mn} \tag{23}$$

$$\vec{\mathbf{e}}_{mn}^{TE} = N_{mn}^{TM}\Psi_{mn}^{(2)} \tag{24}$$

$$\vec{\mathbf{h}}_{mn}^{TM} = Y_{mn}^{TM}\hat{\mathbf{z}} \times \vec{\mathbf{e}}_{mn}^{TM} \tag{25}$$

$$Y_{mn}^{TM} = \frac{\varepsilon_r k_0}{k_z}\frac{1}{\eta_0} \tag{26}$$

$$N_{mn}^{TM} = \frac{1}{\sqrt{\varepsilon_r k_0}}\frac{k_z}{\sqrt{|k_z|}}\sqrt{\eta_0} \tag{27}$$

$$\hat{\mathbf{z}} e_{mn}^{TM} = -\hat{\mathbf{z}} N_{mn}^{TM} \quad \left(\frac{k_c}{k_z}\right)\Psi_{mn} \tag{28}$$

$$\hat{\mathbf{z}} h_{mn}^{TM} = 0 \tag{29}$$

If $k_Z = 0$, use the preceding $k_z \neq 0$ formulas with $k_Z = \alpha$ where $0 < \alpha << 1$ is a small constant.

If $k_C = 0$

$$\vec{\mathbf{e}}_{mn}^{TEM1} = N^{TEM}\tilde{\Psi}^{(1)} \tag{30}$$

$$\vec{\mathbf{h}}_{mn}^{TEM1} = Y^{TEM}\,\hat{\mathbf{z}} \times \vec{\mathbf{e}}_{mn}^{TEM1} \quad (31)$$

$$\vec{\mathbf{e}}_{mn}^{TEM1} = N^{TEM}\tilde{\Psi}^{(2)} \quad (32)$$

$$\vec{\mathbf{h}}_{mn}^{TEM2} = Y^{TEM}\,\hat{\mathbf{z}} \times \vec{\mathbf{e}}_{mn}^{TEM2} \quad (33)$$

$$Y^{TEM} = \sqrt{\frac{\varepsilon_r}{\mu_r}}\frac{1}{\eta_0} \quad (34)$$

$$N^{TEM} = \frac{1}{\sqrt{Y^{TEM}}} \quad (35)$$

Incident Waves Theory

There are different kinds of incident wave sources in HFSS. Analytical wave forms are defined by formulas. The following analytical wave forms exist:

- Plane Wave
- Evanescent Plane Wave
- Elliptically Polarized Plane Wave
- Electric Spherical Wave (Electric Hertzian Dipole)
- Magnetic Spherical Wave (Magnetic Hertzian Dipole)
- Cylindrical Wave
- Gaussian Beam
- Linear Antenna

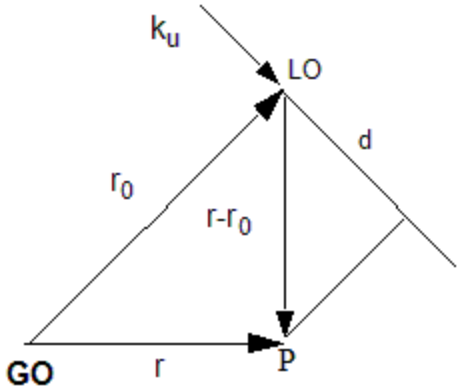
Numerical Wave Forms can come from the solution of another HFSS project or from a non-HFSS project via DataLink. Two numerical wave forms exist:

- Near Field Wave
- Far Field Wave

Plane Wave

An incident plane wave is a wave that propagates in one direction and is uniform in the directions perpendicular to its direction of propagation. The angle at which the incident wave impacts the device is known as the angle of incidence.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The equation that HFSS uses to calculate the incident wave is

$$E_{inc} = E_0 e^{-jk_0 k_u (\hat{r} \cdot r_0)}$$

where

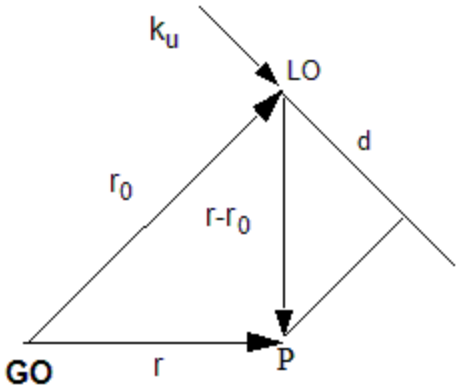
- E_{inc} is the incident wave.
- E_0 is the E-field polarization vector.
- k_0 is the free space wave number. It is equal to $\omega \sqrt{\mu_0 \varepsilon_0}$.
- $\hat{k}$ is the propagation vector. It is a unit vector.
- *r*is the position vector and is equal to $x\hat{x} + y\hat{y} + z\hat{z}$.

Incident wave excitations are specified in a peak sense. That is, if the incident wave magnitude is 5 V/m, then the real time function of the incident field is **E**(**t**) = 5cos(***k****r***+ωt).

Evanescent Plane Wave

An evanescent plane wave resembles the regular plane wave except that it decays in one direction. Its propagation constant is complex (see the equations).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

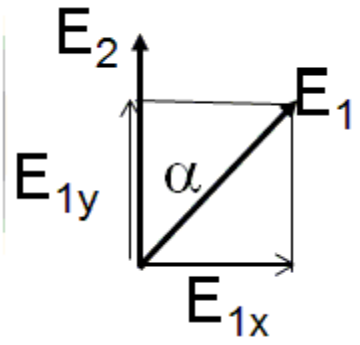


$$d = |k_u \bullet (r - r_0)| \qquad \alpha = Re(|k|)$$

$$\beta = Im(|k|) \qquad \vec{E} = \vec{E}_0 e^{-\alpha d} e^{-jkd}$$

$$\vec{H}_0 = \frac{k}{\omega \mu_0 \mu_r}(\vec{k_\mu} \times \vec{E}_0) = \frac{\beta - j\alpha}{\omega \mu_0 \mu_r}(\vec{k_\mu} \times \vec{E})$$

Elliptically Polarized Plane Wave



$$E'_1 = E_{10}\cos(\omega t) \qquad (1)$$

$$E'_2 = E_{20}\cos(\omega t + \varphi) \qquad (2)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$E_x^{inc} = E_1 \cos(\omega t) \quad (3)$$

$$E_y^{inc} = E_2 \cos(\omega t + \psi) \quad (4)$$

where

$$E_1 = E_{10} \sin(\alpha) \quad (5)$$

$$E_2 = \sqrt{(E_{10}\cos\alpha + E_{20}\cos\varphi)^2 + (E_{20}\sin\varphi)^2} \quad (6)$$

$$\psi = -arctg\frac{E_{20}\sin\Psi}{E_{10}\cos\alpha + E_{20}\cos\varphi} \quad (7)$$

$$E_a = \frac{1}{2}\left(\sqrt{E_1^2 + E_2^2 - 2E_1E_2\sin\psi} + \sqrt{E_1^2 + E_2^2 + 2E_1E_2\sin\psi}\right) \quad (8)$$

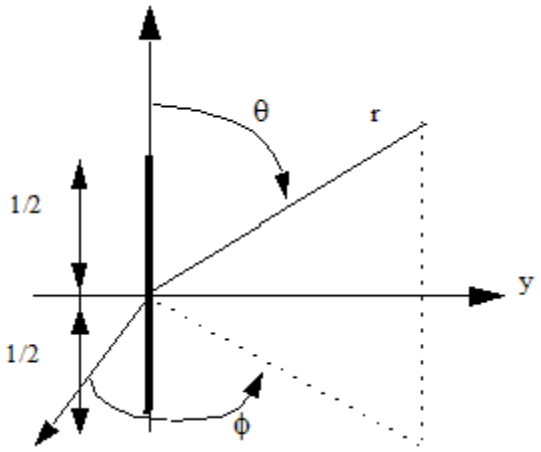
$$E_b = \frac{1}{2}\left(\sqrt{E_1^2 + E_2^2 - 2E_1E_2\sin\psi} - \sqrt{E_1^2 + E_2^2 + 2E_1E_2\sin\psi}\right) \quad (9)$$

Input:

$$ratio = E_b / E_a; \qquad \psi$$

Electric Spherical Wave (Electric Hertzian Dipole)

The analytical formulas of an electric Hertzian dipole are:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$H_r = 0 \qquad H_\theta = 0$$

$$H_\phi = j\frac{kI_0 l \sin\theta}{4\pi r}\left[1+\frac{1}{jkr}\right]e^{-jkr} \qquad E_r = \eta\frac{I_0 l\cos\theta}{2\pi r^2}\left[1+\frac{1}{jkr}\right]e^{-jkr}$$

$$E_\theta = j\eta\frac{kI_0 l\sin\theta}{4\pi r}\left[1+\frac{1}{jkr}-\frac{1}{(kr)^2}\right]e^{-jkr} \qquad E_\Phi = 0$$

Magnetic Spherical Wave (Magnetic Hertzian Dipole)

The analytical formulas of a magnetic Hertzian dipole are:

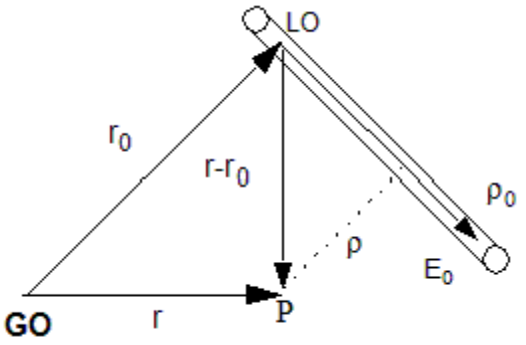
$$E_r = 0 \qquad E_\theta = 0$$

$$E_\phi = -j\frac{kI_0 l\sin\theta}{4\pi r}\left[1+\frac{1}{jkr}\right]e^{-jkr} \qquad H_r = \frac{I_m l\cos\theta}{2\pi\eta r^2}\left[1+\frac{1}{jkr}\right]e^{-jkr}$$

$$H_\theta = j\frac{kI_m l\sin\theta}{4\pi\eta r}\left[1+\frac{1}{jkr}-\frac{1}{(kr)^2}\right]e^{-jkr} \qquad H_\Phi = 0$$

Cylindrical Wave

The analytical formulas of a Cylindrical Wave are:



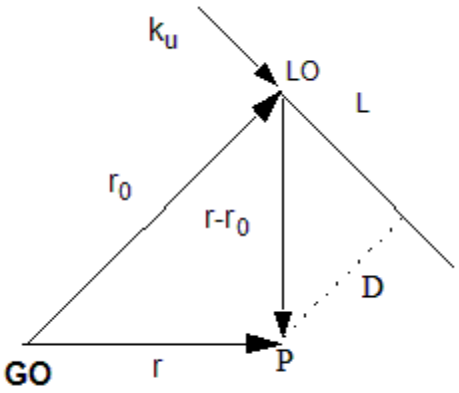
$$E_z(\rho) = \frac{C_1 e^{-jk\rho}}{\sqrt{\rho}} \quad \text{where} \quad C_1 = ZI^e\sqrt{k/8\pi}\,e^{j\pi/4}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$H_\phi(\rho) = \frac{C_2 e^{-jk\rho}}{\sqrt{\rho}} \quad \text{with} \quad C_2 = C_1 / Z$$

Gaussian Beam

The analytical formulas of a Gaussian Beam are:



Where

$$L = (r - r_0) \bullet k_u D = \left|(r - r_0) \times k_u\right|$$

$$W(L) = W_0 \left[1 + \left(\frac{L\lambda}{\pi W_0^2 n}\right)^2\right]^{0.5}$$

$$R(L) = L\left[1 + \left(\frac{\pi W_0^2 n}{L\lambda}\right)^2\right]$$

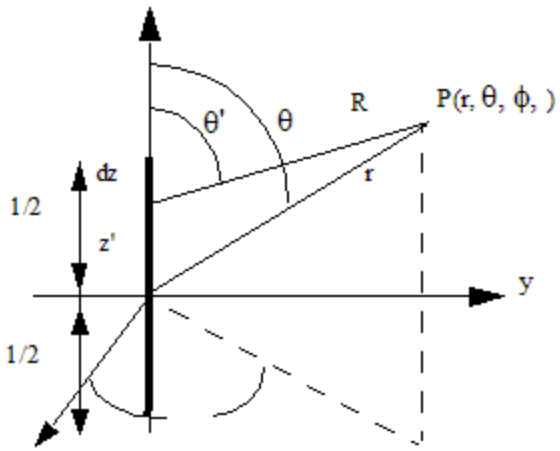
$$\Psi(L) = \text{atan}\left[\frac{L\lambda}{\pi W_0^2 n}\right]^2$$

$$E^{inc} = E_0 \frac{W_0}{W(L)} e^{-D^2/W(L)^2} e^{\left(-jk \bullet (r - r_0) - jk\frac{D^2}{2R(L)} + j\Psi(L)\right)}$$

Linear Antenna

The analytical formulas of a linear antenna are:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



$$E_\theta \cong j\eta \frac{I_0 e^{-jkr}}{2\pi r}\left[\frac{\cos\left(\frac{kl}{2}\cos\theta\right) - \cos\left(\frac{kl}{2}\right)}{\sin\theta}\right]$$

$$H_\phi \cong \frac{E_\theta}{\eta} \cong j\frac{I_0 e^{-jkr}}{2\pi r}\left[\frac{\cos\left(\frac{kl}{2}\cos\theta\right) - \cos\left(\frac{kl}{2}\right)}{\sin\theta}\right]$$

Simulating Circuits Containing N-Port Models from a Full-Wave Field Solver

This note looks at some of the issues involved in taking an N-port black box model from a full-wave field solver, such as HFSS or SIwave, and simulating it in a circuit tool, such as HSPICE, AEDT Circuit, or Nexxim. There are certain subtle differences between these models and the familiar low-frequency RLC equivalent circuit models from parasitic extractor tools like Q3D. In order to explain these differences, we will “open up” the N-port black box model and peek inside to see what is going on with its implementation. Armed with this information, we will then be able to better appreciate the capabilities and limitations of such models.

Some Background on Lumped Models

Consider a Spice subcircuit that consists of two resistors, R1 and R2, as shown below in Figure 1. The resistors in this case might represent the partial resistances for two nets, as computed by

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a tool like Q3D Extractor.

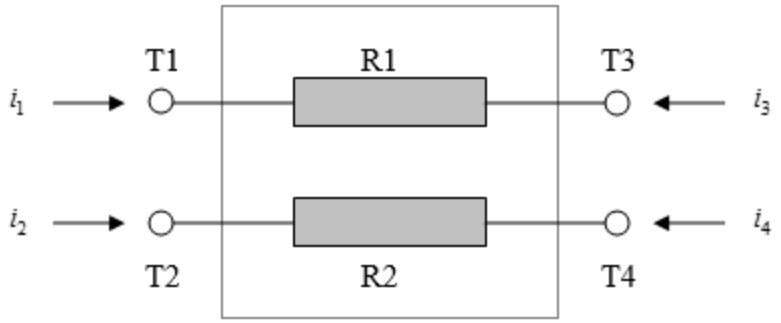


Figure 1: A conventional Spice subcircuit with two resistors.

This subcircuit has four terminals, labeled T1, T2, T3 and T4 in the figure. We can associate a node voltage with each of these terminals. We will call these v_1, v_2, v_3 and v_4, respectively. It should be noted that these node voltages are measured with respect to some global ground reference—node 0 in Spice. We can also define a set of terminal currents, one for each terminal, called i_1, i_2, i_3 and i_4, respectively. For consistency, the direction of these terminal currents is taken to be “into” the subcircuit.

Given the structure of this subcircuit, we have a fair amount of flexibility. We could compute the resistance of the top net by hooking a current source across T1 and T3 and measuring the resulting voltage drop. We could do the same with the bottom net. Or we could measure the loop resistance by shorting T3 and T4 together, and putting a current source across T1 and T2 (and then measuring the resulting voltage drop between T1 and T2.)

You need to be very careful with how you use connections to ground in such a model. Consider the example shown below in Figure 2. On the top, we show an incorrect attempt at measuring the loop resistance. The problem is that the user has grounded both terminals, T2 and T4. This effectively shorts out the resistor R2, and so the apparent resistance will only be R_1. The correct way of setting up the circuit is to remove the ground at terminal T4; this allows us to measure the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

true loop resistance, $R_1 + R_2$.

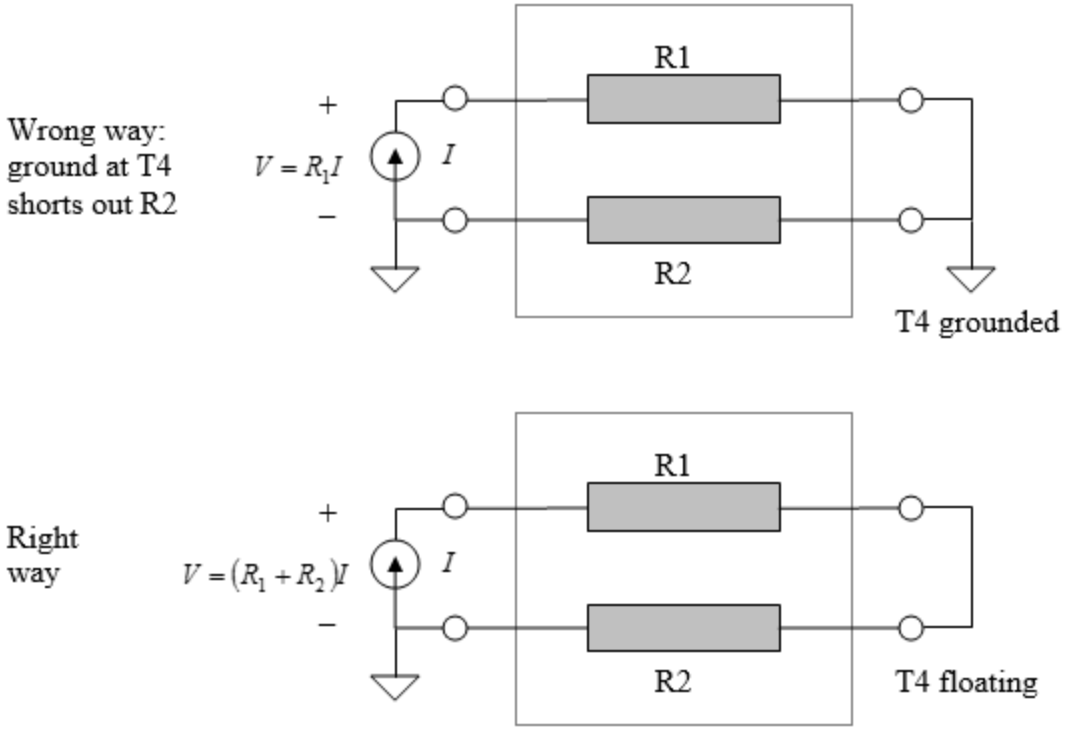

Figure 2: Illustration of the right (bottom) and wrong (top) ways to measure the loop resistance, in the case of a subcircuit consisting of standard RLC Spice elements.

As a general rule, when a conventional RLC circuit model is used, at most one terminal of the subcircuit should be connected to ground. If more than one terminal is grounded, you will be implicitly placing an ideal short circuit across those pairs of grounded terminals. The short circuit will bypass internal current flow paths, often resulting in unexpected behavior. Note that it is possible that none of the subcircuit's terminals will be grounded; the connection to ground may be made through some external circuitry.

A 2-Port Model

Now let's consider creating a 2-port model of this same circuit. We could choose S, Y or Z parameters, or other more exotic descriptions, but these are all basically equivalent. For the purposes of this note, we will use Y-parameters.

The first step is to choose the ports. If we suppose that the two resistors represent a signal conductor and its ground return, then the logical place for the ports is between the two nets. We

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

will set up the ports as shown Figure 3.

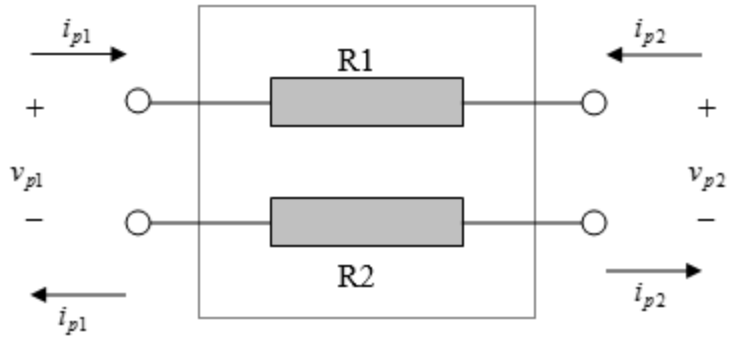

Figure 3: A 2-port model for the subcircuit.

Each port is created using a pair of terminals. Port 1 was created between terminals T1 and T2, and port 2 was created between terminals T3 and T4. We associate a port voltage (v_{p1} and v_{p2}) and a port current (i_{p1} and i_{p2}) with each port. These port voltages and port currents are related to the terminal voltages and currents as follows:

$$v_{p1} = v_1 - v_2 \text{ and } v_{p2} = v_3 - v_4 \qquad (1)$$

$$i_1 = i_{p1} \text{ and } i_2 = -i_{p1} \qquad (2)$$

$$i_3 = i_{p2} \text{ and } i_4 = -i_{p2} \qquad (3)$$

You will immediately notice that the ports have introduced some additional constraints that were not present before. In particular, due to the presence of the ports, the currents in the top and bottom resistors are no longer independent of one another. Whatever current enters the positive reference terminal (T1) for port 1 will flow back out of the negative reference terminal T2. Similarly, the current for port 2 goes into T3 and comes back out of T4. The placement of the ports in this circuit thus forces the bottom resistor to act as the return path for the current in the top resistor.

We now illustrate how the Y-parameters for this 2-port circuit are computed. Two voltage sources are connected at the ports, as shown in Figure 4 below. Illustration of how the Y-parameters for the 2-port circuit are computed. Two voltage sources are applied to control the port voltages, and the resulting port currents are calculated. These voltage sources directly

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

control the port voltages v_{p1} and v_{p2}.

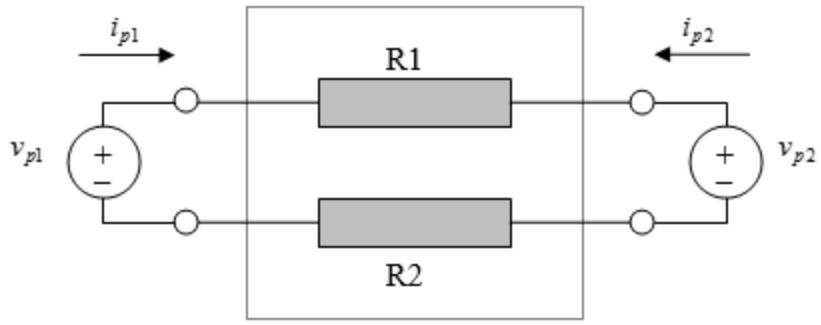

Figure 4: Illustration of how the Y-parameters for the 2-port circuit are computed. Two voltage sources are applied to control the port voltages, and the resulting port currents are calculated.

Using simple circuit analysis, the resulting port currents can be expressed in terms of the port voltages:

$$i_{p1} = \frac{1}{R_1 + R_2} v_{p1} - \frac{1}{R_1 + R_2} v_{p2} \qquad (4)$$

$$i_{p2} = -\frac{1}{R_1 + R_2} v_{p1} + \frac{1}{R_1 + R_2} v_{p2} \qquad (5)$$

These relationships can also be expressed in matrix form as

$$\begin{bmatrix} i_{p1} \\ i_{p2} \end{bmatrix} = \begin{bmatrix} \frac{1}{R_1 + R_2} & \frac{-1}{R_1 + R_2} \\ \frac{-1}{R_1 + R_2} & \frac{1}{R_1 + R_2} \end{bmatrix} \begin{bmatrix} v_{p1} \\ v_{p2} \end{bmatrix} \qquad (6)$$

The 2x2 matrix here is the admittance matrix (or Y-matrix) for the 2-port black box.

Observe that each of the Y-parameters depends on the sum $(R_1 + R_2)$. Even if we measure all 4 matrix entries, we will never be able to determine the value of the individual resistances R_1 and R_2 from the Y-matrix. The information about the individual resistance values has been lost when we condensed the circuit down to a 2-port representation.

It is also interesting to compare the circuit of Figure 4 with the one in Figure 5 below. The Y-parameters of the two circuits will be found to be identical. Therefore, we have no way of

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

distinguishing between the two networks if we have only their 2-port Y-parameter descriptions.

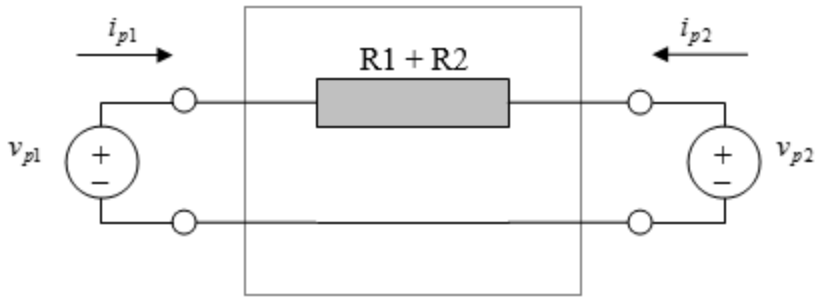

Figure 5. A different circuit that has the same Y-parameters as the one in Figure 4.

Implementing an N-port Network Model in a Circuit Simulator

An N-port network can be implemented within a circuit simulator by introducing N different 2-terminal circuit elements (or branches) as shown Figure 6. For each branch, the port voltage is taken to be the difference between the two node voltages at its terminals, and the port current is taken to be the current flowing in the branch. In addition to creating this element topology, the circuit simulator will be responsible for enforcing the branch relationships expressed in Equation 6 above.

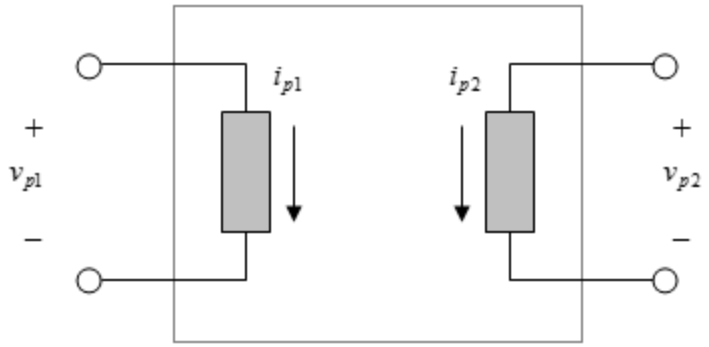

Figure 6. Illustration of how an N-port network is implemented within a circuit simulator, for the case of a 2-port network. In this topology, each port has its own reference node.

Another way of representing an N-port network is to use a common reference terminal, as shown in Figure 7 below. Because we will often choose to ground the negative reference terminal of a port, it may be more convenient to use this representation, because there are roughly half as many terminals to wire up. This is the approach taken by HSPICE (with the S element N-port S-parameter device) and also by Electronics Desktop (for imported S-parameter data.)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

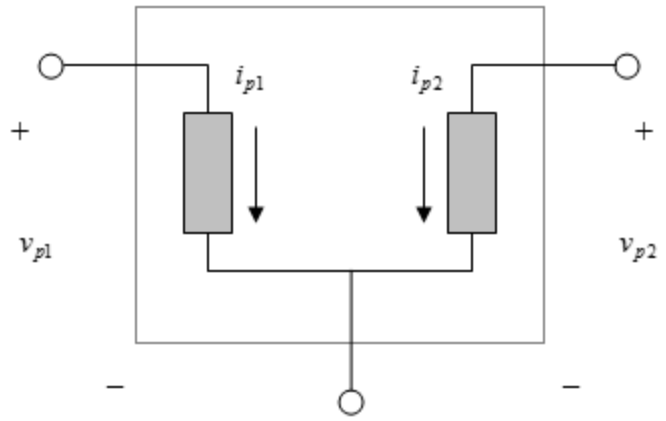

Figure 7. An N-port network with a common reference terminal (illustrated for the case of a 2-port).

Still another possibility is to suppress the reference terminal completely. In this case, the common reference terminal is internally wired to node 0. Only the positive reference terminals are exposed for external connections to the subcircuit. This is the approach taken by Electronics Desktop for dynamically linked field solver projects.

Using an N-Port Model for a Circuit Simulation

Let's consider how we would use this circuit. Suppose that we want to evaluate the loop resistance for the two conductors. We will place a current source in parallel with port 1 and a short circuit across port 2 to create the desired current loop, and then we will measure the resulting voltage across port 1. The resulting circuit is shown in Figure 8. This experiment is essentially the same as the one that we conducted on the "conventional" Spice equivalent circuit illustrated in Figure 2 and so (at first glance) it seems reasonable to use the same circuit topology. However, now that we are working with the 2-port representation we will see some

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

interesting differences in the details, although of course the final result will be the same.

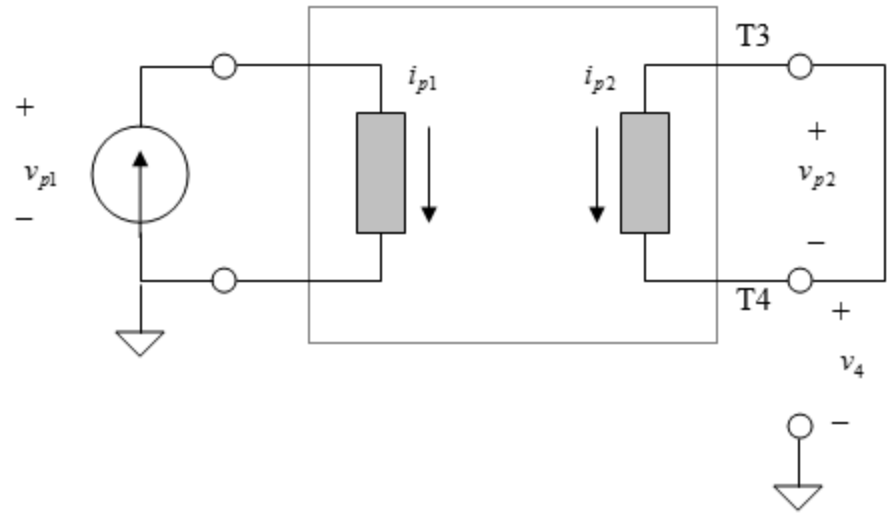

Figure 8. Computing the loop resistance using the 2-port black box model. This circuit looks correct (compare the bottom circuit of Figure 2) but actually causes simulation problems in Spice because the node voltage v4 at terminal T4 is ill-defined.

The first, and most important detail, is that the circuit simulator will probably fail if we try to simulate the 2-port circuit exactly as it is drawn in Figure 8. A typical error message would complain that there is “no DC path to ground” from the node corresponding to terminals T3 or T4. Another possibility would be an error message referring to a singular matrix, time step too small, Gmin stepping failed, or some other numerical problem.

What has gone wrong? The figure actually makes the problem fairly clear. Thanks to the short circuit, there is no question that the port voltage v_{p2} is zero and hence the node voltages at terminals T3 and T4 are clearly the same. The problem is that these two node voltages are “floating” with no connection to ground, and so they could assume any values at all, as long as they are the same. An ill-defined problem of this sort is tantamount to a singular matrix equation—a system of equations with more unknowns than equations. Circuit simulators do not deal gracefully with this ambiguous situation, because they want to return specific values for the node voltages.

To make this a bit more rigorous, consider the problem of writing down the nodal Kirchhoff’s current law (KCL) equation at terminal T4. (This is what the circuit simulator will do internally.) We have a current i_{p2} leaving the node through terminal T3, and the same current i_{p2} entering the node through terminal T4. As a result, the circuit simulator writes the equation

$$i_{p2} - i_{p2} = 0 \qquad (7)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This, of course, is a tautology: 0 = 0. Because this equation effectively contributes no information about the circuit, the simulator is unable to come up with a unique solution.

The problem can be resolved by introducing some sort of DC conduction path between terminal T4 (or T3) and ground. One way would be to add a resistor between T4 and ground. The KCL equation at the node then becomes

$$i_{p2} - i_{p2} + \frac{1}{R} v_4 = 0 \qquad (8)$$

Of course, all that this equation really says is that $v_4 = 0$. But that's enough to give us a well-defined solution to the system of equations, and the circuit simulator will now succeed.

It's interesting to note that the value of the grounded resistor we use is immaterial to the final solution. Because $v_4 = 0$ no matter what value of resistor is used, we may as well simply connect terminal T4 to ground (node 0 in Spice.) The solution to the problem will not change.

Based upon previous experience with Spice, it may be tempting to use a large-valued resistor (perhaps in the giga-Ohm range) instead of a direct connection to ground. But Equation 8 shows that this is a bad idea. If we make the resistance too large, then v_4 / R becomes vanishingly small and the equation again becomes equivalent (in the finite-precision arithmetic that computers use) to 0 = 0. In practice, what will happen is that the linear equation solver in the simulator will return increasingly inaccurate solutions as the value of the grounded resistor is increased. Therefore, using a large grounded resistor is a bad idea.

We should check what value of loop resistance will be returned by the simulator if we ground terminal T4. Looking back at Equation 4, we see that port voltage $v_{p2} = 0$, and therefore

$$I = \frac{1}{R_1 + R_2} v_{p1}$$

and so we will have $v_{p1} / I = R_1 + R_2$. This is the correct value of the loop resistance.

In the case of the standard RLC Spice subcircuit, we argued that you should never connect more than one subcircuit terminal to ground. The reason for observing this practice was to avoid shorting out internal conduction paths in the internal RLC network. We have just seen that this same restriction does not apply to the 2-port model. We grounded two of the terminals, and yet we still obtained the correct loop resistance. How can this be?

Returning to the equivalent circuit model of a 2-port in Figure 6, we see that there are no internal circuit elements connected from the positive or negative terminals of port 1 to the positive or

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

negative terminals of port 2. Therefore, it's clear that we cannot accidentally short out an internal circuit element by grounding, unless we happen to ground both terminals of a single port.

There is one thing about the solution we obtained using the 2-port model that appears at first glance to be incorrect. If we refer back to the original Spice model (drawn at the bottom of Figure 2), it's clear that the voltage at the "floating" terminal T4 is $R_2 I$, not zero. So is the 2-port model producing the wrong answer—or are we interpreting it incorrectly?

It turns out that the interpretation of the voltage is the problem. If we look back at the Y-matrix expression in Equation 6 , we see that it basically expresses port currents in terms of the port voltages. These port voltages are simply the voltage differences between the terminals, as expressed by Equation 1. We have previously argued (using Figure 5 as an illustration) that the N-port model has no way to tell whether the resistance lies in the upper or lower conductor. All it can do is to predict the correct voltage differences at the ports, given the port currents. So, because we have chosen to anchor terminal T4 to ground, the absolute voltage at this terminal disagrees with the predictions of the original subcircuit model. However, the voltage differences at the ports are in complete agreement.

We give a circuit interpretation of what is going on in Figure 9. Here we are taking the 2-port circuit of Figure 8 (with terminal T4 "grounded") and re-drawing it with the real internal network of 2 resistors.

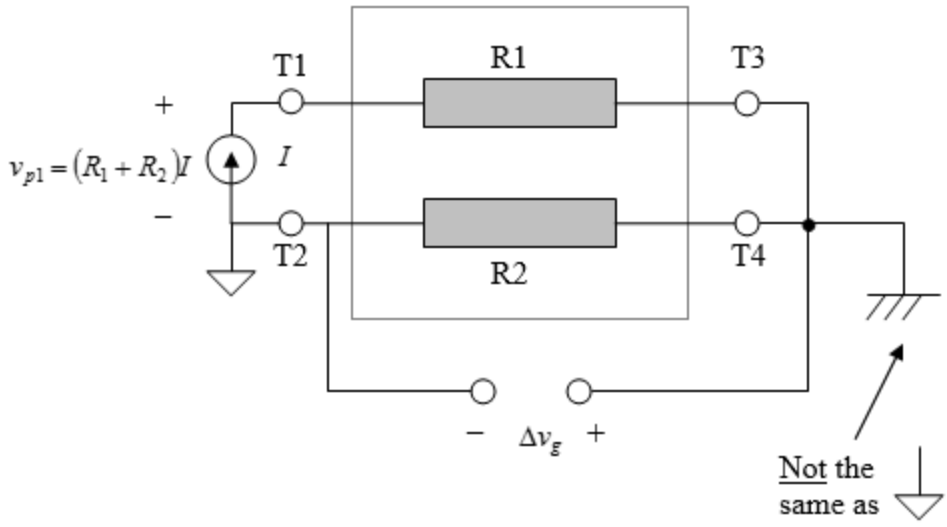

Figure 9. Interpretation of the different grounds being used in the two-port model.

Δv_g between the different grounds can easily be computed as $R_2 I$

Voltage Sources

A voltage source in HFSS can be defined on surface located anywhere in the 3D problem space, but it typically makes sense to place the source on a surface between two conductors such that a user defined total voltage is maintained between the conductors.

A voltage source is implemented in HFSS by forcing the electric field on the source surface to maintain a user-specified voltage drop along the voltage line. You can specify any surface as the source surface, but the prescribed field pattern is best suited for rectangular planar surfaces or non-planar surfaces obtained from the side wall surface of cylinders with uniform cross-sections such as a circular cylinder. The enforced electric field pattern is obtained by projecting a static uniform field onto the source surface with the electric field in the direction of the user defined voltage line.

A voltage source cannot be used to extract S-parameters. For S-parameter computations of an HFSS design involving a mixture of ports and voltage sources, all the voltage sources are shorted by treating the voltage source surface as a perfect electric conductor.

Current Sources

A current source in HFSS can be defined on a surface located anywhere in the 3D problem space, but it typically makes sense to place the source on a surface between two conductors such that it injects the user defined total current onto the conductors. A current source is implemented in HFSS by weakly enforcing the jump across the source surface of the tangential component of the magnetic field, $\Delta\vec{H}$, to be related to a surface current density, $\vec{J_S}$:

$$\hat{n} \times \Delta\vec{H} = \vec{J_S}$$

where $\hat{n}$ is the unit normal of the surface. The surface current density can be expressed as $\vec{J_S} = J_0\hat{u}$ where J_0 is the magnitude and $\hat{u}$ is the unit vector in the direction of current flow.

The unit vector is in the direction of the user defined current flow direction line. The magnitude is obtained by first assuming that the surface is a rectangle such that the width, *w*, is equal to the area divided by the length of the current flow direction line. The magnitude is set equal to the total current specified by the user divided by *w*. Note that any source surface is allowed but considering the definition of the surface current density it is recommended to only use a planar rectangular surface.

A current source cannot be used to extract S-parameters. For S-parameter computations of an HFSS design involving a mixture of ports and current sources, all the current sources are kept

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

opened by treating the current source surface as a natural boundary condition where no special behavior of the electric field is explicitly enforced.

Magnetic Bias Sources

When you create a ferrite material, you must define the net internal field that biases the ferrite by assigning a magnetic bias source. The bias field aligns the magnetic dipoles in the ferrite, producing a non-zero magnetic moment. In HFSS, a ferrite's permeability tensor is a direct result of an applied static magnetic bias field. The static field causes the tensor to assume an hermitian form, with cross coupling terms between field components perpendicular to the bias.

When the applied bias field is assumed to be uniform, you will specify net internal bias field as well as the tensor coordinate system through a rotation from the global coordinate system. When the applied bias field is non-uniform, neither specified coordinate system rotations nor specified bias are allowed. The permeability tensor's local coordinate system and bias field are calculated on a tetrahedron by tetrahedron basis, both of which are determined by the calculated static solution. HFSS references the static solution project as the source of the non-uniform magnetostatic field information during solution generation.

Multiple uniform bias excitations may be included in a design, but only non-uniform bias is allowed. In addition, a design cannot contain a bias excitation of both types. If only one excitation is included in a design, its type can be changed from uniform to non-uniform, and visa versa.

Uniform Applied Bias Fields

The applied DC bias that causes ferrite saturation is always in the positive z direction of the tensor coordinate system. Initially the tensor coordinate system is assumed to be aligned with the fixed coordinate system; the tensor's z-axis is the same as the model's z-axis. To model other directions of applied bias, the permeability tensor must be rotated so that its z-axis lies in another direction on the fixed coordinate system. This is accomplished by specifying the rotation angles about the axes when you assign a magnetic bias source to a model surface.

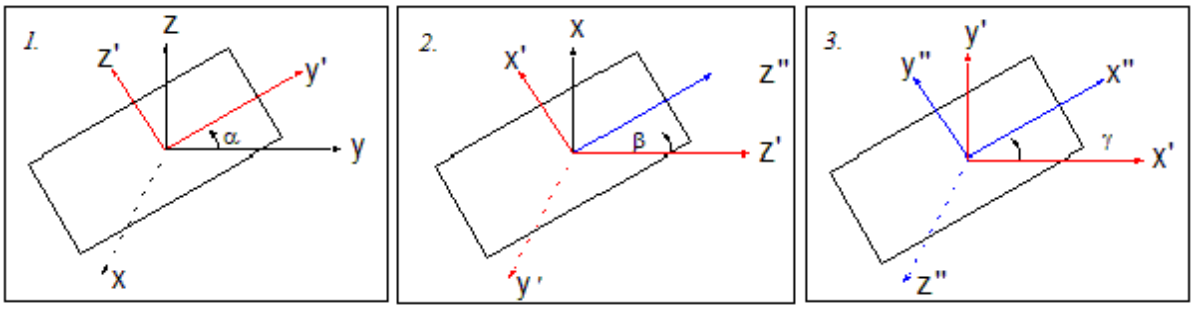
The rotation angles should be defined in the **Magnetic Bias Source** dialog box in such a way that the tensor coordinate system is obtained in the following manner:

1. Rotating the tensor coordinate system by α degrees (from the **X Angle**) around the fixed x-axis.
2. Rotating the resulting tensor coordinate system by β degrees (from the **Y Angle**) around the new y-axis.
3. Rotating the new tensor coordinate system by γ degrees (from the **Z Angle**) around the new z-axis.

This concept is illustrated in the following graphic. In the first panel, the permeability tensor is rotated α degrees about the x-axis. In the second panel, the tensor is rotated β degrees about the y'-axis (the new y-axis). In the third panel, the tensor is rotated γ degrees about the z''-axis

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(the new z-axis). The resulting tensor has the coordinate system (x"y"z") relative to the fixed coordinate system.



For example, to model the DC bias in the x direction you would rotate the tensor coordinate system so that its z-axis lies along the x-axis of the fixed coordinate system. To do this you would enter **0** for the **X Angle**, **90** for the **Y Angle**, and **0** for the **Z Angle**.

Non-uniform Applied Bias Fields

To accurately model a ferrite in an applied static magnetic bias field, the non-uniform magnetic bias fields must also be calculated. In HFSS, a ferrite's permeability tensor is a direct result of an applied static magnetic bias field. The static field causes the tensor to assume an hermitian form, with cross coupling terms between field components perpendicular to the bias. A uniform bias field is difficult to achieve in practice. Even if the bias field is nearly uniform, a non-ellipsoidal-shaped ferrite material will have non-uniform demagnetization, resulting in non-uniform fields in the ferrite.

Use the magnetostatic solver provided in the Maxwell 3D Field Simulator to generate a solution for non-uniform magnetostatic fields. Once a solution is generated it may be imported into HFSS.

> **Note:**
>
> To specify the non-uniform bias field, you must have purchased the Maxwell 3D Field Simulator. Refer to the Maxwell 3D Field Simulator documentation for instructions on solving for non-uniform magnetostatic fields.

Deembedding

Deembedding means adding or subtracting transmission line. In HFSS only wave ports and Floquet ports are allowed to be deembedded where the S-parameters are modified as described in Deembedding S-Matrices. Fields used for visualization and the calculator can also be

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

modified by selecting Include Post Processing Effects in the Edit Sources panel. The new results appear instantaneously. Be careful if you deembed cutoff-modes because you may get non-physical results.

This section shows an example where subtracting transmission line can be useful and an example where adding transmission line can be useful. A following section describes When HFSS Needs Port Calibration in deembedding.

Consider the aperture-coupled patch antenna shown in Fig. 1. A microstrip trace located below a ground plane feeds a patch antenna located above the ground plane. A slot in the ground plane couples power from the microstrip trace to the antenna.

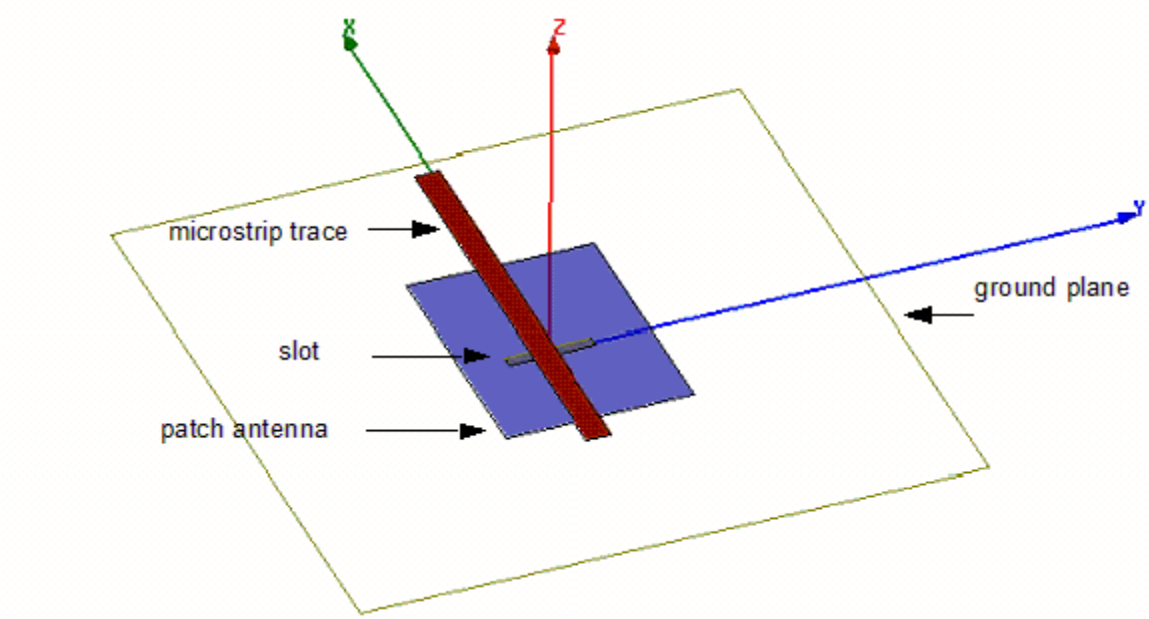


Fig. 1 Aperture-coupled patch antenna

A port is located at the beginning of the trace. It cannot be located very close to the slot, since a port has to be located in a position where a clean transmission-line mode is expected, at some distance from the first discontinuity. The port is shown in Fig. 2. One edge coincides with the ground plane. The other edges are such that the port width is several times the trace width and the port height several times the substrate thickness. The red arrows represent the port field solution. Notice that the three non-ground-plane edges don't influence the port solution noticeably, so this port is large enough.

Fig. 2 Magnitude of S11 in dB

The S-parameter characteristic is shown in Fig. 3 in a rectangular plot and in Fig. 4 in a Smith chart. Note that the resonance frequency in Fig. 3 corresponds to the point in Fig. 4 where the curve is closest to the center of the chart. Also note that the curve circles the chart several times.

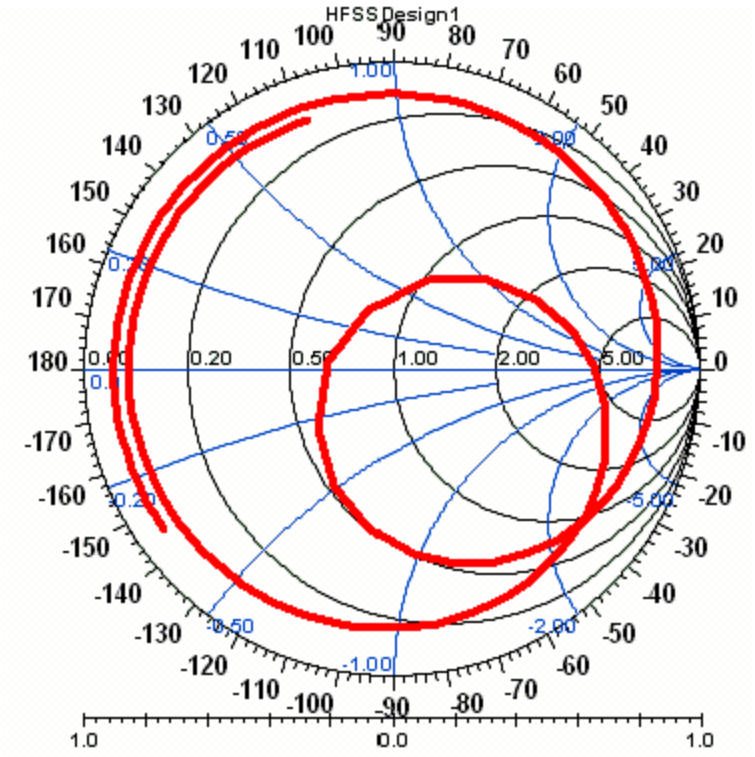

Fig. 4 Smith Chart before deembedding

Antenna designers who need to design a matching circuit close to the feed point may want to see the Smith chart with the reference point located close to the feed point of the antenna, that is. close to the slot, rather than some distance away from the feed point. That can be achieved by deembedding. Fig. 5 shows the Smith chart after deembedding.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

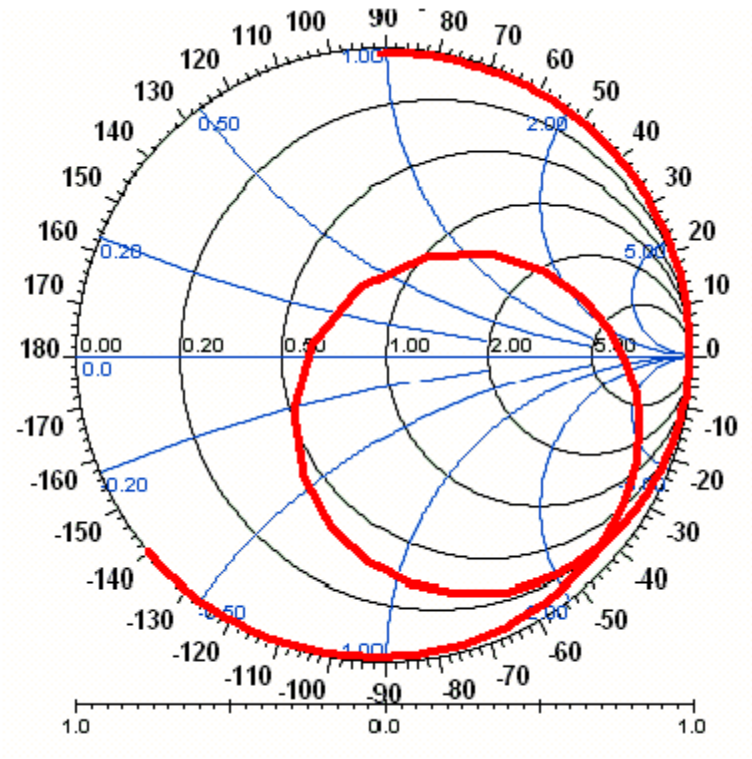

Fig. 5 Smith Chart after deembedding

Note that after this kind of deembedding, where transmission line was removed, the curve circles the Smith chart fewer times.

As an example where adding transmission line may be useful, consider an IC package or a connector mounted on a printed circuit board. Fig. 6 shows a connector on a printed circuit board. The connector designer has included short sections of traces on the board in his model. These are coupled differential lines, and because of the coupling they share one port. Again, there is some distance between the port and the first discontinuity, so the fields that reach the port form clean transmission-line modes. To model the connector accurately, this model is sufficient.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

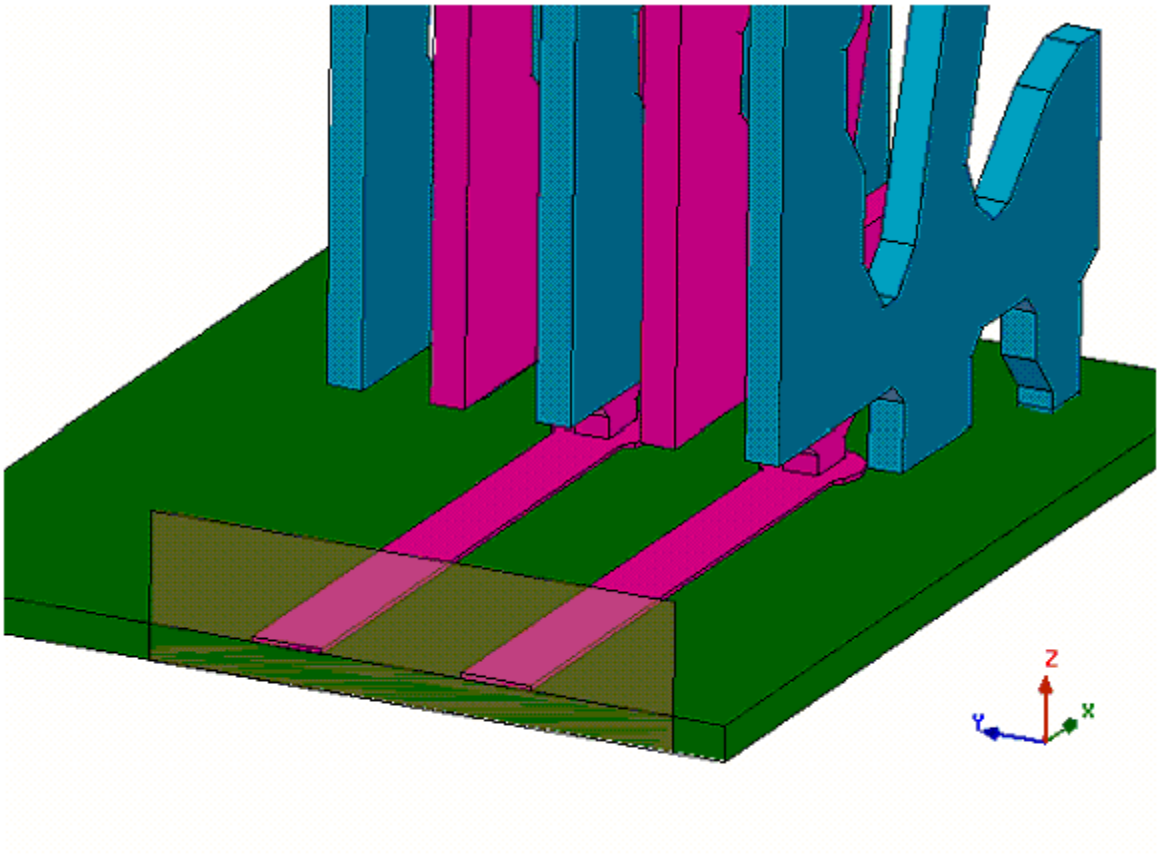

Fig. 6 Connector on printed circuit board

On the board, the traces may continue as uniform transmission lines for some distance. To evaluate system performance, it may be desirable to include that length in the S-parameters that are to be exported to a circuit simulator. With deembedding, uniform transmission line can be added as a matrix post processing step.

Another example where adding transmission-line length through deembedding may be useful is modeling long cables with frequency-dependent materials, for example, in back planes. In HFSS, only a short section would be modeled, and its behavior over the entire frequency range analyzed accurately. Analyzing only a short section has the benefits of both speed and accuracy. Then, with deembedding, the cable can be extended to any desired length. The S-parameters for the full length can be exported to a circuit simulator to be incorporated into a system.

Relative Permeability

The permeability of dielectrics is assumed to be complex, as follows:

$$\mu = \mu' - j\mu''$$

The relative permeability is a dimensionless quantity, defined as follows:

$$\mu' = \mu_r \mu_0$$

where μ_0 is the permeability of free space.

The permeability can also be expressed as

$$\mu = \mu'\left(1 - j\frac{\mu''}{\mu'}\right)$$

where μ' is the real portion of μ and μ''/μ' is the magnetic loss tangent.

Relative Permittivity

The permittivity of dielectrics is assumed to be complex, as follows:

$$\varepsilon = \varepsilon' - j\varepsilon''$$

which can also be expressed as

$$\varepsilon = \varepsilon'\left(1 - j\frac{\varepsilon''}{\varepsilon'}\right)$$

where ε' is the real portion of ε and from which the relative permittivity is defined as:

$$\varepsilon' = \varepsilon_r \varepsilon_0$$

where $\varepsilon_0$is the permittivity of free space.

$\varepsilon''/\varepsilon'$ is the dielectric loss tangent.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If a material's losses due to bulk conductivity will be significant, such as in semiconductor dielectric materials, an additional bulk conductivity value, σ, must be added. From the time harmonic form of Maxwell's equations, the complex permittivity, ε_c is defined as

$$\nabla \times H = (\sigma + j\omega\varepsilon)E = j\omega\varepsilon_c E$$

where

$$\varepsilon_c = \varepsilon\left(1 - j\tan\delta - j\frac{\sigma}{\omega\varepsilon}\right)$$

Bulk Conductivity

HFSS is capable of including conductivity in the model either as a bulk material loss factor, similar to dielectric loss tangent, or as an impedance boundary condition applied to the outer surfaces of the object. The choice of bulk material loss instead of the boundary condition is made by selecting **Solve Inside** in the **Properties** window.

The choice between bulk material loss and the surface boundary condition is problem dependent. The boundary condition should be applied whenever the conductor is much thicker than the skin depth at the solution frequency. In this case, the unknowns within the conductor are not included in the unknown vector, resulting in a smaller matrix and a faster analysis. However, if the conductor is not thick relative to the skin depth, the bulk material conductivity must be used to arrive at an accurate solution. With this assumption, the wave equation reduces to

$$\nabla\times\left(\frac{-1}{j\omega\mu}\nabla\times\boldsymbol{E}\right) = (j\omega\varepsilon + \sigma)\boldsymbol{E}$$

The threshold where HFSS will automatically choose whether an object will be solved inside can be accessed via the **Tools>Options>HFSS Options**.

Dielectric Loss Tangent

To represent a dielectric that dissipates the power of a high-frequency electric field, enter a dielectric loss tangent, $\varepsilon''/\varepsilon'$, property value for the material. The smaller the loss tangent, the less lossy the material.

The dielectric loss tangent may vary with frequency. To simulate the variances, define a function for the dielectric loss tangent.If a wide-band frequency sweep is being solved, the Frequency Dependent Material property may be appropriate.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Magnetic Loss Tangent

To represent a dielectric that dissipates the power of a high-frequency magnetic field, enter a magnetic loss tangent, μ''/μ', property value for the material. The smaller the loss tangent, the less lossy the material.

> **Note:**
>
> If you plan to do a fast frequency sweep for a design that includes dielectrics, make sure that the dielectric or magnetic loss tangent does not vary significantly over the requested frequency range. If they do, the results may not be what you expect. In cases where the loss tangent does vary significantly over the frequency range in which you are interested, copy and solve the design several times, adjusting the loss tangent and associated frequency range for the copied design so that the loss tangent is relatively stable over the design's requested frequency range.

Ferrite Materials

Ferrite materials are used to model the interaction between a microwave signal and a material whose magnetic dipole moments are aligned with an applied bias field. The gyrotropic quality of the ferrite is evident in the permeability tensor which is Hermitian in the lossless case. The Hermitian tensor form leads to the non-reciprocal nature of the devices containing microwave ferrites. If the microwave signal is circularly polarized in the same direction as the precession of the magnetic dipole moments, the signal interacts strongly with the material. When the signal is polarized in the opposite direction to the precession, the interaction will be weaker. Because the interaction between the signal and material depends on the direction of the rotation, the signal propagates through a ferrite material differently in different directions.

If you assign a ferrite material to an object, you must assign a magnetic bias source to the object.

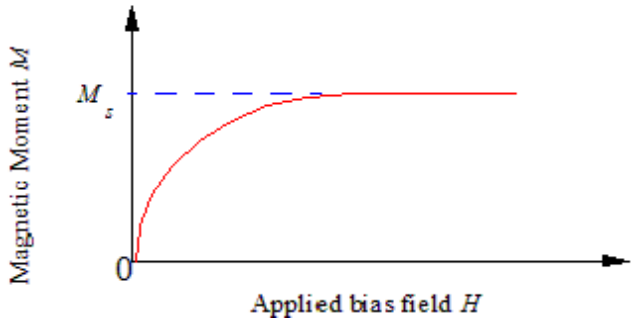
- Magnetic Saturation
- Lande G Factor
- Delta H
- Ferrite Permeability Tensor in HFSS

Magnetic Saturation

A material with a non-zero magnetic saturation is considered to be a ferrite. When a ferrite is placed in a uniform magnetic field, the magnetic dipole moments of the material begin to align with the field. As the strength of the applied bias field increases, more of the dipole moments align. The magnetic saturation, M_s, is a property that describes the point at which all of the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

magnetic dipole moments of the material become aligned. At this point, further increases in the applied bias field strength do not result in further saturation. The relationship between the magnetic moment, *M* and the applied bias field, *H*, is shown below.



You specify $4\pi M_s$ when entering a value for Magnetic Saturation in the Materials database for HFSS.

Lande G Factor

The Lande *g* factor is a ferrite property that, on a microscopic level, describes the total magnetic moment of the electrons according to the relative contributions of the orbital moment and the spin moment. When the total magnetic moment is due entirely to the orbital moment, *g* is equal to one. When the total magnetic moment is due entirely to the spin moment, *g* is equal to two. For most microwave ferrite materials, *g* has a range from 1.99 to 2.01. The Lande *g*factor is dimensionless.

Delta H

Delta H is the full resonance line width at half-maximum, which is measured during a ferromagnetic resonance measurement. It relates to how rapidly a precessional mode in the biased ferrite will damp out when the excitation is removed. The factor ΔH doesn't appear in the permeability tensor; instead, the factor α appears. The factor α is computed from

$$\alpha = -\frac{\gamma \mu_0 \Delta H}{2\omega}$$

The factor α changes the κ and χ terms in the permeability tensor from real to complex, which makes the tensor complex non-symmetric (where it had been hermitian for lossless ferrites).

Enter the full resonance line width at half maximum in the **Delta H** value box. Delta H is measured at a specific frequency. That frequency needs to be entered by the user at the interface. 9.4 GHz is the frequency where Delta H is typically measured.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ferrite Permeability Tensor in HFSS

Gyrotropic Permeability

The ferrite capability of HFSS is based on the Polder susceptibility tensor small signal approximation of the Landau-Lifshitz equation of motion of a magnetic dipole in a uniform bias field [1] [2].

The formulas are given in CGS units. The formulas assume a saturated ferrite sample, and both M_s and H_o should be set to 0 for the unbiased demagnetized case.

$$\bar{\mu} = \mu_0 \begin{bmatrix} 1+\chi & j\kappa & 0 \\ -j\kappa & 1+\chi & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (1)$$

Where

$$\chi = \frac{\omega_o \omega_m}{\omega_o^2 - \omega^2} \quad (2)$$

$$\kappa = \frac{\omega \omega_m}{\omega_o^2 - \omega^2} \quad (3)$$

With

$$\omega = 2\pi f \quad (4)$$

$$\omega_o = \gamma \mu_o H_o \quad (5)$$

$$\omega_m = \gamma \mu_o M_s \quad (6)$$

If M_s is not = 0 this tensor overrides any value of permeability
even if magnetic bias is set to 0.

And

$$\gamma = g_l \gamma_e \quad (7)$$

γ_e is half of the electron charge to mass ratio and g_l is the Lande g factor. The Lande g factor is typically between 1 and 2, with 1 corresponding to orbital angular momentum and 2 for spin.

If the ferrite has magnetic losses, we replace ωo by $\omega o + j\omega\alpha$ where α is computed from the ferromagnetic resonance linewidth:

$$\alpha = \frac{\mu_o \gamma \Delta H}{4\pi f_{FMR}} \quad (8)$$

When HFSS assembles the finite element matrices for ferrite materials it computes the permeability tensor, 1, based on several different inputs:

1. **Frequency** - ω
2. **Material properties** - all of which are specified in the material manager
   a. Saturation Magnetization - *M*s
   b. Lande g factor - *g*l
   c. Loss factor - computed from Δ*H* and *f*FMR
3. **Magnetostatic bias field** - Magnetic Bias source, either:
   a. Uniform bias - *H*o and direction specified in the interface
   b. Non-uniform bias - *H*o and local tensor $\hat{z}$ direction determined by the magnetostatic field solution from Maxwell3D. When the Magnetic Bias source is nonuniform, the permeability tensor will be different in each ferrite tetrahedron.

Anisotropic Materials

Anisotropic materials have characteristics that vary with direction. These characteristics are defined by their anisotropy tensors. You must define three diagonals each for anisotropic permittivity, electric loss tangent, conductivity, permeability, and magnetic loss tangent. Each diagonal represents a tensor of your model along an axis. The alignment of the materials axis with respect to the object is discussed in Assigning Material Property Types.

- Anisotropic relative permeability tensors
- Anisotropic relative permittivity tensors
- Anisotropic conductivity tensors
- Anisotropic dielectric loss tangent tensors
- Anisotropic magnetic loss tangent tensors
- Anisotropic materials and ports

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Anisotropic Relative Permeability Tensors

The permeability tensor for an anisotropic material is described by

$$[\mu] = \begin{bmatrix} \mu_1\mu_0 & 0 & 0 \\ 0 & \mu_2\mu_0 & 0 \\ 0 & 0 & \mu_3\mu_0 \end{bmatrix}$$

where

- μ_1 is the relative permeability along one axis of the material's permeability tensor.
- μ_2 is the relative permeability along the second axis.
- μ_3 is the relative permeability along the third axis.
- μ_0 is the permeability of free space.

The relationship between *B* and *H* is:

$$\begin{matrix} x \to \mu \\ y \to v \\ z \to w \end{matrix} \quad \begin{bmatrix} B_x \\ B_y \\ B_z \end{bmatrix} = [\mu] \begin{bmatrix} H_x \\ H_y \\ H_z \end{bmatrix}$$

To specify the relative permeability for an anisotropic material, enter the μ_1, μ_2, and μ_3 values in the **Value** boxes of the **T(1,1)**, **T(2,2)**, and **T(3,3)** rows, respectively. If the relative permeability is the same in all directions, use the same value for μ_1, μ_2, and μ_3. These values can also be entered as variables.

Anisotropic Relative Permittivity Tensors

The permittivity tensor for an anisotropic material is described by

$$\varepsilon = \begin{bmatrix} \varepsilon_1\varepsilon_0 & 0 & 0 \\ 0 & \varepsilon_2\varepsilon_0 & 0 \\ 0 & 0 & \varepsilon_3\varepsilon_0 \end{bmatrix}$$

where

- ε_1 is the relative permittivity of the material along one tensor axis.
- ε_2 is the relative permittivity along the second axis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- ε_3 is the relative permittivity along the third axis.
- ε_0 is the permittivity of free space.

The relationship between *E* and *D* is then

$$\begin{matrix} x \to \mu \\ y \to v \\ z \to w \end{matrix} \quad \begin{bmatrix} D_x \\ D_y \\ D_z \end{bmatrix} = [\varepsilon] \begin{bmatrix} E_x \\ E_y \\ E_z \end{bmatrix}$$

To specify the relative permittivity for an anisotropic material, enter the ε_1, ε_2, and ε_3 values in the **Value** boxes of the **T(1,1)**, **T(2,2)**, and **T(3,3)** rows, respectively. These values can also be entered as variables.

Anisotropic Conductivity Tensors

The conductivity tensor for an anisotropic material is described by

$$[\sigma] = \begin{bmatrix} \sigma_1 & 0 & 0 \\ 0 & \sigma_2 & 0 \\ 0 & 0 & \sigma_3 \end{bmatrix}$$

where

- σ_1 is the conductivity along one axis of the material's conductivity tensor.
- σ_2 is the conductivity along the second axis.
- σ_3 is the conductivity along the third axis.

The relationship between *J* and *E* is then:

$$\begin{matrix} x \to \mu \\ y \to v \\ z \to w \end{matrix} \quad \begin{bmatrix} J_x \\ J_y \\ J_z \end{bmatrix} = [\sigma] \begin{bmatrix} E_x \\ E_y \\ E_z \end{bmatrix}$$

To specify the conductivity for an anisotropic material, enter the σ_1, σ_2, and σ_3 values in the **Value** boxes of the **T(1,1)**, **T(2,2)**, and **T(3,3)** rows, respectively. The values of σ_1 and σ_2 apply to axes that lie in the xy cross-section being modeled. The values of σ_3 apply to the z-component. These values affect current flowing in dielectrics between the conductors. These values can also be entered as variables.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Anisotropic Dielectric Loss Tangent Tensors

The dielectric loss tangent tensor for an anisotropic material is described by

$$[\bar{\varepsilon}] = \begin{bmatrix} \varepsilon'_1(1 - j\tan\delta_1) & 0 & 0 \\ 0 & \varepsilon'_2(1 - j\tan\delta_2) & 0 \\ 0 & 0 & \varepsilon'_3(1 - j\tan\delta_3) \end{bmatrix}$$

where

- $\tan\delta_1$ is the ratio of the imaginary relative permittivity to the real relative permittivity in one direction.

  $$\tan\delta_1 = \frac{\varepsilon''_1}{\varepsilon'_1}$$

- $\tan\delta_2$ is the ratio of the imaginary relative permittivity to the real relative permittivity in the second direction.

  $$\tan\delta_2 = \frac{\varepsilon''_2}{\varepsilon'_2}$$

- $\tan\delta_3$ is the ratio of the imaginary relative permittivity to the real relative permittivity in the third orthogonal direction.

  $$\tan\delta_3 = \frac{\varepsilon''_3}{\varepsilon'_3}$$

- ε'_1, ε'_2, and ε'_3 are the real relative permittivity's specified earlier.ε

The relationship between *D* and *E* will then be

$$\begin{matrix} x \to \mu \\ y \to v \\ z \to w \end{matrix} \quad \begin{bmatrix} D_x \\ D_y \\ D_z \end{bmatrix} = [\bar{\varepsilon}] \begin{bmatrix} E_x \\ E_y \\ E_z \end{bmatrix}$$

To specify the electric loss tangent for an anisotropic material, enter the $\tan\delta_1$, $\tan\delta_2$, and $\tan\delta_3$ values in the **Value** boxes of the **T(1,1)**, **T(2,2)**, and **T(3,3)** rows, respectively. These values can also be entered as variables.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Anisotropic Magnetic Loss Tangent Tensors

The magnetic loss tangent tensor for an anisotropic material is described by

$$[\bar{\mu}] = \begin{bmatrix} \mu'_1(1 - j\tan\delta_{M1}) & 0 & 0 \\ 0 & \mu'_2(1 - j\tan\delta_{M2}) & 0 \\ 0 & 0 & \mu'_3(1 - j\tan\delta_{M3}) \end{bmatrix}$$

where

- $\tan\delta_{M1}$ is the ratio of the imaginary relative permeability to the real relative permeability in one direction.

  $$\tan\delta_{M1} = \frac{\mu''_1}{\mu'_1}$$

- $\tan\delta_{M2}$ is the ratio of the imaginary relative permeability to the real relative permeability in the second direction.

  $$\tan\delta_{M2} = \frac{\mu''_2}{\mu'_2}$$

- $\tan\delta_{M3}$ is the ratio of the imaginary relative permeability to the real relative permeability in the third orthogonal direction.

  $$\tan\delta_{M3} = \frac{\mu''_3}{\mu'_3}$$

- μ'_1, μ'_2, and μ'_3 are the real relative permeabilities specified earlier.

The relationship between *B* and *H* will then be

$$\begin{matrix} x \to \mu \\ y \to v \\ z \to w \end{matrix} \begin{bmatrix} B_x \\ B_y \\ B_z \end{bmatrix} = [\bar{\mu}] \begin{bmatrix} H_x \\ H_y \\ H_z \end{bmatrix}$$

To specify the magnetic loss tangent for an anisotropic material, enter the $\tan\delta_{M1}$, $\tan\delta_{M2}$, and $\tan\delta_{M3}$ values in the **Value** boxes of the **T(1,1)**, **T(2,2)**, and **T(3,3)** rows, respectively. These values can also be entered as functions.

Anisotropic Materials and Ports

An anisotropic material can be in contact with a port under the following conditions:

- One principal axis of the anisotropic material is aligned normal to the port.

Debye Materials

If the material is a lossy dielectric with a lower frequency near DC, use the **Loss Model Material Input** dialog box to specify the material's conductivity at DC or, if you prefer, its loss tangent value at the lower frequency. HFSS also enables you to specify the lossy dielectric material's high frequency/optical permittivity.

In materials commonly encountered in microwave applications ion and dipole polarization dominate. These polarization types can be described by Debye's relaxation polarization model:

$$\varepsilon_{rcomplex} = \varepsilon_{roptical} + \frac{(\varepsilon_{rstatic} - \varepsilon_{roptical})}{1 + j\omega\tau}$$

where

τ = the relaxation time.

$\varepsilon_{rstatic}$= the static permittivity.

$\varepsilon_{roptical}$ = the high frequency/optical permittivity.

HFSS uses the values you specify in the **Loss Model Material Input** dialog box in Debye's equation above to determine the relative permittivity at any frequency.

Debye's model is valid for most microwave applications. If the frequency exceeds the limit of Debye's model, other models that take atomic and electron polarization into account are available.

Frequency-dependent materials are appropriate for problems solved using a discrete or interpolating sweep. In a fast sweep, frequency dependent material properties are evaluated at the center frequency which may result in less accurate results at the sweep extremes, depending on the sweep range and frequency dependence of material property.

In the simulation of high speed connectors or PCB boards, it is important to take the losses into account. Especially, in the case of transient analysis, where the improper specification of the frequency dependence of the materials would lead to unphysical results. This section discusses the loss mechanism of dielectric materials. Magnetic losses could also be taken into account, but materials commonly encountered in these applications are non-magnetic.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A lossy dielectric material is characterized by two measured values at a certain frequency: dielectric constant ε_r and loss tangent $tg\delta$. There are two problems with the specification of the frequency dependence of dielectric materials:

- The frequency range, in which the solution has to be calculated, is much wider than the range where measured material data are available. It is very common to have just two measured points. A low frequency point, which can be taken as DC value and a higher frequency point, which serves to describe the behavior of the material at high frequency. The question arises: What is an appropriate model across the measured range as well as outside the measured range?
- A measurement always suffers from errors. If the measured data are not consistent, it could cause unphysical effects during the time domain analysis. A question arises again: how to check whether the measured data are consistent, and how to adjust them if they are not.

To answer the questions raised we need to discusses the polarization loss mechanism of dielectric materials.

Figure 1 shows the different polarization mechanisms occur in the frequency domain. It can be seen from the figure that up to the microwave region, ion and dipole polarization dominate. These polarization types can be described by Debye's relaxation polarization model:

$$\varepsilon_{rcomplex} = \varepsilon_{roptical} + \frac{(\varepsilon_{rstatic} - \varepsilon_{roptical})}{1 + j\omega\tau} \quad (1)$$

where

τ is the relaxation time,$\varepsilon_{rstatic}$,and $\varepsilon_{roptical}$ are the static and high frequency permittivity, respectively. Debye's model is valid for the most of microwave applications. If the frequency exceeds the limit of Debye's model, there exists other models which take the atomic and electron polarization into account [1].

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

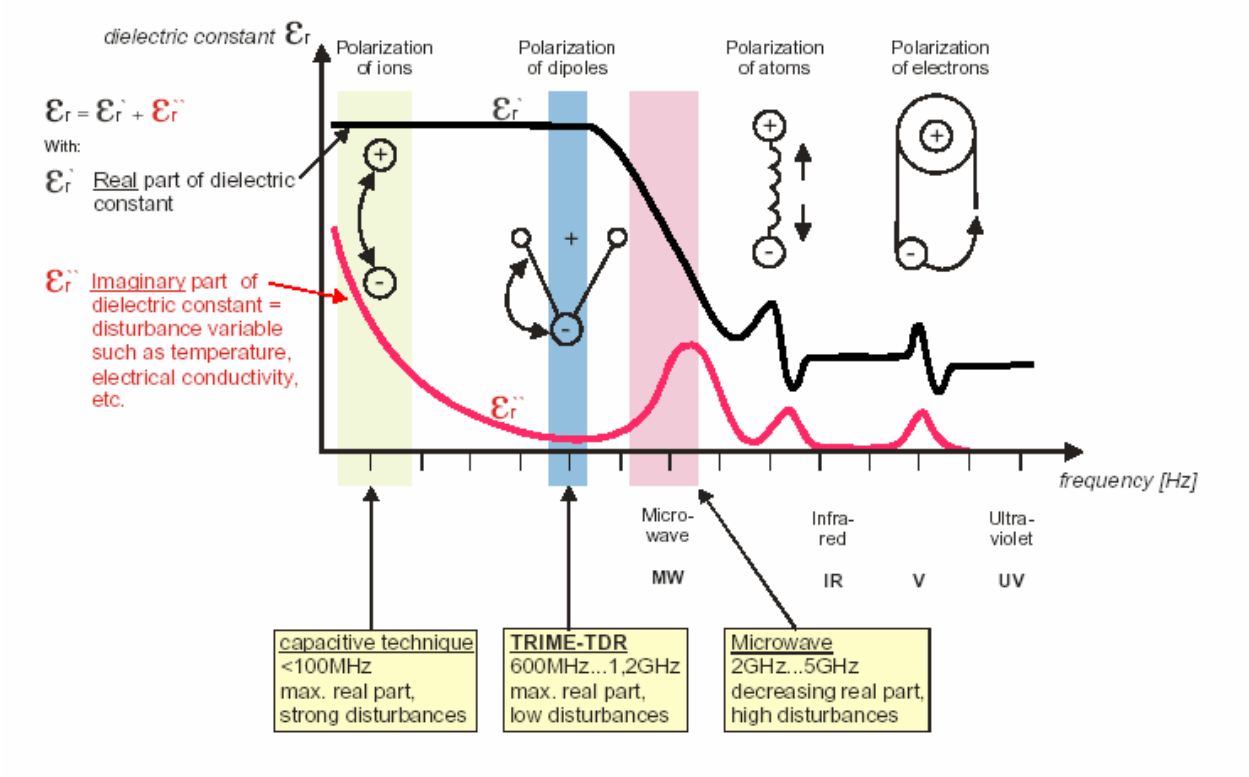

Figure 1: Polarization mechanisms

The question is now how to fit Debye's model to the actual material characteristics. In order to do this, let us express the real part of the dielectric constant and the conductivity from Eq. (1):

$$\varepsilon_r = \varepsilon_{roptical} + \frac{(\varepsilon_{rstatic} - \varepsilon_{roptical})}{1 + (\omega\tau)^2} \quad (2)$$

$$\sigma = \sigma_o + \frac{\omega^2 \varepsilon_o \tau (\varepsilon_{rstatic} - \varepsilon_{roptical})}{1 + (\omega\tau)^2} \quad (3)$$

where

σ_o is the DC conductivity.

Eqs (2) and (3) have 4 parameters: σ_o, $\varepsilon_{rstatic}$, $\varepsilon_{roptical}$ and τ.

Usually, measured data are available at two frequencies for a regular material. The measured data are the dielectric constant and the loss tangent. One set of the measured data is at low frequency

($f_1 \approx 1MHz$, $\varepsilon_{r1}, \sigma_1$) and the other set is at higher frequency ($f_2 \approx 1 \sim 2\,GHz$, $\varepsilon_{r2}, \sigma_2$).

The static or dc values can be considered as the low frequency measured data. So,

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\varepsilon_{rstatic} = \varepsilon_{r1} \quad (4)$$

and

$$\sigma_o = \omega_1 \varepsilon_o \varepsilon_{r1} \tan \delta_1 \quad (5)$$

The critical need is to predict the high frequency behavior of the material.

If we know $\varepsilon_{roptical}$ from measurement, the high frequency behavior of Debye's model is set. We just need to calculate the relaxation time as:

$$\tau = \frac{b - \sqrt{b^2 - 4}}{2\omega_2} \quad (6)$$

where

$$b = \frac{\omega_2 \varepsilon_o (\varepsilon_{rstatic} - \varepsilon_{roptical})}{\sigma_2} \quad (7)$$

and

$$\sigma_2 = \omega_2 \varepsilon_o \varepsilon_{r2} \tan \delta_2 - \sigma_o \quad (8)$$

Knowing τ, Eqs. (2) and (3) prescribe the material characteristic in the whole frequency region.

If we do not know $\varepsilon_{roptical}$, it can be calculated by simultaneously solving the following two equations to get $\varepsilon_{roptical}$ and τ:

$$\varepsilon_{r2} = \varepsilon_{roptical} + \frac{(\varepsilon_{rstatic} - \varepsilon_{roptical})}{1 + (\omega\tau)^2} \quad (9)$$

$$\sigma_2 = \sigma_o + \frac{\omega^2 \varepsilon_o \tau (\varepsilon_{rstatic} - \varepsilon_{roptical})}{1 + (\omega\tau)^2} \quad (10)$$

where ε_{r2} is measured and σ_2 is determined by Eq.(8).

Solving equations (9) and (10), we get:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\tau = \frac{\varepsilon_o \left| \varepsilon_{rstatic} - \varepsilon_{r2} \right|}{\left| \sigma_2 - \sigma_o \right|} \quad (11)$$

This method also yields the parameters of the Debye's model, but the accuracy of the method, especially at high frequencies, depends on the accuracy and the consistency of the measurement at

frequency f_2.

Typical Debye's model material characteristics can be seen in Fig. 2, where $\varepsilon' = \varepsilon_r$.

$$\varepsilon'' = \frac{\omega\tau(\varepsilon_{rstatic} - \varepsilon_{roptical})}{1 + (\omega_2\tau)^2} \quad (12)$$

$$\varepsilon_{roptical} = \varepsilon_{rstatic} - \left| \varepsilon_{rstatic} - \varepsilon_{r2} \right| \left(\frac{1 + (\omega_2\tau)^2}{(\omega_2\tau)^2} \right) \quad (13)$$

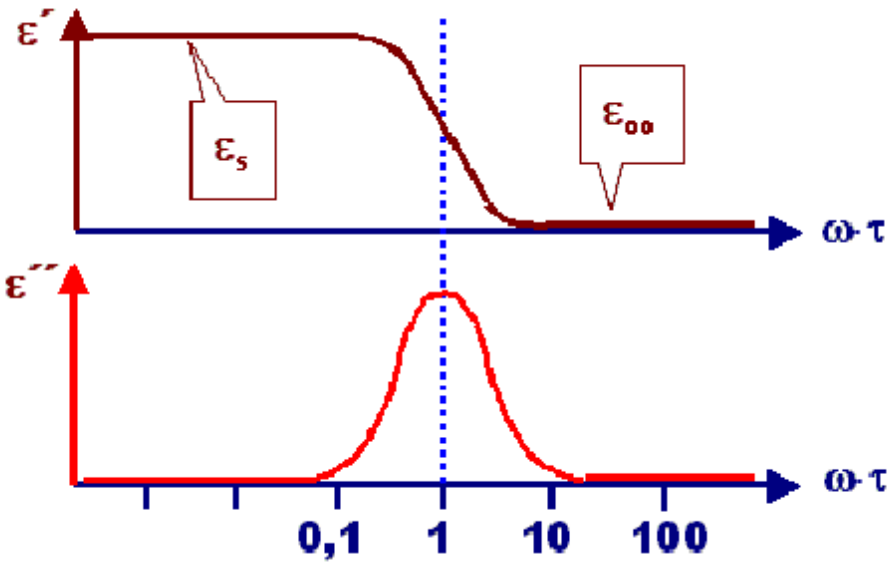

Figure 2: Material characteristics of a Debye model

The model was verified by using a double strip line filled by FR4 material. A 10 mils section of the line was modeled by HFSS and de-embedded into a 34 inch long line. The structure of HFSS model can be seen in Fig. 3.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

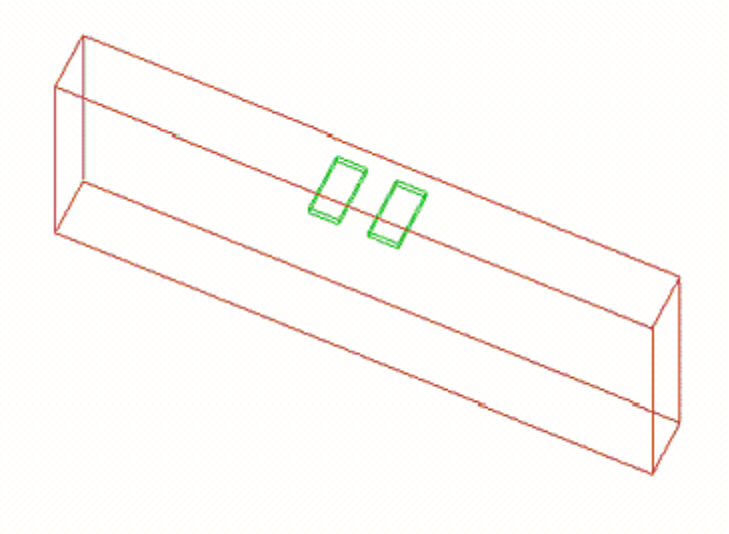

Figure 3: A 10 mils long structure of a double strip line

The input data panel of HFSS for FR4 can be seen in Fig. 4:

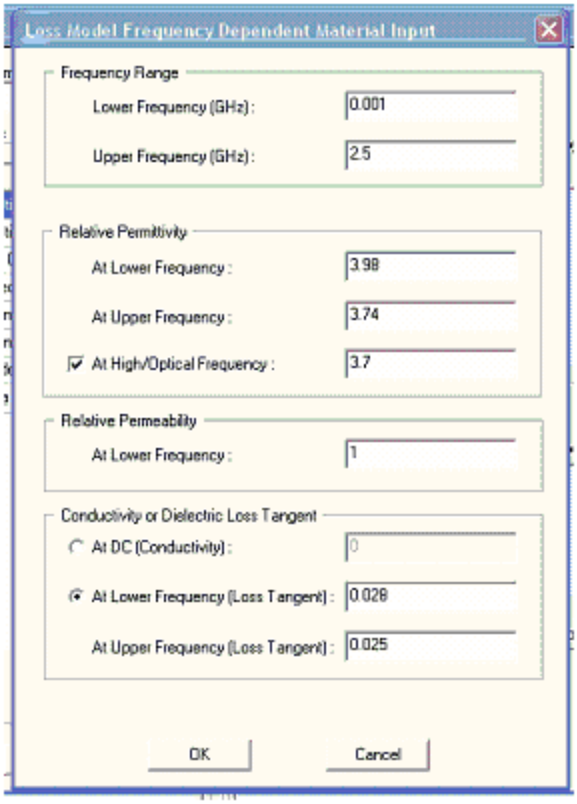

Figure 4: Input data panel for FR4 material in HFSS

It can be seen from the panel that:

$$\varepsilon_{rstatic} = 3.98 \quad \varepsilon_{roptical} = 3.7 \quad \tan\delta_2 = 0.025 \quad \tan\delta_1 = 0.028$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The calculated and measured frequency response of S_{12} can be seen in Fig. 5. The agreement between the calculated and measured values is good.

The transient response of the line to an input pulse also has been calculated. The schematic arrangement of the model in Maxwell Spice is shown in Fig. 6. The output signal is plotted in Fig. 7. The green curve is the transient response of an ideal reference line (lossless) of the same length.

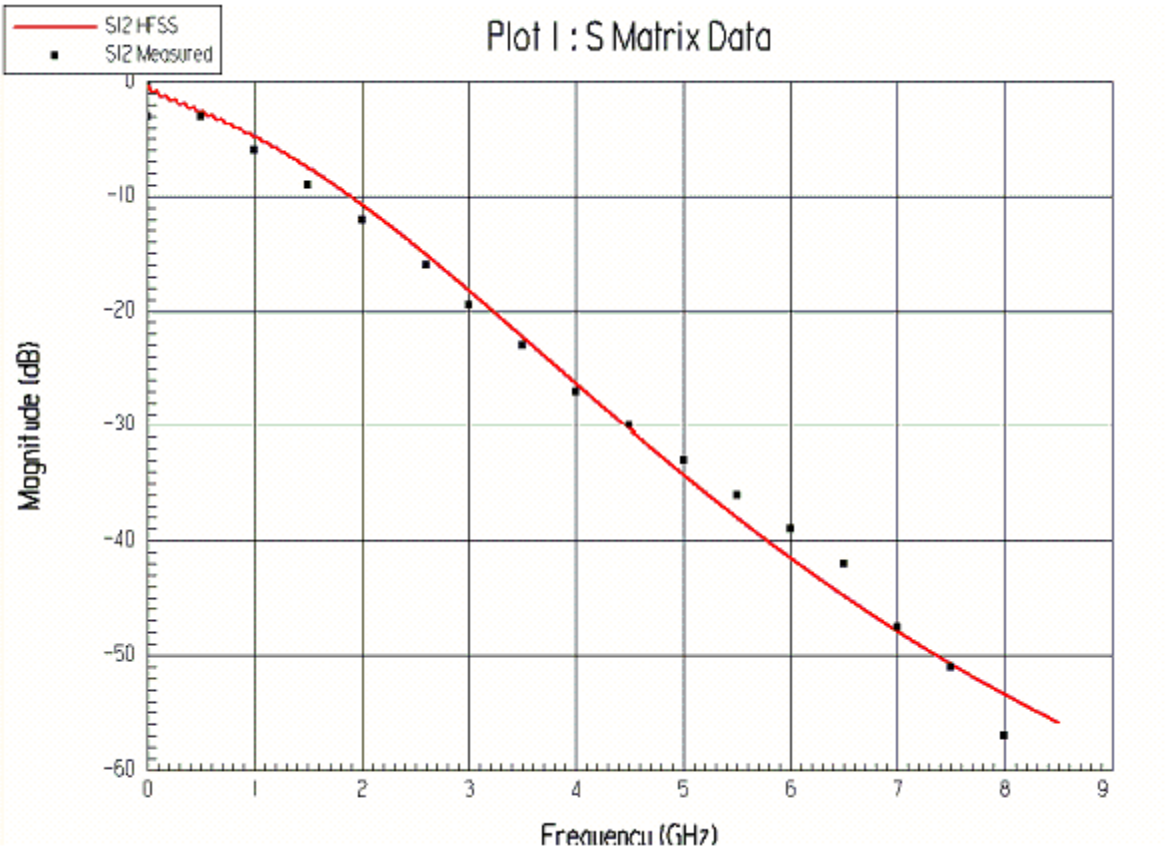

Figure 5: Calculated and measured frequency response of S_{12}

Figure 7: Transient response by Maxwell Spice

Debye's material loss model predicts the dielectric losses in the whole frequency range within an acceptable accuracy. The model can be set up by using low frequency and higher frequency measured dielectric constants and loss tangents and the optical dielectric constant. If the latter is not available, the model might be less accurate at high frequencies. Using Debye's model, no unphysical phenomena can be observed at the transient response.

Multipole Debye Model

The classical Debye model is based on a single pole or time constant. The Multi-Pole Debye Model attempts to generalize the Debye model by adding multiple poles providing greater flexibility in matching arbitrary measurement data.

A lossy dielectric has a complex relative permittivity denoted as follows:

$$\varepsilon(j\omega)$$

It can be expressed as follows:

$$\varepsilon(j\omega) = \varepsilon_r(j\omega) + j\varepsilon_i(j\omega) = \varepsilon_r(j\omega)[1 - j\delta(j\omega)] = \varepsilon_r(j\omega) - j\varepsilon_r(j\omega)\delta(j\omega)$$

where

$\varepsilon_r(j\omega)$= real valued permittivity and $\delta(j\omega)$ = loss tangent

If the relative permittivity and loss tangent measured at a finite set of frequency points are known, a rational function model can be fit to this data. This approximating rational function can be expressed in pole-residue form as

$$\tilde{\varepsilon}(j\omega) = k_0 + \sum_{i=1}^{N} \frac{k_i}{j\omega - p_i}$$

where

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

p_i = the i-th pole and
k_i = the corresponding residue

Both are potentially complex valued quantities.

N = number of poles which needs to be determined.
k_0 = a high frequency limit, or "optical" permittivity and is also a fitting parameter.

The fitting problem can be expressed as follows: minimize the sum of the least squares differences:

$$E = \sum_{n=1}^{N_f} |\tilde{\epsilon}(j\omega_n) - \epsilon(j\omega_n)|^2$$

where

N_f = number of frequencies
ω_n = measurement frequencies that you supply.

HFSS will pre-process the measured data to ensure that it obeys the Hilbert transform (Kramers-Kronig) causality conditions. It then determines a set of stable poles that provide a good model to the frequency variation of the measured data. Finally the residues are determined through least-squares fitting.

The resulting model ensures a causal response for the dielectric when used in time domain simulation. This is because the impulse response of the multi-pole Debye model can be expressed analytically in the time domain as follows:

$$E(t) = k_0\delta(t) + \sum_{i=1}^{N} k_i \exp(p_i t)\, u(t)$$

where

$\delta(t)$ =Dirac Delta function
$u(t)$ = the Heaviside step-unit function

The above impulse response is zero for time t < 0 and so, it is casual.

Recall the approximating multi-pole Debye model function:

$\tilde{\epsilon}(j\omega)$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

After computing this approximating multi-pole Debye model, HFSS splits the model into its real and imaginary parts. The real part corresponds to the approximation for the relative permittivity and the imaginary part divided by the real part gives the approximation for the (negative of the) loss tangent. The resulting (very complicated) expressions are then filled in for the new material model created.

Djordjevic-Sarkar Model Parameter Calculation

The model parameters can be calculated if the following information about the material is known:

- DC conductivity, σ_{DC} (optional; default value is 0)
- DC permittivity, ε_{DC} (optional; you have to choose the default. See below)
- A triplet of real numbers, consisting of
- the measurement frequency ω_1
- the real permittivity ε_1 at this frequency
- the loss tangent tan δ_1 at this frequency

From the model equation, observe that

$$\begin{aligned}\varepsilon(\omega_1) &= \varepsilon_\infty + \frac{\Delta\varepsilon}{\ln(\omega_B/\omega_A)}\ln\left(\frac{\omega_B + j\omega_1}{\omega_A + j\omega_1}\right) + \frac{\sigma_{DC}}{j\omega_1\varepsilon_0} \\ &\cong \varepsilon_\infty + \frac{\Delta\varepsilon}{\ln(\omega_B/\omega_A)}\ln\left(\frac{\omega_B + j\omega_1}{j\omega_1}\right) + \frac{\sigma_{DC}}{j\omega_1\varepsilon_0} \\ &= \varepsilon_\infty + \frac{\Delta\varepsilon}{\ln(\omega_B/\omega_A)}\ln\left(\frac{\sqrt{\omega_B^2+\omega_1^2}}{\omega_1}\right) - j\left[\frac{\Delta\varepsilon}{\ln(\omega_B/\omega_A)}\cdot\tan^{-1}\left(\frac{\omega_B}{\omega_1}\right) + \frac{\sigma_{DC}}{\omega_1\varepsilon_0}\right]\end{aligned} \tag{3}$$

We know the imaginary part of $\varepsilon(\omega_1) = -\varepsilon_1 . \tan\delta_1$. Therefore we get,

$$\varepsilon_1 \tan\delta_1 = \frac{\Delta\varepsilon}{\ln(\omega_B/\omega_A)}\cdot\tan^{-1}\left(\frac{\omega_B}{\omega_1}\right) + \frac{\sigma_{DC}}{\omega_1\varepsilon_0} \tag{4}$$

and so

$$K = \frac{\Delta\varepsilon}{\ln(\omega_B/\omega_A)} = \frac{\varepsilon_1\tan\delta_1 - \dfrac{\sigma_{DC}}{\omega_1\varepsilon_0}}{\tan^{-1}\left(\dfrac{\omega_B}{\omega_1}\right)} \tag{5}$$

The following equation for the real part also holds:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\varepsilon_1 = \varepsilon_\infty + K \ln\left(\frac{\sqrt{\omega_B^2 + \omega_1^2}}{\omega_1}\right) \quad (6)$$

Inserting the above expression allows us to solve for the high-frequency permittivity:

$$\varepsilon_\infty = \varepsilon_1 - K \ln\left(\frac{\sqrt{\omega_B^2 + \omega_1^2}}{\omega_1}\right) \quad (7)$$

If you know the DC value of real permittivity, you can find $\Delta\varepsilon = \varepsilon_{DC} - \varepsilon_\infty$ and use the above expression to calculate the lower transition frequency.

$$\omega_A = \frac{\omega_B}{\exp\left(\frac{\Delta\varepsilon}{K}\right)} \quad (8)$$

Check the computed value of lower transition frequency to make sure that it is much less than the measurement frequency. If not, raise the DC permittivity; this will reduce the value of the lower transition frequency. If you do not know the DC permittivity value, you may choose one yourself to satisfy the condition:

$$\omega_A << \omega_1$$

A simple heuristic is to choose $\Delta\varepsilon = 10 \cdot \tan\delta_1 \cdot \varepsilon_\infty$.

For more information, see Djordjevic-Sarkar Causal Dielectric Model.

Expressions for Permittivity and Conductivity

The final expressions are as follows:

Relative Permittivity:

$$\varepsilon(f) = \varepsilon_\infty + \frac{K}{2} \ln\left(\frac{f_B^2 + f^2}{f_A^2 + f^2}\right) \quad (9)$$

Conductivity:

$$\sigma(f) = \sigma_{DC} + 2\pi f \varepsilon_0 K \cdot \left[\tan^{-1}\left(\frac{f}{f_A}\right) - \tan^{-1}\left(\frac{f}{f_B}\right)\right] \quad (10)$$

Here $f_A = \omega_A/2\pi$ and $f_B = \omega_B/2\pi$ is the frequency in Hz.

- In the above expressions:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$f_B = 10^{12} / 2\pi \tag{11}$$

$$K = \frac{\varepsilon_1 \tan\delta_1 - \frac{\sigma_{DC}}{\omega_1 \varepsilon_0}}{\tan^{-1}\left(\frac{\omega_B}{\omega_1}\right)} \tag{12}$$

$$\varepsilon_\infty = \varepsilon_1 - \frac{1}{2} K \ln\left[\left(\frac{\omega_B}{\omega_1}\right)^2 + 1\right] \tag{13}$$

$\Delta\varepsilon = \varepsilon_\infty - \varepsilon_{DC}$ if the DC permittivity is known; else $\Delta\varepsilon = 10 \cdot \tan\delta_1 \cdot \varepsilon_\infty$

$$f_A = \frac{f_B}{\exp\left(\frac{\Delta\varepsilon}{K}\right)} \tag{14}$$

Conductivity and Permittivity Limits

The slope parameter K must be > 0. Therefore we must have

$$\varepsilon_1 \tan\delta_1 - \frac{\sigma_{DC}}{\omega_1 \varepsilon_0} > 0 \tag{15}$$

This can occur if you enter a DC conductivity higher than the effective conductivity at the measurement frequency. This is impossible in the Djordjevic model, because its conductivity increases monotonically with frequency. Another way for it to happen is for the measurement frequency to be too low (Hz instead of GHz, for example) or for the permittivity value to be unreasonably low.

For the model to be passive, we must have $\varepsilon_\infty \geq 1$

Therefore from (5) and (7) the following is true.

$$\varepsilon_\infty = \varepsilon_1 - \frac{\varepsilon_1 \tan\delta_1 - \frac{\sigma_{DC}}{\omega_1 \varepsilon_0}}{2\tan^{-1}\left(\frac{\omega_B}{\omega_1}\right)} \ln\left[\left(\frac{\omega_B}{\omega_1}\right)^2 + 1\right] \geq 1 \tag{16}$$

Define the quantity

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\tan \delta_{\max} = \frac{2 \tan^{-1}\left(\frac{\omega_B}{\omega_1}\right)}{\ln\left[\left(\frac{\omega_B}{\omega_1}\right)^2 + 1\right]} \tag{17}$$

Using this in 16 simplifies the expression as follows.

$$\varepsilon_1 \cdot \tan \delta_{\max} - \left(\varepsilon_1 \tan \delta_1 - \frac{\sigma_{DC}}{\omega_1 \varepsilon_0}\right) \geq \tan \delta_{\max} \tag{18}$$

Then, the condition for passivity can be written as follows:

$$\varepsilon_1 \cdot \left(\tan \delta_{\max} - \tan \delta_1\right) \geq \tan \delta_{\max} - \frac{\sigma_{DC}}{\omega_1 \varepsilon_0} \tag{19}$$

For this to hold, with $\varepsilon > 0$, the following two conditions are necessary

$$\tan \delta_{\max} - \tan \delta_1 > 0 \quad \text{or} \quad \tan \delta_1 < \tan \delta_{\max} \tag{20}$$

$$\varepsilon_1 \geq \varepsilon_{1,\min} = \frac{\tan \delta_{\max} - \frac{\sigma_{DC}}{\omega_1 \varepsilon_0}}{\tan \delta_{\max} - \tan \delta_1} \tag{21}$$

We see from the expression for tan δ_{max} given in (17) that the maximum loss tangent is a function of only the upper corner frequency and the measurement frequency.

Reducing the upper corner frequency will generally increase the value of tan δ_{max} at least as long as the following condition is realized.

ω_B is much greater than ω_1

But reducing the upper corner frequency is not very attractive, because it has not been observed in experimental data. Therefore it is an upper bound on the loss tangents that the Djordjevic-Sarkar model can handle. Equation (21) indicates that if the permittivity is too low, then the optical permittivity will go below 1. If this condition is violated, two possible fixes are to raise the value of ε or to reduce the measurement frequency. But by the same argument as before, reducing the upper corner frequency is not attractive and it is the minimum value of the permittivity. If you reduce the value of the measured loss tangent; this makes the denominator in (21) larger and lowers the value of $\varepsilon_{1,min}$.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Force per Unit Area in HFSS

This is mainly for the purpose of mapping surface force density in HFSS to Work Bench Mechanical. We will also provide it for post processing within HFSS. This feature should work regardless of HFSS solution types as long as surface forces exist. Surface forces may exist when one side is conductor but the other is not, or finite conductivity and layered impedance boundary.

The task is to calculate the force per unit area ($\mathbf{f}_s$) distribution on the surface or on a section of the surface of a solid body in HFSS. We presume the solution is known, so both the electric and the magnetic field is available in any point.

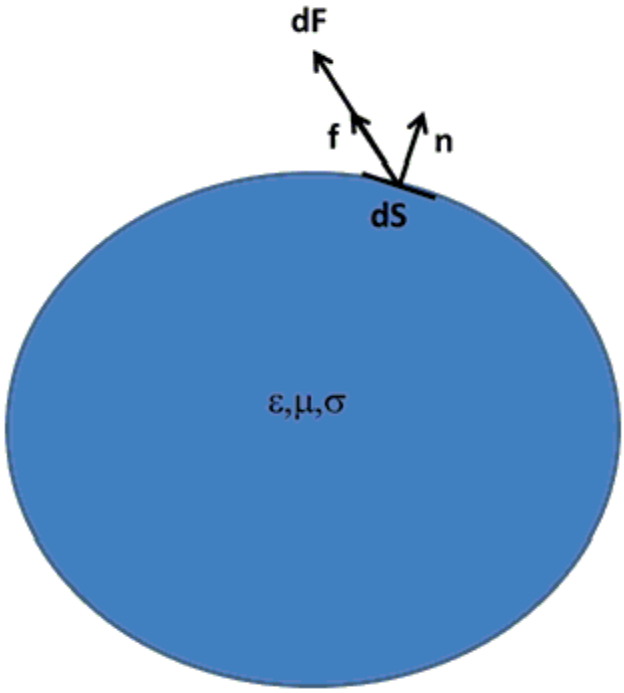

Fig. 1: Force and force per unit area on a solid body

Fig. 1 shows a solid body of homogeneous or inhomogeneous material characteristics (ε,μ, σ). **dS** is an elementary section of its surface and **n** is the normal vector of the surface. If **dF** [N] is the force acting on the elementary surface **dS**, then:

$$\mathbf{f}_s = \frac{\mathbf{dF}}{dS} \quad (1)$$

where $\mathbf{f}_s$ is the force per unit area. Knowing the electromagnetic field, **dF** can be calculated as:

$$\mathbf{dF} = \mathbf{T}^{em}\mathbf{n}\,dS \quad (2)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

then

$$\mathbf{f}_s = \mathbf{T}^{em}\mathbf{n} \quad (3)$$

where $\mathbf{T}^{em}$ is the electromagnetic Maxwell's stress tensor, which consists of the electric and the magnetic stress tensor as:

$$\mathbf{T}^{em} = \mathbf{T}^{e} + \mathbf{T}^{m} \quad (4)$$

(5)

$$\mathbf{T}^{e} = \begin{bmatrix} D_1E_1 - 0.5DE & D_1E_2 & D_1E_3 \\ D_1E_2 & D_2E_2 - 0.5DE & D_2E_3 \\ D_1E_3 & D_2E_3 & D_3E_3 - 0.5DE \end{bmatrix}$$

(6)

$$\mathbf{T}^{e} = \begin{bmatrix} B_1H_1 - 0.5BH & B_1H_2 & B_1H_3 \\ B_1H_2 & B_2H_2 - 0.5BH & B_2H_3 \\ B_1H_3 & B_2H_3 & B_3H_3 - 0.5BH \end{bmatrix}$$

$$DE = D_1E_1 + D_2E_2 + D_3E_3 \quad (7)$$

$$BH = B_1H_1 + B_2H_2 + B_3H_3 \quad (8)$$

Indices 1,2 and 3 mean the first, second and third component. For example, in Cartesian coordinates, the meaning is x, y and z.

Using the notations:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(9)

$$\mathbf{T}^{em} = \begin{bmatrix} T_{11}^{em} & T_{12}^{em} & T_{13}^{em} \\ T_{21}^{em} & T_{22}^{em} & T_{23}^{em} \\ T_{31}^{em} & T_{32}^{em} & T_{33}^{em} \end{bmatrix}; \qquad n = \begin{bmatrix} n_1 \\ n_2 \\ n_3 \end{bmatrix}$$

The force per unit area from Eq. (3) is:

(10)

$$\mathbf{f}_S = \mathbf{T}^{em}\mathbf{n} = \begin{bmatrix} T_{11}^{em} n_1 & + T_{12}^{em} n_2 & + T_{13}^{em} n_3 \\ T_{21}^{em} n_1 & + T_{22}^{em} n_2 & + T_{23}^{em} n_3 \\ T_{31}^{em} n_1 & + T_{32}^{em} n_2 & + T_{33}^{em} n_3 \end{bmatrix}$$

Note two things:

Stress tensor is defined on the surface of **S**

Force density might have both normal and tangential components on the surface

The filed quantities in formulas (1) - (10) are time dependent or static. We want to have the forces in steady state time harmonic case, too, by using the complex notations as the field quantities are defined in HFSS. It is derived for the magnetic stress tensor. The derivation for the electric stress tensor can be got by replacing B_k and H_k by D_k and E_k, respectively, where index k refers to the k-th component. The real time function of the k-th component of a complex field quantity can be written as:

$$B_k = Re(B_{ck} e^{j\omega t}) = \frac{1}{2}(B_{ck} e^{j\omega t} + B_{ck}^* e^{-j\omega t}) \quad (11)$$

where subscript c denotes complex quantity and superscript '*' means complex conjugate.

The stress tensor just contains products of $B_k H_k$ where k =1,2,3 and l =1,2,3. Applying Eq. (10), we get:

(12)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$B_k H_k = \frac{1}{4}(B_{ck} e^{j\omega t} + B^*_{ck} e^{-j\omega t})(H_{cl} e^{j2\omega t} + H^*_{cl} e^{-j2\omega t}) =$$

$$\frac{1}{4}(B_{ck} H^*_{cl} + B^*_{ck} H_{cl} + B^*_{ck} H^*_{cl} e^{-j2\omega t})$$

Eq. (12) has a constant component and a sinusoidal component of 2ω. If we are interested in the time average force, Eq. (12) should be integrated for one period and divided by the period time:

$$\langle B_k H_k \rangle = \frac{1}{T}\int_0^T \frac{1}{4}(B_{ck} H^*_{cl} + B^*_{ck} H_{cl} + B_{ck} H_{cl} e^{j2\omega t})dt = \frac{1}{2}\mathrm{Re}(B_{ck} H^*_{cl}) \quad (13)$$

Performing the calculations for *k*=1,2,3 and *l*=1,2,3 the elements of the magnetic and electric stress tensor can be calculated as:

$$\langle B_k H_k \rangle = \frac{1}{2}\mathrm{Re}(B_{ck} H^*_{cl}); \qquad \langle D_k E_k \rangle = \frac{1}{2}\mathrm{Re}(D_{ck} E^*_{cl}) \quad (14)$$

The time average surface force density is:

$$\mathbf{f}_S = \mathbf{T}^{em} = \begin{bmatrix} \langle T_{11}{}^{em} \rangle n_1 + \langle T_{12}{}^{em} \rangle n_2 + \langle T_{13}{}^{em} \rangle n_3 \\ \langle T_{21}{}^{em} \rangle n_1 + \langle T_{22}{}^{em} \rangle n_2 + \langle T_{23}{}^{em} \rangle n_3 \\ \langle T_{31}{}^{em} \rangle n_1 + \langle T_{32}{}^{em} \rangle n_2 + \langle T_{33}{}^{em} \rangle n_3 \end{bmatrix} \quad (15)$$

The volume force acting on a closed surface is:

$$\langle \mathbf{F} \rangle = \oint_S \langle \mathbf{f}_s \rangle dS \quad (16)$$

If a surface is selected to calculate the force, smoothing should not go through this surface.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The calculations just need post processing operations.

The relativistic electromagnetic momentum (radiation pressure), which is associated with the volume sources, has been neglected in the formulas. If it is necessary, it can be taken into account

Energy Normalization of Eigen Solutions in HFSS

The energy of a system is the sum of the electric and magnetic energy:

$$W = W_e + W_m \tag{1}$$

$$W_e = \frac{1}{2}\int_V \mathbf{E} \bullet \mathbf{D} dV \quad \text{and} \quad W_{em} = \frac{1}{2}\int_V \mathbf{H} \bullet \mathbf{B} dV \tag{2}$$

The filed quantities in formulas (1)-(2) are time dependent. We want to have the energy in steady state time harmonic case, by using the complex notations as the field quantities are defined in HFSS. The real time function of a complex field quantity can be written as:

$$\mathbf{D} = \mathrm{Re}(\mathbf{D}_c e^{j\omega t}) = \frac{1}{2}(\mathbf{D}_c e^{j\omega t} + \mathbf{D}_c^* e^{-j\omega t}) \tag{3}$$

where subscript c denotes complex quantity and superscript '*' means complex conjugate.

The energy contains products of **E** and **D**. Applying Eq. (3), we get:

$$\mathbf{D} \bullet \mathbf{E} = \frac{1}{4}(\mathbf{D}_c e^{j\omega t} + \mathbf{D}_c^* e^{-j\omega t}) \bullet (\mathbf{E}_c e^{j\omega t} + \mathbf{E}_c^* e^{-j\omega t}) = \frac{1}{4}(\mathbf{D}_c \bullet \mathbf{E}_c^* + \mathbf{D}_c^* \bullet \mathbf{E}_c + \mathbf{D}_c \bullet \mathbf{E}_c e^{j2\omega t} + \mathbf{D}_c^* \bullet \mathbf{E}_c^* e^{-j2\omega t}) \tag{4}$$

Eq. (4) has a constant component and a sinusoidal component of 2ω. If we are interested in the time average energy, Eq. (4) should be integrated for one period and divided by the period time:

$$\langle \mathbf{D} \bullet \mathbf{E} \rangle = \frac{1}{T}\int_0^T \frac{1}{4}(\mathbf{D}_c \bullet \mathbf{E}_c^* + \mathbf{D}_c^* \bullet \mathbf{E}_c + \mathbf{D}_c \bullet \mathbf{E}_c e^{j2\omega t} + \mathbf{D}_c^* \bullet \mathbf{E}_c^* e^{-j2\omega t}) dt = \tag{5}$$

$$\frac{1}{2}\mathrm{Re}(D_c \bullet E_c^*)$$

Performing algebra, the elements of the electric and magnetic energy can be written as:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$W_m = \frac{1}{2}\mathrm{Re}(B_c H_c^*) \qquad W_e = \frac{1}{2}\mathrm{Re}(D_c E^*_c) \quad (6)$$

Generally, the normalized field can be written as the solution field times a constant:

$$\mathbf{E}_{norm} = c\mathbf{E}_{solve} \quad (7)$$

For normalization to $\mathbf{E}_{max}$=1

$$c = \frac{1}{\mathbf{E}_{solve_max}} \qquad \mathbf{E}_{norm} = \frac{\mathbf{E}_{solve}}{\mathbf{E}_{solve_max}} \quad (8)$$

For normalization to $\mathbf{W}_{norm}$ =1

$$c = \sqrt{\frac{1}{W_{solve}}} \qquad \mathbf{E}_{norm} = \sqrt{\frac{1}{W_{solve}}}\mathbf{E}_{solve} \quad (9)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

29 - Glossary

This section defines the terminology used in the Ansys desktop help topics. Terms are listed in alphabetical order.

A **B** **C**
D **E** **F**
G **H** **I**
J **K** **L**
M **N** **O**
P **Q** **R**
S **T** **U**
V **W** **X**
Y **Z**

Glossary: A

A/D

See Analog-to-Digital.

ACPR

Adjacent channel power ratio.

Active Substrate

A hybrid or multichip module substrate formed from a semiconductor. Termed active because components such as transistors can be fabricated directly into the substrate.

Active Trimming

The process of trimming components such as resistors while the circuit is under power. Such components are fabricated directly onto the substrate of a hybrid or multichip module, and the trimming is usually performed using a laser beam.

Active-High

A signal whose active state is considered to be a logic 1.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Active-Low

A signal whose active state is considered to be a logic 0.

Actuator

A transducer that converts an electronic signal into a physical equivalent. For example, a loudspeaker is an actuator which converts electronic signals into corresponding sounds.

Adaptive Hardware

Refers to devices which allow new design variations to be "compiles" in real-time, which may be thought of as dynamically creating subroutines in hardware (see also Virtual Hardware and Cache Logic).

Additive Process

A process in which conducting material is added to specific areas of a substrate. Groups of tracks, individual tracks, or portions of tracks can be built up to precise thicknesses by iterating the process multiple times with selective masking.

Address Bus

A unidirectional set of signals used by a computer to point to memory locations in which it is interested.

Analog

A continuous value that most closely resembles the real world and can be as precise as the measuring technique allows.

Analog Circuit

A collection of components used to generate or process analog signals.

Analog-to-Digital (A/D)

The process of converting an analog value into its digital equivalent.

Anisotropic Adhesive

Special adhesives which contain minute particles of conductive material. These adhesives find particular application with the flipped-chip techniques used to mount bare die on the substrates of hybrids, multichip modules, or circuit boards. The conducting particles are only brought in contact with each other at the sites where the raised pads on the die are pressed down over their corresponding pads on the substrate, thereby forming good electrical connections between the pads.

Anti-Fuse Technology

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A programmable logic device technology in which conducting paths (anti-fuses) are grown by applying signals of relatively high voltage and current to the device's inputs.

Anti-Pad

The area of copper etched away around a via or a plated through-hole on a power or negative signal plane, thereby preventing an electrical connection being made to that plane.

Application-Specific Integrated Circuit (ASIC)

A device whose function is determined for a particular application or group of applications.

Application-Specific Standard Part (ASSP)

Refers to an integrated circuit created by a device manufacturer using ASIC technologies, and for these components to be sold as standard parts to anybody who wants to buy them.

ASIC

See Application-Specific Integrated Circuit.

ASIC Cell

A logic function in the cell library defined by the manufacturer of an application-specific integrated circuit.

Assertion-Level Logic

Special symbols which are used to more precisely indicate the function of gates with active-low inputs.

ASSP

See Application-Specific Standard Part.

Asynchronous

A signal whose data is acknowledged or acted upon immediately, irrespective of any clock signal.

Atto

Unit qualifier (symbol = a) representing one millionth of one millionth of one millionth, or 10-18. For example, 3aS stands for 3 x 10-18 seconds.

Attenuator

A passive device used to reduce signal strength while maintaining proper input and output impedance.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Glossary: B

Backplane

The medium used to interconnect a number of circuit boards. Typically refers to a special, heavy-duty printed or discrete wired circuit board.

Ball Grid Array (BGA)

A packaging technology similar to a pad grid array, in which a device's external connections are arranged as an array of conducting pads on the base of the package. However, in the case of a ball grid array, small balls of solder are attached to the conducting pads.

Bandpass

The frequency limits between half-power points of a signal or filter.

Bare Die

An unpackaged integrated circuit.

Base

Refers to the number of digits in a numbering system. For example, the decimal numbering system is said to be base-10. May also be referred to as the "radix".

Basic Cell

A pre-defined group of unconnected components that is replicated across the surface of a gate array.

BER

Bit error rate.

BGA

See Ball Grid Array.

BiCMOS

A technology in which the function of each logic gate is implemented using low-power CMOS, while the output stage is implemented using high-drive bipolar transistors

Binary Encoding

A form of state assignment for state machines that requires the minimum number of state variables.

BiNMOS

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A relatively new low-voltage integrated circuit technology in which complex combinations of bipolar and NMOS transistors are used to form sophisticated output stages providing both high speed and low static power dissipation.

Bi-quinary

A system which utilizes two bases, base-2 and base-5, to represent decimal numbers. Each decimal digit is represented by the sum of two parts, one of which has the value of decimal zero or five, and the other the values of zero through four. The abacus is one practical example of the use of a bi-quinary system.

Bit

Abbreviation of binary digit.

Bipolar Junction Transistor (BJT)

A family of transistors.

Blackbox

Same as N-Port.

Blind Via

A via that is only visible from one side of the substrate.

Bobble

A small circle used on the inputs to a logic gate symbol to indicate an active-low input or control, or on the outputs to indicate a negation (inversion) or a complementary signal. Some engineers prefer to use the term bubble.

Bounce Pad

A special pattern etched onto the power or negative signal plane of a microwire circuit board to be used in conjunction with a laser beam which is employed to create blind vias. The laser beam evaporates the epoxy forming the outer layers of the board and continues down to the bounce pad which reflects, or bounces, it back up, thereby terminating the via.

Braze

To unite or fuse two pieces of metal by heating, or with a hard solder with a high melting point.

Bulk Storage

Refers to some form of media, typically magnetic, such as tape or a disk drive which can be used to store large quantities of information relatively inexpensively.

Buried Via

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A via used to link conducting layers internal to a substrate. Such a via is not visible from either side of the substrate.

Bundle

A set of signals related in some way that makes it appropriate to group them together for ease of representation or manipulation. May contain both scalar and vector elements; for example, {a,b,c,d[5:0]}.

Bus

A set of signals performing a common function and carrying similar data. Typically represented using vector notation; for example, address[7:0].

Byte

A group of eight binary digits, or bits.

Glossary: C

Capacitance

A measure of the ability of two adjacent conductors separated by an insulator to hold a charge when a voltage differential is applied between them. Capacitance is measured in units of Farads.

CDMA

Code division multiple access.

Cell Library

The collective name for the set of logic functions defined by the manufacturer of an application-specific integrated circuit. The designer decides which types of cells should be realized and connected together to make the device perform its desired function.

Ceramic

An inorganic, nonmetallic material, such as alumina, beryllia, steatite, or forsterite, which is fired at a high temperature and is often used in electronics as a substrate or to create component packages.

CGA

See Column Grid Array.

Channel

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(1)The area between two arrays of basic cells in a channeled gate array.

(2)The gap between the source and drain regions in a MOS transistor.

Channeled Gate Array

Application-specific integrated circuit organized as arrays of basic cells. The areas between the arrays are known as channels.

Channel-Less Gate Array

Application-specific integrated circuit organized as a single large array of basic cells. May also be referred to as a "sea of cells" or a "sea of gates" device.

Checksum

The final cyclic-redundancy-check value stored in a linear feedback shift register (or software equivalent). Also known as a "signature" in the guided-probe variant of functional test.

Chip

Popular name for an integrated circuit.

Chip-On-Board (COB)

A process in which unpackaged integrated circuits are physically and electrically attached to a circuit board, and are then encapsulated with a "glob" of protective material such as epoxy.

Chip-On-Chip (COC)

A process in which unpackaged integrated circuits are mounted on top of each other. Each die is very thin and it is possible to have over a hundred dies forming a 3D cube.

Chip-On-Flex (COF)

Similar to chip-on-board (COC), except that the unpackaged integrated circuits are attached to a flexible printed circuit.

Circuit Board

The generic name for a wide variety of interconnection techniques, which include rigid, flexible, and rigid-flex boards in single-sided, double-sided, multilayer, and discrete wired configurations.

CMOS

Logic gates constructed using both NMOS and PMOS transistors connected in a complementary manner.

Coaxial Cable

A conductor in the form of a central wire surrounded first by a dielectric (insulating) layer, and then by a conducting tube which serves to shield the central wire from external interference.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Coefficient of Thermal Expansion

Defines the amount a material expands and contracts due to changes in temperature. If materials with different coefficients of thermal expansion are bonded together, changes in temperature will cause shear forces at the interface between them.

Cofired Ceramic

A substrate formed from multiple layers of "green" ceramic that are bonded together and fired at the same time.

Column Grid Array (CGA)

A packaging technology similar to a pad grid array, in which a device's external connections are arranged as an array of conducting pads on the base of the package. However, in the case of a column grid array, small columns of solder are attached to the conducting pads.

Combinatorial

A digital function whose output value is directly related to the current combination of values on its inputs. Also known as combinational.

Compiled Cell Technology

A technique used to create portions of a standard cell application-specific integrated circuit. The masks used to create components and interconnections are directly generated from Boolean representations using a silicon compiler. May also be used to create data-path functions and memory functions.

Complementary Output

Refers to a function with two outputs carrying complementary logical values. One output is referred to as the true output and the other as the complementary output.

Complex Programmable Logic Device (CPLD)

A device that contains a number of PLA or PAL functions sharing a common programmable interconnection matrix.

Component

Components are items placed on schematics and layouts to represent electrical elements and sub circuits. The component information defines a signal-processing function or source, or secondarily a data source, data channel, or similar entity. Components have pins for connections, bitmaps in the project tree, and properties for simulation. The information that constitutes a component includes its component chooser bitmap, schematic symbol, layout footprint, pin properties, parameters and parameter values, and netlist string definition. A component can be associated with more than one simulation if it can be analyzed in more than one simulator.

Computer-Generated Hologram (CGH)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refers to a slice of quartz or similar material into which three-dimensional patterns are cut using a laser. The angles of the patterns cut into the quartz are precisely calculated for use in the optical communication strategy known as holographic interconnect. All of these calculations are performed by a computer, and the laser used to cut the three-dimensional patterns into the quartz is also controlled by a computer. Thus, the slice of quartz is referred to a computer-generated hologram.

Conductive Ink Technology

A technique in which tracks are screen printed directly onto the surface of a circuit board using a conductive ink.

Configurable Hardware

A product whose function may be customized once or a very few times (see also Reconfigurable Hardware, Remotely Reconfigurable Hardware, Dynamically Reconfigurable Hardware, and Virtual Hardware).

Conjunction

Propositions combined with an AND operator; for example, "You have a parrot on your head AND you have a fish in your ear." The result of a conjunction is true if all the propositions comprising that conjunction are true.

Conversion Loss

The ratio in dB of the IF output of a mixer to the RF input power. All conversion loss measurements and specification are normally based on the mixer being terminated on all ports and a stated LO signal power level being applied.

Cost Function

In an optimization setup, a cost function is based on goal values specified for at least one solution quantity. Optimetrics changes the design parameter values to fulfill the cost function. In HFSS, the cost function can be based on any solution quantity that HFSS can compute, such as field values, S-parameters, and eigenmode data.

CPLD

See Complex Programmable Logic Device.

CRC

See Cyclic Redundancy Check.

CSIC

See Customer-Specific Integrated Circuit.

Customer-Specific Integrated Circuit (CSIC)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

An alternative and possibly more accurate name for an ASIC, but this term is rarely used in the industry and shows little indication of finding favor with the masses.

Chemical Vapor Deposition (CVD)

A process for growing thin films on a substrate, in which a gas containing the required molecules is converted into a plasma by heating it to extremely high temperatures using microwaves. The plasma carries atoms to the surface of the substrate where they are attracted to the crystalline structure of the substrate. This underlying structure acts as a template. The new atoms continue to develop the structure to build up a layer on the substrate's surface.

Chemical Vapor Infiltration (CVI)

A process similar to chemical vapor deposition (CVD) but, in this case, the process commences by placing a crystalline powder of the required substance in a mold. Additionally, thin posts, or columns, can be pre-formed in the mold, and the powder can be deposited around them. When exposed to the same plasma as used in the CVD technique, the powder coalesces into a polycrystalline mass. After the CVI process has been performed, the posts can be dissolved leaving holes through the crystal for use in creating vias. CVI processes can produce layers twice the thickness of those obtained using CVD techniques at a fraction of the cost.

CW

Continuous wave; refers to an unmodulated sine-wave signal.

Cyclic Redundancy Check (CRC)

A calculation used to detect errors in data communications, typically performed using a linear feedback shift register. Similar calculations may be used for a variety of other purposes such as data compression.

Glossary: D

D/A

See Digital-to-Analog.

Data Bus

A bi-directional set of signals used by a computer to convey information from a memory location to the central processing unit and vice versa. More generally, a set of signals used to convey data between digital functions.

Data-Path Function

A well-defined function such as an adder, counter, or multiplier used to process digital data.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

dBm

Power level relative to 1mV rms.

DC Balance

Stream of data encoded to ensure an equal balance of 1 or 0 . 8b10b encoding has been developed to ensure DC balancing.

DC Coupling

A method of coupling two different circuits together, allowing them to share both the static DC and varying AC characteristics of a signal.

Decoder (digital)

A logic function that uses a binary value, or address, to select between a number of outputs and to assert the selected output by placing it in its active state.

Deep Sub-Micron

Typically taken to refer to integrated circuits containing structures which are smaller than 0.5 microns.

DeMorgan Transformation

The transformation of a Boolean expression into an alternate, and often more convenient, form.

Design

Designs are the building blocks of projects, and can be Circuit designs or 3D models. Designs consist of schematics or geometrical models, model data, solution setup information, output graphs and tables, and other pieces of information that go into describing simulation of electrical circuits. A design is the largest single simulatable entity in a project.

Design Variation

A single combination of variable values that is solved during a parametric or optimization setup.

Device

A discrete, separate electrical entity such as a diode, a capacitor or a packaged transistor.

Die

(1)An unpackaged integrated circuit. In this case, the plural of die is also die (in much the same way that "a shoal of herring" is the plural of "herring"). (2)A piece of metal with a design engraved or embossed on it for stamping onto another material, upon which the design appears in relief.

Die Separation

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The process of separating individual die from the wafer by marking the wafer with a diamond scribe and fracturing it along the scribed lines.

Die Stacking

A technique used in specialist applications in which several bare die are stacked on top of each other to form a sandwich. The die are connected together and then packaged as a single entity.

Dielectric Layer

(1) An insulating layer used to separate two signal layers.

(2) An insulating layer used to modify the electrical characteristics of an MCM-D substrate.

Diffusion Layer

The surface layer of a piece of semiconductor into which impurities are diffused to form P-type and N-type material. In addition to forming components, the diffusion layer may also be used to create embedded traces.

Digital

A value represented as being in one of a finite number of discrete states called quanta. The accuracy of a digital value is dependent on the number of quanta used to represent it.

Digital Circuit

A collection of logic gates used to process or generate digital signals.

Digital Signal Processor (DSP)

A primarily digital component used to process either digital or analog signals. In the case of the latter, the signal may first be conditioned, then converted into a digital equivalent using an analog-to-digital (A/D) converter function. The signal conditioning and A/D functions may either be external to the DSP or resident in the device. A typical DSP application might be the compression/decompression of video data.

Digital-to-Analog (D/A)

The process of converting a digital value into its analog equivalent.

Diode

A two-terminal device that only conducts electricity in one direction; in the other direction it behaves like an open switch. The term diode is typically taken to refer to a semiconductor device, although alternative implementations such as vacuum tubes are available.

Diode-Transistor Logic (DTL)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Logic gates implemented using particular configurations of diodes and bipolar junction transistors. For the majority of today's designers, diode-transistor logic is of historical interest only.

Discrete Device

Typically taken to refer to an electronic component such as a resistor, capacitor, diode, or transistor that is presented in an individual package. More rarely, the term may be used in connection with a simple integrated circuit containing a small number of primitive gates.

Discrete Wire Board (DWB)

A form of circuit board in which a special computer-controlled wiring machine ultrasonically bonds extremely fine insulated wires into the surface layer of the board. This discipline has enjoyed only limited recognition, but may be poised to emerge as the technology-of-choice for high-speed designers.

Discrete Wire Technology

The technology used to fabricate discrete wire boards.

Doping

The process of inserting selected impurities into a semiconductor to create P-type or N-type material.

Double-Sided

A printed circuit board with tracks on both sides

DPSK

Differential phase-shift keying.

DQPSK

Differential quadrature phase-shift keying.

DRAM

See Dynamic RAM.

DSP

See Digital Signal Processor.

DTL

See Diode-Transistor Logic.

DUT

Device under test.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Dynamic Flex

A type of flexible printed circuit which is used in applications that are required to undergo constant flexing such as ribbon cables in printers.

Dynamic RAM (DRAM)

A memory device in which each cell is formed from a transistor-capacitor pair. Called dynamic because the capacitor loses its charge over time, and each cell must be periodically recharged if it is to retain its data.

Glossary: E

E2PROM

See electrically Erasable Programmable Read-Only Memory.

EBE

See Electron Beam Epitaxy.

ECL

See Emitter-Coupled Logic.

Edge port

A place in a layout or footprint geometry through which excitation signals enter and leave the structure.

Edge-Sensitive

An input that only affects a function when it transitions from one logic value to another.

EEPROM

See electrically Erasable Programmable Read-Only Memory.

electrically Erasable Programmable Read-Only Memory (EEPROM or E2PROM)

A memory device whose contents can be electrically programmed by the designer. Additionally, the contents can be electrically erased allowing the device to be reprogrammed. Also known as EEPROM and E2PROM.

Electromigration

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(1)A process in which structures on an integrated circuit's substrate are eroded by the flow of electrons in much the same way as land is eroded by a river (also known as subatomic erosion). (2)The process of forming transistor-like regions in a semiconductor using an intense magnetic field.

Electron Beam Epitaxy (EBE)

A technique for creating thin films on substrates in precise patterns, in which the substrate is first coated with a layer of dopant material before being placed in a high vacuum. A guided beam of electrons is fired at the substrate causing the dopant to be driven into it, effectively allowing molecular-thin layers to be "painted" onto the substrate where required.

Electron Beam Lithography

An integrated circuit fabrication process in which fine beams of electrons are used to draw extremely high-resolution patterns directly into the resist without the use of a mask.

Electro-Static Discharge (ESD)

The process of moving around can generate static electricity. The term electro-static discharge refers to a charged person, or object, discharging static electricity. Although the current associated with such a static charge is low, the electric potential can be in the millions of volts and can severely damage electronic components. CMOS devices are particularly prone to damage from static electricity.

EM

Electromagnetic.

Emitter-Coupled Logic (ECL)

Logic gates implemented using particular configurations of bipolar junction transistors.

Enzyme

One of numerous complex proteins which are produced by living cells and catalyze biochemical reactions at body temperatures.

EPROM

See Erasable Programmable Read-Only Memory.

Equivalent Gate

A concept in which each type of logic function is assigned an equivalent gate value for the purposes of comparing functions and devices. However, the definition of an equivalent gate varies depending on who you're talking to.

Equivalent Integrated Circuit

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A concept used to compare the component density supported by diverse interconnection technologies such as circuit boards, hybrids, and multichip modules

Erasable Programmable Read-Only Memory (EPROM)

A memory device whose contents can be electrically programmed by the designer. Additionally, the contents can be erased by exposing the die to ultraviolet light through a quartz window mounted in the top of the component's package.

ESD

See Electro-Static Discharge.

Etching

The process of selectively removing any material not protected by a resist using an appropriate solvent or acid. In some cases the unwanted material is removed using an electrolytic process.

Eutectic Bond

A bond formed when two pieces of metal, or metal-coated materials, are pressed together and vibrated at ultrasonic frequencies.

Euler Angles

Euler angles are used in Ansoft software to carry out a coordinate transformation from one coordinate system to another. The Swiss mathematician and physicist Leonhard Euler first developed the classical rotation theorem to describe rotations in 3D space. The angles used are Euler angles and can be used to describe any 3D rotation. These angles, given by (ö, è, ø) represent a series of sequential rotations about two axis of the coordinate system. The first rotation (ö) represents a rotation about the Z-axis of the source coordinate system (X, Y, Z) which results in an intermediate coordinate system denoted by (X'', Y'', Z''). The second rotation (è) represents a rotation of the intermediate coordinate system about the X''-axis, again resulting in an intermediate coordinate system denoted by (X', Y', Z'). The third and final rotation (ø) represents a rotation about the Z'-axis of the intermediate coordinate system. The final rotation completes the rotation and results in the "target" coordinate system denoted (X, Y, Z).

For further information see, Eric W. Weisstein, "Euler Angles." From *MathWorld* - A Wolfram Web Resource.

http://mathworld.wolfram.com/EulerAngles.html .

Eye Diagram

Eye diagrams are commonly used to analyze signal integrity issues with communications channels. The bits are superimposed at unit intervals representing the duration of each bit.

Eye Mask

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The size of the eye opening in the center of an eye diagram indicates the amount of voltage and timing margin available to sample this signal. Thus, for a particular electrical interface, a fixed reticule or window could be placed over the eye diagram showing how the actual signal compares to minimum criteria window, know as the eye mask. If a margin rectangle with width equal to the required timing margin and height equal to the required voltage margin fits into the opening, then the signal has adequate margins. Voltage margin can often be traded off for timing margin.

Glossary: F

Fan-Out Via

In the case of surface mount devices attached to double-sided or multilayer boards, each component pad is usually connected by a short length of track to a via which forms a link to other conducting layers, and this via is known as a fan-out via. The term fan-out via is generally also taken to include any vias that fall inside the device's footprint (under the body of the device). Some designers attempt to differentiate these vias from those that fall outside the device's footprint by referring to them as fan-in vias, but this is not an industry-standard term.

Falling-Edge

A transition from a logic 1 to a logic 0. Also known as a negative edge.

Falltime

The time it takes for a waveform to transition from the high logic state to the low logic state. Falltime is usually measured from 90% of the total signal swing to 10% of the signal swing.

Fan-In and Fan-Out Vias

In the case of surface mount devices attached to double-sided or multilayer boards, each component pad is usually connected by a short length of track to a via which forms a link to other conducting layers, and this via is known as a fan-out via. The term fan-out via is generally also taken to include any vias that fall inside the device’s footprint (under the body of the device). Some designers attempt to differentiate these vias from those that fall outside the device’s footprint by referring to them as fan-in vias, but this is not an industry-standard term.

Femto

Unit qualifier (symbol = f) representing one thousandth of one millionth of one millionth, or 10-15. For example, 3fS stands for 3 x 10-15 seconds.

FET

See Field-Effect Transistor.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Field-Effect Transistor (FET)

A transistor whose control, or gate, signal creates an electro-magnetic field which turns the transistor ON or OFF.

Field-Programmable Gate Array (FPGA)

A programmable logic device which is more versatile than traditional programmable devices such as PALs and PLAs, but less versatile than an application-specific integrated circuit. Some field-programmable gate arrays use fuses such as those found in programmable logic devices, but others are based on SRAM equivalents.

Field-Programmable Interconnect Chip (FPIC)

An alternative, proprietary name for a field-programmable interconnect device (FPID).

Field-Programmable Interconnect Device (FPID)

A device which is used to connect logic devices together, and which can be dynamically reconfigured in the same way as standard SRAM-based FPGAs. Because each FPID may have around 1,000 pins, only a few such devices are typically required on a circuit board.

Filter

Filters are used to block out undesired frequencies. There are two types of filters: band pass and rejection. A band pass filter permits only the desired range to pass through, while the rejection filter attenuates an undesired range of frequencies.

Firmware

Refers to programs, or sequences of instructions, that are hard-coded into non-volatile memory devices.

First-In First Out (FIFO)

A memory device in which data is read out in the same order that it was written in.

Flash (e.g., Gold Flash)

An extremely thin layer of gold with a thickness measured on the molecular level which is either electroplated or chemically plated onto a surface.

FLASH Memory

An evolutionary technology that combines the best features of the EPROM and E2PROM technologies. The name FLASH is derived from the technology's fast reprogramming time compared to EPROM.

Flex

See Flexible Printed Circuit.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Flexible Printed Circuit (FPC or Flex)

A specialist circuit board technology, often abbreviated to "flex", in which tracks are printed onto flexible materials. There are a number of flavors of flex, including static flex, dynamic flex, and rigid flex.

Flipped Chip

A generic name for processes in which unpackaged integrated circuits are mounted directly onto a substrate with their component-sides facing the substrate.

Flipped TAB

A combination of flipped chip and tape automated bonding.

Footprint

The area occupied by a device mounted on a substrate.

Fourier Analysis

A mathematical procedure used to determine the collection of sine waves (differing in frequency and amplitude) that is necessary to make up the square-wave pattern under consideration.

FPC

See Flexible Printed Circuit.

FPGA

See Field-Programmable Gate Array.

FPIC

See Field-Programmable Interconnect Chip.

FPID

See Field-Programmable Interconnect Device.

FR4

The most commonly used insulating base material for circuit boards. FR4 is made from woven glass fibers which are bonded together with an epoxy. The board is cured using a combination of temperature and pressure which causes the glass fibers to melt and bond together, thereby giving the board strength and rigidity. The first two characters stand for "Flame Retardant". FR4 is technically a form of fiberglass, and some people do refer to these composites as fiberglass boards or fiberglass substrates, but not often.

Free-Space Optical Interconnect

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A form of optical interconnect in which laser-diode transmitters communicate directly with photo-transistor receivers without employing optical fibers or optical waveguides.

Full Custom

An application-specific integrated circuit in which the designer has complete control over every mask layer used to fabricate the device. The manufacturer does not provide a cell library or pre-fabricate any components on the substrate.

Functional Latency

Refers to the fact that, at any given time, only a portion of the logic functions in a device or system are typically active (doing anything useful).

Functional Test

A test strategy in which signals are applied to a circuit's inputs, and the resulting signals which are observed on the circuit's outputs are compared to known good values.

Fuse

See Fusible-Link Technology.

Fusible-Link Technology (Fuse)

A programmable logic device technology which employs links called fuses. Individual fuses can be removed by applying pulses of relatively high voltage and current to the device's inputs.

Fuzz-Button

A small ball of fibrous gold used in one technique for attaching components such as multichip modules to circuit boards. Fuzz-buttons are inserted between the pads on the base of the package and their corresponding pads on the board. When the package is forced against the board, the fuzz-buttons compress to form good electrical connections. Even when the pressure is removed, the fuzz-buttons act in a similar manner to Velcro and continue to hold the component in place. One of the main advantages of the fuzz-button approach is that it allows broken devices to be quickly removed and replaced. Even though fuzz-button technology would appear to be inherently unreliable, it is used in such devices as missiles, so one can only assume that it is fairly robust.

Glossary: G

Gain

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The ratio of the power output to the power input of the amplifier in dB. The gain is specified in the linear operating range of the amplifier where a 1 dB increase in input power gives rise to a 1 dB increase in output power. Gain = 20*log(S21)

Gate Array

An application-specific integrated circuit in which the manufacturer pre-fabricates devices containing arrays of unconnected components organized in groups called basic cells. The designer specifies the function of the device in terms of cells from the cell library and the connections between them, and the manufacturer then generates the masks used to create the metallization layers.

Glue Logic

Simple logic gates used to interface more complex functions together.

Gold Flash

An extremely thin layer of gold with a thickness measured on the molecular level which is either electroplated or chemically plated onto a surface.

Goal

In an optimization setup, a goal is the value of a solution quantity that you want to be achieved during the optimization. A goal is represented as one row in the cost function table. Each cost function defined in an optimization setup must include at least one goal.

Gray Code

A sequence of binary values in which each pair of adjacent values differs by only a single bit; for example, 00, 01, 11, 10.

Green Ceramic

Unfired, malleable ceramic.

Ground Bounce

Momentary noise on the device negative signal plane causing a 0 signal to erroneously be seen as a 1. Ground bounce is caused by simultaneously switching outputs (SSO).

Guard Condition

A Boolean expression associated with a state transition in a state diagram or state table. The expression must be satisfied for that state transition to be executed.

Guided Probe

A form of functional test in which the operator is guided in the probing of a circuit to isolate a faulty component or track.

Guided-Wave

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A form of optical interconnect, in which optical waveguides are fabricated directly on the substrate of a multichip module. These waveguides can be created using variations on standard opto-lithographic thin-film processes.

Glossary: H

Hard Macro (Macro Cell)

A logic function defined by the manufacturer of an application-specific integrated circuit. The function is described in terms of the simple functions provided in the cell library and the connections between them. The manufacturer also defines how the cells forming the macro will be assigned to basic cells and the routing of tracks between the basic cells.

Hardware

Generally understood to refer to any of the physical portions constituting an electronic system, including components, circuit boards, power supplies, cabinets, and monitors.

Harmonic

Integer multiples of the fundamental frequency of interest commonly produced by a non-linear amplifier.

Harmonic Balance

A frequency domain analysis technique for simulating nonlinear circuits and systems. This method assumes the input stimulus consists of a relatively few steady state sinusoids. Therefore the solution can be expressed as a sum of steady state sinusoids that includes the input frequencies in addition to any significant harmonics or mixing terms. A circuit with a single input source will require a single tone HB simulation. The harmonic balance simulation is ideal for situations where transient simulation methods are problematic, such as:

- Components modeled in frequency domain, for instance (dispersive) transmission lines
- Circuit time constants large compared to period of simulation frequency
- Circuits with lots of reactive components

Harmonic balance methods, therefore, are the best choice for most microwave circuits excited with sinusoidal signals (e.g., mixers, power amplifiers).

Harmonic Tuning

Impedance-matching at the harmonic frequencies for enhanced performance and efficiency.

Hertz (Hz)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Unit of frequency. One Hertz equals one cycle, or one oscillation, per second.

Heterojunction

The interface between two regions of dissimilar semiconductor materials. The interface of a hetrojunction has naturally occurring electric fields which can be used to accelerate electrons, and transistors created using hetrojunctions can switch much faster than their counterparts of the same size.

Hexadecimal

Base-16 numbering system. Each hexadecimal digit can be directly mapped onto four binary digits, or bits.

High Impedance State

The state on a signal that is not being driven by any value. A high-impedance state is indicated by the character Z.

Holographic Interconnect

A form of optical interconnect based on a thin slice of quartz, into which three-dimensional images are cut using a laser beam. Thus, the quartz is referred to as a computer-generated hologram, and this interconnection strategy is referred to as holographic.

Homojunction

An interface between two regions of semiconductor having the same basic composition but opposing types of doping. Homojunctions dominate current processes because they are easier to fabricate than heterojunctions.

Hybrid

An electronic sub-system in which a number of integrated circuits (packaged and/or unpackaged) and discrete components are attached directly to a common substrate. Connections between the components are formed on the surface of the substrate, and some components such as resistors and inductors may be fabricated directly onto the substrate.

Hydrogen Bond

The electrons in a water molecule are not distributed equally, because the oxygen atom is a bigger, more robust fellow which grabs more than its fair share. The end result is that the oxygen atom has an overall negative charge, while the two hydrogen atoms are left feeling somewhat on the positive side. This unequal distribution of charge means that the hydrogen atoms are attracted to anything with a negative bias; for example, the oxygen atom of another water molecule. The resulting bond is known as a hydrogen bond.

Hz

See Hertz.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Glossary: I

IBIS

IBIS (I/O Buffer Information Specification) is a standard for electronic behavioral specifications of integrated circuit input/output analog characteristics. The core of an IBIS model is a table of current versus voltage and I/O switching timing information. Xilinx IBIS models contain tables for typical, slow/MIN (weak transistors, high temperature, low voltage) and fast/MAX (strong transistors, low temperature, high voltage) process corners. IBIS models are derived from SPICE simulation results and/or lab measurements. The benefit for IBIS model user is fast and accurate simulation while preserving IC vendors intellectual property (information about circuit and process details).

IC

See Integrated Circuit.

ICR

See In-Circuit Reconfigurable.

Impedance

The resistance to the flow of current caused by resistive, capacitive, or inductive devices (or undesired elements) in a circuit.

Impedance Matching

Function of ensuring that the impedance of the transmitter, the receiver, and the transmission line are identical. Mismatched impedances could result in signal reflections, ringing, overshoot, undershoot, and stairstep waveforms.

Incident Voltage

The user specified voltage at an input.

In-Circuit Reconfigurable (ICR)

An SRAM-based, or similar component which can be dynamically reprogrammed on-the-fly while remaining resident in the system.

Inductance

A property of a conductor that allows is to store energy in a magnetic field which is induced by a current flowing through it. Inductance is measured in units of Henries (the base unit is a Henry).

Insertion Loss

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Insertion Loss (dB) is defined as the drop in power as a signal enters an RF component. This value not only includes the reflected incoming signal, but also the attenuation of the component.

In-System Programmable (ISP)

An E2-based, FLASH-based, or similar component which can be reprogrammed while remaining resident on the circuit board.

Integrated Circuit (IC)

A device in which components such as resistors, capacitors, diodes, and transistors are formed on the surface of a single piece of semiconductor.

Ion

A particle formed when an electron is added to, or subtracted from, a neutral atom or group of atoms.

Ion Implantation

A process in which beams of ions are directed at a semiconductor to alter its type and conductivity in certain regions.

Isolation

The ratio (expressed in dB) of the power level at one port compared to the resulting power level of the output port.

ISP

See In-System Programmable.

Glossary: J

JEDEC

See Joint Electronic Device Engineering Council.

Jitter

The jitter of a periodic signal is the delay between the expected transition of the signal and the actual transition. Jitter is a zero mean random variable. When worst case analysis is undertaken the maximum value of this random variable is used.

Jitter Tolerance

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Jitter tolerance is defined as the peak-to-peak amplitude of sinusoidal jitter applied on the input that causes a predefined, acceptable loss at the output. For example jitter applied to the input of an OC-N equipment interface that causes an equivalent 1dB optical power penalty.

Jitter Transfer

Jitter transfer is defined as the ratio of jitter on the output of a device to the jitter applied on the input of the device, versus frequency. Jitter transfer is important in applications where the system is utilized in a loop-timed mode, where the recovered clock is used as the source of the transmit clock.

Joint Electronic Device Engineering Council (JEDEC)

A council which creates, approves, arbitrates, and oversees industry standards for electronic devices. In programmable logic, the term JEDEC refers to a textual file containing information used to program a device. The file format is a JEDEC approved standard and is commonly referred to as a JEDEC file.

Jumper

A small piece of wire used to link two tracks on a circuit board.

Glossary: K

Karnaugh Map

A graphical technique for representing a logical function. Karnaugh maps are often useful for the purposes of minimization.

Kelvin Scale of Temperature

A scale of temperature which was invented by the British mathematician and physicist William Thomas, first Baron of Kelvin. Under the Kelvin, or absolute, scale of temperature, 0 K (corresponding to -273oC) is the coldest possible temperature and is known as absolute zero.

Kilo

Unit qualifier (symbol = K) representing one thousand, or 103. For example, 3KHz stands for 3 x 103 Hertz.

Kirchhoff's current law

The sum of all currents entering a node is equal to the sum of all currents leaving the node.

Kirchhoff's voltage law

The directed sum of the electrical potential differences around a circuit must be zero.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Glossary: L

Laminate

A material constructed from thin layers or sheets. Often used in the substrate of circuit boards.

Large-Scale Integration (LSI)

Refers to the number of logic gates in a device. By one convention, large-scale integration represents a device containing 100 to 999 gates.

Laser Diode

A special semiconductor diode which emits a beam of coherent light.

Last-In First-Out (LIFO)

A memory device in which data is read out in the reverse order to which it was written in.

Latch-Up Condition

A condition in which a circuit draws uncontrolled amounts of current, and certain voltages are forced, or "latched-up", to some level. Particularly relevant in the case of CMOS devices which can latch-up if their operating conditions are violated.

Lateral Thermal Conductivity

Good lateral thermal conductivity means that the heat generated by components mounted on a substrate can be conducted horizontally across the substrate and out through its leads.

Layers (and Stackup)

Layers are used in the layout editor to organize and isolate sets of geometry or other visual indicators. Signal, Negative Signal, and Dielectric are common physical layers, while Symbol (to show component symbols in layout), Error, and Ratsnest (to show connectivity) are non-physical layers. The stackup contains additional properties of the physical layers, such as material, thickness, and elevation. Geometrical information on these layers is used to generate masks for manufacturing.

LDMOS

Laterally diffused metal oxide semiconductor.

Lead

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(1) A metallic element (chemical symbol Pb).

(2) A metal conductor used to provide a connection from the inside of a device package to the outside world for soldering or other mounting techniques. Leads are also commonly called pins.

Lead Frame

A metallic frame containing leads and a base to which an unpackaged integrated circuit is attached. After encapsulation, the outer part of the frame is cut away and the leads are bent into the required shapes.

Lead Through-Hole (LTH)

A technique for populating circuit boards in which component leads are inserted into plated through-holes. Often abbreviated to "through-hole" or "thru-hole". When all of the components have been inserted, they are soldered to the board, usually using a wave soldering technique.

Level-Sensitive

An input whose effect on a function depends only on its current logic value or level, and is not directly related to it transitioning from one logic value to another.

LFSR

See Linear Feedback Shift Register.

Library

A library is a collection of one or more components or component dependencies (materials, symbols, footprints, or padstacks) stored in a container file. A library must be configured to a circuit before use, either by the user (manually) or by loading technology files (automatically). User libraries and Personal libraries are used to add foundry support, user defined models, and any custom set of components or simulation models. See the Library Overview topic for more information.

LIFO

See Last-In First-Out.

Limiting Level

The input power level when the output power is goes into compression and no longer becomes linear.

Line

Used to refer to the width of a track; for example, "This track has a line-width of 0.12mm."

Linear Feedback Shift Register (LFSR)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A shift register whose data input is generated as an XOR or XNOR of two or more elements in the register chain.

Linearity

Describes how closely an output signal is to a perfectly scaled multiple of a corresponding input signal.

Load Pull

Automated measurement of RF performance of a device under test (at a constant frequency) by varying the source and load impedance presented to the device

Logic Function

A mathematical function that performs a digital operation on digital data and returns a digital value.

Logic Gate

The physical implementation of a logic function.

Logic Synthesis

A process in which a program is used to optimize the logic used to implement a design.

Low-Fired Cofired

Similar in principle to standard cofired ceramic substrate techniques. However, low-fired cofired uses modern ceramic materials with compositions that allow them to be fired at temperatures as low as 650oC to 750oC. Firing at these temperatures in an inert atmosphere such as nitrogen allows non-refractory metals such as copper to be used to create tracks.

LSI

See Large-Scale Integration.

LTH

See Lead Through-Hole.

Glossary: M

Mask Programmable

A device such as a read-only memory which is programmed during its construction using a unique set of masks.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Maximal Displacement

A linear feedback shift register whose taps are selected such that changing a single bit in the input data stream will cause the maximum possible disruption to the register's contents.

Maximal Length

A linear feedback shift register that sequences through (2n - 1) states before returning to its original value.

Maxterm

The logical OR of the inverted variables associated with an input combination to a logical function.

MBE

See Molecular Beam Epitaxy.

MCM

See Multichip Module.

Medium-Scale Integration (MSI)

Refers to the number of logic gates in a device. By one convention, medium-scale integration represents a device containing 13 to 99 gates.

Meg

Unit qualifier (symbol = M) representing one million, or 106. For example, 3MHz stands for 3 x 106 Hertz.

Metallization Layer

A layer of conducting material on an integrated circuit that is selectively deposited or etched to form connections between logic gates. There may be several metallization layers separated by dielectric (insulating) layers.

Metal-Oxide Semiconductor (MOS)

A family of transistors where the controlling terminal is connected to a plate that is separated from the semiconduxtor by an insulating layer. This plate was originally made out metal (we now use polysilicon, or poly) and the insulator is an oxide -- hence the "metal-oxide" appellation.

Meta-Stable

A condition where the outputs of a logic function are oscillating uncontrollably between undefined values.

Micro

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Unit qualifier (symbol = u) representing one millionth, or 10-6. For example, 3uS stands for 3 x 10-6 Seconds.

Microwave

The range in the electromagnetic spectrum from 300 MHz to 30 GHz (with corresponding wavelengths from 100 cm to 1 cm).

Microwire

A trade name for one incarnation of discrete wire technology. Microwire augments the main attributes of multiwire with laser-drilled blind vias, allowing these boards to support the maximum number of tracks and components.

Millman's method

The voltage on the ends of branches in parallel is equal to the sum of the currents flowing in every branch divided by the total equivalent conductance.

Minterm

The logical AND of the variables associated with an input combination to a logical function.

MMIC

Monolithic Microwave Integrated Circuit

Mod or Modulus

Refers to the number of states that a function such as a counter will pass through before returning to its original value. For example, a function that counts from 00002 to 11112 has a modulus of 16 and would be called a modulo-16 or mod-16 counter.

Molecular Beam Epitaxy (MBE)

A technique for creating thin films on substrates in precise patterns, in which the substrate is placed in a high vacuum, and a guided beam of ionized molecules is fired at it, effectively allowing molecular-thin layers to be "painted" onto the substrate where required.

MOS

See Metal-Oxide Semiconductor.

MOSFET

Metal-oxide semiconductor field-effect transistor.

MSI

See Medium-Scale Integration.

Multichip Module (MCM)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A generic name for a group of advanced interconnection and packaging technologies featuring unpackaged integrated circuits mounted directly onto a common substrate.

Multilayer

A printed circuit board constructed from a number of very thin single-sided and/or double-sided boards which are bonded together using a combination of temperature and pressure.

Multiplexer (digital)

A logic function that uses a binary value, or address, to select between a number of inputs and conveys the data from the selected input to the output.

Multiwire

A trade name for one incarnation of discrete wire technology.

Multizone

A stackup that contains zones or areas, each of which contains a subset of the layers in the stackup.

Mutual Capacitance

The capacitance between two conductors (one considered aggressor, the other victim) when all other conductors are connected together and then regarded as an ignored ground. It describes the amount of coupling due to the electric field. The mutual capacitance will inject an often undesired current into the victim line proportional to the rate of change of voltage on the aggressor line. Mutual Capacitance it a cause of crosstalk.

Mutual Inductance

The inductance between two conductors (one considered aggressor, the other victim) placed close enough that the magnetic field induced by a current flowing into the aggressor line encompasses the victim. The mutual inductance will inject an often undesired voltage noise onto the victim proportional to the rate of change of the current on the aggressor line.

Glossary: N

Nano

Unit qualifier (symbol = n) representing one thousandth of one millionth, or 10^{-9}. For example, 3nS stands for 3 x 10^{-9} Seconds.

Nanobot

A molecular-sized robot (see Nanotechnology below)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Nanophase Materials

A form of matter which was only recently discovered, in which small clusters of atoms form the building blocks of a larger structure. These structures differ from those of naturally occurring crystals, in which individual atoms arrange themselves into a lattice.

Nanotechnology

Nanotechnology is an elusive term that is used by different research-and-development teams to refer to whatever it is that they're working on at the time. However, irrespective of their particular area of interest, nanotechnology always refers to something extremely small. One of the more exciting branches of nanotechnology that has been suggested as having potential in the future is that of micro-miniature electronic products that assemble themselves.

N-channel MOS (NMOS)

Refers to the order in which the semiconductor is doped in a MOS device. That is, which structures are constructed as N-type versus P-type material.

Negative-Edge

A transition from a logic 1 to a logic 0. Also known as a falling edge.

Negative Ion

An atom or group of atoms with an extra electron.

Negative Logic

A convention which dictates the relationship between logical values and the physical voltages used to represent them. The more negative potential is considered to represent TRUE and the more positive potential is considered to represent FALSE. Also known as negative true logic.

Negative Resist

A process where ultraviolet radiation passing through the transparent areas of a mask causes the resist to be cured. The uncured areas are then removed using an appropriate solvent.

Negative Signal Plane

A conducting layer in, or on, a substrate providing a grounding, or reference, point for components. There may be several negative signal planes separated by insulating layers.

Negative-True

A convention which dictates the relationship between logical values and the physical voltages used to represent them. The more negative potential is considered to represent TRUE and the more positive potential is considered to represent FALSE. Also known as negative logic.

Nibble

See Nybble.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

NMOS

See N-channel MOS.

Noise Figure / Noise Factor

The Noise Factor of a transducer at a specified input frequency is the ratio of (a/b) where “a and b” are:

(a) the available Signal to Noise Ratio (SNR) at the signal generator terminals per unit bandwidth when the temperature of the input termination (generator or source) is 290 K and the bandwidth is limited by the transducer, to

(b) the available SNR per unit bandwidth at the output terminals of the transducer.

Traditionally:

Noise Figure NF = 10 log(noise factor F)

Noise Temperature (T_e) = T_o(F - 1)

Where:

- T_e is the noise temperature
- T_o is standard temperature 290 K
- F is noise factor

Noise Floor

This is defined as the lowest possible input to a chain or a component, that will produce a detectable output.

Noise Temperature

This is the amount of thermal noise in a chain or a component. Noise Factor and Noise Temperature (T_e) are related as follows:

Noise Temperature (T_e) = (F - 1)T_o

Where:

- T_e is the noise temperature
- T_o is standard temperature 290 K
- F is noise factor

For example, a noise figure of 2.0 dB is equivalent to a Noise Temperature of 170 K.

Nominal Design

The original model on which Optimetrics analyses are based.

Non-Volatile

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A memory device which does not lose its data when power is removed from the system.

Non-Volatile RAM

A device which is generally formed from an SRAM die mounted in a package with a very small battery, or as a mixture of SRAM and EEPROM cells fabricated on the same die.

Norton's theorem

Any two-terminal collection of voltage sources and resistors is electrically equivalent to an ideal current source in parallel with a single resistor.

NPN (N-type - P-type - N-type)

Refers to the order in which the semiconductor is doped in a bipolar junction transistor.

N-Port

An N-port component is typically characterized by network parameter data contained in the N-port itself in spreadsheet form or (more usually) by network parameter data contained in an external file.

N-type

A piece of semiconductor doped with impurities that make it amenable to donating electrons.

Nybble

A group of four binary digits, or bits (also called a nibble).

Glossary: O

Octal

Base-8 numbering system. Each octal digit can be directly mapped onto three binary digits, or bits.

Ohm

Unit of resistance. The Greek letter omega, *, is often used to represent ohms; for example, 1M* indicates one million ohms.

Ohm's law

The voltage across a resistor is the product of its resistance and the current flowing through it.

One-Hot Encoding

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A form of state assignment for state machines in which each state is represented by an individual state variable.

One-Time Programmable

A device such as a PAL, PLA, or PROM that can only be programmed a single time and whose contents cannot be subsequently erased.

Optical Interconnect

The generic name for interconnection strategies based on opto-electronic systems, including fiber-optics, free-space, guided-wave, and holographic techniques.

Optical Lithography

A process in which radiation at optical wavelengths (usually in the ultraviolet range) is passed through a mask, and the resulting patterns are projected onto a layer of resist coating the substrate material.

Optical Mask

A sheet of material carrying patterns that are either transparent or opaque to the wavelengths used in an optical-lithographic process. Such a mask can carry hundreds of thousands of fine lines and geometric shapes.

Opto-Electronic

Refers to a system which combines optical and electronic components.

Organic Resist

A material which is used to coat a substrate and is then selectively cured to form an impervious layer. These materials are called organic because they are based on carbon compounds as are living creatures.

Organic Solvent

A solvent for organic materials such as those used to form organic resists.

Organic Substrate

Substrate materials such as FR4, in which woven glass fibers are bonded together with an epoxy. These materials are called organic because epoxies are based on carbon compounds as are living creatures.

Overglassing

One of the final stages in the integrated circuit fabrication process in which the entire surface of the wafer is coated with a layer of silicon dioxide or silicon nitride. This layer may also be referred to as the barrier layer or the passivation layer. An additional lithographic step is required to pattern holes in this layer to allow connections to be made to the pads.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Glossary: P

Package

Leaded assembly (inside of which one or more dies are mounted and connected) for use in larger circuits.

Pad

An area of metallization on a substrate used for probing or to connect to a via, plated through-hole, or an external interconnect.

Pad Grid Array (PGA)

A packaging technology in which a device's external connections are arranged as an array of conducting pads on the base of the package.

Padstack

Refers to any pads, anti-pads, and thermal relief pads associated with a via or a plated through-hole as it passes through the layers forming the substrate.

Padcap

A special flavor of circuit board used for high-reliability military applications. Distinguished by the fact that the outer surfaces of the board have pads but no tracks. Signal layers are only created on the inner planes, and tracks are connected to the surface pads by vias.

Parallel-In Serial-Out (PISO)

Refers to a shift register in which the data is loaded in parallel and read out serially.

Parasitic Effects

The effects caused by undesired resistance, capacitance, or inductance inherent in the material or topology of a track or component.

Passive Trimming

A process in which a laser beam is used to trim components such as thick-film and thin-film resistors on an otherwise unpopulated and unpowered hybrid or multichip module substrate. Probes are placed at each end of a component to monitor its value while the laser evaporates some of the material forming the component.

Pass-Transistor Logic

A technique for connecting MOS transistors such that data signals pass between their source and drain terminals. Pass-transistor logic minimizes the number of transistors required to

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

implement a function, and is typically employed by designers of cell libraries or full-custom integrated circuits.

PGA

See either Pad Grid Array or Pin Grid Array.

Photo-Transistor

A special transistor which converts an optical input in the form of light into an equivalent electronic signal in the form of a voltage or current.

Pico

Unit qualifier (symbol = p) representing one millionth of one millionth, or 10^{-12}. For example, 3pS stands for 3 x 10^{-12} Seconds.

PIN Diode

A diode where a thin layer exists between the N and P regions. Rectification with pin diodes is limited. They actually behave more like a variable resistor that changes based upon the DC bias.

Pin Grid Array (PGA)

A packaging technology in which a device's external connections are arranged as an array of conducting leads, or pins, on the base of the package.

PISO

See Parallel-In Serial-Out.

Place-Value

Refers to a numbering system in which the value of a particular digit depends both on the digit itself and its position in the number.

PlasmA gaseous state in which the atoms or molecules are dissociated to form ions.

Plated Through-Hole (PTH)

(1) A hole in a double-sided or multilayer board that is used to accommodate a through-hole component lead and is plated with copper.

(2) An alternative name for the lead through-hole technique for populating circuit boards in which component leads are inserted into plated through-holes.

PMOS (P-channel MOS)

Refers to the order in which the semiconductor is doped in a MOS device. That is, which structures are constructed as P-type versus N-type material.

PNP (P-type - N-type - P-type)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refers to the order in which the semiconductor is doped in a bipolar junction transistor.

Polysilicon Layer

An internal layer in an integrated circuit used to create the gate electrodes of MOS transistors. In addition to forming gate electrodes, the polysilicon layer can also be used to interconnect components. There may be several polysilicon layers separated by dielectric (insulating) layers.

Populating

The act of attaching components to a substrate.

Positive Logic

A convention which dictates the relationship between logical values and the physical voltages used to represent them. The more positive potential is considered to represent TRUE and the more negative potential is considered to represent FALSE. Also known as positive true logic.

Positive Resist

A process where radiation passing through the transparent areas of a mask causes previously cured resist to be degraded. The degraded areas are then removed using an appropriate solvent.

Positive-Edge

A transition from a logic 0 to a logic 1. Also known as a rising edge.

Positive-True

A convention which dictates the relationship between logical values and the physical voltages used to represent them. The more positive potential is considered to represent TRUE and the more negative potential is considered to represent FALSE. Also known as positive logic.

Power Amplifier

A class of amplifier with the primary purpose of delivering high output power (usually accompanied by significant dissipated power).

Power Plane

A conducting layer in or on the substrate providing power to the components. There may be several power planes separated by insulating layers.

Prepreg

Non-conducting semi-cured layers of FR4 used to separate conducting layers in a multilayer circuit board.

Primitives

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Simple logic functions such as BUF, NOT, AND, NAND, OR, NOR, XOR, and XNOR may be referred to as primitive logic gates or primitives.

Product Term

A set of literals linked by an AND operator.

Programmable Array Logic (PAL)

A programmable logic device in which the AND array is programmable but the OR array is pre-defined.

Programmable Logic Array (PLA)

The most user-configurable of the traditional programmable logic devices, because both the AND and OR arrays are programmable.

Programmable Logic Device (PLD)

The generic name for a device constructed in such a way that the designer can configure, or "program" it to perform a specific function.

Programmable Read-Only Memory (PROM)

A programmable logic device in which the OR array is programmable but the AND array is pre-defined. Usually considered to be a memory device whose contents can be electrically programmed (once) by the designer.

Project

A container that groups designs and their associated settings, including report definitions, in a file with a .adsn extension. To the fullest extent possible, projects are portable in that they include, rather than merely refer to, the library elements (graphical symbols, materials, footprints, and so on) of the components and models they contain. Multiple projects can be open simultaneously.

PROM

See Programmable Read-Only Memory.

Pseudo-Random

An artificial sequence of values that give the appearance of being random.

PTH

See Plated Through-Hole.

P-type

A piece of semiconductor doped with impurities that make it amenable to accepting electrons.

Pulling

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The difference between the maximum frequency of a VCO when the phase angle of the load impedance reflection coefficient varies through 360 degrees.

Pulsed Radar

A transmit and receive system used for ranging and detection that transmits a train of short bursts of high microwave signals and receives return signals reflected from a target.

Pushing

The change in frequency when the supply voltage changes, expressed in MHz/V.

Glossary: Q

Q

Quality factor; a measure of stored energy/dissipated energy. Also a measure of bandwidth.

QAM

Quadrature amplitude modulation.

QFP

See Quad Flat Pack.

QPSK

Quadrature phase-shift keying.

Quad Flat Pack (QFP)

The most commonly used package in surface mount technology to achieve a high lead count in a small area. Leads are presented on all four sides of a thin square package.

Quinary

Base-5 numbering system.

Glossary: R

Radio Frequency (RF)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The range in the electromagnetic spectrum loosely defined from 30 MHz to 3 GHz (with corresponding wavelengths from 1000 cm to 10 cm).

Radix

Refers to the number of digits in a numbering system. For example, the decimal numbering system is said to be radix-10. May also be referred to as the "base".

Rats Layer

A non-physical, default layer in the stackup that displays a drawing of logical connections between different components, circuit elements, and net connections. A single connection is called a rat and all of the connections on a rat layers is a rat's nest.

Reed-Müller Logic

Logic functions implemented using only XOR and XNOR gates.

Refractory Metal

Metals such as tungsten, titanium, and molybdenum which are capable of withstanding extremely high, or refractory, temperatures.

Remotely Reconfigurable Hardware

A product whose function may be customized remotely, by telephone or radio, while remaining resident in the system (see also Configurable Hardware, Reconfigurable Hardware, Dynamically Reconfigurable Hardware, and Virtual Hardware).

Reflection

The appearance of a previously transmitted signal on the transmission line causing interference with the current signal. Reflections are caused by a poorly terminated or discontinuous transmission line, where the signal energy is not fully absorbed within the receiver and is therefore transmitted back toward the transmitter.

Resist

A material which is used to coat the substrate and is then selectively cured to form an impervious layer.

Resistor-Transistor Logic (RTL)

Logic gates implemented using particular configurations of resistors and bipolar junction transistors. For the majority of today's designers, resistor-transistor logic is of historical interest only.

Return Loss

Return Loss (dB) is defined as a ratio of the incoming signal to the same reflected signal as it enters a component.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Return Loss (dB) = 10 * LOG10(Reflected Power/Incident Power)

RF

See Radio Frequency.

RF Power

A class of engineering. Circuits and signals primarily concerned with power levels ranging from a few watts to tens of thousands of watts in the RF spectrum.

RF Power Transmitter

A discrete packaged transistor used in the amplification of RF power.

Rigid Flex

Hybrid constructions which combine standard rigid circuit boards with flexible printed circuits, thereby reducing the component count, weight, and susceptibility to vibration of the circuit, and greatly increasing its reliability.

Ringing

Common name for the waveform that is seen when a transmission line ends at a high impedance discontinuity. The signal first overshoots, then dips down below the target value, and continues this with decreasing amplitude until it converges on the target voltage.

Risetime

The time it takes for a signal to rise from 10% of its total logic swing to 90% of its total logic swing.

Rising-Edge

A transition from a logic 0 to a logic 1. Also known as a positive edge.

RTL

See Resistor-Transistor Logic.

Glossary: S

Sample Rate

Time increment of analysis. Sometimes referred to as sampling rate.

Sampling

The process of converting an analog signal into a series of digital values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scalar Notation

A notation in which each signal is assigned a unique name; for example, a3, a2, a1, and a0.

Scaling

A technique for making transistors switch faster by reducing their size. This strategy is known as scaling, because all of the transistors features are typically reduced by the same proportion.

Schematic

Common name for a circuit diagram.

Scrubbing

The process of vibrating two pieces of metal, or metal coated materials, at ultrasonic frequencies to create a friction weld.

Seed Value

An initial value loaded into a linear feedback shift register or random number generator.

Sensor

A transducer that detects a physical quantity and converts it into a form suitable for processing. For example, a microphone is a sensor which detects sound and converts it into a corresponding voltage or current.

Sequential

A function whose output value depends not only on its current input values, but also on previous input values. That is, the output value depends on a sequence of input values.

Side-Emitting Laser Diode

A laser diode constricted at the edge of an integrated circuit's substrate such that, when power is applied, the resulting laser beam is emitted horizontally; that is, parallel to the surface of the substrate.

Sign Bit

The most significant binary digit, or bit, of a signed binary number. If set to a logic 1, this bit represents a negative quantity.

Signal Conditioning

Amplifying, filtering, or otherwise processing a signal.

Signal Layer

A layer carrying tracks in a circuit board, hybrid, or multichip module. See also wiring layer.

Signature

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refers to the checksum value from a cyclic-redundancy-check when used in the guided-probe form of functional test.

Signature Analysis

A guided-probe functional-test technique based on signatures.

Signed Binary Number

A binary number in which the most-significant bit is used to represent a negative quantity. Thus, a signed binary number can be used to represent both positive and negative values.

Sign-Magnitude

Negative numbers in standard arithmetic are typically represented in sign-magnitude form by prefixing the value with a minus sign; for example, -27. For reasons of efficiency, computers rarely employ the sign-magnitude form. Instead, they use signed binary numbers to represent negative values.

Silicon Bumping

The process of depositing additional metallization on a die's pads to raise them fractionally above the level of the Barrier Layer.

Silicon Chip

Although a variety of semiconductor materials are available, the most commonly used is silicon and integrated circuits are popularly known as silicon chips, or simply chips.

Silicon Compiler

The program used in compiled cell technology to generate the masks used to create components and interconnections. May also be used to create data-path functions and memory functions.

Single-Sided

A printed circuit board with tracks on only one side.

Sintering

A process in which ultra-fine metal powders weld together at temperatures much lower than those required for larger pieces of the same materials.

SIPO (Serial-In Parallel-Out)

Refers to a shift register in which the data is loaded in serially and read out in parallel.

SISO (Serial-In Serial-Out)

Refers to a shift register in which the data is both loaded in and read out serially.

Skew

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Time delay between different bits transmitted at the same time, measured at the receiver.

Skin Effect

In the case of high frequency signals, electrons are only conducted on the outer surface, or skin, of a conductor. This phenomenon is known as the skin effect.

Small-Scale Integration (SSI)

Refers to the number of logic gates in a device. By one convention, small-scale integration represents a device containing 1 to 12 gates.

SMD

See Surface Mount Device.

SMOBC

See Solder Mask Over Bare Copper.

SMT

See Surface Mount Technology.

SNR

Signal-to-noise ratio.

Soft Macro (Macro Function)

A logic function defined by the manufacturer of an application-specific integrated circuit. The function is described in terms of the simple functions provided in the cell library and connections between them. The assignment of cells to basic cells and the routing of the tracks is determined at the same time, and using the same tools, as for the other cells specified by the designer.

Solder Bumping

A flipped chip technique in which spheres of solder are formed on the die's pads. The die is flipped and the solder bumps are brought into contact with corresponding pads on the substrate. When all the chips have been mounted on the substrate, the solder bumps are melted using reflow soldering or vapor-phase soldering.

Solder Mask

A layer applied to the surface of the substrate that prevents solder from sticking to any metallization except where holes are patterned into the mask.

Solder Mask Over Bare Copper (SMOBC)

A technique in which the solder mask is applied in advance of the tin-lead plating. This results in lighter circuit boards because the tin-lead alloy is only used to plate the pads.

Solution

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A solution is the successful result of an analysis, or imported results available for plotting.

Space

Used to refer to the width of the gap between adjacent tracks.

SPICE

Simulated Program for Integrated Circuit Emulation

SRAM

See Static RAM.

SS-CDMA

Spread-spectrum code-division multiple access.

SSI

See Small-Scale Integration.

Stackup

An arrangement of physical signal and dielectric layers that is used in the design of circuit boards. In Circuit, the stackup editor lists conceptual non-stackup layers with the physical stackup layers.

Standard Cell

An application-specific integrated circuit which, unlike a gate array, does not use the concept of a basic cell and does not have any pre-fabricated components. The manufacturer creates custom masks for every stage of the device's fabrication allowing each logic function to be created using the minimum number of transistors.

State Assignment

The process by which the states in a state machine are assigned to the binary patterns that are to be stored in the state variables.

State Diagram

A graphical representation of the operation of a state machine.

State Machine

The actual implementation (in hardware or software) of a function that can be considered to consist of a set of states through which it sequences.

State Table

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A tabular representation of the operation of a state machine. Similar to a truth table, but also includes the current state as an input and the next state as an output.

State Transition

An arc connecting two states in a state diagram.

State Variable

One of a set of registers whose values represent the current state occupied by a state Static Flex.

Statement

A sentence that asserts or denies an attribute about an object or group of objects.

Static Flex

A type of flexible printed circuit which can be manipulated into permanent three-dimensional shapes for applications such as calculators and high-tech cameras which require efficient use of volume and not just area.

Static RAM (SRAM)

A memory device in which each cell is formed from four or six transistors configured as a latch or a flip-flop. The term static is used because, once a value has been loaded into an SRAM cell, it will remain unchanged until it is explicitly altered or until power is removed from the device.

Steady State

A condition in which nothing is changing or happening.

Subatomic Erosion

A process in which structures on an integrated circuit's substrate are eroded by the flow of electrons in much the same way as land is eroded by a river (also known as electromigration)

Substrate

Generic name for the base layer of an integrated circuit, hybrid, multichip module, or circuit board. Substrates may be formed from a wide variety of materials, including semiconductors, ceramics, FR4 (fiberglass), glass, sapphire, or diamond depending on the application. Note that the term substrate has traditionally not been widely used in the circuit board world, at least not by the people who manufacture the boards. However, there is an increasing tendency to refer to a circuit board as a substrate by the people who populate the boards. The main reason for this is that circuit boards are often used as substrates in hybrids and multichip modules, and there is a trend toward a standard terminology across all forms of interconnection technology.

Subtractive Process

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A process in which a substrate is first covered with conducting material, then any unwanted material is subsequently removed, or subtracted.

Superconductor

A material with zero resistance to the flow of electric current.

Surface Mount Device (SMD)

A component whose packaging is designed for use with surface mount technology.

Surface Mount Technology (SMT)

A technique for populating hybrids, multichip modules, and circuit boards, in which packaged components are mounted directly onto the surface of the substrate. A layer of solder paste is screen printed onto the pads and the components are attached by pushing their leads into the paste. When all of the components have been attached, the solder paste is melted using either reflow soldering or vapor-phase soldering.

Surface-Emitting Laser Diode

A laser diode constricted on an integrated circuit's substrate such that, when power is applied, the resulting laser beam is emitted directly away from the surface of the substrate.

Sweep Definition

Also called *variable sweep definition*. A set of variable values within a range that Optimetrics drives the Electronics Desktop to solve when a parametric setup is analyzed. A parametric setup can include one or more sweep definitions.

Synchronous

(1)A signal whose data is not acknowledged or acted upon until the next active edge of a clock signal. (2)A system whose operation is synchronized by a clock signal.

System Gain

The net loss of a system as a measure of reliability with respect to system parameters. It measures the difference between the output power and minimum input power required for satisfactory performance. It represents a system net loss, and is represented as a negative dB value that is larger than or equal to the summed gains and losses of a signal propagating in a system from transmitter to receiver.

Glossary: T

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Tap

A register output which is used to generate the next data input to a linear feedback shift register.

Tape Automated Bonding (TAB)

A process in which transparent flexible tape has tracks created on its surface. The pads on unpackaged integrated circuits are attached to corresponding pads on the tape which is then stored in a reel. Silver-loaded epoxy is screen printed on the substrate at the site where the device is to be located and onto the pads to which the device's leads are to be connected. The reel of TAB tape is fed through an automatic machine which pushes the device and the TAB leads into the epoxy. When the silver-loaded epoxy is cured using reflow soldering or vapor-phase soldering, it forms electrical connections between the TAB leads and the pads on the substrate.

TDM

Time-division multiplexing.

TDMA

Time-division multiple access.

Technology File

A technology file is a collection of information, specifiable by name at design-creation time using the Choose Layout Technology dialog box, that specifies material stackup properties for layout, substrates for simulation, and component libraries for design creation. A technology (.asty) file may be saved from the current project via the File menu. A technology file initializes a design with a set of data to avoid repeated entry of commonly used data. This data can consist of layers and stackup information for layout, configured libraries of components, and substrate definition (s) for circuit analysis. Users and foundries can customize Technology files for their own manufacturing process and simulation models.

Tertiary Logic

An experimental technology in which logic gates are based on three distinct voltage levels. The three voltages are used to represent the tertiary digits 0, 1, and 2, and their logical equivalents FALSE, TRUE, and MAYBE.

Thermal Impedance

Relates the temperature rise for a given dissipated power (which employs an analogy to the voltage-current relationship of impedance).

Thermal Relief Pad

A special pattern etched around a via or a plated through-hole to connect it into a power or ground plane. A thermal relief pad is necessary to prevent too much heat being absorbed into the power or ground plane when the board is being soldered.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Thermal Tracking

Typically used to refer to the problems associated with optical interconnection systems whose alignment may be disturbed by changes in temperature.

Thevenin's theorem

Any two-terminal combination of voltage sources and resistors is electrically equivalent to a single voltage source in series with a single resistor.

Thick-Film Process

A process used in the manufacture of hybrids and, to a lesser extent, multichip modules in which signal and dielectric (insulating) layers are screen-printed onto the substrate.

Thin-Film Process

A process used in the manufacture of hybrids and multichip modules in which signal layers and dielectric (insulating) layers are created using opto-lithographic techniques.

Time-Of-Flight

The time taken for a signal to propagate from one logic gate or opto-electronic component to another.

Tin-Lead Plating

An electroless plating process in which exposed areas of copper on a circuit board are coated with a layer of tin-lead alloy. The alloy is used to prevent the copper from oxidizing and provides protection against contamination.

Tinning

An abbreviation of tin-lead plating, which is an electroless plating process in which exposed areas of copper on a circuit board are coated with a layer of tin-lead alloy. The alloy is used to prevent the copper from oxidizing and provides protection against contamination.

Toggle

Refers to the contents or outputs of a logic function switching to the inverse of their previous logic values.

TOI

Third-order intercept point.

Total Voltage

Total voltage = Incident voltage + reflected voltage, that is $V^T = V^a + V^b$. See discussion in Excitations in the Time Domain.

Trace

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A conducting connection between electronic components. May also be called a track or a signal. In the case of integrated circuits, such interconnections are often referred to collectively as metallization.

Tracks

A conducting connection between electronic components. May also be called a trace or a signal. In the case of integrated circuits, such interconnections are often referred to collectively as metallization.

Transducer

A device that converts input energy of one form into output energy of another.

Transistor

A three-terminal semiconductor device that, in the digital world, can be considered to operate like a switch.

Tri-State Function

A function whose output can adopt three states: 0, 1, and Z (high-impedance) The function does not drive any value in the Z state and, in many respects, may be considered to be disconnected from the rest of the circuit.

Truth Table

A convenient way to represent the operation of a digital circuit as columns of input values and their corresponding output responses.

TTL (Transistor-Transistor Logic)

Logic gates implemented using particular configurations of bipolar junction transistors.

Glossary: U

ULA

See Uncommitted Logic Array.

Ultra-Large-Scale Integration (ULSI)

Refers to the number of logic gates in a device. By one convention, ultra-large-scale integration represents a device containing a million or more gates.

ULSI

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See Ultra-Large-Scale Integration.

Uncommitted Logic Array (ULA)

One of the original names used to refer to gate array devices. This term has largely fallen into disuse.

Unsigned Binary Number

A binary number in which all the bits are used to represent positive quantities. Thus, an unsigned binary number can only be used to represent positive values.

Undershoot

The percentage a waveform falls below its lowest determined value before setting at the correct value.

Glossary: V

Vapor-Phase Soldering

A surface mount process in which a substrate carrying components attached by solder paste is lowered into the vapor-cloud of a tank containing boiling hydrocarbons. This melts the solder paste thereby forming good electrical connections. However, vapor-phase soldering is becoming increasingly less popular due to environmental concerns.

Vaporware

Refers to either hardware or software that exist only in the minds of the people who are trying to sell them to you.

Variable Sweep Definition

Also called *sweep definition*. A set of variable values within a range that Optimetrics drives HFSS or Q3D to solve when a parametric setup is analyzed. A parametric setup can include one or more sweep definitions.

Vector Notation

A notation used in logic simulation and synthesis in which a single name is used to reference a group of signals, and individual signals within the group are referenced by means of an index; for example, a[3:0] = a[3], a[2], a[1], and a[0].

Very-Large-Scale Integration (VLSI)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Refers to the number of logic gates in a device. By one convention, very-large-scale integration represents a device containing 1,000 to 999,999 gates.

Via

A hole filled or lined with a conducting material which is used to link two or more conducting layers in a substrate.

Virtual Hardware or Virtual Logic

An extension of dynamically configurable hardware based on a new generation of FPGAs which were introduced around the beginning of 1994. In addition to supporting the dynamic reconfiguration of selected portions of the internal logic, these devices also feature: no disruption to the device's inputs and outputs; no disruption to the system-level clocking; the continued operation of any portions of the device that are not undergoing reconfiguration; and no disruption to the contents of internal registers during reconfiguration, even in the area being reconfigured (see also Configurable Hardware, Reconfigurable Hardware, Remotely Reconfigurable Hardware, and Dynamically Reconfigurable Hardware).

Virtual Memory

A trick used by a computer's operating system to pretend that it has access to more memory than is actually available. For example, a program running on the computer may require ten mega-bytes to store its data, but the computer may have only five mega-bytes of memory available. To get around this problem, whenever the program attempts to access a memory location that does not physically exist, the operating system performs a slight-of-hand and exchanges some of the contents in the memory with data on the hard disk.

VLSI

See Very-Large-Scale Integration.

Volatile

Refers to a memory device which loses any data it contains when power is removed from the system; for example, random-access memory in the form of SRAM or DRAM

Glossary: W

Wafer Probing

The process of testing individual integrated circuits while they still form part of a wafer. An automated tester places probes on the device's pads, applies power to the power pads, injects a

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

series of signals into the input pads, and monitors the corresponding signals returned from the output pads.

Wave Soldering

A process used to solder circuit boards populated with through-hole components. A wave generating mechanism maintains a wave of hot, liquid solder traveling back and forth across the surface of a tank. The populated circuit boards are passed over the wave soldering machine on a conveyor belt. The velocity of the convener belt is carefully controlled and synchronized such that the solder wave brushes across the bottom of the board only once.

Waveguide

A transparent path bounded by non-transparent, reflective areas, which is fabricated directly onto the surface of a substrate. Used in the optical interconnection strategy known as guided-wave.

W-CDMA

Wideband code-division multiple access. Typically defined with 5 MHz channels and 3.84 MHz carrier signals.

Wire Bonding

The process of connecting the pads on an unpackaged integrated circuit to corresponding pads on a substrate using wires that are finer than a human hair. Wire bonding may also be used to connect the pads on an unpackaged integrated circuit, hybrid, or multichip module to the leads of the component package.

Wiring Layer

A layer carrying wires in a discrete wired board. See also signal layer.

Word

A group of signals or logic functions performing a common task and carrying or storing similar data; for example, a value on the data bus could be referred to as a data word.

Glossary: X

X-Ray Lithography

Similar in principle to optical lithography, but capable of constructing much finer features due to the shorter wavelengths involved. However, X-ray lithography requires an intense source of X-rays, is more difficult to use, and is considerably more expensive than optical lithography.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Glossary: Y

Yield

The number of devices that work as planned, specified as a percentage of the total number actually fabricated.

Glossary: Z

Zepto (z)

The symbol used to represent the high-impedance state in tri-state logic.

Zone

A spatial area on a printed circuit board that may contain a subset or all of the layers in the board’s stackup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
