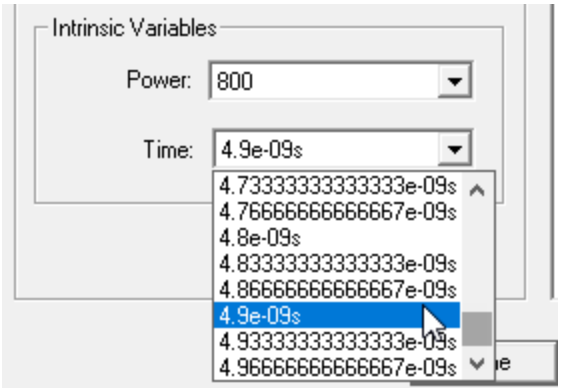
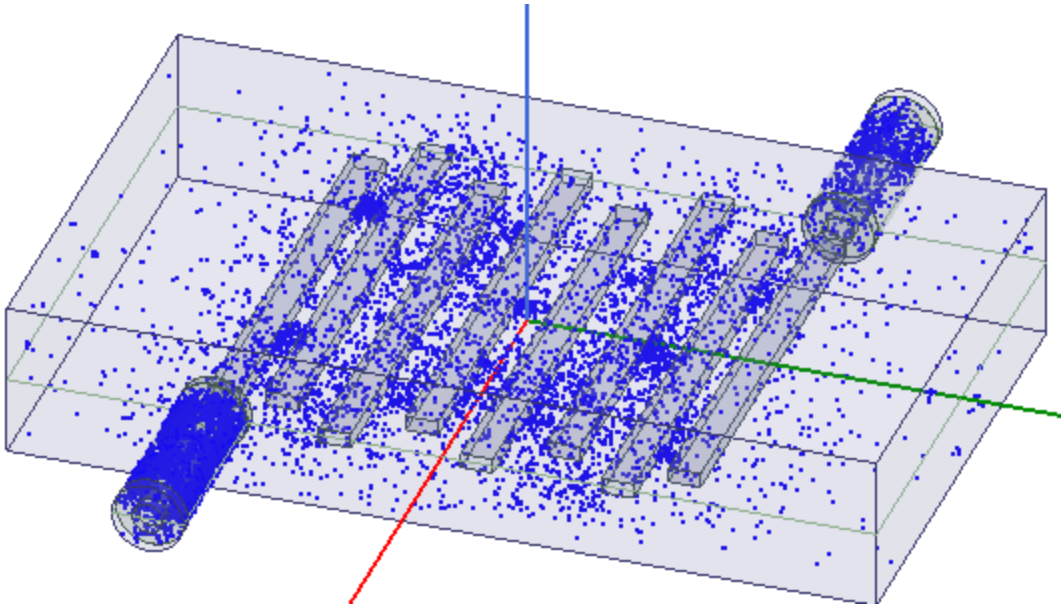
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

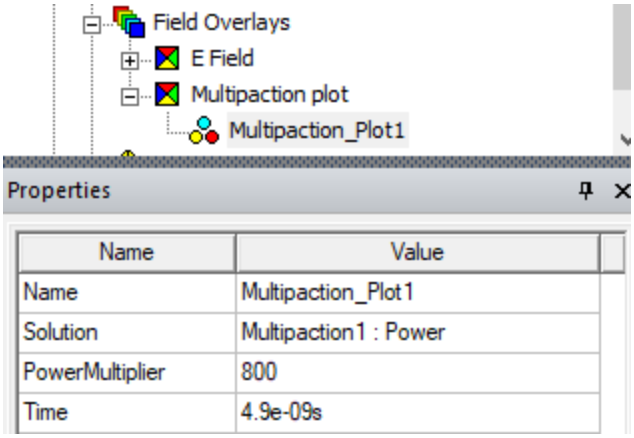


Click **Done** to cause a Particle plot to appear in the Modeler window.

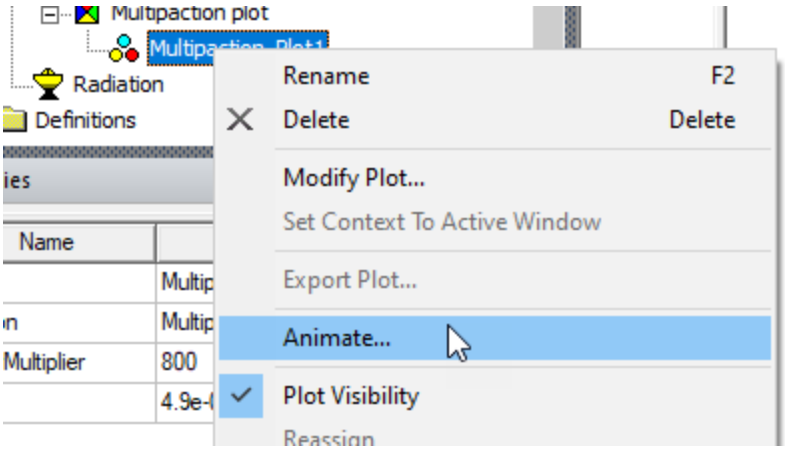


The properties of the particle plot are shown in the Properties window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

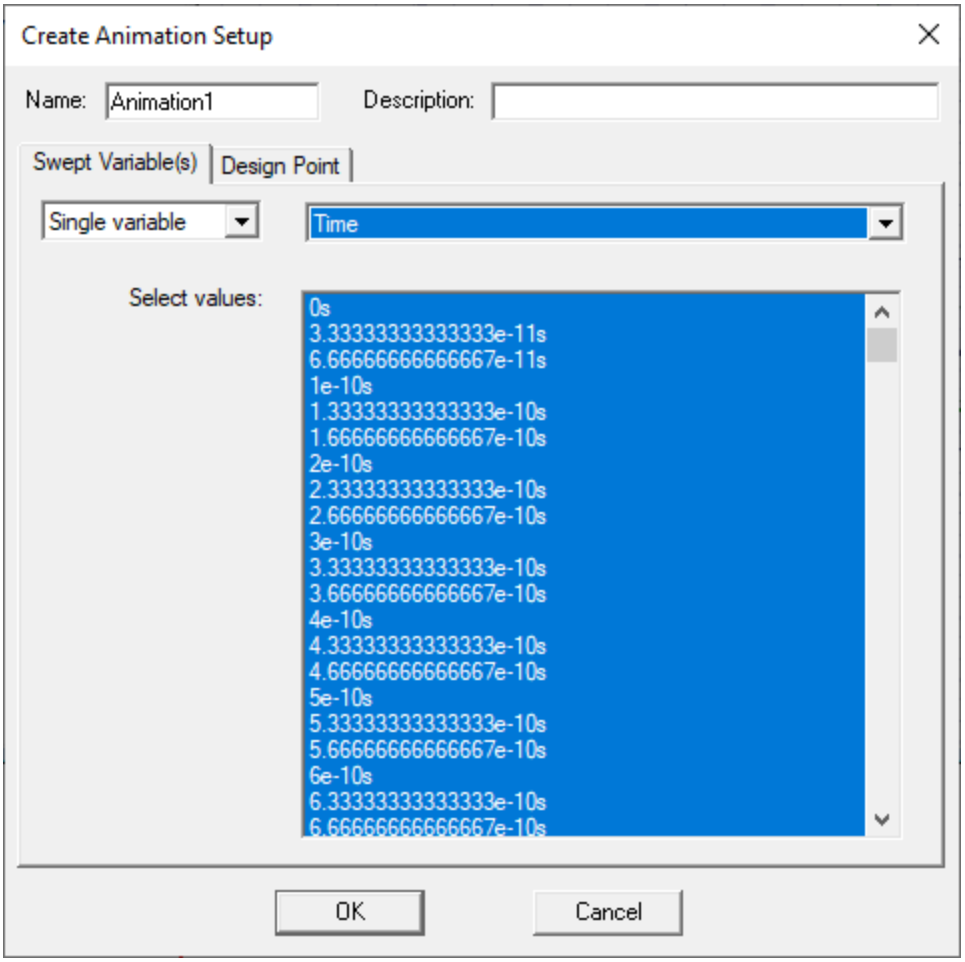


Once you have generated the Multipaction Plot in the Field Overlays, you can create an animation of the movement of the charged particles. Right-click the Multipaction Plot and select **Animate...** from the shortcut menu.



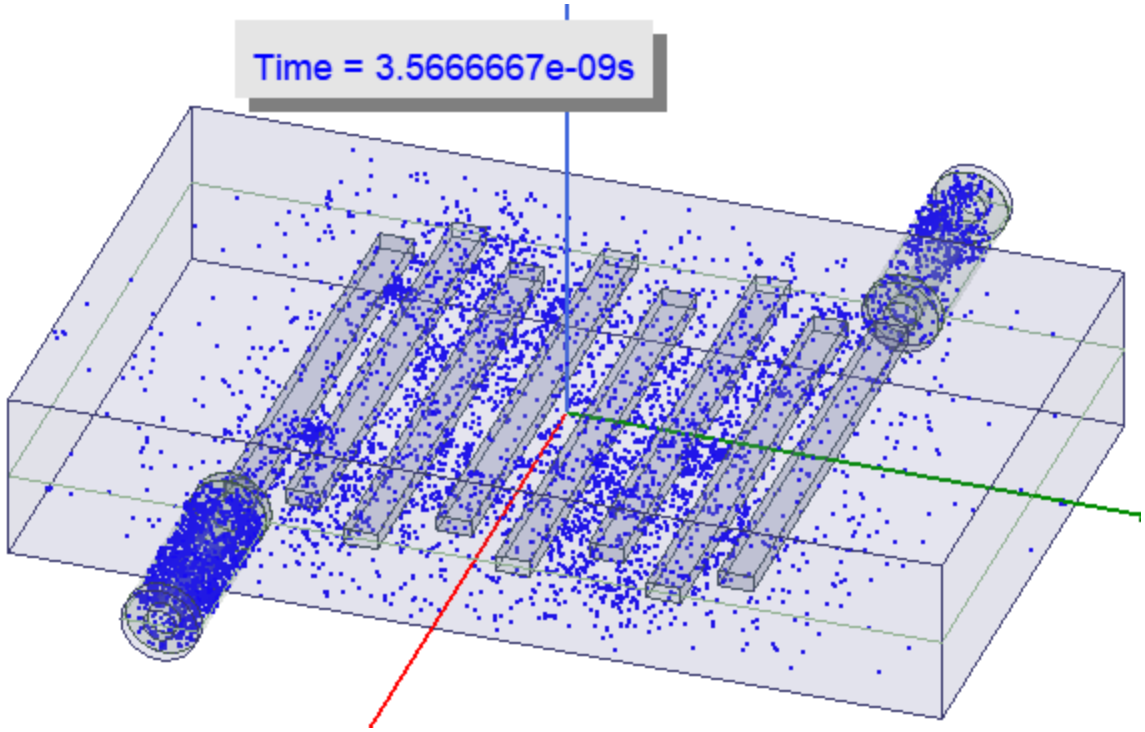
If you have previously created an animation for the plot, the **Select Animation** dialog box will open. You can select an animation to view, Edit, or Delete, or select **New...** to open the **Create Animation Setup** dialog box. If you have not previously created an animation, the Create Animation Setup dialog opens automatically.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

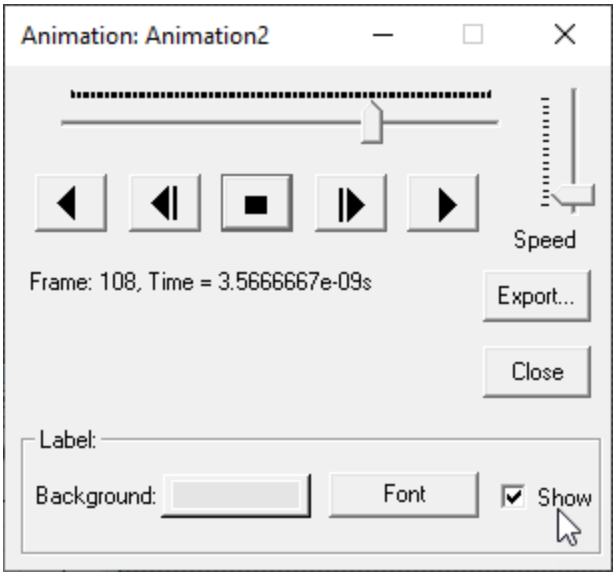


By default, the charge distribution for all time steps will be animated. The animation comes with a label showing the current time.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

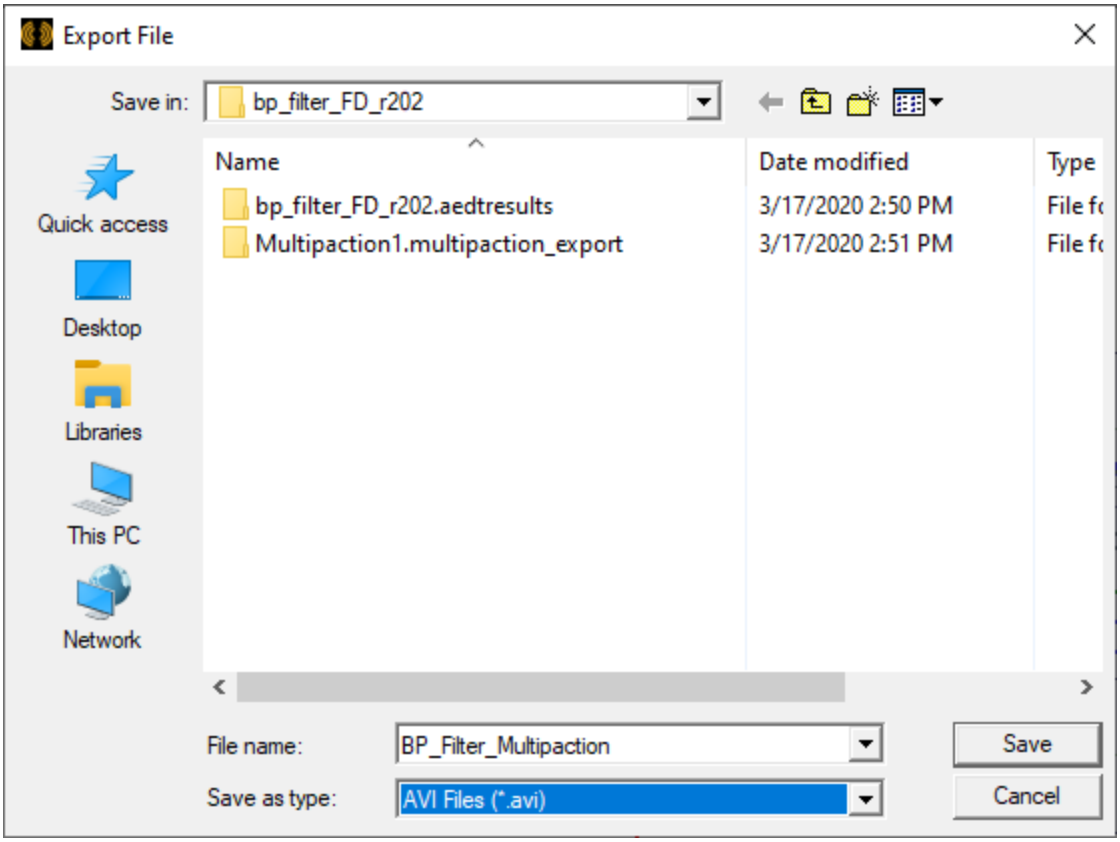


You can remove the label by unchecking Show in the Animation control panel.



To save an animation file, click **Export...** and choose the path and file type of the animation.

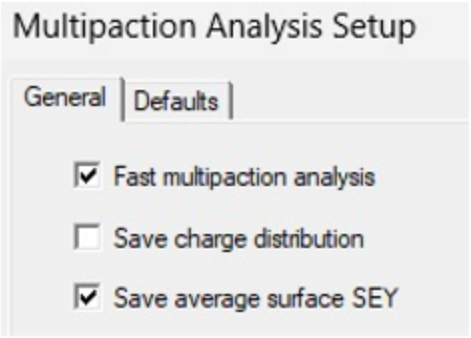
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Files can be AVI Files (*.avi), Animated GIF (*.gif), or Web M Files (*.webm).

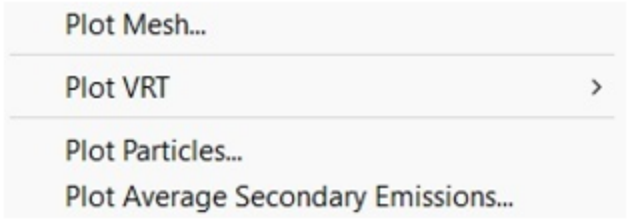
Displaying and Saving Average SEY on Material Surfaces

For displaying the average secondary emission yield (SEY) on material surfaces, you must select Save average surface SEY in the Multipaction Analysis Setup before running a multipaction simulation.



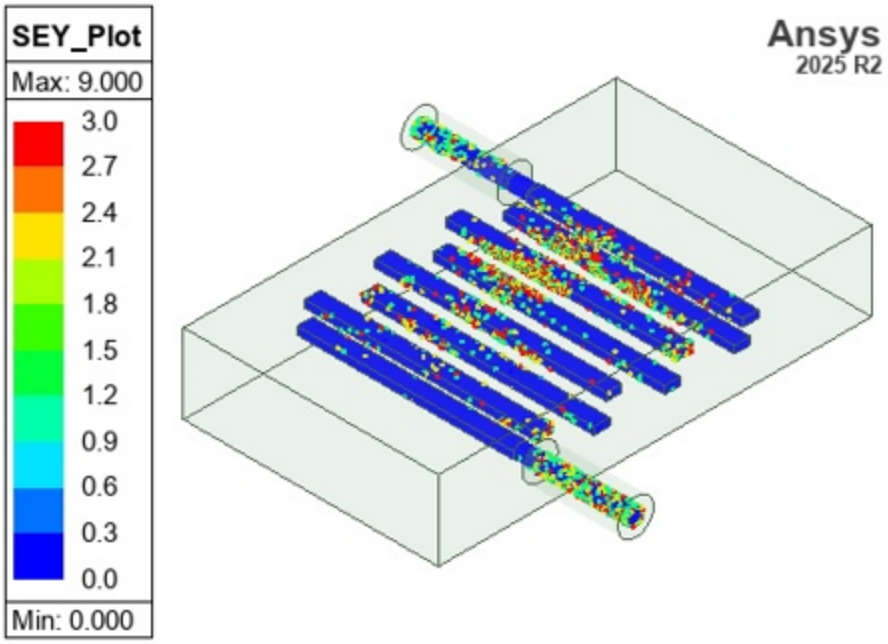
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once the simulation is completed, you can plot the average secondary emission yield on selected material surfaces.



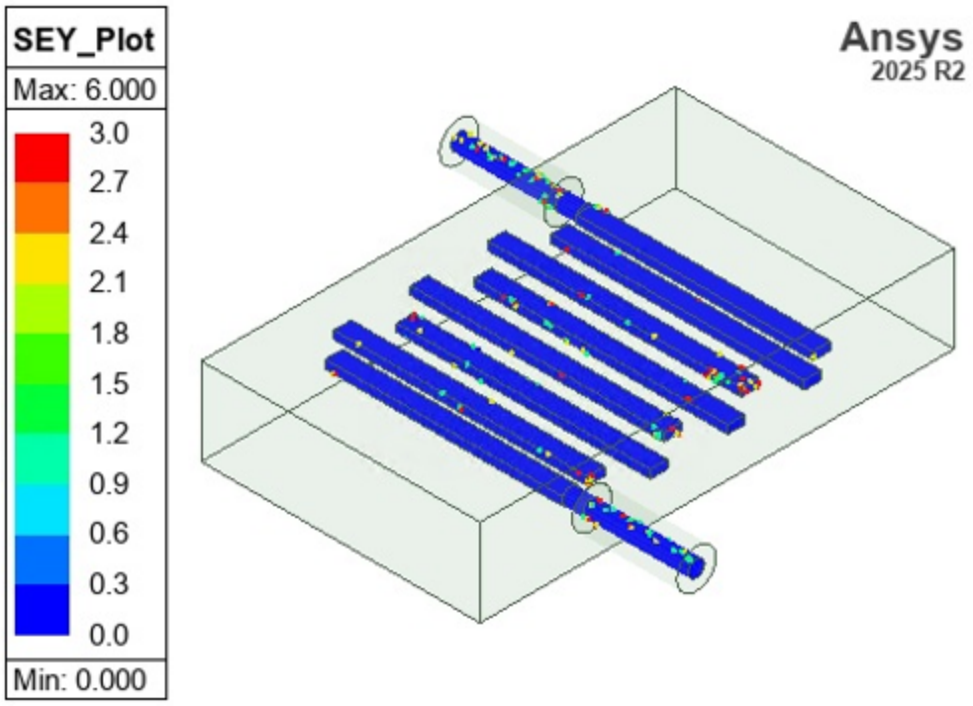
The information is typically used to identify hot spots of multipaction or to check the effectiveness of multipaction suppression tactics.

For example, the following plot shows the collision points and their corresponding average SEY for a bandpass filter with multipaction.



After applying magnetic biases to the coaxial feeds, the multipaction is effectively reduced so the SEY plot is mostly dark.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To Store and Obtain Power via a Script

You may want to get the power threshold for each autosolve analysis without reading the entire breakdown status table and figuring out the power threshold through a complicated script. You can access the power threshold through a single line of script. Although the power threshold should not be time-dependent, with the current implementation we can sample the value at t = 0.

```
# ----------------------------------------------
# Script Recorded by Ansys Electronics Desktop Version 2025.2.0

15 - HFSS RF Discharge

HFSS RF Discharge targets applications related to aerospace and satellite communications where electrical breakdown in gases is a concern. A small number of free electrons naturally exist in gases due to photoionization and irradiation. When the electrons are accelerated by RF/microwave waves, they gain enough kinetic energy to ionize neutral gas atoms or molecules. The ionization is easier to happen at high altitudes or a space environment due to low gas pressures and abundant cosmic rays. If the number of electrons grows exponentially due to cumulative ionization, it can eventually trigger a discharge to damage RF/microwave circuits and sources. At high frequencies, the discharge mainly depends on the electron transport properties of the gases rather than the electron emission properties of the electrodes. This tool solves for the condition which leads to the onset of gas discharge not completely bridging material walls.

An RF discharge analysis is useful for predicting electrical breakdown in the following applications:

- TT&C (Telemetry, Tracking, and Command) subsystem switched on during satellite launching
- Uplink transmission to communication satellites
- Outgassing during the lifetime of satellites or space probes
- Re-entry vehicles and interplanetary missions
- Airborne radars and communication systems

It requires the time-harmonic fields being solved for a driven-terminal or driven-modal projects. Therefore, the RF discharge setup and associated DC magnetic bias (possibly nonuniform through Maxwell link) should be added to aforementioned types of HFSS projects. You can also perform an RF Discharge simulation on an Eigenmode solution. Other solution types, such as Transient, Characteristic Mode, and SBR+, do not support the RF discharge analysis. By option, you can save and plot electron density data.

Prerequisites

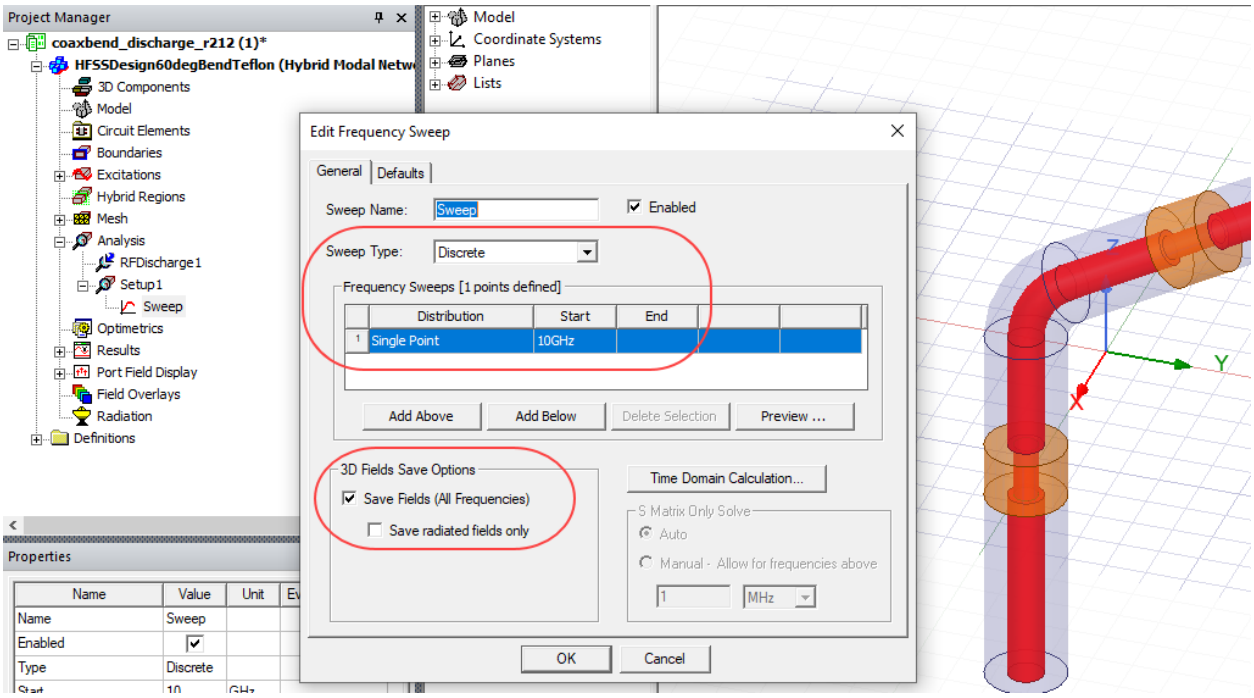
The Solution type must be Driven Terminal or Driven Modal or Eigenmode.

Save Fields for a Driven Terminal or Driven-Terminal Project

An RF discharge simulation requires time-harmonic fields as excitations. You must edit the frequency sweep of a driven-modal or driven-terminal project to save fields. However, storing fields takes time and disk space, especially when the size of the project and the number of frequency points are large. In addition, the RF discharge solver will solve one Paschen curve for each frequency. To reduce the simulation time and avoid clogging the RF discharge plot, should

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

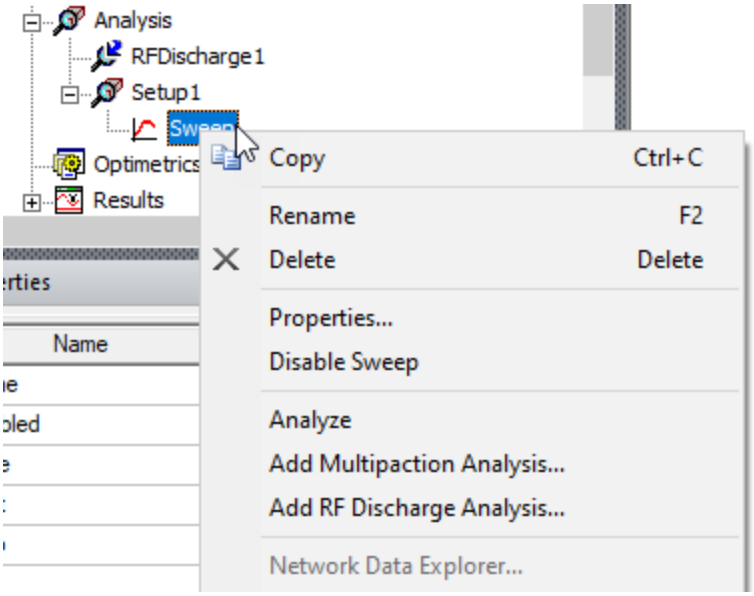
create a frequency sweep with few frequency points for linking with an RF discharge analysis. A frequency sweep for interpolating sweep of S-parameters over hundreds of frequency points is not suitable for linking with an RF discharge analysis.



Add an RF Discharge Analysis to a Driven Solution

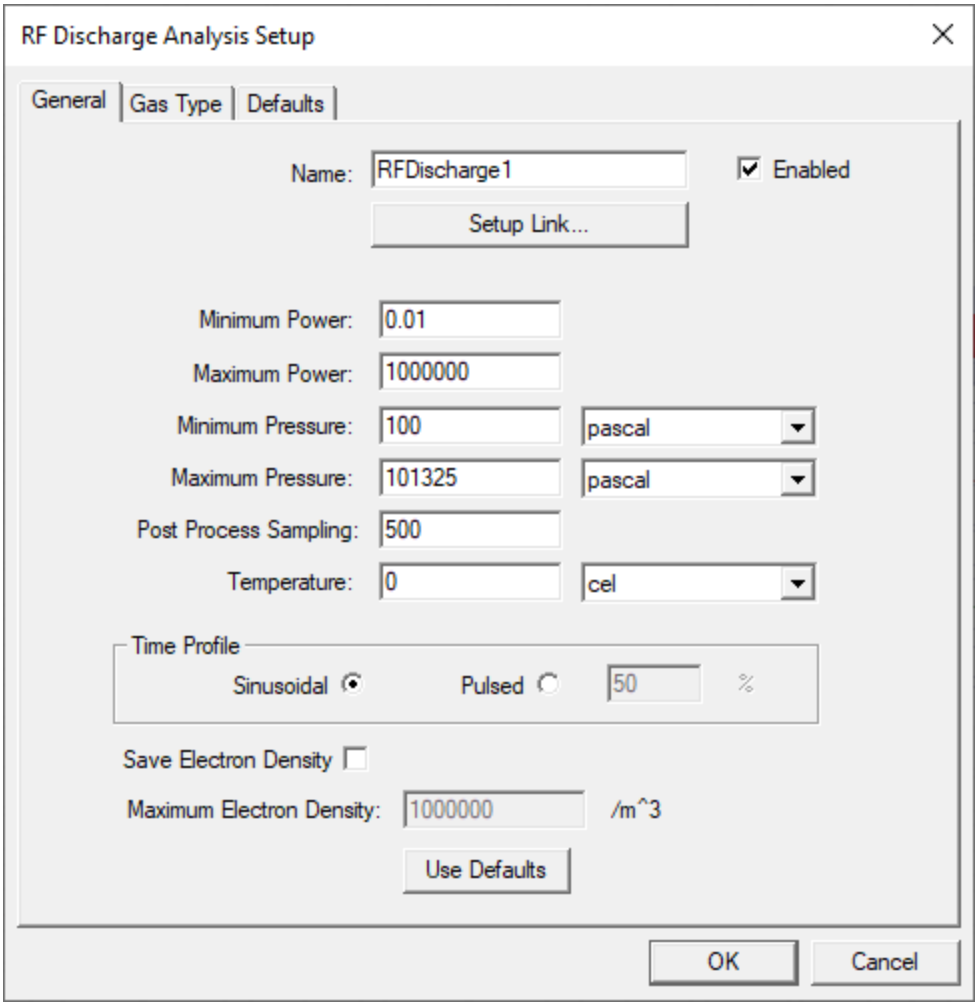
An RF discharge analysis can be created only when there is a frequency sweep with **3D Fields Save Options** checked. Otherwise, the featured is grayed out. Right click the frequency sweep to **Add RF Discharge Analysis**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **RF Discharge Analysis Setup** dialog lets you specify General parameters for Maximum and Minimum Power and pressure, as well as sampling and temperature values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

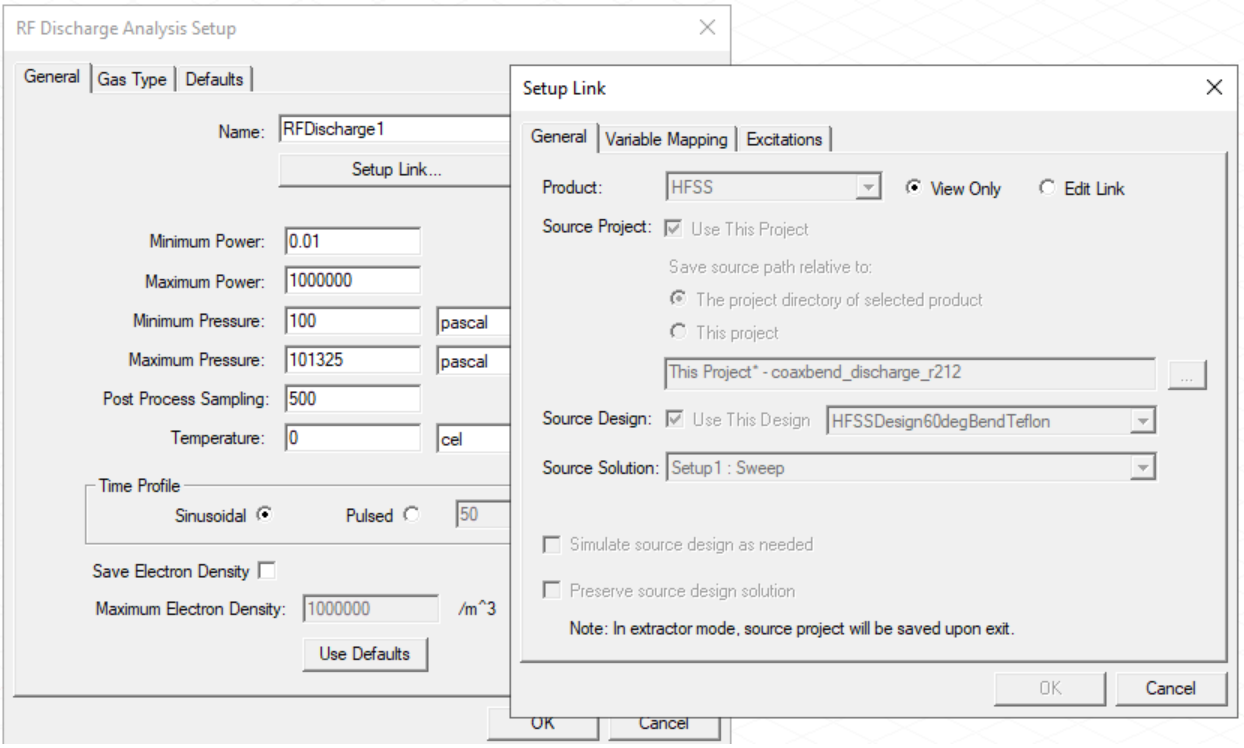


By default, the pressure ranges from 0.1 to 101.325 kPa. You set appropriate power and pressure bounds according to the operating range of your designs.

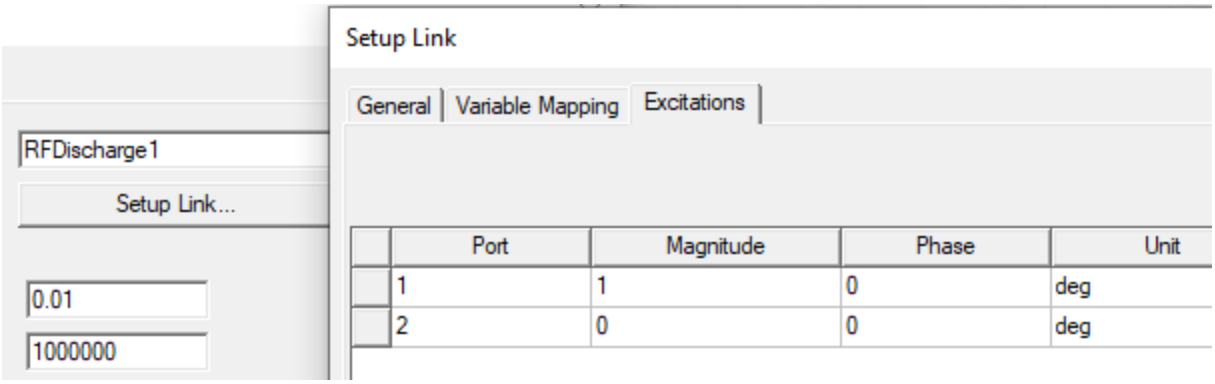
Select the Source and Port Excitations

A driven design must contain at least one active frequency sweep with at least one active port for you to set up the source link. When the solution type is Modal Network or Terminal Network, the total field used in discharge simulation is a linear combination of field patterns of individual ports weighted by the complex multipliers (phasors) listed in the table. You set the input power of each active port on the **Excitations** tab of the **Setup Link** dialog to one Watt.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



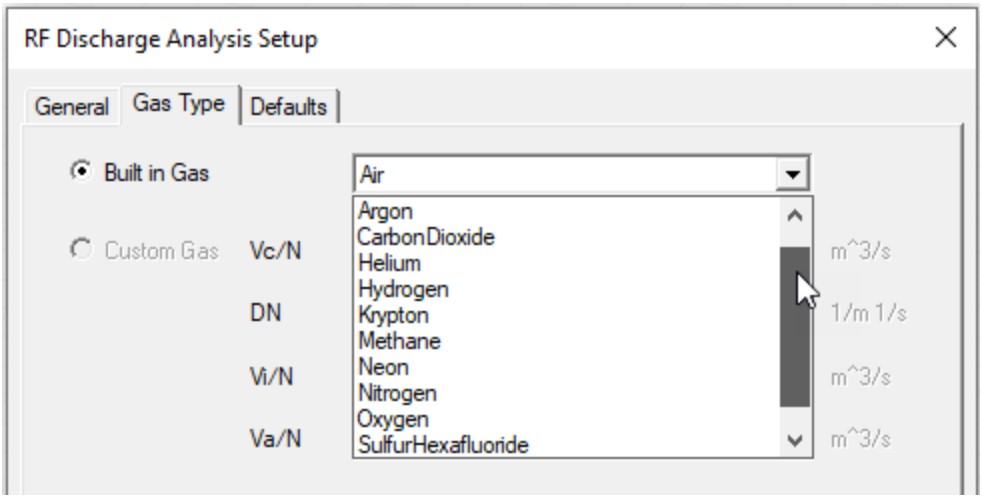
The total field used in discharge simulation is a linear combination of field patterns of individual ports weighted by the complex multipliers (phasors) listed in the table. You set the input power of each active port on the **Excitations** tab of the **Setup Link** dialog to one Watt.



OK the **Setup Link** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Gas Type for RF Discharge Analysis



Click the **Gas Type** tab to select either Built-in or Custom gases. There are 12 built-in gases in the default gas library: Air, Argon, Carbon Dioxide, Helium, Hydrogen, Krypton, Methane, Neon, Nitrogen, Oxygen, Sulfur Hexafloride, and Xenon. Use the arrows to scroll through the drop-down list. Non-conductive materials in the simulation domain with relative permittivities no more than 1.02 and relative permeabilities in between 0.99999 and 1.00001 will be replaced by the gas selected from the list. For example, air and vacuum in the HFSS material library will be replaced according to the above rule.

A Custom Gas can be specified by four datasets of the electron collision frequency (V_c/N in m^3s^{-1}), the diffusion coefficient (DN in $m^{-1}s^{-1}$), the ionization rate (V_i/N in m^3s^{-1}), and the attachment rate (V_a/N in m^3s^{-1}) as functions of the reduced electric field E/N (Td). If the project or the design does not have any dataset defined, the Custom Gas parameters will be grayed out on the **Gas Type** tab of the dialog.

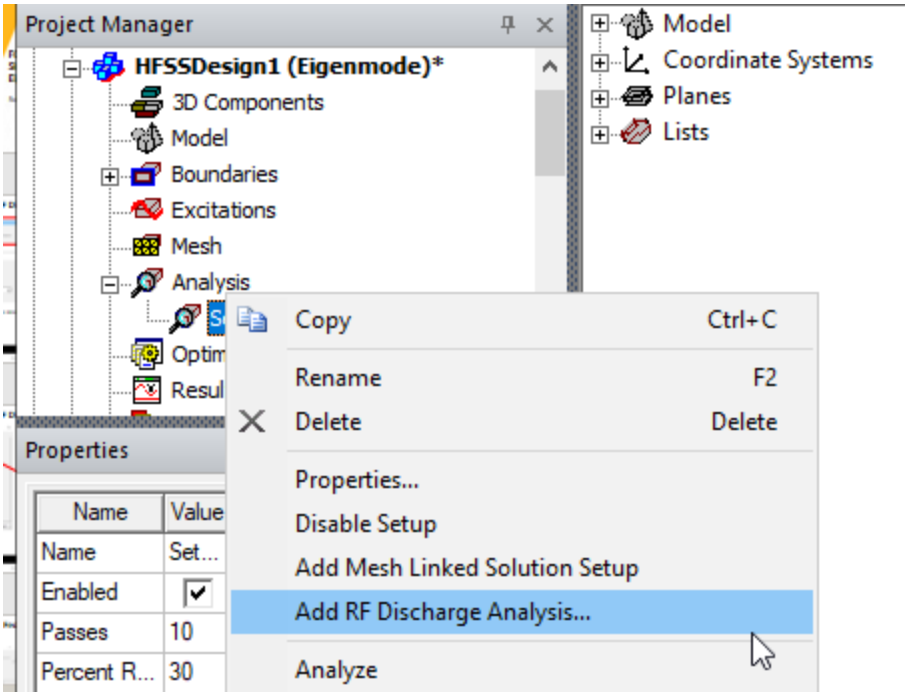
Click **OK** to complete the setup.

Please note that the gas parameters of built-in gases are based on measured data with E/N between 0.1 and 5000 Td. The limitation may cause simulation results to deviate from ideal Paschen curves especially at low pressure.

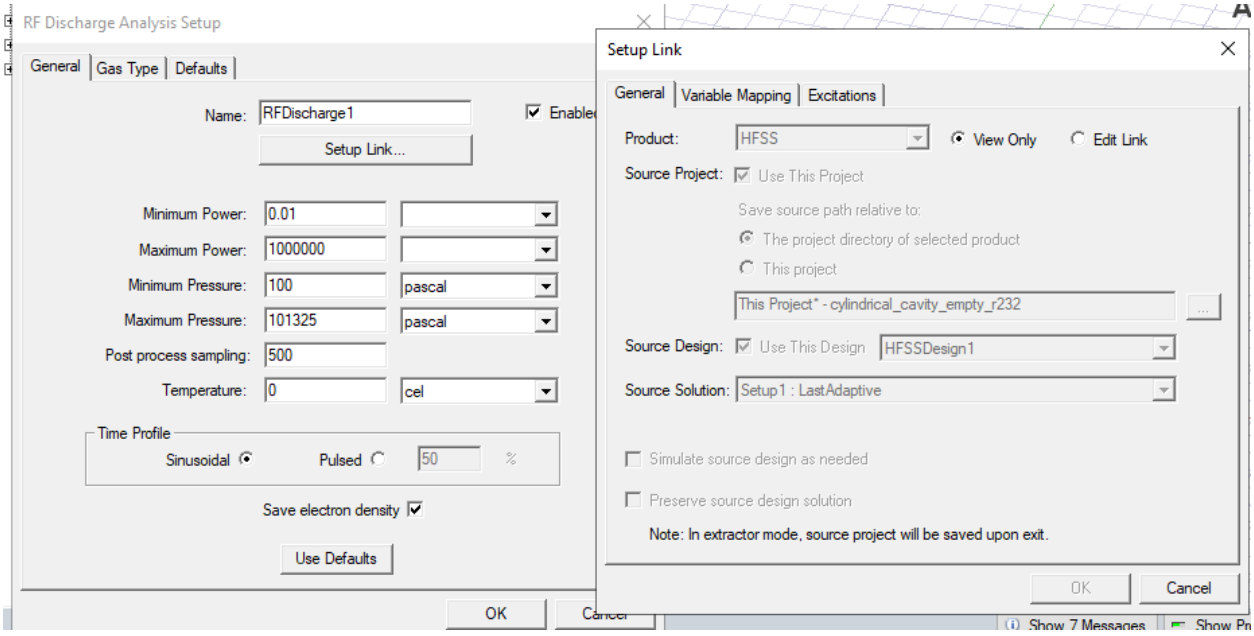
Add an RF Discharge Analysis to an Eigenmode Solution

You can add an RF Discharge analysis to Eigenmode solution.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



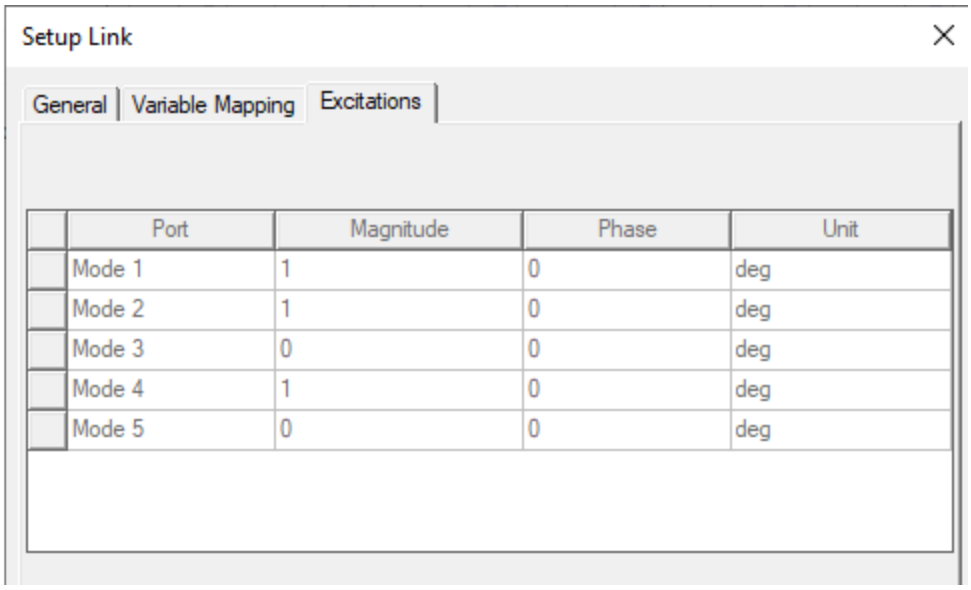
Use the **Add RF Discharge Analysis...** command to set parameters in the and **Setup Link...**



When the solution type is Eigenmode, the fields used in discharge simulation are individual field patterns of each mode weighted by the complex numbers (phasors) listed in the table. In the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

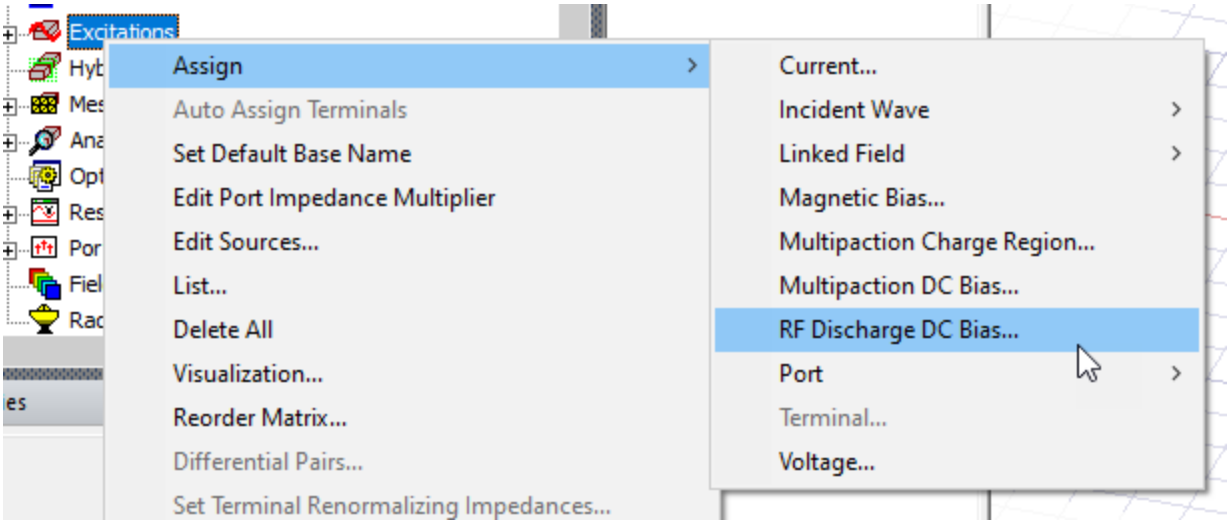
following example setup, you set the stored power of Mode 1 on the **Excitations** tab of the **Setup Link...** dialog to be one Watt.



Please note that there will be one Paschen curve for each mode. The excitation is not a linear combination of eigenmodes in RF discharge simulation.

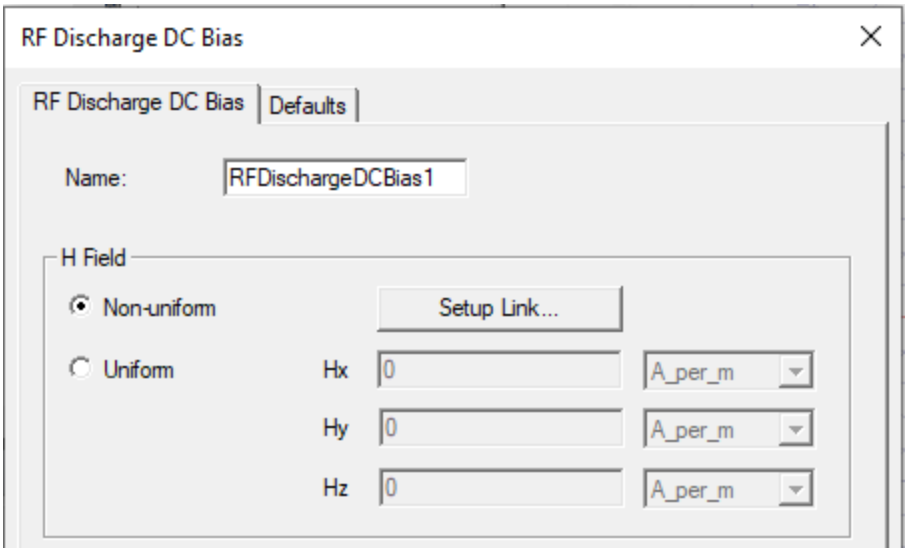
(Optional) Assign DC Magnetic Bias

To assign a DC magnetic bias in an RF discharge simulation, the first set the Model Window Selection Mode must be changed to Object. Then select the relevant object in the Model window or History tree, and right-click a solid object to assign an RF Discharge DC Bias.

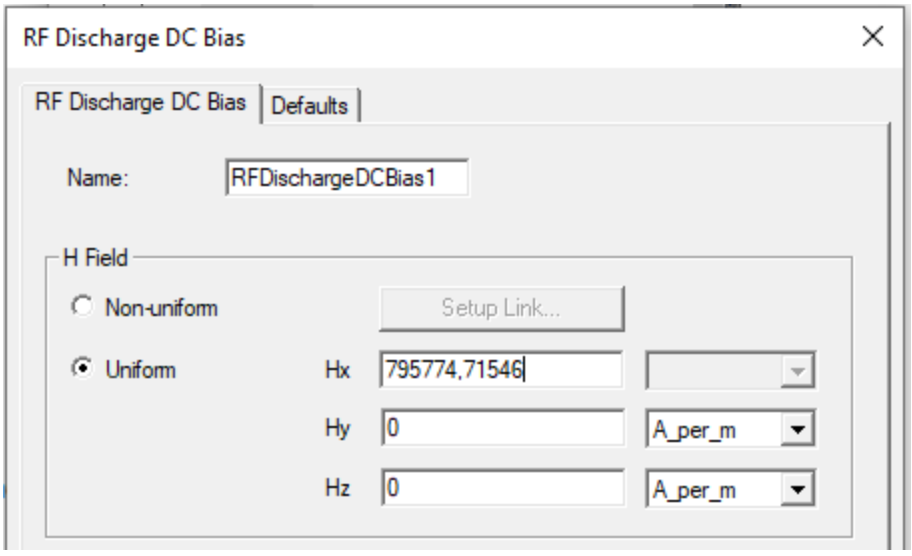


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **RF Discharge DC Bias** dialog opens. You can specify a uniform bias, or setup a link to a Maxwell project for a non-uniform bias mapped to the selected region.



For example, in the following figure, the region is assigned a uniform magnetic bias of one Tesla (T). The conversion is through $Bx\ (T) = \mu 0\ (Tm/A)\ Hx\ (A/m)$, where $\mu 0 = 4\pi \times 10^{-7}$ is the free space permeability.

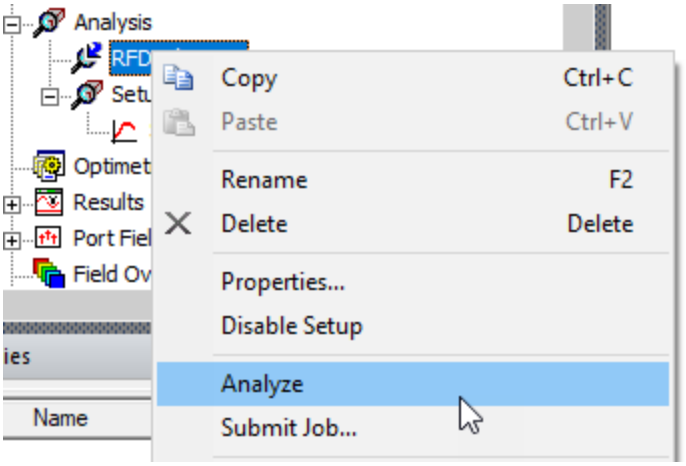


You can also assign a nonuniform magnetic bias through Maxwell link where the solution of the linked Maxwell project is mapped to the selected region in the RF discharge simulation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Run RF Discharge Simulation

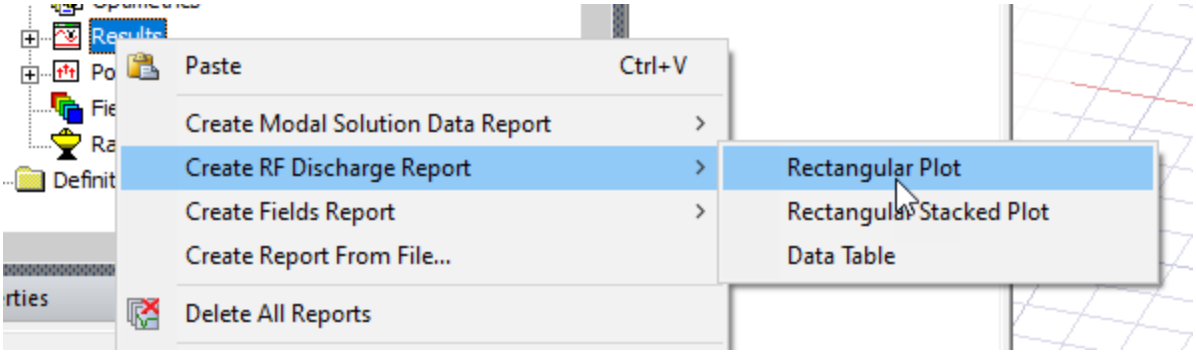
Once the analysis setup has been completed and the magnetic bias has been added, click **Analyze** to run the RF discharge simulation.



The Frequency Sweep will run first, then the RF Discharge simulation. You watch these occur through the Progress window. At completion, a message appears in the Message window.

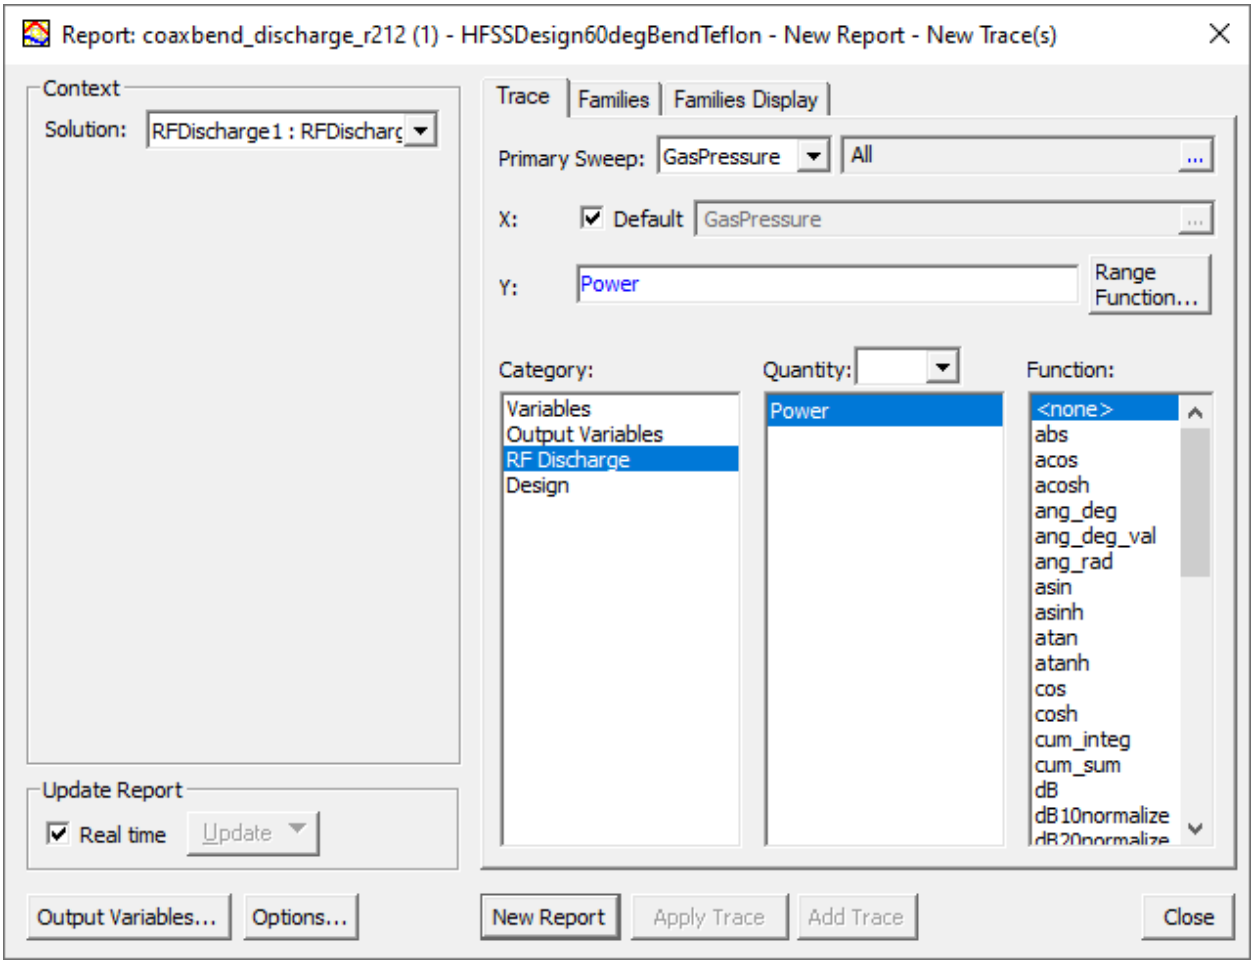
Create an RF Discharge Report

Right click on the **Results** icon and select **Create RF Discharge Report** and the type of plot.



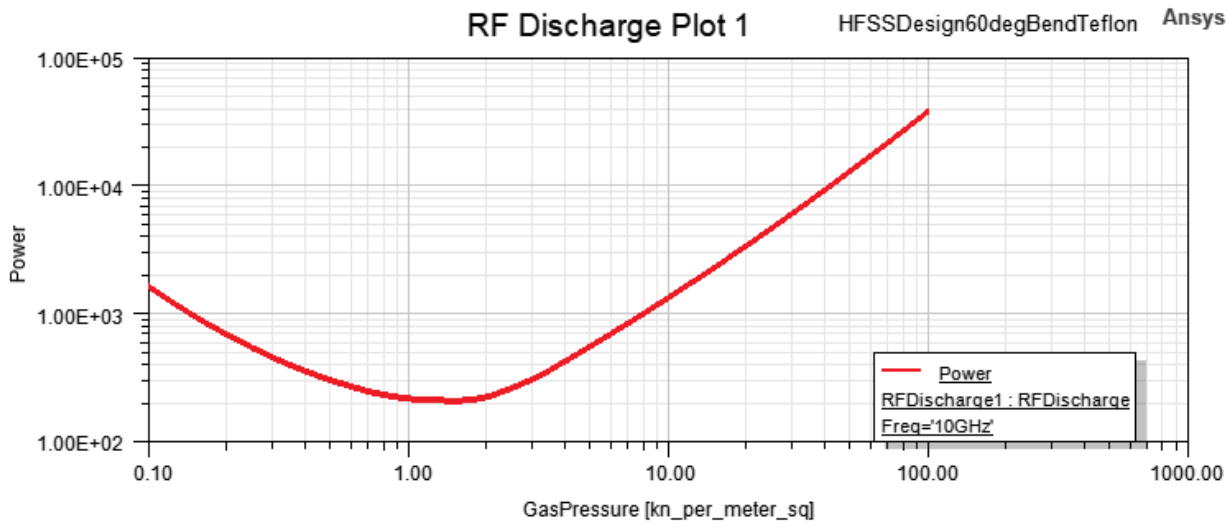
The **Report** dialog opens up. Select **RF Discharge** as the Category and **Power** as the Quantity.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The Paschen curve shown in the plot represents the breakdown power as a function of the gas pressure. In this example, circuit designers mainly care about the minimum breakdown power and the critical pressure where the coaxial bend is most prone to microwave discharge during satellite launch or spacecraft re-entry.

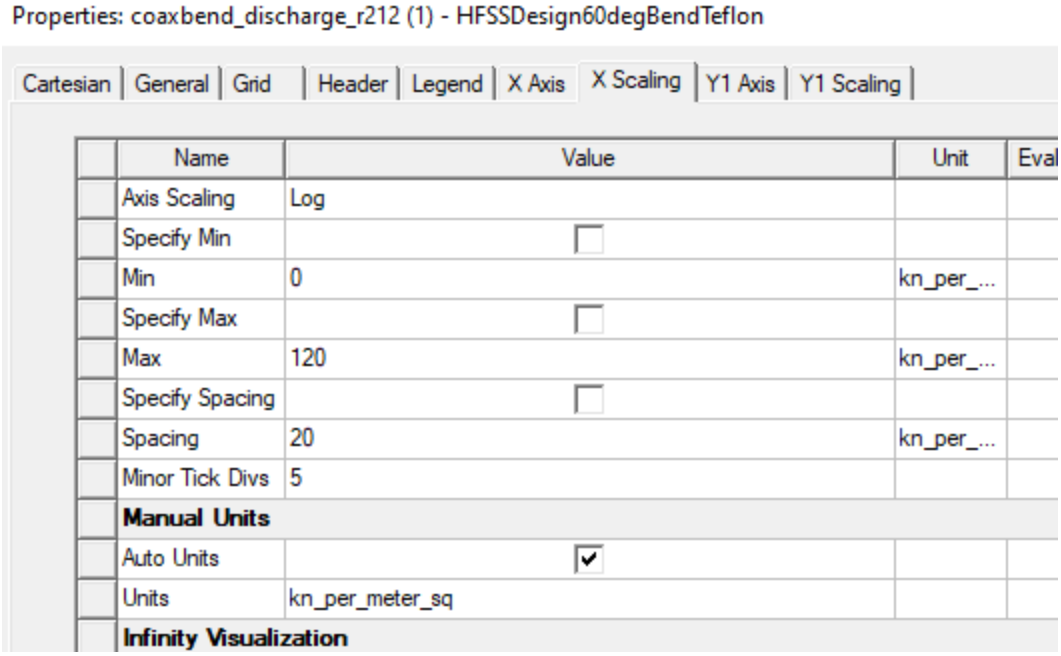
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For an eigenmode solution, the breakdown stored energy is equal to the breakdown power divided by the eigen frequency.

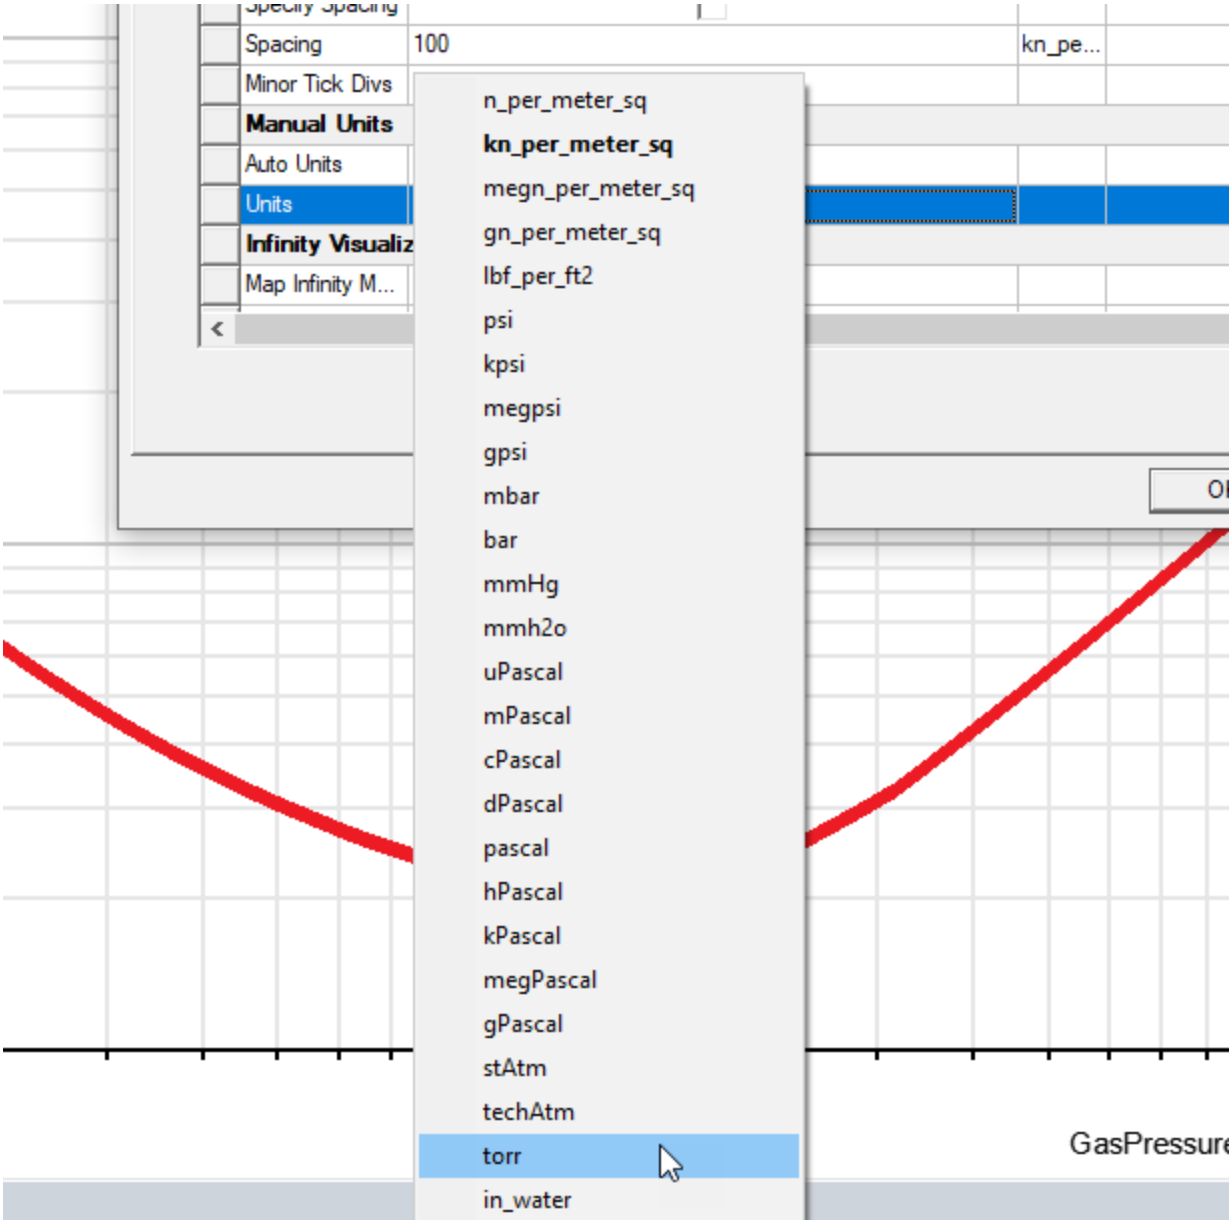
(Optional) Change the Pressure Unit

To change the pressure unit, double click Curve Info to open the Properties dialogue and select the X Scaling tab.



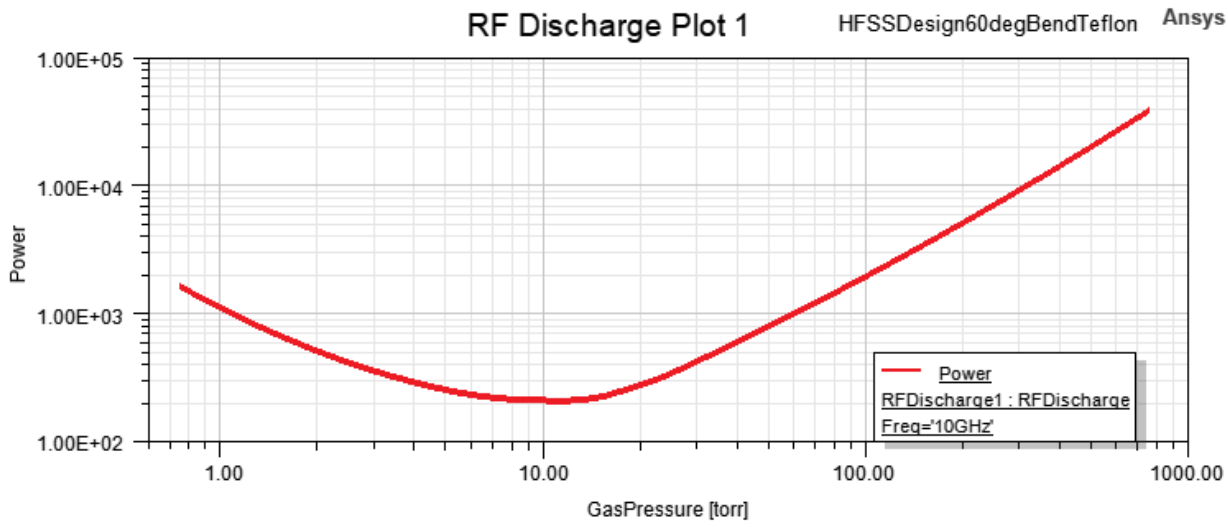
Uncheck Auto Units and on the Units line, use the drop-down menu to select torr.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The plot will become the following by adjusting the bounds of X and Y values to fit the curve in the window.

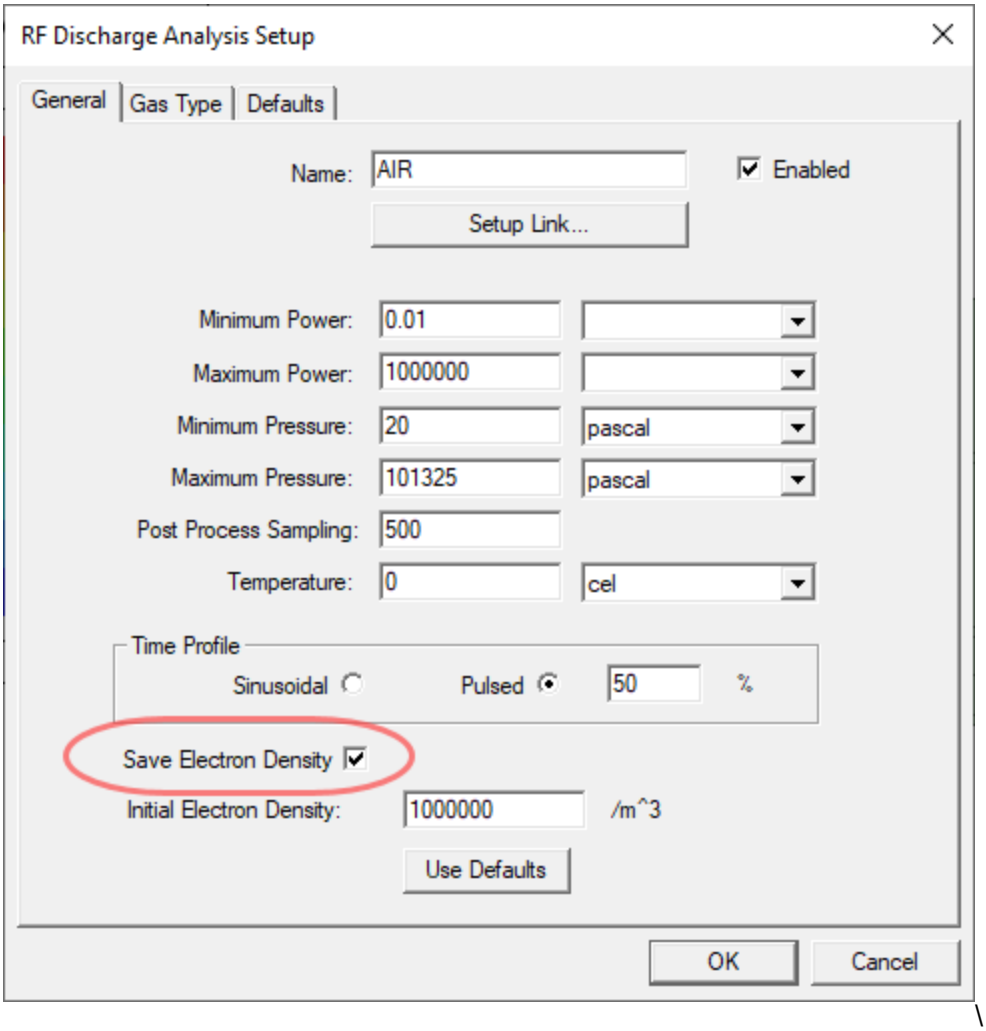
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



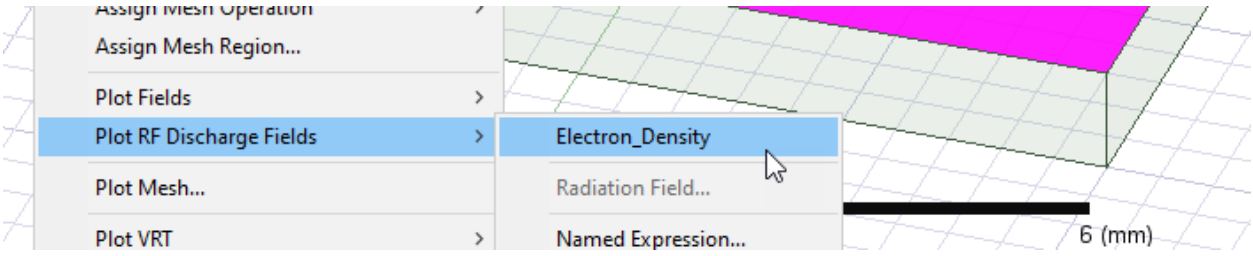
Create an Electron Density Plot or the RF Simulation

Enable the data for an electron density plot in an **RF Discharge Analysis Setup** checking **Save electron density**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

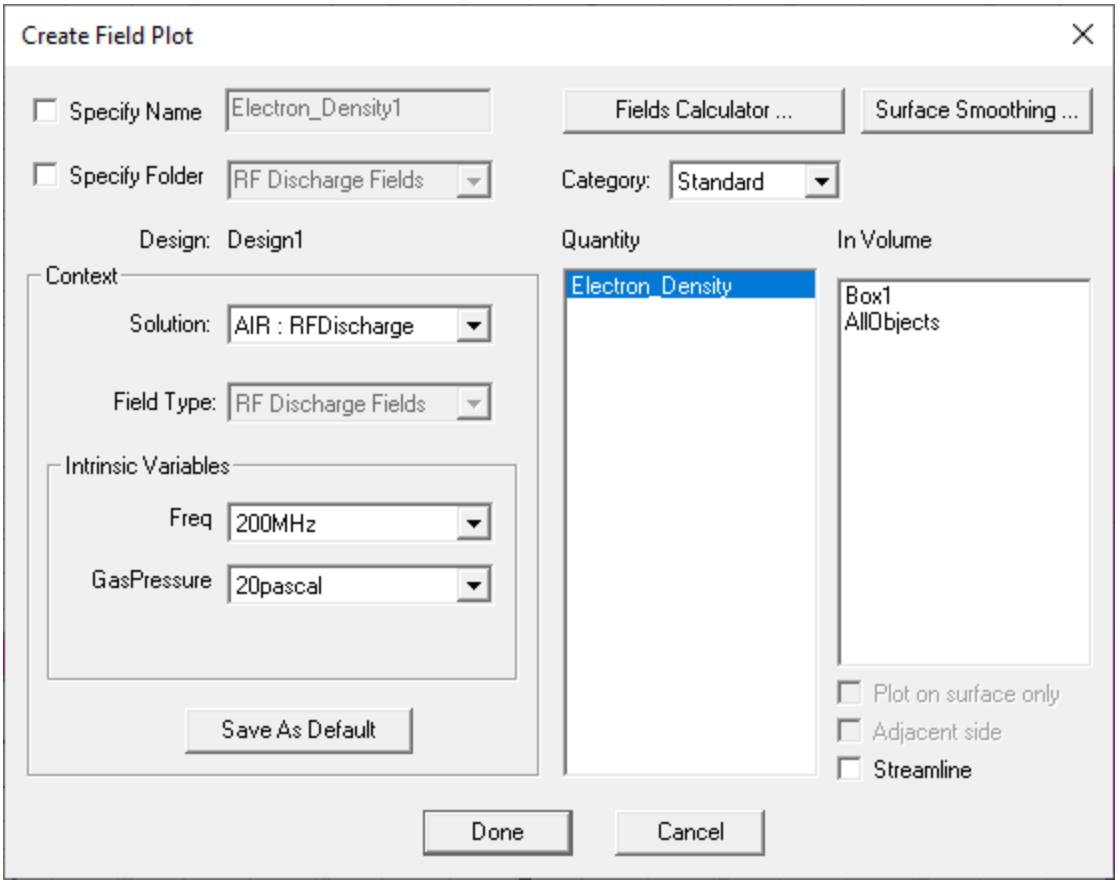


After you solve with this checked, select a face of the object for which you want to plot fields. Then right-click in the **Modeler** window and select the enabled **Plot RF Discharge Fields>Electron Density** menu.



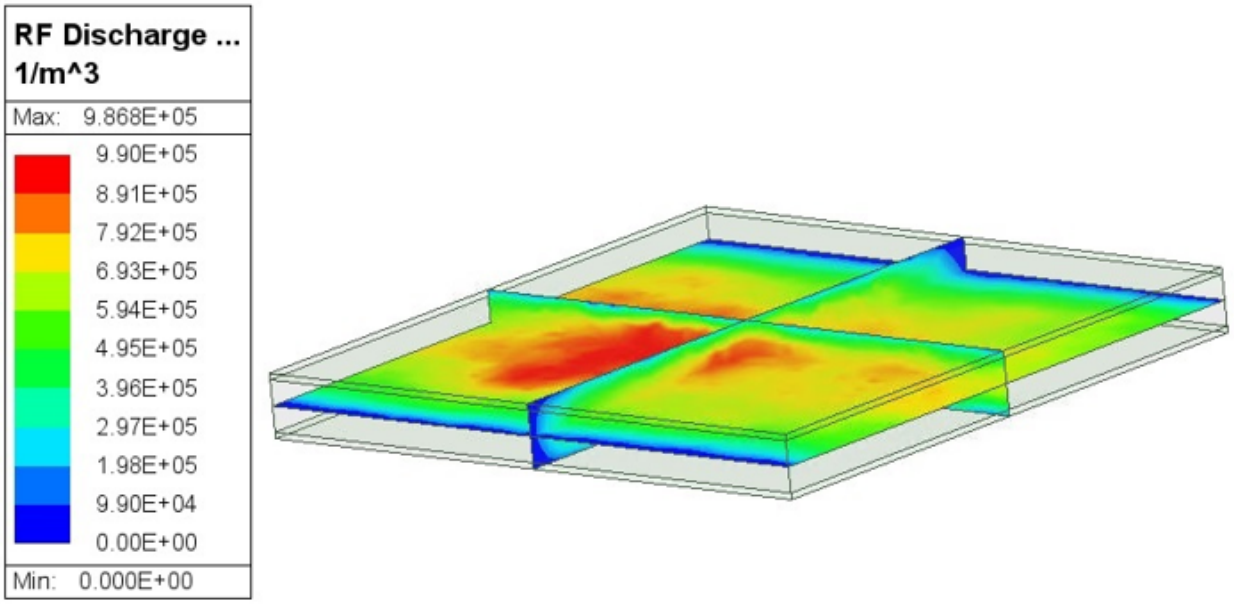
Specify parameters in the **Create Field Plot** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

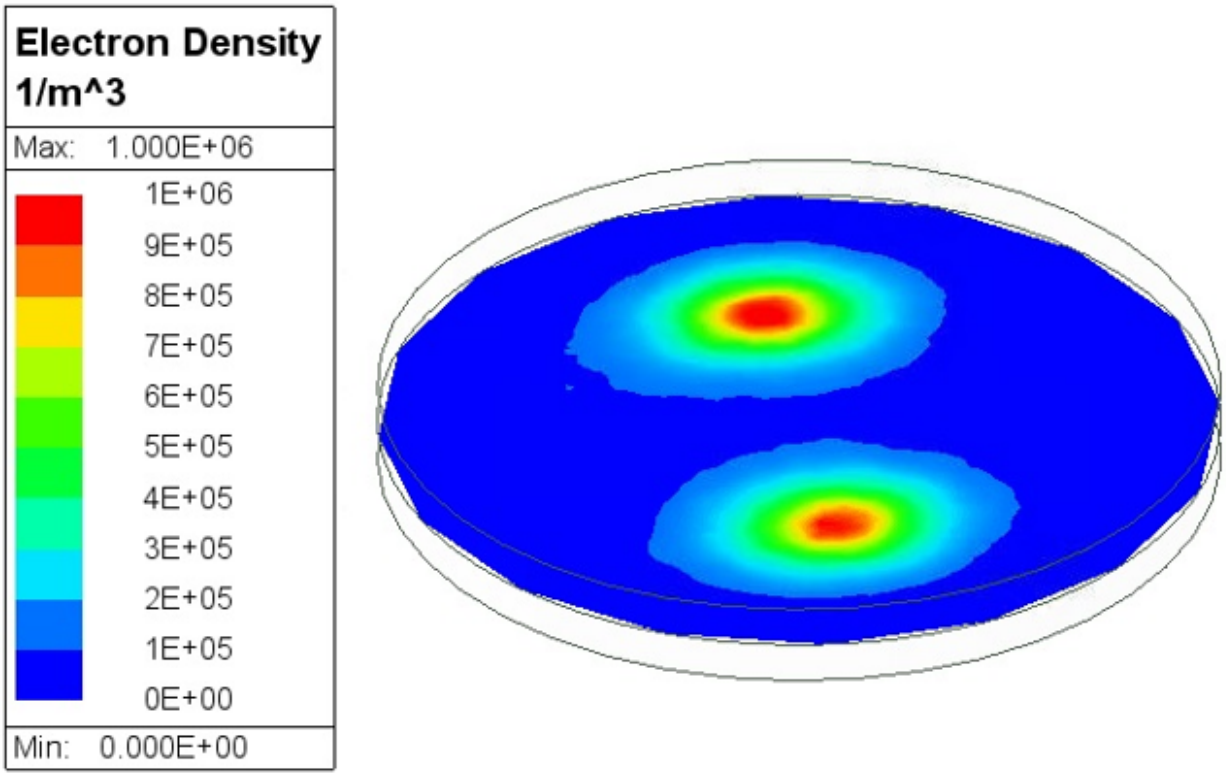


Make Variable and In Volume Selections and click **Done**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can also create an electron density plot for an Eigenmode simulation.



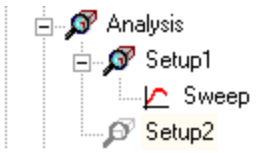
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For getting smoother electron density plots, it is often required to use mesh seeding to increase uniformity and density of the mesh. With an increasing mesh density, we can select low order basis functions in Mesh/Solution Options to save simulation time.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

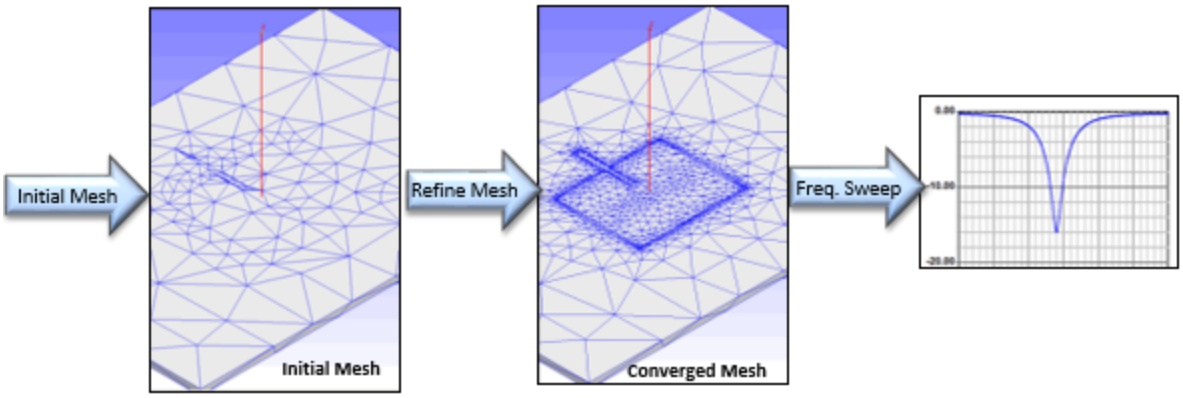
16 - Specifying Solution Settings

Specify how Ansys Electronics Desktop will compute a solution by adding a solution setup to the design. You can define more than one solution setup per design.



Each solution setup includes the following information:

- General data about the solution's generation.
- Adaptive mesh refinement parameters, if you want the mesh to be refined iteratively in areas of highest error.
- Whether to **Save Fields** (the default) and if so, whether to save **Save radiated fields only**. You must save fields for fields post processing, plotting and animating plots.
- If you want to solve of a range of frequencies, you can add a frequency sweep.

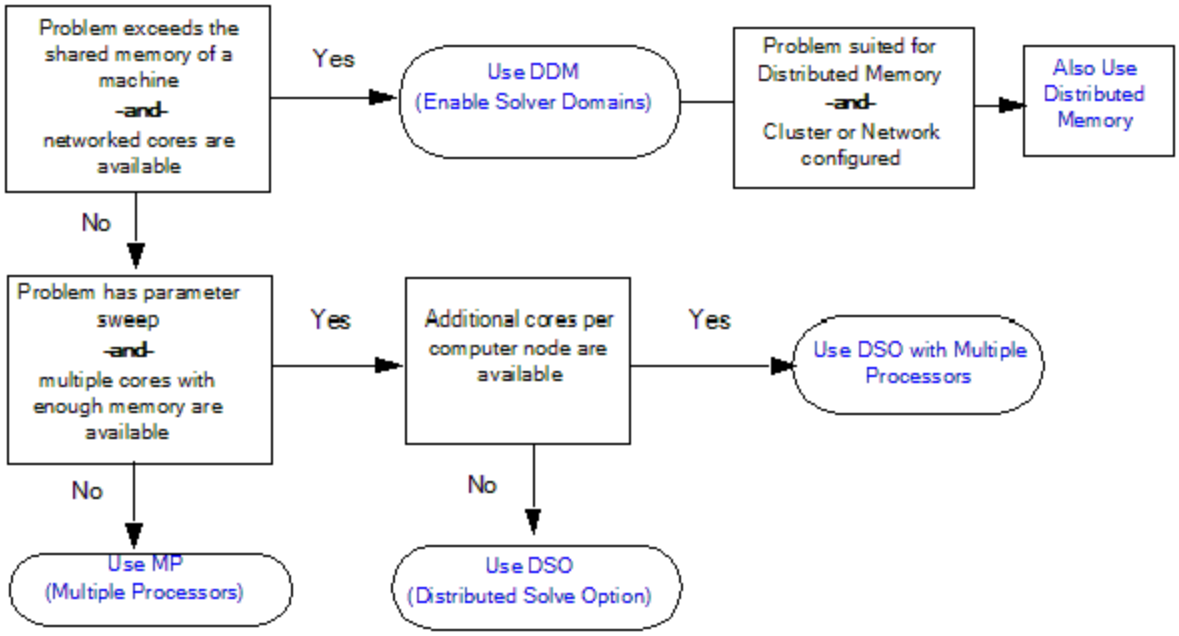


What do you want to do?

- Add a Solution Setup to an HFSS Design
- Add a Solution Setup to an HFSS Design with Hybrid and Arrays
- Add a Solution Setup to an HFSS Transient Design
- Add a Solution Setup for an SBR+ Design
- Add a Solution Setup for an Eigenmode Design
- Add a Characteristic Mode Analysis Setup and Generate Reports

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For large problems, depending the whether the solution involves a parameter sweep and your resources of shared machine memory, networked cores and cores per computing node, you can configure for different high performance computing solutions:



Additionally, a command line Large Scale DSO is used for 'large scale parallel' jobs, which either fail or scale poorly as Regular DSO jobs. A Large Scale DSO job does not support the output of full parametric results, but produces 'reduced' datasets corresponding to predefined Rectangular plots.

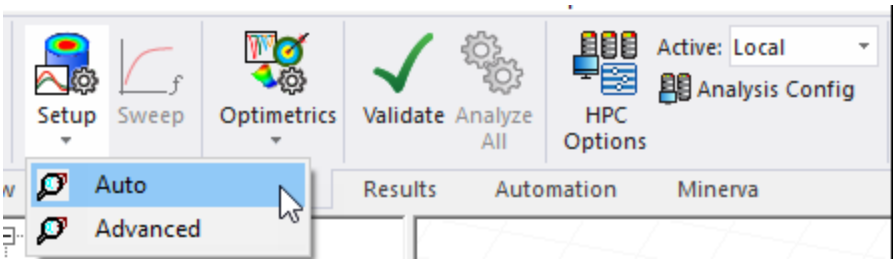
Adding a Solution Setup to an HFSS Design

If you have an existing setup, you can **Copy** and **Paste** it, and then edit parameters. If you have already created a solution and you want to use an existing mesh, you can click **Add Dependent Solve Setup**. To add a new solution setup to an HFSS Solution Type design:

1. Select a design in the project tree.
2. Click **HFSS** > **Analysis Setup** > **Add Solution Setup**, or right-click **Analysis** in the project tree, and then click **Add Solution Setup** on the shortcut menu, or select the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Simulation tab on the ribbon, and click the **Setup** icon:

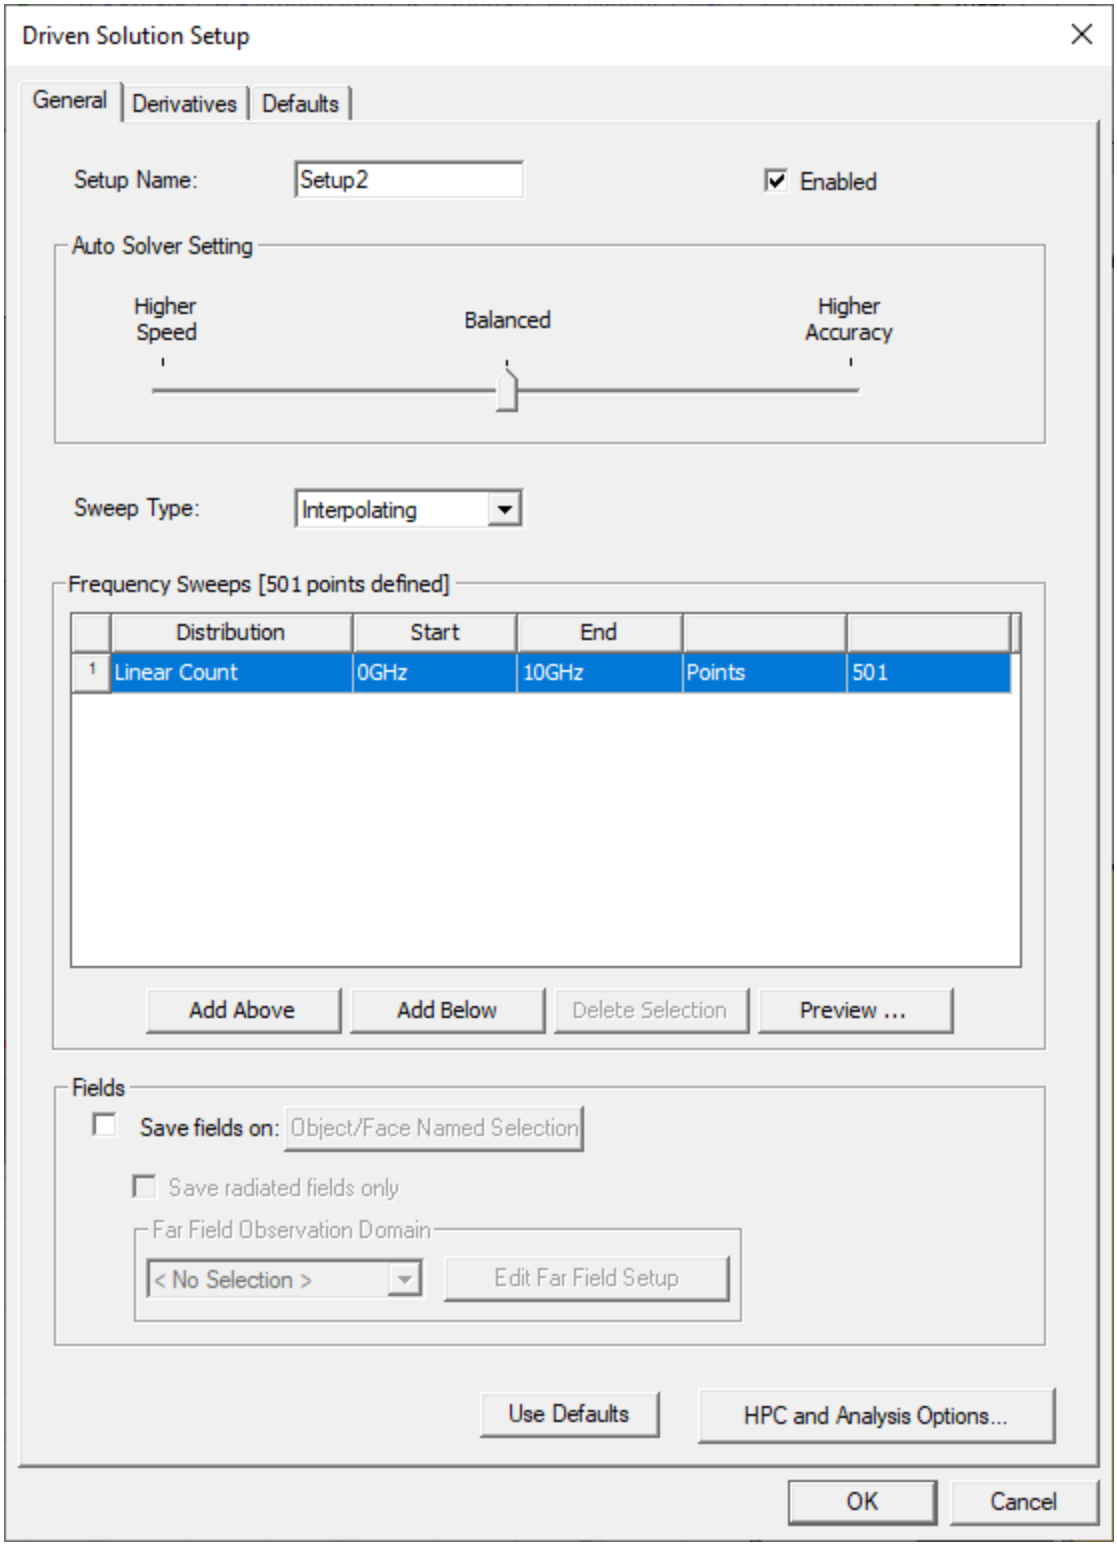


For HFSS designs you can choose **Auto** or **"Advanced Solution Setup" on page 16-7**.

Auto Solution Setup

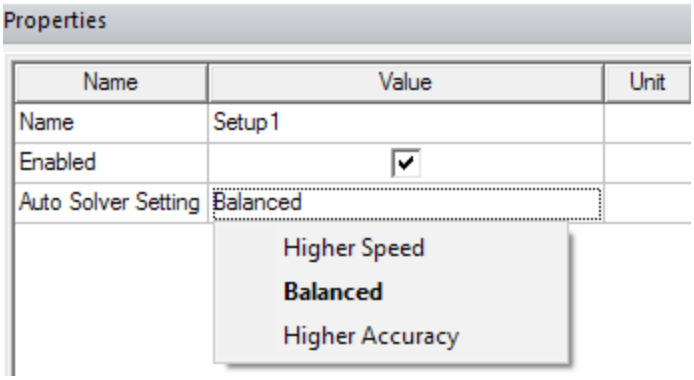
In order to use Auto setup, "Use Automatic Settings" under Analysis Configuration must be checked. **Auto** features a simplified dialog box with a slider bar that you can adjust from **Higher Speed** (which sacrifices accuracy to achieve optimum speed), to **Balanced** (which is more accurate but faster than the highest accuracy setting) to **Higher Accuracy** (which takes the time to ensure optimal accuracy).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



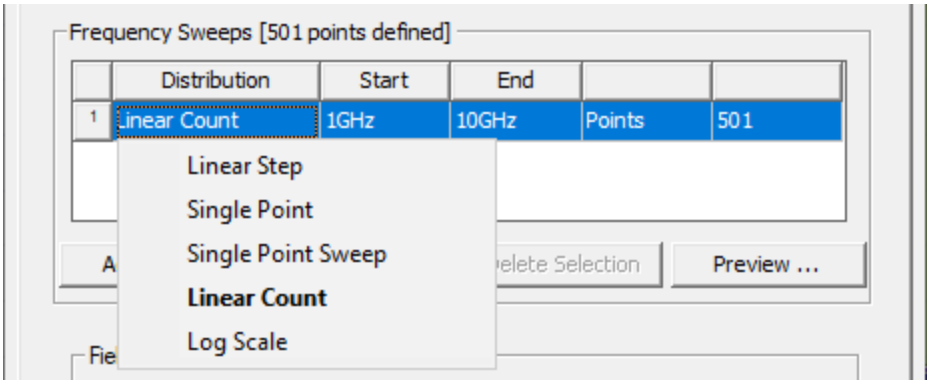
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Properties for the Auto Solver Setting includes the same choices.



The Auto setup includes a single sweep, for which you can edit the Distribution, Start, and End. If the design does not include a port, the sweep type can only be Discrete. If one or port ports exist, the sweep can be Interpolating or Discrete.

- You specify sweeps in terms of Distribution type, which can be Linear Step, Linear Count, Log Scale, Single Point , or Single Point Sweep, which adds a set of 10 Single Point Sweeps, defaulting from 1 GHz to 10 GHz in increments.. The **Add Above**, and **Add Below** buttons permit you to add additional sweeps, including mixed sweep types. This feature provides flexibility. For example, you can define sweeps with log scale at lower frequencies, and linear step at higher frequencies.



If you add more sweeps, you can **Delete** a selected distribution.

The **Preview** button displays the sweep(s) as currently defined.

The **Auto** setup includes tabs for **General**, **Derivatives**, and **Defaults**.

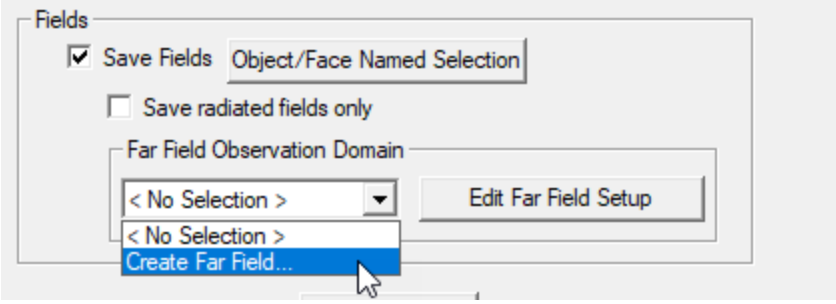
General Includes general solution settings. You can specify the name, change the slider bar to do different solver settings, choose sweep type, set frequency range, choose **Save Fields** and **Save radiated fields only** options, (required if you intend to Plot Field

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Overlays) and do **HPC** settings.

Includes settings for mesh linking, mesh assembly for designs that include 3D components, absorbing boundaries on ports, wave port adapt options, and whether to **Save Fields** and **Save radiated fields only**. You must save fields if you intend to plot or post process fields.

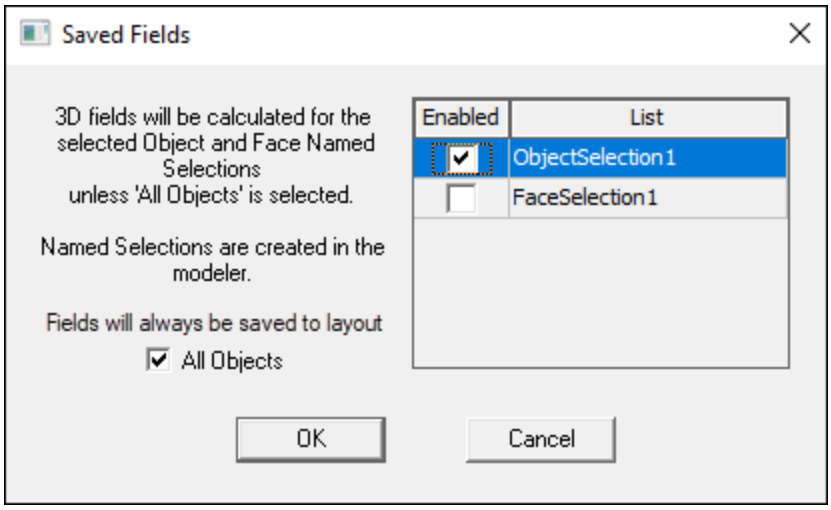
For HFSS solutions the Fields area contains a Far Field Observation Domain area that allows you to specify a Far Field sphere or edit an existing setup. To evaluate radiated fields in the far-field region, you must check Saved Fields in the solution and sweep setups, and set up an infinite sphere that surrounds the radiating object. You can set up the infinite sphere by selecting **Create Far Field...** from the menu. For the procedure, see Setting up a Far Field Infinite Sphere.



If you do so, fields are generated during the solve and for any dependent frequency sweeps, and written as .ffd files rather than as a post processing step. After the simulation, editing or deleting the selected far field setup invalidates the last adaptive solution of the driven setup as well as its dependent sweep's solution.

For very large designs, saving fields can potentially result in very large files. In such cases, you can use the **Object/Face Named Selection** button to open a **Saved Fields** dialog box to choose from object or face selections you have predefined. You would then save 3D fields only on certain objects or faces, which could save disk space. The default is All Objects.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The selection in the solve setup will dictate the behavior of the frequency sweep solve. Changing the selected lists will invalidate the last adaptive solution. If you subsequently create a Near Field or Far Field Radiation setup and select a list there, you receive a warning if your selections do not match those selected for the solve..

Derivatives If your design contains variables, they are listed here. HFSS can calculate derivatives for your variables.

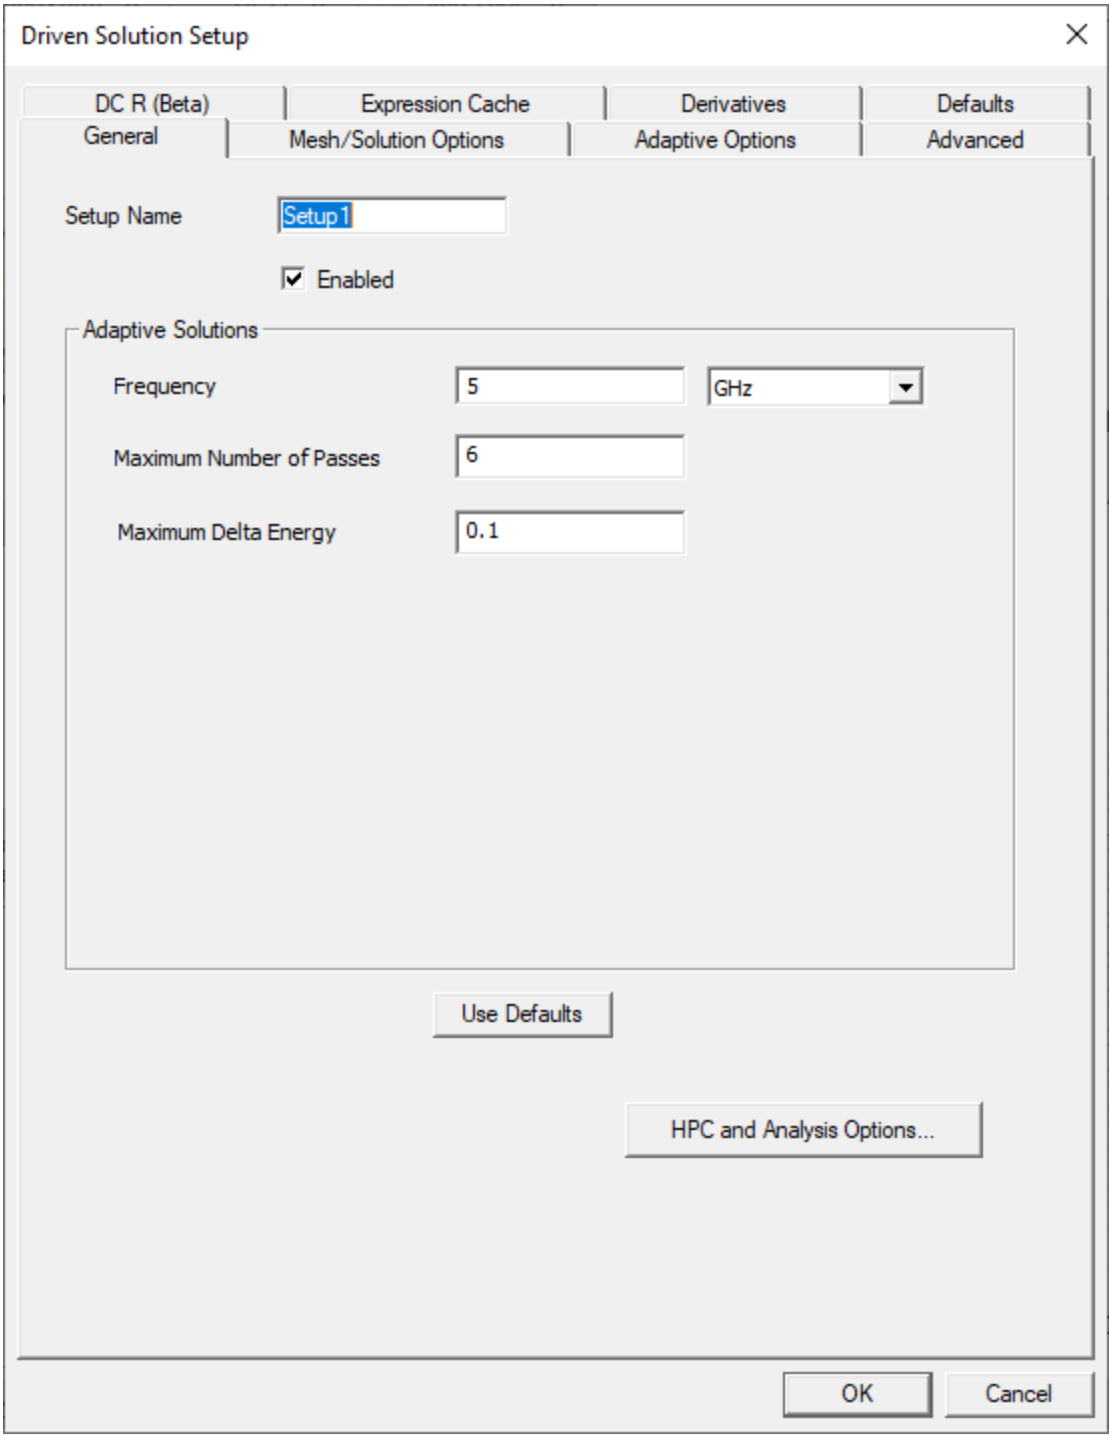
Defaults Enables you to save the current settings as the defaults for future solution setups or revert the current settings to HFSS's standard settings.

Advanced Solution Setup

The Advanced Solution Setup lets you have more control over the settings, and provides more options. For all HFSS solution types, if you choose **Advanced**, the **Solution Setup** dialog box appears. The appearance differs depending on the Solution Type. For example for

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Driven Solution Terminal Types, the DC R (Beta) tab also appears.



It is divided among the following tabs:

General Includes general solution settings, including frequency and S-parameter

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

settings.

Mesh/Solution Options

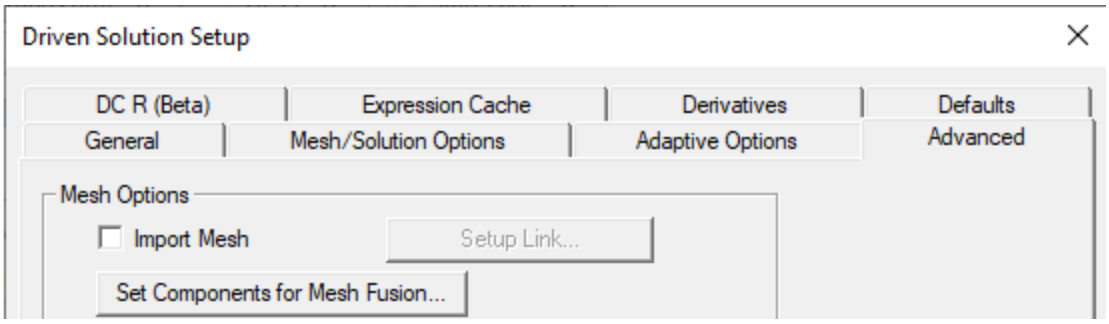
Includes Initial Mesh option settings for lambda refinement.

The **Solution** options include the Order of Basis setting, whether to use the direct solver or iterative solver, whether to enable the use of solver domains (if available for the solution type, and for designs containing lumped ports and/or circuit ports as sources), and whether to use **Enhanced low frequency accuracy**.

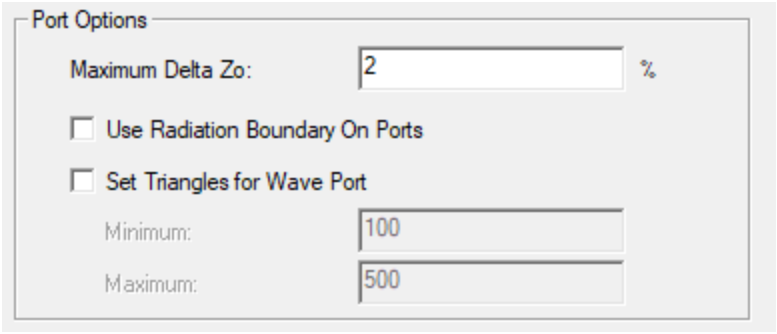
When **Enhanced low frequency accuracy** is enabled, the solver is tuned to reliably solve lumped ports at low frequencies. In addition, for designs with only lumped ports and/or circuit ports, interpolating sweeps are tuned to solve more low frequency points in order to accurately represent very low frequency results.

Advanced

Includes settings for mesh linking, and for designs that include 3D components, Mesh Fusion.



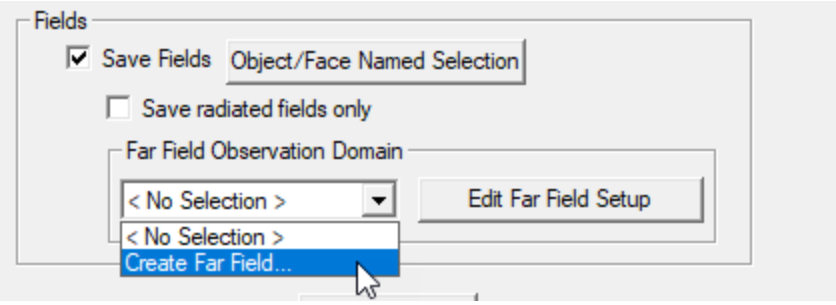
For assigned Ports includes areas that are active if you have Use Radiation Boundaries on Ports, and wave port adapt options.



The Fields pane lets you specify whether to **Save Fields** and **Save radiated fields only**. You must save fields if you intend to plot or post process fields.

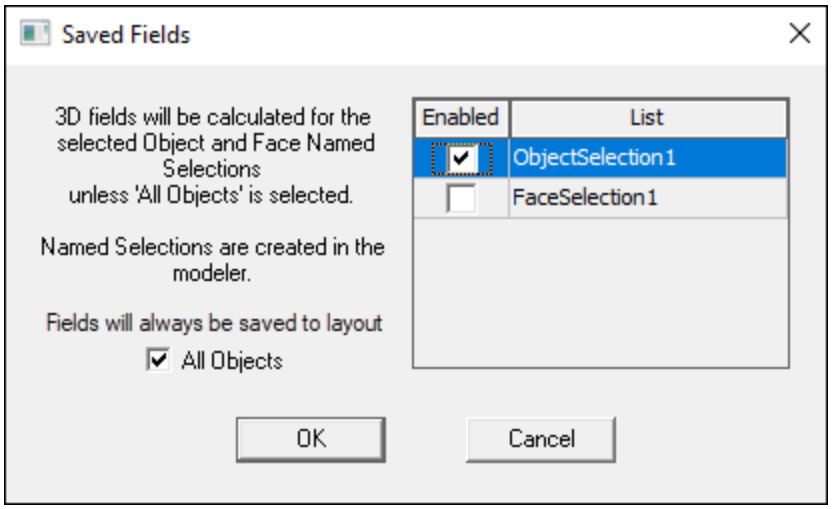
For HFSS solutions the Fields area contains a Fields Observation Domain area that allows you to specify a Far Field sphere or edit an existing setup. If you do so, fields are generated during the solve,

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If you do so, fields are generated during the solve and for any dependent frequency sweeps, and written as .ffd files rather than as a post processing step. After the simulation, editing or deleting the selected far field setup invalidates the last adaptive solution of the driven setup as well as its dependent sweep's solution.

For very large designs, saving fields can potentially result in very large files. In such cases, you can use the **Object/Face Named Selection** button to open a **Saved Fields** dialog to choose from object or face selections you have predefined. You would then save 3D fields only on certain objects or faces, which could save disk space. The default is All Objects.

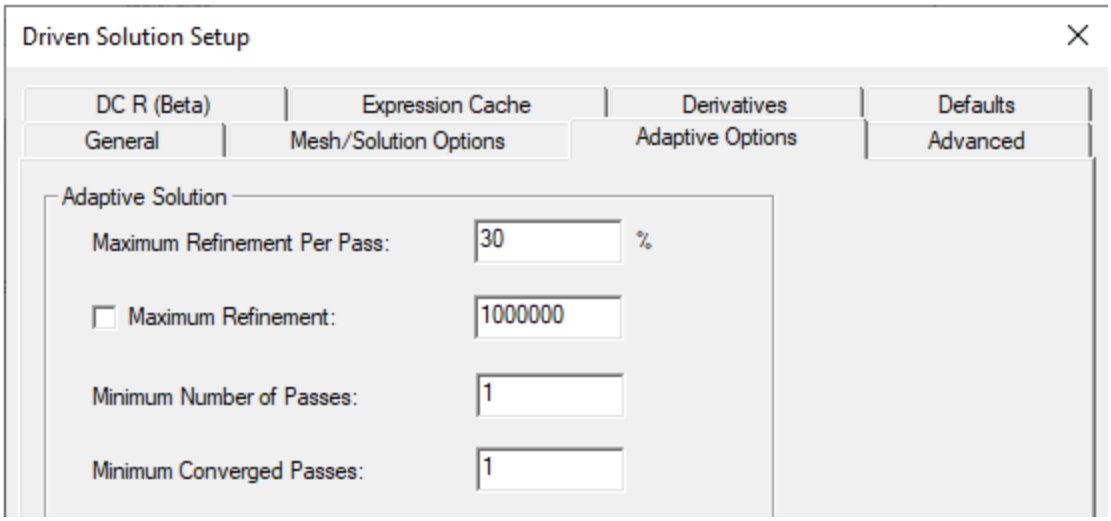


The selection in the solve setup will dictate the behavior of the frequency sweep solve. Changing the selected lists will invalidate the last adaptive solution. If you subsequently create a Near Field or Far Field Radiation setup and select a list there, you receive a warning if your selections do not match those selected for the solve.

Adaptive Options

The Adaptive Options include Maximum Refinement per pass, Maximum Refinement, and Minimum Number of Passes, and Minimum Converged Passes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



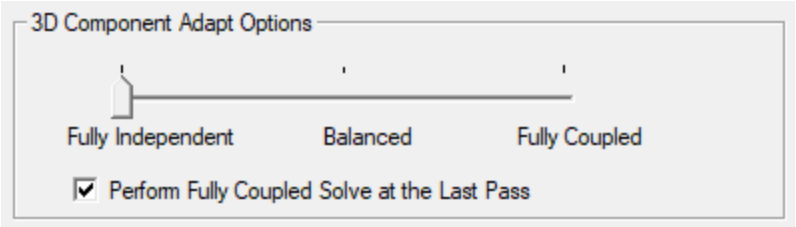
Maximum Refinement Per Pass

Maximum Refinement

Minimum Number of Passes

Minimum Number of Converged Passes

If you have set the Beta Option for Parallel Component Mesh Adapt, and the design contains 3D components, the **Adaptive Options** tab also lets you select 3D Component Adapt Options.

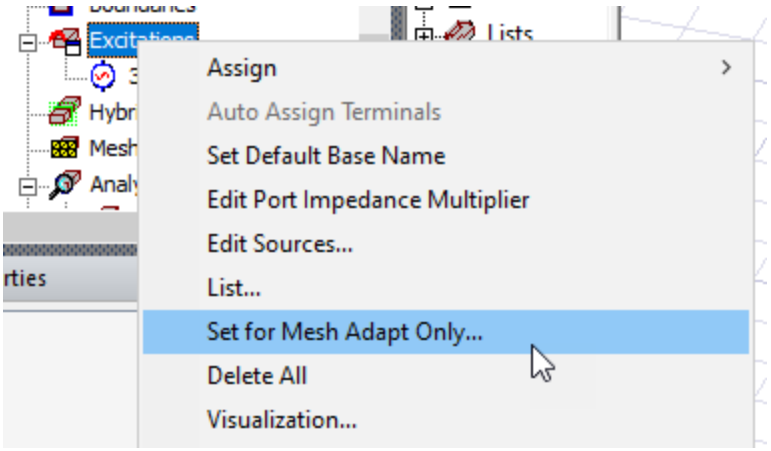


Parallel component adapt for mesh fusion workflow in MCAD including both 3D component array and general mesh fusion. During the component adapt, the multiple components are solved in parallel during each adaptive pass. You can select from Fully Independent adapt (the default for a Mesh Fusion project), Balanced adapt, and Fully coupled adapt. If you select Fully Independent or Balanced, you can specify that the last adaptive solve performs a Fully Coupled Solve, or if unchecked, a memory estimation.

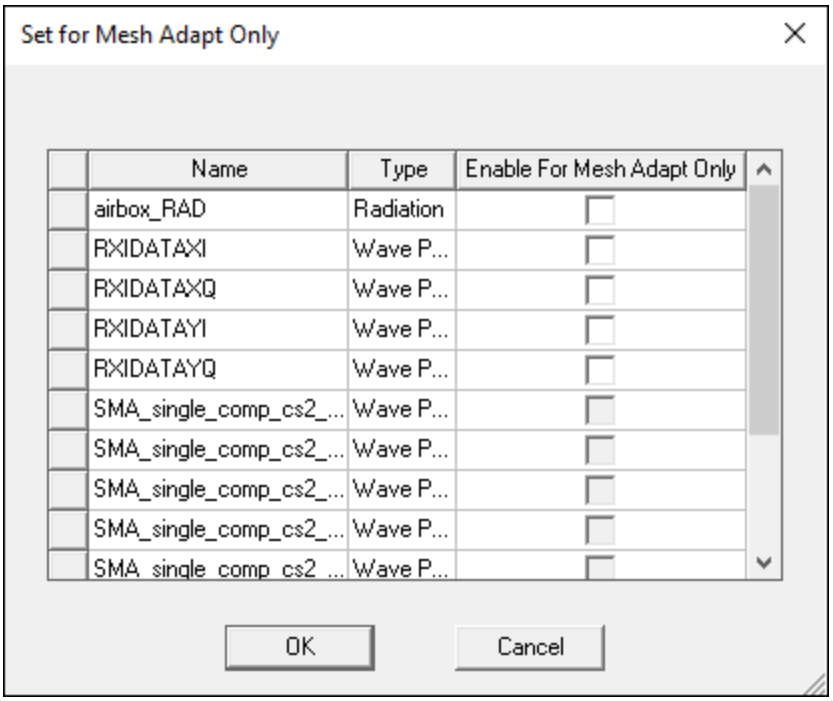
You can assign certain boundaries and ports to improve adaptive accuracy.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For example, for component without any ports, certain ports together with a PEC boundary can be added to drive the adaptive pass. These boundaries and/or ports are present during adaptive pass only and will be removed automatically during full design solve. To do so, right-click on the Excitations icon and select **Set for Mesh Adapt Only...**



This opens a dialog listing the ports/boundaries.



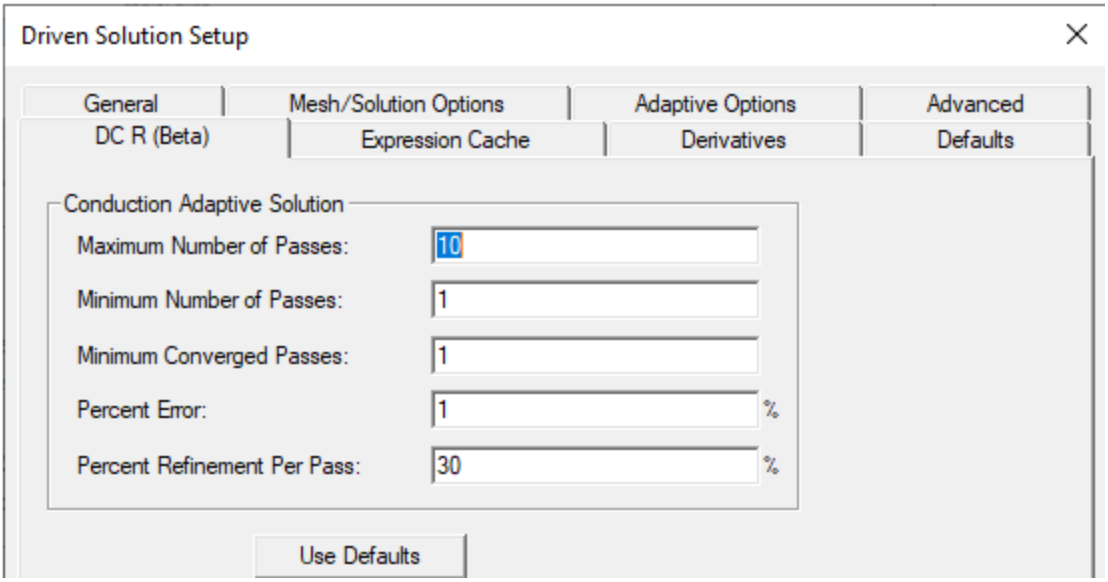
When an adapted port is present, you have an option to display s-parameter results that do or do not include adapted ports (full s-matrix or reduce s-matrix) for adaptive solves. Ports selected here do not appear in the Edit Sources

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

dialog. Because there is no LastAdaptive solution if you turn off “Perform Fully Coupled Solve at the Last Pass”, the far field plot will be blank.

DC R

The ability to Use Q3D for DC Simulation in HFSS causes an additional **DC R (Beta)** tab to appear in the **Driven Solution Setup** dialog for HFSS Network Analysis Terminal solution types.



The fields allow you to adjust the values for DC point calculation in HFSS. Also see Options for Interpolating Sweeps, and Options for Discrete Sweeps where you can select and option to **Use Q3D to Solve the DC Point**.

Expression Cache Includes a list of expressions (including post processing variables) that you can use for convergence for adaptive analysis.

Derivatives If your design contains variables, they are listed here. HFSS can calculate derivatives for your variables.

Defaults Enables you to save the current settings as the defaults for future solution setups or revert the current settings to HFSS's standard settings.

3. Click the **General** tab.
4. The **Enabled** check box on **General** tab permits to you to disable a setup so that it does not run when you select Analyze All.
5. For Driven solution types, do the following:
   a. Select whether you want to solve for Single frequency, Multi-Frequency, or Broadband, and enter the appropriate **Solution Frequency** data and select the frequency units from the pull down list.
   b. Optionally, select **Solve Ports Only**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. If you are performing an adaptive analysis, enter **2** or more passes in the **Maximum Number of Passes** box, and then specify the remaining adaptive analysis parameters for HFSS.
7. The lower right corner also contains a button for HPC and Analysis options. Here you can select or create an analysis configuration.
8. Click **OK**.
9. Optionally, add a frequency sweep to the solution setup.

Add Dependent Solve Setup

For driven setups (not Eigenmode), to apply all settings from an existing setup to a child setup:

1. Select an existing setup in the project tree.
2. Right-click the setup in the project tree, and then click **Add Dependent Solve Setup** on the shortcut menu.

A dependent setup icon appears, which has an altered graphic to distinguish it from the parent setup icon. The child setup name is "*parent_setup name*_1." All of the settings from the parent setup are copied to the child setup. The dependent setup uses the mesh from the parent setup. This is shown under the **Advanced** tab of the **Solution Setup** dialog box, **Specifying a Source** for the initial mesh. You can add a dependent setup to another dependent setup, and form of the name shows the hierarchical dependence by appending "_1" to show further dependence.

If you intend to change any of the settings, you do this just as you would for a new setup.

The **Enabled** check box on General tab permits to you to disable a setup so that it does not run when you select Analyze All. If a solve is disabled, the **Analyze** command on the shortcut menu for the Project tree is disabled and the **Enable Setup** command is available.

Renaming a Solution Setup

Do the following to rename a solution setup:

1. In the project tree, under **Analysis**, right-click the setup you want to rename.
   A shortcut menu appears.
2. Select **Rename** from the shortcut menu.
   The setup name text is highlighted in the project tree.
3. Type the new name for the setup, and press **Enter**.

You can also rename the solution setup by changing the text in the Name text box of the appropriate **Solve Setup** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Copying a Solution Setup

Solution setups may be copied and pasted within a design or across designs of the same type. This is beneficial for setups having a large number of parameters to specify, or where minor changes to a setup are being evaluated.

Do the following to copy a solution setup:

1. In the project tree, under **Analysis**, right-click the setup you want to copy.

   A shortcut menu appears.

2. Select **Copy** from the shortcut menu.

   The setup parameters are copied to the clipboard.

3. In the project tree, right-click the **Analysis folder to receive the copied setup**.

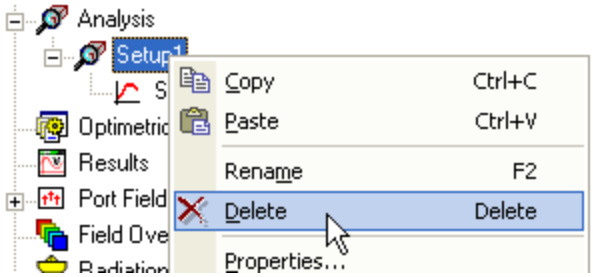
   A shortcut menu appears.

4. Select **Paste** from the shortcut menu.

   The setup parameters are copied to the **Analysis** folder as a new setup.

Deleting a Solution Setup

To delete an existing solution setup, select it in the Project tree, right-click to display the shortcut menu and select **Delete**.

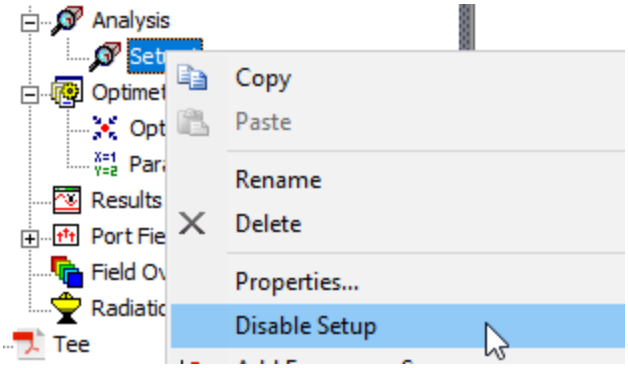


Disabling and Enabling an Analysis Setup

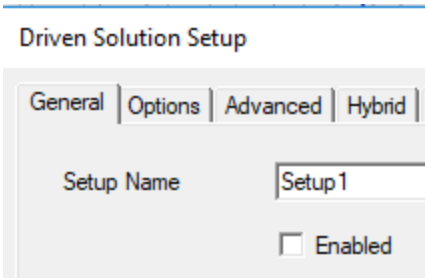
To disable an Analysis setup definition without deleting it:

1. Expand the tree hierarchy under the **Analysis** icon in the Project Manager.
2. Right-click the icon for the setup definition. In the shortcut menu that appears, click **Disable Setup**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can also disable an analysis setup by selecting **Properties** from the shortcut menu to open the **Edit Properties** window. In the upper right corner of the **Edit Properties** window, uncheck the **Enabled** box. Then click **OK**.



To reactivate the analysis setup, open the shortcut menu again and select **Enable Setup**.

You can also reactivate the analysis setup by selecting **Properties** from the shortcut menu for the sweep to open the **Edit Properties** window. Check the **Enabled** box in the upper right corner, and click OK to apply the change and close the window.

Setting the Solution Frequency

For Driven solution types.

For every Driven solution setup, specify whether to solve a **Single Frequency**, **Multi-Frequency**, or **Broadband**, and provide the **frequency** information and units at which to generate the solution. Each method changes the fields shown in the dialog to those needed for the selection. If you enable HPC, multiple frequencies will be distributed.

If a single frequency sweep is solved, an adaptive analysis is performed only at the solution frequency. If you want to solve over a range of frequencies, define a frequency sweep or a Mult-Frequency or Broadband solve. You must first assign an excitation for the Mult-Frequencies and Broadband options to appear on the setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In multiple frequencies solve, port adapt is at the highest frequency and lambda refine is based on an algorithm that uses the highest and lowest user frequencies to allow maximum reuse of solved data. The lambda refinement frequency is the "nominal frequency". The mesh at each pass is solved at multiple frequencies and energy error from all frequencies points are used to drive the mesh refinement for the next pass. The adaptive solution is converged when the simulation reaches the maximum number of passes or when all frequency points reach the targeted maximum delta S. The minimum converged passes and minimum number of passed parameters apply as the total requested passes.

Single Frequency

If you select Single for solution frequency, you specify a value and units with a maximum delta S (or Matrix Convergence), plus the maximum number of passes.

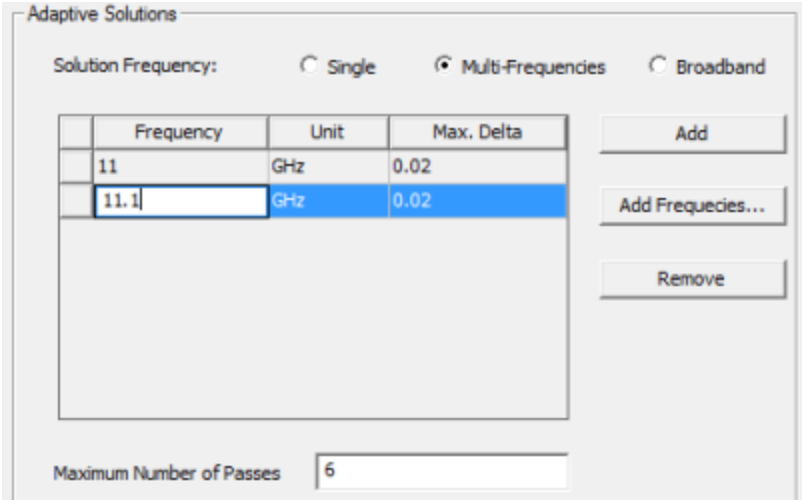
- Enter a value for **Solution Frequency** and select the frequency units from the pull down list.
- Specify the **Maximum Number of Passes** and Maximum Delta Energy.

> **Note:**
>
> For Fast sweeps, HFSS uses the solution frequency as the center frequency if it is within the frequency range (greater than the start frequency and less than the stop frequency.) Otherwise the middle of the frequency range is used as the center frequency.

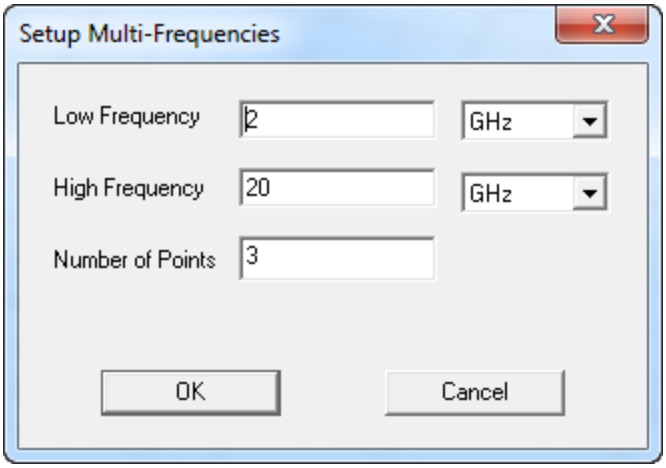
Multi-Frequency

If you select **Multi-Frequencies**, you can click **Add** to add additional frequencies, and edit the value, units, and Max. Delta for each frequency.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can use the **Add** button to specify one frequency at a time or click **Add Frequencies…** to use the **Setup Multi-Frequencies** dialog to populate a range of frequencies. The frequencies added by the Setup Multi-Frequencies matches the first batch of frequencies solved in an interpolating sweep



When you OK the dialog box, rows for the frequencies across the number of points appear in the **Solution Setup** dialog.

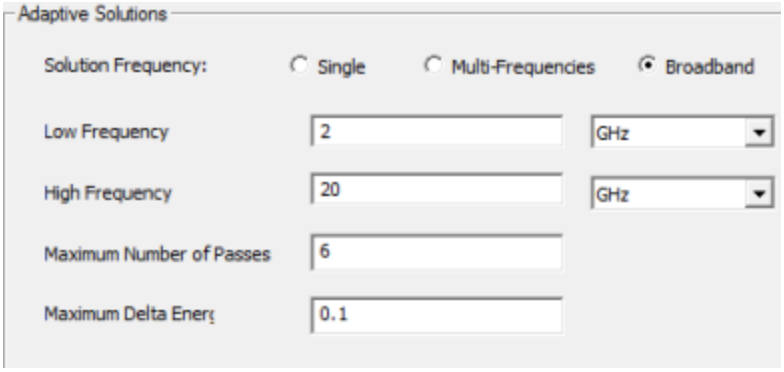
You can use **Remove** to remove any selected items in the Frequency Sweeps table.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

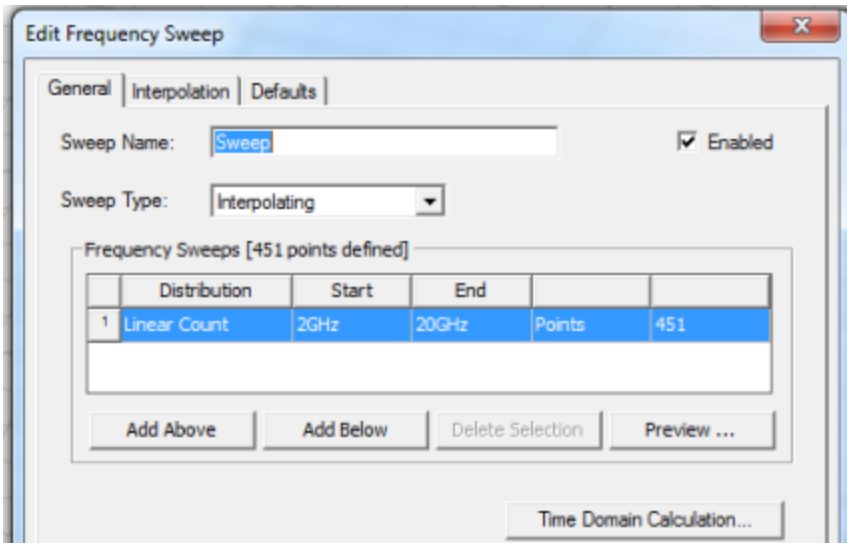
> **Note:**
>
> If you want to create a Frequency animation of field results, you must specify the frequencies here in the Multi-Frequency **Solution** setup.

Broadband

If you select Broadband, you define the frequency band by providing the low and high frequency, with a maximum delta S (that is applied to all solved frequencies), plus the maximum number of passes. The meshing frequencies include the Low and High with the remaining points determined automatically by HFSS. When the user requests DC as the low frequency, the lowest frequency solved by the adaptive meshing process is determined by an algorithm that looks at the range of frequencies you entered.



When you OK the Solution Setup for Broadband, you are automatically presented with a dialog for specifying an Interpolating sweep.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Simulation and Convergence

In multiple frequencies modes, when frequency point p convergences prior to frequency point q, keep adapting at p until q and all other points achieve convergence.

The convergence data in the solution data dialog for single frequency mode is calculated in the same way as before. In multiple frequencies mode, the convergence plotted on the convergence display item corresponds to the global maximum delta S. Convergence data such as “Max. Delta S” appear in the reporter as standard solution quantity so that you can easily plot the maximum delta S for each frequency point vs. pass.

Solution Reporting

For multiple frequencies adapted solutions, the S-Matrix solution display let you to view matrix data across different frequencies of its AdaptivePass and LastAdaptive solutions.

In “Broadband” mode, the nominal frequency is solved and its results are available for all post processing, Optimetrics and expression cache setup. In this mode, results of other solved frequencies will be shown in the S-Matrix solution display but will not be available in reporter, Optimetrics and expression cache setup. In “Muti-Frequencies” mode, all post postings of the AdaptivePass and LastAdaptive will be extended to support results at all user-specified frequencies. Creating a report with solution across multiple frequencies will be the same as creating such report with a sweep solution.

Solving for Ports Only

For Driven solution types with ports.

To quickly compute only the 2D excitation field patterns, impedances, and propagation constants at each port:

- Under the **General** tab of the **Solution Setup** dialog box, select **Solve Ports Only**.

This disables the remaining settings for **Maximum number of passes** and **Convergence per pass**.

HFSS calculates the natural field patterns (or modes) that can exist inside a transmission structure with the same cross-section as the port. These 2D field patterns serve as boundary conditions for the full 3D problem.

Setting the Minimum Frequency

For Eigenmode solution types.

For every Eigenmode solution setup, specify the minimum f**requency** at which to search for eigenmodes. HFSS searches for the user-specified number of modes with a higher resonant frequency than the **Minimum Frequency value**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Under the **General** tab of the **Solution Setup** dialog box, type a **Minimum Frequency** and the frequency units.
- You can set the Minimum frequency as a variable by typing a name in the field and pressing Enter. This displays the **Add Variable** dialog for you to enter the value and units. Click OK to close the dialog box. The variable is listed in the Setup and in the Design Properties.

> **Warning:**
>
> Because the minimum frequency is used to normalize some matrices, if the frequency is set too low, HFSS tries to solve a nearly singular matrix, which may erode the accuracy of the calculations. As a general rule, do not enter a frequency less than 0.01 times the suggested, or default, value for **Minimum Frequency**.

Setting the Number of Modes

For Eigenmode solution types.

For every Eigenmode solution setup, specify the number of eigenmode solutions that the solver finds. If you enter **5**, the solver calculates the first 5 eigenmode solutions above the minimum frequency.

The Eigenmode solver can find up to 20 eigenmode solutions.

- Under the **General** tab of the **Solution Setup** dialog box, enter a value for **Number of Modes**.

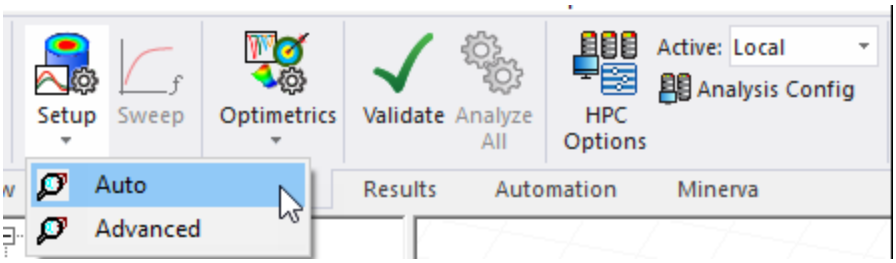
Adding a Solution Setup to an HFSS with Hybrid and Arrays Design

If you have an existing setup an HFSS with Hybrid and Arrays solution type, you can **Copy** and **Paste** it, and then edit parameters. If you have already created a solution and you want to use an existing mesh, you can click **Add Dependent Solve Setup**. To add a new solution setup to a design:

1. Select a design in the project tree.
2. Click **HFSS** > **Analysis Setup** > **Add Solution Setup**, or right-click **Analysis** in the project tree, and then click **Add Solution Setup** on the shortcut menu, or select the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Simulation tab on the ribbon, and click the **Setup** icon:

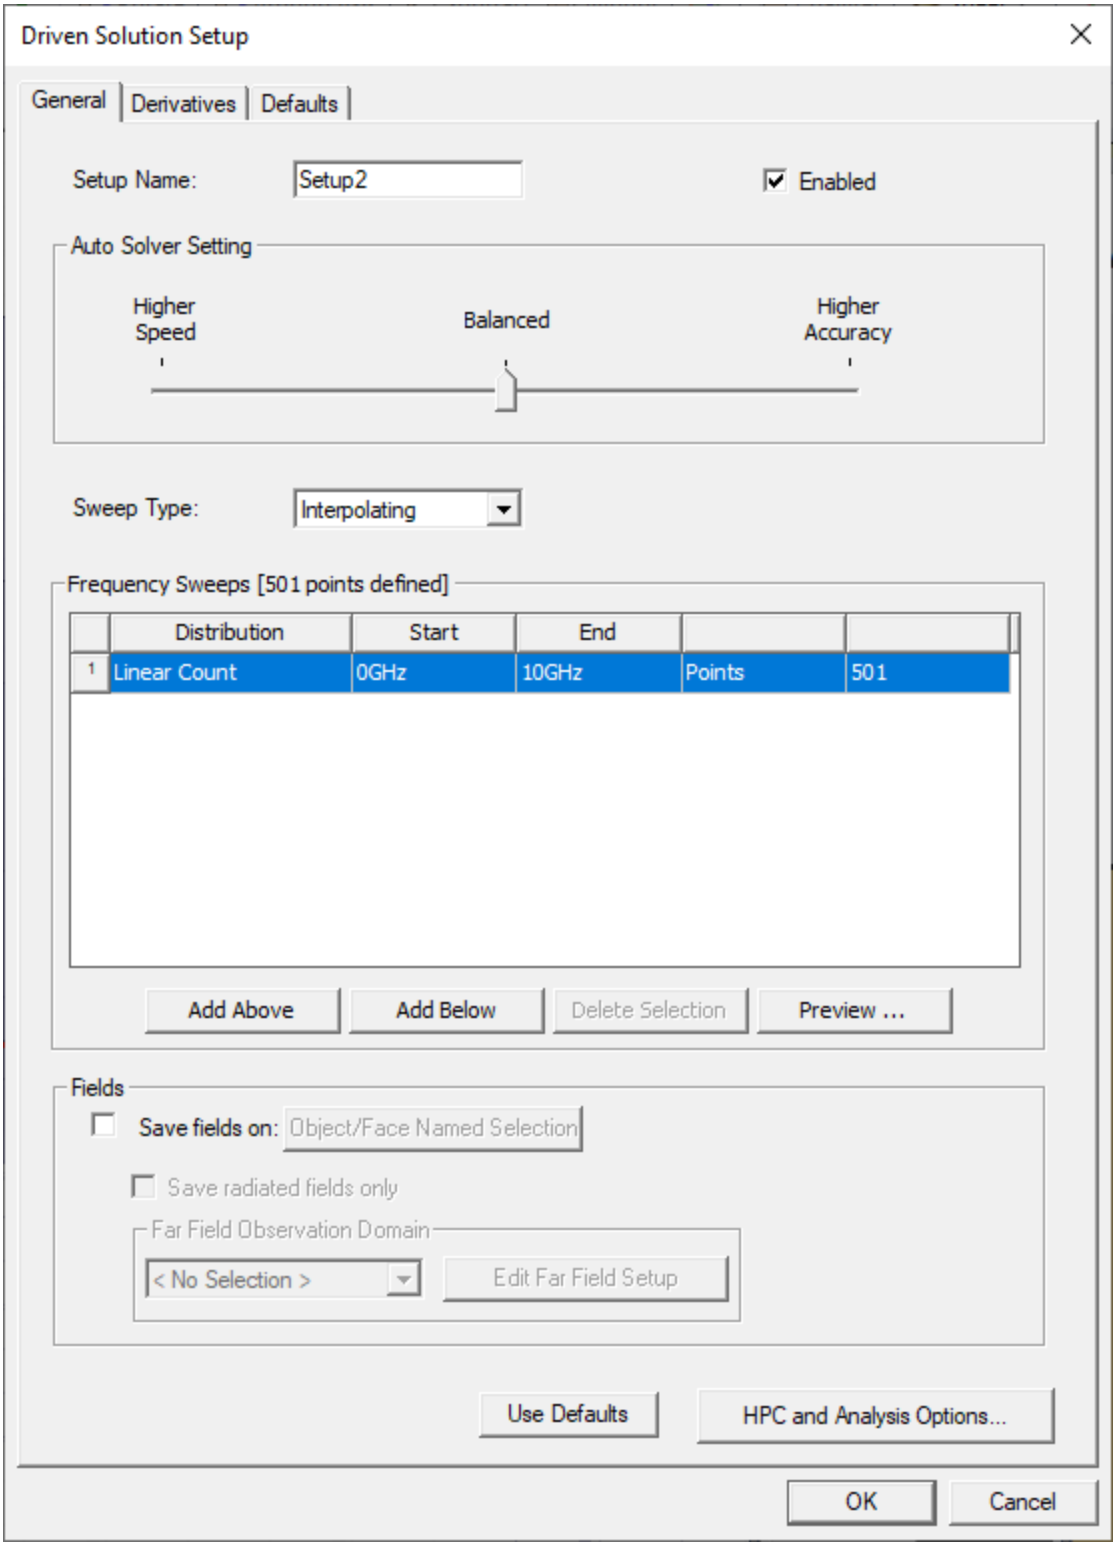


For HFSS with Hybrid and Arrays solutions, you can choose **Auto** or **"Advanced Solution Setup" on page 16-27**.

Auto Solution Setup

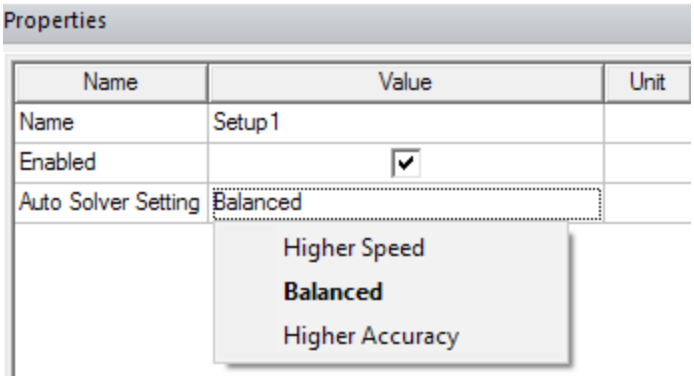
In order to use Auto setup, "Use Automatic Settings" under Analysis Configuration must be checked. **Auto** features a simplified dialog with a slider bar that you can adjust from Higher Speed (which sacrifices accuracy to achieve optimum speed), to Balanced (which is more accurate but faster than the highest accuracy setting) to Higher Accuracy (which takes the time to ensure optimal accuracy). These settings also apply to any FEBI or IE Regions that use the IE Solver in a design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



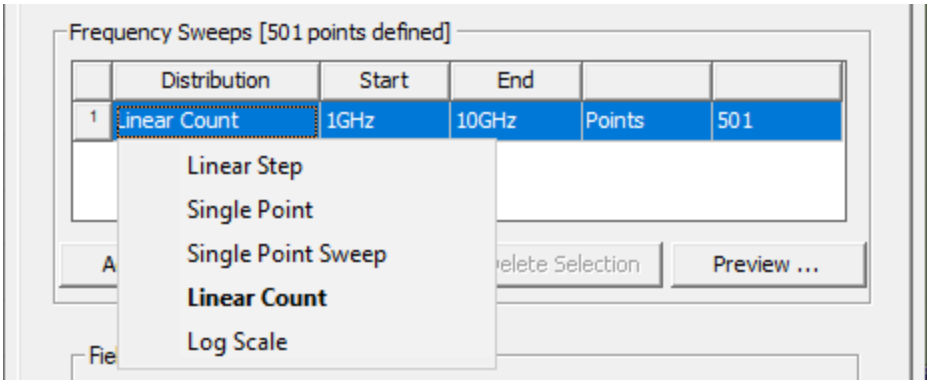
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Properties for the Auto Solver Setting includes the same choices.



The Auto setup includes a single sweep, for which you can edit the Distribution, Start, and End. If the design does not include a port, the sweep type can only be Discrete. If one or port ports exist, the sweep can be Interpolating or Discrete.

- You specify sweeps in terms of Distribution type, which can be Linear Step, Linear Count, Log Scale, Single Point , or Single Point Sweep, which adds a set of 10 Single Point Sweeps, defaulting from 1 GHz to 10 GHz in increments.. The **Add Above**, and **Add Below** buttons permit you to add additional sweeps, including mixed sweep types. This feature provides flexibility. For example, you can define sweeps with log scale at lower frequencies, and linear step at higher frequencies.



If you add more sweeps, you can **Delete** a selected distribution.

The **Preview** button displays the sweep(s) as currently defined.

The **Auto** setup includes tabs for **General**, **Derivatives**, and **Defaults**.

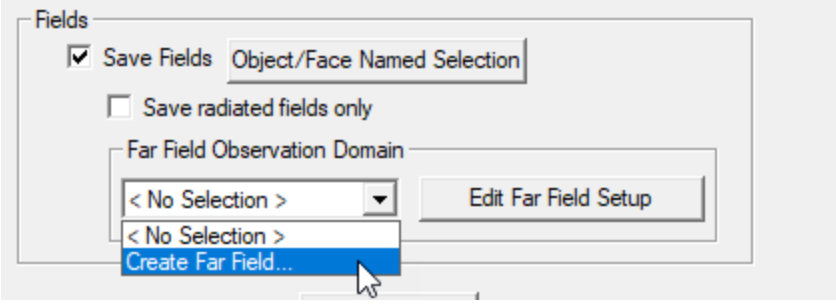
General Includes general solution settings. You can specify the name, change the slider bar to do different solver settings, choose sweep type, set frequency range, choose **Save Fields** and **Save radiated fields only** options, (required if you intend to Plot Field

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Overlays) and do **HPC** settings.

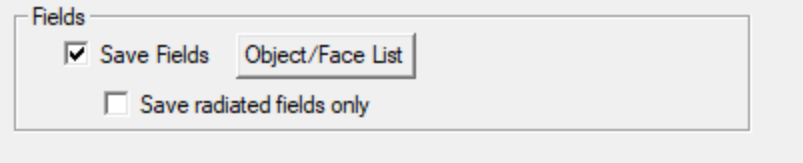
Includes settings for mesh linking, mesh assembly for designs that include 3D components, absorbing boundaries on ports, wave port adapt options, and whether to **Save Fields** and **Save radiated fields only**. You must save fields if you intend to plot or post process fields.

For HFSS solutions without Hybrid Regions, the Fields area contains a Far Field Observation Domain area that allows you to specify a Far Field sphere or edit an existing setup. To evaluate radiated fields in the far-field region, you must check Saved Fields in the solution and sweep setups, and set up an infinite sphere that surrounds the radiating object. You can set up the infinite sphere by selecting **Create Far Field...** from the menu. For the procedure, see Setting up a Far Field Infinite Sphere.



If you do so, fields are generated during the solve and for any dependent frequency sweeps, and written as .ffd files rather than as a post processing step. After the simulation, editing or deleting the selected far field setup invalidates the last adaptive solution of the driven setup as well as its dependent sweep's solution.

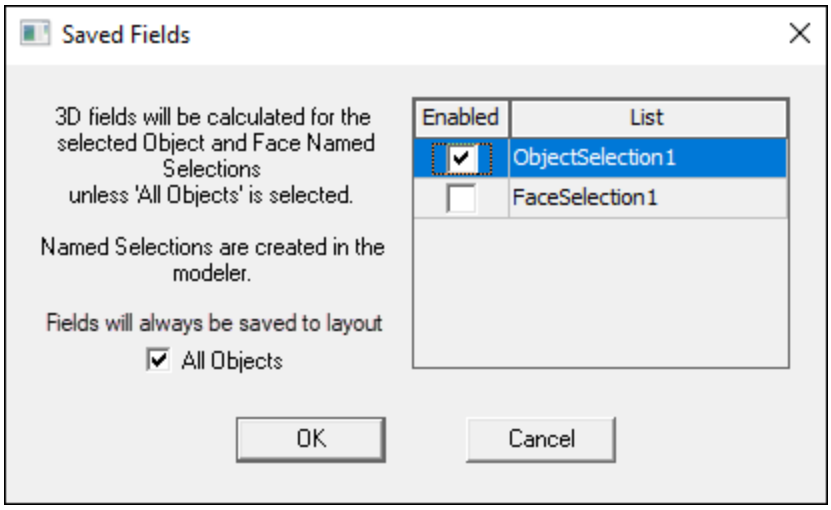
If an HFSS with Hybrid and Arrays project contains an SBR+ Hybrid Region, the Fields area does not contain the Fields Observation Domain area.



For very large designs, especially for finite array designs, saving fields can potentially result in very large files. In such cases, you can use the **Object/Face Named Selection** button to open a **Saved Fields** dialog box to choose from object or face selections

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

you have predefined. You would then save 3D fields only on certain objects or faces, which could save disk space. The default is All Objects.



The selection in the solve setup will dictate the behavior of the frequency sweep solve. Changing the selected lists will invalidate the last adaptive solution. If you subsequently create a Near Field or Far Field Radiation setup and select a list there, you receive a warning if your selections do not match those selected for the solve.

For very large designs, especially for finite array designs, this can potentially result in very large files. In such cases, you can use the **Object/Face Named Selection** button to select from object or face selections you have predefined. You would then save 3D fields only on certain objects or faces, which could save disk space.

The selection in the solve setup will dictate the behavior of the frequency sweep solve. Changing the selected lists will invalidate the last adaptive solution. If you subsequently create a Near Field or Far Field Radiation setup and select a list there, you receive a warning if your selections do not match those selected for the solve.

Derivatives If your design contains variables, they are listed here. HFSS can calculate derivatives for your variables.

Defaults Enables you to save the current settings as the defaults for future solution setups or revert the current settings to HFSS's standard settings.

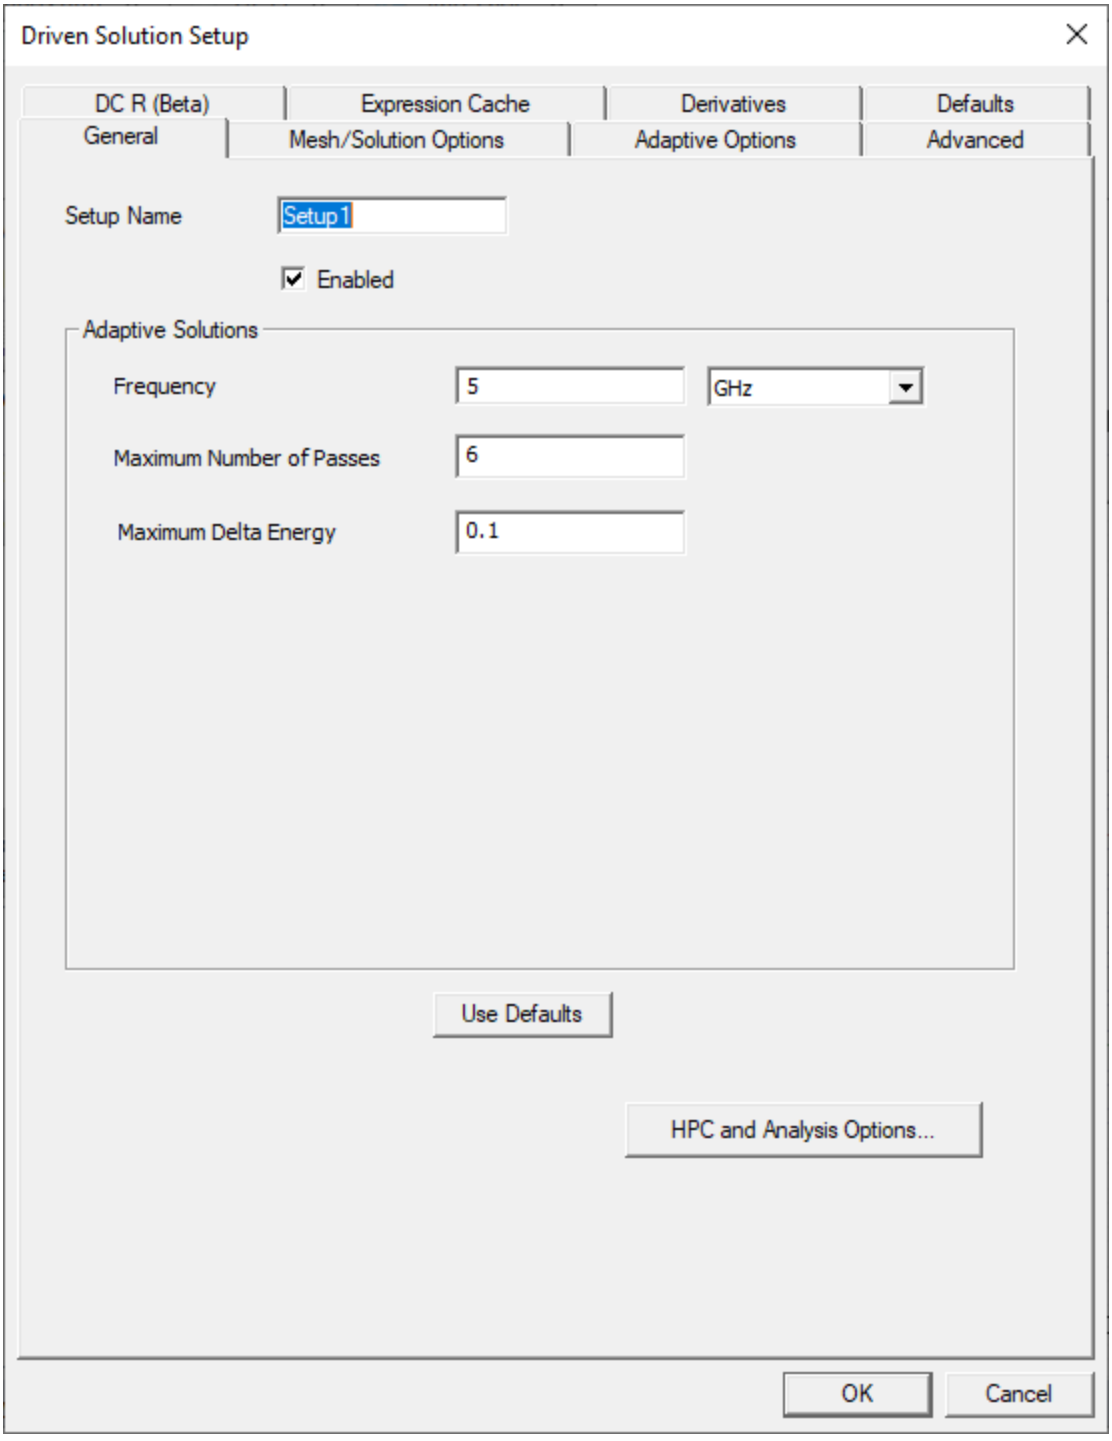
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Advanced Solution Setup

The Advanced Solution Setup lets you have more control over the settings, and provides more options. For all HFSS solution types, if you choose **Advanced**, the **Solution Setup** dialog box appears. The appearance differs depending on the Solution Type. For example for

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Driven Solution Terminal Types, the DC R (Beta) tab also appears.



It is divided among the following tabs:

General Includes general solution settings, including frequency and S-parameter

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

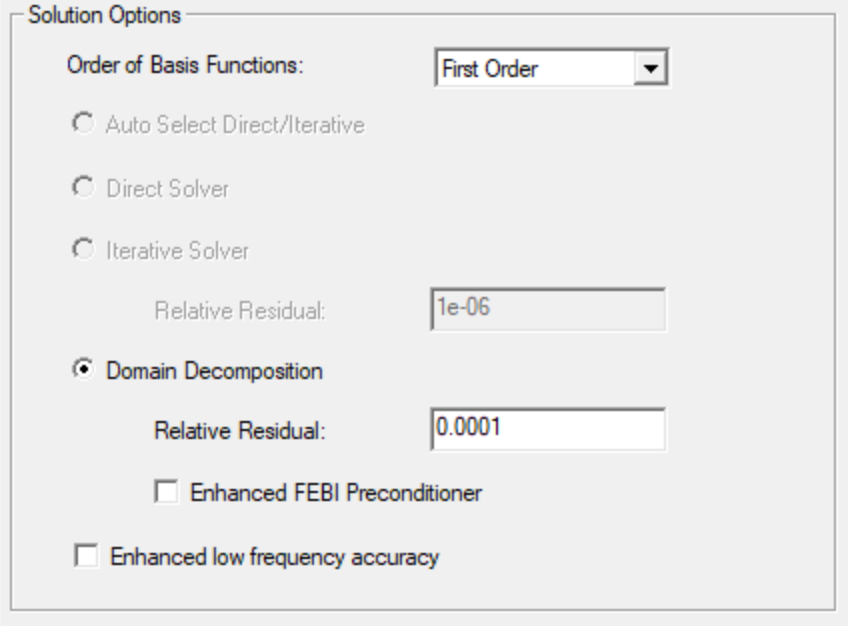
settings.

Mesh/Solution Options

Includes settings for lambda refinement, adaptive analysis and solution options, the Order of Basis setting, whether to use the direct solver or iterative solver, whether to enable the use of solver domains, if available for the solution type, and for designs that contain only lumped ports as sources, or a combination of lumped and circuit ports, whether to use **Enhanced low frequency accuracy**.

In those cases, when you enable **Enhanced low frequency accuracy** the solver is tuned to reliably solve low frequencies. In addition, for designs with only lumped ports and/or circuit ports, interpolating sweeps are tuned to solve more low frequency points in order to accurately represent very low frequency results.

In the case of a design that includes a 3D Component Array and a FE-BI Hybrid Region, the **Mesh/Solution** options includes an option to select **Enhanced FEBI Preconditioner**.



When an HFSS 3D Component Array design has a FEBI region, the setup only allows you to select the Domain Decomposition solver. The **Enhanced FEBI Preconditioner** allows you to achieve faster simulation speed for most cases, at the cost of more memory.

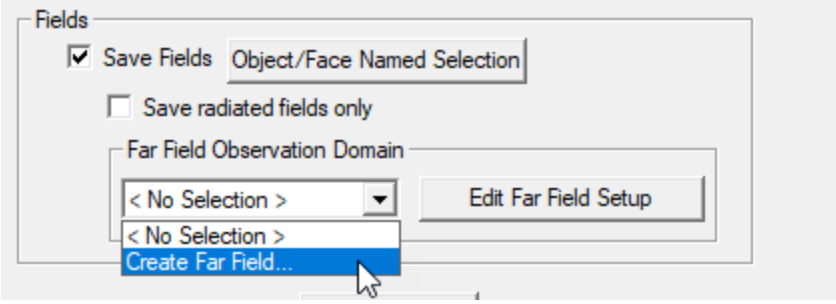
Advanced

Includes settings for mesh linking, mesh assembly for designs that include 3D components, absorbing boundaries on ports, wave port adapt options, and whether to **Save Fields** and **Save radiated fields only**. You must save fields if you intend to plot or post process fields.

For HFSS with Hybrid and Arrays solutions that do not contain SBR+ Hybrid

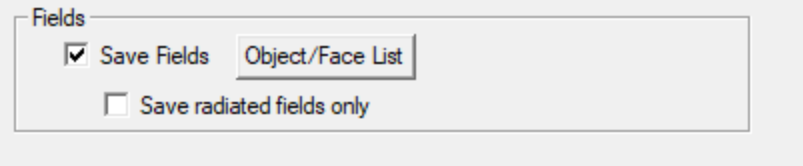
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Regions, the Fields area contains a Fields Observation Domain area that allows you to specify a Far Field sphere or edit an existing setup. If you do so, fields are generated during the solve,



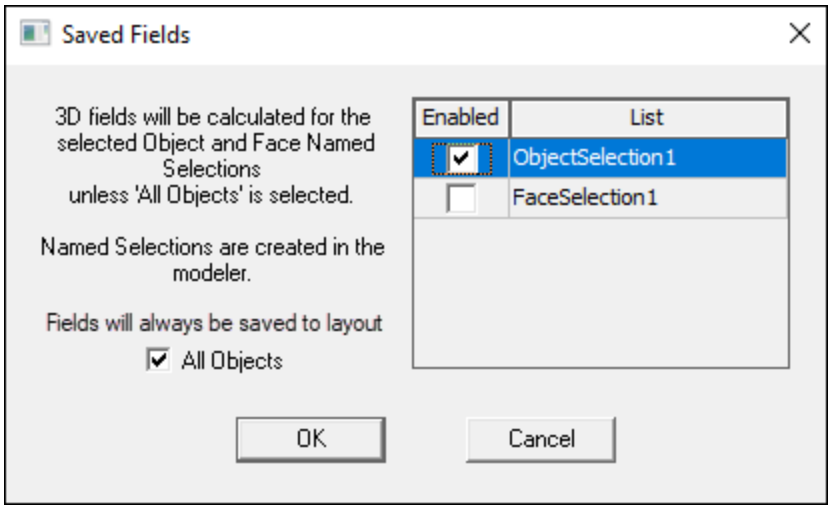
If you do so, fields are generated during the solve and for any dependent frequency sweeps, and written as .ffd files rather than as a post processing step. After the simulation, editing or deleting the selected far field setup invalidates the last adaptive solution of the driven setup as well as its dependent sweep's solution.

If an HFSS project contains an SBR+ Hybrid Region, the Fields area does not contain the Fields Observation Domain area.



For very large designs, especially for finite array designs, saving fields can potentially result in very large files. In such cases, you can use the **Object/Face Named Selection** button to open a **Saved Fields** dialog box to choose from object or face selections you have predefined. You would then save 3D fields only on certain objects or faces, which could save disk space. The default is All Objects.

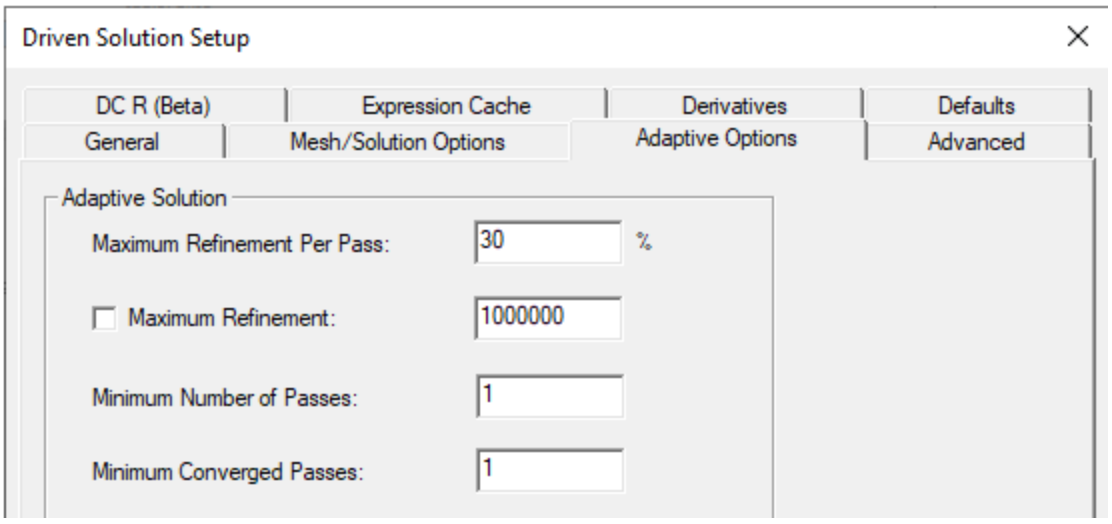
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The selection in the solve setup will dictate the behavior of the frequency sweep solve. Changing the selected lists will invalidate the last adaptive solution. If you subsequently create a Near Field or Far Field Radiation setup and select a list there, you receive a warning if your selections do not match those selected for the solve.

Adaptive Options

The Adaptive Options include Maximum Refinement per pass, Maximum Refinement, and Minimum Number of Passes, and Minimum Converged Passes.



Maximum Refinement Per Pass

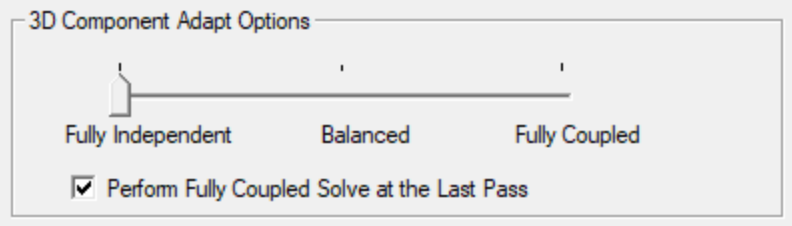
Maximum Refinement

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Minimum Number of Passes

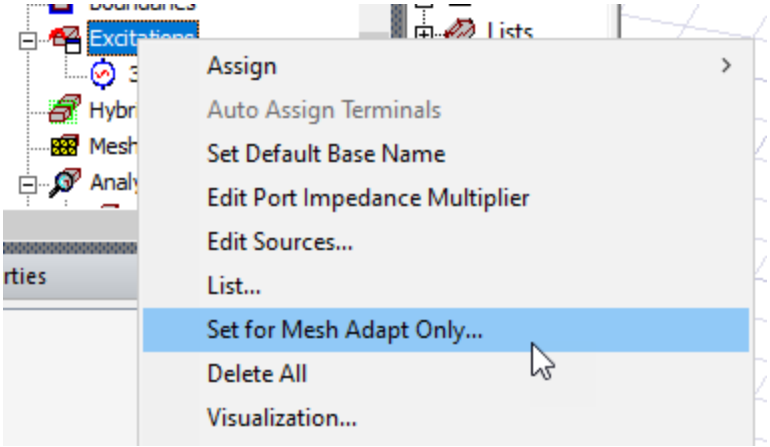
Minimum Number of Converged Passes

If you have set the Beta Option for Parallel Component Mesh Adapt, and the design contains 3D components, the **Adaptive Options** tab also lets you select 3D Component Adapt Options.



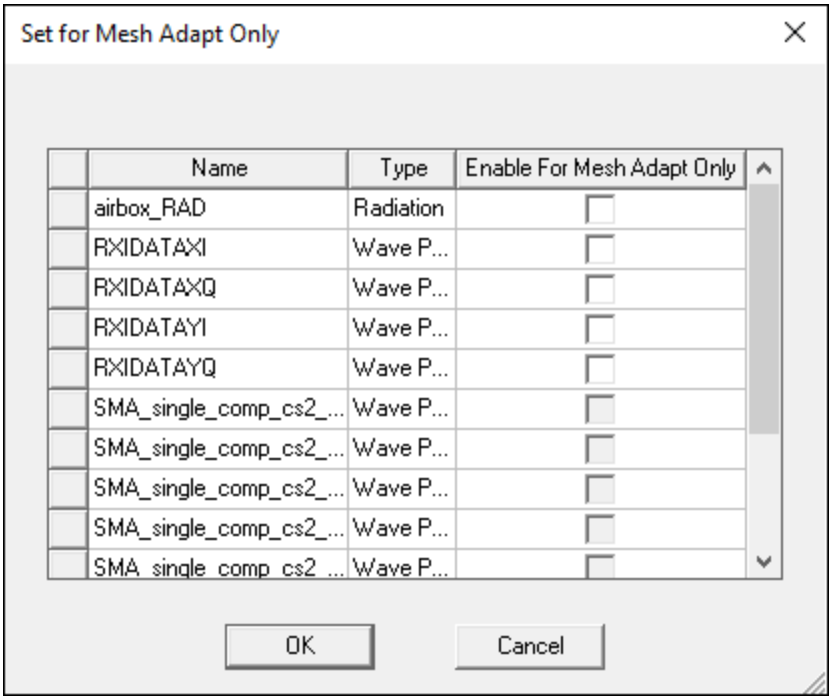
Parallel component adapt for mesh fusion workflow in MCAD including both 3D component array and general mesh fusion. During the component adapt, the multiple components are solved in parallel during each adaptive pass. You can select from Fully Independent adapt (the default for a Mesh Fusion project), Balanced adapt, and Fully coupled adapt. If you select Fully Independent or Balanced, you can specify that the last adaptive solve performs a Fully Coupled Solve, or if unchecked, a memory estimation.

You can assign certain boundaries and ports to improve adaptive accuracy. For example, for component without any ports, certain ports together with a PEC boundary can be added to drive the adaptive pass. These boundaries and/or ports are present during adaptive pass only and will be removed automatically during full design solve. To do so, right-click on the Excitations icon and select **Set for Mesh Adapt Only...**



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This opens a dialog listing the ports/boundaries.

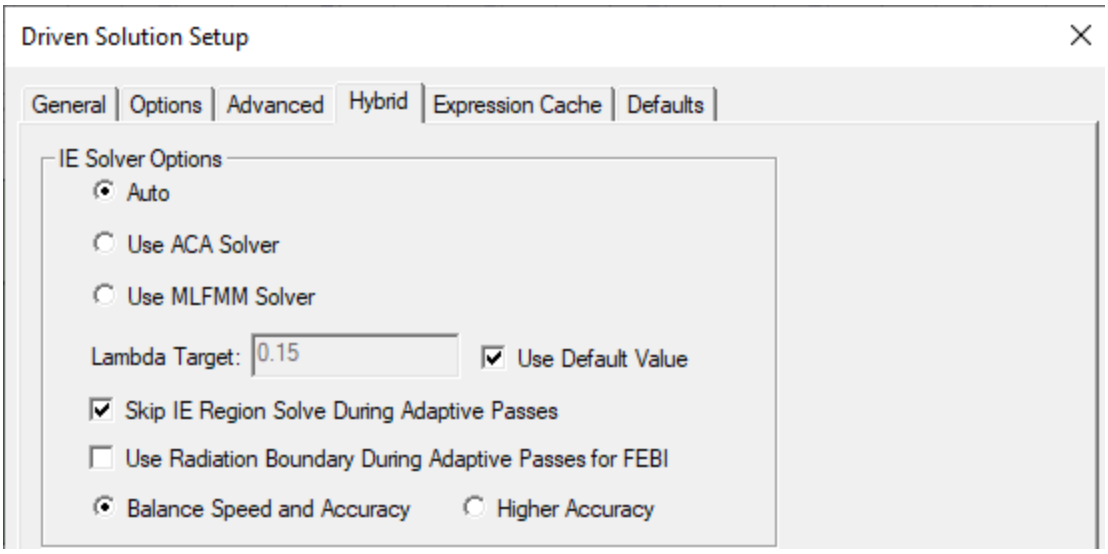


When an adapted port is present, you have an option to display s-parameter results that do or do not include adapted ports (full s-matrix or reduce s-matrix) for adaptive solves. Ports selected here do not appear in the Edit Sources dialog. Because there is no LastAdaptive solution if you turn off “Perform Fully Coupled Solve at the Last Pass”, the far field plot will be blank.

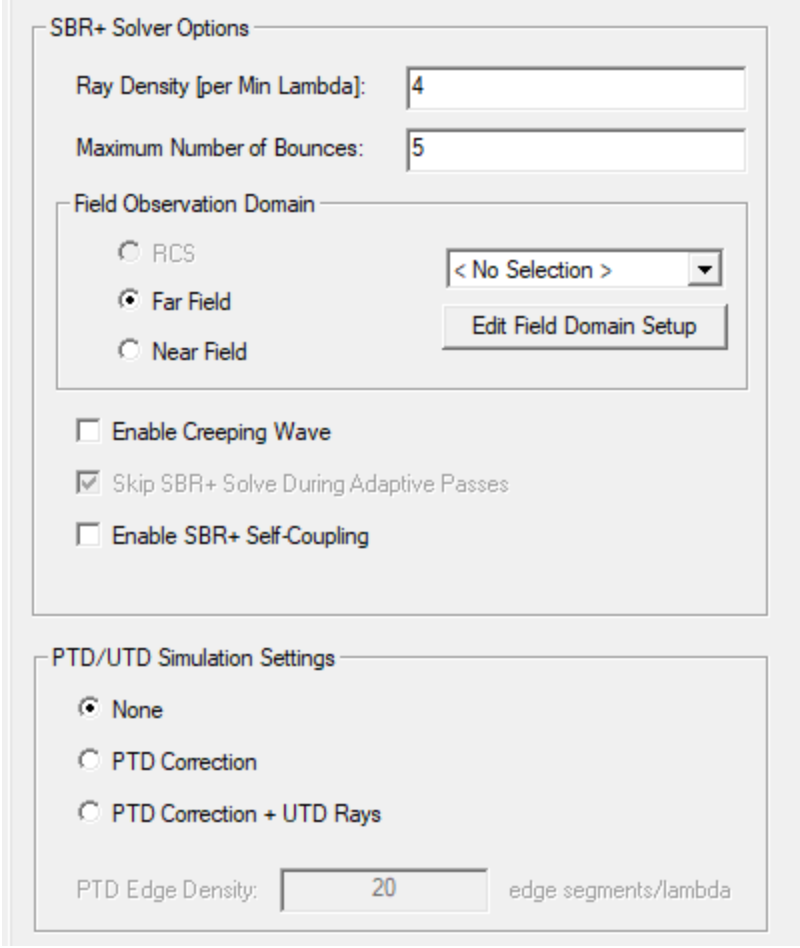
Hybrid

If the design includes Hybrid regions, this tab for Setting Hybrid Parameters for HFSS.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If SBR+ Regions are present, you can set SBR+ Solver Options.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

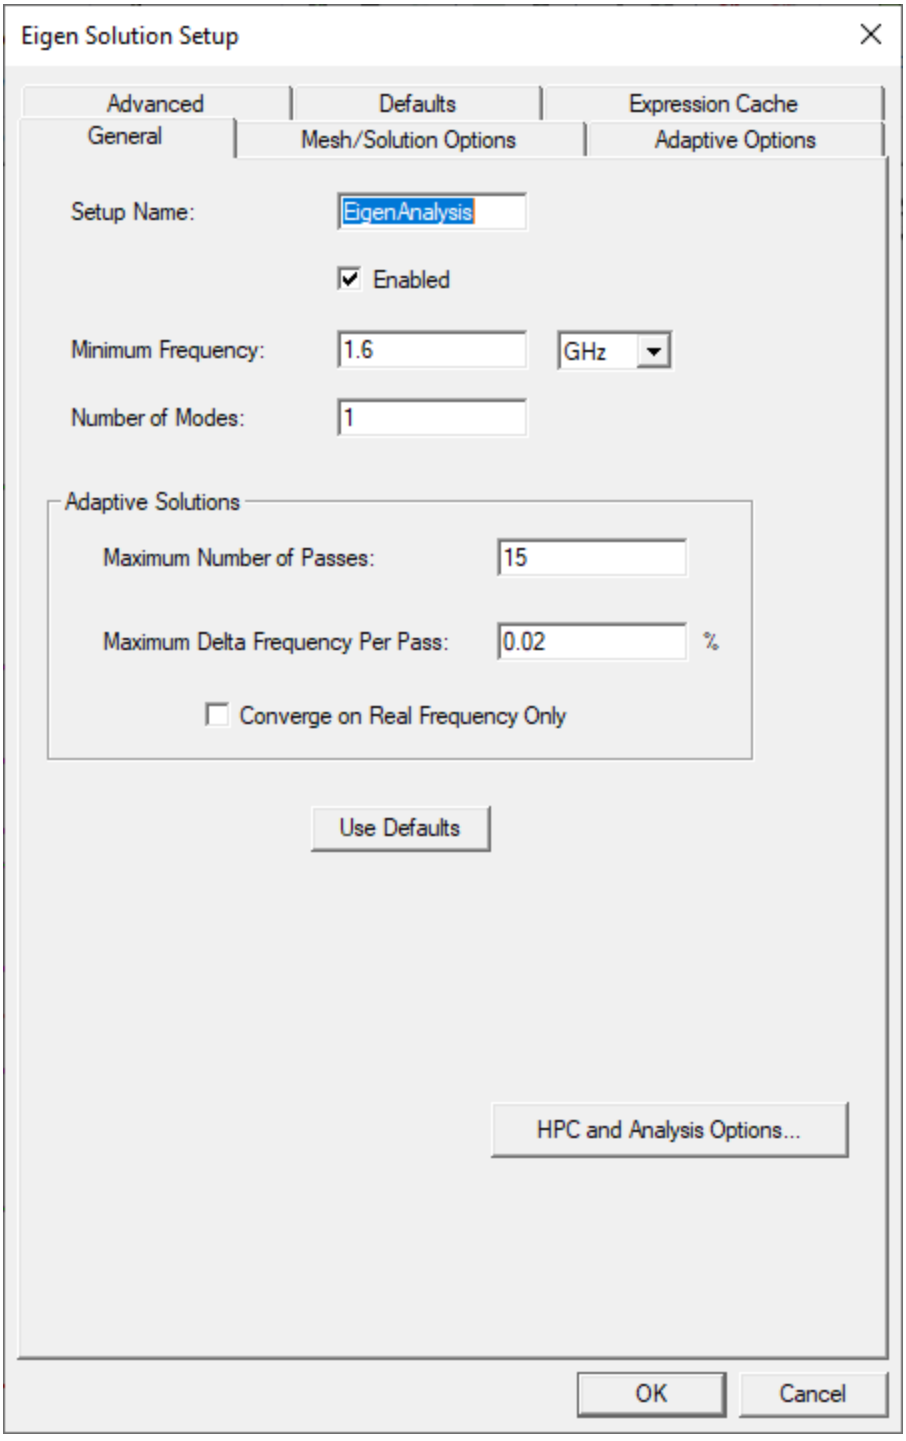
Expression Cache	Includes a list of expressions (including post processing variables) that you can use for convergence for adaptive analysis.
Derivatives	If your design contains variables, they are listed here. HFSS can calculate derivatives for your variables.
Defaults	Enables you to save the current settings as the defaults for future solution setups or revert the current settings to HFSS's standard settings.

3. Click the **General** tab.
4. The **Enabled** check box on **General** tab permits to you to disable a setup so that it does not run when you select Analyze All.
5. For Driven solution types, do the following:
    a. Select whether you want to solve for Single frequency, Multi-Frequency, or Broadband, and enter the appropriate **Solution Frequency** data and select the frequency units from the pull down list.
    b. Optionally, select **Solve Ports Only**.
7. The lower right corner also contains a button for HPC and Analysis options. Here you can select or create an analysis configuration.
8. Click **OK**.
9. Optionally, add a frequency sweep to the solution setup.

Adding an Eigenmode Solution Setup

For calculating the eigenmodes, or resonances, of a structure. The Eigenmode solver finds the resonant frequencies of the structure and the fields at those resonant frequencies. Eigenmode designs cannot contain design parameters that depend on frequency, for example a frequency-dependent impedance boundary condition. For an Eigenmode Solution Type, **HFSS>Analysis Setup>Add Solution Setup...** or right-click on **Analysis** in the Project tree, and select **Add Solution Setup...** from the shortcut menu displays the following dialog:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For Eigenmode solution types, do the following:

a. Enter the **Minimum Frequency** and the frequency units.
b. Enter the **Number of Modes**. The number must be greater than 0 and less than 20.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you are performing an adaptive analysis, enter **2** or more passes in the **Maximum Number of Passes** box, and then specify the remaining adaptive analysis parameters for HFSS.

For Eigenmode solutions, if you are not performing an adaptive analysis, entering **0** will enable you to bypass the adaptive analysis process and just perform a frequency sweep. For driven problems HFSS always requires at least one adaptive pass. Entering **1** will also bypass adaptive analysis, generating a solution only at the solution frequency you specified.

You can check Converge on Real Frequency Only.

The lower right corner also contains a button for HPC and Analysis options. Here you can select or create an analysis configuration.

The **Adaptive Options** tab includes adaptive analysis settings.

- Maximum Refinement Per Pass
- Maximum Refinement
- Minimum Number of Passes
- Minimum Number of Converged Passes

The **Mesh/Solution Options** tab contains the following options: Mesh settings for lambda refinement options, the Order of Basis setting.

The **Advanced** tab contains settings for mesh linking, and whether to **Save Fields** and **Save radiated fields only**. You must save fields if you intend to plot or post process fields.

Adaptive Meshing Methods In HFSS

The adaptive mesh refinement feature in HFSS automatically generates accurate and reliable solutions and lets you focus on setting up your design efficiently instead of spending time in determining and creating the best mesh. The Solution Frequency setup offers the flexibility of adapting the mesh at various frequencies for your design. HFSS offers three Solution Frequency setups for generating adapted meshes:

- Single
- Broadband
- Multi-Frequencies.

> **Note:**
>
> The Single Solution Frequency setup is applicable for all solution types. Broadband and Multi-Frequencies are applicable for modal and terminal solutions only.

Based on the solution frequency setup and the convergence criteria HFSS automatically creates a suitable mesh for your design and generates accurate solutions. Once the final mesh is

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

generated, HFSS also creates a solution across a frequency range of interest provided you defined a frequency sweep.

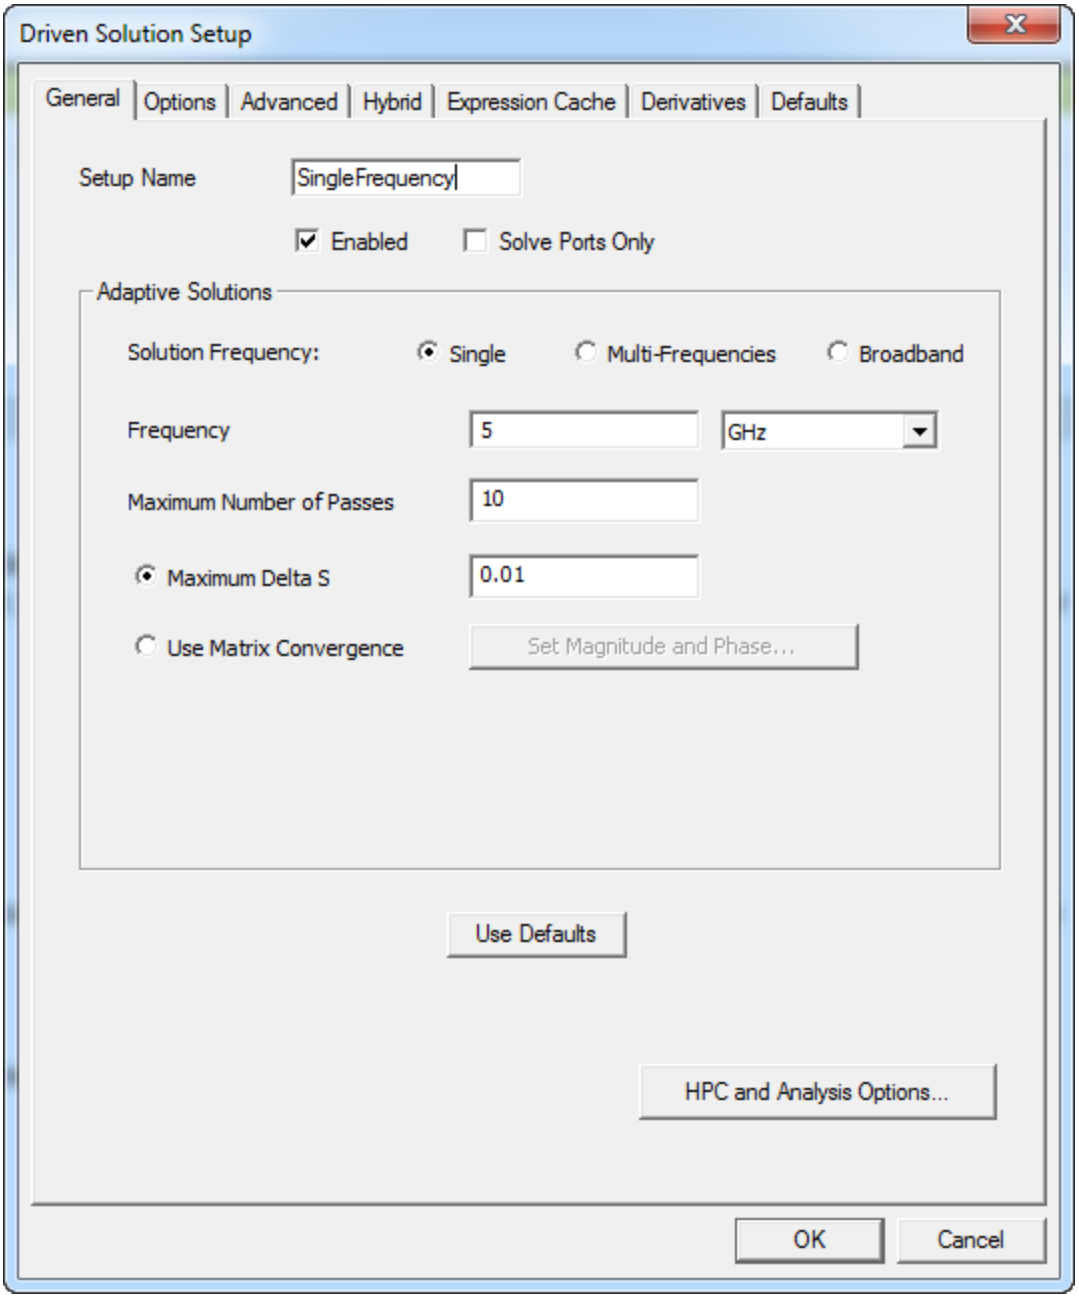
Single Solution Frequency

If you define the Single frequency setup HFSS performs adaptive mesh refinement at that frequency for your design until the convergence criterion is satisfied. The most common convergence criterion is determined by the difference in the S-parameter value between two consecutive solves known as **Maximum Delta S**, which should be less than the specified magnitude. Once the solution converges, the final mesh is used to evaluate the electromagnetic characteristics of the design. If you define a frequency sweep, solution data is generated across this range of frequencies.

To specify the Single Solution Frequency setup, perform these steps:

1. Right-click **Analysis** in the project tree and select **Add Solution Setup**.
2. Select **Single** as the **Solution Frequency**.
3. Specify the **Maximum Number of Passes** and the **Maximum Delta S**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Broadband Frequency

For most problems, specifying the Single solution frequency setup is adequate to obtain accurate results. If you desire increased reliability for broadband devices and more accurate solutions, you can specify the **Broadband** option for the Solution Frequency setup. The Broadband setup enables HFSS to intelligently determine the appropriate frequencies at which to adapt the mesh. The virtue of automatic broadband adaptive meshing lies in eliminating

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

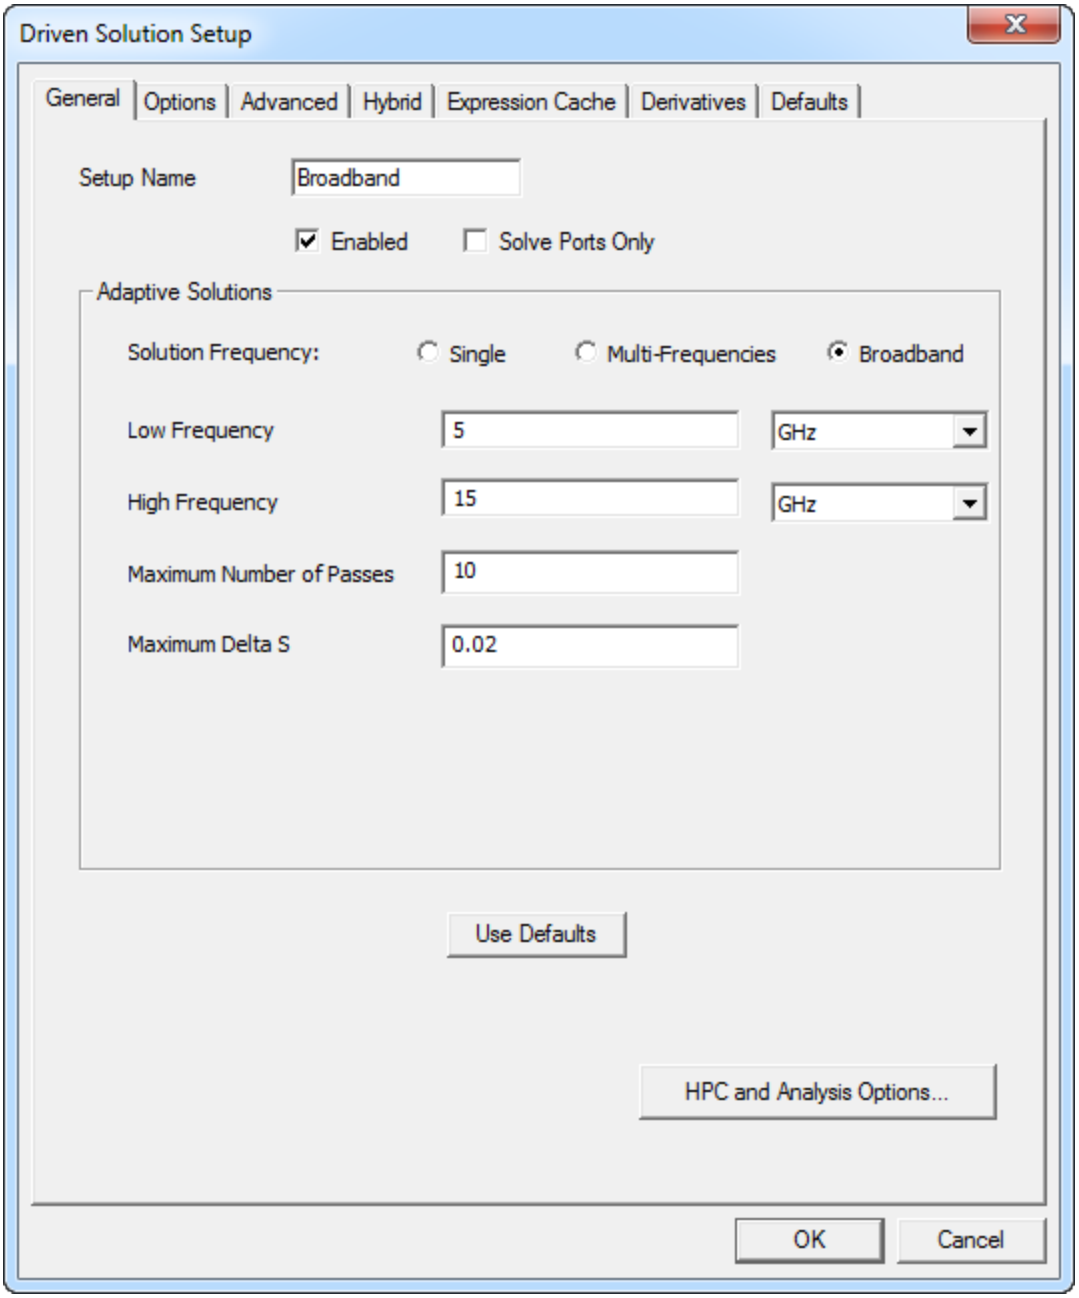
uncertainty in choosing the best frequency for adapting the mesh. You need only specify the highest and lowest frequencies of the range and HFSS determines the frequencies at which to adapt the mesh. The mesh is always adapted for a minimum of three frequencies within the specified frequency range. Adaptive meshing at additional frequencies require enabling the high performance computing (HPC) feature and availability of sufficient computational resources.

The adaptive mesh refinement process occurs at various frequencies within the specified frequency range until the convergence criterion is met. In this case, the values of **Maximum Delta S** between consecutive solves are calculated for each frequency. The weighted average of **Maximum Delta S** across all frequencies must be below the specified magnitude of **Maximum Delta S** for the simulation to converge. You also have the option to set **Maximum Number of Passes** as the stopping criterion.

For Broadband adapt, HFSS prompts you with an interpolation sweep predefined by a range of frequencies identical to the Broadband frequency range. In addition, the algorithm chooses the adapt frequencies in a way that they can also be reused in the frequency sweep. This increases the efficiency of the solution process.

> **Note:**
>
> Broadband frequency setup does not allow viewing the fields for the adapted frequencies. You can define a discrete sweep including the adapt frequencies and solution data will be provided without re-solving.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



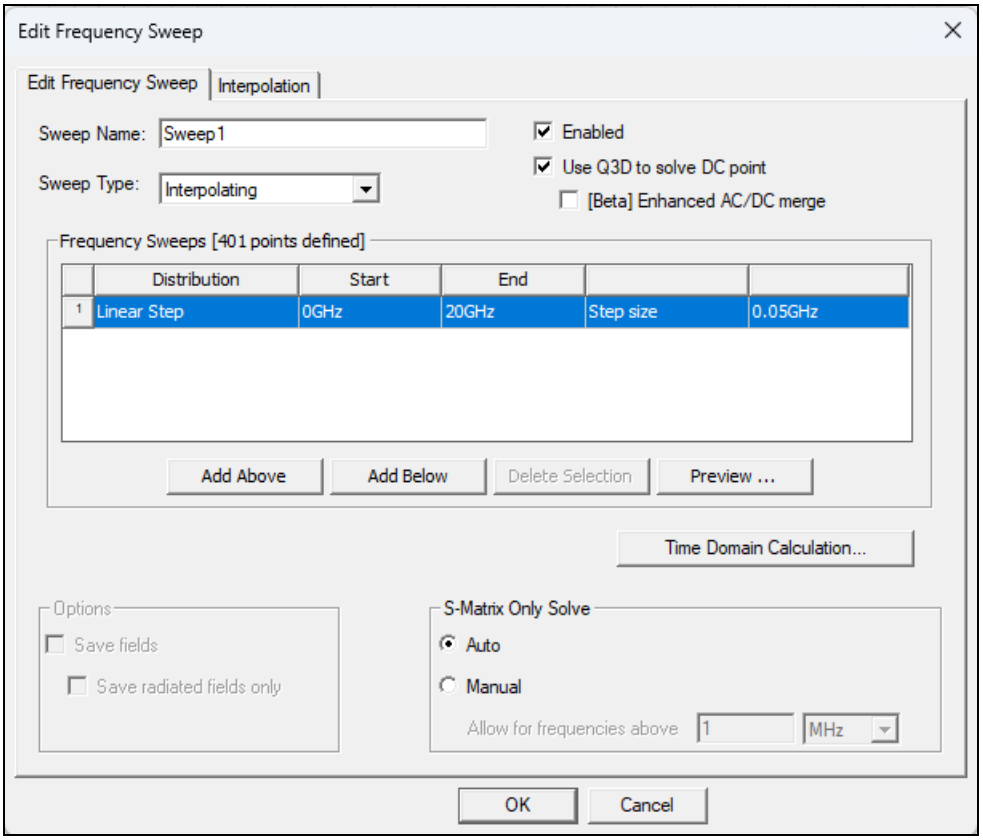
To specify the broadband frequency option, perform these steps:

1. Right-click **Analysis** in the project tree and select **Add Solution Setup**.
2. Select **Broadband** as the **Solution Frequency**.
3. Specify values for **Low Frequency** and **High Frequency**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Specify the convergence criteria that include **Maximum Number of Passes** and the **Maximum Delta S** and click **OK**.

   The **Edit Frequency Sweep** window appears automatically. The interpolating sweep is automatically populated with **Start** and **End** values, which are identical to the low and high frequency values of the broadband frequency range specified in the solution setup window.



Multi-Frequencies

If you know apriori the frequencies at which to adapt the mesh for your design, you can specify the **Multi-Frequencies** setup. You can specify a number of individual frequencies in this setup and adaptive meshing occurs at all the frequencies.

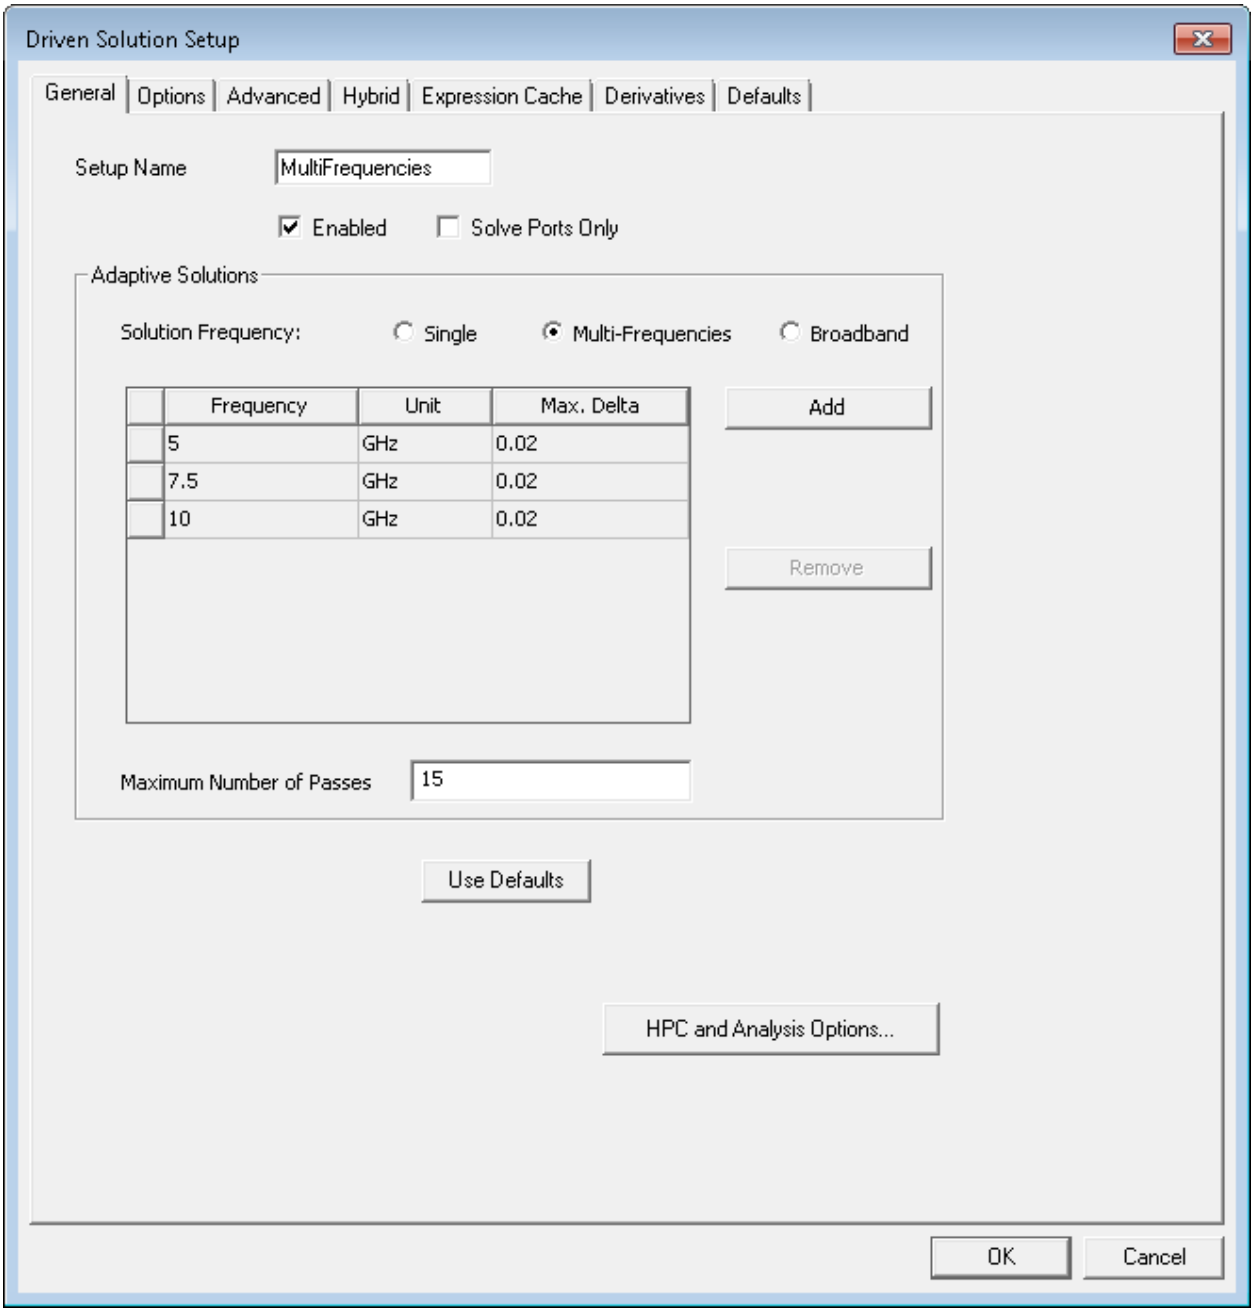
You have the option to set different values of **Maximum Delta S** for the specified frequencies. For each frequency the individual target Delta S value must be reached in order for the entire solution to converge. For instance, if you define 4 frequencies for adapting the mesh, the target value of **Maximum Delta S** for each of the 4 frequencies must be satisfied for the solution to reach convergence.

To specify individual frequencies in the Multi-Frequencies setup, perform these steps:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Right-click **Analysis** in the project tree and select **Add Solution Setup**.
2. Select **Multi-Frequencies**.
3. Edit the existing frequency field to a value of your choosing.

To enter additional frequency points, use **Add** and edit the corresponding value in the **Frequency** column.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setting Adaptive Analysis Parameters for HFSS

When you set up an adaptive analysis, define the following parameters under the **General** tab of the **Solution Setup** dialog box:

- Enter the Solution Frequency and select the frequency units from the pull down list.
- Optionally, select Solve Ports Only.
- Maximum Number of Passes
- Maximum Delta S or Use Matrix convergence (for designs with ports). Here you can set matrix values for convergence, including maximum delta for Mag S and Phase S.
- Maximum Delta Energy for convergence per pass (for designs with voltage sources, current sources, incident waves, or magnetic bias, or for Characteristic Modes solution types).
- For Eigenmode solutions, specify Maximum Delta Frequency Per Pass and, if desired, Converge on Real Frequency Only.
- For Characteristic Modes solutions, Maximum Number of Modes and Minimum Modal significance.

Under the **Mesh/Solution Options** tab of the **Solution Setup** dialog box, you can edit the following settings:

- Lambda Refinement
- Maximum Refinement Per Pass
- Maximum Refinement
- Minimum Number of Passes
- Minimum Number of Converged Passes
- Order of Basis functions
- Enable the Auto Select Direct/Iterative Solver
- Enable the Direct Solver
- Enable Iterative Solver and associated Relative Residual Setting.
- Enable Domain Decomposition

Under the **Advanced** tab of the **Solution Setup**, depending on the solution type, you can edit the following settings.

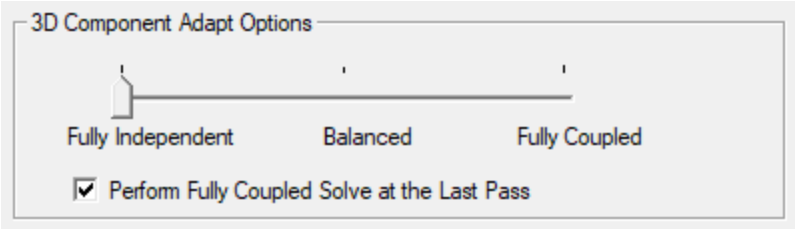
- Initial Mesh Options for mesh linking
- Port options (Maximum Delta Z_o, whether to Use Radiation Boundary on Ports and Min/Max Port Triangle settings)
- Whether to **Save fields**, and/or whether to save radiated fields only. You must save fields to generate field overlays and reports for near and far fields. To view a port field display, you must save fields. Save fields options also occur for Discrete and Fast Sweeps.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Under the **Adaptive Options** tab of the **Solution Setup**, you can edit the following settings:

- Maximum Refinement Per Pass
- Maximum Refinement
- Minimum Number of Passes
- Minimum Number of Converged Passes

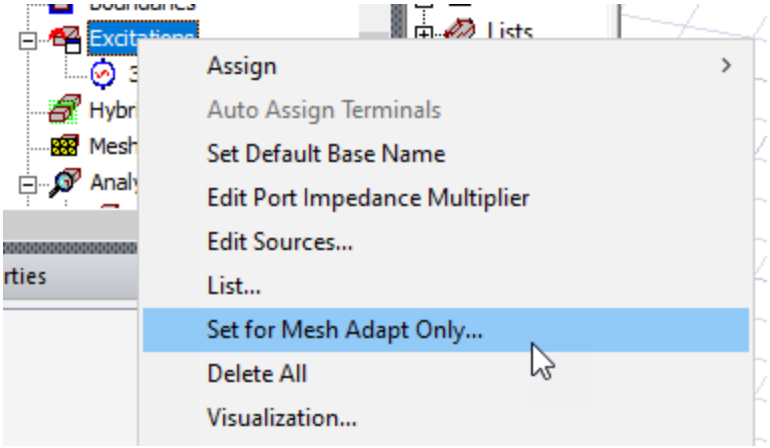
If you have set the Beta Option for Parallel Component Mesh Adapt, and the design contains 3D components, the **Adaptive Options** tab also lets you select 3D Component Adapt Options.



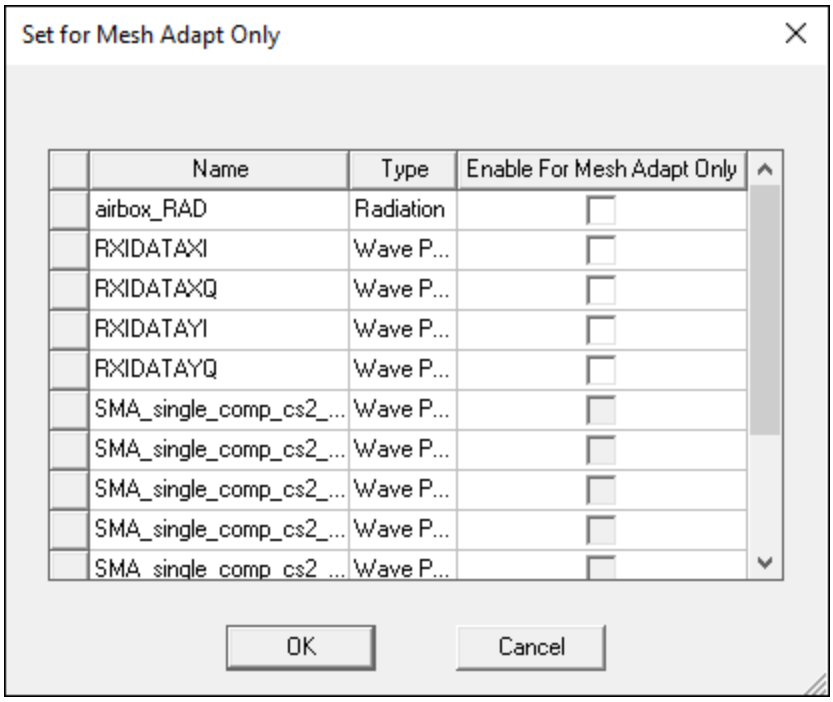
Parallel component adapt for mesh fusion workflow in MCAD including both 3D component array and general mesh fusion. During the component adapt, the multiple components are solved in parallel during each adaptive pass. You can select from Fully Independent adapt, Loosely coupled adapt, and Fully coupled adapt. If you select Fully Independent or Loosely Coupled, you can specify that the last adaptive solve performs a Fully Coupled Solve, or if unchecked, a memory estimation. Because there is no LastAdaptive solution if you turn off “Perform Fully Coupled Solve at the Last Pass”, the far field plot will be blank.

You can assign certain boundaries and ports to improve adaptive accuracy. For example, for component without any ports, certain ports together with a PEC boundary can be added to drive the adaptive pass. These boundaries and/or ports are present during adaptive pass only and will be removed automatically during full design solve. To do so, right-click on the Excitations icon and select **Set for Mesh Adapt Only...**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This opens a dialog listing the ports/boundaries.



When an adapted port is present, you have an option to display s-parameter results that do or do not include adapted ports (full s-matrix or reduce s-matrix) for adaptive solves. Ports selected here do not appear in the Edit Sources dialog.

Under the Hybrid tab of the of the Solution Setup, you can set solve parameters for any Hybrid Regions you have assigned in the design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Under the **Expression Cache** tab of the **Solution Setup**, you can create and manage expressions to use for adaptive convergence.

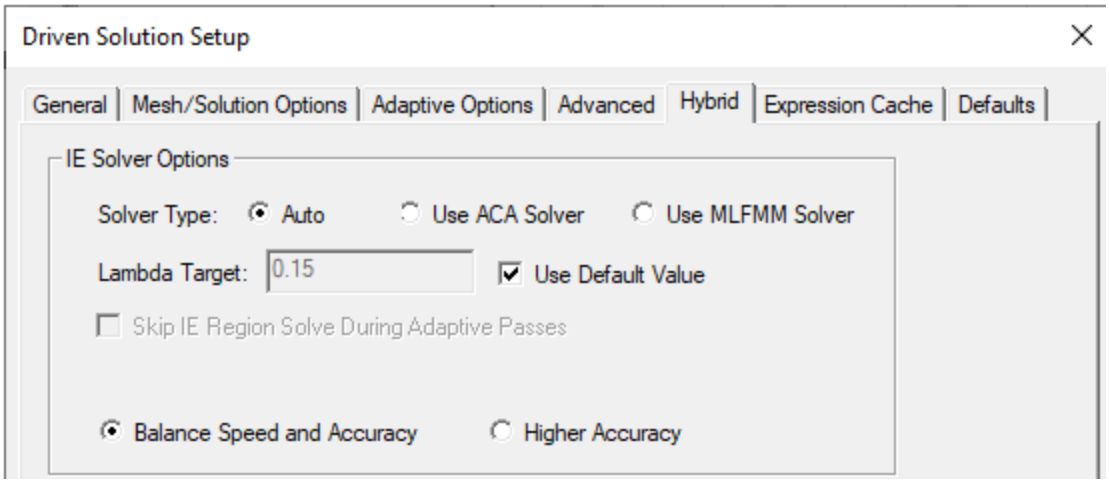
Under the **Derivatives** tab of the **Solution Setup**, you can:

- Specify which variables to use for calculating derivatives.

Setting Hybrid Region Parameters for HFSS

When you set up an adaptive analysis for an HFSS with Hybrid and Arrays solution type, define the following parameters under the **Hybrid** tab of the Advanced **Solution Setup** dialog box:

- **IE Solver Options**. You can specify the IE Solver type as ACA (the traditional method) or as MLFMM, which is superior to ACA for models with large FE-BI surfaces, and also works for IE regions. The default choice is Auto, in which the choice is made based on the characteristics of the design.



Both IE solvers support distributed memory using MPI. The MLFMM solver option provides a more efficient solution to certain classes of scattering problems. The MLFMM solver is typically more efficient (in memory and speed) than the ACA solver for problems having electrically large, mostly smooth, scattering surfaces which are comparable in all three dimensions. For a more detailed discussion, see MLFMM Usage Guidelines.

- **Lambda Target for IE Solvers**. This refers to the background material. For these fields to be active, the Do Lambda Refinement option on the **Options** tab must be enabled. If the Use Default Value check box is checked, the text box is disabled, and the 0.15 Lambda target value is used. If you uncheck Use Default Value, you can specify a target value for the background material for IE regions. This can be useful for designs that include curvilinear elements.
- **Skip IE Region Solve During Adaptive Passes**. If the design contains at least one FE-BI domain and at least one IE region or PO boundary, you can choose this to solve the FE-

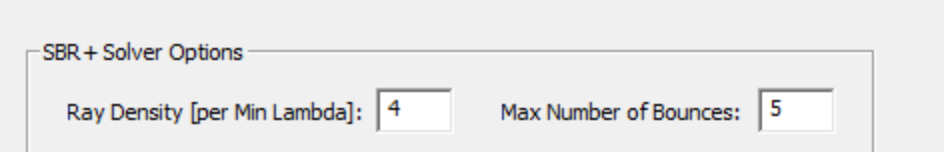
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

BI region before solving coupled FE-BI and IE and PO regions. An IE port is not allowed for skipping IE region solve during adaptive passes. If the design also contains SBR+ Regions, the **Skip SBR+ Solve During Adaptive Passes** feature must also be selected.

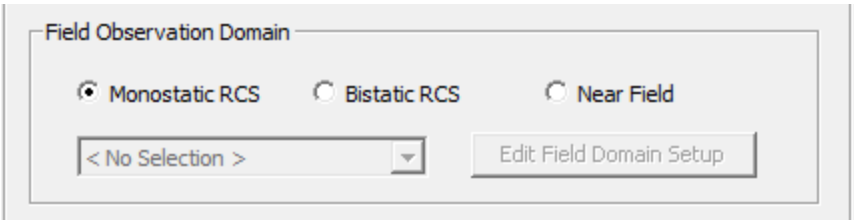
- **Use Radiation Boundary During Adaptive Passed for FEBI**. If selected, the solver uses a radiation boundary instead of FEBI during adaptive passes. When it converges, solver enables the FEBI for the last adaptive pass. If the FEBI surface is sufficiently large, this option can lead to a faster adaptive mesh run.
- **Balance Speed and Accuracy** or **Higher Accuracy**. This refers to the balance of speed and accuracy applied to IE Hybrid Regions. Higher Accuracy corresponds to the Higher Accuracy setting in the Automatic Solution setup. The IE solver is slower and uses more memory when you select this option.

Additional Options for SBR+

- **Ray Density and Maximum Number of Bounces**: If you have assigned an SBR+ Region, you can specify the SBR+ Solver Options for Ray Density (Per Wavelength) and Max Number of Bounces. This lets you balance solution speed and desired accuracy.



- **Field Observation Domain**: If you want to consider Near or Far fields, you can create new Near Field Setup, an new Far Field setup, or edit an existing setup.

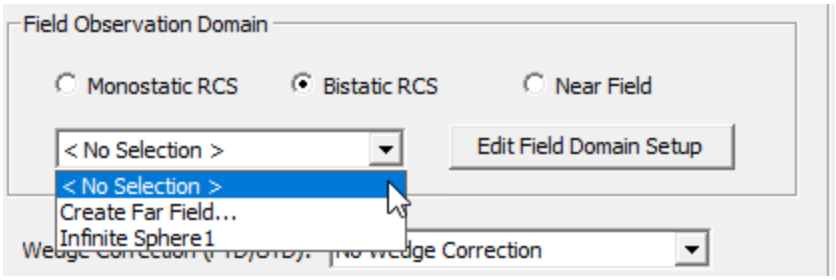


By default, a Far Field Setup is an Infinite Sphere, discussed below. By default the Near Field setup is a rectangle. For setup and use for Near Field setups, see Overlay of Contour Plot of Near Field Rectangle.

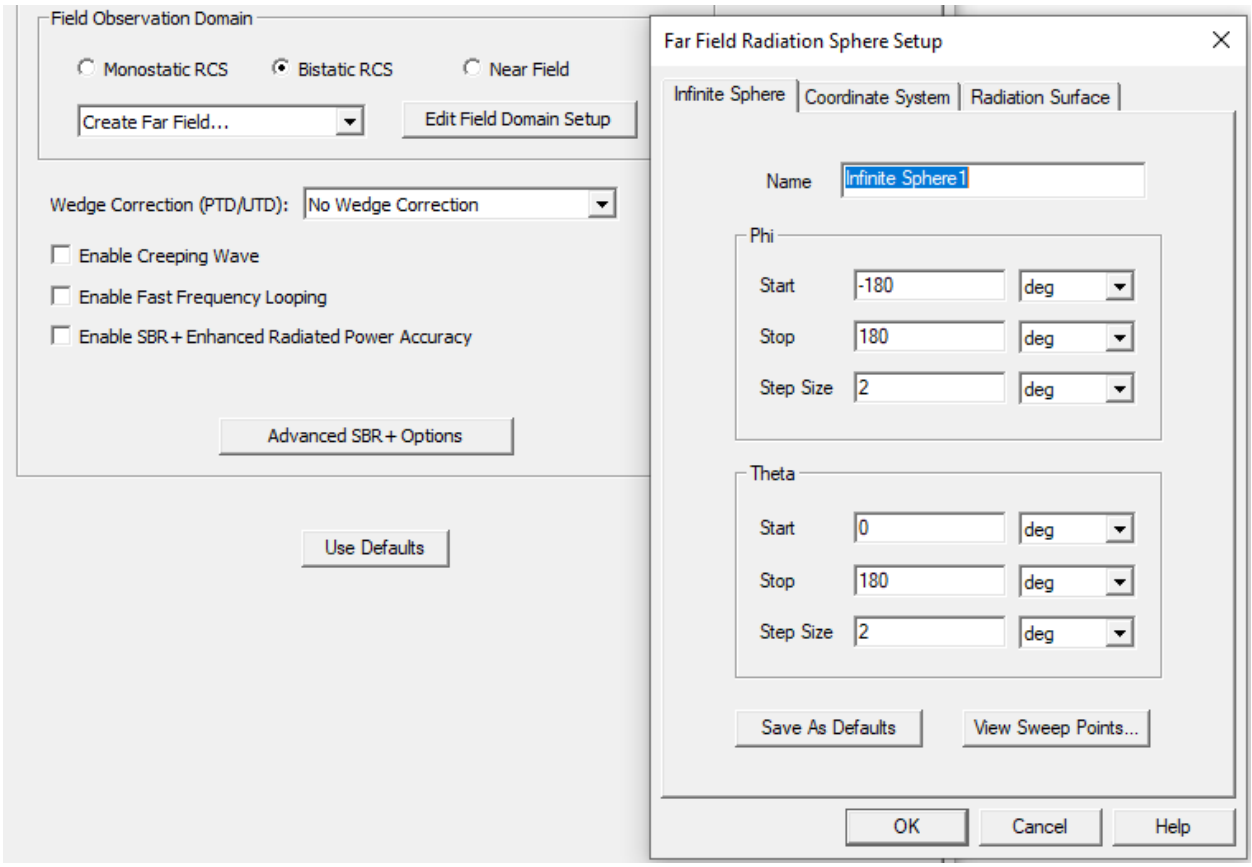
- **RCS Type**: SBR+ supports assigning an Incident Plane wave for calculating RCS. If you have assigned an Incident Plane wave, the options include the RCS Type as Monostatic or Bistatic. If you select Monostatic, you do not need to create an infinite sphere.If you select have assigned both an SBR+ region and an Incident Plane wave, and select Bistatic as the RCS Type, the Far Field Observation domain fields are enabled, and the **Far Field Radiation Sphere Setup** dialog appears as follows, allowing you to create an

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

infinite sphere.

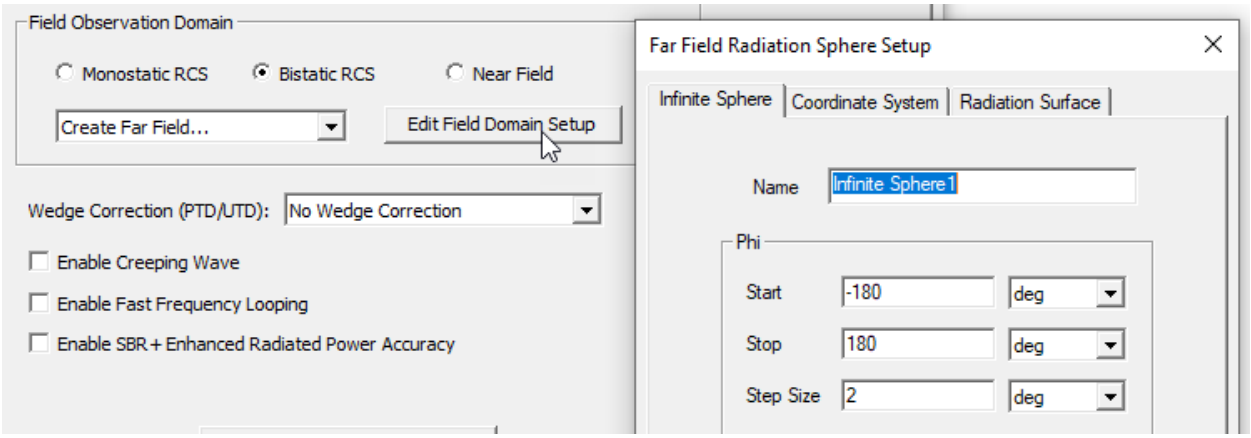


You can create far field, or edit an existing Far Field Infinite Sphere in the drop down list by selecting it and by clicking **Edit Field Domain Setup**.



If you have created one or more infinite spheres, these are listed on the dropdown. You can edit an existing Far Field Infinite Sphere by clicking **Edit Field Domain Setup**.

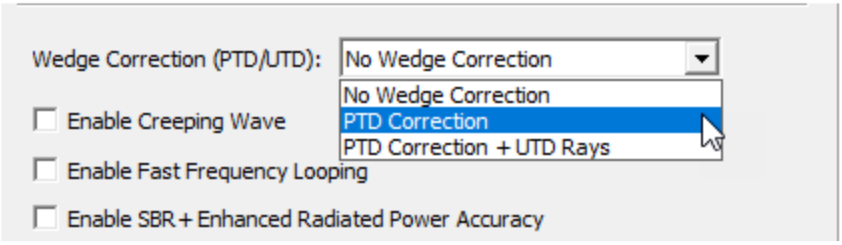
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- **Enable Creeping Wave**: For a description of the requirements and circumstances when you might enable Creeping Waves, see Creeping Wave for Antenna Placement on Curved Surfaces in SBR+ Simulation or Creeping Wave for RCS Analysis of Curved Surfaces in SBR+ Simulation.
- **Skip SBR+ Solve During Adaptive Passes option**. SBR+ regions are not being mesh adapted and SBR+ solutions have no impact on field solutions on FEM or IE regions. However, SBR+ does impact stopping criteria in some cases such as coupling between two separate source antennas. Therefore, to speed up mesh adaption, you can choose to not solve SBR+ regions until source regions have converged in isolation. However, SBR+ does impact stopping criteria in some cases in the form of cache expression such as coupling between two separate source antennas or far field pattern. In such cases, SBR+ solve could not be skipped. Moreover, SBR+ solve will always be launched when maximum number of passes is reached regardless of source region convergence. If you have selected **Skip IE Region Solve During Adaptive Passes**, you must also select **Skip SBR+ Solve During Adaptive Passes**.

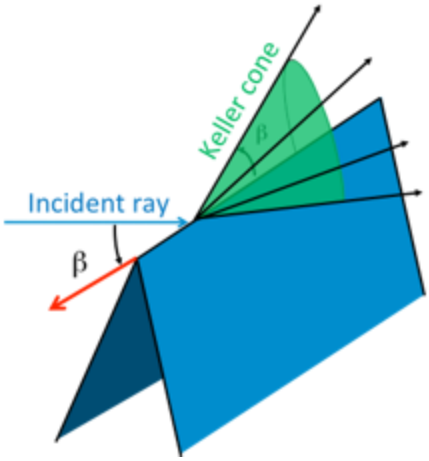
- The **Wedge Correction (PTD/UTD)** simulation settings allow for the inclusion of additional wedge diffraction phenomenology that can improve the accuracy of SBR+ simulations. You can opt out of using the PTD/UTD settings, or select PTD Correction or PTD Correction + UTD Rays. Selecting one of the PTD Correction options enables a field for specifying PTD Edge Density.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



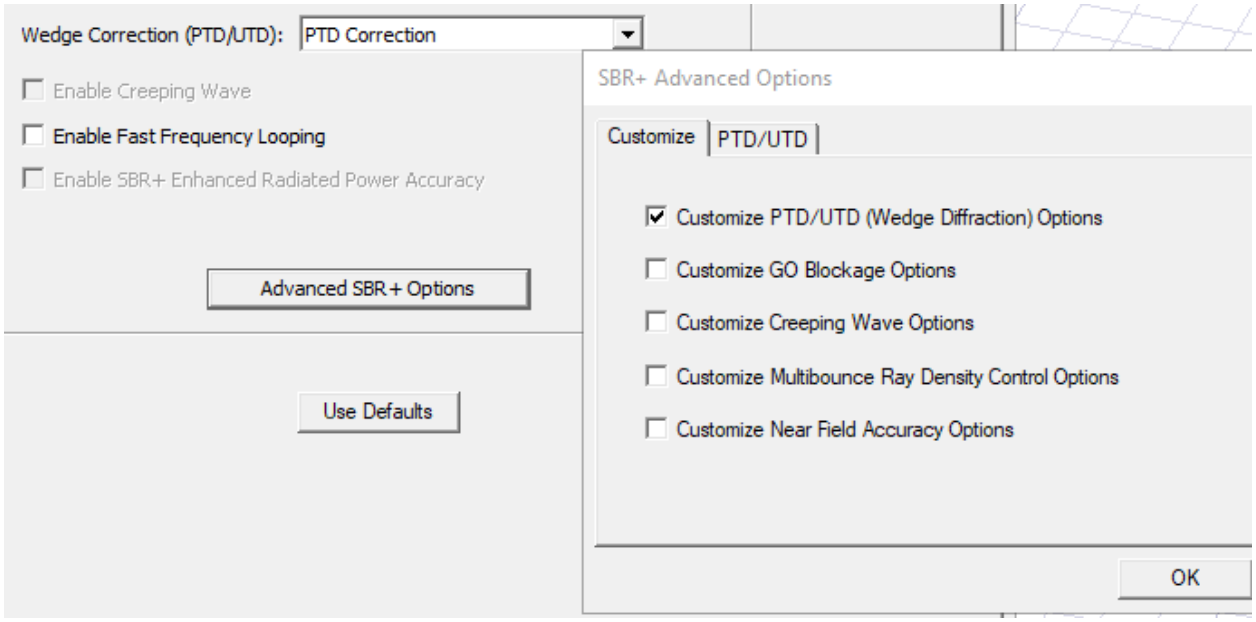
The PTD and UTD wedge features are only deployed for metallic wedges with line-of-sight visibility from the source (Tx) location. If either adjacent surface of the wedge is non-PEC and not within the tolerance for PEC-like, or if the entire edge segment is not visible to the source, the wedge will be ignored in the SBR+ simulation and for visual ray tracing (VRT)

For SBR+ simulations, the Physical Theory of Diffraction (PTD) and Uniform Theory of Diffraction (UTD) features can account for additional phenomenology not well predicted by plain SBR due to truncation of uniform Physical Optics (PO) currents at sharp angular discontinuities ("wedges") on metallic surfaces and blockage of SBR's Geometrical Optics (GO) rays. PTD is a numeric correction to the scattered fields radiated by PO currents near wedges. UTD launches bundles of edge-diffraction rays from directly illuminated portions of each wedge along the Keller cone. Once launched, the UTD rays behave exactly like regular SBR rays, propagating according to GO and painting PO currents at each bounce that contribute to the scattered field. The UTD rays often illuminate portions of the SBR scattering geometry that are never reached by SBR GO rays launched directly from the field source.

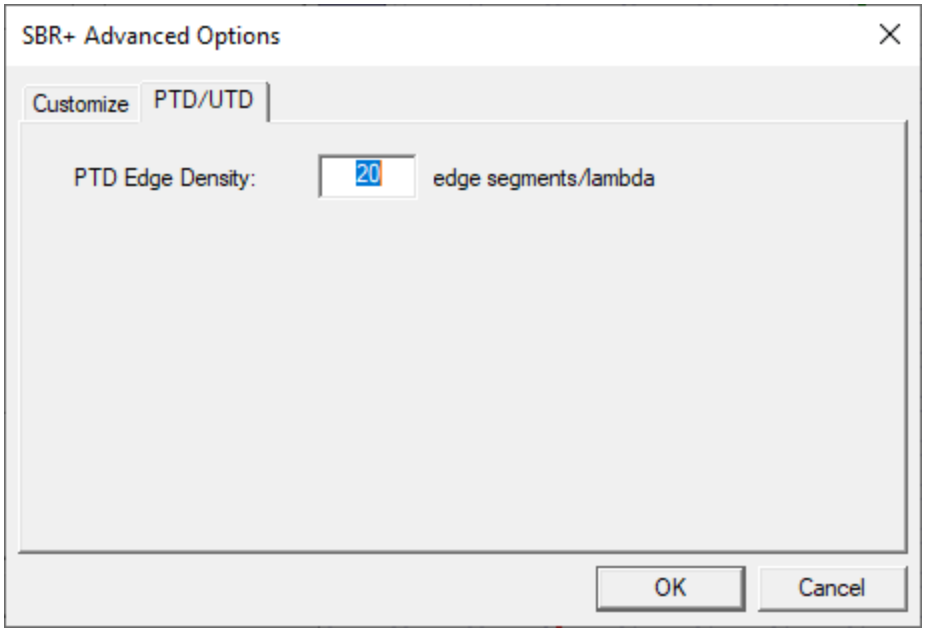


If you select one of the PTD Correction options you can then select the **Advanced SBR+ Options** button to Enable PTD/UTD (Wedge Diffraction) Options.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Enabling PTD/UTD (Wedge Diffraction) Options opens **PTD/UTD** tab for specifying PTD Edge Density.



- Advanced Option for **NF Accuracy Settings** for SBR+

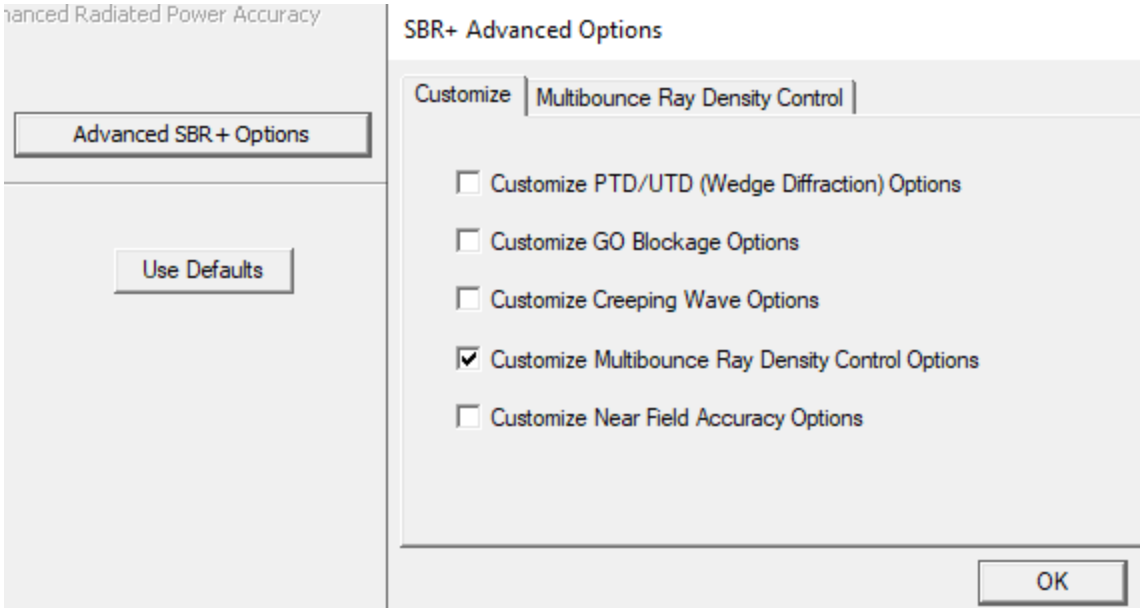
The NF Accuracy settings (Beta feature, NF Accuracy Controls for SBR+) provide access to methodology settings relating to cases where Tx antennas, Rx antennas, and near-field

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

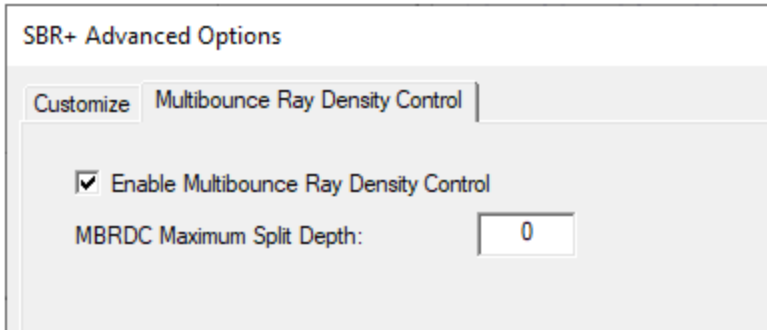
observation points are in proximity to the scattering geometry (i.e., the platform CAD model). When this feature is switched off, HFSS SBR+ uses default near-field accuracy settings that should be adequate for most situations, including close-proximity Tx/observer conditions that this feature is designed to tune.

- Advanced Option for **Multibounce Ray Density**

By option you can select the Advanced SBR+ Options and enable Customize Multibounce Ray Density Control Options.



You can then select the **Multibounce Ray Density Control** tab.



Use the checkbox to **Enable Multibounce Ray Density Control** and enter the maximum number of subdivisions to be used in the solve. Enabling the feature may increase the solve time.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **MBRDC Maximum Split Depth** field value increases the number of spawned ray tracks on each ray bounce.The MBRDC algorithm is designed to achieve the ray density per wavelength criterion at any bounce depth. If a footprint at depth *N* in a ray track does not satisfy the ray-density criterion, the MBRDC algorithm attempts a refined ray shoot from an earlier bounce, just for the ray in question. The size of the triggering footprint informs the level of refinement. If the refined shoot is not successful in achieving the desired footprint size, or new footprints are too large, the MBRDC algorithm attempts further, recursive refinements. The **MBRDC Maximum Split Depth** setting limits how aggressively the refinement algorithm is applied by specifying the maximum number of split recursions. For this reason, linear increases in **MBRDC Maximum Split Depth** can yield a geometric progression in the total number of rays shot and associated solution time.

When both MBRDC and UTD are enabled, first-bounce UTD rays and bright points on wedges are recomputed during the MBRDC splitting process, but only the original raytrack is rendered up to the 1st bounce. Similarly, length-based ray filters are applied to the original UTD initial ray track up to 1st bounce rather than using the information in the additional MBRDC tracks. This is a known limitation.

- Advanced Option for **Geometrical Optics (GO) Blockage**

SBR+ normally applies a physical optics (PO) blockage model where blockage effects emerge from partial cancellation of the incident field by the scattered field. PO blockage not only occurs in connection with the incident field from the Tx antennas, but also within the scattered field itself when reflected fields from the previous bounce are diminished by a blocking surface along the geometrical-optics (GO) reflection path at the current bounce by evaluating the scattering contribution of the incident ray field at that bounce.

In cases of significant blockage by a large obstruction, the PO blockage model requires accurate currents over the extent of the obstruction. Sometimes, this is hard to achieve in the ray tracing approximation. For example, the obstruction may not be well illuminated by direct rays from the Tx antenna or multi-bounce rays after an earlier reflection. An alternative is to use a GO blockage model where scattered field contributions are added to an observation point subject to a line-of-sight (LOS) blockage check performed by the ray tracer. In some cases, this is more accurate than the default PO blockage formulation, while in others it is less accurate. GO blockage also entails a non-trivial computational cost, as the blockage check with the ray tracer must be performed for each observation angle (or point) for each ray hit point.

In addition to GO Blockage for SBR and UTD ray tracks, this feature is also available for PTD and CW.

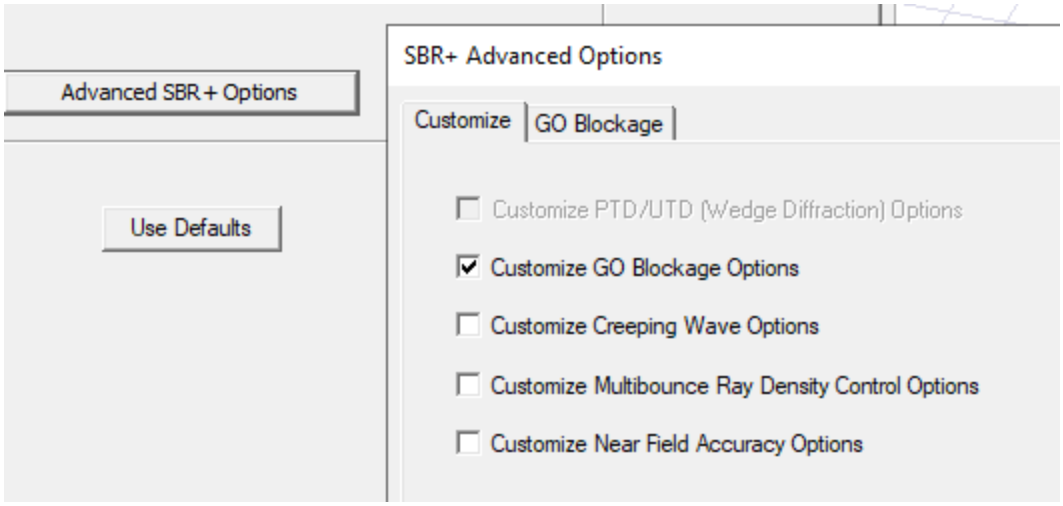
Limitations for GO Blockage:

GO Blockage formulation is suited specifically for SBR+ ray tracks, including UTD ray tracks. While GO Blockage for CW and PTD has been implemented for the first time in this release, results can be surprising and/or inaccurate, as a limitation of the methodology.

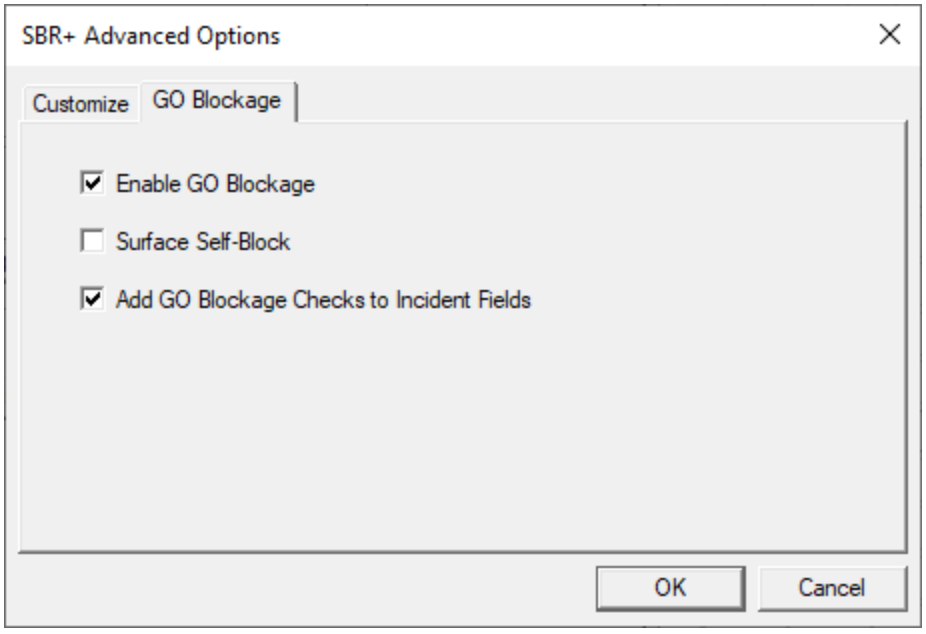
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Summary Workflow for GO Blockage:

Click the **Advanced SBR+ Options** button to open the **SBR+ Advanced Options** window. On the **Enable** tab, Check GO Blockage Options to enable the **GO Blockage** tab.



On the GO Blockage tab, you have check box options to enable or disable GO Blockage and enable or disable Surface Self-block.

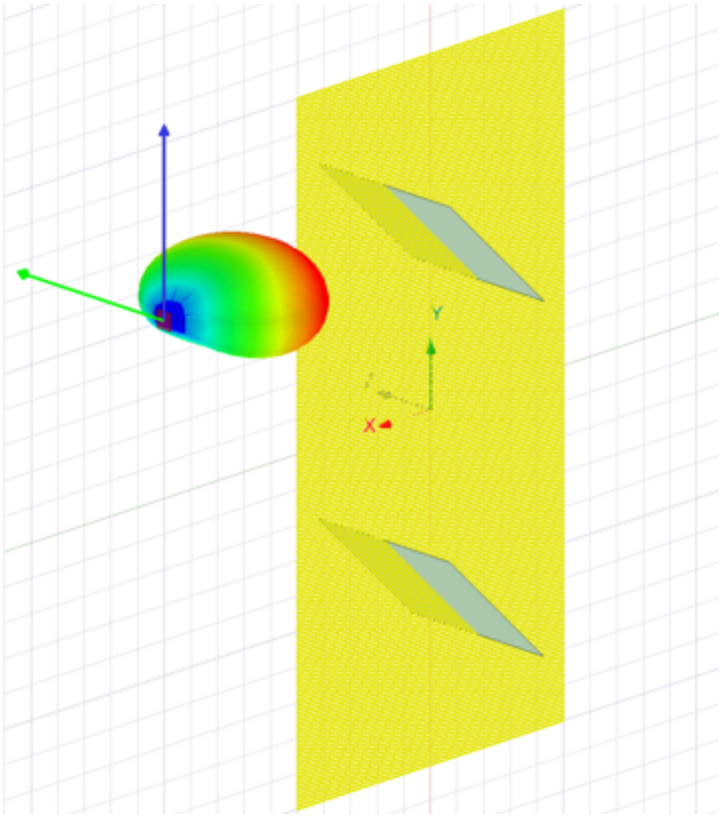


Surface Self-Block: if enabled, the surface where the footprint is radiated from is used for blockage check, that is, anything below the surface with respect to the incoming ray is not in line of sight. If the setting is disabled, the footprint surface is not used for blockage checks

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

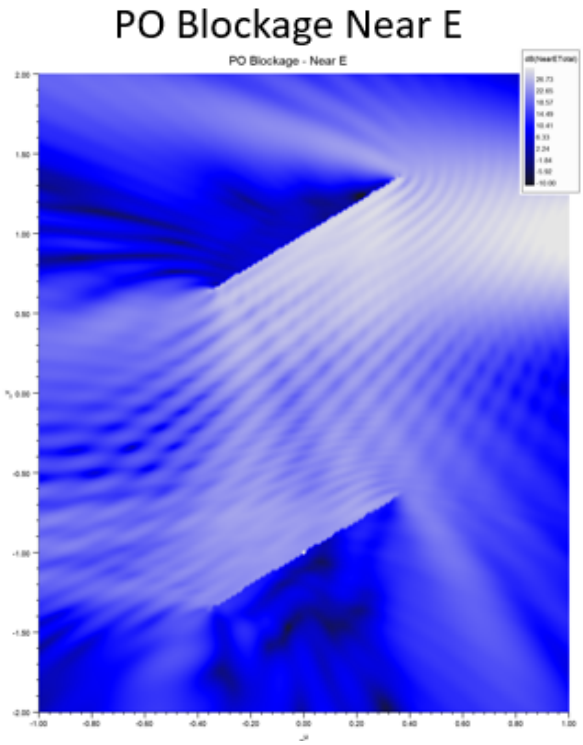
(anything below the surface with respect to the incoming ray is in line of sight), but other surfaces are used for blockage.

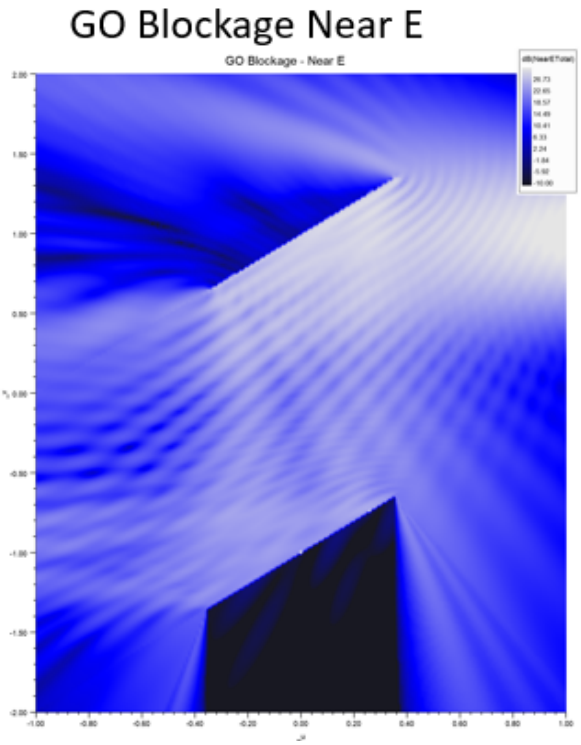
For example, consider a parametric beam antenna illuminating a series of plates.



In the plots, the shadows behind the plates are much more pronounced with GO Blockage enabled, but the fields have non-physical discontinuities.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





- **Enable SBR+ Self Coupling** computation capability for driven designs means that the diagonal S-param term takes into consideration the SBR+ scattering effect, and is more accurate. For a discussion of SBR coupling see, Select Tx/Rx Antennas for SBR+ Solutions.

MLFMM Usage Guidelines

The MLFMM solver option in HFSS enables the use of the Multi-Level Fast Multipole Algorithm to increase the efficiency of the iterative solution of IE problems in FE-BI and IE-Region problems. This document provides a brief description of the solver and guidelines for its use.

- The MLFMM Solver
- Further Details of the MLFMM Algorithm
- Guidelines for Choosing Between ACA and MLFMM IE Solver Options

The MLFMM Solver

The MLFMM solver is based on a hierarchical algorithm that relies on the underlying physics of electromagnetic interactions to provide a more efficient scheme to compute the matrix vector product that is at the heart of every iterative IE solver. The algorithm views a matrix vector

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

product as the computation of E and H fields and it computes these fields using a multi-level multi-pole expansion.

The algorithm can be conceptually broken down in to the following 6 steps.

1. Hierarchical decomposition of the geometry into a set of nested boxes (Figure 1) and identification of near and far interactions for each box (Figure 2).

   The reason for the separation of near and far interactions is to be able to efficiently compute far interactions using multi-poles. See additional explanations in Further Details of MLFMM Algorithm.

2. Computation of multi-poles at the center of each box at the lowest level due to the currents contained in the boxes (Basis functions projected on to multipoles)

   In HFSS, the multi-poles are plane waves sampled on the surface of a sphere of diameter equal to the diagonal of the box and centered at its center.

3. Hierarchical computations of multi-poles at the center of each "higher" level box due to multi-poles at the centers of its children (Up-tree traversal).

   Since the multi-poles are effectively plane-waves, this step is equivalent to resampling plane waves on a larger sphere using spherical interpolation.

4. Construction of fields at each box center at the "highest" level due to all multi-poles at this level (Translation).

   The fields at the receiving box can be again computed on a per-multi-pole (per-plane-wave) basis using the addition theorem for the Green's function. The fields at the receiving box center are, thus, again represented using plane-waves.

5. Hierarchical computation of fields at the center of each "child" box due to the "received" fields at its parents (Down-tree traversal)

   Due to the plane-wave nature of the multi-poles, this step is equivalent to a "down-sampling" from a sphere at the parent level to one at the child level.

6. Computation of fields at the observer locations inside each lowest level box (local fields projected to testing function)

   This is done using integration (summation) over all the plane-waves to compute the field, followed by testing using appropriate testing functions.

The first step, the computation of the absolute "near-field" and all RHS-independent pre-computations possible for steps 2 - 6 are performed during the "Matrix Assembly" stage and the remaining computations for steps 2 - 6 are performed during the "Iterative Solution" stage (Figure 3).

Due to the way the algorithm is constructed the MLFMM solver will take significantly less amount of time than ACA for "Matrix Assembly". It is, however, possible that the MLFMM solver may take

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a larger amount of time than ACA per iteration for "Matrix Solution". Further, due to its construction, MLFMM algorithm tends to use significantly less memory than the ACA solver for large problems.

Further Details of the MLFMM Algorithm

Near-field interactions for a given reference box are defined to be between itself and the boxes that it touches at the same level. Far-field interactions for a given reference box are computed explicitly for all boxes it does not touch which reside in its parent's near field. The hierarchical nature of the algorithm automatically provides the near-field interactions at level n+1 when computing the various interactions at level n. This can be inferred by studying Figure 1 and 2. An outcome of this fact is that only the lowest level contains explicit near-field interactions which are done using standard MoM. Further, note that the far-field interactions between a reference box and boxes which are further away than the near-field of its parent are accounted for by the far-field interactions of its parent (and higher level parents if they exist).

Figure 1: shows a cross-section of "hierarchically nested" boxes overlaid on the mesh of an arbitrarily shaped sheet.

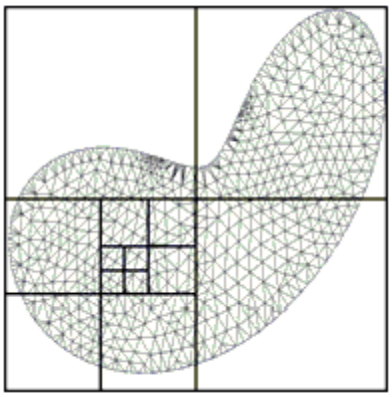


Figure 2: shows the decomposition of boxes into "near" and "far" fields at levels 1, 2, and 3. In each case, a reference box is shown in green and its immediate parent is shown with a red border. The orange color indicates boxes in the near-field of the reference box and the blue color indicate boxes in the far-field at each level. Note that the "near field" exists only at level 1.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

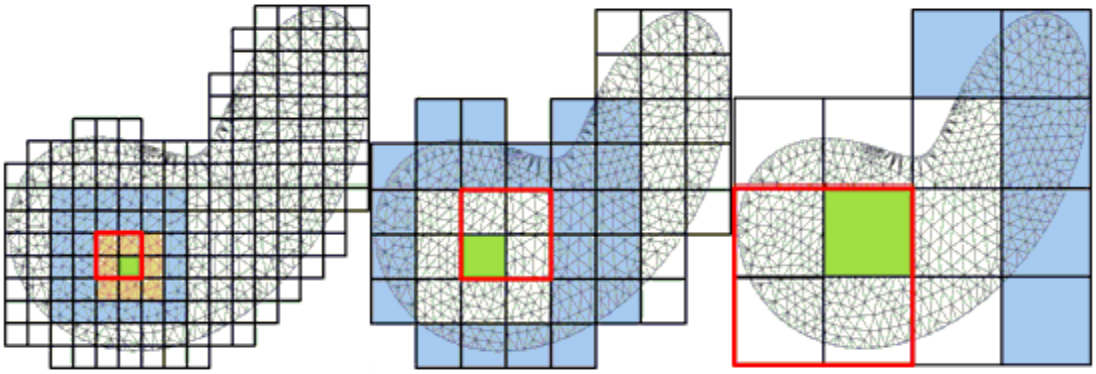

Figure 3: illustrates steps 2-6 in the MLFMM algorithm above. The black arrows indicate the multipole creation from basis functions and construction of the tested field from multipole expansions (steps 2 and 6). Orange arrows indicate the up-tree and down-tree traversals (steps 3, 5), and the red arrow indicates the translation of multipoles to its far field (step 4).

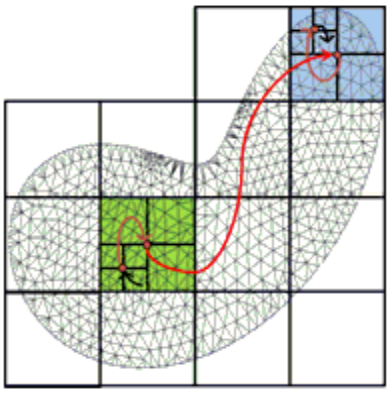
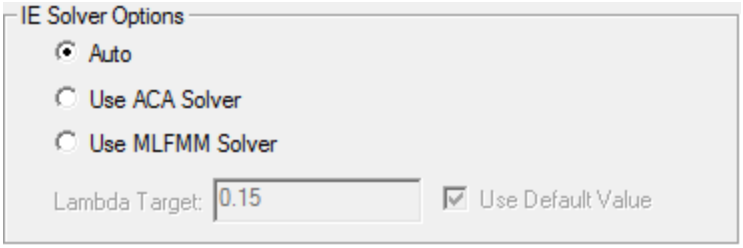


Guidelines for Choosing Between ACA and MLFMM IE Solver Options

The following guidelines have been arrived at by analyzing the features of the MLFMM algorithm and comparing its performance to ACA for several test problems.



1. Problem size

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In general, the **ACA solver will be more efficient** than the MLFMM solver in terms of both memory and solution time for problems whose scattering surface(s) has (have) **less than 100,000 surface unknowns (~100,000 triangles)**.

2. Aspect Ratio (largest dimension : smallest dimension):

In general, the **ACA solver will be more efficient** in memory and speed than MLFMM for problems whose geometry has a **bounding box with a highly skewed aspect ratio (on the order of 100:1 or higher)**.

3. Design Type

HFSS-IE

Number of Excitations:

For problems having **very few excitations (<10)**, the **MLFMM solver will be more efficient** than ACA in both speed and memory for problems that satisfy items 1 and 2 above. Since the time required for matrix multiplication is higher in MLFMM, **as the number of excitations increases** (e.g., mono-static RCS problems), the # of unknowns in the problem needed to realize the increase in speed provided by MLFMM (vs. ACA) will increase (with respect to the limits provided in 1, above). However, **the memory savings provided by MLFMM will remain consistent** even while the number of excitations increases.

HFSS - FE-BI

For FE-BI surfaces involving **few excitations the MLFMM solver will provide similar or slightly better performances in solution time** and **better performance in memory** for problems that satisfy items 1 and 2 above.

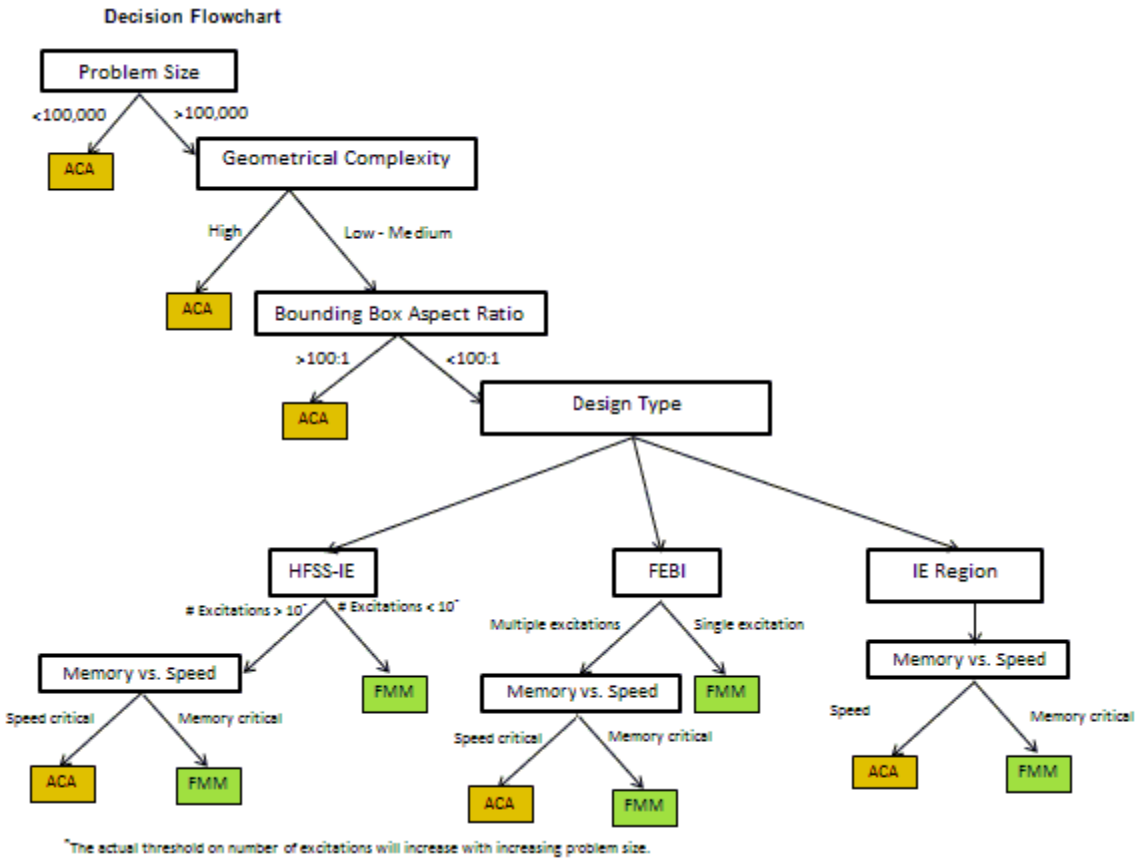
For FE-BI surfaces involving **a large number of excitations** (e.g., several ports, mono-static RCS problems), the **MLFMM solver's solution time may be larger than that for ACA but the memory savings** will remain.

IE Regions

For IE region problems the **ACA solver will nearly always be faster than the MLFMM solver**. However, the **MLFMM solver will provide memory savings** for problems satisfying criteria 1 & 2 above.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Decision Flowchart for Deciding on the IE Solver Options



Setting the Maximum Number of Passes

The **Maximum Number of Passes** value is the maximum number of mesh refinement cycles that you would like HFSS to perform. This value is a stopping criterion for the adaptive solution; if the maximum number of passes has been completed, the adaptive analysis stops. If the maximum number of passes has not been completed, the adaptive analysis will continue unless the convergence criteria are reached.

To set the maximum number of passes for an adaptive analysis:

- Under the **General** tab of the **Solution Setup** dialog box, enter a value for **Maximum Number of Passes**.

For driven problems and no frequency sweeps, HFSS requires at least one adaptive pass. Entering **1** will bypass adaptive analysis, generating a solution only at the solution frequency you specified.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> The size of the finite element mesh — and the amount of memory required to generate a solution — increases with each adaptive refinement of the mesh. Setting the maximum number of passes too high can result in HFSS requesting more memory than is available or taking excessive time to compute solutions.

To shorten the solution time for solutions with a frequency sweep, you can set the **Maximum number of passes** to 0 to skip the adaptive pass phase during simulation.

Selecting 0 passes for a setup means that when you create a Report or a Field Overlay, in the Context field, the Solutions menu will not list ‘Adaptive Passes’ and ‘Last Adaptive’ for those setups. However, you can still plot the fields based on Sweep solutions if ‘Save field’ is turned on. Also, you can plot meshes using ‘Last Adaptive’ and this ‘Last Adaptive’ should be initial mesh or mesh link source mesh plus user defined mesh (if any).

If you change **Maximum number of passes** from non-zero to 0, then all plots or reports related to Last Adaptive or Adaptive pass are deleted once you click OK in the Driven Setup window. You can Undo this to recover if this was done in error. Messages in the Message window describe these actions.

If you choose 0 as the **Maximum number of passes**, the Solution Profile reports that analysis does not perform adaptive meshing.

Setting the Maximum Delta S Per Pass

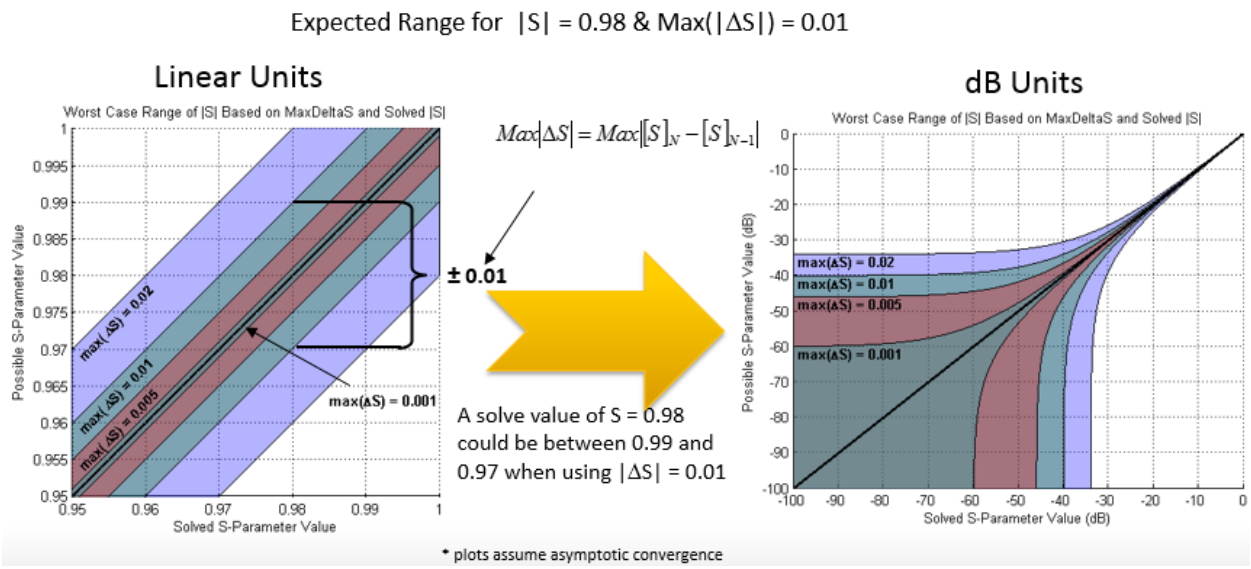
For designs with ports or Transient Solutions for Device Characterization.

The delta S is the magnitude of the change of the S-parameters between two consecutive passes. The solver reports the worst case violation. The value you set for **Maximum Delta S** is a stopping criterion for the adaptive solution. If the magnitude of the change of all S-parameters are less than this value from one iteration to the next, the adaptive analysis stops. Otherwise, it continues until the requested number of passes is completed. The default value is reasonable for most cases. Setting the Maximum Delta S too small wastes computer resources and time. Setting it too large jeopardizes accuracy. Always set the Delta S with your error tolerance in mind.

Consider the worst case scenarios when setting the Maximum Delta S.

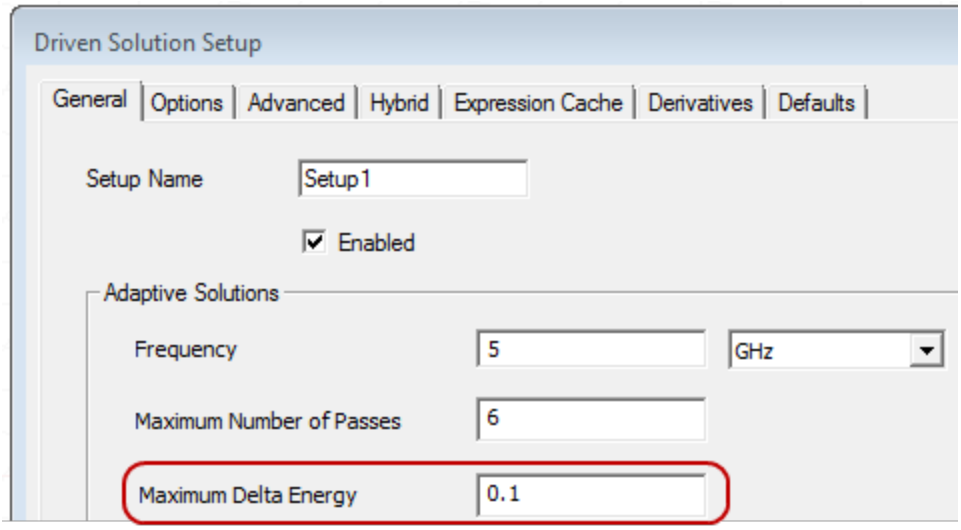
- Determine the worst case magnitude error by assuming the S-parameter magnitude is the only source of error (phase is perfectly accurate).
- Most likely the actual solution is much closer since the error will be split between the magnitude and the phase solve value.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To set the maximum delta S per adaptive pass:

- Under the **General** tab of the **Solution Setup** dialog box, enter a value for **Maximum Delta S**.



Delta S data is available only after HFSS completes two iterations of the adaptive analysis process.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> Delta S is computed on the appropriate S-parameters - modal or terminal - after the S-parameters have been de-embedded and renormalized.

Setting the Maximum Delta Energy Per Pass

For designs with voltage sources, current sources, incident waves or magnetic bias or Transient Solutions for Field Visualization.
Not applicable to designs with ports.

The delta Energy is the difference in the relative energy error from one adaptive solution to the next. The value you set for **Maximum Delta Energy** is a stopping criterion for the adaptive solution. If the delta Energy falls below this value, the adaptive analysis stops. Otherwise, it continues until the convergence criteria are reached.

To set the maximum delta Energy per adaptive pass:

- Under the **General** tab of the **Solution Setup** dialog box, enter a value for **Maximum Delta Energy**.

Delta Energy data is available only after HFSS completes two iterations of the adaptive analysis process.

Setting the Maximum Delta Frequency Per Pass

For Eigenmode solution types

The delta Frequency is the percentage difference between calculated eigenmode frequencies from one adaptive pass to the next. The value you set for **Maximum Delta Frequency Per Pass** is a stopping criterion for the adaptive solution. If the eigenmode frequencies change by a relative amount less than this value from one pass to the next, the adaptive analysis stops. Otherwise, it continues until the maximum number of passes is completed.

Maximum Frequency Delta Per Pass = max | F_current - F_previous|/|F_previous|

To set the **Maximum Delta Frequency Per Pass**:

- Under the **General** tab of the **Solution Setup** dialog box, enter a value for **Maximum Delta Frequency Per Pass**.

Delta Frequency data is available only after HFSS completes two iterations of the adaptive analysis.

Specifying Convergence on Real Frequency Only

For Eigenmode solution types.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Selecting **Converge on Real Frequency Only** causes the percent difference calculation among a set of frequencies to be based only on the real parts of the frequencies; the imaginary parts of the frequencies are ignored. When the project contains only lossless material, the eigen frequency will be real, so checking this option does not make any difference. For lossy problems, selecting this option means the solver checks delta frequency on real part only as the eigen mode frequency in this case will be complex.

- Under the **General** tab of the **Solution Setup** dialog box, select **Converge on Real Frequency Only**.

Specifying Expressions for Adaptive Convergence

You can specify additional convergence criteria through the use of expressions and output variables. The **Max Delta** or the **Max Percent Delta** defined for expression convergence represents the difference in values of the expressions between consecutive adaptive passes. If the difference in the value of the expression between consecutive passes is less than the **Max Delta** or the **Max Percent Delta** value, this part of the convergence criteria is satisfied.

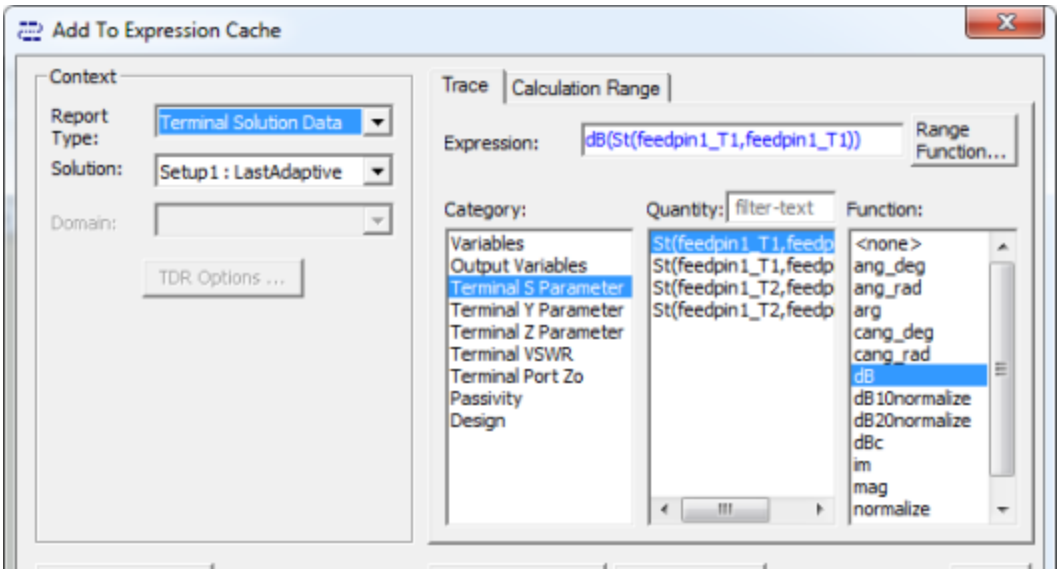
- For **driven solutions**, if the **Maximum Delta S**, **Maximum Delta E**, or alternate matrix convergence criteria are achieved in addition to any specified expression convergence criteria, the adaptive analysis stops. Otherwise, the solution continues until the requested number of passes is completed.
- For **eigenmode solutions,** if the **Maximum Delta Frequency Per Pass** criteria is achieved in addition to any specified expression convergence criteria, the adaptive analysis stops. Otherwise, the solution continues until the requested number of passes is completed.

To set expressions as **Convergence** criteria:

1. Double-click the Analysis setup icon in the Project tree to open the **Solution Setup** dialog.

2. Click the **Expression Cache** tab in the **Solution Setup** and click **Add...** to open the **Add to Expression Cache** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Specify the context for the expression you define. For Modal Solution Data, you do not need context other than the Solution. Other selections require more context:
   - Emission Test also requires a digital signal.
   - Far Field also requires a geometry such as an infinite sphere.
   - Fields or Near Fields also require a geometry such as a polyline.
4. Under the **Trace** tab, select from the Category, Quantity and Function lists to create expressions.

   Selecting a listed category lists the Quantities and Functions available for each category. If you have defined one or more output variables, you can see them listed as Quantities by selecting the **Output Variables** Category. The Output Variables button opens a dialog that lets you define additional output variables.

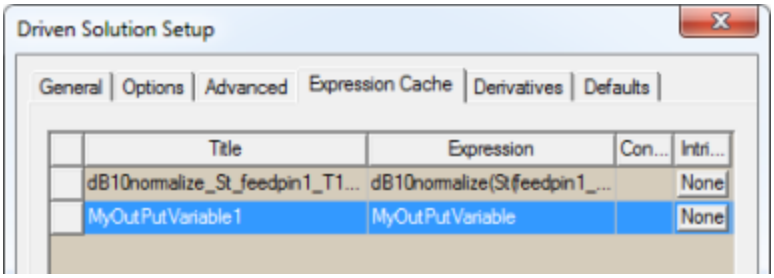
   When you have created an expression, it appears in the Expression field of the **Trace** tab. If desired, you can use the Range Function button to select range functions to apply to the expression.

   Under the **Calculation Range** tab, you can view the values of available sweep variables. Clicking the ellipsis [...] button in the Edit column opens a list of values.
5. When you have created an expression that you want to add to the cache, click **Add Calculation**.

   This adds the selected expression and the associated context to a table in the **Expression Cache** tab. You can select any additional expressions with contexts and add them in the same way.
6. When you have added the expressions you want, click **Done** to close the **Add to Expression Cache** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Expression Cache** tab of the **Solution Setup** lists the expressions you have added as a table.



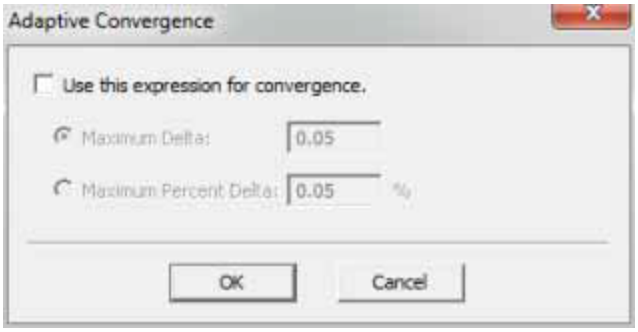
- The Title field is editable, by default showing the name as built from the expression, but removing underscores.
- The Expression field shows the full expression. If necessary, you can resize the **Solution Setup** dialog box. You can also resize each column in the table.
- The Context column shows None for Modal solutions, or the appropriate geometry for Fields calculations.
- The Intrinsics column shows a clickable button that opens an **Edit Calculation Range** dialog box. If the column button shows None you cannot edit the value. If the button shows variables, click the ellipsis [...] in the Edit column to display a list of the variable values that you can select. Click **OK** to close the **Edit Calculation Range** dialog box and apply your selections to the Expression Cache.
- The Convergence column contains a check box that lets you designate post processing variables, such as for renormalization or de-embedding. You can also use this feature to assign variables to non-model objects (for example, the properties of a solid, sheet or lines used for field calculations). You can also assign a PP Variable to a coordinate system (CS) that is not associated with model objects.

To excite particular sources for particular output variables, you can assign a post process variable to the magnitude of sources you might want to edit, and assign the expression value in the Expression Cache. With PP Variables, you can control convergence based on several combinations of active sources.

7. To designate one or more expressions for convergence, click the field for the Convergence column for each expression.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This opens an **Adaptive Convergence** dialog box.



Check **Use this expression for convergence** to enable the radio buttons. You can then specify the **Max Delta** between passes or the **Max Percent Delta** criteria. The **Max Delta** solves a potential issue if your expression is essentially zero and the numeric noise from pass to pass causes the maximum percentage delta to remain high. In that case adaptive refinement continues until you get to the maximum number of passes.

> **Note:** If you check **Use this expression for convergence**, the pass will be considered converged if both the energy error **and** the expression cache results have converged, not just expression cache.

8. Click **OK** to close the **Solution Setup** window.

Specifying a Source for the Initial Mesh

You may choose to specify a source for the initial mesh from either the current design or another design. The source mesh should represent a geometrically equivalent model.

> **Note:**
>
> For more information see Mesh Linking and Mesh Link Requirements.

To specify a source for the initial mesh:

1. Under the **Advanced** tab of the **Solution Setup** dialog box, click the check box for **Import Mesh**.

   This displays the *Setup Link* dialog box. By default, the **Source Project** check boxes for **Use This Project** and the **Source Design** check box for **Use This Design** are selected.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> When you setup a link to an external source, the **Lamda refinement** option is deselected under the **Options** tab to avoid over-refinement of the linked mesh.

If you uncheck **Use This Project**, you enable fields for selecting a different project and radio buttons to specify whether to save the source path relative to **The project directory of the selected project** or **This project**.

2. To specify a Source Project file click the ellipsis [...] button to open a file browser window.

   When you selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to **Open as read only**.

   Use the radio buttons to specify whether to save the source path relative to **The project directory of the selected project** or **This project**.

   When you select a Project File, the Design field and the Solution field are filled in with default values, and the drop down menus contain any available Projects and solutions.

   The "Default" solution is the product dependent solution of the first Setup. That is the setup listed first in the source design's project tree (alphanumerical order). A product specific solution of this setup becomes the default solution. In most products, it is LastAdaptive. In a Transient solution type, it is "Transient."

   > **Note:**
   >
   > The solution in the source design must provide data for the target design's adaptive frequency as well as its sweeps. That is, the adaptive frequency for the target design must be included in the sweep in the source design.
   >
   > If necessary, you can open the source design and add an appropriate frequency point to an existing sweep.

3. For the Source Design, if you leave **Use This Project** checked, you can uncheck **Use This Design** to enable the a drop-down menu for to select from other available designs.
4. For the **Source Solution** field, you can use the drop-down menu to select from other possible solutions.
5. Use the check box specify whether to **Simulate the source design as needed** to produce the mesh.
6. Use the check box to specify whether to **preserve the source design solution**. Note that in the **Extractor mode**, the source project will be saved upon exit. **Extractor mode** means that the software is opened during the link solely for the purpose of solving.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7. The second tab, **Variable Mapping**, lets you view any variables contained in the Project you select.

   When there are variables in the source design, you can choose to "map" these variables to constant values, expressions or variables in the target designs. Variable mapping becomes more important when the datalink type requires source and target design to be geometrically identical and source design is geometrically parameterized.

   When a variable in the target design has the same name of a source design variable but the 2 variables are not mapped, the **Parameter** tab will become the active tab with the following message box popped.

   You can exit the **Setup Link** dialog directly by selecting "Accept Setup and Exit Dialog" or reexamine the parameter mapping by selecting "Return to Setup Dialog".

   In the **Setup Link** dialog box, for linked designs with variables of the same name, you can click **Map Variables by Name** to automatically map same named variables. A variable that does not have a same named counterpart, and retains its value in the source design.

   Click **OK** to proceed without the variable mapping.

8. You can select the **Additional mesh refinements** tab to specify the following:
   - For Mesh Operations, you can select radio buttons to either **Apply mesh operation in target design on the imported mesh**, or **Ignore mesh operations in target design** (default).
   - For *Port Adapt*, you can check **Perform port adapt in target solve setup**.
9. Click **OK** to accept the setup and close the **Setup** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Clearing Linked Data

Linked data can be a mesh, field results, or some other post-processing data that the source design generated. The target design for the link caches the data internally to minimize the need to activate the source design.

If you have previously setup links to a design, the **HFSS**> **Analysis**> **Setup** shortcut menu contains an option to **Clear Linked Data**. This removes the linked data for all links in a design, therefore invalidating the solutions. You can also clear linked data through **HFSS**> **Results**> **Clean Up Solutions**, which displays a dialog box that includes options to let you selectively delete linked data only, or as part of other deletions.

Clearing linked data for some link types requires HFSS to revert to the initial mesh. Thus in some cases, this command removes the current mesh of the target design.

Mesh Linking

You can obtain a broadband mesh by linking between designs as follows:

- Link a mesh from an Eigenmode solution to a Driven Modal or a Driven Terminal design.
- Use a cascade of mesh links within the same design where each link adapts the mesh at a different frequency.

Mesh Link Requirements

If you want to reuse a mesh from an existing source design, make sure that the geometries in the target and source are identical. This is a requirement for a mesh link. There are two ways to generate geometrically equivalent models.

- Copy the entire source design and paste it in the **Project Manager** window to create the target design.
- Use **Import from Clipboard** as follows:

1. In the model window of the source design, press **Ctrl+A** to select all the objects.
2. Right-click the Modeler field and select **Edit>Copy** from the short-cut menu.
3. On the target design, go to **Modeler>Import from Clipboard** to paste in the design.

After you paste using one of the above methods, create a solution setup in the target, select **Import Mesh** on the **Options** tab, and link the mesh from the **Setup Link** dialog box.

> **Note:**
>
> For more information about linking the mesh, see Specifying a Source for the Initial Mesh.

Setting Lambda Refinement

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Lambda refinement is the process of refining the initial mesh based on the material-dependent wavelength. It is recommended and selected by default.

HFSS performs solution-adaptive mesh refinement to produce accurate results. Lambda Refinement is necessary to avoid false convergence and achieve accuracy to the field data, especially for electrically large problems (approximately greater than 2*lambda). The Lambda refinement process helps simulation start with the optimal balance between element count and element size. For efficient convergence, the initial mesh should meet some element electrical size requirements determined by lambda refinement. Typically, a few elements per wavelength are needed for accurate results. Because wavelength depends upon the material, the element length target differs for each material. You can specify the size of the element target by which HFSS refines the mesh in the Lambda Target field or select the recommended Use Default Value. The default value in the Lambda Target field also depends upon the order of the basis functions. For example, if the lambda target is 0.3333, the initial mesh is refined such that on each solid the length of the elements are approximately smaller than 0.333*wavelength. Lambda refinement stops if the input mesh already reaches the Lambda refinement target.

If you use the **Advanced** tab to link to a mesh from another design or project, **Do Lambda Refinement** is unchanged.

To specify the size of the target value by which HFSS will refine the mesh:

1. From the **Solution Setup** window, select the **Options** tab and enable **Do Lambda Refinement**.

   This enables the **Target** field and the **Use free space lambda** check box. It also enables Lambda refinement from the background material for the IE solver. See: IE Solver Options area on the Advanced tab.

2. In the **Target** field, enter a value for the wavelength or accept the default.

   The **Target** defaults depend on the Order of Basis function selections. For example, for Driven solutions and a First Order basis function, the default target is 0.3333, which means that HFSS will refine the mesh until most element lengths are approximately one-third wavelength.

   For Eigenmode solutions and a First Order basis function, the default target is 0.2

   If you change the Order of Basis functions in the **Solution Setup** window, the default changes automatically. Setting the Order of Basis affects the default value of the lambda refinement in the solution setups as follows.

Zero order:	driven 0.1	eigenmode 0.1
First order:	driven 0.3333	eigenmode 0.2 (as is)
Second order:	driven 0.6667	eigenmode 0.4
Mixed order	driven 0.6667	eigenmode 0.6667

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. If you want the initial mesh to be refined based on the wavelength in free space, select **Use free space lambda**. Material-dependent lambda refinement will be deactivated.

> **Note:**
>
> Changing the Lambda refinement target invalidates any solutions that were performed with the previous lambda refinement.
>
> If an object is highly conductive, very little energy will penetrate into it, so it does not need a dense mesh. In such cases, free space mesh is applied.

Setting the Percent Maximum Refinement Per Pass

The value you set for percent **Maximum Refinement Per Pass** determines how many tetrahedra are added at each iteration of the adaptive refinement process. The tetrahedra with the highest error will be refined. The default value is 30%.

To set the percent refinement per adaptive pass:

- Under the **Options** tab of the **Solution Setup** dialog box, enter a value for percent **Maximum Refinement Per Pass**.

Setting the Maximum Refinement

This specifies the maximum number of tetrahedra that can be added during an adaptive pass. By default, this unchecked, to that there is no maximum. If you enable the **Maximum Refinement**, the initial value is 1000000.

To set a new value for the Maximum Refinement:

1. Under the **Options** tab of the **Solution Setup** dialog box, click the **Maximum Refinement** check box to enable the text field.
2. Enter the number of tetrahedra for **Maximum Refinement**.

You can also control these values in the docked properties window that displays when you select the setup with the **View>Properties** enabled. With the properties window displayed. you can click the check box for **Use Max Refinement** to apply the value in the Max Refinement text field.

Setting the Minimum Number of Passes

An adaptive analysis will not stop unless the minimum number of passes you specify has been completed, even if convergence criteria have been met.

- Under the **Options** tab of the **Solution Setup** dialog box, enter a value for **Minimum Number of Passes**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> For a solve setup with zero passes, no sweeps, and that is not ports only, validation produces a warning message.

Setting the Minimum Number of Converged Passes

An adaptive analysis will not stop unless the minimum number of converged passes you specify has been completed.

- Under the **Options** tab of the **Solution Setup** dialog box, enter a value for **Minimum Converged Passes**.

The convergence criteria must be met for at least this number of passes before the adaptive analysis will stop.

Setting Matrix Convergence Criteria

For designs with ports.

You can specify different stopping criteria for specific entries in the S-matrix. This is done in the **Matrix Convergence** dialog box. The adaptive analysis will continue until the magnitude and phase of the entries change by an amount less than the specified criteria from one pass to the next, or until the number of requested passes is completed.

To set the matrix convergence:

1. Under the **General** tab of the **Solution Setup** dialog box, select **Use Matrix Convergence**.
2. Click **Set Magnitude and Phase**.

   The **Matrix Convergence** dialog box appears.

3. Select one of the following from the **Entry Selections** drop-down menu:

All	Sets all of the matrix entries at once. (The default).
Diagonal/Off-Diagonal	Sets all of the diagonal matrix entries at once, all off-diagonal matrix entries at once, or both diagonal and off diagonal entries at once.
Selected Entries	Sets individual matrix entries that you will select.

   For the selection **All**, enter the convergence criteria for the **Maximum Delta (Mag S)** and the **Maximum Delta (Phase S)** in the fields to the right.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For the selection **Diagonal**/**Off-Diagonal**, first check **Diagonal Entries**, **Off-Diagonal Entries**, or both, to enable the convergence criteria field or fields. Then enter the convergence criteria for the **Maximum Delta (Mag S)** and the **Maximum Delta (Phase S)** in the fields to the right.

For both of these **Entry Selections**, you can set the **Ignore Phase when Mag is less than** value. See the note on technical issues under step 4 c.

4. If you chose **Selected Entries**, the Matrix Convergence dialog displays some new fields:
   - a table showing columns for Matrix Entry 1, Matrix Entry 2, and the Delta Mag and Delta Phase.
   - **Entry 1** and **Entry 2** fields, which contain drop-down menus of ports and associated modes (or terminals).
   - an **Insert** button with which to move selections from the port list selections to the table

   To select the desired ports and mode (or terminal) pairs, do the following:

   a. Select Entry 1 and Entry 2 from their drop-down menus.
   b. In the **Magnitude** box, enter the maximum change in magnitude from pass to pass from the Entry 1 to Entry 2.
   c. In the **Phase** box, enter the maximum change in phase, in degrees, from pass to pass from Entry 1 to Entry 2.

      > **Note:** When the Mag S becomes small (near to zero) its phase becomes indefinite and insignificant due to mathematical issues. In HFSS 10 and 11 there was a 0.05 magnitude threshold that caused that Phase Margin to be discarded. However, some users may want to continue running additional passes to stabilize phase margins even when the S-parameter magnitude is below this threshold. For this reason, the magnitude threshold has been removed. This calls for caution if you want to see a good phase convergence for S_{12}, which is near to 1. If you set a small delta_phi with small delta_s, after a couple of passes, S_{12} will converge, but S_{11} never, since S_{11} ~0 and its phase changes with the mesh noise because the phase is indefinite. In other words, under these conditions the adaptive process never stops, so you should abort it.

   d. Click **Insert.**

      The entries appear in the table above. If you have selected multiple entries, all combinations of matrix entry1 and matrix entry2 populate the table.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Selecting a Row in the table enables the Delete button, if you need to remove a row from the table.

Clicking in the Delta Mag and Delta Row fields of the selected row enables editing in those fields.

5. Click **OK** to apply the values and close the dialog.

Setting the Order of Basis Functions

You can change the basis functions HFSS uses to interpolate field values from nodal values.

- Under the **Options** tab of the **Solution Setup** dialog box, select **Order ofBasis**.

This can be First Order (the default), Zero Order, Second Order, or Mixed order.

Setting the Order of Basis functions affects the default value of the Lambda Refinement in the Solution setups as follows.

Zero order:	driven 0.1,	eigenmode 0.1
First order:	driven 0.3333,	eigenmode 0.2 (as is)
Second order:	driven 0.6667,	eigenmode 0.4
Mixed order	driven 0.6667	eigenmode 0.6667

The Zero order option is useful when a model requires a mesh that produces more than 100,000 tetrahedra, but the model size is small compared to wavelength. The higher order options solve progressively more unknowns for each tetrahedron. Mixed order uses higher order where more accuracy is required, and lower order where fields are weaker.

> **Warning:**
>
> If you select **Zero Order Solution Basis**, all tetrahedra in the model must have edge lengths less than $1/20^{th}$ wavelength. Thus, this option is usually selected in combination with a specific lambda refinement setting.

Enable Direct Solver

The direct solver provides a multi-frontal (MF) approach when a matrix is not well-conditioned for an iterative solution. The iterative solver significantly reduces memory usage, and it can also provide a savings in the solution time for large simulations.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When you select the **Enable Direct Solver** option, HFSS automatically invokes the multi-frontal solver. If you select **Iterative Solver** and HFSS decides that the matrix is not conditioned well enough to take advantage of the iterative approach HFSS still uses the multi-frontal solver.

Enable the Direct Solver

From the **Solution Setup** window, select the **Options** tab. Then select **Direct Solver** from the *Solution Options* group box.

> **Note:** The Iterative Solver is not available for zero order basis solutions.

Enable Iterative Solver

The iterative solver provides an alternative to the multi-frontal solver when a matrix is well-conditioned for an iterative solution. The iterative solver significantly reduces memory usage, and it can also provide a savings in the solution time for large simulations.

When you select **Enable Iterative Solver**, HFSS automatically invokes the iterative solver when it decides that the matrix is conditioned well enough to take advantage of the iterative approach. HFSS uses the multi-frontal solver if the matrix does not meet this requirement.

For more detail, see the technical notes for Iterative Matrix Solver.

Enable the Iterative Solver

From the **Solution Setup** window, select the **Options** tab. Then select **Iterative Solver** from the *Solution Options* group box.

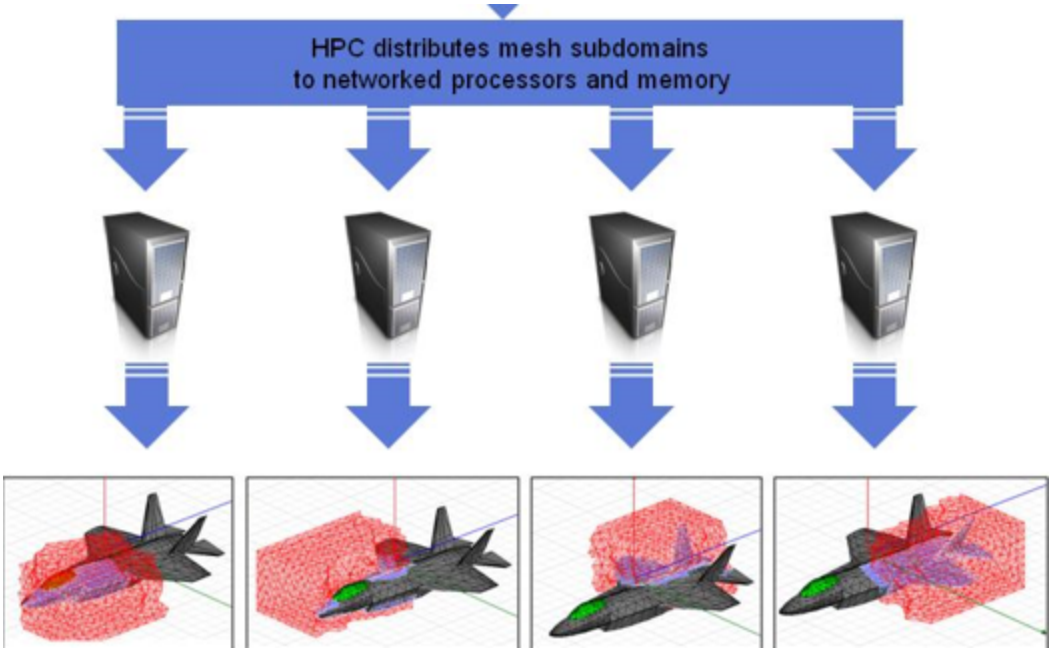
This enables the **Relative Residual** check box. The residual measures the convergence of the iterative solver. Check the box, if desired, and enter a **Relative Residual** value in the adjacent text field (default value is 1E-6).

> **Note:** The Iterative Solver is not available for zero order basis solutions.

Enable Domain Decomposition

If a problem is too large to solve on one machine, HFSS can automatically partition a design into domains that can be solved by separate processes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



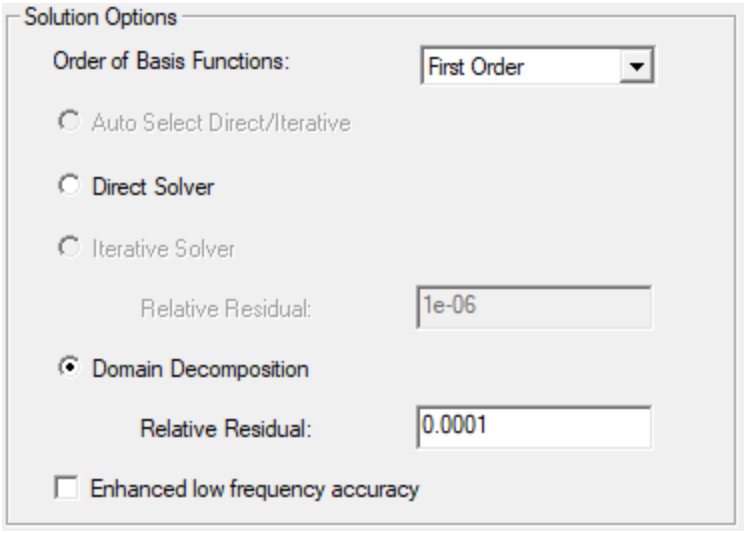
Before enabling solver domains, you must have the HPC license option, and you must have allocated at least three distributed machines to the solve workgroup. The number of domains that the solver creates will not exceed N-1, where N is the number of machines listed in the workgroup. (The first machine in the workgroup acts as the head node and is responsible for domain assembly, mesh refinement, and solution management). If more machines are present in the solve workgroup than are needed, HFSS creates the number of domains that leads to increased overall solver efficiency. Consequently, some machines remain idle if the problem size does not justify their use. See the Technical Note on domain decomposition for further details.

> **Note:**
>
> You can use the Domain Decomposition method and setup HPC to solve a large problem such as a helical antenna. HFSS automatically apportions the helical antenna design into domains and solves them by separate processes. See the discussion associated with the helical antenna example project that can be accessed with **File** > **Open Examples** > **Antenna**.

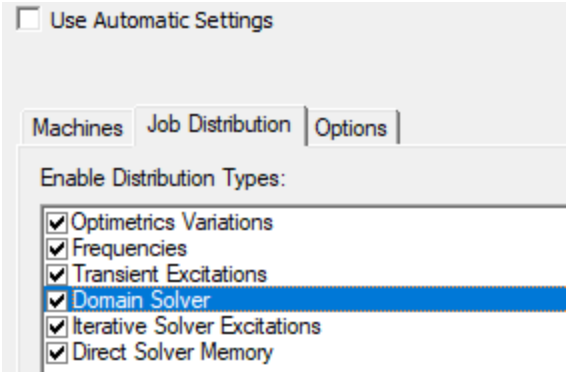
Domain use can be invoked for a solve when

- The **Domain Decomposition** radio button under the Solution Setup Options tab is checked.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- You have the HPC License.
- You have provided at least three distributed machines in the workgroup.
- Domain Solver is enabled in the Analysis configuration, either explicitly (as shown) or by selecting "Use automatic settings".



- The solver determines that the problem is large enough (the mesh has enough tets) to bother with domains.
- The design includes IE Regions and/or FE-BI Radiation Boundaries.

If you have configured your installations properly, the Domain solve can use Distributed Memory solutions. Memory used by the MPI-enabled HFSS solver is therefore limited by the set of machines that are available rather than the shared memory available on any single machine. This allows you to simulate larger structures than before and to optimally reconfigure the cluster of machines for the problem at hand. If an HFSS problem involves solver domains or a finite array, then frequency sweeps will not be done using DSO. Also, DSO for Optimetrics will not be allowed.

Restrictions on solver domains are that the design and analysis setup cannot include:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The design cannot contain primary and secondary (Lattice Pair) boundaries.
- Eigenmode solution type.
- Fast frequency sweeps.

If any condition is not met, the problem is solved with the non-domain solver defined under the solution options. When these conditions are met:

- The solver chooses the number of domains to use, based on the machines available. The number of domains chosen will likely be close to the maximum. The maximum is one less than the total because the first machine in the workgroup is used to control domain iterations.
- The solver creates the domain meshes of roughly the same size
- Domain meshes are created every time the global mesh changes (before each adaptive pass)

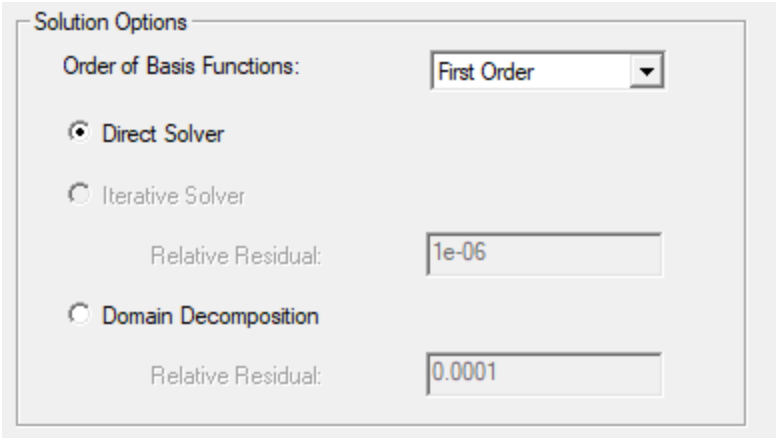
Note:

- You provide resources for the distributed solve by adding machines to the distributed machine workgroup. A machine can appear in the workgroup more than once. You should use this capability to maintain a balanced load.
- Because the domains should be roughly the same size, you should provide balanced resources.

Beta Option for Domain Decomposition Allowing Distributed Direct Solver

This release includes a Beta Option allowing to use the Direct Solver for regular arrays and 3D component arrays. When the option is enabled, and the design is appropriate, the Direct Solver radio under the under the Solution Setup Options tab can be selected. Both non-distributed and distributed direct are used the same way as traditional direct solver. This can be very beneficial in some cases such as non-radiating structures which may a long time for standard Domain Decomposition iterations to converge.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Distributed Right-Hand-Side Solver in Domain Decomposition

For versions prior to HFSS16 in the domain decomposition solver, domains are distributed across separate machines and each right hand side (RHS) or excitation is solved one at a time. For designs with several excitations, this process can take much time. In HFSS16 a distributed right hand side (RHS) solver can use extra machines (if available) and speed up simulation.

Balancing Resources for Domains

The Domain Decomposition option for large models requires that you provide resources for the distributed solve by adding machines to the distributed machine workgroup.

Because the domains should be roughly the same size, you should provide balanced resources. As an example of balancing the load, suppose that machine called Biggie has 256 GB and another called Smalls has 64 GB. If you want up to five domains, it makes sense to enter Biggie in the workgroup four times and Smalls once.

Under Analysis Configuration Options, you should set the **RAM Limit %** to the memory desired for each individual domain.

In the example above, a good choice for Mem_Limit_Soft would be 64 GB.

Remember:

- A machine can appear in the workgroup more than once. The user should use this capability to maintain a balanced load.
- The first machine in the workgroup is used to control domain iterations.
- Under the Analysis Configuration Machine tab, the **Number of Cores** is also set per domain.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In the example above, a machine named Biggie has 16 processors and a machine named Smalls has 8 processors. Four domains will go on Biggie, so **Number of Processors** should be set to 4. Four processors on Smalls will be unused.

Recommendation: it is more important to use memory efficiently than to use all the processors.

Domains with FE-BI Radiation Boundaries or IE Regions

The solve uses domain solvers if there is a FE-BI radiation boundary and/or at least one IE Region.

- Solve sequentially using domains if solver domains are not enabled
- Solve distributed using domains if solver domains are enabled, even if mesh not big enough to split into solver domains

Number of domains

- One or more for FEM region (depending on whether using solver defined domains)
- One or more for FE-BI surfaces and dielectric cavity, depending on size and connectivity
- One or more for metallic IE Regions, depending on size and connectivity
- With solver defined domains, determines number of machines

Use Radiation Boundary on Ports

If the design includes wave ports, the **Use Radiation Boundary on Ports** option is enabled under the **Advanced** options tab of the **Solution Setup** dialog box.

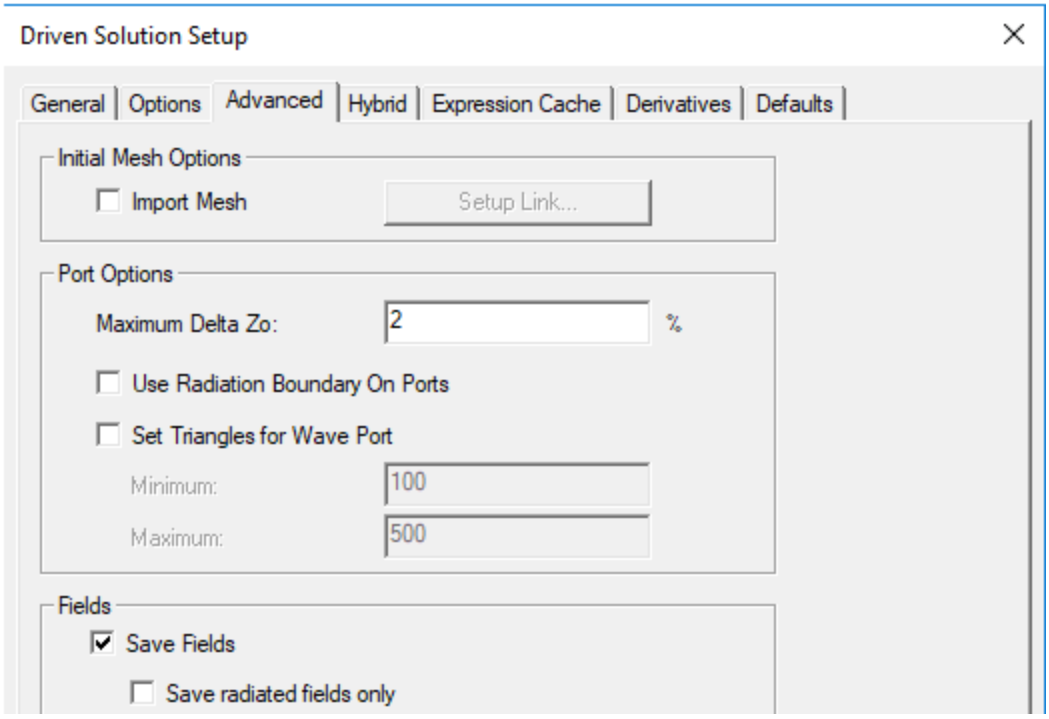
- If you select this setting, edges that touch a port and are assigned to an ABC have a radiation boundary condition applied during the port solution.
- If you do not select this setting, a perfect conducting boundary condition is used during the port calculations.

In most cases this setting has a limited effect on the overall fields or post processed quantities.

Port Options

If the design includes wave ports, the **Port Options** appear under the **Advanced** options tab of the **Solution Setup** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



These options include:

- **Maximum Delta Zo** - change to Zo specified as a target percentage. The default is 2%. The port solver computes mode patterns and propagation constants based on solutions of a finite element system of equations. The finite element mesh associated with each port is a 2D mesh of triangles corresponding to the faces of the tetrahedra that lie on the planar port surface. The port solver performs an iterative refinement of the triangular mesh. During the port solve a 2D adaptive process analogous to the well known 3D process is employed to determine the fields for the port. As we have a max delta S for the overall 3D solution, on the port the convergence criteria is tracking the port impedance, Zo, as a function of these rapid 2D passes to the port. For a technical explanation, see Mesh Refinement on Ports.
- Use Radiation Boundaries on Ports
- **Set Triangles for Wave Port -** unchecked by default.

If you check **Set Triangles for Wave Port**, the **Minimum** and **Maximum** fields are enabled. You can edit the default values of 100 for the minimum and 500 for the maximum.

For designs with lumped ports, this option is not active. Higher numbers of triangles would not benefit a solution setup in this case.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Beta Option: Enhanced Tau Port Meshing

The port solver requires an all planar mesh on ports. If the ports overlap with other objects or faces, occasionally the initial mesher may generate a non-planar mesh or an inaccurate mesh and then the port solver will fail or rejects the mesh. In such situation, you may need to use this Beta feature for accurate port mesh.

It uses a two stage approach to mesh generation. In stage-1, mesh on all the ports or user specified “high priority surface representation” faces will be generated, and strict mesh verification will be applied. Repair methods are involved if an inaccurate port mesh is found. This ensures that a satisfactory port solver driven mesh is created. Then in stage-2, all the remaining objects will be placed to the pool for the mesh. When an overlap or tiny gap is found, these faces will be treated as lower priority objects compared to ports.

Technical Notes: Port Solutions

Produce Derivatives for Selected Variables

The **Derivatives** tab of the **Solution Setup** window allows you to produce derivatives of S-parameters and related matrix quantities, such as Y or Z. The solver can also output partial derivatives of *E* and *H* over radiation surfaces. You can then create reports to calculate the partial derivative of the far fields using of *E* and *H* over the radiation surfaces based on the same formulation as far fields. Thus the tuned far fields are derived from the nominal fields and the partial derivative of the far fields.

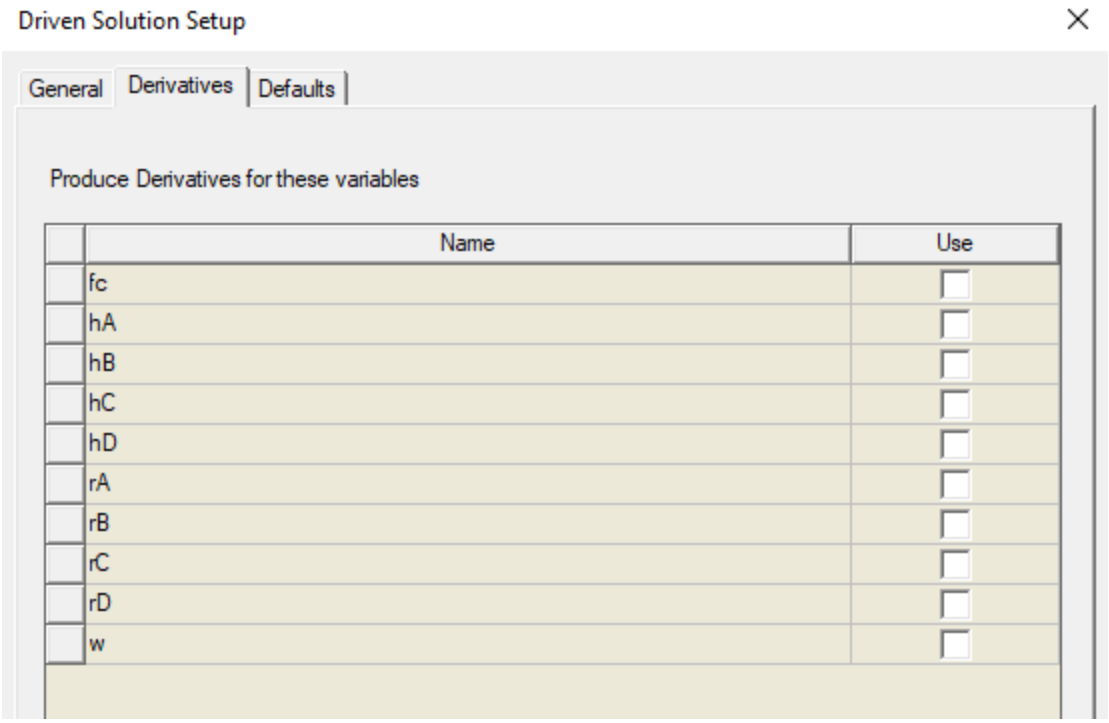
Far field tuning supports:

- Incident Wave
- Linked Field
- Voltage Source
- Current Source
- Magnetic Bias

> **Note:**
>
> Sensitivity analysis of a design variable associated with the magnetic bias region assumes that the magnetic bias field does not change. In some cases, this assumption may not be appropriate and requires user discretion to ensure its applicability, especially for non-uniform ferrite models.

You can select design properties and project variables as variables of differentiation. If your design has appropriate candidate variables, the **Derivatives** tab of the **Solution Setup** window lists them. Enable the derivative calculation(s) by selecting the appropriate **Use** check boxes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can view the computed derivatives in the Reporter. You can also use them through the Tune Reports command for interactive exploration of small variations in the design without the need to solve again.

Important:

This feature has the following limits:

- HFSS Transient projects do not support derivatives.
- HFSS Eigenmode projects do not support derivatives.
- Derivatives are not computed in a ports-only solution.
- Derivatives are supported in projects with non-port excitations, including incident waves, linked fields, voltage or current sources.
- Parameters of differentiation may not affect Floquet ports.
- Parameters of differentiation many not affect de-embedded Lumped ports.
- Derivatives are not supported for any solution employing Domain Decomposition Method (DDM), which includes FE-BI radiation boundaries, IE Regions, Finite Arrays.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Units for Calculated Derivatives

The derivatives calculated by HFSS are dependent on the units of the design parameters. For example, if the design parameter *p* is originally defined with units of millimeters, then the value of the derivative gives the (linearized) change in the output quantity when *p* is varied by one unit (1 mm). If the units of *p* are changed to an equivalent value in micrometers, and the derivative is recomputed, then it will appear to drop in magnitude by a factor of 1000 because it now represents how much the output changes when *p* is varied by one unit (now 1 micrometer.) Therefore, when reporting derivative values it is necessary to record the units of the output quantity as well as the units for the variable of differentiation.

Adding a Frequency Sweep (HFSS)

For Driven solution types.

To generate a solution across a range of frequencies, add a frequency sweep to the Advanced solution setup (an Auto Setup includes a discrete sweep by default). HFSS performs the sweep after the adaptive solution. If an adaptive solution is not requested, the sweep is the only solution generated. You can also disable a sweep, so that you can run only the adaptive solution (or a ports-only solution) without the sweep, then later reactivate the sweep definition.

To add a frequency sweep:

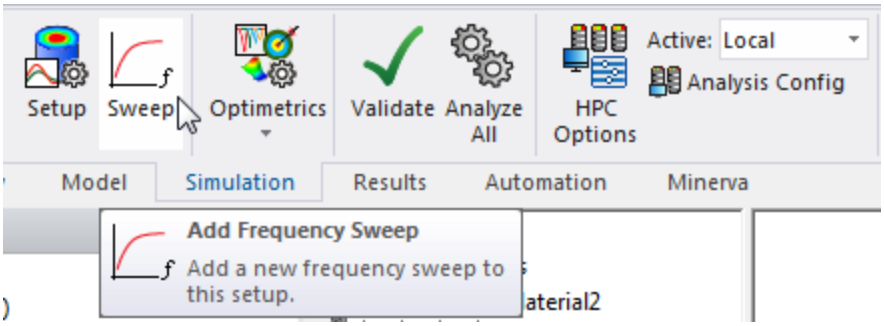
1. Click **HFSS**>**Analysis Setup**>**Add Frequency Sweep** .

   A dialog appears which lists the solution setups.

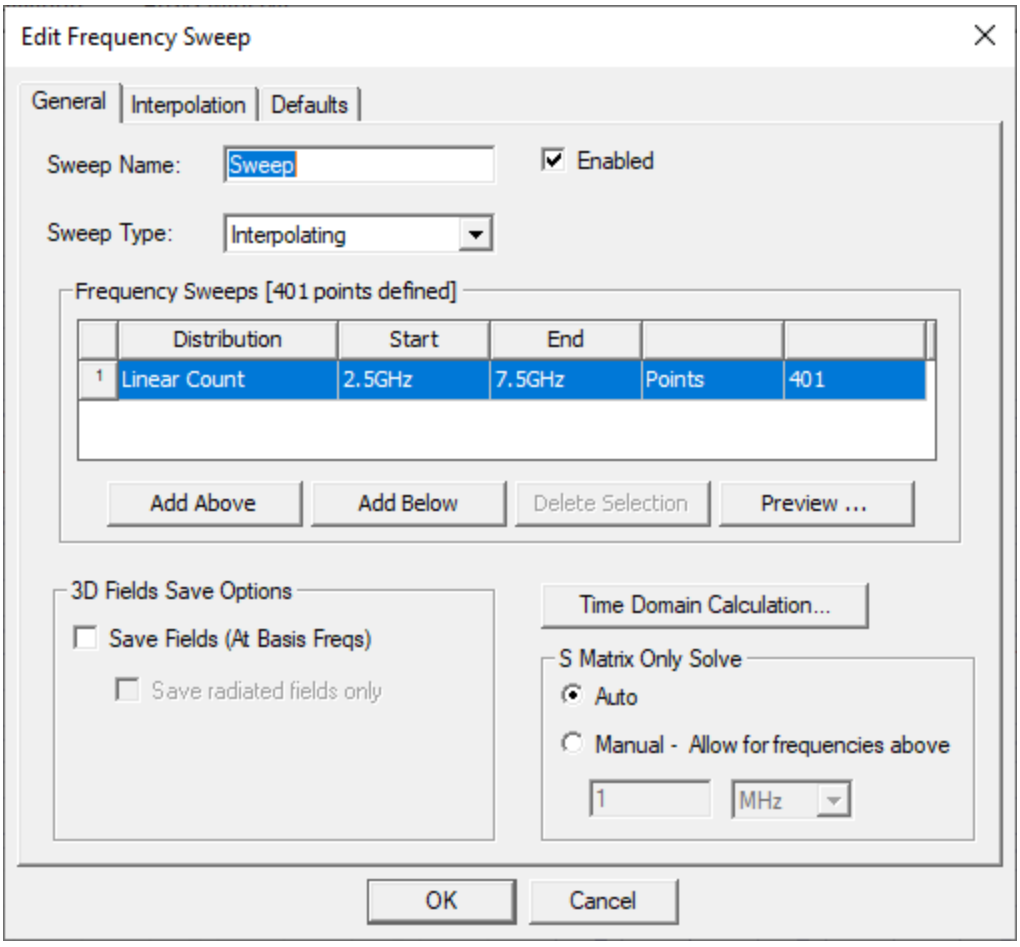
   Select the solution setup to which the sweep applies. To bypass this dialog right-click the desired setup in the Project tree and select **Add Sweep** from the shortcut menu, or select a

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup in the Project tree and on the Simulation tab, click the **Sweep** icon:



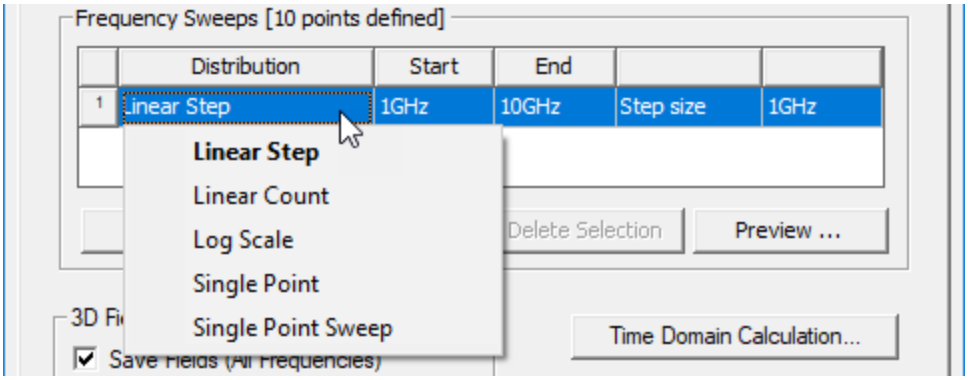
The **Edit Frequency Sweep** dialog box appears.



2. Specify the following sweep parameters:
   - Sweep Name.
   - Enabled check box.

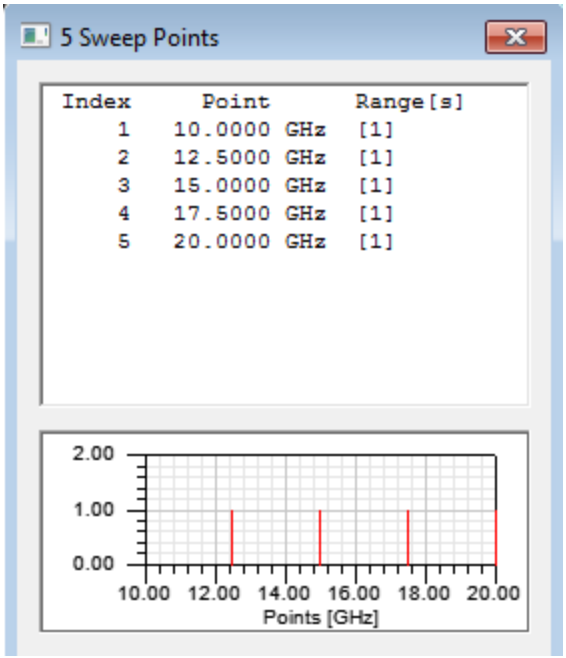
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Sweep type - Discrete, Fast, or Interpolating (the default). Each selection affects the tabs and options available. If a port is not assigned, Interpolating selection does not appear. The 3D Fields options are slightly different for each sweep type.
- Frequency Sweeps. You specify sweeps in terms of Distribution type, which can be Linear Step, Linear Count, Log Scale, Single Point, or Single Point Sweep, which adds a set of 10 Single Point Sweeps, defaulting from 1 GHz to 10 GHz in increments. The **Add Above**, and **Add Below** buttons permit you to add additional sweeps, including mixed sweep types. This feature provides flexibility. For example, you can define sweeps with log scale at lower frequencies, and linear step at higher frequencies. You can edit the Distribution, Start and End fields for any sweep.



If you have added more sweeps, you can **Delete** a selected distribution.

The **Preview** button displays the sweep(s) as currently defined.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. If you plan to perform a Full-Wave SPICE analysis, click Time Domain Calculation tool to obtain assistance determining a suitable frequency sweep range for the solutions. Also see the Requirements for Full-Wave SPICE.
5. If you expect to use the same settings often, you can got to the Defaults tab and click the **Set Defaults** button. To use previously saved settings, click the **Use Defaults** button.

Once you have created a sweep, an icon for the sweep appears in the Project tree under the associated setup. Selecting the sweep icon causes the docked properties dialog to show the name, start, stop, step size, and sweep type. It also includes an **Enabled** check box.

Edit, Copy and Paste Existing Sweeps.

You can select an existing sweep, use the **Edit** commands to **Copy** it, and then and **Paste** the sweep into the Project tree. (By default, the copy is named Sweep*n*, where *n* increments with each new sweep.) You can edit the new copies of the sweep to make desired changes. For example, you can change a specific parameter, or for a distributed solve, you could assign different start and end points for each copy of the setup.

The **Paste** command for sweeps is design sensitive (that is, you cannot paste between Driven and Eigenmode designs) and context sensitive (for example, a sweeps can only be pasted in a setup.) Dependent setups are pasted along with the copied setup. You are warned if the dependent setup is already in the design and setup is not pasted again.

> **Note:**
>
> For a solve setup with zero passes, no sweeps, and that is not ports only, validation produces a warning message.

Selecting the Sweep Type

For Driven solution types.

Specify the type of sweep you want to perform in the **Edit Frequency Sweep** window. Choose one of the following sweep types.

Fast Sweep Options	Generates a unique full-field solution for each division within a frequency range. Best for models that will abruptly resonate or change operation in the frequency band. A Fast sweep will obtain an accurate representation of the behavior near the resonance. Fast sweeps are disabled if an anisotropic boundary condition is present.
Interpolating Sweep Options	Estimates a solution for an entire frequency range. Best when the frequency range is wide and the frequency response is smooth, or if the memory requirements of a Fast sweep exceed your resources.
(default)	All discrete basis solutions are solved prior to interpolating sweeps because it

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	is possible that an interpolating sweep can re-use already solved frequencies from a discrete sweep. For Time Domain Reflectometry plots (TDR), you must use an interpolating sweep. When you select Interpolating sweeps in the **Edit Sweep** dialog box, the **Interpolation** options tab is activated. This lets you specify a maximum number of solutions, and other interpolation values.
Discrete Sweep Options	Generates field solutions at specific frequency points in a frequency range. Best when only a few frequency points are necessary to accurately represent the results in a frequency range.

If you expect to use the same option settings often, you can click **Set Defaults**. To use previously saved settings, click **Use Defaults**.

Options for Discrete Sweeps

For Discrete sweeps, the **Edit Sweep** dialog options you can set include

- Sweep Name
- Enabled Checkbox
- The ability to Use Q3D for DC Simulation in HFSS means the dialog includes a Use Q3D to solve the DC point option.

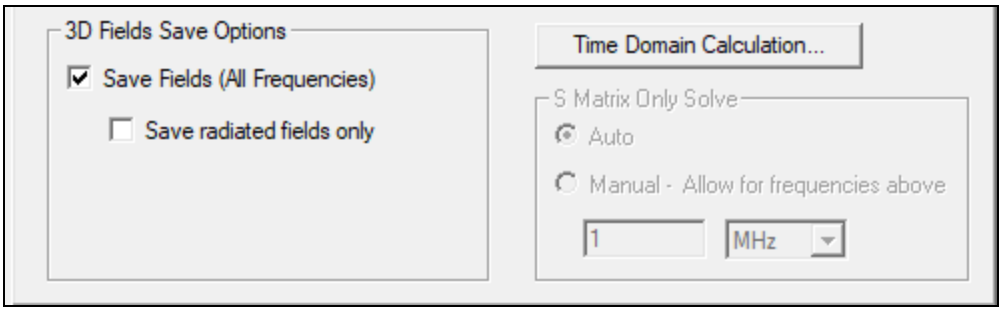
  If Q3D is turned on, the project will succeed only if classic can mesh the original model. Models where tau succeeds but classic fails fail if you turn on Q3D.

- Performance of HFSS with/without Q3D can be compared only with classic mesh. One can not compare it to tau.
- Frequency Setup

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- 3D Fields Save Options.

  With **Save Fields** not selected, the default is for Auto **S Matrix Only Solve**. Here, the solver automatically determines threshold of S-matrix only solve. The **Manual** option is available for situations when:
  - The direct solver is being used.
  - If S-matrix only solve has a singularity matrix, you might want to increase the manual threshold.
  - If you want faster simulation, you might want to decrease the manual threshold.
- Whether to **Save Fields** (for all Frequencies). By default, all frequencies are saved. (This field is disabled under a Solve Ports Only setup. You can view port fields for the discrete frequencies under the port field display in the project tree.)
- For discrete sweeps, you can specify whether you want to save the 3D fields. Checking **Save Fields (All Frequencies)** enables the option to **Save radiated fields only**.



If you expect to use the same settings often, you can click **Set Defaults**. To use previously saved settings, click **Use Defaults**.

Options for Fast Sweeps

For Fast sweeps, the **Edit Sweep** dialog options you can set include:

- Sweep Name
- Frequency Setup

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For Fast Sweeps, you can select Save Fields, Save radiated Fields only, and whether to Generate fields at solve time (All frequencies).

  By default, all fields are saved. (This field is disabled under a Solve Ports Only setup. You can view port fields for the discrete frequencies under the port field display in the project tree.)

  Selecting **Save Fields** enables the check box for **Generate Fields for all frequencies while solving**. By default, fields are not generated. If you have more than 100 frequencies, checking the box generates a warning that disk space use may be excessive.

  If you select this option, HFSS solves the fast sweep and then computes the fields at each freq in the sweep, and saves them. This has two effects: (a) the simulation takes longer due to saving the fields, (b) Post processing is much faster.

  Since this option is exercised at solve time, it doesn't apply to existing solutions. Enabling this option for a previously solved sweep and re-solving will access the previously solved data and generate the requested fields.

- DC Extrapolation options (appearing depending on the Design Settings for DC Extrapolation)

If you expect to use the same settings often, you can click **Set Defaults**. To use previously saved settings, click **Use Defaults**.

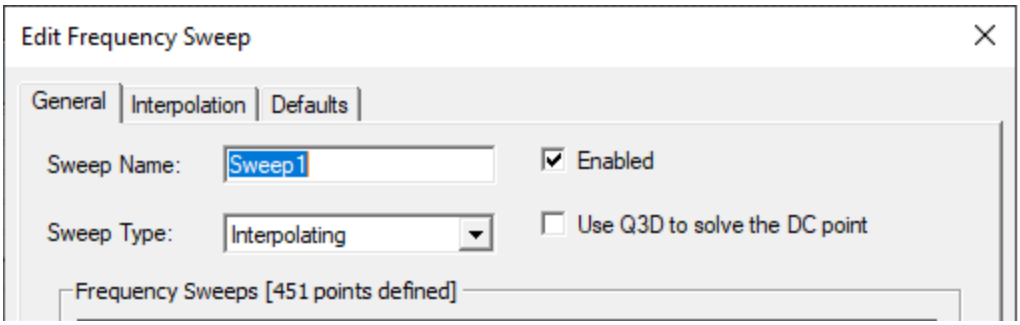
Options for Interpolating Sweeps

A wave port must be assigned for the Interpolating option to appear. For Interpolating sweeps, **Edit Frequency Sweep** options include:

General tab:

- Sweep Name
- Enabled check box
- Due to the ability to **Use Q3D for DC Simulation** in HFSS, the **General** tab includes a checkbox to **Use Q3D to solve the DC point**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



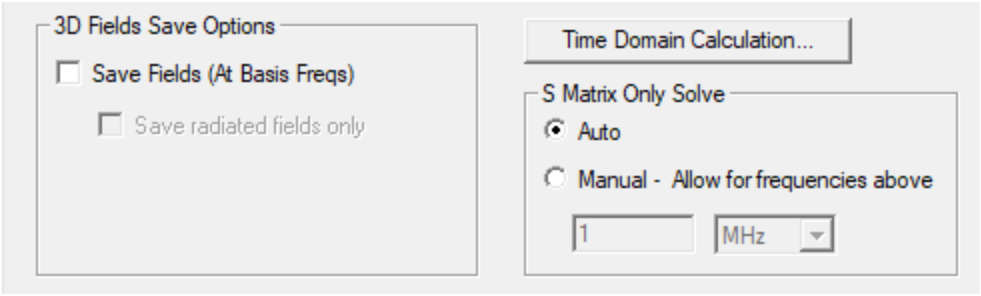
This feature accepts designs with gap type of lumped port, where the terminals touch planar faces. It is limited to RLC, finite conductivity and PEC for boundary. A Q3D DC solve will only use the classic/phi mesher. You can look at the S-parameter result for DC point, but no field will be available.

If Q3D is turned on, the project will succeed only if classic can mesh the original model. Models where tau succeeds but classic fails fail if you turn on Q3D.

- Performance of HFSS with/without Q3D can be compared only with classic mesh. One can not compare it to tau.

Note: Use Q3D to solve DC point provides network data only and cannot be used for fields overlays.

- Frequency Setup
- 3D Fields Save Options.



With **Save Fields (At Basis Freqs** not selected, the default is for Auto **S Matrix Only Solve**. Here, the solver automatically determines threshold of S-matrix only solve. The **Manual** option is available for situations when:

- If the direct solver is being used.
  - If S-matrix only solve has a singularity matrix, you might want to increase the manual threshold.
- If you want faster simulation, you might want to decrease the manual threshold.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Save Fields (at Basis Freqs)** selected:

  You can save fields or radiation only on the basis frequencies of the interpolating sweep. If you do so, the sweep will be available for selection by a target SBR+ design.This permits directivity and gain in the target SBR+ design.

Interpolation tab:

- Max Solutions
- Error Tolerance
- Click the **Advanced Options...** button to open the Interpolating Sweep Advanced Options dialog.

DC Extrapolation tab (appearing depending on the Design Settings for DC Extrapolation):

- DC Extrapolation option

If you expect to use the same settings often, you can click **Set Defaults** on the Defaults tab. To use previously saved settings, click **Use Defaults**.

DC Extrapolation options

If the Design Setting for DC Extrapolation is set to Advanced, the **DC Extrapolation** tab appears for Fast and Interpolating sweeps. Otherwise, an effective DC value is calculated.

1. Setting the Initial Frequency to 0 enables DC extrapolation for a sweep.
2. Enter a value for the **Minimum Solved Frequency**. This value represents the smallest frequency in the sweep for which a full solution is generated. The default is 100 Mhz.

> **Note:**
>
> The Minimum Solved Frequency that you enter is solved independently of the step size.

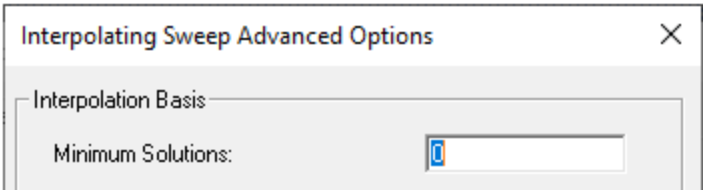
If you expect to use the same settings often, you can click **Set Defaults**. To use previously saved settings, click **Use Defaults**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

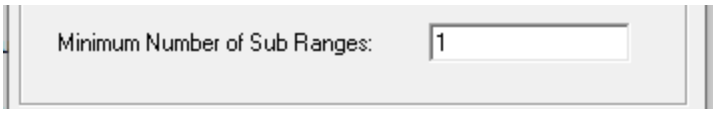
Set up Interpolating Sweep Advanced Options

For Interpolating sweeps, the **Setup Interpolating Sweep Advanced Options** dialog lets you specify the following settings for a sweep:

- The **Minimum Solutions** value is the minimum number of solutions that will be used for an interpolation basis of the desired frequency sweep. The finished sweep will satisfy both the desired error tolerance and the minimum number of bases. For example, if the minimum solutions is set to ten, then at least ten frequency points will be solved and used as a basis for the sweep even if the sweep converges before the ten points.



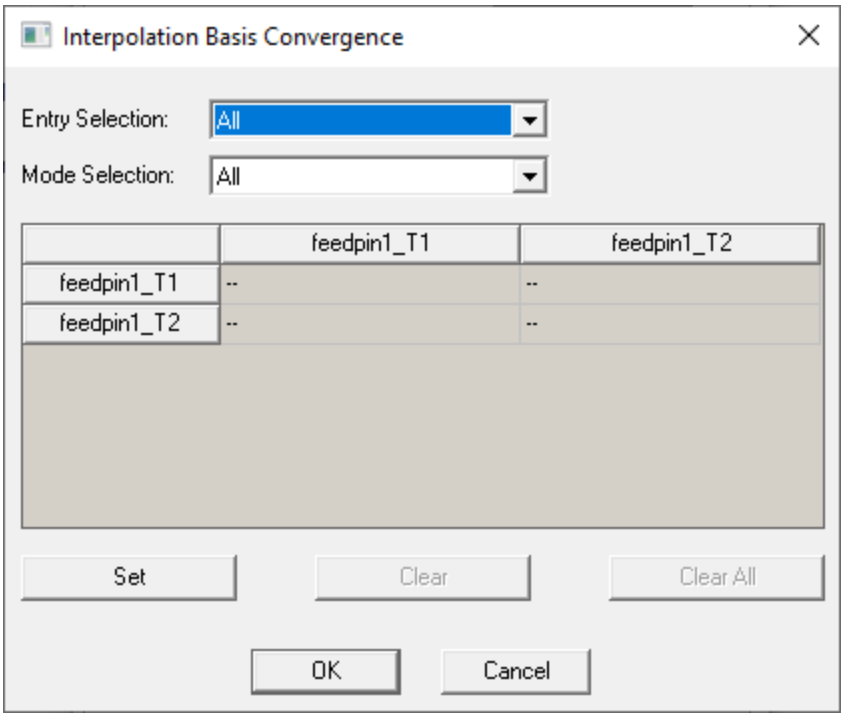
- Specify a **Minimum Number of Sub Ranges**. This number acts as an initial condition on the sweep to force initial even breakup of the null range into sub ranges. The end points and middle of each subrange will be solved. This controls the points at which the interpolating sweep is broken up and prevents redundant effort caused by neighboring interpolating sweeps solving the same point. For example, the 1GHz to 4GHz and the 4GHz to 9 GHz sweeps do not both solve the 4 GHz data point.



- Whether to use all or selected entries in the matrix of data types for the convergence. To choose, click the **Select Entries** button to display the Interpolation Basis Convergence

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

dialog.



- The Data Types for Convergence. The defaults selections differ depending on the solution setup.

For Driven modal, Network Analysis 3D Solution Interpolating sweeps:

- S-Matrix - checked
- Port Impedance - unchecked.
- Propagation constants - checked.

For Driven terminal, Network Analysis 3D Solution Interpolating sweeps:

- S-Matrix - checked
- Port Impedance - checked.
- Propagation constants - checked.

For Driven modal, Network Analysis ports-only, interpolating

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- S-Matrix - unchecked
- Port impedance - checked
- Propagation constants - checked

For Driven terminal, Network Analysis ports-only, interpolating

- S-Matrix - unchecked
- Port impedance - checked
- Propagation constants - checked

If the design contains them, you can select **Derivatives**. If you select **Derivatives**, you can also set the **Error Tolerance**, overriding the tolerance specified in the Edit Sweep dialog..

> **Note:**
>
> If a driven setup's ports-only setup changes and then the problem type switches between driven modal and driven terminal, HFSS resets the interpolation basis data types for the interpolating sweep.

Enforce Passivity – This applies to driven modal and Terminal solutions.

Select this check box to enable passivity enforcement of an interpolating sweep at the requested sampling frequencies with the specified error tolerance. For instance, tolerance of .001 means simulation should attempt to reduce passivity to less than 1.001 at all sampling frequencies. You can view passivity using the reporter. Passivity is enforced on 50 ohm renormalized single ended terminals for terminal projects and 50 ohm renormalized modes for modal projects.

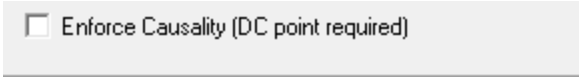
When using passivity, you may want to increase the Max Solutions value.

During an interpolating sweep, HFSS first adds basis points (solution frequencies) until the convergence goal is reached, and then tests the sampling frequencies using the converged sweep for whether they meet the specified passivity requirement. The sampling frequency having the worst passivity violation is selected for solving. After solving for a passivity violation frequency, the solver adds the newly solved data to the interpolation basis.

If necessary, the solver returns to solving for convergence, limited by the maximum number of solutions for the sweep and resumes passivity checking after reestablishing convergence. Messages in the Solution Profile indicate when the interpolated solver is working toward convergence or working to resolve passivity. If any of the bases violates the passivity, the current sweep terminates with a warning message.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Enforce Causality(DC Point Required) -- This applies to Terminal solutions. Causality means that an output signal cannot start to change before the input signal changes. Causality can be enforced only when there is a DC point in the sweep. A design should follow "Best Practices for Accurate and Causal Broad Band Frequency Sweeps." In addition, you can select "Enforce Causality" so the sweep fits (rather than interpolates) the s-parameter results to a set of causal basis functions, thereby ensuring the extraction of a causal model..



Note:

You should follow recommended guidelines whenever setting up a numerical model in HFSS (provide correct material definitions, including information about frequency dependent behavior, and defining appropriate boundary conditions). Also when extracting s-parameter models for signal integrity designs, where providing passive and causal results is important, besides using this option, see "Best Practices for Accurate and Causal Broad Band Frequency Sweeps".

Note:

If you start and stop an interpolated sweep and change the convergence value and/or passivity tolerance, you may generate a non-repeatable sequence of frequencies in the basis. Both regular and passivity frequencies are used when re-evaluate convergence.

If you change sampling frequency delta subsequent passivity behavior may be totally different, since it is evaluated at new sampling frequencies.

Setting the Error Tolerance

For Interpolating sweeps.

The **Error tolerance** value is the maximum relative difference allowed between two successive interpolation solutions. Because interpolating sweeps converge non-uniformly, that is, the error will jump around, false convergence is possible. To prevent this, a secondary check based on the Loewner matrix must also succeed: the condition of the Loewner matrix must also be less than the error tolerance.

The default 0.5 percent for interpolating sweeps is usually satisfactory. However, if the Interpolated sweep Advanced Options include **Enforce Causality** and **Enforce Passivity**, you

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

may need to specify a lower tolerance (for example, 0.1). This is because of the sensitivity of Enforce Causality and Passivity.

To set the error tolerance for an Interpolating sweep:

1. Open the **Edit Sweep** dialog box (by either viewing the properties of an existing Sweep or by Adding a Frequency sweep to an existing Setup).
2. Type a value in the **Error Tolerance** box.

If you expect to use the same settings often, you can click **Set Defaults**. To use previously saved settings, click **Use Defaults**.

Setting the Maximum Number of Solutions

For Interpolating sweeps.

The **Max Solutions** value is the maximum number of solutions that will be solved for the frequency range. For fast sweeps and for interpolating sweeps the default is 250. The value must be greater than 3. To change the value:

1. Open the **Edit Sweep** dialog box (by either viewing the properties of an existing Sweep or by Adding a Frequency sweep to an existing Setup).
2. Type a value in the **Max Solutions** box and click **OK**.

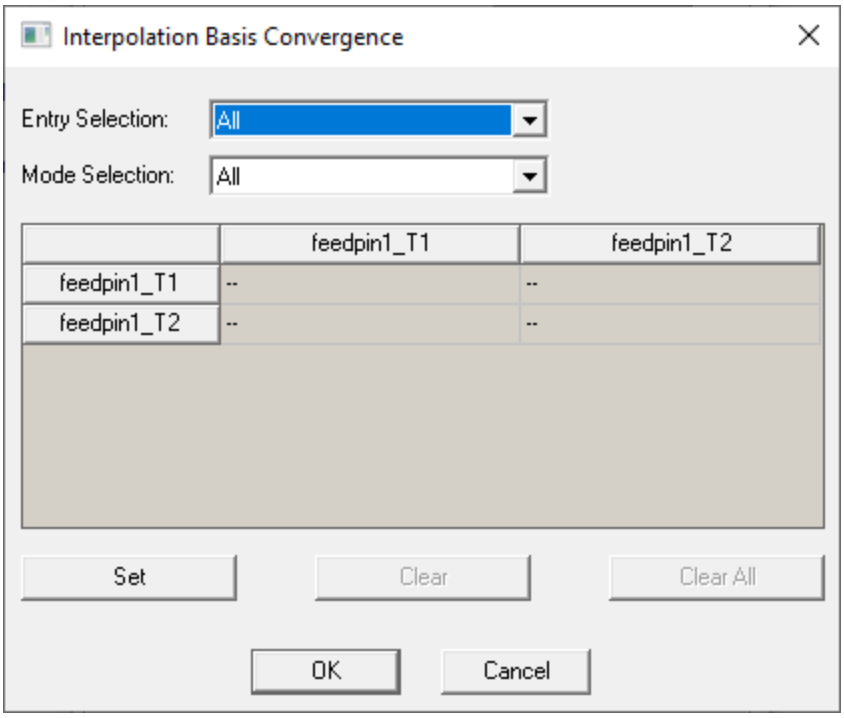
If you expect to use the same settings often, you can click **Set Defaults**. To use previously saved settings, click **Use Defaults**.

> **Note:**
>
> HFSS automatically subdivides the interpolating sweep range so that no single subrange gets too many basis elements. The effect is that you can now (if appropriate) request hundreds of basis elements in the Max Solutions box for interpolating sweep setup, without incurring any basis seeding performance penalty.

Interpolation Basis Convergence

From the Setup Interpolations Basis dialog box, select the **Use Selected Entries** radio button to enable the **Select Entries** button. Select this to display the **Interpolation Basis Convergence** dialog box. This dialog permits you to specify the convergence basis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



1. Select one of the following from the **Entry Selections** drop-down menu:

All	Selects all of the matrix entries at once. (The default).
Diagonal	Selects all of the diagonal matrix entries at once.
Off-Diagonal	Selects all of the off-diagonal matrix entries at once.

2. If you chose **All**, **Diagonal**, or **Off-Diagonal**, you may fine-tune the matrix entry selection process by selecting one of the following options from the **Mode Selection** drop-down menu:

All	Selects all of the mode matrix entries. Select in conjunction with **All**, **Diagonal**, or **Off-Diagonal** entry selections.
Dominant Only	Selects only the dominant mode matrix entries. Select in conjunction with **All**, **Diagonal**, or **Off-Diagonal** entry selections.
Higher Order Only	Selects only the higher-order mode matrix entries. Select in conjunction with **All**, **Diagonal**, or **Off-Diagonal** entry selections.

As you select the wave ports for convergence, you use the **Set**, **Clear**, and **Clear All** buttons in connection with the **Entry Selection** and **Mode Selection** settings. These buttons are enabled when the wave port matrix state and selection settings permit them do something.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For example, The **Clear** button is not enabled until there are entries in the wave port matrix to clear and those selections are permitted by the entry selection. The **Set** button is not enabled unless the available mode selections permit entries to be set.

You can also select individual entries in the wave port matrix by clicking on grid cells. This action displays a dropdown menu that lets you select ON or "-".

3. Specify **EntrySelections** and **Mode Selections** as desired and click **SET**, or click individual wave port cells and select ON.

In the table location corresponding to the selection, the dash in the display is replaced by ON. For example, selecting the first element in the row list and the fourth element in the column list, and then **Set Selection** places an ON in the first row, fourth column. You can select one entry at a time via the dropdown in the matrix cell, or clear the entire table with the **Clear All** button. You can also **Clear** only the entries specified by the **Entry** and **Mode** selection settings (such as off-diagonal, higher order).

4. Click **OK** to close apply the selections and close the dialog.

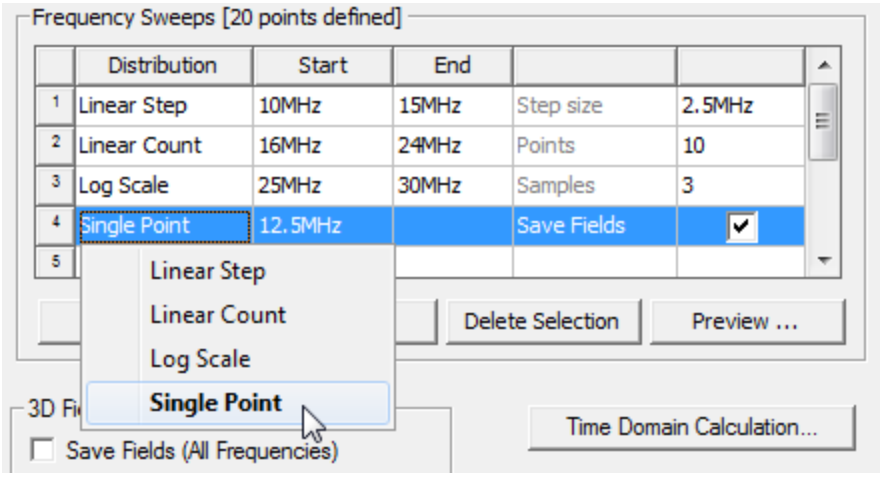
Specifying the Frequency Points to Solve

You can specify the following types of frequency points to solve within a frequency sweep:

Linear Step	A linear range of frequency points in which you specify a constant step size.
Linear Count	A linear range of frequency points in which you specify the number, or count, of points within the frequency range.
LogScale	A logarithmic range of frequency points in which you specify a frequency range and a samples number.
Single Points	Individual frequency points. *For Discrete sweeps*.

Select the type of frequency point entry from the **Type** dropdown menu.

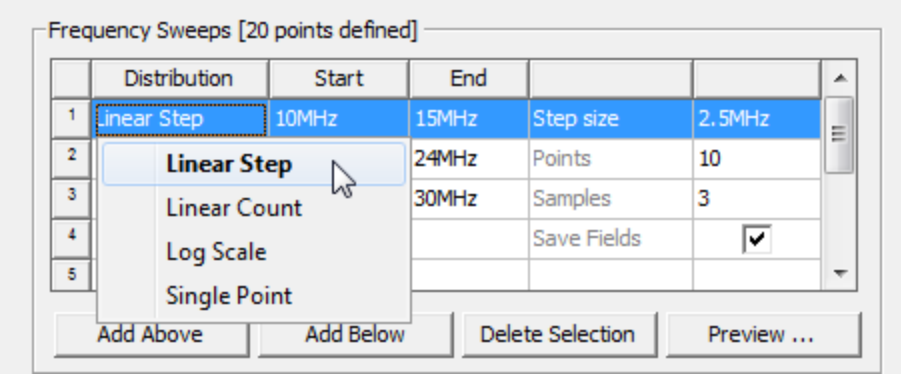
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Edit Frequency Sweeps window contains a Time Domain Calculation tool that you can use to help calculate frequency step sizes and maximum frequencies, particularly if you intend to perform Full-Wave Spice analysis. For Discrete sweeps, HFSS always solves the frequencies from highest to lowest.

Specifying Frequency Points with a Linear Step Size

1. In the **Edit Sweep** dialog box, click **Linear Step** in the **Type** pull-down list.



2. In the **Start** text box, type the starting frequency of the frequency sweep.

   For Fast and Interpolating sweeps, setting the initial value to 0 enables the DC Extrapolation option.

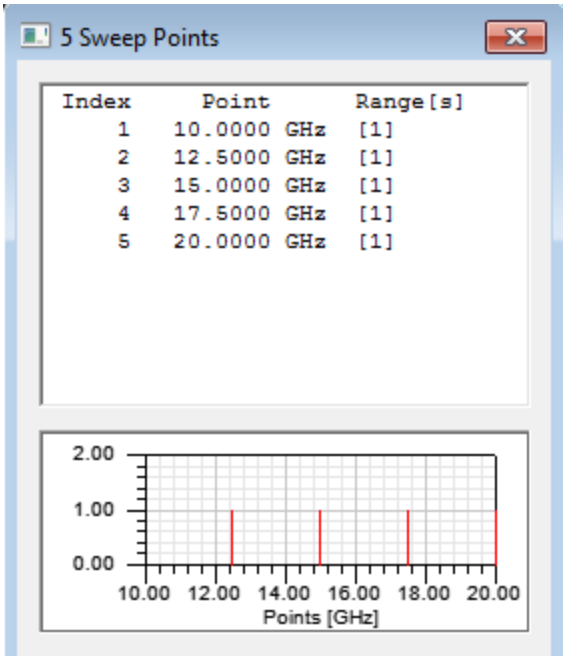
3. In the **End** text box, type the ending frequency of the frequency sweep.
4. In the **Step Size**box, type the difference between frequency points.

HFSS will solve the frequency point at each step in the specified frequency range, including the start and stop frequencies. For Discrete sweeps, HFSS always solves the frequencies from highest to lowest.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For example, specifying **10** for the start frequency, **20** for the stop frequency, and **2.5** for the step size**for a Discrete sweep** instructs HFSS to compute a solution for frequencies of 10, 12.5, 15, 17.5, and 20.

To view a table of the frequencies and count, click the **Preview** button.



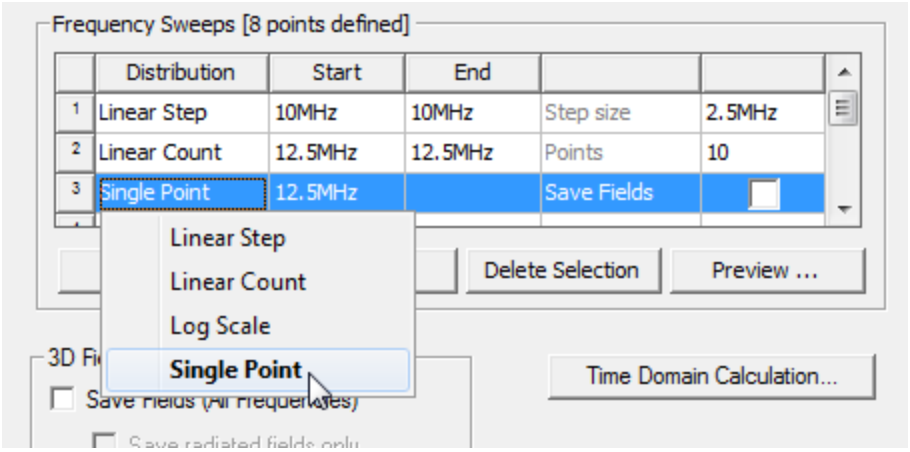
If the list of frequencies is longer than the visible display, you can use a scroll bar to view the list to the end of the count.

1. For Fast sweeps, select **Save Fields** if you want to save the calculated 3D field solutions associated with all port modes at the chosen frequencies.

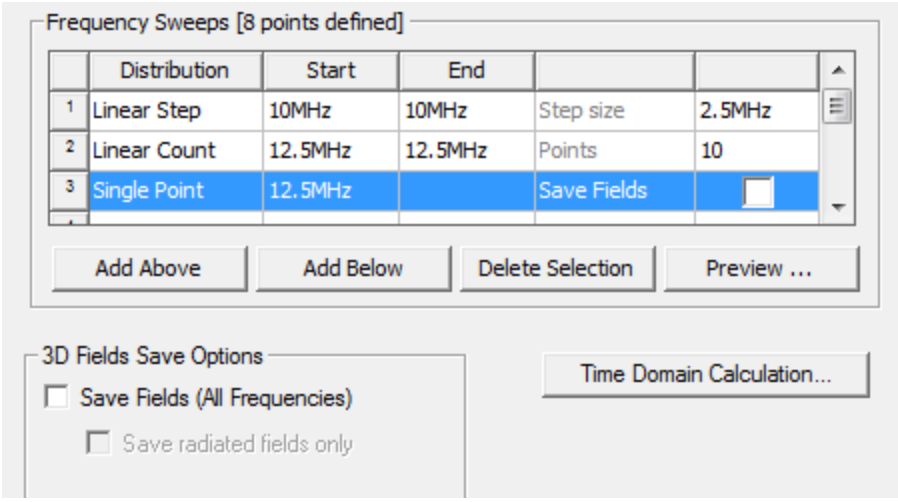
For Discrete sweeps, select **Save Fields (All Frequencies)** if you want to save the calculated 3D field solutions associated with all port modes at the chosen frequencies.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If want to save the fields for just one or a few Discrete sweep frequencies, create a single point sweep for that frequency.



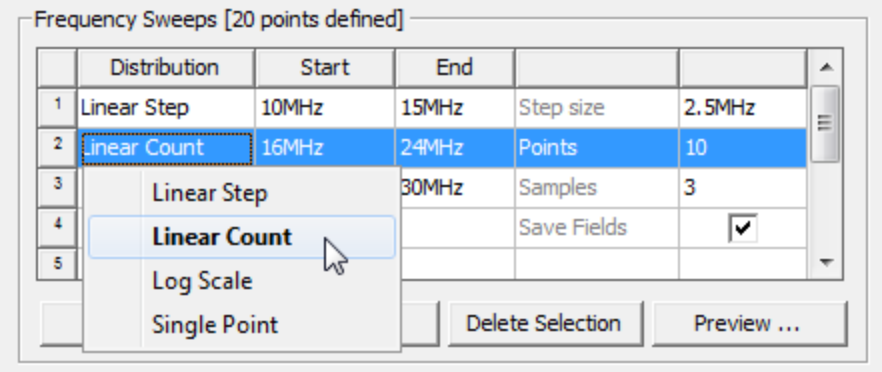
This single point sweep has a **Save Fields** column with a check box for each single point frequency you define. You can select the **Save Fields** check box for the desired frequency, or click the **Save Fields** (All Frequencies) check box to check or uncheck all frequencies.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Specifying a Linear Count of Frequency Points

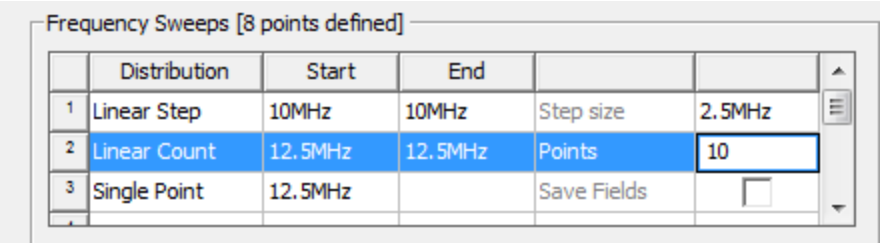
1. In the **Edit Sweep** dialog box, click **Linear Count** in the **Type** pull-down list.



2. In the **Start** text box, type the starting frequency of the frequency sweep.

For Fast and Interpolating sweeps, setting the initial value to 0 enables the DC Extrapolation option.

3. In the **End**text box, type the ending frequency of the frequency sweep.
4. In the Points text box, type the number of points in the sweep. The count value includes the Start and End values.



HFSS will divide the frequency range into the count you specify and solve each frequency point in the count.

To view a table of the frequencies and count, click the **Display** button. If the list of frequencies is longer than the visible display, you can use a scroll bar to view the list to the end of the count.

5. For Fast sweeps, select **Save Fields** if you want to save the calculated 3D field solutions associated with all port modes at the chosen frequencies.

For Discrete sweeps, select **Save Fields (All Frequencies)** if you want to save the calculated 3D field solutions associated with all port modes at the chosen frequencies.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

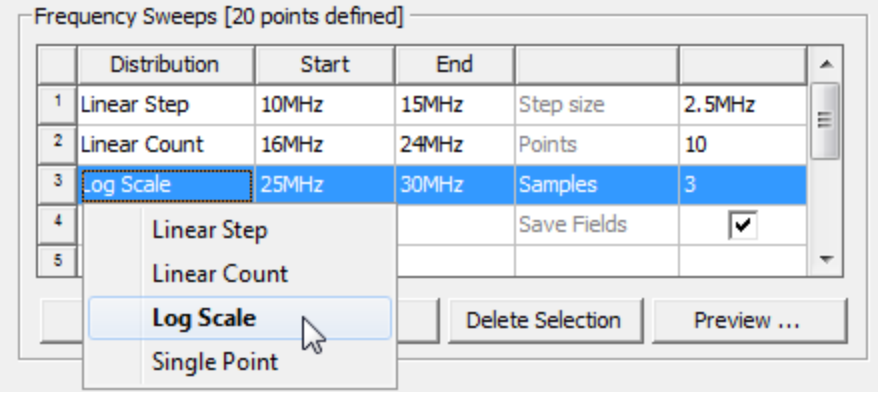
If want to save the fields for just one or a few Discrete sweep frequencies, define a Single Point sweep for those frequencies and check the Save Fields box for that point.

For Discrete sweeps, HFSS always solves the frequencies from highest to lowest.

Specifying a Logarithmic Spaced Frequency Sweep

For Discrete sweeps.

1. In the **Edit Sweep** dialog box, click **LogScale** in the **Type** drop-down menu.



2. In the **Start** text box, type the starting frequency of the frequency sweep.

   For Fast and Interpolating sweeps, setting the initial value to 0 enables the DC Extrapolation option.

3. In the **End** text box, type the ending frequency of the frequency sweep.
4. In the **Samples** text box, specify the number of frequency points to sample.

   HFSS assigns the sampled points using intervals based on a logarithmic scale.

   To view a table of the frequencies and count, click the **Display** button. If the list of frequencies is longer than the visible display, you can use a scroll bar to view the list to the end of the count.

5. Select **Save Fields (All Frequencies)** if you want to save the calculated 3D field solutions associated with all port modes at the chosen frequencies.

For Discrete sweeps, HFSS always solves the frequencies from highest to lowest.

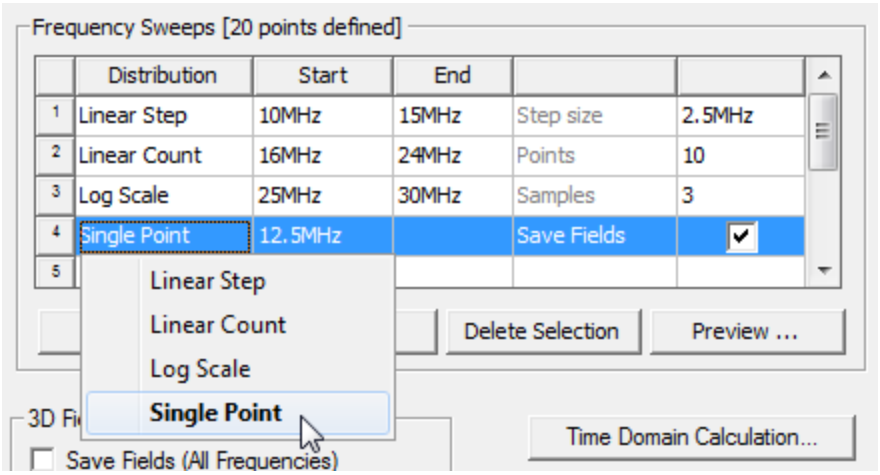
Specifying Single Frequency Points

For Discrete sweeps.

To specify Single Frequency points:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the **Edit Sweep** dialog box, click **Single Points** in the **Type** pull-down list.



2. In the **Single** text box, type a desired frequency point, and then select the frequency units.

A check mark in the **Save Fields** column indicates that the fields for the point will be saved. Optionally, click the check box in the **Save Fields** column.

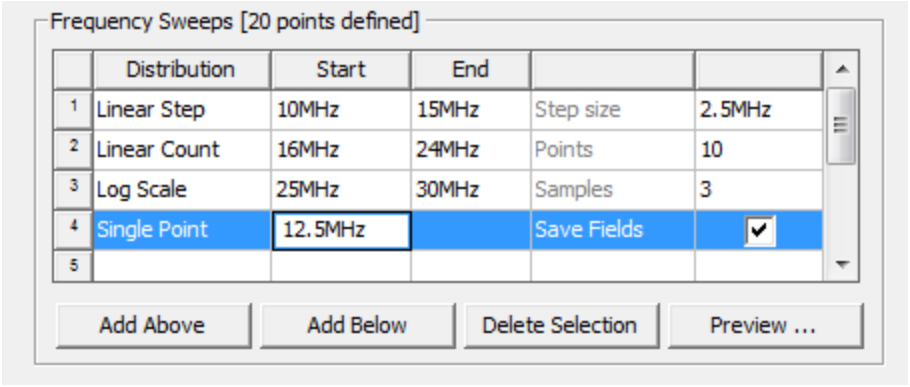
3. Create additional Single point sweeps for each frequency point you want to solve.

For Discrete sweeps, HFSS always solves the frequencies from highest to lowest.

Change the Value of an Existing Frequency Point

To change the value of an existing frequency point in a discrete sweep in the **Edit Sweep** dialog:

1. In the **Edit Sweep** dialog either select the text field in the Frequency column and edit an existing value field directly:



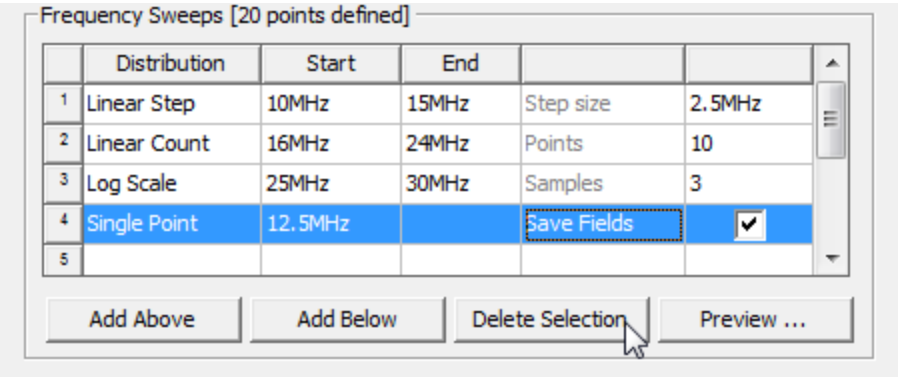
2. You could also create a new single point sweep.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Select **Save Fields** if you want to save the calculated 3D field solutions associated with all port modes at that frequency.
4. Repeat for changing additional points.

Deleting Frequency Points

1. To delete a single frequency point from a sweep, select the row containing the frequency you do not want to solve.

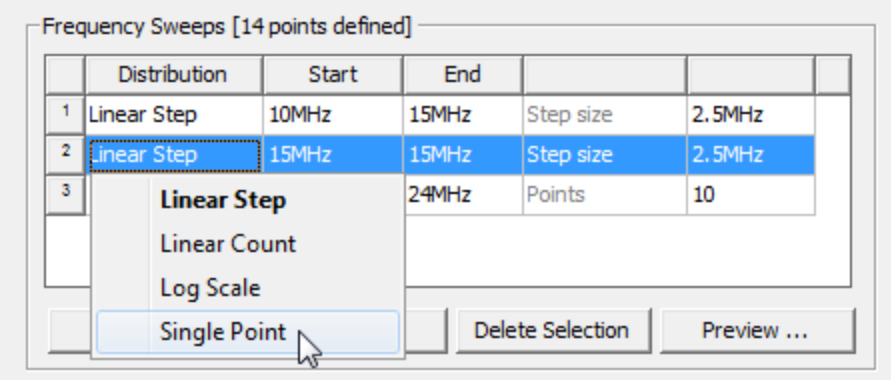


2. Click **Delete**.

Inserting Frequency Points

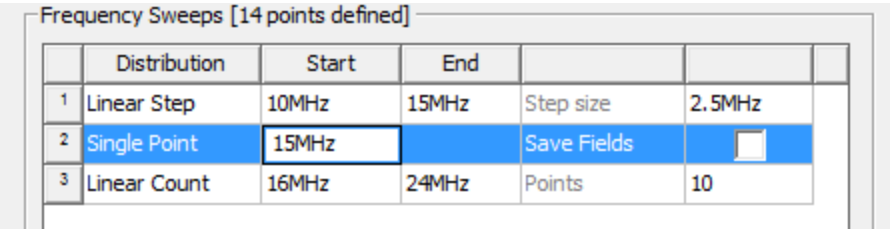
For Discrete sweeps, you can insert, change, or delete specific frequency points that you want to solve in the frequency range. They can be inserted individually to a new display, or to an existing display of uniform frequency points.

1. To pre-specify an initial uniform range of frequency points, use the Frequency setup of the **Edit Sweep** dialog to define the linear step, linear count, or log scale range you want.
2. Select an existing sweep and click Add Above or Add Below to insert the new sweep definition.
3. Select **Single Point** from the Distribution drop-down menu.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. In the **Start** text box, type a desired frequency point in the frequency units.



5. Select the **Save Fields** if you want to save the calculated 3D field solutions associated with all port modes at that frequency. You can also select, or deselect the check box to specify individual frequencies.
6. Add or edit additional Single Point frequency sweeps, and then click **OK** to save the current definitions.

For Discrete sweeps, HFSS always solves the frequencies from highest to lowest.

Choosing Frequencies for Full-Wave SPICE

If you plan to perform a full-wave SPICE analysis, use the **Time Domain Calculation** dialog box to help determine a suitable frequency sweep range for the solution.

To perform the calculation of suitable frequencies to solve:

1. In the **Edit Sweep** dialog box, click **Time DomainCalculation**.

   The **Time Domain Calculation** dialog box appears.

2. Type a minimum rise time value in the **Signal Rise Time** box.

   This value represents the time scale that will characterize the rate of change of the input time signal, which will be applied in the circuit simulator.

3. Type a value in the **Time Steps Per Rise Time** box.

   The time sampling increment for the entire signal is calculated using

$$\Delta t = \frac{\tau}{N_\tau} \quad (1)$$

   where

   - Δt is the time sampling increment.
   - τ is the signal rise time.
   - N_τ is the number of time steps per signal rise time.

4. Type a value in the **Number of Time Points** box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that the input time signal duration is determined using $N \times \Delta t$, where *N* is the number of time points.

5. Click **Calculate**.

- HFSS now determines the **Maximum Frequency** using

$$F_{max} = \frac{0.5}{\Delta t} \quad (2)$$

- where F_{max} is the maximum frequency.

  HFSS determines the **Frequency Step Size** using $\frac{F_{max}}{N}$.

6. Click **OK** to transfer the data to the frequency sweep fields in the **Edit Sweep** dialog box.

Guidelines for Calculating Frequencies for Full-Wave SPICE

Keep the following guidelines in mind when you set up the calculation for the suggested frequency step size and maximum frequency:

- The maximum frequency should be at least five times the inverse of the rise and fall times. If the specified frequency band is too wide, an HFSS frequency sweep may have convergence problems. If this happens, try to decrease the maximum frequency until the solution converges.
- It is recommended, though not required, that the minimum frequency be less than the maximum frequency divided by the number of frequency steps. It is usually recommended to have at least 500 frequency steps. A higher number will slightly improve the full-wave SPICE solution accuracy, but will also increase CPU and memory requirements to solve the problem. For most cases, using 1000 frequency steps provides a good trade-off between the accuracy and computational requirements.

  > **Warning:**
  >
  > Occasionally, HFSS can fail to solve for the minimum frequency during a Discrete or Interpolating frequency sweep due to a failure of the port solver to converge. If this happens, try to increase the minimum frequency until the solution process completes successfully. However, the minimum frequency should be as low as possible because the low-frequency response determines the steady-state time response.

- The suggested frequency sweep ranges are estimates. You may have a pulse with a wider frequency content and HFSS's recommended frequency sweep range may miss some of the high frequencies.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Requirements for Full-Wave SPICE

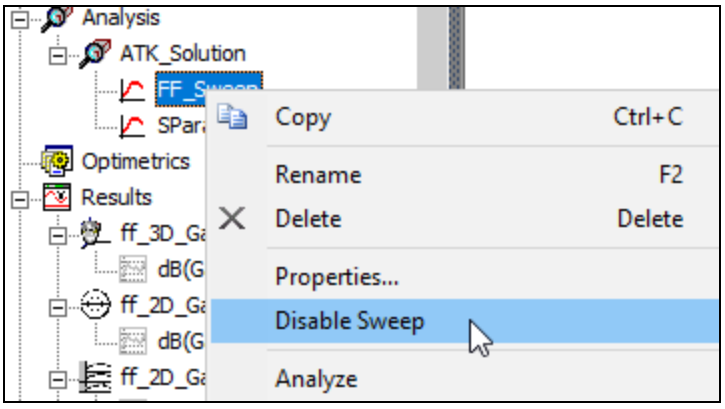
The Full-Wave Spice requirements are as follows:

1. The design problem type in which the solution data panel is opened must be driven terminal.
2. In the Matrix Data panel, for non-imported data, the view type for the solution data must be "Terminal Data" (not "Modal Data").
3. The data must be interpolating, or it must be discrete.
4. If the data is discrete:
    a. It must either be native terminal data, or it must be inferred as terminal. For instance, in a Touchstone file, the comment line "! Terminal data exported" will cause HFSS to interpret the data as terminal, while the comment line "! Modal data exported" will cause HFSS to interpret the data as modal. If HFSS finds neither comment line, it assumes that the data is terminal.
    b. At least 20 frequency points must be provided.
    c. HFSS must be able to generate an interpolation basis that converged with <= 0.5% error using no more than 100 basis elements.

Disabling or Enabling a Frequency Sweep

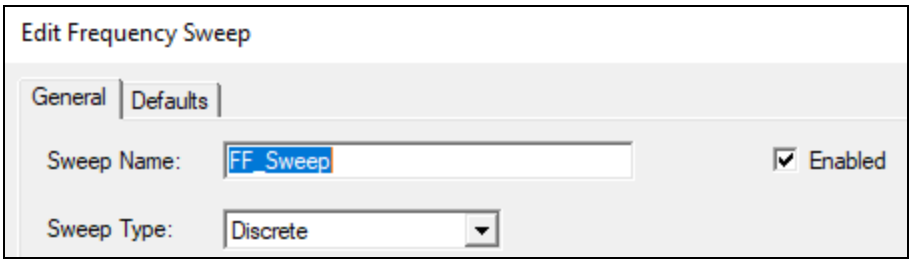
You can activate or deactivate a sweep definition. Disabled sweeps has an “empty graph” icon, and are not analyzed until enabled. To deactivate a sweep definition without deleting it:

1. Expand the tree hierarchy under the **Analysis** icon in the **Project Tree**.
2. Expand the tree hierarchy under the icon for the analysis setup that includes the sweep.
3. Right-click the icon for the sweep definition and select **Disable Sweep Analysis**. (To reactivate the sweep, right-click again and select **Enable Sweep Analysis**.)



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Also deactivate a sweep by right-clicking and selecting **Properties** to open the **Edit Properties** window. In the upper-right corner of the **Edit Properties** window, uncheck the **Enabled** area. Then click OK to apply the change. (To reactivate the sweep, re-open the **Edit Properties** window and check the **Enabled** area. Then click OK.)



Specifying the Number of Processors

If you want to use more than one processor, see HPC and Analysis Options,.

Specifying the RAM Limit Percentage

The **RAM Limit** (%) setting requests a restriction on the amount of memory the default solver used by the Ansys Electronics Desktop may allocate before it must stop solving on-core—solving processes entirely in memory—and start solving off-core. In off-core mode, the solver creates temporary solution files to which it spills, or shifts, data from memory, instead of relying on the operating system to start disk swapping. The default solver is finely tuned at handling its own memory, and can optimize loading only those blocks of memory required for its immediate needs.

Using this option may help to keep the entire solver from being swapped out in the normal course of process management on your computer. This kind of control may be especially important when multiple solvers are running on the same machine. Of course, if the total memory requirement of all processes grows large enough, the operating system will be forced into disk swapping.

> **Note:**
>
> The Iterative solver doesn't go off-core for efficiency reasons. Once the limit is exceeded, iterative solver will issue an "Out of memory" error message.

Regardless of this setting, processes are limited to 4TB of address space on 64 bit operating systems - no matter how much physical memory is installed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> Regardless of the RAM Limit setting, if allocation fails, the solvers will automatically switch to off-core mode.

In case you receive an error message regarding insufficient memory on a 64-bit operating system, you may have reached a point where the sum of physical RAM plus available swap space exceeds the minimum amount of RAM needed by the off-core solver. Even for the off-core solver, the RAM usage cannot be made arbitrarily small. Off core does not mean it will use system swap space. Instead, the solver actively uses disk space to solve the problem. Users specify the % RAM allowed to be consumed by the solver on each node. The solver checks the total RAM on the node and applies the % RAM to arrive at the total memory that can be used. However, if you allow off core and it did not complete the solve the message estimates the minimum memory required to solve the off core solve.

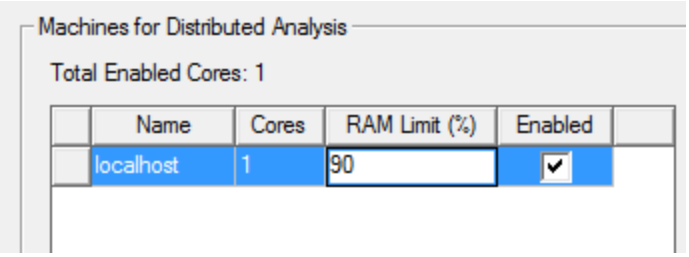
For Linux schedulers, where the environment may be non-uniform/heterogeneous, you have the option of using a batchoption to specify a RAMLimitPerCoreInGB. See the discussion under Distribution Command Line Options.

To specify the **RAM Limit** (%) of the machine on which Ansys Electronics Desktop s installed:

1. Click **Tools>Options>Setting HPC and Analysis Options**.
2. This opens the HPC and Analysis Options dialog.
3. Specify the Design Type for which you want to set a RAM limit. Make the Local machine Active.
4. In the **HPC and Analysis Options** dialog click the Edit button.

This opens the **Analysis Configuration** dialog.

5. Select the **Machines** tab. specify a **RAM Limit (%)** in the text field for the active machine list.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. This setting affects all projects for the current configuration for the user and machine..

> **Note:**
>
> Ansys recommends that you use the **RAM Limit**setting if you wish to limit the RAM that the MPS (default) solver may allocate. However, the Iterative solver doesn't go off-core for efficiency reasons. Once the limit is exceeded, iterative solver will issue an "Out of memory" error message.

> **Note:**
>
> Allocation of greater than 2 GB of RAM on 32-bit hardware platforms is only possible with the appropriate operating system and boot settings, even if more than 2 GB are physically installed.

Distributed Memory Solutions with HFSS

When properly configured, and with Domain Decomposition selected as a Setup option, the HFSS solver uses the industry standard Message Passing Interface ("MPI") and can perform solutions that distribute memory use across machines in a cluster or network. Memory used by the MPI-enabled HFSS solver is therefore limited by the set of machines that are available rather than the shared memory available on any single machine. This allows you to simulate larger structures than before and to optimally reconfigure the cluster of machines for the problem at hand.

To use the distributed memory solution in HFSS you will need to install HFSS and MPI software from one of the supported third party vendors on all the machines you intend to use. You may need to set passwords depending on the MPI vendor for authentication on the machines. Settings within HFSS are used to turn on distributed memory solutions and define the list of machines you intend to use. If an HFSS problem involves solver domains or a finite array, then frequency sweeps will not be done using DSO. Also, DSO for Optimetrics will not be allowed.

Detailed instructions about how to get distributed memory HFSS solutions up and running are outlined in the following sections.

- Installation Requirements for Distributed Memory Solutions with HFSS
- Setting up HFSS and Running Distributed Memory Solutions
- Select the MPI Version
- Running HFSS Distributed Memory Solutions from the Command line
- Discussion of HFSS Distributed Memory Solution
- Interconnects for HFSS Distributed Memory Simulation

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Authentication on Linux (RSH & SSH) for HFSS
- Troubleshooting for HFSS Distributed Memory Solutions

Installation Requirements for Distributed Memory Solutions with HFSS

You must install HFSS on all the machines you intend to use during the HFSS distributed memory solution process. The installation locations for HFSS must be identical and the machines must be uniform: all 64 bit, all Windows or all Linux. The machines must all use the same interconnect.

In addition, on Windows, you must install one of the supported versions of MPI from either Microsoft or Intel. Be sure to install the same version of MPI on all machines in your cluster. (Solving on a single Windows machine does not require MPI installation. Users running on Linux do not need to install MPI manually).

Platform	MPI Software
Linux Intel & AMD	Intel MPI 2018.3.210
Windows 10	Microsoft MPI 10.0
	Intel MPI 2018.3.210

You will need to set the password you want to use for your MPI runs on all the machines in the cluster. You can either use the batch command provided by Ansys to set your password or refer to the MPI vendor's documentation.

InfiniBand Support for Windows

By default, the MPI vendors use the fastest interconnect by default (typically InfiniBand is faster than Ethernet). If you want to override the default behavior and force the use of Ethernet, you can set the ANSOFT_MPI_INTERCONNECT environment variable to “eth” for the job.

Setting up HFSS and Running Distributed Memory Solutions

After setting up your HFSS project, you normally need to set the list of machines used for the distributed memory solution process and configure the distributed memory interface.

The distributed machine list is selected under Tools>Options>HPC and Analysis Options, and created under the Analysis Configuration dialog.

Distributed memory solutions are turned using the **Domain Decomposition** radio button under the Solution Setup Options tab.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

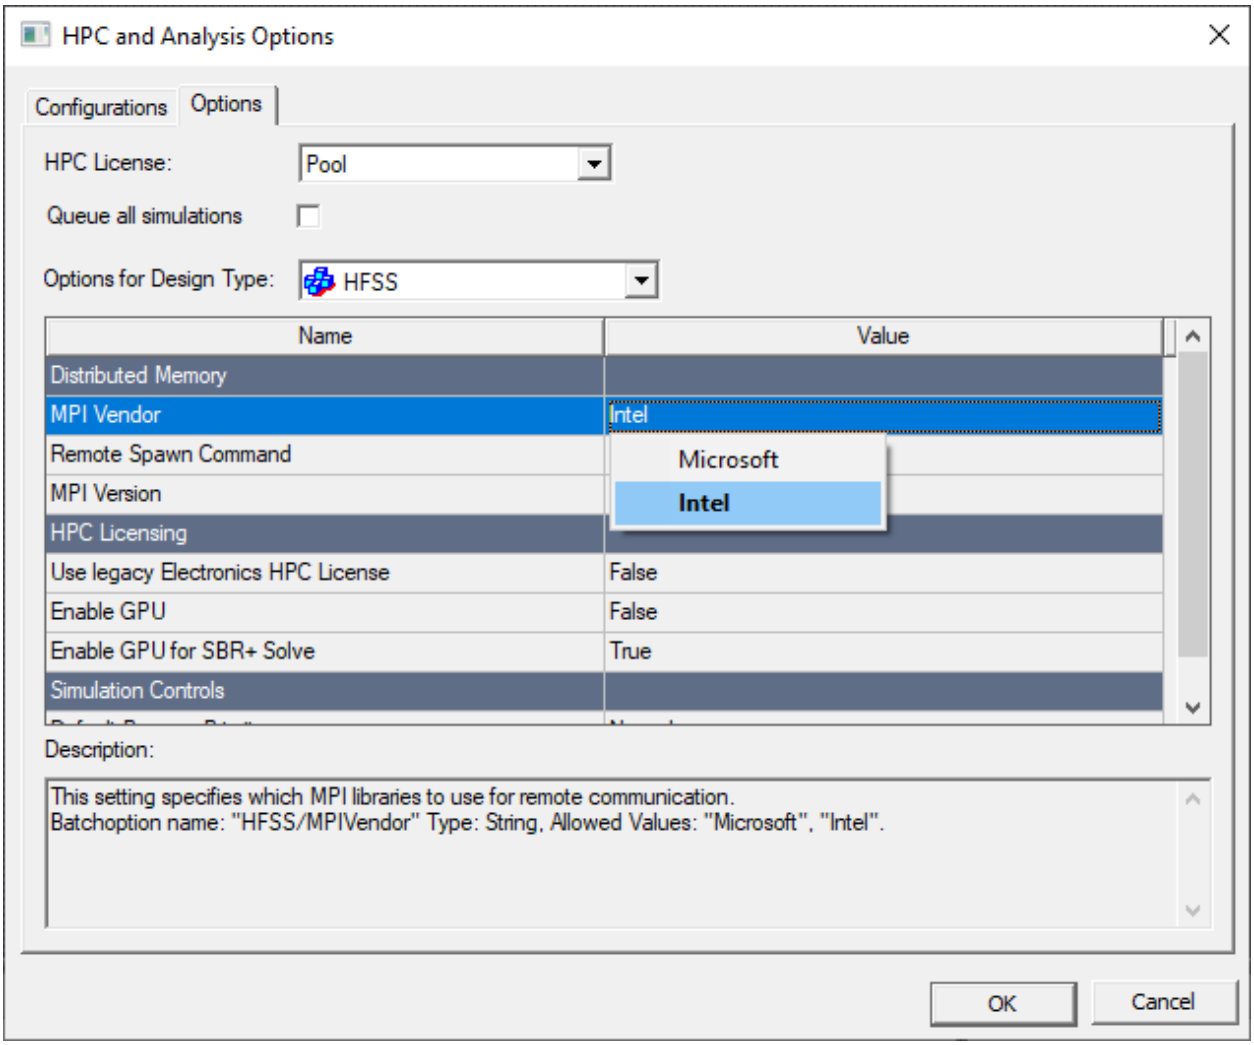
If an HFSS problem involves solver domains or a finite array, then frequency sweeps will not be done using DSO. Also, DSO for Optimetrics will not be allowed. Distributed frequency solutions are also known as "DSO" solutions.

MPI Vendor and MPI Version

For HFSS, HFSS 3D Layout, Q3D Extractor, Maxwell, and Icepak design types:

These settings may be used to specify the MPI Vendor and Version for distribution via MPI.

Go to the **Options** tab of the **HPC and Analysis Options** dialog box, and select the design type. Then you can select the MPI Vendor and MPI version.



MPI Vendor

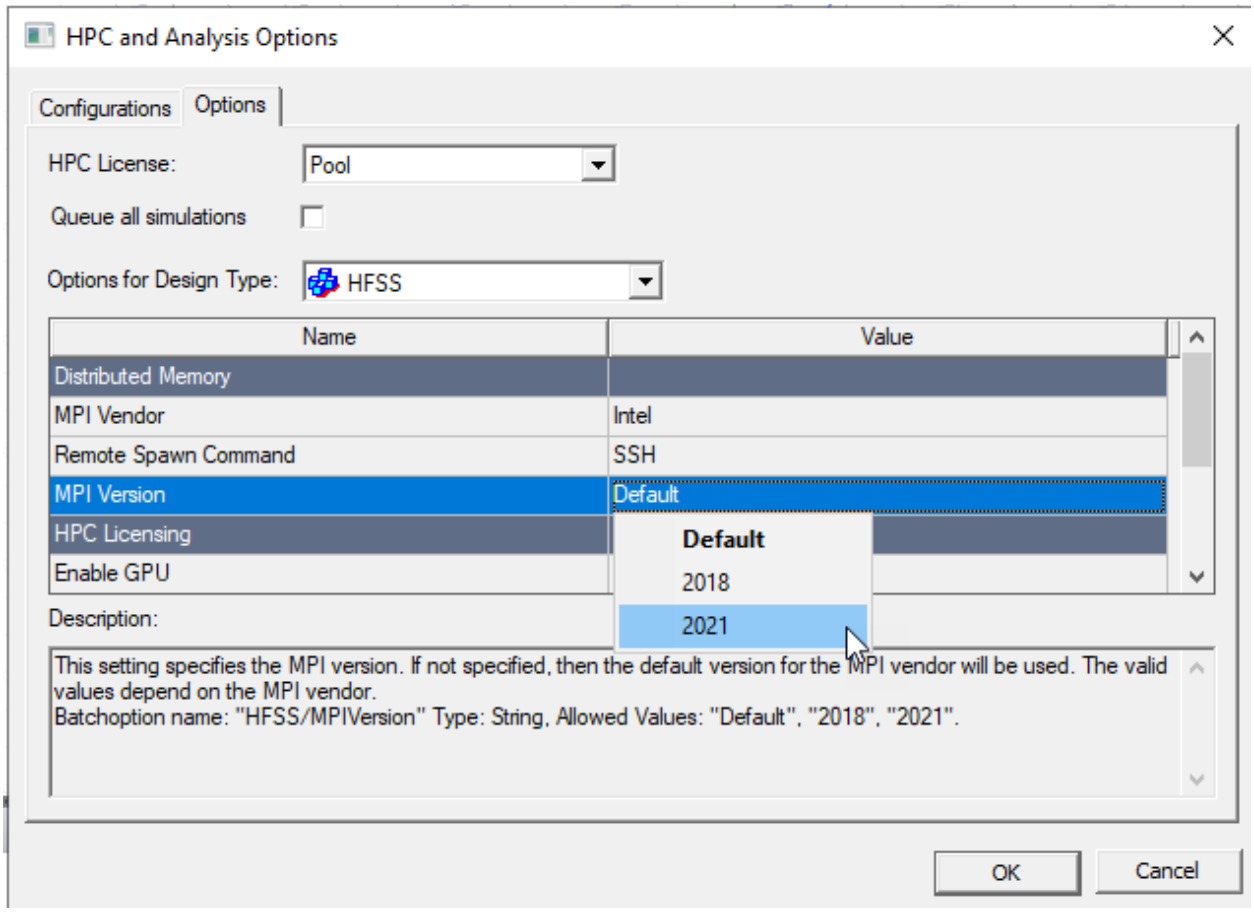
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The default MPI Vendor is "Intel". On Linux, "Intel" is the only supported MPI vendor. On Windows, both "Intel" and "Microsoft" are supported MPI vendor options. For jobs distributed to multiple hosts, the "Microsoft" MPI Vendor is only supported when running as a Windows HPC job.

MPI Version

If only a single MPI Version is supported for the selected MPI Vendor, then the MPI Version option is ignored. Multiple versions are only supported for Intel MPI, as follows:

- The value "Default" indicates that the default Intel MPI version should be used. This is Intel MPI 2021 in most cases.
- The value "2018" indicates that Intel MPI 2018 should be used.
- The value "2021" indicates that Intel MPI 2021 should be used.



Also see Setting Intel MPI Interconnect for more details.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setting the Intel MPI Interconnect

To use a particular interconnect or interconnect variant, the user must set ANSOFT_MPI_INTERCONNECT and ANSOFT_MPI_INTERCONNECT_VARIANT environment values. For example, if you want to override the default behavior and force the use of Ethernet, you can set the ANSOFT_MPI_INTERCONNECT environment variable to appropriate Ethernet interface name for the job.

Supported options for MPI interconnect with Electronics Desktop based on Intel MPI Versions are described below.

With Intel MPI 2018

- ANSOFT_MPI_INTERCONNECT = mpi-auto-selected | shmem | myri | myrinet | ib | infiniband | default | eth | ethernet | (not set)
- For Linux ANSOFT_MPI_INTERCONNECT=infiniband | ib, you can set interconnect variant values to:
  ANSOFT_MPI_INTERCONNECT_VARIANT = ofed | infinipath | dapl | (not set)

With Intel MPI 2021

The Intel® MPI Library switched from the Open Fabrics Alliance* (OFA) framework to the Open Fabrics Interfaces* (OFI) framework and currently supports libfabric*. The DAPL, TMI, and OFA fabrics are deprecated.[1]

Intel MPI 2021 interconnect selection for Windows

- ANSOFT_MPI_INTERCONNECT = mpi-auto-selected | shmem | ib | infiniband | default | eth | ethernet | efa | (not set)

By default, MPI vendors use the fastest interconnect by default (typically InfiniBand is faster than Ethernet). To override the default behavior and force the use of specific interconnect, you can set the ANSOFT_MPI_INTERCONNECT.

Intel MPI 2021 interconnect selection for Linux

- ANSOFT_MPI_INTERCONNECT = mpi-auto-selected | shmem | ib | infiniband | default | eth | ethernet | efa | (not set)
- For ANSOFT_MPI_INTERCONNECT=infiniband | ib, user can set interconnect variant values to:
  ANSOFT_MPI_INTERCONNECT_VARIANT = verbs | mlx

For Linux environments, Intel MPI 2021 requires setting fabric provider variables, FI_PROVIDER, I_MPI_OFI_PROVIDER and FI_TCP_IFACE/FI_VERBS_IFACE (i.e. in case fabric provider is TCP/VERBS respectively) for a successful run. AEDT will set these values based on the available interconnects on Linux. AnsysEM will always prefer ethernet.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:** This interconnect selection by AEDT does not guarantee the selection of faster interconnect. To bypass this interconnect selection, the user needs to set FI_ PROVIDER and I_MPI_OFI_PROVIDER explicitly.

[1] https://www.intel.com/content/www/us/en/developer/articles/technical/mpi-library-2019-over-libfabric.html

Running Distributed Memory Solutions from the Command line

You can run distributed memory HFSS solutions from the command line using the -BatchSolve option. Set the distributed memory solve setup option before running the simulation and use the "BatchSolve" flag with the "Distributed" and MachineList" options. For example:

```
ansysedt -BatchSolve -Distributed -MachineList list="machine1,
machine2" TheProject.aedt
```

This simulates "TheProject.aedt" as a distributed memory solution on machines "machine1" and "machine2."

Note the distributed memory solve setup option can be turned on via scripting if desired.

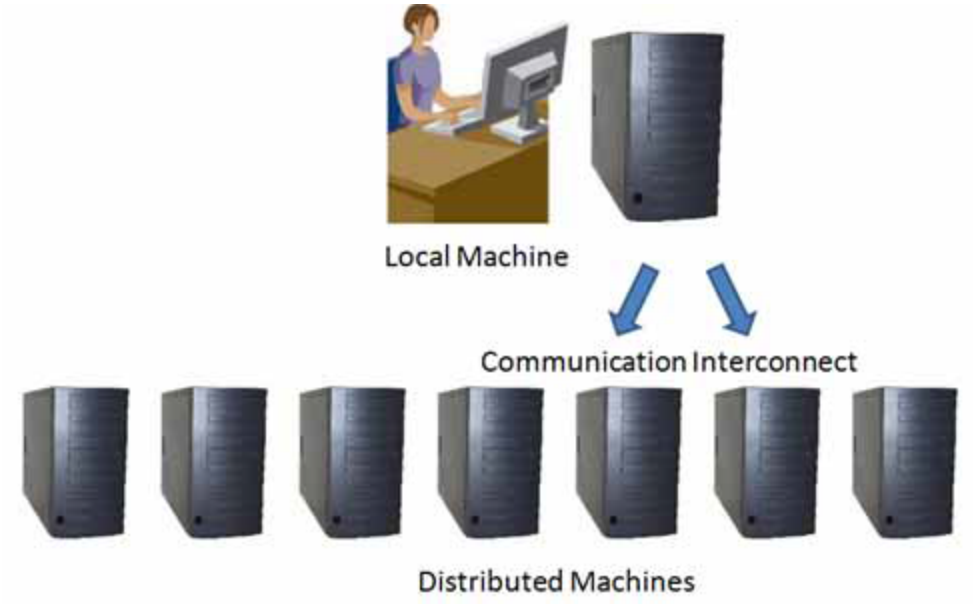
Discussion of HFSS Distributed Memory Solutions

Each machine or "compute node" is connected to the other nodes via a "communication interconnect" and relies on the message passing library (MPI) to exchange data and synchronize computational tasks. Ethernet, Myrinet and Infiniband are common communication interconnects. Each node is identified by a unique integer ID or rank number. The local machine is known as the "Rank-0 node" and is the master. The Rank-0 machine has many tasks including:

- Management of all communication with the HFSS user interface. None of the distributed machines communicate directly with the user interface but pass all information through the Rank-0 machine.
- Mesh generation. The mesh is generated only on the Rank-0 machine.
- Disk access. None of the distributed machines access their local discs. The simulation mesh, intermediate and solution data are passed to and from the distributed machines using MPI.
- Distribution and control of computational tasks on the distributed machines. The simulation process is dynamic and the Rank-0 machine will determine which of the distributed machines has memory available to distribute tasks accordingly.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Post-processing of the HFSS Distributed Memory Solution



The algorithms used in the distributed memory version of the HFSS solver engine resemble those used in the non-distributed memory version. The matrix solution algorithms in the distributed memory version of HFSS have been adjusted to use slightly more memory so that larger problems can be simulated in less time.

Most of the ANSYS solvers are multi-threaded. You can specify the hostname, # tasks, and # cores instead of repeating the hostname multiple times. The "auto" mode eliminates the need for end-users to specify tasks. They simply indicate the number of cores to use on the specified machine.

During the "Matrix Assembly" and "Matrix Solve" steps of the solution process the HFSS engine attempts to distribute memory use evenly. At various points in the matrix solution process the software will poll the machines in the cluster and determine which machine has the most memory available and then reserve a block of memory on that machine. If a particular machine does not have a large block of memory available the memory use on that machine will grow only slowly. If none of the machines in the cluster have sufficient memory the solution process will terminate and an error message will be posted to the HFSS message window.

Many factors affect solution time. In general, the solution time will decrease as the number of compute nodes increases. However, parallel efficiency decreases as the ratio of communication to computation increases so to some extent you need to match the size of the problem to the size of parallel machine. Simulating small structures on a large cluster will not be efficient and may take longer and use significantly more memory than if the structure was simulated on a single machine.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Network interconnect speed and topology can affect performance significantly in homogeneous clusters. Performance can degrade if machines are "doubled up" to the point of causing memory bus contention or if the cluster is significantly inhomogeneous and certain faster machines need to wait for slower machines to catch up to synchronization points in the solution process.

Interconnects for HFSS Distributed Memory Simulation

To obtain the best possible performance we recommend the use of a network interconnect that supports communication speeds greater than 1000MB/sec or higher. Some high performance interconnects plug into a PCI (Peripheral Component Interconnect), PCI-X (extended), or PCIe (PCI Express) slot on the system.

HFSS-IE 15 supports the following network interconnects:

Platform	Interconnects
Win32	Ethernet/GiGE
Win64	Ethernet/GiGE (default), Myrinet, Infiniband
Linux	Ethernet/GiGE (default), Myrinet, Infiniband

Ethernet/GiGE is the default interconnect on all platforms. You can choose one of the alternate interconnects by setting the ANSOFT_MPI_INTERCONNECT environment variable to "myri" for Myrinet and "ib" for Infiniband.

Interconnect variants are supported on Linux. Set the ANSOFT_MPI_INTERCONNECT_ VARIANT to the desired interconnect variant. For example, set "ANSOFT_MPI_ INTERCONNECT_VARIANT=silverstorm" to use the silverstorm variant.

Authentication on Linux (RSH & SSH) for HFSS

An important step in using a high performance cluster is setting up authentication across machines in such a way that the machines can be accessed without a password. By default HFSS uses SSH authentication on Linux to spawn commands on the remote machines but also supports RSH. The selection of which to use is made on the **Options** tab of the Tools/Options/HPC and Analysis Options dialog .

Troubleshooting for Distributed Memory Simulations

A number of things can prevent distributed memory solutions from completing successfully. This section provides suggestions to debug problems.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

It is often a good idea to set up and run a small simulation with two processes on a single machine before moving to a large cluster. Using a single machine will allow you to verify that the EM software and MPI are installed correctly while eliminating problems arising from remote installation, authentication and firewall settings.

Many problems occur because the MPI software cannot start and run due to authentication and firewall issues. Please check with your MPI vendor and their end user documentation for information about how to verify that authentication and firewall settings are correct.

Recall that HFSS must be installed in the same directory on all machines in the cluster and that the cluster must be uniform (e.g., all Linux machines, all 64 bit Windows machines).

Verify that the version of the third party MPI software is identical on all the machines and that it is a supported version.

Verify that the machine names are correct and that all the machines can be reached on the network.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

17 - Assigning Boundaries in HFSS

Boundary conditions specify the field behavior at the edges of the problem region and object interfaces. Within the context of HFSS, boundaries exist for two main purposes:

1. to create either an open or a closed electromagnetic model or,
2. to simplify the electromagnetic or geometric complexity of the electromagnetic model.

In an open problem, an air volume encompassing the outer radiating surfaces is modeled by a surrounding object. Radiation boundary conditions (ABC, PML or FEBI) are assigned to the outer radiating surfaces (i.e., faces of the region) to absorb all outgoing waves. HFSS users can choose one of the three workflows to analyze an "open" design.

1. Auto-open region mode using the Solution type setting.

   This workflow eliminates as much as possible the required interactions from a user and allows a designer to get to a robust solution quickly. It is intended for users who do not want to be aware of the region and the exterior radiation boundaries.

   The open problem is enforced by the software automatically creates/maintains the region object and the ABC boundaries. HFSS applies the most appropriate out-of-the-box settings based on the geometries and the operating frequency. You do not need to (and cannot) edit these settings directly.

   This mode restricts the design to a single solve setup. Users cannot manually create the region object, radiation boundaries or PML in this mode. Infinite ground plane, metallic IE region, primary/secondary (Lattice pair) and symmetry boundaries are also not allowed.

2. Automation in setting up an open region problem using the **Create Open Region** command and **Update Open Region Padding** commands.

   This workflow provides automations that assist a user to quickly setup an open problem. As a single user-customizable command, the software creates the region and the radiation boundaries based on user's selections on the region padding type, radiation boundary type, etc.

   If necessary, you can further customize the design by editing these design objects directly.

3. Advance mode

   This is the original workflow where you manually set up the open design by assigning radiation boundary conditions.

You may assign the following types of boundaries to an HFSS design:

Anisotropic	Represents a boundary condition used to replace a surface a planar screen

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Impedance	or grid with periodic geometry.
Aperture	Represents a hole in a metallic sheet assigned as an IE Region.
Finite Conductivity	Represents an imperfect conductor.
Fresnel (SBR+)	Represents either a perfect absorbing boundary or a user-defined Fresnel table file that describes a good approximation of the reflection of an arbitrary wavefront off a surface. Supported for driven modal/terminal and SBR+ solution types.
Gradient Surface Roughness	Gradient Surface Roughness Boundaries address the situation where the conductors drawn in CAD models are perfectly smooth, but the manufactured surface is bumpy at microscopic scale.
Half Space	Represents a background comprising a dielectric half space. For antenna and scattering problems in HFSS in which all objects are assigned as Hybrid IE Region.
Impedance	Represents a resistive surface.
Lattice Pair	A Coupled pair, the same as one Primary Boundary and one Secondary Boundary together, but with an auto-set coordinate system. A red arrow points from the primary to the secondary face of the Lattice Pair.
Layered Impedance	Represents a structure with multiple layers as one impedance surface.
Linked Impedance	Represents a data link to an isotropic or anisotropic impedance boundary in another design. These can include infinite ground planes and shell elements.
Lumped RLC	Represents any combination of lumped resistor, inductor, and/or capacitor in parallel on a surface.
Multipaction SEE	For Multipaction Analysis, this represents multipaction Secondary Electron Emission (SEE). The Multipaction SEE boundaries should be added to vacuum-material interfaces where secondary electrons will be generated.
Perfect E	Represents a perfectly conducting surface.
Perfect H	Represents a surface on which the tangential component of the H-field is the same on both sides.
PML	Represents an open boundary condition using several layers of specialized materials that absorb outgoing waves.
Primary	Represents a surface on which the E-field at each point is matched to another surface (theSecondary boundary) to within a phase difference.
Radiation	Represents an open boundary by means of an absorbing boundary condition (ABC) that absorbs outgoing waves.
Secondary	Represents a surface on which the E-field at each point has been forced to match the E-field of another surface (the Primary boundary) to within a phase difference.
Symmetry	Represents a perfect E or perfect H plane of symmetry.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You may also choose to designate a perfect E, finite conductivity, or impedance boundary as an infinite ground plane if you want the surface to represent an electrically large ground plane when the radiated fields are calculated during post processing.

> **Note:**
>
> Hiding boundaries also turns off a check for boundary overlaps during boundary assignment. In the case of very large models with many boundaries, hiding boundaries can prevent delays during boundary assignment. Full model validation will subsequently check for boundary overlaps.

For convenience, you can access the **Edit Global Materials** command from the Boundaries menu.

> **Note:**
>
> By default, the history tree in the 3D modeler window groups sheet objects according to boundary assignment. To change this, select the **Sheets** icon and right-click to display the **Group Sheets by Assignment** check box.

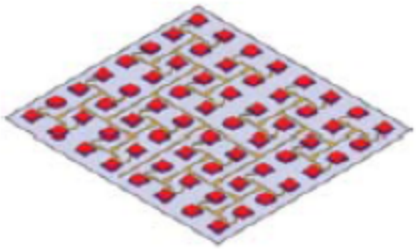
Boundaries for Open or Closed Models

In HFSS a closed model simply represents a structure, or a solution volume, where no energy can escape except through an applied port. For an Eigenmode simulation, this could be a cavity resonator. For a driven modal or terminal solution, this could be a waveguide or some other fully enclosed structure.

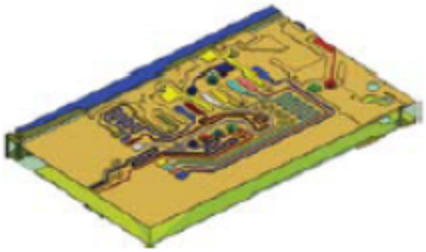
An open model represents an electromagnetic model that allows electromagnetic energy to emanate or radiate away. Common examples would be an antenna, a PCB, or any structure that is not enclosed within a closed cavity. While most HFSS simulations deal with models that are open, by default, HFSS initially assumes that any given model is closed. HFSS assumes all outer surfaces of the solution space are covered, or coated, by a perfect electric conductor boundary. In order to create an open model, you specify a boundary on the outer surfaces that will overwrite the default perfect electric conductor boundary.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Electromagnetically "Open" Structures



Antenna Array



Printed Circuit Board

Electromagnetically "Closed" Structures

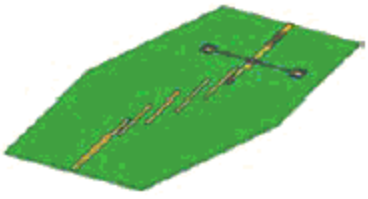
Waveguide

Cavity Resonator

Boundaries for Simplifying Models

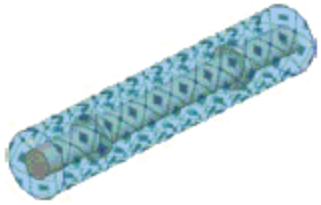
Boundaries can be used within HFSS to decrease the geometric/electromagnetic complexity of a given structure or model. These boundaries should only be used internally to a model or possibly on a symmetry plane (as in the Dielectric Resonator Antenna example or the Coax Bend Transient example). They should be applied to specifically created 2D sheet objects or to specific surfaces of 3D objects. While boundaries can be very useful, a user should exercise caution when using them as they can create unintended results if applied incorrectly.

Electromagnetically Simplified Structure



Filter where microstrip traces are modeled using 2D objects with boundary applied.

Geometrically Simplified Structure



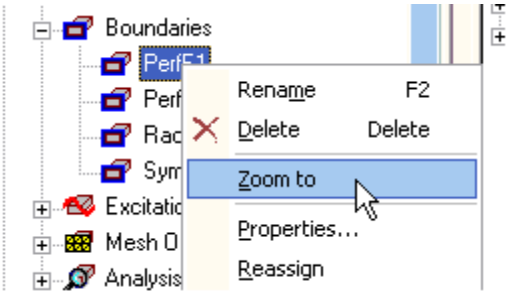
Coaxial structure where "shield" is replaced by appropriate boundary.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Not every HFSS model, however, will use simplifying boundaries. When using boundaries to create simpler models, users should take care to not create a model that has unreasonable or inappropriate boundaries applied.

Zoom to Selected Boundary

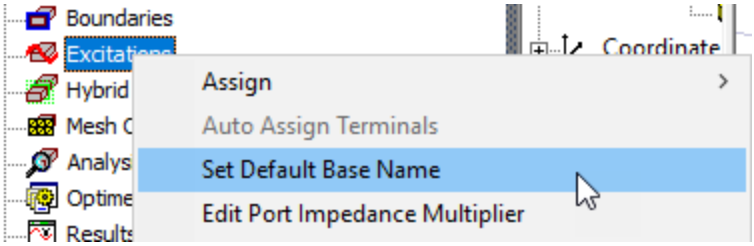
To zoom to a selected boundary, right-click a boundary name in the Project and select the **Zoom to** command on the pop-up menu. This zooms the view in the Modeler window in or out to show the selected boundary. The current orientation does not change. This can be very useful checking the assigned geometry.



Setting Default Boundary, Hybrid Region and Excitation Base Names

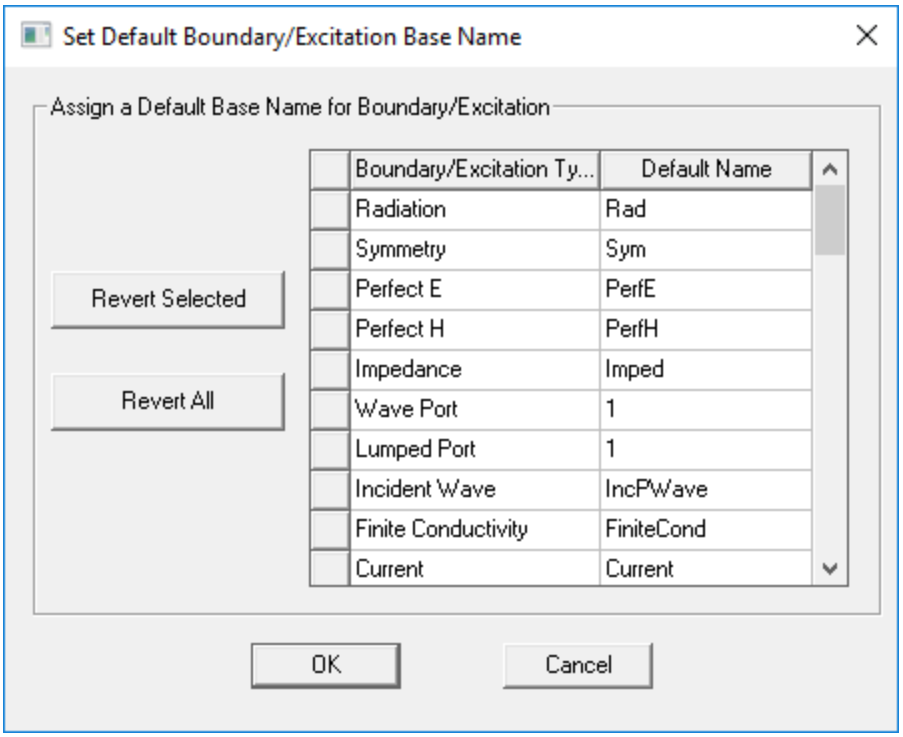
To change the default boundary, hybrid region, or excitation base names, so that subsequent names increment from the base of your choosing:

1. Click **Boundaries** > **Set Default Base Name** or **Excitations** > **Set Default Base Name** or **Hybrid Regions** > **Set Default Base Name**.



This displays the **Set Default Boundary/Excitation Base** dialog box. This contains a list of all boundary, hybrid region, and excitation types, and the base names for each. The base names for each type have editable text fields. The base names for boundaries and excitations are incremented from the base names here.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Edit the text fields to your preferred naming conventions. Names must be less than sixty characters and cannot include spaces. Letters, numbers, and special characters are permitted. Illegal names are not accepted and generate a warning message.
3. Click **OK** to accept the changes or **Cancel** to close the dialog box without accepting changes.

If you want to revert all or selected names to defaults, use the **Revert All** or **Revert Selected buttons**.

Excitation Name Ordering Conventions

Ansys Electronics Desktop tries to sort excitations by name, using a sort of "improved" dictionary (lexicographic) ordering that takes into account trailing numerals as a special case.

So if you create some ports in the following chronological order, Port3, Port1A, Port10, Port1, Port3A, Port1A1, Port10A, you will find that they appear in the list as:

Port1, Port3, Port10, Port10A, Port1A, Port1A1, Port3A

Explanation:

- Port1, Port3, and Port10 start with the same string but end in trailing numerals, so they are sorted according to the numeric value of the trailing numerals: 1 < 3 < 10. This is different from the standard dictionary sorting order, which would order them as Port1, Port10, Port3.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Port10A and Port1A both start with 'Port1' but don't end with trailing numerals, so standard dictionary sorting applies. Numbers come before letters, thus Port10A comes before Port1A (0 is before A in position 6).
- Shorter string ABC comes before longer string ABCD (ABC is a "prefix" of ABCD), so Port10 is before Port10A, and Port1A is before Port1A1.

If the leading strings contain punctuation characters (. and _). The ordering is by the character's ASCII code, so period (ASCII 46) is before underscore (ASCII 95.)

Automation in Setting up an Open Problem

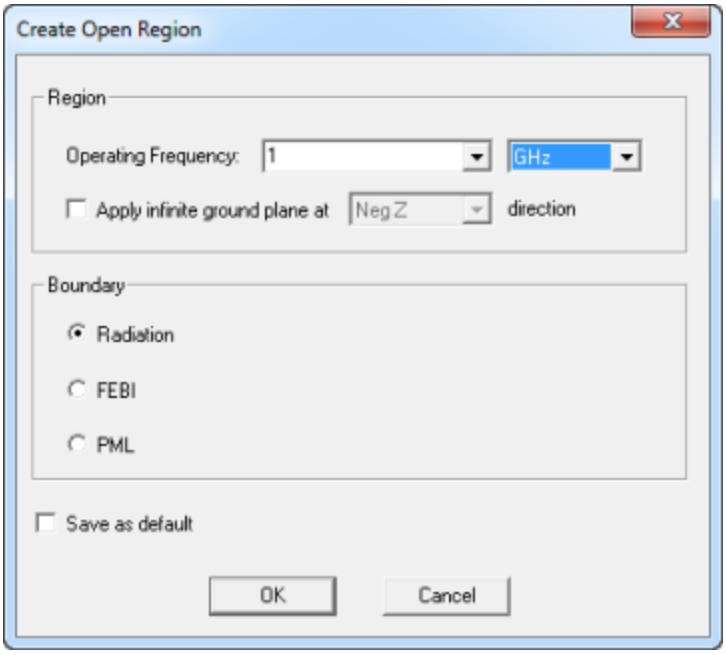
In an open problem, an air volume encompassing the outer radiating surfaces is modeled by a surrounding object. Radiation boundary conditions (ABC, PML or FEBI) are assigned to the outer radiating surfaces (i.e., faces of the region) to absorb all outgoing waves. HFSS users can use the **Create Open Region** command and **Update Open Region Padding** command to automate the setup of an open region problem. If you have specified the **Auto Open Region** check box in the Solution type, you will receive an error message. You must leave that check box unchecked to use this approach to automating an open problem.

You can access the **Create Open Region** command in three different ways:

- Right-click in the modeler window and select **Create Open Region...** from the context menu.
- Click **HFSS>Model>Create Open Region...**
- Right-click Model in the Project tree and select **Create Open Region...**

This displays the **Create Open Region** wizard.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Your selections here guide the software in setting up the region and boundaries that are required to model the device as an open problem.

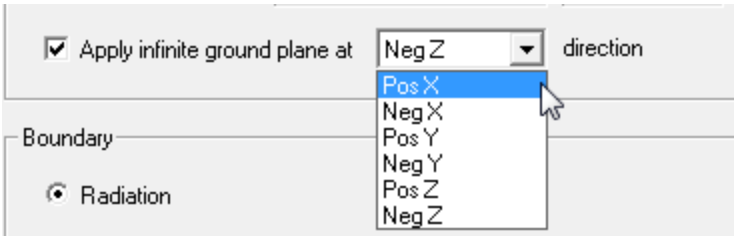
- Operating Frequency: This value is used to determine the region padding and CANNOT be parameterized. The default factory value is 1 GHz when there is no solve setup in the design.

  If you can created two or more solution setups, a pull-down provides you the ability to select the adaptive frequency. The default is to use the value from the first solve setup (in alphabetical order).

  By option you can manually type in a value.

- Infinite ground plane can be specified at one of the 6 directions by checking Apply infinite ground and selecting from the drop-down menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Default is at the Neg Z direction.

- Boundary can be one of:

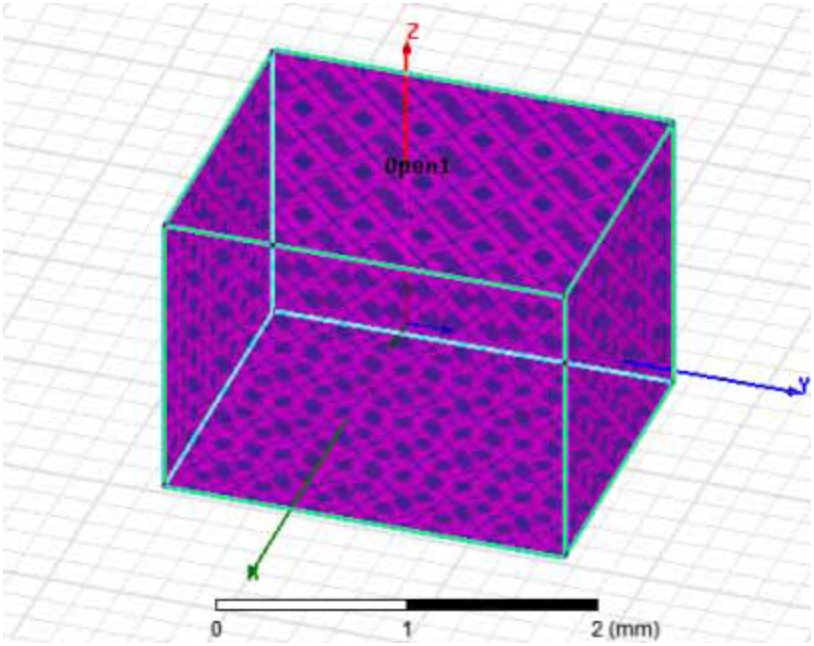
Radiation, an absorbing boundary condition (ABC) that absorbs outgoing waves..

FEBI, finite element-boundary integral (FEBI) method. Unlike ABC and PML, the IE hybrid region can be of arbitrary shape, both concave and convex thus in some cases allowing the size of the finite element solution domain to be significantly reduced.

PML, perfectly matched layer, uses several layers of specialized materials that absorb outgoing waves.

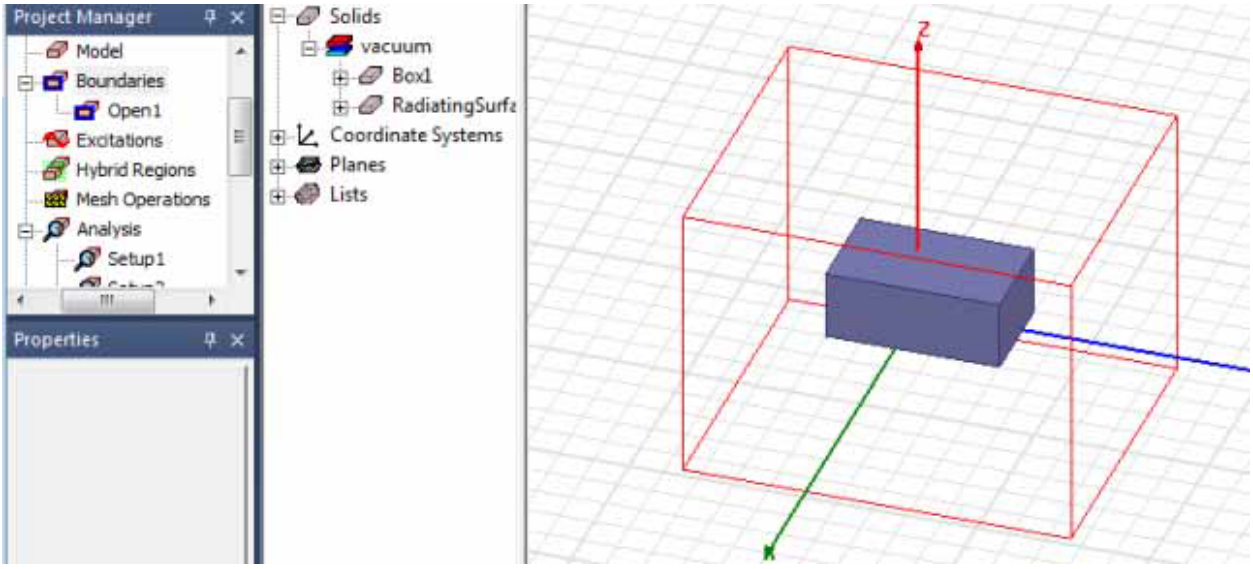
Default region padding = min(L/2, Lambda/<Boundary Type Specific>) where L is the diagonal of device's bounding box and Lambda is the wavelength of the operating frequency. This is the same formulation used in the "auto-open" design mode. The padding for ABC = min(L/2, Lambda/3). The padding for FEBI is min(l/2, Lambda/8). The padding for PML = min (L/2, Lambda/4).

When you have made your selections, and OK the dialog, region is created and displayed as a wireframe with the boundary highlighted as selected.

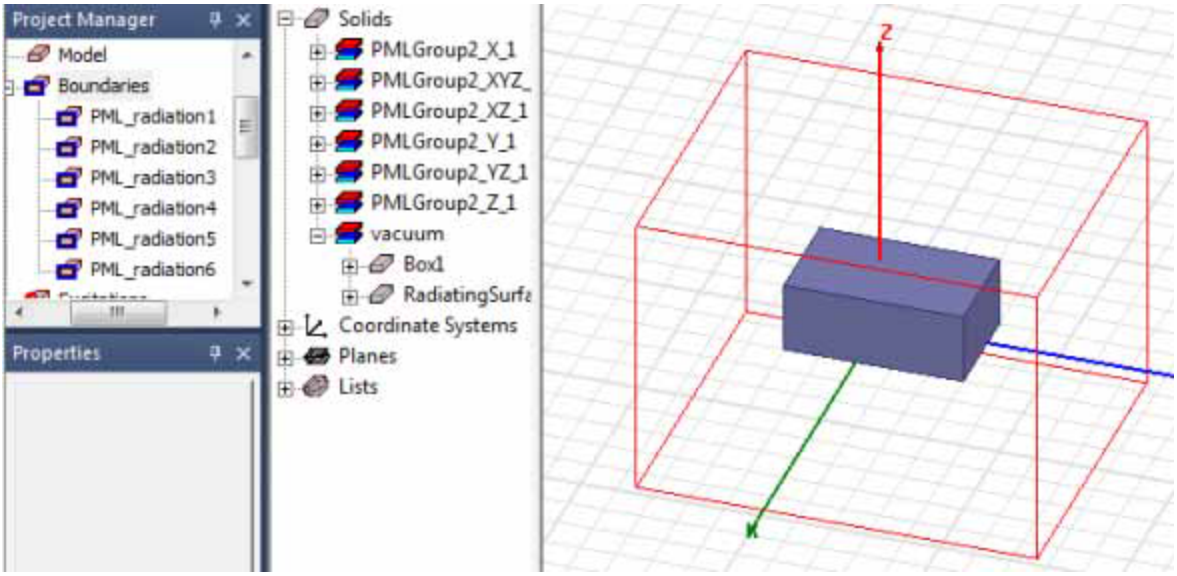


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Clicking outside the boundary de-selects the boundary. The boundary appears in the Project tree under boundaries (for Radiation and PML) or Hybrid regions (for FEBI) and under radiating surface in the history tree.



In the case of a PML, the Project manager window and history tree show the PML objects. The visibility of these objects are defaulted to off.



You can edit the properties of the created region objects in the history tree. You can also edit the properties of radiation and FEBI boundaries in the Project tree. More direct control of PML settings can be had by creating the PML boundaries via the PML wizard.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The region's size is automatically updated if you change the size of your modeled device, but the region padding is not updated automatically.

Recalculate the Padding for Regions

The **Update Open Region Padding** command is enabled whenever there is a region object in a design. To Recalculate the Padding for Regions, select **Update Open Region Padding**.

- Right-click in the modeler window and select **Update Open Region Padding...** from the context menu.
- Click **HFSS>Model>Update Open Region Padding...**
- Right-click Model in the Project tree and select **Update Open Region Padding...**

This opens the **Update Open Region** dialog.

The function resembles that in the **Create Open Region** dialog box, where you can specify the operating frequency by selecting an already created setup or manually typed a value.

On **OK**, the region padding is updated based on the out-of-the box formulation min(L/2, Lambda/4) where L is the diagonal of the device's bounding box and Lambda is the wavelength of the adaptive frequency of the solve setup. The region is automatically resized when users edit the solve setup's adaptive frequency. Initial meshes and solutions are invalidated when the region is resized.

For example, suppose you began with a device diagonal size as 10 mm. You then launched the wizard and specified an operation frequency of 10 GHz. This ends with the region padding set to 5 mm. You then increase the device diagonal to 20 mm. The region is resized to encompass all geometries but padding remains at 5 mm. You then launch **Update Open Region Padding** and specify an operation frequency of 10 GHz On **OK**, the region padding is updated to 7.5 mm.

Assigning Perfect E Boundaries

A perfect E boundary is used to represent a perfectly conducting surface in a structure.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To create a Perfect E boundary

1. Select a surface on which to assign the boundary and click **HFSS>Boundaries>Assign>Pefect E** to bring up the **Perfect E Boundary** dialog box.

2. For HFSS projects, you can select **Infinite Ground Plane** if you want the surface to represent an electrically large ground plane when the radiated fields are calculated during post processing. For PEC boundaries only, multiple infinite ground planes are supported.

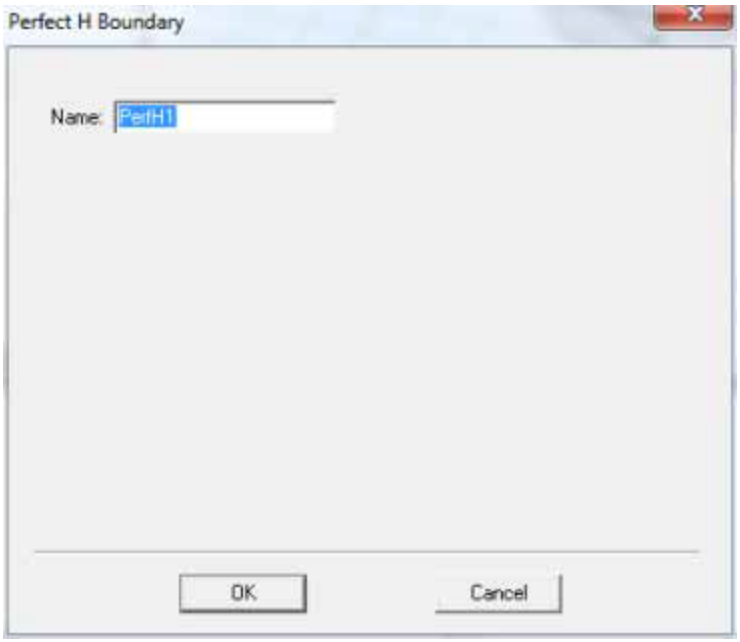
Assigning Perfect H Boundaries

A perfect H boundary represents a surface on which the tangential component of the H-field is the same on both sides. For internal surfaces, this results in a natural boundary through which the field propagates. For surfaces on the outer surface of the model, this results in a boundary that simulates a perfect magnetic conductor in which the tangential component of the H-field is zero.

To Assign a Perfect H Boundary:

1. Select a surface on which to assign the boundary and click **HFSS>Boundaries>Assign>Pefect H** to bring up the **Perfect H Boundary** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

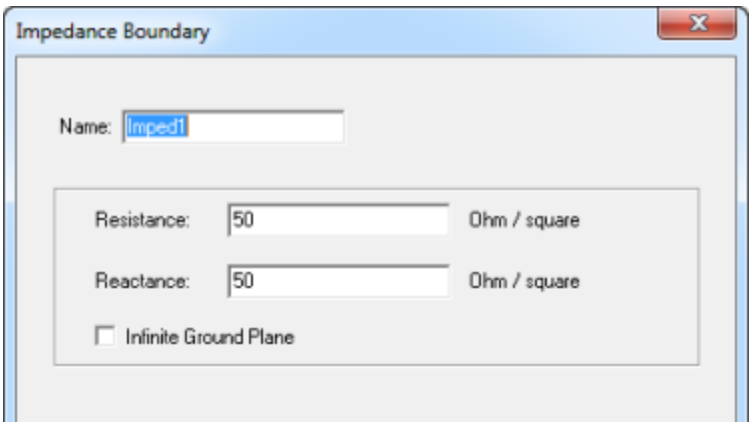


2. No parameters need be set..

Assign Impedance Boundaries

An impedance boundary (IB) represents a resistive surface. The behavior of the field at the surface and the losses generated by the currents flowing inside the resistor are computed using analytical formulae. Ansys Electronics Desktop does not simulate any fields inside the resistor.

1. Select a surface on which to assign the boundary, right-click **Assign Boundary>Impedance** to bring up the **Impedance Boundary** dialog box.



2. Enter the **Resistance** and **Reactance** for the boundary.

The default Resistance and Reactance are 50 Ohms per square.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you want to create a boundary that demonstrates **spatial dependence**, you must first assign that boundary to a sheet object. Then to define a spatial dependence for the boundary, you can create an expression for resistance or reactance using x, y, or z. For example, 50+y.

3. Select **Infinite Ground Plane** if you want the surface to represent an electrically large ground plane when the radiated fields are calculated during post processing. .

> **Note:**
>
> If you select **Infinite Ground Plane**, the effect of the impedance boundary will be incorporated into the field solution in the usual manner, but the radiated fields will be computed as if the lossy ground plane is perfectly conducting. Only one infinite ground plane is permitted in designs with impedance boundaries

> **Note:**
>
> You can assign a variable as the resistance and reactance values. Eigenmode designs cannot contain design parameters that depend on frequency, for example, a frequency-dependent impedance boundary condition.

Assigning Radiation Boundaries

> **Note:** For information on assigning radiation boundaries for Maxwell, see Assigning a Radiation Boundary for the AC Magnetic (Eddy Current) Solver.

For Eigenmode, Driven Modal or Driven Terminal Designs

A radiation boundary is used to simulate an open problem that allows waves to radiate infinitely far into space, such as antenna designs. Ansys Electronics Desktop absorbs the wave at the radiation boundary, essentially ballooning the boundary infinitely far away from the structure. In HFSS, these are sometimes described as Absorbing Boundary Condition, or ABC.

A radiation surface does not have to be spherical, but it must be exposed to the background, convex with regard to the radiation source, and located at least a quarter wavelength from the radiating source. In some cases the radiation boundary may be located closer than one-quarter wavelength, such as portions of the radiation boundary where little radiated energy is expected.

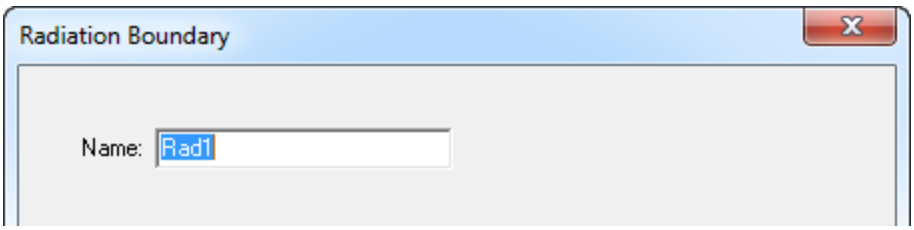
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

Whenever additions/changes are made to radiation boundaries that affect fields, it invalidates those solutions that can possibly have fields. Meshes are not invalidated.

To assign a radiation boundary:

1. Select a surface on which to assign the boundary and click **HFSS** > **Boundaries** > **Assign** > **Radiation** to bring up the **Radiation Boundary** dialog box.



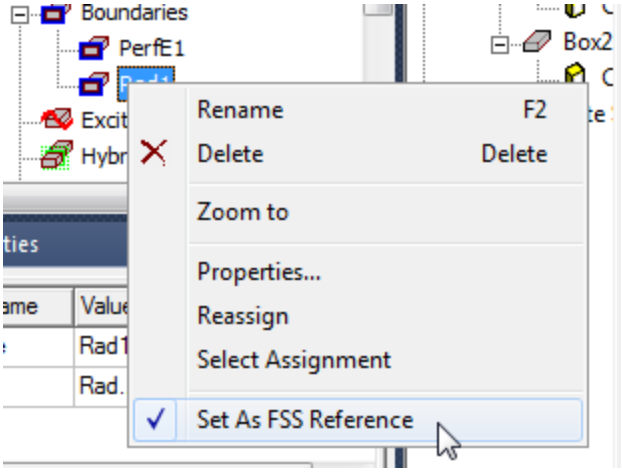
Note:

Do not define a surface that cuts through an object to be a radiation boundary.

In general, do not define the interface of two internal objects to be a radiation boundary. The only exception is when one object is a perfectly matched layer boundary (PML) and the other is the PML base object.

Set as Frequency Selective Surface Reference

You can set one reference of a Frequency Selective Surface. To setup Frequency Selective Surface, users right-click a radiation boundary and click the menu **Set As FSS Reference.** A check indicates that the boundary is selected as reference. This menu is always enabled. Inappropriate setups are handled by design validation checks.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This surface become the input surface for calculations of the reflection/transmission coefficients. The other radiating surface automatically becomes output. Only one FSS can be defined in a given model. Using the option is advantageous for highly reflective and resonant structures. Reflection/Transmission coefficients for FSS designs can be viewed in the solution data panel as S-parameters or you can create an S-parameter report.

The requirements are:

- At most one reference is permitted
- Can only be set on a single face
- When a radiation boundary is selected as reference, there must be exactly one plane propagating incident wave that is without geometry assignment or assigned to the face of the radiation boundary
- Require at least one primary/secondary (Lattice pair) boundary
- Incompatible with ports (design cannot have ports)

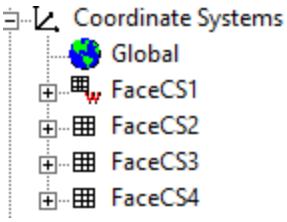
Assigning PML Boundaries

A perfectly matched layer (PML) boundary is used to simulate materials that absorb outgoing waves. Setting up a PML boundary is similar to setting up a radiation boundary. You start by selecting faces on the radiating object or by drawing a virtual object around the radiating structure. However, instead of placing a radiation boundary on its surfaces, you add PMLs to fully absorb the electromagnetic field. You can also assign PMLs to Region objects. Ansys Electronics Desktop can create PMLs automatically with the PML Setup Wizard, or using the Create Open Regions command, or you can create them manually. Create PMLs automatically if the base object touching the PML is planar and its material is homogeneous. HFSS creates a separate PML object for each covered face. The following figure shows PML objects automatically generated around a cubic region. The objects are grouped in the History tree as PML groups.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

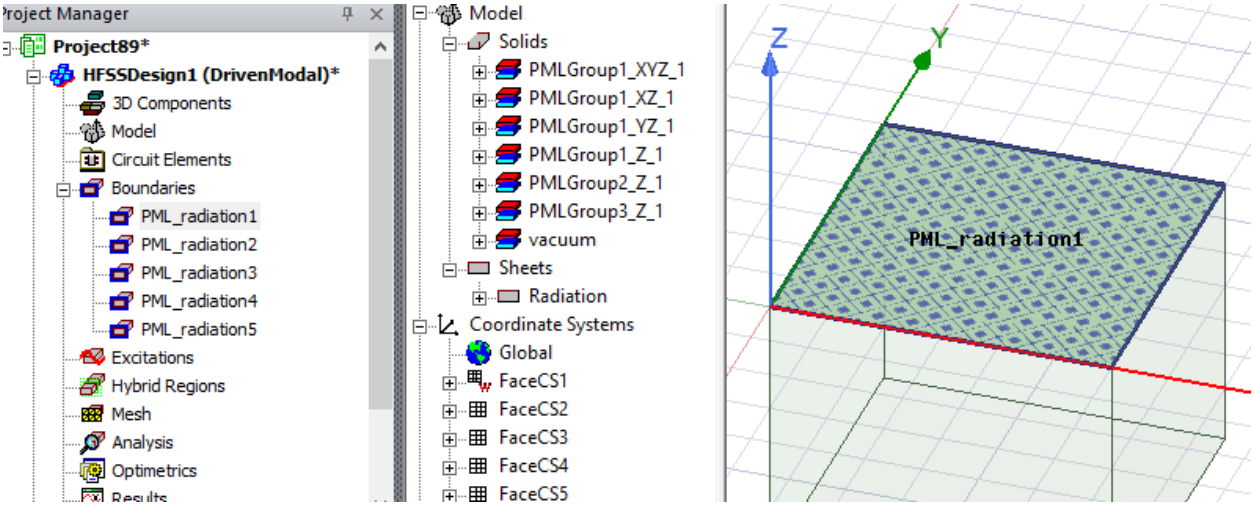
	Name	/	C...	Relative Permittivity	Relative Permeability	Bulk Co...	Dielectric Loss Tangent	Magnetic Loss Tangent
	PMLGroup1_XYZ_1	Pr...	N...	(1.596723046027...	(1.59672304602784,...	0	(1, 1, 1)	(1, 1, 1)
	PMLGroup1_XZ_1	Pr...	N...	(1, 0.01, 1)	(1, 0.01, 1)	0	(0, 509.904897143286, 0)	(0, 509.904897143286, 0)
	PMLGroup1_YZ_1	Pr...	N...	(0.01, 1, 1)	(0.01, 1, 1)	0	(509.904897143286, 0, 0)	(509.904897143286, 0, 0)
	PMLGroup1_Z_1	Pr...	N...	(1.596723046027...	(1.59672304602784,...	0	(1, 1, -1)	(1, 1, -1)
	vacuum	Pr...	N...	1	1	0	0	0

Each PML object is created on a Face coordinate system. You will see each FaceCS for PMLs listed under the Global CS.

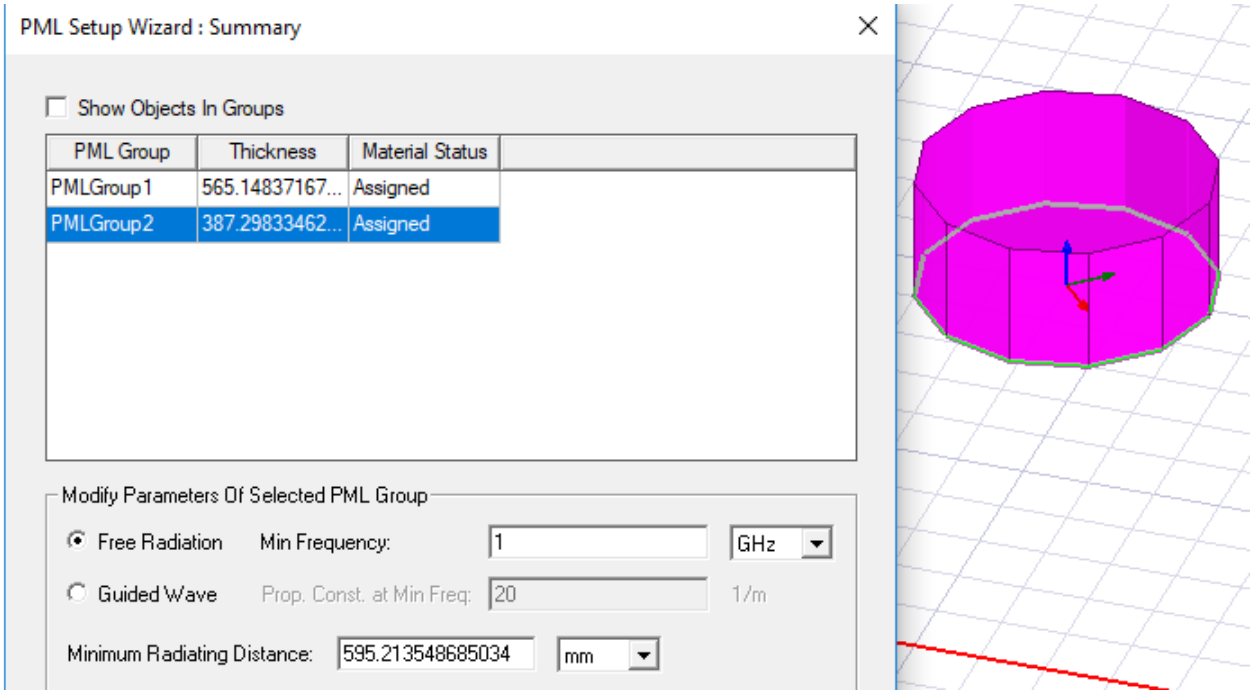


The PML boundaries are grouped in the **Project** tree under the **Boundaries** icon. Within these groupings, you can edit the radiation parameters (for example, as Incident Wave Port) in order to set up the right total field excitation based on the physical optics approach.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In creating PMLs, you can select non rectangular sheet objects as long as they do not touch any other selected face.



You can assign variables to the dimension properties of the base object. Changing the variable values then changes the associated PMLs. PML objects on a region are automatically updated when the region is updated by changing a region property or variable value.

Limitations

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you do assign PML objects to a region, you cannot perform geometry operations or copy and paste operations on that region.
- Region-dependent CS cannot be set as current CS.
- PML radiation boundaries are not generated in Eigenmode projects.
- The underlying object for assigning PML Boundaries does not have to be a box. However, any touching faces must be locally box-like.

PML Compared to Radiation Boundaries

Compared to Radiation boundaries, which create absorbing boundary conditions (ABC), PMLs in general make it more difficult for the iterative solver to reach convergence compared to the same model with using ABCs. PMLs also require significantly more RAM. The advantages for PMLs are that they absorb a much wider range of waves in terms of frequency and direction. As a result, you can put PMLs much closer to the discontinuities. This gives a smaller model. ABCs efficiently absorb normal incident waves. You have to put ABCs far away enough from the discontinuities.

What do you want to do?

Create PMLs automatically using the PML Wizard.

Create PMLs manually.

Guidelines for Assigning PML Boundaries

Creating PMLs Automatically

1. Draw a PML base object at the radiation surface.
2. Depending on the design you may select one or more faces of the object or all faces of object.

   When you create a PML that completely covers an object, for example, an air box or region around an antenna, you may find it convenient to select the object and have a boundary applied to all faces of the object.

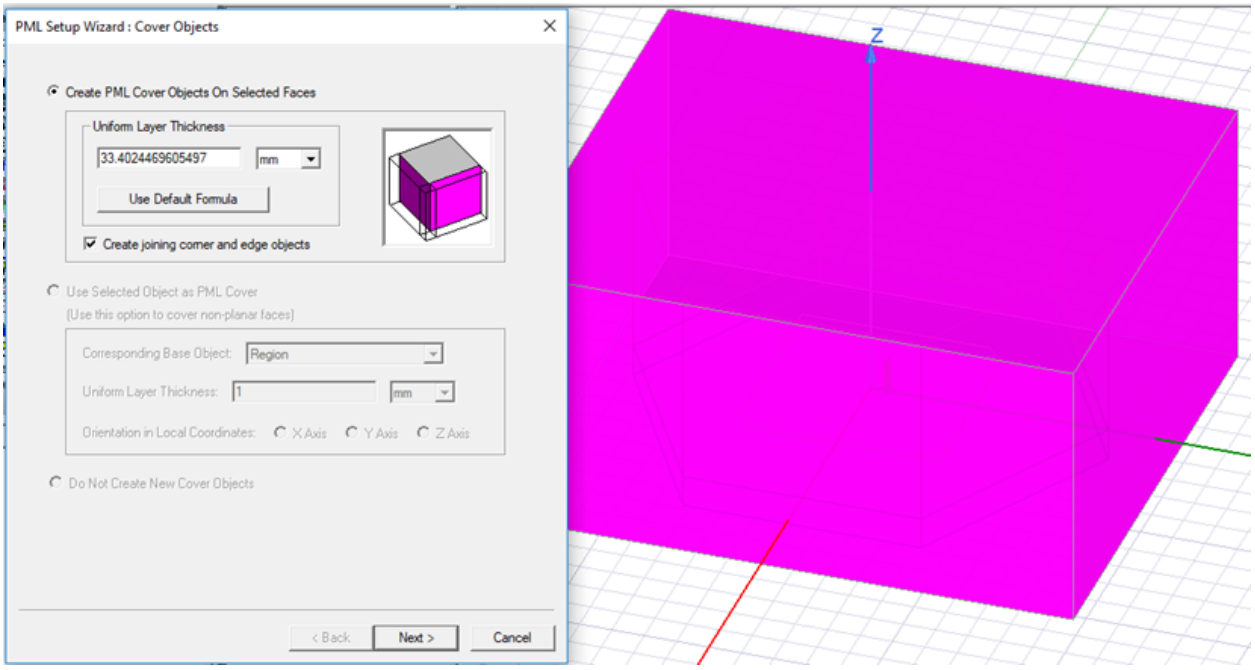
   You can select the faces of the PML base object to turn into PMLs. In these cases, select only external, planar faces and exclude faces defined as symmetry boundaries.

3. Click **HFSS** > **Boundaries**>**PML Setup Wizard**.

   The **PML Setup** wizard appears.

4. If you have selected a non-planar object for a PML or one that completely covers another object, you can select **Use Selected Object** *objectName* **as PML Cover**. If you have selected object faces, select **Create PML Cover Objects on Selected Faces**.

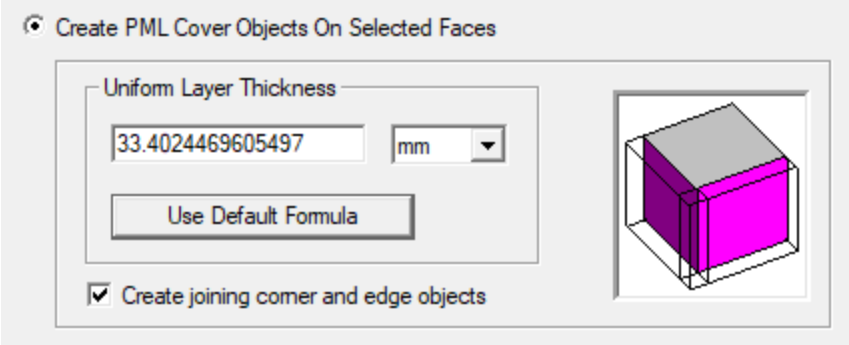
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. Type the thickness of each layer in the **Uniform Layer Thickness** text box. You can assign a variable as the thickness value.

> **Note:**
>
> The layer thickness cannot be modified directly after PML objects have been created. If you want to be able to modify the thickness, assign a variable as the thickness value.

If you do not assign a value, you can select **Use Default Formula** to have HFSS calculate a value for you based on geometrical analysis.

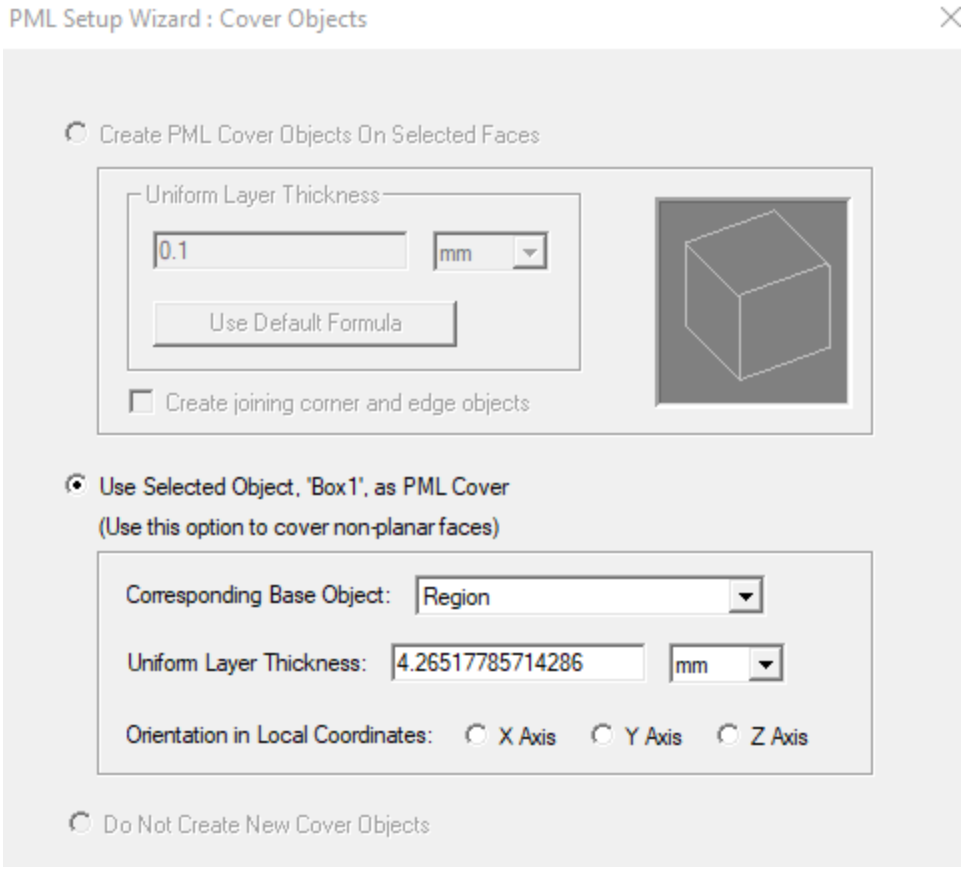


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. If the selected faces are on a box object. you can see the option to select **Create joining corner and edge objects**.

Edge and corner PML objects will be created to join adjacent PML surfaces together, ensuring complete coverage.

If the design contains another qualified object that you select, the **Use Selected Object** fields will be enabled.



If the selected object does not have a PML prefixed, you will see a dialog asking you to OK a name change. Clicking **Next** creates a PML cover object, but not a PML boundary.

If you select a face on a design that has a PML cover object defined, the dialog lets you chose to Create PML Cover Objects on Selected Faces or Do Not Create New Cover Objects. There is also a check box for **Reference for FSS** where you can also specify whether the surface is used as **Reference for FSS**, that is, as a Frequency Selective Surface - this surface becomes the input surface for calculations of the reflection/transmission coefficients. The other radiating surface automatically becomes output. Only one FSS can be defined in a given model. Using the **Incident Field** option together with **Reference for FSS** is advantageous for highly reflective and resonant structures. Reflection/Transmission

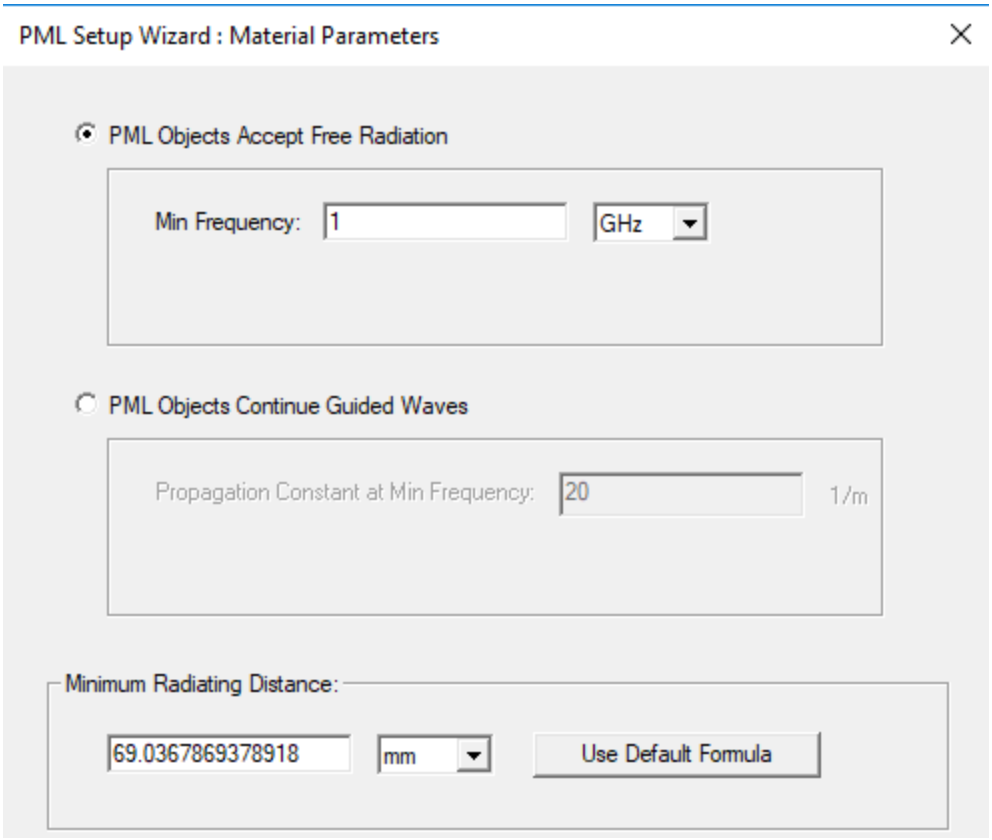
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

coefficients for FSS designs can be viewed in the solution data panel as S-parameters or you can create an S-parameter report.

If you check **Reference for FSS**, the PML objects will stay visible.

8. Click **Next**.

Ansys Electronics Desktop creates PMLs from the faces you selected. Names are automatically given to the layers. that start with *PML*, which is necessary for Ansys Electronics Desktop to recognize them as PMLs.



9. Specify how the PMLs terminate by selecting one of the following:
   a. **PML Objects Accept Free Radiation** if the PMLs terminate in free space.
      - Then enter the lowest frequency in the frequency range you are solving for in the **Min Frequency** text box.
   b. **PML Objects Continue Guided Waves** if the PMLs terminate in a transmission line.
      - Then specify the propagation constant at the minimum frequency.
10. Specify the minimum distance between the PMLs and any of the radiating bodies in the **Minimum Radiating Distance** text box. You may choose to have HFSS calculate the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

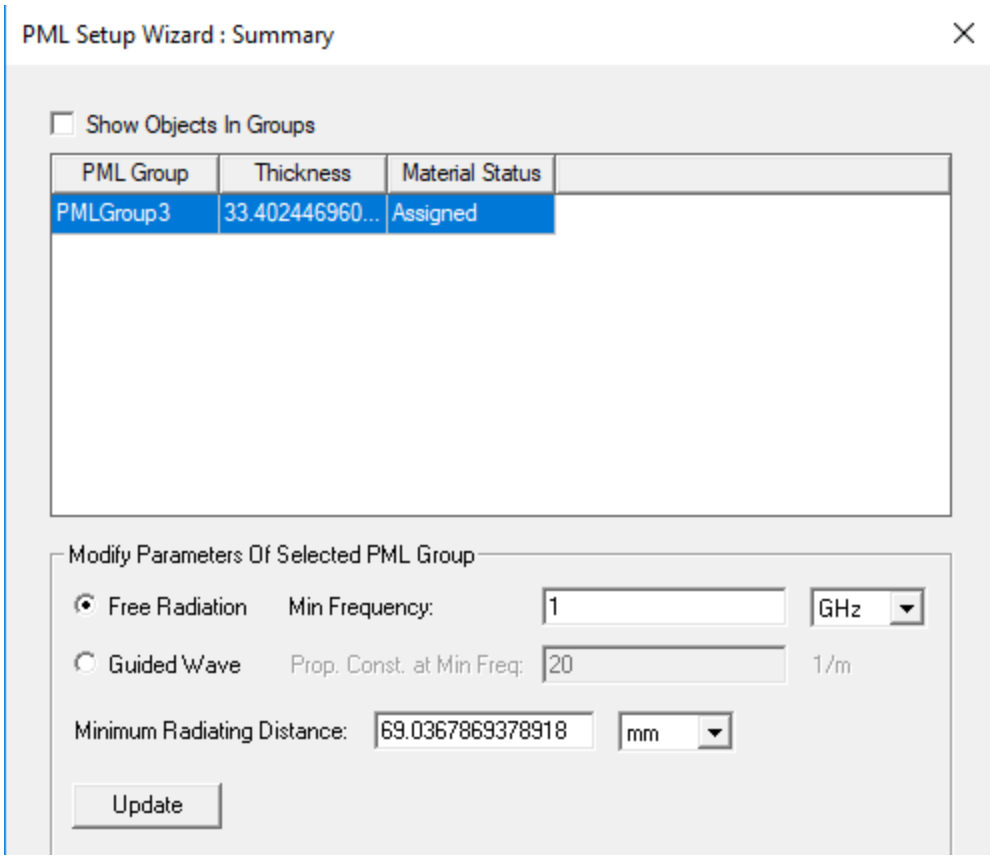
value by clicking **Use Default Formula**. The default distance is based on the extent of base object geometry.

The PML material characteristics depend on the cumulative effect of their near fields at the location of the PML surfaces.

11. Click **Next**.

Ansys Electronics Desktop calculates the appropriate PML materials based on the settings you specified and the material of the base object, and assigns these materials to the objects in the PML group.

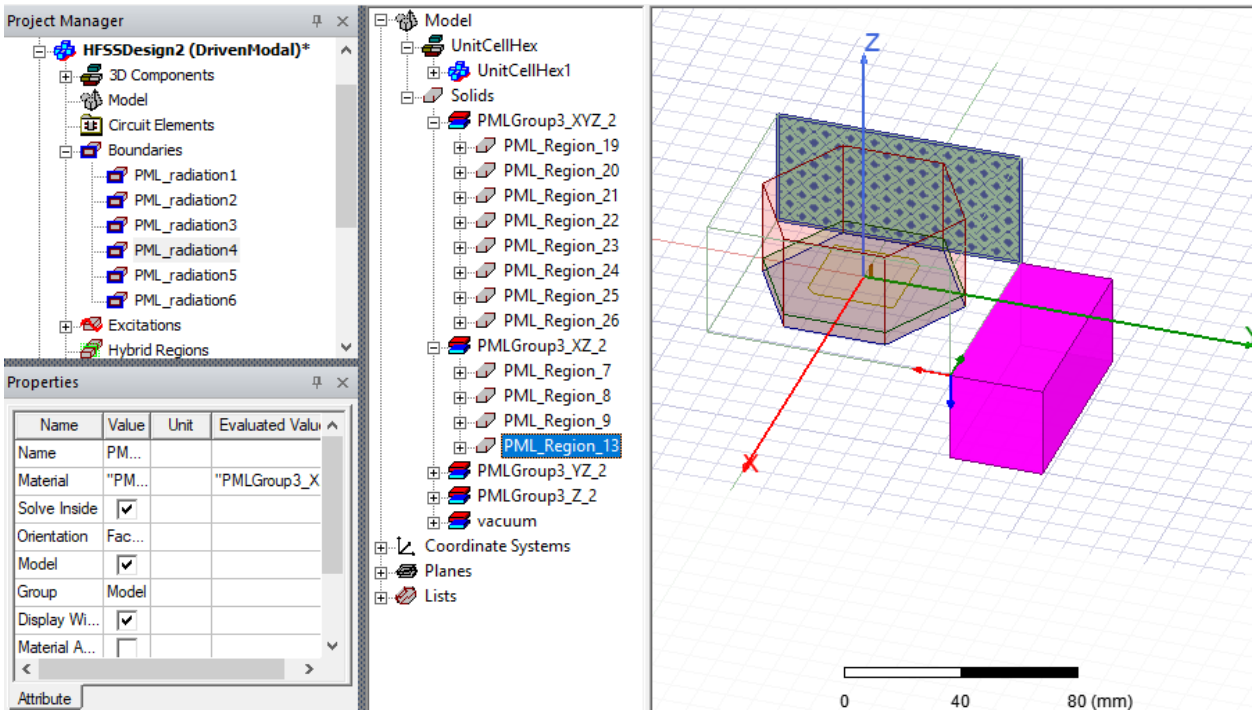
A summary dialog box appears, enabling you to modify the settings you specified.



12. Click **Finish**.

You can Fit the View to see the newly created PML boundaries in the Project tree and the PML groups and objects in the History tree. Selecting the boundaries or objects lets you view them in the Modeler window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Creating PML Boundaries Manually

See Guidelines for Assigning PML Boundaries.

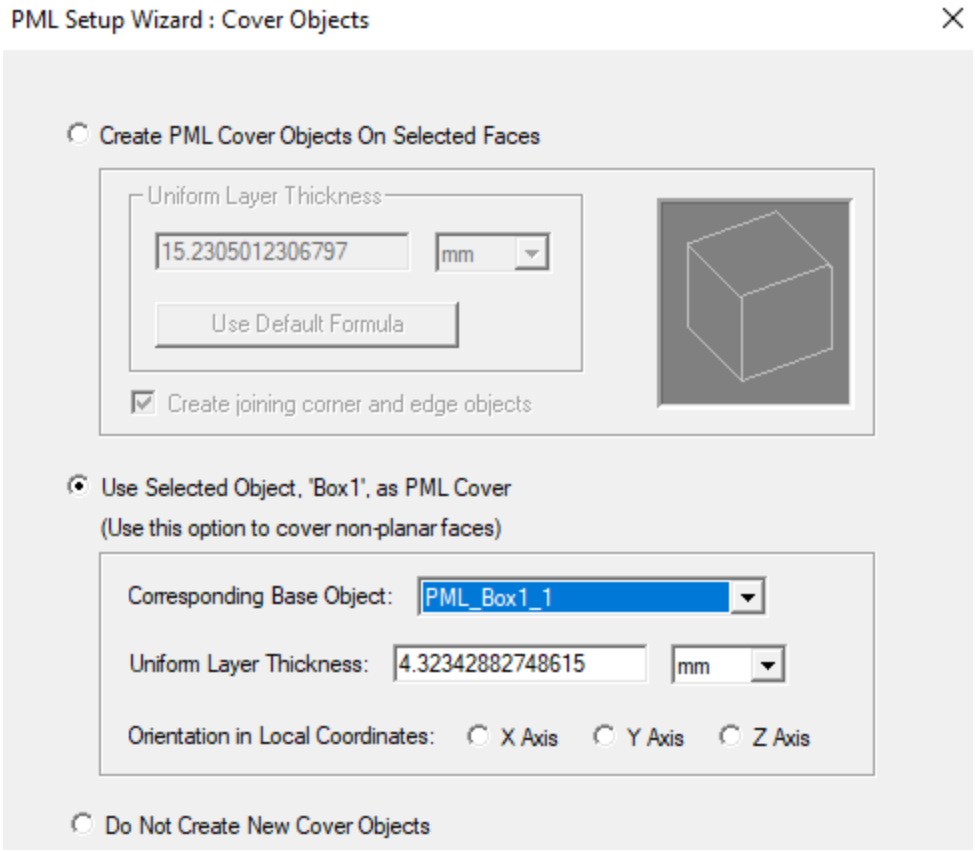
1. Draw the PML object at the radiation surface, and then select it.
2. In the **Properties** window, give the object a name with the prefix *PML*. If you so not change the name in advance, in a later step, you are prompted to allow an automatic name change.

Object names that start with *PML* are necessary for Ansys Electronics Desktop to recognize them as PMLs.

3. Click **HFSS>Boundaries>PML Setup Wizard**.

The **PML Setup** wizard appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



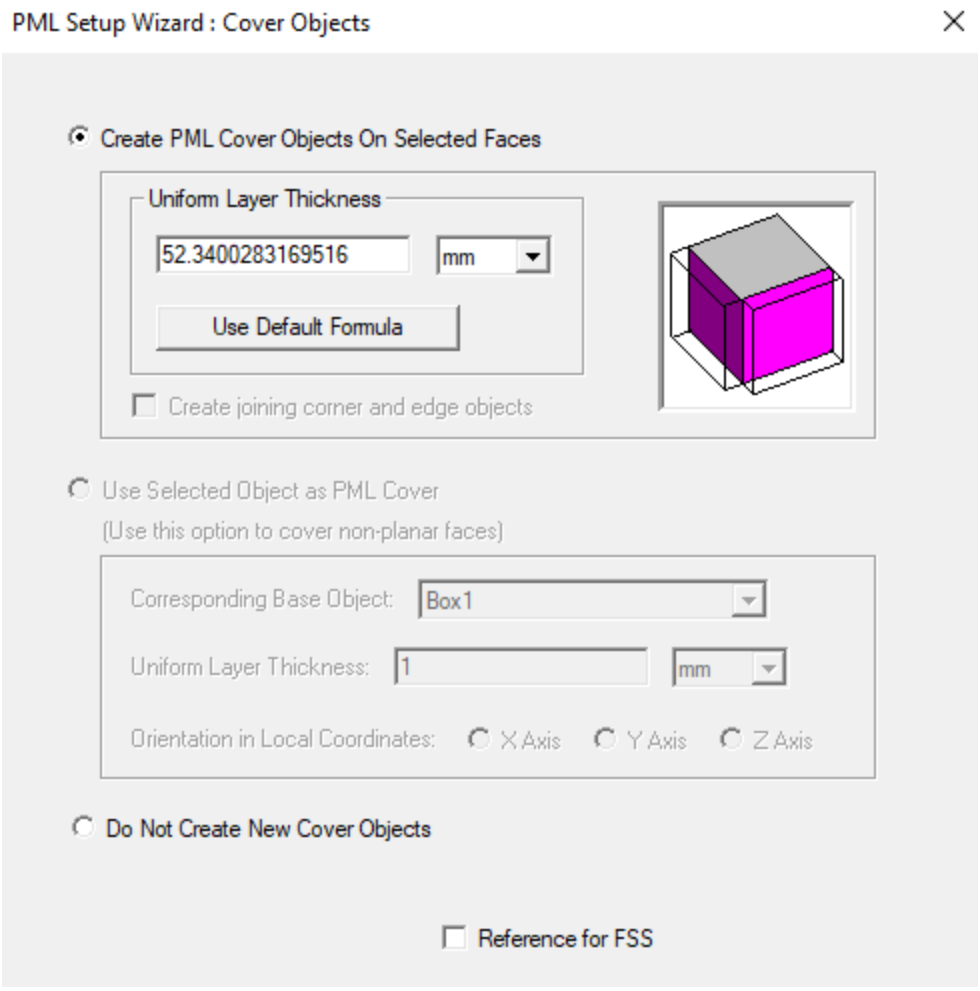
4. Select **Use Selected Object as PML Cover**.
5. Select the **Corresponding Base Object**, the object touching the PML, from the pull-down list.
6. Type the thickness of each layer in the **Uniform Layer Thickness** text box. You can assign a variable as the thickness value.
7. Select the **Orientation in Local Coordinates** of the PML object, X, Y or Z axis, the direction of outward propagation, in the relative, or local, coordinate system.
8. Under **Base Face Radiation Properties**, click a radio button to specify one of the following:

   If you selected a surface, the dialog will select **Create PML Cover Objects on Selected Faces** and disable **Use Selected Object as PML Cover**. You can also specify whether to **Do Not Create New Cover Objects** and designate whether a selected surface is used as **Reference for FSS**, that is, as a Frequency Selective Surface - this surface becomes the input surface for calculations of the reflection/transmission coefficients. The other radiating surface automatically becomes output. Only one FSS can be defined in a given model. Using the **Incident Field** option together with **Reference for FSS** is advantageous for highly reflective and resonant structures. Reflection/Transmission

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

coefficients for FSS designs can be viewed in the solution data panel as S-parameters or you can create an S-parameter report.

If you check **Reference for Frequency Selective Surface (FSS)**, the PML objects will stay visible.



9. Click **Next**.

If the selected object does not have a PML prefixed, you will see a dialog asking you to OK a name change. Clicking **Next** creates a PML cover object, but not a PML boundary.

10. Specify how the PML terminates by selecting one of the following:
    a. **PML Objects Accept Free Radiation** if the PML terminates in free space.
    - Enter the lowest frequency in the frequency range you are solving for in the **Min Frequency** text box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. **PML Objects Continue Guided Waves** if the PML terminates in a transmission line.

- Specify the propagation constant at the minimum frequency.

11. Specify the minimum distance between the PML and the radiating body in the **Minimum Radiating Distance** text box. You may choose to let HFSS calculate the value by clicking **Use Default Formula**.The default distance is based on the extent of base object geometry.

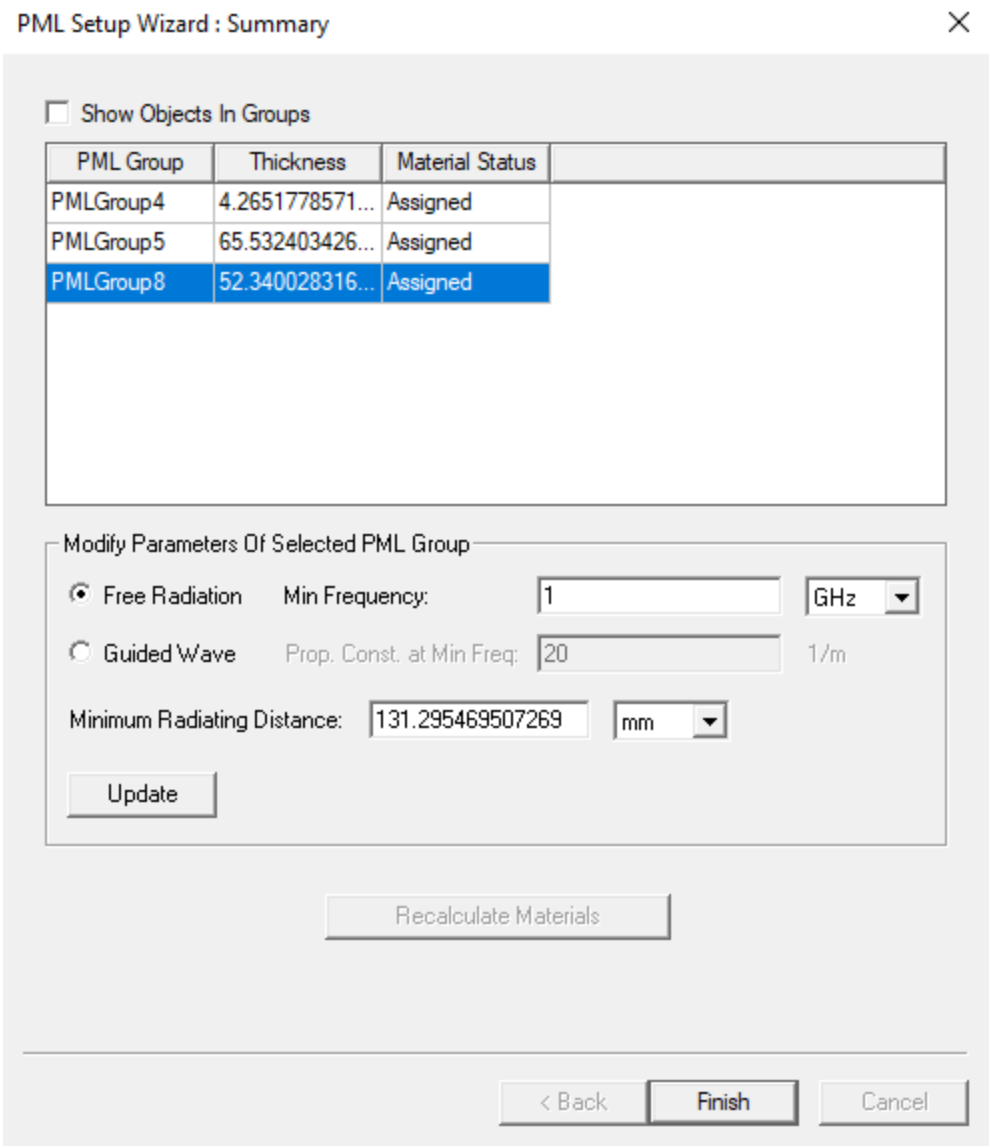
The PML material characteristics depend on the cumulative effect of their near fields at the location of the PML surfaces.

12. Click **Next**.

If Ansys Electronics Desktop calculates the appropriate PML material based on the settings you specified and the material of the base object, and assigns this material to the PML.

A summary dialog box appears, enabling you to modify the settings you specified.

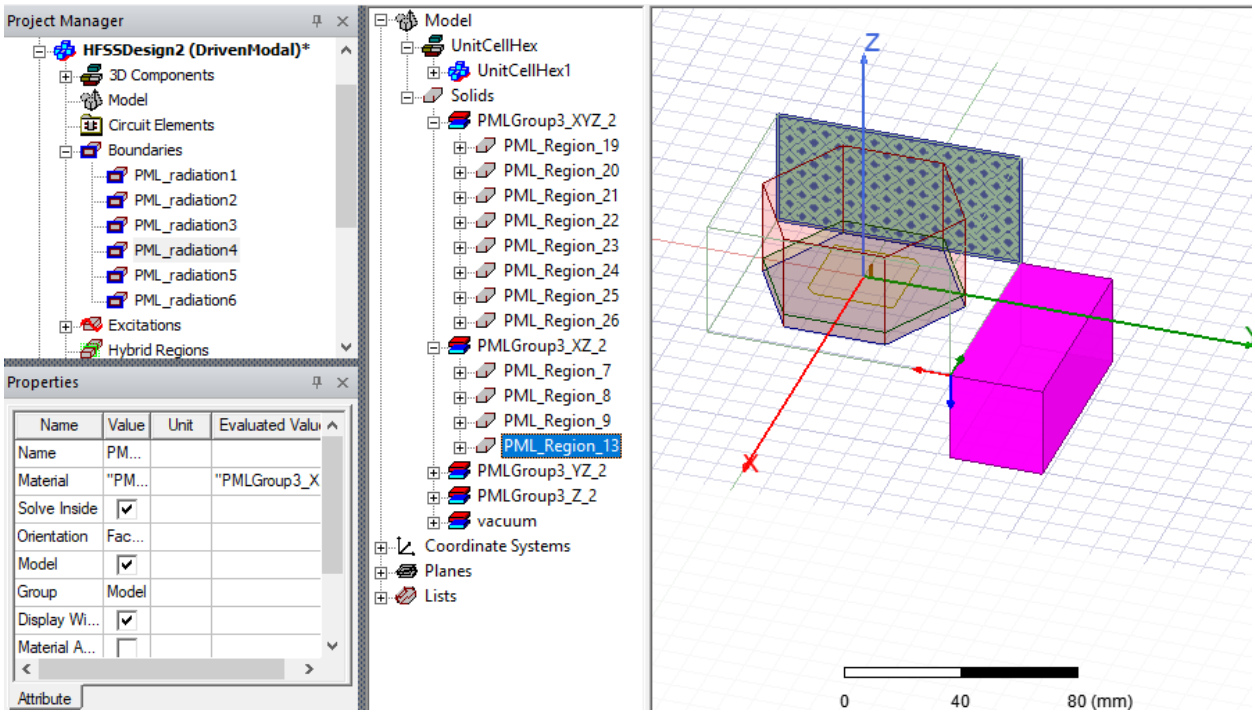
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



13. Click **Finish**.

You can Fit the View to see the newly created PML boundaries in the Project tree and the PML groups and objects in the History tree. Selecting the boundaries or objects lets you view them in the Modeler window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Guidelines for Assigning PML Boundaries

Keep the following guidelines in mind when assigning PML boundaries:

- When automatically creating PMLs, Ansys Electronics Desktop creates a new relative coordinate system for each PML object. This results in the z direction of the PML object coinciding with the normal direction of the base object's face.
- Ansys Electronics Desktop treats PMLs uniformly with regard to thickness. If the PMLs in your design vary in thickness, create a separate PML group for each thickness.

You should manually create a PML in the following situations:

- The base object is curved.

  Ansys Electronics Desktop calculates the PML material properties using the normal vector at the center of the base object's face. If the face is curved, the normal vector changes with position. The PML materials will only be good approximations if the normal vector at each point on the face is close to the normal vector at the face center.

  It is a good idea to segment the curved surface of the base object for greater accuracy. Create separate PMLs for each segment. Note that each segment's thickness is treated uniformly. The view angle of the segments should be no wider than 45 degrees. The smaller the angle of each segment, the greater the accuracy of the corresponding PML.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The material of the corresponding base object touching the PML is not homogenous. An example is a metal-shielded microstrip line with a substrate. One PML could be drawn to terminate the microstrip and another could correspond to the substrate.

Create as many PML objects as there are subsections of material properties in the base object.

Modifying PML Boundaries

You can modify parameters of PML boundaries through the **PML Setup Summary** dialog box. You can also modify the dimensions of PML boundaries by editing the History tree properties for the original object for which you assigned the PML boundaries.

To modify dimension properties for the original PML object:

1. Go to the History tree and open the hierarchy under the original PML base object.
2. Select the CreateBox command for each part of the geometry you want to modify.
3. In the Properties dialog for that geometry command, edit the properties for XSize, YSize, or ZSize as required.

   The changes to the CreateBox parameters apply to the associated PML objects. Note that you can create variables to parameterize these properties.

To modify PML parameters:

1. Make sure that nothing is selected in the **3D Modeler** window.
2. Click **HFSS**>**Boundaries**>**PML Setup Wizard**.

   The **Summary** dialog box of the **PML Setup** wizard appears. By default the Show Objects in groups box is not checked. A table shows each PML Group, its thickness, and material status. Checking the box causes the table list the objects under each group.

3. If more than one group of PMLs were defined, select the PML group you want to modify from the table.
4. Modify the PML parameters.

   A Radio button lets you select either the **Free Radiation** minimum frequency and units, or the **Guided Wave** propagation constant at a minimum frequency.

   You can also specify a Minimum Radiating distance and units.

5. If you make changes, click **Update**.

   This performs the update and enables the **Recalculate Materials** button.

6. Click **RecalculateMaterials** to apply the updates.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electronics Desktop automatically recalculates and assigns the appropriate PML materials to the objects in the PML group.

7. Click **Finish**.

> **Note:**
>
> If objects are modified after PMLs are created, the PML materials will be invalid and must be recalculated in the **PML Setup Wizard**. For example, if the material of the PML base object is modified, the associated PML materials must be recalculated in the **PML Setup Wizard**.

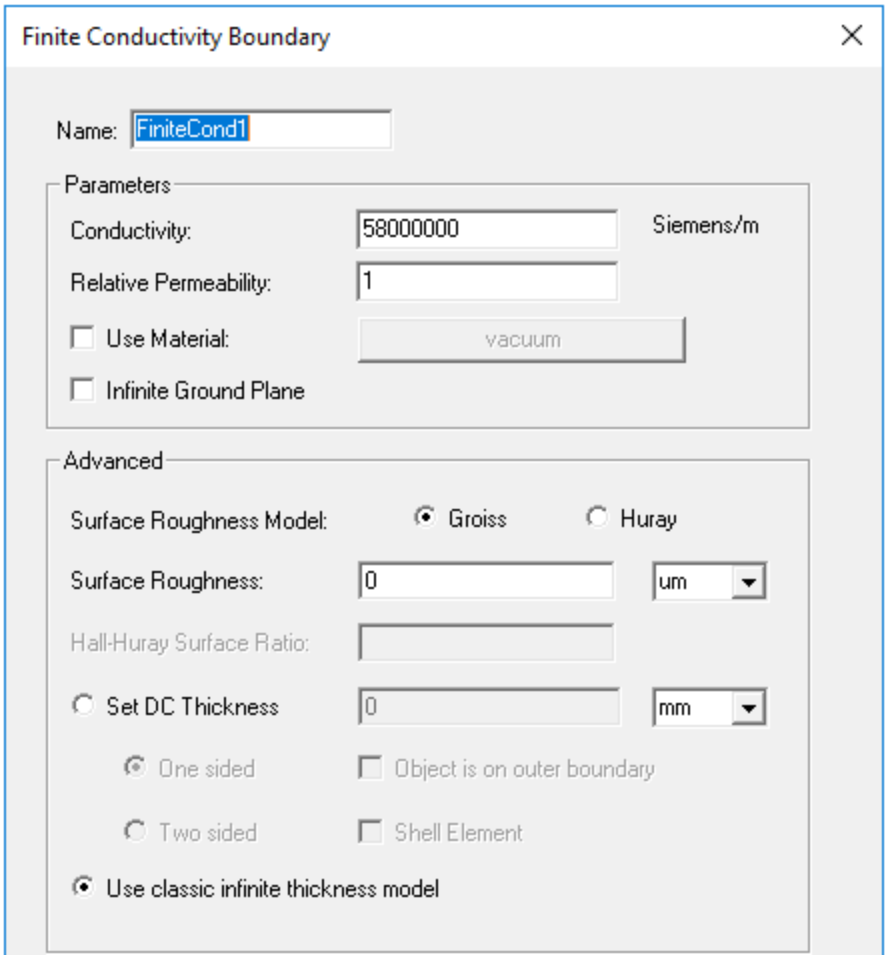
Assigning Finite Conductivity Boundaries

A finite conductivity boundary the behavior of the field at the object surface. The finite conductivity boundary is valid only if the conductor being modeled is a good conductor, that is, if the conductor's thickness is much larger than the skin depth in the given frequency range. If the conductor's thickness is in the range or larger than the skin depth in the given frequency range, HFSS takes the thickness into account, if it has been defined.

To assign a Finite Conductivity boundary:

1. Select a surface on which to assign the boundary and click **HFSS>Boundaries>Assign>Finite Conductivity** or **HFSS>Boundaries>Assign>Surface Roughness>Groiss (Finite Conductivity) ...** to bring up the **Finite Conductivity Boundary** dialog box with Gross selected as the Surface Roughness Model. If you select, **HFSS>Boundaries>Assign>Surface Roughness>Huray (Finite Conductivity) ...**, the Huray model is selected. For a description of the Huray model, see step 4 below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Do one of the following:

- Enter the conductivity in inverse ohm-meters, and then enter the permeability.

> **Note:**
>
> You can assign a variable as the conductivity or permeability values or roughness model parameters.

To assign Finite Conductivity so that the boundary is **spatially dependent** (that is, in which the material properties change over the length), use the method described via this link.

- Select **Use Material**, click the default material name button , and then choose a material from the material editor. The conductivity and permeability values of the material you select will be used for the boundary. Note that selecting a perfectly conducting material for a finite conductivity boundary triggers a validation error.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Select **Infinite Ground Plane** if you want the surface to represent an electrically large ground plane when the radiated fields are calculated during post processing.

Note that if you select **Infinite Ground Plane**, the effect of the finite conductivity boundary will be incorporated into the field solution in the usual manner, but the radiated fields will be computed as if the lossy ground plane is perfectly conducting.

For designs with port excitations but no FE-BI boundary and metallic IE region defined, selecting Infinite Ground Plane affects only the calculation of near field and far field radiation during post processing; otherwise, the design has to be re-simulated to model the effects of infinite ground plane. The boundary condition infinite ground plane divides the problem region into two halves. The entire model resides in the half above the boundary, and the radiated fields are set to zero in the half below the boundary. Antenna parameters involving radiated power are consistent with these properties.

Lossy ground planes can be approximated by selecting the Infinite Ground Plane check box when defining Finite Conductivity Boundary or Impedance Boundary. The effects of these boundary conditions are incorporated in the field solution and in the radiated fields accordingly.

Remember the following requirements when defining an infinite ground plane:

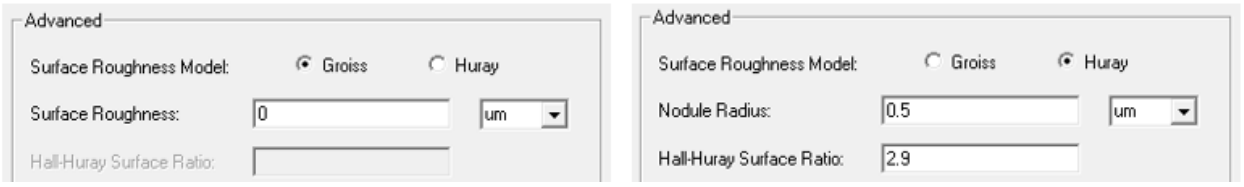
- It must be defined on a planar surface.
- All infinite ground planes and symmetry planes must be mutually orthogonal.
- For impedance, layered impedance, or finite conductivity boundaries, only one infinite ground plane can exist in a design. For perfect E boundary conditions, multiple infinite ground planes are supported and they must be co-planar.

4. Because surface roughness can increase conductor power losses more than two times, HFSS models surface roughness model based on the visible features of copper conductors used in circuit fabrication.To select the **Surface Roughness Model** used for surfaces such as the interface between the conductor and the substrate for a microstrip line, select either Groiss or Huray.

For the Groiss model, you specify a Surface Roughness parameter (traditional case) as a value (or variable) and units. The default is 0 um. Legacy projects use the Groiss model by default.

For the Huray Model, you specify the Nodule radius value (or a variable), which describes the radius of copper spheres that model the surface roughness. The default is 0.5 um. Also for the Huray model, you specify the Hall-Huray Surface Ratio, a unitless quantity. The default is 2.9. HFSS implements an enhanced version of the Huray surface roughness model. In addition to the benefits of the original Huray model (accurate broad-band modeling of the losses in very rough copper foils typically used in printed circuit board manufacturing), the enhanced model is causal, making it more suitable for time-domain signal integrity studies, and it accurately predicts increased phase delay due to the surface roughness.

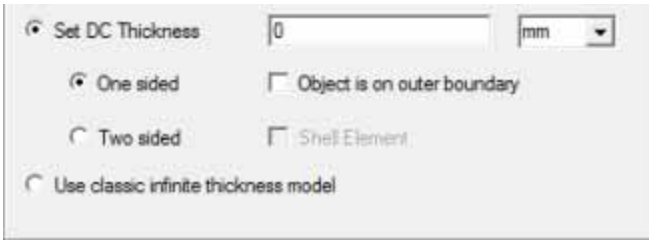
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



(Using surface roughness with the Finite Conductivity boundary may be more intuitive than using a layered impedance boundary to model the effects.)

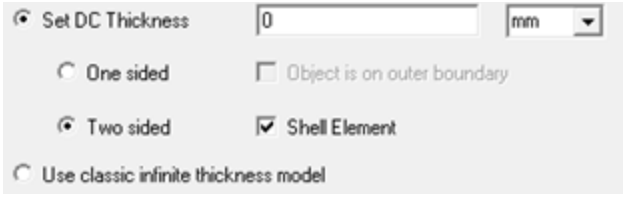
5. You can select either Set DC Thickness or Use classic infinite thickness model. You can specify a DC thickness to more accurately compute DC resistance of a thin conducting object for which Solve Inside is not selected. Skin impedance of the object will be calculated using the defined finite thickness.

To Set DC thickness, click the radio button to enable the **Layer Thickness** field, and enter a value and select units. You can also specify whether a One-sided object is on outer boundary of the model.



.

If you select **Two sided**, you can also specify whether to treat the boundary as a **Shell Element**. Shell elements maintain two sets of unknown coefficients for the top and bottom surface



Meshing thin layers such as signal traces or thin substrates of PCBs can be difficult and cause very inefficient simulation performance. Instead of meshing these thin layers, they can be replaced with sheets along with appropriately assigned boundary conditions. The appropriate boundaries are 2-sided layered impedance or finite conductivity boundaries where the latter is only applicable for a single layer of metallic material such as a signal trace made of copper.

When to Use Shell Elements

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

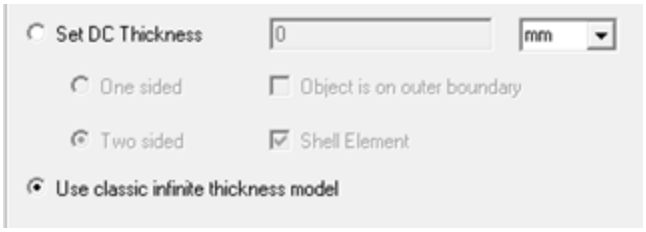
You can consider using **shell elements** on the sheet for enhanced accuracy at high frequencies where the currents on the two sides of the sheet will be allowed to be different and therefore better model the non-uniform current distribution of a thin structure at high frequencies. Some examples for this application would be studying shielding effects of a car chassis by modeling the chassis with sheets or replacing an antenna radome model with a thin sheet. Note that the shell element option is applicable for all frequencies and can therefore be used for broadband simulations without the need to modify boundary options depending on the simulation frequency. Further, a sheet in the above discussion can also be a face of a solve inside object.

For technical details, see Shell Elements Theory.

The following features are not currently supported when using shell elements:

- Fast sweep
- Scattered field formulation
- Eigen solver
- IE solver

Selecting **Use classic infinite model** disables the fields for Set DC Thickness and the outer boundary check box. Calculations for DC then assume infinite thickness.

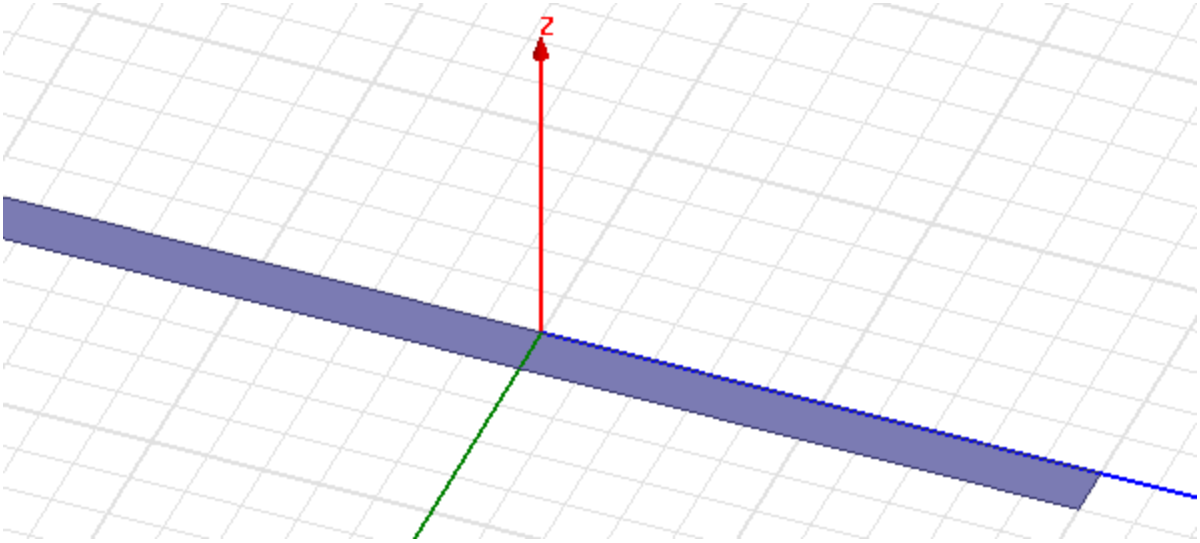


Also see Assigning DC Thickness under Materials for a discussion of design defaults and the how DC thickness is used and calculated.

Spatially Dependent Boundaries

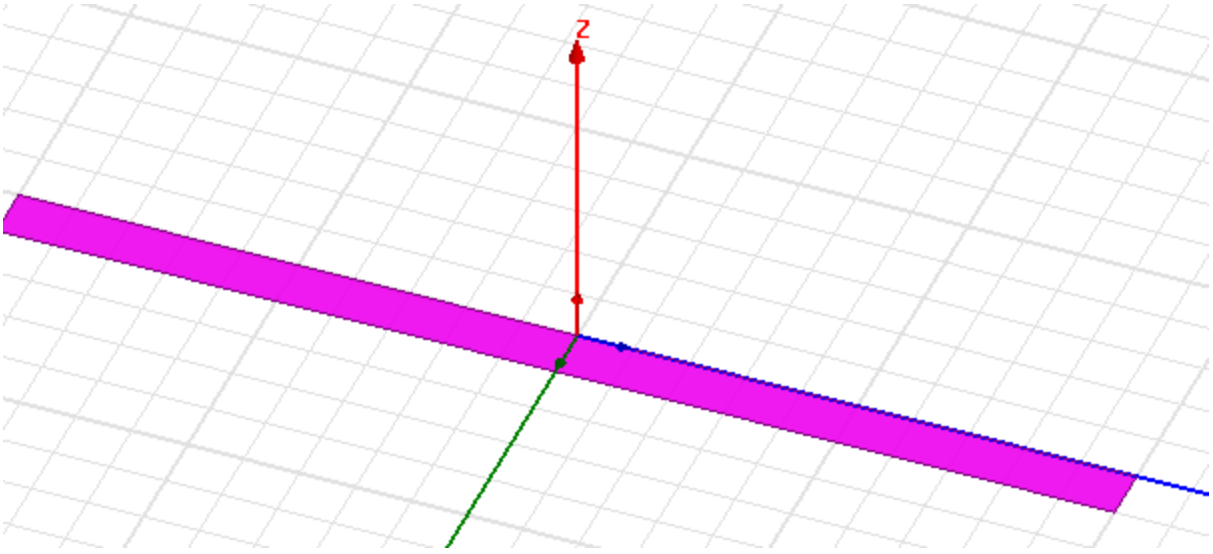
HFSS supports spatially dependent materials, that is, materials whose properties change over their length. Consider a long rectangular sheet object that lies on the XY plane along the Y axis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



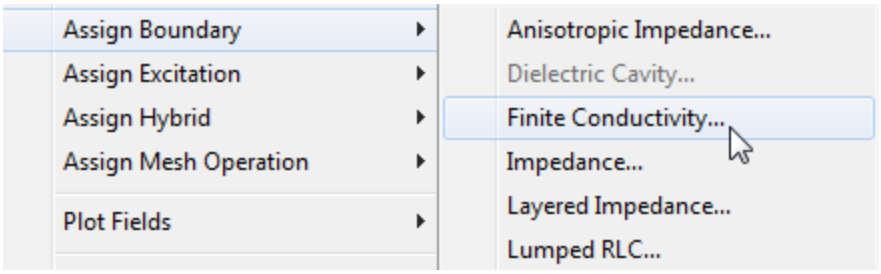
To assign **Finite Conductivity** such that the boundaries are spatially dependent follow these steps:

1. Select the line as shown in the figure below.



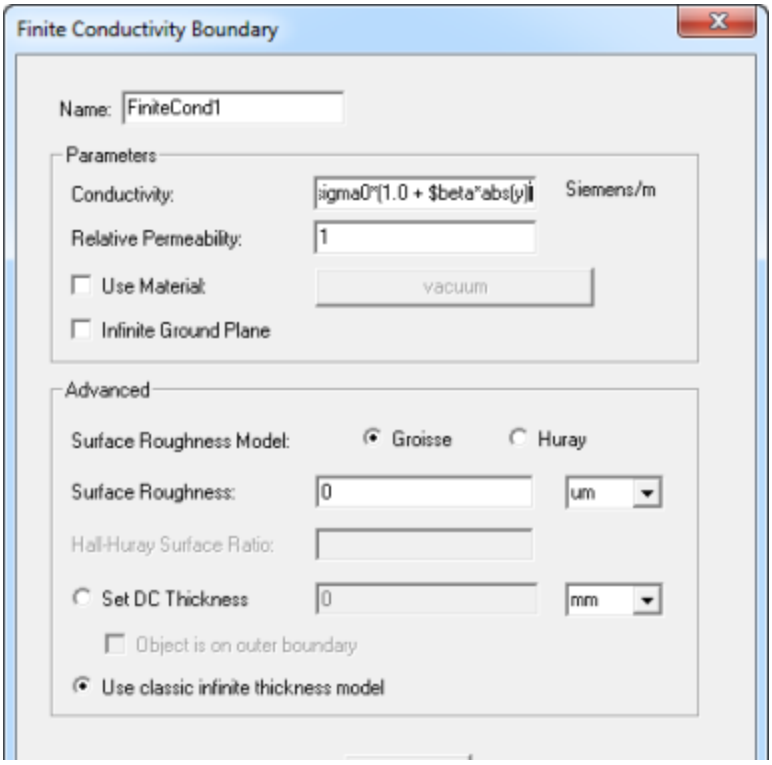
2. Right-click anywhere in the modeler and select **Assign Boundary** > **Finite Conductivity** as shown below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This causes the **Finite Conductivity Boundary** dialog box to appear as shown below.

3. Type the expression in the **Conductivity** field to include the spatially dependent material properties of the sheets. For example, in this design, the **Conductivity** field has the following expression: $sigma0*(1.0 + $beta*abs(y)), where $sigma and $beta are the predefined project variables and y specifies the local y co-ordinate associated with the sheet.



Note: Whatever model units you define, specify the expression in the **Conductivity** field in SI units. To verify the **Coordinate System** associated with the sheet, double-click the **Create Rectangle** command associated with the object from the History Tree to open the **Attribute** window as shown below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Command

	Name	Value	Unit	Evaluated Value
	Command	CreateRectangle		
	Coordinate System	Global		
	Position	0.1 ,-1 ,0	mm	0.1mm , -1mm , 0mm
	Axis	Z		
	XSize	-0.1	mm	-0.1mm
	YSize	7	mm	7mm

Note: The spatial dependency can only be expressed in Cartesian coordinates.

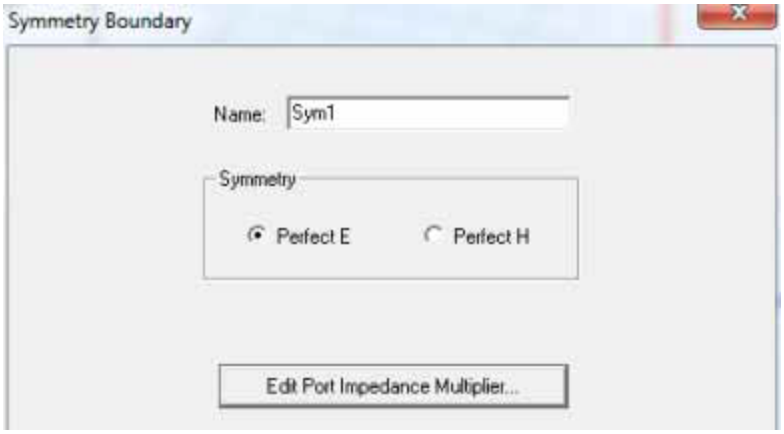
Assigning Symmetry Boundaries

For Driven Modal or Eigenmode Designs

A symmetry boundary represents a perfect E or perfect H plane of symmetry. Symmetry boundaries enable you to model only part of a structure, which reduces the size or complexity of your design.

To assign a Finite Conductivity boundary:

1. Select a surface on which to assign the boundary and click **HFSS> Boundaries> Assign> Symmetry** to bring up the **Symmetry Boundary** dialog box.



2. Select the type of symmetry plane the boundary represents: **Perfect E** or **Perfect H**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Click **Impedance Multiplier**.

   If the design includes a port, you must adjust the impedance multiplier or the computed impedances will not be for the full structure.

   The **Port Impedance Multiplier** dialog box appears.

4. Type a value in the **Impedance Multiplier** box, and then click **OK**.

Assigning Coupled Lattice Pair Boundaries

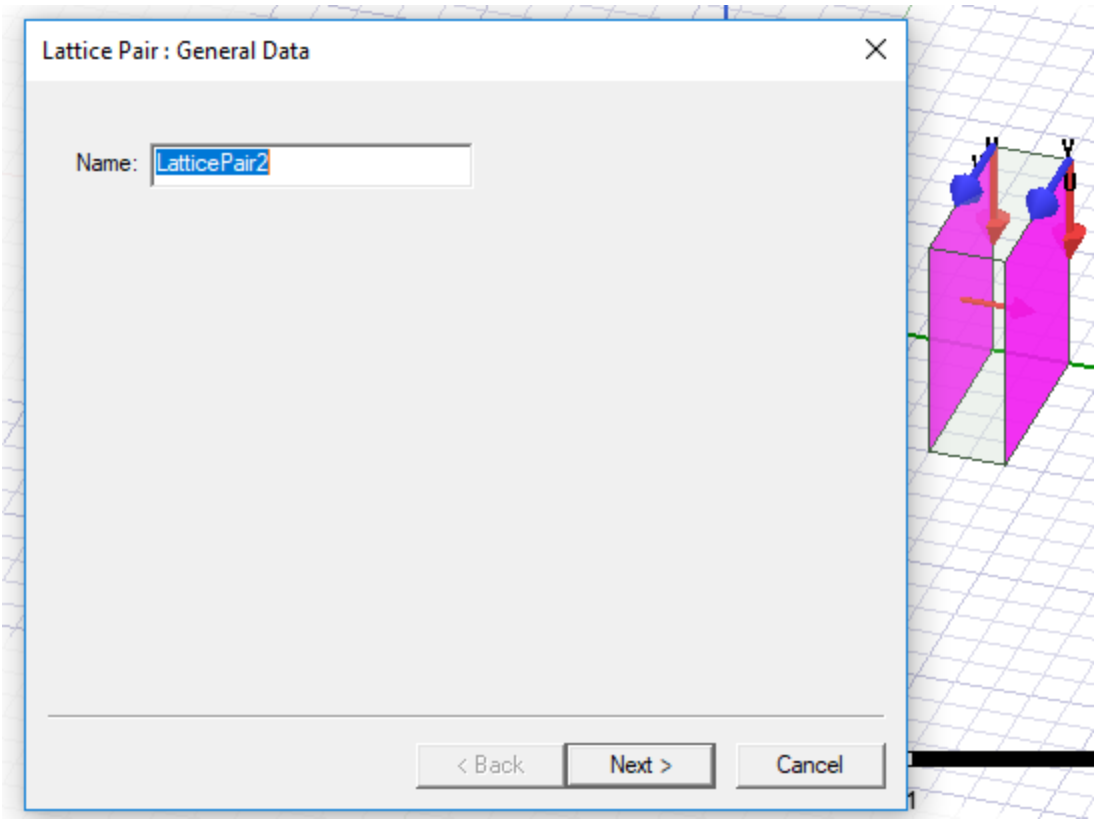
Coupled Lattice Pair boundaries enable you to model planes of periodicity where the E-field at every point on the Secondary boundary surface is forced to match the E-field of every corresponding point on the Primary boundary surface to within a phase difference. The transformation used to map the E-field from the Primary to the Secondary is determined by an auto-set coordinate system for the coupled lattice pair. The boundaries are useful in creating unit cells and arrays. (You can also assign Primary and Secondary boundaries for a coupled lattice pair separately.)

To assign a Coupled Lattice Pair:

1. Select two surfaces on which to assign the coupled lattice pair and click **HFSS>Boundaries>Assign>Couple...>Lattice Pair...**to bring up the **Lattice Pair** dialog

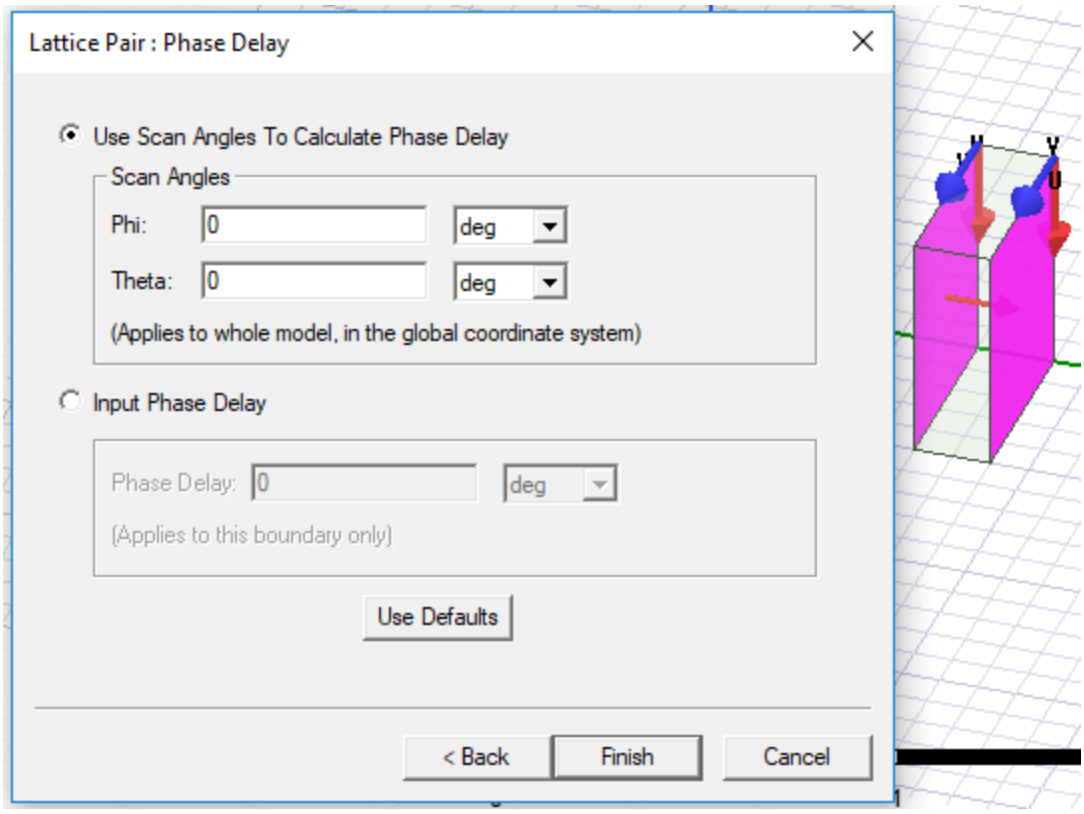
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

box.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click **Next**.



You have the option to relate the Secondary boundary's E-fields to the Primary boundary's E-fields in one of the following ways:

For driven designs, select **Use Scan Angles to Calculate Phase Delay** to enable the **Scan Angle fields**. Then enter **Phi** and **Theta** scan angles. These apply to whole model, in the global coordinate system. The phase delay is calculated from the scan angles; however, if you know the phase delay, you may enter it directly in the **Phase Delay** box.

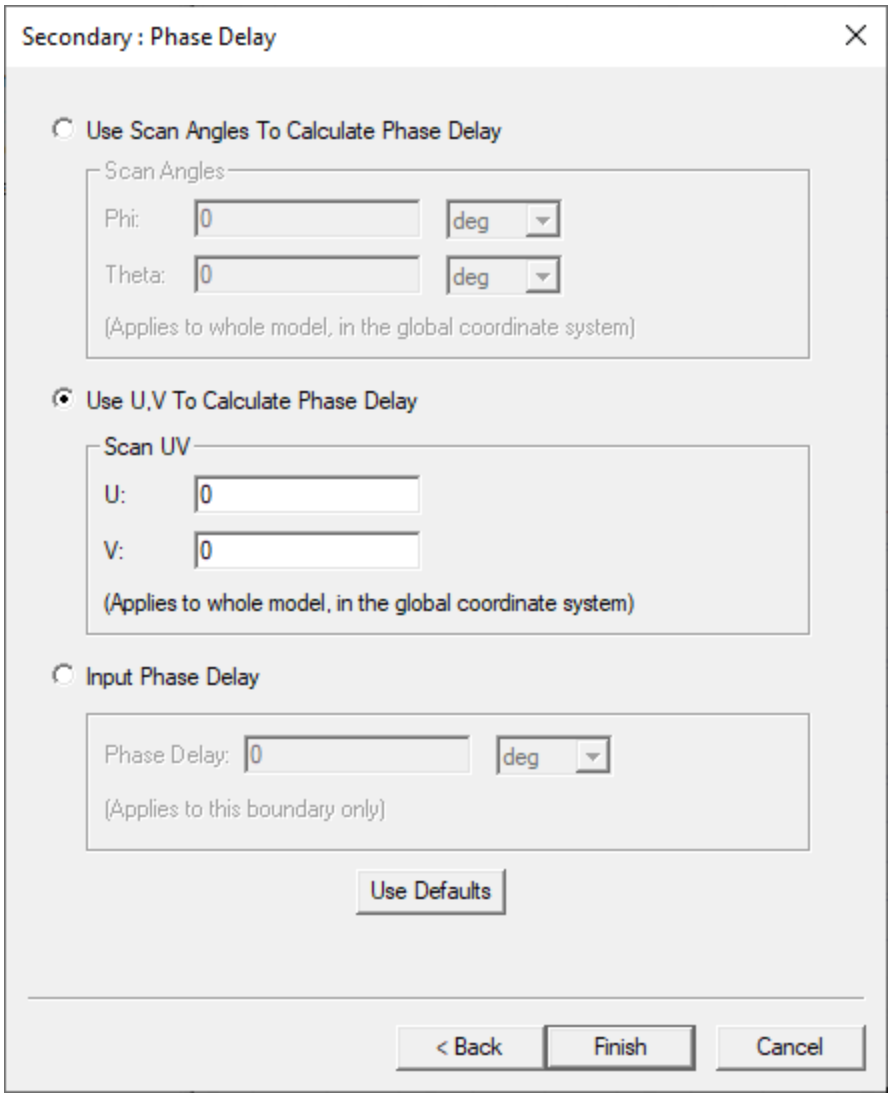
> **Note: Note**: For Eigenmode problems, the **Use Scan Angles to Calculate Phase Delay** fields are disabled.

Select **Input Phase Delay**, and then enter the phase difference, or phase delay, between the boundaries' E-fields in the **Phase Delay** box. The phase delay applies only to this boundary.

> **Note:** : You can assign a variable as the phi, theta, or phase delay values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A Beta Option allows you to **Use U,V to Calculate Phase Delay**.



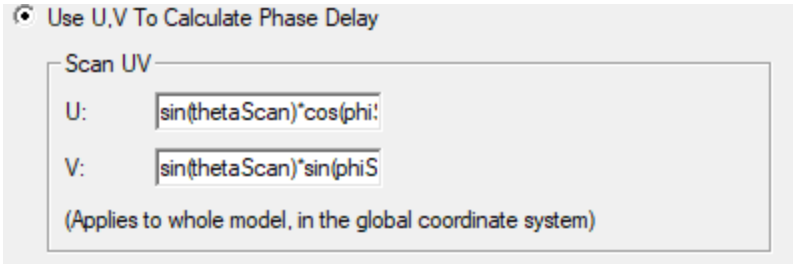
This permits you to scan to scan in the invisible range which is conveniently specified by u,v coordinates. U or V can span anything between -infinity to + infinity or practically some large negative value to large positive value. When $U^2+V^2 > 1$, it is the invisible range. You can specify U and V as equations in this form:

$$u = \sin\theta \cdot \cos\varphi$$

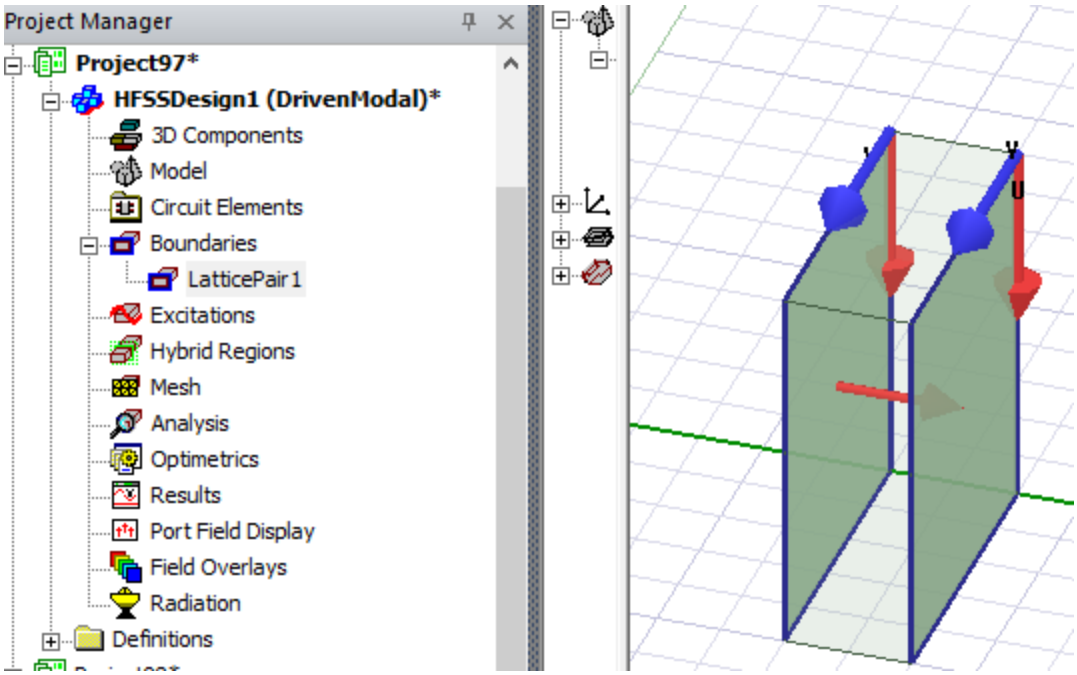
$$v = \sin\theta \cdot \sin\varphi$$

Note that you can employ variables in the equations:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ansys Electronics Desktop will compute the E-field on this boundary and map it to the Secondary boundary using the transformation defined by the Primary and Secondary coordinate systems.



Assigning Primary Boundaries for a Coupled Lattice Pair

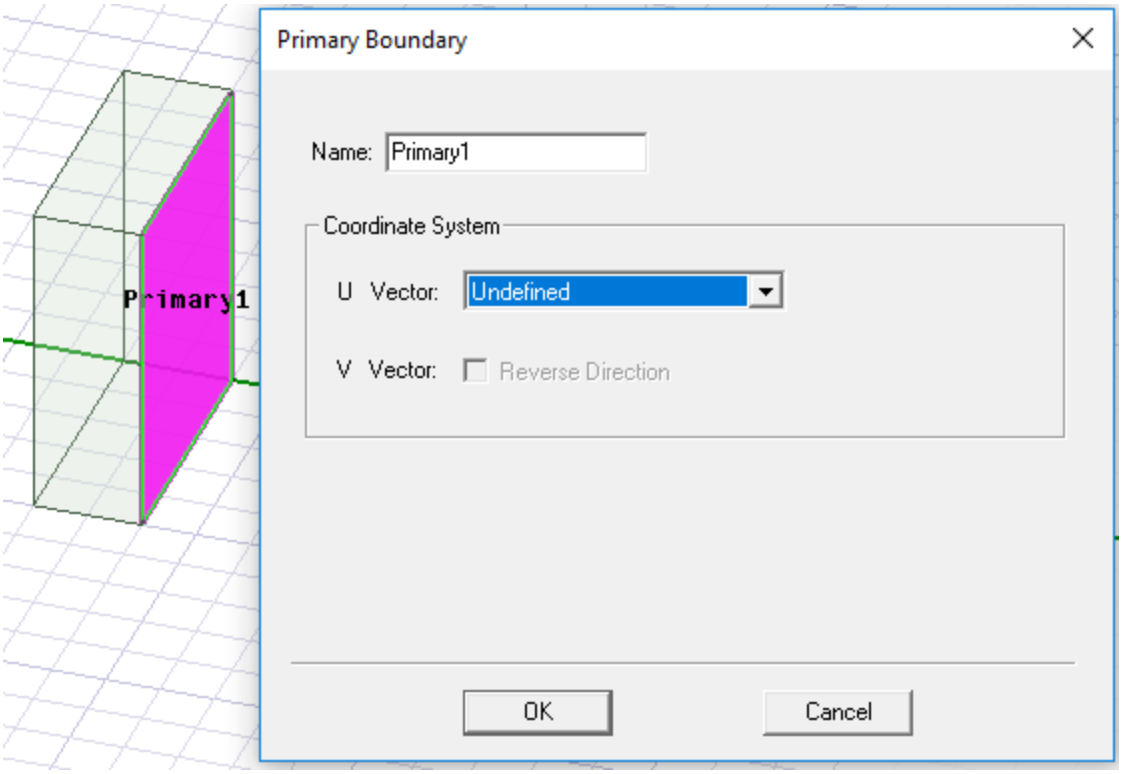
Coupled Lattice Pair boundaries enable you to model planes of periodicity where the E-field at every point on the Secondary boundary surface is forced to match the E-field of every corresponding point on the Primary boundary surface to within a phase difference. The transformation used to map the E-field from the Primary to the Secondary is determined by specifying a coordinate system on both the Primary and Secondary boundaries. You can use the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Coupled...>Lattice Pair... command to auto-set the coordinate system, for both Primary and Secondary boundaries together, you have the option of assigning the Primary boundary directly.

To assign a Primary boundary:

1. Select a surface on which to assign the boundary and click **HFSS>Boundaries>Assign>Primary** to bring up the **Primary Boundary** dialog box.



2. You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. HFSS uses the U vector that you draw and the normal vector of the boundary face to calculate the Vvector. If necessary, you can reverse the direction of the V vector.
   a. Select **New Vector** from the **U Vector** drop-down menu.

      The **Primary Boundary** dialog box disappears while you draw the U vector.

   b. Select the U vector's origin, which must be on the boundary's surface, either by:
      - Clicking the point for the vector origin.
      - Typing the point's coordinates in the **X**, **Y**, and **Z** boxes.

   c. Select a point on the u-axis to indicate the U vector direction.

      The **Primary Boundary** dialog box reappears and the model display shows the U vector and V vector as red and blue arrows respectively.

   d. If you need to reverse the direction of the V vector, select **Reverse Direction**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

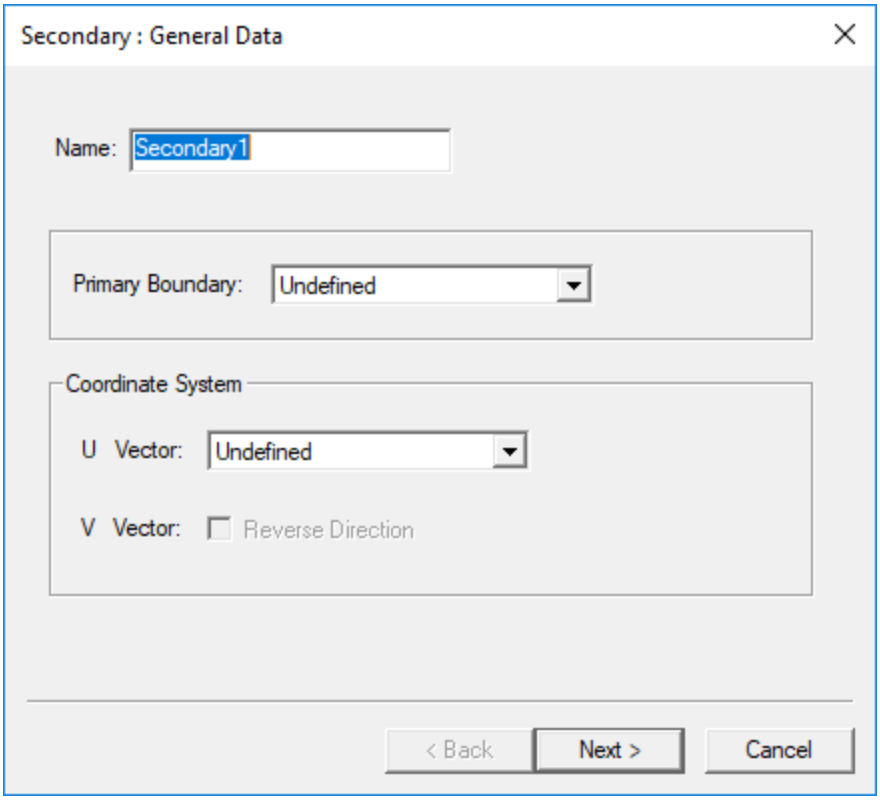
Ansys Electronics Desktop will compute the E-field on this boundary and map it to the secondary boundary using the transformation defined by the Coupled Lattice Pair coordinate systems.

Assigning Secondary Boundaries for Lattice Pair

Coupled Lattice Pair boundaries enable you to model planes of periodicity where the E-field at every point on the Secondary boundary surface is forced to match the E-field at every corresponding point on the Primary boundary surface to within a phase difference. The transformation used to map the E-field from the Primary to the Secondary is determined by specifying a coordinate system on both the Primary and Secondary boundaries. You can use the **Coupled...> Lattice Pair...** command to auto-set the coordinate system, for both Primary and Secondary boundaries together, you have the option of assigning the Secondary boundary directly.

To assign a Secondary boundary:

1. Select a surface on which to assign the boundary and click **HFSS> Boundaries> Assign> Coupled...> Secondary** to bring up the **Secondary Boundary** dialog box.



2. Select the corresponding Primary boundary from the **Primary Boundary** drop-down menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If a primary boundary has not yet been defined, return to make this selection when it has been defined.

3. You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. HFSS uses the U vector that you draw and the normal vector of the boundary face to calculate the V vector. If necessary, you can reverse the direction of the V vector.
   a. Select **New Vector** from the **U Vector** drop-down menu.

      The **Secondary** dialog box disappears while you draw the U vector.

   b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:
      - Click the point for the vector origin.
      - Type the point's coordinates in the **X**, **Y**, and **Z** boxes.

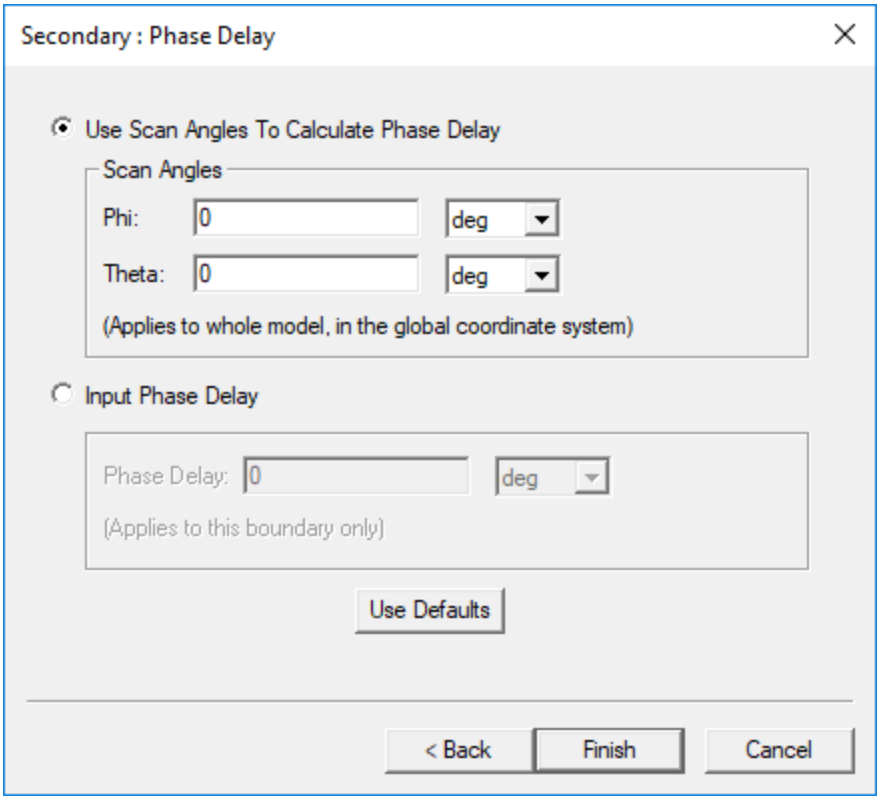
   c. Select a point on the u-axis to indicate the U vector direction.

      The **Secondary Boundary** dialog box reappears and the model display shows the U vector and V vector as red and blue arrows respectively.

   d. If you need to reverse the direction of the V vector, select **Reverse Direction**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click **Next**.



5. You have the option to relate the secondary boundary's E-fields to the primary boundary's E-fields in one of the following ways:
   - For driven designs, select **Use Scan Angles to Calculate Phase Delay** to enable the **Scan Angle** fields. Then enter **Phi** and **Theta** scan angles. These apply to whole model, in the global coordinate system. The phase delay is calculated from the scan angles; however, if you know the phase delay, you may enter it directly in the **Phase Delay** box.

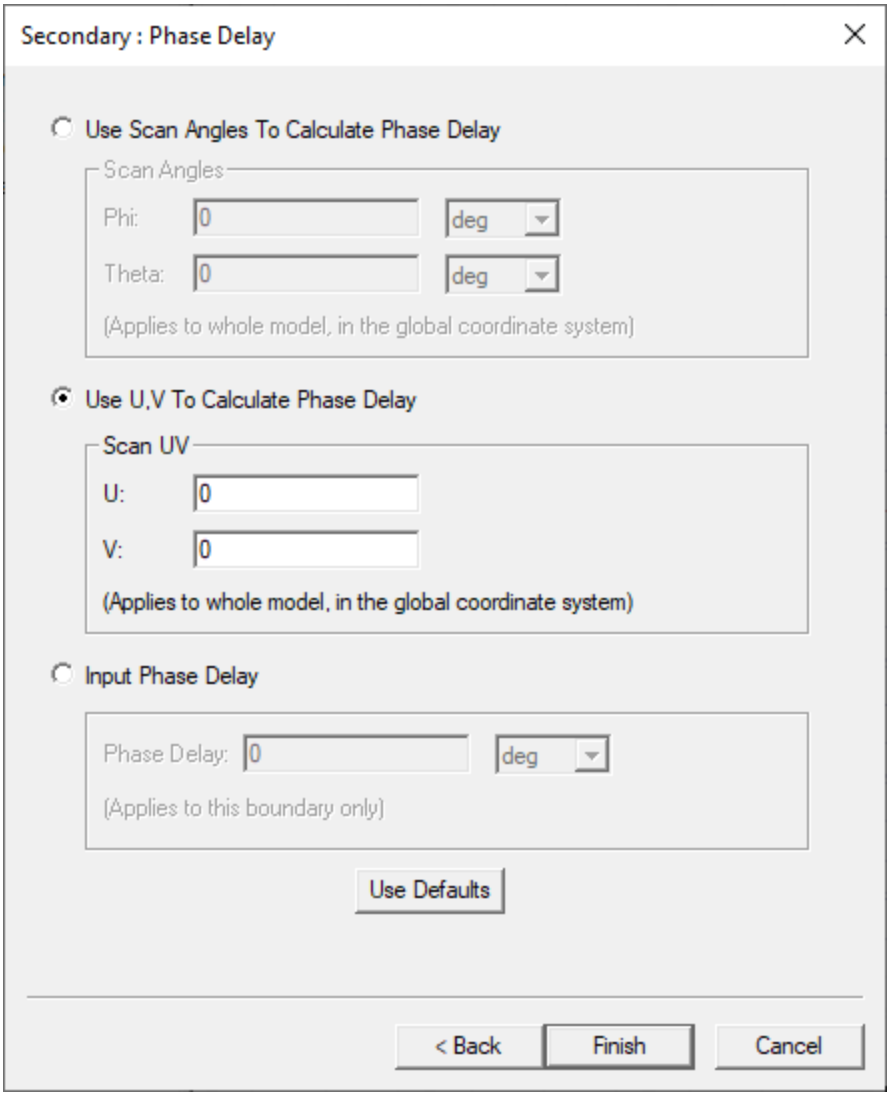
     > **Note:**
     >
     > For Eigenmode problems, the **Use Scan Angles to Calculate Phase Delay** fields are disabled.

   - Select **Input Phase Delay**, and then enter the phase difference, or phase delay, between the boundaries' E-fields in the **Phase Delay** box. The phase delay applies only to this boundary.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> You can assign a variable as the phi, theta, or phase delay values.

A Beta Option allows you to **Use U,V to Calculate Phase Delay**.



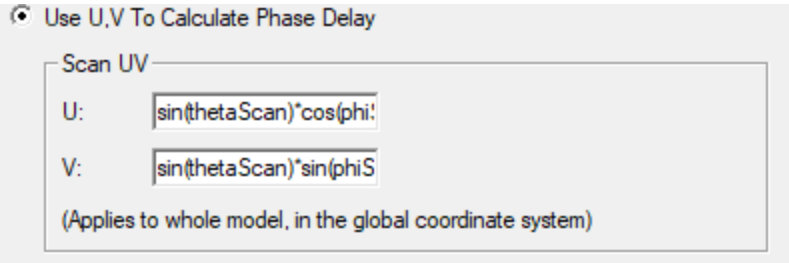
This permits you to scan to scan in the invisible range which is conveniently specified by u,v coordinates. U or V can span anything between -infinity to + infinity or practically some large negative value to large positive value. When $U^2+V^2 > 1$, it is the invisible range. You can specify U and V as equations in this form:

$u = \sin\theta \cdot \cos\varphi$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

v = sinθ·sinφ

Note that you can employ variables in the equations:



Ansys Electronics Desktop will compute the E-field on the primary boundary and map it to this boundary using the transformation defined by the Primary and Secondary Boundary coordinate systems.

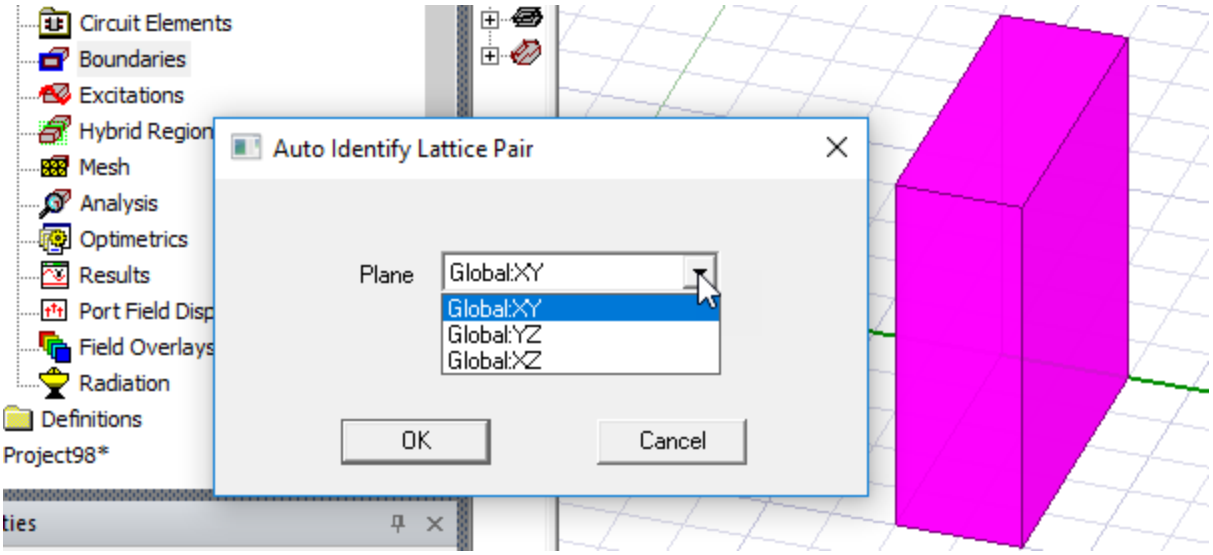
Auto Identify Lattice Pair for Coupled Boundaries

Coupled Lattice Pair boundaries enable you to model planes of periodicity where the E-field at every point on the Secondary boundary surface is forced to match the E-field of every corresponding point on the Primary boundary surface to within a phase difference. The transformation used to map the E-field from the Primary to the Secondary is determined by specifying a coordinate system on both the Primary and Secondary boundaries. You can use the **Auto Identify Lattice Pair** command to auto-set the coordinate system for all surfaces and assign lattice pairs to all faces parallel to the selected plane.

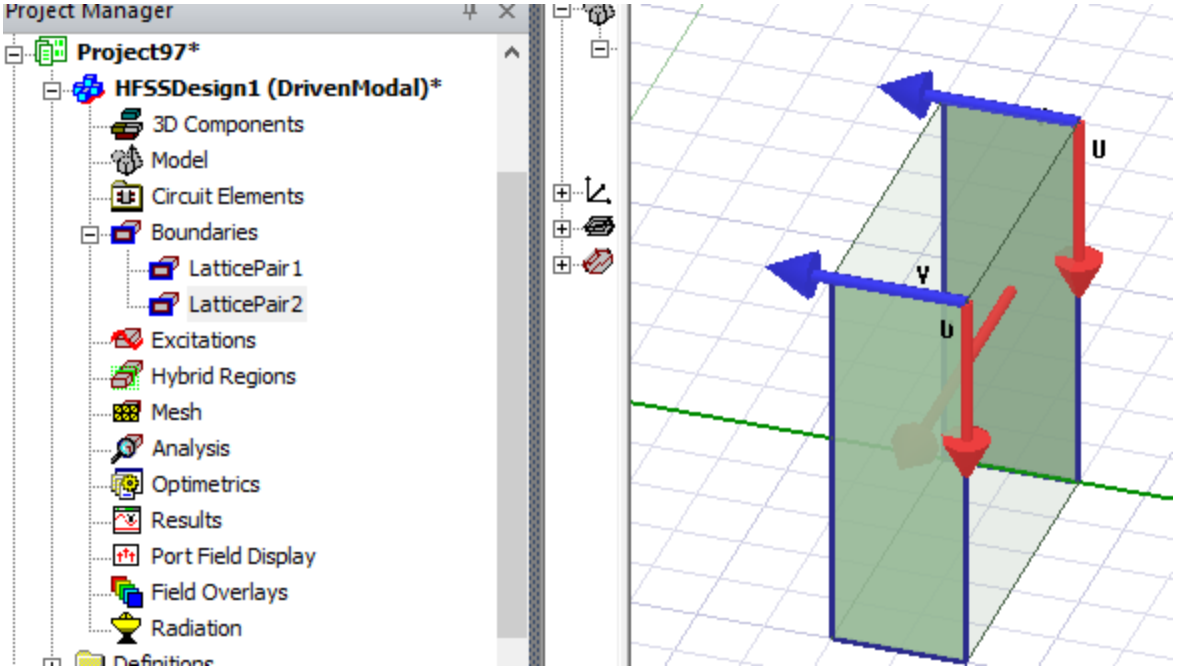
To automatically identify and assign lattice pairs on a selected object:

1. Select an object on which to assign lattice pairs and click **HFSS>Boundaries>Assign>Coupled>Auto Assign Lattice Pair**to bring up the **Auto Identify Lattice Pair** dialog box. Select a plane from the menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Click **OK**.
   Lattice Pair boundaries will be assigned to all the pairs of parallel faces which are perpendicular to the selected plane. Each pair is formed by exactly two parallel faces. Notice that in this example two Lattice Pairs appear in the history tree, with the second highlighted in the modeler.



Ansys Electronics Desktop will compute the E-field on this boundary and map it to the secondary boundary using the transformation defined by the Coupled Lattice Pair coordinate systems.

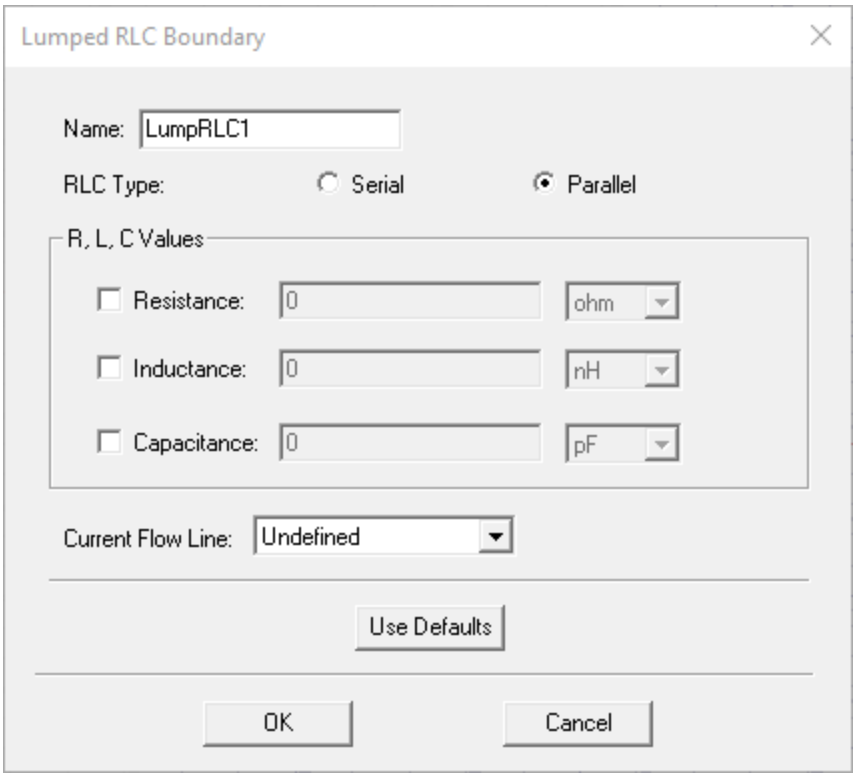
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning Lumped RLC Boundaries

A lumped RLC boundary represents a parallel or serial combination of lumped resistor, inductor, and/or capacitor applied to a surface. Multiple RLC boundaries can be used to model other circuit configurations. For example, a lumped RLC serial circuit connection can be modeled with three connected RLC surfaces: one with only resistance, one with only inductance, and one with only capacitance.

To create a lumped RLC boundary:

1. Select a surface on which to assign the boundary and click **HFSS >Boundaries>Assign>Lumped RLC** to bring up the **Lumped RLC Boundary** dialog box.



2. Select **Resistance**, **Inductance**, and **Capacitance** as needed and specify values and units for each selected element. Optionally, you can assign a variable to any of these values.
3. To specify where on the surface the current and voltage will be controlled, define a **Current Flow Line**. The selection field initially appears as **Undefined**. Select **New Line** to define a vector line on the boundary surface.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> HFSS assumes the lumped RLC is assigned to a rectangular face. If you assign a non-rectangular face, HFSS issues a warning, but proceed with the solution. Using a non-rectangular face can result in less accurate representation of the lumped RLC. See the technical notes on RLC boundaries for more information.

Vector Line

To draw a vector line to indicate the current flow:

1. Select **New Line** from the Lumped RLC Boundary dialog's drop-down menu.

   The dialog box disappears while you draw the vector line.

2. Select the start point in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes on the status bar.
3. Select the endpoint using the mouse or the keyboard.
4. Once the line has been defined, you can edit it as follows:

   Select **Swap End Points** from the dialog drop-down menu to switch the start and endpoints of the line, reversing the line's direction.

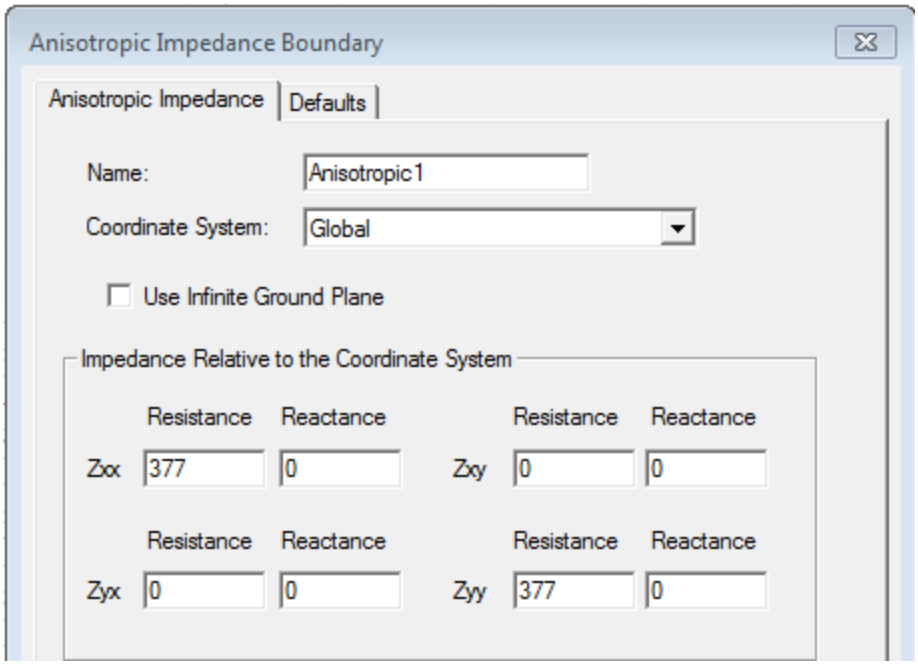
Assigning Anisotropic Impedance Boundaries

Planar screens or grids of large extent with periodic geometry can be replaced by an Anisotropic impedance boundary. The boundary applies a homogeneous characteristic impedance to the surface in an effort to create an equivalent electrical representation of the geometric grid pattern. For legacy designs, this boundary replaces the Screening Impedance boundary.

To assign an Anisotropic Impedance boundary

1. Select a surface on which to assign the boundary and click **HFSS>Boundaries>Assign>Anisotropic Impedance** to bring up the **Anisotropic Impedance Boundary** dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. The Coordinate System drop-down menu lists the Global Coordinate system and any relative coordinate systems if you have defined them in the design. Select the Coordinate System that defines the anisotropic characteristic of the impedance boundary. (See Creating a Relative Coordinate System.)

> **Note:**
>
> An anisotropic boundary must not touch ports in a design.

3. Select **Infinite Ground Plane** if you want the surface to represent an electrically large ground plane when the radiated fields are calculated during post processing.
4. In the Impedance Relative to the Coordinate System area, you set the **Resistance** and **Reactance**. If Anisotropic Impedance is checked, the wizard shows Resistance and Reactance fields for X Axis alignment and Y axis alignment. These values can be numeric or can reference variables, including spatial variables x, y, and z. Isotropy will be inferred if Zxy and Zyx are left as zero.

Assigning Layered Impedance Boundaries

A layered impedance boundary is used to model multiple thin layers in a structure as one impedance surface. The effect is the same as an impedance boundary condition, except that Ansys Electronics Desktop calculates the impedance of the surface based on data you enter for the layered structure, including surface roughness.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Materials with thermal modifiers can have layered impedance boundaries assigned to them. The layered impedance boundary is supported for single-frequency solutions and for Discrete and Interpolating frequency sweeps. The order of the layers does not matter to the implementation.

Layered impedance boundaries can be one sided or two sided. One-sided boundaries terminate their model in an infinite space, such as air or vacuum. Two-sided boundaries do not. Two-sided boundaries can be used in 3D models. By default, Ansys Electronics Desktop assumes the layered structure is one sided, external to the design.

If the layered structure is within a 3D model, meshing thin layers and solving inside is inefficient. You can replace the highly conductive thin layer by a shell element. Shell elements are 3D layers that have been replaced by a sheet. They cannot represent a one-sided impedance boundary. The **Shell Element** option only applies to HFSS Driven solution types and does not apply to HFSS Eigenmode and Transient solution types or to HFSS-IE designs. Shell elements maintain two sets of unknown coefficients for the top and bottom surface. If the angle of incident deviates significantly from the boundary, then the accuracy of the shell elements degrades and you should use a layered impedance boundary instead.

Practical uses of shell elements in simulations include:

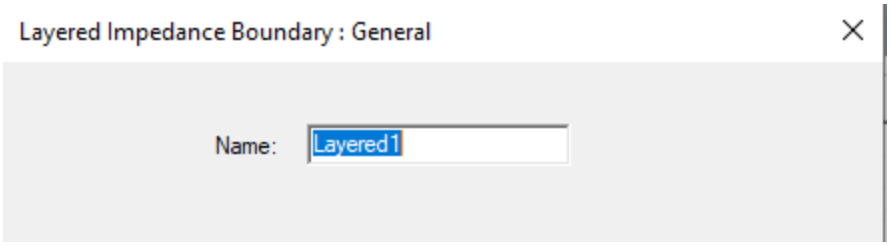
- an antenna inside a car chassis when the chassis is modeled using sheets
- an antenna inside a dielectric radome when the radome is modeled using sheets

If you specify that a two-sided sheet is to be modeled as a shell element, the following HSS features are disabled:

- Scattered field formulation: HFSS disables this when all boundaries are radiating boundaries AND when the design has an Incident Wave excitation.
- IE solver

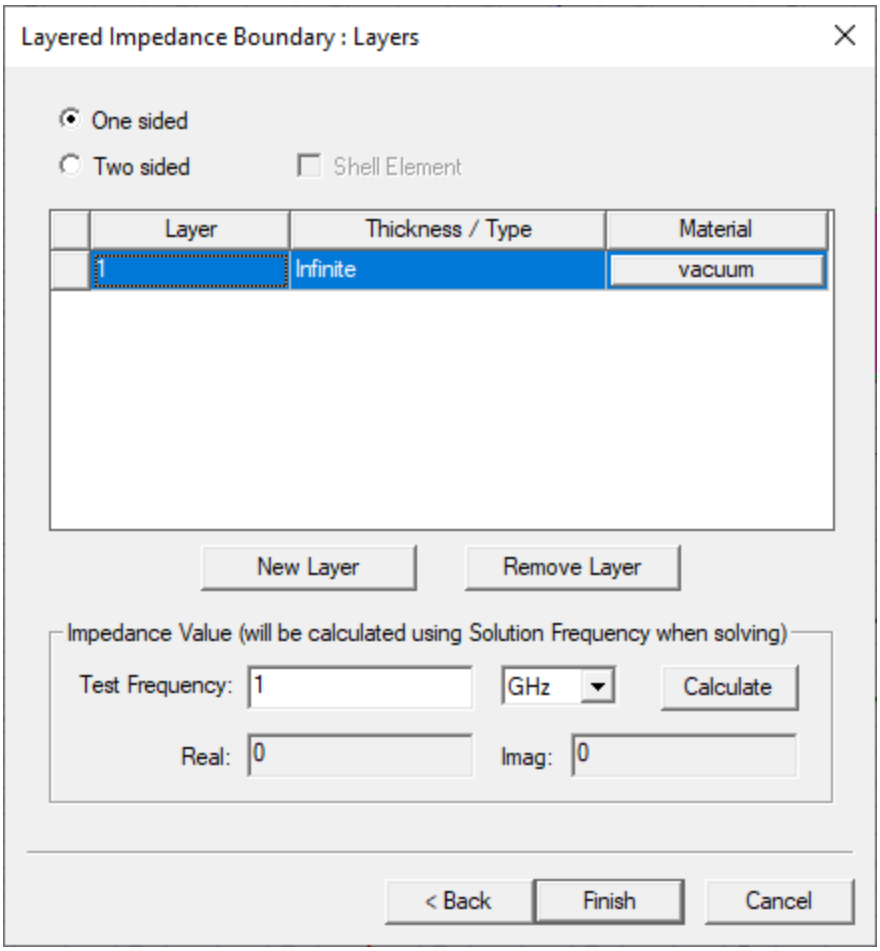
To assign a layered impedance boundary:

1. Select a surface on which to assign the boundary and click **HFSS**> **Boundaries**>**Assign**>**Layered Impedance** or **HFSS**>**Boundaries**>**Assign**>**Surface Roughness**> **Groiss (Layered Impedance) ...**to bring up the **Layered Impedance Boundary** window.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click **Next** or the **Layers** tab, depending on the general option setting.



3. If the layered structure is external to the design, do the following:

   By default, Ansys Electronics Desktop assumes the layered structure is **One sided**, external to the design; the outermost layer of the structure is listed.

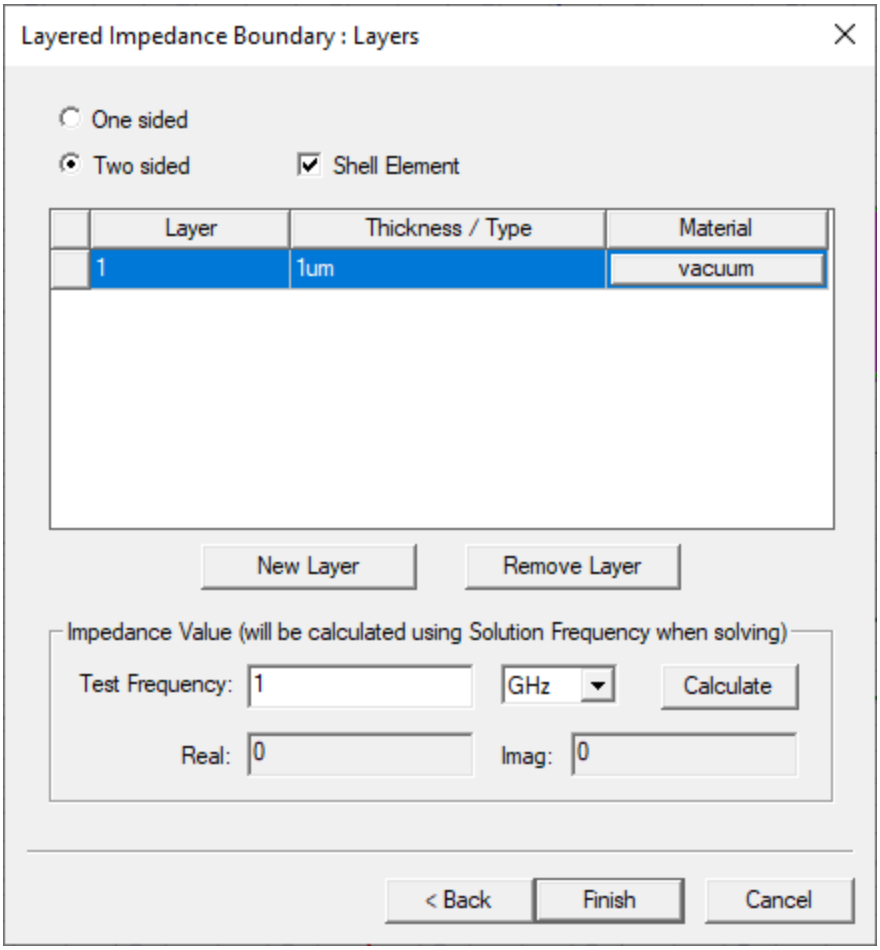
   a. Select whether this layer is an **Infinite**, **Perfect E**, or **Perfect H** layer from the **Thickness/Type** column.
   b. If the layered structure is within a 3D model, do the following:
      1. Select the **Two sided** option.
      2. Enter a thickness for the first layer in the **Thickness/Type** column. You can assign a variable as this value.

      If it is a two-sided BC and not assigned to an SBR+ region, layer thickness should not exceed lambda/10 for for dielectric objects. For thin conductors, if the skin depth is much smaller than the layer thickness, you cannot replace it by an internal sheet.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Neither of these restrictions apply if the layered structure is part of an SBR+ region. For an SBR+ objects, there is no limit to the electrical thickness (i.e., measured in wavelengths) of the layers for result quality. However, it is not recommended that the absolute thickness of the layers exceed 20% of the lateral extent of the surface to which the BC is applied.

4. To change the first layer's material, click **vacuum** and follow the procedure for assigning a material. The material properties that will apply to the layers can be functions of complex numbers.
5. The **Shell Element** check box is for HFSS Driven situations where the layered structure is within the 3D model and you want to use sheets to model thin but finite thickness objects.



6. To add a new layer to the structure:
   a. Click **New Layer**. The new layer is added at the end of the list.
   b. Enter a thickness for the layer in the **Thickness/Type** column. You can assign a variable as this value.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

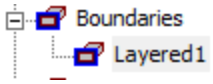
c. To change the layer's material, click **vacuum** and follow the procedure for assigning a material.

7. Optionally, to reorder layers, click the first row square and drag the row to the desired position.
8. Optionally, to view the impedance values that will be calculated based on the data provided, do the following:
   a. Enter the frequency at which the solution is being solved in the **Test Frequency** text box.
   b. Click **Calculate**.

      The real and imaginary components of the Ansys Electronics Desktop-calculated layered impedance value appear.

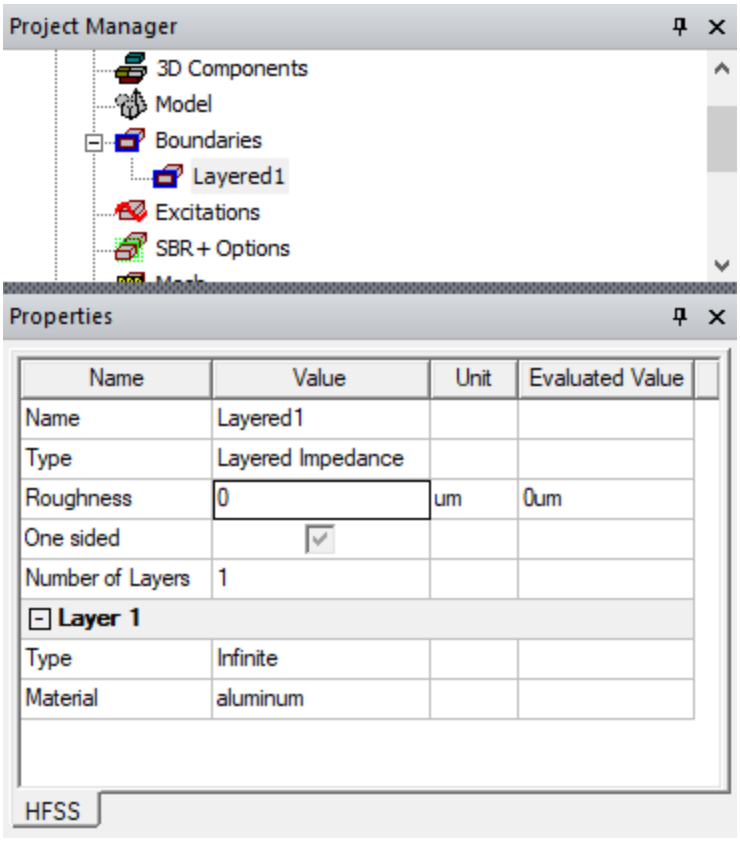
      Enter the **Surface Roughness** for the layered structure.
      If the layered structure is internal to the design, enter the average surface roughness of the two outermost sides. You can assign a variable as this value. Ansys Electronics Desktop uses the Groiss model for surface roughness. When surface roughness is activated, it is applied to the first conducting layer (not necessarily the first layer) for an external boundary, and to both the first and the last conducting layer for an internal boundary.

9. Click **Finish** to assign the boundary. The boundary appears under the **Boundaries** icon in the **Project** tree.



Optionally, you can use the **Properties** dialog to enter the **Surface Roughness** for a layered structure. Selecting the boundary displays the Properties.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If the layered structure is internal to the design, enter the average surface roughness of the two outermost sides into the **Roughness** field. You can specify Units by clicking the drop-down menu in the Units column. You can assign a variable as this value. Ansys Electronics Desktop uses RMS deviation of the conductor surface from a plane. When surface roughness is activated, it is applied to the first conducting layer (not necessarily the first layer) for an external boundary, and to both the first and the last conducting layer for an internal boundary.

> **Note:**
>
> If a fast sweep is defined in a design that contains a layered impedance boundary, the impedance may only be accurate for the center frequency.

Assigning Linked Impedance Boundaries

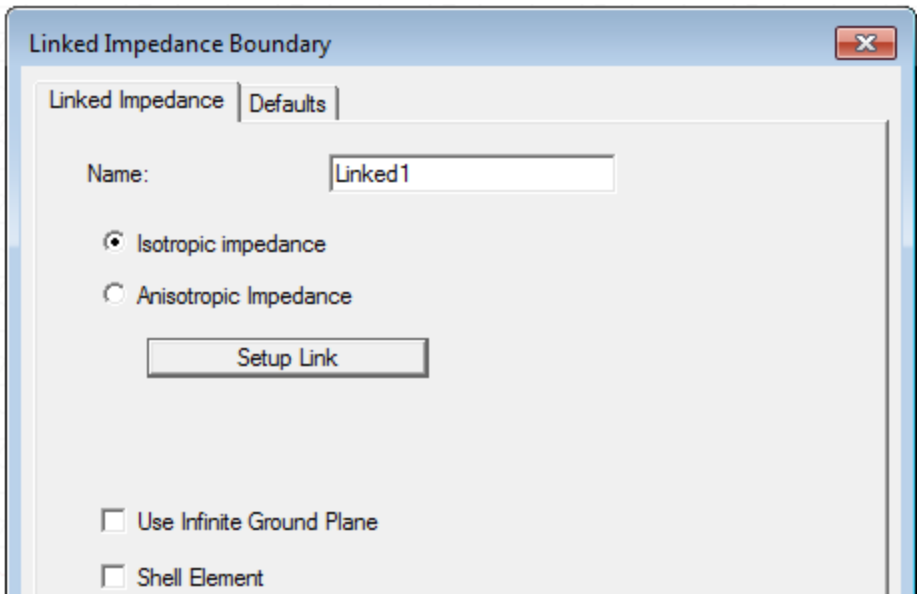
A linked Impedance boundary can be an isotropic or anisotropic impedance boundary in another design. Planar screens or grids of large extent with periodic geometry can be replaced by an Anisotropic impedance boundary. The boundary applies a homogeneous characteristic

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

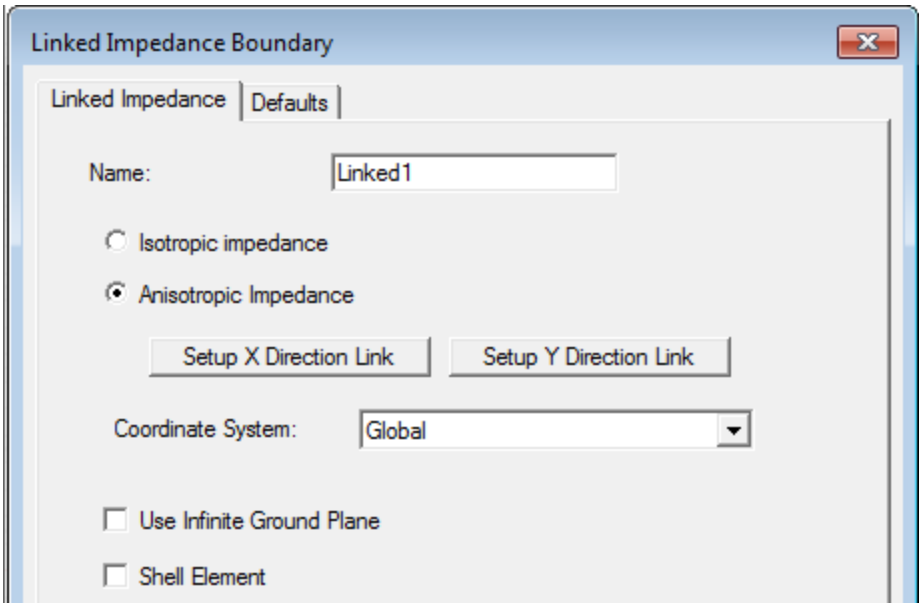
impedance to the surface in an effort to create an equivalent electrical representation of the geometric grid pattern. The link boundary can use an infinite ground plane and shell elements.

To assign a Linked Impedance boundary

1. Select a surface on which to assign the boundary and click **HFSS>Boundaries>Assign>Linked Impedance** to bring up the **Linked Impedance Boundary** dialog.



2. If you select Anisotropic Impedance, the dialog includes buttons to Setup X Direction Link, Setup Y Direction Link and a selection list for the Coordinate System.



If the linked projects have wave ports, x and y directed projects are different and have to

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

have one mode per port.
If the linked projects have Floquet ports, x and y directed projects should be identical and have to have 2 modes per port (TE and TM modes). In that case, the field of mode 1 serves as x directed field, while the field of mode 2 serves as y directed field. It is also a valid setup to assign two different projects with Floquet ports, but with one mode per port.

3. The Coordinate System drop-down menu lists the Global Coordinate system and any relative coordinate systems if you have defined them in the design. Select the Coordinate System that defines the anisotropic characteristic of the impedance boundary. (See Creating a Relative Coordinate System.)

> **Note:**
>
> An anisotropic boundary must not touch ports in a design.

4. Select **Infinite Ground Plane** if you want the surface to represent an electrically large ground plane when the radiated fields are calculated during post processing.
5. Select Shell Elements if you want to the boundary modeled as a shell element.

With shell elements: Make sure two ports are defined, and for isotropic 1 mode on each port and for anisotropic 1 mode one each port when two designs are linked and 2 modes on each port when one design is linked.

Without shell elements: Allow either one or two ports but only 1 mode each for isotropic, 1 mode each for anisotropic with two linked designs, and 2 modes each for anisotropic with one linked design. An info or warning message is issued when two ports are defined in the design to let you know we only extract the link from one of the ports and specifies which one.

Get Impedance from External Design

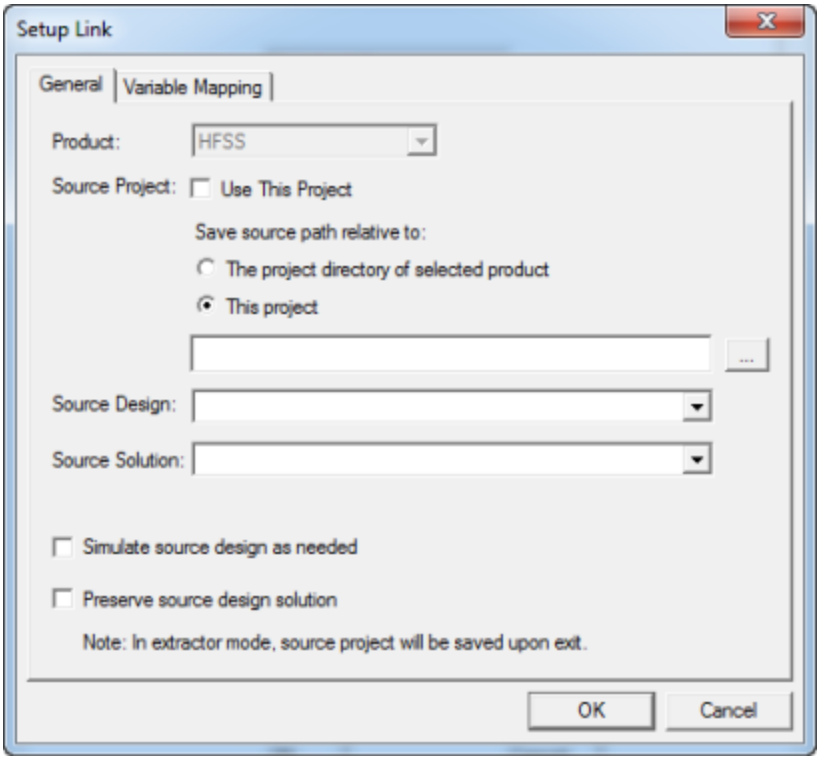
To get impedance from an external design for a Linked Impedance Boundary for an isotropic design:

1. Click the **Setup Link** button to display the **Setup Link** dialog.

For Linked anisotropic impedance cases, select **Setup X Direction Link** button to chose a design which will define the impedance in the X direction. Then select **Setup Y Direction Link** button to chose a design which will define the impedance in the Y direction.

The **Setup Link** dialog has three fields under the **General** tab: Project File, Design, and Solution.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Specify the Project file for the design that is the source. A browse button [...] lets you look through your file system. If you do not specify a project file, but select the current model, the current Project File is automatically filled in.
3. Specify the Design for the source. If the source is in the current design, you can select this from a drop down menu. If you select the current model, the Project File is automatically filled in.
4. Use the radio button to specify whether to save the source path relative to **The project directory of the source project** or **This project**.
5. Specify the Solution to use. A drop down list lets you select from the available solutions.

The "Default" solution is the product dependent solution of the first Setup.

That is the setup listed first in the source design's project tree (alphanumerical order). A product specific solution of this setup becomes the default solution. In most products, it is LastAdaptive. In a Transient solution type, it is "Transient."

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

The solution in the source design must provide data for the target design's adaptive frequency as well as its sweeps. That is, the adaptive frequency for the target design must be included in the sweep in the source design.

If necessary, you can open the source design and add an appropriate frequency point to an existing sweep.

6. Use the check box specify whether to **Simulate source design as needed**.
7. Use the check box to specify whether to **preserve the source design solution**. Note that in **Extractor mode**, the source project will be saved upon exit. **Extractor mode** means that the software is opened during the link solely for the purpose of solving.
8. Under the **Variable Mapping** tab, you can set the desired variable values in the source design. If the source and target designs contain same named variables, you can choose to Map Variable By Name. In this case, same named variables are mapped automatically.
9. Click OK to close the **Setup Link** dialog and return to the Linked Impedance Boundary dialog.

Assign Gradient Surface Roughness Boundaries

Gradient Surface Roughness Boundaries address the situation where the conductors drawn in the model are perfectly smooth, but the manufactured surface is bumpy at microscopic scale. It generates a frequency dependent dataset for resistance and reactance values behind the scene for solve.

Parameters of the gradient model in HFSS are:

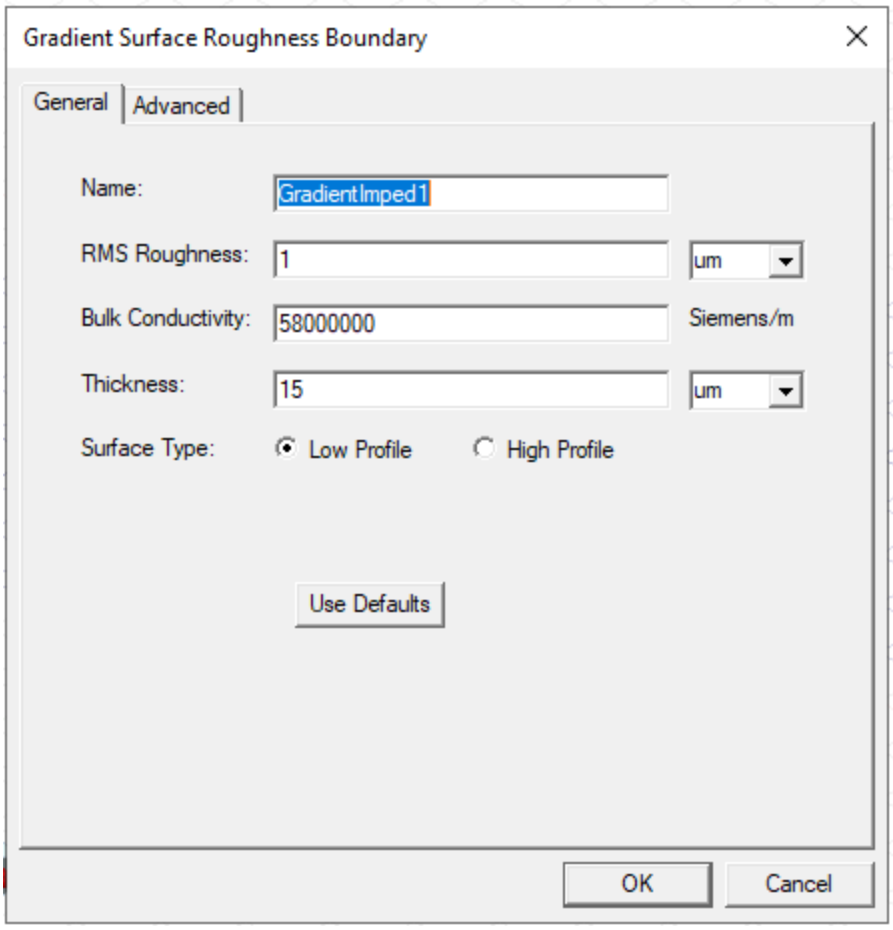
- The RMS Roughness parameter describes the root mean square (RMS) roughness of the surface (Rq). It is routinely measured by manufacturers, and can be entered as a value with units.
- The metal’s bulk conductivity.
- The conductor thickness.
- The surface profile. Choose Low-Profile for low-profile foils and polished surfaces, and High-Profile for high-profile foils and rough conductors.
- On the **Advanced** tab, the maximum frequency of interest in the simulation.

The next section first describes how to assign a Gradient Suface Roughness Boundary and the subsequent section provides a technical overview.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning Gradient Surface Roughness Boundary

1. Select a surface on which to assign the boundary, right-click **Assign Boundary** > **Gradient Surface Roughness** or **Assign Boundary**> **Surface Roughness**>**Gradient...** to bring up the *Gradient Surface Roughness Boundary* dialog box.



2. Set the Parameters. and click **OK**. The boundary is listed in the Project Manager and displayed in the Modeler window.

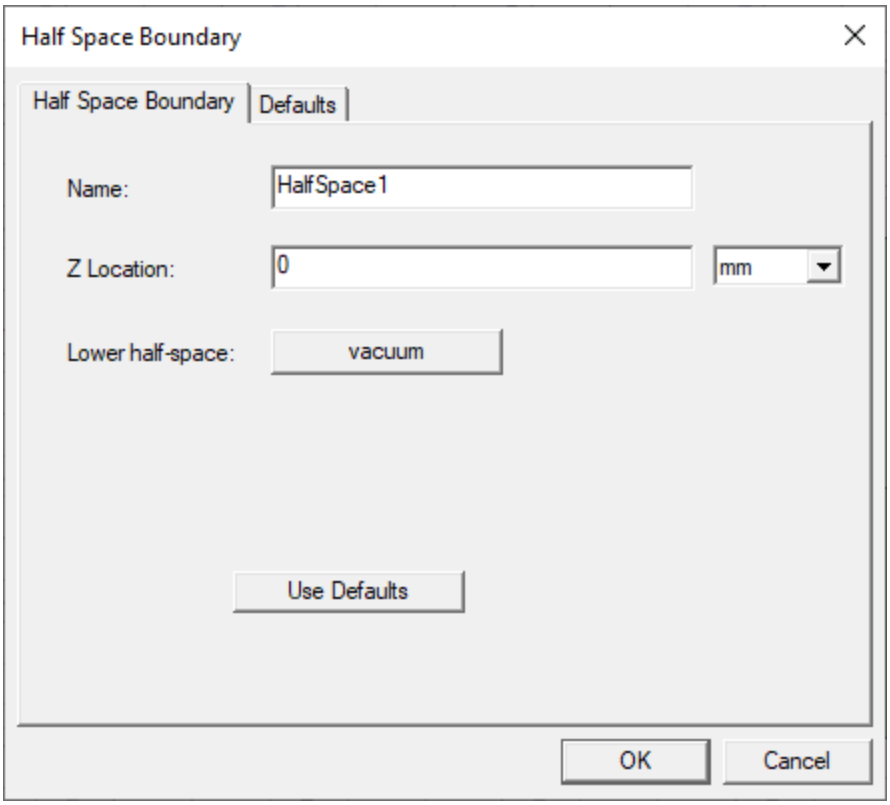
Assigning Half Space Boundaries in HFSS

The Half Space boundary is designed for solving antenna and scattering problems with a background comprising a dielectric half space. The Half Space boundary splits the background material along a z=constant plane. The antenna or scatterer can be located in the top medium (for example, air) or the bottom medium (for example, sea water) or embedded in both. Half space boundary is only available to an HFSS Hybrid and Arrays design but can include both

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

FEM areas and IE regions. An HFSS Hybrid and Arrays design can only have one half space boundary. You do not select an object to assign a Half Space boundary. For such projects, compared to solving with a single domain, using a Half Space boundary the results will be similar though not identical but will use less time and fewer resources.

Right-click **Boundaries>Assign>Half Space** to display the Half Space Boundary dialog.



- Specify a Name in the text field.
- Specify a Z Location, Z and select units from the menu.
- Specify the lower-half space material. The "lower half-space" material defines the material in the lower half-space, and the upper half-space is defined using the global background material.

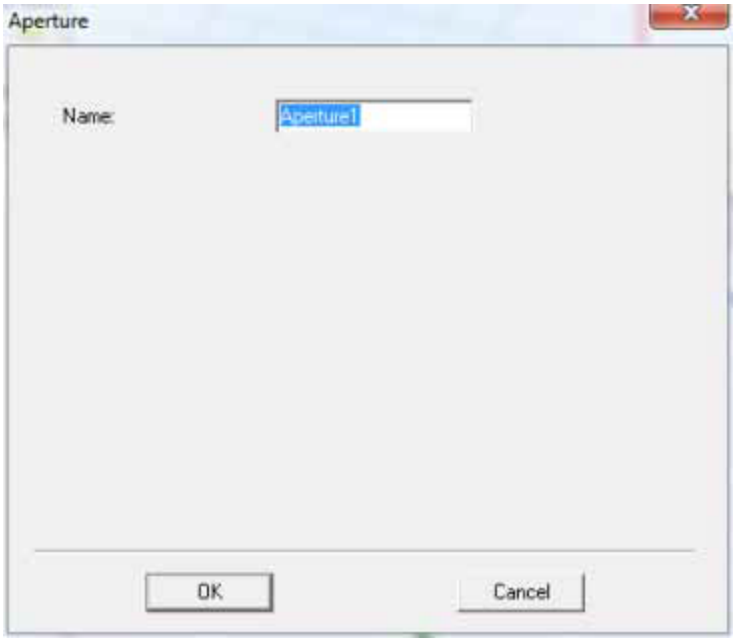
The Boundary appears in the Project tree. If you select the boundary in the Project tree, a rectangle representing the boundary shows in the Modeler window, and the docked properties shows the properties.

An aperture boundary can only be assigned on a 2D sheet object assigned as IE Region. These objects will be meshed as part of the solution process.

To create an aperture boundary in HFSS:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

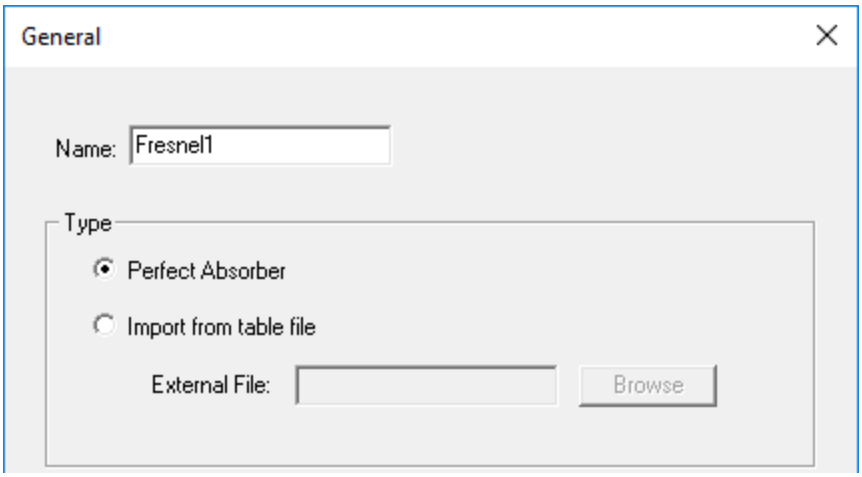
1. Create a 2D sheet object on the XY plane at the elevation of ground plane.
2. Select the object and right-click **Assign Hybrid>IE Region**.
2. Select the object and right-click **Boundaries>Assign>Aperture** to display the **Aperture** dialog.



3. Type the boundary's name in the **Name** text box or accept the default name. (To change the default base name to one of your choosing, see Setting Default Boundary/Excitation Base Names.)

Assigning (SBR+) Perfect Absorber Boundaries

The **Assign Boundary>Fresnel (SBR+)** command allows you to specify a perfect absorber.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

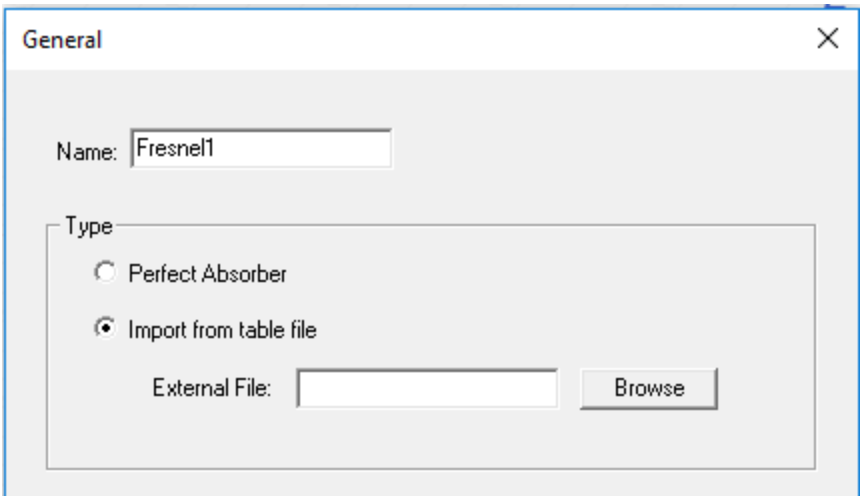
Perfect Absorber: Incident SBR+ rays are absorbed by surfaces with this boundary, and no reflection or transmission rays are generated.

This does not imply that there is no radiation from surface currents on perfectly absorbing boundaries. The perfect absorber still generates very strong forward scattering. This scattering is associated with the incident GO ray fields at the surface. These ray fields are converted into equivalent currents at the surface that are radiated to observation angles and receiving antennas in any direction (including the backward direction); it tends to be strongest in the forward direction. At the same time, since the reflected ray has zero field strength (and therefore no reflected ray is traced), the equivalent surface currents associated with the reflected ray are also zero, so scattering in the backward half-space is weak.

The Fresnel (SBR+) **Import from table file** option lets you directly load the Fresnel tables from an external file.

Assigning (SBR+) Fresnel Table Boundaries

The **Assign Boundary>Fresnel (SBR+)** command allows you to specify either a perfect absorber or to import a Fresnel table file that describes reflection and transmission coefficients.



Fresnel coefficients are based on the assumption of plane-wave incidence and reflection and represent the ratio of the reflected field to the incident field. Ray bundles can represent complex wavefronts, and each ray represents a sample of that wavefront that is assumed to be locally planar. Provided that the wavefront is not too irregular, and the coatings are not too thick compared to their lateral extent, the Fresnel coefficients applied in conjunction with individual rays provide a good approximation of the reflection of an arbitrary wavefront off a surface

When an SBR+ boundary is configured as an Impedance Boundary or a Layered Impedance boundary, a table of Fresnel coefficients is internally generated for use during the SBR+ ray-tracing simulation. The Fresnel (SBR+) **Import from table file** option lets you directly load the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

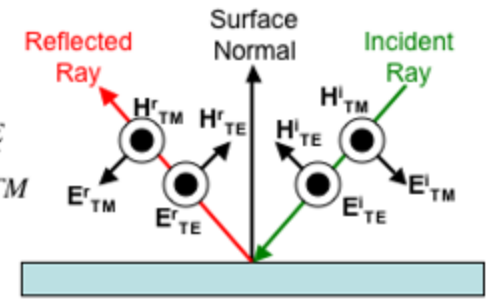
Fresnel tables from an external file. You can develop these from a number of sources, including analytic formulas, specialized codes for simulating the boundary (e.g., HFSS for simulating a frequency selective surface), or measurements. Two types of boundary tables are supported:

- reflection coefficients
- reflection + transmission coefficients

Tables of reflection + transmission coefficients are explained later.

Fresnel coefficients depend on the polarization of the incident plane wave. There are two unique, orthogonal polarizations: transverse electric (TE) and transverse magnetic (TM). HFSS-SBR+ adopts the convention given in the diagram below. In this convention, PEC metal has a TE reflection coefficient of -1 and a TM reflection coefficient of +1. In general, reflection coefficients are complex quantities that depend on incident angle and frequency

$$E^r_{TE} = R_{TE} E^i_{TE}$$
$$E^r_{TM} = R_{TM} E^i_{TM}$$



Reflective Coating Described by Fresnel Reflection Coefficients

When a ray hits a surface, the solver determines its incidence angle relative to the surface normal. The incident ray tube fields are decomposed into TE and TM components. The solver then looks up the TE and TM reflection coefficients for that angle, whether internally generated or provided by an external table as described here. These are applied to the respective incident ray field components to determine the TE and TM components of the reflected ray field. This, in turn, influences the surface currents and scattered fields generated at the current bounce and subsequent bounces.

Fresnel Reflection Table File Format

The Fresnel reflection table file format is documented in the header comments in the example below. This first example is for a table defined at a single frequency, which means it will be used at all frequencies during a simulation. A multi-frequency example is provided later for a reflection/transmission table, but since their formats are nearly identical, the same encoding can be used for a reflection-only table

```
# Reflection table file.
# Blank lines and lines beginning with are ignored.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

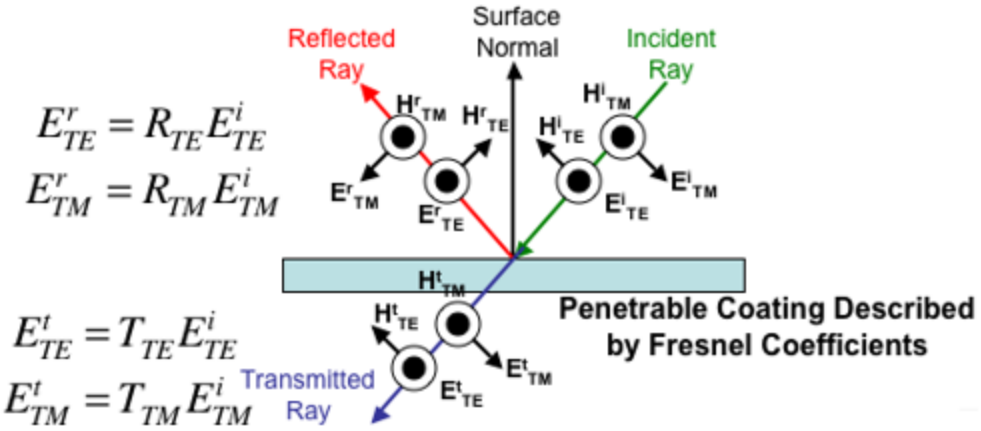
Penetrable boundaries, as are encountered in the case of canopies and radomes, should be described by both reflection and transmission coefficients. Likewise, arbitrary boundaries that are penetrable can be entered as a table.

When a ray hits a penetrable coatings, it generates both a reflected ray and a transmitted ray, as shown in the diagram below, which also extends the polarization convention of the previous diagram. In the diagram below, it is intentional that the transmitted ray is shown as starting from the top of the surface, rather than the bottom. In the modeler, CAD models can represent infinitely thin surfaces. The effect of boundary thickness is entirely captured in the reflection and transmission coefficients. Hence, in creating a reflection + transmission table input, it is critical to do so such that the phase reference of the transmission coefficient is the surface nearest the incident ray. That way, the transmitted ray will include the correct phase delay given that it is launched from exactly the same point as where the incident ray hits the surface



The following example reflection + transmission table is very similar in structure to the reflection-only table. The only difference is that each line in the table has four extra numbers to represent the complex TE and TM transmission coefficients. This particular example also shows how to define a frequency dependent table of coefficients

Designating Infinite Ground Planes

To simulate the effects of an infinite ground plane in an HFSS design:

- Select the **Infinite ground plane** check box when setting up a perfect E, finite conductivity, or impedance boundary condition. For Impedance, Layered Impedance, and Finite Conductivity Boundary conditions, HFSS supports only one infinite boundary condition per design. For PEC, multiple antenna ground planes are supported.

This selection only affects the calculation of near- and far-field radiation during post processing. Ansys Electronics Desktop models the boundary as a finite portion of an infinite, perfectly conducting plane. If the infinite ground plane does not touch a radiation boundary, you will receive a warning. A finite sheet, which does not touch the radiation boundary condition cannot be an infinite ground plane.

Modifying Boundaries

To change the properties of a boundary, do one of the following:

- Double-click the boundary's icon in the project tree.

The boundary's dialog box appears, in which you can edit its properties.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Right-click the boundary in the project tree, and then click **Properties** on the shortcut menu.

The boundary's dialog box appears, in which you can edit its properties.

- Click **HFSS**>**List**.

The **Design List** dialog box appears, in which you can modify the properties of one or more boundaries.

Deleting Boundaries

To delete *one boundary*:

1. Select the boundary you want to delete by selecting its icon in the project tree.
2. On the **Edit** menu, click **Delete** .

To delete *all boundaries*:

- Click **HFSS**>**Boundaries**>**Delete All**.

You can also *delete one or more boundaries* in the **Design List** dialog box:

1. Click **HFSS** menu, click **List**.

   The **Design List** dialog box appears.

2. Under the **Boundaries** tab, click the row of the boundary you want to delete.
3. Click **Delete**.

Reassigning Boundaries

You can reassign a boundary to another surface. This is useful when you have modified objects with assigned boundaries, invalidating the boundaries. For example, if you unite two objects with assigned boundaries, the second object's boundary will become invalid because united objects maintain the characteristics of the first object selected. In this case, you would need to reassign the boundary or delete it. You can use a **Reassign Boundary** dialog box accessed through the [*solver*] > **Boundary** > **Reassign** menu, or right-click the Boundary of interest in the **Project** tree, and select from the shortcut menu to **Reassign**, **Add to Assignment**, or **Remove from Assignment**. You can also determine current assignments by right-clicking on the boundary on the Project tree and using the **Select Assignment** command on the short cut menu.

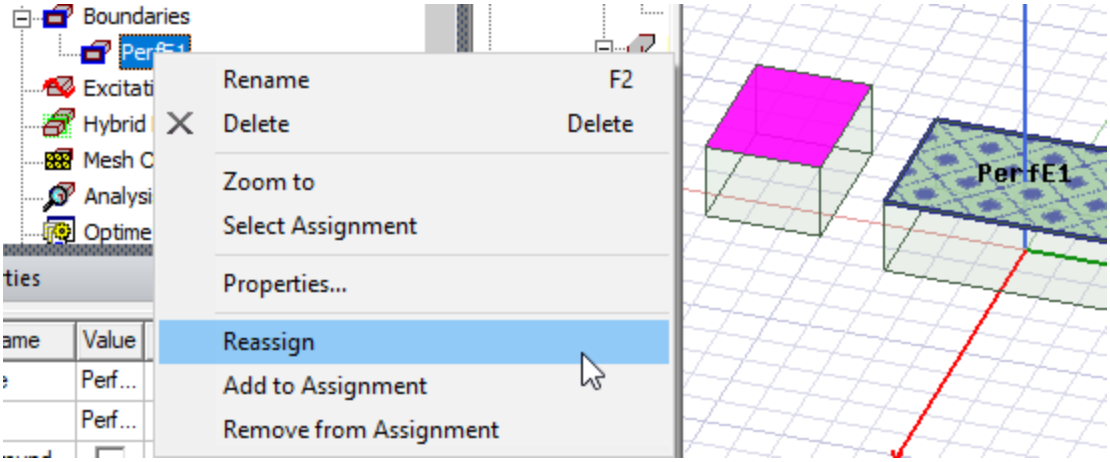
Prerequisites:

- You must first select the surface or object that you want to reassign, or add to an assignment, or remove from an assignment.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To use the short-cut menu to reassign, add assignment, or remove from assignment:

1. With the target surface selected, right-click the Boundary of interest to invoke the menu.



2. Select from the menu to make the change you want.

The boundary assignments change.

> **Note:**
>
> When reassigning a boundary that includes vectors in its definition, Ansys Electronics Desktop attempts to preserve the vectors with the new assignment, but this is not always possible.

Reprioritizing Boundaries

Each boundary you assign overwrites any existing boundary which it overlaps. You can change the priority of a previously assigned boundary to be greater than a more recently assigned boundary.

The order of boundaries and excitations is important because, for any given triangle of the mesh, only one boundary or excitation can be visible to the solvers. The highest priority boundary condition applied on a certain surface overwrites the lower priority one(s) applied on the same surface. If any surfaces with boundary conditions have a partial overlap, then in the overlap region, the precedence rule applies. The highest priority boundary condition takes precedence over the lower one(s) such that for all mesh nodes on any surface carrying a boundary condition, only one boundary condition is actually enforced and visible to the solver.

Excitations cannot be reprioritized. Only boundaries can be reprioritized.

1. Click **HFSS** > **Boundaries** > **Reprioritize** to reprioritize boundaries.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Reprioritize Boundaries** window appears. The order the boundaries and excitations appear in the list indicates the order in which they were defined. The lowest priority assignment appears at the top of the list.

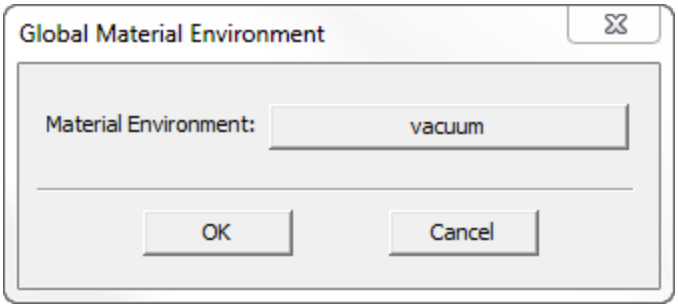
Ports are automatically placed at the bottom (highest priority) of the list; you cannot move a boundary to a higher priority than a port. Magnetic Bias Excitations (if any) have the lowest priority. Other boundaries and excitations appear between these two extremes.

2. Drag the boundary you want to change to the desired order of priority.

> **Note:**
>
> The order of boundaries and excitations in the project tree is alphabetical. The order does not correspond to the order of boundaries and excitations visible to the solvers.

Editing The Global Material Environment

For HFSS, the **Boundaries>Edit Global Material Environment** command displays the **Global Material Environment** dialog box. You can access the command via both the **Tools** menu and via right-click **Boundaries** in the Project window for the shortcut menu.



By clicking the **Material** button, you can access the Select Definition dialog box. This lets you work with the materials library.

This setting tells HFSS what material properties to use when calculating far fields. The default setting is vacuum. If you simulate an antenna underwater, for example, you should set the **GlobalMaterial Environment** to water.

Selecting anisotropic material is disabled because the solver doesn't support that.

See additional discussion of the effect this setting has on calculations in Global Material Environment.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Duplicating Boundaries and Excitations with Geometry

To duplicate a boundary or excitation when its geometry is pasted or duplicated:

1. Click **Tools**>**Options>GeneralOptions** to open the **Options** dialog.
2. Under **HFSS>Boundaries**, select **Duplicate boundaries with geometry**.

All boundaries and excitations will be duplicated with their associated geometries until you choose to clear this option.

> **Tip:**
>
> Use this option to copy and paste boundaries. For example:
>
> 1. Select the face to which you want to assign the boundary.
> 2. Click **Modeler**>**Surface**>**Create Object From Face**.
> 3. Assign the boundary to the new face object.
> 4. Copy and paste the new face object to copy and paste the boundary.

Showing and Hiding Boundaries and Excitations

You can choose to show or hide a boundary or excitation's geometry, name, or vectors, in the active view window or in all view windows.

What do you want to do?

Show or hide a boundary or excitation in the active view window.

Show or hide a boundary or excitation in every view window.

Showing and Hiding Boundaries and Excitations in the Active View Window

1. On the **View** menu, click **Visibility>** **Active View Visibility**.

   The *Active View Visibility* dialog box appears.

2. Select the tab for the objects you want to show or hide. The dialog box contains tabs for 3D Modeler objects, Color Key objects, Boundaries, Excitations, and Fields Reporter objects.
3. Under the tab you need, select the **Visibility** option for the objects you want to show in the active view window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click the **Boundaries** tab if you want to show or hide boundaries.

   > **Note:**
   >
   > Hiding boundaries also turns off a check for boundary overlaps during boundary assignment. In the case of very large models with many boundaries, hiding boundaries can prevent delays during boundary assignment. Full model validation will subsequently check for boundary overlaps.

   Click the **Excitations** tab if you want to show or hide excitations.

   - For designs with large numbers of objects, you can resize the dialog for easier selection.
   - By default, objects are listed in alphabetical order. You can invert the order by clicking the Name bar above the Name fields. A triangle in the bar indicates the direction of the listing.
   - You can also use the **Name** field to type in an object name and apply the visibility via the **Show** and **Hide** buttons.

   The objects you select and designate as Visible (by selecting the property or using Show) appear.

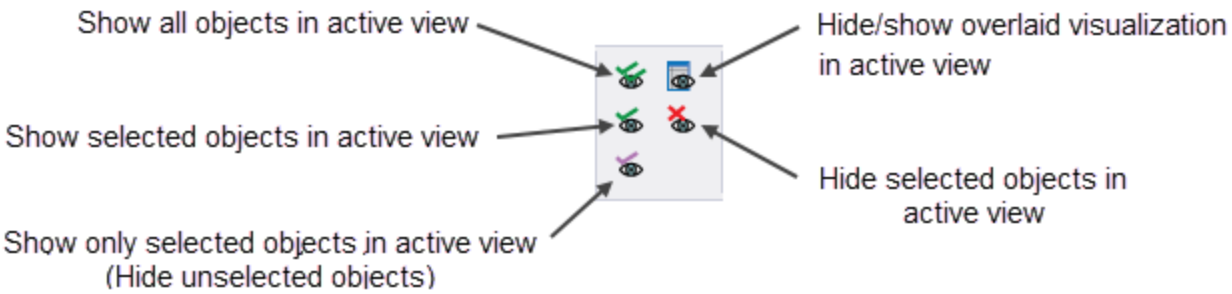
5. Clear the **Visibility** selection of boundaries or excitations that you want to hide from view.

   The boundary or excitation will only be visible in the active view window if it is selected.

6. Select the **Visibility** option for boundaries or excitations that you want to show in the active view window.

   The boundary or excitation will be visible in the active view window when it is selected or when it is not selected.

   You can also use the show/hide icons on the **View, Draw,** and **Model** ribbon tabs:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Showing and Hiding Boundaries and Excitations in Every View Window

1. Click **HFSS> Boundaries> Visualization** if you want to show or hide boundaries. Or:

   Click **HFSS> Excitations> Visualization** if you want to show or hide excitations.

2. Clear the **View Geometry**, **View Name**, or **View Vector** option for boundaries and excitations that you want to hide from view. Select the options you want to show.

   The options affect all view windows.

> **Note:**
>
> Hiding boundaries also turns off a check for boundary overlaps during boundary assignment. In the case of very large models with many boundaries, hiding boundaries can prevent delays during boundary assignment. Full model validation will subsequently check for boundary overlaps.

Reviewing Boundaries and Excitations in the Solver View

After you have assigned all the necessary boundaries and excitations to a model, you should review their order of priority according to the Ansys Electronics Desktop solver. Reviewing the solver's view of the model's boundaries and excitations enables you to verify that their order during the solution process will be as you intended.

To check the solver's view of boundaries and excitations:

1. On the **HFSS** menu, click **Boundary Display (Solver View)**.

   Ansys Electronics Desktop generates an initial mesh and determines the locations of the boundaries and excitations on the model.

   The **Solver View of Boundaries** window appears, which lists all the boundaries and excitations for the active model in the order specified in the **Reprioritize Boundaries and Excitations** dialog box.

2. Select the **Visibility** option for the boundary or excitation you want to review.

   The selected boundary or excitation will appear in the **3D Modeler** window in the color it has been assigned.

- **Visible to Solver** will appear in the **Solver Visibility** column for each boundary or excitation that is valid.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Overridden** will appear in the **Solver Visibility** column for each boundary or excitation that will be ignored by the solver as a result of it overlapping an existing boundary or excitation with a higher priority.

3. Verify that the boundaries or excitations you assigned to the model are being displayed as you intended for solving purposes.
4. If the order of priority is not as you intended, reprioritize the boundaries and excitations.

Setting Default Values for Boundaries and Excitations

When assigning a boundary or excitation, many of the fields in the boundary and excitation dialog boxes have default values associated with them. These default values are initially set by Ansys Electronics Desktop, but can be overridden.

To modify the default values associated with a specific boundary or excitation type:

1. Assign a boundary or excitation.
2. Modify any default values.
3. Close the boundary or excitation's dialog box.
4. Re-open the new boundary or excitation's dialog box. It now includes a **Defaults** tab.
5. Under the **Defaults** tab, click **Save Defaults**.

   The values assigned to this boundary are saved as the default values and will be assigned when new boundaries of this type are created.

6. Optionally, click **Revert to Standard Defaults**.

   The default values you set for this boundary type will be cleared and will revert to the default values set by Ansys Electronics Desktop.

> **Note:**
>
> For PML boundaries, the defaults are set via a formula, rather than a value.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

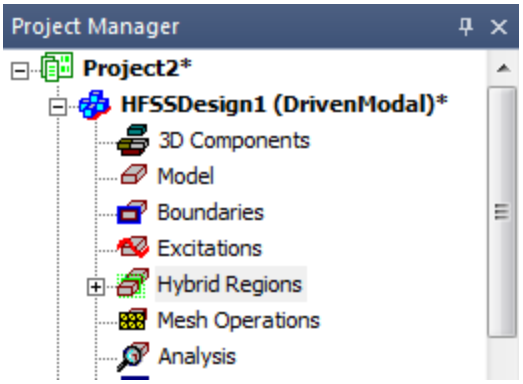
18 - Assigning Hybrid Regions in HFSS

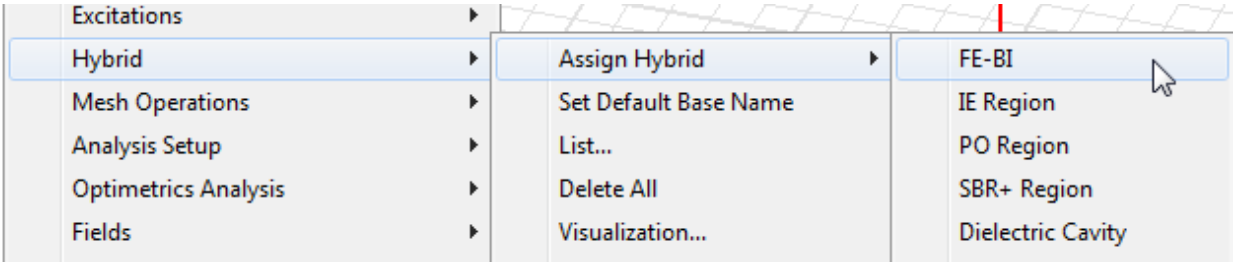
To use Hybrid Regions, the solution type must be HFSS with Hybrid and Arrays. Hybrid regions can include:

- **FE-BI** – only Radiating and Incident Field types are supported.
- **IE Region** – using the Integral Equation solver.
- **PO Region** – using a Physical Optics solver, which can provide a fast approximation for a class of problems.
- **SBR+ Region** – using shooting and bouncing ray (SBR) technology to compute scattered field contributions of defined platform geometry to antenna coupling (S-parameters) and far-field radiation results.
- **Dielectric Cavity**

The Project tree contains a folder for Hybrid regions.

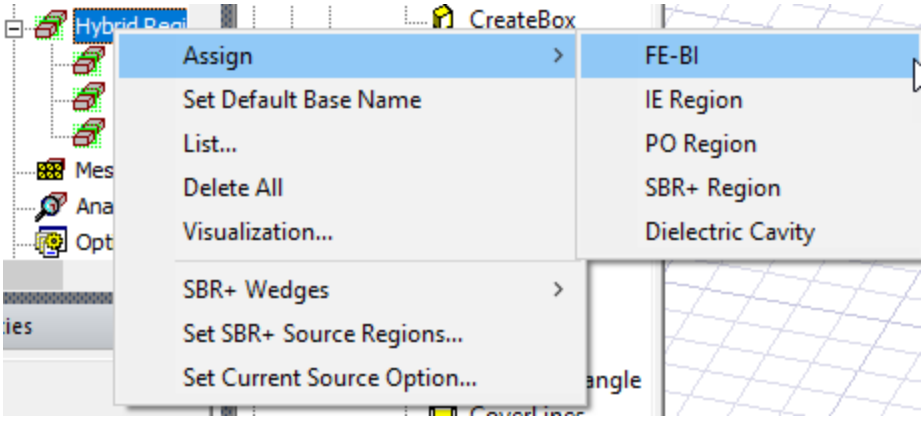


Assign Hybrid regions by selecting an object in the 3D Modeler window, or an object in the History tree, right-click for the shortcut menu, click **Assign Hybrid** and selecting from the enabled options. You can use **HFSS > Hybrid > Assign Hybrid** for the options to be enabled. The selection must meet the conditions for that assignment.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can also right-click the **Hybrid Regions** icon in the Project tree to access a shortcut menu there:



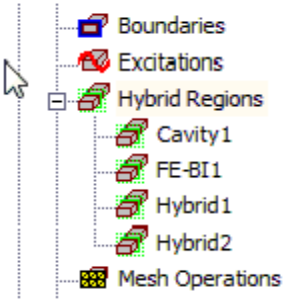
The Toolbar menu and Project tree right-click menus for Hybrid regions display commands for managing Hybrid regions.

- **Set Default Base Name**: opens a dialog for setting default names for new boundaries, excitations, and hybrid regions.
- **List ...**: opens the Design list dialog to the **Hybrid Regions** tab.
- **Delete All**: deletes all hybrid regions.
- **Visualization...**: opens a Visualization Options dialog that lets you show or hide regions and other design objects.
- **SBR+ Wedges**: for designs with SBR+ regions assigned, this command includes further menu for Settings, for Wedge visibility, and for Set Current Source option (see below).
- **Set Coupling**: for designs without SBR+ regions assigned, this command appears and opens a menu that lets you specify whether regions are all one-way coupled or two-way coupled. In one-way coupling, one design acts as as the field source, and the other as a target. This feature improves the efficiency of the solver. If an SBR+ region is assigned, the design becomes one-way coupled and the **Set SBR+ Source Regions** command replaces **Set Coupling** on the short-cut menu. The **Advanced** command on the **Set Coupling** menu opens a dialog that lets you group region objects, other than SBR+ Region objects. Grouped objects become two-way coupled when the design is otherwise one-way linked. See Set Coupling for Hybrid Regions for details.
- **Set SBR+ Source Regions**: for designs with SBR+ assigned, the **Hybrid Regions** right-click menu provides this command for you to group source regions for SBR+ regions in the design. If a source region contains multiple FEBI or IE regions, you can decide if the regions are 1-way or 2-way coupled. All source regions interact as one-way links to SBR+ and coupling between the source regions are handled by SBR+ using reciprocity theory. The dialog excludes all SBR+ regions as those are targets of the sources defined in the interface.

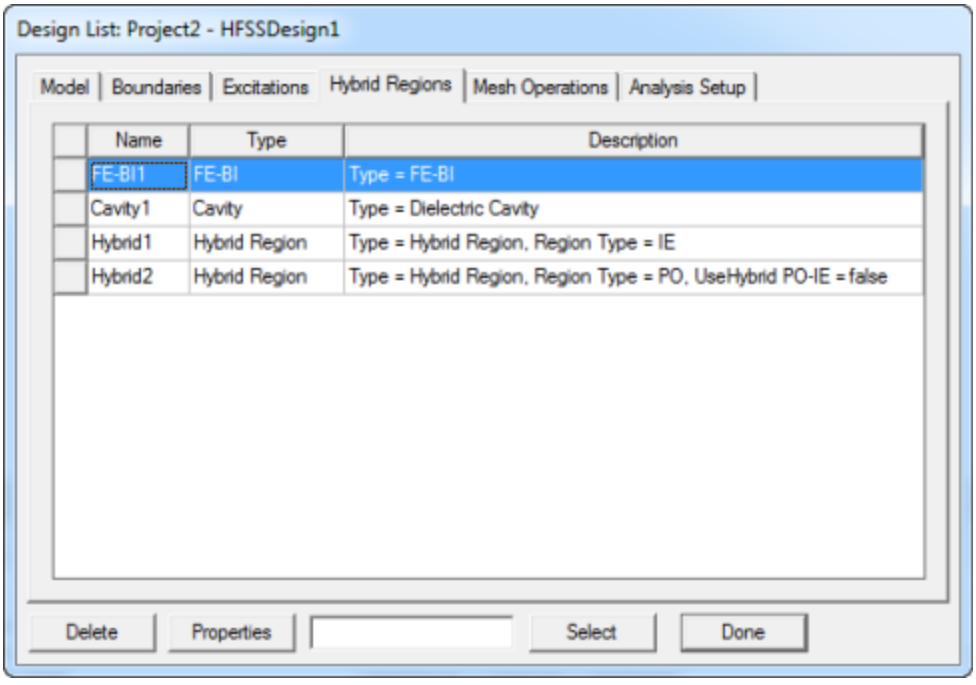
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Set Current Source Options...**: this allows you to specify customized power fraction for designs with SBR+ Regions assigned. Use Global is the default. Enabling Thin Sources lets you specify a Power fraction should be greater than 0.1 and less than 1. Solutions are invalidated if you change current source conformance, use Thin Sources, Power Fraction, or change the Global option.

To view existing Hybrid Regions assignments, you can expand the list under the Hybrid Regions icon in the Project tree. Selecting an assigned region in the list also highlights that region in the Modeler window.



You can also select the **Hybrid Regions** icon in the Project Tree and right-click for menu and select **List.** This shows the **Design List** dialog with the **Hybrid Regions** tab selected.



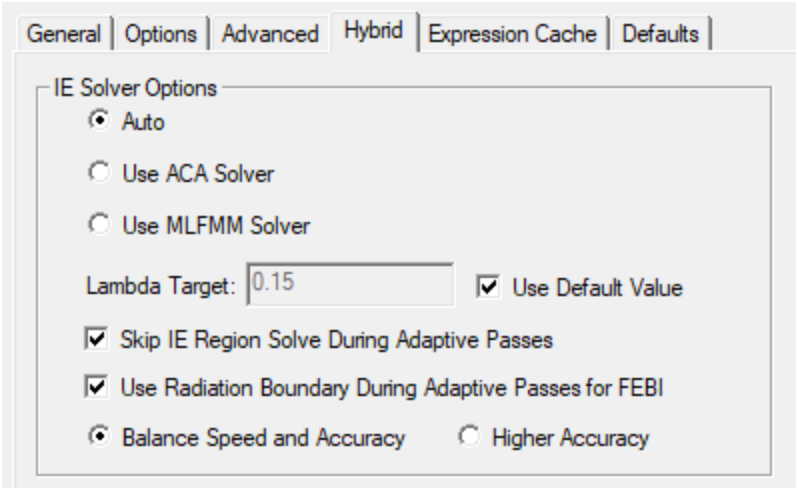
Click Delete to remove the assignment from the selected object(s).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning FE-BI Hybrid Regions

FE-BI- this uses integral equation formulation, which is an exact transparent condition. By taking advantage of conformal radiation volumes to reduce the overall finite element solution domain, using the FE-BI hybrid region will result in more efficient simulation for electrically large open boundary problems. It can be close to or on the structures, but for performance, 0.05 wavelength is recommended. If it is on a surface, you must turn off curvilinear elements. The FE-BI hybrid region should enclose the entire structure by itself, or with an Infinite ground plane. (Compare Assigning IE Regions). If you model a radiation boundary as a FE-BI hybrid region, the solution setup cannot include calculations of derivatives on those regions. Contact with dielectric IE Region or PO Region is allowed.

In the Solution Setup, when the **Hybrid** tab option, **Use Radiation Boundary During Adaptive Passes for FEBI** is enabled, solver uses a radiation boundary instead of FEBI during adaptive passes. When it converges, solver enables the FEBI for the last adaptive pass. If the FEBI surface is sufficiently large, this option can lead to a faster adaptive mesh run.



To assign a FE-BI Hybrid Region:

1. Select the object you want to assign as FE-BE, and use one of the following menus:

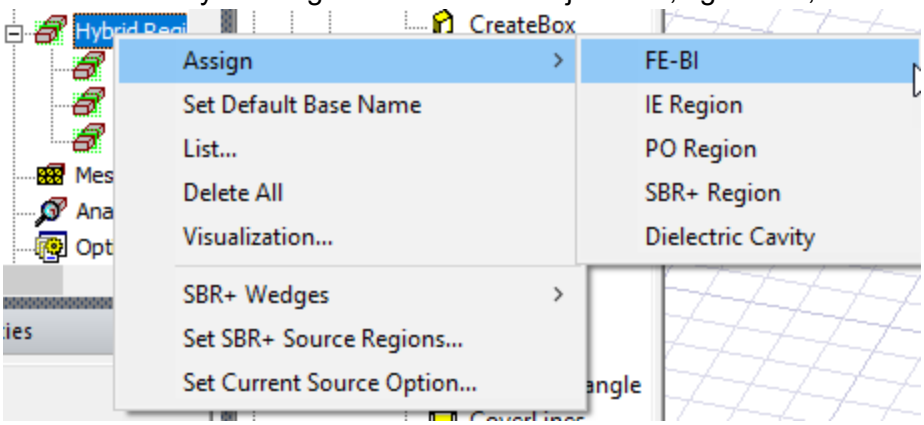
   HFSS>Assign Hybrid>Assign>FE-BI

   Right-click in the Modeler window and select **Assign Hybrid>FE-BI**.

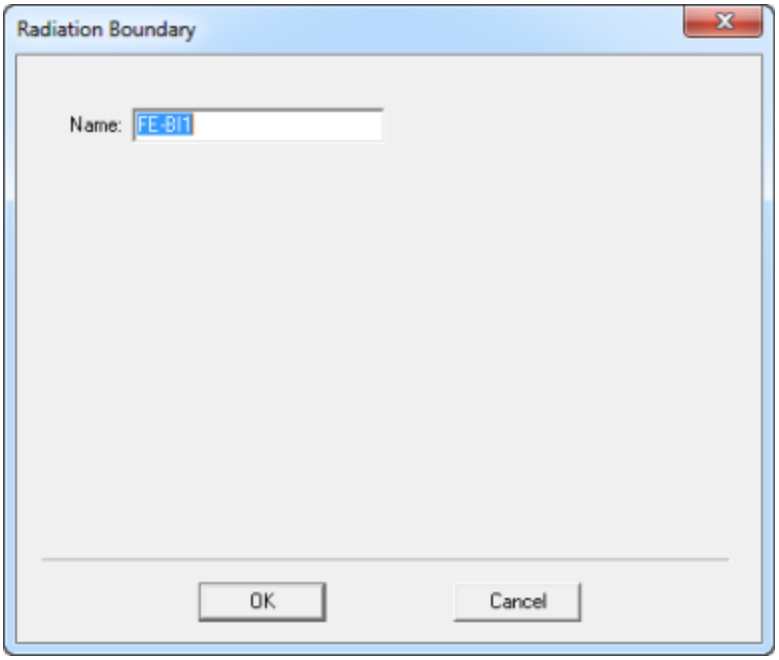
   Right-click in the Modeler window and select **Assign Hybrid>FE-BI**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Select the Hybrid Regions icon in the Project tree, right-click, and click **Assign>FE-BI**.



The **Radiation Boundary** dialog opens, showing the default name and FE-BI assignment.



2. When you OK the dialog box, the assignment appears under the Hybrid Region icon in the Project tree.

Assigning IE Regions

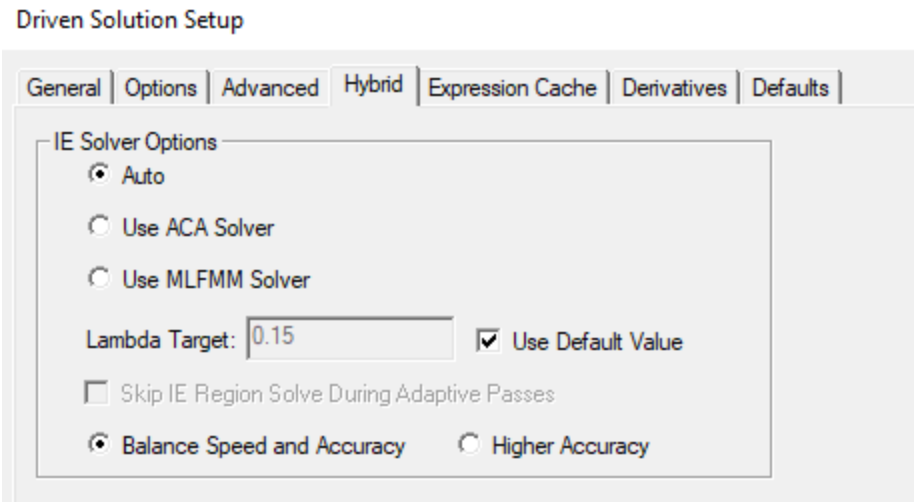
For driven modal and driven terminal solutions you can assign dielectric or conducting objects or sheets as IE Regions to be solved with the IE Solver as part of a hybrid simulation approach, using the advantages of the FEM and Hybrid Region solvers. IE Regions use an integral equation solver (sometimes called method of moments = MoM) and solves for the currents on *surfaces of objects.* It creates a triangular surface mesh on all objects - it solves for the currents

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

or equivalent currents on conducting and dielectric objects. In general, HFSS uses the finite element method (FEM) to solve for the electromagnetic fields in the solution region. It meshes over the *entire solution volume* (other than areas assigned as one of the Hybrid Regions) and solves for the electric field throughout that volume.

To use Hybrid IE Regions, the solution type must be HFSS with Hybrid and Arrays.

If you assign Hybrid regions, you can use the Hybrid tab in the Advanced **Solution** setup to specify the IE Solver type as ACA (the traditional method) or as MLFMM, which is superior than ACA for models with large FE-BI surfaces, and also works for IE regions. The default choice is Auto, in which the choice is made based on the characteristics of the design. See Guidelines for Choosing Between ACA and MFFMM IE Solver Options.



To Assign an IE Region

To use Hybrid IE Regions, the solution type must be HFSS with Hybrid and Arrays.

You must select an appropriate object or face in order to enable the menu.

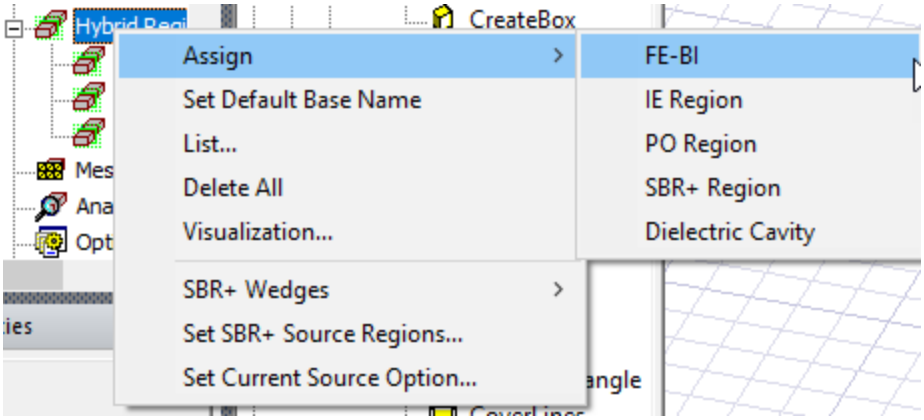
1. Select the object you want to assign as an IE Region, and use one of the following menus:

   HFSS>Hybrid>Assign Hybrid>IE Region

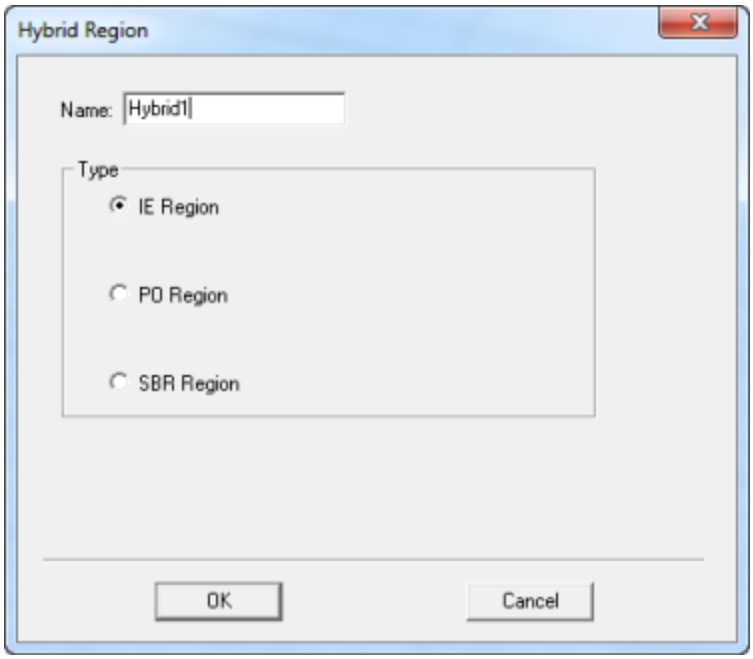
   Right-click in the Modeler window and select **Assign Hybrid>IE Region**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Select the Hybrid Regions icon in the Project tree, right-click, and click **Assign>IE Region**.

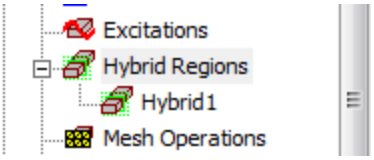


The dialog for **Hybrid Region** opens, showing the default name and type selection as IE Region. Because you may decide to change an assignment for IE Regions, and PO Regions, the dialog shows these types as radio button selections.



2. When you OK the dialog box, the assignment appears in the **Project** tree under **Hybrid Regions**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Applications and Technical Considerations for Using IE Regions

Application areas for IE Regions include:

- Radar cross section (RCS)
- Antenna placement (for example, antenna on a vehicle)
- Stand alone antennas
- Coupling. EMI/EMC
- When a layered impedance boundary touches a dielectric to model paint on fascia which is important for ADAS radar simulations

In assigning IE Regions:

- 3D objects must be dielectric or conducting based on bulk material conductivity. Some boundary conditions can also be assigned on the surfaces of 3D objects. These boundaries are: PEC, Finite Conductivity, Impedance, Layered Impedance, Lumped RLC, and Anisotropic Impedance.
- Sheet objects can also be allowed only if they have supported boundaries assigned. These boundaries are: PEC, Finite Conductivity, Impedance, Layered Impedance, Lumped RLC, or Anisotropic Impedance boundaries. They cannot be dielectric.
- An infinite ground is allowed with dielectric IE region.
- Dielectric Cavity must either:
  - be contained within a FEM solve inside object.
  - have its surface covered by FEM solve inside objects.
- A free standing dielectric IE/PO region must not:
  - touch other free standing IE/PO regions.
  - have a conducting boundary assignment on free standing dielectric IE/PO region
  - have an IE/PO region to be assigned to both dielectric objects and metallic objects. One IE/PO region can only be metallic or dielectric
- Metallic IE Region must either
  - (Interior) Be contained within a Dielectric Cavity.
  - (Exterior) Be outside entire FEM region.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Faces of two dielectric IE Regions can touch. We allow metal IE region to touch (or to be contained in) a DIE. We also allow DIE regions to touch a DIE. The IE region can be a solid conductor, or a conducting/impedance sheet. You can also assign a boundary condition on the surfaces of a dielectric IE region.
-
  - Allow IE regions (solid metal or metal/impedance sheet) to touch dielectric IE region (DIE).
  - Allow boundary assignment on the face of dielectric IE region.
  - Allow metallic IE (both solid and sheet objects) contained inside dielectric IE.
  - Allow metallic sheet placed at the interface of two dielectric IE regions.
  - Allow mixed IE region with infinite ground.
- Two dielectric IE components can touch.
- Dielectric Cavity may contain implicitly subtracted FEM objects (and imply solver handling like FEBI on their interface)
- Metallic IE Region may touch FEBI surface.
- Models with IE Regions for curved surfaces (for example, a large antenna dish) benefit from improvements to the Tau mesher.

Note:

For designs like antennas mounted on a platform such as an aircraft or battleship, it is beneficial both in terms of memory and solution time to model antennas using the finite element method, while modeling remaining metallic structures as metallic IE regions. In these cases, a metallic IE region is actually in contact with a FEBI hybrid region where appropriate boundary conditions are enforced at the interface between the two solvers.

In cases where an IE region is in contact with a FEBI hybrid region, it is recommended that the FEBI hybrid region be placed at least a third wavelength away so that the FEM domain can have sufficient space to perform its adaptive mesh refinement more accurately.

The near field calculation can be inaccurate inside a cavity made from any metal boundary applied to a box made of background material. For PEC boundary or other metal boundaries at high enough frequencies, the total fields inside this cavity should be zero but that might not be the case due to solver formulation employed on surfaces with metal boundaries. However, the exterior to the cavity will be accurate.

There are two cases we do not handle:

- Mixed IE region with high loss impedance assigned to the surface of a closed IE region;
- Mixed IE region with a sheet (IE region) larger than the touching surface of a dielectric IE Region.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Solver issues an error for these cases.

The accuracy of this approach is the same as enclosing the structure inside a FEBI box. Performance is faster than the FEBI apporach.

IE Region Ports

You can assign ports on an IE Region. This is helpful, for example, when an antenna is attached to a large metal body. One-way coupling between regions allows for an easier setup in HFSS design, where you can switch between one way link and full solution in a single setup. The following cases are allowed:

- IE region ports in the presence of one or more non-port FEBI, IE, PO and SBR+ regions.
- One-way coupled for the above case.
- Can allow an IE component with port but skips port refinement for an IE component with port.

The following restrictions will still apply:

- IE region port cannot mix FEM ports with IE ports.
- IE region port is not allowed to contact both PO region and SBR+ region.
- IE region port cannot coexist with incident waves and FEM ports
- IE region port does not support composite excitation.

Assigning PO Region Hybrid Region

While IE Region provides an efficient and accurate alternative to FEM solver for metallic and finite conducting structures, for very electrically large structures it is time consuming and memory demanding. The physical Optics (PO) solver provides first-order scattering information and proves to be efficient approximation for metallic, smooth, locally flat structures. For such geometries for example, a dish reflector, physical optics (PO) can provide an accurate approximation with a significantly reduced computational resource requirement. PO Hybrid Regions are dielectric objects and perfectly conducting objects or sheets solved with physical optics formulation. In light of this, PO Region provides a fast alternative to IE region.

To use PO Region, the solution type must be HFSS with Hybrid and Arrays.

However, because PO is not a full wave solver, we stress that inappropriate use of PO Region may lead to an incorrect solution. PO Region is optimal when the following conditions are satisfied:

1. Structure is flat or locally flat, such as a dish reflector;
2. Frequency is sufficiently large such that the structure is more than 10 wavelengths in dimension and the structure is sufficiently far away (more than 10 wavelengths) from the radiating source.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Only a single incident wave excites the PO Region.
4. A free standing dielectric IE/PO region cannot touch other free standing IE/PO regions.

When these conditions are met, a large portion of the structure is visible to the radiating source. This region is called a lit region. The remaining region is termed a shadow region. Figure 1 shows visualization of such a concept.

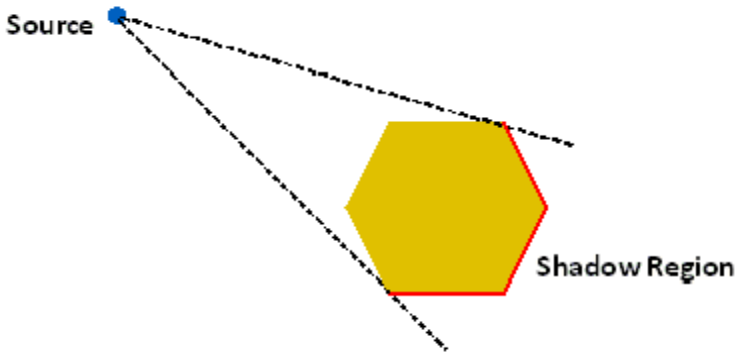


Figure 1 Shadow region of PO solver

In PO approximation, the currents on shadow regions are identically zero. This approximation is acceptable only when frequency is large. In the situation where condition 1) is not met but 2) is satisfied, PO region could still provide reasonable results.

While the accuracy of PO depends on an accurate identification of shadow region, this region is determined based on source location as can be seen from Figure 1. Therefore for the situation where there are multiple sources, shadow regions due to each source could be vastly different. In this situation PO region solver does not provide reliable results. Consequently PO region will only allow a single incident wave direction. Furthermore if there are multiple disjoint FEBI boundaries, the solver will report error message when it detects that a shadow region due to each FEBI box does not mostly overlap. Contact between dielectric PO region and a FE-BI region is allowed.

Note that PO regions may be used together with other useful features like 3D components. For parametric sweeps that vary the distance between assembled 3D components, you can preserve and reuse the component-level meshes between these variations. For example, if a horn and a reflector are defined as 3D components with enabled Do Mesh Assembly option, you can do a placement study running the parametric sweep over the distance between the horn and the antenna, recycling the mesh to speed up the parametric sweep simulations.

The following guidelines summarize the use of PO region.

- Use PO Region when you want a faster solution with sacrifice of accuracy.
- Use PO Region for smooth flat and locally flat structures at the operating frequency.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note several limitations of the PO region option. First, every conducting material of the metallic PO region will be treated as perfect conductor, and every surface will be treated as PerfE boundary condition disregarding actually assigned materials and boundary conditions. The warning message will be issued if the PO region is assigned on a metal object or a boundary condition that is not a perfect electric conductor. Assigning the PO region to a dielectric object automatically turns this hybrid region to a dielectric PO region. Second, if there are multiple sources modeled with multiple disjoint FE-BI boundaries that makes it hard to accurately define the shadow region, the PO region solver does not provide reliable results. Furthermore, the solver will report an error message when it detects that a shadow region due to each FE-BI region does not mostly overlap.

To Assign a PO Region:

To use PO Region, the solution type must be HFSS with Hybrid and Arrays.

1. Select the object you want to assign as an PO Region, and use one of the following menus:

   HFSS>Hybrid>Assign Hybrid>PO Region

   Right-click in the Modeler window and select **Assign Hybrid>PO Region**.

   Select the Hybrid Regions icon in the Project tree, right-click, and click **Assign>PO Region**.

   The dialog for **Hybrid Region** opens, showing the default name and type selection as PO Region. Because you may decide to change an assignment for IE Regions, and PO Regions,

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the dialog shows these types as radio button selections.

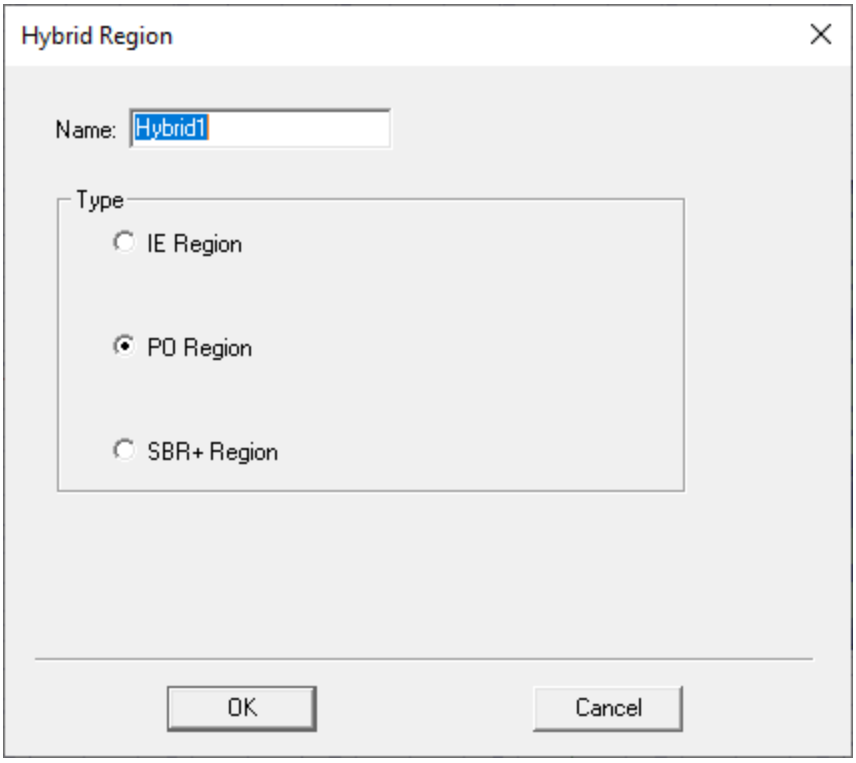

Fig. 2 Hybrid Region dialog for PO region

2. When you OK the dialog box, the assignment appears under the Hybrid Regions icon in the Project tree.

Examples of PO Hybrid Simulations

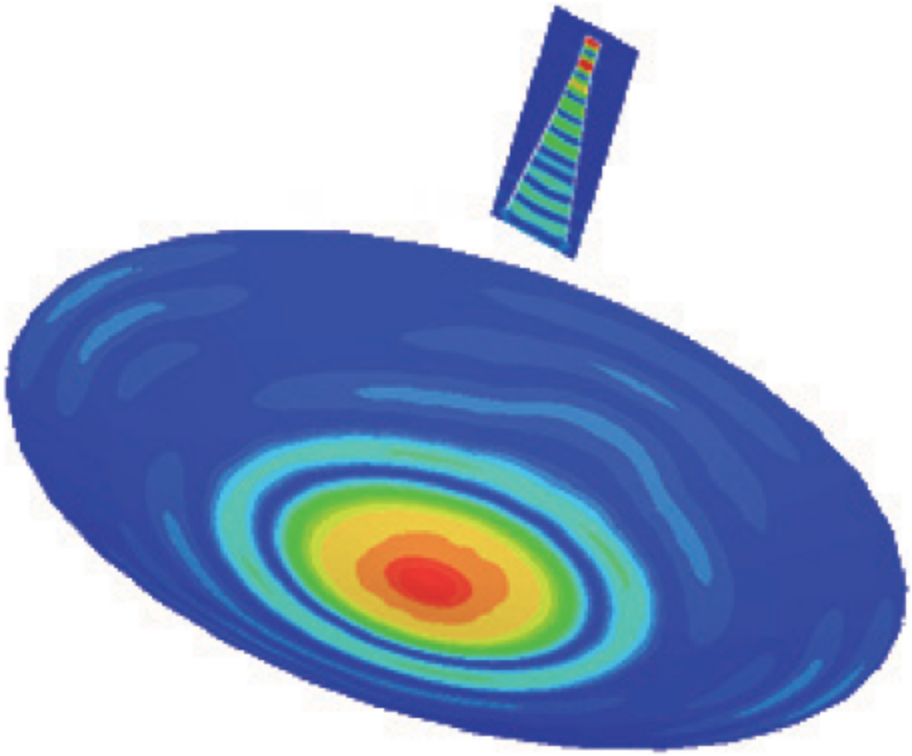
This section looks at three different projects that use PO Hybrid Regions.

Horn Fed Reflector Antenna with PO

An electrically large reflector of 22 wavelengths in diameter is fed with a rectangular horn. To model the system using a hybrid solution with the reflector solved as a PO region, all geometry objects are placed in an HFSS design. The horn geometry is surrounded by an air box named RadiatingSurface. The faces of this object are assigned as hybrid FEBI region, the assignment corresponds to radiation FE-BI boundary in previous versions of Ansys HFSS. To assign, select the air volume surrounding FEM part of a design, and use menu item **HFSS > HYBRID> ASSIGN HYBRID > FE-BI**. The reflector is modeled as a 2D sheet object with PerfE boundary condition assigned. This sheet object is modeled as a hybrid metallic PO region. To assign, select the reflector and use menu item **HFSS > HYBRID > ASSIGN HYBRID > PO REGION**. All hybrid regions are listed under the hybrid regions entry in the project manager.

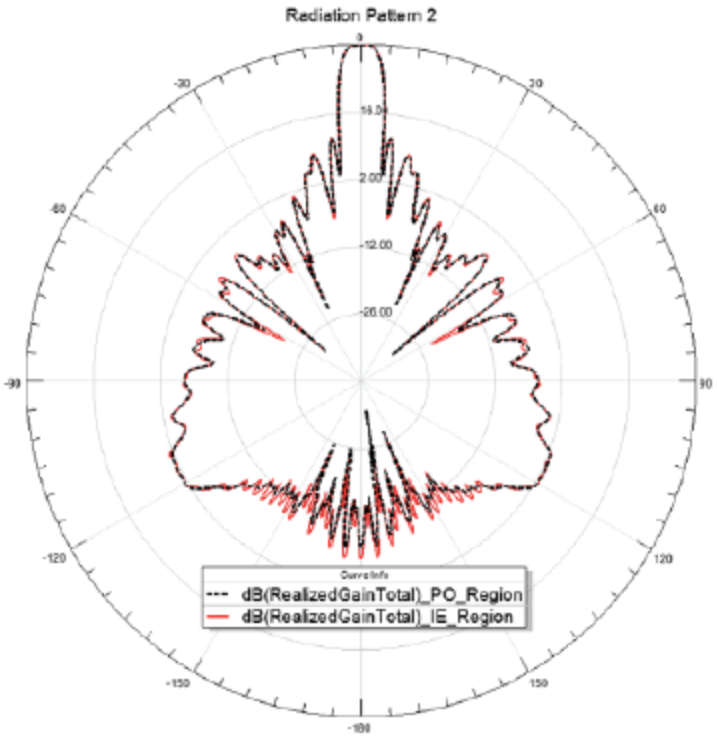
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

After the solution has completed, standard result reports like field plots, S-parameters and far field characteristics are available. The following figure shows an E-field plot in the FE-BI region assigned to the horn and a J-field plot on the PO region assigned to the reflector dish.



The same geometry was solved with the reflector assigned as an IE region. We can see that the radiation patterns are almost identical and differ only for back lobes, while the PO region option significantly saves computational resources.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

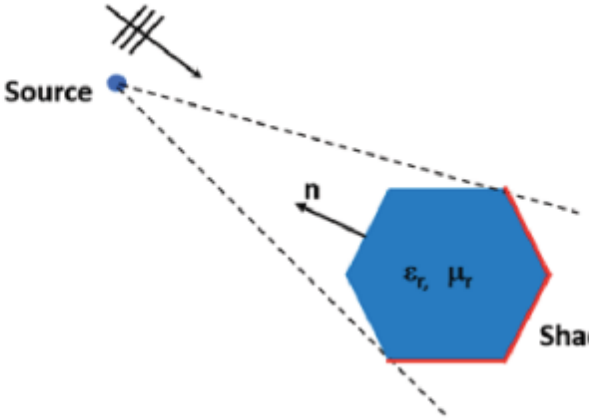


Reflector assigned as	RAM 1st pass	Time (1 core used) Mesh + 1st pass
IE Region	2.49GB	10 min 31sec
PO Region	1GB	1 min 27 sec

Antenna with Raydome using Dielectric PO Hybrid Region

The dielectric PO region option is well suited for simulating antennas covered with radomes. To model the system using the dielectric PO region, all geometry objects are placed in a single HFSS design. Horn geometry is surrounded by the air box that is assigned as a hybrid FE-BI region. The radome geometry should be a standalone 3D object assigned with dielectric material. This object is also assigned as a hybrid dielectric PO region.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



$$\mathbf{j} = (1-R)\mathbf{n}\times\mathbf{H}^{inc}$$
$$\mathbf{e} = (1+R)\mathbf{n}\times\mathbf{E}^{inc}\times\mathbf{n}$$

Lit Region

$$R = \frac{k_z^{\,2} - k_{zs_\mu}^{\,2} - (k_z^{\,2} - k_{zs_\mu}^{\,2})\,e^{-2jk_{zs}dd}}{(k_z + k_{zs_\mu})^2 - (k_z - k_{zs_\mu})^2\,e^{-2jk_{zs}dd}}$$

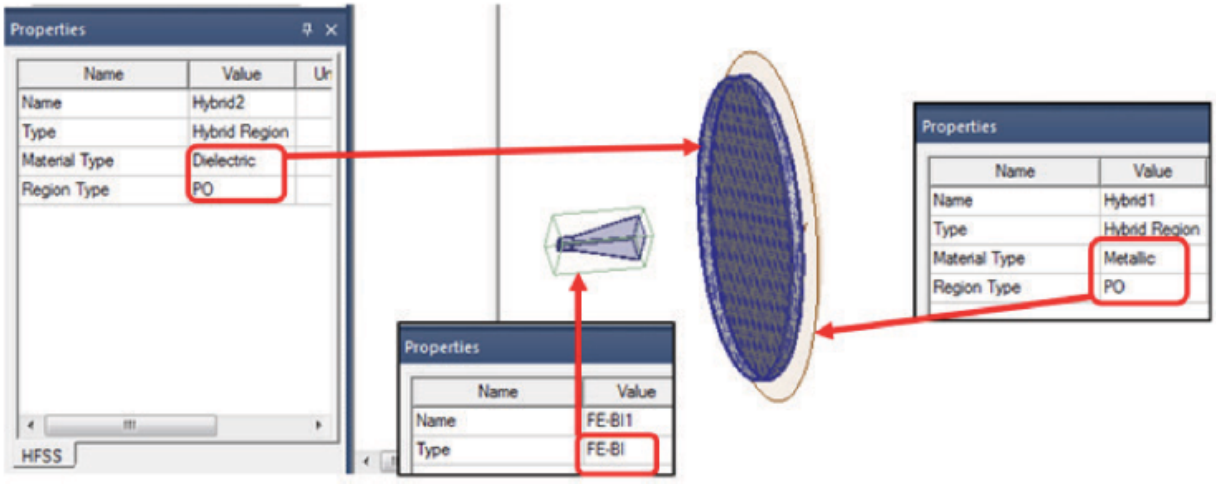
$$T = \frac{4(k_z k_{zs_\mu})e^{-jk_{zs}dd}}{(k_z + k_{zs_\mu})^2 - (k_z - k_{zs_\mu})^2\,e^{-2jk_{zs}dd}}$$

$$\mathbf{j} = -T\mathbf{n}\times\mathbf{H}^{inc}$$
$$\mathbf{e} = -T\mathbf{n}\times\mathbf{E}^{inc}\times\mathbf{n}$$

Shadowed Region

$$k_z = k_0,\quad k_{zs} = k_z\sqrt{\varepsilon_r\mu_r},\quad k_{zs_\mu} = k_{zs}/\mu_r$$

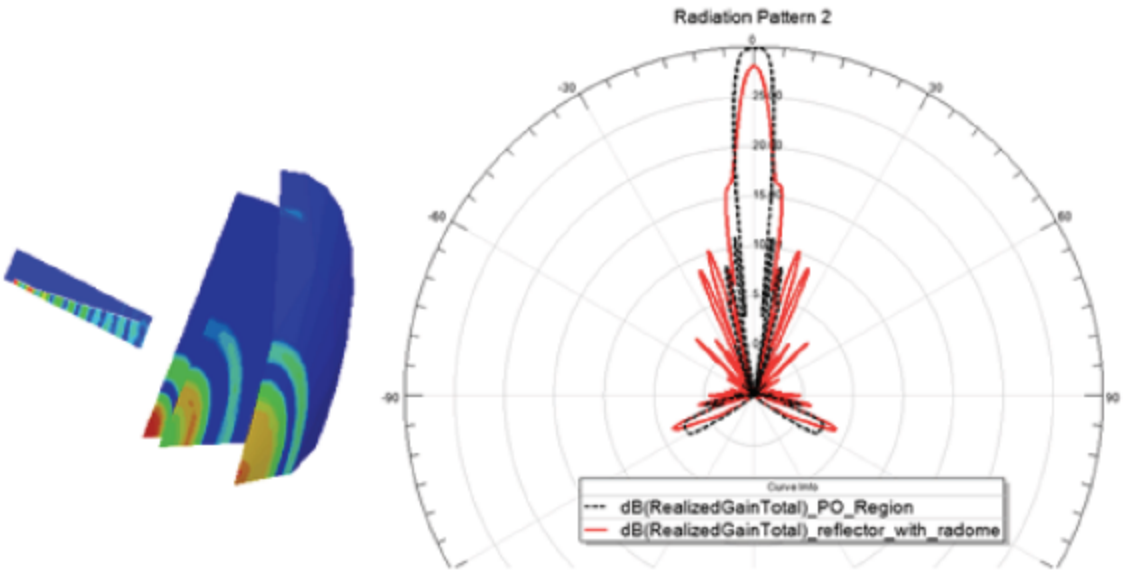
To assign, select the radome and use the menu item **HFSS > HYBRID > ASSIGN HYBRID > PO REGION**. The dielectric PO region should not touch any other model geometry. This option may be used in the same design together with other hybrid regions. Below is the example of reflector with the flat FR4 radome between the reflector and the horn. Three hybrid regions are assigned: FE-BI for the air box around horn, metallic PO for the PerfE reflector and Dielectric PO for FR4 radome.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note some limitations for a dielectric PO region: no boundary condition may be assigned on the surface of a dielectric PO region; dielectric PO region cannot touch any other metallic IE or PO regions. However, several touching dielectrics like layers of the radome may be assigned as one hybrid dielectric PO region.

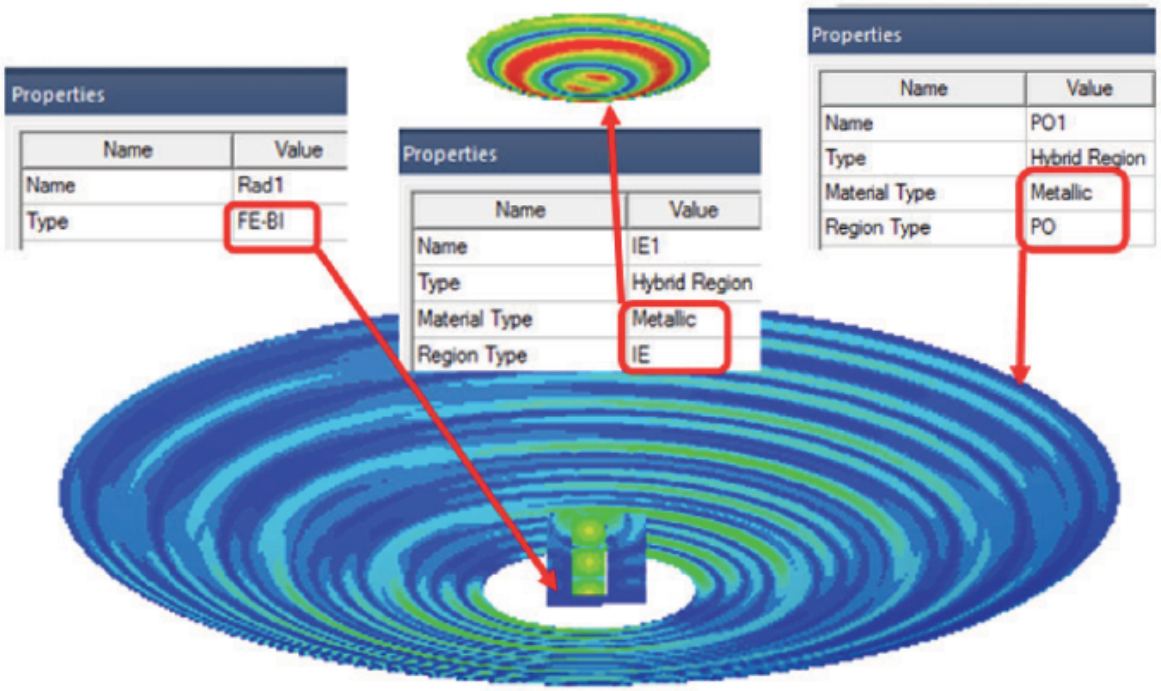
The following figure shows solved fields for a design with three hybrid regions, including, dielectric PO region for FR4 plate radome. Only a quarter of geometry is displayed for a field plot. In the Radiation Pattern plot, the black dotted line represents the far field of the reflector without radome, and the red line refers to the design with FR4 plate between the horn and the reflector.



Cassegrain Reflector: PO and IE Hybrid Regions in One Design

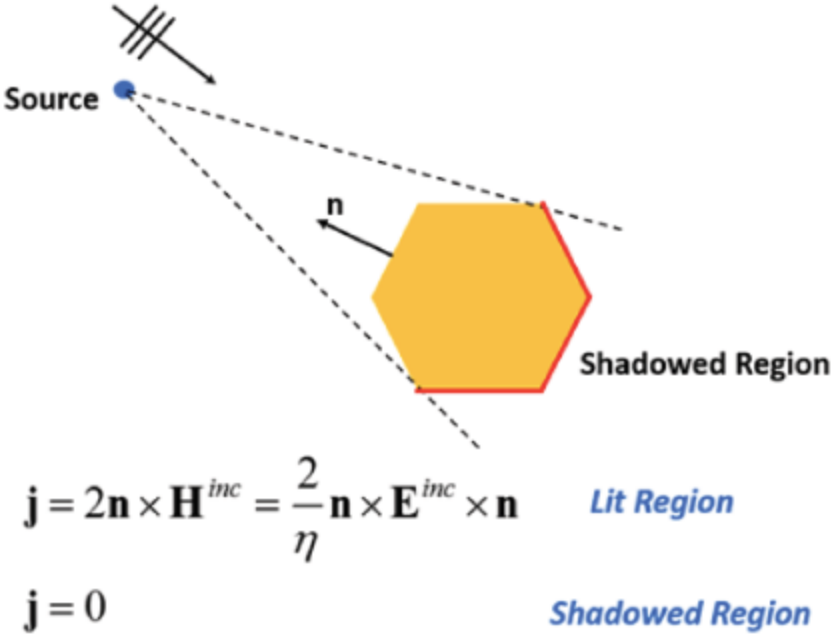
Hybrid PO regions may be combined with IE hybrid regions if desired. For applications like the Cassegrain reflector, there are 2 regions suitable for IE solver: a sub-reflector and a main reflector. A sub-reflector is usually not very large electrically but accuracy of the field solution on the sub-reflector is very important. A main reflector may be electrically very large and smooth making PO approximation justified for the main reflector. Below is the solved field for the Cassegrain system with a relatively small main reflector: The air box around the horn is assigned as a FE-BI region, the sub-reflector is assigned as a metallic IE region and the main reflector is assigned as a metallic PO region.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Technical Notes for Hybrid Regions and PO Solver

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Assigning SBR+ Hybrid Regions

HFSS can use shooting and bouncing ray (SBR) technology to compute the scattered field contribution of defined platform geometry via one-way coupling. This allows you to efficiently calculate installed near field patterns, far-field patterns and coupling (S-parameters) between antennas in the presence of an electrically large scattering geometry.

Note that the same SBR+ mesh used for both SBR+ simulation and VRT is also used in extracting wedges according to the user-specified criteria. This is done so that the wedge locations extracted are very near the physical edges of the SBR+ geometry model in the simulation, preserving accuracy of the line-of-sight visibility check for wedges.

- An SBR+ Region can only be assigned to no-solve inside object (metal).
- When an object is assigned as an SBR+ region, Boundary conditions (BCs) may be assigned to the geometry inside the SBR+ region(s), but there are some limitations in what boundary conditions are supported. HFSS currently supports assignment of Perfect E, Perfect H, Impedance, Finite Conductivity, and Layered Impedance boundaries to geometry in the SBR+ region. Other boundaries are not yet supported for SBR+, and produce an error. Infinite Ground Planes are not supported with SBR+. Note also that surface roughness must be set to “0” for all BCs assigned to SBR+ region geometry.
- An SBR+ Region cannot be contained by a dielectric cavity.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Incident plane waves are allowed. If you include an incident plane wave in the design, the Hybrid tab for the Driven Solution Setup dialog includes options for RCS type as Monostatic or Bistatic.
- If an SBR+ Region is assigned, the design becomes one way coupled. (See Assigning Hybrid Regions.) You can use the **Set SBR+ Source Regions** command to group source regions for SBR+ for two-way couplings between the grouped regions.
- Terminal ports with multiple terminals are supported if a an SBR+ region is present.
- Designs with SBR+ regions provide options to view total, scattered, or incident fields.
- SBR+ Region simulations can benefit from GPU Acceleration. See Setting HPC and Analysis Options.
- If your design contains an SBR+ Hybrid Region, you have an option on the Initial Mesh Settings dialog to **Allow tolerant meshing for SBR+ regions**, which can speed up the solve.
- If you want to consider far fields or near fields, the field sample points for SBR+ Hybrid regions must be defined as part of the simulation setup, rather than during post processing as is done for HFSS near and far fields. See the discussion of the **Setup** dialog box, **Hybrid** tab in step 3 below.
- HFSS with Hybrid and Arrays designs that include blockages have an enhanced work flow described.
- When a project contains SBR+ region and the following error appears: "[error] Solving adaptive frequency ... (Domain solver), process hf3d error: Error in using SBR+ region: Each source region should contain at least one excitation."

  "Each source region should contain at least one excitation" means there is at least one source region without an excitation. To work around the issue, please go to Set SBR+ Source Regions and, select all regions and click "**Group**".

You must select an appropriate object in order to enable the menu.

To assign an SBR+ Hybrid Region:

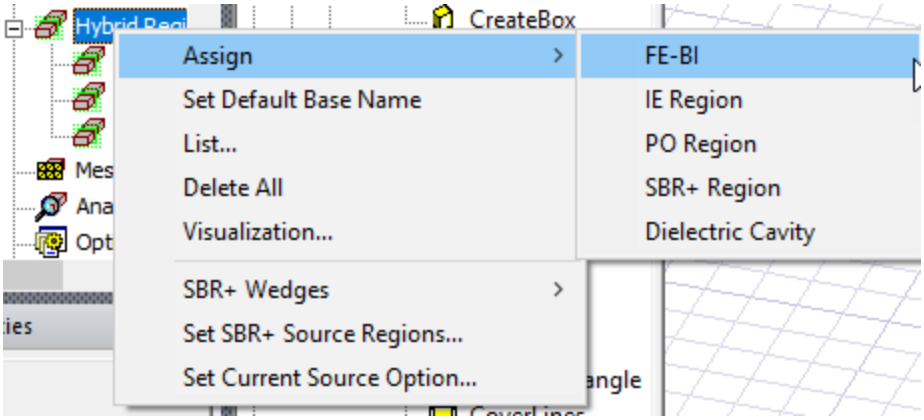
1. Select the object you want to assign as an SBR+ Region, and use one of the following menus:

   HFSS > **Hybrid** > **Assign Hybrid** > **SBR+ Region**

   Right-click in the Modeler window and select **Assign Hybrid** > **SBR+ Region**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

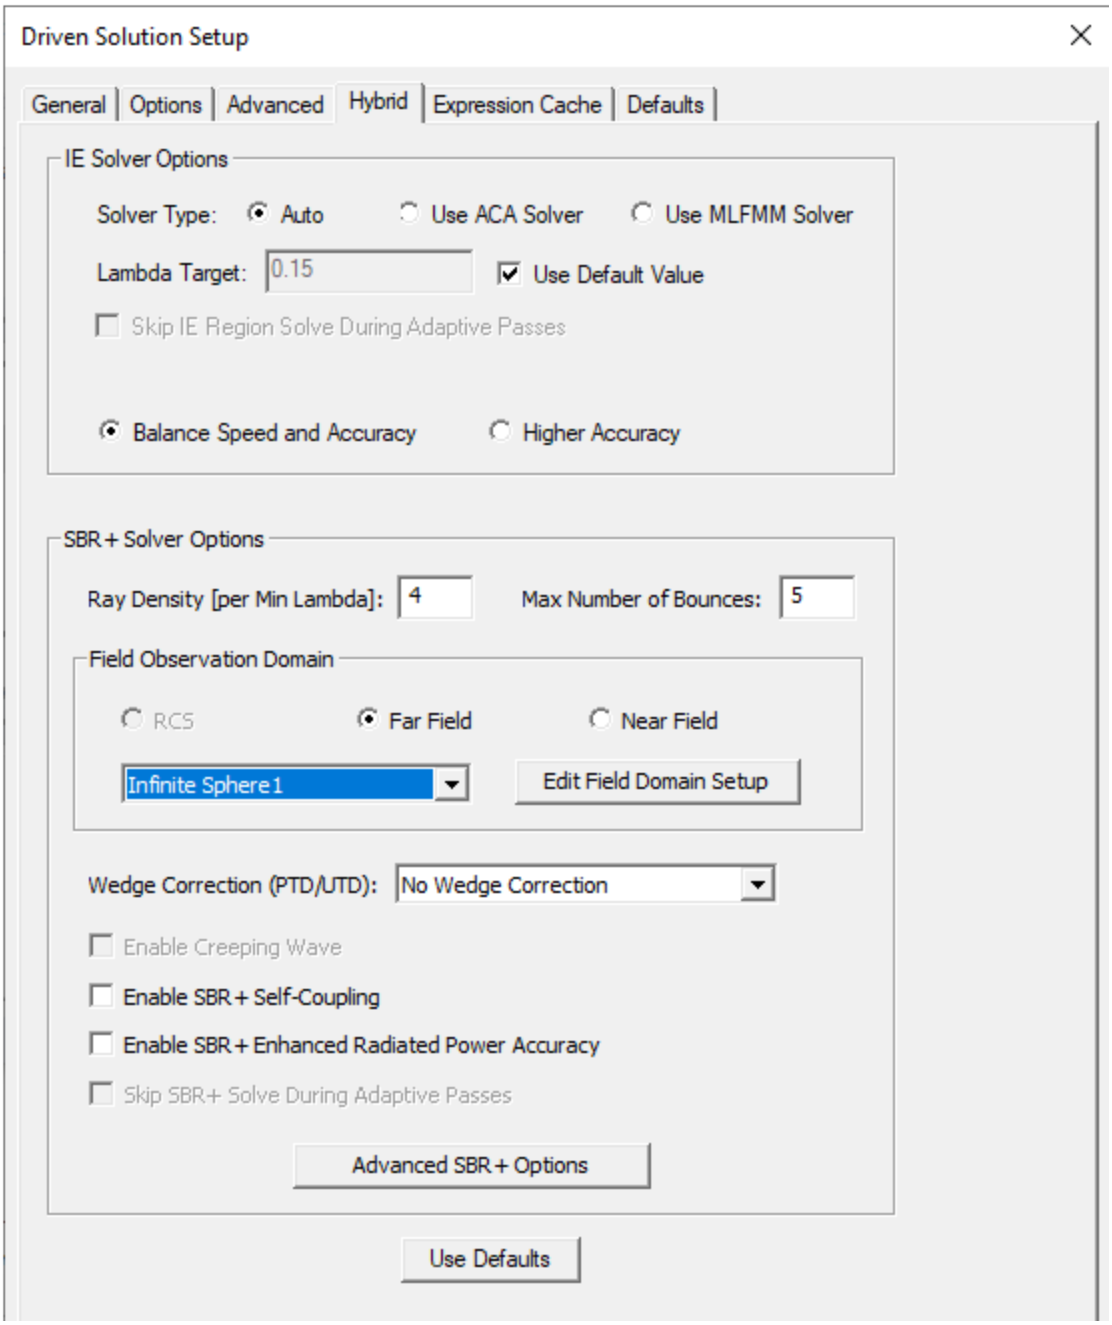
Select the Hybrid Regions icon in the Project tree, right-click, and click **Assign** > **SBR+ Region**.



The dialog for **Hybrid Region** opens, showing the default name and type selection as IE Region. Because you may decide to change an assignment for IE Regions, and PO Regions, the dialog shows these types as radio button selections.

2. When you **OK** the dialog box, the assignment appears in the Project Tree under Hybrid Regions.
3. SBR+ Solver Options are enabled in Solve setups for HFSS when an SBR+ Region is present.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

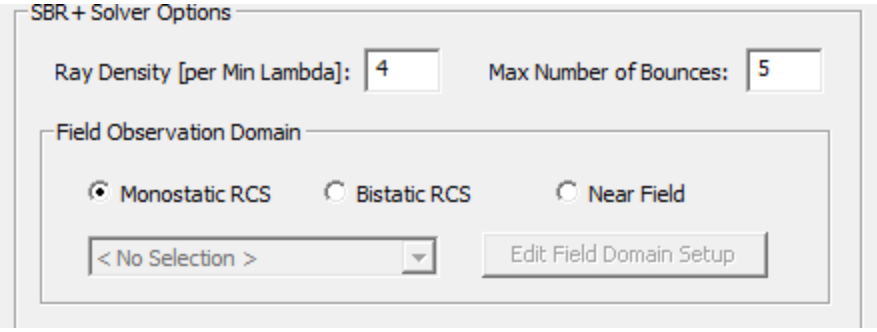


You can set Ray Density Per Wavelength and Maximum Number of Bounces, and if you have not done so, create or edit an infinite sphere setup for Far Field Observation. See Setting Hybrid Region Parameters for HFSS. You can also choose to Skip SBR+ Solve During Adaptive Passes. SBR+ regions are not being mesh adapted and SBR+ solutions have no impact on field solutions on FEM or IE regions. However, SBR+ does impact stopping criteria in some cases such as coupling between two separate source antennas. Therefore, to speed up mesh adaption, you can choose to not solve SBR+ regions until

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

source regions have converged in isolation. However, SBR+ does impact stopping criteria in some cases in the form of cache expression such as coupling between two separate source antennas or far field pattern. In such cases, SBR+ solve could not be skipped. Moreover, SBR+ solve is always launched when the maximum number of passes is reached regardless of source region convergence.

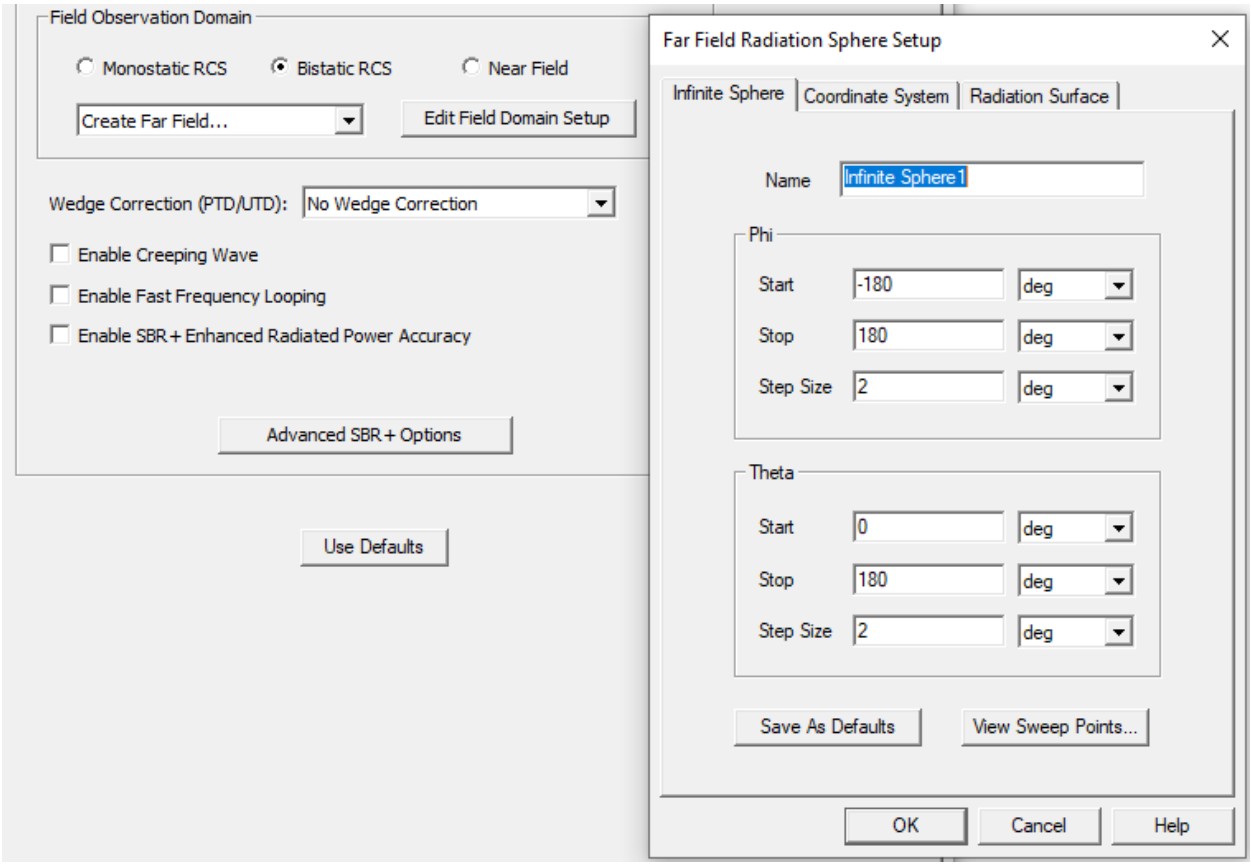
If you created an Incident Plane Wave for the design, the **Hybrid** tab lets you make an RCS Type selection for Monostatic or Bistatic.



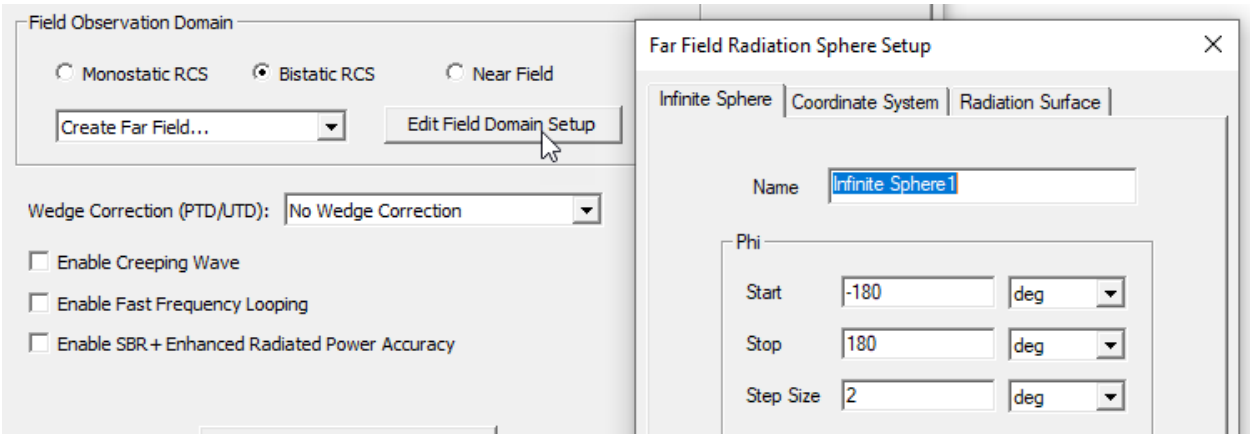
If you select Monostatic, the infinite sphere setup is disabled. In this case, the solver computes the scattered field in the direction of the plane wave. The Reporter will not require a geometry selection, and offers a range of Monostatic quantities for Monostatic RCS traces. See Generating Reports for Monostatic RCS.

If you select have assigned both an SBR+ region and an Incident Plane wave, and select Bistatic as the RCS Type, the Near Field and Far Field Observation domain fields are enabled, and the **Far Field Radiation Sphere Setup** dialog appears as follows, allowing you to create an infinite sphere for a Far Field or a rectangle for examining near fields. You can edit an existing Far Field Infinite Sphere or Near Field Rectangle setup by selecting from the drop down menu and clicking **Edit Field Domain Setup**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If you have created one or more field observation domains, these are listed on the dropdown. You can edit an existing Far Field Infinite Sphere or Near Field Rectangle by clicking **Edit Field Domain Setup**.

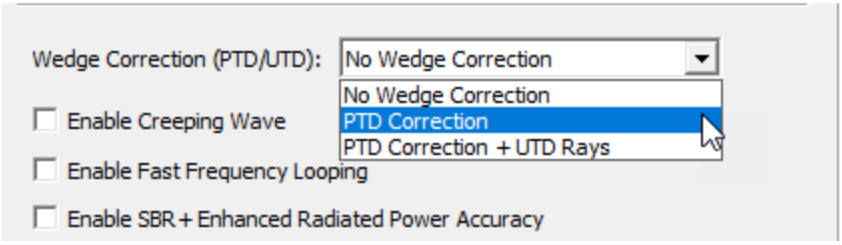


For Near Field rectangle setups, you can use the feature described in Overlay Contour Plot of Near Field on Rectangle.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Enable SBR+ Self Coupling computation capability for driven designs means that the diagonal S-param term takes into consideration the SBR+ scattering effect, and is more accurate. For a discussion of SBR coupling see, Select Tx/Rx Antennas for SBR+ Solutions.

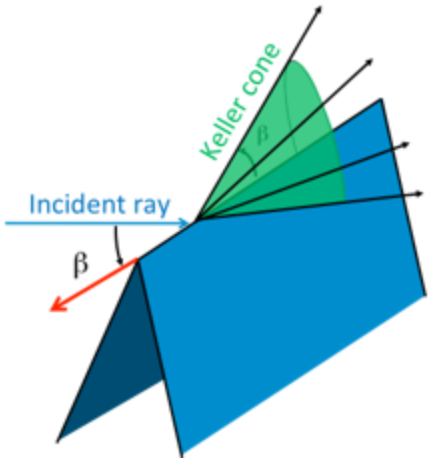
5. The PTD/UTD Simulation Settings allow for the inclusion of additional wedge diffraction phenomenology that can improve the accuracy of SBR+ simulations. You can opt out of using the PTD/UTD settings, or select PTD Correction or PTD Correction + UTD Rays. Selecting one of the PTD Correction options enables a field for specifying PTD Edge Density. This controls how densely wedges are segmented when establishing line of sight from the field source (for example, Tx antenna) to each wedge segment.



For SBR+ simulations, the Physical Theory of Diffraction (PTD) and Uniform Theory of Diffraction (UTD) features can account for additional phenomenology not well predicted by plain SBR due to truncation of uniform Physical Optics (PO) currents at sharp angular discontinuities (“wedges”) on metallic surfaces and blockage of SBR’s Geometrical Optics (GO) rays. PTD is a numeric correction to the scattered fields radiated by PO currents near wedges. UTD launches bundles of edge-diffraction rays from directly illuminated portions of each wedge along the Keller cone. Once launched, the UTD rays behave exactly like regular SBR rays, propagating according to GO and painting PO currents at each bounce that contribute to the scattered field. The UTD rays often illuminate portions of the SBR scattering geometry that are never reached by SBR GO rays launched directly

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

from the field source.



The PTD and UTD wedge features are only deployed for metallic wedges with line-of-sight visibility from the source (Tx) location. If either adjacent surface of the wedge is non-PEC and not within the tolerance for PEC-like, or if the entire edge segment is not visible to the source, the wedge will be ignored in the SBR+ simulation and for visual ray tracing (VRT).

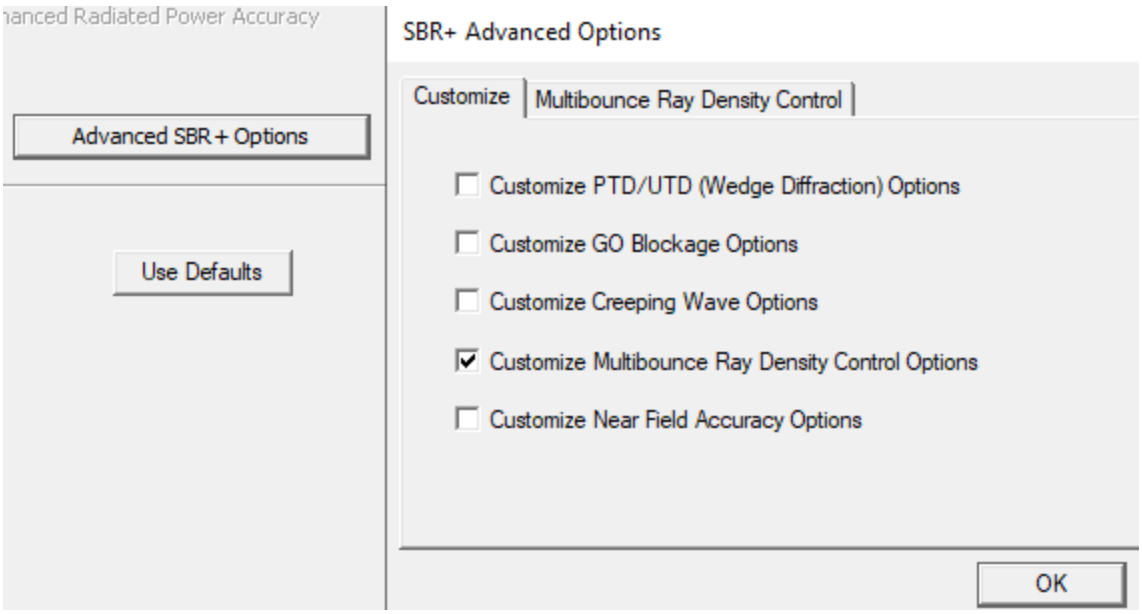
6. Advanced Option for NF Accuracy Settings for SBR+

The NF Accuracy settings (Beta feature, NF Accuracy Controls for SBR+) provide access to methodology settings relating to cases where Tx antennas, Rx antennas, and near-field observation points are in proximity to the scattering geometry (i.e., the platform CAD model). When this feature is switched off, HFSS SBR+ uses default near-field accuracy settings that should be adequate for most situations, including close-proximity Tx/observer conditions that this feature is designed to tune.

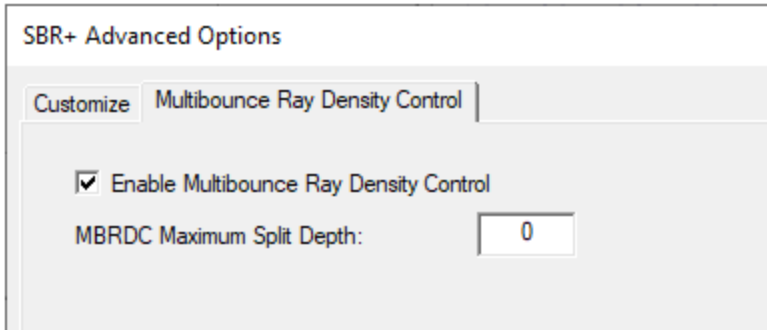
7. Advanced Option for Multibounce Ray Density

By option you can select the **Advanced SBR+ Options** and enable Customize Multibounce Ray Density Control Options.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can then select the **Multibounce Ray Density Control** tab.



Use the checkbox to **Enable Multibounce ray density** and enter the maximum number of subdivisions to be used in the solve. Enabling the feature may increase the solve time.

The **MBRDC Maximum Split Depth** field value increases the number of spawned ray tracks on each ray bounce. The MBRDC algorithm is designed to achieve the ray density per wavelength criterion at any bounce depth. If a footprint at depth *N* in a ray track does not satisfy the ray-density criterion, the MBRDC algorithm attempts a refined ray shoot from an earlier bounce, just for the ray in question. The size of the triggering footprint informs the level of refinement. If the refined shoot is not successful in achieving the desired footprint size, or new footprints are too large, the MBRDC algorithm attempts further, recursive refinements. The **MBRDC Maximum Split Depth** setting limits how aggressively the refinement algorithm is applied by specifying the maximum number of split recursions. For this reason, linear

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

increases in Maximum Split Depth can yield a geometric progression in the total number of rays shot and associated solution time.

When both MBRDC and UTD are enabled, first-bounce UTD rays and bright points on wedges are recomputed during the MBRDC splitting process, but only the original raytrack is rendered up to the 1st bounce. Similarly, length-based ray filters are applied to the original UTD initial ray track up to 1st bounce rather than using the information in the additional MBRDC tracks. This is a known limitation.

8. Advanced Option for Geometrical Optics (GO) Blockage

SBR+ normally applies a physical optics (PO) blockage model where blockage effects emerge from partial cancellation of the incident field by the scattered field. PO blockage not only occurs in connection with the incident field from the Tx antennas, but also within the scattered field itself when reflected fields from the previous bounce are diminished by a blocking surface along the geometrical-optics (GO) reflection path at the current bounce by evaluating the scattering contribution of the incident ray field at that bounce.

In cases of significant blockage by a large obstruction, the PO blockage model requires accurate currents over the extent of the obstruction. Sometimes, this is hard to achieve in the ray tracing approximation. For example, the obstruction may not be well illuminated by direct rays from the Tx antenna or multi-bounce rays after an earlier reflection. An alternative is to use a GO blockage model where scattered field contributions are added to an observation point subject to a line-of-sight (LOS) blockage check performed by the ray tracer. In some cases, this is more accurate than the default PO blockage formulation, while in others it is less accurate. GO blockage also entails a non-trivial computational cost, as the blockage check with the ray tracer must be performed for each observation angle (or point) for each ray hit point.

In addition to GO Blockage for SBR and UTD ray tracks, this feature is also available for PTD and CW.

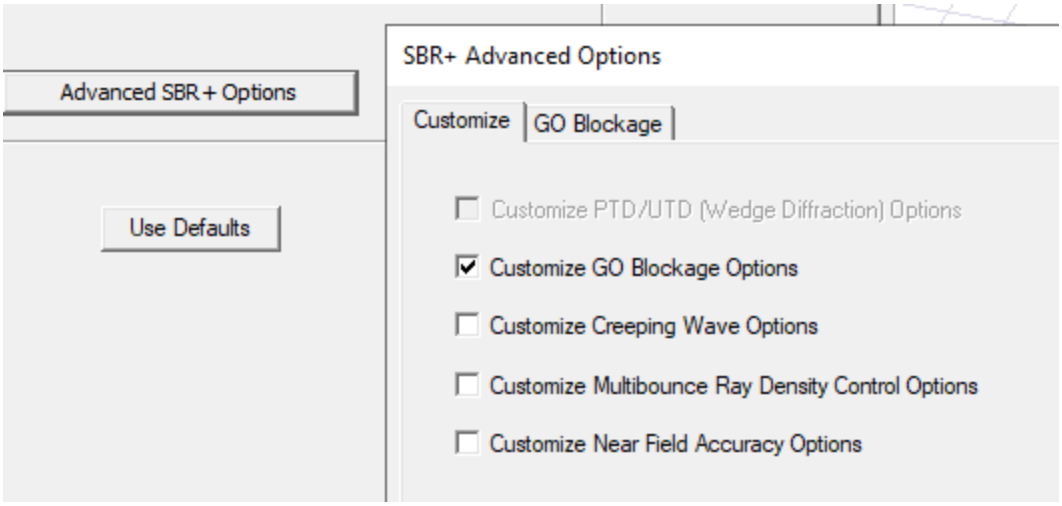
Limitations for GO Blockage:

GO Blockage formulation is suited specifically for SBR+ ray tracks, including UTD ray tracks. While GO Blockage for CW and PTD has been implemented for the first time in this release, results can be surprising and/or inaccurate, as a limitation of the methodology.

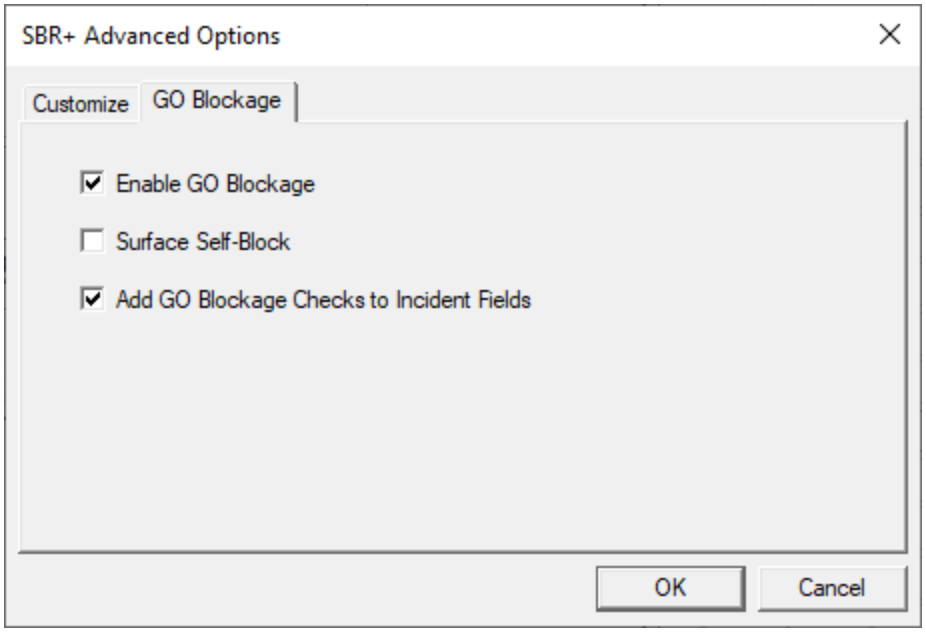
Summary Workflow for GO Blockage:

Click the **Advanced SBR+ Options** button to open the **SBR+ Advanced Options** window. On the **Enable** tab, Check GO Blockage Options to enable the **GO Blockage** tab.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



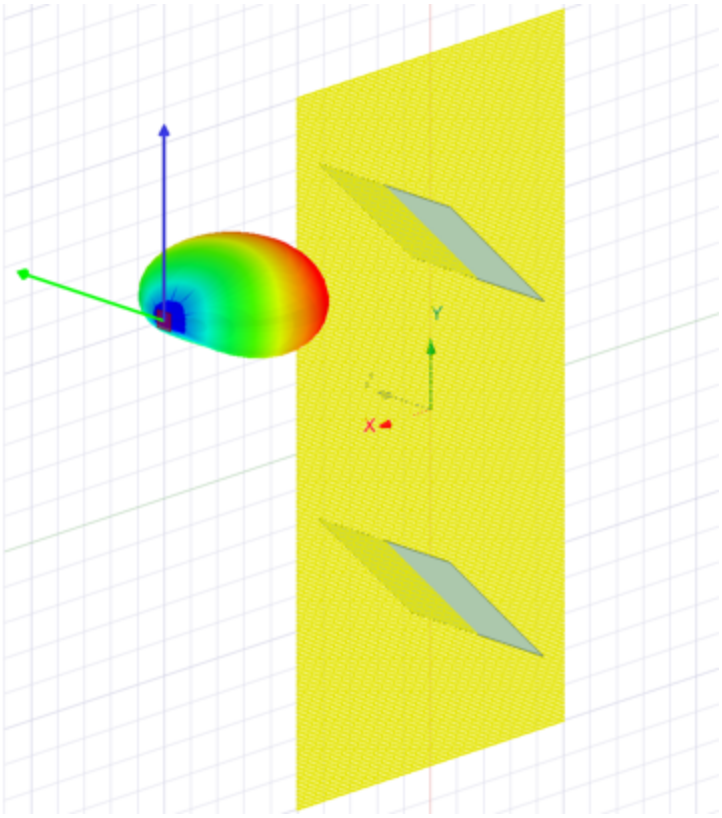
On the **GO Blockage** tab, you have check box options to enable or disable GO Blockage, Surface self-block, and GO Blockage Checks for Incident Fields..



Surface Self-Block: if enabled, the surface where the footprint is radiated from is used for blockage check, that is, anything below the surface with respect to the incoming ray is not in line of sight. If the setting is disabled, the footprint surface is not used for blockage checks (anything below the surface with respect to the incoming ray is in line of sight), but other surfaces are used for blockage.

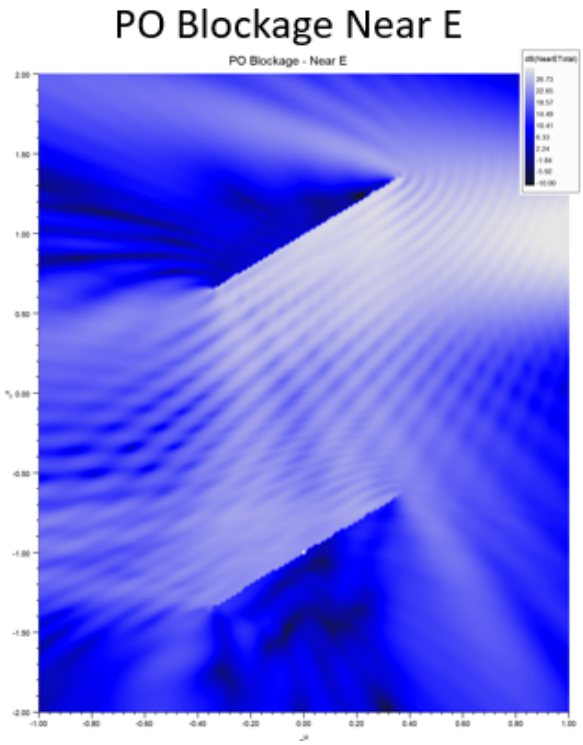
For example, consider a parametric beam antenna illuminating a series of plates.

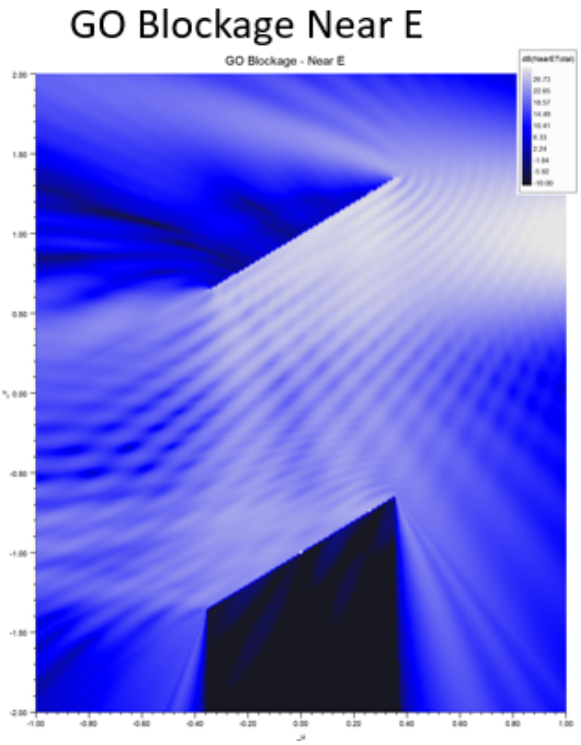
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In the plots, the shadows behind the plates are much more pronounced with GO Blockage enabled, but the fields have non-physical discontinuities.

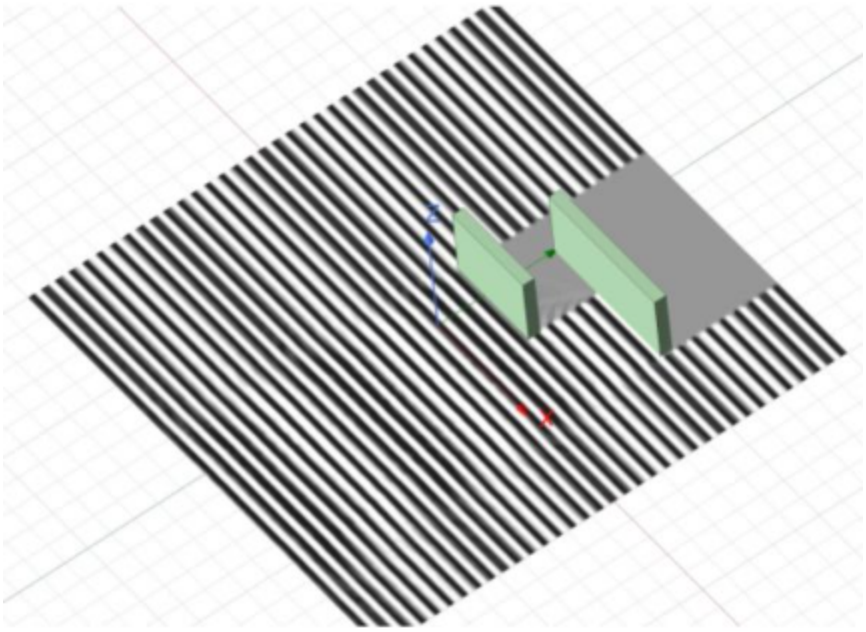
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



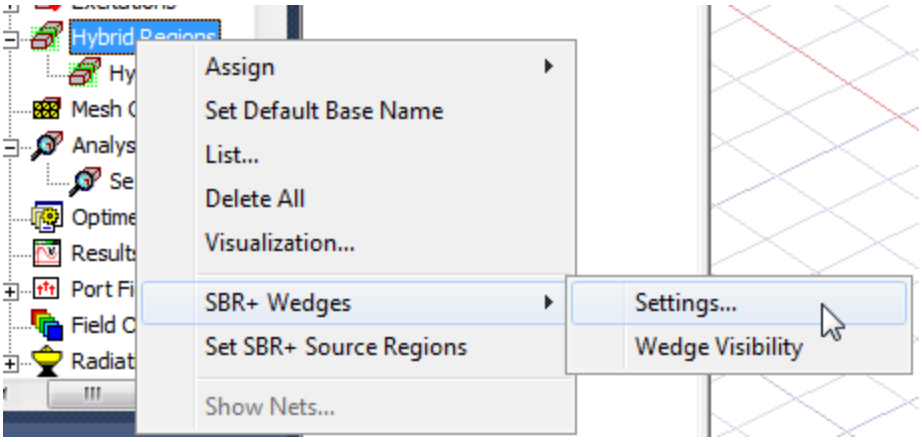


Add GO Blockage Checks to Incident Fields: if enabled, GO blockage effects will also be calculated for the incident field via line-of-sight checks from sources to field points, effectively computing a direct field in the Geometrical Optics sense. For example, the figure below shows the total E-field of a planewave incident on PEC bodies with this option enabled.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



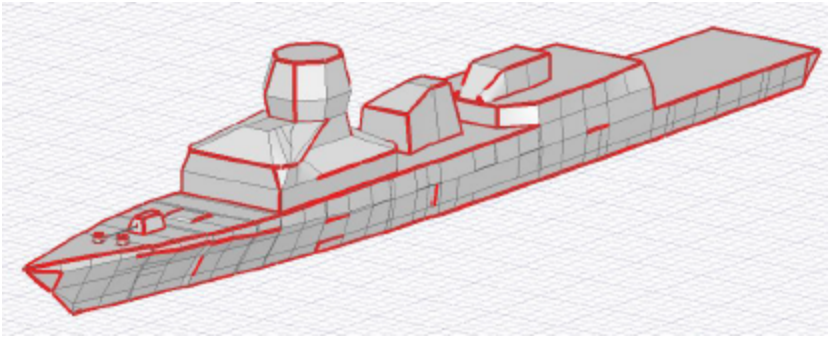
9. Wedge settings for the SBR+ simulation with PTD/UTD are only accessible for an SBR+ design. Wedges are based on theAutomatic Wedge Generation settings, optional Interactive Wedge Editing, and the initial mesh. The initial mesh is automatically generated on launch of the SBR+ Wedge Settings dialog box, if needed. The dialog will not launch if an initial mesh is not available and cannot be generated. The **SBR+ Wedge**s submenu can be accessed through a right-click the Hybrid Regions icon in the Project tree.



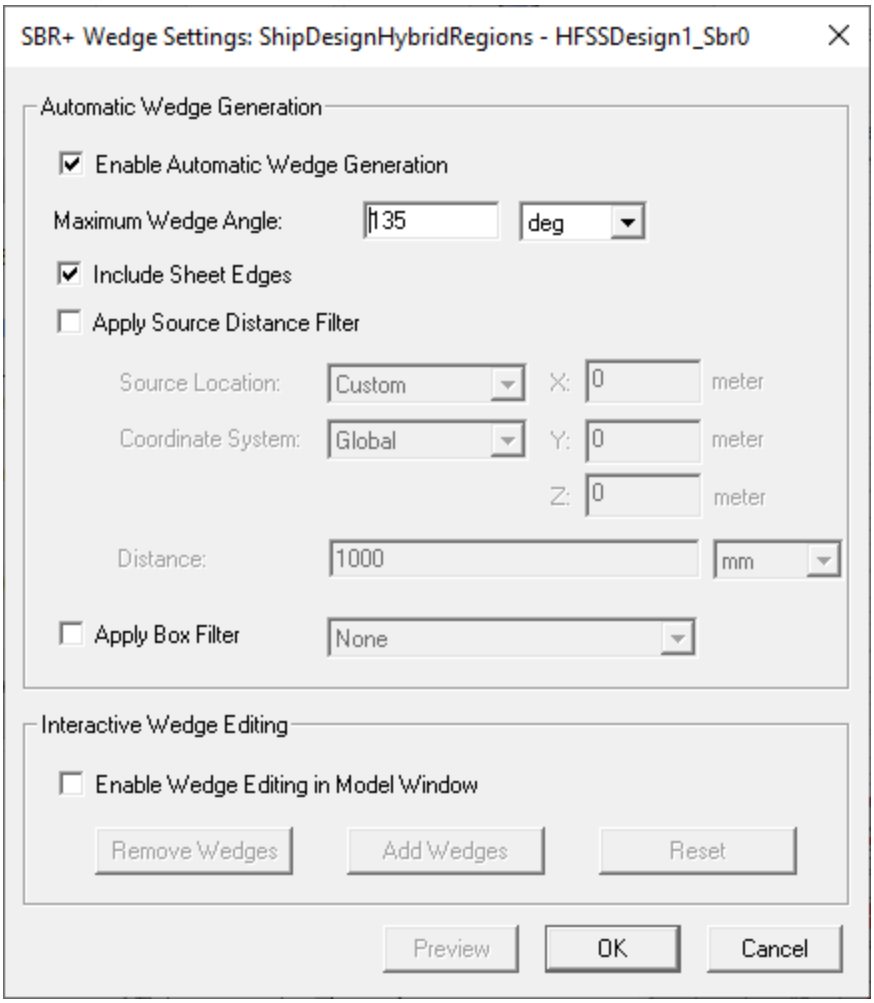
The submenu contains the option for opening the **SBR+ Wedge** > **Settings** dialog box and a checkable option for enabling or disabling **Wedge Visibility**. If visible, wedges are shown as thick red lines in 3D model window for automatically generated wedges, and as

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

blue lines for interactively edited wedges. Visualization is turned off when there is design edits that invalidate the initial mesh.



The **SBR+ Wedge Settings** dialog box contains the Automatic Wedge Generation parameters and the Interactive Wedge Editing feature.

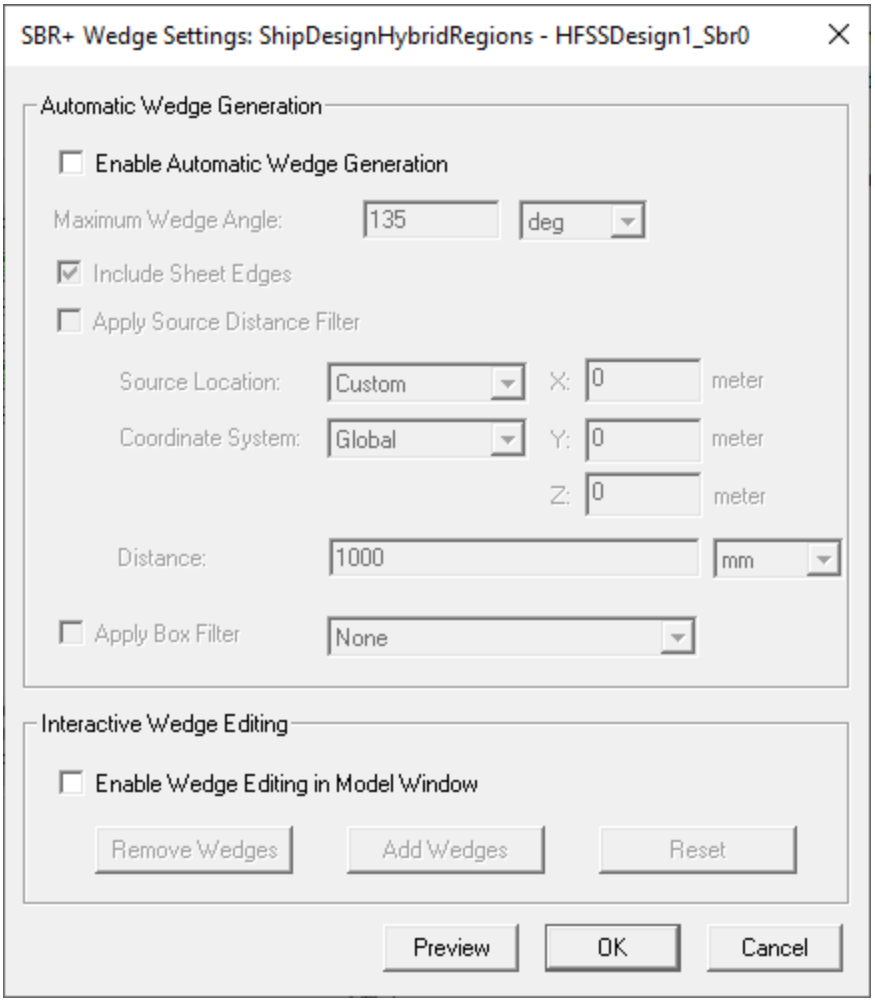


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Wedge Generation parameters are used to determine the candidate set of wedges to be included, with optional filters that can restrict their location on the geometry. The final set of wedges to be used in the SBR+ simulation is the intersection of all the wedge generation criteria, and the effects of any optional Interactive Wedge Editing. complete flexibility in specifying where the wedges are to be used for the simulation. This is important since adding many wedges on very large geometry structures (aircraft, vehicles, etc.) can significantly impact the SBR+ simulation time.

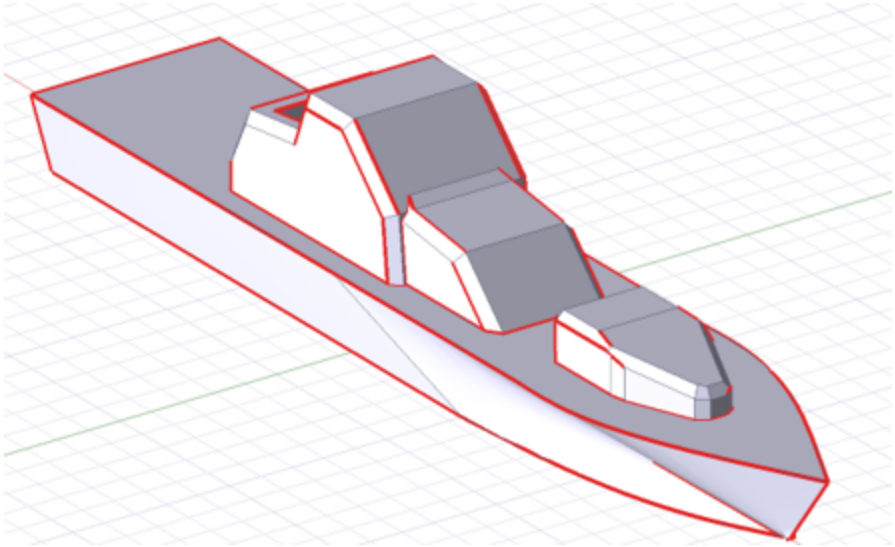
Enable Automatic Wedge Generation.

By default, the checkbox is enabled, allowing access to the automatic features and parameters. If you un-check it, the automatic features are disabled. You can independently enable Wedge Editing.



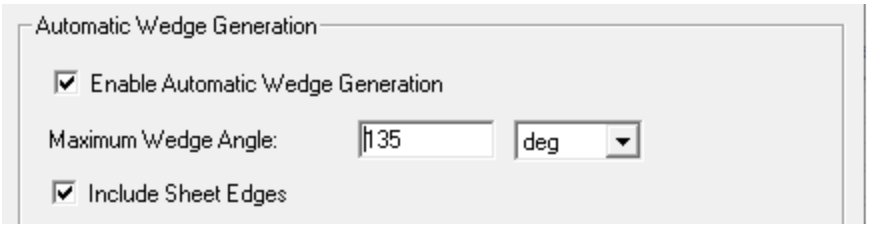
Wedges added through Automatic Wedge Generation are displayed in red.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Maximum Wedge Angle:

An angular criteria can be specified for the maximum wedge angle to help filter the desired set of wedges - default value is 135 deg. This wedge angle ranges from minimum 0 deg to maximum 180 deg. All wedges are included that are less than or equal to the specified maximum angle. An angle equal to 0 deg would be created by a “collapsed” wedge (like a closed hinge), while an angle equal to 180 deg would be created by a completely “open” wedge (like a fully open hinge). You can assign a design variable to Maximum Wedge angle, but you cannot create a design variable within the dialog.



Include Sheet Edges:

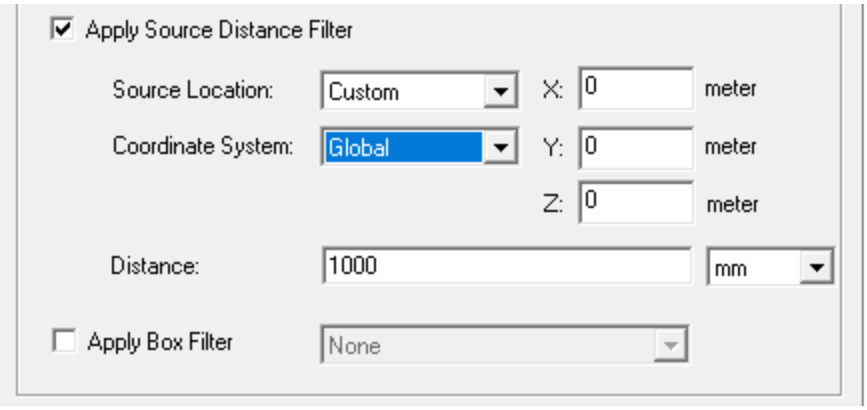
You can choose to include or exclude the edges from sheets (non-connected edges, also known as “knife edges”). The default value is true which includes these edges. Sheet edges are triangle edges with no adjacent/connected triangle along that edge. In the physical object we are modeling these may represent extremely thin surfaces such as metal “fins”, etc.

Optional parameters:

Apply Source Distance filter:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A “source distance filter” allows you to specify that you want to include wedges within a finite 3D distance from a point (the “source”).



You can choose model Points from drop down as source location, or specify the absolute X, Y, Z in model units. X, Y, Z can be specified in global coords or relative to a custom CS. When you select a geometry Point, its coordinate system and X, Y, Z are displayed.

The Distance default is 1 <model unit>. You can assign an existing design variable to the Distance. Default value is false (no Source Distance Filter).

Apply Box Filter:

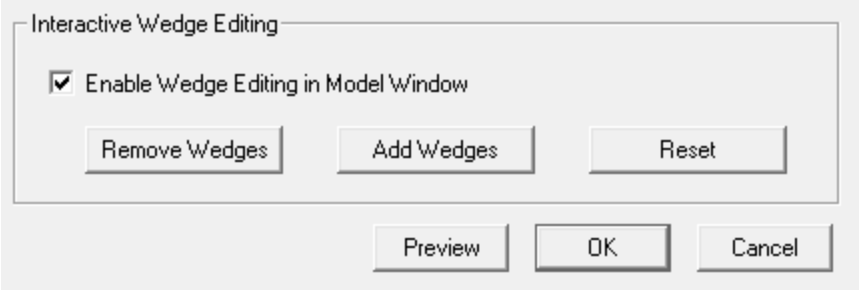
You can select any non-model box that is aligned with the Global Coordinate System axes via a drop-down menu, within which wedges will be included. Default value is false (no Box Filter).

Optional Interactive Wedge Editing

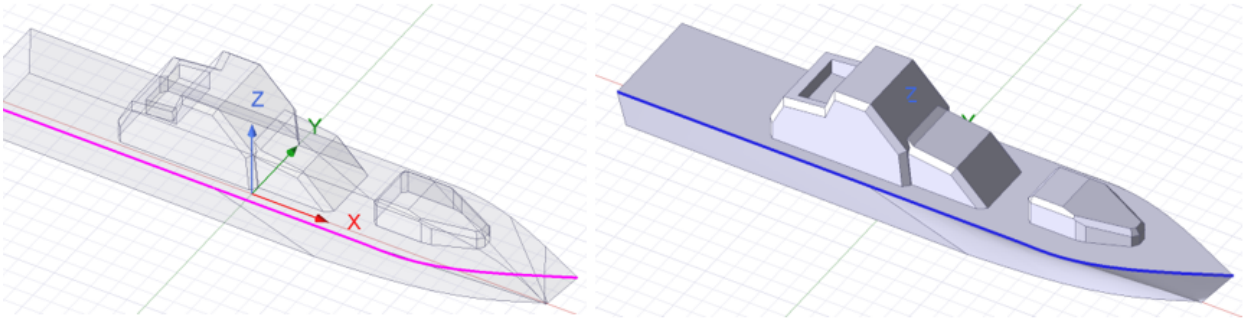
This feature provides complete flexibility in specifying where the wedges are to be used for the simulation. This is important since adding many wedges on very large geometry structures (aircraft, vehicles, etc.) can significantly impact the SBR+ simulation time.

Checking the Enable Wedge Editing the Model Window box enables the buttons for removing wedges from selected geometries (faces, objects, etc.) , adding wedges to selected geometries, and resetting edits.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



After you select a geometry and **Add Wedges**, the interactively added wedges appear in blue.



If you select **Remove Wedges**, all wedges on the selected geometry objects are removed. These can be automatically generated wedges or interactively added wedges.

Click **Reset Wedges** to undo all interactive wedge editing operations. A confirmation dialog appears. Press Yes to reset all wedge editing operations. The reset button is disabled if no wedge edit operations are present.

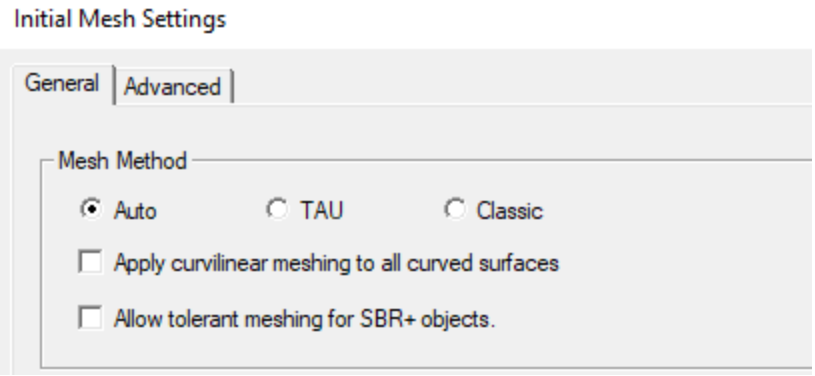
Current Limitations on PTD/UTD Wedge Generation/Editing

Situations where wedges cannot be generated:

Light Weight Imported STL Geometries: STL models imported as light weight geometries are currently not supported for interactive wedge editing (as of R24.1).

In the Initial Mesh Settings for SBR+ Solution type or for HFSS with Hybrid and Arrays that include SBR+ regions, you can turn off tolerant meshing.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In this case you should consider Current Limitations on PTD/UDT Wedge/Generation Editing.

Configure Simulation with SBR+ Antenna Geometry Blockage (HFSS with Hybrid and Array Solution Type):

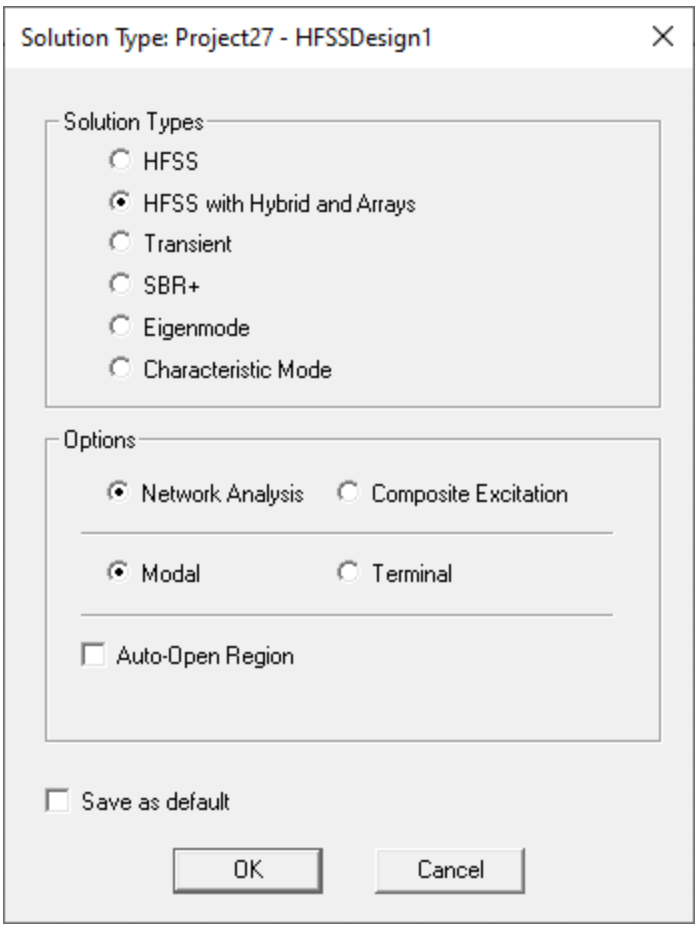
The typical configuration begins with a fully integrated model with all geometry. You then select the near antenna region including any nearby geometry interacting with the antenna for analysis by HFSS – either by identifying these objects by hybrid region assignment, or by copying them out to a separate source antenna design to be solved with the HFSS solver, etc. The nearby antenna geometry could even be something different than what is used for the integrated model, such as a flat plate or other structure for considering the nearby antenna interactions. This source antenna design should likely be enclosed in a FE-BI region to allow for easier downstream processing, whether we are in a Hybrid or SBR+ solution type. If you use a separate source antenna design, you can re-introduce it to the target design with the full geometry model by creating a 3D component for an antenna that is a linked design to the source design. This means you no longer need to designate any “Model Blockage” when setting up the linked design. You do this as a separate step outside creation of the linked design by selecting geometry from the SBR+ region to be designated as “Model Blockage” associated with a particular source antenna. Note there is no restriction on what objects and/or materials can be designated as “model blockage” geometry. Also note that for either solution type, SBR+ or hybrid HFSS-SBR+, that this selection will be from the available SBR+ region geometry objects, which is different than the previous workflow. Once you select these antenna blockage geometries for each source antenna, HFSS with SBR+ can solve the combined target SBR+ design.

You can also specify HFSS Hybrid solution type with SBR as a source for a target SBR+ design as a far field linked design with antenna blockage support. In such cases, you can optionally configure antenna blockage settings in the source design. You must solve the design before you can link it to the SBR+ target design. You cannot link a Hybrid solution type with with SBR+ regions source design to a target HFSS design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The preferred work flow is this.

1. Create/open an design with HFSS with Hybrid and Arrays solution type.

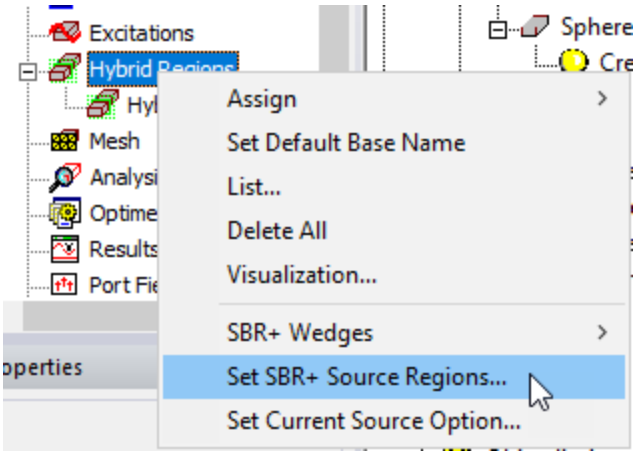


2. Configure the source excitation, including adding or creating any nearby geometry.
3. Create a hybrid FE-BI region to enclose the source excitation and all the nearby geometry objects to be part of the HFSS simulation.
4. Add all the additional geometry objects that will be part of the hybrid analysis, configuring all materials/boundaries as desired.
5. Create/assign a hybrid SBR+ region to all the desired geometry objects to the design.
6. If you want to designate multiple SBR+ geometry objects as blockage, select them in the 3D Modeler window and create an object selection using **Modeler** > **Named Selection** > **Create** > **Object Selection**. You may want to name the selection appropriately. If only a single object is to be designated as a geometry blockage, skip this step.

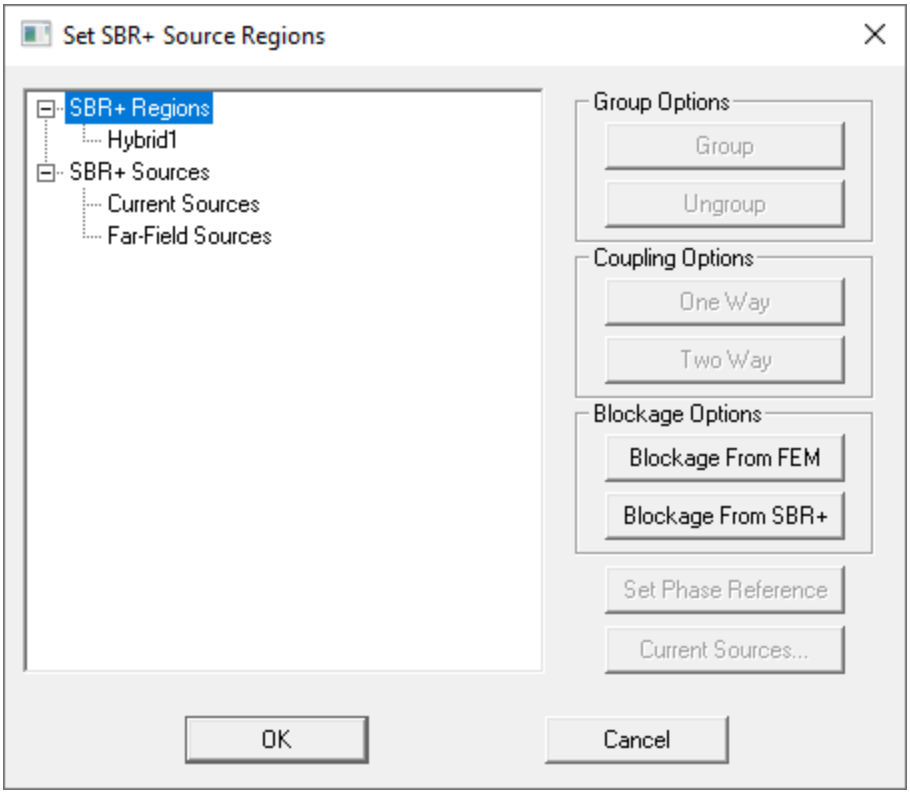
   Only object selections that contain exclusively SBR+ can be selected for antenna blockage.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7. Open the dialog to configure SBR+ source regions (which includes antenna blockage) via the menu option for **Hybrid Regions** > **Set SBR+ Source Regions...**.

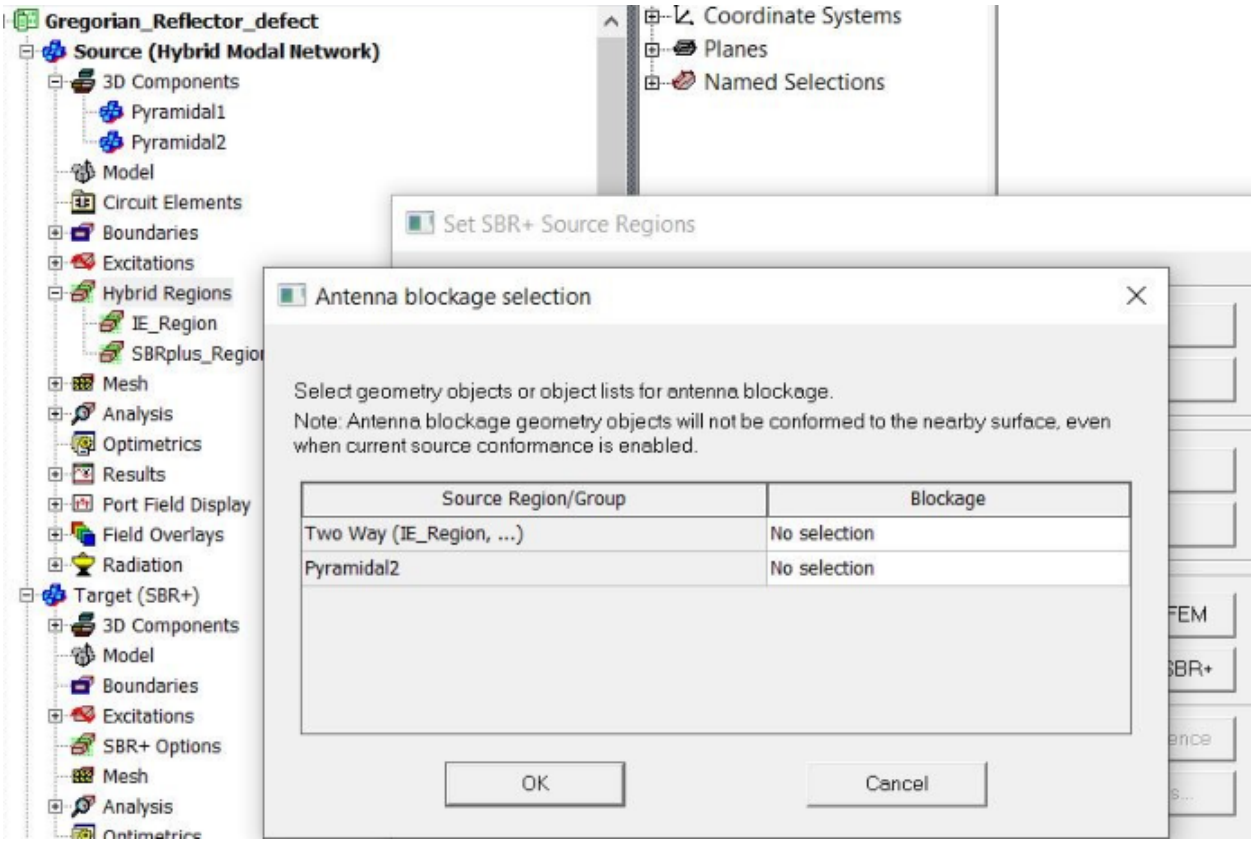


This opens the **Set SBR+ Source Regions** dialog box:



Click the **Blockage from SBR+** button to bring up the antenna blockage dialog box:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

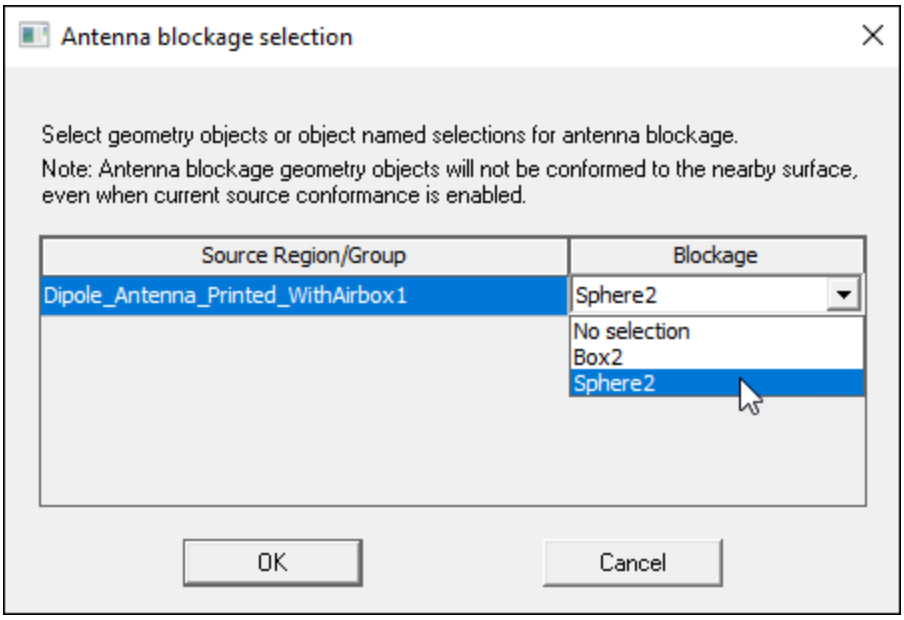


8. (Optional) Configure antenna blockage settings in the source design. Both blockage dialogs (FEM and SBR+) can be used concurrently.

   For each antenna source, use the “Blockage" column to select the geometry blockage from the drop-down. Each cell in the column contains a drop-down list of all geometry

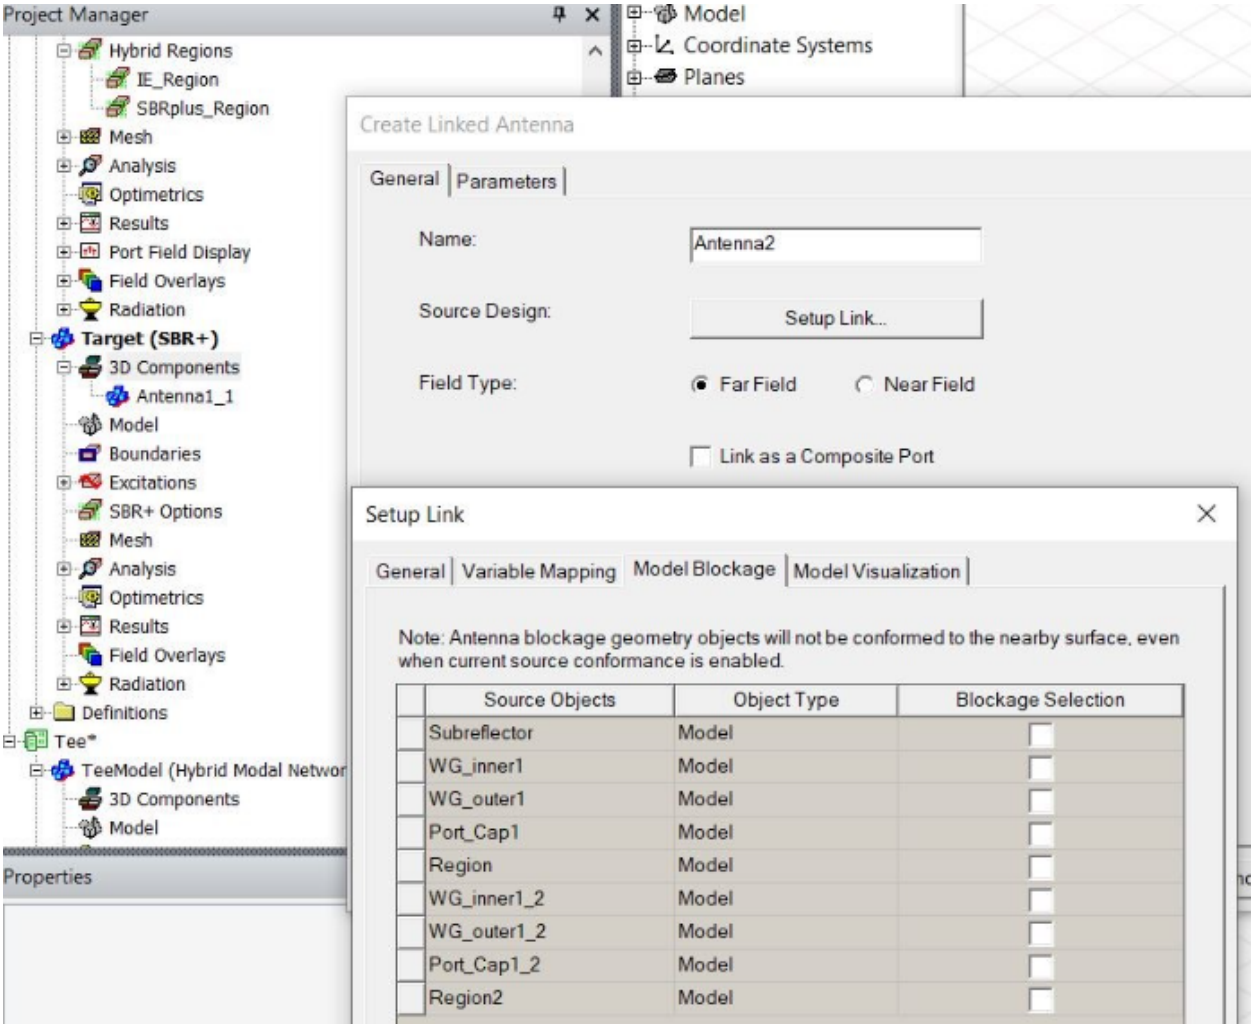
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

objects and all user-created object selections.



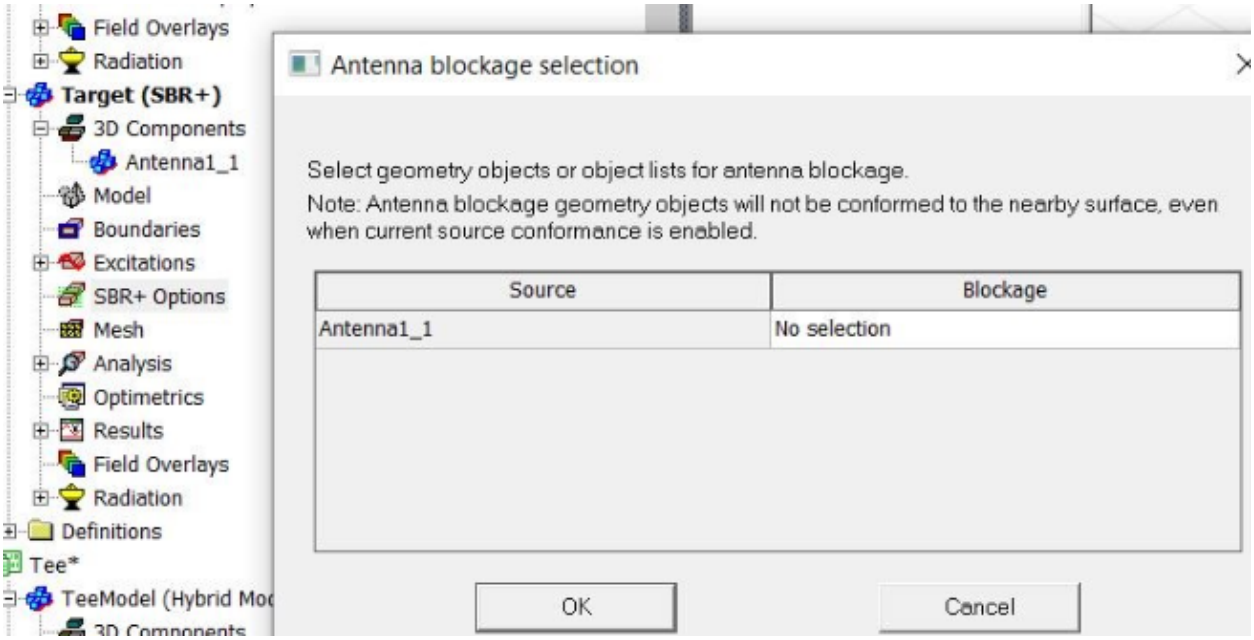
9. Click **OK** to save the configuration.
10. Create an **Analysis Setup**.
11. Run the simulation.
12. For Hybrid Solution type with SBR+ as a source for an HFSS SBR+ design (the target design), create an antenna link to the source design. Only far field links are currently supported. Source designs with multiple FEBI regions and blockage selections are not supported.
13. (Optional) Configure antenna blockage settings in the link dialog. SBR+ region objects from the source design should appear in the object list. Objects selected for blockage in the source design will be selected in the link blockage dialog by default.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

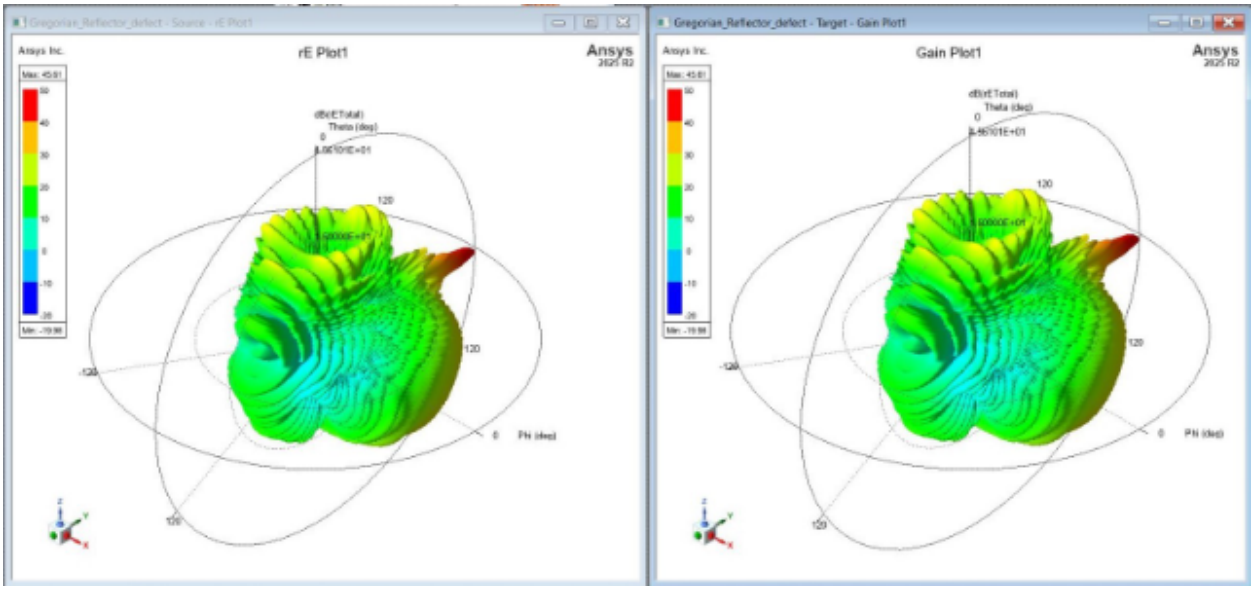


14. (Optional) Configure antenna blockage settings in the target design antenna blockage dialog. These selections will work together with the link dialog blockage selections.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



15. Analyze target design and inspect results. The incident field shown in the target design should match the total field of the source design.



Assigning a Dielectric Cavity

To assign a region as a Dielectric Cavity, the object must have a dielectric material assignment. The Lambda refinement setting in the Solution Setup is ignored in a dielectric cavity. Two

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

dielectric cavities can be in contact.

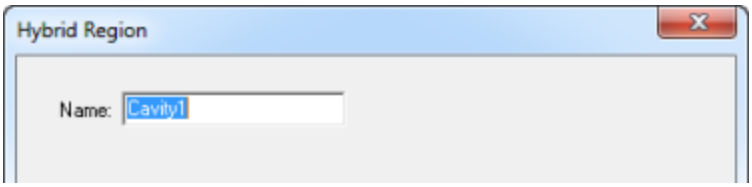
1. Select the object you want to assign as an Dielectric Cavity, and use one of the following menus:

   HFSS>Assign Hybrid>Assign>Dielectric Cavity

   Right-click in the Modeler window and select **Assign Hybrid>Dielectric Cavity**.

   Select the Hybrid Regions icon in the Project tree, right-click, and click **Assign>Dielectric Cavity**.

   The **Hybrid Region** dialog opens.



2. When you OK the dialog box, the assignment appears in under Hybrid Regions icon in the Project tree.

Set Coupling for Hybrid Regions

The **Set Coupling** Command for Hybrid Regions opens a menu that lets you specify one-way, two-way or advanced region coupling. Two-way coupling is the default for all HFSS designs, and fully models the field interaction between regions. One-way coupling includes propagation from source to target regions, and a single bounce of interaction between all regions. This is more efficient than two-way coupling, but also more accurate than traditional one-way links. The Advanced command on the **Set Coupling** menu lets you place regions in two-way coupled groups in a design that is otherwise one-way coupled..

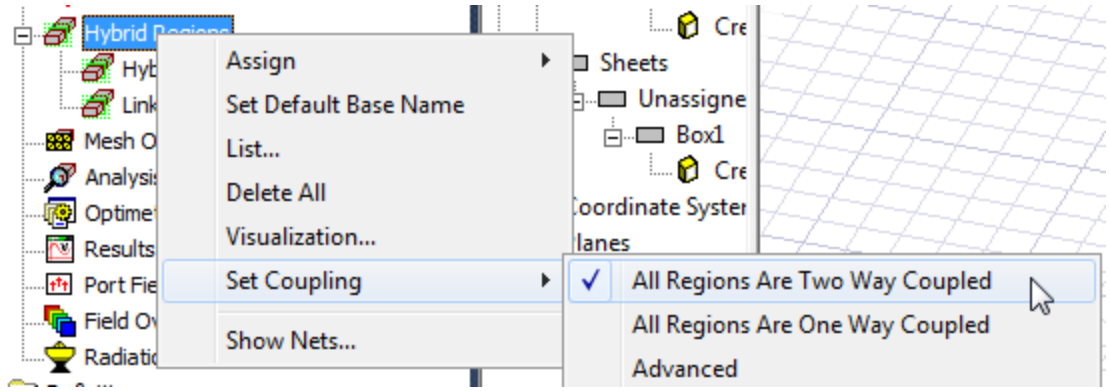
In some cases the coupling between regions is restricted:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Two-way coupling is always used for:
  - Regions of the same mesh type that are in contact:
    - Contact between FE-BI / Dielectric Cavity regions
    - Contact between IE/PO Regions
  - Physically separated objects that are part of the same region assignment, for example, two boxes that don't touch, but are in one FE-BI region
- One-way coupling is always used between:
  - Linked regions and all other regions
- Designs containing SBR+ regions will always be set to All One-Way and the Set Coupling menu will be replaced by the **Set SBR+ Source Regions** command. Non-SBR+ regions will serve as sources, and interact with each other through the SBR+ regions.

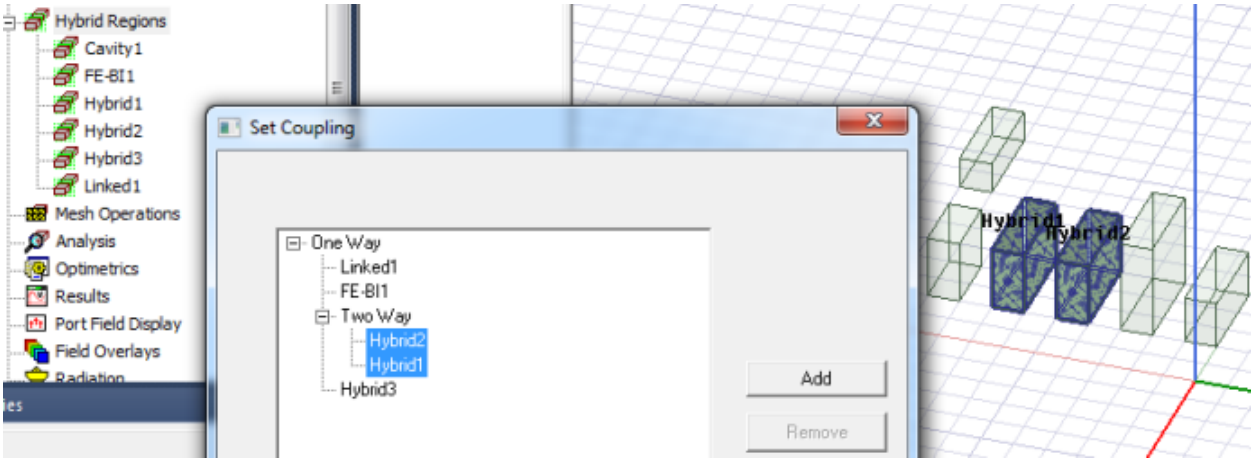
These restrictions are either enforced by design validation or implicitly handled by the solver.

The Set Coupling menu appears in the right-click menu of the Hybrid folder at the project tree and at the **HFSS>Hybrid** menu.

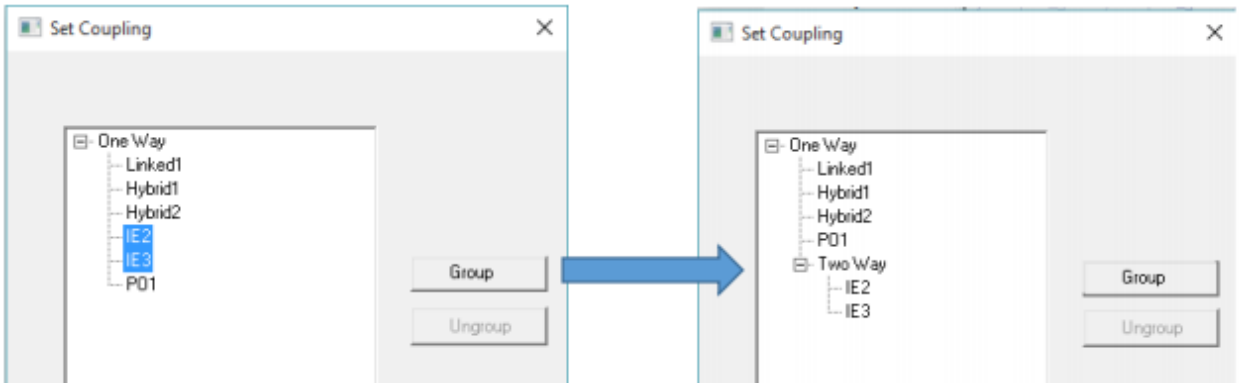


Selecting **Set Coupling>Advanced** opens a **Setup Coupling** dialog setup that lists the coupling settings of all the hybrid regions in the design. Any Selected regions in this dialog are highlighted in the view window. You can edit groupings (as shown below) but remember that editing groups invalidates existing solutions.

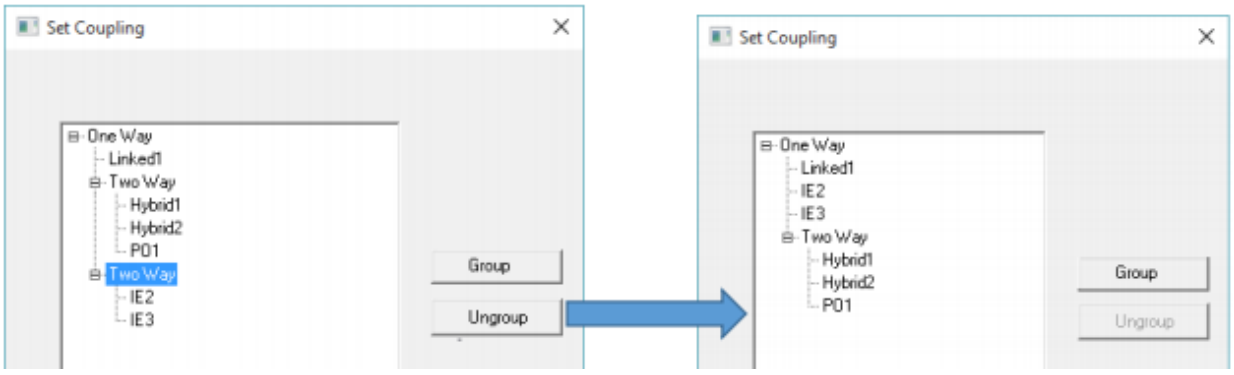
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can add a Two Way coupling group by first selecting the regions to be coupled and then click **Group** and Ok.



You can un-group a Two Way Coupled group by selecting it and clicking **Ungroup** and clicking Ok.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

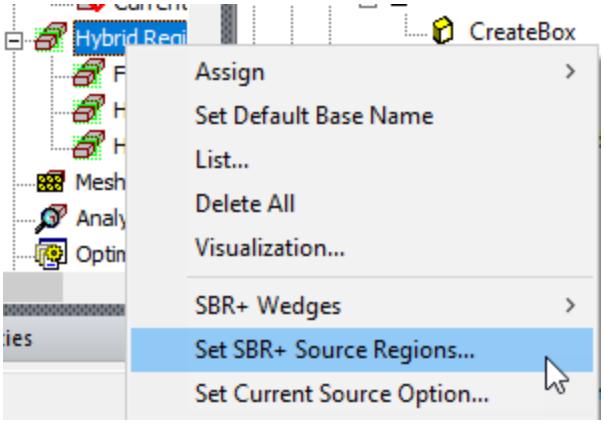
You can also edit grouping by dragging and dropping from one group to another. On Ok, any empty Two Way groups are automatically removed. You will be asked to fix the coupling if you have a Two Way group with only one region.

Set SBR+ Source Regions

The **Set SBR+ Source Regions** Command for Hybrid Regions opens a dialog that lets you group source regions for SBR+. Designs containing SBR+ regions will always be set to All One-Way and the **Set Coupling** menu is replaced by the **Set SBR+ Source Regions** command. Non-SBR+ regions will serve as sources, and interact with each other through the SBR+ regions. All source regions interact as one-way links to SBR+ and coupling between the source regions are handled by SBR+ using reciprocity theory.

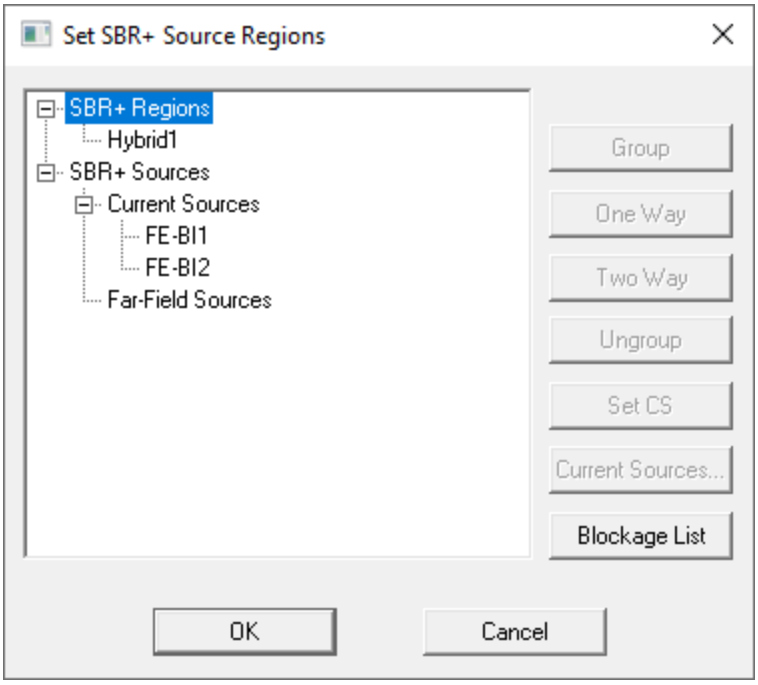
> **Note:** The result using far field source option for SBR+ region is sensitive to the phase reference defined when the excitation is close to the SBR+ Region. Phase reference needs to be carefully adjusted to obtain reasonable result.

The **Set SBR+ Source Regions** command appears in the right-click menu of the Hybrid folder at the project tree and at the **HFSS>Hybrid** menu if an SBR+ Region is assigned.

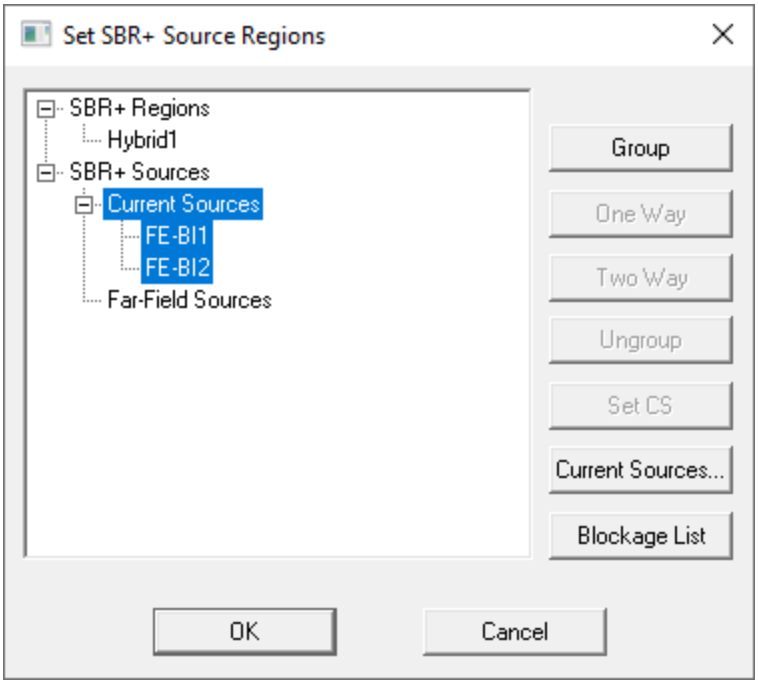


Selecting **Set SBR+ Source Regions** opens a **Set SBR+ Source Regions** dialog that lists the SBR+ Regions and the SBR+ Sources in the design. If the design includes an Incident Wave excitation, you see a message that such designs do not support advanced coupling. However, designs with Current Sources and Far Field Sources will be listed in the dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

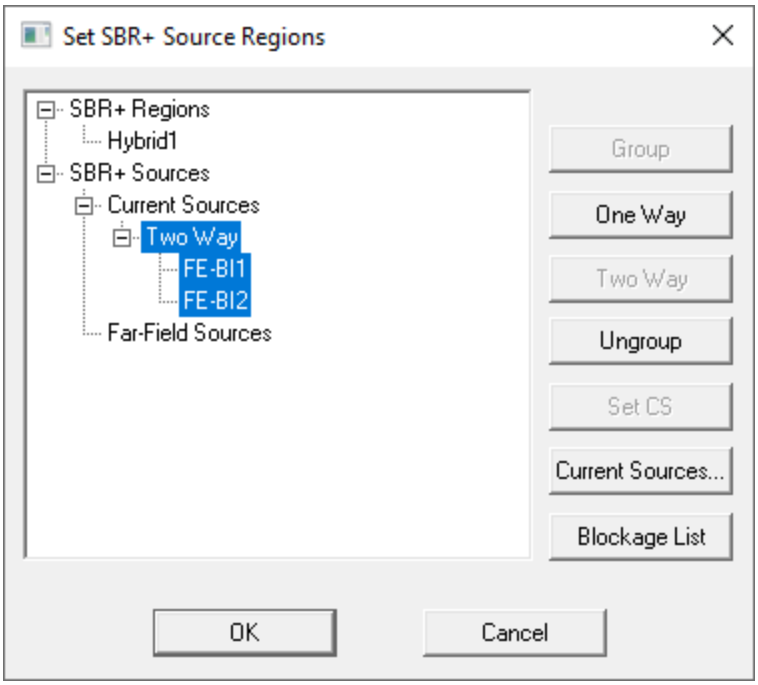


Any Selected regions in this dialog are highlighted in the view window. You can edit groupings (as shown below) but remember that editing groups invalidates existing solutions.



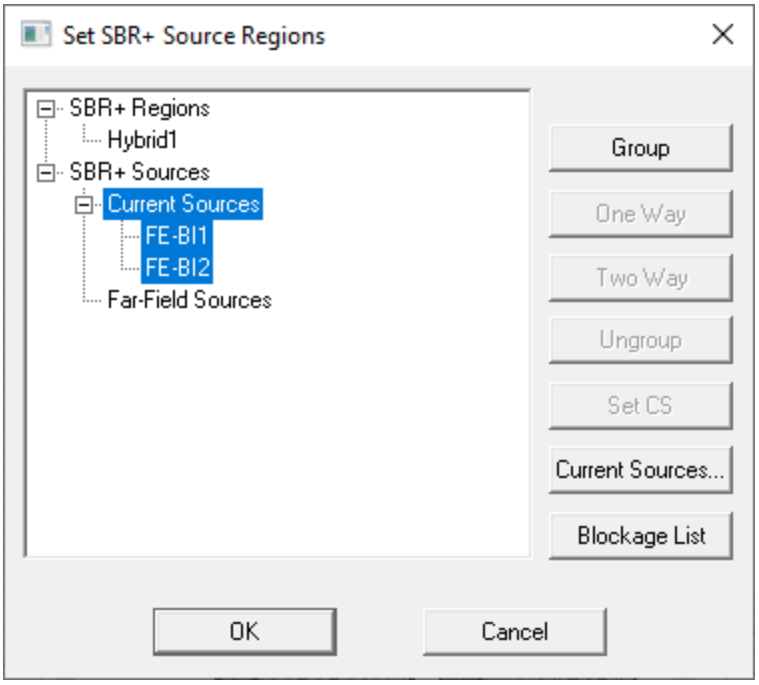
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Selecting one or more sources enables the **Group** button provides a means to designate two-way couplings within a group. The regions so grouped are assigned Two Way coupling. The **One Way** button is enabled so that you can change their assignment as One Way couplings. The **Ungroup** button lets you remove coupling groupings.



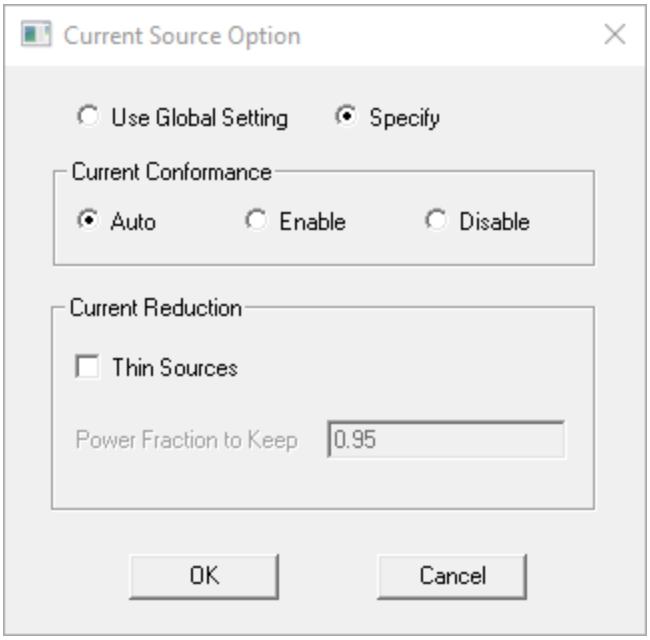
If the design includes Current Sources or Far Fields, these are listed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Clicking **Current Sources...** pops up the **Current Source Option** dialog that allows you to customize current-source conformance and thinning behavior for the Current Sources region(s) that is currently selected under SBR+ Sources. In this dialog, **Use Global Setting** is selected by default; in this case, the settings configured in the global-defaults version of the **Current Source Option** dialog are adopted. If you instead select Specify, then settings for Current Conformance and Current Reduction become enabled and allow configuration that is specific to the Current Sources region(s) selected in the parent dialog. The behaviors and intended usages for these features are further explained in the HFSS Technical Notes for Excitations for SBR+ and Current Conformance and Array Conformance in SBR+.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Current Conformance Settings

For ground-plane backed sources you intend to conform to an SBR+ region, you should place them very near the metallic surface of the SBR+ region to which they will be conformed, and this should be a high-conductivity metal surface or Perfect E boundary. While the conformance algorithm is designed to handle imprecise vertical placement of the source, one should strive to precisely place the source on the intended surface point of the SBR+ region. Also, the conformance algorithm has no ability (or knowledge) to compensate for imprecision in the horizontal placement of the source. Here, “vertical” and “horizontal” mean perpendicular and parallel to the SBR+ region placement surface, respectively.

In the case of sources enclosed by FE-BI boundaries, you should also place a Perfect E infinite ground plane on the FE-BI face nearest the placement surface of the SBR+ region. This ground plane serves two purposes. First, when the source is solved separately and in isolation from the SBR+ region (i.e., in a one-way coupling context), it will experience a grounding environment that best represents the presence of the metallic SBR+ region. Second, this ground plane establishes the reference plane against which current source original heights are measured. When conformance shifts the current sources down toward the SBR+ region placement surface, it will maintain these original heights relative to each underlying point on the SBR+ region placement surface, as explained and illustrated in Current Conformance and Array Conformance in SBR+. Also, when the current sources are generated along the FE-BI faces from their fields during the SBR+ component of the analysis, no current sources will be generated along this ground-plane surface, nor are they required.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

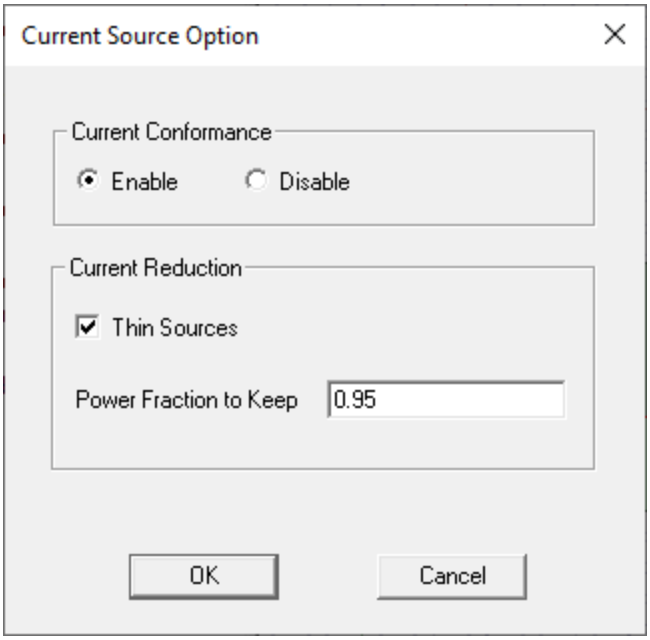
The options for Current Conformance are Auto, Enable, and Disable. When set to Disable, conformance is switched off and neither the absolute nor relative positioning of current sources of the SBR+ source are altered.

When Current Conformance is set to Enable, HFSS will attempt to conform the current sources of the ground-plane backed SBR+ source to the nearest surface of the SBR+ region, even in cases where the SBR+ source is far displaced from any SBR+ region. Only select this option when the source defined by current sources is a ground-plane backed antenna that is intended to sit atop and conform to a metallic surface of the SBR+ region.

When Current Conformance is set to Auto, the recommended and default setting, HFSS will automatically determine whether the SBR+ source is a good candidate for conformance. The qualifying criterion is that the source be placed within a small tolerance separation from the nearest SBR+ region surface, this tolerance being determined as one-twentieth (1/20) of the diagonal displacement of source's bounding box. In addition, in the case of a source enclosed by FE-BI boundaries, if none of these faces is assigned a Perfect E infinite ground plane, Auto conformance will automatically insert one on the FE-BI face nearest the SBR+ region.

Current Reduction Settings

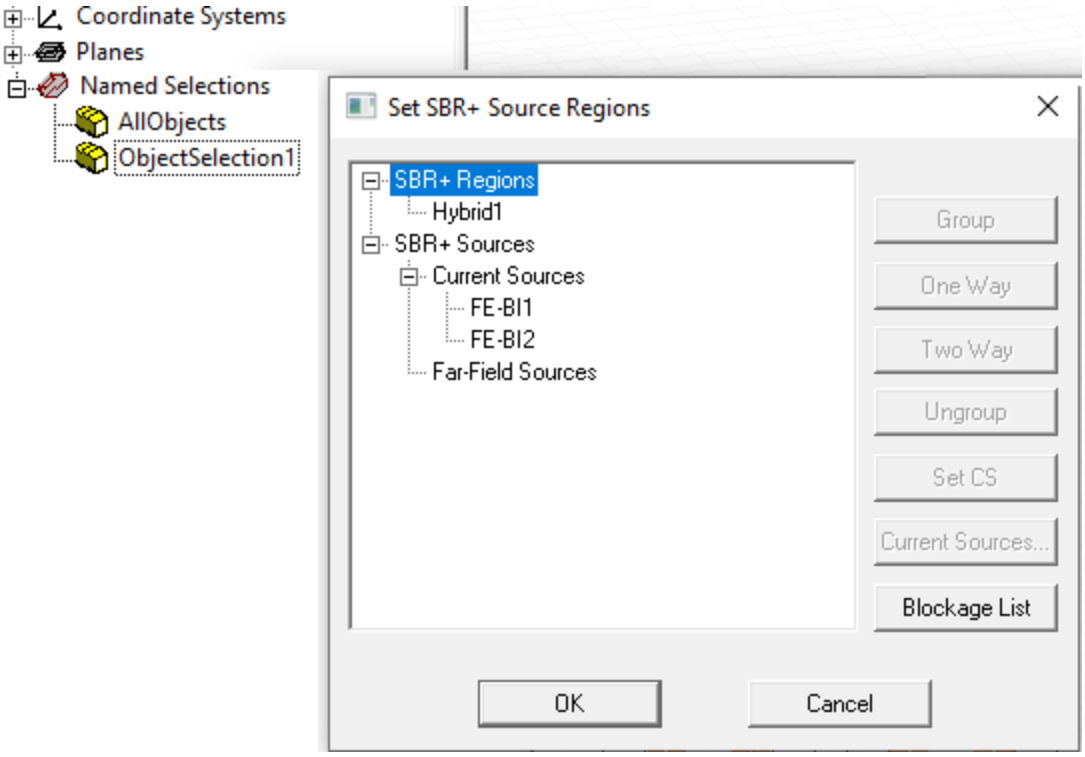
Enabling Thin Sources lets you specify a Power Fraction to Keep between 0 and 1, with lower values implying more thinning, faster solutions, and less accuracy; setting this below 0.9 is not recommended due to the potential excessive accuracy loss. Power Fraction to Keep should not be confused with directly controlling the fraction of current sources to retain; for SBR+ sources with a large number of current sources (e.g., a large FE-BI antenna), substantial thinning far exceeding 10% can be achieved with Power Fraction to Keep set at 0.9 or higher.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

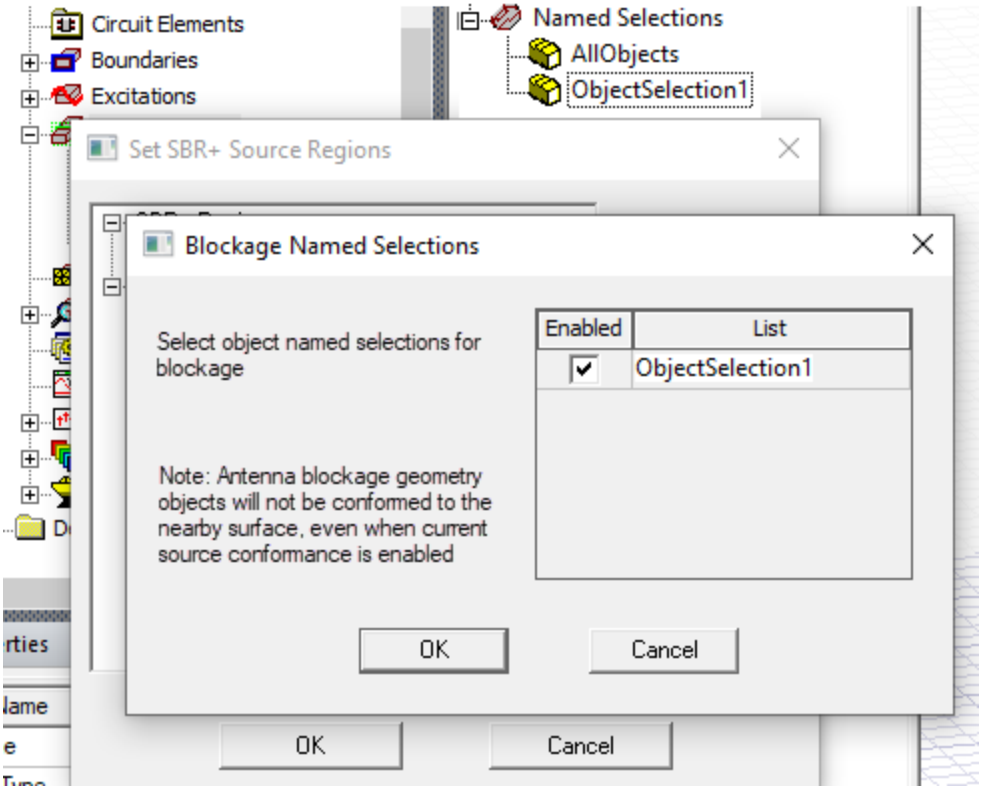
Blockage List for SBR+ Source Regions

The **Blockage List** button opens a dialog that lets you view blockage lists. Blockages are allowed when an SBR+ region exist in driven modal and terminal designs. You can easily define an object selection for simulation, and automatically assign blockage structures for each antenna.



Click the **Blockage List** button to open a table of available ObjectSelections. Such lists must contain at least one conducting object and have no SBR+ Regions. Enable those lists to treat the objects as blockages.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

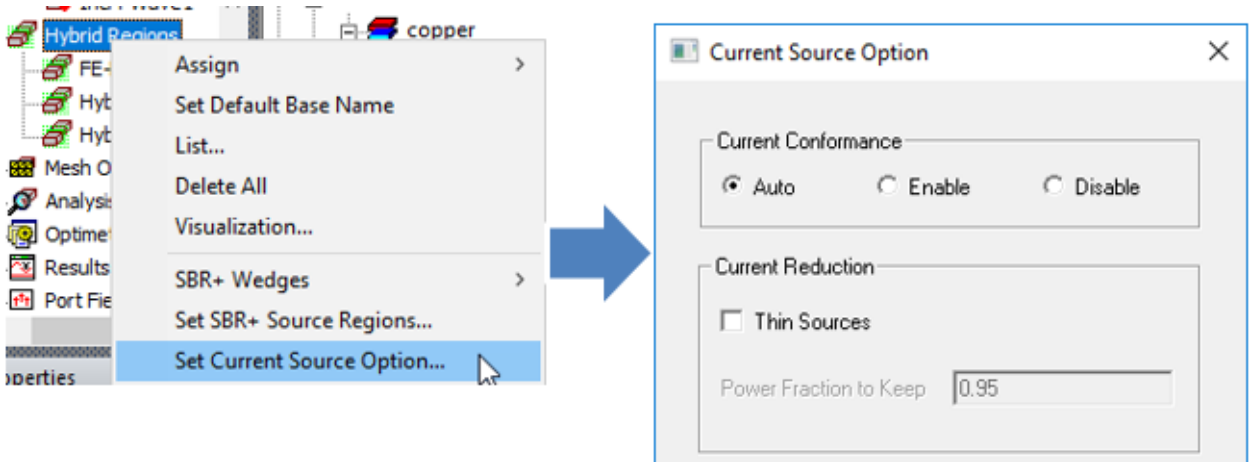


Set Current Source Option

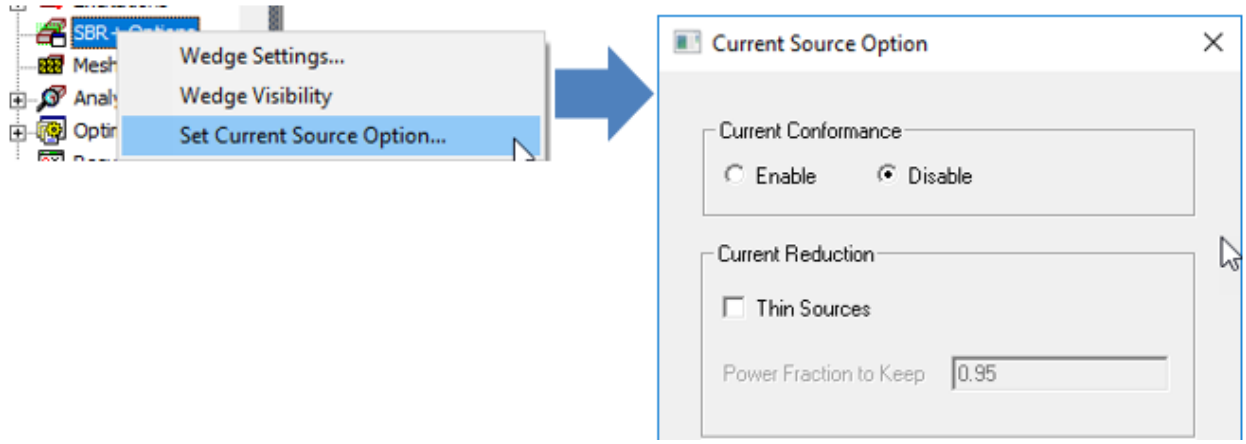
This feature allows configuration of current-source conformance and thinning that applies to all SBR+ sources defined by a distribution of current sources. These are global settings, but they can be overridden for particular SBR+ Sources in the HFSS with Hybrid and Arrays Solution Type and particular near-field linked sources in the SBR+ Solution Type, as explained below. Solutions are invalidated if you change the Current Conformance or Current Reduction settings, whether at the global or local level. The behaviors and intended usages for these features are further explained in the HFSS Technical Notes for Excitations for SBR+ and Current Conformance and Array Conformance in SBR+.

For the HFSS with Hybrid and Arrays Solution Type, you can right click on the Hybrid Regions icon in the Project tree and access the **Set Current Source Option...** dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

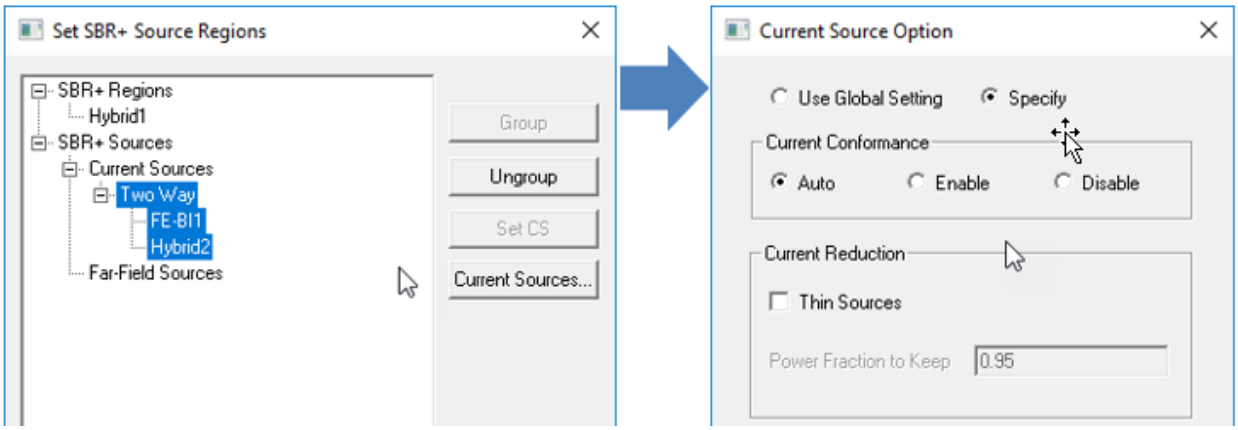


For the SBR+ Solution Type, you can also access **Set Current Sources Option…** through the SBR+ Options.

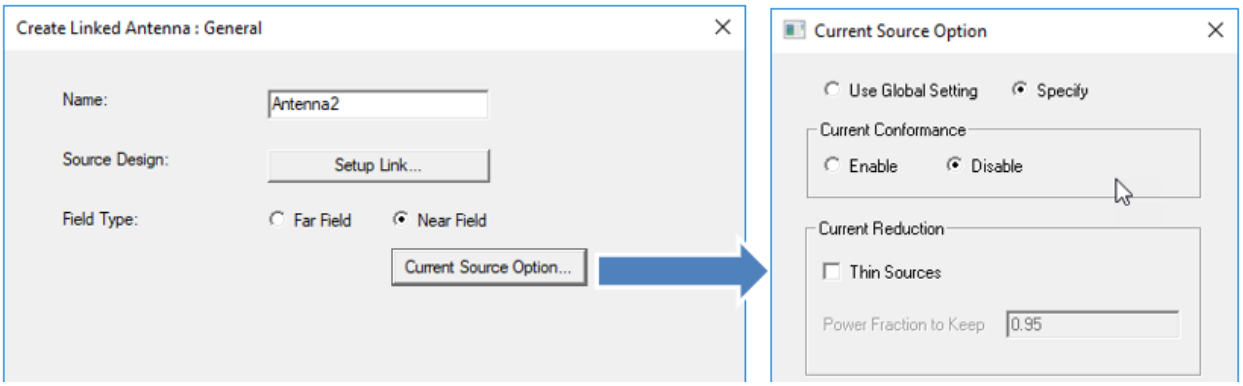


In the HFSS with Hybrid and Arrays Solution Type, you can override the global Set SBR+ Source Regions settings for a particular source through Set SBR+ Source Regions by clicking **Current Sources…** in the dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For the SBR+ Solution Type, you can override the global Current Source Option settings when you create aNear Field antenna from a driven Modal design to SBR+.



Current Conformance Settings

For ground-plane backed sources you intend to conform to an SBR+ region, you should place them very near the metallic surface of the SBR+ region to which they will be conformed, and this should be a high-conductivity metal surface or Perfect E boundary. While the conformance algorithm is designed to handle imprecise vertical placement of the source, one should strive to precisely place the source on the intended surface point of the SBR+ region. Also, the conformance algorithm has no ability (or knowledge) to compensate for imprecision in the horizontal placement of the source. Here, “vertical” and “horizontal” mean perpendicular and parallel to the SBR+ region placement surface, respectively.

In the case of sources enclosed by FE-BI boundaries (or Radiation boundaries for SBR+ Solution Type), you should also place a Perfect E infinite ground plane on the enclosure face nearest the placement surface of the SBR+ region. This ground plane serves two purposes. First, when the source is solved separately and in isolation from the SBR+ region (i.e., in one-

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

way hybrid coupling or near-field link context), it will experience a grounding environment that best represents the presence of the metallic SBR+ region. Second, this ground plane establishes the reference plane against which current source original heights are measured. When conformance shifts the current sources down toward the SBR+ region placement surface, it will maintain these original heights relative to each underlying point on the SBR+ region placement surface, as explained and illustrated in Current Conformance and Array Conformance in SBR+. Also, when the current sources are generated along the enclosing boundary faces from their fields during the SBR+ component of the analysis, no current sources will be generated along this ground-plane face, nor are they required.

The options for Current Conformance are Enable and Disable; additionally, the HFSS with Hybrid and Arrays Solution Type provides a third option: Auto. When set to Disable, conformance is switched off and neither the absolute nor relative positioning of current sources of the SBR+ source are altered.

When Current Conformance is set to Enable, HFSS will attempt to conform the current sources of the ground-plane backed SBR+ hybrid or near-field linked source to the nearest surface of the SBR+ region, even in cases where the SBR+ source is far displaced from any SBR+ region. Only select this option when the source defined by current sources is a ground-plane backed antenna that is intended to sit atop and conform to a metallic surface of the SBR+ region.

When Current Conformance is set to Auto, the recommended and default setting in the HFSS with Hybrid and Arrays Solution Type, HFSS will automatically determine whether the SBR+ source is a good candidate for conformance. The qualifying criterion is that the source be placed within a small tolerance separation from the nearest SBR+ region surface, this tolerance being determined as one-twentieth (1/20) of the diagonal displacement of source's bounding box. In addition, in the case of a source enclosed by FE-BI boundaries, if none of its enclosing faces is assigned a Perfect E infinite ground plane, Auto conformance will automatically insert one on the face nearest the SBR+ region.

Current Reduction Settings

Enabling Thin Sources lets you specify a Power Fraction to Keep between 0 and 1, with lower values implying more thinning, faster solutions, and less accuracy; setting this below 0.9 is not recommended due to the potential excessive accuracy loss. Power Fraction to Keep should not be confused with directly controlling the fraction of current sources to retain; for SBR+ sources with a large number of current sources (e.g., a large FE-BI antenna), substantial thinning far exceeding 10% can be achieved with Power Fraction to Keep set at 0.9 or higher.

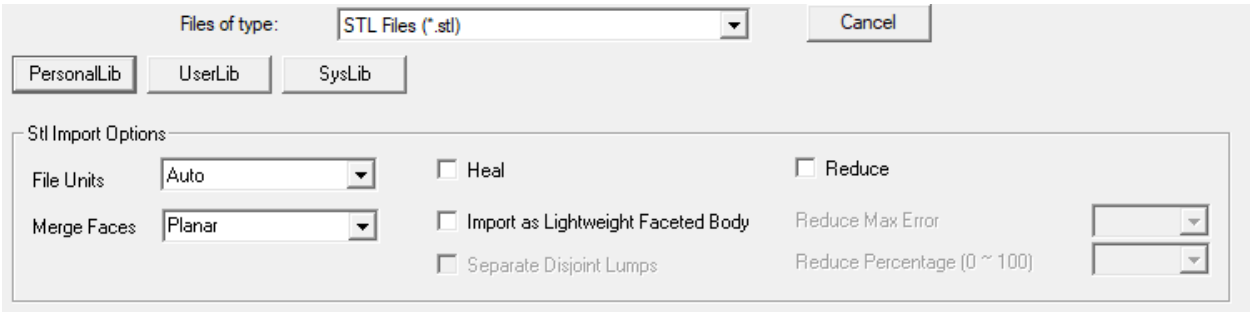
Lightweight Geometry for HFSS Hybrid Regions Designs

Importing large stl files into Ansys Electronics Desktop can be time consuming. STL files contain triangulations of objects, and importing them to the modeler creates a face out of every triangle, and an edge out of every triangle edge. This creates a large number of faces and edges. which

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

can slow down operations. The lightweight geometry feature gives you the option to import objects as one face, without edges or vertices in them. Internally, the modeler does not create bodies for these objects. The Beta lightweight geometry feature supports all hybrid design, including IE, PO and SBR+.

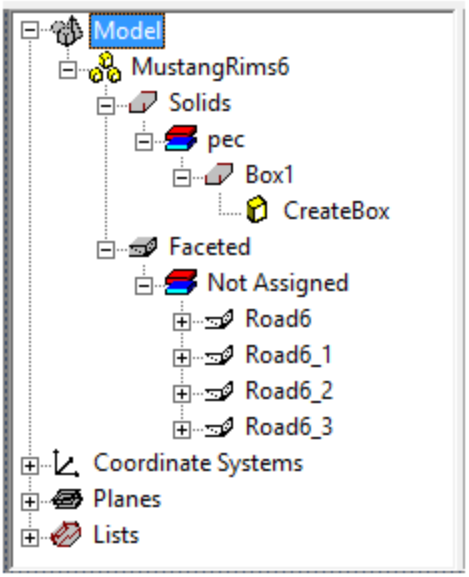
When the Beta Feature for Lightweight Geometry for Hybrid Regions is enabled for HFSS with Hybrid and Arrays Solution type, the Import File dialog for STL files contains several options.



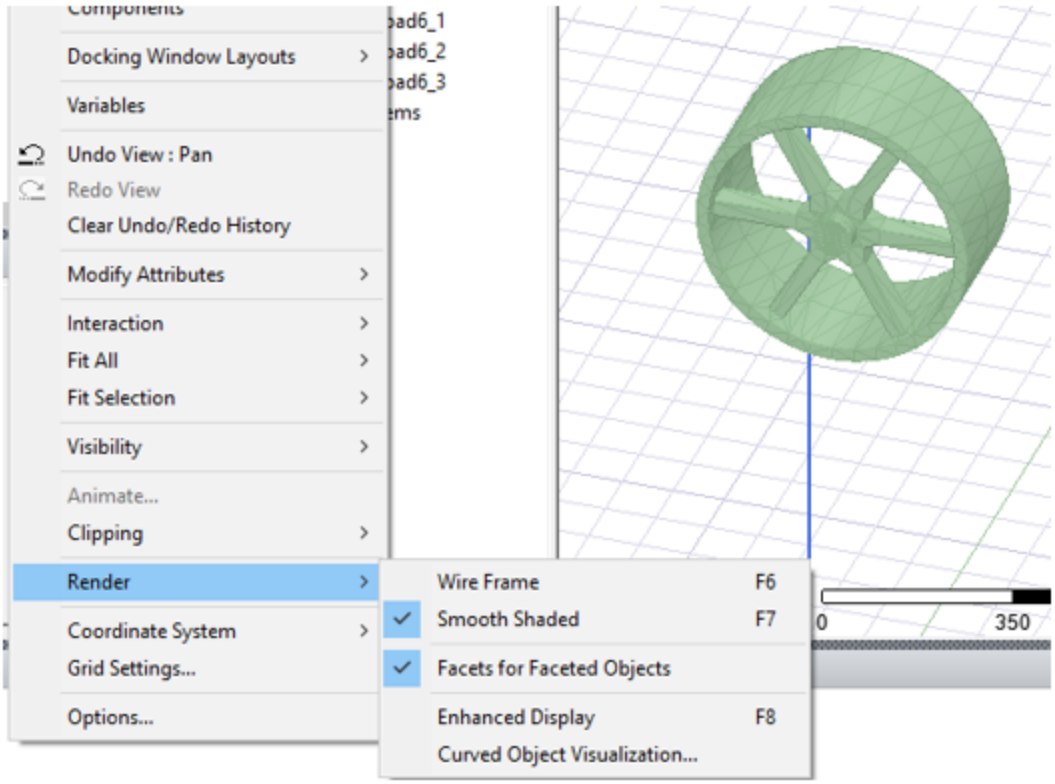
- **Heal** attempts to remove common issues while importing stl files, including closing solids when they are open due to minor cracks in triangulation and removing self-intersections.
- **Import as Lightweight Faceted Body**, if checked, creates faceted bodies from imported objects and enables the Separate Disjoint Lumps option.
- **Separate Disjoint Lumps** option, if checked, create multiple parts if the .stl files have objects having disjoint lumps.
- **Reduce** enables lets you reduce the number of facets in faceted objects while keeping the overall shape of the object. Checking **Reduce** enables fields for specifying Reduce Max Error and Reduce Percentage.

Once imported, faceted objects have distinct icons in history tree. They can also be grouped together, as shown in the following figure.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



A new option, **Facets for Faceted Objects**, is provided in **View>Render** menu for Hybrid solution types. When this option is check on, the modeler renders edges of triangle contained in the faceted bodies. These edges cannot be selected. See the following figure:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

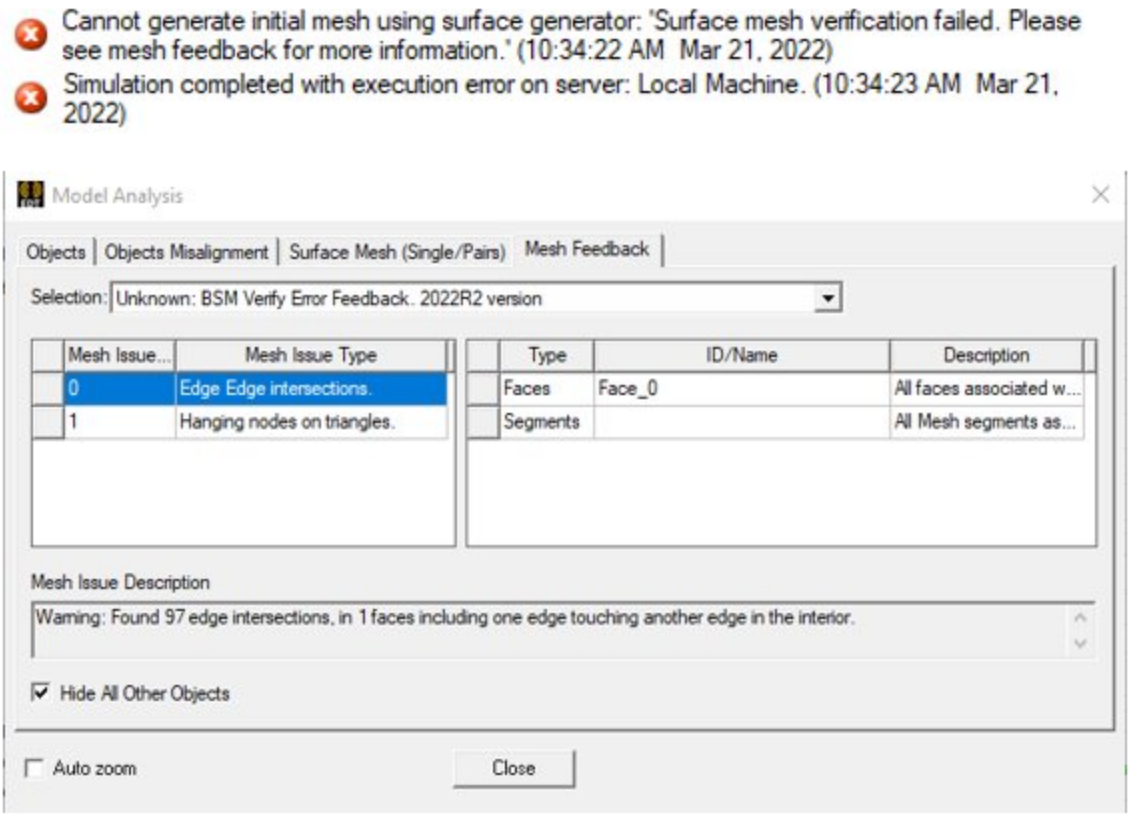
Initial Mesh Operations for Lightweight Geometries

Importing a lightweight geometry into an HFSS with Hybrid design will internally use Tolerant Meshing (add link) technique and disable the "Apply curvilinear meshing to all curved surfaces" option.

Lightweight Geometry Verification for the IE Solver

The IE solver has stricter requirements toward lightweight geometry. For example, any triangle intersection or overlapping is not allowed. Mesh feedback is generated when performing tolerant meshing to help you better identify any geometry issue.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Permitted Modeler Operations on Faceted Objects

- Arrange operations such as Move, Rotate, Mirror.
- Duplicate along line, around axis, with mirror.
- Scale.
- Copy-Paste.
- Create object CS - you can snap to vertices of facets to create object CS.
- Create face CS - you can pick any point, determine the triangle on which the picked point lies, and store the position relative to the triangle vertices. **Note:** this capability is particularly useful for antenna placement on lightweight geometry models in SBR+ designs.
- Create 3D components out of faceted objects.
- Selecting faces for assigning boundaries, coordinate systems, excitations or hybrid regions. **Note:** the entire object boundary is selected.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Other Characteristics of Faceted Objects

- Solid and sheet objects are identified in the History tree.
- Object Measure dialog shows the correct volume, and surface area of faceted objects.
- Faceted objects are skipped during intersection checks and containment checks done during geometry validation.
- Faceted objects cannot be exported from the Modeler.

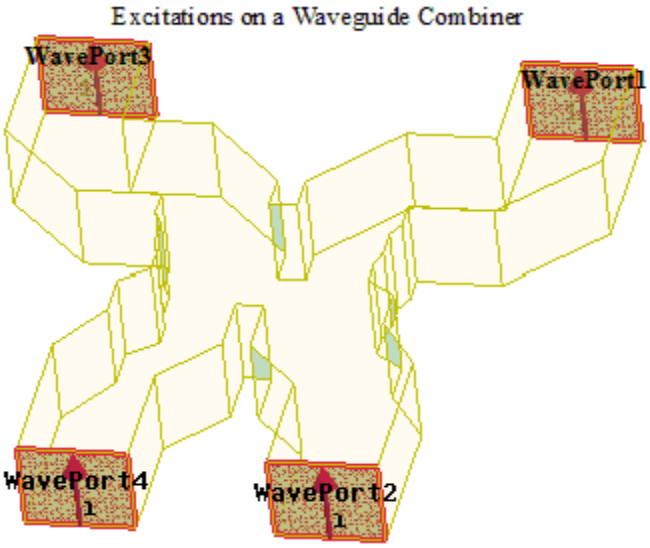
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

19 - Assigning Excitations for HFSS or HFSS-Transient

Excitations are sources of electromagnetic fields in the design. HFSS has various options to generate incident fields that interact with a structure to produce the total fields. Some of these excitations are local sources residing within the structure such as wave ports and voltage sources, while other excitations such as plane waves are created from local sources away from the structure.The available excitations depend upon the product. They are as follows:

- HFSS Excitations including SBR+
- HFSS Transient Excitations



Also see Circuit Elements in HFSS.

HFSS Excitations

You can assign the following excitations to an HFSS design:

Circuit Port	Represents an HFSS 3D Layout feature implemented in HFSS. Circuit ports can be thought of as Lumped Ports assigned to a pair of edges. In the driven modal problem, the integration line for the circuit port will be the vector from the middle of the second edge to the middle of the first edge. In

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	the driven terminal problem, the two edges are populated as terminal and reference under circuit port. For designs with only lumped ports or a combination of lumped and circuit ports, the Advanced Solution Setup, **Options** tab includes an option to use Enhanced low frequency accuracy.
Wave Port	Represents the *external* surface through which a signal enters or exits the geometry. It is effectively a semi-infinite waveguide attached to the model. This waveguide has the same cross-section and material properties as the port. Wave ports are placed on this interface to provide a means to link the model device to the external world.
Lumped Port	Represents an *internal* surface through which a signal enters or exits the device. It is effectively a lumped element for exciting the device and measuring S-parameters. For designs with only lumped ports or a combination of lumped and circuit ports, the Advanced Solution Setup, **Options** tab includes an option to use Enhanced low frequency accuracy.
Terminal	A terminal is defined by one or more conductors in contact with the port. HFSS treats microwave structures as a black box that may have one or more terminals, each of which has a voltage/current pair. Terminals are assigned automatically.
Floquet Port	Floquet Ports are used exclusively with periodic structures defined by Primary and Secondary (Coupled Lattice Pair) boundaries. They contain plane waves whose frequency, phasing, and the geometry of the periodic structure determine the propagation direction. Chief examples are planar phased arrays and frequency selective surfaces when these may be idealized as infinitely large and analyzed using a unit cell.
Incident Wave	Represents a propagating wave impacting the geometry.
Linked Field	Represents a Far Field Wave or Near Field Wave or Cable Network. You can also link a driven Modal HFSS design to SBR+.
Voltage Source	Represents a constant electric field across feed points.
Current Source	Represents a constant electric current across feed points.
Magnetic Bias	Used to define the net internal field that biases a saturated ferrite object.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Multipaction Charge Region	In HFSS Multipaction analysis, charges are added to the simulation domain as excitations.
Multipaction DC Bias	In HFSS Multipaction analysis, sets up DC bias fields for a multipaction analysis
SBR+ Antenna Components	For SBR+ Solution types, use Antenna components to represent port excitations using the available Parametric Antennas, Parametric Arrays, or via Linked Source design. Individual transmit/receive antenna port couple pairs can be assign for the SBR+ simulation by using the Tx/Rx Selection dialog.
Circuit Elements	For driven Modal and Terminal solutions, you can convert Lumped Ports and Terminals to Circuit Elements, based on Touchstone files or linked projects.

HFSS Transient Excitations

You can assign the following types of excitation. For HFSS Transient designs, the properties for each excitation include a **Transient** tab, enabling you to designate each excitation as Active or Passive.

Wave Port	Represents the *external* surface through which a signal enters or exits the geometry. It is effectively a semi-infinite waveguide attached to the model. This waveguide has the same cross-section and material properties as the port. Wave ports are placed on this interface to provide a means to link the model device to the external world.
Lumped Port	Represents an *internal* surface through which a signal enters or exits the device. It is effectively a lumped element for exciting the device and measuring the S-parameters.
Terminal	A terminal is defined by one or more conductors in contact with the port. HFSS treats microwave structures as a black box that may have one or more terminals, each of which contains a voltage/current pair. Terminals are assigned either manually or automatically.
Plane Wave	Represents a wave that propagates in one direction and is uniform in the directions perpendicular to that of its propagation.
Voltage Source	Represents a constant electric field across feed points.
Current Source	Represents a constant electric current across feed points.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This release offers a beta feature to allow you to mix wave ports and terminals in a transient waveguide simulation.

Assigning Circuit Ports

Circuit Ports in HFSS are equivalent to those in HFSS 3D Layout. These ports provide major benefits for HFSS:

- Good low frequency accuracy (Hz range)
- Good for multi-physics work flows as there is no restriction about being planar
- For designs with only lumped ports or a combination of lumped and circuit ports, the Advanced Solution Setup, **Options** tab includes an option to use Enhanced low frequency accuracy.

Circuit ports can be thought of as Lumped Ports assigned to a pair of edges. In a driven modal solution, the integration line for the circuit port will be a vector from second edge to the first edge. In the driven terminal problem, the two edges are populated as terminal and reference under circuit port. Deleting either edge will delete the circuit port. You can create circuit ports, translate between circuit ports and lumped ports, and include circuit ports in N-port circuit elements. They are treated exactly as lumped ports.

You should not assign a circuit port on an exterior surface as solver will assign an implicit PEC boundary on the same location, leading to port being shorted.

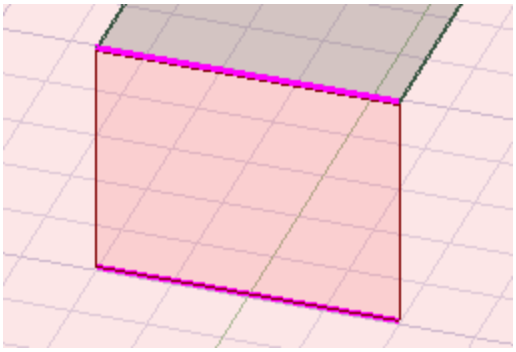
If you change the solution type between driven modal and driven terminal, the integration line will be converted to terminal and reference under circuit port and vice versa.

Addition, deletion, modification of circuit ports will invalidate solutions. Editing the impedance will invalidate. Changing or deleting the assignment will invalidate.

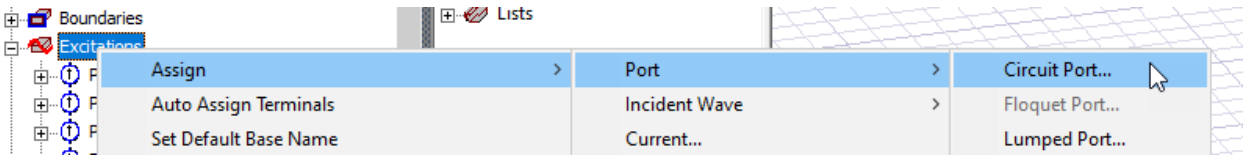
To assign a Circuit Port:

1. Select two edges in the modeler window. The order of selection is significant. For a driven modal design, an integration line will go from the second edge to the first edge. For a driven terminal design, the first edge will be assigned a terminal, and the second edge will be assigned a reference.

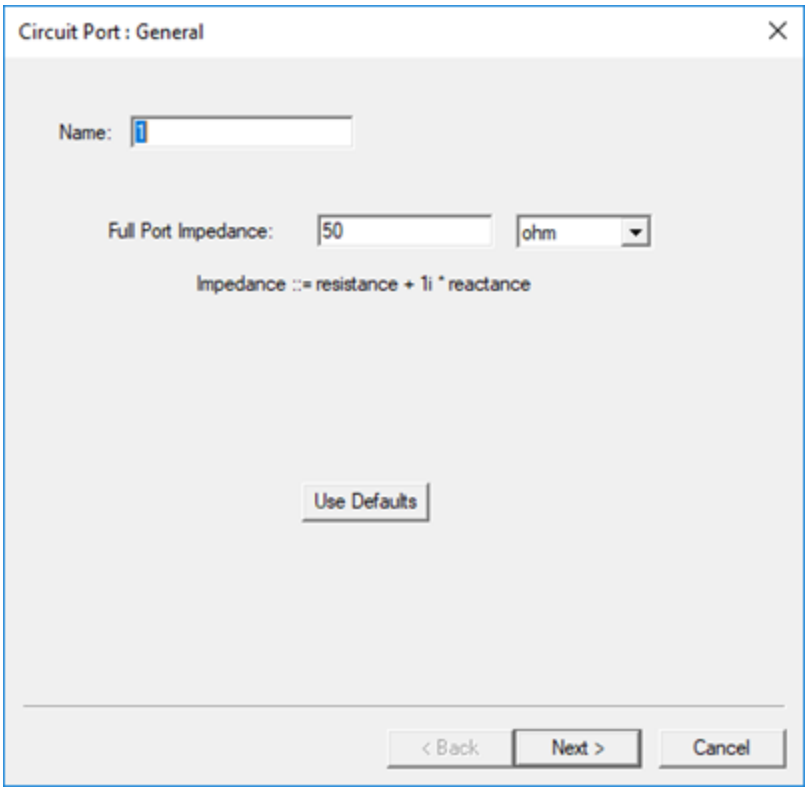
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Right-click the **Excitations** Icon in the Project Manager and select **Assign> Port>Circuit Port...** You can also use the HFSS toolbar menu to select **Excitations> Assign>Port> Circuit Port...**, or right-click in the Modeler window and click **Assign Excitation>Port> Circuit Port...**.



The **Circuit Port: General** dialog box appears.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. You can set the Full Port Impedance. Click Next to view the Port Processing tab. These are slightly different for Modal and Terminal solutions.

   For Modal solutions, the default is *Do Not Normalize*, but you can choose *Renormalize All Modes* and specify the *Full Port Impedance*. For Terminal solutions, the default is *Renormalize all terminals*. You can also enable *Deembed*.

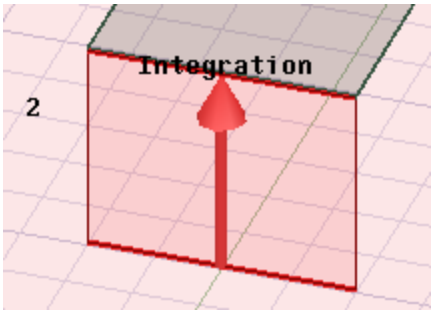
4. Click Finish.

   For Terminal solutions, the History Tree will show the Circuit Port with Terminal and Reference. Selecting the Circuit Port highlights both edges in the Modeler window. Selecting the Terminal or the Reference highlights the associated edge. Terminal is assigned to the first edge selected, and the reference is assigned to the second edge selected. The renormalization impedance belongs to the terminals. Terminal and reference from the circuit port cannot be added to or deleted from the circuit port; exactly one terminal and one reference is required by the circuit port. However, you can reassign terminal and reference independently. Reassigning a circuit port means that its assignment is then populated into the terminal reference.

   For Modal solutions, selecting the Circuit port in the Project Manager highlights both edges and shows the integration line from the second edge selected to the first edge

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

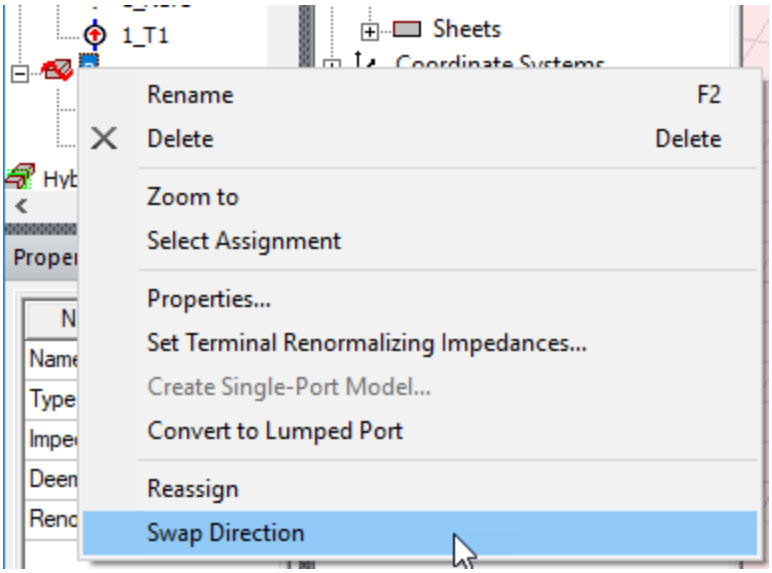
selected.



When you create circuit ports, you can do the following:

Swap Assignment

Right click on the Circuit Port and click **Swap Assignment** to swap the direction of an integration line or a terminal reference assignment.



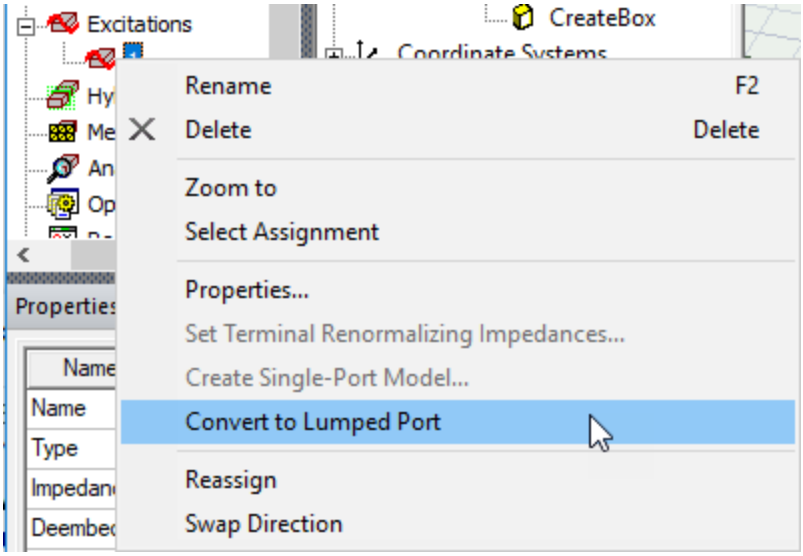
Create a Circuit Element from a Circuit Port

See Circuit Elements in HFSS.

Convert a Circuit Port to a Lumped Port

Select a circuit port, right-click and select **Convert to Lumped Port** from the short-cut menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For driven modal solutions:

- If the two edges are on the same face, the lumped port will be assigned to that face, and the integration line is preserved.
- If the two edges are not on the same face but on the same plane, then a sheet will be created, and the lumped port is assigned to that sheet.
- Otherwise, the conversion fails.

For terminal solutions:

- The terminal is transferred to the lumped port.
- The lumped port face determination is similar to driven modal using the edges from the terminal and the reference.

Convert a Lumped Port to a Circuit Port

Select a lumped port, right click and select **Convert to Lumped Port.**

For driven modal solutions:

- The integration line is preserved
- If the integration line is defined by two end points on edges, the two edges are the assignment of the circuit port.
- Otherwise, the conversion fails.

For driven terminal solutions:

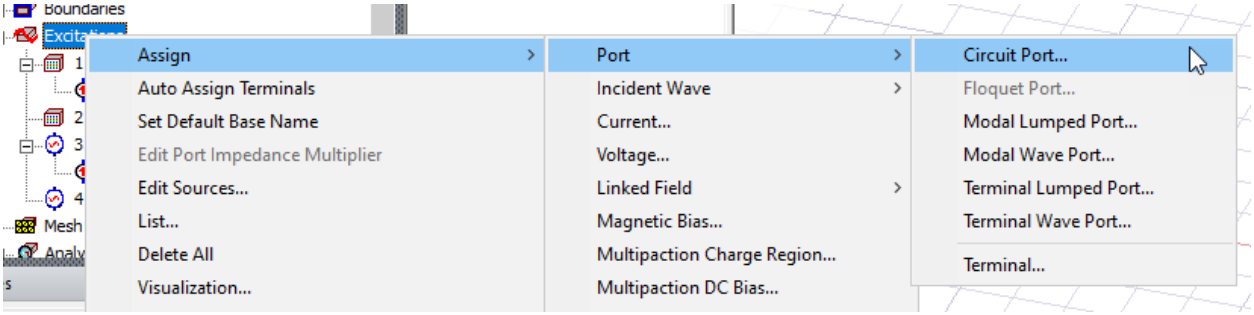
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The terminal is transferred to the circuit port.

  The reference edge is determined by the terminal assignment and the lumped port face assignment. An edge touching a conductor from the face, and not touching the terminal will be the reference edge.

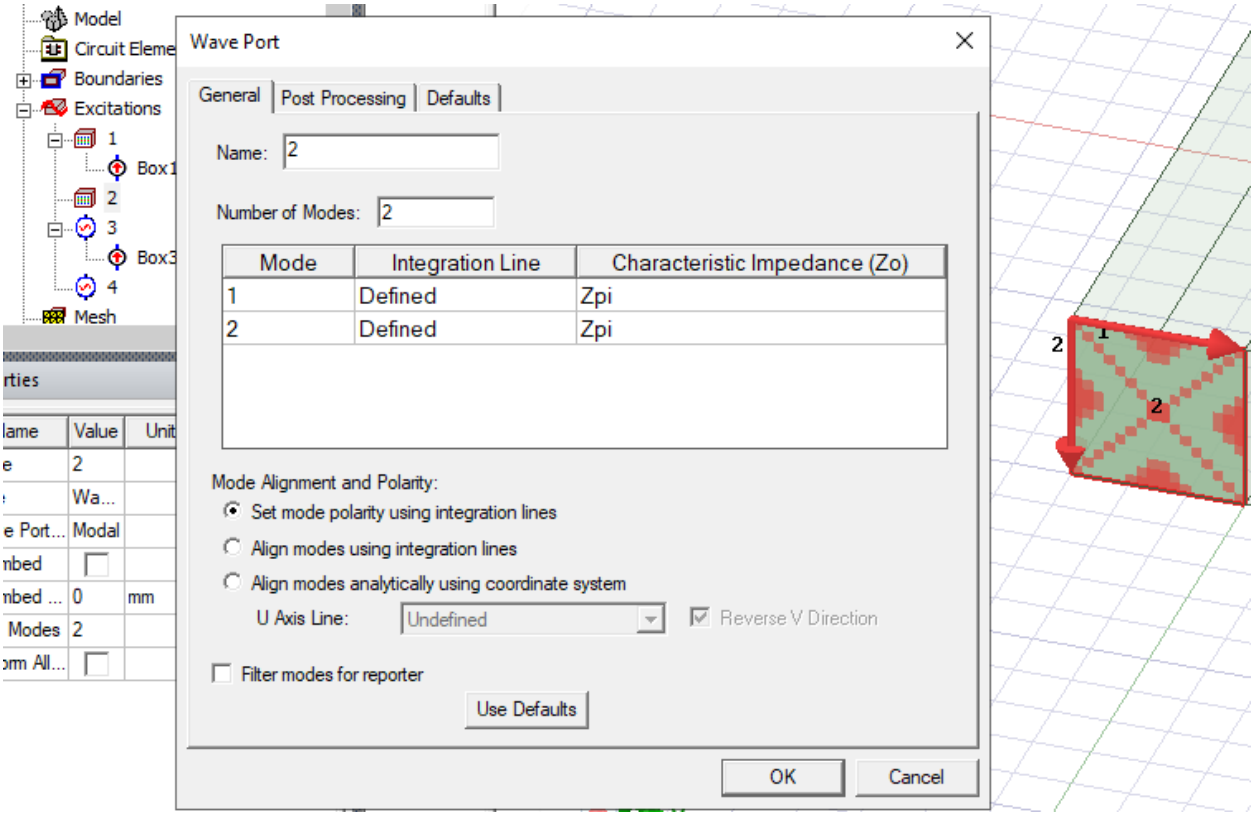
Multimode Simulations in HFSS Terminal Solutions

This release allows you to mix modal and terminal ports in an HFSS Terminal Solution. You can add Modal Wave Ports, Modal Lumped Ports, Terminal Wave Ports, and Terminal Lumped Ports to a single simulation. This is particularly helpful for component assembly where one component cones from modal design, and another from terminal design. You can now assemble them in a single design without having to manually edit component definition as the same solution type. The Excitations menu shows these ports as available.



For mixed modal/terminal in HFSS Terminal simulation, the modal Wave Port dialogs are the same as before.

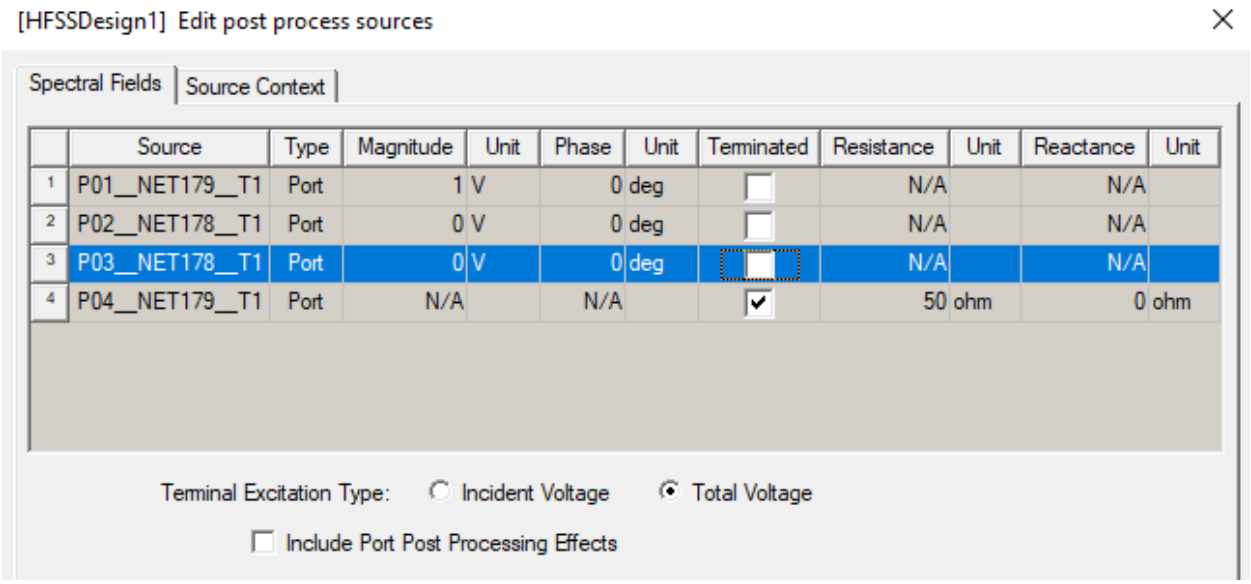
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



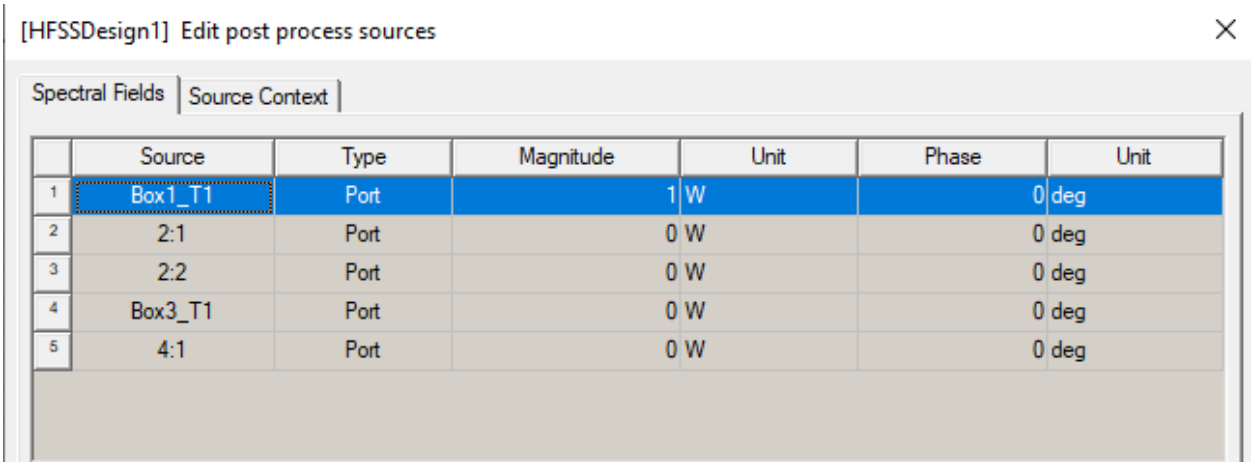
You can mix each kind of wave and terminal ports with the others.

For an HFSS Terminal simulation with only terminal ports, the transient results in reporter are in Volts units, and you edit sources is in Volts units.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For an HFSS Terminal simulation with all modal or mixed modal/terminal, the results in are in Watt units.

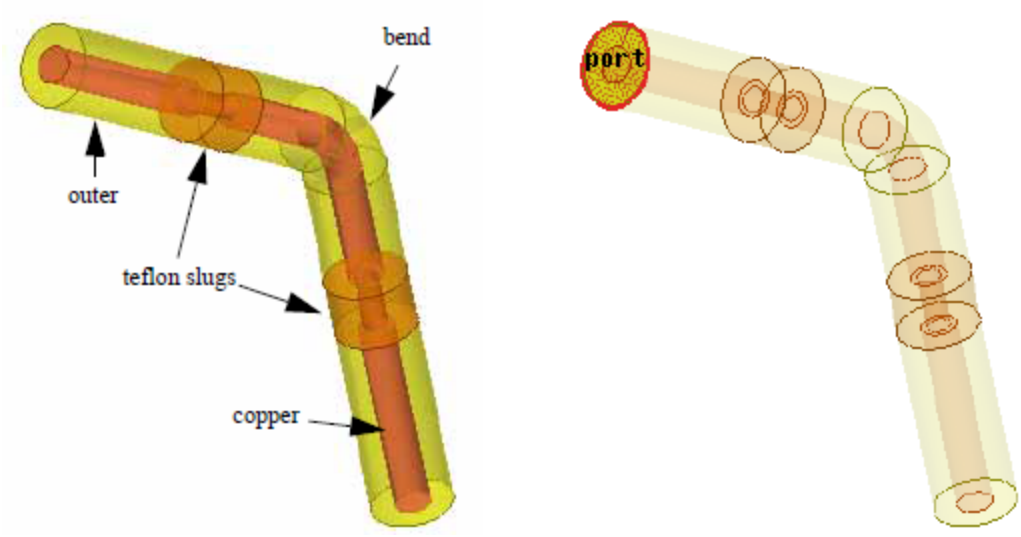


Consequently, for all modal, and mixed modal/terminal simulations, you edit sources in Watt units.

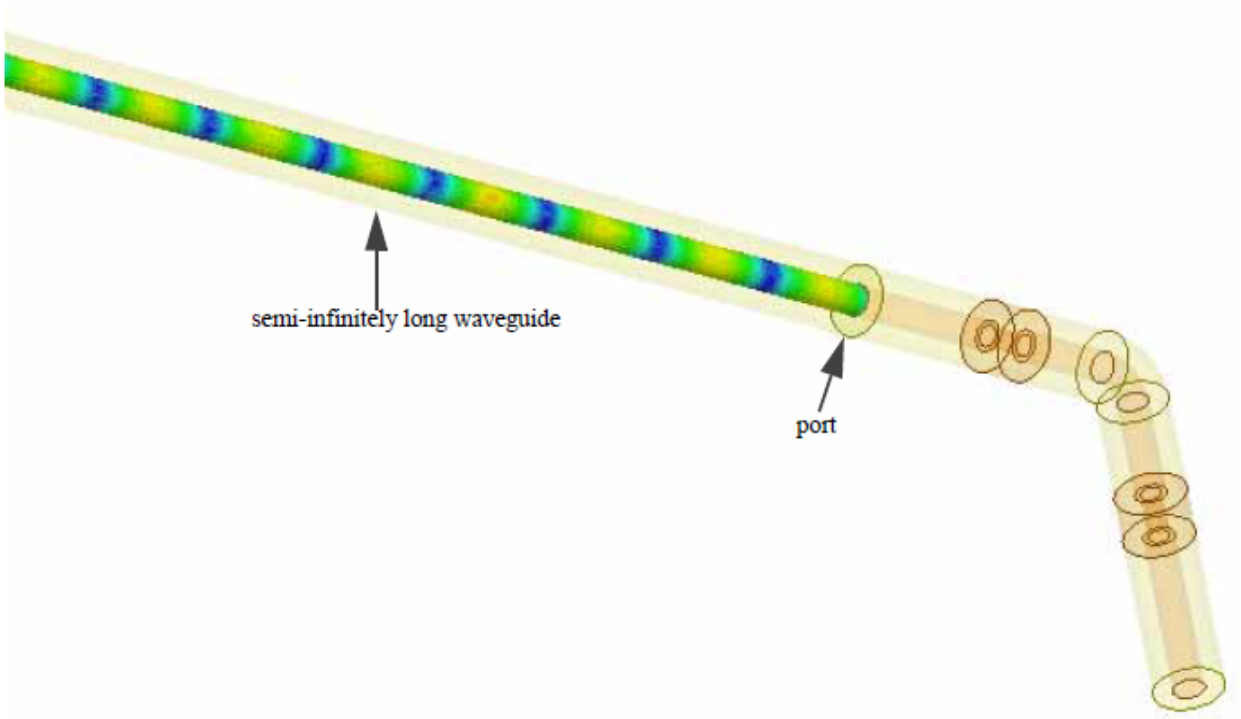
Wave Ports

The objective of this section is to provide a thorough description of wave ports. You must know what a wave port represents in HFSS to understand its capability. To illustrate we will use an HFSS model of a coaxial bend as an example where the wave port is assigned on the outer face.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



HFSS treats this wave port as though a waveguide or a transmission line of the exact same cross-section (in this case the cross-section of the coaxial bend) and material properties, comes from infinity and ends at the port as shown in the following figure.



The properties and the cross-section of the waveguide or the transmission line determine the natural field patterns called modes that excite the model and the HFSS port solver determines the propagating modes that the waveguide or transmission line will carry.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

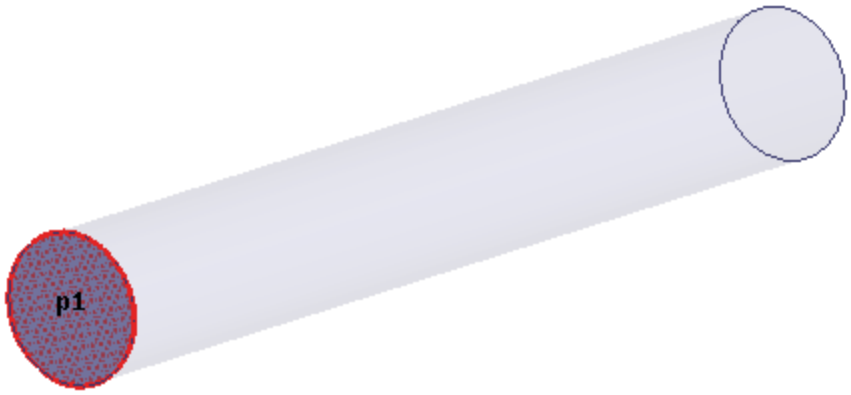
A wave port can be placed internal to a model as long as it is backed by a PEC object.

Wave Port Size

Wave ports are used for exciting transmission lines and waveguide structures. Wave ports that are assigned on waveguide structures are naturally defined by the cross-section of the waveguides. However, for transmission lines (e.g., microstrip, CPW, slotline) ports should be defined carefully. Sometimes transmission lines are part of a large PCB structure which makes it your responsibility to define the port size properly. This section provides guidelines for the appropriate port sizes for transmission lines. Examples of different waveguide and transmission line structures are as follows:

Circular Waveguide

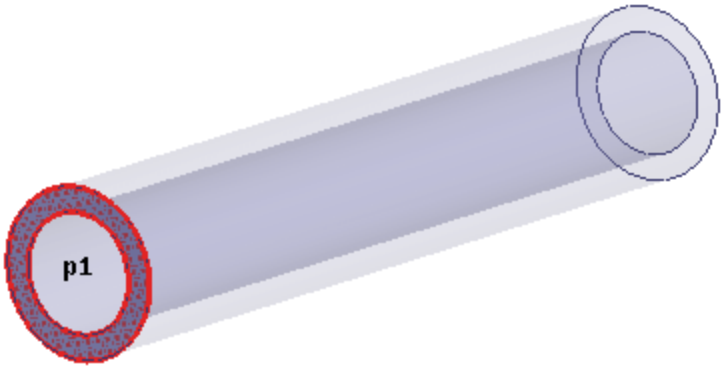
An HFSS model of a cylindrical waveguide of uniform circular cross-section along its length excited with a wave port *p1* is shown below. You do not need to define the port size because it is naturally defined by the cross-section.



Coaxial Cable

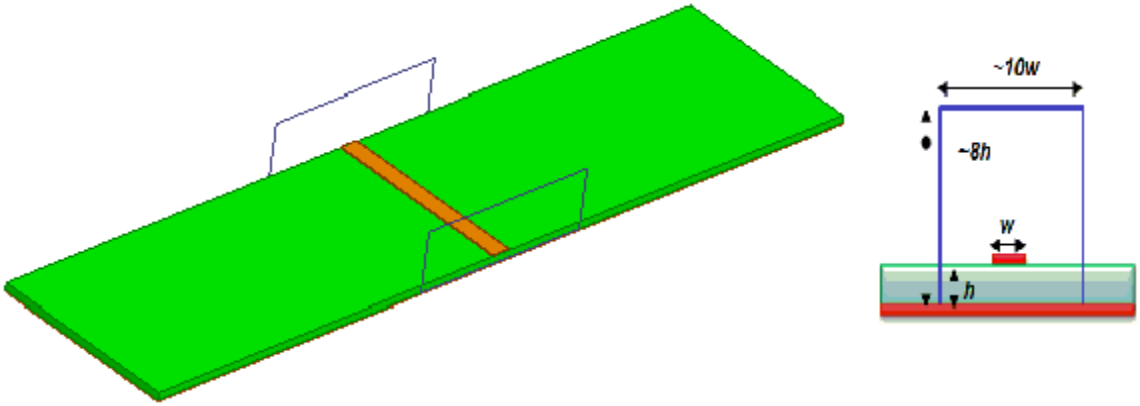
The following figure represents a coaxial cable. You do not need to define the port size as it is naturally determined by the inner and outer radii of the shield.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

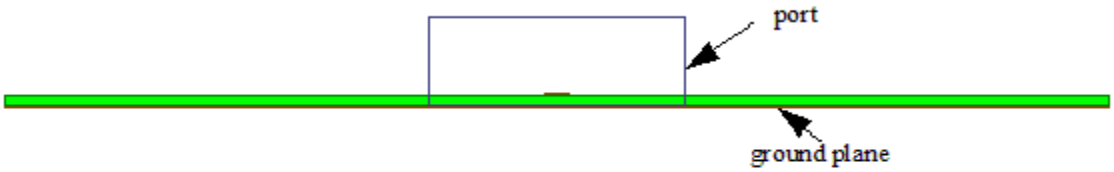


Microstrip Transmission Line

The figures below show an HFSS model of a microstrip transmission line and guidelines for setting the wave port dimensions.



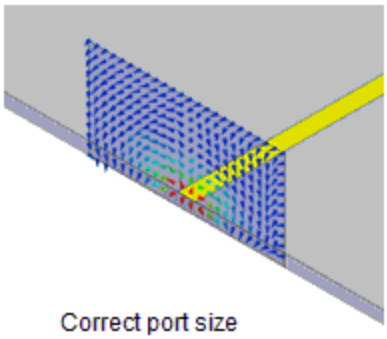
See the HFSS model at scale in the following figure. The bottom of the port touches the ground plane of the microstrip.



The port width affects the port impedance and the propagating modes. If the defined port is too narrow more fields will couple to the side walls. The height of the port is affected by the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

permittivity of the substrate. If the permittivity is too high less fields will propagate in the air, so the wave port can be made shorter.

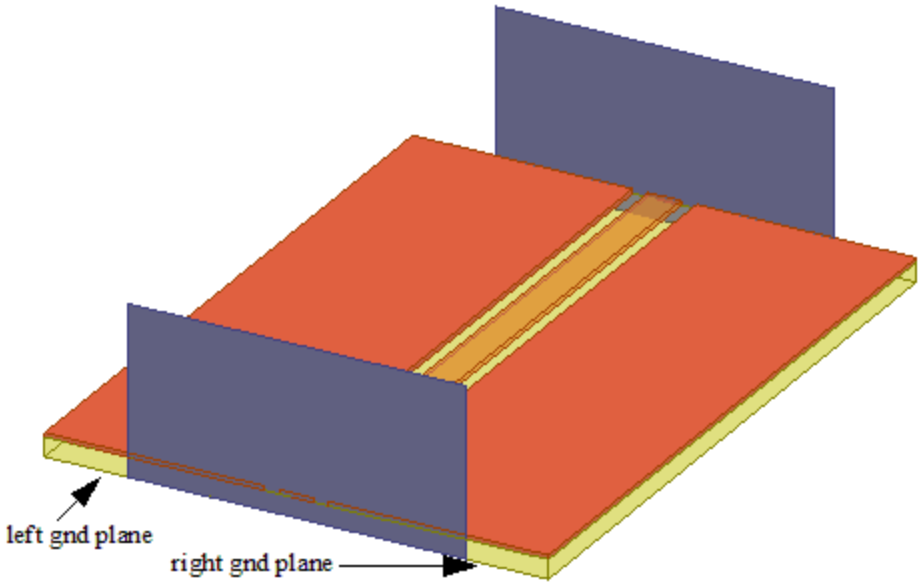


Correct port size

Port too narrow
(fields coupled to sidewalls)

Coplanar Transmission Line

The following figure shows an HFSS model of a coplanar transmission line. The left and right edges of each port must touch the left and right ground planes. We recommend that you make the port size 8h x 10w where "w" represents the width of the trace and "h" represents the height of the substrate.

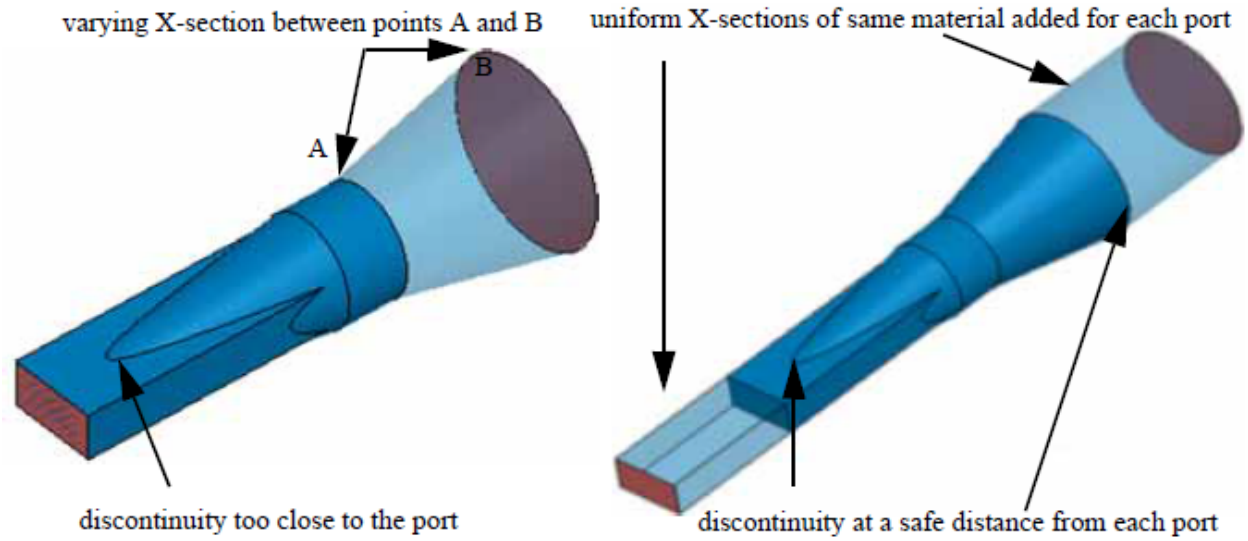


Wave Port Placement

HFSS treats each port that you define to be connected to a semi-infinitely long waveguide or transmission line that has the same cross-section and properties as the wave port. The placement of the wave port is critical because it can affect the accuracy of the solutions. If the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

wave port is close to a discontinuity due to change in shape, dimension, or material of a structure the resulting 3D field can be a superposition of propagating and non-propagating modes.



Hence, the first discontinuity should be at an appropriate distance away from the port surface. This allows any energy reflected into an evanescent mode of the port to decay before reaching the port. Without this separation the resulting accuracy of the S-parameters will be compromised. To precisely determine a distance you can solve the 'port only' with one additional mode (for a correct port definition this mode will be evanescent) and extract the decay length of this mode from its complex gamma. Then, as a rule of thumb, place the first discontinuity at least three times this decay length. Such rigor is not usually necessary and experience over time will give you a solid understanding of typical spacings for their port geometries and frequencies of analysis.

Number of Modes

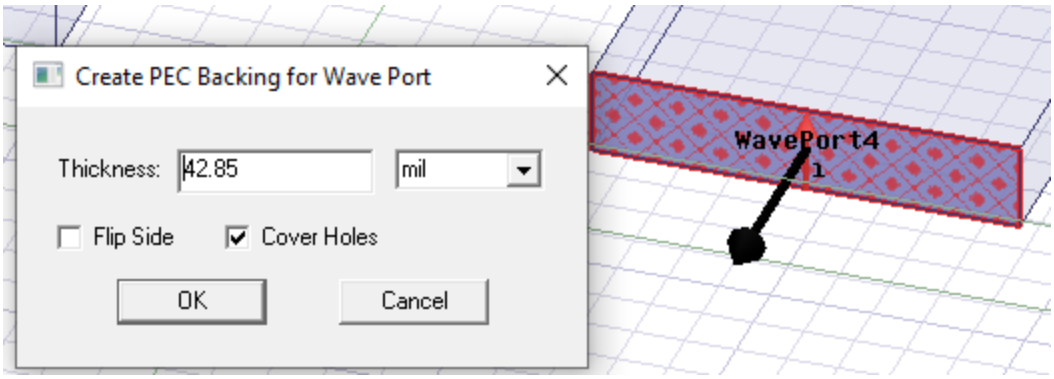
The electrical size of a port at the highest frequency of interest determines the number of modes to be included in the port definitions. If the guidelines on discontinuity discussed above are followed, the number of modes equals the number of propagating modes at the highest frequency; if they are not followed then, the port as a boundary condition will not be accurate. Regardless of whether they are propagating or not, the solver will solve these modes for calculating the S-parameters.

Automatic PEC Creation on Wave Ports

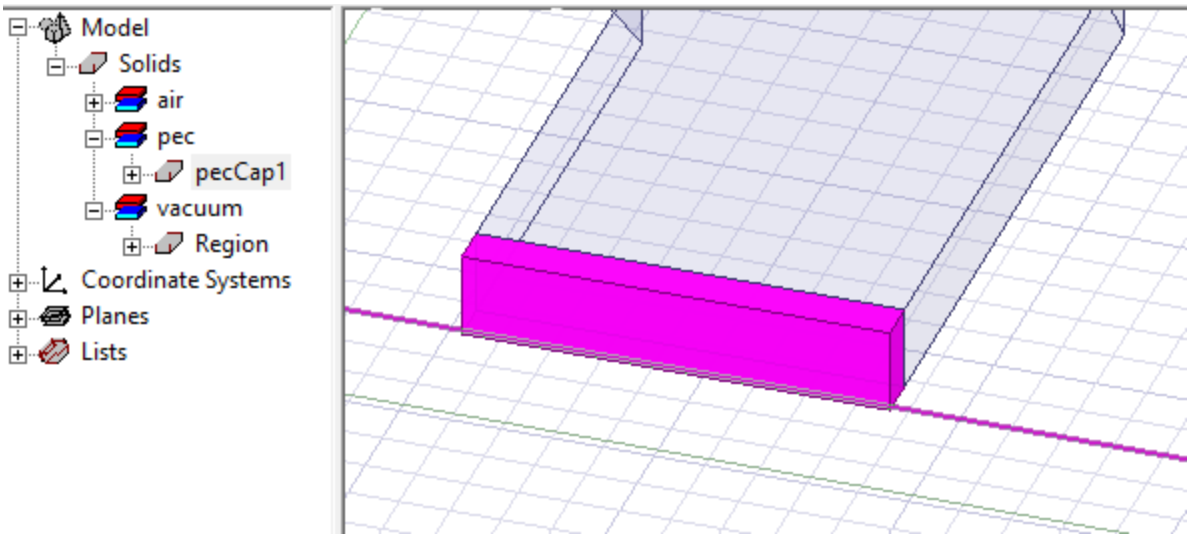
In HFSS, A wave port must have 'solve inside' objects on one side only. An internal wave port would require a PEC object to be attached to and cover the opposite side before the solution can proceed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This HFSS Boundary Assignment Option automatically adds a PEC backing to every newly created wave port when necessary. When a new wave port is created and requires a PEC backing, a dialog window opens to let users create such backing by extruding the port face with specified thickness. You have the option to flip the side of the PEC backing. If the wave port has holes, you have the option to create backing that covers the holes. You can also set the thickness as a variable.



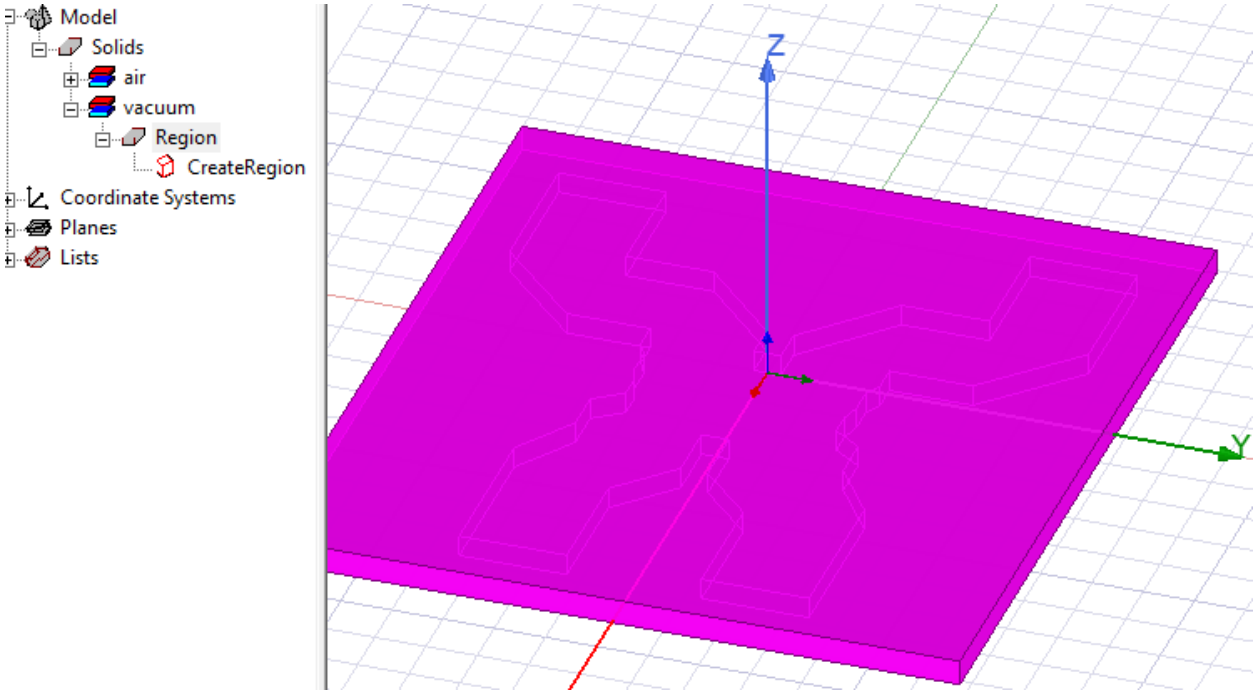
After clicking OK, the PEC backing is created and the new PEC object appears in the History tree.



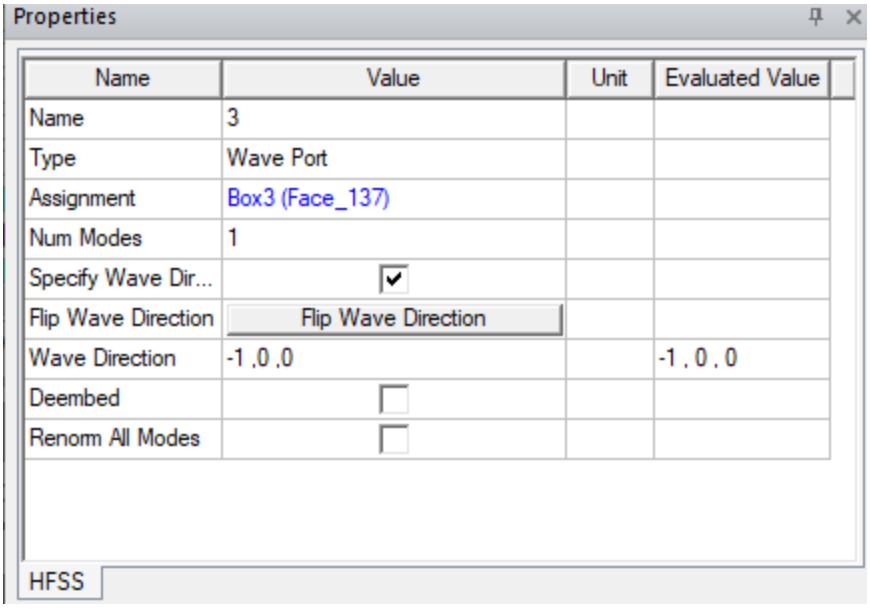
Example Using the Waveguide Combiner Example

Open the HFSS example project “wg_combiner.aedt”. Add a region with padding around the design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

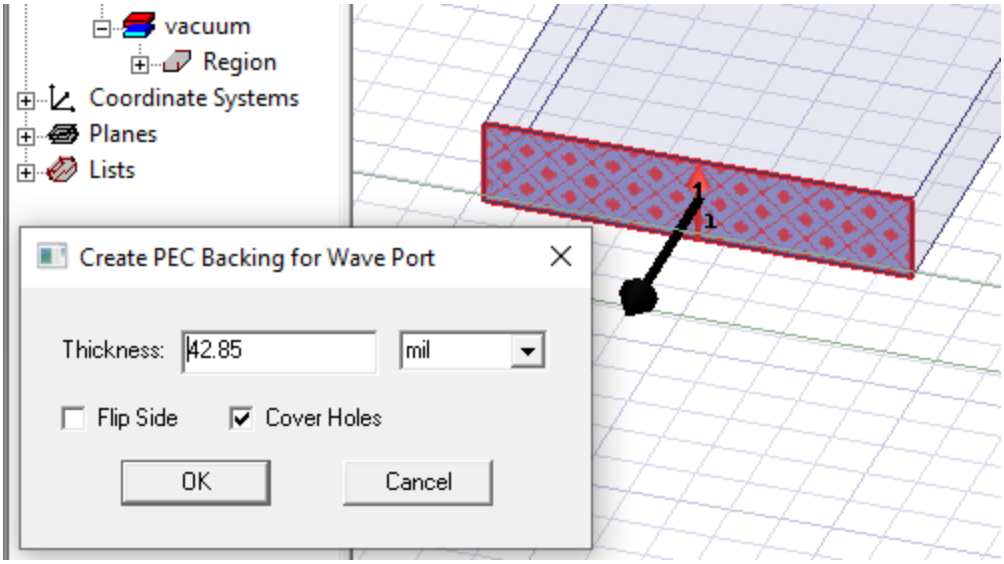


This will make all the wave ports internal to the design invalid. You can specify a wave direction for each port using the Flip Wave Direction property:

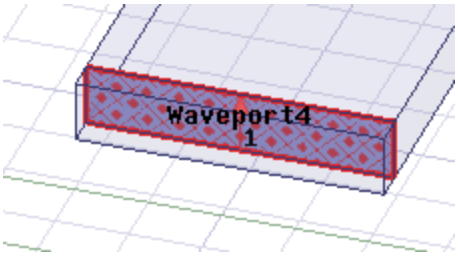


Or you can automatically attach a PEC that covers the opposite side when creating a new port. In this example, delete one of the wave ports and create a new one the same location, you will see this dialog after it is created.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can edit the Thickness and units. The black arrow on the selected wave port shows the side on which the backing is applied. If necessary, you can check Flip side to change the arrow direction. In this example, this is the correct side, so leave that unchecked. Click OK to see the PEC backing.



If direction has been assigned to the other ports, they pass validation also.

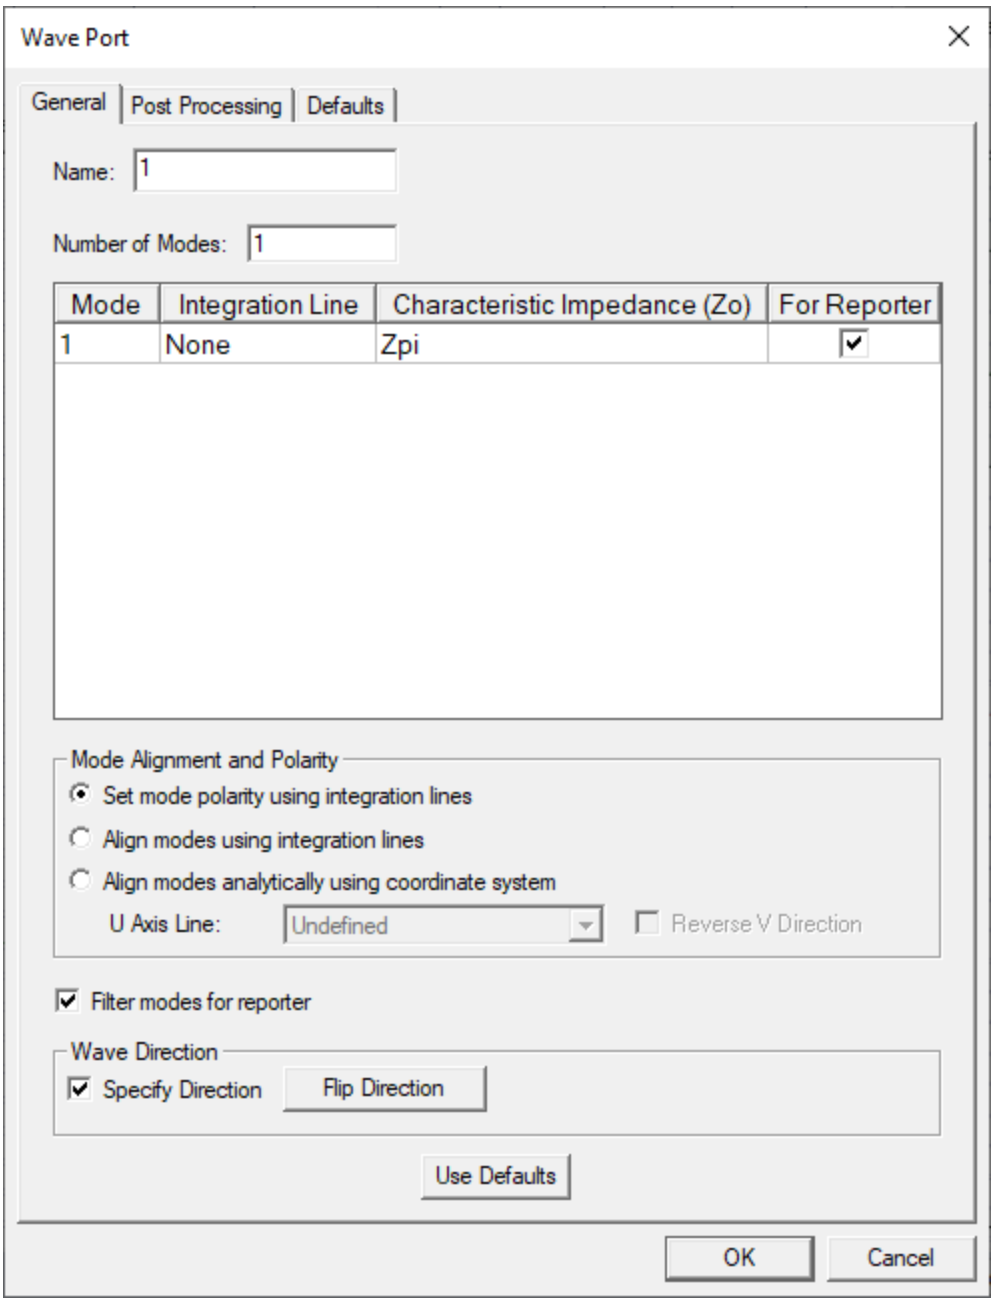
Wave Port Dialog for Modal Solutions

A **Wave Port** dialog box with its default settings is shown below. On this dialog box you can set the number of modes, their alignment, mode polarity, the choice of characteristic impedance etc.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

The option **Use Wizards for data input when creating new boundaries** under **Tools** > **Options** > **HFSS Options** >**Boundary Assignment** is unchecked; so the dialog box appears in the tabbed format. For more information about the appearance of the **Wave Port** dialog box, see **HFSS Options**.



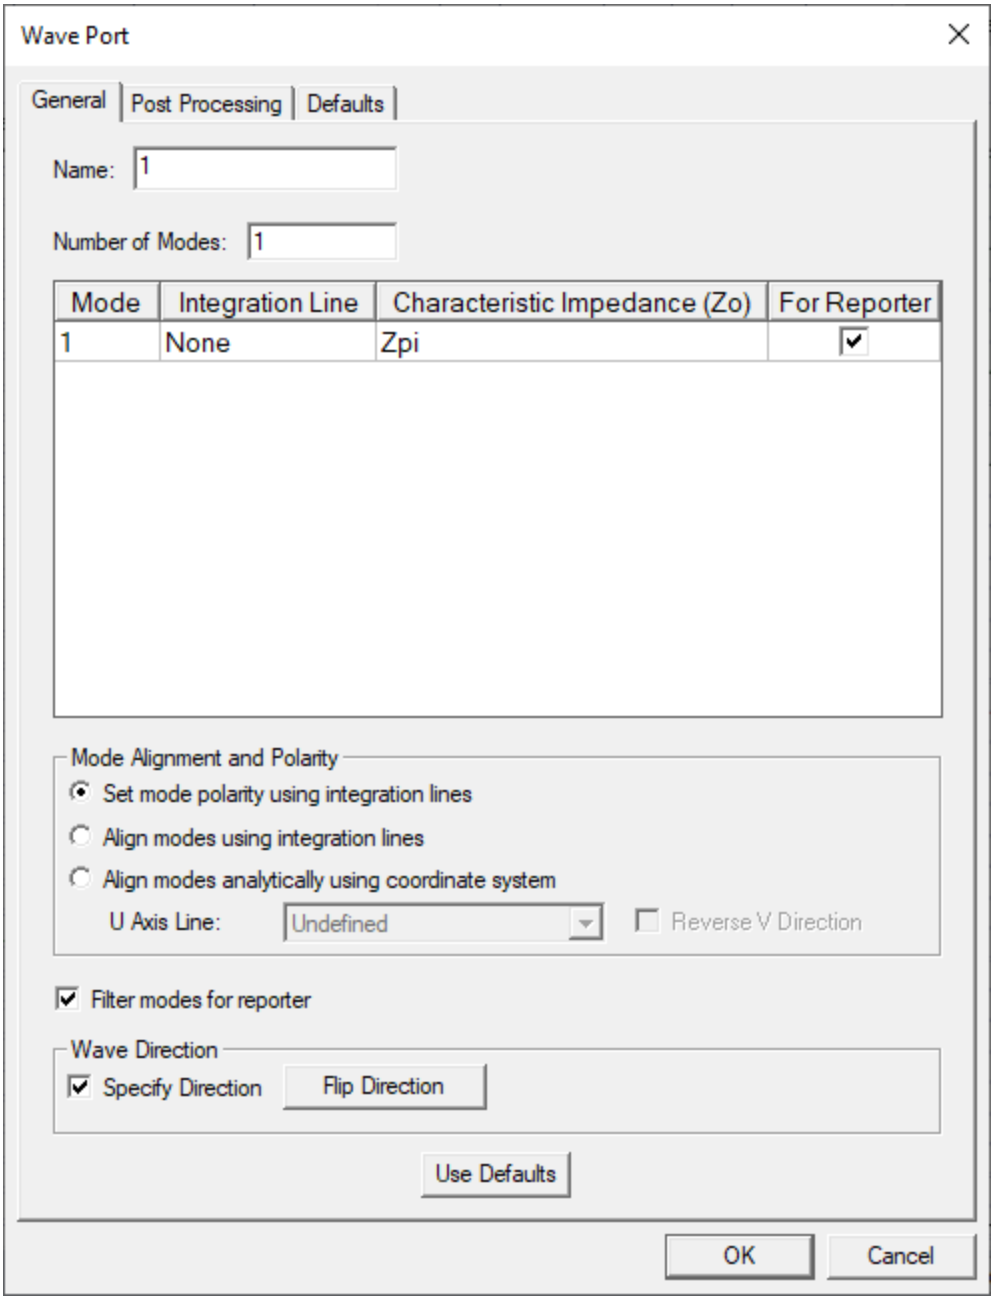
The different tabs and their sub-panels are described in the following subsections.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- General Tab
- Post Processing
- Defaults

General Tab: Wave Ports

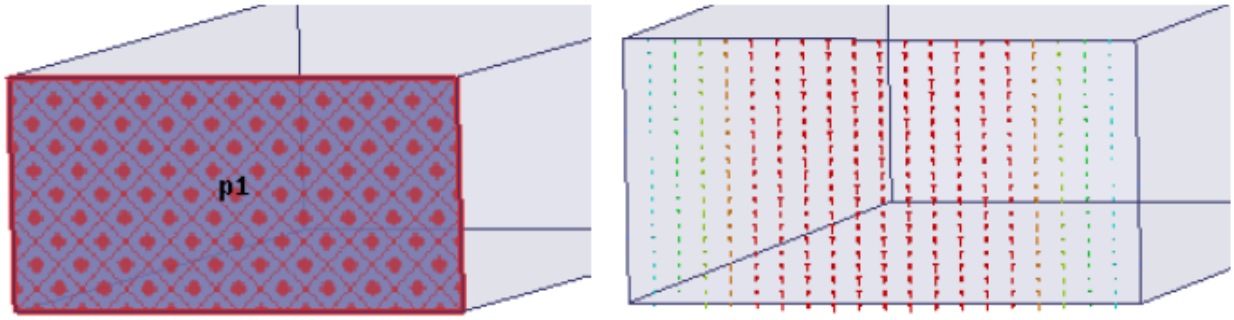
This panel contains a field where you can enter the name of the wave port, as well as the number of modes, set integration lines, and define mode alignment, polarity, and characteristic impedance. Subsequent sections describe all these options and the effect they have on the port field.

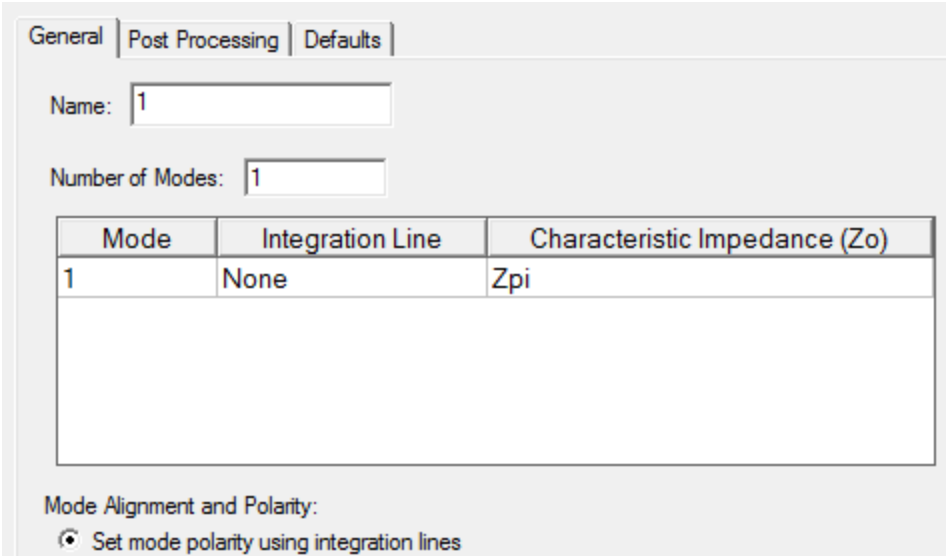


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modes with Default Settings

The following figure shows a wave port assigned on the face of a rectangular waveguide. The default settings in the **General** tab of the **Wave Port** dialog box are used and the port is named *p1*. No integration line has been defined. From the **Project Tree** if you select the option **Mode1** under **Port Field Display** you can see the electric field patterns for that mode. The direction of mode propagation for the corresponding wave port is shown below. Notice that the intensity is highest in the middle (indicated by the red arrows) and tapers to zero on the sides for the TE01 mode for the rectangular waveguide. Since no integration line has been defined, the polarity is arbitrarily up or down.

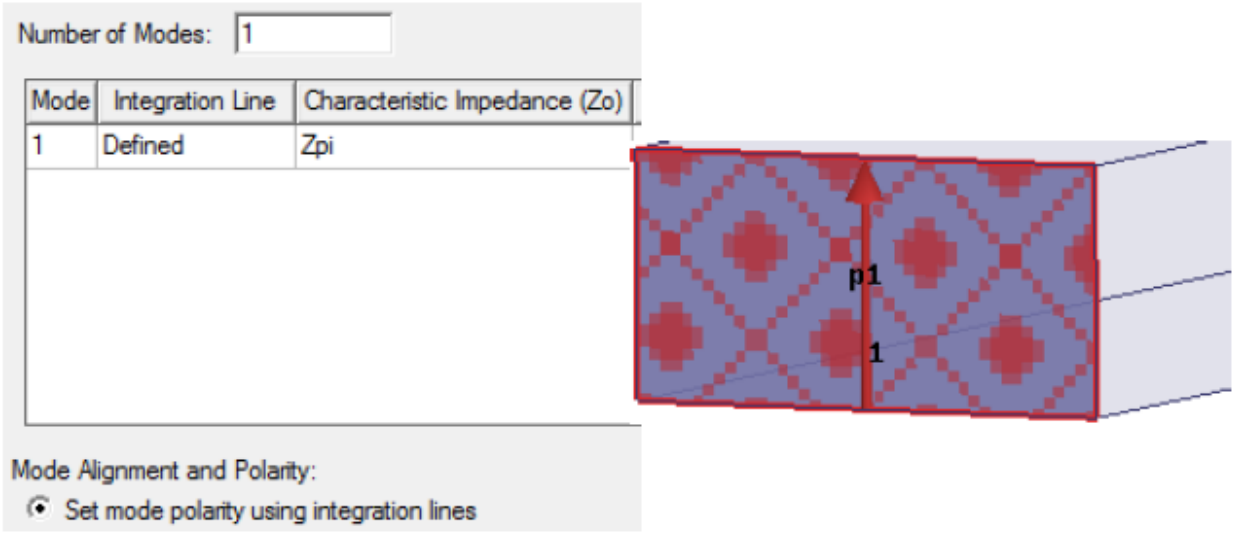




Set Mode Polarity Using Integration Line

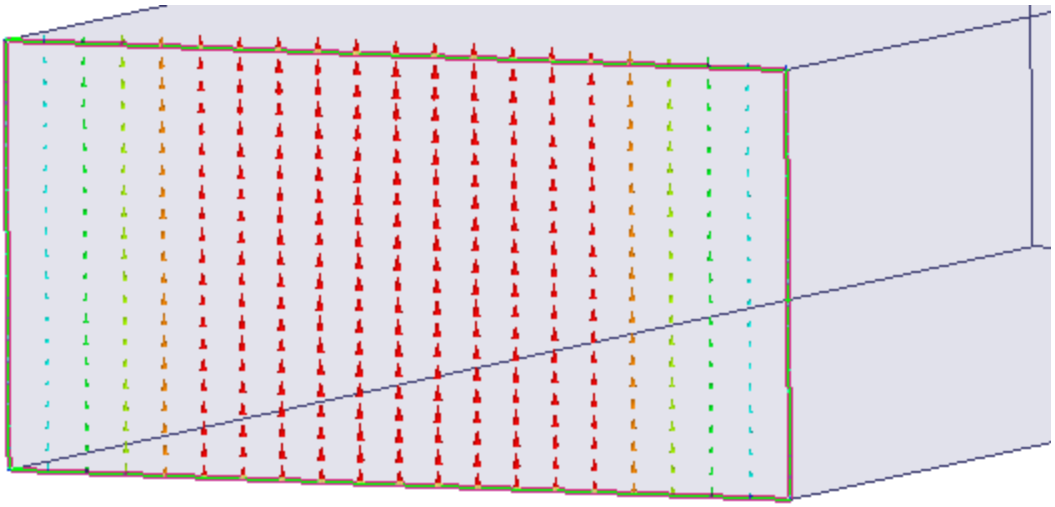
By drawing integration lines you can set mode polarity. The settings in the **General** tab of the **Wave Port** dialog box for a single mode and the integration line drawn for a WR-90 rectangular waveguide are shown below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



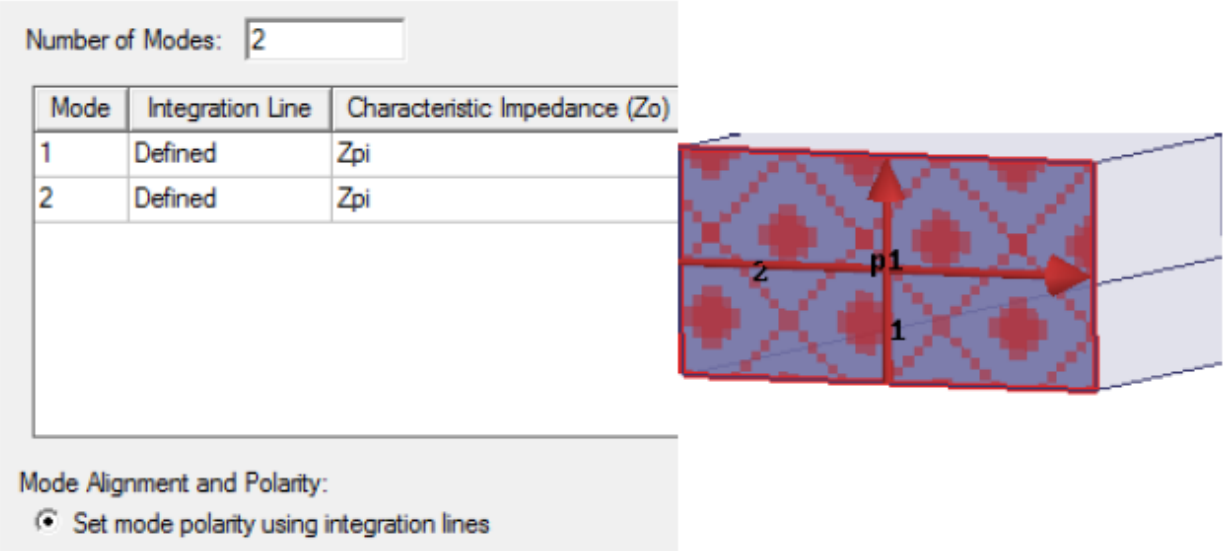
The mode alignment can also be set using the integration lines. In this case the direction is flipped upward as set by the direction of the integration line.

.

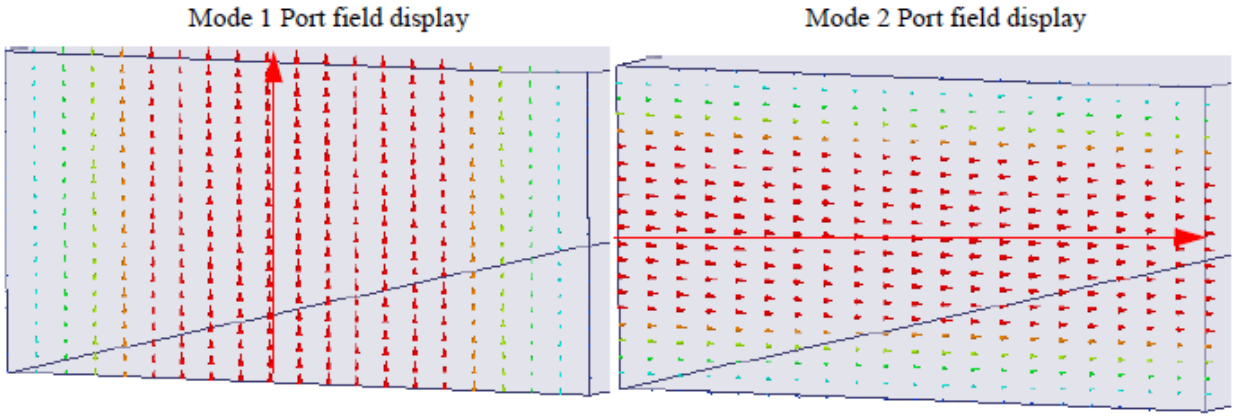


See the settings for another WR-90 waveguide with the integration lines 1 and 2 defined for two modes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The corresponding port field display are as follows:



Note:

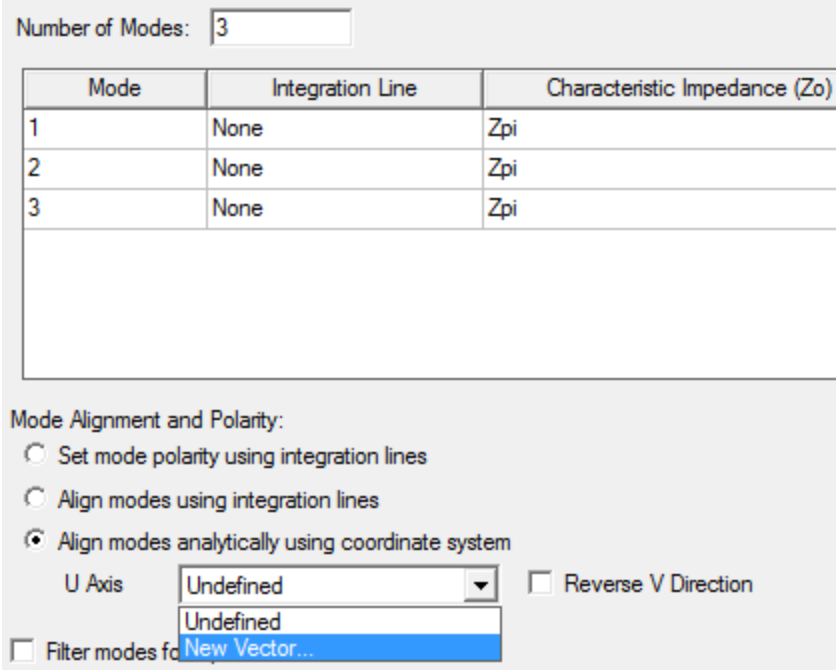
The voltage along integration line 1 is positive for Mode 1 and the voltage along the integration line 2 is positive for Mode 2.

Align Modes Analytically Using Coordinate System

This option is used to align modes for standard waveguides such as square waveguides, rectangular waveguides, coaxial waveguides etc. (For a complete list, see the section Analytic Port Types). On the **General** tab of the **Wave Port** dialog box, select the last radio button and **New Vector** from the drop-down menu. Draw the U-V axes to determine the mode alignment.

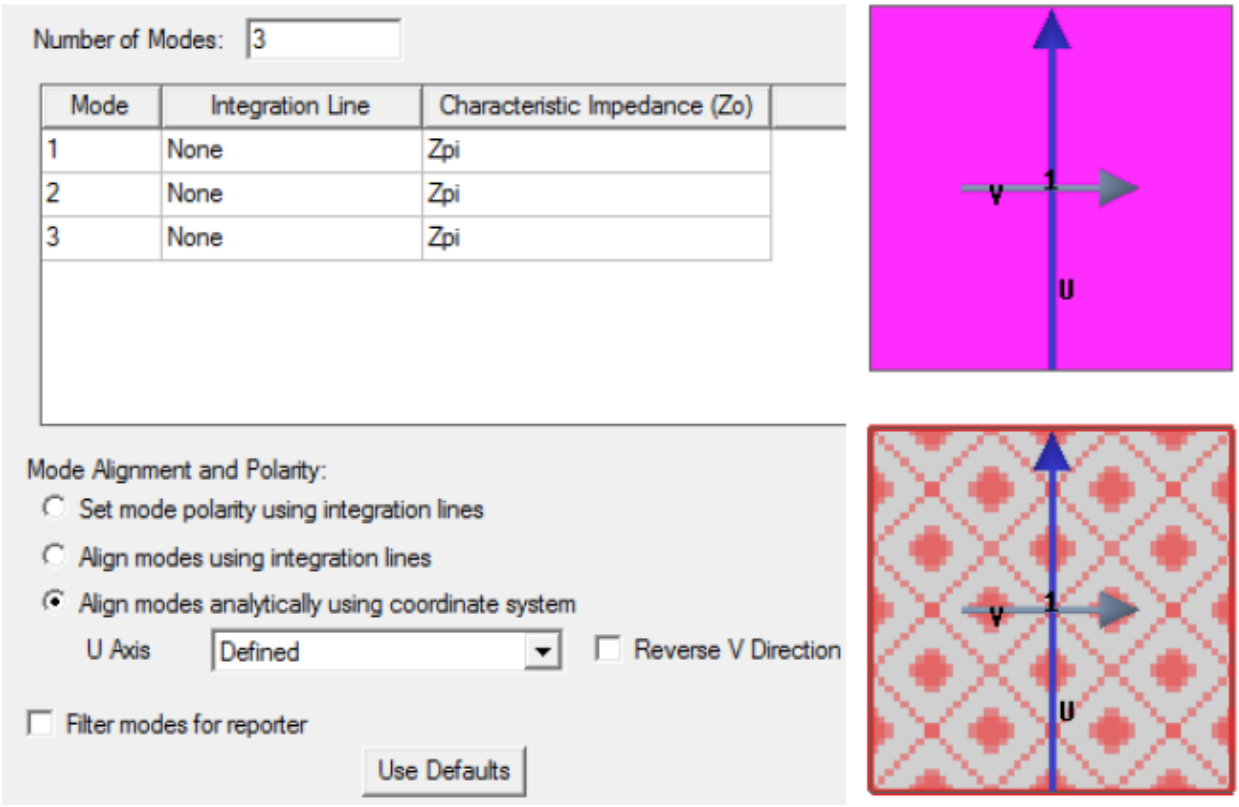
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

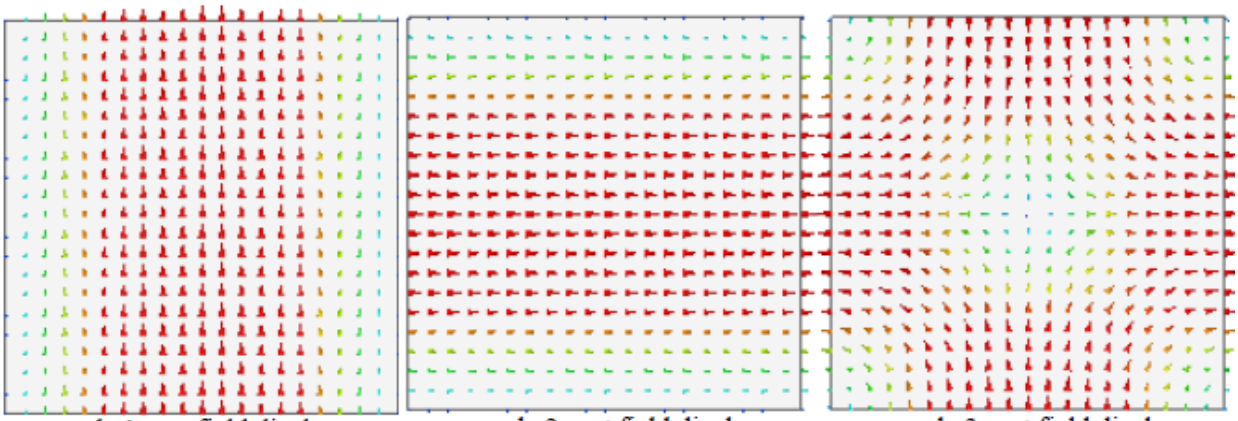
The U axis must lie on the center of the port plane and split the port into equal haves. Otherwise an error message will pop up.



The figures below show the cross-section of a square wave guide for which the U-V axes are set and no integration lines defined for 3 modes. The U-axis must lie along the port plane and split the port into two equal halves. After you define the **Solution Setup** and run the simulation, the **Port Field Display** for the 3 modes are also shown in the figures below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





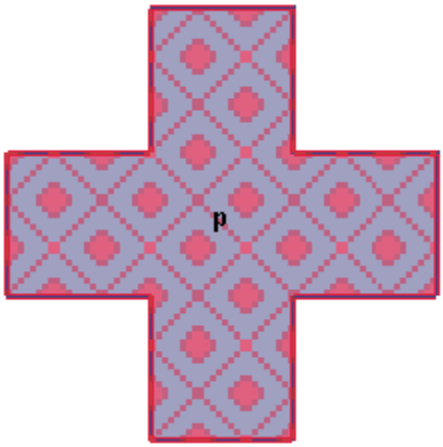
mode 1 port field display | mode 2 port field display | mode 3 port field display

Align Modes Using Integration Lines

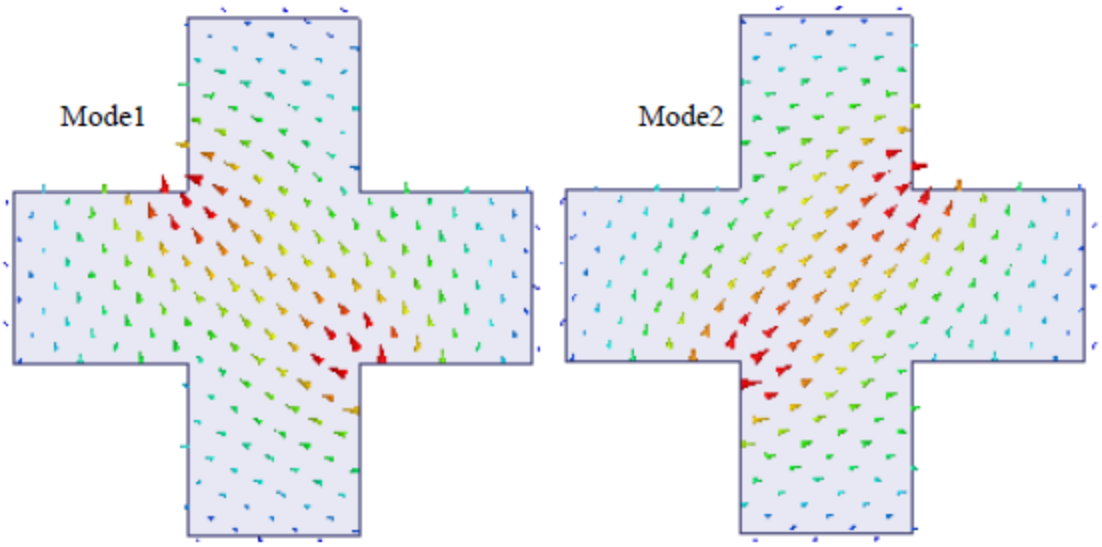
This option is for advanced users working with non-standard waveguides which may have degenerate modes. First we will investigate the fields for a wave port assigned on the surface of a symmetric cross-waveguide (shown below) using the default settings on the **General** tab of

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the **Wave Port** dialog box. (**Set mode polarity using integration lines**) for 2 modes. No integration line is defined.

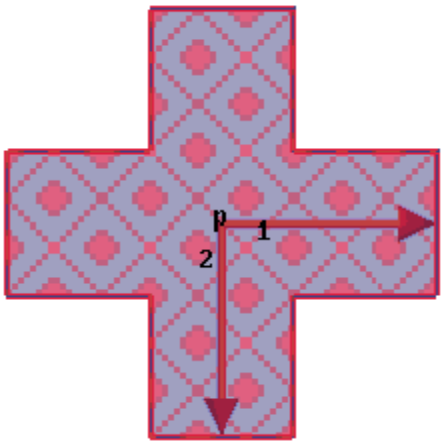


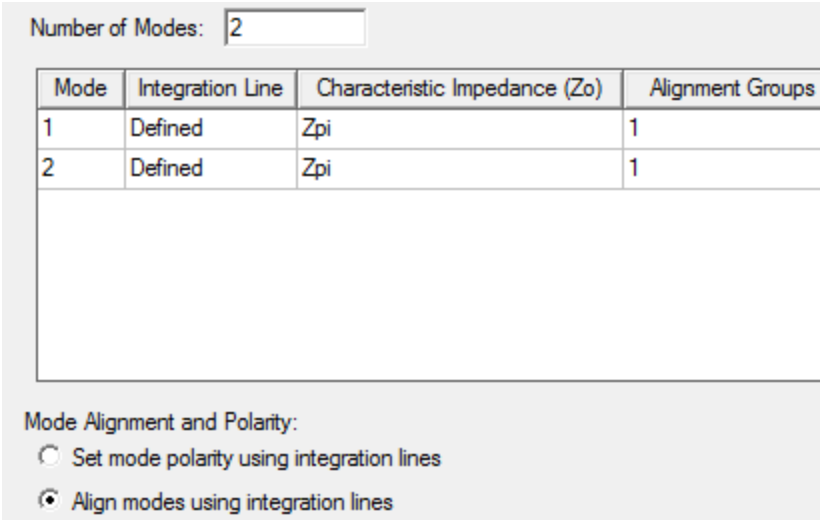
The solver arbitrarily assigns the polarity for the modes 1 and 2.



Any combination of degenerate modes results in just another combination of degenerate modes. There is no uniqueness in the orientation of the modes. To get a unique orientation advanced users can select this option **Align modes using integration lines** and define the integration lines appropriately. Prior knowledge of the mode pattern is necessary before you define the Integration Lines for mode alignment. You cannot draw the integration lines randomly. They are extremely important to get the mode alignment that you want. See the integration lines 1 and 2 defined on a port face shown below and the settings in the **Modes** sub-panel.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

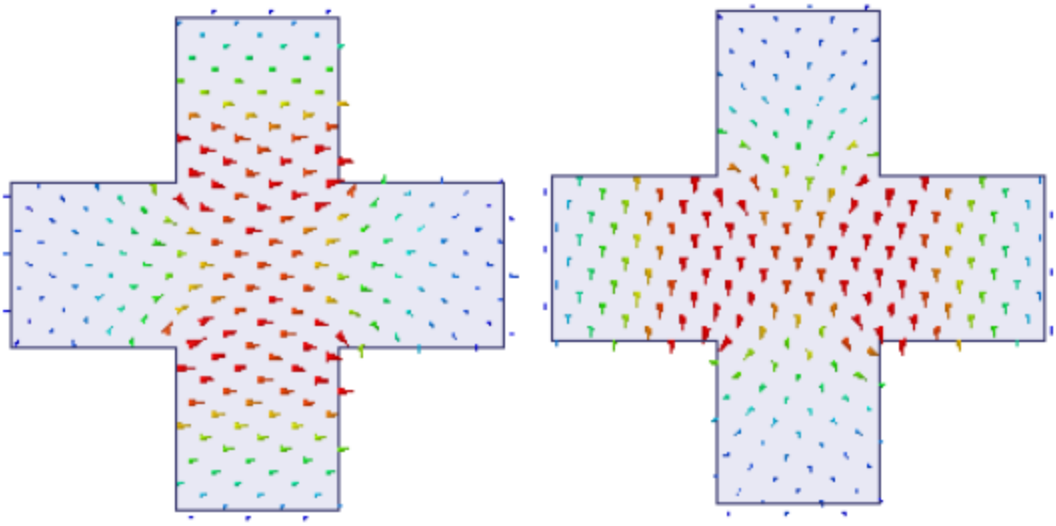




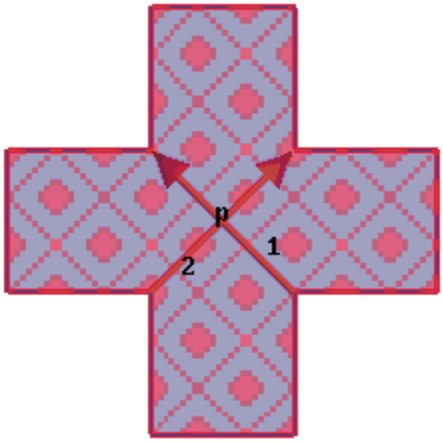
Alignment Groups

This column appears only when you select the option **Align modes using integration lines**. The modes that have the same **Alignment Group** number are degenerate. To help the solver choose which modes are degenerate you must assign the **Alignment Groups.** When you set the alignment group numbers the solver accumulates the modes of a specific group number and causes each mode within that group to have a positive voltage along its own integration line and zero voltage along all other integration lines. For example, defining integration lines 1 and 2 at right angles to each other for the port face (shown above) will cause the modes to be aligned as illustrated in the following figures.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

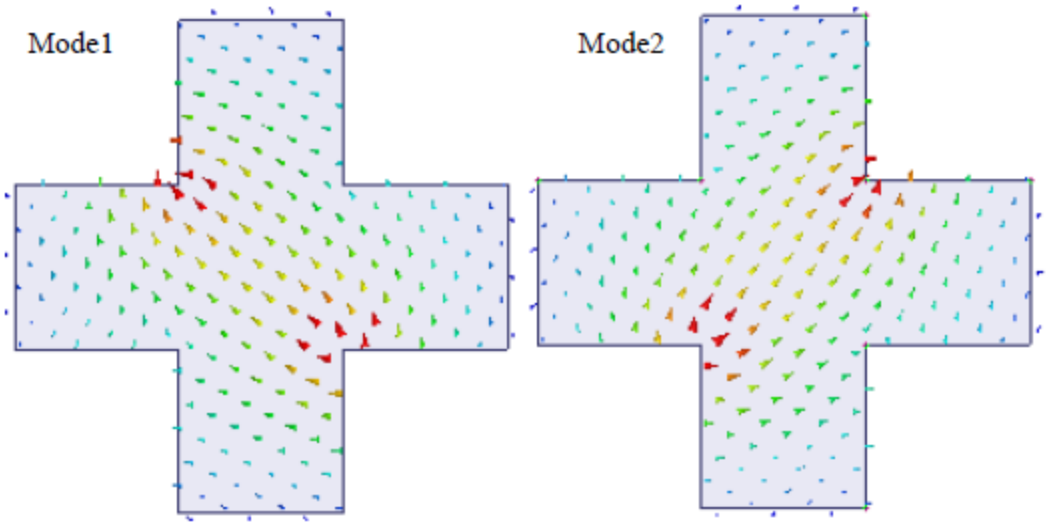


Suppose you want the modes to be aligned along the integration lines 1 and 2 defined diagonally as shown in the following figure.



According to this definition of the integration lines, the solver aligns the modes within a given group (1 in this case) such that Mode *n* has a positive voltage along integration line *n* and zero voltage along all other integration lines.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

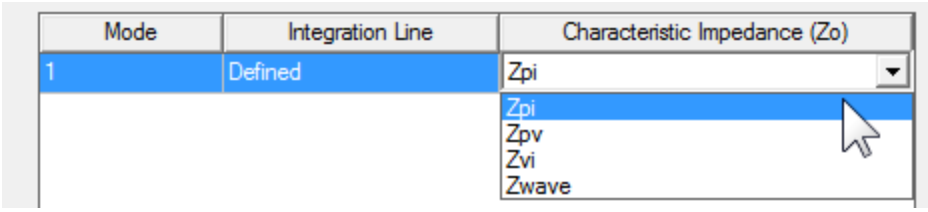


Note:

For more information, see Mode Alignment.

Characteristic Impedance Column

The **Characteristic Impedance Column (Zo)** lists four options (**Zpi, Zpv**, **Zvi, and Zwave)** in its drop-down menu. The options **Zpv**and **Zvi** will appear only if you provide a voltage through defining an integration line for a specific mode such that a unique voltage for that mode can be computed. These quantities **Zpi, Zpv**, and **Zvi** need not be equal to each other. Other than TEM modes, these three quantities will give different results since the voltage is not unique and the result depends on the path used to compute the voltage. Zwave is strictly only applicable for homogeneous waveguides but we use this equation for any ports which should be OK for weakly inhomogeneous waveguides as well.



In case you do not define an integration line only **Zpi** is shown.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mode	Integration Line	Characteristic Impedance (Zo)
1	None	Zpi
2	None	Zpi

Note:

For more information, see calculate the characteristic impedance.

Electromagnetic power **P** = **E** x **H** (with magnitude of **P**) is injected into the 3D model to calculate the fields, voltages, and currents. The basic equations for characteristic impedance are as follows:

$$Zo = \frac{V}{I} \quad ; \quad P = V \cdot I$$

The expressions for characteristic impedance in terms of power vary as follows:

When using **Zpi:**

$$Zpi = \frac{P}{I^2}$$

When using **Zpv:**

$$Zpv = \frac{V^2}{P}$$

For **Zvi** the following expression holds

$$Zvi = \sqrt{Zpi \cdot Zpv}$$

For **Zwave**:

$$Zwave = \int \frac{(nxE \bullet nxE)}{P}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

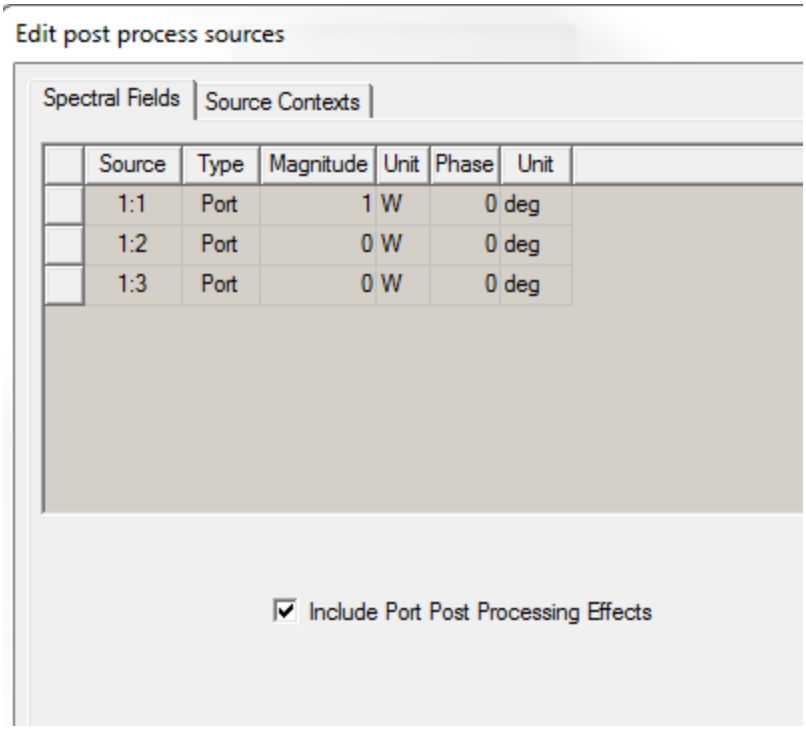
For more information about how HFSS defines these values, see Calculating the Z_{PI} Impedance, and Calculating the Z_{PV} Impedance.

Port Post Processing Tab: Modal Solutions

De-embedding and renormalization are the two post processing options available in HFSS. De-embedding changes the reference plane where the port is placed rather than literally defining a new port on a different reference plane. Reference plane is the location where the S-parameters are calculated. De-embedding helps to calculate the S-parameters near or on the plane of a discontinuity or when a long transmission line is attached to the port plane instead of explicitly modeling it in HFSS.

Renormalization changes the load impedance of the port.

Both renormalization and deembedding affect the network parameters. They will also affect the fields if the **Include Port Post Processing Effects** option is selected in the **Edit Sources** dialog box.

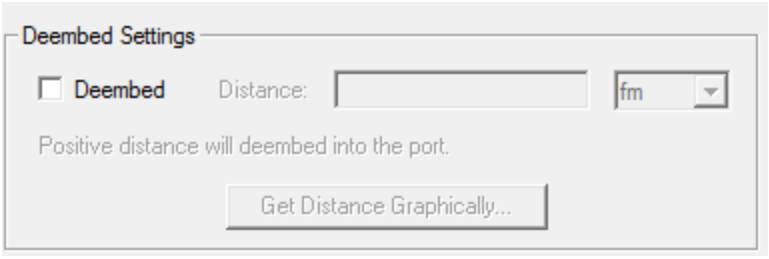


We will now explain the concept of **De-embedding** and **Renormalization**.

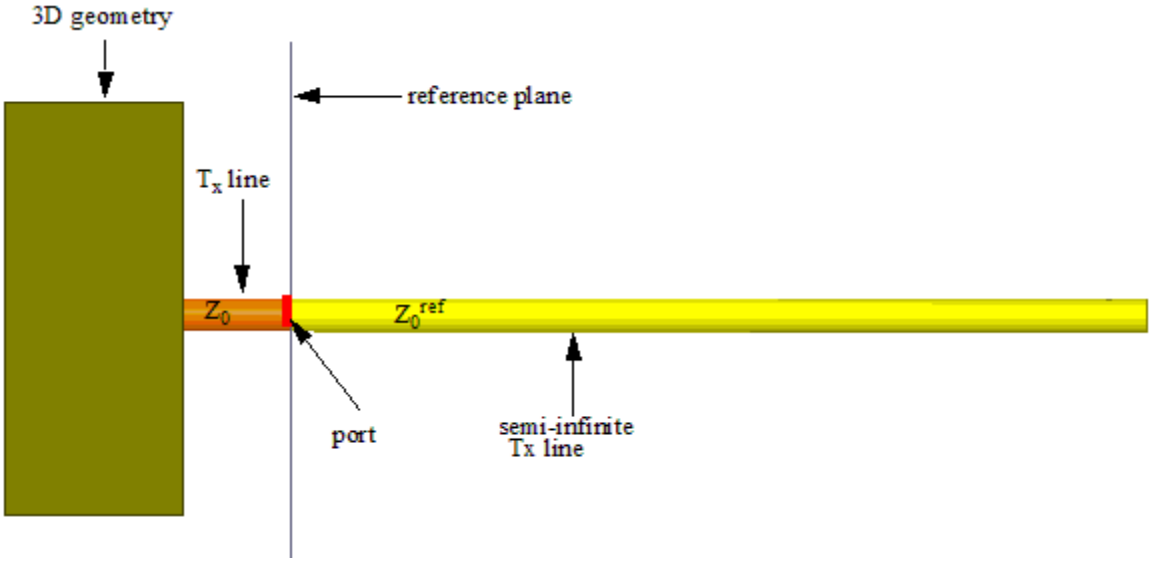
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Deembed Settings

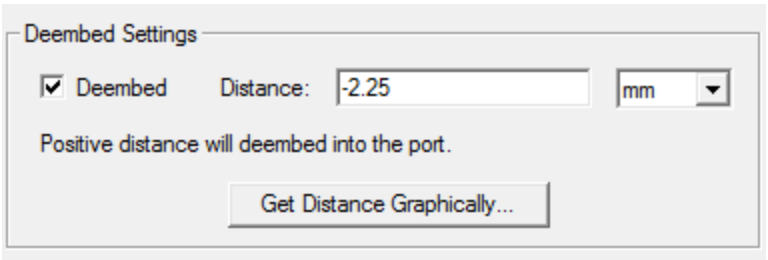
First we will not employ deembedding as shown under **Deembed Settings** of the wave port post processing dialog box.



In this situation, by default the reference plane will be along the port surface as shown below.

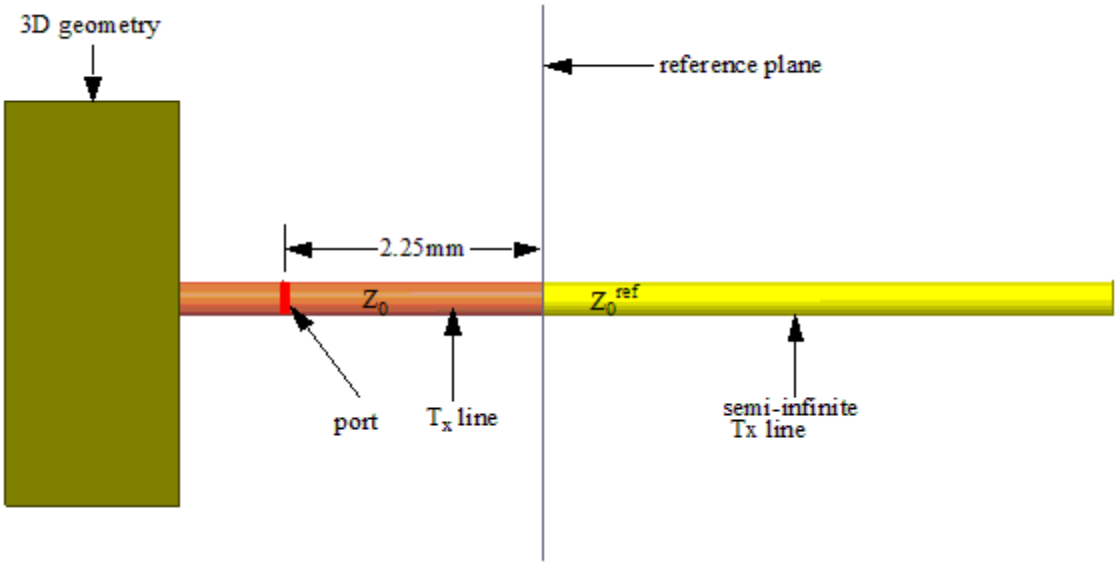


We will now employ deembedding.



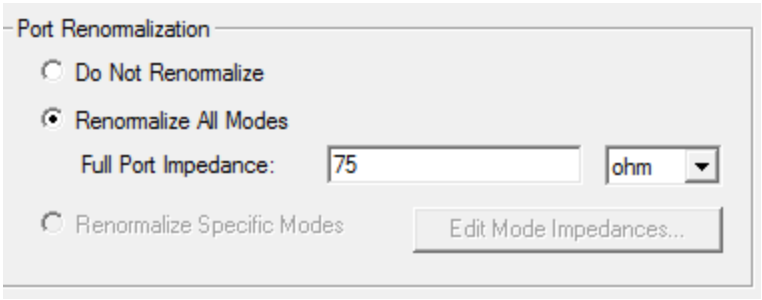
HFSS shifts the reference plane when you deembed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Renormalization

This option lets you vary the value of Z_0^{ref}. When you do not renormalize Z_0^{ref} is Z_0 . When you renormalize as shown in the following figure, Z_0^{ref} will no longer be Z_0 but it will be assigned the value that you enter in the **Full Port Impedance** field. The settings in the following figure makes Z_0^{ref} = 75 ohm.



If you want to enter a complex impedance, enter it in the form *<re>* + *<im>j.*, for example 50ohm + (-5ohm) * 1i . You can assign a variable to these values, (for example " resistance + (reactance) * 1i"). This variable can be dependent on the frequency, which allows use of a dataset for frequency dependent impedance, (for example, pwl(ds1,freq) + (pwl(ds2,freq)) * 1i).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> You do not need to re-run a simulation in order to renormalize a port. Post-processing reports are automatically updated to reflect the renormalized S-matrix.

Assign Wave Ports for Modal Solutions

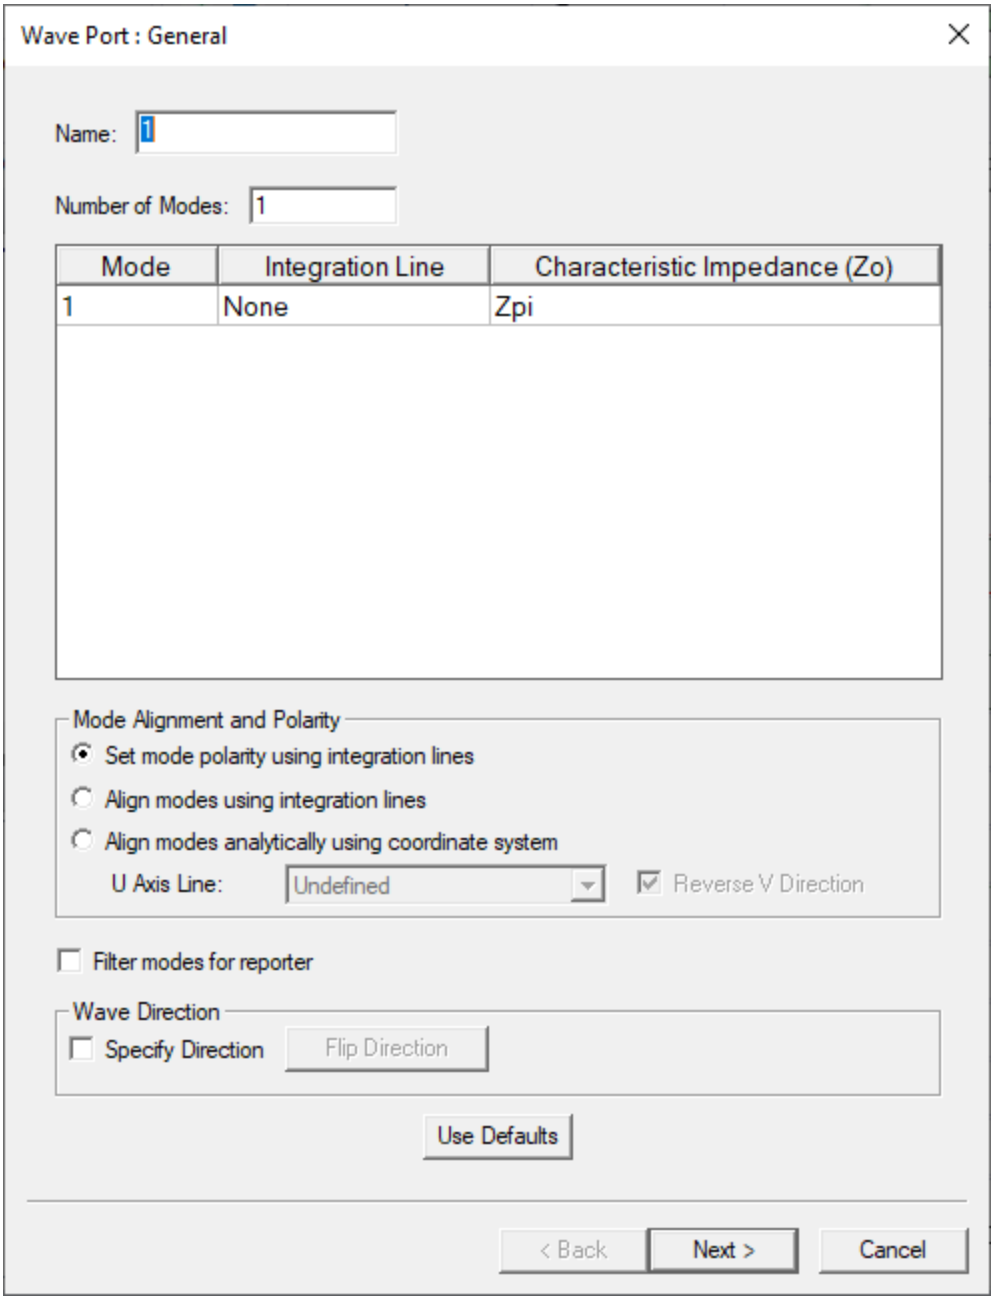
This section outlines the steps for defining excitations for modal solutions.

1. Select coplanar face(s) that you want to excite.
2. Click **HFSS>Excitations>Assign>Wave Port**

   The **Wave Port** dialog menu appears with the **General** tab selected.
3. Enter the name of the wave port.
4. Specify the number of modes for a port.
5. If necessary define the integration lines for each mode, and set the characteristic impedance. and specify whether to filter modes for the reporter.

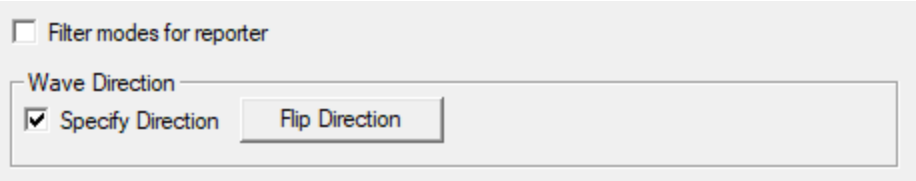
   > **Note:**
   >
   > For more information about the **Integration Lines**, see Defining an integration line.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

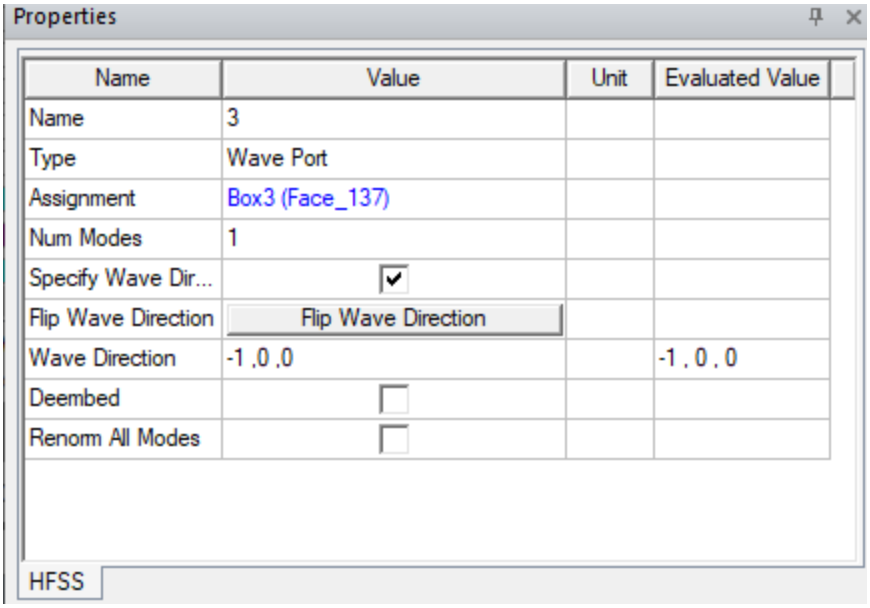


6. You can specify whether to filter modes for the reporter. See Define Mode Alignment and Polarity.
7. A checkbox for Wave Direction allows you to specify the direction indicated by an arrow in the modeler window. You can flip the direction by clicking an enabled **Flip Direction** button. If you specify direction, a PEC cap is not required for an internal wave port.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In the “Properties” page, the “Wave Direction” specifies the normal direction to a port surface as the wave propagation direction.



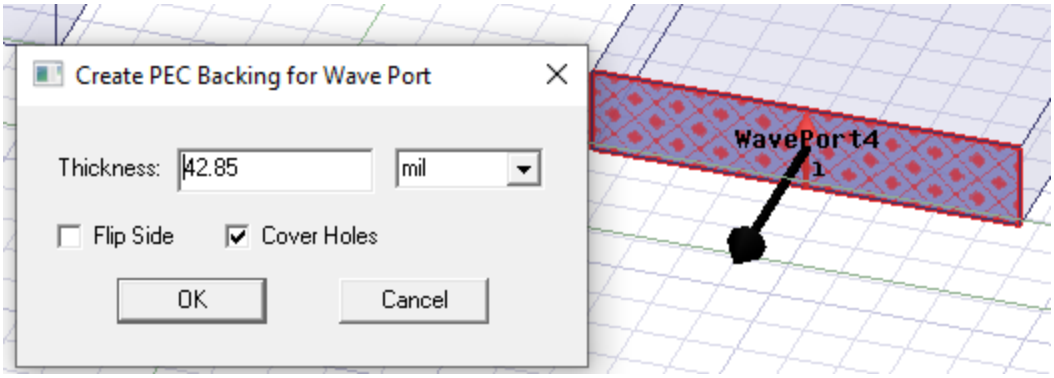
Similar to shell elements, the solver would treat the port surface as a split two side sheet, with the “Wave Direction” side as wave port and the other side as PEC. Put in way, this approach shrinks the sides of an otherwise PEC backing object to zero thinness, but leaves the top and bottom surfaces intact.

Automatic PEC Creation on Modal Wave Ports

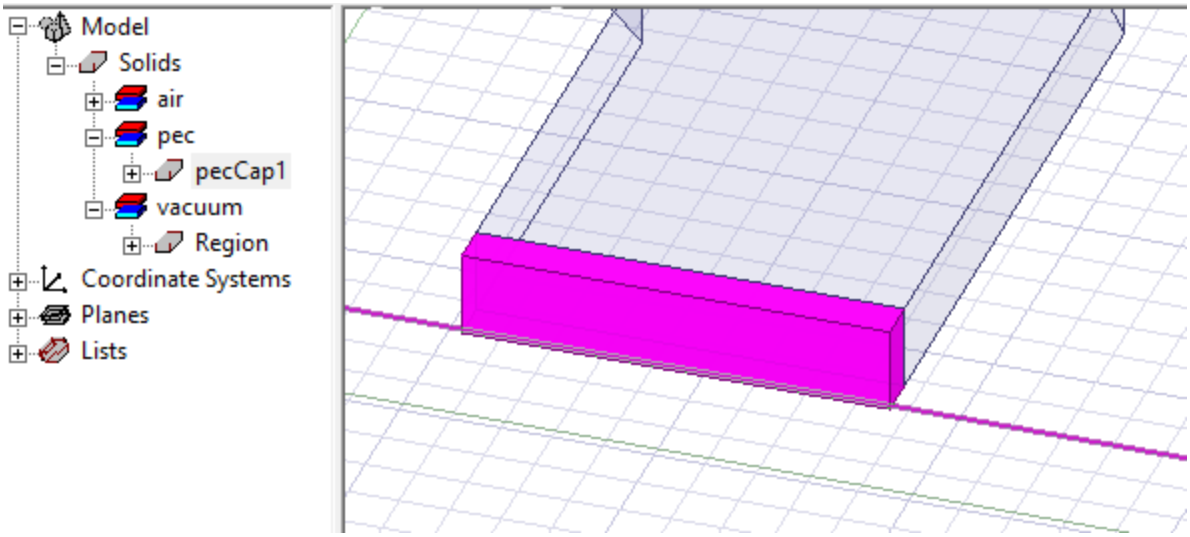
In HFSS, A wave port must have 'solve inside' objects on one side only. An internal wave port can include a PEC object to be attached to and cover the opposite side.

This HFSS Boundary Assignment Option automatically adds a PEC backing to every newly created wave port when necessary. When a new wave port is created and requires a PEC backing, a dialog window opens to let users create such backing by extruding the port face with specified thickness. You have the option to flip the side of the PEC backing. You can also set the thickness as a variable.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



After clicking OK, the PEC backing is created and the new PEC object appears in the History tree.



Once the PEC cap is created it is associated with the port. If you edit the geometry of the port or the geometry/material of the cap, association is deleted and a message is issued. If you reassign or delete the port, the PEC cap is deleted, and a warning is issued.

For an example, see Automatic PEC Creation for Wave Ports.

Define Mode Alignment and Polarity

This section discusses the options under Modes alignment and Polarity that appears on the **Wave Port** dialog box. First bring up the **Wave Port** dialog box as follows:

1. Select the face that you want to excite, right-click, and select **Assign Excitations**>**Wave Port**.
2. Name the port.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

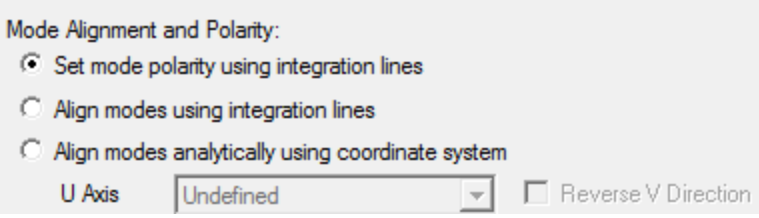
The three options under **Mode Alignment and Polarity** are described below.

Use Set mode polarity using integration lines

This is the default. Use this option as follows:

1. Bring up the **Wave Port** dialog box, access the Modes panel.
2. Enter the number of modes, select the radio button **Set mode polarity using integration lines** to control the polarity.

> **Note:**
>
> HFSS will arbitrarily align the E fields of the modes.

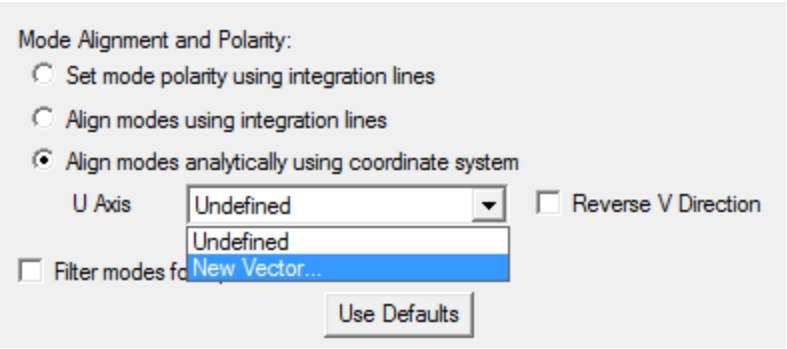


> **Note:**
>
> For more information, see Modes with Default Settings and Set Mode Polarity Using Integration Lines.

Use Align modes analytically using coordinate system

Use this option if the port corresponds to an analytic port type.

1. Bring up the **Wave Port** dialog box and select this option.



2. Select **New Vector** from the U Axis drop-down menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Draw the U axis to split the port symmetrically.

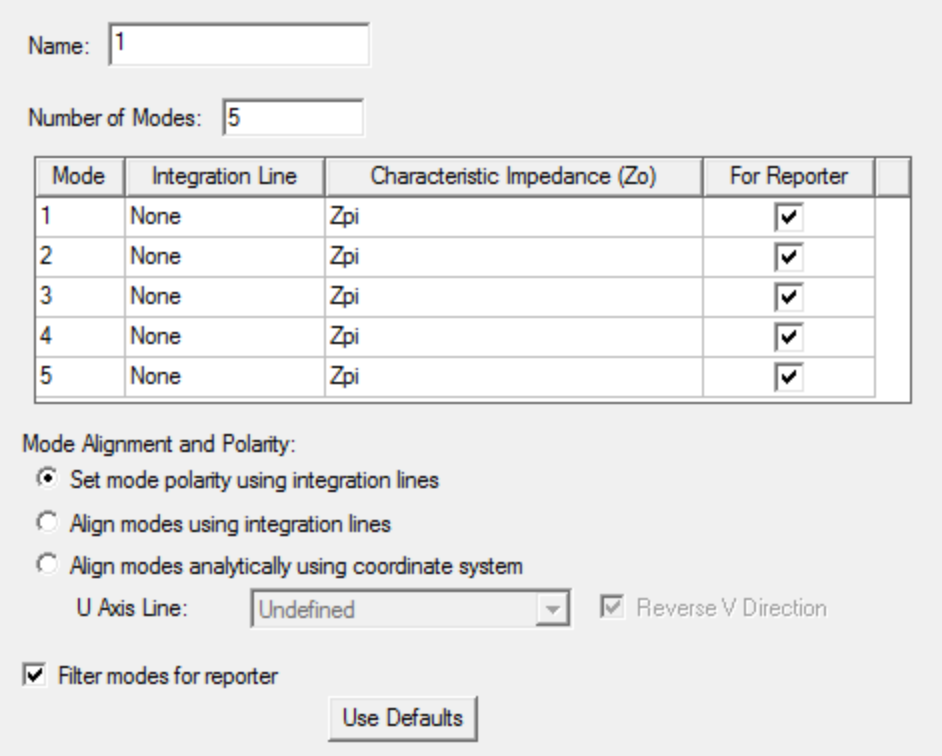
   The V direction is computed automatically and can be flipped using the **Reverse V Direction** check box. The solver polarizes the fields by aligning them with analytic mode patterns that are generated on the U-V coordinate system.

   > **Note:**
   >
   > For legacy projects, when reading in a port, if alignment is requested but only one mode exists, HFSS turns alignment OFF. This prevents an error in validation, and preserves the behavior of having the fields polarized but not aligned.

   If desired, you can check the **Filter Modes for Reporter** check box on the lower left (see below).

   This adds a new column to the Mode table, which lets you use a check box to designate a mode **For Reporter**. For designs with multiple modes, this function will simplify your selections when you create traces for reports.

   For more information, see Align Modes Analytically Using Coordinate System.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Use Align modes using integration lines

This option meant for advanced users causes polarization for non-analytic ports. There is no restriction on the port geometry, materials, or integration lines.

1. Bring up the **Wave Port** dialog box.
2. Specify more than one mode.
3. Select **Align modes using integration lines**.

   A column **Alignment Groups** is added in the Modes table.

4. Select **Alignment Groups** from the corresponding drop-down menu.
5. Define the **Integration Lines** on the port surface as needed.

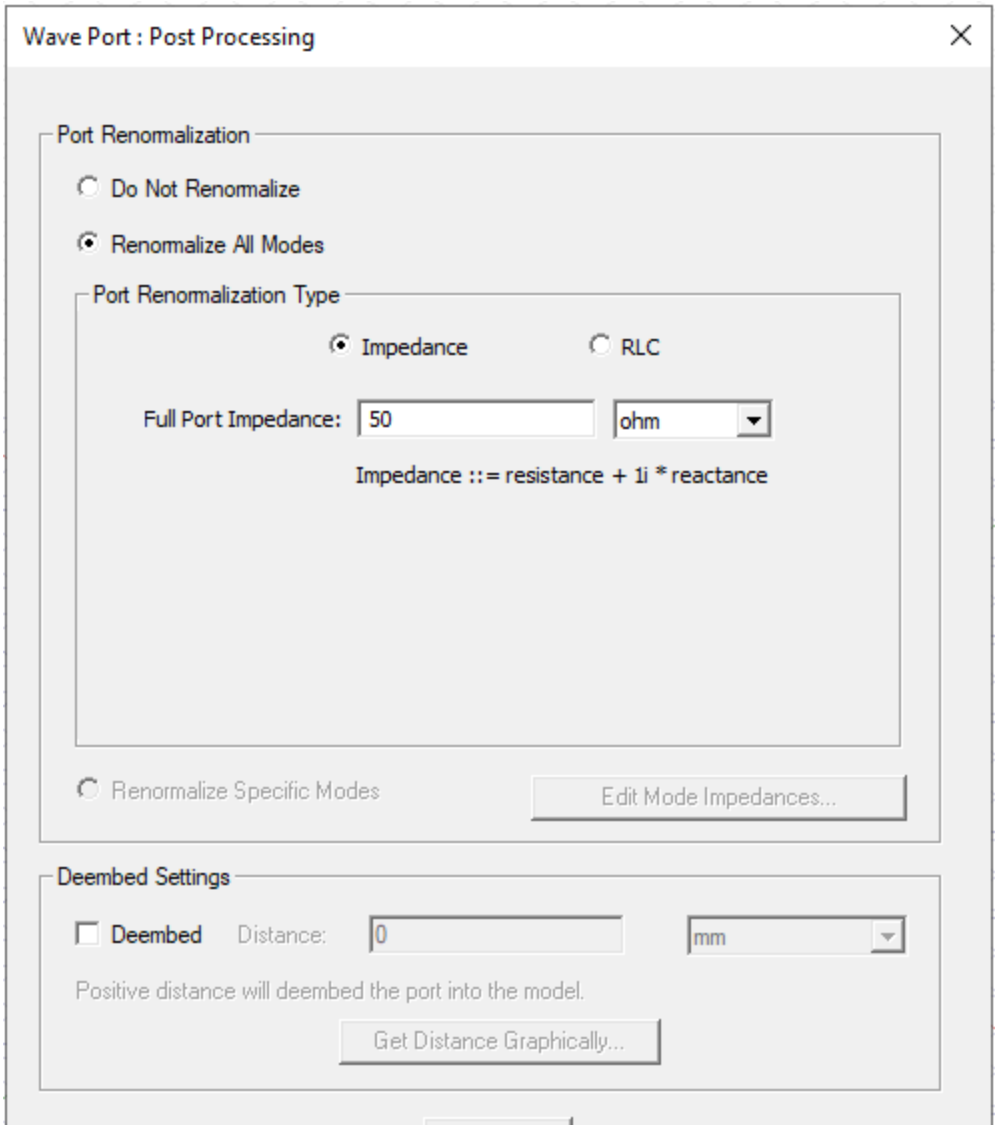
For more information about this option and the effect of **Integration Lines**, see Align Modes Using Integration Lines.

Post Processing: Wave Ports

The **Post Processing** sub-panel has options to renormalize the port to 50 ohms (or any other desired value) or just accept the default option **Do Not Renormalize** and also the **Distance** field to de-embed a port into or out of the model as needed.

A **Wave Port: Post Processing** panel is shown below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



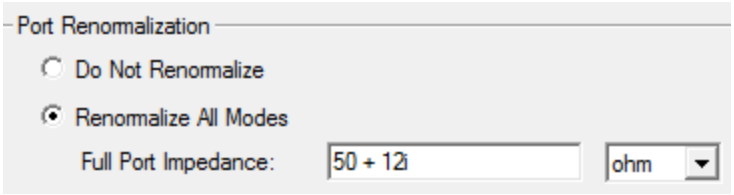
The Port Renormalization choices include:

- **Do Not Renormalize:** This is the default.
- **Renormalize All Modes**: Enables the **Port Renormalization** selections for **Impedance** and **RLC**.
  The default impedance for re-normalization of each mode is 50 ohms.

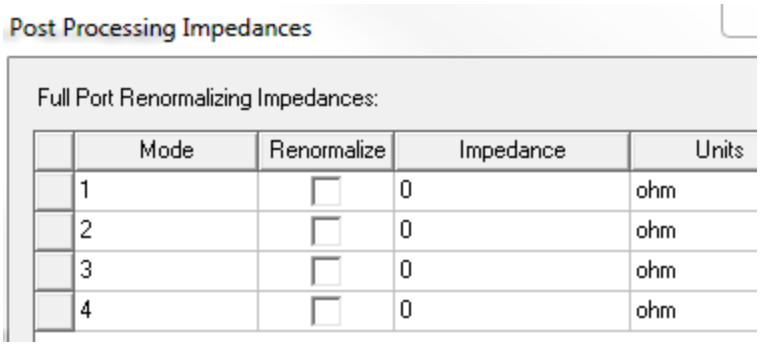
  If you select Impdence, complex impedance should be entered in the form: *<re> + <im>j* or *<re> + <im>i*. Either *j* or *i* entered into the field is displayed as *i* in the field and in a

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

recorded script. See figure below.

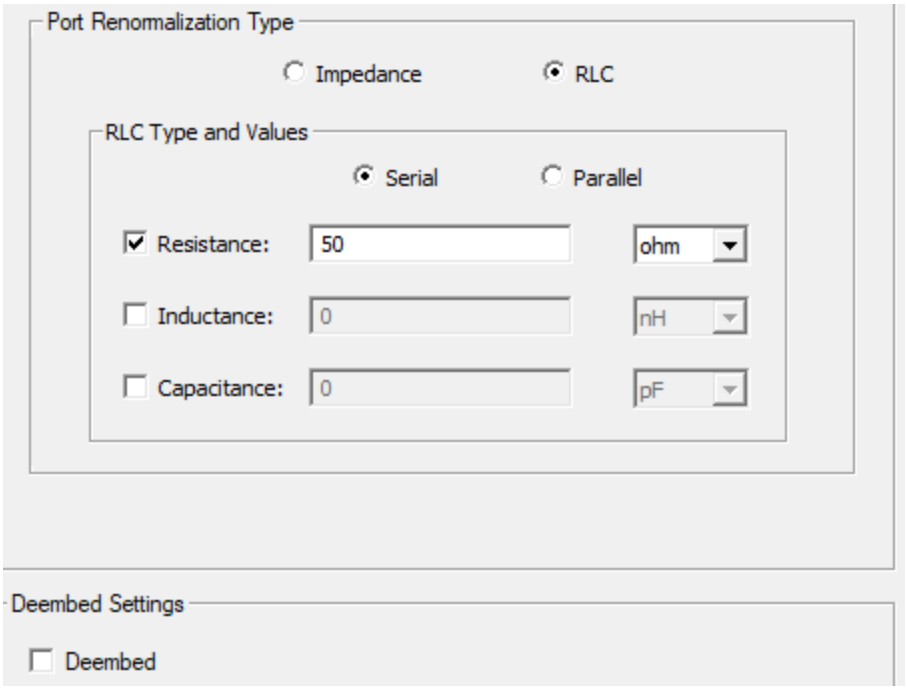


- For multiple modes, the **Renormalize Specific Modes** is enabled, causing the **Edit Mode Impedances** button to be active. Click this button to renormalize the impedance of desired modes.

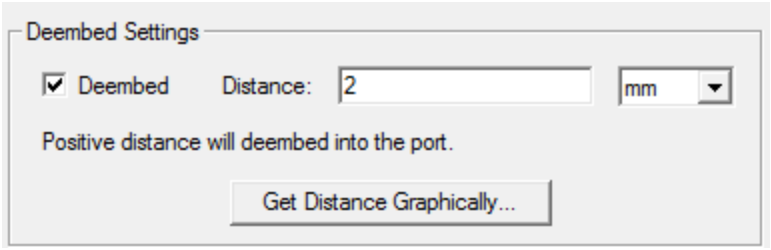


If you select RLC, you can specify Resistance, Inductance, and Capacitance and designate the RLC type as Serial or Parallel.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Enter the **Deembed** distance in the field or draw a line on the model to represent the distance and get it graphically. You can also assign a variable in the **Distance** field.



Important:

The orientation of the **Deembed** arrows in the modeler is determined by the modeler direction of the normal of the face where the port is defined. From the standpoint of the S-parameters what is correct is the sign of the deembed distance.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

- A positive distance value will deembed the port into the structure. A negative distance value will deembed the port out of the structure.
- Make sure you are not creating a non physical situation when you deembed cutoff modes. For example, when you enter a positive distance to deembed a port with a cutoff mode into the model the resulting field values for that mode can be very large.

Wave Ports for Terminal Solutions

HFSS treats a wave port as a semi-infinitely long waveguide or transmission line. For terminal solutions, we deal with transmission lines only. Terminals are the ends of signal traces that intersect the plane of a port.

To fit circuit theory HFSS has options for assigning terminals and expressing the relationship between currents and voltages. Terminals are especially useful when you are dealing with circuit simulators since the S-parameters obtained in terms of currents and voltages are in a format that is compatible with most circuit simulators.

Terminals and Modes

Example of Terminals

Reference Conductors

Terminals and Modes

A terminal is assigned on a conductor in contact with the port. A port with *n+1* distinct conductors that do not touch each other will support *n* terminals, where the remaining conductor is the local reference ground. The solver generates an error if the number of terminals exceeds *n* conductors.

The solver uses as many modes as terminals. These modes are not eigen modes and sometimes referred to as terminal modes. The solver computes terminal modes where all the terminal modes are a superposition of eigen modes such that the S-parameters computed by the solver constitute the corresponding terminal S-Matrix instead of the eigen S-Matrix.

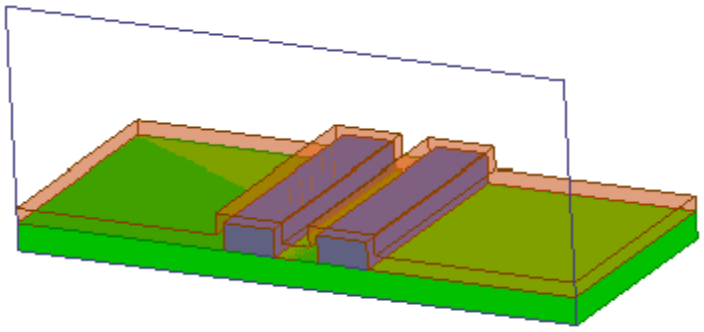
For terminal projects we will deal only with transmission lines and assume that the currents and voltages correspond to quasi-TEM modes. The number of terminal modes is dictated by the number of conductors on the port in the project. Proper port definitions should ensure that no higher order propagating modes exist in the transmission lines.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

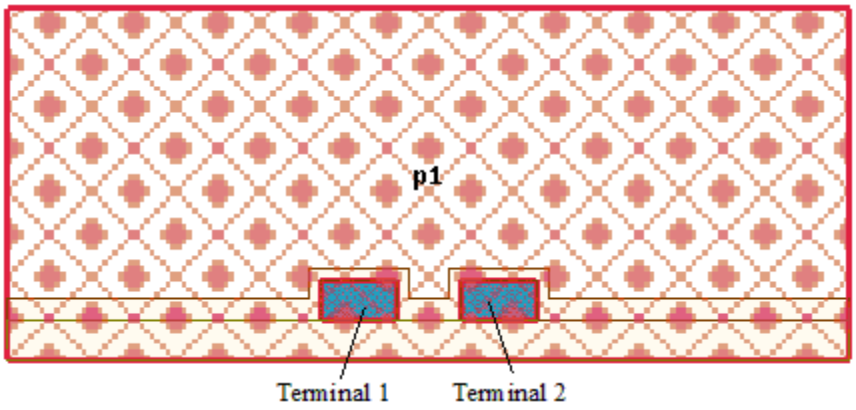
Example of Terminals

A terminal is essentially an insertion point for voltage and current on a multi-trace transmission line.

An HFSS model of a coupled microstrip transmission line is shown below.



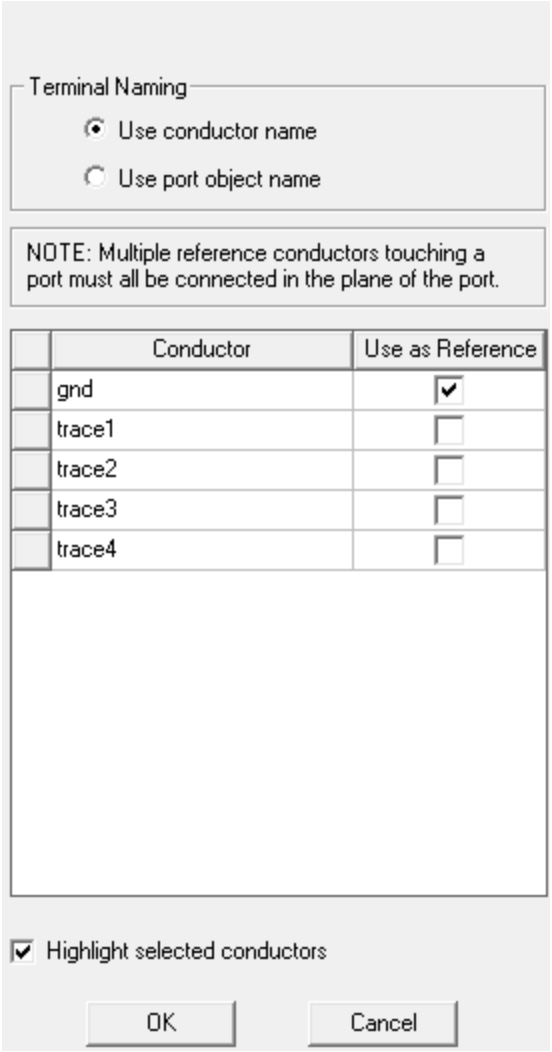
The terminals are defined at the ends of the signal traces where they intersect with the surface of the port as shown below.



Reference Conductors

The **Reference Conductors**dialog box contains a table that lists all the conducting objects used in a model. In this dialog box you will choose the conductor(s) that will act as reference. You can name terminals based on the name of their conductors or their associated ports.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

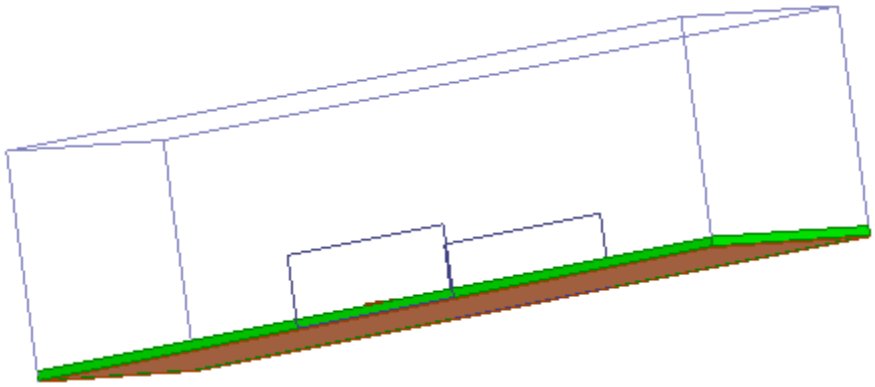


We will depict a couple of scenarios that you may encounter while assigning terminals to conductors in your model. For both scenarios we will consider the same microstrip line with modifications to the model.

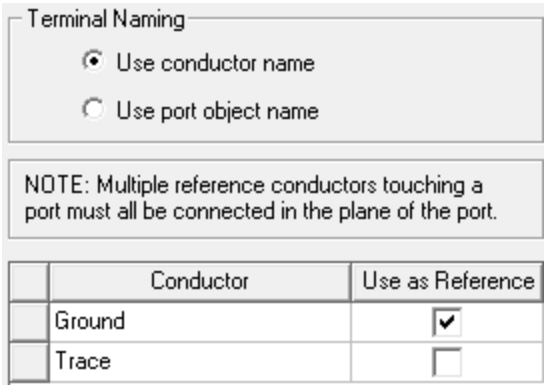
Scenario 1: Explicit Reference Conductor

The following figure shows a microstrip line enclosed by an air box. The model has an explicit ground plane that is orange in color.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



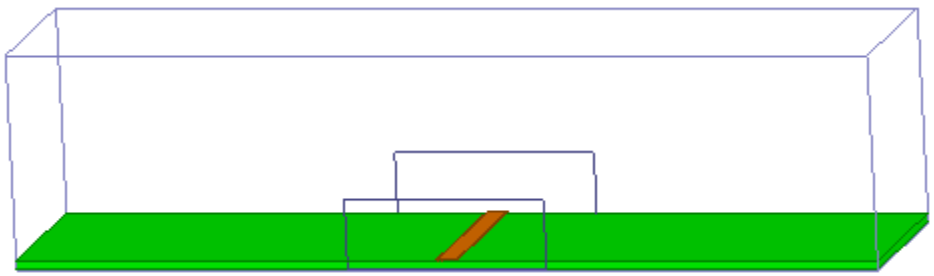
The ground is an explicit object and so it will appear as a conductor in the **Reference Conductors for Terminals** dialog box when assigning terminals to the trace.



Select **Ground** as reference so that the terminal appears only on the *Trace* and not on the *Ground*.

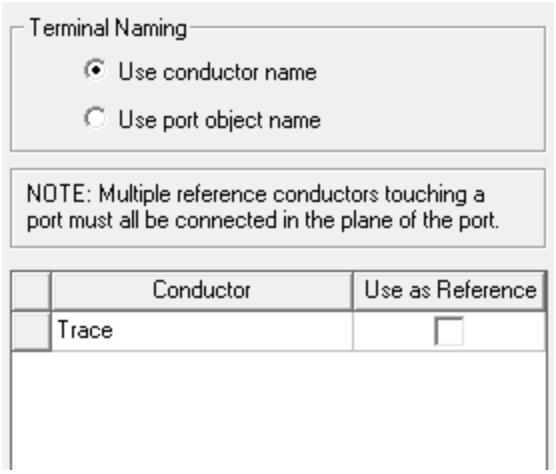
Scenario 2: Implicit Reference Conductor

The following figure illustrates the same microstrip line enclosed by an air box without the radiation boundary. This model does not have the explicit ground plane.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

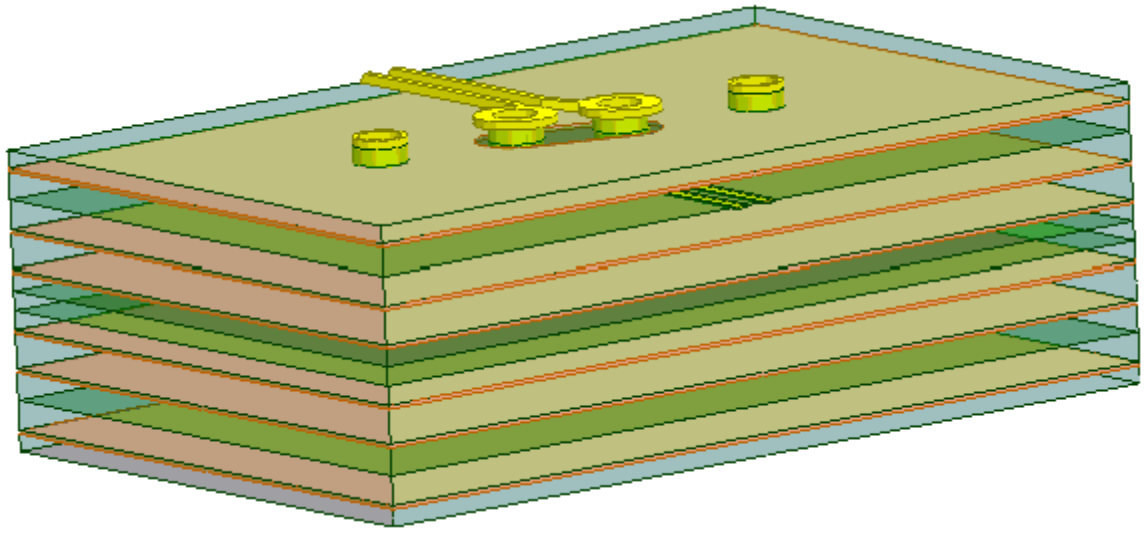
The solver treats the boundary of the air box as PEC because no other explicit boundary condition is applied to it. The air box acts as a reference conductor but will be treated as an implicit conductor that does not appear in the dialog box. In this case do not define the reference conductor as it is already assumed by the solver.



Assign Wave Ports for Terminal Solutions

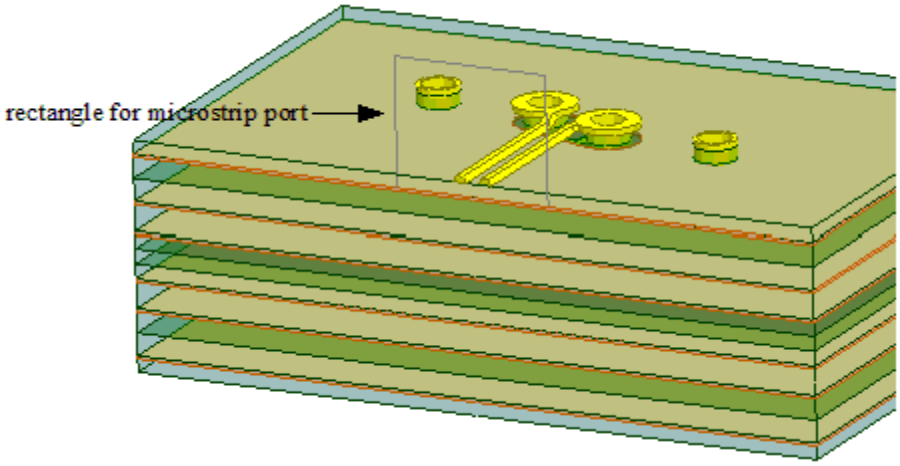
A terminal is a geometry intersection of a conducting object with a port face. The intersection can be a face or an edge in a conducting geometry. The edge can even extend outside the port and though it can be defined as a terminal in the user interface, only the portion of the edge that overlaps with the port is used to define the terminal edge for the solver.

In this section we will assign wave ports on a differential pair via model shown below.

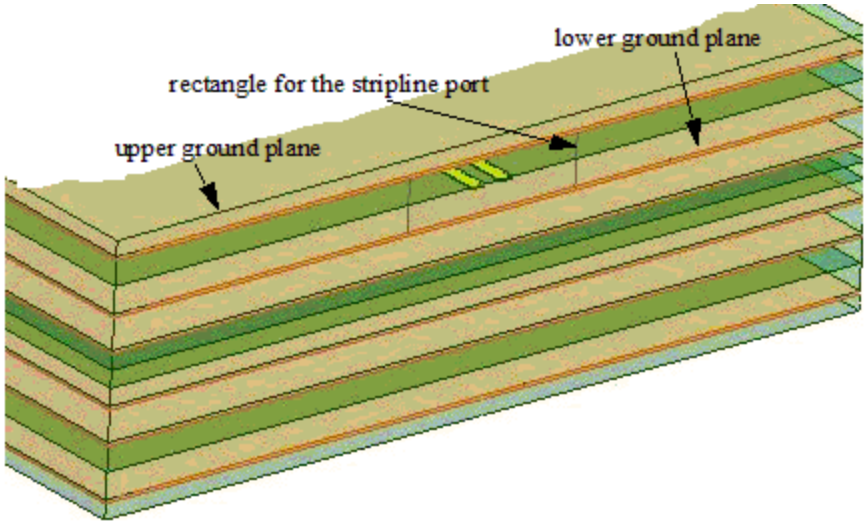


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

We will assign a microstrip port and a stripline port. The guidelines for defining port size introduced in the Microstrip Waveguide section are also applicable for the differential pair model. The microstrip port size is defined as (10w+s + 2w) x 8h where w = microstrip trace width, s = separation between the traces, and h = height of the substrate.



The stripline port is defined as (10b + c + b) x d where b = stripline trace width, c = separation between the traces and d = the distance between the upper and the lower ground plane.

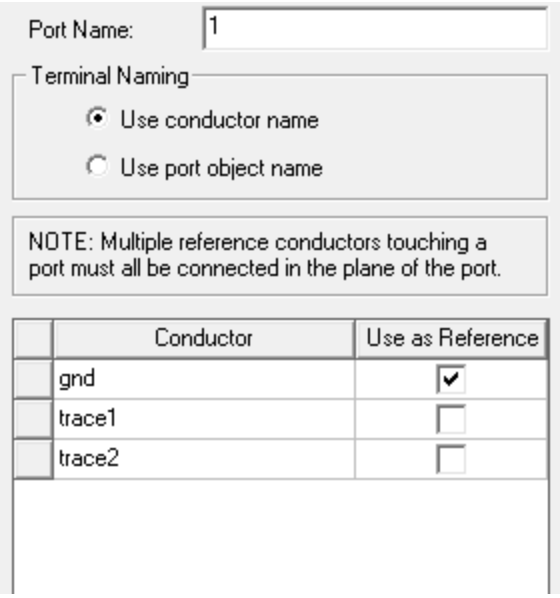


Perform the following steps for terminal assignment.

1. Right-click the rectangle for the microstrip port and select **Assign Excitations**>**Wave Port.**

   The **Reference Conductors** dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Select the **gnd** conductor as reference and click **OK**.

   > **Note:**
   >
   > Number of terminals = Number of conductors - 1 = 3-1 = 2.

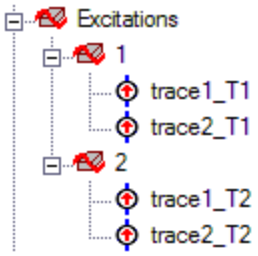
   The port gets assigned and the terminals appear automatically on the microstrip.

3. Similarly assign a wave port on the stripline rectangle.

   The port gets assigned and the terminals appear automatically on the stripline.

   > **Note:**
   >
   > - In rare cases when automatic terminal assignment fails, you can manually assign a terminal by selecting the face of the conductor.
   > - Identification of conductors depends on a threshold conductivity value. The threshold is based on the material assignment or the boundary assignment if a conducting boundary is assigned to the object.
   > - The project manager window gets populated as shown in the following figure.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note:

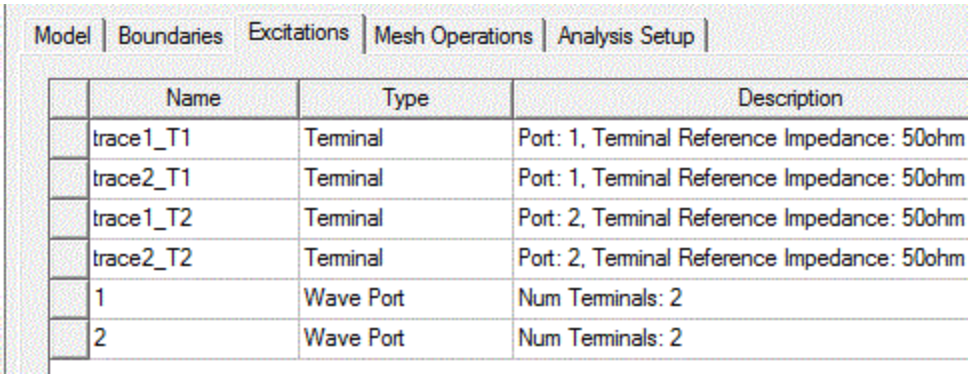
Terminal naming conventions are based by default on the first geometry in the assignment selection for the terminal. You can change the names from the Set Default Boundary/Excitation Base Name dialog box. For auto assign terminals, you can also specify whether naming uses the conductor or the port object name.

Multi-Select Ports and Terminals

To view all of the assigned excitations at the same time, perform the following steps:

1. Double-click **Excitations** from the **Project Manager** window.

   This brings up the **Design List** dialog box.



Name	Type	Description
trace1_T1	Terminal	Port: 1, Terminal Reference Impedance: 50ohm
trace2_T1	Terminal	Port: 1, Terminal Reference Impedance: 50ohm
trace1_T2	Terminal	Port: 2, Terminal Reference Impedance: 50ohm
trace2_T2	Terminal	Port: 2, Terminal Reference Impedance: 50ohm
1	Wave Port	Num Terminals: 2
2	Wave Port	Num Terminals: 2

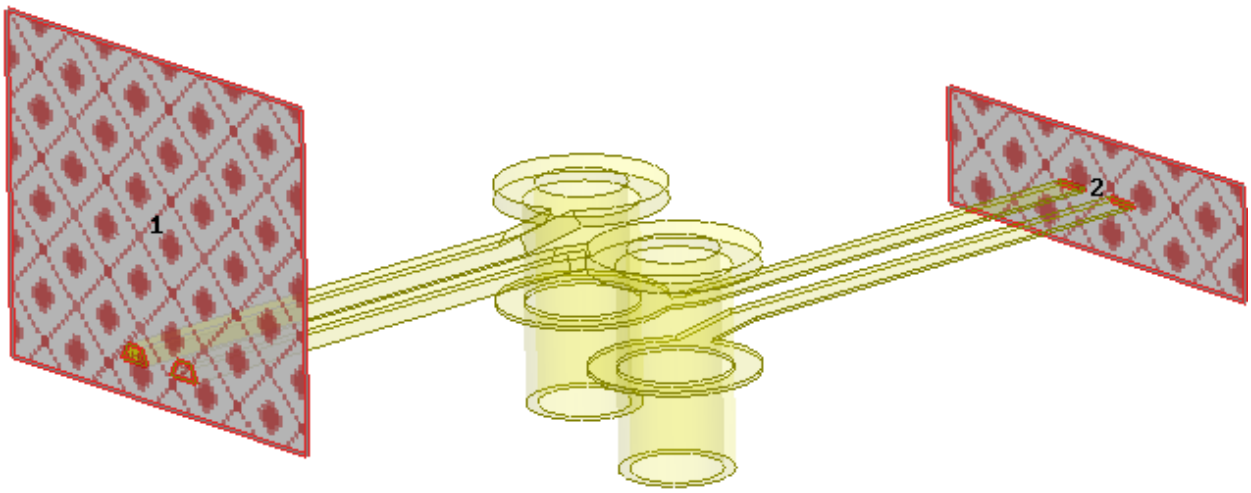
2. Press **Ctrl** and select the excitations that you want to see in the model.

   The selected excitations get highlighted in the model.

3. Click **Done** to close the dialog box.

   For example, the following figure shows all the excitations on the differential pair.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Specify Wave Direction or enable Automatic PEC Creation on Terminal Wave Ports

In HFSS, A wave port must have 'solve inside' objects on one side only. An internal wave port would require a direction assigned, by using the Specify Wave Direction Property:

Properties

Name	Value	Unit	Evaluated V
Name	1		
Type	Wave Port		
Assignment	Box1 (Face_40)		
Wave Port Type	Terminal		
Num Terminals	0		
Specify Wave Direction	☑		
Flip Wave Direction	Flip Wave Direction		
Wave Direction	-1 ,0 ,0		-1 , 0 , 0
Deembed	☐		
Renorm All Terminals	☑		

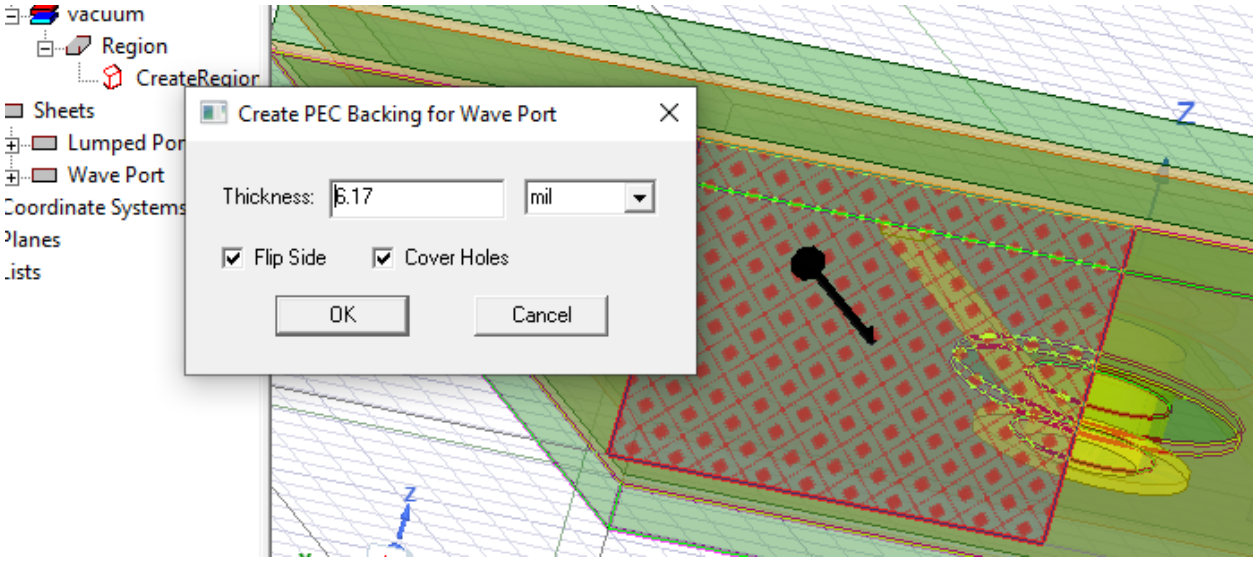
HFSS

When you enable Specify Wave Direction, you can also Flip Wave Direction.

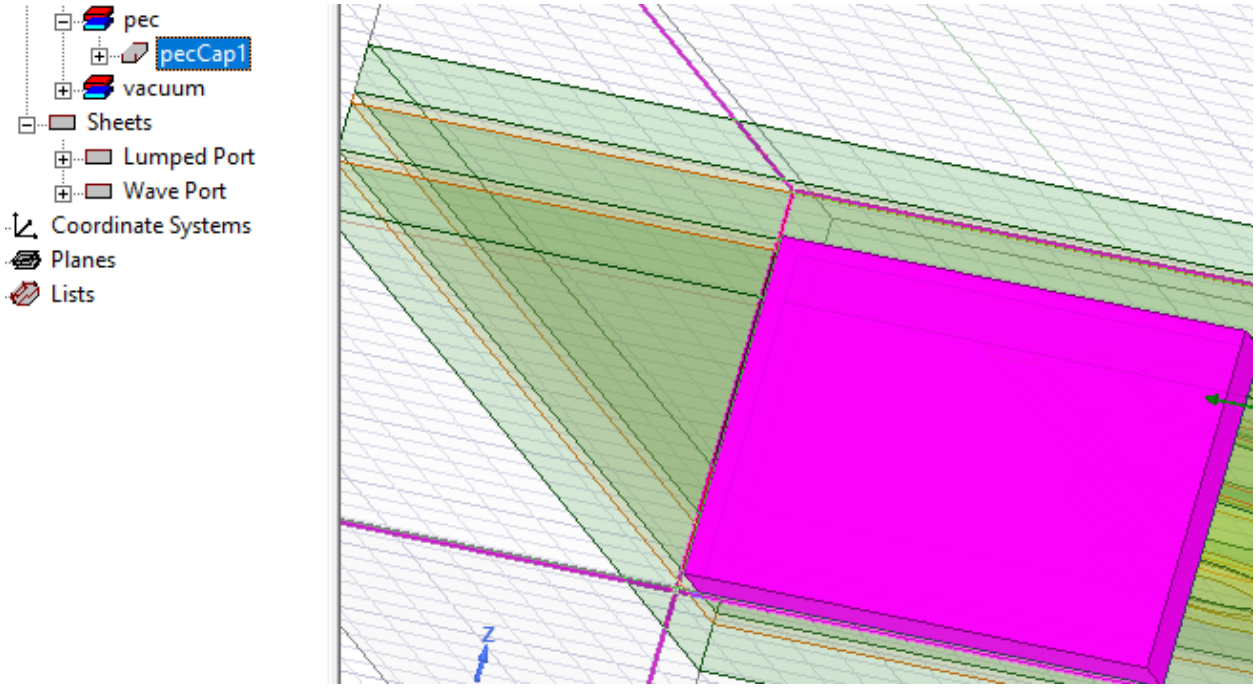
If you do not specify a wave direction, you can attach a PEC object and cover the opposite side before the solution can proceed. This HFSS Boundary Assignment Option automatically adds a

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

PEC backing to every newly created wave port when necessary (that is, if you do not specify direction). When a new wave port is created and requires a PEC backing, a dialog window opens to let users create such backing by extruding the port face with specified thickness. You have the option to flip the side of the PEC backing. You can also set the thickness as a variable.



After clicking OK, the PEC backing is created and the new PEC object appears in the History tree.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once the PEC cap is created it is associated with the port. If you edit the geometry of the port or the geometry/material of the cap, association is deleted and a message is issued. If you reassign or delete the port, the PEC cap is deleted, and a warning is issued.

For an example, see Automatic PEC Creation for Wave Ports.

Associating Terminals and Ports

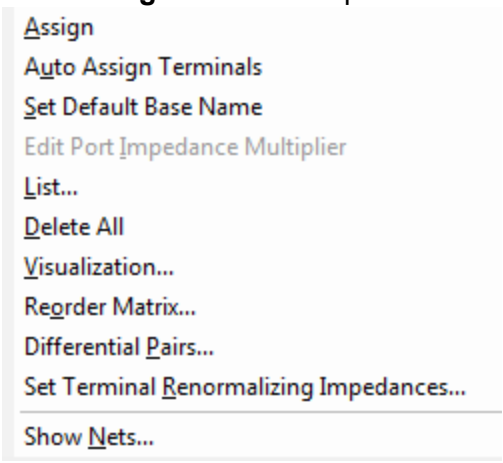
HFSS can automatically associate terminals with the ports whether you assign the ports first and then define the terminals or vice versa. You can define terminals from the **Excitations** level (in the **Project tree**) when the ports already exist. Regardless of the order in which they are assigned, a terminal is associated with the port containing the signal and reference conductors that define the terminal.

> **Note:**
>
> At either the port level or for all excitations, you can set the renormalizing impedance for all terminals.

the Auto-assign terminals on ports option on the **Tools>Options>HFSS Options** dialog on the **General** tab or use the Auto Assign Terminals command.

Auto Assign Terminals

Right-click **Excitations** from the project tree to bring up the shortcut menu that contains the **Auto Assign Terminals** option.



This option assigns terminals automatically. When you change the **Solution Type** of a model from **Driven Modal** to **Driven Terminal**, you can use this option to define the terminals for the conductors on the existing ports.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In exceptional cases with complicated arrangement of conductors or geometry with slight coordinate misalignments, auto assign may create either too few or too many terminals on a port. In such cases, you can manually assign the terminals.

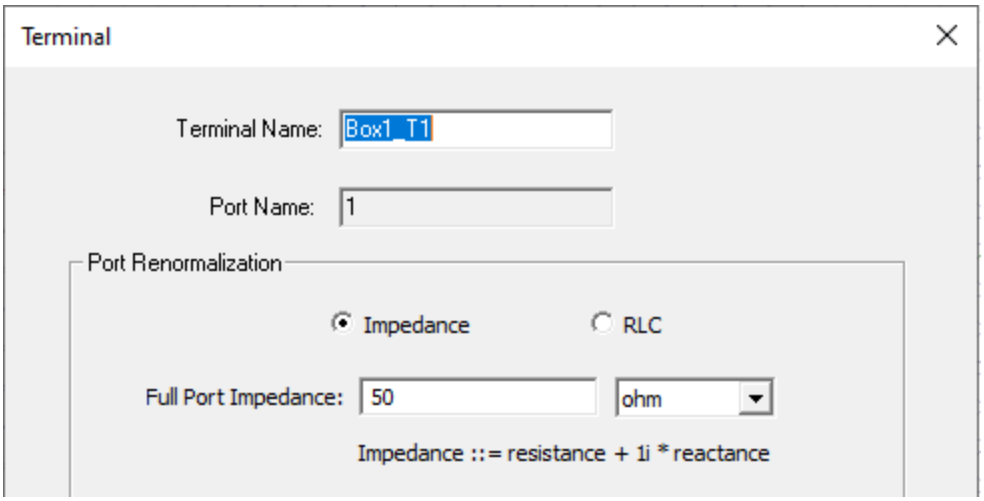
Post Processing Operations

As a post processing operation you can renormalize the impedance of the individual terminals that you assigned. This is done as follows.

1. Double-click the terminal from the **Project Tree**.

The **Terminal** dialog box appears.

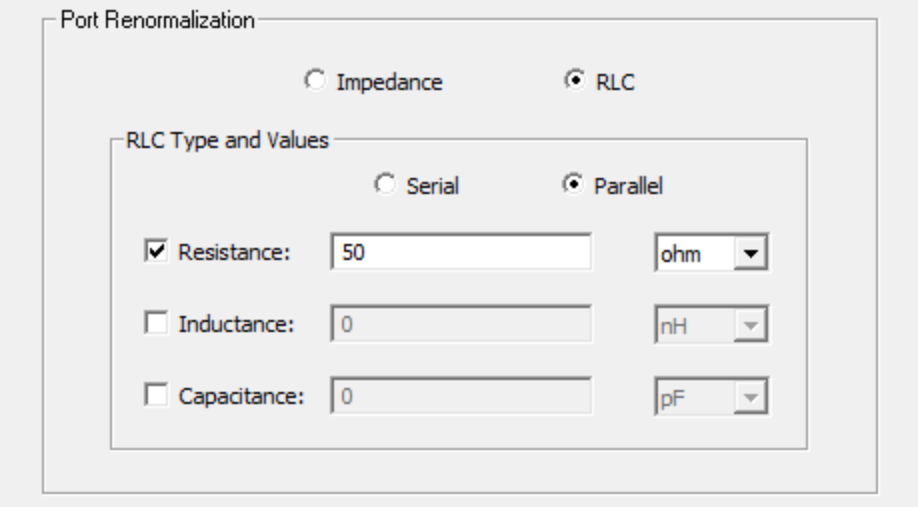
2. If you select Port Renormalizations as Impedance, enter the value in the **Resistance** and set the units from the drop-down menu and click **OK**.



If you select RLC, you can specify Resistance, Inductance, and Capacitance and

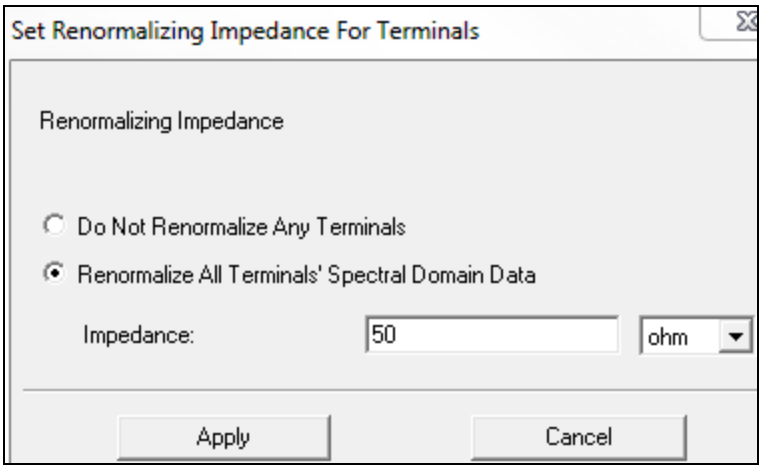
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

designate the RLC type as Serial or Parallel.



Set Renormalizing Impedance for Terminals

The setup panel for each terminal includes its post processing renormalizing impedance. You can set this value either for all excitations, or for a specific port. If a design includes at least one wave port, the setup panel also includes the radio buttons **Do Not Renormalize Any Terminals**, or **Renormalize All Terminals' Spectral Domain Data** .



To set the renormalizing impedance for **all excitations**:

1. Right-click **Excitations** in the Project tree and select **Set Terminal Renormalizing Impedances**.

   The **Set Renormalizing Impedance for Terminals** dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the field for **Impedance**, set the value, and select the units from the pull down.

   The format is "<real_part> + <complex_part>*i ohm", for example 50ohm + (-5ohm) * 1i

   > **Note:**
   >
   > The reference impedance is meant to represent the component modeled by the lumped port. You can assign a variable to these values, (for example " resistance + (reactance) * 1i"). This variable can be dependent on the frequency, which allows use of a dataset for frequency dependent impedance, (for example, pwl (ds1,freq) + (pwl(ds2,freq)) * 1i).

3. Click the **Apply** button to close the dialog and apply the change.

To Set the Reference for All terminals on a Port:

1. Right-click the port icon in the Project tree and click **Set Terminal Renormalizing Impedances**.

   The **Set Renormalizing Impedance for Terminals** dialog appears. It differs from the related command for all excitations by specifying that the **Renormalizing Impedance** is for terminals on the selected port.

2. In the field for **Impedance**, set the value, and select the units from the pull down.

   This value can be a variable. This variable can be dependent on the frequency, which allows use of a dataset for frequency dependent impedance.

3. Click the **Apply** button to assign the impedance value.

   > **Note:**
   >
   > For more information, see Scaling a Source Magnitude and Phase.

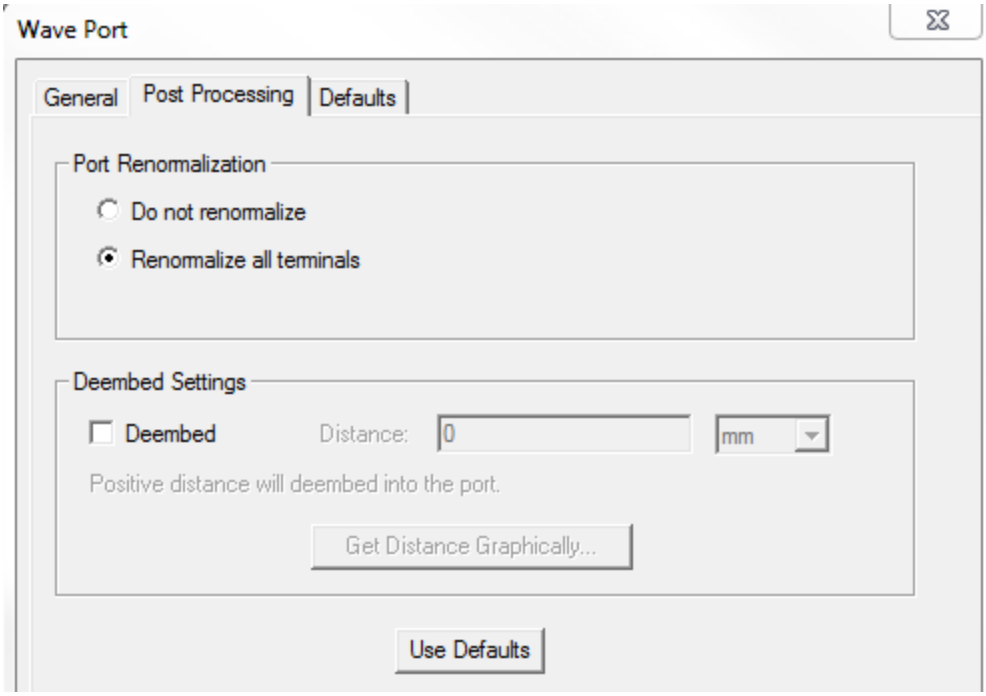
You can also set the Terminal Reference Impedance on a port by selecting the port and editing the value in the **Properties** dialog.

In designs with at least one wave port, where you want to view un-renormalized Zo impedance and/or the corresponding S parameters in either the Matrix data or in a report, you can select the **Do Not Renormalize Any Terminals** radio button.

Renormalize Terminals from the Port Level

1. Double-click the wave port in the **Project** tree to display the **Properties** window for the wave port and select the **Post Processing** tab.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Values here affect S-Parameters only. Port Renormalization choices include:

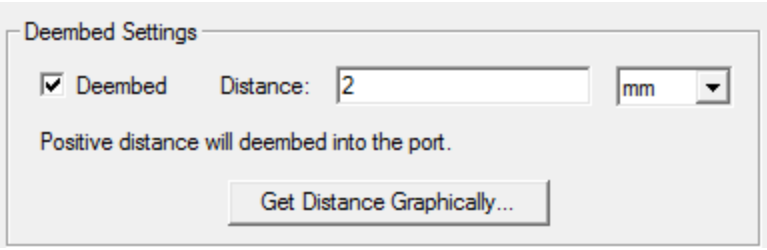
- **Do Not Renormalize** (the default). Selecting this disables the Impedance fields for the port and terminals.
- **Renormalize All Terminals**. The default impedance for re-normalization of each port is 50 ohms. To specify a different impedance, you must open the Properties for the terminal and specify a value in the **Terminal Renormalizing Impedance** field.

If you want to enter a complex impedance, enter it in the following form: *<re>* + *<im>j*, for example 50ohm + (-5ohm) * 1i . You can assign a variable to these values, (for example " resistance + (reactance) * 1i"). This variable can be dependent on the frequency, which allows use of a dataset for frequency dependent impedance, (for example, pwl(ds1,freq) + (pwl(ds2,freq)) * 1i).

- If there are multiple modes, **Renormalizing Impedance for Specific Terminals** is enabled. Click this to enable the **Edit Terminal Impedances** button. This opens an editable table with the impedances for each terminal.

2. Enter the **Deembed** distance in the **Distance** field or draw a line on the model to represent the distance and get it graphically. You can also assign a variable in the **Distance** field.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Important:

After you enter the value, a blue arrow depicts the deembedding distance in the graphics window when the port is selected. When a wave port has been defined on a sheet, the inward or the outward normal will dictate the direction of the arrows. The orientation of the deembedding arrows in the modeler is determined by the direction of the normal of the face where the port is defined upon. From the standpoint of the S-parameters what is correct is the sign of the deembed distance.

Note:

- A positive distance value will de-embed the port into the model. A negative distance value will de-embed the port out of the model.
- Make sure you are not creating a non physical situation when you deembed cutoff modes. For example, when you enter a positive distance to deembed a port with a cutoff mode into the model the resulting field values for that mode can be very large.

3. For HFSS Transient solutions, you can designate a port as Active or Passive.

Set Differential Pairs

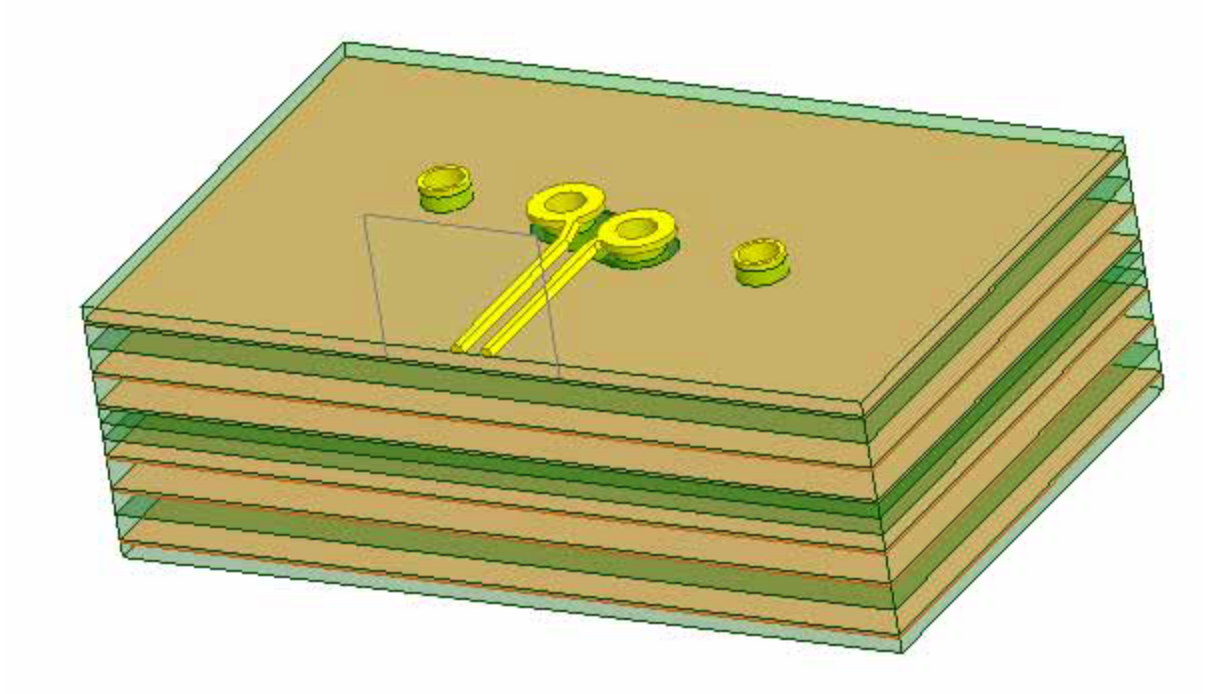
A differential pair represents two circuits, one positive and one negative routed close together so they will pick up nearly the same amount of noise. The two signals are subtracted from each other by a receiver, yielding a near "noise-free" version of the signal.

You can define one or more differential pairs from terminal excitations assigned on existing wave ports. Differential pairs can span ports, use lumped ports, and be enabled or disabled. To allow automated calculation of differential S-parameters from lumped ports, you can select terminals from two arbitrary ports, whether wave ports or lumped ports, for use in a differential pair.

Because differential pairs can span ports or occur within a port, the **Differential Pairs** command is accessible at corresponding levels in the Project tree via the right-click menu both at the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

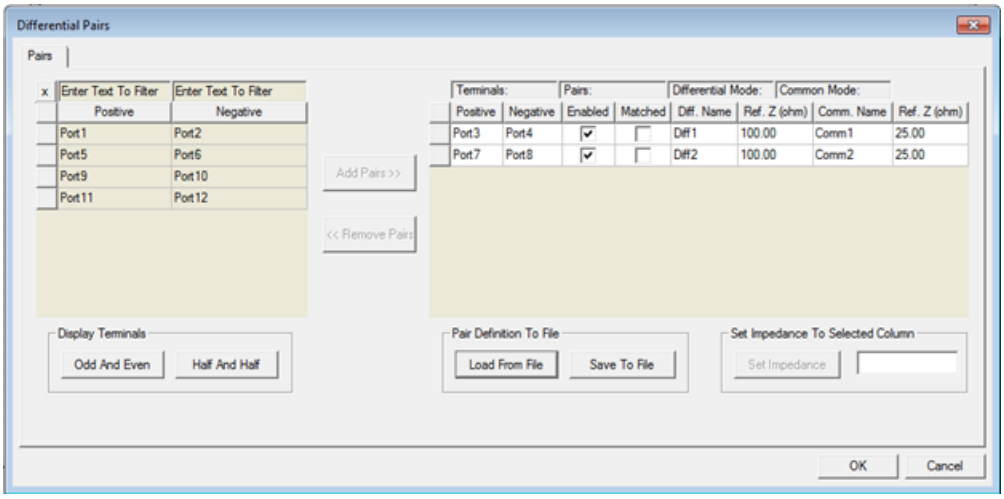
Excitations level, and at the port name level. If a differential pair involves terminals from two different ports, the **Differential Pairs** command for those ports can only be accessed at the **Excitations** level. If an individual wave port has multiple terminals defined, the **Differential Pairs** command is enabled when you select that port and right-click to display the shortcut menu. In order to combine differential pairs across ports, both ports must have the same renormalization setting; that is, either ports have **Do not Renormalize** on, or both have it off. For Transient Network solutions, differential pairs cannot include passive terminals. We will use a differential pair via model to assign the differential pairs. See Figure below.



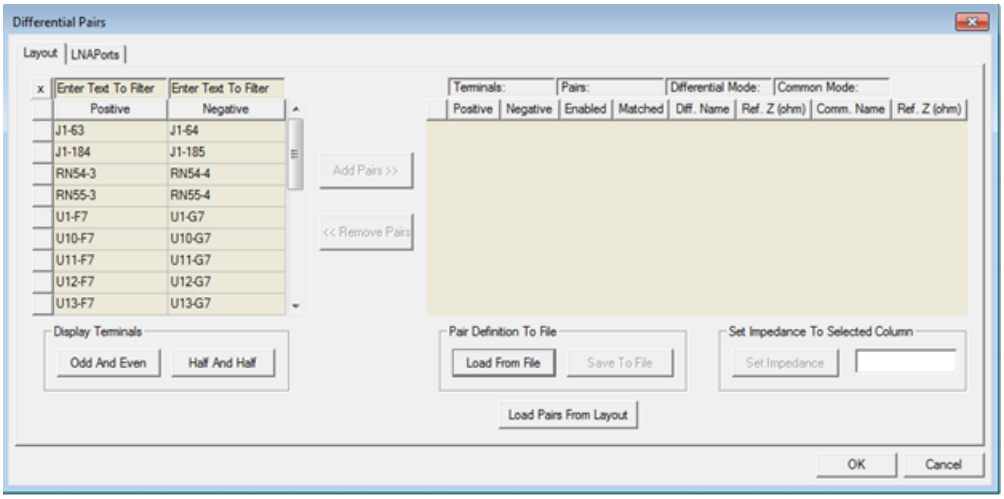
Differential Pairs Dialog can be opened from multiple places:

- Network Data Explorer: Edit > Define Differential Pairs
- Ports Folder in a Nexxim Design: right-click Ports > Differential Pairs
- Excitations Folder in a 3D Layout Design: right-click Excitations > Differential Pairs

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Differential Pairs can be defined for both design layout and LNA setups if both are available. Both pairs will be available in two tabs of the same dialog as shown below.



To set up a differential pair:

1. All terminals that are not already in pairs are shown in columns Positive and Negative of the Terminals list (on left):

- Clicking on a cell, selects that cell; Multiple selection is allowed using Ctrl+click and Shift+click; if one cell in each column is selected, Add Pairs button is enabled; clicking that button will add the pair to the bottom of the Pairs list (on right)
- Clicking on a row button in Terminals list selects that row; user can select multiple rows using Ctrl+click and Shift+click; when one or more rows are selected, Add Pairs button is enabled; clicking that button will add the pairs to the bottom of the Pairs list
- If anything is selected in Terminals list, accelerator Ctrl+A will select all rows

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Click-dragging a cell in Terminals list to different position in same column or to any position in the other column will move that terminal to the drop position
- Entering text into the first cell in each column will be used to filter which pins are shown in the column; * wildcard character is supported. See the Layout List dialog for an example of this.

2. Display Terminals group:

- Clicking Odd and Even will move odd position terminals to Positive column and even position terminals to Negative column; the filters will still be applied
- Clicking Half and Half will move terminals in the first half of the original list to the Positive column and terminals in the second half to the Negative column; filters will still be applied

3. Pairs list shows all terminal pairs that have been defined:

- Clicking Enabled or Matched header will toggle the check boxes in those columns; if Matched check box is checked, remove text from both Z Ref cells and disable those cells; if check box is subsequently unchecked restore Z Ref cells to previous values
- Clicking Positive, Negative, or Name column headers will toggle sorting the pairs alphanumerically on that column
- Clicking the Ref Z column headers will select the column
- Clicking on a row button in Pairs list selects that row; user can select multiple rows using Ctrl+click and Shift+click; when one or more rows are selected, Remove Pairs button is enabled; clicking that button will remove the pairs and add the corresponding Terminals back into the Terminals list
- If anything is selected in Pairs list, accelerator Ctrl+A will select all rows; if Del key is clicked, it will remove the selected pairs
- Clicking in a cell for Name or Ref Z will allow user to edit that value directly; names must satisfy pin name restrictions; Ref Z must be positive number with optional resistance units (typing “k” is acceptable for kohm)

4. Set impedance group:

- Entering a positive number with option units into the edit box will enable the Set impedance button
- If a Ref Z column is selected in the Pairs dialog box, clicking the Set impedance button will change all values in that column to the value in the edit box

5. Pair Definition file group:

- Clicking Save To File button will open Save File dialog with library location buttons; entering a name and clicking Save will save the Pair configuration to that file in csv format; this button is not enabled if there are no pairs defined
- Clicking Load from File button will open Open File dialog with library location buttons; choosing a .txt file will load the previously saved Pair configuration; this will show an error and NOT load if the file syntax is incorrect. Note that the file may contain pair definitions that do not reference pins that exist in the circuit; those definitions won’t be applied. Only definitions where both terminals actually exist will be applied.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

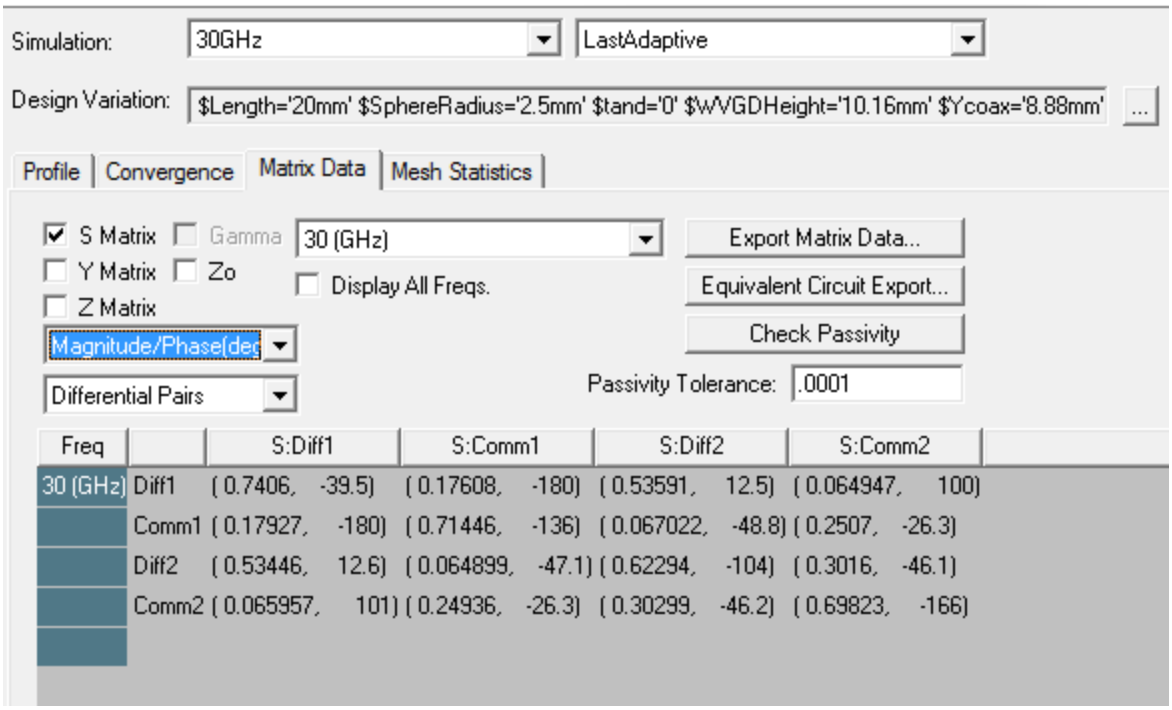
- Saving a file and then subsequently loading a file should open a window already showing the last file saved or loaded.

6. Load Pairs from Layout button:

- This button will only be shown when the pairs dialog is launched from HFSS 3D Layout; clicking it will load pairs corresponding to Differential Pair net assignments

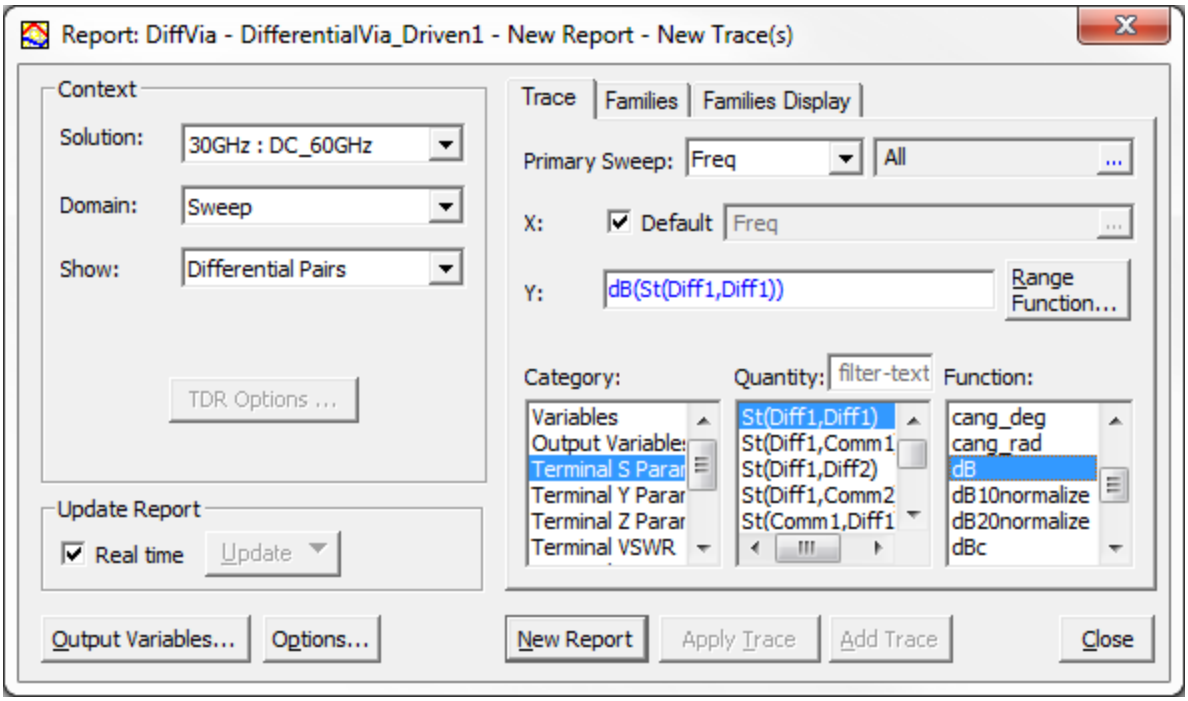
> **Note:**
>
> Scripting for loading/saving differential pairs from/to a file will not be recorded as part of the scripting in the dialog box. The user can hardcode the scripting as follows:
>
> - LoadDiffPairsFromFile(filename)
> - SaveDiffPairsToFile(filename)

After a solution has been generated, view the common and differential quantities of the differential pair under the **Matrix** tab of the **Solution Data** window as shown below.



When the design has differential pairs (link), the reporter can display quantities for the defined pairs or for the single-ended terminals upon which they are based. A drop-down menu will appear in the **Context** area of the **Report** creation dialog which allows the user to select which quantities will be displayed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can freely mix differential and single-ended terminal quantities. However, single ended quantities are computed as if no differential pairs existed. So, in the unlikely case of several terminals where only a subset are combined into pairs, the results may not be as expected.

Lumped Ports

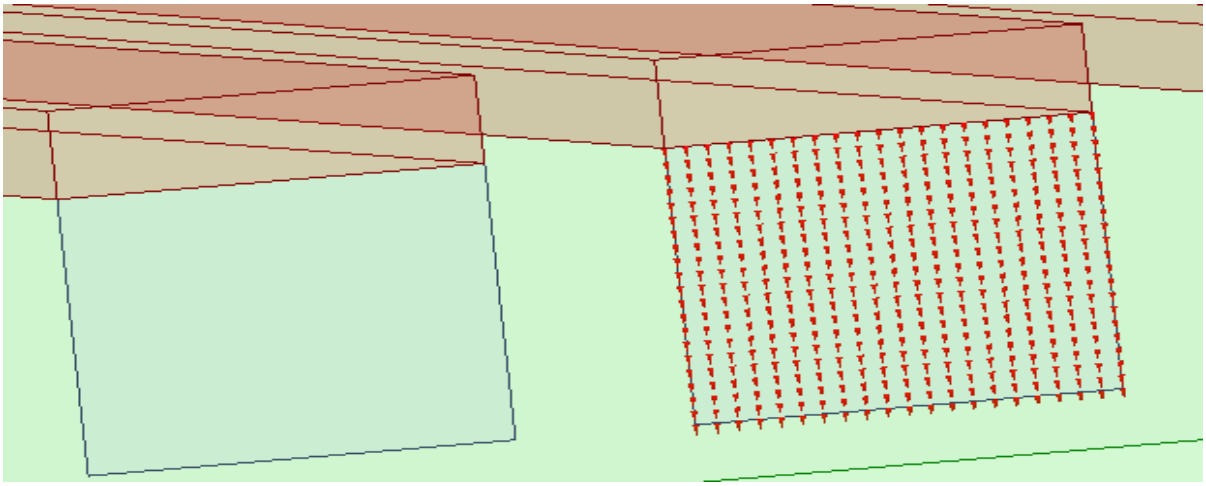
Lumped ports support single mode excitations when S-parameters have to be extracted at internal locations of a model. It can also be used to represent a terminal of a passive component to be subsequently optimized in a circuit simulator using S-matrix description of the model.

For designs with only lumped ports or a combination of lumped and circuit ports, the Advanced Solution Setup, **Options** tab includes an option to use Enhanced low frequency accuracy. The previous port solution procedure can experience failures at low frequencies. Once enabled, the feature is transparent to the user. There may be slight variations in the number of triangles, but these are not reported for lumped ports. Reported 3D mesh size may be different, and the number of adaptive passes may change.

For lumped ports all edges that do not touch metal are treated as perfect H boundaries. From this definition the resulting field distribution on the lumped port geometry is solved with the wave port solver. For a rectangular lumped port this results in electric fields orientated parallel to these perfect H sides. See figures below. The physical geometry of the rectangular lumped port carries current with the corresponding H fields resulting in parasitic inductance. For these same

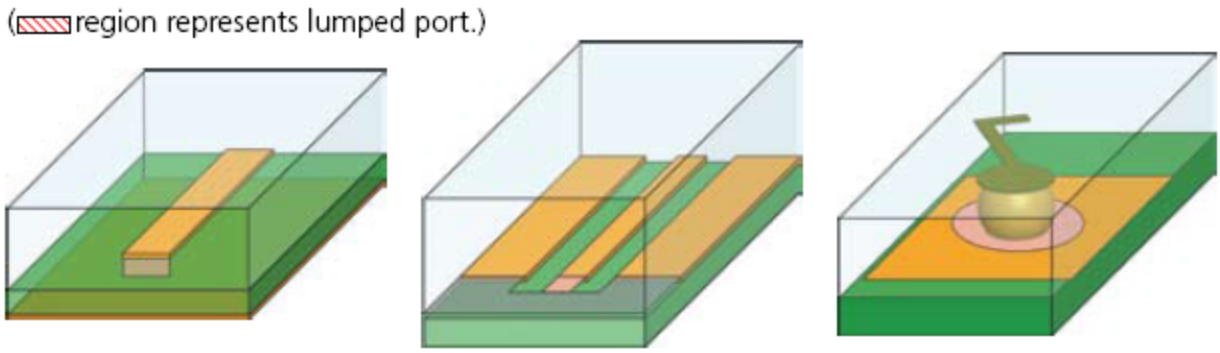
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

rectangular lumped ports the parasitic inductance can be calibrated out of the s-parameter response with the deembedding option for lumped ports.



Examples of Lumped Port

Lumped ports can be used in a variety of ways as shown below.



They vary as follows:

- For 1: The 2D port rectangle touches the signal trace with one edge while the opposite edge touches the ground plane.
- For 2: The 2D port rectangle touches the signal trace with one edge while the opposite edge touches the PEC objects (drawn in grey).
- For 3: the port is an annular ring around the BGA ball where the resulting field patterns closely resemble those for a coaxial TEM mode.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> Use lumped ports only for those surfaces that are internal to the model and wave ports to model *exterior* surfaces through which a signal enters or exits the geometry.

Assign Lumped Ports for Modal Solutions

While assigning lumped ports for modal solutions, you will be prompted to set the complex full port impedance which must be non-zero, set the non-negative resistance, and finally define the integration line for the single mode. You can assign lumped ports in 3 different ways:

- Selecting a Face or Sheet and Manually Drawing an Integration Line
- Selecting Two Linear Edges that Do Not Intersect
- Selecting a Face and a Linear Edge

Selecting a Face or Sheet and Manually Drawing an Integration Line

The steps are as follows:

1. Select a surface to which you want to assign the port and click **HFSS>Excitations>Assign>Lumped Port** to bring up the **Lumped Port: General**

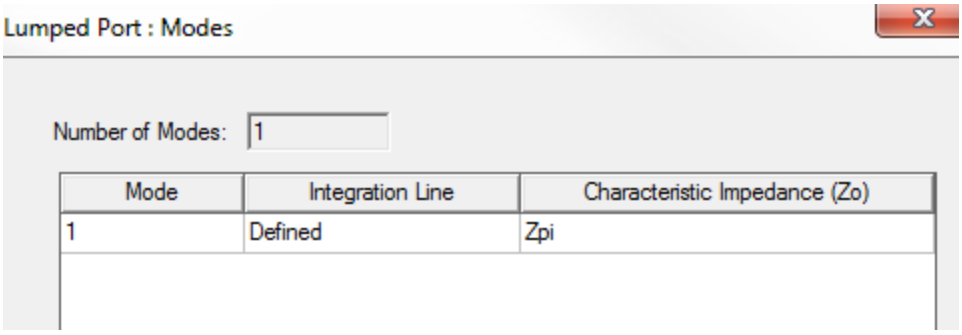
   dialog box.
2. Define the complex **Full Port Impedance** in the text field. The format is "<real_part> + <complex_part>*i ohm", for example 50ohm + (-5ohm) * 1i

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> The reference impedance is meant to represent the component modeled by the lumped port. You can assign a variable to these values, (for example " resistance + (reactance) * 1i"). This variable can be dependent on the frequency, which allows use of a dataset for frequency dependent impedance, (for example, pwl (ds1,freq) + (pwl(ds2,freq)) * 1i).

3. Click **Next** to display the **Lumped Port: Modes** dialog box.

> **Note:**
>
> The field **Number of Modes** is not editable because only one mode is allowed.



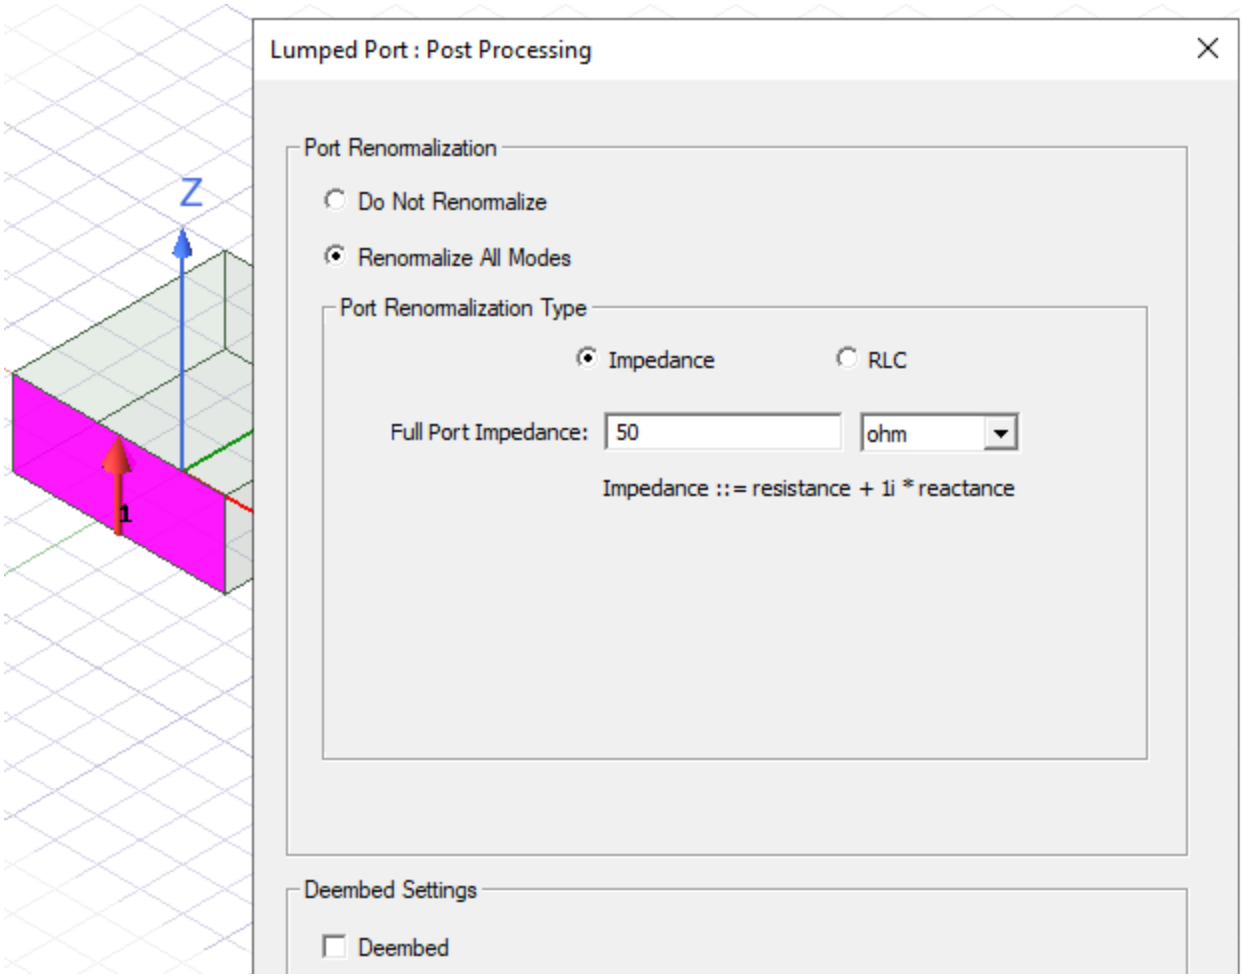
4. Integration line must be drawn for a lumped port.

   The **Characteristic Impedance (Zo)** column shows the Zpi method usually used to calculate the characteristic impedance. If Zpi is zero, HFSS uses Zpv.

   For definitions of how HFSS defines these values, see Calculating the Zpi , and Calculating the Zpv.

5. Click **Next** and the Post Processing settings appear.

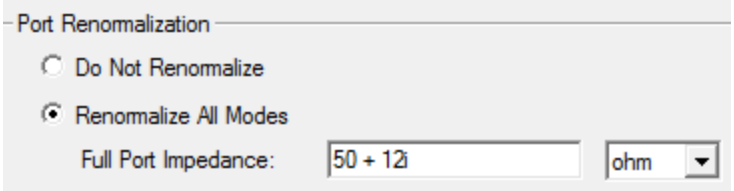
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The Port Renormalization choices include:

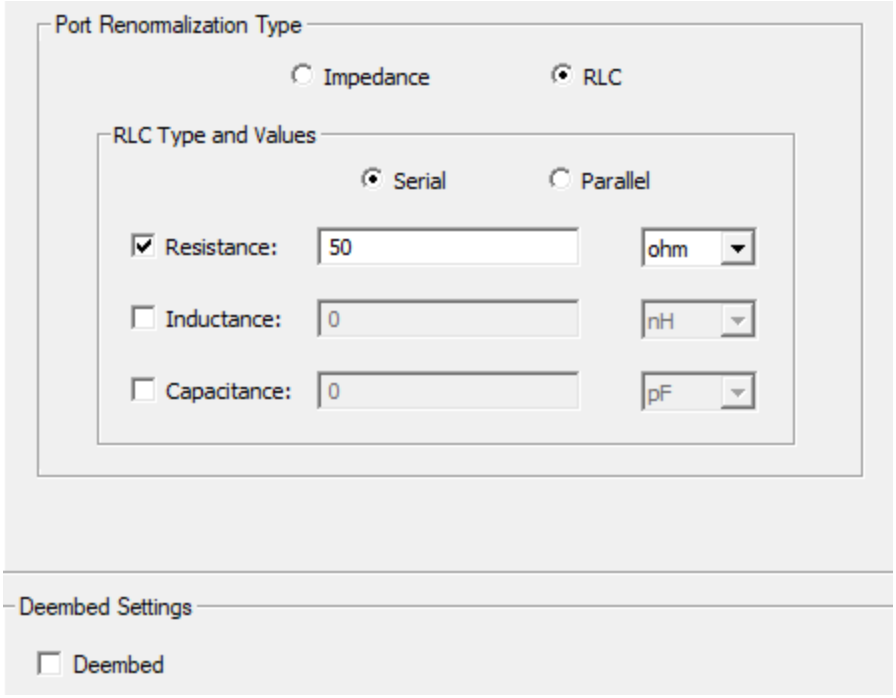
- **Do Not Renormalize:** This is the default.
- **Renormalize All Modes**: Enables the **Full Port Impedance** text box. The default impedance for re-normalization of each mode is 50 ohms.

  Complex impedance should be entered in the form: *<re> + <im>j* or *<re> + <im>i*. Either *j* or *i* entered into the field is displayed as *i* in the field and in a recorded script. See figure below.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you select RLC, you can specify Resistance, Inductance, and Capacitance and designate the RLC type as Serial or Parallel.

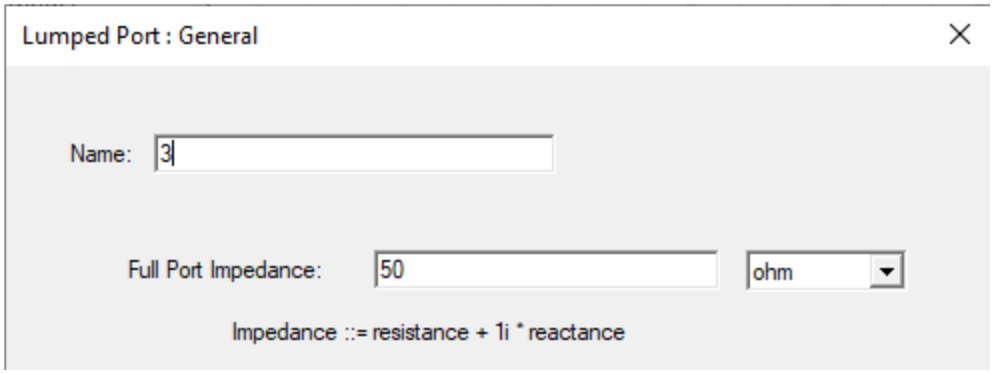


For designs with only lumped ports or a combination of lumped and circuit ports, the Advanced Solution Setup, **Options** tab includes an option to use Enhanced low frequency accuracy.

Selecting Two Linear Edges that Do Not Intersect

An integration line will be automatically drawn from the second linear edge selected to the first. The steps are as follows:

1. Set the selection mode to Edge or Multi, select the edge to which you want to assign the port and click **HFSS>Excitations>Assign>Lumped Port** to bring up the **Lumped Port: General** dialog box.

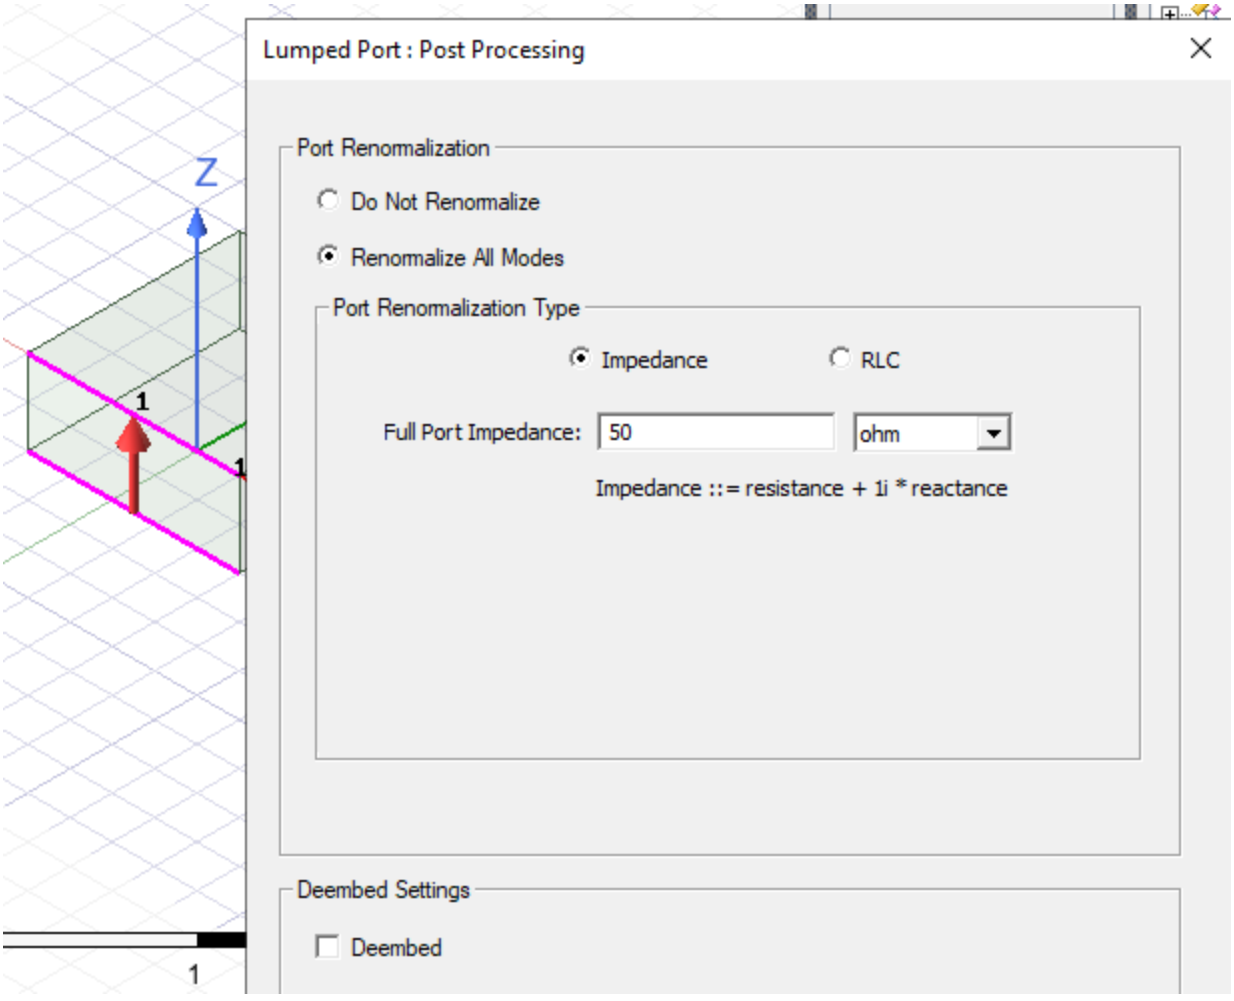


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Define the complex **Full Port Impedance** in the text field. The format is "<real_part> + <complex_part>*i ohm", for example 50ohm + (-5ohm) * 1i

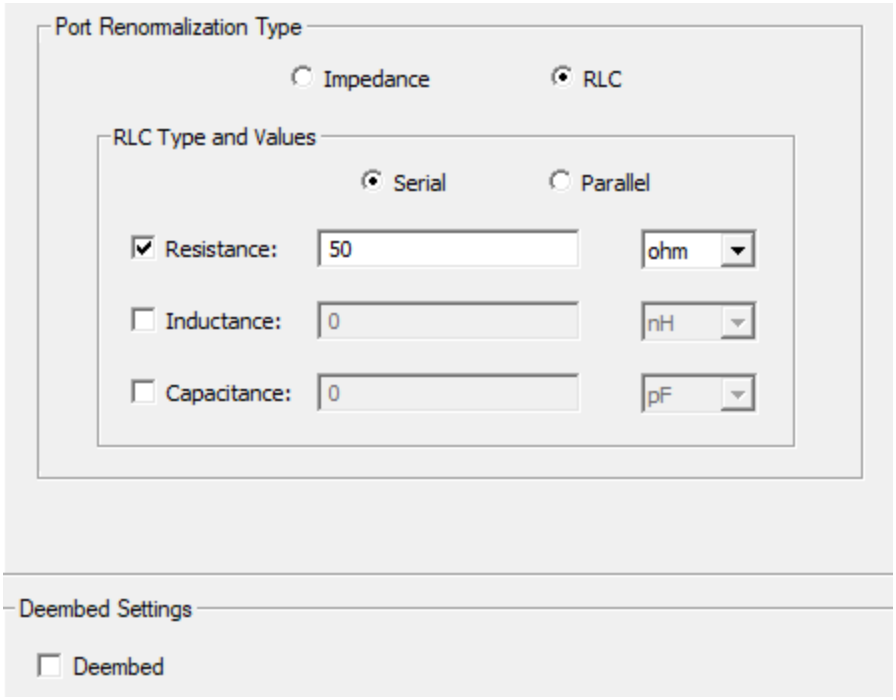
> **Note:**
>
> The reference impedance is meant to represent the component modeled by the lumped port. You can assign a variable to these values, (for example " resistance + (reactance) * 1i"). This variable can be dependent on the frequency, which allows use of a dataset for frequency dependent impedance, (for example, pwl (ds1,freq) + (pwl(ds2,freq)) * 1i).

3. Click **Next**. An integration line is automatically drawn and the Post Processing settings appear.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you select RLC, you can specify Resistance, Inductance, and Capacitance and designate the RLC type as Serial or Parallel.

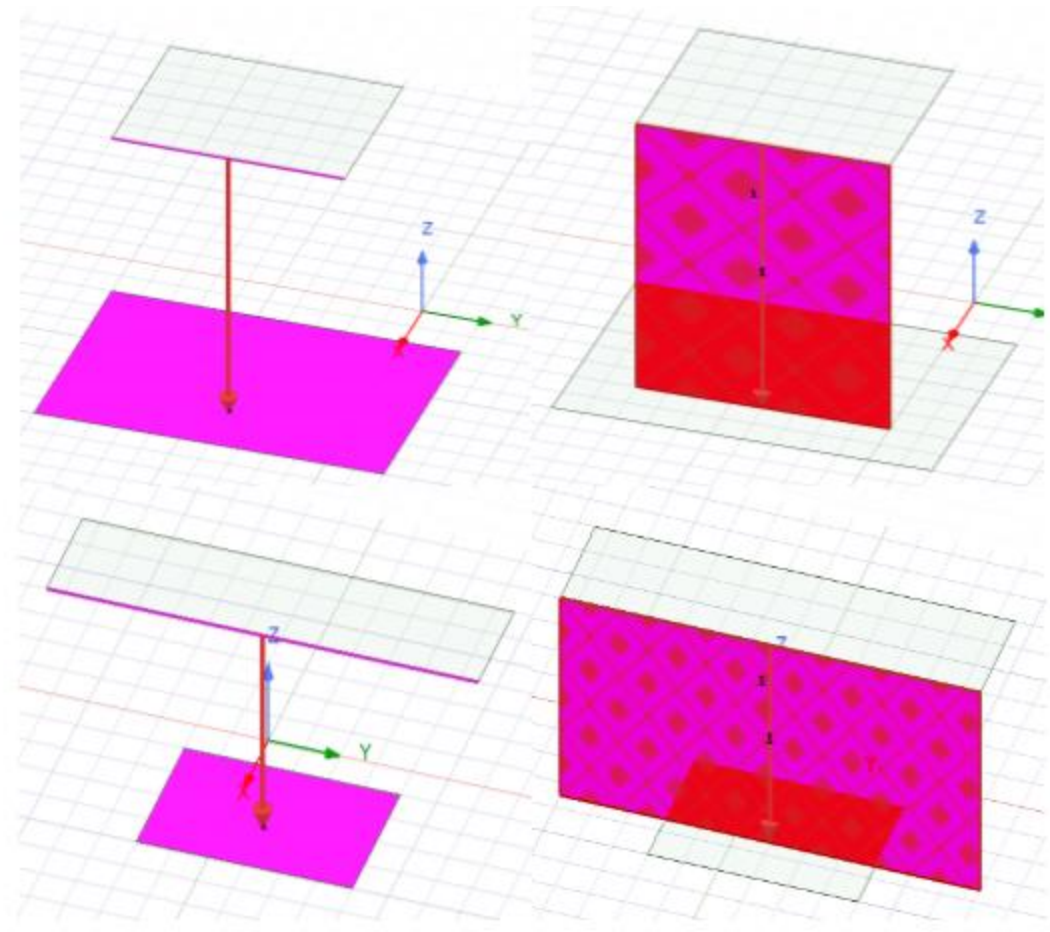


For designs with only lumped ports or a combination of lumped and circuit ports, the Advanced Solution Setup, **Options** tab includes an option to use Enhanced low frequency accuracy

Selecting a Planar Face and a Linear Edge

You can select exactly one linear edge and one planar face and create a lumped port to launch the dialog. For a modal lumped port, the Mode Page is skipped and an integration line is automatically created. As to the associated sheet created for the lumped port, if the edge intersects with the face, or the edge is vertical to the face, or most part of the edge cannot be projected on the face, an error message is issued. Otherwise, the 2 endpoints of the edge and the 2 projected point of the face are used to create a sheet that is vertical to the selected face.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The steps are as follows:

1. Select a face and a linear edge where you want to assign the lumped port and click **HFSS>Excitations>Assign>Lumped Port** to bring up the **Lumped Port: General**

   dialog box.
2. Define the complex **Full Port Impedance** in the text field. The format is "<real_part> + <complex_part>*i ohm", for example 50ohm + (-5ohm) * 1i

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> The reference impedance is meant to represent the component modeled by the lumped port. You can assign a variable to these values, (for example " resistance + (reactance) * 1i"). For designs with only lumped ports or a combination of lumped and circuit ports, the Advanced Solution Setup, **Options** tab includes an option to use Enhanced low frequency accuracy.

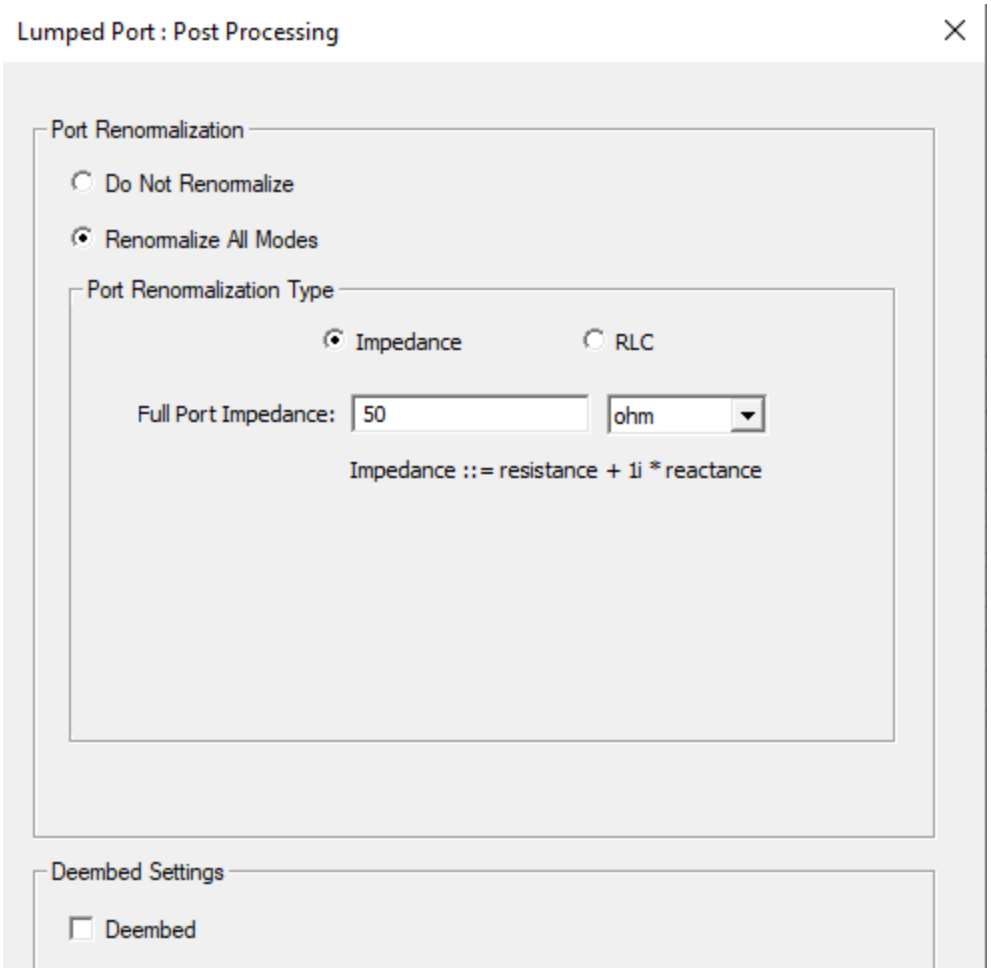
Lumped Port: Post Processing

The parasitic inductance can be calibrated out of the s-parameter response with the deembed option for lumped ports. Click **Next** on the **Lumped Port: Modes** dialog box, to bring up the **Lumped Port: Post Processing** dialog.

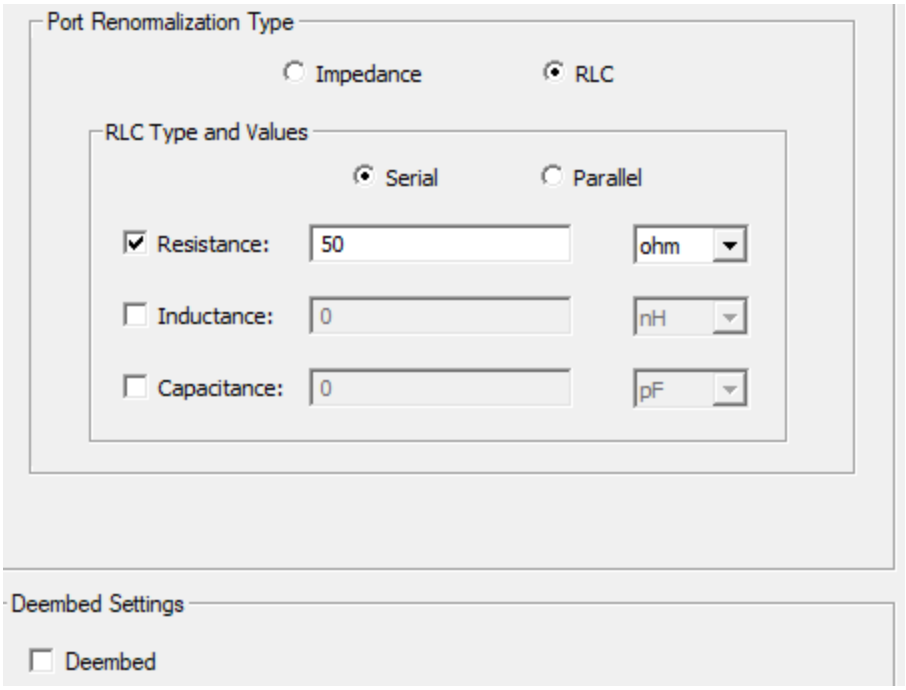
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Values here affect S-Parameters. They will also affect the spectral fields if you selected the **Include Post Processing Effects** on the **Edit post process sources** dialog box. By default, lumped ports are renormalized to a 50 Ohm full port impedance. You can override the default by entering a value of your choice in the **Full Port Impedance** field. If you want to enter a complex impedance, enter it in the form *<re> + <im>j.*, for example 50ohm + (-5ohm) * 1i . You can assign a variable to these values, (for example " resistance + (reactance) * 1i"). This variable can be dependent on the frequency, which allows use of a dataset for frequency dependent impedance, (for example, pwl(ds1,freq) + (pwl(ds2,freq)) * 1i).

If you select RLC, you can specify Resistance, Inductance, and Capacitance and designate the RLC type as Serial or Parallel.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For designs with only lumped ports or a combination of lumped and circuit ports, the Advanced So

Lump port de-embedding available on any shaped lump ports assigned. This capability de-embeds from the resulting s-parameters the parasitic inductance associated with the port's geometry

> **Note:**
>
> For more information about the port calibration technique, see the topic When HFSS Needs Port Calibration (Deembedding).

The Deembed option can be turned on or off as a post processing operation without invalidating solutions. If multiple lumped ports are selected in the Excitations List panel, changes to the

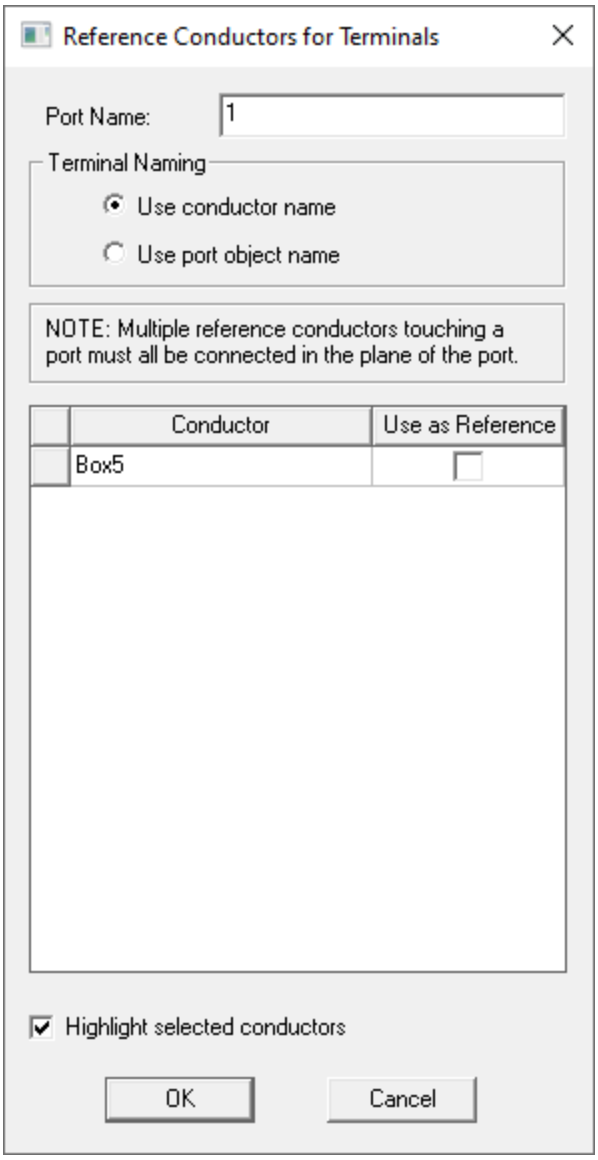
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

common Deembed property change the setting for all lumped ports at once, but only for those that support calibration.

If a port is selected for calibration but the validation checks fail for some variation (which could happen with a parametric solve), then the matrix data will not load for that variation. Also, if the fields are to include port post processing effects, then the fields do not load.

Assign Lumped Ports for Terminal Solutions

After making selections for assigning a lumped port, and selecting **HFSS>Excitations>Assign>Lumped Port**, you see the **Reference Conductors for Terminals** dialog.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For details, see Reference Conductors.

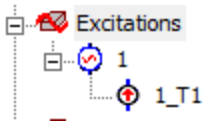
As with lumped ports for modal solutions, while assigning lumped ports for terminal solutions, you will be prompted to set the complex full port impedance. The real part (resistance) must be positive. The imaginary part (reactance) must be non-zero if the resistance is zero. There are three ways to assign lumped ports for terminal solutions.

- Selecting a Face or Sheet
- Selecting Two Linear Edges that Do Not Intersect
- Selecting a Face and a Linear Edge

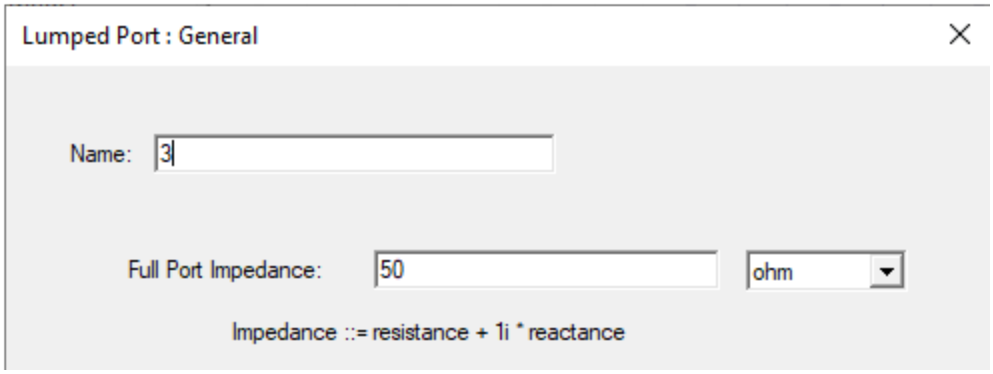
Selecting a Face or Sheet

The steps are as follows:

1. Select a surface to which you want to assign the port and click **HFSS>Excitations>Assign>Lumped Port** to bring up the Reference Conductors dialog. After you OK the Reference Conductors dialog, you see the Port assigned in the Project tree.



2. Double click on the Port to open **Lumped Port: General** dialog box.

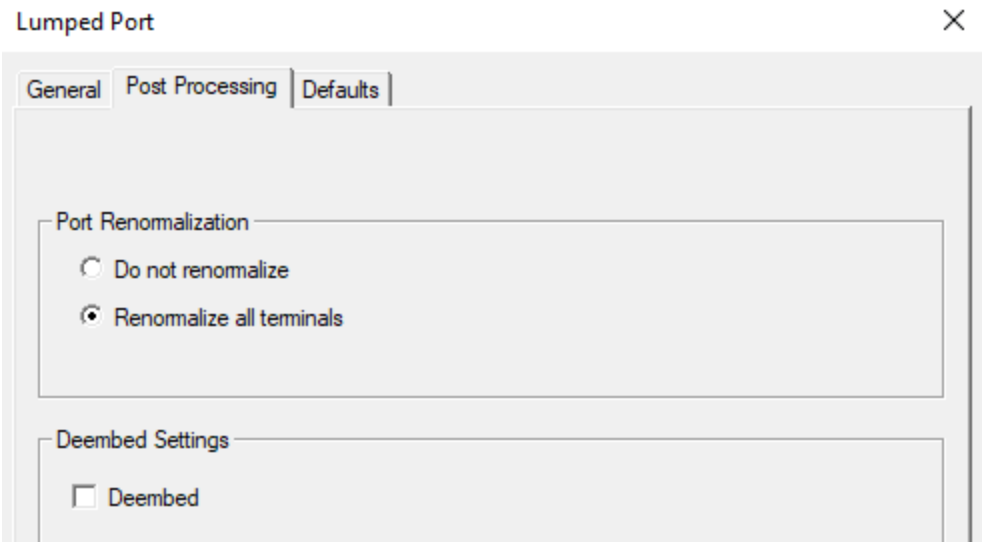


2. Define the complex **Full Port Impedance** in the text field. The format is "<real_part> + <complex_part>*i ohm", for example 50ohm + (-5ohm) * 1i

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> The reference impedance is meant to represent the component modeled by the lumped port. You can assign a variable to these values, (for example " resistance + (reactance) * 1i"). This variable can be dependent on the frequency, which allows use of a dataset for frequency dependent impedance, (for example, pwl (ds1,freq) + (pwl(ds2,freq)) * 1i).

3. Click the **Post Processing** tab to see the Post Processing settings.



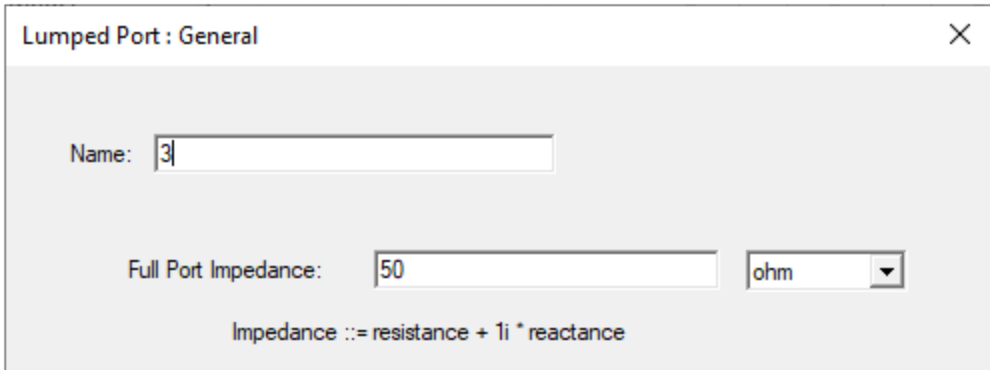
For designs with only lumped ports or a combination of lumped and circuit ports, the Advanced Solution Setup, **Options** tab includes an option to use Enhanced low frequency accuracy.

Selecting Two Linear Edges that Do Not Intersect

A terminal will be assigned to the first edge selected. The steps are as follows:

1. Set the selection mode to Edge or Multi, select the edge to which you want to assign the port and click **HFSS>Excitations>Assign>Lumped Port** to bring up the Reference Conductors dialog. After you **OK** the Reference Conductors dialog, you see the **Lumped Port: General** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Define the complex **Full Port Impedance** in the text field. The format is "<real_part> + <complex_part>*i ohm", for example 50ohm + (-5ohm) * 1i

> **Note:**
>
> The reference impedance is meant to represent the component modeled by the lumped port. You can assign a variable to these values, (for example " resistance + (reactance) * 1i"). This variable can be dependent on the frequency, which allows use of a dataset for frequency dependent impedance, (for example, pwl (ds1,freq) + (pwl(ds2,freq)) * 1i).

3. Click **Next**. The Post Processing settings appear.

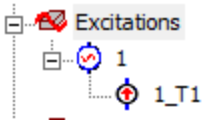
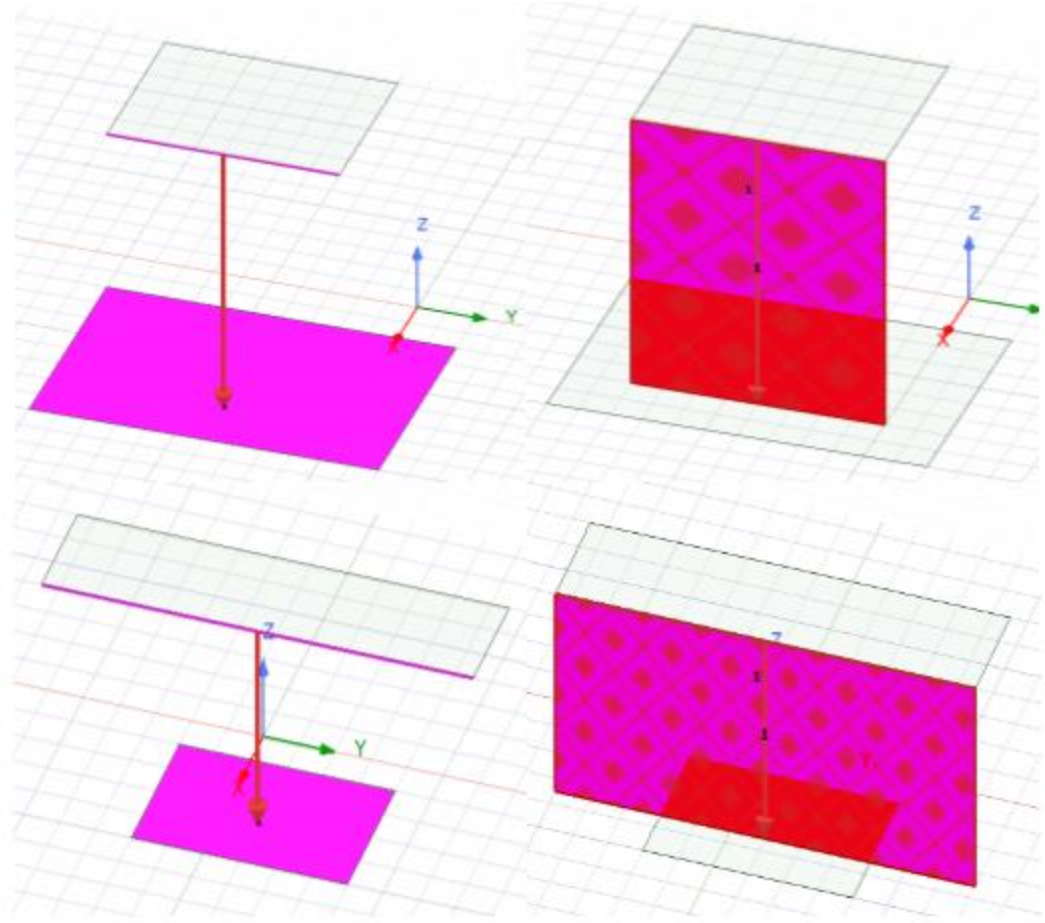
4. Click **Finish** to see the Port in the Project tree.



For designs with only lumped ports or a combination of lumped and circuit ports, the Advanced Solution Setup, **Options** tab includes an option to use Enhanced low frequency accuracy

Selecting a Planar Face and a Linear Edge

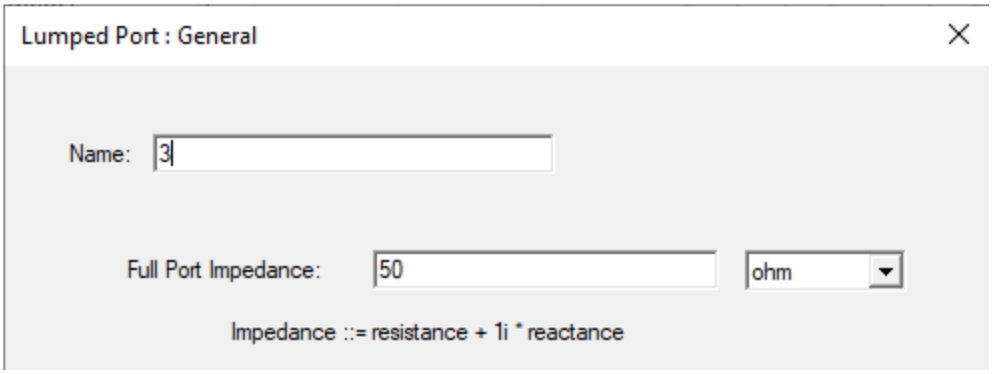
You can select exactly one linear edge and one planar face and create a lumped port to launch the dialog. As to the associated sheet created for the lumped port, if the edge intersects with the face, or the edge is vertical to the face, or most part of the edge cannot be projected on the face, an error message is issued. Otherwise, the 2 endpoints of the edge and the 2 projected point of the face are used to create a sheet that is vertical to the selected face.



The steps are as follows:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select a face and a linear edge where you want to assign the lumped port and click **HFSS>Excitations>Assign>Lumped Port** to bring up the **Lumped Port: General**



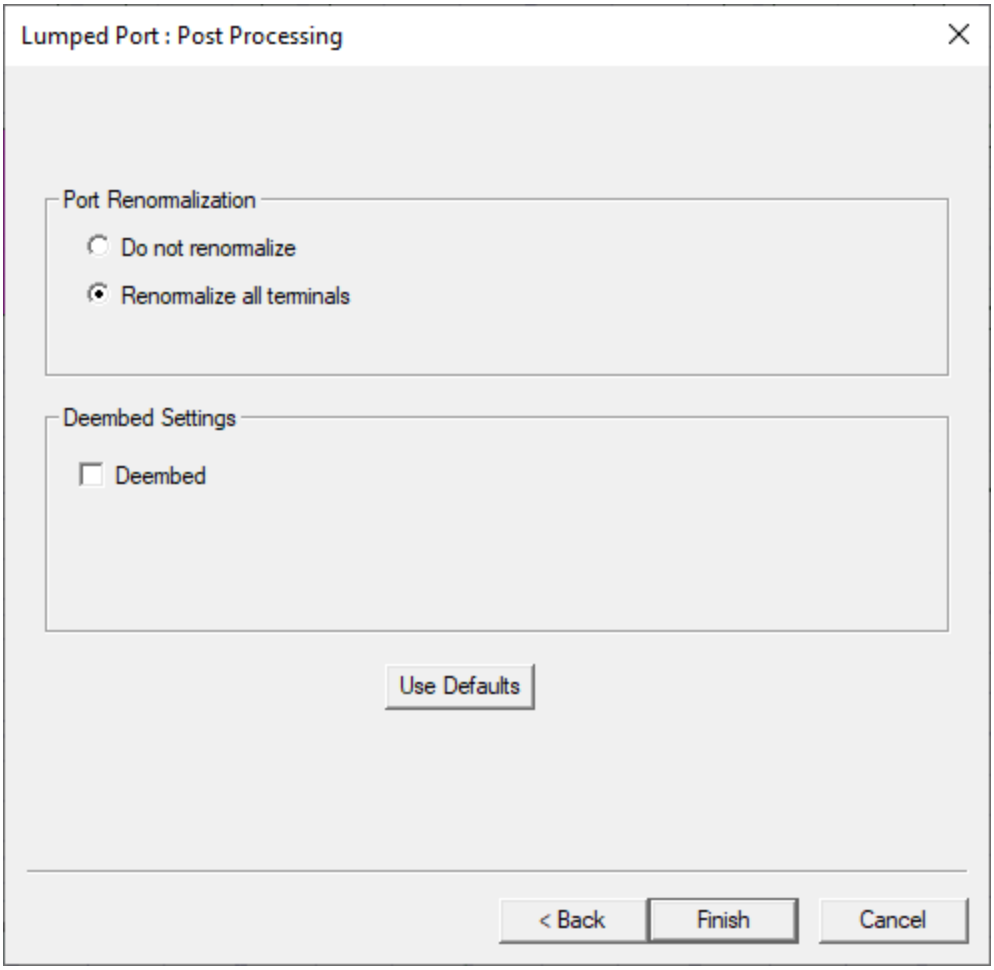
dialog box.

2. Define the complex **Full Port Impedance** in the text field. The format is "<real_part> + <complex_part>*i ohm", for example 50ohm + (-5ohm) * 1i

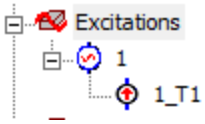
> **Note:**
>
> The reference impedance is meant to represent the component modeled by the lumped port. You can assign a variable to these values, (for example " resistance + (reactance) * 1i"). This variable can be dependent on the frequency, which allows use of a dataset for frequency dependent impedance, (for example, pwl (ds1,freq) + (pwl(ds2,freq)) * 1i).

3. Click **Next**. An integration line is automatically drawn, and the Post Processing settings appear.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. Click **Finish** to see the Port in the Project tree.



For designs with only lumped ports or a combination of lumped and circuit ports, the Advanced Solution Setup, **Options** tab includes an option to use Enhanced low frequency accuracy.

Floquet Ports

The Floquet port in HFSS is used exclusively with planar-periodic structures. Chief examples are planar phased arrays and frequency selective surfaces when these may be idealized as infinitely large. The analysis of the infinite structure is then accomplished by analyzing a unit cell. Linked boundaries most often form the side walls of a unit cell, but in addition, a boundary condition is

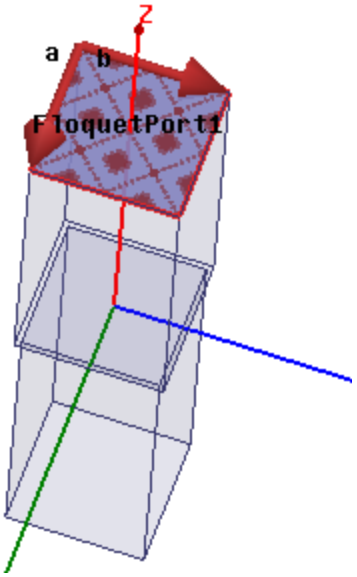
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

required to account for the infinite space above. Floquet ports must be placed along the Z axis. The Floquet port is closely related to a wave port in that a set of modes ("Floquet modes") represents the fields on the port boundary. Fundamentally, Floquet modes are plane waves with propagation direction set by the frequency, phasing, and the geometry of the periodic structure. Just like Wave modes, Floquet modes too have propagation constants and experience cut-off at low frequency. When a Floquet port is present, the HFSS solution includes a modal decomposition that gives additional information on the performance of the radiating structure. As in the case of a wave port, this information is cast in the form of an S-matrix interrelating the Floquet modes. In fact, if Floquet ports and wave ports are simultaneously present, the S-matrix will interrelate all Wave modes and all Floquet modes in the project.

For further discussion and a sample exercise, click **Help> HFSS Getting Started Guides> Floquet Ports**.

Example of Floquet Ports

As a simple example, consider an infinite array of radiating rectangular apertures in a ground plane. The following figure depicts a simple HFSS model for the unit cell of the infinite array. The model consists of two boxes. The lower box represents the feeding waveguide and the upper box is the unit cell for the region above the plane. The dimensions and geometry of the unit cell reflect the lattice vectors of the array. Linked boundaries are defined on the cell walls and a wave port provides the array element excitation. Floquet ports must be placed along the Z axis, as shown in this example.



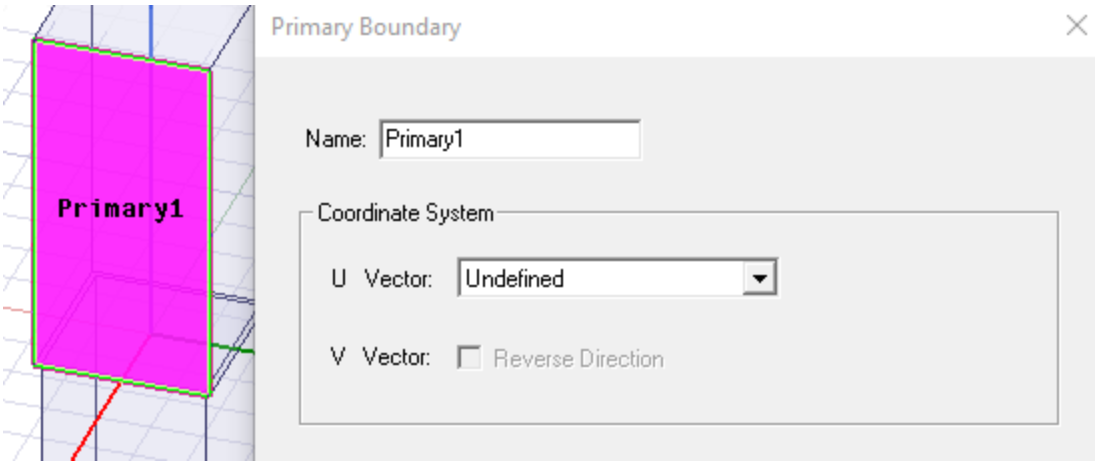
For further discussion and a sample exercise, click **Help> HFSS Getting Started Guides> Floquet Ports**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

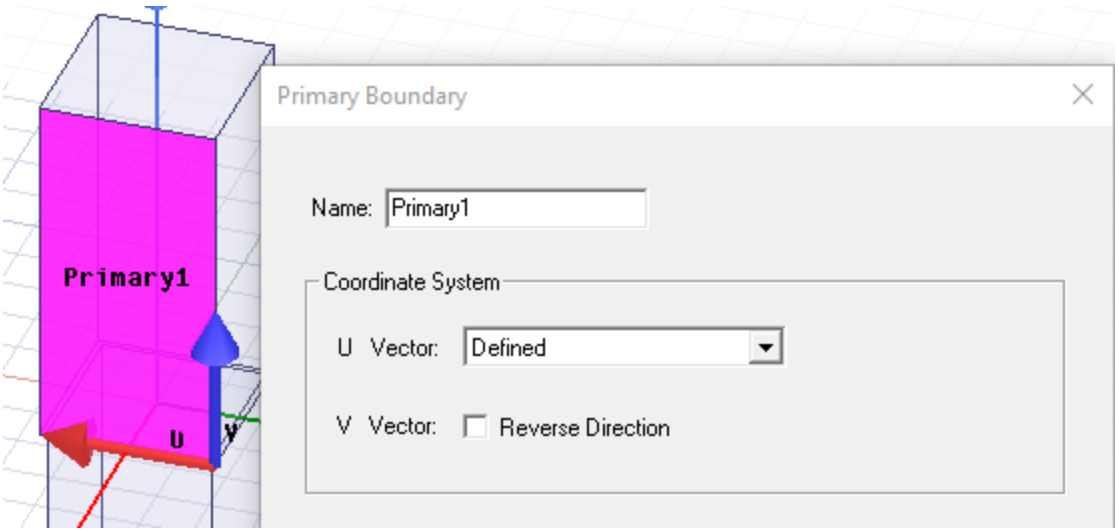
Assign Primary and Secondary Boundaries

In this section we will illustrate a key requirement for setting up a unit cell--the perimeter of a Floquet port must be covered by Primary and Secondary boundaries. You will assign the boundaries as follows:

1. Select the face of the box and click **HFSS**> **Boundaries**> **Assign**> **Coupled**> **Primary**.

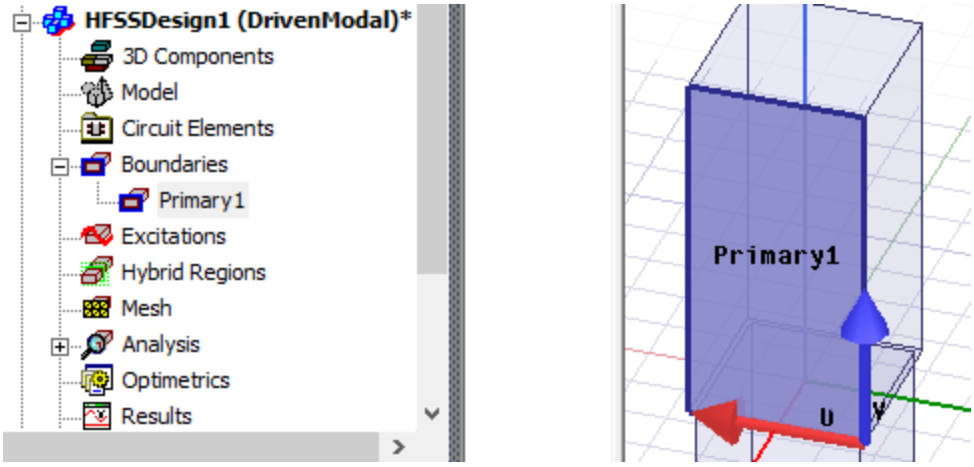


2. Select New Vector from the the U Vector menu and draw the U-V vectors as shown below, from right edge to left.

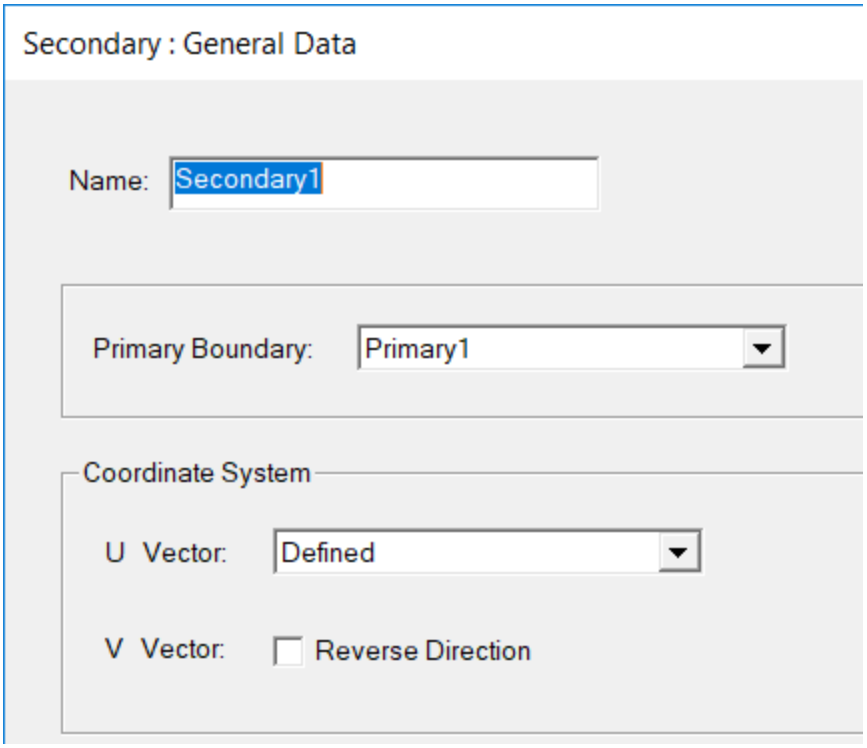


The Primary1 boundary gets assigned as shown in the following figure.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

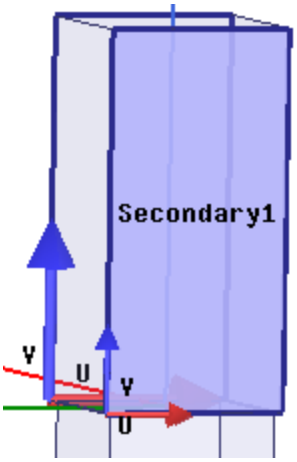


3. Access the face opposite to Primary1 and click **HFSS**> **Boundaries**> **Assign**> **Coupled**> **Secondary**.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Assign the secondary boundary as shown in the following figure.



Direction of the U-V Vectors

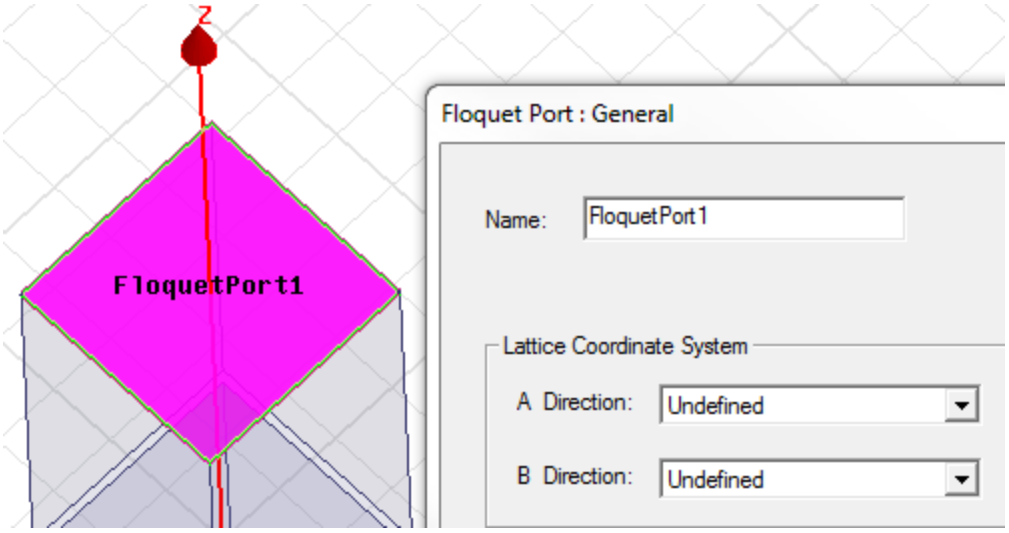
HFSS uses the U-V vectors to set up a local co-ordinate system. A point on the primary boundary must correspond to that on the secondary. A point on the secondary needs to be paired on the primary so that a one-to-one correspondence can be established. Such a co-ordinate system should be constructed and aligned properly in the same direction so that the mapping is accomplished successfully. Therefore, when the V-vector is directed downwards (when it is below the U vector), you must check the **Reverse Direction** option to keep it on the face of the box and not pointing outside of it.

Assign Floquet Ports

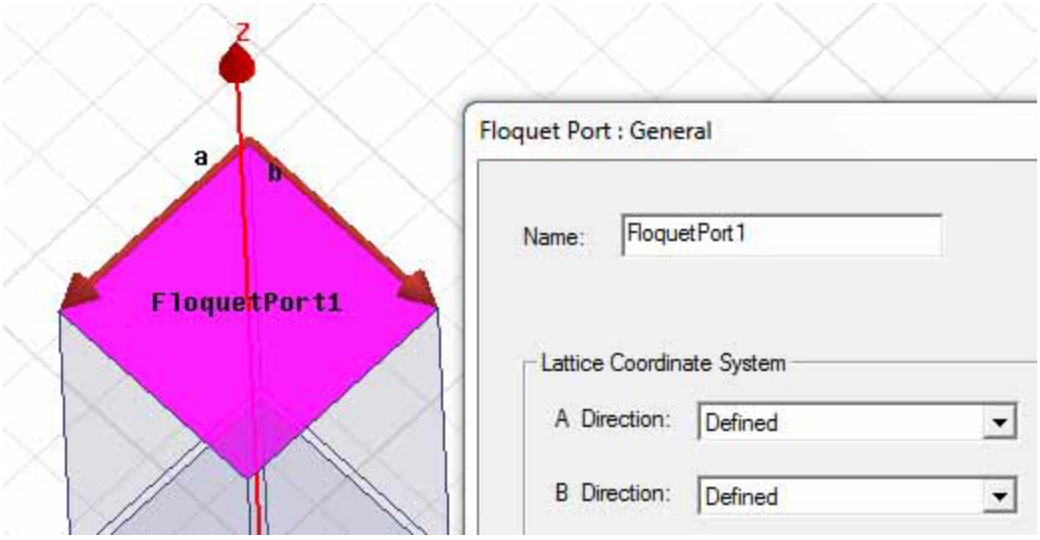
This section describes how to assign Floquet Ports on the unit cell after you define the Primary and Secondary boundaries. To assign the Floquet port perform the following steps.

1. Floquet ports must be placed along the Z axis, as shown. Select the top face of the unit cell, right-click, and select **Assign**> **Excitation**> **Floquet Port** from the shortcut menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

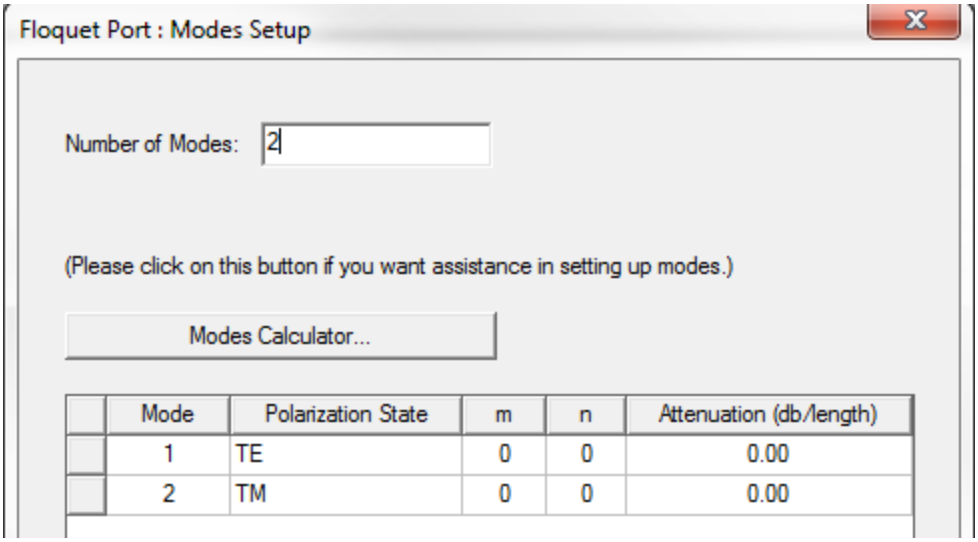


2. Specify the A and B directions for the Lattice coordinate system. These define the periodicity of the planar lattice. The vector arrows must start and end at points on the face of the Floquet port and must have a common initial point.



3. The **Modes Setup** window displays a field for the **Number of Modes**, a button for access to the **Modes Calculator**, and a table.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. On the post processing panel, if needed, the deembed distance can be specified.

Floquet Port Dialog Box

This section describes the settings on each of the tabs available on the **Floquet Port** dialog box.

Topics in this Section:

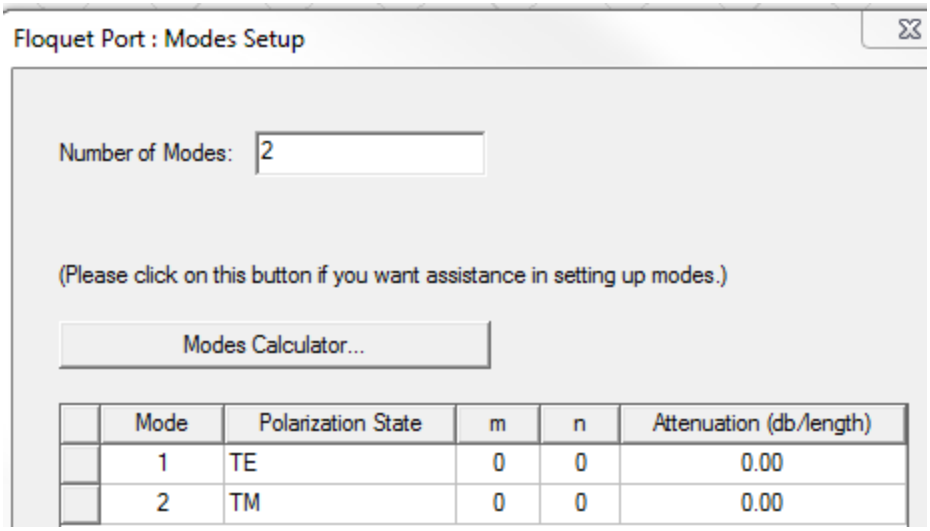
- Floquet Port: Mode Setup
- Floquet Port: Post Processing
- Floquet Port: 3D Refinement
- Floquet Ports: Lattice Coordinate System
- Floquet Port: Modes Calculator

For further discussion click **Help> HFSS Getting Started Guides> Floquet Ports**.

Floquet Port: Mode Setup

In general Floquet modes are specified by two modal indices and a polarization setting. These designations resemble the textbook notation for rectangular waveguide modes, such as ``TE10."

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The default mode table specifies a pair of Floquet modes. The default modes both have modal indices equal to zero and are sometimes called "specular" modes, which are always an essential part of the Floquet mode set. For general frequency and scan conditions, other higher-order Floquet modes will be needed. A modes calculator, invoked by selecting the **Modes Calculator** button, is available to set these up for the user.

The values under **Attenuation** represent the modal loss in amplitude along the direction normal to the Floquet port plane. The numbers in this column are computed by the modes calculator that will help you decide which modes to keep.

Attenuation for a mode is a function of both the frequency and the scan angle specified in the modes calculator. When the latter includes more than one scan direction, the least amount of attenuation experienced by the mode over all the specified scan directions.

Thus when the table gives a value of 0 dB, at one or more scan directions specified in the modes calculator the particular mode propagates without attenuation. Similarly, when the table displays say 60 dB, a 60 dB per unit length is the least amount of attenuation at all specified scan directions. At any given direction, only the same or larger attenuations (for example, 70 dB per length) will occur. To improve simulation efficiency and interpret the results easily eliminate any modes that are not necessary. Do this by editing the **Number of Nodes** field in the **Modes Setup** tab.

> **Note:**
>
> The list is trimmed from the bottom.

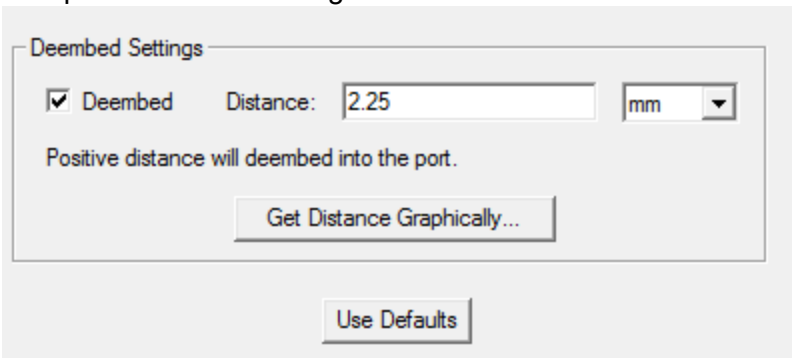
To change the order of items in the final Modes list, drag each corresponding line by the square box at the left of each row.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Floquet Port: Post Processing

This tab lets you specify a de-embedding distance. This optional post processing step is employed when you are interested in the phase of the S parameter elements. The interface for deembedding a Floquet port is the same as that for a wave port.

This panel contains settings that affect the fields once the field solution is complete.

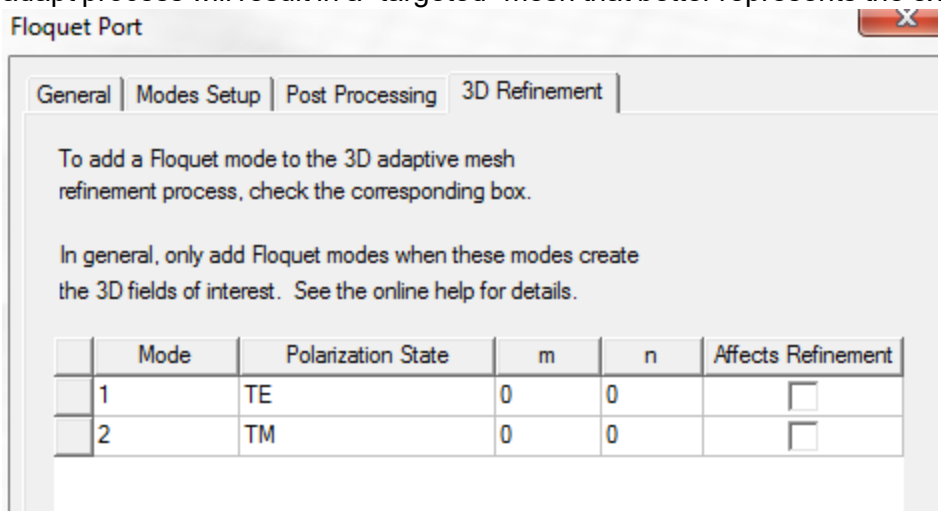


This enables the distance and units field for the positive value to deembed the port into the mode, and for a negative value to deembed the port out of the model.

Floquet Port: 3D Refinement

This panel contains the **Affects Refinement** check boxes which allows you to specify **Floquet** modes in the 3D adaptive refinement process. Typically, you select no modes or only one or both specular (TE00 or TM00) modes. Selecting more than this may affect the efficiency and accuracy of the solution process.

In 3D adaptive refinement the generated mesh is a compromise which simultaneously represents the 3D field patterns of every mode included in the adapt process. If the field patterns of certain modes represent the fields of interest and others do not, excluding the latter from the adapt process will result in a "targeted" mesh that better represents the excitation field pattern.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For antenna array simulations in which the active impedance or embedded-element pattern is sought, the Wave or Lumped ports modeling the feed structure provide the fields of interest. In this case, no Floquet modes should be included in the adapt process. On the other hand, if the per-cell RCS is of interest, one or both specular Floquet modes provide the fields of interest and should be included in the 3D adapt process by checking the corresponding **Affects Refinement** boxes. Similarly, for an FSS simulation with two Floquet ports, specular modes provide the fields of interest and should be selected to participate in the 3D adapt process.

In certain simulations (for example, a frequency-selective surface) you will set up a second Floquet port. Note that when you do this HFSS automatically copies the lattice vectors, modes table, and 3D refinement settings from the first Floquet port to the second.

Floquet Ports: Lattice Coordinate System

In the **Floquet Port** dialog box, **General** tab, for each Vector (A and B Direction):

1. Select the drop-down menu and click **New Vector**.

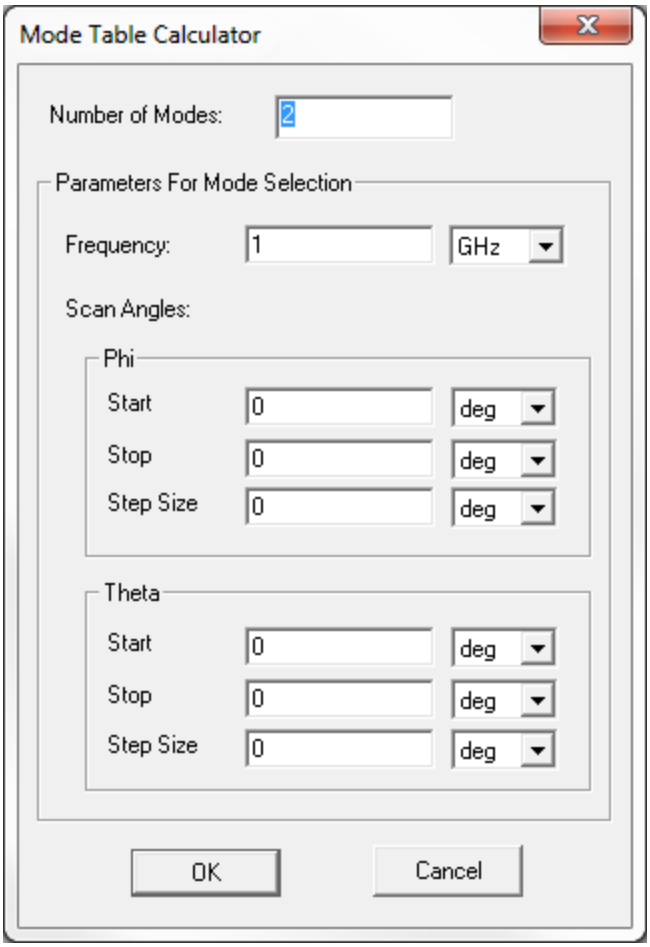
   This opens a **Measure Data** dialog and causes the cursor to drag a visual marker that drops a dashed line to the reference plane, and shows a location indicator on the Floquet plane.

2. Drag the marker to select a location for the Direction vector. Click to set the origin point, and drag and click to specify the position 2 point that defines the direction from that origin. The vector arrows must start and end at points on the face of the Floquet port and must have a common initial point.
3. Clicking the second point closes the **Measure Data** dialog box, and exits the New Vector mode. The drop-down menus for Position A and Position B now include an entry called "Defined" along with "Undefined" and "New Vector."

Floquet Port: Modes Calculator

1. In the **Floquet Port: Modes** tab, if you select the **Modes calculator** button, the **Mode Table Calculator** window displays.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Enter the following fields:

- **Number of modes** - you can trim this value later, as you learn which modes are needed and which are not.
- **Frequency** - if the problem setup contains one or more frequency sweeps, usually you will set this value to the highest frequency.
- **Scan Angles -**enter the values and select units for Phi and Theta, including Start, Stop, and Step size. The **Mode Table Calculator** calculates a set of Floquet modes on the basis of all the angles defined.

These inputs constitute the information required to create a set of recommended modes for the Floquet port. The inputs are used by the mode selection algorithm but do not affect the problem setup.

1. Click **OK** to leave the **Mode Table Calculator** and to compute the recommended list of modes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The new modes table appears on the **Modes Setup** tab of the **Floquet Port** properties/setup window. The attenuation associated with a listed mode represents the minimum (or worst case) for that mode over the range of scan angles.

Incident Waves

An incident field is the electromagnetic field in the absence of any scatterers. We suppose that the incident field is present everywhere and it comes from a source residing in some location. The source can even be another HFSS project or an SIwave project.

Incident waves can be of the following types:

- Plane Wave
- Hertzian-Dipole Wave
- Cylindrical Wave
- Gaussian Beam
- Linear Antenna Wave

For incident analytical waves (plane waves through linear antenna waves) HFSS supports two basic methods: scattered field formulation and total field formulation.

Etotal = **E**incident + **E**scattered

The total field formulation is useful for viewing weak total fields while scattered field formulation is useful for viewing weak scattered fields.

For near field and far field waves we are merely specifying the fields on the radiation surfaces. So, we cannot view only the total fields.

Radiation Boundary Panel

When assigning an incident wave either a radiation boundary, PML boundary, or Hybrid Region Finite Element Boundary Integral (FE-BI) method must be defined at least on one section of the surface of the model. The Radiation Boundary panel is shown below.

For more information see Assigning Radiation Boundaries

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To assign a FE-BI, use Hybrid>Assign>FE-BI.

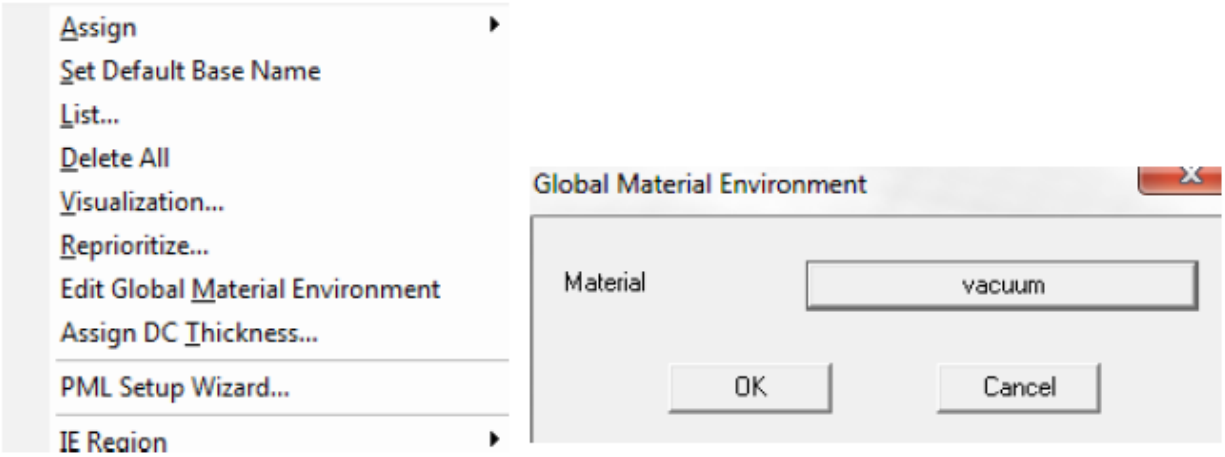
Global Material Environment

A plane wave is described by the following equation.

$$\vec{E} = \vec{E}_0 \, e^{-j\vec{k}\cdot\vec{r}}$$

The **k** vector also depends on the material of the radiation boundary. More precisely it is the wave number of the global background material.

You can set the global material environment which is otherwise vacuum by default. Right-click **Boundaries** and select **Edit Global Material Environment** to bring up the dialog box.



The material specified in the **Global Material Environment** panel can impact an HFSS design in the following three areas:

- All incident waves except evanescent plane waves and near and far field links are assumed to have been generated in the global background material.
- All fields outside the computational domain are obtained using the global background material.
- The currents on exterior HFSS-IE regions are computed assuming the global background material.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

The PML and simple ABC are constructed assuming the interior material touching the radiation surface is the same as the exterior global background material. The actual material used is the interior in this case in order to allow different materials to be in contact with the radiation surface as is the case when truncating the substrate of a PCB design. To obtain consistent results when viewing fields outside the computational domain, ensure that the interior material touching the radiation surface is the same as the global background material.

Incident Plane Wave

A plane wave is a wave that propagates along a fixed direction where the electric and magnetic fields are in the transverse plane and perpendicular to each other.

A plane wave is defined by the following equation:

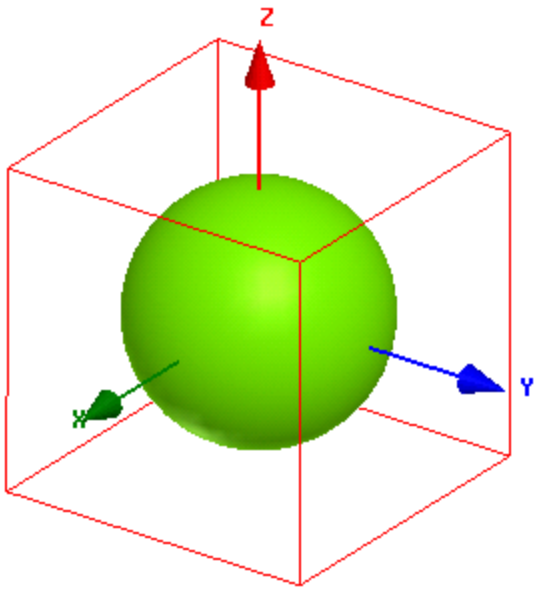
$$\vec{E} = \overrightarrow{E_0} e^{-j\vec{k}\cdot\vec{r}} \qquad \text{where} \qquad \vec{k} = k\hat{k}$$

$$\text{and} \qquad \overrightarrow{E_0} = E_0\hat{e}_0$$

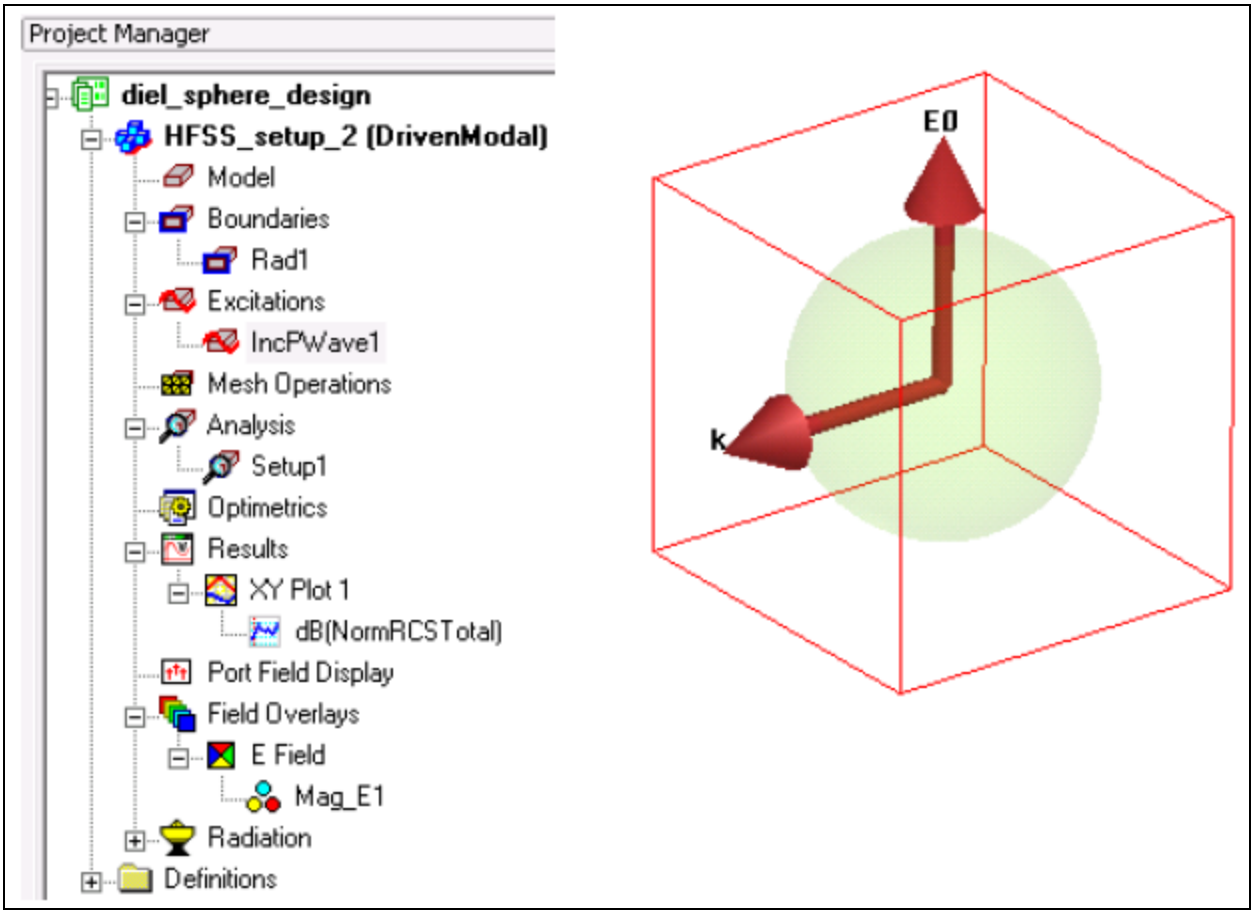
The term *k* represents the wave number of the global background material for regular/propagating plane waves.

An HFSS model of a dielectric sphere is shown to illustrate the incident plane wave setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

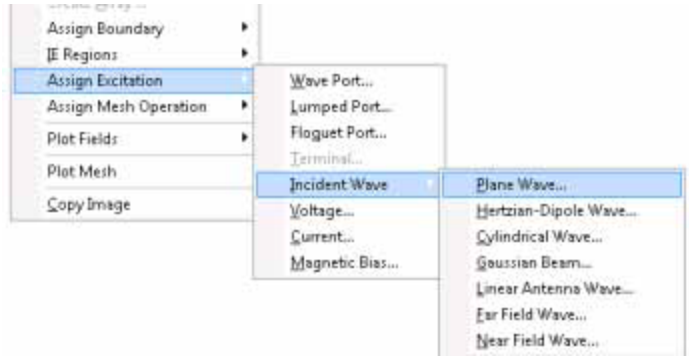


After a plane wave is defined, the propagation direction and the electric field direction can be visualized as shown in the following figure.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To define a plane wave, right-click anywhere in the Modeler and select **Assign Excitation> Incident Wave> Plane Wave.**



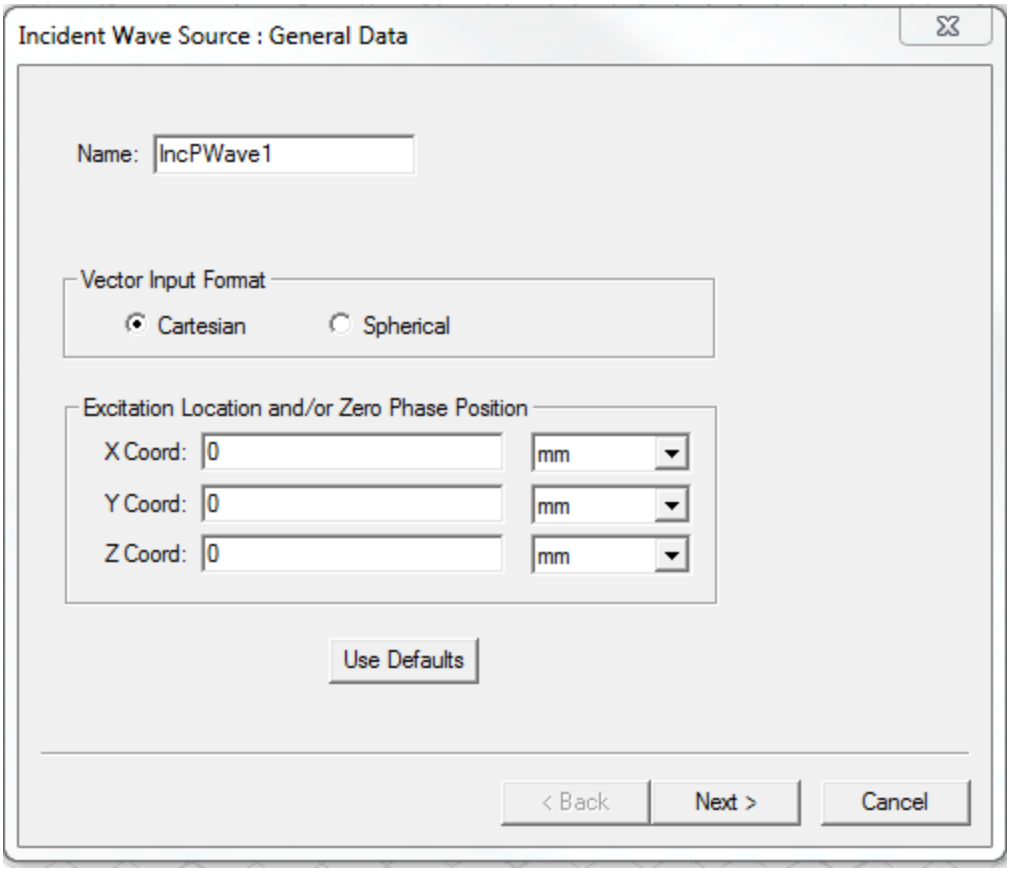
The **Incident Wave Source: General Data** dialog box appears. You can select either **Cartesian** or **Spherical** for the **Vector Input Format**.

Cartesian Vector Setup

Enter the Cartesian co-ordinates on the **Incident Wave Source: General Data** dialog box to set the zero phase location for propagating wave and click **Next**.

> **Note:**
>
> For evanescent waves, Cartesian co-ordinates are defined for the Excitation location.

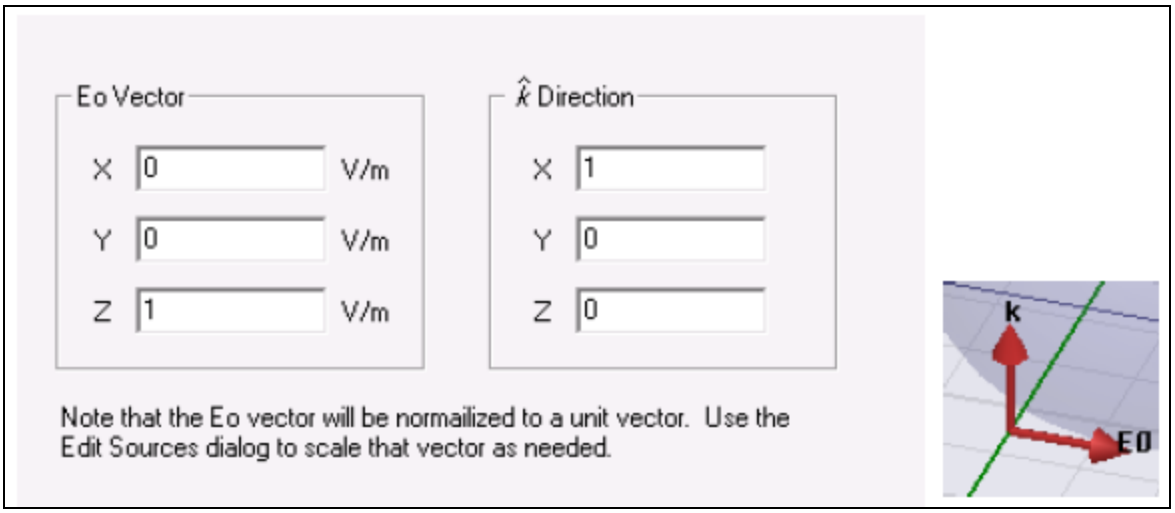
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The following figure shows the **Cartesian Vector Setup** panel. Define the direction of **Eo**. Regardless of the magnitude of the field vector **Eo**, HFSS normalizes it to 1. However, the magnitude of **Eo** can be scaled to the desired value on the **Edit post process sources** panel.

Also, define the direction of the unit vector of propagation, $\hat{k}$. It is your responsibility to ensure that the direction of propagation, $\hat{k}$ of the plane wave is perpendicular to **E0.L**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Click **Next** to specify the the type of plane wave on the **Plane Wave Options**panel.

Recall the equation that describes a plane wave:

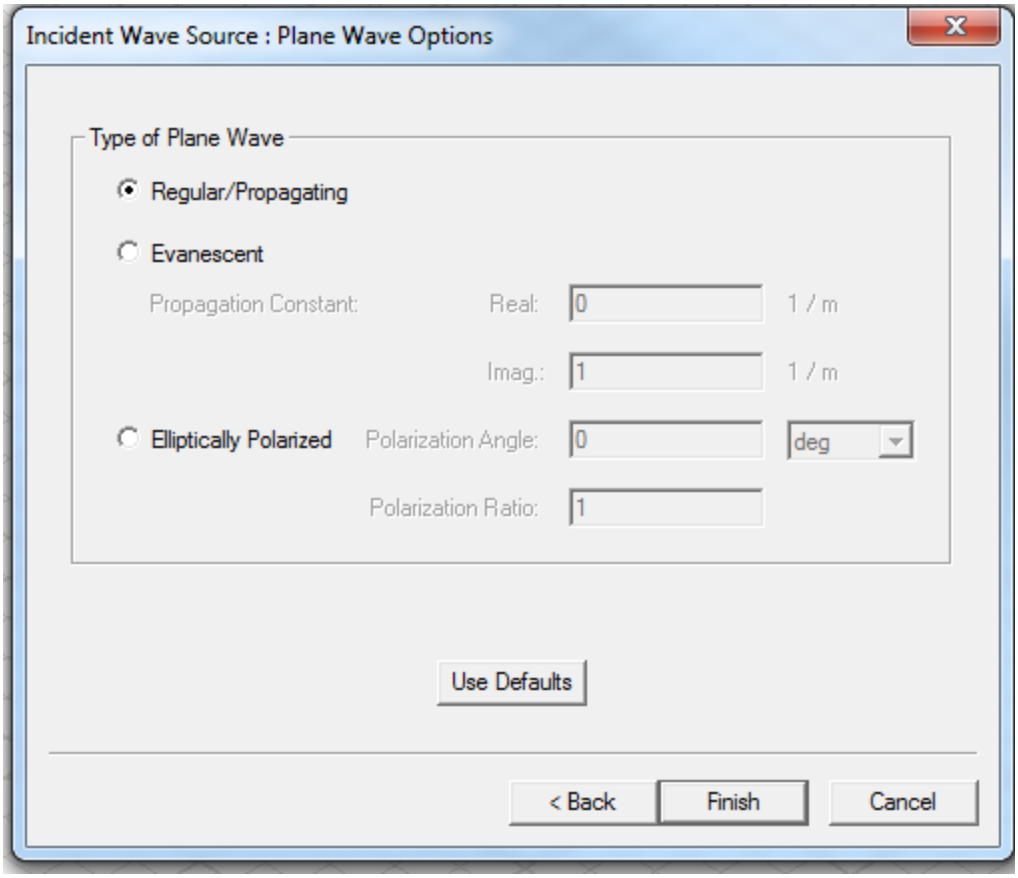
$$\vec{E} = \overrightarrow{E_0} e^{-j\vec{k}\cdot\vec{r}} \qquad \text{where} \qquad \vec{k} = k\hat{k}$$

$$\overrightarrow{E_0} = E_0\hat{e}_0$$

where k is the wave number of the global background material for regular/propagating plane waves. In most cases, the values defined for **Eo** and **k** are meant for regular/propagating plane waves. For evanescent waves, since $k = \beta + j\alpha$ it overrides the magnitude of the complex propagation constant.

> **Note:**
>
> In HFSS, evanescent waves do not depend upon the global background material. However, the post-processed near or far fields depend upon the global background material. For more information see the section Global Material Environment.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



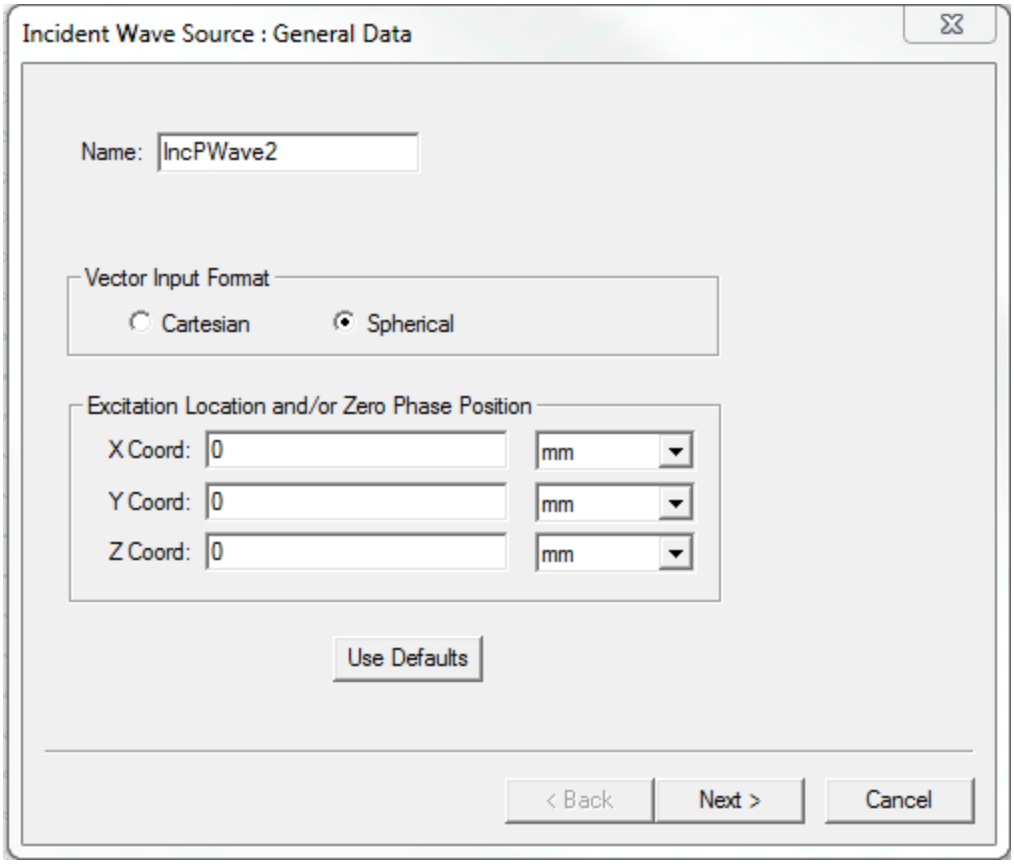
If you select the type of plane wave as **Elliptically Polarized**, specify the ratio of the large axis to the small axis of the ellipse and the phase angle of the large axis. For more information, see the section Elliptically Polarized Plane Wave.

Spherical Vector Input Format

This section demonstrates the same incident plane wave by defining the vector input format for a Spherical setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

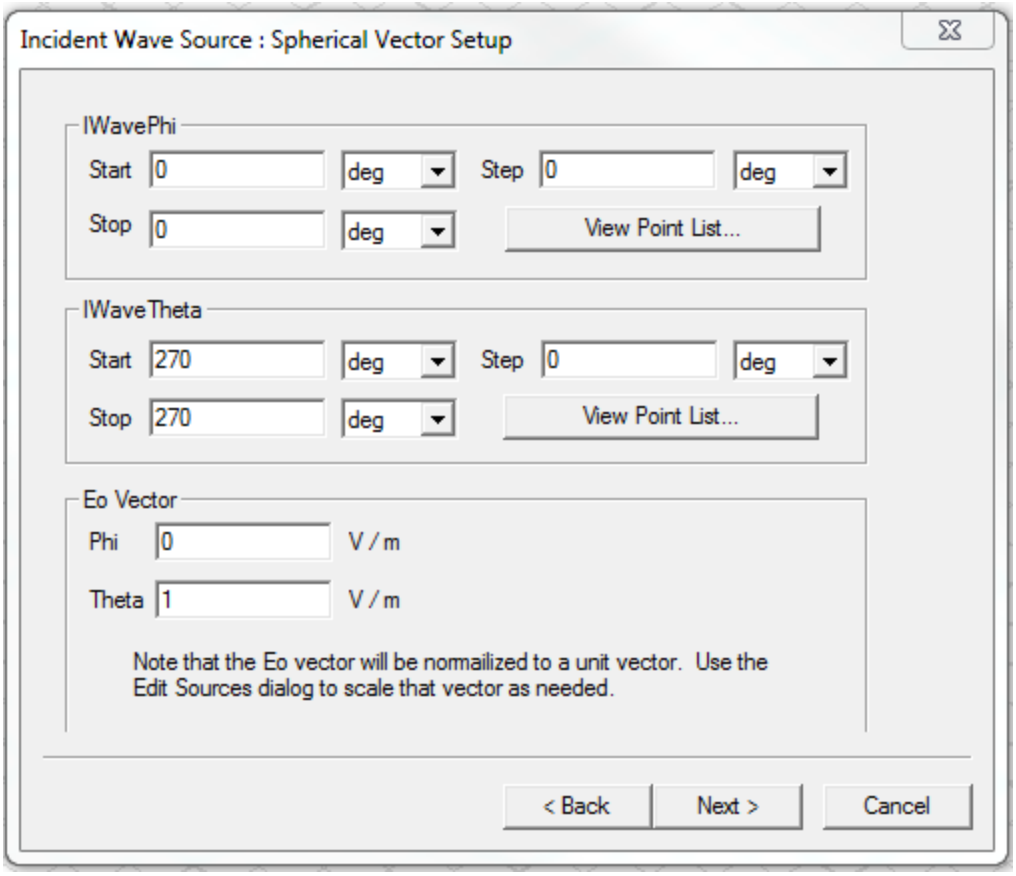
1. On the **Incident Wave Source: General Data** dialog box, select the option **Spherical**.



2. Click **Next** and edit the **IWavePhi**, **IWaveTheta**, and **Eo Vector** fields as shown in the following figure.

   This setup provides an alternate way of defining plane waves using spherical vector format. The orthogonality of $\hat{k}$ and **Eo** is automatically satisfied since $\hat{k}$ is in the $\hat{r}$ direction. Regardless of the magnitude of **Eo**, HFSS normalizes it to 1. However, the magnitude of **Eo** can be scaled to the desired value on the **Edit post process sources** panel.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

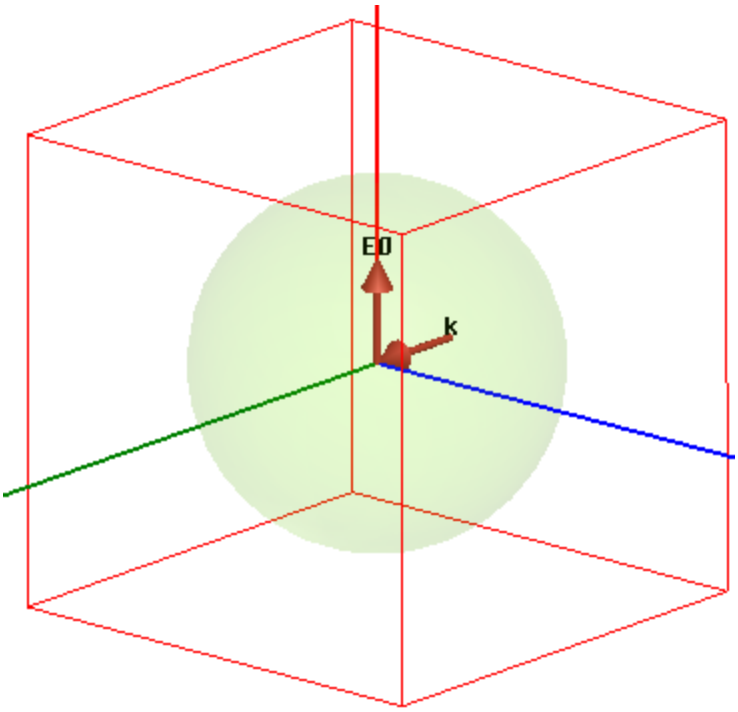


> **Note:**
>
> If you enter values in the **Step** fields and click the **View Point List** button, you can see all the phi or theta values.

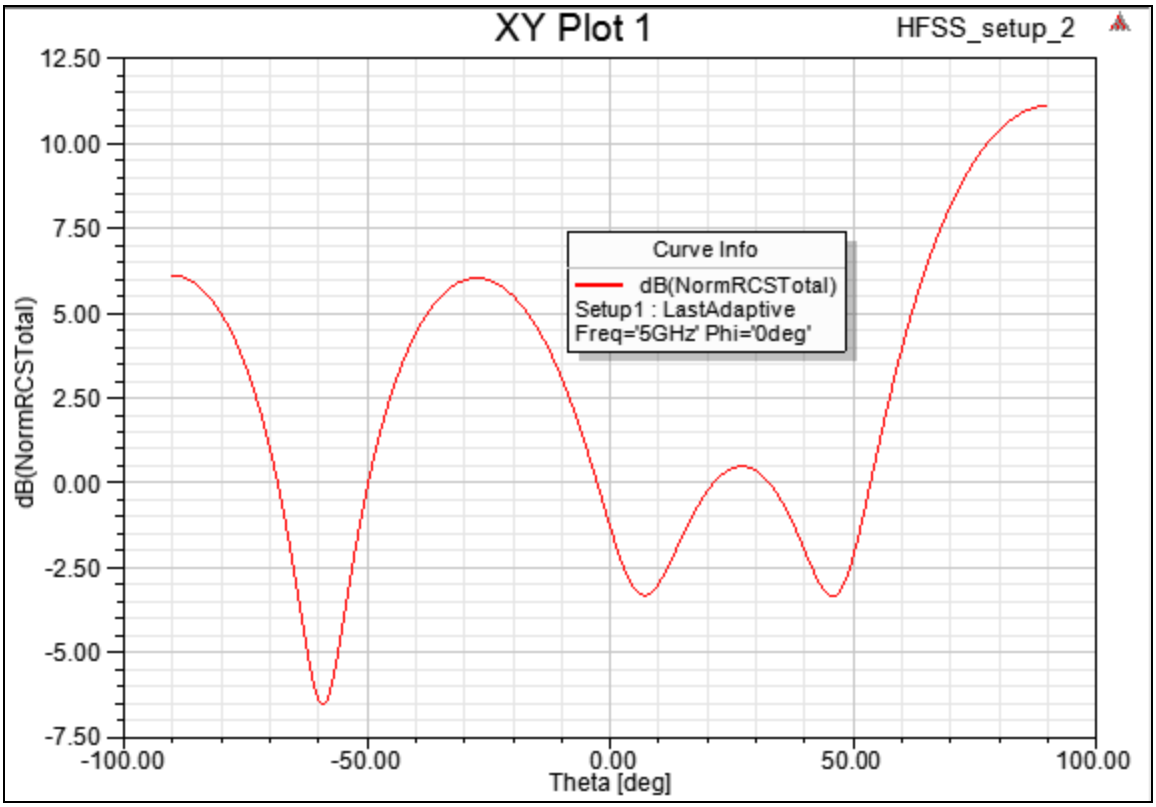
For a spherical incident wave you can specify an expression to define an angle in the start field only. If use an expression, the dialog disallows any stop/step values. In other words, we allow only a single angle if you choose to parametrize the start angle.

You can visualize the propagation direction and the electric field direction for a plane wave defined for spherical vector setup as shown in the following figure.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

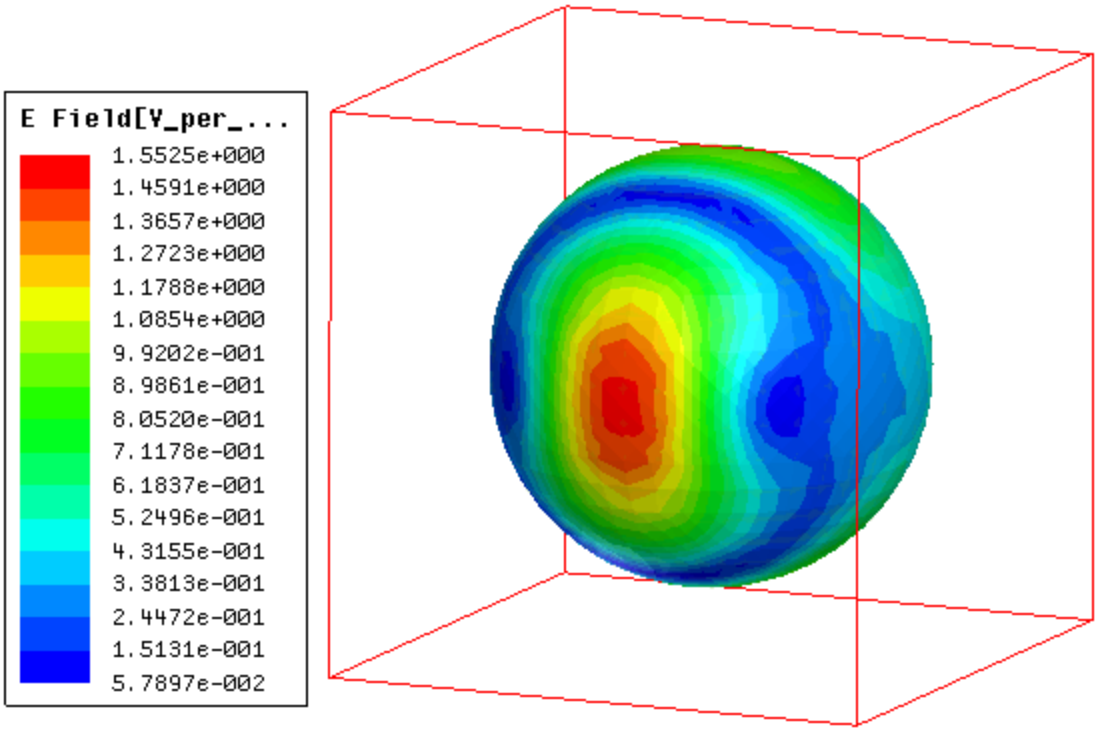


The normalized bistatic RCS plot for theta scan at phi = 0 plane is shown below.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The following figure shows the scattered E-field plot on the surface of a dielectric sphere (radius = 30mm, relative permittivity = 10, and solution frequency = 5 GHz.)



Note:

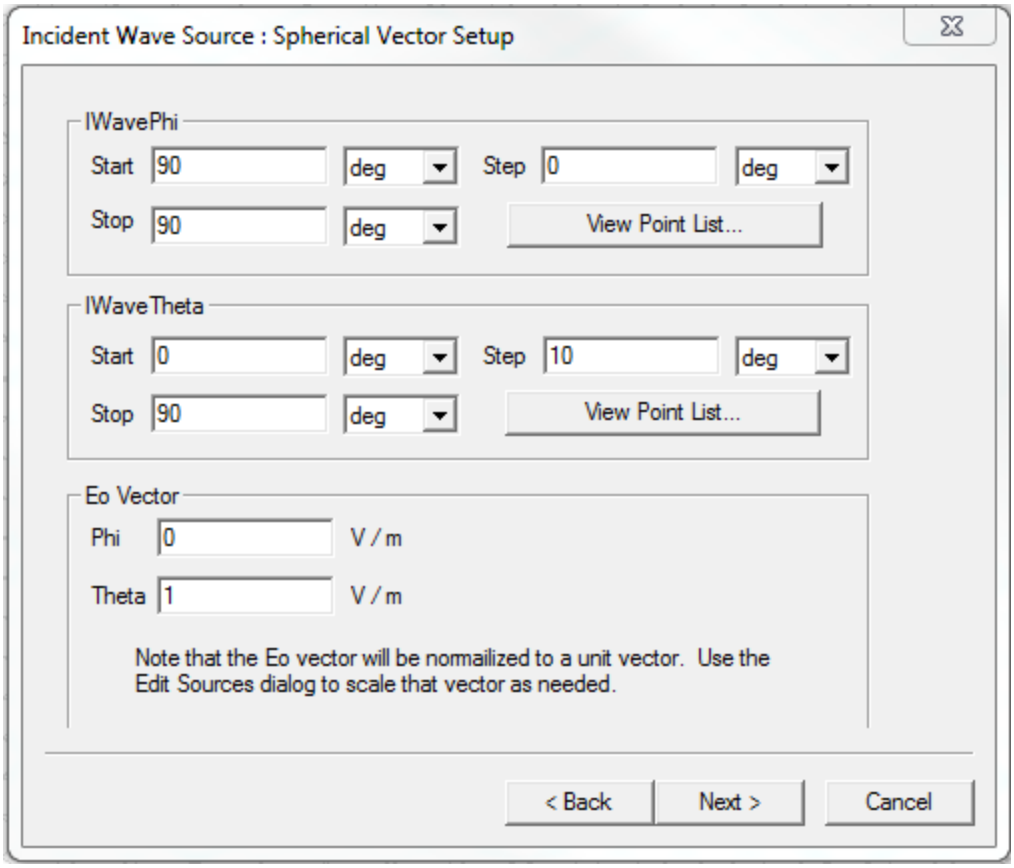
The Spherical vector input format provides a convenient way of specifying multiple incident angles.

Defining Multiple Plane Waves

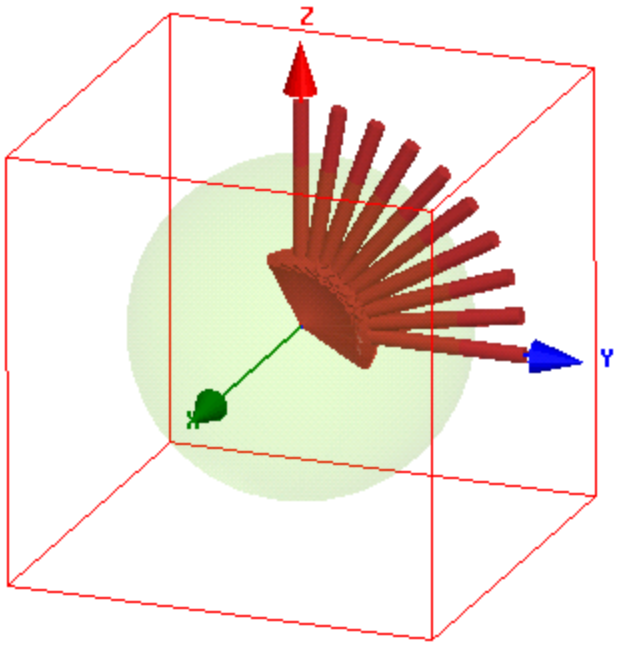
This section describes how to define multiple plane waves using **Spherical Vector Setup**.

The following figure shows the **Spherical Vector Setup** panel. An incident wave sweep is defined in the phi = 90 degrees plane for theta, with step size of 10 degrees.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

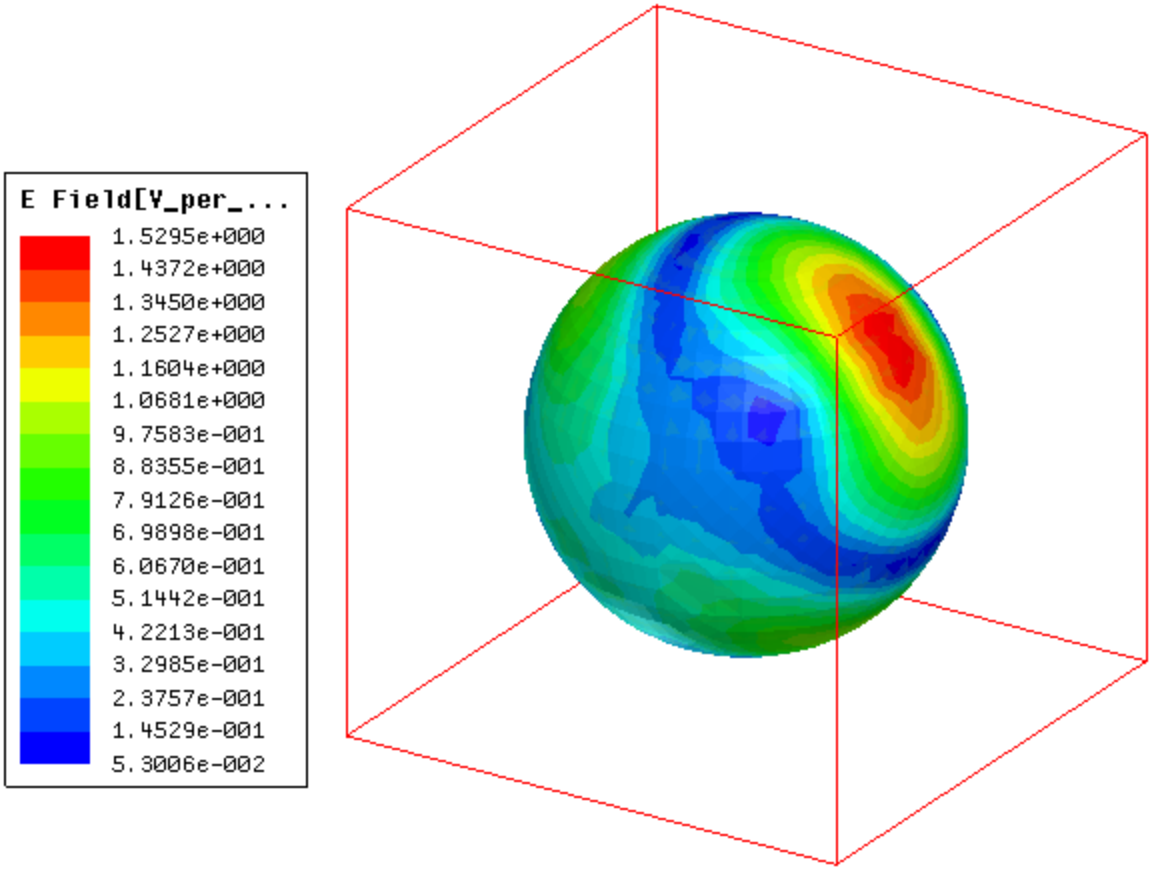


This setup defines eleven incident plane waves as source as shown in the following figure.



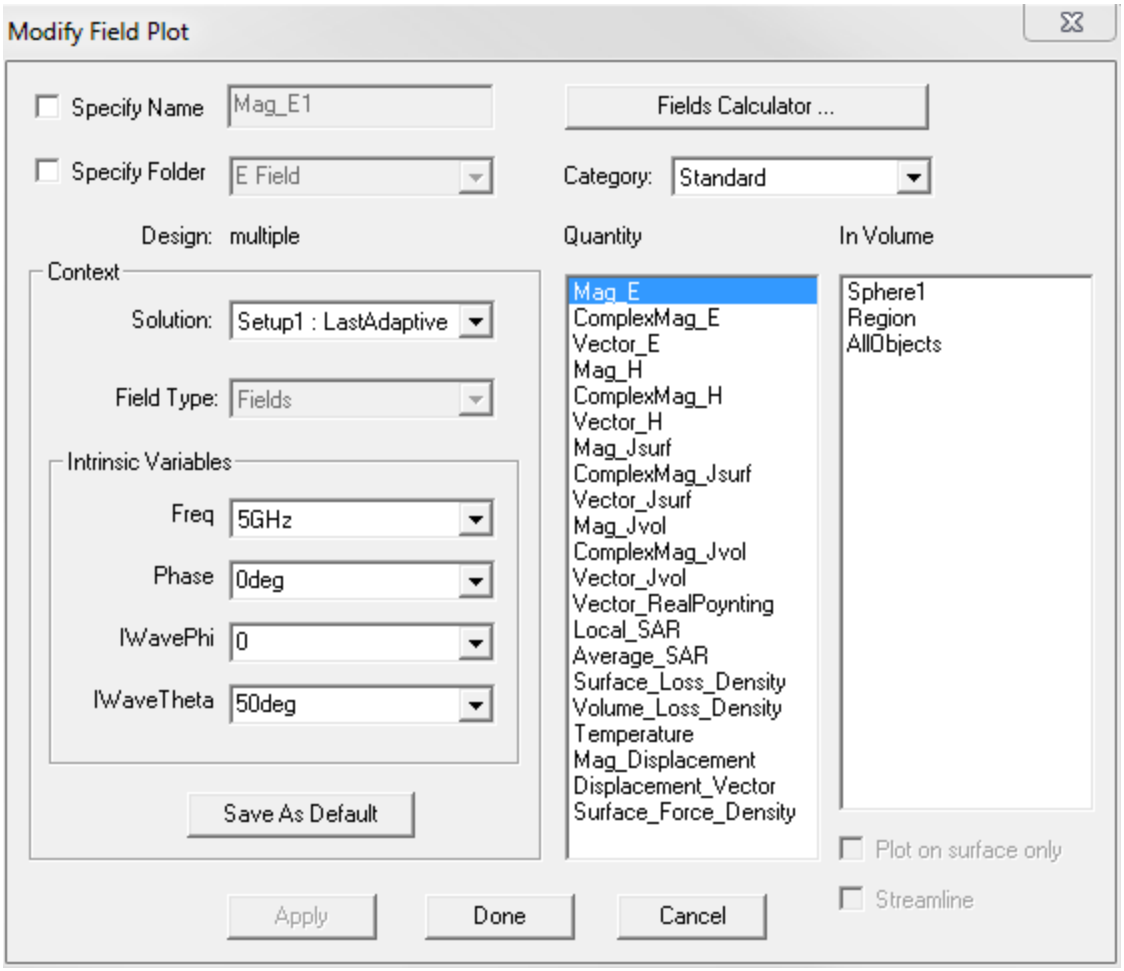
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The following figure shows the scattered E-field plot on the surface of the dielectric sphere (radius = 30mm, relative permittivity = 10, and solution frequency = 5 GHz) at incident angle of theta = 40 degrees.



This E-field plot is defined for IWaveTheta = 50 deg and IWavePhi = 0 deg.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



> **Note:**
>
> Although the incident field sweep defines multiple plane waves, only one scale factor is applied on all the plane waves. This scale factor can be edited on the **Edit post process sources** panel.

Both the overlay field panel and the Reporter provides you options to select the desired incident plane wave.

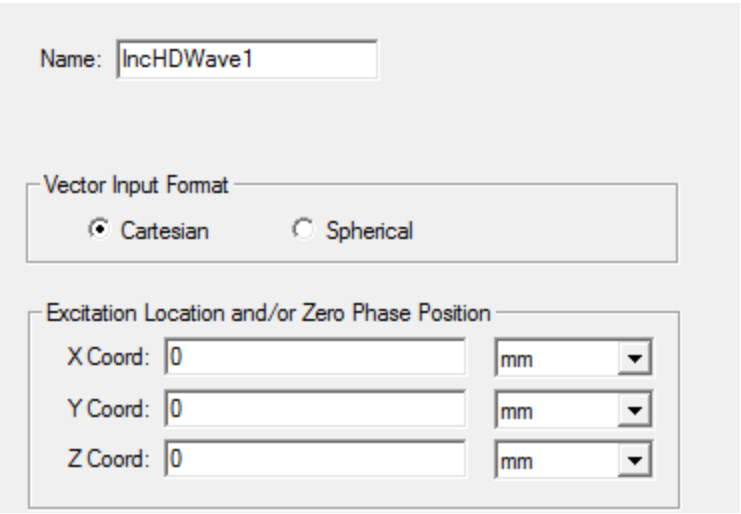
Hertzian-Dipole Wave

An incident Hertzian-Dipole wave can be specified as either an Electric dipole or a Magnetic dipole. The Electric dipole simulates the field of an elementary short dipole antenna placed at the origin. The Magnetic dipole is useful for EMC/EMI applications. Specify a Hertzian dipole as follows:

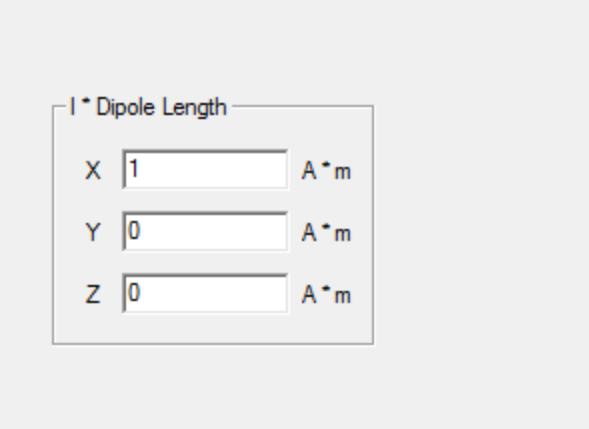
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cartesian Coordinates

1. Click **HFSS>Excitations>Assign>Incident Wave>Hertzian-Dipole Wave**.



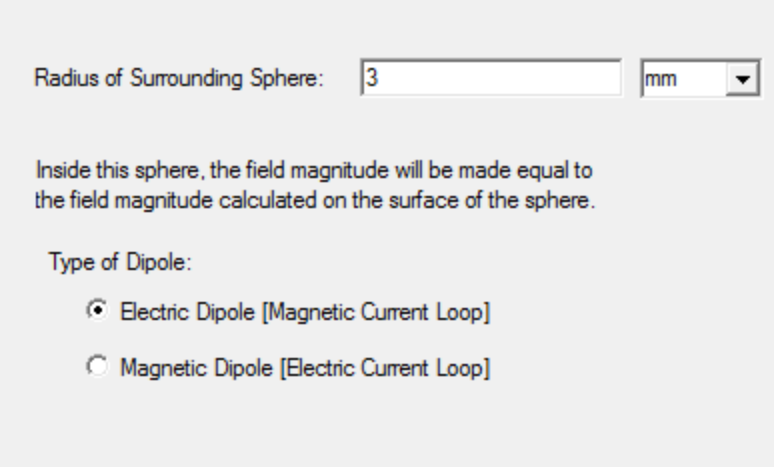
2. Select **Cartesian** and click **Next**, the subsequent dialog lets you define the dipole length.



3. Define the types of dipole and the radius in the **Hertzian-Dipole Wave Options** dialog box. The radius of Surrounding Sphere should be small enough so that a Hertzian dipole is placed into the computational domain when scattered field formulation is used. If you place a Hertzian dipole out of the computational domain, the Surrounding sphere can

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

have any radius.



Incident Cylindrical Wave

An incident Cylindrical wave is a wave that simulates the far field of an infinite line current placed at the origin.

1. Click **HFSS>Excitations>Assign>Incident Wave>Cylindrical Wave**.
2. Select the **Vector Input Format** as **Cartesian** coordinates.
3. Enter the X-, Y-, and Z-coordinates of the **Excitation Location and/or Zero Phase Position** (the origin for the incident wave).
4. Click **Next**.
5. If you selected **Cartesian**, the **Incident Wave Source: Cartesian Vector Setup** page appears. Enter the X-, Y-, and Z-components for **the I Vector** in the **X**, **Y**, and **Z** boxes. **I** is the current amplitude (peak value). Units are Amps (A).

   A single incident wave will be defined.

> **Note:**
>
> Only a single incident wave angle can be defined for periodic structures which are defined with primary and secondary (Lattice pair) boundaries

6. Click **Next**. the **Incident Wave Source: Cylindrical Wave Options** page appears.
7. Select the **Radius of Surrounding Cylinder**. Inside this cylinder, the field magnitude will be made equal to the field magnitude calculated on the surface of the cylinder. To restore the default (10 mm), click **Use Defaults**.
8. Click **Finish**.The incident wave you defined is added to the **Excitations** list in the **Project**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Gaussian Beam Wave

An incident Gaussian Beam wave propagates in one direction and is of Gaussian distribution in the directions perpendicular to its direction of propagation. The steps for assigning a Gaussian Beam Wave are the same as those for assigning Plane Wave. The only difference is that in this case **Gaussian Beam Wave Options** will appear as one of the tabs instead of **Plane Wave Options** on the **Incident Wave Source** dialog box. For more information see Plane Wave.

Linear Antenna Wave

An incident linear antenna wave is a wave that simulates the far field of a linear antenna placed at the origin. The steps for assigning a Linear Antenna Wave are the same as those for assigning a Hertzian Dipole wave. The only difference is that in this case **Linear Antenna Wave Options** will appear as one of the tabs instead of **Hertzian Dipole Wave Options** on the **Incident Wave Source** dialog box. For more information see Hertzian Dipole Wave.

Far Field Wave

A far field wave originates at a distance several wavelengths from the computational domain. Far field values are defined on the surface of a unit sphere.

When you use a Far Field link, the origin of the global coordinate system of the source project should be in the phase center of the antenna.

- Far Field Wave Options
- External Data File for Far Field Wave
- Setup Link for Far Field or Near Field Wave
- Example That Uses Far Field Links
- Near/Far Field Polarization Definition Table for HFSS, SBR+ and Hybrid Designs

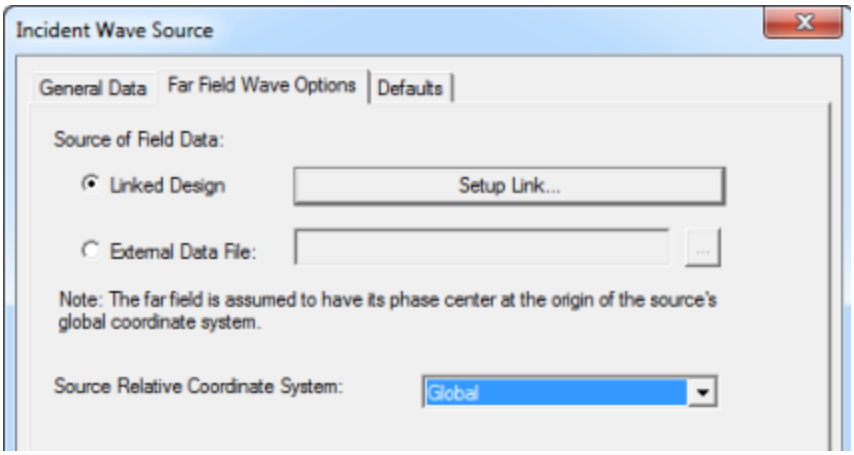
Far Field Wave Options

This section describes the panel **Far Field Wave Options**. Bring up this panel on the **Incident Wave Source** dialog box as follows.

First click **HFSS>Excitations>Assign>Linked Field>Far Field Wave** and then, click **Next** on the **Far Field Wave Options** tab.

Click **Setup Link** on the **Incident Wave Source** dialog to browse for a source project for specifying the linked design.

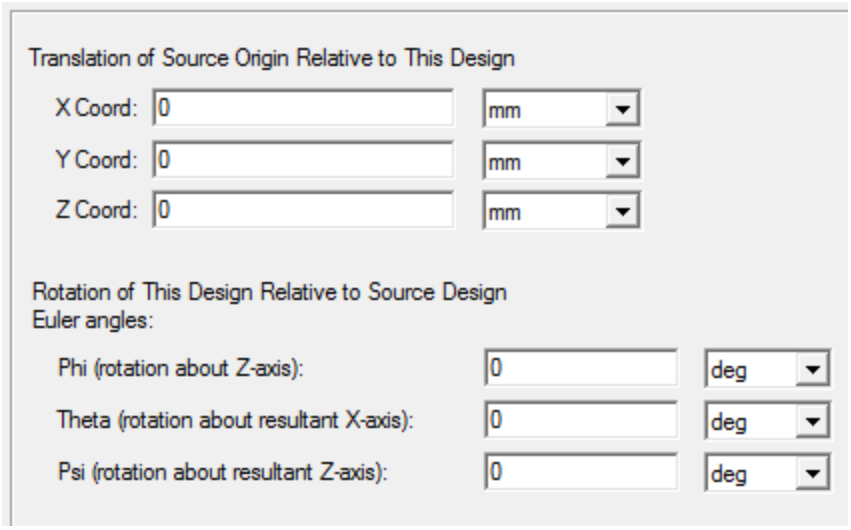
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Use a local coordinate system defined in the target design to represent the source origin and rotation relative to target design. All the legacy origin and Euler angles will be translated into local coordinate system.

Legacy Translation of Source Origin Relative to This Design

For legacy projects if the coordinate system you are using in the source design is different from that in the target design, you originally defined the relationship between those coordinate systems as a translation and a rotation. The translation is the offset between the **origins** of the two coordinate systems, and the rotation was defined through the use of **Euler angles.**



The X-, Y-, and Z-coordinates of the source location and/or Zero Phase Position (the origin for the incident wave) represents the translation of the source design's origin with respect to the target design's origin. For instance, if the source design's origin is located in the target design co-

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ordinate system at (-2, -2, 1), then the translation between the two coordinate systems is (-2, -2, 1).

The Euler angles represent the angles through which you can rotate the target design to achieve the desired rotation angles.

All the legacy origin and Euler angles will be translated into local coordinate systems.

> **Note:**
>
> A figure that represents the angles and the rotation of a design is at the end of the section.

See Computing Antenna Parameters for a description of how to obtain antenna parameters during post processing.

X, Y, Z Source Coordinate System

External Data File for Far Field Wave

You can define a Far Field **Incident Wave Source** as a plain text data file with a .ffd suffix. The fields can be independent or dependent on the frequency.

> **Note:**
>
> The far field data file must be a plain text file. Wordpad includes invisible characters that HFSS does not support. The code tolerates white space separators anywhere (blank, tab, newline, carriage return). Between double values in same logical grouping, it tolerates comma or semicolon separators.

Examples of ffd format files

- Frequency Independent Far Fields
- Frequency Dependent Far Fields

Related Topics

Setup Link for a Far Field or Near Field Wave

Frequency Independent Far Fields

In this case, the file format is simple. No keywords are used. The first two lines contain doubles representing start, stop, and num points for the sweeps of theta and phi. The angle units are degrees. In order to have a unique coordinate system theta and phi should be in the range of 0 < theta < 180 and 0 < phi < 360.

```
ThetaStart ThetaStop ThetaNumPoints
PhiStart PhiStop PhiNumPoints
```

Then, the subsequent lines give the complex components of electric far field in the theta and phi directions. By definition, far field is the scattering amplitude of the electric field at the region that is at a large distance from the antenna. Typically the distance must be much greater than 2 D * D / wavelength where D is the largest dimension of radiator or scatterer. The unit of far field is Volt as it is the product of distance and electric field. For these lines, theta will be held constant while phi is swept through all values, then theta will increment to the next value, etc. So the lines will correspond to (th1, ph1), (th1, ph2), (th1, ph3),…,(th1, phN), (th2, ph1), (th2, ph2), etc… Note that this format enforces a strict uniform grid of theta and phi samples.

```
E_theta_real E_theta_imag E_phi_real E_phi_imag
E_theta_real E_theta_imag E_phi_real E_phi_imag
...
```

See the following example of a data file:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> Instead of commas you can use double-space or semicolon separators.

Frequency Dependent Far Fields

For **frequency-dependent** far field links, the data is supplied in blocks. The syntax for a frequency dependent far field uses the following format.

thetaStart, *thetaStop*, *count* (specified as *degrees, degrees, integer*, for example, `0,180,2`

phiStart, phiStop, count (specified as *degrees, degrees, integer*), for example, `0,360,5`

frequencies *count* (specified as *string*, *integer*), for example, `frequencies 3`

frequency *freq* (specified as *string*, *double*), for example, `frequency 3.0e9`

Then for each point,

real E(theta), imag E(theta), real E(phi), imag E(phi), that is, 4 doubles, for example, `0.0,0.0,0.0,1.0`

Then the rest of the points

Then the rest of the frequencies

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If the infinite sphere setup is not Theta-Phi (CS definition in the infinite sphere dialog) then theta is in reverse order.

```

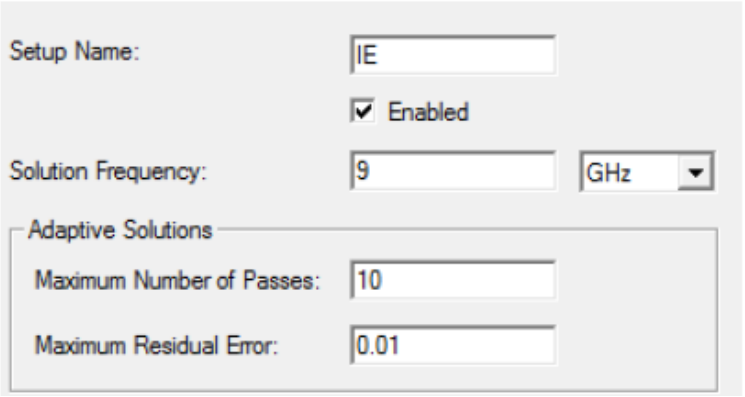
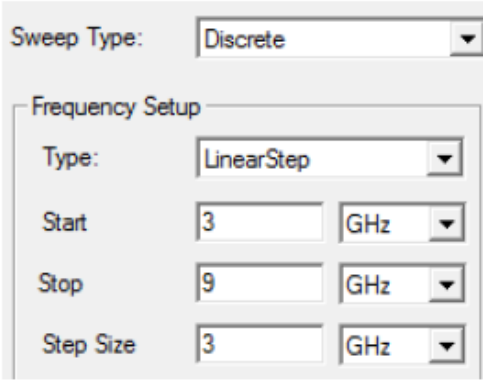
The syntax and their values are as follows:

- 0, 180, and 2 are the values of ThetaStart, ThetaStop, and ThetaNumPoints in the first line.
- The values 0, 360, and 5 do the same thing for Phi.
- NumFrequencies represents the number of blocks defined in the data file. In this example, 3 frequency blocks are defined.
- FrequencyValue represents the value of frequency for which you supply the far field data. In the Data File Example, FrequencyValue is as follows:
- 3.0e9 Hz for the first block;
- 6.0e9 Hz for the second block;
- 9.0e9 Hz for the third block.

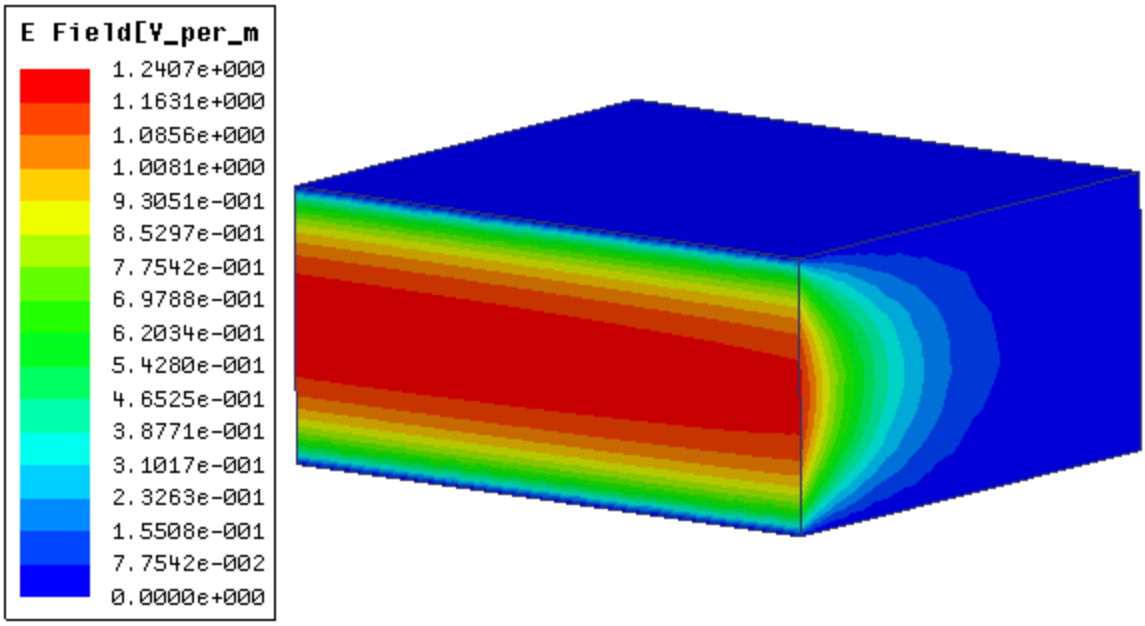
HFSS supports only the discrete sweep type for Far Field (and Near Field) data links. The frequencies defined in the sweep must be consistent with the frequencies specified in the data file. If not, an error message will pop up. So make sure that all the frequencies that you supply in the data file are consistent with those in the **Frequency Setup** section of the **Edit Frequency Sweep** dialog box. For example, based on the **Frequency Setup** shown below in the target project HFSS will expect to find data for 3GHz, 6 GHz, and 9 GHz in the data file. Also, the **Solution Frequency** in the **Solution Setup** should match one of the frequencies in the data file and the sweep if the project type is HFSS in the target design. Also, the frequency blocks can appear in any order in the data file.





Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

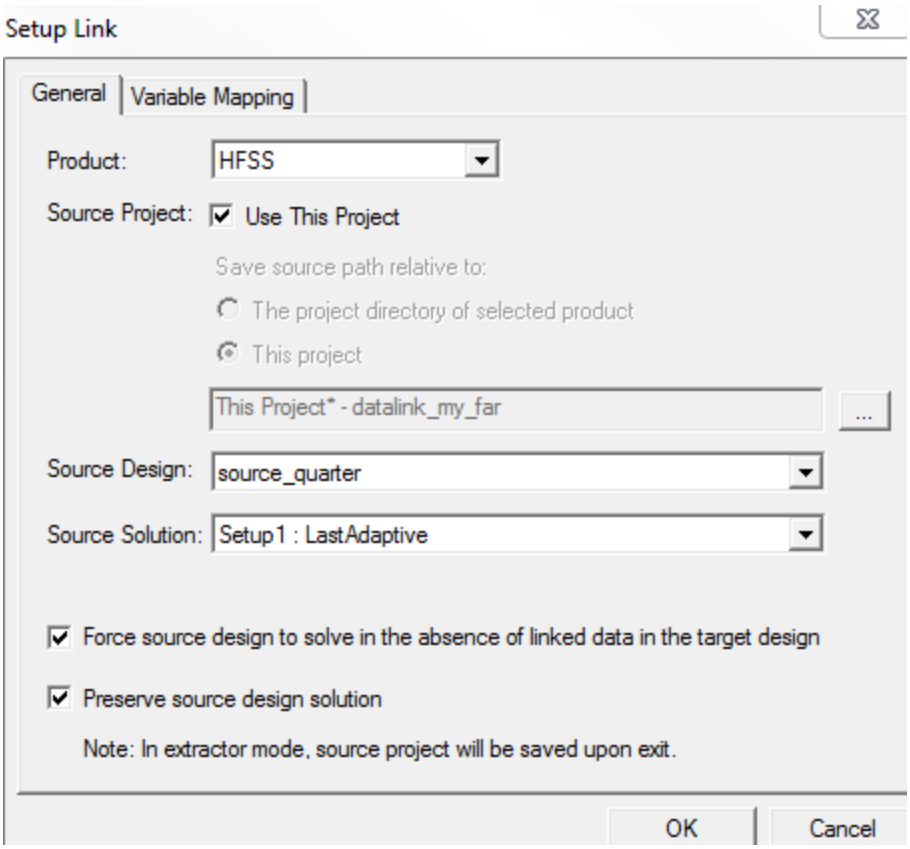
The sample frequency dependent data file was used to apply far field on an open ended WR-90 waveguide. The frequency sweep shown was used to simulate it. The results for the E-field at 9 GHz are shown below.



Setup Link for Far Field or Near Field Wave

You can access the **Setup Link** dialog from the Far Field Wave options dialog or Near Field Wave options or from an SBR+ design linked to a Driven Modal antenna.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



1. Select the **Edit Link** radio button to activate the options in the panel.
2. Select the type of the source project (e.g., HFSS, HFSS 3D Layout, SIwave, Maxwell) from the **Product** drop-down menu.

   > **Note:**
   >
   > An **HFSS-IE** project can be used as target or source. **Maxwell** does not appear in the drop-down menu because it is not applicable for far fields.

3. Browse for the source project or check **Use This Project**. If you check the latter option, you must select a source design from the current project.

   > **Note:**
   >
   > The origin of the global coordinate system of the source project should be in the phase center of the antenna, when you use a Far Field link.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Specify the **Source Solution**. The first option in the Source Solution field is the default.

> **Note:**
>
> The solution in the source design must provide data for the target design's adaptive frequency as well as its sweeps. That is, the adaptive frequency for the target design must be included in the sweep in the source design. If necessary, you can open the source design and add an appropriate frequency point to an existing sweep.

5. Use the last two check boxes at the bottom of the panel as needed.

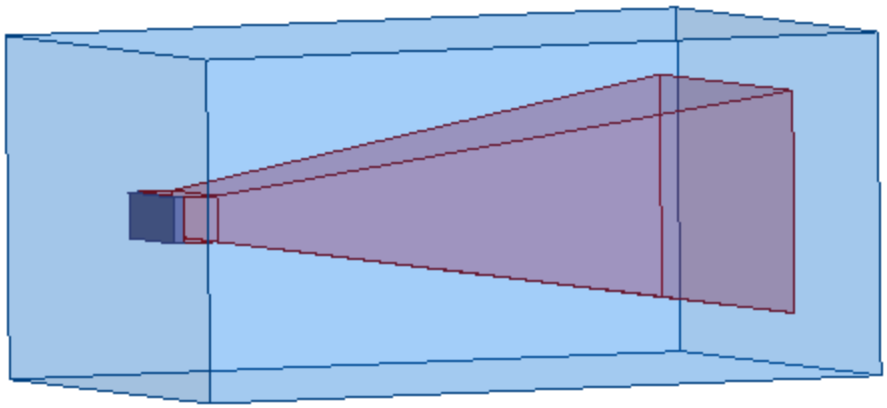
> **Note:**
>
> **Extractor mode** means that the software is opened during the link solely for the purpose of solving.

6. Under the **Variable Mapping** tab, you can set the desired variable values in the source design. If the source and target designs contain same named variables, you can choose to Map Variable By Name. In this case, same named variables are mapped automatically.

Example That Uses Far Field Links

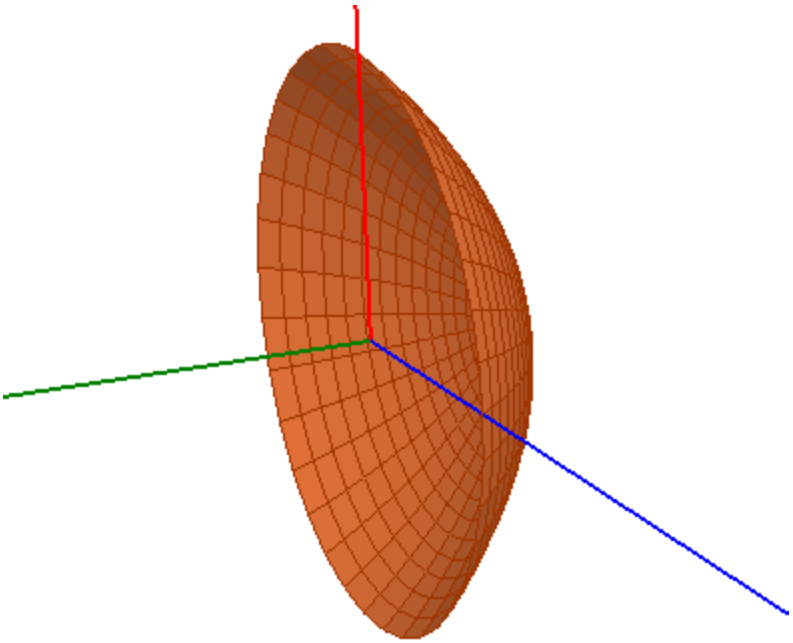
This section describes linking an HFSS project to an HFSS-IE project while using the common feature of assigning Far Field Wave excitation.

The horn antenna enclosed in an air box in the figure below represents the source project designed in HFSS.

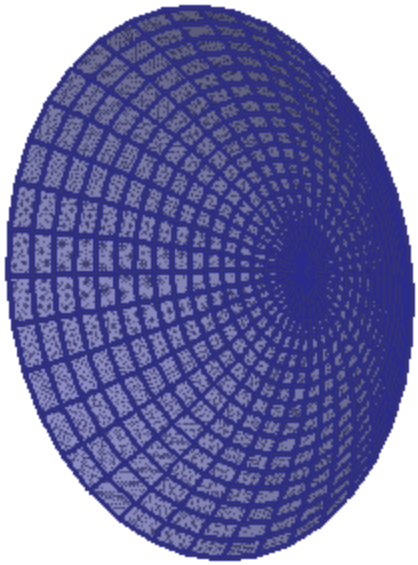


The dish/reflector in the following figure is the target project designed in HFSS-IE.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

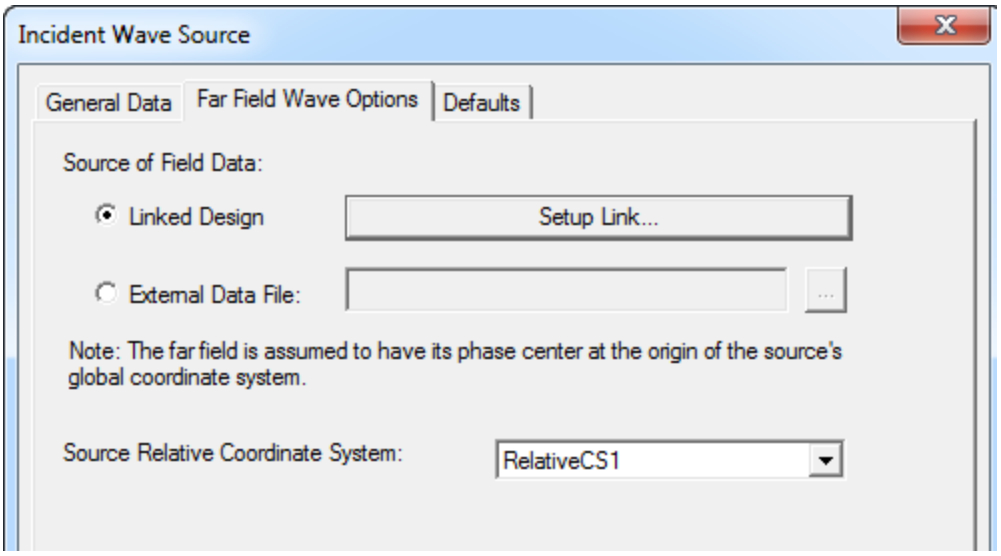


A perfect E-boundary is assigned on the reflector.

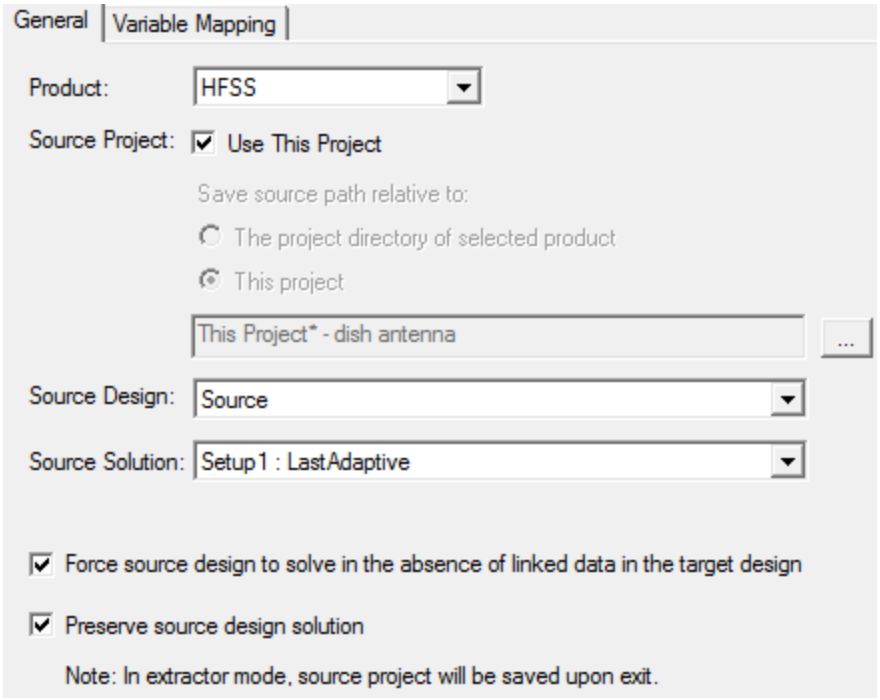


The **Far Field Wave Options** panel has the following settings.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

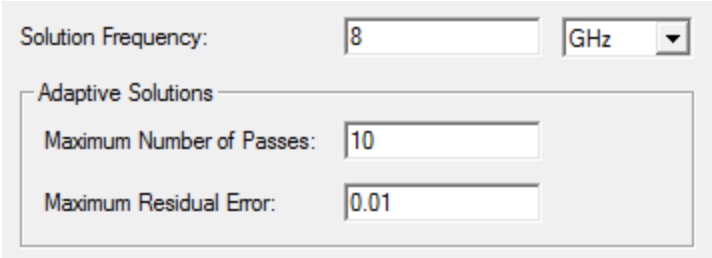


From the **Setup Link** option, the fields are set as shown in the figure to link the target to the source project (the horn antenna).

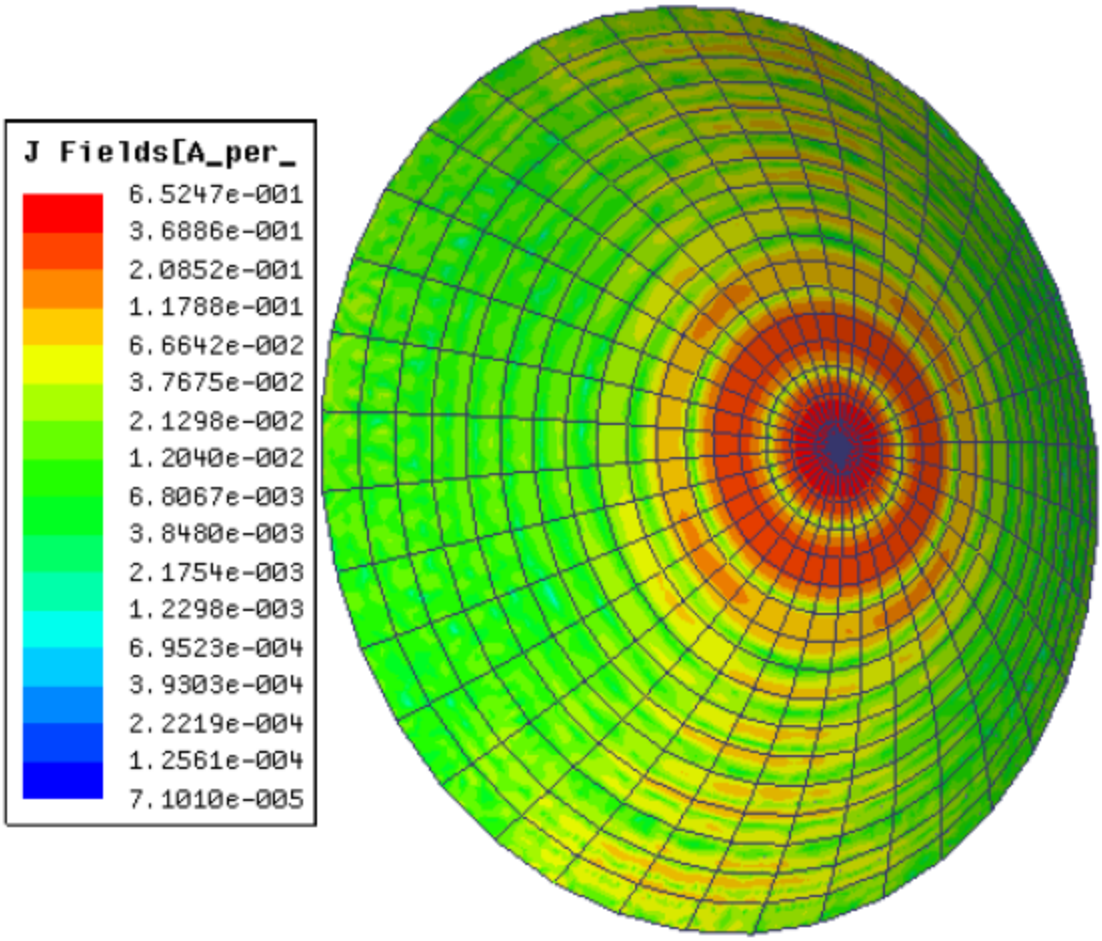


A sample solution setup for this project is shown below:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The resulting J Fields (magnetic fields) after solving the project are shown below.



Near Field Wave

A Near Field wave source is close enough to the design for near field effects to occur, typically within one wave length. Objects in the near field wave source project should NOT be too close to

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the radiation surface where a Near Field Wave pings in. Near field waves tend to have both evanescent and propagating content.

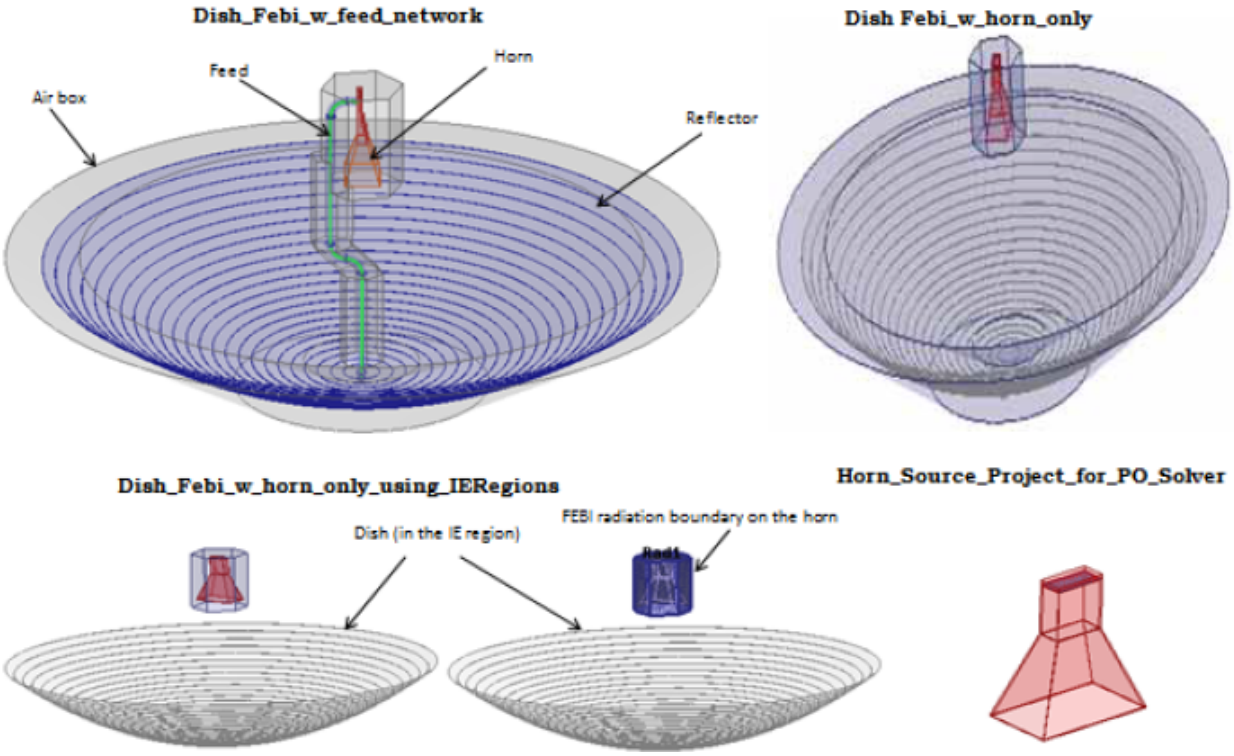
- Assign Near Field Wave
- Example that Uses Near Field Links
- Access Near Field External Data File
- Ansys Near Field Data File
- Generate Near Field Data File
- Near/Far Field Polarization Definition Table for HFSS, SBR+ and Hybrid Designs
- *Technical Notes*: Ansys Near Field Description Format Specification.

> **Note:**
>
> HFSS can also use dynamic links to other simulation tools to create one seamless workflow. The source designs can be created in HFSS, HFSS 3D Layout, SIwave or Maxwell3D. Refer to Using Field Solutions from Other Simulations.

Assign Near Field Wave

This section describes the **Near Field Wave Options** panel on the **Incident Wave Source** dialog box and how to assign near field waves. The following designs illustrate different ways of using near field sourcing to run a range of analyses on a dish antenna fed by a circular horn antenna.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

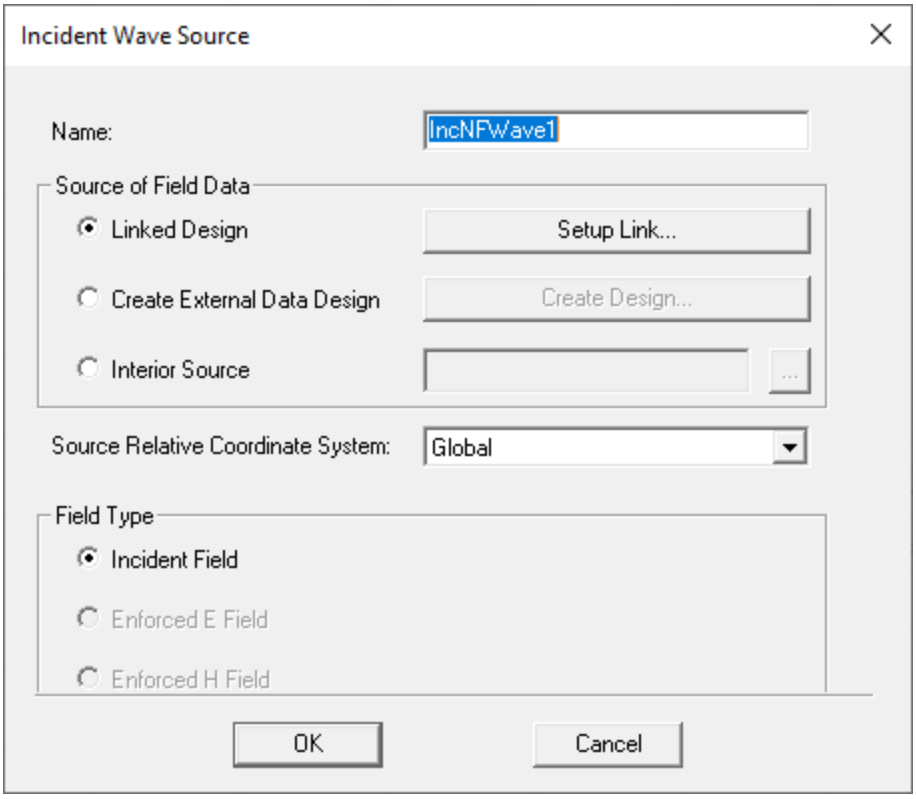


First we will bring up the **Near Field Wave Options** panel and then, assign Near Field Wave.

1. Click **HFSS>Excitations>Assign>Linked Field>Near Field...**.

   The **Incident Wave Source** dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You assign the **Excitation** name or accept the default.

You can select Linked Design, Create External Data Design, or Interior Source. If you are using a linked design go to step 4.

If you are using an external data file to use to **Create External Data Design...**, go to Access Near Field External Data Fileand follow the instructions.The dialog supports the choices of E field only and H field only if you select external data.

Do to the nature of the data link, both of these approaches inevitably lose the source design mesh information. Although it might be a reasonable approximation when mesh is complex, in other cases you may want to directly define mesh and near field field, especially when data link source is an external near field design and when source geometry is composed of near field primitives with relatively simple mesh.

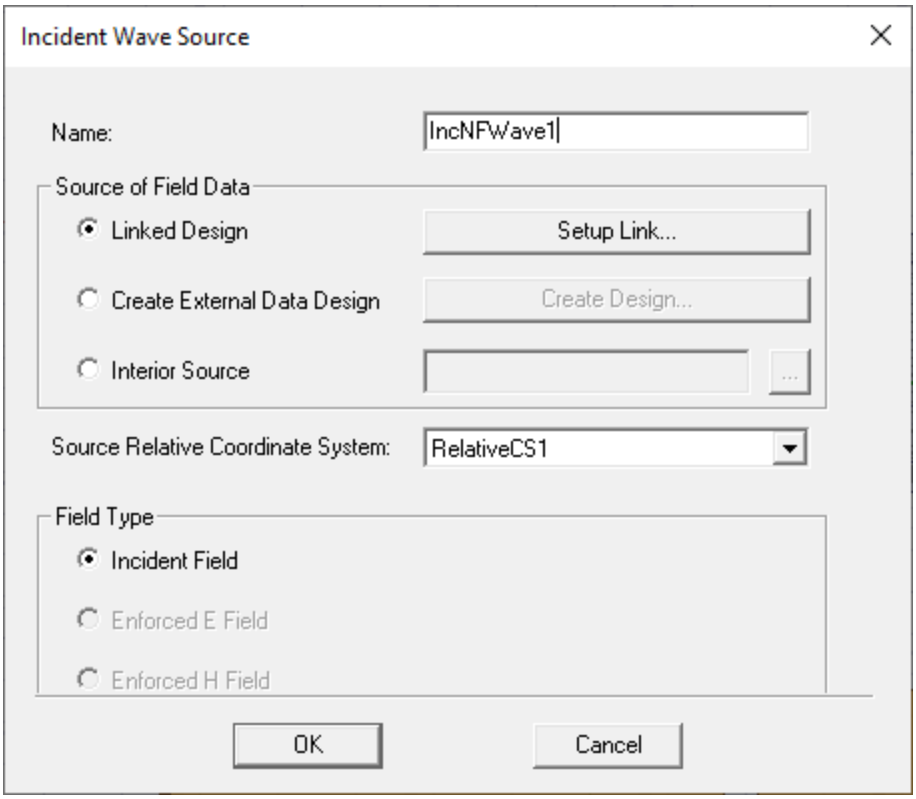
HFSS includes an option to add this external near field link as "interior" source. When you select Interior Source you select a data file (.and/.nfd) and HFSS then automates a series of setups, such as near field geometries, mesh operation setup and solution setup, similar to what current Linked Design does. This interior source has the same effect as if its equivalent external near field design is linked to that target design. This interior source also allow relative coordinate system definition. For an example see Example with Interior Source for Near Field Link.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click **Next** to access the **Near Field Wave Options** panel.

> **Note:**
>
> For array problems, the **Active** option includes the effects of the Near Field in the simulation. To disable the effects, uncheck the **Active** option.

3. Determine whether you want to use a linked design, an external data file, or an interior source. If you are using a linked design go to step 4. If you are using an external data file to use to **Create External Data Design...**, go to Access Near Field External Data Fileand follow the instructions.



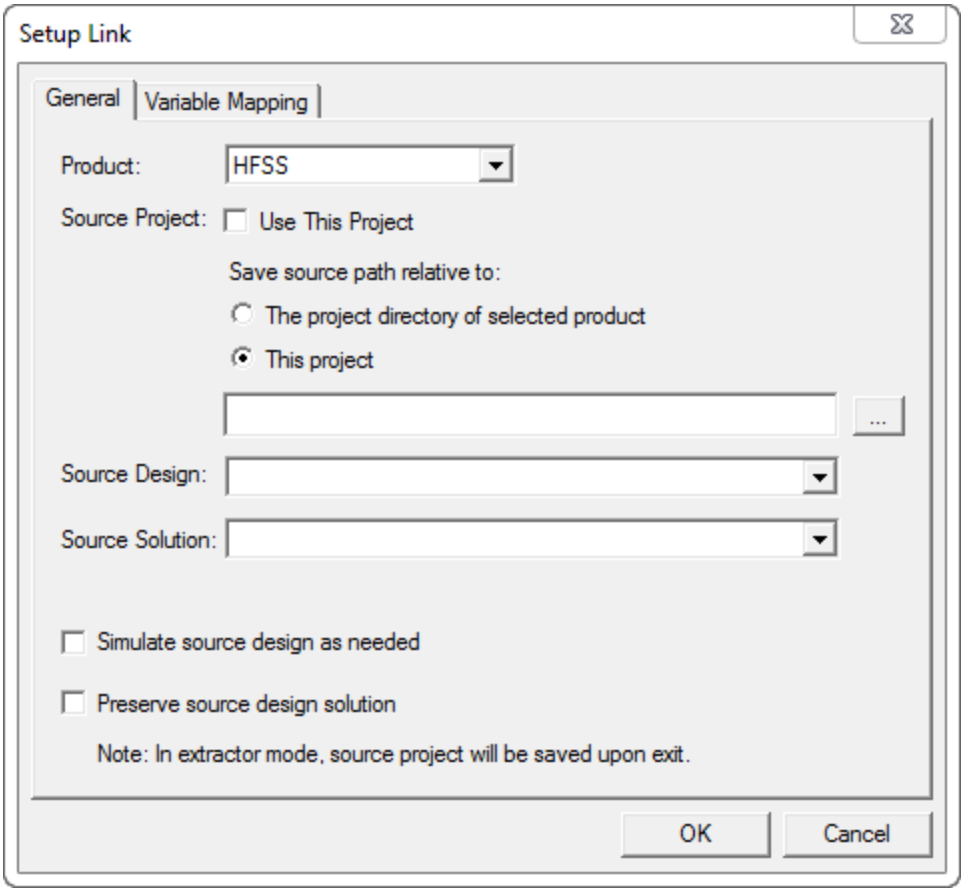
4. Click **Setup Link** on the **Incident Wave Source** dialog to specify the linked design.

> **Note:**
>
> It is through the **Setup Link** dialog box that you will link the source design to your target design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. On the **Setup Link** dialog box select the radio button **Edit Link**.

   The fields in the dialog box become active and editable as shown below.



6. Select the product in which you created your source design from the **Product**drop-down menu.

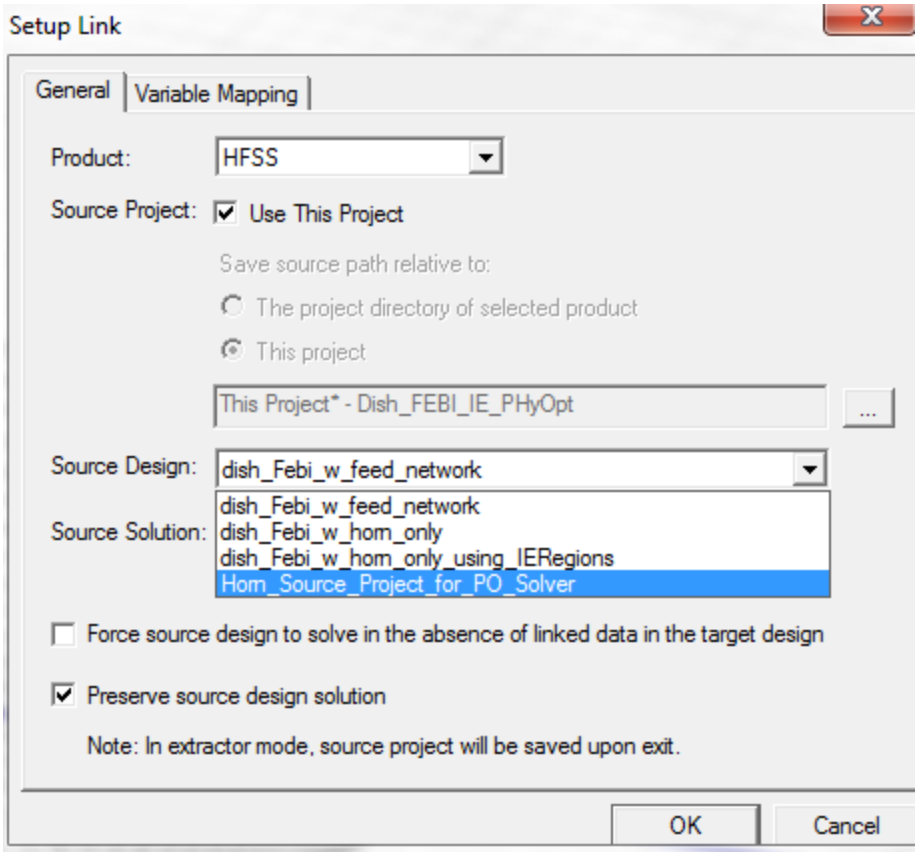
> **Note:**
>
> Only HFSS, Maxwell, and SIwave appear in this list.

7. Specify the project that has the source design in one of the following ways:
   a. Check **Use This Project** to pick a design from a current working project.
      b. Click the ellipsis and browse your computer to pick the design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

The option **The project directory of selected product** points to the default project directory location relative to the product that you selected from the drop-down menu. This is the same project directory that you set on the **General Options** dialog under **Tools> Options.** This option is useful especially, when you link across different products. The option **This project** points to the directory relative to where your current working project is located.



8. Pick the source design from the **Source Design** drop-down menu which lists all the designs in the specified project.
9. Pick the setup type from the **Source Solution** pull-down menu (e.g., Last Adaptive, Sweep).

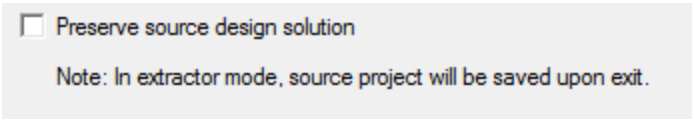
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

10. Select the last two check boxes as needed and click **OK**.

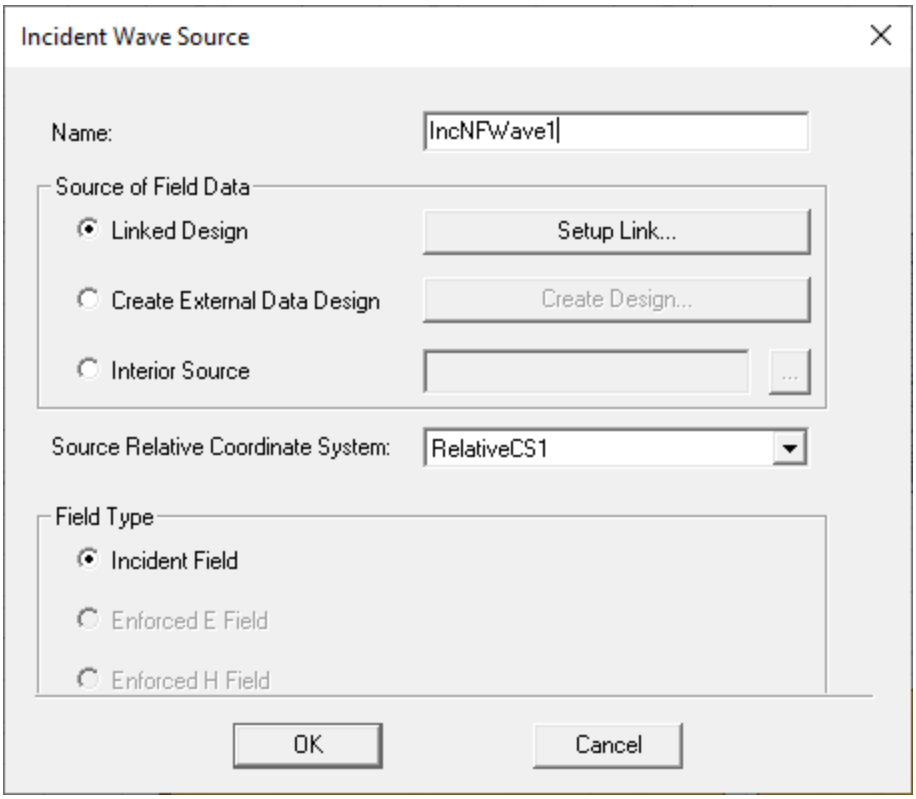
> **Note:**
>
> Go to Simulate source design as needed, for more information about that option.

Preserve source design solution

This is the last option on the **Setup Link** dialog box. When the source design is closed or it is not included in the project manager window containing the target design, the source design will not be saved. However, if you select this option, which is useful when you are using Maxwell or SIwave the results of the source design is saved.



11. Close the Setup Link dialog, and if necessary, specify the Source Relative Coordinate System on the **Near Field Wave Options** panel of the **IncidentWave Source** dialog box.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

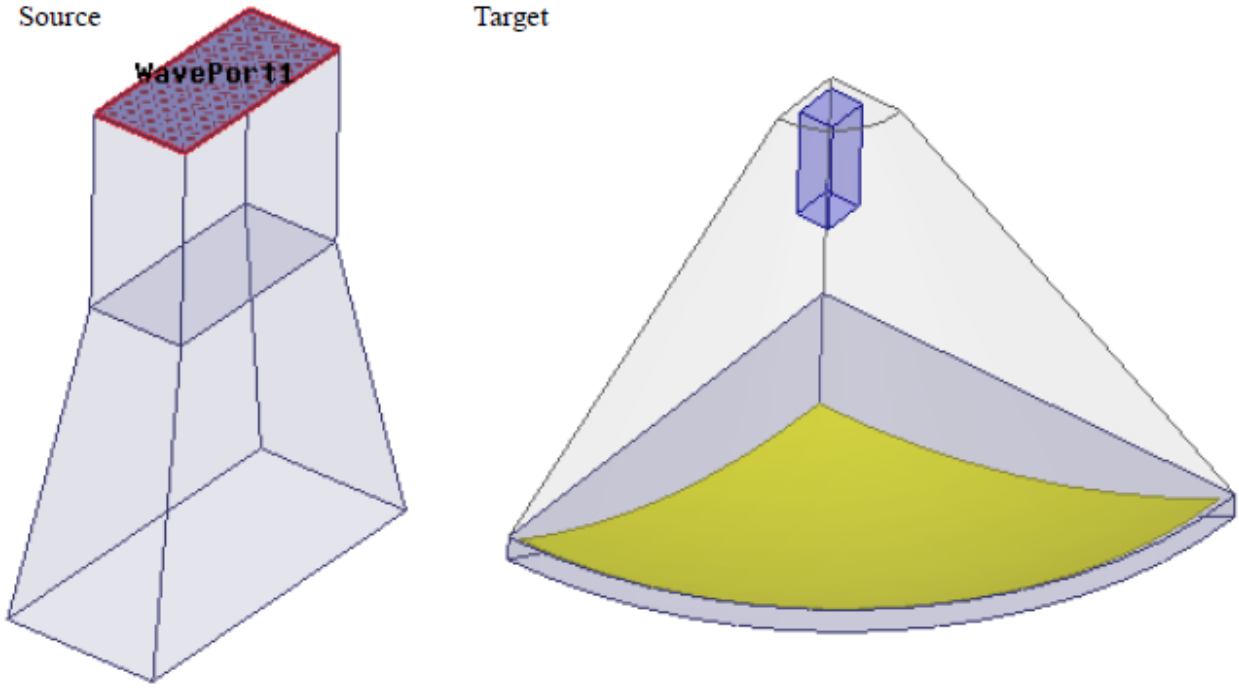
12. Click **OK** to close the dialog. The **Near Field** wave source point and direction is highlighted in the modeler window, and the wave appears in the **Excitations** list in the **Project**.

Simulate source design as needed

Select this option if you modify the source design and you want an updated source design solution to be linked to the target design. If you select this option, make sure that you invalidate the cached link data in the target. To do this, right-click **Analysis** and select the option **Clear Linked Data** from the short-cut menu.

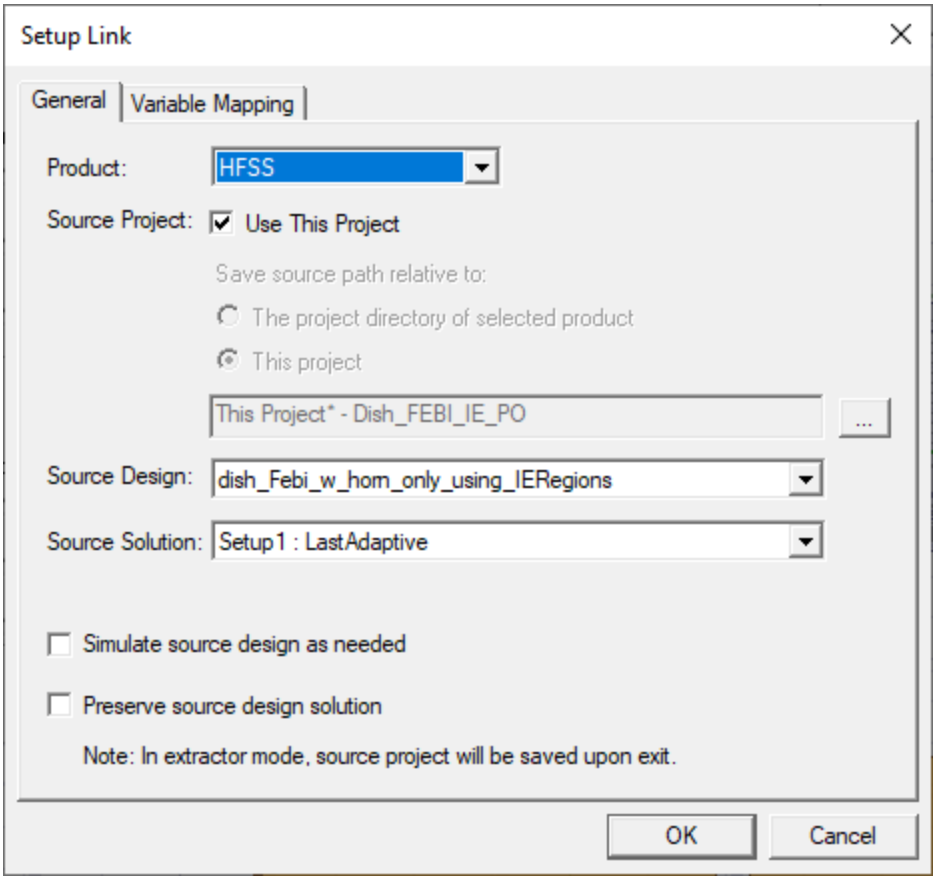
Example that Uses Near Field Links

The following figure shows a horn antenna that will be dynamically linked to a target disk where the source will be included inside of the target.



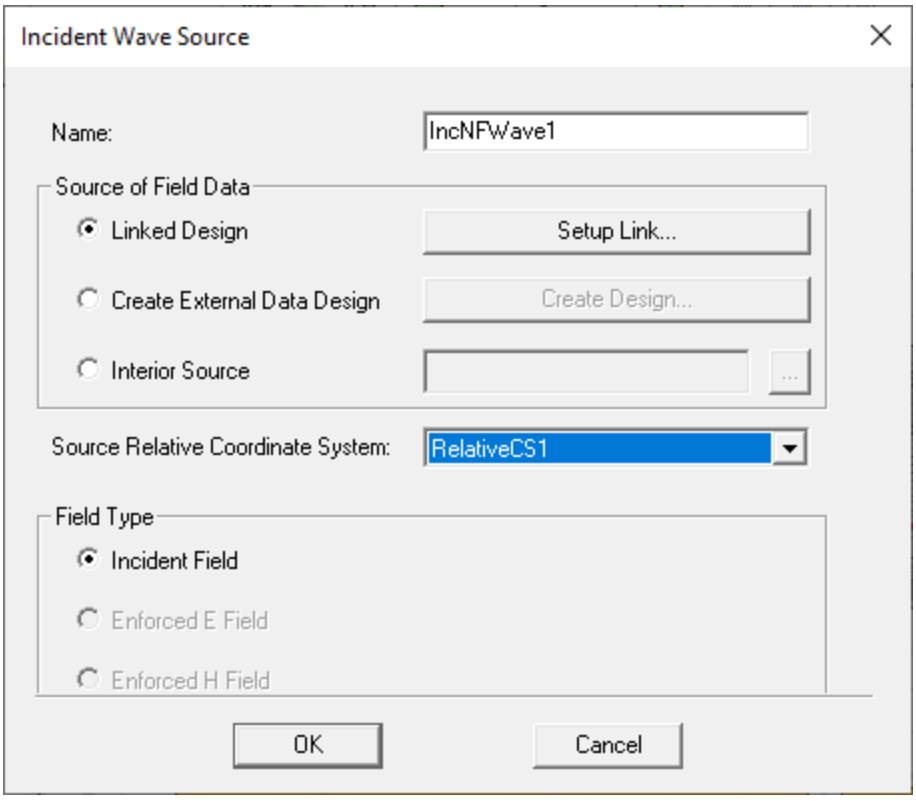
The Near Field Setup Link settings are as shown in the following figure.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

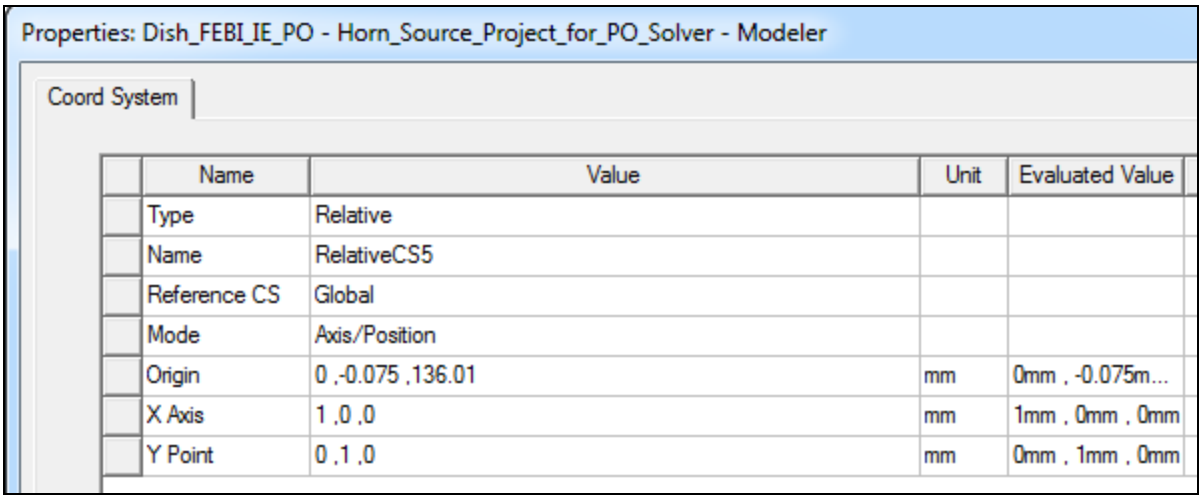


In the example of the horn antenna linking to a target dish, the co-ordinate systems of the source and the target coincide.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



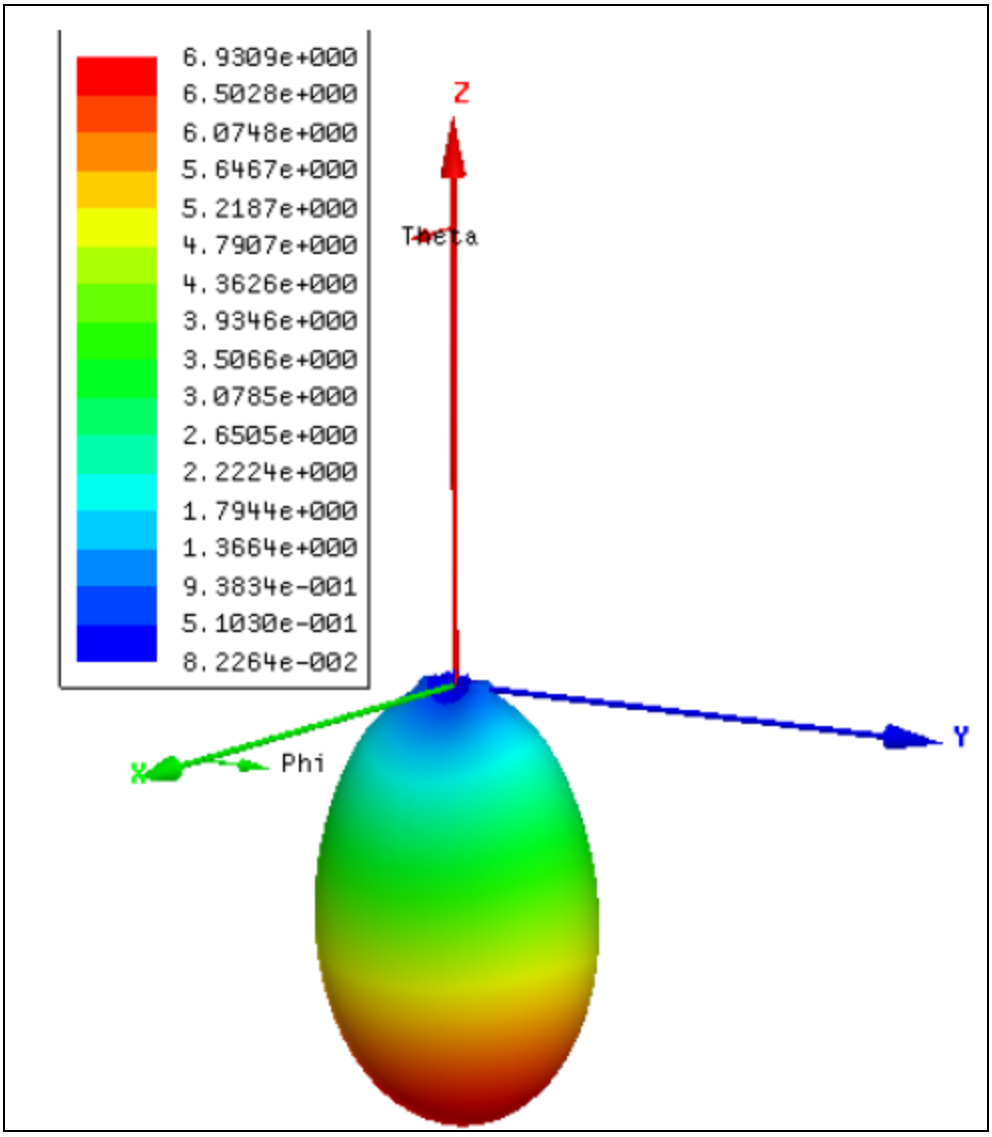
You can use the **Source Relative Coordinate System menu** to select the source co-ordinate system. For instance if you want to move the source and its co-ordinate system closer to the dish by 15 mm you can edit the Relative CS properties for the origin.



Name	Value	Unit	Evaluated Value
Type	Relative		
Name	RelativeCS5		
Reference CS	Global		
Mode	Axis/Position		
Origin	0 ,-0.075 ,136.01	mm	0mm , -0.075m...
X Axis	1 ,0 ,0	mm	1mm , 0mm , 0mm
Y Point	0 ,1 ,0	mm	0mm , 1mm , 0mm

The 3D polar plot with the values of directivity for the source project (the standalone horn antenna without the dish) is shown below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

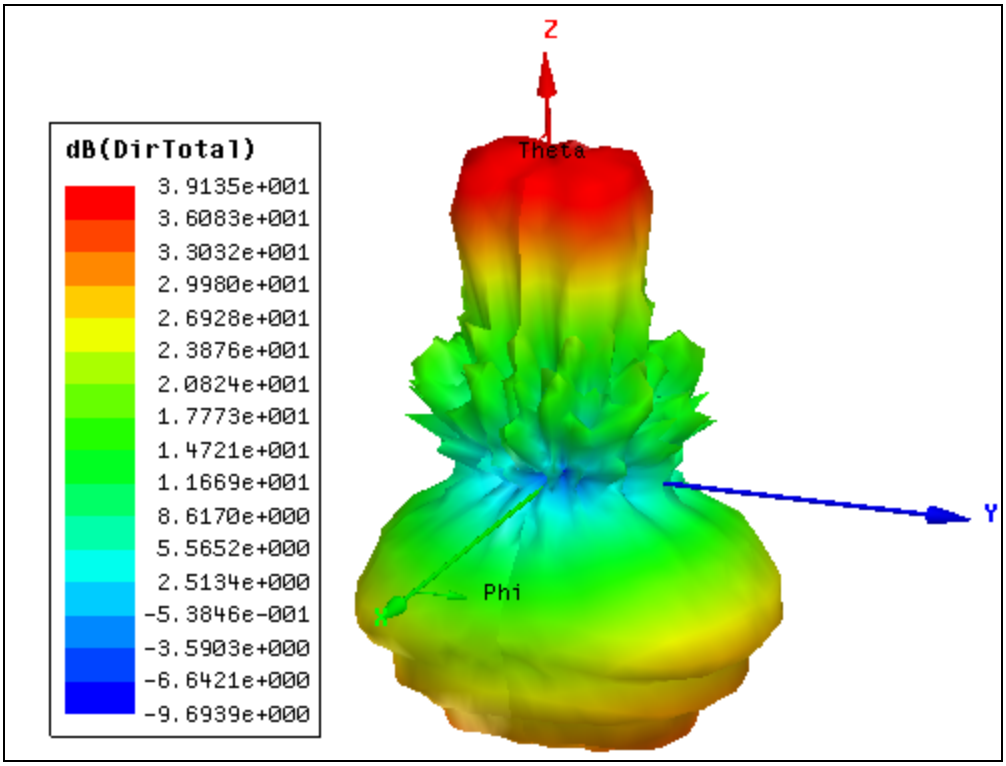


Then, when we apply the fields to the Target project with the dish, we get the values of the directivity shown in the following figure.

Note:

The standalone horn antenna without the dish radiates in the negative Z direction while the target project which includes the dish antenna, radiates in the positive Z-direction. The 3D polar plot with the values of directivity after the application of the Near Field link is shown in the following figure.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Example with Interior Source for Near Field Links

HFSS includes an option to add this external near field link as "interior" source. When you select Interior Source you select a data file (.and/.nfd) and HFSS then automates a series of setups, such as near field geometries, mesh operation setup and solution setup, similar to what current Linked Design does. This interior source has the same effect as if its equivalent external near field design is linked to that target design. This interior source also allow relative coordinate system definition.

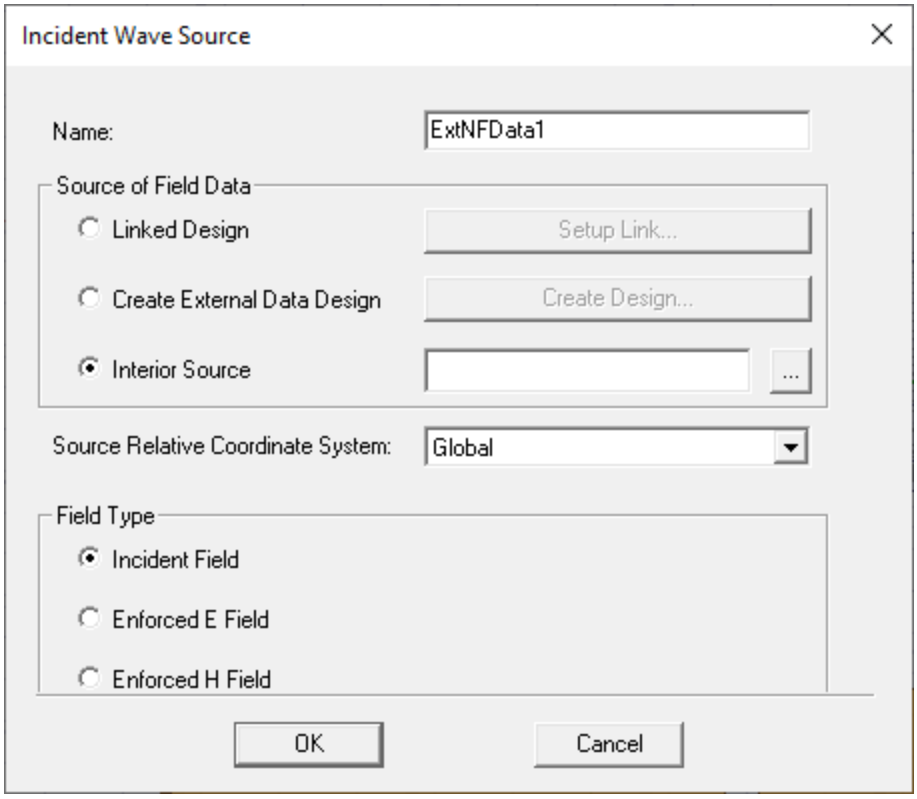
First we will bring up the **Near Field Wave Options** panel and then, assign Near Field Wave.

1. Click **HFSS>Excitations>Assign>Linked Field>Near Field...**.

   The **Incident Wave Source** dialog box appears. Select Interior Source.

The Interior Source settings are as shown in the following figure.

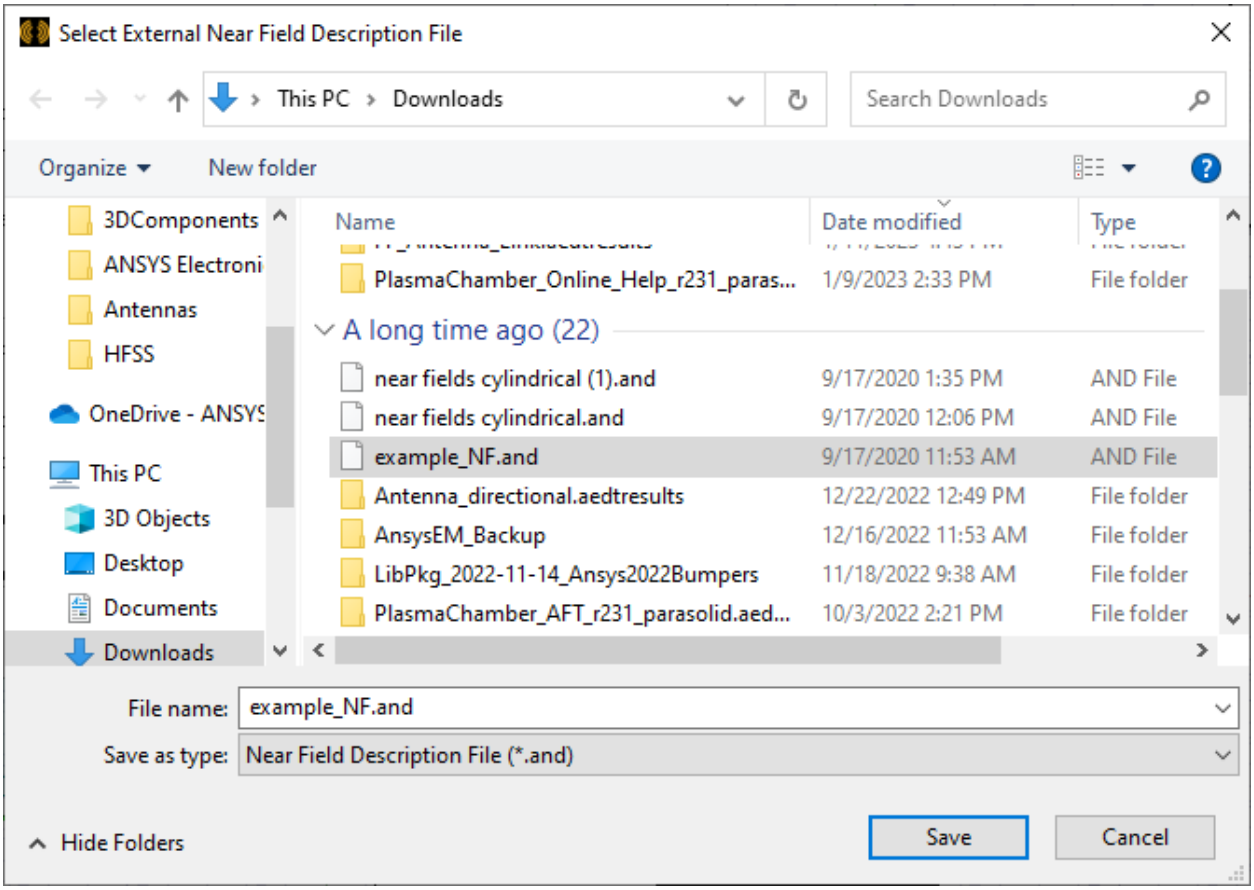
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Click **...** to open a browser to select the .and file with the near field data.

   The **Select External Near Field Description File** dialog box appears.

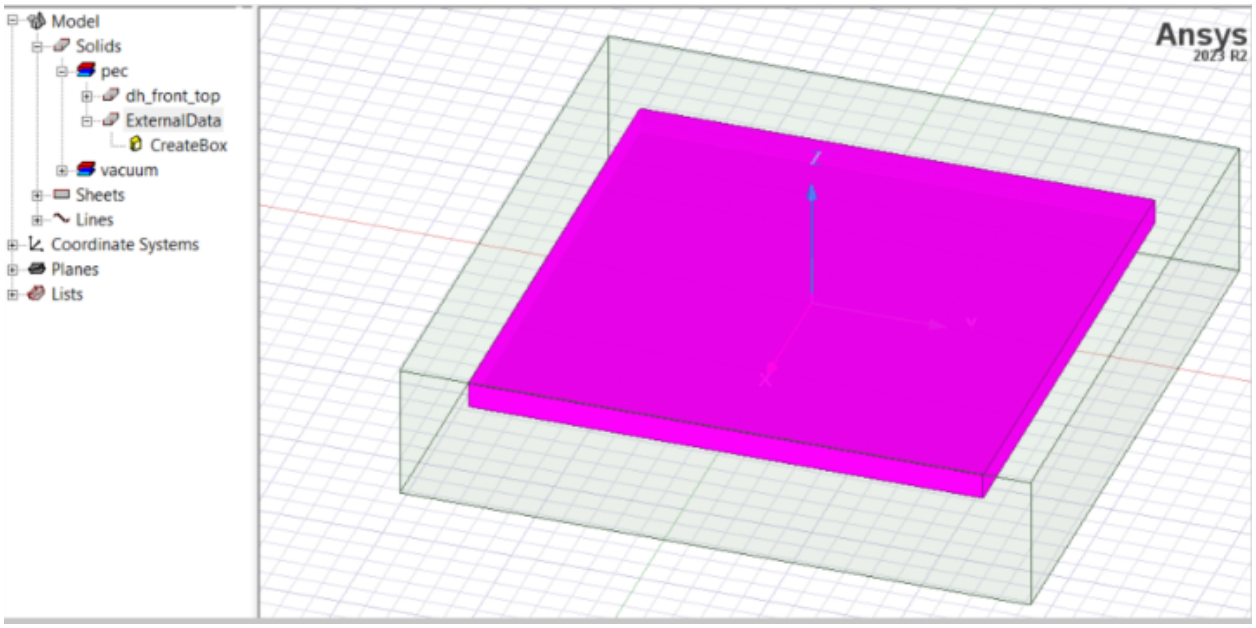
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



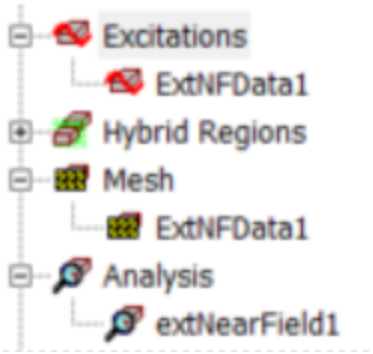
3. Select a previously prepared Near field description file (*.and) and Save.

   HFSS then creates the near field geometry as specified in the .and file. It also creates a corresponding mesh setup and solution setup if design doesn't have them.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



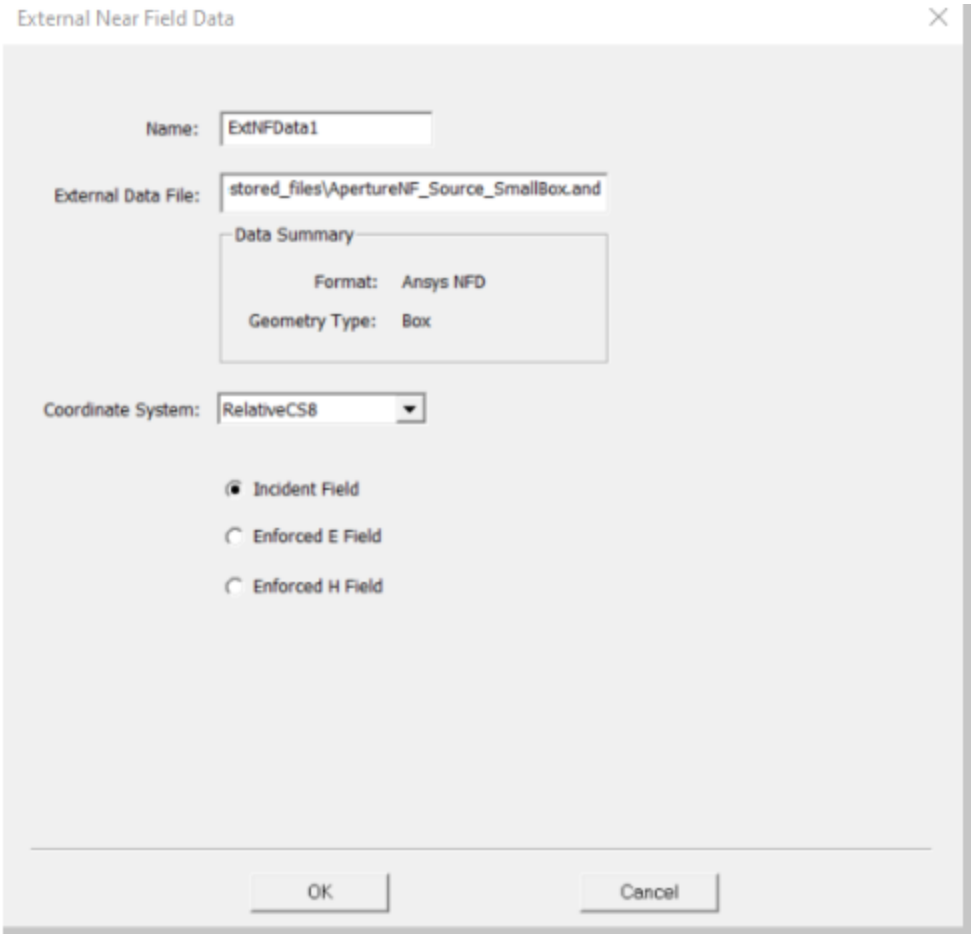
The Project tree shows the Linked Field External Near Field Data, the new mesh, and a setup for the near field interior source.



Editing the Interior Near Field Source

You can edit this interior near field source by either double clicking the excitation or through the right-click menu. A different configuration dialog appears, where you can change the data file, the coordinate system, and the field type.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Access Near Field External Data File

In this section we will show how to access a source of near field which is imposed on a target design through a data file. Instead of using a **Linked Design** as a source for a near field you can also use data files to impose the near field upon your target project.

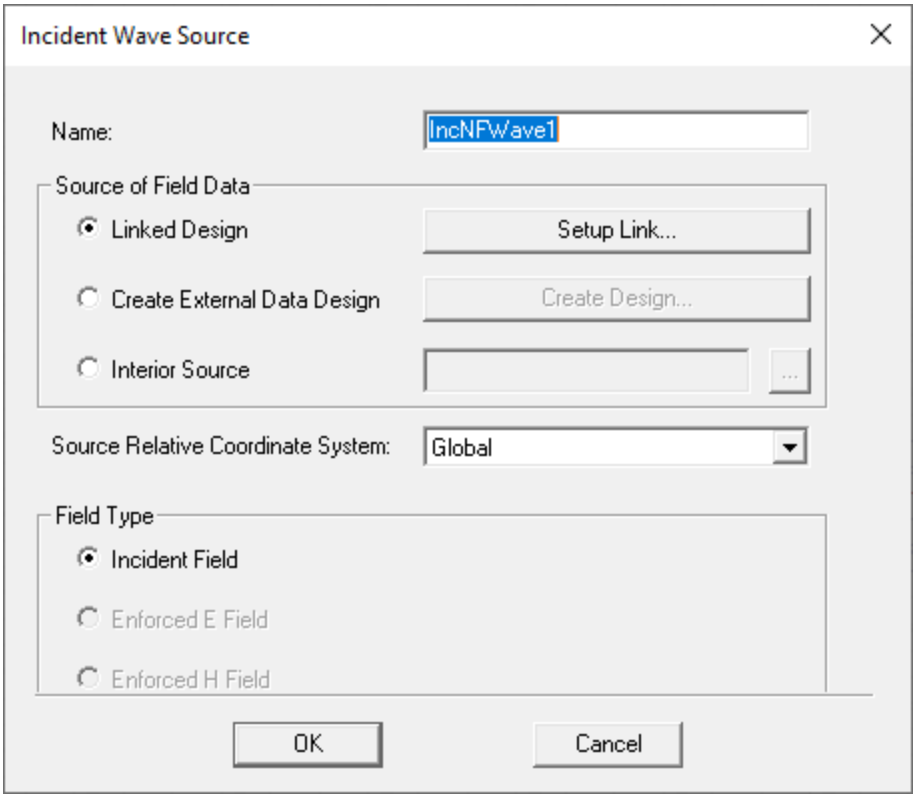
> **Note:**
>
> For more information about Ansys Near Field Data File (**.and*) format see the Ansys Near Field Data File section.

Presupposing that you have prepared the *.and file and associated near field data files:

1. Go to **HFSS**>**Excitations**>**Assign**>**Linked Field**>**Near Field Wave...**.

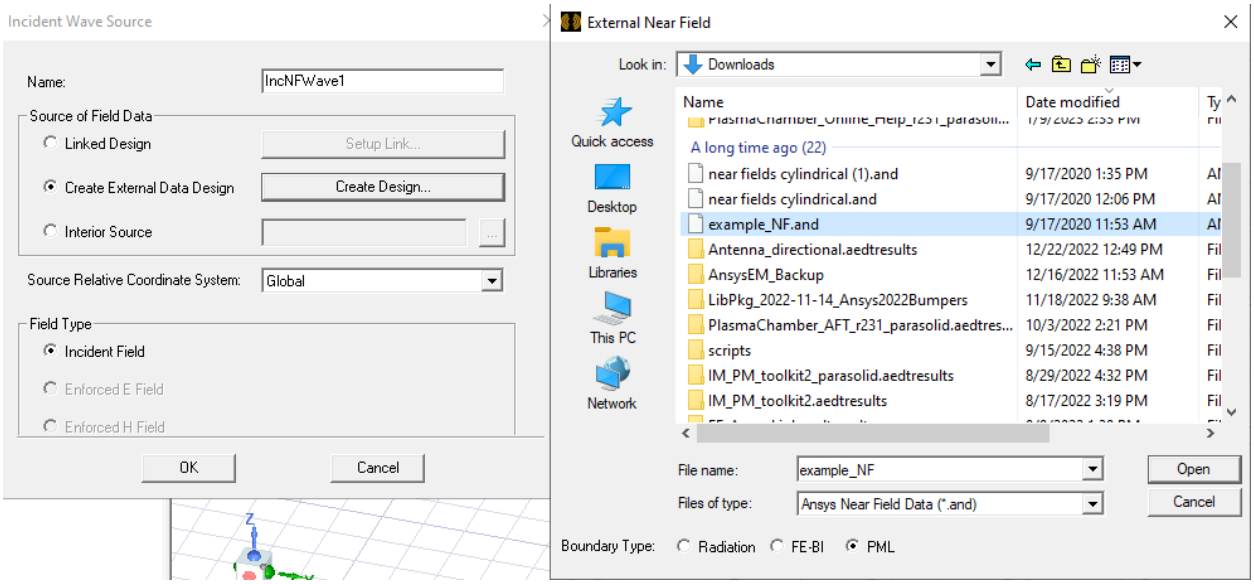
   The **Incident Wave Source**:dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



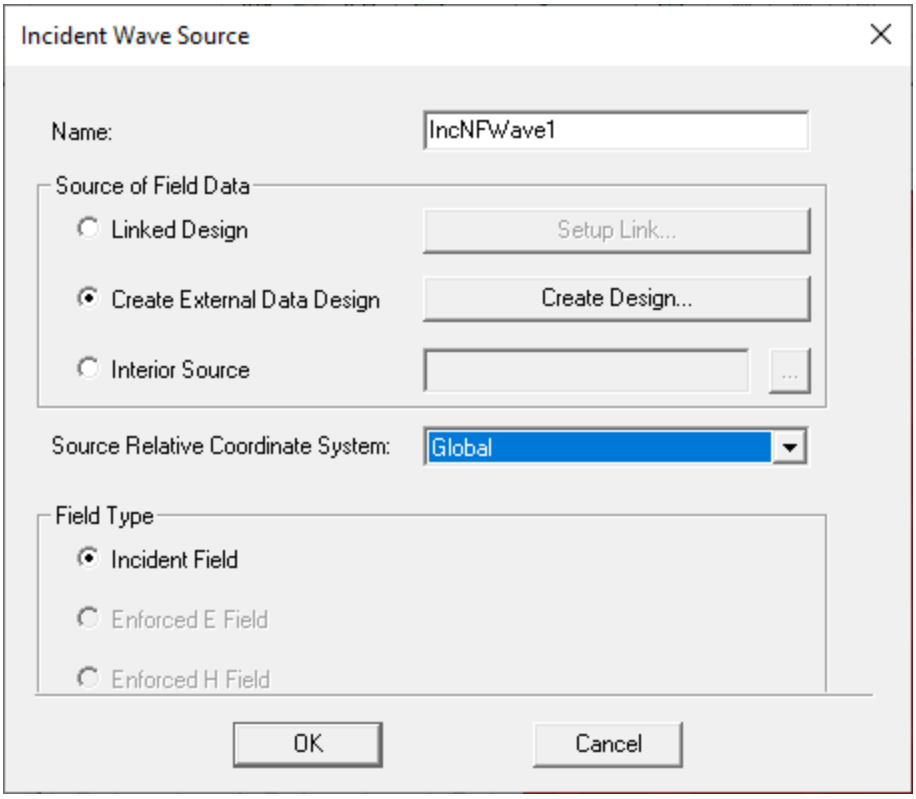
3. Select the **Create External Data Design** radio button to enable the **Create Design...** button.
4. Click **Create Design...** to browse your computer to access a previously created **.and* file, which describes the name and location of one or more the near field data files (*.nfd).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

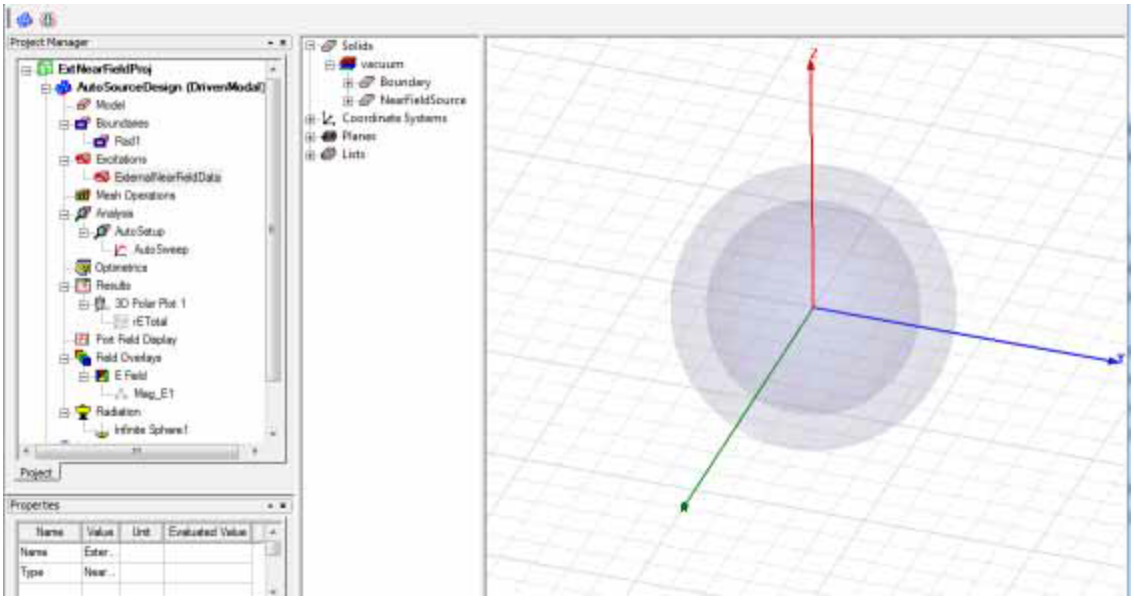


4. Select the Boundary Type for the auto-generated design, as Radiation, FE-BI or PML (the default).
5. If necessary, specify the Source Relative Coordinate System on the **Near Field Wave Options** panel of the **Incident Wave Source** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Upon a successful source design generation, the datalink setup for the near field incident wave source will be automatically set to the generated source design.

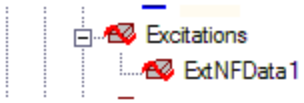


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This auto-design generation is neither undo-able nor scriptable. This design becomes the source design for external near field. This workflow allows you to view the external field data via HFSS.

Automatically generated design components include:

- **Geometry**: the external geometry and a region.
- **Boundaries**: your choice of Radiation, FE-BI or PML (the default).
- **Excitations**: an External Near Field Data Excitation. This is an excitation type for user defined external near field.

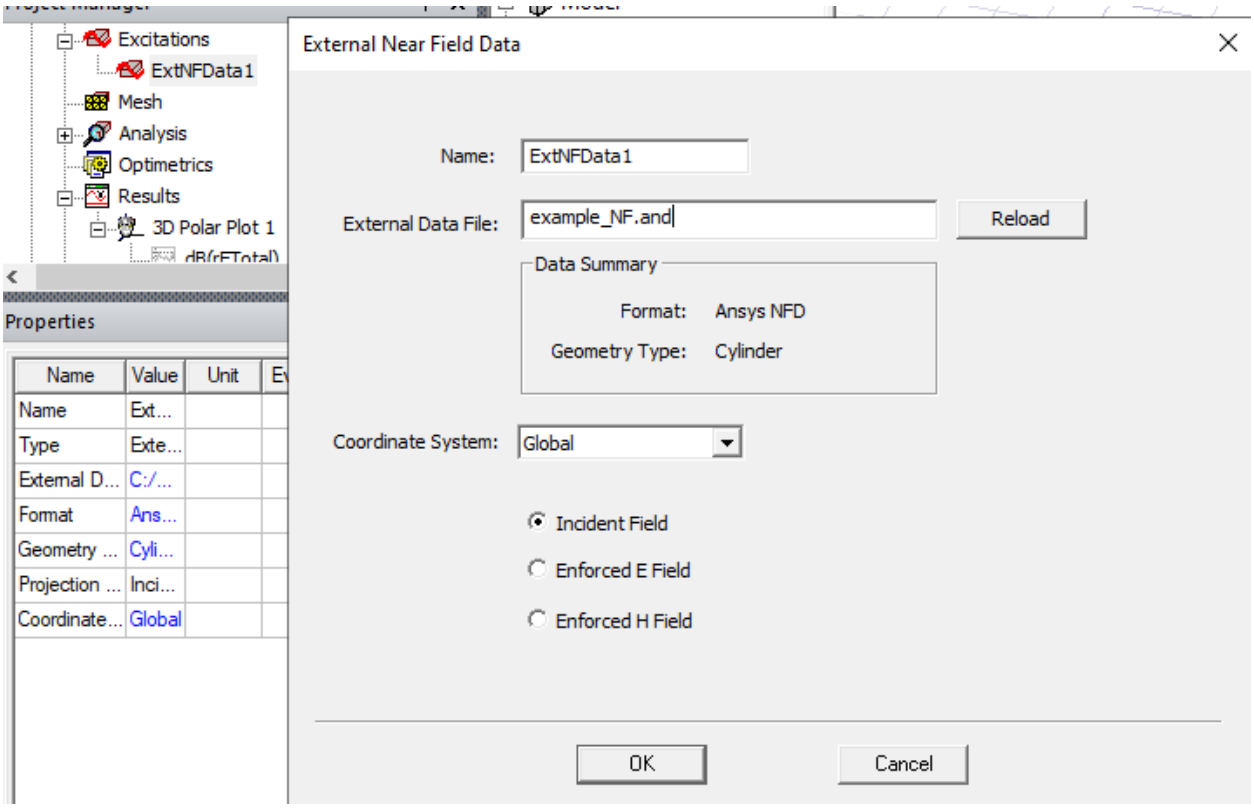


The padding ratio is the same as open region.

- For plane case (where "plane" is the geometry specified in the .AND file), it is an open region.
- For all other cases (for other geometries specified in the .AND file), it is auto-open.

  Accessing the **External Near Field Data Excitation** dialog can only be done through the Auto Design under Excitations in Project tree. Other than the Name, no other properties this Excitation are editable through this dialog. It exists to provide you with information about the AND File that was used to create this Auto-Design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- **Analysis**:

  A default solve setup is created with the adaptive frequency set to the highest frequency in the external data

  A discrete frequency sweep is created if multiple frequencies are present in the External Data.

6. When you run the Analysis of your target design, it uses this newly created source design for the Near Fields.

Near/Far Field Polarization Definition Table for HFSS, SBR+ and Hybrid Designs

This table summarizes which coordinate system is used to report Near and Far field polarization components (XYZ and Phi/Theta) in HFSS design with only FEM solver, SBR+ design, and HFSS design with Hybrid SBR+ region.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Near Field and Far Field setup options and design type	CS used to report XYZ polarization	CS used to report Theta/Phi polarization
SBR+ design type		
NF rectangle	Global CS	Global CS
NF sphere	Global CS	Global CS
Far Field sphere	Relative FF CS	Relative FF CS
HFSS (FEM) design type		
NF rectangle	Global CS	Global CS
NF sphere	Relative NF sphere CS	Relative NF sphere CS
Far Field sphere	Relative FF CS	Relative FF CS
HFSS (FEM) design type with Hybrid SBR+ region		
NF rectangle	Global CS	Global CS
NF sphere	Global CS	Global CS
Far Field sphere	Relative FF CS	Relative FF CS

Ansys Near Field Data File

The data file that you select when you click **Create External Design** of the **Incident Wave Source** dialog box is in the **.and* format. The **.and* file describes the location and contents of one or more Ansys Near Field Data Files which are in the **.nfd* format. If no units are specified for spherical, cylindrical, or Cartesian coordinates, the **.ndf* files use SI units of radians and meters respectively. You can append units, such as mm or deg, as needed for each coordinate value.

An example of a **.and* file is shown below, followed by examples of .nfd files with Cartesian and Cylindrical coordinate systems. The File format specification is provided in *Technical Notes*: Ansys Near Field Description Format Specification.

Sample **.and* File Sphere Geometry

```
$begin 'NearFieldHeader'
  type = 'nfd'
  geometry = 'sphere'
  center = '0mm, 0mm, 0mm'
  radius = '20mm'
  fsweep='1GHz, 10GHz'
$end 'NearFieldHeader'

$begin 'NearFieldData'
  FreqData("1GHz", "exportfields-1GHz.nfd")
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
  FreqData("2GHz", "exportfields-2GHz.nfd")
  FreqData("3GHz", "exportfields-3GHz.nfd")
  FreqData("4GHz", "exportfields-4GHz.nfd")
  FreqData("5GHz", "exportfields-5GHz.nfd")
  FreqData("6GHz", "exportfields-6GHz.nfd")
  FreqData("7GHz", "exportfields-7GHz.nfd")
  FreqData("8GHz", "exportfields-8GHz.nfd")
  FreqData("9GHz", "exportfields-9GHz.nfd")
  FreqData("10GHz", "exportfields-10GHz.nfd")
$end 'NearFieldData'
```

This example is a simple text file and saved with the *.and* extension. It is clear from the sample that the near field data was generated on a sphere centered at the origin and radius = 20mm for frequencies 1 GHz through 10 GHz. For the sample **.and* file 10 **.nfd* files are specified so 10 **.nfd* files were generated. Examples of such Ansys Near Field Data Files (*exportfields-1GHz.nfd*) are shown below.

Users can also use external data in the field format of J and M, J only and M only.

Sample *.and File, Cylinder Geometry

The following example shows a **.and* file using a Cylindrical Coordinate System

```
$begin 'NearFieldHeader'
  type='nfd'
  fcoords='cylindrical'
  geometry='cylinder'
  center='0mm,0mm,0mm'
  axis='0,0,1'
  radius='20mm'
  height='258mm'
  fsweep='1GHz'
$end 'NearFieldHeader'
$begin 'NearFieldData'
FreqData("1GHz", "fields_cylinder.nfd")
$end 'NearFieldData'
```

Sample NFD File in Cartesian Coordinate System

The sample below shows the near field data that the *.nfd file contains. The file uniquely specifies the position of several points (700 in this case) and the real and imaginary values of the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

E field and H field vectors at these points along the x, y, and z axes in the Cartesian Coordinate system.

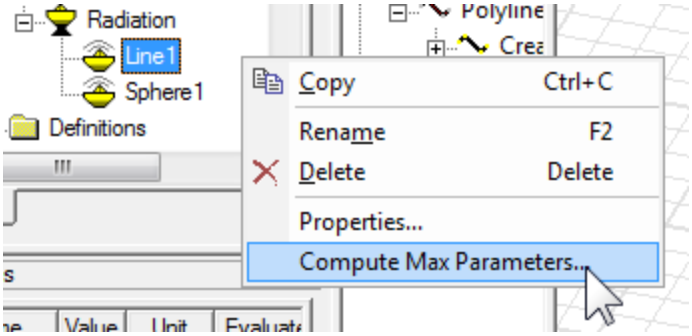
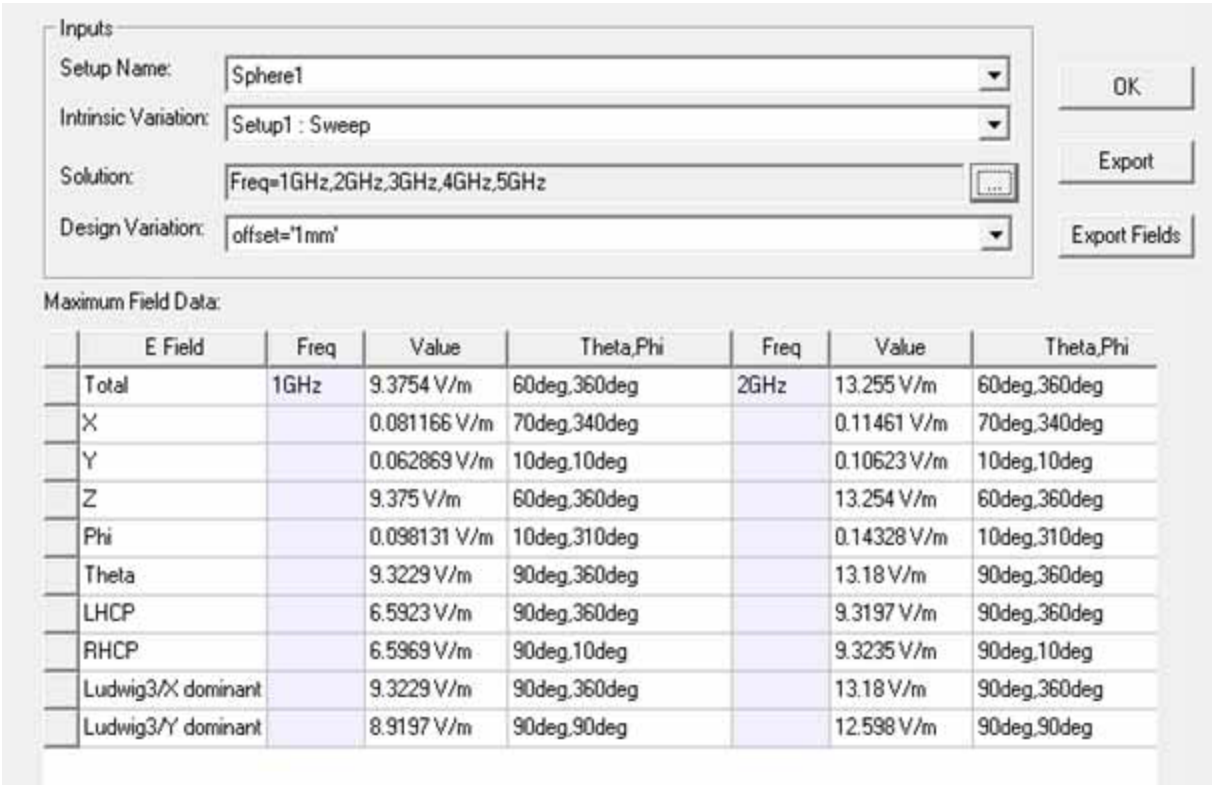
Generate Near Field Data File

Generate the ***.nfd*** file from your existing data or from solved HFSS design with near fields using the following steps.

1. Right-click the previously created near-field **Sphere or Line1** under **Radiation** as shown below.



2. Select **Compute Max Parameters**.
3. The **Max Field Data** dialog box appears for the selected Line or Sphere as shown below.



E Field	Freq	Value	Theta,Phi	Freq	Value	Theta,Phi
Total	1GHz	9.3754 V/m	60deg,360deg	2GHz	13.255 V/m	60deg,360deg
X		0.081166 V/m	70deg,340deg		0.11461 V/m	70deg,340deg
Y		0.062869 V/m	10deg,10deg		0.10623 V/m	10deg,10deg
Z		9.375 V/m	60deg,360deg		13.254 V/m	60deg,360deg
Phi		0.098131 V/m	10deg,310deg		0.14328 V/m	10deg,310deg
Theta		9.3229 V/m	90deg,360deg		13.18 V/m	90deg,360deg
LHCP		6.5923 V/m	90deg,360deg		9.3197 V/m	90deg,360deg
RHCP		6.5969 V/m	90deg,10deg		9.3235 V/m	90deg,10deg
Ludwig3/X dominant		9.3229 V/m	90deg,360deg		13.18 V/m	90deg,360deg
Ludwig3/Y dominant		8.9197 V/m	90deg,90deg		12.598 V/m	90deg,90deg

4. Click **Export Fields** and save the file in the *.nfd* format.

You can use an *.and file to refer to one or more *.nfd files to describe near fields.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Using Field Solutions from Other Simulations

HFSS can use dynamic links to other simulation tools to create one seamless workflow. The source designs can be created in HFSS, HFSS 3D Layout, SIwave or Maxwell3D. Some example uses for dynamic links include:

- a detailed and optimized design of a cell phone radiating in a large environment (HFSS to HFSS).
- a Driven Modal (HFSS to HFSS SBR+).
- a complicated printed circuit board in an HFSS 3D Layout project file causing EMC/EMI problems in and around its housing (SIwave to HFSS).
- an electromechanical component causing EMC/EMI problems in a vehicle (Maxwell3D to HFSS).

In all cases, radiated fields from the source project are imposed as an incident wave in the target project. These radiated fields can be far fields and near fields.

> **Note:**
>
> It may be necessary to create the environment variable **`SIWAVE_INSTALL_DIR`** before executing the target application (e.g., SIwave is launched from HFSS and not separately).

> **Note:**
>
> From the target project, radiation boundaries must be assigned to specify where the fields from the source project enter the target project.

> **Note:**
>
> To avoid singular far field integral calculations, do not use identically sized and shaped surfaces in the target and source projects. Use surfaces that are smaller or larger.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Using a Dynamic Link Between HFSS and HFSS 3D Layout (Example)

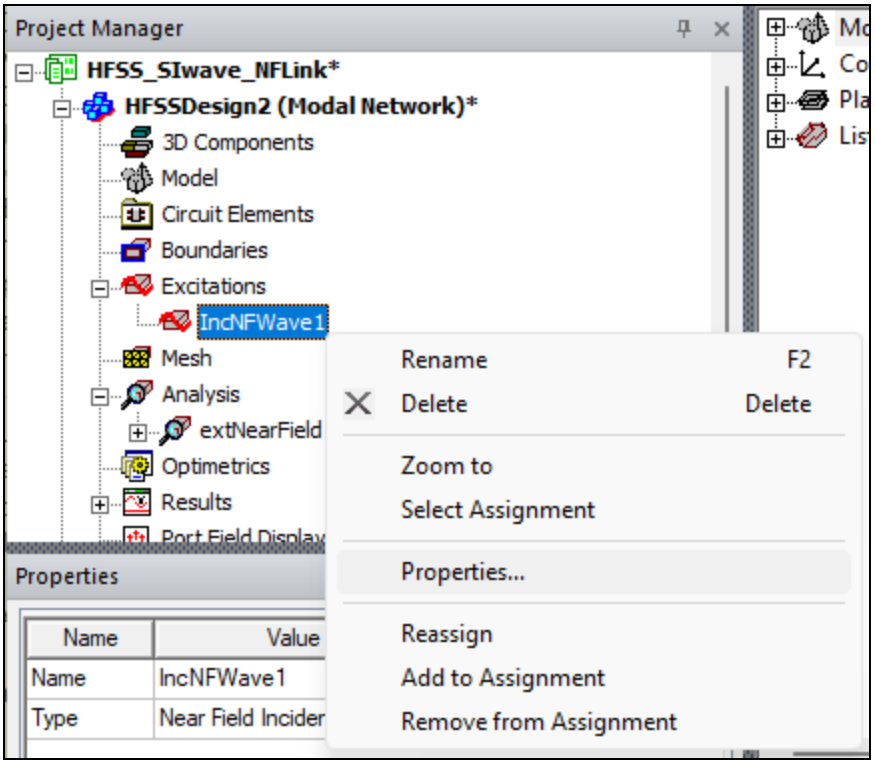
> **Note:**
>
> To execute the following instructions, the user will need an Ansys Electronics Enterprise license or an Ansys Electronics Premium SIwave Plus license.

Add a dynamic link between HFSS and HFSS 3D Layout to utilize HFSS 3D Layout's built-in **SIwave Near Field** solver. Among other benefits, integrating HFSS and HFSS 3D Layout allows bidirectional data and eliminates manual steps in the process, saving time and improving accuracy.

Complete the following steps to create a dynamic link between HFSS and HFSS 3D Layout.

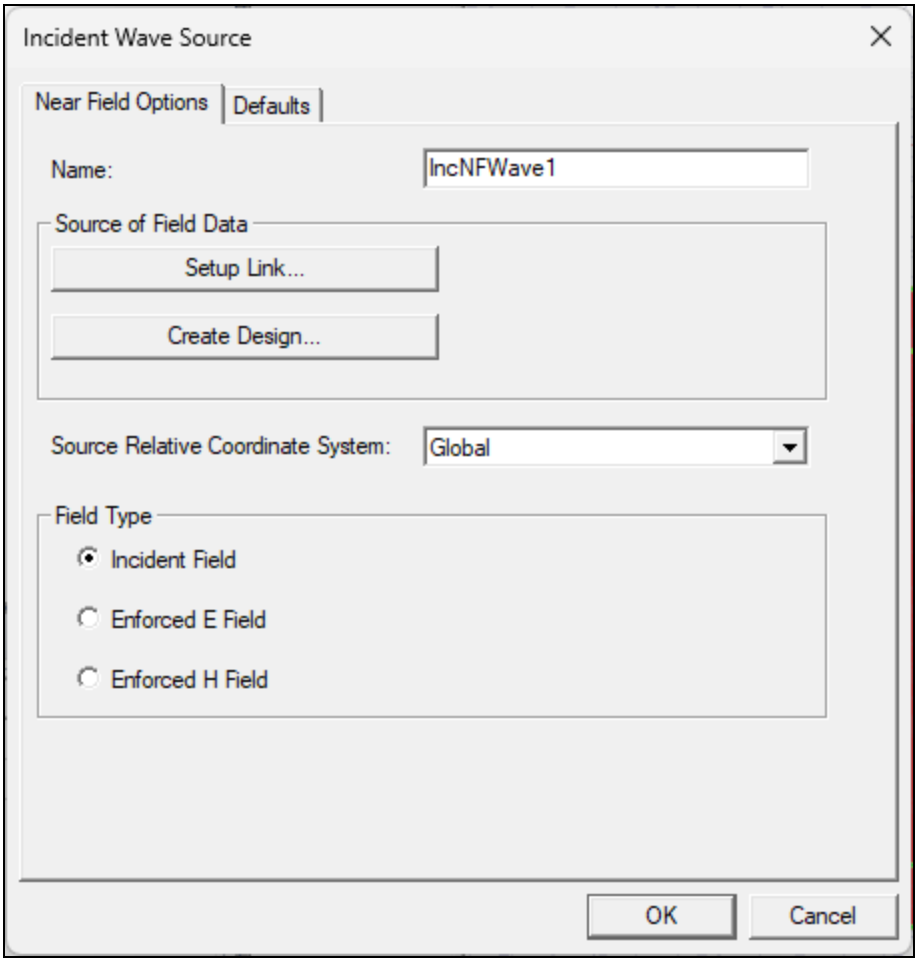
1. From the appropriate target HFSS file, create an Incident Plane Wave excitation.
2. From the **Project Manager** window, expand the **Project Tree** > ***active design folder*** (e.g., **HFSSDesign2**) > **Excitations**. Then do one of the following to open the **Incident Wave Source** window.
    - Double-click the excitation (e.g., **IncNFWave1**).
    - Right-click the excitation and select **Properties**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



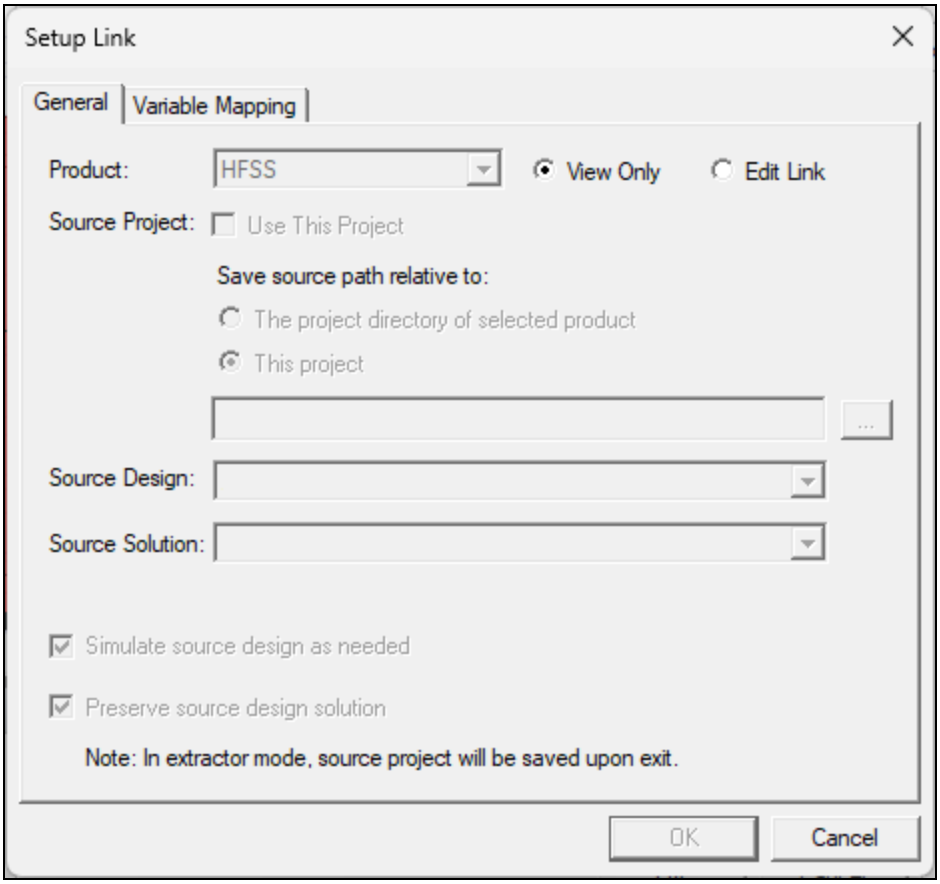
3. From the **Incident Wave Source** window, enter a **Name** for the excitation or accept the default (e.g., **IncNFWave1**).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



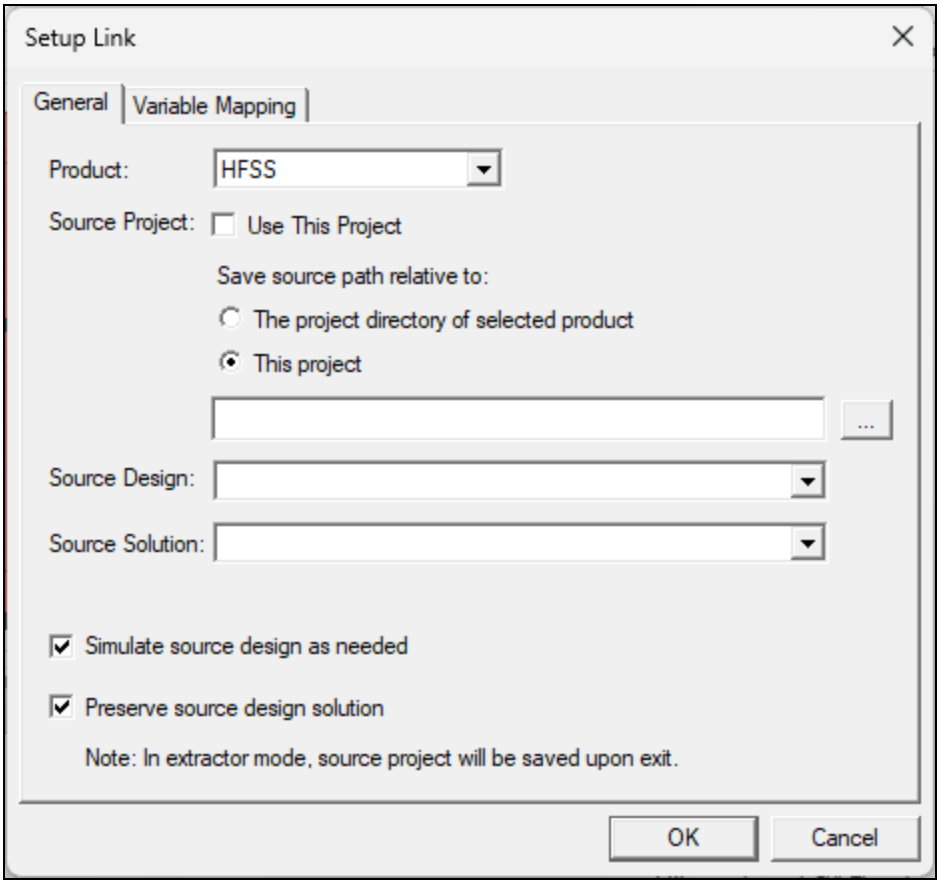
4. From the **Source of Field Data** area, click **Setup Link** to open the **Setup Link** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



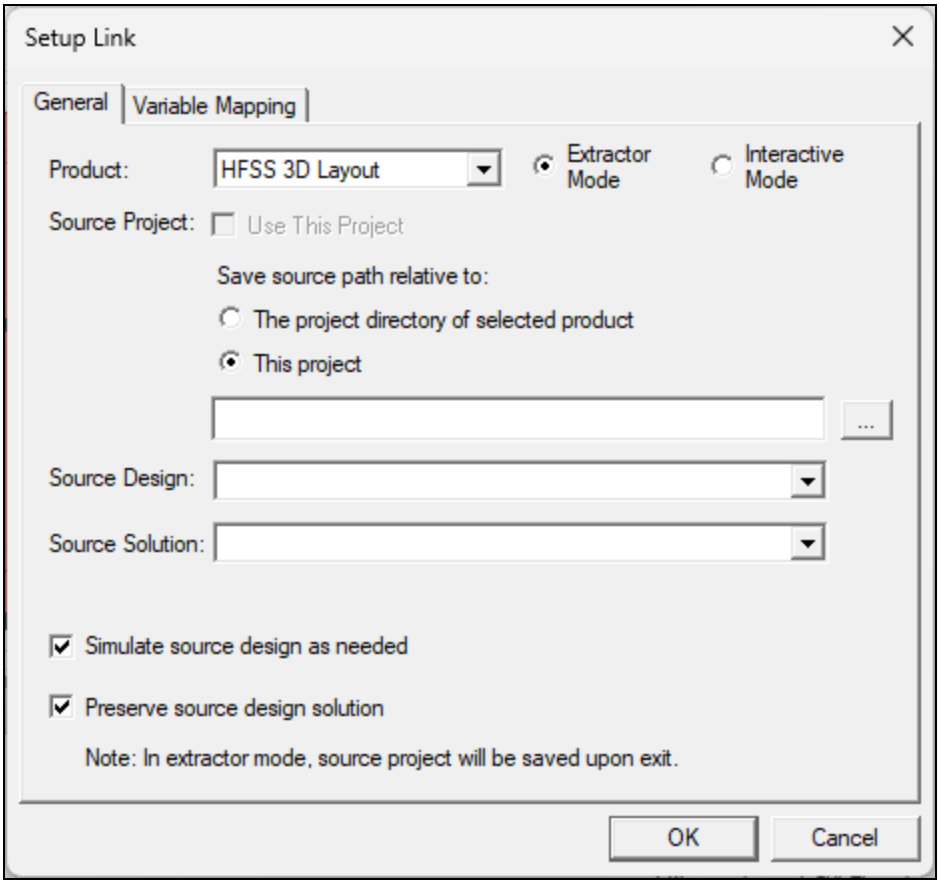
5. From the **Setup Link** window, click **Edit Link** to activate the window and make its contents editable.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



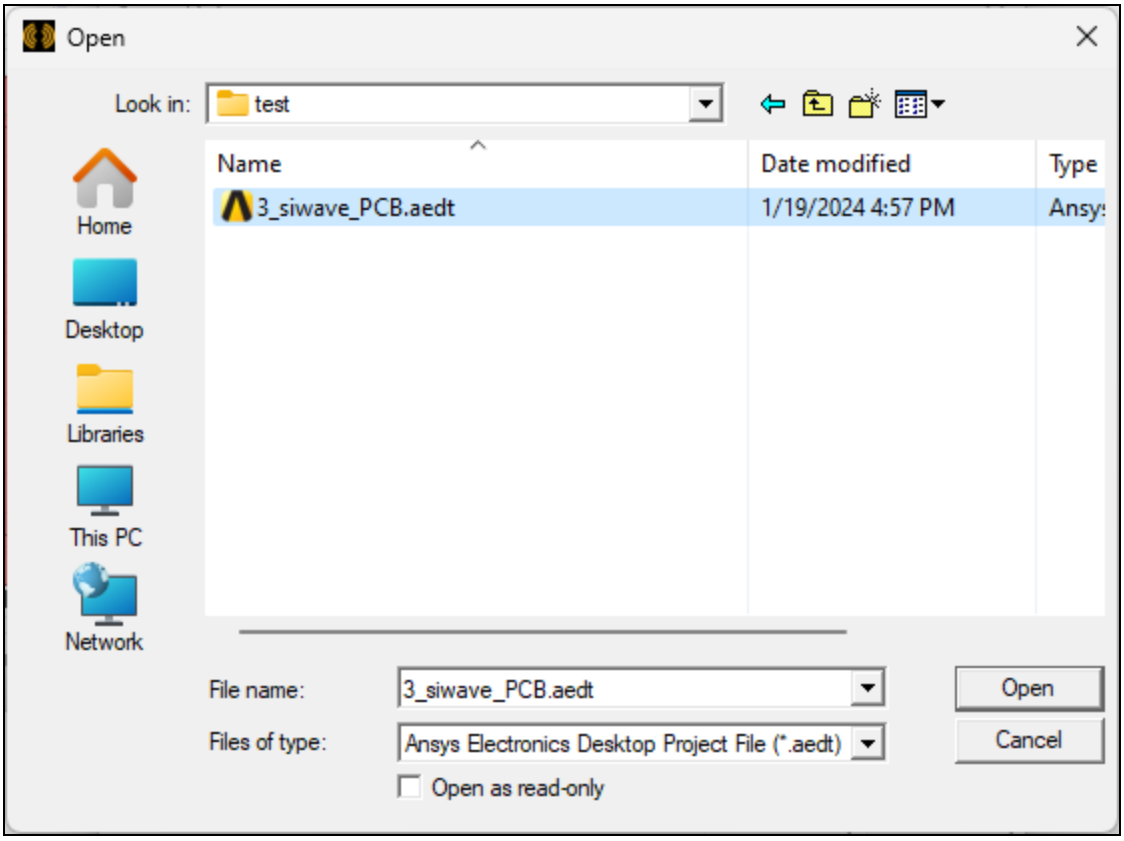
6. Select **HFSS 3D Layout** from the **Product** drop-down menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



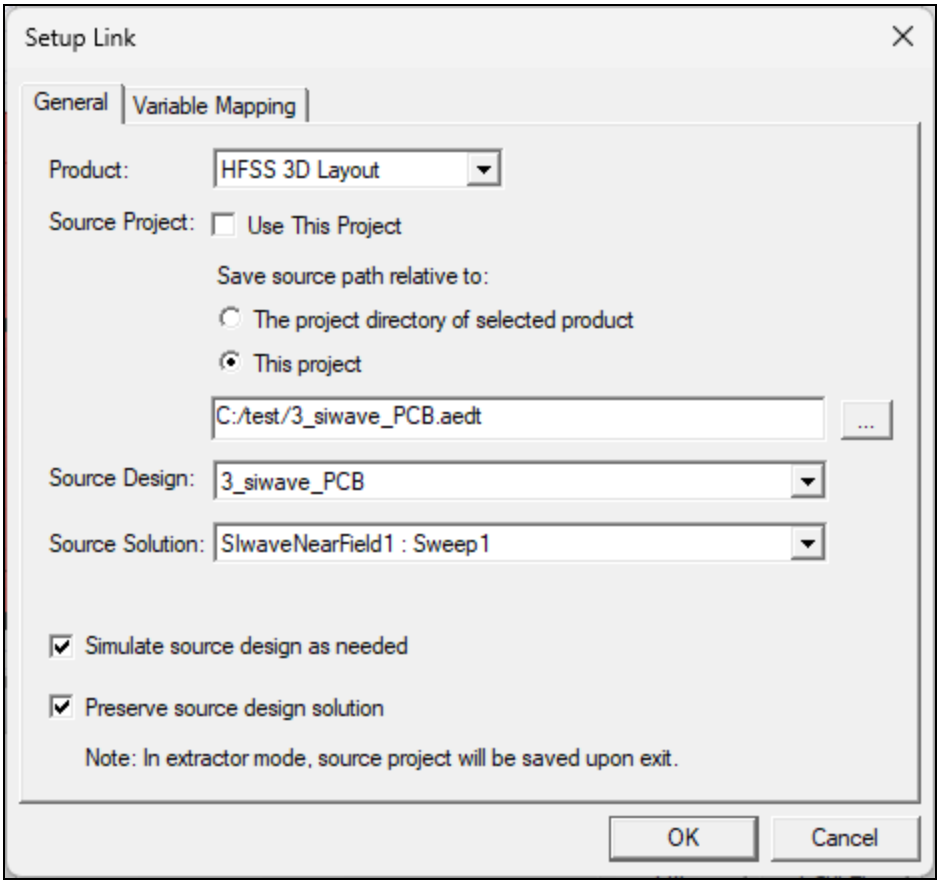
a. Click the **ellipsis** adjacent to the empty field to open an explorer window. Then navigate to the appropriate project file. Either double-click the file or select it and click **Open**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Setup Link** window will populate with the path to the source file, the available designs, and the available solutions. If the user has not already opened the source file, it will open in **Electronics Desktop** and appear in the **Project Manager** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



7. If necessary, select a more appropriate **Source Design** and/or **Source Solution** from the drop-down menu(s).
8. Check or uncheck the boxes adjacent to the following options:
   - **Simulate source design as needed** — if the source design has been modified, select this option to update the source design solution linked to the target design.

     > **Note:**
     >
     > Ensure the cached link data in the target design is invalidated before proceeding (i.e., from the **Project Manager** window, right-click **Analysis** and select **Clear Linked Data**.

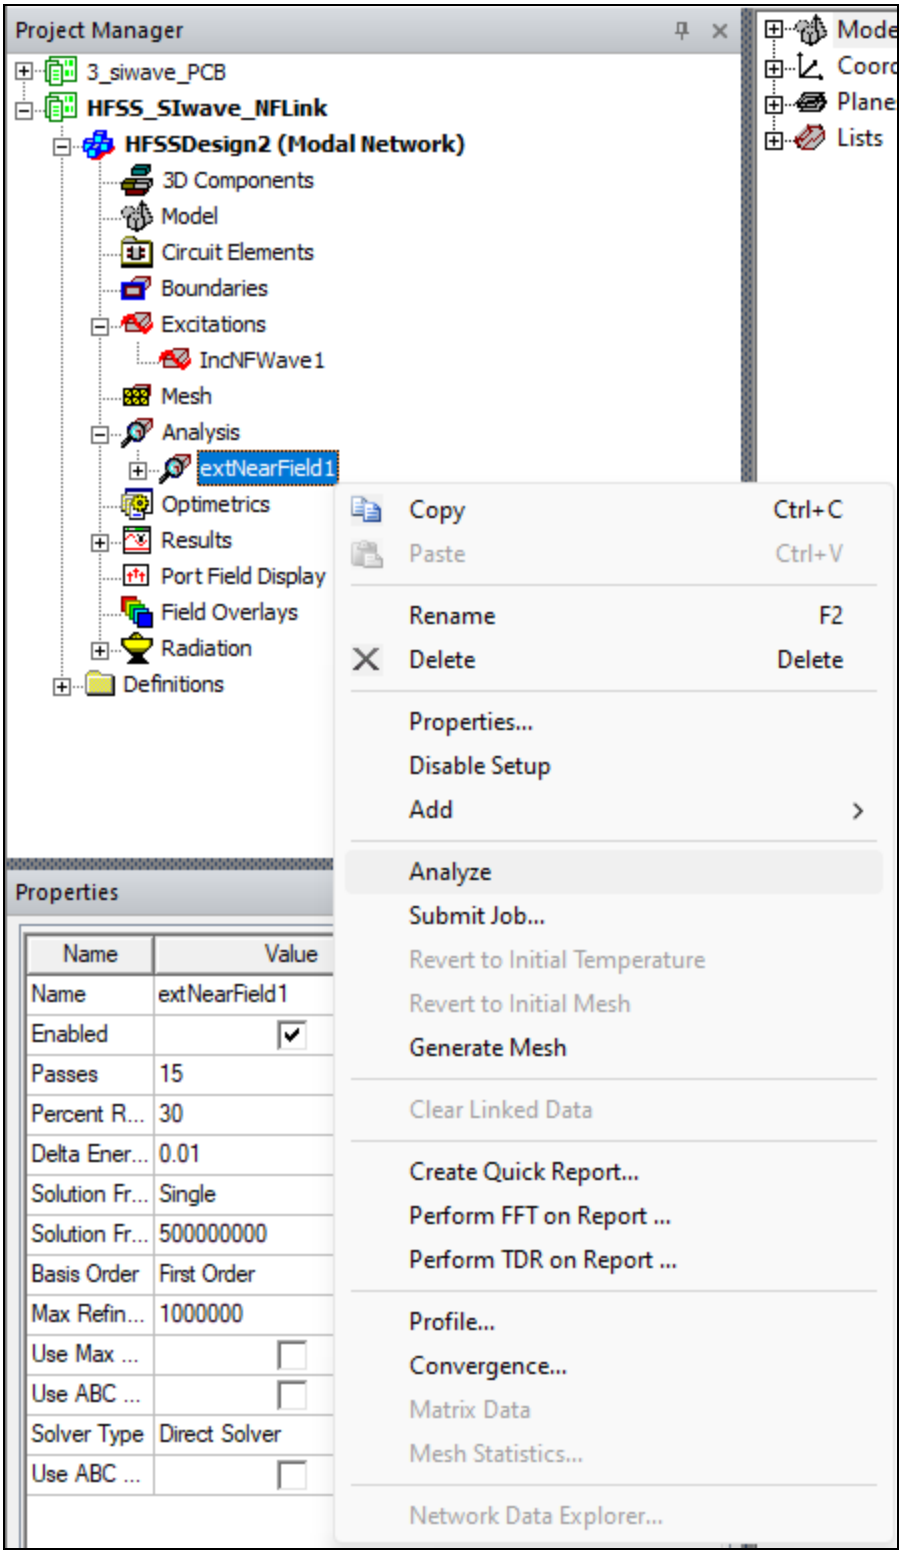
   - **Preserve source design solution** — if the source design is closed, it is **not** included in the **Project Manager** window containing the target design and the source design will **not** be saved. Select this option to save the design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> **Preserve source design solution** is most useful if the source design is an HFSS 3D Layout, Maxwell, or SIwave file.

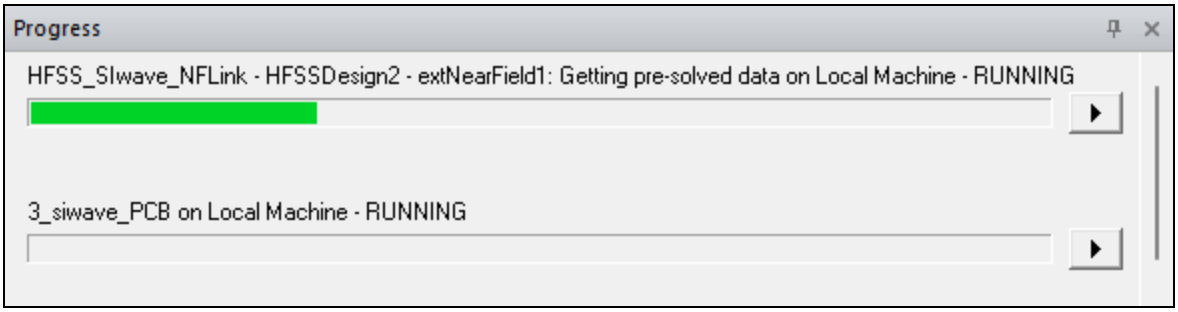
9. Click **OK** to close the **Setup Link** window and establish the link.
10. Click **OK** to close the **Incident Wave Source** window.
11. From the **Project Manager** window, expand **Analysis**. Then right-click the near field solution (e.g., **extNearField1**) and select **Analyze** to begin analysis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

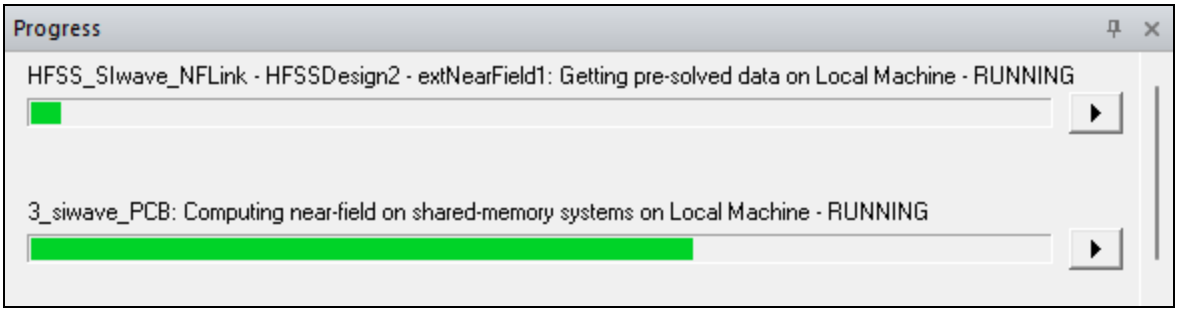


As the analysis proceeds, view its status in the **Progress** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



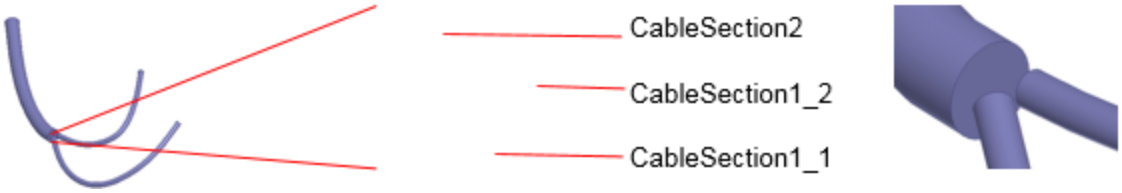
The analysis will utilize HFSS 3D Layout's **SIwave Near Field** solver to complete the simulation.



Cable Network

A Cable Network is linked field excitation used as part an overall cable solution implemented as dynamic data links between HFSS, 2D Extractor, and Circuit.

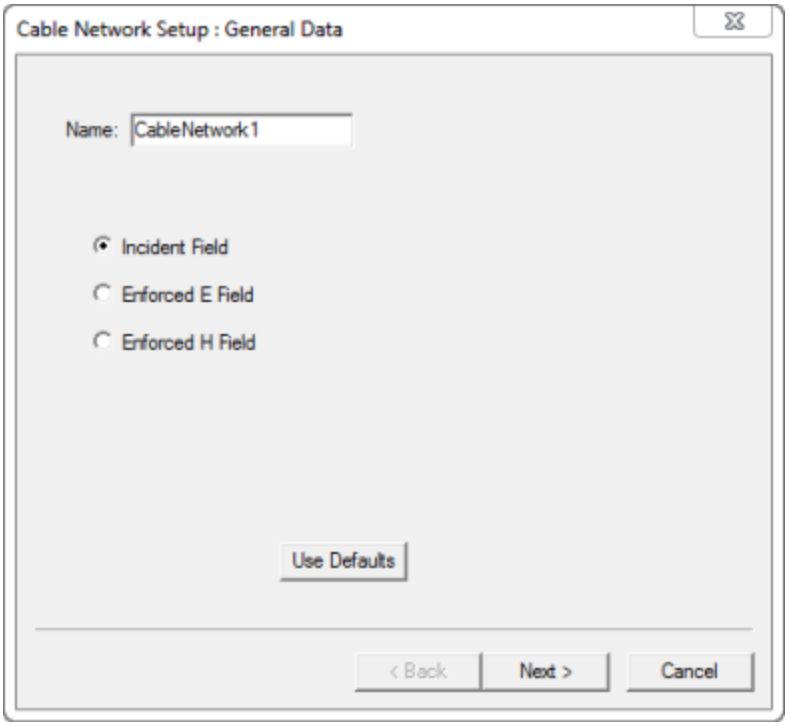
- Each cable harness in HFSS is modeled as a single external field source based on quasi-static simulation of each cable cross-section in 2D Extractor and an analysis of the cable network in Circuit. The magnitude and distribution of the fields along each cable section is determined by the voltages and currents at the ends of each section, and then transmission line model is applied to propagate these fields along the cable length.



This HFSS design is a target of a new “Cable Field” coupled field datalink. The source of the datalink is the Circuit design that models the cable network. Each Cable Network will be treated as a single source and can be scaled at Edit Sources.

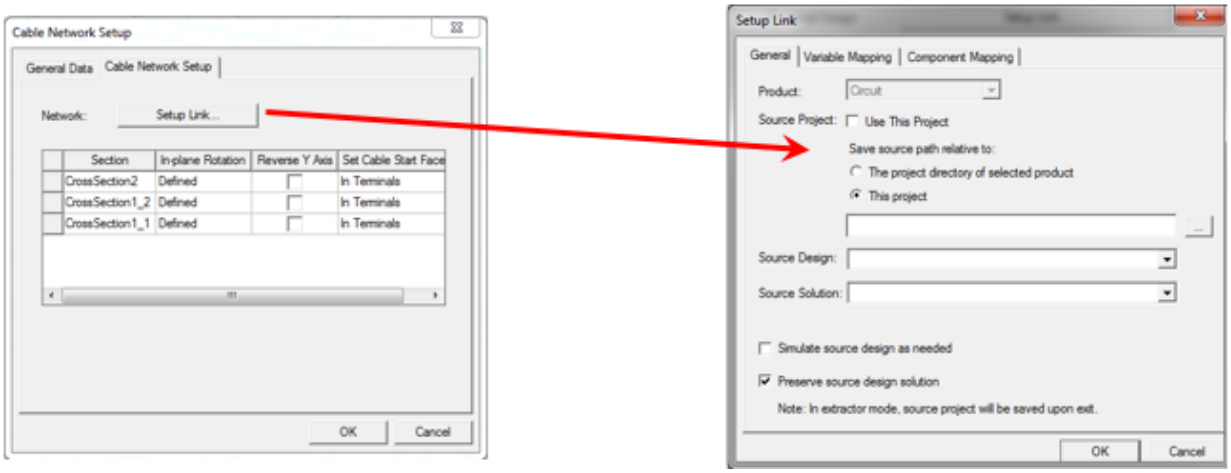
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To setup a Cable Network datalink, in the HFSS Modeler window, you select all 3D cable cables that are part of a network. Then click **HFSS>Excitations>Assign>Linked Field>Cable Network...** or right-click **Excitations>Assign>Linked Field>Cable Network...** This opens the **Cable Network Setup** dialog:



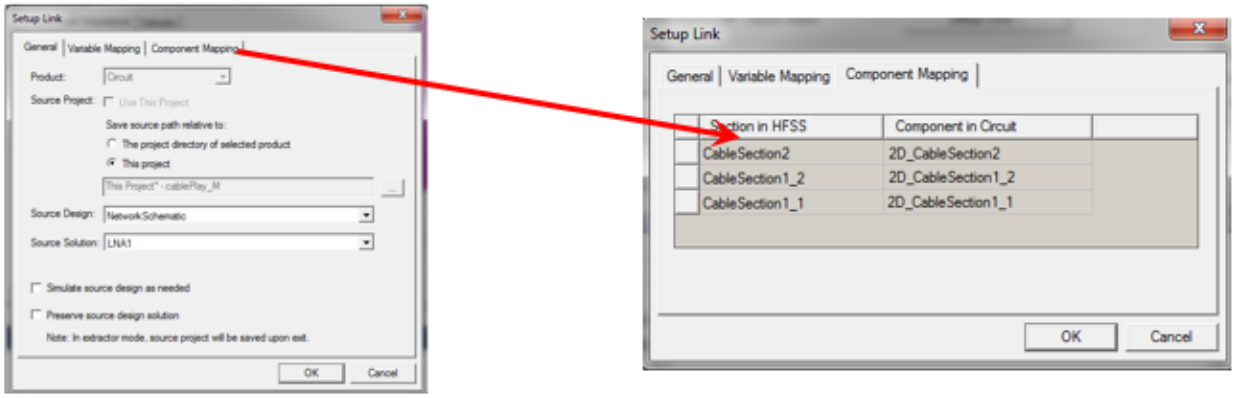
You have a field for the name, and selections for Incident Field, Enforced E Field, and Enforced H Field.

- To specify the Circuit design, user can go to the second page and click the button “Setup Link…”. This displays the **Setup Link** dialog.

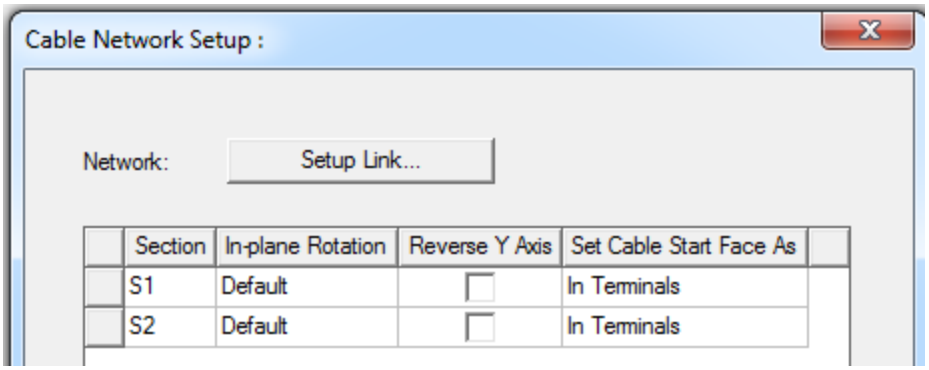


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- After specifying the source design, you switch to the **Component Mapping** tab to set up the mapping between each cable section in HFSS and a circuit component.



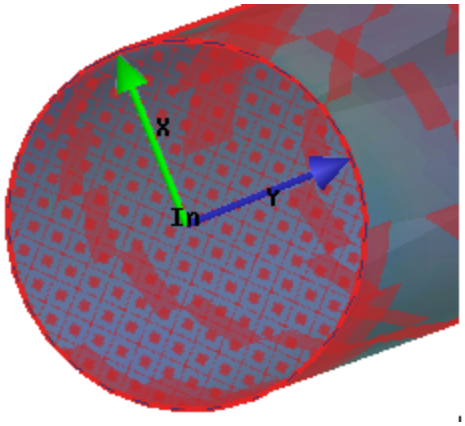
Click OK to exit the **Setup Link** dialog and complete the rest of the link setup in the **Cable Network Source** dialog.



For each cable section, you need to specify:

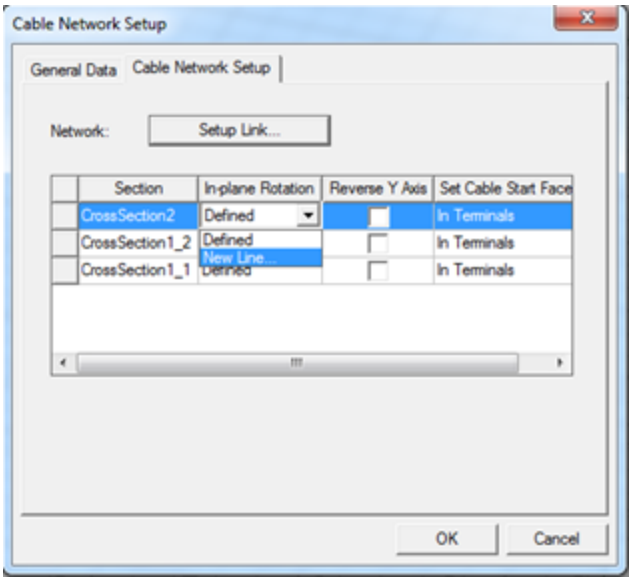
1. The In-plane rotation of the HFSS 3D section to the 2D Extractor cross-section by a direction line (which will be the local X axis of the cable cross-section face). The default is zero in-plane rotation, which is represented by a direction line originated at the starting point of the polyline and ended at the seam of the cable.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



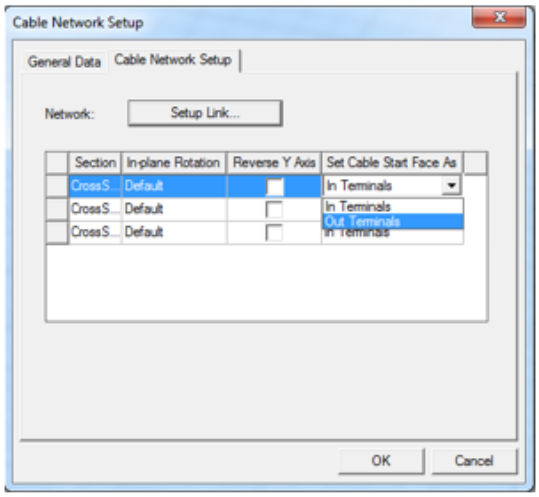
You can create new line or reverse the Y axis of the start cable cross-section face.

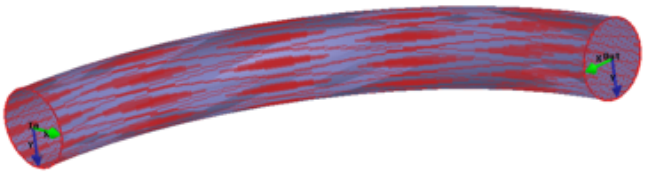
2. The X and Y axis on both start and end faces are shown, which is useful when you want to align multiple cable orientations.



3. You map pins in Circuit to wires at ends of the cable in HFSS by specifying the starting end of the cable as “In Terminals” or “Out Terminals”. By default, the starting end of the cable is selected as the “In Terminals”. The “In” and “Out” faces are highlighted in the View window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





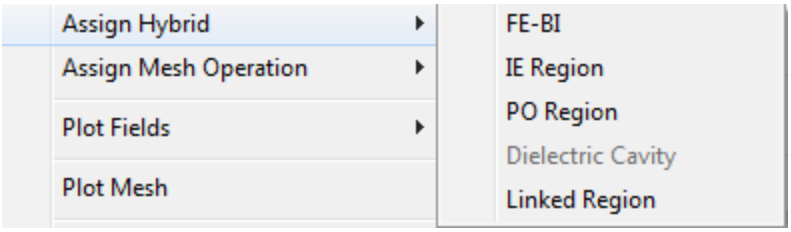
You can override the default selection by toggling the menu at the “Set Cable Start Face As” column.

Floating Cable/Linked Region

A Floating cable is defined as a cable object floating outside of FEM solution region. In order to define a floating cable, you need to define a linked region. A Linked region is used only for one-way link. We assume the source is inside the linked region, and the linked region only radiates to the field but does not have field scattered back to the region.

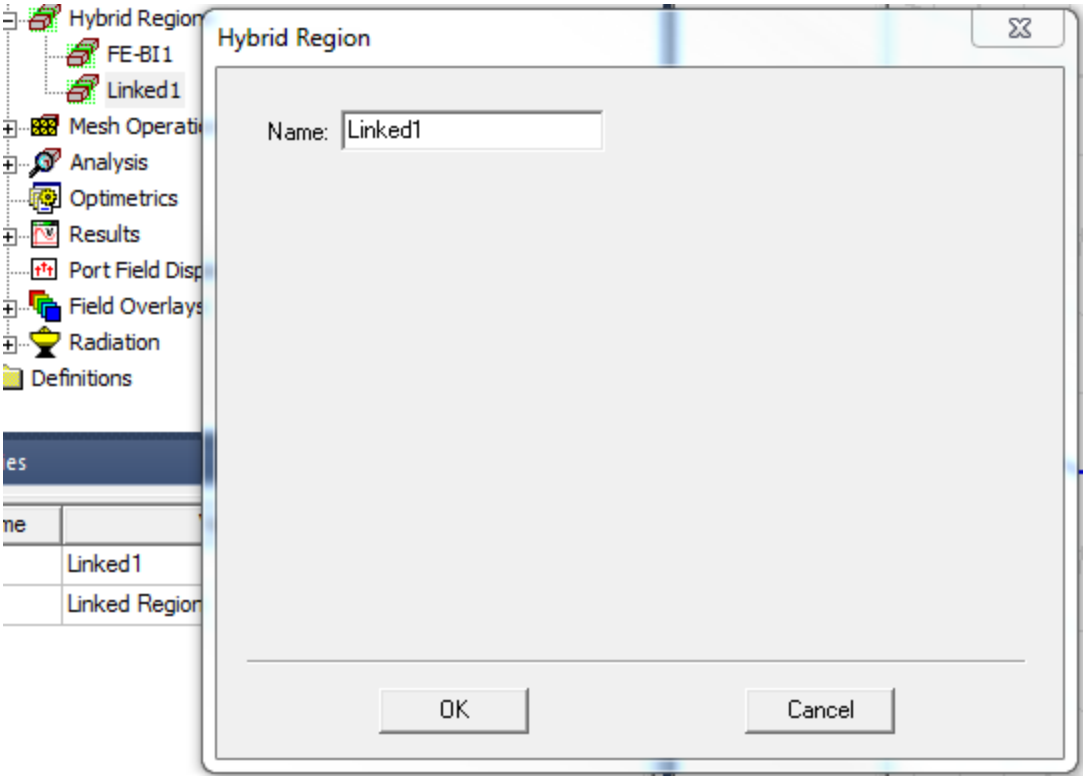
You can assign near/far field as well as a cable network to a linked region.

The Assign Linked Region menu item is in Assign Hybrid.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Linked region appears under “Hybrid Region” folder in project tree.



Cable Network Link Validation

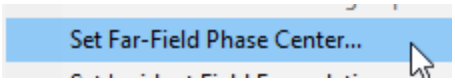
1. The number of 2D Extractor components in circuit should be equal to number of HFSS cable object
2. For each cable object, the 2D cross-section center should match the center of the start face in local coordinate system.
3. For each cable object, the 2D cross-section perimeter should match the perimeter of the start face.
4. The cross-section should be perpendicular to the cable path in HFSS.

Link from Driven Modal or Terminal Antenna to SBR+ Design

HFSS lets you create a one-way link from a Driven Modal design or a Driven Terminal design with a single terminal to an SBR+ design. The source can be a finite array design, including designs with blockages. For finite array design, the phase center is configured using the physical cells, and automatically transformed to the virtual cells. The source design **Excitations** menu includes a **Set Far Field Phase Center** command that lets you specify the phase center for

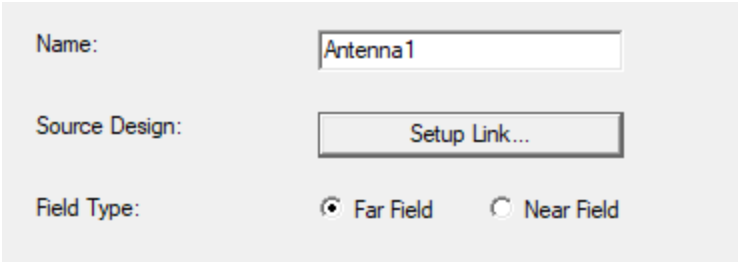
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

each lumped port and wave port it contains. You assign the phase center to a coordinate system. The far-field phase center determines the point from which SBR+ rays are launched when the linked source is configured as far-field. It has no effect for linked sources configured as near-field. It can affect the Export Element Pattern from Antenna Parameters dialog.



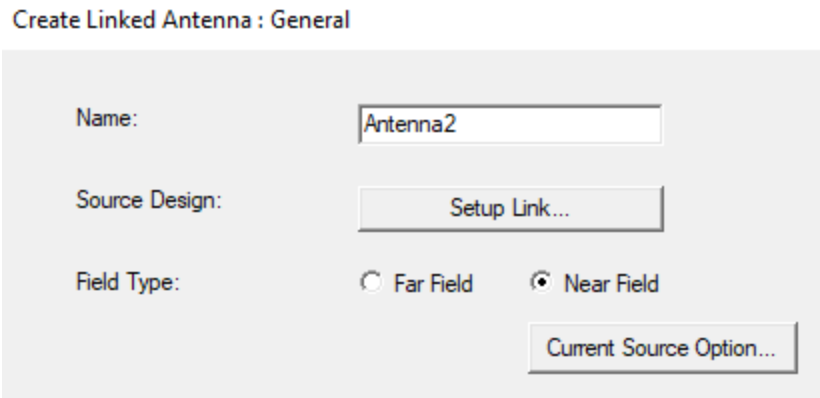
The target SBR+ design includes the associated command **3D Component>Create Antenna>Link to Source Design**.

From the target design, you can select either Far-Field or Near-Field as the linked field style.

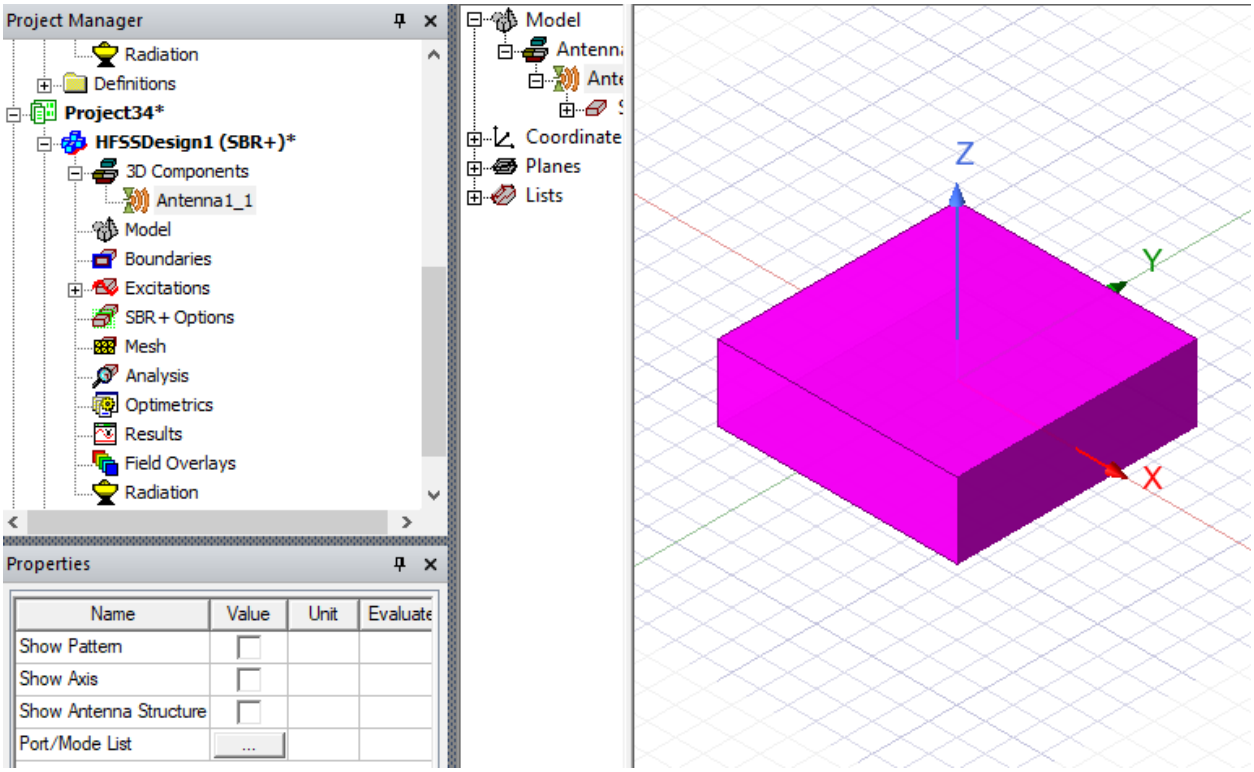


If you select Near Field, the **Create Linked Antenna** dialog includes a button for **Current Source Option...** allowing you to specify a customized power fraction. Use Global is the default. Enabling Thin Sources lets you specify a Power fraction should be greater than 0.1 and less than 1. Solutions are invalidated if you change current source conformance, use Thin Sources, Power Fraction, or change the Global option.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



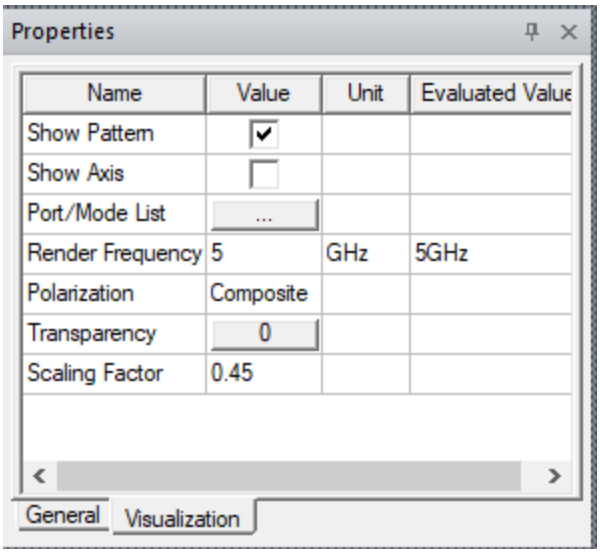
In the target design, the antenna link brings over the source design model and includes visualization options. The selected geometry is shown in its shaded view in the SBR+ target design with its designated color and transparency..



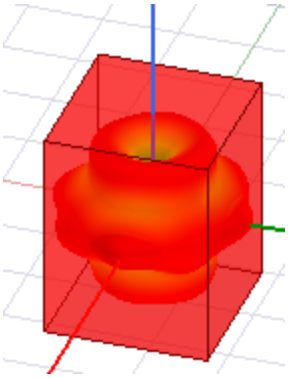
The linked source design appears in the target design under 3D Components. The source design ports appear in the target design under the excitation folder. You have the option when linking to a source project to Link as Composite Port, to simplify and speed up source projects with many excitations. However, you cannot edit those imported ports because they are part of the linked antenna component. You can turn on Field visualization of the source design by

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

checking **Show Pattern** on the **Visualization** tab of the 3D component property in the target design.



With **Show Pattern** checked, the source pattern is visible from the linked 3D Component bounding box in the target SBR+ design.



Prerequisites

- Set the phase center in the source design. The source design requires the presence of at least one wave port or lumped port to activate the **Set Far-Field Phase Center...** command.
- The source design must be solved before you can **Show Pattern** for the 3D Component Instance in the target SBR+ design.
- For simulation, the target design SBR+ solution frequency range must be in the range of source design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To support directivity and gain in the SBR+ design with the link, you must use an interpolating sweep with the 3D Fields Save Option selected in the linked design, either **Save Fields (At Basis Freqs)** or **Save radiated fields only**. This provides interpolatable S-parameters from the source design for the SBR+ target design.
- To model EM scattering effects of antennas in SBR+ simulations, you can select geometries from the source design to represent blockages. These can be model, or non-model objects. For this feature the SBR+ solver is passed a CAD representation of the antenna and it ignores this CAD representation when launching the rays from the antenna source but includes it when tracing the reflected rays from the platform.

Limitations

When the source design is in Composite-Driven Modal solution type or Composite-Driver Terminal with a single terminal:

- You can only choose one single phase center as the global phase center for all ports.
- Composite excitation becomes an incident wave in the target design. Therefore, we naturally should not have the port/mode option anymore.
- For Terminal designs, a single terminal is permitted.

When you select **Show Pattern**, the pattern data is cached for future use. The cached data is available until the design is closed. If you update the source design, **Clear Linked Data** is available for you to clear the cached data. If you clear the Linked data, field pattern is re-computed when you select **Show Pattern** again.

To model blockage structures, the source design can be Driven Modal or Driven terminal or a finite array. If you use a finite array, the **Model Blockage** tab on the **Setup Link** dialog shows up if the array has model / non-model blockage objects. The GUI operations for array blockages are same as non-array projects. See steps 4 to 7 below.

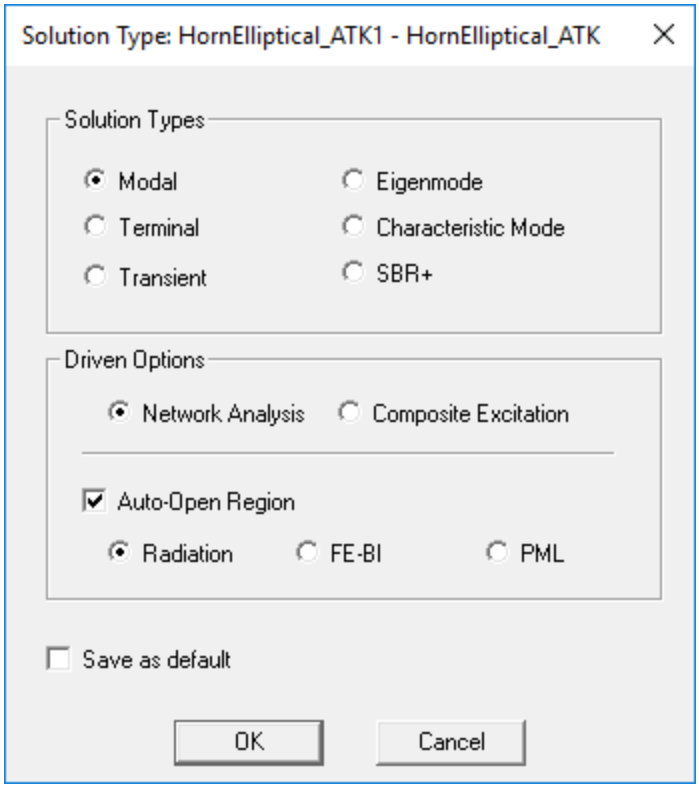
Creating a Link from Driven Modal or Driven Terminal Source to SBR+ Target

To create a link from a Driven Model Source or Driven Terminal Source to an SBR+ target:

1. Set up a driven Modal solution or Driven Terminal as the source.

   You can choose any **Modal** options, although if you choose **Composite Excitation**, you must choose a single phase center for all ports. You can use **Auto-Assign Region** options if convenient.

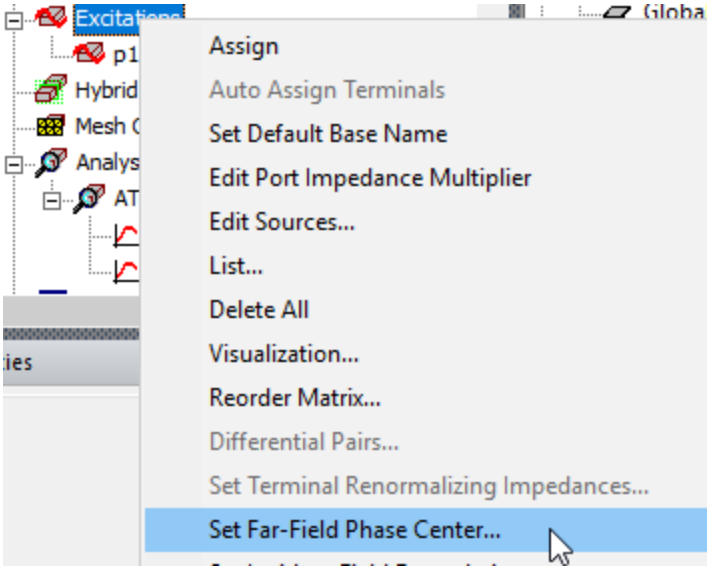
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



All ports in the source design must be either wave ports or lump ports.

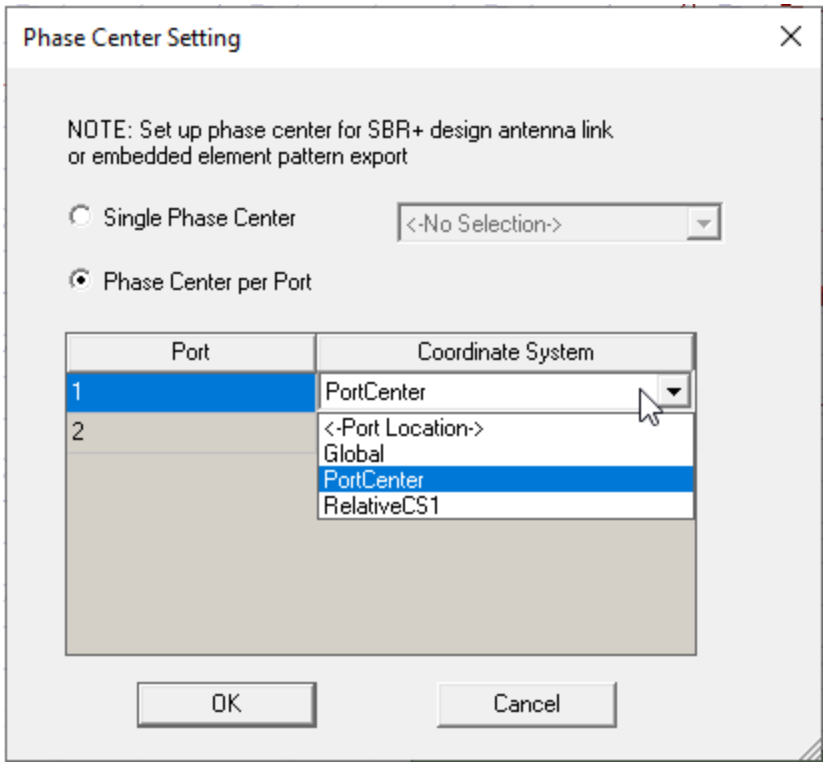
2. Set the Phase Center in the Source design. The phase center(s) determine the point(s) from which SBR+ rays are launched when the linked source is configured as far-field. It is important for accurate results to position the phase center as near as possible to the physical phase center of the antenna for the selected port, especially if the source is placed nearby to SBR+ scattering structures. Otherwise, the accuracy of ray fields illuminating nearby structures will be compromised, leading to inaccurate scattered fields and final results. Either right-click **Excitations** in the Project tree and select **Set Far Field Phase Center...** or click **HFSS>Excitations>Set Far Field Phase Center...**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



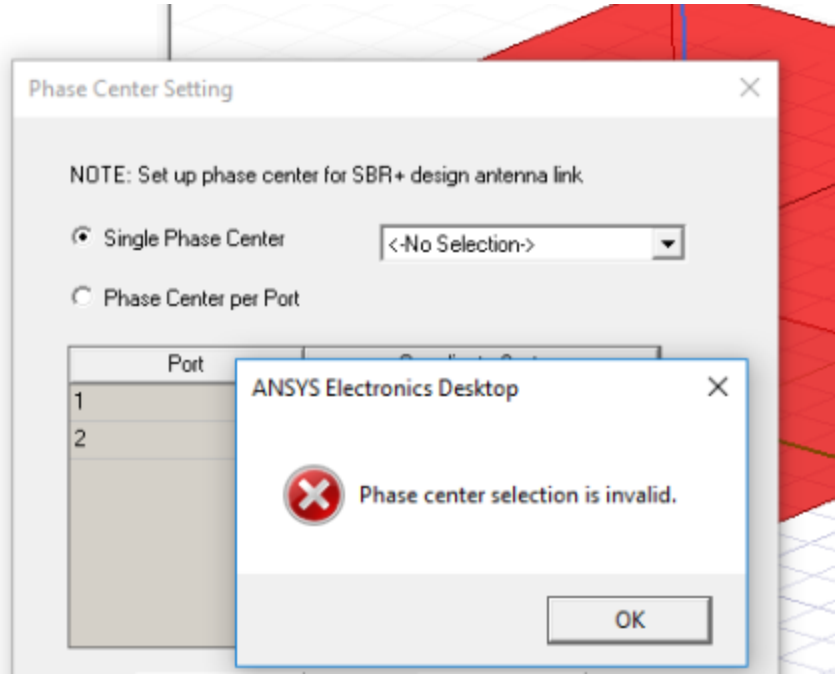
The **Phase Center Setting** dialog appears, with **Phase Center per Port** selected as default with the mode <- Port Location->. By using **Phase center per Port**, you have more fine-grained control over each phase center. This feature provides a convenient option to assign phase center at port location (port geometrical center), which is a common selection for Phase Center per Port mode. If you have created additional Coordinate Systems, these appear in the drop-down menu as options for the phase center.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



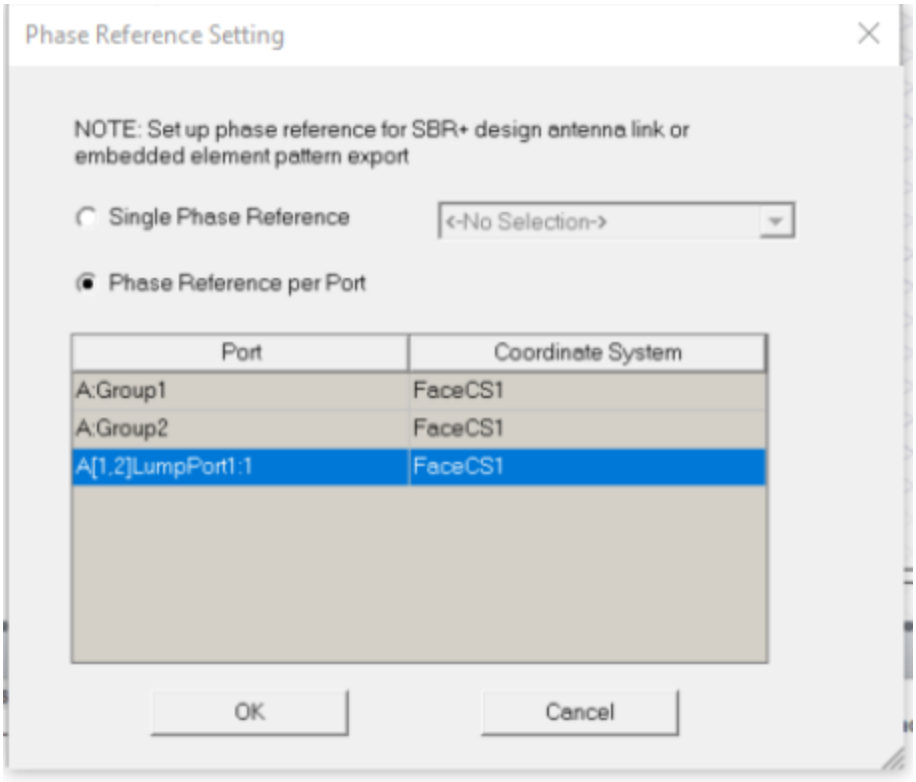
Single Phase Center is to assign the global option to all the ports (one port or multiple ports with the same phase center option). You also have the option to select Link as Composite Port when you setup up the link from HFSS to SBR+ design. Phase Center Per Port lets you specify different phase centers for different ports. Validation checks to ensure that each port is assigned a valid phase center. You must not leave any ports with <No Selection>.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

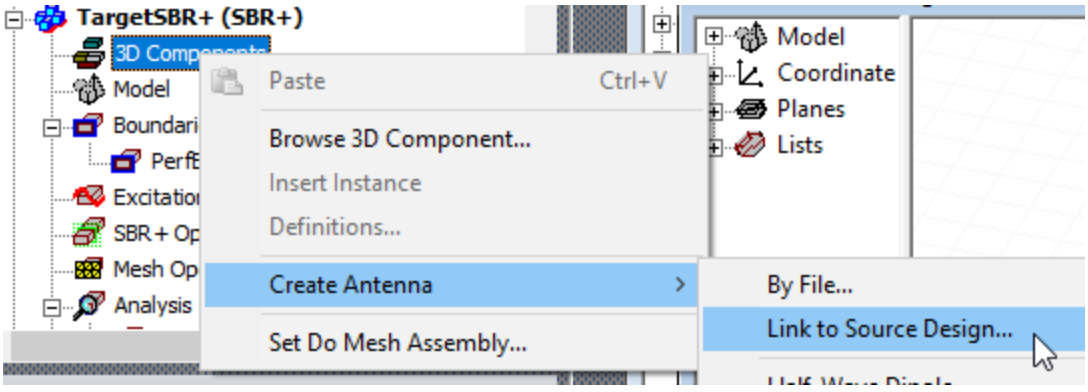


In the case of a design using the Beta feature for subarrays, the **Phase Reference Setting** dialog shows composite groups if you want to specify unique phase reference for each group. In this case, the “Port Location” selection is not available, and you must select an actual reference coordinate system.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

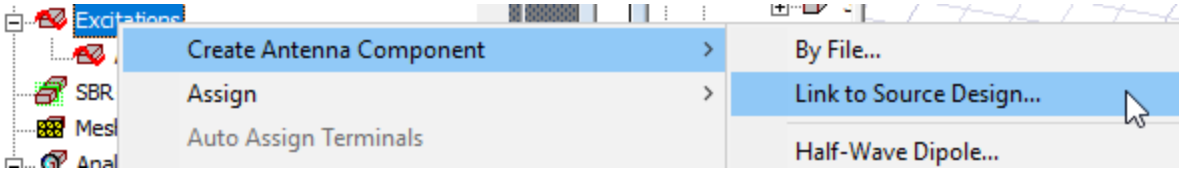


3. When you have completed the source design setting (phase centers, solve setups, etc) and solved it, create an SBR+ design as the target design.
4. Right-click **3D Components** in the Project tree and select **Create Antenna>Link to Source Design...**

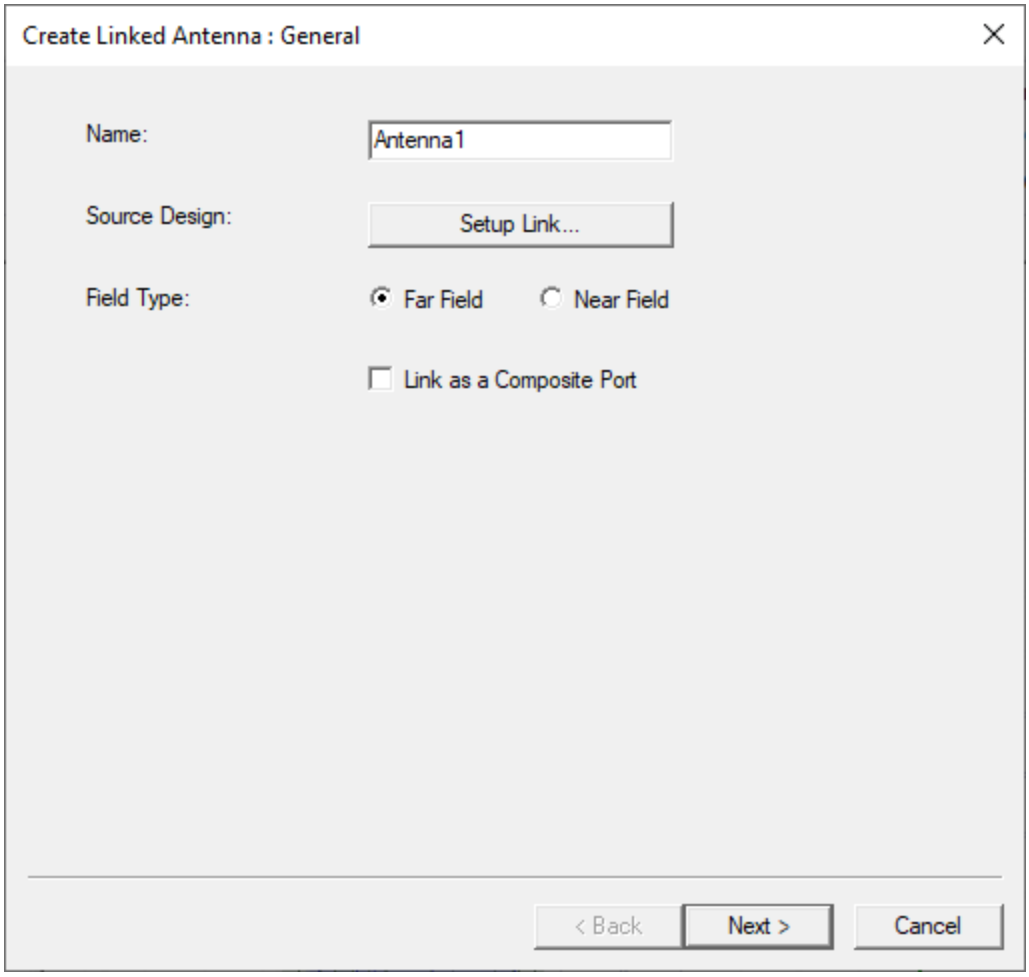


You can also right-click **Excitations** in the Project tree to select **Create Antenna>Link to Source Design...**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Create Linked Antenna** dialog appears.



Select **Far Field** or **Near Field** as appropriate.

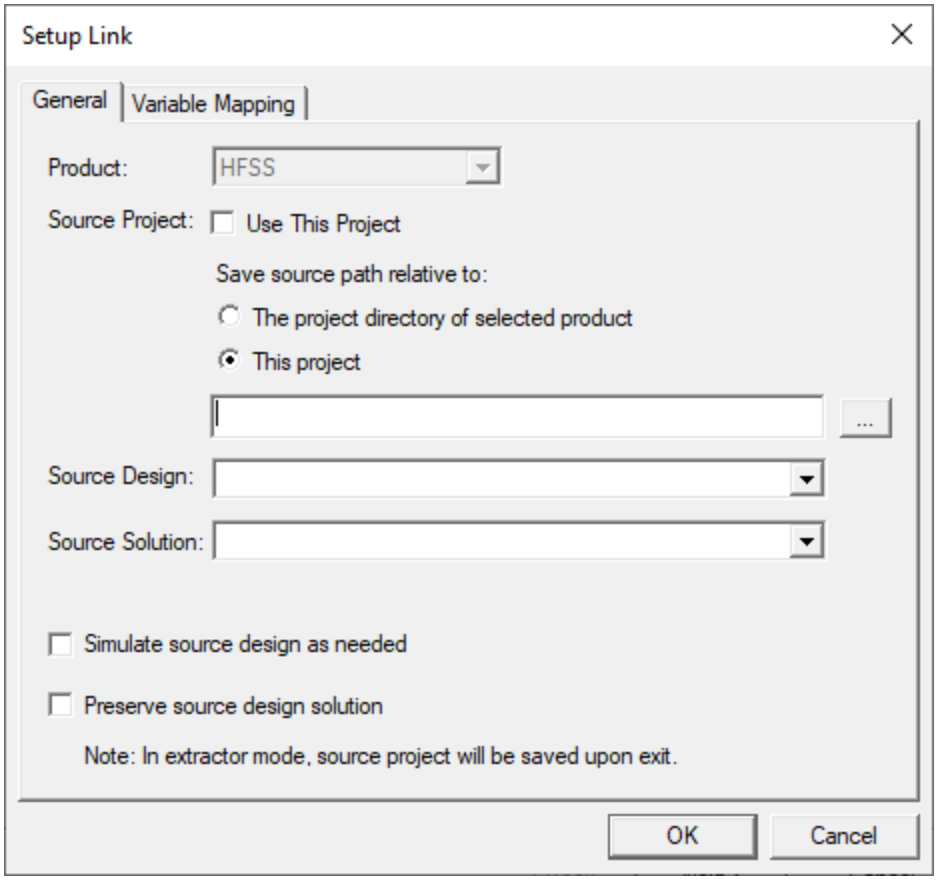
The **Link as Composite Port** option addresses the situation where an imported design contains many ports. By default, the model window displays the same number of virtual ports in the SBR+ target design. However, if the source design contains many virtual ports, they will look cluttered and require significant computational resources to solve. You create a single composite port in the SBR+ target design to represent all the ports in the HFSS source design. During computation, the SBR+ target design sends the information about a single

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

composite port to the solver, rather than information about all the ports. This saves a significant amount of resources. For further discussion, see Link as Composite Port.

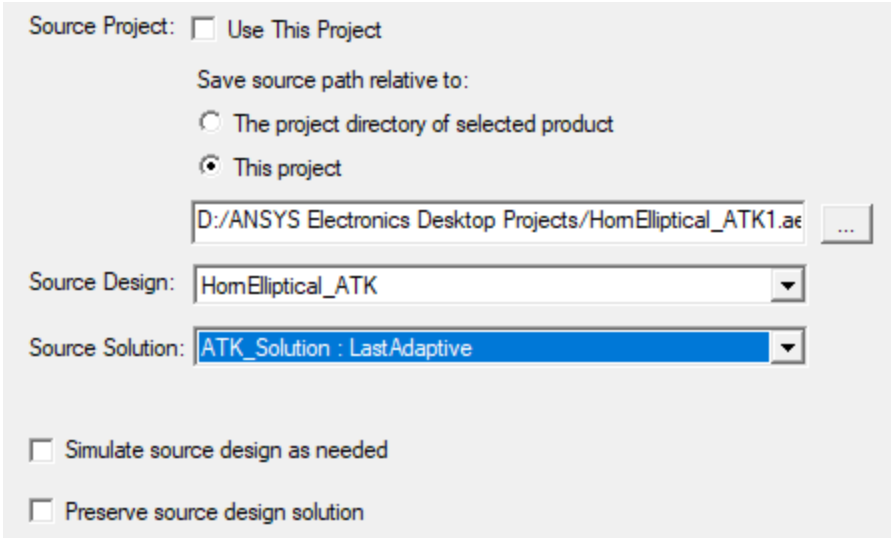
5. Click **Setup Link...**

The **Setup Link** dialog appears.



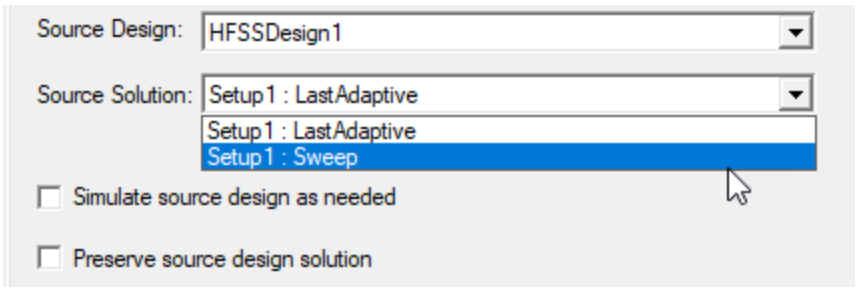
If the source design is in a different project, you can click the ellipsis button **[...]** to open a file browser to select the project of interest. When you select the project and OK the browser, the fields are filled in.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If the source design is in the same project, you can check **Use this Project** and select from available Source Designs.

If you have defined an interpolating frequency sweep in the source design, you can select it on the drop-down for the source solution. (This feature supports directivity and gain in the SBR+ design with the link. (See "Requirements for Creating a Gain Report for SBR+ Design with Driven Modal or Terminal Source" on page 19-192). It provides the S-Parametersfrom the source to the target. In the source sweep setup, you must have selected a 3D Fields Save Option.)



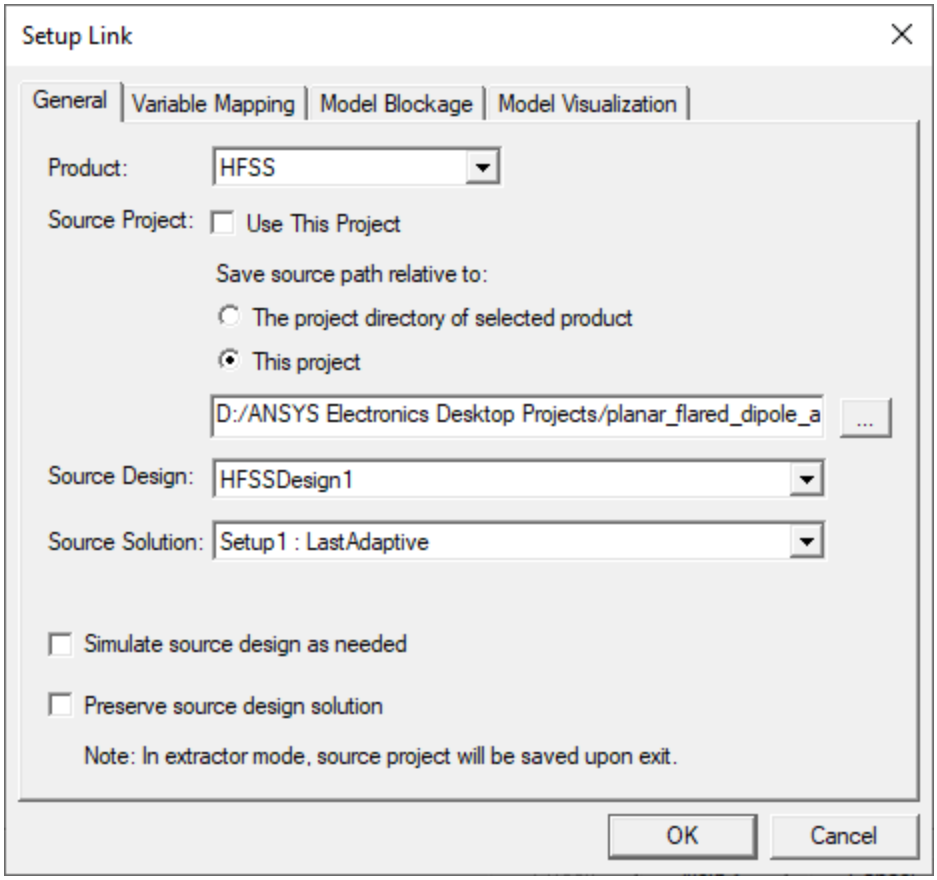
For this release Model blockages can handled as a separate step outside creation of the linked design, by selecting geometry from the SBR+ region to be designated as “Model Blockage” associated with a particular source antenna, as described in the Section "Configure Simulation with SBR+ Antenna Geometry Blockage (HFSS with Hybrid and Array Solution Type)" in Assigning SBR+ Hybrid Regions.

Note there is no longer any restriction on what objects and/or materials can be designated as “model blockage” geometry. For either solution type, SBR+ or hybrid HFSS-SBR+, this selection is from the available SBR+ region geometry objects. Once you specify antenna

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

blockage geometries for each source antenna, we can then solve the combined target SBR+ design. For details see Design Flow for SBR+ Solution Type.

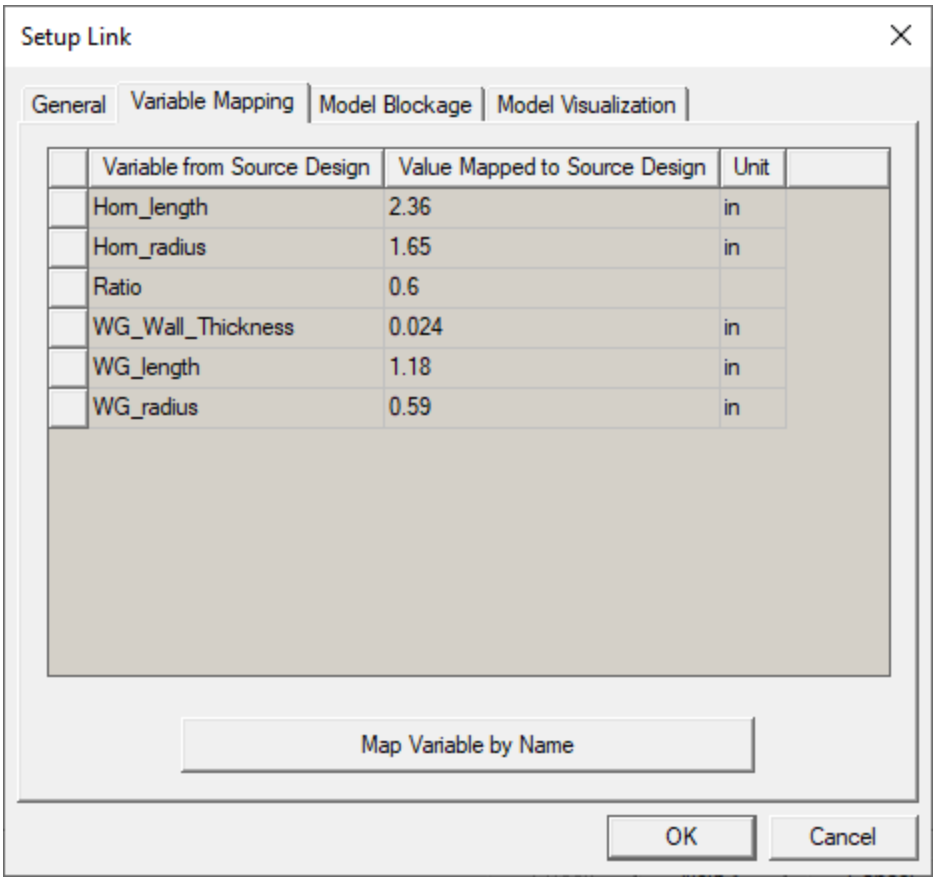
If you use the older method for designating blockages, once you select the source design, additional tabs for **Model Blockage** (if model or non-model blockages exist in the source) and **Model Visualization** appear.



The **Visualization** tab lets you specify how the linked model is displayed in the SBR+ target design.

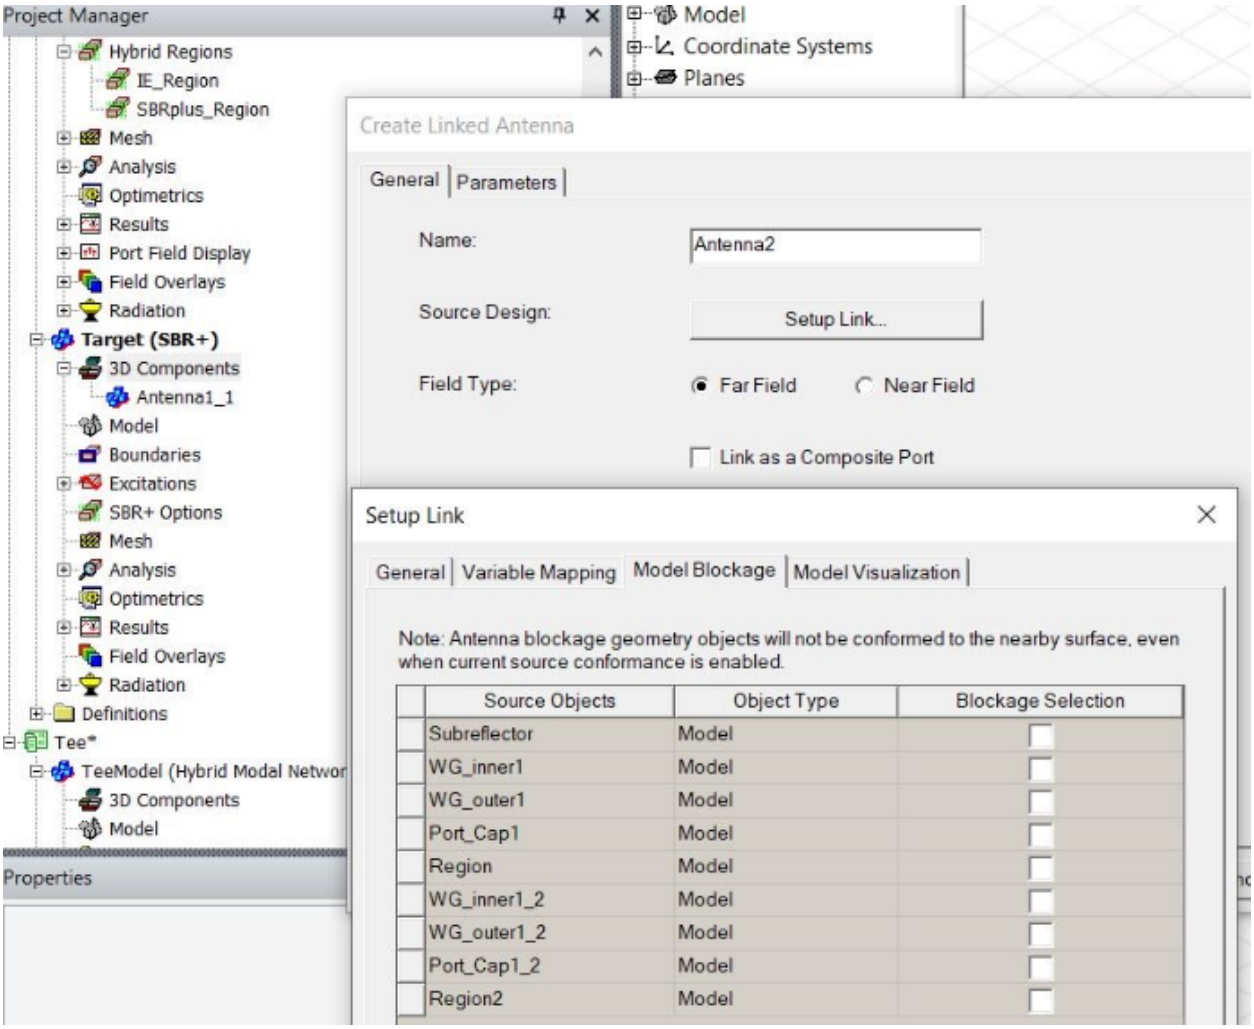
6. The **Variable Mapping** tab lists variables and lets you define mappings between the driven modal source design and the SBR+ target design, if necessary.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

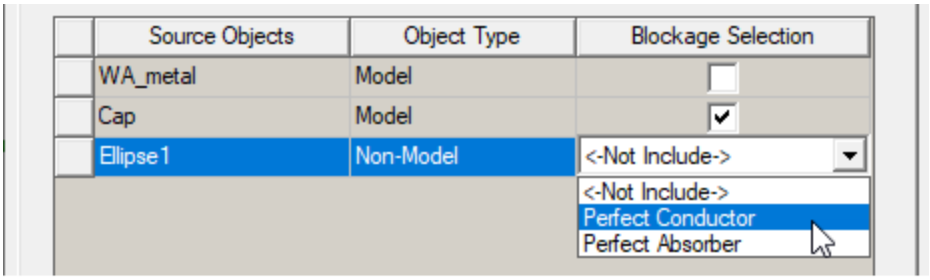


7. The **Model Blockage** tab lets you select geometries from source design to represent the blockage structure. SBR+ region objects from the source design should appear in the object list. Objects selected for blockage in the source design will be selected in the link blockage dialog by default. Non-solve inside, and non-model objects are available for selection.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For Non-model objects, you can select <Not Include> Perfect Conductor, or Perfect Absorber.



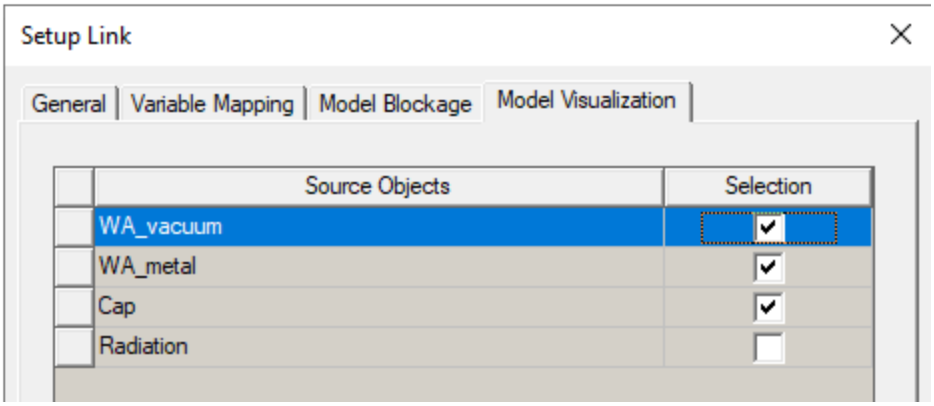
In many cases, it is sufficient to represent SBR+ sources entirely in terms of their far-field or near-field radiation characteristics, and there is no need to configure Model Blockage. However, in some cases, the antenna structure can generate significant secondary

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

scattering after rays have first reflected off the main scattering geometry that the source illuminates. An example would be a feed antenna blocking part of the main beam of a reflector antenna, where the reflector surface is simulated using SBR+. Model and non-model structures selected under Blockage Selection will have special behavior relative to SBR+ ray-tracing. These surfaces will be invisible to SBR+ rays when they are first launched from the source. However, after the first bounce, they will interact with SBR+ rays just like any other surfaces in the scattering geometry (with some further qualification, described shortly). For example, to capture reduced reflector antenna gain due to blockage by the feed horn, you may select the elements representing the body of the horn under Blockage Selection. In some cases, the antenna structure may be too detailed to effectively interact with SBR+ rays, recognizing that ray-tracing is a high-frequency (short wavelength) approximation. In those situations, one may instead create a simplified blocking structure, such as a rectangular or circular plate, to stand in for the physical antenna structure. To do this, create the simplified blocking structure as one or more non-model objects in the source design and then select them under Blockage Selection, configuring them as either Perfect Conductor or Perfect Absorber.

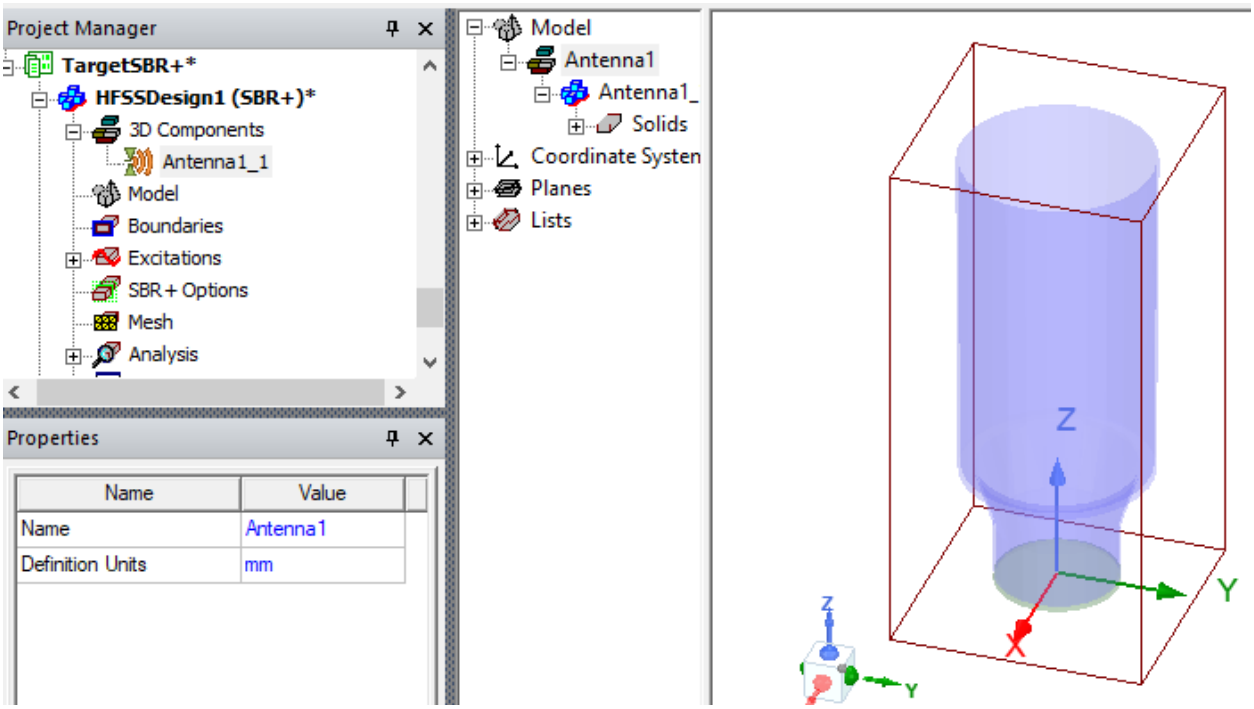
The behavior of model and non-model objects selected under Blockage Selection have some further qualifications in the context of SBR+ with multiple source antennas. Suppose there are two antennas A and B, and both have Model Blockage objects selected, designated as S_A and S_B, respectively. S_A will be invisible to first-bounce SBR+ rays launched from antenna A, and then become visible on subsequent bounces. However, S_B will always be visible to SBR+ rays launched from antenna A, even on the first bounce. A related point is that when rays hit S_A, they will generate scattered fields to every antenna accept to antenna A. Likewise, when rays hit S_B, they generate scattered fields to every antenna accept to antenna B.

8. The **Visualization** tab lets you specify how the linked model is displayed in the SBR+ target design.

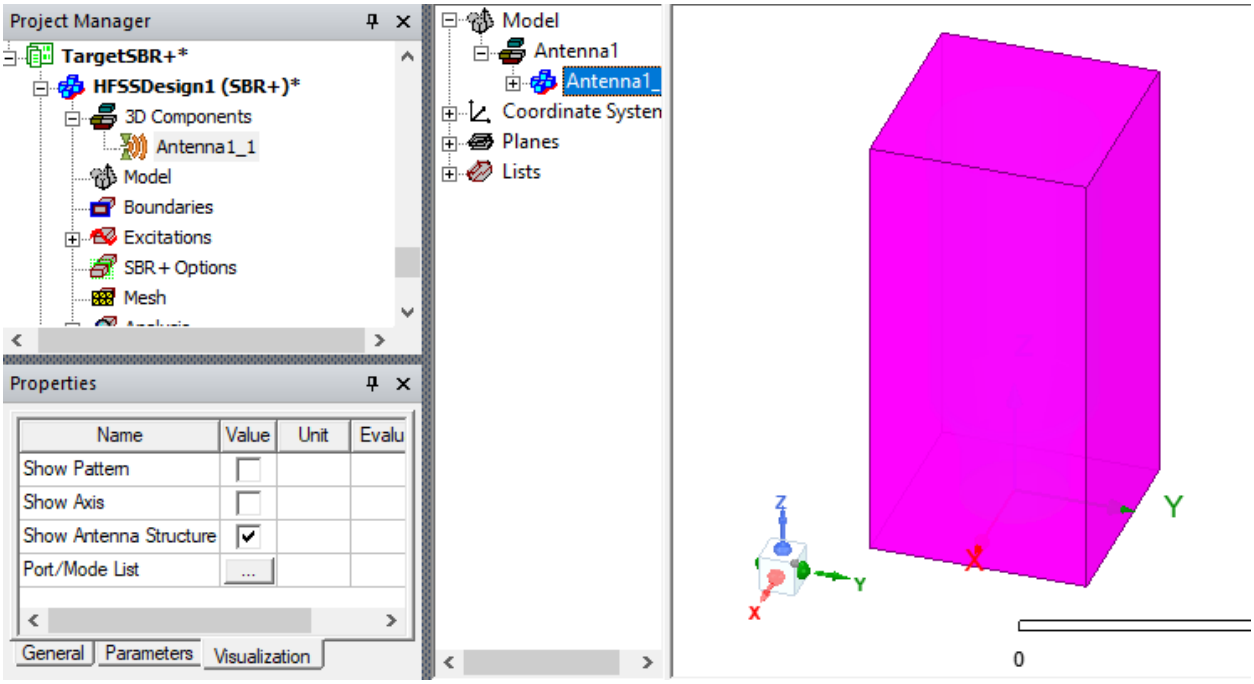


For example:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

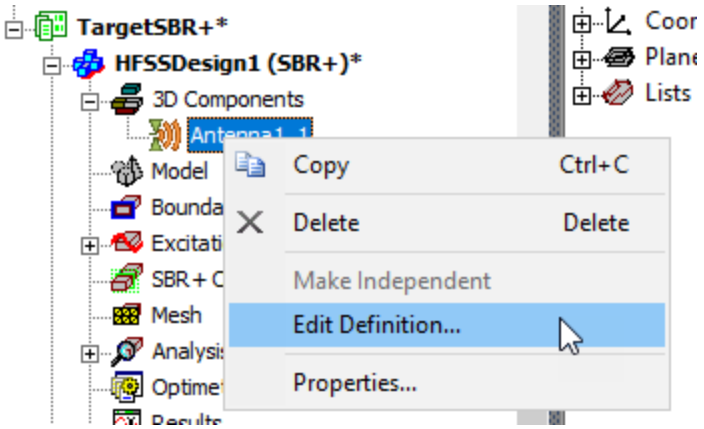


Selecting the linked 3D Component also provides a **Visualization** tab in the properties with additional control over how a linked project displays in the SBR+ target design.



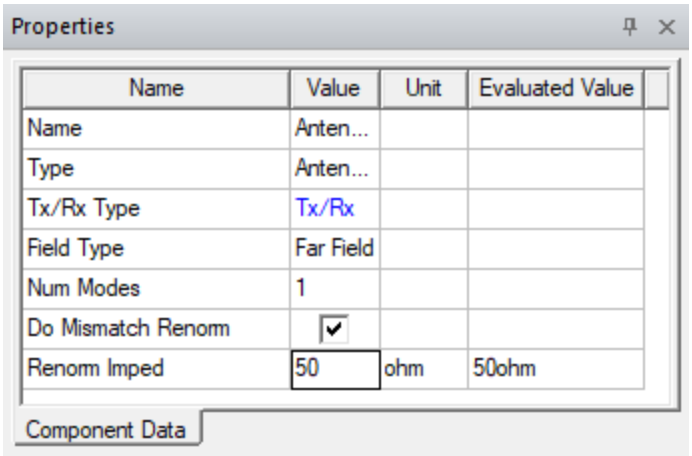
You can also gain access to the Setup Link **Visualization** tab by Editing the definition of the 3D Component.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



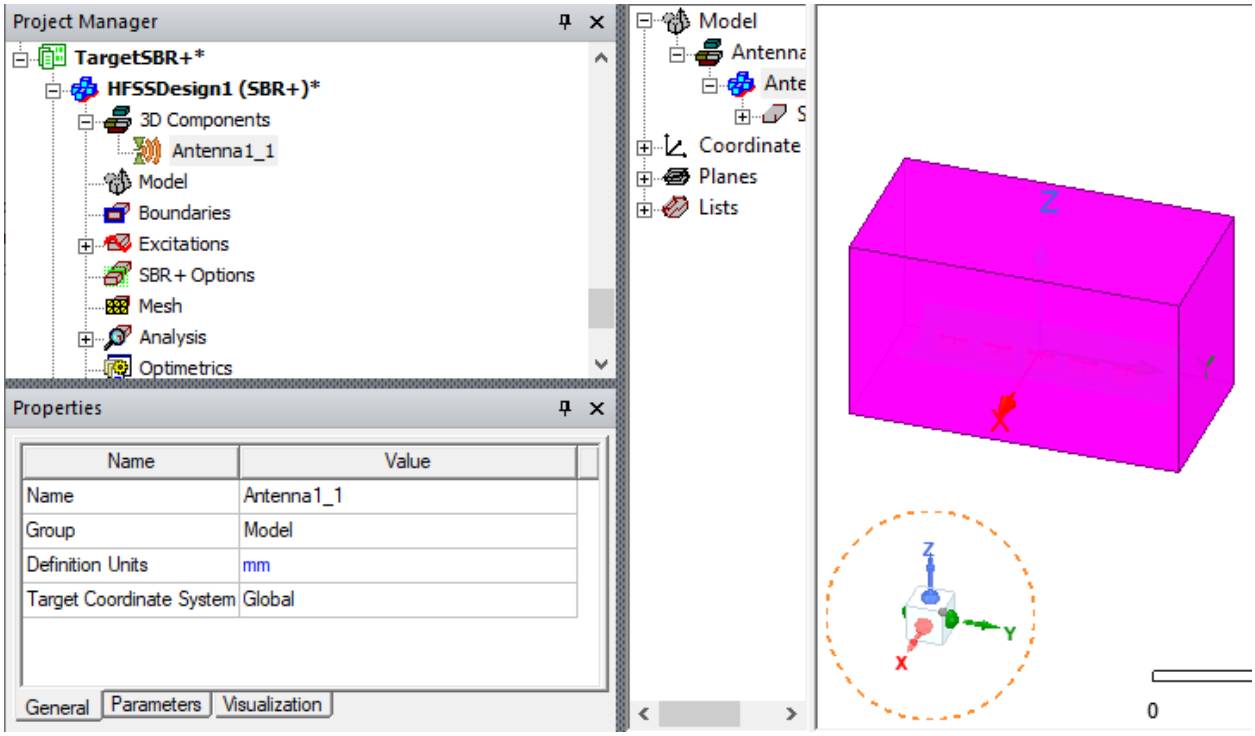
This opens the **Setup Link: General** window, where you can click the **Setup Link...** button.

9. Click **OK** to finish importing a linked antenna to the target SBR+ Design. The target design displays the linked antenna as a 3D Model in the Project tree and in the Model window as a model based on how you specify the visualization.
10. Ports appear in the **Project** tree under **Excitations**. If you right click on the **Excitations** icon, you can view and edit Tx/Rx selection for all fields, including coupling between ports within the same antenna and self coupling. The properties for each excitation shows the current Tx/Rx type. If you select do **Mismatch Renorm**, an editable **Renorm Imped** property appears which lets you Renormalize linked ports.

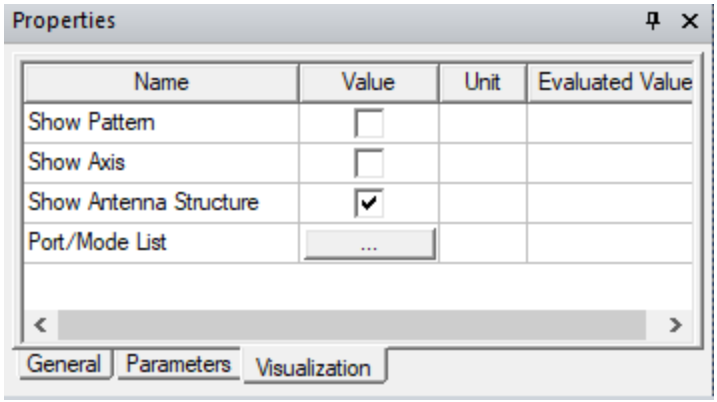


11. Select the 3D Component for the source antenna in the target **Project** tree to view the properties.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

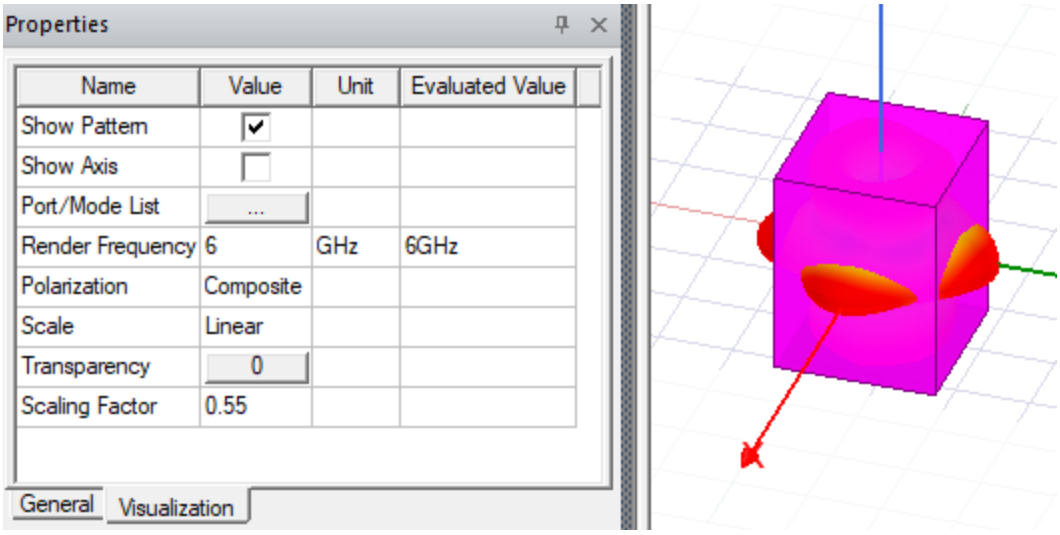


If you select the **Visualization** tab, you see the following properties.

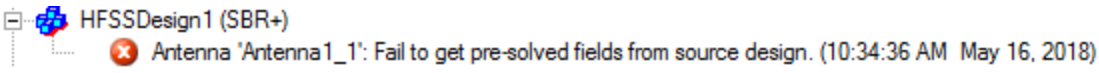


If you have previously solved the source design, and correctly assigned valid phase centers, you can check **Show Pattern**, and see additional display properties. The antenna pattern is computed and displayed in the bounding box in the Model window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

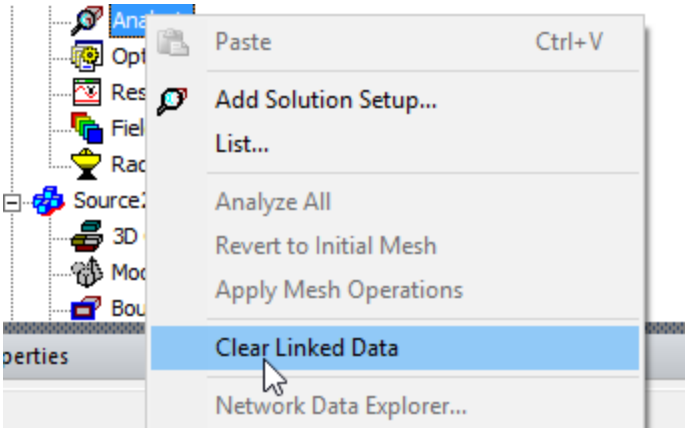


If the source design has not been solved, the **Message** window will display an error message.



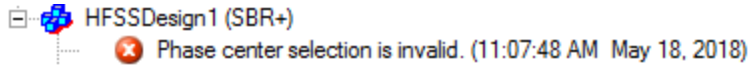
If you update the source design, the **Clear Linked Data** command becomes available for you to clear the cached data.

If you clear the linked data, the field pattern is re-computed when you check **Show Pattern** again.

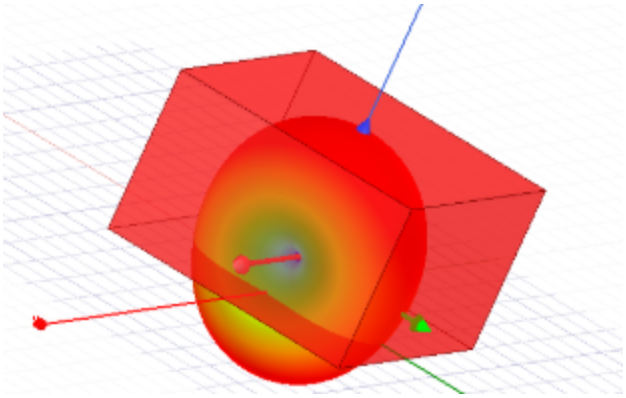


If you made changes to the source design that conflict with the link or phase center configuration, an error message is displayed.

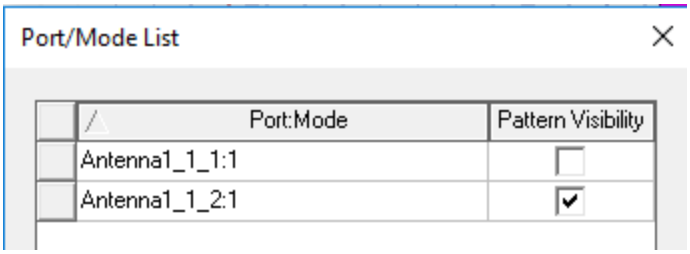
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If you check the **Show Axis** property, the phase center axis is shown at the antenna pattern.

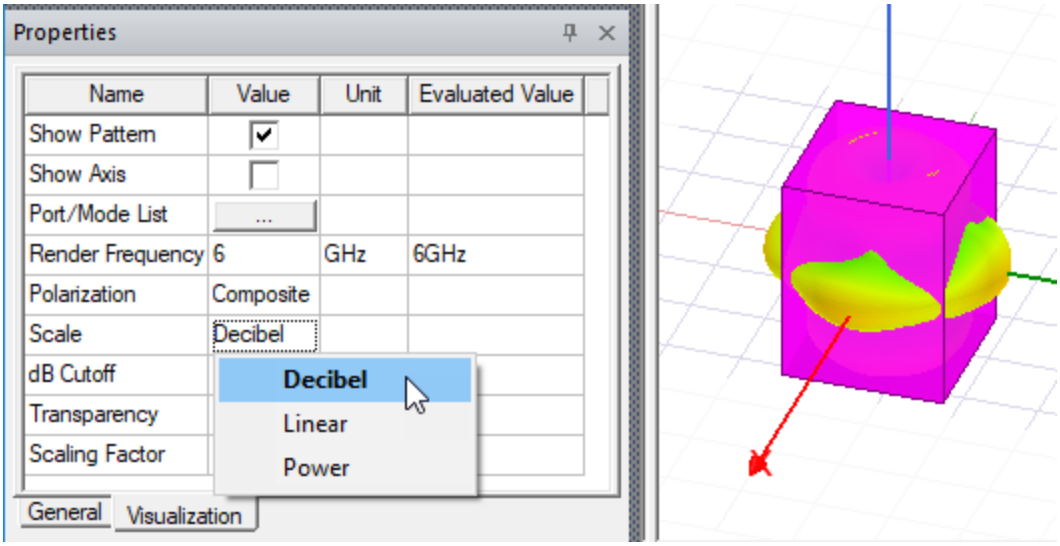


The **Port/Mode List** is available unless the source design is driven modal composite. If you click the ellipsis [...] button for **Port/Mode List** on the **Visualization** tab properties, a dialog displays that lets you select which ports to show:

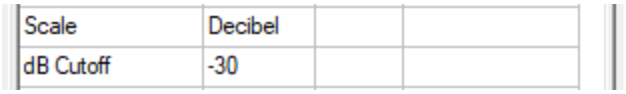


The **Scale** property can be Decible, Linear, or Power.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If you select Decibel, an additional property for dB Cutoff appears.

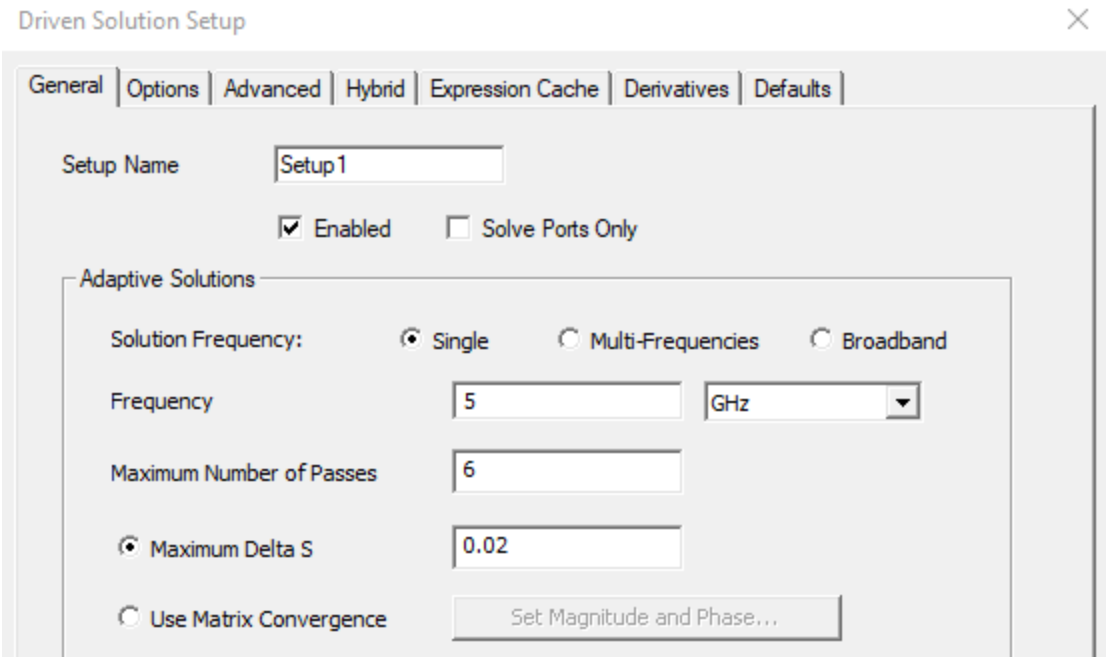


Simulation Setup for Driven Modal Antenna to SBR+ Design Link

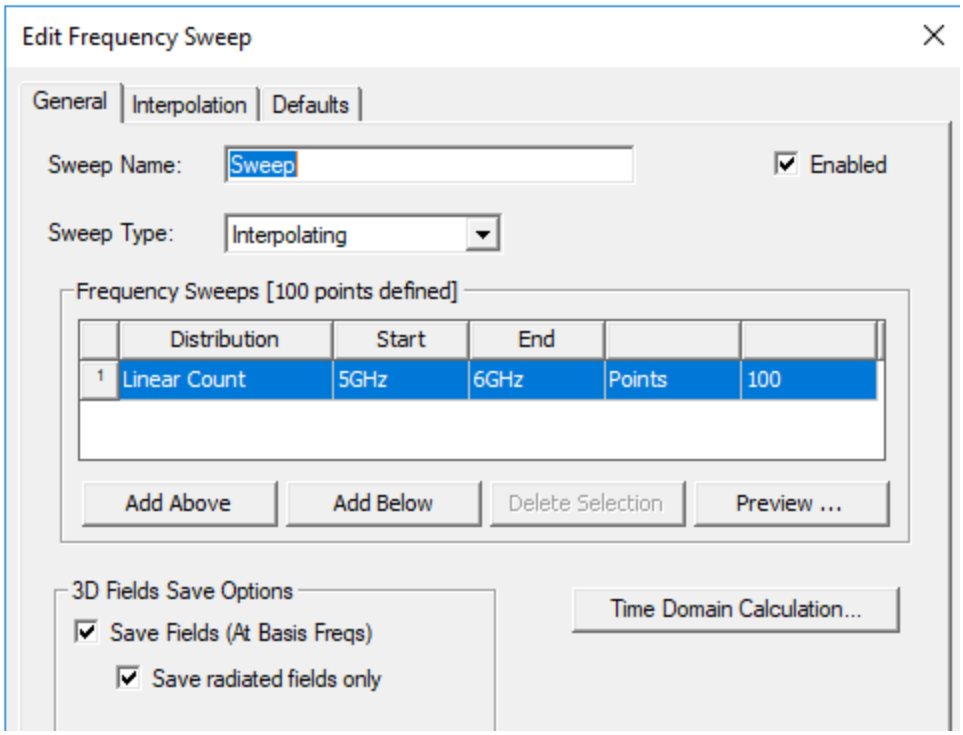
Once you have configured the SBR+ design with a Linked Antenna, you set up a model object and **Solution Setup**. The simulation frequencies in target design must fall in the range of the source design frequencies. Below is an example of source design setting and target design setting, using compatible frequencies. and Save Far fields so that Gain can be plotted.

Example Source Design Setup

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



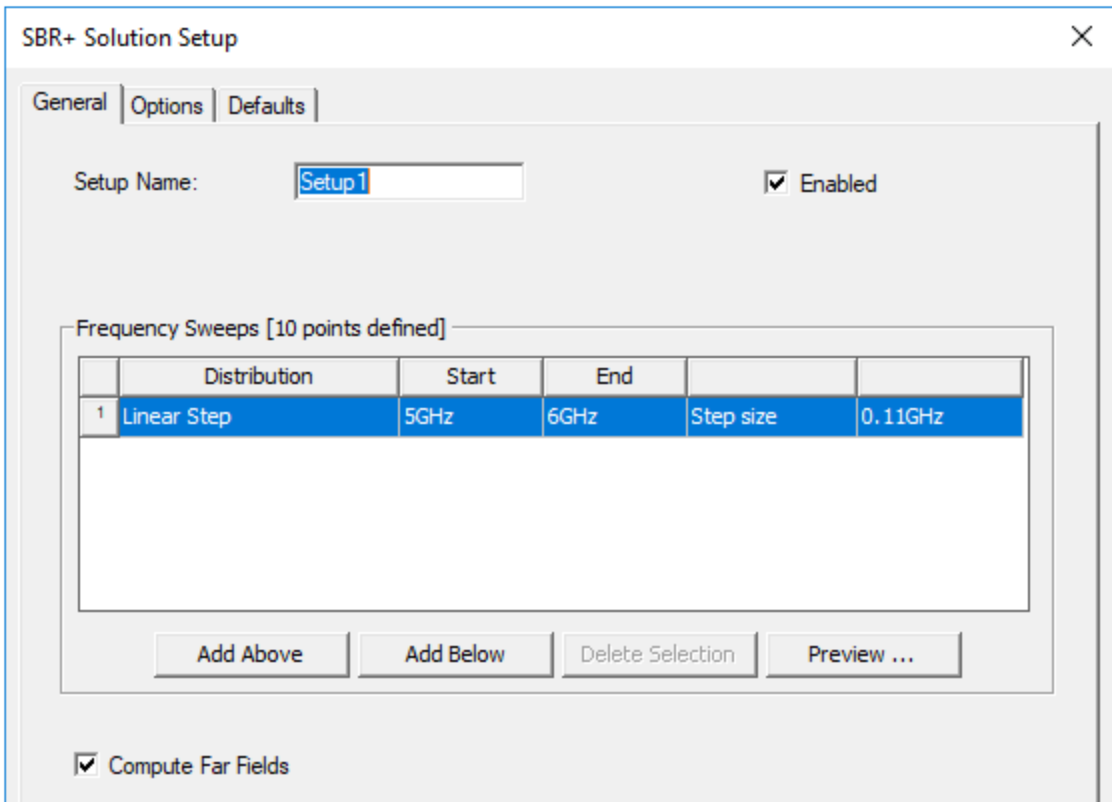
Source Design Frequency Sweep



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The sweep will be selectable in the Source link, and the **3D Fields Save Options** permit the Target SRB+ design to compute far fields and plot gain.

Example Target Design Solution Setup

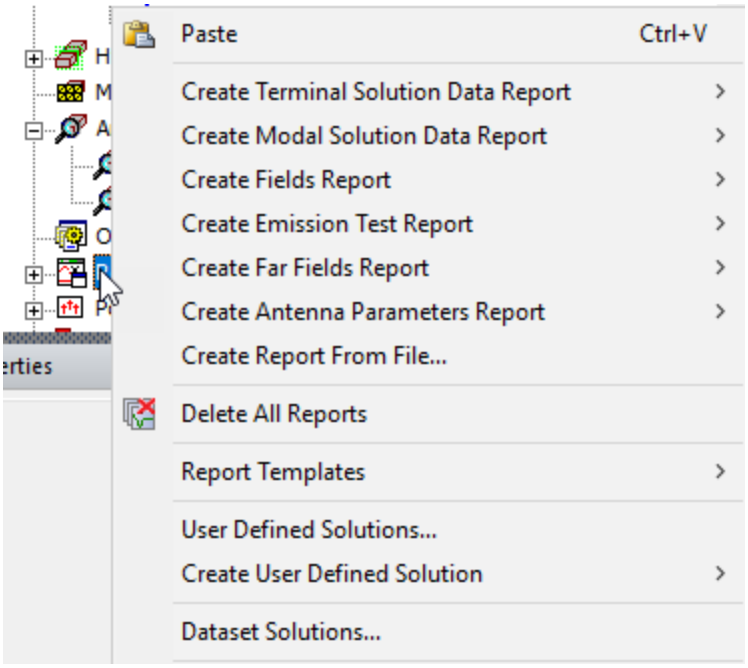


Compute Far fields is so that a Gain Report can be plotted based on the fields saved from an interpolating sweep in the linked source design..

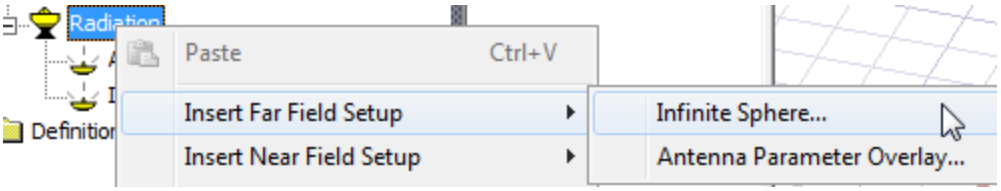
Viewing Results in the SBR+ Simulation

After you run an SBR+ simulation with linked Model antenna, you can create a variety of reports, including S Parameters, Far Fields, Gain, and Antenna Parameters.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You must create a Far Field Setup to access the Far Fields and Antenna Parameters reports.

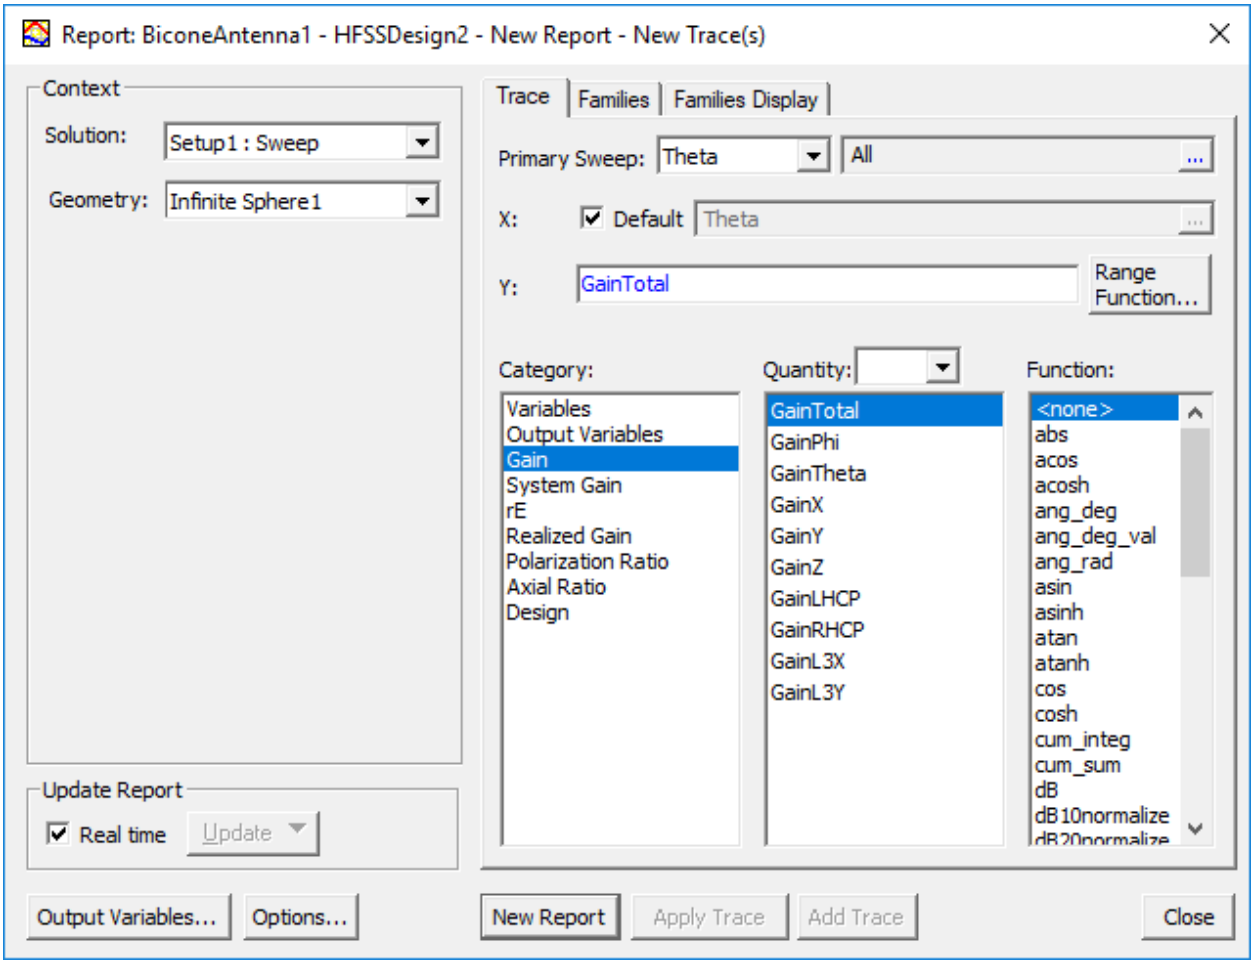


When a driven modal or driven terminal antenna is linked to an SBR+ target, an additional SBR+ power loss is considered for radiated power calculation. See *Technical Notes*: Radiated Power.

Requirements for Creating a Gain Report for SBR+ Design with Driven Modal or Terminal Source

If you have created an Infinite Sphere, solved an Interpolating Frequency sweep in the Source design and saved the 3D fields, and selected Compute Far Fields in the Source setup, you can create a Gain Report.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Select Tx/Rx Antennas for SBR+ Solutions

The SBR+ solution type allows you to create parametric antennas for a streamlined workflow in Ansys Electronics Desktop HFSS, which helps support ADAS and other similar application areas with large scene models. To allow for more efficient simulations, SBR+ Tx/Rx Antenna Selection lets you specify how each antenna is to be used in the simulation, as either Transmit, Receive, Transmit and Receive, or Off (Tx, Rx, Tx/Rx, or Off). This can dramatically reduce the number of antenna-to-antenna coupling pairs that must be simulated for a given scenario using SBR+ so that full NxN coupling analysis is not required. Even though SBR+ can handle these larger scene models more efficiently than some other approaches, if you select the specific Tx-Rx roles for each antenna you can obtain dramatically shorter runtimes because each transmitting antenna requires a separate ray trace. Near field Analysis for SBR+ Solutions is available if you specify Tx or Rx/Tx roles.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

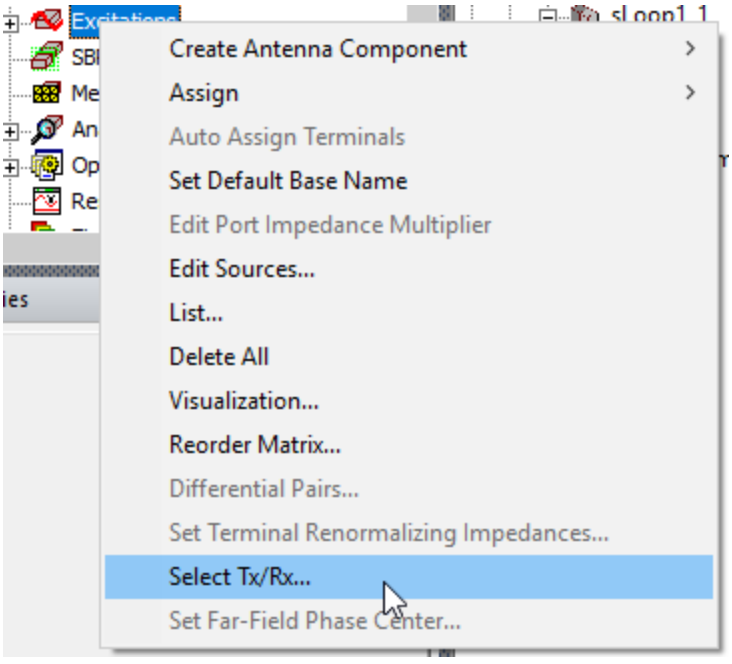
When antenna are assigned NxN full coupling among all sources as in all previous SBR+ region applications, HFSS SBR+ averages the values of cross coupling S matrix terms Smn and Snm to force them to be the same. When all antenna are assigned to TxRx, Smn and Snm might not be both available in the final solution. As a result, when the TxRx feature is assigned, such averaging is performed only when HFSS SBR+ detects that both Smn and Snm are present.

Prerequisites

- SBR+ Solution Type
- Parametric Antenna Components

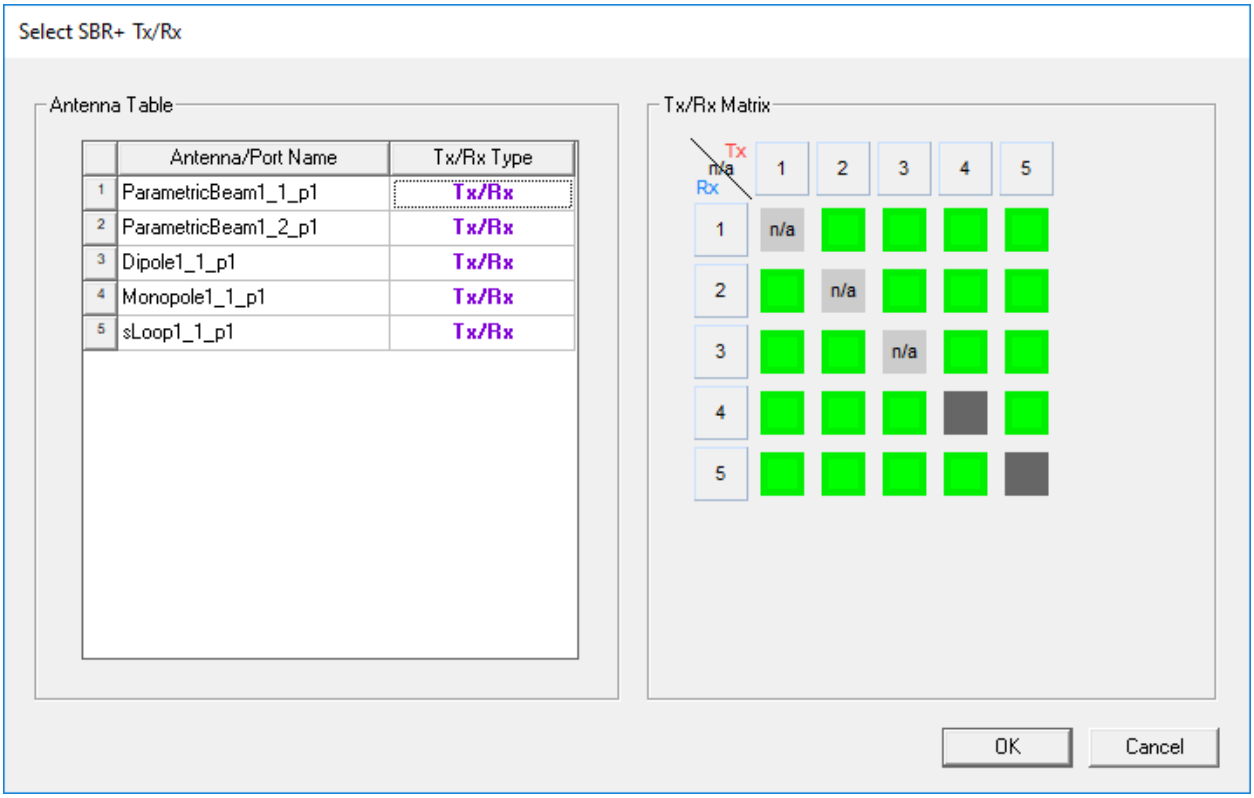
To Assign Transmit and Receive Assignments for Antennas in SBR+

1. Right-click the **Excitations** icon in the Project tree, and click, **Select Tx/Rx...** or click **HFSS>Excitations>Select Tx/Rx...**



This opens the **Select SBR+ Tx/Rx** dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The left panel contains the list of all available antennas/ports available and their configured Tx/Rx Types, and the right panel contains the matrix (the S-param matrix) of active/inactive indicators for each transmit/receive (tx/rx) pair configured for the simulation. You can resize the dialog both horizontally and vertically to show more antennas in the list and more cells in the matrix. Scrollbars appear for both the table and the matrix if there are too many antennas/ports to fit in the dialog size.

Default types are set to “Tx/Rx” for all antennas/ports, with all Tx/Rx matrix cells set to active. This corresponds to a full NxN coupling configuration. If you want full NxN coupling for an SBR+ simulation there is no need to open or configure the Tx/Rx Selection settings.

Beta Feature HFSS Interactive Dialogues. If you enable this feature, you can edit the design outside the **Select Tx/Rx** dialog, and the dialog will update. The supported edits include:

Antenna Table Updates:

- New source is created: added to the last row of antenna table. Default Tx/Rx type is “Tx/Rx”.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

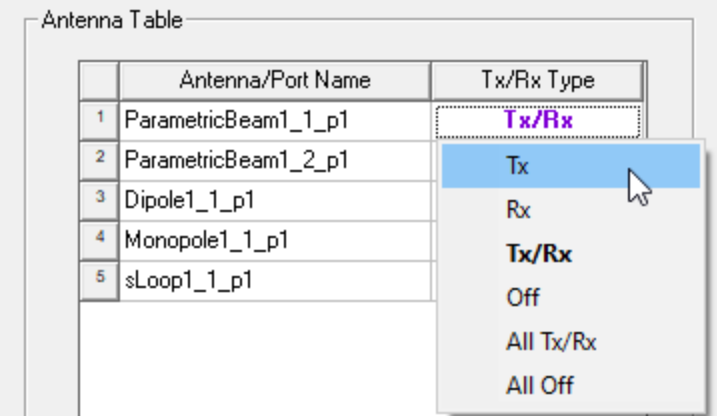
- Sources are deleted: remaining sources retain the original order on the table, with deleted sources removed.
- Source name changes: corresponding source name on the table updates to the new name.

Tx/Rx Matrix Update

- New source is created: a new row and column will be added to the matrix. Depending on the number of Tx and Rx channels in the matrix, the number of buttons added to the matrix will adjust itself to form the new matrix. Default button state is on, except the buttons that have the same source of Tx and Rx.
- Sources are deleted: corresponding Tx and Rx of those sources in the matrix are deleted.
- Source Tx/Rx type changes: row and column visibility updates based on the change of Tx/Rx matrix.

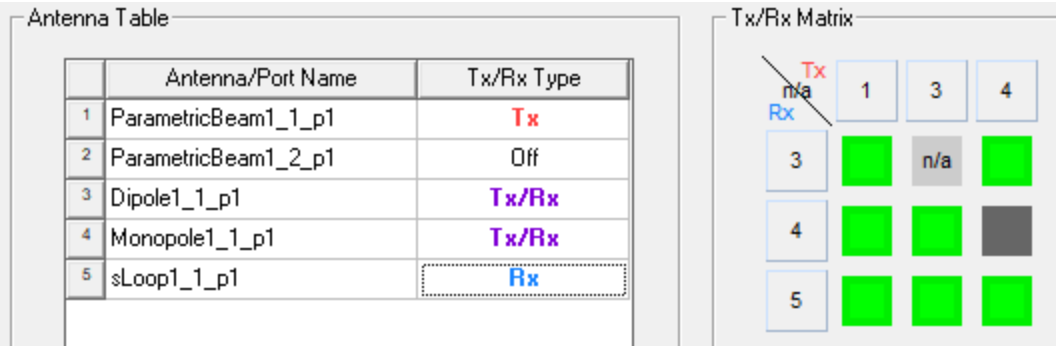
Note: The dialog supports undo and redo for creating, deleting and renaming elements. After undo/redo, added elements will recover to default Tx/Rx type and button state.

2. For the Antennas table, you can assign each antenna/port a type of **Tx**, **Rx**, **Tx/Rx**, or **Off**. This is done via a drop-down menu selection on the table cells under the **Tx/Rx Type** column. For convenience, the selection list includes **All Tx/Rx** and **All Off** selections.



The text color changes with the Tx/Rx Type selection as follows: Tx = red, Rx = blue, Tx/Rx = purple, Off = black.

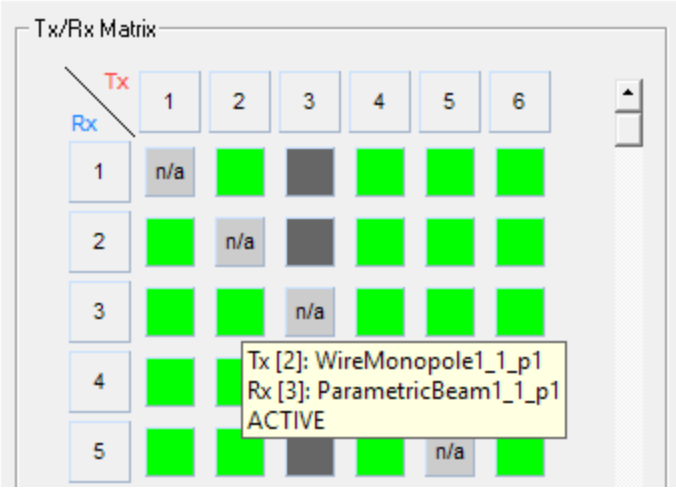
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Tx/Rx Type** also determines which rows and columns are displayed in the **Tx/Rx Matrix** panel on the right. Transmit antennas appear as columns across the top (notice the red Tx label), and receive antennas appear as rows down the left side (notice the blue Rx label), just as shown in the S-parameters matrix (available under Results>Matrix Data). If you set the type to **Tx**, an antenna/port will only show its **Tx** column in the matrix, and the **Rx** row has all its cells set to inactive and is not shown. Similarly if you set the type to **Rx**, the **Tx** column for that antenna/port in the matrix has all its cells set to inactive and hidden.

Antenna rows/columns are numbered to match those used in the table on the left. The order of both corresponds to the order of the antennas/ports in the output data, and may be different than the alphabetical order shown in the project tree under the **Excitations** folder.

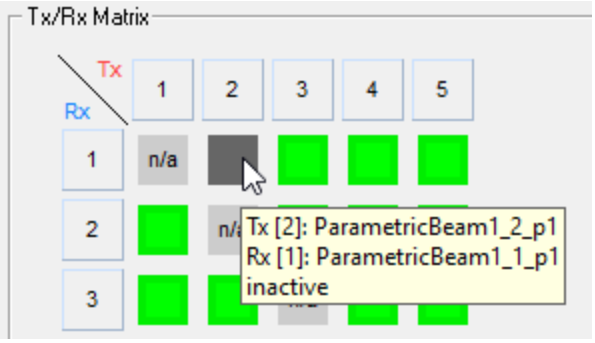
In the **Tx/Rx** matrix, tooltips are shown when the mouse is hovered over any cell in the matrix to show the corresponding antenna/port names and active/inactive status.



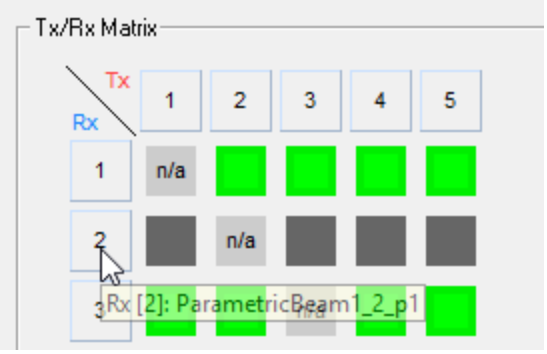
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A green indicator means this Tx/Rx combination is active and the SBR+ simulation compute results for the interactions between this antenna port pair; dark grey means it is inactive for the simulation. Any self-coupling cells are marked with "n/a" as not applicable for the SBR+ solution type and may not be modified, which includes the diagonal matrix cells as well as any self-coupling cells for multi-port antennas.

3. To toggle a Tx/Rx combination as active/inactive simply click on the corresponding cell in the matrix. The color will toggle between green (ACTIVE) and dark grey (inactive).



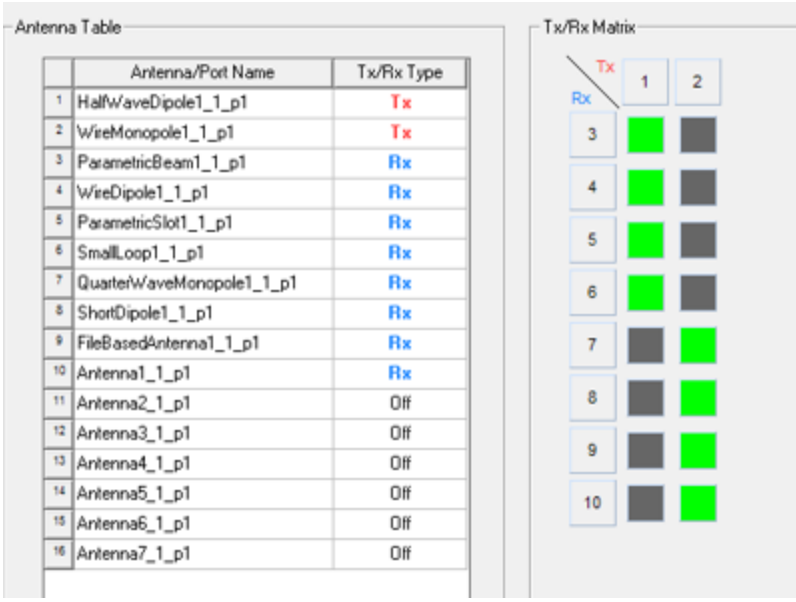
4. To toggle an entire Tx column or Rx row, click one of the numbered header cells. Clicking a Tx column has the effect of turning this Tx either on or off to all receivers, and likewise, clicking an Rx row has the effect of turning this Rx on or off to all transmitters.



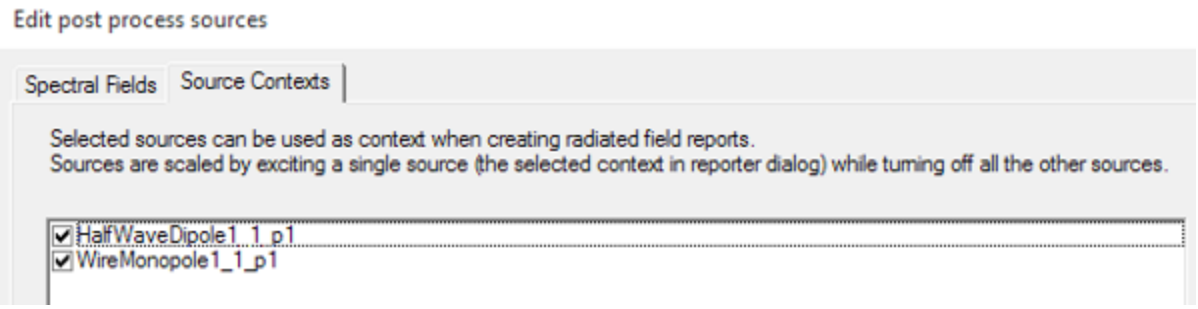
> **Note:**
>
> Turning an entire row or column off (making it inactive) achieves a similar end to specifying an antenna as either **Tx** only or **Rx** only.

The **Tx/Rx** roles you select in the SBR+ **Tx/Rx Selection** dialog can impact the post-processing sources available for the simulation. For example, suppose you configure an antenna/port to be **Rx** or **Off**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

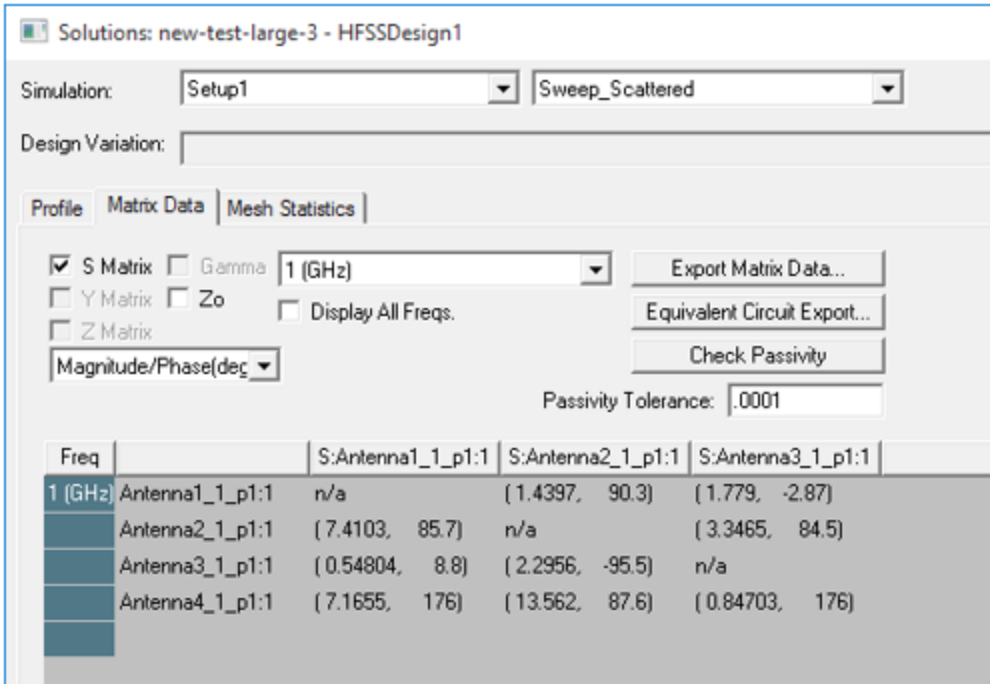


Then that item will not be available as a post-processing source context under Edit Sources. Only **Tx** or **Tx/Rx** antennas/ports will appear on the **Source Contexts** tab, since those are the only antennas/ports configured to produce radiating fields (ie, transmitting).

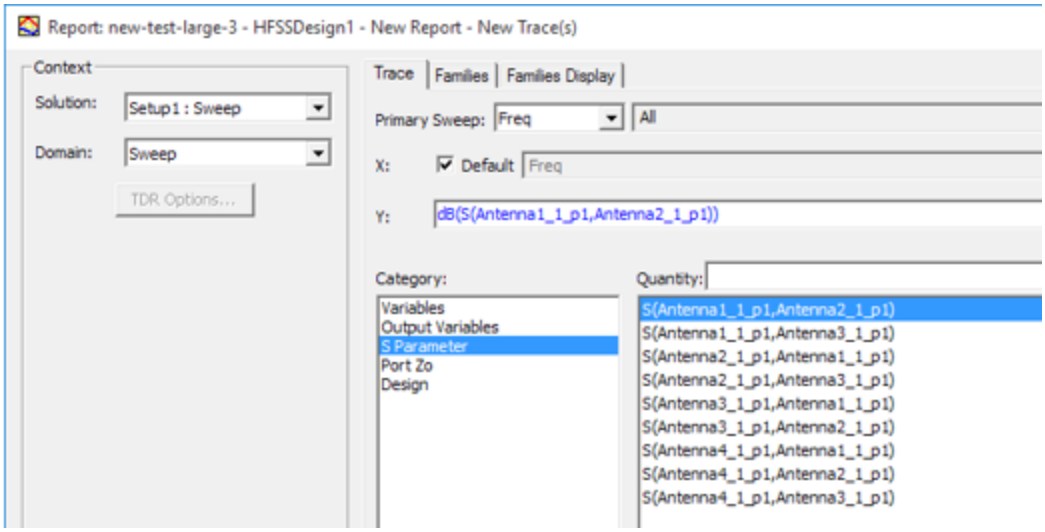


5. Upon completion of the simulation, the results in the S-parameter matrix data display will correspond directly to the Tx/Rx Matrix configuration, with simulation results only computed for ACTIVE (green) cells. All other inactive and "n/a" cells will show "n/a" results for those same entries in the S-parameter matrix since no SBR+ simulation data was computed for those coupling pairs.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



6. In the **Create Report** dialog box, you see only the active Tx/Rx coupling pairs listed as the available report quantities, not the full list of NxN coupling matrix pairs (unless configured as full NxN coupling).



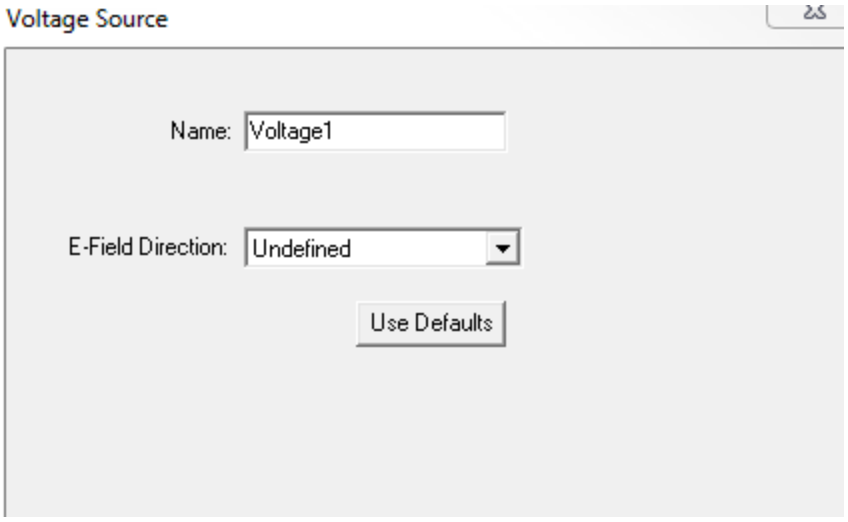
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Assigning Voltage Sources

A voltage source in HFSS can be defined on a surface located anywhere in the 3D problem space. Typically the source is placed on a surface between two conductors such that a user defined total voltage is maintained between the conductors. Voltage source is used when the feed structure is very small compared to the wavelength and a constant electric field may be assumed across the feed points; in this case, HFSS assigns a constant electric field across the gap on which you specified the voltage.

> **Note:**
>
> For more information, see Voltage Source in **Technical Notes**.

1. Select the object face to which you want to assign the voltage source, and click **HFSS>Excitations>Assign>Voltage** to display the **Voltage Source** dialog box.



2. Specify the direction of the electric field by drawing a vector.

   When the source is selected, an arrow indicates the direction and a letter v indicates the type of source.

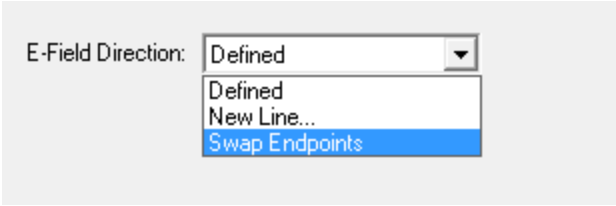
   > **Note:**
   >
   > For Transient Solution types, you also designate sources as Active and Passive.

Port sources are created and solved with unit magnitude and 0 degree phase. They can be scaled within the Edit Sources dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

The **E-field** direction can be reversed from the **Voltage Source** dialog box.



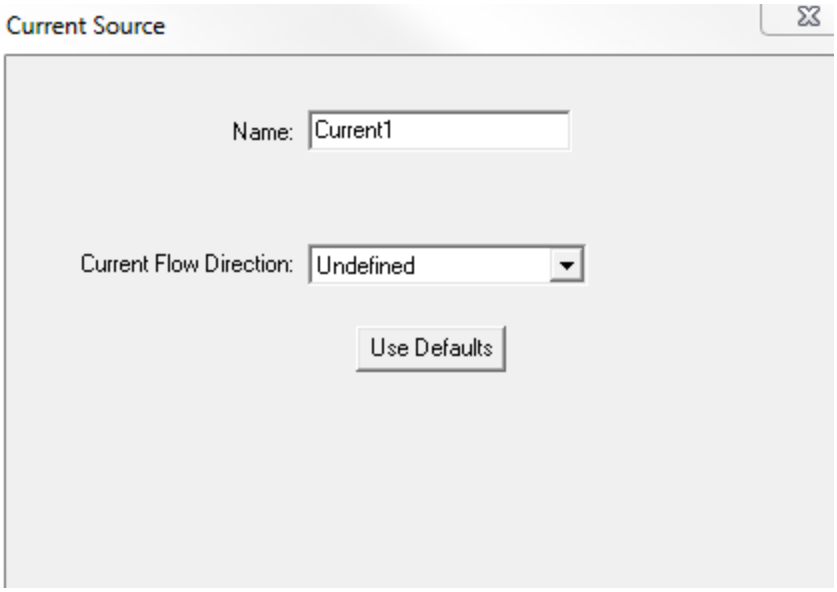
Assigning Current Sources

Assign a current source when you want to define the direction of the current flow through a surface. A current source is used when the feed structure is very small compared to the wavelength and the electric current on the surface is assumed to be constant across the feed points.

Note:

For more information, see Current Sources in **Technical Notes**.

1. Select the object face to which you want to assign the current source and click **HFSS>Excitations>Assign>Current** to display the **Current Source** dialog box.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Specify the current flow direction by drawing a vector:

   When the source is selected, an arrow indicates the direction and a letter i indicates the type of source.

3. For Transient Solution types., you also designate sources as Active and Passive.

Port sources are created and solved with unit magnitude and 0 degree phase. They can be scaled within the Edit Sources dialog.

Modifying Voltage or Current Sources

To change the name, value, or electric field direction of an assigned voltage/current source:

1. Double-click the source's icon under **Excitations** in the project tree.

   The **Voltage Source/Current Source** dialog box appears.

2. Edit the name or value of the source.
3. Select **Swap Endpoints** from the **E-Field Direction**/Current Flow Direction drop-down menu to reverse the direction of the e-field/current flow.

   The start and endpoints of the E-field/current flow line are switched; the line's direction is reversed.

Assigning Magnetic Bias Sources

When you create a ferrite material, define the net internal field that biases the ferrite by assigning a magnetic bias source. The bias field aligns the magnetic dipoles in the ferrite, producing a non-zero magnetic moment.

1. Select the 3D ferrite object to which you want to assign the magnetic bias source.
2. Click **HFSS>Excitations>Assign>Magnetic Bias**.
3. Specify whether the applied bias field is **Uniform** or **Non-uniform**.

   If a design already contains a magnetic bias field, you cannot assign another of a different type. If a single bias field exists in a design, you can edit the type.

4. If you selected the **Uniform** radio button, click **Next** and do the following:
   a. In the **Internal Bias** field, type the value of the ferrite in amperes/meters. You can assign a variable as this value.
   b. Enter the rotation of the permeability tensor with respect to the xyz-coordinate system in the **X Angle**, **Y Angle**, and **Z Angle** boxes. You can assign variables to these values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you selected **Non-uniform**, select the **Setup Link...** button to display the **Setup Link** dialog box. Under the **General** tab, do the following:

a. Select the radio button for **Extractor Mode** (the default) or **Interactive Mode.** Note that in **Extractor mode**, the source project will be saved upon exit. **Extractor mode** means that the software is opened during the link solely for the purpose of solving. Selecting **Interactive Mode** launches Maxwell.

(If you open the **Setup** dialog for a pre-existing Magnetic Bias source, the **General** tab shows radio buttons for **View Only** and **Edit Link**. With **View Only** selected (the default), all of the link settings are unavailable. Selecting **Edit Link** enables the fields and changes the radio buttons to **Extractor Mode** and **Interactive Mode**.)

b. Type the name of a Maxwell 3D Field Simulator project in the **Project File** box, or click the ellipsis [...] browse button display a file browser to select the project.

HFSS uses the Maxwell 3D project as the source of the non-uniform magnetostatic field information during solution generation. Linking invokes a Maxwell 3D window to provide the solution for the targeted HFSS project.

c. If there are multiple designs available for the project, you can select from the drop-down menu.
d. If there are multiple solutions available, you can select from the drop-down menu.

The "Default" solution is the product dependent solution of the first Setup.

That is the setup listed first in the source design's project tree (alphanumerical order). A product specific solution of this setup becomes the default solution. In most products, it is LastAdaptive. In a Transient solution type, it is "Transient."

e. Use the radio button to specify whether to save the source path relative to **The project directory of the source project** or **This project**.
f. Use the check box specify whether to **Simulate source design as needed**.
g. Use the check box to specify whether to **preserve the source design solution**. Note that in **Extractor mode**, the source project will be saved upon exit. **Extractor mode** means that the software is opened during the link solely for the purpose of solving.

The **Setup Link** dialog also contains a **Variable Mapping** tab.

It lists variables available within the Maxwell 3D Field Simulator and the value can (and often will) be a variable in the HFSS Setup. You can edit the Value fields by typing, and the Units fields by selecting from a drop-down menu. You can choose to Map Variable By Name. In this case, same named variables have their values mapped automatically. Different named variables are unaffected.

To accept the settings and close the **Setup Link** dialog box, click **OK**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Click **Finish to close the Magnetic Bias wizard**.

   The magnetic bias source is assigned to the selected object. If you have set up a link, HFSS invokes a Maxwell 3D window to provide the solution for the targeted HFSS project.

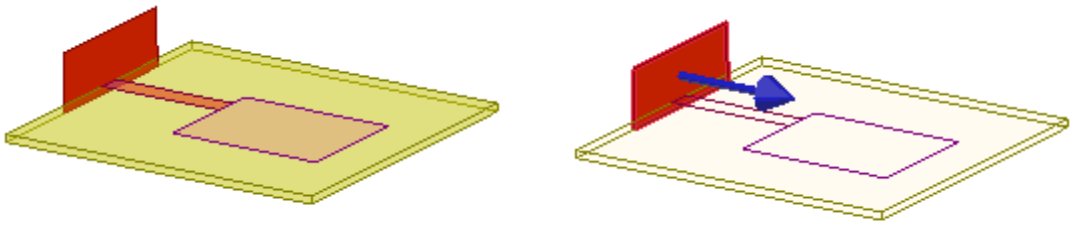
You can also access and edit the magnetic bias source information via the **Properties** dialog for the source. Magnetic bias sources always have the lowest priority compared to boundaries and other excitations in the solver view.

Applications for Deembedding

Deembedding helps to calculate the S-parameters near or on the plane of a discontinuity or when a long transmission line is attached to the port plane instead of explicitly modeling it in HFSS. For lossless ports, when you deembed them into or out of the model, there is change only in the phase of the S-parameters but not in the magnitude. For lossy ports, aside of the change in the phase of the S-parameters, there is only a slight change in the magnitude. Deembedding saves time and significantly reduces the simulation efforts.

Extract Input Impedance: Use Deembedding

This section describes how to extract the input impedance in the microstrip fed patch antenna model shown in the following figure. The port (highlighted in red ink) is placed at an appropriate distance away from the discontinuity. We cannot place the port near the discontinuity (the intersection of the trace and the patch antenna). However, if you want to measure the input impedance at the discontinuity, you can deembed the port as shown by the blue arrow in the figure.



For lossless ports, deembedding will not change the magnitude of the S-parameters. It will only change the phase.

Setup Link Window

Linked data can be a mesh, field results, or some other post-processing data that the source design generated. The possibilities depend on the source and target design and the solution types. The **Setup Link** window permits you to link the current project to another for

- Magnetic Bias source
- Near Field Wave source
- Far Field Wave source
- Initial Mesh source
- Linked Impedance Boundaries in HFSS

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can link HFSS projects. This link is controlled with a "Near Field" or "Far-Field" Incident Wave source that is grouped with the Excitations.

Modifying Excitations

To change the properties of an excitation, do one of the following:

- Double-click the excitation's icon under **Excitations** in the project tree.

  The excitation's properties window appears, in which you can modify its properties.

- Right-click the excitation in the project tree, and then click **Properties** on the shortcut menu.

  The excitation's dialog box appears, in which you can modify its properties.

- On the **HFSS** menu, click **List**.

  The **Design List** dialog box appears. Under the **Excitations** tab, you can modify the properties of one or more boundaries.

The following modifications to an excitation are possible:

- Change its properties.
- Delete it.
- Reassign it to another surface.
- Reprioritize it.
- Hide it from view.
- Show Nets for DC Continuity for 3D Conductors.
- Modify the impedance multiplier.
- Deembed the port.
- Set up Differential Pairs

For HFSS Transient solutions, render it Active or Passive.

> **Note:**
>
> The most common source of errors in simulations are related to defining ports. Examine your ports, their definitions, and inspect problem areas by using the **Zoom to** option. For more information, see Zoom to Selection.

To show or Hide Excitations:

See Setting Boundary and Excitation Visualization Options.

See Show Nets for DC Continuity for 3D Conductors.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Deleting Excitations

To delete *one excitation*:

1. Select the excitation you want to delete by clicking its icon in the project tree.
2. Click **Edit**>**Delete** .

   The excitation is removed from the design and the project tree.

   For terminal solutions, if you delete a port with terminals associated with it, deleting the port also removes the associated terminals.

To delete *all excitations*:

- Click **HFSS**>**Excitations**>**Delete All**.

You can also *delete one or more excitations* in the **Design List** dialog box:

1. Click **HFSS**>**List**.

   The **Design List** dialog box appears.

2. Under the **Excitations** tab, click the row of the excitation you want to delete.
3. Click **Delete**.

Reassigning Excitations

You can reassign an excitation to another surface. This is useful when you have modified objects with assigned excitations, invalidating the excitations. For example, if you unite two objects with assigned excitations, the second object's excitation will become invalid because united objects maintain the characteristics of the first object selected. In this case, you would need to reassign the excitation or delete it. You can use a **Reassign Excitation** dialog accessed through the [*solver*]**>Excitation>Reassign** menu, or right-click the Excitation of interest in the Project tree, and select from the shortcut menu to **Reassign**, **Add to Assignment**, or **Remove from Assignment**. You can also determine a current assignment by right-clicking on the excitation in the **Project** tree and by using the **Select Assignment** command on the short cut menu.

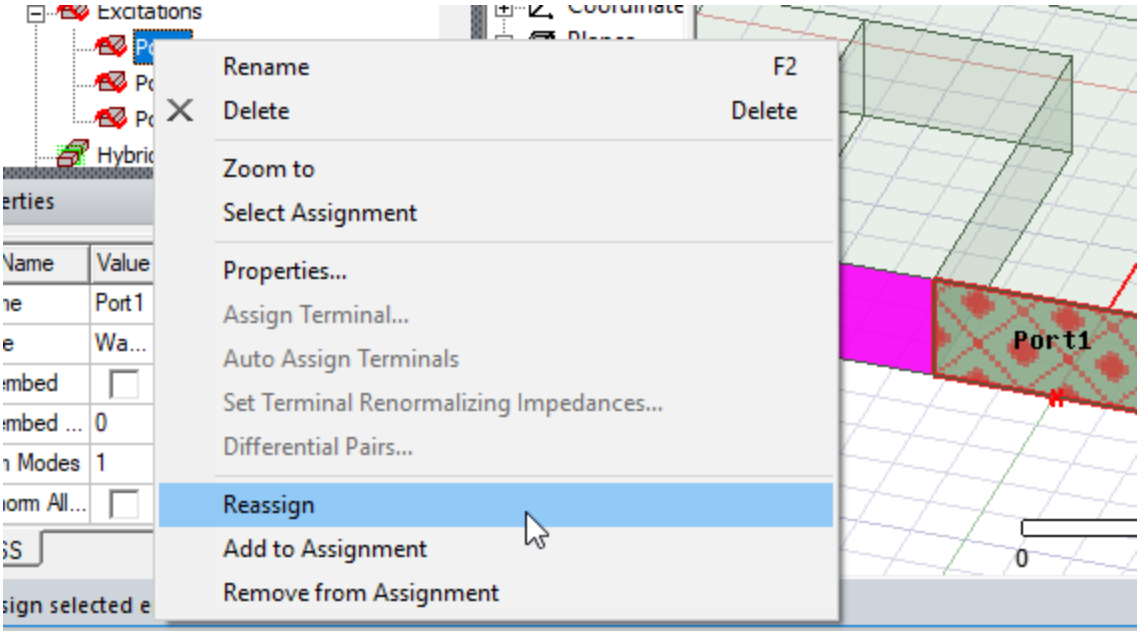
Prerequisites:

- The surface to which you want to **Reassign**, or **Add to Assignment** must be on the same plane as existing assignment. It does not have to be in contact to **Reassign**, but must be in contact to **Add to Assignment**.
- You must first select the surface that you want to reassign or add to an assignment.

To use the short-cut menu to reassign or add an excitation:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. With the target surface selected, right-click the Excitation of interest to invoke the menu.



2. Select **Reassign** to change the assignment to the selected surface, or **Add to Assignment** to include surface.

To use the shortcut menu to Remove a selected surface from an assignment:

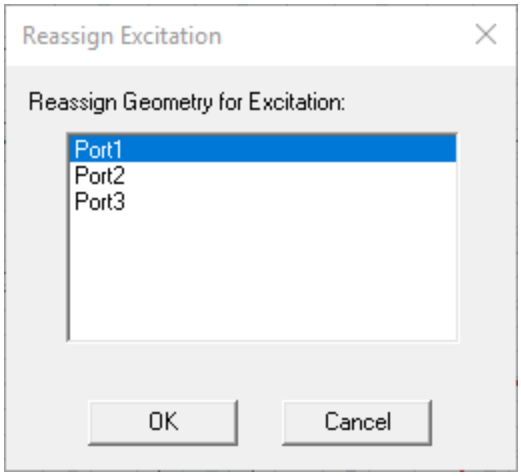
1. With the target surface selected, right-click the Excitation to invoke the menu:
2. Click **Remove from Assignment**.

To use the solver Menu and the **Reassign Excitation** dialog:

1. Select the object or object face to which you want to assign an existing excitation.
2. Click **HFSS>Excitations>Reassign**.

The **Reassign Excitation**window appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Select an existing excitation from the list, and then click **OK**.

The excitation is reassigned to the object or object face.

> **Note:**
>
> When reassigning an excitation that includes vectors in its definition, HFSS attempts to preserve the vectors with the new assignment, but this is not always possible.

Setting the Impedance Multiplier

For designs with ports.

If one or more symmetry planes have been defined or if only a wedge of a structure is modeled, you must adjust the impedance multiplier or the computed impedances will not be for the full structure.

> **Note:**
>
> Changing the impedance multiplier invalidates solutions in projects where lumped ports are defined. In such projects, you need to re-solve the project after the change.

1. Click **HFSS>Excitations>Edit Impedance Multiplier**.

The **Port Impedance Multiplier** dialog box appears.

2. Type a value in the **Impedance Multiplier** box.

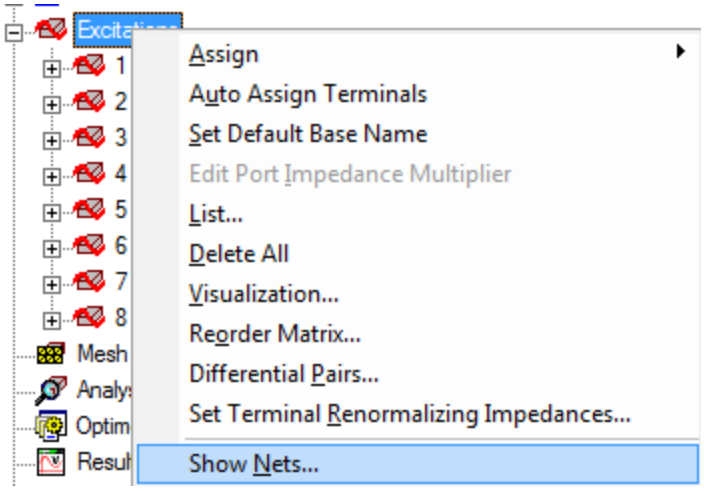
You can assign a variable as this value.

3. Click **OK**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Show Nets for DC Continuity for 3D Conductors

The **Show Nets** command appears in the **HFSS>Excitations** menu and by right-clicking on **Excitations** in the Project tree.



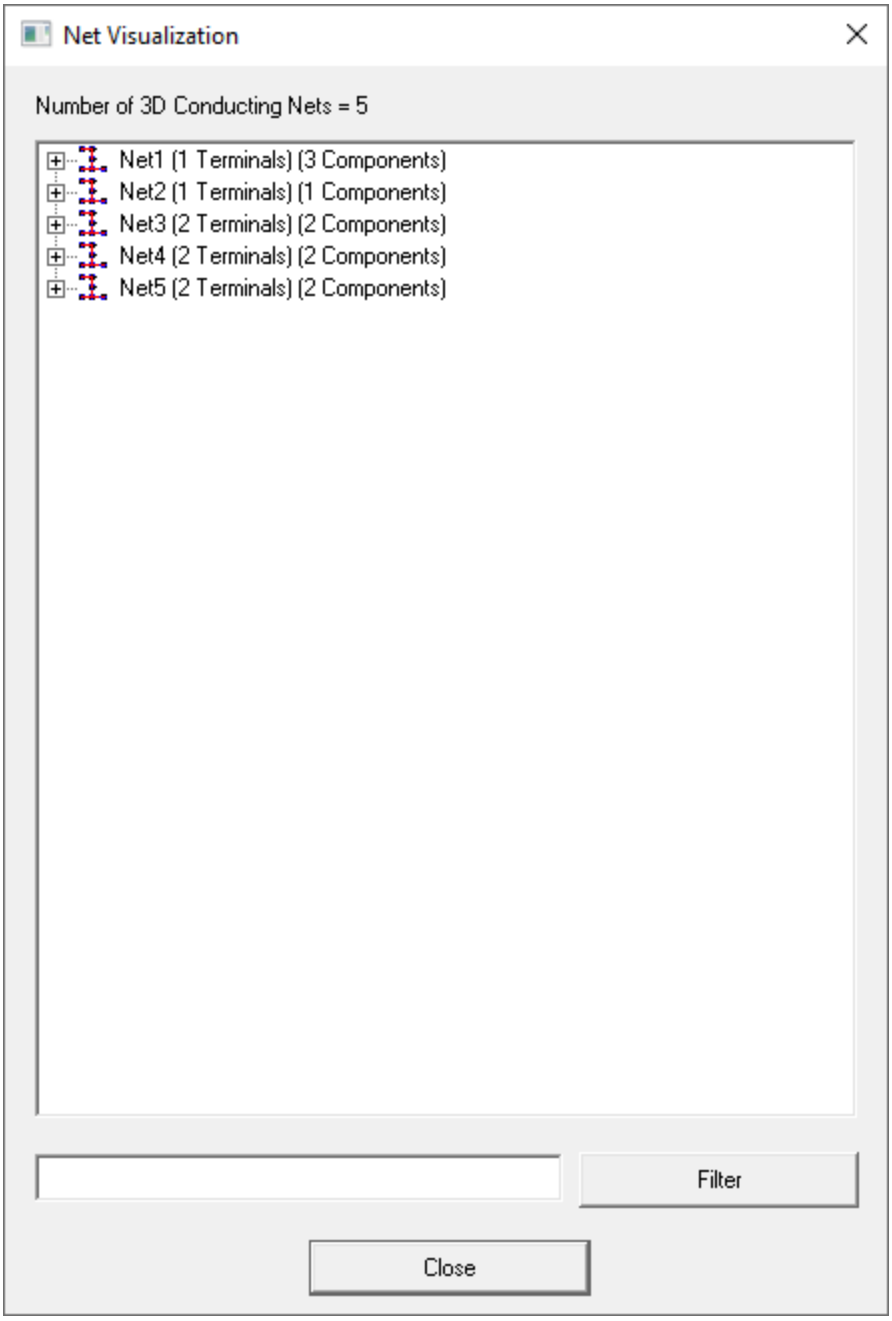
Selecting **Show Nets...** displays the **Net Visualization** dialog that lists the nets and associated terminals. You can use the dialog to select any net or terminal. You can continue to work in the Modeler window with the dialog open.

> **Note:**
>
> For a net to appear in the **Net Visualization** dialog box, the conductivity of the assigned material must be equal to or greater than 20,000 siemens/m, or the **Resistance** must be less than 3.142 ohms. Conductivity is set by material assignment (in the **3D Modeler** window or a boundary condition), and **Resistance** is set by boundary conditions (e.g., **Impedance** or **LumpedRLC**).

In the **Net Visualization** dialog, you can sort the nets in ascending or descending order, relative to the number of terminals. This helps you locate GND nets, which have no terminals.

Text at the top of list box provides the total number 3D Conducting nets. Naming of nets is automatic and follows the convention: "Net1 (0 Terminals)", "Net2 (1 Terminals)"…"Net<N> (<T> Terminals)". Net Names are not editable.

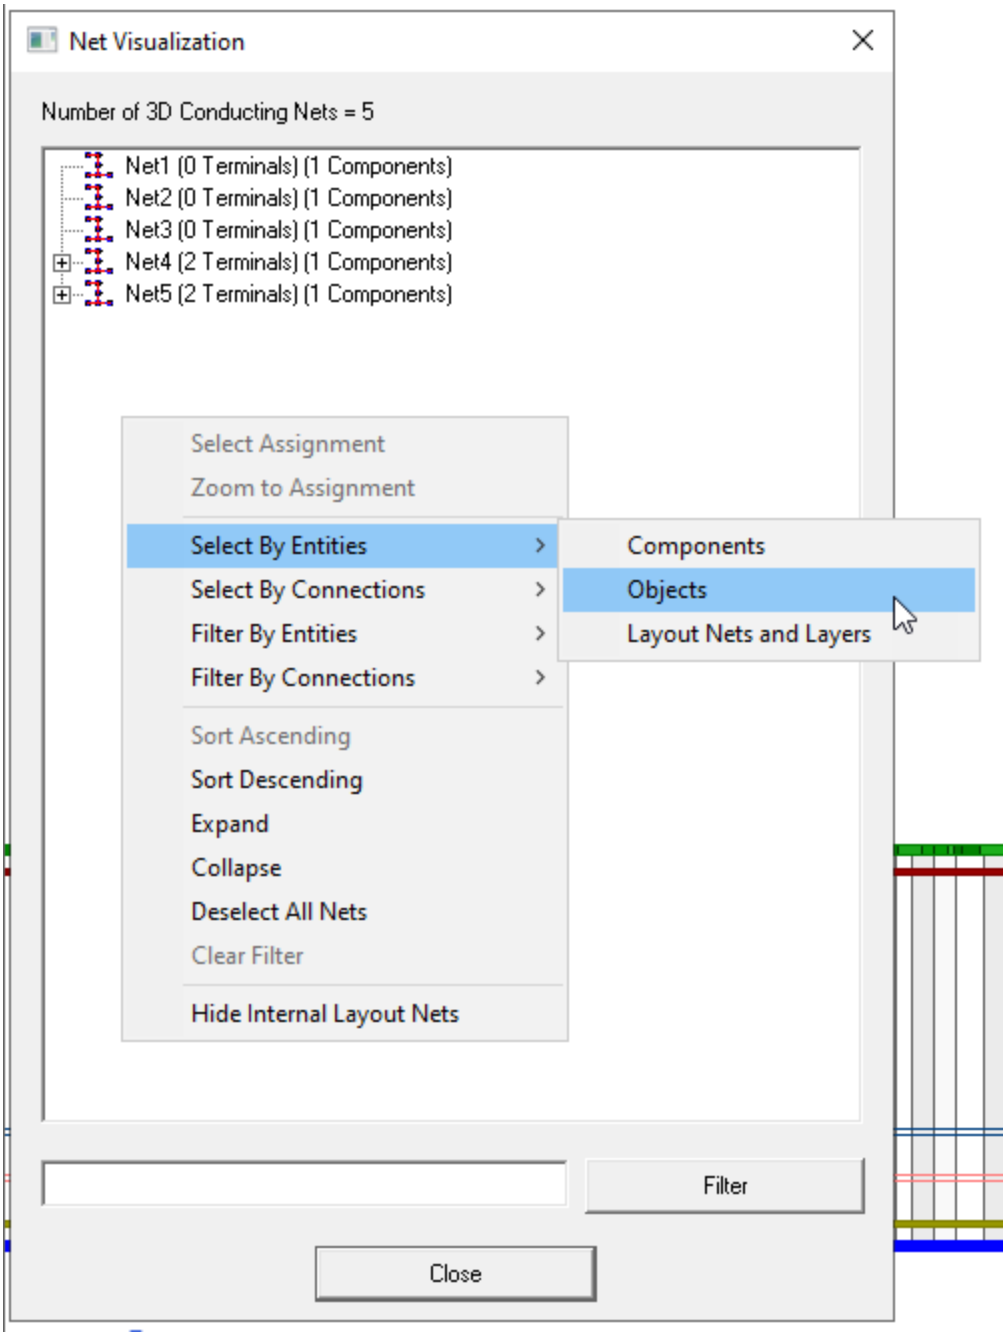
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For designs with many nets, you can enter text and wild cards in the field, and click the Filter button.

Right-click in the **Net Visualization** dialog to view the short-cut menu. The menu is context sensitive, depending on whether you click on a particular net object, or in the white area.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- **Select assignment**: If you right-click over selection in the tree, selects entities present in the selection. If the right click menu is invoked on the surrounding blank space, this menu item is disabled as there is no selection.
- **Zoom to assignment**: If you right click over a selection in the tree, zooms to the entities present in the selection. If you right click menu on the surrounding blank space, this menu

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

item is disabled as there is no selection.

- **Select by entities**: If you right invokes a dialog containing object, component, or net and layer names present in the selection if the right click menu is invoked over some selection in the tree. If the right click menu is invoked on the surrounding blank space, all object or component names present in the project are displayed. Selecting one or multiple of these object or component names selects all the nets which contain any of the selected entities.
- **Select by connections**: If you right click over some selection in the tree this produces a dialog containing object or component names present in the selection . If you right click menu on the surrounding blank space, a dialog with all object or component names present in the project displays. Selecting a pair of these object or component names selects all the nets which contain this pair of entities, signifying a direct or indirect connection between these entities.
- **Filter by entities**: A new dialog is invoked containing object, component, or net and layer names present in the selection if the right click menu is invoked over some selection in the tree. If the right click menu is invoked on the surrounding blank space, all object or component names present in the project are displayed. Selecting one or multiple of these object or component names filters all the nets which contain any of the selected entities.
- **Filter by connections**: A new dialog is invoked containing object or component names present in the selection if the right click menu is invoked over some selection in the tree. If the right click menu is invoked on the surrounding blank space, all object or component names present in the project are displayed. Selecting a pair of these object or component names filters all the nets which contain this pair of entities, signifying a direct or indirect connection between these entities.
- **Sort ascending**: Sorts the nets in ascending order of their names.
- **Sort descending**: Sorts the nets in descending order of their names.
- **Expand**: Expands the selection in the tree if the right click menu is invoked over some selection in the tree. If the right click menu is invoked on the surrounding blank space, menu item expands all the nets.
- **Collapse**: Collapses the selection in the tree if the right click menu is invoked over some selection in the tree. If the right click menu is invoked on the surrounding blank space, menu item collapses all the nets.
- **Deselect All Nets**: Deselects all the entities present in the project. Clears the selection of all the previously selected entities.
- **Clear Filter**: Clears all the filtering applied on nets and shows all the nets.
- **Hide internal layout nets**: Hides all the nets which are internal to layout component

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

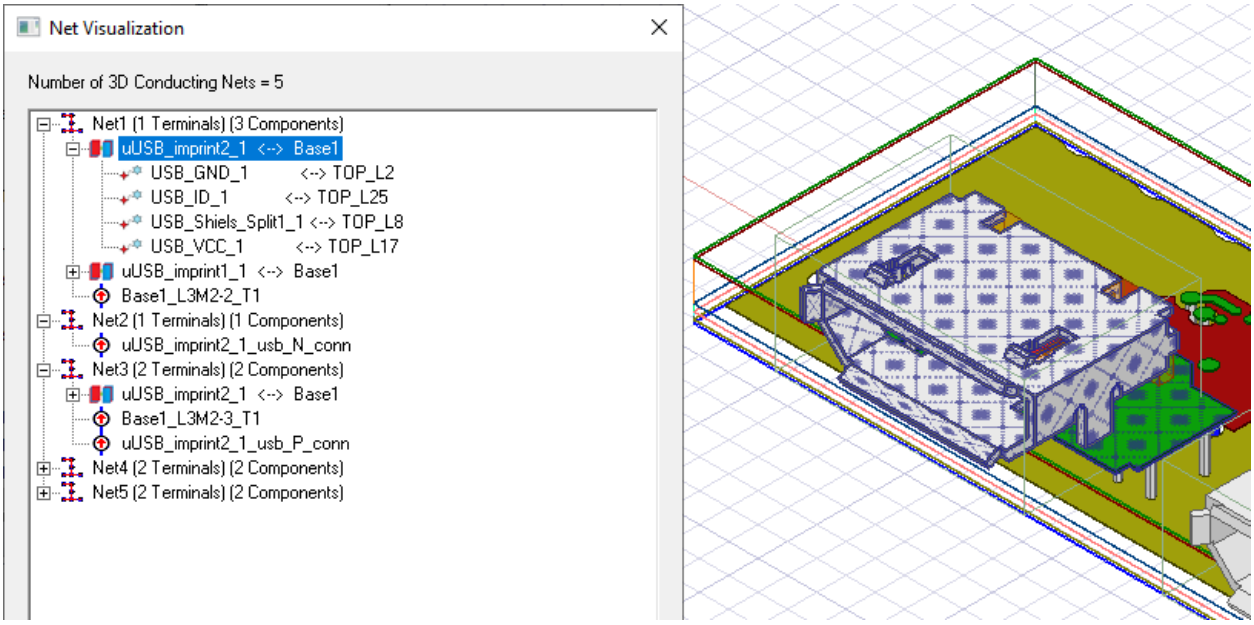
Along with the “filter by entities” and the “filter by connections” menu items, you can also filter nets using text input. The text box for this functionality is shown below:

Features of this text box are:

- It accepts one or more object or component names.
  - Multiple entries can be entered by separating them with comma operator (“,”).
  - Entity connections can be entered by separating entity names with dash operator (“-”).
  - Wild cards “*” and “&” can be applied. For example, LayoutComp1 and HfssComp2 can both be represented simultaneously as “*Comp*”.

  Similarly, LayoutComp1 and LayoutComp2 can be represented simultaneously as “LayoutComp&”. For example, (Box1, Box2, Comp1 – Comp2): This string applies filter based on if a net contains Box1, or Box2, or connection between Comp1 and Comp2.

Selected nets/components are highlighted in the Modeler window.



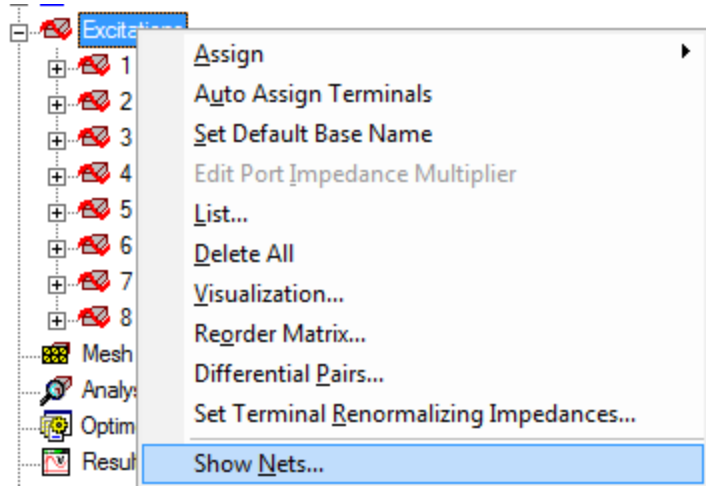
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Show Nets for Layout Components in HFSS 3D Geometries

For Terminal Solution types, HFSS designs that include Layout Components, you can use the **Show Nets** command to visualize conducting nets and terminal associations formed by 3D geometries and layout components in a HFSS design. You can also select a Layout Component, and use the "Nets Tab for Viewing Nets" on page 19-225.

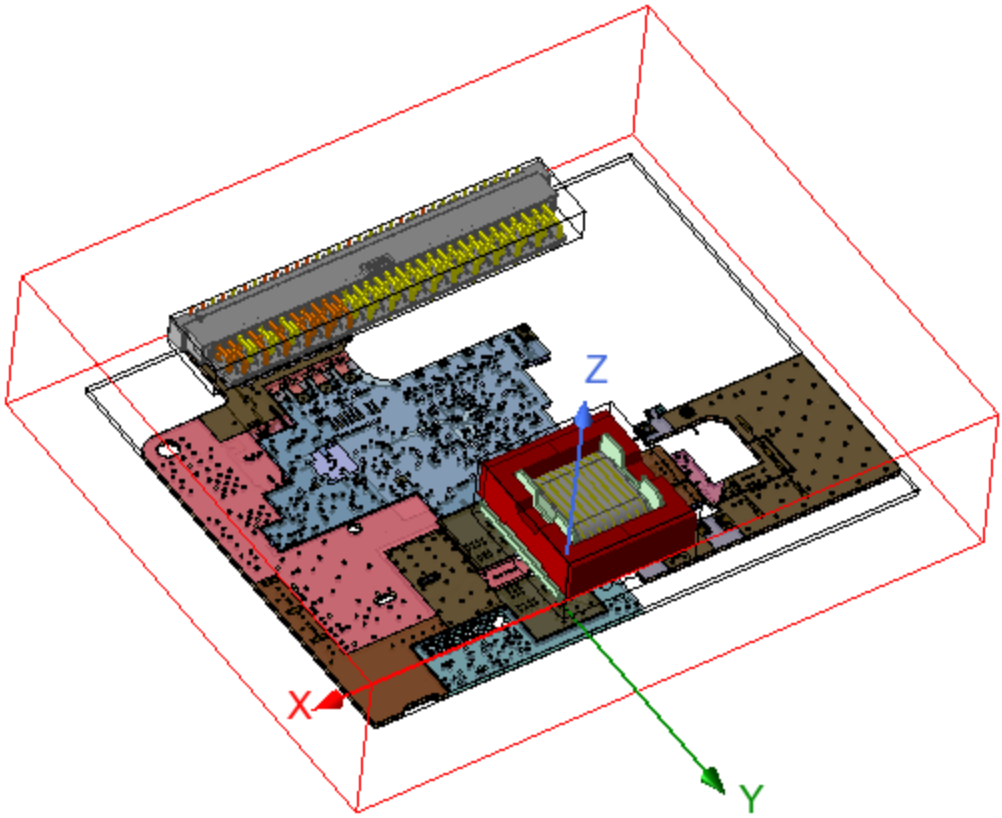
Show Nets Command

The **Show Nets** command appears in the **HFSS** > **Excitations** menu and by right-clicking on **Excitations** in the Project tree.



Selecting **Show Nets...** displays the **Net Visualization** dialog box that lists the nets and associated terminals and includes any included Layout Components. You can use the dialog box to select any net or terminal. You can continue to work in the Modeler window with the dialog open. Consider the following example design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note:

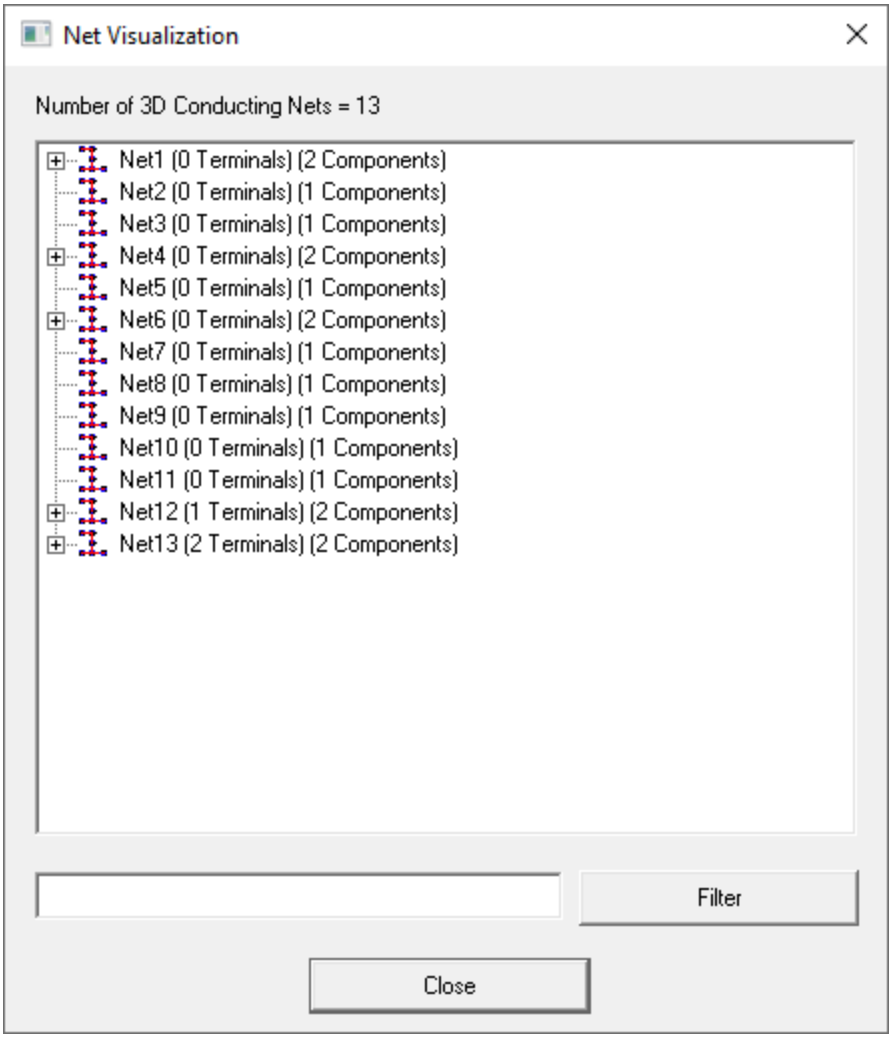
For a net to appear in the **Net Visualization** dialog box, the conductivity of the assigned material must be equal to or greater than 20,000 siemens/m, or the **Resistance** must be less than 3.142 ohms. Conductivity is set by material assignment (in the **3D Modeler** window or a boundary condition), and **Resistance** is set by boundary conditions (e.g., **Impedance** or **LumpedRLC**).

In the **Net Visualization** dialog box, you can sort the nets in ascending or descending order, relative to the number of terminals. This helps you locate GND nets, which have no terminals.

Text at the top of list box provides the total number 3D conducting nets. Naming of nets is automatic and follows the convention: "Net1 (0 Terminals)", "Net2 (1 Terminals)"…"Net<N> (<T> Terminals)". Net Names are not editable.

The **Net Visualization** dialog box is shown below.

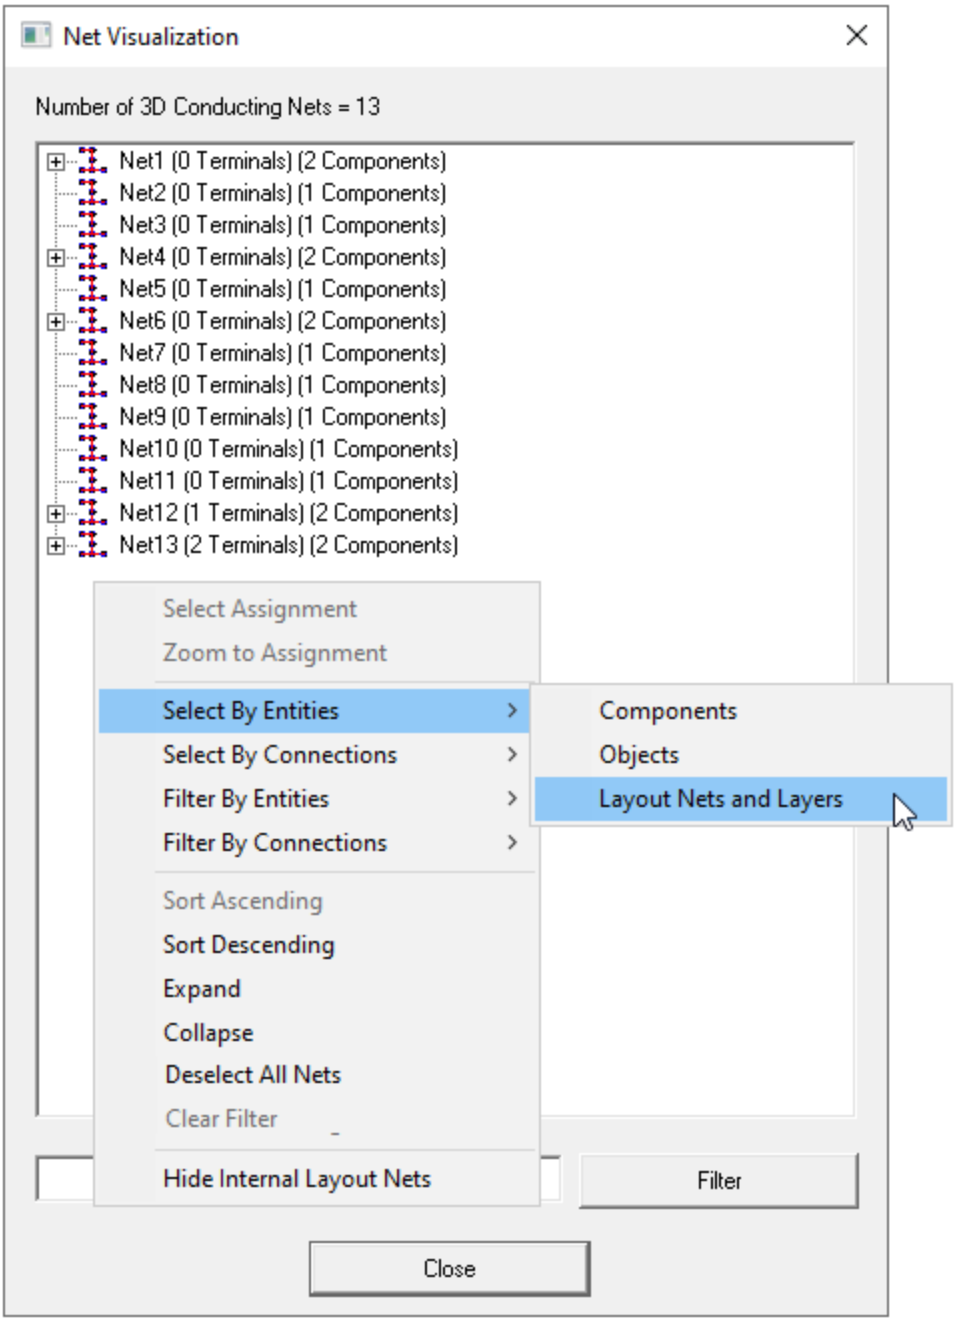
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For designs with many nets, you can enter text and wild cards in the field, and click the **Filter** button.

Right-click in the **Net Visualization** dialog box to view the short-cut menu. The menu is context sensitive, depending on whether you click on a particular net object, or in the white area.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- **Select Assignment**: If you right-click over selection in the tree, selects entities present in the selection. If the right-click menu is invoked on the surrounding blank space, this menu item is disabled as there is no selection.
- **Zoom to Assignment**: If you right-click over a selection in the tree, zooms to the entities present in the selection. If you right-click on the surrounding blank space, this menu item is disabled as there is no selection.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Select by Entities**: Invokes a dialog box containing object, component, or net and layer names present in the selection if the right-click menu is invoked over some selection in the tree. If the right-click menu is invoked on the surrounding blank space, all object or component names present in the project are displayed. Selecting one or multiple of these object or component names selects all the nets that contain any of the selected entities.
- **Select by Connections**: If you right-click over some selection in the tree, this produces a dialog box containing object or component names present in the selection. If you right-click in the surrounding blank space, a dialog box with all object or component names present in the project displays. Selecting a pair of these objects or component names selects all the nets that contain this pair of entities, signifying a direct or indirect connection between these entities.
- **Filter by Entities**: A new dialog box is invoked containing object, component, or net and layer names present in the selection if the right-click menu is invoked over some selection in the tree. If the right-click menu is invoked on the surrounding blank space, all object or component names present in the project are displayed. Selecting one or multiple of these objects or component names filters all the nets that contain any of the selected entities.
- **Filter by Connections**: A new dialog box is invoked containing object or component names present in the selection if the right-click menu is invoked over some selection in the tree. If the right-click menu is invoked on the surrounding blank space, all object or component names present in the project are displayed. Selecting a pair of these objects or component names filters all the nets that contain this pair of entities, signifying a direct or indirect connection between these entities.
- **Sort Ascending**: Sorts the nets in ascending order of their names.
- **Sort Descending**: Sorts the nets in descending order of their names.
- **Expand**: Expands the selection in the tree if the right-click menu is invoked over some selection in the tree. If the right-click menu is invoked on the surrounding blank space, it expands all the nets.
- **Collapse**: Collapses the selection in the tree if the right-click menu is invoked over some selection in the tree. If the right-click menu is invoked on the surrounding blank space, it collapses all the nets.
- **Deselect All Nets**: Deselects all the entities present in the project. Clears the selection of all the previously selected entities.
- **Clear Filter**: Clears all the filtering applied on nets and shows all the nets.
- **Hide Internal Layout Nets**: Hides all the nets that are internal to layout component

Along with the “filter by entities” and the “filter by connections” menu items, you can also filter nets using text input. The text box for this functionality is shown below:

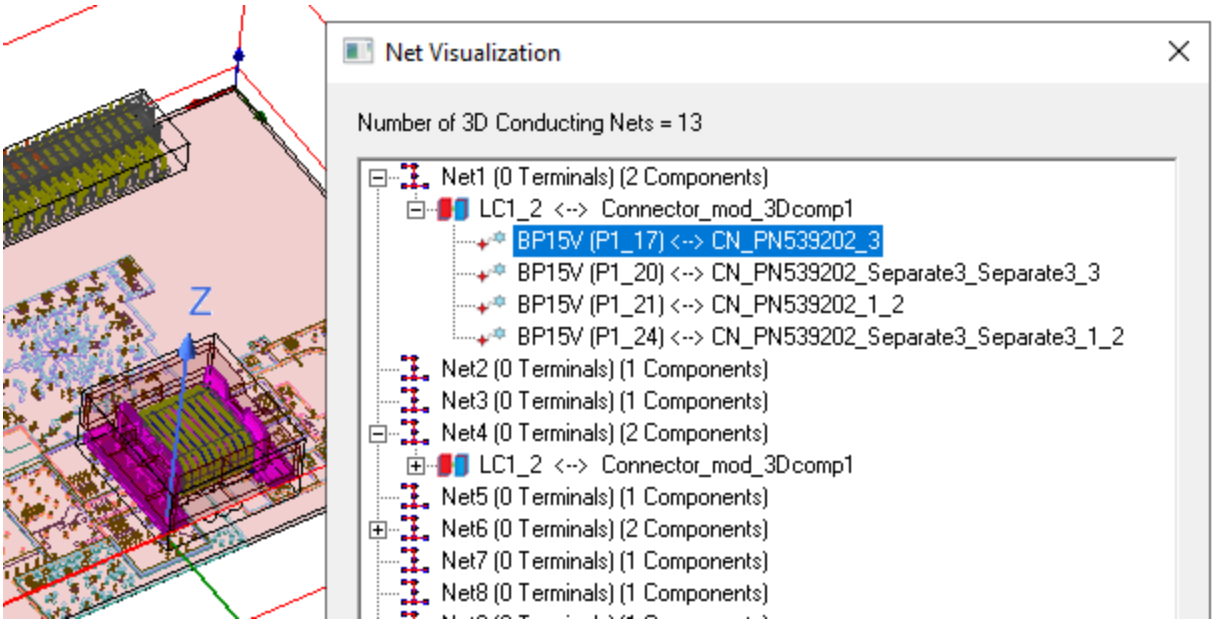
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Features of this text box are

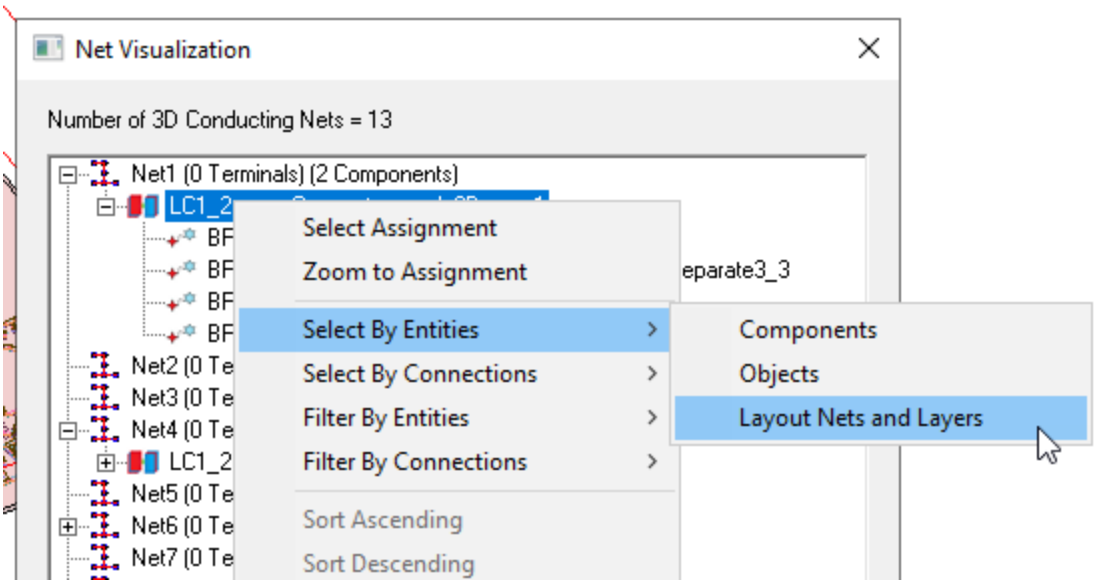
- **Select Assignment**: If you right-click over selection in the tree, selects entities present in the selection. If the right-click menu is invoked on the surrounding blank space, this menu item is disabled as there is no selection.
- **Zoom to Assignment**: If you right-click over a selection in the tree, zooms to the entities present in the selection. If you right-click on the surrounding blank space, this menu item is disabled as there is no selection.
- **Select by Entities**: Invokes a dialog box containing object, component, or net and layer names present in the selection if the right-click menu is invoked over some selection in the tree. If the right-click menu is invoked on the surrounding blank space, all object or component names present in the project are displayed. Selecting one or multiple of these object or component names selects all the nets that contain any of the selected entities.
- **Select by Connections**: If you right-click over some selection in the tree, this produces a dialog box containing object or component names present in the selection. If you right-click in the surrounding blank space, a dialog box with all object or component names present in the project displays. Selecting a pair of these objects or component names selects all the nets that contain this pair of entities, signifying a direct or indirect connection between these entities.
- **Filter by Entities**: A new dialog box is invoked containing object, component, or net and layer names present in the selection if the right-click menu is invoked over some selection in the tree. If the right-click menu is invoked on the surrounding blank space, all object or component names present in the project are displayed. Selecting one or multiple of these objects or component names filters all the nets that contain any of the selected entities.
- **Filter by Connections**: A new dialog box is invoked containing object or component names present in the selection if the right-click menu is invoked over some selection in the tree. If the right-click menu is invoked on the surrounding blank space, all object or component names present in the project are displayed. Selecting a pair of these objects or component names filters all the nets that contain this pair of entities, signifying a direct or indirect connection between these entities.
- **Sort Ascending**: Sorts the nets in ascending order of their names.
- **Sort Descending**: Sorts the nets in descending order of their names.
- **Expand**: Expands the selection in the tree if the right-click menu is invoked over some selection in the tree. If the right-click menu is invoked on the surrounding blank space, it expands all the nets.
- **Collapse**: Collapses the selection in the tree if the right-click menu is invoked over some selection in the tree. If the right-click menu is invoked on the surrounding blank space, it collapses all the nets.
- **Deselect All Nets**: Deselects all the entities present in the project. Clears the selection of all the previously selected entities.
- **Clear Filter**: Clears all the filtering applied on nets and shows all the nets.
- **Hide Internal Layout Nets**: Hides all the nets that are internal to layout component

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Selecting any component or net in the **Net Visualization** list highlights it. For example, the following figure shows a Layout Component selected in the expanded tree list and highlighted in the **Modeler** window.

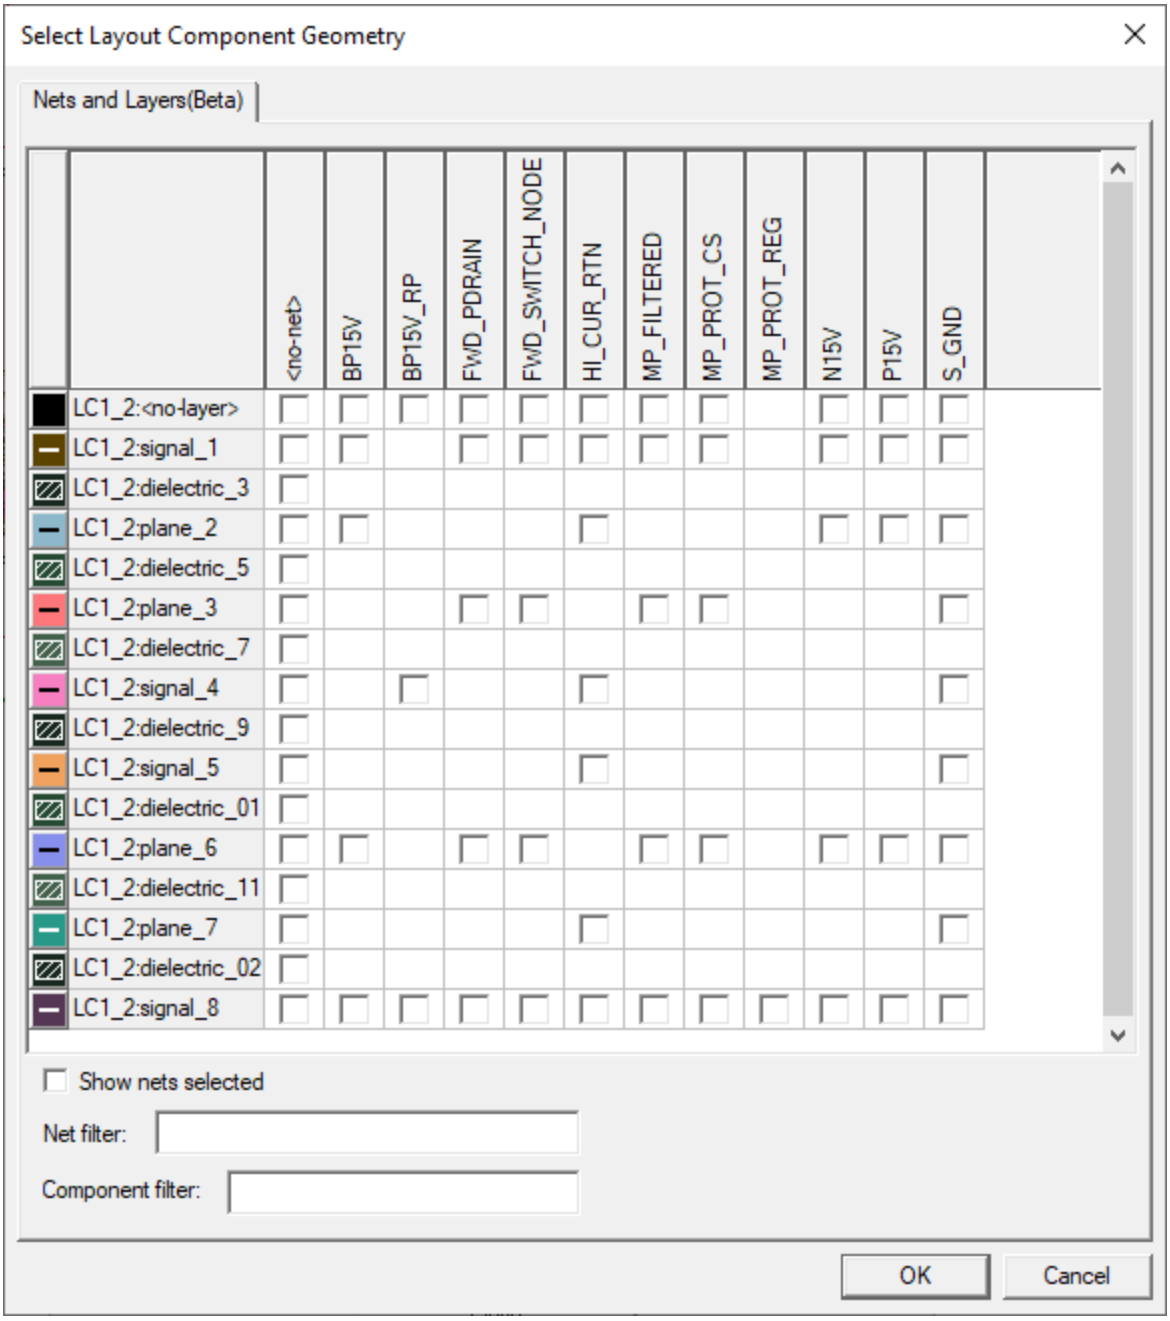


For example, right-click on the Layout Component name in the **Net Visualization** dialog box to display the menu and select **Select by Entities** > **Layout Nets and Layers**.



This displays the **Select Layout Component Geometry** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



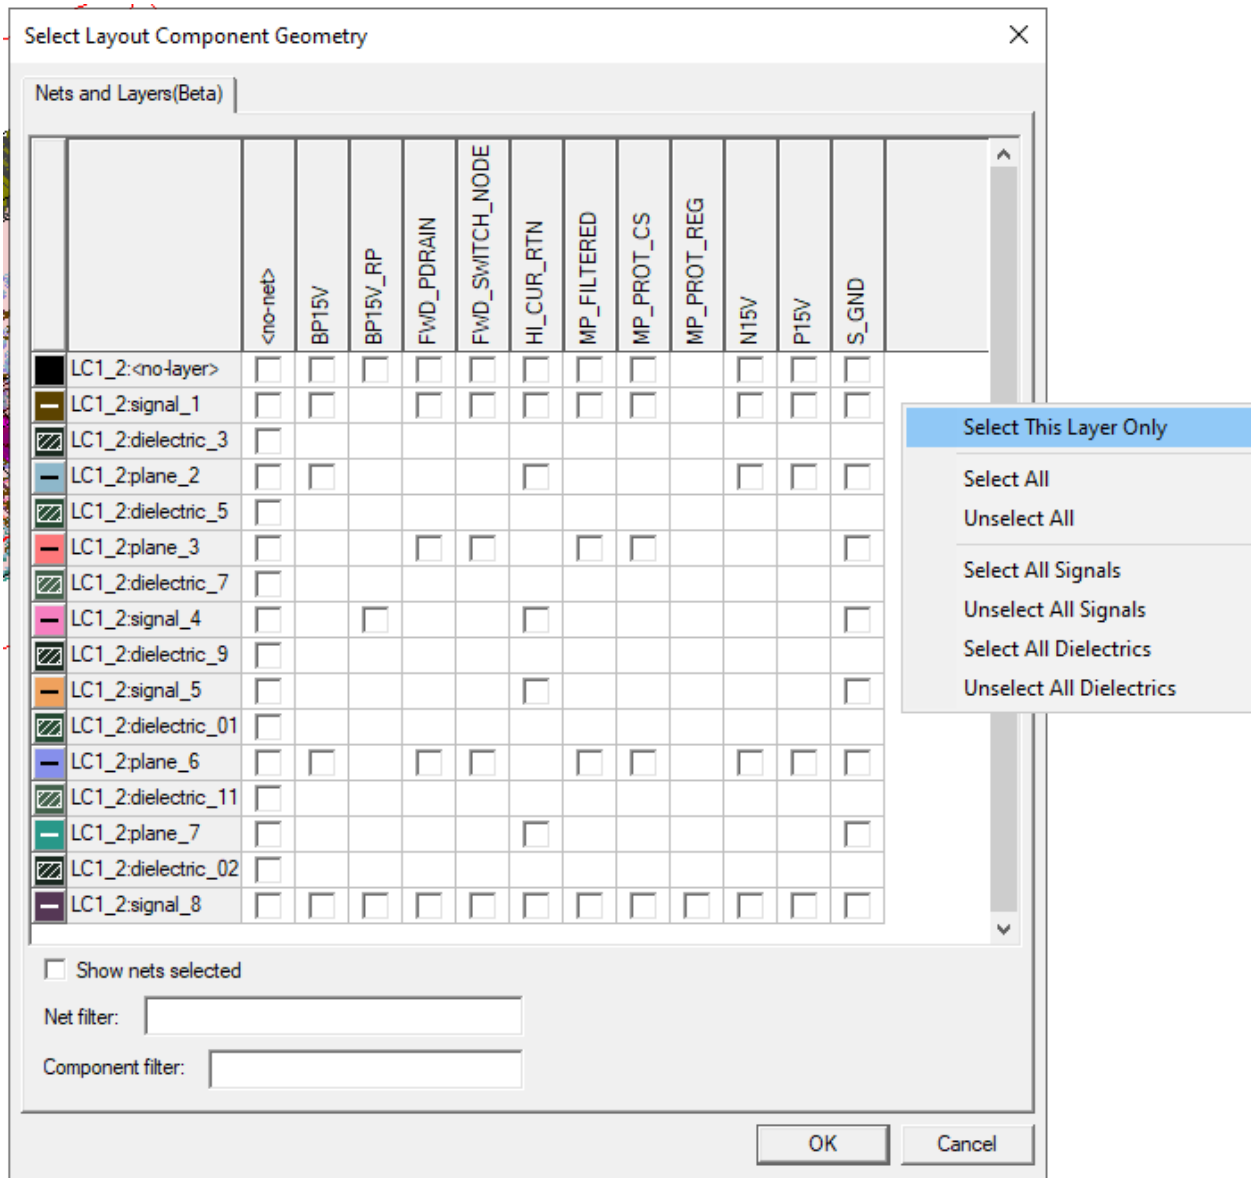
With the **Select Layout Component Geometry** dialog box, you can select objects from layout components' local nets and layers and search for nets in the overall design that contain these objects. This dialog displays all the layers and local nets of every layout component in the design. If there are objects in the layout component that belong to a specific layer and net, a checkbox will become available for you to select. Once you make selections and click **Apply**, you can go back to the parent **Net Visualization** dialog box and click **Select** button, which selects all the nets in the **Net Visualization** dialog that contain these objects.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Select Layout Component Geometry** dialog is modeless, that means you can work in the 3D Modeler while keeping this dialog box open. This way, you can use the modeler window to better find the layout component objects you want to search for.

By clicking the column headers, you can select or deselect checkmboxes in the entire column. The **Show nets selected** check box can be toggled to move all the selected nets to the left side of the table. Use the Net filter and Component filter to filter fields to designate specific nets and components. These filters support '*' and '?' wildcards and can delimit multiple filters with comma. The table is refreshed each time users update the filter text.

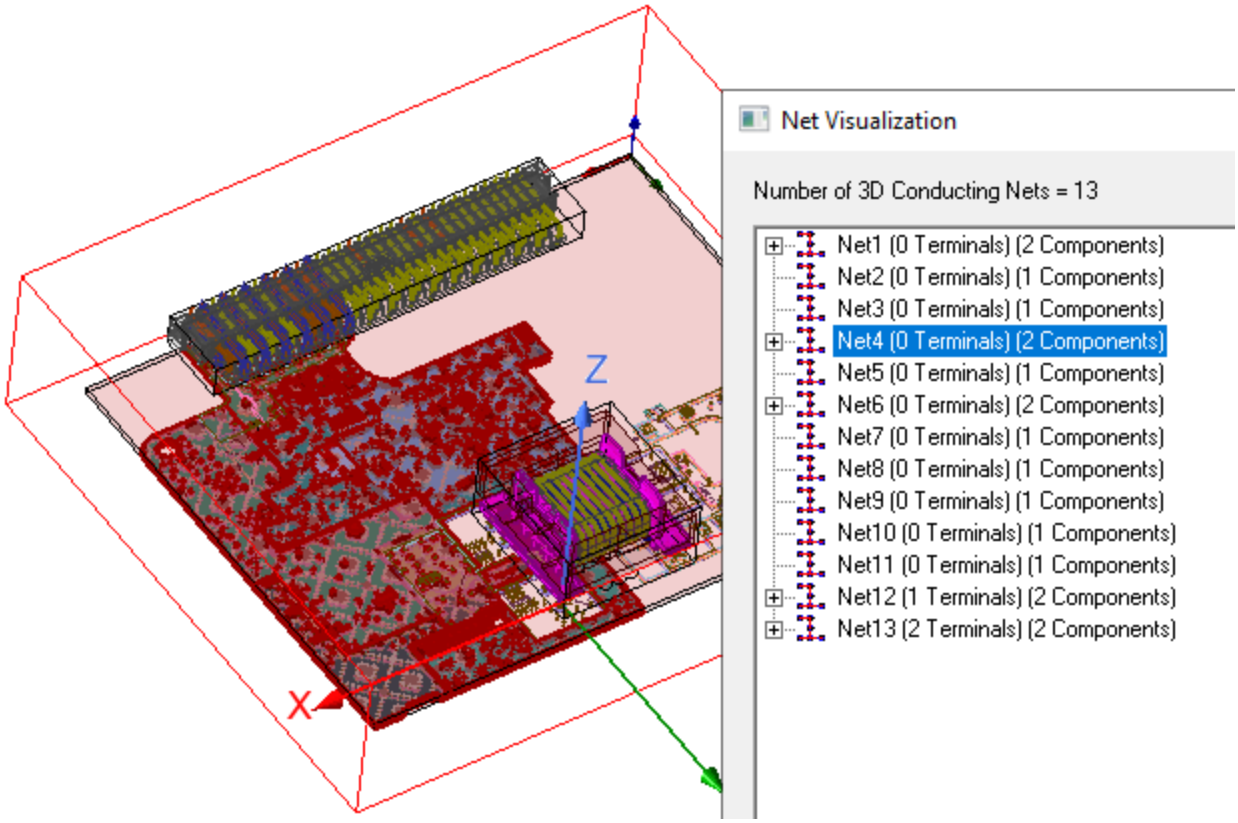
Additionally, the **Select Layout Component Geometry** dialog box has a right-click menu as shown below.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

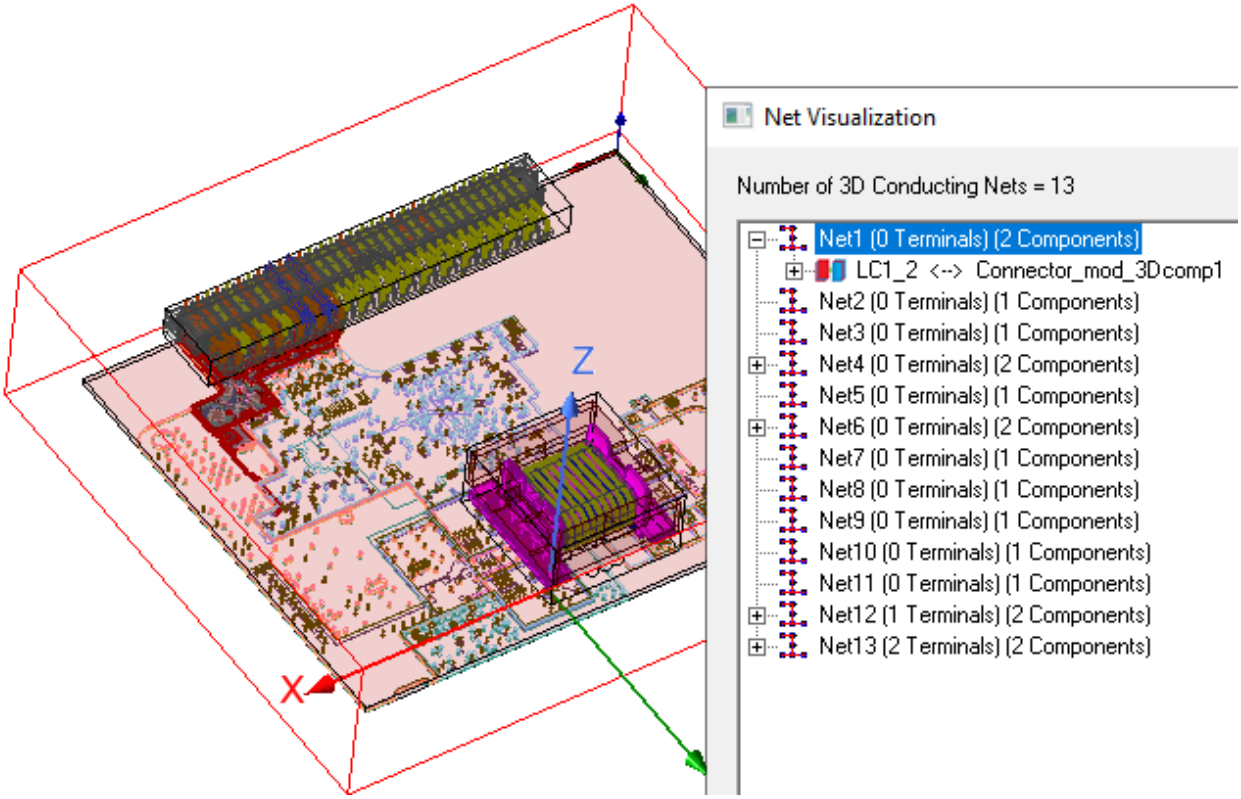
You can use the dialog to select any net or terminal. You can continue to work in the Modeler window with the dialog box open.

The **Net Visualization** dialog box identifies all nets and will include both 3D geometries and layout components with correct terminal associations. As shown in the figure below, any net you select in the Net Visualization list highlights the objects in the net in the modeler window. By default, 3D geometries are highlighted with blue texture, and objects from layout components will be highlighted with red texture. The rest of objects in the layout component not belonging to the selected net will be shown as wireframes.



The next figure shows a different selection from the list of 3D conducting nets to illustrate the changed highlighting.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

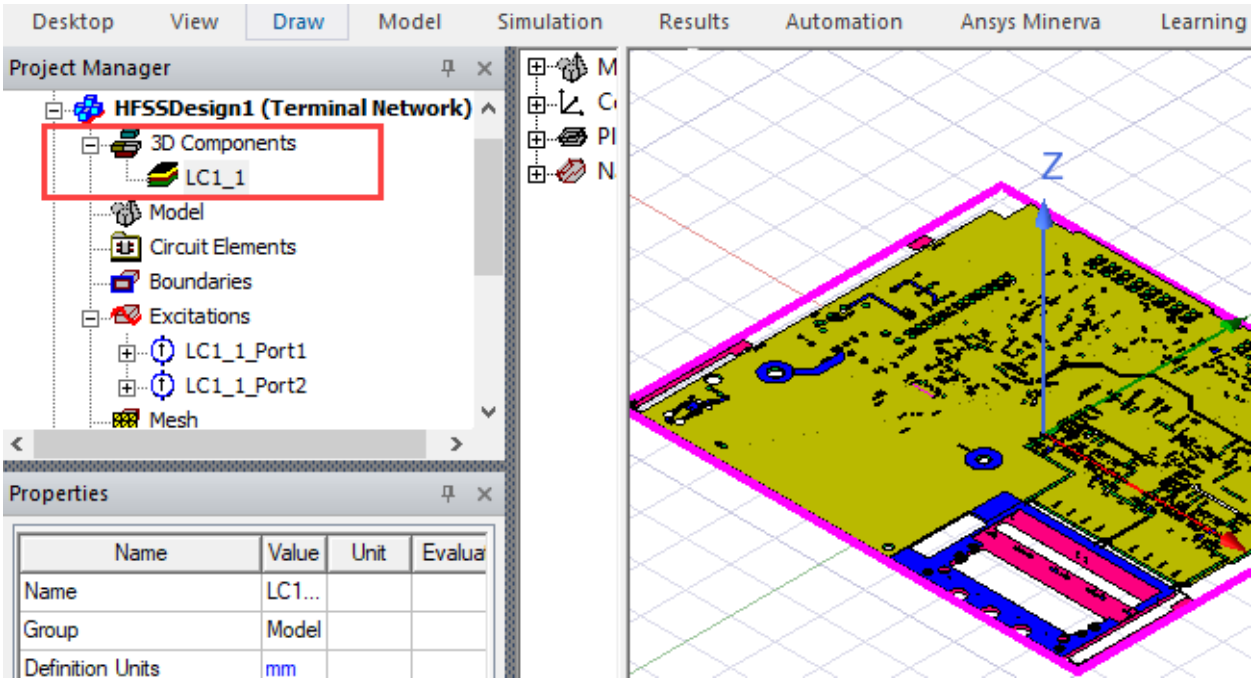


All the functionalities in the Net Visualization dialog that works for regular nets are also supported for nets containing layout component objects, such as **Zoom To**. Because layout components do not have any actual geometries in the modeler window, the **Select Assignment** will only select 3D geometries in each net.

Nets Tab for Viewing Nets

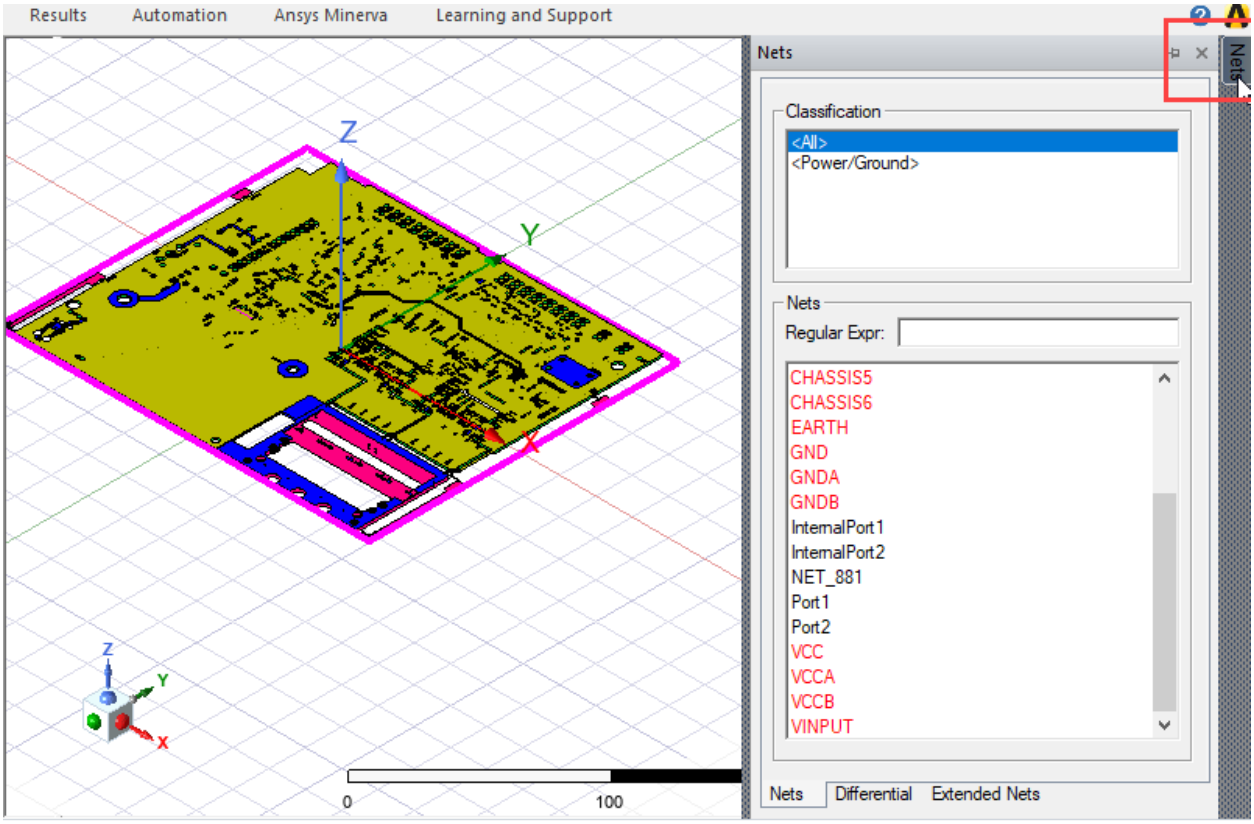
You can also view nets by selecting a Layout Component and then selecting the **Nets** tab on the right side of the Modeler window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



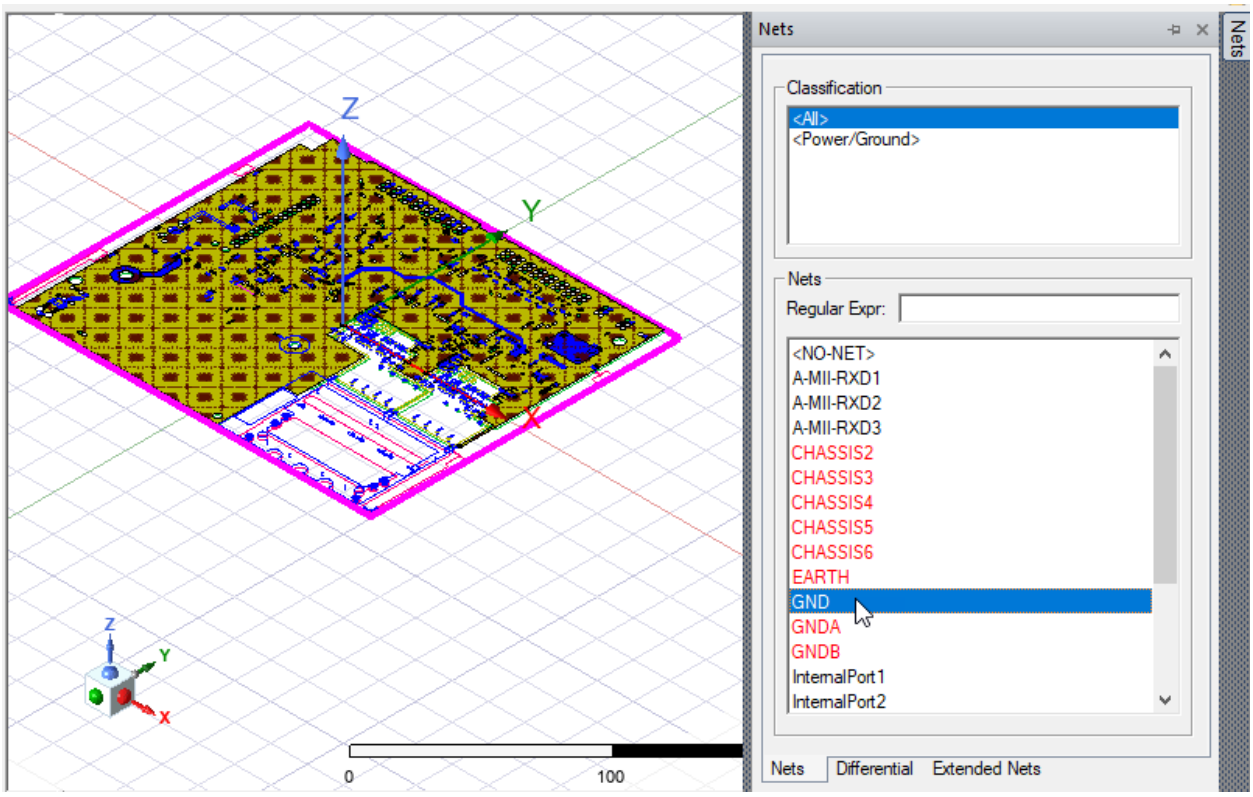
Then click the **Nets** tab on the right of the Modeler window to open the **Nets** display window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The Nets you select in the list become highlighted in the Modeler window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



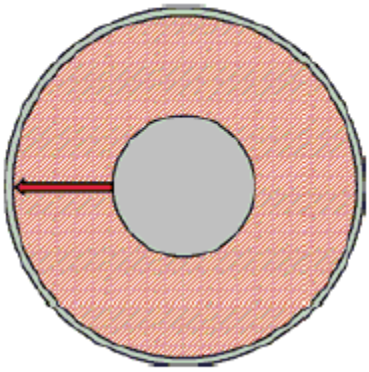
Define an Integration Line

An integration line is a vector that can represent the following:

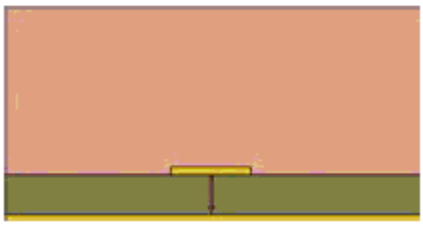
- A calibration line that specifies the direction of the excitation field pattern at a port. If you are analyzing more than one mode at a port, define a separate integration line for each mode; the orientation of the electric field differs from mode to mode.
- An line along which to integrate **E**.dl to compute a voltage for Zpv or Zvi impedance of a port. In this case, select two points at which the voltage differential is expected to be at a maximum. For example, on a microstrip port, place one point in the center of the microstrip, and the other directly underneath it on the ground plane. In a rectangular waveguide, place the two points in the center of the longer sides.

> **Note:**
>
> For more information, see Wave Port Dialog For Modal Solutions. For definitions of how HFSS defines these Zpv and Zvi values, see Calculating the PV Impedance, and Calculating the VI Impedance.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



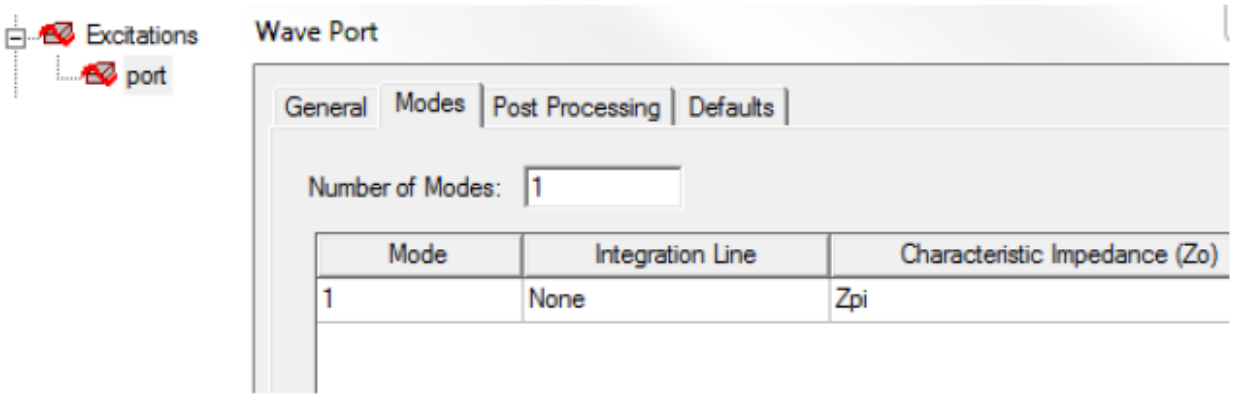
Coaxial cable wave port showing integration line (in red). Line is drawn between points of maximum potential difference. In this case, it is drawn in the space between the center conductor and the shield.



Microstrip wave port showing integration line (in red). Line is drawn between points of maximum potential difference. In this case, it is drawn in the space between the signal line conductor and the "ground" plane.

To define an integration line:

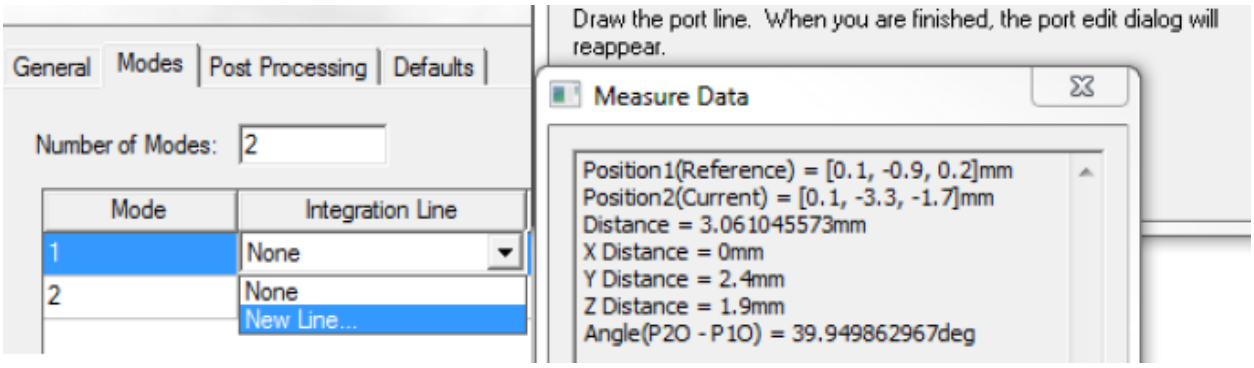
1. Double-click the port excitation from the project tree to bring up the **Wave Port** dialog box and click the **Modes** tab.



2. From the **Integration Line** column, select **New Line**.

   The port dialog box disappears. If the **Show Measure** dialog option on the Modeler Options: Drawing tab is selected, the **Measure Data** dialog appears when you draw the vector.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Use the **Measure Data** dialog to locate the start and end points and draw the integration line.

> **Note:**
>
> The **Measure Data** dialog displays data for the face area, and the positions for the reference point (start point) and end point (end point) as you define them.

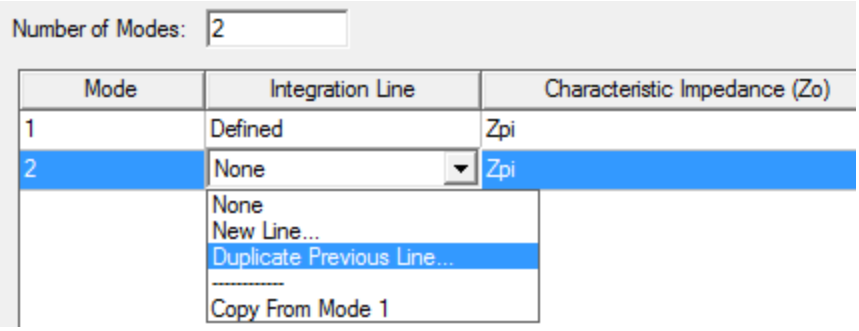
Duplicating Integration Lines

You can duplicate an integration line along a vector multiple times and assign to additional modes at the port. This section shows how to duplicate the integration line in the following figure.

1. In the **Wave Port** dialog box, click the **Modes** tab and draw the integration line 1 on the port.

2. Enter the number of modes and select **Duplicate Previous Line** from the Integration Line column.

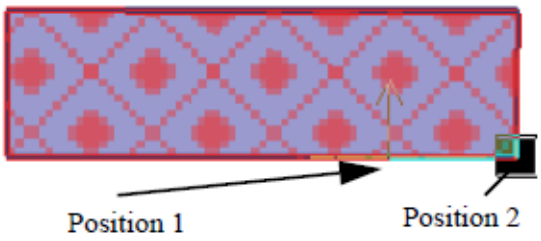
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

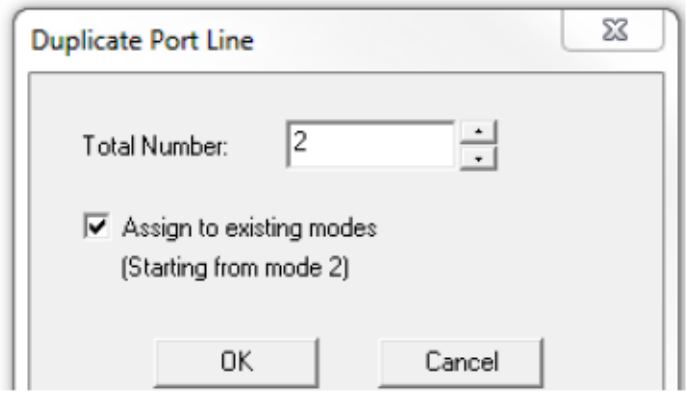


3. Click an arbitrary anchor point on the edge of the port face for position 1 and drag the cursor along the edge to position 2 as shown in the figures below.

   The **Integration Line 2** shifts from **Integration Line 1** by a distance equal to that between Position 1 and Position 2.

   > **Note:**
   >
   > Use the **Measure Data** dialog to set this distance.





4. Enter the total number of lines, including the original and duplicates, to make in the **Duplicate Port Line**.

   If you type a value that is greater than the number of assigned modes, the extra duplicates will appear as gray integration lines until they are assigned to a mode.

5. Optionally, select **Assign to existing modes**. The duplicates will be assigned to the modes defined for the port, beginning with the mode after the one with the line that was duplicated.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modifying Integration Lines

Modify an existing integration line under the **Modes** tab in the **Wave Port** or **Lumped Port** dialog boxes.

To *swap the coordinates* of an integration line's start point and endpoints:

- Select **Swap Endpoints** from the mode's **Integration Line** list.

The line's direction will be reversed.

To *copy* a previously defined Wave Port integration line's points:

- Select **Copy from Mode*n*** from the mode's **Integration Line** list.

The new integration line will have the same start and endpoints as the selected mode's integration line.

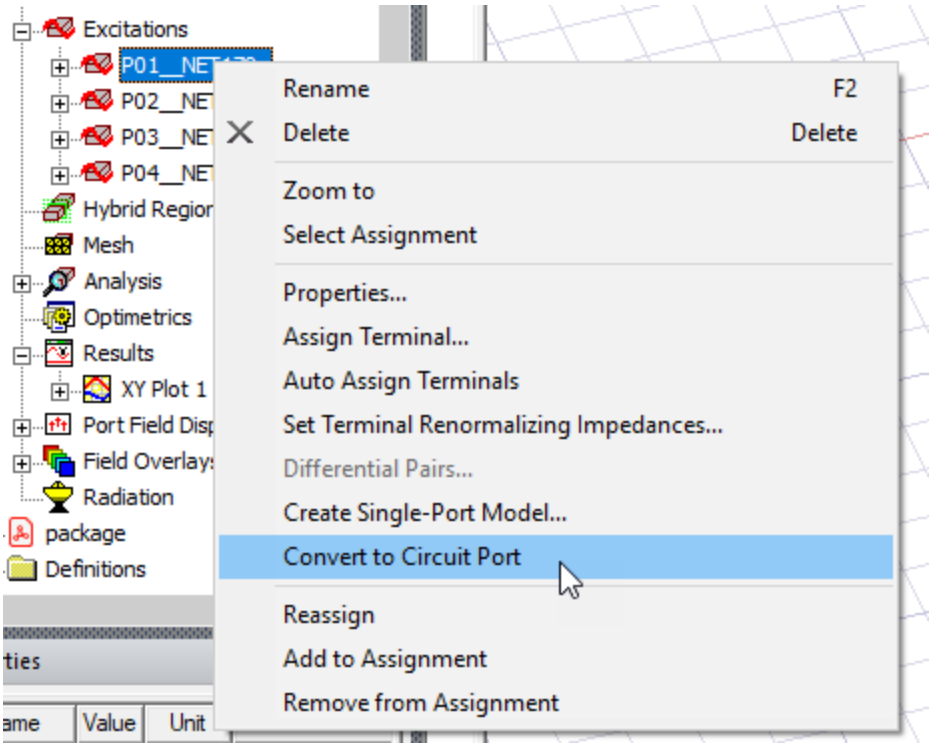
To *delete* a defined integration line for a mode:

Select **None** from the mode's **Integration Line** list.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

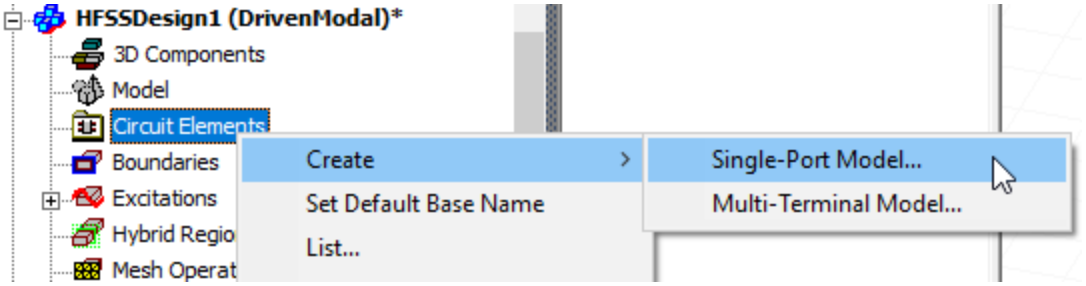
20 - Circuit Elements in HFSS

HFSS supports the creation of circuit elements using lumped ports or circuit ports in both driven modal and terminal solution types. Circuit ports are allowed with the DDM solver, including FEBI and IE Hybrid Regions. You can directly convert a selected lump port to a circuit port and from a circuit port to a lump port.

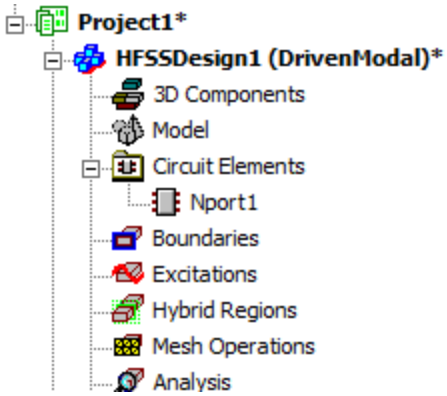


You can import N-port models a from a library of previously created Touchstone files for the S-matrix or link to projects from HFSS, Q3D, 2D Extractor, or SIwave. Within the approach of using touchstone files in HFSS the port inductance is present as added in series to the embedded touchstone file. In case the port inductance deembedding is intended then this needs to be done manually with the touchstone file as this will not be done within HFSS. You can create models as Parametric N-port models or use Nexsys Matlab models. You can also convert Circuit Elements back to lump ports in the HFSS project.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

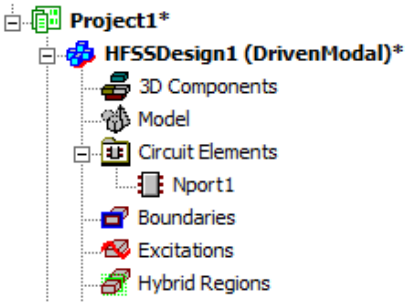


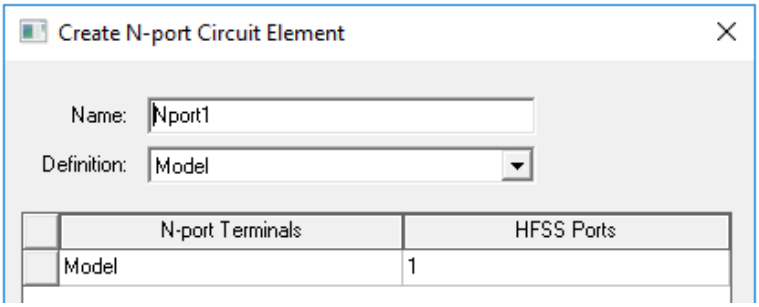
A folder named **Circuit Elements** appears in the **Project tree** where the circuit elements are added.



There are three cases to consider when you create these circuit elements:

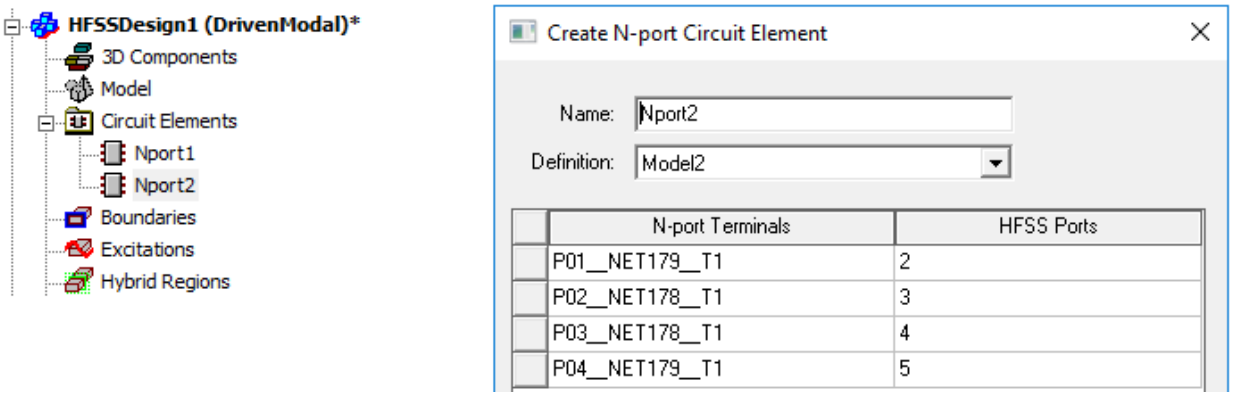
- Single-Port Model definition: A 1x1 or 2x2 S-matrix that requires you to select a single lumped port or circuit port to create the circuit element.



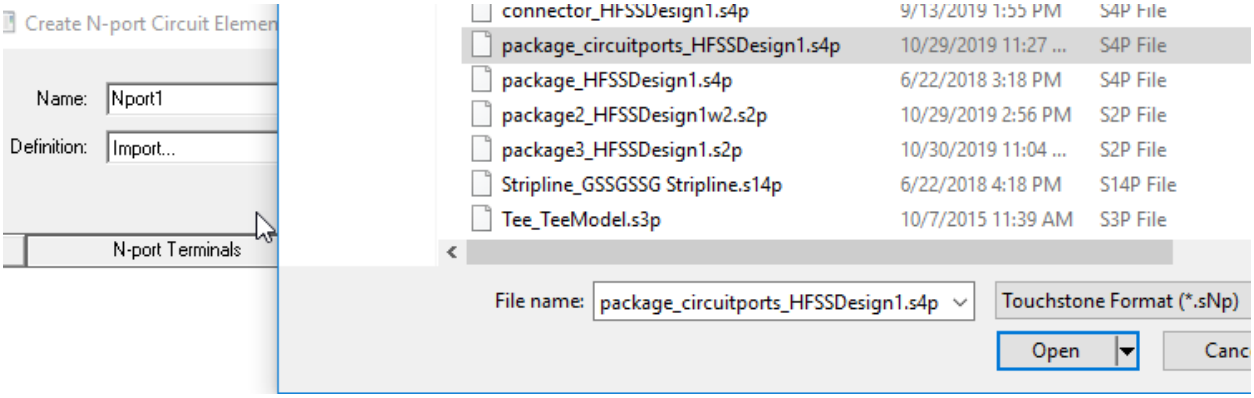


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Multi-Terminal Model definition: An S-matrix 2x2 or higher that would require you to select the corresponding number of lumped ports or circuit ports.

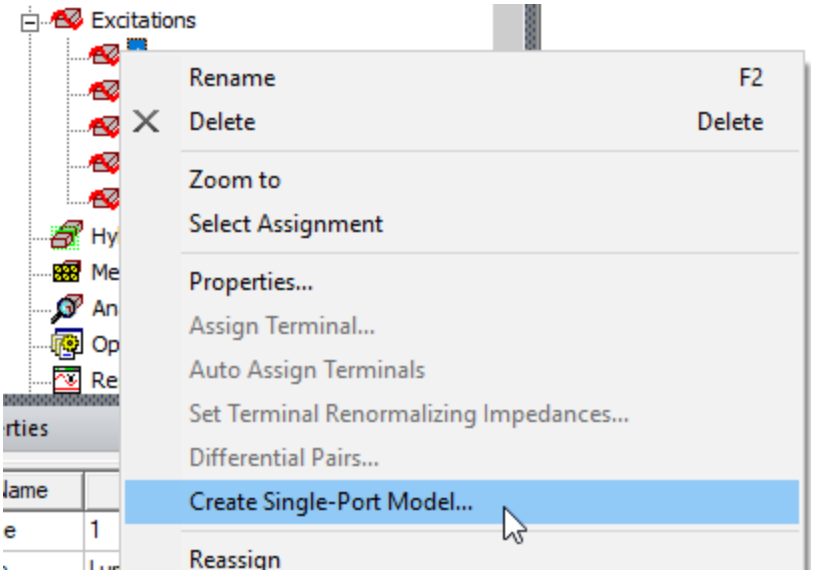


- Touchstone file import for circuit elements.

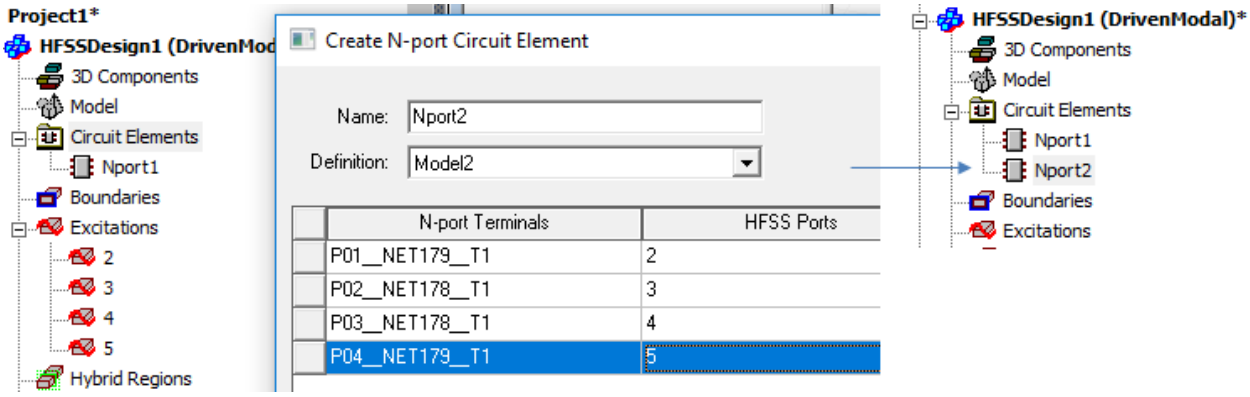


In the case of a Single-Port Model, you can also access the menu by right-clicking on a lump port in the **Project** tree.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

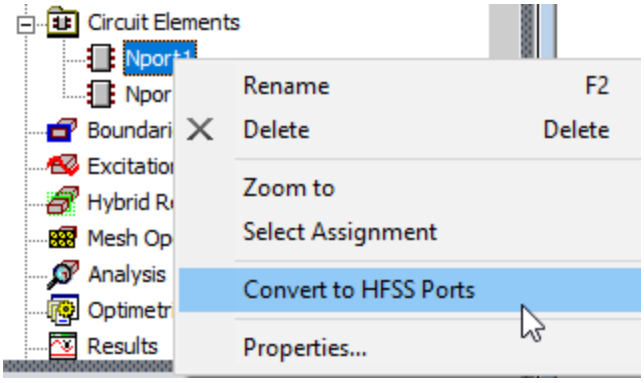


When you change a lump port to a circuit model, the selected port or ports are removed from the **Excitations** list as the models are displayed under the **Circuit Elements** list. The port post processing setting will not be effective once converted to circuit element.

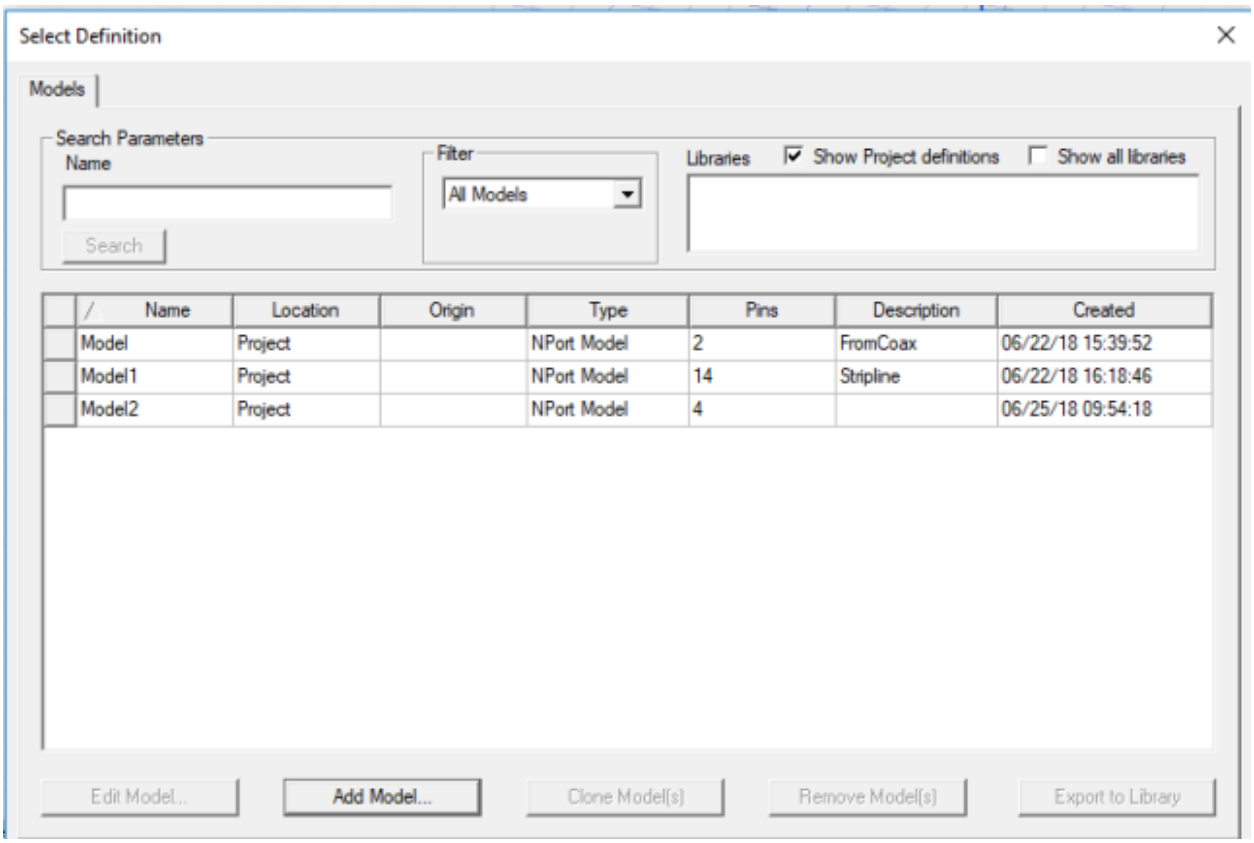


You can change a circuit element to an HFSS port.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can also Create Models and Manage Circuit Model Libraries.



Prerequisites/Limitations

- Designs must be Driven Modal or Driven Terminal.
- Existing lump ports or circuit ports can be changed to circuit elements.
- Only passive S-parameter model is supported.
- Fast sweep is not supported.

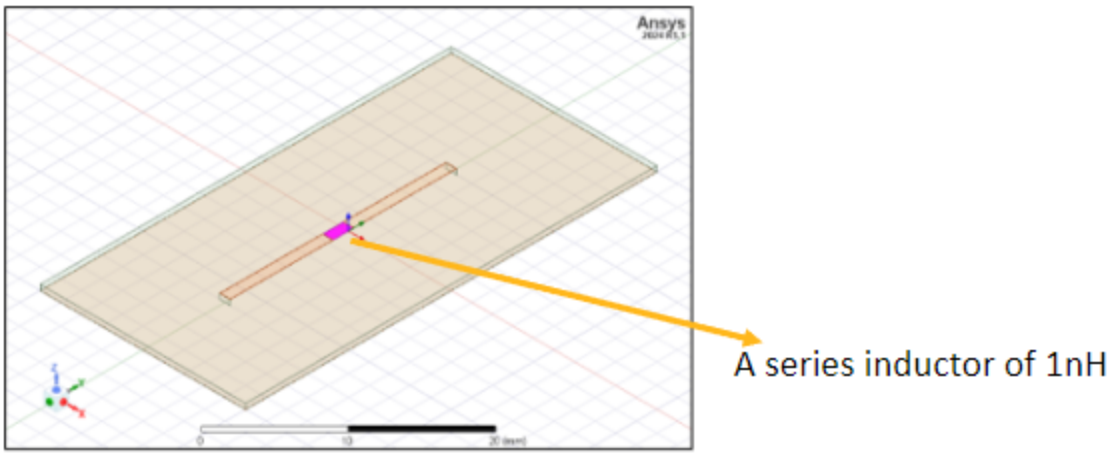
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Sensitivity analysis is not compatible with circuit elements. The solver detects unsupported use and issues a warning and returns zero for the derivatives.
- 3D Components created from these designs include the circuit elements. The Create 3D component dialog has a Circuit Elements tab for these designs.

Beta Feature: De-embedding for Circuit Elements

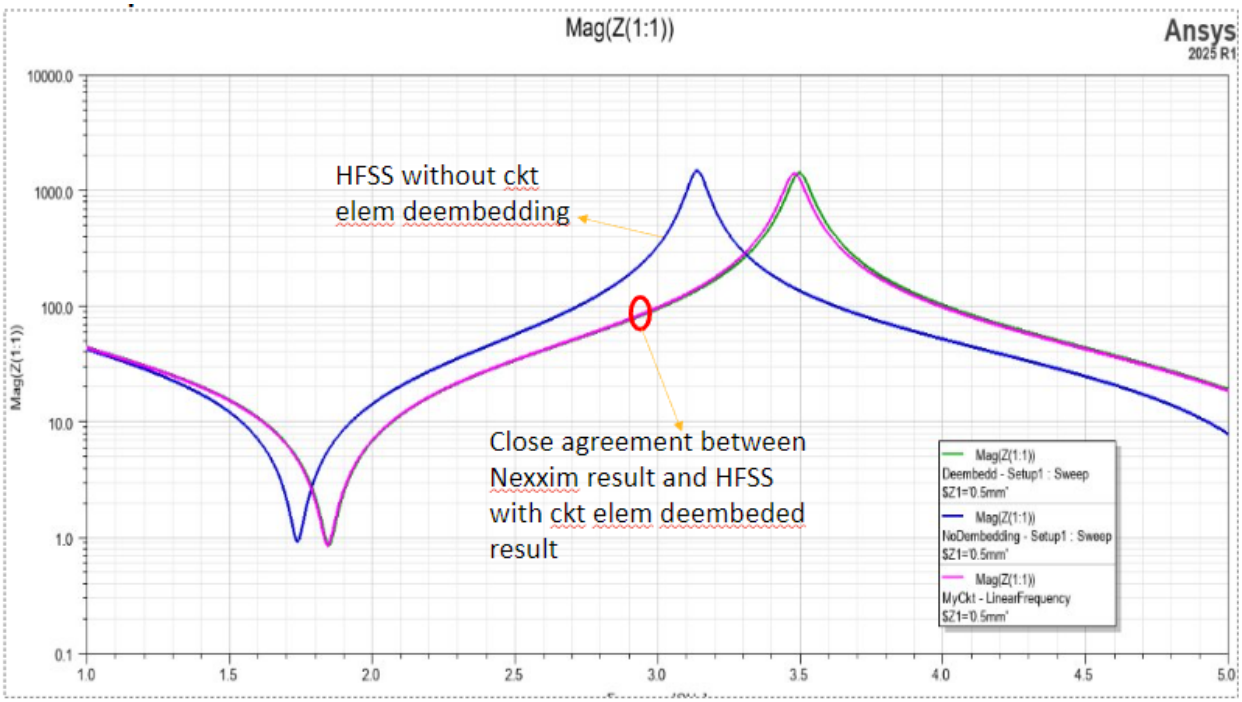
A Beta Feature allows de-embedding for Circuit Elements. For long and narrow circuit elements, the final S-parameters could show some difference. If you enable the HFSS Solver Beta option for HFSS Deembed circuit elements, all of the circuit elements in the geometry will be deembedded.

With the feature enabled, you can solve in HFSS and account for deembedding.



Compared to solving without deembedding for this kind of circuit, HFSS solve with deembedding is comparable to a Nexxim solve.

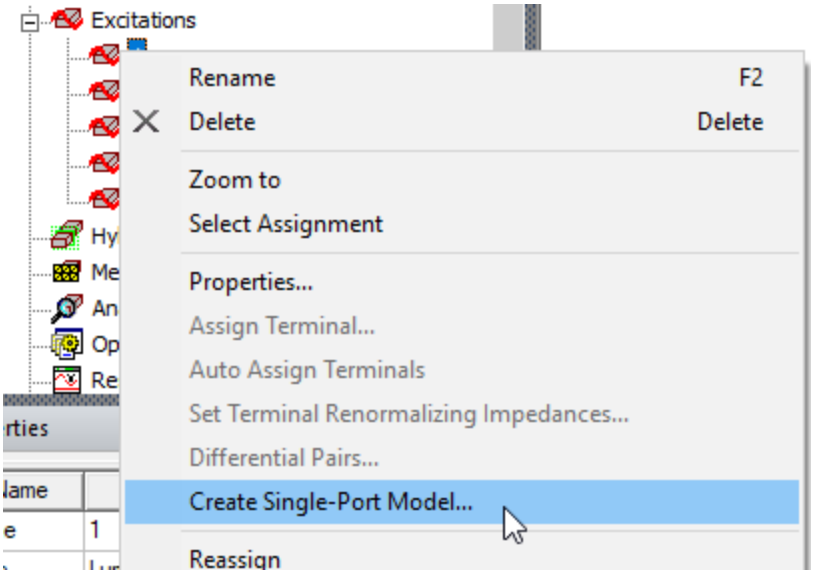
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Creating a Single Port Circuit Element in HFSS

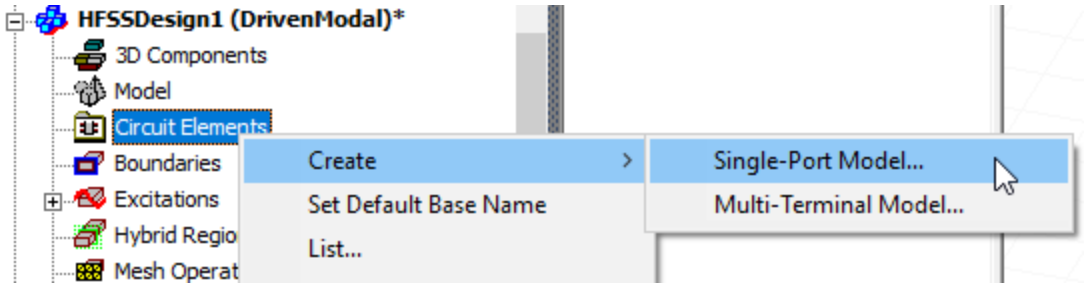
To create a single port Circuit Element:

1. Right click on a Lumped port in the **Project** tree and click **Create Single-Port Model**,

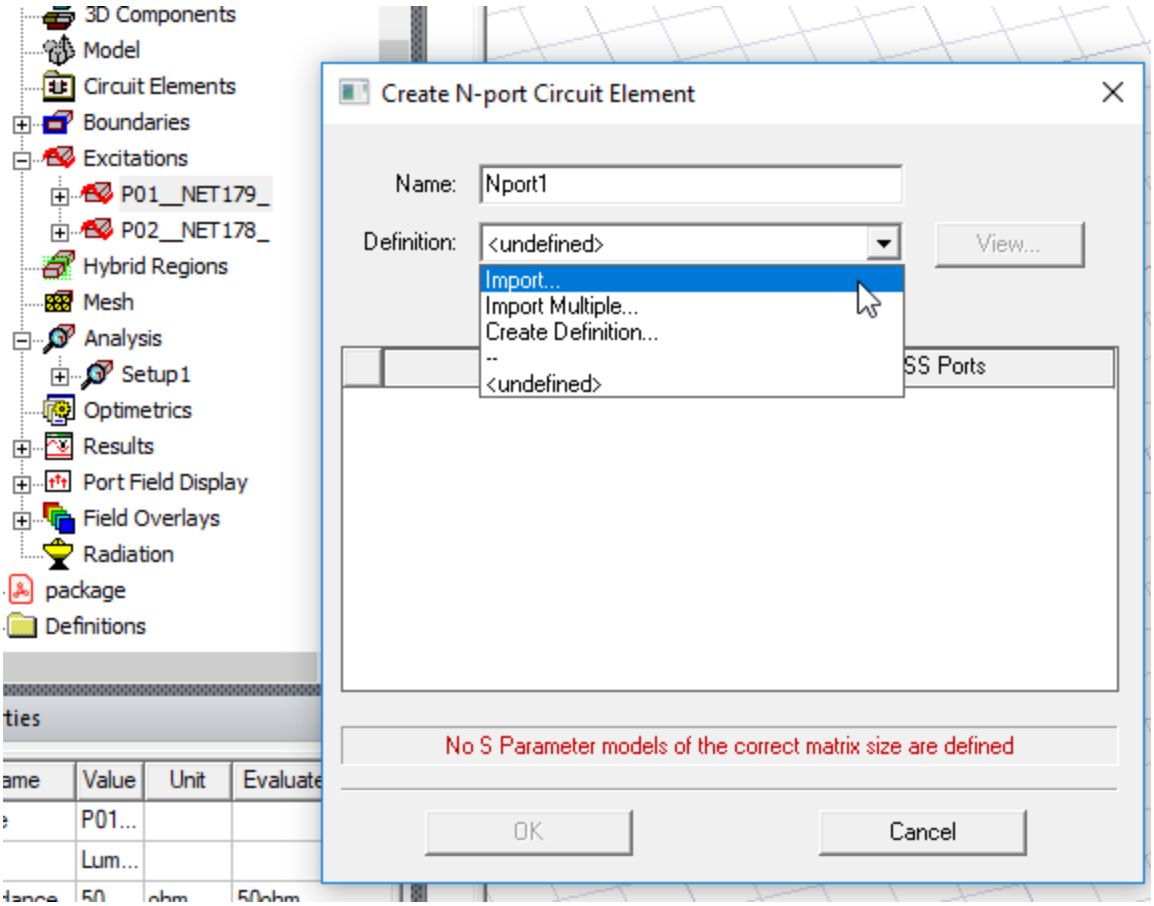


or right click on the **Circuit Elements** folder and select **Create>Single Port Model...**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Create N-port Circuit Element** dialog opens. If you selected the port menu, the dialog shows the HFSS Port assignment. If you selected from the Circuit Element menu, you can click on the HFSS Ports cell to select from available ports.



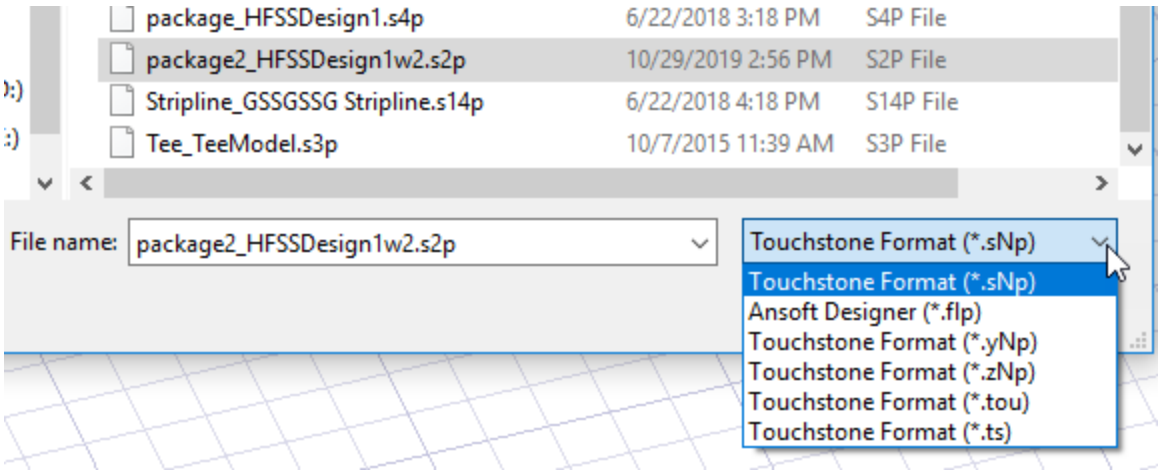
The Definition menu allows you to **Import...** for Touchstone information contained in a single file. The first example follows that choice.

Select "Import Multiple... Option" on page 20-10 if you want have access to multiple Touchstone files Indexed for selectable port definition (discussed below).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

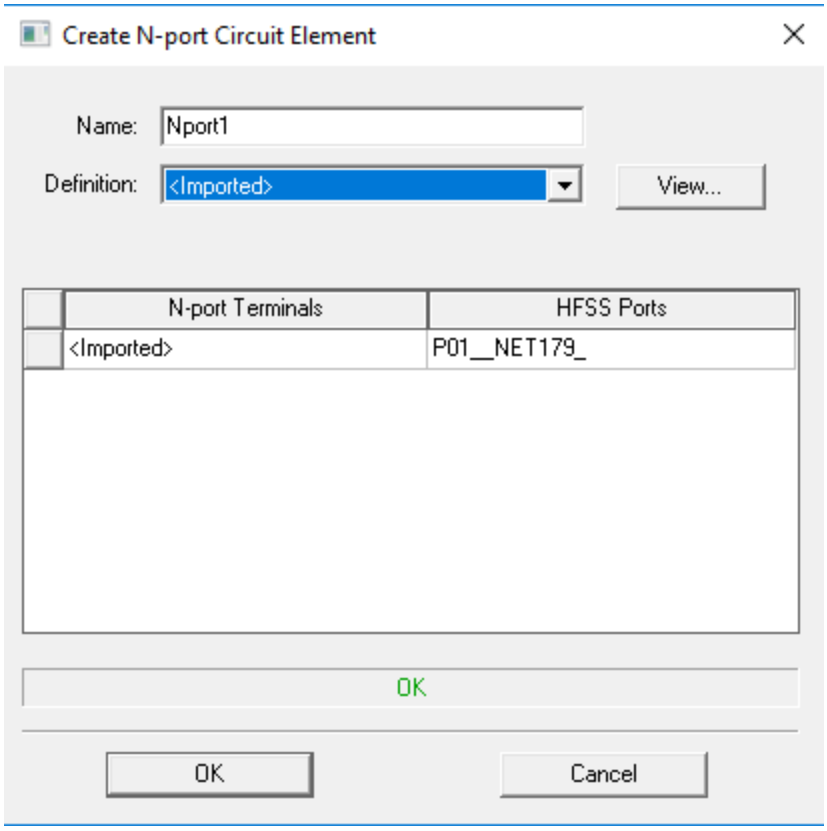
Select Create Definition, or, if you have previously accessed appropriate models, select from models listed. If you select **Create Definition...** you will see the **Select Definition** window where you can select and create circuit models and manage libraries.

If you have previously created Touchstone files of the correct matrix size you can use **Import...** to open a File browser to select one.

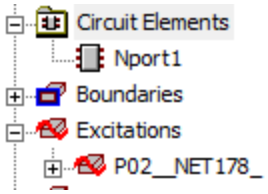


If the model has the corresponding Matrix size, the **Create N Port Circuit Element** dialog can assign the HFSS ports, and shows that the assignment is valid with a green OK. If a valid assignment cannot be made, the field has a red text describing the issue. With valid assignments, the **View** button ins enabled lets you open the port definition in Network Data Explorer. .

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



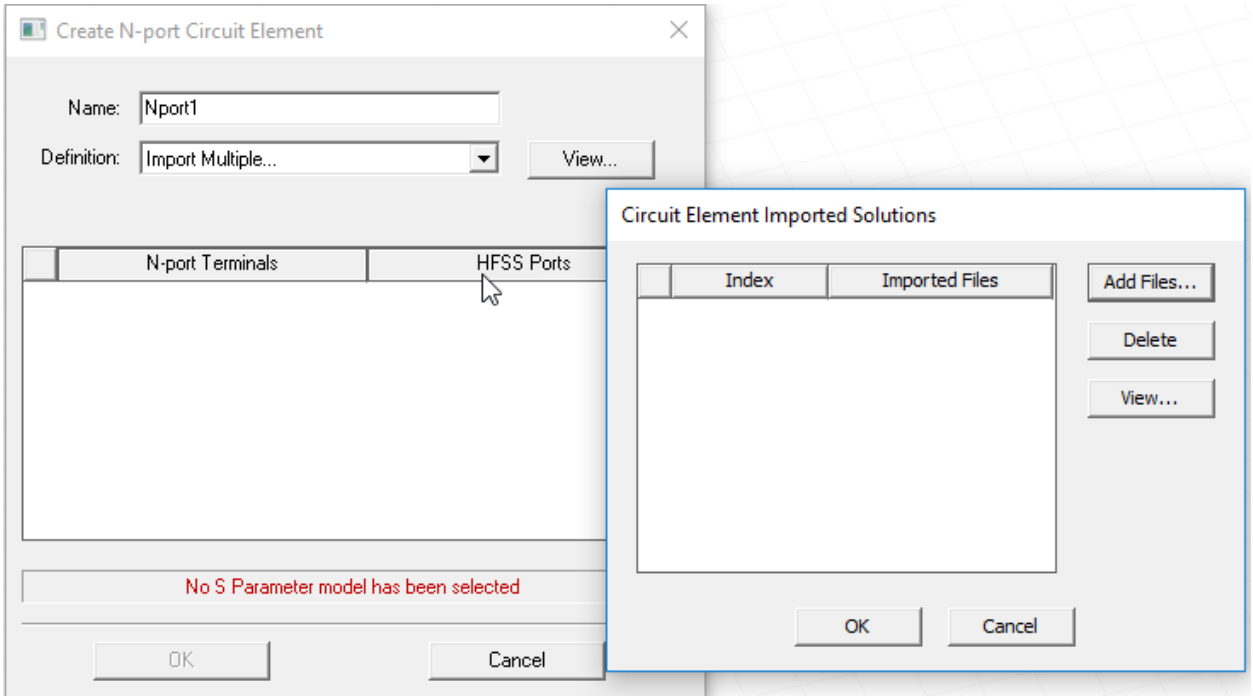
2. You can OK the dialog box, and see the **Circuit Element** listed in the **Project** tree.



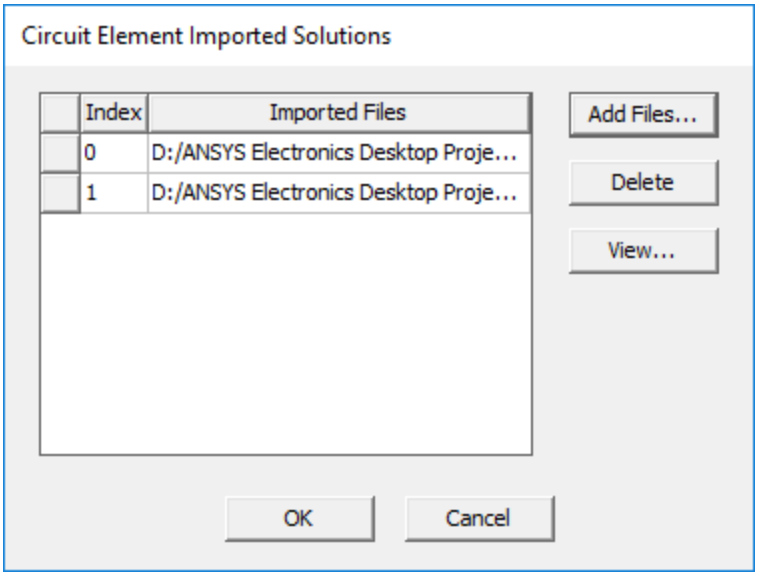
Import Multiple... Option

If you select **Import Multiple...** in the **Create N-port Circuit Element** dialog box, the **Circuit Element Imported Solutions** dialog opens.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

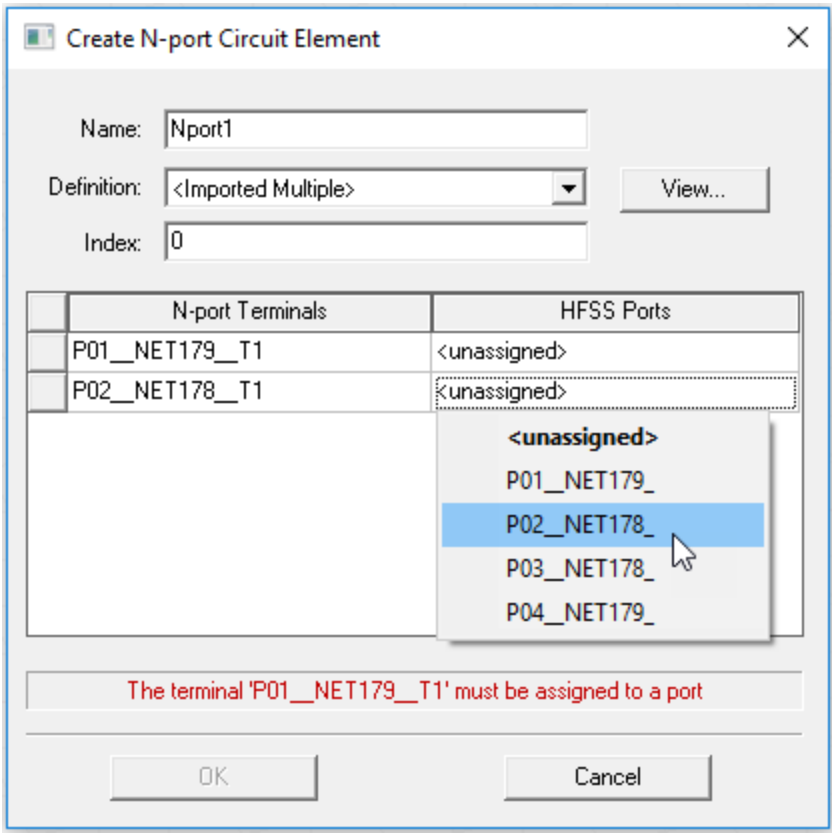


Click **Add Files...** to open a browser to add suitable Touchstone models. When you have added the models they are listed as Imported Files and you can OK the browser. The **View...** button opens the selected file in Network Data Explorer. **Note**: Each file you select has an **Index** assigned here that you can use to identify which file to use for the Circuit Element.



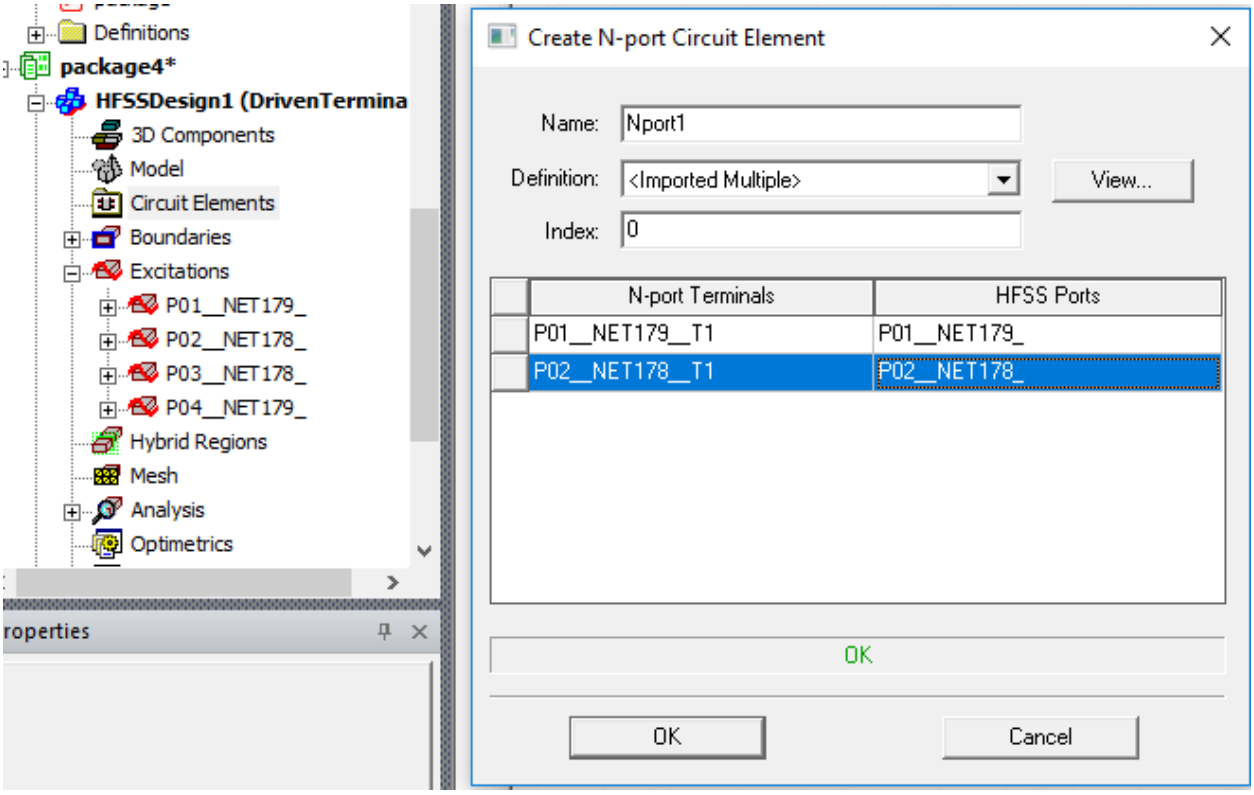
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

OK to close the dialog box. You then make HFSS Port assignments in the **Create N-port Circuit Element** dialog box. The **View...** button allows you to use Network Data Explorer for the selected Touchstone file.



When you have made the assignments, the message field reports **OK** in green. The **View...** button allows you to use Network Data Explorer for the selected Touchstone file.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

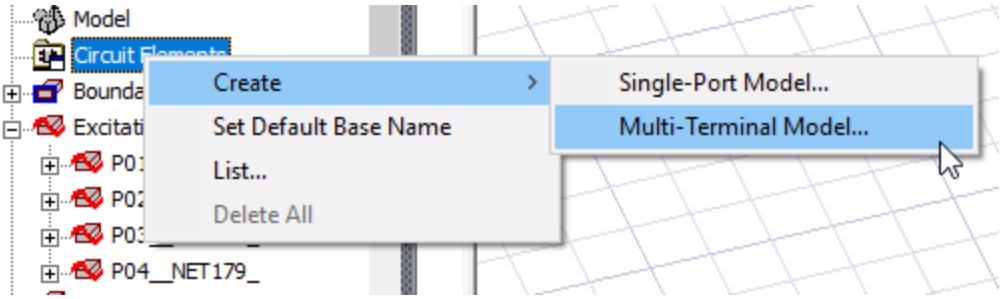


Notice that the **Index** value can control which touchstone file listed in the **Circuit Element Imported Solutions** dialog is used in the simulation by index. The Index value can be parameterized, that is, defined as a variable so to be used in a parametric study or exposed as a component parameter when included in a 3D component.

Creating a Multi-Terminal Circuit Element in HFSS

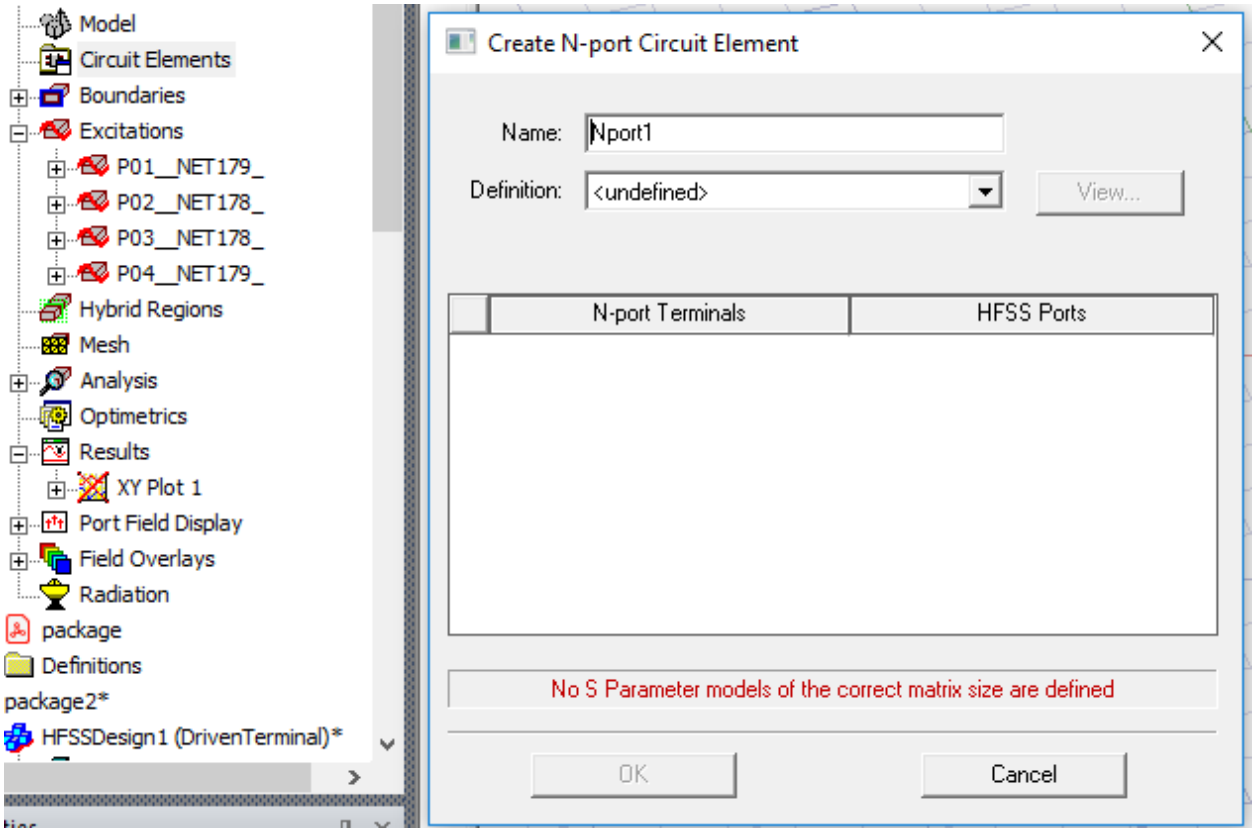
To create a Multi-Terminal model as a circuit element:

1. Right click on the **Circuit Elements** folder and select **Create>Multi-Terminal Model...**.



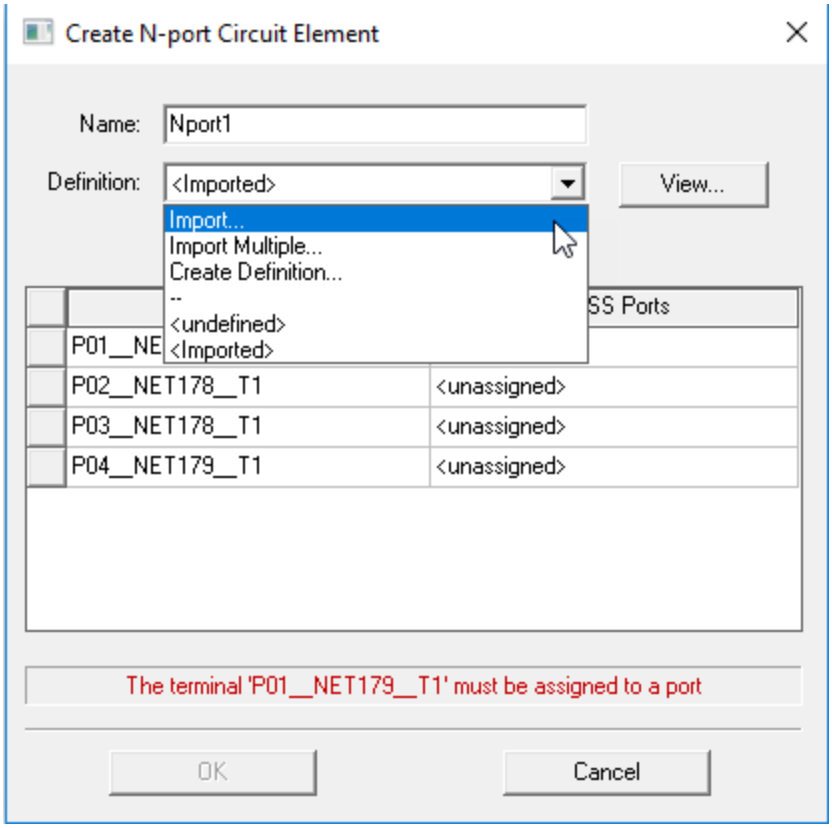
The **Create N-port Circuit Element** dialog opens.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



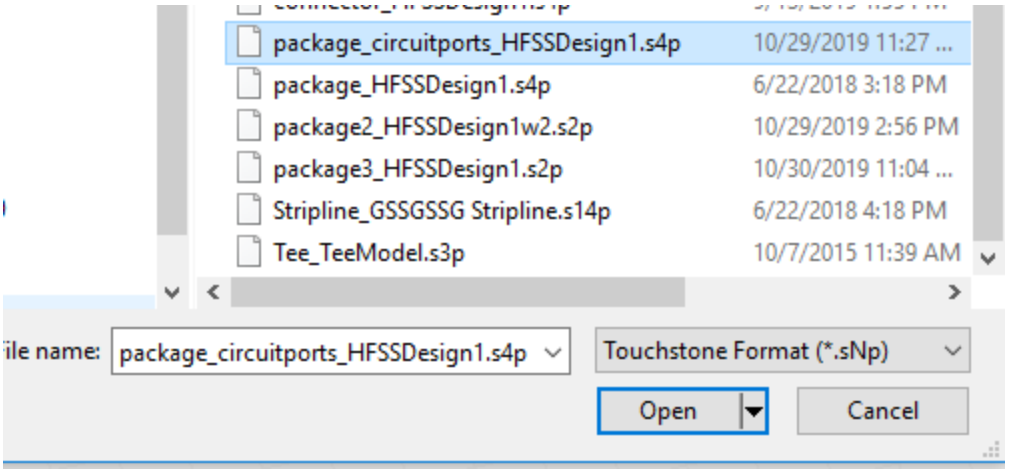
2. Select from the **Definition** pulldown to open a file browser to import a touchstone file containing models of the HFSS ports. The **View...** button allows you to use Network Data Explorer for the selected Touchstone file.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



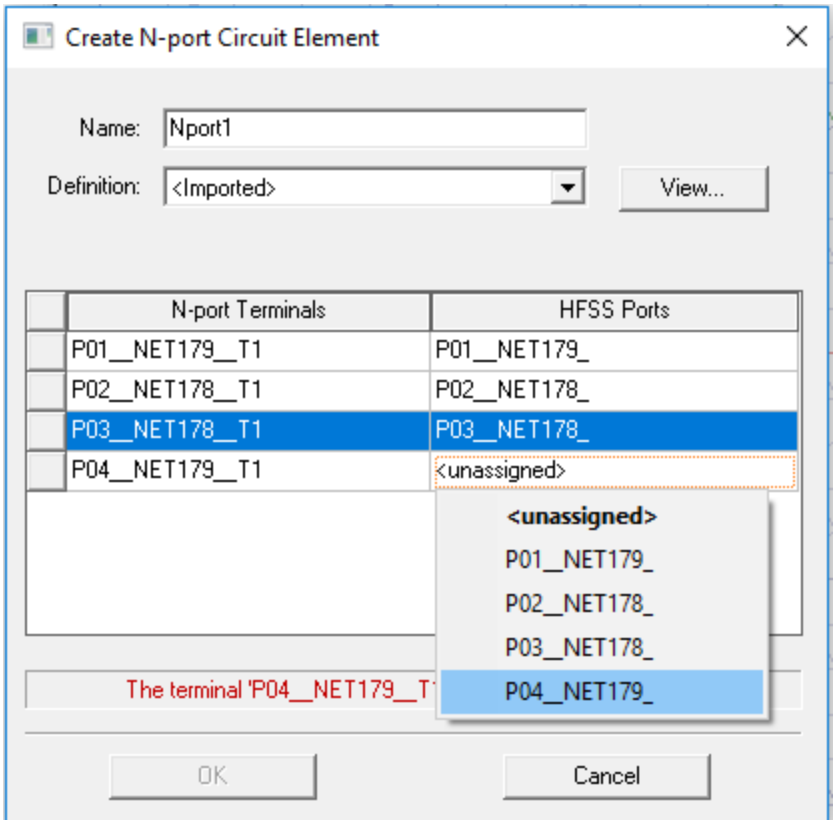
Select **Import...** to import a Touchstone file that contains solution information for all ports. This first example follows this choice. You could also use "Import Multiple... Option" on page 20-17 (discussed below) if you want have access to multiple Touchstone files Indexed for selectable port definition. You can use Create Definition to create and access libraries of Touchstone files.

3. Select an appropriate Touchstone file in the browser, and **OK**. You can select additional formats on the Touchstone dropdown menu.



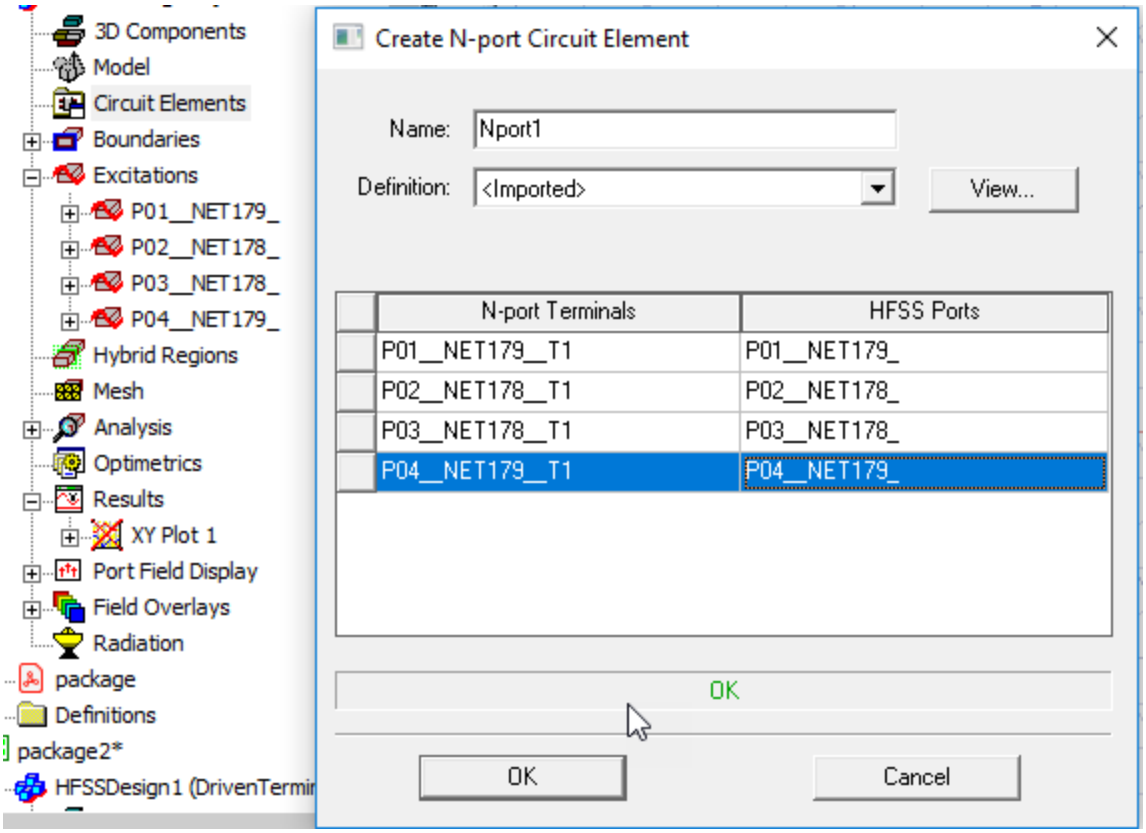
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Use the drop down menu for the HFSS Port rows to make terminal assignments. The **View...** button allows you to use Network Data Explorer for the selected Touchstone file.

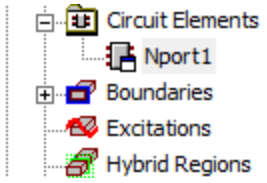


4. If you have selected a suitable model and assigned ports correctly, message field will show a green OK. The **View...** button allows you to use Network Data Explorer for the selected Touchstone file.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



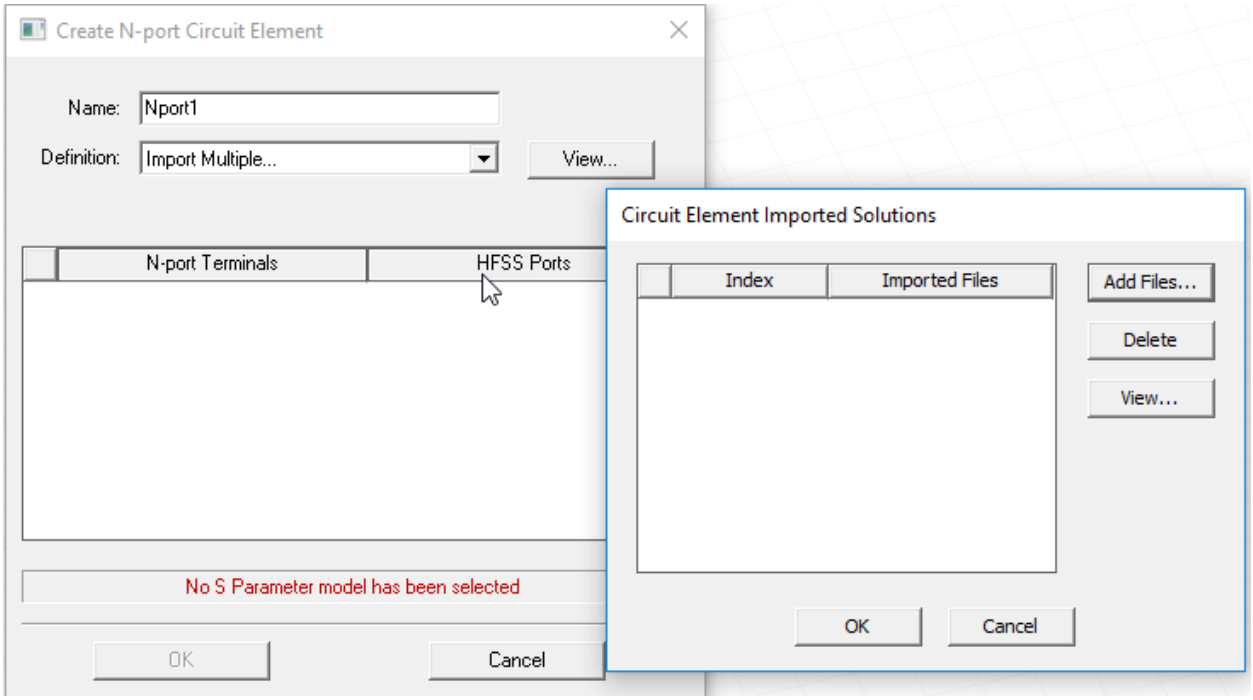
5. You can **OK** the dialog box, and see the **Circuit Element** listed in the **Project** tree and the Ports you selected are removed from the **Excitations** list.



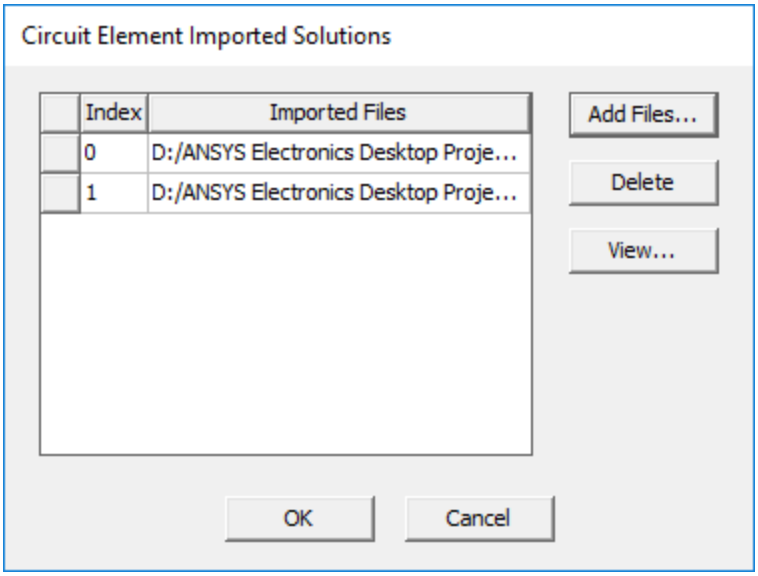
Import Multiple... Option

If you select **Import Multiple...** in the **Create N-port Circuit Element** dialog box, the **Circuit Element Imported Solutions** dialog opens.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

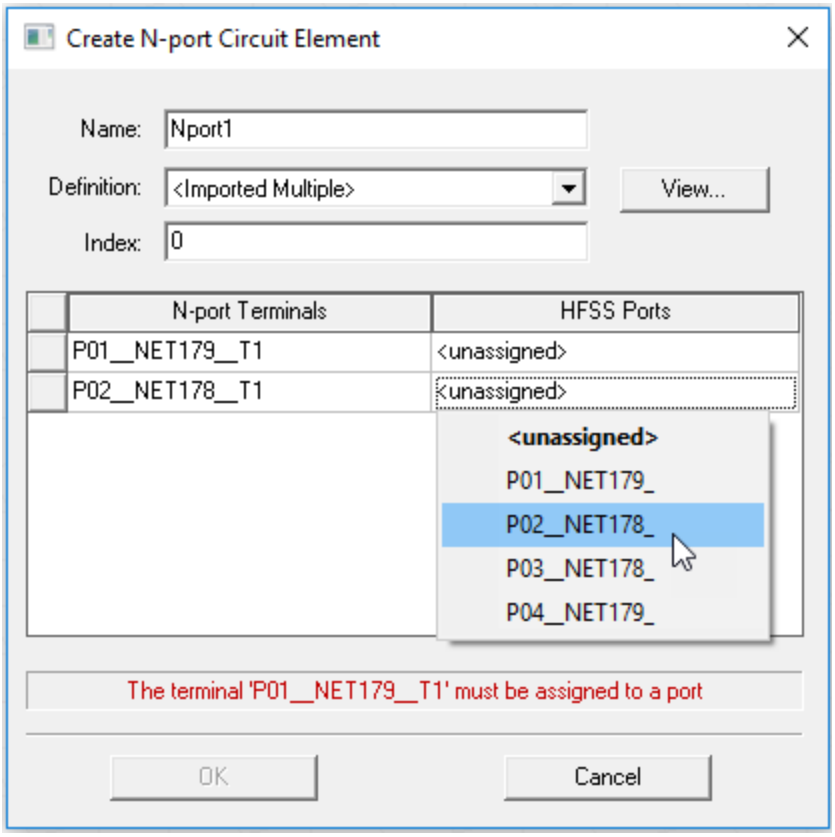


Click **Add Files...** to open a browser to add suitable Touchstone models. When you have added the models they are listed as Imported Files and you can OK the browser. The **View...** button opens the selected file in Network Data Explorer. **Note**: Each file you select has an **Index** assigned here that you can use to identify which file to use for the Circuit Element.



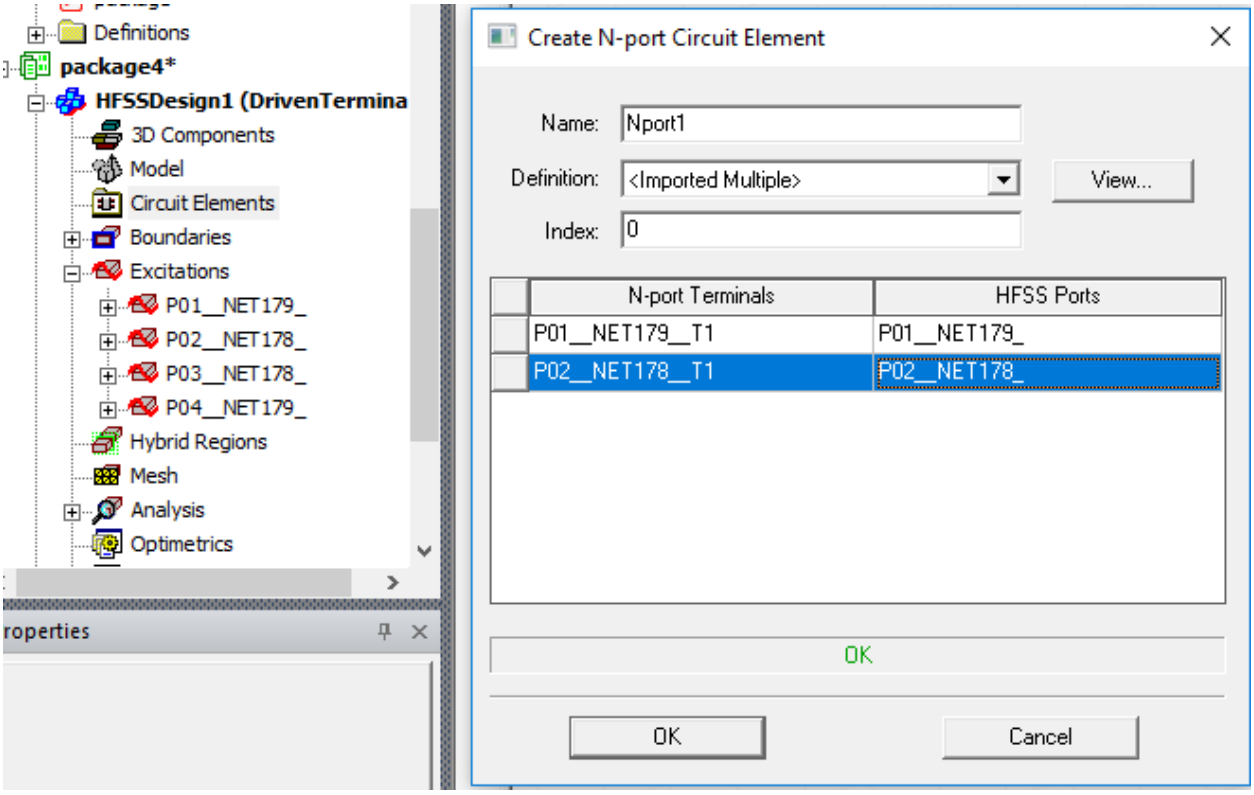
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

OK to close the dialog box. You then make HFSS Port assignments in the **Create N-port Circuit Element** dialog.



When you have made the assignments, the message field reports **OK** in green.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

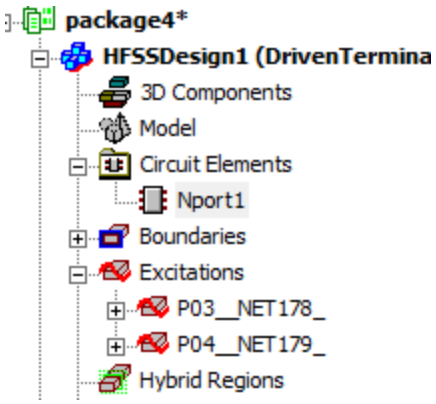


Notice that the **Index** value can control which touchstone file listed in the **Circuit Element Imported Solutions** dialog is used in the simulation by index. The Index value can be parameterized, that is, defined as a variable so to be used in a parametric study or exposed as a component parameter when included in a 3D component.

With valid assignments, the **View** button is enabled and lets you open the port definition in Network Data Explorer.

OK the dialog box. The N-port Terminal for which you have assigned HFSS Ports is created, and the corresponding Excitations are removed from the Project tree.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

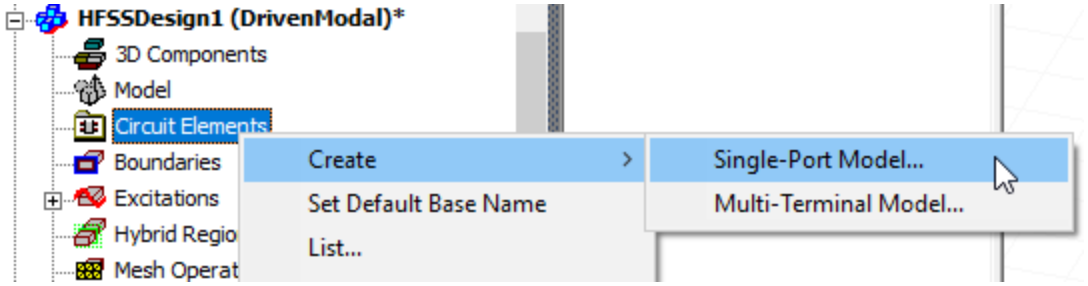


Import Touchstone Files for Circuit Elements in HFSS

To create a circuit element, you can import Touchstone files to create the definition for a Single Port Model or a Multi-Terminal Model:

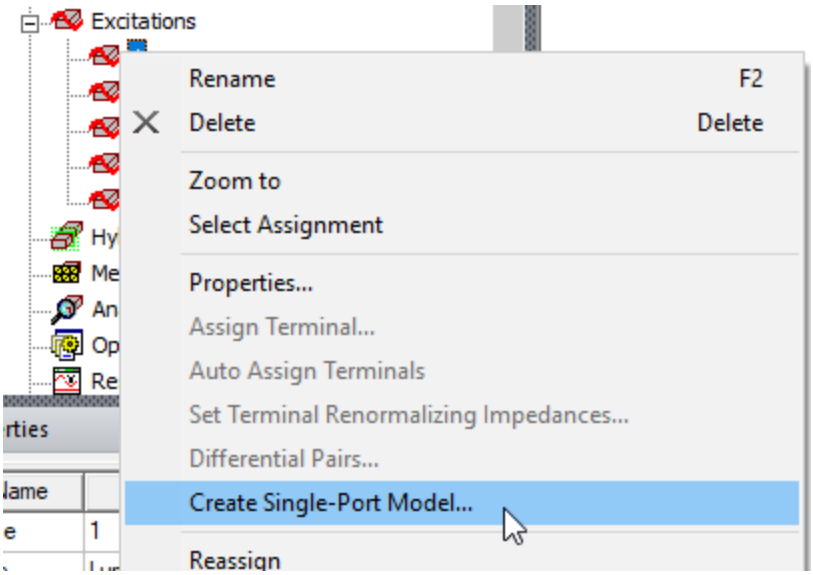
For a single Terminal Model:

1. Right click on a Lumped port in the **Project** tree and click **Create Single-Port Model**,

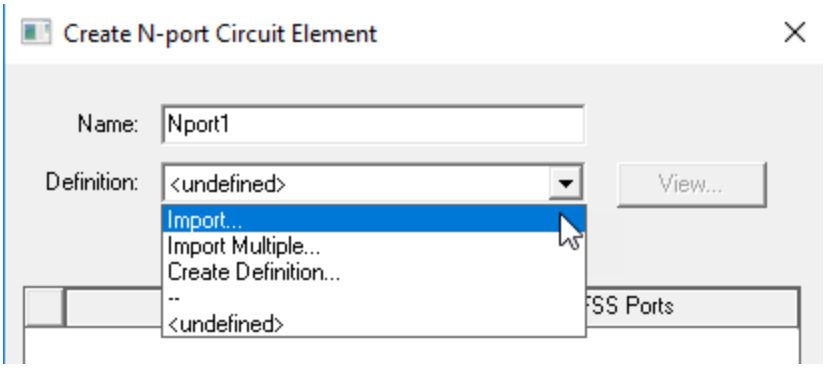


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

or right click on the **Circuit Elements** folder and select **Create>Single Port Model...**.

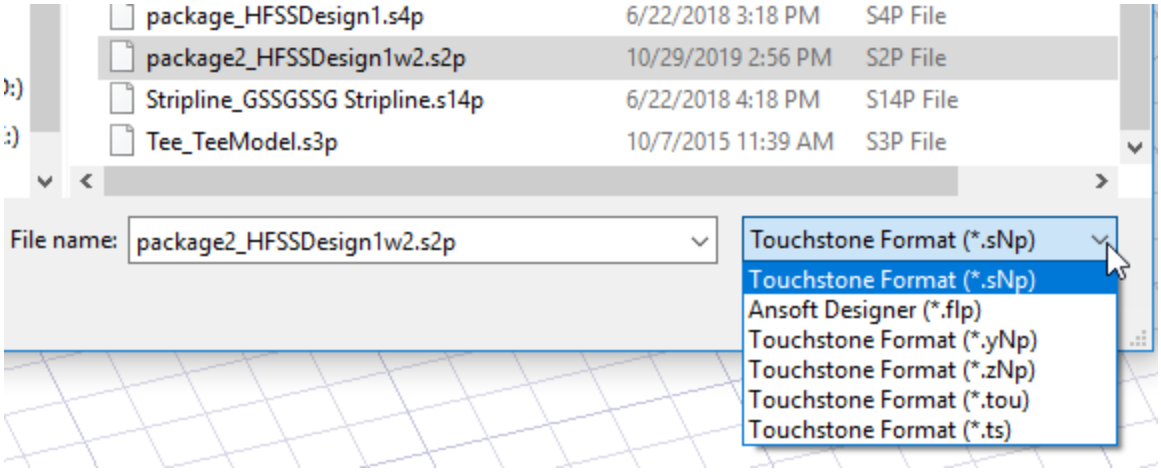


The **Create N-port Circuit Element** dialog opens. If you selected the port menu, the dialog shows the HFSS Port assignment. If you selected from the Circuit Element menu, you can click on the HFSS Ports cell to select from available ports.

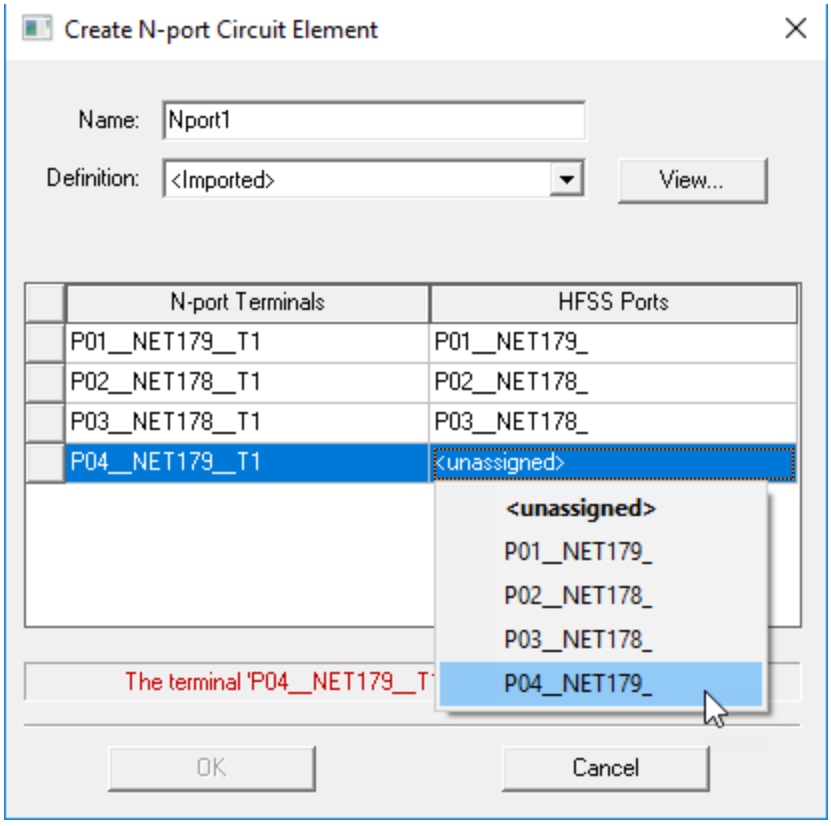


Selecting **Import...** automatically opens a browser window. You can select the Touchstone format and an appropriate file.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

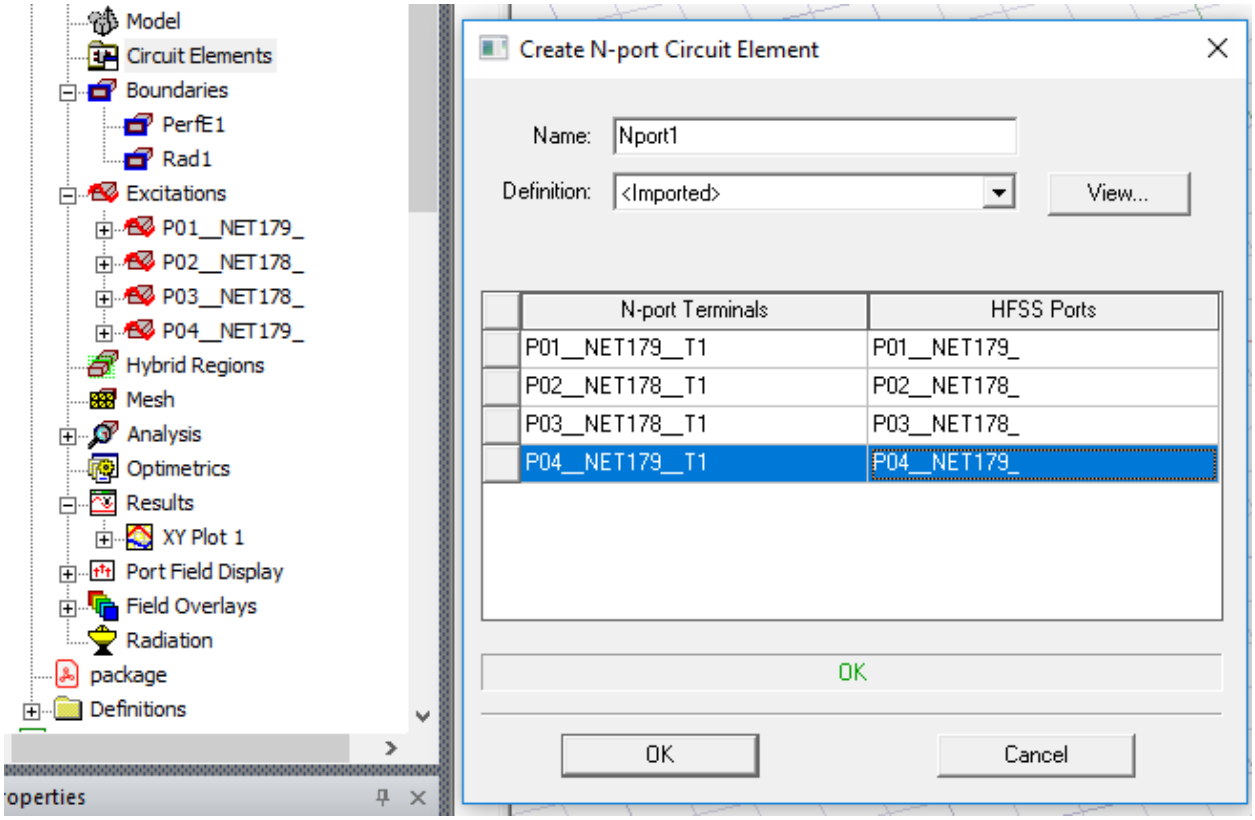


If the Touchstone file is consistent with the design and selection, the Create N-port Circuit Element dialog shows where you can make port assignments.

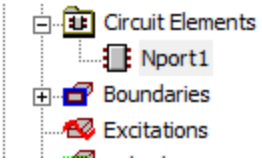


When you can competed Port/Terminal assignments, the Message field changes to a green OK.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

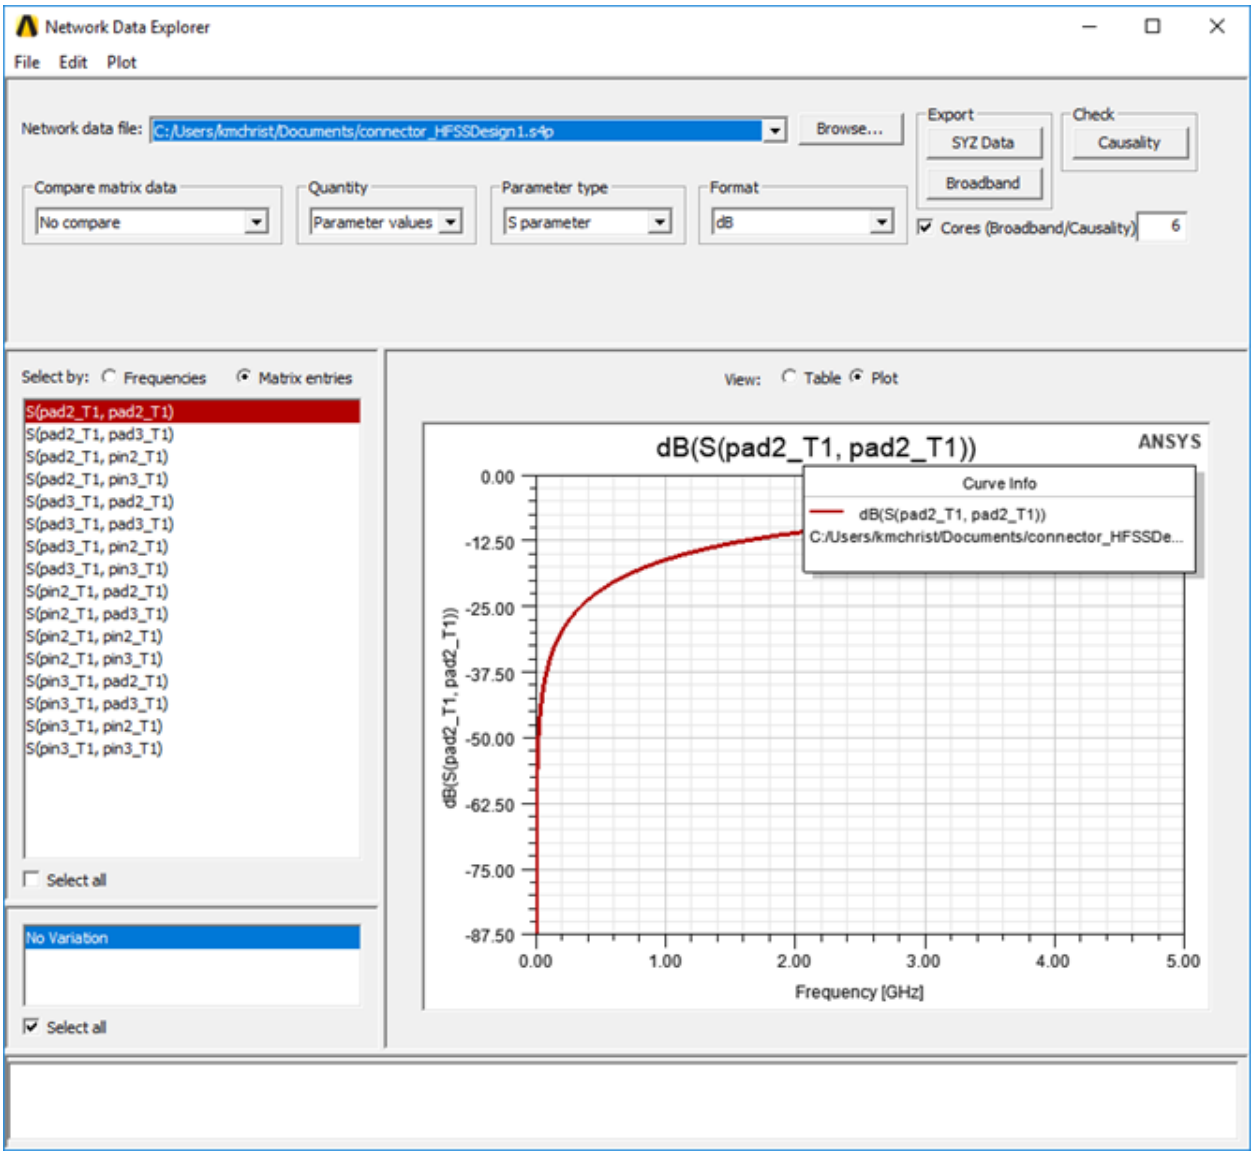


When click OK, the dialog closes, and the in Project tree, the Excitations are removed an Nport appears under the Circuit Elements.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. The **View...** button in the Create N Port dialog opens the circuit port in ndExplorer

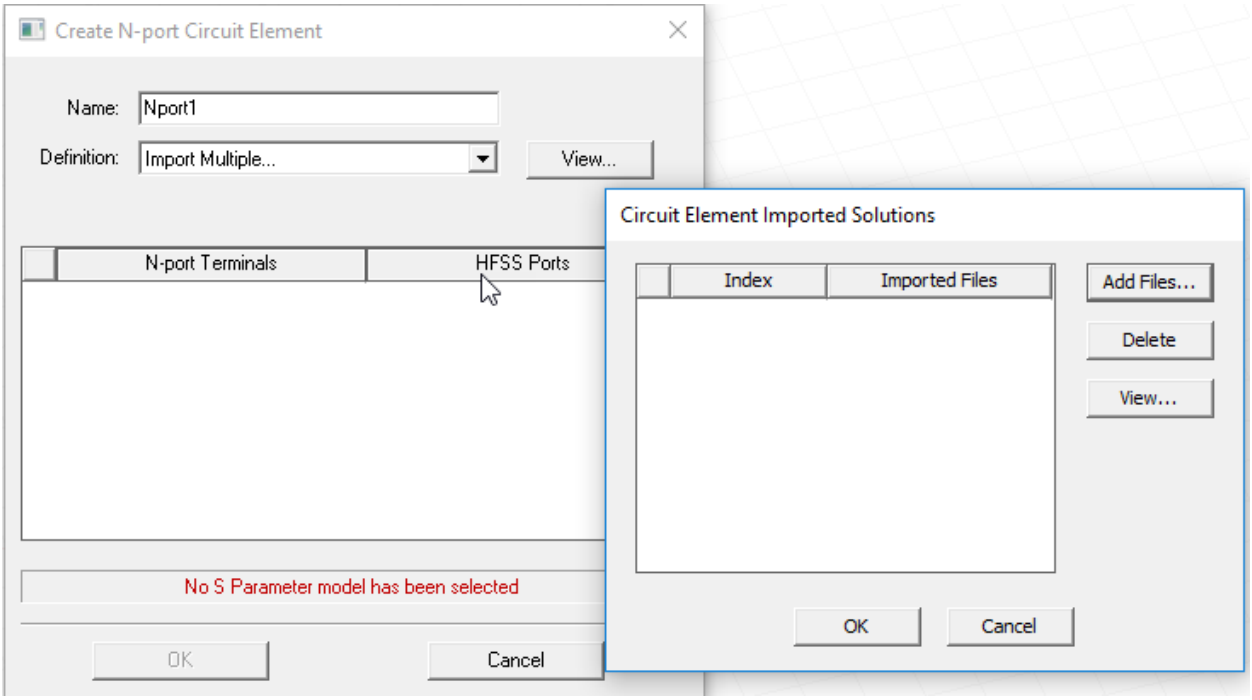


For a description of ndExplorer, see Network Data Explorer.

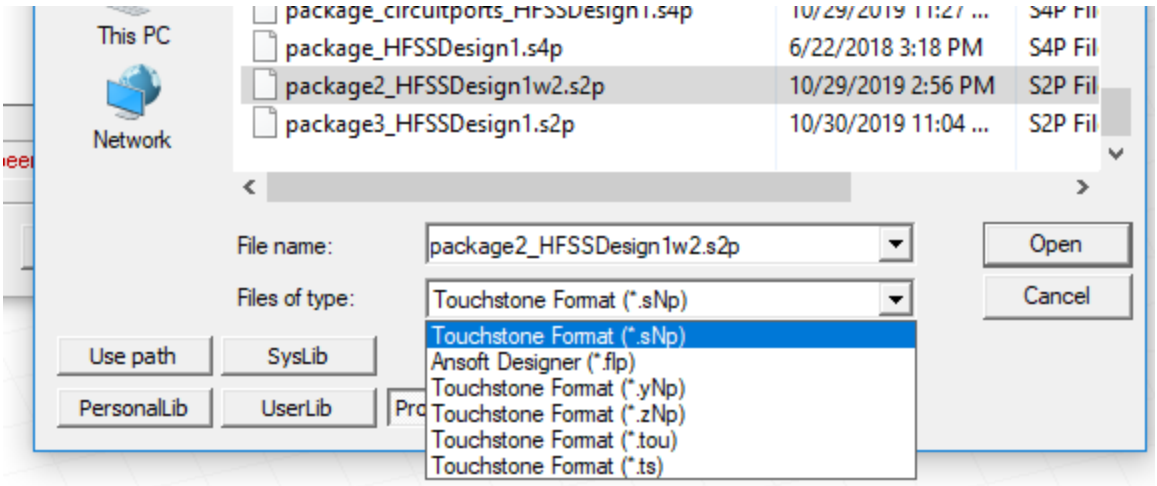
Using **Import Multiple ...** for Touchstone files.

If you select **Import Multiple...** in the **Create N-port Circuit Element** dialog box, the **Circuit Element Imported Solutions** dialog opens.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

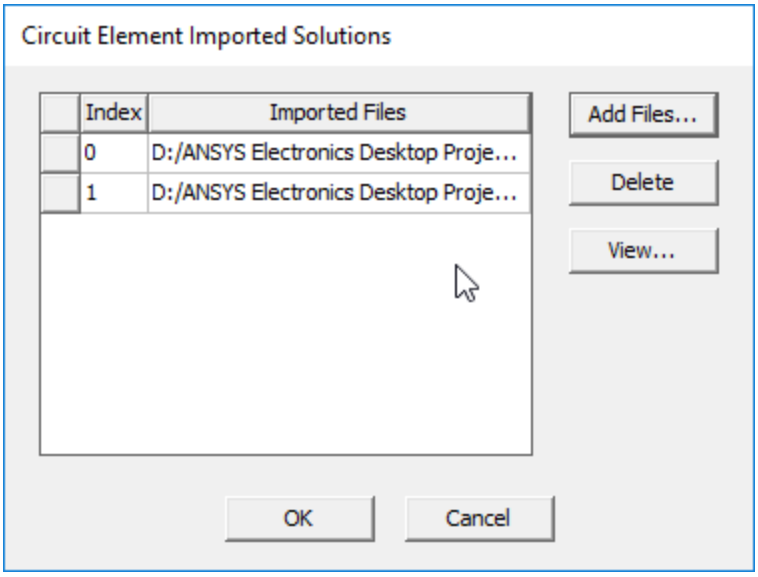


If no imported files are listed, you can click Add Files to open a file browser to add suitable touchtone solution files, such as those created when you Export Matrix data from the Solutions dialog.

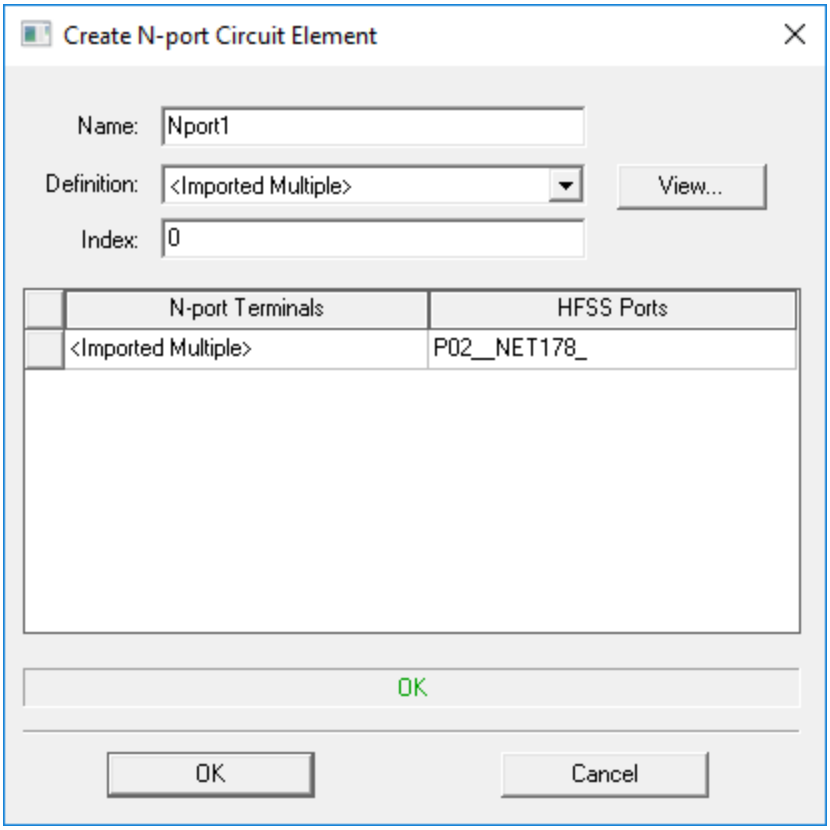


Added files are then listed as **Circuit Element Imported Solutions**. The **View...** button opens the selected solution file in NDExplorer.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

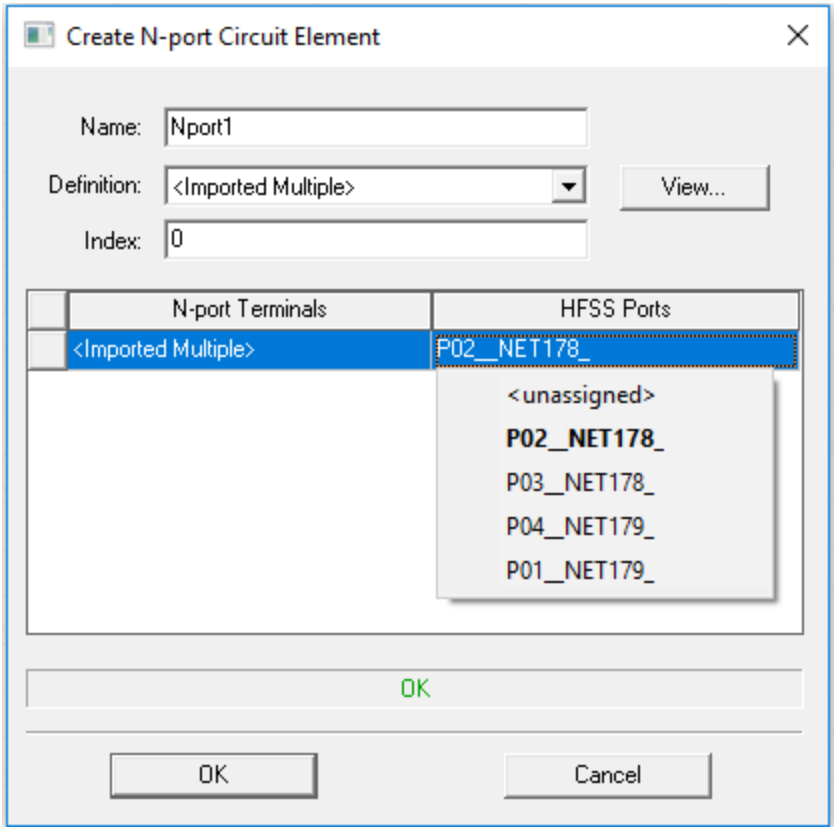


Click OK to close the dialog box. The Create N-port Circuit Element dialog shows an HFSS Port assignment, based on the solution file.

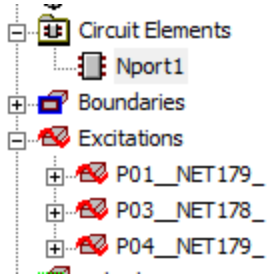


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If the Solution files contains information for multiple ports, you can change the assignment by selecting from the drop-down menu.

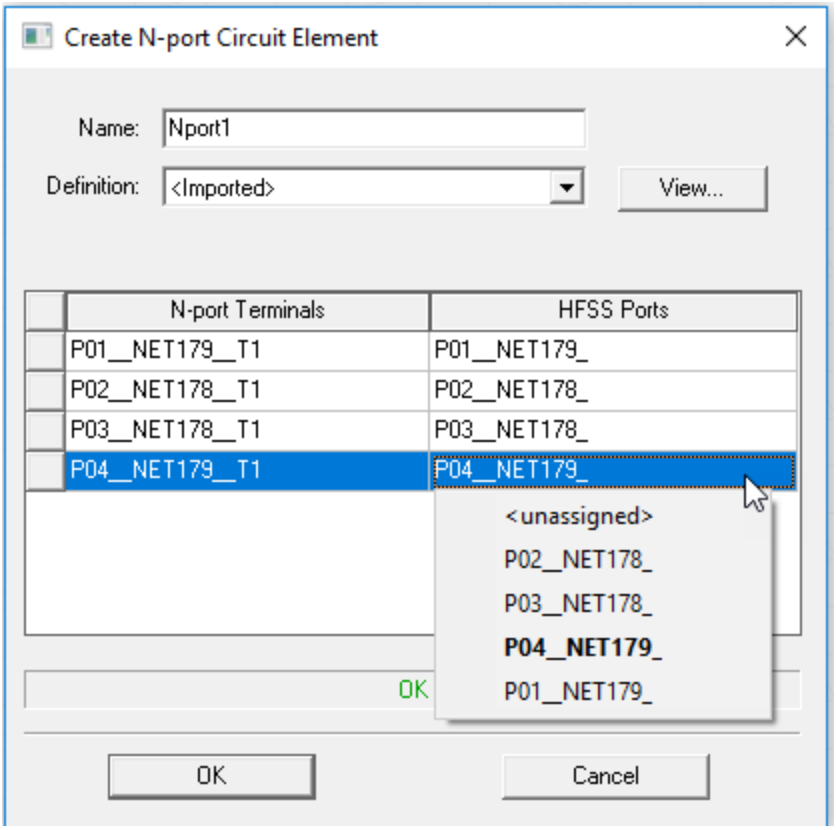


Click OK to close the dialog box. The Project tree will show the nPort listed as a Circuit Element, and the Excitation that corresponded to the assignment is not listed.

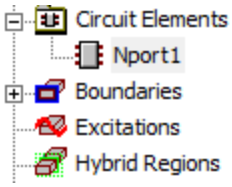


If you select **Multiple Terminal Model**, and the selected Touchstone file contains solution information for all N-port Terminals, the Create N-Port Circuit Element dialog allows you to make assignments for all available HFSS Ports.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



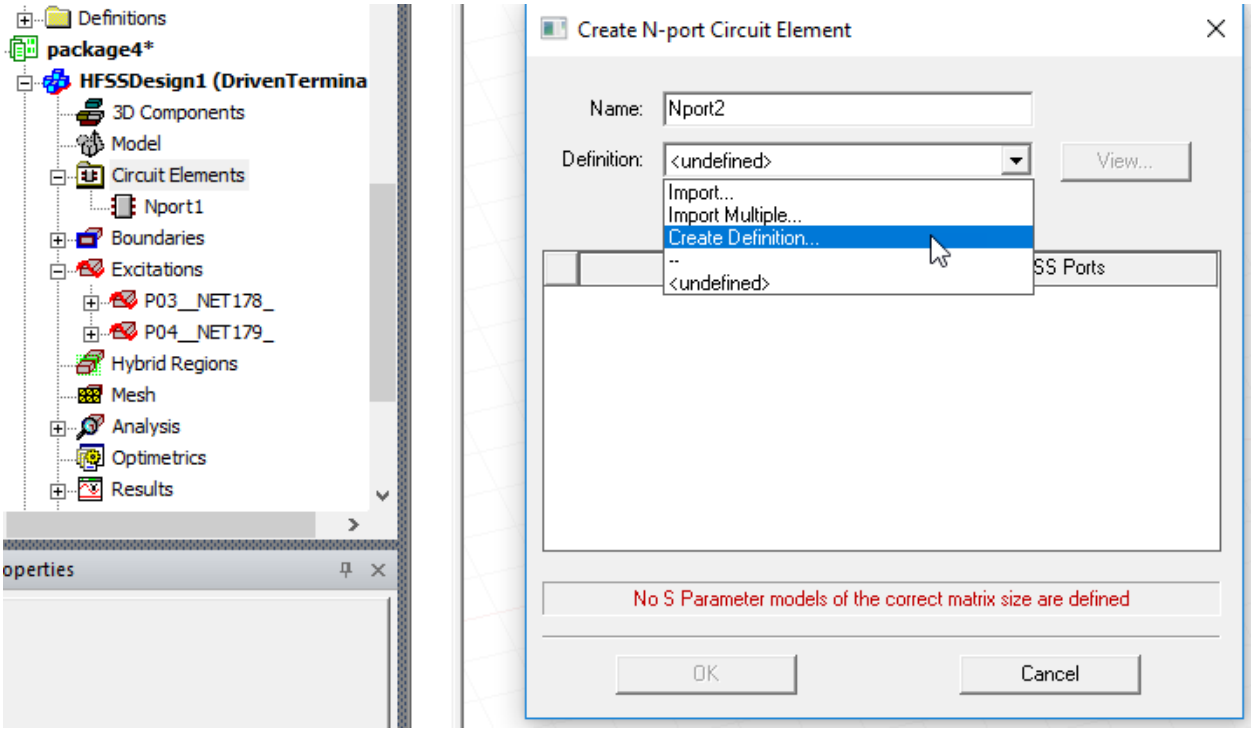
In this case, the click OK to close the dialog box. In this case the N Port replaces all assigned HFSS Ports.



Creating Circuit Models and Managing Libraries in HFSS

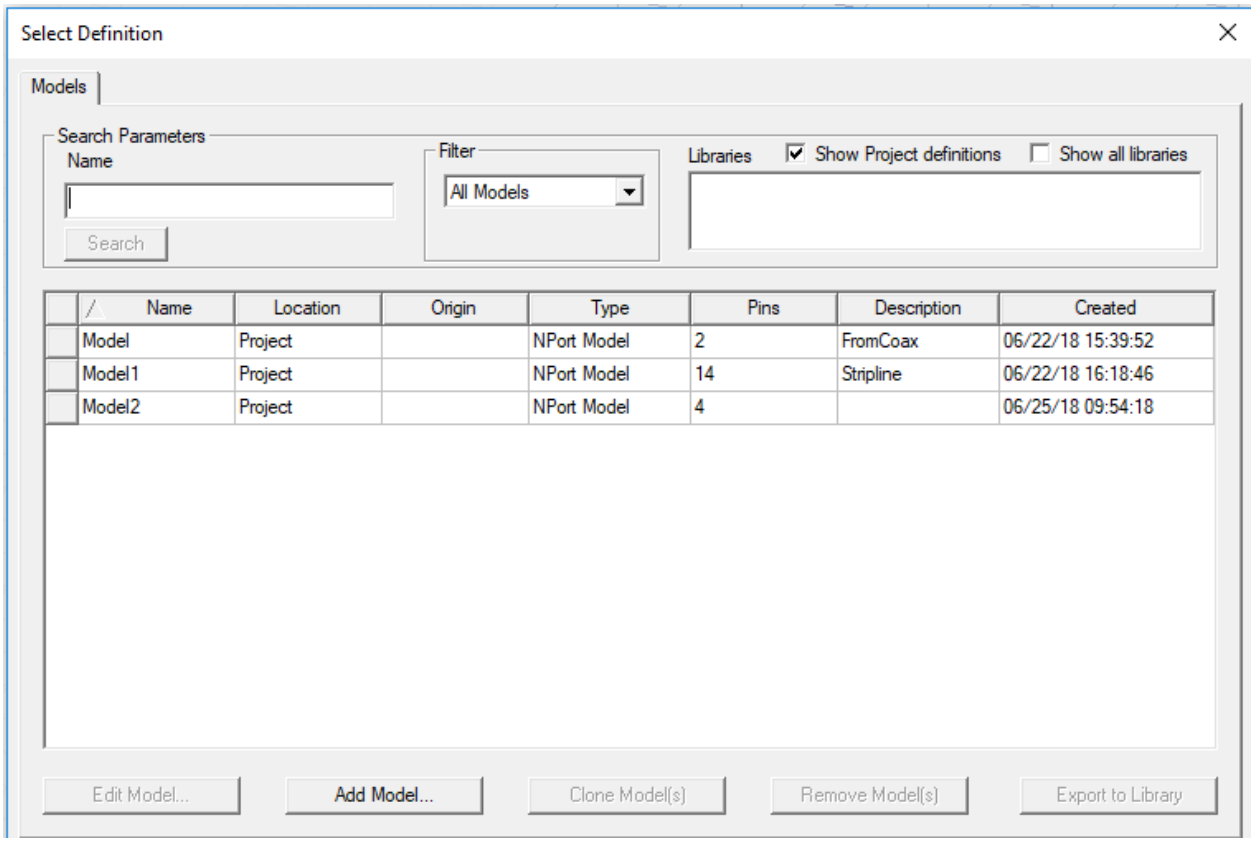
The **Create Definition...** command appears as a definition option on the **Create N-port Circuit Element** dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

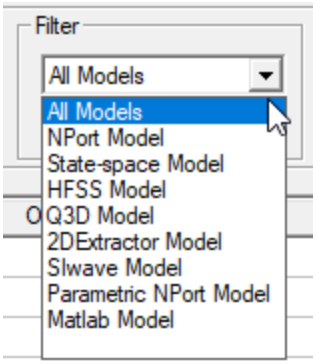


Selecting **Create Definition...** opens the the **Select Definition** dialog allows you to view, create, edit, filter and remove circuit models for the Circuit Elements feature in HFSS. It shows existing models in your library, and allows you add and organize your models.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

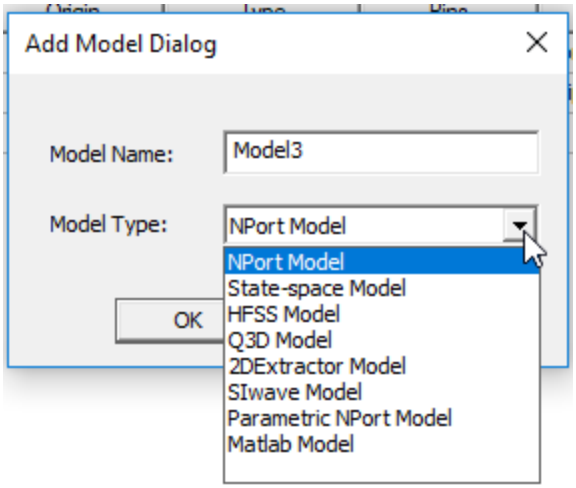


The dropdown menu in the Filter menu lets you display the models in your present library according to their original source.

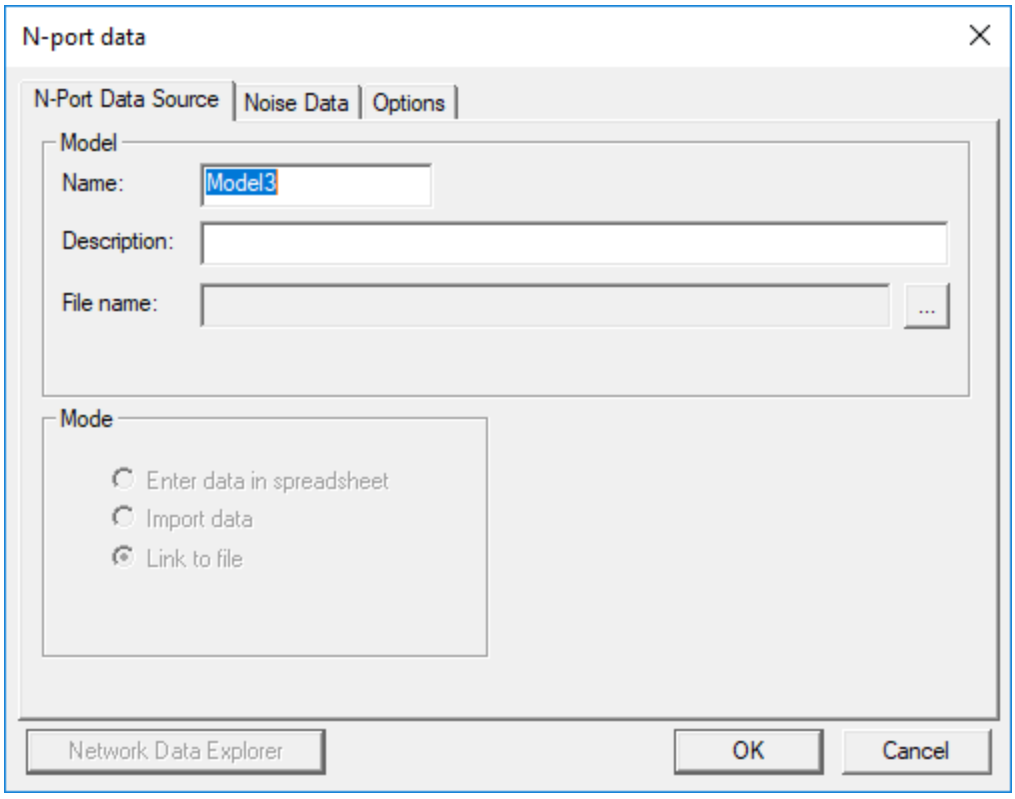


Click **Add Model...** to include additional models in your library. This opens the **Add Model Dialog.**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

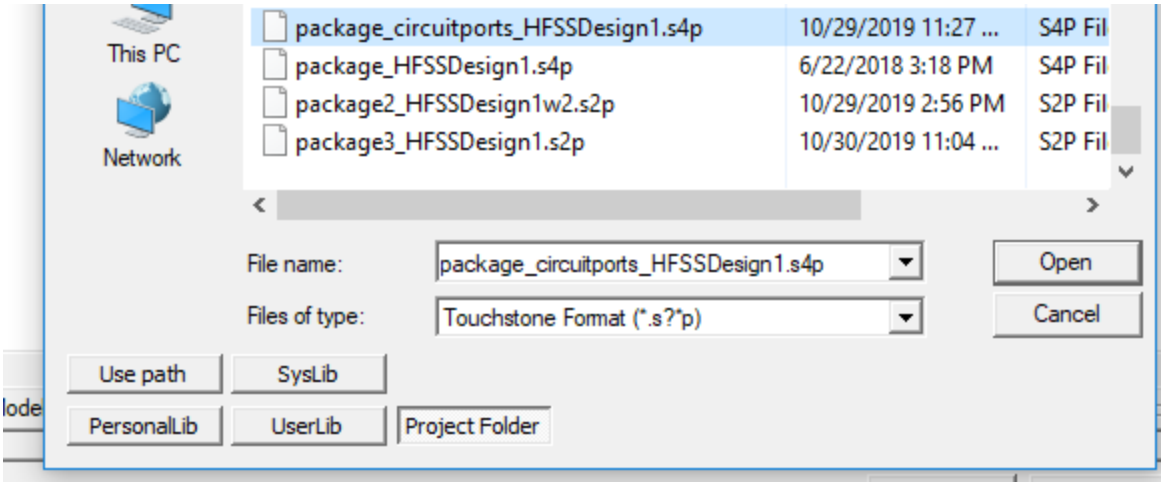


The **Add Model Dialog** contains a **Model Type** menu. Each selection leads to a dialog with options appropriate to that selection. For example, NPort Model or State space menu choices opens N-Port Data.

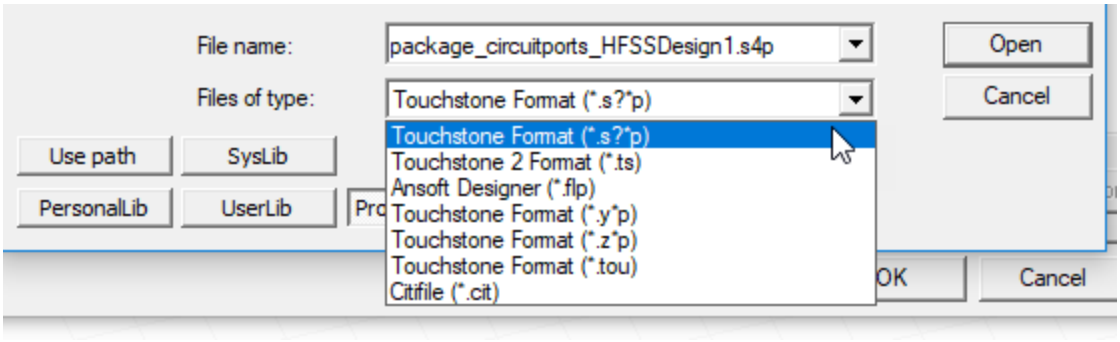


Here you can use the ellipsis button [**...**] to open a file browser to select a Touchstone file.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

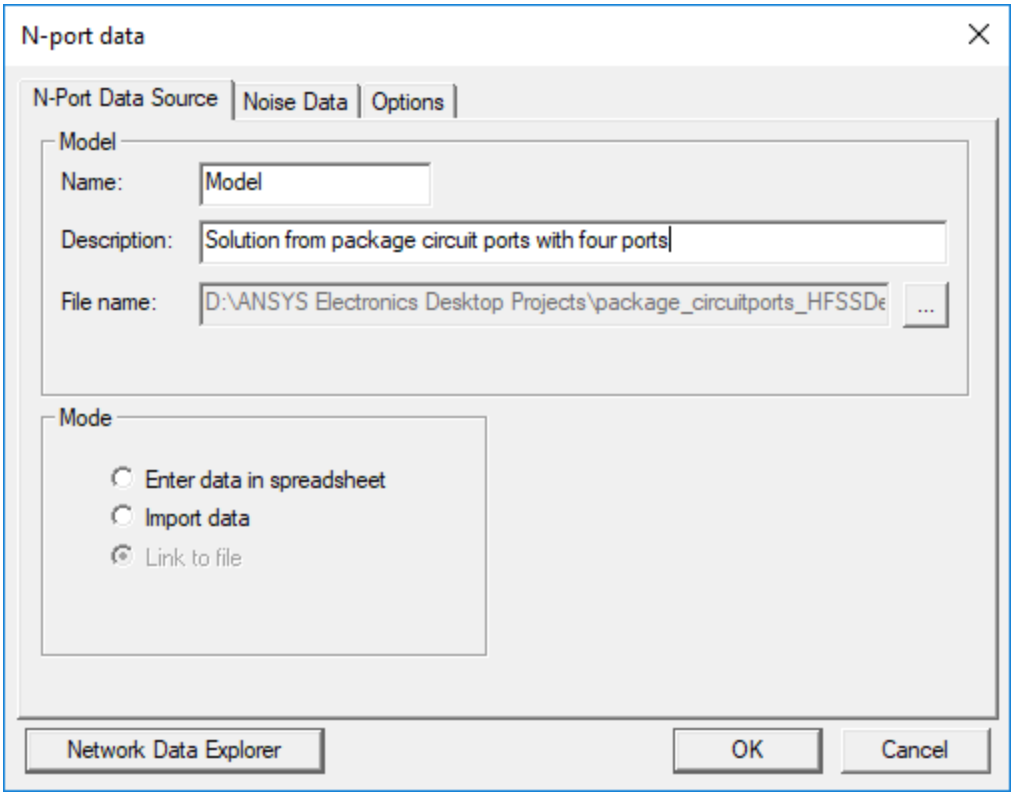


The **Files of Type** field includes a drop down listing the supported import formats.



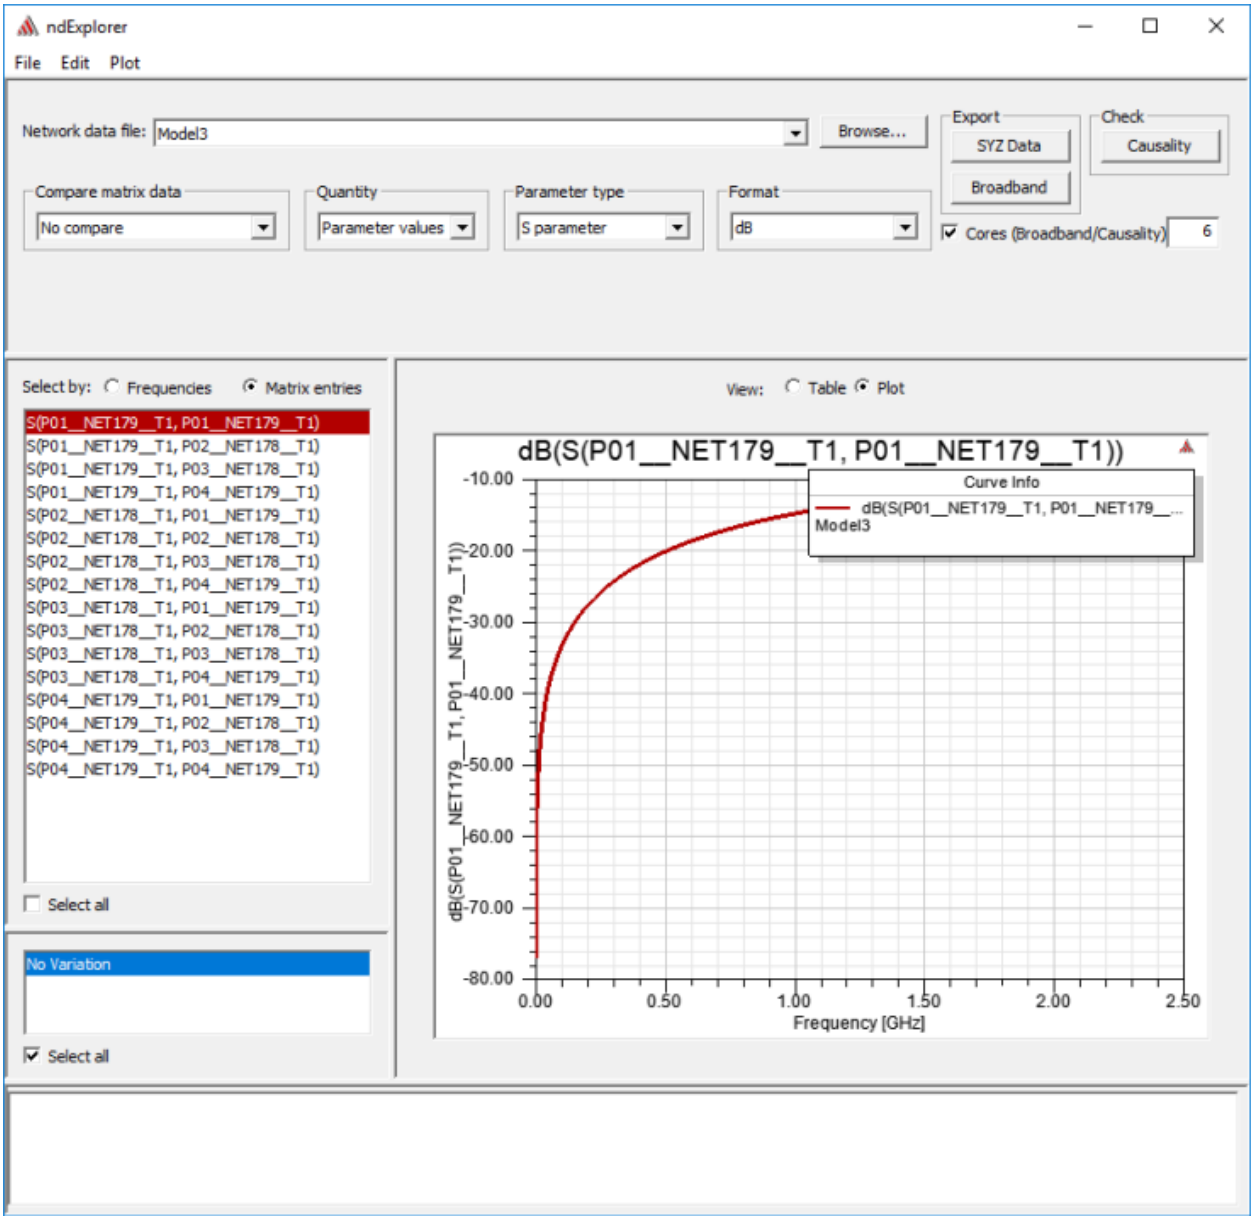
When you have selected the file, and clicked OK to close the browser, you can enter a description in the N-port data dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



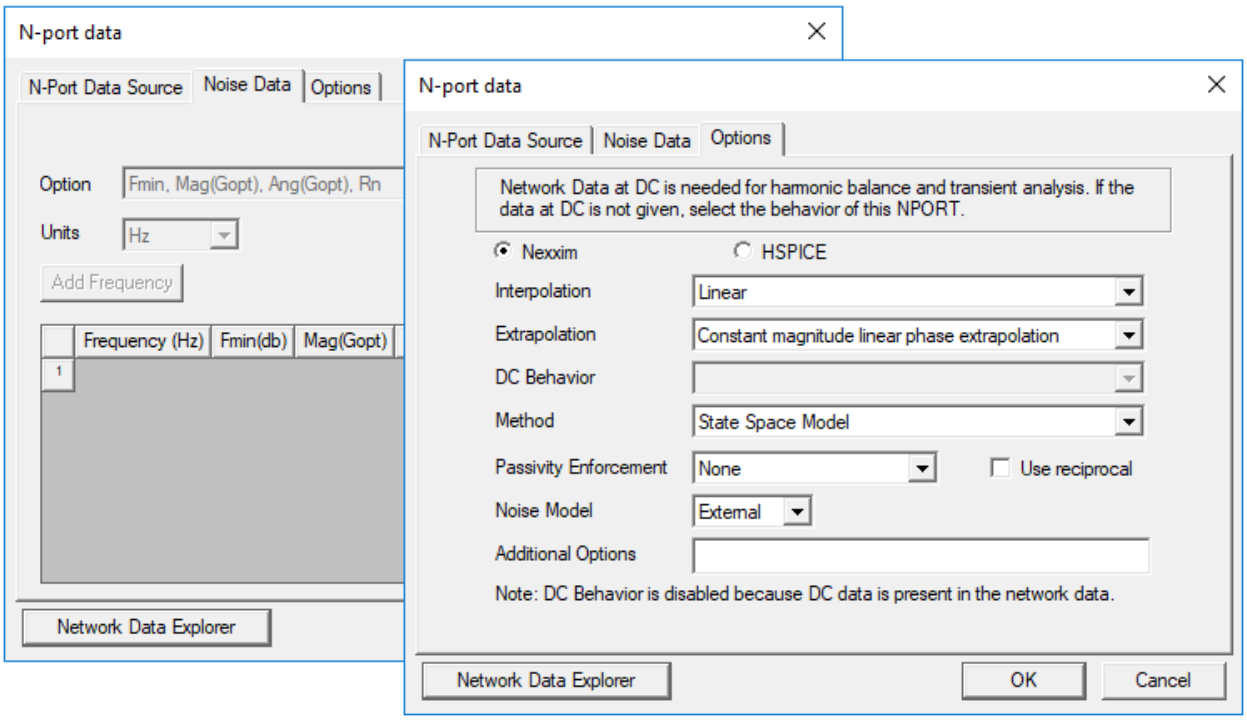
The **Network Data Explorer** button is enabled. You can use ndExplorer to view tables or plots of the matrix data.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



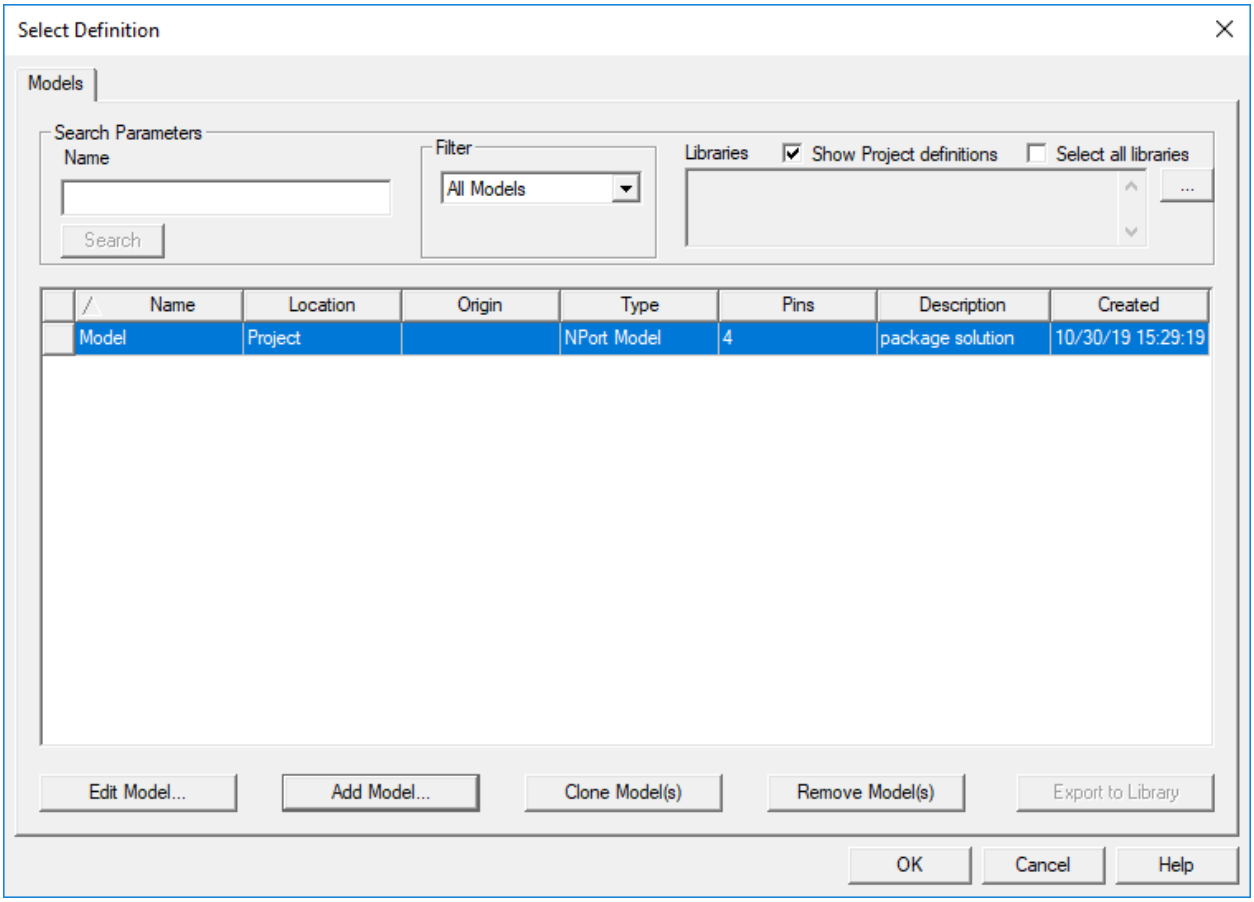
When you have selected a Touchstone file for the **N-port Data** dialog box, the **Noise Data** and **Options** tabs are enabled as well.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



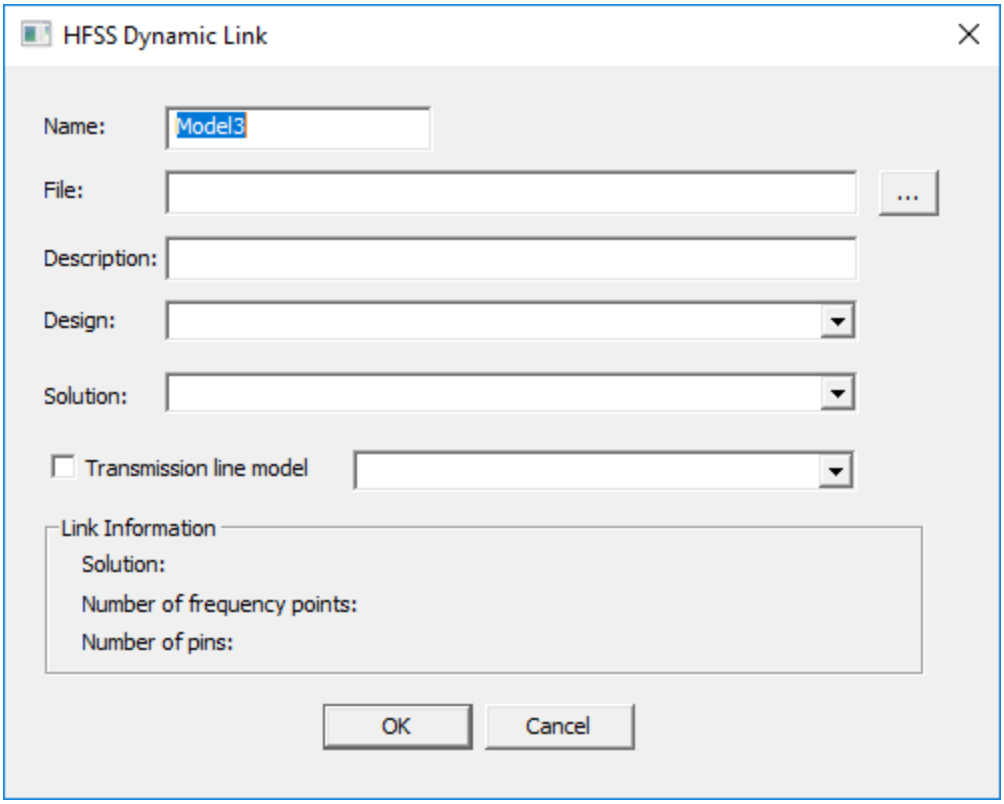
When you close the **N-port data** dialog box, the **Select Definition** window lists the newly added model.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



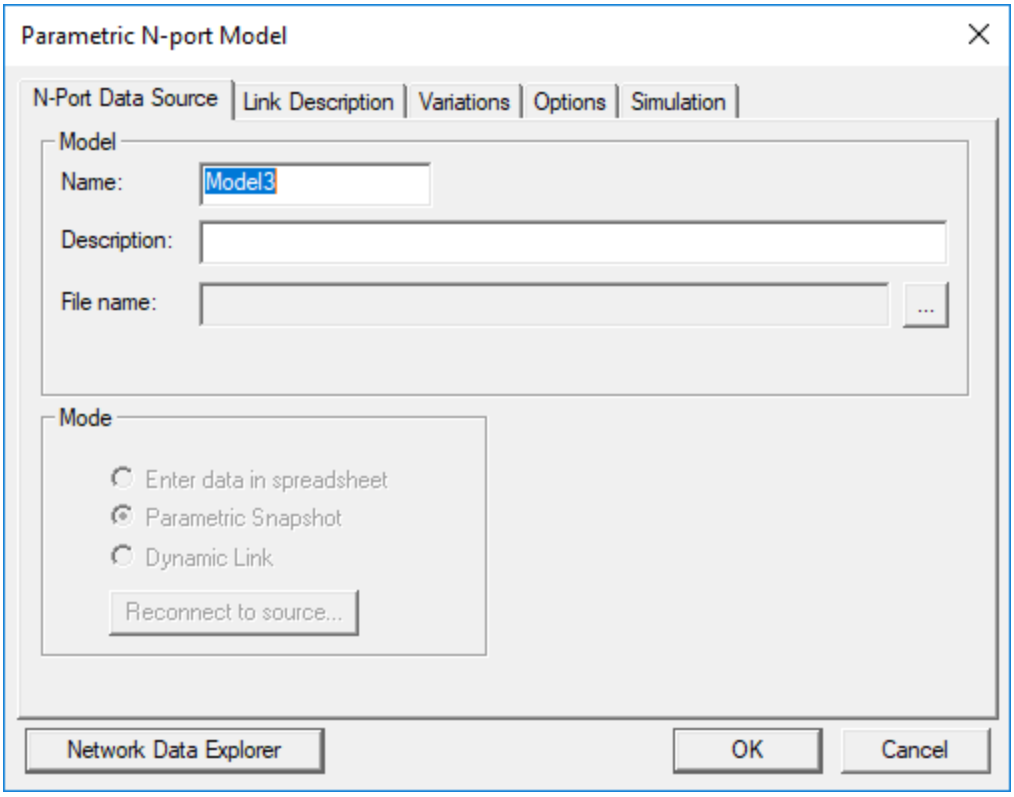
Add Model dialog choices for HFSS, Q3D, 2D Extractor, or SIwave open a **Dynamic Link** dialog box, that lets you select the project file, as well as the Design and Solution to use. If one or more transmission lines is available, you can optionally enable selection:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

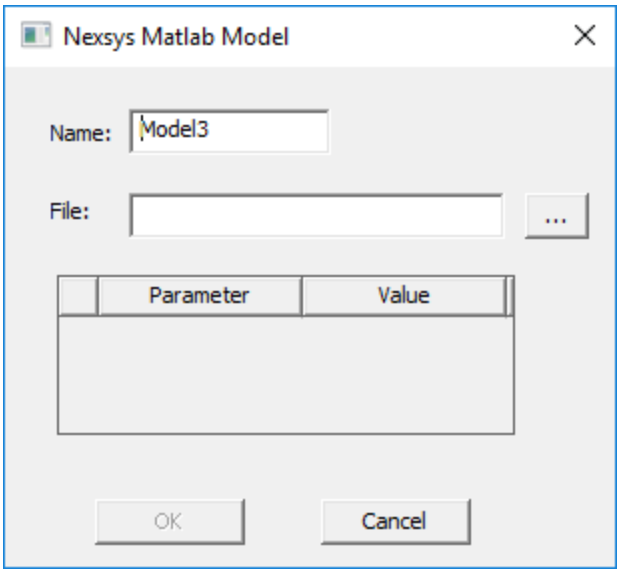


Add Model dialog choice for **Parametric N-port Model** opens a dialog with tabs for **N-Port Data Source**, **Link Description**, **Variations**, **Options**, and **Simulation**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Add Model dialog choice for **Matlab Model** opens a **Nexys Matlab Model** dialog that lets you select a file by opening a browser with the ellipsis button **[...]**.



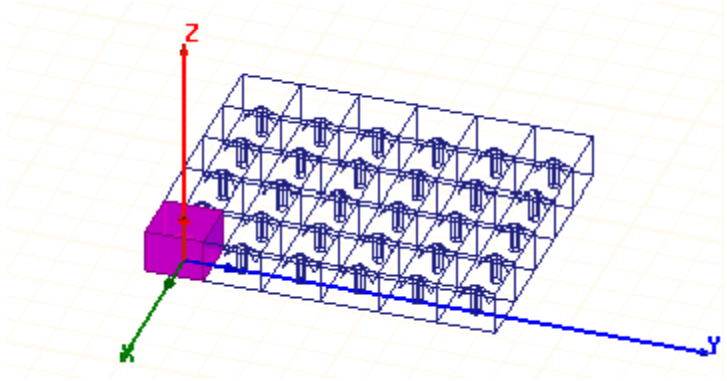
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

21 - Assigning Arrays in HFSS

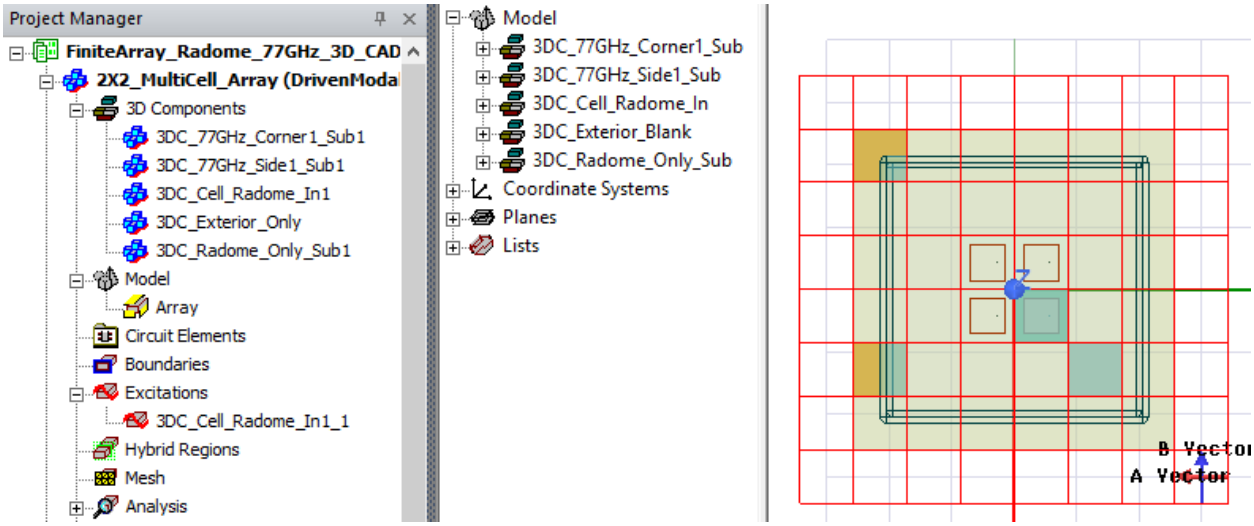
HFSS permits you to assign a virtual array based on a unit cell object, which can be a native design, a 3D component, or a SBR+ Parametric Antenna. For driven Modal and driven Terminal designs for HFSS with Hybrid and Arrays Solution Types, you can then simulate the array model using distributed processing, treating the instances as parent and child objects. This permits faster definition, display, and simulation of array based designs, such as antenna arrays. You can plot and animate array fields on cutplanes, lines or points. Post processing lets you view fields on any virtual instance.

The unit cells for an array can be rectangular, parallelogram, or hexagonal. HFSS SBR+ allows you to create Parametric Arrays from any of the parametric antennas. You can define the required primary and secondary boundaries so as to create offset arrays. You can only edit the settings in the physical cell and these settings will be applied to the corresponding instances in the virtual cells.

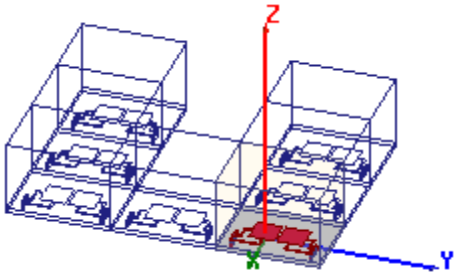


You can also create 3D components from unit cells, and use them to create a 3D Component Array.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Once you have defined an array, you can designate any cell in the array as active or passive, or as padding. You can use the padding cell designation to define arbitrarily irregular arrays. Cells designated as padding are treated as background material for fields calculations.



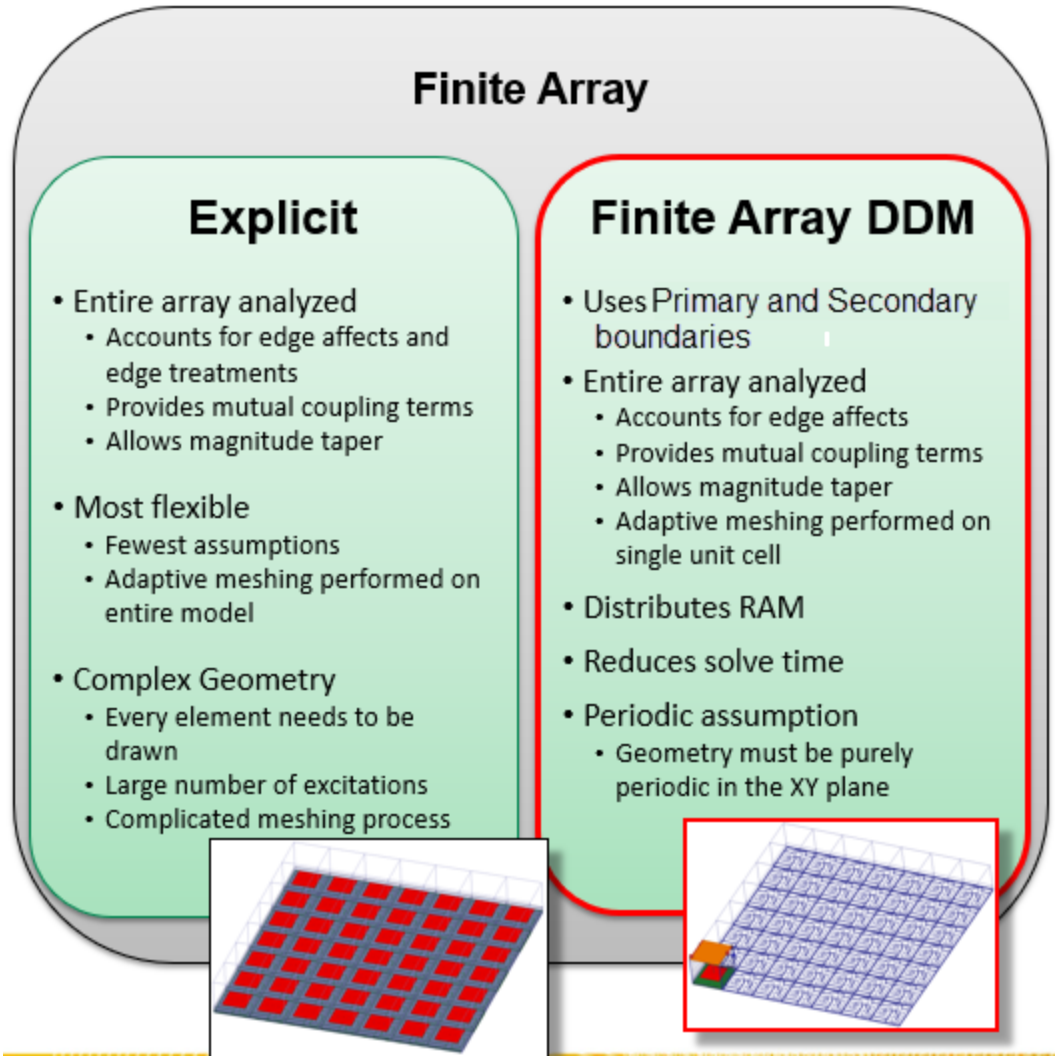
Most boundaries and excitations defined in the physical unit cell will have their corresponding instances in each virtual cell. The exception is incident wave, which is applied across the whole model and should include the 'expanded' model based on the array setup.

Components can now have different bounding box sizes (i.e., non-uniform sizing). In addition, HFSS supports arbitrary-sized internal air paddings, allowing flexibility for minor adjustments to existing arrays. However, to maintain array integrity, the array must remain perfectly tiled.

A Beta Feature allows you to have Multiple Component arrays in an HFSS design.

When the target design is a finite array, having both enforced E and enforced H options is not allowed. For all analytic incident waves except plane wave such as Gaussian beam, scatter field formulation is not supported for finite array design. HFSS supports all Incident Wave and Linked field sources to a target finite array DDM design. You can perform an explicit solve by modeling all cells in the modeler, or a Finite Array DDM solve by using Array Definition of a Unit cell object.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



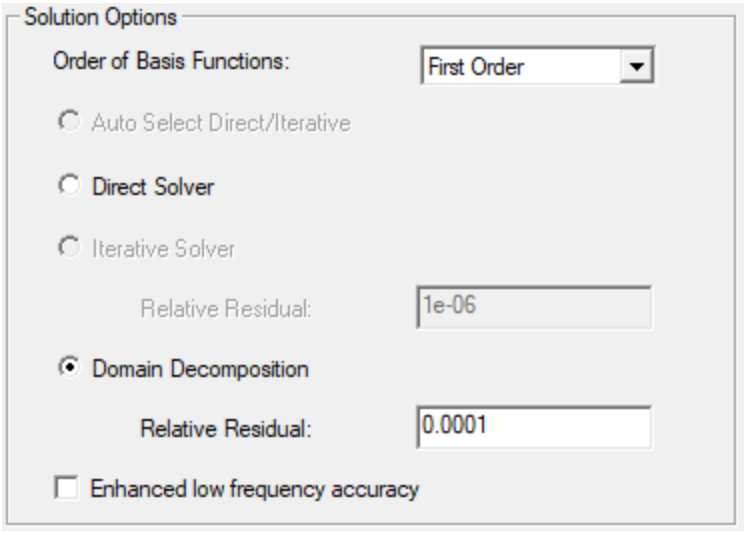
The basic process flow for using **HFSS>Model>Create Array...** or in the **Project** tree, right-click on the **Model** icon, and click **Create Array...** on the short-cut menu, is:

1. Draw the unit cell, containing all appropriate boundaries and source definitions. The design can contain at least one native geometry with no less than two pairs of lattice boundaries, or at least one 3D component with no less than two pairs of lattice boundaries. For native geometry unit cells, the regular array dialog is enabled. For 3D components, the 3D Component array dialog is enabled. Native geometries and 3D components cannot be mixed in an array.
2. Create the antenna array, including name, dimensions, Primary and Secondary boundaries where needed for conformal meshing, and selection of row and column primary and secondary pairs for implicit definition of lattice propagation vectors. Designate which cells are active, passive, and padding.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Set up the distributed processor pool. Designs with arrays require HPC licenses.
4. Provide a memory statistic for the amount of RAM guaranteed on each DSO processor.

The Solution Option for **Domain Decomposition** is automatically checked and Direct Solver and Iterative Solver options are disabled.



The domains are UI defined through the array definition, not solver defined domains. Given a valid configuration, an Array solve can use a distributed memory solution.

The UI will provide the antenna array definition to the domain manager. This will cause the following to occur:

1. Instantiation of domains to represent the cells of the antenna array plus surrounding air padding cells.
2. Creation of internal domain manager data structures that are needed to support the solve and post processing. This includes appropriate domain parent/child relationships, transformations from the physical domain, interface information per pair of domains, and support for locating a domain by row/column coordinates within the antenna array.

For linking to the Desktop, the network data from HFSS will include both physical and virtual cells. This applies to both port locations and push excitations.

For Optimetrics solution quantities of both virtual and physical cells can be used for calculation.

For 2D Reports for models with Arrays, matrix solution quantities of virtual cells will be expanded into a vector in the same fashion as without the array. The entries are listed according to their [row, column] order in the corresponding "expanded" matrix.

For Port Field Display there is no GUI change. Only physical ports/terminals will be listed. There is no need to support visualization of user-selected cell (like field overlay plot) because the field patterns of the virtual modes are the same as those in the physical cells.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For designs with an Array, the Edit Sources dialog listing order will be as follows: Sources will be listed according to their cell [row, column] order in the array. For each cell, port/terminals are listed in creation/assignment order with mode in each port listed sequentially. Other type of sources, such as incident waves and linked field sources, will be listed after ports/terminals. You can also create Source Groups for dealing with finite array sources.

There will be no change in the far/near field pattern setup and far/near fields will be computed from radiation surfaces on all cells (both physical and virtual).

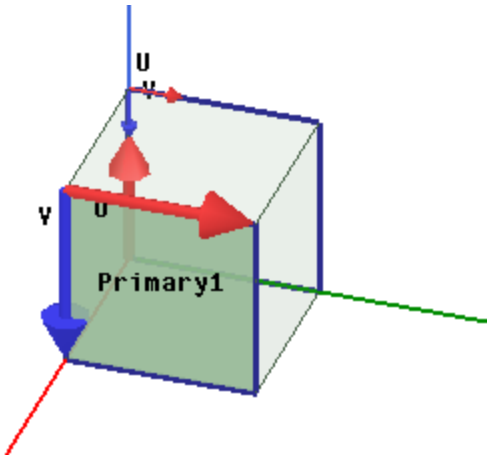
Copy/Paste design will copy an array. Copy/Paste geometry will NOT copy an array.

Note: A legacy regular array, with one component with at least two pairs of lattice boundaries, can be opened, but you cannot create a new regular array based on this condition. Regular array can only be created based on native geometries. If you delete a legacy with these conditions, you could only recreate it as a 3D component array.

Creating a Unit Cell for an Array

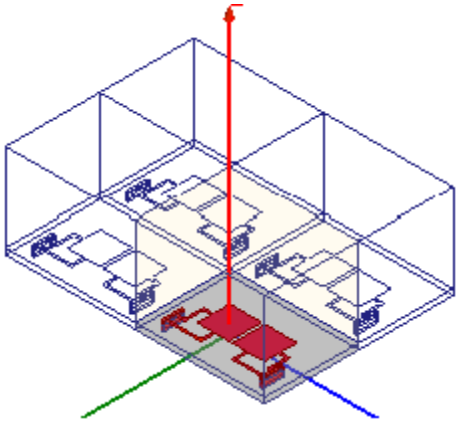
You use the Modeler to create a unit cell for an array.

- The unit cell can be rectangular, parallelogram or hexagonal.
- You must define appropriate Primary and Secondary boundaries, as well as other boundaries required for the model. Deleting a primary or secondary boundary that is referenced by an existing array also deletes the array. Typically, you define Primary and Secondary boundaries as opposite sides of a cell.

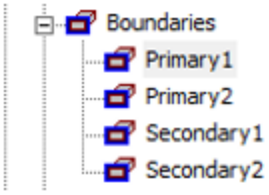


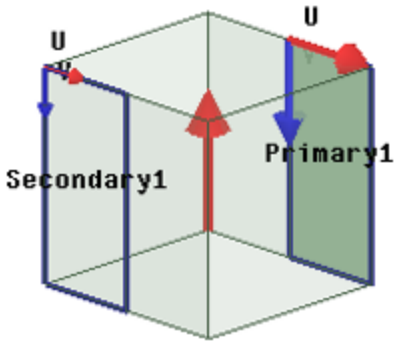
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

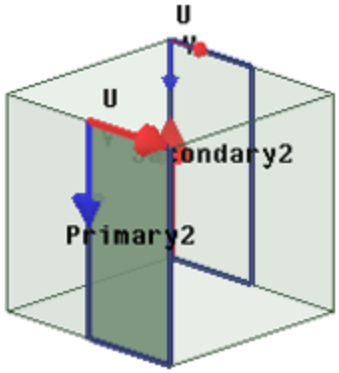
In such cases, with Primary and Secondary boundaries on opposite sides, the array sides align.



However, you can arrange Primary and Secondary boundaries to create an offset array. In such cases, you create both a Primary and a Secondary boundary for corresponding sections of a cell side, and assign Primary and Secondary to create offset alignment.

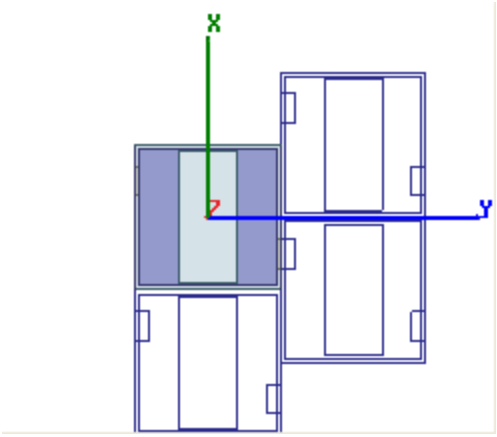






With all boundaries defined in this manner, the array can be offset.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- In making source definitions for unit cell for the unit cell, you cannot assign a Floquet port.
- Each driven Modal or driven Terminal design can contain a single array.

Editing the model object for an existing array invalidates any existing solutions. Once you have created a model, you may choose to make into a 3D Component. The Create Array... command provides different options, depending on whether you use a native geometry or a 3D component.

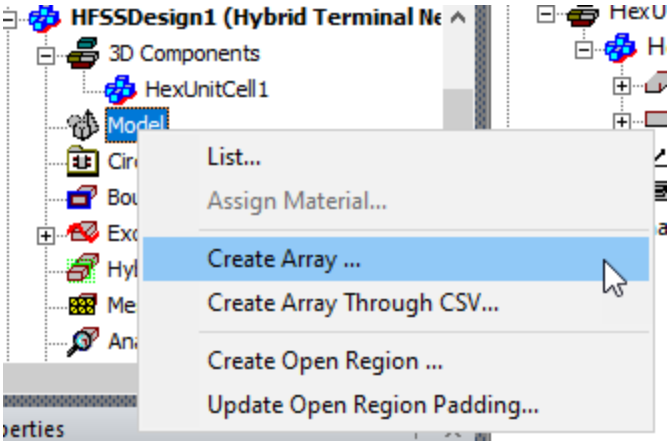
Create Array Command for Native Geometries

The **Create Array** command is enabled for Modal and Driven Terminal problems for the HFSS with Hybrid and Arrays Solution Types after you have assigned Primary and Secondary lattice pair boundaries to your unit cell model. You can access the command in three ways: click **HFSS>Model>Create Array**, right-click the Model icon in the Project tree and select **Create Array...** from the shortcut menu, or select the unit cell in the modeler window, and select **Create Array ...**from the short-cut menu. You also have the option to **Create Array Through CSV...**. This option is useful especially for defining large-scale arrays when defining through the UI dialogs requires a lot of manual work. This section describes the **Create Array...**. command. The **Create Array Through CSV...** command is described in a separate section.

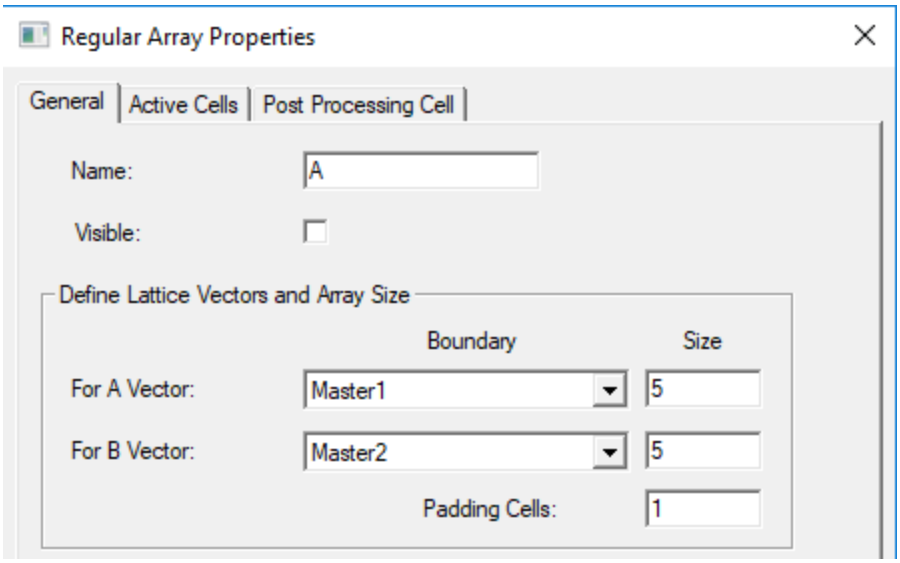
Create Array... Command Procedure

Right-click the Model icon in the Project tree and select **Create Array...** from the shortcut menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



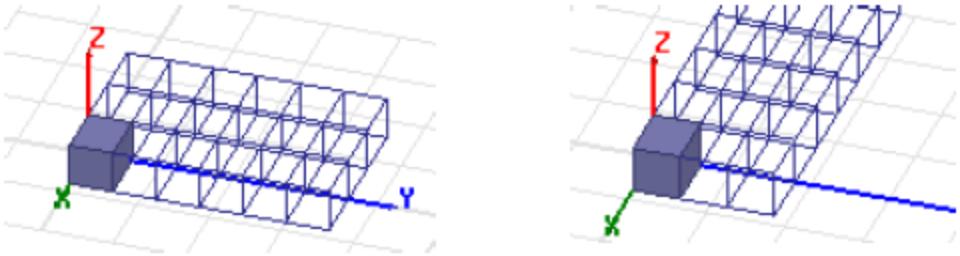
This displays the **Regular Array** dialog where you specify parameters for Number of Cells, Unit Cell Position and Lattice Vectors.



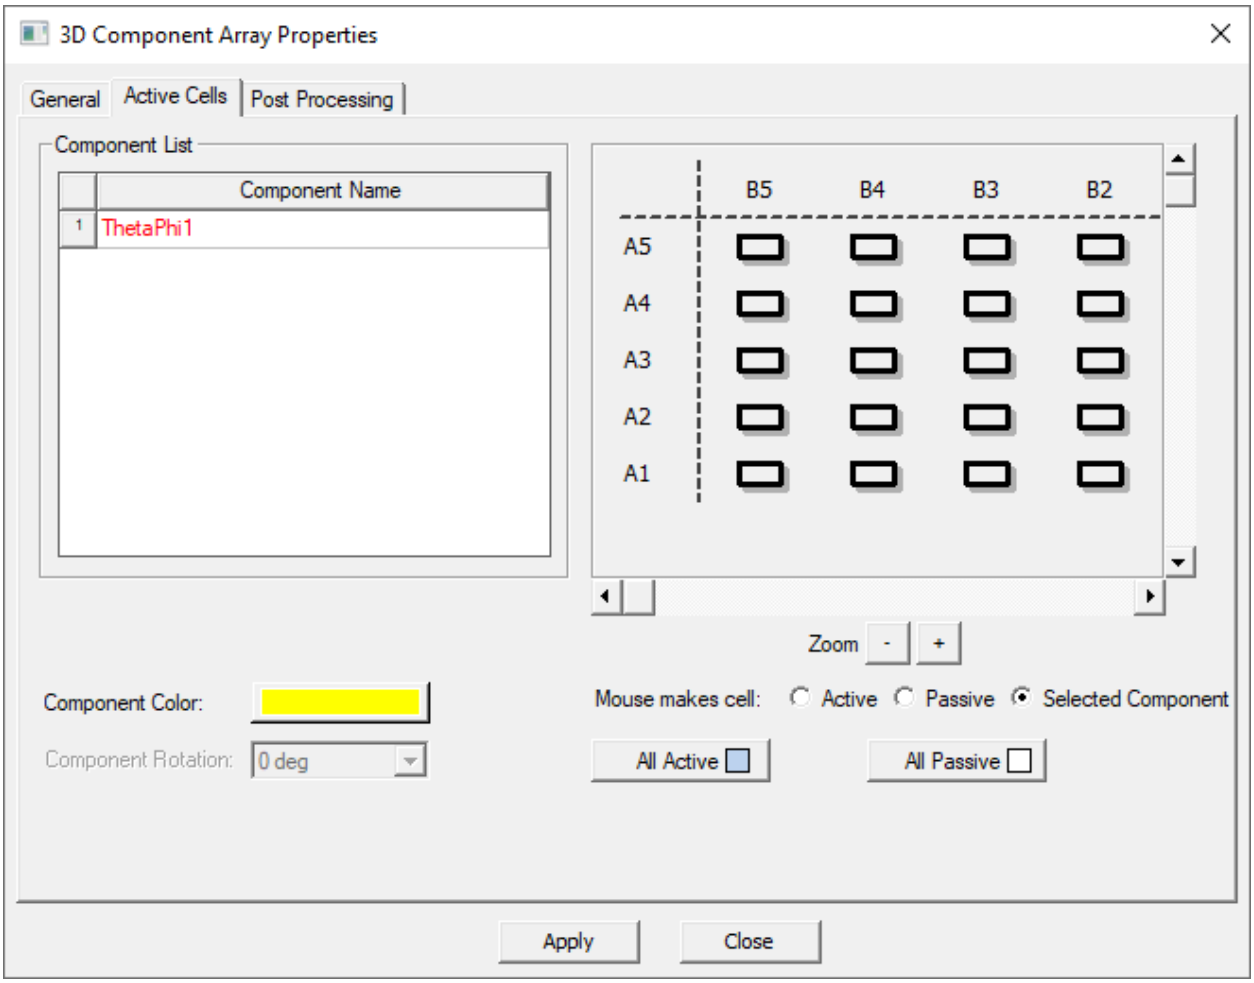
- If you have **Visible** enabled, you can see any changes.
- To Define Lattice Vector directions for A and B Vectors, select the different primary boundary from the drop down list for each..
- To define the array size, for the A and B vectors, specify the number of cells for each row and column, respectively.
- For example, the following figure shows the results when the initial Lattice Vectors are

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

swapped.

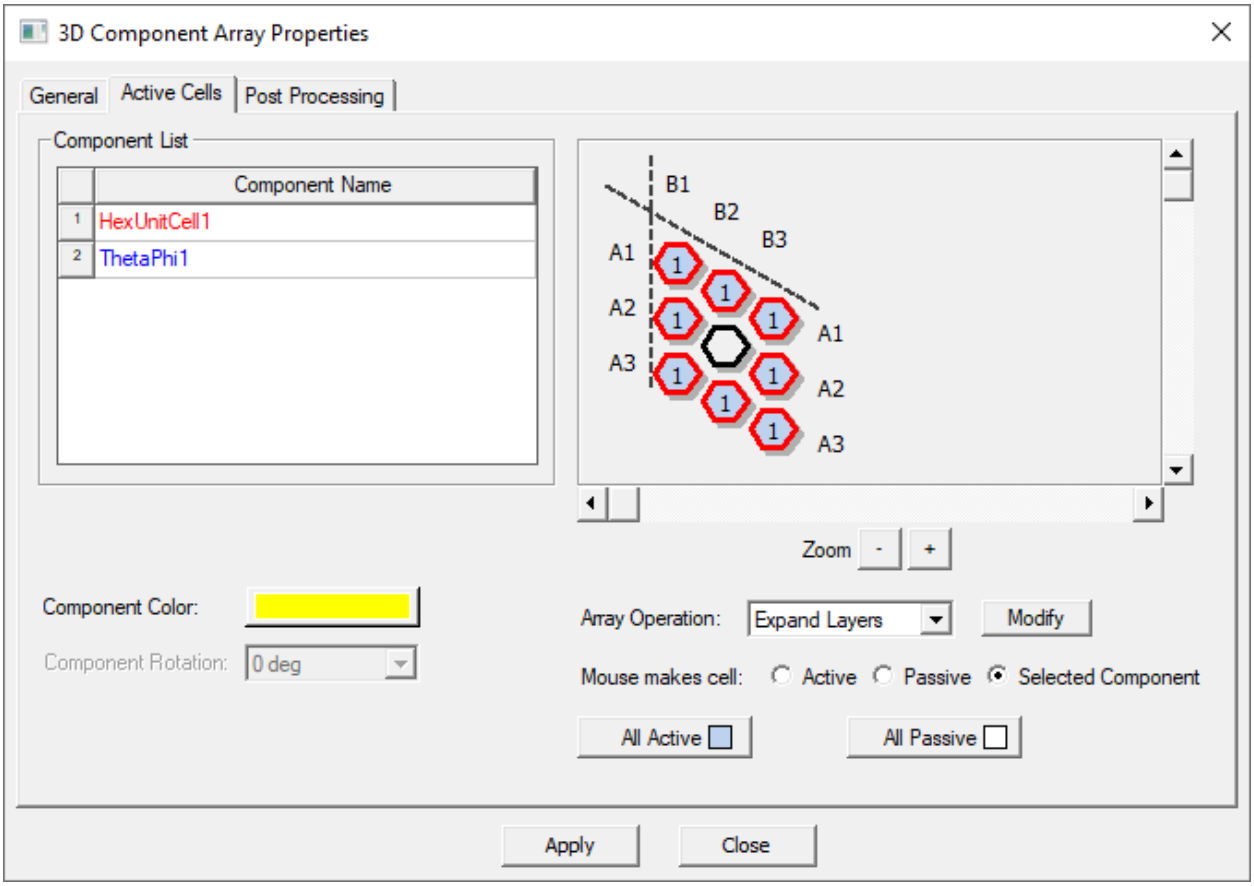


To create an irregular array, select the **Active Cells** tab, select the radio button for **Mouse makes cell** as **Padding**.



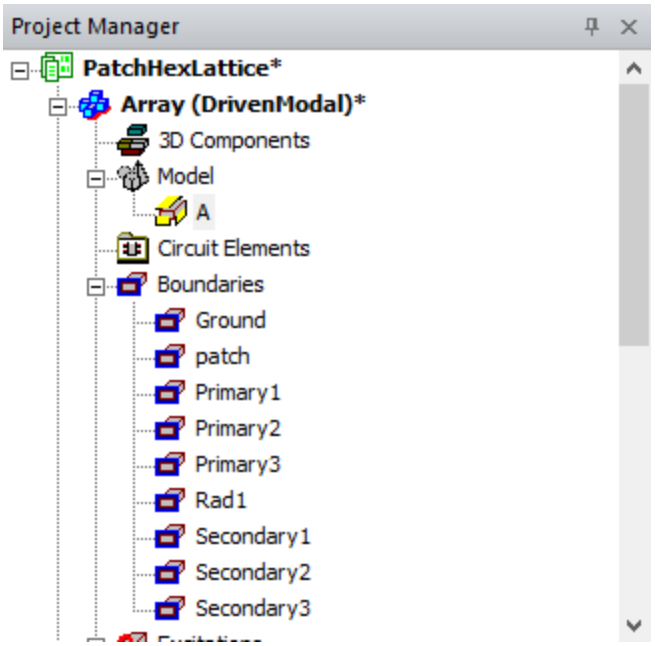
For non-rectangular components, the arrays are displayed appropriately.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

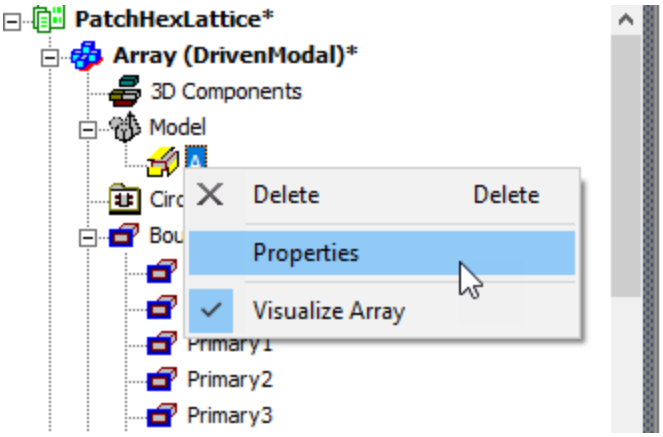


Once you have specified the parameters, the Array object appears in the Project tree under the Model. Only one Array is permitted for a model. The **Create Array** command is disabled if an array is defined.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

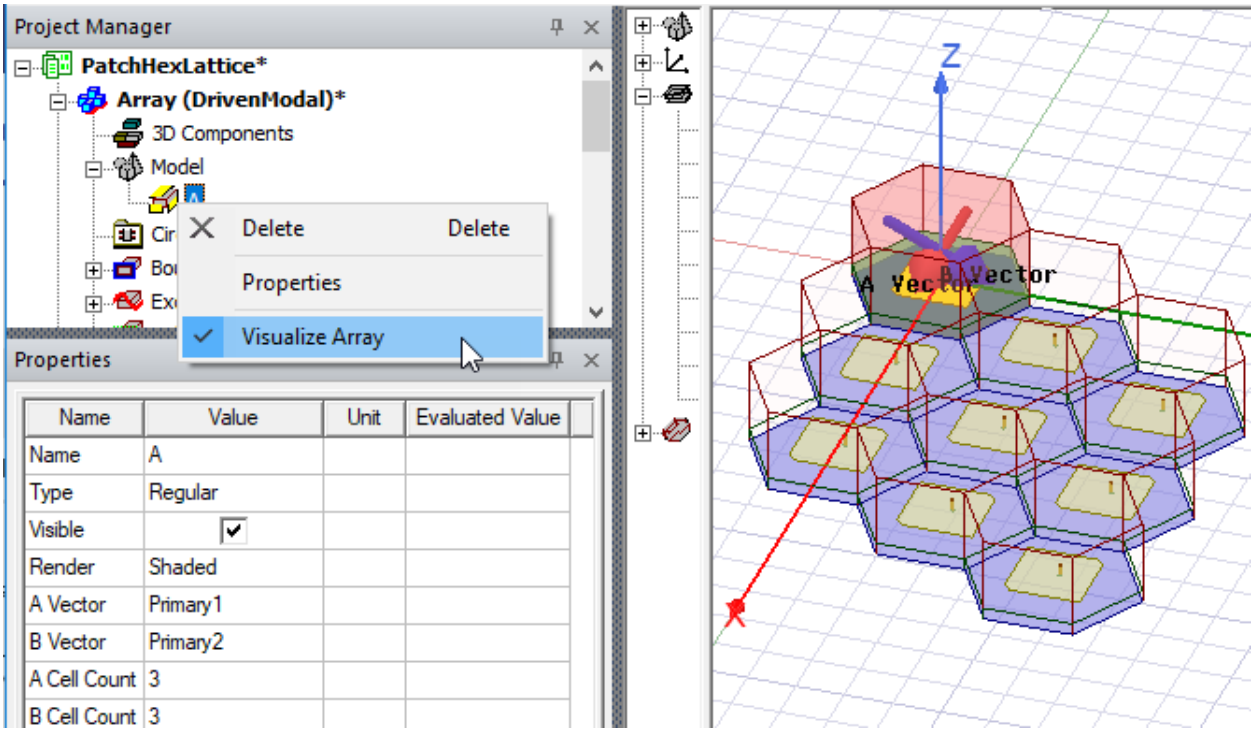


By selecting the Array icon in the **Project** tree, you right-click for the short cut menu.

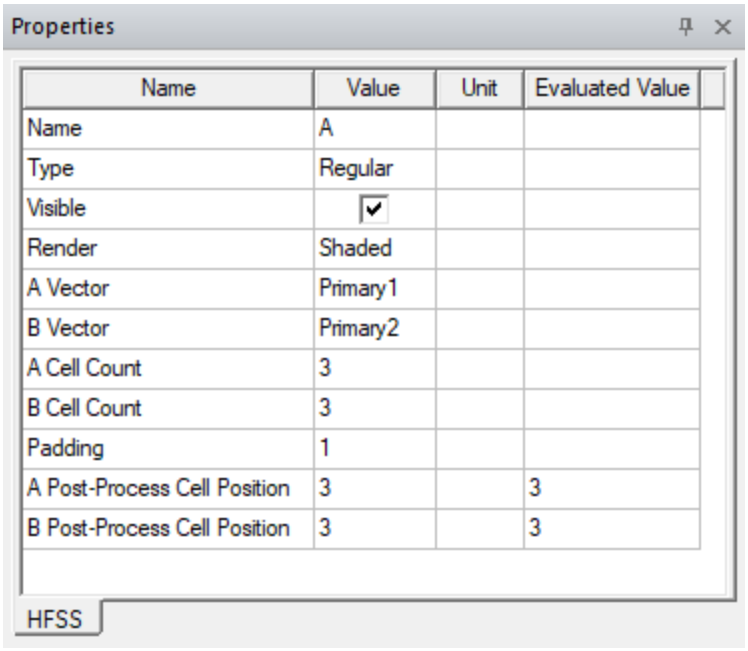


- Selecting **Delete** removes the array from the Model.
- Selecting **Properties** displays the **Regular Array** dialog.
- Selecting Visualize Array lets you toggle the array display. A check mark indicates that the array is being displayed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



With the Array icon in the **Project** tree selected, if you have a docked Properties window displayed, you can see and edit Array Properties. All edits are undoable and informational messages will be posted to the Message window when design data is deleted.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

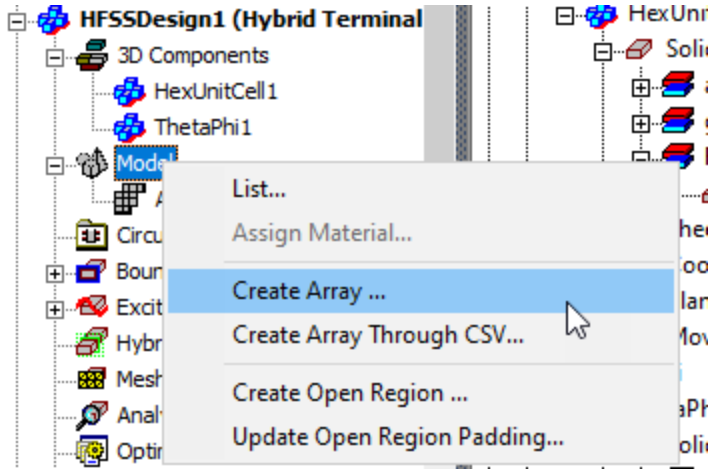
Multiple Finite Arrays (Beta)

For some HFSS 3D problems like Z-axis stacked up arrays, or multiple arrays on the same platform, the HFSS Multiple Component Arrays Beta feature allows multiple array setups with the same UI access as you use to create a single array. You must define each array center position by different relative coordinate systems, and each array has its own lattice vectors, component list and array mask.

Each array must be enclosed by an airbox. If multiple arrays have different airboxes, each airbox must be assigned as FEBI. Multiple arrays cannot have contact with lattice boundary faces.

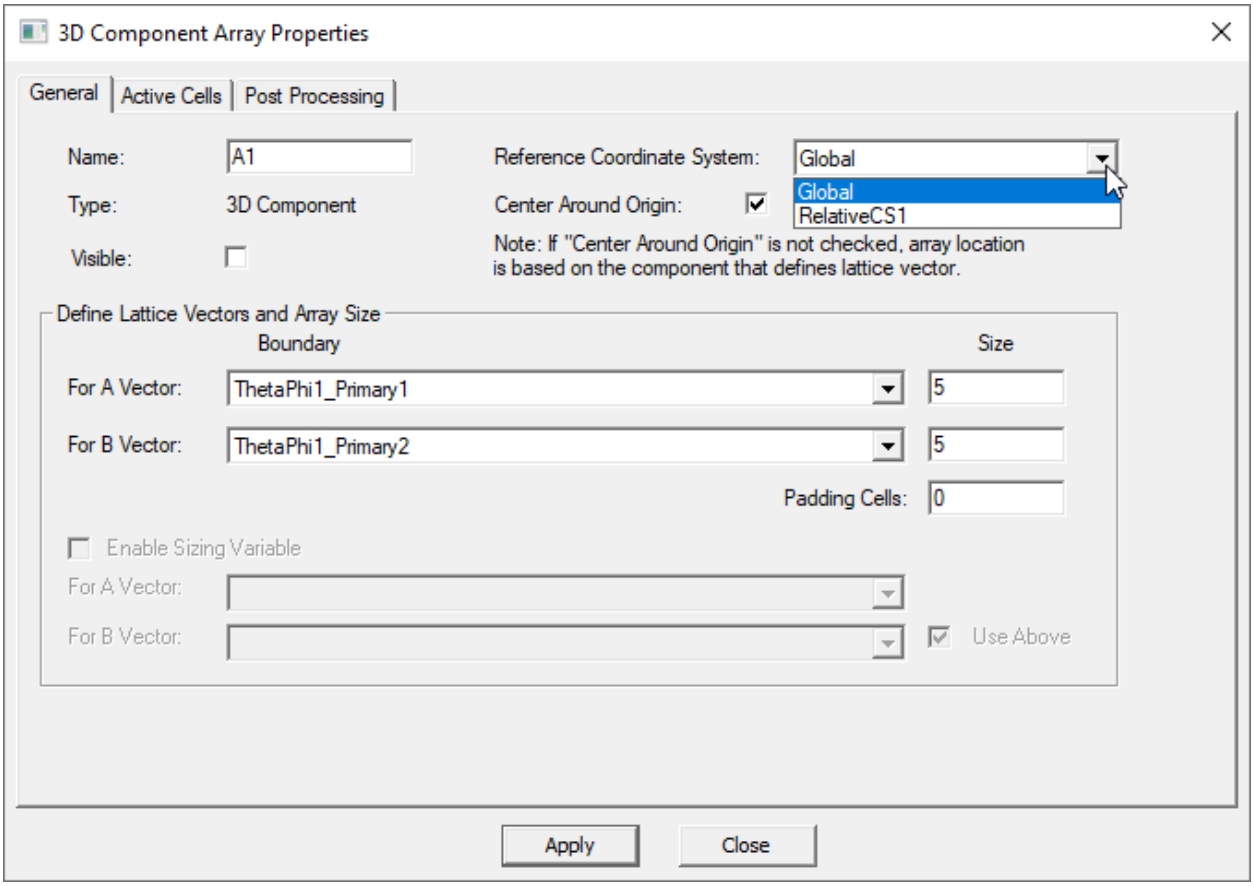
Creating Multiple Arrays

The process of creating each additional array uses the same commands as for creating a single array. Once you have a single array setup available, repeat the same array creation process by placing the Unit cell you want to use for the added array, and then select **Model > Create Array ...**



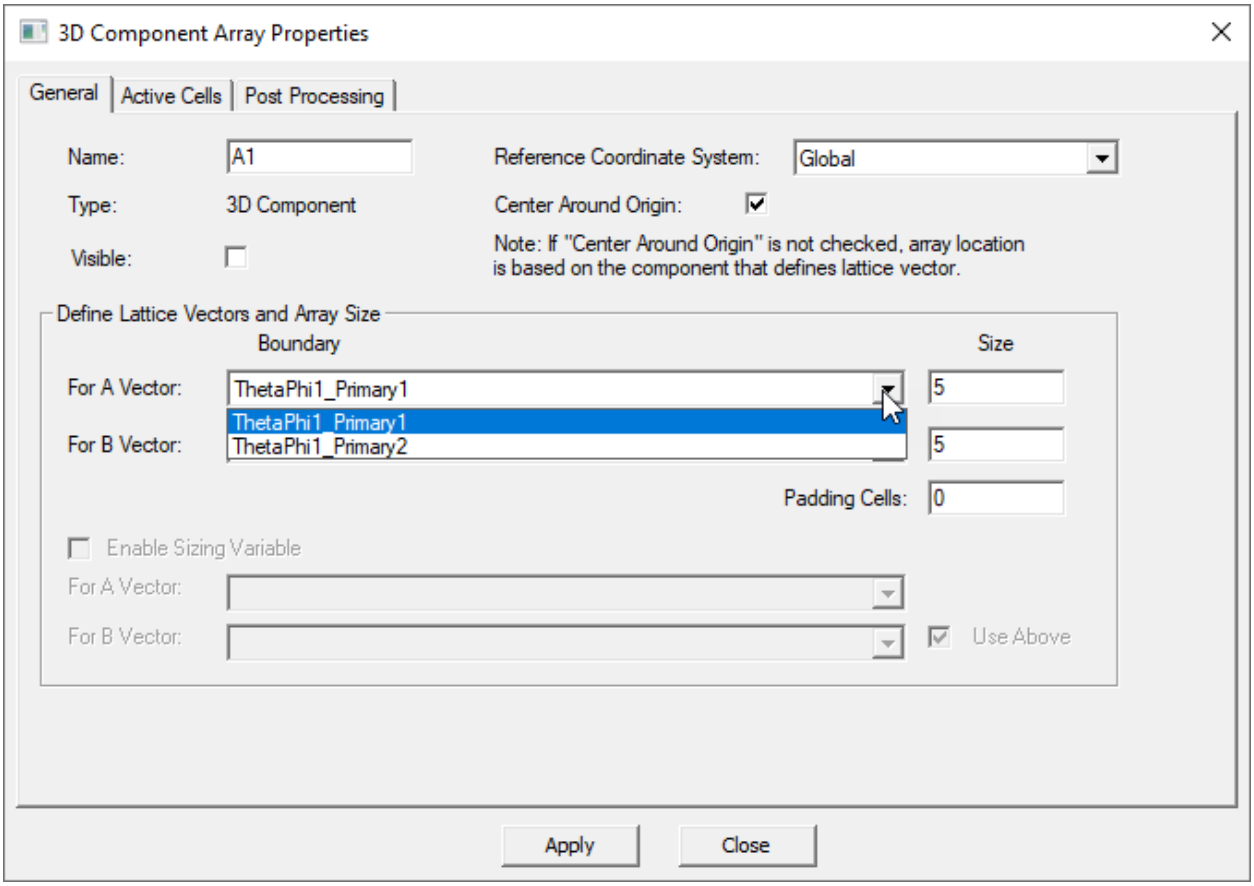
In the **3D Component Array Properties** dialog, first select the coordinate system that you associate with the Unit cell placement for the additional array.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



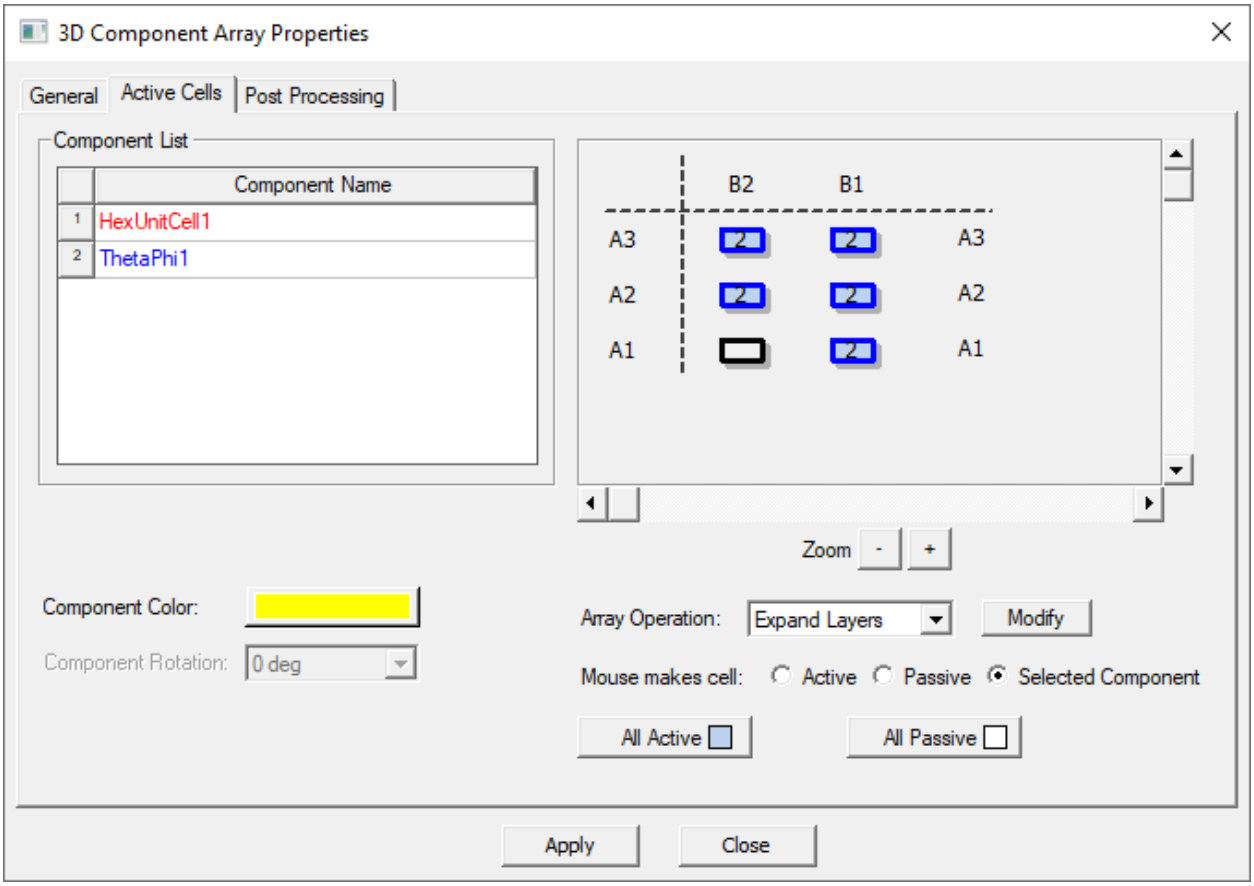
You can then select lattice vectors from available unit cell boundaries, and then define the array size and padding. A checkbox lets you make the array visible in the Modeler window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



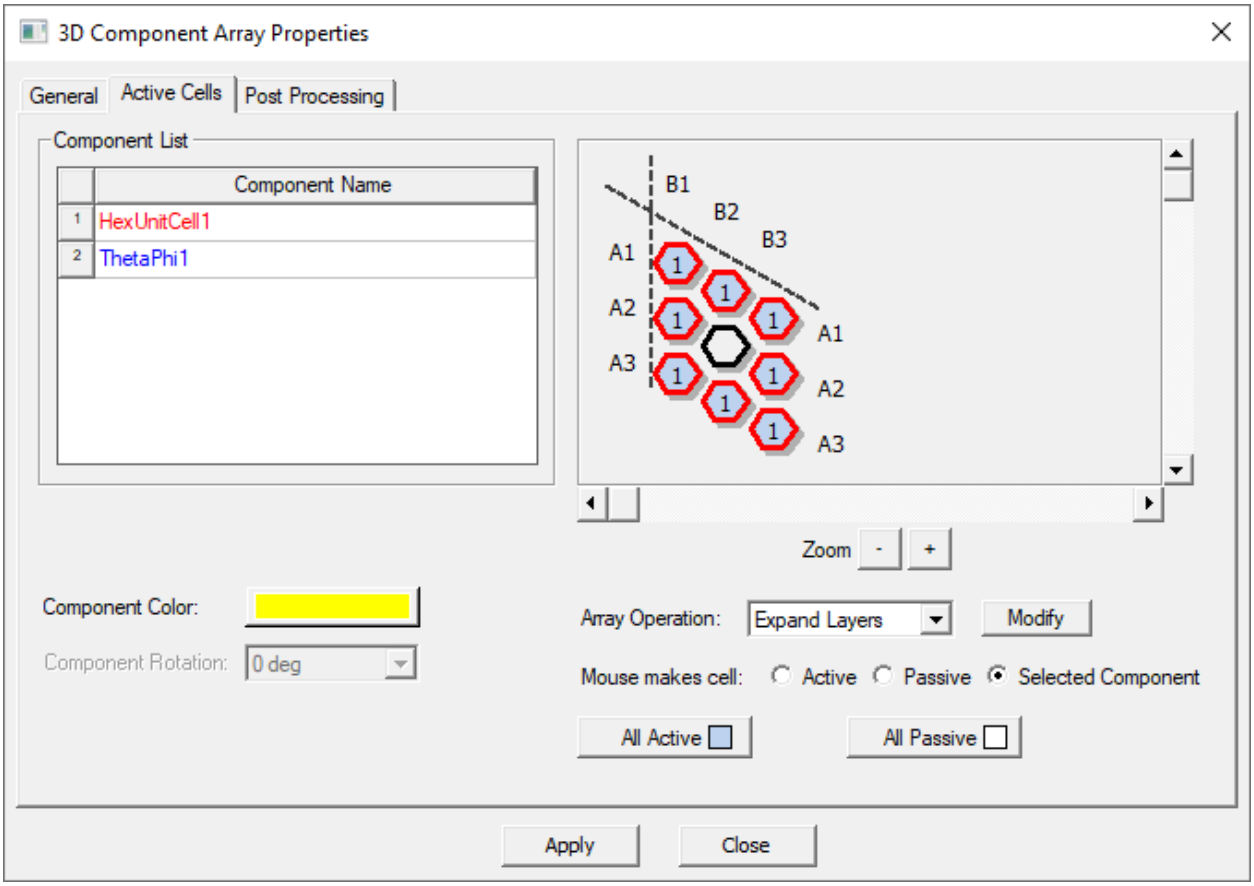
Then use the **Unit Cells** tab to select the array cells and define the component mask

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

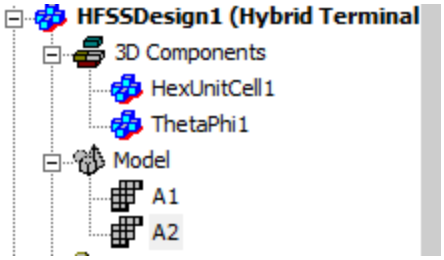


For non-rectangular cells, the array is displayed appropriately.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The added array appear in the Project tree and, if you have enabled visualization, in the Modeler window.



Create Array Through CSV

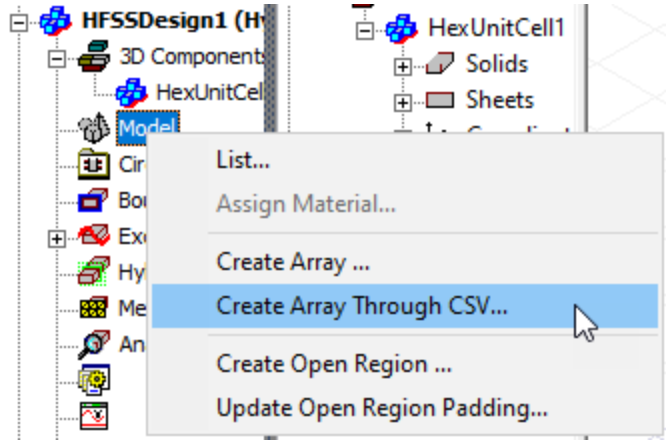
The **Create Array Through CSV...** command is enabled for Modal and Driven Terminal problems for the HFSS with Hybrid and Arrays Solution Types after you have assigned Primary and Secondary lattice pair boundaries to your unit cell model. This option is useful especially for

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

defining large-scale arrays when defining through the UI dialogs requires a lot of manual work. You can access the command in three ways: click **HFSS>Model>Create Array Through CSV...**, right-click the Model icon in the Project tree and select **Create Array Through CSV...** from the shortcut menu, or select the unit cell in the modeler window, and select **Create Array Through CSV...**from the short-cut menu. The **Export Array Though CSV** command section includes a description of the csv format.

Create Array Through CSV... Command Procedure

Right-click the Model icon in the Project tree for and select **Create Array Through CSV...** from the shortcut menu.

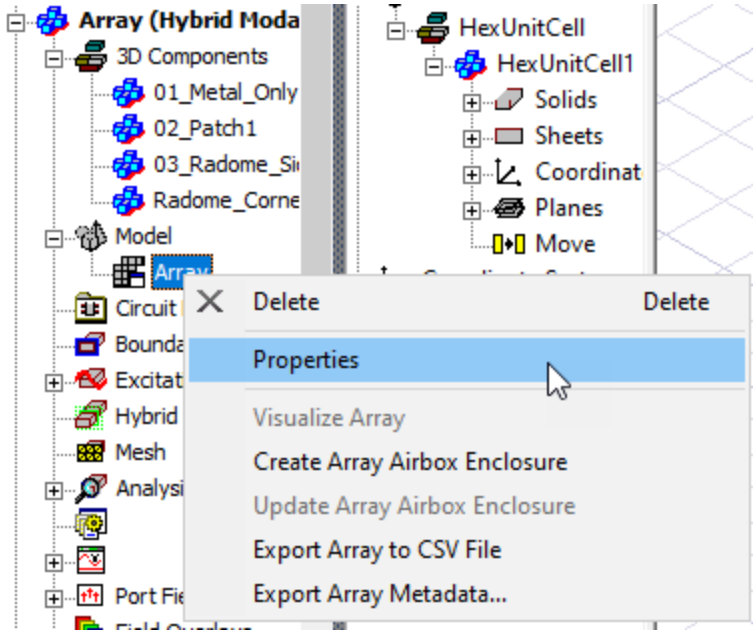


This opens a browser that you can use to navigate to and select the CSV file.

When you click Open, the array is created based on the .csv definition and the Array object appears in the Project tree under the Model. Only one Array is permitted for a model. The **Create Array Through CSV...** command is disabled if an array is defined.

By selecting the Array icon in the **Project** tree, you right-click for the short cut menu.

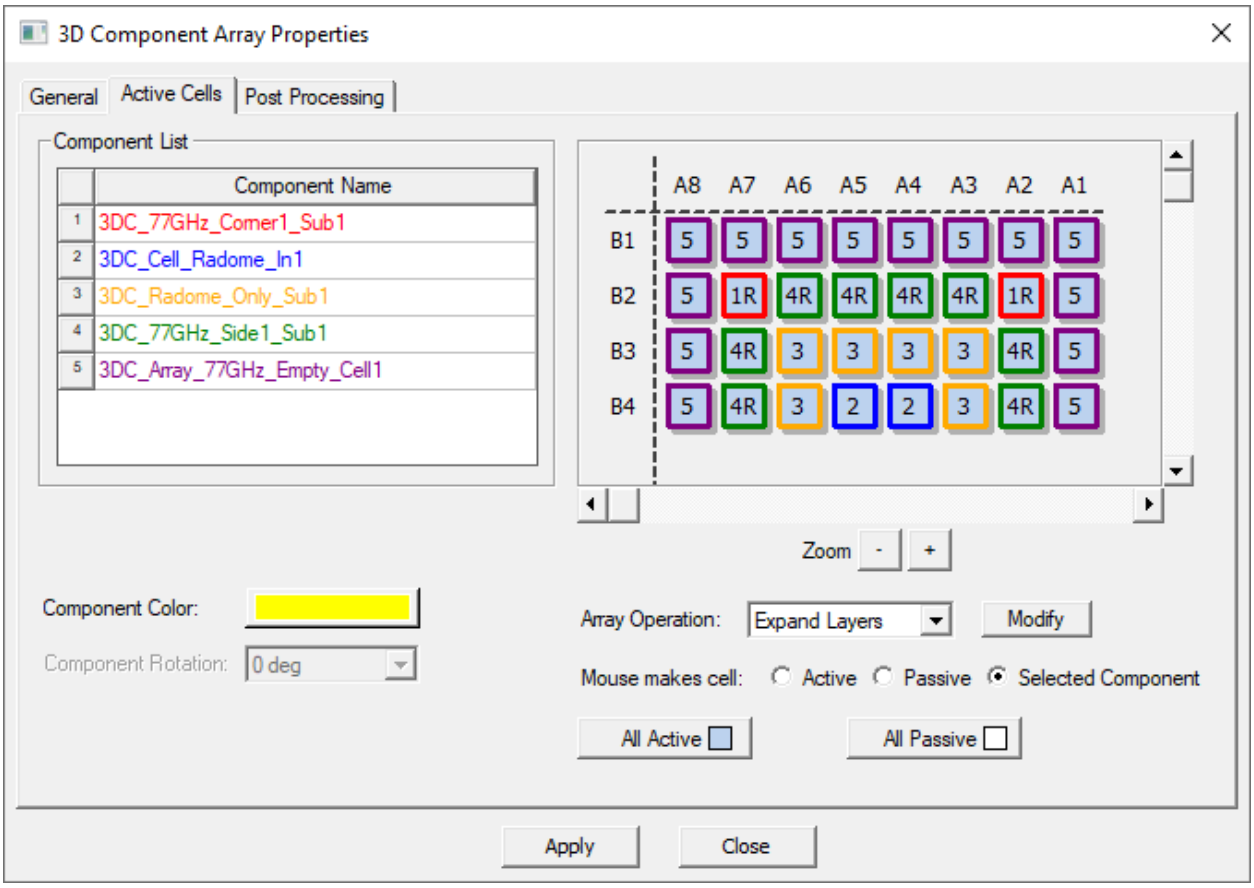
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Selecting **Delete** removes the array from the Model.

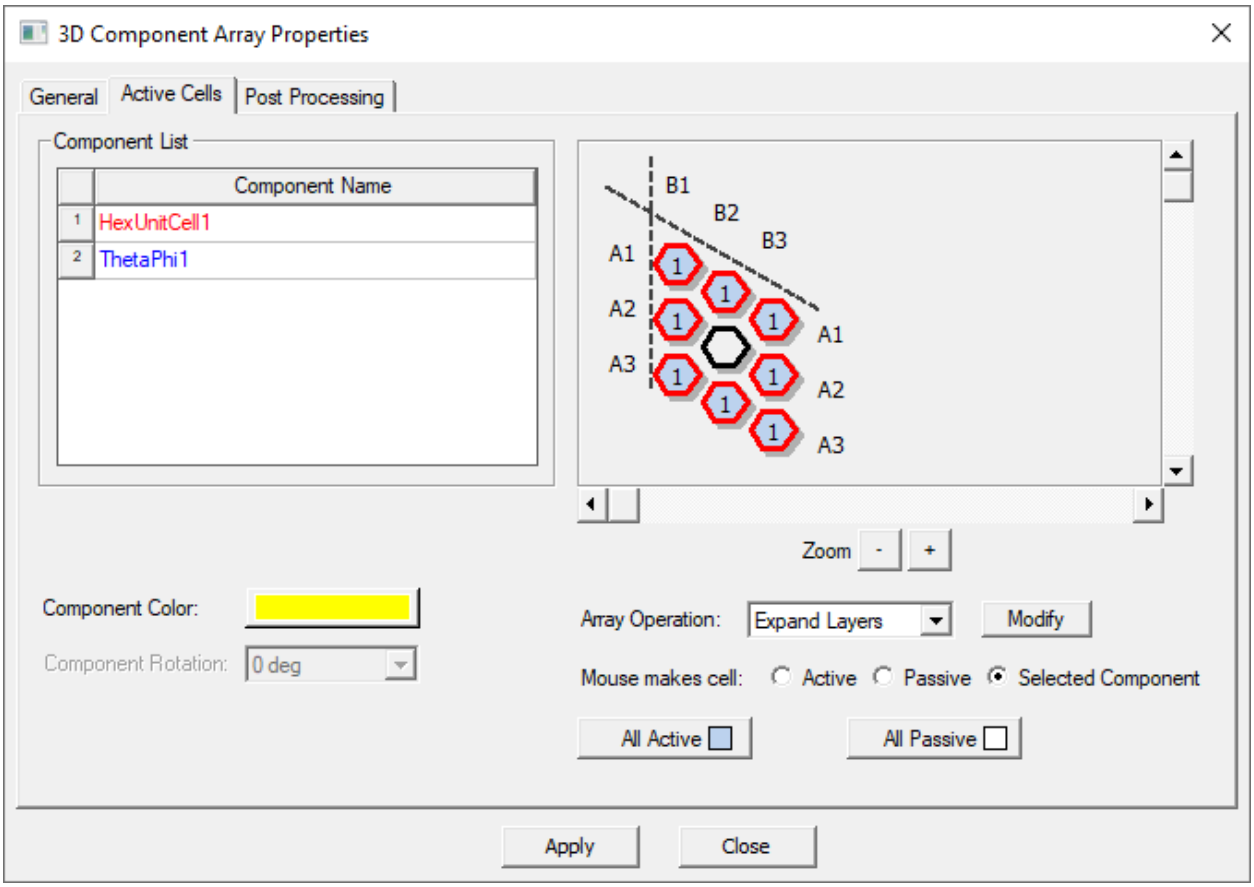
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Selecting **Properties** displays the **Regular Array** dialog. The Unit Cells tab shows the Component list for the array and the array definition.



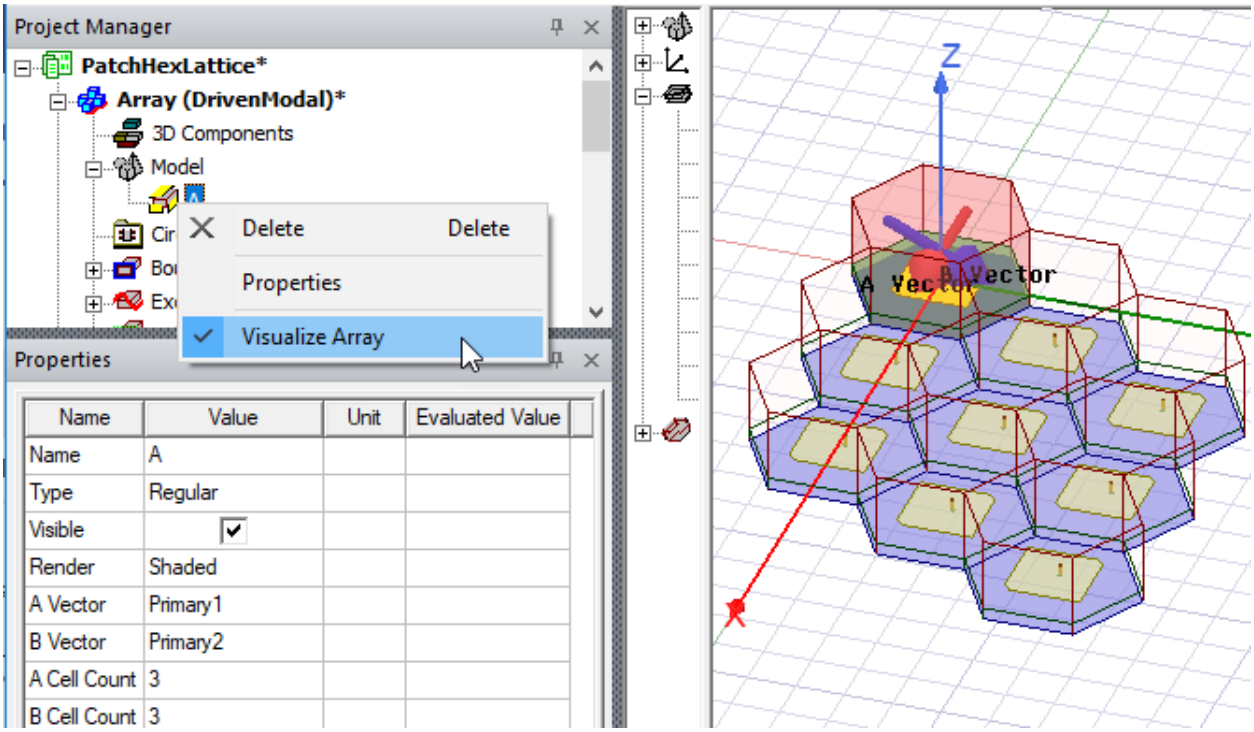
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For non-rectangular arrays, the cells are displayed appropriately.

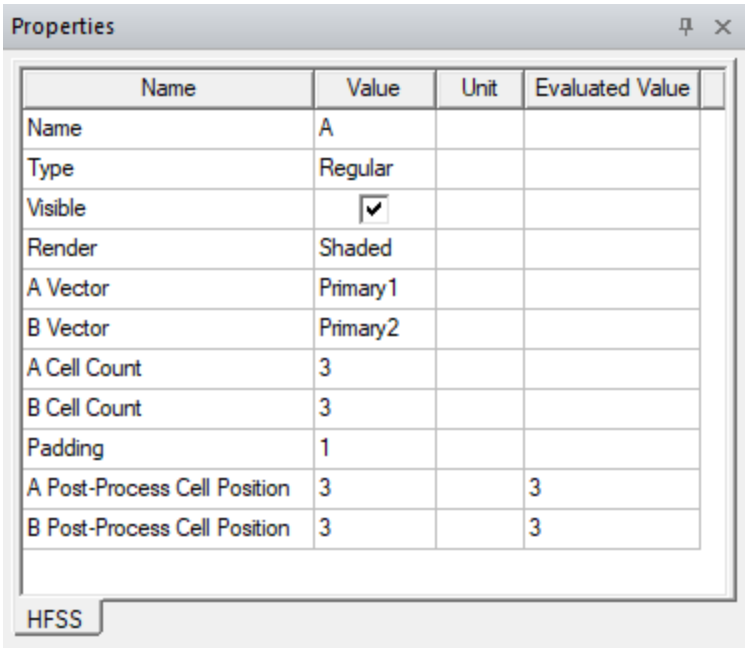


- Selecting Visualize Array lets you toggle the array display. A check mark indicates that the array is being displayed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



With the Array icon in the **Project** tree selected, if you have a docked Properties window displayed, you can see and edit Array Properties. All edits are undoable and informational messages will be posted to the Message window when design data is deleted.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

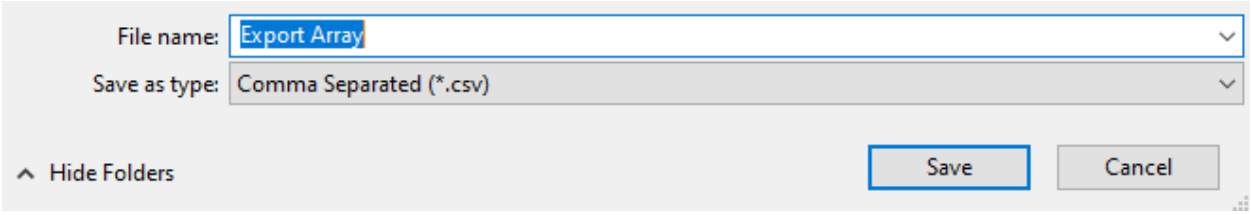
Exporting Array to CSV File

After you have defined an array, the **Export Array to CSV File** command is enabled for Modal and Driven Terminal problems for the HFSS with Hybrid and Arrays solution types. This option is especially useful for defining large-scale arrays when doing so through the UI would require a lot of manual work.

There are three ways to access the command:

- Select **HFSS** > **Model** > **Export Array to CSV File**.
- From the **Project Manager**, right-click **Model** and select **Export Array to CSV**.
- In the modeling window, right-click the unit cell and select **Export Array to CSV**.

Performing any of these three actions opens a browser you can use to navigate and select a location for CSV file:



Example CSV File

The exported file looks something like the one below. The imported file will be identical.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ArrayName	Array

Size Along A Vector	8
Size Along B Vector	8
A Vector	02_Patch1_LatticePair1
B Vector	02_Patch1_LatticePair2

Component Index	Component Name
1	02_Patch1
2	01_Metal_Only1
3	03_Radome_Side1
4	Radome_Corner1

Source Row	Source Column	Source Name	Magnitude	Phase
3	3	02_Patch1_1:1	ScanMag1*1	ScanPhase1 + (2*ScanPhaseShiftA + 2*ScanPhaseShiftB)
3	4	02_Patch1_1:1	ScanMag1*1	ScanPhase1 + (2*ScanPhaseShiftA + 3*ScanPhaseShiftB)
3	5	02_Patch1_1:1	ScanMag1*1	ScanPhase1 + (2*ScanPhaseShiftA + 4*ScanPhaseShiftB)
3	6	02_Patch1_1:1	ScanMag1*1	ScanPhase1 + (2*ScanPhaseShiftA + 5*ScanPhaseShiftB)
4	3	02_Patch1_1:1	ScanMag1*1	ScanPhase1 + (3*ScanPhaseShiftA + 2*ScanPhaseShiftB)
4	4	02_Patch1_1:1	ScanMag1*1	ScanPhase1 + (3*ScanPhaseShiftA + 3*ScanPhaseShiftB)
4	5	02_Patch1_1:1	ScanMag1*1	ScanPhase1 + (3*ScanPhaseShiftA + 4*ScanPhaseShiftB)
4	6	02_Patch1_1:1	ScanMag1*1	ScanPhase1 + (3*ScanPhaseShiftA + 5*ScanPhaseShiftB)

Array	Format: Component_index:Rotation_angle:Active_or_Passive						
4	4	3	3	3	3	3	4:90.0deg
3:270.0deg	2	2	2	2	2	2	3:90.0deg
3:270.0deg	2	1	1:0	1	1	2	3:90.0deg
3:270.0deg	2	1	1	1	1	2	3:90.0deg
3:270.0deg	2	1	1	1	1	2	3:90.0deg
3:270.0deg	2	1	1	1	1	2	3:90.0deg
3:270.0deg	2	2	2	2	2	2	3:90.0deg
4:270.0deg	3:180.0deg	3:180.0deg	3:180.0deg	3:180.0de	3:180.0de	3:180.0de	4:180.0deg

The CSV file contains four blocks:

- The first block provides the array name.
- The second block provides the A and B vector dimensions of the array, as well as vector IDs.
- The third block is for updating/editing source information:
  - Each line represents an update
  - The **Source Row** and **Source Column** fields identify cells that need to be updated.
  - The **Source Name** column shows the name of the source, formatted <SourceName>:<index>
  - The **Magnitude** and **Phase** columns show the weight of the sources. The default values are 0. If both values are 0, there is no need to list them here. If the magnitude

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

and phase are variable, as in the example below, the units should be input as well:

```
ArrayName,A
X,Y
5,5
Component_index,Component_name
1,terminalComponent1
Source_row,Source_column,Souce,Magnitude,Phase
1,1,terminalComponent1_T1,1V,1deg
1,1,terminalComponent1_T2,2V,2deg
1,1,terminalComponent1_T3,3V,3deg
1,1,terminalComponent1_T4,4V,4deg
1,2,terminalComponent1_T1,6V,6deg
1,2,terminalComponent1_T2,5V,5deg
1,2,terminalComponent1_T3,7V,7deg
1,2,terminalComponent1_T4,8V,8deg
Array
1,1,1,,,
,,,,,
,,,,,
,,,,,
,,,,,
```

- The fourth block is the array matrix, with dimensions x and y. Each element in the matrix represents the information for one cell. The format for each cell is A:B:C where each value is optional:
  - A is the component index. B and C cannot be provided if there is no A.
  - B is the rotation angle (default: 0deg). B must always have the unit deg (for example, 1:90deg). Without the unit, A:B will be recognized as A:C.
  - C indicates whether a cell is passive. If a cell is passive, C is 0. Otherwise, it is active by default.

You can check scaling and magnitide assignments by using the Edit Source command.

Create Array Command for 3D Component

The **Create Array...** command is enabled for Modal and Driven Terminal problems with the HFSS with Hybrid and Array Solution Type, after you have inserted a 3D Component that has assigned Primary and Secondary boundaries to your original unit cell model. 3D Component Array has non-conformal mesh interface between unit cells, which greatly reduces the memory

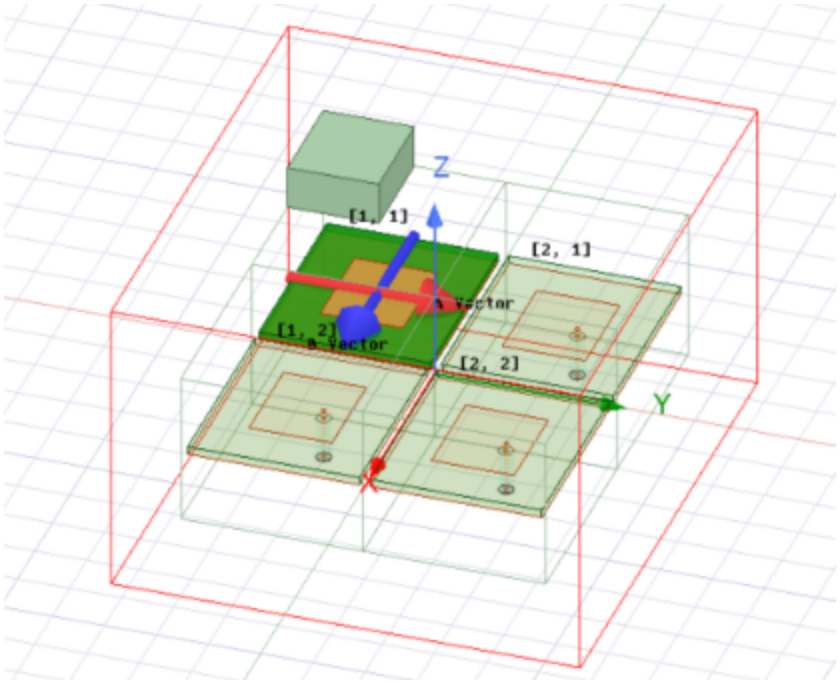
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

footprint and improves the performance. Once you have created a 3D Component Array, you can place it inside a region, and then assign a PML Boundary, a FEBI Hybrid Region, or a Radiation Boundary on the outside of the region. When a 3D component is placed inside of a region object, no native model object other than the region and its dependent objects are allowed.

Components can now have different bounding box sizes (i.e., non-uniform sizing). However, to maintain array integrity, the array must remain perfectly tiled. The following restrictions apply:

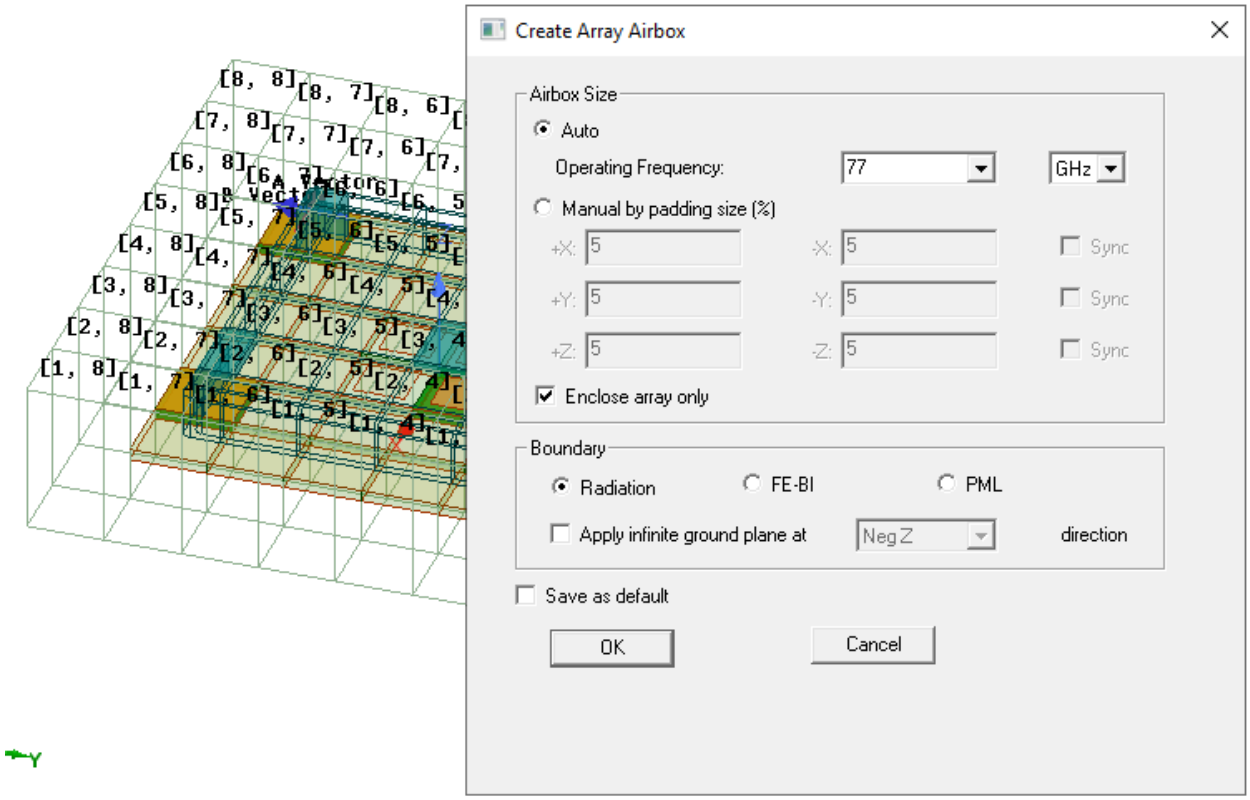
1. Lattice Vectors Must Be Orthogonal: All lattice vectors must maintain 90-degree angles.
2. Consistent Vector Sizes for Indexed Cells: Cells sharing the same A-index must have the same A-vector size, and cells sharing the same B-index must have the same B-vector size. This ensures that the array remains perfectly tiled. This rule also applies to aircell rows/columns, meaning that you can only adjust air padding sizes (using **Modify Air Padding Size**) when the entire row or column consists of aircells.

The **Create Array Array Airbox Enclosure** command is enabled after you have used the **Create Array...** command to describe the array and designate active cells. Given an existing component array design, you can add arbitrary native FEM geometries around the component array, as long as all geometries are enclosed by an airbox. This feature greatly expands the use cases of existing component array definition.

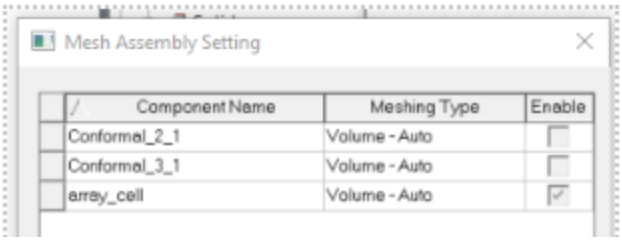


The **Create Array Airbox** dialog supports Auto definition of an airbox by frequency. It also has a checkbox to calculate airbox size based on either array itself, or array plus all FEM geometries.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

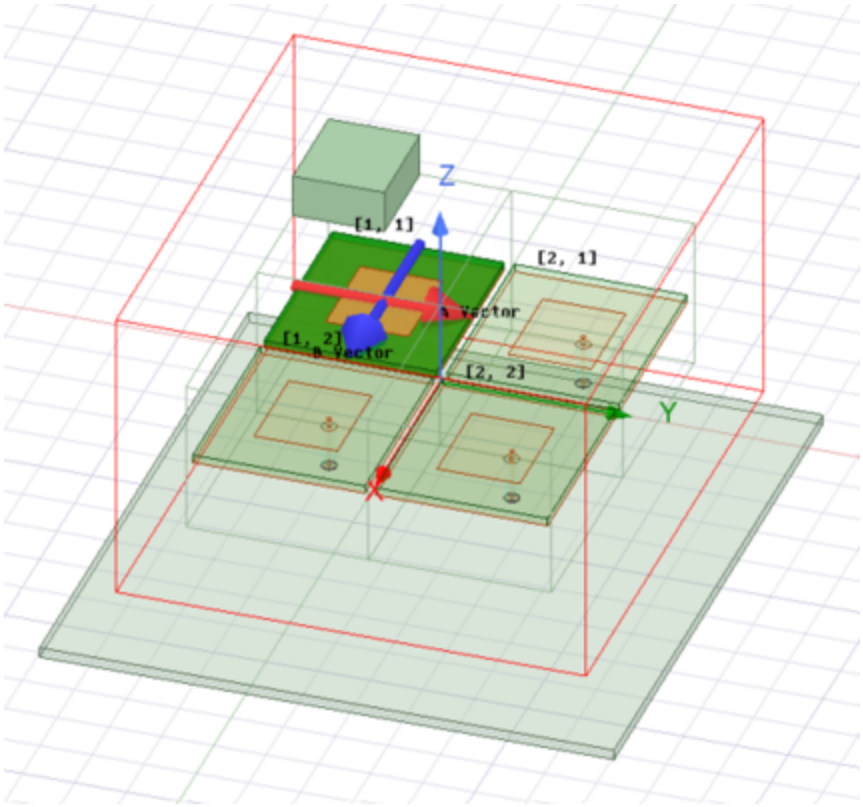


Component array design supports non-array components (that is, components without at least two lattice boundaries). You can add these components to array design just like native geometries. Mesh assembly is not supported in this case.

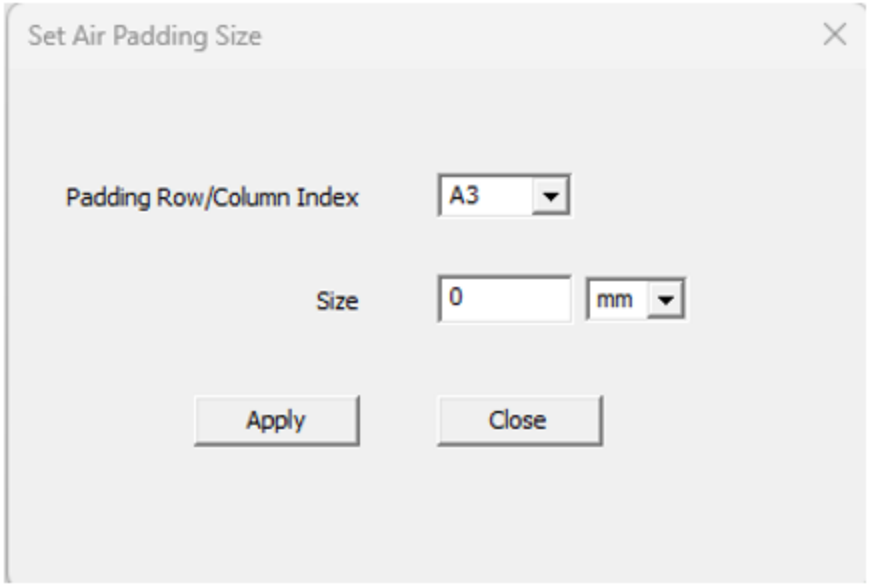


Component array design with surrounding geometries supports SBR+ regions. In this case, all geometries except SBR+ regions must be enclosed by an airbox. After you create a 3D Component array, you can define SBR+ geometry in 3D Component Array design to take advantage of leveraging the current component array and SBR+ techniques and workflows. This can provide significant enhancement to design and simulation efficiency. For use with SBR+ you must enclose the component array with an airbox and assign it as either FEBI, Radiation or PML.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



See the SBR+ and 3D Component Array section for the process, which including automatic airbox create/update, array reference CS, and hybrid coupling dialog.

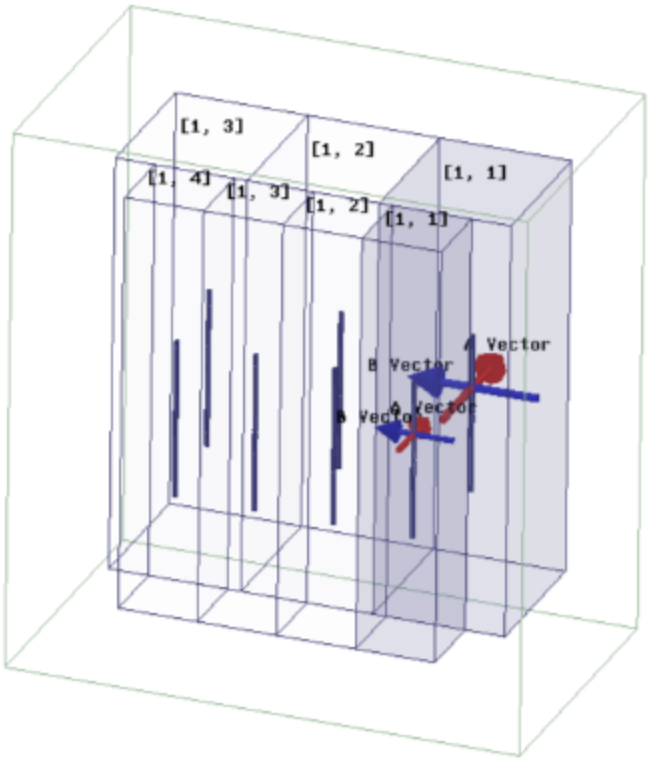


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Multiple Finite Arrays (Beta)

For some HFSS 3D problems like Z-axis stacked up arrays, or multiple arrays on the same platform, the HFSS Multiple Component Arrays Beta feature allows multiple array setups with the same UI access as you use to create a single array. You must define each array center position by different relative coordinate systems, and each array has its own lattice vectors, component list and array mask. You can define arrays within SBR+ Regions.

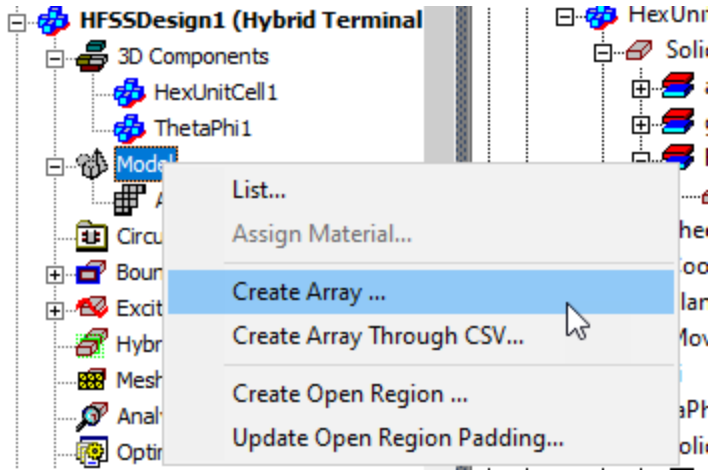
Each array must be enclosed by an airbox. If multiple arrays have different airboxes, each airbox must be assigned as FEBI. Multiple arrays can now have contact with lattice boundary faces.



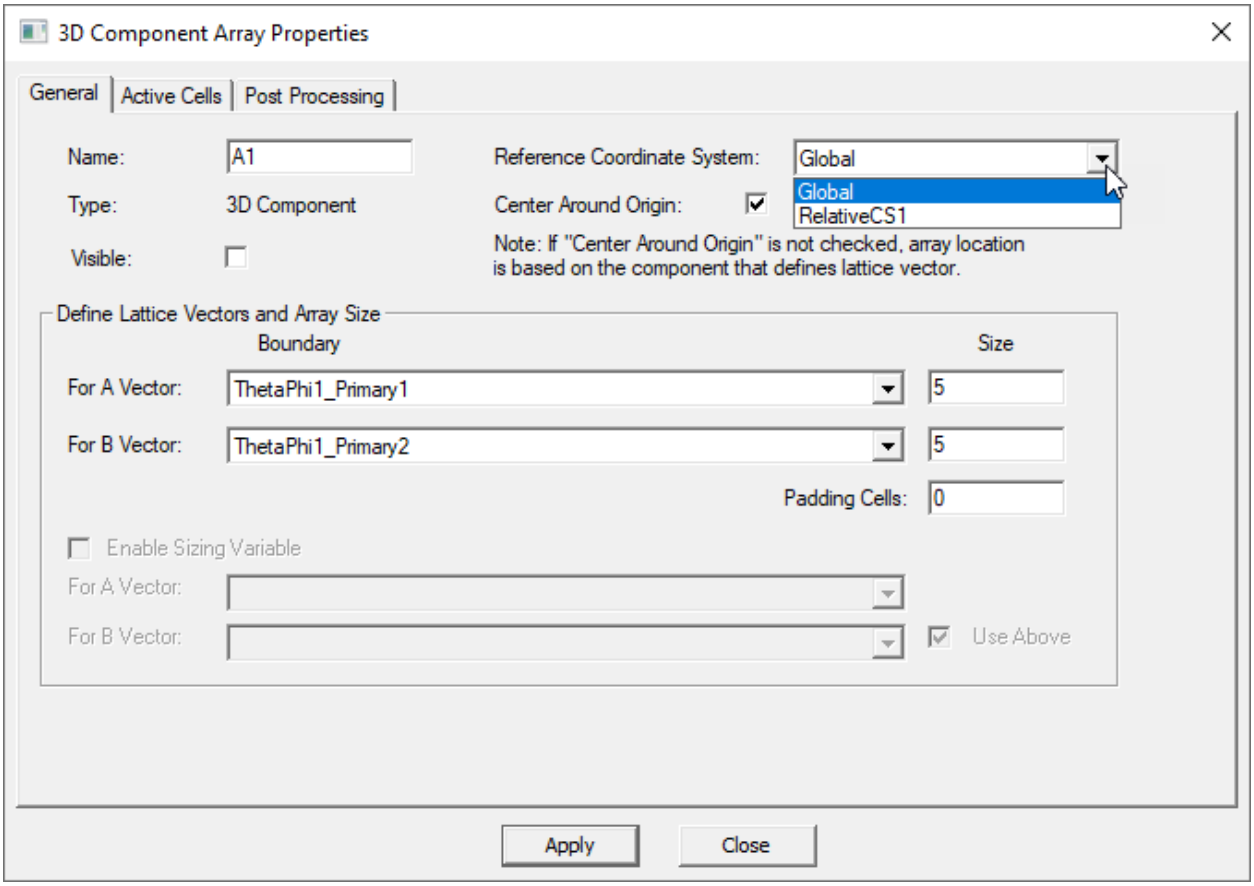
Creating Multiple Arrays

The process of creating each additional array uses the same commands as for creating a single array. Once you have a single array setup available, repeat the same array creation process by placing the Unit cell you want to use for the added array, and then select **Model > Create Array ...**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

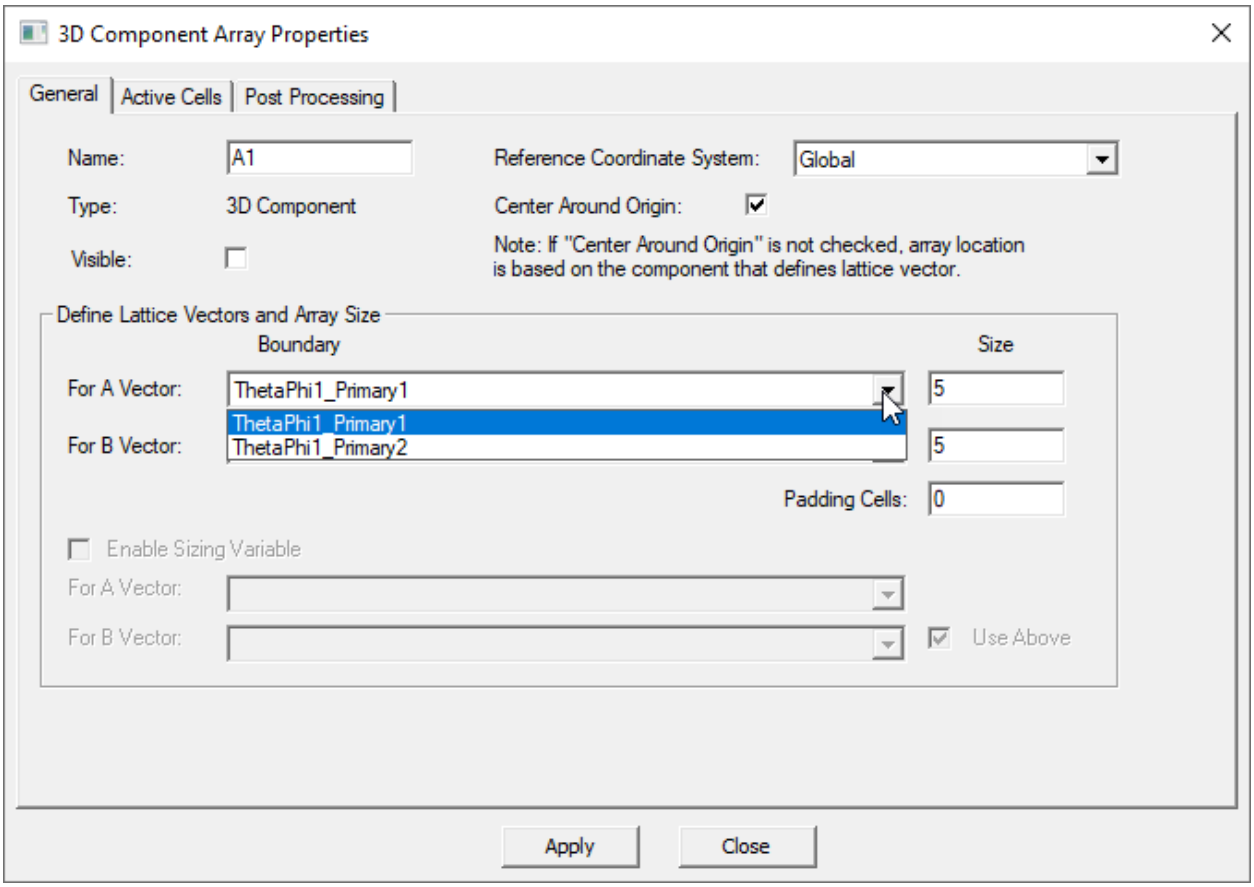


In the **3D Component Array Properties** dialog, first select the coordinate system that you associate with the Unit cell placement for the additional array.



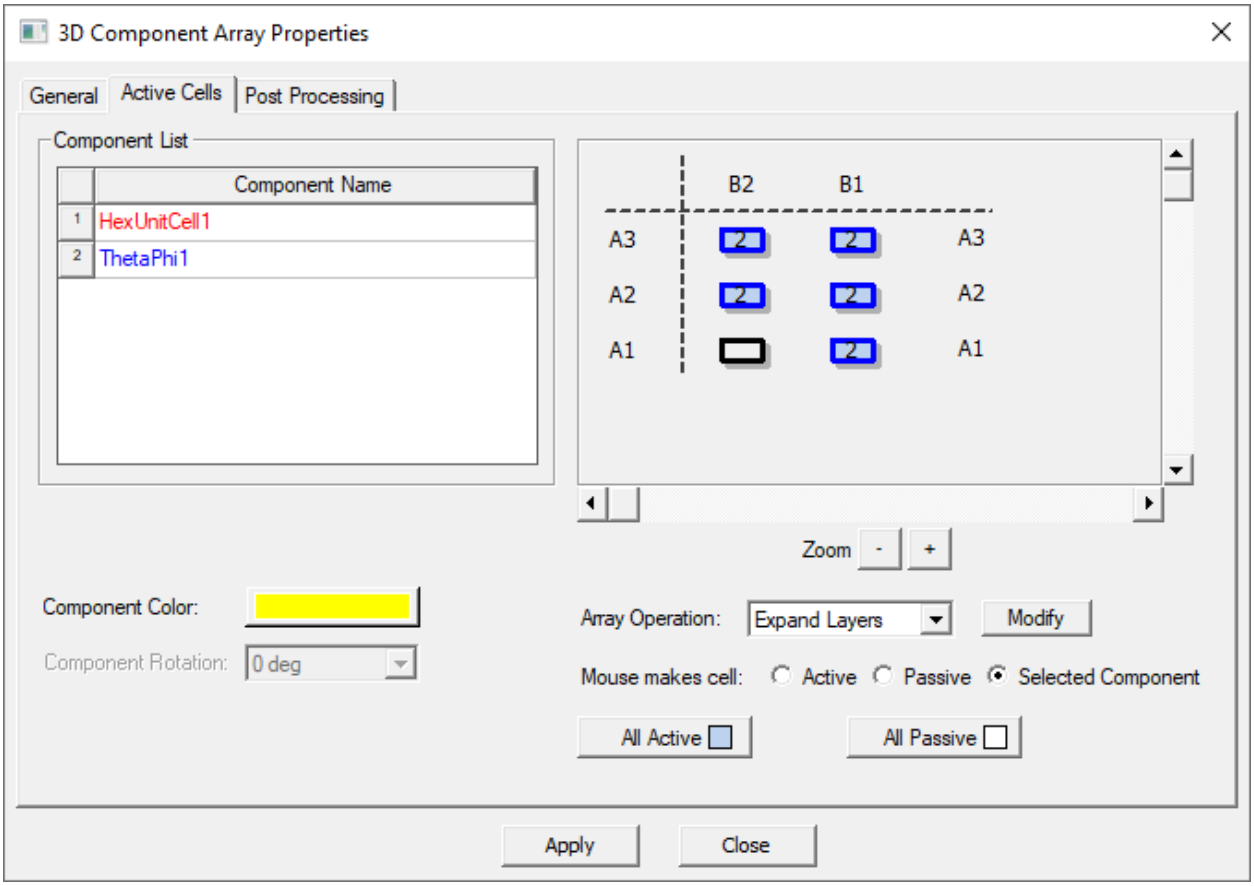
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can then select lattice vectors from available unit cell boundaries, and then define the array size and padding. A checkbox lets you make the array visible in the Modeler window. The Center Around Origin flag, when disabled, allows arrays to be positioned without being centered on the relative coordinate system. In this mode, the array's location will be determined by its master component (the component used to define lattice vectors).



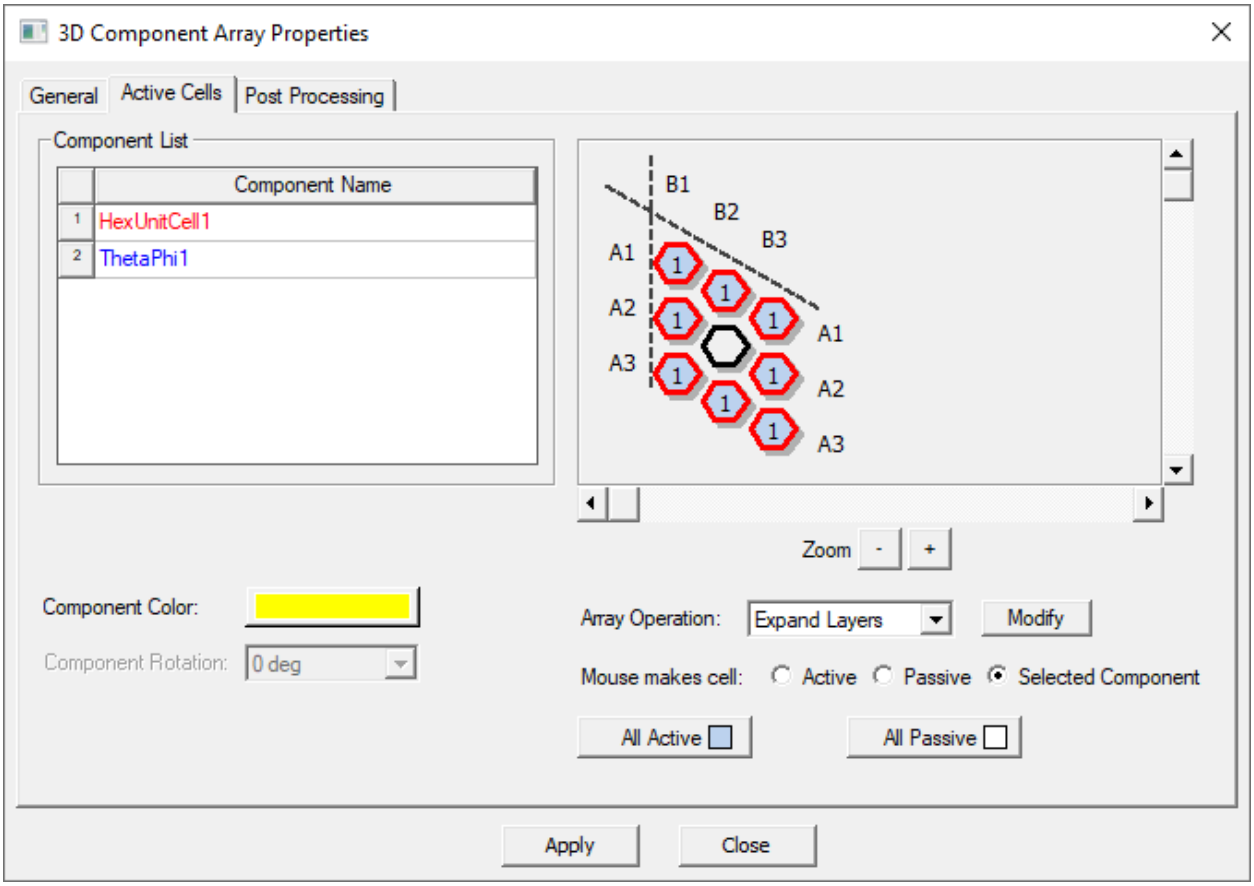
Then use the **Unit Cells** tab to select the array cells and define the component mask

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

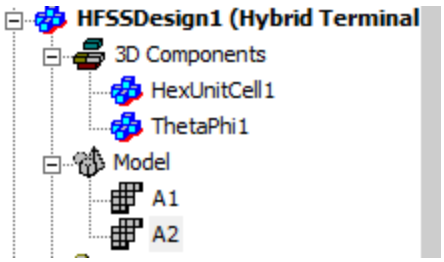


If the component cells are non-rectangular, the array representation reflects this:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The added array appear in the Project tree and, if you have enabled visualization, in the Modeler window.

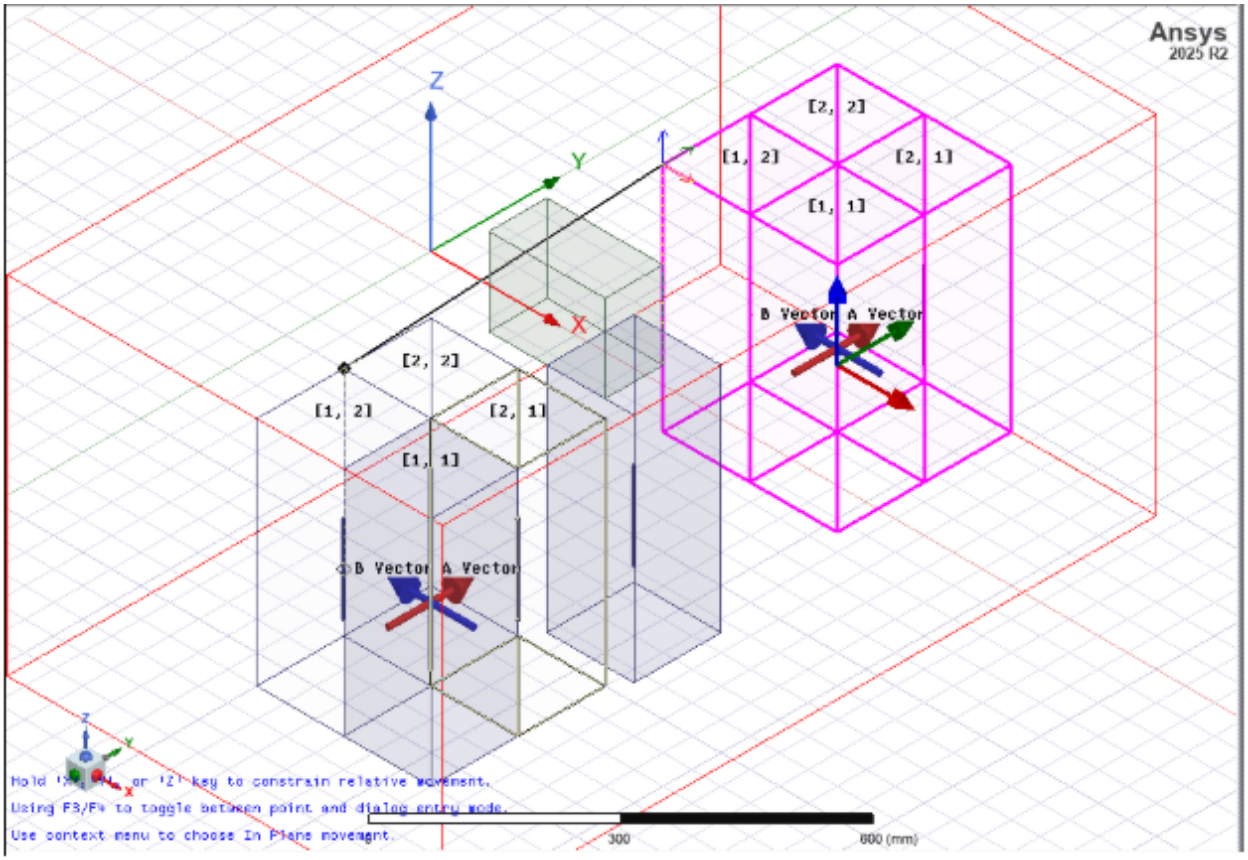


Using Snapping Points for Placing Arrays

To position Array A based on an "anchor" point on the virtual cell of Array B:

1. Select Array A, which includes all its components.
2. Use a geometry operation to move Array A using snapping points.

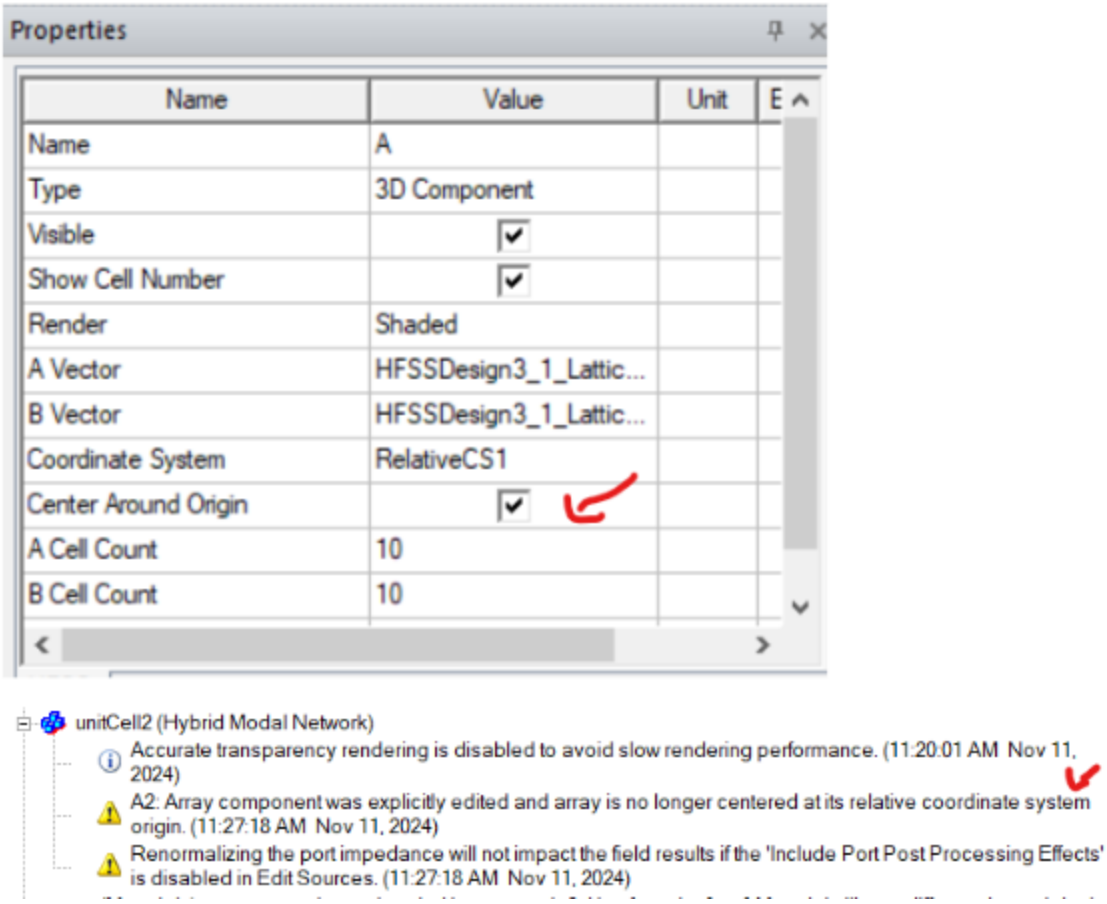
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



During this process:

- A warning message will notify the user that the array is no longer centered on its relative coordinate system.
    - The "Center Around Origin" property will be disabled to reflect this change.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Array A will then be anchored based on its master component (used to define its lattice vectors).

Copy/Paste for Arrays

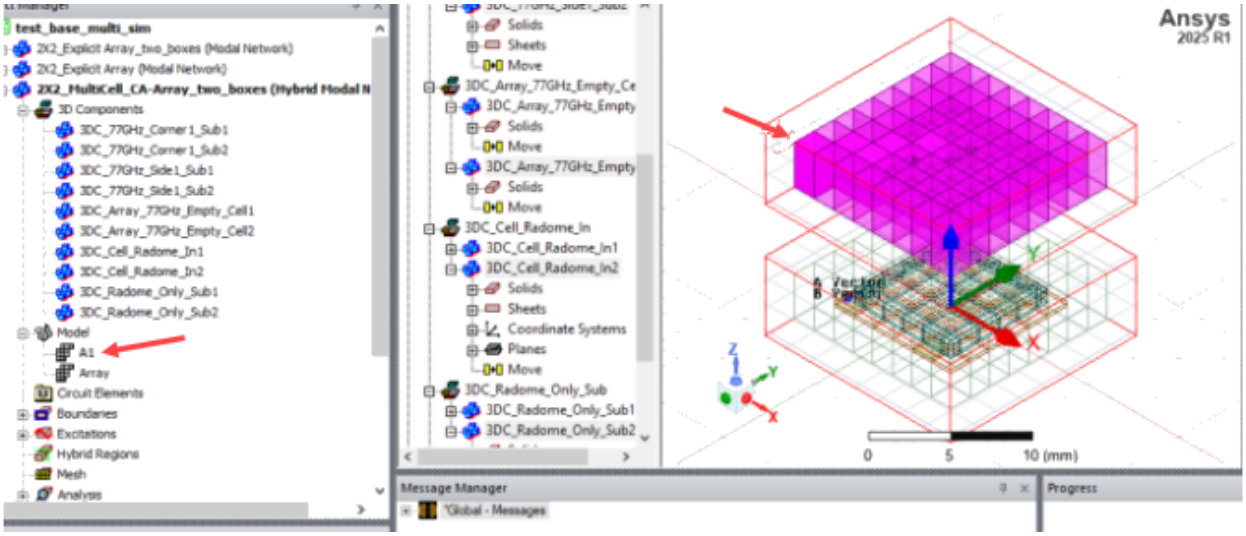
Since multiple arrays are supported in HFSS, it's natural to define new arrays based on existing arrays. HFSS supports array copy/paste like 3D component copy/paste. This operation first creates new array component instances and then duplicates array definitions, such as component mask and component rotation angles). By default, the pasted array uses the active coordinate system as the array reference coordinate system.

When the Beta feature for Multiple Arrays is not enabled, the copy/paste functionality still works if the pasted design does not have an existing array.

Array Component Highlighting

When you select an array item, all related components are highlighted. This new functionality works when the Beta feature for Multiple Arrays is off.

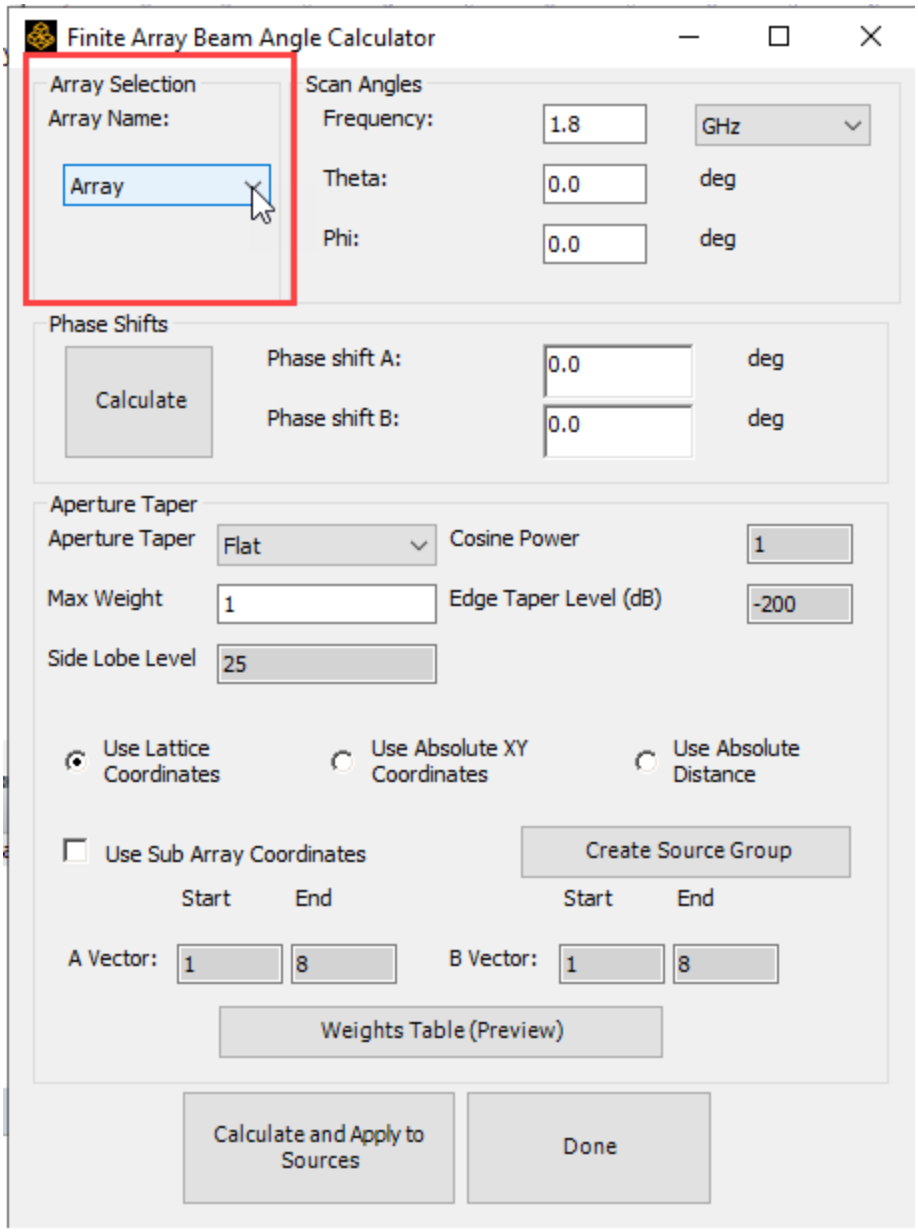
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Multiple Arrays Beam Angle Calculator Toolkit

The Finite array beam angle calculator toolkit automatically calculates the edit source setting given aperture taper parameters and is very useful in array beam design. In 25.1 the feature extends to multiple array designs and each array can be calculated individually. When the Beta feature for Multiple Arrays is off, the new “Array Selection” control box still appears in the Toolkit, but only one array can be selected.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

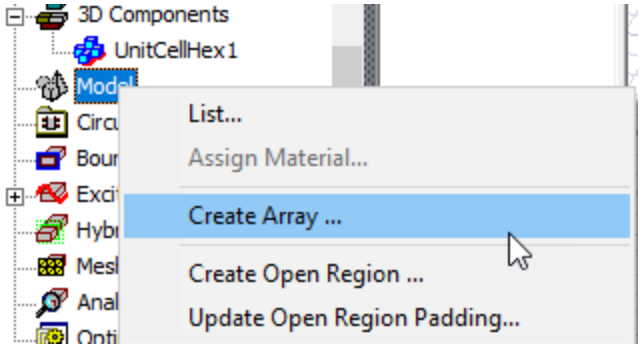


Create Array Command for 3D Component

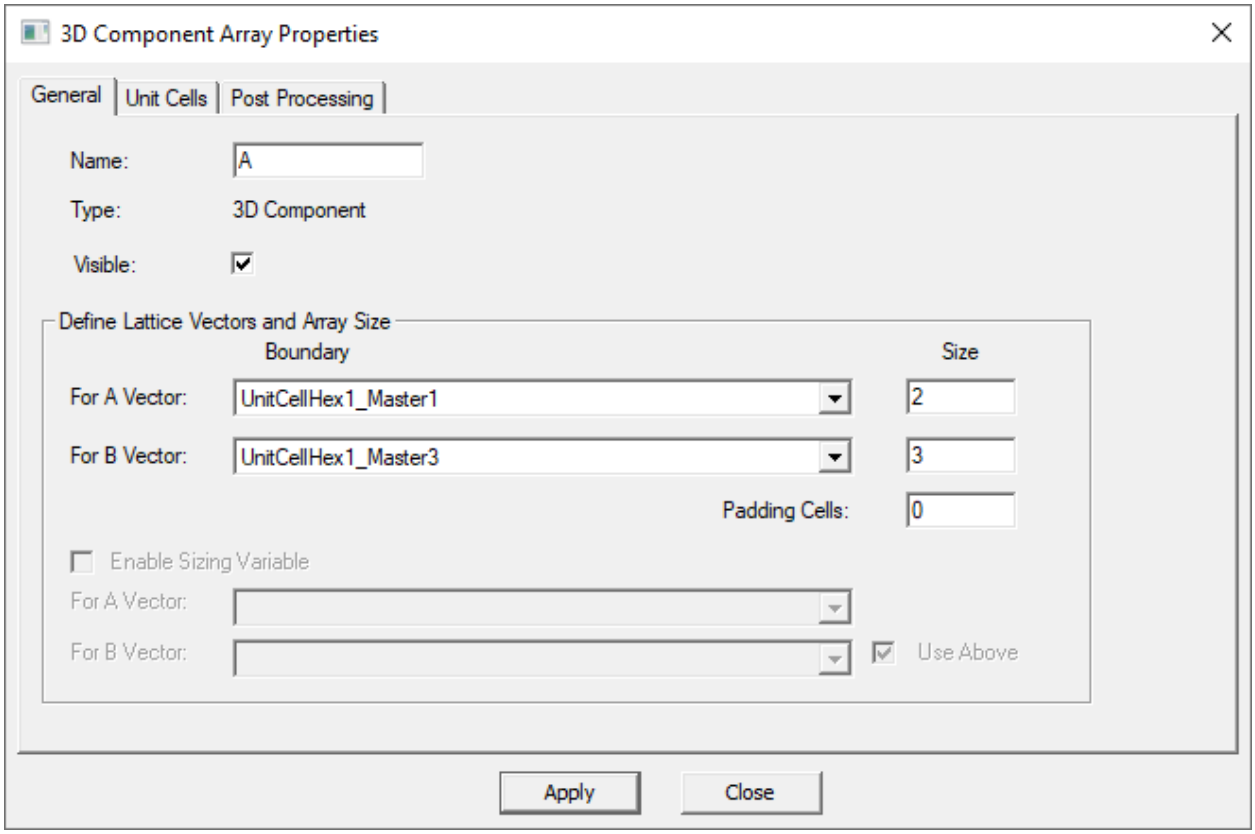
Create Array for 3D Component Process Flow

1. You can access the command in three ways: click **HFSS>Model>Create Array...**, right-click the Model icon in the Project tree and select ...**Create Array** from the shortcut menu, or select the 3D component in the modeler window, and select **Create Array...** from the short-cut menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

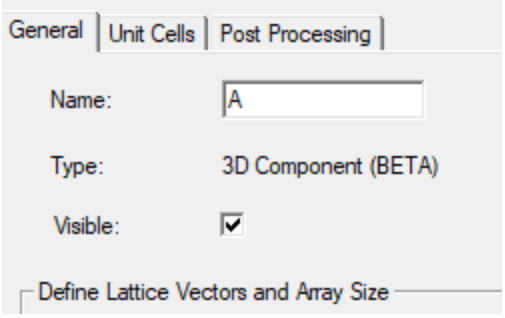


This displays the **3D Component Array Properties** dialog where you use the **General** tab to select the cell boundaries that define for Lattice Vectors, the number of cells in each vector, and any padding.

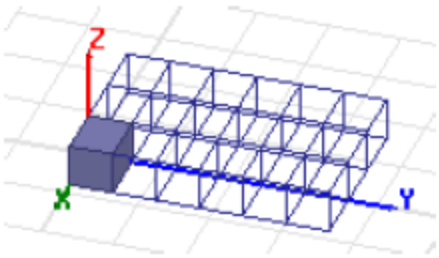


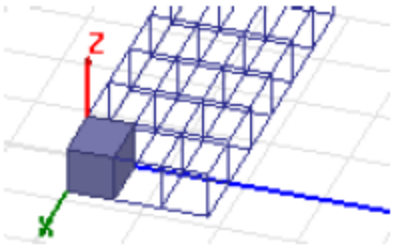
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you have **Visible** enabled, you can see any changes.



- To Define Lattice Vector directions for A and B Vectors, specify a different primary boundary for each. Drop down menus let you select from the available primary boundaries, two for square or trapezoidal components and three for hex components.
- To define the array size, for the A and B vectors, specify the number of cells for each row and column, respectively.
- The following figure shows the results when the initial Lattice Vectors are swapped.

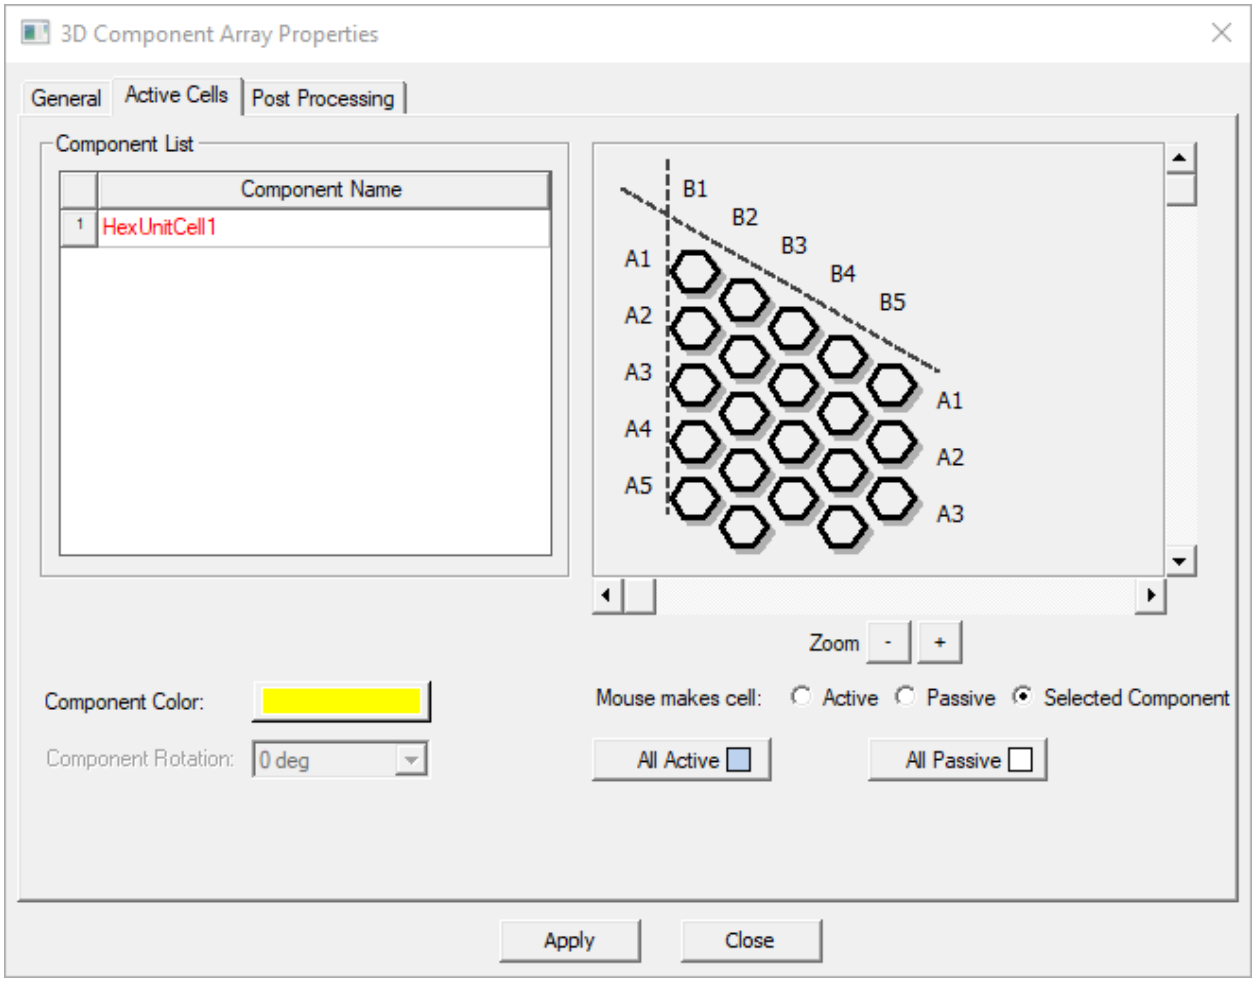




- If you have defined Design Variables for Length, the checkbox to Enable Sizing Variables is available. This feature should only be used when you create a new 3D Component. See Sizing Variables for New 3D Component Array.

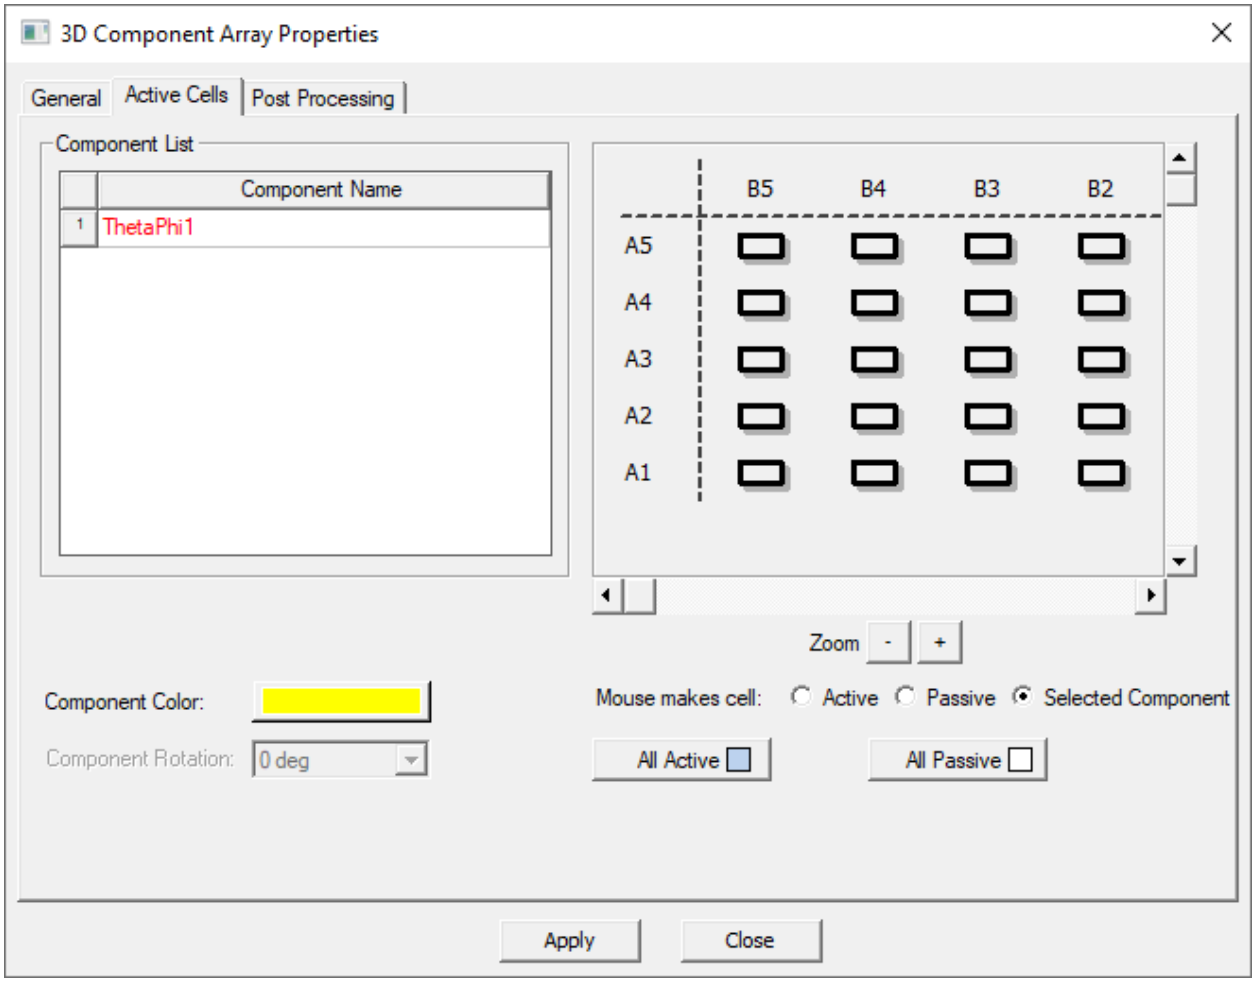
2. Select the **Active Cells** tab. Non-rectangular cells are displayed as the would be seen from above.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

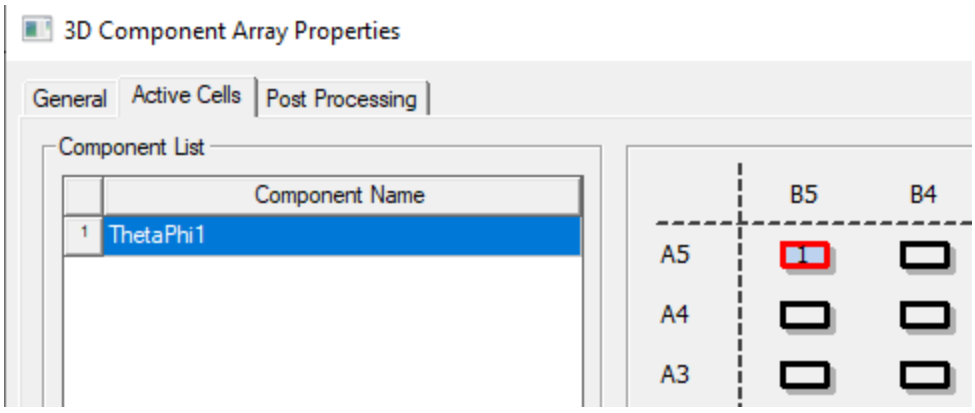


The rectangular components are displayed on a grid.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



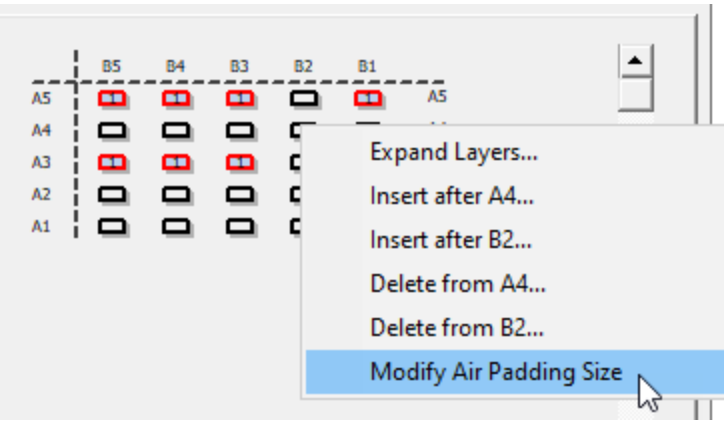
The component list shows the available components. You must select at least one component as active.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Components can now have different bounding box sizes (i.e., non-uniform sizing). However, to maintain array integrity, the array must remain perfectly tiled. The following restrictions apply:

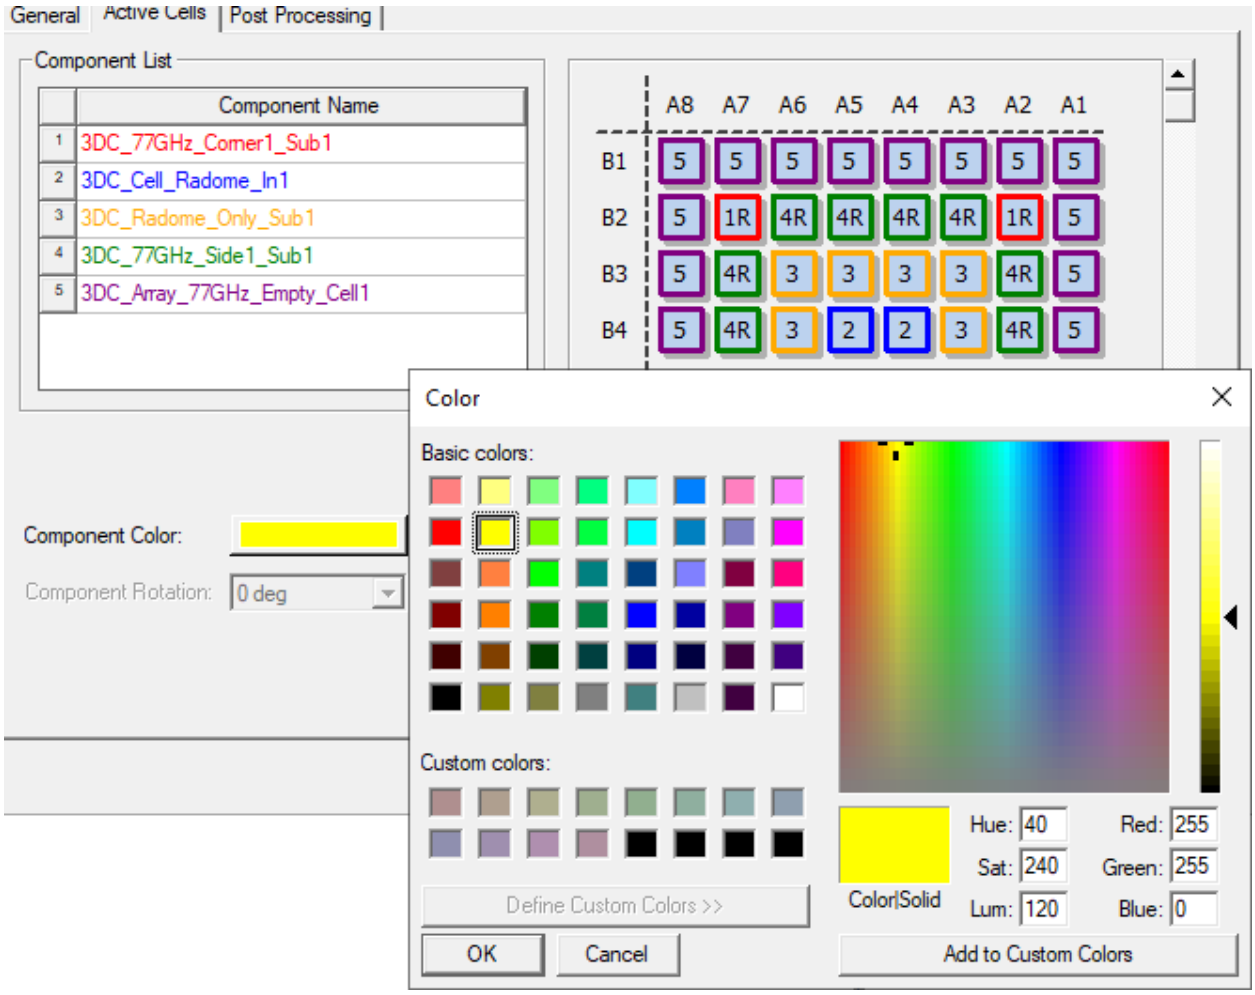
- Lattice Vectors Must Be Orthogonal: All lattice vectors must maintain 90-degree angles.
- Consistent Vector Sizes for Indexed Cells: Cells sharing the same A-index must have the same A-vector size, and cells sharing the same B-index must have the same B-vector size. This ensures that the array remains perfectly tiled. This rule also applies to aircell rows/columns, meaning that you can only adjust air padding sizes (using **Modify Air Padding Size**) when the entire row or column consists of aircells.



Custom Colors

The **Custom Colors** button opens a dialog that lets you specify a color for how the selected component appears in the array.

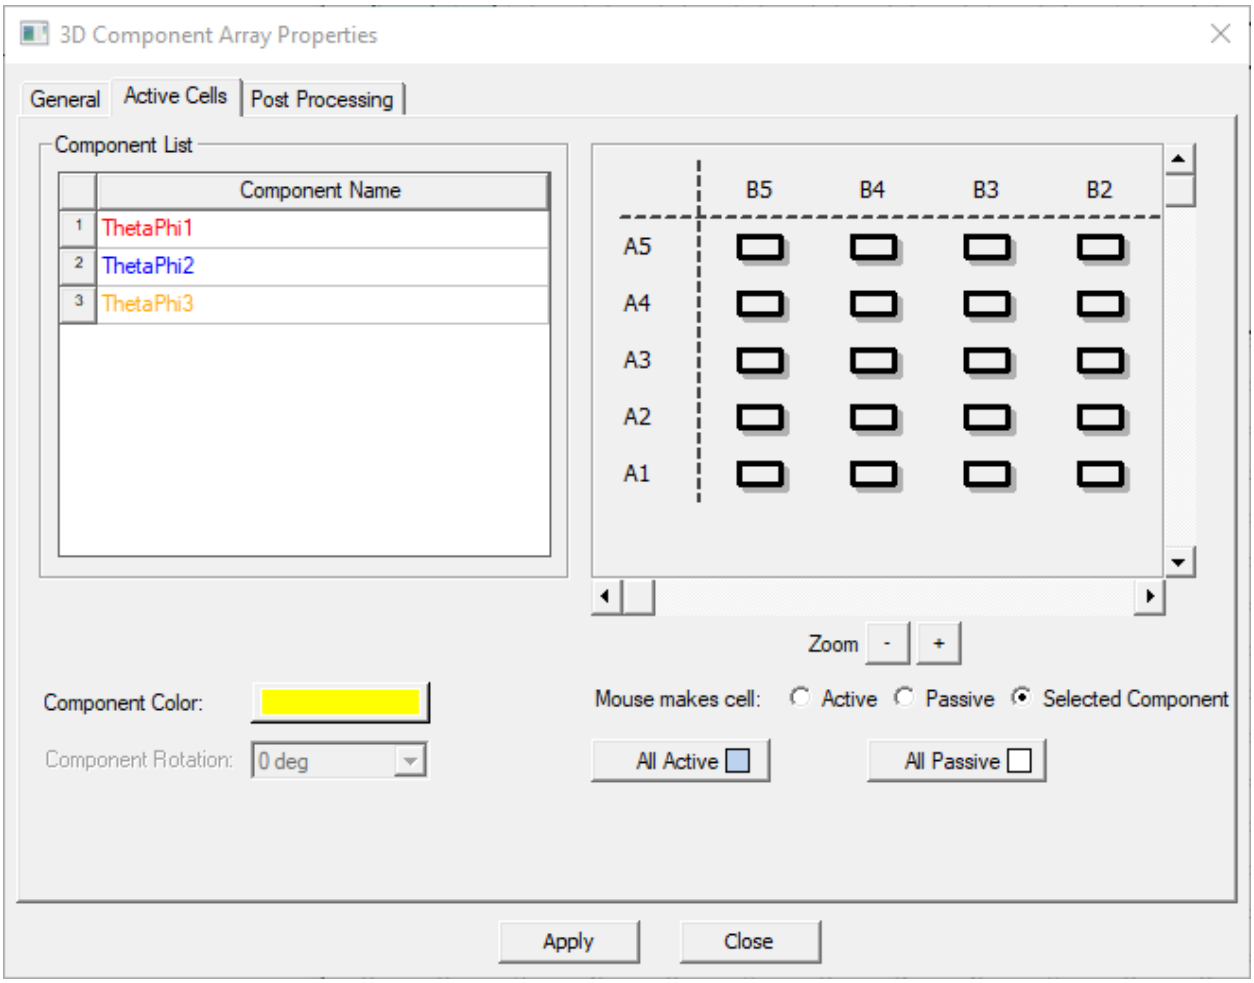
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Assigning Components to Array Cells

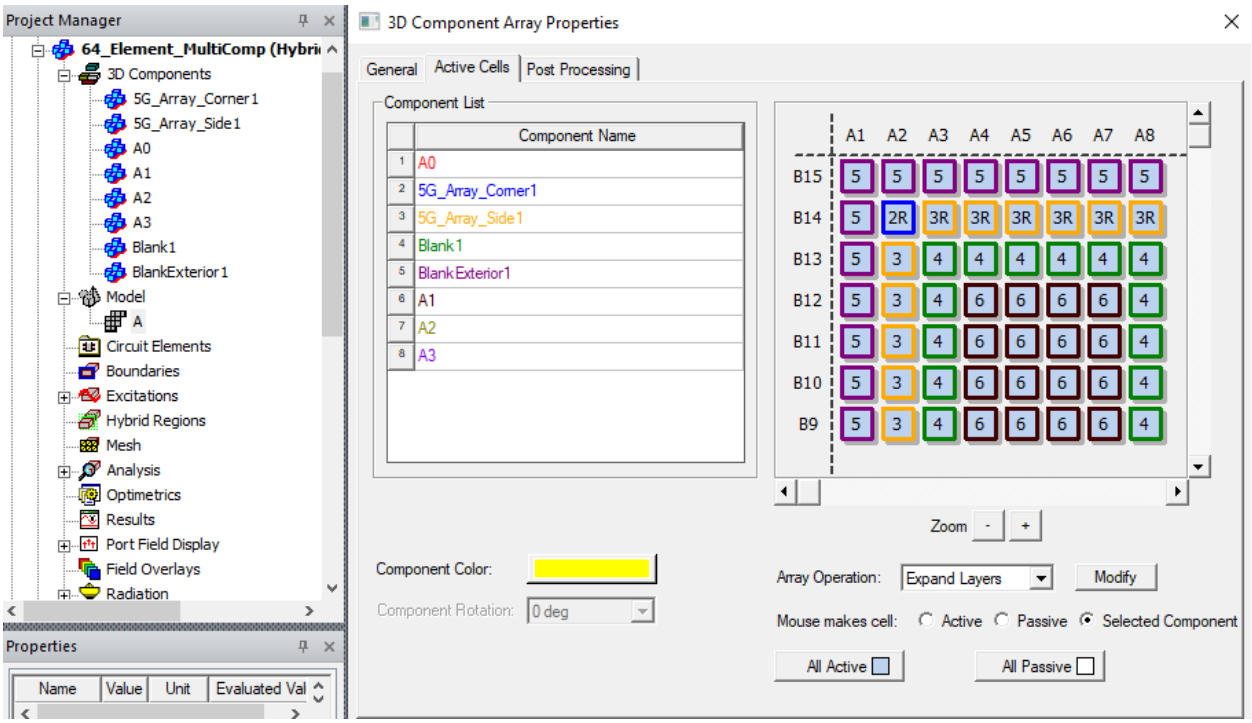
3. The component list shows the available components. Select the Component Name under the component list. You must designate at least one component as active.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



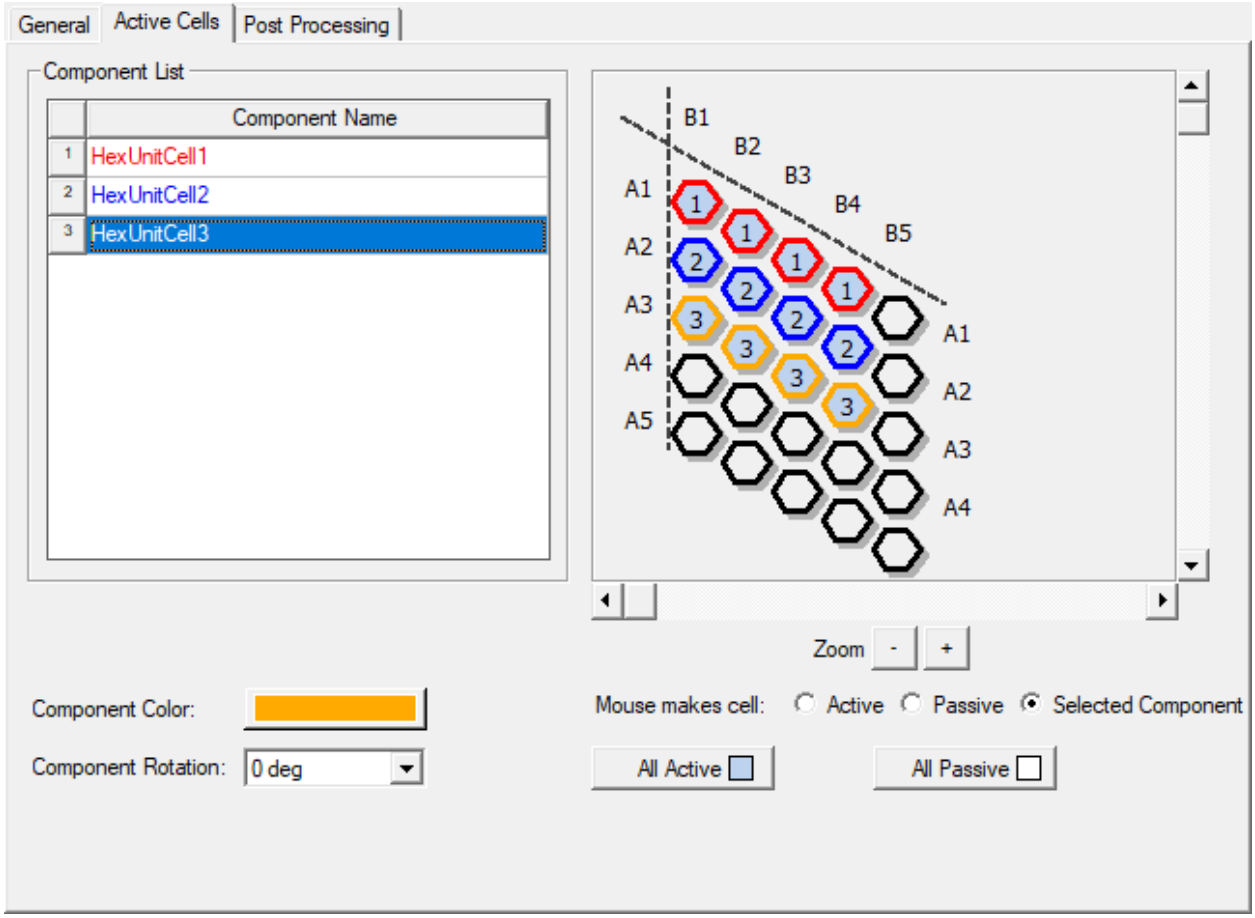
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. If the model contains more than one component you can select from the list.



5. With **Mouse makes cell**: set to **Selected**, click on the cells to populate with that component.

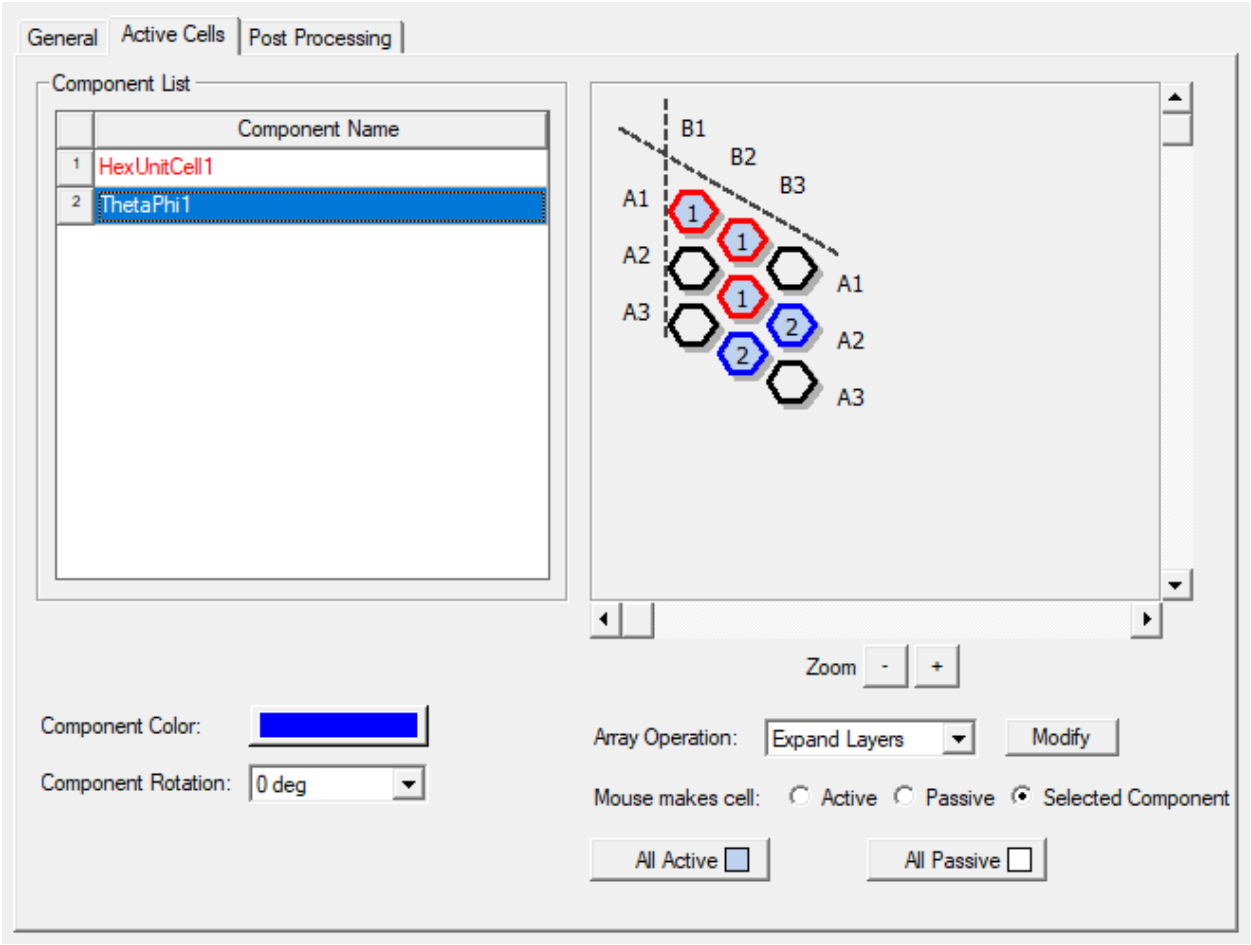
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Irregular Arrays and Air Cells

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

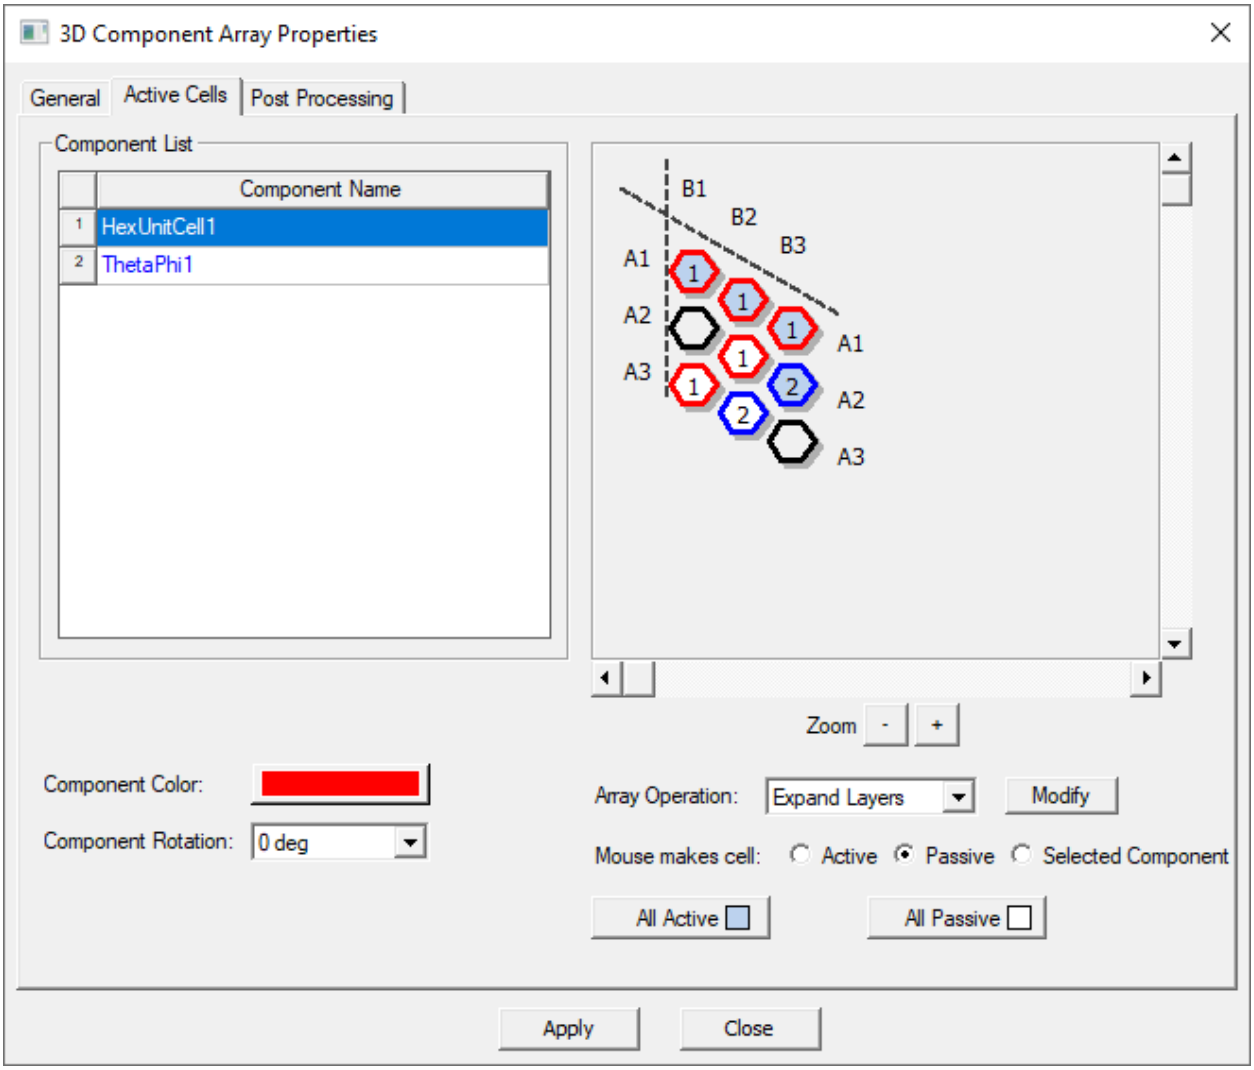
You can create an irregular 3D component array, depending on how you specify Selected components. Not selecting a 3D Component effectively sets the cell as an air cell.



Assign Cells as Active or Passive

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

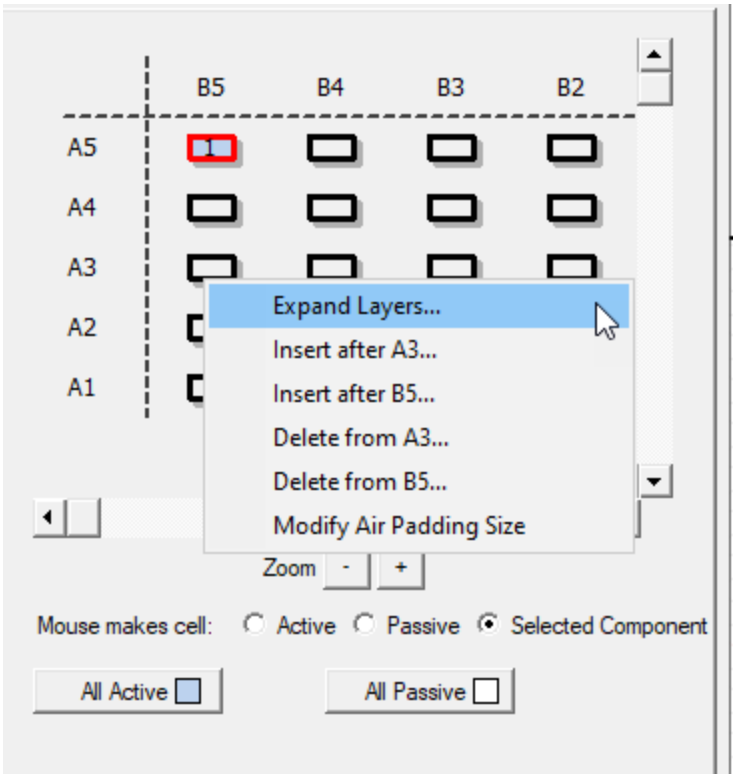
You can also designate cells as Active or Passive. When designated as passive, the cells are displayed as light inside the color boundary.



Array Editing Commands

The right-click menu on the array lets you select one of **Expand Layers...**,**Insert after A*n*...**, **Insert after B*n*Columns**, **Delete from A*n***, or **Delete after B*n***, where ***n*** corresponds to the A and B vector number that you right click on.

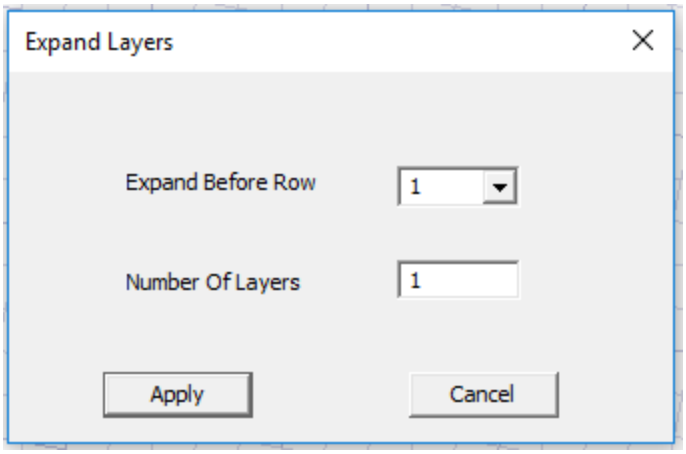
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Each of these commands opens a dialog, as discussed below.

If your design has A or B vectors without cells assigned, **Modify Air Padding Size** is enabled.

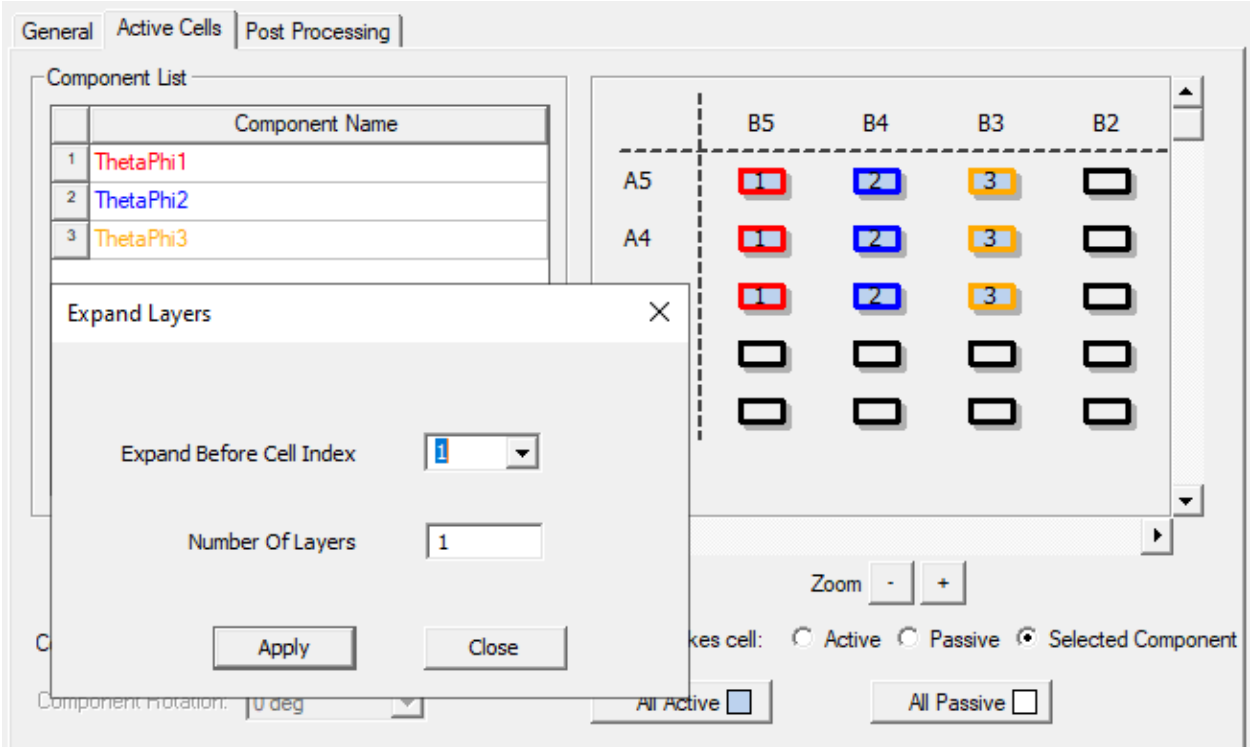
Expand Layers



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

After selecting (or inputting) the row to start, inputting the number of layers to add, and clicking **Apply** button, the original array is expanded the corresponding number of layers before the inputted row from the center.

If no component name is selected in Component List, the newly added layers are filled in with air cells.

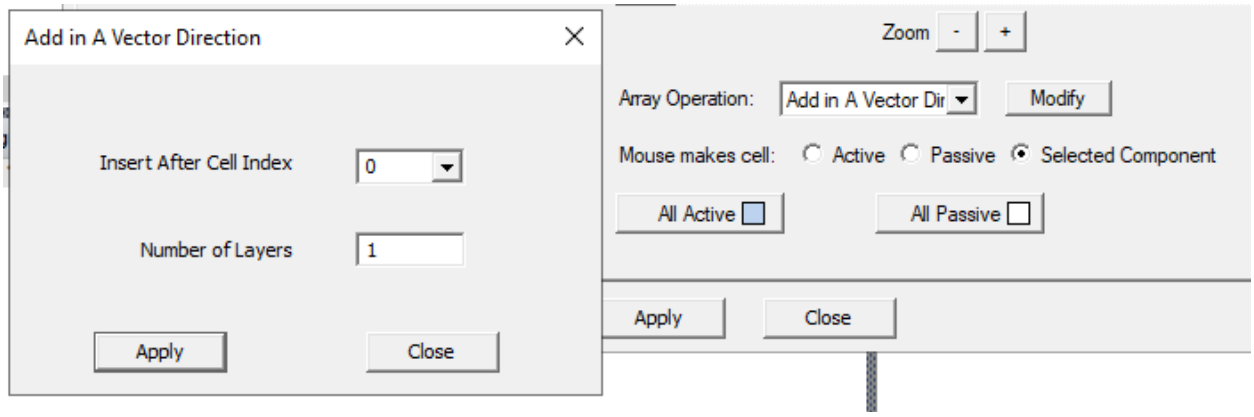


If some component name is selected in Component List, the newly added layers are filled in with the selected component cells. The expanded layers have their middle cell repeated.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Add in A Vector Direction

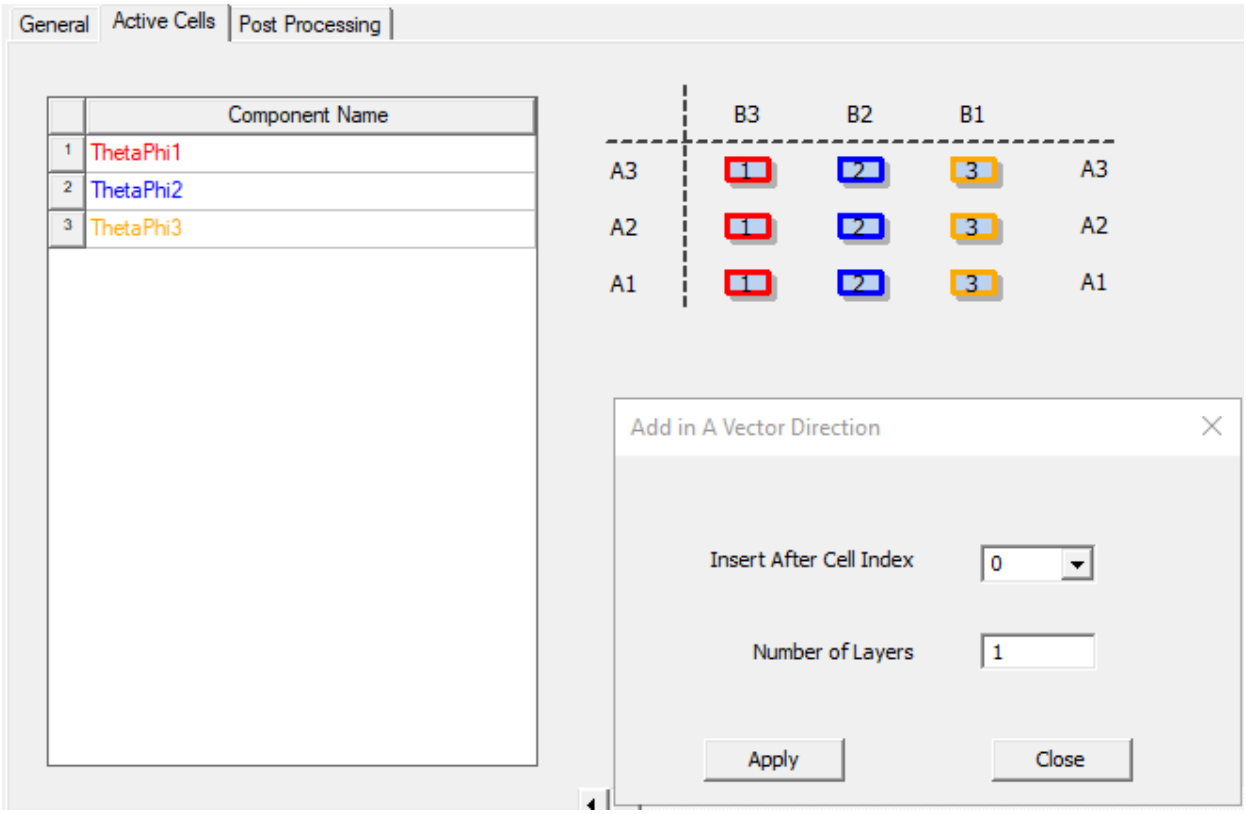
From the right-click menu, select **Add in A Vector Direction**. This opens the **Add in A Vector Direction** dialog.



After selecting (or inputting) the Insert After Cell Index to start, inputting the number of layers to add, and clicking **Apply** button, the original array is added the inputted number of layers after the corresponding cell index.

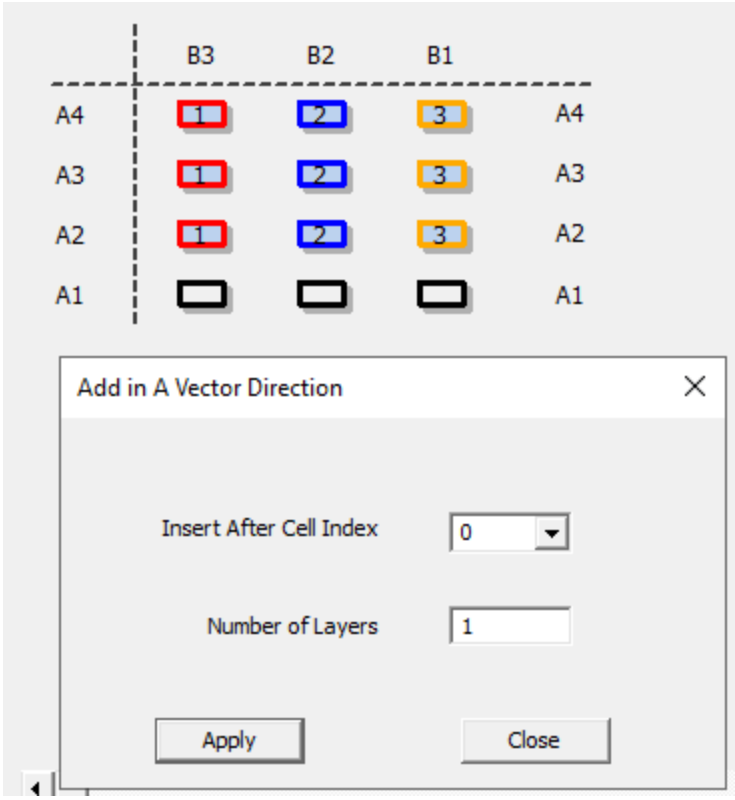
If you do not select a component name is selected in Component List, the newly added layers are filled in with air cells.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

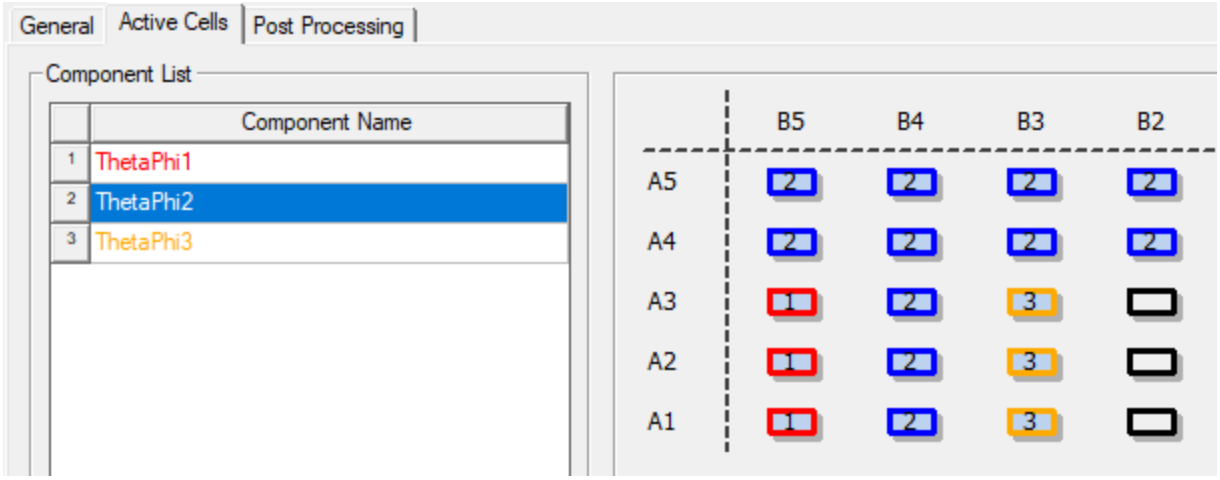


Click **Apply**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

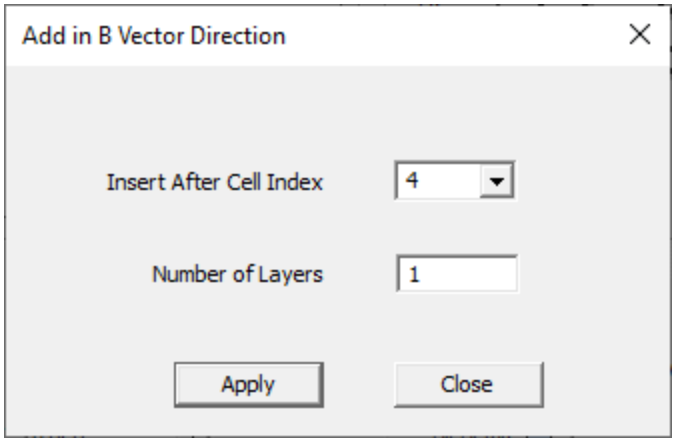


If some component name is selected in Component List, the newly added cells are filled in with the selected component.



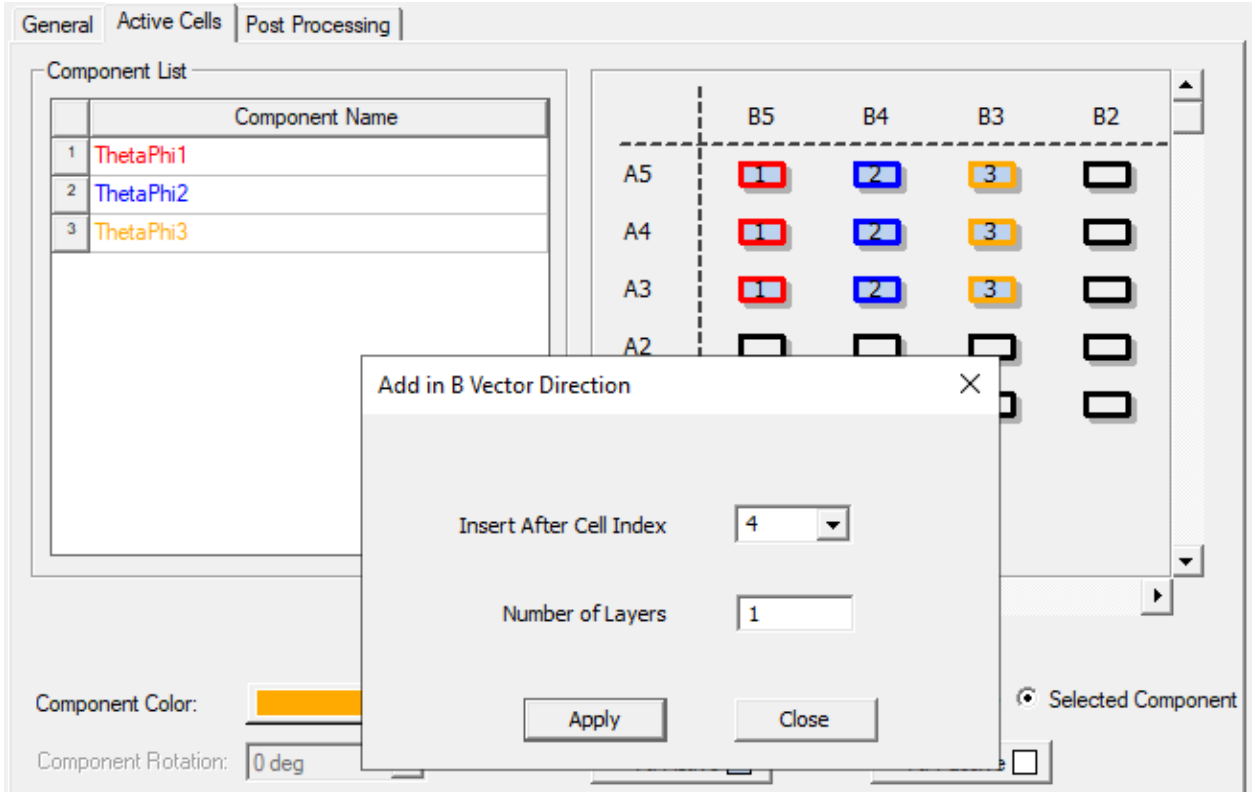
Add in B Vector Direction

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

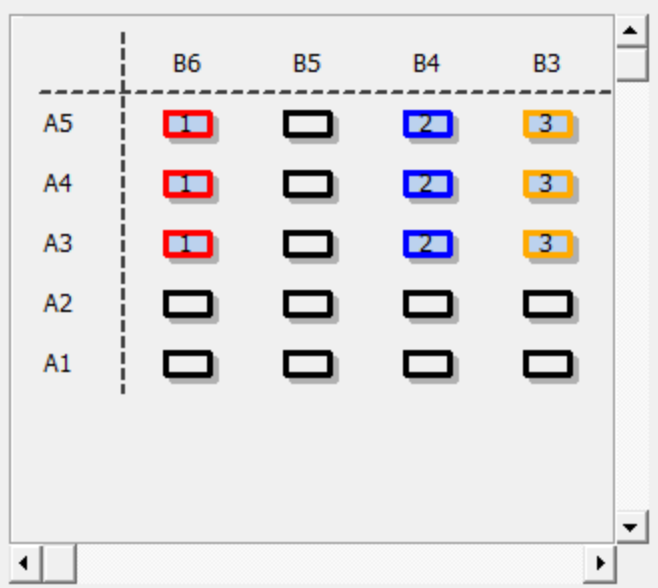


After selecting (or inputting) the B vector to start, inputting the number of layers to add, and clicking **Apply** button, the original array is added the inputted number of B vectors after the corresponding cell index.

If you do not have a component name is selected in Component List, the newly added B vectors are filled in with air cells.

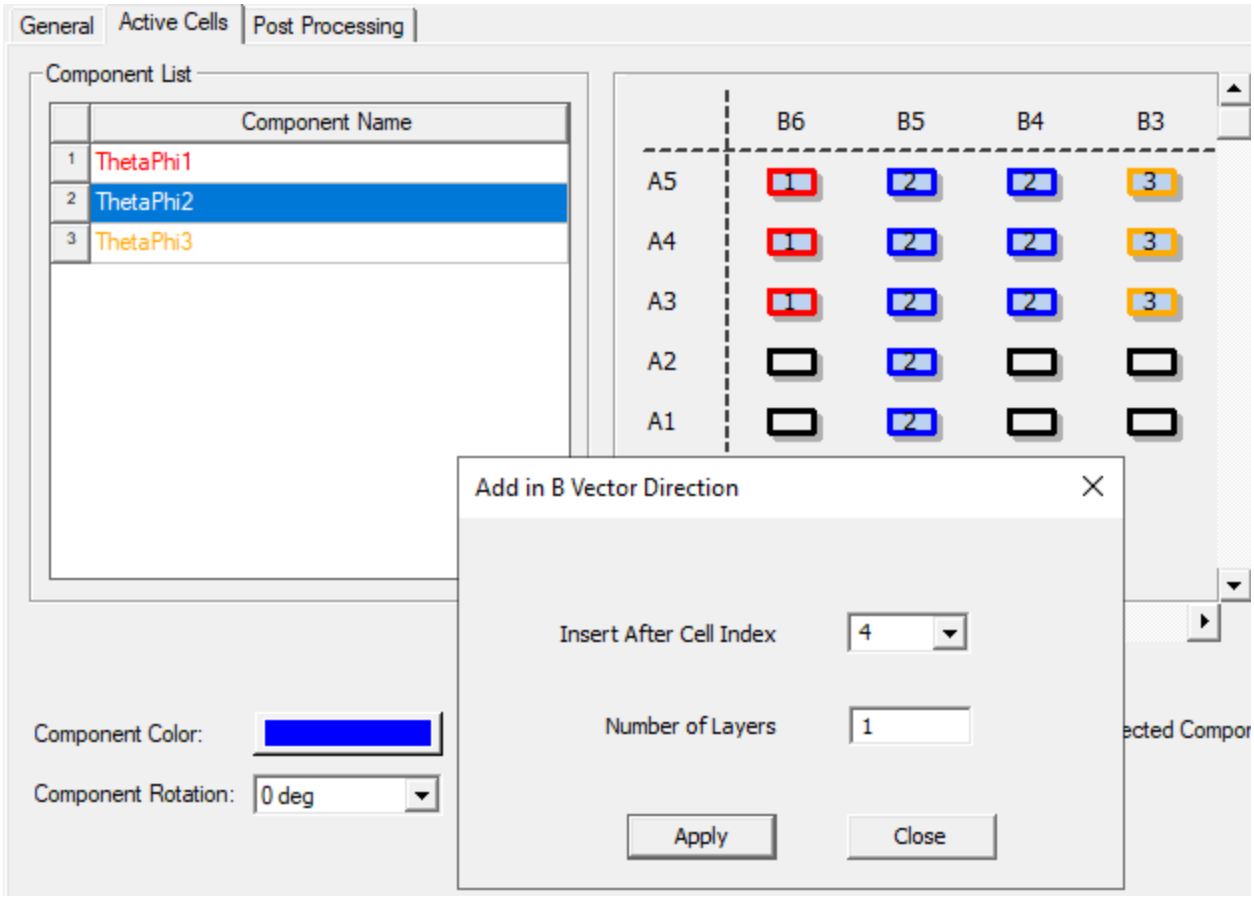


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



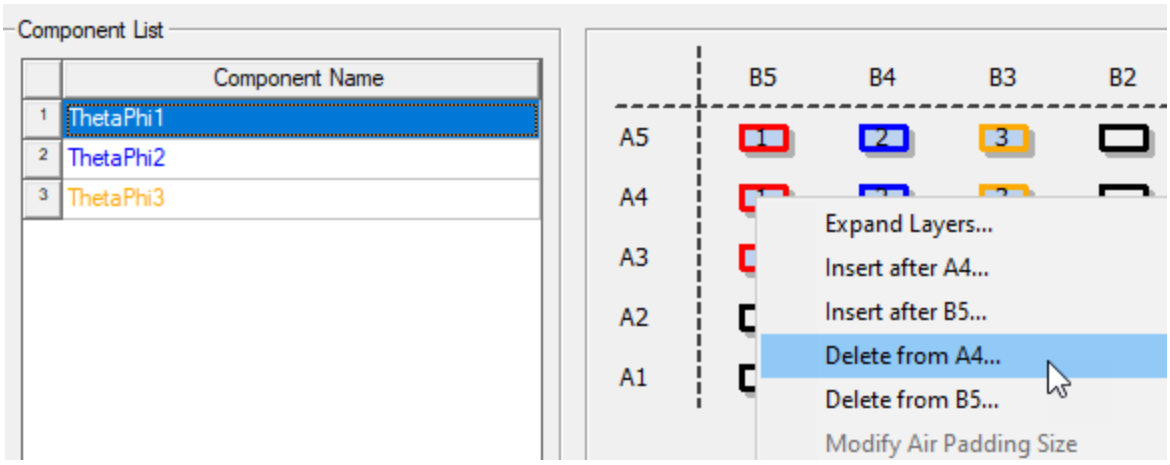
If you select a component name in the Component List, the newly added B vectors are filled in with the selected component cells.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



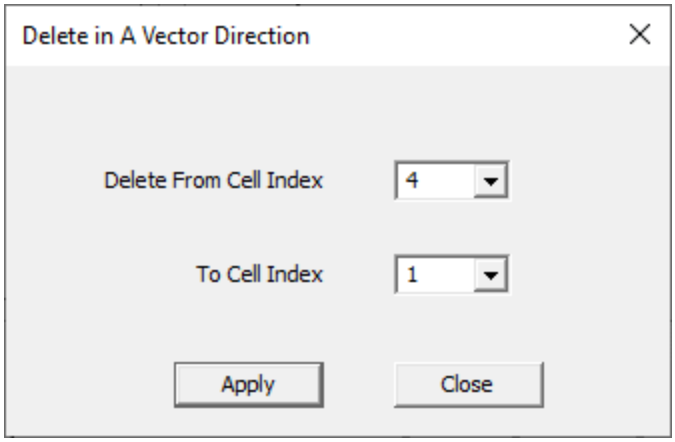
Delete from A Vector

Right-click on the A vector you want to delete and select from the short-cut menu.

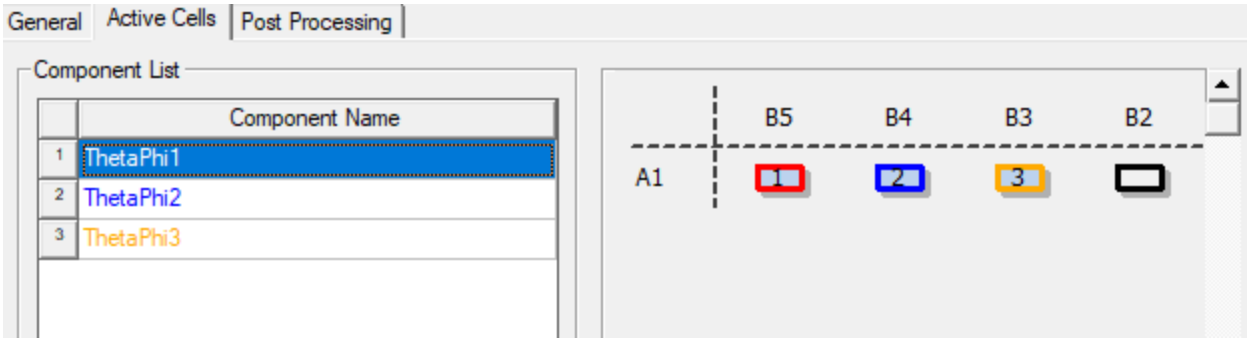


This displays the **Delete in A Vector Direction** dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

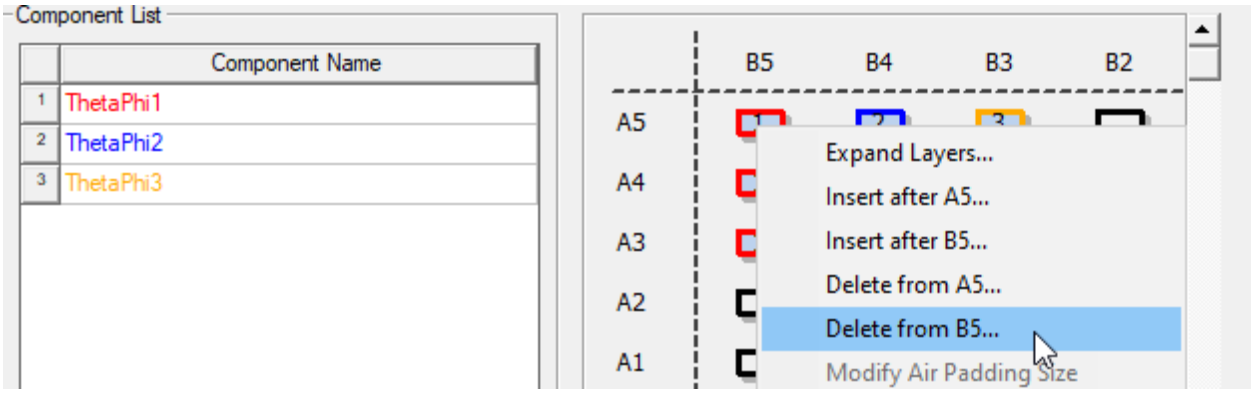


You can change the Delete from Cell and To Cell Index values. Click the **Apply** button to delete A vectors in the range.



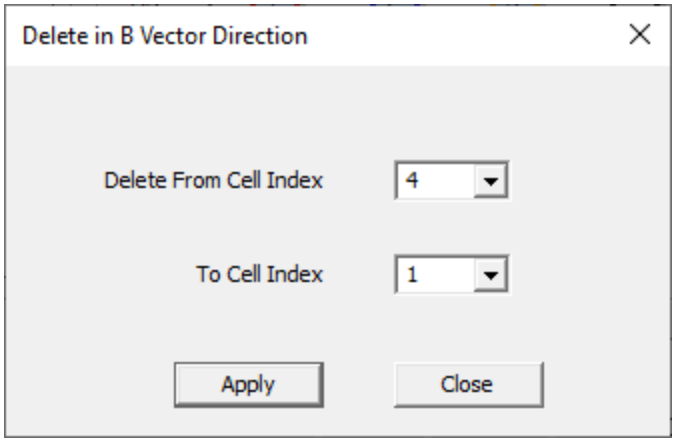
Delete from B Vector

Right-click on the B vector you want to delete and select from the short-cut menu.



This displays the **Delete in B Vector Direction** dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can change the Delete from Cell and To Cell Index values. Click Apply to to delete B vectors in the range.

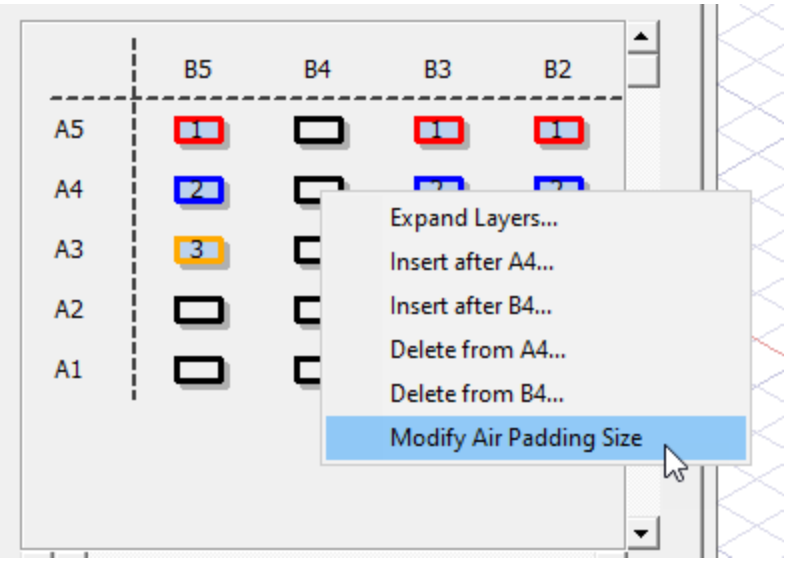
Modify Air Padding Size

Non-uniform arrays allow you to create arbitrary-sized internal padding by utilizing aircell rows or columns. If an entire row or column consists only of aircells, you can modify the size of that row or column.

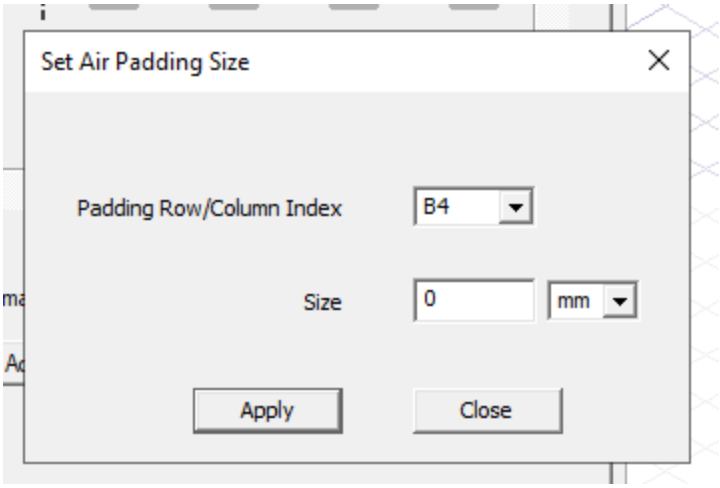
To adjust the air padding:

- Right-click on the aircell row/column and select **Modify Air Padding Size** from the pop-up menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This opens the **Set Air Padding Size** dialog.



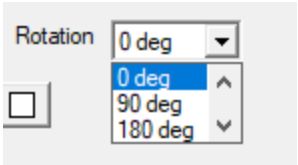
- Choose the padding A or B Vector index.
- Specify the desired padding size and **Apply**.

Rotation for Selected Cells

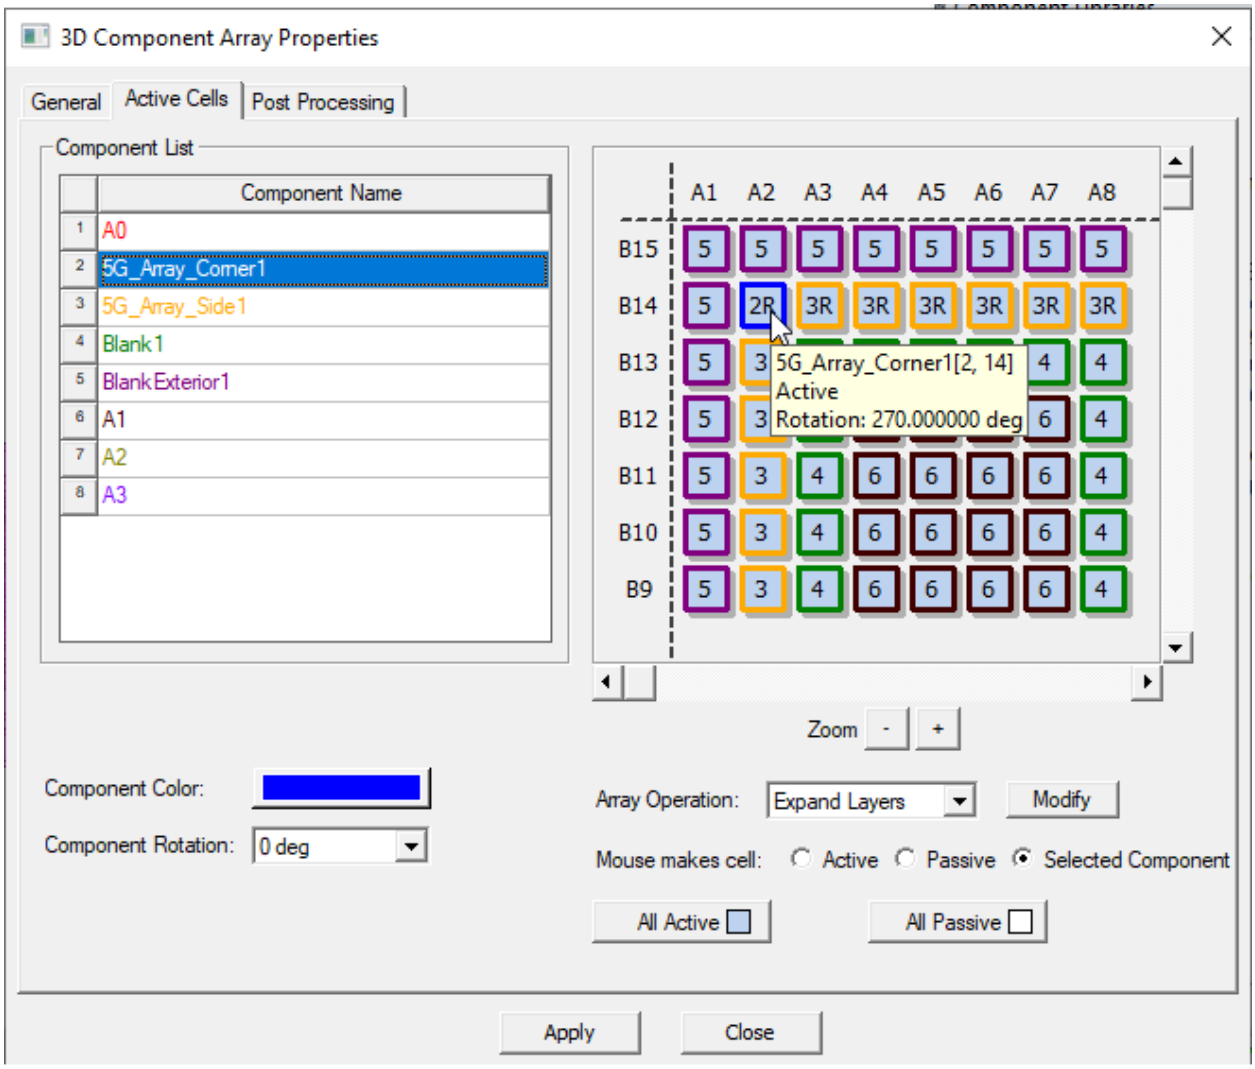
All component cells are initialized with 0 degree rotation (i.e. no rotation as default). You could first select the component name from Component List, then select the rotated degree from the rotation combobox at the bottom right, and then click the cell desired to rotate. The rotated cell is labeled “R” after the index to remind user. If no component is selected (i.e. air cell), the rotation combobox is disabled.

Note: rotation cannot be applied to any array cell containing a port.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



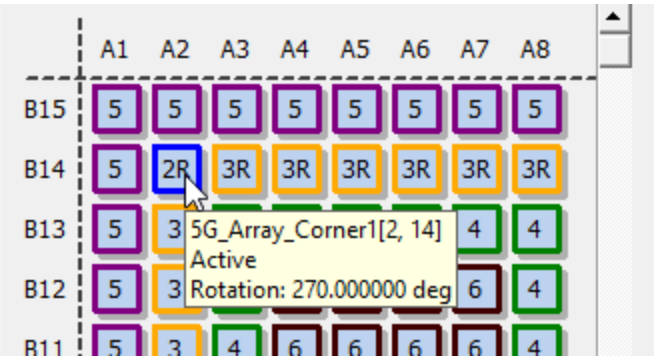
After setting the rotated cells and clicking **Apply** button in the **3D Component Array Properties** dialog box, the array is visualized.



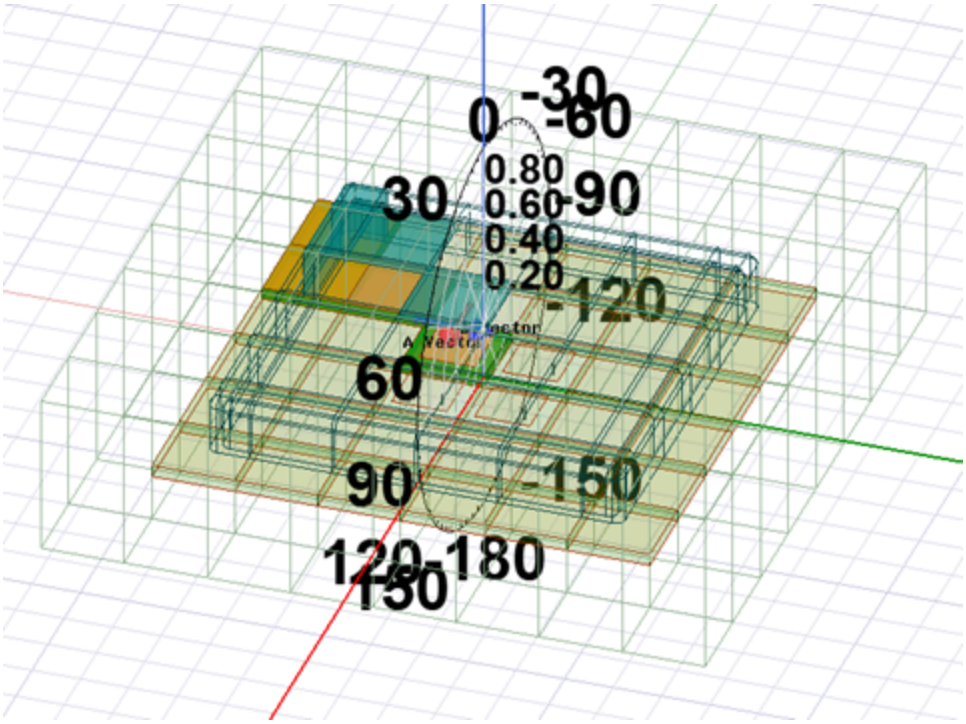
For the example above, the cells [B14, A2] through [B14, A8] are rotated 270 deg,

When you move the mouse on a component cell, a tooltip provides information including the domain name, state, and rotation angle.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

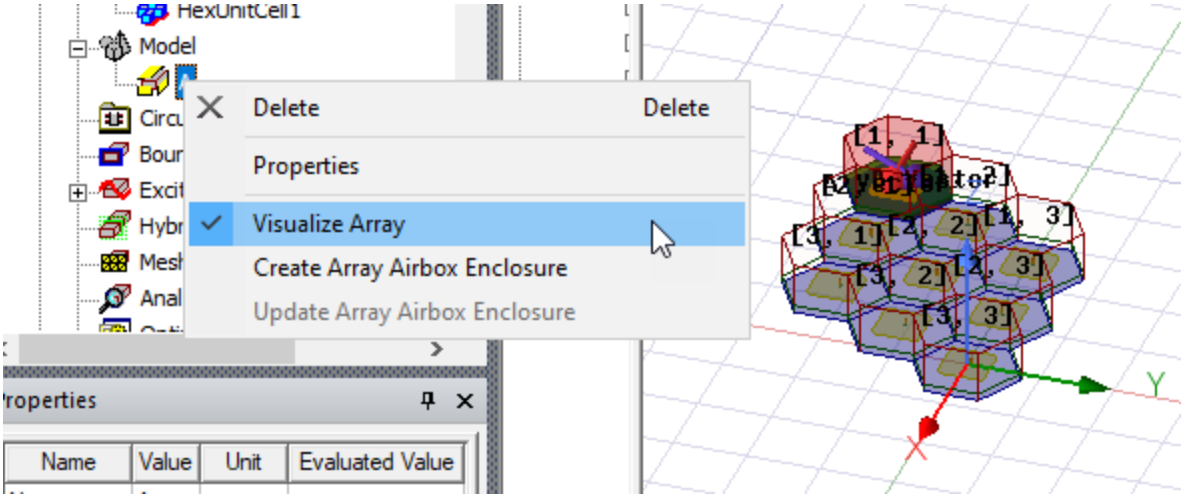


Below is a visualized array:



5. Click **Apply** to create the array you have defined and displayed. Right click on the **Array** icon to see the short cut menu that lets you manage the model properties, and visualization.

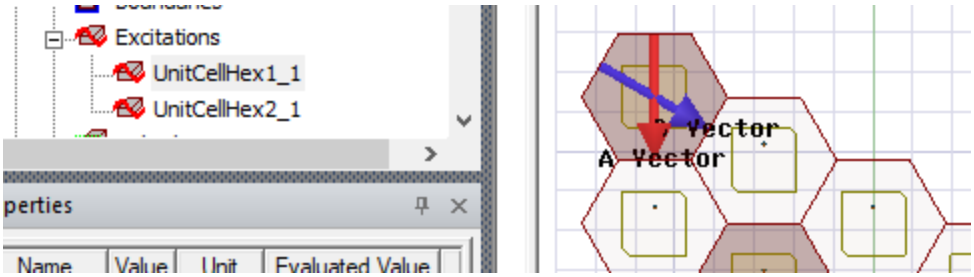
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



When you have defined an 3D Component array, an array icon appears under the Model icon in the **Project** tree. Only one Array is permitted for a model. The **Create Array** command is disabled if an array is defined.

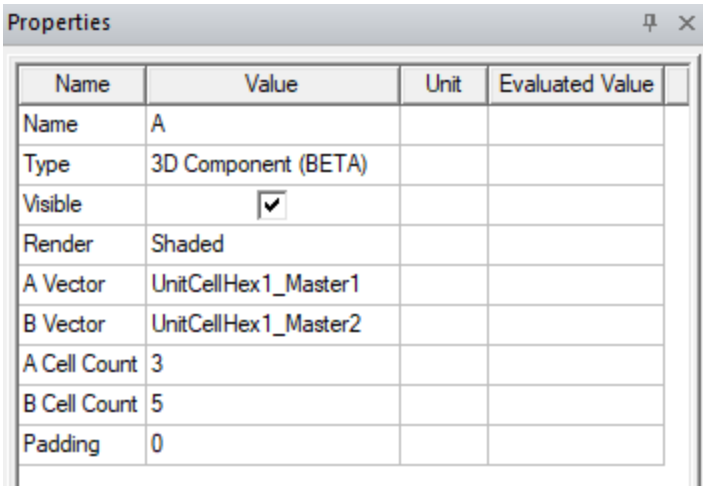
- Selecting **Delete** removes the array from the Model.
- Selecting **Properties** displays the **3D Component Array** dialog.
- Selecting Visualize Array lets you toggle the array display. A check mark indicates that the array is being displayed.

To view the lattice vectors, select the Excitation for the 3D Component.

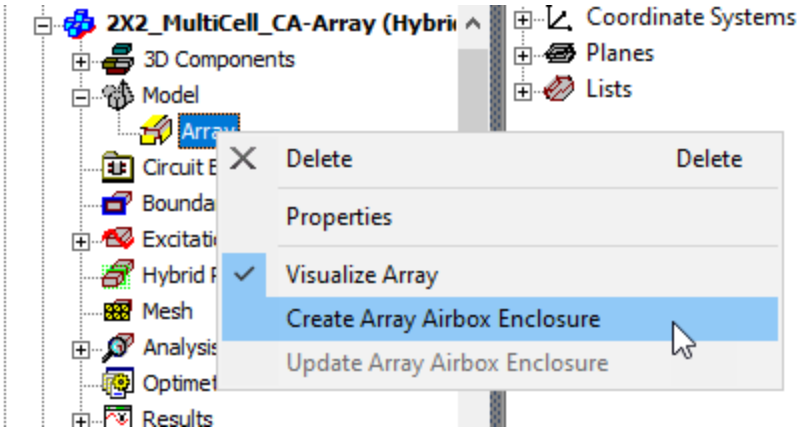


With the **Array** icon in the **Project** tree selected, if you have a docked Properties window displayed, you can see and edit array **Properties**. All edits are undoable and informational messages will be posted to the **Message** window when design data is deleted.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

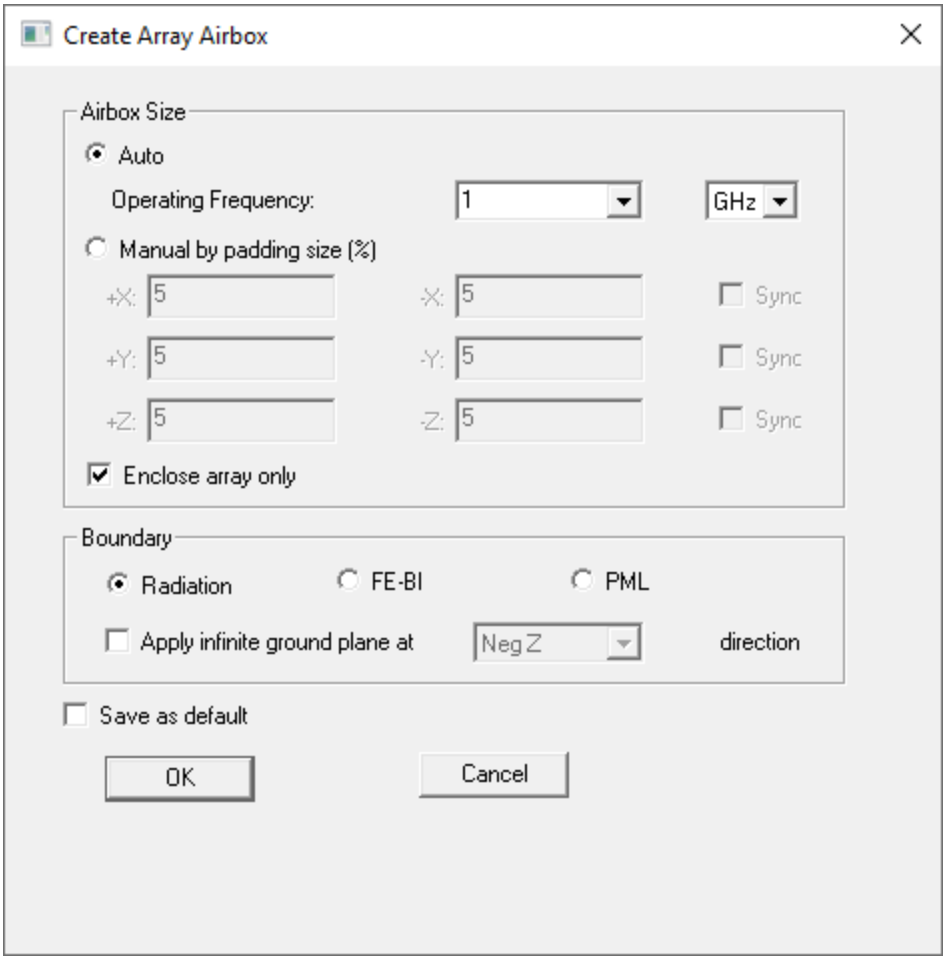


When you have defined the Component Array with Active cells designated, the **Create Airbox Enclosure** command is enabled.



This opens the **Create Array Airbox** dialog.

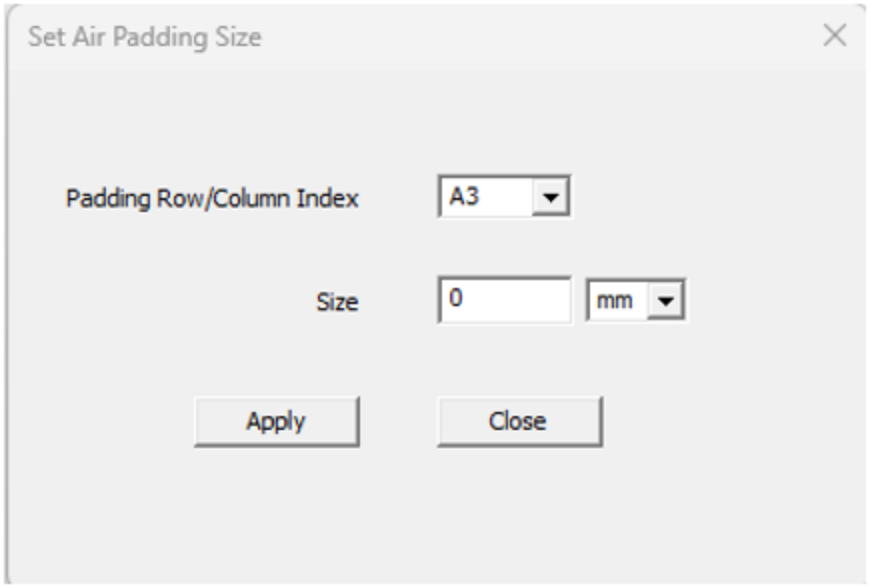
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The array airbox dialog supports Auto definition by frequency and has a checkbox to calculate airbox size based on either the array itself (**Enclose array only**), or the array plus all FEM geometries. By option you can uncheck Auto and manually specify dimensions as padding. You can assign the airbox boundary as Radiation, FE-BI, or PML. And you can assign an infinite ground plane.

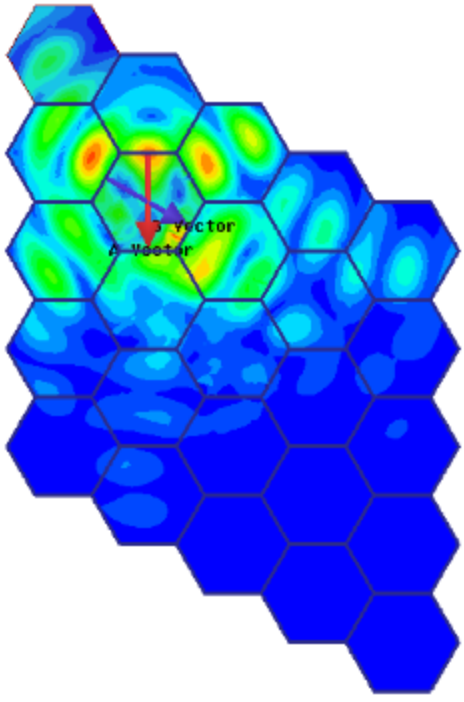
In setting **Analysis** options for an 3D Component Array simulation, if you select an **Advanced** setup, the **Options** tab lets you **Skip 3D Component Array Solve during Adaptive Passes**. This option is on by default. The mesh for each component is independently adapted, which significantly improves the performance compared to full array adapt with a minimum lose of accuracy. Even it is a composite design, the solver still adapts each component as non-composite during component adapt. As a result, even though it showa Max Delta Normalized Power due to UI constraints, the underlining calculations are all based on the Max Mag Delta S from each component.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Post Processing

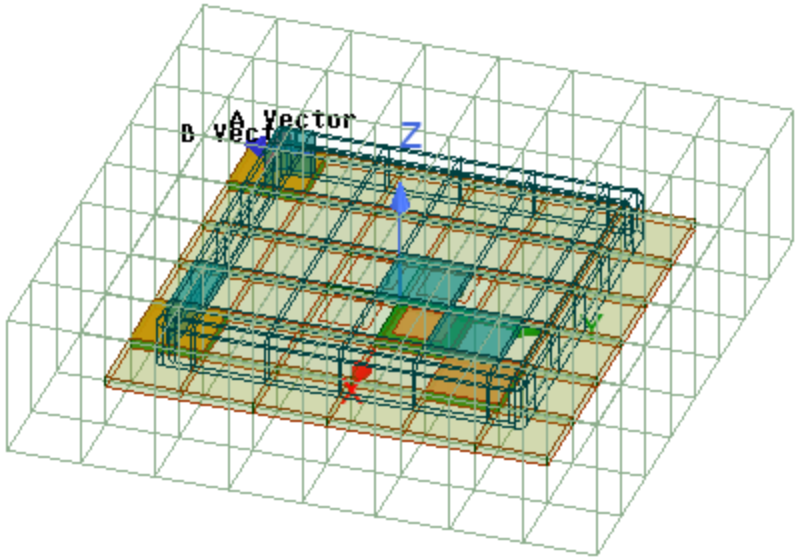
Once you have run analysis, you can view Solutions Profiles including matrix data, create reports and, if you have checked Save Fields on the analysis setup, you can create fields plots.



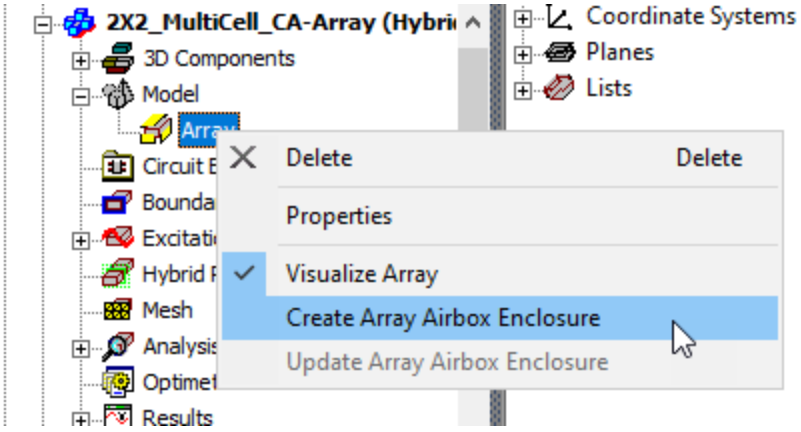
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

SBR+ and 3D Component Array

Assume that you have already created a 3D Component array, such as the “FiniteArray_Radome_77GHz_3D_CADDM” in Examples, HFSS>Antennas.

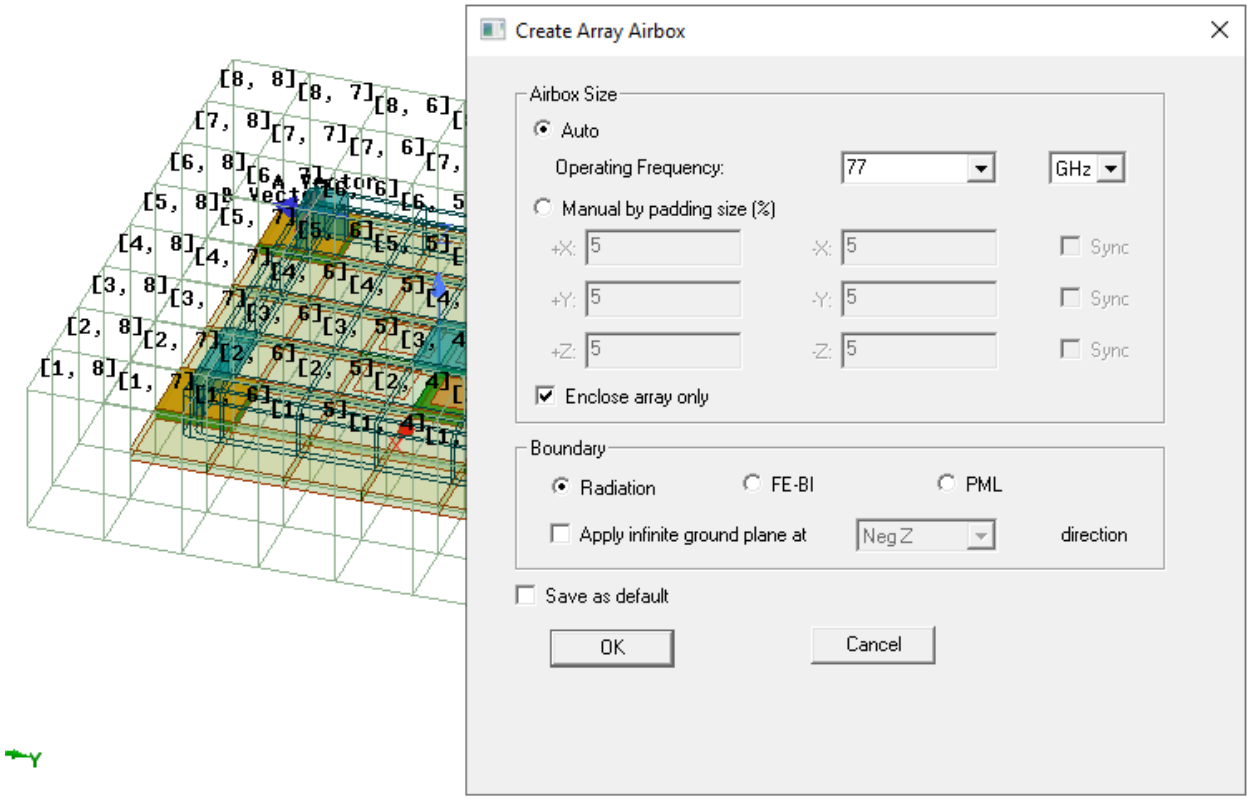


To create an SBR+ component array, you must have one FEM array airbox that encloses the entire array and add an SBR+ region. For the array airbox, you can manually define it as you wish, or right click the **Model > Array** icon in the Project and select **Create Array Airbox Enclosure** from the shortcut menu.



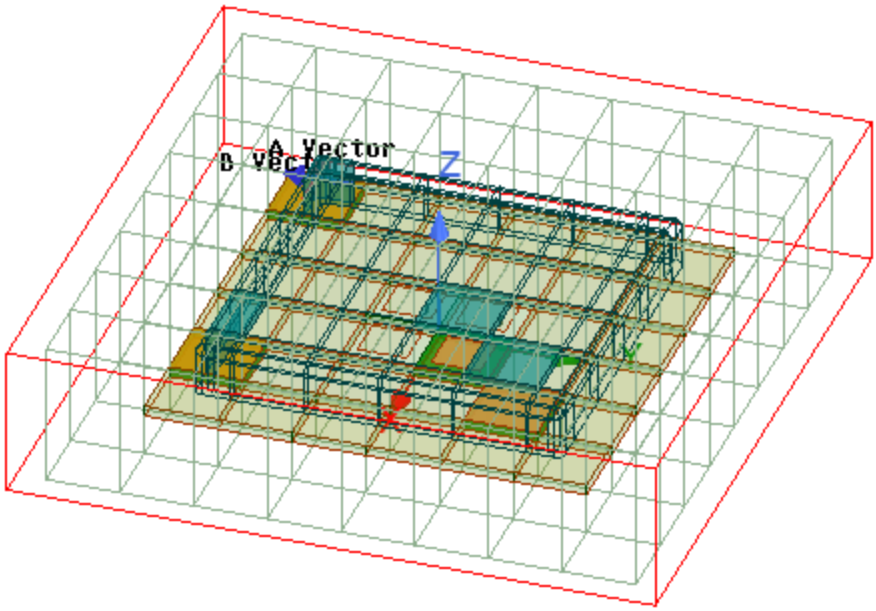
This opens the **Create Array Airbox** dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



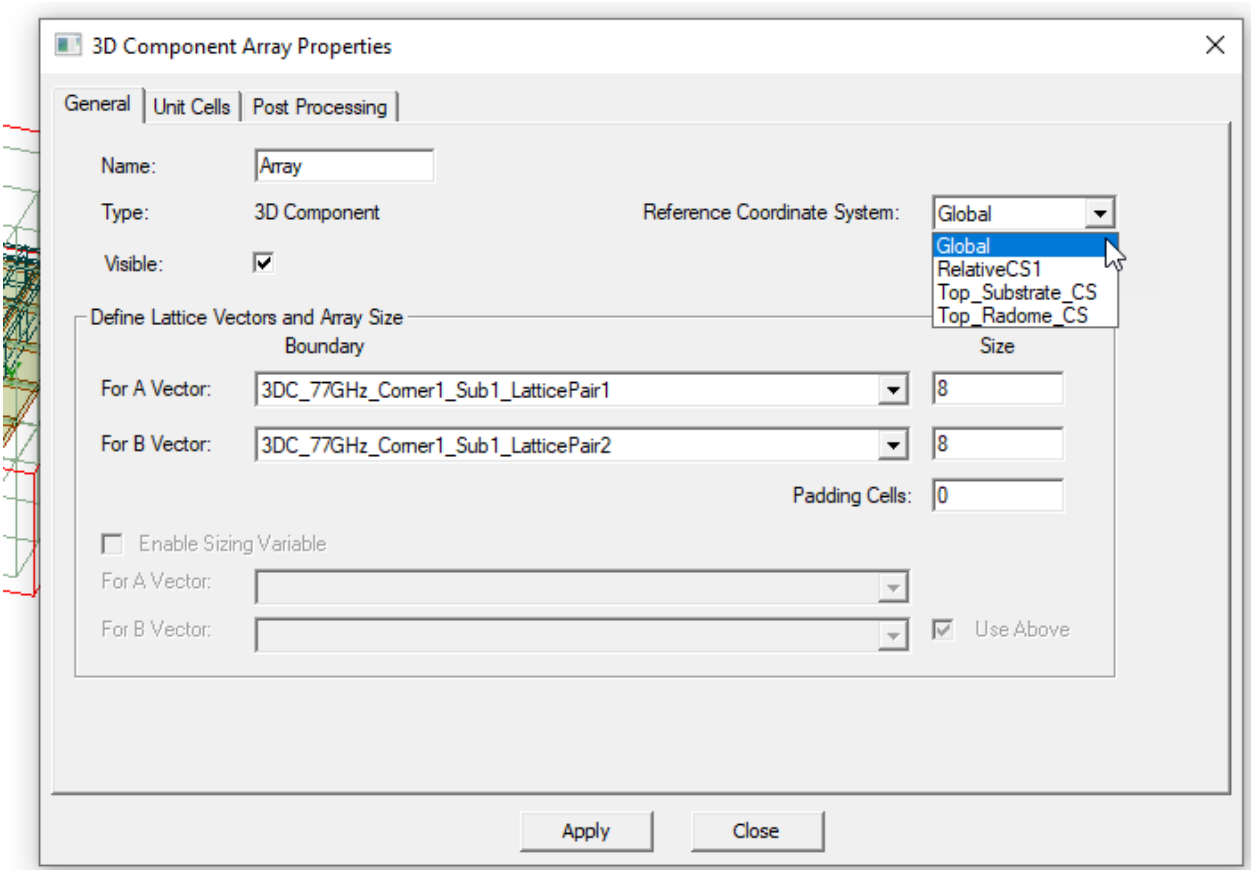
The **Create Array Airbox** dialog supports Auto, which is defined by frequency and enclose array only or calculated by array plus all other surrounding geometries.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



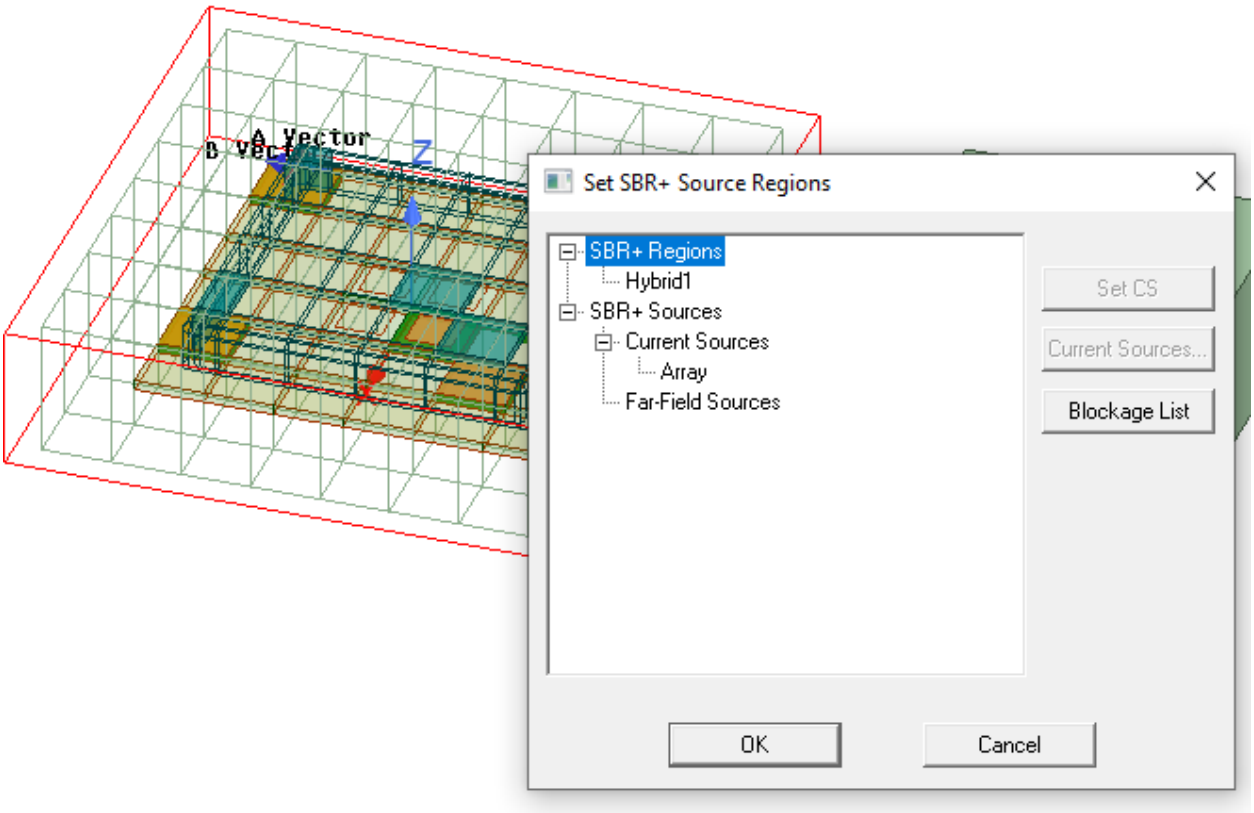
An option in the component array Property page lets you reposition the whole array (and array airbox, if it has been defined at this point) to a new reference coordinate system. This can be helpful if you define the SBR+ region in a reference CS.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The SBR+ component array design supports any SBR+ workflows like the normal SBR+ design, except that excitation is limited to port only and no incident wave is allowed. Some UI controls are also improved for component array use. For example, the “SBR Source Region” is simplified since the component array is the only SBR+ source in SBR+ component array design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



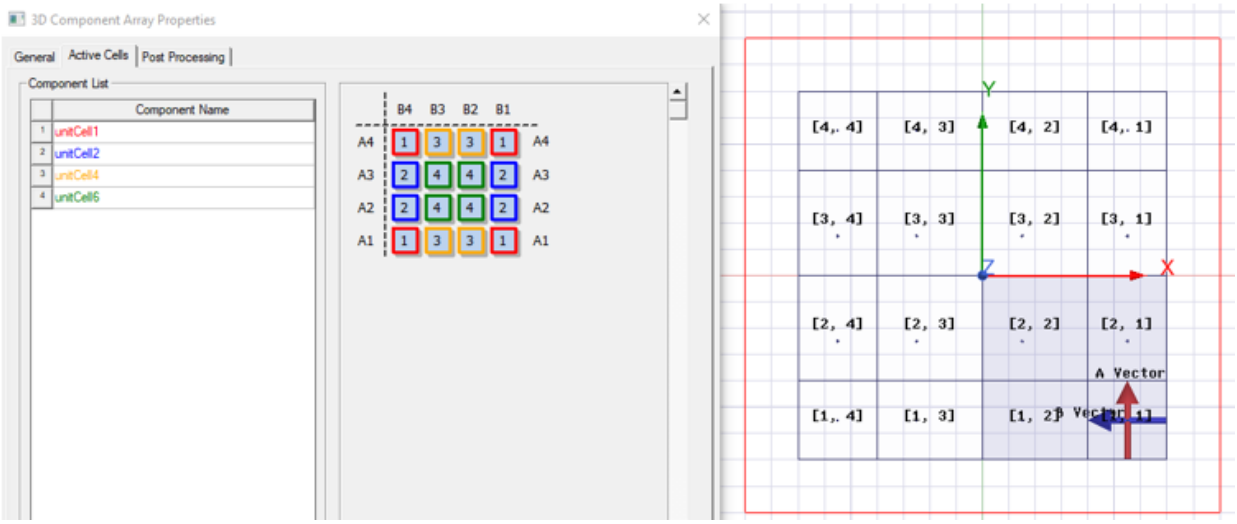
Non-uniform Arrays

Components can now have different bounding box sizes (i.e., non-uniform sizing). In addition, HFSS supports arbitrary-sized internal air paddings, allowing flexibility for minor adjustments to existing arrays. However, to maintain array integrity, the array must remain perfectly tiled. The following restrictions apply:

- Lattice Vectors Must Be Orthogonal: All lattice vectors must maintain 90-degree angles.
- Consistent Vector Sizes for Indexed Cells: Cells sharing the same A-index must have the same A-vector size, and cells sharing the same B-index must have the same B-vector size. This ensures that the array remains perfectly tiled. This rule also applies to aircell rows/columns, meaning that users can only adjust air padding sizes when the entire row or column consists of aircells.

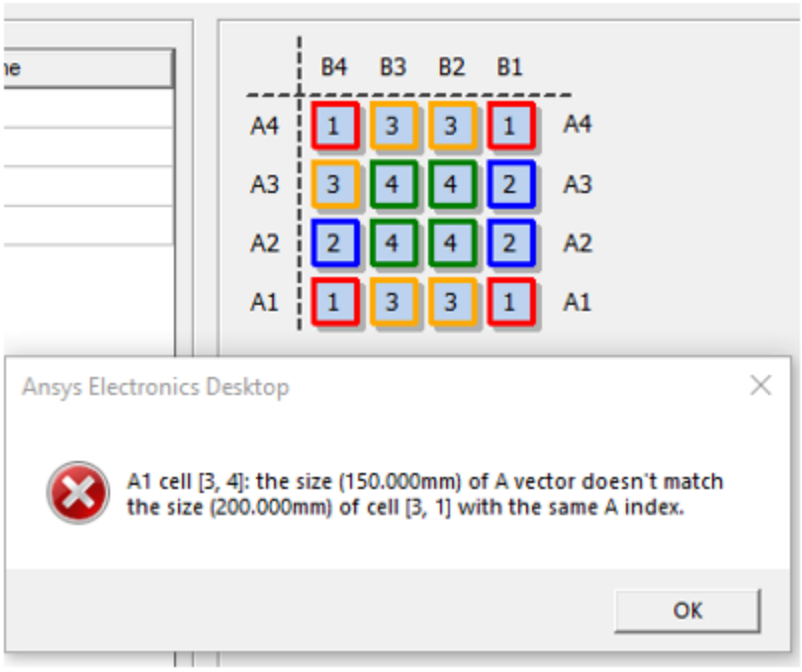
The process of setting up a non-uniform array resembles that for uniform arrays. After you add the candidate components to the design, they appear in the Component List, allowing you to place them into the array mask as with uniform arrays.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



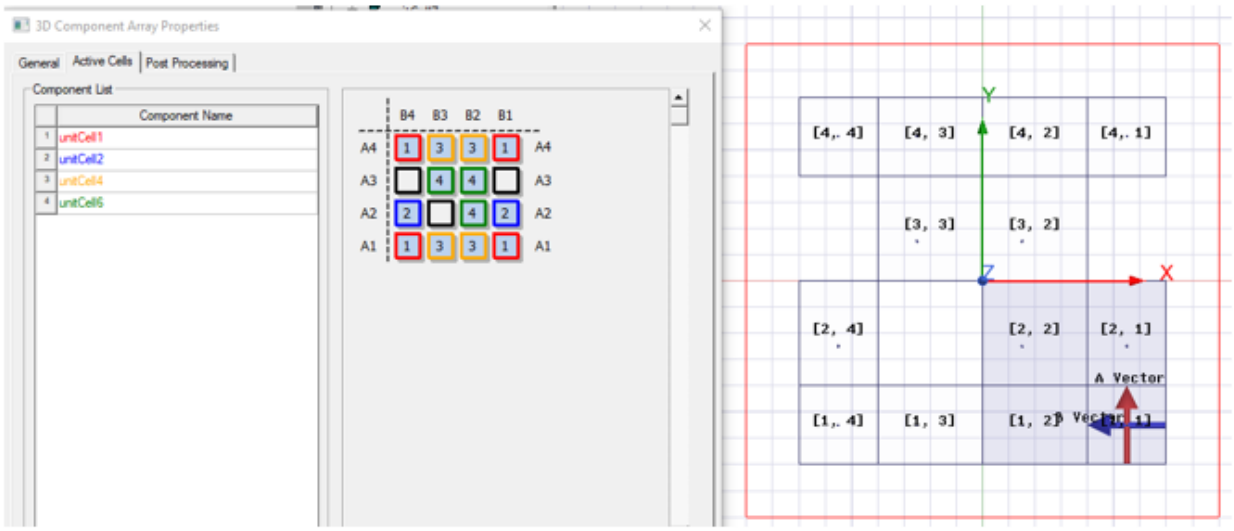
However, there are two important things to note:

1. **An Array Must Be Perfectly Tiled**: The array setup must be perfectly tiled, meaning that cells sharing the same A/B index must have the same A/B vector size. Any mismatch will trigger an error in the dialog.



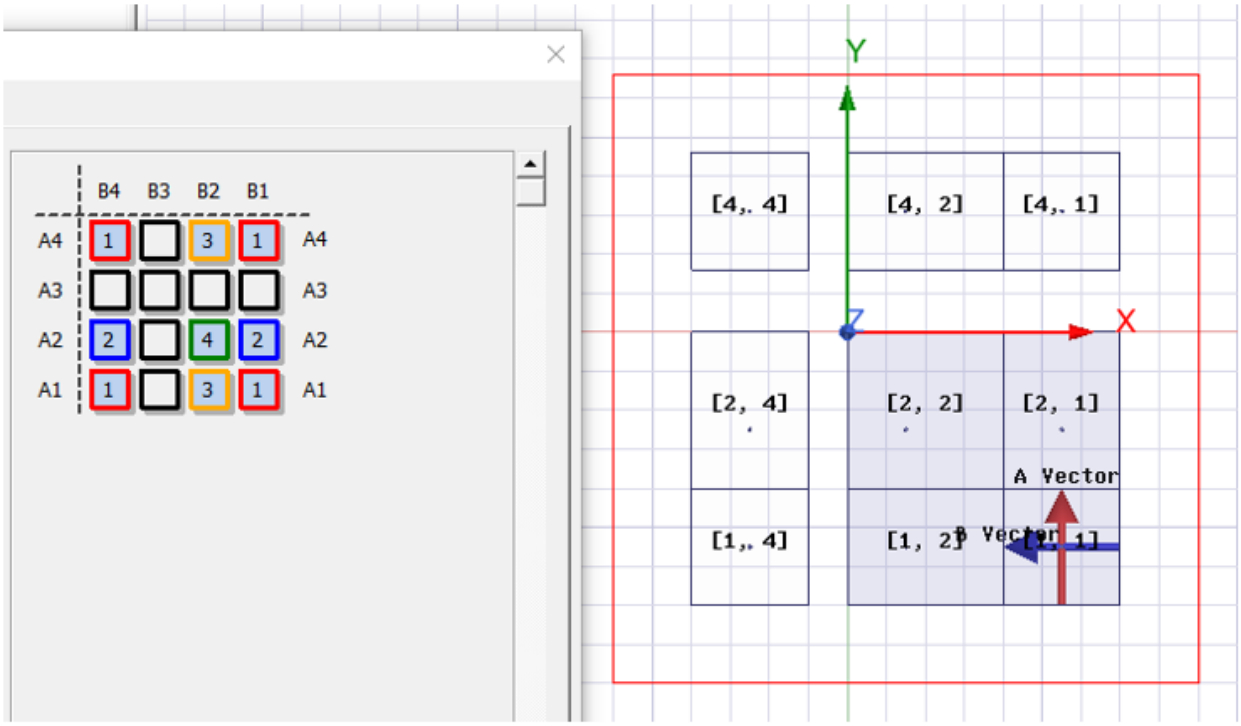
2. Automatic Aircell Resizing: If an aircell is present, it will automatically resize to match the dimensions of the component cells to ensure proper alignment.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Adding Internal Air Paddings between Rows or Columns

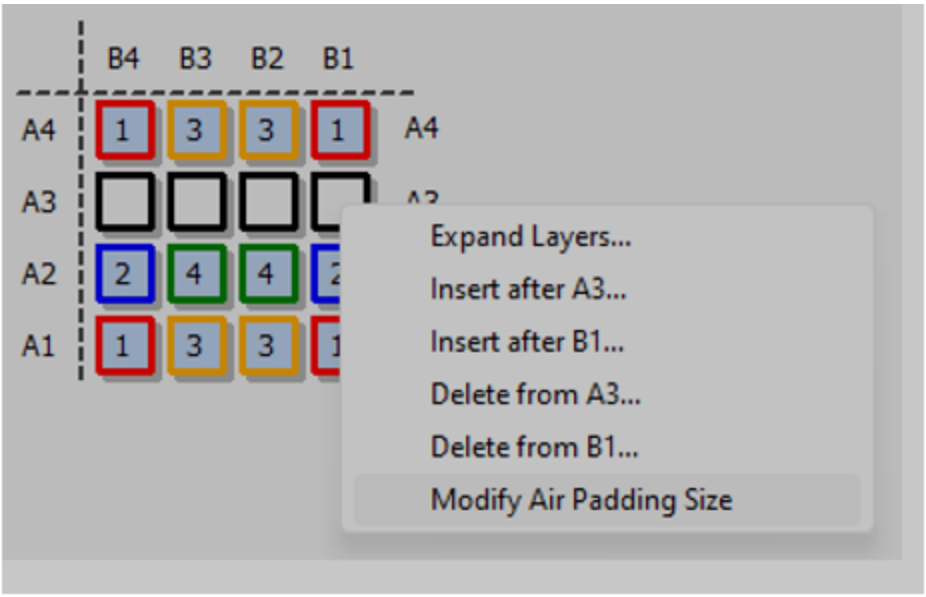
Non-uniform arrays allow you to create arbitrary-sized internal padding by using aircell rows or columns. If an entire row or column consists only of aircells, you can modify the size of that row or column.



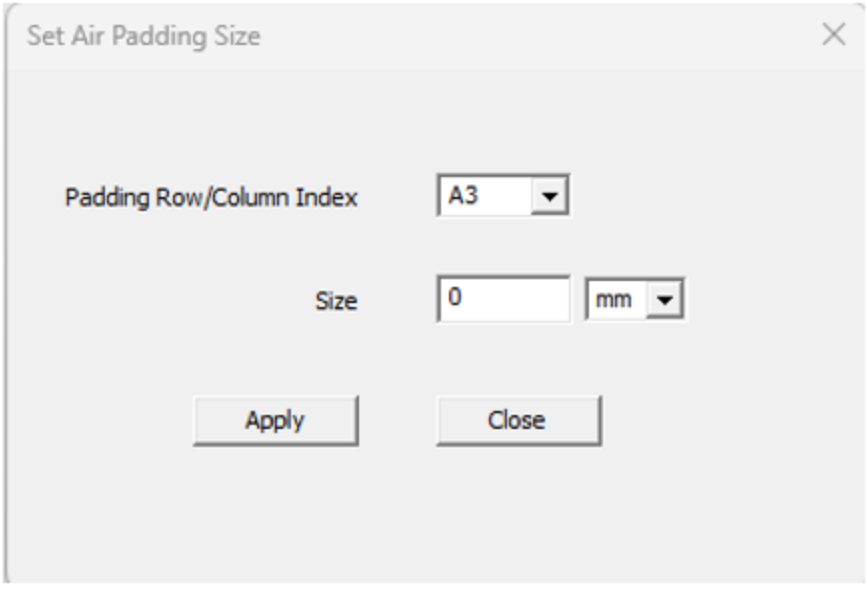
To adjust the padding:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Right-click on the aircell row/column and select **Modify Air Padding Size** from the pop-up menu.



2. Choose the padding row or column index.
3. Specify the desired padding size.



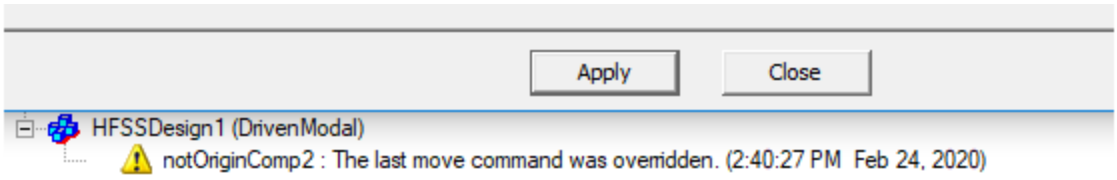
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Sizing Variable for a New 3D Component Array

When you create a new 3D Component array, you can employ a sizing variable. This variable should only be used when you create a new component for a 3D component array. The feature does not appear for a regular array. The sizing variables control array's row vector and column vector (i.e. size of component's bounding box) and enable you to do related sizing research. The functionality involves passing sizing variables to the Move command during a component's automated placement. When you create a new variable, you ensure that the 3D Component expands or shrinks from the center point, rather than the starting point. Otherwise, the placement controlled by the variable will be incorrect.

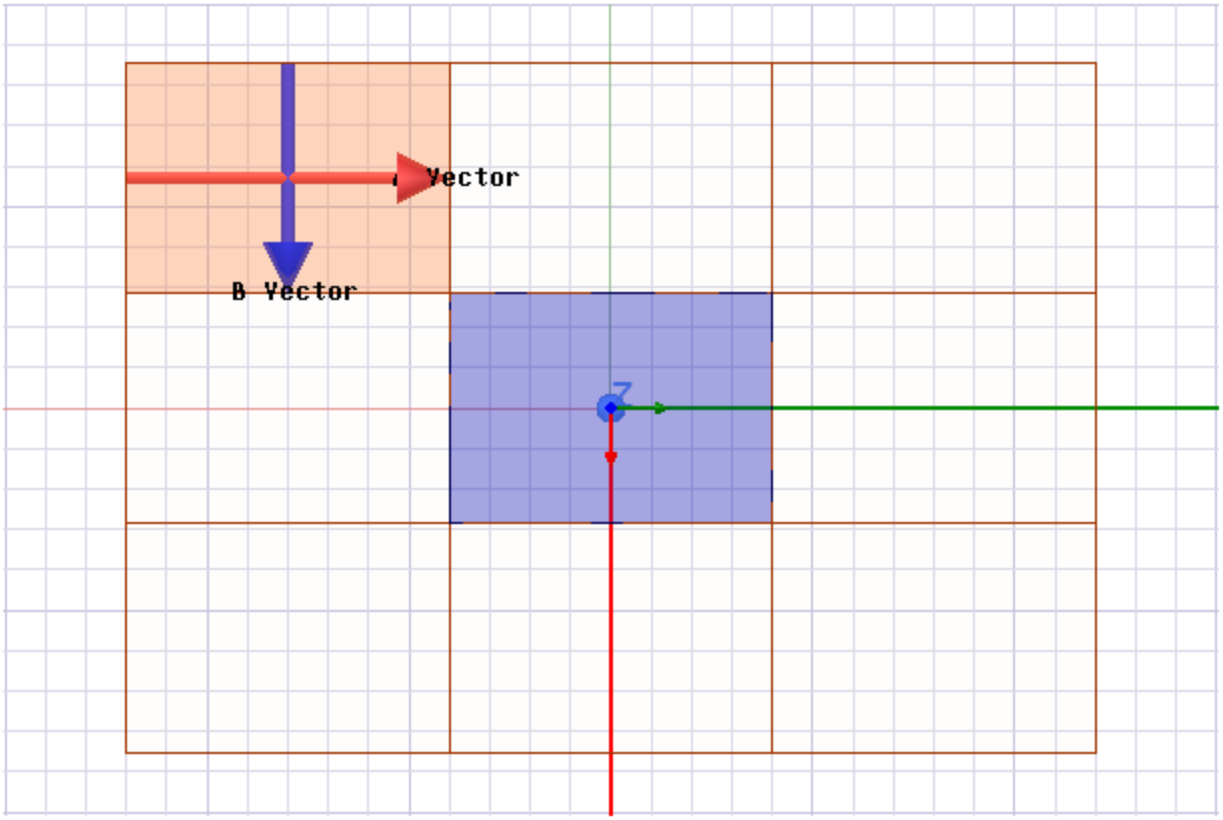
	Name	Value	Unit	Evaluated Value	Description
	Command	Move			
	Coordinate Sys...	Global			
	Move Vector	-0.5*aaa+1.1 ,-0.5*bbb+0.5 ,0		-1.75meter , -3....	
	Suppress Com...				

After you create or edit a 3D component array and hit the Apply button, if the component has had move commands with its last move command 1) based on global coordinate system and 2) different from the expression of the current move command, the Modeler directly overrides the component's last move command and shows a warning message in the Message Manager.

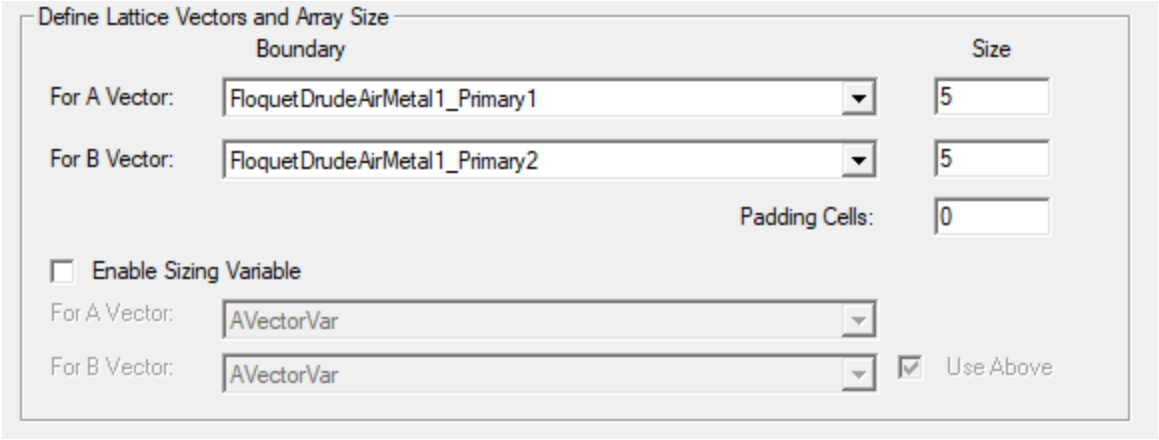


To be valid, the sizing variables must be created as Design Variables of Length, and must match their corresponding Row/Column Lattice Vector Length.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

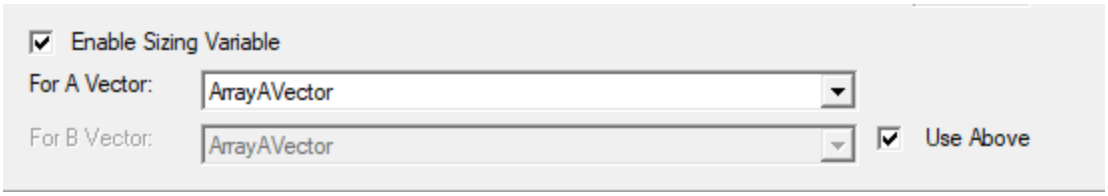


If you have defined Design Variables for Length, the checkbox to Enable Sizing Variables is available.



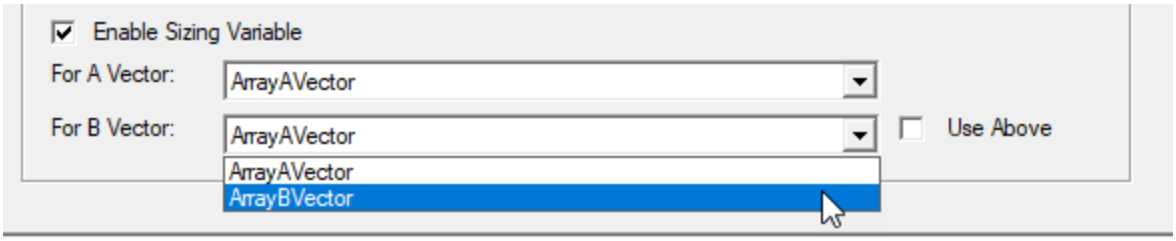
Check Enable Sizing Variable enable the selection menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can select available Length variables from the drop down. If you select a variable that does not match the corresponding vector, a warning message displays. Most of the time, array's row vector and column vector have the same length, which means one 1 sizing variable can control both vectors. By default, Use Above is checked, so For B Vector is grayed out. We only need to select the correct sizing variable For A Vector, and the currently selected variable in combo-box For B Vector is automatically changed to the same one as in A.

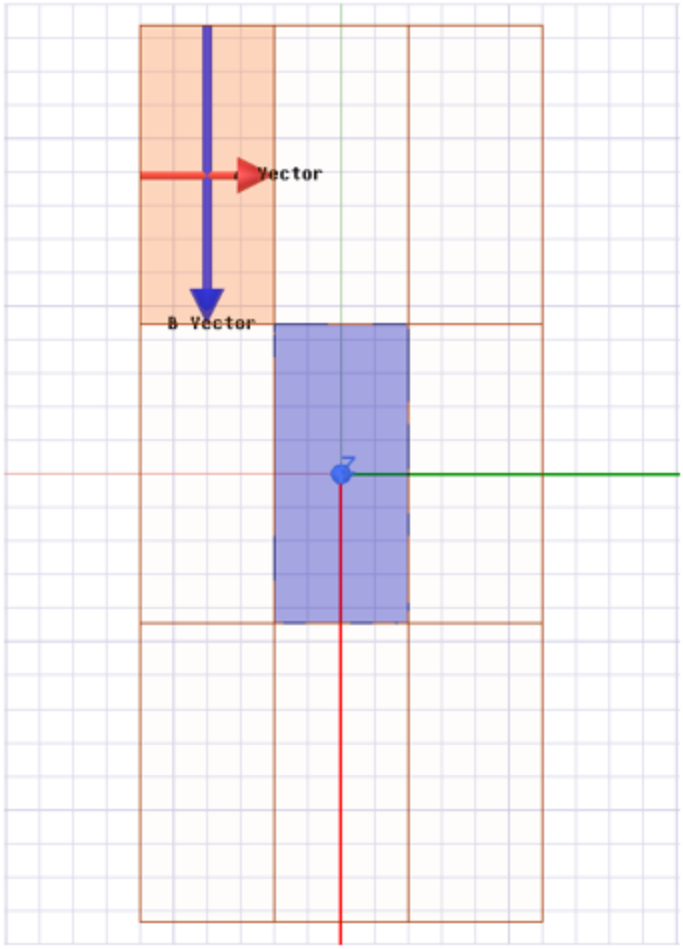
If you uncheck Use Above, you can select available Length variables from For B Vector drop down.



After you modify values of the sizing variables from Design Properties dialog or Design Properties property window, each component directly changes its size but is still placed in the correct position (that is, the array is still normal).

Name	Value	Unit	Evaluated Value	Type
aaa	8.9	meter	8.9meter	Design
bbb	4	meter	4meter	Design

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Important Notice:

Make sure that the component's bounding box expands or shrinks from the center point to the surroundings evenly.

Assume that the start position is on the top left with coordinate (x, y, 0), and the original center position is (x_0, y_0, 0) with x_0, y_0 constant. It's obvious we have relationship $x + 0.5a = x_0$ and $y + 0.5b = y_0$. Therefore, the start position should have the coordinate expression as ($x_0 - 0.5a$, $y_0 - 0.5b$, 0).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Name	Value	Unit	Evaluated Value
Command	CreateBox		
Coordinate...	Global		
Position	-0.5*a ,-0.5*b ,0meter		-1meter , -0.5m...
XSize	a		2meter
YSize	b		1meter
ZSize	1	meter	1meter

In the above example, since the center point is originally located at the origin, the expression of the start point should be (-0.5a, -0.5b, 0).

a) Assume that the component has had several Move commands and some move commands except the last one also contain variables before its current placement. Then after the current placement, if we modify the value of some variable contained in the middle Move commands, it's very possible that the current placement is messed up (i.e. the array is abnormal).

The reason is that for each component, the Move commands are executed in order, and some intermediate positions become incorrect after we modify the variable value.

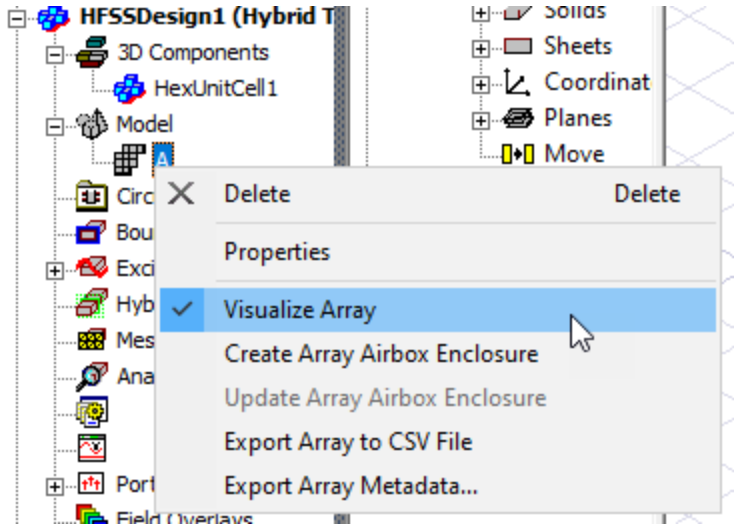
Therefore, before we execute the current placement, it's better that we either don't include variables in the previous move commands except the last one, or don't modify their values casually.

b) When you create the bounding box of the component, the start position is at either top left or bottom right. However, if you control an array via a Sizing Variable, the Modeler expands or shrinks the component bounding box from the center point. When you create the component, **you must set the center point** to make sure that the component expands from the center to the surroundings evenly. Otherwise the component expands from the top-left or bottom right, which creates problems. After you create a component, you cannot set the center point again.

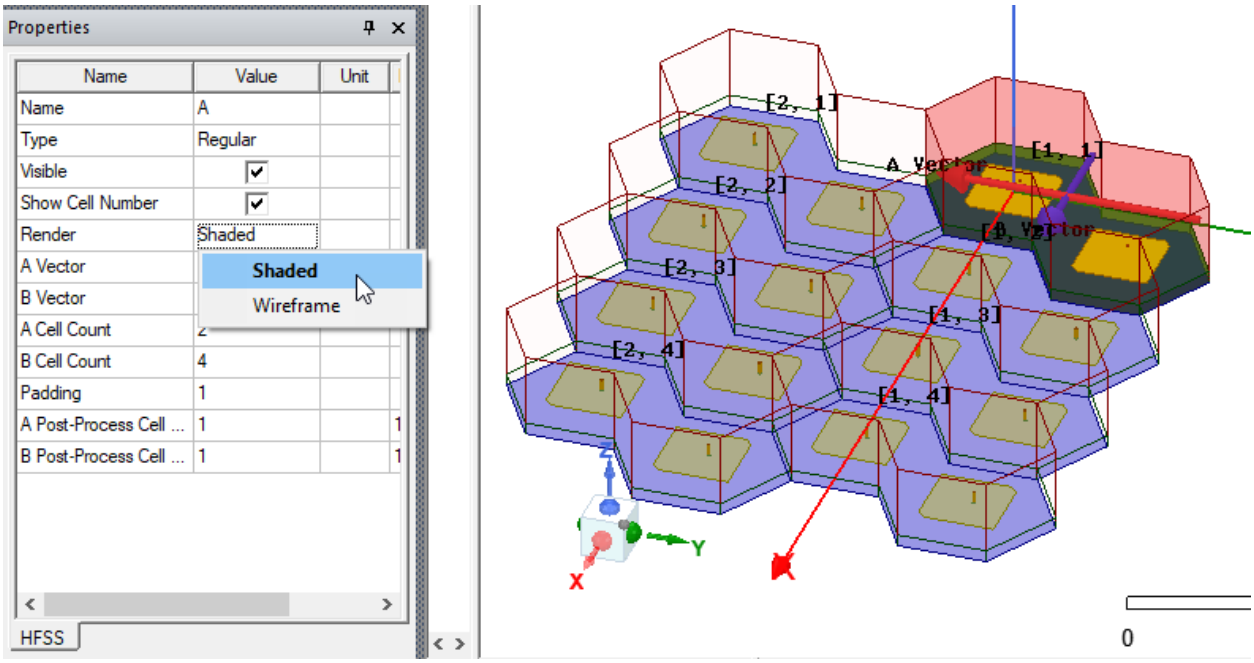
Array Visualization

You control the visualization of an array by selecting an existing Array in the Project tree and toggling the **Visualize Array** command on the short-cut menu or the Visble check box for the Array properties.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

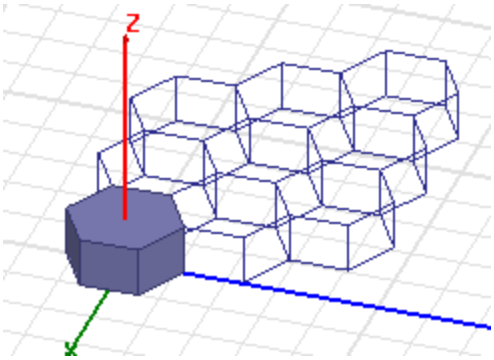


Virtual objects in an array can display as Wireframe or as Shaded, depending on your selection in for Render in the Array **Properties** window.



If the all virtual objects for an array do not appear in the view modeler window, perform a **View>Fit All** operation. If you change the view, you can also use **Ctrl+D** to fit the array into the current view.

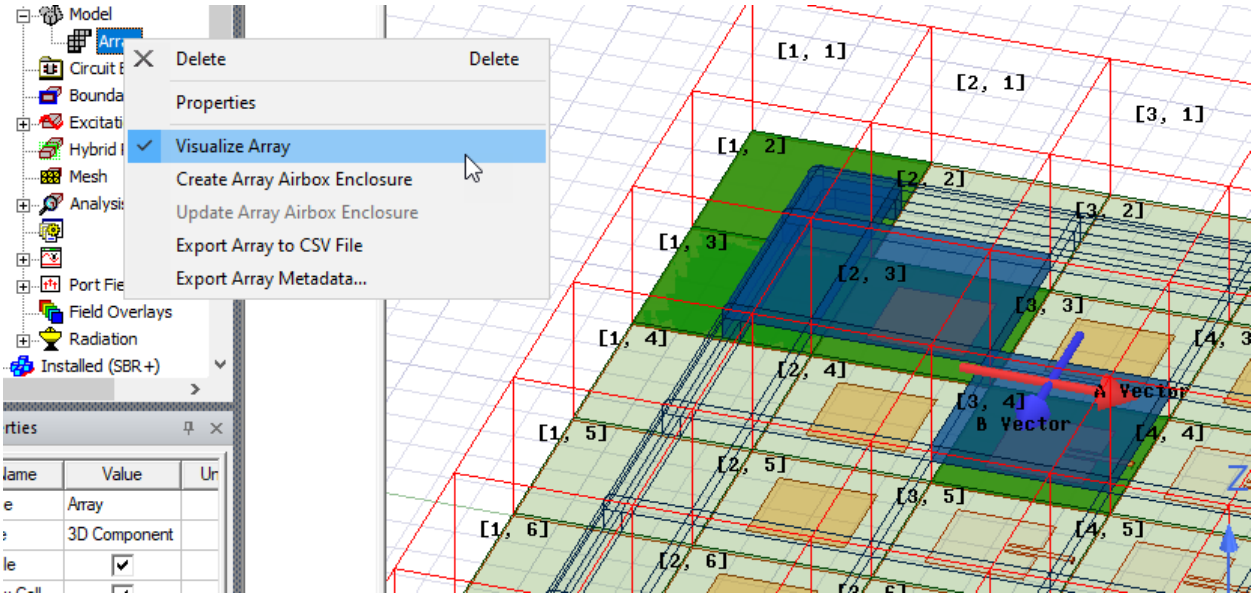
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can disable the array visualization by clicking on the **Visualize Array** option again. A check mark appears in front of **Visualize Array** if the option is already ON. This option will also be present in general active view visibility options, **View>Active View Visibility**.

The visualize array option will be applied to the current active view. You can have multiple windows in the modeler, each window will have its own **Visualize Array** setting. This allows you to use different windows to look at unit cell display and whole array display at the same time.

If the **Visualize Array** option is set to true, the array will be visible when you open the project.



Set up and Run an Array Simulation

There are some changes in the GUI for setting up the adaptive simulation for designs with a virtual array and if the design uses 3D components However, the solution quantities of the virtual cells will be available for convergence setup (In both adaptive and interpolating sweep). There

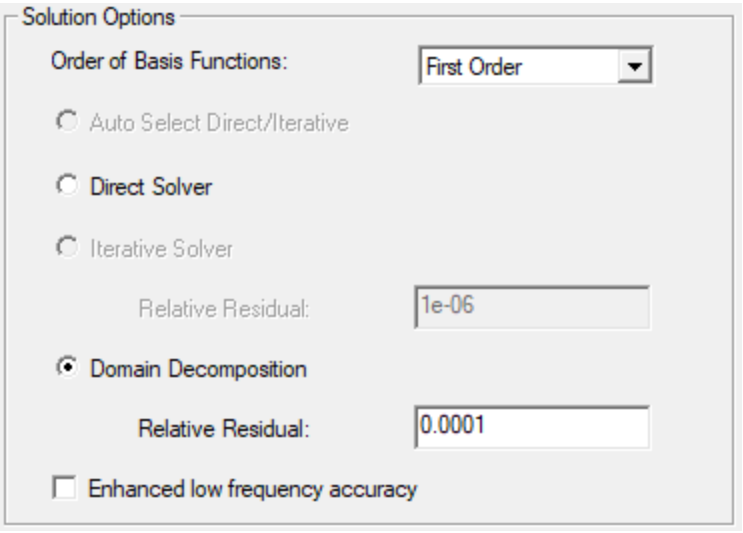
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

are no changes in the way convergence information is presented on the Convergence tab of the **Solution** Display panel.

If your design contains a virtual array and/or 3D Components, the **Solution** setup can have some differences.

- If an array contains 3D Components, the Solution Setup Options tab contains a **Skip 3D Component Array Solve During adaptive Passes** option.

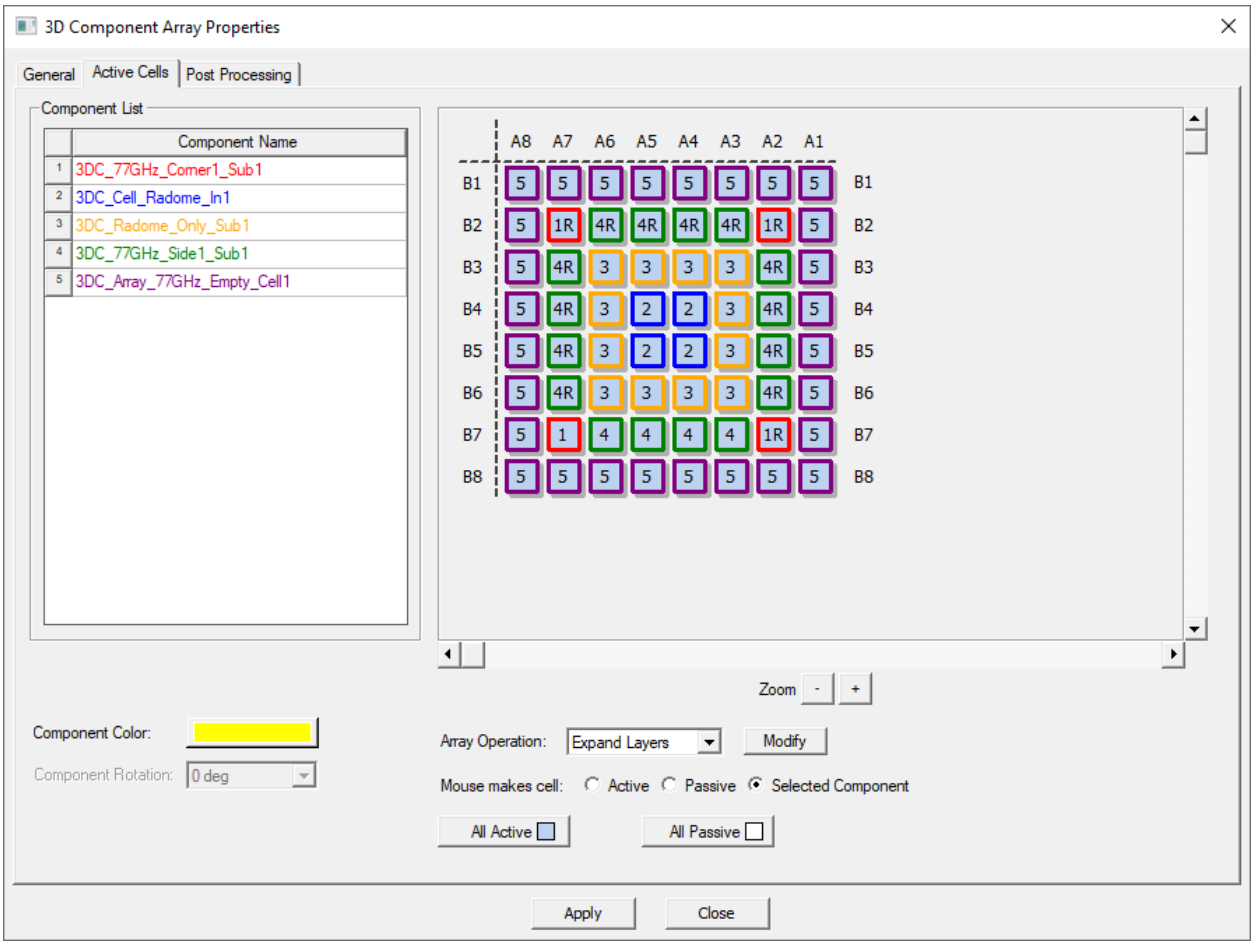
  This option is on by default. The mesh for each component is independently adapted, which significantly improves the performance compared to full array adapt with minimum lost of accuracy. Even it is a composite design, the solver still adapts each component as non-composite during component adapt. As a result, even though it's showing Max Delta Normalized Power due to UI constraints, the underlining calculations are all based on Max Mag Delta S from each component.
- The Solution Option for **Domain Decomposition** is automatically checked. You can choose Direct Solver. Iterative Solver options are disabled. The domains are UI defined through the array definition, not solver defined domains.



- Set up the distributed processor workgroup. Designs with arrays require HPC licenses.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- General Setup for Virtual Array Simulation for Matrix Convergence, if you choose Selected Entries.
- Interpolating Sweep Advanced Options for Array Simulation
- Fast sweep is not supported.
- You can also set up the expression cache at solve setup. The expression cache interface for accessing array elements is the same as those used in report setup.
- Use the **Active Cells** tab on the **Regular Array** dialog or **3D Component Array** dialog to designate which cells are active or passive for a simulation. You can make All Active, All Passive or select which cells are active or passive. The more active cells there are for a simulation, the more processing is required. By default, clicking the corresponding array elements toggles the current selection, You can also choose the **Mouse makes cell** setting to click for Active or Passive, whichever is most convenient. Clicking on an A or B vector direction number applies the mouse click command to all cells in that vector direction. Dragging the cursor over cells performs the current operation on them.



It is important to understand the impact of passive ports on antenna parameters. For accepted power calculations, passive ports are not included when computing the total power

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

passing through the union of all port surfaces. This means that the passive ports can be viewed as a loss mechanism for the device and it is not equivalent to viewing the passive ports as active ports with zero excitations.

- Report setup for Arrays.

The solution/matrix quantities are grouped by category. The entries in each category are listed according to their order in the corresponding matrix.

The entries will be listed A or B vector direction, with the A or B vector followed by the vector index.

The existing "Filter" capability can help locate the desired quantity from the potentially very long list.

Beta Feature: Parallel Component Mesh Adapt

If **Skip 3D Component Array Solve During Adaptive Passes** is selected and you enable the Beta feature **Parallel Component Mesh Adapt**, if a design contains multiple 3D Components in an array, and is run through HPC, the Solution Profile can show multiple hf3d solvers for frequency solves.

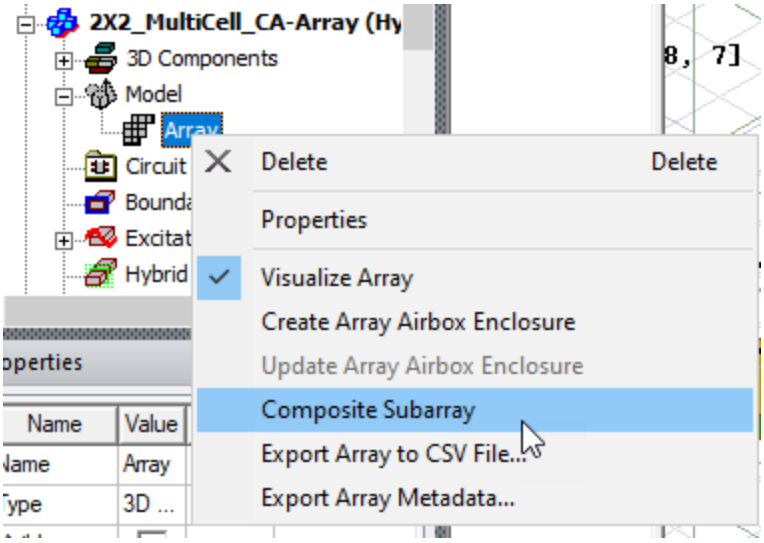
Beta Feature: Composite Subarray in HFSS Finite Array Design

A composite excitation is simply a specific superposition of defined sources. Using composite excitations can speed up analysis and reduce storage requirement for fields when there are many sources, and you are only interested in a few combinations of those sources (for example, for 5G antennae).

This feature resembles the composite solution type in which all source excitations are combined into a single source. Here, however, you can combine a subset of sources into a single source. This feature supports multiple, named, subsets of sources. When solved, each subset presents as a single source to the reporter. Each combined source (namely composite group) is accessible from **Edit Sources** to control its magnitude and impedance.

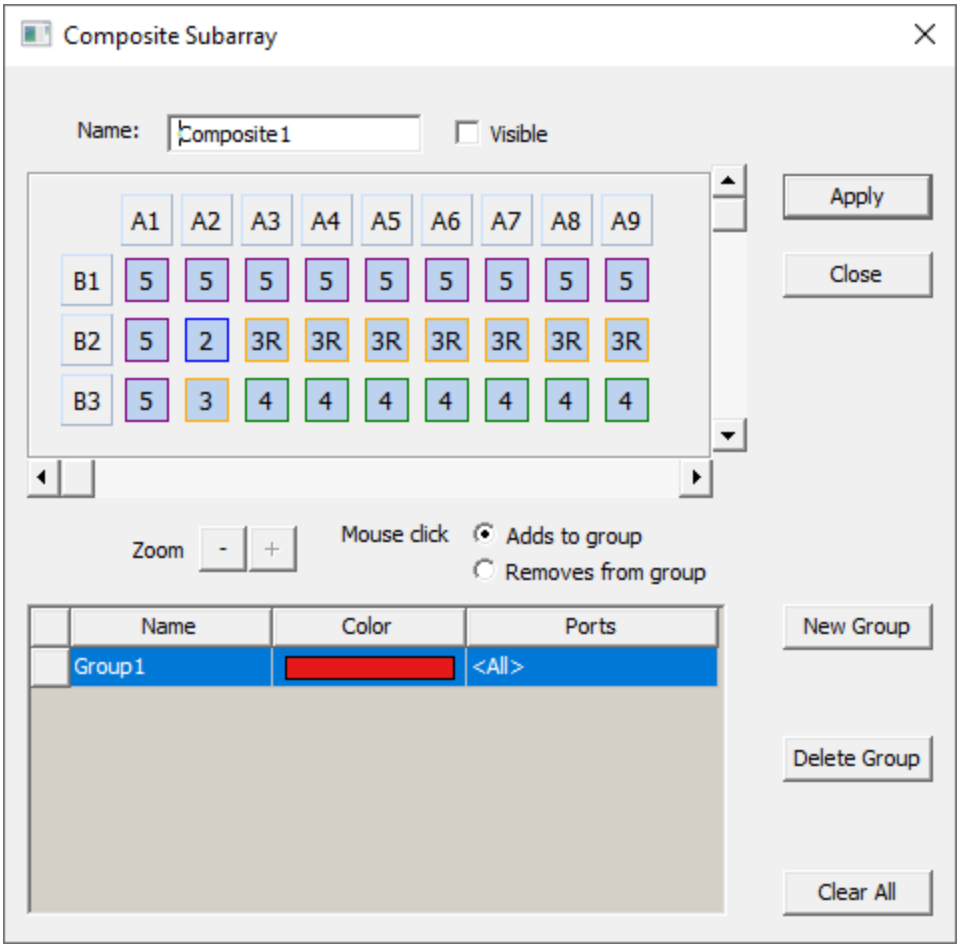
For an HFSS design with a finite array, and the Beta Feature **Composite Subarray in Network Analysis** enabled you can access the composite subarray functionality by right-clicking on the Array Item in the Project tree and selecting **Composite Subarray** in the menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



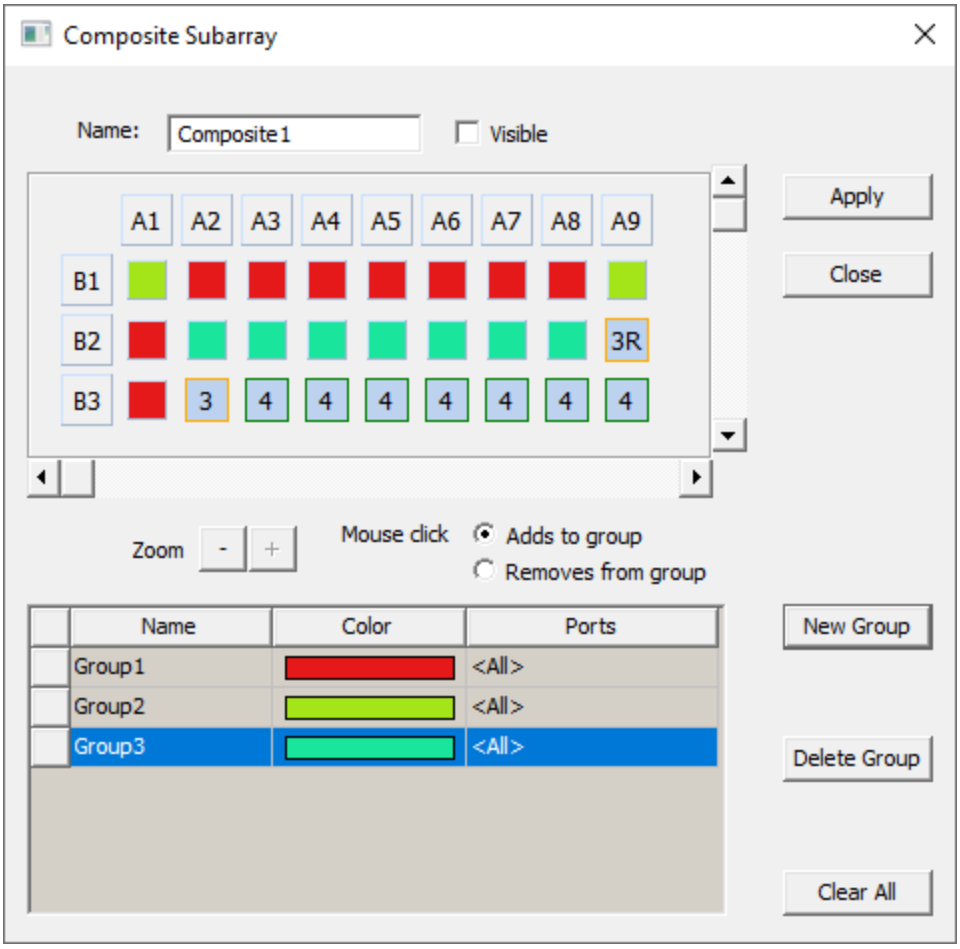
In the **Composite SubarrayArray** dialog, you can create/edit/delete composite groups and assign array cells to composite groups in a similar way that you defined the array itself. If the design includes an existing subarray, it is depicted in the dialog. Notice that the boundary colors for the defined cell are independent of those applied to define each new group. You can click on individual cells to assign them to the currently active group.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

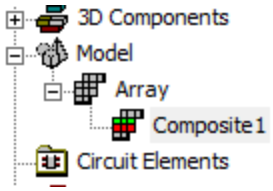


You can click on individual cells to assign them to the currently active group, or click on the Row or Column number to assign that row or column. You can resize the dialog and use the vertical and horizontal scroll bars to view array cells for selection. Click the New Group for a new one which will be given new colors, and by default, an incremented name.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

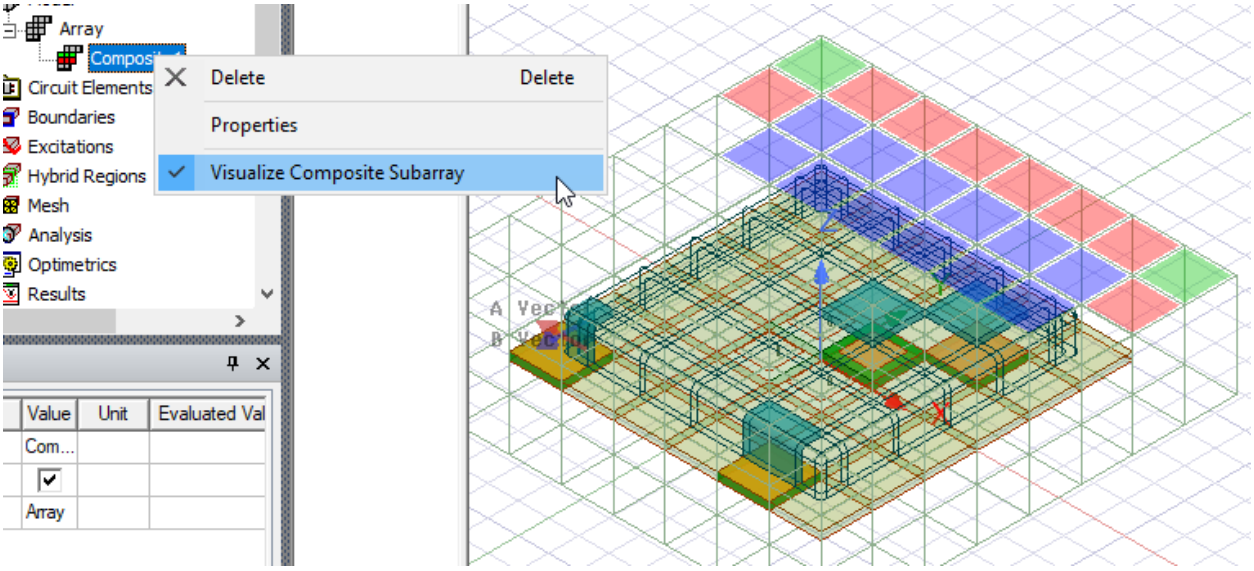


Click **Apply** to activate the Group Assignment in the Modeler window display. Once you have defined a subarray, it appears in the Project tree.



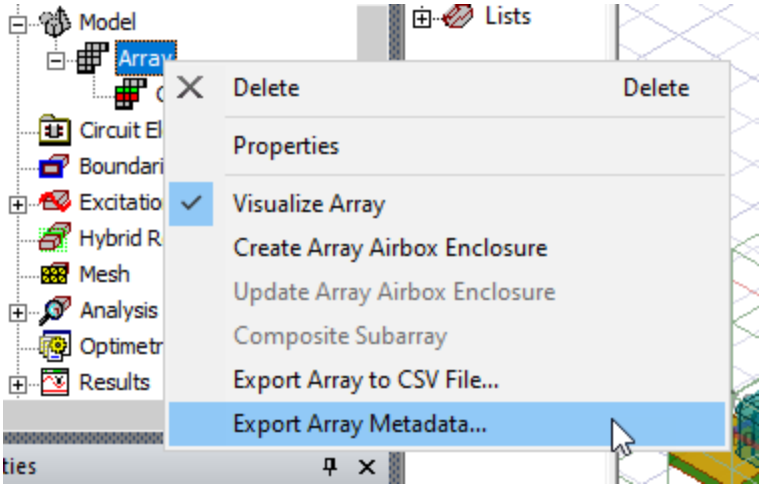
You can right-click on the Composite subarray to view the **Properties** window, and to Visualize Current Subarray assignments in the **Modeler** window. Once the composite array is defined and is set to visible, each composite group would be visualized using a unique color overlay in the modeler.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



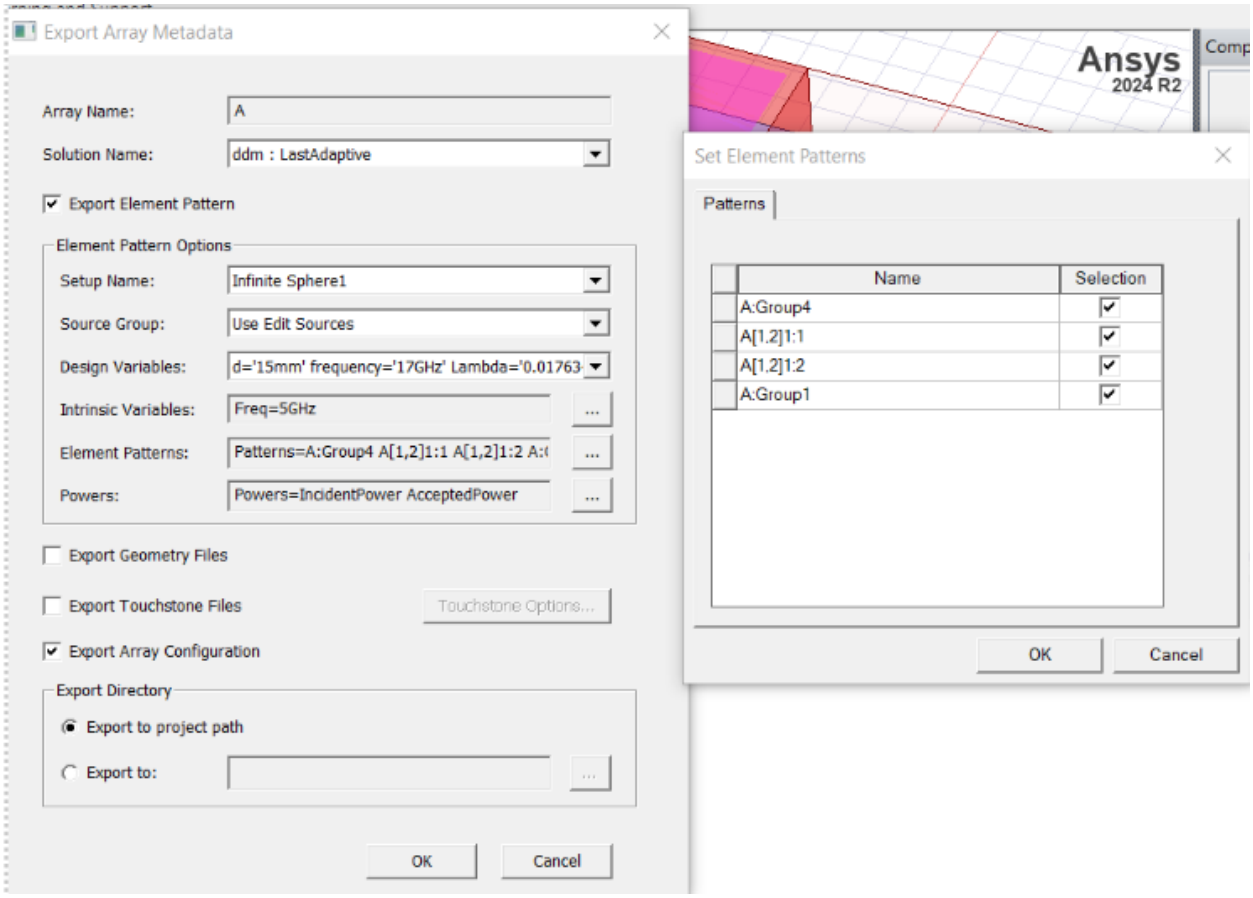
Note that in the example figure, the blue color for the cells in Row three in the dialog has been applied to the cells in the Row 3 modeler window.

After a composite subarray design is solved, you can export array metadata by right clicking the array item in project tree:, you can right-click on Array to Export Array Metadata.



In the **Export Array Metadata**dialog the element pattern selection shows composite groups instead of individual ports.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



For designs that Link from Driven Modal Design to SBR+, the **Phase Reference Setting** dialog also offers choices for composite groups if you want to specify unique phase reference for each group.

Similarly, the powers in the export metadata header file would clearly show the group names and group element patterns (i.e., only this composite group is excited). For example:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
<ElementPatterns>
  <Source name='A:Group1'>
    <Filename>exportfield_0.ffd      </Filename>
    <ReferenceLocation>-0.075000,0.075000,0.300000      </ReferenceLocation>
      <PowerInfo>
          <Power Freq='1GHz'>
            <IncidentPower>1.000000              </IncidentPower>
            <AcceptedPower>0.264860              </AcceptedPower>
            <SystemPower>1.000000              </SystemPower>
            <RadiatedPower>0.271018              </RadiatedPower>
          </Power>
      </PowerInfo>
  </Source>

  <Array name='A'>
    <LatticeVectorA>0.000000,150.000000,0.000000      </LatticeVectorA>
    <LatticeVectorB>-150.000000,0.000000,0.000000      </LatticeVectorB>
      <CompositeSubArray name='Composite1'>
        <Group name='Group1'>

        </Group>
        <Group name='Group2'>
          <Cell>[2, 1] [2, 2] [2, 3]             </Cell>
        </Group>
        <Group name='Group3'>
          <Cell>[3, 1] [3, 2] [3, 3]             </Cell>
        </Group>
      </CompositeSubArray>
  </Array>
</ArrayInfo>
```

Composite Array Post-Processing

Once a finite array design with composite array is solved, post-processing treats each composite group as if it is a single excitation. For example, in an S-parameter table, you can examine the S

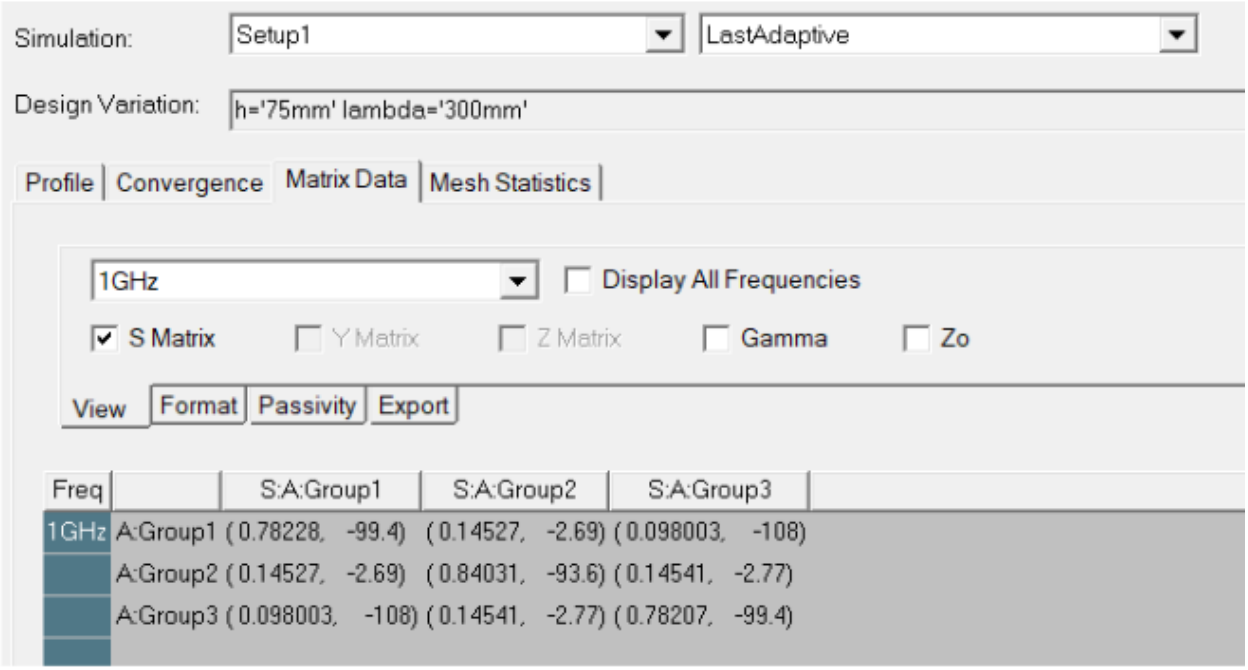
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

parameter between each group in modal solution reporter and matrix display, where the composite group name is shown instead of an individual port.

S Parameter Table 1

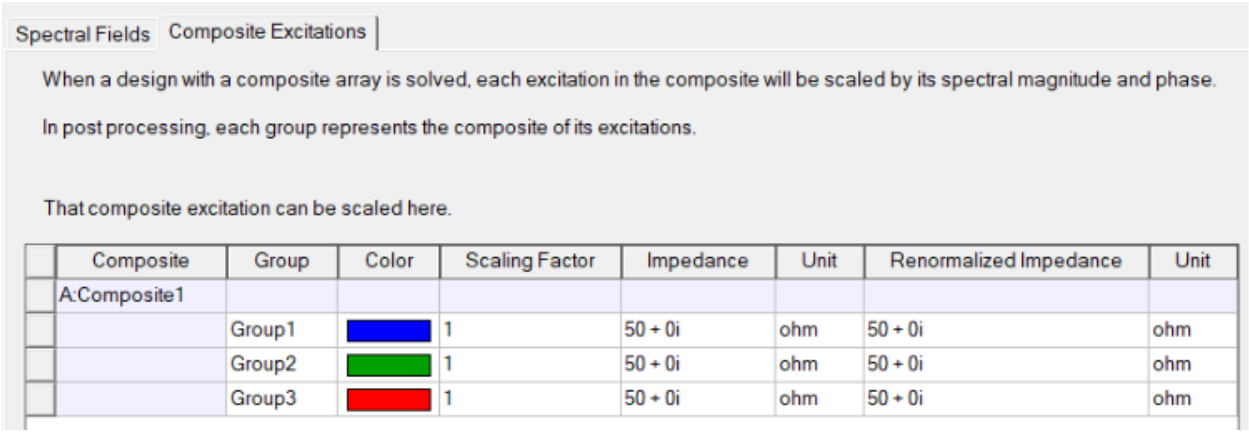
	Freq [GHz]	dB(S(A:Group1,A:Group1)) Setup1 : LastAdaptive	dB(S(A:Group2,A:Group1)) Setup1 : LastAdaptive	dB(S(A:Group3,A:Group1)) Setup1 : LastAdaptive	dB(S(A:Group1,A:Group2)) Setup1 : LastAdaptive	dB(S(A:Group2,A:Group2)) Setup1 : LastAdaptive
1	1.000000	-2.132799	-16.756288	-20.175226	-16.756288	-1.511248

The **Matrix Data** tab of the **Solution Data** does the same thing, showing composite group names, rather than port names.



For field post-processing, the **Edit Source** dialog includes the settings of each port, and each group has its own scaling factor, which can be defined in the **Composite Excitation** tab.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



As with an individual port, you can also define impedance and renormalized impedance for composite groups, but the underlying logic is slightly different.

Due to limitations you must explicitly define the Z_0 of composite group, and the renormalized impedance will be used as Z_0 (i.e., composite group always applies post-processing effects). On the other hand, the concept of "Impedance" is introduced solely to account for the matrix renormalization effect (e.g. for S matrix normalization) which is based on the ratio of impedance and renormalized impedance.

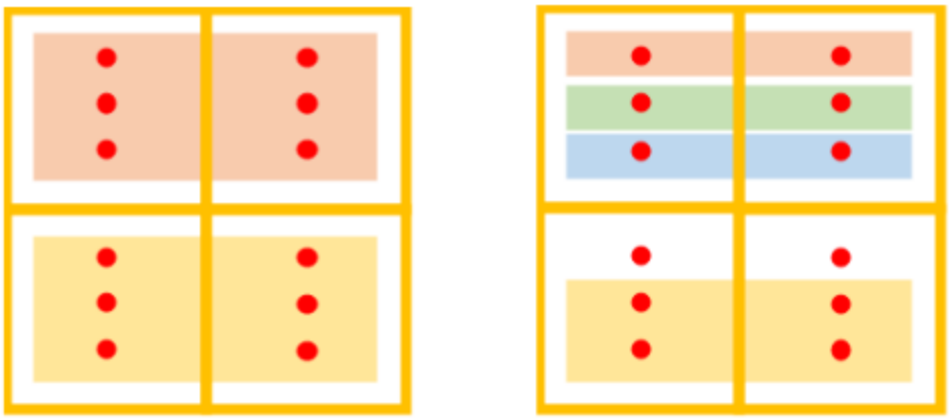
For example, a composite group with A impedance and B renormalized impedance can be seen as an individual port with A impedance and B renormalized impedance, with renormalization effect turned on. Therefore, if you do not want any renormalization for composite group, you must simply ensure that A and B are the same and match the expected impedance value.

The impedance and renormalized impedance is only used for matrix quantity (e.g., S parameter, Z_0) but not for fields results. The "Include Post Processing Effects" option is disabled to reflect this concept.

Multi-band Composite Subarray

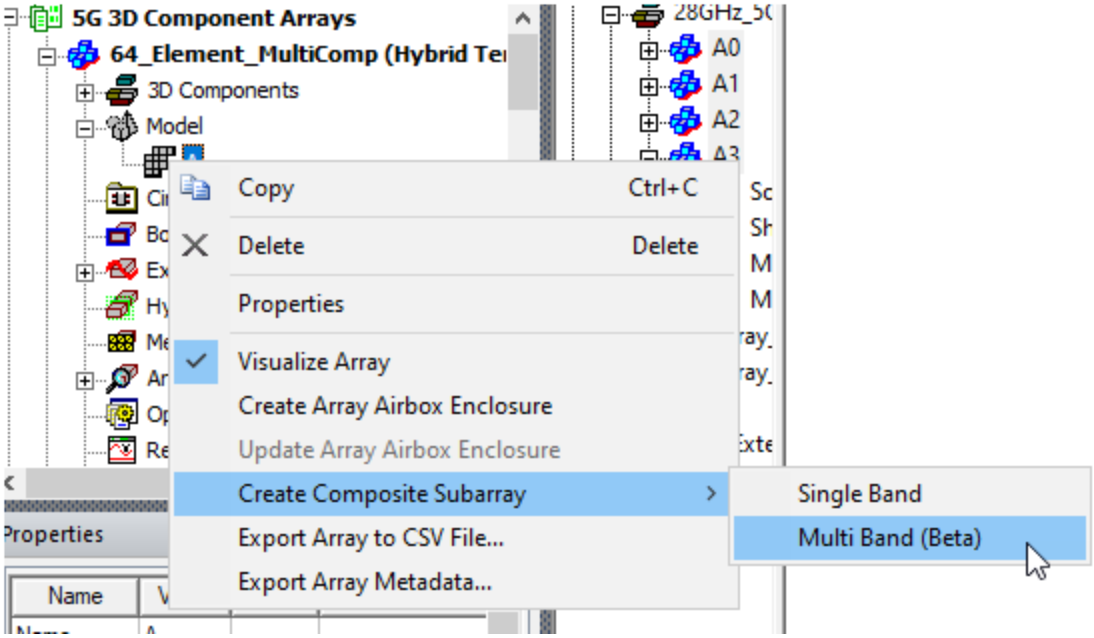
HFSS support multiple composite excitations within a given design, along with S-parameters between these excitations. A composite excitation is a specific superposition of defined sources. Leveraging composite excitations can significantly enhance analysis efficiency and reduce storage requirements for field data. A Beta feature allows multi-band composite subarrays, addressing realistic and complex scenario requirements. If array cells have multiple ports, you can further subdivide existing composite groups to include specific ports, as shown in the figure below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



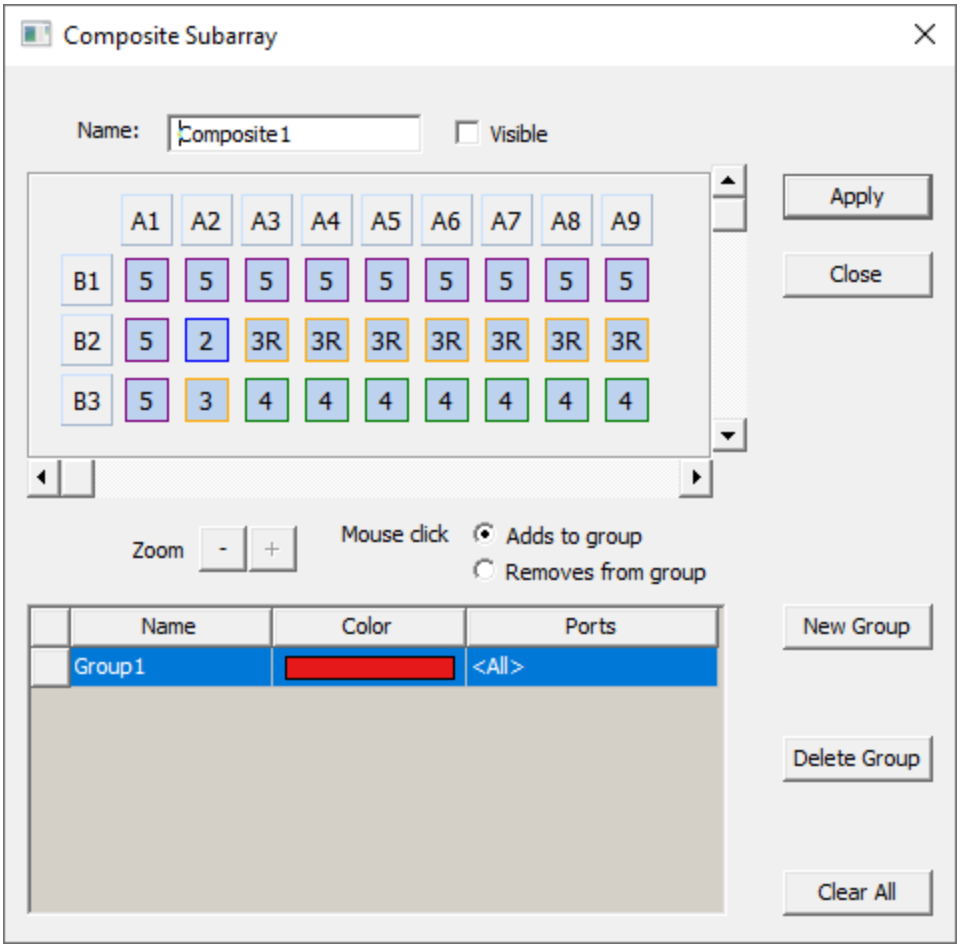
Single Band Multi Band

When feature is enabled, and the design has an array and multiple ports defined click the array right-click menu to select **Create Composite Subarray>Multi Band (Beta)**:

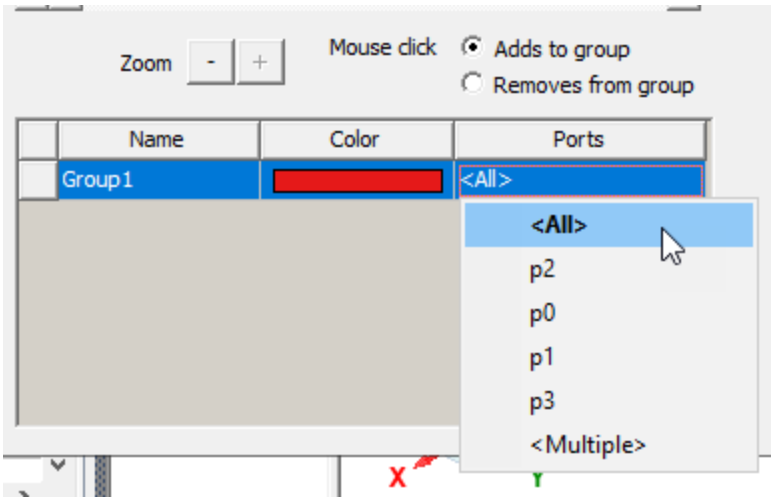


This opens the **Composite Subarray** dialog, with Rows and Columns appropriate to the design to select which port(s) to be included in a composite group. The interface differs from the Single Band version in that it contains a Ports column with a field that allows you to select single or multiple ports to define additional bands.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Right-click on the Ports for the group to see a drop down with the available ports listed.



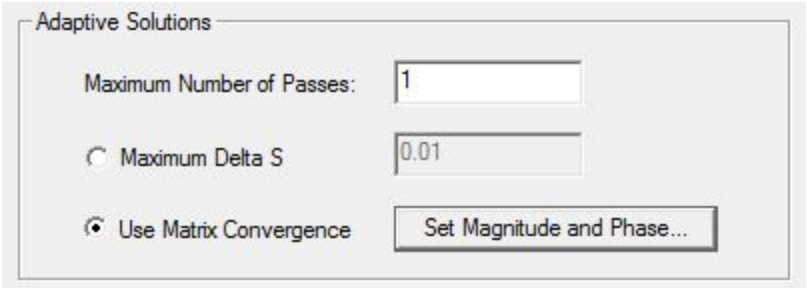
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can select either all ports (making a single-band composite subarray), one port or <Multiple> for a subset of ports.

You can define additional groups and edit the contents of groups.

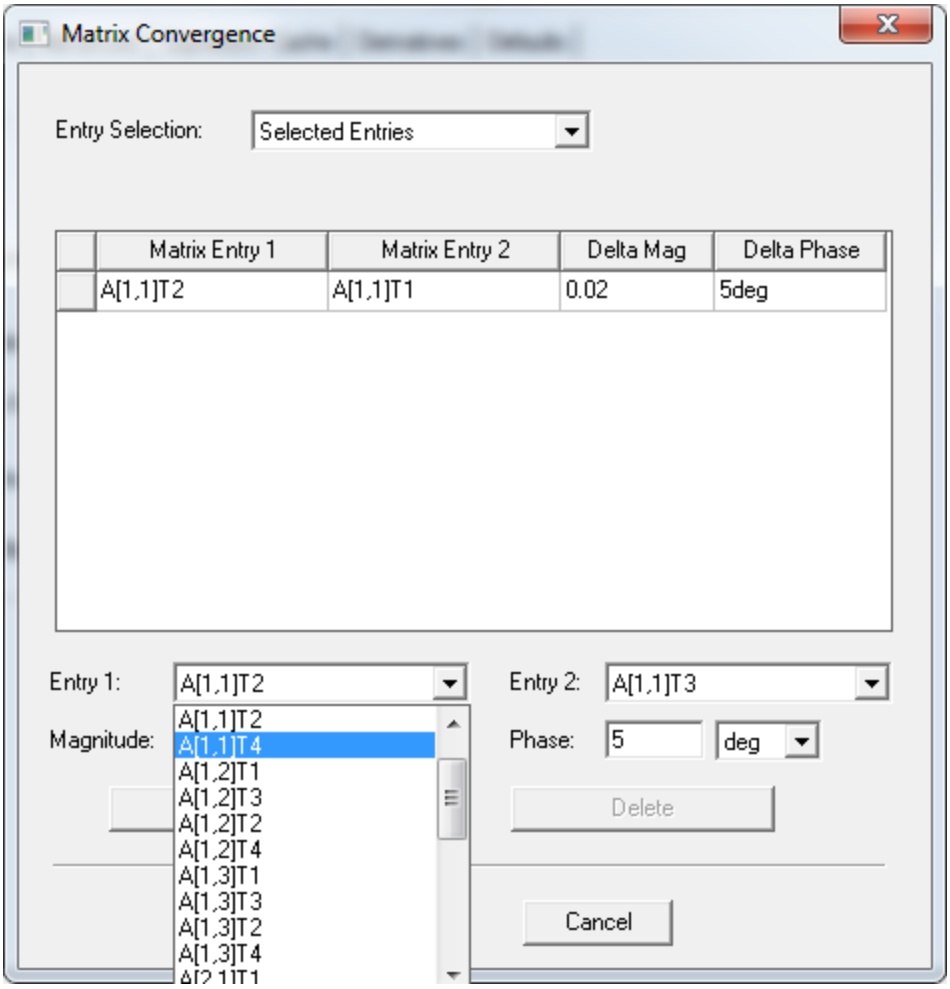
General Setup for Virtual Array Simulation

For a project with an array the General Setup some differences appear in how you can specify Matrix convergence.



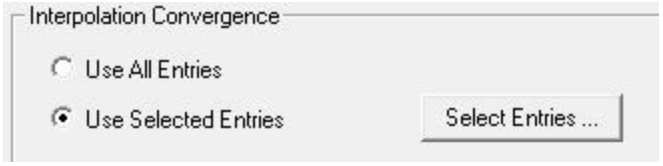
If you select Matrix Convergence, and click **Set Magnitude and Phase**, you will see the Matrix convergence dialog box. In the Matrix Convergence dialog box, if for **Entry Selection** you choose Selected Entries, (rather than All or Diagonal/Off Diagonal), you will see scrollable drop-down menus that let you select from all Array elements to define pairs of Matrix entries.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



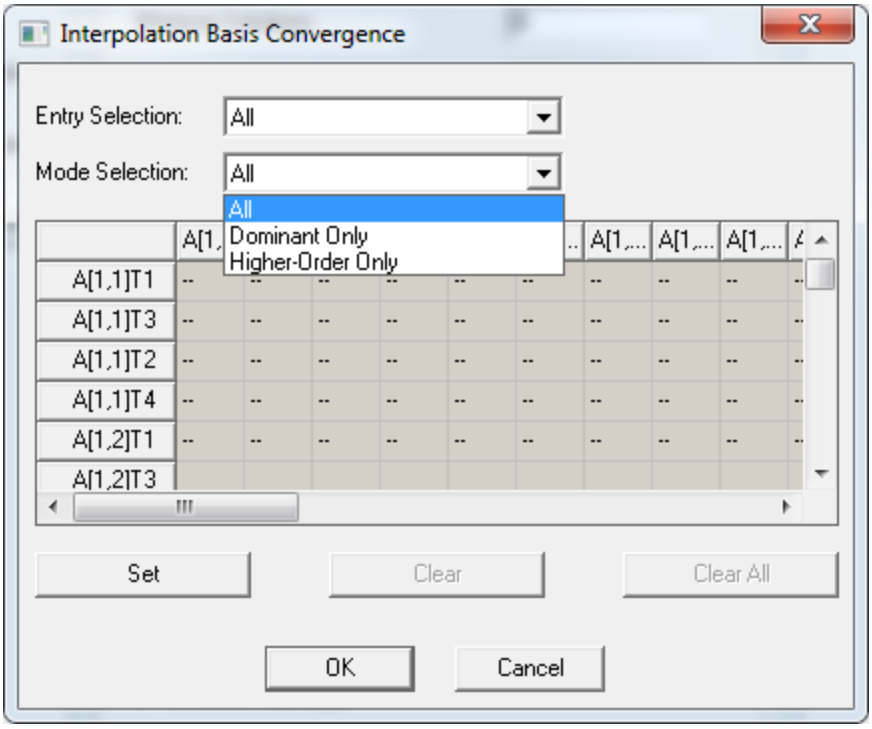
Interpolating Sweep Advanced Options for Arrays

For an Interpolating Sweep Advanced Options, if you select **Use Selected Entries**,



Clicking the **Select Entries** button displays an Interpolation Basis Convergence dialog that lists the Array elements.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note that the matrix entries are listed according to the Matrix Sort Order as specified by user.

Entry Selection can be All, Diagonal, or Off-Diagonal.

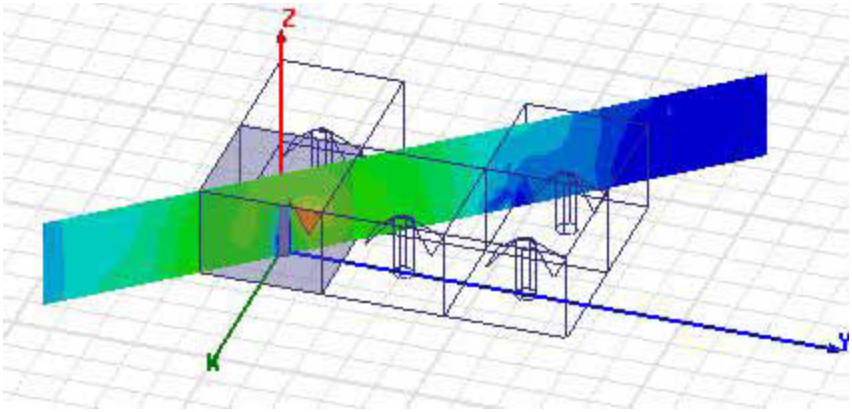
Mode Selection can be All, Dominant Only, or Higher-Order Only.

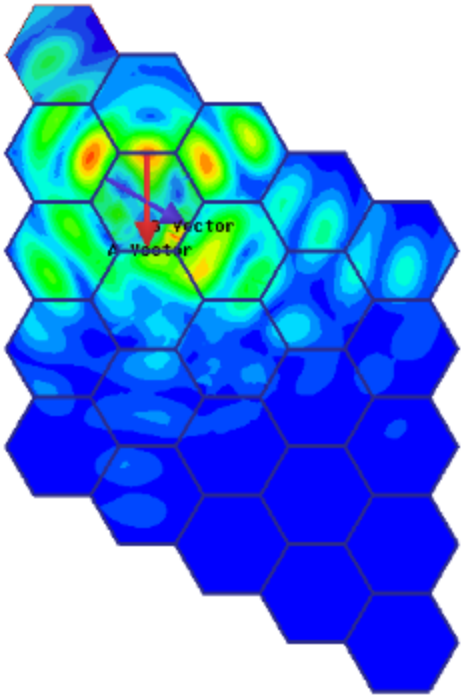
Post Processing for Array Models

Solution quantities of both physical and virtual cells are available for post-processing. You must select **Save Fields** in the Solution setup before running an analysis to enable the **Plot Fields** selections.

Radiation fields (near and far) post processing is over the whole array. You can plot and animate fields on non-model cut planes, vectors, and points, as well as on selected model object faces. Any padding cells in or around the array are treated as background material. You can plot and animate fields on cut planes, non-model objects set on the same coordinates as object or array surfaces, vectors, and points.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





You can use the Fields calculator to define calculated expressions.

HFSS can also post process individual cells in an array one at a time. You can select an arbitrary cell and do fields post processing on that cell. HFSS post processes on a single user selected cell in the array.

For Port Field Display there is no GUI change. Only physical ports/terminals will be listed. There is no need to support visualization of user-selected cell (like field overlay plot) because the field patterns of the virtual modes are the same as those in the physical cells.

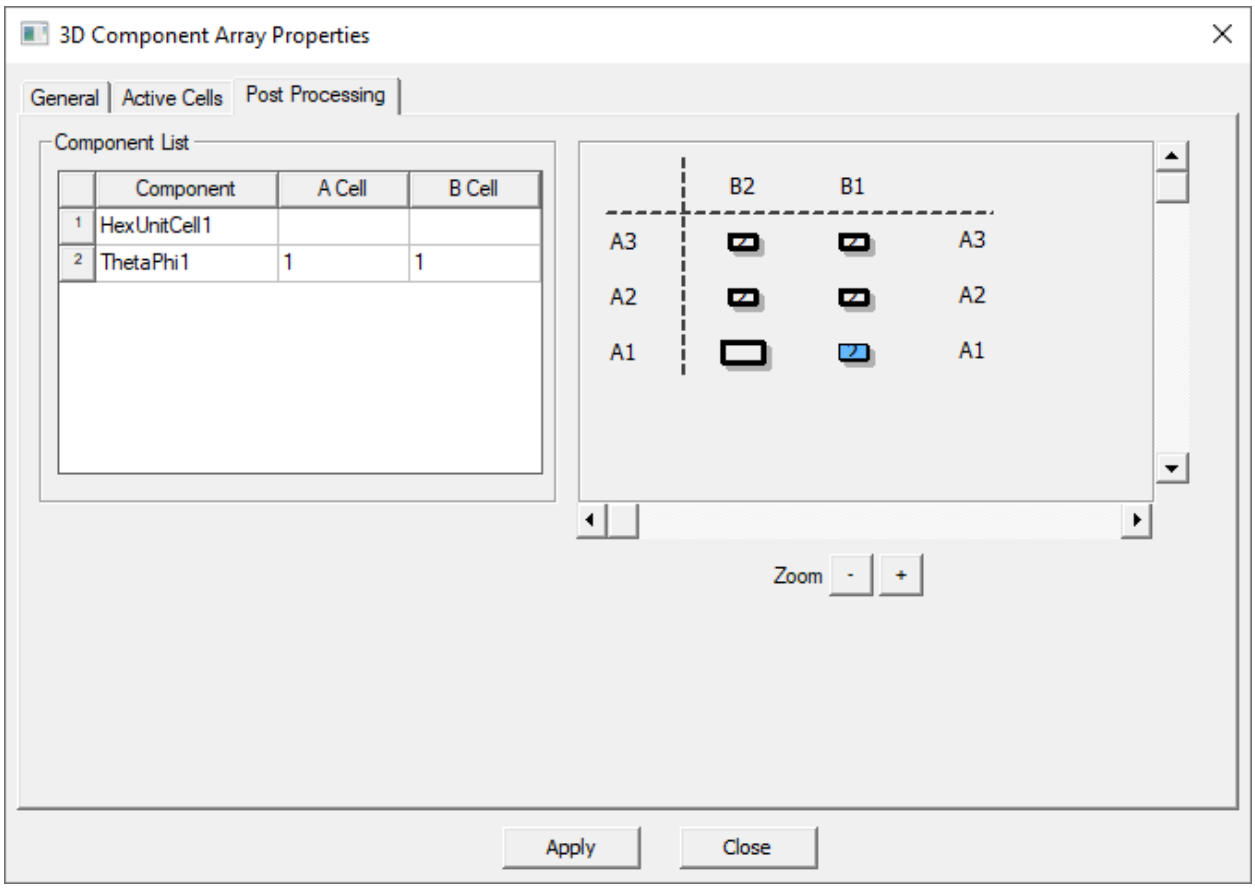
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Reports for Arrays
- Plotting Fields for Array Models
- Fields Calculator Applications for Geometries in Arrays
- Fields Post Processing for Selected Cells in Arrays

Reports for Arrays

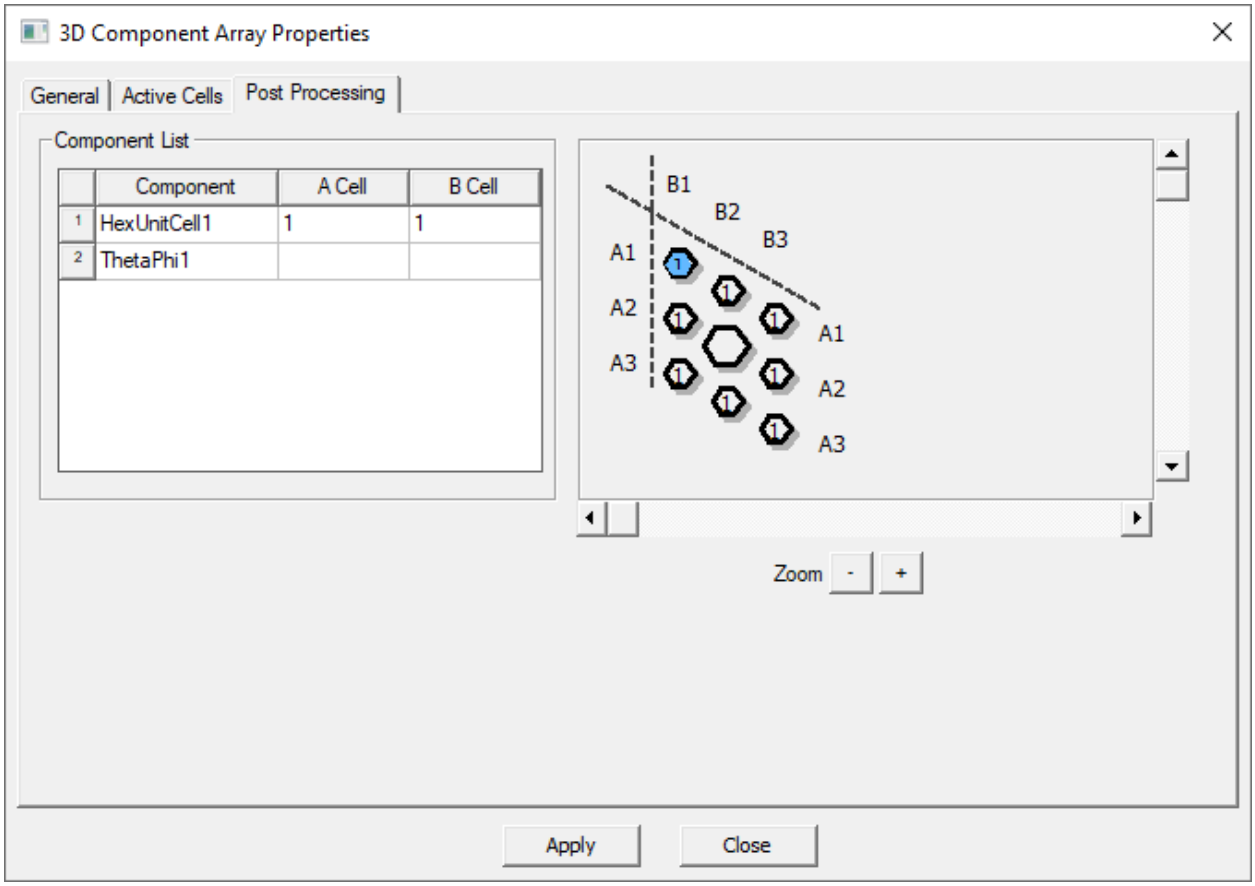
There are some differences in the Report setup for Arrays.

1. The solution/matrix quantities are grouped by category. The entries in each category are listed according to their [A vector, B vector Index] order in the corresponding matrix.



For a non-rectangular cells, the display is also controlled by A and B vectors and indices.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

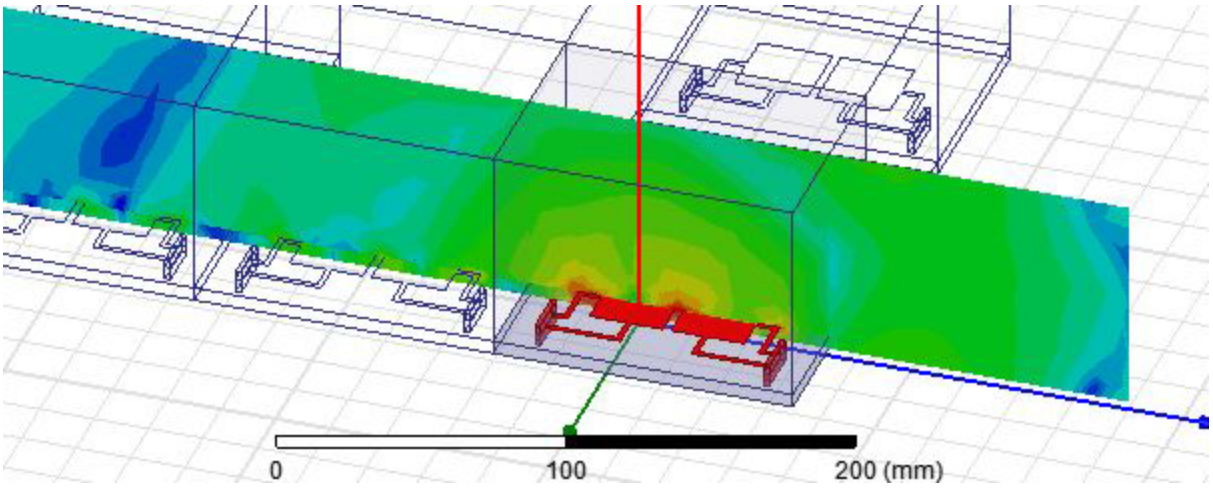


2. The existing "Filter" capability can help locate the desired quantity from the potentially very long list.

Field Plots for Arrays

You can generate field plots on object faces, as well as on non-model planes, lines, and points. The plots display calculated fields where ever the selected geometry intersects the array cells based on whether the cells are active, passive, or padding in the array properties. Locations designated as padding are treated as background material in field calculations. The virtual cells do not need to be visible to affect the generated field plots.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can also create animations of field plots. If the plotted geometry is controlled by a swept variable (such as plane angle or a point location) the animation displays the correct values where ever they intersect the array based on the designations as active cells, passive cells, or padding cells.

Fields Calculator Applications for Arrays

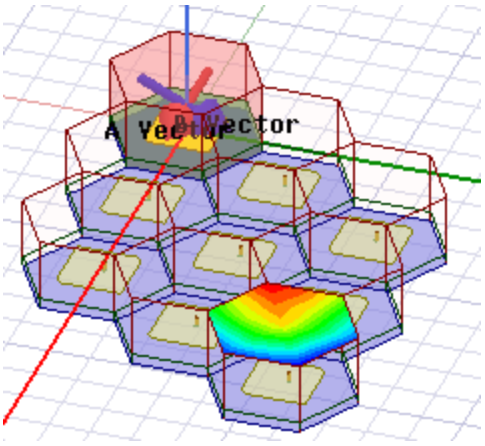
Geometries selected for Fields Calculator expressions can intersect any active, passive, or padding cells defined for the array. You can generate animated field output in which each frame is a snapshot of the fields on a different plane of the modeled volume. The Fields Calculator cookbook describes an example of the technique. Any derived field quantity can be plotted in this manner.

Fields Post Processing on a Designated Array Cell

For post processing fields information for arrays, you can select an arbitrary cell and do fields post processing on that cell.

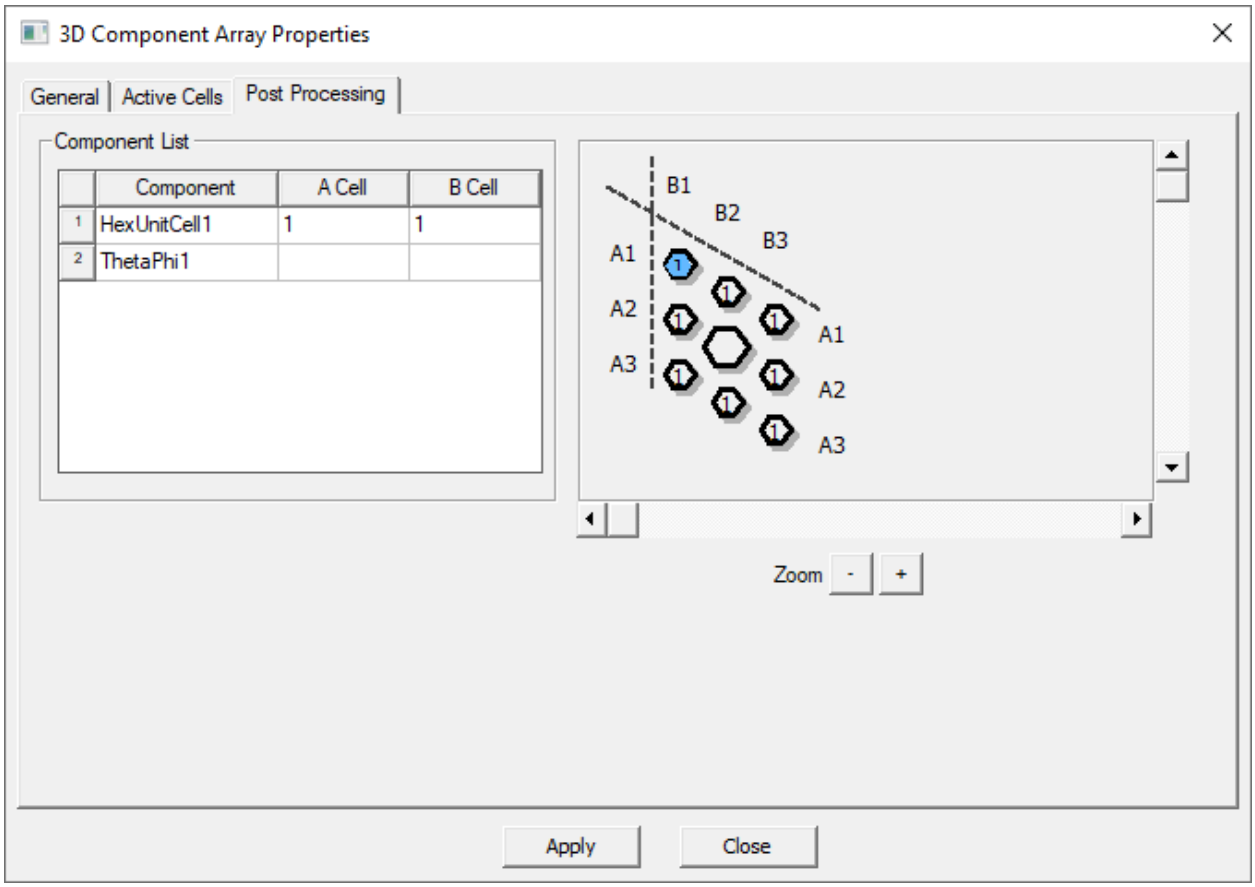
The unit cell mesh from position (1,1) will be translated to the user selected cell and fields will be plotted in the user selected cell.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



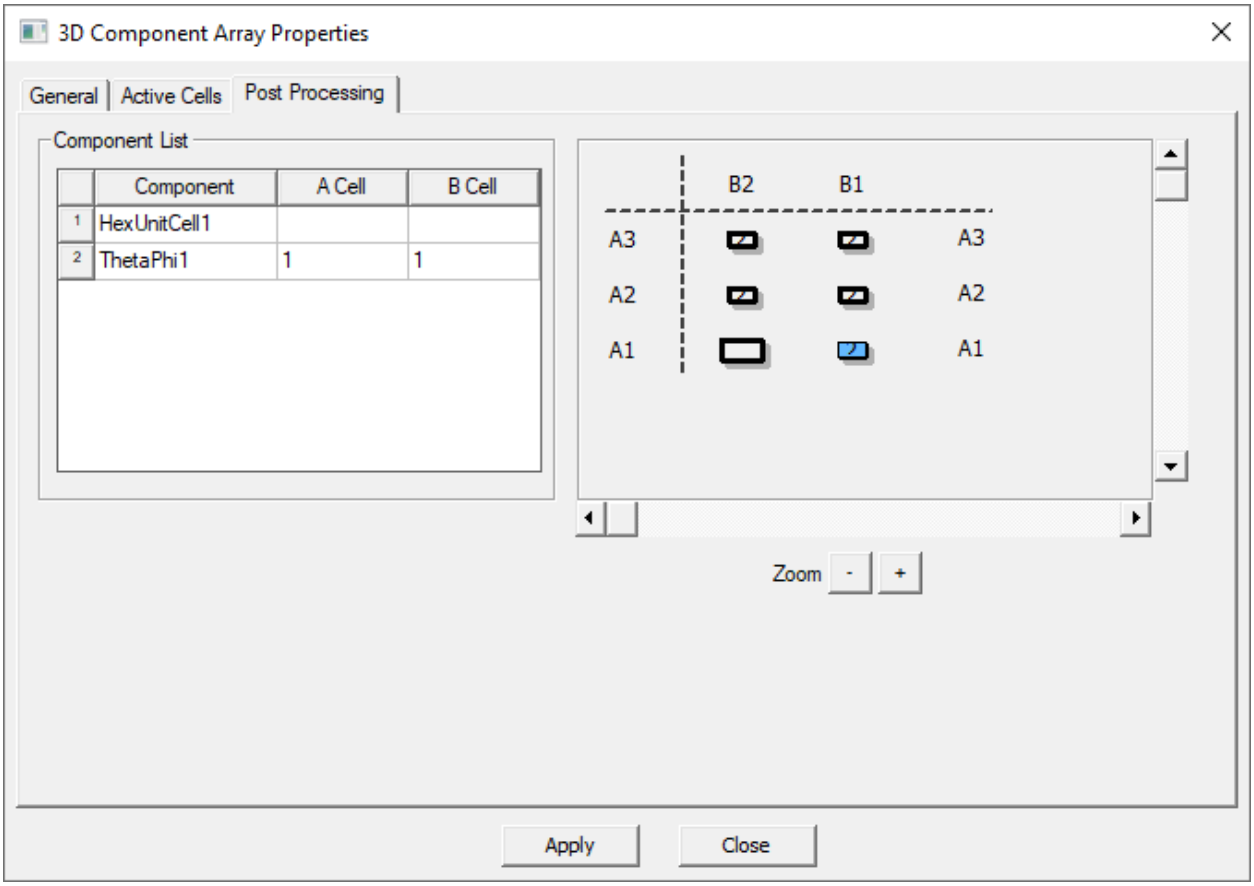
The procedure is:

1. Select objects in the unit cell
2. Use the Array dialog to specify the cell to post process for fields, either by clicking on a the corresponding array position indicator in the Post Processing Cell tab in or by giving the A and B direction indices.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For rectangular cells, the cells are also displayed according to A and B vectors and indices.



The Field plot will be visible in the user selected cell.

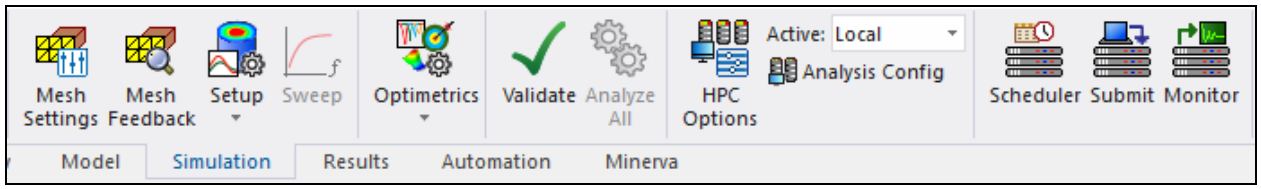
Radiation fields post processing will be over the whole array.

Jsurf is calculated inside the geometry of the cell but it will be equal to 0 along cell borders.

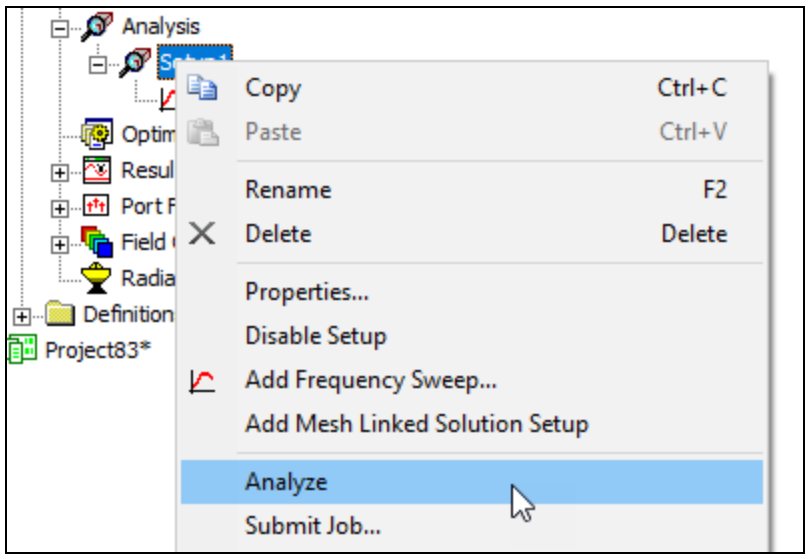
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

22 - Running Simulations

After you specify how Ansys Electronics Desktop is to compute the solution, you need to begin the solution process. You can access the **Analyze** commands for a specific setup by right-clicking on a solution or sweep in the **Project** tree and selecting from the shortcut menu, you by selecting the **Analyze All** from the solver menu, or the **Analyze All** icon on the **Simulation** tab of the ribbon.

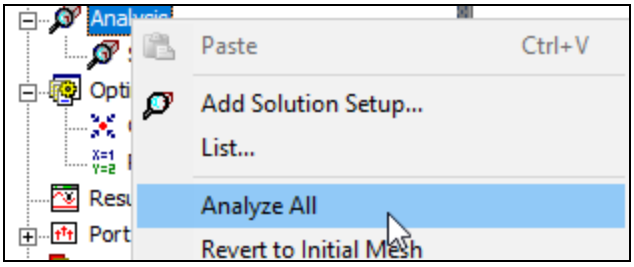


In general, the **Analyze** command on the shortcut menu applies to the selected setup and associated sweeps, if any, or to a selected sweep. To use this command, right-click on a setup or sweep in the Project Manager and click the command on the context menu.



The **Analyze All** command applies to allenabled setups,dependent setups, and sweeps at or below the level invoked in the Project Manager. To use this command, either click **HFSS**> **Analyze All** or right-click the **Analysis** icon in the *Project Manager* and select **Analyze All**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



What do you want to do?

- Local Analysis
- Solve a single setup with or without sweeps (when applicable)
- Solve a specific sweep
- Enable a queue so that multiple simulations can run sequentially as resources become available.
- Run more than one simulation, whether multiple setups, or multiple sweeps under a single setup, or setups with dependencies.
- Enable or Disable one or more solution setups or sweeps.
- Submit Job to RSM or HPC Scheduler
- Monitor queued simulations
- Monitor the solution process
- Change a solution priority for system resources
- Abort an analysis
- Re-solve after modifying a design
- Re-solve after Ansys Workbench Feedback

Local Analysis

Ansoft RSM Service does not need to be installed or running for local analysis and should not be running if the user only will be running local analysis. If running a distributed analysis, consult Distributed Analysis.

> **Note:**
>
> MPI distribution may be affected by starting or stopping a VPN, even if the MPI distribution is limited to the local host.

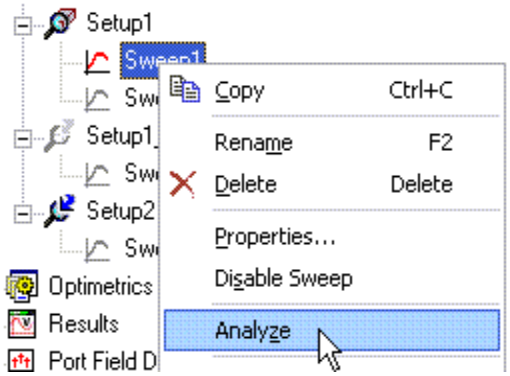
To run more than one analysis at a time, follow the same procedure while a simulation is running. If you have enabled queuing, the next solution setup will be solved when the previous solution is complete.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solving a Single Setup or Sweep

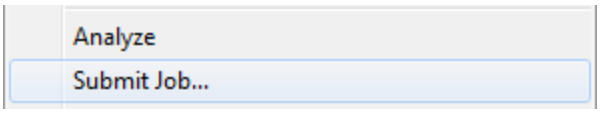
To run a single setup or sweep:

1. Select a solution setup or sweep in the Project Manager.
2. Right-click and select **Analyze** from the shortcut menu. The graphic shows a single sweep selected for analysis.



The 3D field solution is computed inside the structure for a solution. For a select sweep, it is computed for the sweep variables.

When you right-click a Setup, rather than a Sweep, the shortcut menu also includes the **Submit Job...** command.



For more information on the **Submit Job...** command see, Distributed Analysis and High Performance Computing (HPC) Integration.

To run more than one analysis at a time, follow the same procedure while a simulation is running. If you have enabled queuing, the next solution setup will be solved when the previous solution is complete.

> **Note:**
>
> If a linked dependency in the setup is already simulating (for example, due to setup links to the same external source for a near or far field wave, or a magnetic bias), Ansys Electronics Desktop will not allow another dependent simulation to start until the first use of the source has completed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

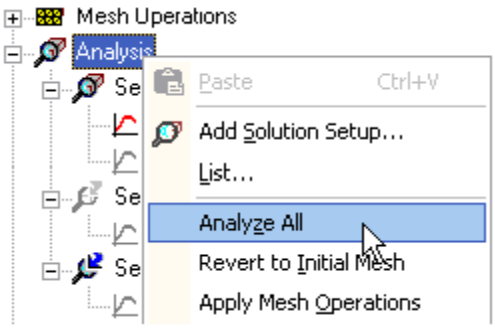
Running More than One Simulation

To solve every enabled solution setup in a design:

1. In the project tree, under the design you want to solve, select **Analysis**.
2. Click **HFSS**> **Analyze All**.

Each enabled solution setup is solved in the order it appears in the Project Manager.

The example here shows an analysis invoked from the Project Manager shortcut menu with three setups: one disabled, two enabled. The first setup has one sweep enabled, and one disabled (shaded icon). The second setup is disabled, and the third is enabled, with a disabled sweep.



Note:

The **General** tab for the Setup includes an **Enabled** check box. By default, this is checked. Clearing the **Enabled** check box excludes a setup from running

Note:

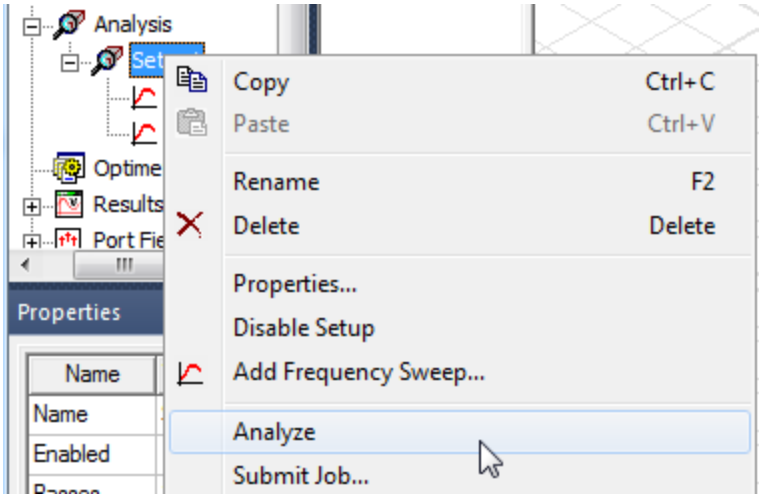
You can simulate all designs in a project by clicking **Project** > **Analyze All**.

To solve *two or more sweeps or two or more parametric analyses under a setup*:

1. In the project tree, under the design you want to solve, right-click **the setup** icon that includes the sweeps of interest.
2. Click **Analyze** on the shortcut menu.

   Each solution sweep under that setup is solved in the order it appears in the Project Manager, using the available machines. The following example shows a setup with two enabled sweeps.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Submitting a Job

Ansys Electromagnetics Desktop supports its own Remote Simulation Management (RSM) and Ansys Cloud Burst Computing along with other High Performance Computing (HPC) software management programs (See: HPC Integration). The **Simulation** tab of the ribbon includes icons for setting HPC Options, creating and selecting analysis configuration, selecting the scheduler, submitting jobs, and monitoring jobs.

There are two ways that the GUI may be used to submit jobs. The first (and most common) mode requires that the Desktop (UI) process run on a host which is also a submission host for the job scheduler. This mode is called local mode or working mode.

The second mode is only supported on Linux in the Ansys Electromagnetics Suite. In the second mode, an administrator configures the RSM Service to act as an interface to the job scheduler, and starts the RSM Service on a submission host for the cluster. The user runs the Desktop (UI) process on another host (which may be called the post-processing host). To submit a job, the user specifies the host where the RSM Service is running, and the Desktop process connects to the RSM Service over the network to submit the job. In this mode, some configuration is required, and the RSM Service typically must run as a privileged user (for example, root), so that it can launch processes as any user. This mode is useful for cases in which the submission hosts are not able to run graphical processes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

For certain methods of resource selection for Windows HPC job submission, Ansys Electronics Desktop checks for nodes being online. In an auto-scaling cluster, nodes can fail the online check because they're not online until a job is running. An environment variable allows customers to bypass this check:

ANSYSEM_SKIP_NODE_ONLINE_CHECK

Set the variable value to 1 to disable the online check. Debug logging fully verifies what aspects of the cluster are causing this check to fail.

Job submission in Windows works without changing settings if environment variable ANSYSEM_SUBMIT_JOB_REQ_NODE_ONLINE is set with value 0. The installation doesn't set this environment variable. ANSYSEM_SUBMIT_JOB_REQ_NODE_ONLINE accepted values: 0 or 1 (0 = disable; 1 = enable, i.e. require nodes to be online for submission). Default: 1 (i.e. if not set, Ansys Electronics Desktop requires nodes to be online for submission).

To submit a job:

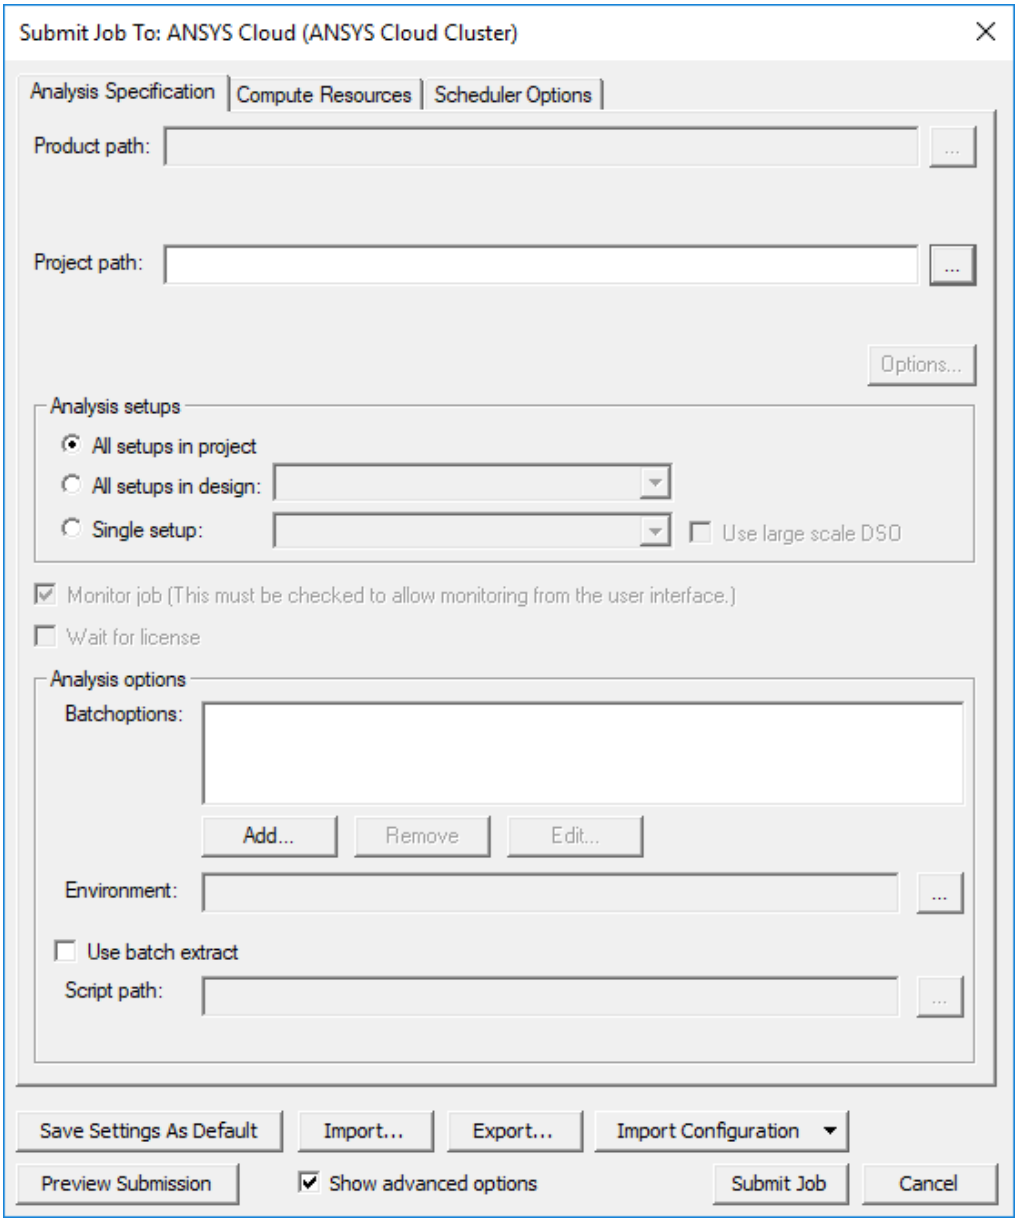
1. Prepare your design.

   For HFSS, Ansys recommends you use **HFSS** > **Design Settings** to turn on S parameter export for frequency so that they can be downloaded quickly after the simulation is complete. They must be exported to default project path for download to work correctly.

2. Open the **Submit Job To** window one of the following ways:
   - On the **Simulation** tab, click the **Submit** icon.
   - Select **Tools** > **Job Management** > **Submit Job**.
   - Select **HFSS** > **Submit Job**.
   - Right-click a solution setup and select **Submit Job**. *In this case, the information in the **Submit Job To** window will be pre-populated from the setup*.
   - From a Command window, use the -showsubmitjob command.

   The **Submit Job To** window appears. The window header indicates your selected scheduler.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This window contains up to three tabs:

- **Analysis Specification** – allows you to specify the product path, project name, setup and analysis options, batchoptions, and environment variables (for advanced users).
- **Compute Resources** – allows you to specify whether to use automatic settings, and to set resource selection and job distribution parameters.
- **Scheduler Options** – allows you to specify the job name and priority. *This tab does not appear if you have selected local RSM as the scheduler*.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. On the **Analysis Specification** tab, specify your desired options.

   The **Product path** and **Project** fields support mapped drives. Click the ellipses (**...**) to select files.

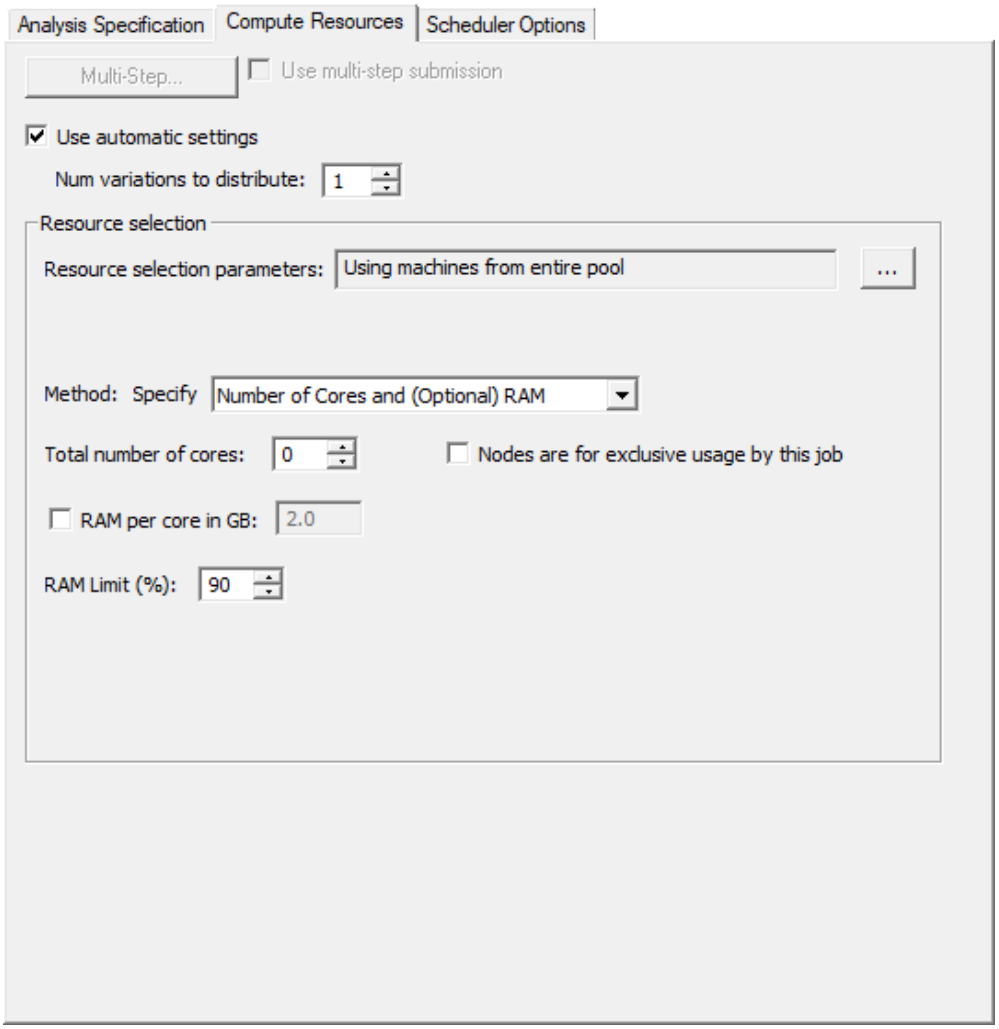
   The project can be an archive. The project file pathname must be a UNC path that is accessible from each compute host used for Ansys Electromagnetics jobs. After clicking the **Project path** field's ellipsis button (**...**), a check box allows you to **Use converted UNC path if mapped drive specified**. If you select a project or product on a mapped drive, and check the option, the converted UNC path equivalent to the mapped drive pathname is used.

   In the **Analysis Setups** area, select the radio button for **All setups in project**, **All setups in design**, or a **single setup**.

   For Parametric setups, you have the option to select **Use Large Scale DSO**. See: Large Scale DSO for Parametric Analysis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Select the **Compute Resources** tab.



Options may vary slightly depending on your selected scheduler.

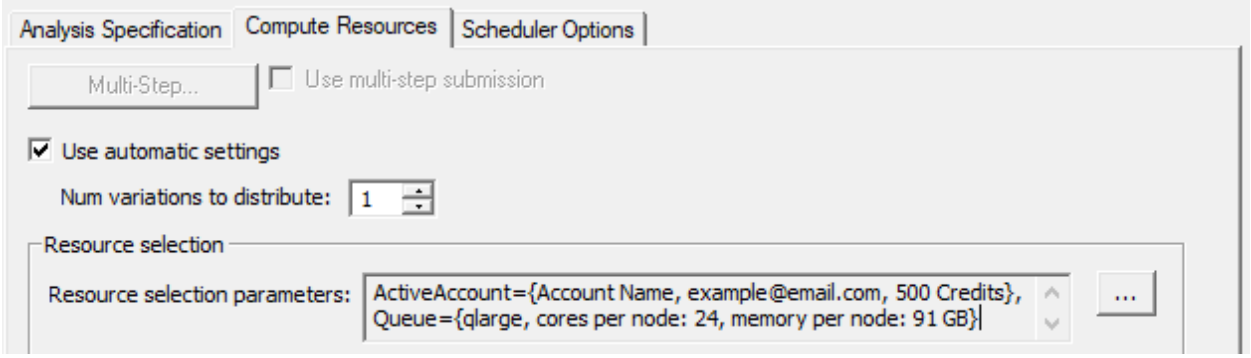
5. If applicable, determine whether or not to **Use multi-step submission**.
6. Determine whether or not to **Use automatic settings**.

> **Note:**
>
> Ansys strongly recommends using Automatic settings.

7. Use the buttons in the **Resource selection** area to allocate resources. See: Job Management for Large Scale DSO. If you are using Ansys Cloud Burst Compute select an active account using the ellipsis […] button to the right of the **Resource selection parameters:** text box and ensure that it has sufficient Core Hour Balance. This balance

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

will be displayed in the **Resource selection parameters:** text box.



8. If you opted not to use automatic settings, you can also set **Job distribution** parameters. See: Distributed Analysis.
9. If applicable, select the **Scheduler Options** tab and set the **Job name** and **Priority**.

10. If desired, import or export job configurations.
11. If desired, click **Save Settings as Default** to save the current settings and overwrite defaults. These settings are saved on a per-scheduler basis.
12. If desired, click **Show advanced options** to see options for advanced users. See: Running Electronics Desktop from a Command Line.
13. If desired, click **Preview Submission** to view the commands to be sent to the scheduler. Ansys Cloud Burst Computing submissions contain queue (pool) configuration details, including the job's hourly cost in Ansys Elastic Units (AEUs).

    The preview text can be copied to the clipboard.
14. Click **Submit Job** to submit the job to your selected scheduler.

Monitoring Queued Simulations

If you have multiple setups for a design and have selected **Analyze All**, the simulations can be queued until there is a machine available. You enable queuing in the HPC and Analysis Options: Options tab. If queuing is enabled, and you run multiple setups, they are solved in the order that they appear in the Project Manager. You can prioritize setups by changing their order in the queue.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. To view the solution queue, click **Tools** > **Show Queued Simulations**.

   This displays a dialog box showing all the simulations and their current status. You can select and remove any simulation from the queue.

   You can also select any setup and use the **Move up** and **Move down** buttons to prioritize them.

2. To remove a simulation from the queue, select the simulation and click **Remove from Queue**.

   This removes the selected simulation from the queue.

Monitoring the Solution Process

While a simulation is running, you can monitor the solution's progress in the **Progress** window. The progress bar shows the relative progress of the simulation.

You can also view the following solution data at any time during or after the solution:

- The convergence data
- The matrices computed for the S-parameters, impedances, and propagation constants
- A profile showing the status of the analysis process, including the progress and number of valid passes completed for adaptive solutions, elapsed time, memory usage, and more
- Mesh statistics (numbers of elements, lengths, volumes, and volume standard deviation; all on a per-object basis).

To view the *Solutions* window:

1. Right-click the solution **Setup** in the Project Manager.

   A shortcut menu appears.

2. Select **Convergence**, **Solutions**, **MatrixData**, **Mesh Statistics**, or **Profile** from the shortcut menu.

   The *Solutions* window appears with the corresponding tab selected and the current data displayed.

For "out of core" problems, quite different amounts of memory may be used for factorization and for solution. So if the amount for factorization is displayed under the progress bar and the amount used is calculated for the profile at the end of the solution, they may be quite different numbers.

To view the solution status:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Click **HFSS** > **Results** > **Browse Solutions**.

  The *Solutions* dialog box appears with the **Browse** tab selected. It displays data about the number of valid passes completed (when adaptive solutions are applicable). It contains a tree structure showing the solutions listed according to Setup, Solution, and Variation. A table lists the setup, the solution, the sweep variable (when applicable), and the state of the solution.

- You can use the **Properties** button to display a dialog box that lets you change the way the Setup, Solution, and Variation are listed in the tree structure of the *Solutions* dialog box.
- You can delete one or more solutions by selecting from the table and clicking **Delete**. Click on a solution to select it, and use Ctrl+click to select multiple solutions, or Shift+click to select a range of solutions. You can also select all solutions using the **Select All** button.

  > **Note:**
  >
  > If a license is lost, the software waits for the license to be regained, checking every 2 minutes or until you abort.

- The **Statistics** tab of the *Solutions* dialog box displays path information as well as format, number of files, and size.

Changing a Solution Priority for System Resources

You can modify the priority of Ansys Electronics Desktop simulations so that system resources are allocated to other computer processes before the solver. If you reduce the priority of Ansys Electronics Desktop simulations, your other software tools will respond as they normally would, but Ansys Electronics Desktop simulations may take longer.

> **Note:**
>
> The Windows Task Manager does not indicate a reduced priority for the Ansys Electronics Desktop solvers. It only lists the priority of the engine manager, which appears normal, not the actual engine. The actual engine is in a separate thread, whose priority is not visible in the Windows Task Manager.

To change the priority of simulations for the system's resources:

1. While a solution is running, right-click the **Progress** window, and click **Change Priority** on the shortcut menu.
   - To affect priority for future simulation runs, click **Tools** > **Options** > **HPC and Analysis** and click the **Options** tab of the resulting dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. From the **Change Priority** menu (or the **Default Process Priority** drop-down menu), select one of the following priorities:

Highest	
Above Normal	
Normal	Default
Below Normal	
Lowest Priority	

3. Click **OK**.

Related Topics

Monitoring Queued Simulations

Aborting an Analysis

To end the solution before the currently running process is complete:

- Right-click in the **Progress** window and click **Abort**.

  The solver ends the analysis immediately. The data for the currently running adaptive pass, frequency point, time step, or variation is lost. Previously completed solutions may or may not be retained (depending on what process was interrupted by the Abort command). If you want to ensure that the results of all completed solutions are saved, use *Clean Stop* instead of *Abort*.

To abort the solution after the currently running process is complete:

- Right-click the **Progress** window and click **Clean Stop** on the shortcut menu.

  The analysis ends after the currently running adaptive pass, frequency point, time step, or variation has been solved. Solutions completed before the stop request are retained.

If you request a clean stop during the third adaptive pass, the solution for the third pass will be available once the third pass has finished solving, but the fourth pass will not run.

Ansys EM Application as an LSF Job

If you have an Ansys EM application running as an LSF job, you can use the command "bkill -s SIGTERM *jobid*" to terminate that application. Here *jobid* is the LSF job id. The response will be "Job <jobid> is being signaled." The response is the same whether the job is actually being signaled or not.

In cases where the SIGTERM parameter is ignored, the command kills the LSF job, but does not clean the lock files, and other files may not be in a consistent state. See http://www.vital-it.ch/support/LSF/programmer/advanced.html for a detailed description under *Signal Handling in Windows*.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Linux

For Linux, you can use TERM commands. Sigterm handling is done in Desktop library. You can abort a running batchsolve by sending a TERM signal to hfss.exe.

Re-solving after Modifying a Design

In some cases, if you modify a design after generating a solution, the solution in memory will no longer match the design. In such cases you receive a warning message that "Solutions have been invalidated. Undo to recover."

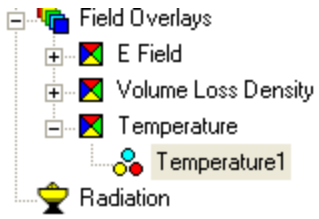
To generate a new solution after modifying a design, follow the procedure for running a simulation.

Also see Re-Solving with Ansys Workbench Thermal Feedback.

Re-solving after Ansys Workbench Thermal Feedback

With the Enable Feedback box in Setting the Temperature of Objects dialog box is checked, you can manage analysis with feedback in Ansys Workbench. After solving an HFSS or Q3D Extractor or Maxwell design, after performing the corresponding linked thermal analysis in Ansys Workbench, you can receive a temperature distribution back from the thermal solution. Ansys Workbench will write the feedback files directly to the Project Solution directory.

After an analysis that includes thermal feedback from Ansys Workbench, you can see temperature changes expressed in Temperature field overlays (both visually in the overlay and in the color key) as well as in the Solution data.



In the **Solution** data Profile tab you will see a new entry for Maximum Delta T, for the change in temperature from the previous simulation. The solver calculates delta in the first iteration by comparing the temperature distribution output from thermal with the initial temperature setting in HFSS/Maxwell/Q3D. Subsequent simulation iterations provide a number for the temperature delta.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solver MCS4	00:00:00	00:00:00	31.4 M	Disk = 0 KBytes, matrix size 3468 , matrix bandwidth
Field Recovery	00:00:00	00:00:00	31.4 M	Disk = 310 KBytes, 2 excitations
				Maximum Delta T = 7.0685

This simulation feedback loop from Ansys Electronics Desktop to Ansys Workbench and back can continue until you decide that Temperature delta reported in the Solution Report low and stable for the designs.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

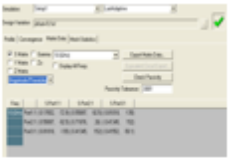
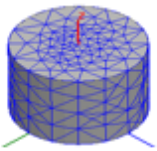
23 - Postprocessing and Generating Reports

As Ansys Electronics Desktop completes a solution, you can display and analyze the results:

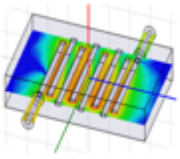
View Solution Data



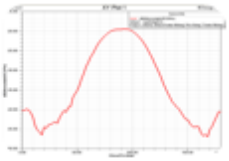
View Optimetrics Results



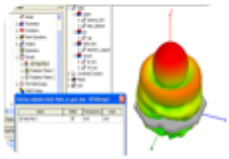
Create Mesh Plots



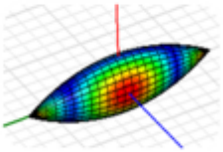
Plot Field Overlays



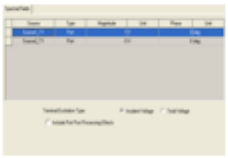
Create or Modify 2D or 3D Reports



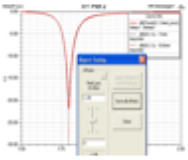
Overlay 3D Field Plot on Model



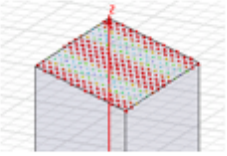
Create Animations



Scale Excitation Mag/Phase



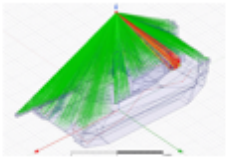
Tune Reports



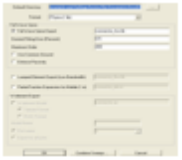
Port Field Display

Specify Output Variables

Radiated Fields Observation Regions

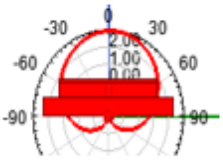


Visual Ray Trace

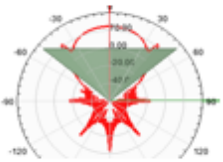


Export Equivalent Circuit Data

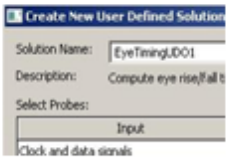
Fields Calculator / Derived Field Quantities



Overlay 2D Radiation Fields



Overlay Monostatic/ Bistatic RCS



User Defined Outputs

User Defined Documents

Network Data Explorer

- View solution data including the following: convergence information, computing resources that were used during the solution process, mesh statistics, and matrices computed for the S-parameters, impedances, and propagation constants during each adaptive, non-adaptive, or sweep solution. For eigenmode solutions, you can view the real and imaginary parts of the frequency and quality factor Q computed for each eigenmode. Solution data can also be viewed while Ansys Electronics Desktop is generating a solution.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- View analysis results for Optimetrics solutions.
- Plot field overlays - representations of basic or derived field quantities - on surfaces or objects.
- Overlay Field Plots on Models
- Create 2D or 3D reports of S-parameters, basic and derived field quantities, and radiated field data.
- Plot the finite element mesh on surfaces or within 3D objects.
- Create animations of field quantities, the finite element mesh, and defined project variables.
- Scale an excitation's magnitude and modify its phase.
- Apply Derivative Tuning to Reports

> **Note:**
>
> Except in the case of non-model boxes drawn in the global coordinate system (CS), non-model objects cannot be used for any fields post processing operation You can use non-model boxes drawn in the global CS for post processing operations, including integration and solution domaining.

Viewing Solution Data

While Ansys Electronics Desktop is generating a solution, or when it is complete, you can view the following information about the solution:

- Convergence information.
- Computing resources, or profile information, that were used during the solution process.
- Matrices computed for the S-parameters, impedances, and propagation constants during each adaptive, non-adaptive, or sweep solution.
- Mesh statistics
- For eigenmode solutions, view the real and imaginary parts of the frequency and quality factor Q computed for each eigenmode.
- For Characteristic Modes solutions, a CMA Data tab reports the the Number of Modes, Characteristic Angle and current, Modal Significance and Quality Factor, and Voltage per port based in edit sources weighting.
- The state of solved solutions.
- For transient solutions, Transient Data.

To access the **Solution Data** window, in which the information above can be accessed, do one of the following:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Click **HFSS**> **Results**> **Solution Data**.
- Right-click **Results** in the Project Manager, and then click **Solution Data** on the shortcut menu.
- Select the **Results** tab on the ribbon, and click the **Solution Data** icon.

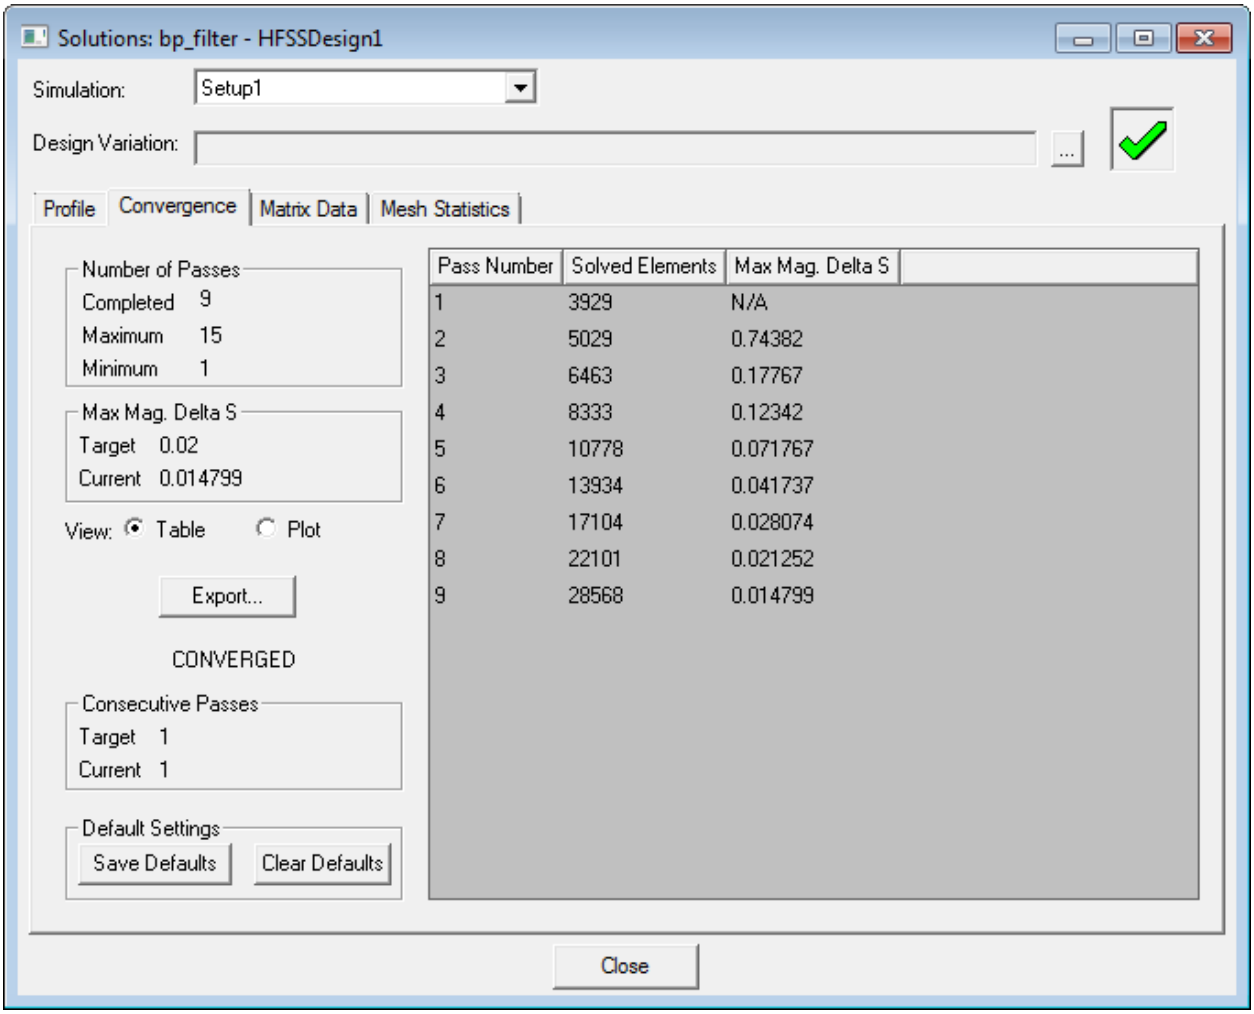
Viewing Convergence Data

To view an adaptive solution's convergence information, either during or after the solution process:

1. In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

   The **Solution Data** window appears. The **Convergence** tab is selected. You can also select the **Results** tab of the ribbon, click the **Solution Data** icon, and click the **Convergence** tab when the **Solution Data** window appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. If you have run multiple simulations, from the **Simulation** list, select the solution setup for which you want to view convergence data.

   By default, the most recently solved solution is selected.

3. Under the **Convergence** tab, depending on your design setup, you can review the following convergence data:
   - Whether the solution is converged or not converged.
   - Number of adaptive passes completed and remaining.
   - The Solved Elements at each adaptive pass, which includes solve inside tetrahedra, and, for projects using IE Regions for metal objects, also includes the number of solved IE surface triangles.
   - Maximum magnitude of delta S between two passes.
   - Maximum delta Energy between two passes.
   - Magnitude margin between passes.

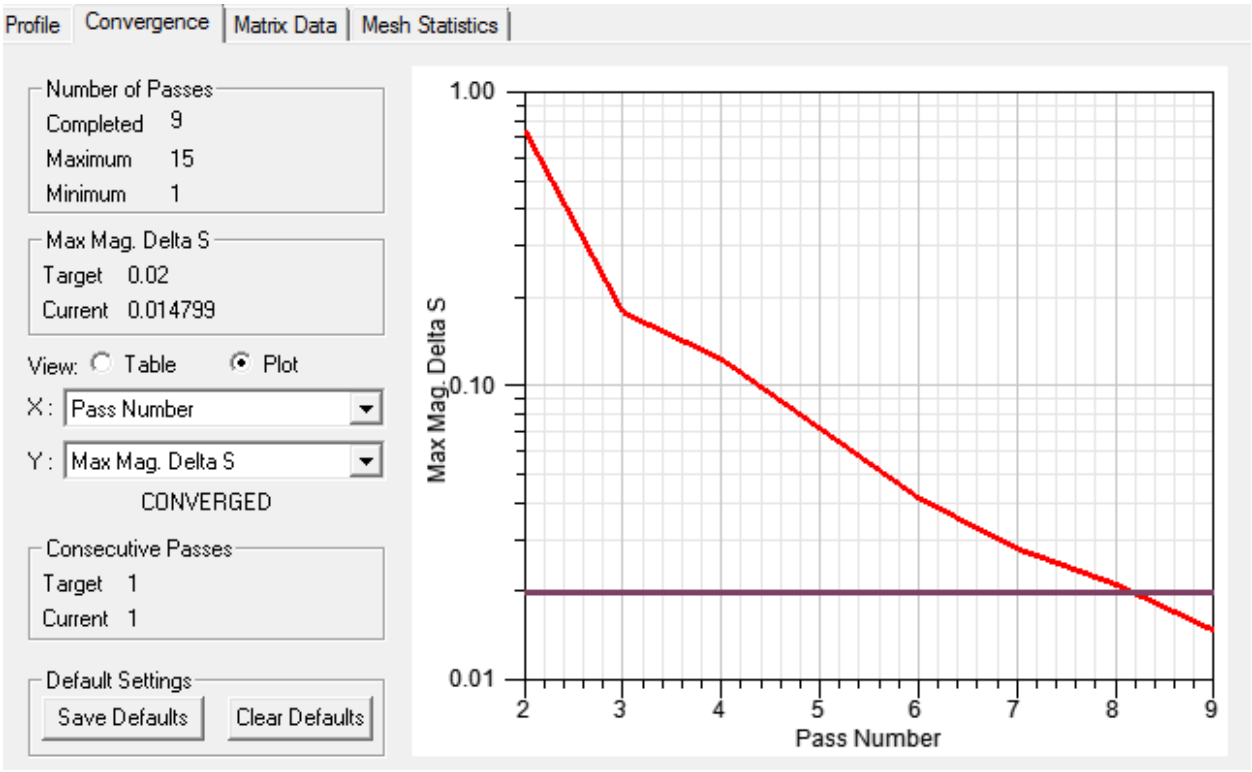
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Phase margin (deg) between passes.
- Maximum delta frequency between passes.

  If for the Solution Setup, you elected to **Use Matrix Convergence**, and selected specific table entries for the Magnitude and Phase, the **Convergence** tab also shows the following values with the Magnitude Margin and Phase Margin:

- Max Delta (Mag S)
- Max Delta (Phase S)

4. Select **Table** to display the convergence data in table format or **Plot** to plot the convergence data on a rectangular (X - Y) plot.



5. If you select **Save Defaults**, the settings for Table vs. Plot, and for Plot, the X and Y axis selections, those settings apply, based on the design-type, each time you open the desktop. You can also select **Clear Defaults** to reset to the original settings.

Note:

If you receive a message that the eigenmodes have not converged, it may indicate that the existing mesh is too coarse. You may need to refine the mesh.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Viewing the Number of Completed Passes

At any time during the solution process, you can view the number of adaptive passes (solve — error analysis — refine cycles) that have been completed and that have yet to be completed. When the solution is complete, you can view the number of adaptive passes that were performed. If the solution converged within the specified stopping criteria, fewer passes than requested may have been performed.

To view the number of passes:

- In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

The **Solution Data** window appears. The **Convergence** tab is selected.

The number of completed and remaining passes is listed in the **Number of Passes** area.

Viewing the Max Magnitude of Delta S Between Passes

For solutions with ports.

At any time during or after the solution process, you can view the maximum change in the magnitude of the S-parameters between two consecutive passes. This information is available after two or more passes are completed.

To view the maximum magnitude of delta S between passes:

- In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

The **Solution Data** window appears. The **Convergence** tab is selected.

The **Max. Mag. Delta S** column lists the maximum magnitude of delta S from one pass to the next.

The **Max. Mag. Delta S** area lists the target change in magnitude of delta S and the change in magnitude of delta S between the last two solved passes.

> **Note:**
>
> Delta S is computed on the appropriate S-parameters - modal or terminal - after the S-parameters have been de-embedded and renormalized.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

You can renormalize mathematically, without having to re-solve, by accessing the postprocessing tab on the port definition panel and de-selecting the **Deembed** selection box.

Viewing the Delta Magnitude Energy

For designs with voltage sources, current sources, or incident waves. Not applicable to designs with ports.

At any time during or after the solution process, you can view the difference in the relative energy error from one adaptive pass to the next. The change in the magnitude of delta energy is available after two or more passes are completed.

To view the delta magnitude E between passes:

- In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

The **Solution Data** window appears. The **Convergence** tab is selected.

The **Delta Mag. Energy** column lists the delta energy from one pass to the next.

The **Delta Mag. Energy** area lists the target change in delta energy and the change in delta Energy between the last two solved passes.

Viewing the Magnitude Margin

For solutions in which convergence criteria for specific S-matrix entries were specified.

At any time during or after the solution process, you can view the solution's proximity to the target delta magnitude, which was specified in the **Matrix Convergence** dialog box. The magnitude margin is available after two or more passes are completed.

To view the magnitude margin between passes:

- In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

The **Solution Data** window appears. The **Convergence** tab is selected.

The **Magnitude Margin** column lists the magnitude margin from one pass to the next.

Viewing the Phase Margin

For solutions in which convergence criteria for specific S-matrix entries were specified.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

At any time during or after the solution process, you can view the solution's proximity to the target delta phase, which was specified in the **Matrix Convergence** dialog box. The phase margin is available after two or more passes are completed.

To view the phase margin between passes:

- In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

The **Solution Data** window appears. The **Convergence** tab is selected.

The **Phase Margin** column lists the phase margin from one pass to the next.

> **Note:**
>
> When the Mag S becomes small (near to zero) its phase becomes indefinite and insignificant due to mathematical issues so that Phase Margin will be discarded.

Viewing the Max Delta (Mag S)

For solutions in which convergence criteria for specific S-matrix entries were specified.

At any time during or after the solution process, you can view the maximum difference of the S matrix magnitudes between two consecutive passes. The Max Delta (Mag S) is available after two or more passes are completed.

To view the Mag S between passes:

- In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

The **Solution Data** window appears. The **Convergence** tab is selected.

The **Max Delta (Mag S)** column lists the Max Delta (Mag S) from one pass to the next.

Viewing the Max Delta (Phase S)

For solutions in which convergence criteria for specific S-matrix entries were specified.

At any time during or after the solution process, you can view the maximum difference of the S Matrix phase between two consecutive passes. The Max Delta (Phase S) is available after two or more passes are completed.

To view the Max Delta (Phase S) between passes:

- In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

The **Solution Data** window appears. The **Convergence** tab is selected.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Max Delta (Phase S)** column lists the Max Delta (Phase S) from one pass to the next.

Viewing the Maximum Delta Frequency

For Eigenmode solutions.

At any time during the solution process, you can view the maximum delta frequency, the largest percent difference in the resonant frequencies from one adaptive pass to the next. It is a measure of the stability of the computed frequencies from pass to pass and is available after two or more passes are completed.

To view the maximum delta frequency between passes:

- In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

The **Solution Data** window appears. The **Convergence** tab is selected.

The **Max Delta Freq. %** column lists the maximum delta frequency from one pass to the next.

The **Max Delta Freq. %** area lists the target maximum delta frequency and the maximum delta frequency between the last two solved passes.

Plotting Convergence Data

To display convergence data vs. pass on a rectangular (x - y) plot:

1. In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

The **Solution Data** window appears. The **Convergence** tab is selected.

2. In the lower-left corner of the window, select **Plot** as the view type.
3. Select the data you want to plot on the x-axis from the **X** drop-down menu.
4. Select the data type you want to plot on the y-axis from the **Y** drop-down list.

The x -y plot appears in the view window.

Viewing a Solution Profile

At any time during or after the solution process, you can examine the computing resources or profile data that were used by Ansys Electronics Desktop solvers during the analysis. The profile data is essentially a log of the tasks performed by Ansys Electronics Desktop during analysis. The log indicates the length of time each task took and how much physical and disk memory was required.

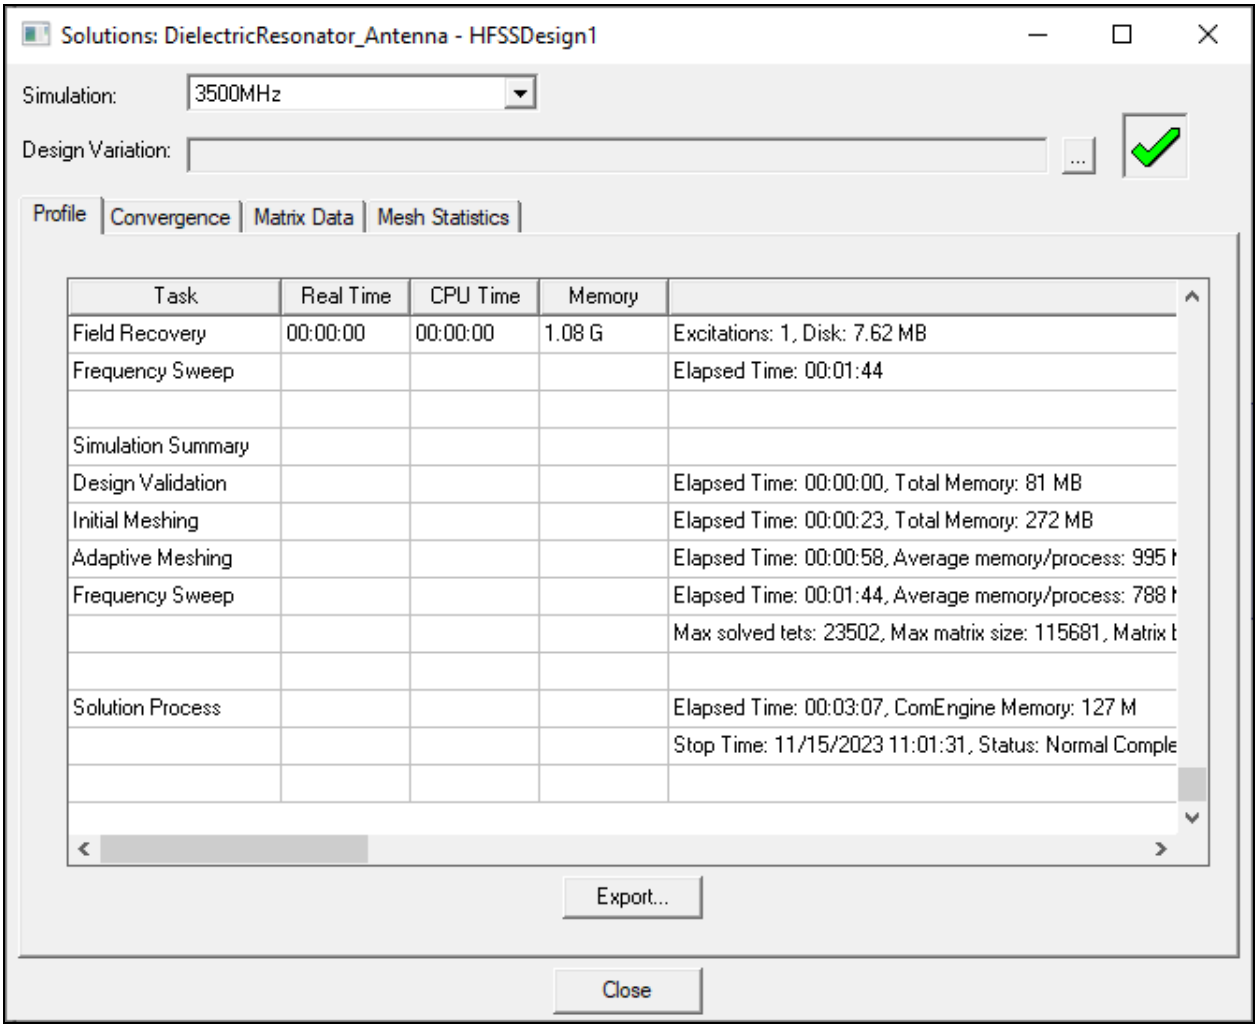
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the project tree, right-click a solution setup, and select **Profile**.

   The **Solutions** dialog box appears, with the **Profile** tab selected. You can also click the **Solution Data** icon on the ribbon to open the **Solutions** dialog box, and then select the **Profile** tab.

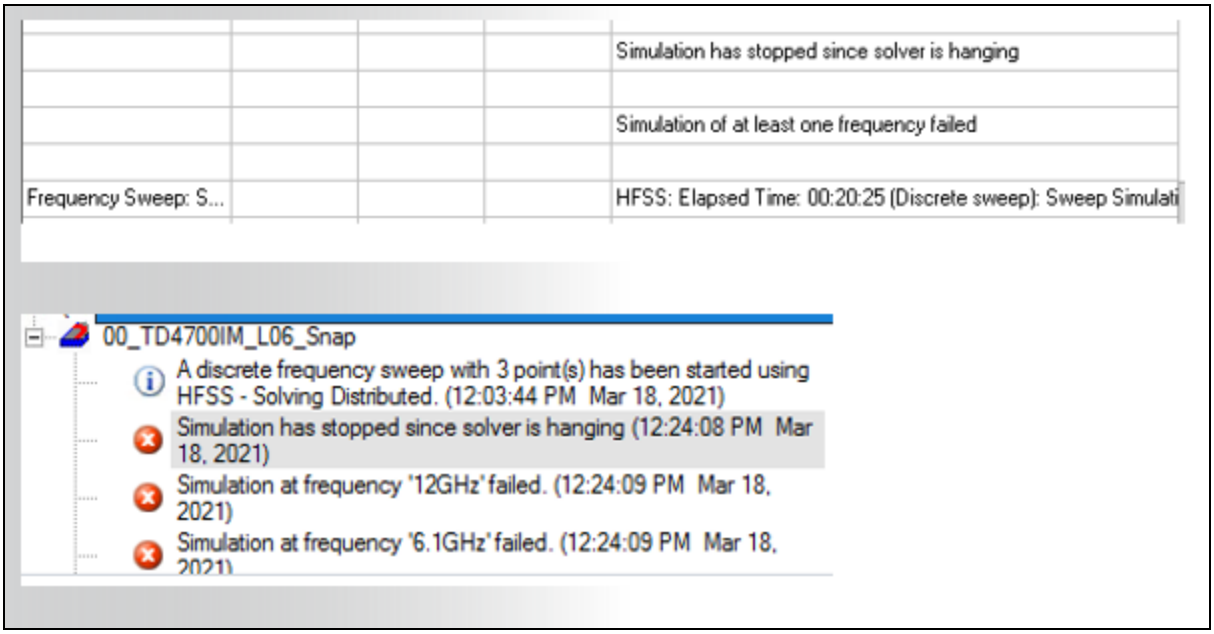
   The displayed data depends on the type of problem and solution setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If the simulation hangs, equivalent messages appear in the Message window and the Solution **Profile** tab.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. If one or more dependent setups exist, you can select the desired profile information from the **Simulation** drop-down menu. In general, the information displayed includes:

Task	Lists the type of task that was performed. Tasks include Start, various Mesh tasks, Simulation Setup, Port Adaptation, Adaptive Pass tasks, including simulation setup, Matrix Assembly, Solver tasks, and Field Recovery, Sweep tasks, and Solution Process summary and Totals for time.
Real Time	The difference in time between the start of the task and the end of the task (elapsed time).
CPU Time	The amount of CPU time required to perform the task.
Memory	The peak amount of physical memory (RAM) used by the individual executable running the task. The memory is freed for other uses after each task is complete.
Information	General information about the solution (for example, the number of tetrahedra used in the mesh, disk use, solver information, sweep information, and totals).

The matrix solver writes specific information in some of these fields, as outlined below:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Task	The matrix solver task reports the type of solution performed by the solver, based on the physics of the problem. It has the form "Solver *pdsn*" (e.g., Solver MRS2, Solver DCS4-L2), where: • *p*, the precision type is: M (mixed for direct solver), or Mxx (for distributed direct solver), or D (double for direct and iterative solver) or E (extended precisions solve) • *d*, the matrix data type is: R (real) or C (complex) • *s*, the symmetry type is: S (symmetric), A (asymmetric), or H (hermitian) • *n*, the number of processors used. You specify the number of available processors on the local machine in the solver options. If a solve does not use all available processors (local or distributed), the number reported may be less than the number available. If a simulation uses the iterative solver, the Solver designation can include a level indicator appended. to an Iterative solver designation (L2 in the example above). The higher the Level number the lower the memory, you will never see L1 (this would be equivalent to direct solver. And a first order solve will only display L2 since it only has one level of order to go down for preconditioning. A second or mixed order solve may display L3 depending on the mesh quality. If the solver switches from the Iterative Solver to the Matrix solver, you see a Matrix solver warning: Switch from Iterative Solver to Direct Solver.
Information	The matrix solver information line includes, for example, Disk = 0 KBytes, matrix size 11137 , matrix bandwidth 20.3. • **Disk** – The amount of hard disk space used during the calculation of the matrix solution. If the disk usage for matrix solver is non-zero in profile, it usually indicates off-core matrix solver. If the matrix solver must solve off-core, smaller blocks of the data to be solved are created on disk, each block is then solved in physical memory, and then the matrix solution is reassembled. As a result of this additional processing, the time required to calculate a solution is higher. • **Matrix size** – The size of the matrix that was solved (the number of unknowns) • **Matrix bandwidth** – An FEM matrix is a sparse matrix. The solver only stores the non-zero entries. The matrix bandwidth is the average number of non-zeros per row. It gives an idea of the sparsity of a FEM matrix.Storage for the sparse matrix is proportional to the total number of nonzeros = #rows x bandwidth. The higher the bases order, the larger the bandwidth. • **Iterations** – For the Iterative Solver.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To export the profile data:

1. Open the **Solutions** dialog box and select the **Profile** tab.
2. Click **Export Profile**.

   This opens a file save dialog box that lets you provide a file name and location.

3. Click **Save**.

   The data is saved in a text file with a .prof extension.

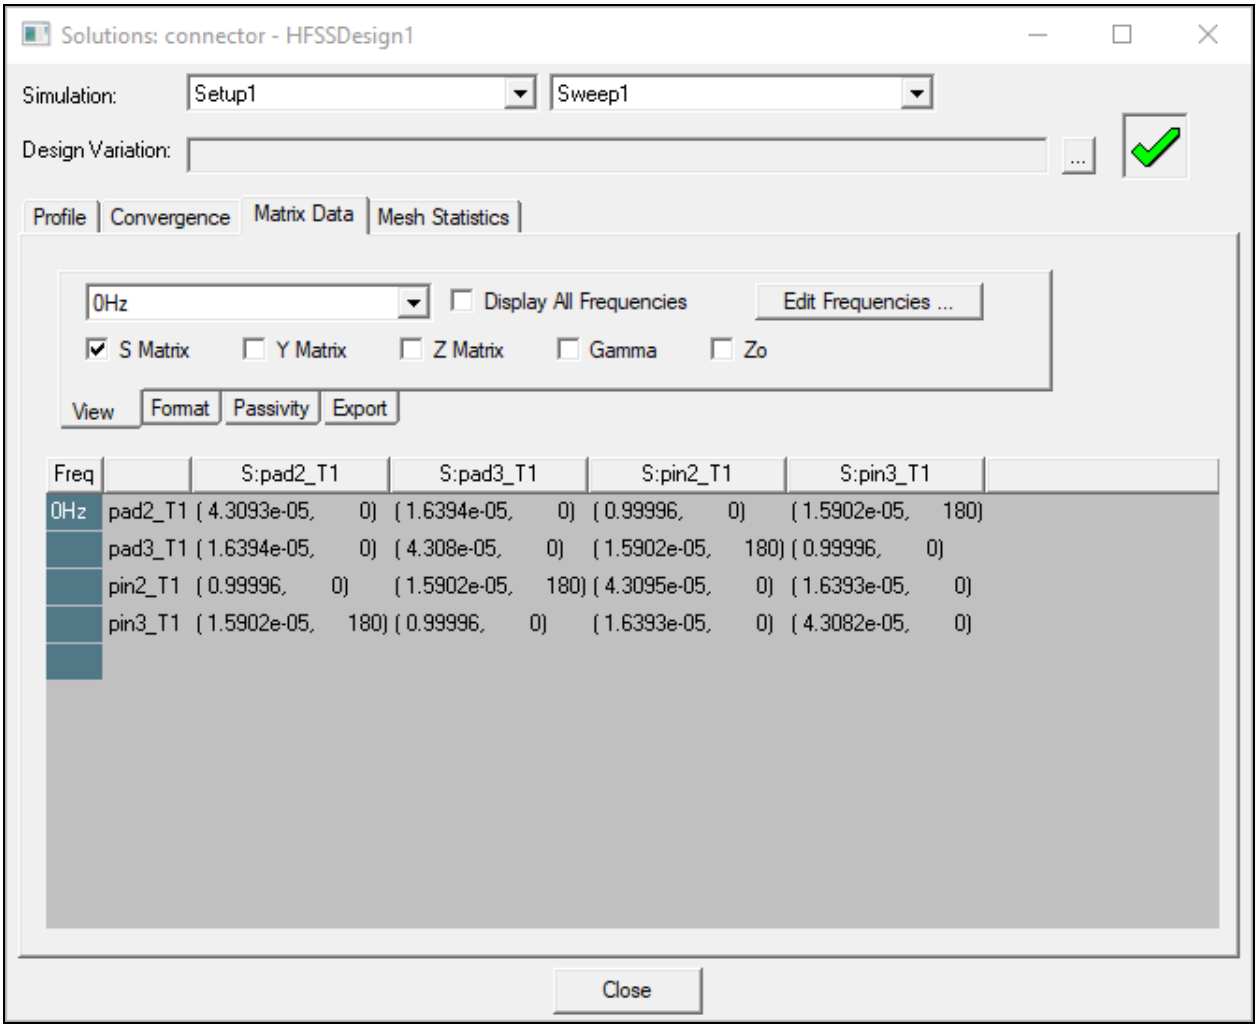
Viewing Matrix Data

To view matrices computed for the S-parameters, impedance, and propagation constants during each adaptive, non-adaptive, or sweep solution:

1. In the **Project** tree, right-click the solution setup of interest, and then click **Matrix Data** on the shortcut menu, or on the **Results** tab of the ribbon, click **Solution Data**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Solution Data** dialog box appears. The **Matrix Data** tab is selected.

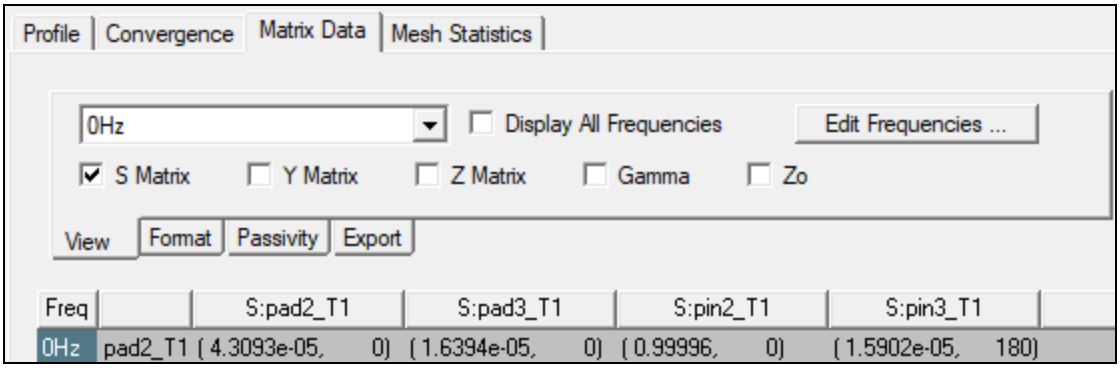


2. Select which pass to view in the drop down list to the right of the **Simulation** list. To select a specific adaptive pass:
    a. Choose **Adaptive Pass**.
    b. On the **View** tab, select the pass you want from the **Pass** list.
3. If design variations exist, in the **Design Variation** text box, specify the design with the matrices you want to view.

    Optionally, choose a design variation solved during an Optimetrics analysis from the **Set Design Variation** dialog box. This lists all the solved variations in the design. This dialog box is accessible from the **Solution Data** window by clicking the ellipsis button on the right of the Design Variation field, and via the **[solver]** > **Results** > **Apply Solved Variation** command.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. In the **Simulation** drop-down menu, click the solution setup and solved pass - adaptive, single frequency solution, or frequency sweep - for which you want to view matrices.
5. Select the type of matrix you want to view: **S-matrix**, **Y-matrix**, **Z-matrix**, **Gamma**, or **Zo** (characteristic impedance.) The available types depend on the solution type.



6. Select the solved frequencies to display:
   - To display the matrix entries for all solved frequencies, select **Display All Freqs**.

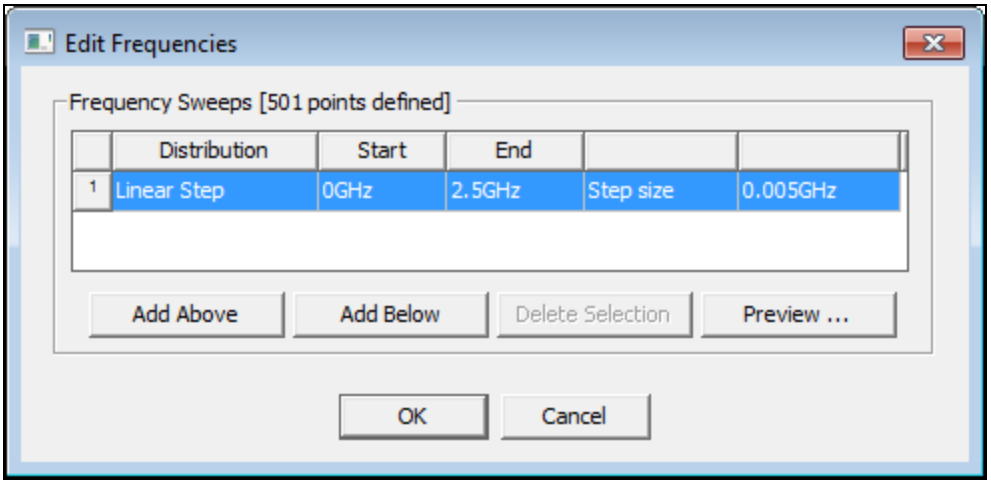
     If **Display All Freqs** is enabled, the drop-down frequency select list is disabled.
   - To show the matrix entries for a selected solved frequency, ensure that **Display All Freqs** unchecked and use the dropdown list to select the solved frequency for which you want to view matrix entries. You can use a scroll bar for selecting from long frequency lists.

     For adaptive passes, only the solution frequency specified in the **Solution Setup** dialog box is available. For frequency sweeps, the entire frequency range is available.
   - To insert or delete one or more displayed frequencies, click **Edit Frequencies**.

> **Note:**
>
> This command is only available if the sweep type is Fast or Interpolating.

Clicking **Edit Freqs** displays the **Edit Frequencies** dialog box. The current values are displayed in a table.

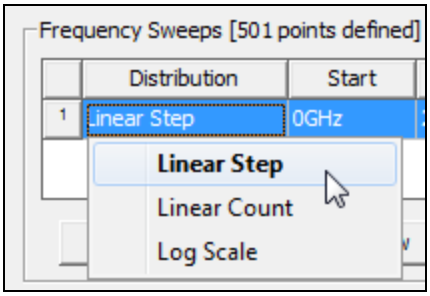
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note:

Changes to the Start value and End value cannot be outside of the initial range. No message is issued: rather the range is implicitly restricted.

Use the **Add Above** or **Add Below** button to add a new frequency to the table above or below the currently selected value. If no value, or the start value is selected, the new frequency repeats the current Start value and increments the count at the start a new row. You can select the type of distribution for a new Row by selecting from the drop down.

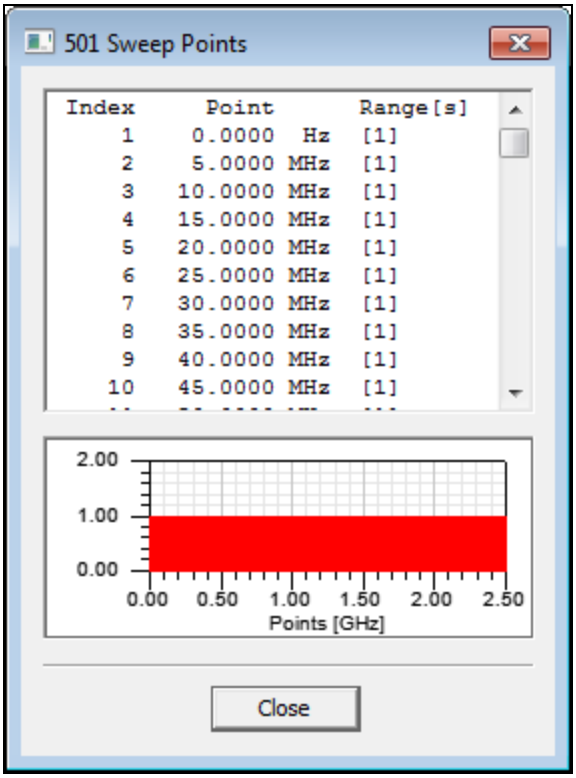


You can then edit the **Start** and **Stop** fields as appropriate for the new row.

The **Delete Selection** button enabled only if a value is selected. **Delete Selection** removes the selected value and decrements the Number of Values field.

The **Preview** button opens a dialog showing the defined sweep points.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



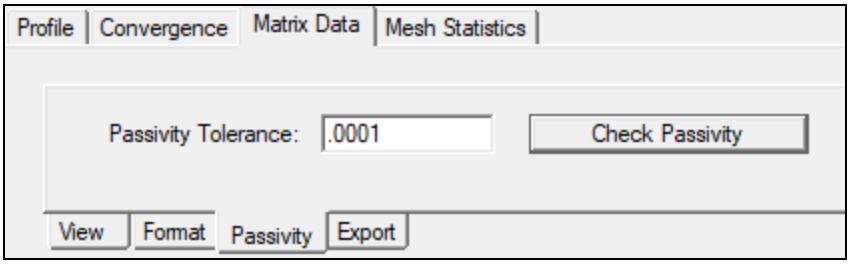
7. Select the display format — On the **Format** tab, select from the drop down menu which has the options **Magnitude/ Phase (deg)**, **Real/ Imaginary**, **dB/Phase (deg)**, **Magnitude**, **Phase (deg)**, **Real**, **Imaginary**, and **dB** — in which to display the matrix information and then in the next drop down menu, select **Terminal Data** or **Differential Pairs**.
8. Click **OK** to apply the changes to the **Solutions** dialog **Matrix Data** tab and close the **Edit Sweep** dialog box, or **Cancel** to close the dialog without applying the changes.

   If you choose to export the matrix data for the Fast or Interpolating sweep after modifying the frequencies in the **Edit Frequencies** dialog box, only those frequencies displayed under the **Matrix Data** tab will be exported.

   The data is displayed in the table. By default, wave ports are listed in alphabetical, then numerical order, just as they appear in the excitation tree. To change the port order, change setting for Default Matrix sort order in the HFSS General options. You may also want see how you can Reorder Matrix Data.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9. Optionally, select the **Passivity** tab and **Check Passivity**.



This passivity check tests whether the S-parameter data from HFSS is passive or not. If the S-Matrix is not passive at one or more frequencies, this check displays a dialog saying that the solution is passive for all frequencies or that identifies the worst frequency violation and identifies the passivity in that case. A uniform renormalization of 50 ohms is performed on the solution data for Passivity checking.

Selecting the Matrix Display Format

The **Solutions** dialog offers a range of formats for the Matrix display. The available formats depend on the matrix type being displayed. When selected, dB formatting only applies to S - matrix data, even if other matrix types are displayed. The column heads in the display identify the format for the matrix type. You can display matrix data in the following formats.

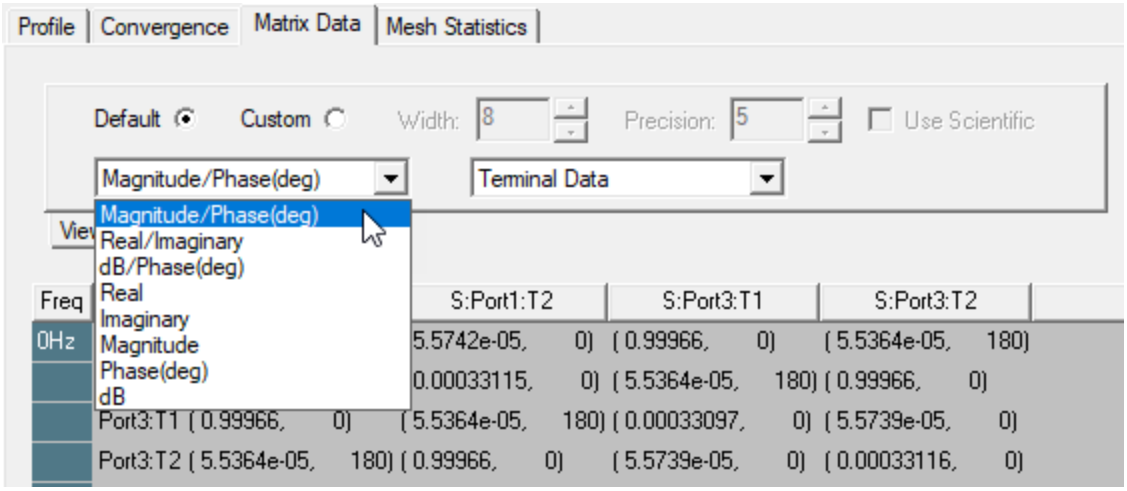
Magnitude, Phase (deg)	Displays the magnitude and phase (in degrees) of the matrix type.
Real, Imaginary	Displays the real and imaginary parts of the matrix type.
dB, Phase (deg)	Displays the magnitude in decibels and phase in degrees of the matrix type.
Magnitude	Displays the magnitude of the matrix type.
Phase (deg)	Displays the phase in degrees of the matrix type.
Real	Displays the real parts of the matrix type.
Imaginary	Displays the imaginary parts of the matrix type.
dB	Displays the magnitude in decibels of the matrix type.

After you select a format, choose whether to display terminal data or differential pairs.

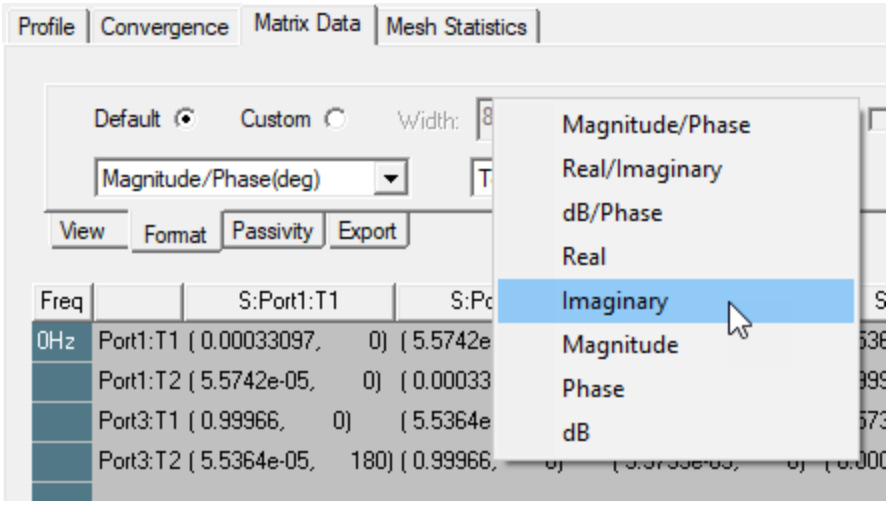
In the **Matrix Data** tab of the **Solutions** window, open the **Format** tab to select the display format in one of two ways:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Select the drop-down menus under the formats:



- right-click the column headings to display a pop-up format menu.



- Selecting from this menu also adds the name of the selected format to the column head, if the format is anything other than dB.

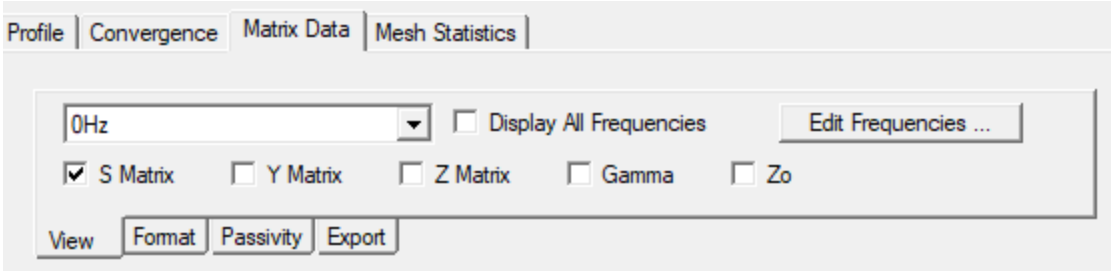
Freq		S:pad2_T1 (Imag)	S:pad3_T1 (Imag)	S:pin2_T1 (Imag)	S:pin3_T1 (Imag)
5 (GHz)	pad2_T1	-0.10414	0.056068	-0.75051	-0.1483
	pad3_T1	0.056068	-0.104	-0.14825	-0.75036
	pin2_T1	-0.75051	-0.14825	-0.16368	0.064232
	pin3_T1	-0.1483	-0.75036	0.064232	-0.1635

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

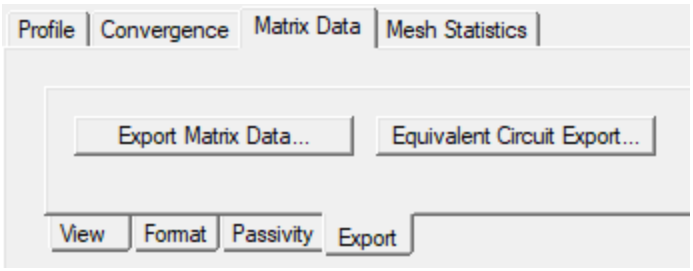
Exporting Matrix Data

1. In the project tree, right-click the solution setup of interest, and then click **Matrix Data** on the shortcut menu.

The **Solution Data** window appears. The **Matrix Data** tab is selected. You can also access the **Solution Data** window from the **Results** tab on the ribbon by clicking the **Solution Data** icon.

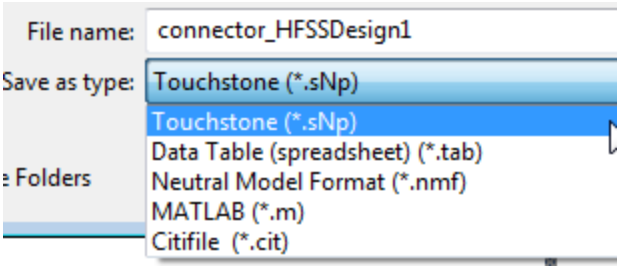


2. Select the type of matrix you want to view: **S-matrix**, **Y-matrix**, **Z-matrix**, **Gamma**, or **Zo** (characteristic impedance.)
3. Select the **Export** tab and click **Export Matrix Data**.



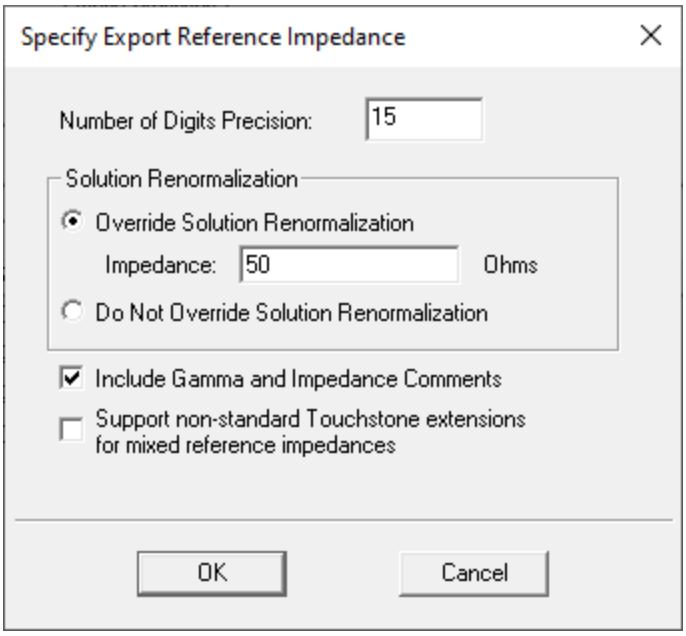
A file browser appears.

4. Type the name of the file you are exporting to in the **File name** text box.
5. Select one of the following file formats from the **Save as type** drop-down menu:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Format	Type	Description
(spreadsheet) *.tab	Data Table	A text file in which the elements of the S-matrix are arranged in a series of columns that are tab-separated and include a first row of headings. The file may be imported into a spreadsheet or similar utility.
***.sNp**	Touchstone	A Touchstone S-parameter file in which the number of ports is indicated by *n*. For example, a Touchstone file with one port would have the file extension .s1p. When you export this format, you are presented with a dialog.



You can specify:

- **Number of Digits Precision** (Default 15)
- **Override Solution Renormalization**. This refers to overriding the renormalization impedances that may have been asked for in the port setup. If so, the export renormalizes impedance
- **Do Not Override Solution Renormalization.** This leaves any port setup renormalization options in place, and grays out the Impedance setting on the dialog.
- **Include Gamma and Impedance Comments**
- **Support for non-standard Touchstone extensions for mixed reference impedances**. Writing gamma and Z_0 is not Touchstone standard, but rather an HFSS "feature" that only HFSS will

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

		recognize.
		If you want to export raw S-Parameter data for later use, you may choose to not renormalize the solution.
		If all ports and associated modes/terminals are normalized to the same impedance and you choose **Do Not Override Solution Renormalization** during export, the Touchstone file header will indicate the normalized impedance.
		The comment header in the Touchstone file lists the port and mode numbers to show which column contains which port name (in case of confusion between alphabetical and force repriority ordering of ports and associated modes).
		`! Touchstone file exported from HFSS 2025.2`
		`! File: D:/Program Files/AnsysEM/v242/Examples/HFSS/Signal Integrity/package.aedt`
		`! Generated: 1:56:02 PM Apr 01, 2020`
		`! Design: HFSSDesign1`
		`! Project: package`
		`! Setup: Setup1`
		`! Solution: Sweep1`
		`!`
		`# GHZ S MA R 50.000000`
		`! Terminal data exported`
		`! Port[1] = P01__NET179__T1`
		`! Port[2] = P02__NET178__T1`
		`! Port[3] = P03__NET178__T1`
		`! Port[4] = P04__NET179__T1`

***.nmf**	Neutral Model format	Neutral Model file format defined by the MAFET Consortium. When you save to this format, if the design includes variables, you are presented with the NMF Parameters dialog that lets you select which variables to select as parameters in the NMF file. Non-selected variables will be give the constant value shown. You are then presented a dialog that lets you specify the number of digits precision for the renormalizing impedance.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

***.m**	MATLAB	The Mathworks' MATLAB file in which the elements of the S-, Y-, or Z-matrix are arranged in a series of rows. Matlab only allows creation of complex numbers by specifying real and imaginary parts, not by specifying magnitude and phase.
***.cit**	Citifile	Common Instrumentation Transfer and Interchange file format. It is an ASCII format defined by instrument and CAE designers.

> **Note:**
>
> For Touchstone files, you no longer see a **Combine Sweeps** option on the **Export Network Data** solution dialog box. This is because the current Sweep setup allows you to define multiple sweeps for a single simulation, meaning any needed combining is defined with the sweep setup.

6. Click **Save**.

The data is exported to the file.

- By default, wave ports are listed in alphabetical, then numerical order, just as they appear in the excitation tree. You can change this order to creation order and back without invalidating the solution on the HFSS Options dialog box.
- If you select Touchstone format, you are first presented with a dialog in which you can specify the Number of Digits precision, and Override the Solution Renormalization. If so, you can specify the export renormalizing impedance (an integer value). Here you also can specify and whether to include **Gamma and Impedance Comments**, and **Number of Digits Precision** (Default 15).
- If you select Neutral File Format, you are presented with a **Specify Export Renormalizing Impedance** dialog that lets you specify the Number of digits precision for the save file.

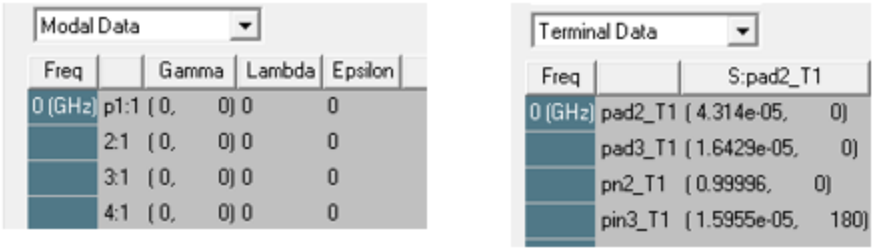
> **Note:**
>
> If you modify the display of solved frequencies in an Interpolating or Fast sweep under the **Matrix Data** tab (by clicking **Edit Freqs** and then modifying the values in the **Edit Sweep** dialog box,) only those frequencies listed will be exported to the file.

Renaming Matrix Data

In the project tree, you can right-click a port excitation to rename it.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When you rename a port excitation, the associated Matrix data is reordered so that it can be presented in the same manner. The reordering is done to match the tree-sort order presented for the ports (renamed matrix data is reordered so that alphabetic values appear before numeric values).



Exports of the matrix data are ordered in the same manner. This reordering is conducted as part of post processing and does not force a re-solve.

Reordering Matrix Data

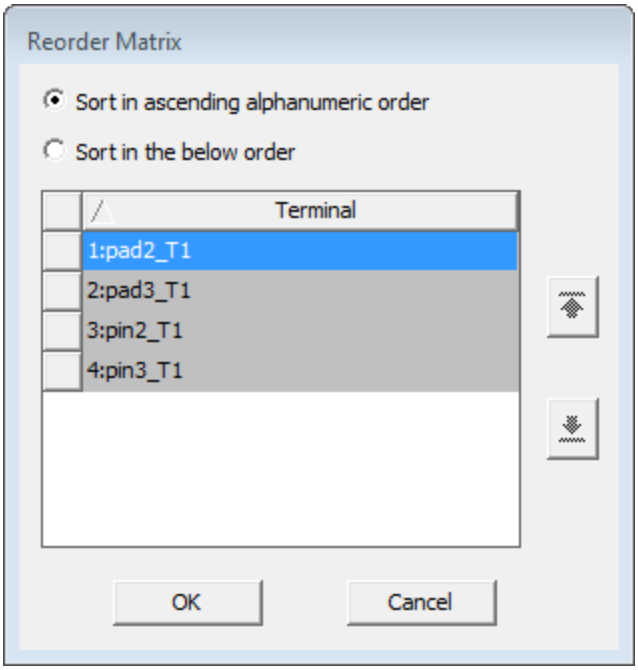
HFSS lets you reorder the matrix data as a post-processing step.

1. To re-order the matrix data, either as the default ascending alphanumeric order, or a user specified order, click **HFSS>Excitations>Reorder Matrix**, or right-click Excitations in the Project tree, and click **Reorder Matrix** on the shortcut menu.

This displays the **Reorder Matrix** dialog. It lists the ports for a modal solution, or the terminals for a terminal solution. For Transient solutions, the dialog displays separate lists for

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

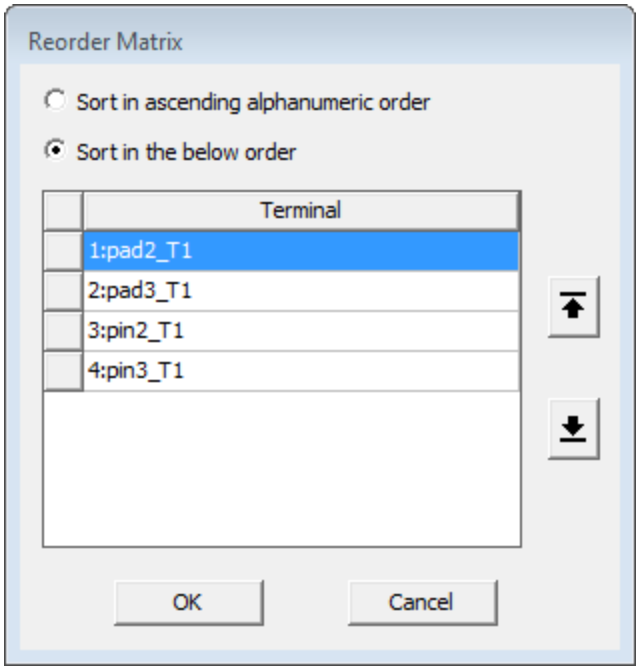
Active and Passive ports.



2. You can select the radio button for **Sort in ascending alphanumeric order**, or **Sort in the below order**.

If you select **Sort in the below order**, you can select any port or terminal to enable the up and down arrow keys. Use the keys to move the ports into any desired order. In the case of Transient, the arrow keys operate only within a partition, that is only within Active or Passive lists.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can also use Ctrl+click to select multiple arbitrary ports, or hold Shift to select a range of ports. Clicking outside the list deselects all selections.

Note:

If there are differential pairs, the sort order is still specified) in terms of the underlying terminal names, but the entries that make up the pair should appear in the appropriate sort location for the terminals that are used to define them.

3. Click **OK** to accept the order specified.

For Transient solutions, removing an active source will not affect the solve but might affect the matrix order. Adding an active source will require a resolve if that source has not already been solved.

Exporting Equivalent Circuit Data

You can export S-parameter data from a Driven Terminal solution to PSpice, HSPICE, Spectre or Maxwell Spice format. Importing the new data file to PSpice, HSPICE, Spectre or Maxwell Spice will enable you to include wave effects in the circuit simulations. You can also export a W-Element model for a port.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

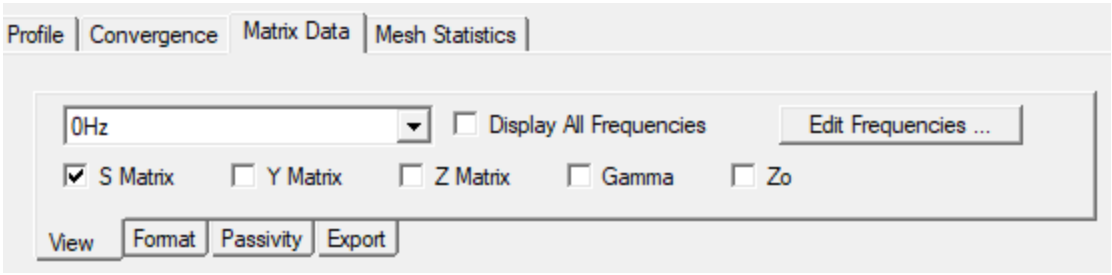
You must have a frequency sweep solution and five or more frequency points to successfully export an equivalent circuit data file. See the *Choosing Frequencies for Full-Wave SPICE* topic of the help for suggestions about the frequency range of the sweep.

The GUI lets you export full-wave Spice for a model that contains differential pairs, but it will silently export the data in its original single-ended form. The full-wave Spice model is a "broadband" equivalent circuit (that is, its S-parameters match those of the solution across the whole frequency sweep range.)

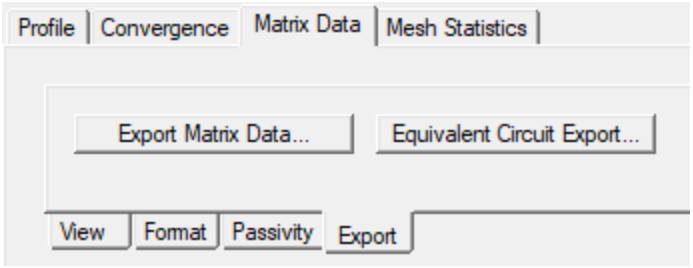
Certain discrete sweeps permit Full-Wave SPICE exports. It is allowed if the discrete data is evenly spaced, includes DC, and has at least 500 frequency points.

1. In the project tree, right-click the solution setup of interest, and then click **Matrix Data** on the shortcut menu.

The **Solution Data** window appears. The **Matrix Data** tab is selected. You can also access the **Solution Data** dialog from the **Results** tab on the ribbon by clicking the **Solution Data** icon.



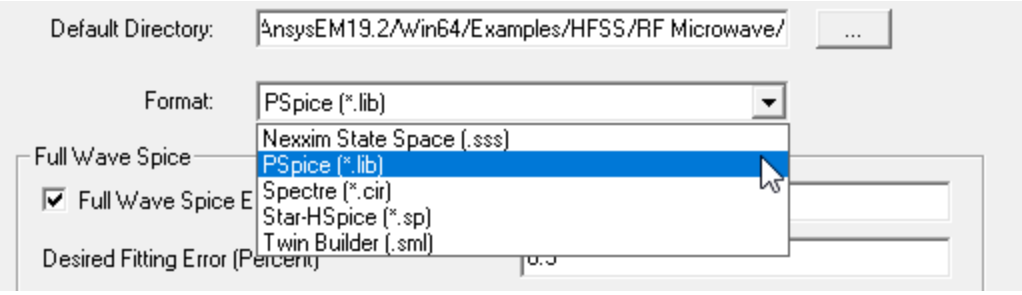
2. Select the **Export** tab and Click **Equivalent Circuit Export**.



The **Equivalent Circuit Export Options** dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Type the name or browse to the directory in which you want to store the data.



4. Click one of the following formats in the **Format** list:

   PSpice (*.lib)
   Nexxim State Space (.sss)
   Spectre (*.cir)
   Star HSpice (*.sp)
   Twin Builder (.sml)

Your format selection affects the options available under **Full Wave Spice Export**. When Twin Builder format is requested, both *.sml and *.png are created. The latter contains the image in GIF format.

> **Note:**
>
> The Export to Twin Builder here does not use the same settings as Nexxim or Network Data Explorer. If you intend to export to Twin Builder, you should use the NdExplorer.

5. If the **Full-Wave Spice Export** check box is enabled, you can select it. Checking the box enables the text field for the file name, and depending on the format selection, other options may be enabled.
6. Desired Fitting Error (percent) has a default value of 0.5. You can edit this.
7. Maximum Order has a default value of 10000.
8. HFSS supports Full Wave Spice Export from a driven modal design as long as all ports have exactly one mode each. However, HFSS does not support definition of differential pairs in a driven modal design.
9. By default **Use Common Ground** is checked and produces circuit models with a "common" (suppressed) ground terminal. Uncheck Use Command Ground to apply one negative reference terminal per port.
10. Optionally, select **Enforce Passivity**. Selecting this enforces passivity in the output file. Passive devices can only dissipate or temporarily store energy, but never generate it.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(You can also check passivity from the **Matrix Data** tab using the Check Passivity button.)

This option is useful in cases where the transient simulation fails due to passivity violations in the circuit model. This circuit model is based on fitting a rational function to the S-parameter data computed by the field solver. Small errors in the data fitting can result in non-passive behavior. Selecting the **Enforce Passivity** option will take more CPU time, but ensures that the resulting model will be passive. The **Enforce Passivity** check box uses "Iterated fitting of passivity violations (IFPV)" method to do the passivity enforcement.

The passivity check tests whether the S-parameter data from HFSS is passive or not. For more information see Passivity.

11. Optionally, select **Lumped Element Export (Low Bandwidth)** if you want to save the data as a low-frequency circuit model using simple lumped elements (resistors, capacitors, inductors, and dependent current sources). The low-bandwidth model is only going to be accurate in a limited frequency range around the adaptive solution frequency

    This option is not enabled for Spectre export.

12. Optionally, select **Partial Fraction Expansion for Matlab** if you want to specify a file that expands the partial fractions for use in Matlab. The partial fractions involved describe the frequency response of the low-bandwidth model from the previous step.
13. You can also select **Combine Sweeps** to select and combine available sweeps into a single output file.

    By option, for Nexxim State Space, Spectre, and Star-HSpice, you can Export W-Element Data.

14. Click **OK**.

    The S-matrices are written to the data file that you specified in the equivalent circuit data format.

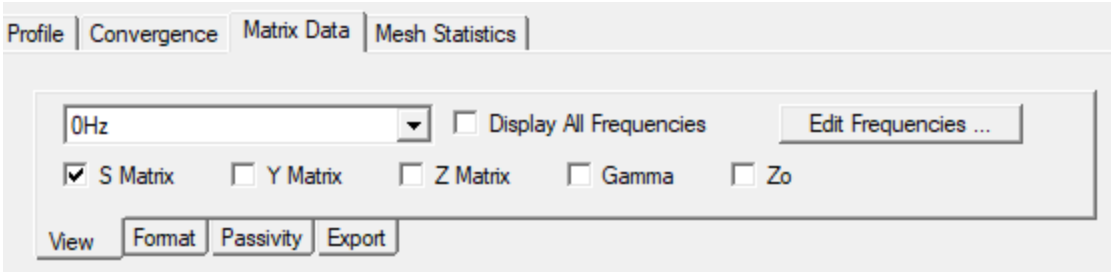
Exporting W-element Data

It is possible to extract a W-element model for a port. This W-element model can be used in a SPICE model to represent a length of transmission line of the same cross-section as the port. A W-element model can be extracted for a port only solution and for a full 3D solution.

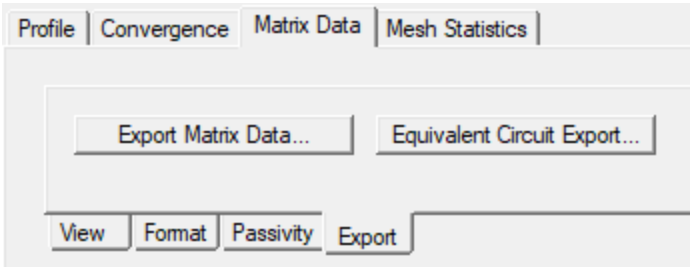
1. In the project tree, right-click the solution setup of interest, and then click **Matrix Data** on the shortcut menu.

   The **Solution Data** window appears. The **Matrix Data** tab is selected. You can also access the **Solution Data** dialog from the **Results** tab on the ribbon by clicking the **Solution Data** icon.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

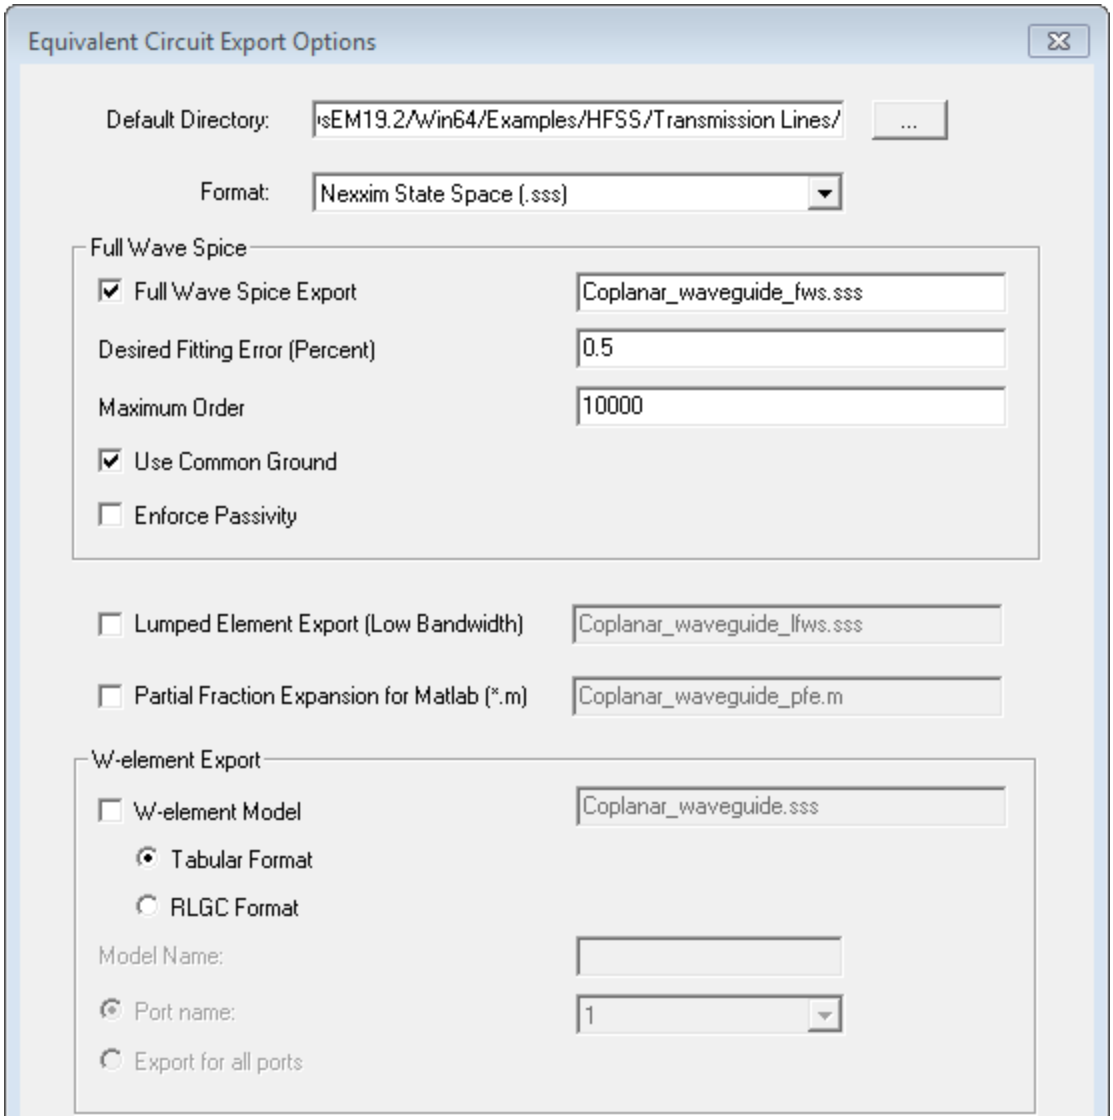


2. Select the **Export** tab and click **Equivalent Circuit Export**.

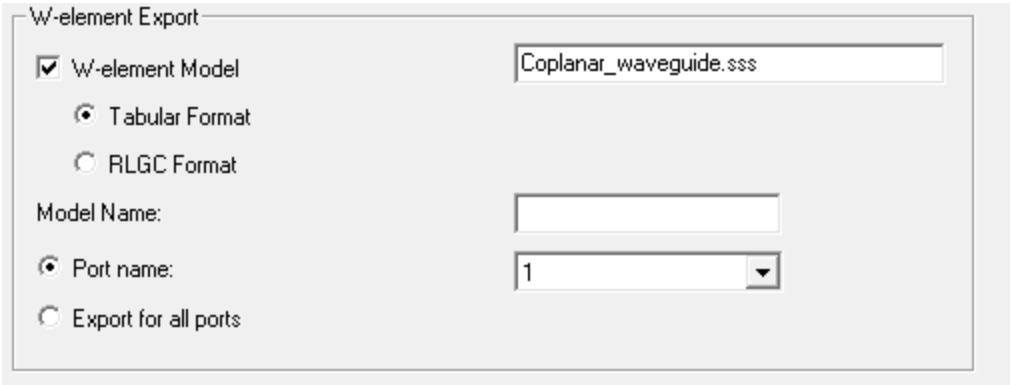


The **Equivalent Circuit Export Options** dialog box appears. If you select the format as Nexxim State Space, Spectre, or Star-HSpice, at the bottom of the dialog you see the W-element model check box enabled.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Click the W-element model check box to enable the W-element fields.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. The W-element model name field has the project name by default. You can change this if desired.
5. Choose the format as Tabular Format (the default) or RGLC format for W-element export.

Tabular Format: provides a unique RLGC model for each frequency in the solution.

RLGC Format: provides a RLGC fit over a frequency range based on Ro, Lo, Go, Co, Rs and Gd parameters.

> **Note:**
>
> For the RLGC Format, if only a single frequency solution is selected (e.g., LastAdaptive) then Rs and Gd parameters are ignored.

6. In the **Model name** field, provide a model name.
7. Either select the port from the **Port Name** pull down, or, to export a W-element model for all ports, select the **Export for All Ports** radio button.
8. Click **OK**.

The W-element model is written to the data file that you specified.

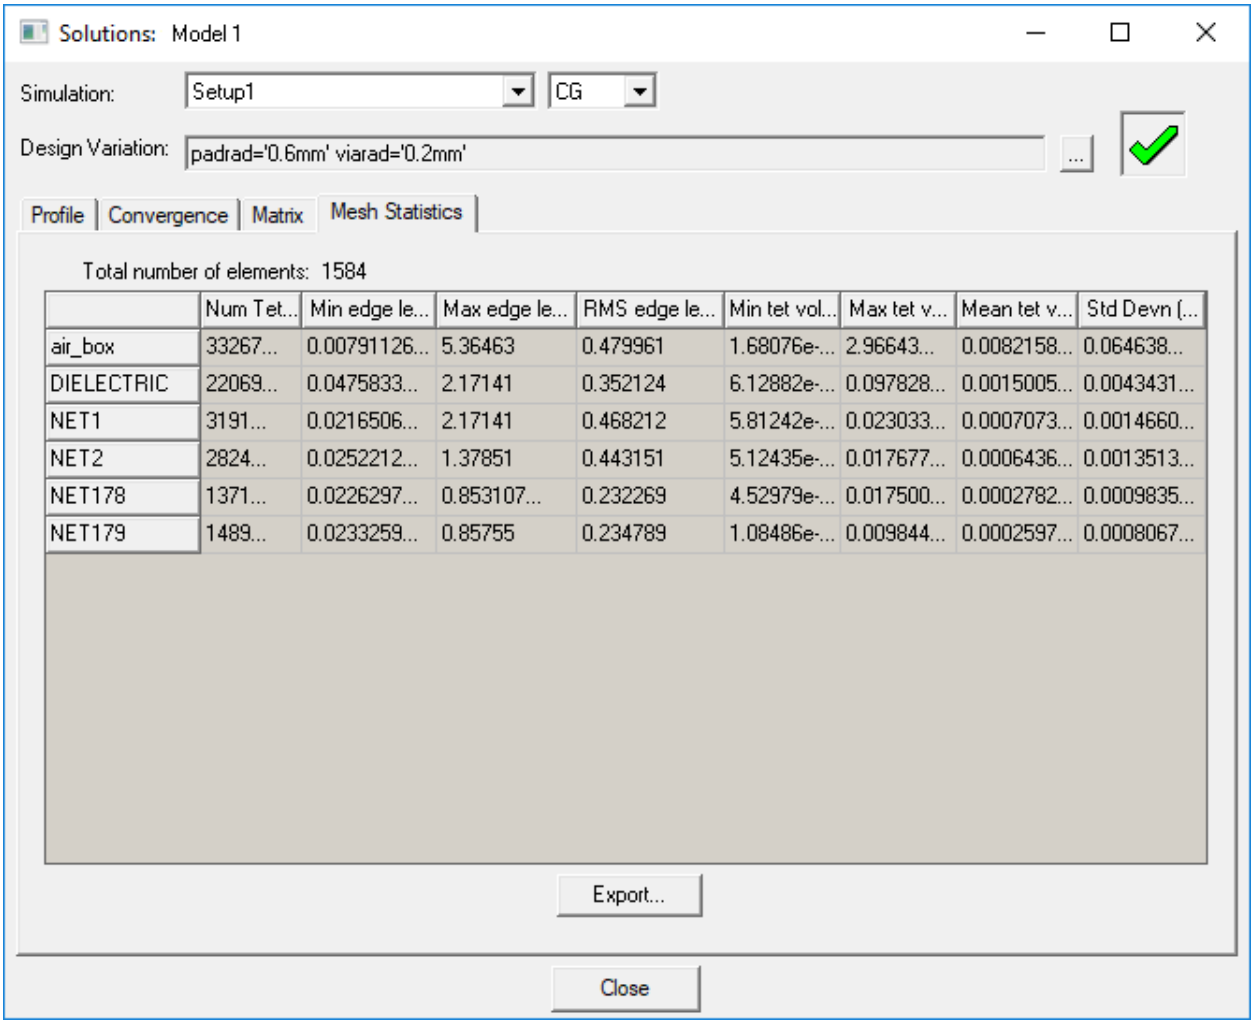
Viewing Mesh Statistics

To view an adaptive solution's mesh information, either during or after the solution process:

1. In the Project Tree, right-click the solution setup of interest, and then click **Mesh Statistics**. Alternately, click the **Solution Data** icon on **Results** tab of the ribbon.

   The **Solutions** window appears with the **Mesh Statistics** tab displayed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The table lists design elements and for each includes: Num Tets, Min edge length, Max edge length, RMS edge length, min tet vol., max tet vol., mean tet vol. and standard deviation (min elem area, max elem area, mean elem area and standard deviation for 2D designs).

For projects with HFSS-IE regions, the Mesh data table is similar but includes min, max, and mean element area information for triangles, instead of tet volume information for solve-inside portions of the project.

If mesh repairs have been performed, two additional columns appear in the table: **Recovered %** and **Repaired %**. These columns indicate the fraction of an object that was successfully recovered, and the fraction that needed some repair.

To sort mesh statistics by column from low to high values or vice-versa, click a column header. This displays a shadowed triangle pointing down to indicate a list ordered from highest to lowest; and a triangle pointing up to indicate a list ordered from lowest to highest. Clicking again inverts the order.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

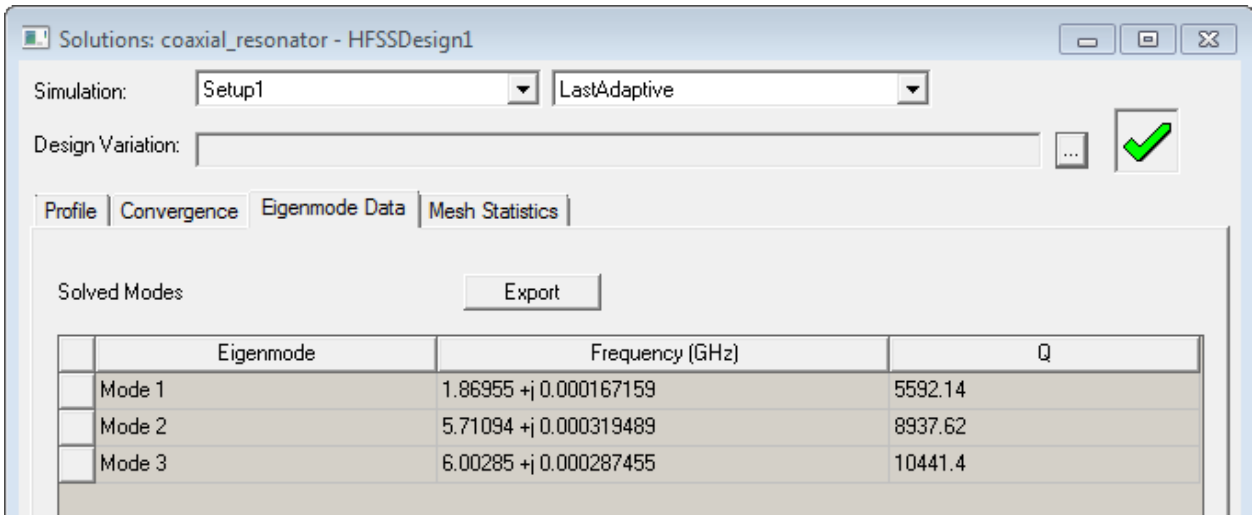
Click on a blank cell above the object list to invert the order of objects. In this case, the cell does not display a directional triangle.

Viewing Eigenmode Solution Data

To view the real and imaginary parts of the frequency and quality factor Q computed for each eigenmode:

1. In the project tree, right-click the solution setup of interest, and then click **Eigenmode Data** on the shortcut menu.

The **Solution Data** window appears. The **Eigenmode Data** tab is selected. You can also select the **Results** tab on the ribbon, and use the **Solution Data** icon.



The solved eigenmodes are listed in the table.

The **Frequency** column lists the real and (for lossy materials) imaginary parts of the frequency (or resonant frequency) for each solved eigenmode.The display uses the *re* + j *im* format.

For lossy Eigenmode solutions, a **Q** column appears, which lists the unloaded quality factor Q computed for each eigenmode.

2. In the **Simulation** drop-down menu, select the solution setup and solved pass - adaptive or single frequency solution - for which you want to view data.
3. To export the Eigenmode solutions to a text file with an eig extension, click the **Export** button.

This displays **Save As** dialog box. You can provide a file name, and if desired, change to a non-default location. click **Save** to save the text file and close the Save As dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

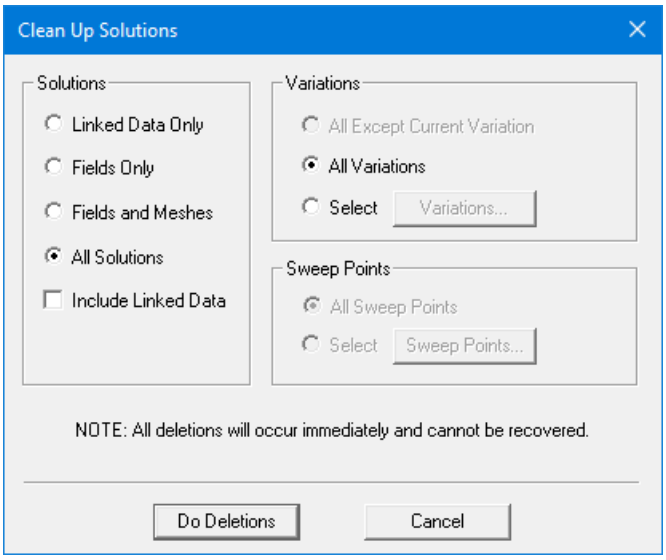
Deleting Solution Data

You can use **Clean Up Solutions** to selectively make deletions, or remove all solutions from the results.

To use **Clean Up Solutions**:

1. Click **HFSS** > **Results** > **Clean Up Solutions**.

   The **Clean Up Solutions** dialog box appears.



2. Under **Solutions**, select whether you want to delete only fields data, only fields and mesh data, only linked data, or all solution data. Deleting all solution data erases all mesh, matrix, and fields data for all adaptive passes and frequency sweeps for the selected **Variations**.

   By option, you can **Include Linked Data** in the deletions.

   Linked data can be mesh, field or some other post-processing data that the source design generated. The target design for the link caches these data internally to minimize the need to activate the source design. If you don't need to resolve the source design, for example, if it has a lengthy solution time, you should not check **Include Linked Data**. If you need to make some change in the source design that would affect the solution, and you want to ensure that the next solve result includes those changes, you should check Include **Linked Data**.

3. Under **Variations**, select which solution data you want to delete:
   - Select **All Except Current Variation** to delete all solution data that does not correspond to the current project and design variable values for the current design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Select **All Variations** to delete all solution data for the current design.
- Select **Select** to specify the variations you wish to delete. Click **Variations** to select the variations for deletion.

4. Click **Do Deletions**.

   The solution data you selected are deleted. Any post processing reports or field overlays you created that included data you deleted will be marked with an X in the project tree. They will be invalid until new solution data are generated.

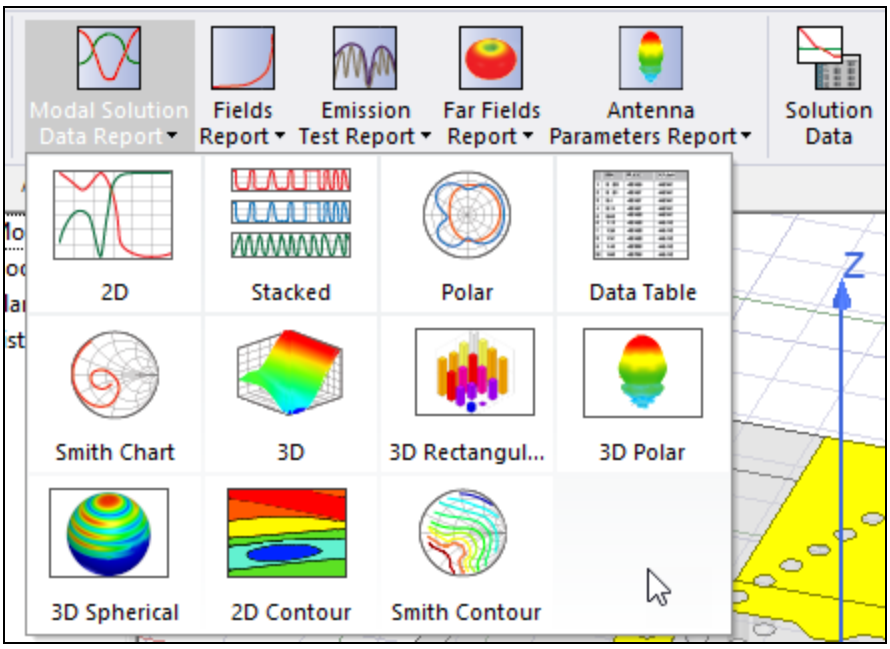
Creating Reports

After a solver generates a solution, you can analyze all the results for that solution. Ansys Electronics Desktop lets you create 2D or 3D plots. A 2D or 3D plot shows the relationship between a design's values and the corresponding results of the analysis. You can create reports using either the **Create Quick Report** option or the **Create *<type>* Report** commands. The **Quick Report** feature lets you select from a list of predefined categories (such as S-parameters) from which to create a rectangular plot.

For each solution **<type>** (for instance, Modal, Terminal, Transient, Eigenmode, Characteristic mode, Fields, Far Fields, Emission test, Partial Discharge, Multipaction, and so forth), the **Results** menus present a list of **Create *<type>* Report** commands based on the solution data of direct interest for the design. For example, for the Eigenmode solution type, the **Results** menu contains templates for Eigenmode Parameters and for Fields. These appear on the menus as **Create Eigenmode Parameters Report** and **Create Fields Report**. For the Modal and Terminal Solution types, several different types appear, appropriate to each solution type. Each of these **Create *<type>* Report** menu items includes a further cascading menu that lists the Display Types available for that report. For some reports you can modify the Display Type from the Properties for that Report. For reports for Transient designs, see this discussion.

The **Results** tab for the Ribbon will show icons and drop-down menus for available report types for the active project.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If you have created custom report templates (for example, including your company name or other format changes), you can also create a report based on that template by selecting **HFSS** > **Results** > **Report Templates** > <***templateName***>. You can also access previously defined 2D templates using **Report2D** > **Report Templates** > **Apply Settings...**. You can save the properties for a modified report to provide the custom default settings for all new reports.

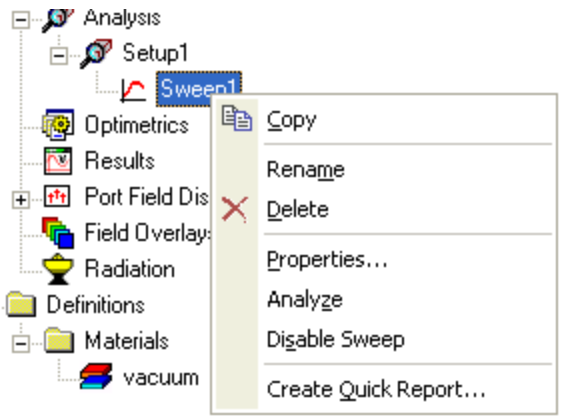
You can also use the **Report2D** > **Export** or **Report 3D** >**Export** feature, select the *Ansoft ReportData Files (.rdat)* format, and **Save** the file, which you can later select to Create Report from File.

Creating a Quick Report

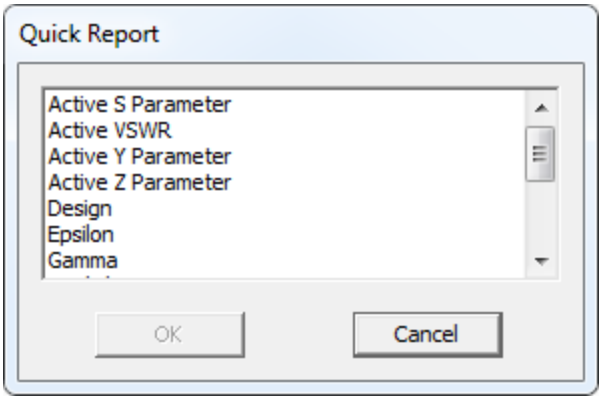
Following is the procedure for creating a quick report.

1. On the Project tree under Analysis, select a **setup** or **sweep icon**, or the **Results** icon.
2. Right-click to display the shortcut menu and select **Create Quick Report**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Quick Report** dialog box appears.



The list of available reports differs depending on the Solution type. The figure shows reports for a Modal solution. Eigen mode solutions and Terminal solutions provide different selections.

3. Select the one or more categories for the report from the list and click **OK**.

A rectangular plot for each selected category displays. The new plot or plots appear in the Project tree under the Results icon. The default Report Name that appears derives from the report type specified in the **Quick Report** dialog box.

Creating a New Report

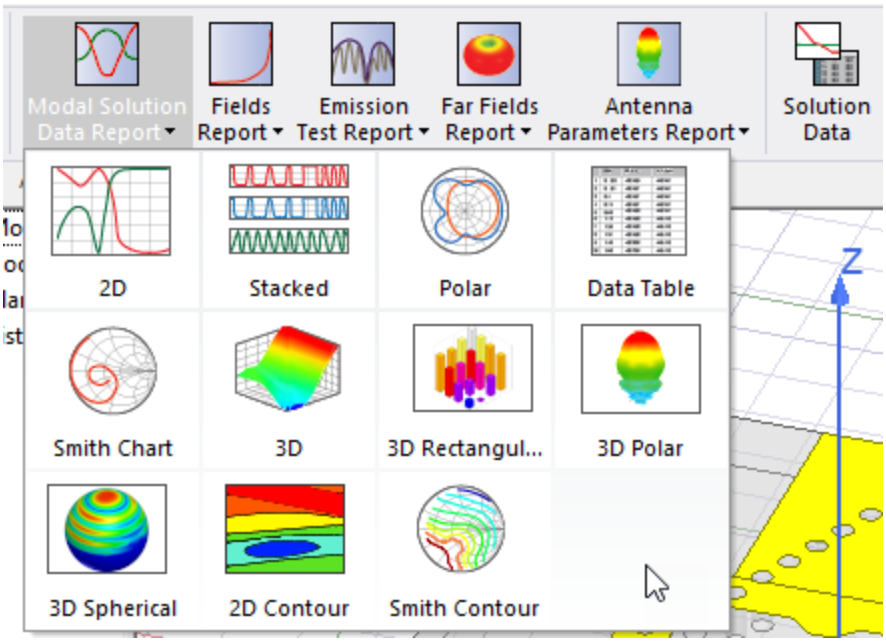
Following is the general procedure for creating a new report:

1. On the **HFSS** menu or the Project Manager, point to **Results**, select **Create *<type>* Report**, and select the **Display Type** template. There are more **Report Type** templates available for terminal solutions (terminal, modal, fields, near fields, and far fields) and for modal solutions (modal and fields). For Eigenmode solutions, the **Report Type *<templates>*** are for Eigenmode Parameters and for Fields. Characteristic Modes

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

solution reports include quantities for Significance, Value, and Angle.

The **Results** tab for the Ribbon will show icons and drop-down menus for available report types for the active project.



If you have created custom report templates (for example, including your company name or other format changes), you can also create a report based on that template by selecting **HFSS** > **Results** > **Report Templates** > **PersonalLib** > *<templateName>*. You can also make such changes the default for new reports by right-clicking a modified report and selecting **Report Templates** > **Save Settings as default**.

When you have selected the report and display type from the **Results** menu, the **Report** dialog box appears, with the **Trace** tab selected by default.

2. In the Context section, you make selections depending on the design and solution type.
3. In the **Y** Component section of the dialog box, make selections for the following:
    a. Categories – those depend on the Solution type and the design. For example, Eigenmode quantities include Eigenmodes, variables, output variables, and the design. Driven solutions include such categories as S parameters. Report categories for Transient designs include Spectral and Transient. For a Transient Network design with differential pairs defined, the Reporter interface allows selection of single-ended or differential signals just as for driven terminal. Characteristic Mode Data Reports include Characteristic Mode quantities for Significance, Value, and Angle. Report categories for SBR+ designs that include an Incident Plane wave and an RCS selection as Monostatic do not require a geometry selection and include a range of Monostatic Quantities when select Monostatic RCS

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

as the Report Category. For SBR+ designs and RCS Monostatic you can choose between Freq, IWaveTheta and IWavePhi variables for specifying sweeps. The selected Category provides the default plot name. You can edit the plot names in the project tree and the plot header text in the report synchronizes.

b. Quantities for Y are relative to the selected category.

> **Note:**
>
> The Quantity text field can be used to filter the Quantity list by typing in text, or by using the four predefined selections. This is useful if the Category selected produces a lengthy Quantities list. See Filtering Quantity Selections for the Reporter.
>
> When the matrix is very large, the number of quantities can be correspondingly huge. Therefore, the Quantities field can optionally use a tree structure to divide matrix quantities into groups by their first element name. The initial display shows groups, without initially listing group members. See Report Setup Options.

c. **Function** list to apply to the Y quantities.

d. Value field displays the currently specified Quantity and Function. You can edit this field directly.

> **Note:**
>
> Color shows valid expression.

e. **Range Function** button – opens the **Set Range Function** dialog box. This applies to the currently specified Quantity and Function.

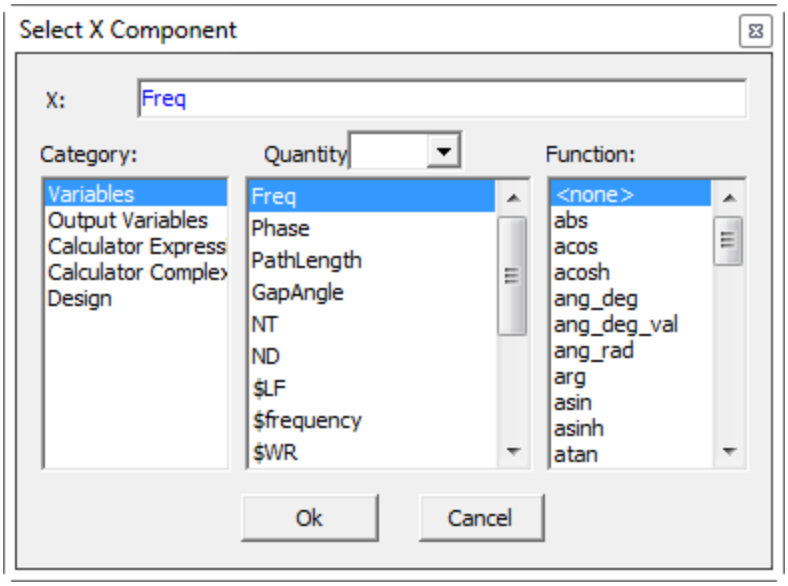
f. To use a dataset in this report, set the **Y** component to a Piecewise Linear Function `pwl(dataset_expression, primary_sweep)` where is the `primary_sweep` is what you set in the next step.

4. In the **X (Primary Sweep)** section, make selections for the following:

a. Select the Primary value(s) from the drop-down menu.

To select an X component that is different from the Primary Sweep, uncheck the Default field to enable the X field and **Browse** [...] button. Click **Browse** [...] to display the **Select X Component** dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This lets you specify the X component as you do the Y; that is, in terms of Categories which define the selectable Quantities, and Functions to apply. After making selections, **OK** the dialog box to assign the X component.

b. If sweeps are available, you can select **Browse** [...] to display a panel that lets you select Use all values, or selected sweep or sweeps, or access an Edit Sweep dialog box with further editing options. Post-Processing variables are Post-Processing sweeps/editable sweeps, so you can use the **Edit Sweep** dialog box to create your own sweep.

c. The **Families** tab provides a way to select from valid solutions for sweeps where a simulation has multiple variables defined (for example, for a parametric sweep). If so, the variables other than the one chosen as the **X (Primary sweep)**, are listed under the **Families** tab with columns for the variable, the value, and an Edit column with an ellipsis [**...**] button. See Using Families tab for Reports.

5. **Update Report** setting
   - **Real Time** checked – enable real time updates for all reports while the reports are being edited.
   - **Real Time** unchecked – enables drop down menu to **Update All Reports** or **Update Report**. Reports will only be updated with one of these user selectable update options or upon exiting the report dialog box. This can be useful if you expect a trace to take time to display. You can then add additional traces without having to wait.
6. The **Report** dialog command buttons permit you create a new report with the settings you provide, or to modify an existing report.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Output Variables** – opens the **Output Variables** dialog box.
- **Add Trace** – this is enabled when you have created or selected a report. Add one or more traces to include in the report.
- **Update Trace** – updates the selected traces in a report based on further processing or changes.
- **New Report**. Adds a report to the Project tree under the Results icon. The new Report is displayed in the Project window.
- **Options** – opens the **Report Setup Options** dialog box. This contains a check box for using the advanced mode for editing and viewing trace components. This mode is automatic if the trace requires it. It also contains a field for setting the maximum number of significant digits to display for numerical quantities.
- **Close** – closes the **Report** dialog box.

7. Click **New Report** to create a new report in the Project Manager.

   The report appears in the view window. It will be listed in the project tree under Results, with the default name based on the Report Category you selected, for example, S Parameter Plot *n* or Output Variables Plot *n*. You can edit the plot names in the project tree and the plot header text in the report synchronizes. Traces within the report also appear in the project tree.

   Some plots may take time to complete. Performing a **File** > **Save** in such cases after the plot has been created will permit you to review the plot later without having to repeat the calculation time when you reopen the project later.

8. To speed redraw times for changed plots, perform a **Save**. This saves the data that comprises expressions. For example if re(S_{11})*re(S_{22}) is requested over multiple widths, each of the S_{11} and S_{22} are stored when you save. If you do not do a save of a changed plot, the changed version is not stored.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

Remember that the evaluated value of an expression is always interpreted in SI units. However, when an angle quantity is plotted in a report, you have the option to plot values in units other than SI. If you want to plot the polar angle of a complex simulation result, S11 say, you can choose between ang_deg(S_{11}) and ang_rad(S_{11}). Both of these return the exact same angle quantity but in degree and radian units respectively.

Note that when used in expressions, some surprising outcomes might result. For example, the expression "1+ang_deg(S11)" represents an 'angle' and the number "1" is treated as "1 rad". The angle SI unit is attached to any unitless number that is added/subtracted from an angle value. If you want to treat "1" as degrees, make it explicit and use "1deg + ang_deg(S_{11})" instead.

If you are interested in unitless degree values, two additional functions exist: ang_deg_val(S_{11}) and cang_deg_val(S_{11}). These return simple numbers and are treated as such by any expression. If the complex S_{11} lies on the positive Y axis say, ang_deg_val (S_{11}) would be 90 and "1 + ang_deg_val(S_{11})" will be 91.

Context Section for Reports

In the **Context** section, make selections from the following field or fields, depending on the design and solution type.

1. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes. The selections for HFSS Transient include Transient, and for Transient Network includes Spectral.
2. Domain field with a drop down selection list. Whether this field appears, and domains are listed, depends on the Solution type and the report ***<type>*** selected. For modal and terminal solution data reports, the domain can be **Sweep** or **Time**.

   Before you can examine the time domain, you must perform an Interpolating sweep for a driven solution (Modal or Terminal). If you select **Time**, the **TDR Options** button is enabled. Select it and follow the directions for time-domain plotting.

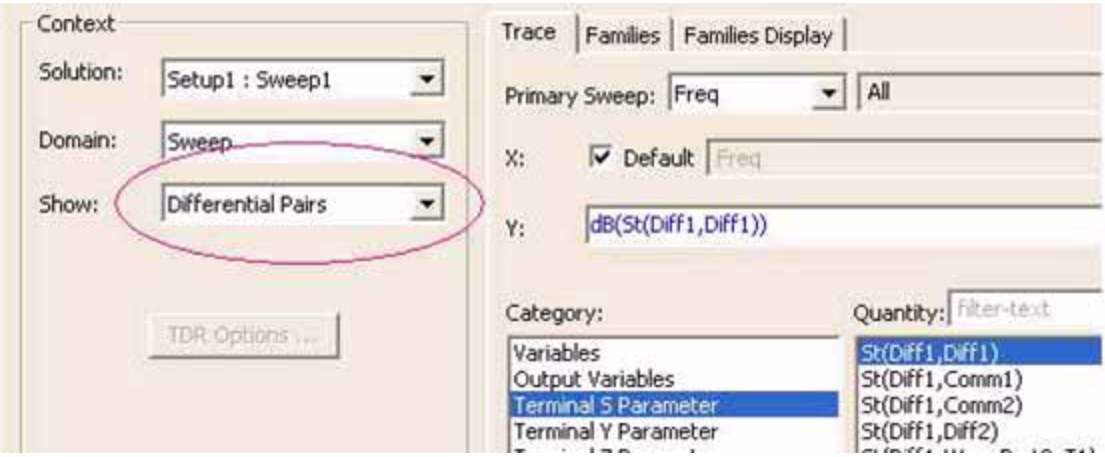
   For Near Field or Far Field report, for a Rectangular Contour Plot, the Domain can be Theta, Phi, or Sine Space. Before you can create a Sine Space plot, you must create the appropriate Radiation Setups. If you manually enter Phi or Theta component of a far field quantity when you using Az/El or El/Az far field infinite sphere definition, then the Report uses the Z axis of the Az/El or El/Az coordinate system definition as pole to calculate theta/phi component for rE.

3. Geometry field with a drop-down selection list. For field and radiated field reports, this applies the quantity to a geometry or radiated field setup. For SBR+ designs with an

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Incident Plane Wave and Monostatic RCS selected, the Geometry field is unavailable. In this case, the solver computes the scattered field in the direction of the plane wave.

4. Show field with a drop-down selection list for Differential pairs or Terminals. This field appears for designs using terminal solutions that have differential pairs defined. It lets you plot either differential pair data, or single-ended terminal data, or both in the same plot without having to disable or enable differential pairs under the Excitations heading in the Project Manager. Note that single-ended quantities are computed as if no differential pairs existed. So in the unlikely case of several terminals where only a subset is combined into pairs, the results may not be as expected.



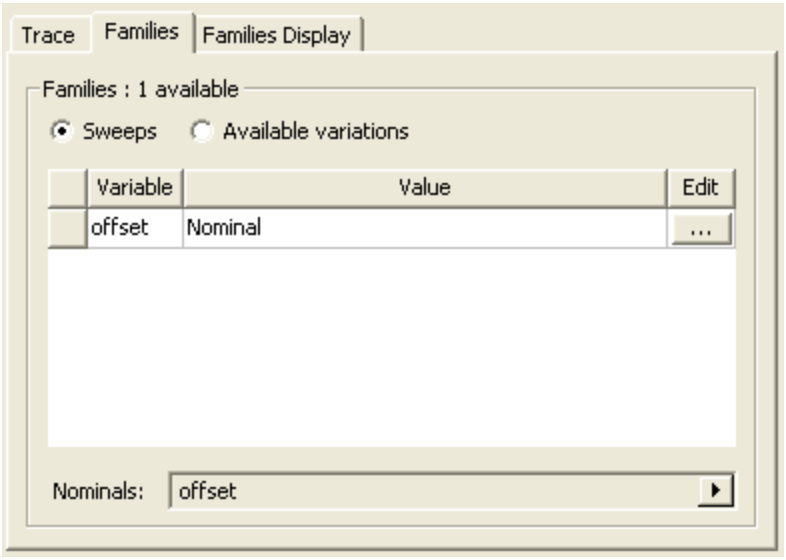
5. Derivative field with a drop-drown selection list of none, all, and specific variables for which you specified **Use** on the Derivatives tab of the solution setup. You can use derivatives in some Optimetrics situations, Far Field reports, non-Port excitations including incident wave, linked field, voltage source, current source, and magnetic bias with the Derivative Tuning feature in the Reporter.
6. A Sources combo box appears in the Reporter when you have specified at least one source in the **Edit Sources** dialog box. See Specifying Source Contexts for Creating Radiated Field Reports. For a usage example, see: *User Defined Solution for MIMO Calculations*.

Using Families Tab for Reports

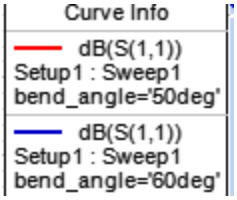
The **Families** tab of the **Report** dialog box provides a way to select from valid solutions for sweeps where a simulation has multiple variables defined and solutions exist for multiple variable values (for example, for a parametric sweep or re-running an analysis with a different variable value). If no variables are defined, or none have solutions for different values, 0 families will be available. If so, the variables other than the **X (Primary sweep)**, are listed under the **Families** tab with columns for the variable, the solution value (which may be All, Nominal, or a Specific value), and an Edit column with an ellipsis [**...**] button. Families gives the number available. If an existing variable is specified as Nominal, only that value is currently available.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can set any solved variables as Nominal, All, or select from values provided for Available solutions.



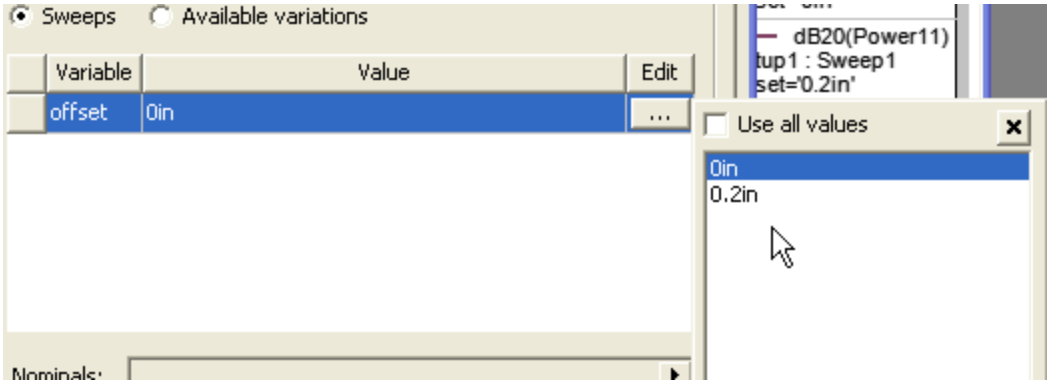
When you select a variable with multiple solved values, a trace for each solved value appears in the Report, with the variable value appended to the trace name in the Report legend.



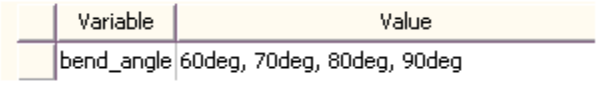
When families are available, you can make selections for the following:

1. Select the **Sweeps** radio button (the default) to list the swept variables you can select or the Available variations button to list and select variation values for which solutions exist.
2. With the **Sweeps** radio button selected, click the ellipsis [**...**] button to display a list of variable values for a particular variable. If many variables exist, you can use a scroll bar to navigate the list.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

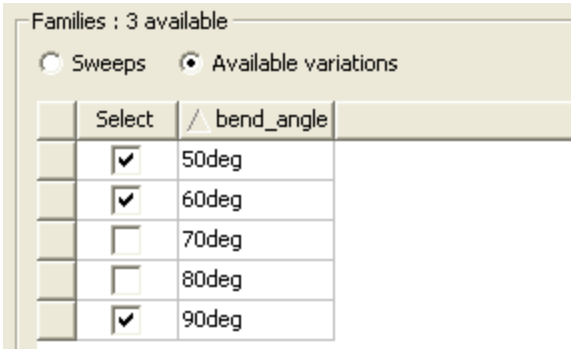


- To select all values, click the check box for **Use all** values. This writes "All" in the value field for that variable. You can also select individual values by clicking on them.
- To select a range of values, hold down the shift key, and click again.
- To select intermittent additional values, hold the Ctrl key and click additional. The values you select are highlighted in the list, and are also listed in the Values column for that variable.
- To select all, use the **Select All** button. This highlights the complete list, as well as listing all values for the variable in the Value field.



- To clear the selections, use the **Clear All** button.

Select the **Available variations** radio button to list the choices that derive from variable combination.

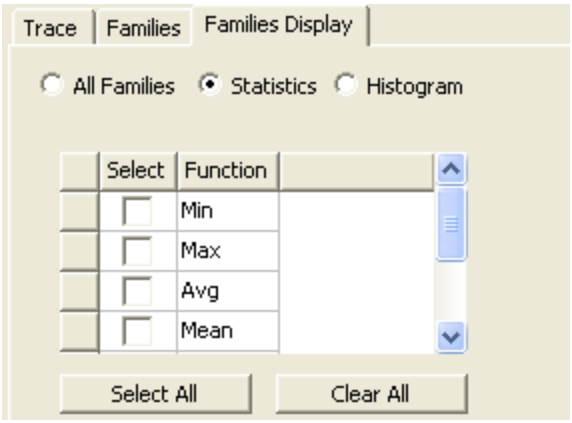


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

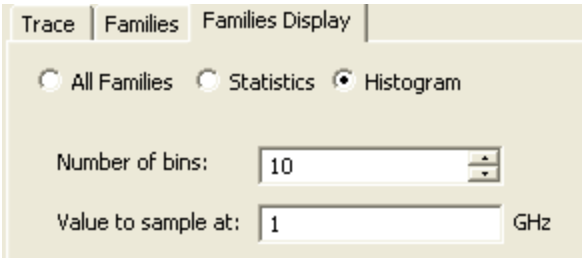
a. To select individual variations, check the select box.
b. To check or clear all variations at once, click the **Select** button at the top of the column.
c. To invert the list order, click the triangle beside the variable name.

The **Families Display** tab has three radio button selections.

a. **All Families**
b. **Statistics** lists a table statistical functions that you can select to apply to the plot. The functions include Min, Max, Avg, Mean, Variance, Std Dev, and Sum. You can use the Select check boxes or the Select All and Clear All button.



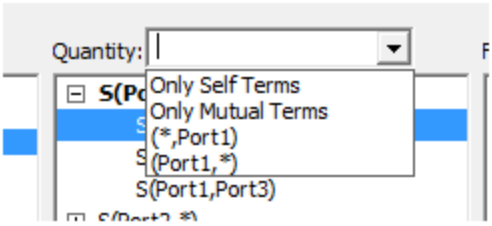
c. **Histogram** lets you select the number of bins to use for a histogram plot, and the sampling frequency to use.



Filtering Quantity Selections for the Reporter

When a two-port quantity Category is selected, four predefined filters are added to the combo box. "Port1" is the first matrix element name found in the quantity list.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Only Self Terms – Only display quantities when the first and second port are same.
- Only Mutual Terms – Only display quantities when the first and second port are different.
- (*,Port1) – Only display quantities when the second element name is "Port1". You can edit the element name to display quantities for other elements.
- (Port1,*) – Only display quantities when the first element name is "Port1". You can edit the element name to display quantities for other element.

Deleting Reports

To use **Delete All Reports**:

1. Click **HFSS** > **Results** > **Delete All Reports.** You can also right-click on the Results folder in the Project Manager, to display the shortcut menu, and click **Delete All Reports.**

   All items under the Results folder in the Project Manager are removed.

To use **Delete** for a selected report:

1. Right-click a report icon in the Project Manager to display the shortcut menu.
2. Click **Delete** to remove this report.

> **Warning:**
>
> Solution data that has been deleted cannot be recovered!

Modifying Reports

To modify the data that is plotted in a report:

1. In the Project Manager, click the report you want to modify.
2. Right-click **Modify Report**.

   The **Report** dialog box appears.

3. The **Report** dialog box command buttons permit you create a new report with the settings you provide, or to modify an existing report.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Output Variables** – opens the **Output Variables** dialog box.
- **Add Trace** – this is enabled when you have created or selected a report. Add one or more traces to include in the report.
- **Update Trace** – updates the selected traces in a report based on further processing or changes.
- **New Report** – adds a report to the Project tree under the Results icon. The new Report is displayed in the main window.
- **Options** – opens the **Report Setup Options** dialog box. This contains a check box for using the advanced mode for editing and viewing trace components. This mode is automatic if the trace requires it. It also contains a field for setting the maximum number of significant digits to display for numerical quantities.
- **Close** – closes the **Report** dialog box.

The updated report appears in the view window.

4. **Update Report** setting
   - **Real Time** checked – enable real time updates for all reports while the reports are being edited.
   - **Real Time** unchecked – enables drop-down menu to **Update All Reports** or **Update Report**. Reports will only be updated with one of these user selectable update options or upon exiting the report dialog box. This can be useful if you expect a trace to take time to display. You can then add additional traces without having to wait.
5. In the **Context** section you make selections depending on the design and solution type.
6. The Families tab provides a way to select from valid solutions for sweeps where a simulation has multiple variables defined (for example, for a parametric sweep). If so, the variables other than the one chosen as the **X (Primary sweep)**, are listed under the **Families** tab with columns for the variable, the value, and an Edit column with an ellipsis [**...**] button. See Using Families tab for Reports.
7. In the **Y** Component section of the dialog make selections for the following:
   a. Categories – those depend on the Solution type and the design. For example, Eigenmode quantities include Eigenmodes, variables, output variables, and the design. Driven solutions include such categories as S parameters. Report categories for Transient designs include Spectral and Transient. For a Transient Network design with differential pairs defined, the Reporter interface allows selection of single-ended or differential signals just as for driven terminal. Report categories for SBR+ designs that include an Incident Plane wave and an RCS selection as Monostatic do not require a geometry selection and include a range of Monostatic Quantities when select Monostatic RCS as the Report Category. For SBR+ designs and RCS Monostatic you can choose between Freq, IWaveTheta and IWavePhi variables for specifying sweeps. The selected category provides the default name of the plot, for instance S Parameter Plot *n*. You can edit

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the plot names in the project tree and the plot header text in the report synchronizes.

b. Quantities for Y are relative to the selected category.

> **Note:**
>
> The Quantity text field can be used to filter the Quantity list by typing in text, or by using the four predefined selections. This is useful if the Category selected produces a lengthy Quantities list. See Filtering Quantity Selections for the Reporter.
>
> When the matrix is very large, the number of quantities can be correspondingly huge. Therefore, the Quantities field can optionally use a tree structure to divide matrix quantities into groups by their first element name. The initial display shows groups, without initially listing group members. See Report Setup Options.

c. **Function** list to apply to the Y quantities.

d. Value field displays the currently specified Quantity and Function. You can edit this field directly.

> **Note:**
>
> Color shows valid expression.

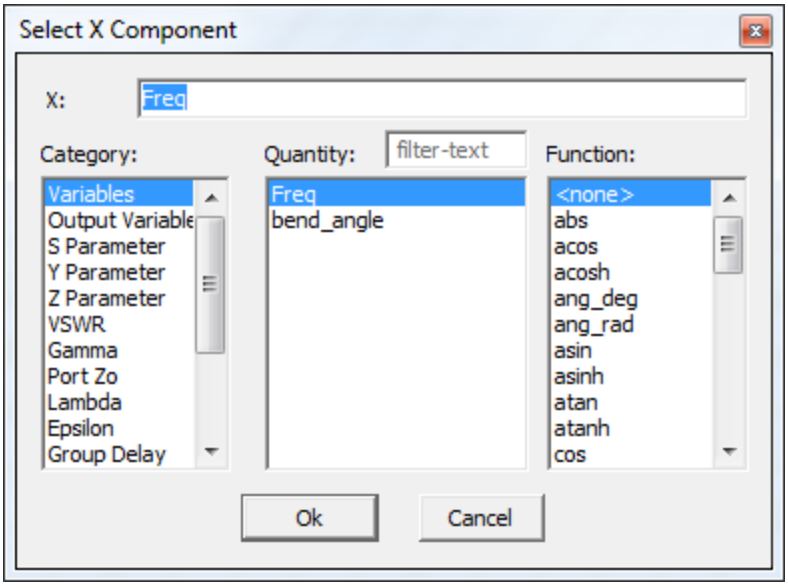
e. **Range Function** button – opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

8. In the **X (Primary Sweep)** section, make selections for the following:

a. Select the Primary value(s) from the drop-down menu.

To select an X component that is different from the Primary Sweep, uncheck the Default field to enable the X field and **Browse** [...] button. Click **Browse** [...] to display the **Select X Component** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This lets you specify the X component as you do the Y; that is, in terms of Categories which define the selectable Quantities, and Functions to apply. After making selections, **OK** the dialog to assign the X component.

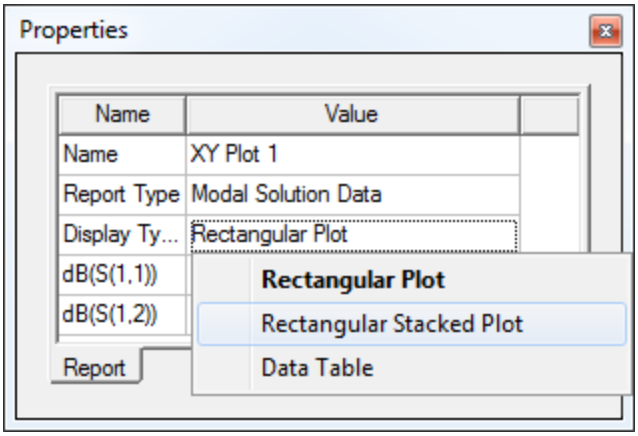
b. If sweeps are available, you can select **Browse** [...] to display a panel that lets you select Use all values, or selected sweep or sweeps, or access an Edit Sweep dialog box with further editing options. Post-Processing variables are Post-Processing sweeps/editable sweeps, so you can use the *Edit Sweep* dialog box to create your own sweep.

c. The **Families** tab provides a way to select from valid solutions for sweeps where a simulation has multiple variables defined (for example, for a parametric sweep). If so, the variables other than the one chosen as the **X (Primary sweep)**, are listed under the **Families** tab with columns for the variable, the value, and an Edit column with an ellipsis [**...**] button. See Using Families tab for Reports.

You can also view and edit the properties of Reports and their traces via their Properties windows. See Modifying the Background Properties of a Report.

You can also modify the display type of an existing plot from the Properties dialog box for that plot. Select the Report icon in the Project Manager to display the **Properties** dialog box. Selecting the Display Type field displays a menu with selections available for that plot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

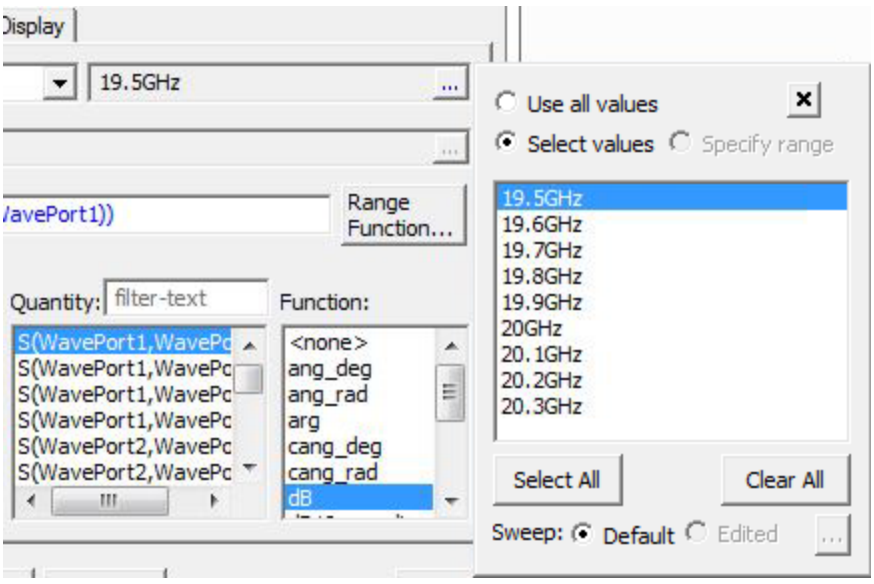


Once you make a selection, the plot display updates for the current selection.

> **Note:**
>
> Remember that for many excitations of interest for plotting, you can control the default base names through the dialog box described here: Setting Default Boundary/Excitation Base Names. This may save you the need to edit individual names in the plots.

Modify Report: Selecting Use All Values or Making Selection

Clicking the browse button on **Primary Sweep** line shows the default selection of **Use all values**. Choose **Select values** to display the sweeps and enable editing, including the **Select All** and **Clear All** buttons.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

With **Select values** selected, you can select one or more by clicking an individual value, dragging to select multiple values, or using Alt+click to select specific values.

You select either the Sweep radio button for Default or Edited selection.

You can also select **Browse** [...] here to display the Edit Sweep dialog for Modify Reports, which includes additional editing features.

Modify Report: Using the Edit Sweep Dialog Box

Clicking **Browse** [...] at the lower right corner of the **Use all values** pane opens the **Edit Sweep** dialog box for Modify Report. This lets you edit the current Primary sweep variable values, including radio button selections for Single value, Linear step or count, and Decade, Octave, or Exponential Counts.

You can specify start, stop and step values and units, and add specific values to the list of current sweep values. The **Add>>** and **Update>>** buttons let you edit the value list.

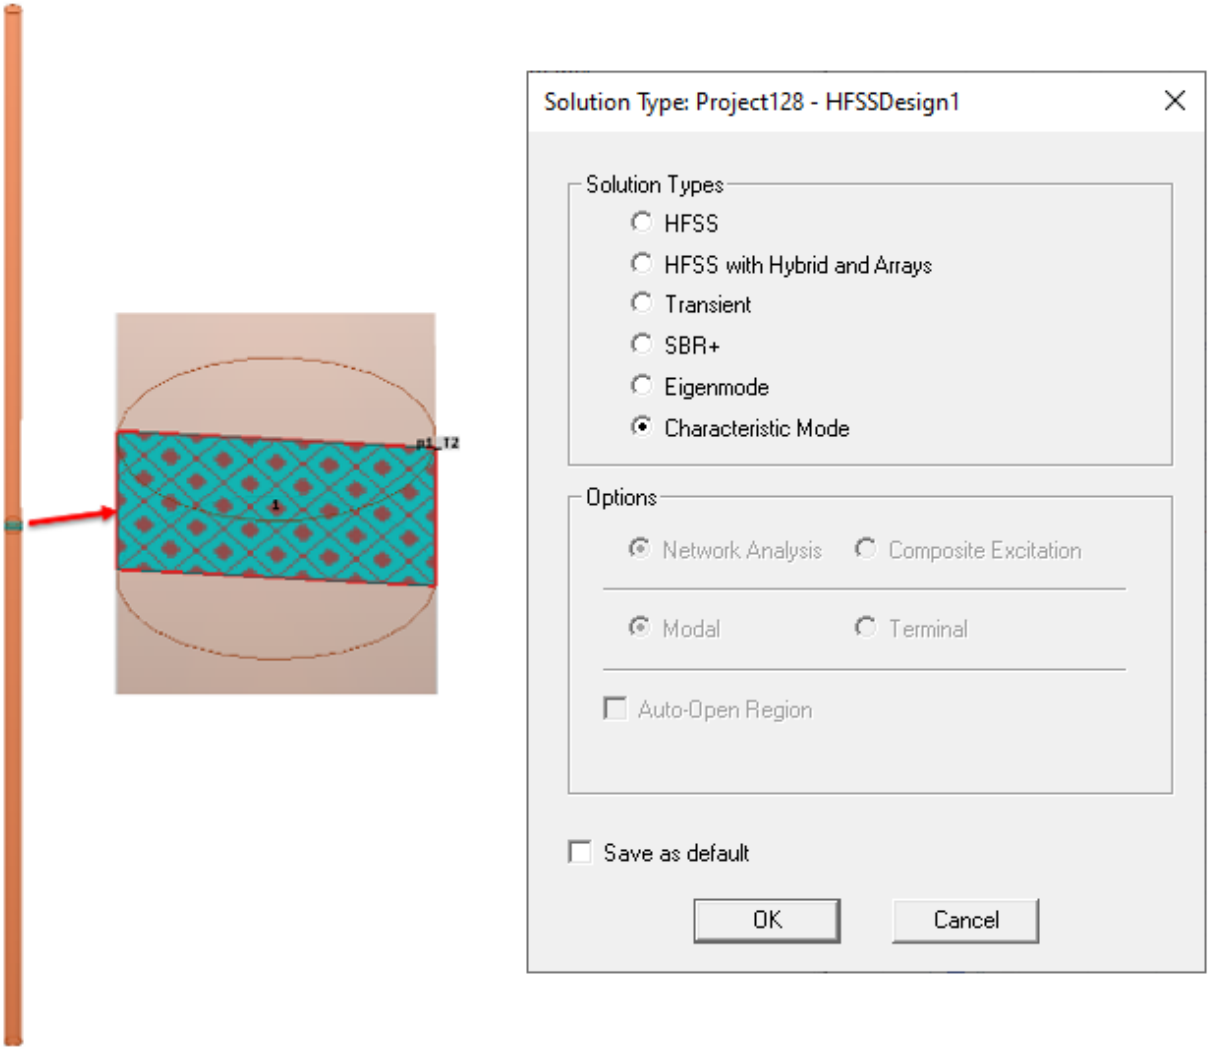
You can use the mouse click, drag, and Alt+click to select values. You can also edit individual values.

Generating Reports For Characteristic Mode Analysis

This section describes how to use the characteristic mode analysis feature in HFSS when designing an antenna and generating characteristic mode analysis reports. The section also

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

covers post processing capabilities available in HFSS when using CMA. To illustrate post processing for characteristic mode analysis, we will use a dipole antenna example. The two conducting arms of the dipole antenna are excited by a lumped port. From the menu item **HFSS > Solution Type**, define **Characteristic Mode** as the solution type.

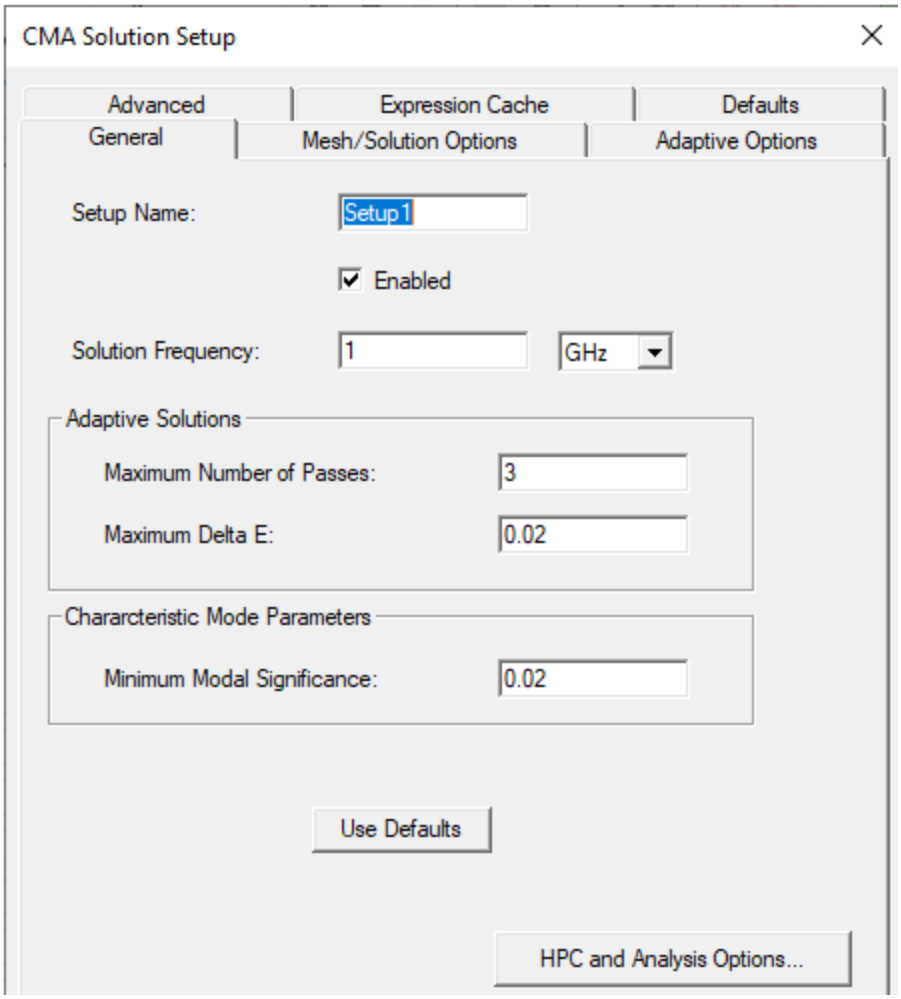


Define the adapt frequency and characteristic mode parameters on the **CMA Solution Setup** dialog box. For Characteristic Modes solution types, these include the following:

a. Solution Frequency
b. Maximum Number of Passes
c. Maximum Delta E
e. Minimum Modal Significance, a measure of how significant a mode is for solving the EFIE at a given frequency. It also determines how hard or how easy it is to excite a

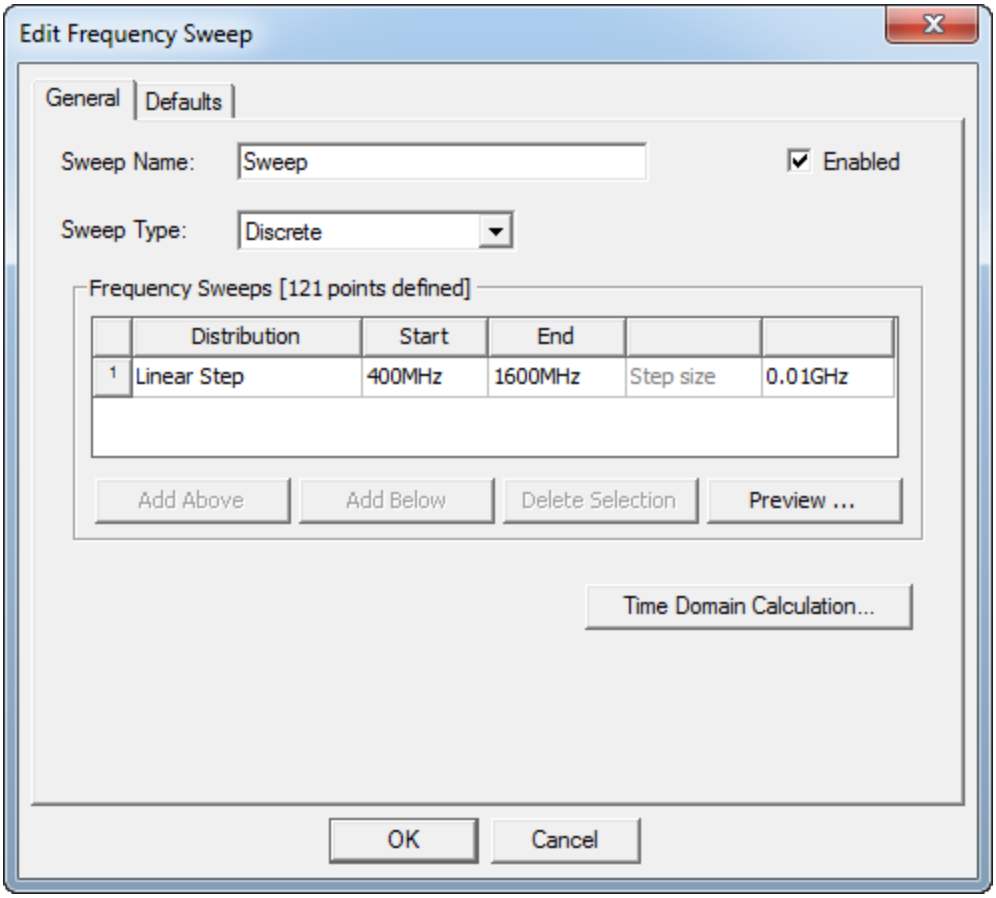
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

mode. The default for Minimum Modal Significance is 0.02. All the modes that are above this value 0.02 are calculated.



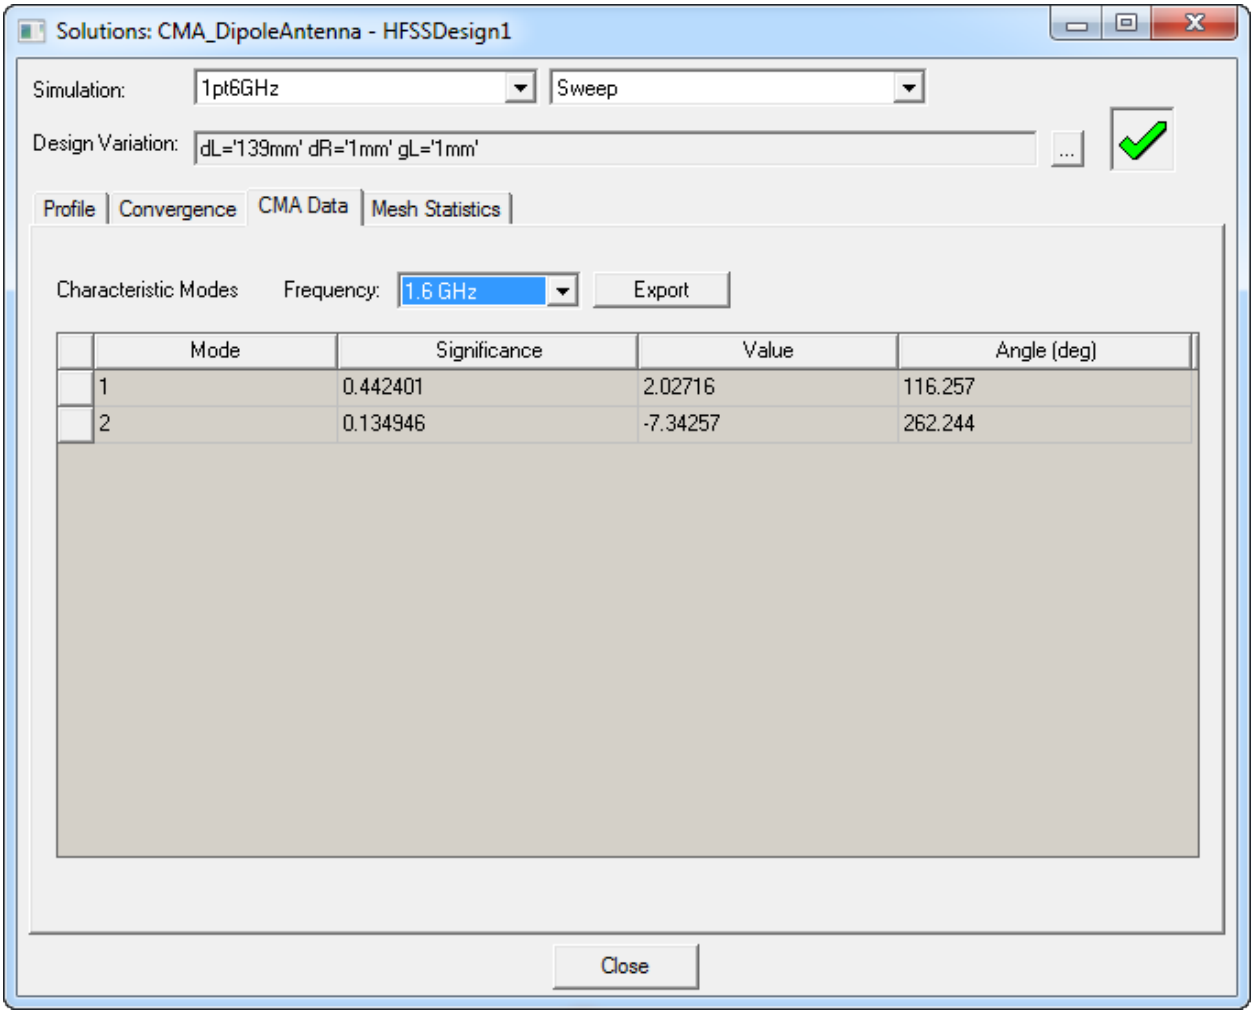
For this design the adapt frequency is set to 1.6 GHz. It's recommended that you define the adapt frequency to be the highest frequency in the discrete sweep.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



After the simulation of the dipole antenna is complete, you can view the number of modes above the minimum modal significance, their characteristic angles, and characteristic values at every frequency in the **Solution Data** dialog box. To bring up this dialog box, right-click Results in the project tree and select **Solution Data** from the shortcut menu. The characteristic mode quantities are displayed in the **CMA Data** panel.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



From the Frequency drop-down menu, select the desired frequency view all the quantities for the characteristic modes. As an example, at the adapt frequency of 1.6 GHz, there are two modes in this dipole antenna above the specified minimum modal significance.

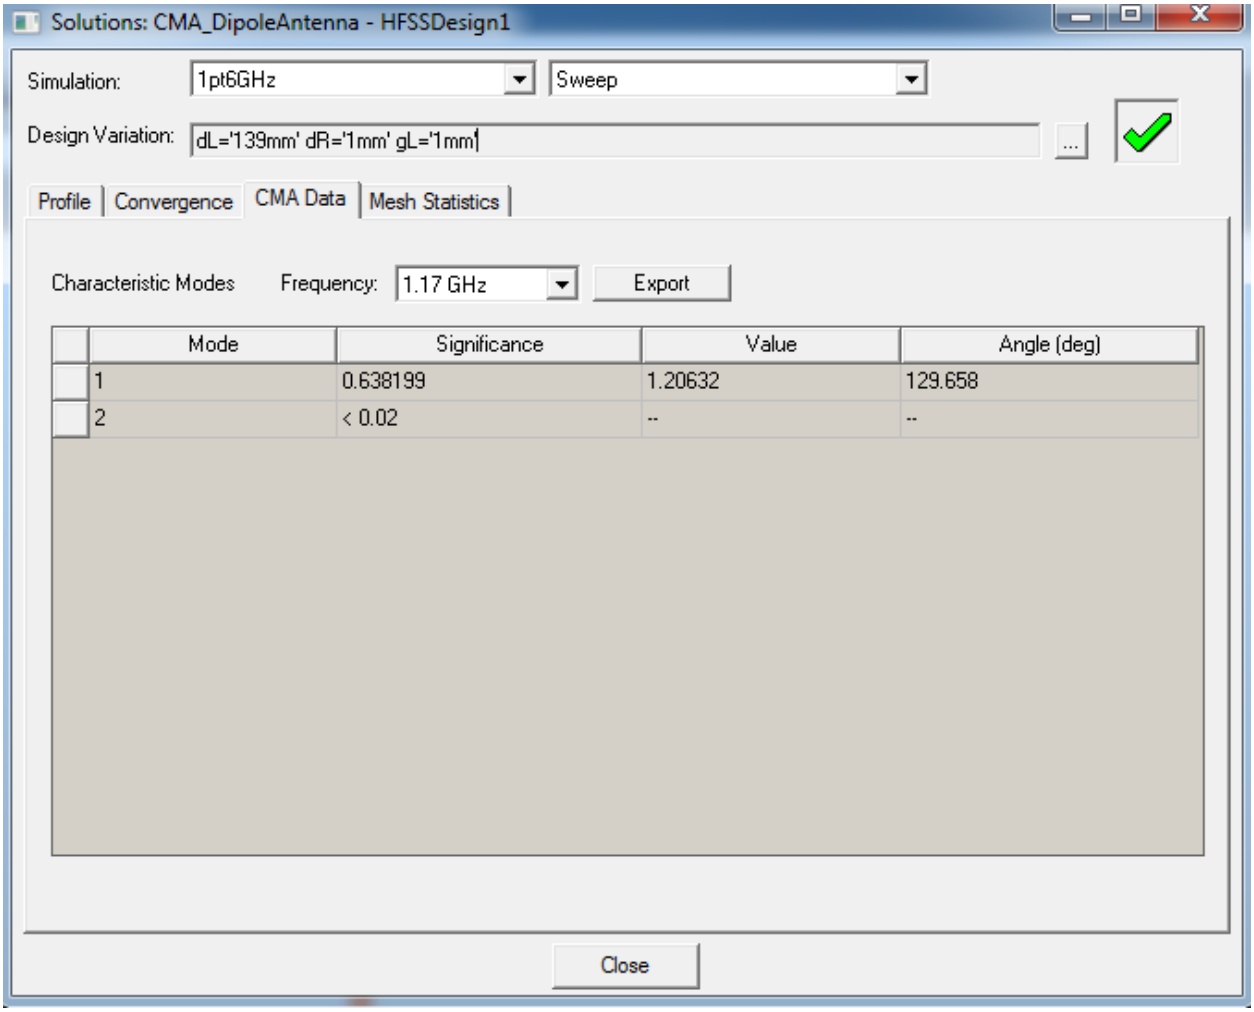
For these two modes:

- Modal Significance MS_1= 0.442401 and MS_2 = 0.134946 at 1.6 GHz
- Characteristic angles α_1= 116.257 degrees and α_2= 262.244 degrees.
- Characteristic values λ_1=+2.02716 and λ_2= -7.34257.

From these values, you can infer that mode 1 is inductive and mode 2 is capacitive.

As you choose lower frequencies, significance of mode 2 reduces and MS_2 approaches a value less than 0.02. At 1.17 GHz, only mode 1 is significant and above 0.02.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

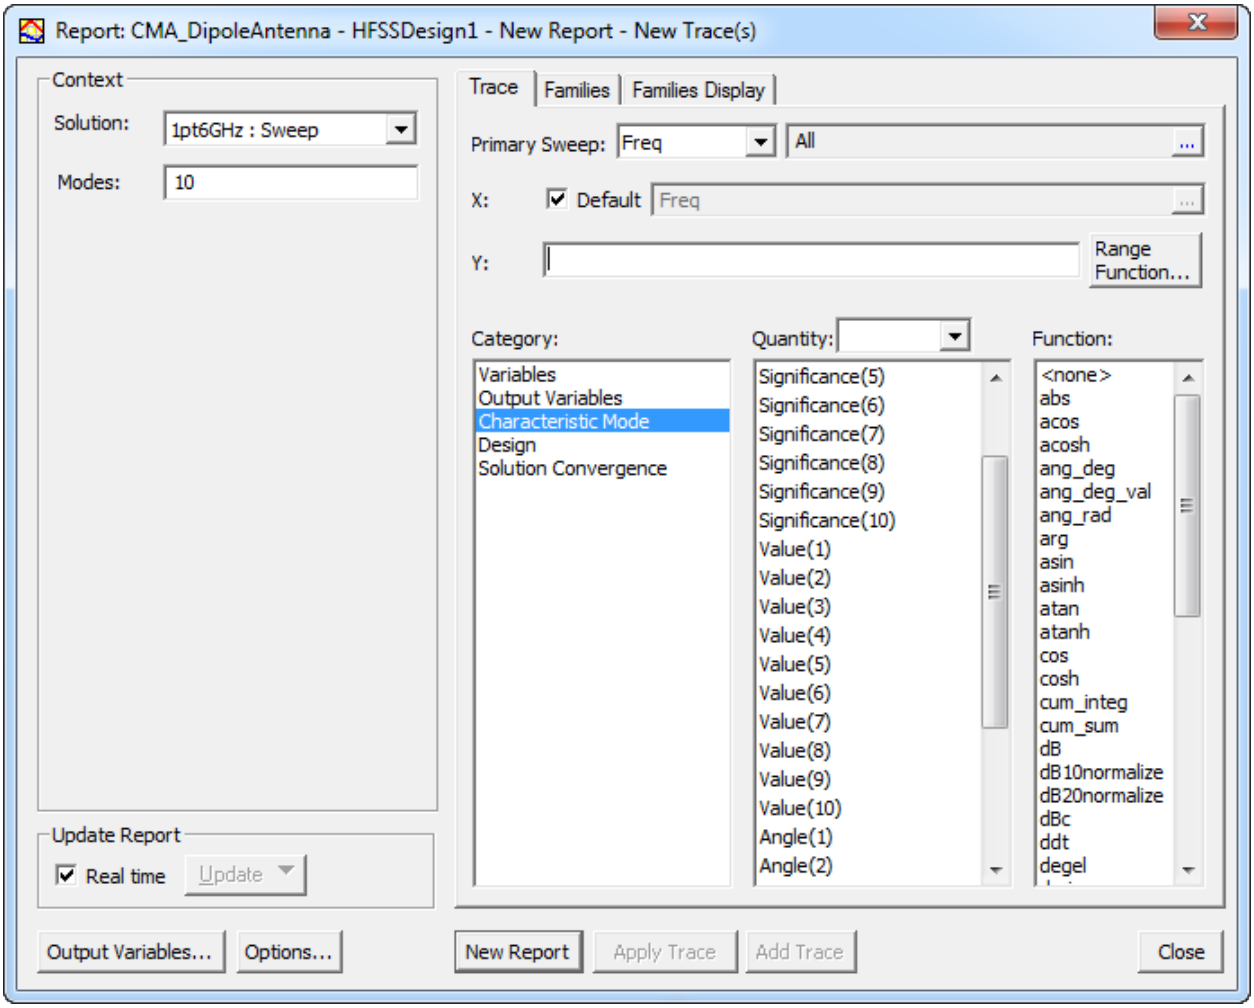


Characteristic Mode Data Report

The process for generating Characteristic Mode Plots for each of these quantities is as follows:

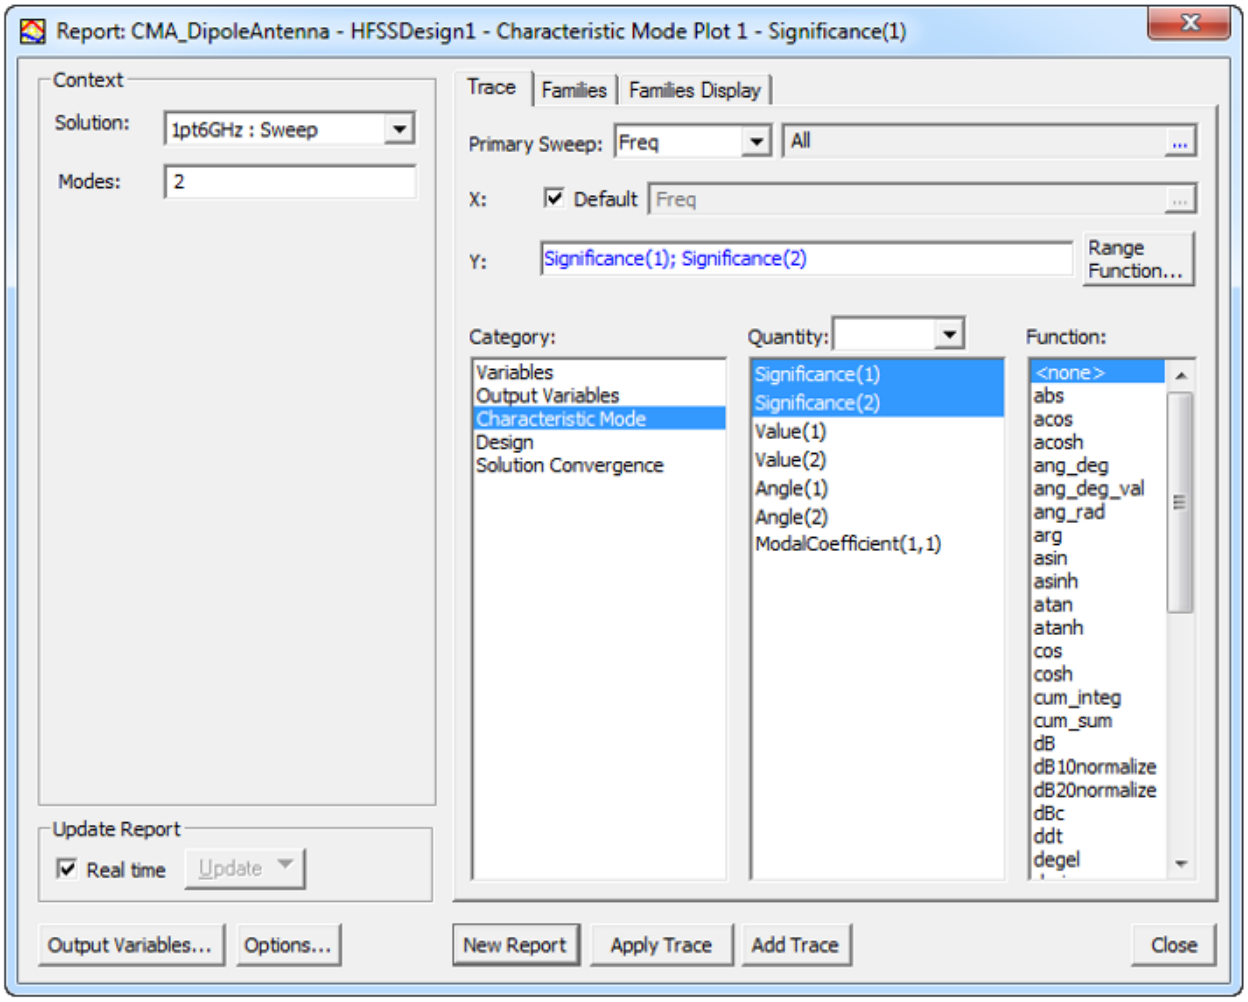
1. Check the maximum number of modes for a design from the **CMA Data** panel at the highest frequency.
2. Right-click **Results > Create Characteristic Mode Data Report > Rectangular Plot**, use the **Results** tab of the ribbon, and select from the **Characteristic Mode Data Report** menu and select the Rectangular Plot icon to open the **Report** dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. In the Context panel the number 10 in the Modes field is the default. You can either leave this value as is or change it to the maximum number of modes that are above the minimum modal significance. For this dipole antenna, the Modes field is set to 2 since there are only two modes at the adapt frequency as displayed in the CMA Data panel.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. Ensure Characteristic Mode is selected in the **Category** and then select the **Quantity** of interest (Significances, Values, and Angles of the desired modes) and leave the **Function** as none.

   For CMA problems, you can also plot the Modal Coefficients. For Plotting Modal Coefficients, you must select a **Function**. These quantities are named "ModalCoefficient (<port>,<mode>) where <port> contains each of the names of the ports in the design and <mode> runs from the number of modes from 1 through N-1 modes where N is the number of modes specified by the user. The solution from a given port excitation is represented as a linear combination of the modal solutions.

$$J = \sum_{n} \alpha_n J_n$$

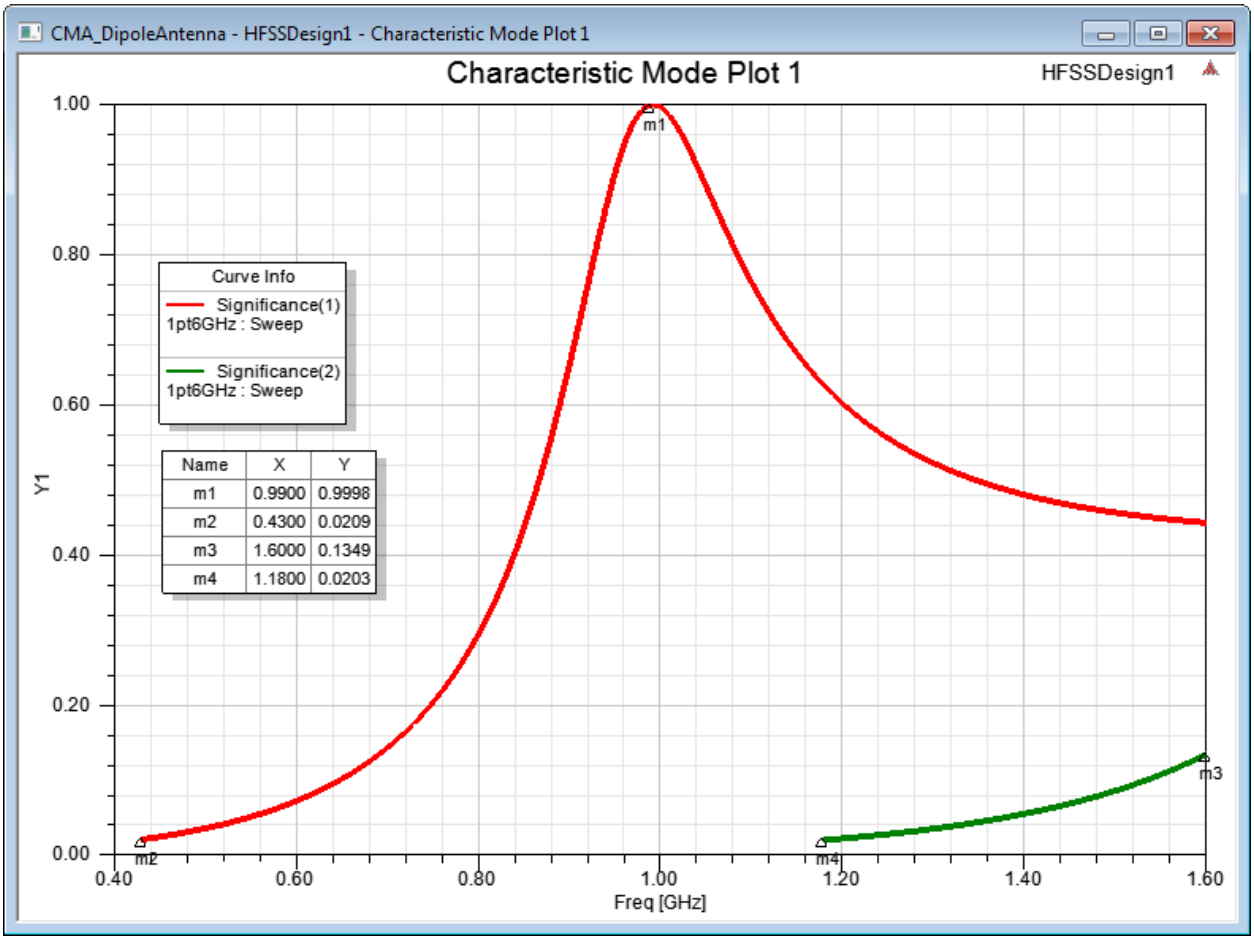
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The modal coefficients are the quantities which we multiply the modal solutions to obtain the port solution.

$$V_{n^i} = \langle J_n, E^i \rangle = \oiint_S Jn \cdot E^i ds.$$

The plots with their corresponding quantities of the characteristic mode are displayed here.

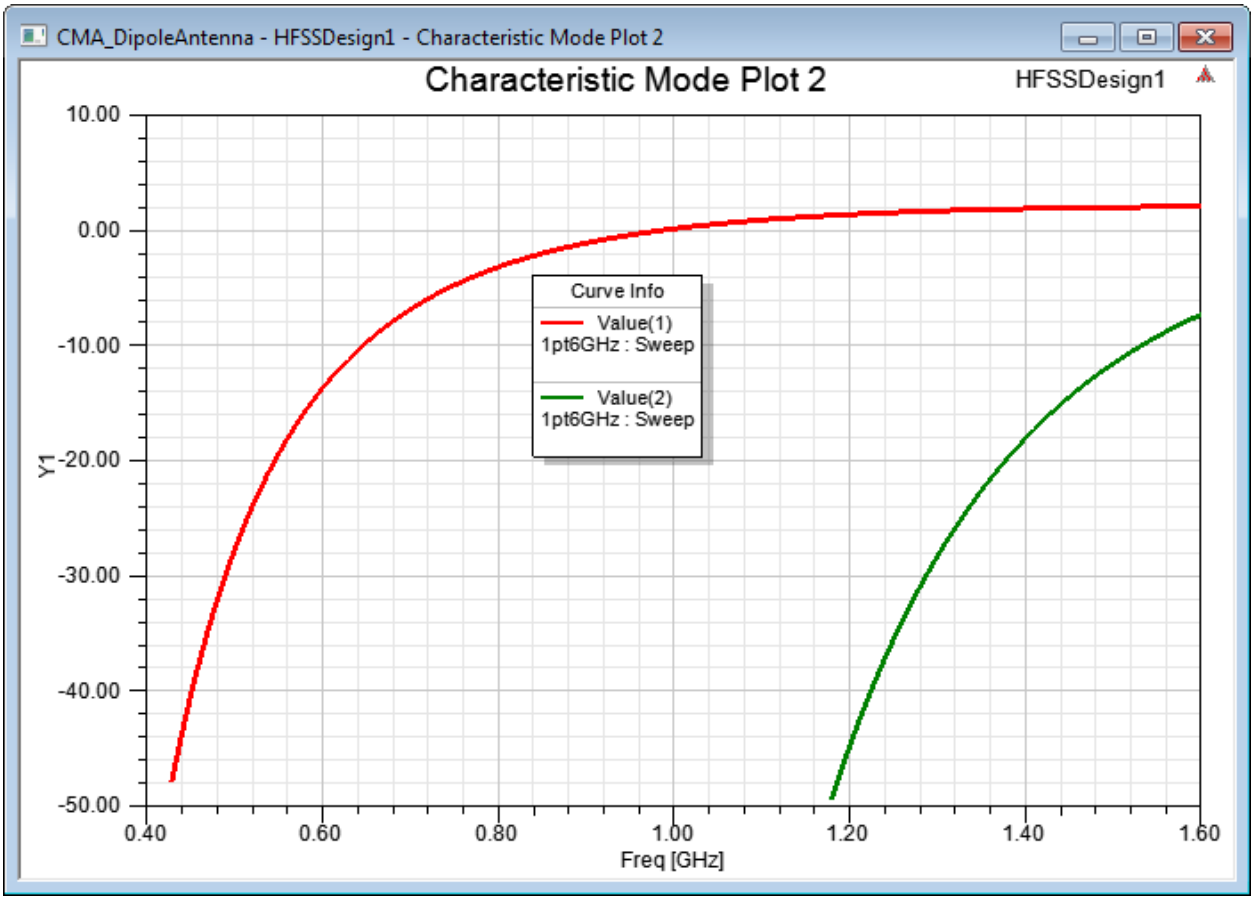
Modal Significance vs Frequency



For this antenna, mode 1 radiates the most at 0.99 GHz and its Significance is 0.9998. Mode 2 radiates most efficiently at 1.6 GHz and its its maximum modal significance 0.1349.

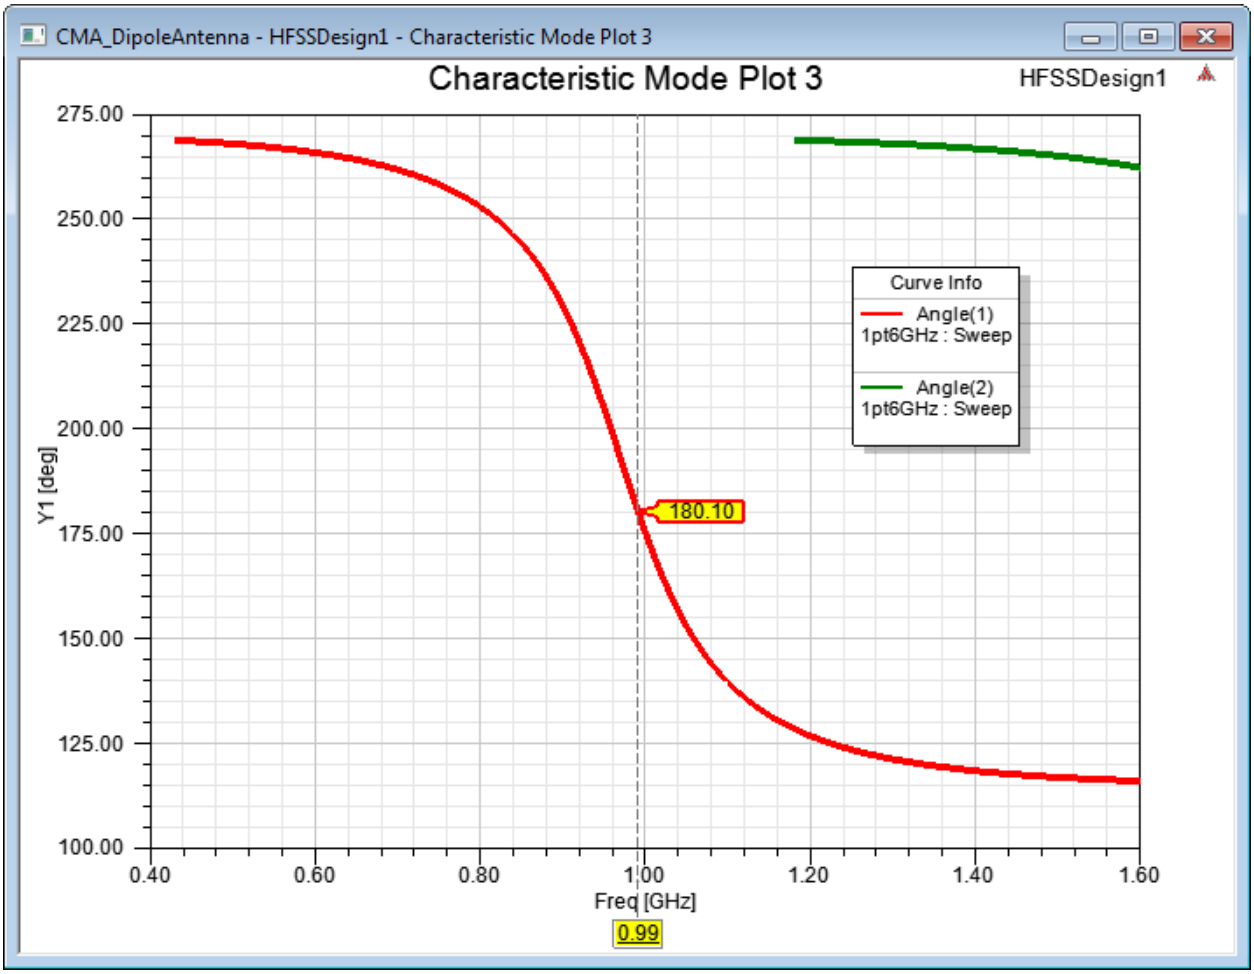
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Characteristic Value vs Frequency



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Characteristic Angle vs Frequency



The character angle for Mode 1 is 180 degrees, when it becomes resonant as shown in the above plot.

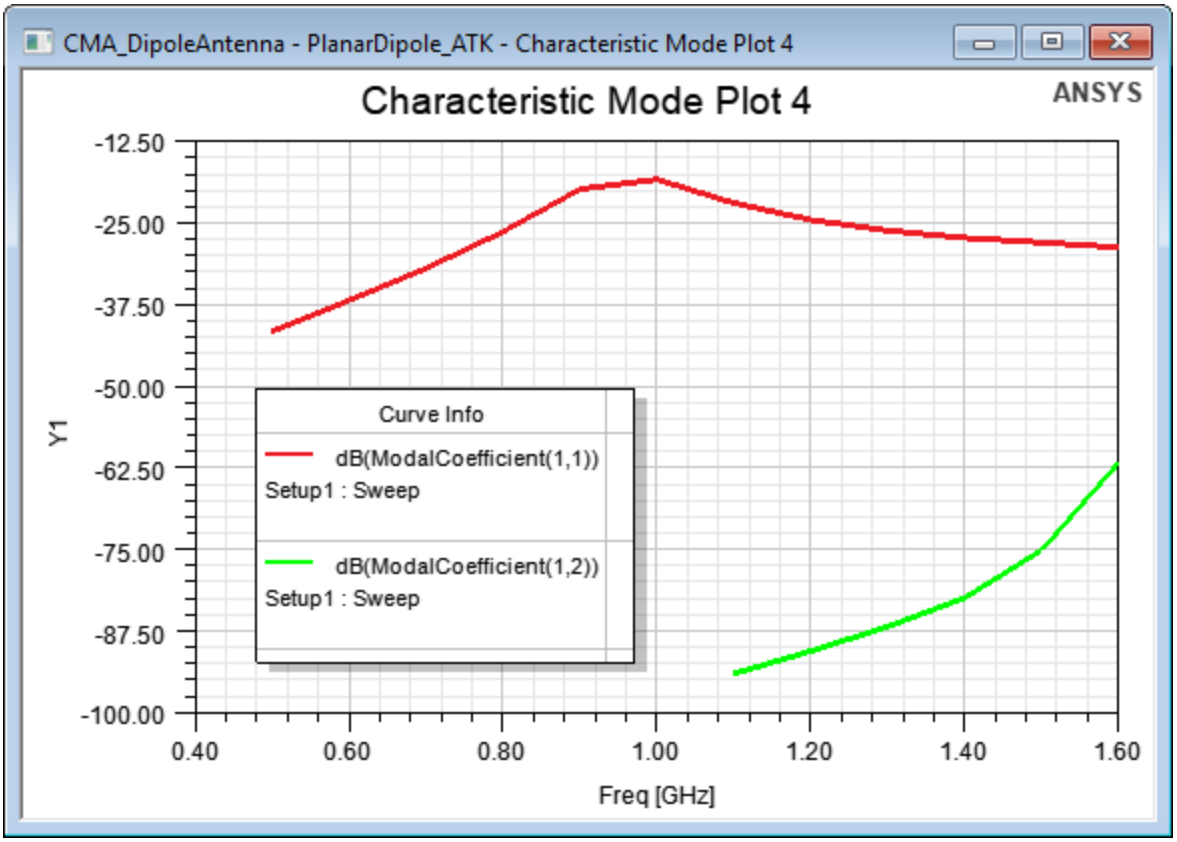
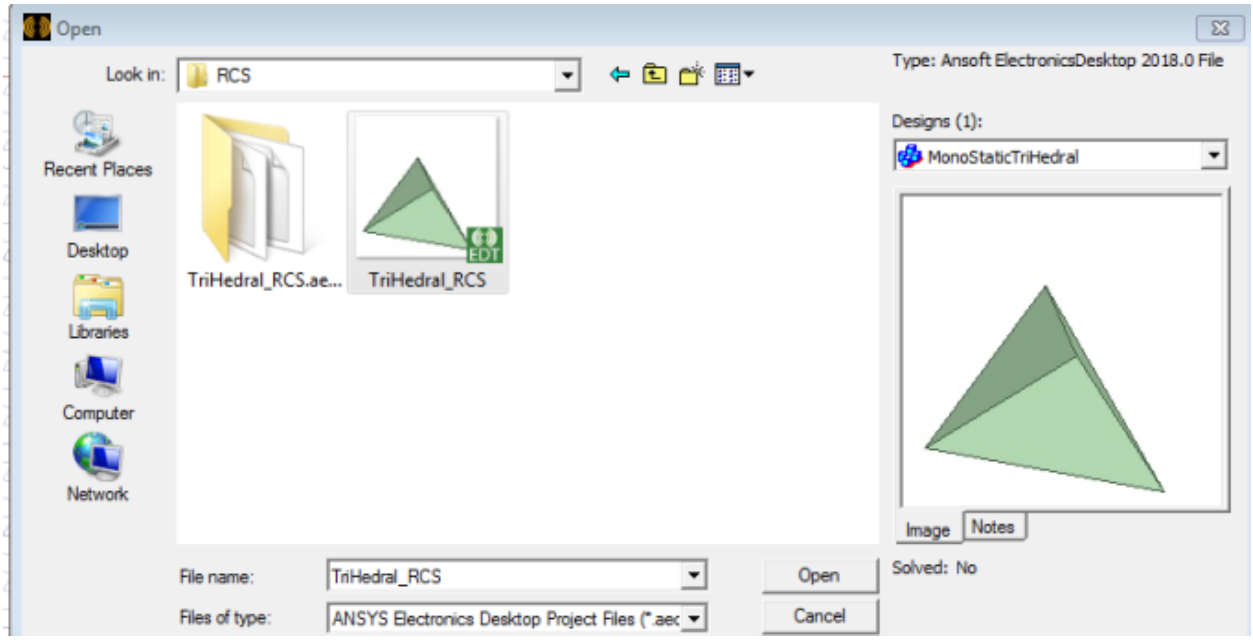
Modal Coefficient Plot



Generating Reports For Monostatic RCS

If you create a design contains both SBR+ Regions and Incident Plane wave you can then create reports for Monostatic RCS. The example projects for HFSS includes an example RCS project that demonstrates this.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

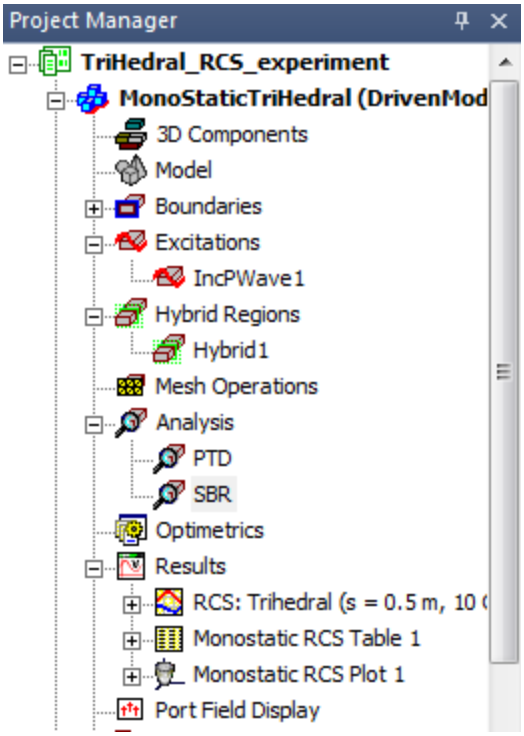


In the case of non-SBR+ projects:

- The new Monostatic report type works with non-SBR+ cases as well.
- For old version projects with Monostatic RCS report already defined it will still work but cannot be modified. The modify dialog will have far fields but not Monostatic RCS in the category column.

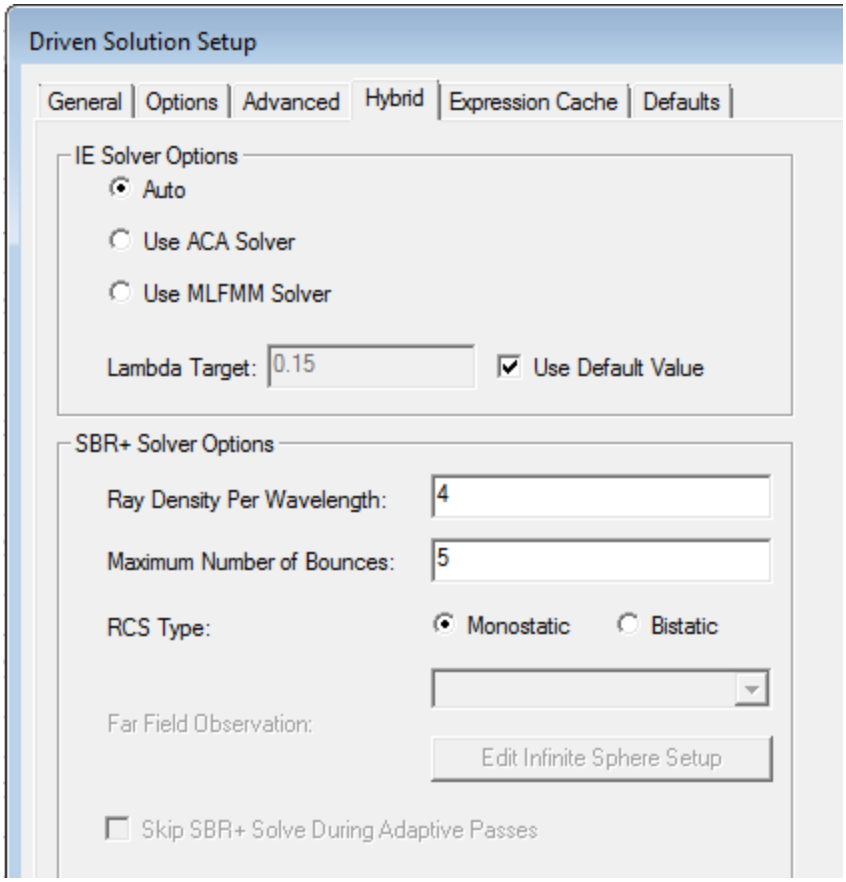
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The RCS example design includes an SBR+ Hybrid Region as well as an incident plane wave:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Designs with these elements include a selection for RCS Type as Monostatic or Bistatic.



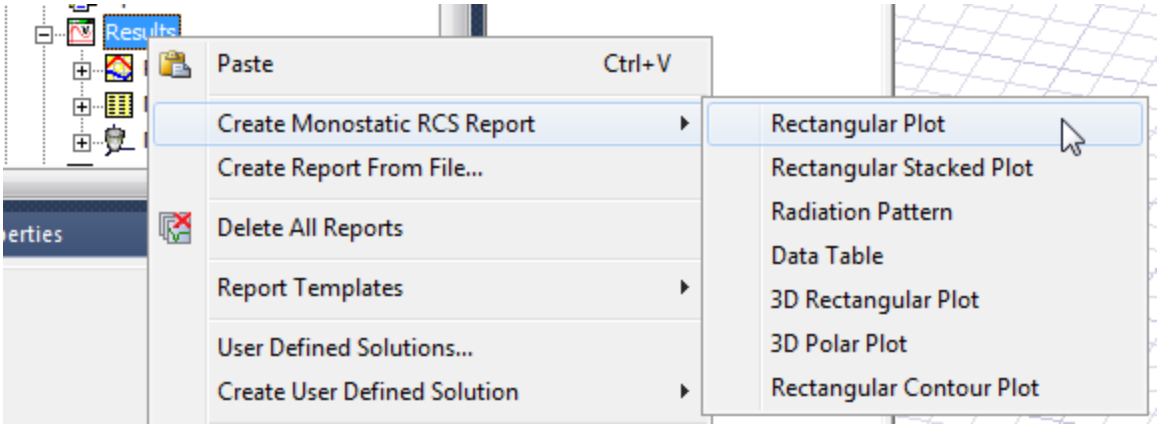
Selecting Monostatic permits you to create Monostatic Reports. In this case, the Infinite Sphere setup is disabled because the solver uses the direction of the Incident Plane wave to calculate the solution.

Monostatic RCS Reports

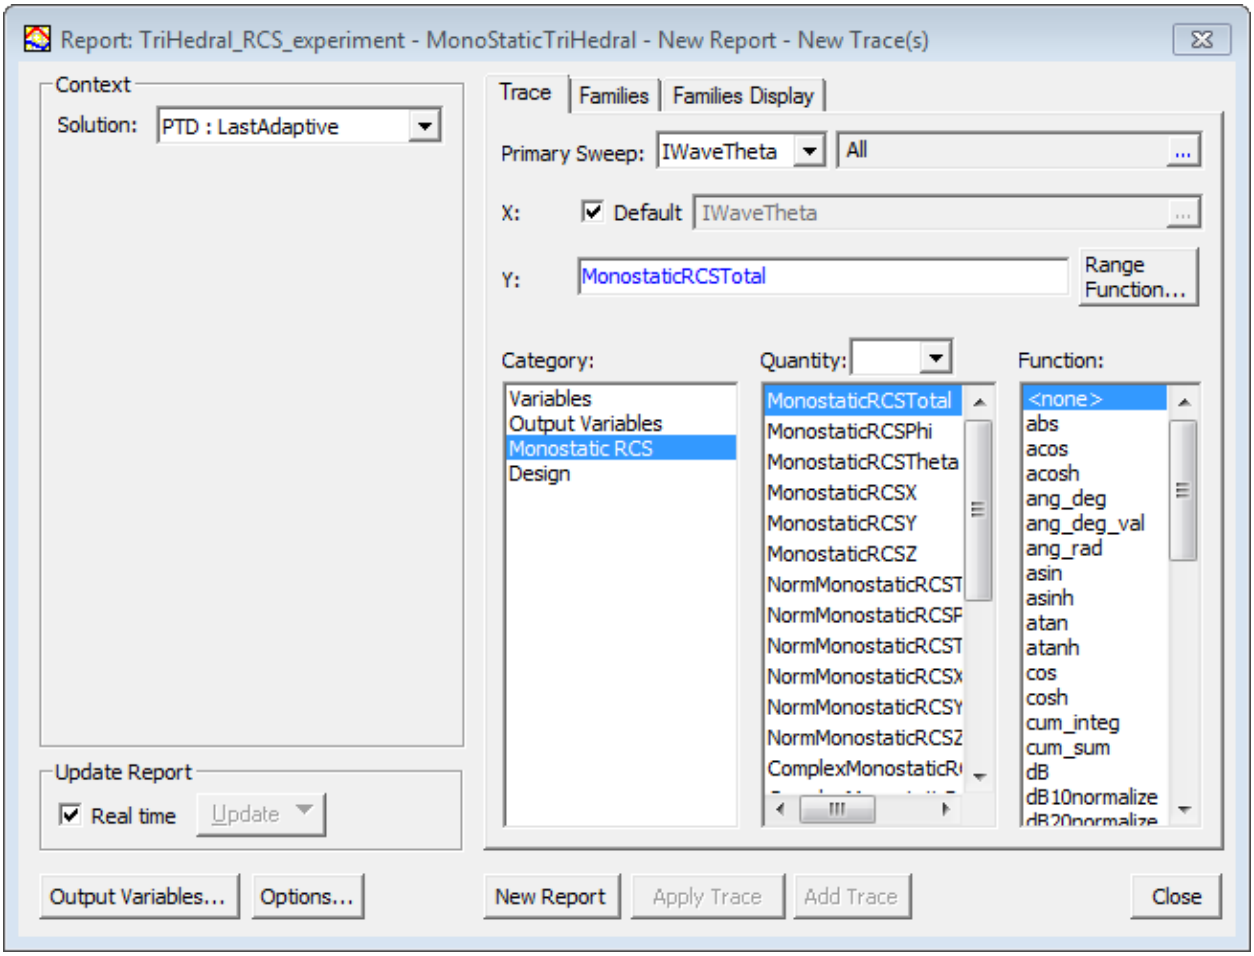
The process for generating Monostatic RCS Plots is as follows--

1. Solve a design containing SBR+ Hybrid Regions and an Incident Plane wave with no other excitations.
2. Right-click **Results > Create Characteristic Mode Data Report > Rectangular Plot** to open the **Report** dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. In the Context panel you can select the solution, but you do not need to select any geometry when using SBR+ and Monostatic RCS. Select the Category as Monostatic RCS to see a Quantity list for Monostatic traces you can create.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. You can choose between Freq, IWaveTheta and IWavePhi variables for specifying sweeps.

Creating a Report from an Ansoft Report Data File

If you have previously saved an Ansoft Report Data Format (using Report2D > Export), you can create a report from that rdat file. This provides a way to reuse the data and/or the format of a previously created report.

1. Right-click the Results icon in the Project Manager to display the short cut menu and select **Create Report From File**, or click **HFSS** or **HFSS-IE** > **Results** > **Create Report From File**.

   A file browser displays.

2. Select an .rdat format file, and click **Open**.

   The report is created. If it contains data, it displays the report with traces. If not, the report uses the format exported to the .rdat file.

Zooming and Fitting Reports

The standard Zoom and Fit commands operate on reports. After clicking in an open report, you can also use a mouse wheel to zoom in and out.

Modifying the Background Properties of a Report

To modify the appearance of a report, or to modify the display properties any object in a report, including traces, axis labels, grids, colors, fonts, legends, color maps, contour color, and so forth:

1. Open the report you want to modify.
2. Select an editable object in the report to be able to edit its properties. Click on an object to select it and to view its properties in the docked **Properties** window. To open a floating **Properties** window, either double-click the selected object, or select **Edit** > **Properties** from the menu bar.

   The **Properties** tabs and options displayed for editable plot objects varies depending on the report type (for example, whether 2D rectangular, 2D polar, Smith, Stacked, or 3D), but can include the following:

   - **Cartesian** – controls the scroll bar and thumb properties for 2D rectangular plots.
   - **Header** – controls the properties for the text displayed at the top of the report, including the Title font, Company Name, Show Design Name, Subtitle Font. The plot title is tied to the report's name and is not a Header property. If you change the report name in the Project tree, plot title synchronizes. The Company Name and the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Show Design Name check box are grouped in the **Properties** dialog box as Subtitle. Edits to the Subtitle Font Property affects both of them.

- **General** – controls the background color (the perimeter around the trace display) for the plot, the contrast color (the trace display background), the Field width, the Precision, and whether to use scientific notation for marker and delta marker displays. (X and Y notation display is set separately, in the Axis property tabs.) An Auto Scale Fonts property is on by default and scales text in plots and colorkey (contour plot, field plots in 3D modeler) for high resolution screens.
- **Legend** – controls the properties for whether to include a Legend Name, Show Trace Name, Solution Name, and Variation Key. At least one of these must be selected. Legend Name is blank by default. When non-empty, a header row for the Legend in plot shows up with that string. You can also specify the File Name Display as Full Path, File Name without Path, or as an Array Index. You can also edit the Font, the background color of the Legend box, the Border Color, the Border Width, Grid Color (for the lines between Trace descriptions), and the Grid line width. See: Modifying the Legend in a Report.
- **Color Key** – for 3D plots, controls the appearance of the color key (colors, transparency, border appearance, fonts, number format, field width and precision.
- **Contour** – for 3D plots, controls the appearance of the color map, including map type, ramp color, spectrum, IsoValType, levels, number of contours, and values shown.
- **Radiation Pattern** – for 2D polar plots, controls whether to show the circular grid and angle lines.
- **Stacked** – for stacked plots, controls properties for X scrollbar, thumb properties, and stack layout, auto fit, and stack height.
- **Smith** – for Smith charts, controls whether to show grids for Imp., Adm., Cir, and angle lines.
- **Traces** – controls the properties for traces, including: Color, Line Style, Line Width, Trace Type, whether to Show a symbol, Symbol Frequency, Symbol style, whether to Fill symbol, symbol color, and whether to show arrows. You can select traces either in the Legend or on the plot. See: Editing the Display Properties of Traces.
- **Axis** for X, Y or Z, or for Phi, Theta or Rho, and circular – the defaults for most of these values (applying to 2D and 3D both) are set in the **Report 2D Options**Axis tab.
    - Display name – check box for whether to display the axis name.
    - Specify name – check box for specifying the Axis name.
    - Name – this describes the axis to which the following properties/options refer. These are selected in the **Report** dialog box.
    - Axis Color – set the color by double-clicking to display the **Set color** dialog box. Select a default or custom color and click OK.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Axis Font – click the cell to display the **Edit Text Font** dialog box. The dialog box lets you select from a list of available fonts, styles, sizes, effects, colors, and script. The dialog box also contains a preview field. OK the selections to apply the font edits and to close the dialog box.
- Display Units – this specifies whether to display the axis units.
- **Window (section):**
  - Window Mode – can be Axis range, Continuous moving window, or Step moving window.
  - Window Width (in) – provide an integer value for the previous selection.
- **Manual Format** (section):
  - Number format – select from the drop down menu, Auto, Decimal, or Scientific notation.
  - Field Width – enter a real value.
  - Field Precision – enter a real value.

■ X or Y or Z **Scaling Tab** – These properties provide control over scaling:

- Axis Scaling – use the drop-down menu to select scaling as Linear or Log. For the Y axis, all zero or negative values are discarded before log scaling is applied. For 3D plots, scaling is on the Axis tabs
- Specify Min – check box
- Min – text entry in same units as axis units. Saved as SI internally.
- Specify Max – check box
- Max – text entry in same units as axis units. Saved as SI internally.
- Specify Spacing – check box
- Spacing – text entry in same units as axis units. Saved as SI internally
- **Manual Units** (section):
  - Auto Units – use the check box compute the correct units for the axis.
  - Units – click on the cell to select from a menu of available units if you have not checked Auto Units.
- **Infinity Visualization** (section):
  - Map Infinity Mode – check box.

    Each axis can be set to treat infinity values in a user defined way. When you check the Map Infinity Mode, any infinity values in the input data get the infinityMap value (negative infinity get the value*-1 and positive infinity the positive value specified). This can be useful if there are zeros, or very small values that HFSStreats as zero, in the data, for example, dB Gain.

  - Map Infinity To – enter a real value for the Map Infinity Mode.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Grid** – properties for grid labels and grid style, appearance, line styles, color, major and minor lines, major and minor circles on polar grids, and scaling. For the 3D rectangular plots, there are separate tabs for the XY, YZ and ZX axes, and for 3D Polar plots, tabs for phi-rho, or theta-rho grids.

3. Edit the properties, and **OK** the dialog box to apply the changes.

Modifying the Legend in a Report

The legend in a report is a list of the curves being plotted. For each curve, the legend gives the name, shows the line color, and lists the setup and the adaptive pass used to generate the curve.

To show or hide a legend in a report:

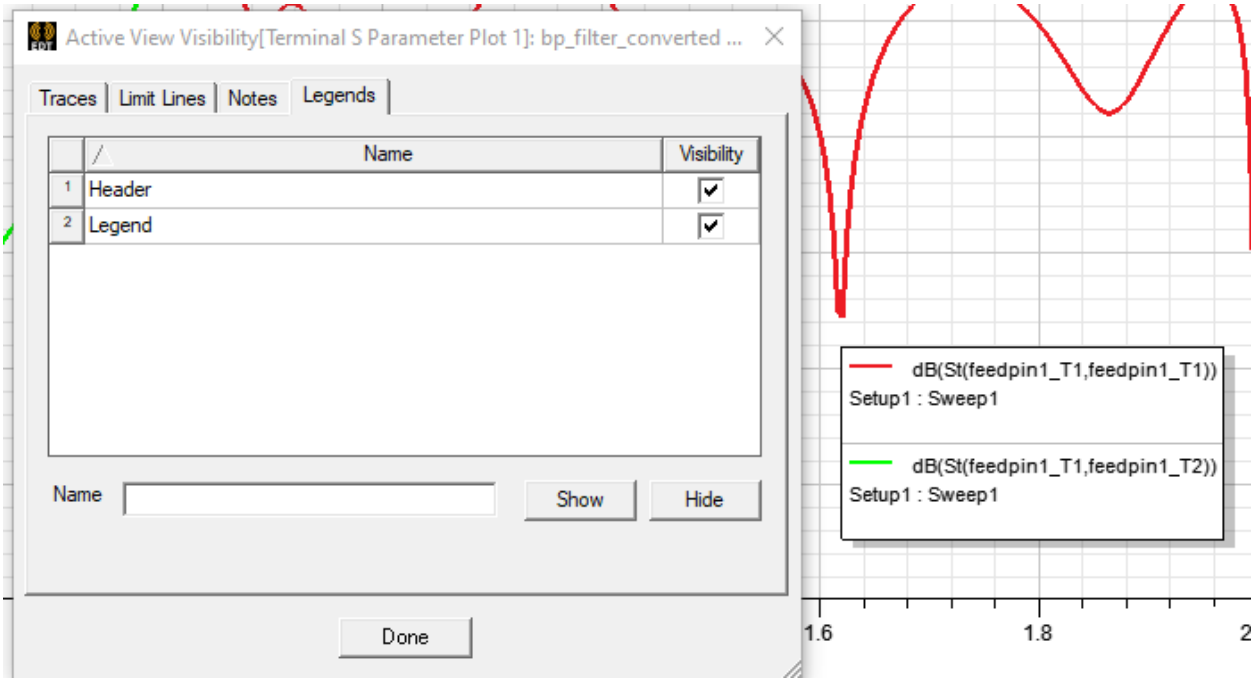
1. Make the report the active view.
2. Use **View** > **Active View Visibility** or the **Show/Hide** icons on the toolbar to display or hide the report.

   Either command displays the **Active View** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Select the **Legend** tab.

   This lists the legend (or legends) in the report.



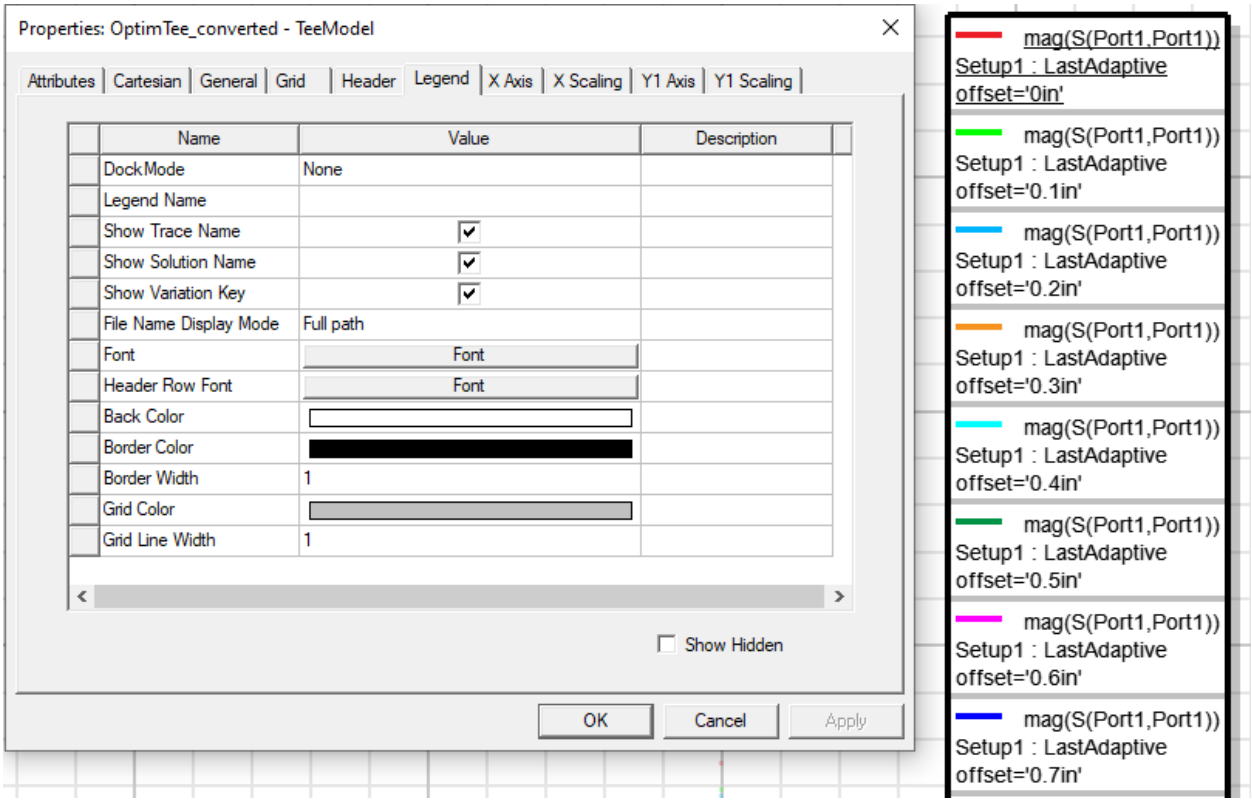
4. Enable the visibility check box, and click **OK** to close the dialog box and apply the change.

To edit the display properties of a legend:

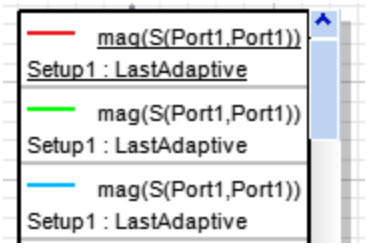
1. Double-click a legend in a report to display a docked properties window, or right-click on the legend and select **Edit** > **Properties** to display the floating **Properties** dialog box.

   This lets you edit the Properties for Dock Mode, Legend Name (default is no name. When non-empty, a header row for the Legend in plot shows up with that string.), whether to Show Trace Name, Solution Name, and Variation Key (which applies to parametric variables, if present). If none of these three are selected, only a trace color shows.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Here is an example with Variation Key off.



You can also edit the Font by clicking the Font cell to display the **Edit Text Font** dialog box. The dialog box lets you select from a list of available fonts, styles, sizes, effects, colors, and script. The dialog also contains a preview field. OK the selections to apply the font edits and to close the dialog box.

You can also edit the background color of the Legend box, the Border Color, the Border Width, Grid Color (for the lines between Trace descriptions), and the Grid line width.

2. Click **OK** to close the **Properties** dialog box and apply the selections.

To change the display name for traces, see: Editing Trace Properties.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To move a legend in a report:

1. Click and hold on the legend.

   The cursor changes to crossed lines with arrow tips.

2. Still holding, drag the legend to a new location and release.

   The legend is released and the crossed lines change back to a mouse pointer.

To resize a legend in a report:

1. Position the mouse tip over the edge you want to resize.

   The mouse pointer changes to a horizontal or vertical line with arrow tips.

2. Click and drag the horizontal or vertical edge to the desire size.
3. Release.

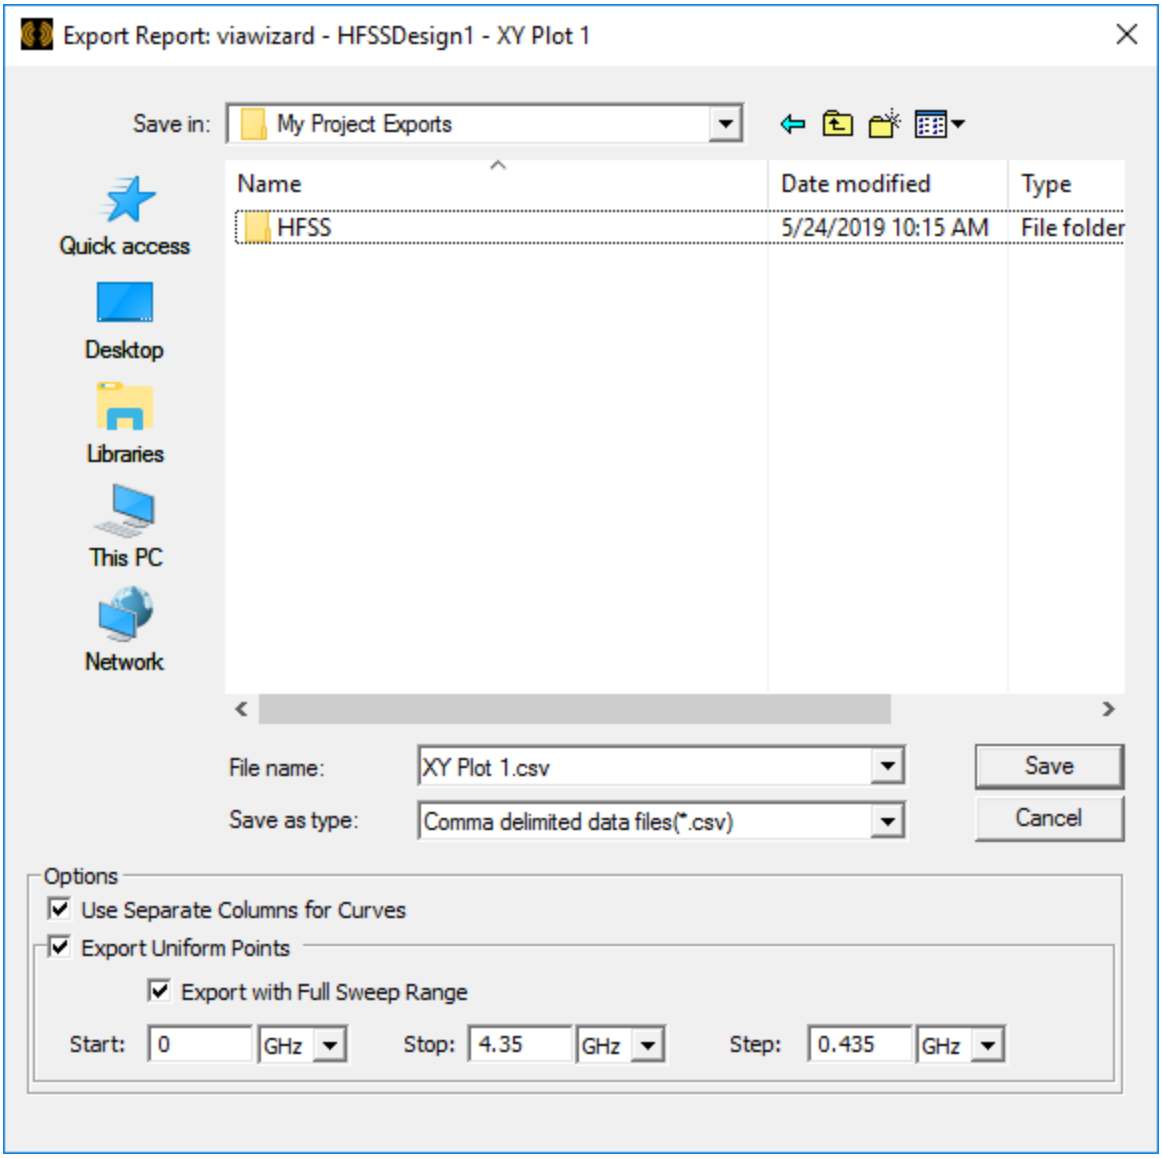
Exporting Ansoft Report Data Format Files

Ansoft Report Data format (*.rdat) files provide a way to export reports or report formats, which you can then import using **Reports> Create Report From File**. This can save repeated editing of properties (for example, the company name or color schemes) when you create other reports. You must have an existing plot open to see the **Report2D** menu.

1. Click **Report2D** > **Export...** or **Report 3D**> **Export...**

   The **Export Report** dialog box appears:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Use the **Save as type** drop-down menu to select **Ansoft Report Data Files (*.rdat)** format.
3. Browse to a destination folder and enter a name for your file in the **File name** field.
4. The **Export Uniform Points** option, if available for your report type, allows the *.rdat file to contain points for the start, stop, and step at the given frequencies. If you do not select this option, the file contains only the current file format, including any modifications you have applied.
5. Click **Save**.

   The file is exported to the specified location as an Ansoft Report Data file (*.rdat).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

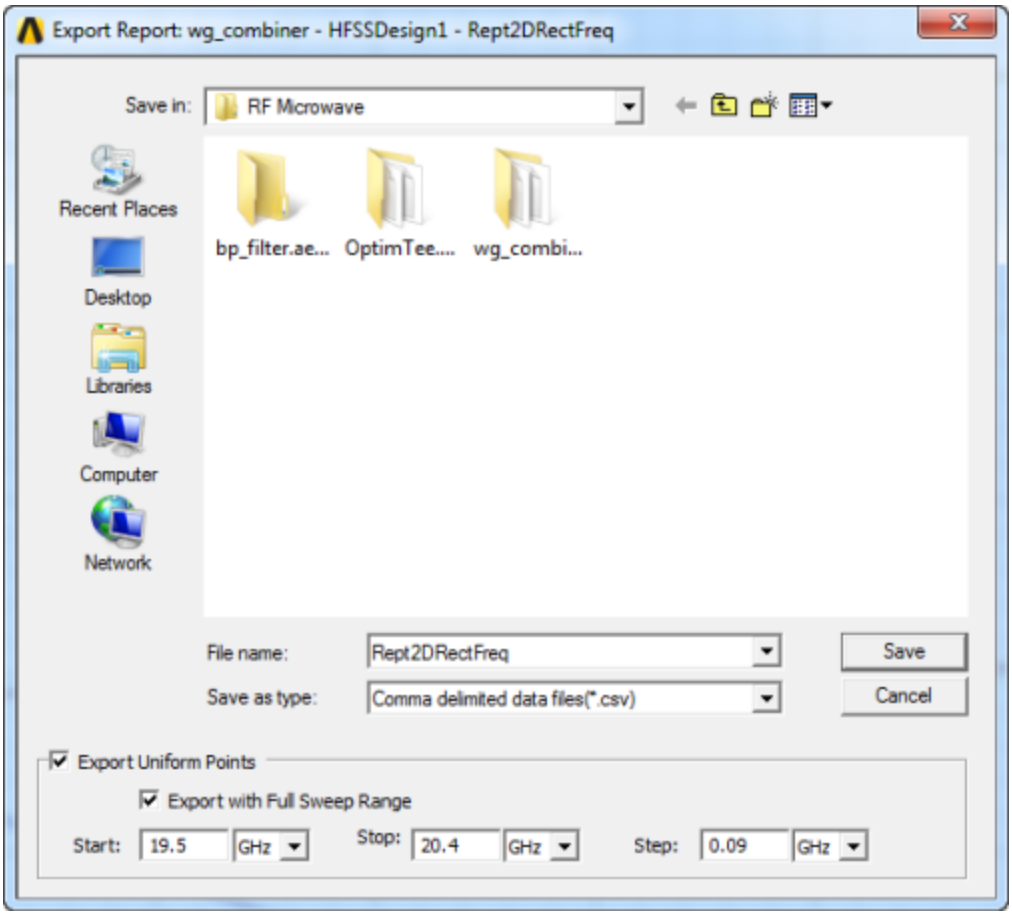
The file will then be available for import using Create Report from file.

Exporting Reports as Graphics

You can export reports as figures in several formats. You must have an existing plot open to see the **Report2D** or **Report 3D** menu.

1. With a report open, click **Report2D** > **Export...** or **Report3D** > **Export...**

   The **Export Report** dialog box appears:



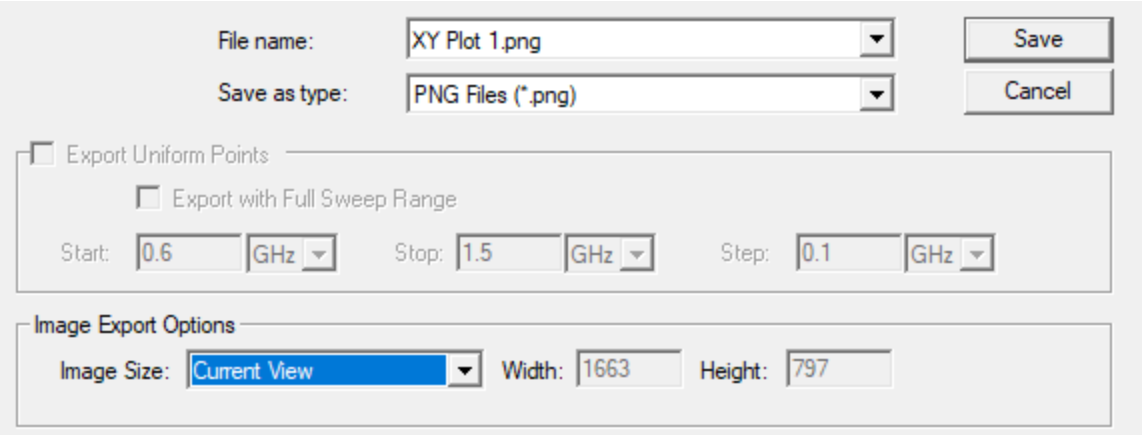
2. Click **Browse...** to open the **Export Report** browser window.
3. Specify the file location and name, and select a graphics format from the drop-down menu:

   - .bmp
   - .gif
   - .jpeg

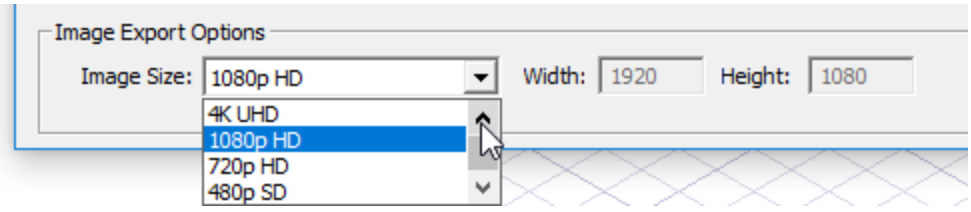
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- .png
- .tiff
- .wrl

4. When you select an image format, the **Image Export Options** appear at the bottom of the dialog box:



5. Specify the **Image Export Options** by selecting from the drop-down menu. You may need to scroll or click the up or down arrows to see all selections. These include: Current View, User Defined (which enables the Width and Height fields), Full Screen, 8K UHD, 4K UHD, 1080p HD, 720p HD, and 480p SD. The resolution for the current selection is displayed in the Width and Height fields.



6. Click **Save** to close the browser window, and then **OK** to close the **Export** window.

To export an image file of a report to specified high resolution, use the scripting commands. The image can be created at a specified resolution. Fonts and line thickness is not scaled. Only the image. You will have to iteratively increase font sizes until you find a suitable output.

Report File Formats

The following table provides information about the file formats that can be imported into plot data reports:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

File Extension	Information
csv	• Uses a comma (,) as the separation character. • The x-axis value is in the first column. Each curve's Y-values make up one column, and the curves are in the same order as in the plot legend. • The first row is the X-axis name [unit] and the information for each curve, which is the same as the plot curve legend. • Other rows are the X-axis value and the Y-value for each curve.
tab	• Uses the tab character as the separation character. • The x-axis value is in the first column. Each curve's Y-values make up one column, and the curves are in the same order as in the plot legend. • The first row is the X-axis name [unit] and the information for each curve, which is the same as the plot curve legend. • Other rows are the X-axis value and the Y-value for each curve.
txt	The txt file must begin with a header that contains the following: • A first line made of 92 equal signs (=) • A second line that begins with the company name and ends with the date in MM/DD/YY format • A third line that begins with a plot name and ends with the time in hh:mm:ss format • A fourth line, which is empty • A fifth line made of 92 hyphens (-) **Note:** Each header line must be 92 characters in length, except the empty line. • Each column has a fixed width, separated by white space. • The x-axis value is in the first column. Each curve's Y-values make up one column, and the curves are in the same order as in the plot legend. • The first row is the X-axis name [unit] and the trace name [unit] for each curve, which is the same as the plot curve legend. • The second row is an empty column and the variable values for each curve, which is the same as the plot curve legend. • Other rows are the X-axis value and the Y-value for each curve.
dat	DAT is an Ansys-specific format. Ansys recommends that you do not generate

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

File Extension	Information
	files using this format. Files imported with these formats should be exported only from Ansys products.
rdat	RDAT is an Ansys-specific format. Ansys recommends that you do not generate files using this format. Files imported with these formats should be exported only from Ansys products.

Creating Custom Report Templates and Defaults

You can edit properties from any report type and save it as a template or as the default. This can save repeated editing of properties (for example, the company name, or color schemes and plot attribute settings) when you create other reports. You can prepare a template by copy/pasting plots settings from one plot to another of the same display type. Once you create templates, you can access them from the **Results** > **Report Templates** > menu and the **Report2D** > **Report Templates** > **Apply Settings** menu.

See Modifying the Background Properties of a Report for a discussion of format changes you can make to any report.

To save an edited report as a template:

1. In the Project Tree, right-click the report name of interest to display the shortcut menu and click **Report Templates** > **Save...**. You can also click **Report2D** > **Report templates** > **Save...** or **Report3D** > **Save As Template...**

   This displays the **Save As Report Template** file browser. By default, the directory is your AnsysEM\<*productName*>\userlib\ReportTemplates directory. You can also save to the SysLib directory.

2. Typically, you accept the directory.
3. You must provide a file name, which will be given an *.rpt extension.

   It is good practice to give the template a descriptive name, showing both the kind of format you begin with (such as XY Plot or 3D Plot) and apt description of the distinguishing edits (such as for company name, or color scheme). Once, saved, this name will appear on the *PersonalLib* menu.

   The **Save As Type** field currently supports the Ansoft Report Format (*rpt) format.

4. Click **Save** to save the template to the PersonalLib menu.

All *.rpt templates in the userLib directory appear on the **Results> Report Templates> PersonalLib** menu. Selecting a report from the PersonalLib menu opens a report that you can then Modify to add traces or perform other edits. Templates in the SysLib directory appear on the **Report Templates** menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To save an edited report as a default:

1. In the Project Tree, right-click the report name of interest to display the shortcut menu and click **Report Templates** > **Save Settings as default**. You can also click **Report2D** > **Report templates** > **Save Settings as default** or **Report3D** > **Save Settings as default**.

Selecting the Report Type

The **Report Types** available for creating a report depend on the simulation setup. The report category provides the default report name for the project tree and the text displayed in the report header. For example, S Parameters as the Category type causes the default report name to be S Parameter Plot *n*. Depending on the setup, you can make a selection from the following report types.

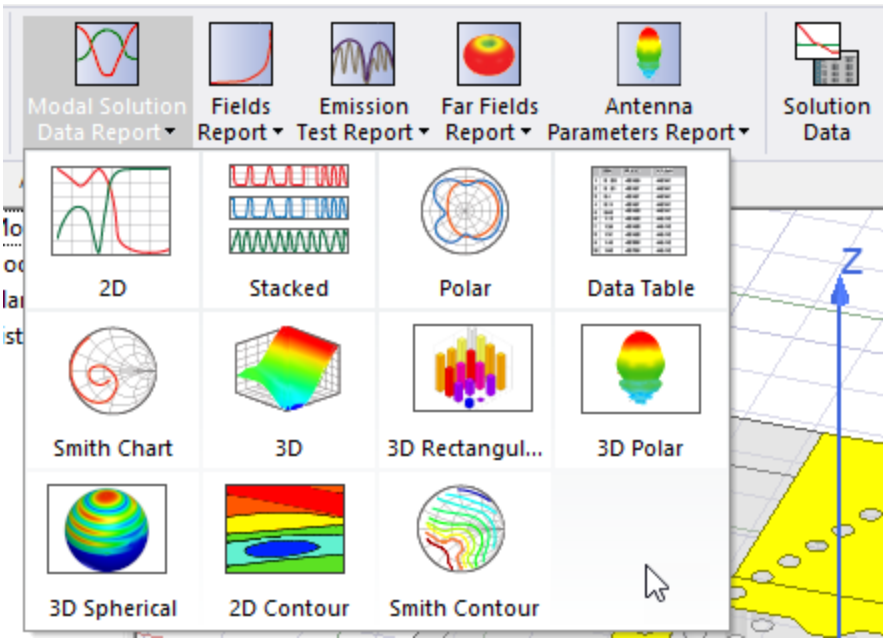
Modal Solution Data	S-, Y-, and Z-parameter data are available to plot, along with propagation constant, characteristic port impedance, reflection/transmission coefficients for HFSS designs, and Voltage Standing Wave Ratio (VSWR) data. For HFSS calculations, phase is currently assigned zero value.
Terminal Solution Data	This solution type results in a terminal-based description in terms of voltages and currents. Some modal data is also available. The terminal-based S-, Y-, and Z- parameters, VSWR, Port Zo, and Active S-, Y-, Z- and VSWR parameters are available to plot.
Eigenmode Parameters	Eigen Modes and Eigen Q data are available to plot.
Characteristic Modes	For HFSS Characteristic Mode solution types, graphing modal significance as a function of frequency lets you easily examine the importance of the modes and understand which of the modes contribute significantly to the radiated power (MS = 1), and the ones that are decaying (MS = 0). This helps toward correct antenna placement on electrically medium-sized structures.
Fields	Basic or derived field quantities calculated on lines or integrated over surfaces or objects are available to plot. Displacement magnitude is available as a predefined modal field result. Predefined thermal field results include temperature, heat flux magnitude, and EM loss densities.
IE Surface Fields	For an HFSS design that uses IE Regions, the solver produces J and Q surface fields for the metallic parts (but not the dielectric parts) of these regions. The Fields Calculator provides access to the IE surface fields quantities.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Far Fields	Radiated fields computed in the far-field region. The following quantities are available to plot: rE, gain, realized gain, beam area, directivity, axial ratio, polarization ratio, and normalized antenna calculated by HFSS. You can do Contour Plots with a Domain of either Theta, Phi, or Sine Space. You must have defined an infinite sphere geometry and at least one radiation or PML boundary to create a far-fields report. If you manually enter Phi or Theta component of a far field quantity when you using Az/El or El/Az far field definition, then the Report uses the Z axis of the Az/El or El/Az coordinate system definition as pole to calculate theta/phi component for rE.
Near Fields	Radiated fields computed in the near-field region. These include: variables, output variables, near E, max near field parameters, and near normalized antenna. You can create Contour Plots with a Domain of either Theta, Phi, or Sine Space. You must have defined a near-field line, box, rectangle, or near-field sphere and at least one radiation or PML boundary to create a near-fields report. Field components and positions in reports are in the local coordinate system of the near field domain, not global coordinates.
Antenna Parameters	Whereas far field reports are computed as points around an infinite sphere, antenna parameters provide one value per quantity for the entire sphere. You must have defined an infinite sphere geometry and at least one radiation or PML boundary to create an antenna parameters report.
Emission Test	You can conduct an emission test under the same conditions as for a near field report except that.an emission test cannot be conducted for a ports-only solution. You must have defined a near-field line or near-field sphere and at least one radiation or PML boundary.

When you click **Product > Results** or right-click **Results** in the Project tree, or select the **Results** tab of the ribbon, one or more of the following report types and displays are available. *Available options depend on the nature of your installation and project(s)*.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



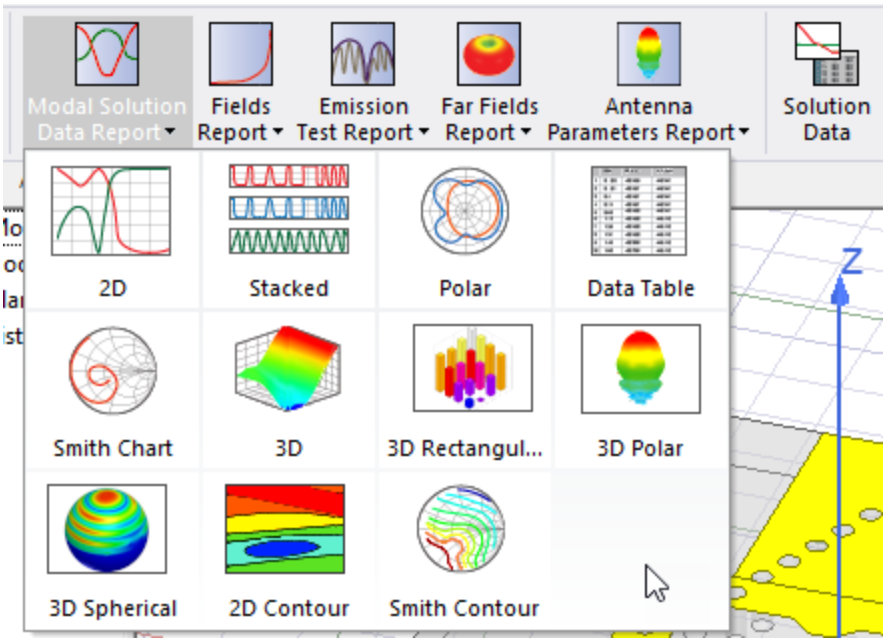
Report Type	Display Type
Create Standard Report	A Standard report can be depicted in any of the following display types: • Rectangular Plot • Data Table • Polar Plot • Smith Chart • Rectangular Stacked Plot • 3D Rectangular Plot • 3D Rectangular Bar Plot • 3D Polar Plot • 3D Spherical Plot • Rectangular Contour Plot • Smith Contour Plot
Create Eye Diagram Report	An Eye Diagram report can be depicted in any of the following display types: • Rectangular Plot • Data Table • Statistical Eye Plot

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Create Constellation Report	A Constellation report can be depicted in any of the following display types: • Rectangular Plot • Data Table
Create Statistical Eye Report	A Statistical Eye report can be depicted in any of the following display types: • Rectangular Plot • Data Table
Create Report From File	A Data File report can be created in any of the available display types using a previous report that has been saved to a file.

Selecting the Display Type

The information in a report can be displayed in several formats. When you select the **Results** tab in the ribbon, depending on reports available for a given design and Solution type, you see a selection of report type groups (for example, Modal Solution Data, or Fields Report, Emission Test, Antenna Parameters, Near Fields, Terminal Solution Report, Far Fields Report, Characteristic Mode Data, etc.), with drop-down menus that displays the kinds of reports available for the design in that group:



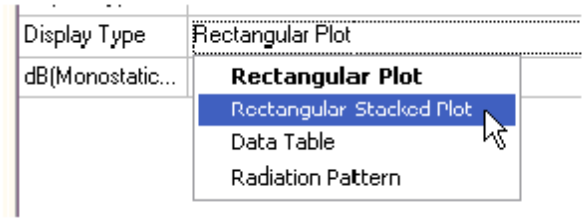
For the initial plot, you can also select from the following **Display Type** formats in the **Create*<type>* Report** submenu:

Rectangular Plot	A 2D rectangular (x-y) graph.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Rectangular Stacked Plot	This choice puts each trace into its own 2D rectangular plot, and stacks each plot, rather than overlaying the traces on the same plot.
3D Rectangular Plot	A 3D rectangular (x-y-z) graph.
3D Rectangular Bar Plot	A 3D plot of rectangular bars.
Rectangular Contour Plot	A rectangular (x-y-z) graph. Contour plots are useful to visualize surfaces (e.g., Directivity as a function of phi/theta).
Polar Plot	A 2D circular chart divided by spherical coordinates.
3D Polar Plot	A 3D circular plot divided by spherical coordinates.
3D Spherical Plot	A 3D circular plot where the radius (rho) of the plot at all points is uniform and is equal to the maximum of all rhos at each (theta, phi) points.
Smith Chart	A 2D polar chart of S-parameters upon which a normalized impedance grid has been superimposed.
Smith Contour Plot	A polar chart. Contour plots are useful to visualize surfaces.
Data Table	A grid with rows and columns that displays, in numeric form, selected quantities against a swept variable or another quantity.
Radiation Pattern	A 2D polar plot of radiated fields.

You can also modify the display type of an existing plot from the **Properties** dialog for that plot. Select the Report icon in the Project tree to display the Properties dialog box. Selecting the **Display Type** field displays a menu with selections available for that plot.



Once you make a selection, the plot display updates for the current selection.

Creating 2D Rectangular Plots

A rectangular plot is a 2D, x-y graph of results.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. On the **Results** menu (under the **HFSS** menu, or right-click **Results** in the Project Manager), click **Create < *type* > Report**, and select **Rectangular Plot**.

   The *Report* dialog box appears.

2. In the **Context** section make selections from the following field or fields, depending on the design and solution type:
   a. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes.
   b. Domain field with a drop down selection list. Whether this field appears, and the domains listed, depend on the Solution type and the report <*type*> selected. For modal and terminal solution data reports, the domain can be **Sweep** or **Time**.

      Before you can examine the time domain, you must perform an Interpolating sweep for a driven solution (Modal or Terminal). If you select **Time**, the **TDR Options** button is enabled. Select it and follow the directions for time-domain plotting.

   c. Geometry field with a drop-down selection list. For field and radiated field reports, this applies the quantity to a geometry or radiated field setup.
3. Under the **Trace** tab, **Y** component section, specify the information to plot along the y-axis:
   a. In the **Category** list, click the type of information to plot. The category selected provides the default plot name.
   b. In the **Quantity** list, click the value to plot.
   c. In the **Function** list, click the mathematical function of the quantity to plot.
   d. Value field displays the currently specified Quantity and Function. You can edit this field directly.

      > **Note:**
      >
      > Color shows valid expression.

   e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.
4. On the **Trace** tab, **X** (Primary sweep) line, specify the quantity to plot along the x-axis in one of the following ways:
   - Select the sweep variable to use from the drop-down list.
   - If sweeps are available, you can select the browse button to display a dialog that lets you select particular sweep or sweeps, or all sweeps. The quantity will be plotted against the primary sweep variable listed.
5. On the **Families** tab, confirm or modify the sweep variables that will be plotted.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

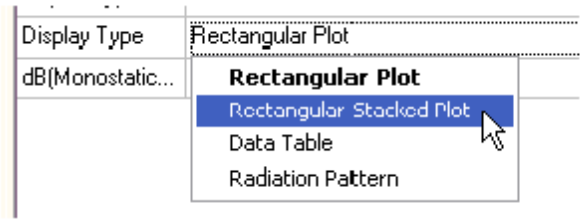
6. Click **New Report**.

   This creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog.

   The function of the selected quantity will be plotted against the swept variable values or quantities you specified on an x-y graph. The plot is listed under **Results** in the project tree and the traces are listed under the plot. The default name is based on the Report Category you selected, (for example, S Parameter Plot *n* or rE Plott *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.

7. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

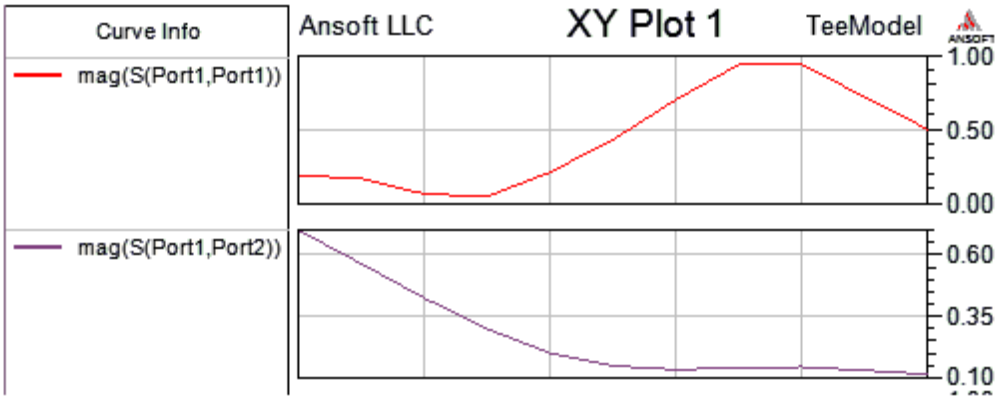
You can also modify the display type of an existing plot from the Properties dialog for that plot. Select the Report icon in the Project tree to display the Properties dialog box. Selecting the Display Type field displays a menu with selections available for that plot.



Once you make a selection, the plot display updates for the current selection.

Creating 2D Rectangular Stacked Plots

A rectangular stacked plot is a 2D, x-y graph of results, with each trace displayed on a separate plot.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. On the **Results** menu (under the **HFSS** menu or right-click **Results** in the Project Manager), click **Create <*type*> Report**, and select **Rectangular Stacked Plot**.

   The *Report* dialog box appears.

2. In the **Context** section make selections from the following field or fields, depending on the design and solution type:
   a. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes.
   b. Domain field with a drop-down selection list. Whether this field appears, and the domains listed, depend on the Solution type and the report **<*type*>** selected. For modal and terminal solution data reports, the domain can be **Sweep** or **Time**.

      Before you can examine the time domain, you must perform an Interpolating sweep for a driven solution (Modal or Terminal). If you select **Time**, the **TDR Options** button is enabled. Select it and follow the directions for time-domain plotting.

   c. Geometry field with a drop down selection list. For field and radiated field reports, this applies the quantity to a geometry or radiated field setup.
3. Under the **Trace** tab, **Y** component section, specify the information to plot along the y-axis:
   a. In the **Category** list, click the type of information to plot. The category you select provides the default plot name.
      b. In the **Quantity** list, click the value to plot.
   c. In the **Function** list, click the mathematical function of the quantity to plot.
   d. Value field displays the currently specified Quantity and Function. You can edit this field directly.

      > **Note:**
      >
      > Color shows valid expression.

   e. **Range Function** button -- opens the *Set Range Function* dialog box. This applies currently specified Quantity and Function.
4. On the **Trace** tab, **X** (Primary sweep) line, specify the quantity to plot along the x-axis in one of the following ways:
   - Select the sweep variable to use from the drop down list.
   - If sweeps are available, you can select the browse button to display a dialog that lets you select particular sweep or sweeps, or all sweeps. The quantity will be plotted against the primary sweep variable listed.
5. On the **Families** tab, confirm or modify the sweep variables that will be plotted.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

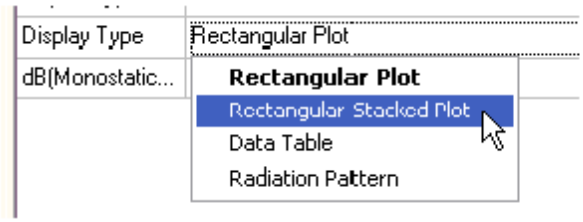
6. Click **New Report.**

   This creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, S Parameter Plot *n* or rE Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The function of the selected quantity will be plotted against the swept variable values or quantities you specified on an x-y graph. The plot is listed under **Results** in the project tree and the traces are listed under the plot. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.

7. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

You can also modify the display type of an existing plot from the Properties dialog for that plot. Select the Report icon in the Project tree to display the Properties dialog box. Selecting the Display Type field displays a menu with selections available for that plot.

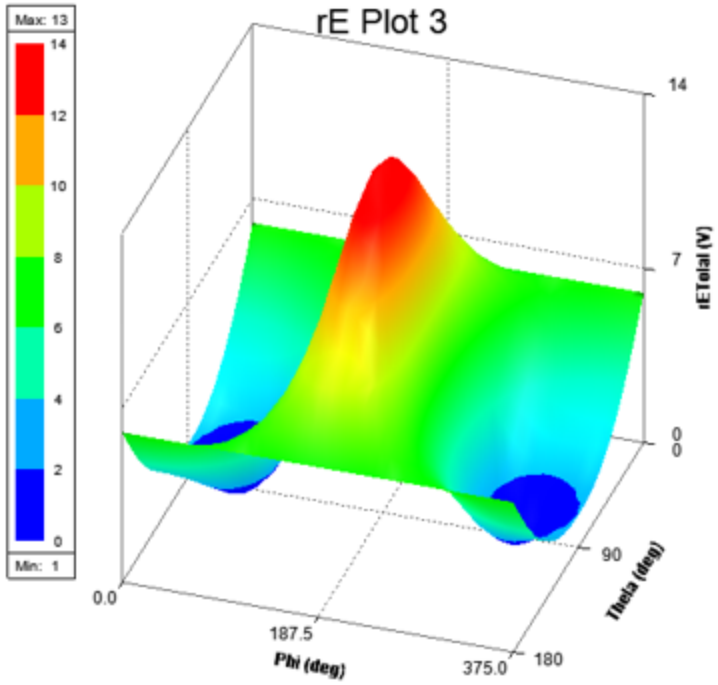


Once you make a selection, the plot display updates for the current selection.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating 3D Rectangular Plots

This is a 3D, x-y-z graph of results.



Working with a 3D Rectangular Plot

You can Rotate, Zoom, and Pan a plot. When you rotate, the Cartesian grid responds so that the curve always remains in front and the grids behind.

Clicking on a plot entity selects it, highlighting the selected entity in bold.

Double-clicking anywhere in the plot brings up the Properties dialog box. The properties are grouped appropriately under various tabs, which correspond to plot entities:

- General: For general plot properties such as Visual Detail level and background color
- Header: Properties related to plot Header/Title.
- Axis [X|Y|Z]: Properties related to the 3 axes
- Grid [XY|YZ|ZX]: Properties related to the 3 grids
- ColorKey: Properties related to ColorKey, including borders, background, Min and Max, as well as number format and precision.
- Contour: Properties related to contouring of all curves/surfaces
- Surface: Properties related to the curve

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Selecting a property also displays its properties in the Property window. You can edit the properties to customize the appearance of the plot. See "Controlling Visual Detail in a 3D Plot" on the facing page.

Creating a 3D Rectangular Plot

1. On the **Results** menu (under the **HFSS** menu or right-click **Results** in the Project Manager), click **Create *<type>* Report**, and select **3D Rectangular plot** from the report type menu.

   The *Report* dialog box appears.

2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   a. Solution field with a drop-down selection list. This lists the available solutions, whether sweeps or adaptive passes.
   b. Geometry field with a drop-down selection list. For field and radiated field reports, this applies the quantity to a geometry or radiated field setup.
3. Under the **Trace** tab **Z** Component area, specify the information to plot along the z-axis:
   a. In the **Category** list, click the type of information to plot. The category you select provides the default plot name.
   b. In the **Quantity** list, click the value to plot.
   c. In the **Function** list, click the mathematical function of the quantity to plot.
   d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

      > **Note:**
      >
      > Color shows valid expression.

   e. **Range Function** button -- opens the *Set Range Function* dialog box. This applies currently specified Quantity and Function.
4. On the **Trace** tab **Y** (Secondary sweep) lines, specify the information to plot along the y-axis in one of the following ways:
   - Select the sweep variable to use from the drop-down list.
   - If sweeps are available, you can select the browse button to display a dialog that lets you select particular values. The quantity will be plotted against the primary sweep variable listed.
5. On the **Trace** tab **X** (Primary sweep) lines, specify the information to plot along the x-axis in one of the following ways:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Select the sweep variable to use from the drop-down list.
- If sweeps are available, you can select the browse button to display a dialog that lets you select particular values. The quantity will be plotted against the primary sweep variable listed.

6. On the **Families** tab, confirm or modify the sweep variables that will be plotted.
7. Click **New Report.**

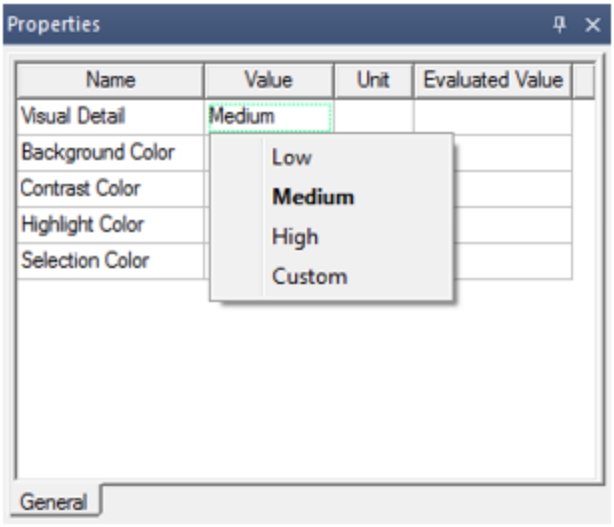
   This creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, S Parameter Plot *n* or rE Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The function of the selected quantity or quantities will be plotted against the values you specified on an x-y-z graph. The plot is listed under **Results** in the Project Manager. When you select the traces or plots, axis or grid labels, plot header, color key, or variable labels, their properties are displayed in the Properties window. The properties for each plot element can be edited directly to modify the plot content and appearance. See Modifying the Background Properties of a Report.

8. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

Controlling Visual Detail in a 3D Plot

If a particular plot seems busy with information, you can edit plot properties, such as Axis and Grid Attributes for discrete levels of visual detail to improve readability. Double-click anywhere on a plot to display the Properties dialog box. The Visual Detail property on the General tab also provides control suited to different screen and plot sizes.

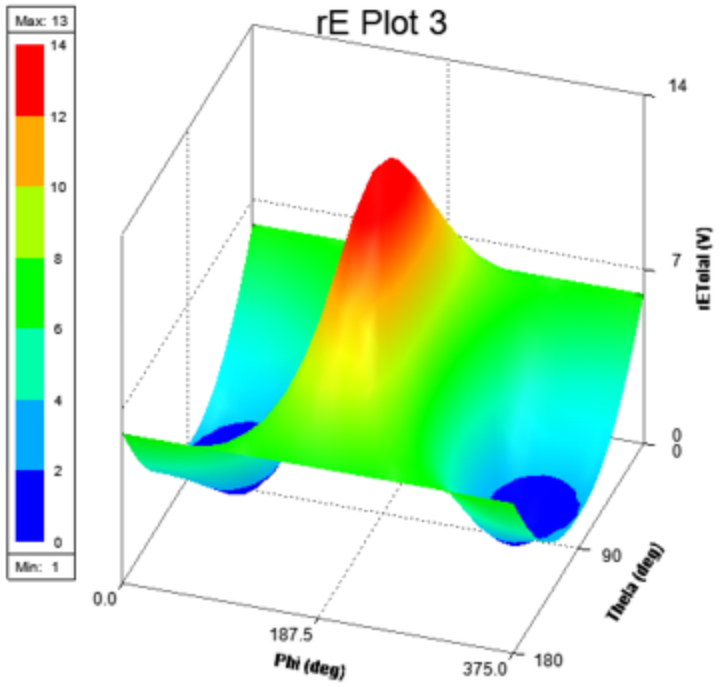


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Visual Detail menu has four options: Low, Medium (the default), High, and Custom. If you select any Visual Detail, the 3D plot is rendered according to the selected Visual Detail level and the properties reflect the values chosen for the selected visual detail level. From this predefined visual detail level, if you modify any properties, Visual Detail is automatically set to Custom (or to another predefined visual detail level if the edits happen to match the settings for that level).

You can also manually set Visual Detail to Custom. In such a case, Custom will inherit property values corresponding to the previous level. This ensures that you can customize settings starting from a baseline provided by the preconfigured Low, Medium or High Visual Detail levels.

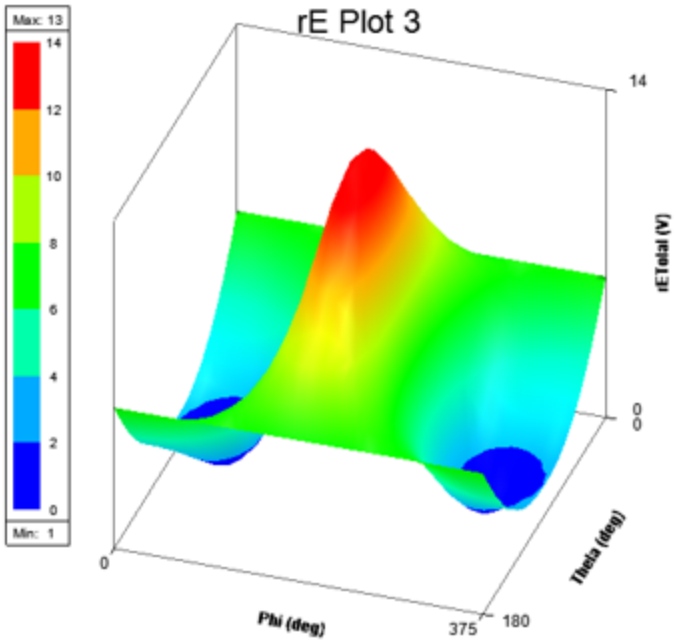
3D Rectangular Plot with Medium Visual Detail



On creation, a 3D Rectangular Plot has Visual Detail set to Medium and looks and feels as shown above. Specifically, under Medium Visual Detail level, a 3D Rectangular Plot has 3 ticks per axis (X, Y, Z axis) which will show min, max and middle value. This setting also shows axes labels.

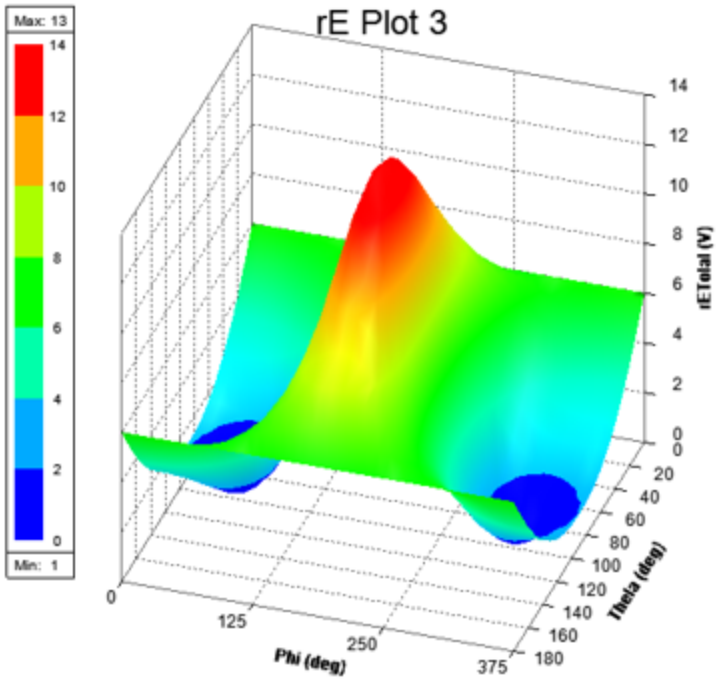
3D Rectangular Plot with Low Visual Detail

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



With Visual Detail set to Low, a 3D Rectangular Plot shows axes with 2 ticks corresponding to min and max values. It also shows axes labels and grid borders.

3D Rectangular Plot with High Visual Detail

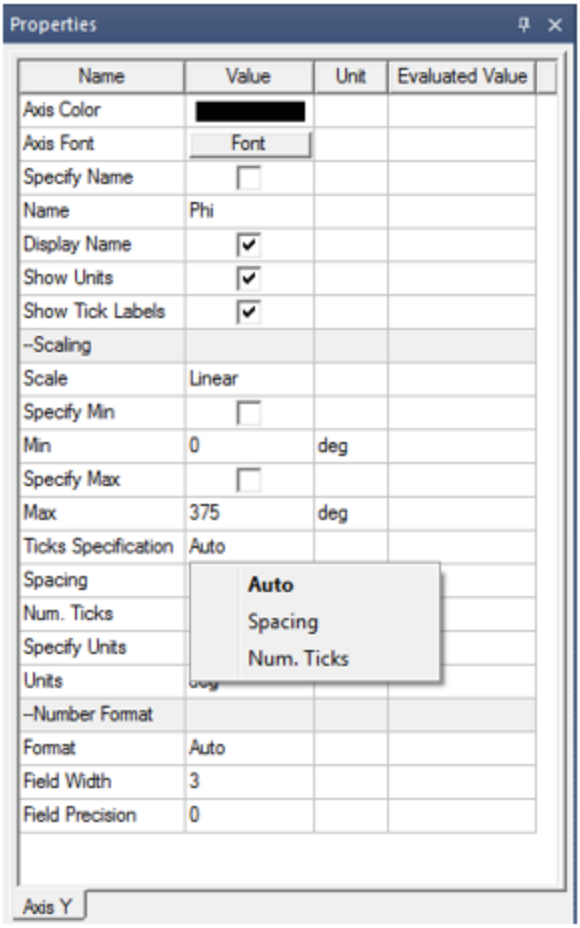


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

With Visual Detail set to High, a 3D Rectangular Plot shows all Cartesian axes and grids together with all ticks and axes labels.

Axis Properties: Ticks Specification and Num. Ticks

Ticks Specification is available on Axis properties, as shown below:



Ticks Specification is a menu with possible values as Auto, Spacing, and Num. Ticks, with Auto being the default value. If Ticks Specification is Auto, then a spacing value is automatically calculated and used to calculate and display the tick labels. **Spacing** shows the calculated value, and Num. Ticks shows the number of ticks based on this spacing value, as shown below:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

--Scaling			
Scale	Linear		
Specify Min	☐		
Min	0	deg	
Specify Max	☐		
Max	375	deg	
Ticks Specification	Auto		
Spacing	125	deg	
Num. Ticks	2		

You can edit the **Spacing** field when Ticks Specification is set to Spacing; otherwise, it is read only.

You can edit the **Num. Ticks** field when Ticks Specification is Num. Ticks; otherwise, it is read only.

Valid Num. Ticks are between 0 and 100, including 0 and 100. If you enter an invalid value, an error message is shown. If you enter a spacing value that results in number of ticks greater than 100, then an appropriate value is shown.

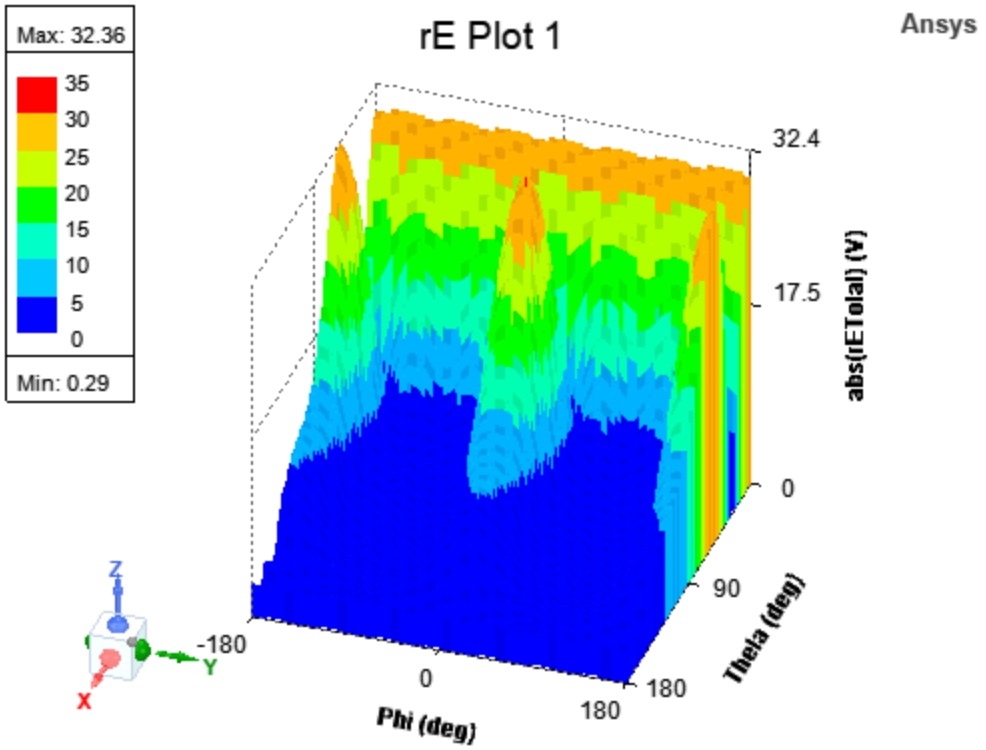
- If Num. Ticks is 0, then no ticks are shown on the axis.
- If Num. Ticks is 1, then only the max value tick is shown on the axis.
- If Num. Ticks is 2, then only the min and max value ticks are shown on the axis.
- If Num. Ticks is greater than 2, then evenly spaced ticks (including min and max) are shown on the axis.

> **Note:**
>
> With the addition of the Ticks Specification property to Axis properties, the **Specify Spacing** property was removed as an Axis property.
>
> - If an R18.0 or R18.1 project is opened with **Specify Spacing** as Unchecked, Ticks Specification is set to Auto.
> - If an R18.0 or R18.1 project is opened with **Specify Spacing** as Checked, Ticks Specification is set to Spacing.

Creating 3D Rectangular Bar Plots

This is a 3D, x-y-z graph of results as rectangular bars.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



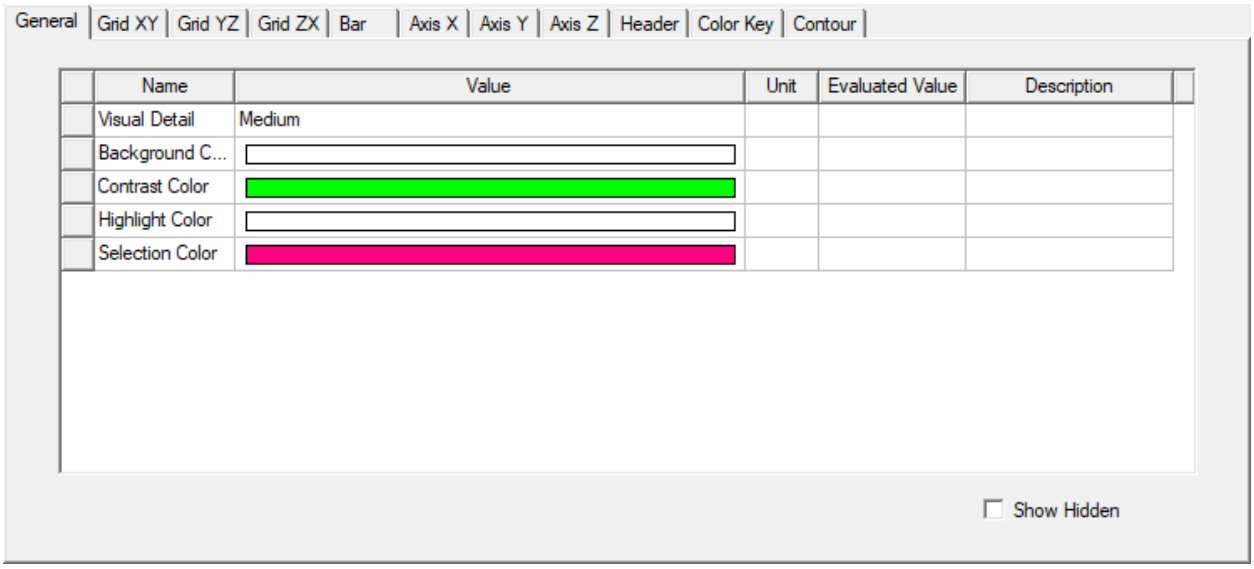
Working with a 3D Rectangular Plot

You can Rotate, Zoom, and Pan a plot. When you rotate, the Cartesian grid responds so that the curve always remains in front and the grids behind.

Clicking on a plot entity selects it, highlighting the selected entity in bold.

Double-clicking anywhere in the plot brings up the **Properties** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The properties tabs for a 3D Rectangular Bar plot are:

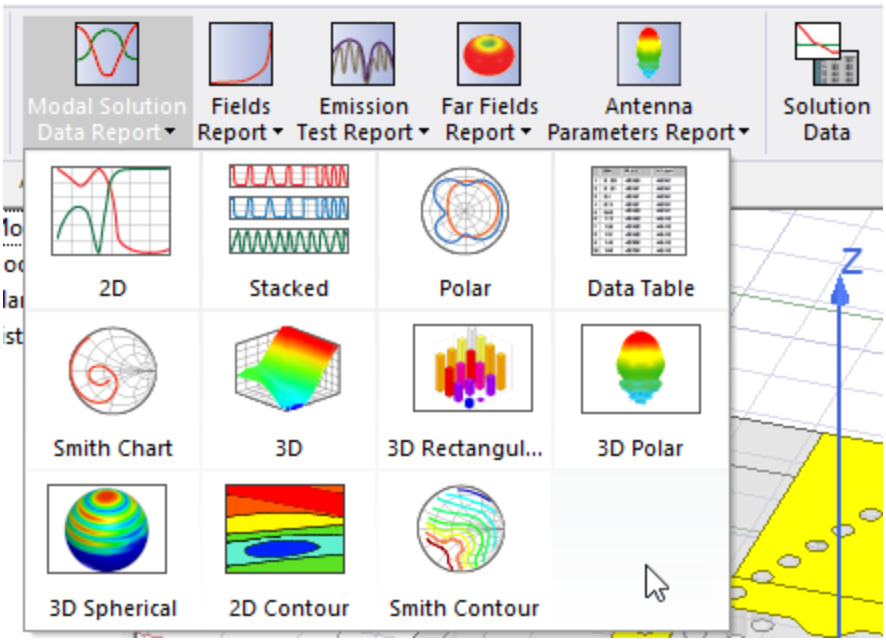
- General: For general plot properties such as Visual Detail level and background color.
- Grid [XY|YZ|ZX]: Properties related to the 3 grids.
- Bar: Properties related to rectangular bars.
- Axis [X|Y|Z]: Properties related to the 3 axes.
- Header: Properties related to plot Header/Title.
- ColorKey: Properties related to ColorKey, including borders, background, Min and Max, as well as number format and precision.
- Contour: Properties related to contouring of all surfaces.

Selecting a property also displays its properties in the **Property** window. You can edit the properties to customize the appearance of the plot. See: "Controlling Visual Detail in a 3D Rectangular Bar Plot" on page 23-104.

Creating a 3D Rectangular Bar Plot

1. Access the Results menu one of two ways:
   - From the **HFSS** menu.
   - From the **Project Manager**, right-click **Results**.
2. From the **Results** menu, click **Create *<type>* Report**, and select **3D Rectangular Bar plot**, or click the **Results** ribbon tab and select the 3D Rectangular Bar icon for the Report type you want to create.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Report** dialog box appears.

3. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
    a. Solution field with a drop-down selection list. This lists the available solutions, whether sweeps or adaptive passes.
    b. Geometry field with a drop-down selection list. For field and radiated field reports, this applies the quantity to a geometry or radiated field setup.
4. Under the **Trace** tab **Z** Component area, specify the information to plot along the z-axis:
    a. In the **Category** list, click the type of information to plot. The category you select provides the default plot name.
    b. In the **Quantity** list, click the value to plot.
    c. In the **Function** list, click the mathematical function of the quantity to plot.
    d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

> **Note:**
>
> Color shows valid expression.

    e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. On the **Trace** tab **Y** (Secondary sweep) lines, specify the information to plot along the y-axis in one of the following ways:
   - Select the sweep variable to use from the drop-down list.
   - If sweeps are available, you can select the browse button to display a dialog that lets you select particular values. The quantity will be plotted against the primary sweep variable listed.
6. On the **Trace** tab **X** (Primary sweep) lines, specify the information to plot along the x-axis in one of the following ways:
   - Select the sweep variable to use from the drop-down list.
   - If sweeps are available, you can select the browse button to display a dialog box that lets you select particular values. The quantity will be plotted against the primary sweep variable listed.
7. Click **New Report.**

   This creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, S Parameter Plot *n* or rE Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The function of the selected quantity or quantities will be plotted against the values you specified on an x-y-z graph. The plot is listed under **Results** in the Project Manager. When you select the traces or plots, axis or grid labels, plot header, color key, or variable labels, their properties are displayed in the Properties window. The properties for each plot element can be edited directly to modify the plot content and appearance. See Modifying the Background Properties of a Report.

8. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

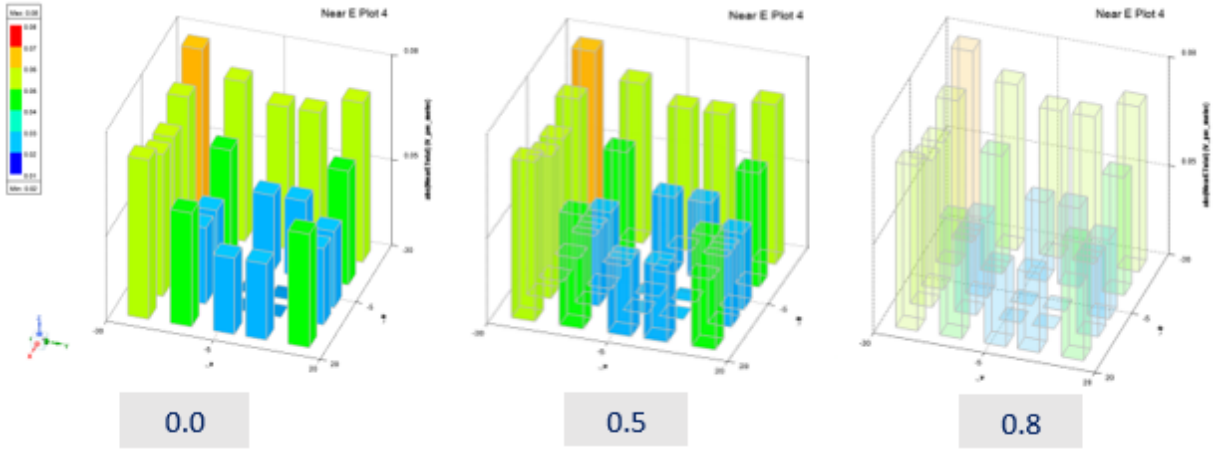
3D Rectangular Bar Customization

Selecting a bar in the plot shows the customizable attributes of bars in a 3D Rectangular Bar plot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

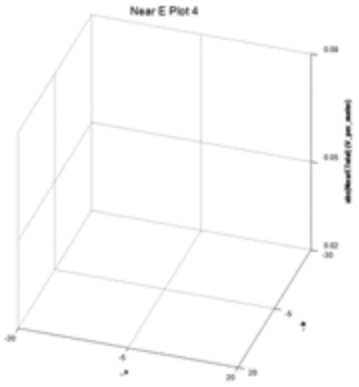
The customizable attributes of the bars in a 3D Rectangular Bar plot include:

- Transparency

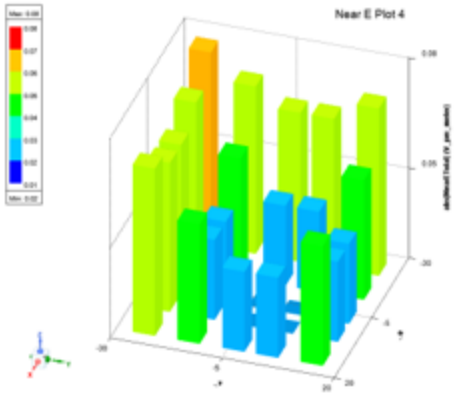


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Filled

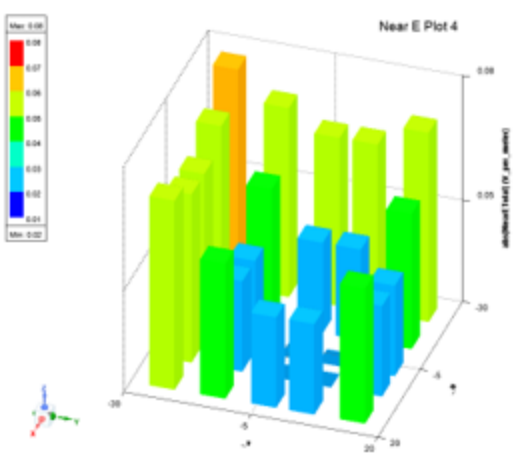


Filled [ ]

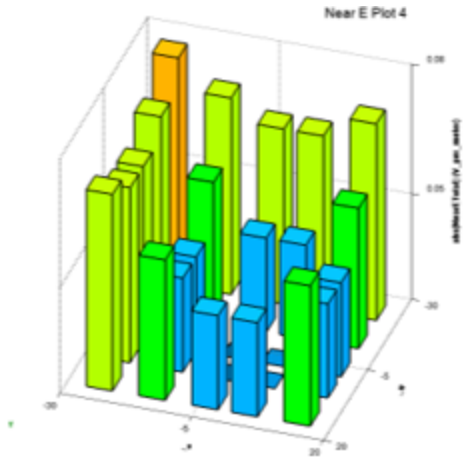


Filled [√]

- Show Outline



Show Outline []

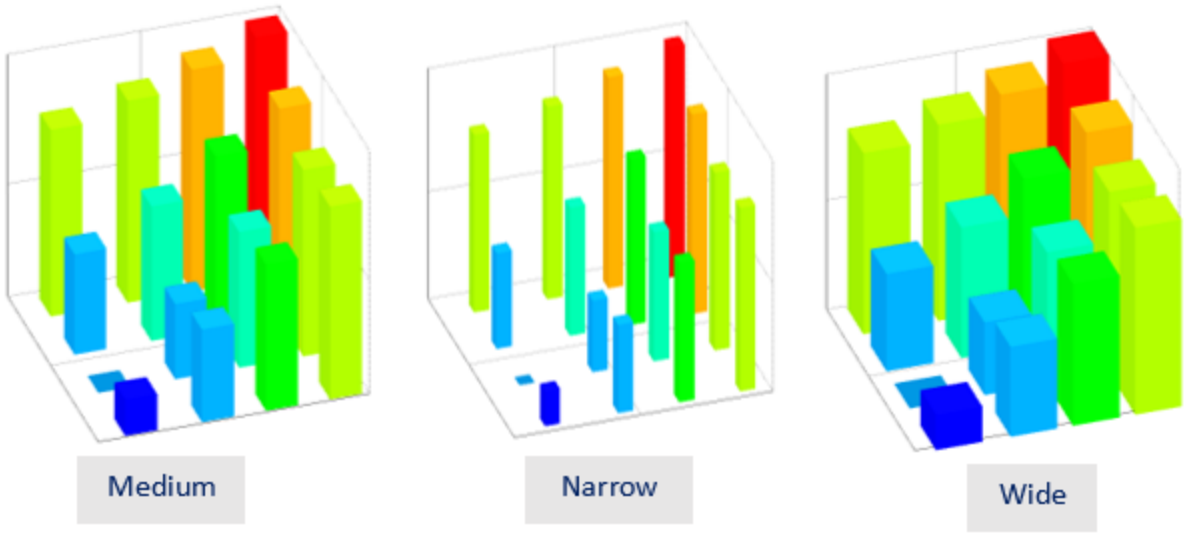


Show Outline [√]

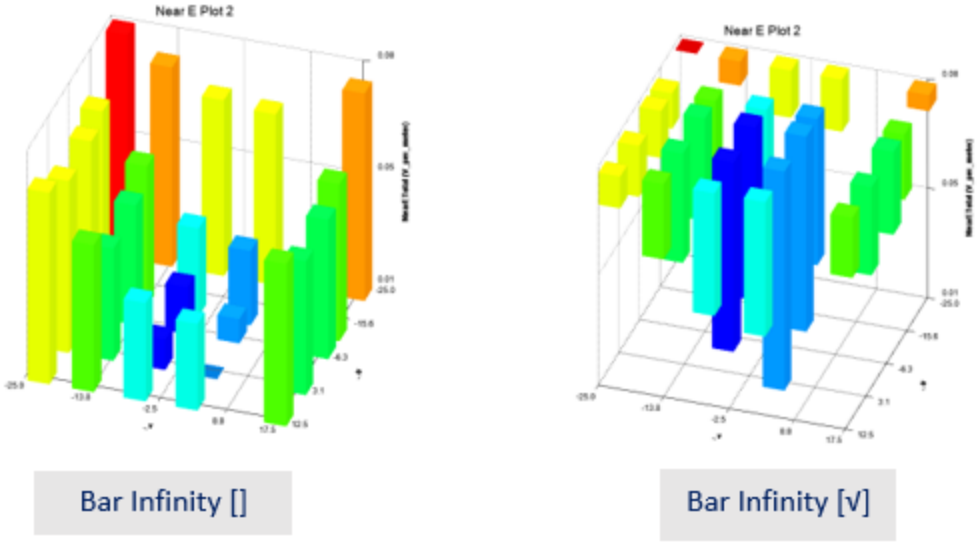
- Outline Color (customizable, see plot above)
- Outline Width (customizable, see plot above)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Bar Width, controls the thickness of the bar. Medium (default), Wide and Narrow are the width that equals to ½, ¾ and ¼ of the min spacing between adjacent points respectively.



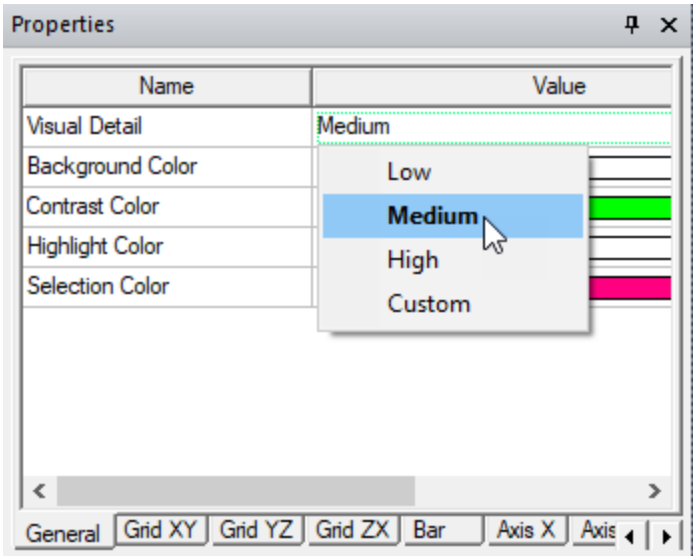
- Bar Infinity represents the third coordinate (z) using the bottom of the bar.



Controlling Visual Detail in a 3D Rectangular Bar Plot

If a particular plot seems busy with information, you can edit plot properties, such as **Axis** and **Grid Attributes** for discrete levels of visual detail to improve readability. Double-click anywhere on a plot to display the **Properties** dialog box. The **Visual Detail** property on the **General** tab also provides control suited to different screen and plot sizes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

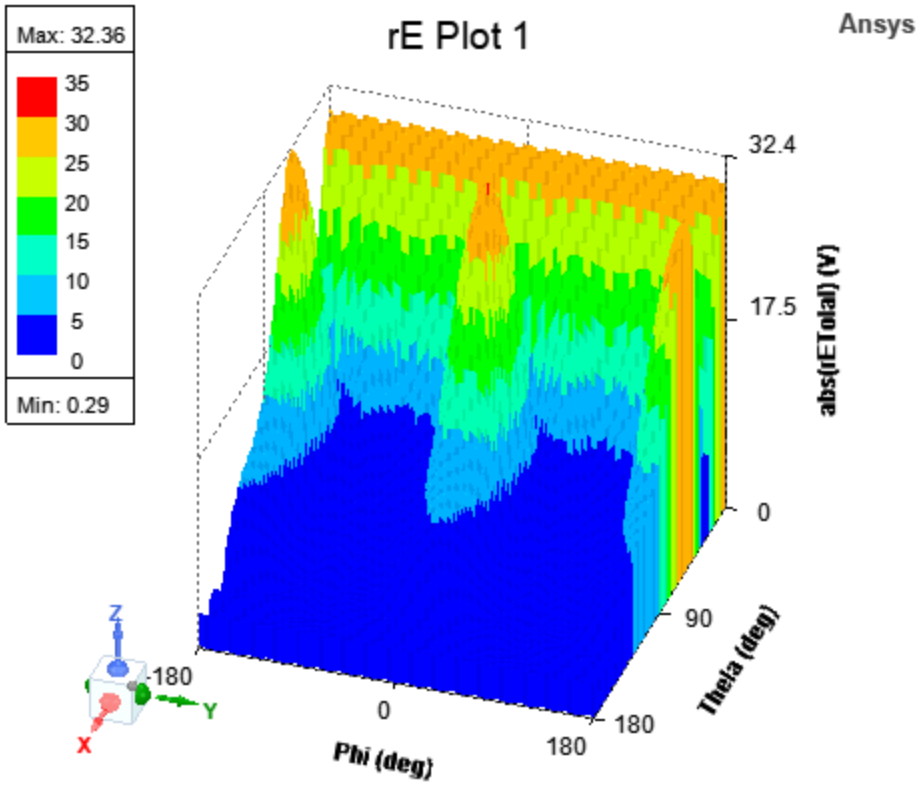


The **Visual Detail** menu has four options: Low, Medium (the default), High, and Custom. If you select any Visual Detail, the 3D plot is rendered according to the selected Visual Detail level and the properties reflect the values chosen for the selected visual detail level. From this predefined visual detail level, if you modify any properties, Visual Detail is automatically set to Custom (or to another predefined visual detail level if the edits happen to match the settings for that level).

You can also manually set Visual Detail to Custom. In such a case, Custom will inherit property values corresponding to the previous level. This ensures that you can customize settings starting from a baseline provided by the preconfigured Low, Medium or High Visual Detail levels.

3D Rectangular Plot with Medium Visual Detail

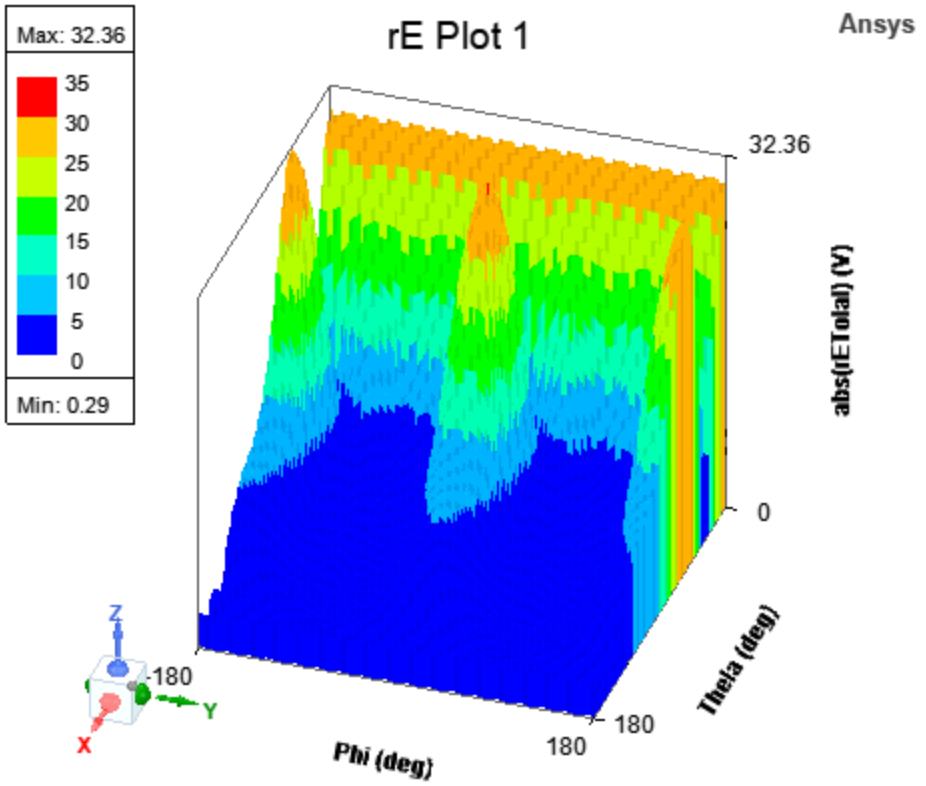
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



On creation, a 3D Rectangular Plot has Visual Detail set to Medium and looks and feels as shown above. Specifically, under Medium Visual Detail level, a 3D Rectangular Plot has 3 ticks per axis (X, Y, Z axis) which will show min, max and middle value. This setting also shows axes labels.

3D Rectangular Bar Plot with Low Visual Detail

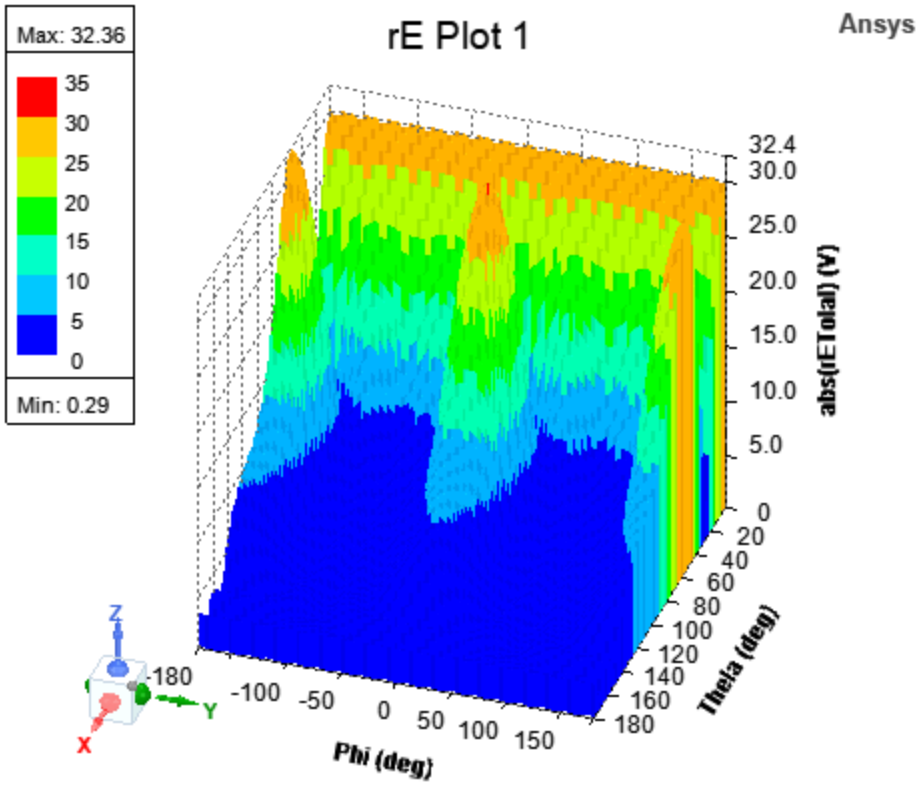
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



With Visual Detail set to Low, a 3D Rectangular Plot shows axes with 2 ticks corresponding to min and max values. It also shows axes labels and grid borders.

3D Rectangular Bar Plot with High Visual Detail

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

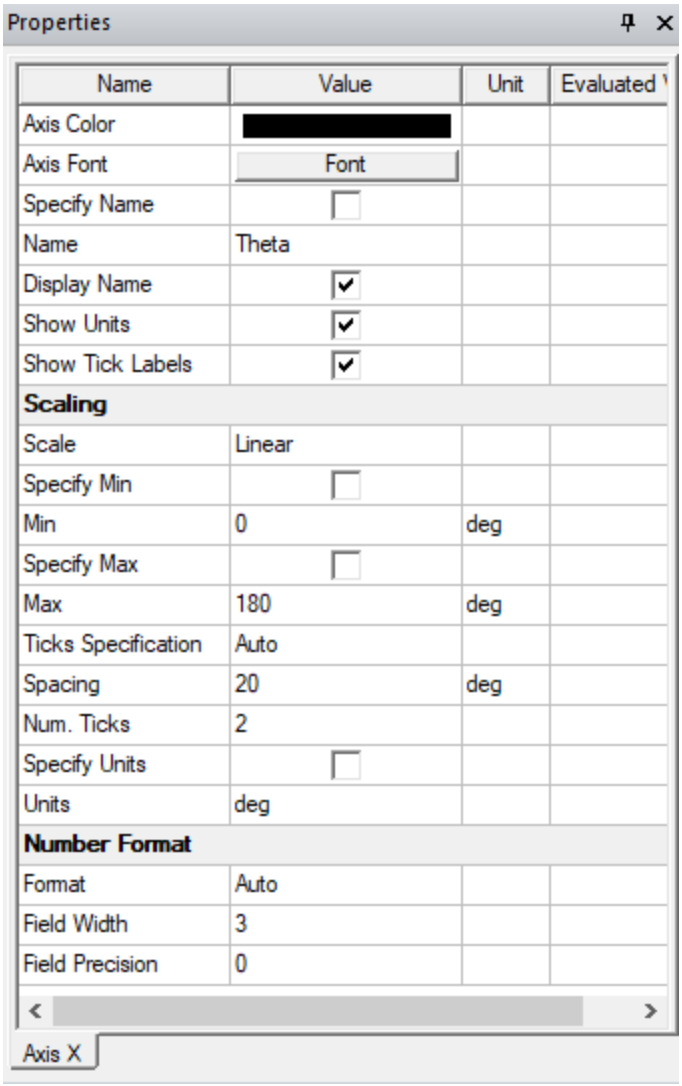


With Visual Detail set to High, a 3D Rectangular Plot shows all Cartesian axes and grids together with all ticks and axes labels.

Axis Properties: Ticks Specification and Num. Ticks

Ticks Specification is available on Axis properties, as shown below:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ticks Specification is a menu with possible values as Auto, Spacing, and Num. Ticks, with Auto being the default value. If Ticks Specification is Auto, then a spacing value is automatically calculated and used to calculate and display the tick labels. **Spacing** shows the calculated value, and Num. Ticks shows the number of ticks based on this spacing value, as shown below:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

--Scaling			
Scale	Linear		
Specify Min	☐		
Min	0	deg	
Specify Max	☐		
Max	375	deg	
Ticks Specification	Auto		
Spacing	125	deg	
Num. Ticks	2		

You can edit the **Spacing** field when Ticks Specification is set to Spacing; otherwise, it is read only.

You can edit the **Num. Ticks** field when Ticks Specification is Num. Ticks; otherwise, it is read only.

Valid Num. Ticks are between 0 and 100, including 0 and 100. If you enter an invalid value, an error message is shown. If you enter a spacing value that results in number of ticks greater than 100, then an appropriate value is shown.

- If Num. Ticks is 0, then no ticks are shown on the axis.
- If Num. Ticks is 1, then only the max value tick is shown on the axis.
- If Num. Ticks is 2, then only the min and max value ticks are shown on the axis.
- If Num. Ticks is greater than 2, then evenly spaced ticks (including min and max) are shown on the axis.

> **Note:**
>
> With the addition of the Ticks Specification property to Axis properties, the **Specify Spacing** property was removed as an Axis property.
>
> - If an R18.0 or R18.1 project is opened with **Specify Spacing** as Unchecked, Ticks Specification is set to Auto.
> - If an R18.0 or R18.1 project is opened with **Specify Spacing** as Checked, Ticks Specification is set to Spacing.

Creating Rectangular Contour Plots

This is an x-y-z graph of results. Any data that you can currently plot in 3D (as 3D Cartesian or 3D polar) is a candidate for a contour plot.

1. On the **Results** menu (**HFSS** menu or right-click **Results** in the Project Manager), click **Create *<type>* Report**, and select **Rectangular Contour plot** from the report type menu.

   The *Report* dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the **Context** section make selections from the following field or fields, depending on the design and solution type:
    a. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes.
    b. Geometry field with a drop-down selection list. For field and radiated field reports, this applies the quantity to a geometry or radiated field setup.
    c. Domain field with a drop-down selection list. For Near and Far Field reports, if you have defined the respective Radiation Setups, a Domain field lists Theta, Phi, and Sine Space.

    For details, see Creating Sine Space plots.
3. Under the **Trace** tab **Z** Component area, specify the information to plot as contours:
    a. In the **Category** list, click the type of information to plot. The selected Category provides the default plot name.
    b. In the **Quantity** list, click the value to plot.
    c. In the **Function** list, click the mathematical function of the quantity to plot.
    d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

    > **Note:**
    >
    > Color shows valid expression.

    e. **Range Function** button -- opens the *Set Range Function* dialog box. This applies currently specified Quantity and Function.
4. On the **Trace** tab **Y** (Secondary sweep) lines, specify the information to plot along the y-axis in one of the following ways:
    - Select the sweep variable to use from the drop-down list.
    - If sweeps are available, you can select the browse button to display a dialog that lets you select particular values. The quantity will be plotted against the primary sweep variable listed.
5. On the **Trace** tab **X** (Primary sweep) lines, specify the information to plot along the x-axis in one of the following ways:
    - Select the sweep variable to use from the drop-down list.
    - If sweeps are available, you can select the browse button to display a dialog that lets you select particular values. The quantity will be plotted against the primary sweep variable listed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. Click **New Report**.

   This creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, for example, S Parameter Plot *n* or Output Variables Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The function of the selected quantity or quantities will be plotted against the values you specified on an x-y-z graph. The plot is listed under **Results** in the Project Manager. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.

   The Trace Properties for Cartesian plots include tabs for:

   - Attributes tab, including Name, Line Style, Line Width, and Color.
   - Contour tab, including Colormap Type, Color, Spectrum, IsoValType, whether to Overlay Contour Lines (on Fringe or Tone plots), Scaling parameters, and Number of contours and spacing.

   Colormap Type can be Spectrum, Ramp, or Uniform.

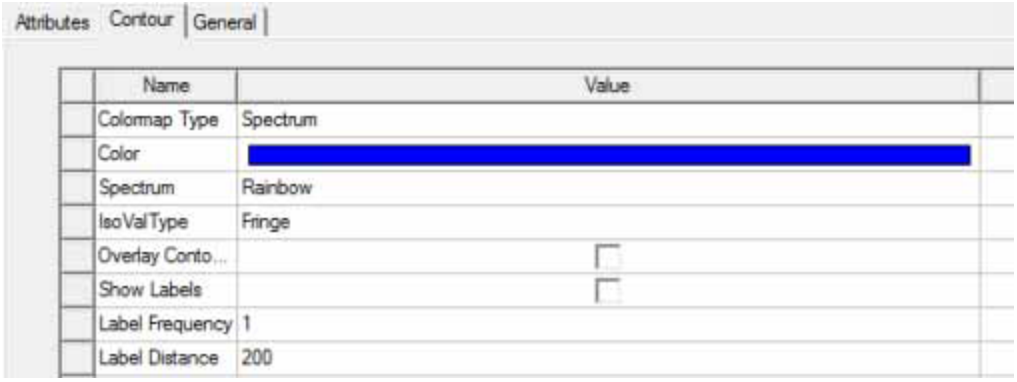
   Spectrum can be Rainbow, Temperature, Magenta, or Gray

   IsoValType can be Line, Fringe, or Tone.

   General tab, including Back Color, Plot Area Color, Enable Y Axis Stripes, Field Width, Prevision, and whether to Use Scientific Notation.

   You can also access these properties by double-clicking on the Contour plot and viewing the **Contour** tab.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



7. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

Creating Sine Space Plots

Sine Space plots provide an alternate way to view radiated field quantities. The transformation from theta, phi space to u, v sine space is defined as follows:

u = sin(theta)*cos(phi)

v = sin(theta)*sin(phi)

Note that this is similar to a polar coordinate system, where the radius is given by sin(theta) and the angle is given by phi. Another way to think about this: Given theta and phi that define a unit sphere, then these u,v coordinates are like viewing the unit sphere from above or below the XY plane. So, a sine space plot is a 2D plot that lies on a unit circle in the u,v space, that shows the values of radiated field quantities projected onto the upper or lower half of a full 3D sphere.

Radiated Fields in HFSS

In HFSS, you create Radiated field setups to specify how radiated fields will be calculated. For a sphere, you provides ranges and step size for theta and phi, or Az over El or El over Az, and can also specify a reference coordinate system and custom radiation surface. The radiated fields are calculated based on these settings, using algorithms that are designed for uniform sampling in theta and phi. If you manually enter Phi or Theta component of a far field quantity when you using Az/El or El/Az far field definition, then the Report uses the Z axis of the Az/El or El/Az coordinate system definition as pole to calculate theta/phi component for rE.

Once radiated field setups have been defined, it possible to create various radiated fields plots in Reporter.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Sine Space Plots

Sine Space plots are implemented as a new Context in Reporter. They will leverage the existing radiated field setups and calculations.

To create a Sine Space plot, after you have specified radiated field Setups.

1. Click **Results> Create Far Fields Report> Rectangular Contour Plot** or **Data Table**

   Results> Create Near Fields Report> Rectangular Contour Plot or **Data Table**.

   The *Report* dialog box displays and shows choices for Domain in the Context field.

   "Theta, Phi" is selected by default and gives the existing functionality.

   Notice that the Context shown above already includes selection of a Geometry, which corresponds to a Radiation setup.

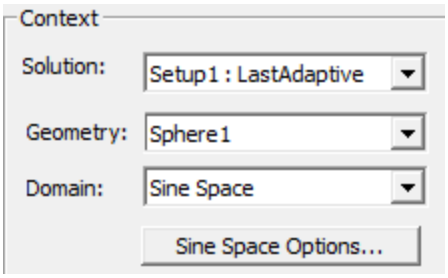
   This radiation setup is used to calculate the fields for the Sine Space plot. Internally, this computes the values of the complex E vector based on the theta, phi sampling in the radiation setup. When data is requested for a sine space plot, it will correspond to some arbitrary theta, phi, and the fields will be interpolated to this location on the sphere. Note that this interpolation will occur on the complex E vector, and can be more detailed than a simple linear interpolation between sample points.

   In order to support sine space plots, the radiation setup must have appropriate sampling in theta and phi. By default, a sphere is defined with phi from 0 to 360 (angle of rotation about Z), and theta from 0 to 180 (angle of rotation away from Z). These settings support a full unit circle representing the upper (theta from 0 to 90) or lower (theta from 90 to 180) half space. If the range of theta is reduced to 0 to 90, it would be possible to support upper half

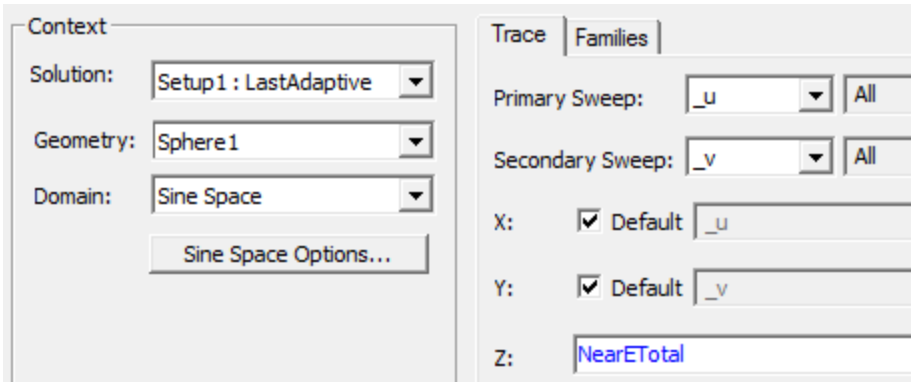
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

space only. Other ranges of theta and phi will likely create odd sine space plots, such as a partial circle, and these are not allowed.

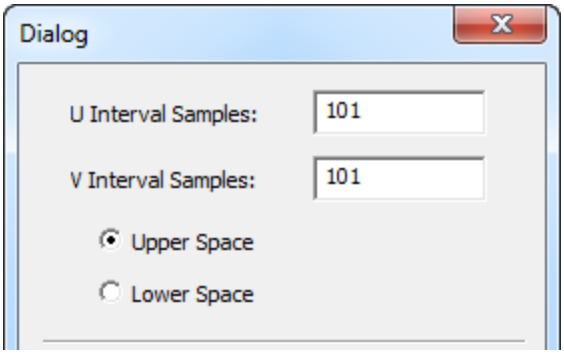
2. Select Sine Space as the Domain. This also enables the **Sine Space** options button.



Selecting "Sine Space" changes the Primary Sweep to U, and the Secondary Sweep to V.



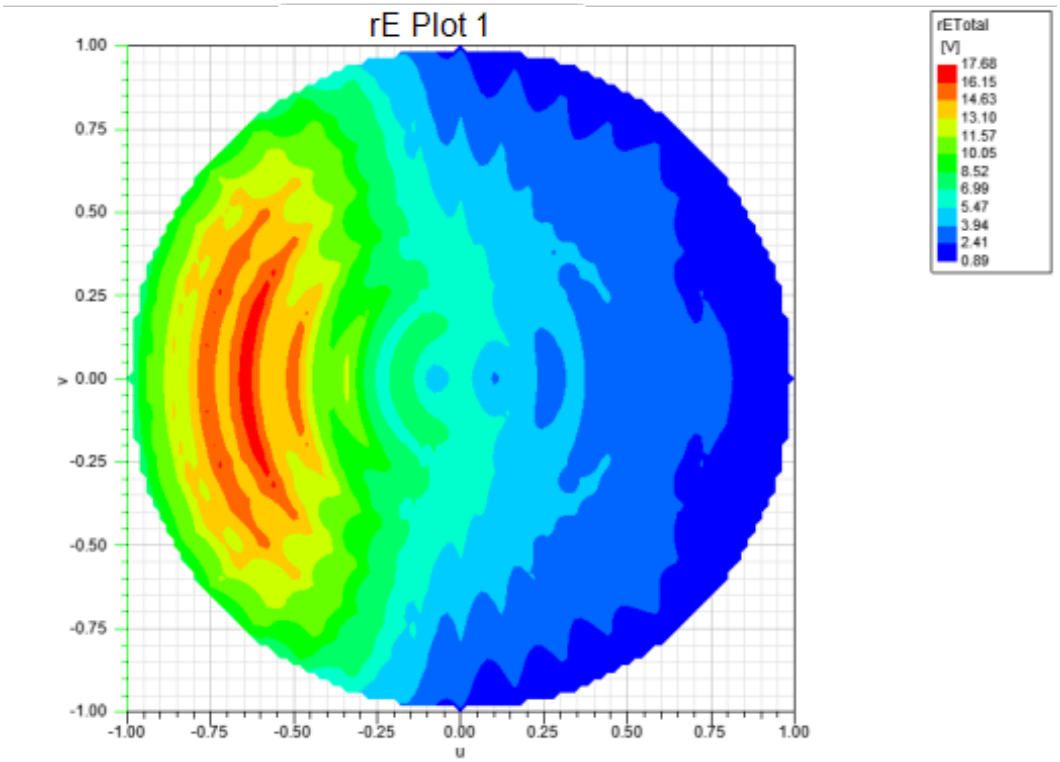
The Sine Space Options provide additional settings, including the sampling interval for the u,v coordinates (default of .05 would provide 40 samples over each axis, -1 to 1) and selection of upper or lower half space (default to upper).



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

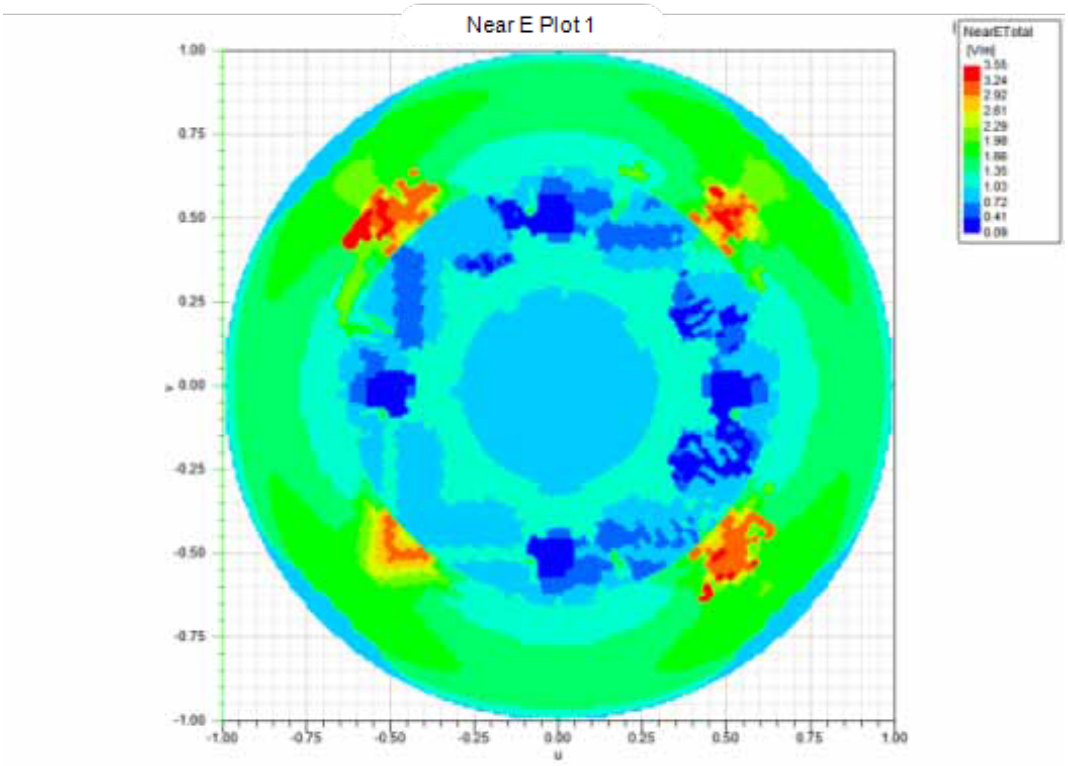
Once you have set up the domain, you define the Sine Space plot, selecting Category, Quantity and Function settings as appropriate. The Report Category you select provides the default report name, for example, S Parameter Plot *n* or Output Variables Plot *n*. Given that the u,v sampling is set in the Sine Space Options, it should not be necessary to modify the sweeps in the Trace area of the dialog box.

Here is an example Sine Space plot of Far Field rETotal.



And here is an example Sine Space plot of Near field E Total.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can use the **Contour** tab of the *Properties* dialog box to modify the appearance of the plot. See Creating Rectangular Contour Plots for discussion and examples.

Creating 2D Polar Plots

In HFSS, a polar plot is a 2D circular chart divided by the spherical coordinates R and theta, where R is the radius, or distance from the origin, and theta is the angle from the x-axis. Following is the general procedure for drawing a polar graph of results:

1. On the **Results** menu (HFSS menu or right-click **Results** on the Project tree), click **Create *<type>* Report**, and select **Polar Plot** from the report type menu.

   The **Report** dialog appears.

2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   a. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes.
   b. Domain field with a drop down selection list. Whether this field appears, and the domains listed depend on the Solution type and the ***<type>*** selected. For modal and terminal solution data reports, the domain can be **Sweep** or **Time**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Before you can examine the time domain, you must perform an Interpolating sweep for a driven solution (Modal or Terminal). If you select **Time**, the **TDR Options** button is enabled. Select it and follow the directions for time-domain plotting.

c. Geometry field with a drop down selection list. For field and radiated field reports, this applies the quantity to a geometry or radiated field setup.

3. In the **Trace** tab **PolarComponent** area, specify the information to plot:
   a. On the **Category** drop-down menu, click the type of information to plot.
   b. On the **Quantity** list, click the values to plot. Use Ctrl+click to make multiple selections.
   c. In the **Function** list, click the mathematical function to apply to the quantity for the plot.
   d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

> **Note:**
>
> Color shows valid expression.

   e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.
4. Click **New Report.**

This creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, S Parameter Plot *n* or rE Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

The function of the selected quantity will be plotted against the swept variable values or quantities you specified on an x-y graph. The plot is listed under **Results** in the project tree and the traces are listed under the plot. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.

5. Optionally, add another trace to the plot by following the procedure above, using **Add Trace rather than New Report**.

Reviewing 2D Polar Plots

For a polar plot of S-parameters, HFSS displays in the lower-left corner the following derived information about the cursor's location:

MP The magnitude and phase of the point.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

RX The normalized resistance (**R**) and reactance (**X**).

GB An alternate view of the normalized resistance and reactance in the form of

$$R + jX = \frac{1}{G + jB}$$

where

- ***G*** = conductance
- ***B*** = susceptance

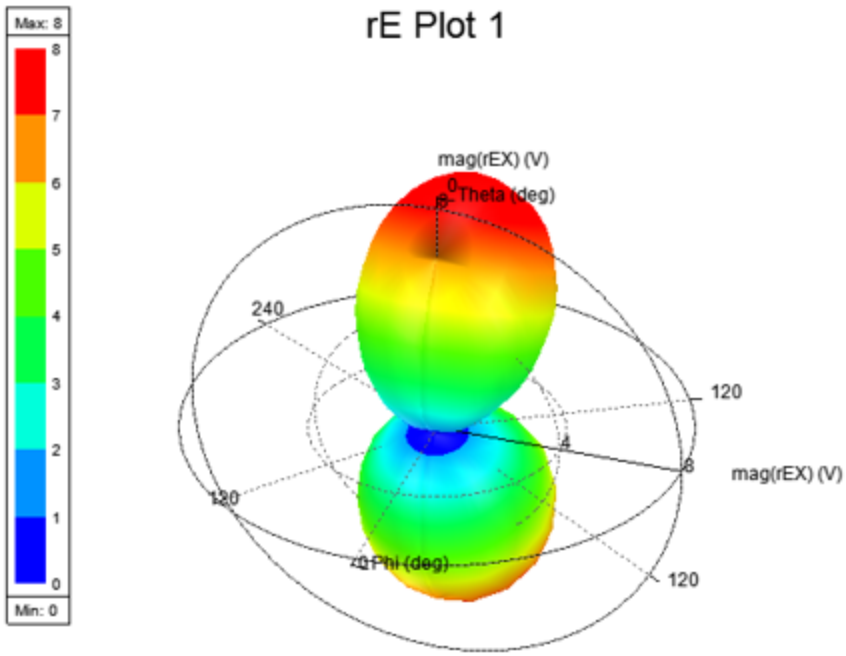
Q The quality factor.

VSWR The voltage standing wave ratio, calculated from the equation $\frac{1 + |S_{ij}|}{1 - |S_{ij}|}$.

A scale below the plot displays the scale of points along the R-axis.

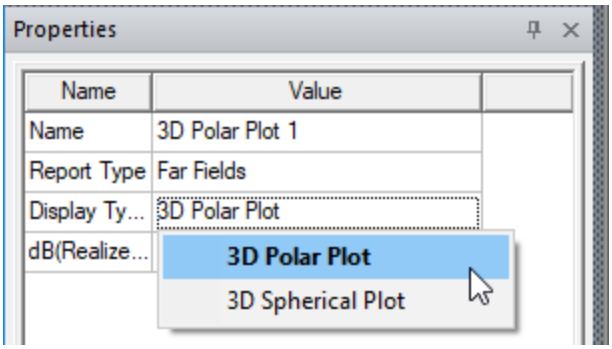
Creating 3D Polar Plots

A 3D polar plot is a 3D circular chart divided by the spherical coordinates R, theta, and phi, where R is the radius, or distance from the origin, theta is the angle from the x-axis, and phi is the angle from the origin in the z direction.

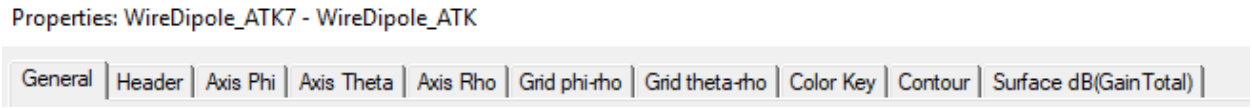


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To convert a 3D Polar plot to a 3D Spherical Plot, select the plot in the Project tree, and select from the Display type menu in the Properties window:



Double-clicking anywhere in the plot brings up the display **Properties** dialog box. The properties are grouped appropriately under various tabs, which correspond to plot entities.



- General: For general plot properties such as Visual Detail level and background color
- Header: Properties related to plot Header/Title
- Axis Phi: Properties related to the circular axis which is in XY plane
- Axis Theta: Properties related to the circular axis which is in YZ plane
- Axis Rho: Properties related to the radial axis
- Grid phi-rho-theta(0): Properties related to phi-rho grid at theta = 0 (XY plane)
- Grid theta-rho-phi(90): Properties related to theta-rho grid at phi = 90 (YZ plane)
- Color Key: Properties related to the color key, including borders, background, Min and Max, as well as number format and precision.
- Contour: Properties related to contouring of all curves/surfaces
- Surface: Properties related to the curve

You can edit the properties on these tabs to customize the appearance of the plot. See "Controlling Visual Detail in a 3D Polar Plot" on page 23-123 below.

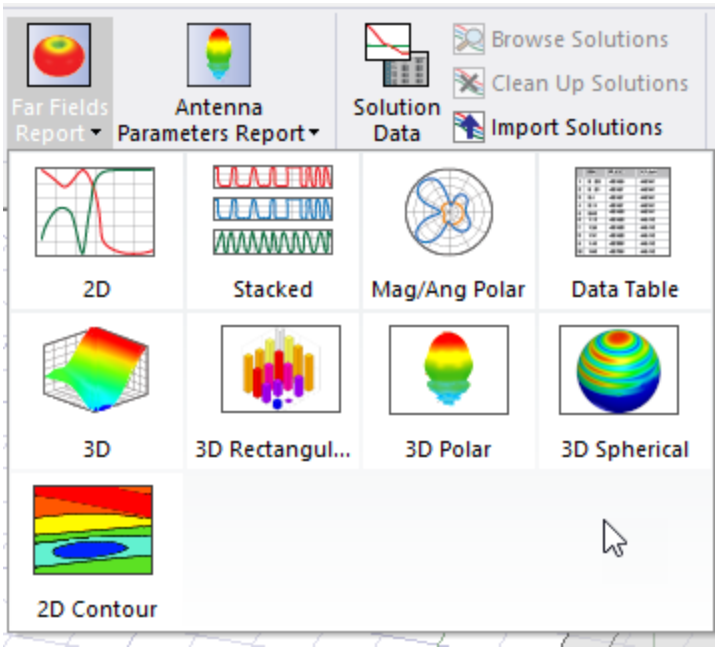
Creating 3D Polar Plots

Following is the general procedure for drawing a 3D polar plot of results:

1. On the **Results** menu (HFSS menu or right-click **Results** on the Project tree), click **Create <*type*> Report**, and select **3D Polar Plot** from the report type menu.

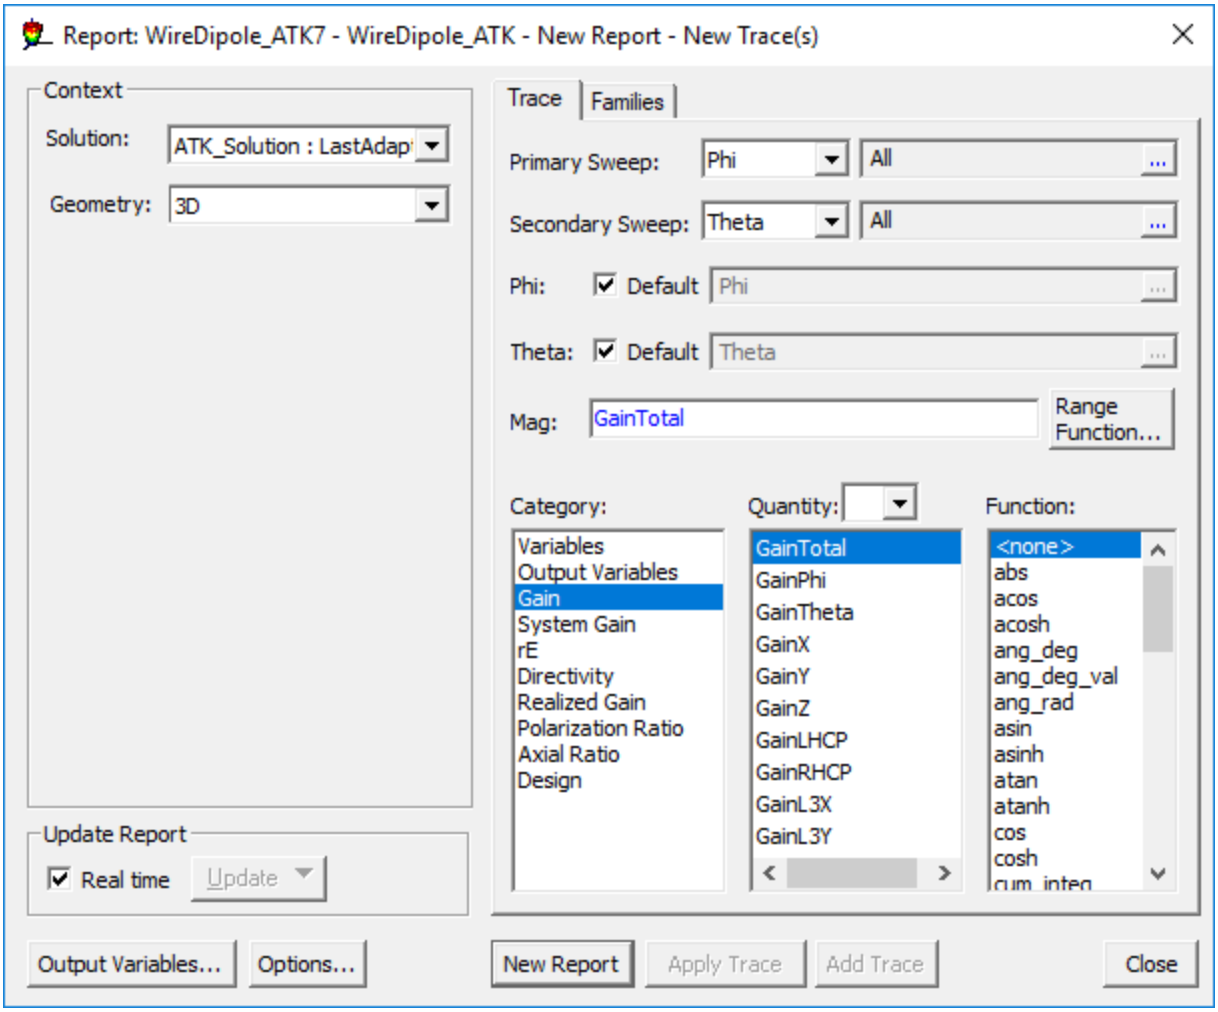
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can also select 3D Polar Plots from the **Results** tab of the ribbon if such plots are appropriate for the current design.



The **Report** dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
    a. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes.
    b. Geometry field with a drop down selection list. For field and radiated field reports, this applies the quantity to a geometry or radiated field setup.
3. In the **Trace** tab **Mag** area, specify the information to plot along the R-axis, or the axis measuring magnitude:
    a. From the **Category** drop-down menu, select the type of information to plot. The selected category provides the default plot name.
    b. In the **Quantity** list, click the values to plot. Ctrl+click to make multiple selections.
    c. In the **Function** list, click the mathematical function to apply to the quantity for the plot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

> **Note:**
>
> Color shows valid expression.

e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

4. On the **Trace** tab **Theta (Secondary Sweep)** line, select the sweep variable from the drop-down menu and specify all values or select values to plot along the theta-axis.
5. On the **Trace** tab **Phi(Primary Sweep)** line, select the sweep variable from the drop-down menu, and specify all values or select values to plot along the phi-axis.
6. Click **New Report.**

   This button creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, S Parameter Plot *n* or rE Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The function of the selected quantity or quantities will be plotted against the R-, phi-, and theta-axes on a 3D polar graph. The plot is listed under **Results** in the project tree. When you select the traces or plots, axis or grid labels, plot header, color key, or variable labels, their properties are displayed in the Properties window. The properties for each plot element can be edited directly to modify the plot content and appearance. See Modifying the Background Properties of a Report

7. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

Interacting with 3D Polar Plots

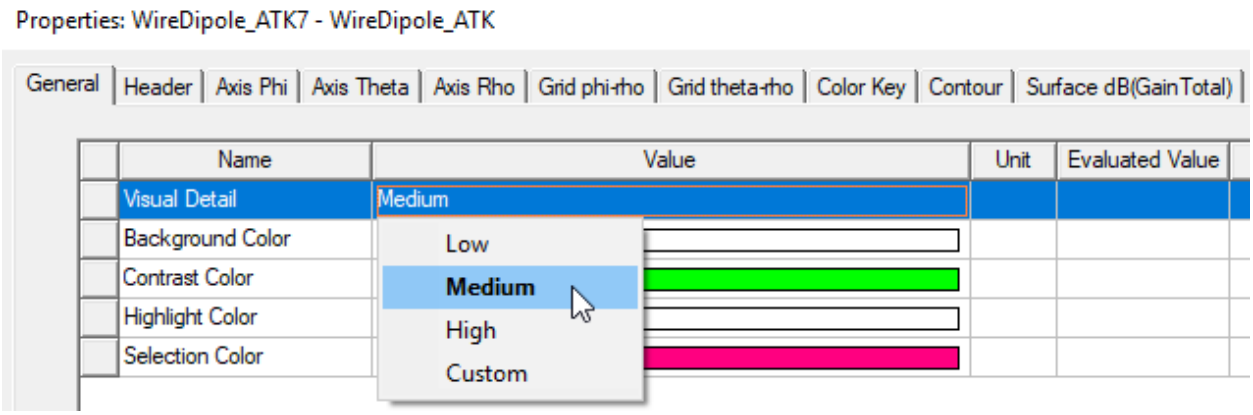
You can Rotate, Zoom, and Pan a plot. When you rotate, the Cartesian grid responds so that the curve always remains in front and the grids behind. Also, see Using the Orientation Gadget.

Controlling Visual Detail in a 3D Polar Plot

If a particular plot seems busy with information, you can edit plot properties, such as Axis and Grid Attributes for discrete levels of visual detail to improve readability. Double-click anywhere on a plot to display the **Properties** dialog box. Clicking on a plot entity selects it, highlighting the selected entity in bold.

The Visual Detail property on the **General** tab also provides control suited to different screen and plot sizes.

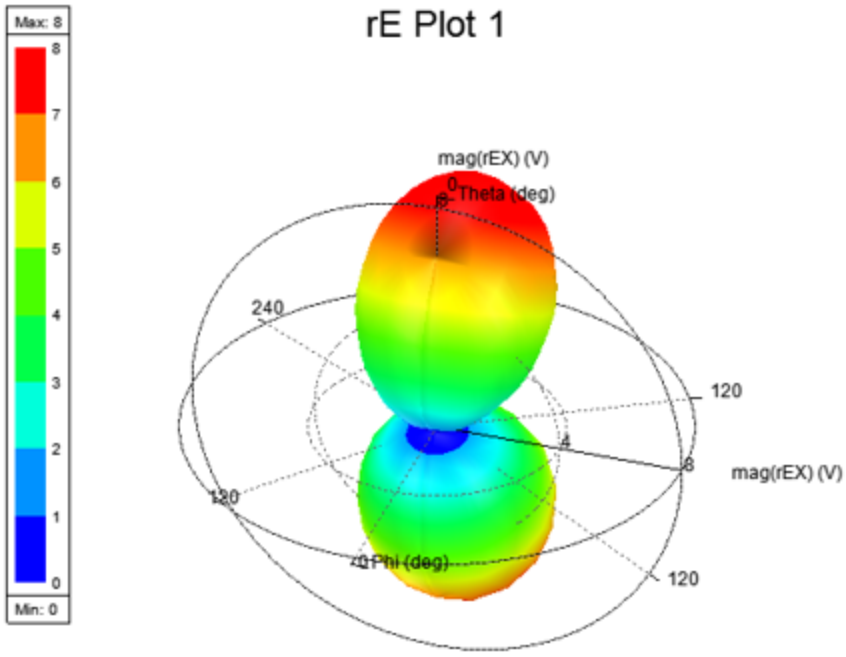
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The Visual Detail menu has four options: Low, Medium (the default), High, and Custom. If you select any Visual Detail, the 3D plot is rendered according to the selected Visual Detail level and the properties reflect the values chosen for the selected visual detail level. From this predefined visual detail level, if you modify any properties, Visual Detail is automatically set to Custom (or to another predefined visual detail level if the edits happen to match the settings for that level).

You can also manually set Visual Detail to Custom. In such a case, Custom will inherit property values corresponding to the previous level. This ensures that you can customize settings starting from a baseline provided by the preconfigured Low, Medium or High Visual Detail levels.

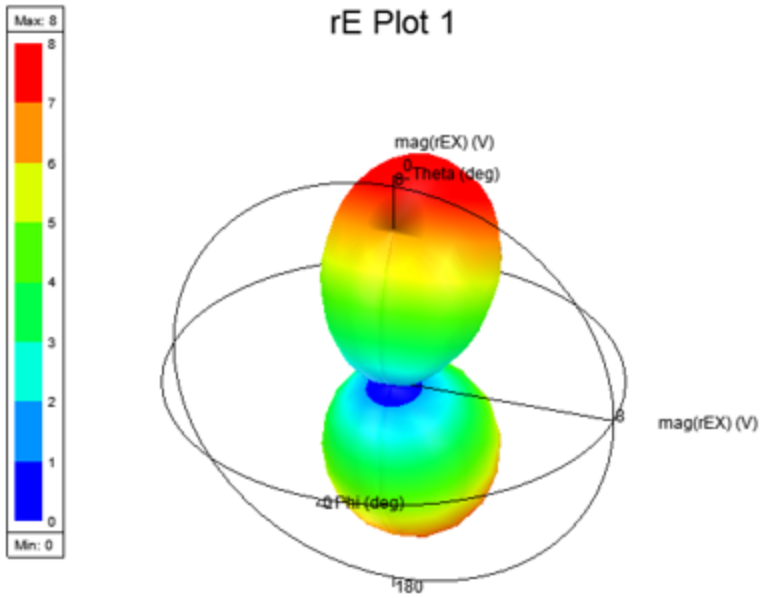
3D Polar Plot with Medium Visual Detail



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

On creation, a 3D Polar Plot has Visual Detail set to Medium and looks and feels as shown above. Specifically, under the Medium Visual Detail level, 3D Polar Plot has 3 ticks per axis (phi, theta and rho axis) which show min, max and middle value. This setting also shows axes labels.

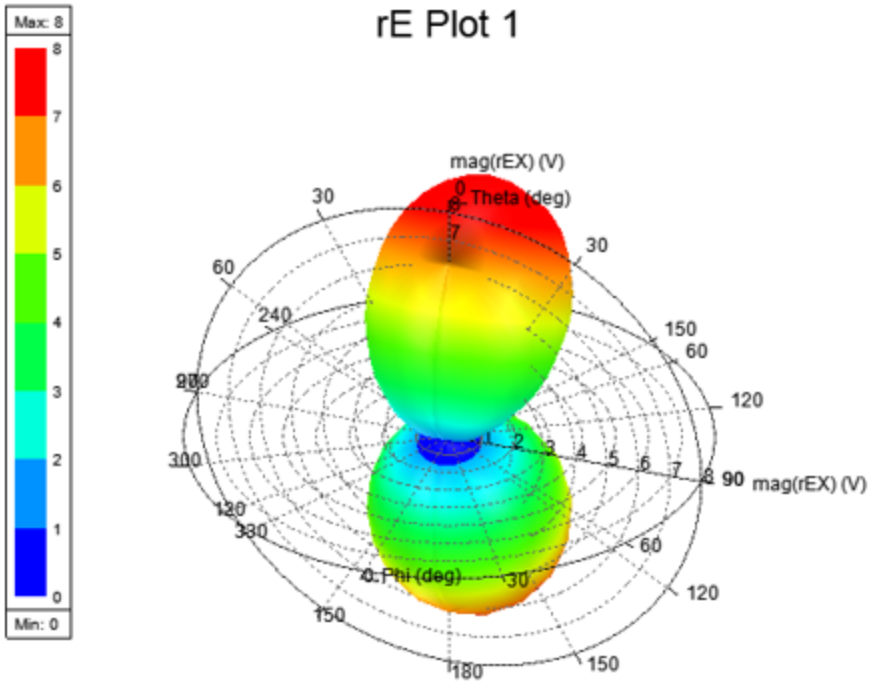
3D Polar Plot with Low Visual Detail



With Visual Detail set to Low, 3D Polar Plot does not show polar grids or grid lines. It only shows axes with 2 ticks corresponding to min and max values. This setting also renders axis labels.

3D Polar Plot with High Visual Detail

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

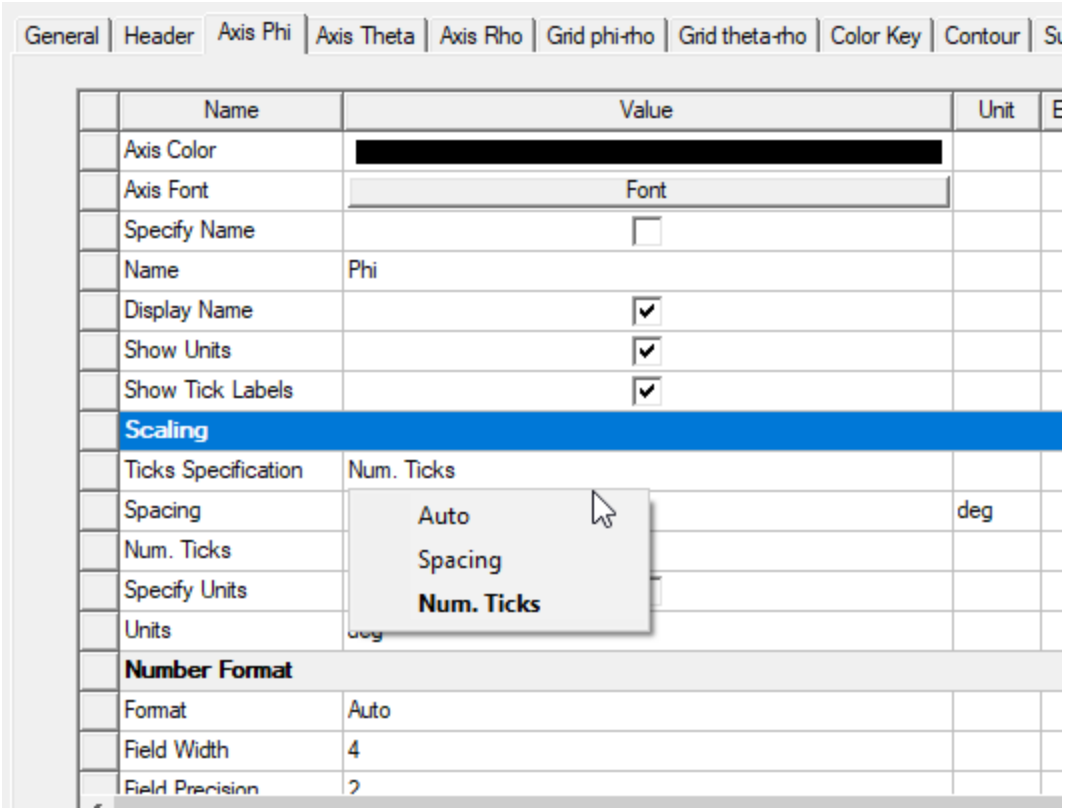


With Visual Detail set to High, a 3D Polar Plot shows all polar axes and grids together with all nice ticks and axes labels. This is ideal for large plot sizes.

Axis Properties: Ticks Specification and Num. Ticks

Ticks Specification is available on Axis properties, as shown below:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ticks Specification is a menu with possible values as Auto, Spacing, and Num. Ticks, with Auto being the default value. If Ticks Specification is Auto, then a spacing value is automatically calculated and used to calculate and display the tick labels. **Spacing** shows the calculated value, and Num. Ticks shows the number of ticks based on this spacing value, as shown below:

--Scaling			
Scale	Linear		
Specify Min	☐		
Min	0	deg	
Specify Max	☐		
Max	375	deg	
Ticks Specification	Auto		
Spacing	125	deg	
Num. Ticks	2		

You can edit the **Spacing** field when Ticks Specification is set to Spacing; otherwise, it is read only.

You can edit the **Num. Ticks** field when Ticks Specification is Num. Ticks; otherwise, it is read only.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Valid Num. Ticks are between 0 and 100, including 0 and 100. If you enter an invalid value, an error message is shown. If you enter a spacing value that results in number of ticks greater than 100, then an appropriate value is shown.

- If Num. Ticks is 0, then no ticks are shown on the axis.
- If Num. Ticks is 1, then only the max value tick is shown on the axis.
- If Num. Ticks is 2, then only the min and max value ticks are shown on the axis.
- If Num. Ticks is greater than 2, then evenly spaced ticks (including min and max) are shown on the axis.

> **Note:**
>
> With the addition of the Ticks Specification property to Axis properties, the **Specify Spacing** property was removed as an Axis property.
>
> - If an R18.0 or R18.1 project is opened with **Specify Spacing** Unchecked, Ticks Specification is set to Auto.
> - If an R18.0 or R18.1 project is opened with **Specify Spacing** Checked, Ticks Specification is set to Spacing.

Grid Properties for Phi-Rho and Theta-Rho

You can control a range of display properties for the pho-rho and theta-rho grids, including line styles and colors for major and minor grids.

Overlay 3D Polar Plot on Model Window

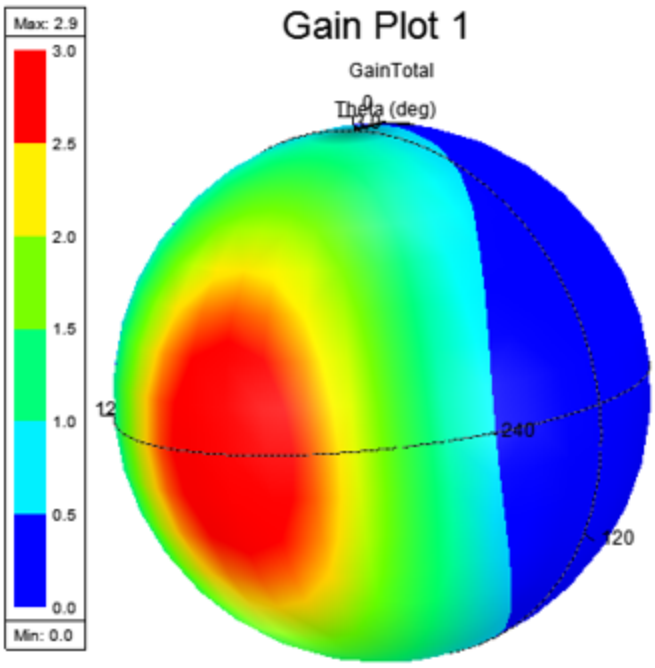
For a 3D polar plot to be eligible for overlay, it must have its primary and secondary sweep from variables Phi and Theta or IWavePhi and IWave Theta in that order. If the plot is unsuitable, the **Overlay** commands are disabled.

Once you create a suitable plot, you can overlay the 3D polar plot on the model window.

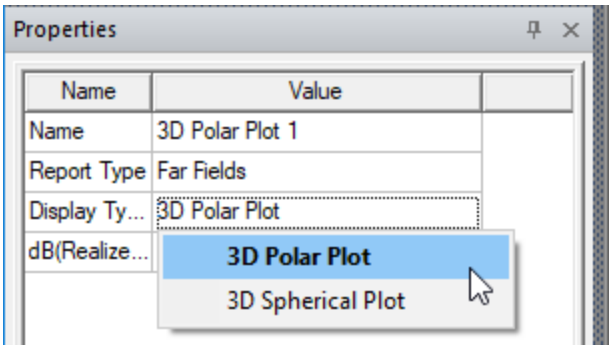
Creating 3D Spherical Plots

A 3D spherical plot resembles a 3D Polar Plot in all aspects except that the radius (rho) of the plot at all points is uniform and is equal to the maximum of all rhos at each (theta, phi) points.

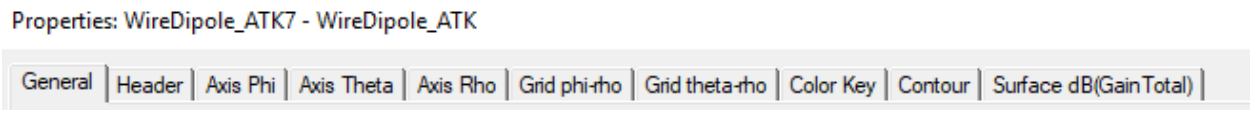
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To convert a 3D Spherical plot to a 3D Polar Plot, select the plot in the Project tree, and select from the Display type menu in the Properties window:



Double-clicking anywhere in the plot brings up the display **Properties** dialog box. The display properties are grouped appropriately under various tabs, which correspond to plot entities.



- General: For general plot properties such as Visual Detail level and background color
- Header: Properties related to plot Header/Title

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Axis Phi: Properties related to the circular axis which is in XY plane
- Axis Theta: Properties related to the circular axis which is in YZ plane
- Axis Rho: Properties related to the radial axis
- Grid phi-rho-theta(0): Properties related to phi-rho grid at theta = 0 (XY plane)
- Grid theta-rho-phi(90): Properties related to theta-rho grid at phi = 90 (YZ plane)
- Color Key: Properties related to the color key, including borders, background, Min and Max, as well as number format and precision.
- Contour: Properties related to contouring of all curves/surfaces
- Surface: Properties related to the curve

You can edit the properties on these tabs to customize the appearance of the plot. See "Controlling Visual Detail in a 3D Spherical Plot" on page 23-132 below.

Creating 3D Polar Plots

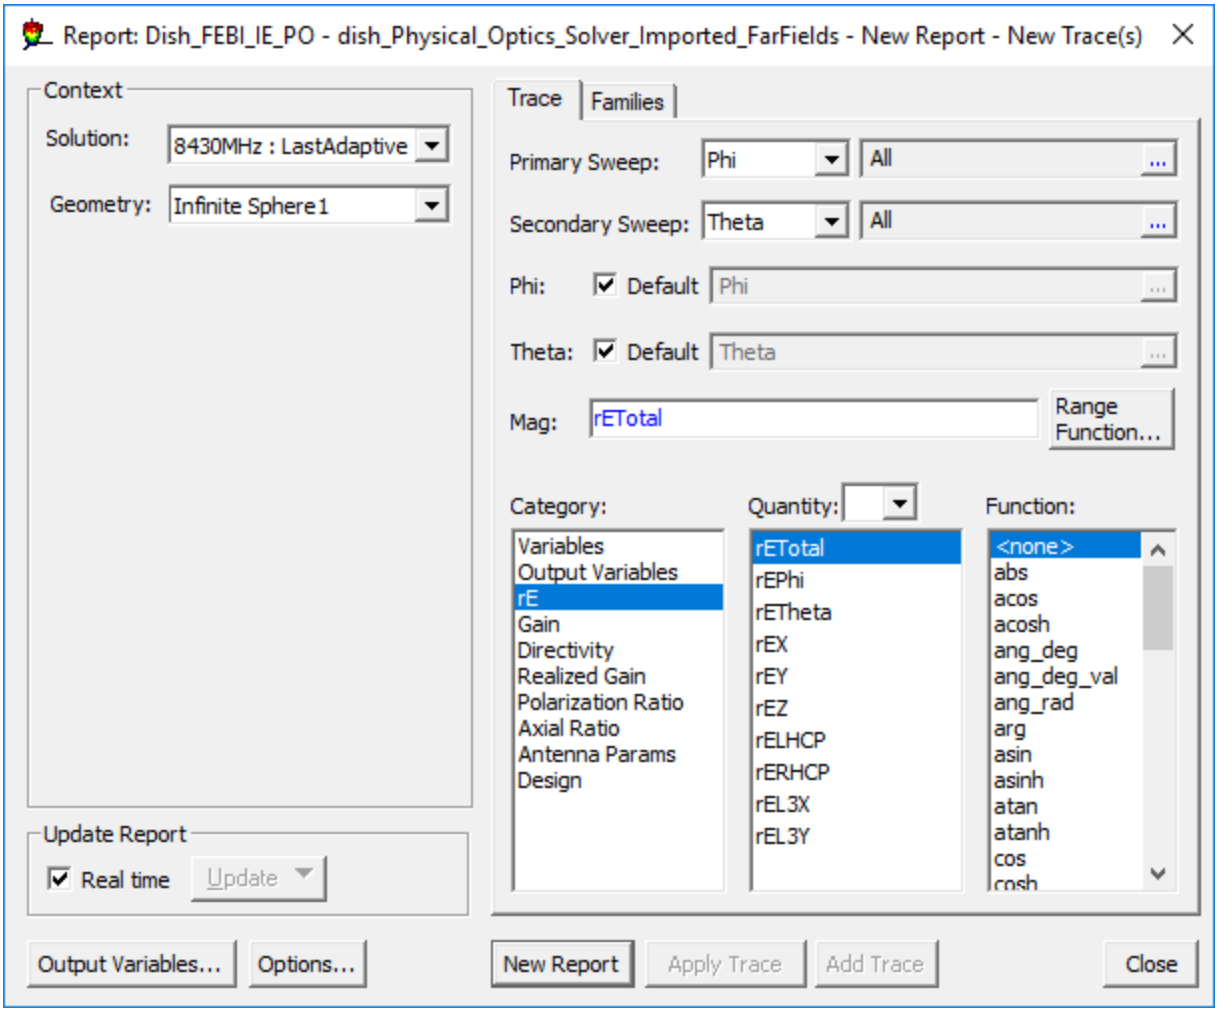
Following is the general procedure for drawing a 3D polar plot of results:

1. On the **Results** menu (HFSS menu or right-click **Results** on the Project tree), click **Create <*type*> Report**, and select **3D Spherical plot** from the report type menu.

   You can also select 3D Polar Plots from the **Results** tab of the ribbon if such plots are appropriate for the current design.

   The **Report** dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. In the **Context** section, make selections from the following field or fields, depending on the design and solution type.
    a. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes.
    b. Geometry field with a drop down selection list. For field and radiated field reports, this applies the quantity to a geometry or radiated field setup.
3. In the **Trace** tab **Mag** area, specify the information to plot along the R-axis, or the axis measuring magnitude:
    a. On the **Category** drop-down menu, click the type of information to plot. The category you select provides the default plot name.
    b. On the **Quantity** list, click the values to plot. Use Ctrl+click to make multiple selections.
    c. In the **Function** list, click the mathematical function to apply to the quantity for the plot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

> **Note:**
>
> Color shows valid expression.

e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

4. On the **Trace** tab **Theta(Secondary Sweep)** line, select the sweep variable from the drop-down menu and specify all values or select values to plot along the theta-axis.
5. On the **Trace** tab **Phi (Primary Sweep)** line, select the sweep variable from the drop-down menu, and specify all values or select values to plot along the phi-axis.
6. Click **New Report.**

   This button creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, S Parameter Plot *n* or rE Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The function of the selected quantity or quantities will be plotted against the R-, phi-, and theta-axes on a 3D polar graph. The plot is listed under **Results** in the project tree. When you select the traces or plots, axis or grid labels, plot header, color key, or variable labels, their properties are displayed in the Properties window. The properties for each plot element can be edited directly to modify the plot content and appearance. See Modifying the Background Properties of a Report.

7. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

Interacting with 3D Spherical Plots

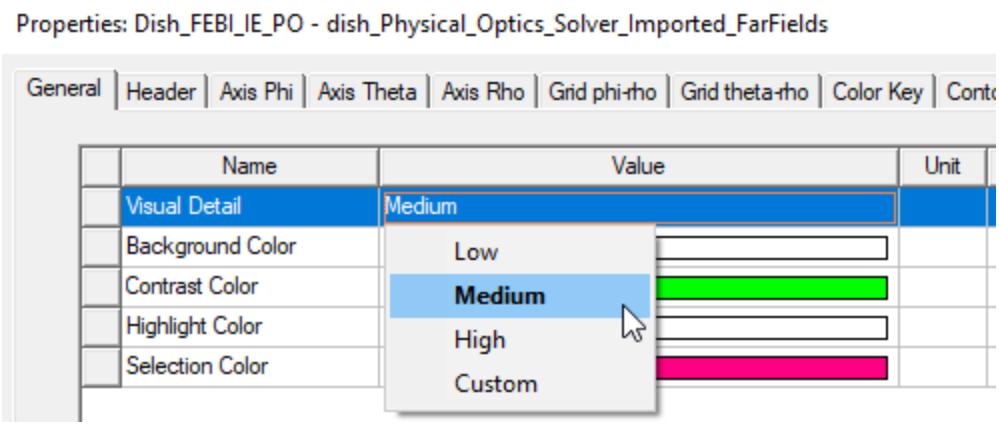
You can Rotate, Zoom and Pan a plot. When you rotate, the Cartesian grid responds so that the curve always remains in front and the grids behind. Also, see Using the Orientation Gadget.

Controlling Visual Detail in a 3D Spherical Plot

If a particular plot seems busy with information, you can edit plot properties, such as Axis and Grid Attributes for discrete levels of visual detail to improve readability. Double-click anywhere on a plot to display the **Properties** dialog box. Clicking on a plot entity selects it, highlighting the selected entity in bold.

The Visual Detail property on the **General** tab also provides control suited to different screen and plot sizes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

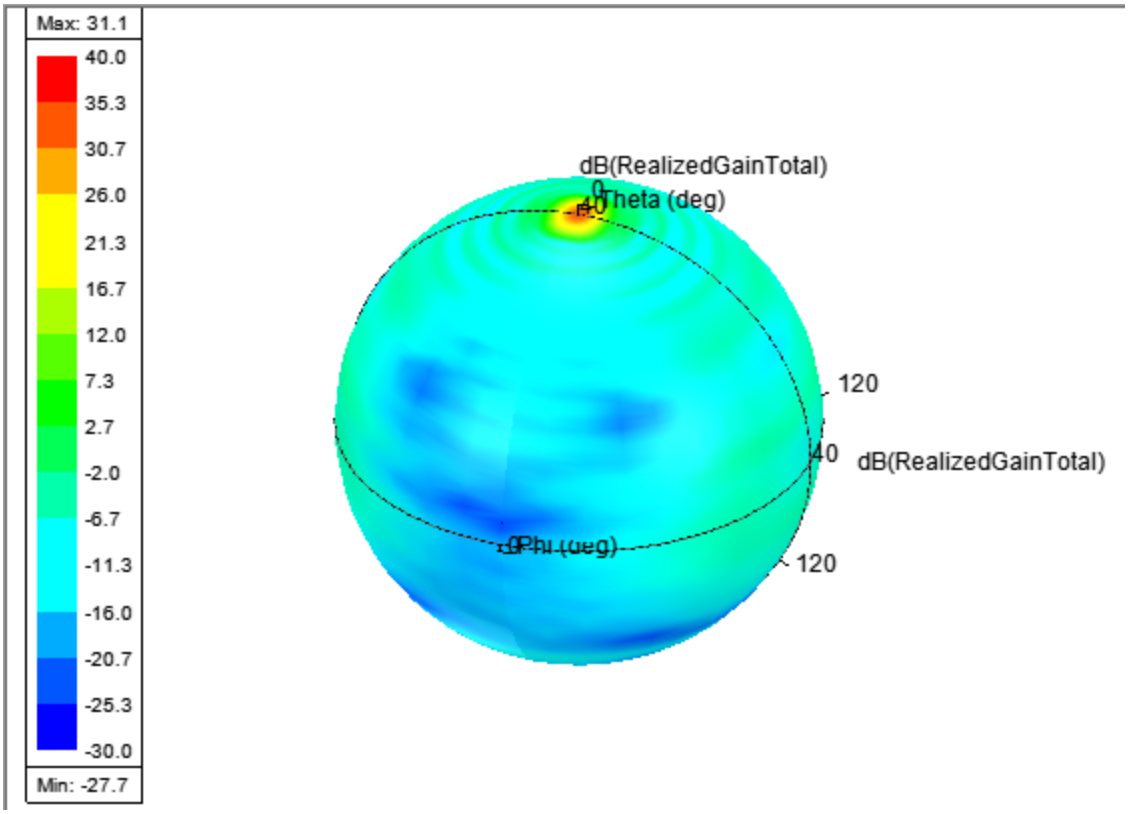


The Visual Detail menu has four options: Low, Medium (the default), High, and Custom. From this predefined visual detail level, if you modify any properties, Visual Detail is automatically set to Custom (or to another predefined visual detail level if the edits happen to match the settings for that level).

You can also manually set Visual Detail to Custom. In such a case, Custom will inherit property values corresponding to the previous level. This ensures that you can customize settings starting from a baseline provided by the preconfigured Low, Medium or High Visual Detail levels.

3D Spherical Plot with Medium Visual Detail

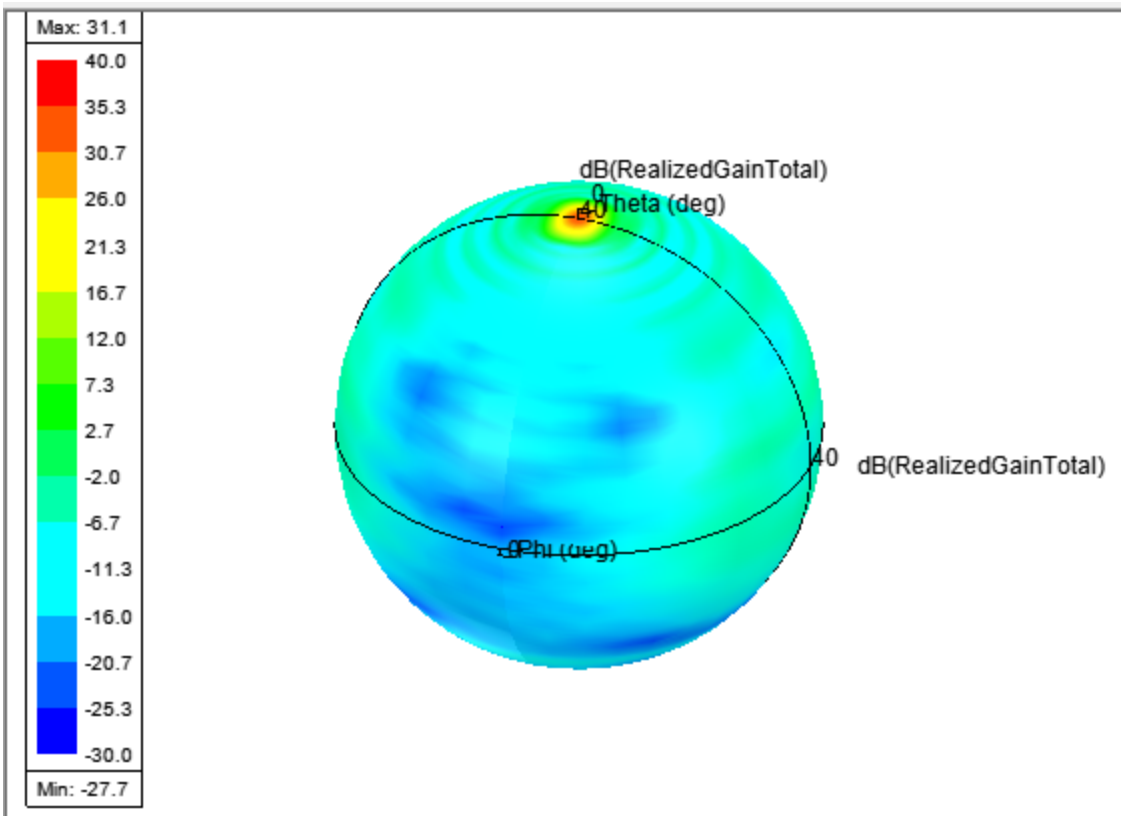
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



On creation, a 3D Polar Plot has Visual Detail set to Medium and looks and feels as shown above. Specifically, under the Medium Visual Detail level, 3D Spherical Plot has 3 ticks per axis (phi, theta and rho axis) which show min, max and middle value. This setting also shows axes labels.

3D Spherical Plot with Low Visual Detail

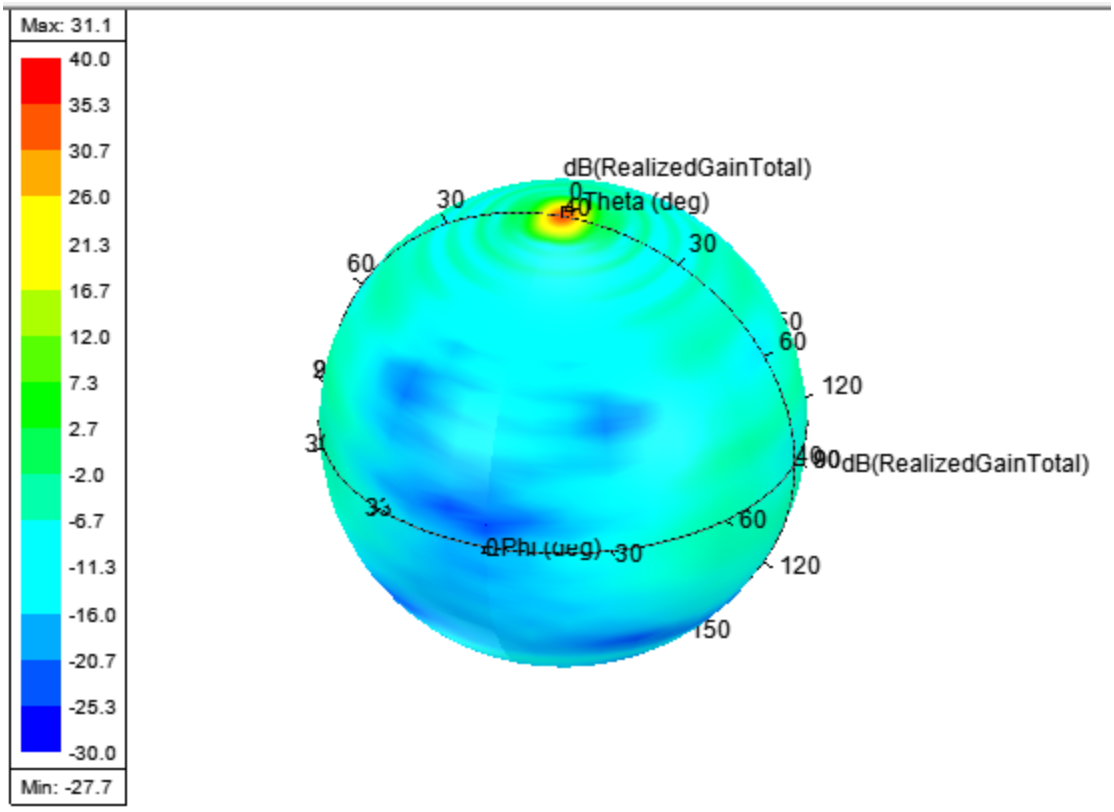
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



With Visual Detail set to Low, 3D Spherical Plot does not show polar grids or grid lines. It only shows axes with 2 ticks corresponding to min and max values. This setting also renders axis labels.

3D Spherical Plot with High Visual Detail

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

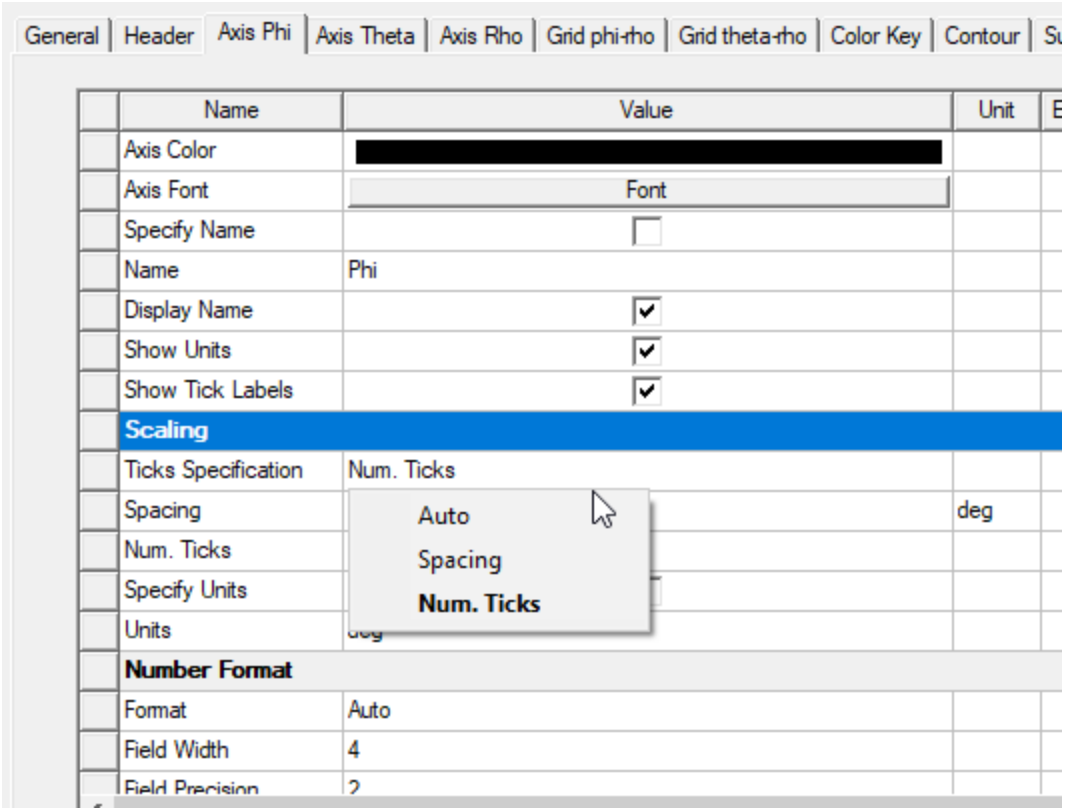


With Visual Detail set to High, a 3D Spherical Plot shows all polar axes and grids together with all nice ticks and axes labels. This is ideal for large plot sizes.

Axis Properties: Ticks Specification and Num. Ticks

Ticks Specification is available on Axis properties, as shown below:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ticks Specification is a menu with possible values as Auto, Spacing, and Num. Ticks, with Auto being the default value. If Ticks Specification is Auto, then a spacing value is automatically calculated and used to calculate and display the tick labels. **Spacing** shows the calculated value, and Num. Ticks shows the number of ticks based on this spacing value, as shown below:

--Scaling			
Scale	Linear		
Specify Min	☐		
Min	0	deg	
Specify Max	☐		
Max	375	deg	
Ticks Specification	Auto		
Spacing	125	deg	
Num. Ticks	2		

You can edit the **Spacing** field when Ticks Specification is set to Spacing; otherwise, it is read only.

You can edit the **Num. Ticks** field when Ticks Specification is Num. Ticks; otherwise, it is read only.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Valid Num. Ticks are between 0 and 100, including 0 and 100. If you enter an invalid value, an error message is shown. If you enter a spacing value that results in number of ticks greater than 100, then an appropriate value is shown.

- If Num. Ticks is 0, then no ticks are shown on the axis.
- If Num. Ticks is 1, then only the max value tick is shown on the axis.
- If Num. Ticks is 2, then only the min and max value ticks are shown on the axis.
- If Num. Ticks is greater than 2, then evenly spaced ticks (including min and max) are shown on the axis.

> **Note:**
>
> With the addition of the Ticks Specification property to Axis properties, the **Specify Spacing** property was removed as an Axis property.
>
> - If an R18.0 or R18.1 project is opened with **Specify Spacing** Unchecked, Ticks Specification is set to Auto.
> - If an R18.0 or R18.1 project is opened with **Specify Spacing** Checked, Ticks Specification is set to Spacing.

Grid Properties for Phi-Rho and Theta-Rho

You can control a range of display properties for the pho-rho and theta-rho grids, including line styles and colors for major and minor grids.

Overlay 3D Spherical Plot on Model Window

For a 3D Spherical plot to be eligible for overlay, it must have its primary and secondary sweep from variables Phi and Theta or IWavePhi and IWave Theta in that order. If the plot is unsuitable, the **Overlay** commands are disabled.

Once you create a suitable plot, you can overlay the 3D spherical plot on the model window.

Creating Smith Charts

A Smith chart is a 2D polar plot of S-parameters upon which a normalized impedance grid has been superimposed. Following is the general procedure for creating a Smith chart of results:

1. On the **Results** menu (HFSS menu or right-click **Results** on the Project tree), click **Create <*type*> Report**, and select **Smith Chart** from the report type menu.

   The **Report** dialog appears.

2. In the **Trace** tab **PolarComponent** area, specify the information to plot:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. On the **Category** drop-down menu, click the type of information to plot. The category selected provides the default plot name.
b. On the **Quantity** list, click the values to plot. Use Ctrl+click to make multiple selections.
c. In the **Function** list, click the mathematical function to apply to the quantity for the plot.
d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

> **Note:**
>
> Color shows valid expression.

e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

3. Click **New Report.**

This creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, S Parameter Plot *n* or rE Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

The function of the selected quantity will be plotted against the values you specified on a polar plot. In addition, each circle on the plot is labeled with values of *R*, measuring normalized resistance, and each line is labeled with values of *X*, measuring normalized reactance. The plot is listed under **Results** in the project tree and the traces are listed under the plot. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.

4. Optionally, add another trace to the plot by following the procedure above, using **Add Trace rather than New Report**.

Creating Smith Contour Charts

A Smith contour chart is a polar plot of S-parameters upon which a normalized impedance grid has been superimposed. Following is the general procedure for creating a Smith chart of results:

1. On the **Results** menu (HFSS menu or right-click **Results** on the Project tree), click **Create <*type*> Report**, and select **Smith Chart** from the report type menu.

The **Report** dialog appears.

2. In the **Trace** tab **Mag** area, specify the information to plot:
   a. On the **Category** drop-down menu, click the type of information to plot. The Category selection provides the default plot name.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. On the **Quantity** list, click the values to plot. Use Ctrl+click to make multiple selections.
c. In the **Function** list, click the mathematical function to apply to the quantity for the plot.
d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

> **Note:**
>
> Color shows valid expression.

e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

3. On the **Trace** tab **(Secondary Sweep)** line,select the sweep variable from the drop-down menu and specify all values or select values to plot along the theta-axis:

To select an Secondary sweep component that is different from the default, uncheck the Default field to enable the X field and **Browse** [...] button. Click **Browse** [...] to display the **Select X Component** dialog box. This lets you specify the X component as you do the Y; that is, in terms of Categories which define the selectable Quantities, and Functions to apply. After making selections, **OK** the dialog to assign the X component.

a. If sweeps are available, you can select **Browse** [...] to display a dialog that lets you select particular sweep or sweeps, or all sweeps.
b. The **Families** tab provides a way to select from valid solutions for sweeps where a simulation has multiple variables defined (for example, for a parametric sweep). If so, the variables other than the one chosen as the **X (Primary sweep)**, are listed under the **Families** tab with columns for the variable, the value, and an Edit column with an ellipsis **[...]** button. See Using Families tab for Reports.

4. On the **Trace** tab **(Primary Sweep)** line,select the sweep variable from the drop-down menu, and specify all values or select values to plot along the phi-axis:

To select an X component that is different from the default, uncheck the Default field to enable the X field and browse [...] button. Click **Browse** [...] to display the **Select X Component** dialog box. This lets you specify the X component as you do the Y; that is, in terms of Categories which define the selectable Quantities, and Functions to apply. After making selections, **OK** the dialog to assign the X component.

a. If sweeps are available, you can select **Browse** [...] to display a dialog that lets you select particular sweep or sweeps, or all sweeps.
b. The **Families** tab provides a way to select from valid solutions for sweeps where a simulation has multiple variables defined (for example, for a parametric sweep). If so, the variables other than the one chosen as the **X (Primary sweep)**, are listed

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

under the **Families** tab with columns for the variable, the value, and an Edit column with an ellipsis [**...**] button. See Using Families tab for Reports.

5. Click **New Report.**

This creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, S Parameter Plot *n* or rE Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

The function of the selected quantity will be plotted against the values you specified on a polar plot. In addition, each circle on the plot is labeled with values of *R*, measuring normalized resistance, and each line is labeled with values of *X*, measuring normalized reactance. The plot is listed under **Results** in the project tree and the traces are listed under the plot. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.

6. Optionally, add another trace to the plot by following the procedure above, using **Add Trace rather than New Report**.

Creating Data Tables

A data table is a grid with rows and columns that displays, in numeric form, selected quantities against a swept variable or other quantities.

1. Click **HFSS**> **Results**> **Create *<type>* Report** or right-click **Results** in the Project Manager and click **Create *<type>* Report**.
2. In the **display type** menu, click **Data Table**.

   The *Report* dialog box appears.

3. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   a. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes.
   b. Domain field with a drop down selection list. Whether this field appears, and the domains listed depend on the Solution type and the report ***<type>*** selected. For modal and terminal solution data reports, the domain can be **Sweep** or **Time**.

      Before you can examine the time domain, you must perform an Interpolating sweep for a driven solution (Modal or Terminal). If you select **Time**, the **TDR Options** button is enabled. Select it and follow the directions for time-domain plotting.

   c. Geometry field with a drop down selection list. For field and radiated field reports, this applies the quantity to a geometry or radiated field setup.
4. Under the **Trace** tab **Y** component section, select the quantity you are interested in and its associated function:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. On the **Category** drop-down menu, click the type of information to plot. The category selected provides the default name for the plot.
b. On the **Quantity** list, click the values to plot. Use Ctrl+click to make multiple selections.
c. In the **Function** list, click the mathematical function to apply to the quantity for the plot.
d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

> **Note:**
>
> Color shows valid expression.

e. **Range Function** button -- opens the *Set Range Function* dialog box. This applies currently specified Quantity and Function.

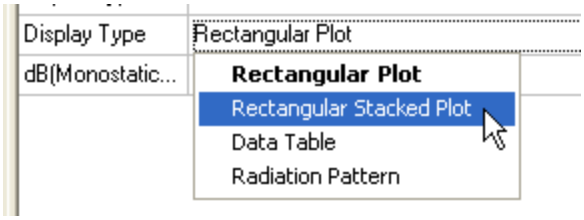
5. On the **Trace** tab **X (Primary sweep)** line, select the sweep variable from the drop-down menu and specify all values or select values.
6. Click **New Report**.

   This creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, for example, S Parameter Plot *n* or Output Variables Plot *n*. You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The Y quantity will be listed at each variable value or additional quantity value you specified. The data table is listed under **Results** in the project tree. The plot is listed under **Results** in the project tree and the traces are listed under the plot. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.

7. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

You can also modify the display type of an existing plot from the Properties dialog for that plot. Select the Report icon in the Project tree to display the Properties dialog box. Selecting the Display Type field displays a menu with selections available for that plot.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once you make a selection, the plot display updates for the current selection.

If you choose to print a data table:

- Selecting print "All" prints the whole table for current data page (if there is more than one data page).
- Selecting print "Pages" prints user-specified pages.
- If the table is bigger than the screen view (that is, it has scroll bar), printing first scrolls right, prints until no more scrolling and then scroll down.
- The Page number appears at the bottom of the page, aligned at center.
- The table layout of each page follows the screen, but with no scroll bar will be printed, and no data page bar as on screen.

Creating Radiation Patterns

A radiation pattern is a 2D polar plot displaying the intensity of near- or far-field radiation patterns. It is divided by the spherical coordinates R and theta, where R is the radius, or distance from the origin, and theta is the angle from the x-axis. Following is the general procedure for drawing a radiation pattern of results:

1. Click **HFSS>Results>Create Far Fields Report>Radiation Pattern**, or right-click the **Results** icon in the **Project tree** and click **Create Far Fields Report>Radiation Pattern**.

The **Report** dialog box appears, and a Radiation Pattern Plots icon appears under **Results** in the Project tree.

3. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
    a. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes.
4. In the **Trace** tab area, specify the Primary Sweep and Ang information to plot along the R-axis, or the axis measuring magnitude. The Primary Sweep field has a drop-down menu of current choices for Theta, Phi, and defined variables. Click the ellipsis button if you want to select from available values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. In the **Ang**, if you want to change the default, uncheck to enable the field and ellipsis button.

   a. On the **Category** drop-down menu, click the type of information to plot. The selected category also provides the default plot name.
   b. On the **Quantity** list, click the values to plot. Use Ctrl+click to make multiple selections.
   c. In the **Function** list, click the mathematical function to apply to the quantity for the plot.
   d. The **Mag** field displays the currently specified Quantity and Function. You can edit this field directly.

> **Note:**
>
> Color shows valid expression.

   e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

5. The **Families** tab is helpful if you want to use the plot as an overlay and you need to restrict the Phi (default) or Theta values to make the plot appropriate for overlay. See Overlaying 2D Radiation Field Plots on Models.
6. Click **New Report.**

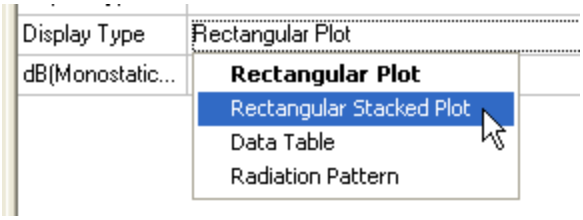
This creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, for example, System Gain Plot *n* or Directivity Plot *n*. You can edit the plot names in the project tree and the plot header text in the report synchronizes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The function of the selected quantity or quantities will be plotted against the values you specified on a 2D polar plot. The plot is listed under **Results** in the project tree and the traces are listed under the plot. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.

7. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

You can also modify the display type of an existing plot from the Properties dialog for that plot. Select the Report icon in the Project tree to display the Properties dialog box. Selecting the Display Type field displays a menu with selections available for that plot.



Once you make a selection, the plot display updates for the current selection.

Delta Markers in 2D Reports

To view the difference between any two marker points in a report:

1. Set the first marker by clicking and holding the mouse button.
2. Move the mouse without releasing left button to another position, and then release the left button to create second marker.

In the marker text window, you see the difference between the two markers instead of the X, Y value of marker.

Plotting in the Time Domain

The idea behind Time-Domain Reflectometry (TDR) is to excite a structure with a step function, and inspect the reflections as a function of time. Before you can examine the time domain, you must perform an Interpolating sweep for a driven solution (Modal or Terminal or Transient). You can then select **Time** from the **Domain** list in the **Report** dialog box. You also need to specify the input signal, whether step or impulse.

With **Time** selected as the domain, you can select from several Categories and associated Quantities to plot, for example mag(S_{11}). When you plot in the Time domain, every frequency domain quantity is first converted to the time-domain before the formula is evaluated. For example, if you type in

$S_{11} / (1 - S_{11})$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

and plot it in the time domain the reporter will plot

IFFT(S_{11} * input)/(IFFT(input)-IFFT(S_{11} * input))

It will NOT plot

IFFT(S_{11}/ (1 - S_{11}) * input)

The two expressions are not equivalent.

If you select Time Domain Impedance as the Category, you can select the TDRZ quantity. This is defined as

TDRZ(t)=Zref*(IFFT(input)+IFFT(S_{11} * input))/(IFFT(input)+IFFT(S_{11} * input))

where "input" denotes the Fourier transform of the input signal (step or impulse) and "IFFT(.)" denotes the inverse FFT.

This equation is the instantaneous ratio of the time-domain voltage v(t) to the time-domain current i(t). That is because voltage and current are defined (in the frequency domain) in terms of the incident and reflected waves a and b, respectively, as

V = sqrt(Zo) * (a + b) = sqrt(Zo) * (1 + S_{ii}) * a

I = 1/sqrt(Zo) * (a - b) = 1/sqrt(Zo) * (1 - S_{ii}) * a

This lets the incident wave be the input step signal, and so when we take the inverse FFT of V and I, we get v(t) and i(t) in the time domain. Taking their ratio as a function of time then yields TDRZ(t). By default, Zo is equal to 50 Ohm. For frequency dependent Z_0, such as from an HFSS waveport, we recommend renormalizing to a constant Z_0, such as Z_0 = 50 ohms. This mimics the measurements techniques from which TDR was developed.

For HFSS, HFSS 3D or Layout Linear Network Analysis on Circuit, to create a plot in the **Time Domain**:

1. For a design with an existing sweep setup, follow steps 1 - 4 for creating a report for design.
2. In the **Report** dialog box, in the **Domain** list, click **Time**.

   This enables the **TDR Options** button and for terminal solution data reports includes the Terminal TDR Impedance in the Category list.

3. Click the **TDR Options button**.

   The **TDR Options** dialog box appears.

4. Select the input signal type, **Step** or **Impulse**.

   A **Step** describes a sustained change in the signal, whereas the **Impulse** is a brief excitation. **Impulse** is a very narrow rectangular pulse, with zero rise and fall time, width of 1 time step, and height of 1/(time step).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Selecting **Step** enables the **Rise Time** field, and **Impulse** disables it.

5. If you selected **Step**, enter the rise time of the pulse in the **Rise Time** text box.

The rise time should be appropriate for the frequency context.

With a band width from DC to f_{max}, the best time resolution that can be achieved is $1/(2f_{max})$.

A rise time of $1/(2f_{max})$ is the shortest rise time that can be resolved. However, a rise time of 0 s gives equally valuable information, so 0 is the default in this panel. See the example plot.

6. Enter the total time on the plot in the **Maximum Plot Time** text box.

The default maximum plot time in the **TDR Options** dialog is related to the delta frequency df in the frequency sweep: it is 1/2df, since that is the extent of time for which the IFFT gives information. This is often very long relative to the time delay that corresponds to the length of your device under test, so you may want to reduce this value. Alternatively, you can adjust the time axis of your TDR plot after it has been created.

7. Set the number of time points to plot in the **Delta Time** text box. By default, this is set to the number of points in the frequency sweep.

The delta time is based on the bandwidth of the sweep: with a frequency sweep from DC to f_{max}, the smallest time resolution you can obtain is given by $1/(2f_{max})$. The IFFT algorithm provides data points as a spacing of $1/(2f_{max})$, but you can smoothly interpolate between points by setting a finer resolution, e.g., $1/(10f_{max})$, at the expense of extra computation time.

8. Optionally, under **TDR Window**, modify the window type and width.
9. You can use the **Save as Default** to set the current values as a default, and the **Use Defaults** button to use previously saved options. Note that when you select a trace, the initial displayed values are those of the selected trace.
10. Click **OK**.

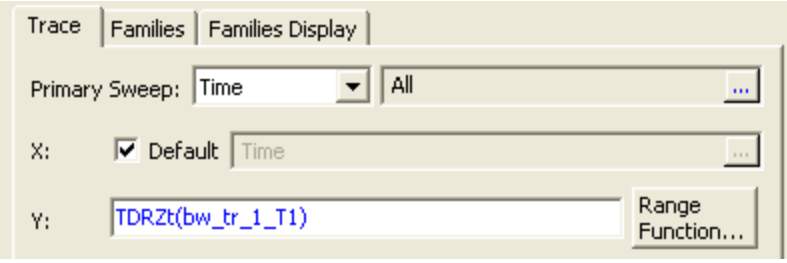
Optionally, to plot Terminal TDR impedance (that is, rather than calculate the S-parameter for waveport1 versus frequency, instead calculate the delay versus time at a particular impedance), do the following:

a. In the **Category** list, click **Terminal TDR Impedance**.
b. In the **Quantity** list, click a quantity to plot.

The default impedance (Zo) for the TDRZ quantity is 50 Ohms, unless you specified differently when you Set Renormalizing Impedance for Terminals when you created the terminals in the model. If you need a different impedance value, you can either edit the value in the **Report** dialog (as shown below), or you can create an Output Variable representing $Zo \times (1+S_{ii})/(1-S_{ii})$ with the Zo of your choice. To edit the Zo value in the **Report** dialog:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. For the Category, select Terminal TDR Impedance, and the Port and Function of interest.



2. Edit the value by placing the cursor in the Value field.

   In this example, the value for Zo is changed from the default to 75 Ohms by typing ',Zo=75ohm' in the Y-column field.

   c. In the **Function** list, click the mathematical function of the quantity to plot.

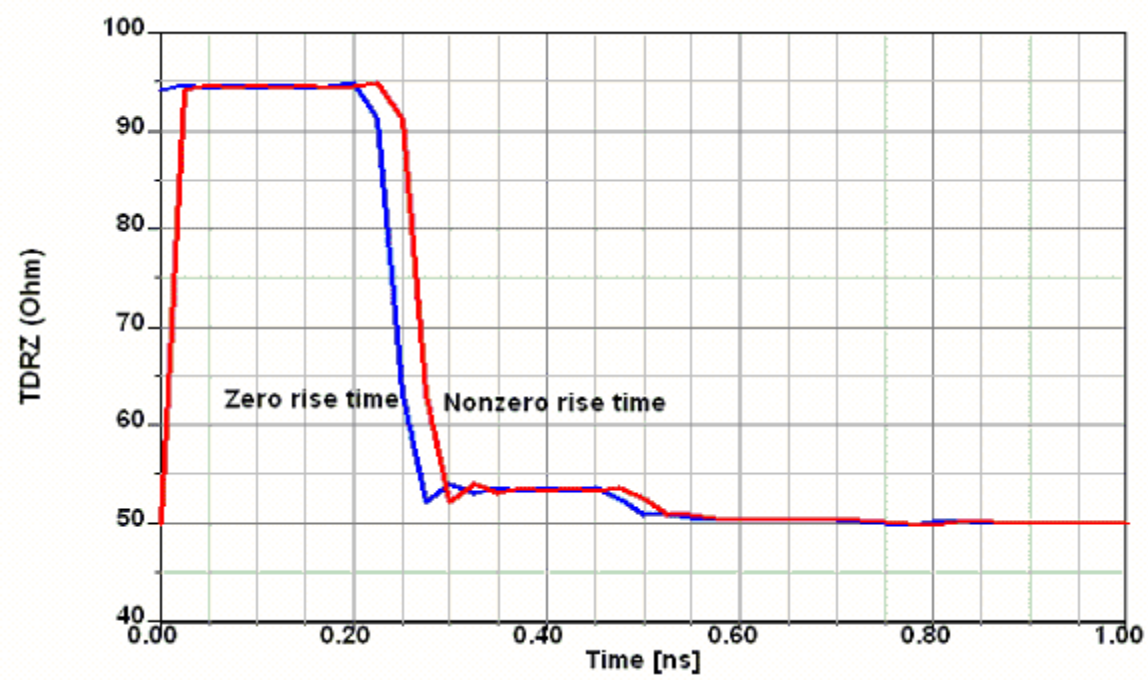
3. Click **Done**.

The report appears in the view window. It will be listed in the project tree.

If S_{11} = 0 at DC, the time-domain step response will settle to zero and the TDRZ step response settles to Zref. If S_{11} is nonzero at DC, the time-domain step response will settle to a nonzero value and TDRZ will settle to a value different from Zref. The time-domain impulse response will always settle to zero, since it can be seen as the derivative of the step response. The TDRZ impulse response will always settle to Zref.

The plot below shows the difference between a short nonzero rise time and zero rise time for a transmission line segment of 94 Ohm. Note that the trace with zero rise time starts at the correct line impedance while the other starts at the renormalizing impedance. Other than that, one trace is a shifted version of the other. The reason the plot with finite rise time starts at 50 ohms is that the time-domain voltage and current are still at their steady state values, so v = Zref * i. As the pulse arrives, the TDRZ response changes from the steady-state behavior because there's a reflection from the transmission line back to the exciting source, which has a different renormalizing impedance from the characteristic impedance of the transmission line.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Some things to keep in mind with TDR:

$$Spatial resolution \Delta x = c/(2B) \quad (1)$$

where c is the speed of light in the medium and B is the bandwidth of the signal. Since TDR is usually based on a frequency band that starts at DC, the spatial resolution becomes

$$\Delta x = c/(2F_{max}) \quad (2)$$

where F_{max} is the highest frequency in the frequency sweep. For example, if F_{max} = 15 GHz and the medium has ε_r=4, the spatial resolution will be (1.5E8 m/s)/(3E10 /s) = 5 mm.

A spatial resolution of $c/(2F_{max})$ corresponds to a resolution in time

$$\Delta t = 1/(2F_{max}) \quad (3)$$

Let N be the number of points in the IFFT. N equals the number of time samples, and it also equals twice the number of frequency samples. The density of frequency samples in the frequency sweep influences the total time T as follows:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$2F_{max}/(\Delta f) = N(\text{number of points in IFFT}) = T/\Delta t \quad (4)$$

So increasing the density of the frequency samples leads to an increase in total time T. In practical case, this often leads to a long tail in the TDR plot with little useful information. Therefore, the TDR Options interface lets you set the maximum plot time to a smaller value.

The TDR Options interface also lets you choose a smaller Δt than given by equation (3) above. When you choose a smaller Δt, you increase F_{max} by "zero padding" (adding zero values for S_{11} beyond the calculated frequency sweep). Whether this is justified depends on your judgment. It leads in practice to a smoother TDR signal.

HFSS also lets you set the rise time of your input signal. The rise time should be at least $1/(2F_{max})$. Even this rise time is a bit short for comfort, as it equals the duration of only one time sample. An input signal with a longer rise time has a smaller high-frequency content and will lead to reduced "ringing" in the TDR response.

A Hamming or Hann filter will also reduce the high-frequency content and tends to lead to a smoother TDR response. With these filters, one can select a width. A width of 100% is often a good choice.

TDR Windowing Functions

Windowing functions cause the FFT of the signal to have non-zero values away from ω. Each window function trades off the ability to resolve comparable signals and frequencies versus the ability to resolve signals of different strengths and frequencies. The window type list includes the following:

Window Function	Preferred Use
Rectangular	A low dynamic range function offering good resolution for signals of comparable strength. Poor when signals have very different amplitudes. $w(n)=1$. Bartlett	A high dynamic range function, with lower resolution, designed for wide band applications. $w(n) = a_0 - a_1\left\lvert\frac{n}{N-1} - \frac{1}{2}\right\rvert - a_2\cos\left(\frac{2\pi n}{N-1}\right)$

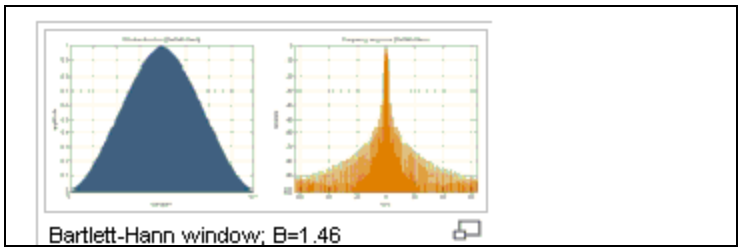
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

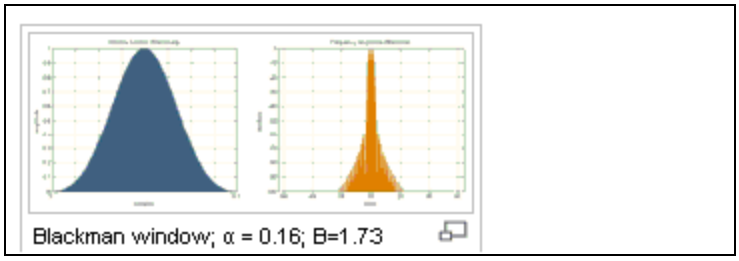
Window Function	Preferred Use
	where a_0=0.62; a_1=0.48; a_2=0.38



Blackman — A high dynamic range function, with lower resolution, designed for wide band applications.

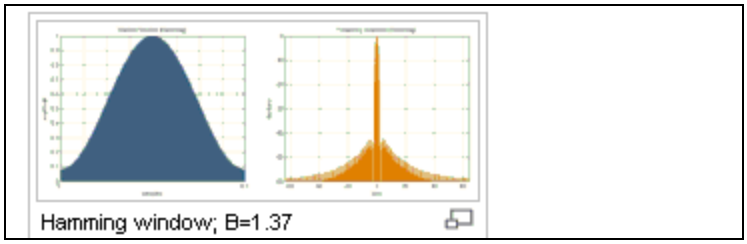
$$w(n) = a_0 - a_1 \cos\left(\frac{2\pi n}{N-1}\right) + a_2 \cos\left(\frac{4\pi n}{N-1}\right)$$

where a_0 =(1-α)/2; α_1=1/2; α_2=α/2



Hamming — A moderate dynamic range function, designed for narrow band applications. It minimizes the maximum sidelobe.

$$w(n) = 0.54 - 0.46\cos\left(\frac{2\pi n}{N-1}\right)$$



Hanning (default) — A moderate dynamic range function, designed for narrow band applications.

$$w(n) = 0.5\left(1 - \cos\frac{2\pi n}{N-1}\right)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Window Function	Preferred Use
	Kaiser	Selecting the Kaiser plot also enables a field to specify an associated Kaiser parameter. The larger the Kaiser parameter, the wider the window. The parameter controls the trade off between width of the central lobe and the area of the side lobes.  Welch	This approach applies a parabola-shaped window to the frequency domain data. It is based on the Bartlett method but splits the signal into overlapping segments, which are then windowed. The intent is to balance the influence of data in the center of the function.

You can use the **Save as Default** to set the current values as a default.

Working with Traces

A trace in a 2D or 3D report defines one or more curves on a graph. A trace in a data table defines part of the displayed matrix of text values.

The values used for a plot's axes (which may be X, Y, Z, phi, theta, or R depending on the display type) can be variables in the design, such as frequency, or functions and expressions based on the design's solutions. If you have solved one or more variables at several values, you can "sweep" over some or all of those values, resulting in a curve in 2D or 3D space.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A report can include any number of traces and, for rectangular graphs, up to 20 independent y-axes. Traces appear in the Project tree under their report. They can be selected, copied and pasted.

When you move a cursor over a trace in a report, the cursor changes to show that you can make a selection:

- For PC systems, the cursor changes to the color of the selectable trace.
- For Linux systems, the cursor changes to a solid black arrow, rather than the default black outline.

In general, to add a trace to a report:

1. Select a report in the Project window and right-click and select **Modify Report**.
2. In the *Report* dialog box, specify the Y component information.
    a. Specify the Category of information you want to plot from the drop-down menu.

       The Category drop-down menu lists the available categories for the Solution type and the current design. Selecting a category changes the Quantity and Function lists to represent what is available for that category.

    b. Specify the Quantity you want to plot by selecting from the Quantity list.

       The selected quantity appears in the Value field, operated on any selected function.

    c. Select the Function to apply to the specified quantity.
    d. The Value field shows the trace being readied for plotting on the Y-axis. This field is editable when the text cursor is present. You can modify the information to be plotted by typing the name of the quantity or sweep variable to plot along an axis directly in the text boxes.

       > **Note:**
       >
       > Color shows valid expression.

    e. **Range Function** button -- opens the *Set Range Function* dialog box. This applies the currently specified Quantity and Function.
3. In the *Report* dialog box, specify the X axis information (for example Primary Sweep).
4. Click **Add Trace**.

   A trace is added to the traces list under its report icon in the Project tree. The trace represents the function of the quantity you selected and will be plotted against other quantities or swept variable values. Selecting a Trace in the Project tree displays the Properties window for that Trace. Selecting a trace in the report or legend displays the display Properties window for that trace.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Trace icons can be selected, copied, and pasted for their definitions or their data. They can be selected and deleted from the Project Manager.

By the default, the Trace name is the definition (the category, quantity and function). The trace will be visible in the report when you click **Add Trace**.

Trace properties can be edited directly in the respective Properties windows or edited in the *Report* dialog box. To change the name or definition of a trace, see Editing Trace Properties. To edit other display properties of a trace, see Editing the Display Properties of Traces

Editing Trace Properties

To edit trace properties such as the name, Y Axis association, the component definition, the context, or the variables select the trace in the Project tree.

To edit a **trace name**:

1. Select the trace in the Project Manager.

   This displays a docked Properties window for the Trace.

2. Check the Specify Name box.

   This enables editing of either the Name field in the docked properties dialog box, or the Trace label text in the Project tree. Editing this name changes the display in the Legend and in the Project tree, but not the underlying Y-component definition.

> **Note:**
>
> To control the display of the Solution Name and Variation Key in the Legend, see Report 2D: Legend Tab.

To edit the Y Axis associated with the trace (2D Rectangular and Rectangular Contour plots):

1. Select the trace in the Project Manager.
2. In the docked properties window for the trace, select the Y Axis to be associated with the trace from the drop-down menu. Up to twenty independent Y axes can be added to a plot.

To edit a **trace component definition**:

1. Select the trace in the Project Manager.
2. In the docked Properties window for the trace, select the component field of interest, and select **Edit...** from the drop-down menu.

   This displays the edit Component field window from which you can edit the category, quantity and function.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Click **OK** to apply the changes and close the dialog box.

To edit a **trace Context**:

1. Select the trace in the Project Manager to display the docked properties window.
2. In properties window, click the **Solution** field or the **Domain** field. If other selections are possible, they can be selected from the drop-down menu.

To edit a **variable** for a trace:

1. Select the trace in the Project Manager to display the docked properties window.
2. Under the **Variables** category, on the Families line, click the **Edit** button to display the Edit families dialog box.

   From this dialog box, you can select the **Sweeps** or **Variations** radio buttons. If other nominal values are available you can click the ellipsis button to select from a list.

Editing the Display Properties of Traces

Editing the display properties of traces differs for 2D and 3D reports. To edit the display properties of a trace for a 2D report:

1. Select a trace in an open **Report** window.
2. Click once on the trace to view settings in the docked *Properties* window, or double-click to open *Properties* dialog box.

   The display properties window for a 2D trace includes a **General** tab and an **Attributes** tab.

   The *General* tab properties apply to the general appearance of the plot. They include the Background color, Contrast color, Field width, and Whether to use Scientific notation for marker and delta marker displays. (X and Y notation display is set separately, in the Axis property tabs.)

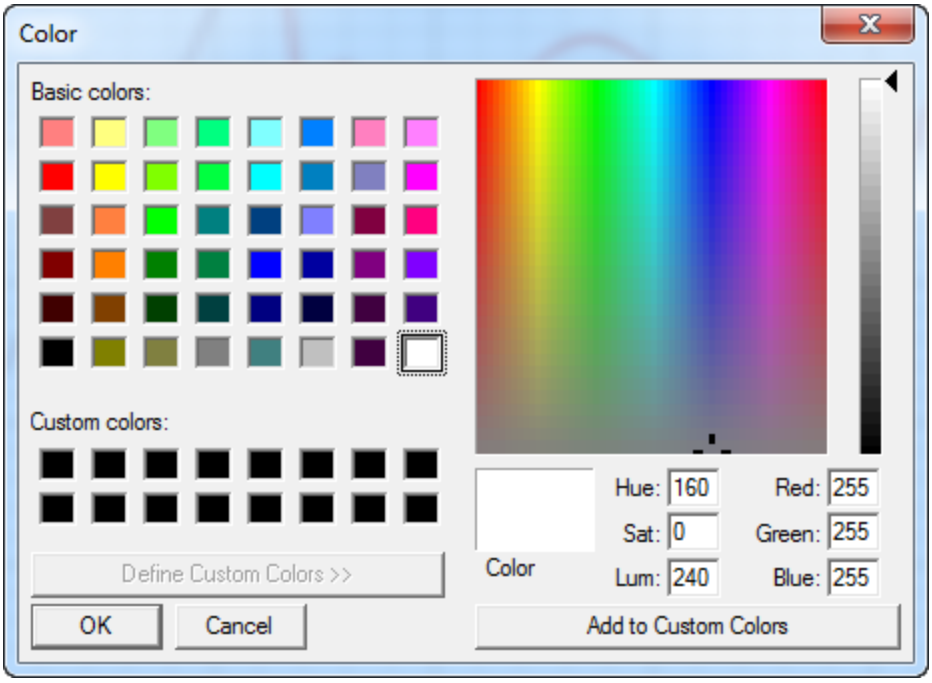
   The *Attributes* tab properties apply specifically to the trace. The defaults are set in the Report2D options. They include:

   - Name -- not editable by selecting the trace from the Report. It shows the characteristics of the trace as defined in the *Report* dialog box.

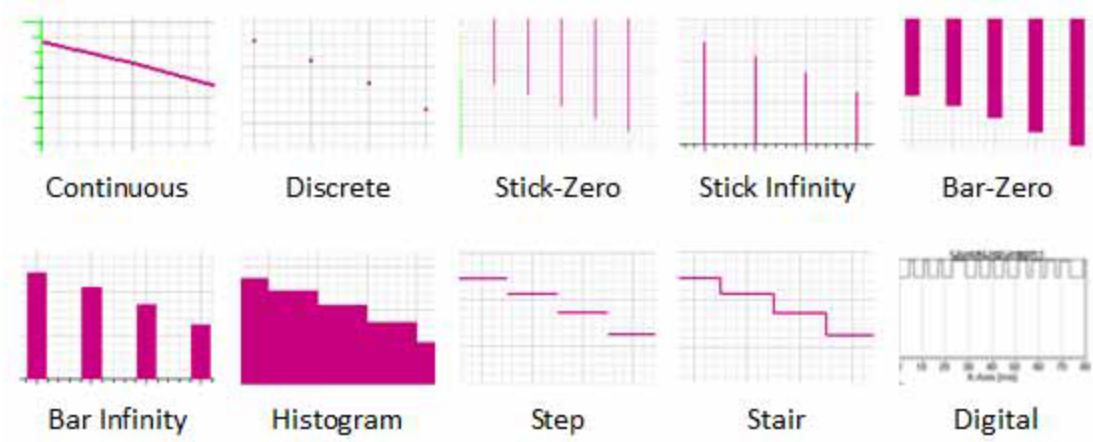
     To edit a trace name, see Editing Trace Properties.

   - Color -- shows the Trace color. Double-click to open a Color dialog box. You can select from Basic colors, or custom colors. You can define up to 16 custom colors by selecting or by editing the values for Hue, Saturation, Luminescence, and the Red, Green, and Blue.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



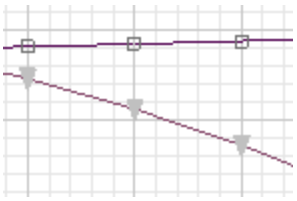
- Line style -- a drop-down menu lets you select Solid, Dot, Dash, or Dot-dash.
- Line width -- a text field lets you edit the numeric value.
- Trace type -- the drop-down menu contains entries for Continuous, Discrete, Bar-Zero, Bar Infinity, Stick Zero, Stick Infinity, Histogram, Step, and Stair.



Notice the difference between Stair and Digital is that each Stair centers on a data point with transitions halfway between points, and Digital transitions from each data point to the next value.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The next four properties work together to define whether to show a symbol on data points, the symbol frequency, the symbol style, and whether to display the symbol as solid or hollow.



- Show Symbol -- whether to show a symbol at the data points on the line.
- Symbol Frequency -- how often to show symbols on the trace, based on the number of data points per symbol used. For example, specify 1 for one symbol per data point. Specify 10 for one symbol for every 10 data points.
- Symbol Style -- use a drop-down menu to select from box, circle, vertical ellipse, horizontal ellipse, vertical up triangle, vertical down triangle, horizontal left triangle, horizontal right triangle.
- Fill Symbol -- use the check box to set the symbol display as a solid or as hollow.
- Symbol Arrows -- use the check box to use arrows on the curve ends.

> **Note:**
>
> So that curves with single points always appear, Box is the default symbol.

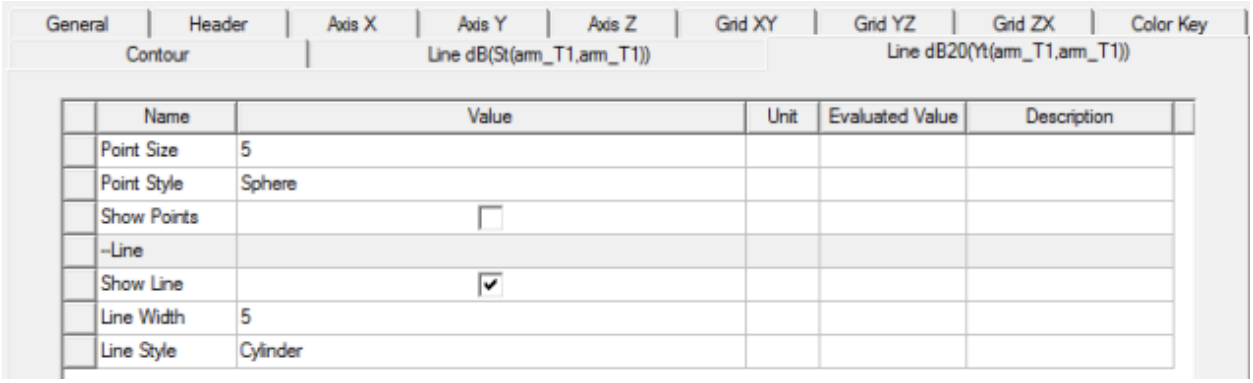
3. Edit the properties, if needed. Click OK to apply the changes and close the window.

To edit the display properties of a trace in a 3D report:

1. Click on the trace. This opens a Properties dialog for the plot with a tab named for the trace selected.
2. The editable properties include Point size, Point Style, whether to show points, whether to

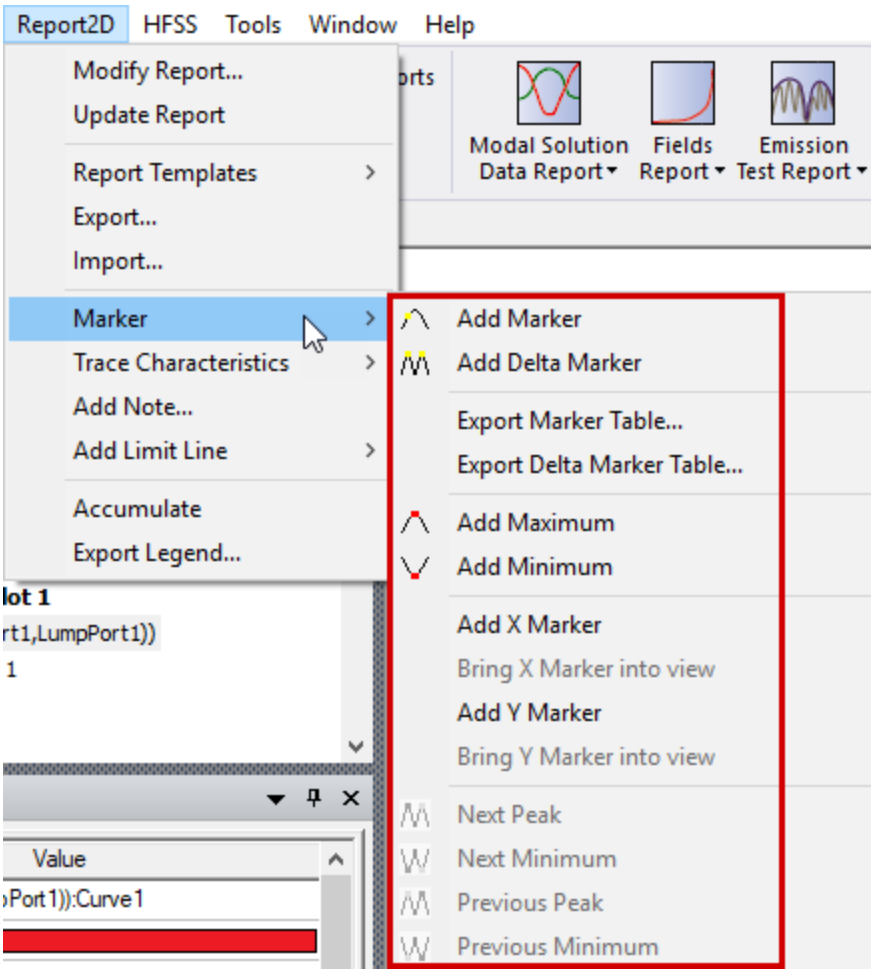
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

show line, line width, and line style.



Adding Data Markers to Traces

The Reporter includes **Report 2D** > **Marker** > menu commands and icons:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can also access these commands from the shortcut menu that appears when you right-click inside a report plot window.

These command let you add markers to traces. A marker appears as "m*N*" at the marked point, where *N* increments from 1 as you place additional markers. Each marker can be selected and has editable properties including name, font, background and color. As you place markers, one or more marker legends may be displayed, depending on the **View** > **Active View Visibility** settings for the legends. The main marker legend appears in the upper left of the plot, and lists the marker names and their X and Y values in a table. You can control the number format for the table values via the properties window, general tab. Under *Marker/Other Number Format*, you can specify field width, precision, and whether to use scientific notation. This value is independent of the Axis tab number properties. A separate marker legend appears for Delta Markers, as described for the **Delta Marker** command.

When you enter Marker mode, the cursor arrow is accompanied by an "m" while a circle on the selected trace shows the current position for a potential marker.

To end Marker mode, right-click to display the shortcut menu, and select **End Marker Mode**.

The available Marker mode commands and associated icons are the following:

- **Marker** – this command lets you place a marker at an arbitrary point on a selected trace.
- **X Marker** – this command adds up to 10 movable markers at the origin of the plot with a vertical line rising from the X axis. Each added marker has its own color and editable properties. To move an X marker, click on the X label and drag it to the desired location. The label at the bottom of the line gives the X coordinate, and flag on the vertical line identifies the Y coordinate on the trace. A trace property lets you lock the drag feature to leave the marker in place. The X markers are cleared by the **Clear All** command.
- **Bring X Marker into view** – this command is enabled if an X Marker is not visible in the plot. It allows you to select from a list of existing X Markers to bring into view.
- **Y Marker** – this commands adds up to 10 Y Markers with a horizontal line extending from the Y axis. For more detail on Y Markers and their use, see Y Markers in stacked XY plots.
- **Bring Y Marker into view** – this command is enabled if a Y Marker is not visible in the plot. It allows you to select from a list of existing Y Markers to bring into view.
- **Maximum** – places a marker at the Maximum value on the selected trace.
- **Minimum** – places a marker at the Minimum value on the selected trace.
- **Delta Marker** – enters delta marker mode, placing a circle on the selected trace. Clicking on the trace sets an initial point and subsequent clicks on arbitrary points on the trace place additional markers until you leave marker mode. These markers have their own legend, which includes the following information for each pair of markers specified:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Name	Delta(X)	Delta(Y)	Slope(Y)	InvSlope(Y)
d(m2,m3)	0.4700	1.8319	3.8976	0.2566

- **Next Peak** – moves a selected marker on the next peak on a trace. You must exit marker mode and select a marker to enable this command.
- **Next Minimum** – moves a selected marker to the next minimum on a selected trace. You must exit marker mode and select a marker to enable this command.
- **Previous Peak** – moves a selected marker on the previous peak on a selected trace. You must exit marker mode and select a marker to enable this command.
- **Previous Minimum** – places a marker on the previous minimum on a selected trace. You must exit marker mode and select a marker to enable this command.
- **Go to Start** (Right arrow) – moves a selected trace marker to the first data point. Enabled by leaving marker mode and selecting a marker.
- **Go to Previous** (Left arrow) – moves a selected trace marker to the previous data point.
- **Go to Next** – moves a selected trace marker to the next data point.
- **Go to End** – moves a selected trace marker to the last data point.
- **Next Curve** – selects the next curve in the report, based on the order in the trace legend.
- **Previous Curve** – selects the previous curve in the report, based on the order in the trace legend.
- **Clear All** – clears all markers on a report.

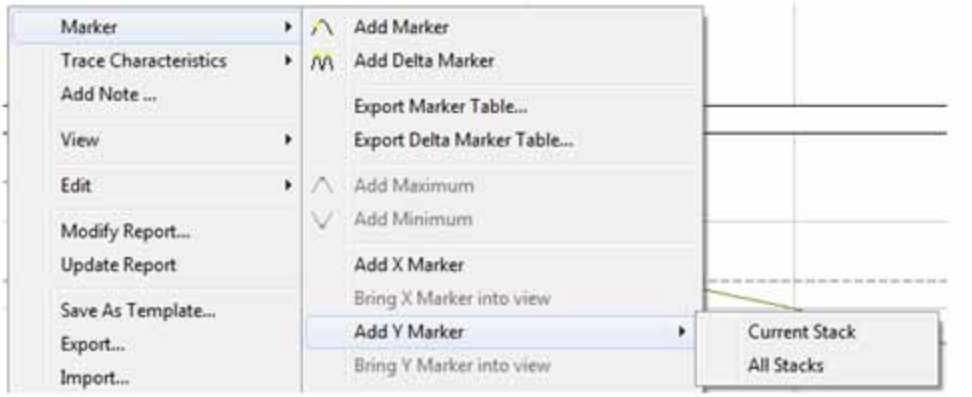
Y Markers in Stacked XY Plots

Y Markers allows for easy analysis and comparison of curves at a particular y-coordinate. Y Markers can be used to compare stacked curves.

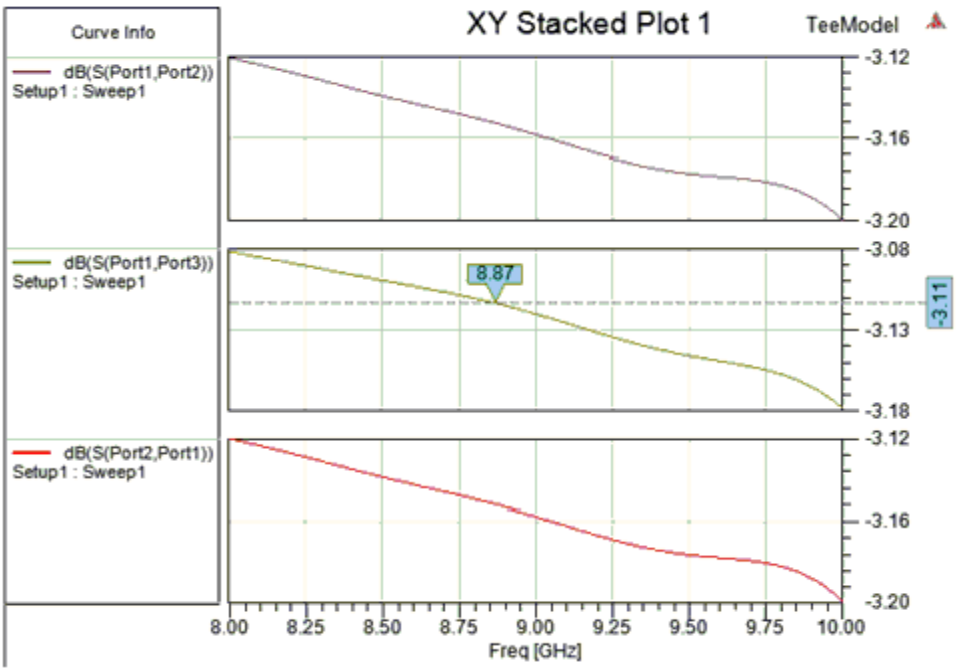
Creating Y Markers in Stacked Plots

There are two ways to create Y Markers in Stacked Plots. You can create a Y Marker for a particular stack or for all stacks. Right-clicking on any stack shows the following shortcut menu:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

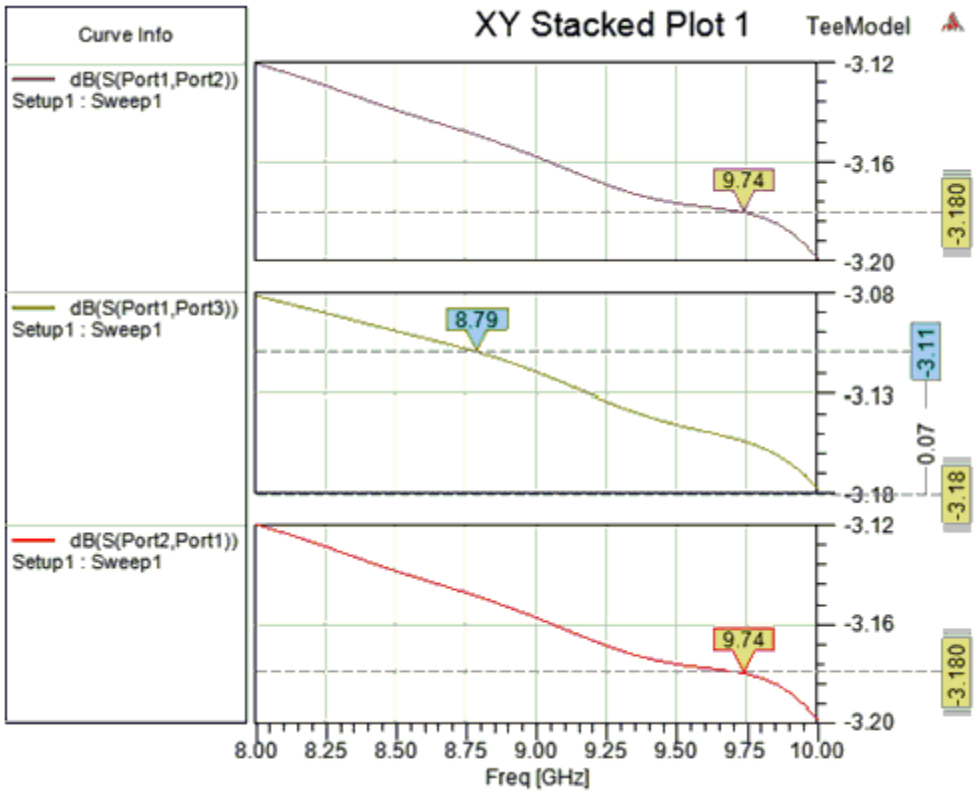


Add Y Marker > **Current Stack** creates a Y marker for the stack on which user performed right mouse button click. The following figure shows that a Y Marker was added to second stack only:



Add Y Marker > **All Stacks** creates one Y marker in each stack with same value. Initially this value is the minimum Y value of the Y ranges in all the stacks. This is shown is figure below:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

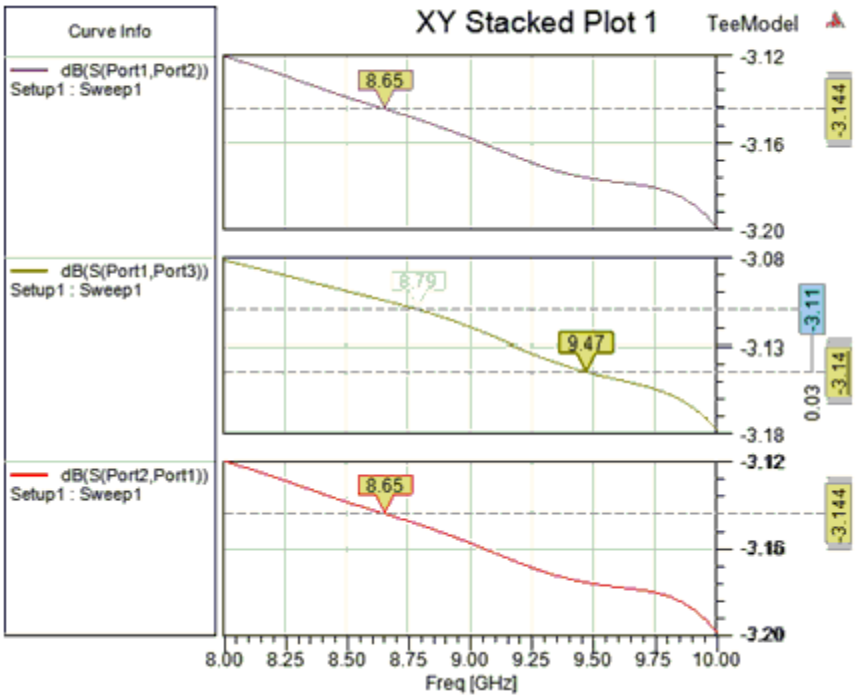


Notice that the Y Marker for All Stacks has a different appearance than the Y Marker for a particular stack, that is, it has double parallel lines above and below the Y Marker textbox.

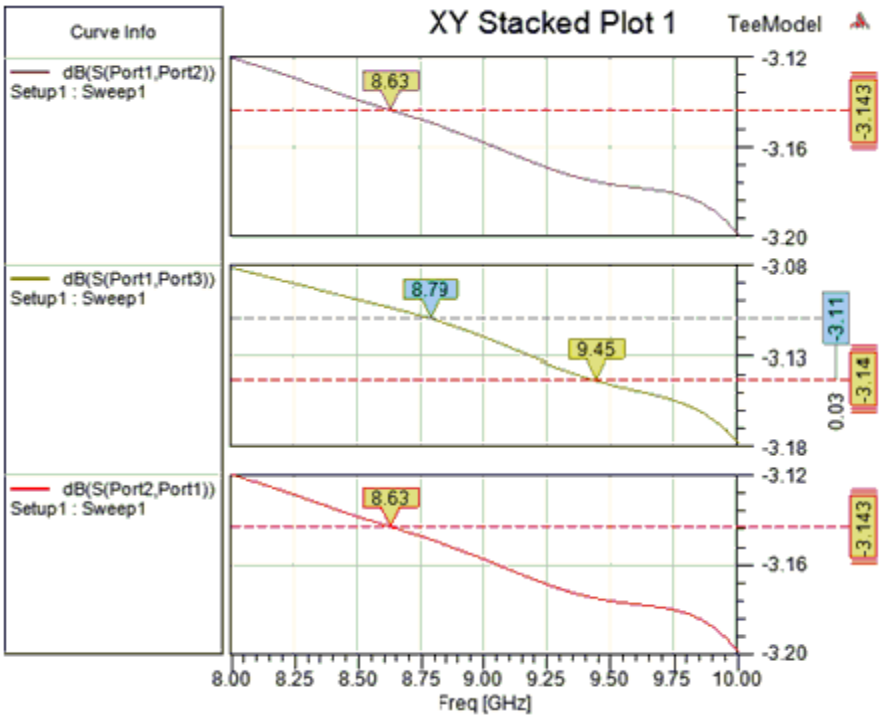
Synchronized Y Markers

All the "same" Y markers for all stacks are synchronized, that is to say that if one Y marker is dragged or it's value is changed, all the "same" Y markers in all the stacks will change their position too. The following figure shows that when Y marker in bottom stack was dragged, Y marker in top stacks moved as well:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



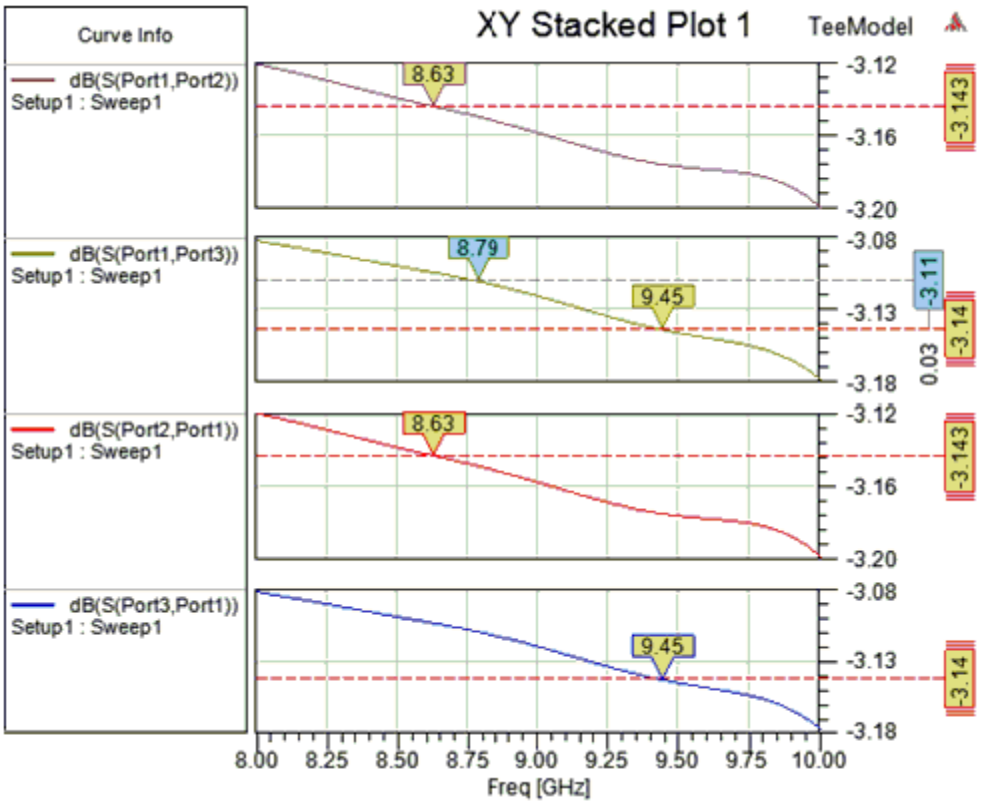
Also if a property of any one Y Marker is changed, all the "same" Y Markers show the change in property as well. For example the following figure shows that when the line color of a Y Marker in the top stack was changed to red color, a Y Marker in bottom stack show the same line color as well:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Automatic Y Markers for the New Stack

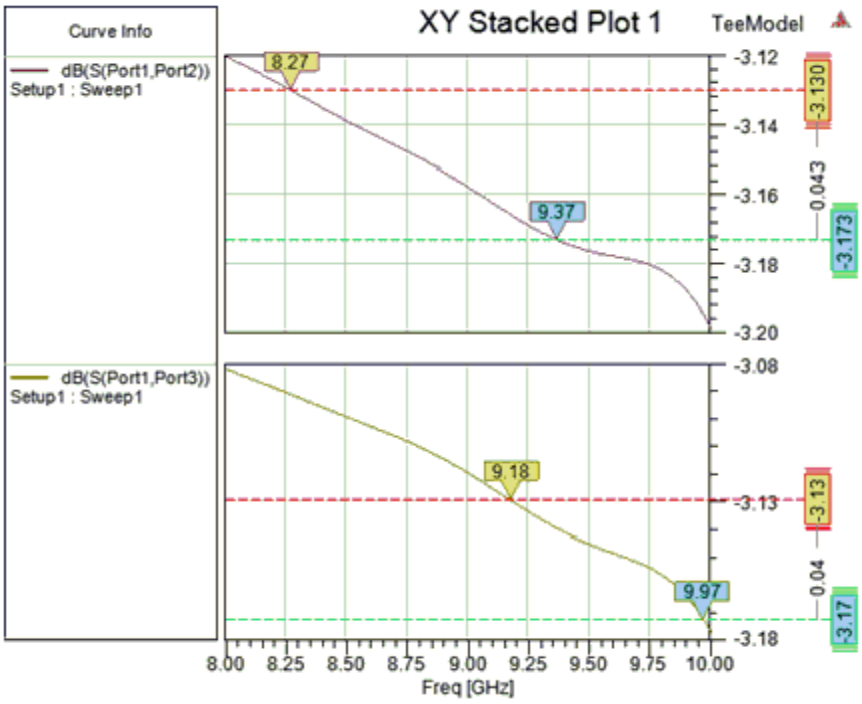
When a new curve is added to the plot, it gets all the Y Markers for all stacks in other stacks, excluding the Y Marker for particular stacks. The following figure shows that when the new curve "dB(S(Port3, Port1)" was added, a Y Marker was added to it with value -3.14 and it has all the same properties as other "same" Y Markers in other stacks:



Y Marker Delta Annotations

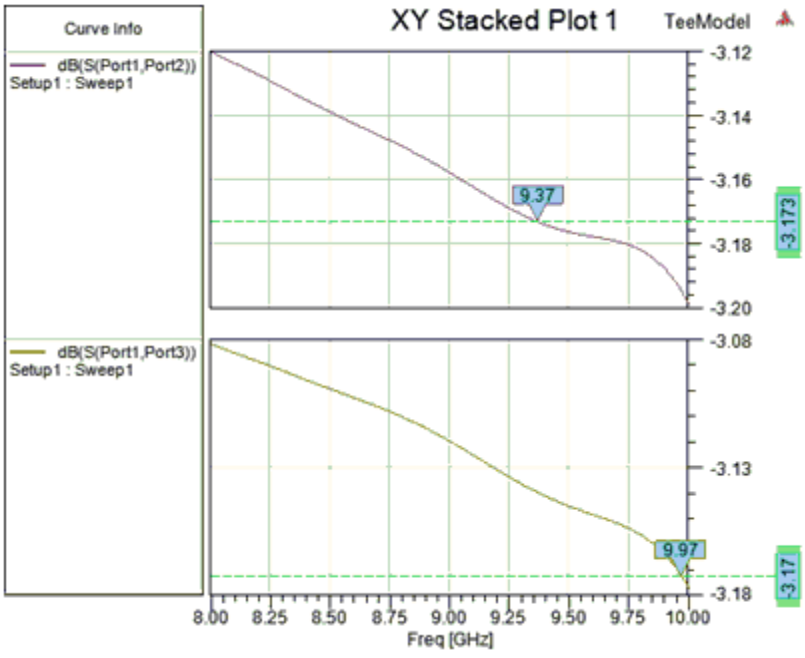
When two more Y Markers are present in a Stacked Eye Diagram, then delta annotations are shown between a pair of adjacent Y Markers in all the stacks, as shown in figure below:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Deleting a Y Marker

To delete a Y Marker, select a Y Marker in any stack and press the Delete key. This action will also delete all the corresponding Y Markers in all the stacks. For example, when the Y Marker with value -3.13 (red Y Marker) was deleted from the bottom most stack, all of the corresponding Y Markers were also deleted:

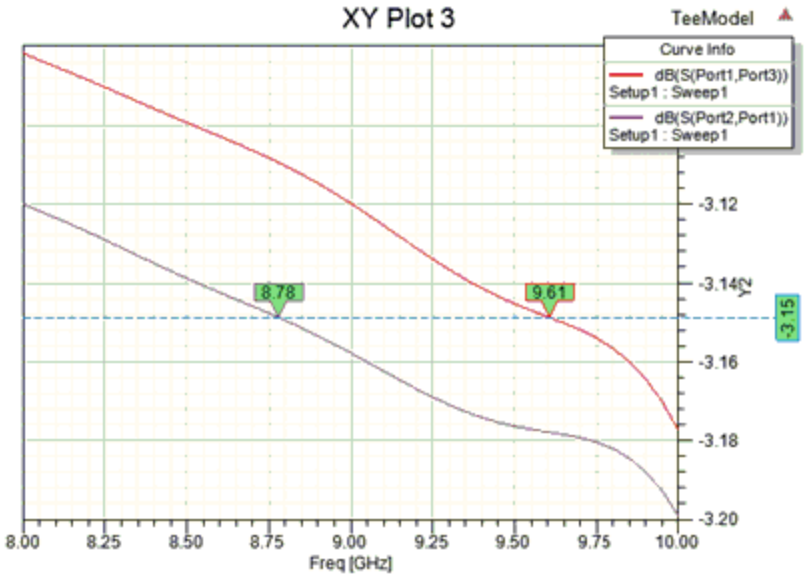


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

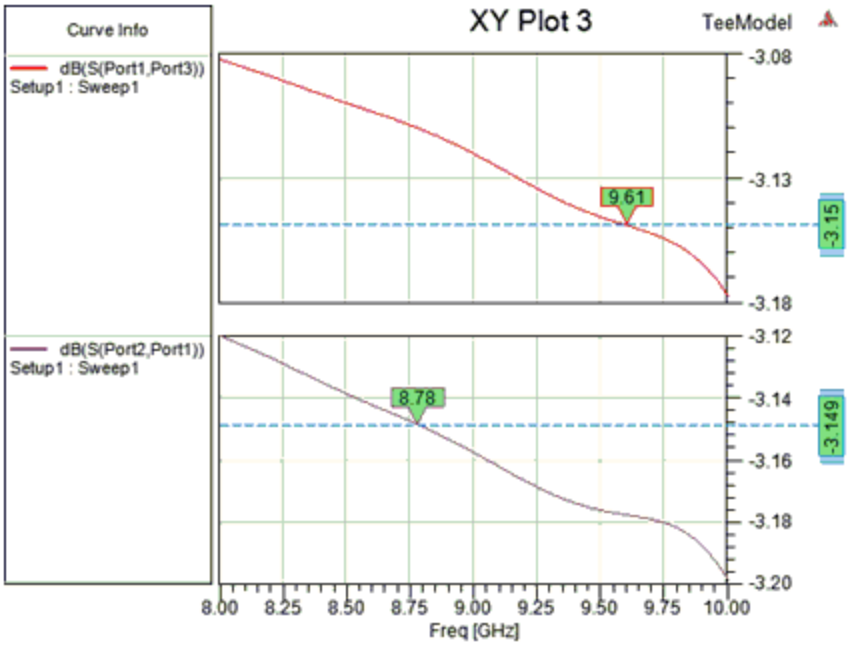
Note that on deleting a stack, Y Markers in other stacks are not affected.

Converting Rectangular XY Plot to Rectangular Stacked XY Plot

The following figure shows a Rectangular XY Plot with two curves and a Y Marker with value -3.15 (blue Y Marker):



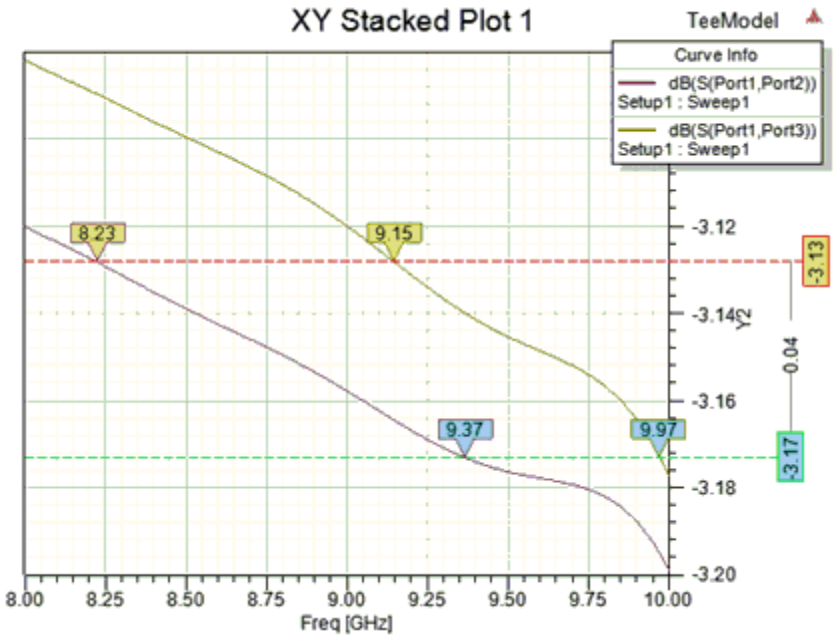
If you change the Display Type property of this plot to Rectangular Stacked Plot then a Rectangular Stacked XY Plot is created with each curve in its own stack and a Y Marker is shown in each stack with value -3.15 (blue Y Marker):



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Similarly when you change a Rectangular Stacked XY Plot to a Rectangular XY Plot then all the "same" Y Markers in all the stacks are shown as a single Y Marker in Rectangular XY Plot as shown in following figures:

The Rectangular Stacked XY Plot in the previous figure, when converted to Rectangular XY Plot, looks like the following figure:



Discarding Report Values Below a Specified Threshold

To prevent real small numbers from skewing a plot, you can discard small values (below a specifiable threshold).

1. Double-click the X or Y axis of interest on an open plot display.

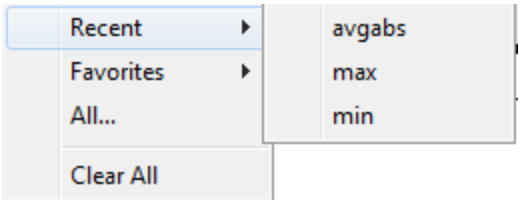
   This opens the **Properties** window for the Axis.

2. Under the **Axis** tab, use the scroll bar to find the **Specify Discard Values** property.
3. Click the check box to enable the property.
4. Enter a value in the **Discard Below** field. Units specified elsewhere in the Axis property are applied to this value. The Discard Below text box is inactive if the Specify Discard Values check box is not enabled.
5. Click **OK** to apply the Discard Values to the report.

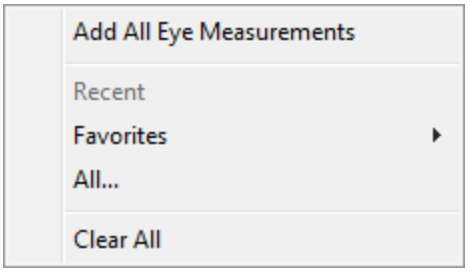
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Adding Characteristics to a Trace

There are several options for adding characteristics to a trace. When you click **Report2D** > **Trace Characteristics**, or right-click a selected trace, the shortcut menu is displayed. The following example shows the menu with expanded **Recent** selections.



The following shows the shortcut menu for Eye Measurements, which includes the **Add All Eye Measurements** option. You can use this option to add all eye measurements at once.



Adding a Recently Used Trace Characteristic

If you recently used a characteristic, you can add it to a selected trace by selecting from a list of recently used characteristics. A maximum of 10 is displayed in the menu, and they are sorted alphabetically.

To add a recently used characteristic to a selected trace:

1. Select a trace in a report plot or legend.
2. Click **Report2D** > **Trace Characteristics**, or right-click the selected trace to display the shortcut menu.
3. Select **Recent**, and then select the function you want. The specified characteristic is added to the trace.

Adding a Trace Characteristic from Favorites

You can add a trace characteristic to a selected trace by selecting from a list of favorites. A maximum of 10 is displayed in the menu, and they are sorted alphabetically.

To add a favorite characteristic to a selected trace:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select a trace in a report plot or legend.
2. Click **Report2D** > **Trace Characteristics**, or right-click the selected trace to display the shortcut menu.
3. Select **Favorites** and then select the function you want. The specified characteristic is added to the trace.

Adding Trace Characteristics to your Favorites

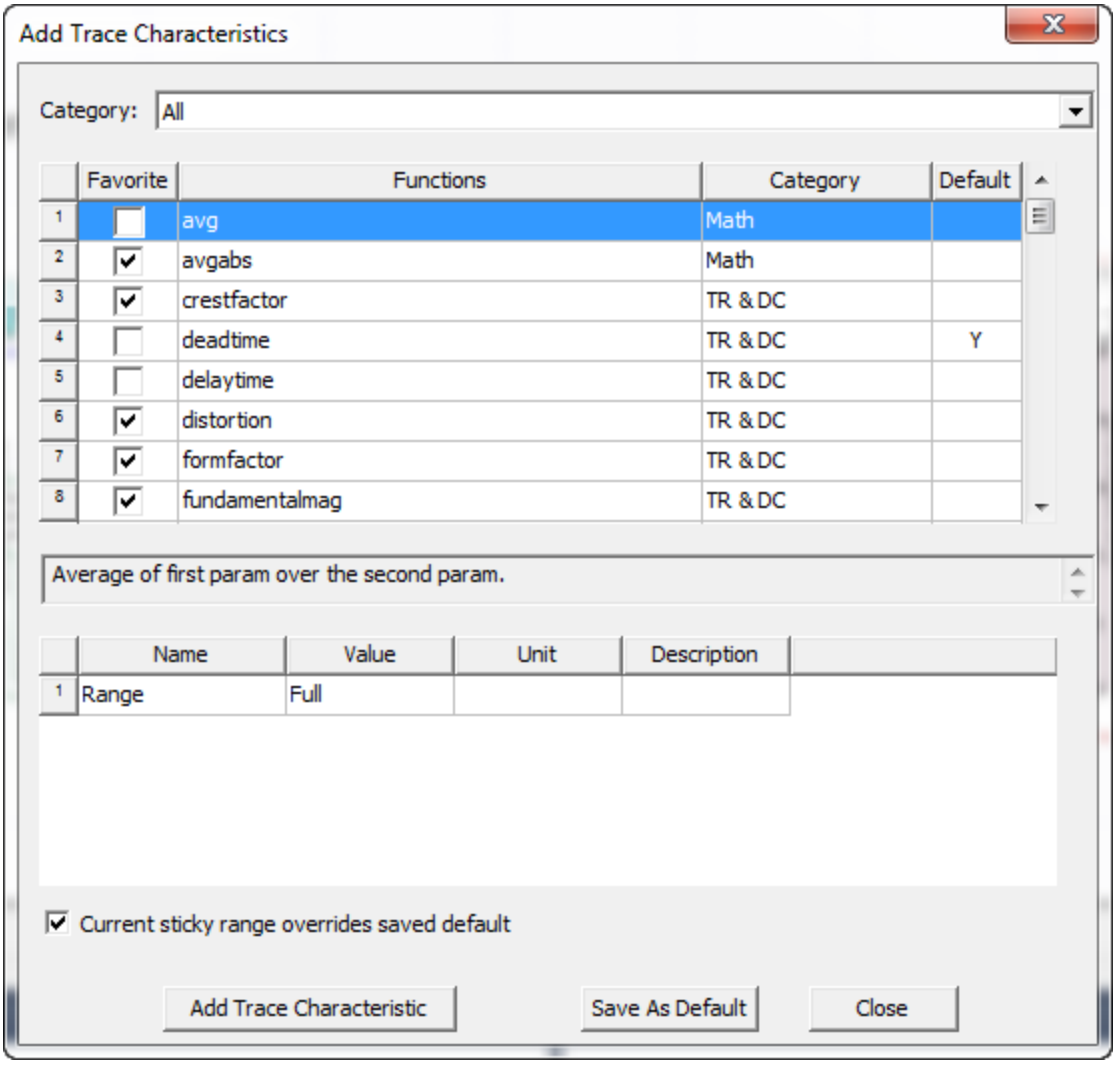
You can add trace characteristics to your list of favorites.

To add characteristics to your list of favorites:

1. Select a trace in a report plot or legend.
2. Click **Report2D** > **Trace Characteristics** or right-click the selected trace to display the shortcut menu.
3. Select **All**.

   The *Add Trace Characteristics* dialog box displays.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. Click the **Favorite** check box in front of any function you want to add to your Favorites. You can define as many favorites as you need, but no more than ten are displayed in the menu, and they are displayed in alphabetical order.
5. Click **Close**. You can view the current favorites by selecting Favorites in the Category drop-down menu.

> **Note:**
>
> You can remove favorites by clearing the **Favorite** check box for one or more functions, and clicking **Close**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

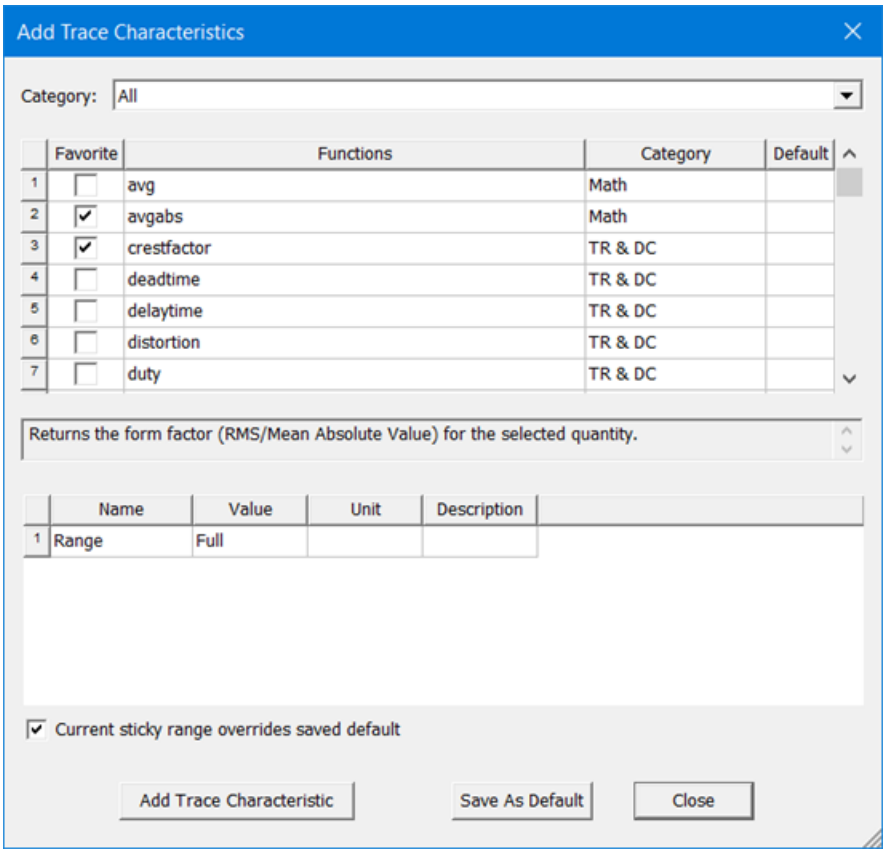
Adding Characteristics Using the Add Trace Characteristics Window

You can add characteristics to a selected trace by selecting from the **Add Trace Characteristics** window.

To add additional characteristics to a selected trace:

1. Select a trace in a report plot or legend.
2. Click **Report2D** > **Trace Characteristics**, or right-click the selected trace to display the short cut menu.
3. Select **All**.

   The **Add Trace Characteristics** window displays:



4. Select the desired **Category**.

   The available categories depend on the plot, and the selecting of a category displays its associated functions.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note: Categories** and **Functions** only appear if they are available for that plot.

Category	Functions
Recent	Displays the most recent functions used, sorted by the time they were added.
Favorites	Displays all favorites. The defaults are avg, max, min, and pk2pk.
All	Displays all available functions.
Math	avg, avgabs, integ, integabs, max, mean, min, pk2pk, pkavg, ripple, rms, rmsAC, stddev, sum, variance, XatYMax, XatYMin, XatYVal, XWidthAtYVal, YatXMax, YatXMin, YatXVal
PulseWidth	pulsefall9010, pulsefront1090, pulsefront3090, pulsemax, pulsemaxtime, pulsemin, pulsemintime, pulsetail50, pulsewidth5050, pw_minus, pw_minus_avg, pw_minus_max, pw_minus_min, pw_minus_rms, pw_plus, pw_plus_avg, pw_plus_max, pw_plus_min, pw_plus_rms
Overshoot/ Undershoot	overshoot, overshootAbs, undershoot, undershootAbs
TR & DC	crestfactor, deadtime, delaytime, distortion, formfactor, fundamentalmag, risetime, settlingtime
Error	iae, ise, itae, itse
Period	per, pmax, pmin, prms
AC	gainmargin, phasemargin, gaincrossover, phasecrossover, lowercutoff, uppercutoff, bandwidth, peakgain, peakgainfreq
Radiation	lSidelobeY, rSidelobeY, lSidelobeX, rSidelobeX, xdb10Beamwidth, xdb20Beamwidth
Eye Measurements	EyeLevelZero, EyeLevelOne, EyeAmplitude, EyeHeight, EyeSignalToNoise, EyeOpeningFactor, EyeWidth, EyeJitterP2P, EyeJitterRMS, EyeRiseTime, EyeFallTime, MinEyeWidth, MinEyeHeight
TDR	Shunt_C_in_pF, Series_L_in_nH

For a selected function, the *Add Trace Characteristics* dialog box displays the function's purpose in a text field. For a list of functions and their definitions, see the table in Defining Traces Using Range Functions.

5. Some categories and functions call for you to specify one or two additional values in a table. You can save these values using the **Save as Default** button. The Default column shows a Y if there is a saved default value for the function.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. Select the **Current sticky range overrides saved default** check box if you do not want the range value in the table to be changed when the function selection is changed: the current range value becomes the "sticky range." If the check box is not checked, the range value is updated from the saved default values and becomes a new sticky range.
7. Click the **AddTrace Characteristic** button to add the specified characteristics to the trace.
8. Click **Close**.

Removing All Trace Characteristics

1. Select a trace in a report plot or legend.
2. Click **Report2D** > **Trace Characteristics** or right-click the selected trace to display the shortcut menu.
3. Select **Trace Characteristics** > **Clear All**.

Trace characteristics are cleared from the selected trace.

Removing Traces

You can remove traces from the traces list in the following ways:

To *remove one trace* from the report:

- Select the trace you want to remove from the Project tree, and then click **Delete**.

To *remove all traces* from the report:

- Select all the traces and click **Delete**.

Copy and Paste of Report and Trace Definitions

You can copy and paste report and individual trace definitions within a single design or across designs. The report or trace definition will be evaluated within the context of the target design or report.

> **Note:**
>
> - If the report or trace definition contains properties that do not exist in the target design (for example, a port name) an error will be posted that indicates a solution does not exist for this trace
> - You must copy and paste trace definitions between the same report types. For example, you cannot copy a trace from a Modal Solution Data report and paste it in a Far Fields report.

To copy a Report Definition:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Right-click the report name in the Project Manager and select **Copy Definition** from the shortcut menu.

To paste the Report Definition:

Right-click Results in the Project Manager of the target design and select **Paste**.

A new report is created and it contains the copied definitions.

To copy an individual Trace Definition(s):

Right-click the trace or traces under a report name in the project tree and select **Copy Definition**.

To paste the Trace Definition(s):

Right-click the report in the target design to which you would like to copy the trace or traces and select **Paste**.

A new trace(s) is added to the report and it contains the copied trace definition(s).

> **Note:**
>
> If you copy and paste a report or trace definition to a design that contains a definition with the same name, then an incremented number is appended to the pasted report or trace name.

Copy and Paste of Report and Trace Data

You can copy and paste report and individual trace data within a single design or across designs. The report and trace definitions and all underlying data within the report or trace are copied and pasted to the target design or report.

To copy all data from a report:

Right-click the report name in the project tree and select **Copy Data**, or use the menu bar **Edit** > **Copy Data**, or right-click within a plot to display a shortcut menu with **Copy Data**.

To paste copied report data:

Right-click Results in the project tree of the target design and select **Paste**.

To copy data from an individual trace(s) in a report:

Right-click the trace or traces under a report name in the project tree and select **Copy Data**.

To paste copied trace data:

Right-click the report in the target design to which you would like to copy the trace data and select **Paste**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

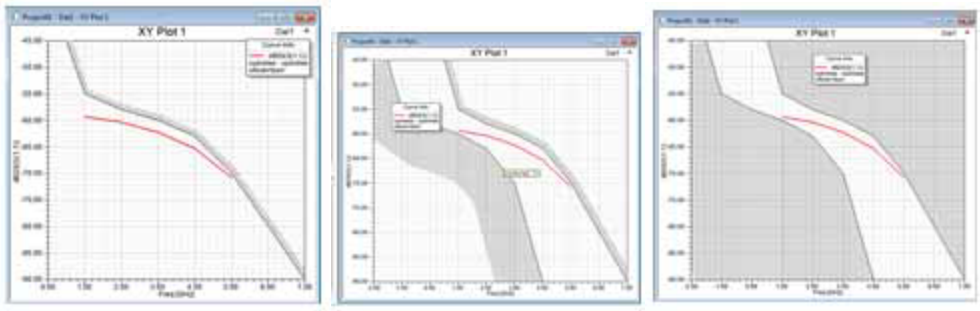
Note:

If you copy and paste report or trace data which contains the same name definition as a report or trace in the target design then an incremented number will be appended to the pasted name.

Limit Lines in Cartesian Plots

Limit lines are simple graphical representation of constraints on XY plots. These are modeled as a sequence of XY point pairs, or as offsets from a selected curve. You can designate a single limit line to delineate an upper limit, or two lines to delineate upper and lower limits, or upper and lower offset lines simultaneously.

You can control the display properties of the line including color and hatch width in pixels. These lines are available only on XY plots (and not on the XY-like plots: bode, stacked etc)

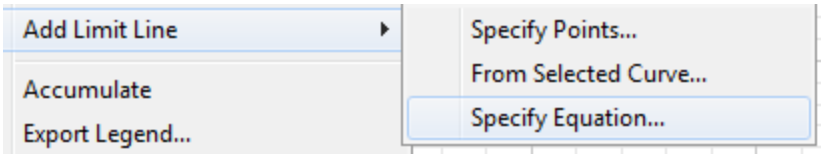


Note:

Limit lines are available only on Rectangular (XY) plots, not on XY-like plots such as Bode or Rectangular Stacked. On 2D Plots, the axes extents are based on the extents of the curves.

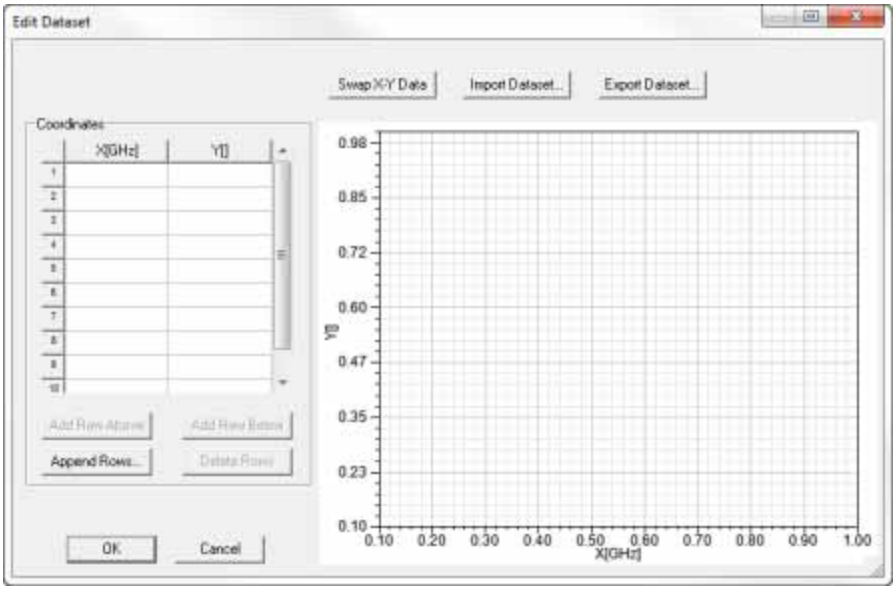
To create a limit line:

1. Click **Report2D** > **Add Limit Line** or right-click an XY plot and select **Add Limit Line...** from the Context menu. You then select whether to **Specify Points**, or **From a Selected Curve**, or **Specify Equation**.

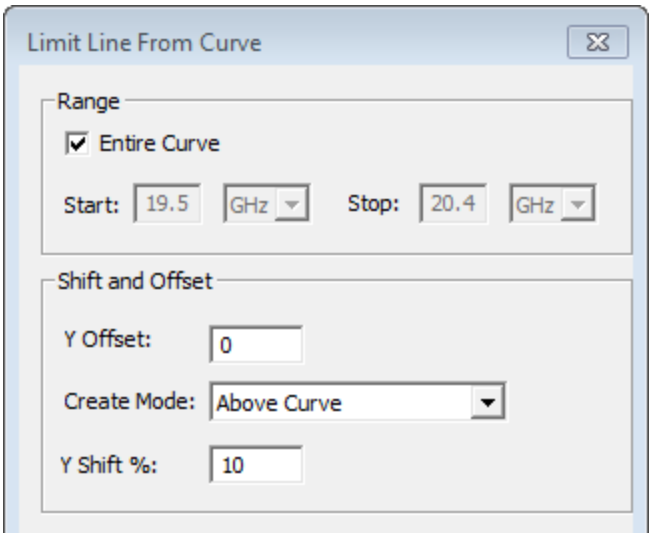


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Select **Specify Points** to open an *Edit Dataset* dialog box so that you can specify points.

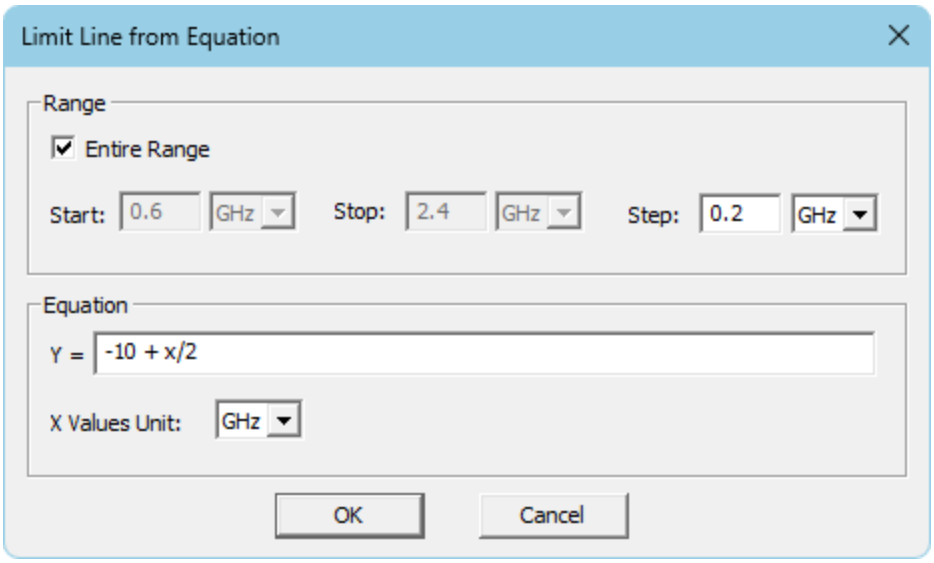


Select **From Selected Curve** to open the *Limit Line From Curve* dialog box.



Select **Specify Equation** to open the *Limit Line from Equation* dialog box. Specify the desired **Equation** (y as a function of x). Choose the **X Values Unit** from the drop-down menu. The available units depend on the type of sweep quantity (frequency, distance, and so on). The default choice is the current X axis unit for the plot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. You can use the *Edit Dataset* dialog box to do the following:
   - enter the EY values directly.
   - import XY values from a .tab file.
   - export Dataset to a file.

   If you require additional data points, you can use the buttons to **Append Rows** to the Coordinates table. If you select a row in the Coordinates table, you can then use the buttons to **Add Row Above**, **Add Row Below** the selected rows, or **Delete Rows**.

   You can use Shift+click to select multiple adjacent rows, or Ctrl+click to select any rows for deletion.

   > **Note:**
   >
   > Each limit line is associated with a particular Y axis (because it has to be scaled the same way as all the curves associated with the axis, follow its log/linear scale and so on). This Y axis association defaults to the first available Y axis when the limit line is created. However, if the plot contains multiple Y axes, it can be associated with a different Y axis later via its properties tab.

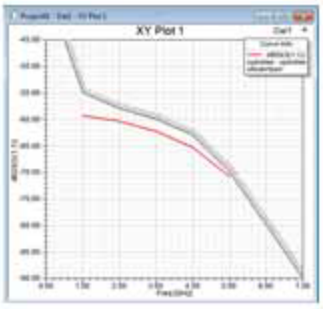
3. You can use the *Limit Line From Curve* dialog box to create a limit line:
   - Define a range using the Entire Curve, or a specified Start and Stop.

   If you uncheck “Entire Curve,” the Start and Stop fields are enabled and initialized based on the zoom level.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

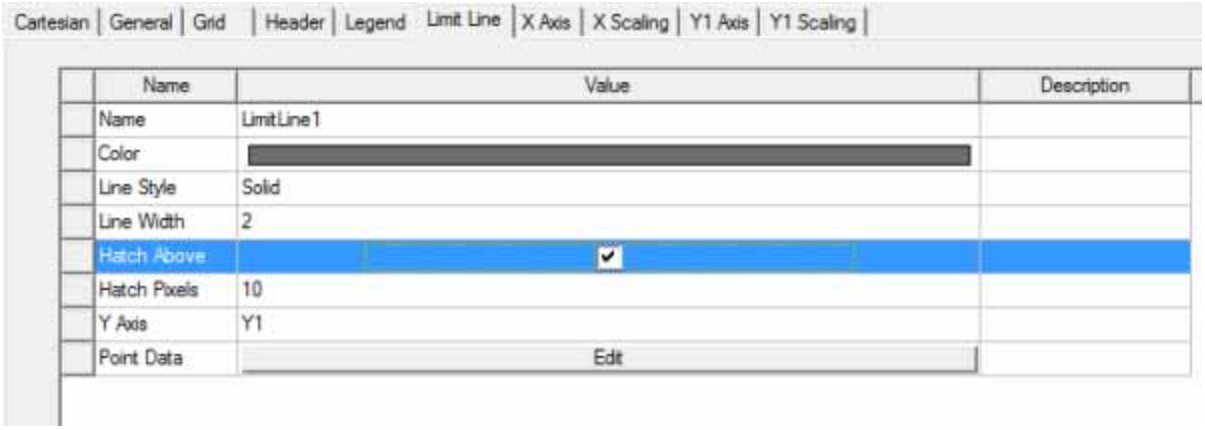
- Shift and Offset relative to the Y, either as a Y Offset value or as a Y Shift %.
- Create Mode as Above Curve, Below Curve, or Above and Below Curve.

4. You can use the *Limit Line from Equation* dialog box to create a limit line based on an equation in the form Y = f(x).
    - Only x variable is allowed
    - x value is linearly sampled and f(x) is evaluated to get y. By default, the entire range for plot is covered. You can uncheck **Entire Range** to specify Start and Stop. You can always edit Step and unit values for x.
    - If y results in NaN, an error is indicated and limit line is shown.
    - If y results in Inf value, then it maps to the MapInfValue specified on its associated y axis.
    - Selecting the limit line added in such a way should show: Start, Stop, Step, and Equation in limit line property window. You can edit these values in the Properties window.
5. Once you click **OK**, the limit line, or lines, you define are added to the plot. Each limit line divides the plot into two regions within the context of its length. By default, the upper region is hatched to designate constraint violation.



6. You can select the limit line in the plot to edit its properties via the **Limit Line** tab of the plot properties.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

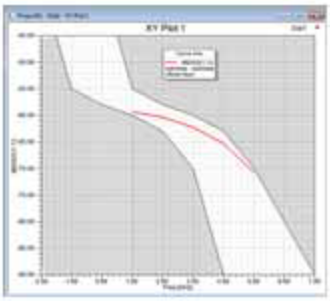


- Line properties: Color, Style and Width
- Y axis association
- Hatch properties
- Hatch width in pixels
- Hatch direction (hatch above or below the Limit line)
- The point definition of the limit line itself.

For a limit line specified as an Equation, the Properties also include:

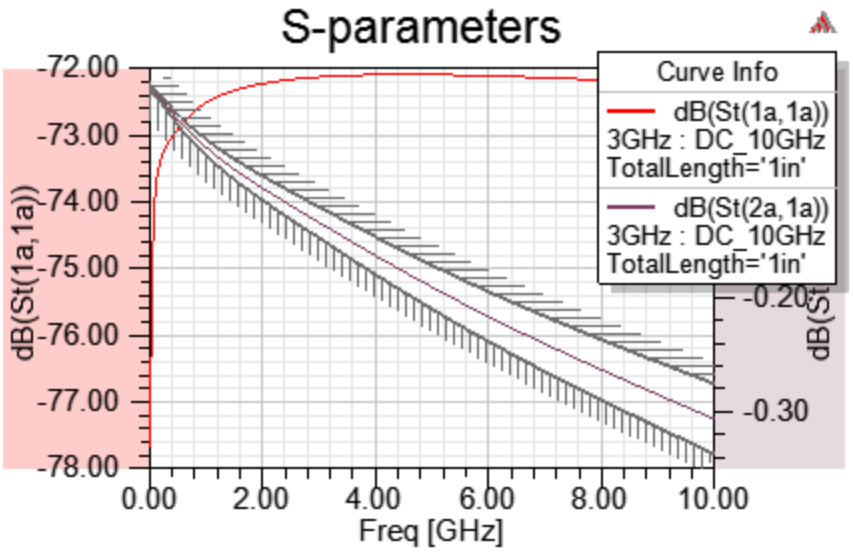
- Start, Stop, Step, and Equation values.

7. If you add a second limit line, you can designate it as hatch below by unchecking **Hatch Above** to produce a tunnel marking upper and lower constraints.



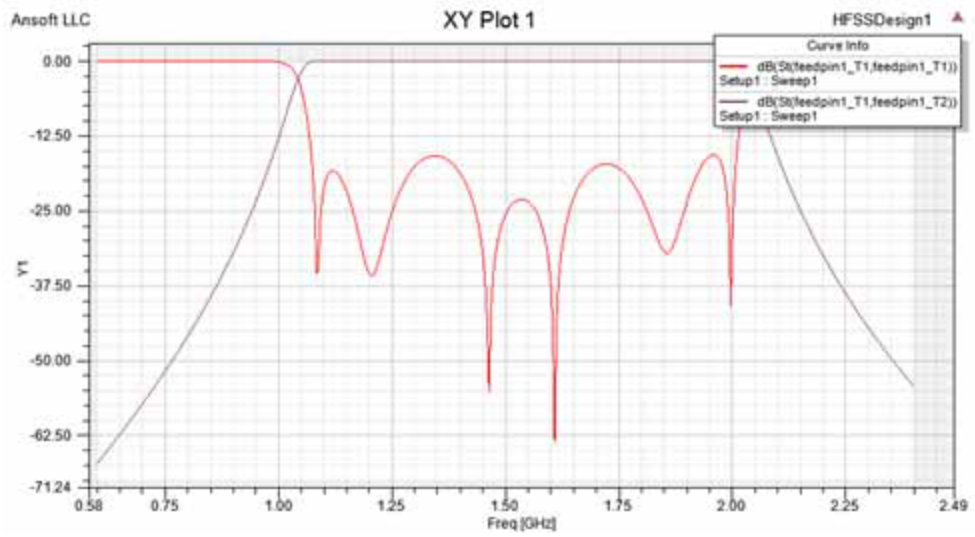
The following example shows the a limit line from curve plot, where the Hatch Above property for the lower limit line has been unchecked.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



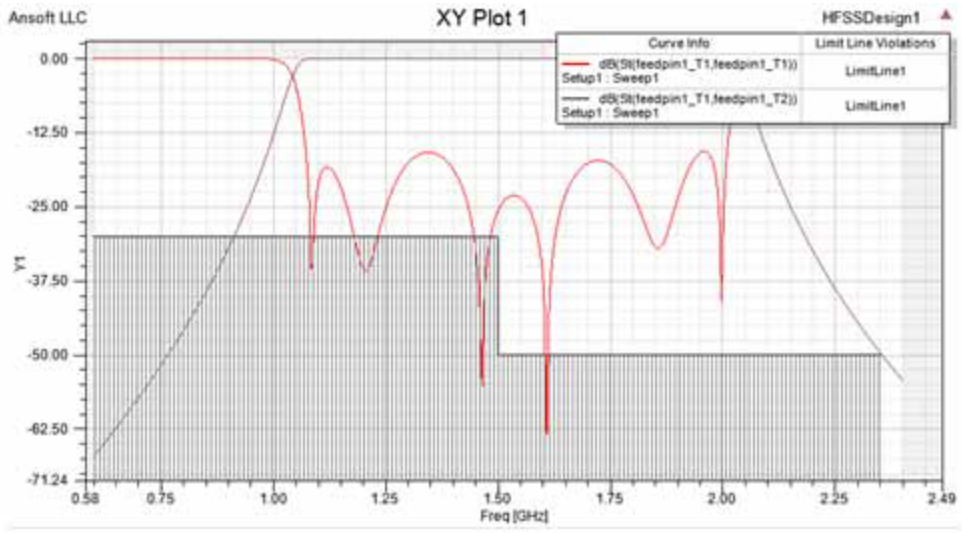
Limit Line Violations

You can use a plotting feature to help you discern whether a curve violates a limit line or not. Consider following plot which shows two curves:

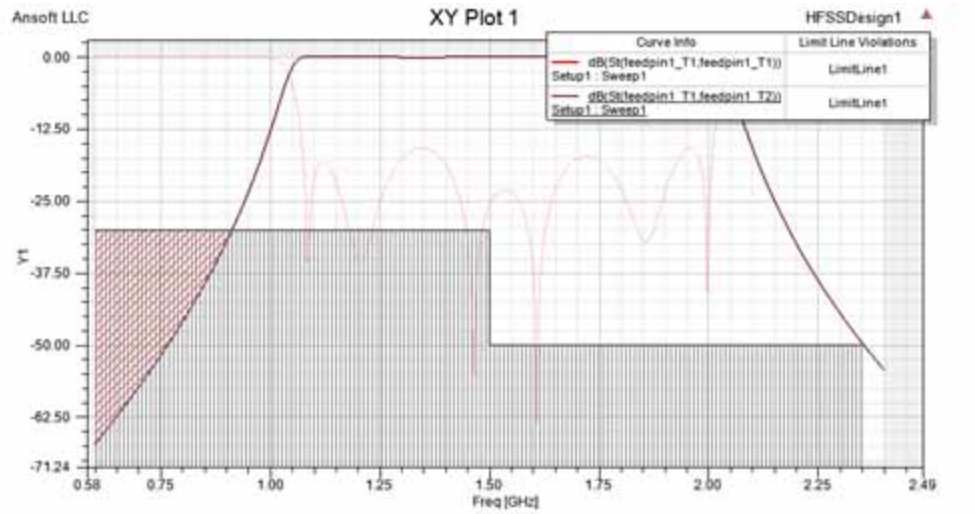


Suppose that the response cannot be below -30 dB until 1.5 GHz, and cannot be below -50 dB at 1.5 GHz or higher. You add a limit line for this requirement in the plot using 'Add a Limit Line' functionality. The plot automatically calculates whether a curve violates this requirement, that is, the limit line and show it in the legends window, as shown in following figure:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



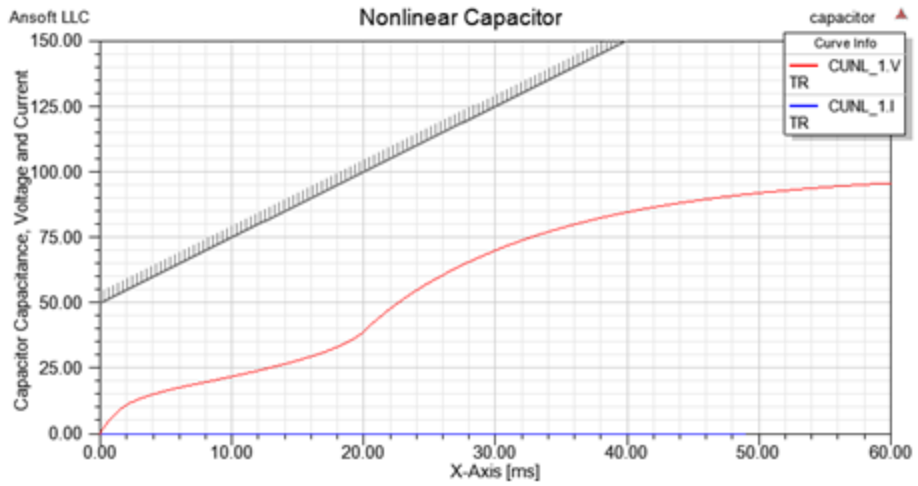
If a curve is selected, then the plot shows the region of the curve that violates the limit line (shaded with slanted red lines), as shown in following figures:



Note:

As shown in the following figure, if no curve violates a limit line, then the limit line hatching is restrained to 10 pixels in length. The minimal hatching keeps the focus on the curve traces rather than the limit lines.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Error Handling

If an error is encountered while calculating Limit Line Violations for a particular plot trace, the *Curve Info* window shows "NaN (<*Limit Line name*>)" under the *Limit Line Violations* column for that curve. For example, if a value is not available or goes to infinity at a particular point, the program is unable to evaluate that point. One of the coordinates is "Not-a-Number" (NaN).

Sweeping a Variable in a Report

In HFSS, a swept variable is a variable that typically has more than one value. You can plot any calculated or derived quantity against one or more of the swept variable's values.

For large projects or projects with many variables, you may obtain faster post processing before generating a solution by selecting which variables function as Sweep variables. Only the variables with Sweep enabled are indexed for post processing. See Adding a Design Variable and Adding a Project variable.

To specify the swept variable values to plot a selected quantity against:

1. In the **Report** dialog box, select the variable from the X (Primary Sweep) drop-down menu.
2. To modify the values that will be plotted for a variable:
    a. Click the ellipsis **[...]** button on the **X (Primary Sweep)** line of the **Report** dialog to displays a pop-up list of the possible values.
    b. Select **Use all values** or click the Edited button to display a dialog that lets you specify the sweeps to use.

    All of the selected variable's values will be plotted.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Sweeping Values Across a Distance

1. If you are plotting a field quantity along a line, define a polyline object in the problem region.

   If you are plotting a near-field quantity along a line, set up a near-field line.

2. In the *Report* dialog box, click the line geometry of interest in the **Geometry** list.
3. Specify the quantities you want to plot along the axes.
4. For the **X (Primary Sweep)**, select the **Distance** variable.

   The values at which the selected quantity or quantities will be plotted are listed to the right. By default, a post-processing polyline object is divided into 100 equally spaced points.

5. For Near field, to plot the selected quantity or quantities at every point on the line, select **All Values**.

   For Near field, to plot the selected quantity, or quantities, at specific points on the line, clear the **All Values** option, and then select the point values on which you want to plot.

> **Note:**
>
> All maximum near-field data calculated by HFSS is at their maximum over the selected line object; if you plot the parameter over a sweep of values, the parameter will have the same value at each point on the plot.

Sweeping Values Across a Sphere

1. Set up a near-field sphere or a far-field infinite sphere.
2. In the **Report** dialog box, click the sphere geometry of interest in the **Geometry** list.
3. For the **Sweeps** variable corresponding to **phi**, select the ellipsis [...] button.

This displays a small dialog.

4. Clear the Use all values check box to enable selection and editing of the sweep values.

All of the possible values for the phi variable are listed in the dialog box. The values are the result of the range of phi you specified during the infinite sphere's setup. To modify the values of phi to be plotted across the sphere, do the following:

a. Click **Edit Sweep**.
b. Specify the following information:

Step or Count	Whether to sweep by steps, or by linear count, decade count, octave count, or exponential count.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Start Value	The point where the rotation of phi begins.
End Value	The point where the rotation of phi ends.
Step or Count	The number of values between the start value and the end value.

c. Click **Update Values**, and then click **OK**.

The values listed are updated to reflect the new number of points.

5. To plot the selected quantity or quantities at every value of phi, select **All Values**.

To plot the selected quantity or quantities at specific values of phi, clear the **All Values** option, and then select the phi values at which you want to plot.

6. For the **Sweeps** variable corresponding to **theta**, follow steps 4 and 5 for modifying the values of theta, if necessary, and specifying the theta values at which to plot the selected quantity or quantities.

> **Note:**
>
> All antenna parameters and maximum far-field data calculated by HFSS is at their maximum over the selected object; if you plot the parameter over a sweep of values, the parameter will have the same value at each point on the plot.

Selecting a Function for a Plot

The value of a quantity being plotted depends upon its mathematical function, which you select from the **Trace** tab **Function** list in the *Report* dialog box. The available, valid functions depend on the type of quantity (real or complex) that is being plotted. The function is applied to the quantity which is implicitly defined by all the swept and current variables. For example, "S(11)" is the value of the S-parameter for every swept combination of variables (e.g., "height", "frequency"). (A smaller set of functions appears for the Function list in the Output Variables dialog.)

These functions can also be applied to previously specified Quantities and Functions as **Range Functions** when using the Set Range Function dialog box.

Some of these functions can operate along an entire curve. These are: min, max, integ, avg, rms, pk2pk, cang_deg and cang_rad.

You can select from the following functions in the **Trace** tab **Function** list or type them directly into the Yor X field, if necessary.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

abs	Absolute value of the simulation quantity which results in a number that is always positive.
acos	Arc cosine (the inverse function of a cosine).
acosh	Inverse hyperbolic arc cosine.
ang	Magnitude of an angle.
ang_deg	Angle (phase) of a complex number, cut at +/-180. Returns angular values in degree units, and not suitable for use in Optimetrics, which works in SI values and evaluates ang_deg expressions in radians. See ang_deg_val.
ang_deg_val	Angle (phase) of a complex number in unitless degree values, and suitable for use in Optimetrics, which works in SI values. Returns simple numbers.
ang_rad	Angle in radians.
arg	Argument of a complex number. It is the angle the complex number makes with the positive x axis. Same as **ang_deg**.
asin	Arc sine (the inverse function of sine).
asinh	Inverse hyperbolic sine.
atan	Arc tangent (the inverse function of a tan).
atanh	Inverse hyperbolic tan.
atan2	Two argument function. For non-0 x,y, the function returns the angle between the + x-axis and the given x,y coordinates.
avg	Returns the average of the values of the selected quantity. avg = (Area between the curve and the X-axis) / (X length of the curve)
avgabs	Returns the mean of the absolute value of the selected quantity.
bandwidth	Returns the 3dB bandwidth of the selected simulation quantity. For bandwidth, the calculation is based on 3dB below the maximum peak.
cang_deg	Cumulative angle (phase) of the first parameter (a complex number) in degrees, along the second parameter (typically sweep variable). Returns a double precision value cut at +/-180. Returns angular values in degree units, and not suitable for use in Optimetrics, which works in SI values and evaluates cang_deg expressions in radians. See cang_deg_val.
cang_deg_val	Cumulative angle (phase) of the first parameter of the selected simulation quantity in unitless degree values and suitable for use in Optimetrics, which works in SI values. . Returns simple numbers.
cang_rad	Cumulative angle of the first parameter in radians along a second parameter (typically a sweep variable). Returns a double precision value.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

cmplx(*re*, *im*)	A complex number, where *re* is the real part and *im* is the imaginary part.
conjg	Conjugate of the complex number.
cos	Cosine.
cosh	Hyperbolic cosine.
crestfactor	Returns the crest factor (peak/RMS) for the selected quantity.
cum_integ	The cumulative integral function returns a set of values that have the same length as the original set of points (the first element will always be zero). Element *I* of the set returned by cum_integ is the integral of elements 1 through *I* of the original data set.
cum_sum	The cumulative sum function returns a data set that has the same length as the original set of points. Element *I* of the set returned by cum_sum is the sum of elements 1 through *I* of the original data set.
dB(x)	20*log10(|x|) to base 10.
dBc	Decibels relative to the carrier. It is the power ratio of the signal to a carrier signal. Gives the relative signal strength.
dBm(x)	10*log10(|x|) +30.
dBm	(for electric field quantities) is computed as: 20.0*log10(x) + 60.0
dBu	(for electric field quantities) is computed as: 20.0*log10(x) + 120.0
dBW(x)	10*log10(|x|).
dB10	10*log(|x|) to base 10.
dB10normalize	10*log [normalize(mag(x))].
dB20	20*log(x) to base 10.
dB20normalize	20*log [normalize(mag(x))].
deadtime	Obtains the latest time when the qtyl is within a tolerance of zero.
delaytime	Obtains the time from zero to 50% of the target point.
degel	Conversion from degrees electrical to seconds with respect to Hz.
deriv	Derivative of a given parameter.
distortion	Returns the total distortion for the selected simulation quantity and an additional argument frequency, which is the frequency in Hz at which to calculate the fundamental RMS of the simulation quantity.
even	Returns 1 if integer part of the number is even; returns 0 otherwise.
exp	Exponential function (the natural anti-logarithm) of the simulation quantity.
fmod	nReturns the double precision remainder of x/y.
formfactor	Returns the form factor (RMS/Mean Absolute Value) for the selected quantity.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

fundamentalmag	Returns the RMS value of the fundamental frequency for the selected quantity, and an additional argument, Frequency, which specifies the fundamental frequency.
gaincrossover	Returns the gain crossover frequency (where the gain is 0 dB) of the selected simulation quantity in Hz.
gainmargin	Returns the gain margin in dB at the phase crossover frequency of the selected simulation quantity. It also requires a reference simulation quantity to which the measured quantity is compared and the AC magnitude and phase angle of the reference quantity. These are entered as the arguments Reference Channel, Base Source Magnitude, and Base Source Angle.
iae	Returns the integral of the absolute deviation of the selected quantity from a target value that is entered via the additional argument.
if	if(cond_exp,true_exp, false_exp).
im	Imaginary part of the complex number.
int	Truncated integer function.
integ	Integral of the selected quantity. Uses trapezoidal area.
integabs	Absolute value of integral.
ise	Returns the integral of the squared deviation of the selected quantity from a target value that is entered via an additional argument.
itae	Returns the time-weighted squared deviation of the selected quantity from a target value that is entered via an additional argument.
itse	Returns the time-weighted squared deviation of the selected quantity from a target value that is entered via an additional argument. To use this function, you need to open the Add Trace Characteristics dialog and select the Error category.
j0	Bessel function of the first kind (0^{th} order).
j1	Bessel function of the first kind (1^{st} order).
jn	Bessel function of the first kind (nth order).
ln	Natural logarithm.
log	Natural logarithm (same as ln).
log10	Logarithm base 10.
lowercutoff	Returns the lower 3dB frequency of the selected simulation channel in Hertz.
lsidelobeX	The 'x' value for the left side lobe: the next highest value to the left of the max value.
lsidelobeY	The 'y' value for the left side lobe: the next highest value to the left of the max value.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

mag	Magnitude of the complex number.
max	Returns maximum value of the simulation quantity.
max_swp	Returns maximum value of a sweep.
max2	Maximum value of the two simulation quantities. For example, **max2 (a,b)** will plot maximum of **a** and **b** for a particular instance.
mean	Returns the average in the set of quantities selected. mean = sum(all y-value) / (number of y-values)
min	Returns the minimum value of the simulation quantity.
min_swp	Returns the minimum value of a sweep.
min2	Minimum value of the two simulation quantities. For example, **min2 (a,b)** will plot minimum of **a** and **b** for a particular instance.
mod	Returns the double precision modulus (x - floor(x/y)*y). Not supported in solvers.
nint	Nearest integer.
none	Returns null value.
normalize	Divides each value within a trace by the maximum value of the trace. ex. normalize(mag(x)).
odd	Returns 1 if integer part of the number is odd; returns 0 otherwise.
overshoot	Calculates peak overshoot given a threshold value and number of evenly spaced points over entire time range.
peakgain	Returns the peak value of gain of the selected simulation quantity in dB.
peakgainfreq	Returns the frequency in Hz at which the peak gain of the selected simulation quantity occurs.
polar	Coverts the complex number in rectangular co-ordinates to polar co-ordinates.
per	Returns the period of a simulation quantity.
phasecrossover	Returns the phase crossover frequency, at which the phase is -180 degrees, in Hz for the selected simulation quantity.
phasemargin	Returns the phase angle in degrees at the gain crossover frequency of the selected simulation quantity.
pk2pk	Peak to peak. Difference between max and min of the first parameter over the second parameter. Returns the peak-to-peak value for the selected simulation quantity.
pkavg	Returns the ratio of the peak to peak-to-average for the selected quantity.
pmax	Maximum period of the selected simulation quantity.
pmin	Minimum period of the selected simulation quantity.
pow	Raises x to the power of y; pow(x,y).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

prms	Period Root Mean Square.
pulsefall9010	Returns the pulse fall time of the selected quantity according to the 90%-10% estimate.
pulsefront1090	Returns the pulse front time of the selected quantity according to the 10%-90% estimate.
pulsefront3090	Returns the pulse front time of the selected quantity according to the 30%-90% estimate.
pulsemax	Returns the pulse maximum from the front and tail estimates for the selected quantity.
pulsemaxtime	Returns the time at which the maximum pulse value of the selected quantity is reached.
pulsemin	Returns the pulse minimum from the front and tail estimates for the selected quantity.
pulsemintime	Returns the time at which the minimum pulse value of the selected quantity is reached.
pulsetail50	Returns the pulse tail time of the selected quantity from the virtual peak to 50%.
pulsewidth5050	Returns the pulse width of the selected quantity as measured from the 50% points on the pulse front and pulse tail.
pwl	Piecewise Linear.
pwl_periodic	Piecewise Linear for periodic extrapolation on x.
pwlx	Piecewise Linear x with linear extrapolation on x.
pw_minus	Pulse width of the first negative pulse.
pw_minus_avg	Returns the average of the negative pulse width input stream.
pw_minus_max	Returns the maximum pulse width of the negative pulse of input stream.
pw_minus_min	Returns the minimum pulse width of the negative pulse of input stream.
pw_minus_rms	RMS of the negative pulse width input stream.
pw_plus	Pulse width of the first positive pulse.
pw_plus_avg	Average of the positive pulse width input stream.
pw_plus_max	Max. Pulse width of the positive pulse of input stream.
pw_plus_min	Min. Pulse width of the positive pulse of input stream.
pw_plus_rms	RMS of the positive pulse width input stream.
re	Real part of the complex number.
rect	Converts the complex number in polar to rectangular co-ordinates.
rem	Returns the fractional part of a decimal number such that rem(x) = x-int (x) Syntax: rem(x)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ripple	Returns the ripple factor (AC RMS/Mean) for the selected quantity.
risetime	Obtains the time taken to go from 10% to 90% of target point.
rms	Returns the root mean square value of the selected quantity.
rmsAC	Returns the AC RMS for the selected quantity.
root	nth root function.
rSidelobeX	Returns the X value of right side-lobe occurrence.
rSidelobeY	Returns the Y value of right side-lobe occurrence.
settlingtime	Returns the latest time at which the value of the selected simulation quantity fell outside its tolerance band. The target value of the quantity and the +/- bandwidth of the tolerance band are the additional args.
sgn	Sign extraction.
sin	Sine.
sinh	Hyperbolic sine.
slidingmean	Returns the moving average value of the selected simulation quantity (specified by the first argument). The average is calculated over a period (specified by the second argument).
slidingrms	Returns the moving RMS value of the selected simulation quantity (specified by the first argument). The RMS value is calculated over a period (specified by the second argument).
sqr	Square of the selected simulation quantity.
sqrt	Square root of the selected simulation quantity.
stddev	Returns the standard deviation of given values.
sum	Returns the sum of the given values.
tan	Tangent.
tanh	Hyperbolic tangent.
undershoot	Calculates peak undershoot given a threshold value and number of evenly spaced points over entire time range.
uppercutoff	Returns the upper 3dB frequency of the selected simulation channel in Hz.
variance	Calculates the variance of the given values.
XAtYMax	Threshold crossing time: report first time (x value) at which an output quantity crosses YMax.
XAtYMin	Threshold crossing time: report first time (x value) at which an output quantity crosses a user definable threshold.
XAtYVal	Returns the X value at the first occurrence of Y value.
XWidthAtYVal	Returns the X width between the first 2 occurrence of Y value.
xdb10beamdwidth	Width between left and right occurrences of values 'x' db10 from max. Takes 'x' as argument (3.0 default). To use this function, you need to

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	open the Add Trace Characteristics dialog and select the Radiation category.
xdb20beamwidth	Width between left and right occurrences of values 'x' db20 from max. Takes 'x' as argument (3.0 default). To use this function, you need to open the Add Trace Characteristics dialog and select the Radiation category.
YAtXMax	Returns the X value at maximum value of Y.
YAtXMin	Returns the Y value at minimum value of X.
YAtXVal	Returns the Y value at the first occurrence of X value.
y0	Bessel function of the second kind (0^{th} order).
y1	Bessel function of the second kind (1^{st} order).
yn	Bessel function of the second kind (nth order).

Selecting Solution Quantities to Plot

When you create a report, each trace in the report includes a quantity that is plotted along an axis. The quantity being plotted can be a value that was calculated by HFSS, a value from a calculated expression, or an intrinsic variable value (such as frequency or theta).

> **Important:**
>
> Available solution quantity categories depend on the design type, solution type, setup parameters, and plot domain. The selected category provides the default name for the plot, such as "S Parameter Plot *n*". You can edit plot names in the project tree and plot header text in the Properties window.

To select solution quantities to plot:

1. Click **Results** > **Standard Report** and select the type of report you would like to generate.

   The **Report** window appears.

2. On the **Trace** tab, select a **Category** from the list.

Category	Description
Variables	Intrinsic variables (such as frequency or theta), or user-defined project variables (such as the length of a quarter-wave transformer).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Category	Description
Output Variables	User-defined expressions applied to derive quantities from the original field solution.
S-Parameter	S-parameters from the S-matrix. For designs which include a Frequency Selective Surface (FSS)-referenced radiation boundary, S_{11} and S_{21} represent the extracted reflection and transmission coefficients, respectively.
Y-Parameter	Admittance matrix parameters computed from the S-parameters and port impedances.
Z-Parameter	Impedance matrix parameters computed from the S-parameters and port impedances.
Group Delay	Quantity calculated as rate of change of the total phase shift with respect to angular frequency, appearing $\frac{d(\Phi)}{d(\omega)}$
VSWR	Voltage standing wave ratio, calculated from the equation: $\frac{1+\lvert S_{ij}\rvert}{1-\lvert S_{ij}\rvert}$
Gamma	Propagation constants for the S-parameters.
Port Z_o	Characteristic port impedances.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Category	Description
Matched S Parameter	Matched S is the S-matrix produced by solver. It becomes useful to view when passive ports exist and the matched S-matrix is rectangular instead of square. When passive ports exist, S is the square matrix of the active ports and the passive ports represent a loss mechanism. Matched S-matrix provides coupling information to the passive ports. In Transient, we show Matched S entries while the simulation is in process which is not clean for regular S when port post processing exists.
Short Circuit Z	Short circuit impedance, calculated as: $\mathbf{ShortCircuitZ}\left(\mathbf{P1}\right) = \mathbf{mag}\left(\frac{1}{\mathbf{Y(P1,\ P1)}}\right)$
Loop Inductance	LoopL computes with all other ports shorted, even ports on other nets. These short circuits permit induced currents to flow in nearby nets, meaning LoopL will always be lower than a more rigorous loop inductance computation. $\mathbf{LoopL}\left(\mathbf{P1}\right) = \frac{\mathbf{im}\left(\frac{1}{\mathbf{Y(P1,\ P1)}}\right)}{\left(2 \times \pi \times \mathbf{freq}\right)}$
Loop Resistance	Calculated as: $\mathbf{LoopR}\left(\mathbf{P1}\right) = \mathbf{re}\left(\frac{1}{\mathbf{Y(P1,\ P1)}}\right)$
Capacitance	This capacitance calculation leaves other nets open-circuited, whereas a rigorous capacitance calculation would short them to ground, meaning "Capacitance" computed here will always be too low. $\mathbf{C}\left(\mathbf{P1}\right) = \frac{\mathbf{im}\left(\frac{1}{\mathbf{Z(P1,\ P1)}}\right)}{\left(2 \times \pi \times \mathbf{freq}\right)}$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Category	Description
Lambda	Guided wavelength.
Epsilon	Effective permittivity.
TDR Impedance	Time-Domain Reflectometry (TDR) impedance for non-terminal problems. The idea is to excite a structure with a step function, and inspect the reflections as a function of time. This quantity is available only when the **Time** domain is selected. Selecting the TDR Impedance category displays the TDRZ of every terminal or mode in the ports. The list of available Functions includes those that can operate on the TDRZ values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Category	Description
Active S-Parameter	Active S parameters represent the reflection coefficient of one port when another port is excited. HFSS offers passive S-parameters as well as active S-Parameters. If you plot Active S-Parameters, HFSS includes the effects of mutual coupling with other ports or elements. One use is in Optimization, to view how S-parameters change as design parameters change. In this case you may plot Active S Parameters. In such cases they allow you to forecast design behavior in the presence of an ideal feed network. A 0w value is a matched load, but 1w values take that into account. Active S-parameters are given as a linear combination of the regular S-parameters, with some weights 'a', based on the matrix equation $\mathbf{b} = \mathbf{S} \times \mathbf{a}$. In the post-processor, the active S-parameter for port*n* is displayed to the user as ActiveS(P*n*:*m*) where "P*n*" indicates the port number and ":*m*" indicates the mode number. Active S, Y, Z, VSWR are supported only for driven modal projects. Power is proportional to the square of the fields. As a consequence, active S-parameters, which are field related, are proportional to the square root of what you set under Edit Sources. You can check this by setting all power to 0 except for one port of interest where you want to see the Active S-parameter. Then for a neighboring port, change the input power in steps, and monitor how the active S-parameter changes. Keep in mind that this involves complex numbers which complicates things. Given a driven model project with a total of *N*port modes, let a_k denote the complex excitation for the *k*-th mode specified in the Edit Sources dialog box. Also let S denote the computed *N* x *N*scattering matrix. If $a_m \neq 0$ define active-S_m, *m* = 1..., *N* by $$active\text{-}S_m \equiv \sum_{n=1}^{N} S_{mn} \frac{a_n}{a_m} \qquad m = 1, ..., N$$
	If S is renormalized or deembedded, the interpretation is that the stimulations are applied to the renormalized external transmission lines at the plane of deembedding.

Ansys Electromagnetics Suite 2025 R2 © ANSYS, Inc. All rights reserved. Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Category	Description
Active Y-Parameter	$Y_0^{(M)}$ is the port admittance of the *m*-th mode. $$active\text{-}Y_m \equiv Y_0{}^{(m)} \frac{1 - active\text{-}S_m}{1 + active\text{-}S_m} \qquad m = 1, ..., N$$
Active Z-Parameter	$Z_0^{(m)}$ is the impedance of the *m*-th mode. $$active\text{-}Z_m \equiv Z_0{}^{(m)} \frac{1 + active\text{-}S_m}{1 - active\text{-}S_m} \qquad m = 1, ..., N$$
Active VSWR	Active Voltage standing wave ratio is supported only for driven modal projects. $$active\text{-}VSWR_m \equiv \frac{1 + \lvert active\text{-}S_m \rvert}{1 - \lvert active\text{-}S_m \rvert} \qquad m = 1, ..., N$$
Passivity	A scalar quantity based on the matrix Q = I - conjugate(transpose(S)) * S For every frequency, the value must be no larger than 1. A uniform renormalization of 50 ohms is performed on the solution data for Passivity checking.
Power	For Composite Excitation Solution types, selecting Power as Category lists Quantities for Accepted (Pacc), Reflected (Pref), and Incident (Pinc) powers/port based on your Edit Sources settings.
Design	Enables you to plot or tabulate properties of objects, such as their volumes.
Expression Cache	The values of expressions listed in the Expression cache of the Solution setup can be plotted, for example, as a function of adaptive pass to monitor their convergence.
Expression Convergence	This is intended to plot convergence, as a function of adaptive pass, of expressions in the Expression cache of the Solution setup. In defining the report, for "Context", select Solution: SetupN:Adaptive Pass. ExprDelta will show the change in the value of the expression as a function of adaptive pass, while ExprGoal will show, for comparison, the convergence goal for this expression, as defined in the Analysis Setup under the panel Expression Cache.

3. Select a **Quantity** from the list.
4. If desired, select a **Function**.
5. Click **Close**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Selecting a Field Quantity to Plot

When plotting field quantities, the quantity can be a value that was automatically calculated by HFSS such as the magnitude of S_{11}, a value from a calculated expression, or an intrinsic (inherent) variable value such as frequency or phase.

To select a field quantity to plot:

1. When you create the report, specify the Report Type as "Fields" and the plot type (for example, radiation pattern.)
2. In the *Report* dialog box, select Geometry for the Context, unless you are plotting scalar (for example, integration). For example, to plot near-field values across a sphere, you select the sphere object from the **Geometry** list in the *Traces* dialog box when you create a report.
3. In the *Report* dialog box, select one of the following categories. The selected category provides the default plot name. You can edit the plot names in the project tree and the plot header text in the report synchronizes.

Variables	Intrinsic variables, such as frequency or phase, or user-defined project variables, such as the length of a quarter-wave transformer.
Output Variables	User defined expressions applied to derive quantities from the original field solution.
Calculator Expressions	Includes scalar and vector field quantities automatically calculated by HFSS, as well as derived field quantities that are defined by calculated expressions you set up in the Fields Calculator.

4. Select a quantity to plot from the **Quantity** list. The available quantities will depend upon the selected category and the setup of the design. See Field Quantities list for definitions.

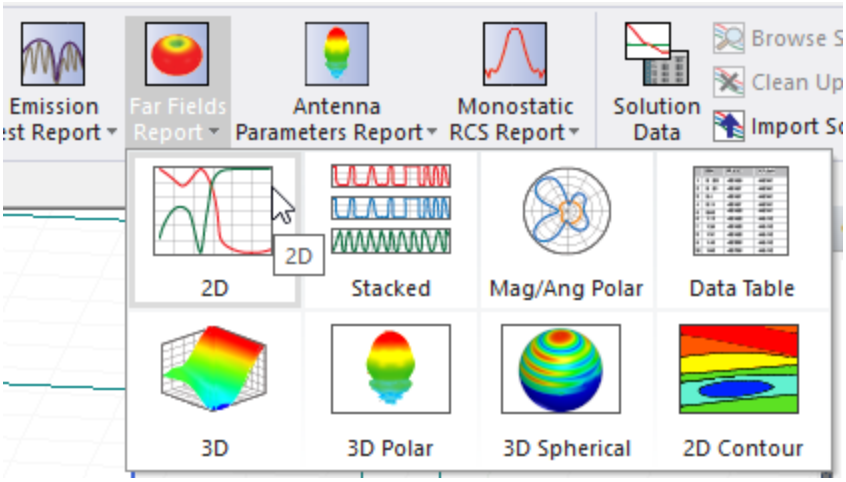
Selecting a Far-Field Quantity to Plot

When plotting far-field quantities, the quantity can be a value that was calculated by HFSS such as antenna gain, a value from a calculated expression, or an intrinsic (inherent) variable value such as frequency or theta.

Prerequisites

For the **Far Field Report** icons to appear on the ribbon, or for the **Create Far Field Reports** command to appear on the **Results** menus, the design must contain radiation boundaries, PMLs or Hybrid regions, and must contain a Far Field Setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

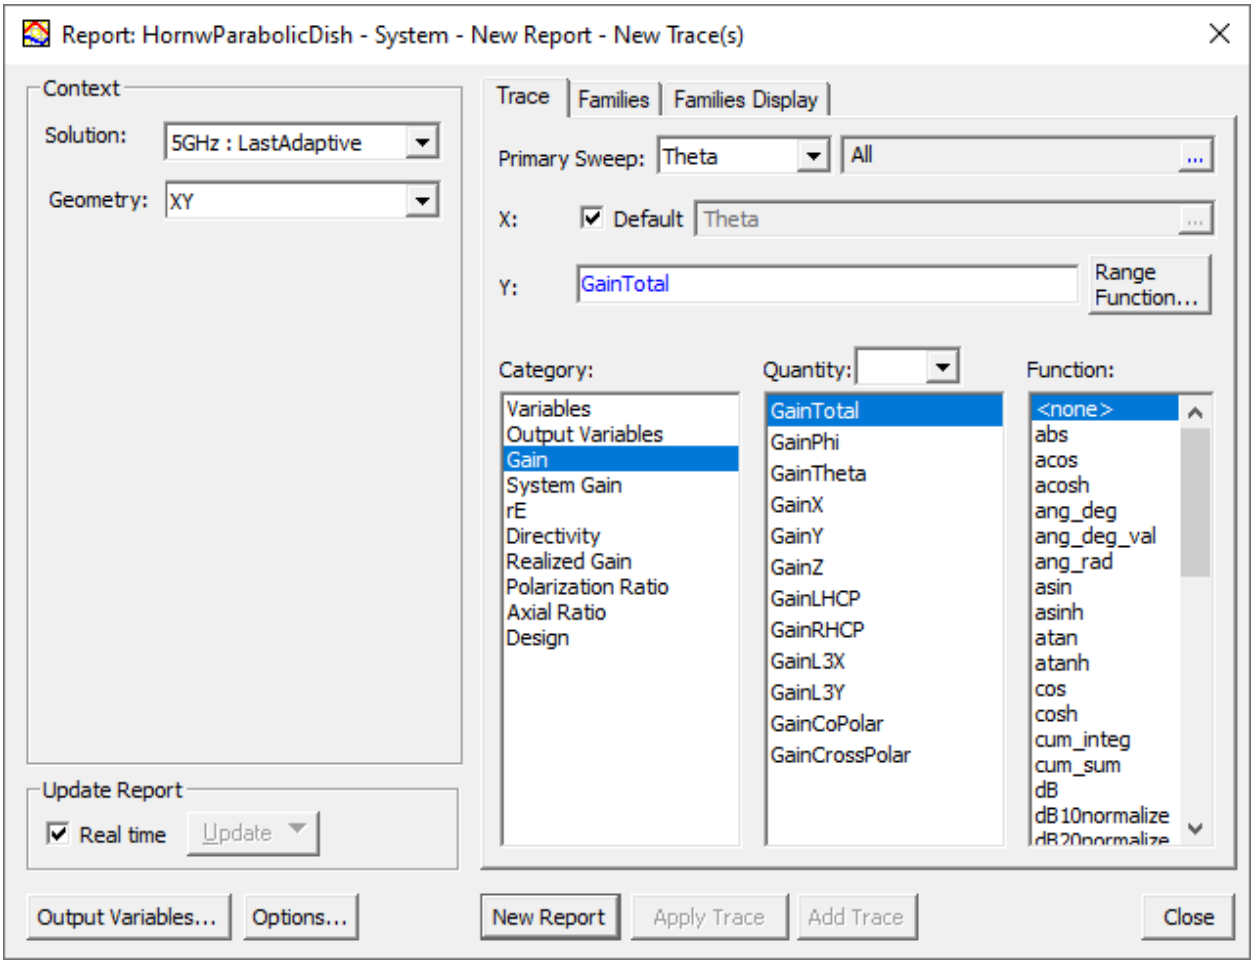


To tune Far Field plots based on partial quantities, the design must include a variable from which derivatives can be calculated. See: Derivative Tuning for Reports.

To plot a far-field quantity:

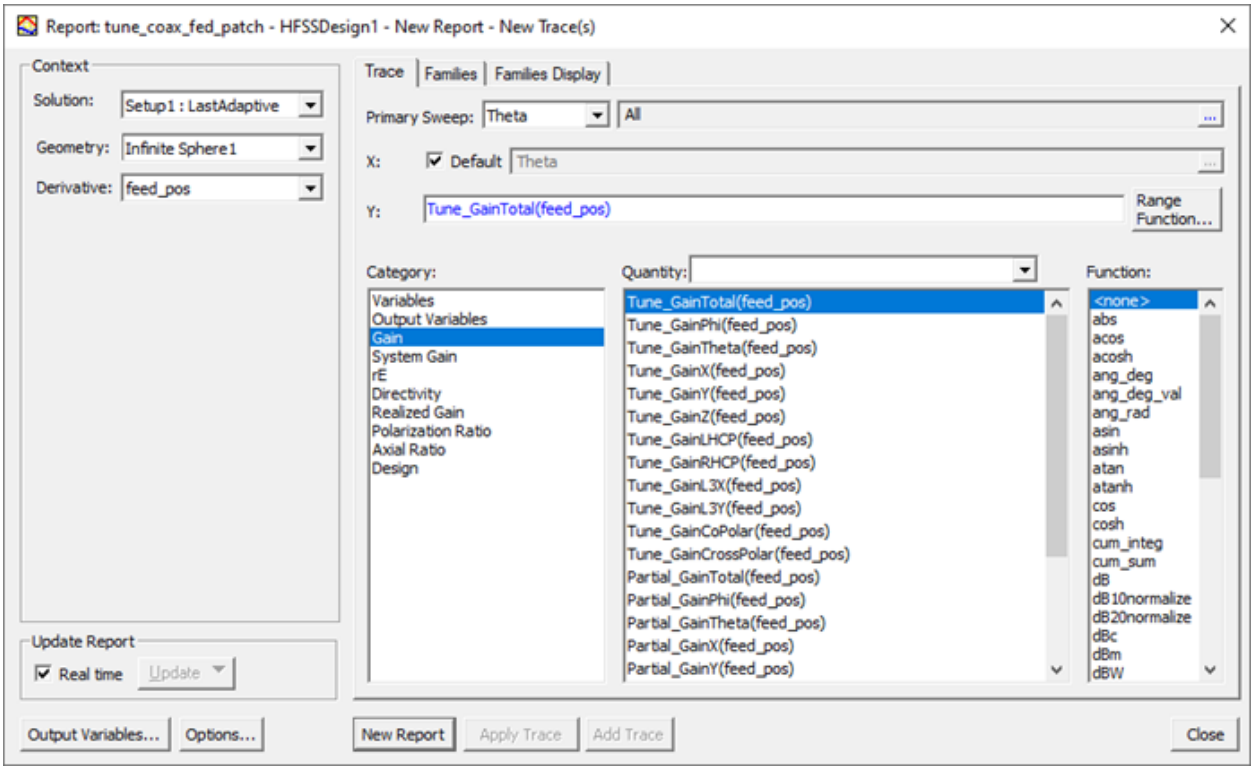
1. From the **Results** ribbon, select the **Far Fields Report** icon, or select **Results** > **Create Far Fields Report** to open the **Report** window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If your design includes one or more variables for derivatives, you can select one or all derivatives. Selecting a **Category** will list tunable **Quantities** available:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. In the **Context** area, select the **Solution**, **Geometry**, and **Source**.

> **Note:**
>
> In the case of finite array, select a Source group.

3. Make a selection from the **Category** list. The available options may differ depending on previous choices. Selecting one or more Derivatives results in Tunable variations of these quantities being listed:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

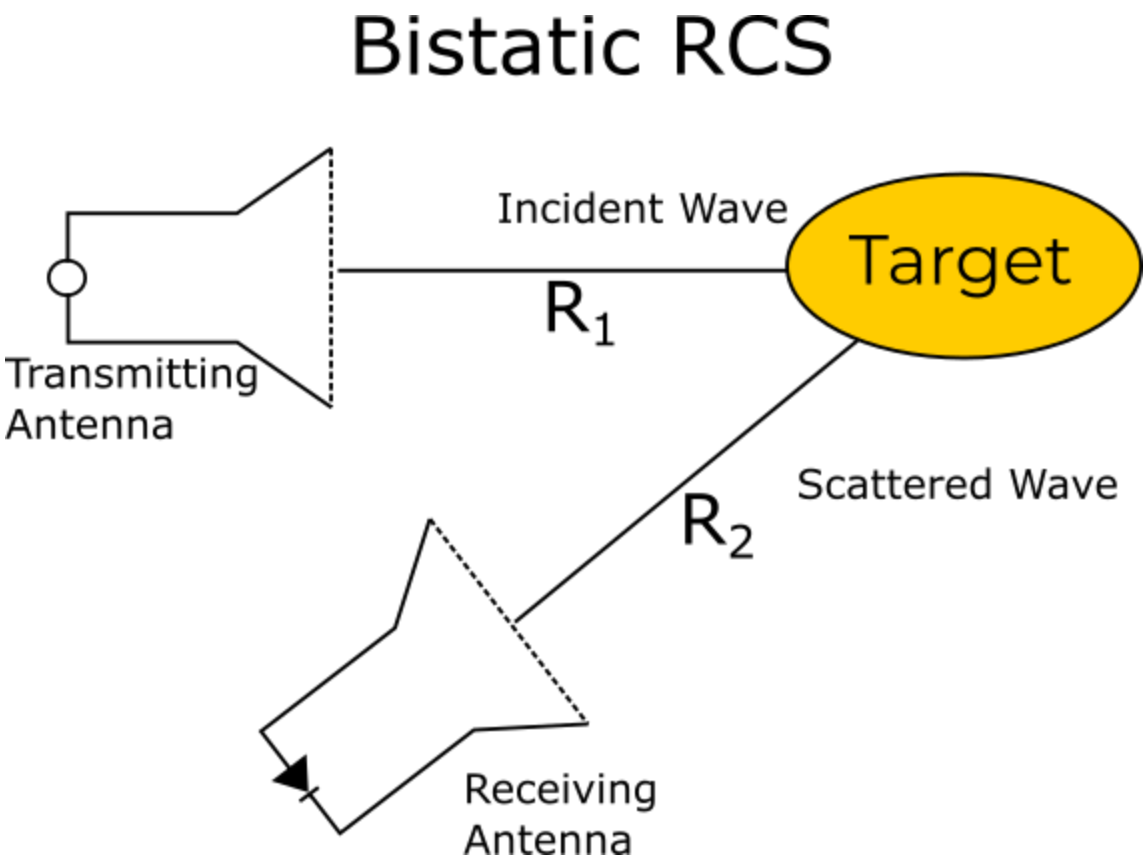
Variables	Intrinsic variables, such as frequency or theta, or user-defined project variables, such as the length of a quarter-wave transformer.
Output Variables	User-defined expressions applied to derive quantities from the original field solution.
Gain	Gain is 4π times the ratio of an antenna's radiation intensity in a given direction to the total power accepted by the antenna.
System Gain	System gain appears in the Quantity list if Edit Sources was used to specify system power for gain calculations. System gain is 4π times the ratio of an antenna's radiation intensity in a given direction to the user-specified power.
rE	The selected component of the radiated electric field, which is multiplied by the radial distance, *r*.
Directivity	Directivity of the antenna.
Realized Gain	Realized gain is 4π times the ratio of an antenna's radiation intensity in a given direction to the total power incident upon the antenna port(s).
Polarization Ratio	Polarization ratio of the electric field.
Axial Ratio	Axial ratio of the electric field.
Normalized Bistatic RCS	The normalized radar cross-section: $\frac{\sigma}{\lambda_0^2}$ where $\lambda_0$is the wavelength of free space. *RCS is supported for designs with Plane Incident Waves. RCS is not supported for other types of incident waves.*
Radar Cross-Section (Bistatic RCS)	The radar cross-section (RCS) or echo area (σ) is measured in meters squared and represented for a bistatic arrangement (e.g., when the transmitter and receiver are in different locations as shown in the figure below). This is represented by: $\sigma = \frac{4\pi r^2 \lvert E_{\text{scat}} \rvert^2}{\lvert E_{\text{inc}} \rvert^2}$ where:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	• E_{scat} is the scattered E-field. • E_{inc} is the incident E-field. *RCS is supported for designs with Plane Incident Waves. RCS is not supported for other types of incident waves.*
Complex (Bistatic) RCS	The equation for complex (bistatic) RCS is calculated as: $\sqrt{\sigma} = 2\sqrt{\pi \mathrm{R}} \frac{E_{scat}}{\lvert E_{inc} \rvert}$ where: • E_{scat} is the scattered E-field. • E_{inc} is the incident E-field. This form retains the phase information. *RCS is supported for designs with Plane Incident Waves. RCS is not supported for other types of incident waves.*
Monostatic RCS	The radar cross-section (RCS) or echo area when the transmitter and receiver are at the same location. For Monostatic RCS, you need not be concerned with the Theta and Phi values defined in the radiation sphere. Only the incident wave Theta and incident wave Phi are used in calculating a Monostatic RCS plot. *RCS is supported for designs with Plane Incident Waves. RCS is not supported for other types of incident waves.* *A proper incident angle sweep should exist at the incident wave source setup before HFSS can plot Monostatic RCS*

The following diagram shows the bistatic RCS concept, with separate transmitting and receiving antennas.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Each **Category** item selected updates the **Quantity** list to offer quantities appropriate to selected category. **Category** selection for a Variable of an Output Variable lists those available in each case. Selecting Antenna Parameters as Category causes the Quantity list to show Antenna parameters. The selected Category provides the default report name, such as rE Plot *n*.

4. Select the **Quantity** to apply to the selected **Category**.

   If the **Category** item is rE, Gain, Directivity, or Realized Gain, you will need to specify the polarization of the electric field by selecting from the **Quantity** list. If you manually enter Phi or Theta component of a far field quantity when using Az/El or El/Az far field definition, the Report uses the Z axis of the Az/El or El/Az coordinate system definition as pole to calculate theta/phi component for rE.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Total	The combined magnitude of the electric field components.
Phi	The phi component (φ).
Theta	The theta component (θ).
X	The x component.
Y	The y component.
Z	The z component.
LHCP	The dominant component for a left-hand, circularly polarized field.
RHCP	The dominant component for a right-hand, circularly polarized field.
CircularLHCP	The polarization ratio for a predominantly left-hand, circularly polarized antenna.
CircularRHCP	The polarization ratio for a predominantly right-hand, circularly polarized antenna.
SphericalPhi	The polarization ratio for a predominantly φ-polarized antenna.
SphericalTheta	The polarization ratio for a predominantly θ-polarized antenna.
L3X	The dominant component for an x-polarized aperture using Ludwig's third definition of cross polarization.
L3Y	The dominant component for a y-polarized aperture using Ludwig's third definition of cross polarization.
CoPolar	Reports fixed polarization rotated around Z axis by “slant” angle from X axis of coordinate system of Infinite sphere definition: $rE_{CoPolar} = \cos(\varphi - a)\hat{\theta} - \sin(\varphi - a)\hat{\varphi}$ where *a* is the slanted angle.
CrossPolar	$rE_{CrossPolar} = -\sin(\varphi - a)\hat{\theta} - \cos(\varphi - a)\hat{\varphi}$ where *a* is the slanted angle.

The plot's Y axis field shows the combined selections.

For example, if you select Gain as the Category and RHCP as the Quantity, HFSS evaluates the equation as:

$$Gain_{RHCP} = \frac{4\pi U_{RHCP}(\theta,\varphi)}{P_{acc}} = \frac{4\pi |rE_{RHCP}(\theta,\varphi)|^2}{2\eta P_{acc}}$$

$$= \frac{4\pi \left| r\vec{E}(\theta,\varphi) \bullet \left(\frac{\hat{\theta} - j\hat{\varphi}}{\sqrt{2}} \right) \right|^2}{2\eta P_{acc}}$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. You can also select a function to apply to the your selections for the **Category** and **Quantity** (e.g., mag).

   As you make selections for **Category**, **Quantity**, and **Function**, the **Y** field shows the combined calculation they describe.

6. When you are finished, click **New Report** to create the report.

   The new report based on your selections is displayed.

Plotting Vertical Cross-Sections of Far Fields

When plotting far fields, a vertical cross-section plot results from holding phi fixed and sweeping theta through a range of values.

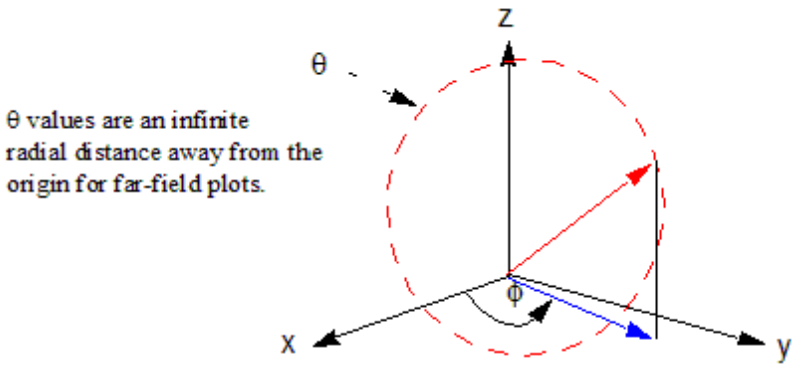
1. Open the **Report** dialog box.
2. Click the ellipsis **[...]** button for the **sweep variable corresponding to phi.**

This displays a dialog listing all values for the phi variable. The values are the result of the range of phi you specified during the infinite sphere's setup.

3. Select the fixed value that phi should take in the plot.

HFSS will display values for the vertical cross-section at selected phi cuts of the problem region at a set of theta rotations.

The figure shown below demonstrates the orientation of the vertical cross-section when ϕ is the fixed variable:



Plotting Horizontal Cross-Sections of Far Fields

When plotting far fields, a horizontal cross-section results from holding theta fixed and sweeping phi through a range of values.

1. Click the ellipsis **[...]** button for the **sweep variable corresponding to theta.**

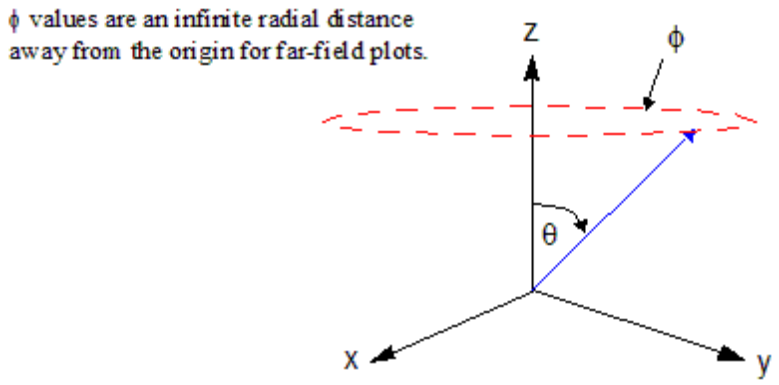
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To the right, all of the possible values for the theta variable are listed. The values are the result of the range of theta you specified during the infinite sphere's setup.

2. Select the fixed value that theta should take in the plot.

HFSS will display values for the horizontal cross-section at selected theta cuts of the problem region at a set of phi rotations.

The figure shown below demonstrates the orientation of the sphere on which the field is computed when θ is the fixed variable:



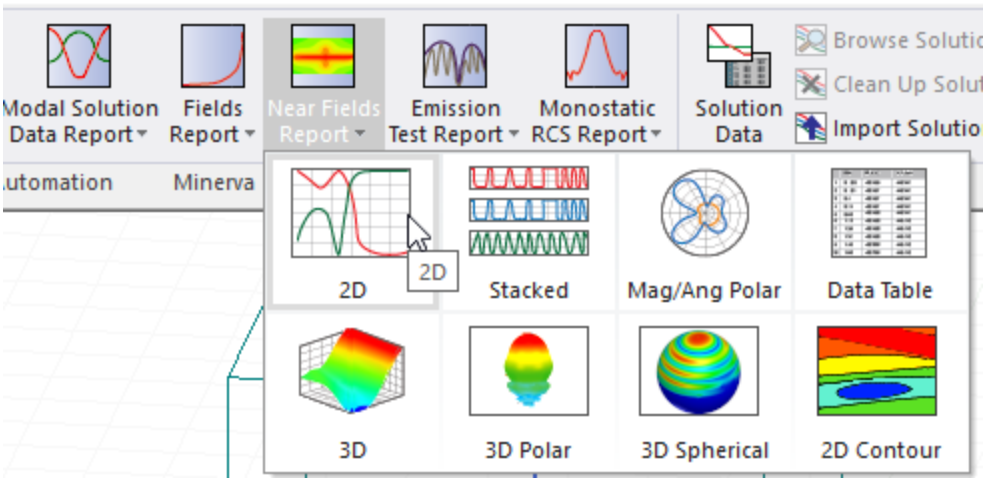
Selecting a Near-Field Quantity to Plot

When plotting near-field quantities, the quantity can be a value that was calculated by HFSS, a value from a calculated expression, or an intrinsic (inherent) variable value such as frequency or theta.

Prerequisites

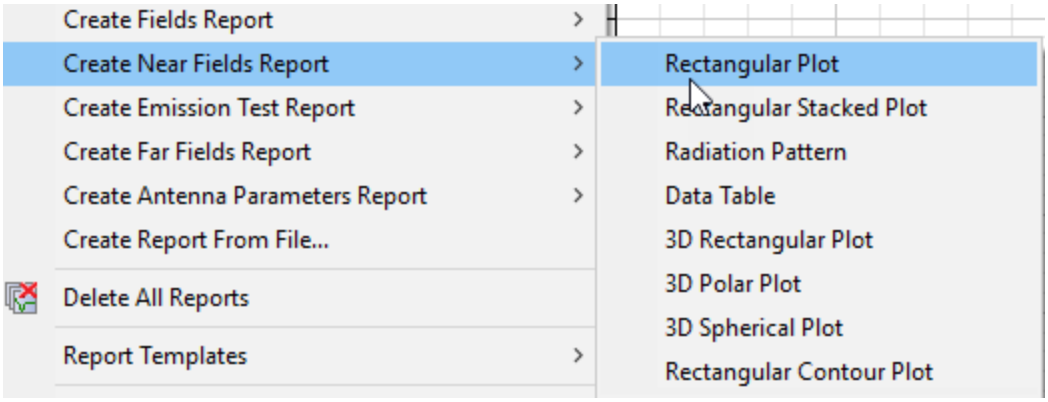
For the **Near Field Report** icons to appear on the ribbon, or for the **Create Near Field Reports** command to appear on the **Results** menus, the design must contain radiation boundaries, PMLs or Hybrid regions, and must contain a Near Field Setup for sphere, line or rectangle.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



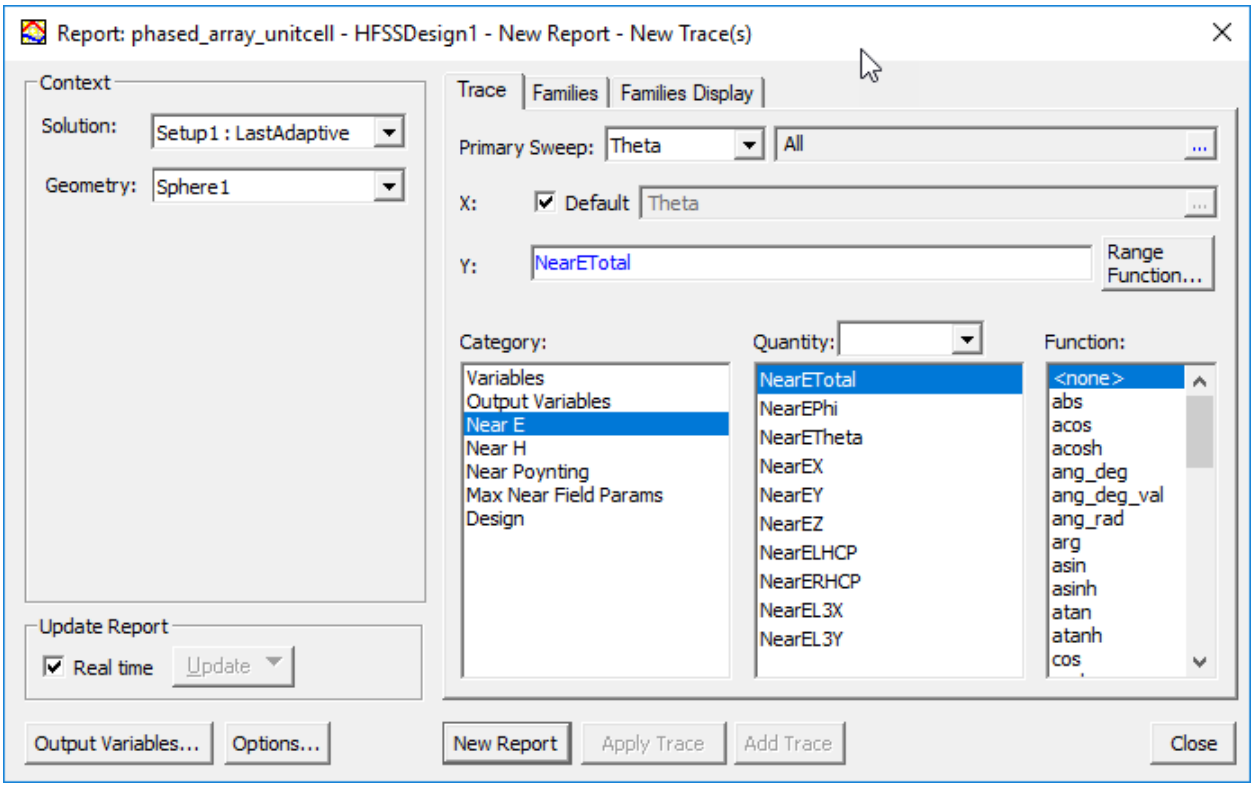
To select a near-field quantity to plot:

1. When you create the report, use the **Results** tab of the ribbon and select the **Near Fields Report** icon to select from the available report types, or if you use the **Results** menus, select **Create Near Fields Report** and select the plot type from the menu.



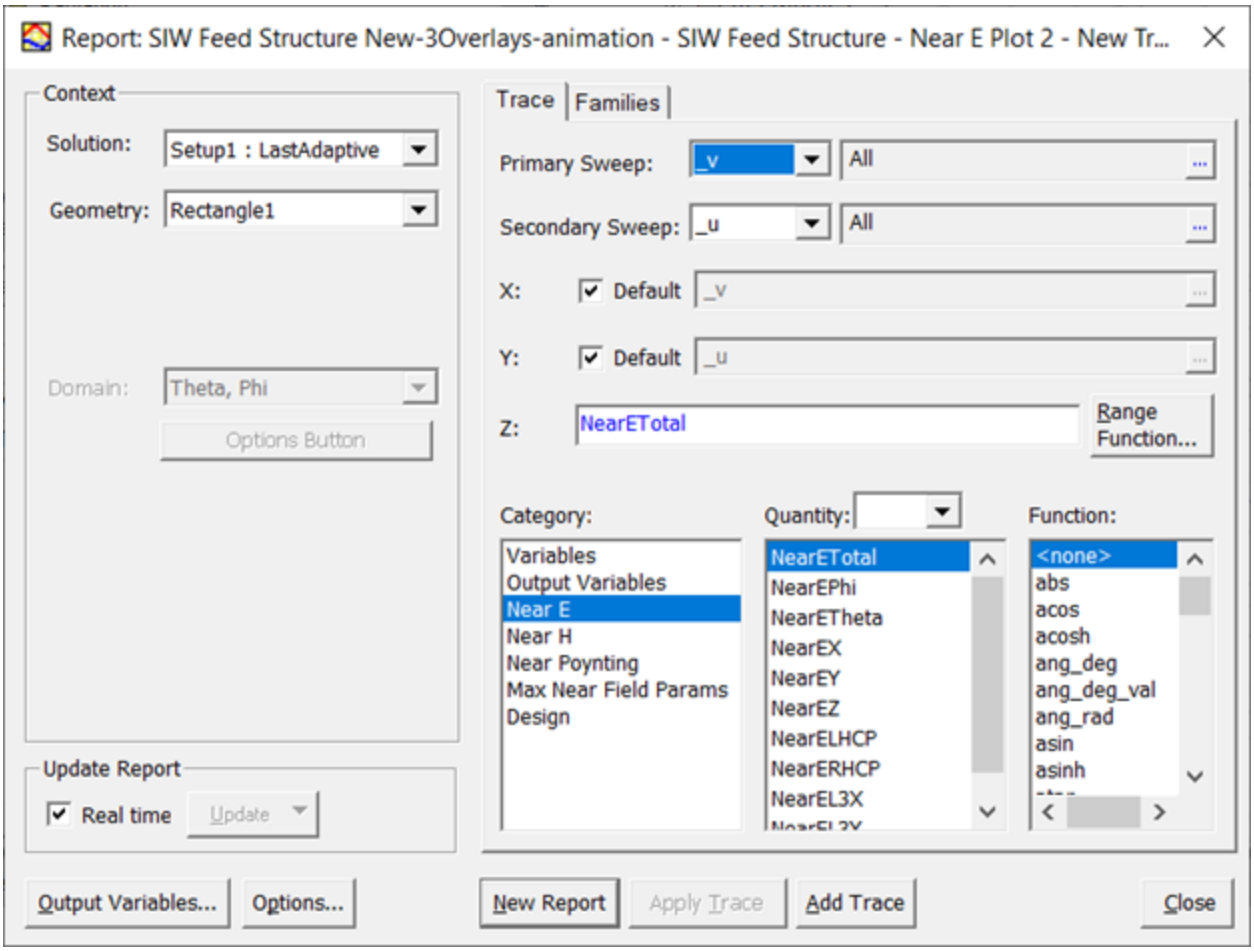
The **Report** dialog appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



When you create a Near Field Rectangular Contour plot, if the Context Geometry is a Rectangle radiation setup and the Primary and Secondary sweep is the combination of _u and _v, then the plot creation dialog is as follows.

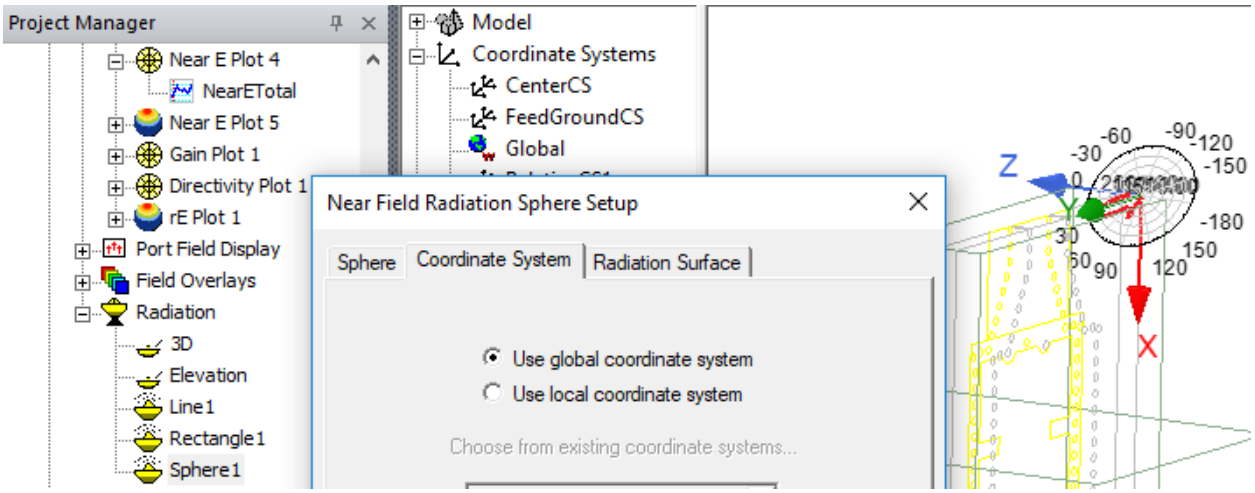
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



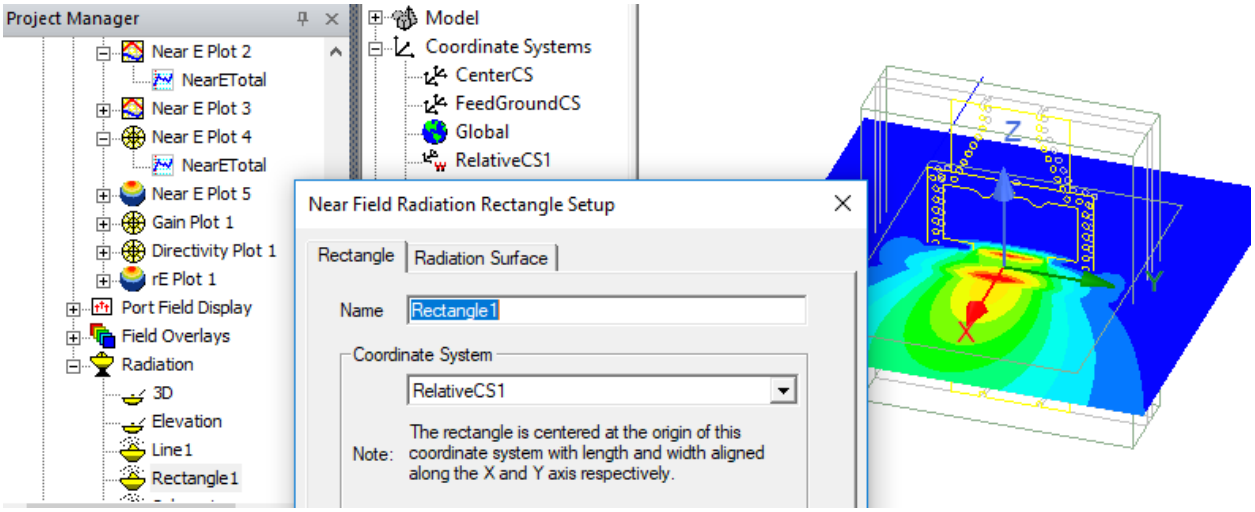
This kind of near field rectangular contour plot can be overlaid in its actual defined rectangle in 3D space in the Modeler window.

2. In the **Geometry** portion, select a predefined Sphere, Rectangle or Line. The geometry selected affects where the plot data is selected and if, where and how the plot will be overlaid on the model, if you choose to do so, after the plot is created. In the following figure, the Near E Polar plot overlaid on the model uses Sphere1 as the Geometry and that geometry uses the Global CS.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

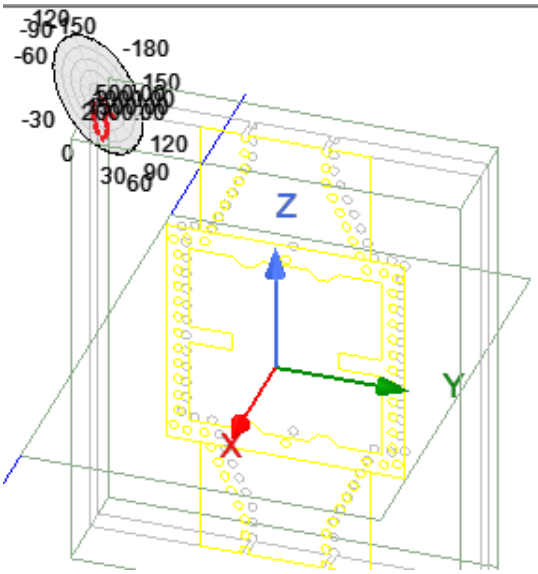


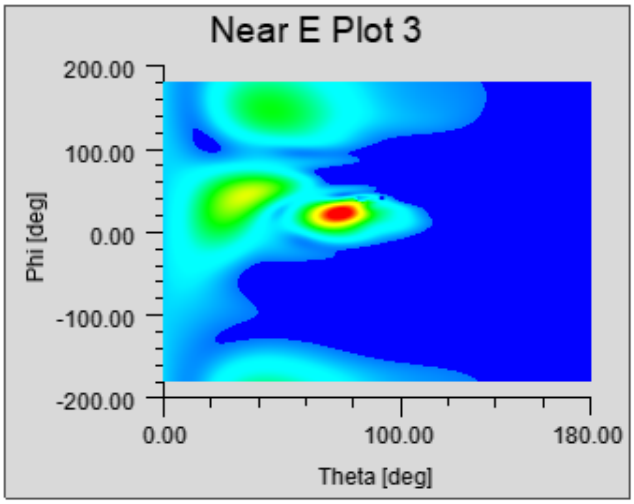
In the following case, Near E Plot 2 Uses Rectangle1, which uses RelativeCS1.



In the case of a plot generated on a line, a plot can be created but not overlaid.
In the case of a 2D Contour Near Field Plot generated on a Sphere, the plot can be overlaid as a plot in the upper right of the model window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





3. In the **Report** dialog box, select one of the following categories. The selected category provides the default name of the report.

Variables	Intrinsic variables, such as frequency or theta, or user-defined project variables, such as the length of a quarter-wave transformer.
Output Variables	User defined expressions applied to derive quantities from the original field solution.
Near E	The radiated electric field in the near field region.
Near H	The radiated H field in the near region
Near Poynting	The Poynting field in the near region. This is 0.5 * E *conj(H).
Max Near Field Params	The maximum radiated electric field in the near region.
Near Normalized Antenna	The resultant plot is: field quantity / (maximum field quantity value over the entire infinite sphere).

4. If you selected the **Near E** category, specify the polarization of the electric field by selecting one of the following types of quantities from the **Quantity** list. The corresponding options appear for Near H and Near Poynting. If you select Max Near Field Params, there are additional **Quantities** for E, H and Poynting.

NearETotal	The combined magnitude of the electric field components.
NearEPhi	The phi component of the electric field.
NearETheta	The theta component of the electric field.
NearEX	The x-component of the electric field.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

NearEY	The y-component of the electric field.
NearEZ	The z-component of the electric field.
NearELHCP	The dominant component for a left-hand, circularly polarized electric field.
NearERHCP	The dominant component for a right-hand, circularly polarized electric field.
NearECircularLHCP	The polarization ratio for a predominantly left-hand, circularly polarized antenna.
NearECircularRHCP	The polarization ratio for a predominantly right-hand, circularly polarized antenna.
NearEL3X	The dominant component for an x-polarized aperture using Ludwig's third definition of cross polarization.
NearEL3Y	The dominant component for a y-polarized aperture using Ludwig's third definition of cross polarization.

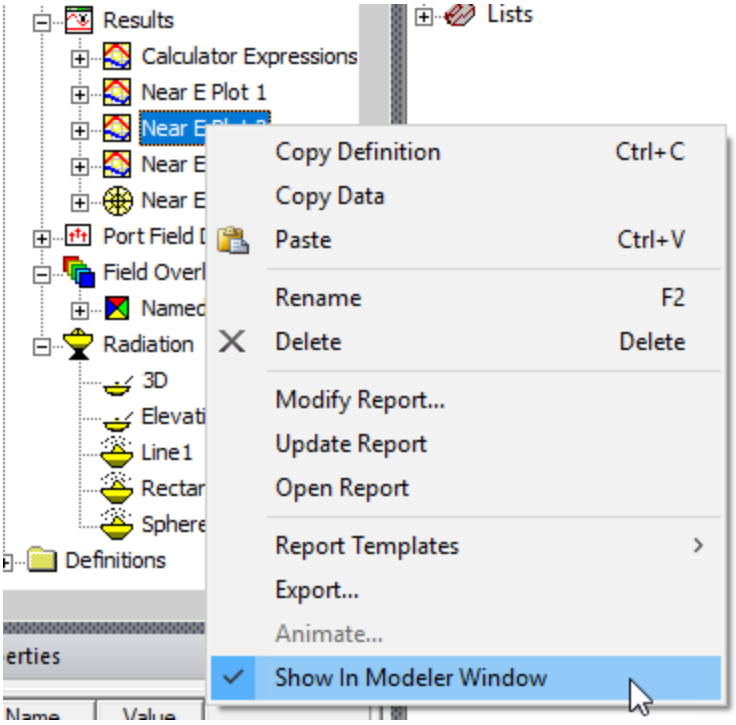
If a Near-field plot takes a long time to plot, be sure to perform **File>Save** when the plot is displayed. This saves the calculated data and permits fast display on subsequent viewings of the plot.

Reports appear under Results, and can be opened as reports. 3D Reports can be overlaid on the model, based on the selected geometry. 2D Near Field Reports on Rectangles can be overlaid as 2D plots.

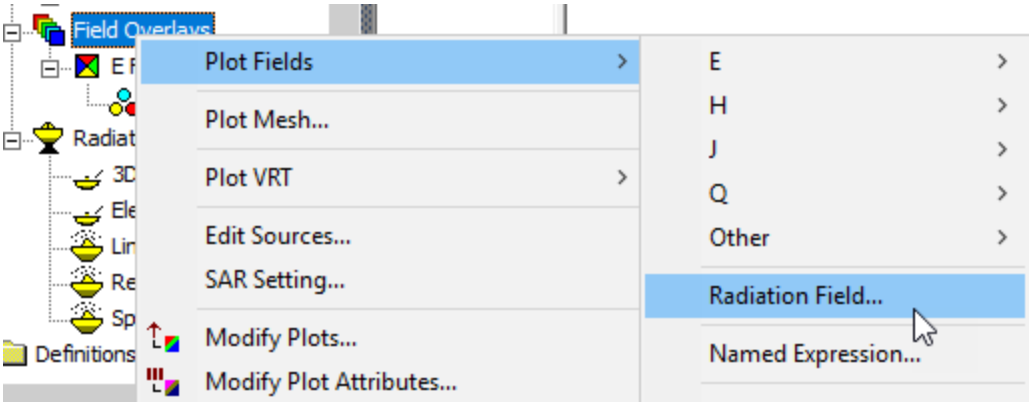
Overlaying Near Field Reports

Depending on the geometry selection and type of plot, some near field plots be shown in the model window. If a plot is appropriate for this purpose, the **Show in Modeler Window** option appears on the **Project** window short cut menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

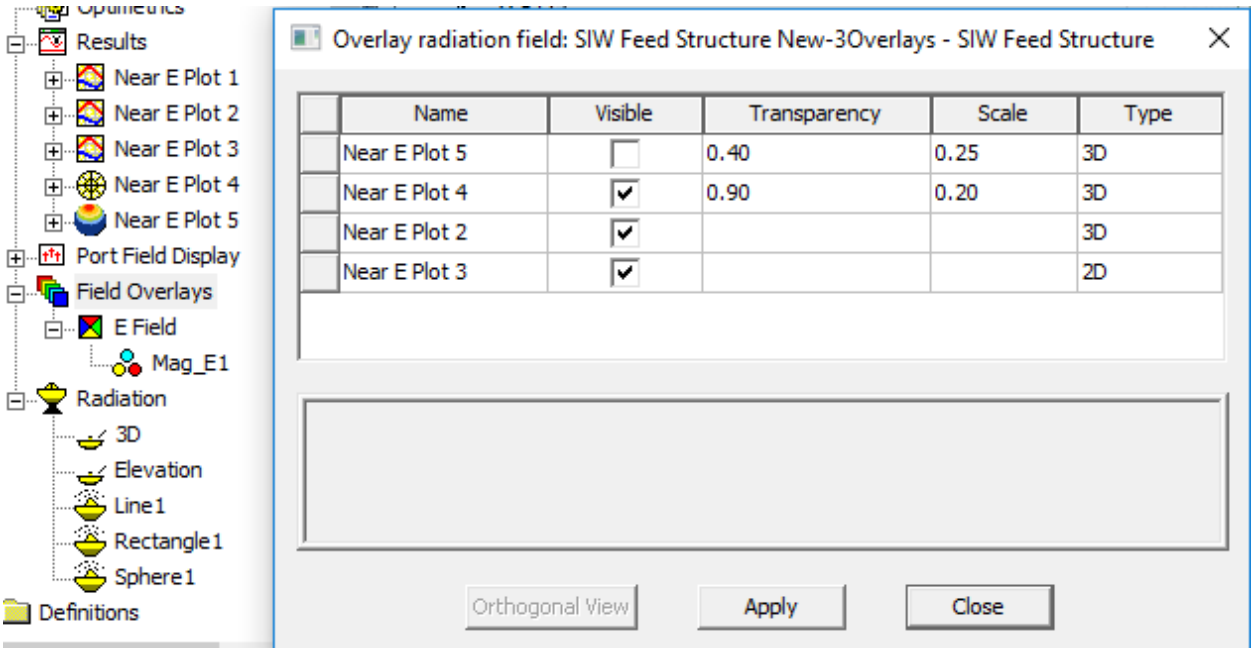


You can also see these plots listed by right clicking on **Field Overlays** in the **Project** tree and selecting **Plot Fields>Radiation Field**.

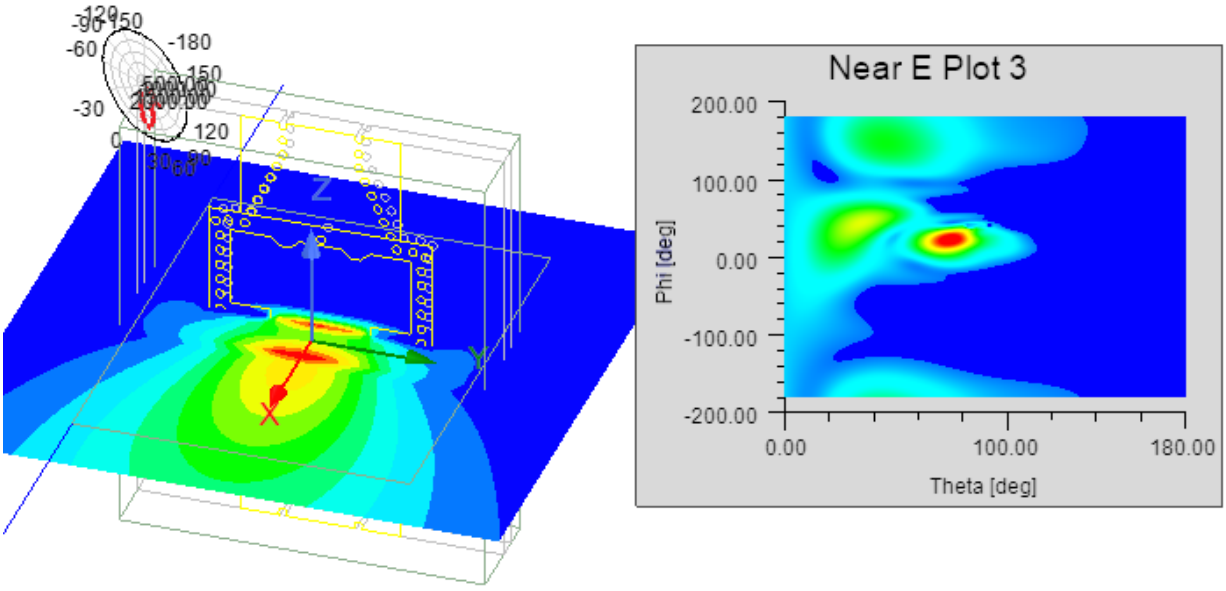


This displays the **Overlay radiation field** dialog box. Notice that it lists **Results** plots that can be overlaid, and not those listed under **Field Overlays**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can display multiple kinds of Plot overlays and Field Overlays at the same time.

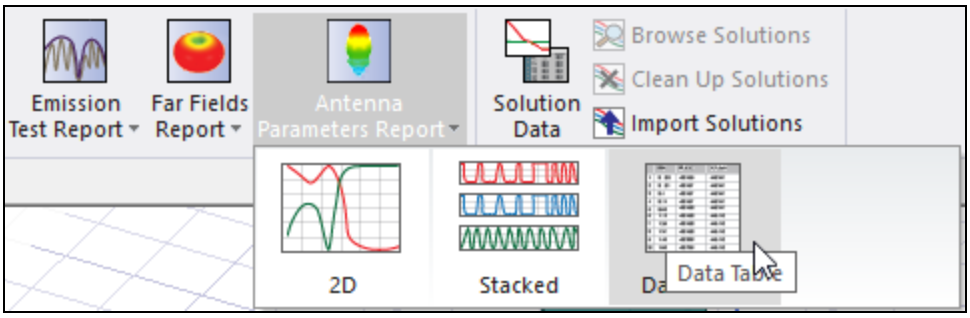


Selecting Antenna Parameters to Plot

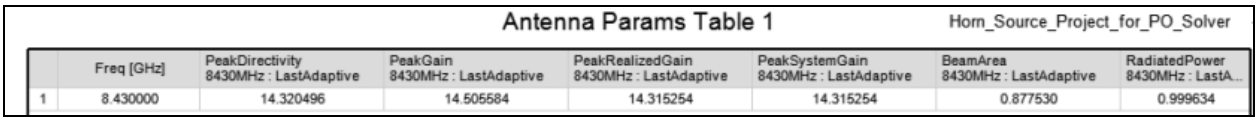
Complete these steps to select and plot antenna parameters.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. When you create the report, select Antenna Parameters, using either **Results>Create Antenna Parameters Report><*reportType*>**, or using the ribbon:



The format can be Data Table, Rectangular Plot, or Rectangular Stacked Plot, but because each trace includes a single quantity, you may prefer Data Table as the most appropriate display.



Antenna Params Table 1 — Horn_Source_Project_for_PO_Solver

	Freq [GHz]	PeakDirectivity 8430MHz : LastAdaptive	PeakGain 8430MHz : LastAdaptive	PeakRealizedGain 8430MHz : LastAdaptive	PeakSystemGain 8430MHz : LastAdaptive	BeamArea 8430MHz : LastAdaptive	RadiatedPower 8430MHz : LastA...
1	8.430000	14.320496	14.505584	14.315254	14.315254	0.877530	0.999634

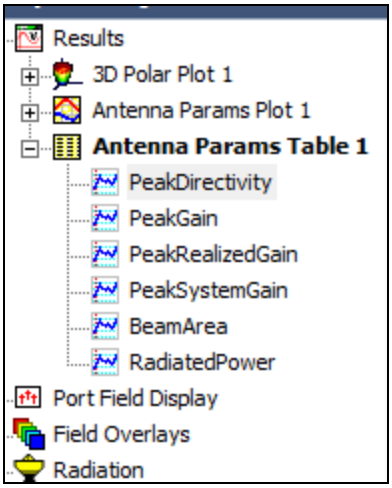
2. In the **Report** dialog box, select Antenna Params as the Category and apply an appropriate Quantity from the list. HFSS-calculated quantities that include peak directivity, peak gain, peak realized gain, beam area*, radiated power, accepted power, radiation efficiency including the total and component values at Phi and Theta, max U, and array factors. For descriptions of CoPolar and Cross Polar, see the table in Step 4 of Selecting a Far Field Quanity to Plot. For far-field setups, the decay factor for lossy materials is calculated as a constant for all far fields. *Beam area is the calculated as the beam solid angle. In its simplest form it is = 4*pi/D; where D is the max directivity.

PeakDirectivity	DecayFactor	MaxrEZCompAtTheta	MaxrELudwig3XComp
PeakGain	FrontToBackRatio	MaxrEThetaComp	MaxrELudwig3XCompAtPhi
PeakRealizedGain	MaxrETotal	MaxrEThetaCompAtPhi	MaxrELudwig3XCompAtTheta
PeakSystemGain	MaxrETotalAtPhi	MaxrEThetaCompAtTheta	MaxrELudwig3YComp
BeamArea	MaxrETotalAtTheta	MaxrEPhiComp	MaxrELudwig3YCompAtPhi
RadiatedPower	MaxrEXComp	MaxrEPhiCompAtPhi	MaxrELudwig3YCompAtTheta
AcceptedPower	MaxrEXCompAtPhi	MaxrEPhiCompAtTheta	MaxErCoPolar
IncidentPower	MaxrEXCompAtTh	MaxrELHCPComp	MaxErCoPolarAtPhi

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	eta		
RadiationEfficiency	MaxrEYComp	MaxrELHCPCompAtPhi	MaxErCoPolarAtTheta
TotalEfficiency	MaxrEYCompAtPhi	MaxrELHCPCompAtTheta	MaxErCrossPolar
SystemEfficiency	MaxrEYCompAtTheta	MaxrERHCPComp	MaxErCrossPolarAtPhi
MaxU	MaxrEZComp	MaxrERHCPCompAtPhi	MaxErCrossPolarAtTheta
ArrayFactor	MaxrEZCompAtPhi	MaxrERHCPCompAtTheta	

3. If appropriate, select one or more options from the **Function** list.
4. Make any other selections, as necessary.
5. Click **New Report**.
6. If necessary, return to the **Report** window to select additional options from the **Quantity** and **Function** lists. Then click **Add Trace**. Each additional trace appears in the report and in the **Project Tree**.



7. Click **OK** to accept the specified values or **Cancel**, **Use Defaults**, or **Save As Default** as appropriate.

Selecting an Emission Test Quantity to Plot

1. When you create the report, select Emission Test.
2. In the **Report** dialog box, select one of the following categories and apply an appropriate Quantity. The selected category provides the default name for the report.

Variables Intrinsic variables, such as frequency or theta, or user-defined project variables, such as the length of a quarter-wave transformer.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Output Variables	User defined expressions applied to derive quantities from the original field solution.
Sphere	A sphere of 1, 3, 10, or 30 meters, or of the same dimensions and RBS Simple or RBS exact (where RBS is random binary [bit] sequence).
Cylinder	A cylinder of 3 or 10 meters, or of the same dimensions and PRBS Simple or PRBS exact.

3. Select a **Function** for the quantity from the function list.
4. For Emission Test, the **Report** dialog also contains a button for specifying the digital signal options. The default values are a rise time of 0 seconds, and a hold time of 1 second. To specify other values, click **Digital Signal...**.

This displays the **Digital Signal Options** dialog box. It contains fields for the rise time and hold time.

5. **OK** the specified values or Cancel, Use Defaults, or Save As Default as appropriate.

Plotting Imported Solution Data

1. In the **Solution** drop-down menu of the *Report* dialog box, click the imported data you want to plot.
2. Follow the procedure for creating a report.

Setting a Range Function

To apply a range function to the Y, Z, or Mag component of a trace:

1. Click **Range Function** in the *Report* dialog box.

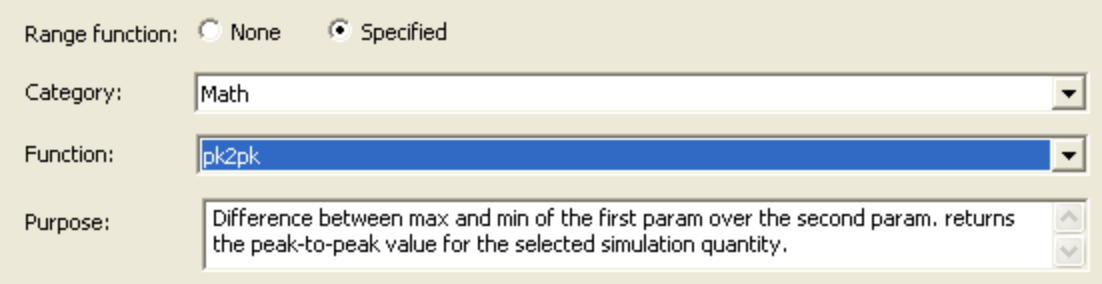
   This opens the *Set Range Function* dialog box. The functions available are the same as described in the Selecting a Function section, with the exception of those for the Eye Measurements category.

2. To enable Range function selection, click the Specified radio button.

   Selecting the None radio button disables the Range Function fields.

3. Select the **Category**, and then an associated Function to apply. The available categories depend on the plot, and Category enables the display of associated functions.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Given a selected Function, and Category, the **Set Range Function** dialog displays a text field that explains the Purpose of the function. See figure above.

Selecting a function causes the display of a description in the **Purpose** field. If the function requires a value (such as the XatYVal Math function or the pw_minus_max Pulse Width function), the following table the function field displays the name, editable value field, unit, and description.

4. Use the **Over Sweep** drop-down menu to select from available sweeps.
5. To select from available Sweeps, or to edit them, use the ellipsis [**...**] button and uncheck **Use All Sweeps**.

   This enables a list of the sweeps. The sweep(s) you select is displayed on the Over Sweep line. You can use the buttons to **Clear All Selections** or **Select All** sweeps.
6. Select the Sweeps **Default** or **Edited** radio buttons to specify whether to accept the default or edited sweeps.
7. To edit the sweeps further, select the ellipsis button to display an *Edit Sweep* dialog box.

   For frequency variables, this lets you specify a single value, linear step, linear count, decade count, octave count, or exponential count. You can **Add** legal values to the list of sweep values, **Update** the list for changes, or **Delete** selected entries.
8. Click **OK** to apply the range function.

Range Functions

The following table shows the **Functions** according to their **Categories**. The most commonly used range categories are **Math** and **Radiation**. Other functions could be used if needed. Use the category links to navigate to tables with definitions of functions.

Category	Functions
Math	max, min, pk2pk, rms, sum, mean, variance, stddev, integabs, avgabs, rmsAC, ripple, pkavg, XatYMin, XatYMax, YAtXMin, YAtXMax, XAtYVal, YAtXVal, XWidthAtYVal

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

PulseWidth	pulsemin, pulsemax, pulsemintime, pulsemaxtime, pulsefall9010, pulsefront1090, pulsefront3090, pulsetail50, pulsewidth5050, pw_plus, pw_minus, pw_plus_avg, pw_minus_avg, pw_plus_max, pw_minus_max, pw_plus_min, pw_minus_min, pw_plus_rms, pw_minus_rms
Overshoot, Undershoot	overshoot, undershoot.
TR & DC	crestfactor, formfactor, distortion, fundamentalmag, delaytime, risetime, deadtime, settlingtime
Error	iae, ise, itae, itse
Period	per, pmax, pmin, prms
AC	gainmargin, phasemargin, gaincrossover, phasecrossover, lowercutoff, uppercutoff, bandwidth, peakgain, peakgainfreq.
Radiation	xdb10bandwidth, xdb20bandwidth, lSidelobeX, lSidelobeY, rSidelobeX, rSidelobeY
Eye Measurements	EyeLevelZero, EyeLevelOne, EyeAmplitude, EyeHeight, EyeSignalToNoise, EyeOpeningFactor, EyeWidth, EyeJitterP2P, EyeJitterRMS, EyeRiseTime, EyeFallTime, MinEyeWidth, MinEyeHeight

> **Note:**
>
> Refer to the SI Wave or Nexxim help for more information. The Purpose field offers brief descriptions of each.

Math Functions	
***avg**	Returns the average of the values of the selected quantity. avg = (Area between the curve and the X-axis) / (X length of the curve)
avgabs	Returns the mean of the absolute value of the selected quantity.
integabs	Absolute value of integral.
max	Returns maximum value of the simulation quantity.
mean	Returns the average in the set of quantities selected. mean = sum(all y-value) / (number of y-values)
min	Returns the minimum value of the simulation quantity.
rms	Returns the root mean square value of the selected quantity.
rmsAC	Returns the AC RMS for the selected quantity.
ripple	Returns the ripple factor (AC RMS/Mean) for the selected quantity.
pkavg	Returns the ratio of the peak to peak-to-average for the selected quantity.
pkp2pk	Peak to peak. Difference between max and min of the first parameter over the second parameter. Returns the peak-to-peak value for the selected

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Math Functions	
	simulation quantity.
sum	Returns the sum of the given values.
stddev	Returns the standard deviation of given values.
variance	Calculates the variance of the given values.
XAtYMax	Threshold crossing time: report first time (x value) at which an output quantity crosses YMax.
XAtYMin	Threshold crossing time: report first time (x value) at which an output quantity crosses a user definable threshold.
XAtYVal	Returns the X value at the first occurrence of Y value.
XWidthAtYVal	Returns the X width between the first 2 occurrences of Y value.
YAtXMax	Returns the X value at maximum value of Y.
YAtXMin	Returns the Y value at minimum value of X.
YAtXVal	Returns the Y value at the first occurrence of X value.

Radiation Functions	
lsidelobeX	The 'x' value for the left side lobe: the next highest value to the left of the max value.
lsidelobeY	The 'y' value for the left side lobe: the next highest value to the left of the max value.
rSidelobeX	Returns the X value of right side-lobe occurrence.
rSidelobeY	Returns the Y value of right side-lobe occurrence.
xdb10beamdwidth	Width between left and right occurrences of values 'x' db10 from max. Takes 'x' as argument (3.0 default). To use this function, you need to open the Add Trace Characteristics dialog and select the Radiation category.
xdb20beamwidth	Width between left and right occurrences of values 'x' db20 from max. Takes 'x' as argument (3.0 default) To use this function, you need to open the Add Trace Characteristics dialog and select the Radiation category.

Pulse Width Functions

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

In this table, the functions with the asterisk (*) do not appear on the Range Function drop-down menu. They can still be used via text entry.

pulsefall9010	Returns the pulse fall time of the selected quantity according to the 90%-10% estimate.
pulsefront1090	Returns the pulse front time of the selected quantity according to the 10%-90% estimate.
pulsefront3090	Returns the pulse front time of the selected quantity according to the 30%-90% estimate.
pulsemax	Returns the pulse maximum from the front and tail estimates for the selected quantity.
pulsemaxtime	Returns the time at which the maximum pulse value of the selected quantity is reached.
pulsemin	Returns the pulse minimum from the front and tail estimates for the selected quantity.
pulsemintime	Returns the time at which the minimum pulse value of the selected quantity is reached.
pulsetail50	Returns the pulse tail time of the selected quantity from the virtual peak to 50%.
pulsewidth5050	Returns the pulse width of the selected quantity as measured from the 50% points on the pulse front and pulse tail.
***pwl**	Piecewise Linear.
***pwl_periodic**	Piecewise Linear for periodic extrapolation on x.
***pwlx**	Piecewise Linear x with linear extrapolation on x.
pw_minus	Pulse width of the first negative pulse.
pw_minus_avg	Returns the average of the negative pulse width input stream.
pw_minus_max	Returns the maximum pulse width of the negative pulse of input stream.
pw_minus_min	Returns the minimum pulse width of the negative pulse of input stream.
pw_minus_rms	Returns the rms of the negative pulse width input stream.
pw_plus	Returns the pulse width of the first postive pulse.
pw_plus_avg	Returns the average of the positive pulse width input stream.
pw_plus_max	Returns the maximum pulse width of the positive pulse of input stream.
pw_plus_min	Returns the minimum pulse width of the positive pulse of input stream.
pw_plus_rms	Returns the rms of the positive pulse width input stream.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Overshoot/Undershoot	
Overshoot	Calculates peak overshoot given a threshold value and number of evenly spaced points over entire time range.
Undershoot	Calculates peak undershoot given a threshold value and number of evenly spaced points over entire time range.

TR & DC Functions	
crestfactor	Returns the crest factor (peak/RMS) for the selected simulation quantity.
formfactor	Returns the form factor (RMS/Mean Absolute Value) for the selected quantity.
distortion	Returns the total distortion for the selected simulation quantity and an additional argument frequency, which is the frequency in Hz at which to calculate the fundamental RMS of the simulation quantity.
fundamentalmag	Returns the RMS value of the fundamental frequency for the selected quantity, and an additional argument, Frequency, which specifies the fundamental frequency.
delaytime	Obtains the time from zero to 50% of the target point.
risetime	Obtains the time taken to go from 10% to 90% of target point.
deadtime	Obtains the latest time when the qtyl is within a tolerance of zero.
settlingtime	Returns the latest time at which the value of the selected simulation quantity fell outside its tolerance band. The target value of the quantity and the +/- bandwidth of the tolerance band are the additional arguments.

Error Functions	
iae	Returns the integral of the absolute deviation of the selected quantity from a target value that is entered via the additional argument.
ise	Returns the integral of the squared deviation of the selected quantity from a target value that is entered via an additional argument.
itae	Returns the time-weighted squared deviation of the selected quantity from a target value that is entered via an additional argument.
itse	Returns the time-weighted squared deviation of the selected quantity from a target value that is entered via an additional argument. To use this function, you need to open the Add Trace Characteristics dialog and select the Error category.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

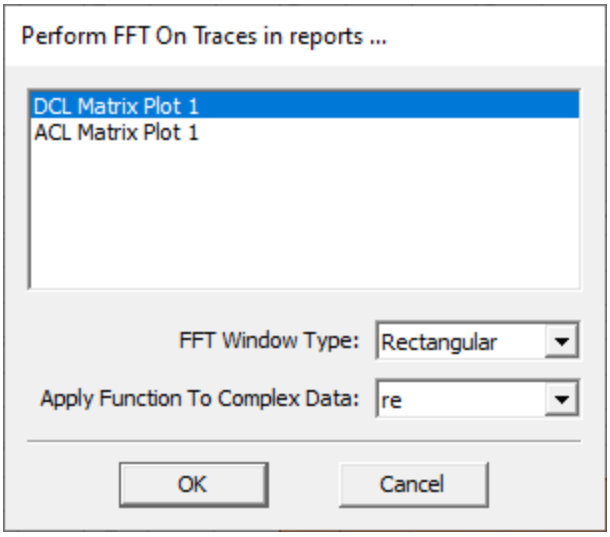
Periodic Functions	
per	Returns the period of a simulation quantity.
pmax	Max period of the selected simulation quantity.
pmin	Minimum period of the selected simulation quantity.
prms	Period Root Mean Square.

AC Functions	
gainmargin	Returns the gain margin in dB at the phase crossover frequency of the selected simulation quantity. It also requires a reference simulation quantity to which the measured quantity is compared and the AC magnitude and phase angle of the reference quantity. These are entered as the arguments Reference Channel, Base Source Magnitude, and Base Source Angle.
gaincrossover	Returns the gain crossover frequency (where the gain is 0 dB) of the selected simulation quantity in Hz.
phasecrossover	Returns the phase crossover frequency, at which the phase is -180 degrees, in Hz for the selected simulation quantity.
phasemargin	Returns the phase angle in degrees at the gain crossover frequency of the selected simulation quantity.
lowercutoff	Returns the lower 3dB frequency of the selected simulation channel in Hz.
uppercutoff	Returns the upper 3dB frequency of the selected simulation channel in Hz.
bandwidth	Returns the 3dB bandwidth of the selected simulation quantity. For bandwidth, the calculation is based on 3dB below the maximum peak.
peakgain	Returns the peak value of gain of the selected simulation quantity in dB.
peakgainfreq	Returns the frequency in Hz at which the peak gain of the selected simulation quantity occurs.

Perform FFT on a Report

You can perform FFT on an existing 2D plot by using the **Results** > **Perform FFT** command. You can perform TDR on an existing 3D plot by using **HFSS** > **Results** > **Perform FFT**. This opens the **Perform FFT on Traces in Reports** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



1. Select the report you want from the list.
2. Select the FFT window type to apply. Winding functions cause the FFT of the signal to have non-zero values away from ω. Each window function trades off the ability to resolve comparable signals and frequencies versus the ability to resolve signals of different strengths and frequencies.
3. Select the function to apply to complex data.

   The new report appears under **Results** in the **Project Manager**. The new report name prefixes FFT to the name of the original report. Trace names are also prefixed with FFT.

FFT Window Functions

The window type list for **Perform FFT on Report** includes:

Window Function	Preferred Use
Rectangular	A low dynamic range function offering good resolution for signals of comparable strength. Poor when signals have very different amplitudes. $w(n)=1$ Tri	A Bartlett window with the endpoints valued at zero.

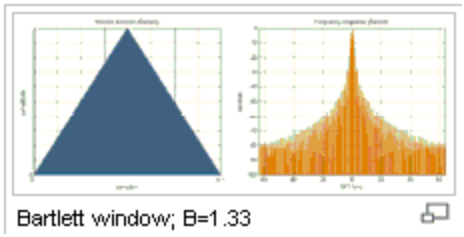
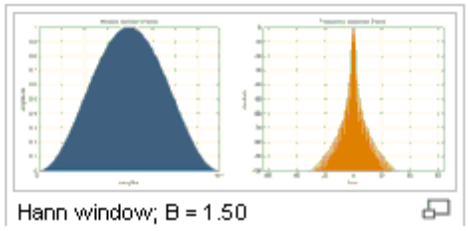
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Window Function	Preferred Use



Van Hann — A moderate dynamic range function, designed for narrow band applications.

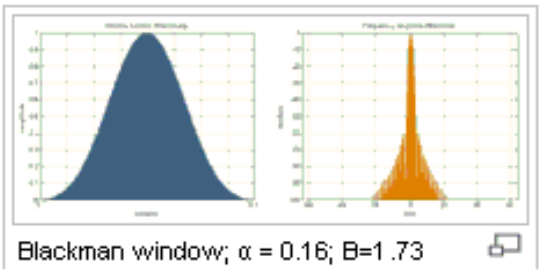
$$w(n) = 0.5(1 - cos\frac{2\pi n}{N-1})$$



Blackman — A high dynamic range function, with lower resolution, designed for wide band applications.

$$w(n) = \alpha_0 - \alpha_1 cos(\frac{2\pi n}{N-1}) + \alpha_2 cos(\frac{4\pi n}{N-1})$$

where $a_0 = (1-\alpha)/2$; $\alpha_1 = 1/2$; $\alpha_2 = \alpha/2$



Hamming — A moderate dynamic range function, designed for narrow band applications. It minimizes the maximum sidelobe.

$$w(n) = 0.54 - 0.46cos\left(\frac{2\pi n}{N-1}\right)$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Window Function	Preferred Use
	 Hamming window; B=1.37
Lanczos	The Lanczos window offers a windowed form of the infinite sinc filter, providing the central lobe of a horizontally stretched sinc, sinc(x/a) for -a £ x £ a.
	 Sinc or Lanczos window; B=1.31
Weber	
Welch	This approach applies a parabola-shaped window to the frequency domain data. It is based on the Bartlett method but splits the signal into overlapping segments, which are then windowed. The intent is to balance the influence of data in the center of the function.

Apply FFT to Report Functions

The choices in the Perform FFT on Traces in Reports dialog include:

ang_deg	**Angle (phase) of a complex number, cut at +/- 180**
ang_deg_val	**Angle (phase of a complex number in unitless degree values. Returns simple numbers.**
ang_rad	**Angle in radians**
arg	
cang_deg	**Cumulative angle (phase) of the first parameter (a complex number) in degrees, along the second parameter (typically sweep**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	variable). Returns a double precision value cut at +/-180.
cang_deg_val	**Cumulative angle (phase) of the first parameter of the selected simulation quantity in unitless degree values. Returns simple numbers.**
cang_rad	**Cumulative angle of the first parameter in radians along a second parameter (typically a sweep variable) Returns a double precision value.**
dB(x)	**20*log10(|x|)**
dB 10normalize	**10*log [normalize(mag(x))]**
dB 20normalize	**20*log [normalize(mag(x))]**
dBc	
GetGroupDelay	
im	**Imaginary part of the complex number**
mag	**Magnitude of the complex number**
normalize	**Divides each value within a trace by the maximum value of the trace. ex. normalize (mag(x))**
re	**Real part of the complex number**

Note:

The evaluated value of an expression is always interpreted in SI units. However, when an angle quantity is plotted in a report, you have the option to plot values in units other than SI. If you want to plot the polar angle of a complex simulation result, S_{11} say, you can choose between ang_deg(S_{11}) and ang_rad(S_{11}). Both of these return the exact same angle quantity but in degree and radian units respectively.

Note that when used in expressions, some surprising outcomes might result. For example, the expression "1+ang_deg(S_{11})" represents an ‘angle’ and the number "1" is treated as "1 rad". The angle SI unit is attached to any unitless number that is added/subtracted from an angle value. If you want to treat "1" as degrees, make it explicit and use "1deg + ang_deg(S_{11})" instead.

If you are interested in unitless degree values, two additional functions exist: ang_deg_val(S_{11}) and cang_deg_val(S_{11}). These return simple numbers and are treated as such by any expression. If the complex S_{11} lies on the positive Y axis say, ang_deg_val (S_{11}) would be 90 and "1 + ang_deg_val(S_{11})" will be 91.

Perform TDR on Report

You can perform TDR on an existing 2D plot by using the **Results** > **Perform TDR on Report** command. You can perform TDR on an existing 3D plot by using the **HFSS 3D Layout** > **Results** > **Perform TDR on Report** command. This opens a **Perform TDR on Traces in reports** dialog box.

> **Note:**
>
> The accuracy of the early time TDR results depends on the highest frequencies simulated in the frequency sweep. Use the **Time Domain Calculation** dialog box to set up the frequency sweep. Set the maximum simulation frequency for your desired rise time.

1. Select the report you want from the list in the dialog box.
2. Specify the input signal as **Step** or **Impulse**.
3. Set the **Rise Time**.
4. In the **Type** drop-down menu, select which window type to apply.

   Windowing functions cause the FFT of the signal to have non-zero values away from ω. Each window function trades off the ability to resolve comparable signals and frequencies versus the ability to resolve signals of different strengths and frequencies.
5. To specify a window width, enter a percentage into the **Width (%)** field.
6. If you select the Kaiser function, specify a number in the **Kaiser Parameter**.

The new report displays and appears in the Project tree. The new report name prefixes TDR to the name of the original report. Trace names are also prefixed with TDR.

Window Functions and Time Domain Plotting

HFSS and SIwave allow for time-domain plotting of S-parameters. Often, this feature is used to calculate a step response or time-domain reflectometry (TDR) plot of the structure being simulated. Fourier analysis provides the mathematical mechanism for transforming frequency sweep data to a time-domain plot, but two approximations are involved. First, the transform is between two sets of discrete data points, as opposed to continuous waveforms. Second, the frequency sweep data cannot have infinite bandwidth, but must truncate at some upper limit. This section discusses the implications of these approximations, and provide information for successful time-domain plotting.

Note: Frequency sweep data consists only of positive frequencies, but the negative frequencies are simply the complex conjugate of the positive: $S(-f) = S^*(f)$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This is true for any frequency-domain function when the corresponding time-domain waveform is real-valued.

Transforming Frequency- To Time-Domain

It is easier to make generalizations about the effect of finite bandwidth if we have continuous functions. Consequently, we will initially assume our frequency- and time- domain data is continuous, and defer discussion of the effects of discretization until later. With a continuous-time sweep over an infinite bandwidth, we could – at least in principle – calculate a time-domain response by multiplying our sweep data $S(f)$ with the spectrum of a time-domain excitation function and evaluating the inverse Fourier integral:

$$f(t) = \int_{-\infty}^{\infty} S(f)E(f)e^{2\pi jft}df$$

In practice, however, sweep data does not extend to infinite frequencies and is restricted to a bandwidth b. If we simply assume that the spectrum is zero-valued outside of the bandwidth, we can interpret the data as an infinite sweep that has been multiplied by a rectangular “window” function $W(f)$, with a value of 1 within the bandwidth and a value of 0 otherwise.

$$f(t) = \int_{-\infty}^{\infty} W(f)S(f)E(f)e^{2\pi jft}df = \int_{-b}^{b} S(f)E(f)e^{2\pi jft}df$$

This process is illustrated in Fig. 1, assuming that $S(f)$ $E(f)$ corresponds to an ideal unit step function in the time domain. In Fig 1.a, the frequency spectrum is truncated beyond a certain upper limit. Since multiplication in the frequency domain corresponds to convolution in the time domain, this has the effect of convolving the time-domain step with a sinc function – the inverse Fourier transform of the rectangle (Fig 1.b). The final result is an edge with a finite rise time and some oscillation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

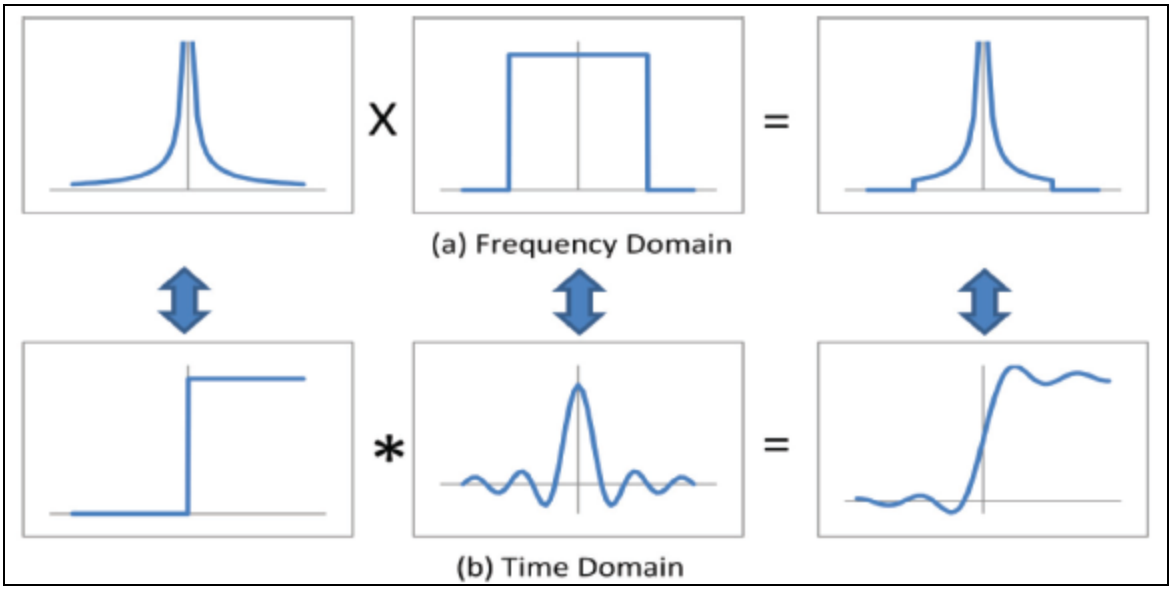

Figure 1. Multiplying the spectrum of a step function with a rectangular window produces a finite edge in the time domain

If the sweep is extended to higher frequencies – making the window function wider – the corresponding sinc pulse more closely approaches an impulse, and the time-domain edge becomes sharper. However, the oscillation never disappears for any finite sweep. Fig. 2 shows a step response for increasingly wider bandwidths.

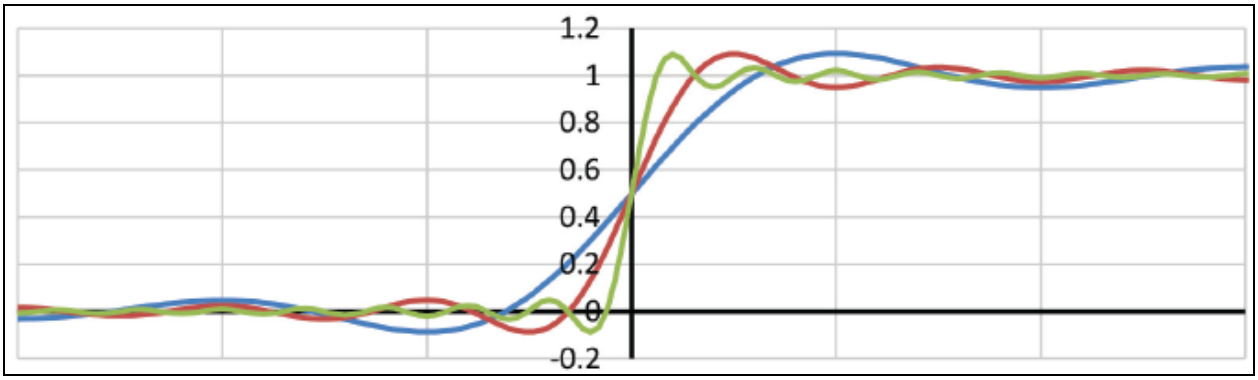

Figure 2. Increasing the width of the rectangular window makes the time-domain edge sharper, but does not eliminate the oscillation

Some distortion of the true time-domain waveform is unavoidable if the frequency sweep does not include the entire bandwidth of the signal, but there are other window functions besides the rectangle which distort the time waveform in ways which may be more desirable. In particular, it

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

would be nice to reduce the spurious oscillation. The next sections will describe the window functions available and discuss their effects.

Window Functions

The window functions available are plotted in Figs. 3 and 4, and their expressions are given in the Appendix. All the window functions have a spectral width *w* and are zero-valued for I*f* I > *w*/2. In addition to truncating the data outside of the bandwidth, the non-rectangular windows filter the spectrum inside. The windows differ from each other in how strongly they attenuate the spectrum as the frequency approaches the upper limit. The Kaiser window has a parameter, which controls how sharply it decays. For $\alpha = 0$, the Kaiser window is equivalent to the rectangular window; for $\alpha = 5.4414$, it is equivalent to the Hamming window; and for $\alpha = 8.885$, the Blackman window.

Although the TDR Options dialog allows for windows that are narrower than the bandwidth of the simulation, it is generally best to set the window width to 100% and take full advantage of the available bandwidth.

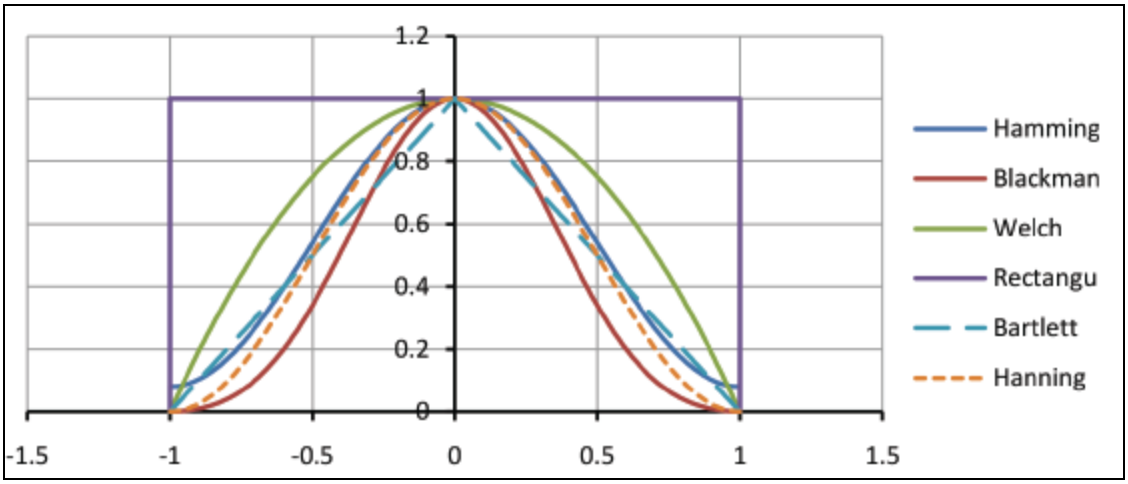

Figure 3. Window functions with a width of *w*=2

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

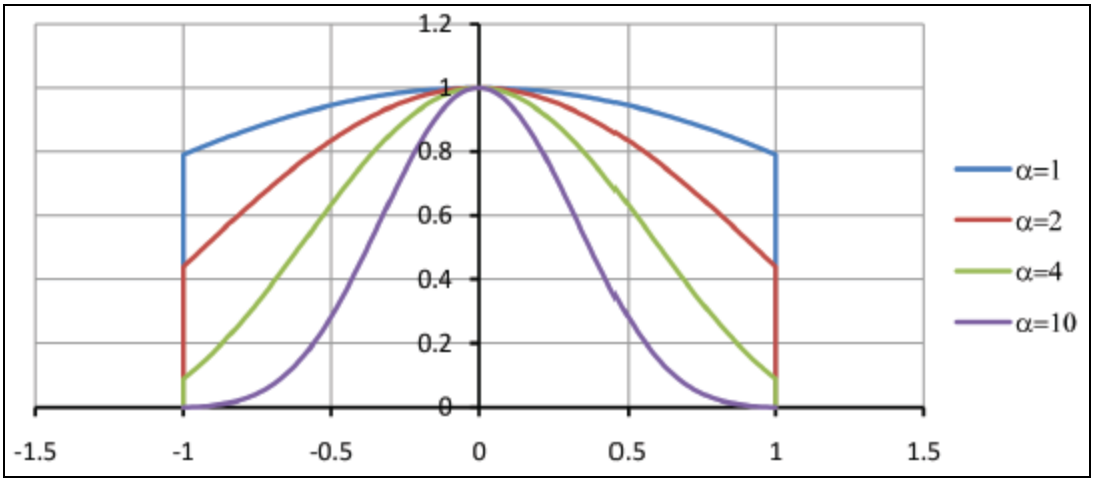

Figure 4. The Kaiser window for a width of *w*=2 and varying values

Because the spectral width *w* includes both positive and negative frequencies, it is twice the bandwidth of the sweep, *b*, which is equal to the (positive) upper frequency limit.

Ideal Step Response

It is immaterial whether we think of the window as multiplying the frequency sweep data, with the spectrum of the time-domain excitation having infinite bandwidth, or if we instead imagine we have infinite sweep data and a windowed excitation spectrum. With the latter interpretation, we can examine the effects of different windows on an ideal step without concern for what the sweep data looks like.

We will apply different windows to an ideal step function, which is approximated in HFSS and SIwave by choosing an edge and setting the rise time to 0. We continue to assume that we have a continuous spectrum, and will defer a discussion of the effects of discretization until later. The effect of the Welch window is shown in Fig. 5.

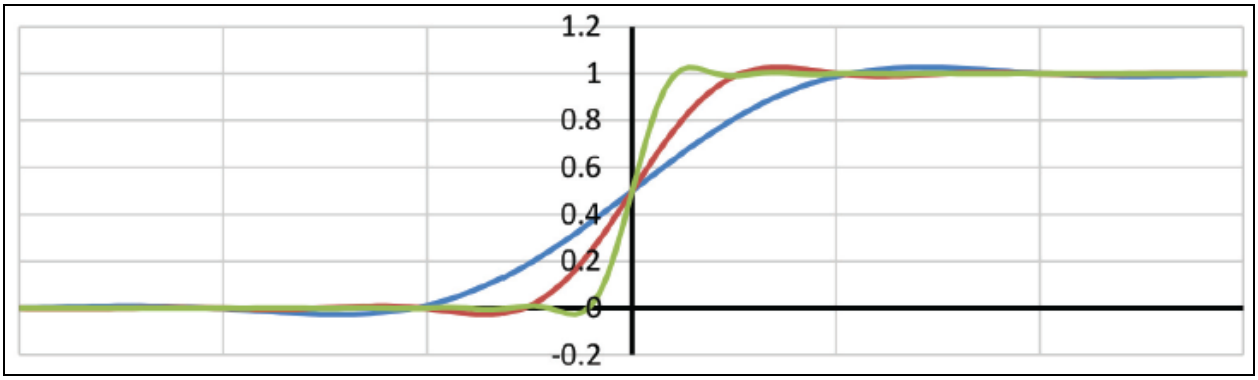

Figure 5. The effect of Welch windows of three different widths on an ideal step

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fig. 5 shows that the Welch window has substantially decreased the signal oscillation that was seen with the rectangular window. As Fig. 6 below demonstrates, the Blackman window results in almost no oscillation.

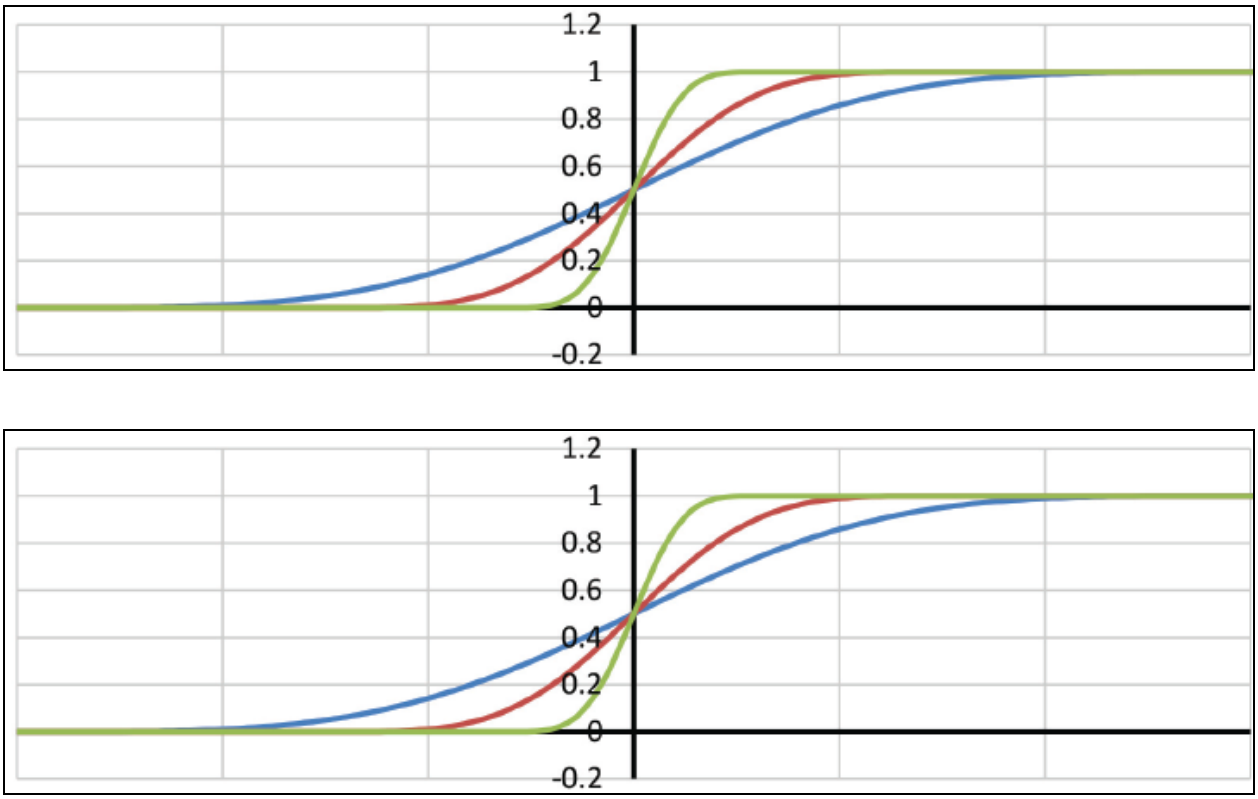

Figure 6. The effect of Blackman windows of three different widths on an ideal step.

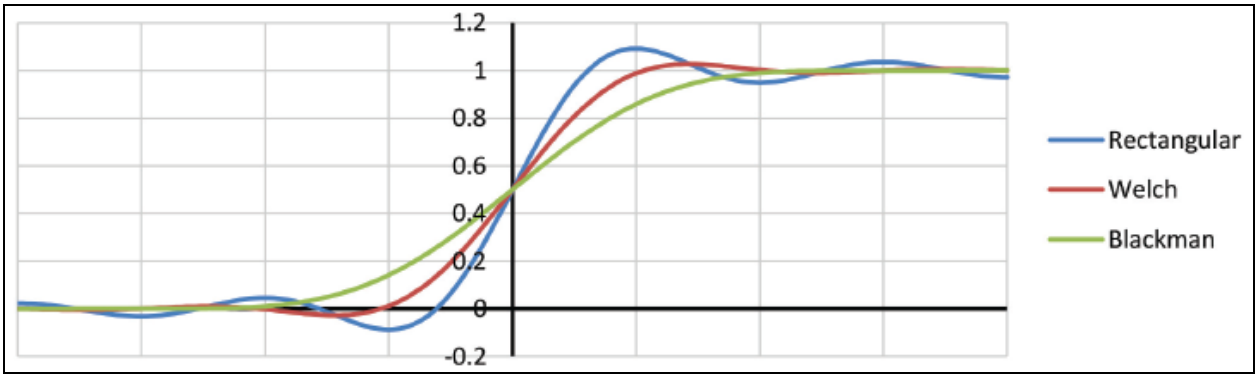

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

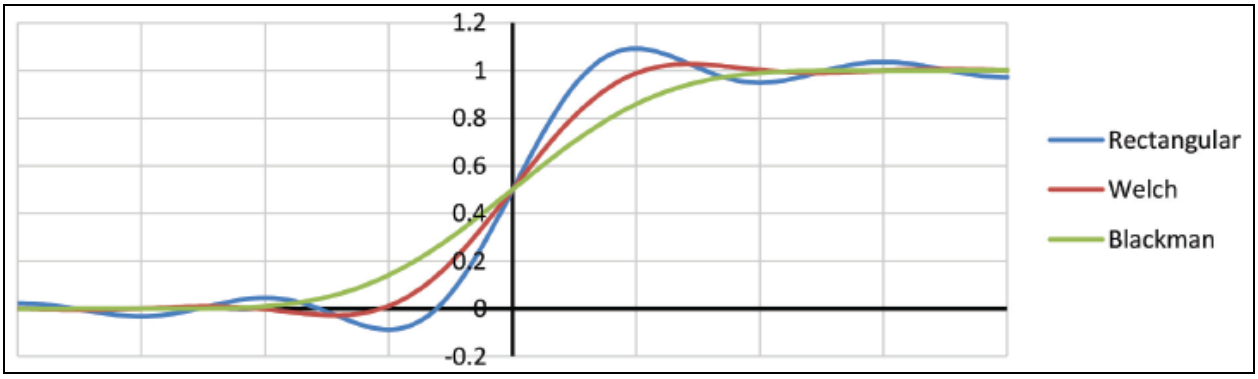

Figure 7. Step response for three different windows, each with the same bandwidth.

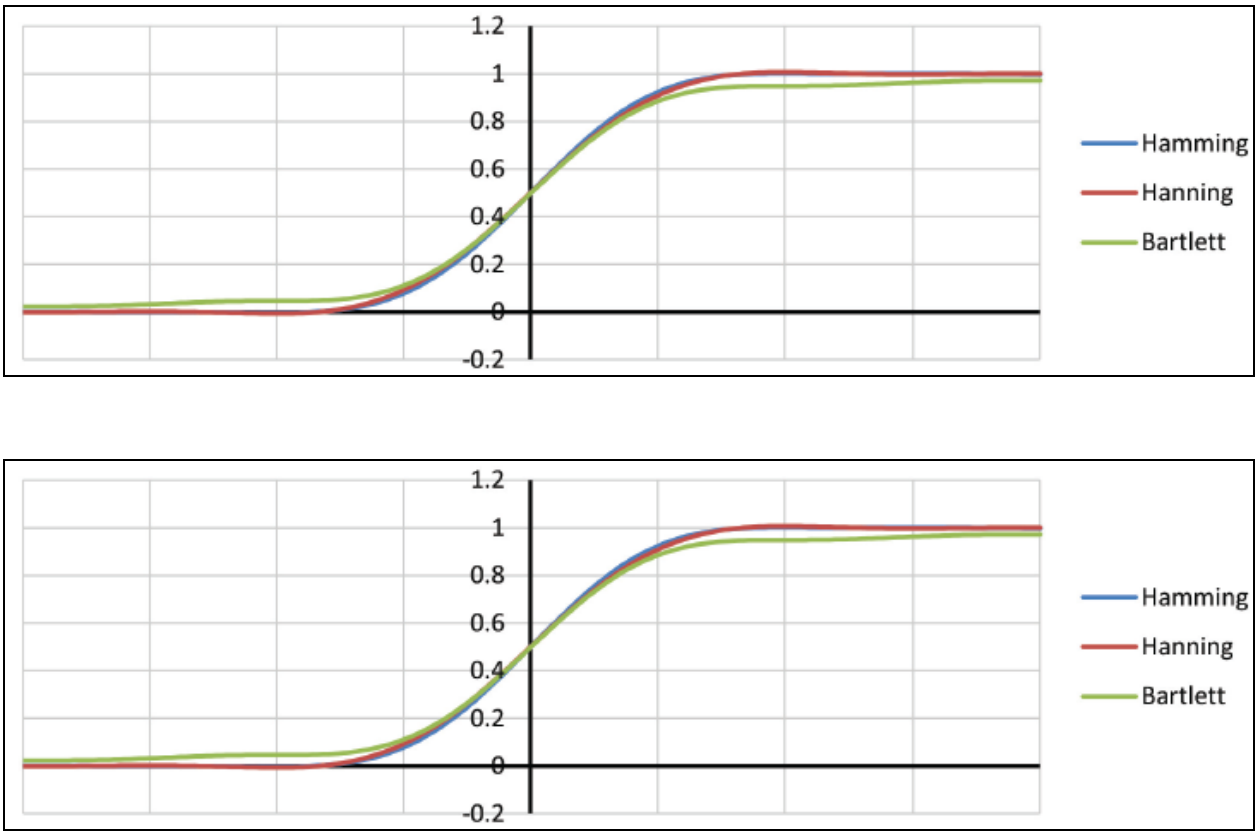

Figure 8. Hamming, Hanning, and Bartlett windows of equal bandwidth

As Fig. 8 suggests, the difference between Hamming and Hanning windows is usually quite small. The Bartlett window is generally not recommended, as it distorts the signal in the vicinity of the edge without providing any advantage over the Hamming and Hanning windows. The Kaiser window gives edges that are slower and less oscillatory with increasing α.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The rectangular, Welch, Hanning, and Blackman windows are sufficient to provide a good sampling of the edge-rate vs. oscillation tradeoff. Table 1 quantifies the characteristics of these windows on an ideal step. With the exception of the Blackman window, it is possible to derive reasonably simple expressions for the step response. In Table 1, *b* is the bandwidth or upper frequency limit of the sweep and Si(χ) refers to the sine integral function:

$$\mathrm{Si}(x) = \int_0^x \frac{\sin z}{z} dz$$

Table 1. Characteristics of selected window functions for continuous time.

Window	*Step Response* $f_s(t)$	*10-90 Edge Rate*	*Max Overshoot*
Rectangular	$\frac{1}{2} + \frac{\mathrm{Si}(2\pi bt)}{\pi}$	$\frac{0.45}{b}$	8.95%
Welch	$\frac{1}{2} + \frac{\cos(2\pi bt)}{2\pi^2 bt} - \frac{\sin(2\pi bt)}{4\pi^3 b^2 t^2} + \frac{\mathrm{Si}(2\pi bt)}{\pi}$	$\frac{0.70}{b}$	2.70%
Hanning	$\frac{2\pi + 2\mathrm{Si}(2\pi bt) - \mathrm{Si}(\pi - 2\pi bt) + \mathrm{Si}(\pi + 2\pi bt)}{4\pi}$	$\frac{0.97}{b}$	0.64%
Blackman	--	$\frac{1.19}{b}$	0.02%

Note that in the expressions for the step response, the time variable is always multiplied by the bandwidth. Changing the bandwidth scales the time response, but does not affect the shape of the edge.

Finite Edge Response

Finite edges can be simulated by providing a nonzero value for the rise time. For finite edges, the same edge rate vs. oscillation tradeoff applies. However, the spectrum of a finite edge declines with frequency at a faster rate than an ideal step. As a result, modest amounts of overshoot can be achieved even with a rectangular window. The continuous time finite edge response of a rectangular window is given by

$$f_e(t) = \frac{1}{2} - \frac{\mathrm{Si}\big(2\pi b(r-t)\big)}{\pi} + \frac{\cos(2\pi bt) - \cos\big(2\pi b(r-t)\big) + 2\pi bt\left(\mathrm{Si}\big(2\pi b(r-t)\big) + \mathrm{Si}(2\pi bt)\right)}{2\pi^2 br}$$

The value of the edge response at $t = 0$ is given by

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$f_e(0) = \frac{1}{2} + \frac{1 - \cos(2\pi br)}{2\pi^2 br} - \frac{\mathrm{Si}(2\pi br)}{\pi}$$

Along with the overshoot, f_e (O) is a useful metric for describing how closely the finite edge response approximates the ideal case, for which f_e (O) = O. The degree to which the windowed edge approximates an ideal finite edge depends only on *br*, the dimensionless product of the bandwidth and the rise time (Fig. 9).

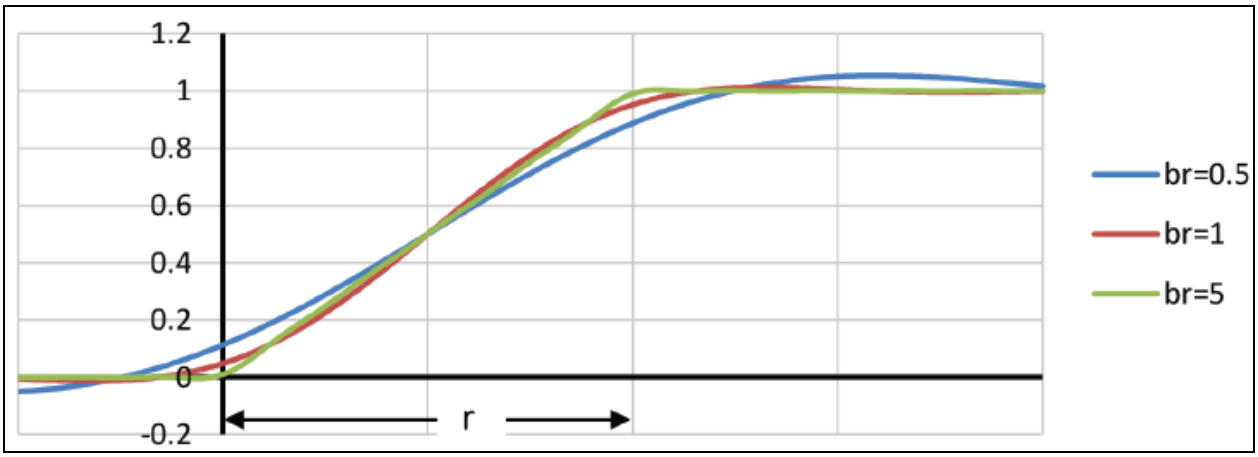

Figure 9. The effect of rectangular windows on edges with rise time *r*. The *y*-intercept and overshoot decline with increasing bandwidth *b*.

Table 2 below quantifies these relationships.

Table 2. Finite edge response for rectangular windows for continuous time

*Bandwidth*Risetime (br)*	*Edge Response at t = 0*	*Max Overshoot*
0.5	0.113	5.34%
0.75	0.056	2.41%
1	0.049	1.19%
2	0.025	0.72%
3	0.017	0.51%
5	0.010	0.32%
10	0.005	0.17%

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

As Fig. 9 and Table 2 show, a fairly good finite edge can be achieved with a *br* of 1, but a *br* of around 5 is needed to give a very close approximation to the ideal finite edge.

Impulse Response

The principles behind the step and edge responses also apply to the calculation of impulse responses. Rectangular windows produce the sharpest impulses, but with the greatest amount of oscillation. Hanning and Blackman windows produce impulses that are more spread out, but with less oscillation (Fig. 10).

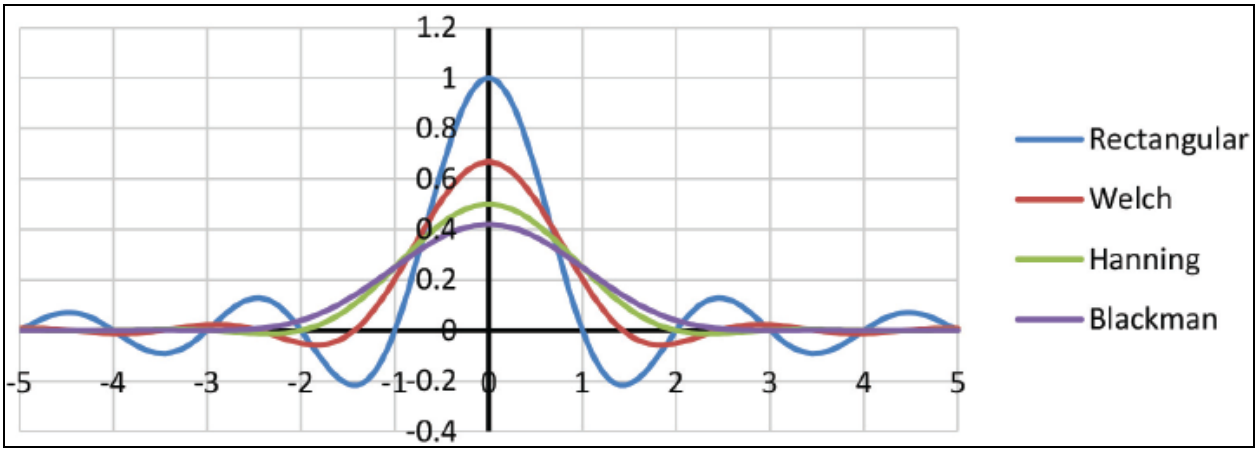

Figure 10. The impulse response for selected windows with a spectral width of 1

Discrete Time Domain Plotting

The preceding discussion treated frequency spectra as continuous functions, but in practice both the frequency and corresponding time data will be discrete. HFSS uses a discrete Fourier transform (DFT) to approximate a continuous time transform, with the frequency step size and upper limit determining the corresponding quantities in the time domain. The default time step and maximum time are given by

$$t_{step} = \frac{1}{2f_{max}} \qquad t_{max} = \frac{1}{2f_{step}}$$

Time resolution is controlled by the upper frequency in the sweep. The maximum time is controlled by the frequency resolution of the sweep. While t_{max} is fixed by the choice of frequency step and cannot be increased after the simulation, t_{step}, or the time delta, can be reduced from the default value within the **TDR Options** dialog box. Decreasing the time delta does not increase the bandwidth of the frequency data, but it does more closely approximate the band-limited continuous time spectra we have so far discussed. Although decreasing the time

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

delta will increase the time required to perform the DFT, the time required is rarely significant. Additionally, a smaller time delta has a significant benefit, as demonstrated in Fig. 11 below.

Fig. 11 shows the step response of a matched lossless transmission line for which the length is controlled by de-embedding the driving waveport, using rectangular window functions. The plots on the left are for a short transmission line length and those on the right correspond to a longer length. Fig. 11a shows the time response using the default values for t_{step}. There is some oscillation in the response, which is expected for a rectangular window, but the amplitude of the oscillation is different for the two length cases. This is problematic; since the line is matched and lossless, we expect that a length change will only affect the time delay of the response, not affect the shape or quality of the rising edge. The variation in the response is an undesirable artifact of the coarse time sampling. We can increase resolution by increasing the bandwidth of the sweep, but this requires additional simulation. Fig. 11b shows the same two cases, but with the time delta reduced using the TDR Options dialog box. The results in Fig. 11b agree with our intuition: the edge shape is the same for both line lengths and the only difference is the location of the edge. Setting the time delta to around 1/5 of the default value is generally sufficient, but finer time steps are needed for precise correlation to Tables 1 and 2.

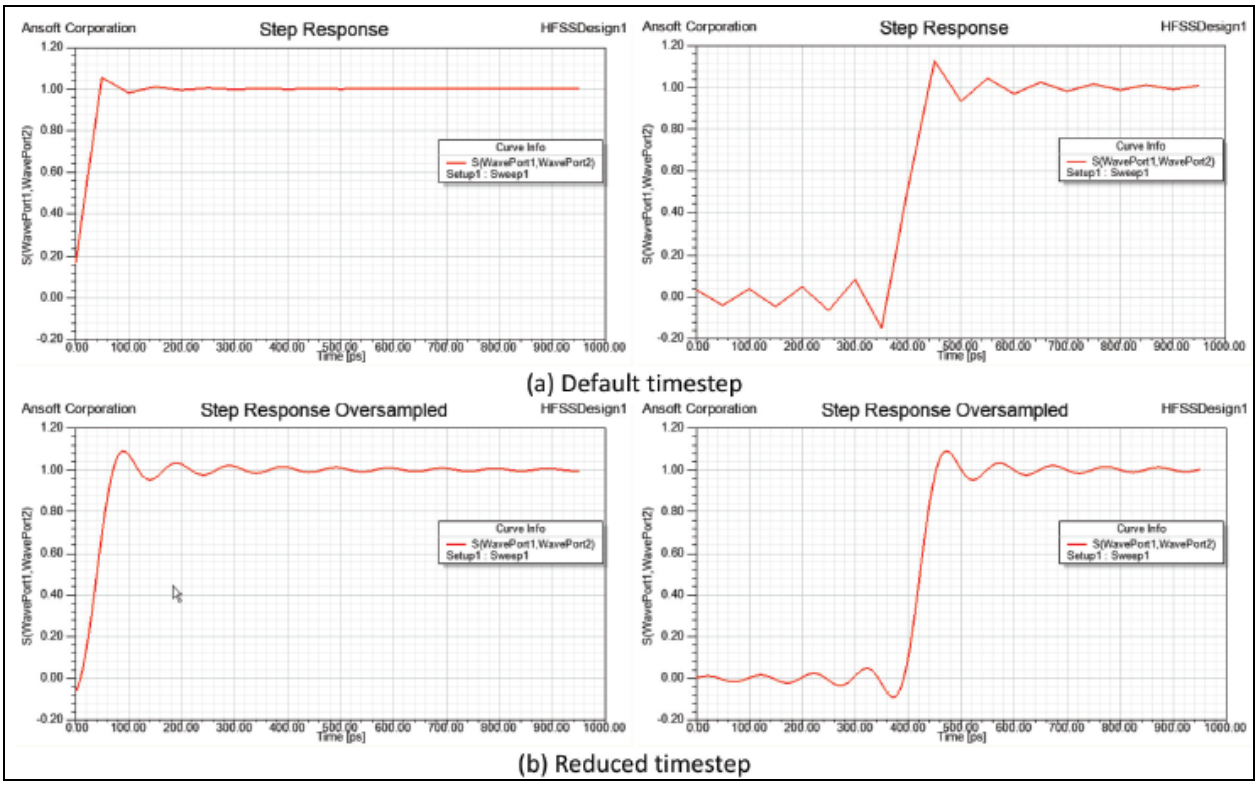

Figure 11. The time domain response of an ideal delay of two different lengths shows that a finer time sampling yields more intuitive results.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The frequency step size governs the length of the time range generated. Although a coarse frequency sampling is often sufficient to generate enough time data for a TDR plot, it is important not to set f_{step} too high in the frequency sweep. Discrete frequency spectra necessarily correspond to periodic time-domain functions, so the calculated step is actually more like a repeating series of long pulses. Fig. 12 shows the how the oscillation decays after the rising edge up to a point, but then begins increasing in anticipation of a falling edge.

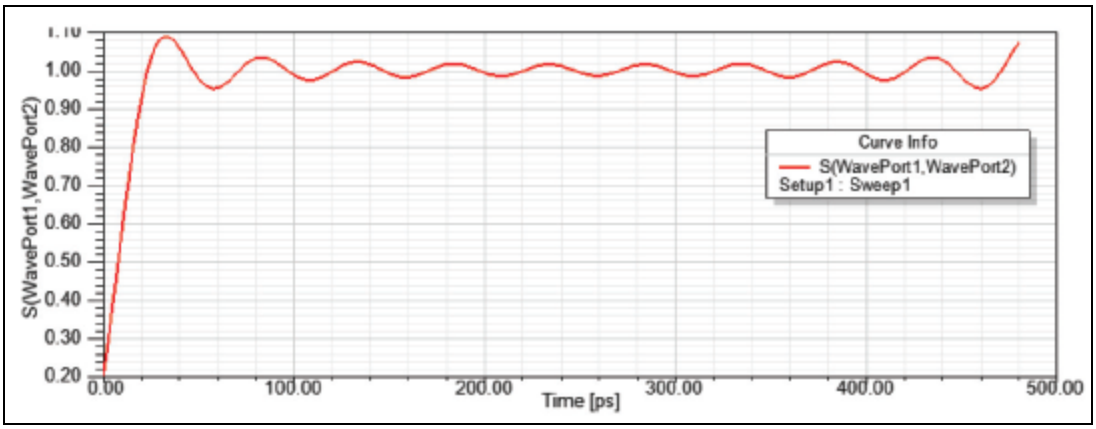

Figure 12. The oscillation caused by a rectangular window eventually starts increasing, due to the periodicity of the waveform

Setting f_{step} to a small value increases the length of the pulse, and minimizes the influence of the future falling edge. Additionally, a smaller f_{step} ensures that resonances and other sharp features in the frequency data are adequately captured. As t_{step} and f_{step} approach zero, the calculated results will converge on the continuous time descriptions given earlier.

Applications

When simulating a TDR plot, we want the fastest edge possible for the bandwidth of our simulation, subject to our preference for oscillation control. Therefore an edge with a rise time of zero is a good choice. Fig. 13 shows TDR plots of a transmission line with several impedance discontinuities. The results for a rectangular and Hanning window with a 20GHz bandwidth are compared with those for a Hanning window with a 50GHz bandwidth, which will necessarily be more accurate due to the higher bandwidth, and can be used as a reference. In all cases, the time step was set substantially lower than the default.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

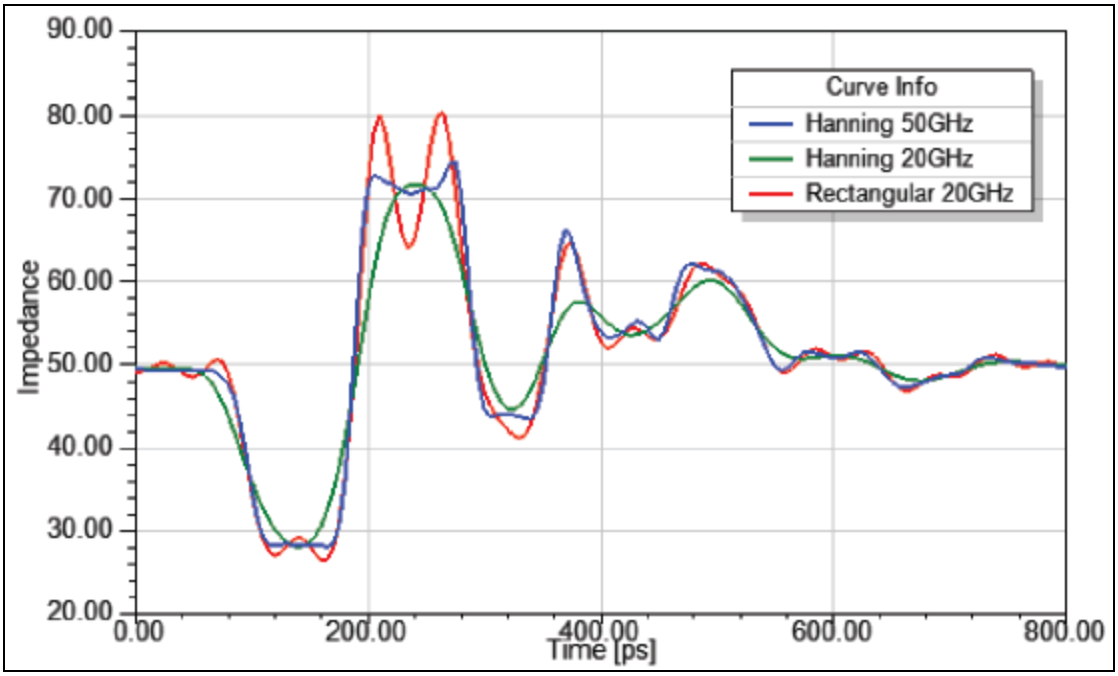

Figure 13. TDR plots for a transmission line with several impedance discontinuities

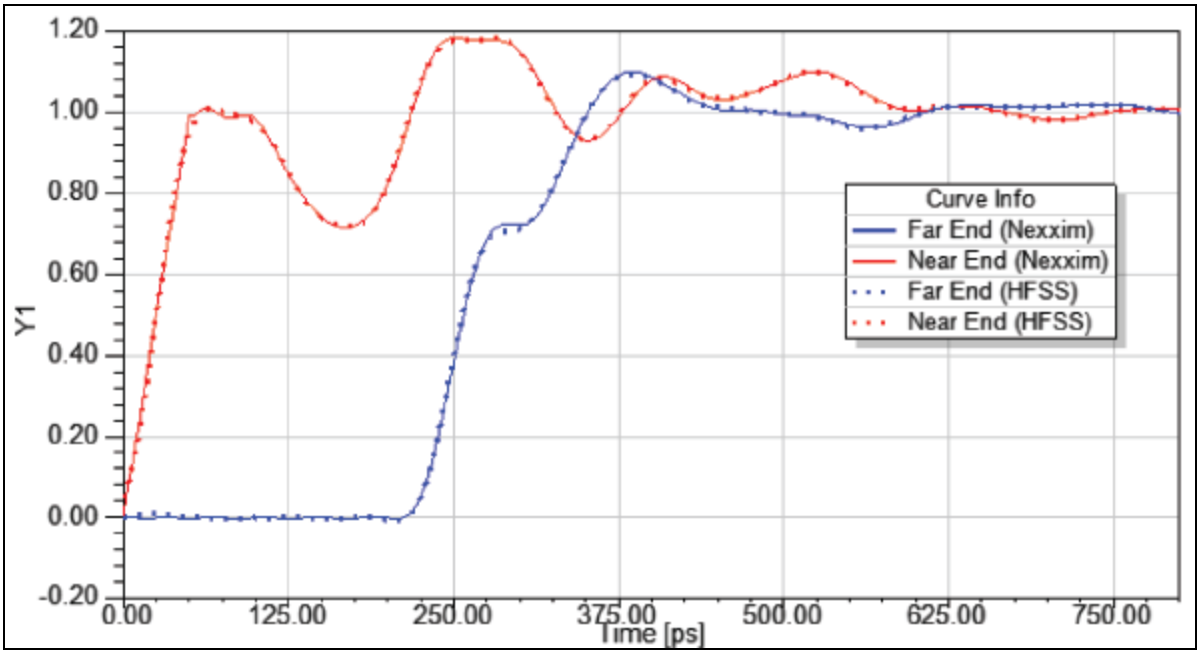
Fig. 13 shows that the rectangular window effectively captures the sharp impedance transitions, but also displays spurious oscillation. The 20GHz Hanning window does not suffer any oscillation, but gives less resolution on the sharp edges. These results are consistent with the step response characteristics of the different windows we have previously shown.

We can also use time-domain plotting to approximate how a structure would behave in a Nexxim transient simulation. When comparing the results to a transient simulation that uses a pulse or piecewise linear source, it makes sense to use a finite edge with a rectangular window. Fig. 14 compares HFSS and Nexxim results for the transmission line, using a rise time of 50ps and a rectangular window with a 20GHz bandwidth *(br* = 1).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



As Fig. 14 shows, very good agreement between Nexxim and HFSS is possible when appropriate settings are used for time domain plotting.

Animated Reports

The following sections describe how you can postprocess field overlay displays to create and then view various animated reports. Any of the field overlay displays can be animated by cycling the overlays as a series of frames. Refer to the following topics for details on creating the field overlays:

- Overlaying Surface Currents on a 3D View
- Overlaying Far Fields on a 3D View
- Overlaying Near Fields on a 3D View

There are two modes of animation: frequency-based and phase-based. Frequency-based animation creates a series of frames by calculating the field overlay at each of the swept frequencies. Phase-based animation creates a series of frames by calculating the field overlay at a fixed set of phase deviations around a selected frequency. The animation controls can also change the simulation design point.

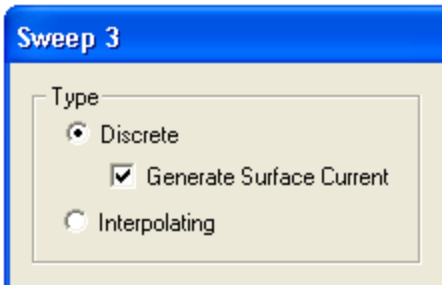
Overlaying Surface Currents on a 3D View

Surface currents calculated as the results of a simulation can be displayed as overlays on the 3D viewer.

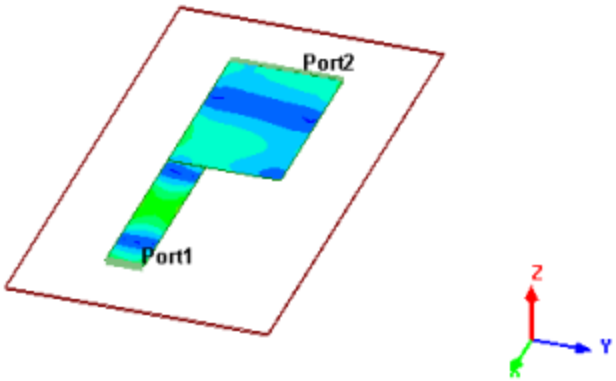
1. To ensure that the surface current information is generated, the sweep setup must specify a **Discrete** frequency sweep, and the **Generate Surface Current** option must be enabled

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(checked):

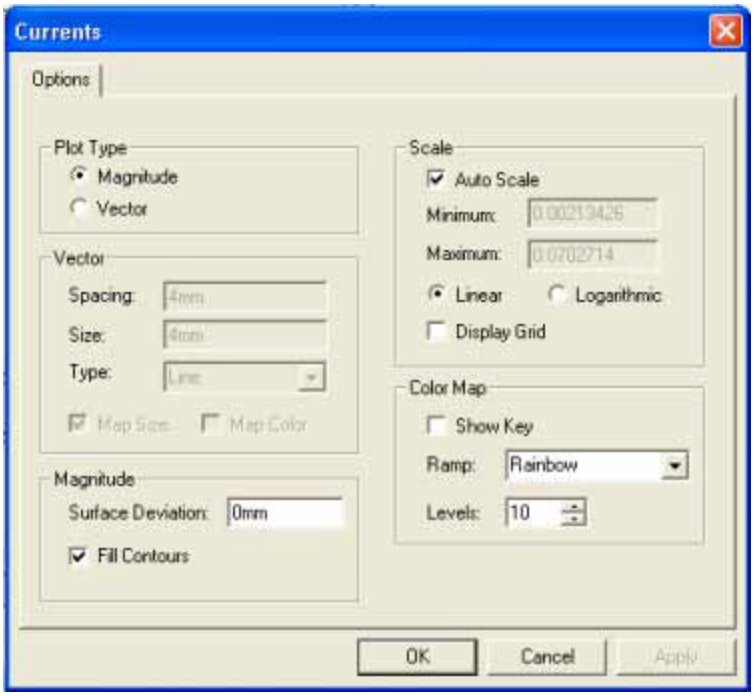


2. Run the analysis with the sweep.
3. To display the surface current as an overlay, expand the **Analysis** icon in the Project window, and select **Setup***m* > **Sweep***n* > **Results** > **Display Currents** (*m* and *n* identify the particular solution setup and sweep setup, respectively). You can also select from a list of corresponding Setup/Sweep overlay choices which are displayed when you right-click **Field Overlays** in the **Project** tree. The 3D viewer window appears with the current values overlaid on the geometry:



4. To change the display properties of the surface current overlay, expand the **Results** icon in the Project window, and select **Setup***m*:**Sweep***n*:**Currents***k* > **Properties** (*m*, *n*, and *k* identify the particular solution setup, sweep setup, and surface current setup, respectively). The **Currents** dialog opens:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In the **Plot Type** panel, select **Magnitude** to enable the **Magnitude** panel options or select **Vector** to enable the **Vector** panel options.

In the **Scale** panel, select **Auto Scale** (the default), or deselect **Auto Scale** and enter custom **Minimum** and **Maximum** scaling values. Select **Linear** or **Logarithmic** scaling (the default is **Linear**), and toggle **Display Grid** on or off (the default is off).

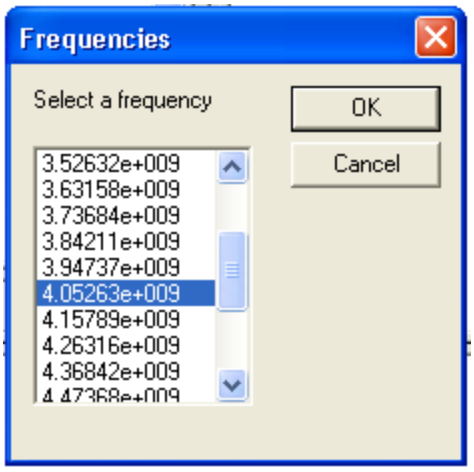
In the **Color Map** panel, select the **Ramp** type (**Rainbow** is the default; other options are **HueScale**, **Magenta**, and **Temperature**), set the number of **Levels** (the default is 10 levels), and toggle the color key (**Show Key**) on and off (the default is off).

Click **Apply** to apply any changes to the display without closing the dialog box. Click **OK** to apply any changes and close the dialog box. Click **Cancel** to close the dialog without changing any options.

5. To select the frequency for the current overlay, expand the **Results** icon in the Project window, and select **Setup***m***:Sweep***n***:Currents***k* > **Frequency** (*m*, *n*, and *k* identify the particular solution setup, sweep setup, and surface current setup, respectively). The

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Frequencies dialog opens:



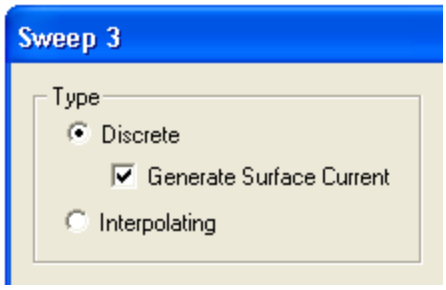
The list displays the frequencies that were swept in the analysis. When you select a frequency from the list, the overlay displays the surface current values calculated at that frequency. Click **OK** to leave the overlay at the selected frequency, or click **Cancel** to close the dialog without applying any frequency changes to the overlay.

6. To dismiss the overlay, expand the **Results** icon in the Project window, right-click **Setup***m*:**Sweep***n*:**Currents***k*, and select **Delete** from the drop-down menu **s** (*m*, *n*, and *k* identify the particular solution setup, sweep setup, and surface current setup, respectively).

Overlaying Far Fields on a 3D View

Far fields calculated as the results of a simulation can be displayed as overlays on the 3D viewer.

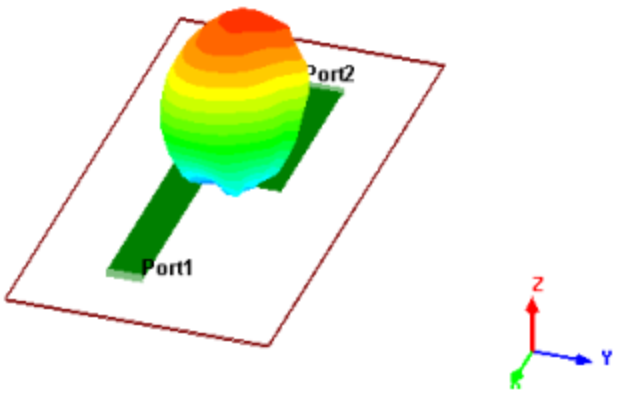
1. To ensure that the far field information can be generated, the sweep setup must specify a **Discrete** frequency sweep, and the **Generate Surface Current** option must be enabled (checked):



2. Run an analysis with the sweep.

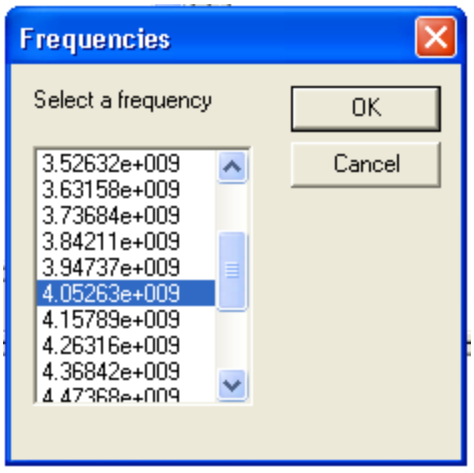
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. To display the far field as an overlay, expand the **Analysis** icon in the Project window, and select **Setup***m* > **Sweep***n* > **Results** > **Far Field** (*m* and *n* identify the particular solution setup and sweep setup, respectively). You can also select from a list of corresponding Setup/Sweep overlay choices which are displayed when you right-click **Field Overlays** in the **Project** tree. The 3D viewer window appears with the far field values overlaid on the geometry:



The display properties of the Far Field overlay cannot be changed. The Ramp type is Rainbow, and the number of levels is 20.

4. To select the frequency for the far field overlay, expand the **Results** icon in the Project window, and select **Setup***m*:**Sweep***n*:**Far Field***k* > **Frequency**. The **Frequencies** dialog opens:



The list displays the frequencies that were swept in the analysis. When you select a frequency from the list, the overlay displays the far field values calculated at that frequency.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

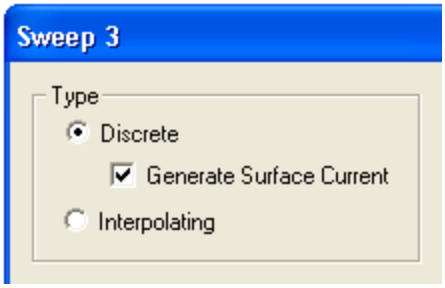
Click **OK** to leave the overlay at the selected frequency, or click **Cancel** to close the dialog without applying any frequency changes to the overlay.

5. To dismiss the overlay, expand the **Results** icon in the Project window, right-click **Setup*m*:Sweep*n*:Far Field*k***, and select **Delete** from the drop-down menu (*m*, *n*, and *k* identify the particular solution setup, sweep setup, and far field setup, respectively).

Overlaying Near Fields on a 3D View

Near fields calculated as the results of a simulation can be displayed as overlays on the 3D viewer.

1. To ensure that the near field information can be generated, the sweep setup must specify a **Discrete** frequency sweep, and the **Generate Surface Current** option must be enabled (checked):

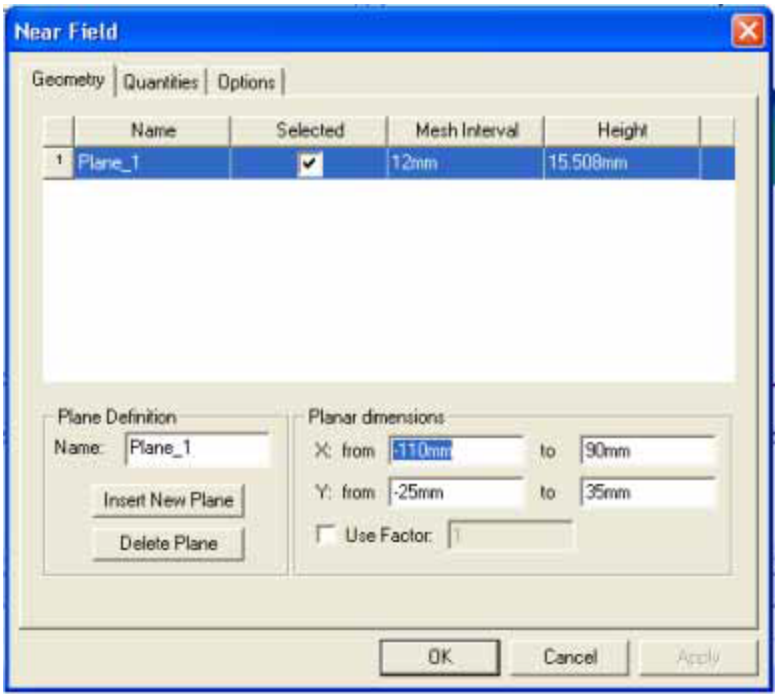


2. Run the analysis with the sweep.
3. To display the near field overlay, expand the **Analysis** icon in the Project window, and select **Setup*m*** > **Sweep*n*** > **Results** > **Near Field** (*m* and *n* identify the particular solution setup and sweep setup, respectively). You can also select from a list of corresponding Setup/Sweep overlay choices which are displayed when you right-click **Field Overlays** in the **Project** tree.
4. The **Near Field** dialog opens. The dialog has three tabs, described below. At the bottom of each tab are three buttons:

- **Apply** is activated whenever you change a value. Click **Apply** to start the display, and then to see the effect of each change. The dialog stays open.
- When no values were changed on any tab, the **OK** button starts the display. When one or more values have been changed, **OK** applies the changes. In either case, **OK** closes the dialog and adds an icon for the overlay under the **Results** icon in the Project window.
- **Cancel** is active as long as no changes have been applied. **Cancel** closes the dialog without changing any values. If the overlay is already displayed, it does not change. If **Cancel** is pressed before any overlay is displayed, the overlay is canceled.

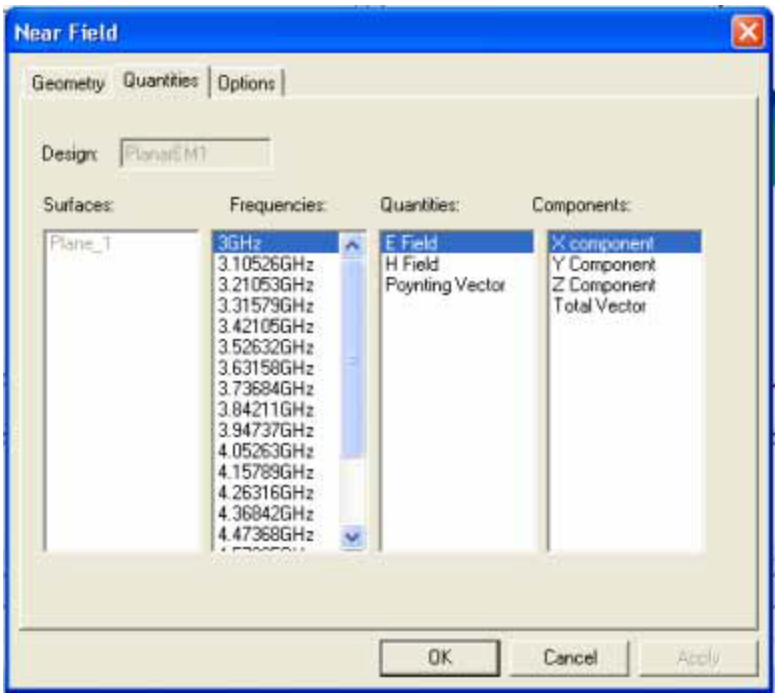
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. The **Near Field** dialog opens with the **Geometry** tab displayed:



Use the options in the **Geometry** tab to select (or define) one or more planes for the calculation, including the dimensions to be used, and a scale factor if desired.

Use the **Quantities** tab to select the near field quantity to be calculated:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

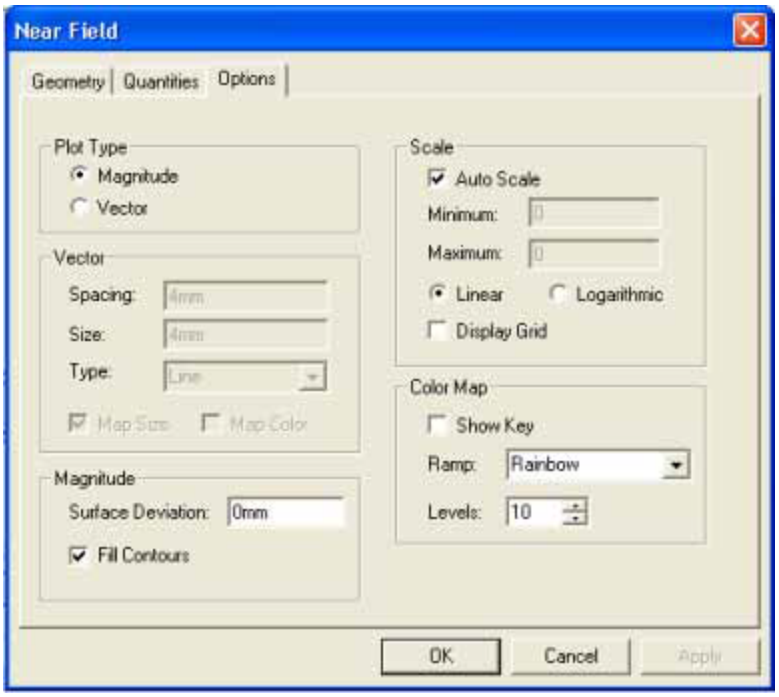
When more than one surface is involved, select a surface from the **Surfaces** list.

Select a frequency from the **Frequencies** list. The frequencies are the ones swept in the analysis.

Select a field type from the **Quantities** list. **E** is the electronic field, **H** is the magnetic field, and the **Poynting Vector** is the (E×H*) field, where H* is the complex conjugate of the H matrix.

Select a vector component from the **Components** field.

Use the **Options** tab to specify the display options for the near field overlay:



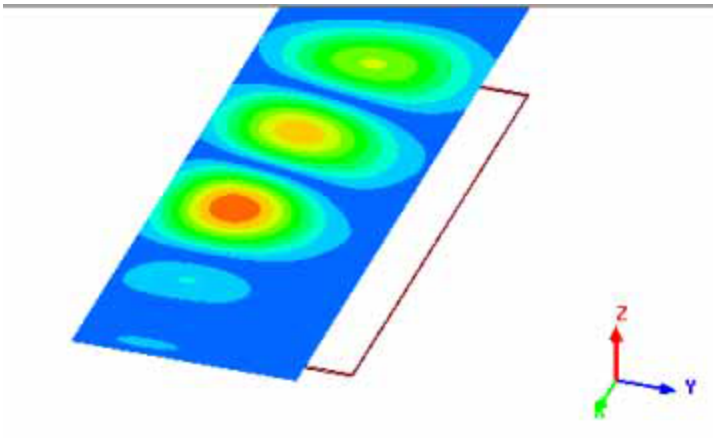
In the **Plot Type** panel, select **Magnitude** to enable the **Magnitude** panel options or select **Vector** to enable the **Vector** panel options.

In the **Scale** panel, select **Auto Scale** (the default), or deselect **Auto Scale** and enter custom **Minimum** and **Maximum** scaling values. Select **Linear** or **Logarithmic** scaling (the default is **Linear**), and toggle **Display Grid** on or off (the default is off).

In the **Color Map** panel, select the **Ramp** type (**Rainbow** is the default; other options are **HueScale**, **Magenta**, and **Temperature**), set the number of **Levels** (the default is 10 levels), and toggle the color key (**Show Key**) on and off (the default is off).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. When you click **Apply** or **OK** in any of the **Near Field** dialog tabs, the 3D viewer window appears with the near field values overlaid on the geometry:



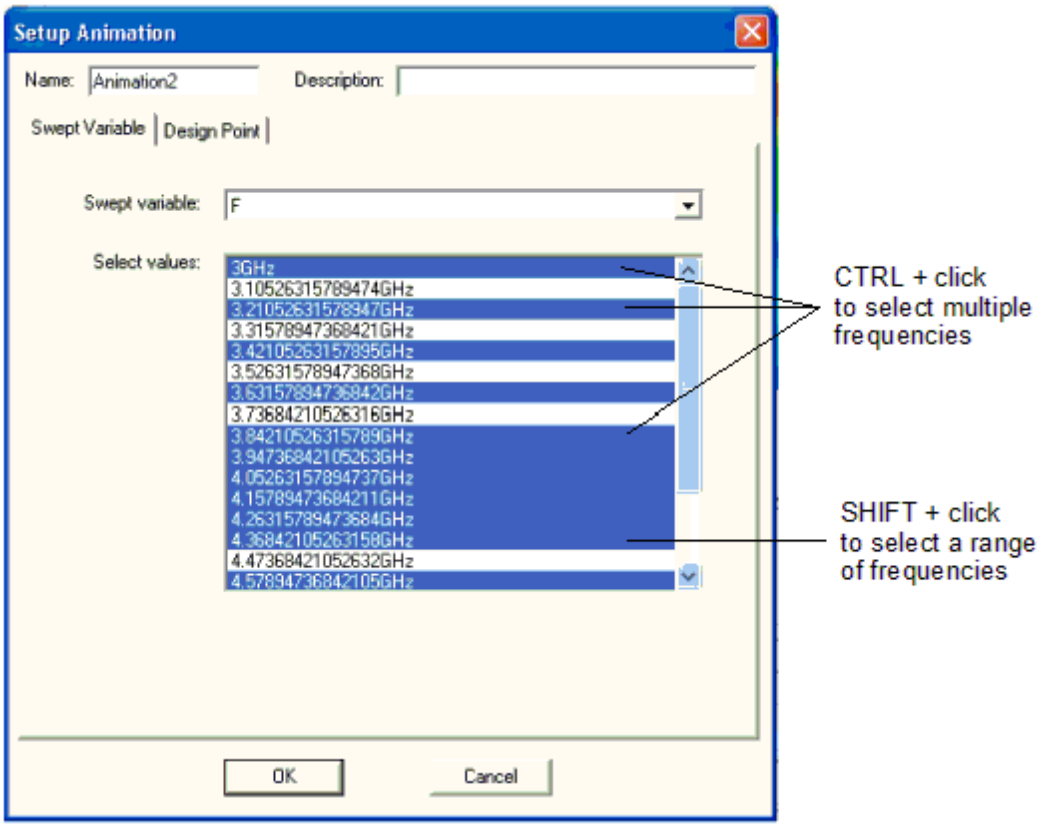
7. To dismiss the overlay, expand the **Results** icon in the Project window, right-click **Setup*m*:Sweep*n*:Near Field*k***, and select **Delete** from the drop-down menu.

Frequency Animation

1. To initiate the animation of the overlay that is currently displayed, do one of the following:
   - Select **Animate** from the **View** menu.
   - Expand the **Results** icon in the Project window, right-click the overlay entry, and select **Animate** from the menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. If no animations have been defined previously, the **Setup Animation** dialog opens:



- Specify a name in the **Name** field (or accept the default, **Animation***n*, where *n* is a numeral). Optionally, enter a description.
- For a frequency animation, select **F** as the **Swept Variable**.
- By default, all the frequencies are selected (highlighted). Hold down the Ctrl key to select multiple individual frequencies, or hold down the Shift key to select a contiguous range of frequencies. [These selection modes are illustrated in the dialog example above].
- Click **OK**.

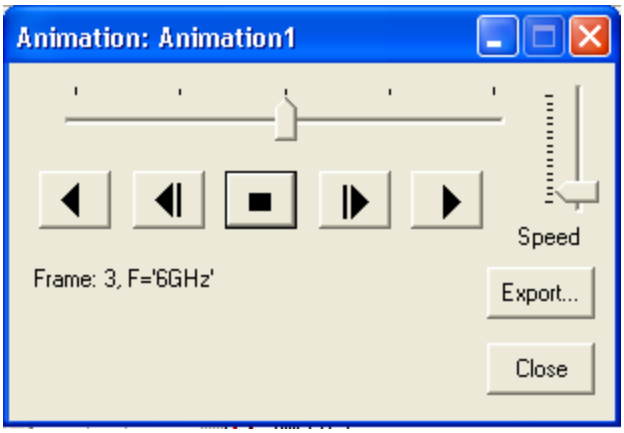
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If one or more animations have been defined, selecting **Animate** from one of the menus opens the **Select Animation** dialog:

The **Select Animation** dialog provides the following operations:

- Click to select one of the animations and click **OK** to start that animation.
- Click **New** to open the **Setup Animation** dialog described above, and close the **Select Animation** dialog.
- Select an animation and click **Delete** to delete the definition.

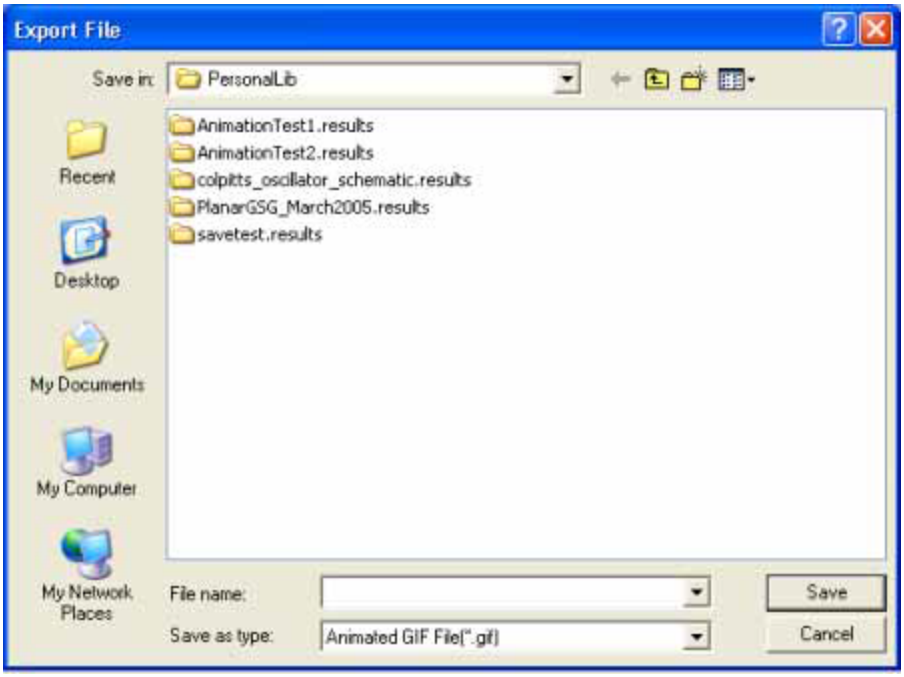
3. The frame data is automatically calculated. If the Progress window is displayed, you can monitor the progress of the calculation. When the frames have been calculated, the animation begins and the **Animation** control panel opens:



- Use the “VCR” buttons to play the animation. From left to right, the buttons are **Reverse**, **FastReverse**, **Stop**, **Fast Forward**, and **Forward**. The indicator at the top of the dialog shows the progress of the animation. Use the **Speed** slider to control the speed of the animation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To export the frame data to a file, click **Export**. The **Export File** dialog opens:



Specify the directory and file name. Use the **Save as type** menu to select the file format (Animated GIF or AVI). Click **Save** to save the data and close the dialog.

- Click **Close** on the **Animation** control panel to stop the animation and close the panel.

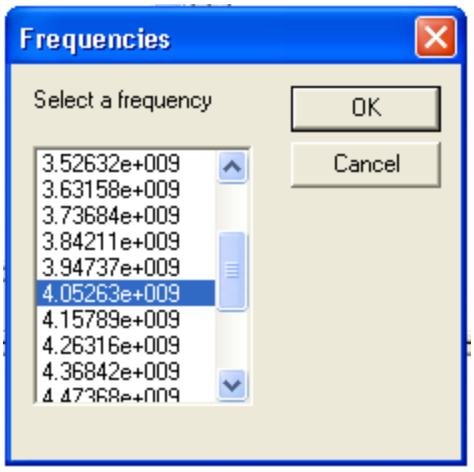
Phase Animation

1. To prepare for phase animation, you must select the base frequency.

- For surface current and far field overlays, expand the **Results** icon in the Project window, right-click the overlay, and select **Frequency** from the menu. The **Frequencies** dialog

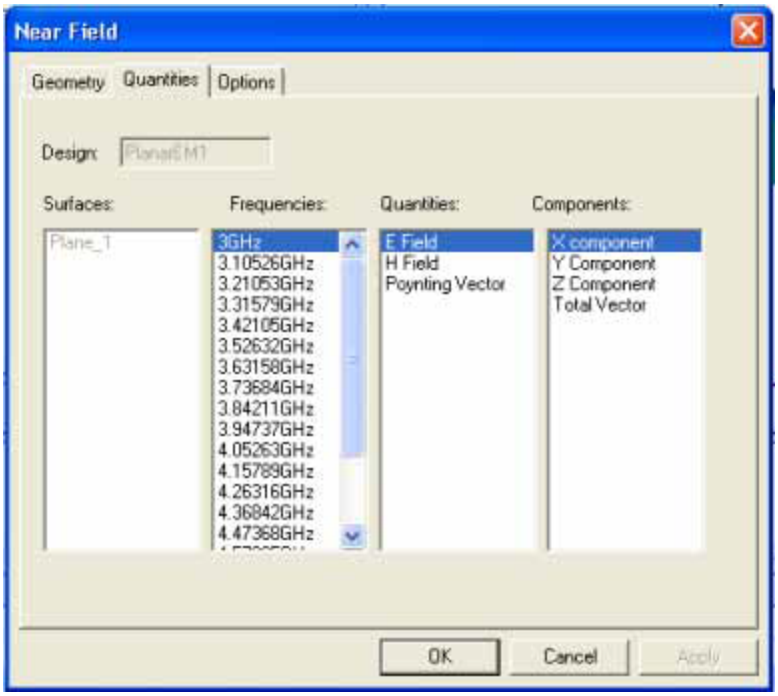
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

opens:



The list displays the frequencies that were swept in the analysis. Select a frequency from the list; the overlay displays the field values calculated at that frequency. Click **OK** to leave the overlay at the selected frequency.

- For near field overlays, expand the **Results** icon in the Project window, right-click the overlay, and select **Properties** from the menu. Use the **Quantities** tab to select a reference frequency for the phase animation:



Click **OK** to apply the frequency and close the dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. To initiate the animation of the overlay that is currently displayed, do one of the following:
   - Select **Animate** from the **View** menu.
   - Expand the **Results** icon in the Project window, right-click the overlay entry, and select **Animate** from the menu.
3. If no animations have been defined previously, the **Setup Animation** dialog opens:

   - Specify a name in the **Name** field (or accept the default, **Animation***n*, where *n* is a numeral). Optionally, enter a description.
   - For a frequency animation, select **Phase** as the **Swept Variable**.
   - Select the Start and Stop phases in degrees.
   - Click **OK**.

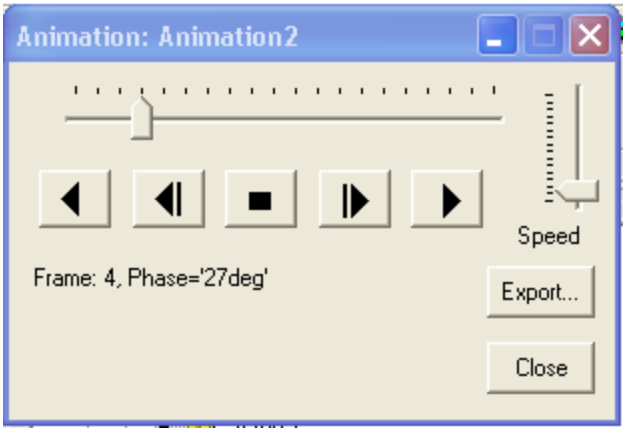
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If one or more animations have been defined, selecting **Animate** from one of the menus opens the **Select Animation** dialog:

The **Select Animation** dialog provides the following operations:

- Click to select one of the animations and click **OK** to start that animation.
- Click **New** to open the **Setup Animation** dialog described above, and close the **Select Animation** dialog.
- Select an animation and click **Delete** to delete the definition.

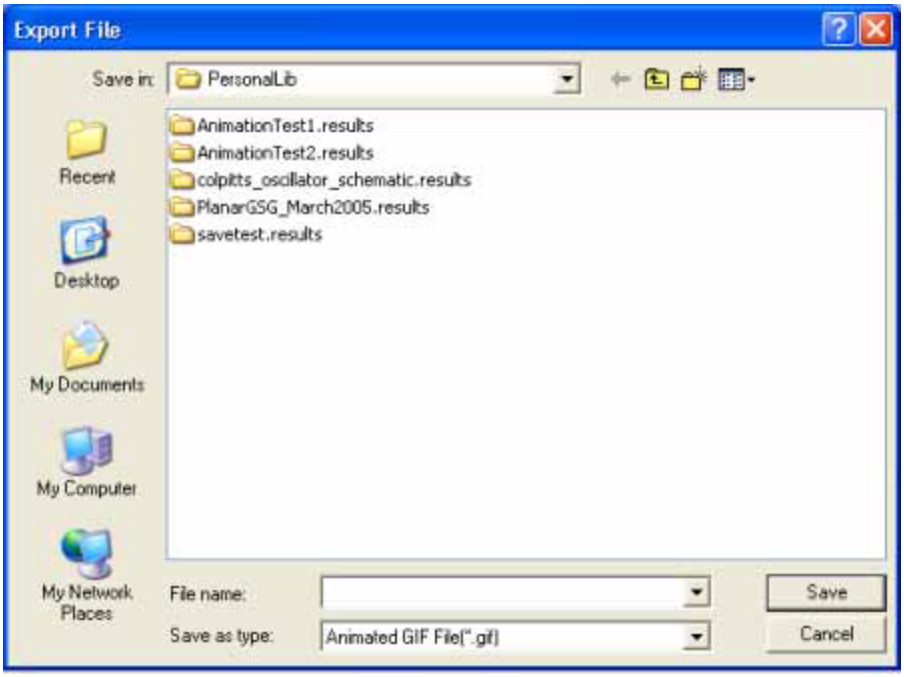
4. The frame data is calculated automatically. If the Progress window is displayed, you can monitor the progress of the calculation. When the frames have been calculated, the animation begins and the **Animation** control panel opens:



- Use the “VCR” buttons to play the animation. From left to right, the buttons are **Reverse**, **FastReverse**, **Stop**, **Fast Forward**, and **Forward**. The indicator at the top of the dialog shows the progress of the animation. Use the **Speed** slider to control the speed of the animation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To export the frame data to a file, click **Export**. The **Export File** dialog opens:



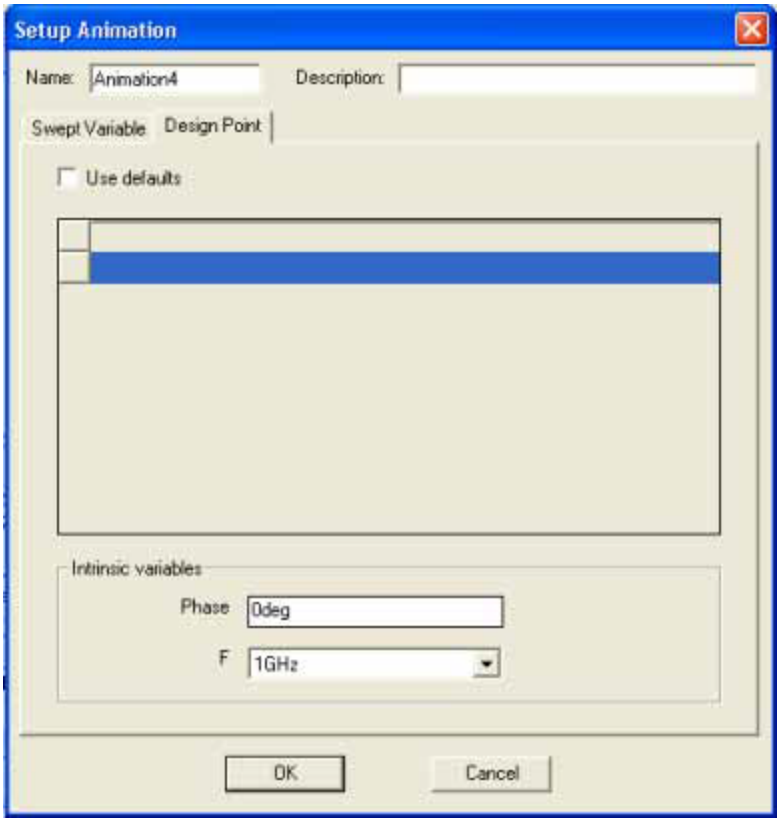
Specify the directory and file name. Use the **Save as type** menu to select the file format (Animated GIF or AVI). Click **Save** to save the data and close the dialog.

- Click **Close** on the **Animation** control panel to stop the animation and close the panel.

Changing the Design Point

Calculating frames for an animation is equivalent to re-simulating the design. You can specify design point parameters for the animation calculations that are different from the ones used in the original simulation. On the **Animation Setup** dialog box, select the **Design Point** tab and deselect the **Use defaults** option. The following fields are displayed:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Make any desired changes, and then click **OK** to apply the changes and close the dialog box. Clicking **Cancel** closes the dialog without making any changes.

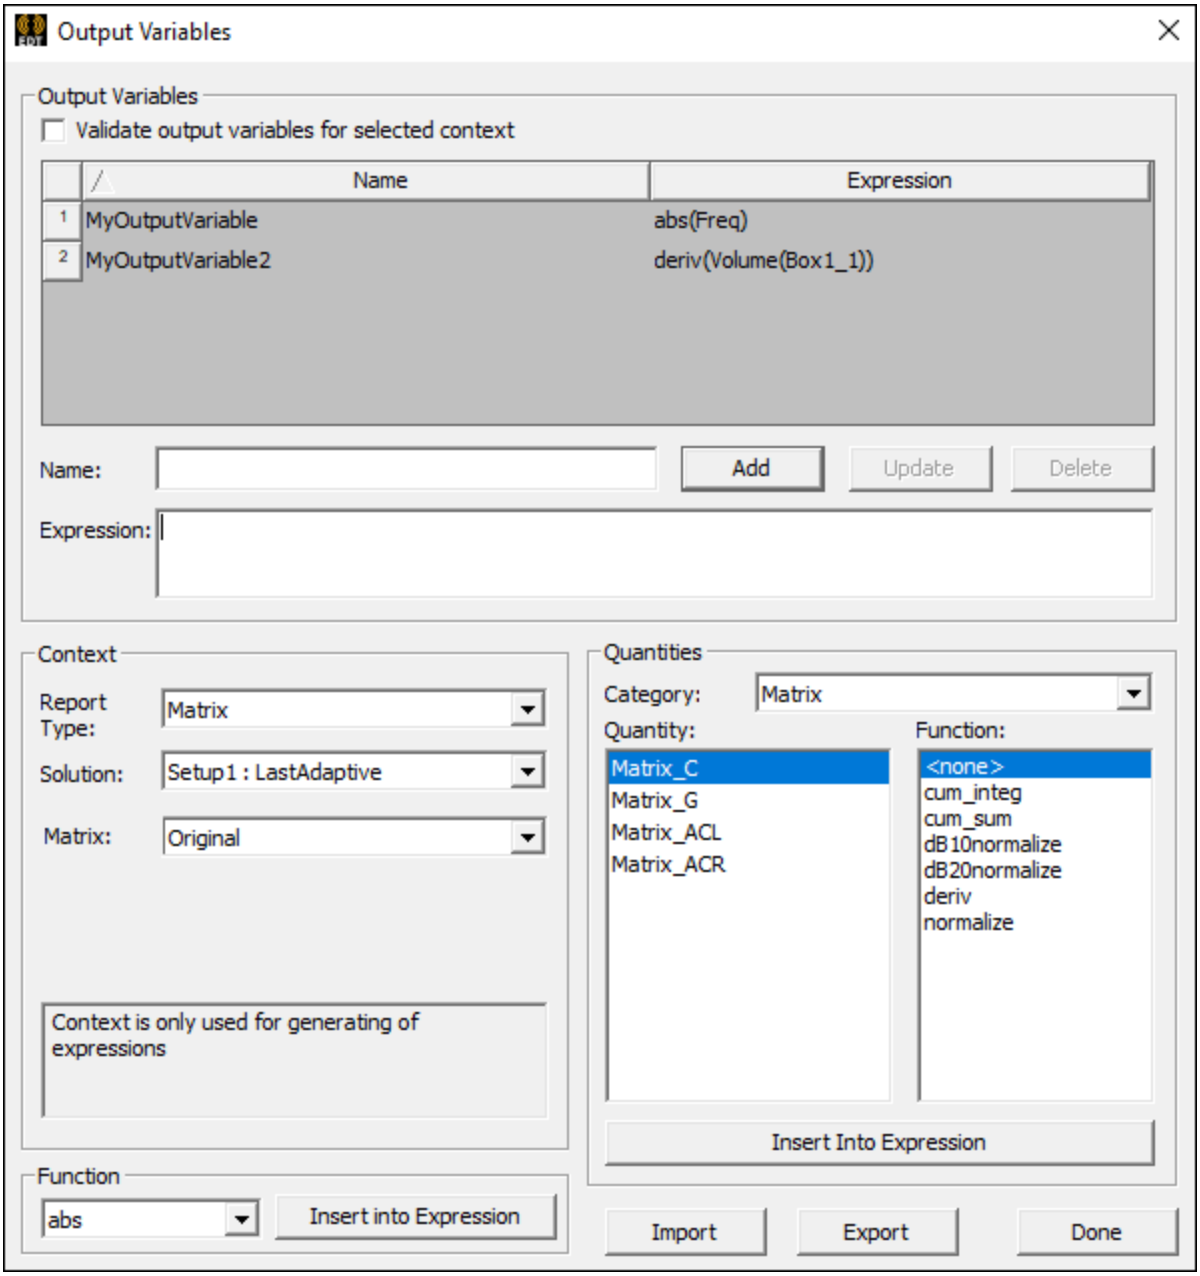
Specifying Output Variables

You can define output variables to use calculated expressions of results as adaptive convergence goals and for reports. You can use output variables in the Expression Cache tab of the **Solution Setup** dialog box and select them as Categories in the **Reports** dialog box, as well as the **Output Variables** window.

Access the **Output Variables** window one of several ways:

- Click **HFSS** > **Results** > **Output Variables**.
- In the Project Manager, right-click **Results** and select **Output Variables** from the shortcut menu.
- In the **Solution Setup** dialog box, select the **Expression Cache** tab, click **Add...** to display the **Add to expression cache** dialog box, and click the **Output Variables** button.
- Click the **Output Variables** button in the **Report** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Output Variables** window contains four sections:

- **Output Variables** – contains a list of existing output variables, and allows you to specify the name and expression for a new output variable. The **Validate output variable...** check box allows you to validate an expression before adding it. Valid expressions appear in blue and invalid expressions appear in red.
- **Context** – specifies the Report Type and Solution. Depending on the type of report selected, additional fields may appear. All selections affect the functions and quantities

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

listed.

> **Note:**
>
> The context is used only for generating expressions.

- **Quantities** – allows you to insert quantities into the Expression area of the **Output Variables** section.
- **Function** – allows you to insert completed expressions into the Expression area of the **Output Variables** section.

To add an output variable:

1. Enter a **Name** for the variable.
2. Specify the **Context**. This impacts the available quantities and functions.
3. Specify the **Quantities** (required) and **Functions** (optional) using the **Insert Into Expression** buttons.
4. Review the **Expression**. When it is ready, click **Add**.

   The new output variable appears in the **Output Variables** list.

To delete an output variable:

1. Remove all references to the output variable from the project.
2. Save the project to erase the command history.
3. Open the **Output Variables** window using one of the methods above.
4. Select the variable from the **Output Variables** list and click **Delete**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

The evaluated value of an expression is always interpreted in SI units. However, when an angle quantity is plotted in a report, you have the option to plot values in units other than SI. For example, if you want to plot the polar angle of a complex simulation result S_{11}, you can choose between ang_deg(S_{11}) and ang_rad(S_{11}). Both of these return the exact same angle quantity, but in degree and radian units respectively.

When using non-SI units in expressions, surprising outcomes might result. For example, the expression 1+ang_deg(S_{11}) represents an angle and the number 1 is treated as 1 rad. The angle SI unit is attached to any unitless number that is added/subtracted from an angle value. If you want to treat 1 as degrees, make it explicit and use 1deg + ang_deg(S_{11}) instead.

If you are interested in unitless degree values, two additional functions exist: ang_deg_val(S_{11}) and cang_deg_val(S_{11}). These return simple numbers and are treated as such by any expression. For example, if the complex S_{11} lies on the positive Y axis, ang_deg_val(S_{11}) would be 90 and 1 + ang_deg_val(S_{11}) would be 91.

Function List for Output Variables

The **Output Variables** window includes a second function list containing functions to enter directly into the Expression field. These functions can also be applied to previously specified Quantities and Functions.

Some of these functions can operate along an entire curve. These are: min, max, integ, avg, rms, pk2pk, cang_deg and cang_rad.

You can select from the functions in the **Output Variables** dialog box's **Function** list or type them directly into the Expression field, if necessary.

Scaling a Source's Magnitude and Phase

You can scale the magnitude and set the phase of ports, voltage and current sources, Eigenmodes, Characteristic Modes, and incident waves in the **Edit post process sources** dialog box. For HFSS modal projects you specify the total voltages. For HFSS terminal projects, you can also select either Incident Voltage or Total Voltage. The incident voltage selection includes magnitude, phase, and the impedance of a hypothetical external line. It is the user specified voltage at an input. The Total Voltage is incident voltage plus reflected voltage, that is, $V^T = V^i + V^r$. For HFSS Transient Network projects, the **Edit Sources** dialog includes tabs that let you specify scales for Spectral and Transient data separately. For HFSS Transient, **Edit Sources** is disabled.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For Driven Modal and Terminal Analysis solution types that involve near or far fields, a **Source Contexts** tab appears on the **Edit post process sources** dialog box. This provides a means to select the sources to use as context when creating a radiated field report. The tab lists the same sources as the Spectral Fields tab. Sources are scaled by exciting a single source (the selected context in the reporter dialog) while turning off all other sources.

For designs containing finite arrays, you have the option to create a Source group. The new Source Group will allow the user to activate a subset of the virtual excitations (e.g. array [5,5]port1:2 …) instead of the physical excitations associated with the unit cell(s).

You may select **Use Per-Element Power Specification for Parametric Array** in **Edit Sources** when only a Parametric Array exists in the scene.

When you select the option, **Edit Sources** defines the input power of an element before applying the Aperture Taper configured in Array Weightings. The Parametric Array with this option gives results similar to HFSS post-processing feature of Antenna Array, and couplings analysis and Enhanced Radiated Power Accuracy are not supported.

You can also **Save to File** and **Load from File**, where the file is comma delimited data (.csv) format or tab delimited data (.txt). This can help in defining source values for projects with a large number of sources. An example of the .csv format for HFSS follows:

```
Name,Magnitude,Phase
Port1:1,1W,0deg
Port2:1,0W,0deg
Port3:1,0W,0deg
```

An example of the tab delimited format follows:

Name Magnitude Phase

Port1:1 1W 0deg

Port2:1 0W 0deg

Port3:1 0W 0deg

Note: A Beta feature for HFSS, HFSS Interactive Dialogs, allows you run the **Edit Sources** dialog and the Antenna Parameters dialog in modeless fashion, that is, if you **Edit Sources** for magnitude or renormalization, affected Antenna Parameters update. Edits for sources that cause an Update of grids include:

- Source is created. A new row will be added to grids.
- Sources are deleted. Corresponding sources in grids will be deleted.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Source name is changed.Name updates in grids.

All changes will be saved in the dialog after the **Edit Sources** Sheet is closed, but they will not be applied until you click **Apply** or **OK**. The dialog supports undo and redo for creating, deleting and renaming elements.

If you edit excitations or ports, or create source groups in the Far Field Setup, the **Edit Source** dialog will close.

Scaling Sources for HFSS

Scaling Sources for HFSS Transient Network

Specifying Source Contexts for Creating Radiated Field Reports

Defining Antenna Arrays

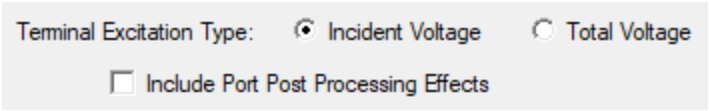
Scaling Sources for HFSS

1. Click **HFSS** >**Fields**>**Edit Sources**.

   The **Edit post process sources** dialog box appears For modal projects, the Spectral fields tab shows the following column headings.

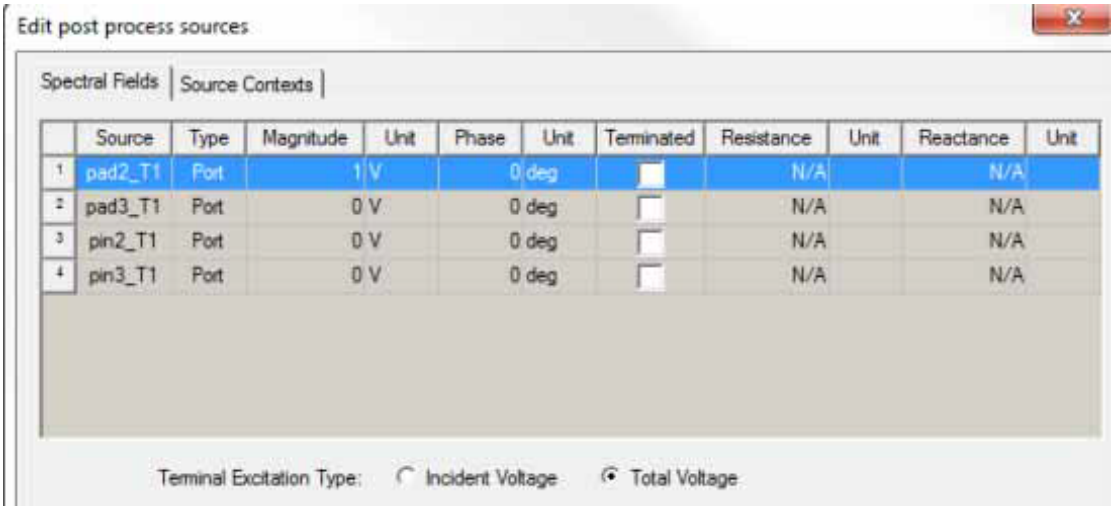
   If the project contains symmetry planes, the dialog includes a reminder that you may need to adjust the scaling factor accordingly.

   For HFSS Terminal solutions, you can select a Terminal Excitation Type as Incident Voltage or Total Voltage.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Selecting Total Voltage adds more columns to the table.



Note that in the **modal** case a unit stimulation means 1 Watt of incident power at the port; in the **terminal** case a unit stimulation means 1 volt of total voltage at the terminal. After converting the voltage stimulation to the equivalent power stimulation the antenna results agree perfectly. In particular, the "ratioed" antenna parameters such as gain, directivity, and efficiency agree between the modal and terminal projects, while absolute antenna quantities such as incident power, accepted power may initially appear different. This is a direct result of the difference in edit-sources stimulations in the two types of projects.

You can scale the sources individually through the source table in the **Edit post processing sources** dialog box, or you can **Save to File** or **Load From File**, using the .csv format or tab delimited data (.txt) format. This feature can help for projects with many sources. The steps below describe how to directly edit the source table.

2. Select the source whose magnitude and phase you want to scale.
3. In the **Magnitude** text box, enter the magnitude you want. Design variables can be used as source scalings.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

You may not enter a negative voltage. To obtain the equivalent of a negative magnitude, add or subtract 180 degrees from the phase value.

If you use a design variable as a scaling factor note that solutions are invalidated if the variable is changed.

If the model contains symmetry planes, the **Edit Sources** dialog alerts you that you may need to adjust the scaling factor accordingly.

At least one source should be excited (non-zero). If you set all sources to zero, you will receive a warning, but the values do go through.

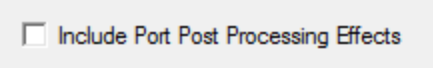
4. In the **Phase** text box, enter the new phase for the source.

The phase of the source is changed by the value that you enter.

5. Optionally, if your solution type is driven terminal, you may specify a complex reference impedance:
   a. For the selected terminal, select **Terminated**.

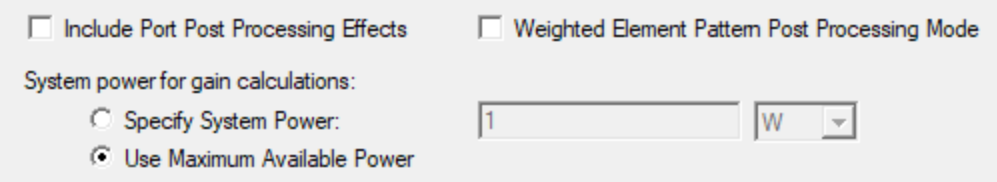
   This disables the values to the left of the check box, and enables the Resistance and Reactance text boxes. Use the scroll bar to view them.

   b. Enter the **Resistance** and the **Reactance** and select the units. Ohms is the default.
6. By option, you can click a check box to **Include Post Processing Effects**. Note that the post processing effect has no impact on the impedance of a terminated port.



Checking this box also enables an **Apply** button.

7. By option you can check **Weighted Element Post Processing Mode** for antenna beam steering applications.



Ansys HFSS is widely used for simulating and analyzing electromagnetic fields in large antenna arrays. Beam steering in phased arrays is a critical function in applications such as radar, wireless communication, and satellite systems. Efficient beam steering allows for dynamically directing the radiation pattern without physically moving the antenna

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

elements. In large arrays, beam steering relies on controlling the phase and amplitude of signals across multiple elements.

The Weighted Element Pattern Mode enhances large array postprocessing for beam steering in HFSS by improving efficiency for multiple beam-steering operations. Precomputation is not an interactive task. It occurs only once when the far-field report is initially loaded. There are two scenarios:

- A far-field report is defined before the simulation. Once the simulation is complete, the report gathers data and triggers pattern precomputation.
- A far-field report is defined after the simulation. In this case, precomputation is triggered once, and the far field is plotted. Any subsequent beam-steering operation will reuse this cache.

Each element pattern cache is associated with a specific variation, solution setup, and far-field setup—similar to the concept of a far-field report. This means that if the solution is invalidated or modified, the cache will be cleared. Additionally, when saving the project, this cache is also saved and can be reused the next time the project is opened.

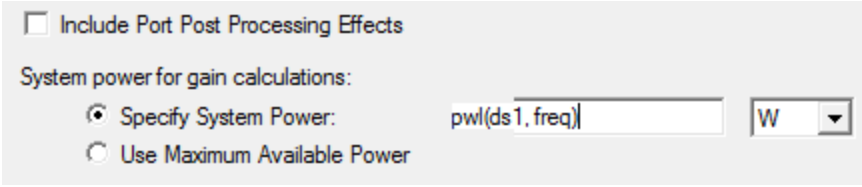
This solution significantly reduces redundant computations, speeds up beam-steering operations, and optimizes resource utilization, making it a scalable approach for handling large arrays in HFSS.

If field solution is available and there is an existing far field report, AEDT begins to generate element pattern cache as suggested by the progress bar. Once it's done, far field report would be updated, and any subsequent beam steering should be done in real time.

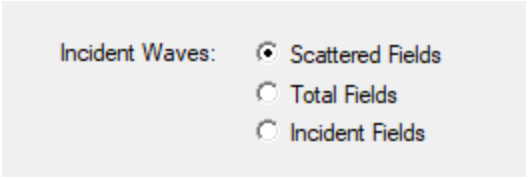
8. For gain calculations, you can check whether to Specify System Power or Use Maximum Available Power. Selecting **Specify System Power** enables a field for value for power and select units. **Use Maximum Available Power** provides a default. The system power typically comes from an external circuit (e.g., a Circuit project), and is used in computing System Realized Gain in antenna parameters and System Gain in far field reports.

You can specify incident power for gain calculations as a function of frequency, for example, pwl(ds1,freq).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



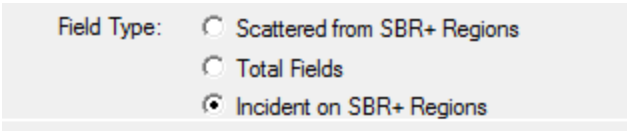
9. For HFSS, if an incident wave is present, use the radio buttons at the bottom of the panel to select one of the following field types to use:



Scattered Fields	The differential field formed by subtracting the incident field from the total field.
Total Fields	The physically measurable field that exists with the model present and a non-zero incident field.
Incident Fields	The plane-wave field that would exist in the absence of the model.

For the total field of a Floquet port *also chosen* as the source in **Edit post process sources**, you should always select **Scattering Fields** as the 2D surface fields, rather than the Total Fields. The Floquet ports are added in the far field calculation when the Solution setup **Save radiated fields only** option is checked. However, if you then create custom radiation surfaces, the 3D volume total fields are used in the calculations. In this specific situation, this causes inconsistent results between the default radiation surfaces the custom surfaces. Otherwise, there is no difference between scattering fields and total fields. since "total fields" = "incident fields (source fields)" + "Scattering fields".

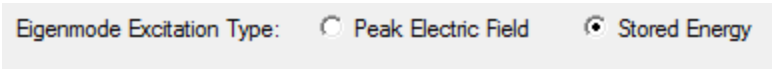
For HFSS with SBR+ designs that include ports, incident waves, or linked incident waves, the Field Type options take this form:



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

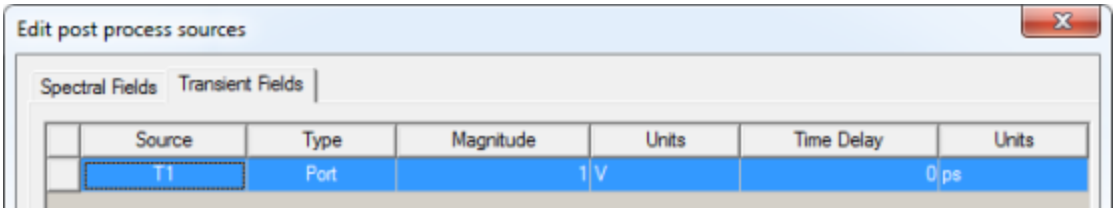
In the case of SBR+ with incident waves, the field type can only be Scattered from SBR+ Regions. For SBR+ designs with Port sources or linked incident waves, you can select from all three types.

For Eigenmode solutions, the **Edit post process sources dialog** displays a Spectral Fields tab and radio buttons for selecting as the Eigenmode Excitation Type, either Peak Electric Field or Stored Energy.



For Stored Energy, the table lists Magnitude and Unit as editable fields. For Peak Electric field, the editable fields are Magnitude, Unit, Phase, and Unit.

10. The Source Contexts tab lets you select the sources to use as context when you create radiated fields reports.



11. Click **OK to apply the changes and close the dialog box, or click Apply t**o view the changes without closing the dialog.

The magnitude and phase are assigned to the selected excitation.

> **Note:**
>
> When you scale an excitation, keep in mind that the original value of the excitation remains unchanged.

Guidelines for Scaling a Source's Magnitude and Phase

When specifying the magnitude of a source keep the following guidelines in mind:

For ports, driven modal case	• The excitation's magnitude specifies time-averaged incident power in watts. • If you are using a symmetry plane, remember to scale the input signal appropriately. For example, if you have one symmetry plane, use an input value of 0.5 watts to excite the full structure with 1 watt; if you have two symmetry planes, use an input value of 0.25 watts to excite the full

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	structure with 1 watt, and so forth. • Generally, use the default value of **1**. This specifies that the solution's E- and H-fields be scaled such that the excitation wave delivers 1 watt of power. To view the solution at some other power, enter a positive value. • Only port-mode combinations with non-zero magnitudes will be used.
For voltage and current sources	• The source magnitude for voltage and current sources specifies peak value volts and peak value amperes, respectively. • If you have defined multiple voltage and current sources, you can "remove" them by setting their magnitudes to **0**. This enables you to easily observe the effects that individual or specific groups of sources have on the problem.
For incident waves	• Source magnitude specifies peak value E-field in volts per meter. • When you scale the incident E-field, the scattered E-field and the total E-field are scaled as well. • This scaling factor affects all incident angles in the incident wave setup.
For ports, driven terminal case	• The excitation's magnitude specifies peak value volts. This is the sum of the incident and reflected waves at this terminal. See the equations here.
For Eigenmodes	• Source magnitude is unitless and represents a relative value. • When you enter a scaling factor for an eigenmode the relative source magnitude is amplified by this value. Exactly one eigenmode must be excited by setting its scaling factor to a non-zero positive number.
Ports of Transient Network solutions	• See Ports and Edit Sources Behavior for Transient Network

When specifying the new phase for ports, generally use zero. This zero-phase solution results from excitations phased in such a way that, at $\omega t = 0$, peak values occur at the port faces.

Scaling Sources and Setting Delays for HFSS Transient Network

For HFSS Transient Network solutions you can separately edit sources for Spectral Fields and Transient Fields. The **Transient** tab on **Edit Sources** controls transient far fields and fields saved on the mesh. The **Spectral Fields** tab on **Edit Sources** controls Frequency domain far fields and antenna parameters.

- Editing Sources for Spectral Fields for Transient Network
- Editing Sources for Transient Fields for Transient Network

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When non-port sources exist, the port post processing effects are off. For both Spectral and Transient fields, you can scale the sources individually through the source table in the **Edit Sources** dialog box, or you can **Save to File** or **Load From File**, using the .csv format or tab delimited data (.txt) format. This feature can help for projects with many sources. The linked steps describe how to directly edit the source table.

In Transient Network analysis each source is solved separately which allows arbitrary superposition of the results from all sources controlled by **Edit Sources** settings. This feature enables users great flexibility in studying a large set of excitation variations in an efficient and convenient manner.

> **Note:**
>
> When superposing results it is assumed that the fields have decayed to zero at the end of the simulation for each source. In practice, the user settings for Target Residual and time duration can cause this assumption to be violated. In this case the displayed field quantities may contain significant error.
>
> For example, consider a design with two sources where the user has specified a large Target Residual setting, and one source converges at 1ns while the other converges at 2ns. If the user had not specified any time shifts in **Edit Sources**, the displayed field quantities will not be reliable in the range 1ns to 2ns because the fields from the first source cannot be assumed to be zero.

Editing Sources for Spectral Fields for Transient Network

For Spectral fields, you can optionally include port post-processing effects. The **Spectral Fields** tab on **Edit post process sources** controls Frequency domain far fields and antenna parameters. The voltage specifications are only for the incident voltage.

1. Click **HFSS**>**Fields**>**Edit Sources**.

   The **Edit post process sources** dialog box appears with the **Spectral Fields** tab selected.

   For HFSS Transient Network, the **Edit post process sources** dialog displays information for sources for Spectral Fields in table format. You can edit the Magnitude and Phase values including the use of variables, and set the units for each. You can scale the sources

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

individually through the source table in the **Edit Sources** dialog box, or you can **Save to File** or **Load From File**, using the .csv format. This feature can help for projects with many sources. The steps below describe how to directly edit the source table.

Note:

You may not enter a negative voltage. To obtain the equivalent of a negative magnitude, add or subtract 180 degrees from the phase value.

If you use a design variable as a magnitude note that solutions are invalidated if the variable is changed.

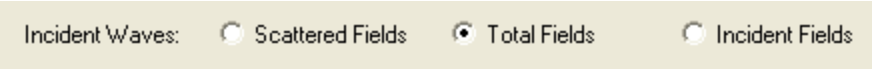
If the model contains symmetry planes, the **Edit Sources** dialog alerts you that you may need to adjust the scaling factor accordingly.

At least one source should be excited (non-zero). If you set all sources to zero, you will receive a warning, but the values do go through.

2. By option, you can click a check box to **Include Post Processing Effects**.

Checking this box also enables an **Apply** button.

3. For HFSS, if an incident wave is present, use the radio buttons at the bottom of the panel to select one of the following field types to use:



Scattered Fields	The differential field formed by subtracting the incident field from the total field.
Total Fields	The physically measurable field that exists with the model present and a non-zero incident field.
Incident Fields	The plane-wave field that would exist in the absence of the model.

Editing Sources for Transient Fields for Transient Network

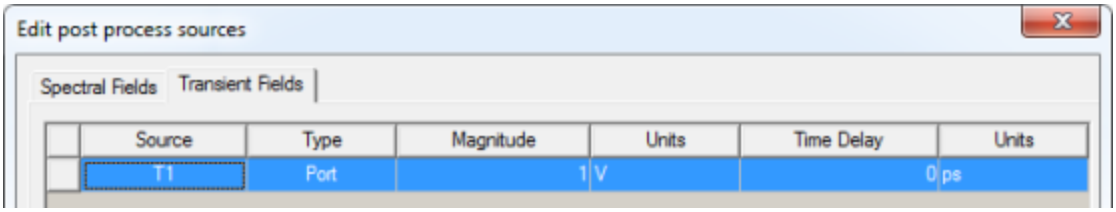
For Transient fields you can set magnitude and time delay for each source. The **Transient** tab on **Edit post process sources** controls transient far fields and fields saved on the mesh. The voltage specifications are only for the incident voltage.

1. Click **HFSS**>**Fields**>**Edit Sources**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Edit post process sources** dialog box appears with the **Spectral Fields** tab selected.

2. Select the **Transient Fields** tab.
3. Edit the Magnitude and Time Delay values as desired, and select the Units for each.



You can scale the sources individually through the source table in the **Edit Sources** dialog box, or you can **Save to File** or **Load From File**, using the .csv format. This feature can help for projects with many sources. An example of the format for HFSS Transient follows:

```
Name,Transient Magnitude,Delay
bw_tr_1_T1,1V,0ps
bw_tr_2_T1,0V,0ps
sb_tr_1_T1,0V,0ps
sb_tr_2_T1,0V,0ps
```

The magnitude and delay are assigned to the selected excitation.

> **Note:**
>
> When you change the Magnitude of an excitation, keep in mind that the original value of the excitation remains unchanged.

Ports and Edit Sources Behavior for Transient Network

Transient Network solutions support the following port features:

- Just as in Driven Terminal we have two types of ports namely wave ports and lumped ports.
- Both implicit and hybrid transient solvers can solve dispersive and/or inhomogeneous wave ports, as well as single TEM terminal ports such as coax and gap ports. The S-parameter results from implicit transient designs will agree with mesh-linked frequency driven terminal designs. Dispersive means the wave-port modes are frequency dependent.
- Wave ports are matched loaded.
- Lumped ports are loaded with the user defined "Full Port Impedance".

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Both ports support renormalization of the spectral quantities S-parameters and far fields including antenna parameters.
- Neither port supports renormalization of transient quantities.

Edit Sources for Transient Network involves specifying the incident voltages at the terminals of the ports not the total voltages. This means that all ports are terminated with the port settings and if the edit source for a given port is set to zero it means that port is loaded with the port setting and it does not imply a short.

	Source	Type	Magnitude	Units	Time Delay	Units
1	strip_T1	Port	1	V	0	ps
2	strip_T2	Port	0	V	0	ps
3	strip_T3	Port	0	V	0	ps
4	strip_T4	Port	0	V	0	ps
5	coax_ctr_T1	Port	0	V	0	ps

As mentioned above, transient fields are not affected by any renormalization but the frequency domain far fields and antenna parameters are affected by renormalization.

In Transient Network analysis each source is solved separately which allows arbitrary superposition of the results from all sources controlled by Edit Sources settings. This feature enables users great flexibility in studying a large set of excitation variations in an efficient and convenient manner.

Note:

When superposing results it is assumed that the fields have decayed to zero at the end of the simulation for each source. In practice, the user settings for Target Residual and time duration can cause this assumption to be violated. In this case the displayed field quantities may contain significant error.

For example, consider a design with two sources where the user has specified a large Target Residual setting, and one source converges at 1ns while the other converges at 2ns. If the user had not specified any time shifts in Edit Sources, the displayed field quantities will not be reliable in the range 1ns to 2ns because the fields from the first source cannot be assumed to be zero.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Specifying Source Contexts for Creating Radiated Field Reports

For Driven Modal and Terminal Analysis solution types that involve near or far fields, a **Source Contexts** tab appears on the **Edit post process sources** dialog box. This provides a means to select the sources to use as context when creating a radiated field report. The **Source Contexts** tab lists the same sources as the **Spectral Fields** tab. Sources are scaled by exciting a single source (the selected context in the reporter dialog) while turning off all other sources.

All types of sources can be enabled as Source context (ports, currents, incident waves). The default for all sources is "disabled". This applies to newly created sources and sources in legacy projects.

Each singly selected source is excited with factory default values. The phase will always be 0 deg and the magnitude will be 1 Watt for modal design and 1 Volt (Total voltage) for terminal design. These factory default values cannot be changed by users.

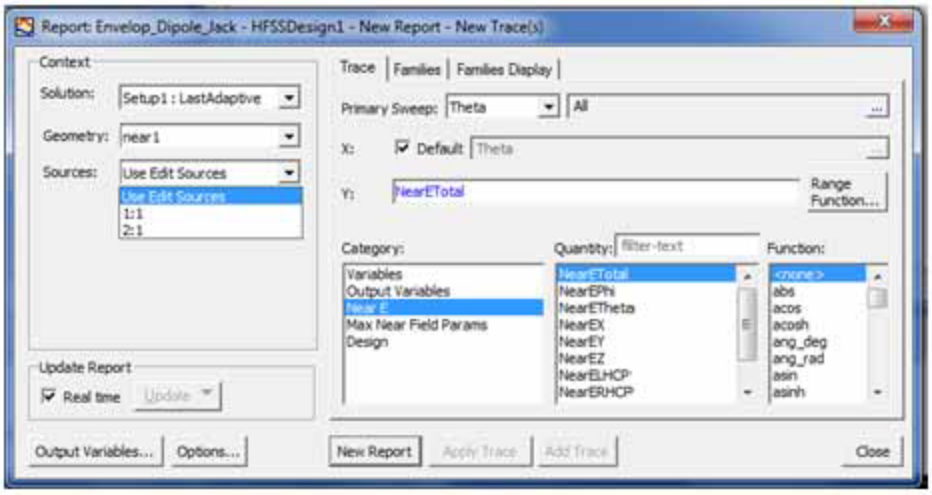
Design **Edit post process sources** settings such as "Include Port Post Processing Effects" are applicable for these singly excited sources. Thus changing any setups on the first tab of the **Edit post processing sources** dialog invalidates all traces that are defined with source context.

Enabling any source as context does not impact traces that are already defined

Disabling source as context invalidates an existing trace that uses that source as context.

This **Edit post process sources** selection applies to a Source selection in the Reporter that allows you to excite a single source.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The Reporter Context selection for "Sources" appears when there is at least one source selected for "Source Contexts". The default selection of this combo box is "Use Edit Sources". When a source is selected, the **Edit Sources** setup in the design will be ignored during trace population. Instead, the trace will be calculated with the selected source excited while turning off all the other sources in the design. The above figure illustrates the extended **Create Near Field Report** dialog box. Note that "1" and "2" are port names and each has 1 mode.

For an example use of these features, see the User Defined Solution for MIMO Calculations example, that describes python scripts for the Toolkits and User Defined Solution features to generate calculations and reports.

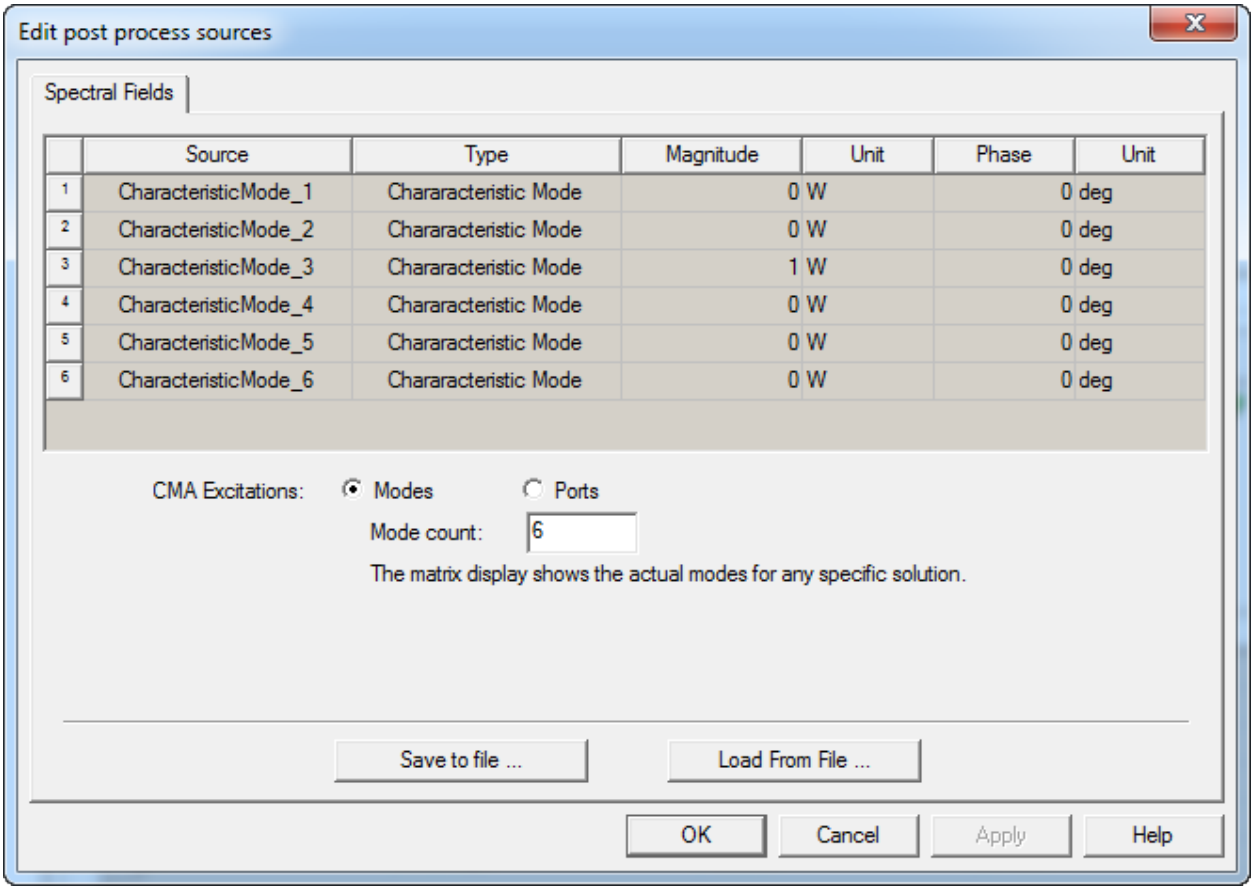
Edit Sources Panel for CMA

For characteristic mode analysis, the Edit Sources panel allows you to specify the modal weight for each characteristic mode used to form the total field displayed. In addition, for designs where ports are defined, you can specify the excitation values of the ports. In the case of port excitations, a linear combination of the solved characteristic modes will be determined, which matches the specified port values. The default value of Mode count in the Edit Sources panel is 10. The CMA data panel in the Solution Data dialog displays the actual modes above the minimum modal significance for any specific solution.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	Mode	Significance	Value	Angle (deg)
	1	0.928011	0.401452	158.127
	2	0.567695	-1.45014	235.41
	3	0.334881	-2.81371	250.435
	4	0.252298	-3.83534	255.386
	5	0.243012	3.99167	104.064
	6	0.0598828	16.6693	93.4331

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Enter this value in the Mode count field. For example, if the matrix display shows 6 modes above the specified value of minimum modal significance, enter 6 in the Mode count field. Excite the magnitude and/or phase of the mode whose current pattern you wish to see in the design. For example, if you want to see surface currents due for Mode 3, define the magnitude or phase for CharacteristicMode_3 and set the other characteristic modes to 0. You can also define the magnitude and/or phase of a combination of characteristic modes.

Derivative Tuning for Reports

The Derivative Tuning feature available in the results menu is based on the derivatives that you can request for selected variables in the solution setup. It is limited to quantities like S-parameters and Far Fields, where far-field tuning supports the following:

- Incident Wave
- Linked Field
- Voltage Source
- Current Source

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

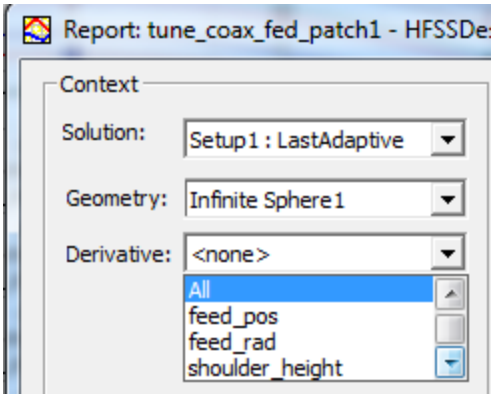
- Magnetic Bias : Note: Sensitivity analysis of a design variable associated with the magnetic bias region assumes that the magnetic bias field does not change. In some cases this assumption may not be appropriate and requires user discretion to ensure its applicability especially for non-uniform ferrite models.

Tuning far field quantities determines the derivatives of the response of electromagnetic devices with respect to variations in geometric or material properties. Designs can include port excitations or non-port excitations (that is, incident waves, linked field, voltage source and current source.

Note: Sensitivity analysis of a design variable associated with the magnetic bias region assumes that the magnetic bias field does not change. In some cases this assumption may not be appropriate and requires user discretion to ensure its applicability especially for non-uniform ferrite models.

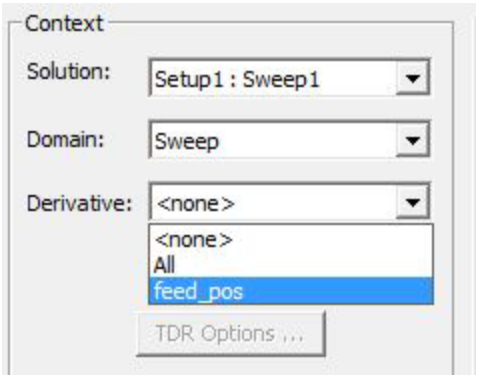
Results obtained by the “Tune Reports” functionality is only an estimate, it is recommended that designs be re-analyzed with the variables values changed to include any tuning offsets to get an accurate result.

Frequencies, and local quantities cannot be tuned. If you have defined variables in the solution setup, the Context area of the Reporter displays the Derivative field, from which you can select the variable(s) for a tunable report.

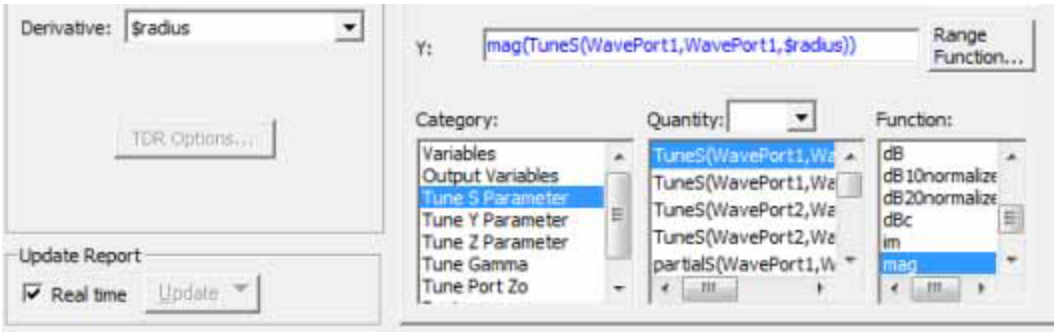


A common way to use this feature is to produce, for an output quantity of interest, two curves in one plot. One curve is produced with the **Report** dialog selection for the Context Derivative as <none>. The other has the All or specific variable selection.

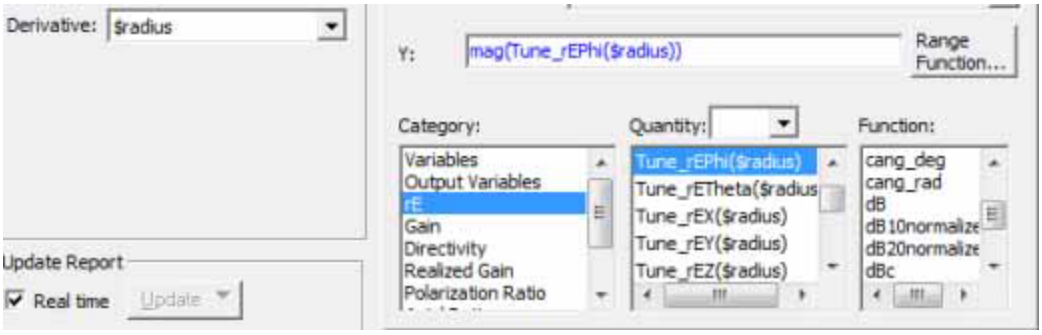
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



When you select All or a variable, notice that the Context field of the Report dialog shows the names of various parameters prefixed with Tune. Some of the Quantities associated with the category also show a Tune prefix. This labeling makes it easier to distinguish the Tuned traces from the reference traces.

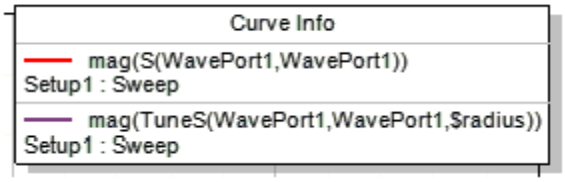


In the case of a Far Fields plot, the Tune prefix appears in only in the Quantity field.

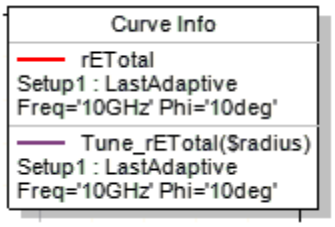


This gives you a plot with initially two identical curves, one on top of the other. The curve info table shows the trace names. This example shows the curve info for a plot with a normal S-parameter trace with a TuneS trace that can be tuned using the value of the $radius variable.

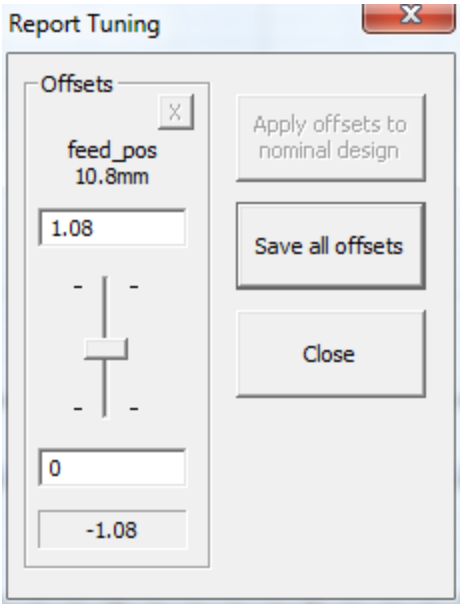
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This example shows the curve info for a plot with a normal rETotal trace with a Tune_rETotal trace that can be tuned using the value of the $radius variable.



You can then right-click Results in the Project tree and select **Tune Reports**. The **Report Tuning** window appears. You can use the slider to tune the Tune curve interactively while the reference curve stays to provide a reference. This way you can see interactively how small changes in variables affect the result. You can then apply those offsets to the original variable values and re-solve the design.



The overall procedure for Report Tuning follows.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

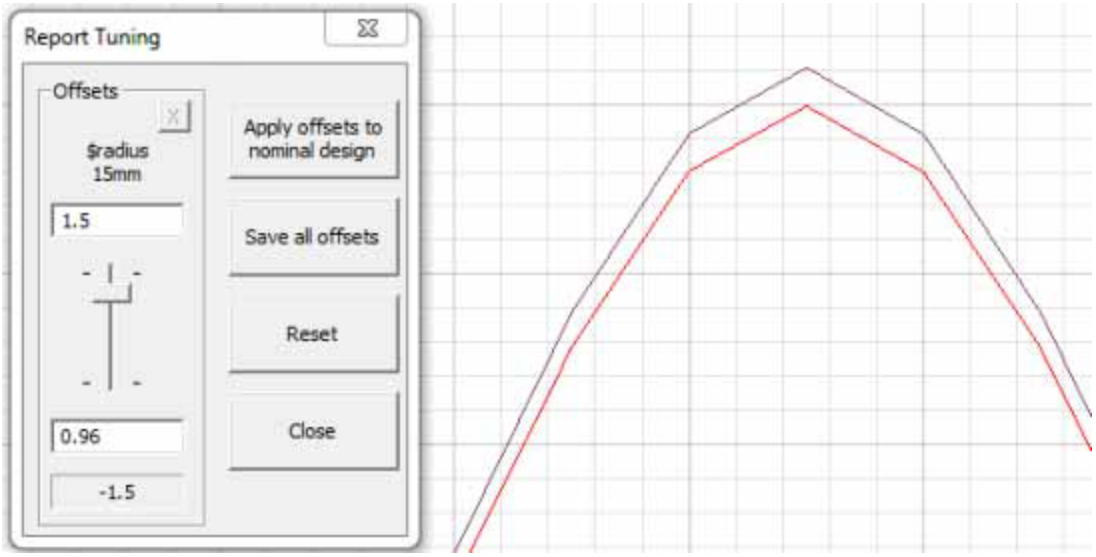
1. Generate a solution with one or more variables for which you select Use on the **Derivatives** tab of the solution setup.
2. Use the Reporter to create one curve with Derivative selection in the Context panel of the report dialog set to None.
3. Then create another curve, but in the Context pane. select for Derivatives, All or the variable of interest. Select to build your new trace from the Categories and Tune Quantities listed.

This gives you two identical curves, one top of the other. Notice that you are not limited in the number of traces that you define. You may choose to limit the number of traces for more ease in observing the results of tuning.

4. Click the **HFSS>Results>Tune Reports** or right-click **Results** in the Project tree and click **Tune Reports** from the short cut menu. The menu item is disabled if no variables have been selected in the Derivatives tab of the solution setup.

This displays a **Report Tuning** dialog which lists the variables available for tuning. The example above shows a **Report Tuning** dialog for a design with only one variable but it can show more.

5. You can use the slider to adjust the value of each available Tune variable. When you move a slider, the **Apply offsets to nominal design** button and the **Save all offsets** buttons are enabled. The Report shows the change to all Tune traces, relative to any reference traces you define.



The Tune dialog displays the change to the variable selected. For example, if the variable is $length with a value of 1mm, and the slider shows 0.1mm, then the effective value of $length for the purpose of derivatives is 1.1mm. If you exit the dialog by applying the offset or offsets

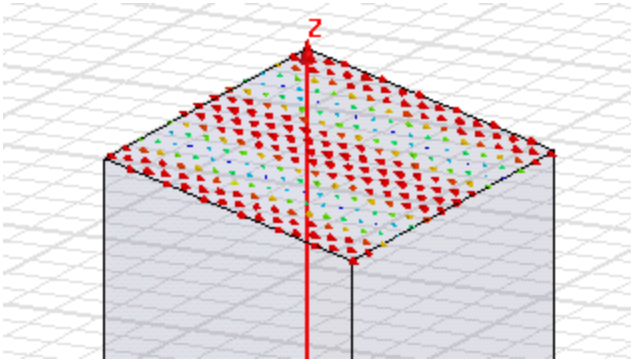
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(click **Apply offsets to nominal design**), $length is assigned a value of 1.1mm. You can then re-solve, and get results based on the derivative's prediction.

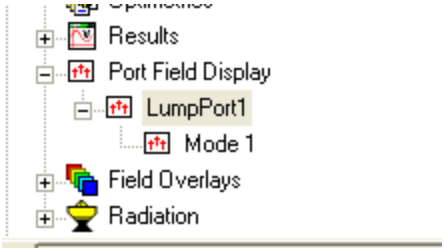
6. **Close** lets you close the dialog.

Port Field Display

The Port Field Display feature lets you see a visualization of the electric field patterns belonging to the modes of the 2D port solution. To have an available solution," Save Fields" must be checked for the Solution setup Advanced tab, or for a fast or discrete sweep. If you select a port mode listed in the **Project** tree, the **Modeler window** displays the a visualization of the selected mode for the port field.

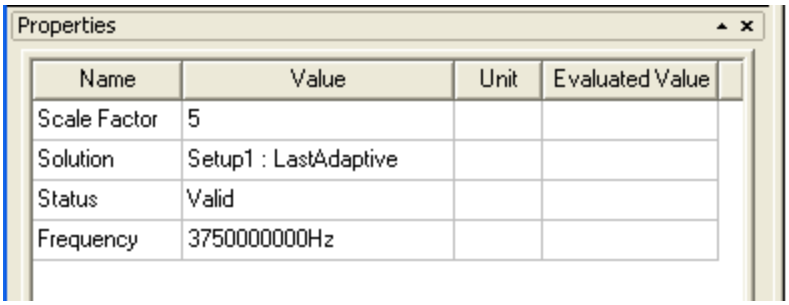


If an HFSS design has ports, they are listed Port Field Display icon in the Project tree. The modes for each port appear under the port name.



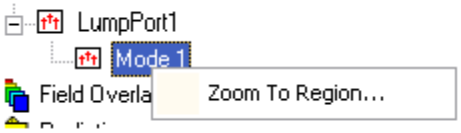
Select a port name to display a **Properties** dialog with the properties for that port, or for individual Modes listed under that port. These are used as subsequent plot defaults for the port field display. Your control of port field displays is purely through the docked **Property** window. You can edit the Scale Factor field, which governs the sizes of the arrows. If multiple solutions or frequencies are available, you can select from a drop-down menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If no 2D solutions exist for the selected port or mode, the Status line of the **Properties** dialog will say "No solutions available."

Depending on the view you begin with, and the location and size of the mode in the design, you may want to right-click the selected mode to display a **Zoom to Region** command.

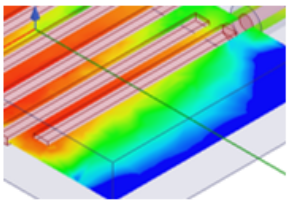


The difference between the Port Field Display and the Field Overlay is that the Port Field Display gives the pure 2D port solution. A Field Overlay provides a the 3D field solution on the port, which is the sum of the excitation in the port and the reflections by the 3D structure. The Port Field display lets you examine the field patterns with which the 3D structure is excited.

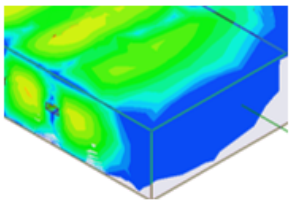
Plotting Field Overlays

Field overlays are representations of basic or derived field quantities on surfaces or objects for the current design variation. You must have selected **Save Fields** in the Solution setup in order to enable the **Plot Fields** selections.

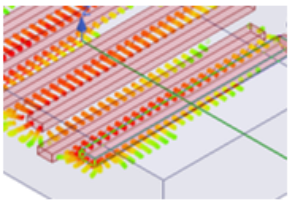
You must select a geometry to create a plot. Selection of line, surface, plane, arbitrary point list, or solid object, and of scalar or vector quantities, or of the streamline option affects the display. You have more control over the display via Modify Plot Attributes.



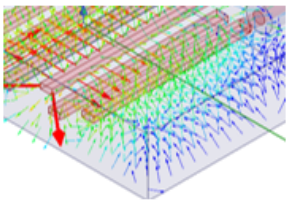
Mag E on Surface



Mag E on Solid



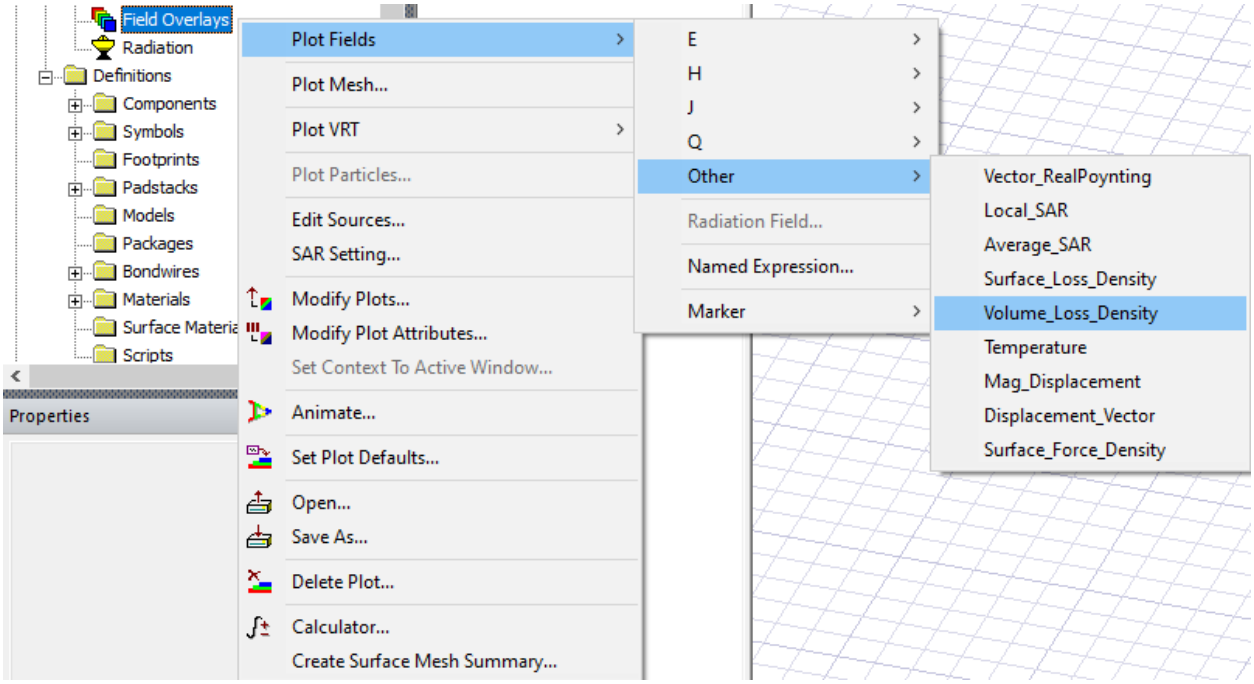
Vector E Streamline



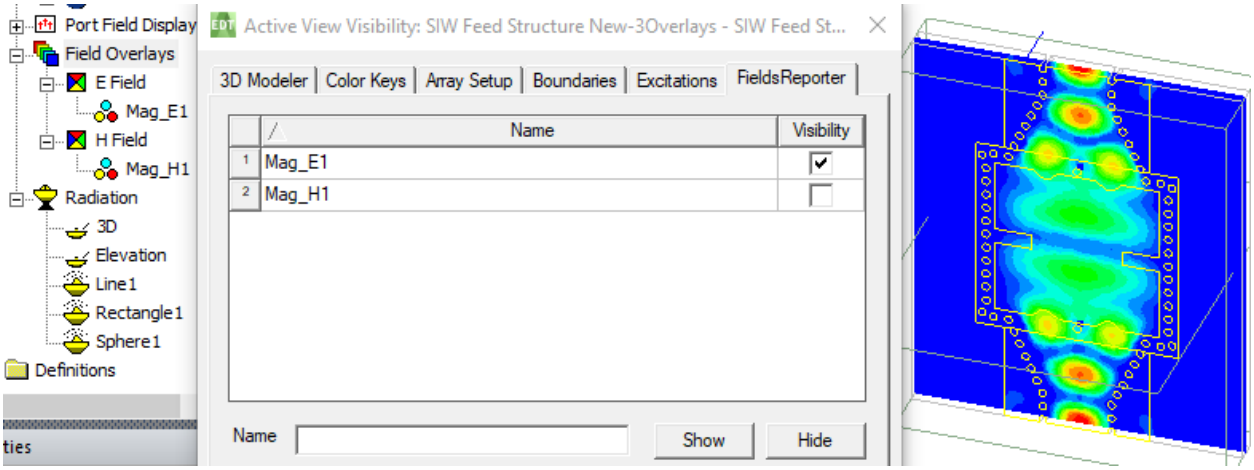
Vector E

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Plot Fields** menu selections depend on the solver selected.

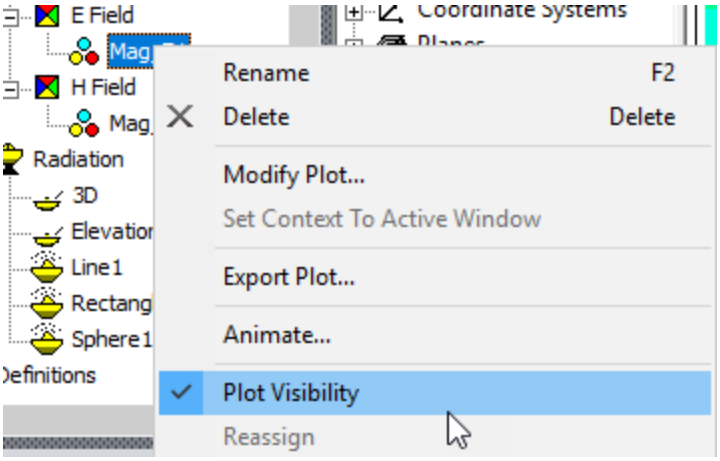


Electronics Desktop allows for the display of existing field overlays in the **3D Model** window and **Layout Editor** views. You can also create plots in Layout view for specified layers and/or nets.

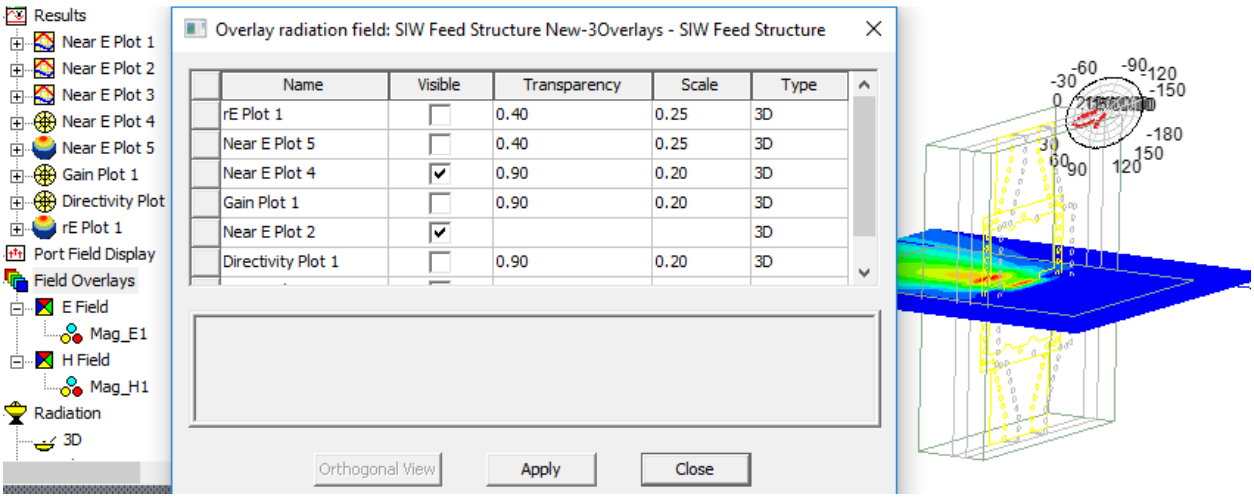


You can control the visibility of field overlays by means of the **View** > **Visibility** > **Active View Visibility** window, **Fields Reporter** tab (shown above) or by right-clicking on the Field plot in the Project Manager and checking or unchecking **Plot Visibility**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

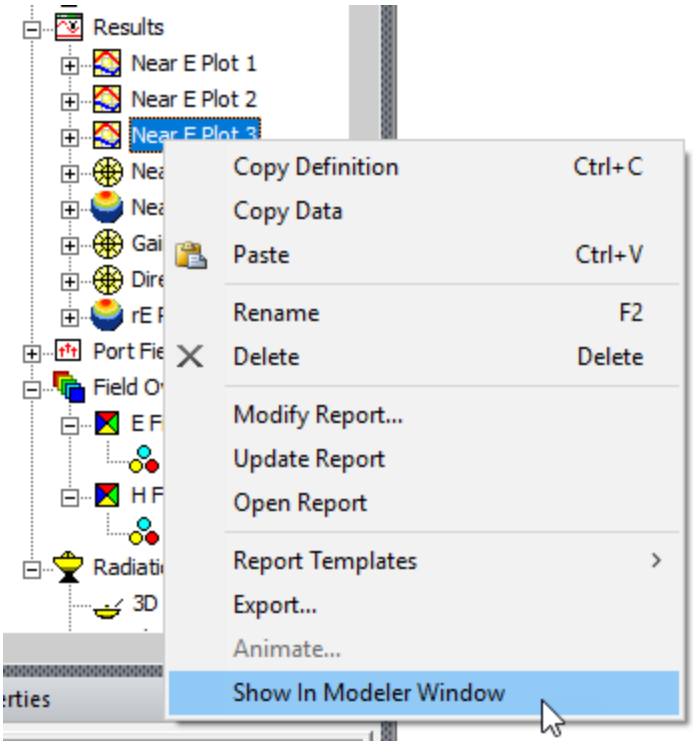


Radiation plots and antenna parameter tables available for overlay can be viewed by right-clicking **Field Overlays** in the **History Tree**, and selecting **Plot Fields** > **Radiation Field...**. This displays an *Overlay radiation field* window that lists each results plot available for overlay.



You can also control the visibility of **Results** plots available for the Modeler by right-clicking on the report and selecting **Show in Modeler Window**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can overlay existing 3D Polar Plots of near or far fields, near field contour plots on a near field rectangle, 2D Radiation Pattern Plots, and Monostatic or Bistatic RCS 2D plots in the model window using the **HFSS 3D Layout** or **HFSS** > **Fields** > **Plot Fields** > **[*Field*]** command, or by right-clicking on **Field Overlays** in the **Project Manager** and selecting **Plot Fields** > **[*Field*]**. You can also create animations of field plots.

You can overlay a 2D contour plot including Range Doppler color mapped plot to model window as a 2D overlay (which means it cannot be rotated like a geometry model). The overlay of near field on Rectangle contour plot or 2D radiation pattern plot is different. It is a 3D overlay as it can be rotated along with geometry model in 3D space.

You can also overlay tables of selected antenna parameters.

If the design includes Layout Components, the **Create Field Plot** dialog contains additional functionality for nets and layers.

To Plot Fields

To plot a basic field quantity after you have run a simulation with **Save Fields** checked on the Solution setup:

1. Select a point, line, surface, plane, cutplane, or object to create the plot on or within. Your choice affects the way the fields are plotted. If you selected an object, you must check **Plot on surface only** to enable the **Surface Smoothing** button

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

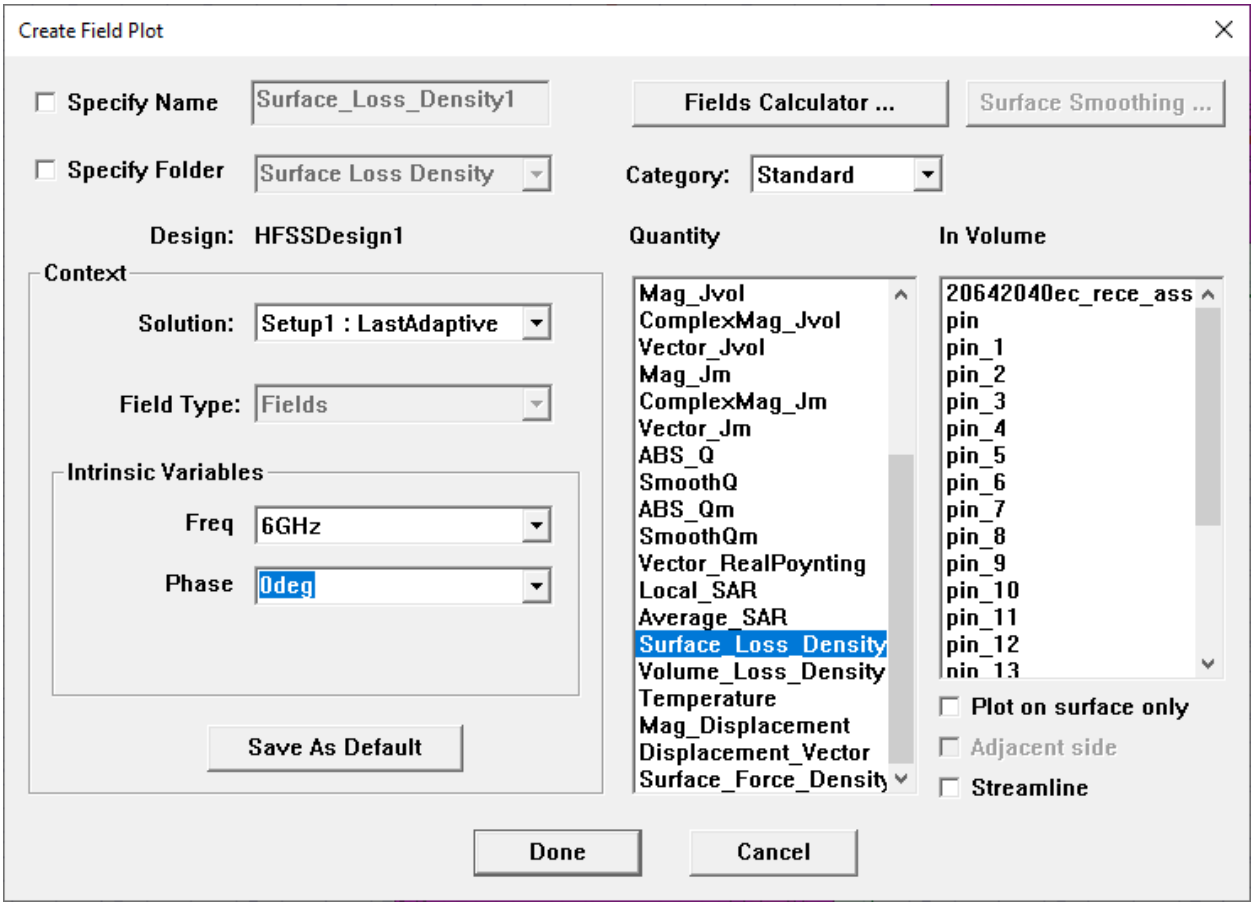
2. Click **HFSS** > **Fields** > **Plot Fields**, or right-click the Field Overlay icon in the Project Manager and select **Plot Fields** , or right-click in the modeler window, and select **Plot Fields** from the context menu.
3. In the **Plot Fields** menu, click the field quantity you want to plot.

   Available selections depend on the solved solution. For definitions of the usual quantities, see the list under Quantity command.

   If you select a scalar field quantity, a scalar surface or volume plot will be created. If you select a vector field quantity, a vector surface or volume plot will be created. If you select a vector quantity, you will be able to specify a Streamline plot. If the quantity you want to plot is not listed, see Named Expression Library.

   For projects with Temperature dependent materials, the **HFSS 3D Layout, HFSS** > **Fields** > **Plot Fields** > **Other...** menu selections include **Temperature**. For Transient projects, the menu selections show "_t" to show that they represent time dependent quantities, such as E_t, H_t, J_t, and so forth.

   After you select the field quantity to plot, the *Create Field Plot* window appears.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Specify Name** field shows a name based on the field quantity you selected, and the **Quantity** list shows the field quantity selected. If the design includes Layout Components, the **Create Field Plot** dialog contains additional functionality for nets and layers.

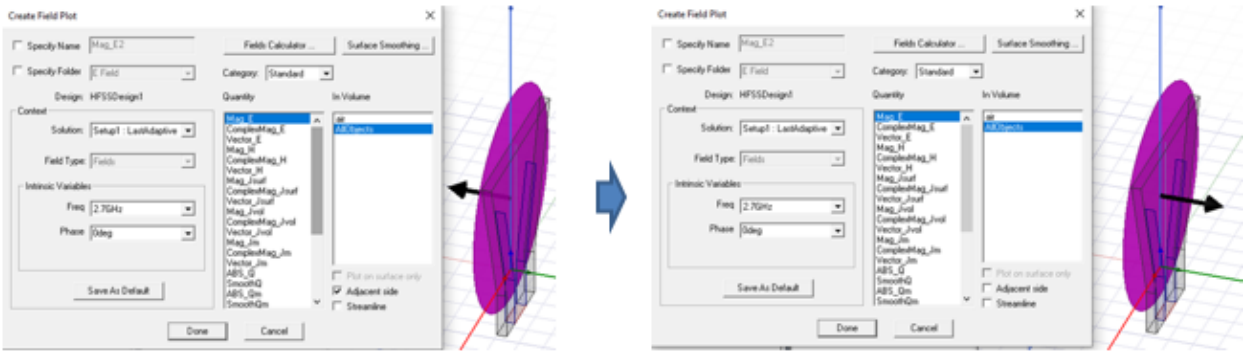
4. To specify a name for the plot other than the default, select **Specify Name**, and then type a new name in the **Name** field.
5. Select the solution to plot from the **Solution** drop-down menu. Set the design variation via the *Set Design Variation* window. Access this window from the *Solution Data* window by clicking the ellipsis button on the right of the Design Variation field, or via the **HFSS** > **Results** > **Apply Solved Variation** command.
6. To specify a folder other than the default in which to store the plot, select **Specify Folder**, and then click a folder in the **Plot Folder** drop-down menu, or type the name you wish to use. Plot folders are listed under **Field Overlays** in the Project Manager. Plot folders let you group plots with the same quantity together. All field plots under the same folder share the same color key.
7. Under **Intrinsic Variables**, select the frequency and phase angle at which the field quantity is evaluated.
8. If desired, you can select a different field quantity to plot from the **Quantity** list. For scalar quantities plotted on the surface of a geometry, the **Surface Smoothing** button is enabled. For vector quantities, the **Surface Smoothing** button is disabled. For details on its use, see Modifying Field Plots.
9. Select the volume (region) in which the field will be plotted from the **In Volume** list.

   This selection enables you to limit plots to the intersection of a volume with the selected object or objects. You can select and deselect any items in the **In Volume** list. You can mix model objects with non-model boxes. For example, you may want to see a plot from part of two model objects by restricting the region to a non-model box overlapping those parts.

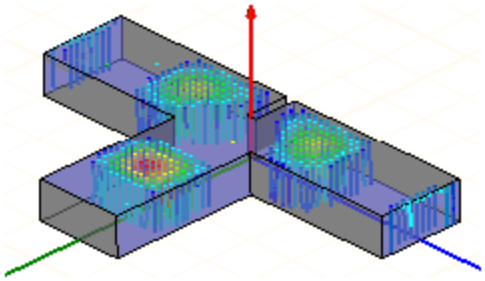
   > **Note:** Multiple selection should be used when there is a discontinuous field on a surface. If not, the field on both sides of the surface are plotted and each interferes with the other.

10. If you are creating a plot on a sheet object, the **Adjacent** checkbox allows you to create field overlays on a sheet object using data from either side of the sheet. An arrow indicates where the data is coming from. While the data is usually the same on the two sides of a sheet object, in a situation where the sheet object is assigned to be a shell element, the field may be different on its two sides. (Shell elements are an option for Layered Impedance Boundaries and Finite Conductivity Boundaries with DC conductivity and two-sided selected.) In such cases, you can visualize the field data on the side you want.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



11. If you selected a **vector** quantity, you can use the check box to select **Streamline** plot. Streamlines are often used to indicate magnetic flux lines, etc. in plots.



Notes for creating Streamline plots:

a. Before creating the plot, select the starting edge (in 2D), starting surface (in 3D), or the starting points for both 2D and 3D.

b. In the Creating Field Plot menu, select "In Volume: Region" which is the volume in which the streamlines will appear and is outside of the sources.

c. After the plot is created, on the Attributes/Plot tab you can, you can reduce "Seeds density" to show more streamlines. If no streamlines appear, reduce this by a factor of 10 (or 100) because the default seeding was too large.

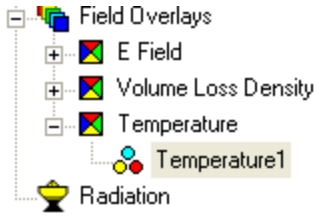
See Setting Field Plot Attributes for adjusting the streamline display and Setting Fields Reporter Options for setting Streamline defaults. For exporting Streamline plots, see Exporting Field Plots.

12. Click **Done**.

The field quantity is plotted on the surfaces or within the objects you selected. The plot uses the attributes specified in the **Plot Attributes** window.

The new plot appears in the view window. It is listed in the specified plot folder in the project tree. Each category of plot is listed separately in the Project Manager.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If you have created a field plot on a simulation in progress, the field plot is updated after the last adaptive solution. If you want to update the field overlay before then, to view progress in the solution, select the Field icon in the Project tree that contains the field plot of interest, right-click to display the shortcut menu, and select **Update Plots**.

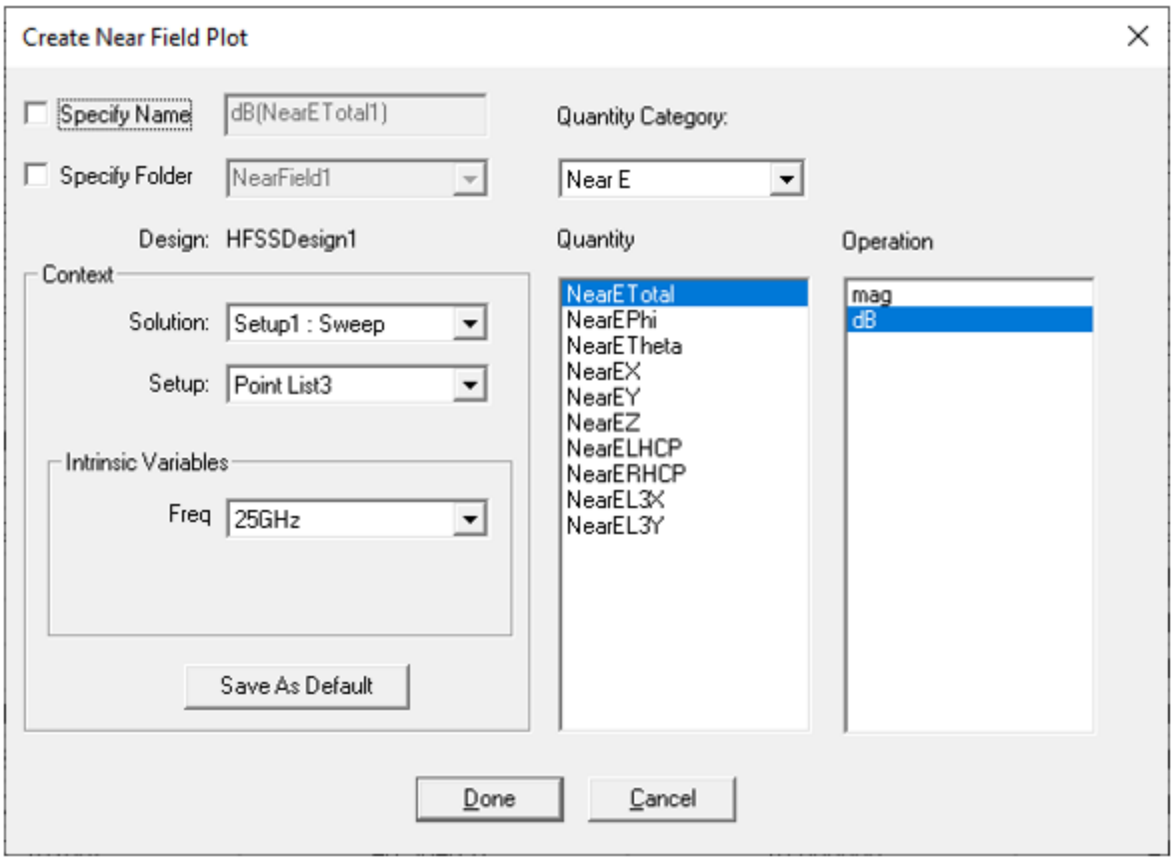
To turn off the display of the plot, right-click on the plot and select **Plot Visibility** from the shortcut menu. Deselect **Plot Visibility** to turn off the plot display.

Generating a Sampled Near Field Plot

To create a Sampled Near Field Plot, based on an arbitrary Point List:

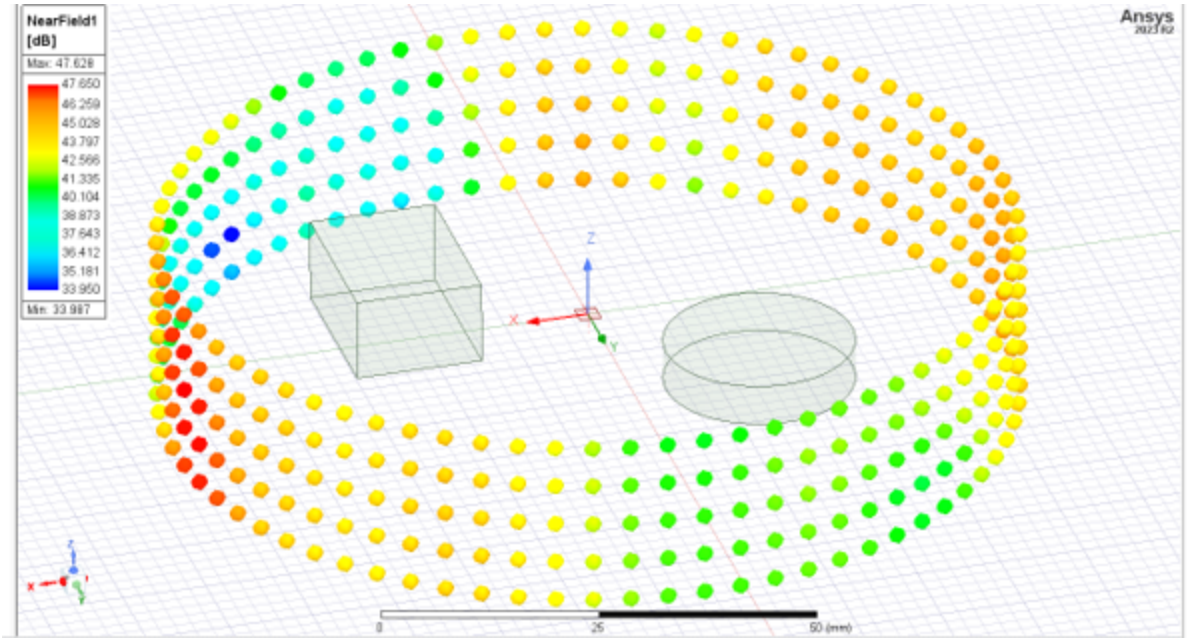
a. Right-click the Field Overlays node in the Project tree, and from the shortcut menu, select **Plot Sampled Near Field ...**. This opens the Create Near Field Plot dialog.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can use the **Create Near Field Plot** dialog to configure which solution, quantity, and so forth.

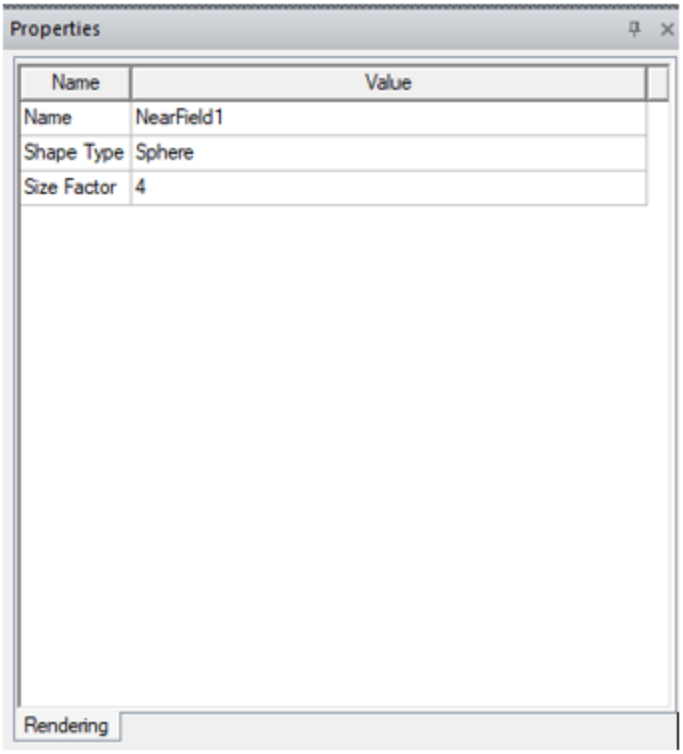
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The Properties for the Plot lets you specify:

- Shape Type [Point, [Point, Sphere, Box, Dot, Plus]
- Size Factor (sets size of shape marker)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



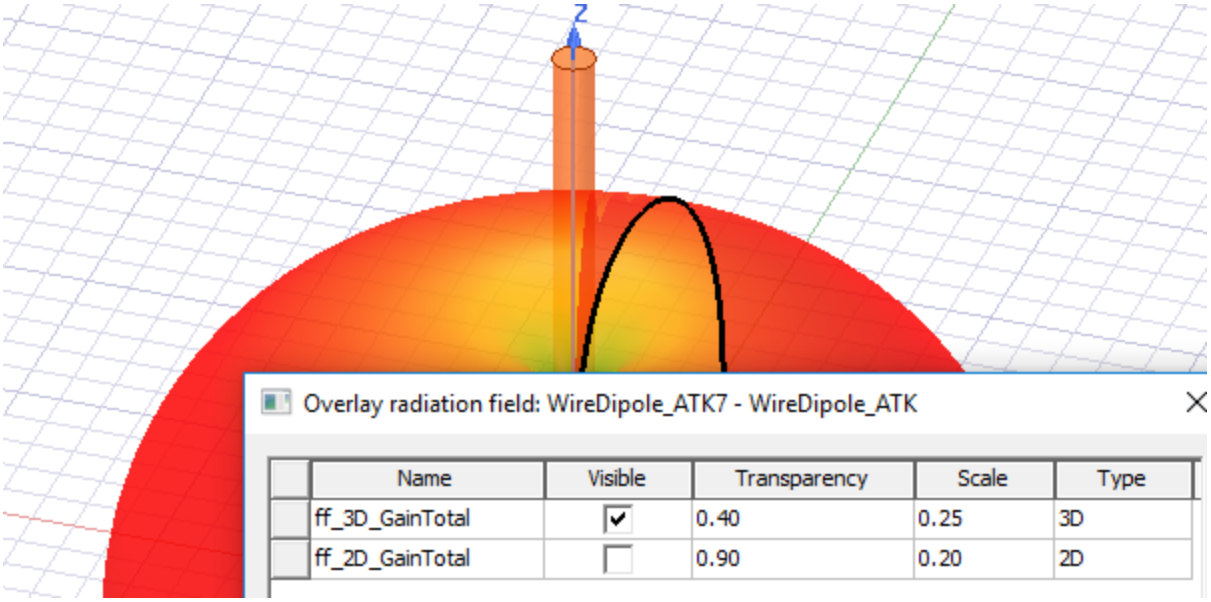
Other attributes can be modified via the Field Plot Attributes dialog box. These attributes include:

- Colormap Spectrum
- Auto Scale [On/Off] - automatically set Minimum/Maximum color scale range
- Minimum/Maximum - color scale range (linear)
- Number of Levels - sets the number of discrete color levels to use in linearly interpolating colors of shape/markers

Overlaying 3D Polar Plots of Near or Far Fields on Models

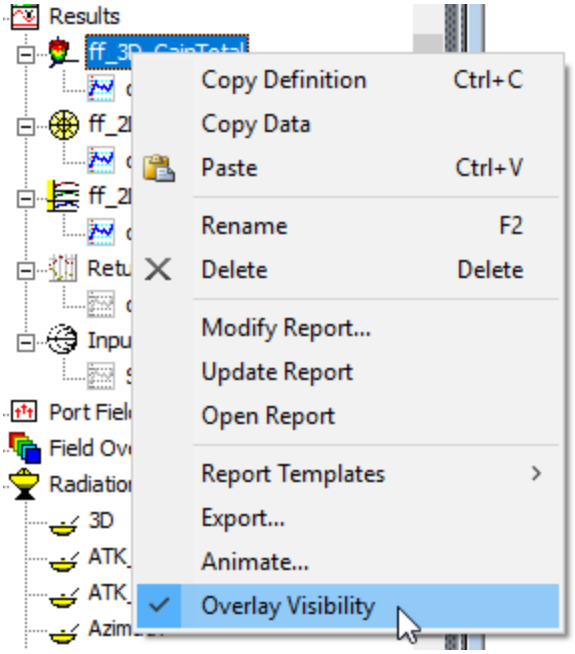
You can overlay existing 3D Polar Plots of near or far fields on the 3D model window by using the **Overlay Radiation** field dialog invoked by using the [*solver*]**>Fields>Plot Fields>Radiation Field...** command, or by right-clicking on Field Overlays in the **Project** tree and selecting **Field Overlays>Radiation Field...**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can edit the visibility, transparency and scale of the polar plot by using the dialog.

You also toggle the overlay of an existing plot by right-clicking on the plot in the **Project** tree and clicking **Overlay Visibility** on the shortcut menu.

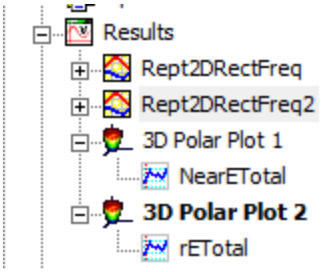


Using the Overlay Radiation Field Dialog

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For a 3D polar plot to be eligible for overlay, it must have its primary and secondary sweep from variables Phi and Theta or IWavePhi and IWave Theta in that order. If the plot is unsuitable, the **Overlay** commands are disabled.

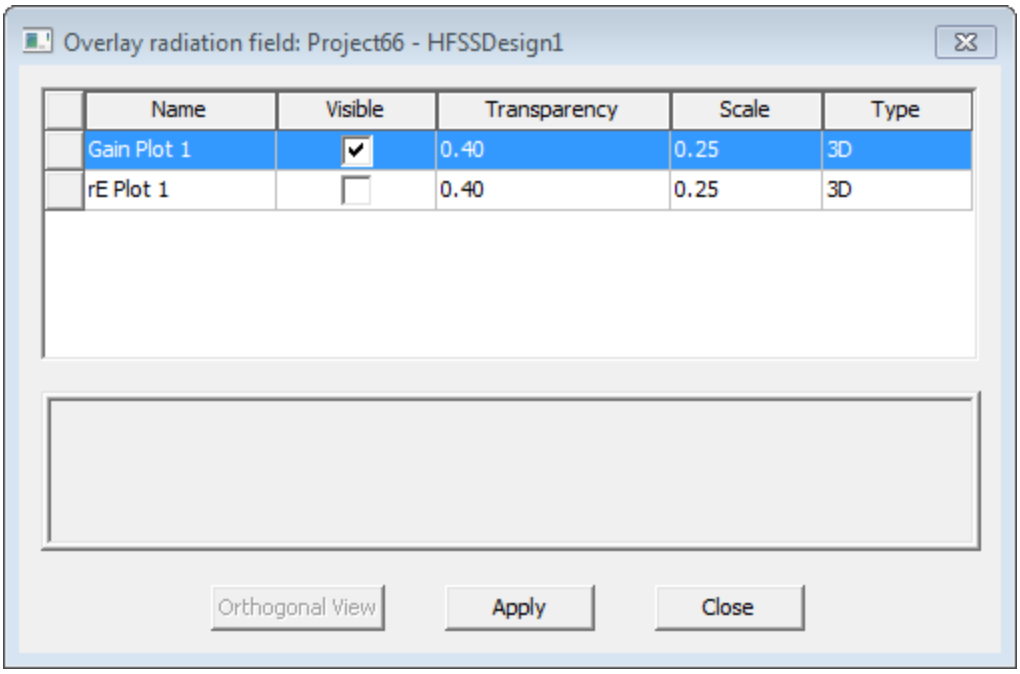
1. Create one or more suitable 3D Polar Plots of near or far fields for your model.



This enables the **Radiation Field...** command on the **Plot Fields** submenu.

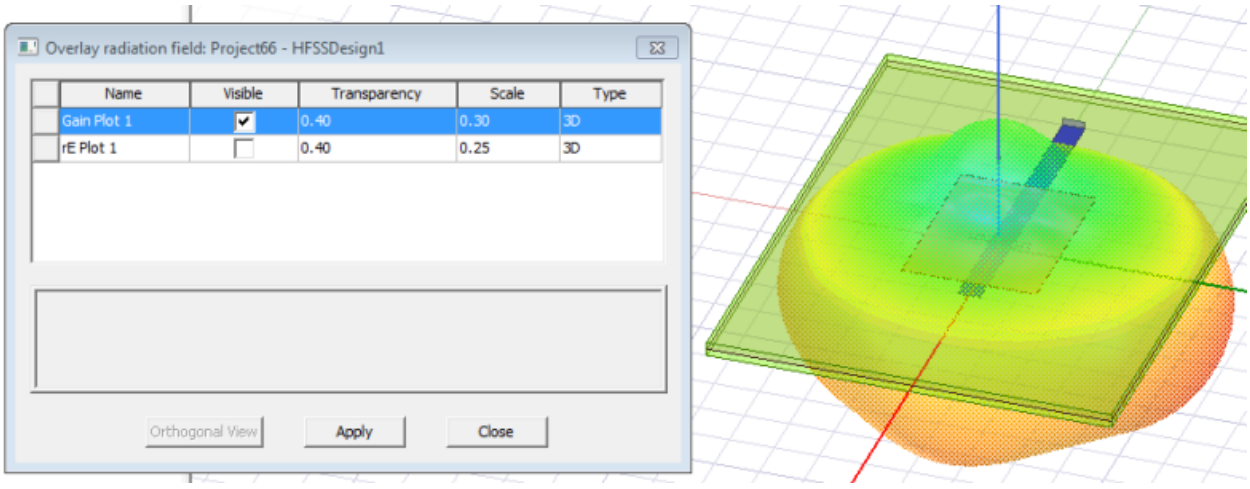
2. Click the [*solver*]**>Fields>Plot Fields>**[*field*] command, or by right-clicking on Field Overlays in the Project tree and selecting **Plot Fields>Radiation Field...**

This displays a dialog listing any existing 3D polar plots of near or far fields.



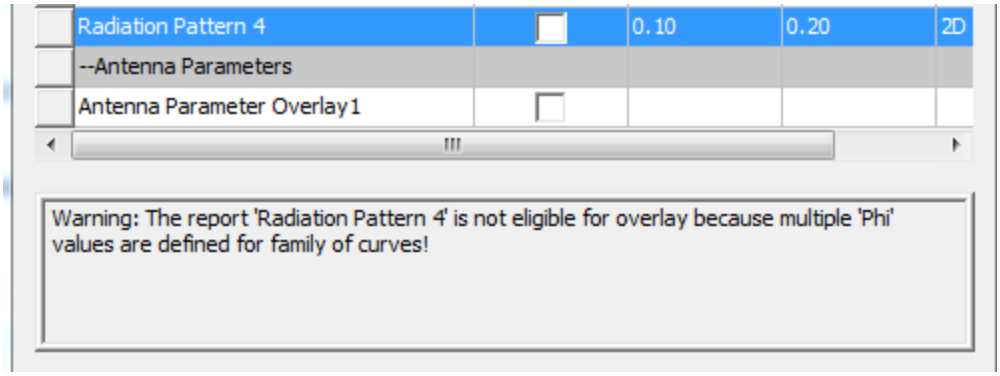
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Check the Visible box and click **Apply** to cause that plot to appear in the model window.



You can also edit the Transparency and Scale in the dialog box. Other properties of the 3D plot are controlled in its properties window.

If a 3D polar plot is unsuitable for overlay, the message field provides a description of the issue.



If you have Saved Antenna Parameters for Overlay, you also use this dialog to control whether to display a table of antenna parameters. See Antenna Parameter: Save for Overlay.

Overlaying 2D Radiation Field Plots on Models

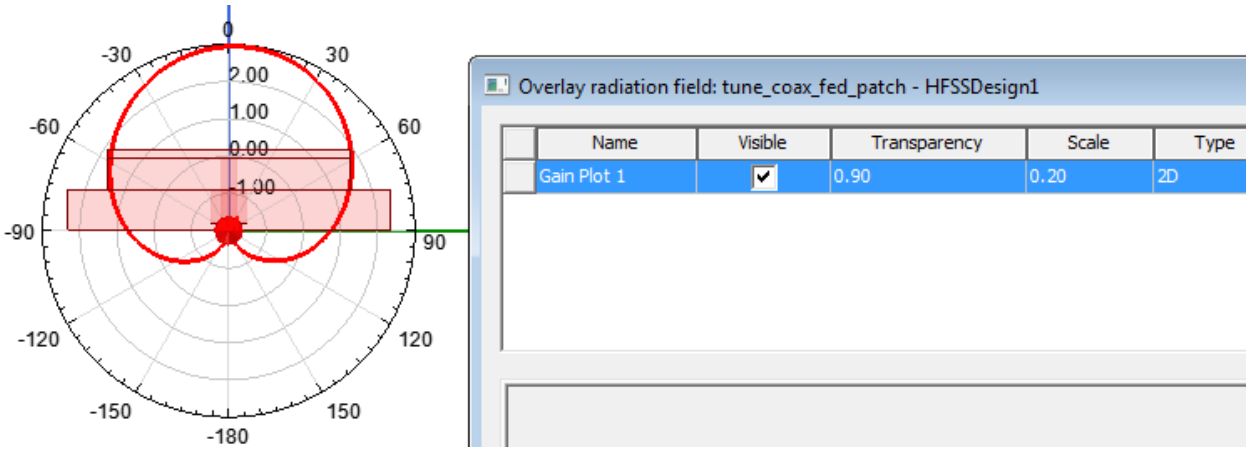
You can overlay Radiation Pattern plots (with restrictions) on the geometry in the Modeler window. The eligibility depends on whether the plot is defined on a single plane. For a Radiation Field plot, you right-click **Results** in the Project tree, and click **Results>Create Far Fields Report>Radiation Pattern**.

There are two cases of eligible radiation pattern plots for overlay, defining a single plane in a 3D Polar Plot.

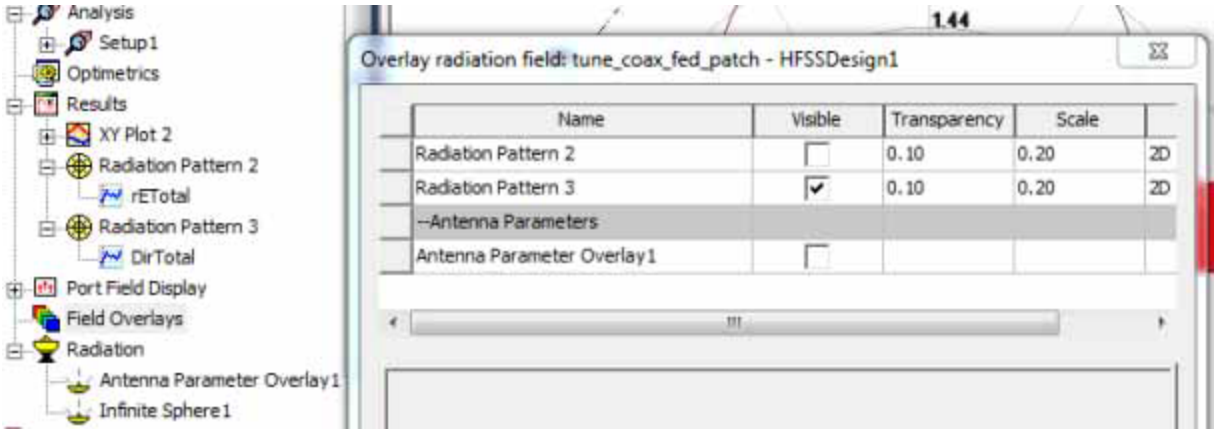
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Primary sweep on "Theta" and with one value for "Phi" in "Families" of curves, typically 0 or 90.
- Primary sweep on "Phi" and with one value for "Theta" in "Families" of curves and "Theta" is either 90deg or -90deg.

Note that the plot can contain multiple traces within this plane - for example traces for multiple frequencies of a discrete sweep. The Radiation Pattern plot will overlay on the 3D view, in the appropriate rotated plane of the far field CS, and include all traces and the axes/grid. There is no need to show the title or legend.



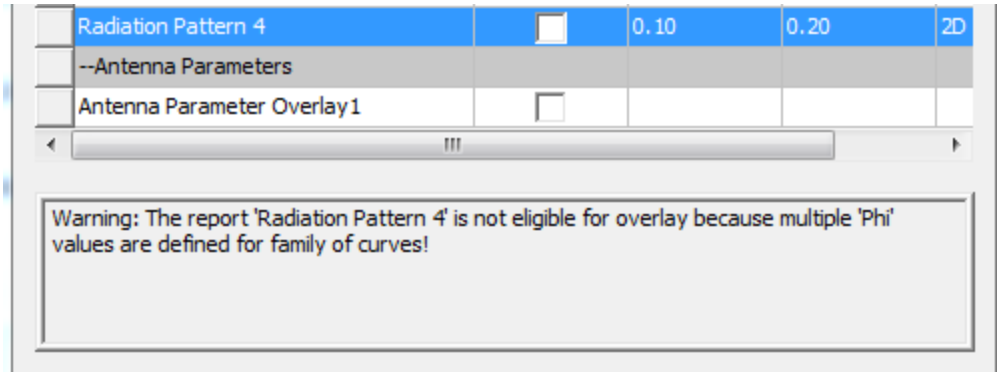
Radiation Pattern plots are added to the **Overlay radiation field** dialog that displays when you right-click **Field Overlays** in the Project Tree and select **Plot Fields>Radiation Field...** from the shortcut menu. The dialog lets you toggle visibility for the Model window and set plot parameters for Transparency, Scale, and Type (2D or 3D).



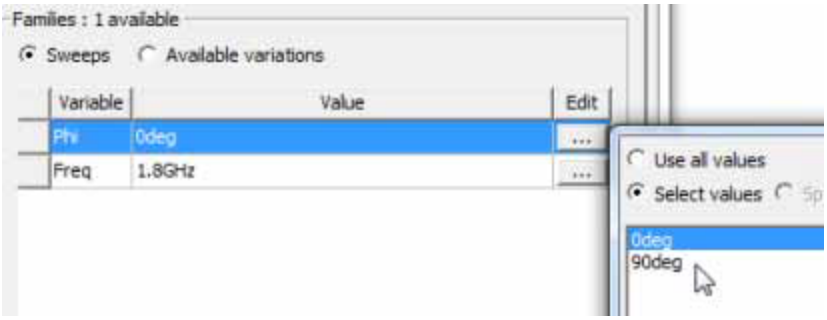
There are several cases mentioned above where an overlay will not be valid for display. This includes any radiation plot that has multiple planes. The **Overlay radiation field** dialog always lists all possibly overlays for selection, whether they are valid or not. However, if you check the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

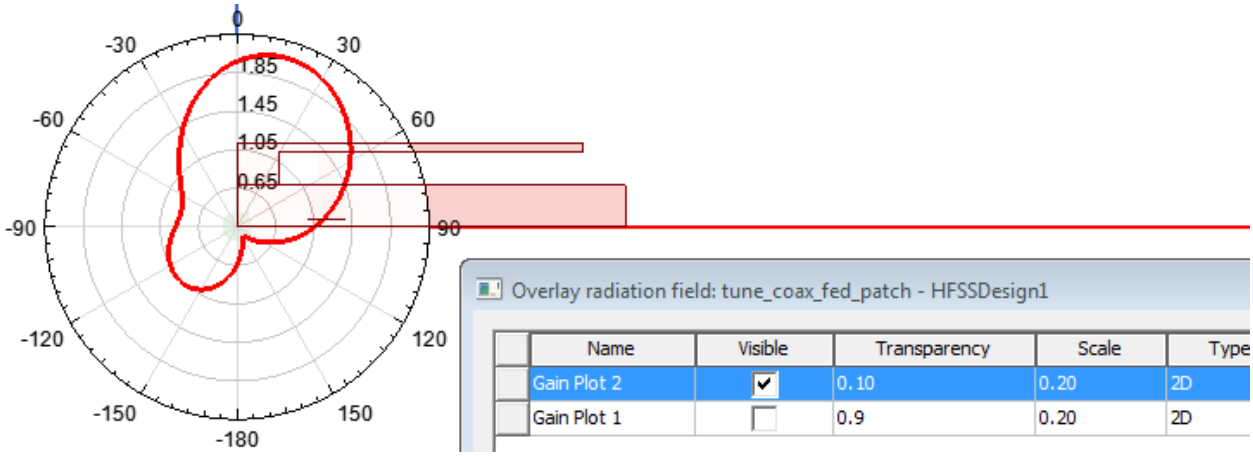
Visibility column an overlay that is not valid, and then click **Apply**, the text field in the dialog gives a warning describing why the overlay is not valid, and then unchecks that overlay. Similarly, if a valid overlay is already being shown, and then you edit the plot settings or antenna parameters such that the overlay becomes invalid, the visibility column becomes unchecked and the overlay stops displaying.



You can then use **Modify Report** to change the plot based on the warning to make it valid for display. Typically, you can select the **Families** Tab, and select the desired Phi value.



When the plot is valid, **Apply** then shows the plot in the modeler window.



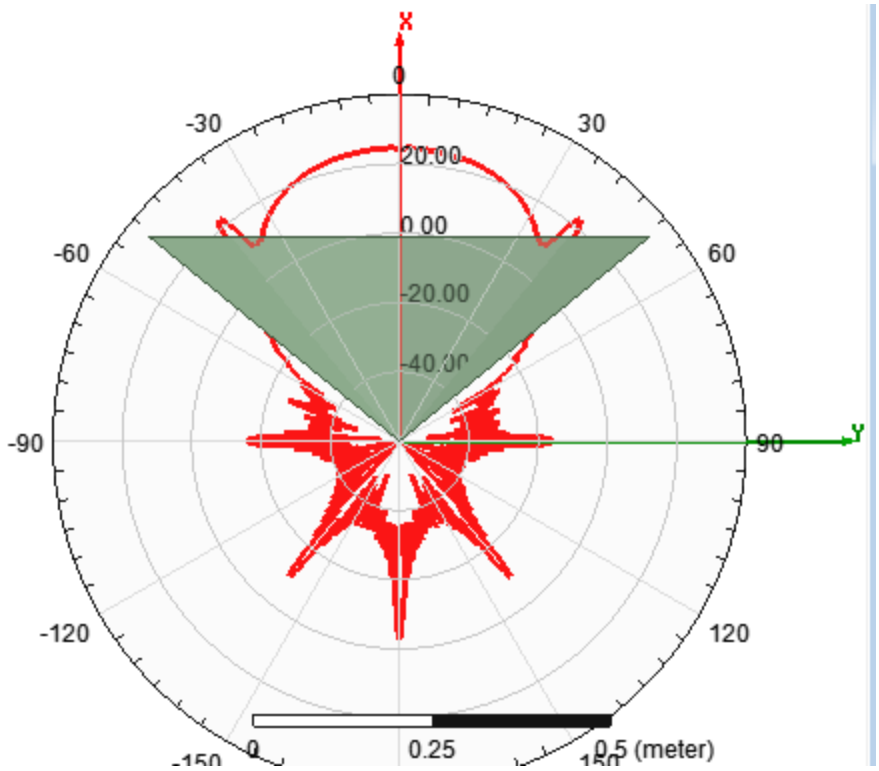
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you have Saved Antenna Parameters for Overlay, you also use this dialog to control whether to display a table of antenna parameters. See Antenna Parameter: Save for Overlay.

Also see Creating 2D Radiation Field Plot Overlay Animations

Overlaying Monostatic and Bistatic RCS 2D Plots

You can Monostatic and Bistatic 2D radiation pattern plots, in a similar way that you can overlay Monostatic RCS 2D Polar plots and Bistatic RCS 2D Polar plots, as well 3D Polar Plots and 2D Radiation patterns. As with regular radiation pattern plots, the eligibility depends on whether the RCS plot is defined on a single plane. The following is an example of a Monostatic RCSTotal Plot for a TriHedral SBR+ model:

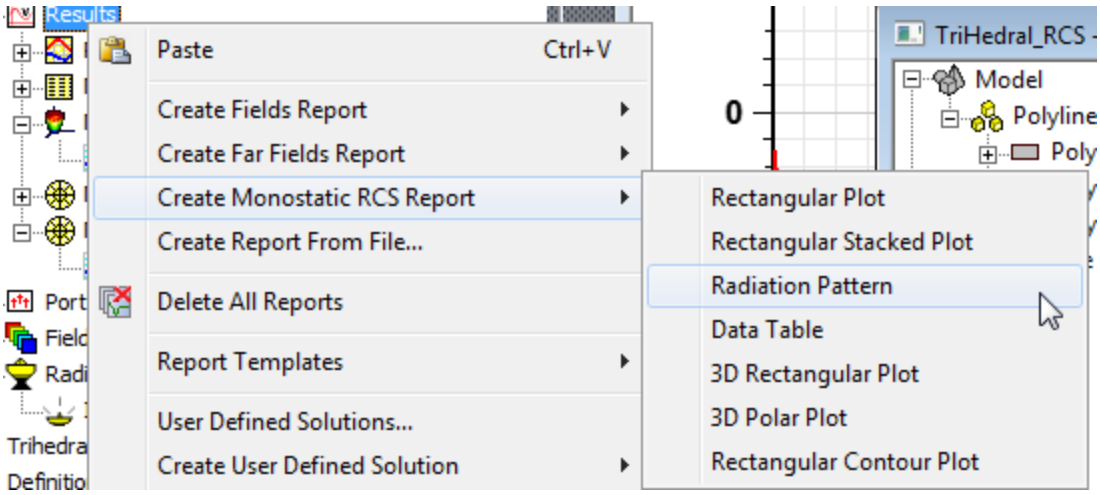


There are two cases of eligible Monostatic and Bistatic plots for overlay, defining a single plane in a 2D Polar Plot.

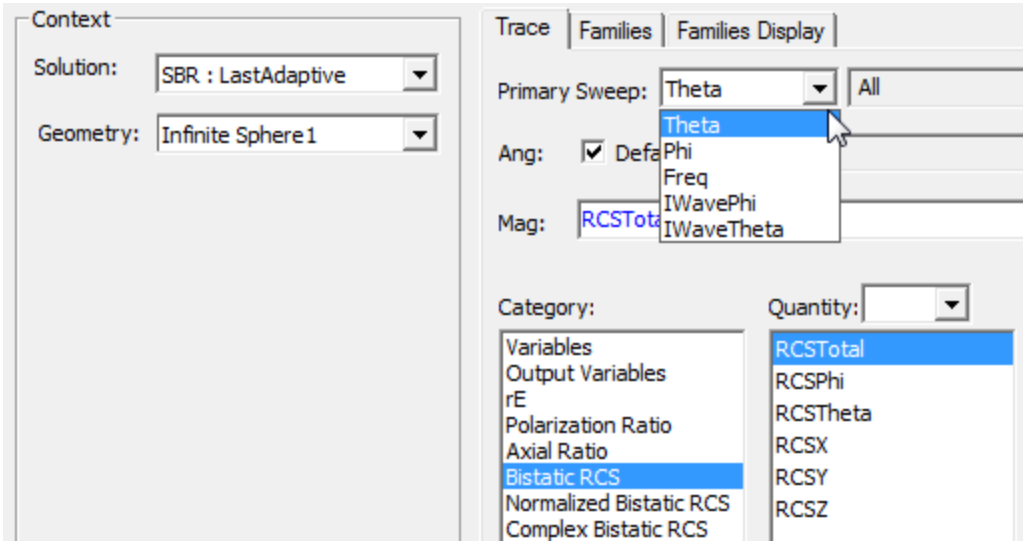
- For Primary sweep on Theta or IWave Theta, with the Phi or or IWavePhi to be any single value of the sweep, typically 0 or 90, but any single phi value is allowed.
- For Primary sweep on Phi or IWavePhi, Theta or IWaveTheta is either +/-90 deg.

Monostatic RCS Reports appear as options for models with SBR+ regions.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

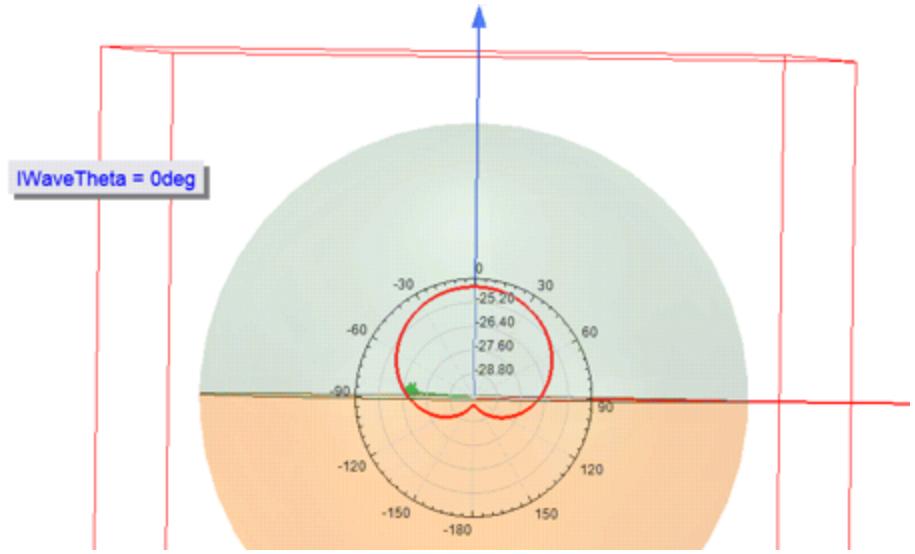


Bistatic RCS appears under Category for Far Field Reports in projects that contain SBR+ Regions.

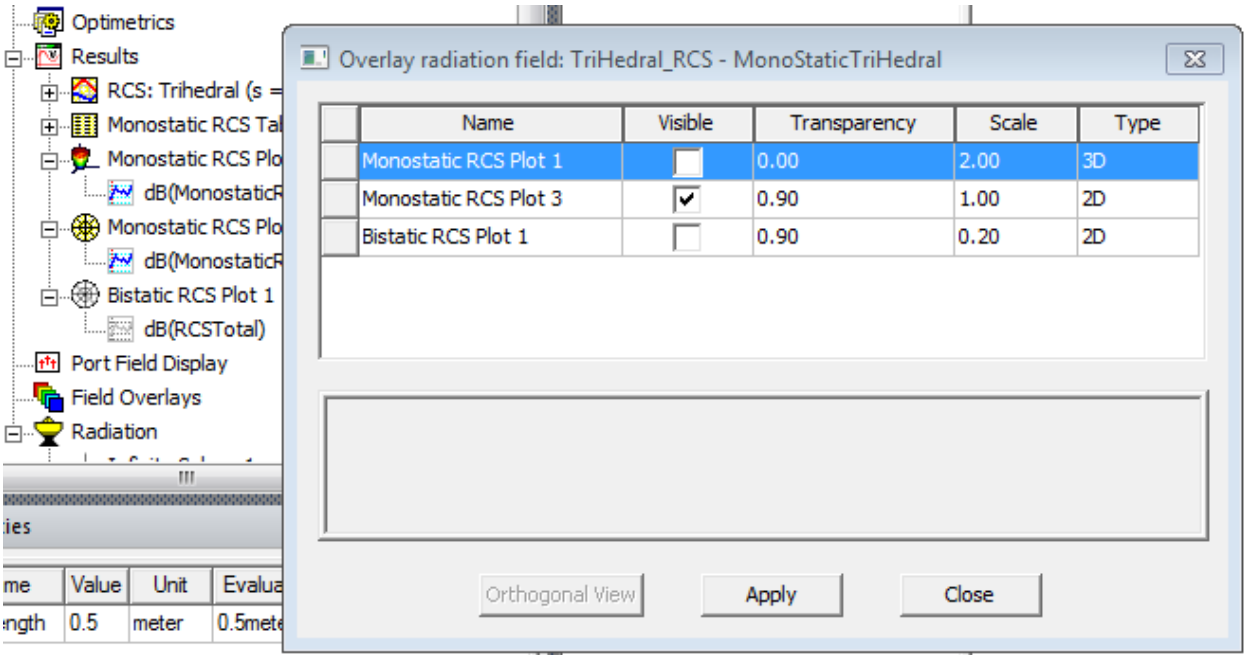


The following figure shows a Bistatic RCS Plot during animation with respect to Theta angle.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



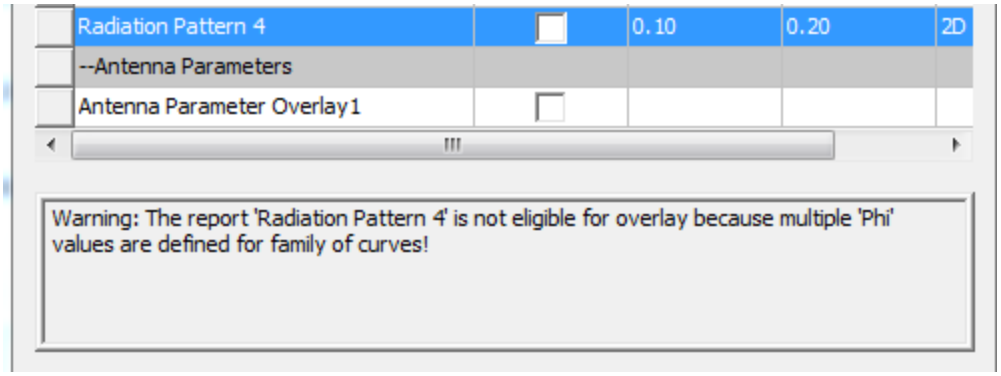
Radiation Pattern plots are added to the **Overlay radiation field** dialog that displays when you right-click **Field Overlays** in the Project Tree and select **Plot Fields>Radiation Field...** from the shortcut menu. The dialog lets you toggle visibility for the Model window and set plot parameters for Transparency, Scale, and Type (2D or 3D).



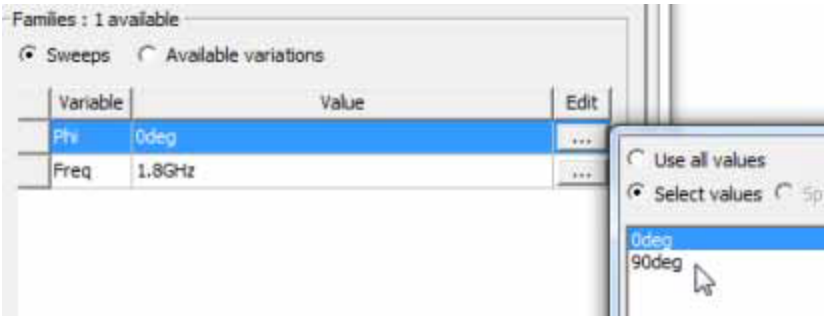
There are several cases mentioned above where an overlay will not be valid for display. This includes any radiation plot that has multiple planes. The **Overlay radiation field** dialog always lists all possibly overlays for selection, whether they are valid or not. However, if you check the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Visibility column an overlay that is not valid, and then click Apply, the text field in the dialog gives a warning describing why the overlay is not valid, and then unchecks that overlay. Similarly, if a valid overlay is already being shown, and then you edit the plot settings or antenna parameters such that the overlay becomes invalid, the visibility column becomes unchecked and the overlay stops displaying.



You can then use **Modify Report** to change the plot based on the warning to make it valid for display.



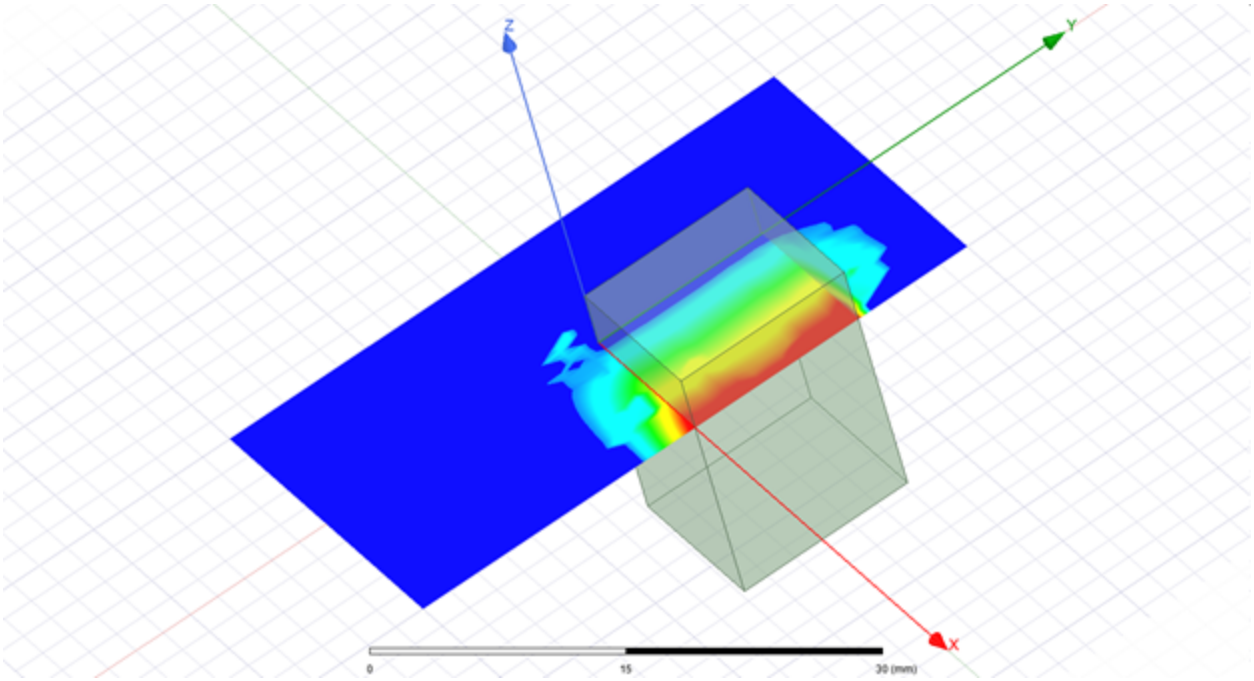
When the plot is valid, **Apply** then shows the plot in the modeler window.

If you have saved Antenna Parameters for Overlay, you also use this dialog to control whether to display a table of antenna parameters. See Antenna Parameter: Save for Overlay.

Overlay of Contour Plot of Near Field on Rectangle

For some contour plots like that for Near Field on a Rectangle radiation setup defined in a local coordinate system with physical dimensions, it makes sense to show the overlay of 2D contour plot in its actual defined rectangle in 3D space.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

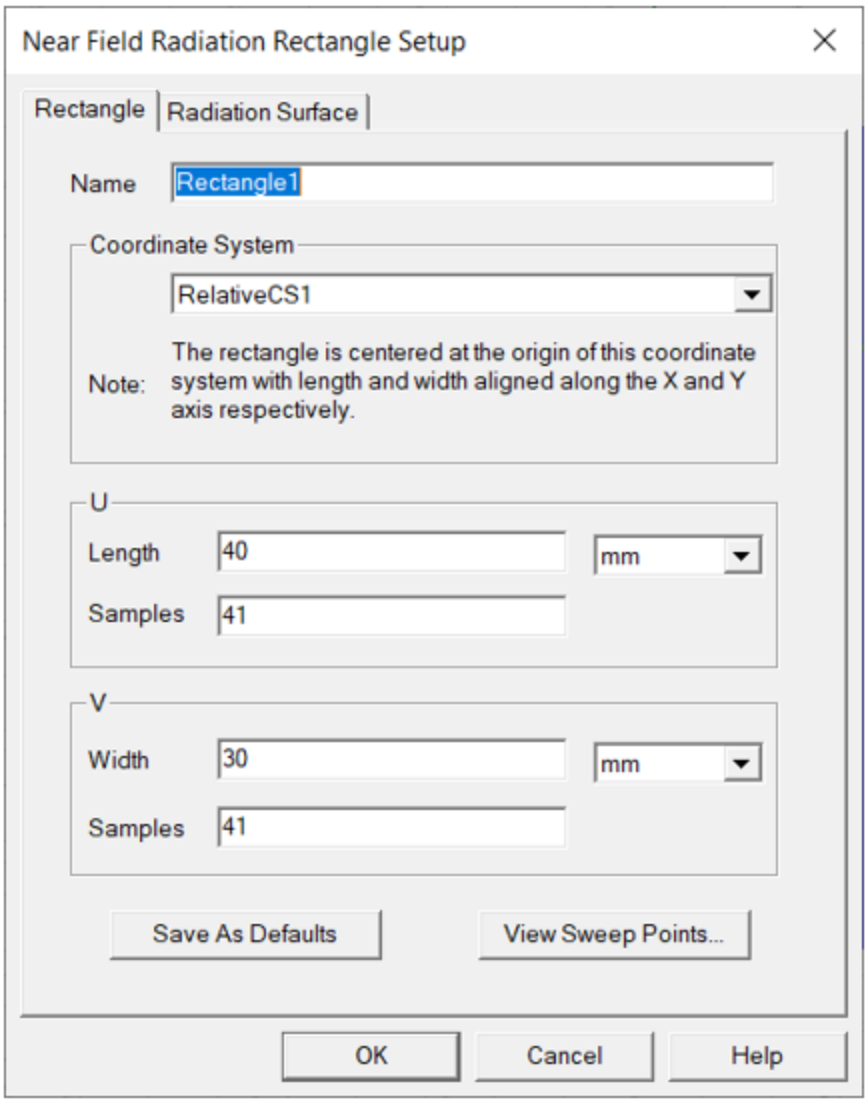


This feature is to allow user to have 3D overlay and its animation for this type of contour plot. The complete criteria of eligibility for overlay of this type of contour plot is as follows:

- Only a single trace plot
- Primary/Secondary sweep is _u and _v or _v and _u
- X/Y component of the trace is _u and _v or _v and _u
- No range function is used for Z component

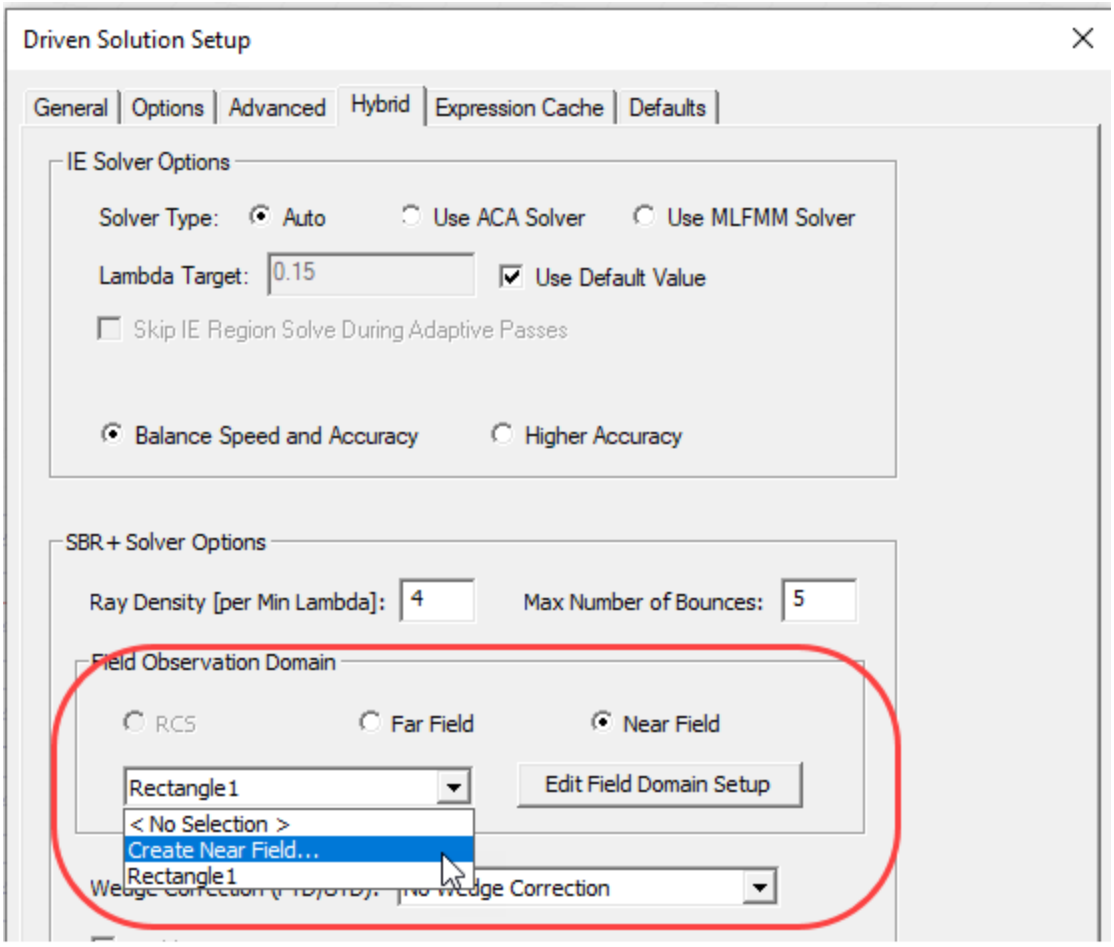
The Near Field rectangle setup looks something like this.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



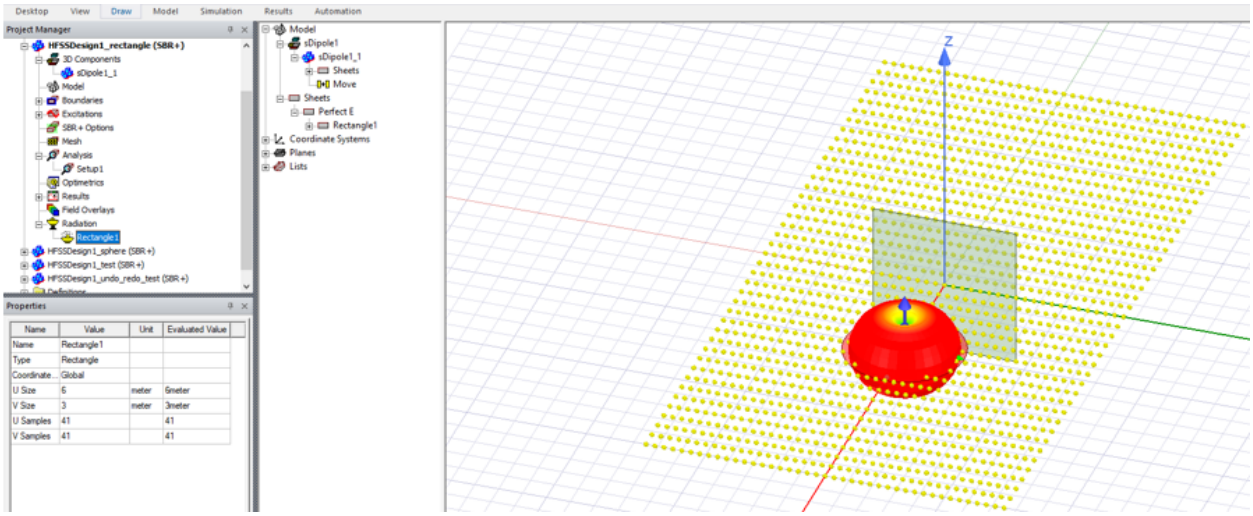
For HFSS Modal or Terminal solution types using SBR+ Regions, or HFSS SBR+ solution types, you must create the Near Field Rectangle before simulation. You can do this through the Field Observation Domain setting on the Hybrid tab of the Advanced Driven Solution Setup for and HFSS Driven Modal or Terminal Solution, or the Options Tab of the Driven Solution setup for an HFSS SBR+ Solution type setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



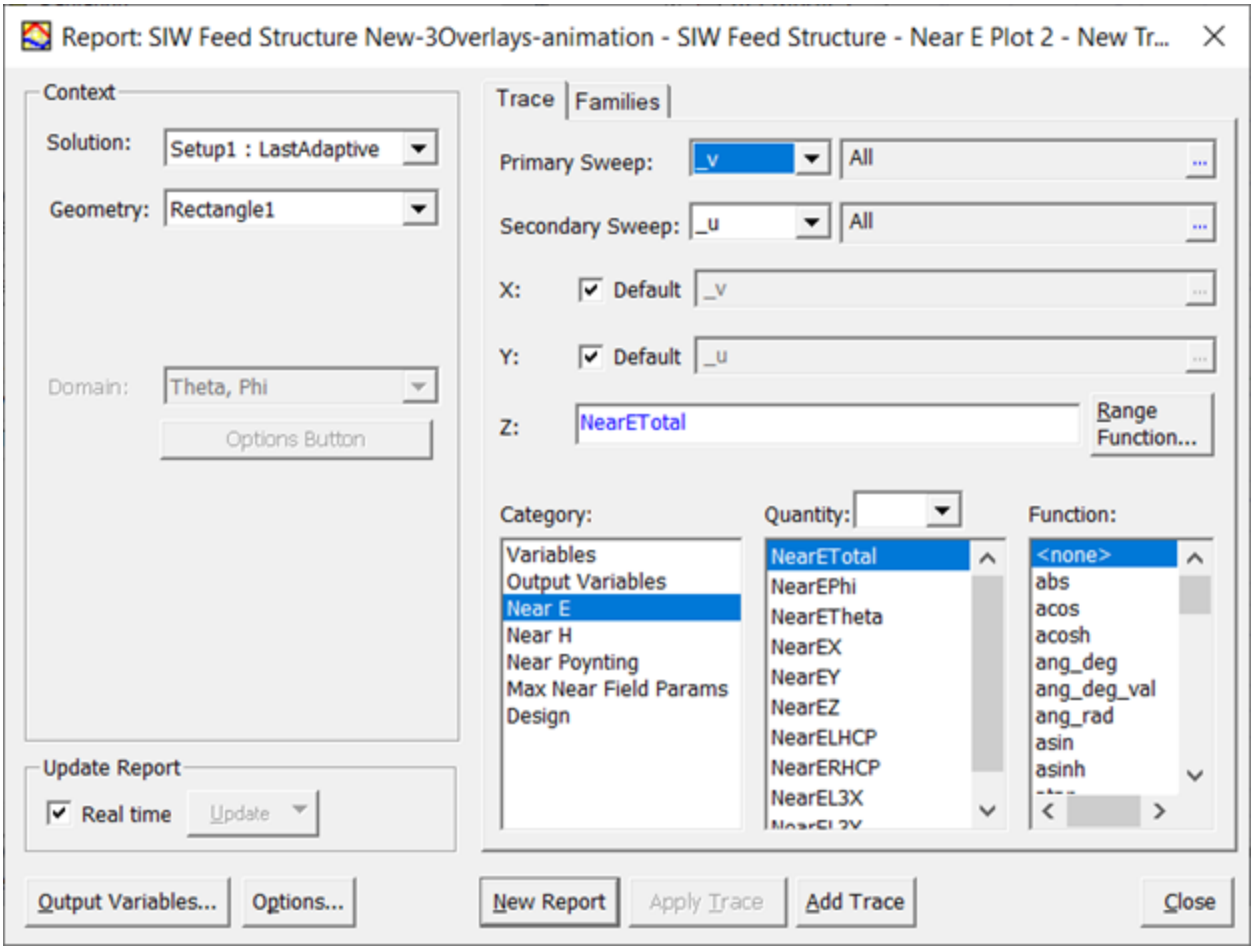
To preview the sampling points for a Near Field Rectangle, select the setup under the Radiation icon in the Project tree.

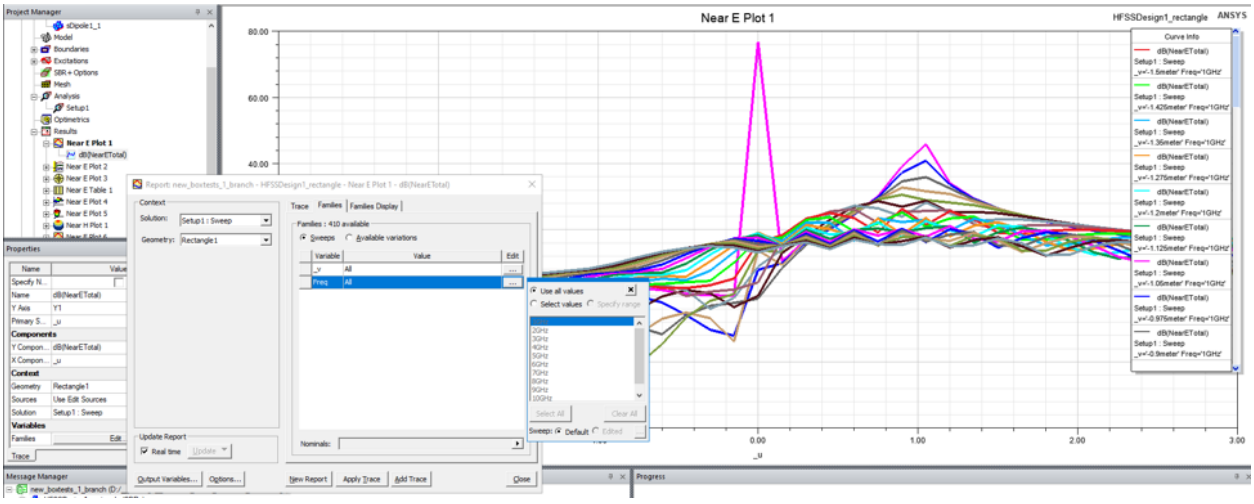
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Report** dialog for a Rectangular Contour plot of near field, using a Near Field Rectangle as the geometry, a combination of _u and _v as the Primary and Secondary sweeps is as follows.

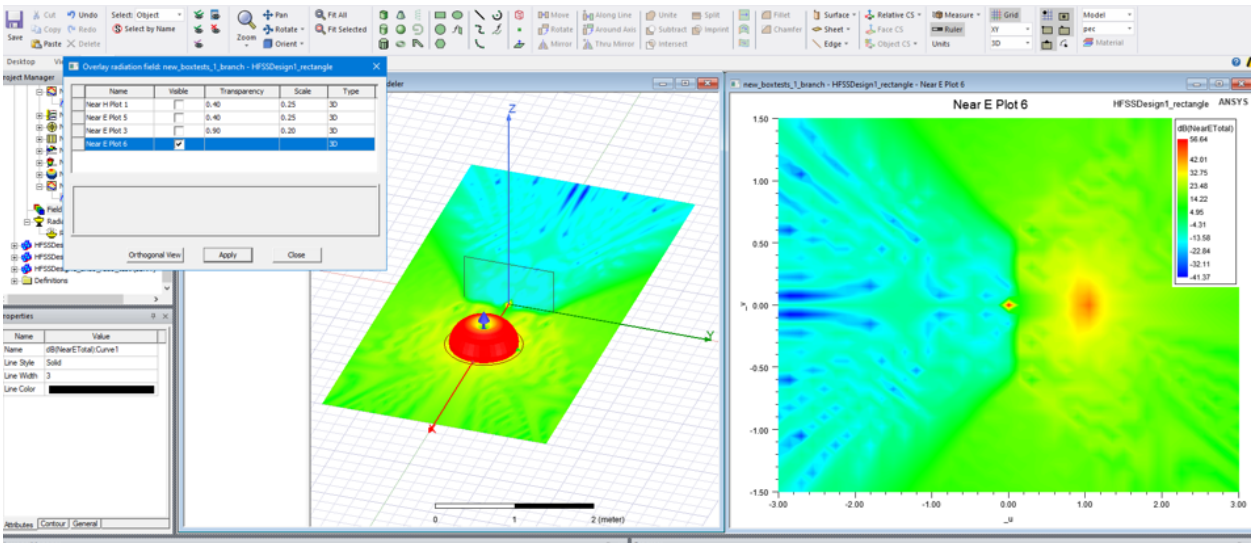
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A rectangular Near Field contour plot can be viewed as a report plot, or overlaid in the model window, just like other overlays, through the context menu. Rectangle size is not reflected in its 2D plot, it is only available in its overlay. The same applies to the coordinate system.



This Near Field Rectangular contour plot overlay can also be animated if there is a sweeping variable which could change the plot as the variable changes (e.g. it could change the rectangle location, etc.)

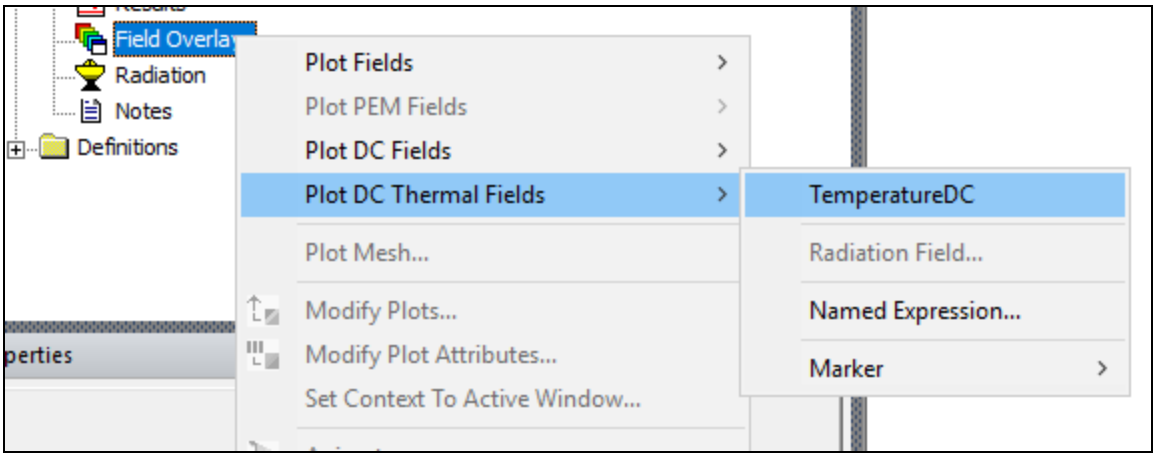
Also see Creating 2D Radiation Field Plot Overlay Animations

Overlaying DC Temperature Fields (General Mode Only)

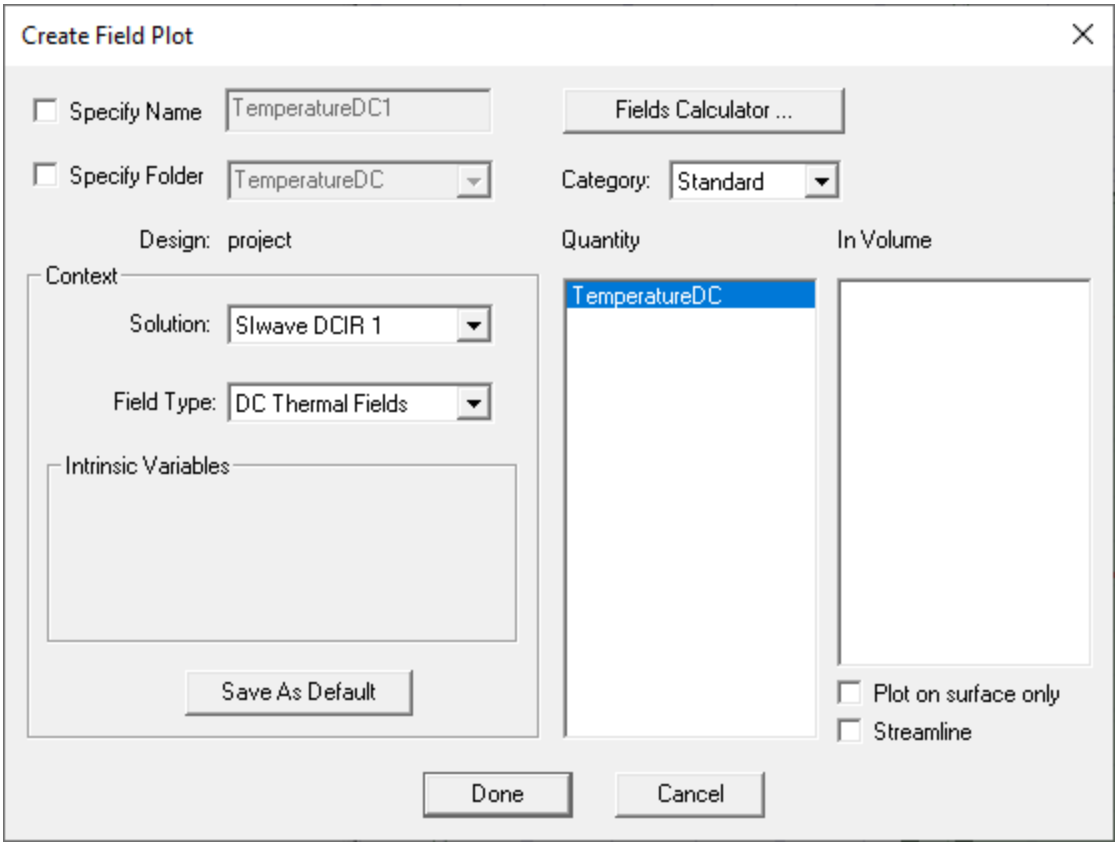
Projects with two-way coupling between Icepak and HFSS 3D Layout can have a field overlay that displays the DC temperatures. The 3D Layout project must have an Icepak DC IR analysis. To create such an overlay:

1. In the Project Manager, open the 3D Layout design and right click **Field Overlays** > **Plot DC Thermal Fields** > **TemperatureDC**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



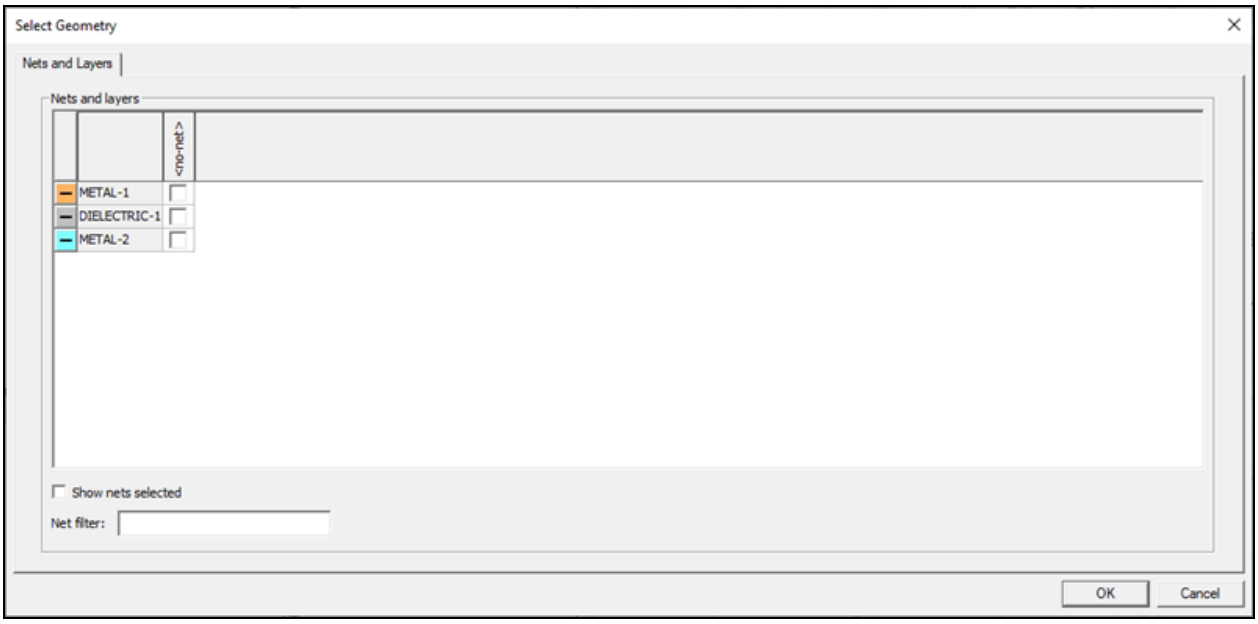
The **Create Field Plot** window opens.



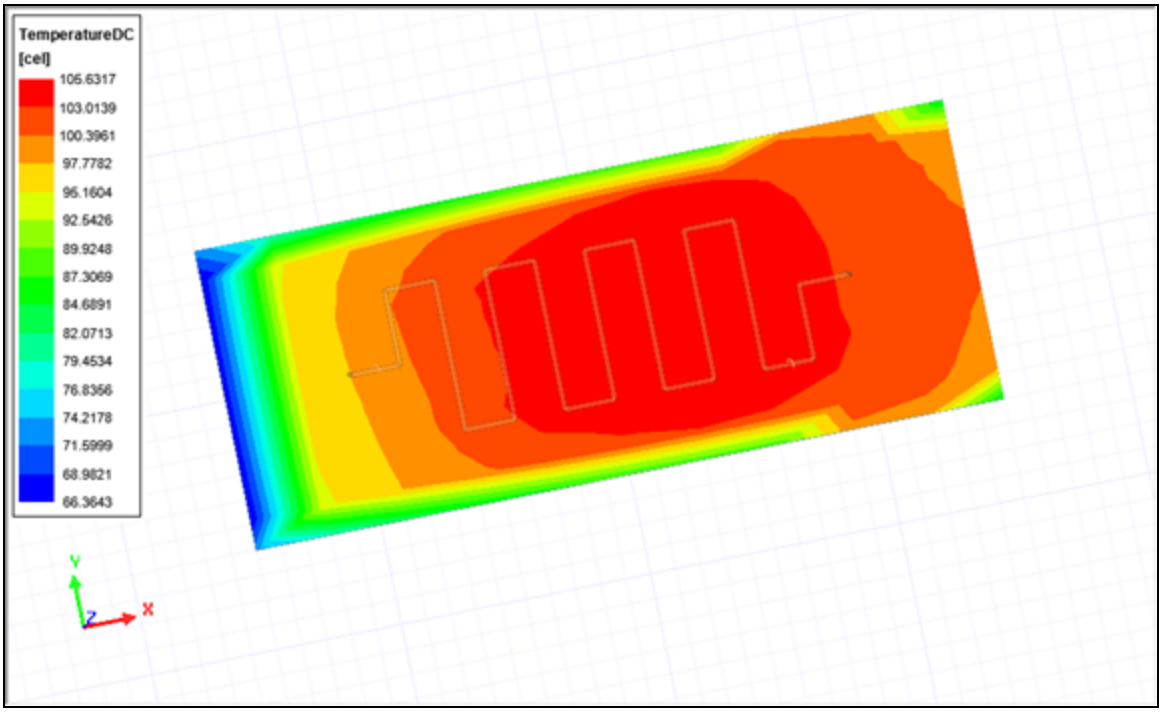
TemperatureDC is automatically selected from the Quantity list.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click **Done**. The **Create Field Plot** window closes, while the **Select Geometry** window opens to its **Nets and Layers** tab.



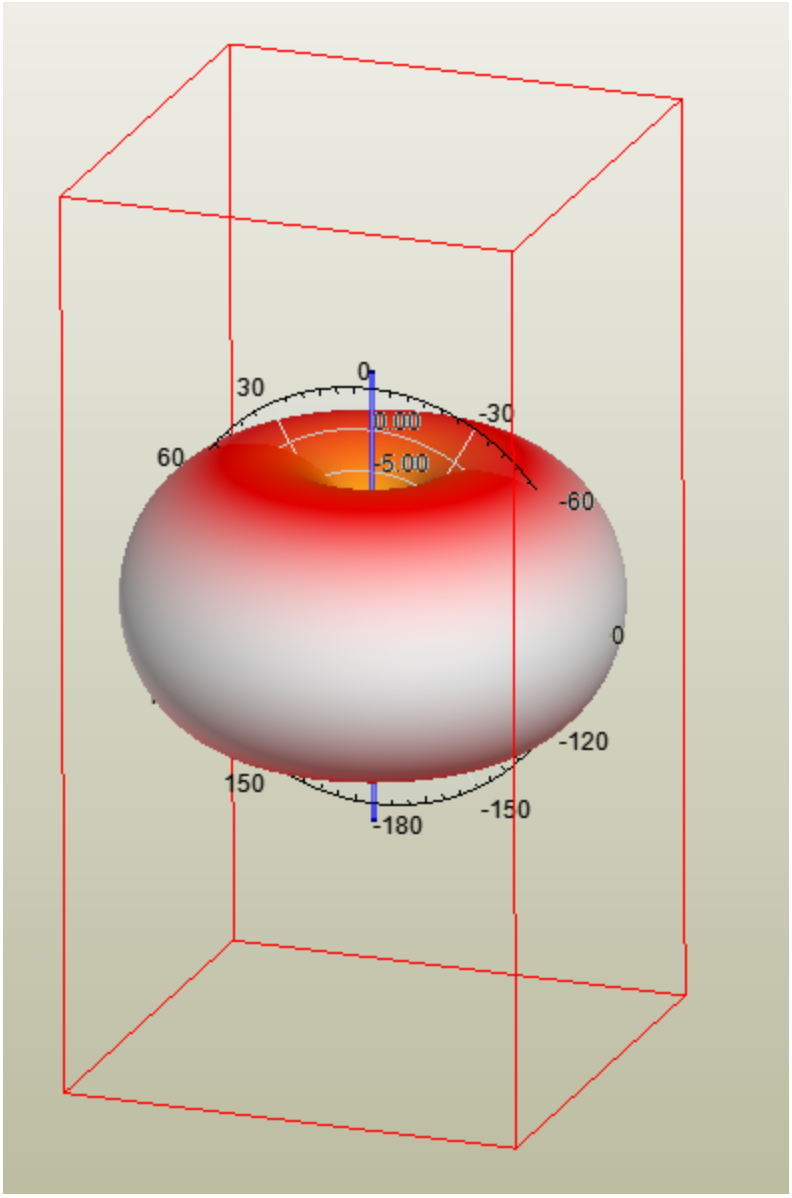
3. Select the layer whose temperature field should display.
4. Click **OK** and the overlay appears.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

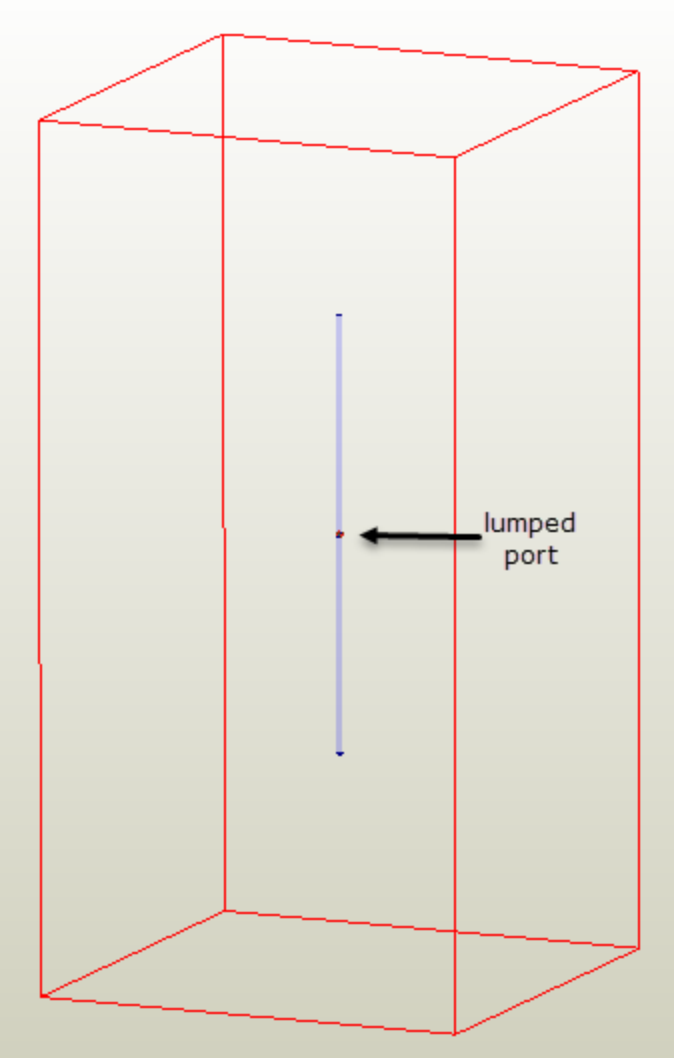
Overlay Visibility

This section describes how to plot radiation fields like Gain or Directivity right there on the geometry in the HFSS 3D Modeler window. Just right-click the plots under **Results** in the project tree and select the **Overlay Visibility** option from the short-cut menu to display the plots on the geometry.



To illustrate this feature, consider a basic dipole antenna design shown in the following figure. The antenna is excited with a lumped port between the two nodes of the dipole.

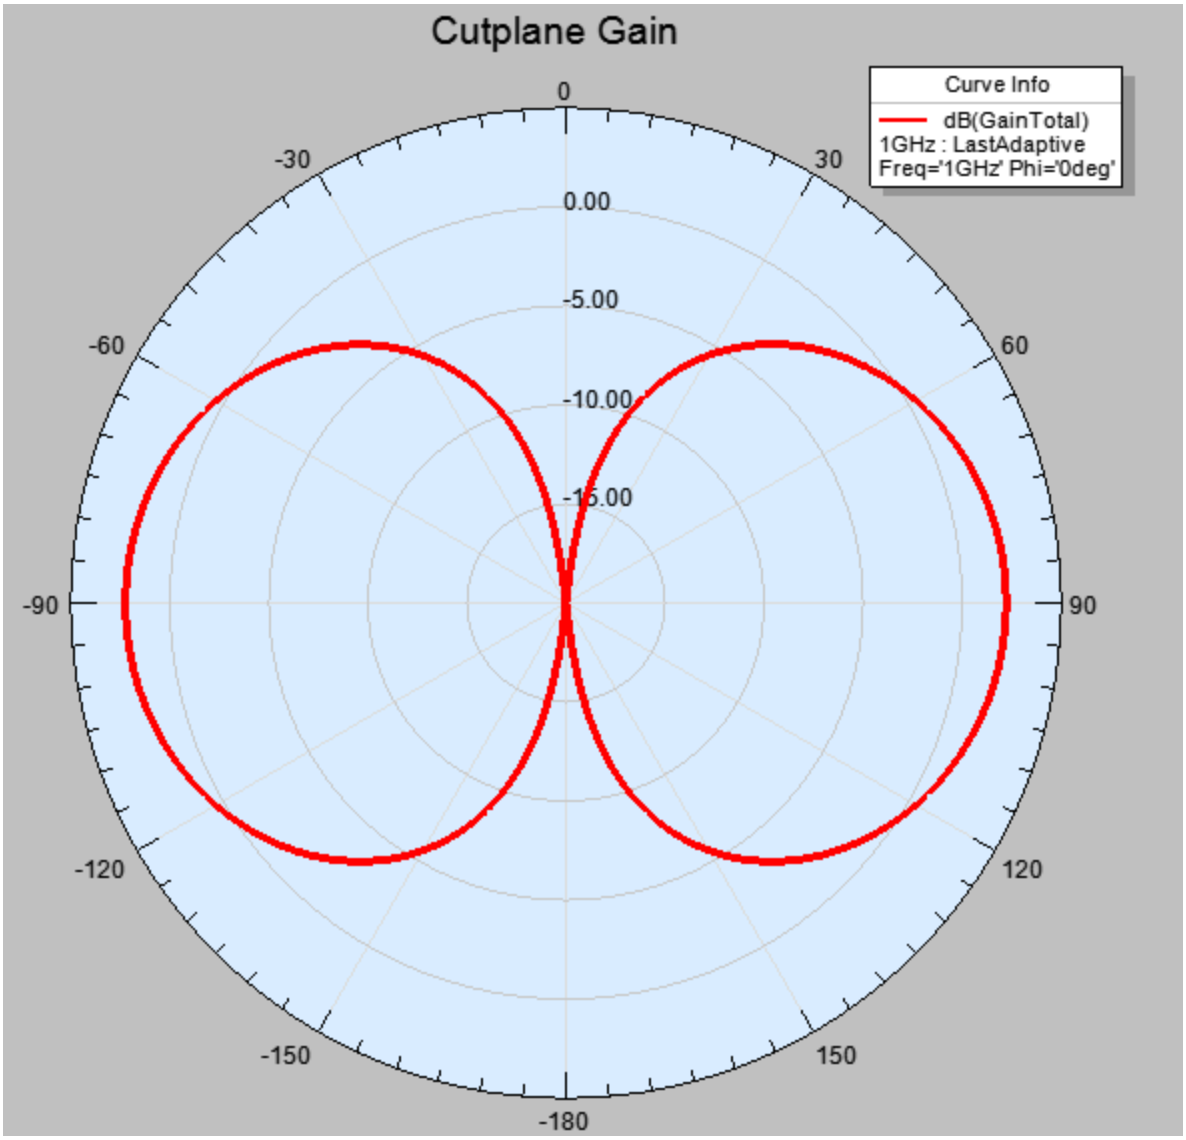
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



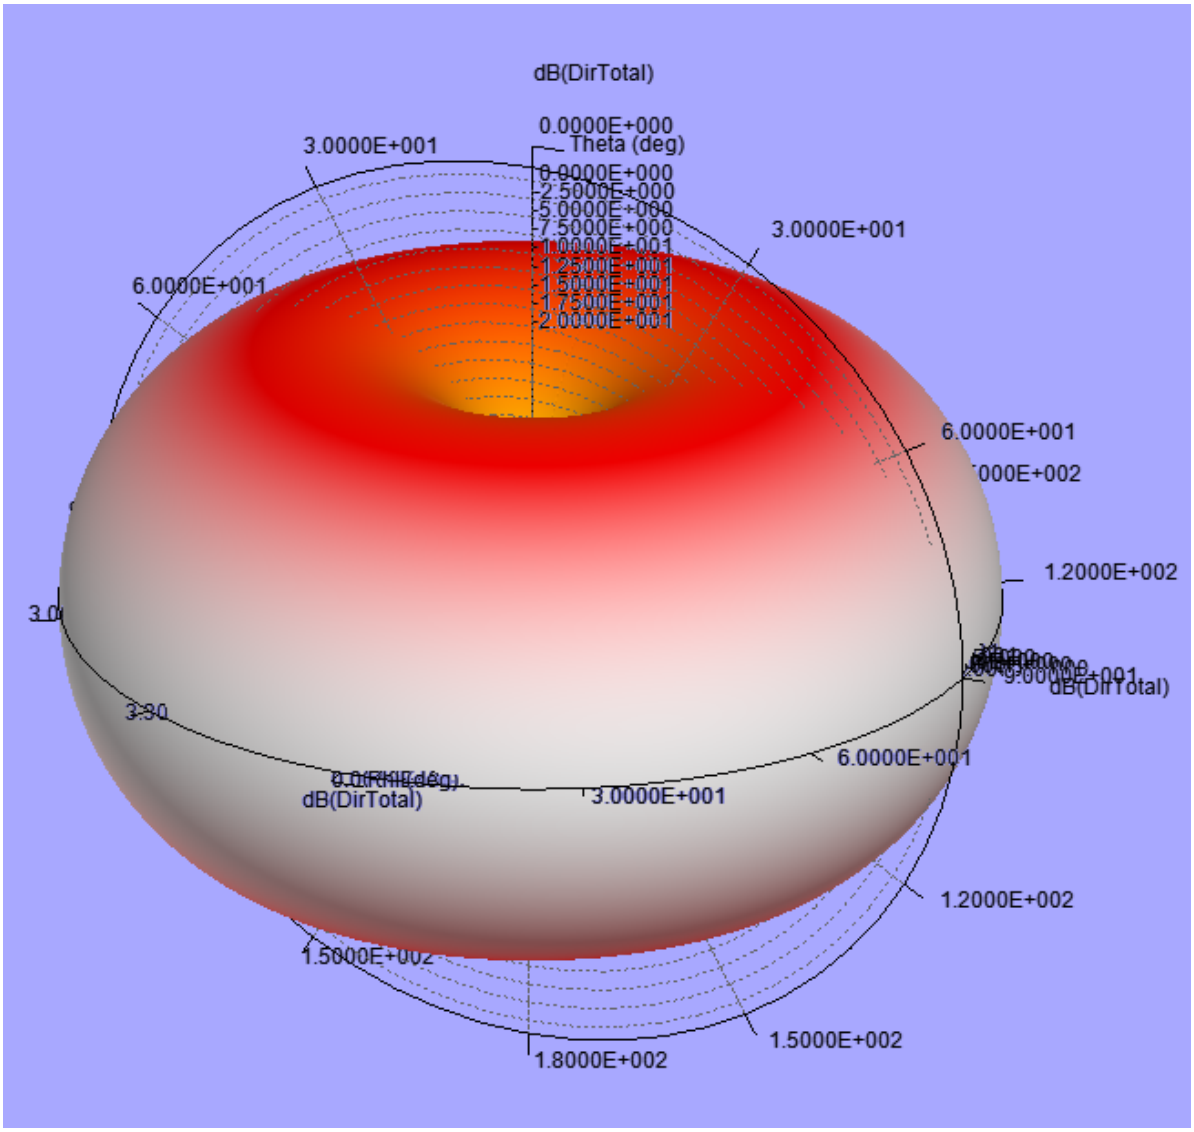
The antenna is simulated at 1 GHz. The generated Cut plane Gain and 3D far field plots can be displayed in their individual report windows. These are shown in the figures below.

> **Note:**
>
> You can also change the background color of these plot windows.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

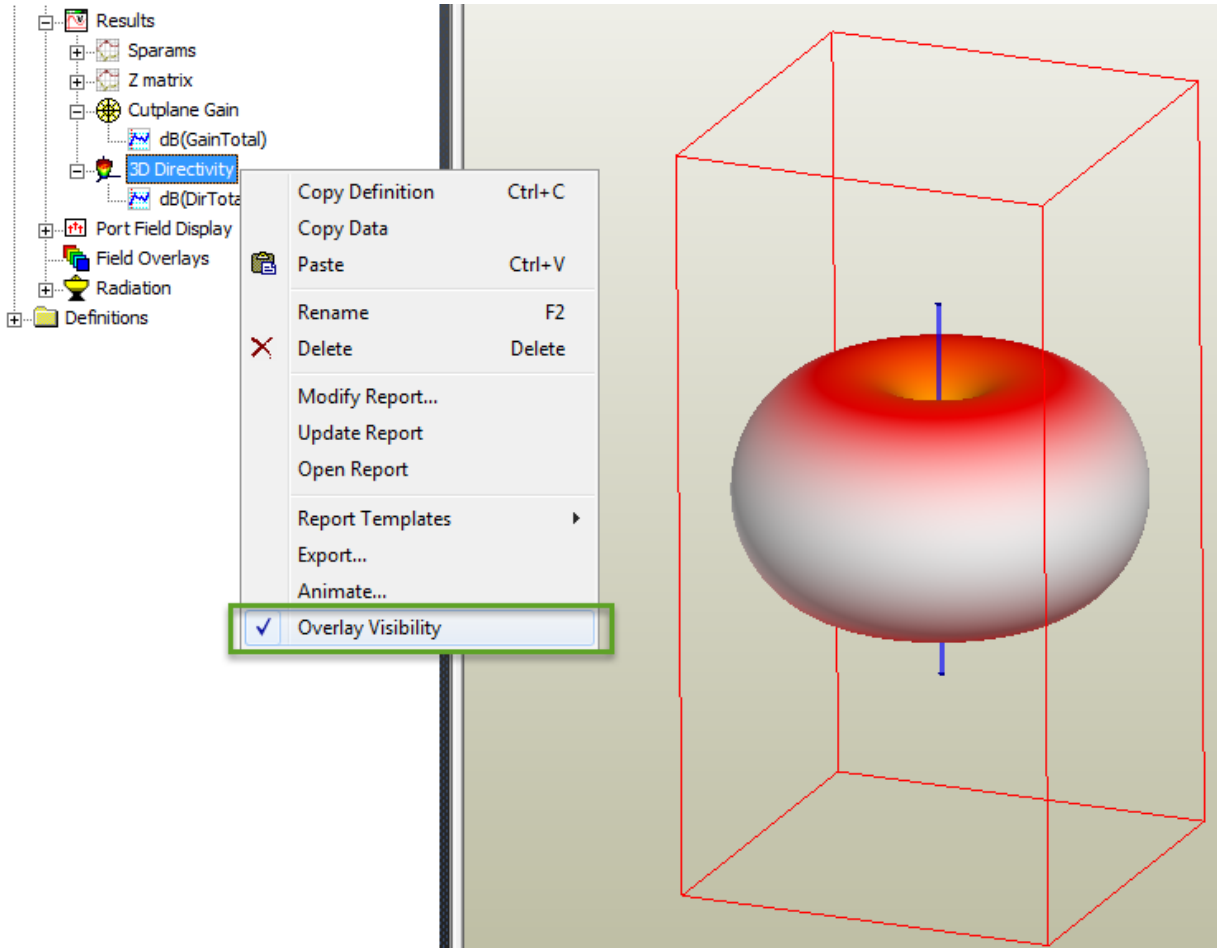


You can overlay these far field radiation patterns on the dipole antenna in the 3D modeler window by using a simple short-cut command. This overlay visibility feature can be very useful if you want to understand the orientation of the far field pattern relative to the structure of the antenna. You can directly apply the cut plane plots or the 3d polar plots right there on the antenna design as follows:

- Right-click the plot under **Results** in the project tree and select the option **Overlay Visibility** as shown below.

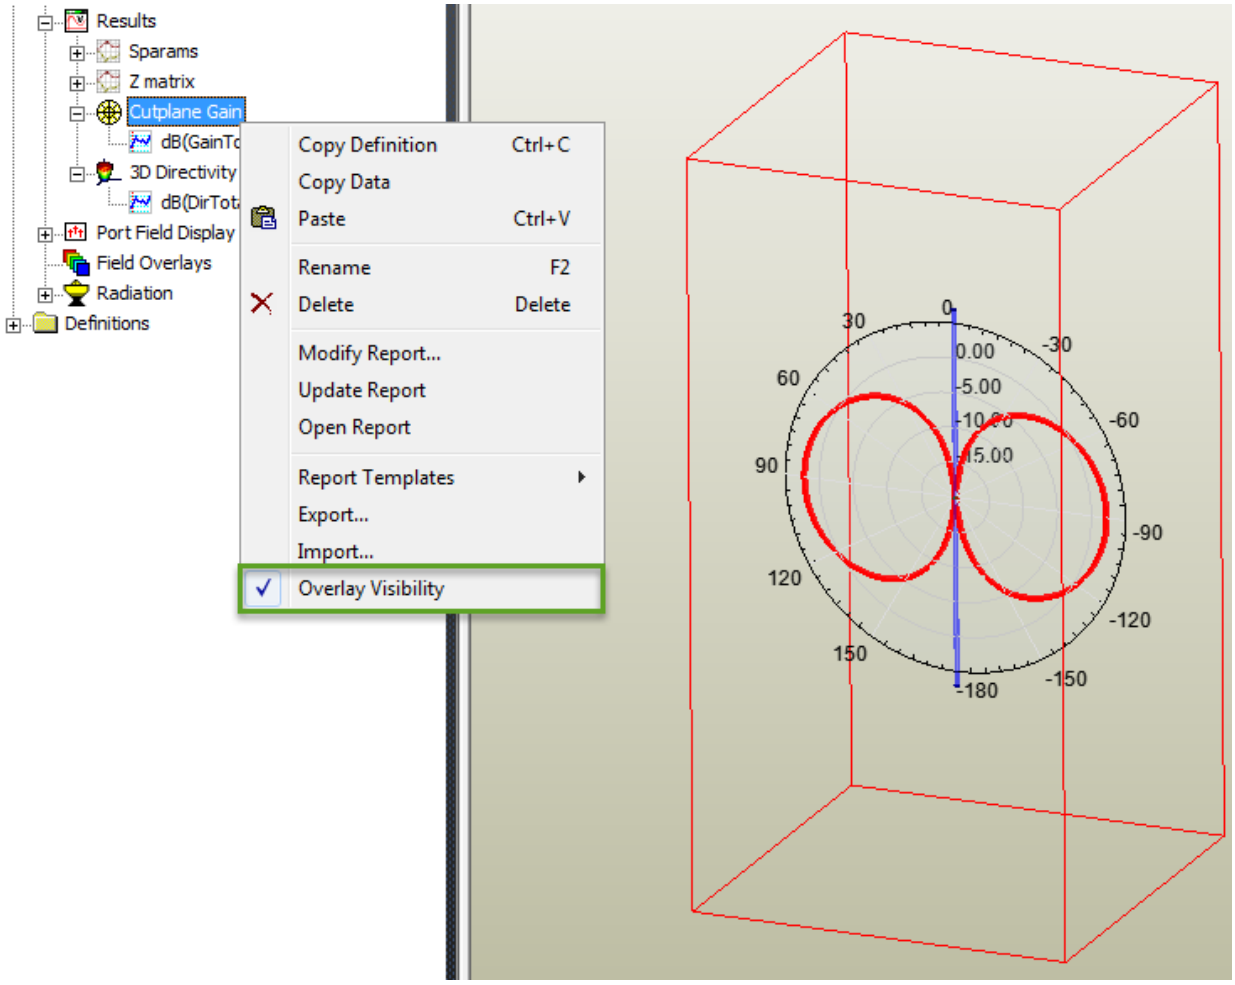
  This command overlays the plot on the antenna design.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The same one-step process also overlays a 2D radiation pattern as shown below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Plotting Derived Field Quantities

Derived field quantities are field quantity representations that have been deduced from the original field solution using the Fields Calculator.

1. Select a point, line, surface, or object to create the plot on or within.
2. On the **HFSS** menu, or right-click on the **Field Overlays** icon in the Project tree, and point to **Fields>NamedExpression**.
3. Select the derived quantity you want to plot, and then click **OK**.

The **Create Field Plot** dialog box appears.

4. To specify a name for the plot other than the default, select **SpecifyName**, and then type a new name in the **Name** text box.
5. Select the solution to plot from the **Solution** drop-down menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. To specify a folder other than the default in which to store the plot, select **Specify Folder**, and then click a folder in the **Plot Folder** drop-down menu, or type the name you wish to use. Plot folders are listed under **Field Overlays** in the project tree.
7. Under **Intrinsic Variables**, select the frequency and phase angle at which the field quantity is evaluated.
8. Select the derived field quantity to plot from the **Quantity** list.
9. Select the volume, or region, in which the field will be plotted from the **In Volume** list.

   This selection enables you to limit plots to the intersection of a volume and the selected object.

10. Click **Done**.

    The derived field quantity you created in the Fields Calculator is plotted on the surfaces or objects you selected. The new plot is listed in the project tree under **Field Overlays**.

Creating 2D Reports from Named Expressions

You can create a 2D report from named expressions that evaluate as a single scalar value or that evaluate along polylines.

To create a report from a named expression evaluating as a single scalar value:

1. Click **HFSS**, and then click **Results** > **Create Report**.

   The *Create Report* dialog box appears.

2. In the **Target Design** drop-down menu, click the design containing the solution data you want to plot.
3. Select **Fields** from the **Report Type** drop-down menu.
4. In the **Display Type** drop-down menu, select the type of report you want to create.
5. Click **OK**.

   The *Traces* dialog box appears.

6. In the **Solution** drop-down menu, click the solution containing the data you want to plot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7. Add one or more traces to include in the report.

   > **Note:**
   >
   > If you select a point for the **Geometry** and a **Category** that is a named expression based on the point (or other scalar, non-3D value), then the **Quantity** list only lists expressions that returns a single scalar value. If you have added named expressions that take the magnitude of the ScalarX(), ScalarY(), or ScalarZ() of a vector point value, then you can create output variables for those expressions only in this case.

8. Click **Done**.

   The report appears in the view window and is listed in the project tree. Once you have created a report, additional options become available on the **Results** submenu.

To create a report from a named expression evaluating along a polyline:

1. Click **HFSS** and then click **Results** > **Create Report**.

   The *Create Report* dialog box appears.

2. In the **Target Design** drop-down menu, click the design containing the solution data you want to plot.
3. Select **Fields** from the **Report Type** drop-down menu.
4. In the **Display Type** drop-down menu, select the type of report you want to create.
5. Click **OK**.

   The *Traces* dialog box appears.

6. In the **Solution** drop-down menu, click the solution containing the data you want to plot.
7. Select the geometry you want to plot from the **Geometry** drop-down menu.
8. Add one or more traces to include in the report.

   > **Note:**
   >
   > If you select a polyline for the **Geometry** and a **Category** that is a named expression based on the line, then the **Quantity** list only lists corresponding expressions. The list will not contain scalar values when a line is selected as the geometry.

9. Click **Done**.

   The report appears in the view window and is listed in the project tree. The default name is based on the Report Category you selected, (for example, S Parameter Plot *n* or rE Plot

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

n). You can edit the plot names in the project tree and the plot header text in the report synchronizes. Once you have created a report, additional options become available on the **Results** submenu.

Creating Scalar Field Plots

A scalar plot uses shaded colors or contoured lines to illustrate the magnitude of field quantities on surfaces or volumes.

1. Do one of the following:
   a. To create a scalar surface plot, select the faces on which you want to plot the fields.
   b. To create a scalar volume plot, select the objects within which you want to plot the fields.
2. Click **HFSS** > **Fields** > **Plot Fields**.
3. On the **Plot Fields** menu, click the scalar field quantity you want to plot.

   The **Create Field Plot** dialog box appears.
4. Follow the procedure for plotting field overlays.

The plot uses the attributes specified in the **Plot Attributes** dialog box.

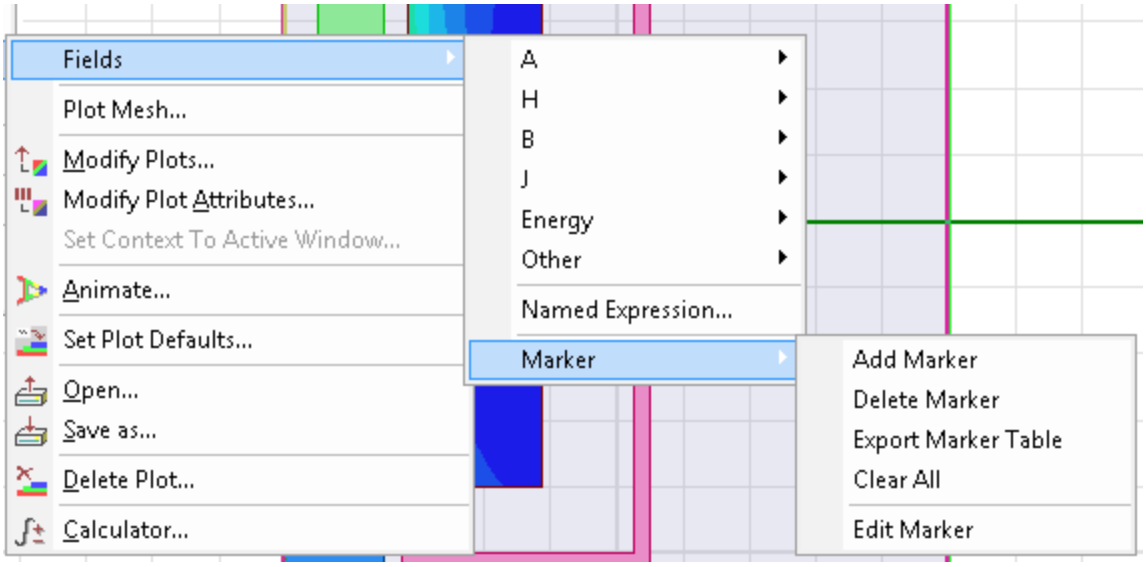
The new plot will be listed in the specified plot folder in the project tree.

Working with Scalar Field Plot Markers

The field overlay plot marker feature enables you to create a marker at selected points in the scalar field overlay plot geometry, and to obtain the field value at that point. The fields Marker sub-menu enables you to:

- Add Marker
- Delete Marker
- Export Marker Table
- Clear All markers
- Edit Marker

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Adding a Field Plot Marker

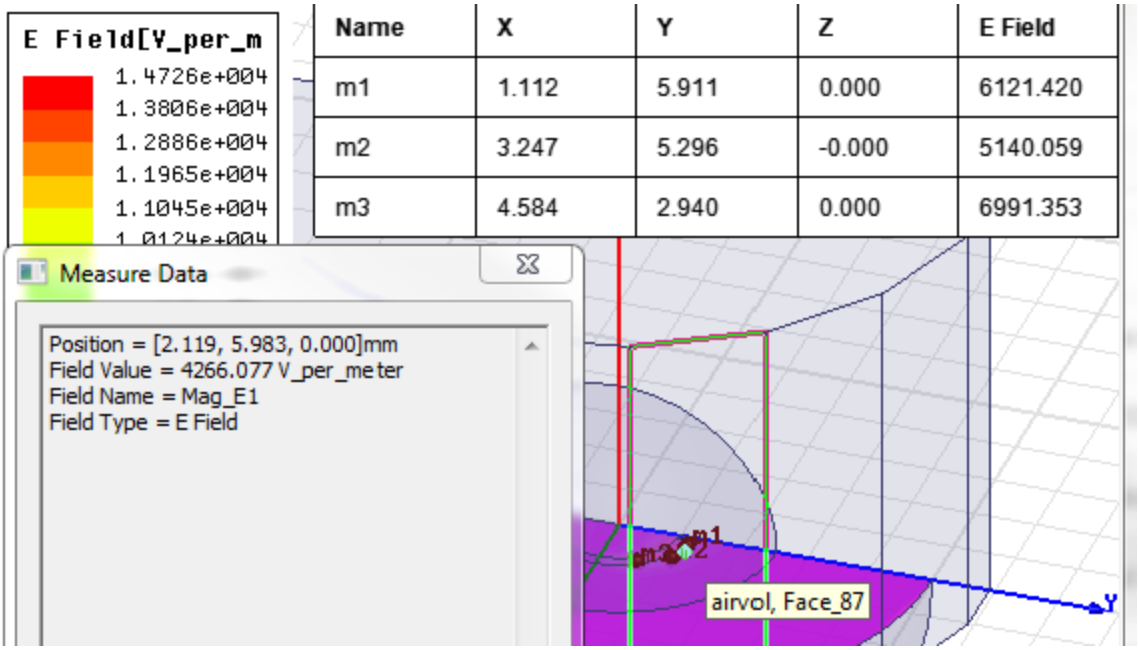
To add one or more field plot markers to a scalar field:

1. On the main menu click **HFSS** and then select **Fields** > **Plot Fields** > **Marker** > **Add Marker**. Alternatively, you can right-click anywhere in the modeler window, or on the Field Overlays folder icon in the Project Manager, and select **Fields** > **Marker** > **Add Marker**.

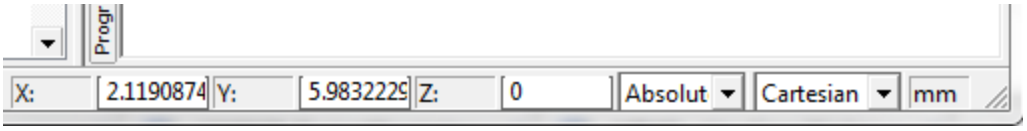
   The *Measure Data* dialog box opens, and a round dot appears at the tip of the cursor.

2. Drag the dot over the spot on the field overlay plot where you want to add a marker. The Measure Data dialog box shows detailed information for the spot currently under the dot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Click the desired point in the field overlay plot to add the marker at that location. Alternatively you can select the position of the marker by entering the values manually in the edit fields at the bottom of the window as shown below.



A table showing the marker coordinates and associated field value is also created and added to the modeler window.

4. Repeat as desired to add additional markers.
5. Press the **Esc** key when finished adding markers.

Deleting a Field Plot Marker

To delete a field plot marker:

1. Click on the marker you want to delete to select it. The row corresponding to the selected marker will be highlighted in the marker table.

   Press and hold the **Ctrl** key and click to select multiple markers.

2. On the main menu click **HFSS** and then select **Fields** > **Plot Fields** > **Marker** > **Delete Marker** to delete the selected marker(s).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Alternatively, you can right-click anywhere in the Modeler window, or on the Field Overlays folder icon in the Project Manager, and select **Plot Fields** > **Marker** > **Delete Marker**.
- You can also simply press the **Delete** key to delete the selected marker(s).

Exporting a Field Plot Marker Table

You can export a field plot marker table to either a comma- or tab-delimited file as follows:

1. On the main menu click **HFSS** and then select **Fields** > **Plot Fields** > **Marker** > **Export Marker Table**.

   Alternatively you can right-click anywhere in the modeler window, or on the Field Overlays folder icon in the Project Manager, and select **Plot Fields** > **Marker** > **Export Marker Table**.

2. In the *Export As* dialog box, choose the export format, either **.csv** or **.tab**, and save the file in the desired location.

   The exported file can then be imported into another application such as a spreadsheet.

	A	B	C	D	E
1	Name	X	Y	Z	H[A_per_m]
2	m1	2	22.935	1.517	1234
3	m2	1.517	17.373	1.517	123
4	m3	2.488	23.516	1.517	234
5	m4	2.751	23.828	1.517	1324

Clearing All Field Plot Markers

To clear all field plot markers in the active modeler window do one of the following:

- On the main menu, click **HFSS** and then select **Fields** > **Plot Fields** > **Marker** > **Clear All**.
- Alternatively, right-click anywhere in the Modeler window, or on the Field Overlays folder icon in the Project Manager, and select **Plot Fields** > **Marker** > **Clear All**.

Deleting all the markers also removes the marker table.

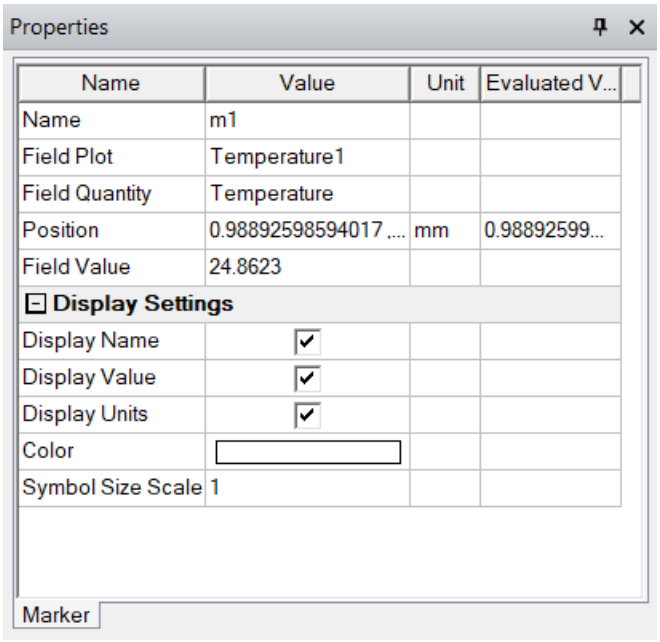
Editing Field Plot Markers

To edit field plot markers:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the marker table, click on the marker you wish to edit. The marker in the 3D Modeler window and its row in the table are highlighted. The properties of the marker are displayed in the **Properties** window.

   > **Note:**
   >
   > Press **Ctrl** and select multiple marker rows in the table to edit marker properties simultaneously.



2. You can edit the following marker properties:
   - **Name**: Specify the name that appears next to the marker in the 3D Modeler window.
   - **Display Name**: Toggle to show or hide the marker's name.
   - **Display Value**: Toggle to show or hide the marker's value.
   - **Display Units**: Toggle to show or hide the marker's units.
   - **Color**: Click the color to change the marker's color in the **Color** dialog box.
   - **Symbol Size Scale**: Enter a different number to adjust the size of the marker in the 3D Modeler window.
3. Optionally, when a marker is selected, press the **Delete** key to delete the marker and its corresponding entry in the marker table.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

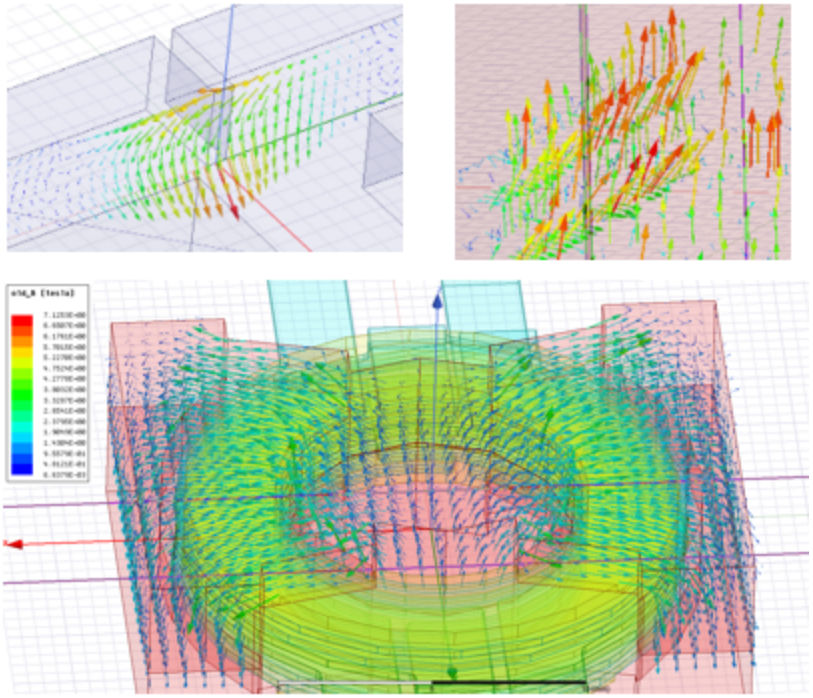
Showing Field Plot Markers

To display field plot markers in the 3D Modeler window, on the main menu click **HFSS** and then select **Fields** > **Plot Fields** > **Marker** > **Show Marker**. The table showing the marker coordinates and associated field value is also displayed in the modeler window.

Alternatively, you can right-click anywhere in the modeler window, or on the Field Overlays folder icon in the Project Manager, and select **Plot Fields** > **Marker** > **Show Marker**.

Creating Vector Field Plots

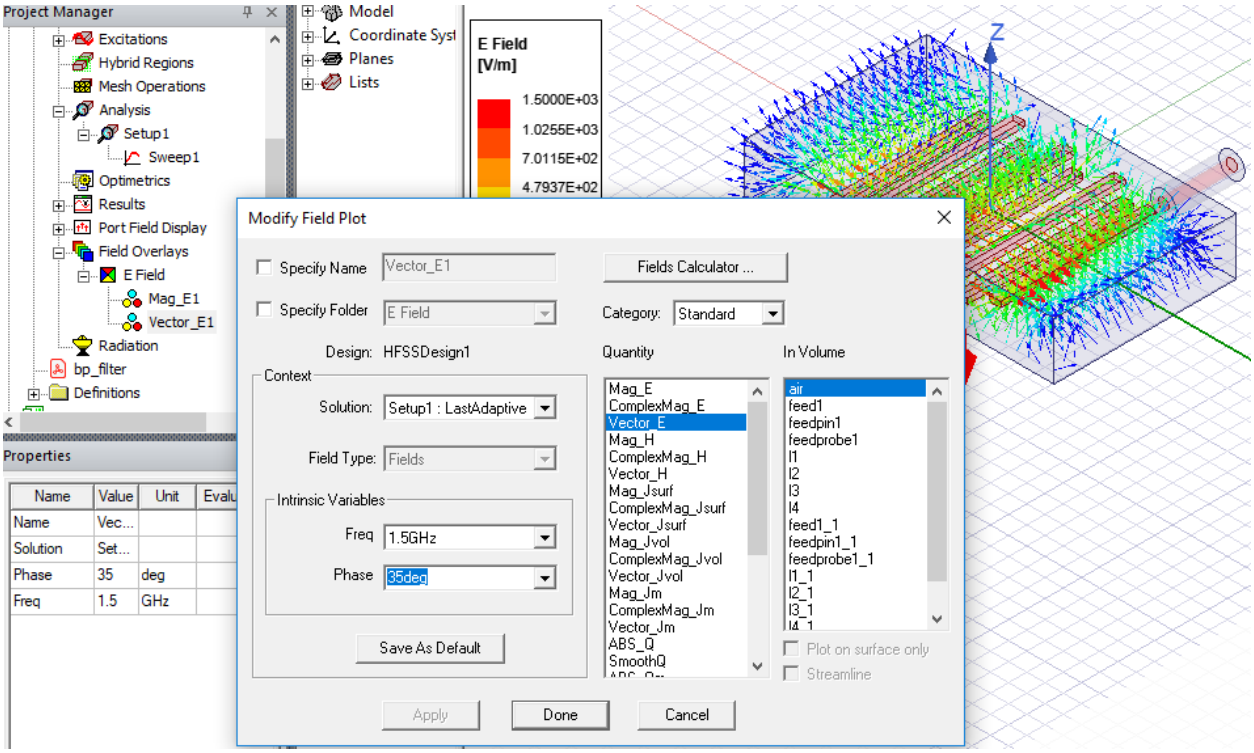
A vector plot uses arrows to illustrate the magnitudes of the x-, y-, and z-components of field quantities. Vector plots can be created on surfaces or volumes. The vector plots calculates a good initial spacing (min, max, and spacing range). The initial min, max spacing is based on a percentage of the plot geometry size and they are in model units. You can edit the vector min and max threshold spacing and the arrow representation.



1. Do one of the following:
    a. To create a vector surface plot, select the faces on which you want to plot the fields.
    b. To create a vector volume plot, select the objects within which you want to plot the fields.
2. Click **HFSS** > **Fields** > **Fields**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

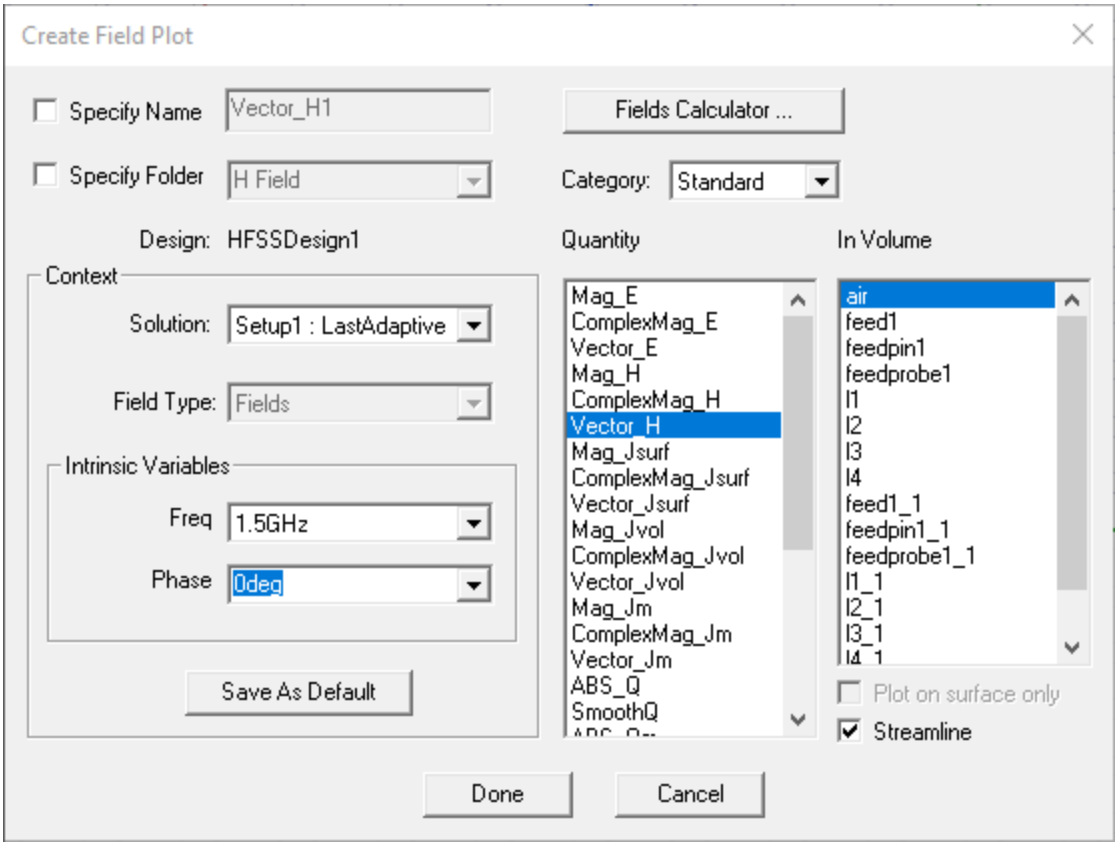
3. From the **Fields** submenu, click the vector field quantity you want to plot.



4. Follow the procedure for plotting field overlays.

If you select a vector quantity when creating a plot, you can also check Streamline for the plot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

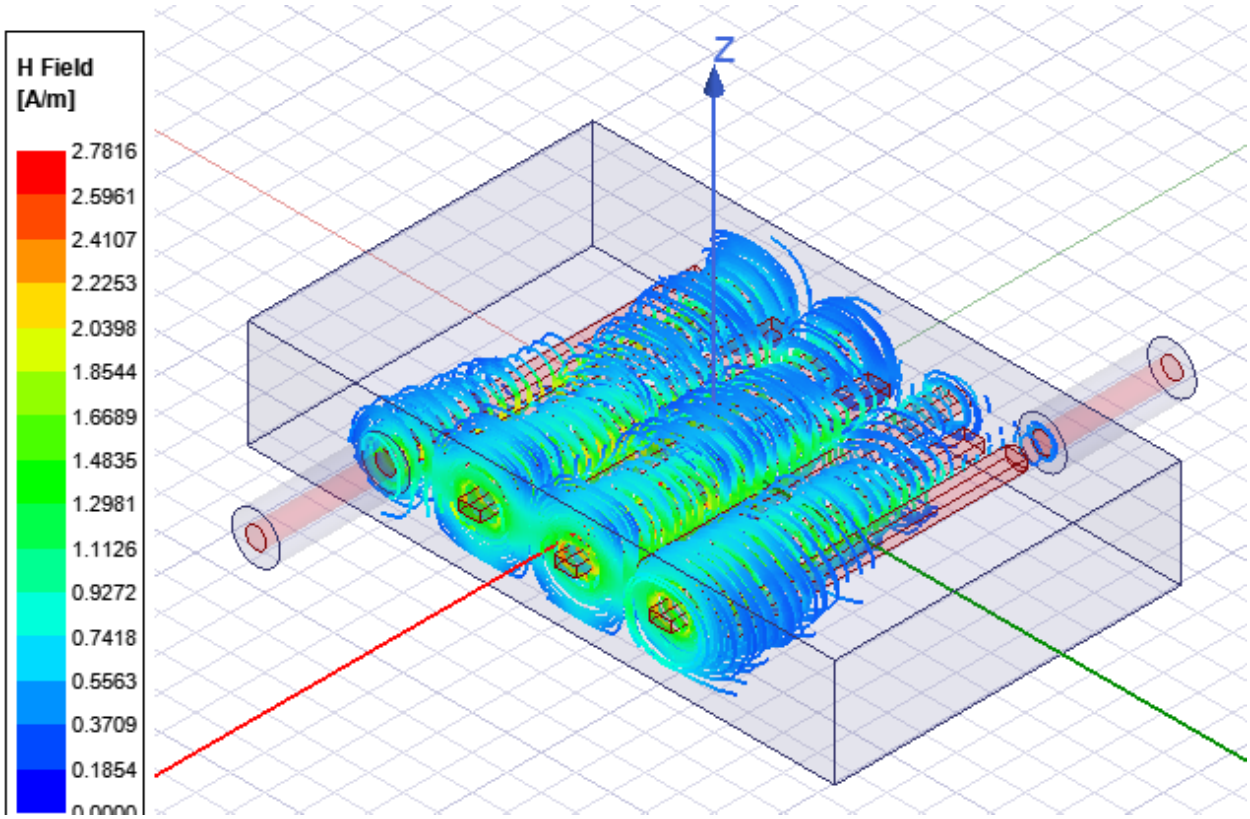


Notes for creating Streamline plots:

1. Before creating the plot, select both starting and ending edges (in 2D) or surfaces (in 3D).
2. In the Creating Field Plot menu, select "In Volume: Region" which is the volume in which the streamlines will appear and is outside of the sources.
3. After the plot is created, on the Attributes/Plot tab reduce "Seeds density" to show more streamlines. If no streamlines appear, reduce this by a factor of 10 (or 100) because the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

default seeding was too large.



Modifying Field Plots

1. Click **HFSS**> **Fields**> **Modify Plots** , or in the Project Manager, select the **Field Overlays** icon, right-click, and select **Modify Plots**, or press the **M** hotkey.

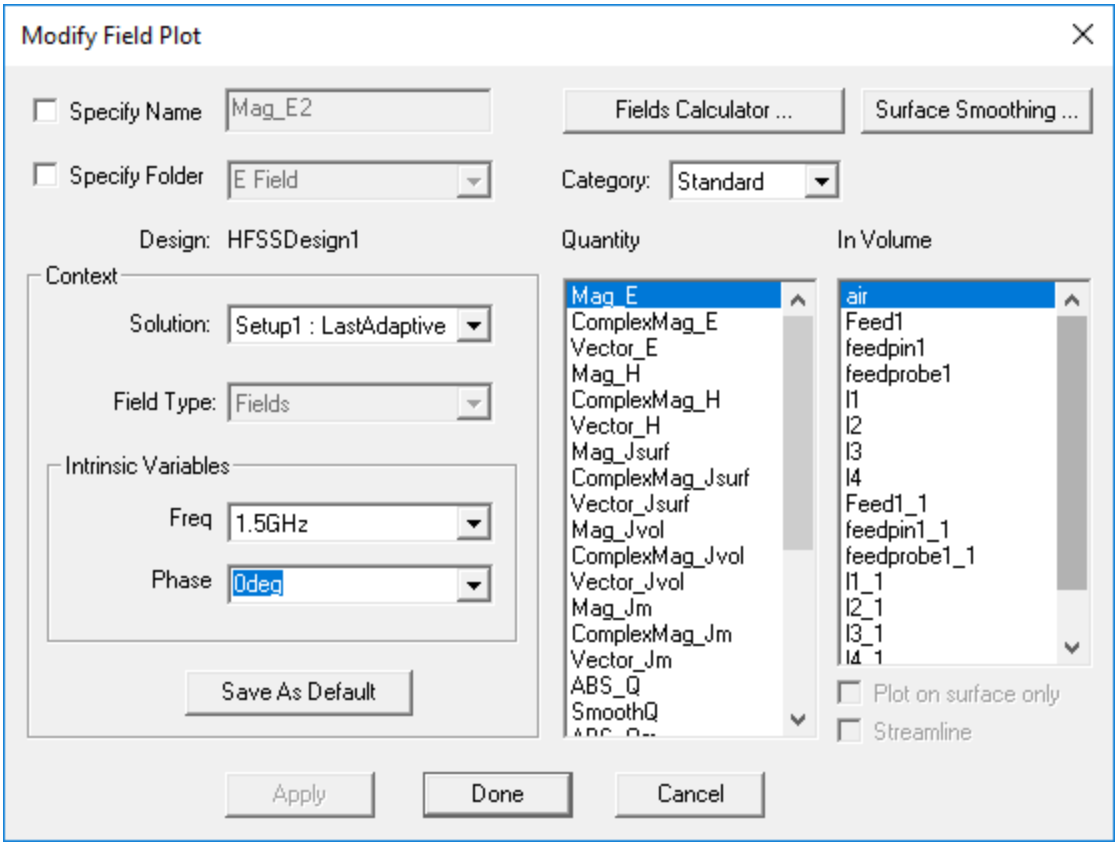
   The **Select Field Plot(s)** dialog box appears.

   Optionally, you can right-click an existing plot listed under the Field Overlays in the Project tree, bypass the **Select Field Plot** dialog box and go to step 3.

2. Select the plot you want to modify in the **Select** column, and then click **OK**.

   The **Modify Field Plot** dialog box opens.

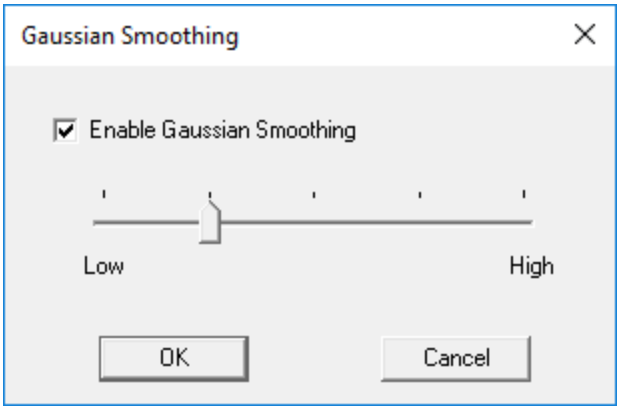
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Optionally, select the **Specify Name** check box to enable the name field.
- Optionally, select the **Specify Folder** check box to enable the drop-down menu.
- Optionally, select a different **Solution** from the drop-down menu.
- Optionally, select a different **Field Type**, if available.

3. Under **Intrinsic Variables**, specify the frequency and phase at which the field quantity will be evaluated.
4. Optionally, select a different field quantity to plot from the **Quantity** list.
   - To choose a calculated expression, select **Calculator** from the **Category** drop-down menu. If you choose Calculator, click the Fields Calculator button to display the calculator.
   - To choose a predefined field quantity, select **Standard** from the **Category** drop-down menu. Select from the Quantity list.
   - For scalar quantities plotted on the surface of a geometry, the **Surface Smoothing** button is enabled. For vector quantities, the **Surface Smoothing** button is disabled. Surface Smoothing applies a selected level of smoothing based on the Gaussian Blur algorithm. Clicking Surface Smoothing opens the Gaussian Smoothing dialog box.

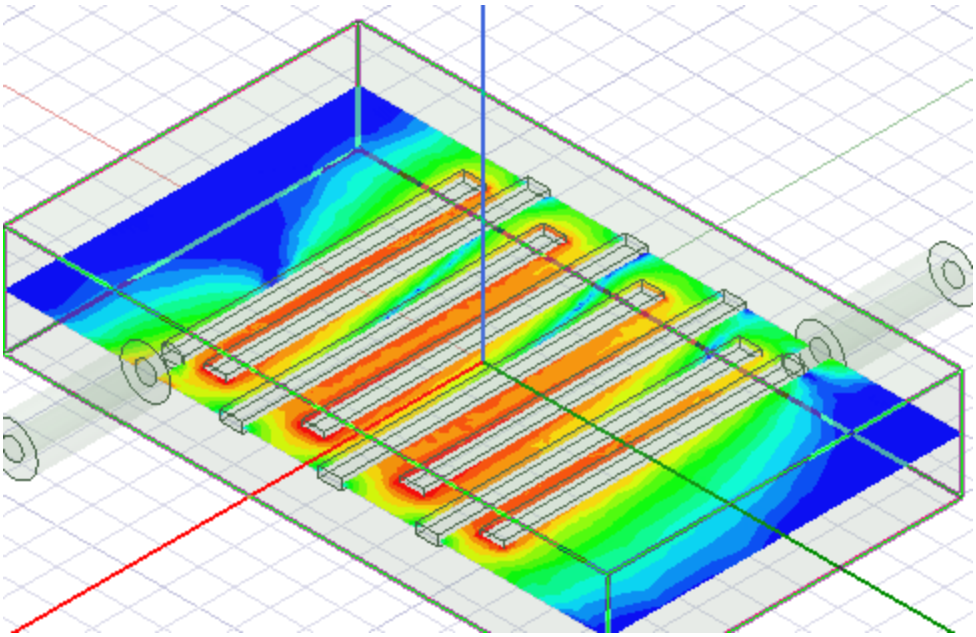
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Select the check box to enable the feature and use the slider to set the degree of smoothing.

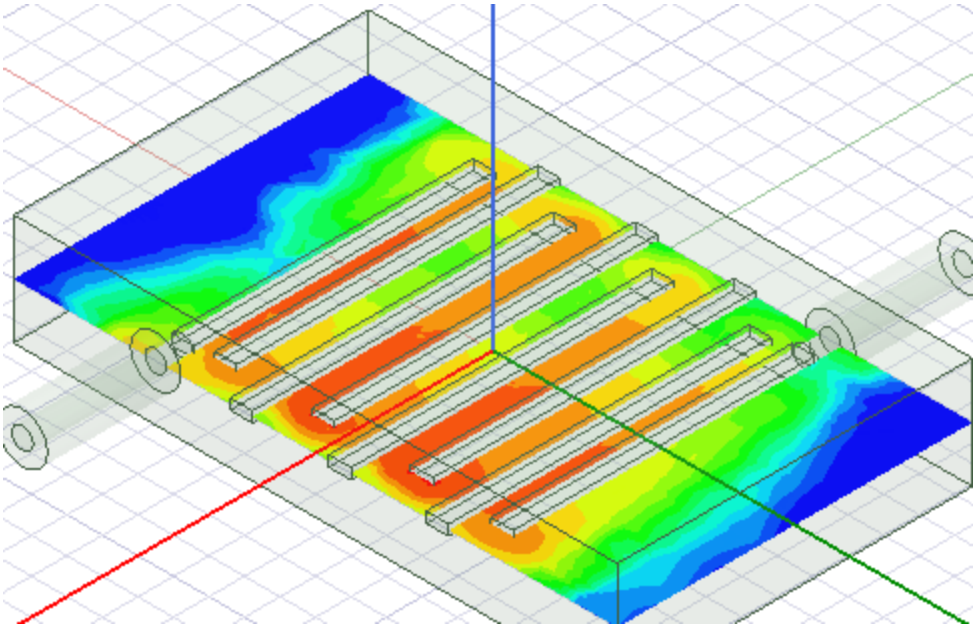
Important: You *must* click **Apply** in the *Modify Field Plots* dialog box to see the changes.

For example, this is a Mag_E fringe plot before applying the smoothing:



This is a Mag_E fringe plot after applying High smoothing:

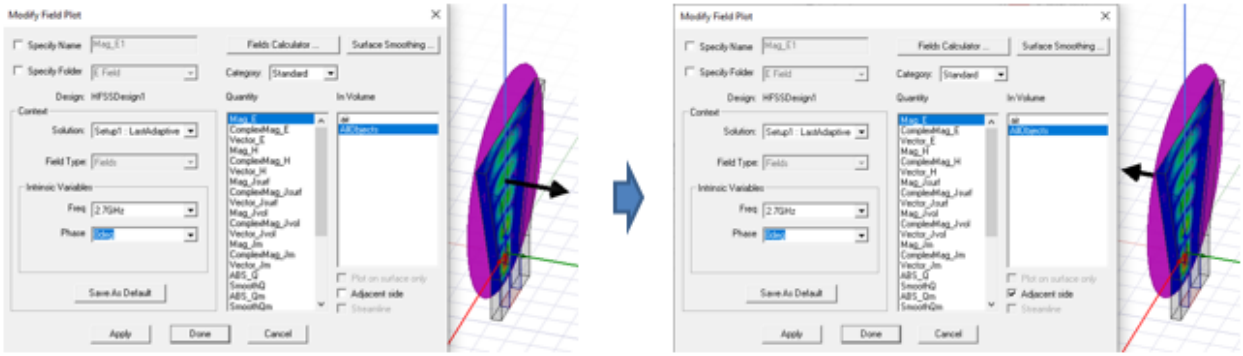
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. Select the volume, or region, in which the field will be plotted from the **In Volume** list.

   This selection enables you to limit plots to the intersection of a volume and the selected object.

6. If you are modifying a plot on a sheet object, the **Adjacent** check box allows you to generate field overlays on a sheet object using data from either side of the sheet. An arrow indicates where the data is coming from. While the data is usually the same on the two sides of a sheet object, in a situation where the sheet object is assigned to be a shell element, the field may be different on its two sides. (Shell elements are an option for Layered Impedance Boundaries and Finite Conductivity Boundaries with DC conductivity and two-sided selected.) In such cases, you can visualize the field data on the side you want.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7. Click **Apply** to make the changes and leave the dialog box open, or click **Done** to apply the changes and close the dialog box.

   The field quantity is plotted on the surfaces or within the objects you selected. The modified plot is listed in the specified plot folder in the project tree.

   The plot uses the attributes specified in the **Plot Attributes** dialog box. For details see Setting Field Plot Attributes.

Setting Field Overlay Attributes

After creating a mesh or field overlay on a surface or volume, you can modify its appearance by changing the settings in the **Plot Attributes** dialog box. You will modify the settings for a plot folder and all plots in that folder will use the same attributes.

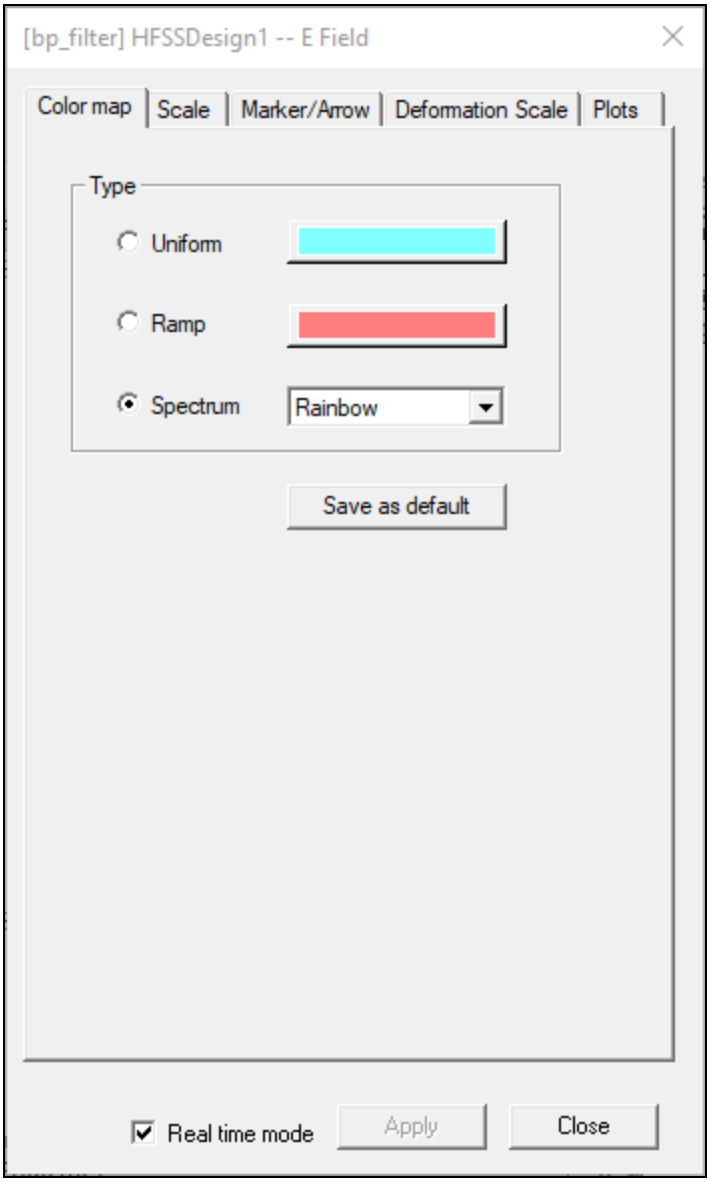
1. Click **HFSS** > **Fields** > **Modify Plot Attributes**. Alternatively, right-click **Field Overlays** in the Project Manager and select **Modify Attributes** from the shortcut menu.

   The **Select Plot Folder** dialog box appears.

2. In the **Select Plot Folder** dialog box, select the plot type that you want to modify and click **OK**. You can also right-click the specific plot in the Project Manager and choose **Modify Attributes** from the shortcut menu.

   A dialog box with attribute settings for the selected plot type (whether a field result or a mesh plot) appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. For field result overlays (not mesh plots), the available plot attributes under each tab in the dialog box are listed in the following table:
    - **Color map:**

      The number of colors used and how they are displayed. The field data must be available for the color key to appear.

    - **Scale tab:**

      The scale of field quantities, including the number of divisions in the scale, whether to use dB as the units, whether to use a linear or log scale, auto schall options, and plot number format.

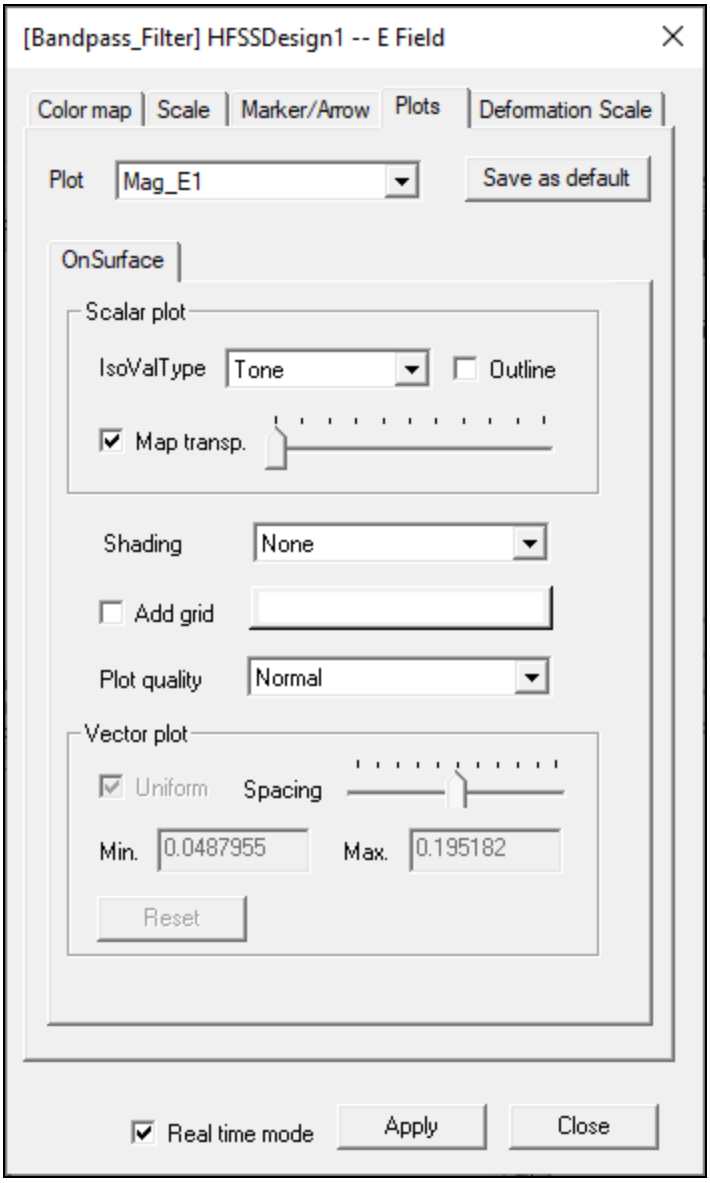
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Marker/Arrow**
  - The appearance of points (for scalar point plots).
  - The appearance of arrows (for vector plots).
  - Magnitude filtering (for vector plots). That is, you uncheck Map size, and specify a Min and Max Magnitude, or use a slider to set the Min threshold.
- **Deformation Scale:**

  This is for use with plots that include Stress feedback from Ansys Workbench Integration.

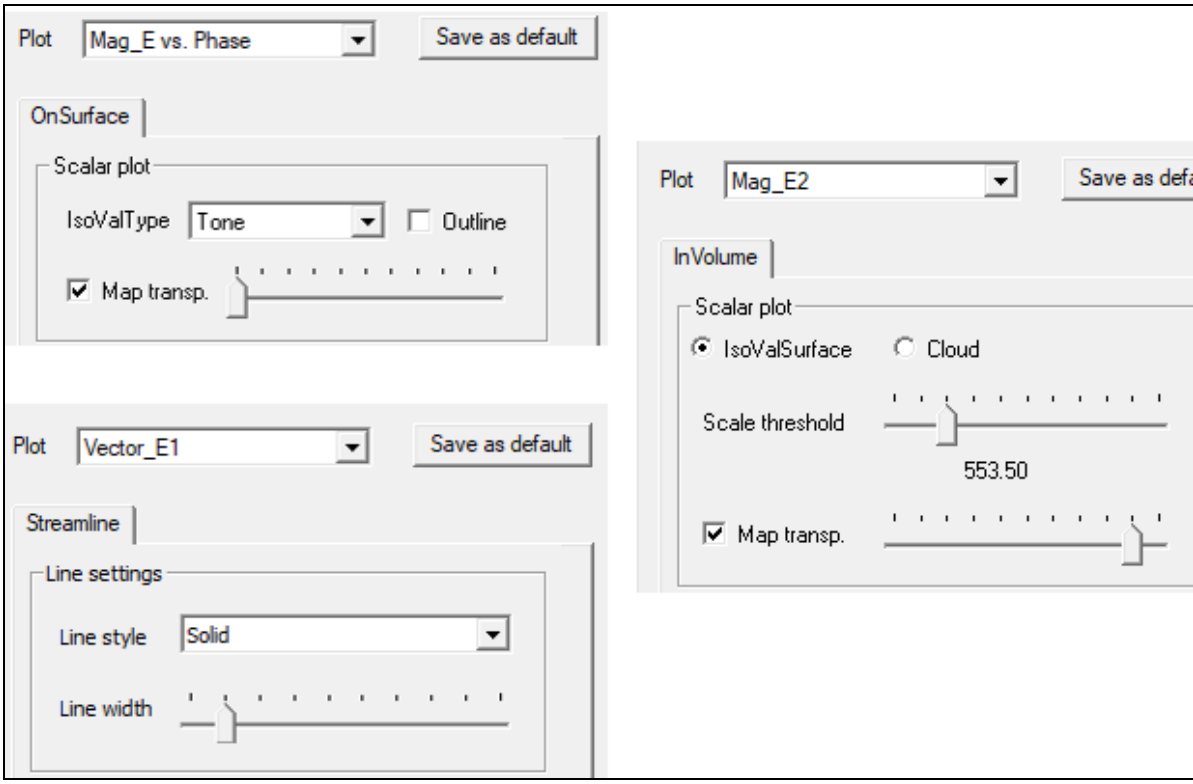
  See Modify Plot Attributes Dialog for Stress Feedback Projects.
- **Plots (if not vector or streamline):**
  - The **Plot** selected. If multiple plots are available, you can select from a drop down menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- Plots can be **OnSurface** or **InVolume** or **Streamline**. The type of plot you select determines the control options shown.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



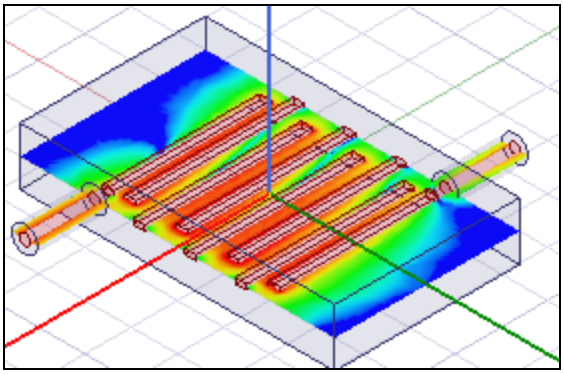
- For scalar surface plots you can select the type of isovalue display. For *Line, Fringe* and *Tone* **IsoValType**, *Outine* is enabled. For *Gourad*, it is disabled.
- Whether to use Shading (for scalar plots), if lighting is turned on. By default, the **Shading** is set to *None* which is equivalent to "Do not use lighting." Shading can be Flat or Smooth.
- **None** Equivalent to selecting **Do not use lighting** on the Lighting Properties dialog box.

  Flat Provides a flat rendering of the field plot.

  Smooth Provides a smooth rendering of the field plot.
- The transparency based on solution value.
- Whether to add a grid (that is, a mesh overlay), and to set the grid color.
- Specify the plot resolution as **Coarse**, **Normal**, **Fine**, or **Very Fine**.

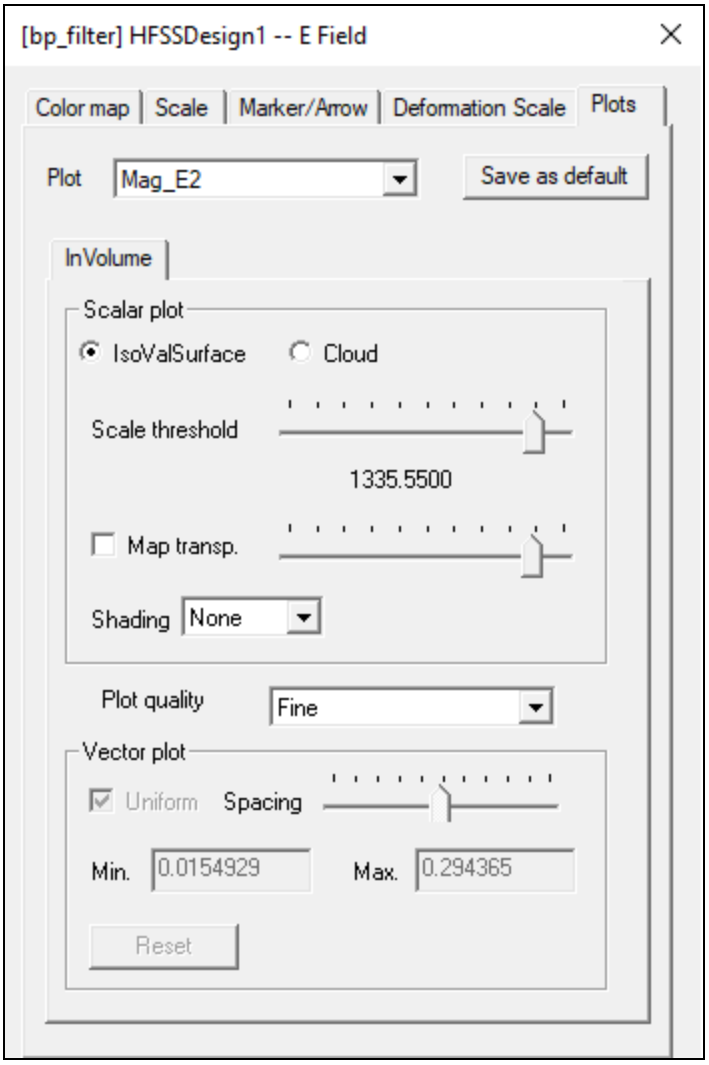
  This affects the use of memory for animating plots. For large plots with more frames to animate, use **Coarse** or **Normal** to reduce memory requirements and improve performance. For smaller plots with few frames, if higher resolution is required, use **Fine** or **Very Fine**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



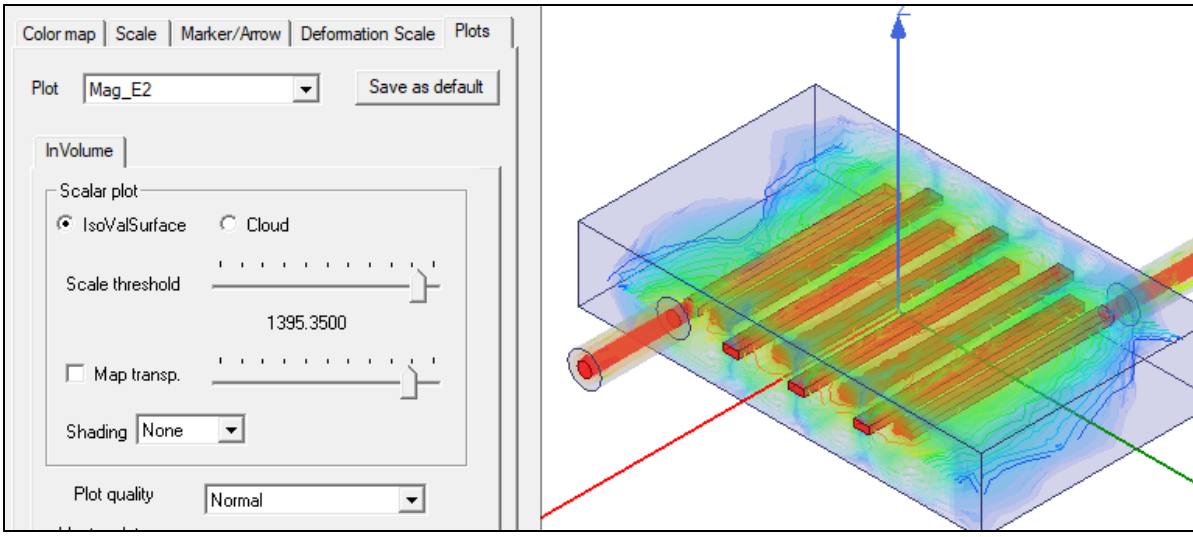
If you select an InVolume plot, display options are available to allow visibility of internal layers and objects, particularly those with high field values. For *IsoValSurface* for an *InVolume* Scalar plot, the choices are for **Scale threshold** and **Map transp**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

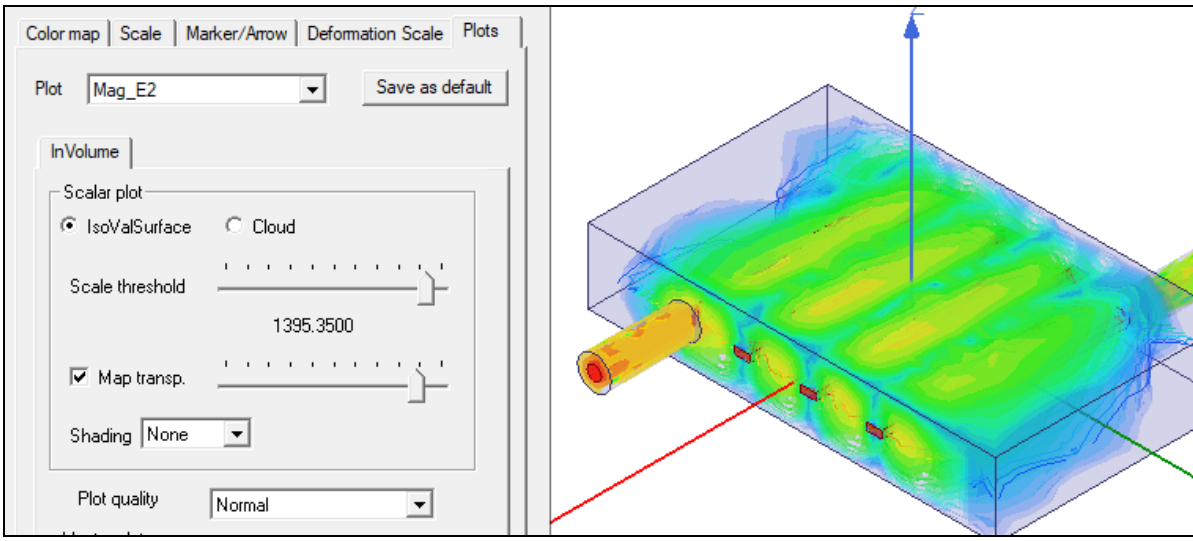


- The "**Scale threshold**" slider bar allows you to set a field value threshold so that iso surfaces with field value lower than the given threshold will show as translucent with given transparency specified by the slider bar below it.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



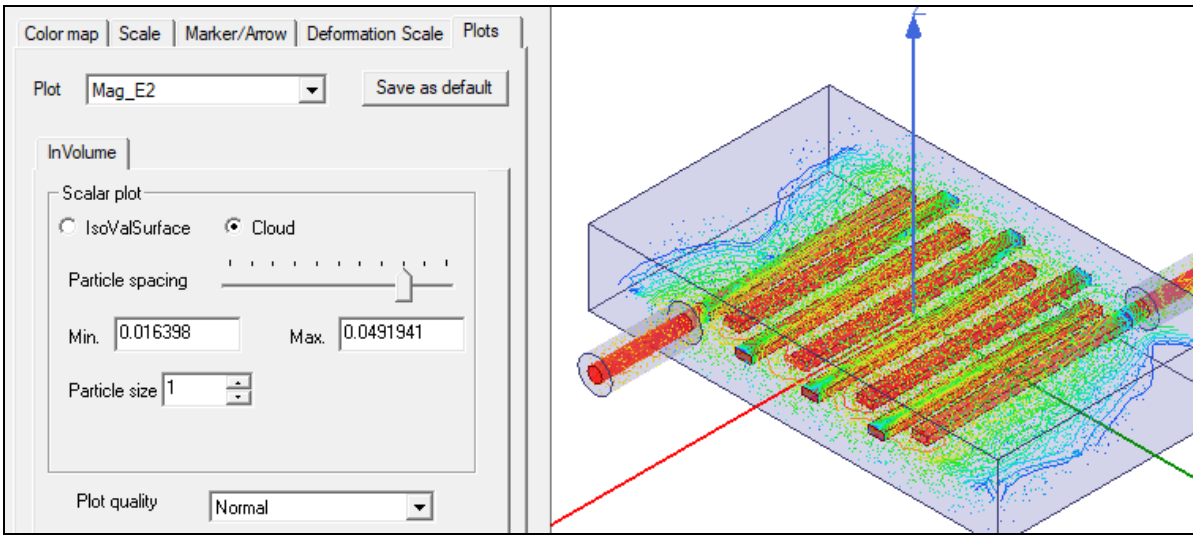
- Iso surfaces with field value higher than the threshold will show as opaque. The range of the "**Scale threshold**" is the same as the color key range from *Min* to *Max*.
- When "**Map transp.**" is checked, translucent iso surfaces field values map to [0.0, transparency] so lower field value map to higher transparency while higher field value to lower transparency. If it is unchecked, all translucent iso surfaces will have the same given transparency from the slider bar.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> When the **Map transp.** slider bar is at the left most position, transparency is 0. This feature is essentially disabled, and the "**Scale threshold**" slider bar will be disabled. Also, high fidelity transparency should be enabled for best results.

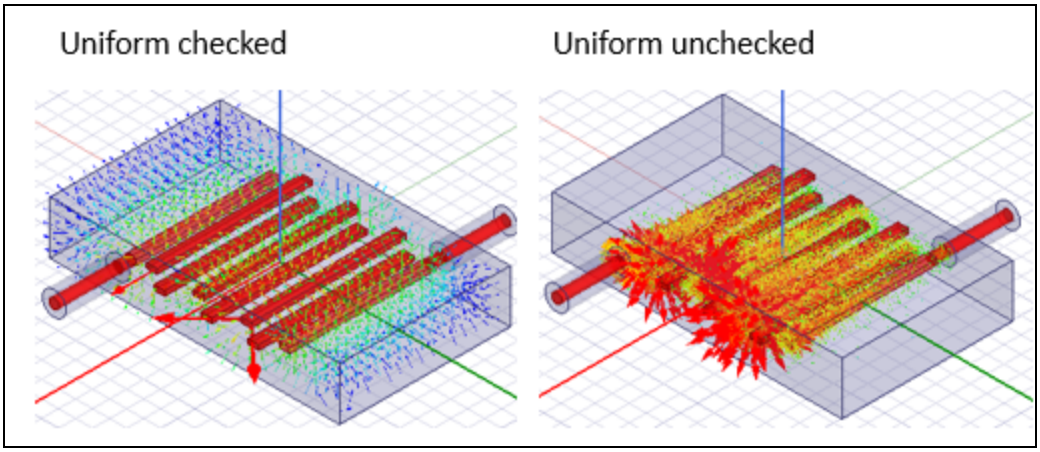
- For *Cloud* plots, field values are represented by points that illustrate the spatial distribution of the solution. You can use the **Particle spacing** slider bar to adjust the plot. The higher the solution value, the greater the cloud density. You can also specify **Min** and **Max** values (numeric values based on the active model length unit) and adjust **Particle size**.



- **Plots (for vector plots):**
  - The **Plot** selected.
  - The **Min** and **Max** spacing of arrows (for vector plots). These values are based on the model's active length unit and are only relevant when the **Uniform** option is selected.
  - **Plot quality**, as *Normal, Coarse, Fine,* or *Very Fine*.
  - **Uniform** vector spacing, based on the *Spacing* slider position and the *Min* and *Max* values.

    When Uniform is *not* selected, a vector is rendered at every node (both corner and mid-side nodes of the elements).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

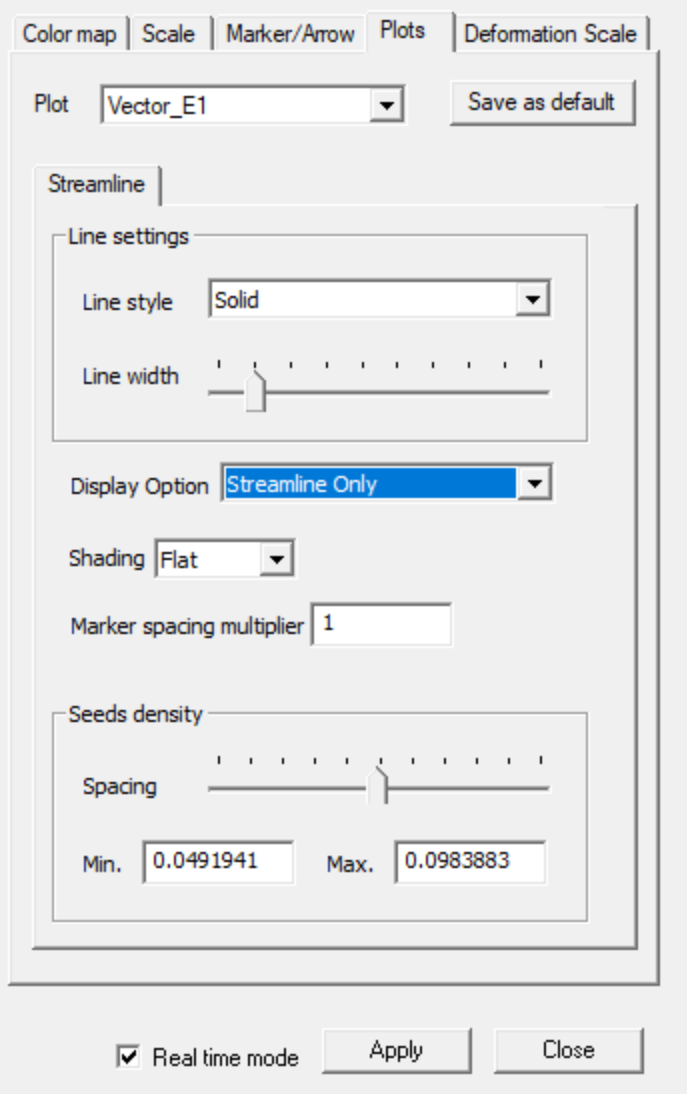


The **Reset** button resets a good initial spacing (and thus Min, Max spacing range) without the need to recreate the field plot.

- **Streamline Plots (if streamline is checked when you create the plot):**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The **Plot** selected.



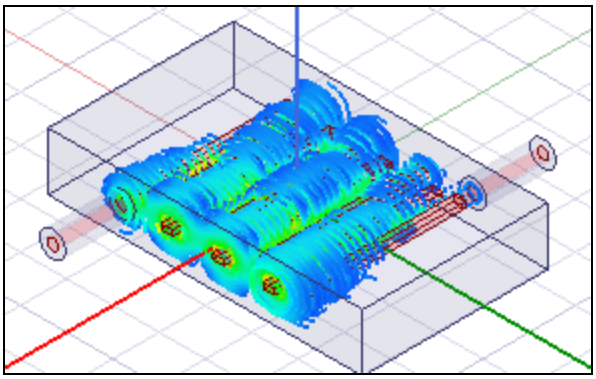
- The **Line style** as *solid* or *cylinder* from drop-down menu.
- **Line width**, specified using a slider.
- Display Option for whether to show Streamline Only, *Marker Only* or *Streamline and Marker*.
- Whether to use Shading, if lighting is turned on. By default, the **Shading** is set to *None* which is equivalent to "Do not use lighting." Shading can be Flat or Smooth.
- **None** Equivalent to selecting **Do not use lighting** on the Lighting Properties dialog box.

  Flat Provides a flat rendering of the field plot.

  Smooth Provides a smooth rendering of the field plot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Seeds density** spacing. This affects the number of stream lines used to represent the quantity in the plot. Moving the slider to the left decreases the spacing and increases the number of stream lines. Moving the slider to the right increases the spacing and decreases the number of lines used to represent the quantity.
- **Min**. and **Max**. values represented (in *Magnitude filtering* settings).



a. Under each tab, click **Save as default** if you want the tab's settings to apply to field overlay plots created after this point.
b. Select **Real time mode** if you want the changes to take effect immediately in the view window.
c. If this option is cleared, click **Apply** when you want to see the changes.

Modifying Field Plot Colors

1. Click **HFSS** > **Fields**> **Modify Plot Attributes** or, in the Project Manager, right-click **Field Overlays** and select **Modify Plots** from the short-cut menu (or use the "m" hotkey).

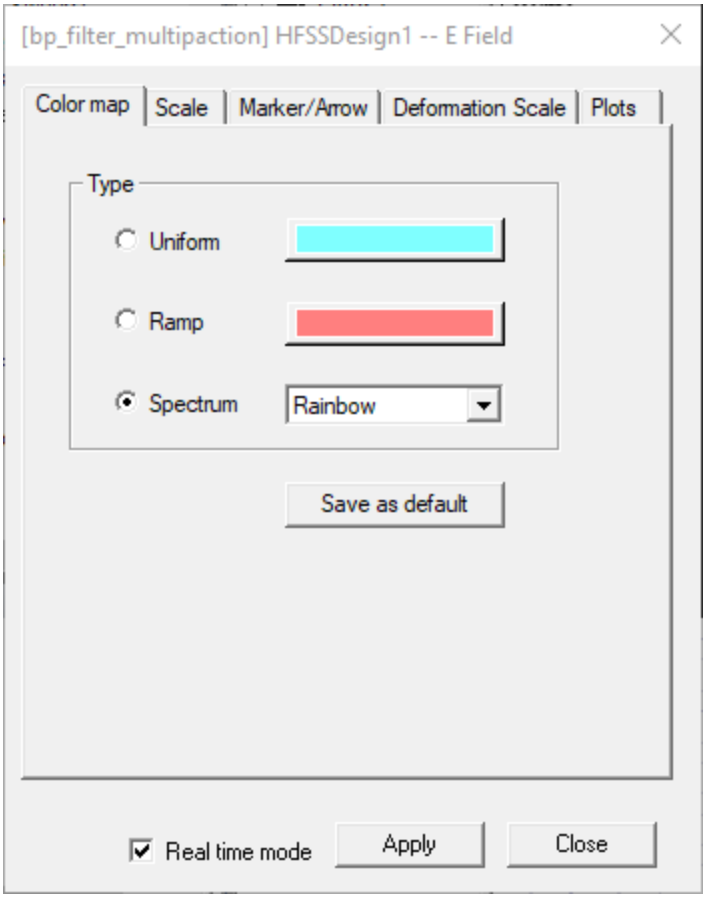
   The **Select Plot Folder** dialog box appears.

2. Select the plot folder you want to modify and click **OK**.

   All plots in the selected folder will be modified.

   A dialog box with attribute settings for the selected folder appears.

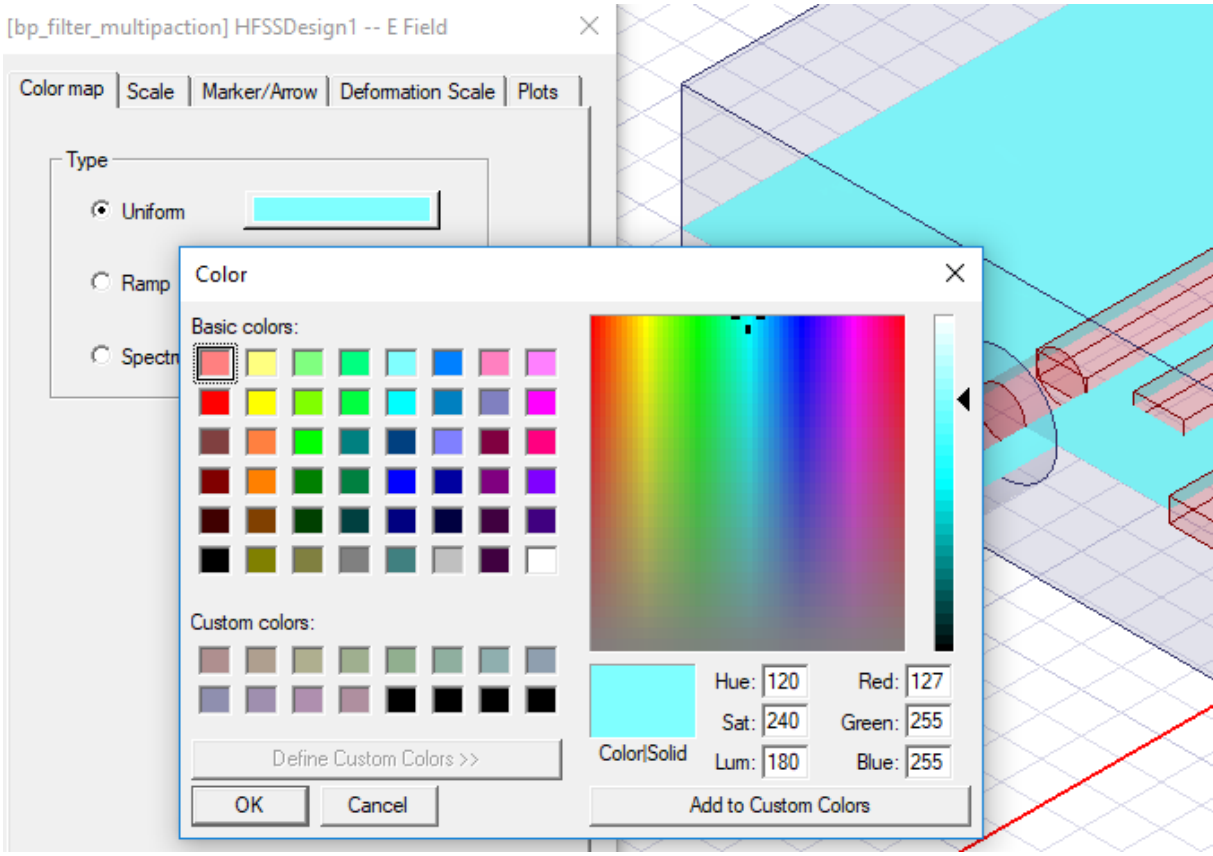
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Click the **Color Map** tab.
4. Select one of the following color types:

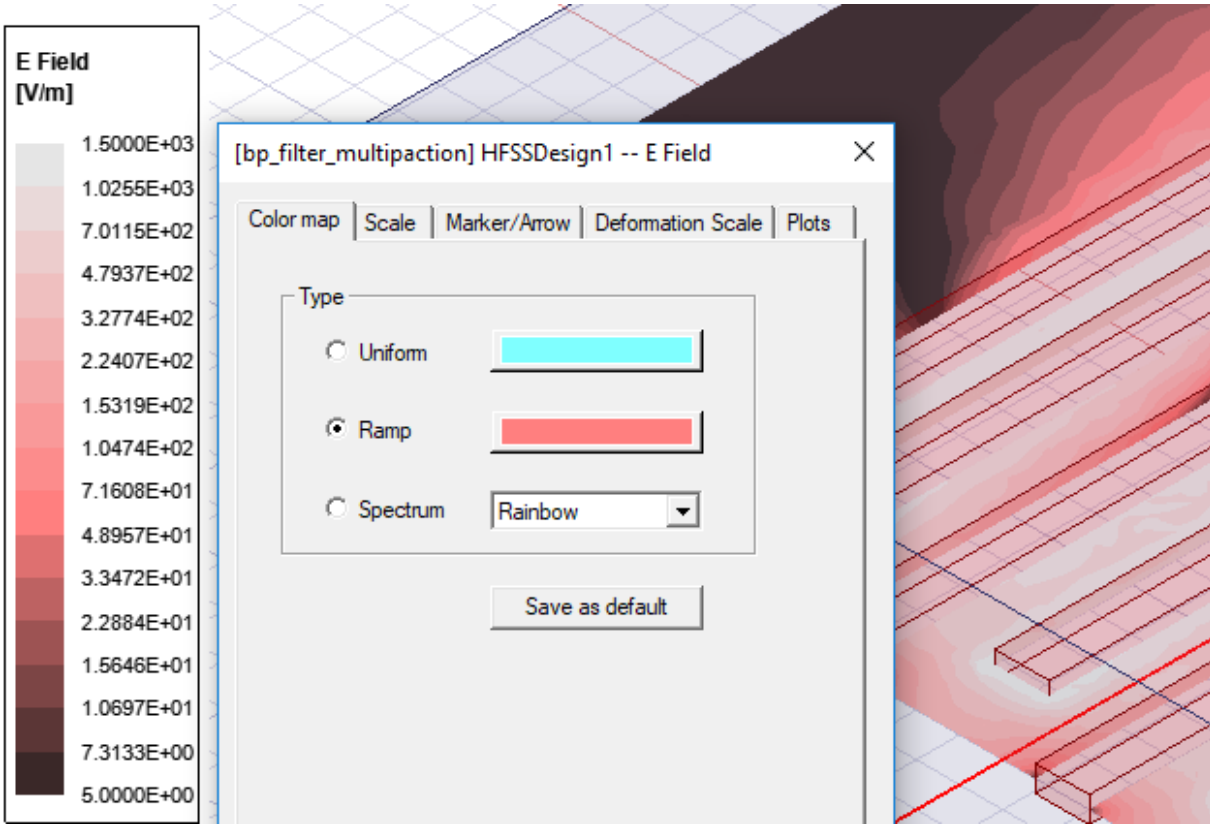
Uniform Field quantities are plotted in a single color. Click the button to choose the plot color from the **Color** button palette.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



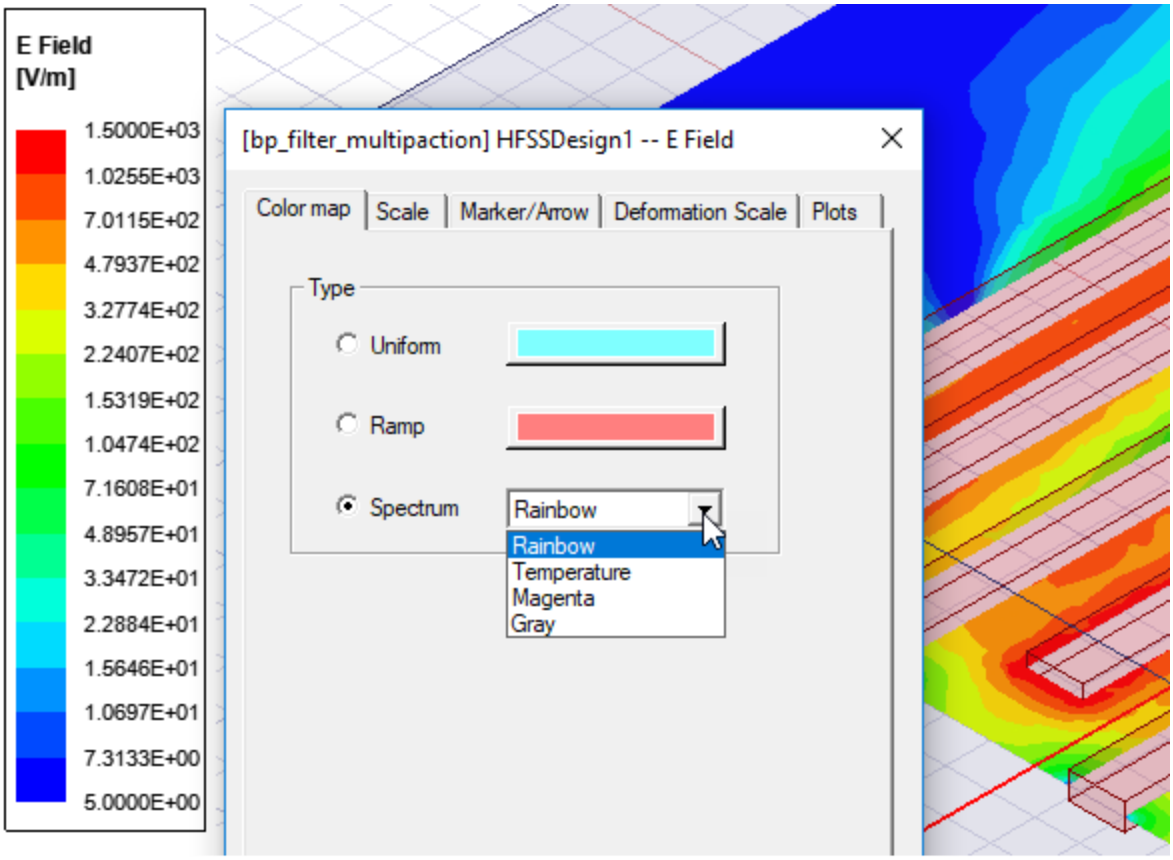
Ramp Field quantities are plotted in shades of a single color. Choose the plot color from the **Color** palette. The shade of the color corresponds to its field value.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Spectrum Field quantities are plotted in multiple colors. Choose a color spectrum from the drop-down menu. The values are Rainbow, Temperature, Magenta, and Grey. Each field value is assigned a color from the selected spectrum.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can choose **Save as Default**, if you want to use the current settings.

Select **Real time mode** if you want these, or subsequent changes to take effect immediately in the view window.

If this option is cleared, click **Apply** when you want to see the changes.

5. Click the **Scale Tab**.
6. In the **Num. Divisions** field, enter the number of colors to use in the plot.

   You can choose **Save as Default**, if you want to use the current settings.

   Select **Real time mode** if you want the changes to take effect immediately in the view window.

   If this option is cleared, click **Apply** when you want to see the changes.
7. Click **Close** to dismiss the dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Color Key Settings

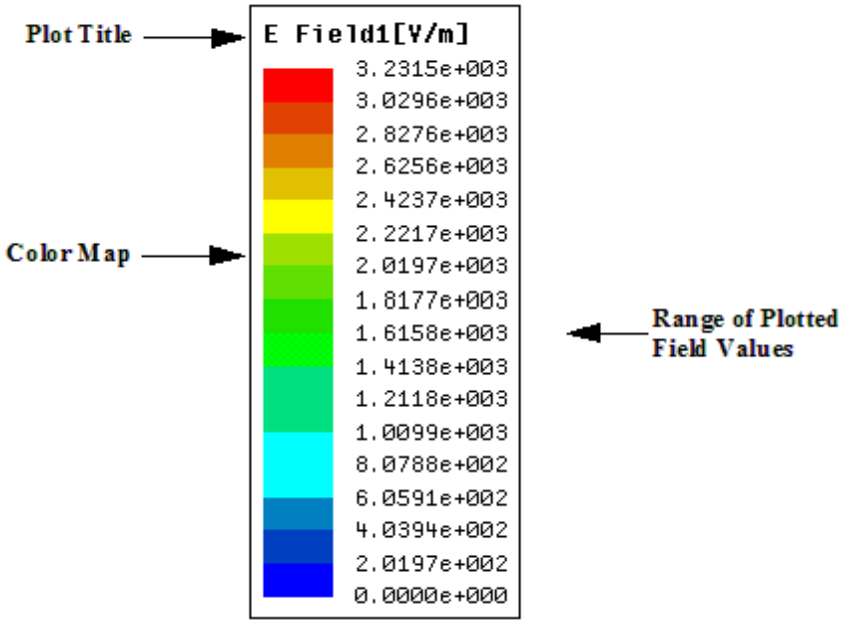
The color key (shown below) displays the range of plotted field values for a field overlay plot. It displays the colors that correspond to the range of field values on the plot. You can click and drag the color key to move it. In the case of no field data, the color key does not appear.

1. Click **View**> **Visibility**> **Active View Visibility**.

   The **Active View Visibility** dialog box appears.

2. Click the **Color Keys** tab.
3. In the **Visibility** column, select the field overlay or mesh plots in which you want to display the color key. Clear the plots in which you want to hide the color key from view.
4. Click **Done** to dismiss the dialog box.

Alternatively, to hide the color key, right-click on the color key in the active view window and choose **Hide** from the shortcut menu.



Color keys will only be visible for the plots that are selected in the **Active View Visibility** dialog box. If a hidden color key is shared by two or more overlay plots (such as a Heat Flux key, which is shared by heat flux magnitude and heat flux vector plots), then the color key will be hidden in all plots that share it. The **Active View Visibility** dialog box only lists a single incidence of a particular key, regardless of how many overlay plots share it. Use this dialog box to restore visibility of hidden color keys.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modifying the Field Plot Scale

To change how field quantities are scaled on the field overlay plot:

1. Click **HFSS** > **Fields** > **Modify Plot Attributes** or, in the Project Manager, right-click Field Overlays and select **Modify Plots** from the shortcut menu (or use the "**m**" hotkey).

   The **Select Plot Folder** dialog box appears.

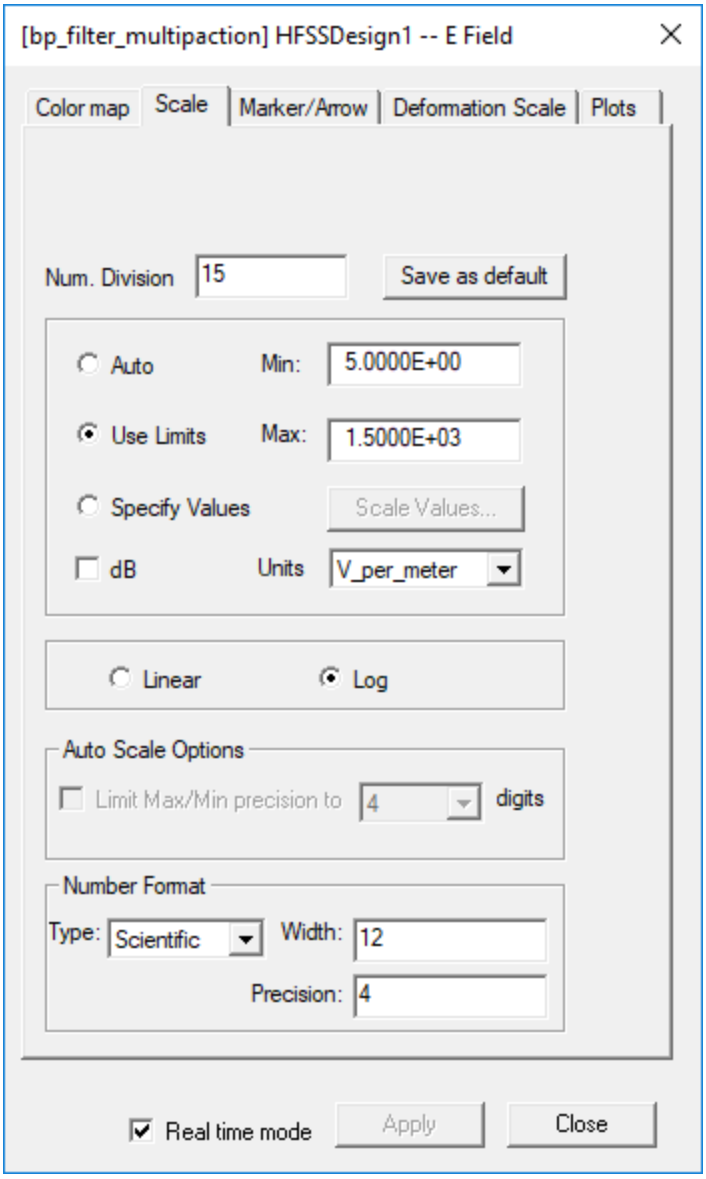
2. Select the plot folder you want to modify and click **OK**.

   All plots in the selected folder will be modified.

   A dialog box with attribute settings for the selected folder appears.

3. Click the **Scale** tab.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. Optionally, to change the number of divisions in the field plot scale, set the **Num. Division** field to a new value. You can click **Save as Default**, if desired.
5. Select one of the following scale options:

Auto The full range of field values will be plotted on the selected surface or volume. Selecting **Auto** enables the **Auto Scale Options** and disables the **Min** and **Max** fields. By default, precision is not limited and auto-min is the actual computed min on the plotted geometry.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Use Limits	Only the field values between the minimum and maximum values will be plotted. Field values below or above these values will be plotted in the colors assigned to the minimum or maximum limits, respectively. Selecting **Use Limits** enables the **Min** and **Max** fields and disables the **Auto Scale Options**. Field values have a precision of at most 6 decimal places (field solution files are saved in floating precision), so Min/Max numbers are displayed to this precision.
Specify Values	This enables a **Scale Values** button.

Optionally, when dB is checked, dB scale is used for the plot. It disables the Units field and the **Linear** is selected.

6. Optionally, use the **Units** drop-down menu to select the default unit of measure for the plot.

   The units specified here appear on the Color map for the fields plot, and for the properties dialog for the field quantities.

7. If you selected **Use Limits**, enter the lowest field value to be plotted in the **Min.** text box and the highest field value to be plotted in the **Max.** text box.

   If you selected **Auto** or **Use Limits** without having dB checked, the **Auto Scale Options** are enabled. You should only changed for cases where auto-min is a small number. Use the 'Limits Max/Min precision to' check box to enable setting the drop-down menu for the precision limit.

   The auto-min is the greater of the following:

   - Actual computed Min
   - Max/pow(10, num digits of field precision)

   If you selected Specify Values, you can click the **Scale Values** button. This opens a dialog with an editable, scrollable list of the current scale values. To apply the changes you make, click **OK**. To close the dialog box without making changes, click **Cancel**.

8. If you selected **Auto** or use **Limits** or **dB**, you can select one of the following options:

Linear	Field values are plotted on a linear scale.
Log	Field values are plotted on a logarithmic scale. If field plots have negative and positive values and when auto-scale is selected, the log-scale choice automatically sets the Min value as the Max/Min Ratio. (If field plots have all negative values, **Log** is not allowed.)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

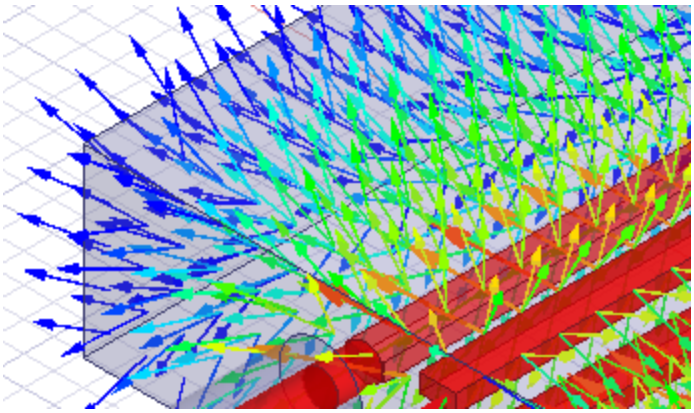
9. Specify the Number Format for the plot as Auto, Scientific Notation, or Decimal. You can also specify Width and Precision for the plot.
10. Select **Real time mode** if you want the changes to take effect immediately in the view window.

    If this option is cleared, click **Apply** when you want to see the changes.
11. Optionally, you can use the **Save As Default** button to save the following to the registry:
    - Whether to limit field precision
    - The number of digits of field precision
    - Whether to use log/linear scale
    - Whether to use dB

    Auto scale is the default for new plots. For scalar-in-volume plots, iso-surface (rather than cloud) is the default display
12. Click **Close** to dismiss the dialog box.

Modifying Vector Field Plot Arrows

To change the appearance of a vector field plot's arrows:



1. Click **HFSS**> **Fields**> **Modify Plot Attributes** or, in the Project Manager, right-click on **Field Overlays** and select **Modify Plot Attributes**. Alternatively, under **Field Overlays** in the Project Manager, right-click a subfolder (overlay type) heading and select **Modify Attributes**.

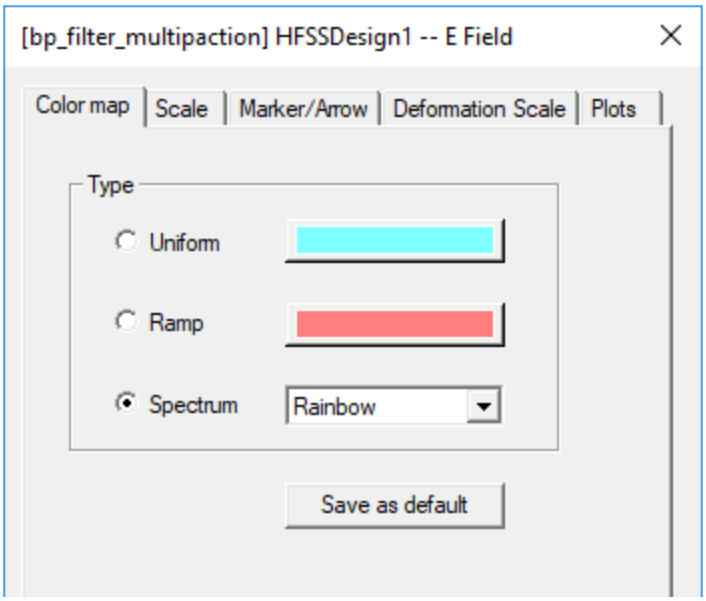
   If you select Modify Plot Attributes, the **Select Plot Folder** dialog box appears. If you select Modify Attributes, the appropriate attributes dialog box appears, bypassing the **Select Plot Folder** dialog box. In this case, skip to step 3.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

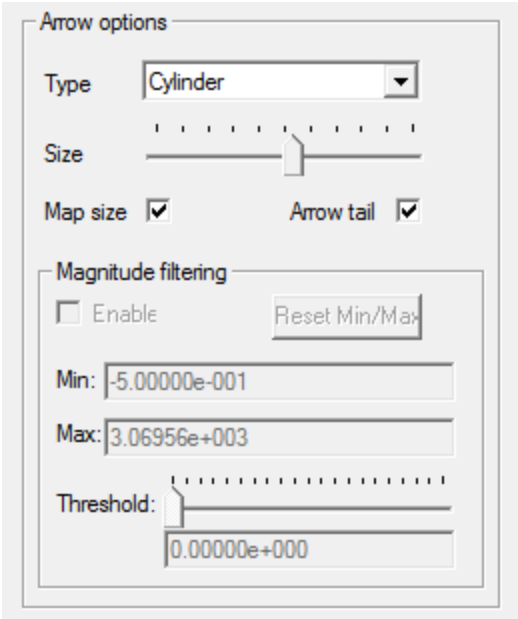
2. Select the plot folder you want to modify, and then click **OK**.

   All plots in the selected folder will be modified.

   A dialog box with attribute settings for the selected folder appears.



3. Click the **Marker/Arrow** tab.



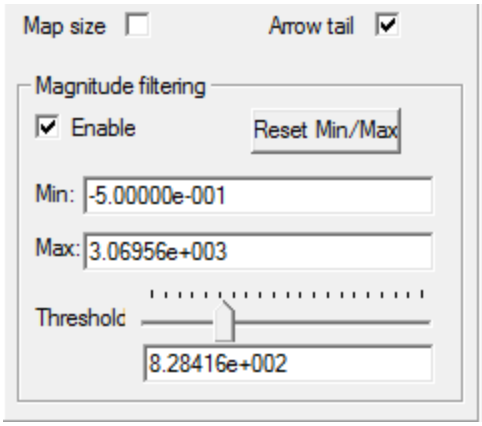
4. Under **Arrow Options**, select one of the following arrow types:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Line	The arrows are displayed as 2D/flat.
Cylinder	The arrow tails are displayed as cylinders. The arrowheads are displayed as 3D/round.
Umbrella	The arrow tails are displayed as 1D lines. The arrowheads are displayed as 3D/round.

5. Use the **Size** slider to increase (move to the right) or decrease (move to the left) the length and dimensions of the arrows. The arrows are resized relative to the size of the model geometry.
6. Select **Arrow tail** to include tails on all arrows.
7. Check **Map size** to scale the size of the arrows to the magnitude of the field quantity being plotted.

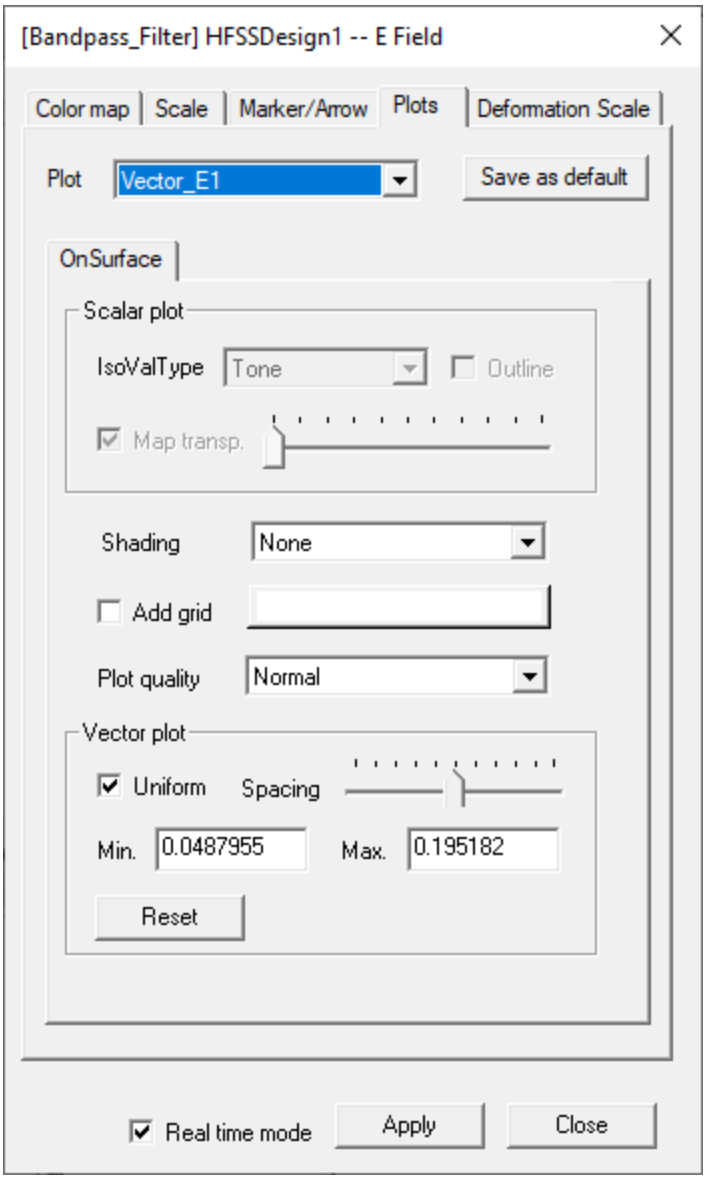
   If you uncheck **Map size**, the Magnitude filtering is enabled. You can specify the Min and Max magnitude filtering, or use a Threshold slider to set a threshold for plotting vectors. Vectors under the threshold or below the Min are not plotted.



The **Reset Min/Max** button lets you reset min/max to the current intrinsic values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. Click the **Plots** tab. To modify Vector or Streamline plot appearances, first select the plot.



The Shading options affect the appearance of arrows and streamlines. Selecting a plot enables the Vector plot settings for spacing and min and max.

9. HFSS plots arrows on a grid that is superimposed on the surface or object you selected for the plot. Under **Vector plot**, use the **Spacing** slider to increase (move to the right) or decrease (move to the left) the distance between arrows (grid points.)
    - Select **Uniform** if you want the arrows to be spaced equally.
10. Select **Real time mode** if you want the changes to take effect immediately in the view window.

    If this option is cleared, click **Apply** when you want to see the changes.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

11. Click **Close** to dismiss the dialog box.

Setting the Mesh Visibility on Field Plots

To display or hide the mesh on field plots, or change the mesh's color:

1. Click **HFSS**> **Fields**> **Modify Plot Attributes** .

   The **Select Plot Folder** dialog box appears.

2. Select the plot folder you want to modify and click **OK**.

   All plots in the selected folder will be modified.

   A dialog box with attribute settings for the selected folder appears.

3. Click the **Plots** tab.
4. Select **Add Grid** to display the mesh.
5. Optionally, select a color for the mesh from the **Color** palette.
6. Select **Real time mode** if you want the changes to take effect immediately in the view window.

   If this option is cleared, click **Apply** when you want to see the changes.

7. Click **Close** to dismiss the window.

Modifying Scalar Field Plot Isovalues

1. Click **HFSS** > **Fields** > **Modify Plot Attributes**.

   The **Select Plot Folder** window appears.

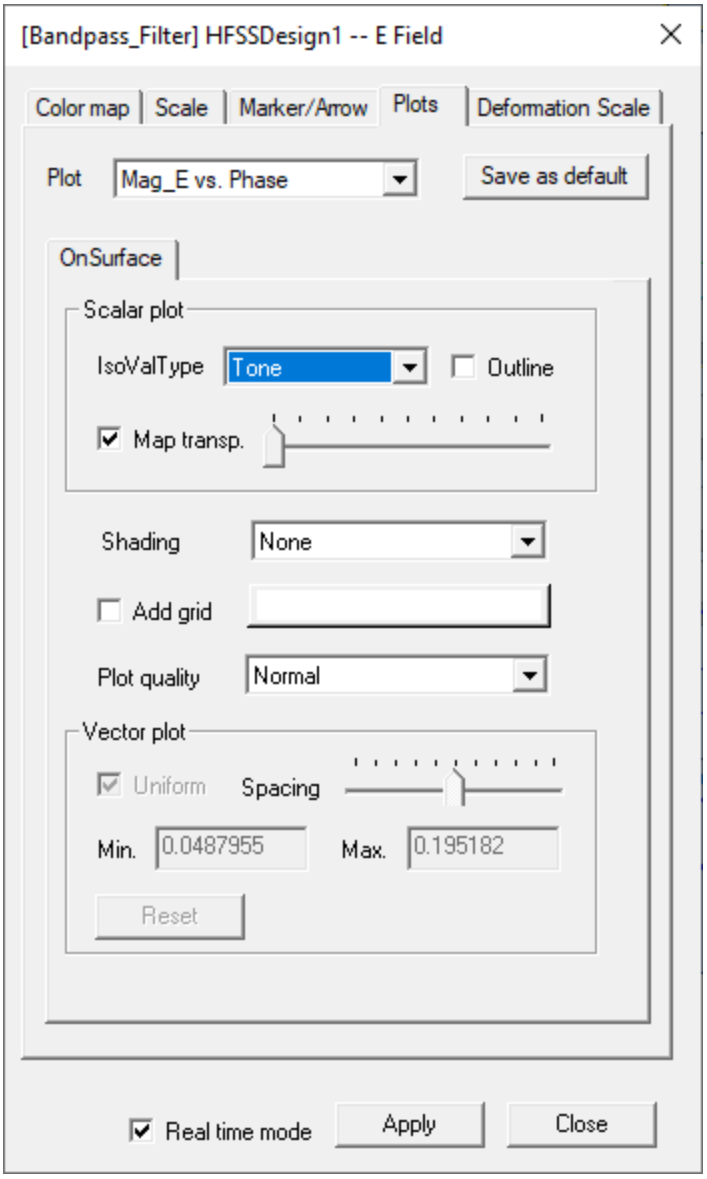
2. Select the plot folder you want to modify, and then click **OK**.

   All plots in the selected folder will be modified.

   A dialog box with attribute settings for the selected folder appears.

3. Click the **Plots** tab. If you have more than one plot, a drop- down menu lets you select the desired plot. The **OnSurface** tab appears for surface plots and **InVolume** for volume plots.

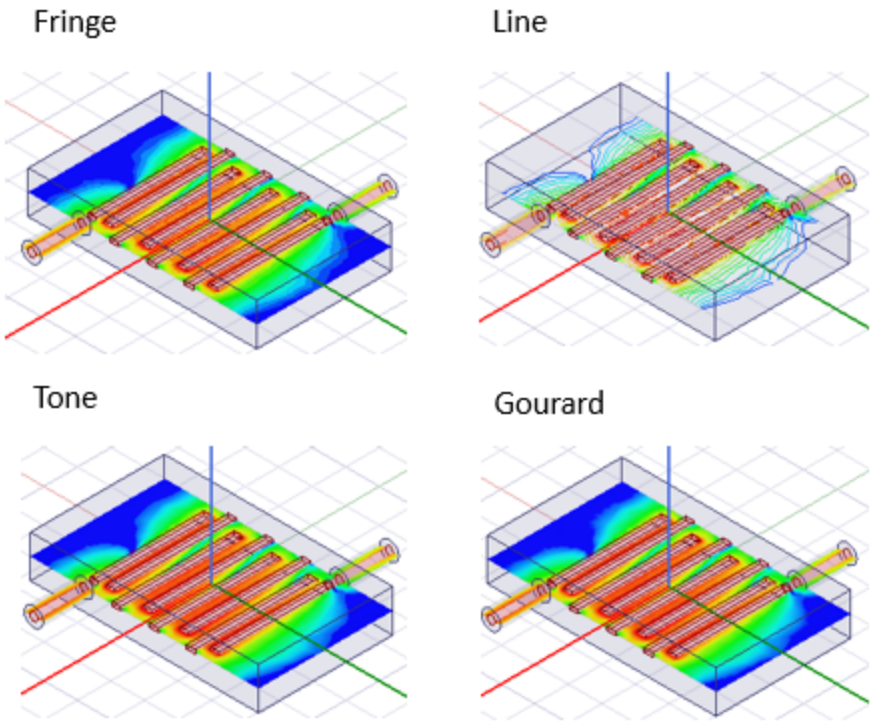
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. If the plot is a scalar surface plot, do the following:
   a. Select one of the following isosurface display types in the **IsoValType** drop-down menu:

Line	Lines are drawn along the isovalues.
Fringe	Color is constant between isovalues.
Tone	Color varies continuously between isovalues.
Gourard	Color varies continuously across the plot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



b. Optionally, if you selected **Fringe** or **Tone**, select **Outline** to add a border line between isovalues.

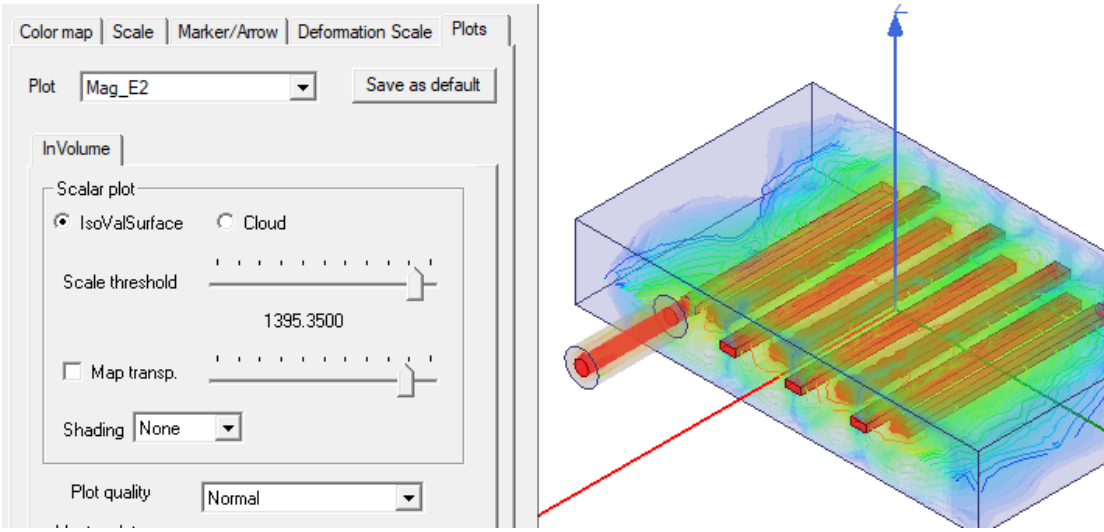
c. For shading on OnSurface plots, if you are using Lighting, you can adjust the Shading as None, Flat, or Smooth.

5. If the plot is a scalar volume plot, do the following:

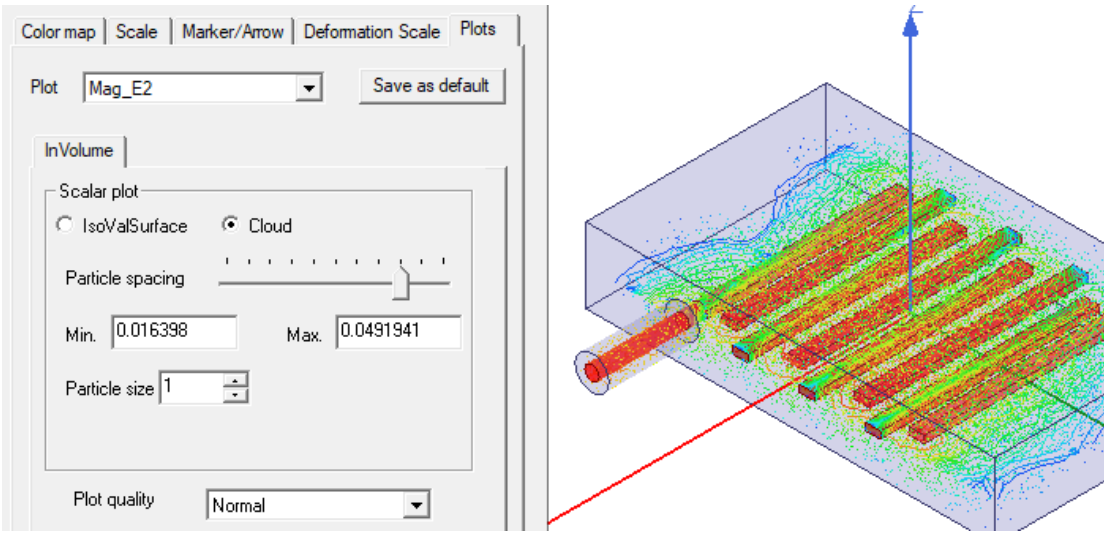
a. Select one of the following display types:

IsoValSurface	Color is drawn on the isovalues. This choice includes “Scale threshold” slider barthat allows you to set a field value threshold so that iso surfaces with field value lower than the given threshold will show as translucent with given transparency specified by the slider bar below it. When "Map transp." is checked, translucent iso surfaces field values map to [0.0, transparency] so lower field value map to higher transparency while higher field value to lower transparency. If it is unchecked, all translucent iso surfaces will have the same given transparency from the slider bar.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Cloud Field values are represented by points that illustrate the spatial distribution of the solution. The higher the solution value, the greater the cloud density. You can adjust particle spacing, Min. and Max, values, and Particle size.



6. Select **Real time mode** if you want the changes to take effect immediately in the view window.

   If this option is cleared, click **Apply** when you want to see the changes.

7. Click **Close** to dismiss the window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modifying Scalar Field Plot Shading

1. Click **HFSS** > **Fields** > **Modify Plot Attributes**.

   The **Select Plot Folder** window appears.

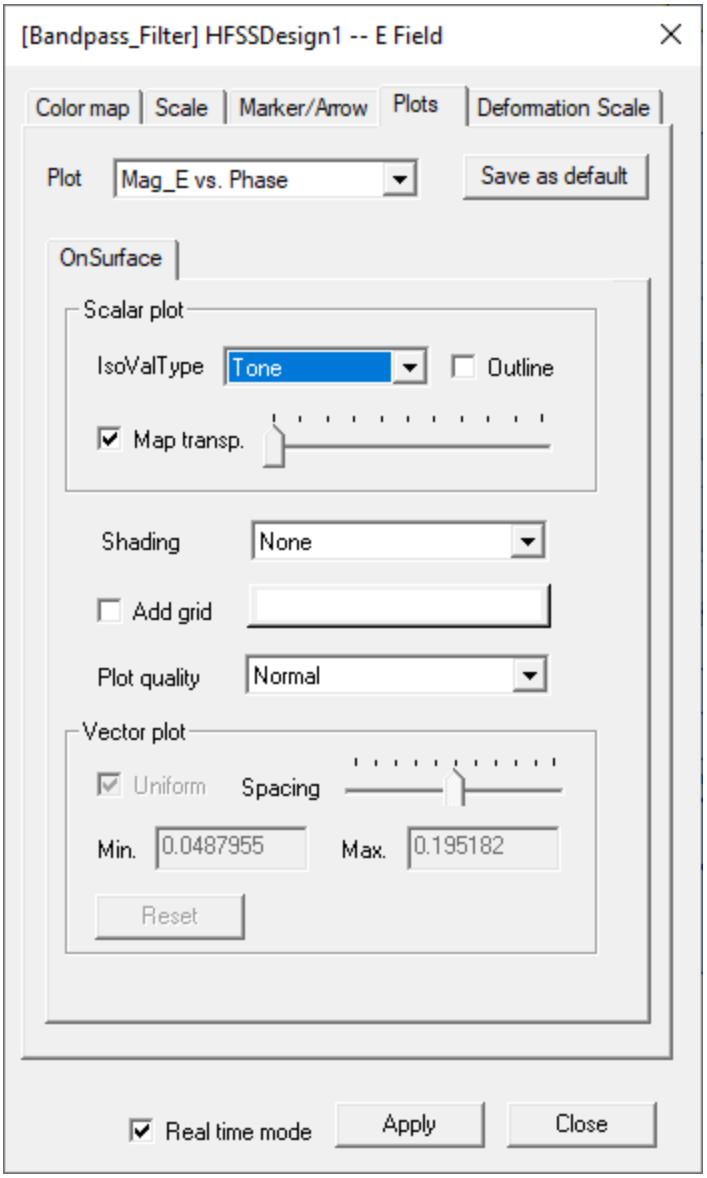
2. Select the plot folder you want to modify, and then click **OK**.

   All plots in the selected folder will be modified.

   A dialog box with attribute settings for the selected folder appears.

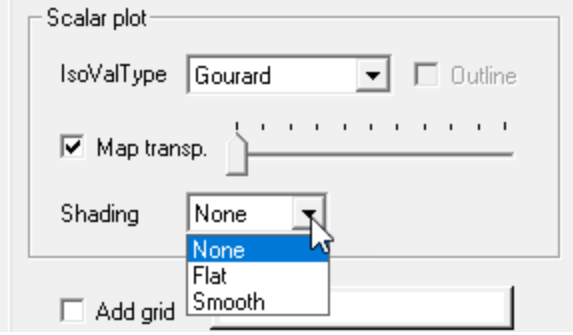
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Click the **Plots** tab. Select the Plot to modify.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. If the plot is a scalar surface plot, do the following:
    a. Select one of the following from the Shading drop-down menu:



None	Equivalent to selecting **Do not use lighting** on the Lighting Properties dialog box.
Flat	Provides a flat rendering of the field plot.
Smooth	Provides a smooth rendering of the field plot.

5. Select **Real time mode** if you want the changes to take effect immediately in the view window.

    If this option is cleared, click **Apply** when you want to see the changes.

6. Click **Close** to dismiss the window.

Mapping Scalar Field Plot Transparency to Field Values

1. Click **HFSS** > **Fields**> **Modify Plot Attributes**.

    The *Select Plot Folder* dialog box appears.

2. Select the plot folder you want to modify, and then click **OK**.

    All plots in the selected folder will be modified.

    A dialog box with attribute settings for the selected folder appears.

3. Click the **Plots** tab.
4. Use the **Map transp.** slider to increase (move to the right) or decrease (move to the left) the transparency of the plot.
    - If you select **Map transp.**, the transparency of field values increases as the solution values decrease.
5. Select **Real time mode** if you want the changes to take effect immediately in the view window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If this option is cleared, click **Apply** when you want to see the changes.

6. Click **Close** to dismiss the dialog box.

Modifying Markers on Point Plots

For scalar point plots, a marker is used to represent a field quantity at a selected point (for vector point plots, arrows are used).

Modify the shape and size of markers in the plot attributes window:

1. Click **HFSS**> **Fields**> **Modify Plot Attributes**.

   The **Select Plot Folder** window appears.

2. Select the plot folder you want to modify, and then click **OK**.

   All plots in the selected folder will be modified.

   A dialog box with attribute settings for the selected folder appears.

3. Click the **Marker/Arrow** tab in the plot attributes window.
4. Under **Marker options**, select one of the marker types to represent the field quantity at the point:
   - **Sphere**
   - **Box**
   - **Tetrahedron**
   - **Octahedron**
5. Use the **Size** slider to increase or decrease the size of the marker.
6. Select **Map size** to scale the size of the marker to the magnitude of the quantity being plotted.
7. Select **Real time mode** if you want the changes to take effect immediately in the view window.

   If this option is cleared, click **Apply** when you want to see the changes.

8. Click **Close**.

Modifying Line Plots

Field quantities can be plotted directly on a line object. Scalar quantities are plotted as 3D color-shaded lines. Vector quantities are plotted as arrows that are based on the line.

To modify the appearance of line plots:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click **HFSS** > **Fields** > **Modify Plot Attributes** .

   The **Select Plot Folder** window appears.

2. Select the plot folder you want to modify, and then click **OK**.

   All plots in the selected folder will be modified.

   A dialog box with attribute settings for the selected folder appears.

3. Click the **Plots** tab.
4. Select one of the following isosurface display types in the **IsoValType** drop-down menu:

Fringe	Color is constant between isovalues.
Tone	Color varies continuously between isovalues.
Gourard	Color varies continuously across the plot.

5. Select one of the following styles for the line object in the **Line style** drop-down menu:

Cylinder	The line object is shaped like a cylinder.
Solid	The line object is a 3D solid.
Dash-Dash	The line object is represented by dashed black line segments.
Dot-Dot	The line object is represented by a series of dots.
Dash-Dot	The line object is represented by a series of alternating dashed black line segments and dots.

6. Use the **Line width** slider to increase (move to the right) or decrease (move to the left) the thickness of the line.
7. By default, a polyline object is divided into 100 equally spaced points for post processing. To modify the number of points on the line, type a new value in the **Number of points** text box.
8. Select **Real time mode** if you want the changes to take effect immediately in the view window.

   If this option is cleared, click **Apply** when you want to see the changes.

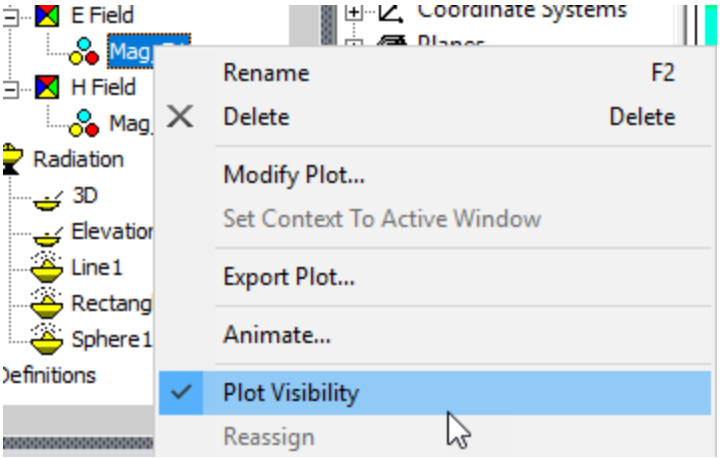
9. Click **Close** to dismiss the window.

Setting a Plot's Visibility

You can control the visibility of Field Overlays by means of the **View> Visibility> Active View Visibility** dialog box, **Fields Reporter** tab (shown below) or by right-clicking on the plot in the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

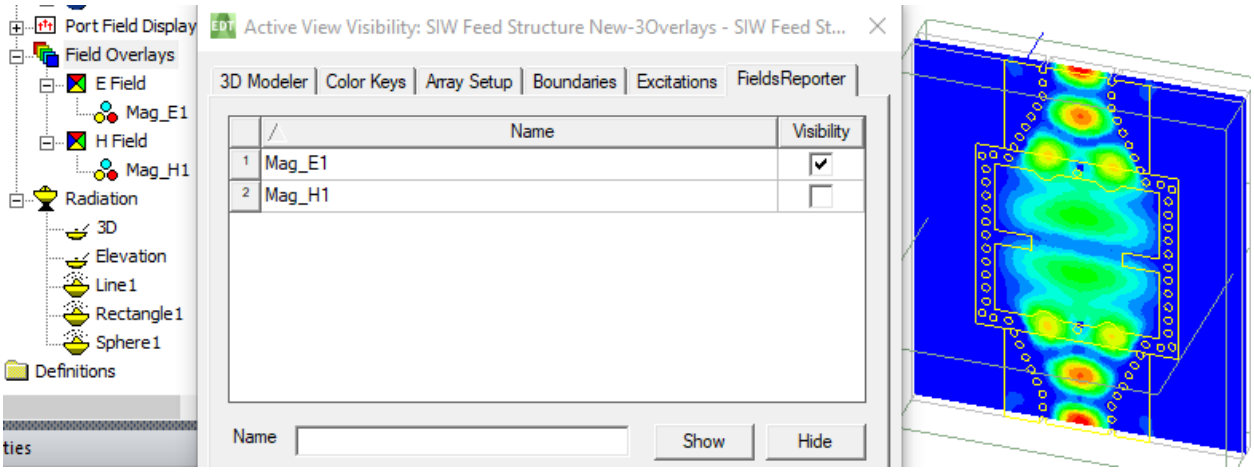
Project Manager and checking or unchecking **Plot Visibility**.



To display or hide a field overlay or mesh plot from view in the *3D Modeler* window:

1. Click **View> Visibility>** **Active View Visibility**. Alternatively, you can select the **Active View Visibility** icon from the **View, Draw,** or **Model** ribbon tabs.

   The *Active View Visibility* dialog box appears.

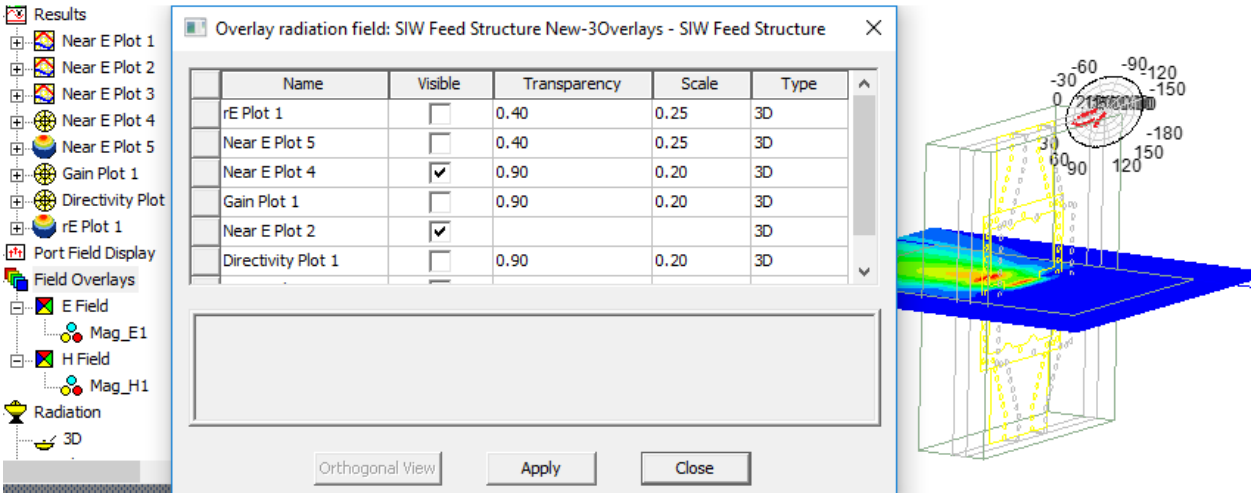


2. Click the **FieldsReporter** tab.
3. In the **Visibility** column, select the field overlay or mesh plots you want to display. Clear the plots you want to hide from view.

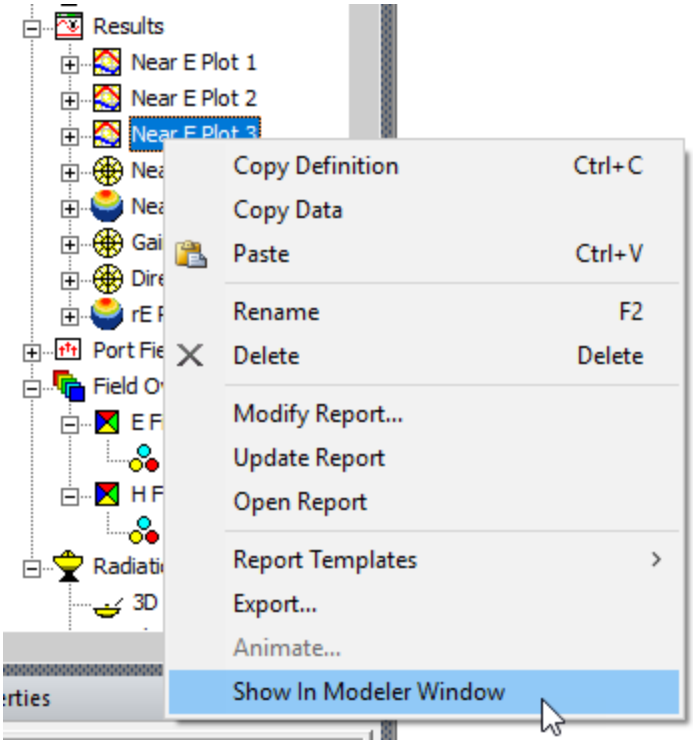
   Only the selected plots will be visible. Multiple plots can be shown at once.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Radiation plots and antenna parameter tables available for overlay can be viewed by right-clicking **Field Overlays** in the *History Tree*, and selecting **Plot Fields> Radiation Field...**. This displays an **Overlay radiation field** dialog that lists each Results plot available for overlay.



You can also control the visibility of **Results** plots available for **Overlay radiation field** by right-clicking on the report and selecting **Show in Modeler Window**.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Saving a Field Overlay Plot

Field overlay and mesh plots are saved in the project file; however, you can save a plot to Field Plot File format (.dsp) and then open it in HFSS.

To save field overlay or mesh plot data to a .dsp file:

1. In the project tree, click the plot you want to export.
2. Click **HFSS** > **Fields** > **Save as** .

   The **Select Field Plot(s)** dialog box appears.
3. Select the plots you want to export by checking the **Select** box, and then click **OK**.

   The file browser appears. **Field Plot Files (.dsp)** is the selected file type.
4. Specify the name of the .dsp file and the location in which to save it.
5. Click **Save**.

The plot is exported to the specified .dsp file.

To open the file you created, click **HFSS** > **Fields** > **Open**.

Opening a Field Overlay Plot

To open a field overlay or mesh plot that you have saved to Field Plot File format (.dsp):

1. Click HFSS > **Fields** > **Open** .
2. The file browser appears. **Field Plot Files (.dsp)** is the selected file type.
3. Browse to the location of the .dsp file you want to open, and then click the file name.
4. Click **Open**.

The plot appears in the view window. It is listed under **Field Overlays** in the project tree.

Deleting a Field Overlay Plot

1. Click **HFSS** > **Fields** > **Delete Plot** .

   The **Delete Plots** dialog box appears.
2. Select the plots you want to delete by checking the **Delete** check box.
3. Click **OK**. The selected plot are deleted.

Alternatively, click the plot in the project tree that you want to delete, and then press **Delete** .

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setting Field Overlay Plot Defaults

Each new field plot uses the default plot settings specified in the **Set Plot Defaults** dialog box.

To modify the default plot settings:

1. If a plot folder has not been created, click **Field Overlays** in the Project Manager.
2. Click **HFSS** > **Fields** > **Set Plot Defaults**.

   The **Set Plot Defaults** dialog box appears.
3. Select the solution to plot from the **Solution** drop-down menu.
4. Select the plot folder in which new plots will be stored from the **Quantity type** drop-down menu. Choose one of the following options:

New Folder	Each new plot will be stored in a separate folder in the project tree.
Automatic	Each new plot will be stored in a folder determined by HFSS as the most appropriate based on the plotted field quantity. For example, all surface magnitude E plots will be stored in the same folder.
An existing folder	Select the existing folder in which you want to store new plots.

> **Note:**
>
> Plots stored in the same folder will use the same color key. The **Auto** scale setting will be based on the maximum field solution value present in a plot.

5. Under **Intrinsic Variables**, specify the frequency and phase angle at which the field quantity is evaluated.
6. Click **OK**.

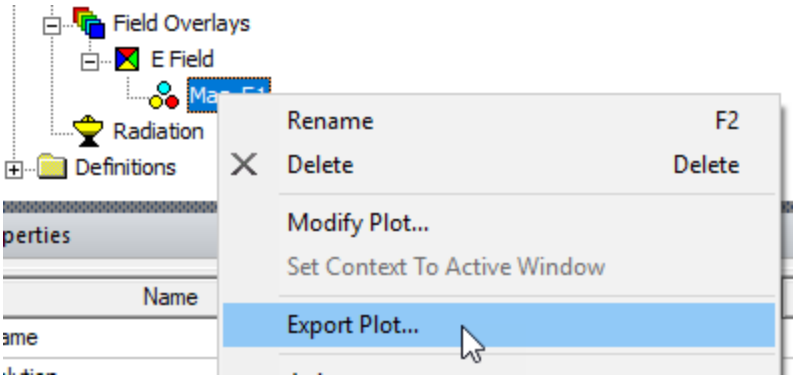
Exporting Field Plots

The **Export Plot...** command lets you export a field plot to a format that supports full data precision without the need to go through the Fields Calculator.

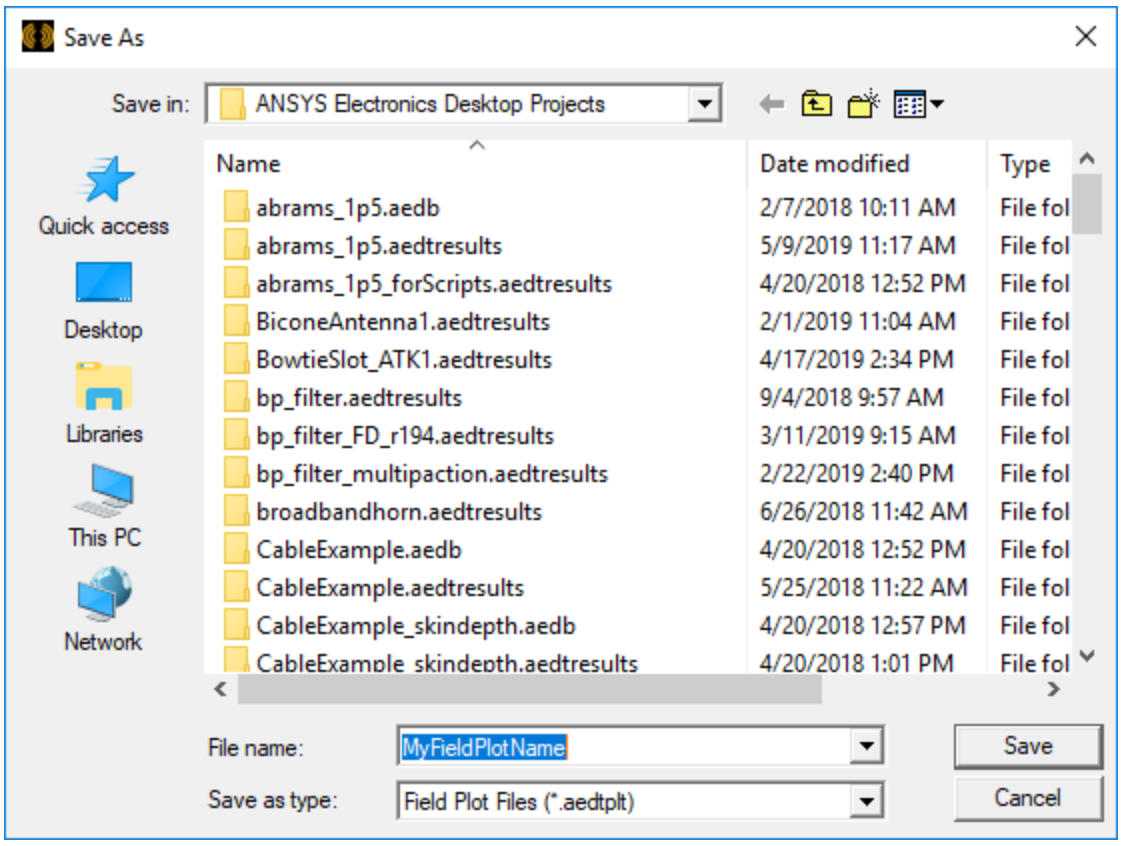
1. Create the field plot you want to export.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the **Project Manager tree**, right click on the field plot icon and in the shortcut menu, click **Export Plot...**.



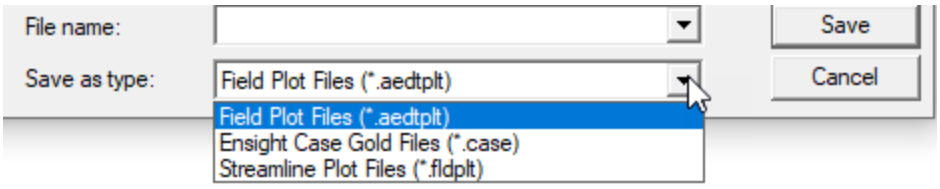
The **Save As** dialog box appears.



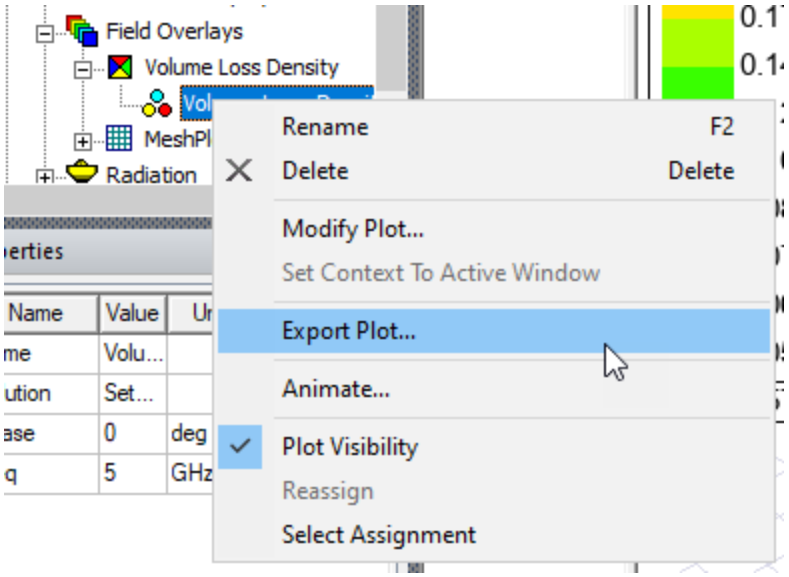
3. Specify the directory to **Save in**, the **File name** and use the **Save as type** as Field Plot Files (*.aedtplot) or Ensight Case Gold Files (*.case). If the Plot is a Streamline plot you can also choose Steamline files (*.fldplt). (See **Notes for creating Streamline plots**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

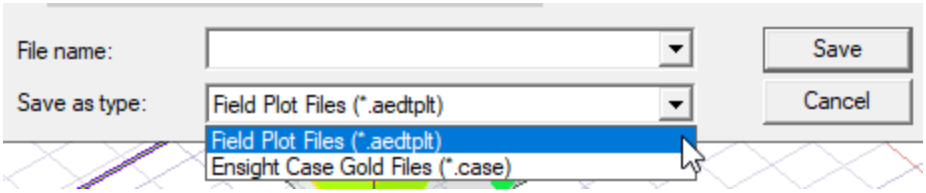
under Plotting Field Overlays).



You can export a Streamline plot in .fldplt format by right-clicking on the plot in the Project tree, and selecting **Export Plot...**



This opens a dialog for you to specify a plot name and location.



The Field Plot is exported to the file format you specified.

Field Plot Data Export Format (*.aedtplt)

A sample first order file with 1 drawing:

```
# Ansys ElectronicsDesktop 2025.2.0
# Field plot export file (*.aedtplt), version 1.0
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

File Format Description

The first line starts with the symbol of “#” and continues with the product name and its version that is used to produce this file. The 2nd line also starts with the symbol of “#” and continue with the file format version. Currently it is version 1.0.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The next line, it shows the number of drawings in this file. The above example shows 1 drawing. The drawing has two big data blocks (the mesh data block and field data block). Each drawing starts with **$begin Drawing_***** and ends with **$end Drawing_***** (where ***** should be replaced with the drawing index, starting from 1).

Mesh data block

It contains all the mesh information about current drawing include element type, number of nodes of each element, node coordinates and element node connectivity. At the beginning of the block, it shows if it has curve element and then it lists the bounding box of this mesh. The bounding box format is **BoundingBox(lowerX, lowerY, lowerZ, upperX, upperY, upperZ)**. They are six double values.

Next comes with elements part starting with **Elements(**. First integer is the total number of nodes for this mesh and the next is the total number of elements. After that, it repeats the following information for each element: element type, reserved integer 1, reserved integer 2 and reserved integer 3, number of nodes for this element, node index 1, node index 2 till to the number of nodes for this element. All these numbers are integers. Please refer to the end of this document to see the list of element types. This part ends with the close paren, ")".

The last part of the mesh data block is the nodes part. It contains the coordinates(x,y,z) of all the nodes for this mesh. It starts with Nodes(and continue with a list of tuples of 3 double values which are the x, y, z coordinates of the first, 2nd, last nodes and it ends with a close paren,")".

Field data block

It contains two parts. The first part includes node field data of each element. Node field data could either be scalar or vector data which means either it has one component or it has three components(x, y, z).

This part starts with **ElemSolution(**, the next two double values are the minimal and maximal field value of this drawing. The next integer shows the total number field data for each element. It should be a multiple of the number of nodes of each element (e.g. if field data is vector data, then it should be 3 times of the number of nodes of each element). For vector data, each element should have data like (**node1_x, node1_y, node1_z, node2_x, node2_y, node2_z, …**). This part ends with close paren, ")".

The 2nd part shows two location points. It starts with **ElemSolutionMinMaxLocation(**. The first 3 double values are the (x,y,z) coordinates of the location where the minimal field value is located while the next 3 numbers for the maximal field value. This part ends with close paren, ")".

Element types:

Element type description	Element type value
point	0
line	1
triangle	2

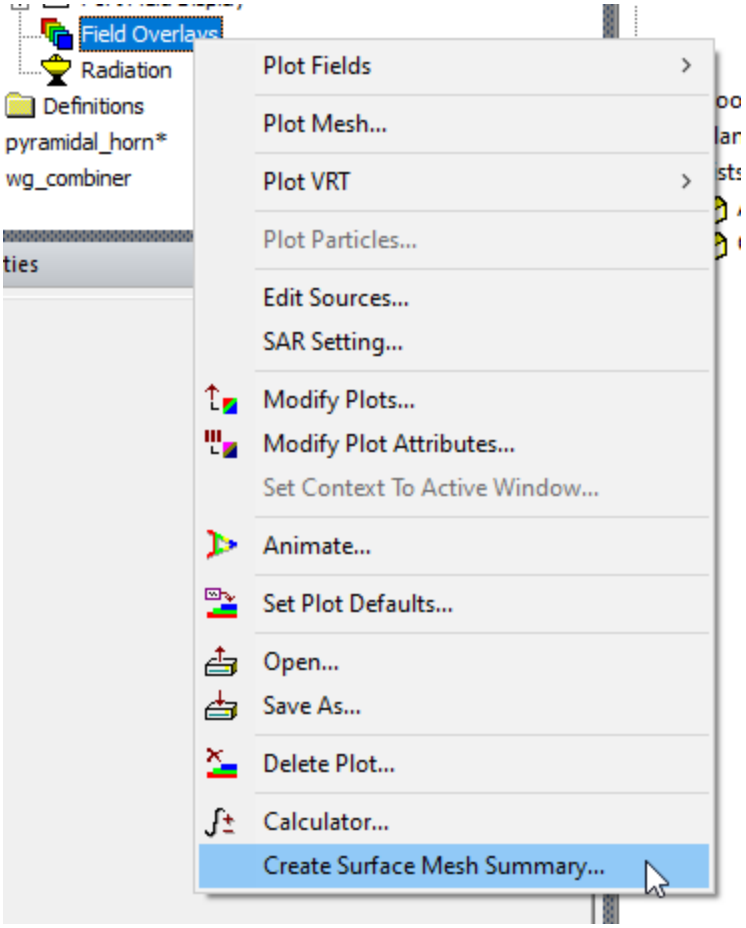
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Element type description	Element type value
quad	3
tetradedron	4
pyramid	5
wedge	6
hexahedron	7

For second order element node index convention, Lagrange Parabolic is used.

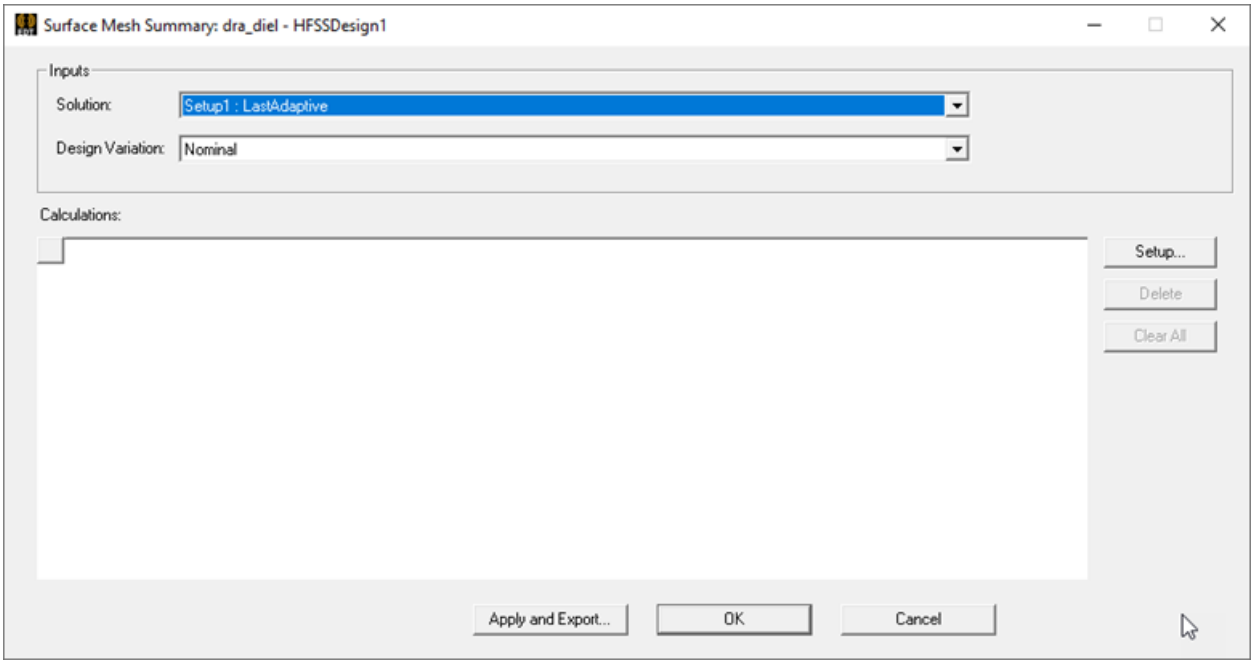
Create Surface Mesh Summary

You can use the **HFSS** > **Fields** > **Create Surface Mesh Summary...** command or the equivalent command on the short-cut menu on the **Field Overlays** icon in the **Project** tree to create a report of mesh statistics on selected surfaces or lists of surfaces.

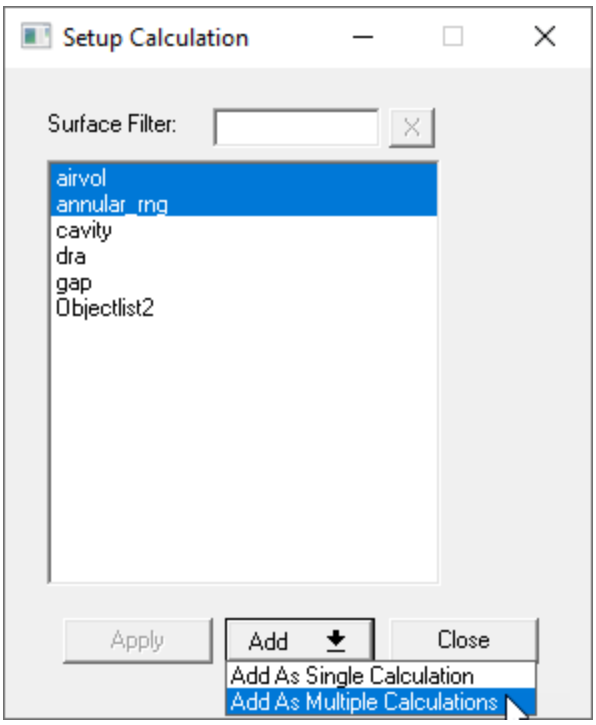


This command opens a dialog box in which you specify the Solution and Design Variation to use.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

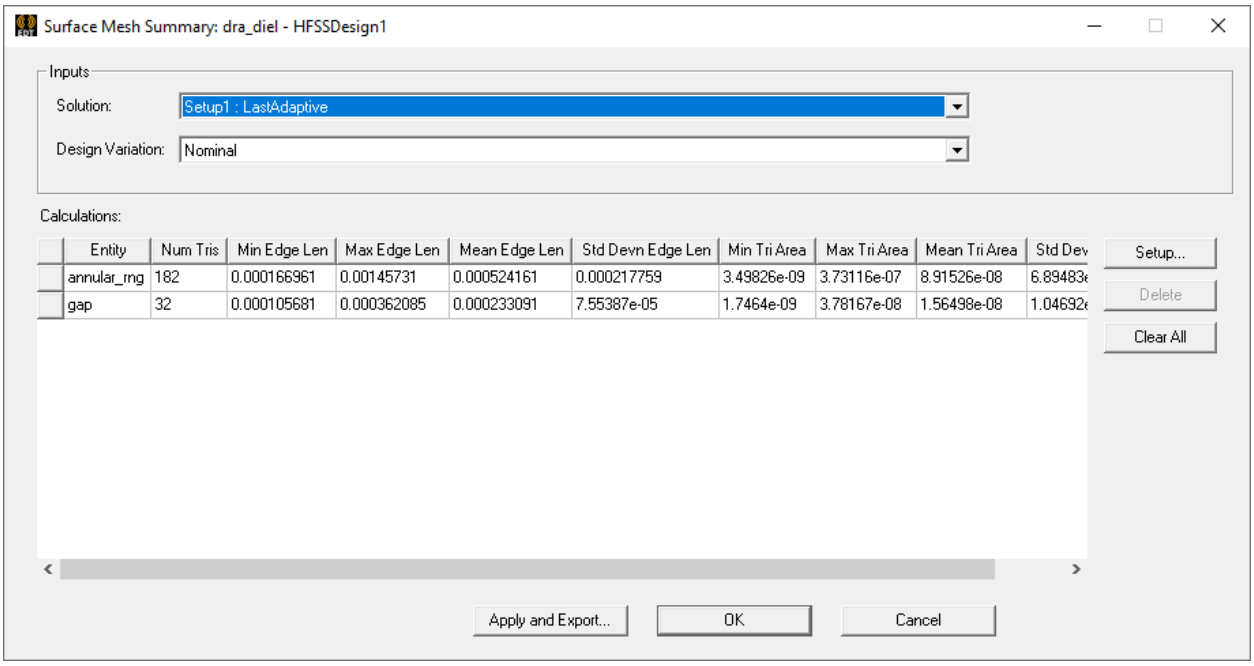


Select the **Setup...** button to open the **Setup Calculation** window, in which you specify the objects or lists for which to calculate mesh statistics. If the number of objects is large, you can use the Surface Filter text box to narrow the search.



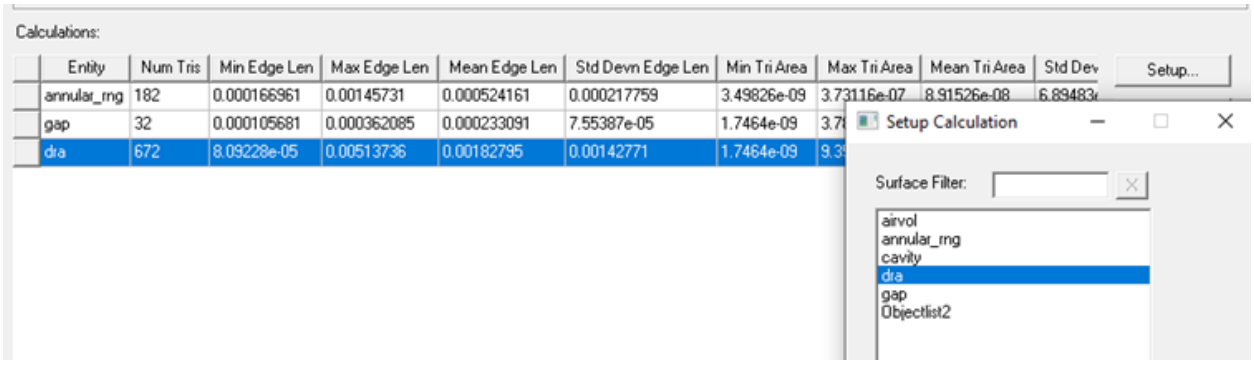
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When you have made your selection, you can **Add as a Single Calculation** or **Add as Multiple Calculations**. The Calculations are displayed in table format, according to the **Setup** specified. If there is no mesh solution, the panel show only the selected entity name and a warning message reports “Failed to load surface mesh results”.



Statistics include Num Tris, Min Edge Length, Max Edge Length, Mean Edge Ledge, Standard Deviation Edge Length, Min Triangle Area, Max Triangle Area, Mean Triangle Area, and Standard Deviation Triangle Area.

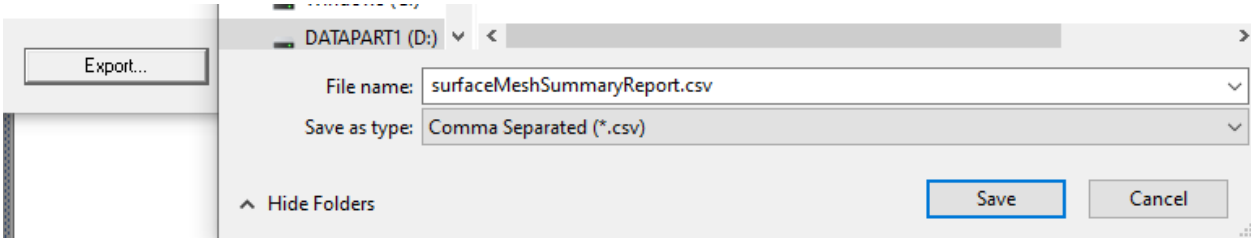
You can add additional rows, select selected rows, or clear all rows. Selecting only one row in the **Surface Mesh Summary** dialog enables the **Apply** button in the **Setup Calculation** dialog box. You can then make selections, then click on the **Apply** button, to use the selection to overwrite the content in the selected row by the entities chosen from the **Setup Calculation** dialog box.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Apply and Export** and **Export** buttons allow you to write out a comma separated (.csv) file of the statistics. Clicking either **OK** or **Apply and Export** saves the current data rows in the panel. The difference between the two buttons is:

- Clicking **OK** saves the data and then closes the dialog box.
- Clicking **Apply and Export** saves the data, then opens the **Save As** dialog box for .csv file export. After you click **Apply and Export**, the dialog box remains open and the button context is converted to **Export**, which means there is no new data to save.



The .csv file can be viewed in a spreadsheet as follows.

SolutionName

	A	B	C	D	E	F	G	H	I	J	K

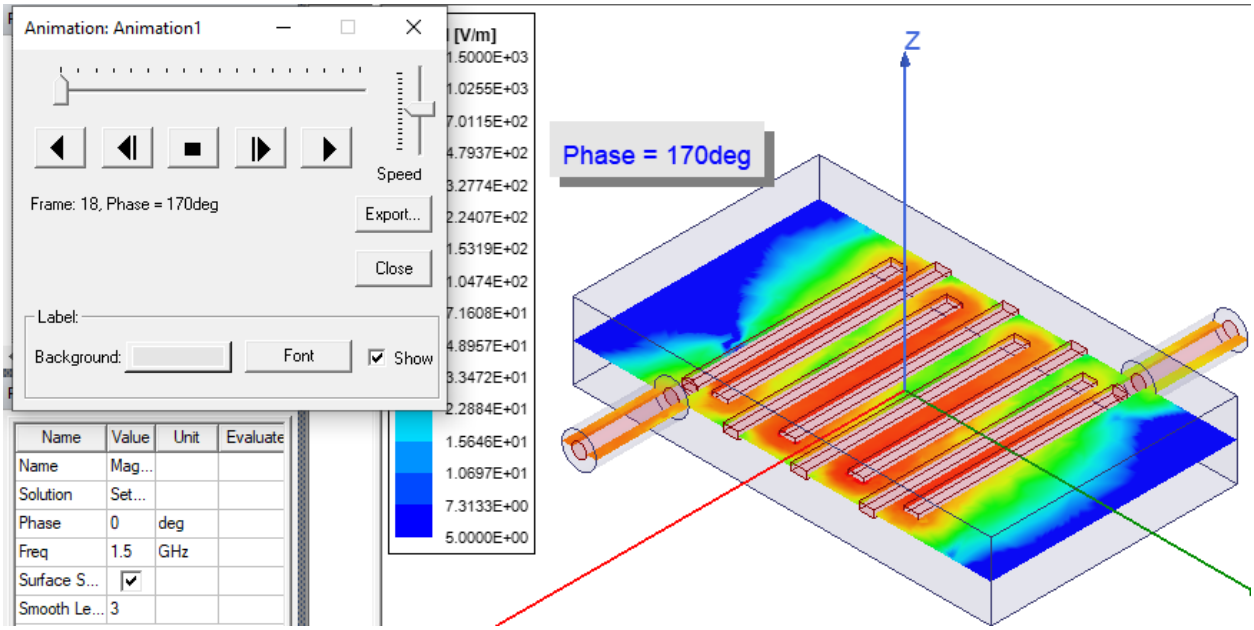
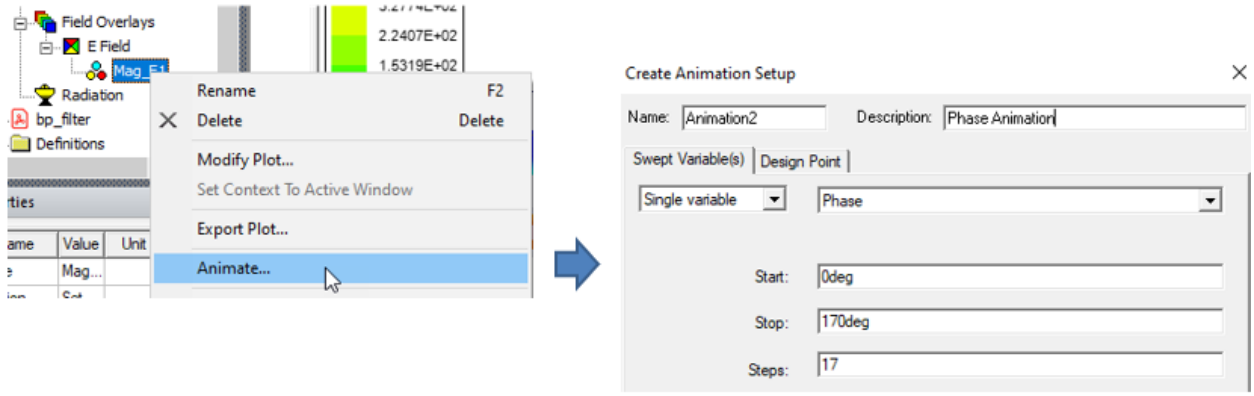
Creating Animations

An animated plot is a series of frames that displays a field, frequency, parametric value, mesh, virtual ray trace or geometry at varying values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To create an animated plot, you specify the values of the plot that you want to include, just as an animator takes snapshots of individual drawings that make up a cartoon. Each value is a frame in the animation. You specify how many frames to include in the animation.



The following sections describe how to create different kinds of animations.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

Each animation frame requires memory for storage which depends upon the mesh size and type of plot. Memory usage may become very large during plot animations. To reduce memory usage, specify the minimum number of frames possible. See General Options for more information.

Note:

Graphics System requirements for Optimal Performance

In order to obtain optimal performance improvements on fields overlay plot, a workstation-class 3D-capable graphics card with at least 512 MB of memory that supports OpenGL version 2.0 or higher is needed.

On Windows, the default OpenGL version support is v1.1, so you might need to update graphics driver to the latest version;

If you access the application through Windows Remote Desktop which only supports Generic GDI (functionally equivalent to OpenGL v1.0), the performance improvement will also not be available;

To view OpenGL version/extensions supported by your card, the OpenGL Extension Viewer tool is accessible via softpedia.com.

If animation is slow, especially for complex models, for some older graphics cards, you can improve performance by accessing **NVIDIA Control Panel**> **3D Settings**> **Manage 3D Settings – Global Settings** tab and choosing the **Workstation App – Dynamic Streaming** option from the **Global Presets** drop-down menu.

You can export the animation to animated Graphics Interchange Format (GIF), to Audio Video Interleave (AVI) format, or to WebM (.webm) format.

Creating Phase Animations

You can create phase animations of field plots of frequency sweeps.

Prerequisites

Before creating a phase animation, you must solve a frequency sweep for the project.

Create a field plot.

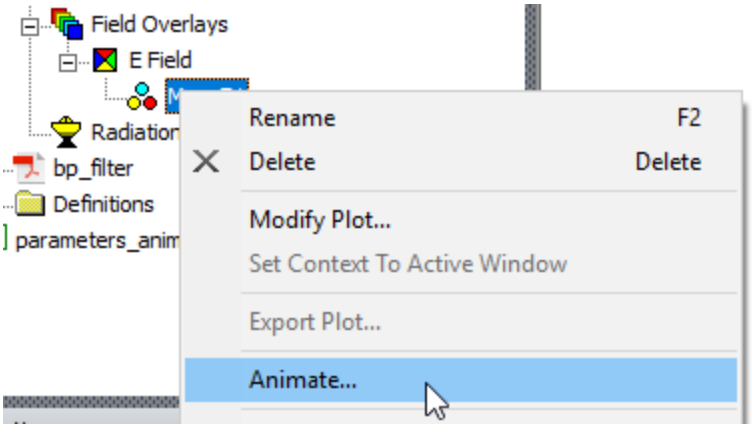
Procedure:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

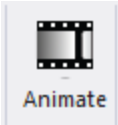
To animate a plot with respect to the phase of the plotted field:

1. Create a field overlay plot to animate.
2. Select the plot in the **Project** tree, and click **HFSS>Fields>Animate...**, or right-click in the **Modeler** window, and click **View>Animate...**.

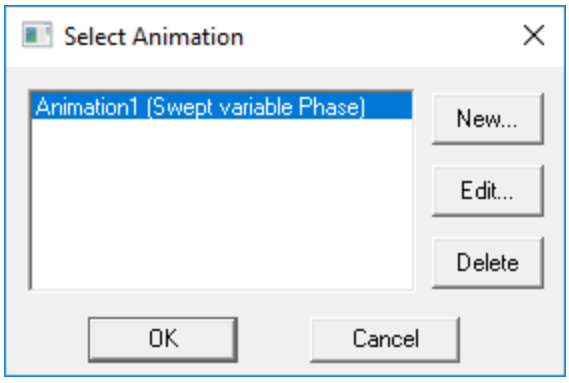
Or right-click the field overlay plot of interest and click **Animate...** from the shortcut menu,



Or select the field overlay plot of interest, select the **View** tab of the ribbon, and click the **Animate** icon.



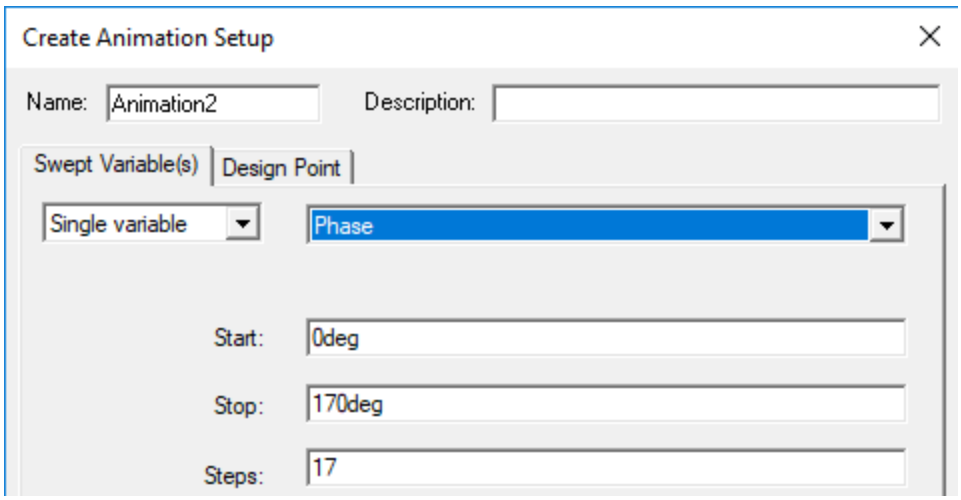
If you already created an animation, the **Select Animation** dialog box appears. Selecting an existing animation from that list starts it.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

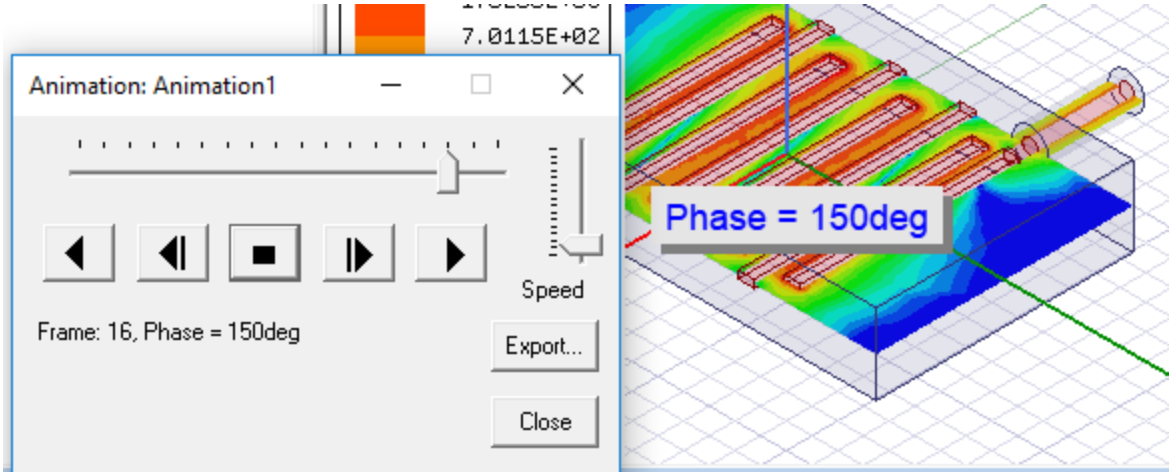
Selecting an existing animation from that list starts it when you click **OK**. Click **Edit...** to open the **Modify Animation Setup** dialog.To create a new animation, click **New**.

The **Create Animation Setup** dialog box appears.



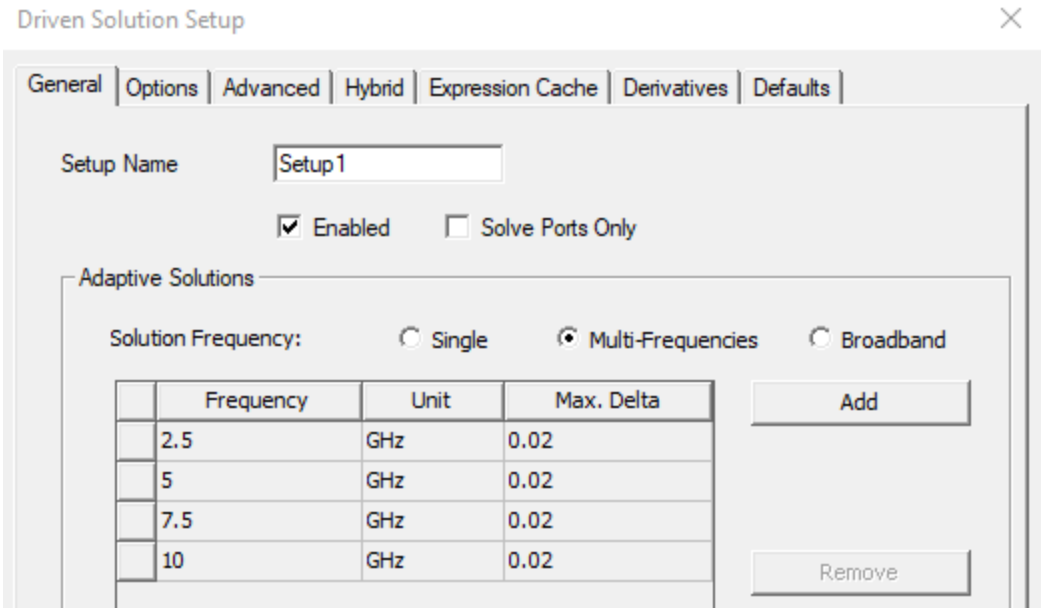
3. Under the **Swept Variable** tab, select **Single Variable** and accept Phase.
4. Specify the phase values you want to include in the animation, as Start, Stop, and Steps to include (e.g., if the **Start** value is **10**, the **Stop** value is **160**, and the number of steps is **10**, the animation will display the plot at 10 phase values between 10 and 160. The start value will be the first frame displayed, resulting in a total of 11 frames in the animation.). If the design has multiple project or intrinsic variables, click the **Design Point** tab to set the values of the non-animated variables.
5. Click the **Design Point** tab.
6. Deselect the **Use defaults** check box.
7. In the table, select the row corresponding to the variable setting of interest.
8. Click **OK** and the animation begins in the view window. The play panel appears in the upper-left corner of the desktop, enabling you to stop, restart, and control the speed and sequence of the frames.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Creating Frequency Animations

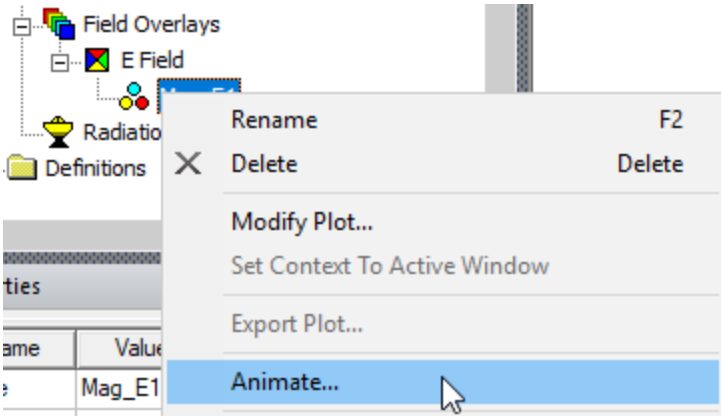
1. In order to create Frequency animations, you must define the frequencies of interest in the Solution setup, using the Multi-Frequencies option.



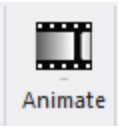
2. After running the analysis, Create a field overlay plot to animate.
3. Do one of the following:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

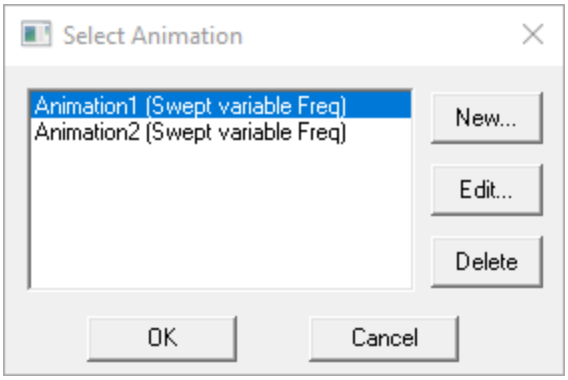
- Click **HFSS>Fields>Animate** .
- Right-click the field overlay plot of interest and click **Animate...** from the shortcut menu.



- Select the field overlay plot of interest, select the **View** tab of the ribbon, and click the Animate icon.

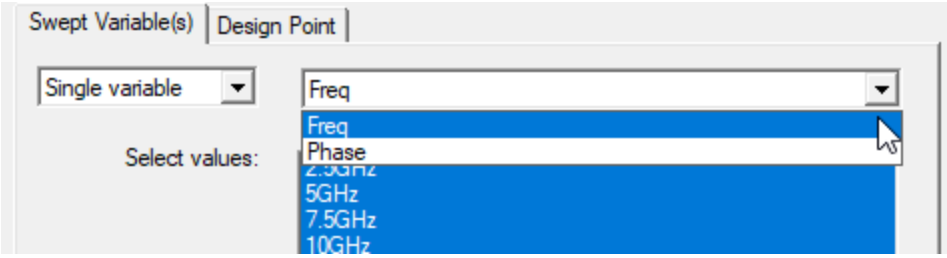


4. If you already created an animation, the **Select Animation** dialog box appears



Selecting an existing animation from that list starts it when you click **OK**. Click **Edit...** to open the **Modify Animation Setup** dialog. To create a new animation, click **New** and the **Create Animation Setup** dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

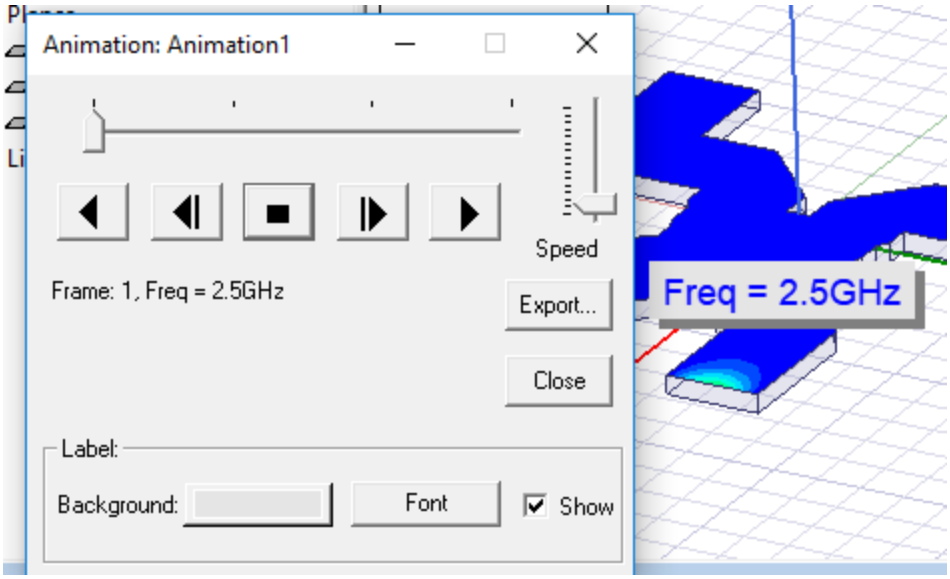


5. Under the **Swept Variable** tab, select **Frequency** from the **Swept Variable** list.
6. Select the frequency values you want to include in the animation from the **Select values** list.

   Use the **Shift** key to select a series of values, and the **Ctrl** key to select values that are not in sequence.
7. If the design has multiple project or intrinsic variables, click the **Design Point** tab to set the values of the non-animated variables.
8. Click the **Design Point** tab.
9. Deselect the **Use defaults** check box. In the table, select the row corresponding to the variable setting of interest.
10. Click **OK** and the animation begins in the view window. It will display one frame for each frequency value you selected. The play panel appears in the upper-left corner of the

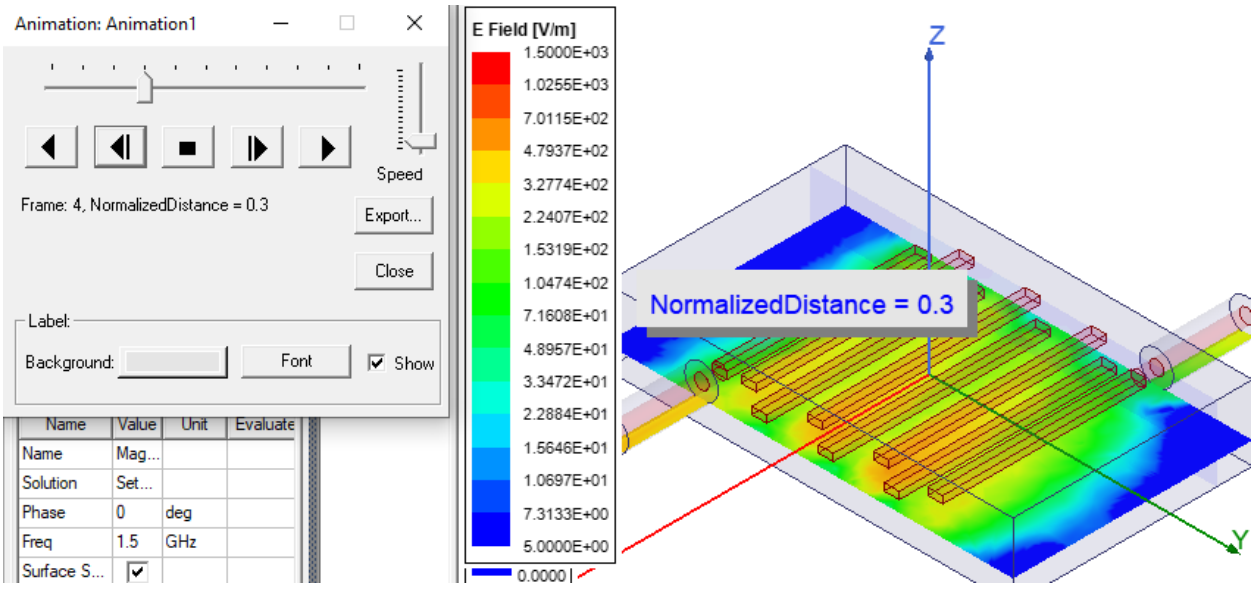
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

desktop, enabling you to stop, restart, and control the speed and sequence of the frames.



Creating Normalized Distance Animations

Before creating a normalized distance animation, you must solve a frequency sweep for the project. You can select Normalized Distance in the **Create Animation Setup** dialog box. This will show slices of the project relative to the plane or surface on which you have created the field plot.

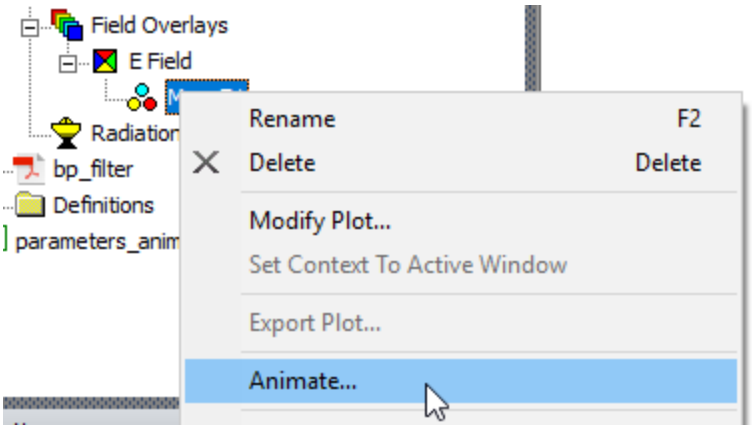


To animate a plot with respect to the normalized distance of steps through of the plotted field:

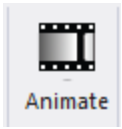
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Create a field overlay plot to animate.
2. Select the plot in the **Project** tree, and click **HFSS>Fields>Animate...**, or right-click in the **Modeler** window, and click **View>Animate...**.

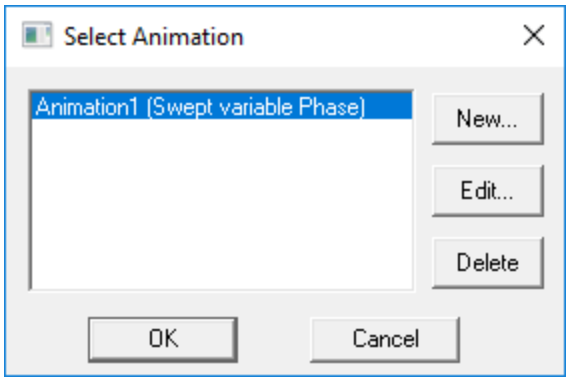
Or right-click the field overlay plot of interest and click **Animate...** from the shortcut menu,



Or select the field overlay plot of interest, select the **View** tab of the ribbon, and click the **Animate** icon.



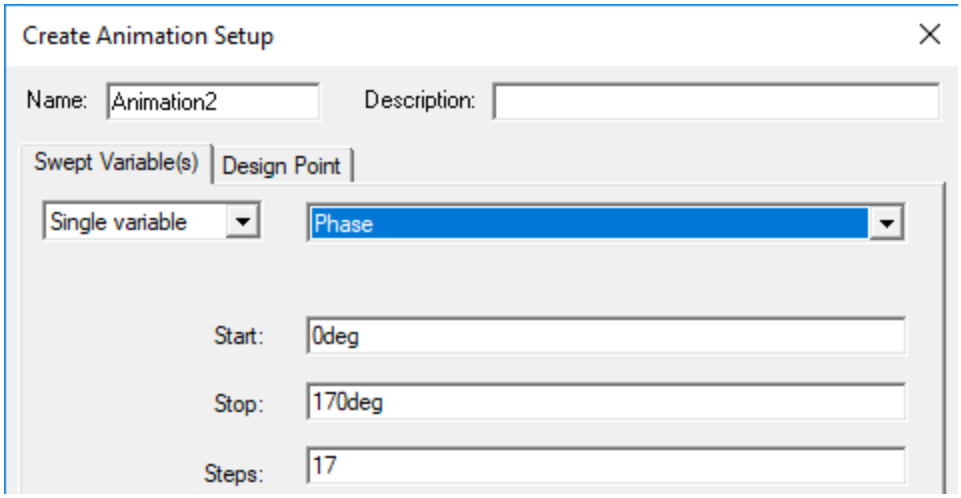
If you already created an animation, the **Select Animation** dialog box appears. Selecting an existing animation from that list starts it.



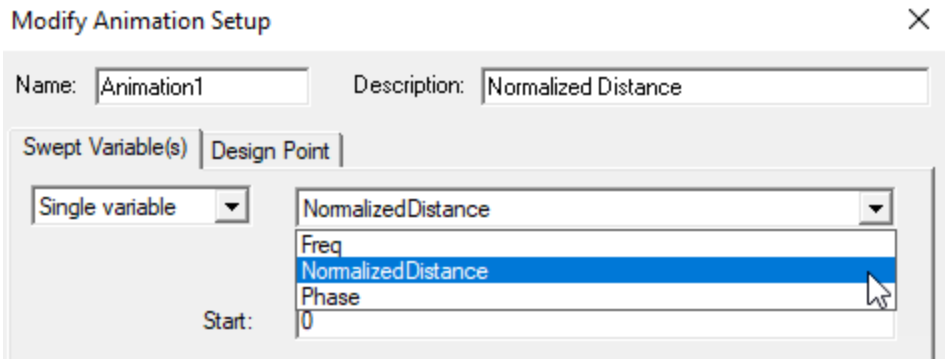
Selecting an existing animation from that list starts it when you click **OK**. Click **Edit...** to open the **Modify Animation Setup** dialog.To create a new animation, click **New**.

The **Create Animation Setup** dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5. Under the **Swept Variable** tab, select **Single Variable** and Select Normalized Distance from the drop-down menu.



6. Specify the Start, Stop, and Steps.

   For example, if the **Start** value is **0**, the **Stop** value is **10**, and the number of steps is **10**, the animation will display the plot at 10 normalized steps between 1 and 10. The start value will be the first frame displayed, resulting in a total of 11 frames in the animation.

If the design has multiple project or intrinsic variables, click the **Design Point** tab to set the values of the non-animated variables.

a. Click the **Design Point** tab.
b. Deselect the **Use defaults** check box.

   In the table, select the row corresponding to the variable setting of interest.

7. Click **OK**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The animation begins in the view window. The play panel appears, enabling you to stop, restart, and control the speed and sequence of the frames.

Creating Geometry Animations

You can create geometry animations to evaluate the effect of varying geometry variables on the model. You can also create more complex animations by creating time variables associated with object locations. This section describes the general procedure for geometry animation, and shows a geometry animation with a field overlay, and a second animation for an HFSS Antenna Example project that includes multiple objects moving with respect to a time variable.

Prerequisites

You must define at least one variable associated with the geometry before you create a geometry animation.

If you want to overlay a Field Solution on a geometry animation you must have solved fields for an Optimetrics setup using the same variable.

Procedure:

Following is the general procedure for creating an animation that varies a part of the model geometry.

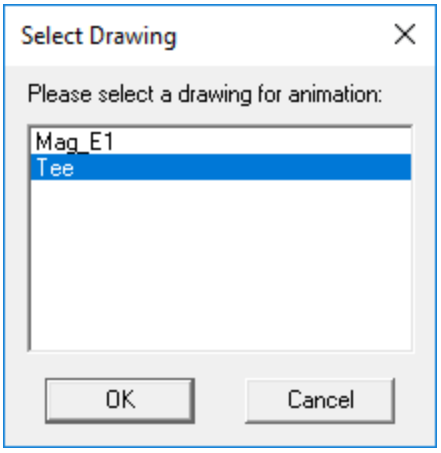
1. Right-click in the *Modeler* window, and click to **View** > **Animate...** or

   Select the **View** tab of the ribbon, and click the **Animate** icon.

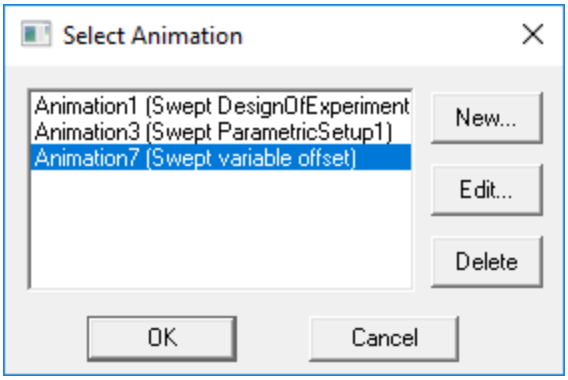
   
   If multiple geometries can be varied in the design, the *Select Drawing* dialog box appears; proceed to step 2. If only one geometry is variable, proceed to step 3.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the *Select Drawing* dialog box, select the object that you want to animate.

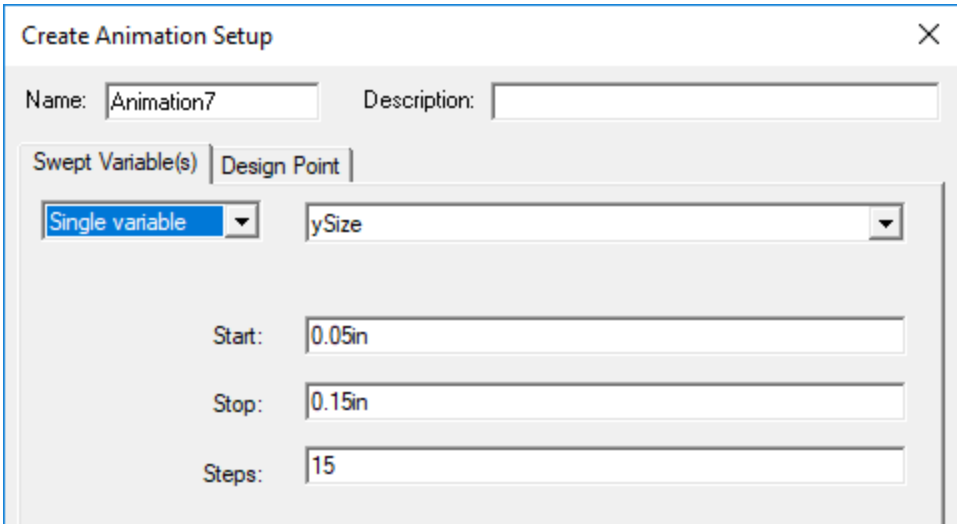


If previous animations have been created for this project, the *Select Animation* dialog box will appear. Selecting an existing animation from that list starts it when you click **OK**. Click **Edit...** to open the *Modify Animation Setup* dialog box. You may choose an animation setup from the list if one is associated with the geometry variable of interest, and the animation will start. If no existing animation setup is acceptable, select **New** and continue at Step 3 below.

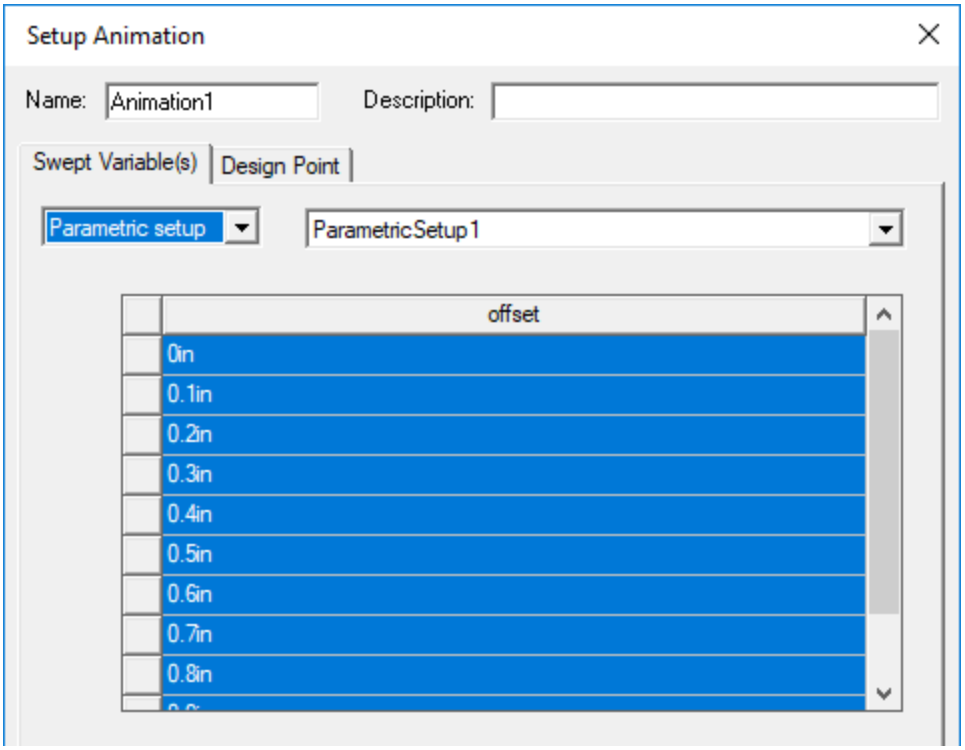


The *Create Animation Setup* dialog box appears:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. For single variable:
   a. Select the geometry variable that you want to animate from the **Swept Variable** list.
   b. Specify the Start, Stop, and Steps values to include in the animation.
4. If your have created one or more Parametric Sweeps for one or more geometric variable, you can select, **Parametric setup**, the setup to use, and the variable values to animate.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. If you have created a **Design of Experiments** setup, you can select to define an animation based on that setup and values.
6. If the design has multiple project or intrinsic variables, you use the **Design Point** tab to set the values of the non-animated variables.
7. Click **OK**.

   The animation begins in the view window. It will display one frame for each variable value.

Creating Parametric Animations

Parametric animations can be based on parametric sweeps. Following is the general procedure for creating an animation of a plot based a parametric sweep.

Prerequisites

- For animation of a field plot/overlay plot over a geometric variable, you must define and solve at least one optimetric sweep with same variable values and Save Fields selected before you can create a parametric animation of a field solution. See Creating Geometry Animations.
- For animation of geometry and VRT plots, solving parametric setup is not required.
- Animations can be based on time variables and objects whose location is linked to the time variable. See the animated example below.

Procedure:

1. Right-click in the **Modeler** window, and click **View**> **Animate...**, or select the **View** tab of the ribbon, and click the **Animate** icon.

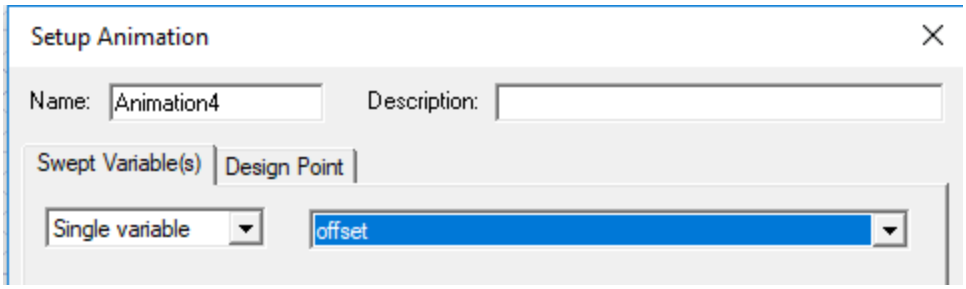
   
   If multiple geometries can be varied in the design, the *Select Drawing* dialog box appears; proceed to step 2. If only one geometry is variable, proceed to step 3.

2. In the *Select Drawing* dialog box:
   a. Select the geometry variable to vary in the animation.
   b. Select the object you want to animate.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

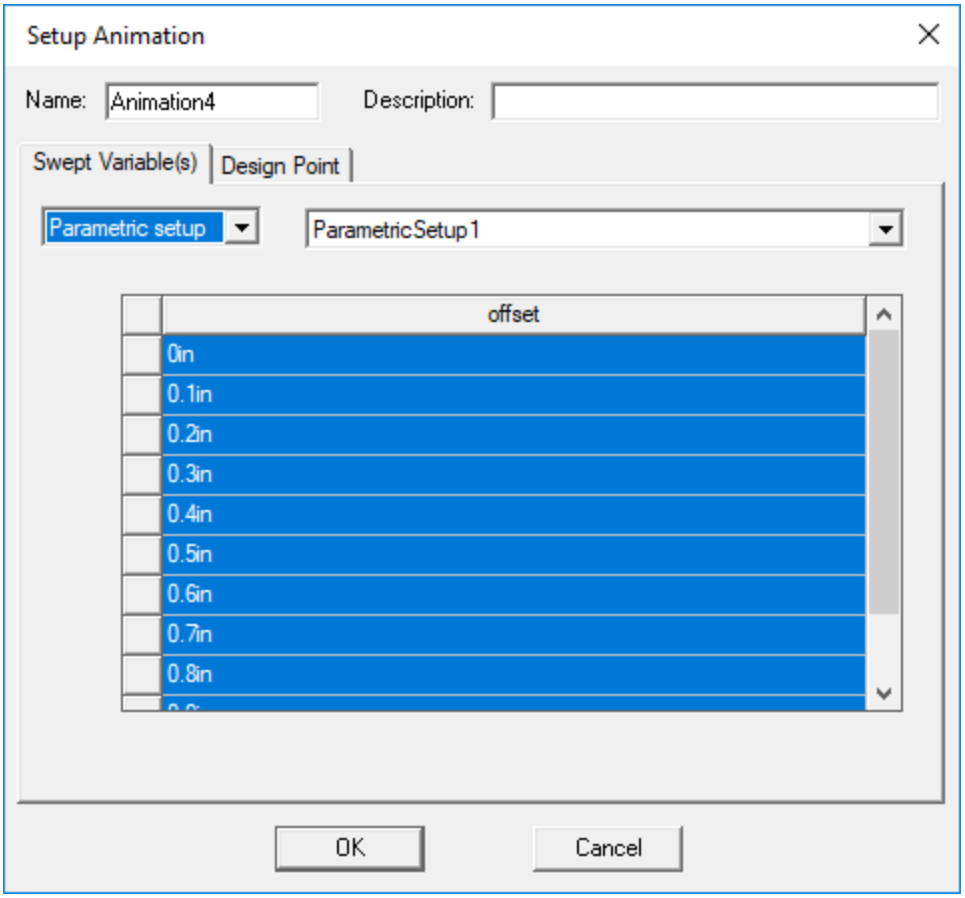
> **Note:**
>
> If previous animations have been created for this project, the *Select Animation* dialog box will appear. You may choose an animation setup from the list if one is associated with the geometry variable of interest, and the animation will start. If no existing animation setup is acceptable, select **New** and continue at Step 3 below.

The *Setup Animation* dialog box appears.



3. If your have created one or more Parametric Sweeps for one or more geometric variables, you can select **Parametric setup**, the setup to use, and the variable values to animate.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

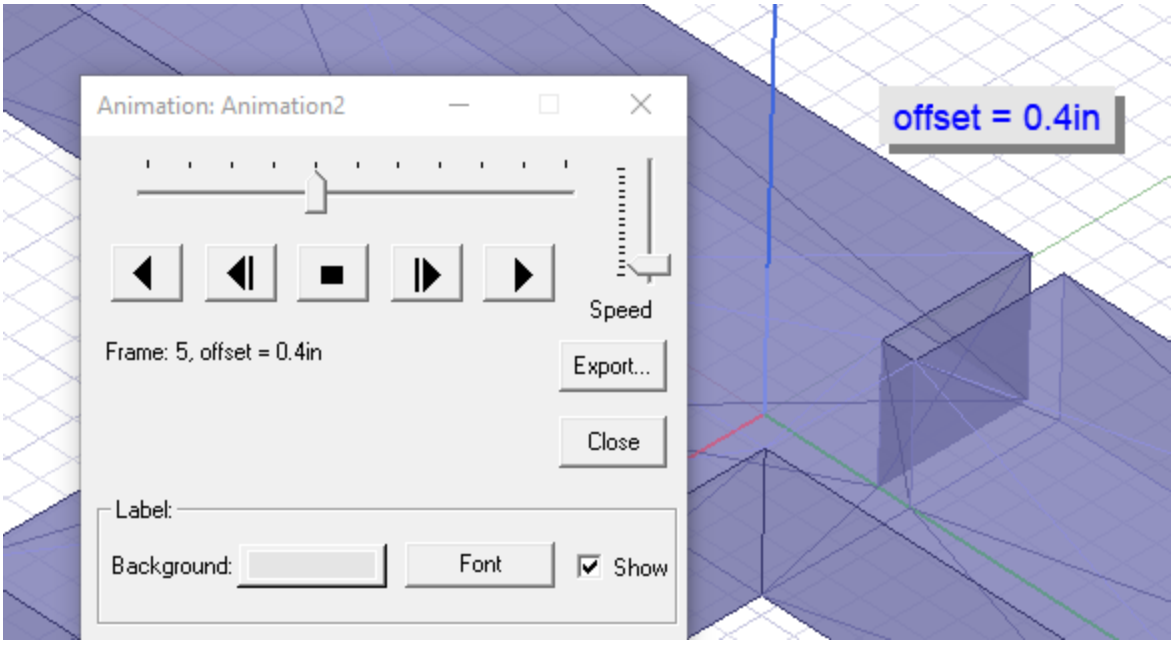


4. Click **OK**.

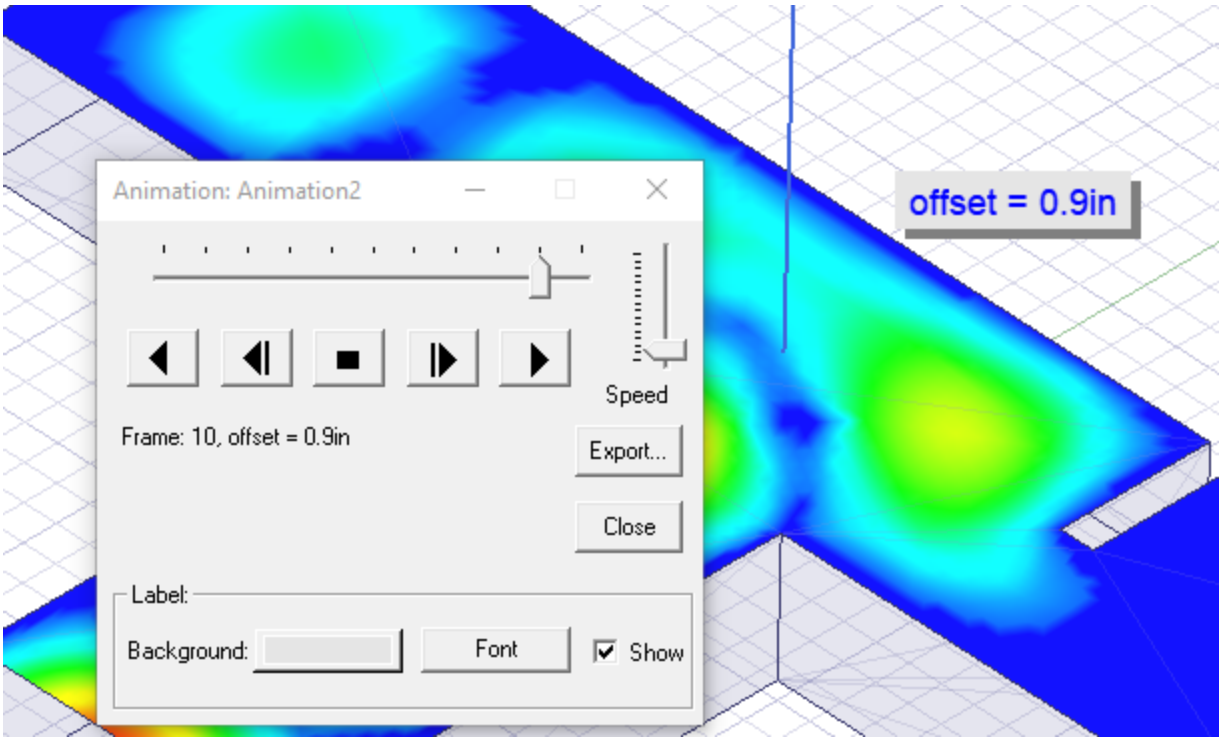
   The animation begins in the view window. It will display one frame for each variable value.

   The **Animation** control panel lets you to stop, restart, and control the speed and sequence of the frames.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



While a parametric animation is running, you can also turn on other field plots.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Creating Mesh Animations

You can create mesh animations to evaluate the effect of single variables or parametric sweep variables on the model. Following is the general procedure for creating a mesh animation that varies a part of the model geometry.

Prerequisites:

- You must define at least one variable associated with the geometry before you create a mesh animation.
- You must create a Mesh plot.

Procedure:

1. Select the Mesh plot in the Project Manager, right-click in the *Modeler* window, and click **View**> **Animate...**, or right-click the Mesh plot, and click **Animate...**

   Select the **View** tab of the ribbon, and click the **Animate** icon.

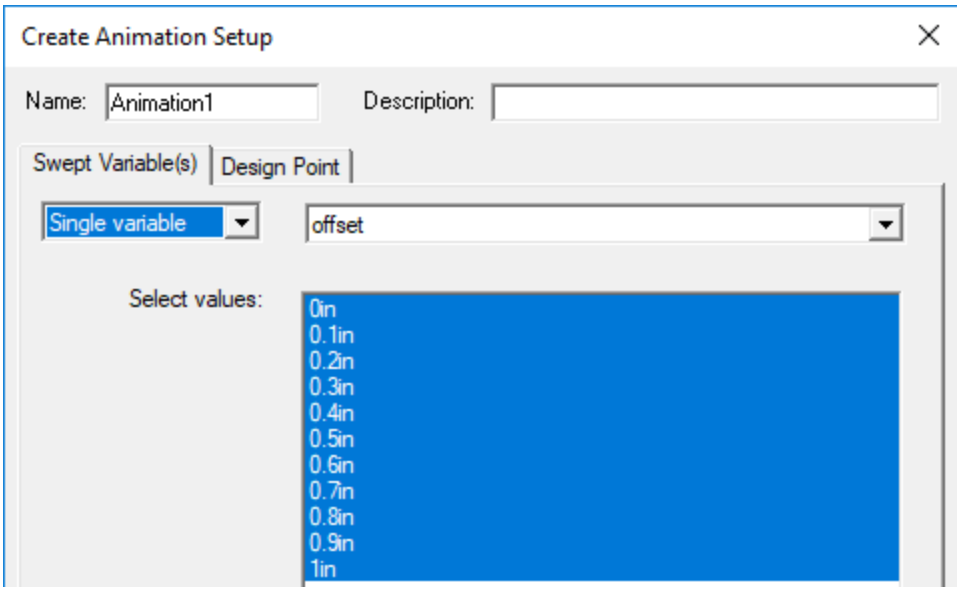
   If multiple geometries can be varied in the design, the *Select Drawing* dialog box appears; proceed to step 2. If only one geometry is variable, proceed to step 3.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the *Select Drawing* dialog box, select the object that you want to animate.

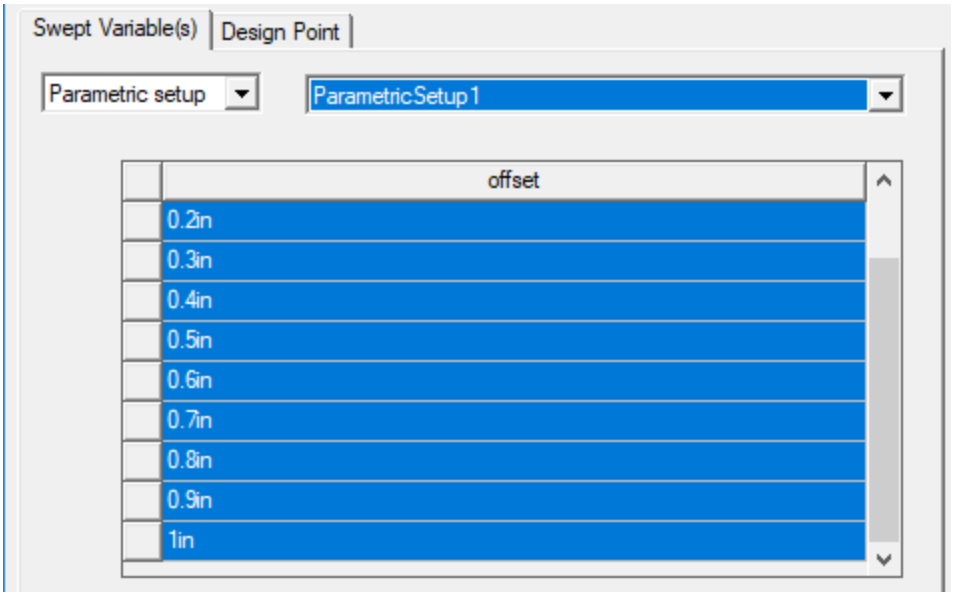
> **Note:**
>
> If previous animations have been created for this project, the *Select Animation* dialog box will appear. Selecting an existing animation from that list starts it when you click **OK**. Click **Edit...** to open the *Modify Animation Setup* dialog box. If no existing animation setup is acceptable, select **New** and continue below.

The *Create Animation Setup* dialog box appears.

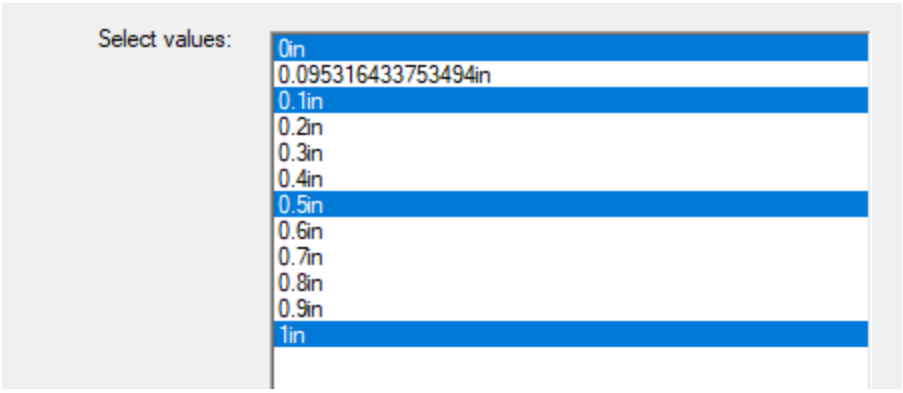


3. In the *Create Animation Setup* dialog box:
   a. Select the Single variable, or Parametric setup, or DOE setup if available. If multiple single variables are available, you can select from a drop-down menu. If one or more Parametric setups exist, you can choose from the drop-down menu. The values for the selected parametric setup are displayed.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



b. If desired, specify the values to include in the animation. Selected values are highlighted.

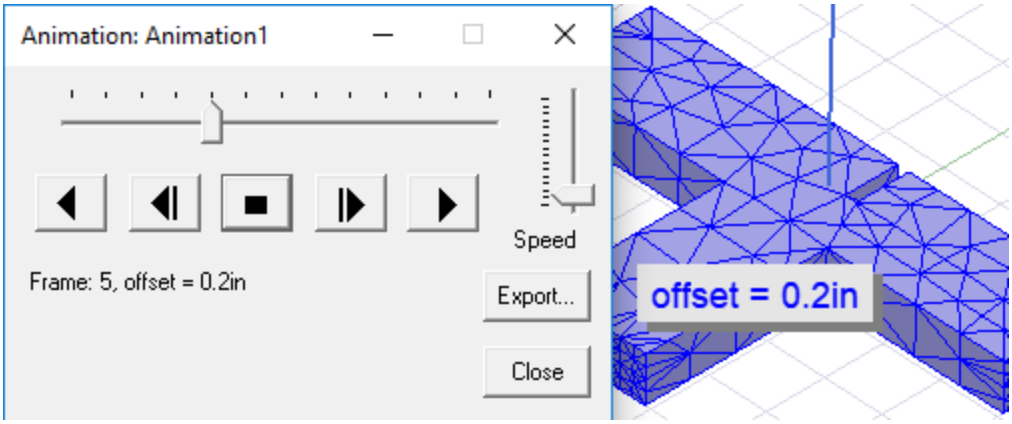


c. If the design has multiple project or intrinsic variables, you use the **Design Point** tab to set the values of the non-animated variables.

4. Click **OK**.

The animation begins in the view window. It will display one frame for each variable value.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

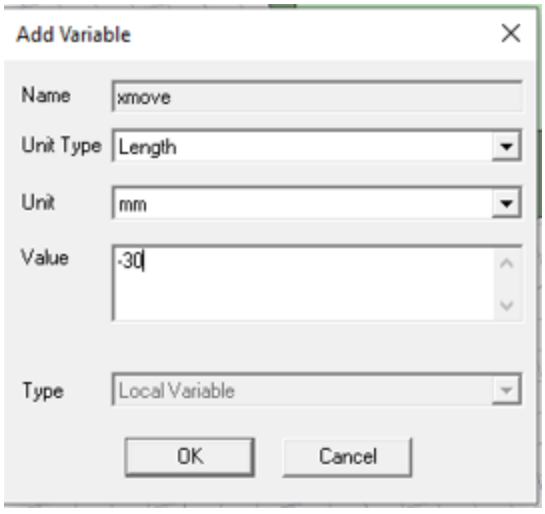


The *Animation* control panel lets you to stop, restart, and control the speed and sequence of the frames.

Animating a Sampled Near Field Plot

When a design or project variable is used to create variations of the design for use with Optimetrics (for example), we can animate the field solutions for the variations in a Sampled Near Field Plot:

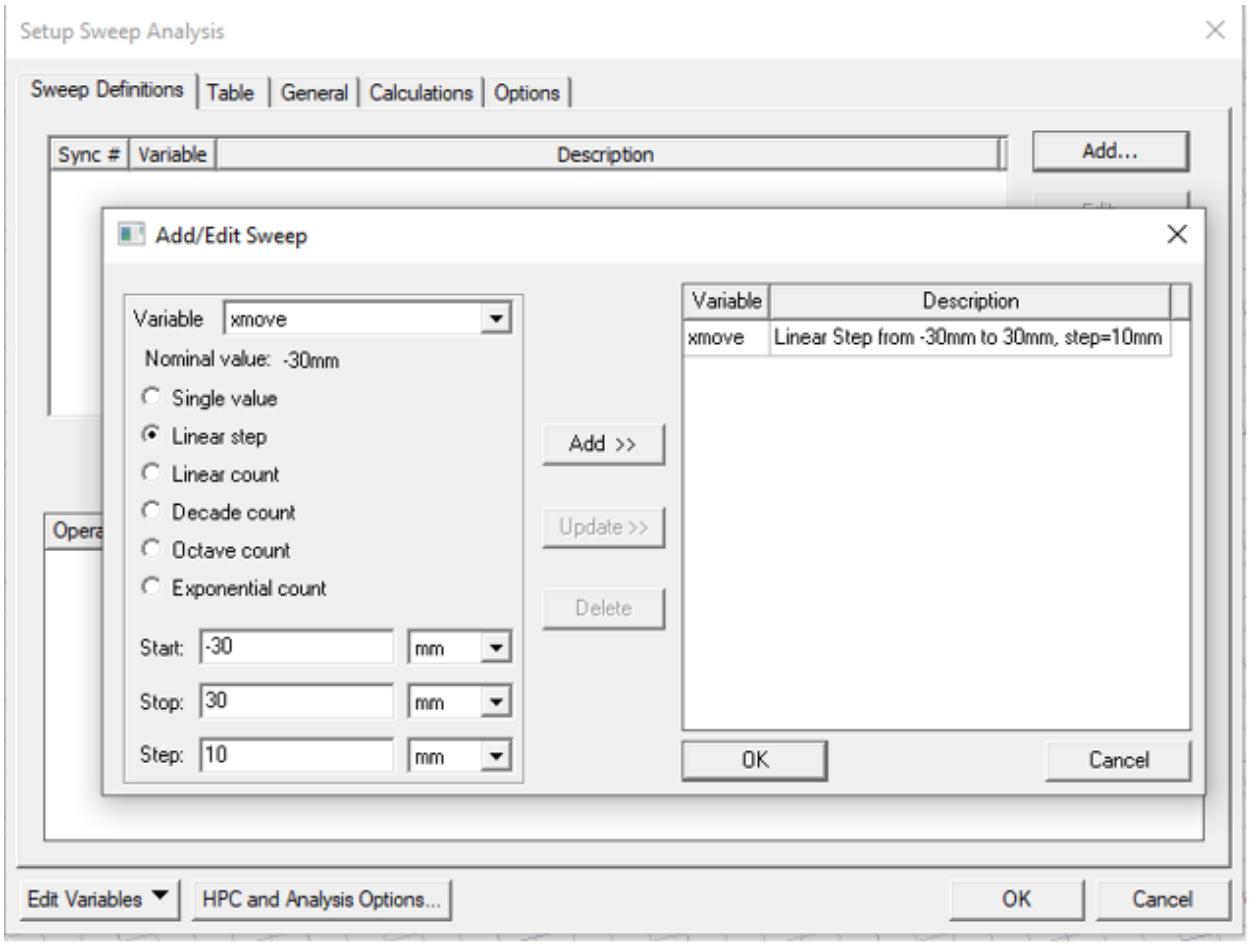
1. Create a design or project variable for the position of a geometry object in the 3D model. You can do this by performing an **Edit** > **Arrange** > **Move** operation on the object, or by creating a new Coordinate System containing the design/project variable and assigning it as the Target Coordinate System for a geometry object.



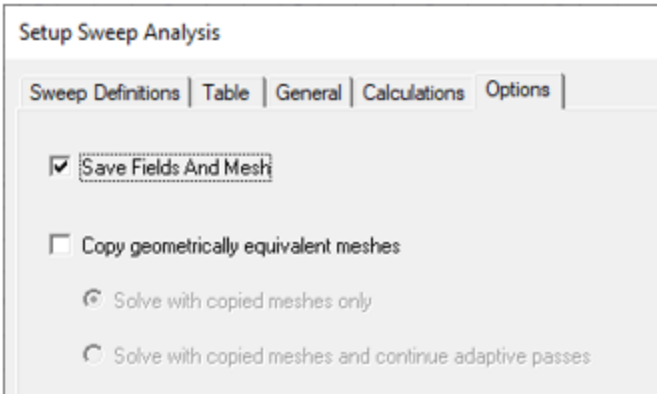
2. Then add an Optimetrics Parametric sweep setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Use the design/project variable that you created for the parametric sweep definition.

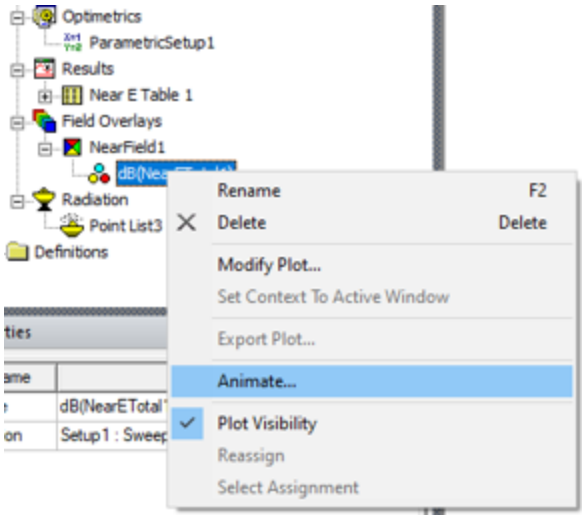


3. Check “Save Fields and Mesh” on the Options page of the sweep setup.



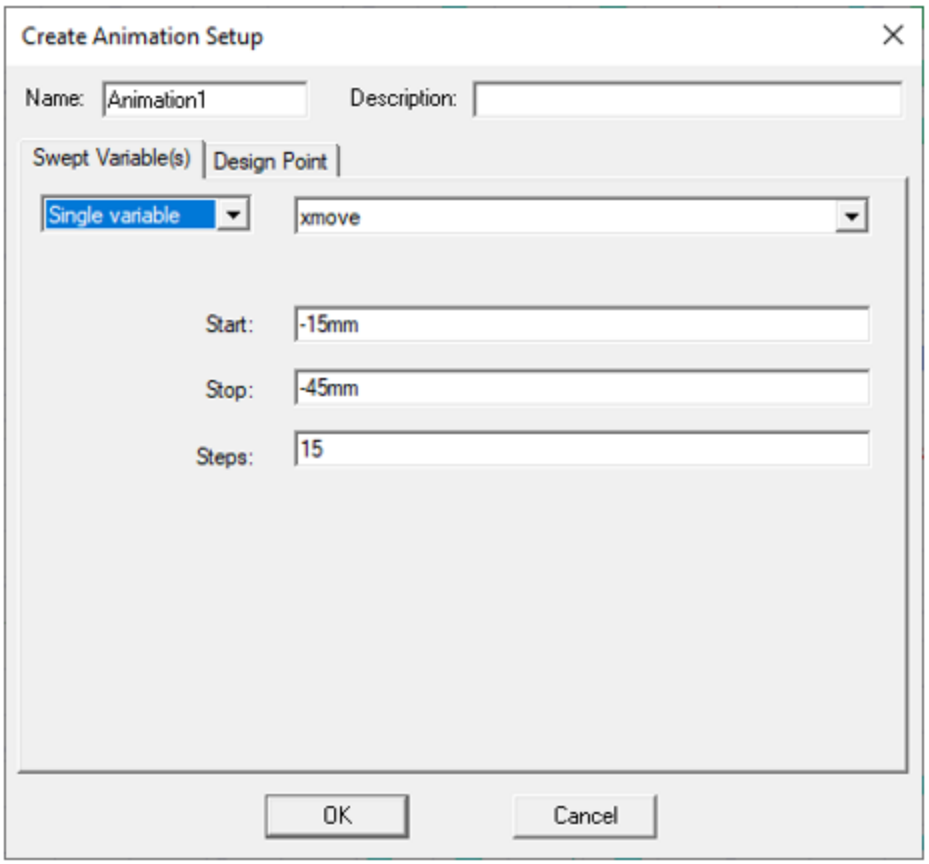
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Run the Optimetrics simulation.
5. After creating a Sampled Near Field Plot as described previously, right-click on the plot object and select **Animate...** to open the **Create Animation Setup**.



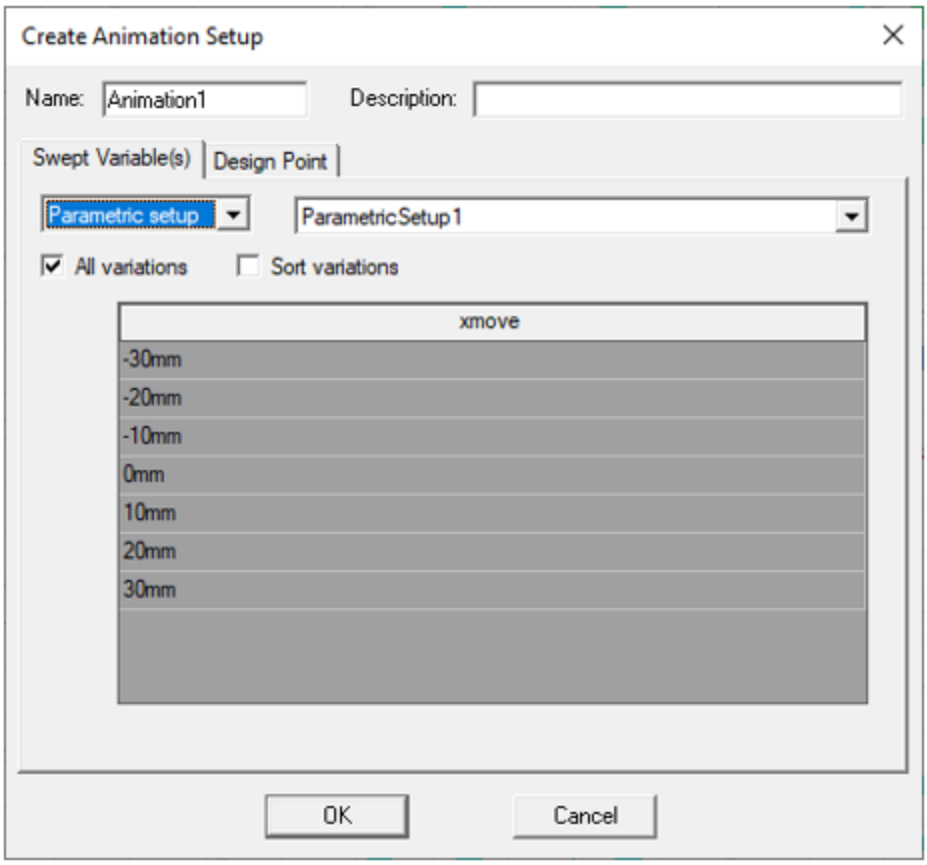
You can select the design/project variable from the list of available sweep variables and create a list of variable values to sweep for the animation. These values should be from the available simulation sweep values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



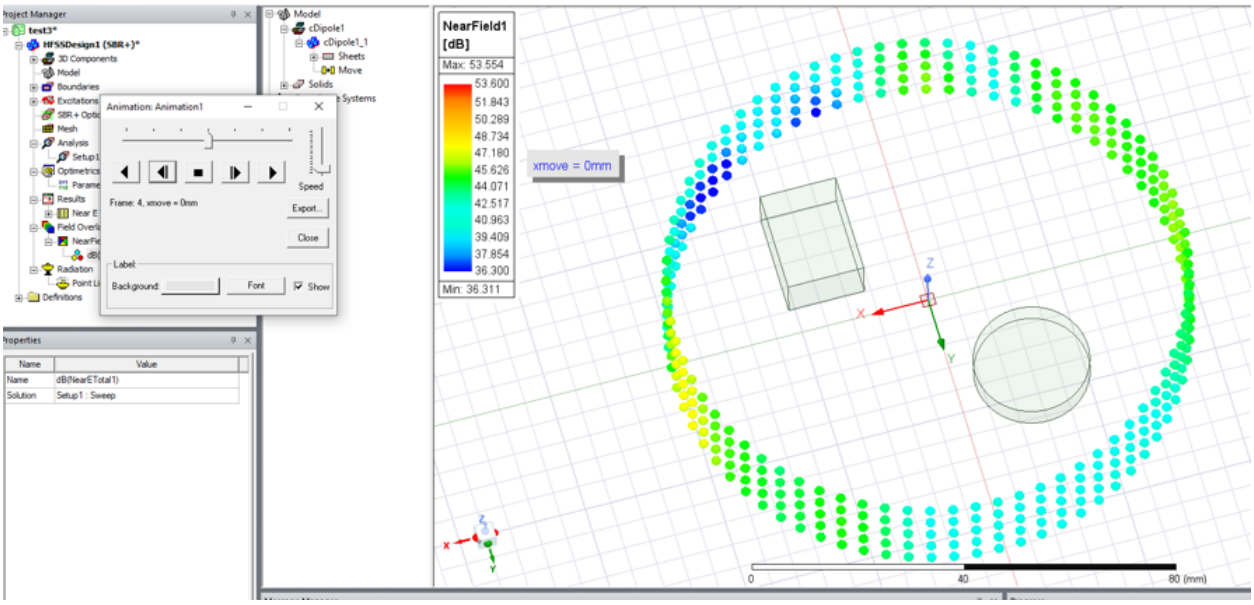
Or you can select the Parametric Setup to use the variable and all values from the specified Optimetric setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



6. Select the created animation sweep setup and click **OK** to generate the animation. The progress bar monitor updates status as all the animation frames are generated.

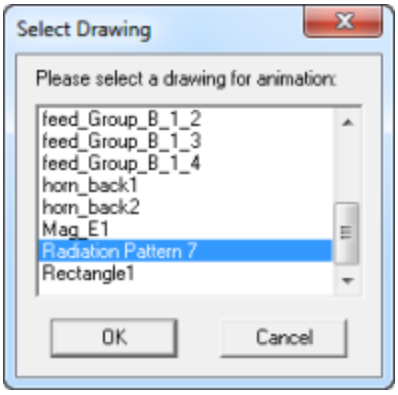
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Creating 2D Radiation Field Plot Overlay Animations

In order for a Radiation Pattern plot to be valid for overlay animation, either theta or phi must be set to a single value, so that the pattern lies in a single plane in 3D space. Note that for animation, the plot must contain at least two traces within this plane - for example traces for multiple frequencies of a discrete sweep. You create the 2D Radiation Field plot as before, but must also prepare it to be suitable for animation. See Overlaying 2D Radiation Field Plots on Models.

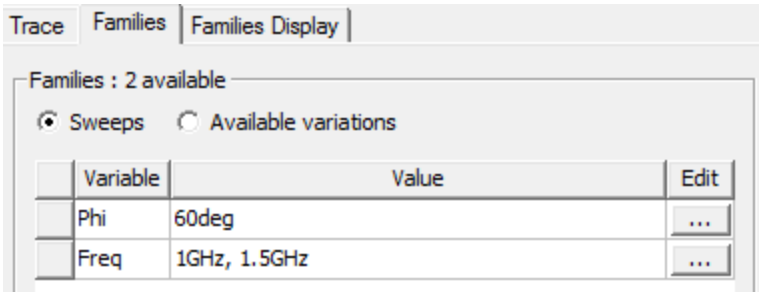
If an existing 2D Plot is a candidate for animation, you will see it listed when you click **View>Animation** to open the **Select Drawing** dialog.



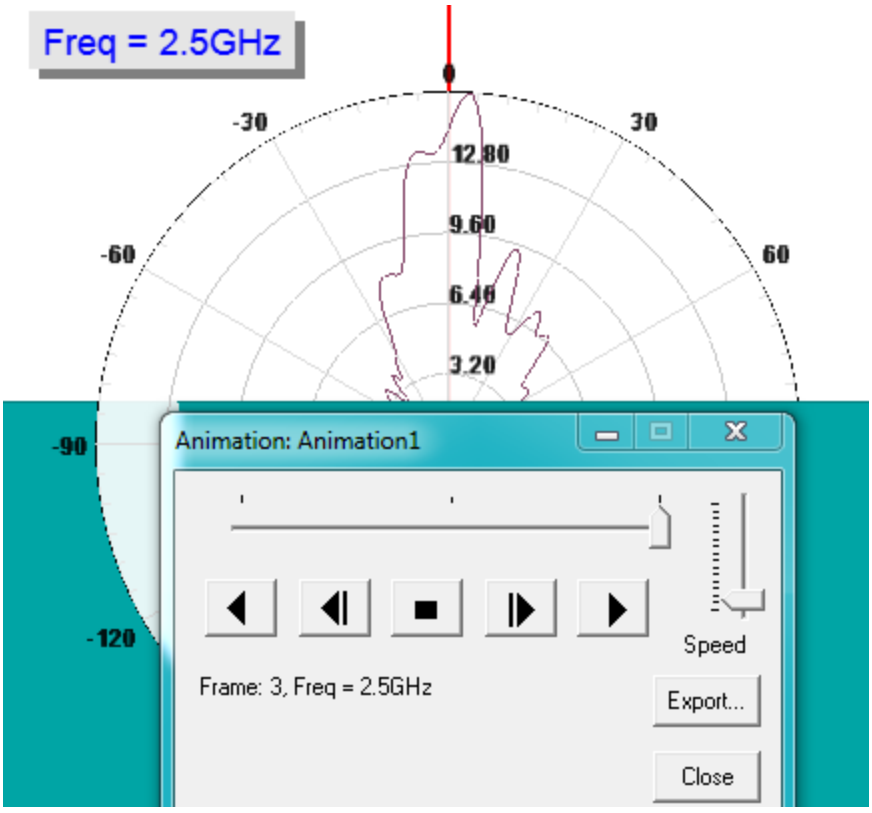
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

However, if the Radiation Pattern plot does not have at least two traces, when you try to set up the animation, you will receive a notice that you need to Modify the plot or simulation setup appropriate or create a new one.

Recall that the Context section on **Modify Plot** may let you select Setup*n*: Sweep, which will permit you to select additional frequencies. Also the Trace tab and Families tab lets you specify a single Phi and/or Theta and select multiple values for other available Variables such as frequency.



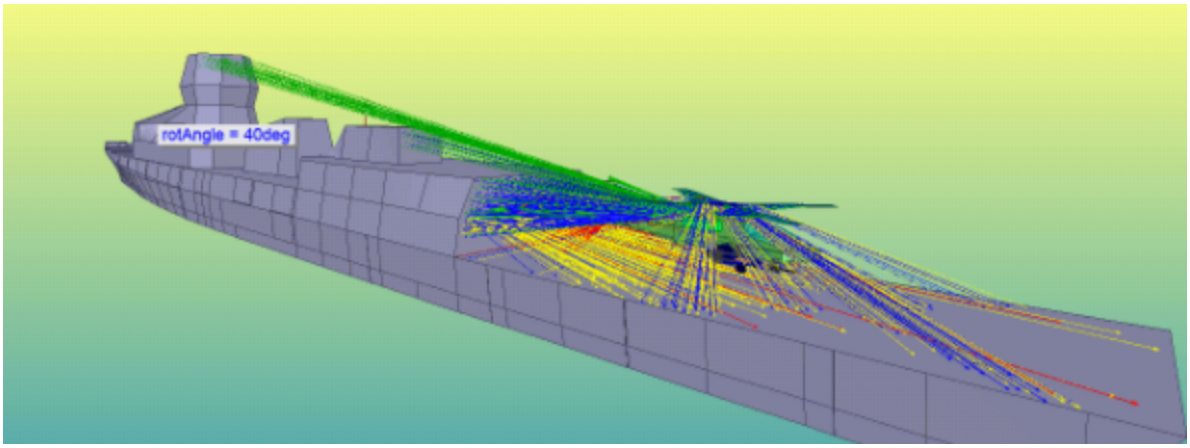
For plot with multiple traces, the animation proceeds through the existing traces.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

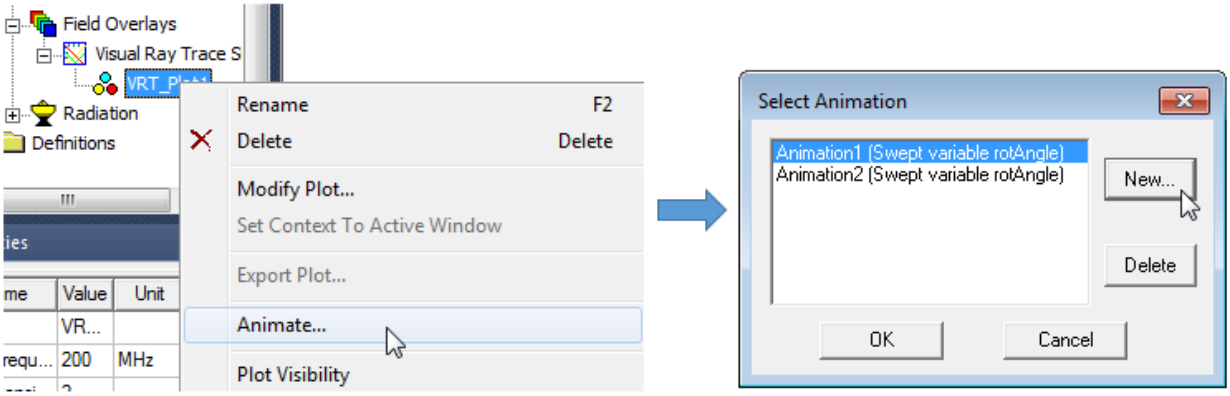
Animating VRT Plots

Visual Ray Trace (VRT) is a powerful feature available in HFSS for visualizing the ray geometry and interactions for an SBR+ simulation. VRT plot animation provides a means to dynamically explore how geometry changes or ray launch point changes affect ray generation. Compared to regular field or mesh plot animation, VRT plot animations differ in that you do not need to solve or generate a mesh before animating a VRT plot.



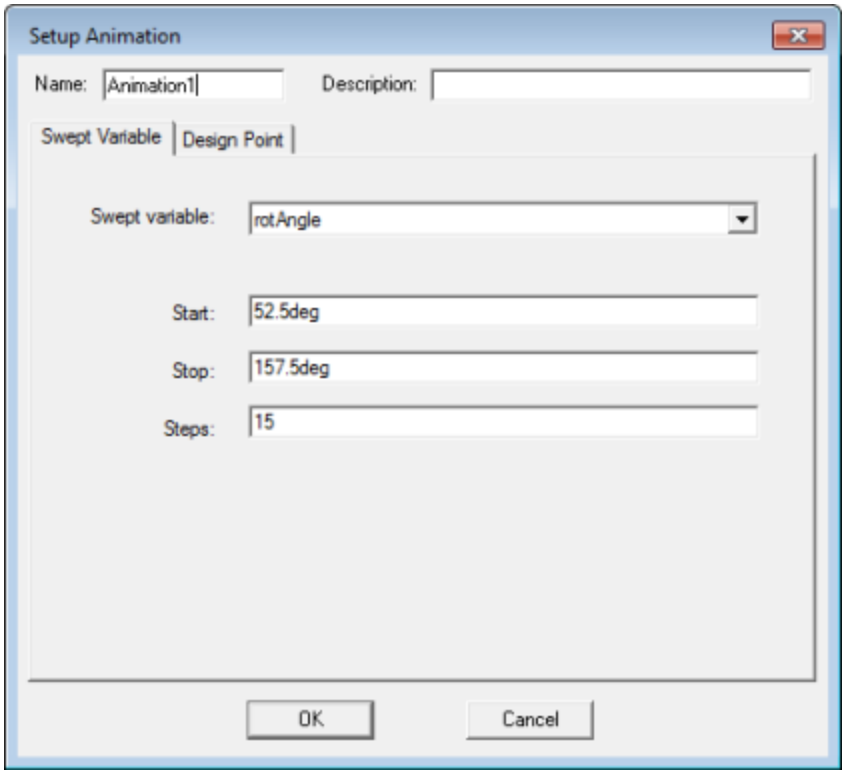
1. To create a new VRT animation, either:

- Right-click a VRT icon in the Project tree and select **Animate...** from the short-cut menu and select **New** in the **Select Animation** dialog box.
- Click **HFSS>Fields>Animate...** and select **New...** in the **Select Animation** dialog.



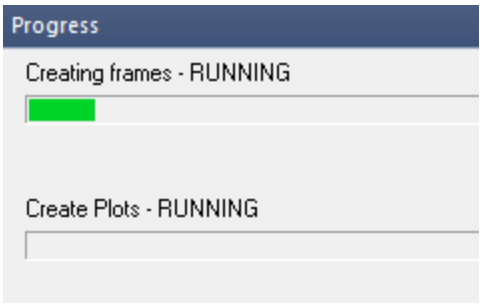
This opens the Setup Animation dialog:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



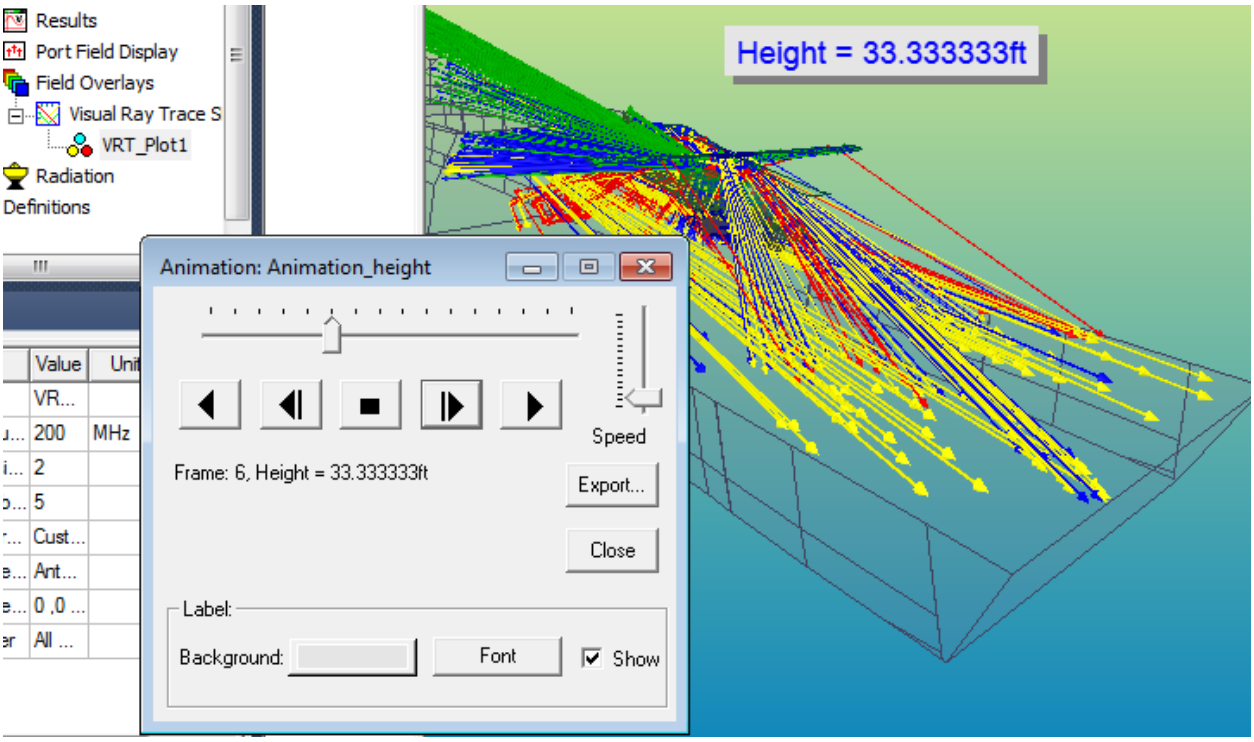
2. Select the Swept variable. If multiple swept variables are available, you can select from the drop-down menu.
3. Specify the Start, Stop and Steps for the animation.
4. The **Design Point** tab has Use defaults checked. If you uncheck it, you can see a listing of design points.
5. If desired, provide a name and description
6. Click OK to produce the animation.

You can click **Show Progress** to watch the progress bars. The arrow button on the right includes an **Abort** command.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When the animation frames have been generated and the plots completed, the animation displays in the **Modeler** window, and the **Animation** control dialog appears.



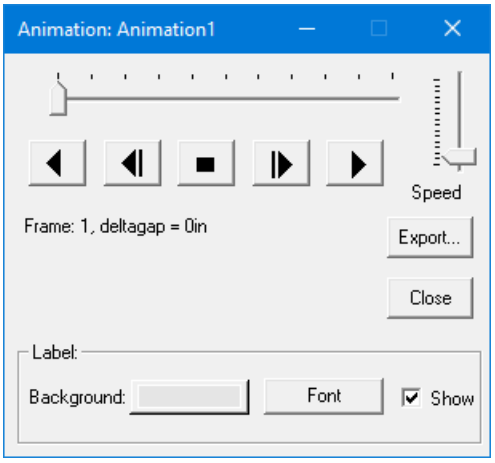
To launch an existing VRT animation, either:

- Right-click a VRT icon in the Project tree and select **Animate...** from the short-cut menu.
- Click **HFSS>Fields>Animate...** and select from any existing animations listed

Controlling the Animation's Display

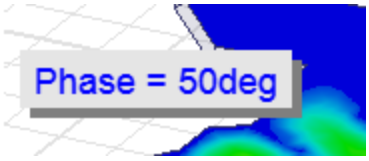
When an animation is displayed in the view window, the **Animation** window (also called the *play panel*) appears in the upper-left corner of the desktop. It has buttons that enable you to control the speed and sequence of the frames, start and stop the animation, and export the animation. Click an area of the window image below to learn its function.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



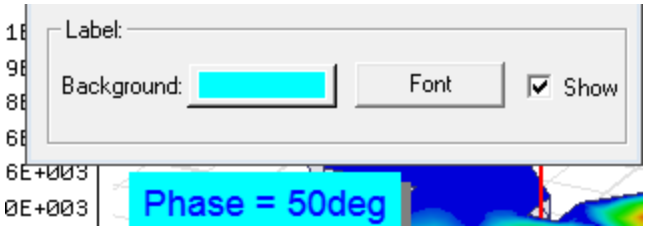
Animation slider	Each dot on the slider represents a frame in the animation. Drag the slider to the right to display the next frame in the animated plot. Drag the slider to the left to display the previous frame in the animation.
	Plays the plot's animation sequence backwards.
	Steps backward through the animated plot one frame at a time.
	Stops the animation.
	Steps forward through the animated plot one frame at a time.
	Plays the plot's animation sequence forwards.
	Drag the **Speed** slider to the top to increase the speed of the animation. Drag the **Speed** slider to the bottom to decrease its speed.
Frame information	The current frame and phase at which the plot is being displayed is listed below the control buttons.
	Enables you to export the animation to an animated Graphics Interchange Format (GIF) or to Audio Video Interleave (AVI) format.
	Closes the animation window.
Show label check box	If you select the Show check box, a label showing the swept variable value appears in the animation. You can select the label with the mouse and drag it to a location.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Background button.

Click the background button to open a color pallet dialog that lets you set the background for the swept variable label.



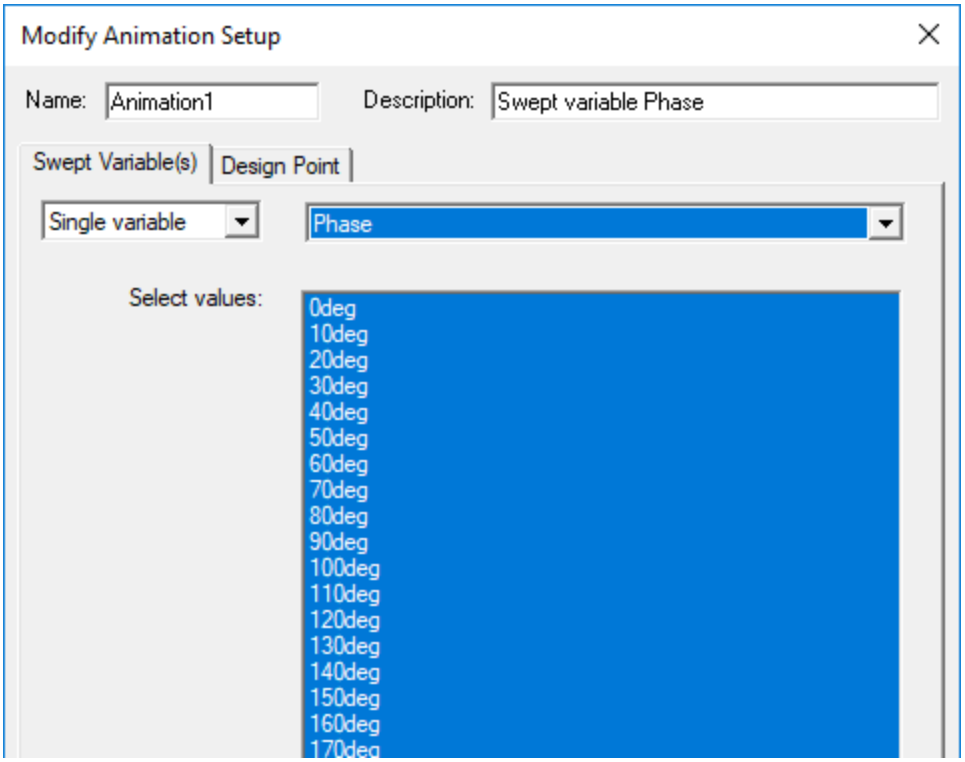
The font button opens a font selection dialog that you can use to set the Font, Font Style, and Size for the label. The Default is Arial Narrow 14pt.

Modifying an Animation Setup

The **Edit** button on the *Select Animation* dialog box opens the *Modify Animation Setup* dialog box.

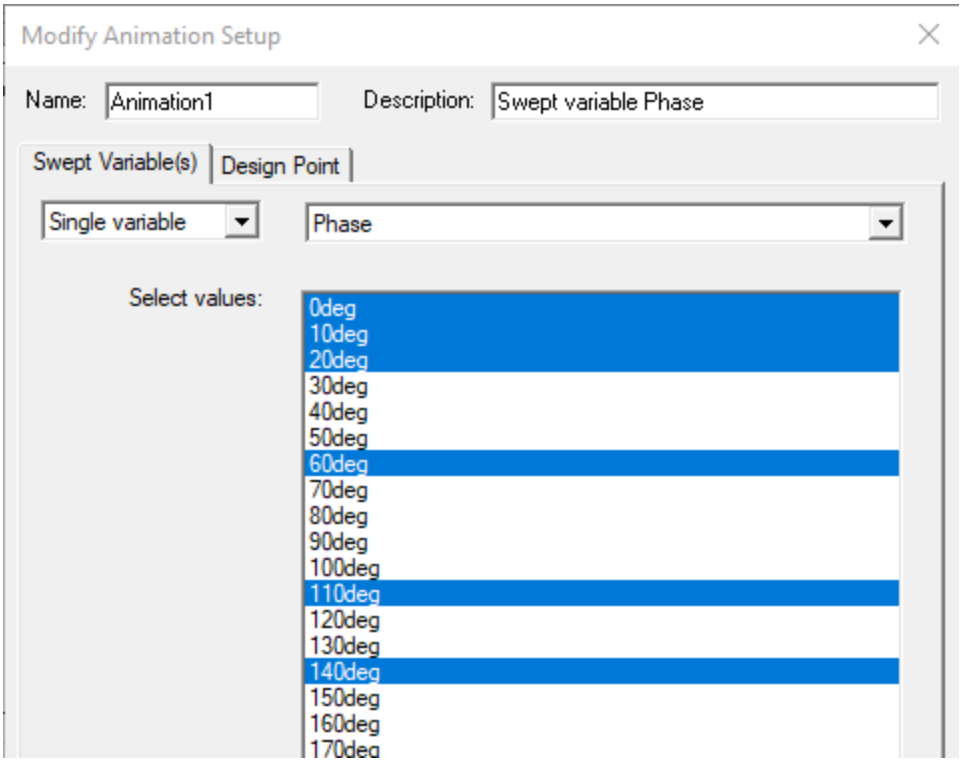
It opens showing the selections for variables and the selected values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

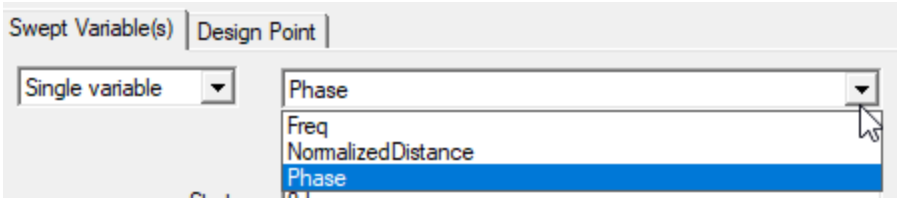


You can de-select or select any values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

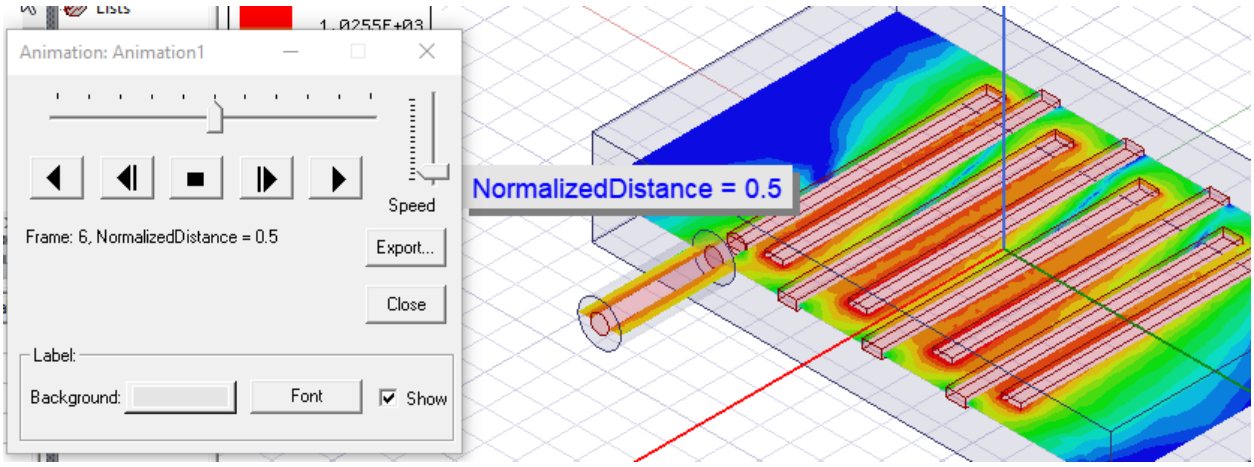


If other variables have been defined, you can select from the drop down list.

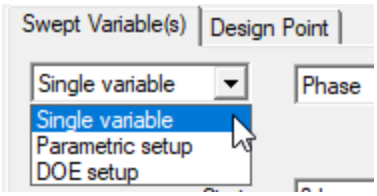


If the other variables have or can be set to appropriate values, you can modify the animation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If Parametric Setups or DOE Setups are available, you can select these.



Creating Animations

Controlling the Animation's Display

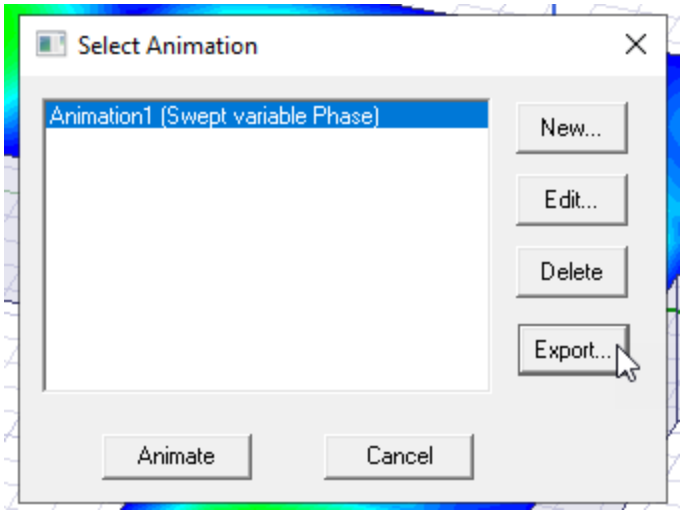
Exporting Animations

You can export animations from the **Animation** control dialog box, or, for Ensight format, from the **Select Animation** dialog box.

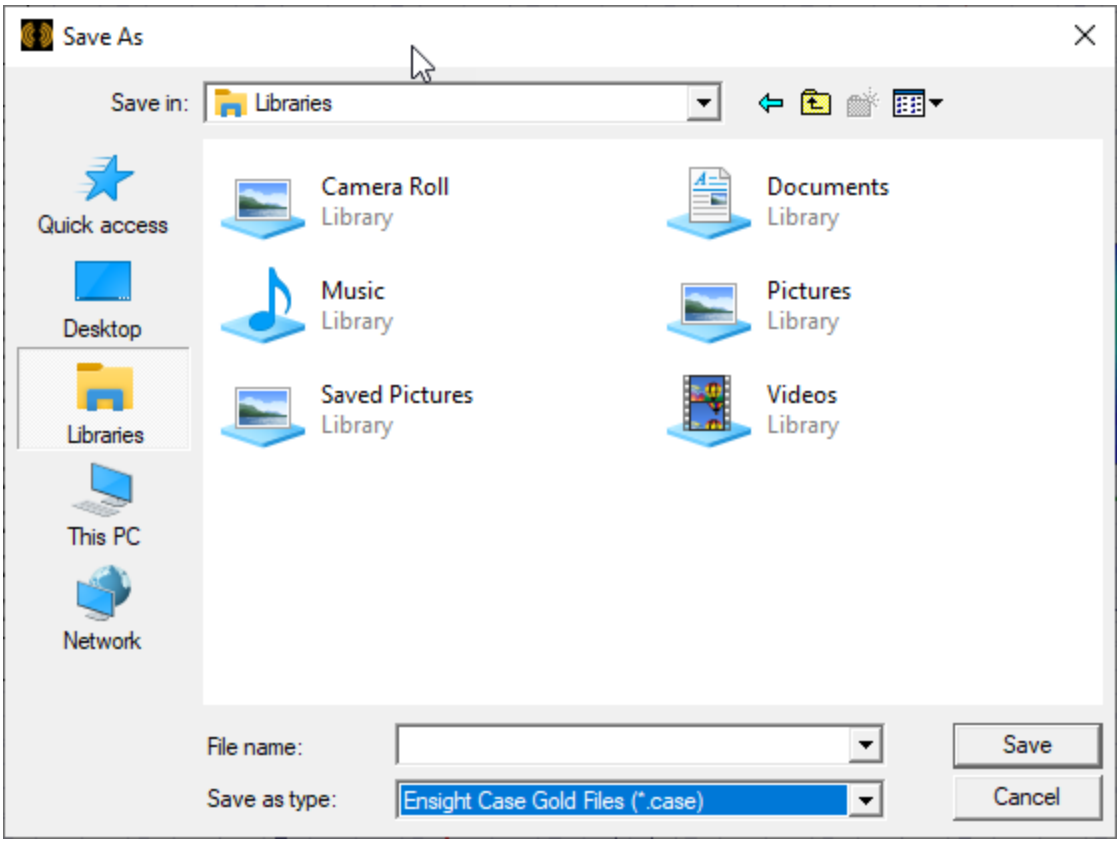
Exporting Ensight from the Select Animation Dialog Box

1. Create the animation you want to export.
2. In the **Select Animation** dialog box, select **Export...**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



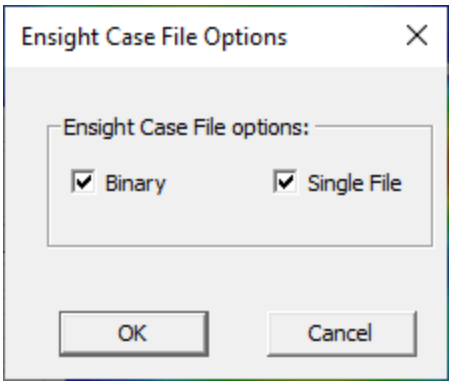
3. This opens the Browser window.



Navigate to the desired location and provide a file name. The format will be Ensight .case files.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

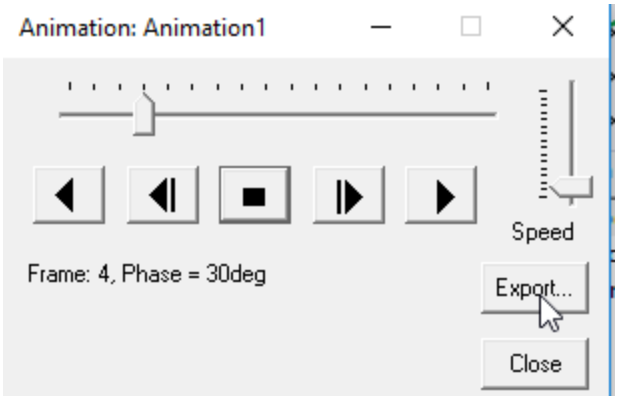
4. When you select **Save**, the **Ensight Case File Options** dialog box opens.



The binary option permits a more compact and efficient animation creation process in Ensight. The Single File options leverages the Ensight transient dataset capability to export all frames of field/geometry data to a single case file. On **OK**, every visible and animatable field plot should generate a case file with name in the format of "UserTypedName_fieldPlotName.case"

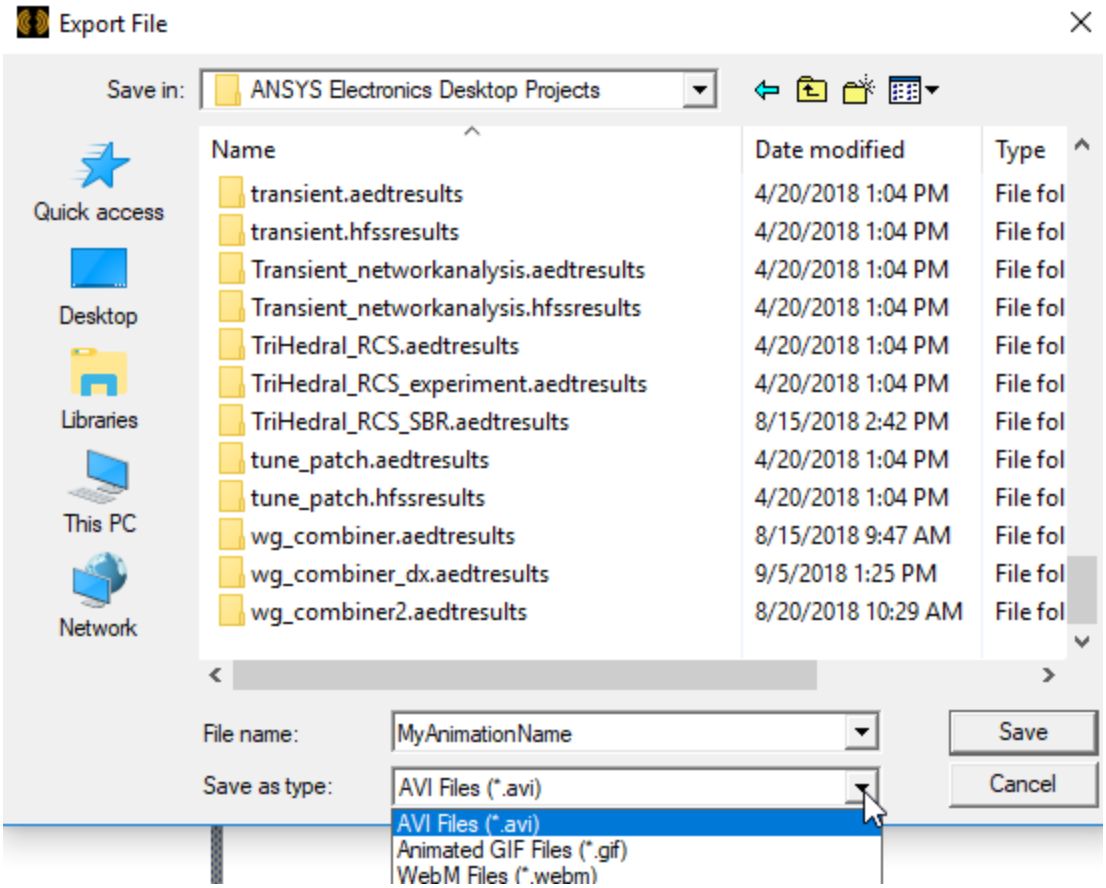
Exporting from the Animation Control Dialog Box

1. Create the animation you want to export.
2. In the play panel, click **Export...**.



The *Export File* dialog box appears.

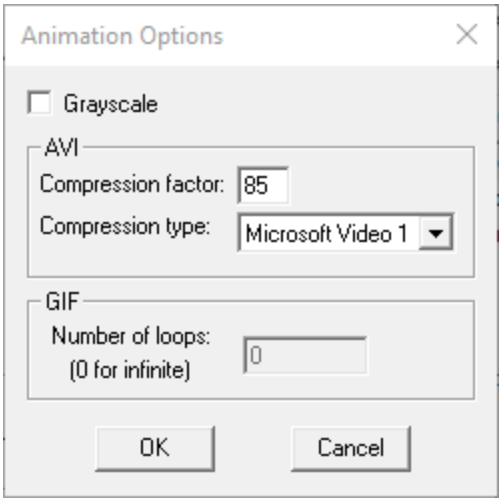
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



3. Specify the directory to **Save in**, the **File name**, and use the **Save as type** drop-down menu to select **Animated GIF File (.gif), AVI File (.avi),** or **WebM File (.webm)**.

   The *Animation Options* dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. To replace colors in the file with 256 shades of gray, select **Grayscale**.

   Grayscale animations tend to use less memory than full color animations.

5. For AVI format export, specify the **Compression factor** (the default is 85) and one of the following **Compression types**:
   - INTEL Indeo
   - Cinepak
   - Microsoft Video 1
   - None
6. For GIF format export, specify the number of loops. The default "0" denotes infinite loops.
7. Click **OK** to close the *Animation Options* dialog box.

   The animation is exported to the file format you specified.

Modifying SAR Settings

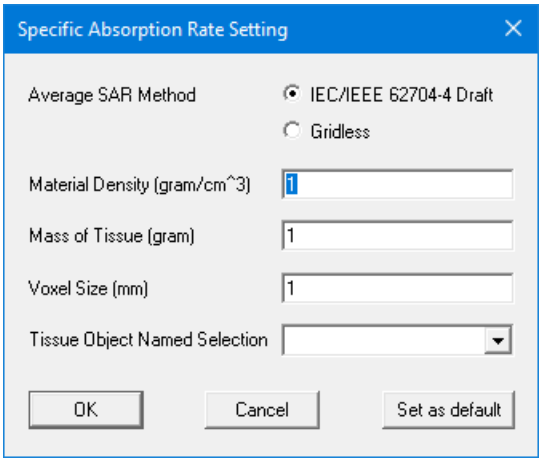
HFSS uses default specific absorption rate (SAR) settings when creating a local SAR or average SAR field overlay plot. It does use mass density for each material if defined for each material. Otherwise (that is, if the mass density for that library material is 0), the density in the **Specific Absorption Rate Setting** dialog will be used.

To change the default settings:

1. Click **HFSS** > **Fields** > **SAR Setting**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Specific Absorption Rate Setting** dialog box appears.



2. To select the Average SAR Method, select the radio buttons for IEC/IEEE 62704-4 Draft or Gridless, which is the legacy Average SAR algorithm. Selecting Gridless disables the Voxel Size and Tissue Object Named Selection fields.
3. In the **Material Density** text box, enter the mass density of the dielectric material in g/cm^3. This provides a default mass density if not specified in the material definition.
4. In the **Mass of Tissue** text box, enter the mass of the material in grams that surrounds each mesh point. The standard values are 1 and 10, corresponding to US or European standards; however, for research purposes you can enter values outside this range.
5. In the **Voxel Size** field, specify a size. The units are millimeters.

The voxelization process takes all elements as rectilinear. So it is better to solve projects with curvilinear off. See Specifying Initial Mesh Settings.

Since the number of voxels depends on the size of the model and the size of the voxel you can expect that computational complexity increases in $O(n^3)$ or more as the model size increases and the voxel size decreases. Below are a few suggestion:

- For large models you can set up an average SAR plot before you solve so that the data from the first phase could be generated at solve time. With the tissue setting you can also perform SAR calculation over partial model.
- Set the solver order to 1 for best performance.
- The algorithm takes full advantage of multi-cores. Set the number of processors to use in the desktop performance tab in **General Options**. If your machine is hyper threaded, you should only use half the number of cores.

6. If the Tissue Object Named Selection field is empty, all conductors are treated as tissues. It is recommended that you create an object selection explicitly to be used as tissue objects. This is to ensure that you have considered which objects should be included in the SAR calculation. You can create object selections for the menu by selecting objects

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

and clicking, **Modeler** > **Named Selection** > **Create** > **Object Selection**. (See Creating an Object Selection.) After saving the Project, you can then select from available object selections. All objects in the active selection are treated as tissues.

7. Click **OK**.

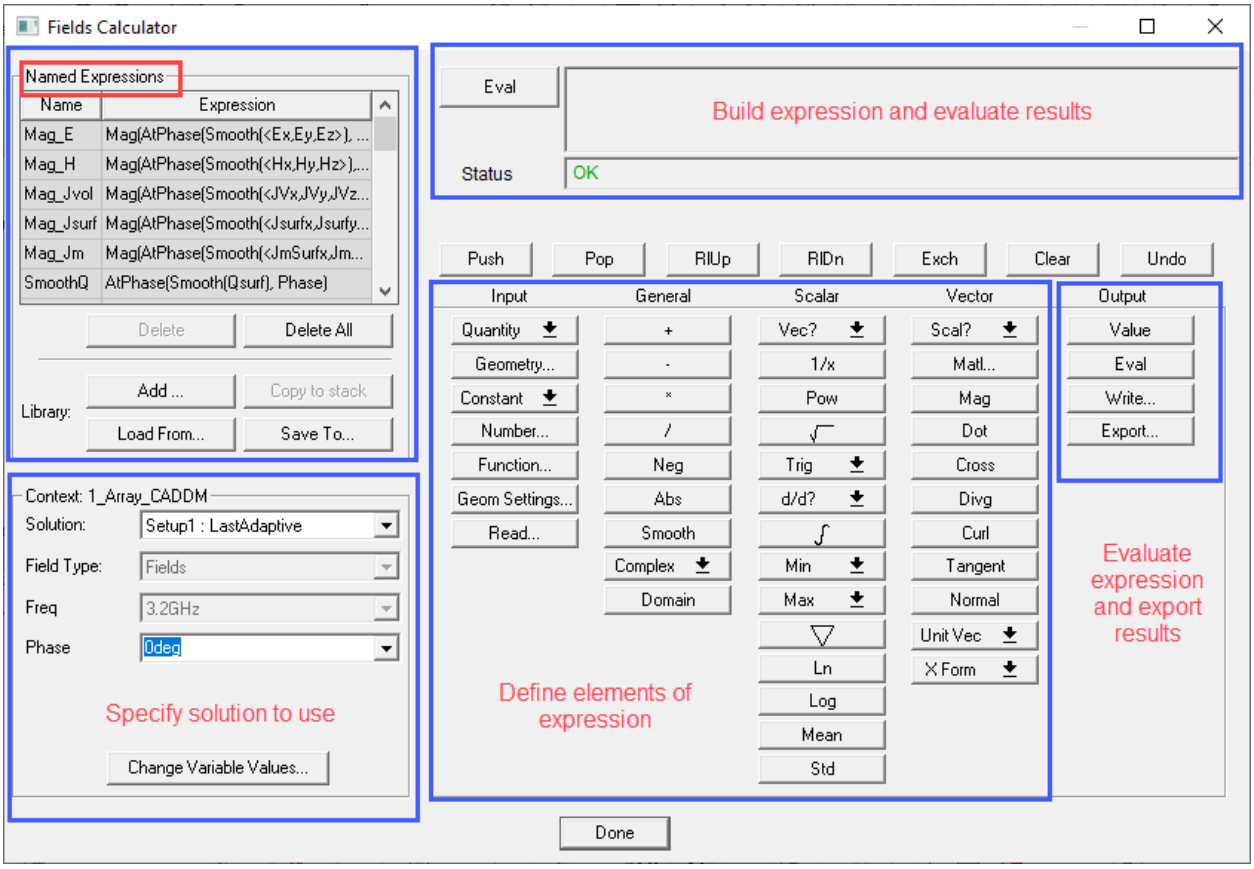
Using the Fields Calculator

The Fields Calculator is a very powerful tool for postprocessing. It is available for HFSS, Maxwell, Q3D, Icepak, and Mechanical solutions. While standard postprocessed results (such as S-parameters, Y or Z matrix, animated field plots, and near and far field patterns) serve most simulation requirements, the Fields Calculator enables you to perform further computations using basic field quantities. The calculator computes derived quantities from the general electric, thermal, or displacement field solution; writes field quantities to files; locates maximum and minimum field values; and performs other operations on the field solution. Using this calculator, you can perform mathematical operations on all saved field data in the modeled geometry at a single frequency. The resulting quantities can be plotted, tabulated, or exported.

The Fields Calculator includes predefined expressions appropriate for each solver and lets you create and save additional named expressions.

To view information on a command or screen area, click over the button or screen area on the illustration below.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



At the top-left corner of the calculator is a list of **Named Expressions**, which are standard or user-defined field quantities that are accessible from outside of the calculator. They can be added, copied to stack, saved to, or loaded from a library file using the buttons right beneath the list.

At the lower-left corner of the calculator is the **Solution Context** section, in which you can select the desired solutions, field types, frequency, and phase for the current session.

The top right of the calculator contains the **Data Stack**, in which calculator entries are held in stack registers. The data type in the Data Stack is denoted by its prefix abbreviation.

Immediately beneath the stack is the row of **Stack Command** buttons that define some basic operations for the data in the Data Stack.

The bottom half of the calculator holds the columns containing the actual calculator buttons, organized into columns, classifying them by the type of operation and the type of data upon which the operation can be performed. These columns are headed Input, General, Scalar, Vector, and Output.

At the very bottom of the calculator is the button to exit, **Done**. The Fields Calculator interface is discussed in detail in subsequent sections.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The calculator does not perform the computations until a value is needed or is forced for a result. This makes it more efficient, saving computing resources and time; you can do all the calculations without regard to data storage of all the calculated points of the field. It is generally easier to do all the calculations first, then plot the results.

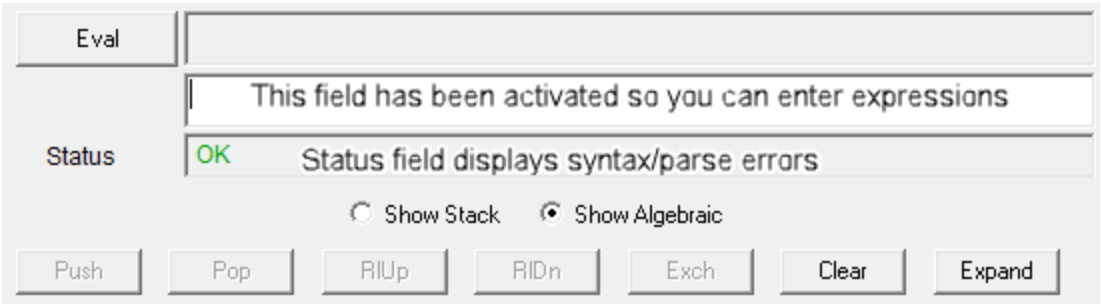
The help for the Fields Calculator includes a "Cookbook" section that provides step-by-step examples of the following operations:

- Calculating Numerical Quantities
- Calculating Quantities for 2D (Line) Plot Outputs
- Calculating Quantities for 3D (Surface or Vector) Plot Outputs
- Calculating Quantities for 3D (Volume) Plot Outputs
- Calculating Quantities for Animated Outputs
- Creating a User Defined Named Expressions Library

Working through these examples is a good way to better understand how to use the Fields Calculator and to see what it can do for you.

Support Expression Input in Fields Calculator

For HFSS, you can create custom field quantities using algebraic expressions. For more information on this functionality, see Algebraic Mode.



Scripting Support

All calculator operations are fully scriptable. You can save the commands used in a Fields Calculator session by first clicking the **Tools** > **Record Script to File** menu and replay the same commands by clicking the **Tools** > **Run Script** menu in a later session.

Preliminary Considerations for Using the Fields Calculator

The following sections provides some consideration notes regarding use of the Postprocessor Field Calculator. Most of the statements below are fairly generalized, and may not apply to all 3D

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

solver projects. When in doubt about the applicability of a particular consideration for a particular project, please feel free to contact your local HF Applications Engineer for further assistance.

Field Convergence and Accuracy

HFSS use finite element method (FEM) field solvers, which arrive upon a solution via adaptive meshing convergence. There are different algorithms available for determining where in each given model mesh adaptation is performed, but convergence is always evaluated by comparison of S-parameters (for driven solutions), changes in overall scattering energy (for incident wave problems) or resonant frequencies (for eigenmode solutions) from pass to pass. Because these quantities represent the results of the model as a whole, they tend to converge more rapidly than the field values. Each point in the modeled space can be said to have converged to some value. As a result, specific field quantities at each mesh point are likely to be less accurate than the overall S-parameter or eigenfrequency result of a project solution.

In order to obtain high accuracy results from calculations on field data, we recommend that you take extra precautions to assure that the model's field data is dependable. This might include:

- Running the project to a tighter than usual convergence value.
- Seeding or manually refining the mesh in the areas to be used for calculations.
- Running parametric variations to isolate sensitivity to modeling parameters (such as adaptation frequency or circular cross-section facetization).
- Specifying expressions for output convergence.

As long as the accuracy of specific field data points to be used has been assured, the results of the Field Calculator operations should provide valuable information for your electromagnetic design tasks.

Fast Sweep and Dispersive Models

If an HFSS solution includes a Fast Frequency Sweep, the Fields Postprocessor can be tuned to display field data at any point in the frequency band swept. The specific frequency selected for viewing need not even be a precise data point at which the S-parameters were calculated. While field calculator operations may be performed at any frequency to which the Fields Postprocessor is set, fast sweep solution field data (away from the center frequency of the sweep) may not be as accurate for lossy and dispersive media, within the interior of solid-meshed finite conductors, etc. For higher accuracy under these conditions, field calculator operations should be performed on a full matrix solution completed at the desired frequency.

Because materials assigned as part of a "Perfectly Matched Layer" (PML) model termination are anisotropic and highly lossy, performing field calculations on the surface of or interior to objects designated as PMLs is not recommended.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Inputs/Excitations

Use **HFSS** > **Fields** > **Edit Sources** to set the field excitation appropriate to the calculation to be performed. In some cases (e.g., FSS calculations) picking the right field solution set (incident, scattered, or total) is also paramount to obtaining the intended result.

Any field calculation that has not yet been completed (such that the calculator stack still shows some form of “text” string rather than a simple numerical value) is merely a placeholder. Altering the field data loaded in the Postprocessor (by altering port excitations, changing frequency, or picking a different solution set using **HFSS** > **Fields** > **Edit Sources**) will result in subsequent evaluation of the placeholder to the newly loaded data. To preserve a placeholder's association to an existing data set before altering the excitation to a different data set, you should export the register stack by using the **Write** button. You can bring the correctly associated quantity back into the stack by using **Read** after you have changed the field data set selection.

Units

All units in Driven HFSS field solutions are expressed in the MKS system, regardless of drawing units. Therefore, E-mag is always in V/m, H-mag in A/m, etc. The exception is that when plotting along a geometry (e.g., along a line) the dimension along the X axis of the graph shows the position along the line in the drawing units, while the vertical (field quantity) axis will be in the MKS system.

Eigenmode Solutions

Field values in Eigenmode solutions are normalized to a peak value of 1.0, since there is no real excitation to which to scale the internal field results. If desired, you can scale the peak value to a user-selected number using the **HFSS > Fields > Edit Sources** menu.

Opening the Fields Calculator

To open the Fields Calculator, from the Desktop Menu bar do one of the following:

- Click **HFSS**> **Fields**> **Calculator**

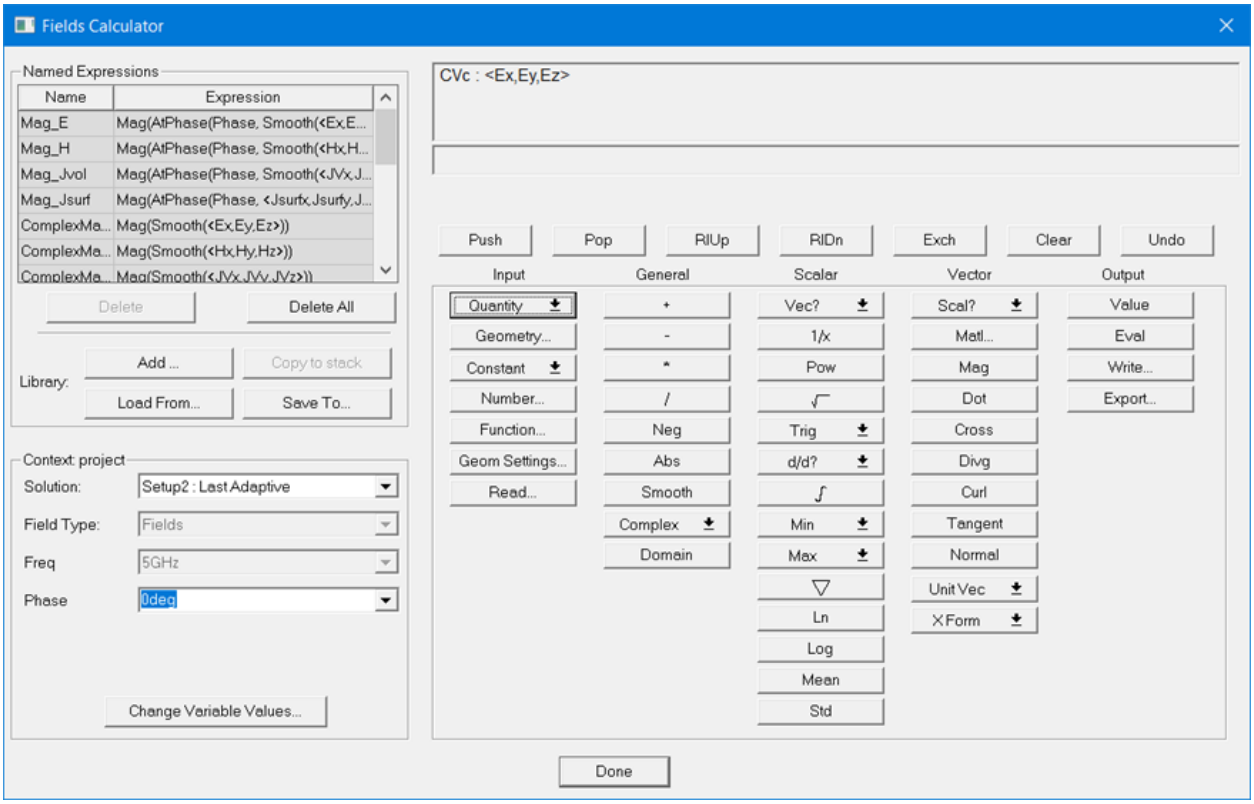
  or

- Right-click **Field Overlays** in the Project Manager and choose **Calculator** from the shortcut menu.

The *Fields Calculator* window appears.

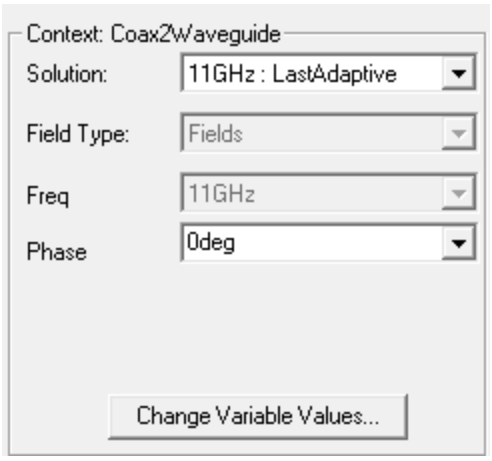
To view information on a command or screen area, click over the button or screen area on the illustration below:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Context Area

The panel at the upper right of the window identifies the context to be used for the calculations. The top line identifies the design. Depending on the design, text entry boxes allow you to select a **Solution**, **Field Type**, **Freq**, **Phase**, **IWavePhi** and **IWaveTheta**. The **IWavePhi** and **IWaveTheta** are available only for incident wave projects in which the wave is defined with spherical coordinates.



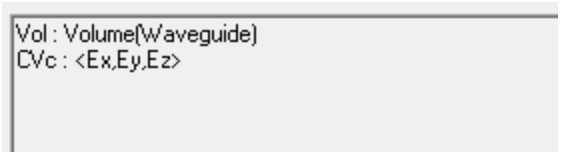
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The Field Type here is not related to the edit sources. This is a general term among Ansys EM products (HFSS, Maxwell, Q3D, Icepak, and Mechanical). Some products have more than one field type for different solution types. If only one Field Type is available the drop-down menu is unavailable. For Hybrid design in HFSS R18, even if the design contains an IE Region, you can select J and Q input quantities. You no longer need to select between Fields and IE Surface Fields.

The **Change Variable Values** button opens a *Set Variable Values* dialog box. By default, it has *Use Nominal Design* checked. Unchecking the box lets you select another variable value. **OK** the dialog box to accept the selection.

The Calculator Stack

The calculator is made up of a stack of registers. Registers are displayed in the register display area at the center of the calculator window.

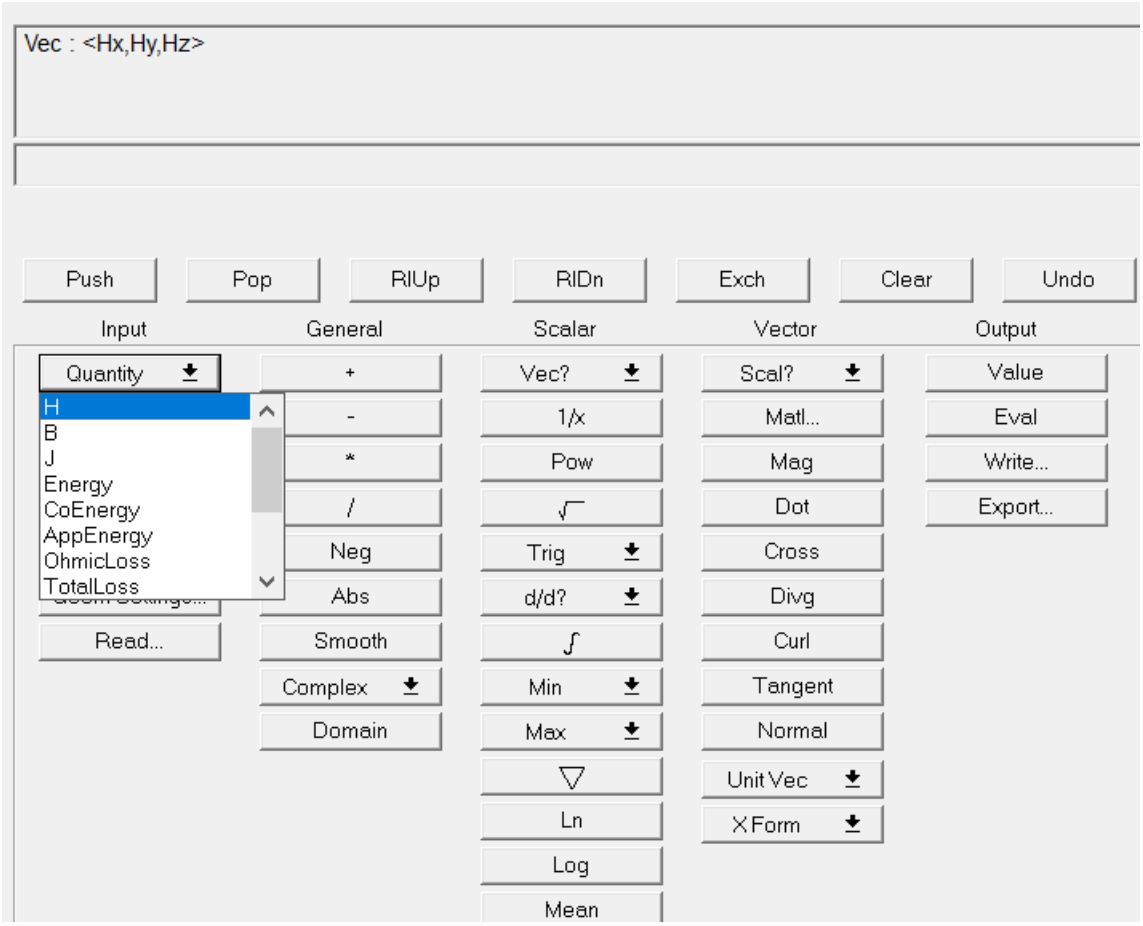


Each register can hold

- field quantities such as the H-field or E-field.
- functional or constant scalars and vectors.
- geometries — points, lines, surfaces, or volumes — on which a field quantity is to be evaluated.

To perform a computation on the field solution, you must first load a basic field quantity into a register on the stack:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Once a quantity is loaded into a register, it can be

- manipulated using mathematical operations such as curls, gradients, cross products, divergences, and dot products.
- integrated over lines, surfaces, or subvolumes of the solution region — either predefined surfaces, volumes, and lists, or lines, surfaces, and volumes that were defined using the **Draw** commands.
- exported to a file, allowing you to superimpose saved solutions.

Stack Commands

Stack Commands influence the entries in the calculator stack and their position. These commands are for manipulating stack contents only, such as copy/paste, delete, or rearrange. The names for these commands match standard stack manipulation conventions. Many are self explanatory, and some can be used in pairs.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Push

Reloads the quantity in the top register onto the top of the stack, creating a new register. The contents of the top two registers are identical.

Pop

Deletes the top register from the stack.

RlUp

Rolls the top register to the bottom of the stack, moving the other registers up the stack.

RlDn

Rolls the bottom register to the top of the stack, moving the other registers down the stack.

Exch

Exchanges the top two registers in the stack.

Clear

Clears the contents of the stack.

Undo

Use this command to undo the effect of the last operation you performed on the contents of the top register. Successive **Undo** commands act on any previous operations.

> **Note:**
>
> You cannot undo a simple operation such as loading a field quantity, constant, function, or geometry into the calculator. Instead, use the **Pop** or **Clear** commands to delete these items from the calculator stack.

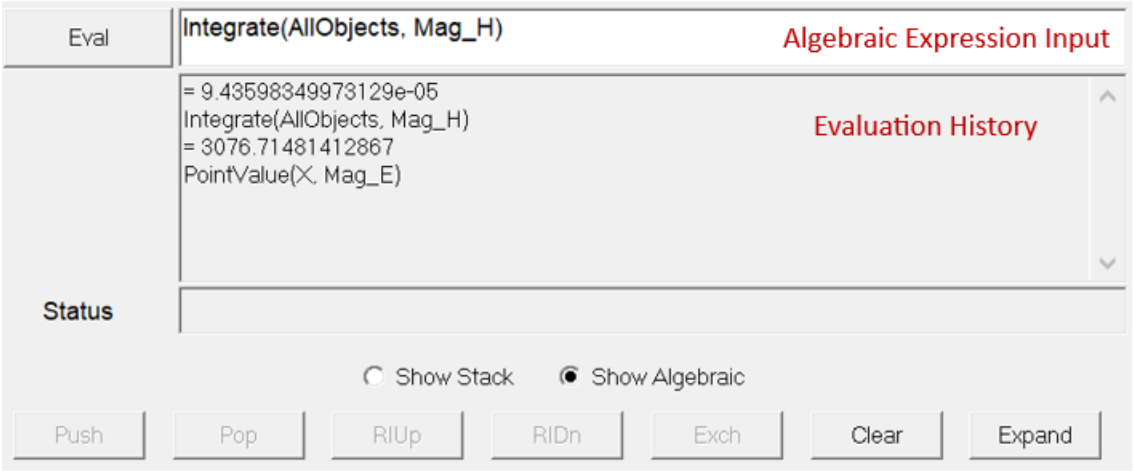
Algebraic Mode

With the **Show Algebraic** option, users can create custom field quantities using algebraic expressions. Users can enter equations directly in the Data field, which is now editable. The text entered is in black when it parses and red when it does not. The Stack Command buttons can

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

also be used to define an algebraic expression; the input text will be inserted at the current insert point in the Data field.

A sample algebraic expression is shown below:



An algebraic expression can be saved in the Named Expressions list. If **Show Algebraic** is selected, all the named expressions will be listed in algebraic format. If **Show Stack** is selected, the named expressions will be listed in stack format.

An algebraic expression is either a `namedExpression`, a `constant`, a `name`, an `operator`, two `expressions` separated by `binaryOperator`, or an `expression` enclosed in parentheses.

An `operator` is an *opName* followed by `arguments`.

An `argument` is either empty parentheses, an `expression` enclosed by parentheses, or two `expressions` separated by a comma and enclosed by parentheses.

A `binaryOperator` is one of the following literals: '+', '-', '*', '/', '%', '^'

A `name` is either a project, design, or intrinsic variable (scalar or vector), or a geometry.

A *constant* can be one of the following:

- scalar literal; for example, "1.5e-10"
- complex number; for example, "3.5-1.0i" or "<(3.5, -1.0)>"
- 3D vector; for example, "<1.0, 2.0, 3.0>"
- complex 3D vector; for example, "<1.0-2.0i, 2.0-3.0i, 3.0-4.0i>" or "<(1.0, -2.0), (2.0, -3.0) ,(3.0, -4.0)>"

The grammar for an algebraic expression is summarized below:

```
expression : namedExpression
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

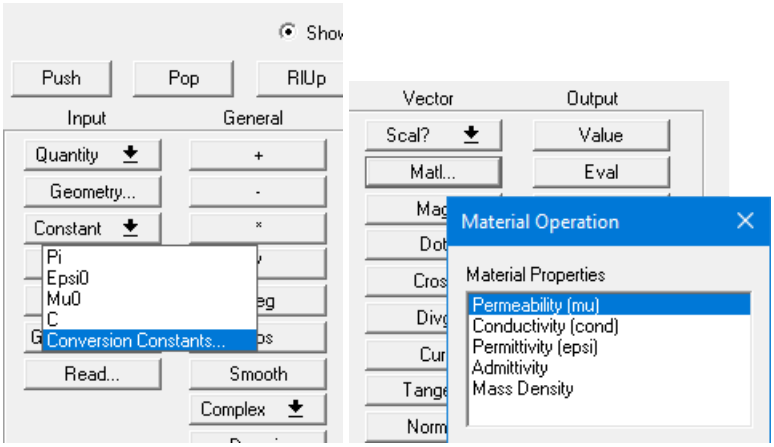
```
    | constant
    | name
    | operator
    | expression binaryOperator expression
    | '(' expression ')'
operator : opName arguments
binaryOperator : + | - | * | / | % | ^
arguments : '(' <empty> ')'
    | '(' expression ')'
    | '(' expression ',' expression ')'
```

Note the following:

- `%` is used for the vector dot product; for example, `Integrate(AllObjects, Real(E%H))`
- `*` supports vectors on both sides as the operand and the cross-product. For example, `Integrate(AllObjects, Mag(E*H))` can be used instead of `Integrate(AllObjects, Mag(Cross(E,H)))`.

Names

The following named constants and material properties are supported as input in the Fields Calculator:



Note that Mass Density corresponds to keyword "`MassDensity`".

If there is a conflict between standard quantity names, user-defined named expressions, and user-defined variables, the default name conflict resolution order is

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Standard quantities such as E and Mag_E
2. User-defined named expression
3. User-defined variables

Words not immediately followed by an open parenthesis will be treated as a quantity or variable. Therefore, a user-defined variable named `Real` not followed by open parenthesis will be recognized as a variable instead of the operator.

The `Var` or `Expr` operator can be used to override the default name conflict resolution. For example, a user-defined design variable named `Mag_E` would normally not be recognized. Instead, the standard quantity `Mag_E` will be assumed, and evaluation will fail:

Name	Value	Unit	Evaluated...	
offset	0	in	0in	D
Mag_E	-2 - 2i		-2 - 2i	P
Real	3		3	P
Var	-1		-1	P
epsi0	-2		-2	P
epsi	-9		-9	P
E	3		3	P

With the `Var` operator, the user-defined variable can be parsed correctly and evaluated for the user -defined value:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

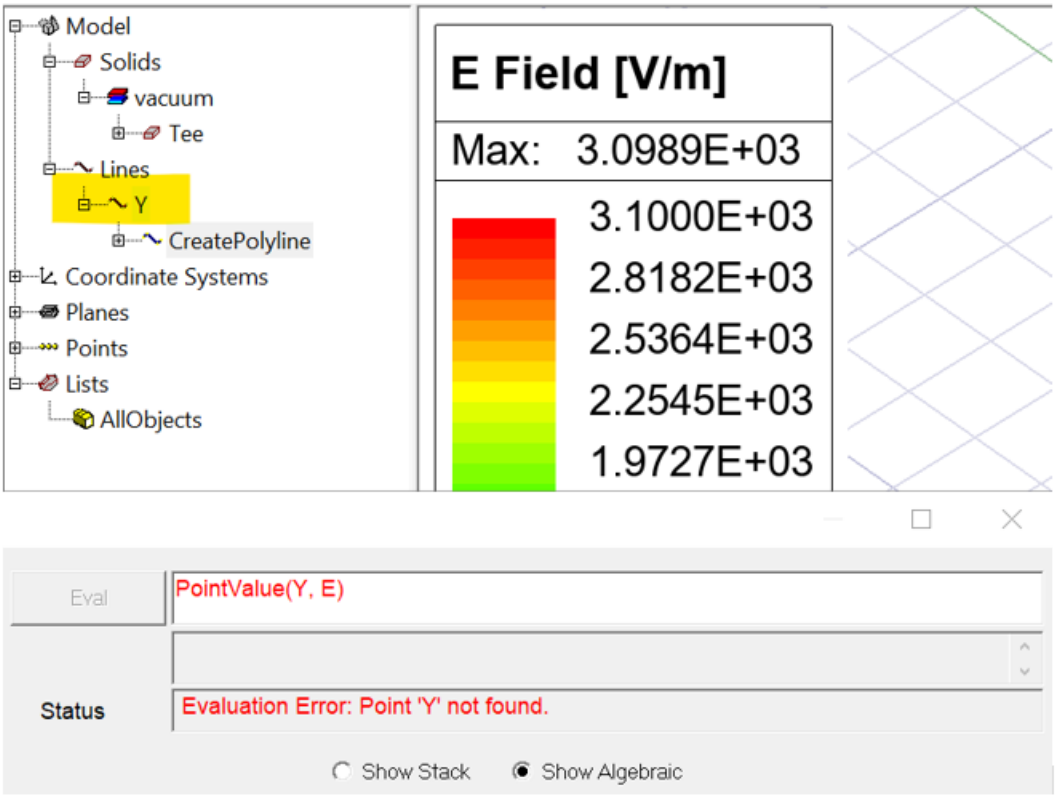
Here is another example that demonstrates how a user-defined variable can conflict with a standard named constant, such as epsi0, the vacuum permittivity, and how to use the `Var` operator to resolve the conflict:

Geometry

If an operator requires a geometry input, the geometry argument can be either first or second in the argument list, or in some cases, both. The operator automatically infers the geometry of the argument; no explicit specifiers are required. For example, `PointValue(GeomX, ExpressionY)` will assume `GeomX` is a point.

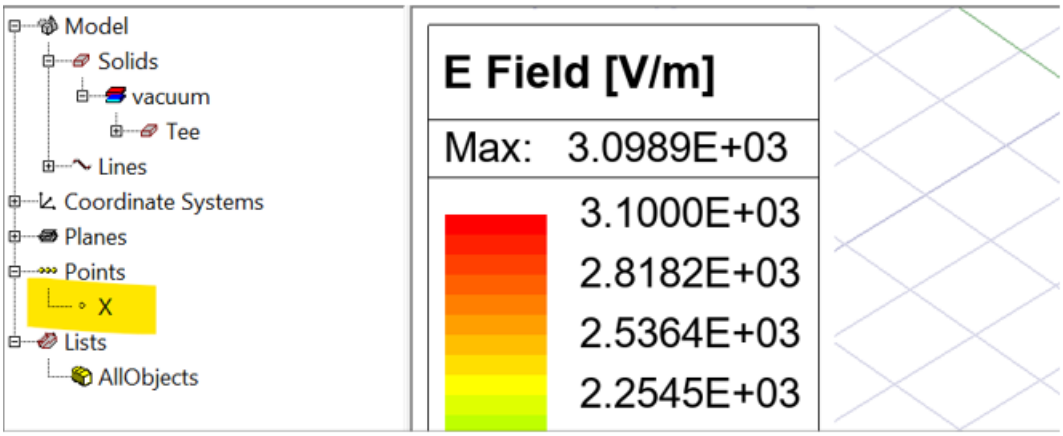
If the user specifies an operator, but uses the wrong type of geometry in the argument list, the Calculator will return an error. In the following example, the `PointValue` operator has a line in its argument list, so the Calculator generates an error:

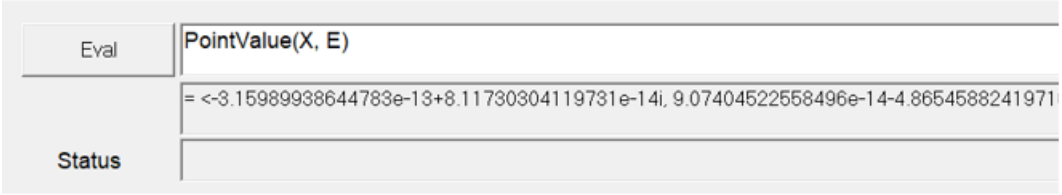
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The following example shows the output when the geometry argument are specified correctly:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.





The following operators assume the geometry operand to be of the Volume type:

- `Integrate`
- `Mean`
- `Std`
- `Min`
- `Max`
- `MinPos`
- `MaxPos`

Registers

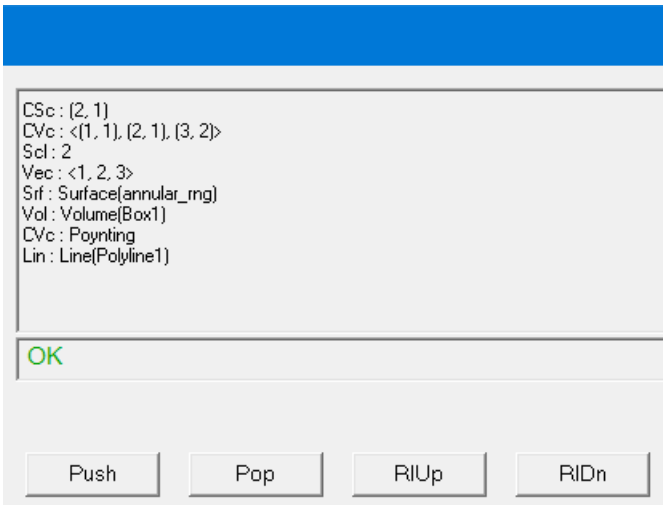
Calculator registers hold field quantities, numbers, vectors, and geometries. No registers are created until you load something into the calculator; therefore, this part of the window is initially blank. As items are loaded into the calculator, it creates new registers to hold them.

> **Note:** For Maxwell and HFSS users, make sure the Calculator is in **Show Stack** mode.

The calculator is capable of performing operations on a number of different data types. In many instances, a calculation requires certain type(s) of data to be present in the correct order in the stack register. Many operations result in a different data type than the inputs. In order to show

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

you the type of data contained in each stack entry, calculator denotes its data type by a prefix indicator as shown in Stack Contents showing Data Type Indicators (at left), below.



The following table describes and defines each indicator, and provides guidance regarding operations which can convert data from one type to another.

Vec	Vector (non-complex) quantities, which have both direction and magnitude at each point in space. The x-, y-, and z-components of these quantities are stored in the register. Vectors are always evaluated in the coordinate system of the model. To convert a vector quantity to a scalar, use the Scal? drop-down menu from the Vector column. Suboptions ScalarX, ScalarY, and ScalarZ will take the appropriate scalar component of the vector data. Optionally, you can also Dot the vector with another vector to obtain the appropriate scalar result, or use the Tangent (return the tangential scalar component of) or Normal (return the normal scalar component of) operations to relate the vector quantity to a geometric data (Lin, Srf) stack entry. Convert to a Complex quantity using the CmplxR and CmplxI operations described in Scl, above.
Scl	Scalar quantities, which have a magnitude only. This is a simple numerical value. To convert a scalar to a vector quantity, use the Vec? drop-down menu in the Scalar column. The choices VecX, VecY, and VecZ convert the scalar data to vector data aligned with the X, Y, or Z unit vectors, respectively. You can also multiply the scalar quantity by a desired vector direction entered manually (Num drop-down in the Input column) or obtained using the Unit Vec button from the Vector column. To convert a scalar to a complex quantity, use either CmplxR (assign the scalar value as the real

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	component of a complex quantity) or CmplxI (assign the scalar value as the imaginary component of a complex quantity), both found under the Cmplx drop-down in the General Column.
Cvc	Complex vector quantities, which are numerical values with real and imaginary components. Convert to a vector quantity using the same techniques described for Scl, above. Convert to a scalar using Real (take the real component), Imag (take the imaginary component), CmplxMag, (take the magnitude of the complex number) or CmplxPhase (take the phase of the complex number), all within the Cmplx dropdown in the General column.
Csc	Complex scalar quantities. This is a numerical value with real and imaginary components. Convert to a vector quantity using the same techniques described for Scl, above. Convert to a scalar using Real (take the real component), Imag (take the imaginary component), CmplxMag, (take the magnitude of the complex number) or CmplxPhase (take the phase of the complex number), all within the Cmplx drop-down in the General column.
Pnt	Points
Lin	Lines, which may be straight, curved, or “polylines” in three dimensional space. Lines may also be open (have two endpoints) or closed (ending vertex same as starting vertex).
Srf	Surfaces. Surfaces need not be planar, and may actually comprise a list of object faces (faces list) as well as planar slices through the entire model space (cutplanes).
Vol	Volumes, which may include sets of discontinuous object volumes created as an Object.
SclLin	Scalar value on a line
VecLine	Vector value on a line
SclSrf	Scalar value on a surface
VecSrf	Vector value on a surface
List	These indicators may exist alone, representing geometric data only, or in combination with one of the categories above, indicating a type of data applied to the geometric entity in question. For example, the notation SclSrf identifies a stack entry containing Scalar data on a Surface geometry set. To select only the portion of a given data entry which exists along, on, or within a given geometry quantity, use the Value button in the Output column of the calculator. Other operations (e.g., integration, the Normal button) operate when a data quantity is in the second stack register and a geometric quantity is in the top stack register. Full descriptions of the register requirements for each individual command is available in the online help.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When examining calculator registers, keep the following in mind:

- To move or delete calculator registers, use the stack commands.
- To save a register to a disk file, use the **Write** command.

Users must be cautious concerning what type of data the Fields Calculator is manipulating and whether or not it is compatible with the desired operation. For example, the integral operation is often misused. Note that the integral sign is in the *Scalar* column, implying that, to integrate complex number/quantities, the user will have to integrate the real and imaginary components separately. In other words, performing integration on complex number/quantities must be achieved by parts.

Enlarging the Register Display Area

If there are too many registers to fit into the display area, do one of the following:

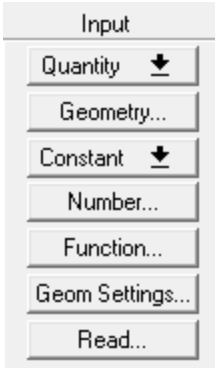
- Use the scroll bars to view the hidden registers.
- Enlarge the calculator window by dragging window's borders.

Units of Measure

Unless you are prompted specifically for the unit of measure, all measurements should be assumed to be in SI base units, not model units.

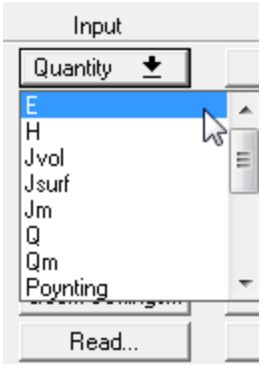
Input Commands

The *Input* Column contains all the calculator functions which place new values into the stack, such as field data, constant, geometry data, coordinate system selection, or user-entered vector or complex numbers.



Field data (e.g., E-field, H-field, Poynting vector) for the current project solution is input from the **Quantity** drop-down menu selection.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The quantities specifically available from the calculator are dependent on the solution type and include the E-field, H-field, J-vol (volume current), Poynting vector, Displacement, Temperature, Heat Flux, and Surface and Volume Loss Densities. All quantities are Peak Phasors, and not RMS quantities, with the phase information captured in the real and imaginary components and the field orientation captured in the vector components. Although the Poynting vector is automatically calculated by the interface as 0.5, it will appear in the calculator stack as a Complex Vector quantity. The imaginary portion should however be zero or ignored.

Use the following commands to load data onto the top of the calculator stack:

Quantity	Basic field quantities, such as E and H, and simple derived quantities such as volume current. For designs with IE Region, select J and Q.
Geometry	Geometries such as planes, points, polylines, 3D lines, face selections, and volumes
Constant	Predefined constants such as π, ε_0, and conversion factors between various units of measurement.
Number	Vector and scalar constants, including complex numbers.
Function	User-defined or intrinsic variables
Geom Settings	Number of equally spaced points used to integrate fields and other quantities on a line.
Read	Read previously saved calculator registers containing field quantities.
Output Vars	This button appears only for eigenmode problems. Freq is the only value there. Evaluation for Freq returns a complex value.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

These quantities can be manipulated using the **Stack** commands, **General** commands, **Scalar** commands, and **Vector** commands. The results of these calculations can then be examined using the **Output** commands.

Quantity Command

The **Quantity** command loads a specified field quantity into the top register of the calculator.

The available quantities are:

E	The electric field, E
E_t	Transient electric field, E.
H	The magnetic field, H
H_t	Transient magnetic field, H.
Jvol	The volume current density, J_{vol}
Jsurf	The surface current density, J_{surf}
Jsurf_t	Transient surface current density.
Poynting	The Poynting vector, defined as 0.5E x H*
Poynting_t	Transient Poynting vector.
LocalSAR	The local Specific Absorption Rate
AverageSAR	Peak spatial average SAR, dependent on the Average SAR Method chosen in the Specific Absorption Rate Setting.
Certification SAR	IEEE standard Specific Absorption Rate certification number. (See Modifying SAR Settings and Calculating the SAR.) To calculate certification SAR on a specific object (rather than the whole model) proceed as follows: 1. In the Calculator Input area, click the **Quantity** button and select **Certification SAR**. Certification SAR is displayed in the calculator stack. 2. In the Calculator, click the **Geometry** button. The *Geometry* dialog box displays with the *Volume* radio button selected and the available geometries listed. 3. Select the Geometry of interest. This enables the OK button. 4. Click the **OK** button. 5. This adds the selected Volume geometry to the calculator stack.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	6. In the Calculator Output area, press the **Value** button. This prepares the calculation for the selected quantity and volume. 7. Press the **Eval** button to evaluate. Both the value and location will be shown on the calculator stack.
SurfaceLossDensity	This contains the surface impedance (if any) loss at every node in every triangle. This is calculated as: $Loss = 0.5 \times Real\left((\vec{E}\ x\ \overrightarrow{normal}) \cdot \overline{(\vec{E} \times \overrightarrow{normal}) \div \overline{Impedance}}\right)$ To export a REG file containing the surface loss density, place the SurfaceLossDensity in the top register and use the **Write...** command, selecting Reg format.
VolumeLossDensity	The volume loss density *p* is calculated as: $p_v = \frac{1}{2}Re(E \cdot \tilde{J} + j\omega B \cdot \tilde{H}) = \frac{1}{2}Re(E \cdot \tilde{J} - curlE \cdot \tilde{H})$ where *E* is the electric field, $\tilde{J}$ is the conjugate of the volumetric current density, *B* is the magnetic flux density, and $\tilde{H}$ is the conjugate of the magnetic field. To export a Reg file containing the volume loss density, place the VolumeLossDensity into the top register, and use the **Write...**.command, selecting the Reg format.
VolumeLossDensity_t	Transient volume loss density, calculated as: 0.5 * *Re*(*E* * *J*)
SurfaceForceDensity	Surface Forces exist when one side is conductor, but the other is not, or finite conductivity and layered impedance boundary. This is mainly for the purpose of mapping surface force density in HFSS to Workbench Mechanical. For details on the calculations, see the technical notes.
Temp	Temperature.
Displacement	This is value is for use with Workbench when exploring stress feedback.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Geometry Command

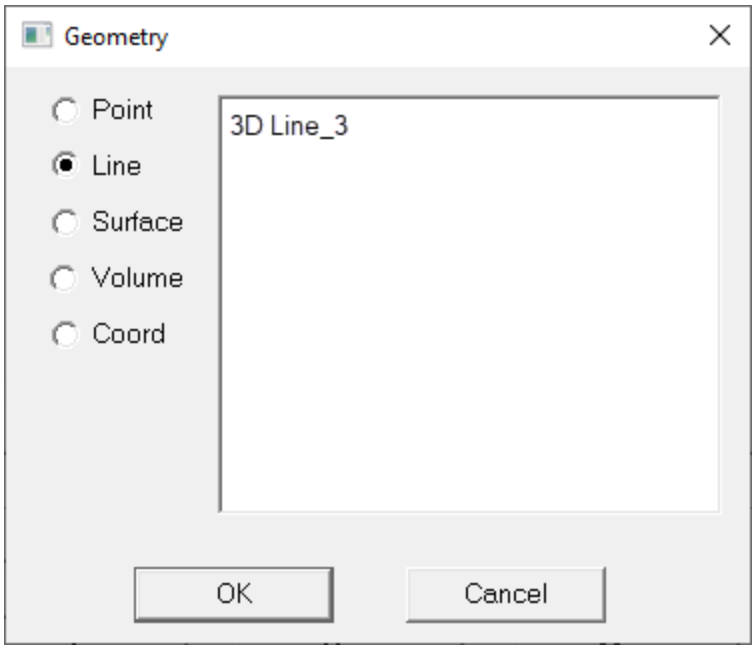
The Fields Calculator **Geometry** command opens a dialog box for selecting a geometry to load into the top register of the calculator.

Do this to

- find the value of derived field quantities on any point, line, surface, or volume.
- plot quantities directly from the calculator.
- display a previously defined isosurface, maximum or minimum field point using the **Draw** command.

The following types of geometries are available:

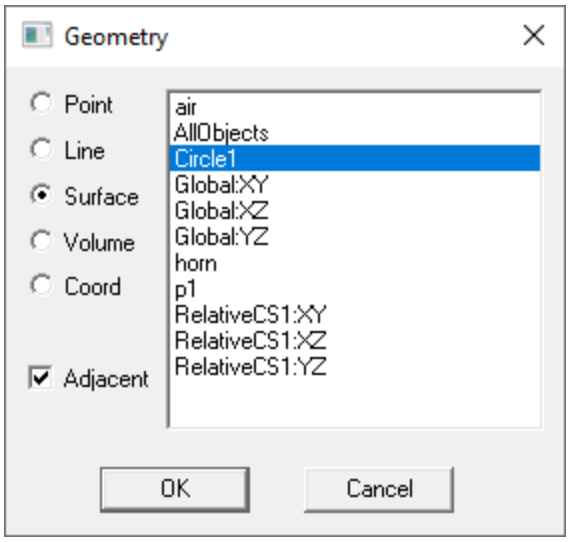
Point	See Drawing a Point Object. Drawn points are listed in the History Tree, and in the calculator's *Geometry* dialog box when **Point** is selected.
Line	See Drawing a Line Segment or Drawing a 3D Line Segment. Drawn lines are listed in the **History Tree**, and in the calculator's *Geometry* dialog box when **Line** is selected. To set the number of points on a line, see Geom Settings. 
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Creatable **Sheet** objects and face selections, (e.g., of radiation boundaries), are listed in the History Tree and in the calculator's **Geometry** dialog box when **Surface** is selected.

Due to the ambiguity of the normal vector of a sheet, the result may require a multiplication by (1) or (-1). If a Sheet object is selected from the face list, the dialog box also lists an **Adjacent** command that controls the side of the sheet on which the fields are calculated.

Surface



This check box is only available when users select a sheet object for surface geometry

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	• Allow operation on the adjacent side surface geometry just like regular surface geometry. • All calculation on this geometry will be done using data from the adjacent side of the surface. • Support scripting, saving and loading expression with adjacent side surface geometry. Volume	3D objects, regions, and object selections (of 3D objects including AllObjects) are available in the calculator's *Geometry* dialog box when **Volume** is selected.
Coord	Coordinate systems are available in the calculator's *Geometry* dialog box when **Coord** is selected.

To load a geometry into the calculator:

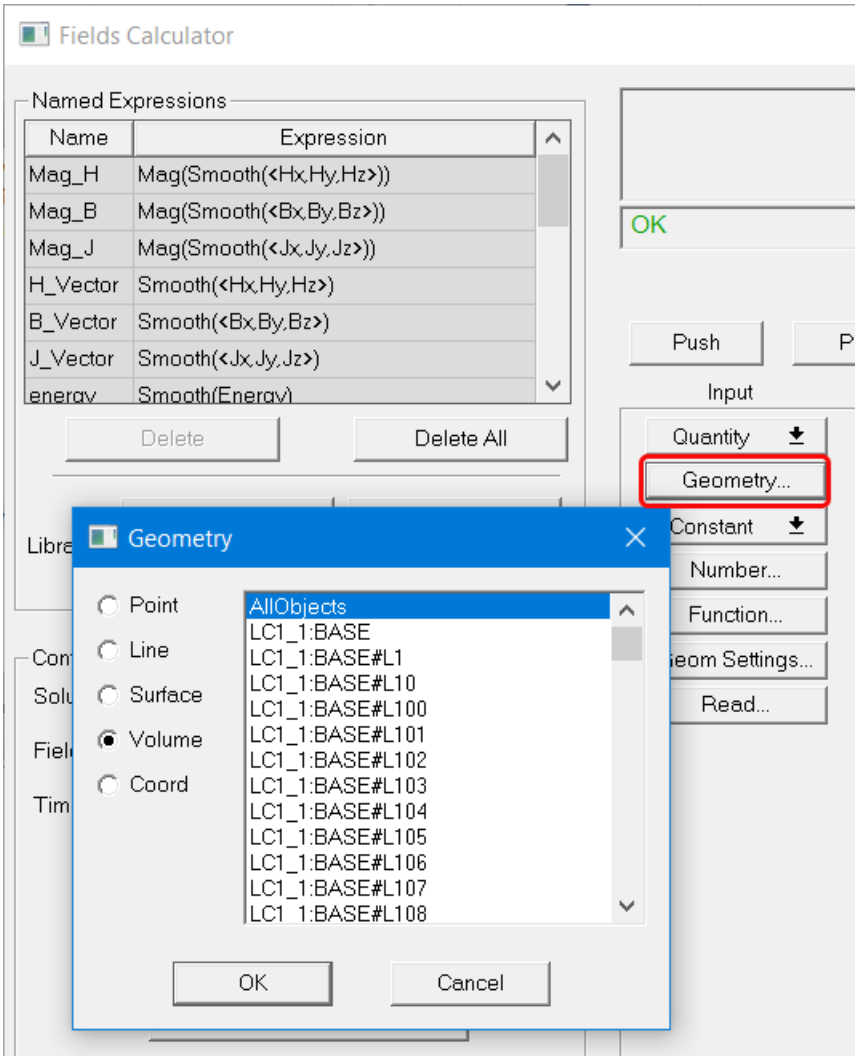
1. In the Fields Calculator, click **Geometry**.

   The **Geometry** dialog box appears.

2. Select a geometry type.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A list of all applicable geometries appears. If a design includes Layout Components, the Geometry list shows the available component geometries as well.



In the modeler window, these Layout Component objects are drawn as visualizations without actual geometry. However, they can be used to calculate field quantities as shown below.

These geometry operators can be used to perform computations just like one constructed from regular 3D geometry. These additional objects are generated only after reading a

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

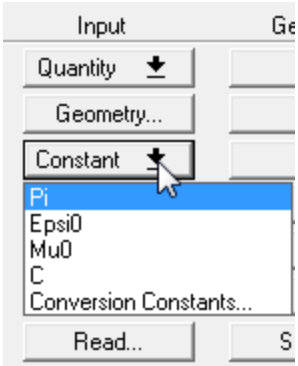
mesh, so they won't show up if there is no solution.

3. Click the geometry.
4. Click **OK** to load the geometry.

> **Note:** Consider a box (Box2) that is completely enclosed in a bigger box (Box1), so that no faces of Box2 are touching any faces of Box1. Box2 is actually implicitly subtracted from Box1 as is done in our solvers. So Box1 is used as if Box2 were already subtracted from Box1. Volume(Box1) is Box1 excluding Box2, and Surface (Box1) contains faces from both Box1 and Box2.

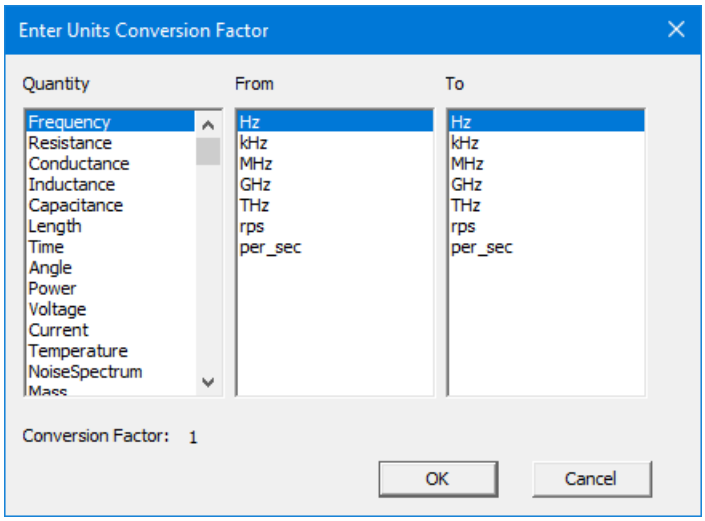
Constant Command

The **Constant** command loads one of the following four predefined constants or a selected conversion constant into the top register of the calculator:



Pi	π
Epsi0	The permittivity of free space, $\varepsilon_0 = 8.85418782 \times 10^{-12}$ C^2/Nm^2
Mu0	The permeability of free space, $\mu_0 = 4\pi \times 10^{-7}$ Wb/Am
c	The speed of light in vacuum, $c = 2.99792458 \times 10^8$ m/s
conversion constant	Displays the *Enter Units Conversion Factor* dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This lists a range of Quantities (such as frequency, resistance, and others) along with a list of Units (Hz to Thz, and rps) to convert From and To. The ratio of the Units From to the Units to is displayed for the selected values as **Conversion Factor**.

Number Command

The **Number** command enters one of the following into the top register of the calculator:

Scalar	A scalar constant. To enter a constant scalar number: 1. Click **Number**. The *Input Number* dialog box appears. 2. Select **Scalar**. 3. Type the scalar value in the **Value** text box. 4. Click **OK** to load the number into the top register.
Vector	A vector constant. To enter a constant vector: 1. Click **Number**. The *Input Number* dialog box appears. 2. Select **Vector**. 3. Enter the x-, y-, and z-components of the vector. 4. Click **OK** to load the vector into the top register.
Complex	A complex constant, entered in the form $C=A+jB$, where A represents the real part of the constant and B represents the imaginary part.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click **Number**.

   The *Input Number* dialog box appears.

2. Select **Scalar** or **Vector**.
3. Select **Complex**.
4. Enter the real and imaginary components of the number.
5. Click **OK** to load the number into the top register.

Function Command

The **Function** command enters a predefined scalar or vector function into the top register of the calculator:

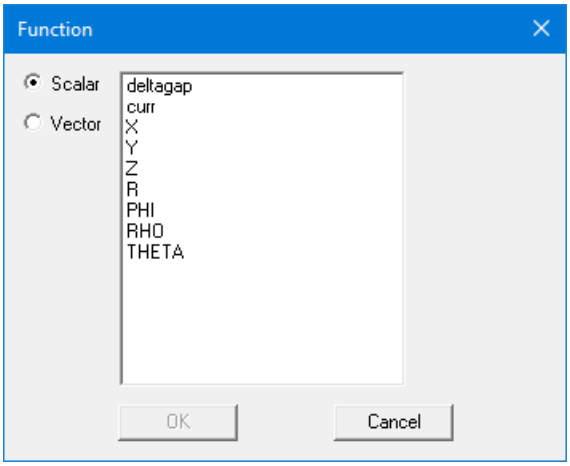
Scalar

A scalar function.

To enter a function:

1. Click **Function**.

   The *Function* dialog box appears.



2. Select **Scalar**.
3. Select the function from the list.
4. Click **OK** to load the functional scalar into the top register.

Vector

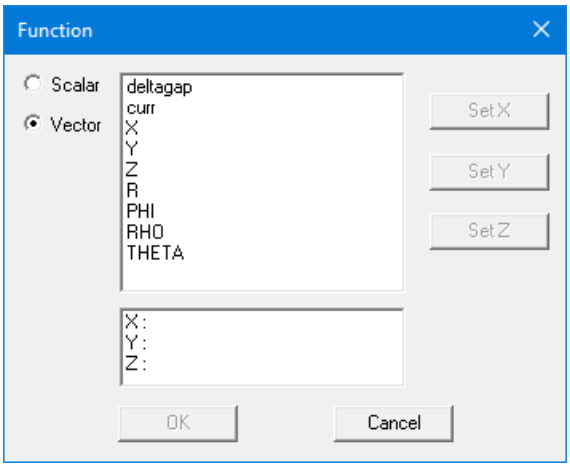
A vector function, in which the values of the vector's x-, y-, and z-components are given by functions.

To enter a functional vector:

1. Click **Function**.

   The *Function* dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Select **Vector**.
3. Select the function from the list.
4. For each component of the vector, click **SetX, SetY,** and **SetZ**.
5. Click **OK** to load the functional vector into the top register.

Note:

The predefined variables **X, Y,** and **Z**; **RHO, THETA, R,** and **PHI**; and any functions that you created can be used to define functional scalar and vector quantities.

Use of the Global Coordinate System is assumed. Local coordinate systems are not used.

Geom Settings Command

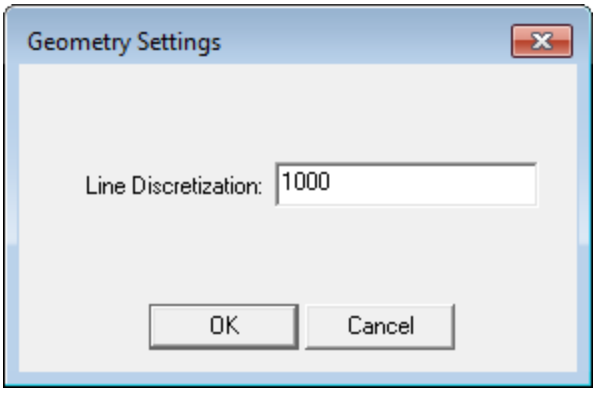
Clicking the **Geom Settings** button opens the *Geometry Settings* dialog box. This dialog box allows you to specify the line discretization, the number of equally spaced points used to integrate fields and other quantities on a line. The default is 1000 points.

To set the line spacing for geometry settings:

1. In the Fields Calculator, click **Geom Settings**.

   The *Geometry Settings* dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



2. Enter a value in the **Line Discretization** text box and click **OK**.

Read Command

This **Read** command copies the contents of a disk file into the top register. The register must be one that has been saved using the Write output command.

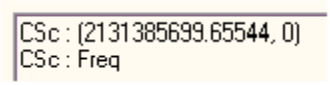
To read in a register:

1. Click **Read**.
2. Use the file browser to specify the register's file name and directory path. A .reg extension is automatically assumed for register files.
3. Click **OK**.

   The contents of the file are copied to the top register in the stack.

Output Vars [Input for Eigenmode problems]

This Output Vars button appears in the **Inputs** column of the Fields calculator only for Eigenmode problems. Freq is the only value listed. After you push Freq to the stack, you can click **Eval** to return a complex value.



General Commands

The General Column contains calculator operations which can be performed on many different data types (e.g., vector, scalar, complex). With the exception of the Complex menu, all are distinct functions. Most are self-explanatory, with the exception of Smooth which performs some data “smoothing” or statistical averaging on the top stack entry.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Use these Fields Calculator commands to perform operations on both vector and scalar quantities.

+ (Add)	/ (Divide)	Smooth
-- (Subtract)	Neg	Complex
* (Multiply)	Abs	Domain

+ (Add)

Adds the quantities in the top two registers of the calculator.

- (Subtract)

Subtracts the quantity in the top register from the quantity in the second register. The two registers must hold the same type of quantity (both scalar or both vector). You cannot subtract a scalar from a vector (or vice versa).

> **Note:** Consider a box (Box2) that is completely enclosed in a bigger box (Box1), so that no faces of Box2 are touching any faces of Box1.
>
> If you explicitly subtract Box2 from Box1, any calculation on the surface (faces) of Box1 will use the 6 exterior faces and the 6 interior faces. Any calculation on the volume of Box1 will use the difference in volume between Box1 and Box2.
>
> If you do not explicitly subtract Box2 from Box1, the inner box is only implicitly subtracted. Any calculation on the surface of Box1 in this case will use only the 6 exterior faces of Box1. Any calculation on the volume of Box1 will use the entire volume without subtracting the volume of Box2.

*** (Multiply)**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Multiplies the quantity in the top register by the quantity in the second register. One of the two registers must contain a scalar value; the other register can be either a scalar or a vector.

/ (Divide)

Divides the quantity in the second register by the quantity in the top register. The second register must contain a scalar value; the top register can be either a scalar or a vector.

Neg

Changes the sign of the quantity in the top register.

Abs

Takes the absolute value of the quantity in the top register.

Smooth

Smooths the quantity in the top register. Because of the numerical solution technique used, field values are not always continuous across the boundaries of the individual elements that make up the finite-element mesh. Smoothing makes the values continuous by taking a weighted average from all of a node's neighboring elements. The weights are based on angles, so elements with larger angles provide larger contributions. In general, use smoothing before plotting a quantity.

Complex

These commands perform operations on a complex quantity in the top register. Complex quantities are indicated by a **C** at the beginning of the register label. They can be represented in terms of real and imaginary components, or in terms of magnitude and phase:

$$C = A + jB = Me^{j\phi}$$

where:

- *A* is the real part of the complex number.
- *B* is the imaginary part of the complex number.
- *M* is its magnitude, which is equal to $\sqrt{A^2 + B^2}$.
- ϕ is its phase, which is equal to **atan**(B/A).

The **Complex** commands includes a drop-down menu that let you do the following:

Real	Takes the real part of the complex quantity (A).
Imag	Takes the imaginary part of the complex quantity (B).
CmplxMag	Takes the magnitude of the complex quantity (M). Due to interpolation issues, the sequence of calculations may cause a loss of accuracy. It is best to define the points , separately obtain the value of the real part, then the

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	imaginary part, and use those values to calculate the magnitude and and phase. For the sequence for using the Fields Calculator to obtain the real and imaginary parts, see the procedure here.
CmplxPhase	Takes the phase of the complex quantity(ϕ).
Conj	Takes the complex conjugate of the quantity in the top register. If a complex number is given by $C = A + jB$, its complex conjugate is given by $C^* = A - jB$.
AtPhase	Lets you specify the phase angle, θ, at which an field quantity is evaluated. These quantities can be represented in the form $A(x,y,z,t) = A(x,y,z)\cos(\omega t + \theta(x,y,z))$. where • ω is the angular frequency at which the quantities are oscillating, specified during the solution. • θ(x,y,z) is the phase angle (the offset from a cosine wave that peaks at t=0). Entering the phase angle lets you compute the real part of the field's magnitude at different points in its cycle.
CmplxReal	Converts the real scalar of the top register to the real part of a complex number.
CmplxImag	Converts the real scalar of the top register to the imaginary part of a complex number.
CmplxPeak	Calculates the peak value of a given complex vector. Intuitively, this calculates the maximum magnitude of the equivalent real vector in a waveform.

Domain

This limits a calculation to the volume you specify. The domain filter works for scalars, vectors, complex scalars and complex vectors. This operation requires the top two entries of the stack to be a volume geometry and a numeric field quantity. To do this:

1. Load the field quantity into the top register, and perform any necessary operations on it.
2. Load the volume using the **Geometry** command.
3. Click **Domain**.

The **Domain** command is often used to limit a calculation or plot to the intersection of a surface and an object or group of objects. If you export a domain filtered numeric, points that are filtered out by the domain will not be written out.

Steps for Calculating the Complex Vector Electric Field

These are the field calculator steps to obtain the real part, the imaginary part, and the magnitude of the x-directed, y-directed, and z-directed components of the phasor electric field. For each of

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

these vector components, the magnitude should be equal to sqrt(real^2+imag^2), but the need to interpolate values and the calculation sequence means that HFSS does not give this value unless the specified location is directly on a mesh element node.

1. Calculate real part of complex vector electric field (in x, y, and z directions):
    a. Qty > E
    b. Complex > Real
    c. Geometry > Point > fieldcalc_point
    d. Value
    e. Eval
2. Calculate imaginary part of complex vector electric field (in x, y, and z directions):
    a. Qty > E
    b. Complex > Imag
    c. Geometry > Point > fieldcalc_point
    d. Value
    e. Eval

Use the real and imaginary components to manually calculate the magnitude as the sqrt (real^2+imag^2).

Scalar Commands

The Scalar Column contains calculator operations which can only be performed on scalar stack entries.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Drop-down menus in this column include Vec? (convert scalar to vector), Trig (trigonometric, containing sin, cos, etc. functions), d/d? (derivative with respect to...), Max and Min (self-explanatory), Gradient, ln (natural logarithm base e), log (logarithm base 10), mean, and Std (standard deviation). Note that the calculator's Integrate function is located in the Scalar column. The implication is that integration can only be performed on scalar quantities. To perform integration upon complex quantities, you must perform the integration separately on real and imaginary subcomponents.

Use these commands to perform operations on scalar quantities.

Vec?	Makes the scalar quantity in the top register a vector component.
1/x	Takes the inverse of the scalar quantity in the top register.
Pow	Raises a scalar quantity to the power you specify.
√? **(Square Root)**	Takes the square root of the quantity in the top register.
Trig	Performs a selected trigonometric operation on the value in the top register of the calculator stack (Sin, Cos, Tan, ASin, ACos, ATan). Angles are in radians. Additionally, the ATan2 operation is available, which requires two arguments. This operator calculates the arc tangent of the following ratio: The second register in the stack divided by the top register.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	Example: If the top register value is 1.5, and the second register value is 2, the ATan2 function returns ATan(2/1.5) = 0.5880 radians. All other Trig functions operate on a single argument (top register only).
d/d?	Takes the partial derivative of the quantity in the top register.
∫? (Integral)	Takes the integral of a scalar quantity over a volume, surface, or line. To perform integration upon complex quantities, you must perform the integration separately on real and imaginary subcomponents.
Min	Computes the minimum of a scalar field quantity on a line, surface, or volume relative to your choice of Value or Position.
Max	Computes the maximum of a scalar field quantity on a line, surface, or volume relative to your choice of Value or Position.
∇ (Gradient)	Takes the gradient of the scalar quantity in the top register.
ln	Takes the natural logarithm (base e) of the scalar quantity in the top register.
log	Takes the logarithm (base 10) of the scalar quantity in the top register.
Mean	Takes the mean of the quantity in the top register.
Std	Takes the standard deviation of the quantity in the top register.

Vec? Command

Makes the scalar quantity in the top register a vector component. Choose from the following:

VecX	The x-component of a vector.
VecY	The y-component of a vector.
VecZ	The z-component of a vector.

1/x (Inverse) Command

Takes the inverse of the scalar quantity in the top register.

Pow Command

Raises a scalar quantity to the power you specify.

To raise a scalar quantity to a power:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Enter the quantity into the calculator.
2. Enter the exponent to which it is to be raised into the calculator.
3. Click **Pow**.

   The results are displayed in the top register.

Square Root Command

Takes the square root of the quantity in the top register.

Trigonometry Commands

Takes one of the following trigonometric values of the value in the top register of the calculator stack:

Sin	Sine
Cos	Cosine
Tan	Tangent
Asin	Arcsine
Acos	Arccosine
Atan	Arctangent
Atan2	A two-argument version of the At.an function. Takes the y and x coordinates of the tangent point (in the top two stack registers)

d/d? (Partial Derivative) Command

Takes the partial derivative of the quantity in the top register:

d/dx	Takes the partial derivative of the quantity with respect to x.
d/dy	Takes the partial derivative of the quantity with respect to y.
d/dz	Takes the partial derivative of the quantity with respect to z.

Integral Command

Takes the integral of a scalar quantity over a volume, surface, or line. The top register must contain a geometry and the second register must contain the scalar quantity to be integrated.

To perform an integration:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Load a quantity into the top register of the calculator, and perform any required operations on it.
2. Use one of the **Geometry** commands to load the line, surface, or volume over which the quantity is to be integrated.

   > **Note:**
   >
   > If you computed the tangent or normal of the quantity to be integrated, you do not have to load any geometry selection onto the calculator stack. HFSS integrates the tangential or normal component of the quantity over the line on which you computed its tangent, or the surface on which you computed its normal.

3. Choose the command to integrate the scalar quantity over the geometry.

To find the numerical results of an integration, use the **Eval** command.

Min Command

Computes the minimum of a scalar field quantity on a line, surface, or volume. Two options are available:

Value	Finds the magnitude of the minimum value of the field.
Position	Finds the point where the minimum field value occurs. You can then: • Plot the minimum field value at the point. • Plot basic field quantities at the point. • Load the point into the calculator. • Change the point's location.

These commands operate in the same way as the **Max** commands. Use the **Eval** command to display the actual minimum field value or the coordinates of the point where it occurs.

Max Command

Computes the maximum of a scalar field quantity on a line, surface, or volume. Two options are available:

Value	Finds the magnitude of the maximum value of the field.
Position	Finds the point where the maximum field value occurs. You can then: • Plot the maximum field at the point.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Plot field quantities at the point.
- Load the point into the calculator.
- Change the point's location.

To compute the maximum field value:

1. Load a field quantity into the calculator, and perform any necessary operations on it. Keep the following in mind:
   - You cannot find the maximum value of a vector quantity. Therefore, make sure that the result is a scalar.
   - Before computing the maximum value of a complex quantity, you must find the real part of the quantity using the **Cmplx/Real** or **Cmplx/AtPhase** commands.
2. Load a point, line, or volume into the calculator using one of the **Geometry** commands.
3. Do one of the following:
   - Choose **Max/Value** to compute the maximum field value on the geometry.
   - Choose **Max/Position** to identify the point at which this value occurs.

Use the **Eval** command to display the actual maximum field value or the coordinates of the point where it occurs.

Gradient Command

Takes the gradient (∇) of the scalar quantity in the top register.

Ln Command

Takes the natural logarithm (base e) of the scalar quantity in the top register.

Log Command

Takes the logarithm (base 10) of the scalar quantity in the top register.

Takes the mean of the quantity in the top register.

Std Command

Takes the standard deviation of the quantity in the top register.

Vector Commands

The Vector Column contains calculator operations which can only be performed on vector stack entries. Drop-down menus in this column are Scal? (convert vector to scalar) and Unit Vec (create unit vector). Standard vector algebra operations (Dot, Cross, etc.) are also present.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Use these commands to perform operations on vector quantities.

Scal?	Replaces the vector in the top register with a scalar quantity whose value is a component of the vector, your choice of ScalarX, Scalar Y, or ScalarZ.
Matl	Multiplies or divides the vector field quantity in the top register by a material property, or if you select MassDensity as the material property, produces a scalar that operates like a named variable.
Mag	Takes the magnitude of the vector quantity in the top register. The magnitude of a complex vector is defined to be the length of the real vector resulting from taking the modulus of each component of the original complex vector.
Dot	Takes the dot product of the vector quantities in the top two registers.
Cross	Takes the cross product of the vector quantities in the top two registers.
Divg	Takes the divergence of the vector quantity in the top register.
Curl	Takes the curl of the vector quantity in the top register.
Tangent	Computes the tangential component of a vector quantity along a line
Normal	Computes the normal component of a vector quantity on a surface such as a cutplane or object surface.
Unit Vec	Computes the normal or tangent unit vector. The unit vector is a "wild card" entry. The context is specified at the time of plotting, integrating, or report generation. The drop-down lets you select from Tangent, Normal, or CoordSys[X, or Y, or Z]
X Form	Transforms to your choice of Cylindrical or Spherical.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scal? Command

Replaces the vector in the top register with a scalar quantity whose value is a component of the vector. Choose from the following:

ScalarX	Returns the x-component of the vector.
ScalarY	Returns the y-component of the vector.
ScalarZ	Returns the z-component of the vector.

Matl Command

Operates on the vector field quantity in the top register of the Fields Calculator based on a material property. At each tetrahedron, the field quantity is operated on by the value of the selected material property — taking the different material attributes of each object into account.

To operate on a vector quantity by a material property:

1. Click **Matl**.

   The *Material Operation* window appears.

2. Select a material property. Available properties are

Permittivity (epsi)	The permittivity, ε.
Permeability (mu)	The permeability, μ.
Conductivity	The conductivity, σ.
Omega (w)	The angular frequency, ω. The angular frequency is equal to $2\pi f$, where f is the frequency at which the solution was generated.
MassDensity	This is based on the value of the Mass Density material property. MassDensity is treated like a named expression. Selecting MassDensity disables the Operation radio buttons for Multiply or Divide in the *Material Operations* dialog box.

> **Warning:** The Matl command is not compatible with nonlinear material properties.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. For Permittivity, Permeability, Conductivity or Omega, select an operation — **Multiply** or **Divide**. Selecting MassDensity disables these operations. The MassDensity scalar can be used like any other named expression.
4. Choose **OK** to operate on the field quantity by a material property or **Cancel** to stop the operation. If you selected MassDensity and click **OK**, a scalar named expression MassDensity is pushed onto the stack.

Mag Command

Takes the magnitude of the vector quantity in the top register. The magnitude of a complex vector is defined to be the length of the real vector resulting from taking the modulus of each component of the original complex vector.

With a complex vector on the calculator stack, the **Mag** button returns a non-negative scalar. In previous software versions, this command returned a complex scalar.

Dot Command

Takes the dot product of the vector quantities in the top two registers.

Cross Command

Takes the cross product of the vector quantities in the top two registers.

Divg Command

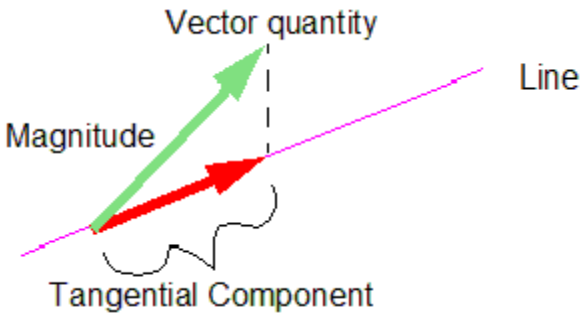
Takes the divergence of the vector quantity in the top register.

Curl Command

Takes the curl of the vector quantity in the top register.

Tangent Command

Computes the tangential component of a vector quantity along a line.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

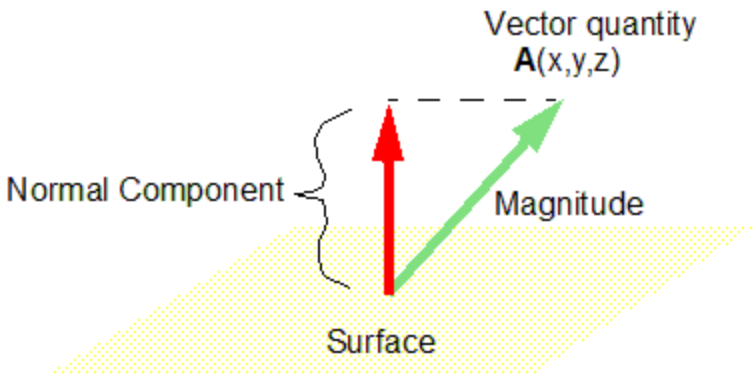
To take the tangent of a vector:

1. Load a vector quantity into the top register.
2. Load a line into the top register using the **Geometry/Line** command.
3. Click **Tangent**.

Normal Command

Computes the normal component of a vector quantity on a surface such as a cutplane or object surface. This is the equivalent of taking the dot product of the quantity with the surface's unit normal vector:

$$Normal = A(x, y, z) \cdot \hat{n}$$



To take the normal of a vector:

1. Load a vector quantity into the top register.
2. Load a surface into the top register using the **Geometry/Surface** command.
3. Click **Normal**.

Note:

Because surface normals of sheets are not well defined the fields calculator can produce incorrect results if an expression is evaluated on a sheet. To enforce the correct direction of the surface normal of a sheet, a faceted 3D object (such as a box) can be defined such that one of its planar faces is coincident with the sheet. Because surface normals of a valid object are always defined in an outward direction in HFSS, the fields calculator uses the surface normal of the face of the 3D object that is coincident with the sheet.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Unit Vec Command

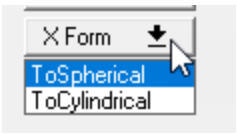
Computes the normal or tangent unit vector. The unit vector is a "wild card" entry. The context is specified at the time of plotting, integrating, or report generation.

Select from the following:

Tangent	Computes the unit vector tangent to the line specified at the time of plotting, integrating, or report generation based on the context.
Normal	Computes the unit vector normal to the surface specified at the time of plotting, integrating, or report generation based on the context.
CoordSys (X)	Computes the unit vector in the X-dimension of the relative coordinate system in the top register of the calculator stack. Add the relative CS as a geometric object using the **Geometry/Coord** command.
CoordSys (Y)	Computes the unit vector in the Y-dimension of the relative coordinate system in the top register of the calculator stack. Add the relative CS as a geometric object using the **Geometry/Coord** command.
CoordSys (Z)	Computes the unit vector in the Z-dimension of the relative coordinate system in the top register of the calculator stack. Add the relative CS as a geometric object using the **Geometry/Coord** command.

X Form

Fields are defined in the Cartesian coordinate system. In many applications it is much more convenient to use a cylindrical or spherical coordinate system – for example, when the object is of cylindrical or spherical shape. The **XForm** command allows the user to transform vectors into either the cylindrical or spherical coordinate system. Selecting **XForm** displays a selection menu for the coordinate system (**ToCylindrical** or **ToSpherical**):

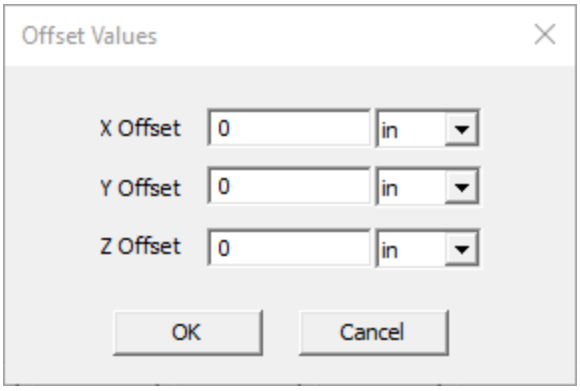


ToSpherical – Transforms the vector in the top register of the calculator stack into the spherical coordinate system.

ToCylindrical – Transforms the vector in the top register of the calculator stack into the cylindrical coordinate system.

After you select the coordinate system you want, the **Offset Values** dialog displays.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Here you enter X, Y, and Z offsets to be used as the origin of the new coordinate system.

Click **OK** to compute the offset coordinate transformation to apply to the (complex) vector quantity in the top register on the calculator stack based on your selection of Cylindrical or Spherical coordinates and your input of X, Y, and Z offsets. The new expression will be pushed onto the stack. This provides the origin of the new coordinate system. It will be something like

CVc : ToCylindrical(<Ex,Ey,Ez>,offset<0mil,0mil,0mil>)

or

CVc : ToSpherical(<Ex,Ey,Ez>,offset<0mil,0mil,0mil>)

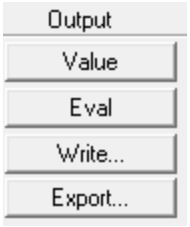
After you transform the quantities, you can then access the vector components in the Fields Calculator.

You will then use the ScalarX/ScalarY/ScalarZ commands under Scal?. For a vector converted to cylindrical coordinates, ScalarX gives the radial component, ScalarY gives the phi (polar) component, and ScalarZ gives the Z component. For a vector in spherical coordinates, ScalarX gives the radial component, ScalarY gives the phi (polar) component and ScalarZ gives the theta (azimuthal) component.

Output Commands

The Output Column contains those calculator operations that result in final data outputs from calculations. The Eval button obtains final numerical results from the last stack placeholder (such as integrations).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Use these commands to compute or evaluate expressions and to output the data in the calculator.

Value command	Computes the value of a field quantity on a geometry.
Eval command	Numerically evaluates and displays the results of calculator operations from the last stack placeholder, such as integrations.
Write command	Saves the contents of the top register to a disk file for future re-use.
Export command	Saves field quantities in a format that can be read by other modeling or post-processing software packages.

To plot/tabulate the extracted data using create report or create field overlays, you should use a named expression.

Value Command

This computes the value of a field quantity at a point. Use it to find:

- The magnitude of a scalar field quantity at that point.
- The x-, y-, and z-components of a vector field quantity at that point.

The **Value** command applies the value of the next-to-top stack entry (a field quantity) on the geometry entry at the top stack entry. The field quantity entry may be scalars, real or complex vectors. The geometry entry may be of any type (point, surface, line, or volume).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For example, if the top stack entry in the Field Calculator is a surface and the second stack register is for the real part of the E Vector ("Real(<Ex, Ey, Ez>)"), the resulting quantity will be an expression for the real part of the E vector on the surface (a VecSrf quantity). Again, the result of this command is still a placeholder expression, not the final numerical values.

Strictly speaking, the Value command provides access to the field quantity, not data outputting. It simply provides a handle to the (numerical) values of a field quantity on a given geometry, and thus the outcome of the command is not numerical values themselves. If the numerical value of a field quantity is desired, you will need to follow it up with one of the three other output commands, or define a named expression for the quantity and plot it with the Reporter.

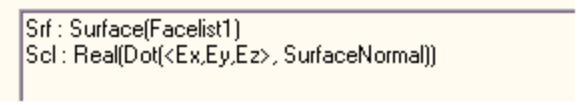
To find the value of a field quantity at a point:

1. Load the field quantity into the top register, and perform any needed operations on it.
2. Load the appropriate point into the calculator using the **Geometry/Point** command.
3. Click **Value**.

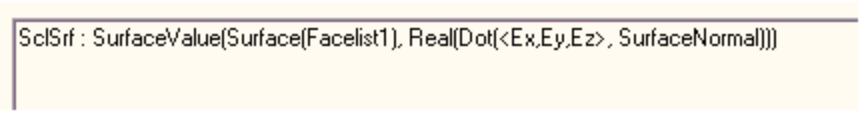
To view the numerical results of this operation, use the **Eval** command.

You can also use the **Value** command to access the intermediate SurfaceValue function.

For example, after inputting an expression for a quantity, such as an E field, and then selecting a surface geometry, the calculator stack displays something like this:



Clicking the **Value** command changes the display to the following, showing the intermediate SurfaceValue function.



In this case, SurfaceValue provides the x, y, z, coordinates of the FEM mesh and Lagrangian points so you can use **Write** to generate an .fld file containing an evaluated scalar quantity at those points.

In general for **Value**:

1. Enter any quantity onto the stack.
2. Enter a volume / surface / line / point onto the stack.
3. Press the **Value** button and you will get an appropriate geometry value on the stack.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

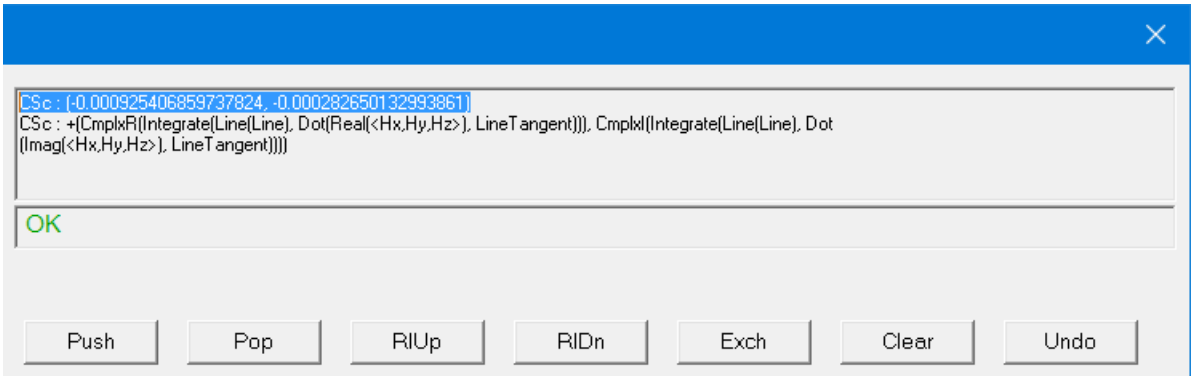
Now you can perform suitable operations such as Write, Integrate, etc. For PointValue you can also do **Eval**.

Eval Command

The **Eval** command finalizes computations and converts the text-string indicating the computation being performed to an actual numerical value. This command numerically evaluates and displays the results of calculator operations such as integrations, maximum or minimum field computations, field values at points, and so forth. For this command to work properly, the stack entry must be reduced to a single-value entry which can be a scalar, complex, or vector (real or complex). The quantity to be evaluated must be in the top register. The **Eval** command computes the numerical results of the operation, which replace the contents of the register. Units of the numerical value are not provided.

For a calculator expression that evaluates to a single value, the **Eval** command offers a quicker way to obtaining the final numerical result than defining a named expression and then trying to plot/tabulate it in the reporter. But for many expressions that don't evaluate to single values, such as the wave impedance along a line mentioned earlier, **Eval** command does not apply. As such, use of named expression and the Report Editor will be the only option.

Evaluate the expression for voltage along a line shows the definition of an expression for the voltage between two conductors by integrating the electric field along a line using the recipe given for Calculating the Current along a Wire or Trace. Then, by clicking the Evaluate command in the Output column, we obtain the numerical value for the voltage as shown in the top of the stack. It can then be either written down or copied/pasted to other programs.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

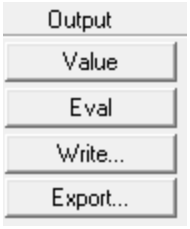
$$I = \oint H \cdot dl$$

Because **H** and **I** are complex quantities, you will need to evaluate the real part of **H** to obtain the real part of **I**, then evaluate the imaginary part of **H** to obtain the imaginary part of **I**. To do this:

1. Load **H** into the calculator using the **Qty** command.
2. Take the real part of **H** using the **Cmplx/Real** command.
3. Load the rectangular loop using the **Geom/Line** command. Create the loop, a closed polyline, to integrate over.
4. Click **Tangent** to get the component of **H** along the line.
5. Take the integral around the loop using the ∫ command.
6. Click **Eval** to evaluate the integral. The real part of **I** appears in the top register.
7. Repeat this process using the imaginary part of **H** (found with the **Cmplx/Imag** command) to obtain the imaginary part of **I**.

Write Command

If the calculator operations performed have obtained a stack entry that is intended for use in still other calculator operations, the stack entry can be saved for this purpose by using the **Write** button in the calculator Output column.



Note that in this case no name will be requested for the expression; only a save filename location will be required. This function will not work for field values derived upon a specific geometric quantity (those containing either Lin, Srf, or Vol in the stack data type indicator) as the calculator cannot know that these geometric quantities exist in identical forms in other postprocessing sessions.

When you try to read a file written with the **Write** command by clicking the **Read** button in the Input column, you must ensure that the mesh used for generating the current solution is the same as the one with which the saved field data is generated. Since the two results must be generated on the same mesh, not only the geometries of the designs on which the **Write/Read** commands were applied must be the same, they must also have gone through the same adaptive meshing process. In practice, this limits the use of Write/Read command to solutions for different frequency sweeps of the same analysis (adaptive) setup of the same design.

This command saves the contents of the top register to a disk file. Use this command to:

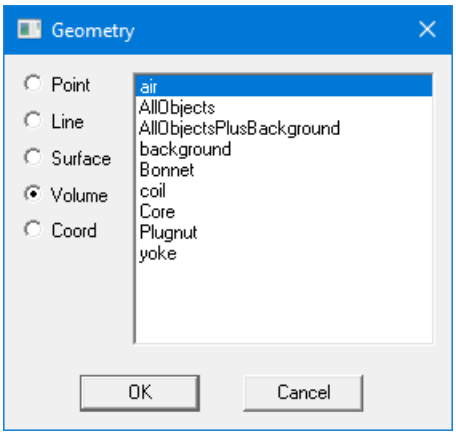
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Save registers for use during a later postprocessing session.
- Save a field quantity for use when postprocessing a different model.

> **Note:**
>
> Use of the Global Coordinate System is assumed. Local coordinate systems are not used.

To save a register:

1. Click **Write**.
2. If the register includes numeric data with a constrained quantity (such as jsurf), you see a dialog box that gives a choice of constraining geometries. For example:



3. Select the geometry of interest, and select **OK**.

   This displays a file browser.

4. Use the file browser to specify the register's file name and directory path. A .reg extension is automatically assigned to register files and a .fld extension is assigned to field files. You can choose to save both .reg and .fld files, or either one.
5. Click **OK**.

   The contents of the register are saved to the file you specified.

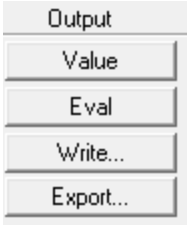
Export Command

To output a field quantity or calculation result for use by some third-party post-processors, use the **Export** button in the calculator Output column. You can map the field quantity to either a customized grid of points specified by a points file or a three-dimensional Cartesian, Cylindrical, or Spherical grid specified interactively through a dialog box. In the latter case, you must specify

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the dimensions and spacing of the grid in the coordinate system with units. For Cylindrical and Spherical coordinate systems, you can also specify an offset from the origin.

The **Export** command opens the **Export Solution** dialog box, from which you can export the field quantity in the top register to a file, mapping it to a grid of points.



Use this command to save field quantities in a format that can be read by other modeling or post-processing software packages. Two options are available for defining the grid points on which to export:

Input grid points from file	Maps the field quantity to a customized grid of points. Before using this command, you must create a file containing the points and units.
Calculate grid points	Maps the field quantity to a three-dimensional Cartesian grid. You specify the dimensions and spacing of the grid in the Cartesian, cylindrical, or spherical coordinates, with units that you specify. The initial units are taken from the model.

> **Note:**
>
> Use of the Global Coordinate System is assumed. Local coordinate systems are not used.

To export a field quantity to a customized grid:

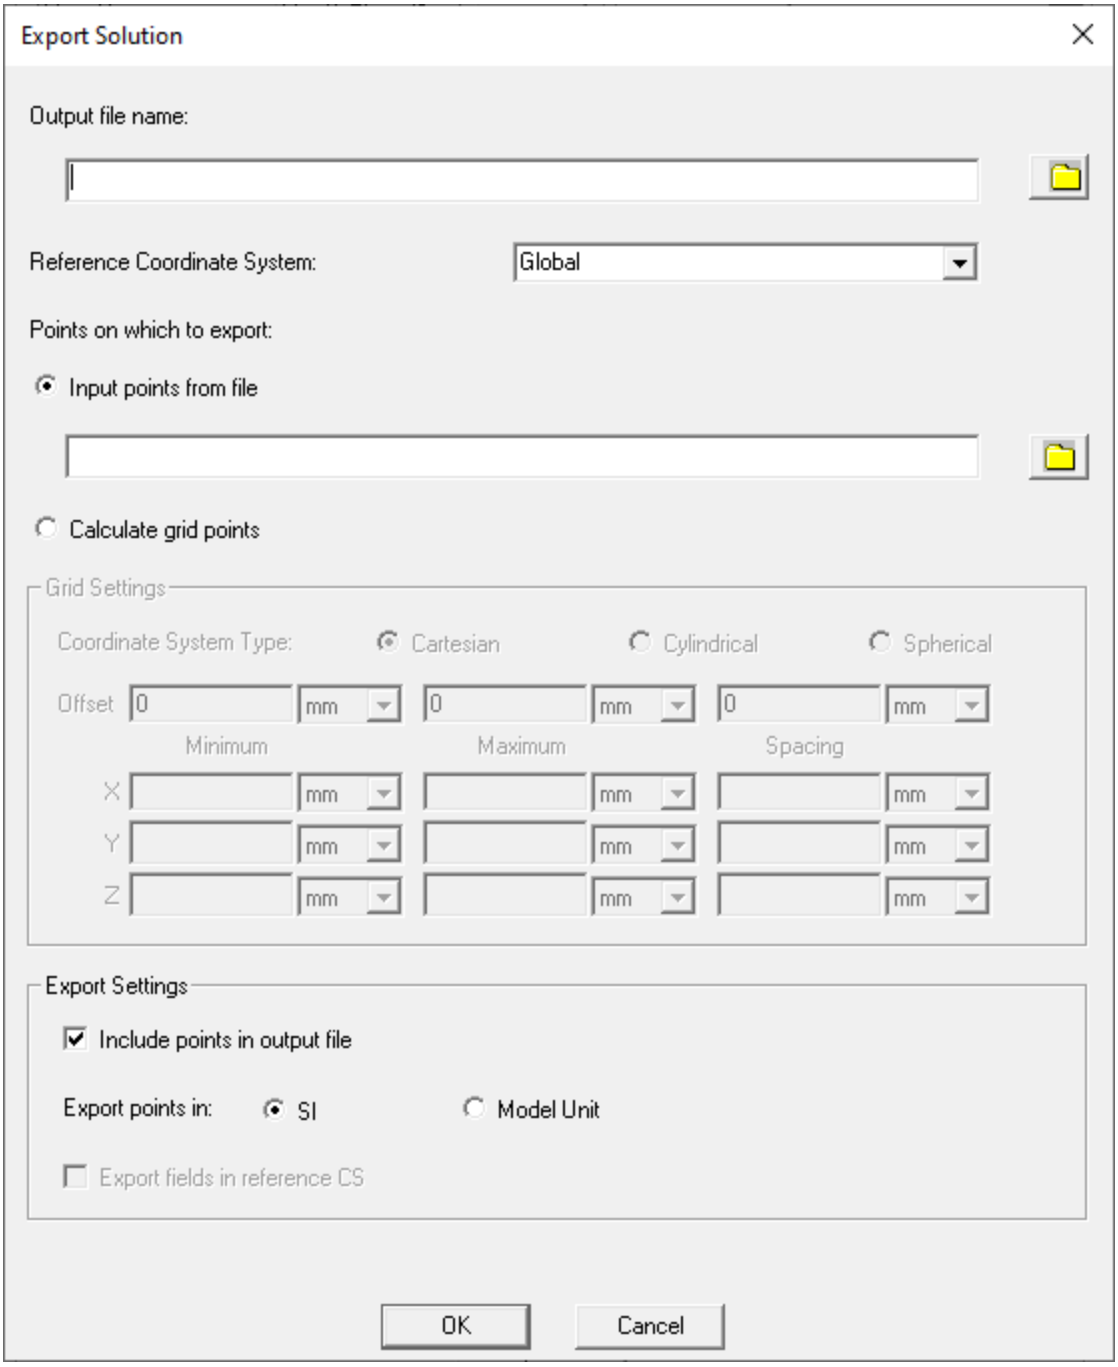
1. Load the quantity into the top register for the fields calculator, and perform any operations on it.
2. If desired, load a volume using the **Geometry** command.

   You can use the Domain command to limit the calculation to the volume you specify. If you export a Domain filtered numeric, points that are filtered out by the domain will not be written out.

3. Click the **Export** button in the Fields Calculator.

   This opens the **Export Solution** dialog box.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



4. Type or select the name of the file in which the field quantity is to be saved in the **Output File Name** text box. You can use the file icon to open the file browser to specify the file name and directory path. The **.fld** extension is automatically assigned to this file.
5. If the design contains multiple coordinate systems, a drop-down menu lets you select the coordinate system to use. This can be helpful in evaluating the fields output when relative

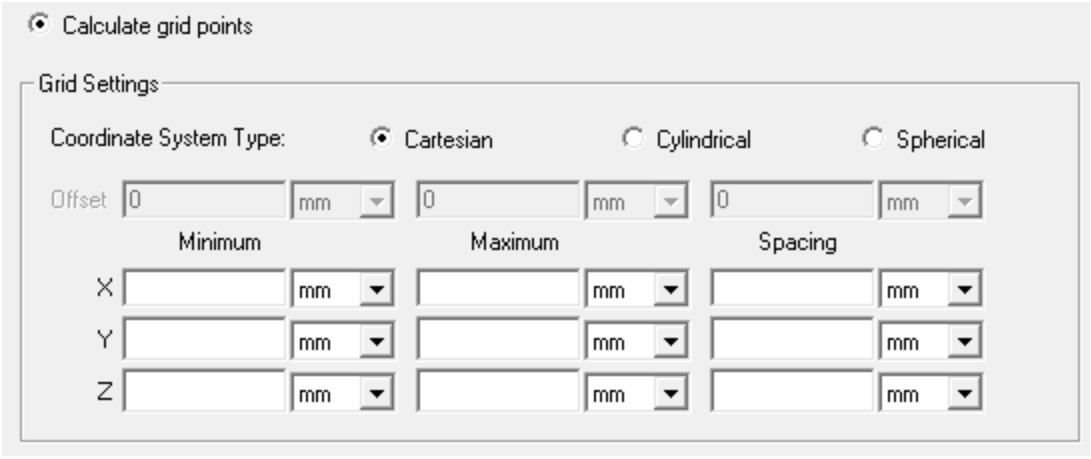
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

coordinate systems used and unitized in the design.

6. Click either the **Input grid points from file** radio button if you have a created a .pts file containing the grid points, or click the **Calculate grid points** radio button.
   - If you select **Input grid points from file**, either type the name and directory of the file containing the points on which the field is to be mapped, or, click on the file icon and use the file browser to locate the point file (**.pts** extension).

     > **Note:**
     >
     > The **.pts** file should contain the units to use for the export as shown in this file stub:
     >
     > Unit=mm
     >
     > -5.5 -5.5 -5.21475
     >
     > -5.5 -5.5 -5.14425
     >
     > -5.5 -5.5 -5.07375
     >
     > -5.5 -5.5 -5.021

   - If you select **Calculate grid points** button, you can specify the coordinate system as Cartesian, Cylindrical, or Spherical.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cartesian: for each grid dimension on **X**, **Y**, and **Z**, enter the Minimum, Maximum, and grid point spacing.

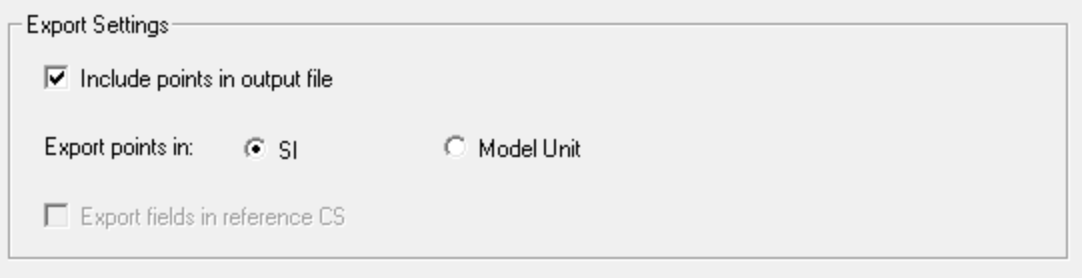
Cylindrical: for each dimension Rho, Phi, and Z, enter the Minimum, Maximum, and grid point Spacing. You can also specify an origin of Offset.

Spherical: for each dimension R, Theta, and Phi, enter the Minimum, Maximum, and grid point Spacing. You can also specify an origin of Offset.

> **Note:** When you export fields on a 1D or 2D line/surface from the field calculator, the start and stop values must be the same for one or two of the coordinate system start/stop ranges. If you specify a zero spacing for a dimension, the export uses only the minimum value.

The default coordinate system will be Cartesian. The default offset will be all zeroes. The length units will default to model unit and default angle unit will be degree. At the start the minimum/maximum/Spacing entries are blank. The user entered values are not remembered when the dialog is closed.

7. For larger files, for the Export Settings, you may want to uncheck the **Include points in output file** box. If you uncheck the box, the file header will include minimum, maximum and spacing information from which you can recalculate the grid points.
8. You can also specify SI or Model Units. Model Units can be helpful to evaluate the fields output when relative coordinate systems are unitized in the design.



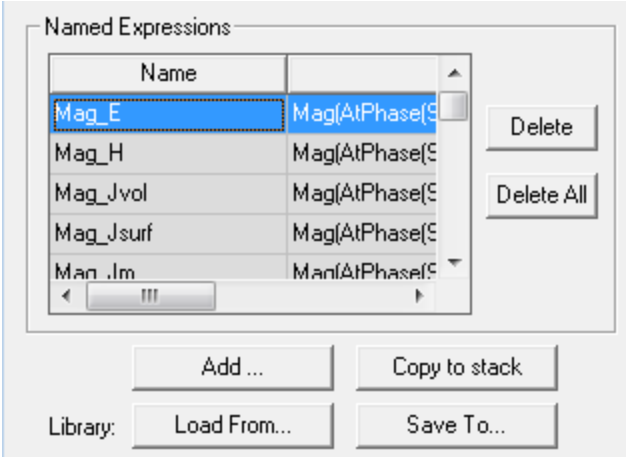
9. If field to be exported has type vector or complex vector, the 'Export Field in reference CS' checkbox is enabled and you can specify that field to be exported in reference CS. It can be helpful to evaluate the fields output when rotated coordinate systems are unitized in the design
10. Click **OK** to export the file.

    The field quantity is mapped to the grid and saved to the file you specified (**.fld** extension).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Calculating Derived Field Quantities Using Named Expressions

The **Named Expressions** panel displays expressions that can be included in register definitions by name. You can add additional expressions to the Named expression list by creating the expression in the register display area and then clicking the Add button. This lets you add to the Named expression library.



Click on a named expression to select it. When a named expression has been selected, the **Copy to Stack** button is activated. Click **Copy to Stack** to push the expression on the top of the stack.

When an HFSS design is open and a Solution Setup has been performed, the following predefined named expressions are available.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Expression Name	Expression Definition
Mag_E	Mag(AtPhase(Smooth (<Ex,Ey,Ez>),Phase))
Mag_E_t	Mag(Smooth(<E_tx,E_ty,Etz>)). Used with Transient projects.
Mag_H	Mag(AtPhase(Smooth (<Hx,Hy,Hz>),Phase))
Mag_H_t	Mag(Smooth(<Hx,Hy,Hz>). Used with Transient projects.
Mag_Jvol	Mag(AtPhase(Smooth (<JVx,JVy,JVz>),Phase))
Mag_Jsurf	Mag(AtPhase(Smooth (<Jsurfx,Jsurfy,Jsurfz>),Phase))
Mag_Jsurf_t	Mag(<Jsurf_tx,Jsurf_ty,Jsruf_ tz>). Used with Transient projects.
ComplexMag_E	Mag(CmplxMag(Smooth (<Ex,Ey,Ez>))
ComplexMag_H	Mag(CmplxMag(Smooth (<Hx,Hy,Hz>))
ComplexMag_Jvol	Mag(CmplxMag(Smooth (<JVx,JVy,JVz>))
ComplexMag_Jsurf	Mag(CmplxMag(Smooth (<Jsurfx,Jsurfy,Jsurfz>))
Vector_E	AtPhase(Smooth (<Ex,Ey,Ez>),Phase)
Vector_E_t	(Smooth(<E_tx,E_ty,E_tz>). Used in Transient projects.
Vector_H	AtPhase(Smooth (<Hx,Hy,Hz>),Phase)
Vector_H_t	(Smooth(<H_tx,H_ty,H_tz>). Used in Transient projects.
Vector_Jvol	AtPhase(Smooth (<JVx,JVy,JVz>),Phase)
Vector_Jsurf	AtPhase(Smooth(<Jsurf_ x,Jsurf_y,Jsurf_z>),Phase)
Vector_Jsurf_t	(Smooth(<Jsurf_tx,Jsurf_ ty,Jsurf_tz>). Used in Transient projects.

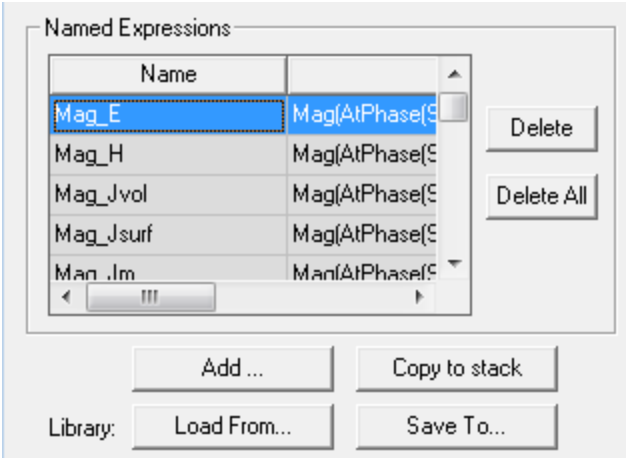
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Vector_RealPoynting	Real(Poynting)
VectorReal_Poynting_t	Poynting_t. Used in Transient projects.
Local_SAR	LocalSAR
Average_SAR	AverageSAR
Surface_Loss_Density	SurfaceLossDensity. See further discussion here.
Volume_Loss_Density	VolumeLossDensity. See further discussion here.
Volume_Loss_Density_t	VolumeLossDensity_t. Used in Transient projects.
Surface_Force_Density	Surface Forces exist when one side is conductor, but the other is not, or finite conductivity and layered impedance boundary. This is mainly for the purpose of mapping surface force density in HFSS to Workbench Mechanical. For details on the calculations, see the technical notes.
Mag_Displacement	Mag(Smooth(<Ux,Uy,Uz>)). Magnitude of displacement, used with Workbench in projects exploring stress feedback.
Displacement_Vector	Smooth(<Ux,Uy,Uz>). Used with Workbench in projects exploring stress feedback.

Named Expression Library

The named expression library in the Fields Calculator provides a way to conveniently calculate frequently used quantities. Some standard field quantities have been predefined and are always accessible. These field quantities have a gray background color and cannot be deleted. You can assign a name to the top entry of Data Stack and add it in the Named Expression list. The library comes with several predefined expressions. Once these new expressions are added/loaded, they are available through HFSS's standard post-process capabilities. For example, they can be copied back to the Data Stack in calculator by **Copy to Stack** for further operations, or be plotted using Report Editor and Field Overlay.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You can combine calculator Input commands in any legal fashion, including complex quantities, to produce new named expressions.

- Adding named expressions to the Fields Calculator expression library
- Copying named expressions to the Calculator Stack
- Saving named expressions to a Personal Library
- Loading named expressions
- Deleting named expressions that you added

To add a named expression of your own to the Fields Calculator list:

1. In the register display area, create the expression by using the calculator Input commands.

   You can combine input commands in any legal fashion, including the use of complex quantities. If you select an input command that is not legal for a current operation, you receive an error message.

2. When you finish creating the expression, click **Add** in the *Named Expressions* panel.

   The *Named Expression* dialog box appears.

3. Type a name for the expression in the **Name** text box.

   The new expression is added to the list of named expressions.

To copy a named expressions to the Calculator Stack:

- You can scroll through the list, select any desired named expression, and click **Copy to Stack** to move it to the calculator stack, where you can use it to generate calculated outputs.

To delete named expressions that you added:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When the *Named Expression* list contains one or more user-defined expressions, the **Delete** and **Clear All** buttons are active. (You cannot delete or clear the predefined named expressions.)

- To delete the selected user-defined named expression, click **Delete**. To delete all user-defined named expressions, click **Clear All**.

To save one or more named expressions for the Fields Calculator to a personal Library:

1. Click **Save To** on the Fields Calculator.

   The *Select Expressions for Saving* dialog box displays.

2. If any new named expressions exist, you can select one or more to save to a file.
3. Specify a file name and click **OK** to save the file.

To load named expressions for the Fields Calculator from a personal library:

1. From the Fields Calculator, click **Load From**.

   This displays a file browser that you can use to search for existing .clc files.

2. Select the library to load and click **OK**.

   This loads the expression file you have selected.

Exiting the Fields Calculator

Click **Done** to exit the Fields Calculator.

Fields Calculator Recipes

The following pages contain calculator recipes for deriving a number of commonly used output parameters from solved HFSS projects.

Calculating Numerical Quantities

Calculating the Current along a Wire or Trace

"Calculating the Voltage Drop along a Line" on page 23-478

"Calculating Net Power Flow through a Surface" on page 23-479

"Calculating the Average of a Field Quantity on a Surface" on page 23-480

"Calculating the Peak Electrical Energy in a Volume" on page 23-482

"Calculating the Q of a Resonant Cavity" on page 23-483

"Calculating the Max Value of a Field Quantity in a Volume" on page 23-485

Calculating Quantities for 3D (Volume) Plot Outputs

"Generating an Iso-Surface Contour for a Given Field Value" on page 23-492

Calculating Quantities for Animated Outputs

"Generating an Animation on Multiple Planes with a Positional Variable" on page 23-493

Creating User Defined Named Expressions Library

"Generating Cartesian/Cylindrical/Spherical-Coordinate Field-Components Library" on page 23-494

Recipe Format

Each calculator recipe will be provided in the format shown below:

EXAMPLE: Title of Current Calculation

Description

The first paragraph will give a brief description of the calculation's intent.

Usage Examples

The second paragraph will give an example of a project type on which the calculation might be useful. It may also comment upon the reasons such a calculation might be of interest.

Prerequisites

The third (optional) paragraph will indicate what must be present before doing the calculator operations, e.g., if certain geometry need to be generated to use in calculations.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Calculator Operation	Resulting Stack Display (top entry only unless noted)
Each button click shown as a step	resulting stack entry/type
drop-down menu>Submenu pick also shown as a single step	Scl: {placeholders for numerical results shown in brackets}
Button steps requiring data entry will have entry quantity shown in {brackets}	resulting stack entry/type (*notes follow in italics)*

Calculating the Current along a Wire or Trace

Description

Obtains the full complex current in a wire or trace conductor (e.g., microstrip, stripline) at a specific location by integrating the magnetic field along a closed path encircling the conductor. .

$$I = \oint_l \vec{H} \cdot \vec{dl}$$

where *l* is a closed path, which could be a circled line object

Usage Examples

To find the current distribution along a wire (dipole, monopole, etc.) antenna, this calculation could be repeated at periodic positions along the length of the antenna.

Prerequisites

You must create a closed line for the integration path using **Draw>Line** before beginning calculator operations. The line must be orthogonal to the direction of current flow, should not intersect the wire/trace, and should not be too much bigger than the wire/trace.

+	CSc: (CmplxR(Integrate(Line(Line1),Dot(…))), CmplxI(Integrate (Line(Line1),Dot(…))))
Eval	CSc : {complex numerical value} *(Final complex current result)*

Calculating the Voltage Drop along a Line

Description

Provide the complex voltage drop, in volts between two points by integrating the E-field along a line.

$$V = \int_{l} \vec{E} \cdot \vec{dl}$$

where *l* is a path between two points on which voltage difference are measured. Usually it is a straight line object.

Usage Examples

To find the voltage excited across the width of a slot antenna element; to test whether a voltage exceeds breakdown in a particular dielectric media.

Prerequisites

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You must create the line along which the E-field is to be integrated using **Draw>Line** before you can complete the calculator routine.

Calculator Operation	**Resulting Stack Display (top entry only unless noted)**

+	CSc: (CmplxR(Integrate(Line(Line1),Dot(…))),CmplxI(Integrate (Line(Line1),Dot(…))))
Eval	CSc : {complex numerical value} (*Final complex voltage result*)

Calculating Net Power Flow through a Surface

Description

This recipe allows calculation of power flow through an open or closed surface by integrating the Poynting vector normal to that surface.

$$W = \int_S Re(\vec{P}) \cdot \vec{n} dS$$

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where *S* is the surface that is used to calculate the power, and $\hat{n}$ is the normal vector to the surface *S.*

Usage Examples

This calculation could be used on scattered field data resulting from an incident wave excited HFSS project to evaluate reflection from a radome filter or FSS (frequency selective surface). It might also be used on the closed exterior surface of a solid volume to determine power dissipation within the volume (due to conservation of energy, what goes in a closed surface must come out, unless there is a loss or storage [e.g., standing wave, resonance] mechanism).

Prerequisites

The surface on which the integration is to be performed must exist prior you can complete the calculation. If the surface is the exterior of a solid object, no customer geometry creation is necessary. If the surface is only a subset of an object's faces, or a slice through the entire plane of the model not already defined by a separate 2D entity, then you must create a Faces List and/or Cutplane to represent the integration location.

Calculator Operation	**Resulting Stack Display (top entry only unless noted)**
Quantity>Poynting	CVc : Poynting
Complex>Real	Vec : Real(Poynting) (*discards the unneeded imaginary component*)

Normal	SclSrf : SurfaceValue(Surface(Facelist1), Dot(Real(Poynting), SurfaceNormal) *(takes the dot product of the vector data with the normal to the surface(s) selected*)
$\int$	Scl : Integrate(Surface..)
Eval	Scl : {numerical value} (*final answer in **watts***)

Calculating the Average of a Field Quantity on a Surface

Description

This recipe permits you to calculate the average of a field quantity on a Surface geometry, by dividing the Integration of the field value on the surface by the surface area.

Usage Examples

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This calculation could be used to determine the average phase of the E-field at a given cutplane through a project, to find the average current on a trace surface, or to calculate the average H-field tangential to a 2D object used as an aperture. The specific example steps below will be for the first usage example mentioned (average phase of an E-field on a surface), but the format for integration on a surface and for finding the area of the surface is identical for the other applications as well.

Prerequisites

The surface on which the integration is to be performed must exist. If the surface is the exterior of a solid object, no customer geometry creation is necessary. If the surface is only a subset of an object's faces, or a slice through the entire plane of the model not already defined by a separate 2D entity, then you must create a Faces List and/or Cutplane to represent the integration location.

Eval	Scl : {numerical value} (*for this example units are in* ***deg*** *or* ***radians***)

Calculating the Peak Electrical Energy in a Volume

Description

This recipe permits you to calculate the peak electrical energy in a volume object. The solution is achieved by integrating **E E** within the volume.

$$W = \int_V \frac{\epsilon_r \epsilon_0 (\vec{E} \cdot \vec{E}^*) dV}{2}$$

where *V* is the volume.

Usage Examples

This calculation could be used to determine the average total energy with respect to time in a terminating resonant cavity. (In a sealed, one-port structure at resonance, energy is converted back and forth between the electrical and magnetic fields, but maintains the same total quantity; therefore, the peak electrical energy is equal to the average total energy.)

Prerequisites

The volume object which the integration is to be performed must exist before the computation can be completed. If the volume for integration consists of the volume of several drawing objects, you must create a single list entry representing their combined volumes using **Modeler** > **Named Selection** > **Create** > **Object Selection**.

Calculator Operation	Resulting Stack Display (top entry only unless noted)

Calculating the Q of a Resonant Cavity

Description

This recipe permits you to calculate the Q in a homogeneous dielectric-filled cavity with uniform wall losses, using the equation:

$$Q_u = \frac{\int_{\Omega} |\mathrm{H}|^2 d\Omega}{\frac{s}{2}\oint_{\Gamma} |\mathrm{n} \times \mathrm{H}|^2 d\Gamma + tg\delta\left(\int_{\Omega} |\mathrm{H}|^2\right) d\Omega}$$

where *s* is skin depth, *tg* is dielectric loss tangent, *n* is the surface normal for the cavity wall faces, and and represent wall surface area and cavity volume, respectively.

Usage Examples

To calculate the Q of an air- or solid-dielectric filled cavity, fed with a below-cutoff port aperture, or obtained via an eigen solution.

Prerequisites

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The object (or object selection) representing the cavity total volume must already exist, as must the face selection corresponding to the total wall surface area of the cavity. You can create both via the Modeler menu. The solution should be tuned to the desired resonant frequency for evaluation.

Calculator Operation	**Resulting Stack Display (top entry only unless noted)**
Quantity>H	CVc : <Hx, Hy, Hz>
Push	*(above entry duplicated)*
Complex>Conj	CVc : Conj(<Hx, Hy, Hz>)
Dot	CSc : Dot(<Hx, Hy, Hz>, Conj(...
Complex>Real	Scl : Real(Dot(<Hx, Hy, ...
Geometry>Volume>{select cavity volume}	Vol : Volume(cav_total) (*above is example; user entry may differ*)
∫	Scl : Integrate(Volume(cav... (*above represents energy stored in cavity*)
Push	*(above entry duplicated)*
Number>Scalar>{enter loss tan for volume}	Scl : {numerical value} (*loss tangent for dielectric fill in cavity*)

The above equation is ***only*** valid for cavities filled with one dielectric material across the entire volume. For cavities with different dielectric fills (e.g., a dielectric resonator within a larger metal cavity), dielectric loss must be evaluated using integration by parts for each dielectric material volume. The equation also assumes the same conductivity for all walls, and no nonreciprocal (e.g., ferrite) property to either walls or fill.

Calculating the Max Value of a Field Quantity in a Volume

Description

This recipe permits you to calculate the Max electrical field (value or position) in a volume object.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Usage Examples

This calculation could be used to determine the Max (or Min) value (or position) of electrical field in a resonant cavity or dielectric object. Find out the hot (or quiet) spot value and location.

Prerequisites

The volume (or surface) object within which the Max function is to be performed must already exist before the computation can be completed. If the volume (or surface) for Max function consists of the volume of several drawing objects, you first create a single list entry representing their combined volumes using **Modeler>List>Create>Object (or Face) List**.

Calculator Operation	Resulting Stack Display (top entry only unless noted)
Named Expressions>Mag_E>Copy to stack	Scl : Mag_E (Mag_E *is used as an example*)
Geometry>Volume..> {select volume}	Vol : Volume(box1) (*above is example, user entry may differ*)

Eval	Scl : {numerical quantity}

Calculating Dielectric (or Conduction) Loss in a Volume

Description

This recipe shows you to calculate the dielectric/conduction loss in a volume object.

Usage Examples

This calculation could be used to determine the loss in a dielectric or metal object. For loss dielectric or finite conductivity metal object, its loss may have significant impact on user"s design performance. Find out the key loss factors is critical for a successful design.

Prerequisites

The volume object within which the loss calculation is to be performed must already exist before the computation can be completed. If the volume for loss calculation consists of the volume of several drawing objects, you must create a single list entry representing their combined volumes using **Modeler** > **Named Selection** > **Create** > **Object Selection**.

Eval	Scl : {numerical quantity} (*above is loss from box1, either dielectric or conductional, **Watt***)

Plotting Wave Impedance along a Line

Description

This recipe generates a 2D plot of wave impedance in ohms vs. length for a line geometry. Wave impedance is obtained directly by taking the ratio of the transverse components of the electric field to the ratio of the transverse components of the magnetic field.

$$Z = \frac{E_o^-(x)}{H_{\bar{o}}(x)}$$

Where $E_o^-(x)$ is the transverse component of the electric field, and $H_{\bar{o}}(x)$ is transverse component of the magnetic field.

Usage Examples

This calculation could be used to display wave impedance vs. position along a length of waveguide with a changing cross-section. It could also be used to display the changes in wave impedance in free space at some boundary (e.g., frequency selective surface, radome) when performed on an incident wave problem.

Prerequisites

The line along which the impedance is to be plotted should be defined before performing this calculation. You can generate a line using **Modeler>Draw>Line**.

Plotting the Phase of E Tangential to a Line/Curve

Description

This recipe generates a 2D plot of the phase of an E-field whose vector component is tangential to a line. The line may also be a curve (faceted polyline).

Usage Examples

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This calculation could be used to display the change in phase of the E field tangential to a circular path within a cylindrical dielectric resonator, when used on either a driven or eigensolution problem. Identifying the phase change along this curved path is often necessary to determine the mode index (e.g., Mode 10) which a particular eigensolution or S-parameter resonance represents.

Prerequisites

You must define the line along which the phase is to be plotted before performing this calculation. Use the **Modeler>Draw>Line** command.

Calculator Operation	**Resulting Stack Display (top entry only unless noted)**

Plotting the Maximum Magnitude of E Tangential to a Line/Curve

Description:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This recipe generates a 2D plot of the maximum magnitude of an E-field tangential to a line. The line may also be a faceted curve. The maximum magnitude is not necessarily tied to the same input phase value along the length of the line.

Usage Example(s):

This calculation could be used to display the maximum magnitude of an E-field at all points along a line or curve in a transmission line structure, where it is the maximum magnitude and not the magnitude along the line corresponding to a single „snapshot in time" (single port excitation phase) that is of interest. Such data could be used to determine whether the present design might exceed dielectric breakdown voltage in a particular location.

Prerequisites:

You should define the line along which the field data is to be plotted before performing this calculation. Use the **Modeler>Draw>Line** command.

Calculator Operation	**Resulting Stack Display (top entry only unless noted)**
Quantity>E	CVc : <Ex, Ey, Ez>

Plotting the E-Field Magnitude Normal to a Surface

Description

This recipe generates a scalar intensity plot of the E-field magnitude normal to a particular surface (or group of object surfaces, list of object faces), relative to a given input phase excitation. where *S* is the surface geometry, and is the normal vector to the surface *S.*

Usage Examples

This calculation could be used instead of the automatic Plot→Fields→MagE upon surface, when only the magnitude of the E-field with a particular vector orientation is desired. For example, to evaluate the field available for coupling to a probe structure with a particular orientation.

Prerequisites

You should create the plane to which the desired field component should be normal before you begin the following steps. Use **Modeler** > **Draw** > **Plane**, or **Modeler** > **Named Selection** > **Create** > **Faces List**, or **Modeler** > **Draw** > **Rectangl**e (or other 2D sheet).

Calculator Operation	Resulting Stack Display (top entry only unless noted)
Quantity>E	CVc : <Ex, Ey, Ez>
Function>Phase	Scl : Phase
Complex>AtPhase	Vec : AtPhase(<Ex,Ey,Ez>, Phase)
Geometry>Surface>{select desired cutplane, faces list, or surface list}	Srf : Surface(faces1) *(faces1 used as example)*
Unit Vec>Normal	Vec : SurfaceNormal
Dot	Scl : Dot(AtPhase (<Ex,Ey,Ez>,Phase),…)
Add Type: E_normal OK	E_normal : Dot(AtPhase (<Ex,Ey,Ez>,0),… (*User defined Named Expression E_normal is added*)
Done	{*exit field calculator window*}
Select the surface (or list) **HFSS** > **Fields** > **Plot**	{Scalar Plot on faces displayed}

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Calculator Operation	Resulting Stack Display (top entry only unless noted)
Fields > **Named Expression** Select E_normal	*(E-field normal component value in* ***v/m)***

Generating an Iso-Surface Contour for a Given Field Value

Description

This recipe generates a geometry entry called an IsoSurface which represents the surface upon which a selected scalar field quantity has a single value. This surface can be displayed, or used in later operations (to plot other quantities upon, etc.).

Usage Examples

This calculation could be used to locate regions of excessive field magnitudes for voltage breakdown or ohmic heating analysis. It could also be used to generate a desired isosurface to be used as an integration surface for another quantity.

Prerequisites

You should plot of the field quantity of interest to determine the isovalue to use. Isovalues should be entered in MKS units (e.g., V/m, A/m) unless the problem is an eigen solution, in which case all field values are normalized to a peak of 1.0.

Calculator Operation	Resulting Stack Display (top entry only unless noted)
Quantity>E	CVc : <Ex, Ey, Ez> (*IsoSurfaces for other quantities can also be created; E used as example*.)
Smooth	CVc : Smooth(<Ex,Ey,Ez>) (*as this routine generates a surface geometry object, data smoothing is recommended*)
Function>Phase	Scl : Phase
Complex>AtPhase	Vec : AtPhase(Smooth(<Ex,Ey,Ez>),Phase)
Scal>ScalarX	Scl : ScalarX(AtPhase(Smooth(<Ex,...
Add... Type: E_x OK	E_x: ScalarX(AtPhase(Smooth<Ex,… (E_x *is used here as an example; you can apply other quantity*)
Done	{*exit field calculator window*}
Highlight the geometry	{*Scalar Plot in the geometry displayed*}

Calculator Operation	Resulting Stack Display (top entry only unless noted)
HFSS>Fields>Plot Fields>Named Expression Select E_x	*(E-field x-component value in **v/m**)*
HFSS>Fields>Modify Plot Attribute… Select the plot OK **Scale** tab: Num. Division: *1* Use Limits: *100 (as an example)* **Plots** tab IsoValSurface checked Apply	{*IsoSurface contour is displayed*}

Generating an Animation on Multiple Planes with a Positional Variable

Description

This recipe generates animated field output in which each frame is a snapshot of the fields on a different plane of the modeled volume. Any derived field quantity could be plotted in this manner, but this example will simply use the E-field magnitude at zero degrees input excitation.

Usage Examples

This calculation permits you to generate animated output results in addition to those automatically available from the post-processor. For example, peak E field (E dot E conjugate) could be plotted at multiple planes in sequence.

Prerequisites

This operation will only work in the global coordinate system if you are using X, Y, or Z positions as the animation variable.

Calculator Operation	Resulting Stack Display (top entry only unless noted)
Quantity>E	CVc : <Ex, Ey, Ez> (*Animations for other quantities can also be created; E used as example*.)
Smooth	CVc : Smooth(<Ex,Ey,Ez>)
Number>Scalar>”0”	Scl : 0

HFSS>Fields>Plot Fields>Named Expression (E_mag0)	*(Plot named expression on YZ plane)*
HFSS>Fields>Plot Animate>New	{*launches Animation Plot Settings*}
Swept variable Normalized Distance OK	{*displays animation*}

Generating Cartesian/Cylindrical/Spherical-Coordinate Field-Components Library

Description

This recipe demonstrates the steps to export user-defined named expressions into a library which can be loaded into and reused in other designs or projects.

Usage Examples

This calculation allows you to generate named expressions in addition to those automatically available ones in the field calculator, and save them as a user library, and reload into other designs/projects for use. For example, Cartesian components of E field are used for demonstration.

Prerequisites

Since this recipe is intended to generate generalized user-defined named-expressions, this operation should not be geometry-related.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Radiated Fields Observation Regions

To analyze the radiated fields associated with a design, define a radiation surface over which the fields will be calculated. Such a surface can be a boundary radiation surface, a geometry, or a custom radiation surface which you define as a face selection. The values of the fields over this surface are used to compute the fields in the space surrounding the device. This space is typically split into two regions — the near-field region and the far-field region. The near-field region exists at less than a wave length from an energy source. The far field is where radiation occurs. See Radiated Fields for the specific equations used in HFSS for calculating the near and far field regions.

You can define a **spherical surface** over which to analyze the **near** or **far** fields by specifying a range and step size for phi and theta, or as Az over El or El over Az. This defines the spherical direction in which radiated fields will be evaluated. If you manually enter Phi or Theta component of a far field quantity when you using Az/El or El/Az far field definition, then the Report uses the Z axis of the Az/El or El/Az coordinate system definition as pole to calculate theta/phi component for rE. You can define a **box** over which to analyze **near fields** by specifying a coordinate system, length, width, height, and samples. You can define a **rectangle** over which to analyze **near fields** by specifying sample number for length and width. You can also draw a **line** along which to calculate the **near fields**.

You can also specify arbitrary near field sample point locations in the Global (or a specified Local) XYZ coordinate system as an external **point list**.

You also may need to edit the Global Material Environment in consideration of the far fields calculation.

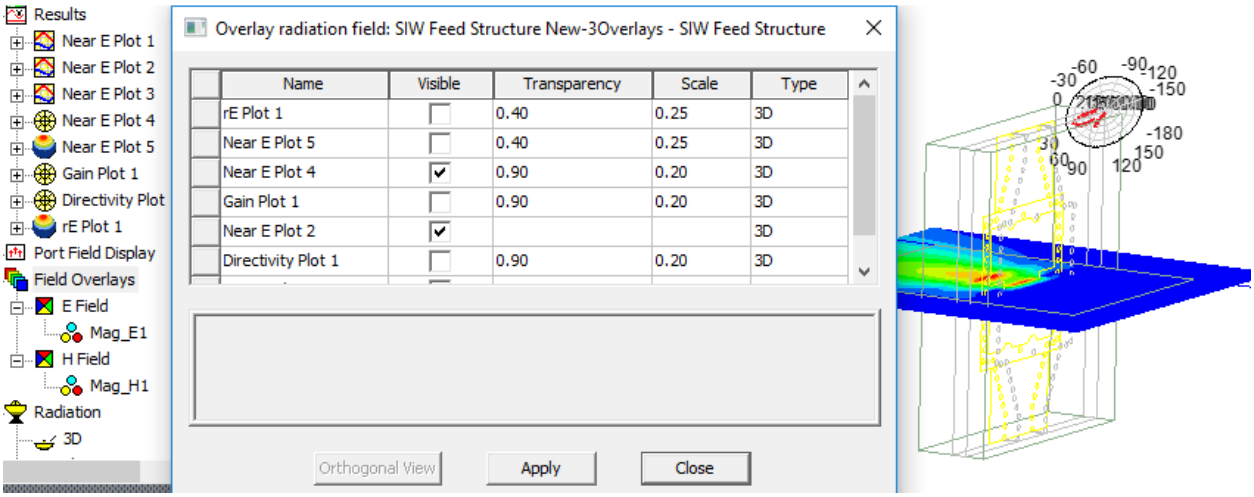
Optionally, after defining the radiation surface, HFSS can compute antenna array radiation patterns and antenna parameters for designs that have analyzed a single array element. HFSS models the array radiation pattern by applying an "array factor" to the single element's pattern when far fields are calculated. You set up the array factor information by defining either a finite, 2D array geometry of uniformly spaced, equal-amplitude elements (a regular array) or an arbitrary array of identical elements distributed in 3D space with individual complex weights (a custom array.)

If the design contains finite arrays, you have the option to create a Source group under the Radiation folder in the Project tree. The Source Group lets you activate a subset of the virtual excitations (e.g. array[5,5]port1:2 …) instead of the physical excitations associated with the unit cell(s).

HFSS can also compute antenna parameters, such as the maximum intensity, peak directivity, peak gain, and radiation efficiency. For near-field analysis, HFSS can also compute maximum parameters, such as the maximum of the total E-field and the maximum E-field in the x-direction. For FEM-only designs, you can optionally set the Radiated Power Calculation method.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once your have created reports, you can overlay appropriate reports on the modeler window. You can overlay multiple Results plots for radiation fields at the same time and in conjunction with other Field Overlays,and antenna parameter overlays.



Note:

When computing near and far fields, keep in mind that you must have defined at least one radiation or PML boundary in the design. You may change the radiation surfaces that HFSS uses when calculating the radiated fields at any time without needing to re-solve the problem, but the radiation-type boundary is still required.

Setting up a Near-Field Sphere

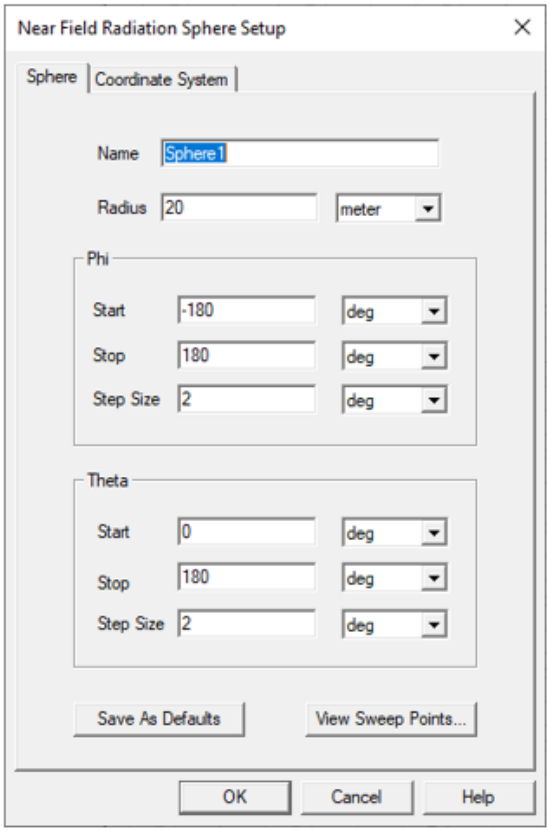
To evaluate near fields on a spherical surface, set up a near-field sphere. Near fields are evaluated at a fixed finite distance from the radiating device. You can use the near-field sphere setup to create near-field reports.

1. To create a near-field sphere setup, click **HFSS** > **Radiation** > **Insert Near Field Setup** > **Sphere** to bring up the **Near Field Radiation Sphere Setup** dialog box. If the design is Modal/Terminal Solution type the dialogue will include a **Radiation Surface** tab. If the design is HFSS SBR+ or includes SBR+ Hybrid Regions, the dialogue does not include the **Radiation Surface** tab because with SBR+ designs, the Radiation surface is defined or selected before simulation using the Field Observation Domain pane in the **SBR+ Solution** setup **Options** tab or the **Hybrid** tab of an HFSS Modal or Terminal setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modal/Terminal

SBR+



2. Use the **Sphere** tab define the **Name**, **Radius**, and sampling of **Phi** and **Theta** for the near-field sphere. The radius is measured from the origin of the sphere's coordinate system, which you specify under the **Coordinate System** tab. You can assign a variable to the radius, and a post-processing variable will often make sense in this context.

   Specify the sphere's sampling in terms of **Start**, **Stop**, and **Step Size** angles given in radians or degrees. To verify your settings, use the **View Sweep Points** button to display a list of the theta and phi sweep points. See Spherical Cross-Sections in the **Technical Notes** for guidelines for setting phi and theta.

   You can use **Save as Defaults** to set the current values as the default for new near-field sphere setups.

3. Use the **Coordinate Systems** tab to specify the orientation of the sphere.

   Use global coordinate system is selected by default, but in some cases the orientation of the antenna requires the use of a local coordinate system. In this case, select **Use local coordinate system**, and choose a local coordinate system that you created previously in the modeler.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. For HFSS Terminal or Modal without Hybrid regions, use the **Radiation Surface** tab to select the solved surface from which to calculate radiated fields.

   Use Boundary Radiation Surfaces is selected by default, indicating that the radiated fields will be calculated using the assigned radiation or PML surface. For some models you may find it it more efficient and/or accurate to use an interior surface. In this case, select **Use Custom Radiation Surface**, and choose a face selection that you previously created in the modeler.

> **Note:**
>
> You must have defined at least one radiation or PML boundary in the design for HFSS to compute near-field quantities, regardless of which radiation surfaces you instruct HFSS to use when calculating the near fields. You do not need to re-solve the problem if you modify radiation surfaces in the **Near Field Radiation Sphere Setup** dialog.

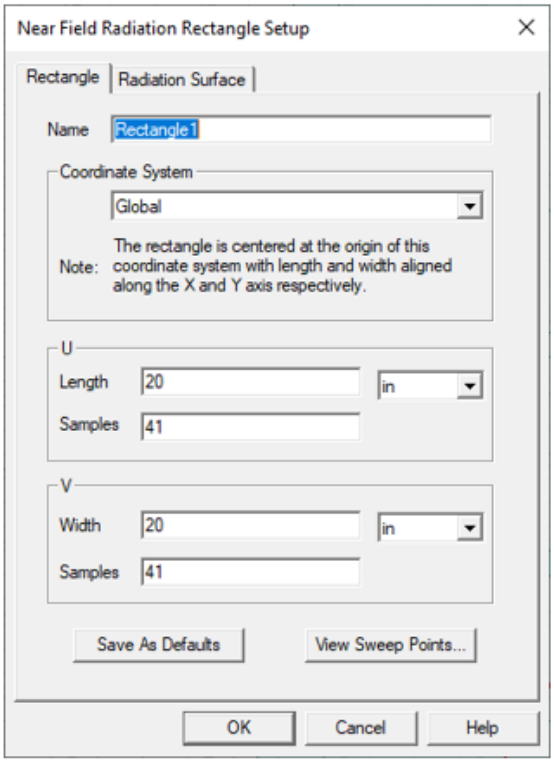
Setting up a Near-Field Rectangle

To evaluate near fields on a rectangle, set up a near-field rectangle. Make sure contour plot on sweep of _u and _v can be overlaid in model geometry. Near fields are evaluated on the rectangle centered at the origin of the defined coordinate system of the rectangle with length and width aligned along the X and Y axis of that coordinate system. The plot should have the same size of the rectangle in model units. You can use the near-field rectangle setup to create near-field reports. A near field plot setup in this way can also be overlaid on the geometry and animated.

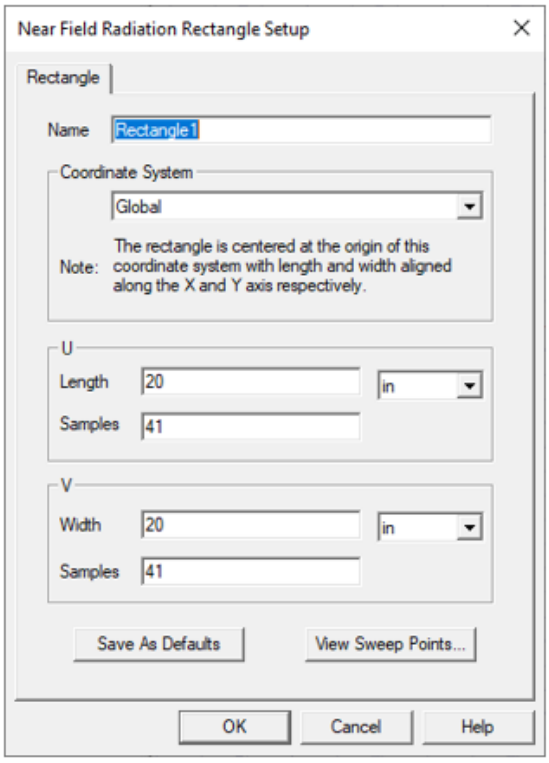
1. To create a near-field rectangle setup, click **HFSS** > **Radiation** > **Insert Near Field Setup** > **Rectangle** to bring up the **Near Field Radiation Rectangle Setup** dialog. If the design is Modal/Terminal Solution type the dialogue will include a **Radiation Surface** tab. If the design is HFSS SBR+ or includes SBR+ Hybrid Regions, the dialogue does not include the **Radiation Surface** tab because with SBR+ designs, the Radiation surface is defined or selected before simulation using the Field Observation Domain pane in the **SBR+ Solution** setup **Options** tab or the **Hybrid** tab of an HFSS Modal or Terminal setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modal/Terminal



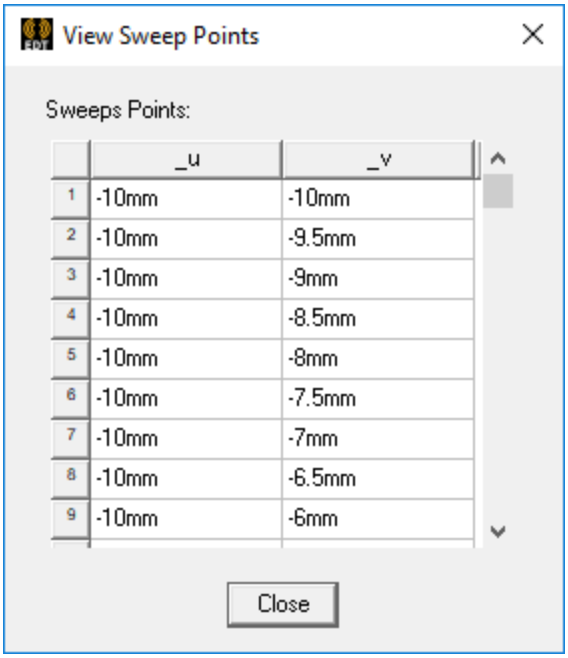
SBR+



2. Use the **Rectangle** tab define the **Name**, Relative Coordinate System, and Length, units, number of samples for U and V for the near-field rectangle. The rectangle is centered at the origin of the coordinate system you specify. You can assign a variable to the length and width, and a post-processing variable will often make sense in this context.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Specify the sphere's sampling as any integer greater than 1. To verify your settings, use the **View Sweep Points** button to display a list of the U and V sweep points.



You can use **Save as Defaults** to set the current values as the default for new near-field rectangle setups.

3. Use the **Coordinate Systems** field and drop down menu to specify the location and orientation of the rectangle. Refer to the Note in the **Setup** dialog.

   The drop down menu consists of the Global CS and all local coordinate systems that you created previously in the modeler

4. For a Terminal or Modal design, use the **Radiation Surface** tab to select the solved surface from which to calculate radiated fields.

   Use Boundary Radiation Surfaces is selected by default, indicating that the radiated fields will be calculated using the assigned radiation or PML surface. For some models you may find it it more efficient and/or accurate to use an interior surface. In this case, select **Use Custom Radiation Surface**, and choose a face selection that you previously created in the modeler.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

You must have defined at least one radiation or PML boundary in the design for HFSS to compute near-field quantities, regardless of which radiation surfaces you instruct HFSS to use when calculating the near fields. You do not need to re-solve the problem if you modify radiation surfaces in the **Near Field Radiation Sphere Setup** dialog box.

Setting up a Near-Field Box

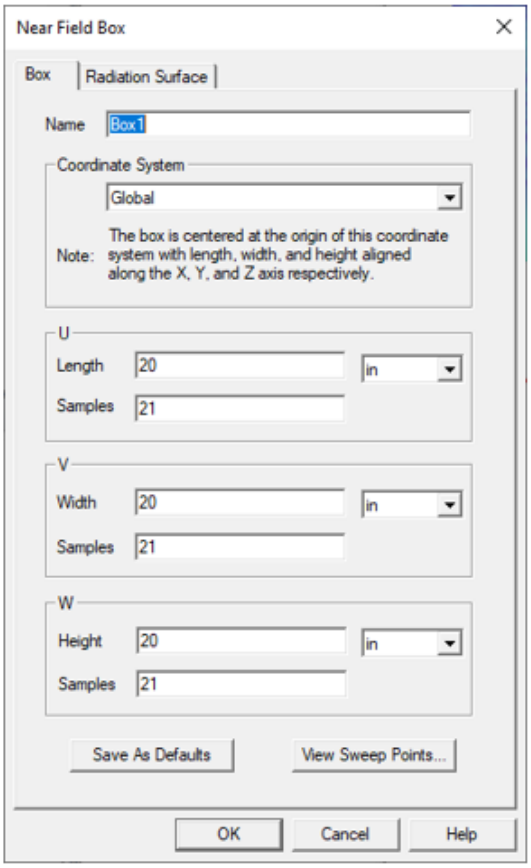
To evaluate the near field in a box, set up a near-field box. The near-field box is defined length, height, and width parameters, and samples parameters for each dimension. To plot near-field values in the box, you will select the box object from the **Geometry** list in the **Traces** dialog box when you create a report.

1. Draw a polyline in post-processing mode.
2. Click **HFSS >Radiation**>**Insert Near Field Setup>Box**.

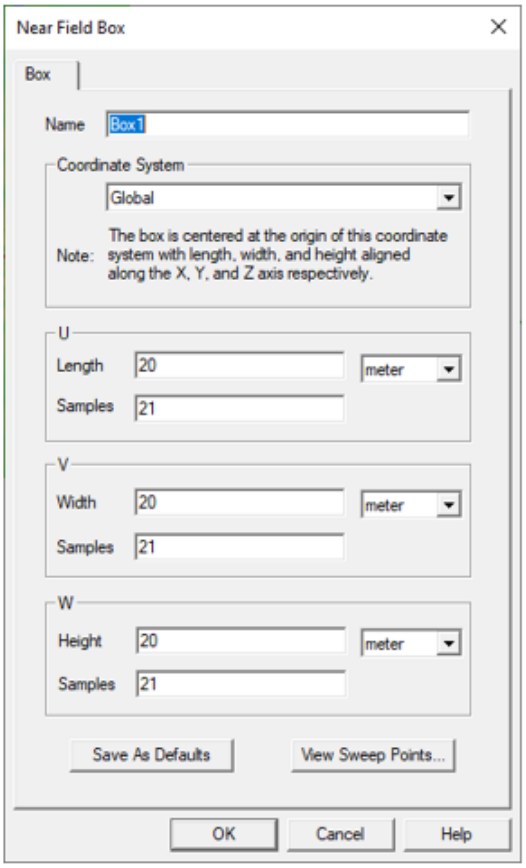
The **Near Field Line Setup** dialog box appears. If the design is Modal/Terminal Solution type the dialogue will include a **Radiation Surface** tab. If the design is HFSS SBR+ or includes SBR+ Hybrid Regions, the dialogue does not include the **Radiation Surface** tab because with SBR+ designs, the Radiation surface is defined or selected before simulation using the Field Observation Domain pane in the **SBR+ Solution** setup **Options** tab or the **Hybrid** tab of an HFSS Modal or Terminal setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modal/Terminal



SBR+



3. Type a name for the box in the **Name** text box.
4. Select a Relative Coordinate system to use for the box.
5. Specify the Length for the U, V, and W, dimension, the units, and the number of samples.

This defines the box and gives the total number of equally spaced sample points in the box.

6. For a Terminal or Modal design, use the **Radiation Surface** tab to select the solved surface from which to calculate radiated fields.

   Use Boundary Radiation Surfaces is selected by default, indicating that the radiated fields will be calculated using the assigned radiation or PML surface. For some models you may find it it more efficient and/or accurate to use an interior surface. In this case, select **Use Custom Radiation Surface**, and choose a face selection that you previously created in the modeler.

7. Click **OK**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You must have defined at least one radiation or PML boundary in the design for HFSS to compute near-field quantities, regardless of which radiation surfaces you instruct HFSS to use when calculating the near fields. You do not need to re-solve the problem if you modify radiation surfaces in the **Near Field Box Setup** window.

> **Note:**
>
> For parts of the near-field box lying outside of the model region, near-field approximation is calculated. However, if parts of the line lie inside the model region, the model fields are used to compute interpolated values. A section of the near-field line is considered to overlap the model if it lies in the enlarged model region after accounting for symmetry planes.

Setting up a Near-Field Line

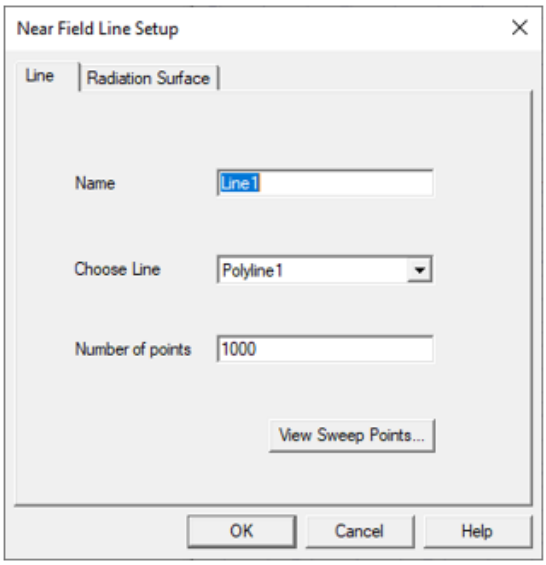
To evaluate the near field along a line, set up a near-field line. The near-field line can be a polyline with one or more segments. To plot near-field values along the line, you will select the line object from the **Geometry** list in the **Traces** dialog box when you create a report.

1. Draw a polyline in post-processing mode.
2. Click **HFSS** > **Radiation** > **Insert Near Field Setup** > **Line**.

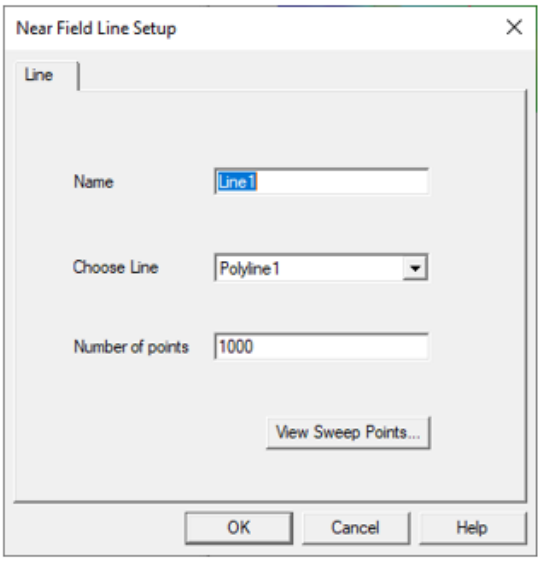
   The **Near Field Line Setup** dialog box appears. If the design is Modal/Terminal Solution type the dialogue will include a **Radiation Surface** tab. If the design is HFSS SBR+ or includes SBR+ Hybrid Regions, the dialogue does not include the **Radiation Surface** tab because with SBR+ designs, the Radiation surface is defined or selected before simulation using the Field Observation Domain pane in the **SBR+ Solution** setup **Options** tab or the **Hybrid** tab of an HFSS Modal or Terminal setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Modal/Terminal



SBR+



3. Under the **Near Field Line Setup** tab, type a name for the line in the **Name** text box.
4. Select the polyline along which you want to evaluate the near fields from the **Choose Line** list.
5. Specify the **Number of points** in the line.

   This is the total number of equally spaced points on the line. Specifying points on the line will enable you to plot the near-field values across a normalized distance, that is, to create a value versus distance plot of a near-field quantity on the line.

   You can click **View Sweep Points** to view a dialog that lists the points.

6. For a Modal or Terminal design, click the **Radiation Surface** tab.

   By default, the **Use Boundary Radiation Surfaces** radio button is selected.

   To specify a surface other than an assigned radiation or PML boundary over which to integrate the radiated fields, you must first create a face selection. To create a face selection, see Creating a Face Selection. The face selection cannot include a face that lies on a PML object.

   If you have created one or more face selection, the **Use Custom Radiation Surface** radio button is enabled.

   a. Select **Use Custom Radiation Surface**.

      This enables the **Choose from existing face named selection** field.

   b. Select a defined face selection from drop-down menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

HFSS will use the surfaces in the face selection as the radiating surfaces when calculating the near fields.

7. Click **OK**.

You must have defined at least one radiation or PML boundary in the design for HFSS to compute near-field quantities, regardless of which radiation surfaces you instruct HFSS to use when calculating the near fields. You do not need to re-solve the problem if you modify radiation surfaces in the **Near Field Line Setup** window.

> **Note:**
>
> For parts of the near-field line lying outside of the model region, near-field approximation is calculated. However, if parts of the line lie inside the model region, the model fields are used to compute interpolated values. A section of the near-field line is considered to overlap the model if it lies in the enlarged model region after accounting for symmetry planes.

Setting up an Arbitrary Near Fields Point List

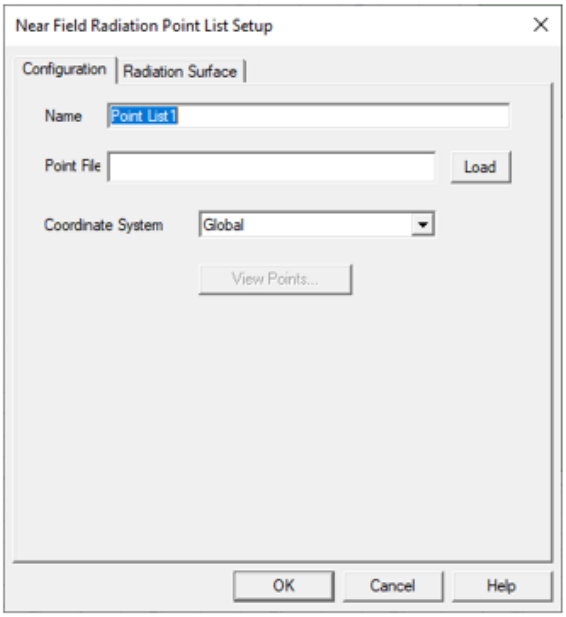
To evaluate the near fields using an arbitrary points, set up an external points list using a global or local coordinate system. The *.pts file format (which is used for exporting field data and specifying field point locations in the Fields Calculator – Export dialog) is also used for specifying 3D near field point locations. Be sure to check “Compute Fields” on the **General** tab on the **Solution Setup**.

1. Prepare a *.pts file format file.
2. Click **HFSS** > **Radiation** > **Insert Near Field Setup** > **Points List**.

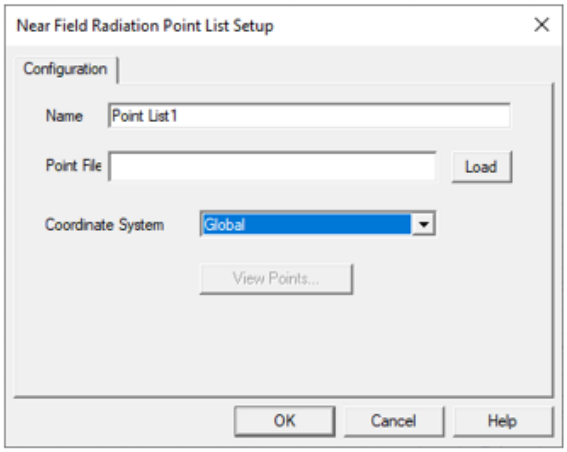
   The **Near Field Radiation Points List Setup** dialog box appears. If the HFSS design is Modal/Terminal Solution type the dialogue includes a **Radiation Surface** tab. If the design is SBR+ the dialogue does not include the **Radiation Surface** tab

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

HFSS with Radiation Boundary Defined



HFSS SBR+



With SBR+ designs, a Near Field Domain Setup is defined or selected *before simulation* using the Field Observation Domain pane in the **SBR+ Solution** setup **Options** tab or the **Hybrid** tab of an HFSS Modal or Terminal setup. (For a solution type other than hybrid or SBR+, you can create and configure a near field radiation setup using File-Based Point List after simulation).

3. Type a name for the point list in the **Name** text box.
4. Select the points file for which you want to evaluate the near fields. Pressing the **Load** button opens a browser.
5. For a Modal or Terminal design, click the **Radiation Surface** tab.

   By default, the **Use Boundary Radiation Surfaces** radio button is selected.

   To specify a surface other than an assigned radiation or PML boundary over which to integrate the radiated fields, you must first create a face selection (see Creating a Face Selection). The face selection cannot include a face that lies on a PML object.

   If you have created one or more face selection, the **Use Custom Radiation Surface** radio button is enabled.

   a. Select **Use Custom Radiation Surface**.

      This enables the **Choose from existing face named selection** field.

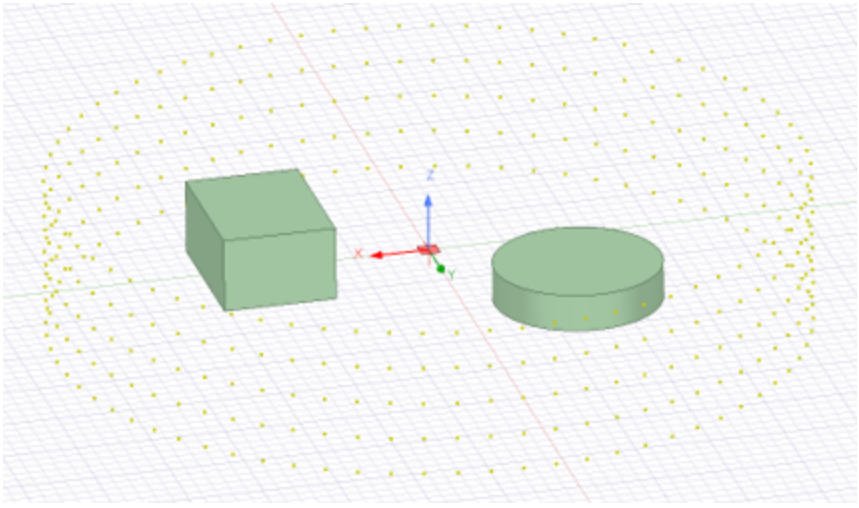
   b. Select a defined face selection from the drop-down menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

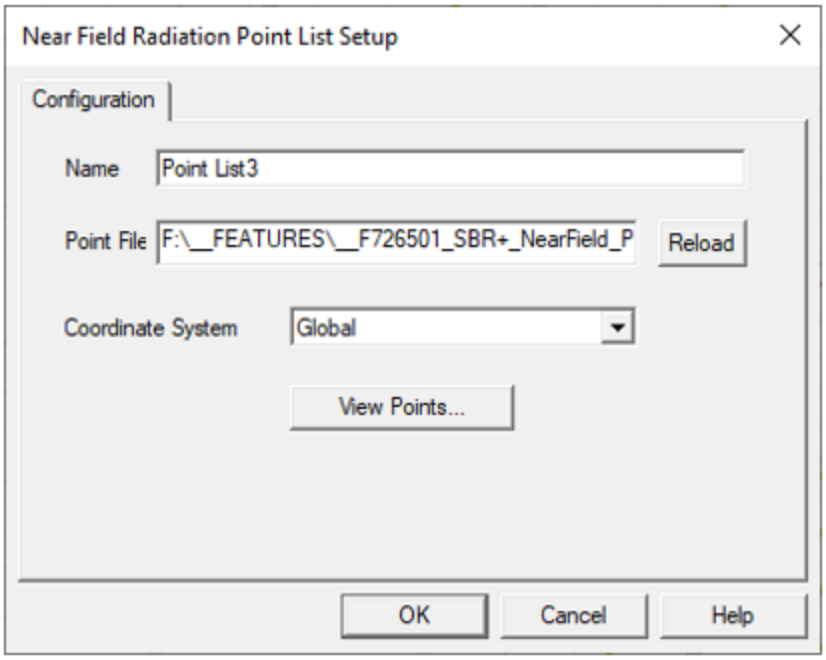
HFSS will use the surfaces in the face selection as the radiating surfaces when calculating the near fields.

6. Click **OK**.

HFSS renders the near field points in the 3D model window.

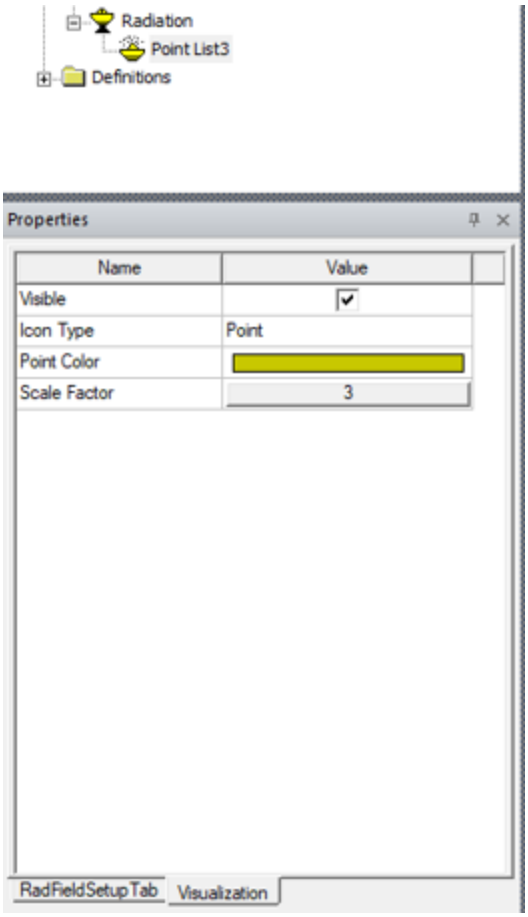


The **View Points** button is enabled and provides a data table view of the XYZ point coordinates loaded from the specified *.pts file.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When you select the Radiation Near Field setup in the **Project** tree, the **Properties** includes a **Visualization** tab.



- Visible [On/Off]
- Icon Type [Point, Sphere, Box, Dot, Plus]
- Point Color (colored button, brings up color chooser)
- Scale Factor (sets size of marker)

When a radiation surface is used, you must have defined at least one radiation or PML boundary in the design for HFSS to compute near-field quantities, regardless of which radiation surfaces you instruct HFSS to use when calculating the near fields.

Generating a Report from Point List

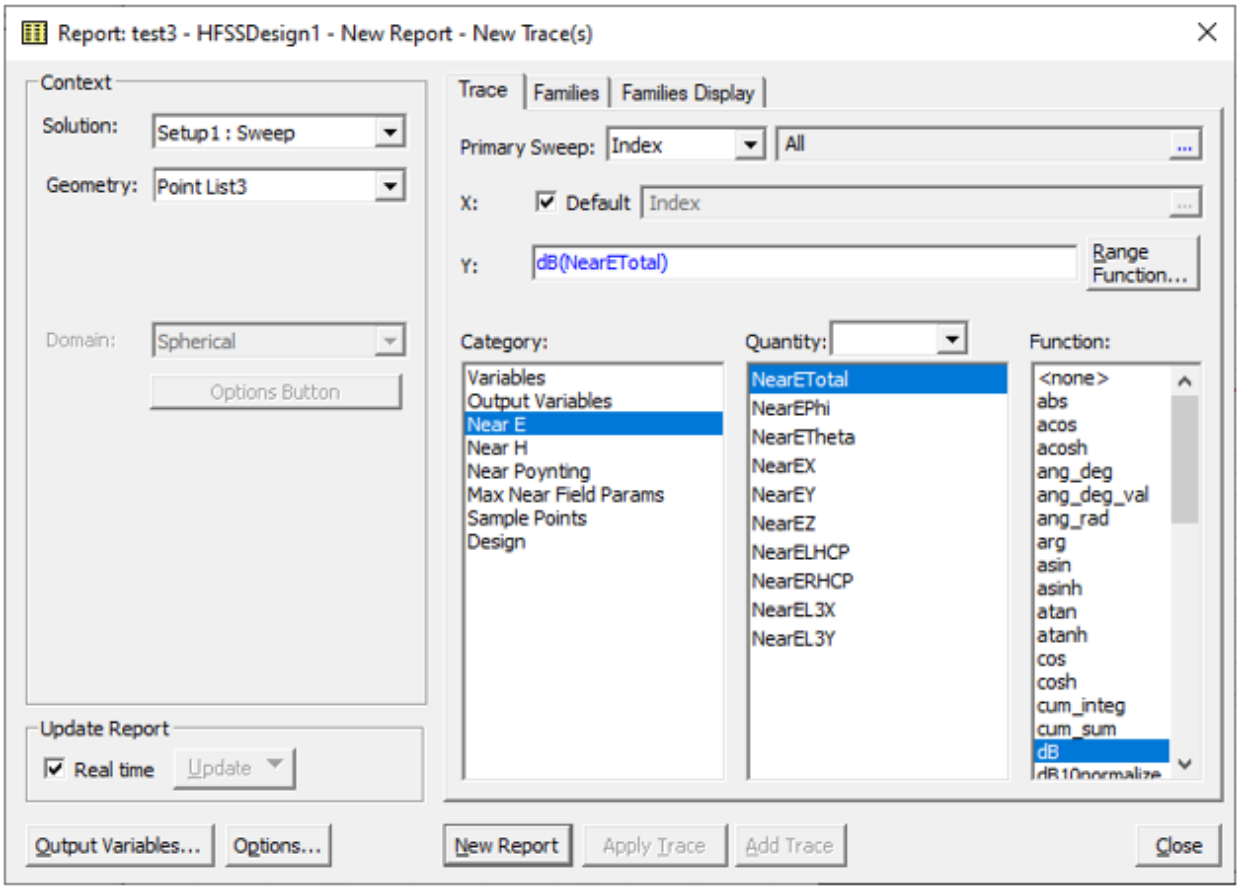
To Generate a Report from a Point List simulation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Under Results node in the **Project** tree select **Near Fields Report** > **Data Table**.

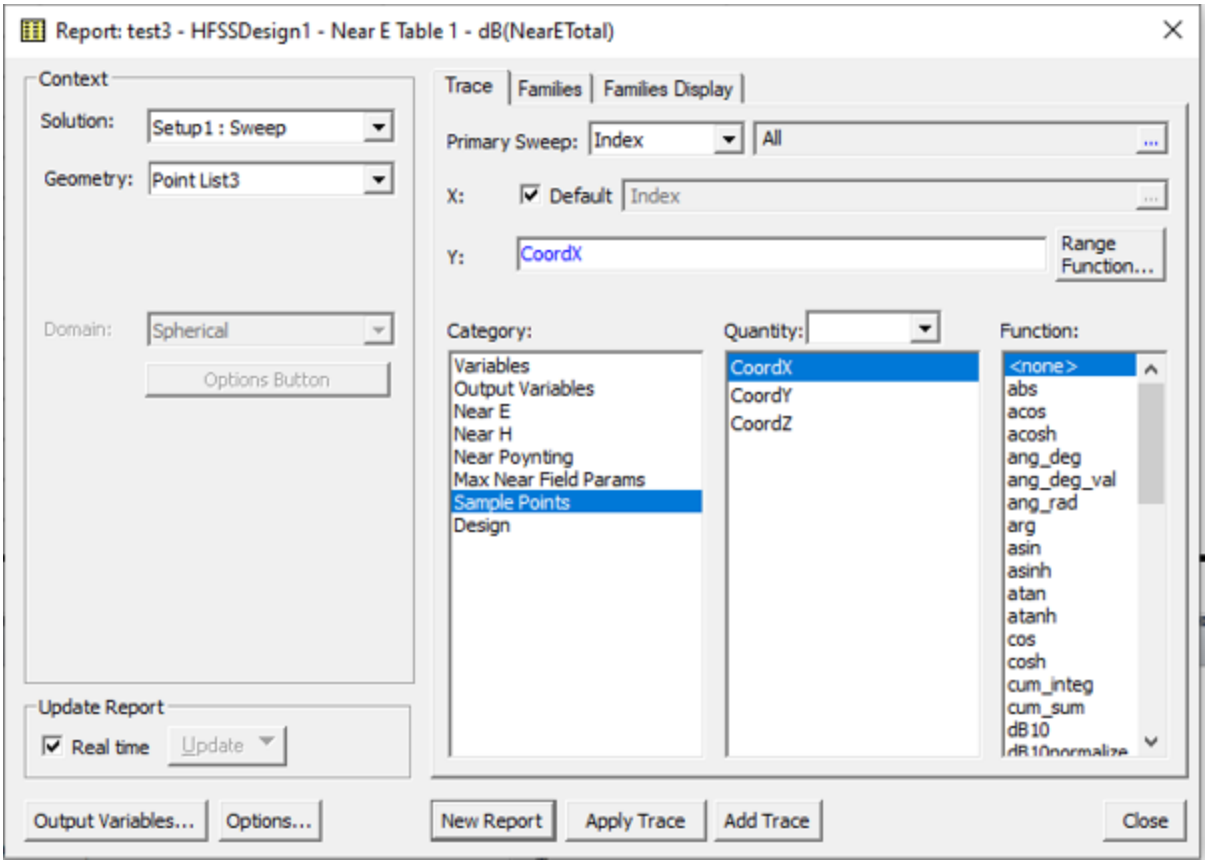
   This opens the **Report** dialog box.

2. Under the Context setup in the **Report** dialog box, set the Geometry selection to the created near field Point List radiation setup; notice the only Primary Sweep available is the point list Index.



Select the desired Category, Quantity, and Function (such as Near E, NearETotal, dB). Notice that the Category: list includes Sample Points.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



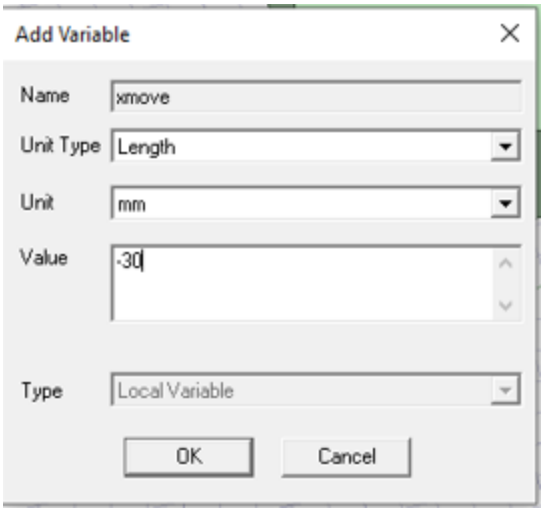
Selecting Sample Points as the Category then include the Quantities for CoordX, CoordY, and CoordZ.

Animating an Near Field Points List Plot

To animate a near field points list plot:

1. Create a design or project variable for the position of a geometry object in the 3D model. You can do this This can be done by performing an **Edit** > **Arrange** > **Move** operation on the object, or by creating a new Coordinate System containing the design/project variable and assigning it as the Target Coordinate System for a geometry object.

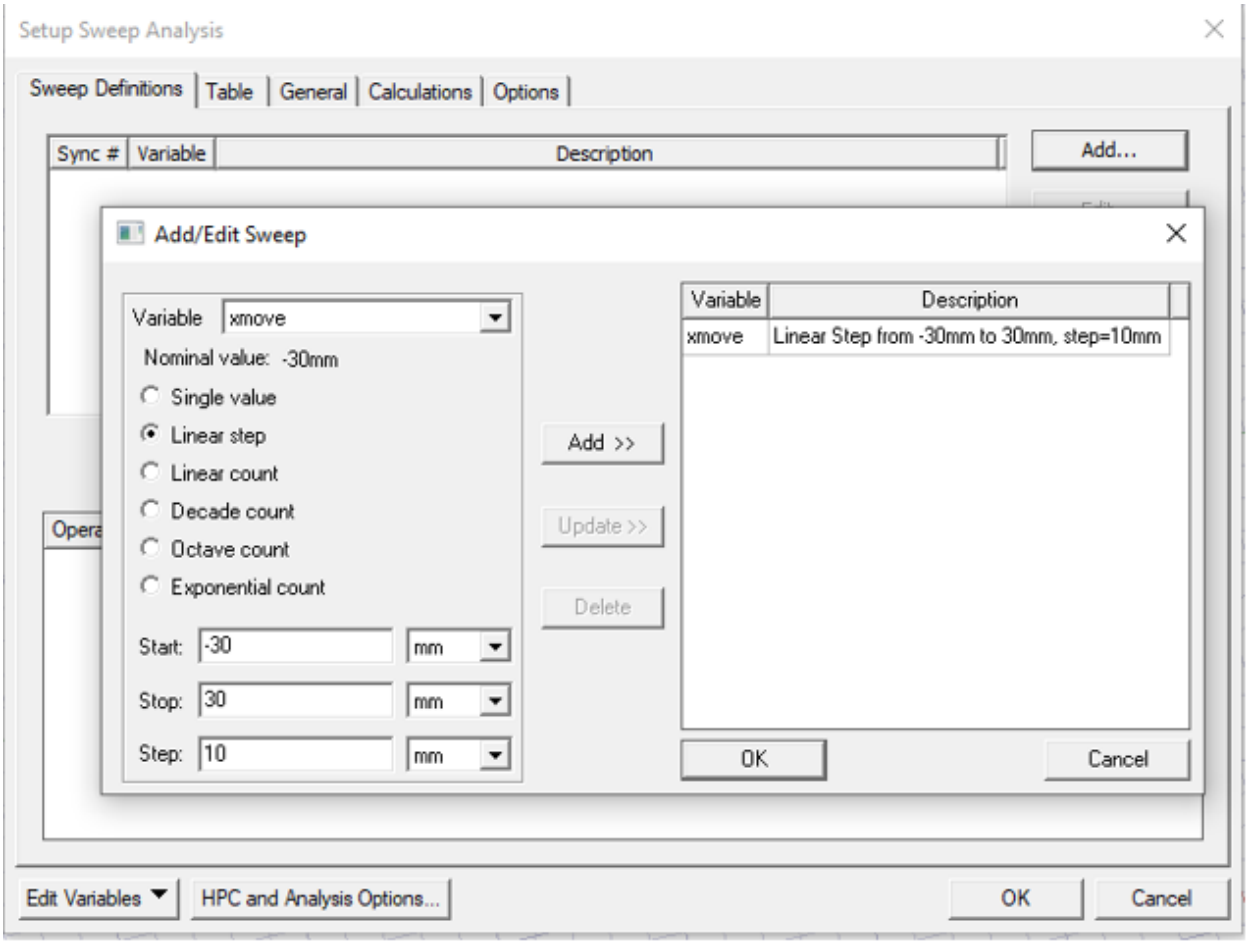
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



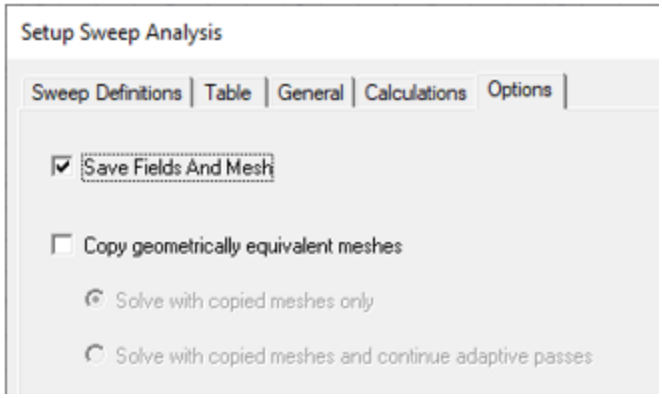
2. Then add an Optimetrics Parametric sweep setup.

   Use the design/project variable that you created for the parametric sweep definition.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



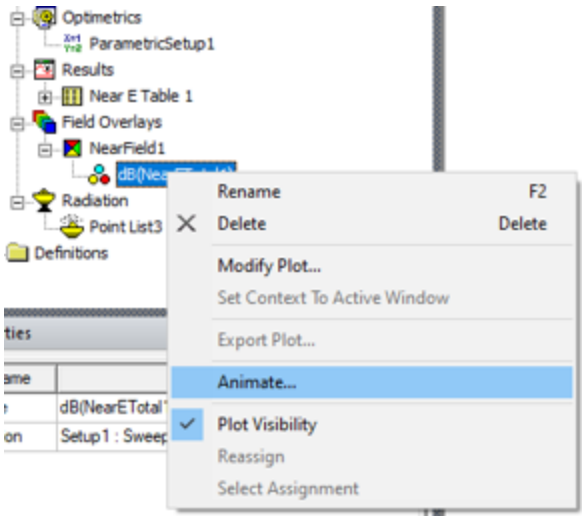
3. Check “Save Fields and Mesh” on the Options page of the sweep setup.



4. Run the Optimetrics simulation.

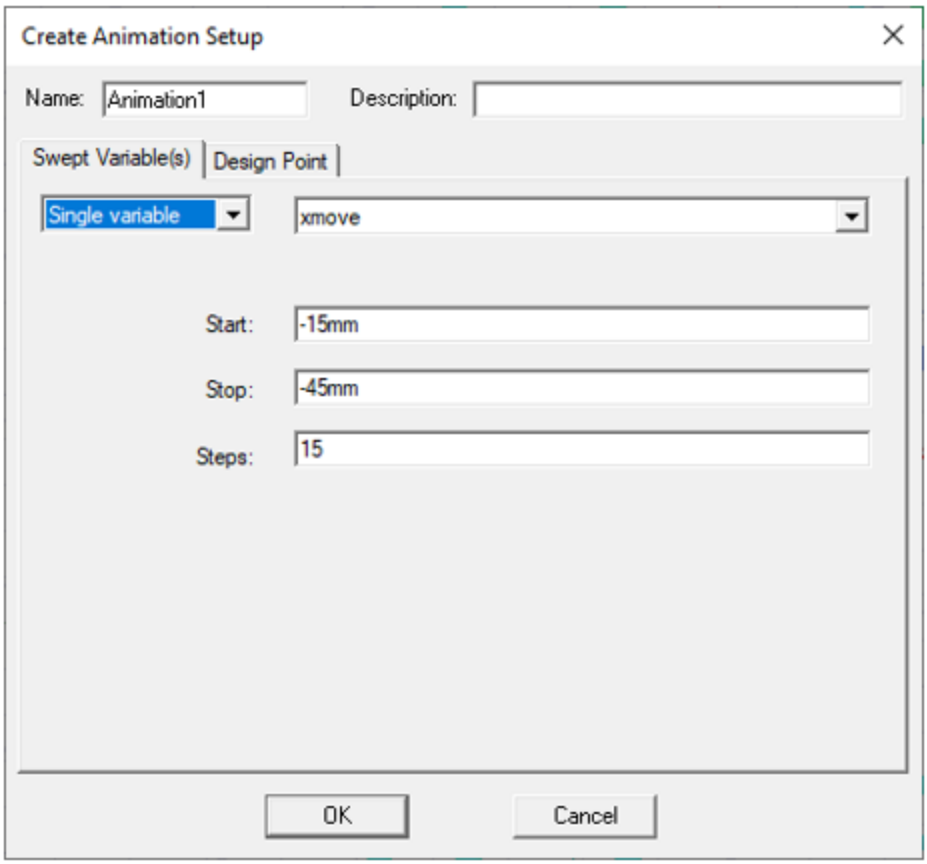
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. After creating a Sampled Near Field Plot as described previously, right-click on the plot object and select **Animate...** to open the **Create Animation Setup**.



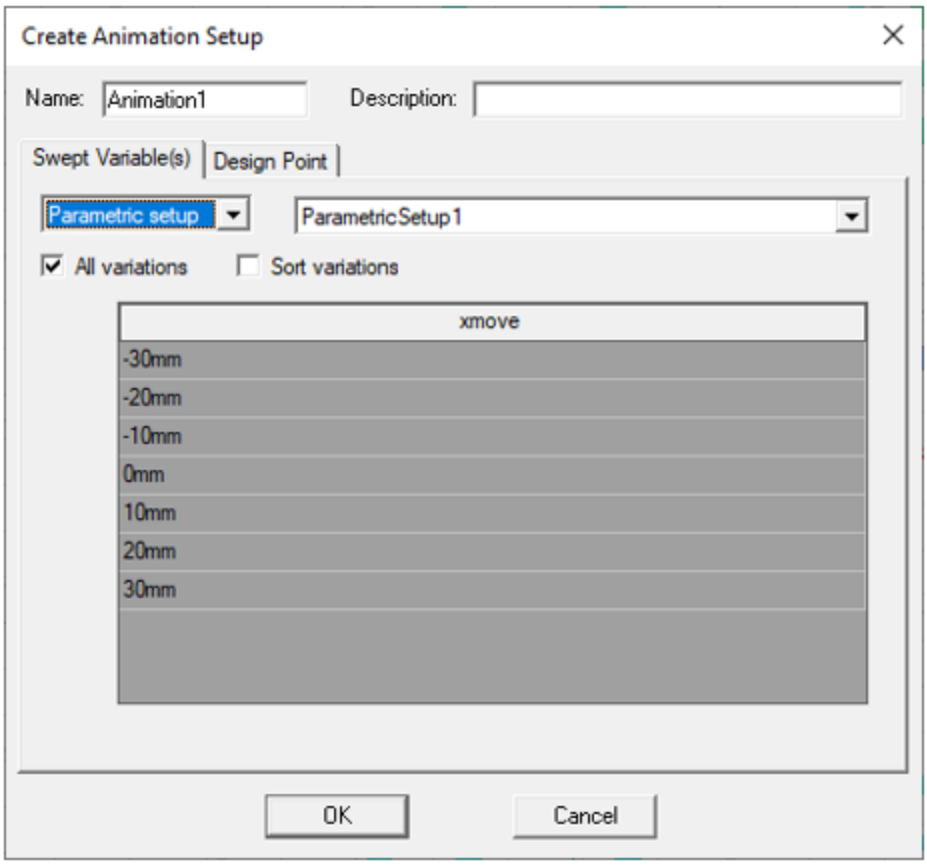
You can select the design/project variable from the list of available sweep variables and create a list of variable values to sweep for the animation. These values should be from the available simulation sweep values.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

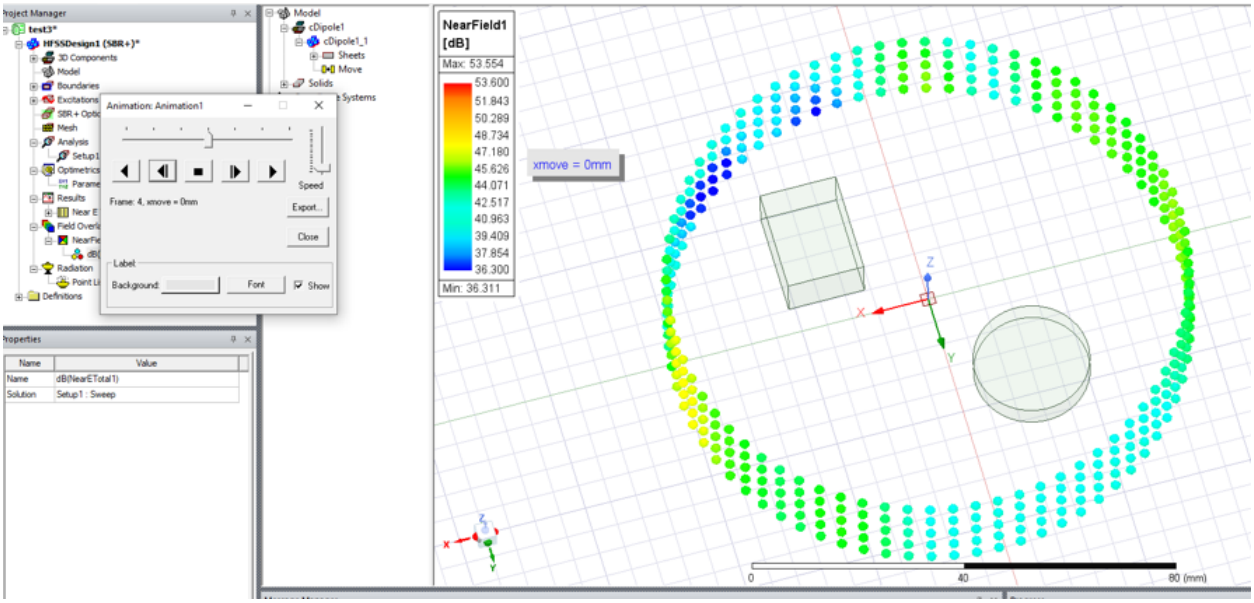


Or you can select the Parametric Setup to use the variable and all values from the specified Optimetric setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



6. Select the created animation sweep setup and click **OK** to generate the animation.

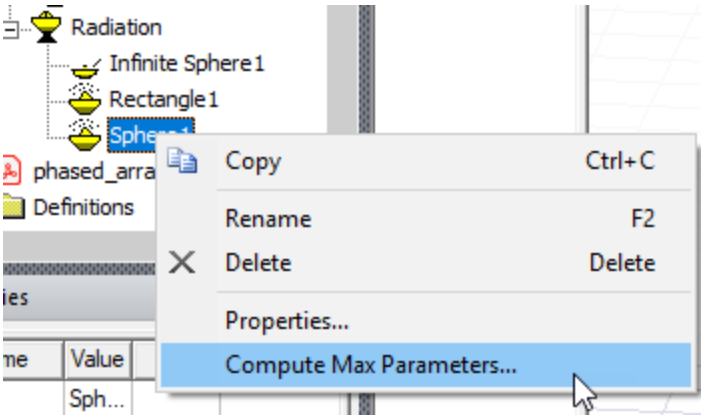


Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Computing Maximum Near-Field Parameters

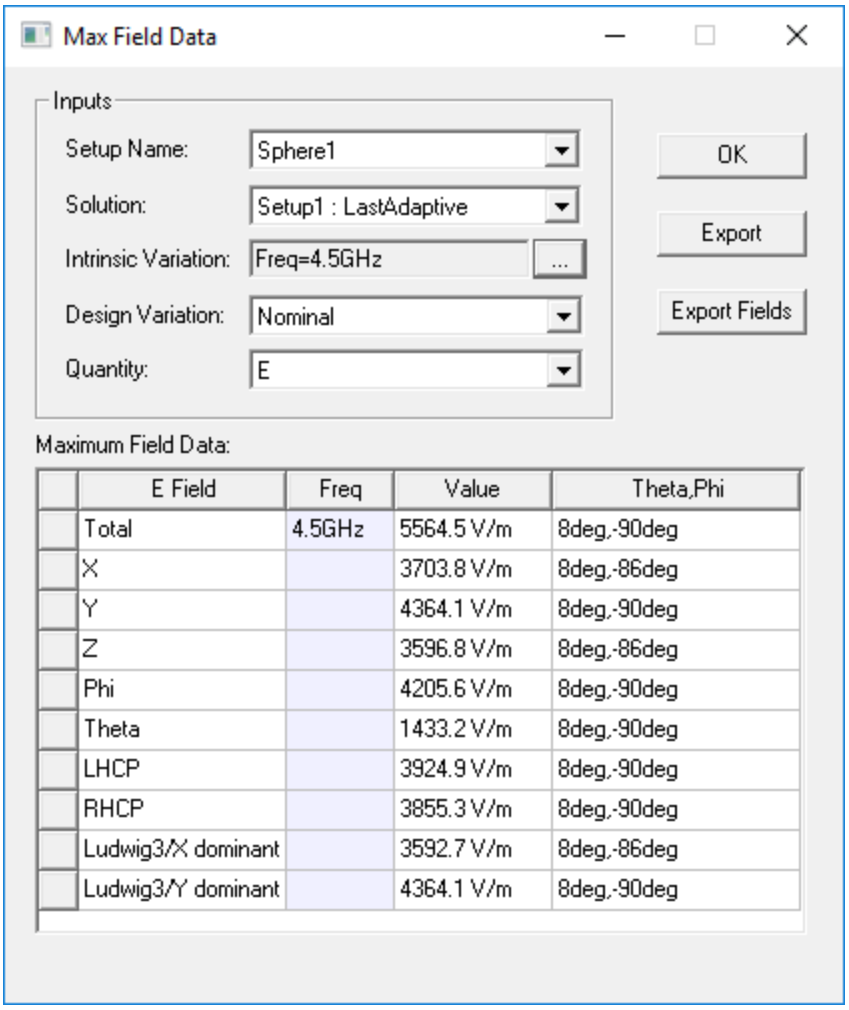
You must have defined at least one radiation or PML boundary in the design for HFSS to compute maximum field data for the near-field region, and you must have defined a near field sphere, rectangle, or sphere.

1. Right-click the **Sphere**, **Rectangle**, or **Line** icon in the project tree, and then click **Compute Max Parameters** on the shortcut menu.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. The Max Field Data window appears.



E Field	Freq	Value	Theta,Phi
Total	4.5GHz	5564.5 V/m	8deg,-90deg
X		3703.8 V/m	8deg,-86deg
Y		4364.1 V/m	8deg,-90deg
Z		3596.8 V/m	8deg,-86deg
Phi		4205.6 V/m	8deg,-90deg
Theta		1433.2 V/m	8deg,-90deg
LHCP		3924.9 V/m	8deg,-90deg
RHCP		3855.3 V/m	8deg,-90deg
Ludwig3/X dominant		3592.7 V/m	8deg,-86deg
Ludwig3/Y dominant		4364.1 V/m	8deg,-90deg

3. For **Setup Name**, you can select from available Near Field setups.
4. For Solution, you can select from available solutions.
5. For Intrinsic Variation and Design Variation, you can select from any available variations.
6. For Quantity, you can select From E, H, or Poynting.

The **Max Field Data** window lists the following information for E for a sphere:

- **Total**
- **X**
- **Y**
- **Z**
- **Phi**
- **Theta**
- **LHCP**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **RHCP**
- **Ludwig 3/X dominant**
- **Ludwig 3/Y dominant**

> **Note:**
>
> When calculating the maximum far-field values, the distance *r* is factored out of the E-field. Therefore, the units for the maximum field data values are given in volts.

The **Export** button lets you export to the parameters to an exportparams.txt file.

The **Export Fields** button lets you export the fields to an exportfields.csv file.

Note: A Beta feature for HFSS, Hfss Interactive Dialogs, allows you run the **Compute Max Parameters**dialog in modeless fashion, that is, if you **Edit Sources** for magnitide or renormalization, affected Max Parameters update. If you edit excitations or ports in the Far Field Setup, or create design variations in Optimetrics, the **Edit Source** dialog will close.

Case that update in this mode:

- Infinite sphere setup created, deleted or renamed: Setup Name combo box changes radiation setup.
- Solution setup created, deleted or renamed.
- Antenna array setup created or deleted.
- Source group created, deleted or renamed.

Note: Intrinsic Variation updates as the solution setup changes. Grids of “Maximum Field Data” update data as any of the combo box selections changes. The dialog closes if solution type is changed. Selections in Quantity combo box will not change.

Technical Notes: Maximum Near-Field Data

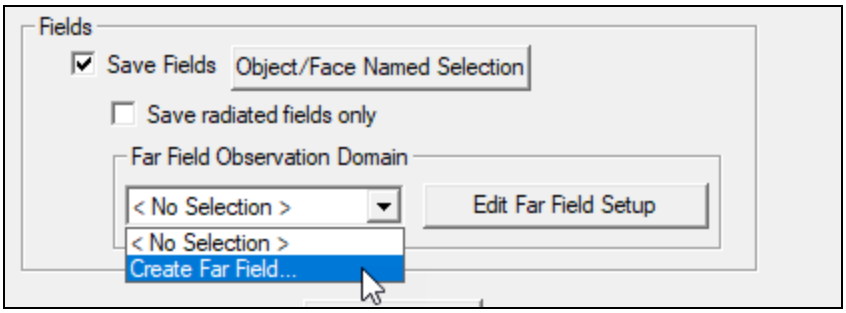
Setting up a Far-Field Infinite Sphere

To evaluate radiated fields in the far-field region, you must have Saved Fields in the solution and sweep setups, and set up an infinite sphere that surrounds the radiating object. To plot far-field

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

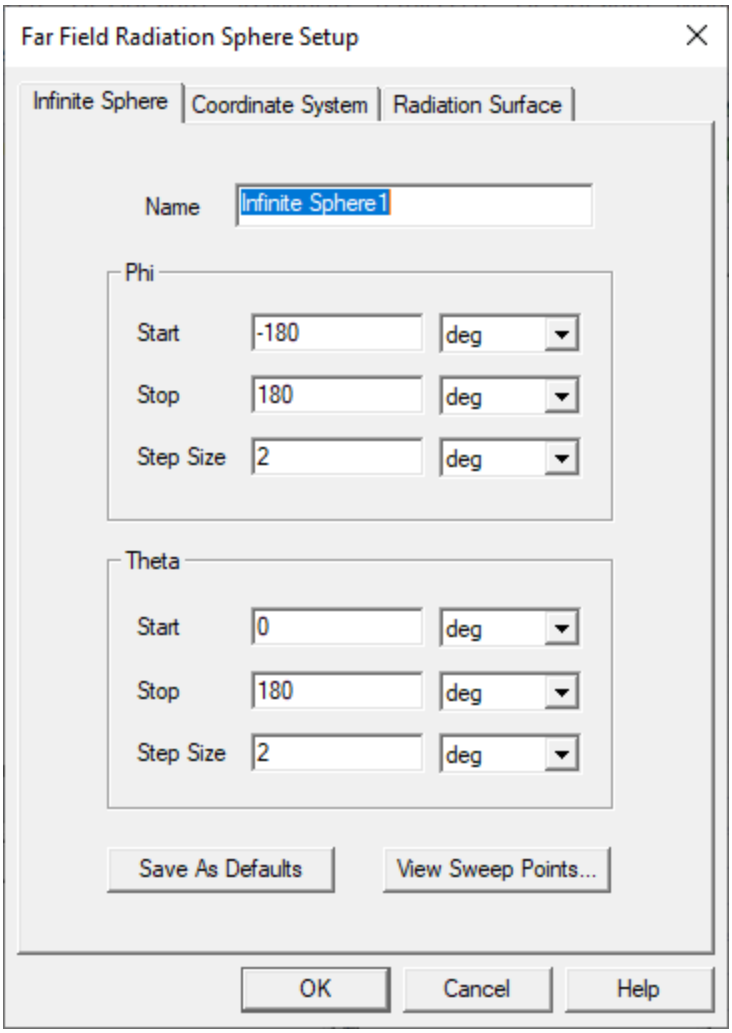
values across the sphere, you will select the sphere object from the **Geometry** list in the **Traces** dialog box when you create a report. To evaluate RCS using a design with an incident plane wave and an SBR+ region, you can also setup an infinite sphere.

1. **Click HFSS** > **Radiation**> **Insert Far Field Setup** > **Infinite Sphere** or, on an Advanced Solution Setup, **Advanced** options tab for an HFSS design without SBR+ Hybrid regions, or for use with **SBR+ Solver options,** Click the **Create...** button under on the **SBR+ Solver options** on **Hybrid** tab of the **Solution setup.**



The **Far Field Radiation Sphere Setup** window appears. Depending on your selections on the **Coordinate System** tab, the basis will be displayed as Phi Theta, Azimuth Elevation, or Elevation Azimuth. The Default is Phi and Theta. The selection there will also affect display of Maximum Far Field Data if you Computer Antenna Parameters.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

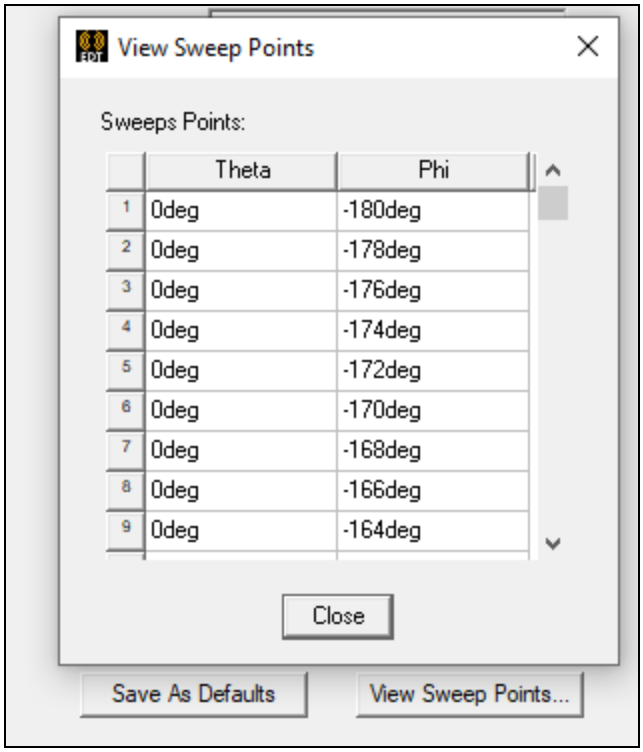


2. Use the **Sphere** tab define the **Name** and sampling in the selected for the far-field sphere.

   Specify the sphere's sampling in terms of **Start**, **Stop**, and **Step Size** angles given in radians, degrees, degree seconds or degree minutes.

   To verify your settings, use the **View Sweep Points** button to display a list of the theta and phi sweep points. See Spherical Cross-Sections in the **Technical Notes** for guidelines for setting phi and theta.

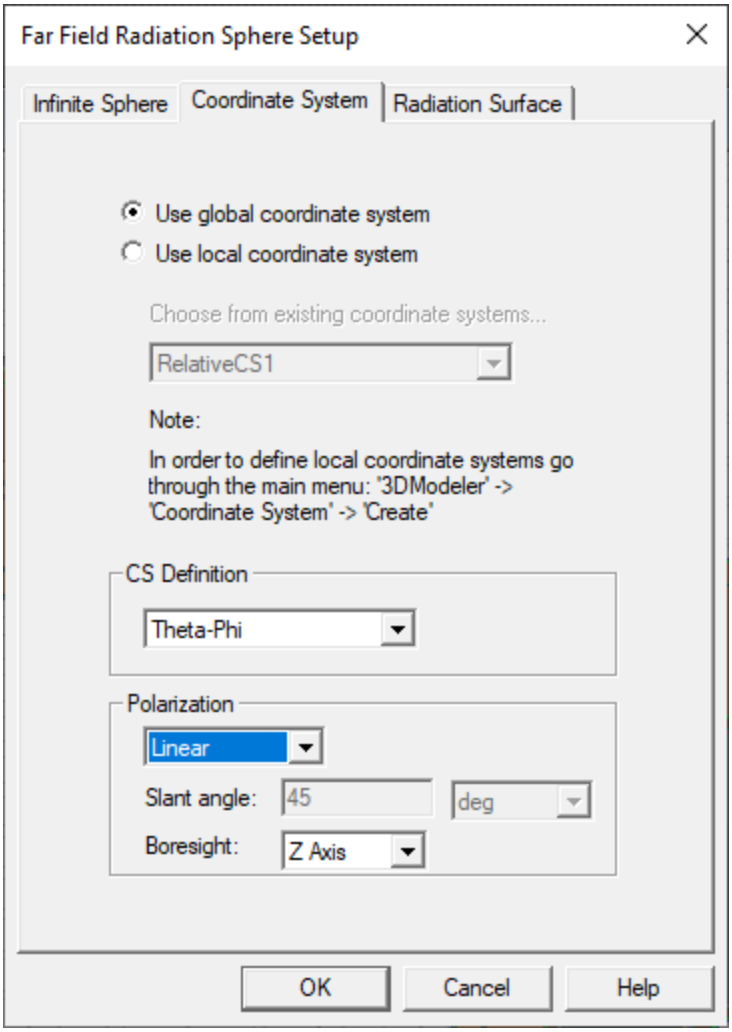
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



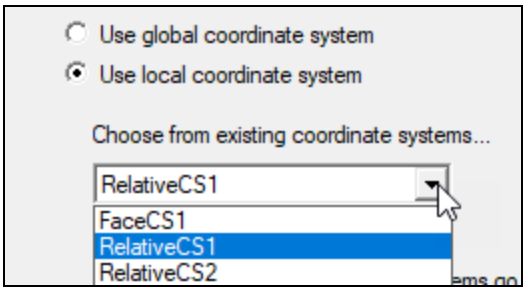
You can use **Save as Defaults** to set the current values as the default for new near-field sphere setups.

3. Use the **Coordinate Systems** tab to specify the orientation of the sphere as well as the CS System Definition, and the Polarization.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

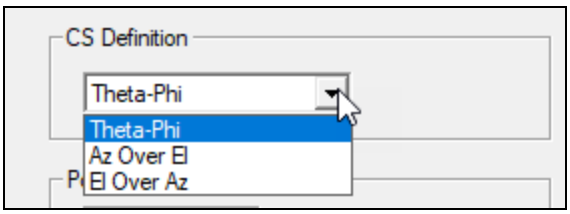


Use global coordinate system is selected by default, but in some cases the orientation of the antenna requires the use of a local coordinate system. In this case, select **Use local coordinate system**, and choose a local coordinate system that you created previously in the modeler.

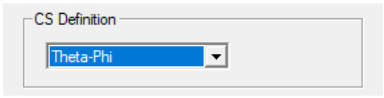


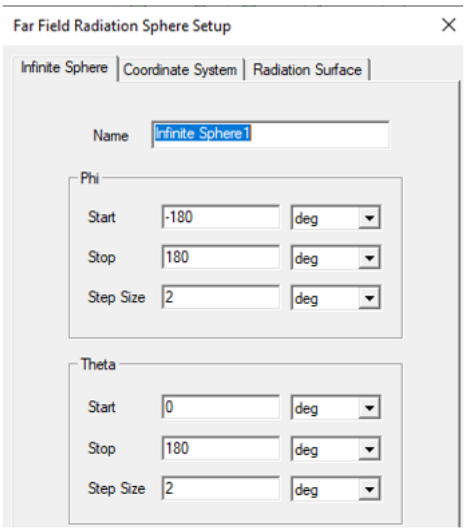
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

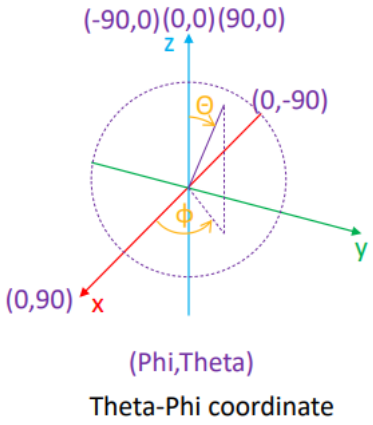
CS Definition: In addition to support Theta-Phi spherical coordinate system, you can select Azimuth over Elevation definition and Elevation over Azimuth definition. Your selection here affects the display on the **Infinite Sphere** tab. The selection there will also affect display of Maximum Far Field Data if you calculate Computer Antenna Parameters.



For Theta-Phi selection as Coordinate System, the Infinite Sphere setup is as follows.

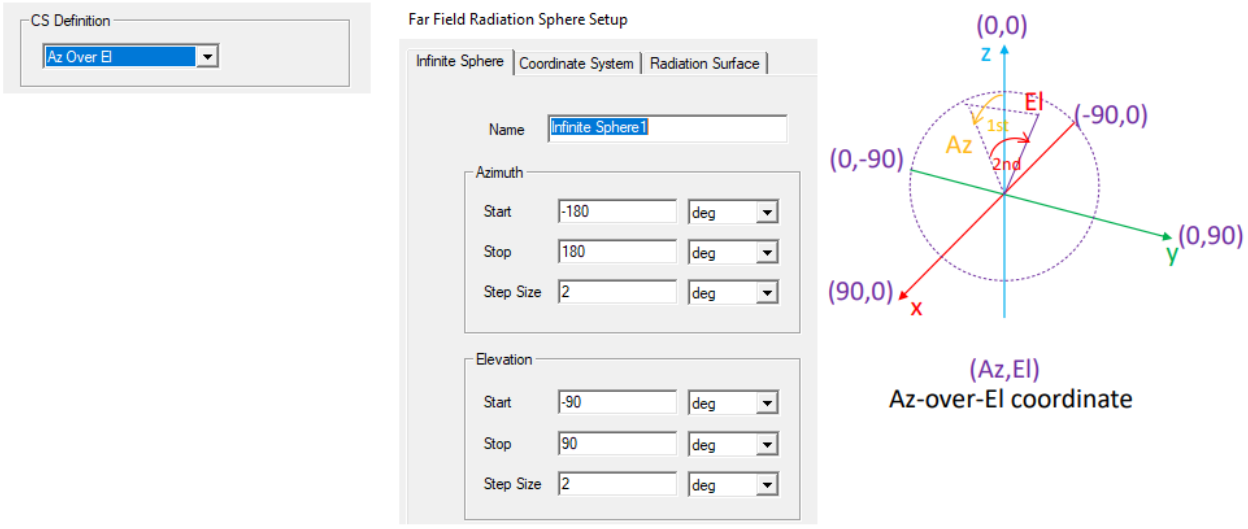




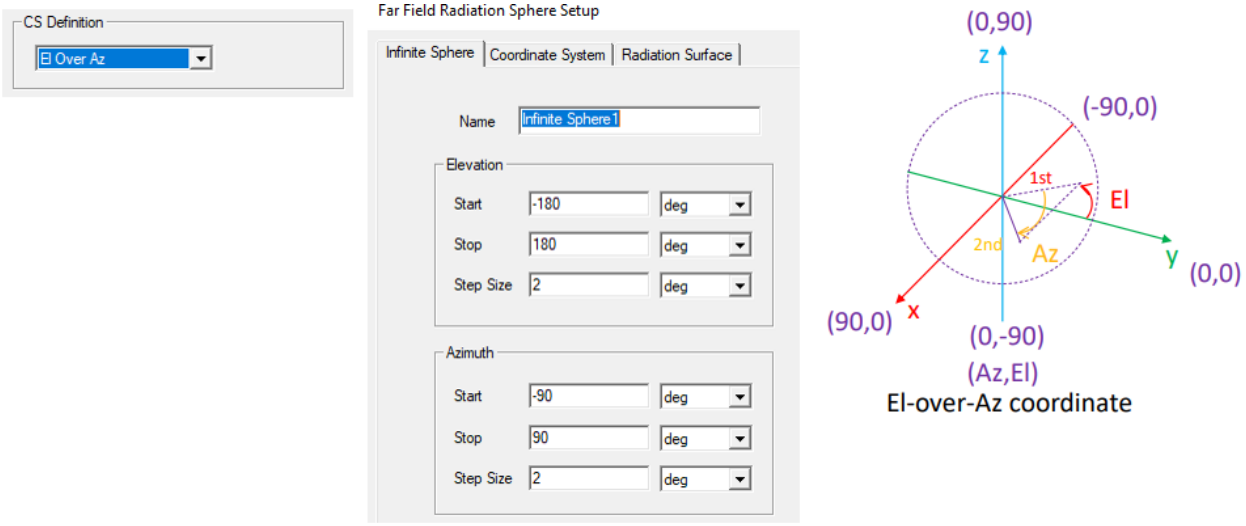


Azimuth over elevation (**Az Over El**) has the pole around Y axis while both azimuth and elevation start their 0 deg angle from Z axis. The pole is at elevation angle of –90 deg and 90 deg.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

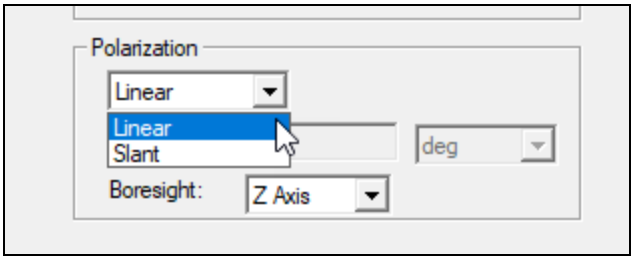


Elevation over azimuth (**El Over Az**) has the pole around X axis while both azimuth and elevation start their 0 deg angle from X axis. The pole is at azimuth angle of –90 deg and 90 deg.

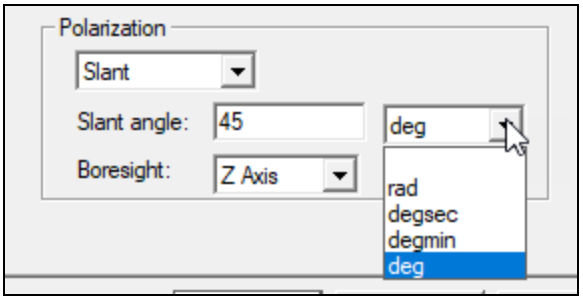


Polarization: specify the field polarization as Linear, or Slant which decomposes the field into axes rotated with slant angle around the Z axis.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

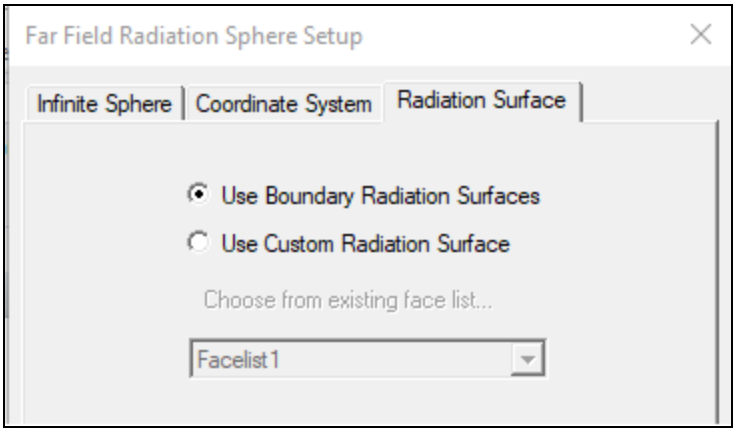


If you select Slant, the field for value and unit menu are enabled. Only CoPolar and CrossPolar values (see Selecting a Far Field Quantity to Plot, Step 4) are affected if Slant polarization is chosen vs. Linear option.



4. Use the **Radiation Surface** tab to select the solved surface from which to calculate radiated fields.

   Use Boundary Radiation Surfaces is selected by default, indicating that the radiated fields will be calculated using the assigned radiation or PML surface. For some models you may find it it more efficient and/or accurate to use an interior surface. In this case, select **Use Custom Radiation Surface**, and choose a face selection that you previously created in the modeler.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> Do not use a sheet-object based face selection as the radiation computation surface.

You can use the **Save as Default** to set the current values as a default, and the **Use Defaults** button to use previously saved options.

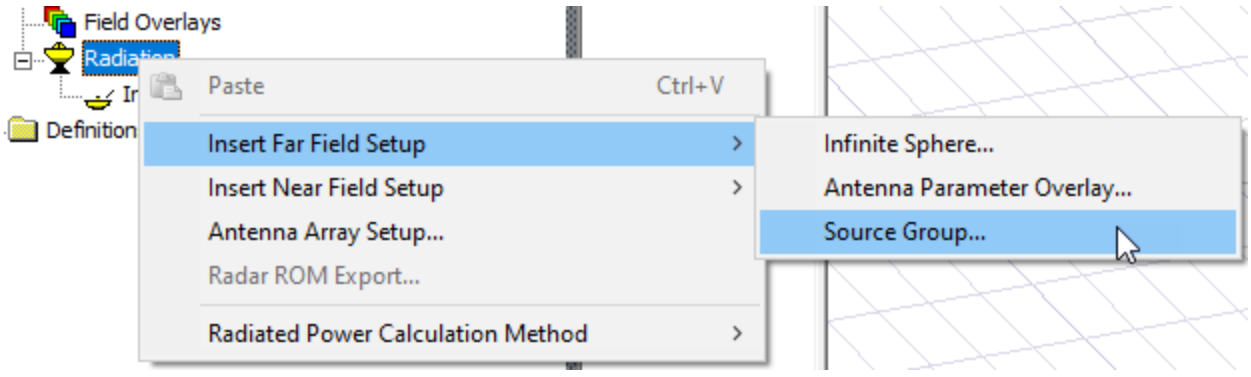
> **Note:**
>
> You must have defined at least one radiation or PML boundary in the design for HFSS to compute far-field quantities, regardless of which radiation surfaces you instruct HFSS to use when calculating the far fields. You do not need to re-solve the problem if you modify radiation surfaces in the **Far Field Radiation Sphere Setup** window.

Setting up a Source Group for a Finite Array

HFSS Edit Sources has had the concept of 'Source Contexts' for far field plots. Each Source Context specifies a single excitation (port) which will be active within the reporter and RadField module. All other excitations are inactive – in Edit Sources terms, they have a magnitude of zero.

This was perfectly adequate for simple antenna simulation, but it fails to meet users' needs with respect to finite arrays. For those users, sets of excitations are needed. That is to say, we need multiple 'Source Contexts' and each context must maintain its own set of active excitations.

A new item, Source Groups, will be first class objects in the project tree. They will be shown under the Radiation folder along with Infinite Sphere and Antenna Parameter overlays. Under the Radiation menu will be the option to create a new Source Group. Within the tree, the normal Edit, Rename, Copy, Paste, and Delete operations will be available to manage Source Groups.



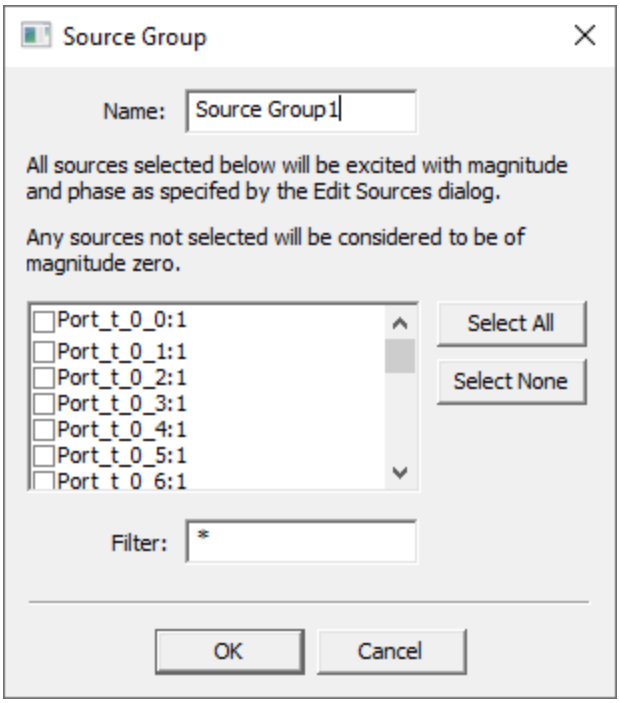
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If a finite array exists in the design, the new Source Group will allow the user to activate a subset of the virtual excitations (e.g. array[5,5]port1:2 …) instead of the physical excitations associated with the unit cell(s).

To evaluate radiated fields in the far-field region, you must set up an infinite sphere that surrounds the radiating object. To plot far-field values across the sphere, you will select the sphere object from the **Geometry** list in the **Traces** dialog box when you create a report. To evaluate RCS using a design with an incident plane wave and an SBR+ region, you can also setup an infinite sphere.

1. **Click HFSS >Radiation>Insert Far Field Setup>Source Group**

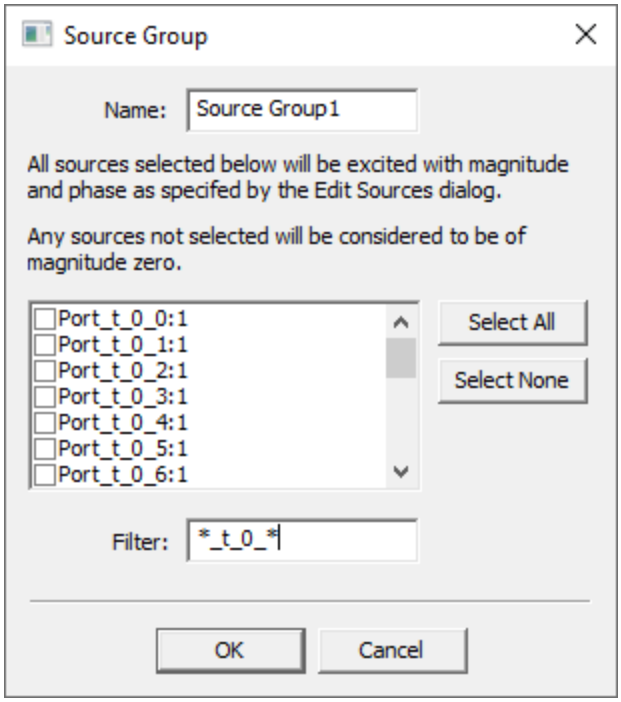
   The **Source Group** window appears.



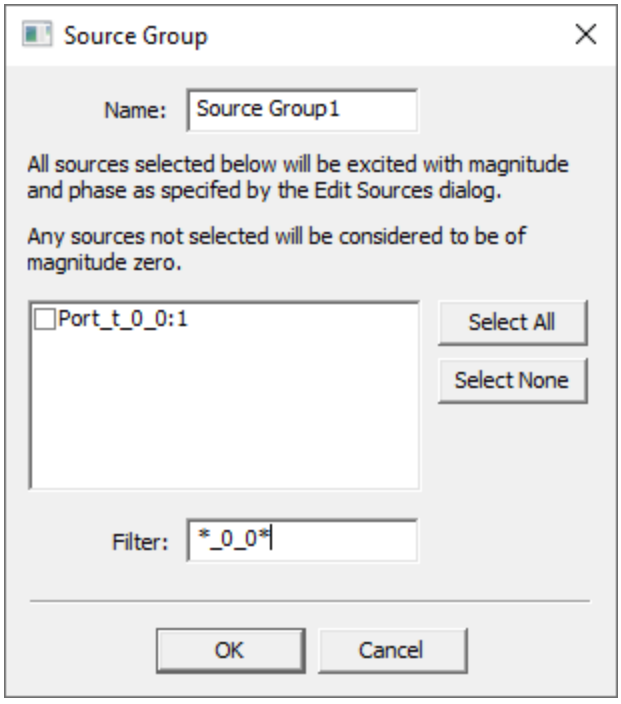
2. Use check boxes and/or **Select All/None** buttons to specify which sources to excite with the magnitude and phase as specified in the Edit Sources dialog.

The Filter: box permits you to sort ports based on regular expressions. For example, where a pattern of port names has been created by a script, the first number is the row number and the second number is a column number. When the filter is *_t_0*, all ports are in the 0th row.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

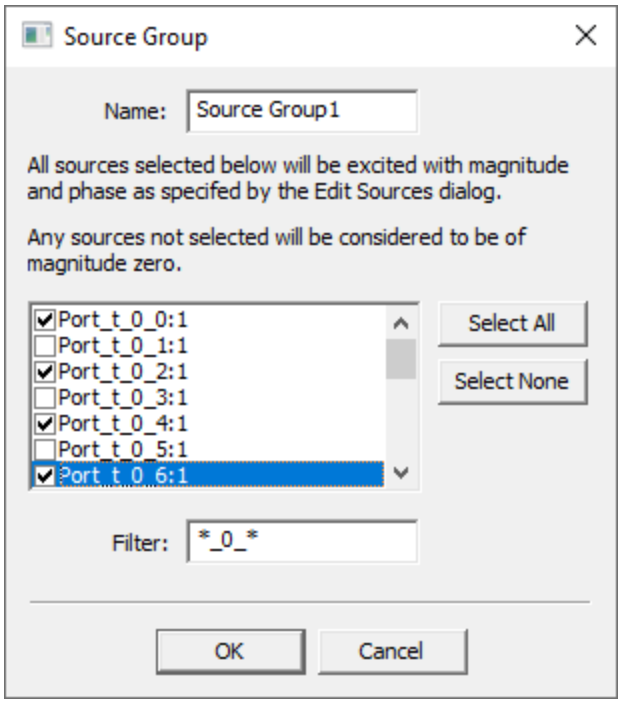


When the Filter is *0_0_* only Port_t_0_0 is selected.



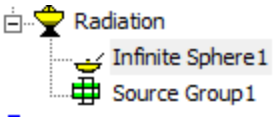
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Check which Ports to excite with a magnitude and phase as specified by the Edit Sources dialog.



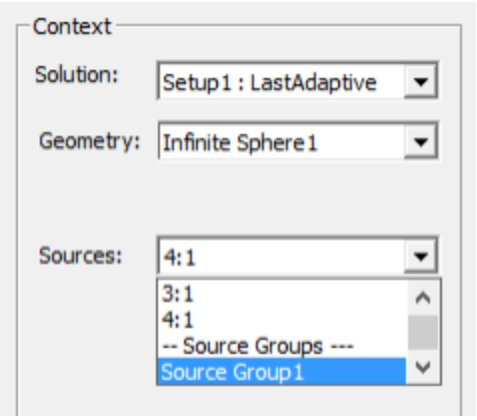
Select All can check all sources. **Select None** deselects all sources. Any sources not selected will be assigned magnitude zero.

3. Click **OK** to close the dialog box. The Source Group appears in the Project tree under the Radiation icon.



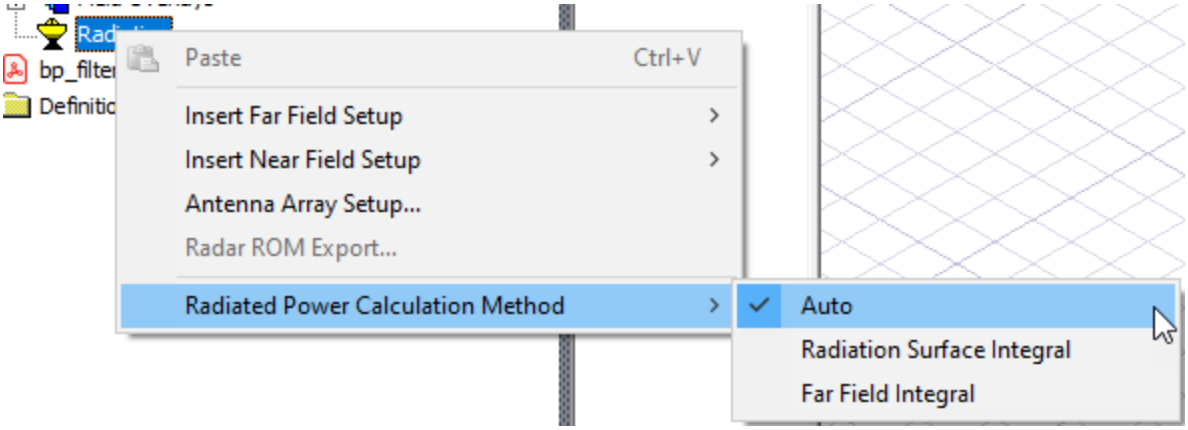
If you create a Radiated Fields report, the Source groups you have created will be listed with other sources in the Context window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Radiated Power Calculation Method

For design that contain only FEM objects, you can select the Radiated Power Calculation method. This can ensure that the radiated power result is continuous in a frequency range or parametric sweep. If the design contains surface regions (IE, PO or SBR+ regions) or linked fields (either a near field or far field link) the power calculation method commands do not appear.



The default selection is Auto.

- For **Auto** mode, the rule is: When design has a single FEM region, we use radiation surface integral. When design has multiple disjointed FEBI regions, we use far field integral. Based on our studies, this rule can ensure the best accuracy for the majority of projects.
- For **Radiation Surface Integral**, near fields are integrated over each element on the radiation surfaces to obtain their contribution of radiated power, and then added together.
- For **Far Field integral**, far field is first calculated over a full sphere, and far fields are integrated over the sphere.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

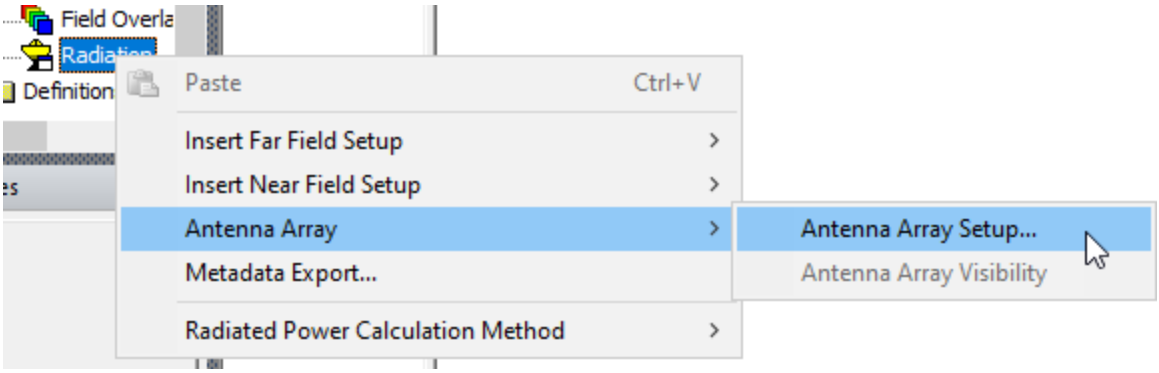
In some case, when the model is barely radiating**, Far Field integral** method may give better accuracy than **Radiation Surface Integral** method.

When **Far Field integral** is used, a correction factor is applied to Radiation Efficiency and Gain calculation (see Computing Antenna Parameters). The correction factor is equal to the ratio of the radiated power calculated from **Radiation Surface Integral** divided by the one calculated from **Far Field Integral**.

Defining Antenna Arrays

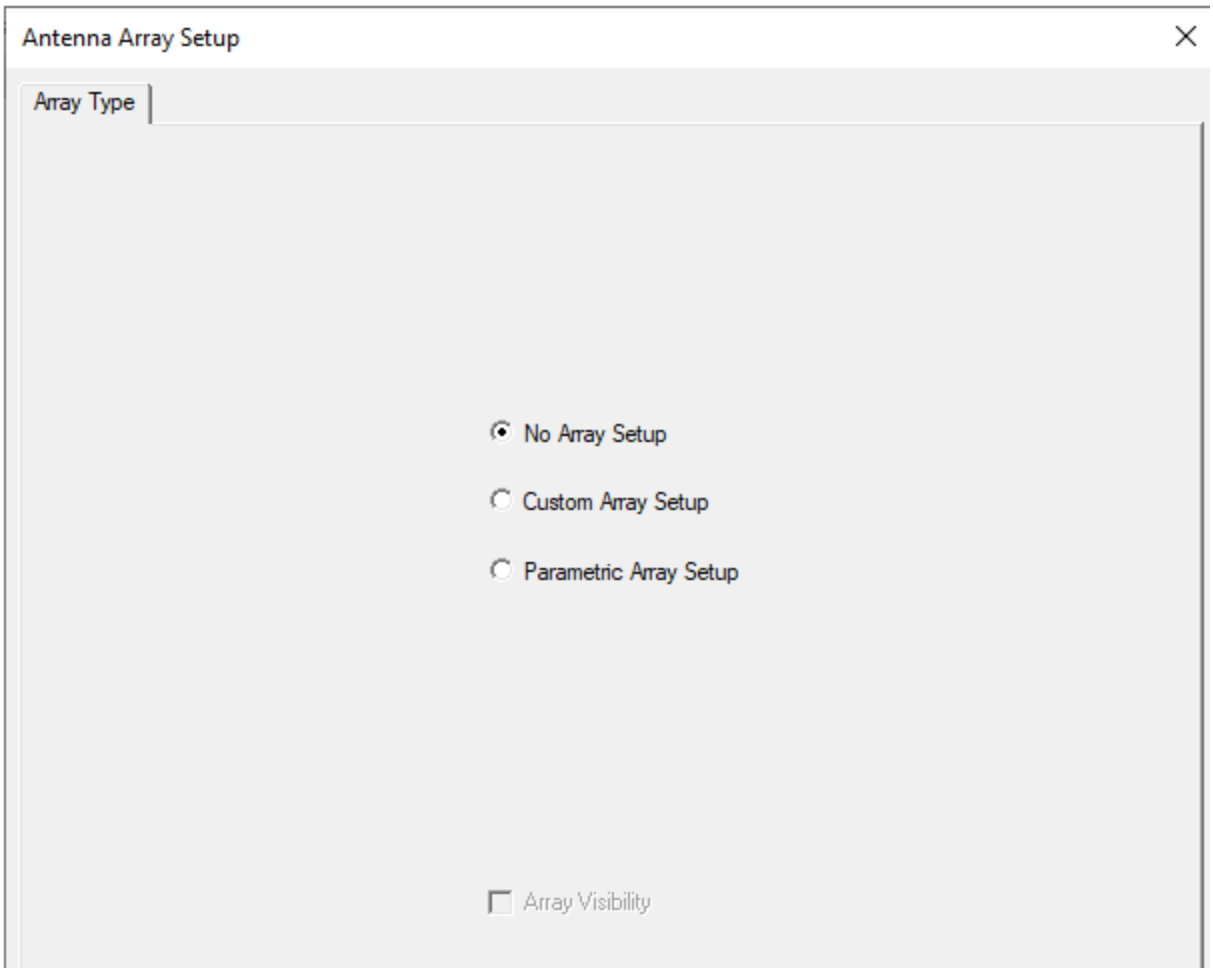
Define a parametric or custom antenna array when you want HFSS to compute antenna array radiation patterns and antenna parameters for designs that have only a single array element. HFSS models the array radiation pattern by applying user specified to the single element's pattern when far fields are calculated.

Click **HFSS >Radiation> Antenna Array>Antenna Array Setup...** or right click on the **Radiation** icon in the **Project** tree and select **Antenna Array>Antenna Array Setup...**



This displays the **Antenna Array Setup** dialog.

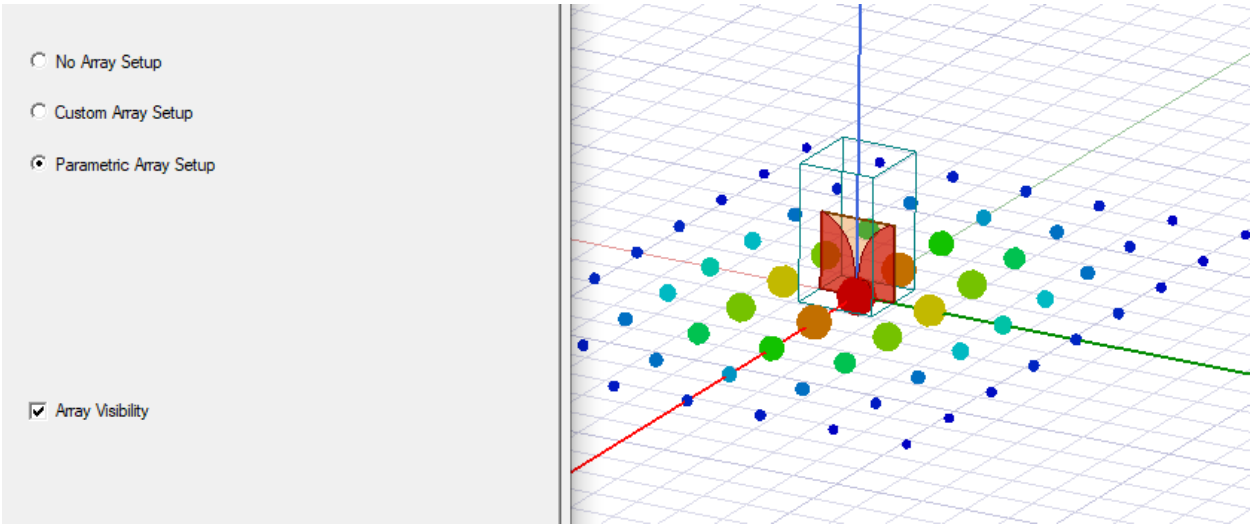
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



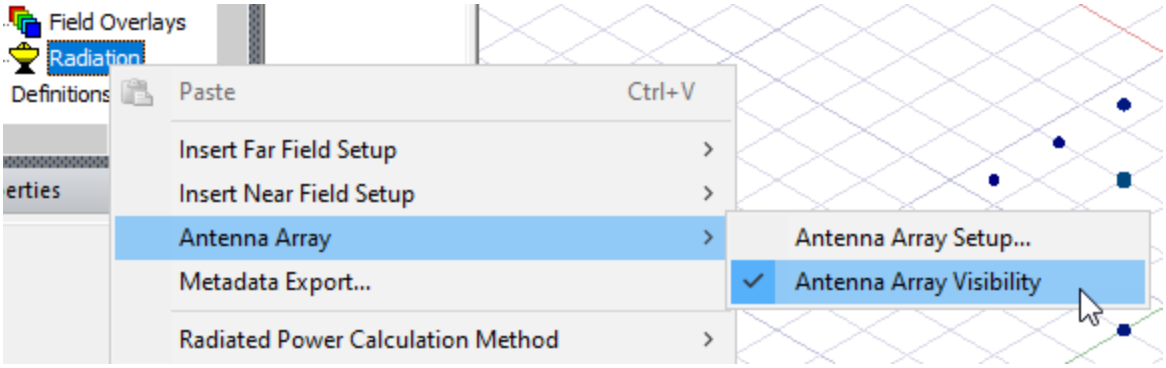
The antenna array setup defines a 2D array based on either a custom array setup based on a text file, or a parametric array setup.

After array type is selected, the **Array Visibility** checkbox is enabled to provides the array visualization based on the parameters provided.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



After antenna array is defined, you can turn on/off the array visualization by toggling on/off the **Antenna Array Visibility** menu .

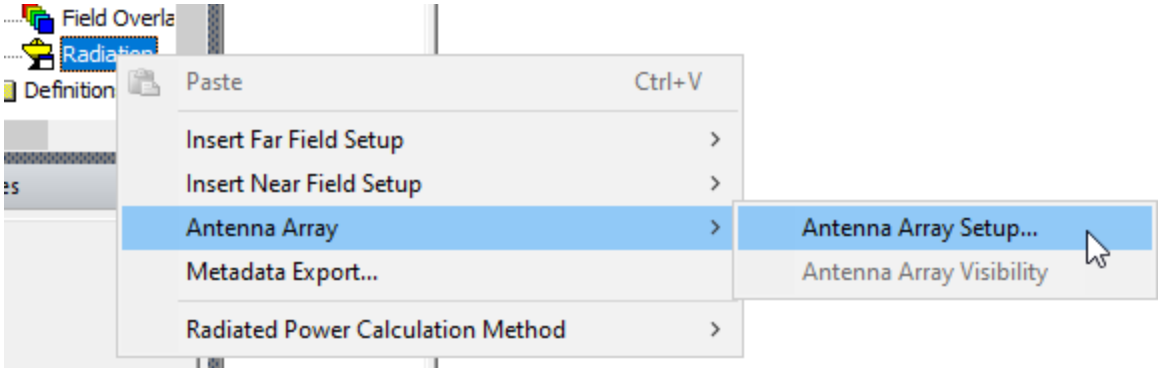


Defining a Parametric Antenna Array

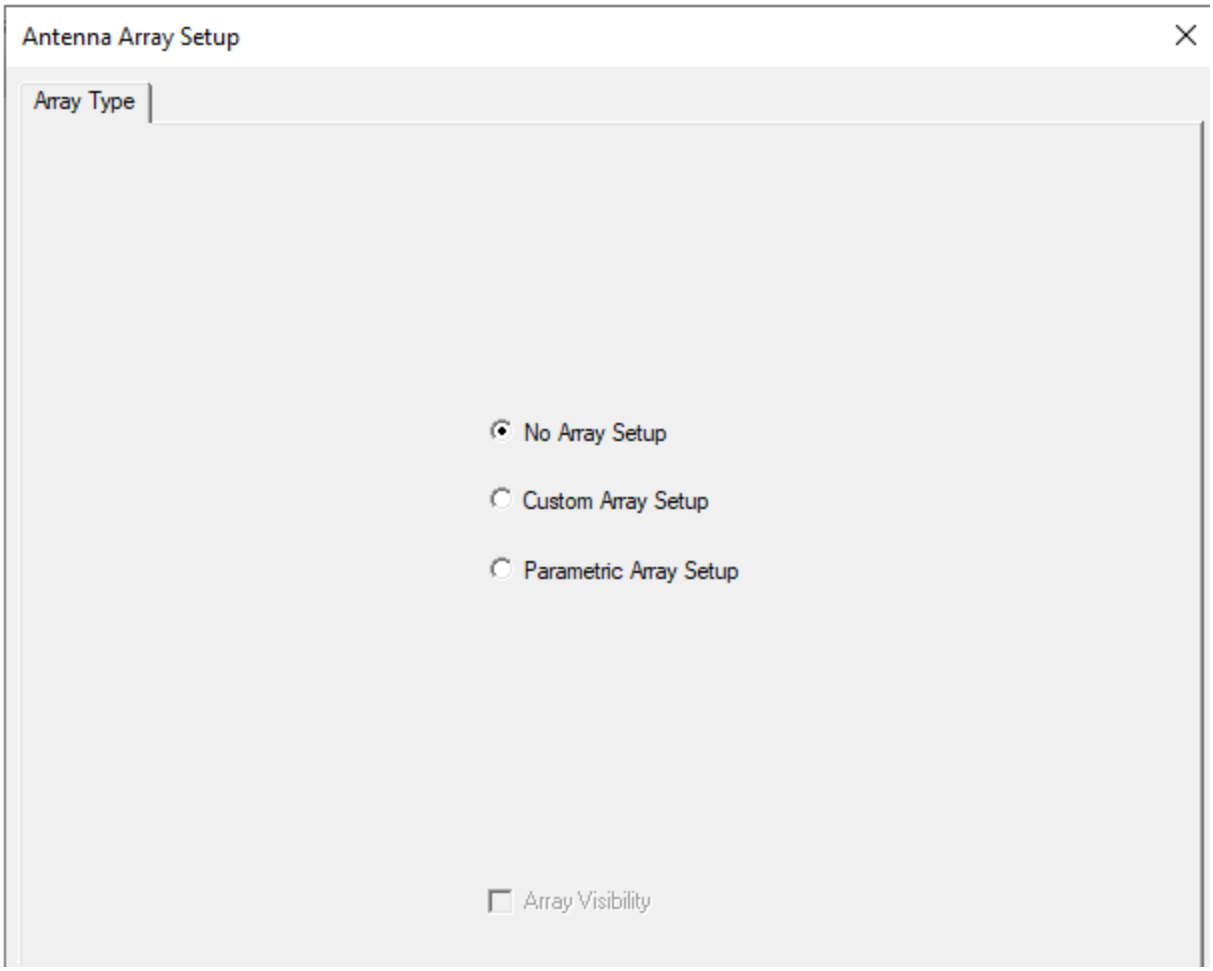
A Parametric antenna array is a finite 2D array geometry, which could easily simulate predefined layout types (rectangular, elliptical, linear), amplitude/weight types (like Uniform, Hamming) and scan definition methods (scan angles, phase shift).

1. Click **HFSS >Radiation> Antenna Array>Antenna Array Setup...** or right click on the **Radiation** icon in the **Project** tree and select **Antenna Array>Antenna Array Setup...**

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



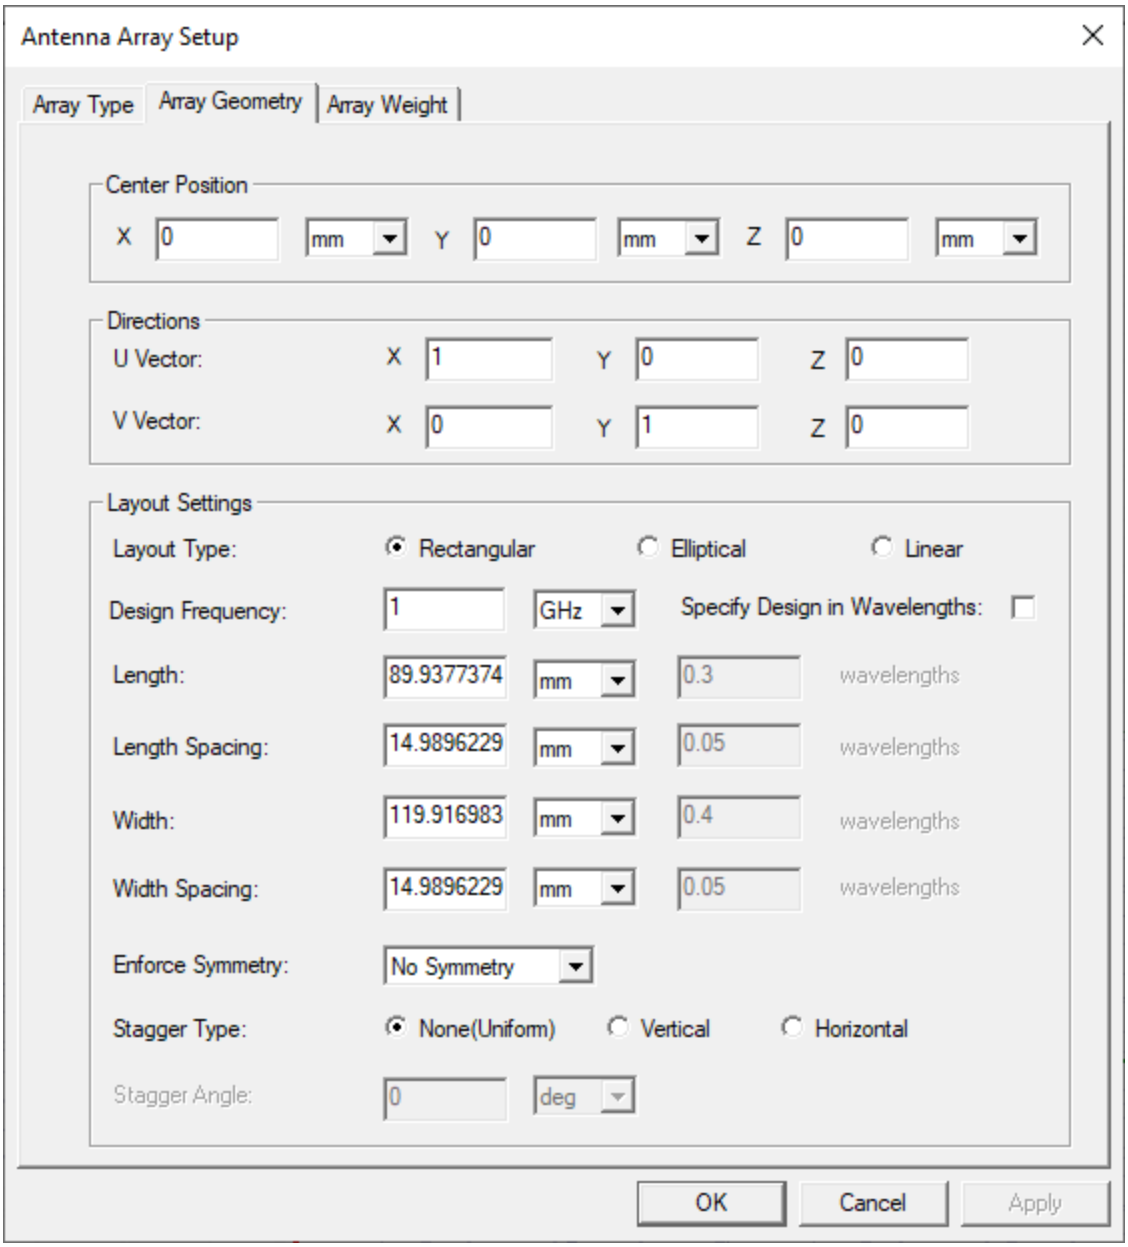
The **Antenna Array Setup** window appears.



2. Under the **Array Type** tab, select **ParametricArray Setup**. The enables tabs for **Array Geometry** and for **Array Weight**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

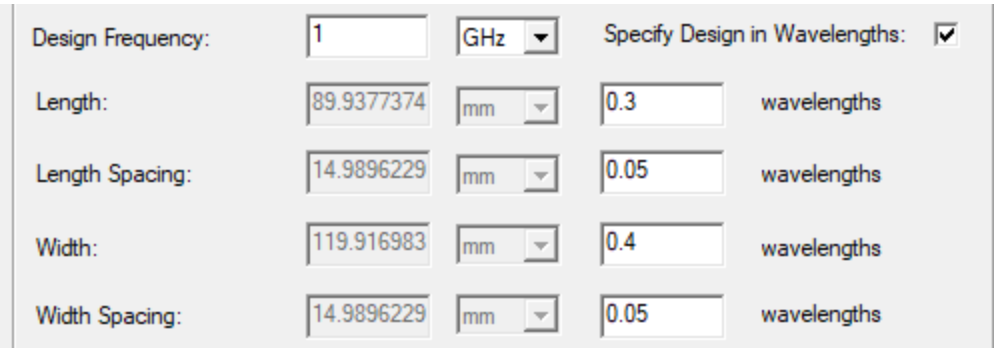
3. Click the **Array Geometry** tab.



4. Under **Center Position**, enter the xyz-coordinates where the center cell is placed.
5. Under **Directions**, define the lattice vectors:
   a. To the right of **U Vector**, enter the vector coordinates in the **X**, **Y**, and **Z** text boxes along which the cells in the U-direction are placed.
   b. To the right of **V Vector**, enter the vector coordinates in the **X**, **Y**, and **Z** text boxes along which the cells in the V-direction are placed.

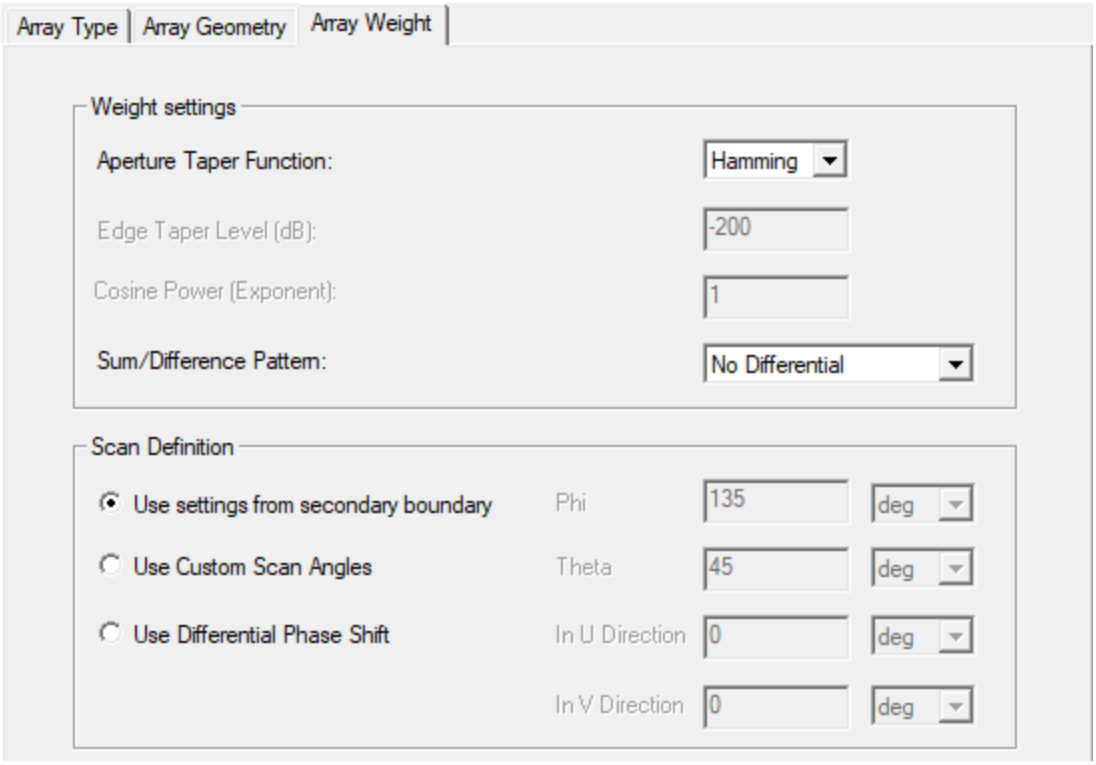
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. Under **Layout Settings**, specify the layout type as Rectangular, Elliptical, or Linear.
7. For **Design Frequency**,by default, specify the Frequency, Length, Length Spacing, Width, and Width Spacing values, as or check to enable Specify Design in Wavelengths.



Note: The “Design Frequency” is only used for array setup and preview. It will not replace the solution frequency. If a Secondary boundary is used, U / V directions and length / width settings would match lattice vectors when setting up a new parametric array.

8. For **Enforce Symmetry**, use the menu to specify No Symmetry, Horizontal Symmetry, Vertical Symmetry, or Horizontal and Vertical Symmetry.
9. For **Stagger Type**, select one of None (Uniform), Vertical, or Horizontal. If you specify a Stagger type, the Stagger Angle field is enabled.
10. Click the **Array Weight** tab.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

11. Under **Weight settings**, select the **Aperture Taper Function** from Hamming, Uniform, Cosine, or Triangular. Each selection enables the appropriate parameters:
    Hamming and **Uniform** require a Sum/Difference Pattern as No Differential, Horizontal Differential, Vertical Differential, or Horizontal and Vertical Differential.
    Cosine requires Edge Taper Level, and Cosine Power [Exponent], as well as Sum/Difference Pattern.
    Triangular requires Edge Taper Level, as well as Sum/Difference Pattern.
12. Under **Scan Definition**, either Use settings from secondary boundary, Use Custom Scan Angles as Phi and Theta, or Use Differential Phase Shift in U or V directions.
13. Click Apply (with Preview Array Layout checked) to view a representation in the Modeler window, and OK to close the dialog and dismiss the preview.

The Array Geometry parameters will be applied, when far fields are calculated.

Defining a Custom Antenna Array

A custom antenna array is an arbitrary array of identical elements distributed in 3D space with individual user-specified complex weights. The array is defined in a text file that includes the element positions, voltage amplitude weights, and phases. See Custom Arrays in the *Technical Notes* for examples of custom array geometry text files.

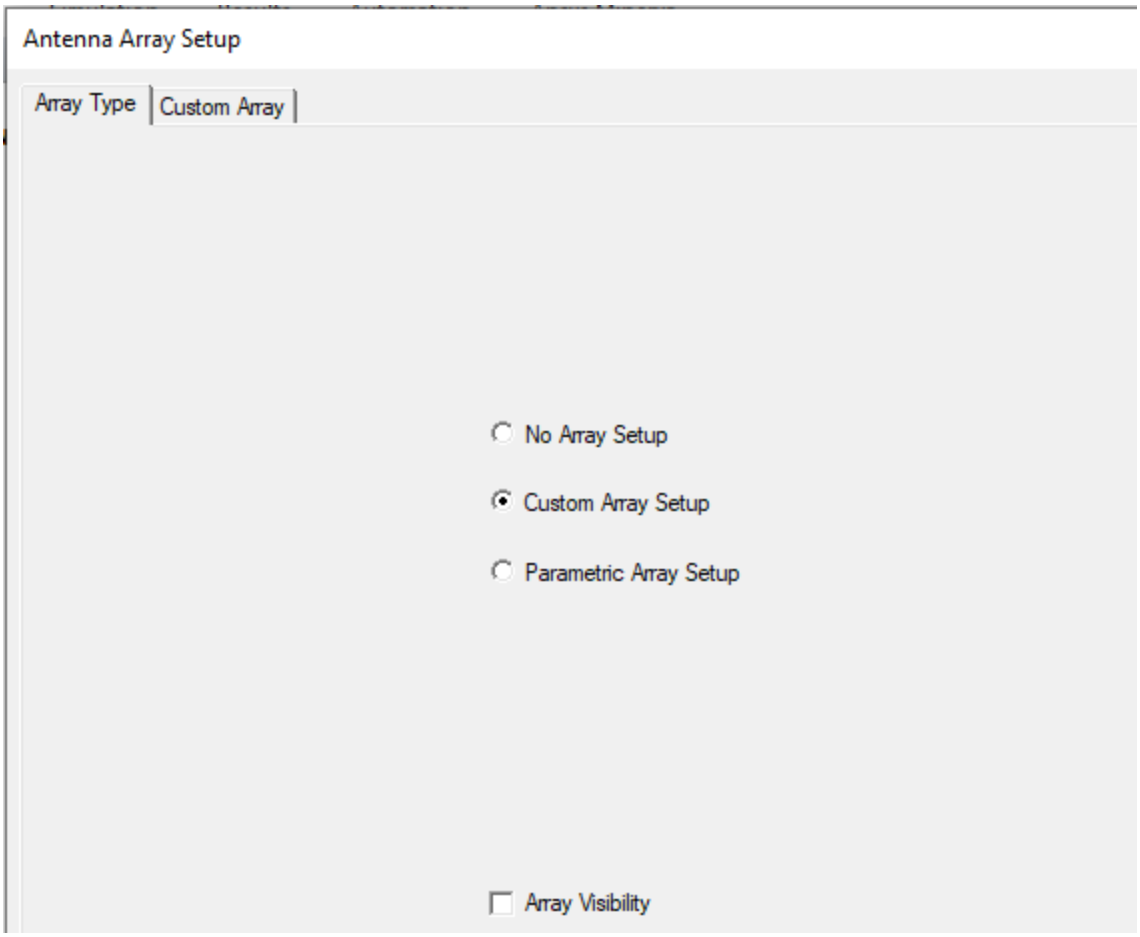
> **Note:**
>
> For custom antenna arrays, phases should be specified in radians.

1. Click **HFSS >Radiation>Antenna Array>Antenna Array Setup...** or right click on the **Radiation** icon in the **Project** tree and select **Antenna Array>Antenna Array Setup...**.

The **Antenna Array Setup** window appears.

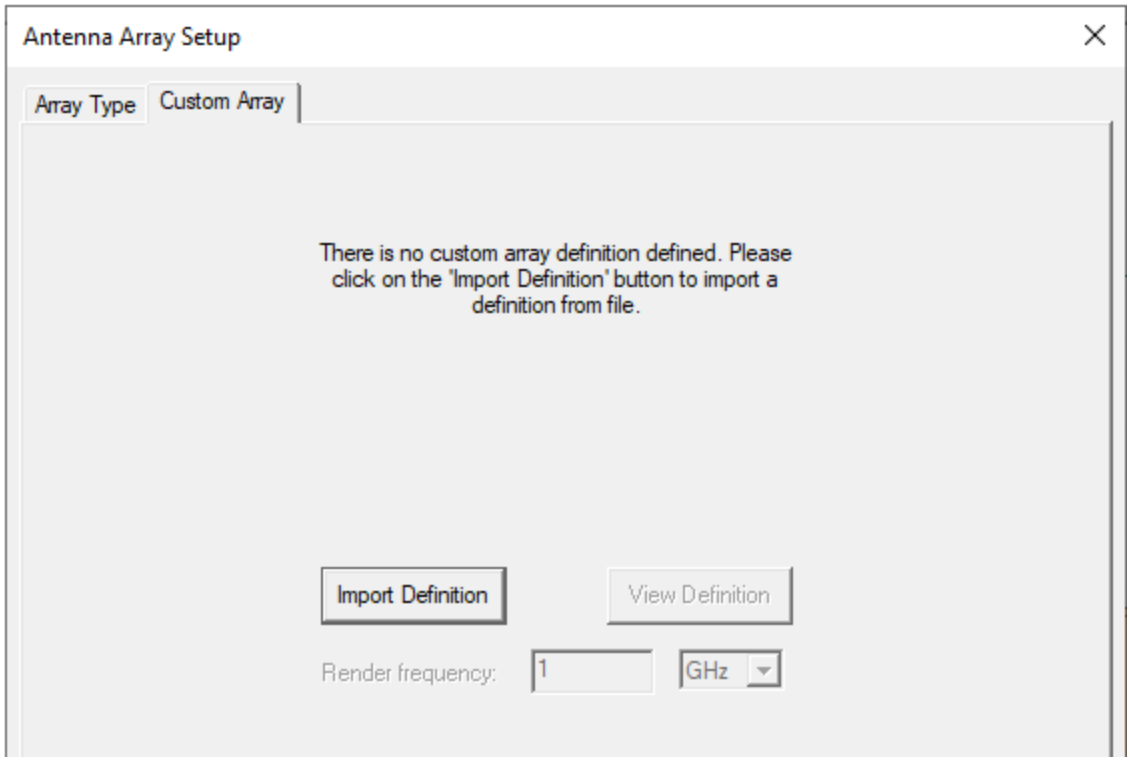
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Under the **Array Type** tab, select **Custom Array Setup**.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Click the **Custom Array** tab.



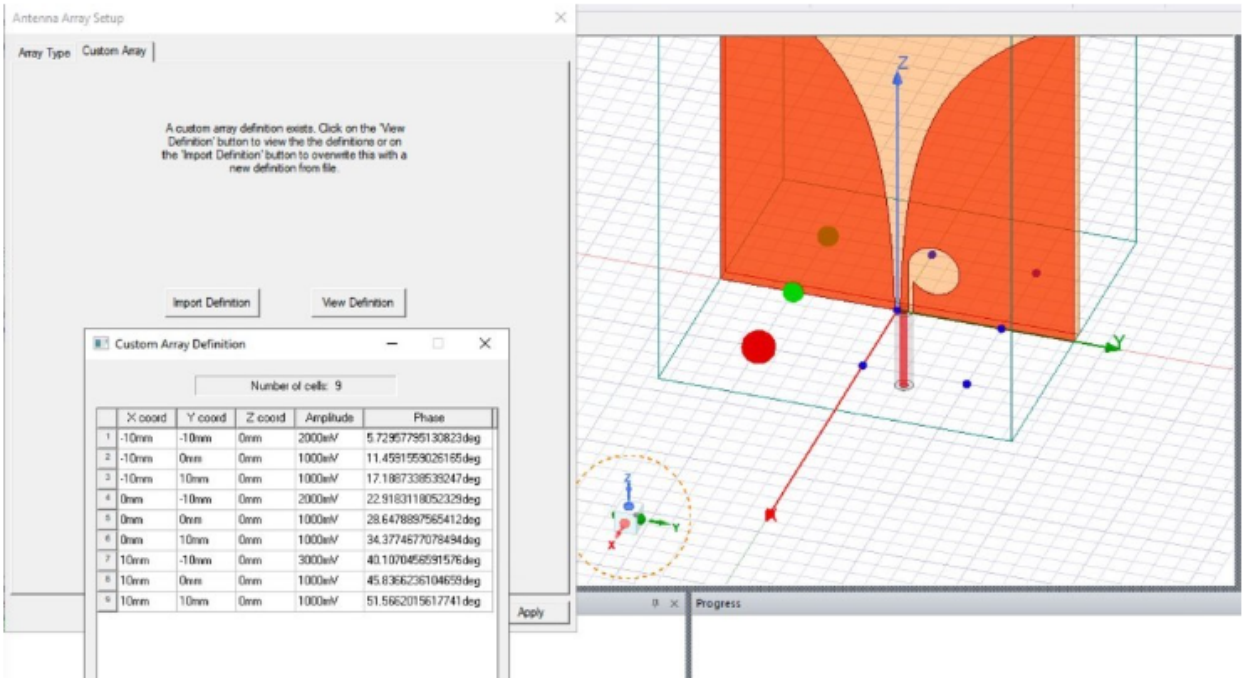
4. Click **Import Definition**.

The **Open** dialog box appears.

5. Follow the procedure for opening a file. Select **.txt** as the file type. When you are finished, click **Open**.
   Note: You can use design / project variables in a definition .txt file. Specifically, the render frequency edit box is enabled if intrinsic variable “freq” is used. As with the parametric array, this render frequency is only used for array preview and will not change the solution frequency.
6. Optionally, review the definition in the text file by clicking **View Definition** under the **Custom Array Setup** tab.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7. With Array Visibility checked, you can Preview a Custom Array Definition in the Modeler window.



8. Click **OK** to dismiss the dialog.

The array factor will be applied, using the information specified in the text file, when far fields are calculated.

Computing Antenna Parameters

You can Export the calculated antenna parameters and maximum field data to a file. You can also Export Fields for a selected setup in the .csv format or .ffd format. This can be useful for situations when want to share the fields without sharing the model geometry. You can save for use on an antenna parameters Overlay. You can also Export Element Pattern the far field relative to the specified inputs and sources

Note: A Beta feature for HFSS, Hfss Interactive Dialogs, allows you run the **Edit Sources** dialog and the **Antenna Parameters** dialog in modeless fashion, that is, if you **Edit Sources** for magnitude or renormalization, affected Antenna Parameters update. If you edit excitations or ports in the Far Field Setup, or create design variations in Optimetrics, the **Edit Source** dialog will close.

Case that update in this mode:

- Infinite sphere setup created, deleted or renamed: Setup Name combo box changes radiation setup.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Solution setup created, deleted or renamed.
- Antenna array setup created or deleted.
- Source group created, deleted or renamed.

Note: Intrinsic Variation updates as the solution setup changes. Grids of “Antenna Parameters” and “Maximum Field Data” update data as any of the combo box selections changes. The dialog closes if solution type is changed.

Prerequisites

You must have defined at least one radiation or PML boundary in the design for HFSS to compute antenna parameters and maximum field data for the far-field region.

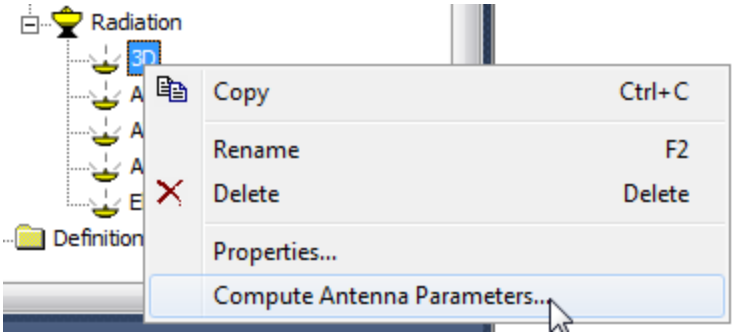
You must have selected Save Fields or Save Radiation Fields only in the Solution setup, and must have generated a solution for a Driven Modal / Driven Terminal / SBR+ / Transient design.

You must have specified and selected Radiation setup.

If the project is a Finite Array, and you want to specify Source Groups, you must previously create them.

Procedure:

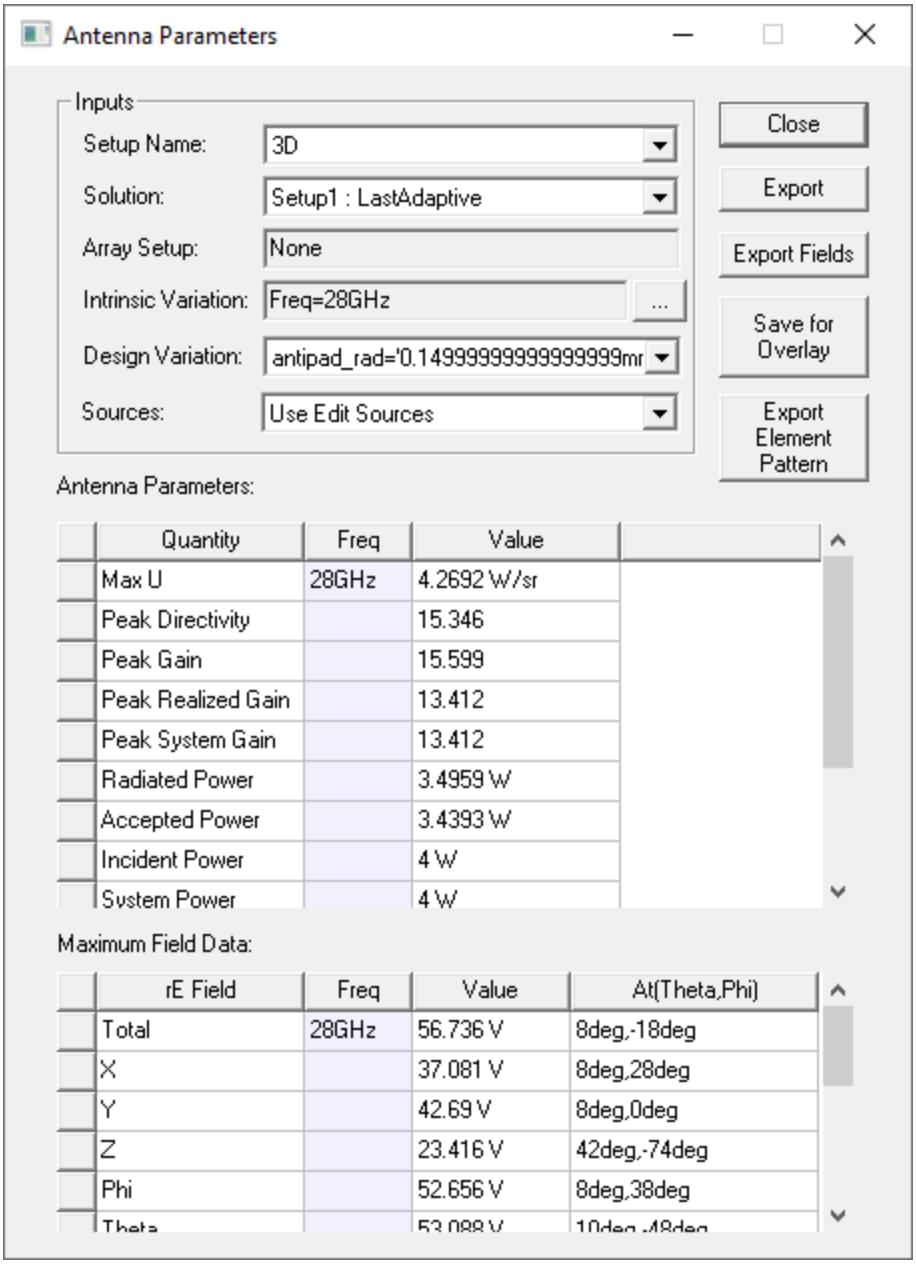
1. To select the radiation setup from the Project tree for a Driven Modal / Driven Terminal / SBR+ / Transient design, right-click the **Infinite Sphere** icon in the project tree under Radiation, and then click **Compute Antenna Parameters** on the shortcut menu.



Or, to select the radiation setup from a dialog, click **HFSS >Radiation>Compute Antenna Max/Params**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

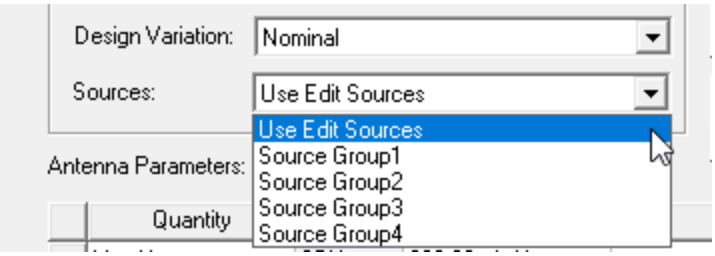
The **Antenna Parameters** dialog box appears.



2. Select the Radiation Setup Name. A dropdown menu lets you select from available setups.
3. For the **Solution**, select the solution for which you want HFSS to compute antenna parameters.
4. If there is an array, select the setup to use.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. For the **Intrinsic Variation**, select the solved frequency point at which you want HFSS to compute antenna parameters.
6. If there is more than one Design Variation available, you can select from the drop-down menu.
7. For Finite Arrays, if you have created one or more source groups, you can select from the drop-downlist.



8. The **Antenna Parameters** table lets you view computed parameters. If the design includes ports, the following antenna parameters are listed:

Maximum intensity (Max U)
- Peak directivity
- Peak gain
- Peak realized gain

System Gain (if specified in Edit Sources)
- Radiated power
- Accepted power

System Power (typically from an external circuit design and specified in Edit Sources)
- Incident power
- Radiation efficiency

System efficiency

Total Efficiency
- Front to Back Ratio
- Decay Factor

> **Warning:**
>
> The computed values of max U and peak directivity depend on the user-determined set of aspect angles chosen for the computation of the radiated fields. If this set does not encompass the actual peak intensity of the radiated pattern, the displayed results for these three parameters will be inaccurate.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> **Accepted Power** is computed from the raw S-parameter data. Post-processing operations are excluded from the calculation, for example, renormalized S-parameters.

> **Note:**
>
> It is important to understand the impact of passive ports (for Transient Network designs or models containing an Array with passive ports) on antenna parameters. For accepted power calculations, passive ports are not included when computing the total power passing through the union of all port surfaces. This means that the passive ports can be viewed as a loss mechanism for the device and it is not equivalent to viewing the passive ports as active ports with zero excitations.

Gain and realized gain are very close to each other when the antenna is matched. However, for designs with a multi-port antenna, gain and realized gain can be different if incident and accepted power are different. There can be a small reflection at the ports and accepted power may still be small if energy injected in one port exits the model through a different port. A review of the S-matrix can show this to be the case. This does not happen in a single port antenna, which is what most users base their expectations on.

When global material environment is a lossy material, antenna parameters such as gain and radiated power are no longer unique because the radiated power depends on the location of the radiation surface since power is lost as the wave travels in the background material.

If the design does not have ports, the following antenna parameters are listed:

Maximum intensity (Max U)
Peak directivity
Radiated power

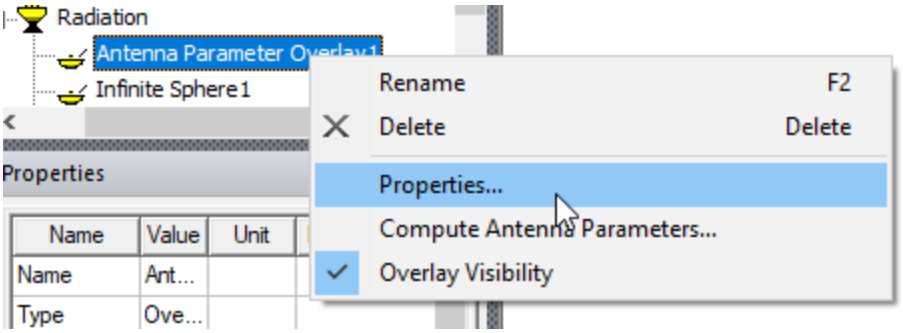
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9. You can view the following maximum far-field data:

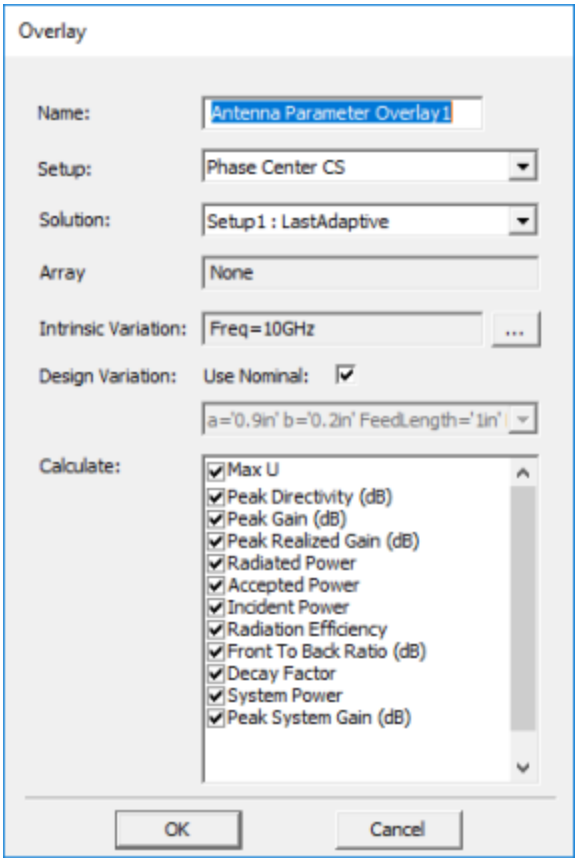
   Total
   X
   Y
   Z
   Phi (depending on CS Definition in the Far Field Infinite Sphere)
   Theta (depending on CS Definition in the Far Field Infinite Sphere)
   Azimuth(depending on CS Definition in the Far Field Infinite Sphere)
   Elevation(depending on CS Definition in the Far Field Infinite Sphere)
   LHCP
   RHCP
   Ludwig 3/X dominant
   Ludwig 3/Y dominant

> **Note:**
>
> When calculating the maximum far-field values, the distance *r* is factored out of the E-field. Therefore, the units for the maximum field data values are given in volts.

You can right click on an Antenna Parameters Overlay in the Project tree to open a Properties dialog that lets you select a set of the available parameters.



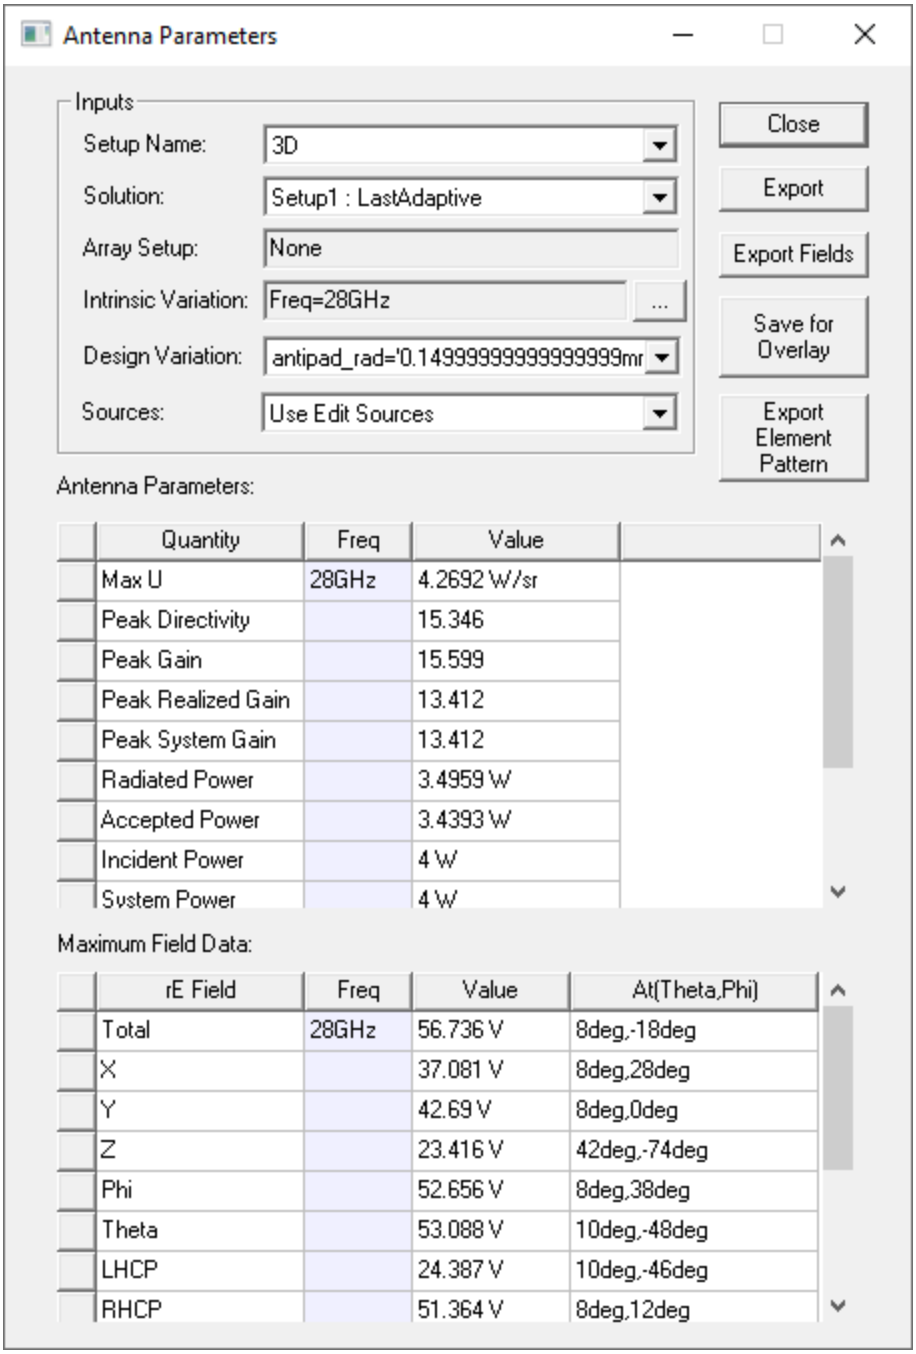
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Exporting Antenna Parameters and Maximum Field Data

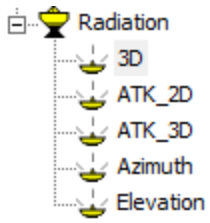
The **Antenna Parameters** dialog displays the calculated antenna parameters and Maximum Field data for a setup. The dialog also includes a buttons to **Export** antenna parameters and to **Export Fields**. The fields can be exported in ffd or .csv format and imported into reporter as a table. You can specify the Setup Name, the Solution, Array Setup (if any), Intrinsic Variation, and Design Variation.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

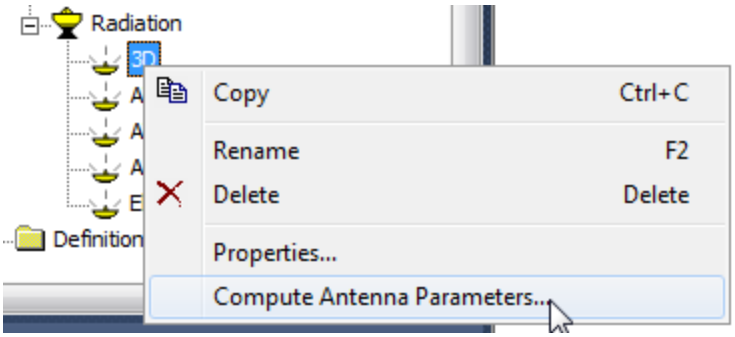


The Setup Name corresponds to the Radiation Setups you create, or that are created by the Antenna Design Kit, for example:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To open the **Antenna Parameters** dialog box, right-click the Radiation setup for which you want to export parameters or fields, and select **Compute Antenna Parameters** from the menu



To export the antenna parameters to a text file:

1. Click **Export** on the **Antenna Parameters** dialog.

   This displays a file browser.

2. Specify the file name and location (or accept the defaults).
3. Click **Save**.

   This saves the text file and closes the browser.

   Parameter Format: The parameters are exported to a text file in the following format:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Quantity	Freq	Value	
Max U	0.9GHz	1.358067	mW/sr
Peak Directivity		1.745194	
Peak Gain		1.752898	
Peak Realized Gain		1.706638	
Radiated Power		9.779070	mW
Accepted Power		9.736095	mW
Incident Power		10.000000	mW
Radiation Efficiency		1.004414	
Front to Back Ratio		1.012037	
Decay Factor		0.000000	

rE Field	Freq	Value		(Theta, Phi)
Total	0.9GHz	1.011920	V	(90deg,-46deg)
X		456.079554	mV	(48deg,180deg)
Y		456.794982	mV	(48deg,-90deg)
Z		1.011920	V	(90deg,-46deg)
Phi		4.228478	mV	(28deg,-52deg)
Theta		1.011920	V	(90deg,-46deg)
LHCP		715.836833	mV	(90deg,-46deg)
RHCP		715.234428	mV	(90deg,-46deg)
Ludwig3/X dominant		1.008985	V	(90deg,0deg)
Ludwig3/Y dominant		1.008579	V	(90deg,-90deg)

To export the maximum field data to a comma separated format file:

1. Click **Export Fields** on the **Antenna Parameters** dialog

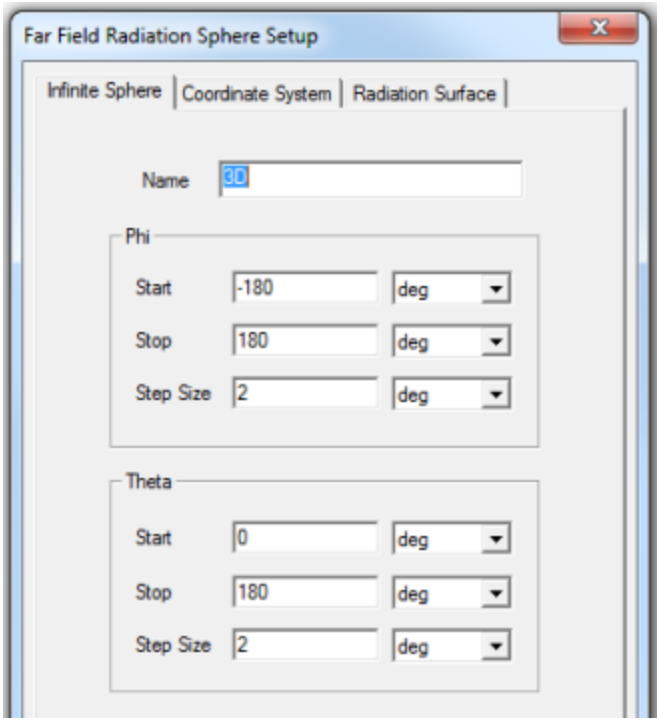
   This displays a file browser

2. Specify the file name and location (or accept the defaults)
3. Select Save as type as Far Field Data (*.ffd) or Comma Separated (*.csv).
3. Click **Save**.

   This saves a text file for the selected Radiation setup in the specified type and closes the browser.

Depending on the kind of Radiation Setup you define, and your Save as type specification, and the coordinate system of the design, the formats will differ. For example for an Infinite Sphere Radiation Setup, using the CS definition as Theta-Phi, will appear as follows:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The first lines of the exported .ffd file show the Theta start and stop, then number of steps and then the Phi start and stop values, then number of steps, followed on the next line by the Frequencies number, then on the next line, the first frequency value, followed by field values for that frequency.

```
0 180 91
-180 180 181
Frequencies 1
Frequency 9.000000000000000e+008
1.064046258878916e-003 -2.994761550861182e-003 1.730463512343075e-003 -1.912365743030195e-003
1.123790376290396e-003 -3.059677824982989e-003 1.692274681823832e-003 -1.806685110620843e-003

If the CS definition in the Infinite Sphere uses ElOverAz, the first line of the .ffd file has a line saying this. After that identification the next two lines are the Elevation over Azimuth angle definitions (i.e. start, end angle and # of angles). The second angle is always the outer loop, same as for theta phi.

```

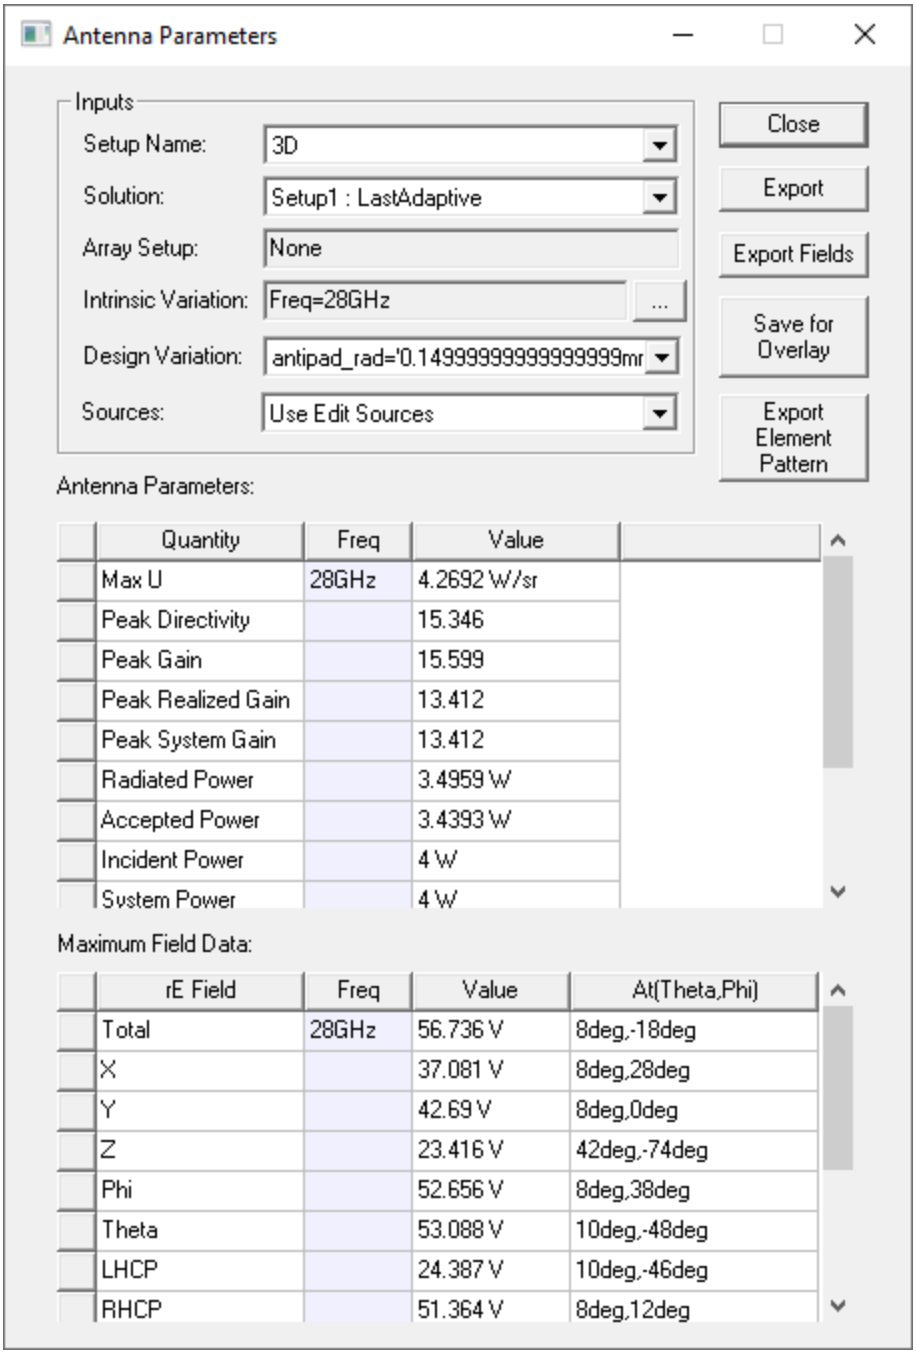
Index, Theta, Phi, Er(real, imag), Etheta(real, imag), Ephi(real,
imag), Hr(real, imag), Htheta(real, imag), Hphi(real, imag)
```

Export Element Pattern from Antenna Parameters

The **Antenna Parameters** dialog displays the calculated antenna parameters and Maximum Field data for a setup. The dialog also includes a button to **Export Element Pattern** for the far field relative to the specified inputs and sources. That is, you can specify the Setup Name, the Solution, Array Setup (if any), Intrinsic Variation, Design Variation and Sources.

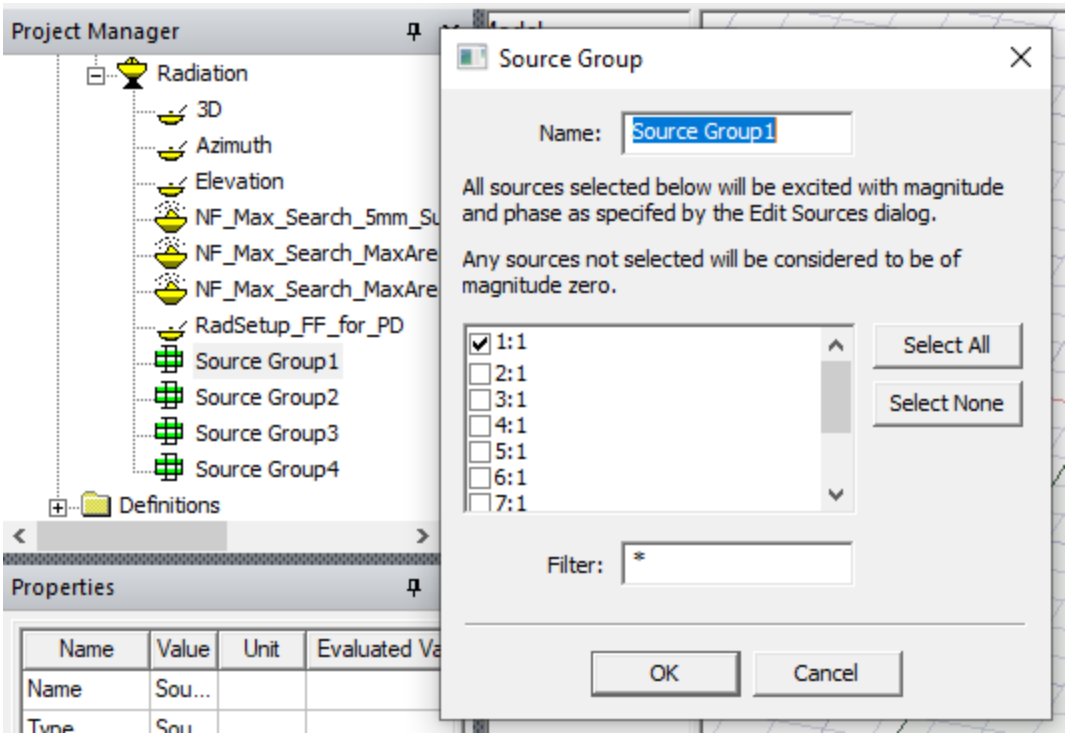
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The element pattern export functionality is based on the source group, which means only export the sources contained in the selected source group. To create Source Groups, see Setting up a Source Group. If you select “Use Edit Sources”, then the export includes the sources in Edit Sources dialog box. For each source in the source group, the export provides far field in one ffd file. And each ffd file name is based on the base file name: base file name + “_” + index, where the index is the order of the source shown in **Edit Sources** dialog box. For clarity, we also export

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

an additional txt file for user, showing the source name to its corresponding ffd file name. The fields are exported in ffd format and can be imported into Reporter as a table.



Since source groups are not supported In Transient solution type, clicking **Export Element Pattern** exports all the sources in **Edit Sources** dialog (i.e. equivalent with “Use Edit Sources”).

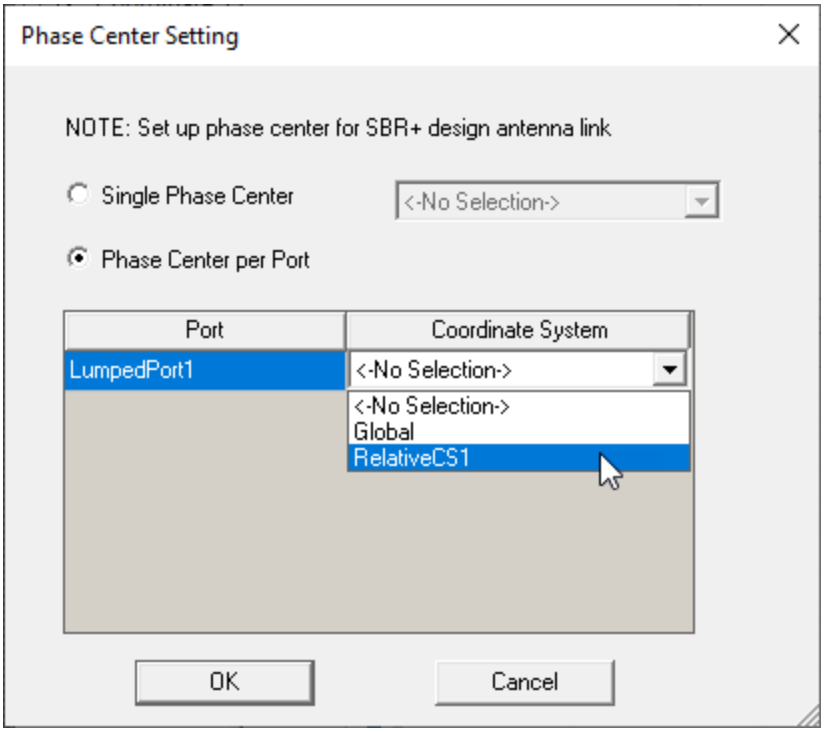
The exported far field data in ffd file is based on the conditions when activated source(s) are excited with 1.0 magnitude in SI units and 0.0 phase, and inactivated sources have 0.0 magnitude and 0.0 phase.

In Driven Terminal solution types, if a source is terminated, no far field file will be exported for it. The other exported sources are affected by the resistance and reactance of the terminated source.

Export Element Pattern respects the phase center setting, if used. (For the **Set Far Field Phase Center** command, see Link from Driven Modal Design to SBR+ Design.)

If a per-port phase center is defined, for a finite array design, the phase center coordinate system (CS) will shift according to the unit cell location (also the same to SBR+ link). If a global phase center is defined, all the ports will use that CS for export. No phase center CS shift will happen.

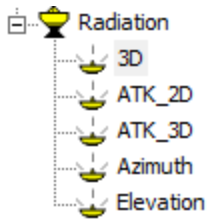
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If the phase center setting is not defined, then the export will use the reference coordinate system in the infinite sphere setup, and there will not be an automatic shift for finite array design for unit cells. So basically all the ports will use the same CS for phase center.

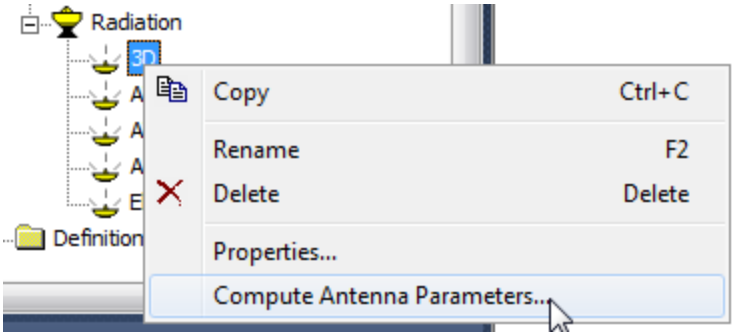
Procedure for Export Element Pattern

The Setup Name corresponds to the Radiation Setups you create, or that are created by the Antenna Design Kit, for example:

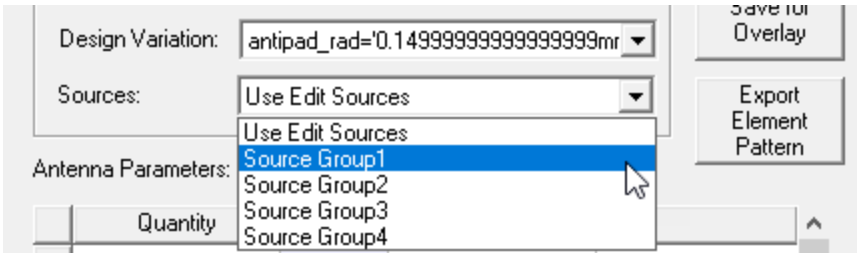


To open the **Antenna Parameters** dialog box, right-click the Radiation setup for which you want to export parameters or fields, and select **Compute Antenna Parameters** from the menu

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Select the desired source group via combo-box named as “Sources”.

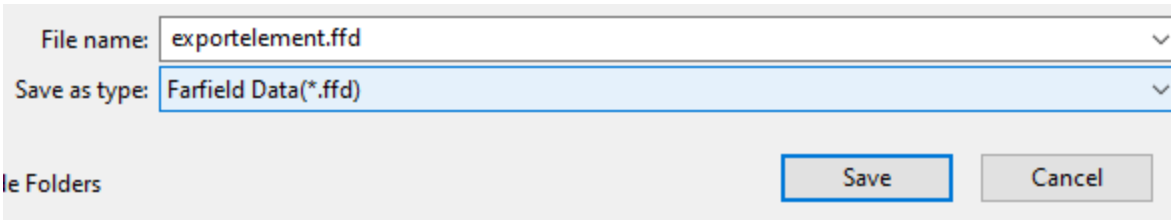


The element pattern export functionality is based on the source group, which means we only export the sources contained in the selected source group. If user selects “Use Edit Sources”, then we will export all the sources in the Edit Sources dialog.

To export the Element patterns to an .ffd text file:

1. Click **Export Element Pattern** on the **Antenna Parameters** dialog

   This displays a file browser

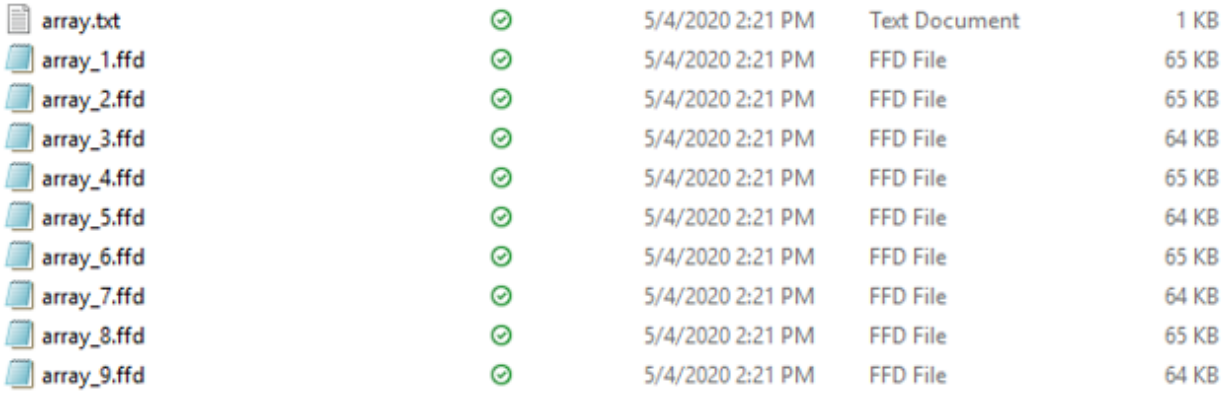


2. Specify the file name and location (or accept the defaults). Save as type is Far Field Data (*.ffd).
3. Click **Save**.

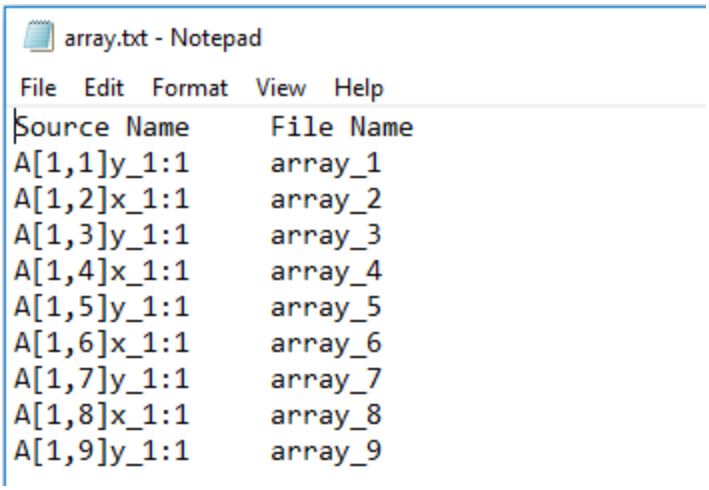
   This saves a text file for the selected Radiation setup in the specified type and closes the browser.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For each source in the source group, we export its far field in one ffd file. And each ffd file name is based on the base file name: base file name + "_" + index, where the index is the order of the source shown in Edit Sources dialog box. For clarity, we also export an additional txt file for user.



This figure shows the content of an array.txt file. It shows the source name to its corresponding ffd file name



The content in each source's ffd file is the far field data on an infinite sphere. If the infinite sphere setup is defined with the CS Definition as Theta-Phi, the first two lines are the theta, phi angle definitions (i.e. start, end angle and # of angles). Each data line contains the eTheta and ePhi in complex #. It has the same format as the far field data file produced by **Export Fields** in Antenna Parameters dialog.

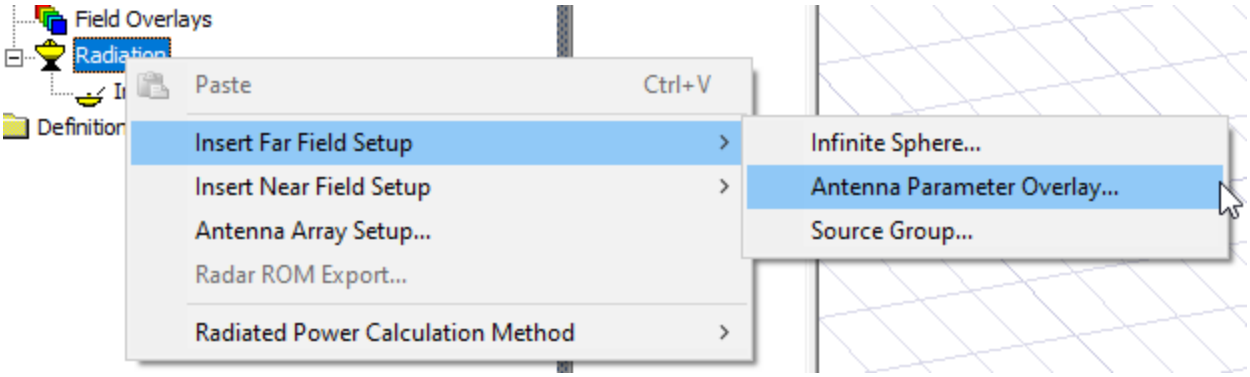
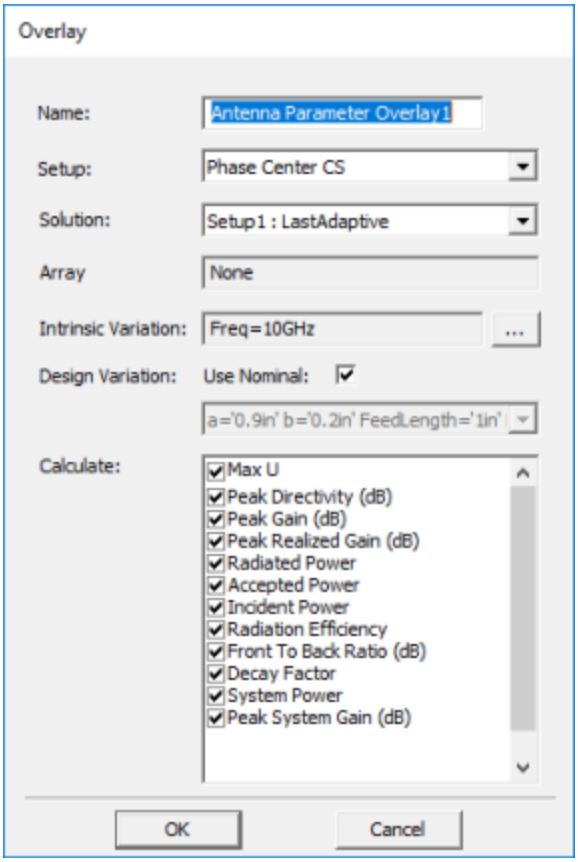
Antenna Parameters: Save for Overlay

To save antenna parameters for overlay, you can either use the Save for Overlay button in the **Antenna Parameters** dialog box, or go through the **HFSS>Radiation>Insert Far Fields Setup>Antenna Parameters Overlay** command, or right-click the Radiation icon for the shortcut menu and select **Insert Far Field Setup>Antenna Parameters Overlay.**



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

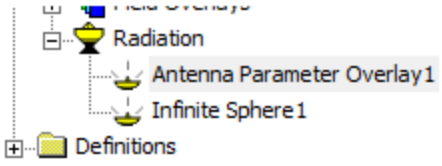
These methods display the **Overlay** dialog.



Here you can specify the Name, the Setup to use, an Array, if any, and which design variation to use. You can then check which antenna parameters to save for use in an overlay.

You can specify multiple intrinsic variations (for example, parameters at several frequencies), just as in the **Compute Antenna Parameters** dialog box. Click the ellipsis button [...] to select from available variations.

When you **OK** the dialog box, the Antenna icon appears under the Radiation icon in the Project tree.



You can rename, delete, undo, or redo just as for any other item in the Project tree.

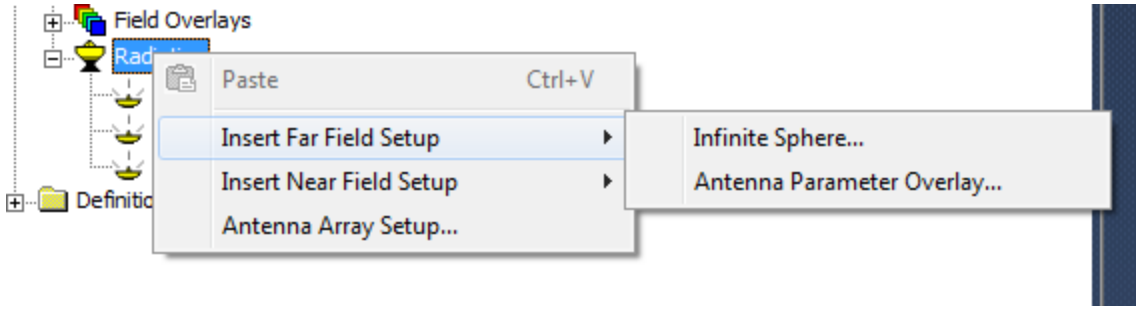
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once you have created an overlay, you can also edit the name, setup, solution, variation, and so forth, and have the changes immediately reflected in the display. To display the saved Overlay, see Creating and Displaying Antenna Parameter Overlays.

Creating and Displaying Antenna Parameter Overlays

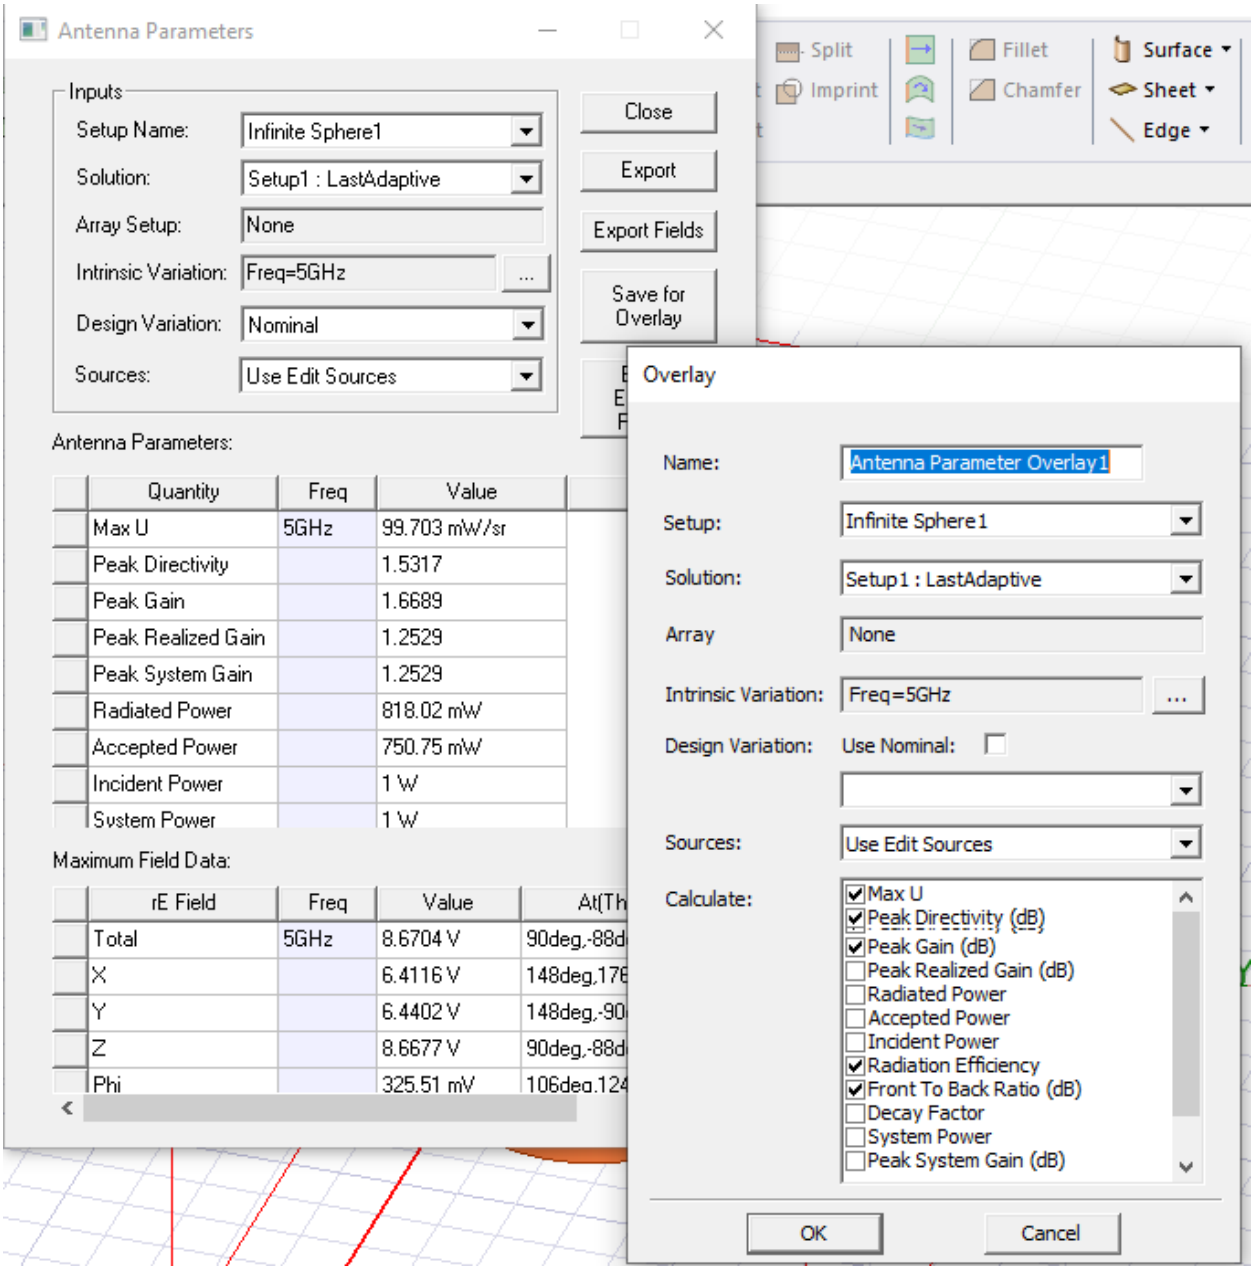
An Antenna Parameter Overlay is a table of antenna parameters that you can overlay on the 3D Modeler window for Far Field radiation plots an animations.

1. To create and display an overlay, you can either use the Save for Overlay button in the **Antenna Parameters** dialog box, or go through the **HFSS>Radiation>Insert Far Fields Setup>Antenna Parameters Overlay** command, or right-click the Radiation icon for the shortcut menu and select **Insert Far Field Setup>Antenna Parameters Overlay.**



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

These methods display the **Antenna Parameters** dialog box. Click **Save for Overlay** to select which parameters to save for the overlay display.

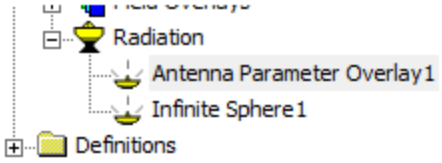


In the Antenna Parameters dialogy, you can specify the Name, the Setup to use, an Array, if any, and which design variation to use. You can then check which antenna parameters to save for use in an overlay.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can specify multiple intrinsic variations (for example, parameters at several frequencies), just as in the **Compute Antenna Parameters** dialog box. Click the ellipsis button [...] to select from available variations.

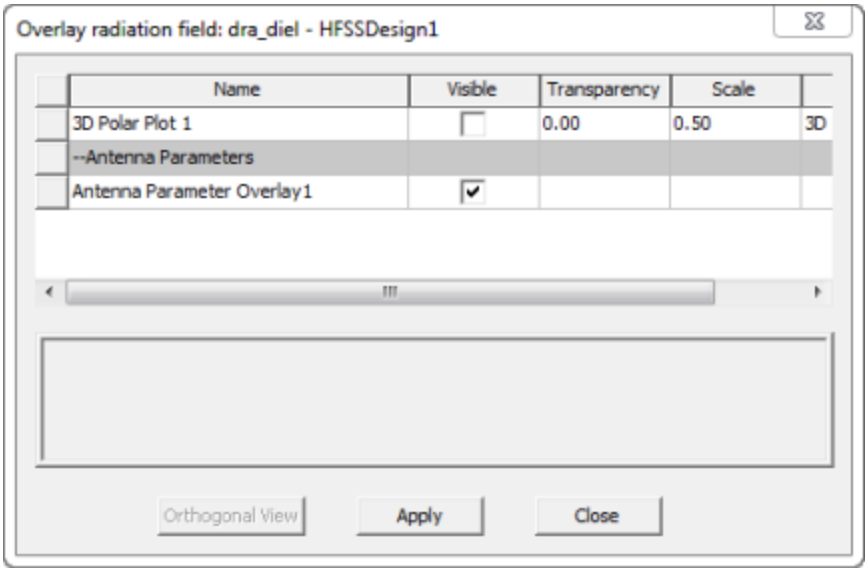
2. When you **OK** the dialog box, the Antenna icon appears under the Radiation icon in the Project tree.



You can rename, delete, undo, or redo just as for any other item in the Project tree.

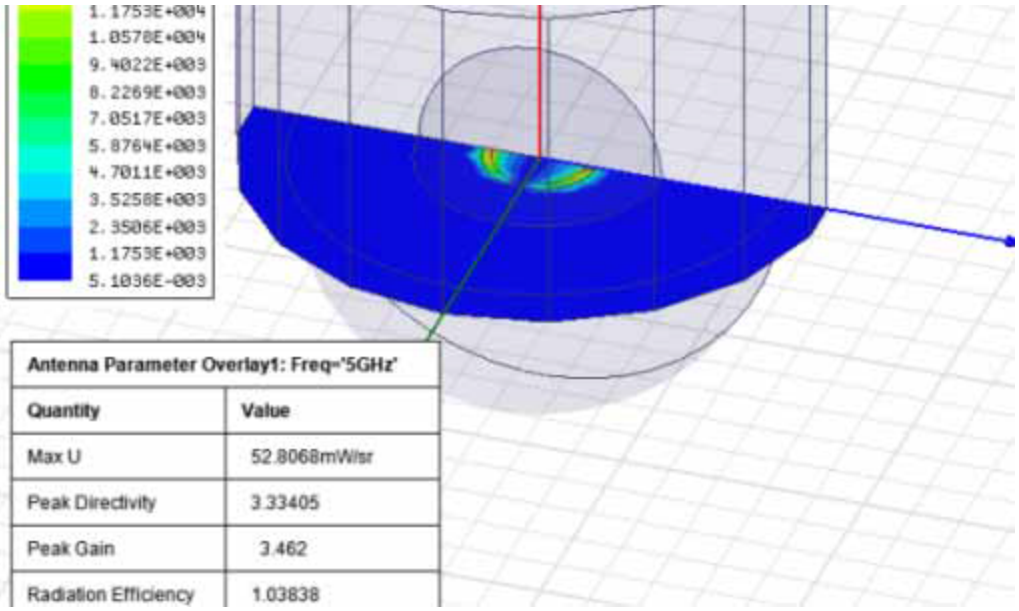
3. To display the Antenna Parameter an overlay, you either click **HFSS>Fields>Plot Fields>Radiation Fields** or right-click **Field Overlays** in the Project tree and select **Plot Fields>Radiation Field** from the short cut menu.

The Antenna parameters appear as a selection on the **Overlay radiation field** dialog.



4. Check the Visible check box and click **Apply** to cause the parameters to display as an overlay on the lower left of the 3D Modeler window.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Once you have created an overlay, you can also edit the name, setup, solution, variation, and so forth, and have the changes immediately reflected in the display.te and display an antenna parameters overlay:

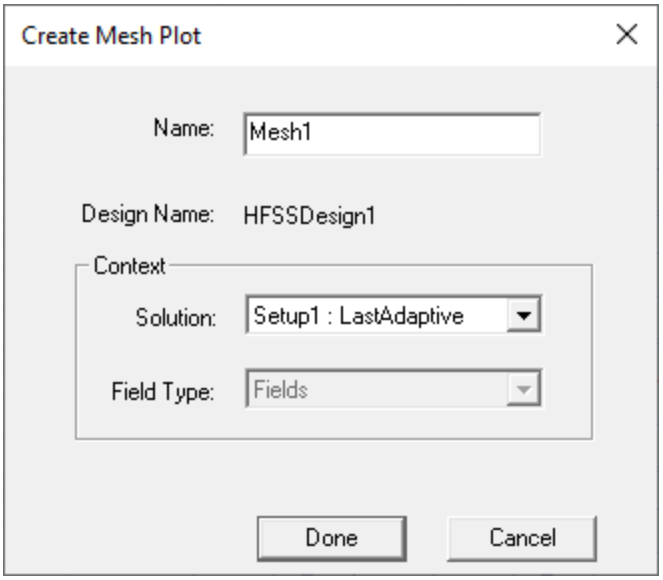
Plotting the Mesh

Before or after the solution is complete, you can plot the finite element mesh on surfaces or within 3D objects. For an HFSS or Maxwell design that includes Layout Components, you can also select nets and layers from the layout components to plot.

1. Select one or more surfaces or objects to create the mesh plot on or within. If the design is HFSS and includes Layout Components, you can select the surfaces either before or after selecting **Plot Mesh**.
2. Select **Plot Mesh** in one of two ways:
   - Click **HFSS** > **Fields**> **Plot Mesh**.
   - In the Project Manager, right-click **Field Overlays** and select **Plot Mesh...**

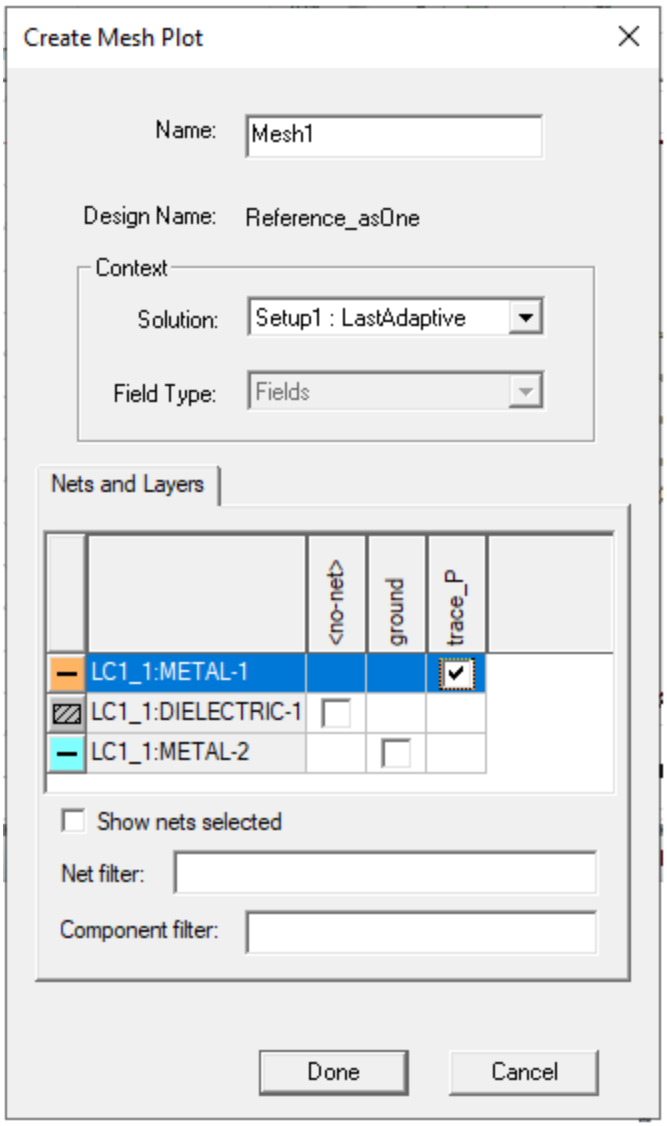
     The *Create Mesh Plot* dialog box appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



If the HFSS design includes Layout Components, the **Create Mesh Plot** dialog box includes a table of Nets and Layers from which you can make selections.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This **Nets and Layers** section displays all the layers and nets of every layout component in the design. Upon opening, it adjusts its size to try to show all the rows and columns for the layout components. You can resize the parent dialog. For objects in the component belonging to a specific layer and net, you can select a checkbox. By clicking the column headers, you can select or unselect checkboxes for an entire column. You can toggle the **Show nets selected** checkbox to move all the selected nets to the left side of the table. You can use the **Net filter** and **Component filter** fields to filter out specific nets and components. The net and component filters support '*' and '?' wildcards and you can delimit multiple filters with commas. The Nets and Layers table is refreshed each time you update the filter text.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

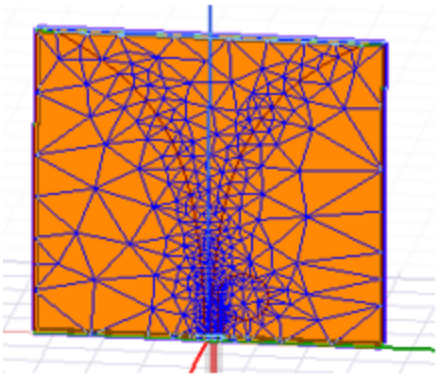
If you right click on the Nets and Layers panel, a short-cut menu appears that lets you Select This Layer Only, Select or Unselect All, Select or Unselect All Signals, or Select and Unselect All Dielectrics.

3. Select the **Solution** to use from the drop-down menu.

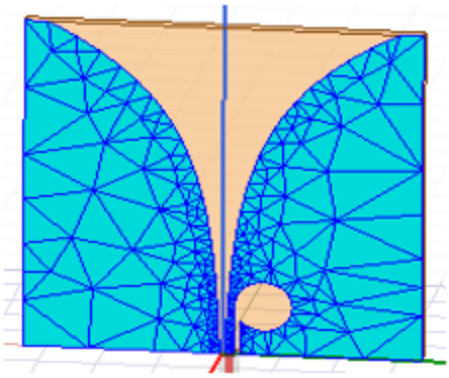
   For HFSS designs that include layout components, see a discussion with example below.

4. If **Field Type** is enabled, you can select from the drop-down menu for a mesh plot.
5. Click **Done**.

   The mesh appears on the surface or object you selected. For example:

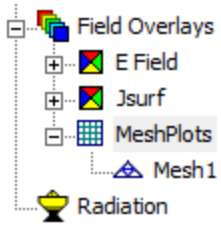


Mesh Plot of All Objects



Mesh Plot of Selected Surfaces

An icon for the mesh also appears in the Project Manager under **Field Overlays** > **Mesh Plots**.



If a solution is ongoing, you can select the **Mesh Plots** icon in the in the Project Tree, right-click to display the shortcut menu, and select **Update Plots**. This updates the mesh plot to include the latest data available. After the last adaptive pass, the mesh plot is automatically updated.

If a mesh includes seeding, these effects appear at the start of the adaptive passes. Any mesh adaptation at the start of a subsequent pass is not plotted until after that pass is completed. This delay ensures that mesh plots and actual solutions remain consistent with each other.

You can modify an existing plot by selecting the plot and changing the properties.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you modify the geometry of an object, the solution is invalidated and the mesh plot is removed.

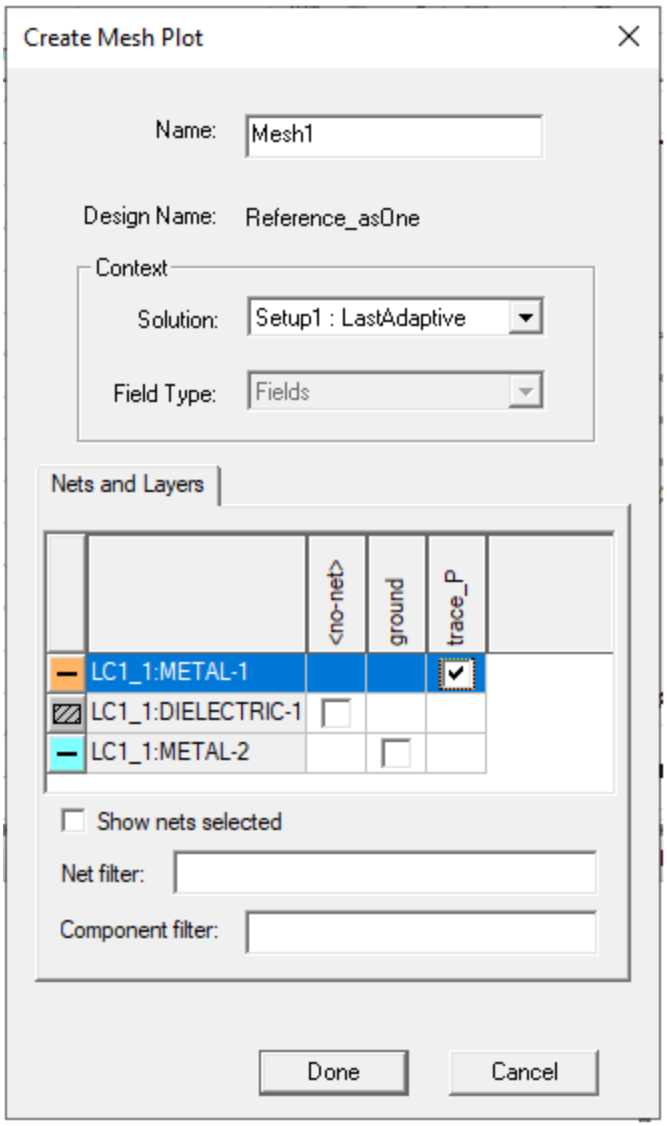
If you have plotted the mesh of a Solve-Inside object, you can view the internal mesh by using either the clip-plane feature or the Model Analysis dialog box.

Also see the discussion here, under **Visualization for Skin Depth Refinement Mesh Results**. The same techniques for visualization for internal mesh plots apply even if seeding is not used.

Example of Mesh Plots for an HFSS Design with Layout Components

First, solve the design. You can either select geometries in the Modeler window before opening the **Create Mesh Plot** dialog, or use the **Nets and Layers** area in the Create Mesh Plot dialog to select objects from the layout components to plot. These objects are represented as combinations of nets and layers and can be selected by checking the corresponding checkboxes.

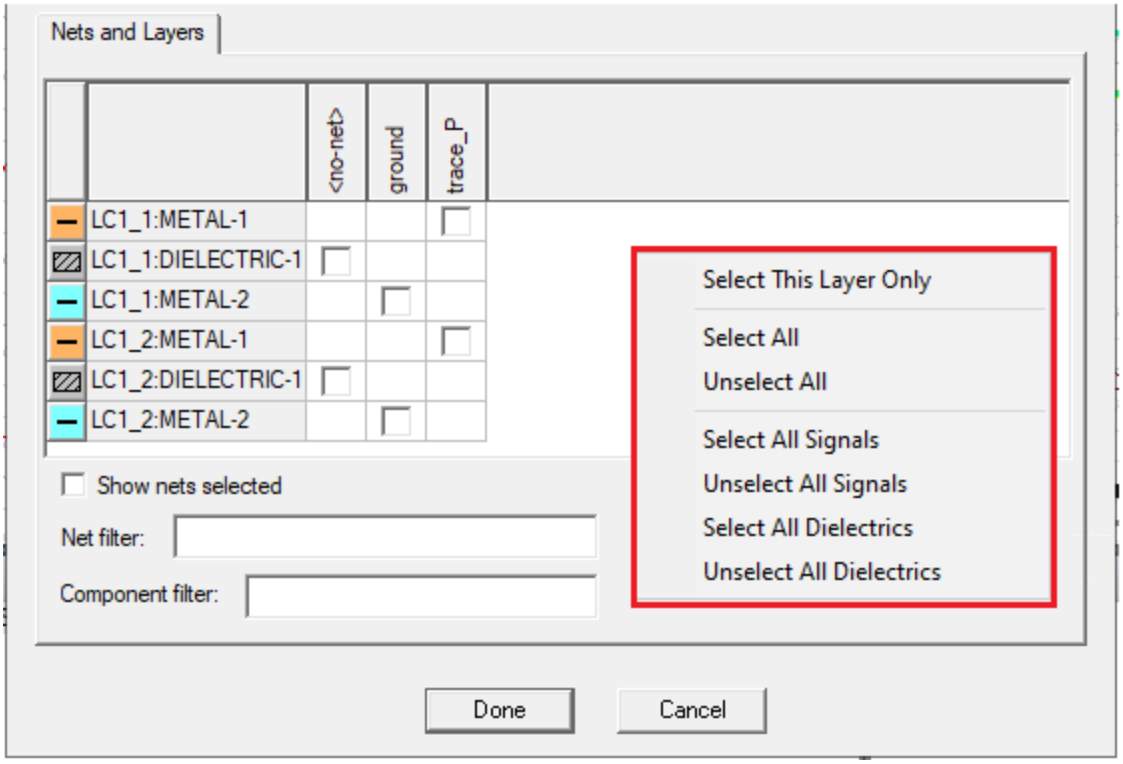
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



This **Nets and Layers** section displays all the layers and nets of every layout component in the design. Upon opening, it adjusts its size to try to show all the rows and columns for the layout components. You can resize the parent dialog. For objects in the component belonging to a specific layer and net, you can select a checkbox. By clicking the column headers, you can select or un-select checkboxes for an entire column. You can toggle the “Show nets selected” checkbox to move all the selected nets to the left side of the table. You can use the **Net filter** and **Component filter** fields to filter out specific nets and components. The net and component filters support ‘*’ and ‘?’ wildcards and you can delimit multiple filters with commas. The Nets and Layers table is refreshed each time you update the filter text.

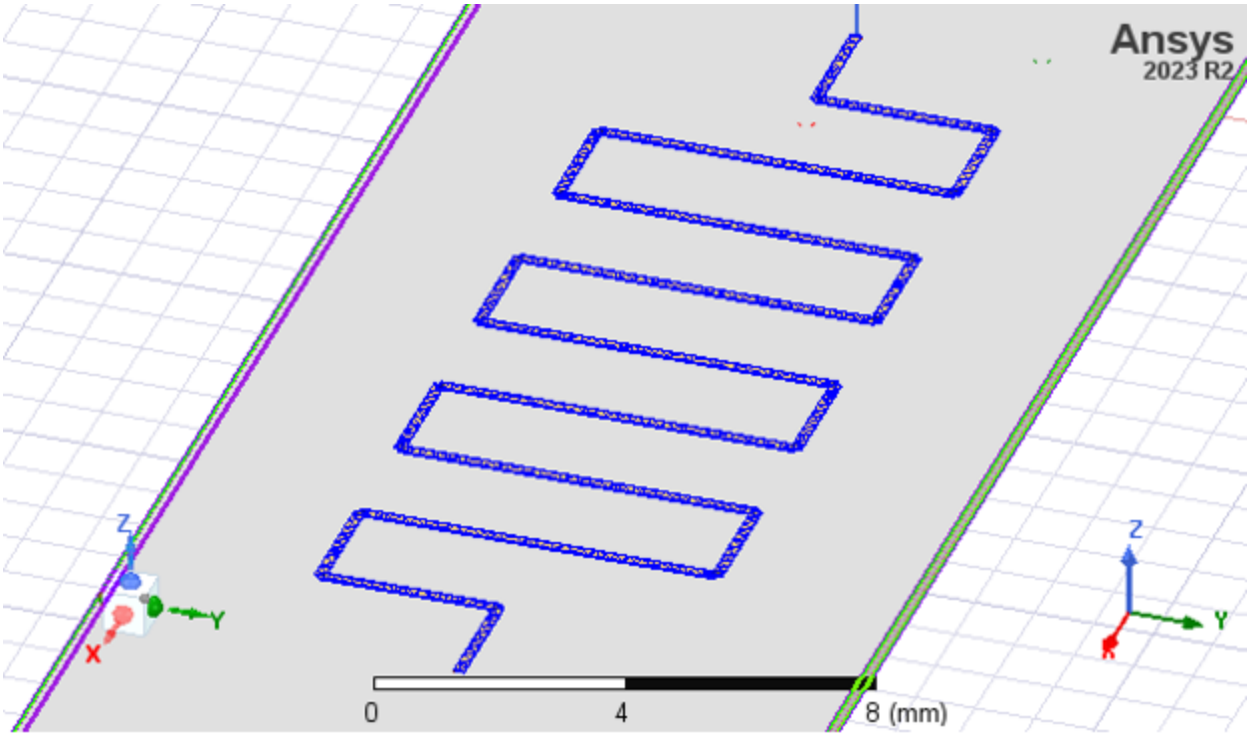
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you right click on the Nets and Layers panel, a short-cut menu appears that lets you Select This Layer Only, Select or Unselect All, Select or Unselect All Signals, or Select and Unselect All Dielectrics.

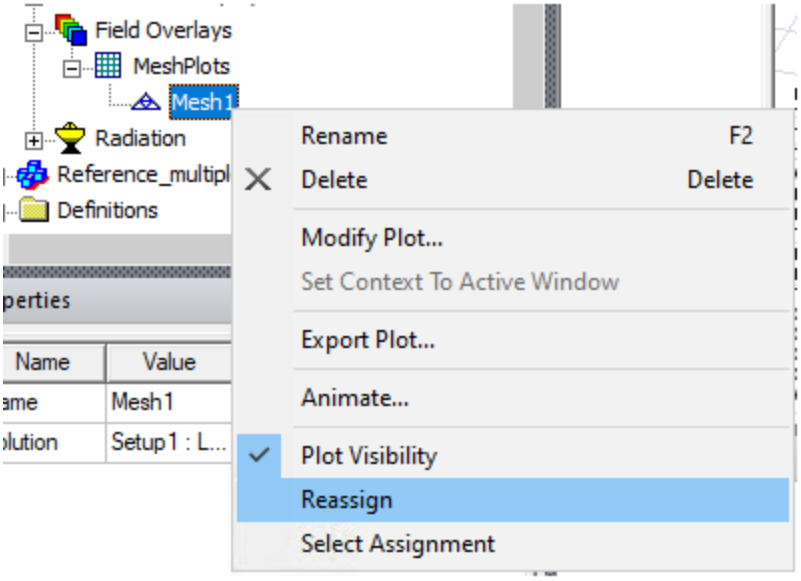


After making selections click **Done**. The mesh plot will be generated on the objects belonging to the selected layer/net combinations.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

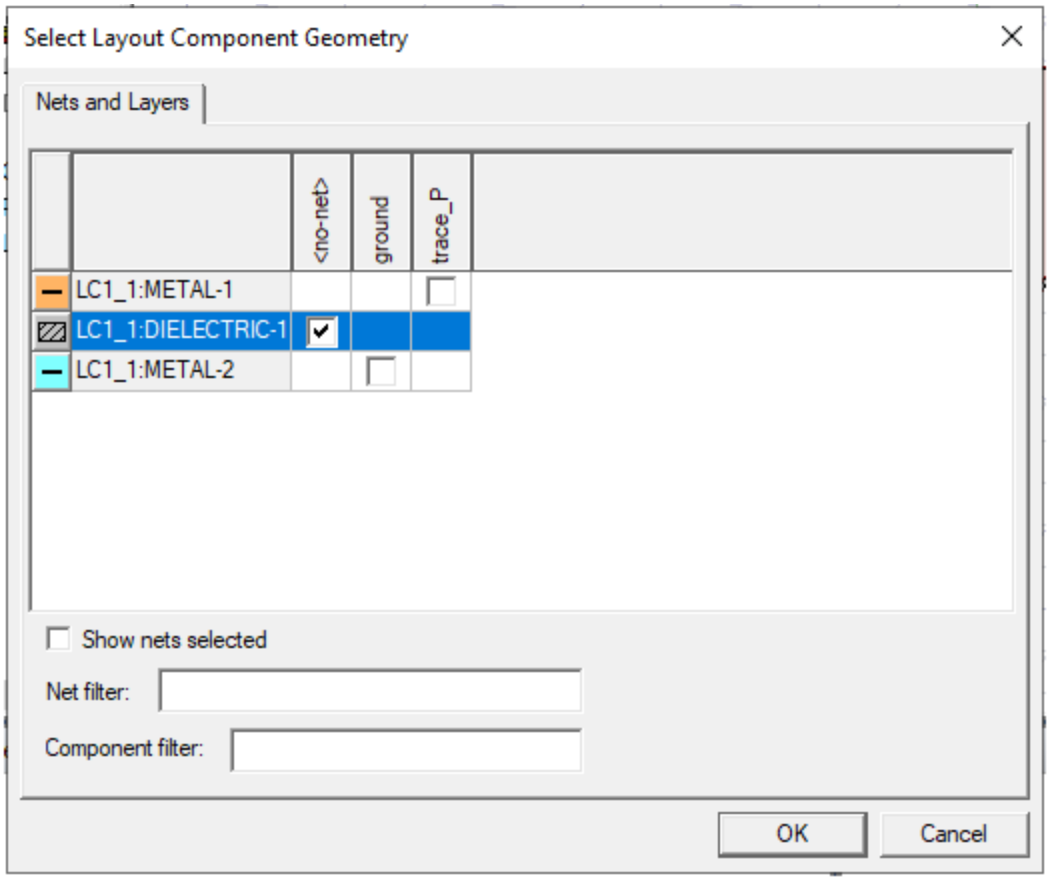


If you want to reassign a mesh or field plot, either select 3D geometries from layout components in the modeler window before selecting **Reassign** in the right-click menu, or select **Reassign**.



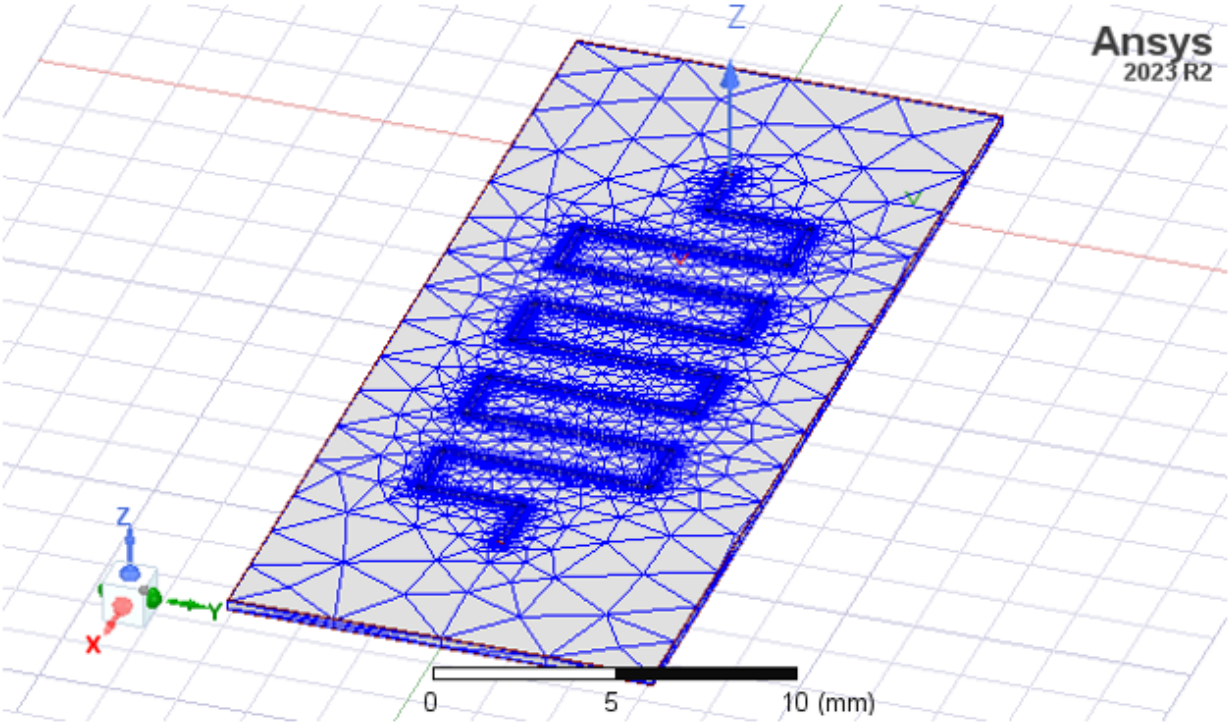
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For HFSS designs with layout components, the **Select Layout Component Geometry** dialog appears. This has the same functionality and menus as the this **Nets and Layers** section of the **Create Mesh Plot** dialog.



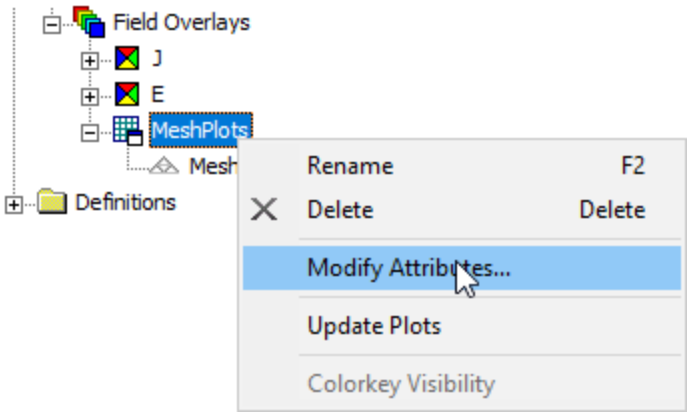
Change the selection in the dialog and click **OK**. The mesh plot will be re-assigned to the newly selected objects, in addition to any 3D geometries previously selected from the modeler window. If you click cancel, the plot is only re-assigned on 3D geometries previously selected. If there are no previously selected 3D geometries, the program issues an error message. Change the selection in the dialog and click **OK** to display the reassigned mesh plot.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



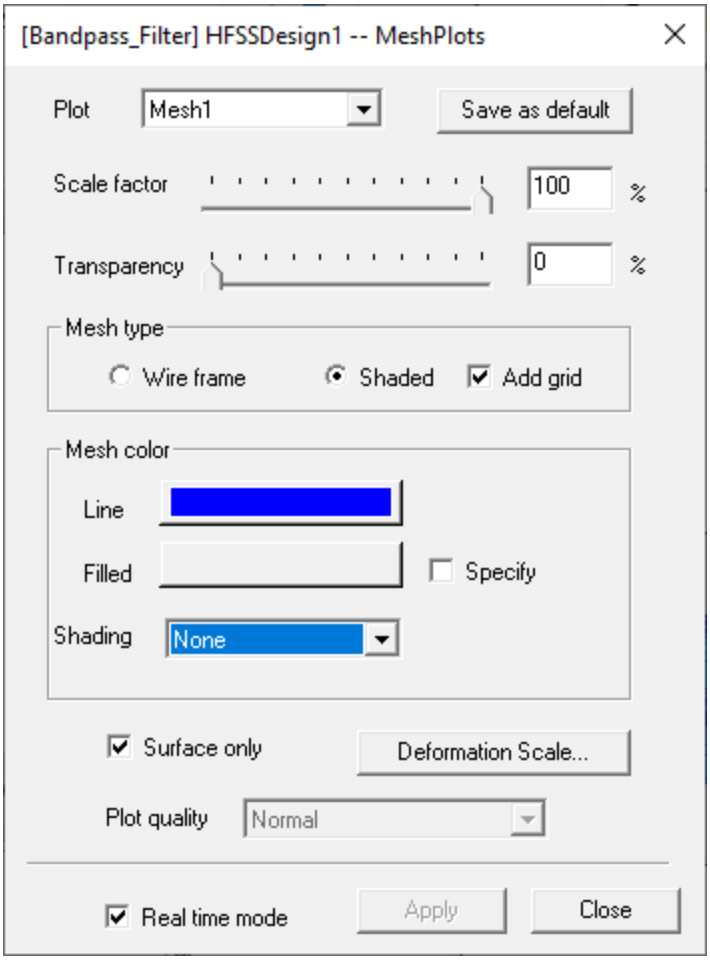
Setting Mesh Plot Attributes

1. In the Project Tree, expand **Field Overlays**.
2. Right-click **Mesh Plots** and select **Modify Attributes**.



The *MeshPlots* window appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note:

You can also open the MeshPlots window from **HFSS** > **Fields** > **Modify Plot Attributes**. You will be prompted to select the folder containing the mesh you want to modify.

For Mesh plots, the following attributes can be modified:

Plot	A drop-down menu of available plots.

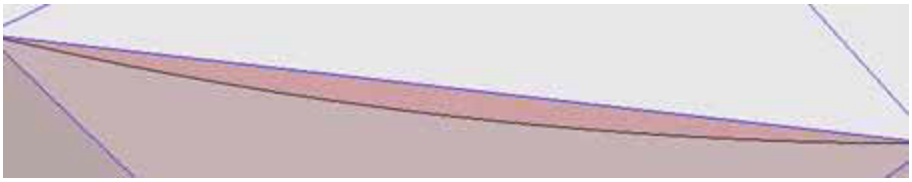
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scale Factor	The size at which the tets are displayed. Scaling may let you analyze particular situations better. For example, a scale factor of 80% draws the tetrahedra at 80% of their original size. Use the **Scale factor** slider to increase or decrease the size of the tetrahedra.
Transparency	The degree of transparency for the tets. This is useful for viewing objects or plots behind the current plot. Use the **Transparency** slider to increase or decrease plot transparency.
Mesh Type	Whether to display the tets as wire frame or shaded, and whether to Add Grid.
Mesh Color for Line and Fill	The color for the tet edge lines and fill. Clicking the button for each displays a color selection dialog box. You must select **Specify** to enable fill color.
Shading	You can specify Shading as None, Flat, or Smooth, with respect to lighting.
Surface Only	Whether to plot the surface only, or all tets inside selected objects.
Plot Quality	The resolution quality of the plot. Normal by default. Use the drop-down menu to select Coarse, Normal, Fine, or Very Fine. The higher the resolution, the more memory used.
Real Time	Whether to show changes to a mesh immediately in the view window. If this option is cleared, click **Apply** when you want to see the changes.

For designs that include Stress feedback from Ansys Workbench Integration, an additional **Deformation Scale** option is available. See: Interface Changes for Stress Feedback from Mechanical to HFSS.

For **Plot Quality**, higher quality selections permit visualization of curvilinear mesh elements. With the **Coarse** setting, facets do not snap to the midpoint edge:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



The **Normal** setting displays snapping to the midpoint edge:

The **Fine** setting displays more of the curvilinear tets:

The **Very fine** setting gives the most accurate display, but uses the most memory:

3. Click **Save as default** button if you want the tab's settings to apply to mesh plots created after this point.
4. Click **Close**.

User-Defined Outputs (UDOs)

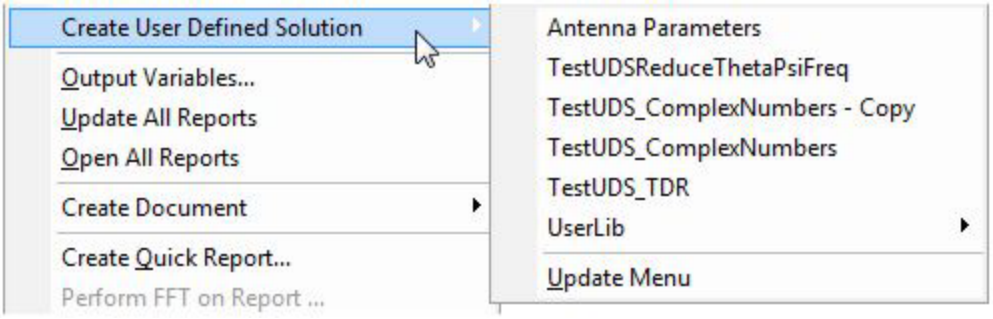
User-defined outputs (UDOs) allow users to define calculations through IronPython scripts or any .NET language (and used by the IronPython script). The UDO scripts need to be in the **UserDefinedOutputs** directory under either **syslib**, **userlib**, or **Personallib** with any directory

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

structure needed for organization. (The **Lib** directory name is special and its purpose will be explained later on in the document.)

The UDO scripts that are placed in syslib/UserDefinedOutputs, userlib/UserDefinedOutputs, or Personallib/UserDefinedOutputs become available to the user to create "User Defined Solutions" through the **Results** > **Create User Defined Solution** menu.

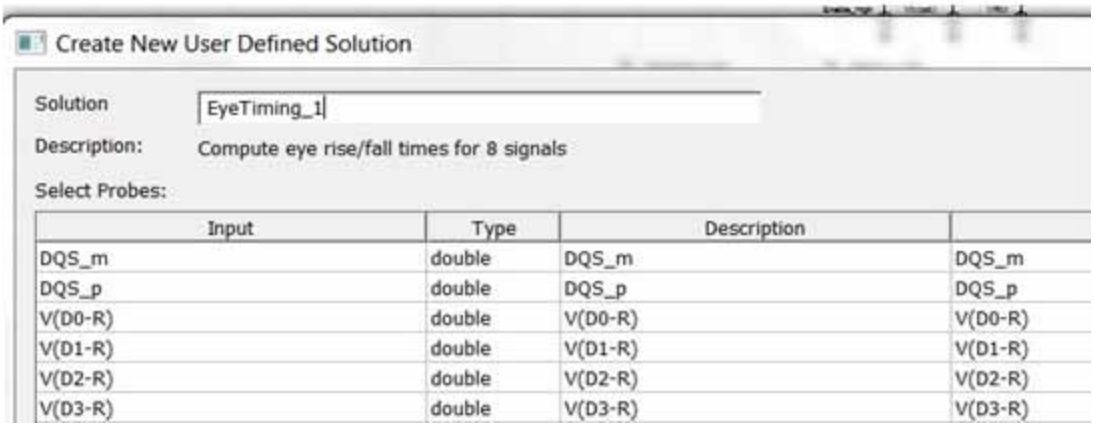
Use **Results** > **Create User Defined Solution** > **Update Menu** to refresh the menu to include the new UDO scripts that might have been copied to syslib, userlib, or Personallib; or exclude them if they have been deleted, after the launch of desktop. Once the user-defined-solution is created, the solution and the calculations defined by UDO become available in Reporter as any other quantities in a new "User Defined" report type.



Named Probes and Properties in User-Defined Outputs

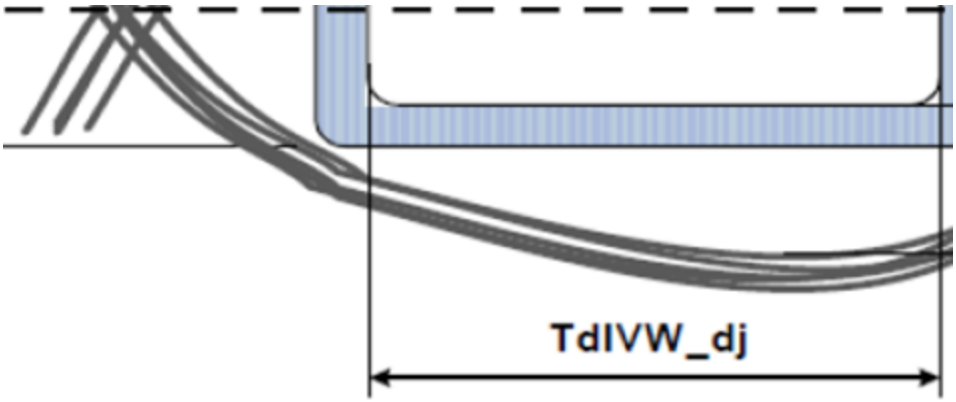
UDOs allow processing data across traces, solutions, and report types. A UDO specifies the named probes and properties for which user selects or enters the values at the time of creation of user-defined solution. Probes are very similar to traces except that the user selects the values of only intrinsic variables for probes. The values of design or project variables are selected when a trace is created based upon the user defined solution in reporter.

For example, you could create a user-defined solution called EyeTiming_1.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can then access this solution in the Reporter.



In another example, you could create a user-defined solution called **UDS Distance Trace Arithmetic Result1**:

Then access this solution in the **Create User Defined Solution** menu:

Computation of Traces Based UDO Calculations

When traces that are based upon UDO outputs are computed, the data for probes is computed and passed to the UDO script for each design variation. Along with the probe data, the values of properties entered by user are also passed. The information about the UDO calculations that need to be computed is also made available. The UDO then performs the computation and passes the results to reporter. Note that UDOs can compute and pass back more calculations than have been requested at that point of time. This allows UDOs to compute a set of calculations that take almost same amount of computational resources as any one calculation in that set and cache that with reporter. *When those calculations are subsequently plotted by user, reporter will use the cached results instead of invoking the computation on UDO*.

Dimensions Reduction by UDO Calculations

The probes in a UDO can have heterogeneous dimensions of data, for example, one probe in a UDO can have data that is a function of *n* intrinsic variable, while another probe in same UDO can have data that is function of *m* intrinsic variables, with *n* and *m* are potentially different. UDOs allow you to reduce any number of these intrinsic variables. In the above example, UDO calculations can be a function of any number of intrinsic variables including not being function of any intrinsic variable at all. UDO calculations can also be a function of an intrinsic variable that none of the probes is function of. *The only restriction is that Freq cannot be reduced if any of the probes are on a Fields report type.*

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Dynamic Probes

In addition to named probes and properties, UDOs can specify named dynamic probes. The difference between probes and dynamic probes is that while the end user of UDO specifies the complete trace definition for probe, the expression for dynamic probe is specified by UDO code itself and not by end user. This allows UDOs to access the data for probes without requiring the end user to enter each individual probe. For example, a UDO can access data for a huge S matrix for 100 port design without having the end user enter the probe information for each of those 10,000 quantities. Each dynamic probe is associated with a named probe that is entered by user. Information about solution, context, and intrinsic variables is used from selected probes; however multiple dynamic probes can be associated with the same user selected probe. The dynamic probes are acquired from UDOs at the time of trace computation and not at the time of creation of user defined solution.

This means that you select solution, context, and values of intrinsic variables just once, and the same information is used (in this case) for all clock and data signals. The expression for those signals comes from the UDO code.

User-Defined Outputs: Python Script API

A User-Defined Output (UDO) extension is implemented as an IronPython script that defines a class with a specific name: **UDOExtension**, which derives from a specific base class **IUDOPluginExtension** and implements its abstract methods.

- UDO Extension Implementation
- Data Types Used in UDO Python Scripts
- Working With Properties for UDO
- Other Application Specific Classes Used in Python Scripts
- User-Defined Outputs: Messaging Methods
- Using .NET Collection Classes and Interfaces in Python Scripts

UDO Extension Implementation

The purpose, argument list, and expected return types for each of the IUDOPluginExtension abstract methods, which the UDO author is expected to implement are described below.

- Import Statements
- UDOExtension Class
- IUDOPluginExtension Abstract Class

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Import Statements

The base class to use and the types it uses in turn are contained in .NET assemblies. The use of these requires that the assemblies be imported into the UDO script. The following import statements should be added to the top of the Python script:

```
from Ansys.Ansoft.ModulePluginDotNet.Common.API import *
 from Ansys.Ansoft.ModulePluginDotNet.Common.API.Interfaces import *
 from Ansys.Ansoft.ModulePluginDotNet.UDO.API.Interfaces import *
 from Ansys.Ansoft.ModulePluginDotNet.UDO.API.Data import *
```

UDOExtension Class

The UDO itself should be implemented as an IronPython class called **UDOExtension** which *must* derive from the **IUDOPluginExtension** abstract base class (from the **Ansys.Ansoft.ModulePluginDotNet.UDO.API.Interfaces** namespace).

Note that power users could derive a class hierarchy tuned toward a specific type of UDOs and that they can derive from their own base classes. The only requirement is that directly or indirectly, the UDO class must derive from **IUDOPluginExtension**.

The UDOExtension abstract class declares the optional Validate abstract method that may be implemented in the UDOExtension class or one of its base classes.

Example:

```
def BaseClassUDO ((IUDOPluginExtension):
 #base class implementation
 …
 def UDOExtension ((BaseClassUDO):
 #UDO class implementation …
```

Validate

This optional method is used to validate the user choices. The values of the properties entered, the probes etc. can be checked for suitability. This function, while a part of the IUDOExtensionabstract class, has a meaningful default implementation and is therefore optional. However, it can be overridden to take advantage of advanced functionality.

UI Access	NA		
Parameters	Name <errorStringList>	Type List<string>	Description [out] C# list of Python strings. Should be set only if validation failed;

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

			ignored if validation is successful. One error string should be set per each validation error.
	<udsProbParams>	List<UDSProbeParams>	[in] C# list of UDSProbeParams objects.
	<propList>	IPropertyList object	[in] list of properties
	< userSelectionForDynamicProbes >	List<UDSProbeParams>	[in] C# list of UDSProbeParams objects.
Return Value	Boolean. True on validation success and false on failure. The default implementation always returns true.		

Python Syntax	Validate (<*errorList*>, <*probeList*>, <*propertiesList*>, <*dynamicProbes*>)

Python Example	`def Validate(self, errorStringList, probeList, propList, dynamicProbes):`
	`  if probeList == None or probeList.Count == 0:`
	`  errorStringList.Add("Empty probe list")`
	`  return False`
	`  return True`

IUDOPluginExtension Abstract Class

The implementation of the IUDOPluginExtension class will be described in this section using a simple UDO example that expects a single probe and reduces its dimension returning as its outputs, the max, min, and average of its input probe data. The script in its entirety will also be listed later on.

Required functions:

The IUDOPluginExtension abstract class declares the following abstract methods that must be implemented in the UDOExtension class or one of its base classes. Not implementing any of these methods will result in a run-time error and a non-functioning UDO. The UDS refers to User Defined Solution parameters.

- GetUDSName
- GetUDSDescription

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- GetUDSSweepNames
- GetCategoryNames
- GetQuantityNames
- GetQuantityInfo
- GetInputUDSParams
- GetDynamicProbes
- Compute

GetUDSName

Return a string that is used as a prefix for all solution instances created using this UDO.

UI Access	NA
Parameters	None
Return Value	String

Python Syntax	GetUDSName

Python Example	`def GetUDSName(self):`
	`  return "MinMaxAvg"`
	`udsName = UDOPluginEntention.GetUDSName`

GetUDSDescription

Returns a description for the UDO, its purpose, etc. This is used in multiple UDO related dialogs in the application to describe the UDO.

UI Access	NA
Parameters	None
Return Value	String

Python Syntax	GetUDSDescription
Python Example	`def GetUDSDescription(self):` `  return "Sample UDO for dimension reducing quantities`

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

GetUDSSweepNames

Returns a list of sweep names to be used for the solution generated by the UDO. These will appear in the sweeps list displayed in the standard reporter dialog when used to create reports from the solution generated by the UDO.

UI Access	NA
Parameters	None
Return Value	List of strings. If the UDO outputs have no sweeps, return the empty list [].

Python Syntax	GetUDSSweepNames

Python Example	`# Returns list of sweeps names`
	`# We have no sweeps as we reduce them.`
	`def GetUDSSweepNames(self):`
	`    return []`

GetCategoryNames

The outputs that the UDO solution provides or generates can be classified into multiple categories, like how the application is displayed in the report creation dialog box.

UI Access	The output will be listed in the categories box in the dialog when creating reports from the UDO generated solution data.
Parameters	None
Return Value	List of strings

Python Syntax	GetCategoryNames
Python Example	`def GetCategoryNames(self):` `    return ["UDOOutputs"]`

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

GetQuantityNames

For each of the category names returned from the GetCategoryNames method, this function is called to return a list of quantities to be organized under that category name.

> **Note:**
>
> The quantity names must be unique across the categories; that is, no two categories can have quantities with the same name.

UI Access	NA		
Parameters	Name <*categoryName*>	Type String	Description [in] Name of category.
Return Value	List of strings		

Python Syntax	GetQuantityNames(<*categoryName*>)

Python Example	`# returns a list of quantity names for the supplied category name`
	`def GetQuantityNames(self, catName):`
	`  if catName == "UDOOutputs":`
	`  return ["min_val", "max_val", "avg_val"]`
	`  else:`
	`  return []`

GetQuantityInfo

For each quantity that the UDO creates, it must also describe the quantity (unit and other details). This method is called for each quantity name (across all categories) as returned from an earlier call of the GetQuantityNames method.

UI Access	NA		
Parameters	Name <*quantityName*>	Type String	Description Name of quantity
Return Value	Object of type QuantityInfo.		

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Python Syntax	GetQuantityInfo(<*quantityName*>)

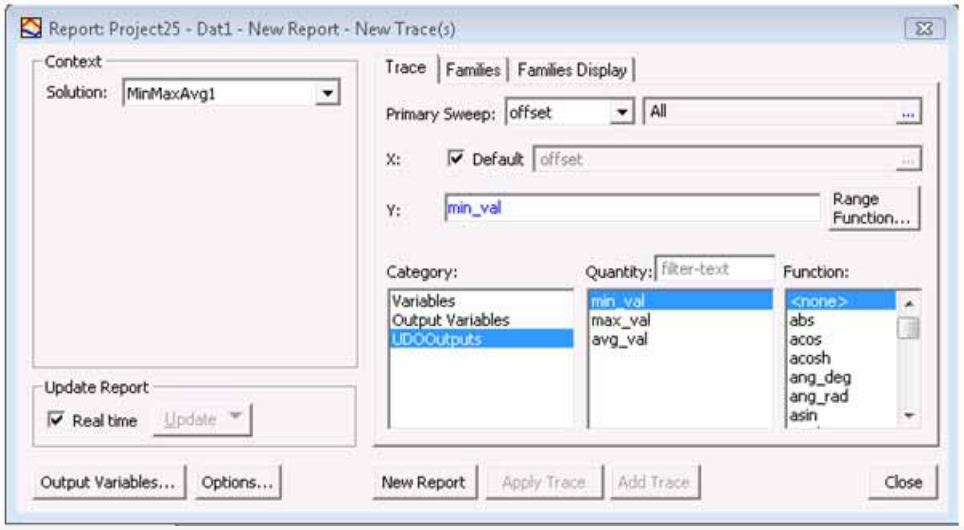
Python Example	`# Returns an instance of QuantityInfo for the qtyName supplied or None if such a`
	`# quantity could not be found`
	`def GetQuantityInfo(self, qtyName):`
	`    # All the quantities we have are simple doubles`
	`    # we can leave them unitless`
	`    return QuantityInfo(Constants.kDoubleParamStr)`

GetInputUDSParams

This is the main definition method of the UDO. The supplied arguments populate details of the parameters to which the UDO user will specify value, specify the probe names and their types as well as the dynamic probe selections.

UI Access	The **GetInputUDSParams** function results in the following dialog when you click **Results**>**Create User Defined Solution**. The mapping from the UDSParams and the properties to the GUI elements should be unambiguous. The name and description of the UDS are also displayed in the **Create New User Defined Solution** window.  When a report is created from the UDO dialog box, the category and quantity names specified by the UDO are used (as seen below).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Parameters

Name	Type	Description
<udsParams>	List< UDSProbeParams >	Parameters for the probe. The UDO script must add one instance of UDSProbeParams for each probe definition it will display. When creating the UDO solution, the UDO user must assign a matching quantity to each probe. When user define a UDS in the GUI, the user must select a design-solution-quantity for each UDSProbeParam .
<propList>	IPropertyList	The propList object is used to add properties that should be displayed to the user for data collection. These properties with their user-supplied values are returned to the UDO script by the Compute method.
<	List<	When user defines a

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	userSelectionForDynamicProbes >	UDSProbeParams >	UDS in the GUI, the user ONLY needs to specify the Design-Solution. This quantity will be assigned dynamically by matching the component-expression defined in each UDSProbeParam.
Return Value	Boolean. If true, the event was handled successfully. If false, it was not.		

Python Syntax	GetInputUDSParams(<*udsParams*>, <*propList*>, <*userSelectionForDynamicProbes*>)

Python Example	`# Returns list of UDSParams and list of dynamic properties`
	`# Adds setup time properties to the propList`
	`def GetInputUDSParams(self, udsParams, propList, userSelectedDynamicProbes):`
	
	`  # Add the probes. We need only one double quantity`
	`  param1 = UDSProbeParams("probe1", "double quantity probe", Constants.kDoubleParamStr, "", "")`
	`  udsParams.Add(param1)`
	
	`  # Add the properties we want the user to supply`
	`  # In this case, we will ask for a start/end range for`
	`  # X parameters. Since we cannot reasonably provide defaults`
	`  # as we have no idea what the sweep limits will be, we will`
	`  # also ask if the limits are to be activated.`
	`  prop = propList.AddNumberProperty("X Min", "0")`
	`  prop.Description = "Start X value to consider"`
	
	`  prop = propList.AddNumberProperty("X Max", "1")`
	`  prop.Description = "End X value to consider"`
	
	`  # For menus, the first option is the default.`
	`  prop = propList.AddMenuProperty("Activate X Limits", ["No", "Yes"])`
	`  prop.Description = "Activate X range"`
	
	`  return True`

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

GetDynamicProbes

This is the primary mechanism by which the UDO script obtains the probe data (as double precision values) for its compute process.

UI Access	NA		
Parameters	Name <*dynamicProbes*>	Type List< UDSDynamicProbes >	Description [out] List of dynamic probes
Return Value	Boolean. If true, the method was successful. If false, it was not.		

Python Syntax	GetDynamicProbes(<*dynamicProbes*>)

Python Example	`# Returns list of UDSParams and list of dynamic properties`
	`# output UDSDynamicProbeCollection probes`
	`def GetDynamicProbes(self, probes):`
	`pass`

Compute

This is the main computation method which generates the data for the quantities that make up the UDO solution.

UI Access	The data is received from the UI using IUDSInputData. It is processed and the result data is sent to the UI using IUDSOutputData.		
Parameters	Name <*inData*> <*outData*> <*propList*> <*progressMonitor*>	Type IUDSInputData IUDSOutputData IPropertyList IProgressMonitor	Description Used to get the input probe data. Used to set the UDO solution quantity and sweep data. Used to get the user entered values for each of the properties defined during the GetInputUDSParams call. This can be used to set progress for long running calculations, check for user initiated abort etc.
Return Value	Boolean. If true, the method was successful. If false, it was not.		

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Python Syntax	Compute (<*inData*>, <*outData*>, <*propList*>, <*progressMonitor*>)

Python Example	`# IUserDefinedSolutionHandle API implementation.`
	`# Calculates output values and sets them using IUDSInputData/IUDSOutputData API.`
	`def Compute(self, inData, outData, propList, progMon):`
	
	`  # Get the sweeps associated with the probe and validate`
	`  # use the probe name that we had defined earlier`
	`  sweeps = inData.GetSweepNamesForProbe("probe1")`
	`  if (sweeps == None or sweeps.Count > 1):`
	`  AddErrorMessage(self.GetName() + "Unexpected sweep count 0 or > 1 in Compute")`
	`  return False`
	
	`  # Get the data associated with our probe`
	`  probeData = inData.GetDoubleProbeData("probe1")`
	`  sweepData = inData.GetSweepsDataForProbe("probe1", sweeps[0])`
	
	`  # Get the user specified properties.`
	`  # Note that ideally, these "X Min" etc names should be`
	`  # written as constant members and referred to in both`
	`  # the GetInputUDSParams and in Compute to reduce the`
	`  # change of typos.`
	`  useXRangeProp = propList.GetMenuProperty("Activate X Limits").SelectedMenuChoice`
	`  xRangeStart = propList.GetNumberProperty("X Min").ValueSI`
	`  xRangeEnd = propList.GetNumberProperty("X Max").ValueSI`
	
	`  # At this stage, one can look at the`
	`  # RequestedQuantities and create a dictionary to later`
	`  # check against. However, I am simply computing all`
	`  # the quantities.`
	`  minVal = 0`
	`  maxVal = 0`
	`  avgVal = 0`

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
# Check if we need to perform range computation
if useXRangeProp == "Yes":
  seenAny = False
  avgSum = 0
  count = 0

# zip is used since we also need to pull in sweep data
# an index and the array notation could also have been
# used
for probeVal, sweepVal in zip(probeData, sweepData):
  if sweepVal < xRangeStart or sweepVal > xRangeEnd:
    pass

# Note that in a better written script, this code

  seenAny = True
  count = 1
else:
  if probeVal < minVal:
    minVal = probeVal

  if probeVal > maxVal:
    maxVal = probeVal

  avgSum += probeVal
  count += 1

if seenAny:
  avgVal = avgSum/count

else:
  seenAny = False
  avgSum = 0
  for probeVal in probeData:
    if not seenAny:
      minVal = probeVal
      maxVal = probeVal
      avgSum = probeVal
```

Data Types Used in UDO Python Scripts

There are several types that you must use while authoring a Python script. Some of them are used to pass data from the UI to a Python script and to provide interface for working with this data. Some are used to pass data from a Python script to the UI.

To pass data from a Python script to the UI, the objects must be created in the Python script. Then they can be set as a function's return values or set to the output parameters using their API.

Constants

- **kTraceTypeStr** : string constant used to specify an input of trace type
- **kSolutionTypeStr** : string constant used to specify an input of solution type
- **kNumberTypeStr** : string constant used to specify an input of number type
- **kTextTypeStr** : string constant used to specify an input of text type
- **kBoolTypeStr** : string constant used to specify an input of boolean type
- **kStandardReportStr** : string constant to specify a standard report
- **kEyeDiagramReportStr** : string constant to specify an eye diagram report
- **kUserDefinedReportStr** : string constant to specify a user defined report
- **kSweepDomainStr** : string constant to specify the sweep domain
- **kTimeDomainStr** : string constant to specify the time domain

Abstract Classes

- IProgressMonitor
- IUDSInput
- IUDSOutput

IUDSInputData

The purpose of this class is to get data (probe and sweep) from Desktop. The IUDSInputData abstract class declares the following abstract methods:

- GetDoubleProbeData
- GetSweepsDataForProbe
- GetComplexProbeData
- GetSweepNamesForProbe
- GetRequiredQuantities

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- GetVariableValues
- GetInterpolationOrdersData

Examples in this section are just to show proper syntax of the function calls. For actual usage of the class, see the Compute function's example.

GetDoubleProbeData

This is the primary mechanism by which the UDO script obtains the probe data (as double precision values) for its compute process.

UI Access	NA		
Parameters	Name <*probeName*>	Type String	Description Name of the probe for which data is requested. This is one of the many probes supplied during a call to the UDO's GetInputUDSParams method. Each probeName must be unique within an UDO.
Return Value	Double array of data for the specified probe if the probe exists or null if the probe is unknown.		

Python Syntax	GetDoubleProbeData (<*probeName*>)
Python Example	`# doubleData is a list of floats` `doubleData = inData.GetDoubleProbeData("probe1")`

GetSweepsDataForProbe

All probe data that is supplied is associated with one or more sweep (an intrinsic quantity like Time, Frequency, Theta, Phi, etc. that is swept) quantities.

UI Access	NA		
Parameters	Name <*probeName*> <*sweepName*>	Type String String	Description Name of the probe for which data is requested. This is one of the many probes supplied during a call to the UDO's GetInputUDSParams method. Each probeName must be unique within an UDO. Name of the sweep.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Return Value	Double array of data for the specified probe and sweep.

Python Syntax	GetSweepsDataForProbe(<*probeName*>, <*sweepName*>)
Python Example	`# sweepData is C# Array of doubles (floats in python)` `sweepData = inData.GetSweepsDataForProbe ("FarFieldsProbe","Freq"])`

GetComplexProbeData

The primary mechanism by which the UDO retrieves data for its input probes (if it expects complex data for the probe).

UI Access	NA		
Parameters	Name <*probeName*>	Type String	Description Name of the probe for which data is requested. This is one of the many probes supplied during a call to the UDO's GetInputUDSParams method. Each probeName must be unique within an UDO.
Return Value	Double array (float in Python) of data for the specified probe. Each pair of floats represents one complex number. The first value is for real part and the second value it the imaginary part. For instance, array [10.0, 0, 5.1, 2.1] represents 2 complex numbers: (10.0, 0) and (5.1, 2.1).		

Python Syntax	GetComplexProbeData(<*probeName*>)

Python Example	`# complexDataAsDouble is C# Array of doubles (floats in Python)`
	`# each pair of floats represents one complex number`
	`complexDataAsDouble = inData.GetComplexProbeData ("FarFieldsProbe")`
	`# creating a list of complex numbers from complexDataAsDouble array`
	`complexData = []`
	`if complexDataAsDouble != None:`
	`  for i in xrange(0,complexDataAsDouble.Count, 2):`

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	`complexData.append(complex(complexDataAsDouble [i],complexDataAsDouble[i+1]))`

GetSweepNamesForProbe

Retrieves a list of sweep quantity names associated with a given probe. This also indicates the dimensionality of the data. One name implies that the probe-data is 2D (probe-quantity vs Sweep Quantity) and two names implies 3D data (probe-quantity vs Sweep 1 X Sweep 2).

UI Access	NA		
Parameters	Name <*probeName*>	Type String	Description Name of the probe for which data is requested. This is one of the many probes supplied during a call to the UDO's GetInputUDSParams method. Each probeName must be unique within an UDO.
Return Value	IList<string> - list of sweep names for the current probe name.		

Python Syntax	GetSweepNamesForProbe(<*probeName*>)
Python Example	`# sweepNames is C# Array of strings` `sweepNames = inData.GetSweepNamesForProbe("FarFieldsProbe")`

GetRequiredQuantities

A given UDO can specify that it provides one or more computed quantities. The user might choose to create a report from only a few among the various available UDO outputs. This function returns the list of UDO output quantities that the user requested. Only these need be computed in the UDO's Compute method.

UI Access	NA
Parameters	None
Return Value	IList<string>

Python Syntax	GetRequiredQuantities()

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Python Example	`# quantities is C# Array of strings` `quantities = inData.GetRequiredQuantities()`

GetVariableValues

This allows the UDO to obtain the names and values of all the design variables for which the UDO quantities are being requested.

UI Access	NA
Parameters	None
Return Value	IDictionary<string,string> of key-value pairs for variables. Both key and value are strings.

Python Syntax	GetVariableValues()

Python Example	`# theDict is C# Dictionary<string, string>`
	`theDict = inData.GetVariableValues()`
	`if theDict != None:`
	`  #varPair is of .Net KeyValuePair type`
	`  for varPair in theDict:`
	`  varName = varPair.Key #string`
	`  varValue = varPair.Value #string`

GetInterpolationOrdersData

Returns the interpolation orders that are associated with the probe-data. The probe data is specified at each value of the various sweeps. Any value in between the sweep data points, can use the interpolation data to get a possibly more accurate (compared to linear interpolation) inter-sweep value.

UI Access	NA		
Parameters	Name *<probeName>*	Type String	Description Name of the probe for which data is requested. This is one of the many probes supplied during a call to the UDO's GetInputUDSParams method. Each probeName must be unique within an UDO.
Return Value	Byte array of interpolation order for the specified probe. These are to be		

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

	treated as 8-bit signed integers, that is, their values range from 0-127.

Python Syntax	GetInterpolationOrdersData(<*probeName*>)

Python Example	`# interData is C# Array of bytes (integers in Python)`
	`interData = inData.GetInterpolationOrdersData(kProbeNames[0])`
	`for interValue in theDict:`
	`  # interValue and order are integers`
	`  order = interValue`

IUDSOutputData

This type is a twin of the IUDSInputData in that it is used to store the values computed by the UDO's Compute method. The IUDSOutputData abstract class declares the following abstract methods:

- SetSweepsData
- SetDoubleQuantityData
- SetComplexQuantityData

Examples in this section are just to show proper syntax is function calls. For actual usage of the class, see the Compute function example.

SetSweepsData

Each quantity that is computed by the UDO can be associated with a sweep. If it is, the values that make up the sweep's data points must be specified using this call.

UI Access	NA		
Parameters	Name	Type	Description
	<*sweepName* >	String	Name of the sweep
	<*sweepData*>	List<floats>	Sweep data for the specified sweep.
Return Value	Boolean. If true, the event was handled successfully. If false, it was not.		

Python Syntax	SetSweepsData (<*sweepName*>,<*sweepData*>)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Python Example	`sweepList = [12.3, 14.5, 16.7]` `outData.SetSweepsData("Freq", sweepList)`

SetDoubleQuantityData

This method is used to record the computed quantity data for each output that is computed. Please note that unless all the sweeps are reduced, this should be used in conjunction with SetSweepsData.

UI Access	NA		
Parameters	Name <*qtyName*> <*qtyData*>	Type String List<Floats>	Description Name of the quantity. Quantity data for the specified quantity.
Return Value	Boolean. If true, the event was handled successfully. If false, it was not.		

Python Syntax	SetDoubleQuantityData (<*qtyName*>,<*qtyData*>)
Python Example	`doubleList = [12.3, 14.5, 16.7]` `outData.SetDoubleQuantityData("V1PlusV2", doubleList)`

SetComplexQuantityData

If the quantity computed is a complex quantity, use this method to set the quantity values. Any sweep values must be set separately via the SetSweepsData method.

UI Access	NA		
Parameters	Name <*qtyName* > <*qtyData* >	Type String List<floats>	Description Name of the quantity. Quantity data for the specified quantity. Complex numbers are passed as pairs of floats in a list.
Return Value	Boolean. If true, the method was successful. If false, it was not.		

Python Syntax	SetComplexQuantityData (<*qtyName*>,<*qtyData*>)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Python Example	doubleFromComplexList=[]
	complexList = [(1+1j), (2+4j), (9.1+3.2j)]
	for aComplex in complexList:
	    doubleFromComplexList.append(aComplex.imag)
	    doubleFromComplexList.append(aComplex.real)
	    outData. SetComplexQuantityData ("V1PlusV2", doubleFromComplexList)

Working With Properties for UDO

A property is the unit for collecting and using input from the user that is used to influence the UDO's Compute. These are initially set up when the UDOs **GetInputUDSParams** method is called and are retrieved in the UDO's Compute method.

There are three supported property types that could be used in the UDO script:

- INumberProperty to specify number properties (with unit support).
- IMenuProperty to allow the user to select from a list of options.
- ITextProperty to allow the user to enter text.

The IPropertyList type implements a collection for these properties:

- IPropertyList Abstract class
- IProperty Abstract class
- INumberProperty Abstract class
- ITextProperty Abstract class
- IMenuProperty Abstract class

IPropertyList Abstract Class

Attributes:

- AllProperties (IEnumerable<IProperty> - see IProperty)
- NumProperties (int)

Functions:

- GetProperty(string propName): Returns a named property as an IProperty.
- GetMenuProperty (string propName): Returns the named property as an IMenuProperty.
- GetTextProperty (string propName): Returns the named property as an ITextProperty.
- GetNumberProperty (string propName): Returns the named property as an INumberProperty.
- DeleteProperty (string propName): Deletes an already added named property.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- AddNumberProperty(string name, string numberWithUnits): Adds a new number property. If a property with the same name already exists, it is overwritten.
- AddTextProperty(string name, string textValue): Adds a new named text property with the supplied value. Any existing property with the same name is overwritten.
- AddMenuProperty(string name, IList<string> menuChoices): Creates a new named menu property with the supplied list of choices. The default selection is set to item 0 (the first item). Any property with the same name is overwritten.

IProperty Abstract Class

Attributes:

- Name (string)
- Description (string)
- PropType (read-only EPropType - see Constants)

Constructor:

- IProperty(string name, EPropType type)

The class is used as base class for INumberProperty, IMenuProperty, and ITextProperty.

INumberProperty Abstract Class

Base class:

- abstract class IProperty

Attributes:

- ValueSI (read-only double)
- ValueInUnits (read-only double)
- Units (read-only string)
- HasUnits (read-only bool)

Constructor:

- INumberProperty(string name)

Functions:

- Set(string numberWithUnits)
- SetDouble(double number, string unitString)

ITextProperty Abstract Class

Base class:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- abstract class IProperty

Attributes:

- Text (string)

Constructor:

- ITextProperty(string name)

IMenuProperty Abstract Class

Base class:

- abstract class IProperty

Attributes:

- MenuSelection (int): This represents the index into the MenuChoices list.
- SelectedMenuChoice (string): This is the item in the MenuChoices list corresponding to the MenuSelection index.
- MenuChoices (IList<string>)

Constructor:

- IMenuProperty (string name)

Example:

```
# adding data to IPropertyList propList; used in Compute function
prop = propList.AddNumberProperty('Offset 1', '0')
prop.Description = 'Trace 1 Offset'
prop = propList.AddNumberProperty("TRATE", "800 MHz")
prop.Description = "Frequency"
prop = propList.AddTextProperty("Text", "The Text")
prop.Description = "Text Property"
prop = propList.AddMenuProperty('Operation', ['Add', 'Subtract',
'Max' ,'Min','Mean'])
prop.Description = 'Operation menu'

# reading data from IPropertyList propList; used in Validate function
numOfNumberProperties = 0
if propList != None and propList.AllProperties != None:
        for prop in propList.AllProperties:
                if prop.PropType == Constants.EPropType.PT_NUMBER:
                        numOfNumberProperties ++
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Other Application-Specific Classes Used in Python Scripts

This section describes other classes used in Python scripts:

Constants Class

UDSProbeParams Class

UDSDynamicProbes Class

QuantityInfo Class

IProgressMonitor Abstract Class

Constants Class

The constants used in a Python script are defined in the Constants class.

Attributes:

- kDoubleParamStr : string constant used to specify *double* as the type of a quantity
- kComplexParamStr: string constant used to specify *complex* as the type of a quantity
- Enum EPropType: (used to set property type)
  - EPropType.PT_NUMBER
  - EPropType.PT_TEXT
  - EPropType.PT_MENU

Example:

```
paramType = Constants.kDoubleParamStr
propType = Constants.EPropType.PT_NUMBER
```

UDSProbeParams Class

This class defines which data quantity that a UDO will be pulled from the design to compute the UDO output (results). The objects of this class must be created in a Python script with the GetInputUDSParams function. They are supplied to the Validate function if implemented.

Attributes:

- ProbeName (read-only string)
- ProbeDescription (read-only string)
- ParamType (read-only string)
- ReportTypeName (read-only string)
- ComponentExpression (read-only string)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Constructor: UDSProbeParams(string probeName, string probeDescription, string paramType, string reportTypeName, string componentExpression);

- probeName - required.
- probeDescription - optional (can be empty string).
- paramType - required; can be one of the Constants:
  - kDoubleParamStr
  - kComplexParamStr
- reportTypeName - optional (can be empty string)
- ComponentExpression - optional (can be empty string)

Example:

```
udsProbParam = UDSProbeParams("probe1","", Constants.kDoubleParamStr,
"", "",)
```

UDSDynamicProbes Class

Attributes:

- UDSParam (read-only UDSProbeParams)
- UserSelectedProbeName (read-only string)

Constructor: UDSDynamicProbes (UDSProbeParams udsParam, string userSelectedProbeName)

- udsParam - required
- userSelectedProbeName - required

Example:

```
udsProbParam = UDSProbeParams("probe1","", Constants.kDoubleParamStr,
"", "",)
selectedName = "probe1"
udsDynamicProbParam = UDSDynamicProbes(udsProbParam, selectedName )
```

QuantityInfo Class

Attributes:

- ParamType (read-only string)
- FullUnitType (read-only string)

Constructors:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- QuantityInfo(string paramType)
- QuantityInfo(string paramType, string fullUnitType)

Parameters:

- paramType can be one of the Constants:
  - kDoubleParamStr
  - kComplexParamStr
- fullUnitType is a case insensitive string representing full unit type. It is not defined in Constants. Instead you can use any of the units in string representation - for example, "mm" or"ghz".

Example:

```
quantityInfo1 = QuantityInfo(Constants.kDoubleParamStr)
quantityInfo2 = QuantityInfo(Constants.kDoubleParamStr,"ghz")
```

IProgressMonitor Abstract Class

The object of this class is a progress monitor. It displays a task's calculated progress in the UI and checks if the user has requested to abort the computation. Use this object for computations that take a long time to complete or if the UI might freeze during the computation. When displayed in the application, each progress message has four items:

- A task name
- A sub-task name
- The progress amount
- A button to abort the task in progress

This class provides the following functionality and abort interaction:

- SetTaskName (string taskName)
- SetSubTaskName (string subTaskName)
- BeginTask (string name)
- SetTaskProgressPercentage(int progressPercent)
- CheckForAbort()
- EndTask (bool passFail)

Example:

```
progMon.BeginTask("Process DQS")
progMon.SetSubTaskName("Compute UI segments")
progMon.SetTaskProgressPercentage(33)
progMon.SetSubTaskName("Compute the rest")
progMon.SetTaskProgressPercentage(100)
progMon.EndTask(True)
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

> **Note:**
>
> There should be the same number of calls to BeginTask as to EndTask.

SetTaskName

Sets the name of the task whose progress is being monitored.

UI Access	NA		
Parameters	Name <*TaskName*>	Type String	Description Name of the task
Return Value	None		

Python Syntax	SetTaskName (<*TaskName*>)
Python Example	`progMon.SetTaskName("Compute UI")`

SetSubTaskName

Sets the name of the subtask whose progress is being monitored.

UI Access	NA		
Parameters	Name <*TaskName*>	Type String	Description Name of the task
Return Value	None		

Python Syntax	SetSubTaskName (<*TaskName*>)
Python Example	`progMon.SetSubTaskName("Compute UI segments")`

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

BeginTask

Sets the name of the task whose progress will be monitored. Call this method only once for each task and subtask.

UI Access	NA		
Parameters	Name <*Name*>	Type String	Description Name of the task
Return Value	None		

Python Syntax	BeginTask (<*Name*>)
Python Example	`progMon.BeginTask("Process DQS")`

SetTaskProgressPercentage

Sets the progress percentage of a task to a specific value.

UI Access	NA		
Parameters	Name <Percent>	Type Integer	Description Percent of progress
Return Value	None		

Python Syntax	SetTaskProgressPercentage (<*Percent*>)
Python Example	`progMon.SetTaskProgressPercentage(33)`

CheckForAbort

Checks if a user has aborted the task. Call this method if the quantities are computationally expensive. This method can be called multiple times.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

UI Access	Abort button on the progress dialog.
Parameters	None
Return Value	Boolean flag that if true indicated that the user requested an abort and you should call EndTask. If false, allow the task to continue.

Python Syntax	CheckForAbort
Python Example	`should_abort = progMon.CheckForAbort`

EndTask

Stops a task from running. Call this method only once for each task and subtask. In a script, there should be the same number of BeginTask calls as **EndTask** calls.

UI Access	NA		
Parameters	Name <PassFail>	Type Boolean	Description Flag that indicates whether to continue the main task or not. If true, the task will continue to process the next subtask. If false, the main task stops and an error icon appears in the UI.
Return Value	None		

Python Syntax	EndTask (<*PassFail*>)
Python Example	`progMon.EndTask(True)`

Using .NET Collection Classes and Interfaces in Python Scripts

Some of the API functions specified above use .Net collection classes and interfaces, that is, Array class, IList interface, IEnumerable interface, and IDictionary interface. The following section describes how to work with the .Net collection objects in Python scripts.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

.NET Array, IEnumerable, and IList objects can be indexed and iterated over as if they were Python lists. You can also check for membership using 'in'. To get .Net Array and IList sizes you can use Python's 'len' or .Net 'Count'.

Example:

Getting size:

```
arraySize = doubleDataArray.Count
   arraySize = len(doubleDataArray)
listSize = sweepsNamesList.Count
 listSize = len(sweepsNamesList)
```

Iterating:

```
for sweep in sweepsNamesList:
   print sweep
for in in xrange(listSize)
      print sweepsNamesList[i]
```

Checking for membership:

```
if 'Time' in sweepsNamesList:
   doThis()
  else:
   doThat()
```

For .NET IDictionary, the same as for Array and IList, you can get size with 'len' or 'Count' and check for membership of the keys using 'in'. Getting values for the keys also works the same way as in Python 'dict'.

Example:

Getting size:

```
varValuesSize = varValues.Count
 varValuesSize = len(varValues)
```

Checking for membership:

```
if 'offset' in varValues:
   print varValues['offset']
```

Getting value:

```
if 'offset' in varValues:
   offsetValue = varValues['offset']
```

As for iteration .NET Dictionary is different from Python dict. While iterating, python dict will return keys, .Net Dictionary will return .Net KeyValuePair.

Example:

Iterating:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

for .NET IDictionary:

```
for varPair in varValues: #varPair is of .Net KeyValuePair type
     varName = varPair.Key
    varValue = varPair.Value
```

for Python dict:

```
for varName in varValues:
   varValue = varValues[varName]
```

You can use Python types instead of .NET types if you prefer. For this, you need to cast .NET array and .Net iList to Python list type and .NET Dictionary to Python dict type.

Casting should not be used for data arrays - it can be extremely costly for the memory usage as well as time consuming.

Example:

```
aPythonList = list(dotNetArray)
  aPythonList = list(dotNetList)
   aPythonDict = dict(dotNetDictionary)
```

User-Defined Outputs: Messaging Methods

Messaging methods are provided to convey additional information to the user from any of the UDOs methods. The Compute function is the one typically location where such use is anticipated. Any message sent via these functions are displayed in the application's message window using the appropriate icon.

These functions can also be used for debugging purposes.

- AddErrorMessage
- AddInfoMessage
- AddWarningMessage

```

AddErrorMessage

Call this method to convey an error condition to the user.

UI Access	NA		
Parameters	Name <message>	Type String	Description Error message
Return Value	None		

Python Syntax	AddErrorMessage (<*message*>)
Python Example	`AddErrorMessage(self.GetName() + "Unexpected sweep count 0 or > 1 in Compute"))`

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

AddInfoMessage

Call this method to convey an informational message to the user. This is the call to use when outputting messages for debugging purposes.

UI Access	NA		
Parameters	Name <message>	Type String	Description Warning message
Return Value	None		

Python Syntax	AddInfoMessage (<*message*>)
Python Example	`AddInfoMessage("Enter starting X value.")`

AddWarningMessage

Call this method to convey a warning message, typically used for conditions that are not ideal but can be tolerated by the script.

UI Access	NA		
Parameters	Name <message>	Type String	Description Warning message
Return Value	None		

Python Syntax	AddWarningMessage (<*message*>)
Python Example	`AddWarningMessage("Unexpected sweep count in Compute")`

User-Defined Outputs: Script Organization

As described in the Introduction section, the UDO scripts should all reside under the **UserDefinedOutputs** folder under either of the three library locations (system, user, or personal).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Using Script Libraries

If you decide that you need base classes, additional data files, and etc., to organize your UDOs better, you can do so. This type of library organization allows code reuse between similar UDOs and can be very helpful. There is special support provided for this type of script-library organization:

- **All script-library and other support files need to be in a *Lib* sub-directory under the *UserDefinedOutputs* directory**. Any *.py* files found in such **Lib** directories are ignored and not displayed in the GUI as a valid UDO choice.
- For a UDO script at any given directory depth, all Lib directories in its parent directories will be automatically added to the system include path (and so, any support script files from any Lib directory through the top level *UserDefinedOutputs* directory can be imported).

Using Additional .NET Assemblies

Because the UDO functionality uses IronPython, we have access to the full .NET eco system. If needed, any subset of the UDO functionality can be implemented in any .NET language and used by the UDO script. There are simple rules to follow to achieve this.

1. Build your .NET assembly for .NET 2.0 runtime.
2. Drop the built assembly in any **Lib** directory upstream of the UDO script location: that is, if you have your UDO script in *C:\Users\x\PersonalLib\UserDefinedOutputs\a\b\c\myudo.py* and have a .NET assembly called *com.Acme.UDOLib* You can keep the .NET assembly under:
    - UserDefinedOutputs\Lib
    - UserDefinedOutputs \a\Lib
    - UserDefinedOutputs \a\b\Lib
    - UserDefinedOutputs\a\b\c\Lib
3. Add the following lines to your Python script:
    - `Import clr`
    - `clr.AddReference("com.Acme.UDOLib")`
    - `import com.Acme.UDOLib` -or- `from com.Acme.UDOLib import * etc`

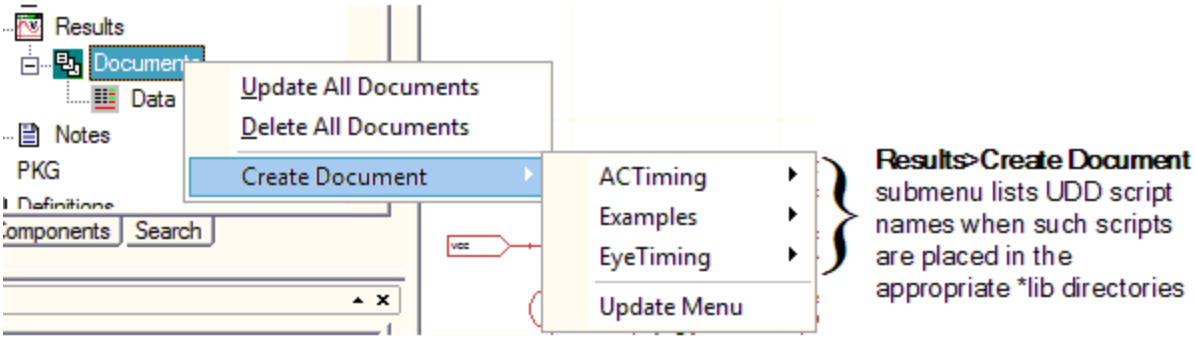
If for some reason you cannot place the .NET assemblies into a Lib directory under *UserDefinedOutputs*, you need to do a couple more steps before step 3 listed above.

```
Import sys
sys.path.append("full path to your .NET assembly location")
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

User-Defined Documents (UDDs)

User-defined documents (UDDs) are custom reports that you define through IronPython scripts. Once placed in a Lib directory, you can access the scripts via the **Create Document** command. The scripts describe a *Create User Defined Document* dialog box that lets you specify trace and solution inputs. After you confirm your input selections, XML, HTML, and PDF documents are generated. A web browser window opens to display the generated HTML file. The created document appears in the Project Manager, under Results in the Documents folder.



The general UDD process flow is as follows:

The UDD Python scripts must be placed in the **UserDefinedDocuments** directory under either of **syslib**, **userlib**, or **Personallib** with any subdirectory structure needed. The Lib directory can contain Python scripts that have common code that other scripts can use.

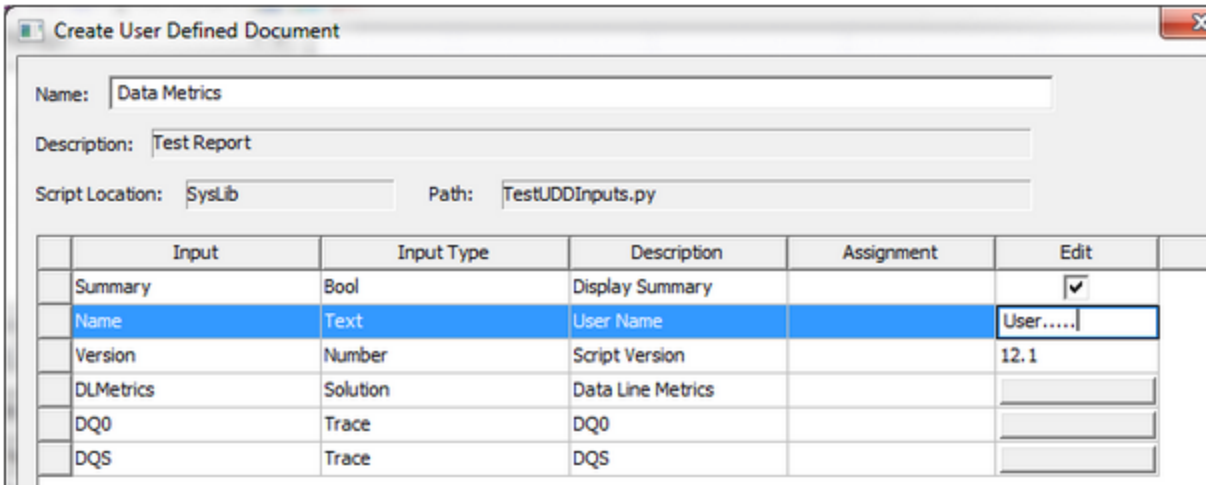
Use **HFSS** > **Results** > **Create Document**> **Update Menu** to refresh the menu to include the new UDD scripts that have been copied to syslib, userlib, or Personallib, or to exclude them if they have been deleted after the launch of desktop.

The UDD scripts that are in syslib/UserDefinedDocuments, userlib/UserDefinedDocuments, or Personallib/UserDefinedDocuments are available through the **HFSS** > **Results** > **Create Document** menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Create User-Defined Document Inputs

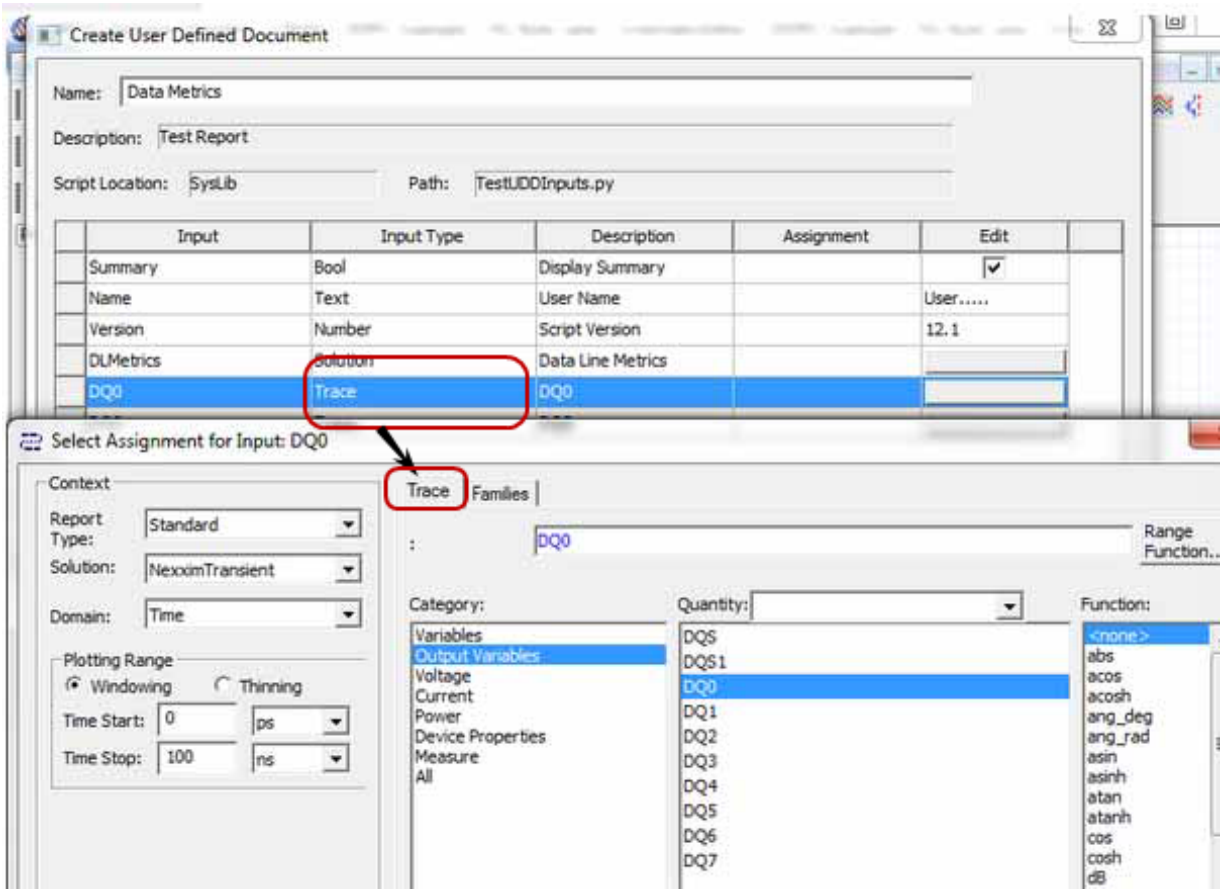
User-defined documents allow data from traces, solutions, and report types as inputs. A UDD can specify the named inputs, which you select or enter the values of in the *Create User Defined Document* dialog box that displays when you run **HFSS** > **Results** > **Create Document**> <*scriptName*>.



Input Types can be of Boolean, number, text, trace, or solution type. The boolean, number, and text type can be given a default value that you can interactively override when the document is created or modified. For example, you can select a trace when you create or modify a UDD document. The trace data is available to the user and can be accessed from the Python script.

At the time of selection, you can choose from the *Reporter* dialog box the report type (Standard, Eye Diagram, User Defined), solution name, context, and the quantity for which you want the trace data.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

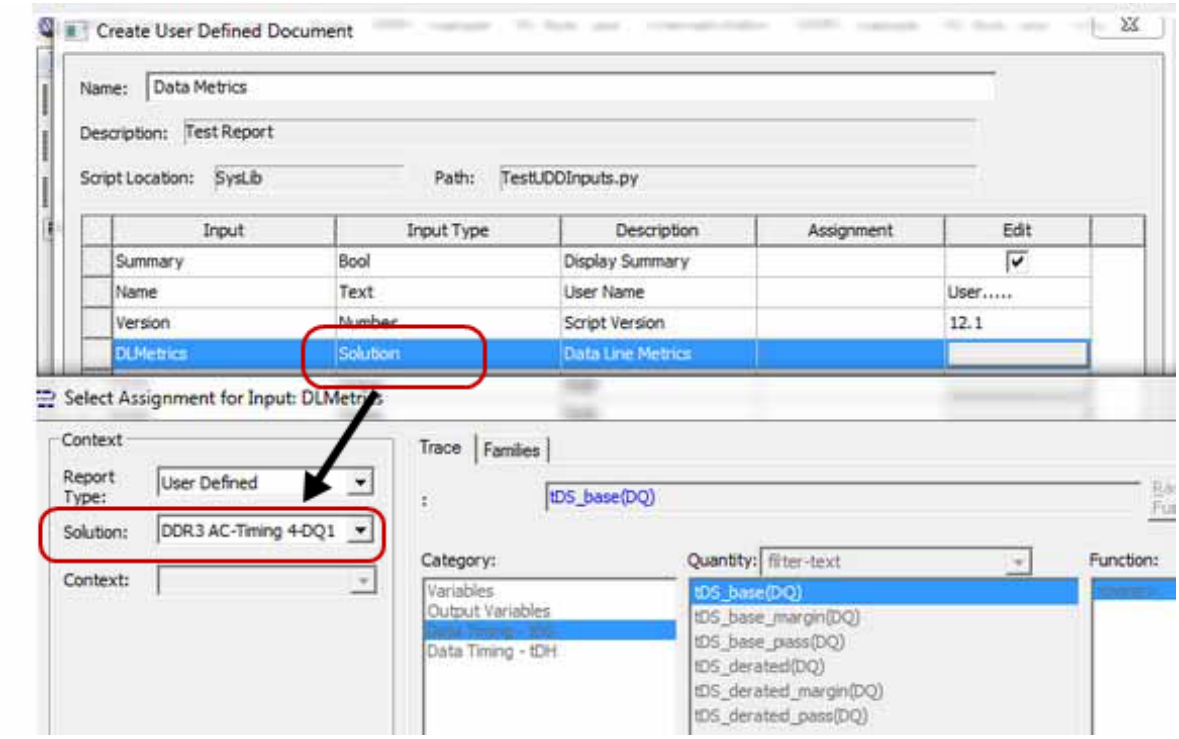


Input Type can also be Solution. You can select an entire solution when the document is created or modified. The solution data in its entirety is now available to the user and can be accessed from the Python script.

At the time of selection, you can choose from the reporter dialog the report type (Standard, Eye Diagram, User Defined), solution name, and context. A specific quantity cannot be selected since data for all quantities in the solution are available.

> **Note:** The Category/Quantity/Function portion of the dialog is disabled for user input.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

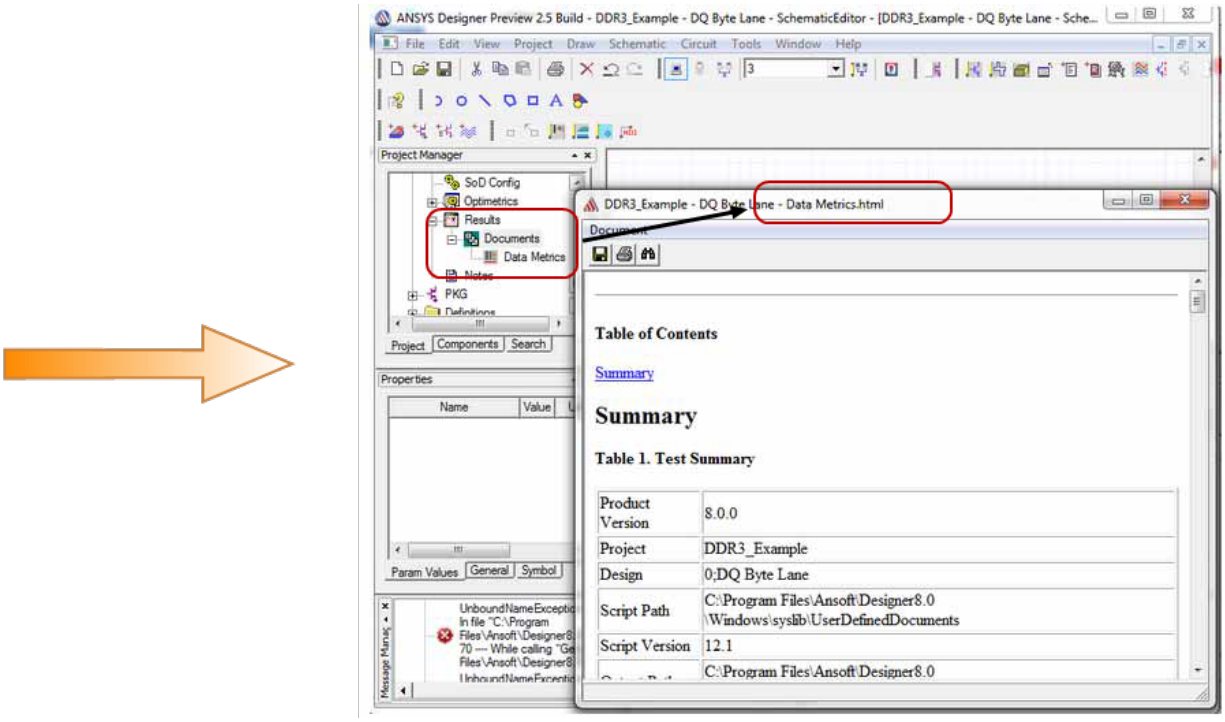


UDD Document Creation and Display

After all the input selections for a UDD are confirmed, based on the script, XML, HTML, and PDF documents are generated based on the inputs provided by the user. (The XML, HTML, and PDF generation is based on specific calls in the Python script, which are explained in a following section.) A web browser window also opens to display the generated HTMLfile.

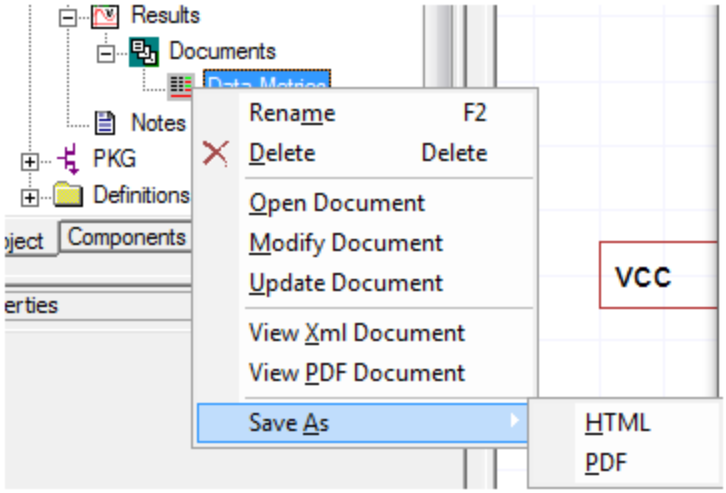
The created document will be placed under a new folder named **Documents** under the **Results** folder. All documents that are created by the user for the design will be placed under this folder.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Managing Documents Listed in the Project Window Under Results

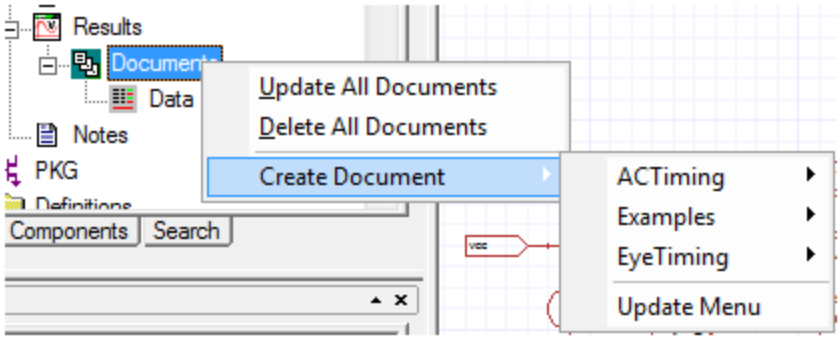
Right-click a user-defined document displayed in the Project Manager tree to bring up a menu where you can rename, delete the document. **Open document** opens the web browser with the html document. **Modify document** opens the setup dialog box, where you can change the selections for the input. To view the XML and the PDF document simply choose the appropriate menu items. There is also a menu item to save the document in a different location.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Documents Folder's Context Menu

Right-click the documents folder has the menu options to **Update All Documents** or **Delete All Documents**. It also provides the option of creating a document from here.

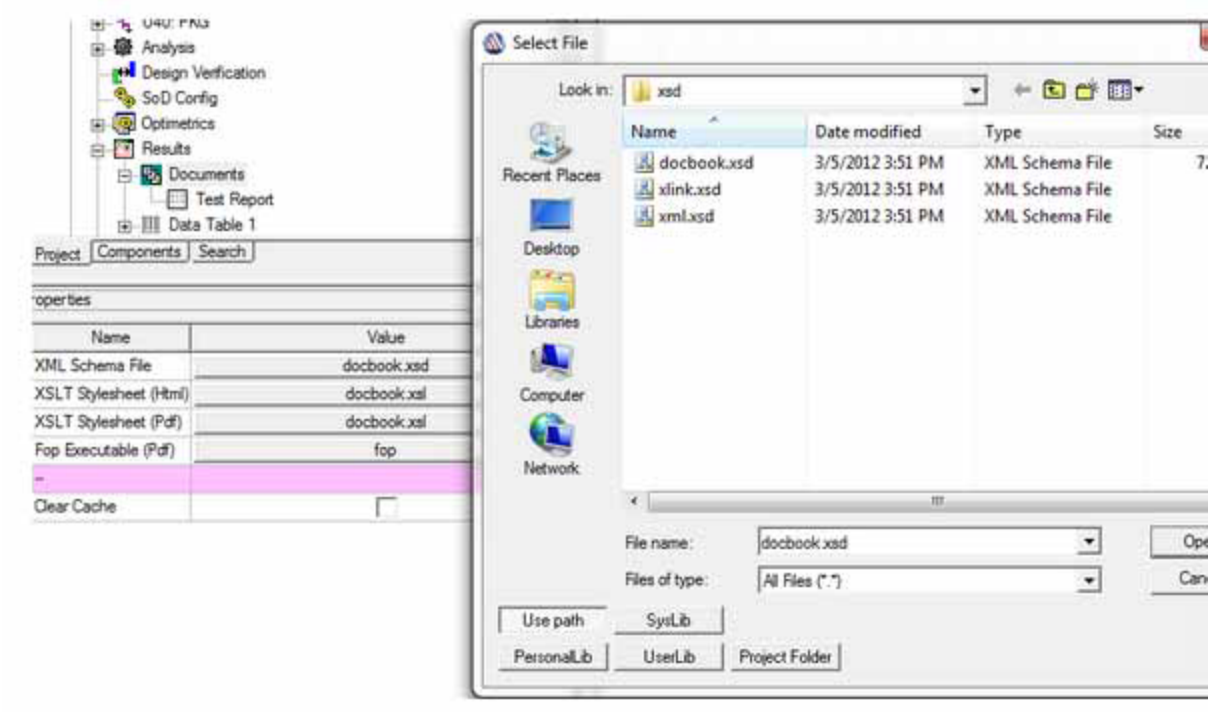


Document Folder's Property Window

When the documents folder is selected, the *Property* window shows the following properties:

- **XML Schema File** - File path to the XML schema file.
- **XSLT StyleSheet (HTML)** - File path to the XSLT stylesheet file used for HTML generation.
- **XSLT StyleSheet (Fo)** - File path to the XSLT stylesheet file used for PDF generation.
- **Fop Executable (PDF)** - File path the Fop executable used for PDF generation.
- **Clear Cache** - Clears the cached XSL transform object and forces creation of a new one. (The caching is done to save time during document generation, so subsequent generation or update of the document can use the cached transform object. But sometimes you may want to force a recompile of the document if you change the stylesheet).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

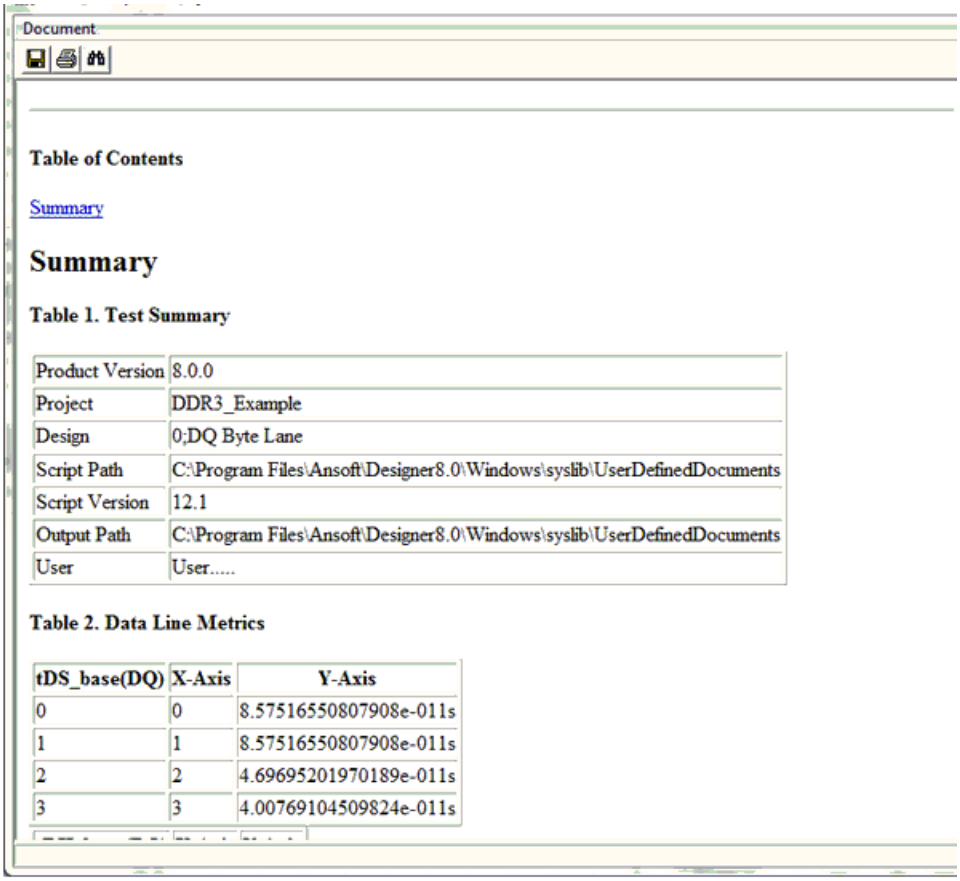


The XML, HTML, and PDF generation require the XML schema file and XSLT stylesheets to generate proper output. In addition, the PDF generation requires a FOP executable. You can use the defaults provided in the installation or provide the file paths of your own preferred stylesheets and fop executable installed in his machine.

Viewing UDDs with an HTML Web Browser

The XML and HTML documents can be viewed in a web browser with some basic functionality like printing the document, searching the document for a phrase or sentence, and saving the document.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



UDD Script Libraries

Base classes and data files shared between similar UDDs can be organized to reuse the code in a better way. All script-library and other support files need to be in a Lib sub-directory under the UserDefinedDefinitions directory. Any .py files found in such Lib directories are ignored and not displayed in the GUI as a valid UDD choice. For a UDD script at any given directory depth, all Lib directories in its parent directories will be automatically added to the system include path (and so, any support script files from any Lib directory through the top level UserDefinedDefintions directory can be imported).

The UDD functionality uses IronPython so we have access to all the .NET assembles. If needed, any subset of the UDD functionality can be implemented in any .NET language and used by the UDD script. There are simple rules to follow to achieve this.

1. Build your .NET assembly for .NET 2.0 runtime.
2. Drop the built assembly in any Lib directory upstream of the UDD script location: that is, if you have your UDD script in C:\Users\x\PersonalLib\UserDefinedDefintions\a\b\c\myudd.py and have a .NET

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

assembly called com.Acme.UDDLib You can keep the .NET assembly under:

- UserDefinedDefintions\Lib
- UserDefinedDefintions\a\Lib
- UserDefinedDefintions\a\b\Lib
- UserDefinedDefintions\a\b\c\Lib

3. Add the following lines to your Python script:

```
Import clr

clr.AddReference("com.Acme.UDDLib")

import com.Acme.UDDLib -or- from com.Acme.UDDLib import * etc
```

If for some reason you cannot place the .NET assemblies into a Lib directory under UserDefinedDefintions, you need to do a couple more steps before step 3 listed above:

```
Import sys

sys.path.append("full path to your .NET assembly location")
```

User-Defined Documents: Python Script API

A User-Defined Documents (UDD) extension is implemented as an IronPython script that defines a class with a specific name: UDDExtension which derives from a specific base class IUDDPluginExtension and implements its abstract methods.

This API supports multiple data types in the forms of constants and classes. It also has several input interfaces.

User-Defined Document scripting commands are provided in this product's scripting guide. An complete example with a line by line explanation of how to use these methods is available.

Import Statements

The base class to be used and the types it uses in turn are contained in .NET assemblies. The use of these requires that the assemblies be imported into the UDD script: the following import statements should be added to the top of the python script:

```
from Ansys.Ansoft.DocGeneratorPluginDotNet.DocGenerator.API.Data
import *
from
Ansys.Ansoft.DocGeneratorPluginDotNet.DocGenerator.API.Interfaces
import *
```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Data Types Used in UDD Python Scripts

There are several types that you must use while authoring a Python script. Some of them are used to pass data from the UI to a Python script and to provide interfaces for working with this data. Some are used to pass data from a Python script to the UI.

To pass data from a Python script to the UI, the objects of the C# class must be created in the Python script using their C# constructors. Then they can be set as a function's return values or set to the output parameters using their API.

Constants

- **kTraceTypeStr** : string constant used to specify an input of trace type
- **kSolutionTypeStr** : string constant used to specify an input of solution type
- **kNumberTypeStr** : string constant used to specify an input of number type
- **kTextTypeStr** : string constant used to specify an input of text type
- **kBoolTypeStr** : string constant used to specify an input of boolean type
- **kStandardReportStr** : string constant to specify a standard report
- **kEyeDiagramReportStr** : string constant to specify an eye diagram report
- **kUserDefinedReportStr** : string constant to specify a user defined report
- **kSweepDomainStr** : string constant to specify the sweep domain
- **kTimeDomainStr** : string constant to specify the time domain

Abstract Classes

- IProgressMonitor Abstract Class
- UDDExtension Class
- UDDInputData class
- UDDInputParams class

IProgressMonitor Abstract Class

The object of this class is a progress monitor. It displays a task's calculated progress in the UI and checks if the user has requested to abort the computation. Use this object for computations that take a long time to complete or if the UI might freeze during the computation. When displayed in the application, each progress message has four items:

- A task name
- A sub-task name
- The progress amount
- A button to abort the task in progress

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This class provides the following functionality and abort interaction:

- SetTaskName (string taskName)
- SetSubTaskName (string subTaskName)
- BeginTask (string name)
- SetTaskProgressPercentage(int progressPercent)
- CheckForAbort()
- EndTask (bool passFail)

Example:

```
progMon.BeginTask("Process DQS")
progMon.SetSubTaskName("Compute UI segments")
progMon.SetTaskProgressPercentage(33)
progMon.SetSubTaskName("Compute the rest")
progMon.SetTaskProgressPercentage(100)
progMon.EndTask(True)
```

> **Note:**
>
> There should be the same number of calls to BeginTask as to EndTask.

SetTaskName

Sets the name of the task whose progress is being monitored.

UI Access	NA		
Parameters	Name <*TaskName*>	Type String	Description Name of the task
Return Value	None		

Python Syntax	SetTaskName (<*TaskName*>)
Python Example	`progMon.SetTaskName("Compute UI")`

SetSubTaskName

Sets the name of the subtask whose progress is being monitored.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

UI Access	NA		
Parameters	Name <*TaskName*>	Type String	Description Name of the task
Return Value	None		

Python Syntax	SetSubTaskName (<*TaskName*>)
Python Example	`progMon.SetSubTaskName("Compute UI segments")`

BeginTask

Sets the name of the task whose progress will be monitored. Call this method only once for each task and subtask.

UI Access	NA		
Parameters	Name <*Name*>	Type String	Description Name of the task
Return Value	None		

Python Syntax	BeginTask (<*Name*>)
Python Example	`progMon.BeginTask("Process DQS")`

SetTaskProgressPercentage

Sets the progress percentage of a task to a specific value.

UI Access	NA		
Parameters	Name <Percent>	Type Integer	Description Percent of progress
Return Value	None		

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Python Syntax	SetTaskProgressPercentage (<*Percent*>)
Python Example	`progMon.SetTaskProgressPercentage(33)`

CheckForAbort

Checks if a user has aborted the task. Call this method if the quantities are computationally expensive. This method can be called multiple times.

UI Access	Abort button on the progress dialog.
Parameters	None
Return Value	Boolean flag that if true indicated that the user requested an abort and you should call EndTask. If false, allow the task to continue.

Python Syntax	CheckForAbort
Python Example	`should_abort = progMon.CheckForAbort`

EndTask

Stops a task from running. Call this method only once for each task and subtask. In a script, there should be the same number of BeginTask calls as **EndTask** calls.

UI Access	NA		
Parameters	Name <PassFail>	Type Boolean	Description Flag that indicates whether to continue the main task or not. If true, the task will continue to process the next subtask. If false, the main task stops and an error icon appears in the UI.
Return Value	None		

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Python Syntax	EndTask (<*PassFail*>)
Python Example	`progMon.EndTask(True)`

IUDDPluginExtension Abstract Class

The **IUDDPluginExtension** abstract class declares the following abstract methods which must be implemented in the UDDExtension class or one of its base classes. If any of these methods are not implemented, a run-time error will occur and the UDD will not function.

- GetUDDName
- GetUDDDescription
- ShowDefaultSetupDialog
- GetUDDInputParams
- Generate

This class also provides for the following optional methods:

- SetupUDDInputParams
- HandleUDDEvents
- GetUDDSchema
- GetUDDStyleSheetForHtml
- GetUDDStyleSheetForPdf
- GetFopExecutable
- GetUDDAppContext
- GetUDDDesignContext

GetUDDName

Retrieves a prefix to use for all solution instances created using this UDD.

UI Access	NA
Parameters	None
Return Value	String that is the prefix

Python Syntax	GetUDDName()

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Python Example	`def GetUDDName(self):` `  return "MinMaxAvg"`

GetUDDDescription

Retrieves a description for the UDD, its purpose, etc.

UI Access	NA
Parameters	None
Return Value	String that is the description

Python Syntax	GetUDDDescription()
Python Example	`def GetUDDDescription(self):` `  return "Sample UDD"`

ShowDefaultSetupDialog

Retrieves whether to show the default setup dialog box. If not, the user might want to implement or show a customized setup dialog.

UI Access	NA
Parameters	None
Return Value	Boolean. If true, the default dialog should be shown. If false, the user does not want to see the default dialog.

Python Syntax	ShowDefaultSetupDialog()
Python Example	`def ShowDefaultSetupDialog(self):` `  return True`

GetUDDInputParams

Retrieves inputs parameters for the User Defined Document. These parameters are the input's name, description, and data type. The UDD user specifies the value of the inputs through a

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

dialog or within the script.

UI Access	Depending on the input parameters, the following dialog may be displayed when you click **HFSS**> **Results**> **Create Document**. The name and description of the UDD are also displayed in this dialog. Parameters	Name: *<uddInputs>* Type: List< UDDInputParams >* Description: The UDD script is expected to add one instance of UDDInputParams for each input definition that it will to display. When creating the UDD, the user will assign a matching value to each such input.
Return Value	Boolean. If true, the method was successful. If false, it was not.

Python Syntax	GetUDDInputParams(*<probeName>*)

Python Example	`def GetUDDInputParams(self, uddInputs)`
	`    # Boolean input`
	`    param1 = UDDInputParams("Summary","Display Summary", Constants.kBoolTypeStr, True)`
	`    uddInputs.Add(param1)`

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
    # Text input
    param2 = UDDInputParams("Name","User Name",
Constants.kTextTypeStr, "Sita Ramesh")
    uddInputs.Add(param2)
    # Number input
    param3 = UDDInputParams("Version","Script Version",
Constants.kNumberTypeStr, 1021)
    uddInputs.Add(param3)
    # Solution input
    param5 = UDDInputParams("DLMetrics","Data Line
Metrics",Constants.kSolutionTypeStr)
    uddInputs.Add(param4)
    # Trace input
    param5 = UDDInputParams
("DQ0","DQ0",Constants.kTraceTypeStr)
    uddInputs.Add(param5)
    return True
```

Generate

This is the main method which accesses the data from the uddInputs and generates the document.

UI Access	NA		
Parameters	Name	Type	Description
	<uddInputs>	List< UDDInputData>	The list of inputs that the user setup in the dialog box. They are now available to query for data.
	<generator>	IUDDGenerator	This is the document generator object which used to create different elements of the document like titles, sections, tables, images and write the data too. See the Document Generator Interfaces.
	<progressMonitor>	IProgressMonitor	This can be used to set progress for long running calculations and check for any user-initiated aborts.
Return Value	Boolean. If true, the method was successful. If false, it was not.		

Python	Generate(*<uddInputs>*, *<generator>*, *<progressMonitor>*)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Syntax	

Python Example	def Generate(self, input, docgen, progMon):
	
	    # Gather data from inputs
	    boolinput = input[0].Data()
	    textinput = input[1].Data()
	    dblinput = input[2].Data()
	
	    # Get document root
	    docroot = docgen.GetDocumentRoot()
	
	    # Add Section
	    section1 = docroot.AddSection("Summary", "Overall Results ")
	
	    # Add a table
	    table1 = section1.AddTable("Test Summary")
	
	    #Add a table group with 2 columns
	    tgroup1 = table1.AddTableGroup(2)
	
	    # get desktop application
	    oApp = self.GetUDDAppContext()
	    if oApp != None:
	        oDesktop = oApp.GetAppDesktop()
	    if oDesktop != None:
	        # version number
	        version = oDesktop.GetVersion()
	        text1 = tgroup1.AddContent()
	        text1 .Add(0, "Product Version")
	        text1 .Add(1, version)
	
	    oProject = oDesktop.GetActiveProject()
	    if oProject != None:
	        projectname= oProject.GetName()
	        text1 = tgroup1.AddContent()
	        text1 .Add(0, "Project")
	        text1 1.Add(1, projectname)
	
	    oDesign = self.GetUDDDesignContext()
	    if oDesign != None:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
        designname = oDesign.GetName()
        text1 = tgroup1.AddContent()
        text1 .Add(0, "Design")
        text1 .Add(1, designname)

    # Provides a script path
    scriptpath = docgen.GetScriptPath()
    text1 = tgroup1.AddContent()
    text1 .Add(0, "Script Path")
    text1 .Add(1, scriptpath)

    #Provides the script version
    text1 = tgroup1.AddContent()
    text1 .Add(0, "Script Version")
    text1 .Add(1, str(dblinput))

    #Provides the output xml path
    outputpath = docgen.GetOutputFilePath()
    text1 = tgroup1.AddContent()
    text1.Add(0, "Output Path")
    text1.Add(1, outputpath)

    #Provides the user information
    text1 = tgroup1.AddContent()
    text1 .Add(0, "User")
    text1 .Add(1, textinput)

    # Generate Xml output
    docgen.Write(False)

    # Generate Html output
    docgen.WriteHTML()

    # Generate PDF output
    docgen.WritePDF()

    return True
```

SetupUDDInputParams

This optional method displays a customized dialog and returns the user choices for the input params.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

UI Access	NA		
Parameters	Name <*uddInputs*>	Type List<UDDInputParams>	Description .NET list of UDDInputParams objects with values for each of them. These can be the user choice for each input obtained through a custom dialog or some other non-graphical assignment. This method cannot process trace and solution types of input with a custom dialog because there is no way of assigning solution data to the input without the invocation of the reporter dialog.
Return Value	Boolean. If true, the event was handled successfully. If false, it was not.		

Python Syntax	SetupUDDInputParams(<*uddInputs*>)

Python Example	`def SetupUDDInputParams(self, uddInputs)`
	`    udddialog = BaseExampleUDDDialog()`
	`    if udddialog.ShowDialog() == Forms.DialogResult.OK:`
	`        # Boolean input`
	`        param1 = udddialog.GetInput("Summary")`
	`        uddInputs.Add(param1)`
	
	`        # Text input`
	`        param2 = udddialog.GetInput("Name")`
	`        uddInputs.Add(param2)`
	
	`        # Number input`
	`        param3 = udddialog.GetInput("Version")`
	`        uddInputs.Add(param3)`

HandleUDDEvents

This optional method is the event handler for all link events set by the SetEventLink() method on a IUDDText. Refer to the definition of the IUDDText object in the Document Generator Interface. The tags associated with the event are received by plugin using this abstract class.

UI Access	NA

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Parameters	Name Type Description <*eventTags*> List<string> Event tags.
Return Value	Boolean. If true, the event was handled successfully. If false, it was not.

Python Syntax	HandleUDDEvents(<*eventTags*>)

Python Example	`def HandleUDDEvents(self, uddLinks):`
	`  if uddLinks[0] == "Open Report":`
	`  # Get Design Name`
	`  oDesign = self.GetUDDDesignContext()`
	`  if oDesign != None:`
	`  oDesign.OpenReport(uddLinks[1])`
	`  return True`

GetUDDSchema

This optional method retrieves the file path of the schema to validate the XML. This will override the default schema used.

UI Access	NA
Parameters	None
Return Value	String containing the full file path of the schema.

Python Syntax	GetUDDSchema()

Python Example	`def GetUDDSchema(self):`
	`  return "C:\\Program Files\\ANSYS Inc\\v252\\AnsysEM\\common\\docbook\\schema\\xsd\\docbook.xsd"`
	`schemaPath = pluginExt.GetUDDSchema()`

GetUDDStyleSheetForHtml

This optional method retrieves the file path of the style sheet used to generate the HTML document. This will override the default stylesheet for HTML.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

UI Access	NA
Parameters	None
Return Value	String containing the full file path of the style sheet.

Python Syntax	GetUDDStyleSheetForHtml()

Python Example	`def GetUDDStyleSheetForHtml(self):`
	`  return "C:\\Program Files\\ANSYS Inc\\v252\\AnsysEM\\common\\docbook\\"`
	`styleSheet = pluginExt.GetUDDStyleSheetForHtml()`

GetUDDStyleSheetForPdf

This optional method retrieves the file path of the style sheet used to generate the PDF document. This will override the default stylesheet for PDF.

UI Access	NA
Parameters	None
Return Value	String containing the full file path of the style sheet.

Python Syntax	GetUDDStyleSheetForPdf()

Python Example	`def GetUDDStyleSheetForPdf(self):`
	`  return "C:\\Program Files\\ANSYS Inc\\v252\\AnsysEM\\common\\docbook\\xsl\\fo\\docbook.xsl"`
	`styleSheet = pluginExt.GetUDDStyleSheetForPdf()`

GetFopExecutable

This optional method retrieves the file path of the fop executable used to generate the PDF document.

UI Access	NA

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Parameters	None
Return Value	String containing the full file path of the fop executable.

Python Syntax	GetFopExecutable()

Python Example	`def GetFopExecutable(self):`
	`  return "C:\\Program Files\\ANSYS Inc\\v252\\AnsysEM\\common\\ApacheFOP\\fop-1.0\\fop"`
	`fopExe = pluginExt.GetFopExecutable()`

GetUDDAppContext

This optional method retrieves the UDD Owner if it is set. This is a Dispatch wrapper that is essentially a COM IDispatch implementation and corresponds to the IDispatch pointing to the desktop app.

UI Access	NA
Parameters	None
Return Value	the IDispatch for the desktop object

Python Syntax	GetUDDAppContext()
Python Example	`oDesktop = self.GetUDDAppContext()`

GetUDDDesignContext

This optional method retrieves the UDD Owner if it is set. This is a Dispatch wrapper that is essentially a COM IDispatch implementation and corresponds to the IDispatch pointing to the design.

UI Access	NA
Parameters	None

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Return Value	IDispatch for the specified design object

Python Syntax	GetUDDDesignContext()
Python Example	`oDesign = self.GetUDDDesignContext()`

UDDExtension Class

The UDD itself should be implemented as an IronPython class called **UDDExtension** which must derive from the IUDDPluginExtension abstract base class (from the **Ansys.Ansoft.DocGeneratorPluginDotNet.DocGenerator.API.Interfaces** namespace).

Note that power users could derive a class hierarchy tuned toward a specific type of UDDs and that they can derive from their own base classes. The only requirement is that directly or indirectly, the UDD class must derive from **IUDDPluginExtension**.

Example:

```
def BaseClassUDD ((IUDDPluginExtension):
#base class implementation
…
def UDDExtension ((BaseClassUDD):
#UDD class implementation
…
```

> **Note:**
>
> This class is modeled after the UDO class UDOExtension, therefore the usage is similar.

UDDInputData Class

This class contains user input data and can be used in the generated document. UDDInputData has the constructor UDDInputData(string name) and the following properties accessors:

Property accessor	Purpose	Form
Name	Get/Set the name of an input.	string Name();
Type	Get/Set the type of an input	string Type();

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The data can be any of the following types, based on the UDDInputParams type specified in the script.

- UDDInputBool
- UDDInputDouble
- UDDInputSolution
- UDDInputText
- UDDInputTrace

UDDInputBool

Method purpose	Return Value	Data type of the returned value in C#
Retrieves boolean value of the input data.	a boolean value of input data	string Data();

UDDInputDouble

Method purpose	Return Value	Data type of the returned value in C#
Retrieves double data.	a double value of input data	double Data();

UDDInputSolution

Method purpose	Return Value	Data type of the returned value in C#
Retrieves x and y double data for a probe	Data collection	IDictionary<double, double> DoubleData (string name);
Retrieves x and y double data for a probe for a particular variation	Data collection	IDictionary<double, double> DoubleData (string name, IDictionary<string, string> variation);
Retrieves x and y complex data for a probe	Data collection	IDictionary<double, double[]> ComplexData (string name);
Retrieves x and y complex data for a probe for a particular variation	Data collection	IDictionary<double, double[]> ComplexData (string name, IDictionary<string, string> variation);
Retrieves x and y text data for a probe	Data collection	IDictionary<string, string> TextData(string name, IDictionary<string, string> variation);

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Retrieves x and y text data for a probe for a particular variation	Data collection	IDictionary<string, string> TextData(string name);
Retrieves a list of category names	A string collection	IList<string> CategoryNames();
Retrieves a list of quantity names given a category name	A string collection	IList<string> QuantityNames(string category);
Retrieves a list of variable values	A string collection	IList<Dictionary<string, string>> VariableValues();

UDDInputText

Method purpose	Return Value	Data type of the returned value in C#
Retrieves string data	a string value of input data	string Data();

UDDInputTrace

Method purpose	Return Value	Data type of the returned value in C#
Retrieves x and y double data	Double	IDictionary<double, double> DoubleData();
Retrieves x and y double data for a particular variation	Double	IDictionary<double, double> DoubleData (IDictionary<string, string> variation);
Retrieves x and y complex data	Double	IDictionary<double, double[]> ComplexData();
Retrieves x and y complex data for a particular variation	Double	IDictionary<double, double[]> ComplexData (IDictionary<string, string> variation);
Retrieves x and y text data	Text	IDictionary<string, string> TextData();
Retrieves x and y text data for a particular variation	Text	IDictionary<string, string> TextData (IDictionary<string, string> variation);
Retrieves a list of variable values	A string collection	IList<Dictionary<string, string>> VariableValues();
Retrieves an image of the trace data in a plot	An image	string Image();

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

UDDInputParams Class

The objects of this class must be created in Python script in the GetUDDInputParams and SetUDDInputParams functions.

Attributes :

- Input Name (string)
- Input Description (string)
- Input Type (string) (This can be boolean, number, text, trace, or solution.)
- BoolData (boolean)
- DoubleData (double)
- TextData (string)
- ReportType (string)
- SolutionName (string)
- DomainName (string)

Constructors:

- UDDInputParams(string name, string description, string type)
- UDDInputParams(string name, string description, string type, bool data)
- UDDInputParams(string name, string description, string type, double data)
- UDDInputParams(string name, string description, string type, string data)
- UDDInputParams(string name, string description, string type, string reportType, string solutionName, string domainName)

Property Accessors :

- Name : Get/Set the name of an input
- Description : Get/Set the description of an input
- Type : Get/Set the type of an input
- BoolData : Get/Set the data of a boolean input
- DoubleData : Get/Set the data of a number input
- TextData : Get/Set the data of a text input
- ReportType : Get/Set the report type
- SolutionName : Get/Set the name of the solution
- DomainName : Get/Set the name of the domain

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

UDD Input Interfaces

The Generate function takes in a list of inputs which allows the user to access data from the design.

IUDDInputBool : This interface exposes 3 methods.

- Name() : Gets the inputs name.
- Type() : Gets the input type.
- Data() : Gets the boolean data, set by the user in the setup dialog.

IUDDInputDouble : This interface exposes 3 methods.

- Name() : Gets the inputs name.
- Type() : Gets the input type.
- Data() : Gets the double data, set by the user in the setup dialog.

IUDDInputText : This interface exposes 3 methods

- Name() : Gets the inputs name.
- Type() : Gets the input type.
- Data() : Gets the text data, set by the user in the setup dialog.

IUDDInputTrace : This interface exposes 9 methods

- Name() : Gets the inputs name.
- Type() : Gets the input type.
- DoubleData() : Method used to return x and y double data as a IDictionary<double, double>
- DoubleData(IDictionary<string, string> variation) : Method used to return x and y double data as a IDictionary<double, double>, given a variation.
- ComplexData() : Method used to return x data and y complex data as a IDictionary<double, double[]>
- ComplexData(IDictionary<string, string> variation) : Method used to return x data and y complex data as a IDictionary<double, double[]>, given a variation.
- TextData() : Method used to return x data and y data as a IDictionary<string, string>
- TextData(IDictionary<string, string> variation) : Method used to return x data and y data as a IDictionary<string, string>, given a variation.
- VariableValues() : Method used to get a list of variations as a IList<Dictionary<string, string>>

IUDDInputSolution : This interface exposes 11 methods

- Name() : Gets the inputs name.
- Type() : Gets the input type.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- DoubleData(string name): Method used to return x and y double data as a IDictionary<double, double>, given a quantity name.
- DoubleData(string name, IDictionary<string, string> variation) : Method used to return x and y double data as a IDictionary<double, double>, given a quantity name and a variation.
- ComplexData(string name) : Method used to return x data and y complex data as a IDictionary<double, double[]>, given a quantity name.
- ComplexData(string name, IDictionary<string, string> variation) : Method used to return x data and y complex data as a IDictionary<double, double[]>, given a quantity name and a variation.
- TextData(string name) : Method used to return x data and y data as a IDictionary<string, string> given a quantity name.
- TextData(string name, IDictionary<string, string> variation) : Method used to return x data and y data as a IDictionary<string, string>, given a quantity name and a variation.
- CategoryNames() : Method to return a list of category names in the solution as an IList<string>
- QuantityNames(string category) : Method to return a list of quantity names in the solution as an IList<string>, given a category.
- VariableValues() : Method used to get a list of variations as a IList<Dictionary<string, string>>

Examples

```
def Generate(self, input, docgen, progMon):
# Getting the boolean data set by the user
boolinput = input[0].Data()
# Getting the double data set by the user
dblinput = input[1].Data()
# Getting the text data set by the user
textinput = input[2].Data()
# Getting the category names in a solution
categories = input[3].CategoryNames()
# Getting the quantity names based on a category
quantities = input[3].QuantityNames(categories[0])
# Getting the XY data from the trace
xydata = input[4].DoubleData()
```

Document Generator Interfaces

This document briefly describes the API interfaces available in the document generator plugin.

(Ansys.Ansoft.DocGeneratorPluginDotNet.dll)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scripting objects available in the script for the Generate function:

- oApp = self.GetUDDAppContext()

  Gets the application context. Use this interface to get the active project ad the version of the product.

```
oDesktop = oApp.GetAppDesktop()
  if oDesktop != None:
  vr = oDesktop.GetVersion()
  oProject = oDesktop.GetActiveProject()
```

- oDesign = self.GetUDDDesignContext()

  Gets the design context. Use this interface to get the design name.

```
oDesign = self.GetUDDDesignContext()
  if oDesign != None:
    nm = oDesign.GetName()
```

- IUDDGenerator interface

  This interface available in the Generate method of the UDDPluginExtension. This interface can be used to:

  1. Set the document output file path.
     ```
     docgen.SetOutput("C:\\Examples\\DocumentOutput.xml")
     ```
  2. Get the document root.
     ```
     docroot = docgen.GetDocumentRoot()
     ```
  3. Write out to the output file.
     ```
     docgen.Write()
     ```
  4. Write HTML document
     ```
     void WriteHTML();
     ```
  5. Write PDF document
     ```
     void WritePDF();
     ```
  6. Load the HTML transform object
     ```
     void LoadHTMLTransform();
     ```
  7. Load the cached PDF transform object
     ```
     void LoadPDFTransform();
     ```
  8. Get script path
     ```
     string GetScriptPath();
     ```
  9. Get output file path
     ```
     string GetOutputFilePath();
     ```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- IUDDRoot interface

  Calling GetDocumentRoot() on the IUDDGenerator interface provides you with the this interface. This interface can be used to:

  1. Add a new section to the document. Provide a section title.
     ```
     section1 = docroot.AddSection("Section title")
     ```
  2. Add a new section to the document. Provide a section title and subtitle.
     ```
     section1 = docroot.AddSection("Section title", "Section subtitle")
     ```
  3. Add a new title
     ```
     section1 = docroot.AddTitle("Title")
     ```
  4. Add a new subtitle
     ```
     section1 = docroot.AddSubtitle("Subtitle")
     ```
- IUDDSection interface

  Calling AddSection() on the IUDDRoot interface provides you with this interface. This interface can be used to:

  1. Set an ID for the section for internal links.
     ```
     section1.SetID("id")
     ```
  2. Add a new table to the document. Provide a table title.
     ```
     table1 = section1.AddTable("Table title")
     ```
  3. Add a new image to the document. Provide an image title and a file path to the image file.
     ```
     image1 = section1.AddImage("Image title")
     ```
  4. Add text to the document.
     ```
     text1 = section1.AddText("Random text........")
     ```
- IUDDImage interface

  Calling AddImage() on the IUDDSection interface provides you with this interface. In this interface, you can call the following methods:

  1. Set an ID for the image for internal links.
     ```
     image1.SetID("id")
     ```
  2. Set alignment information; can be "center", "left", and "right".
     ```
     image1.SetAligment("center")
     ```
  3. Set the file path of the image file; not necessary if image file path is set through the AddImage() method.
     ```
     image1.SetFileRef("Image path")
     ```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Set the format of the image file; can be "BMP", "PNG", "JPEG", "JPG", "DVI", etc.
   ```
   image1.SetFormat("format")
   ```

- IUDDText interface

  Calling AddText() on the IUDDSection interface provides you with the this interface. In this interface, you can call the following methods:

  1. Set an ID for the text for internal links.
     ```
     text1.SetID("id")
     ```
  2. Set the emphasis attribute on the text.
     ```
     text1.SetEmphasis()
     ```
  3. Set the quotes attribute on the text.
     ```
     Text1.SetQuotes()
     ```
  4. Set the block quotes attribute on the text.
     ```
     text1.SetBlockquotes()
     ```
  5. Set quotes on the text.
     ```
     Text1.SetQuotes()
     ```
  6. Set the wordsize attribute on the text
     ```
     text1.SetSize(size as an integer)
     ```
  7. Set a link to an ID of any element to provide internal links
     ```
     text1.SetLink("linkname")
     ```
  8. Set an event link to handle an event. The HandleUDDEvents method should be implemented in the script to handle the event.
     ```
     text1.SetEventLink("linkname")
     ```

- IUDDTable interface

  Calling AddTable() on the IUDDSection interface provides you with the this interface. In this interface, you can call the following methods:

  1. Set an ID for the table for internal links.
     ```
     table1.SetID("id")
     ```
  2. Set alignment information; can be "center", "left", and "right".
     ```
     table1.SetAlignment("center")
     ```
  3. Set the background color of the table
     ```
     table1.SetBgColor(string bgcolor)
     ```
  4. Set the frame type; can be "all", "bottom", "top", "sides", and "topbot".
     ```
     table1.SetFrame(string frame)
     ```
  5. Add a table group and specify the number of columns. A table can have multiple table groups.
     ```
     IUDDTableGroup table1.SetTableGroup(int columns)
     ```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- IUDDTableGroup interface

  Calling AddTableGroup() on the IUDDTable interface provides you with the this interface. In this interface, you can call the following methods:

  1. Set an ID for the table group for internal links.
     ```
     tgroup1.SetID("id")
     ```
  2. Set alignment information; can be "center", "left", and "right".
     ```
     tgroup1.SetAlignment("center")
     ```
  3. Set the column width of a column given the index of the column and the required width. Width can be set in 2 ways.
     - Width can be set relative to 1. E.g Setting it to "2*" makes the column width double the width of the others.
     - If the entire table width is considered to be 99.99 units. Width can be a number relative to this.

     ```
     tgroup1.SetColumnWidth(int index, string width)
     ```
  4. Add a header to the table group
     ```
     IUDDTableRow tgroup1.AddHeader()
     ```
  5. Add a header with multiple rows to the table group; it takes number of sub rows.
     ```
     IUDDTableRow tgroup1.AddHeader(int rows)
     ```
  6. Add a row of content to the table group
     ```
     IUDDTableRow tgroup1.AddContent()
     ```
  7. Add content with multiple rows to the table group; it takes number of sub rows.
     ```
     IUDDTableRow tgroup1.AddContent(int rows)
     ```
- IUDDTableRow interface

  Calling AddHeader() & AddContent() on the IUDDTableGroup interface provides you with the this interface. In this interface, you can call the following methods:

  1. Set an ID for the table row for internal links.
     ```
     trow1.SetID("id")
     ```
  2. Set alignment information; can be "center", "left", and "right".
     ```
     trow1.SetAlignment("center")
     ```
  3. Set cell text; can be cell content or header text. It takes a column index and a text string. It is added to the first row.
     ```
     IUDDTextElement trow1.Add(int column, string text)
     ```
  4. Set cell text; can be cell content or header text. It takes a column index, row index and a text string and takes in a row number because a table row can have multiple sub rows.
     ```
     IUDDTextElement trow1.Add(int column, int subrow, string
     text)
     ```

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Set cell content; takes a column index and an int value. It is added to the first row.
   ```
   IUDDTextElement trow1.Add(int column, int value)
   ```
6. Set cell content; takes a column index, row index and a int value.
   ```
   IUDDTextElement trow1.Add(int column, int subrow, string text)
   ```
7. Set cell text; takes a column index and a double value. It is added to the first row.
   ```
   IUDDTextElement trow1.Add(int column, double value)
   ```
8. Set cell text; takes a column index, row index and a double value.
   ```
   IUDDTextElement trow1.Add(int column, int subrow, double value)
   ```
9. Set cell text spanning two columns; can be cell content or header text. It takes a sub-row index , starting column index, ending column index, and a text string.
   ```
   IUDDTextElement trow1.AddSpanningcolumnst(int subrow, int columnstart, int columnend, string text)
   ```
10. Set cell text; can be cell content or header text. It takes a column index, starting sub-row index, ending sub-row index, and a text string.
    ```
    IUDDTextElement trow1.AddpanningRows(int column, int subrowstart, int subrowend, string text)
    ```

Includes all the methods exposed by the IUDDText interface.

Toolkit

The Toolkit command in the solver menu provides access to a design type specific IronPython script, such as the Hearing Aid Compliance Test, MIMO calculation or a module specific task, such as for Boundary, Excitation, or Solve Setup. The Hearing Aid Compliance Test toolkit example involves multiple modules. The MIMO example includes a Toolkit script and a User Defined Solution Script. The Cable modeling toolkits serve automotive cable applications and oil and gas applications.

An **MI Materials Gateway** toolkit that can interact with the Granta Gateway to bring in new materials at a project level, and so, it appears on the **Tools>Toolkit** menu, rather than the **<solver>Toolkit** menu. It works in conjuction with scripting commands.

The python script provides default but customizable UI and canned automations. The UDD format can be adjusted/extended as needed. The default UI is a modal dialog.

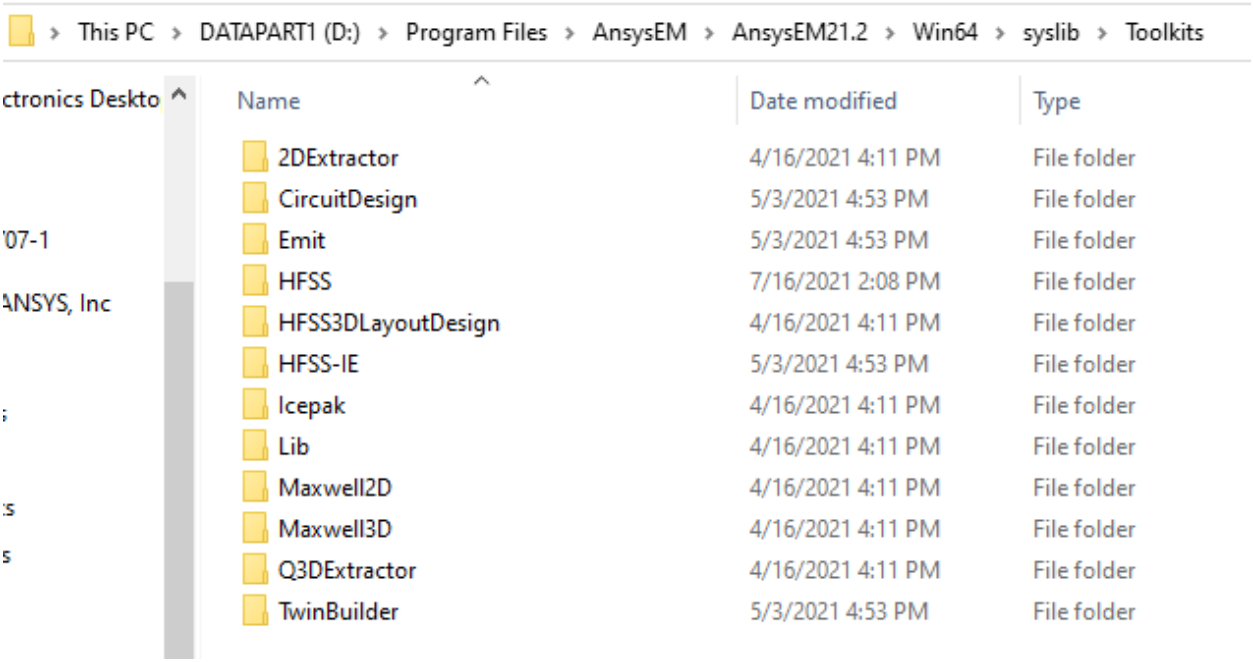
This allows us to support changing standards, or multiple standards, without necessarily being tied to the product release cycle. Similarly, you can create new UDD to customize the test report.

UDD are saved in project result directory. This type of reports can be created prior to simulation, but will only be populated when there is solution.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

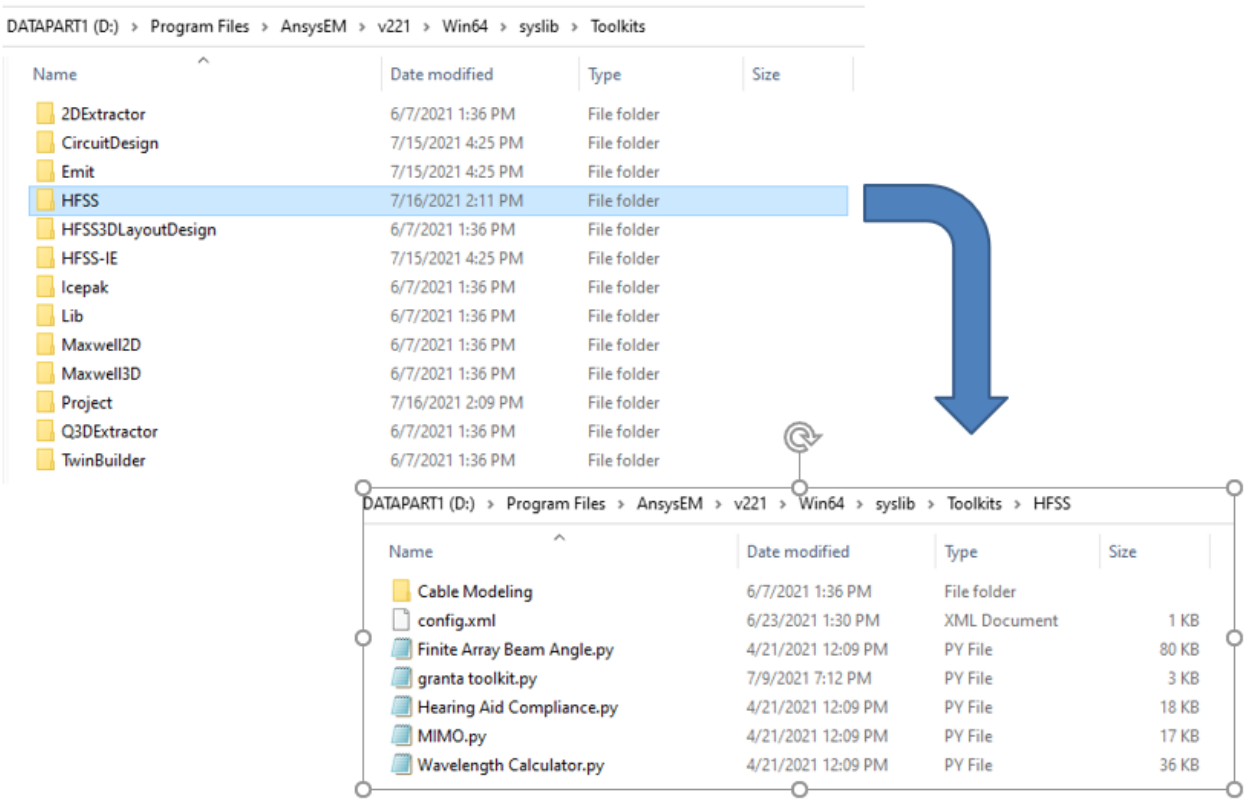
Undo/Redo/Scripting is supported. If a script includes multiple commands, it takes multiple undo (s) to revert all the changes made by the python script. Also, the script playback might not work if the baseline of the design has changed.

A directory called "Toolkits" appears in the syslib, userlib and personallib of HFSS installation. Menu items for files found in <installation>/syslib will be inserted at the first level of the menu.



There are product specific directories in "Toolkits" and each directory contains toolkits (scripts) that are specific for that product. The following snapshot illustrates the file structure on disk that provides access to the "HearingAidCompliance" toolkit at the design level menu.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Chip Model Analyzer (CMA)

Ansys Chip Model Analyzer (CMA) is an advanced Chip Power Model (CPM) creation tool for performance checking and failure diagnosis of the Power Delivery Network (PDN). CMA can use either HSpice or Nexxim simulators. HSpice and external Nexxim require licenses, but the Nexxim Internal simulator does not.

CMA does not currently interact with Electronics Desktop. However, you can launch CMA from within Electronics Desktop by clicking **Tools** > **Chip Model Analyzer (CMA)**.

From there, you can import CPM files for analysis or create a pseudo CPM.

For more information about using CMA, consult the CMA training documentation by launching CMA and selecting **Help** > **Content**.

PinToPinUtility

The PinToPin utility can quickly extract HFSS or SIwave models for specified nets of package and PCB geometries. It establishes a repeatable process for robust geometry extraction, port configuration, and passive model assignment. Process execution can be done via the user interface (Windows only) or in non-graphical mode (Windows or Linux).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For more information, consult the SIwave and HFSS 3D Layout help.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

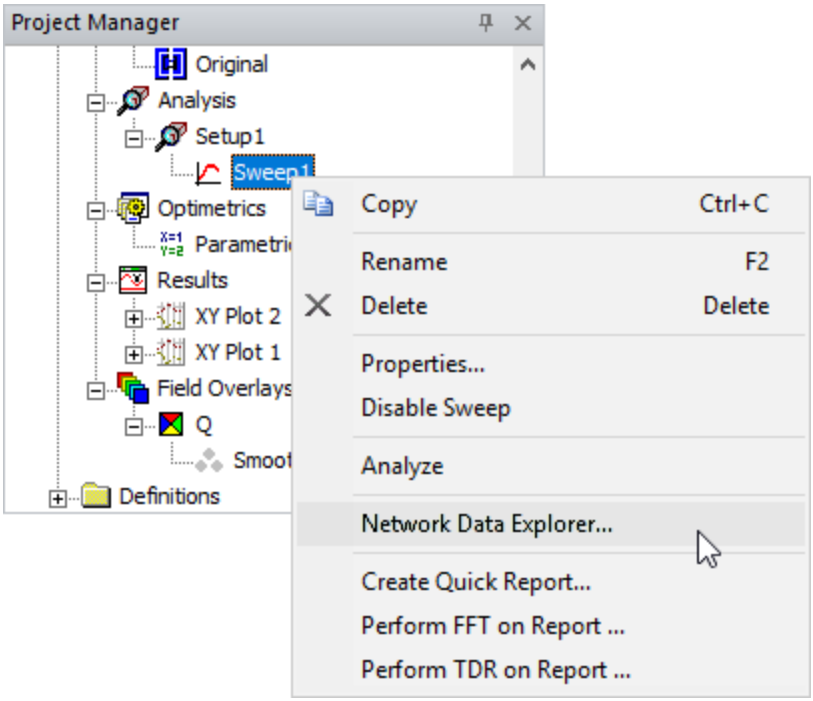
24 - Network Data Explorer

The Network Data Explorer provides visualization, analysis, and manipulation tools for network data.

To access Network Data Explorer, click **Tools** > **Network Data Explorer**.

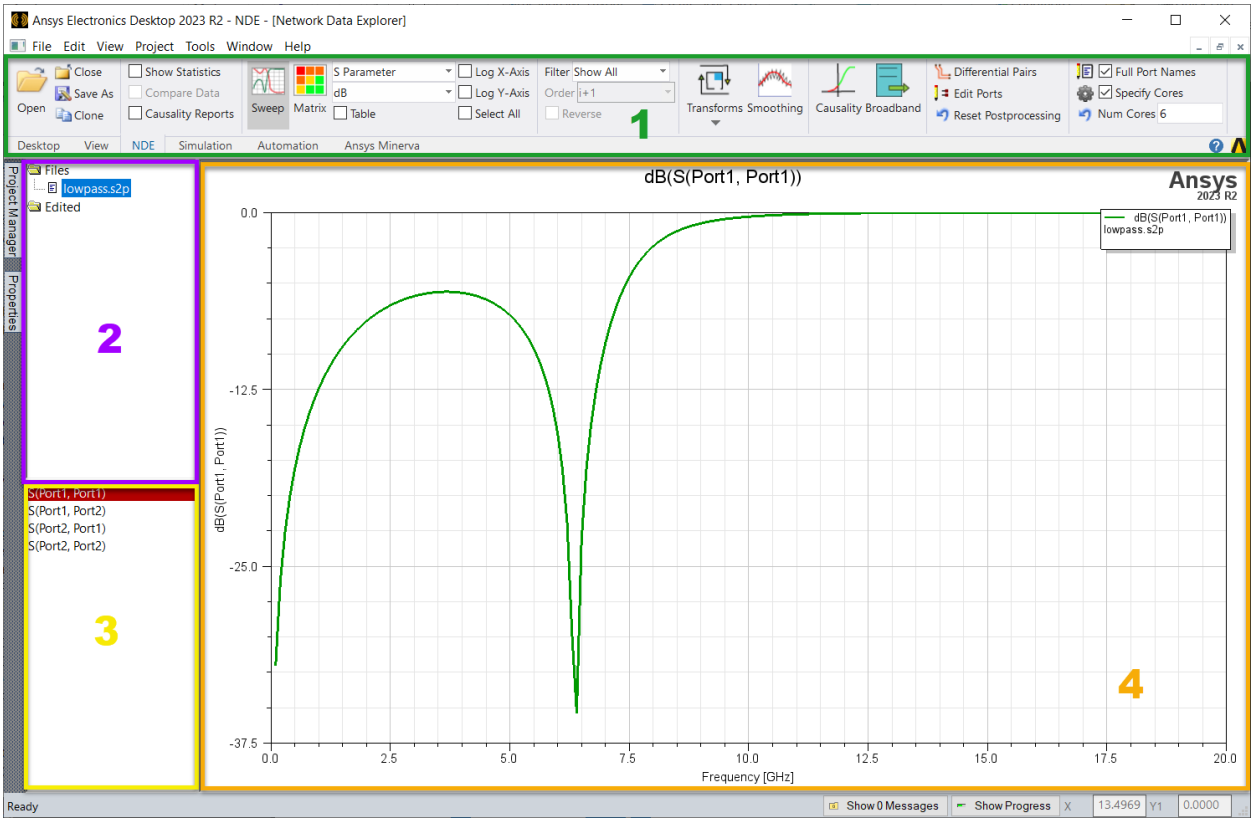
If you have added a Frequency Sweep, you can also access Network Data Explorer through the Sweep shortcut menu in the Project Manager.

> **Note:**
>
> Accessing Network Data Explorer from this menu automatically loads sweep data.



The **Network Data Explorer** window appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



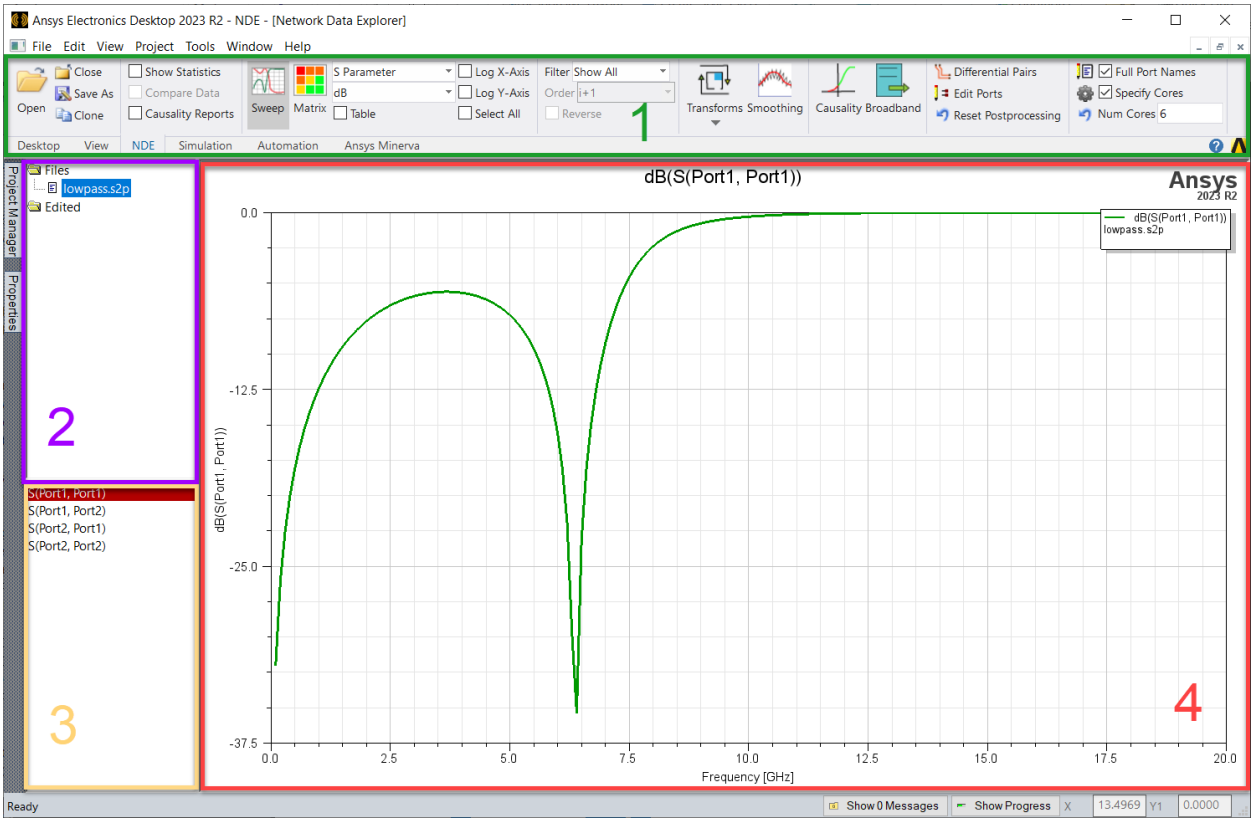
Network Data Explorer Overview

The Network Data Explorer window is divided into the following panes:

1. **NDE ribbon** – allows you to perform many functions of the Network Data Explorer.
2. **Network Data Selection pane** – allows you to select a network data file.
3. **Cell and Frequency Selection pane** – allows you to narrow your selection.
4. **Data View pane** – displays data in table or plot format.

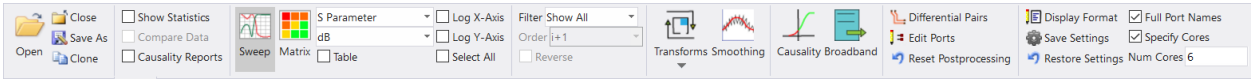
The panes are shown in the following figure. Additional information about each pane follows.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



NDE Ribbon

The ribbon provides access to many of the Network Data Explorer's functions and display options.



On this ribbon, you can control:

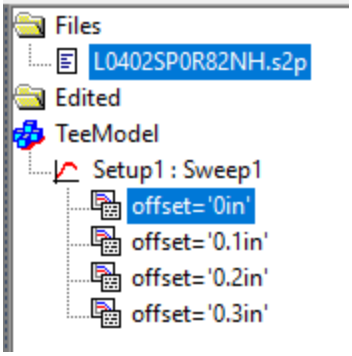
- Plotting - allows you to determine how the data is displayed.
- Quantity – allows you to select the type of quantity to display (parameter values, matrix statistics, or causality plots).
- Parameter Type – allows you to choose the parameter for display (S, Y, or Z parameters, Port Impedance, or Gamma).
- Format – allows you to decide the display function to apply to the data (e.g., magnitude, phase, dB, real, imaginary).

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Export – allows you to export either SYZ data (*.s1p, *.ts, *.nmf, *.tab, *.m, *.cit) or Broadband data (*.sp).
- Check – allows you to check causality.
- Cores – allows you to enable or disable multithreading.
- Post-Process Selection – allows you to choose between Terminal Data and Differential Pairs, if your design includes Differential Pairs

Network Data Selection Pane

This pane allows you to view and compare various data sets. Original data sets appear under **Files**. Click one of these to see the data set as it was when it was opened. Altered data sets are listed under **Edited**. These data sets appear here when they have been smoothed, transformed, or changed in some way.



This pane also lists available variations for AEDT design solution data. Variations are listed under a setup name icon (for example “Setup1 : Sweep1”) that is listed under a design icon (“TeeModel”). Variations can be selected and displayed just like other data sets.

Use the **Shift** and **Ctrl** keys to select and display data sets from multiple files simultaneously. Multiple data sets can be selected to display multiple traces in sweep plots, but not in tables. Click the **Files** icon to select all data sets under **Files**. Click the **Edited** icon or a design/setup icon to do the same.

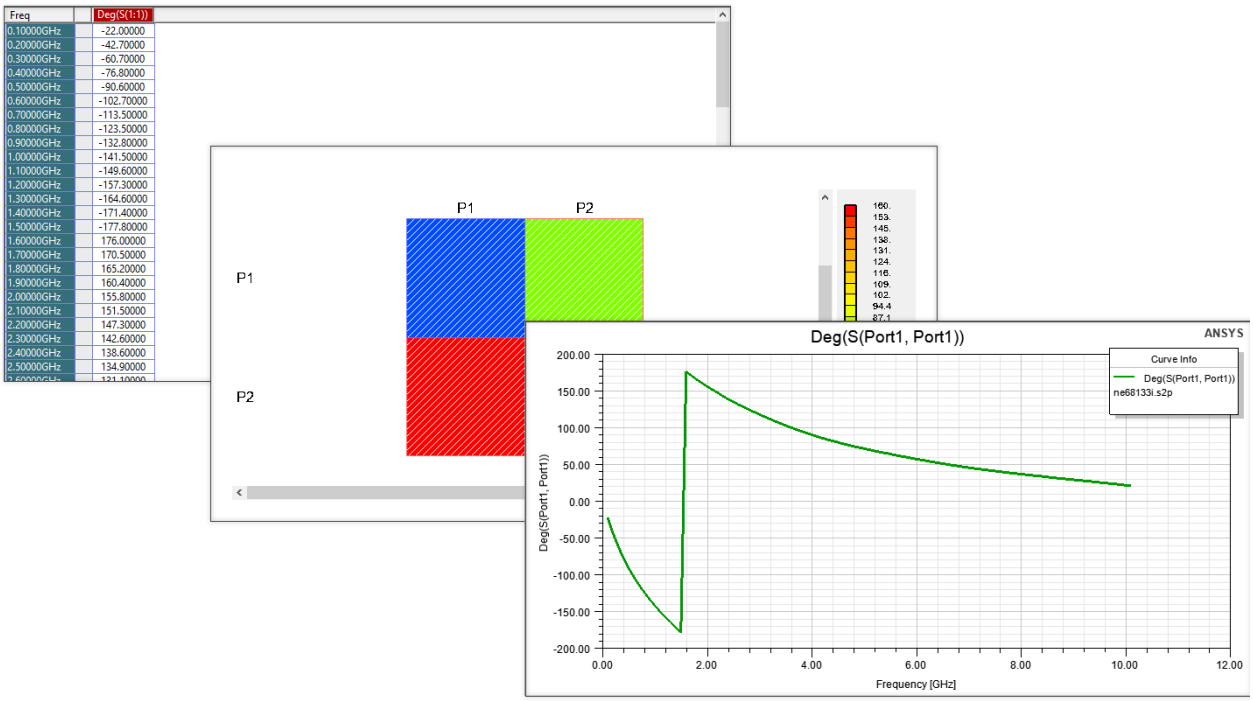
Cell and Frequency Selection Pane

Select the **Sweep** button on the NDE ribbon to display cell entries, for example S(1,1). Select the **Matrix** button to display frequencies. When displayed by frequency, the entire matrix is presented in the Data View pane for each selected frequency. When displayed by matrix cell, the data for the individually chosen cells is shown across all frequencies. Use the **Select All** check box to select all frequencies or cells.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Data View Pane

The Data View Pane displays data for **Sweep** or **Matrix** in either plots or a table, depending on your selection.



Loading Data into Network Data Explorer

You can launch **Network Data Explorer** from within several Ansys products. In the Project Manager, open <project> > **Analysis** > **Setup***n* > **Sweep***n*. Right click on the sweep and click **Network Data Explorer** in the shortcut menu. The current solution data is automatically loaded and ready for viewing. Otherwise, you must load a data file into Network Data Explorer.

> **Note:** When solution data that is loaded into NDE is modified and resimulated in another Ansys product, the NDE data automatically updates.

You can import the following file types:

- Touchstone Format (*.s*p)
- Touchstone 2 Format (*.ts, *.sp)
- Citifile (*.cit)
- Neutral Format (*.nmf)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- State Space File (*.sss)

> **Note:**
>
> When this type of file is loaded, Network Data Explorer regenerates s-parameter data based on the file.
>
> You can compare the regenerated s-parameters to the original data.

To import a file into Network Data Explorer, either drag and drop an analysis from the Project Manager into Network Data Explorer or

1. On the **NDE** ribbon, click **Open**. An **Open** window opens.
2. Navigate to and select a file.
3. Click **Open**. The file appears in the **Files** tree.

The file browser allows you to open multiple files at a time. However, the displayed data always corresponds to the data set indicated in the Network Data Selection pane. Click the file you want in that pane to switch between data sets.

Exporting Data from Network Data Explorer

Network Data Explorer allows you to export data to a variety of different file formats.

In this section, you will learn about:

Exporting SYZ Data

Exporting Macro Model

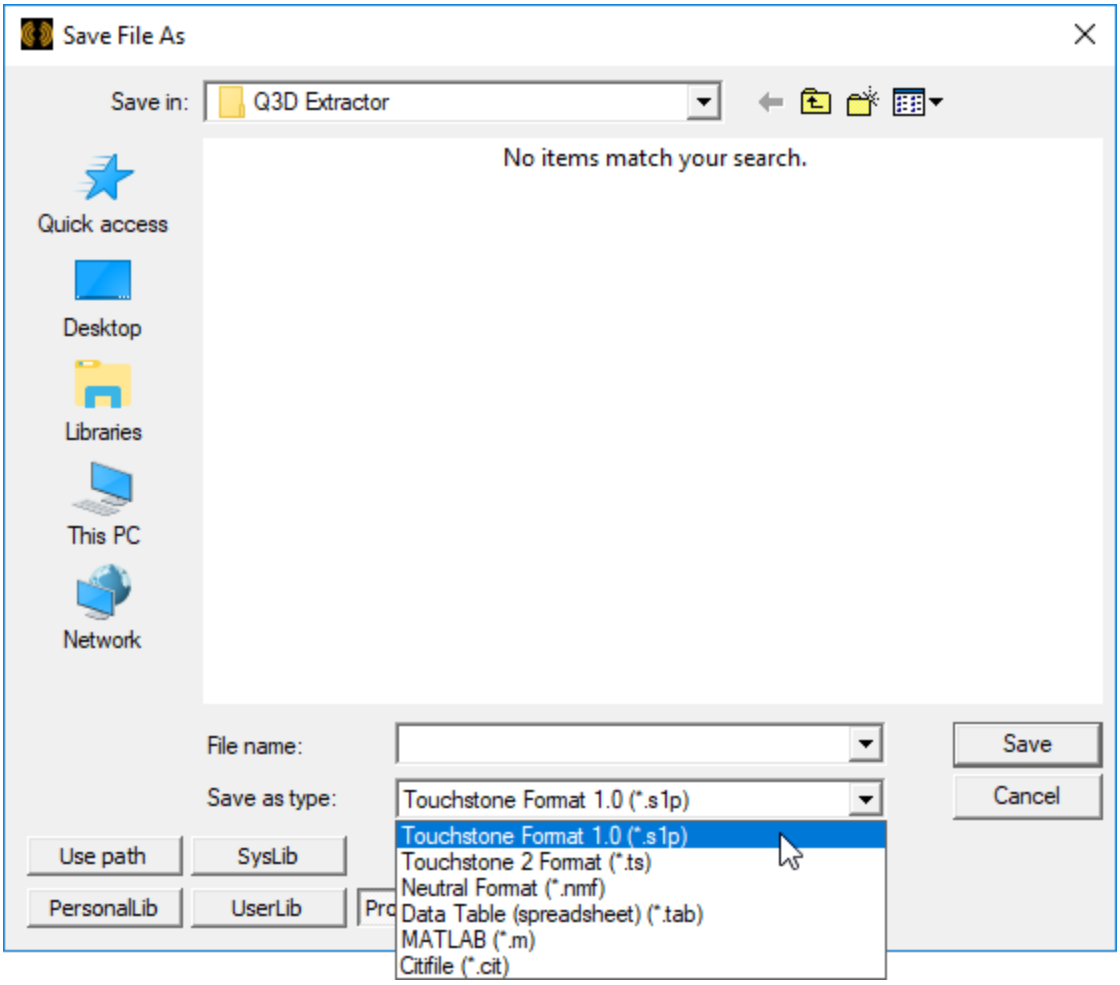
Creating an NPort Model

Scripting for Network Data Explorer

Exporting SYZ Data

To export SYZ data from within Network Data Explorer, click the **Save As** icon on the **NDE** ribbon. The **Save File As** window appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

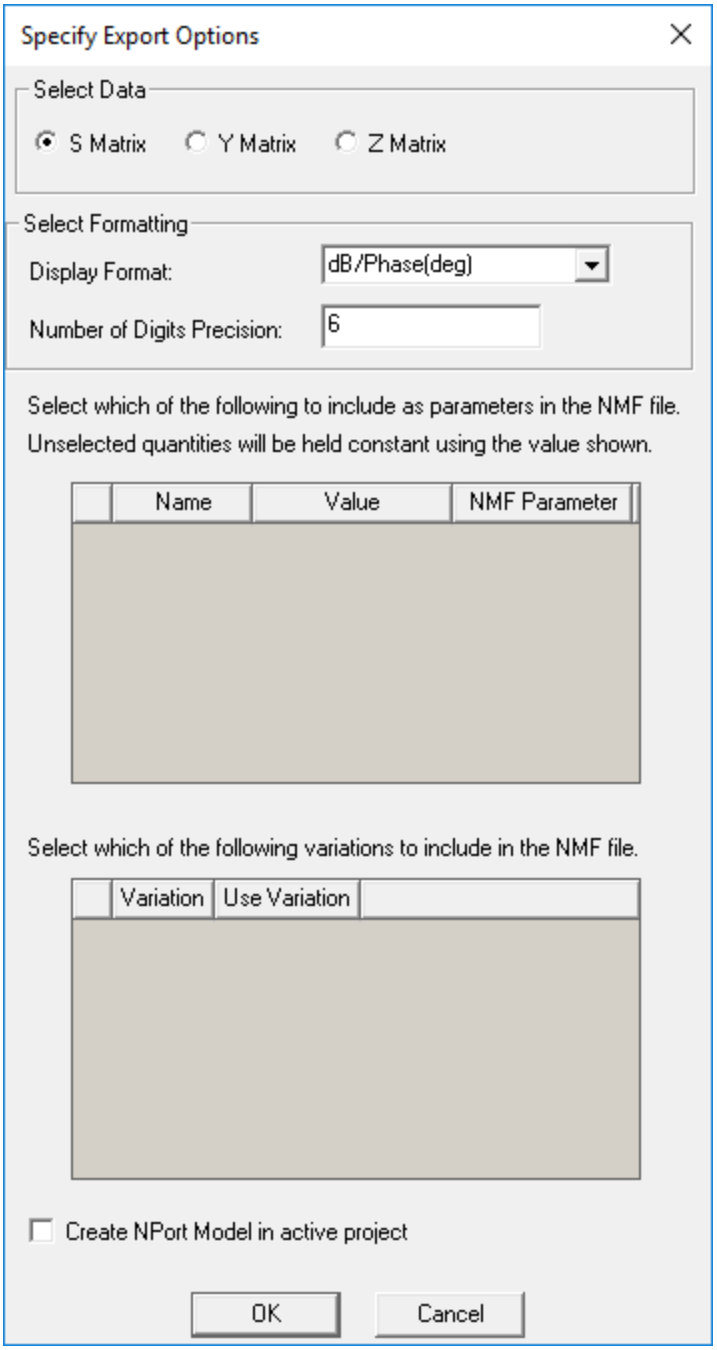


You can export data in any of six file types:

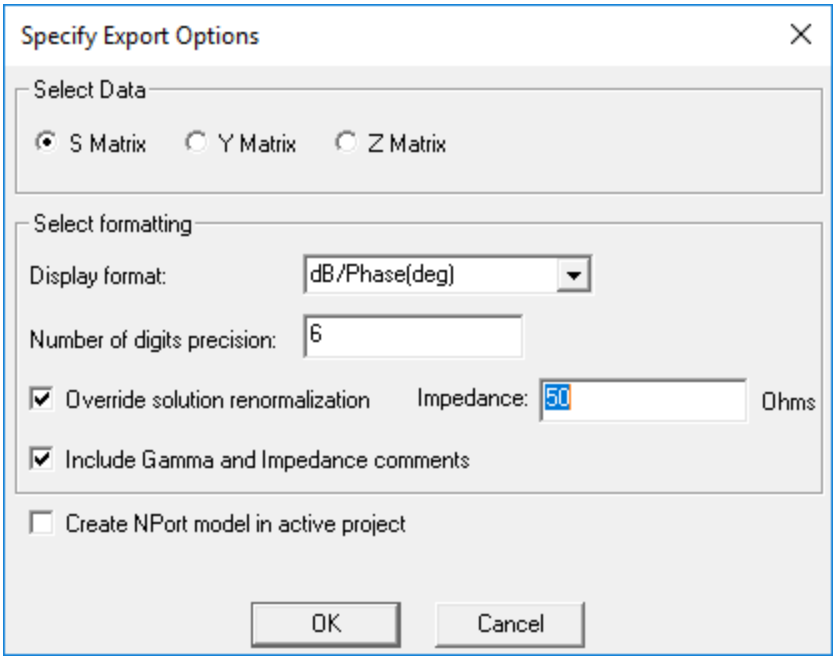
- Touchstone Format 1.0 (*.s*p)
- Touchstone 2 Format (*.ts)
- Neutral Format (*.nmf)
- Data Table Spreadsheet (*.tab)
- MATLAB (*.m)
- Citifile (*.cit)

Select a file type and name for export. A **Specify Export Options** window appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Depending on the type of export file, different options appear. However, all file types allow you to:

- Select from **S Matrix**, **Y Matrix**, and **Z Matrix** data.
- Select the **Display Format**.

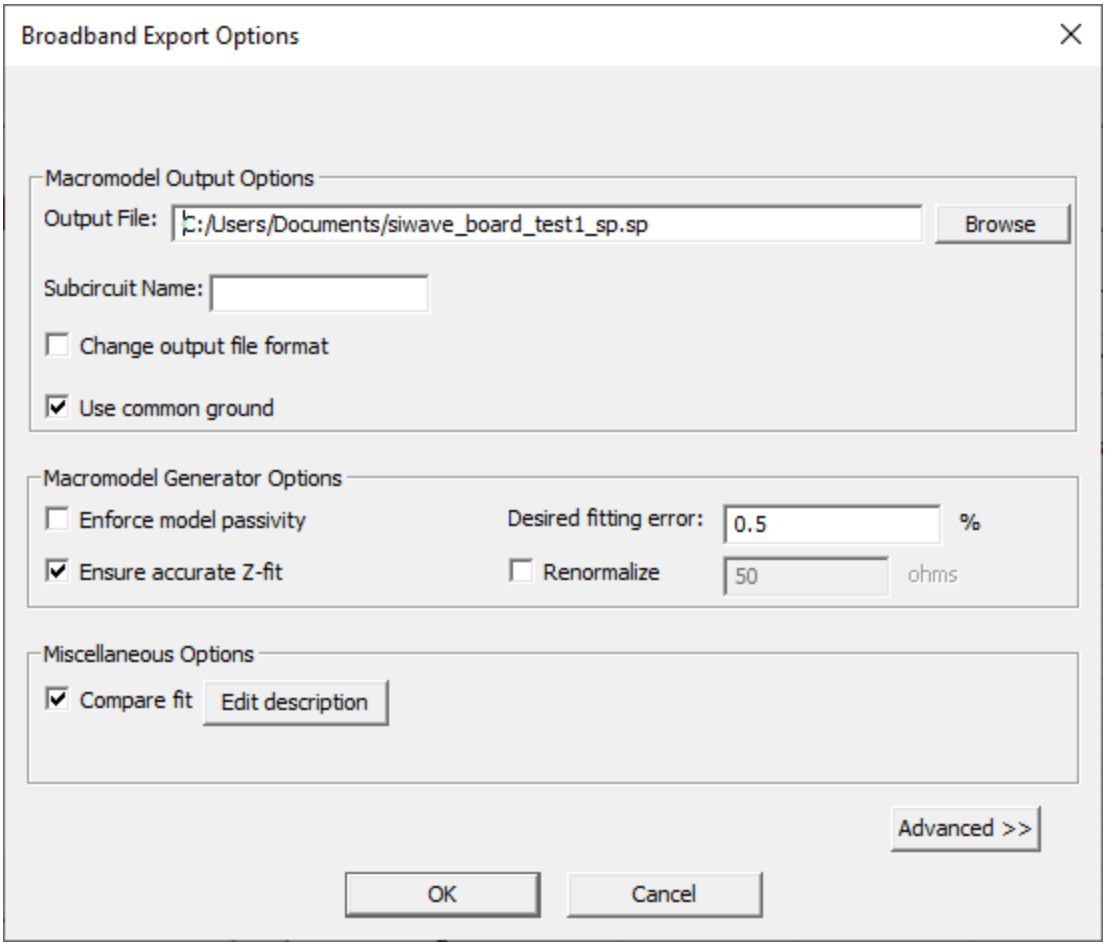
Some types allow you to create an NPort Model in the active project.

Exporting Macro Model

Network Data Explorer lets you export macro model data. To export data, click the **Broadband** icon on the **NDE** ribbon.

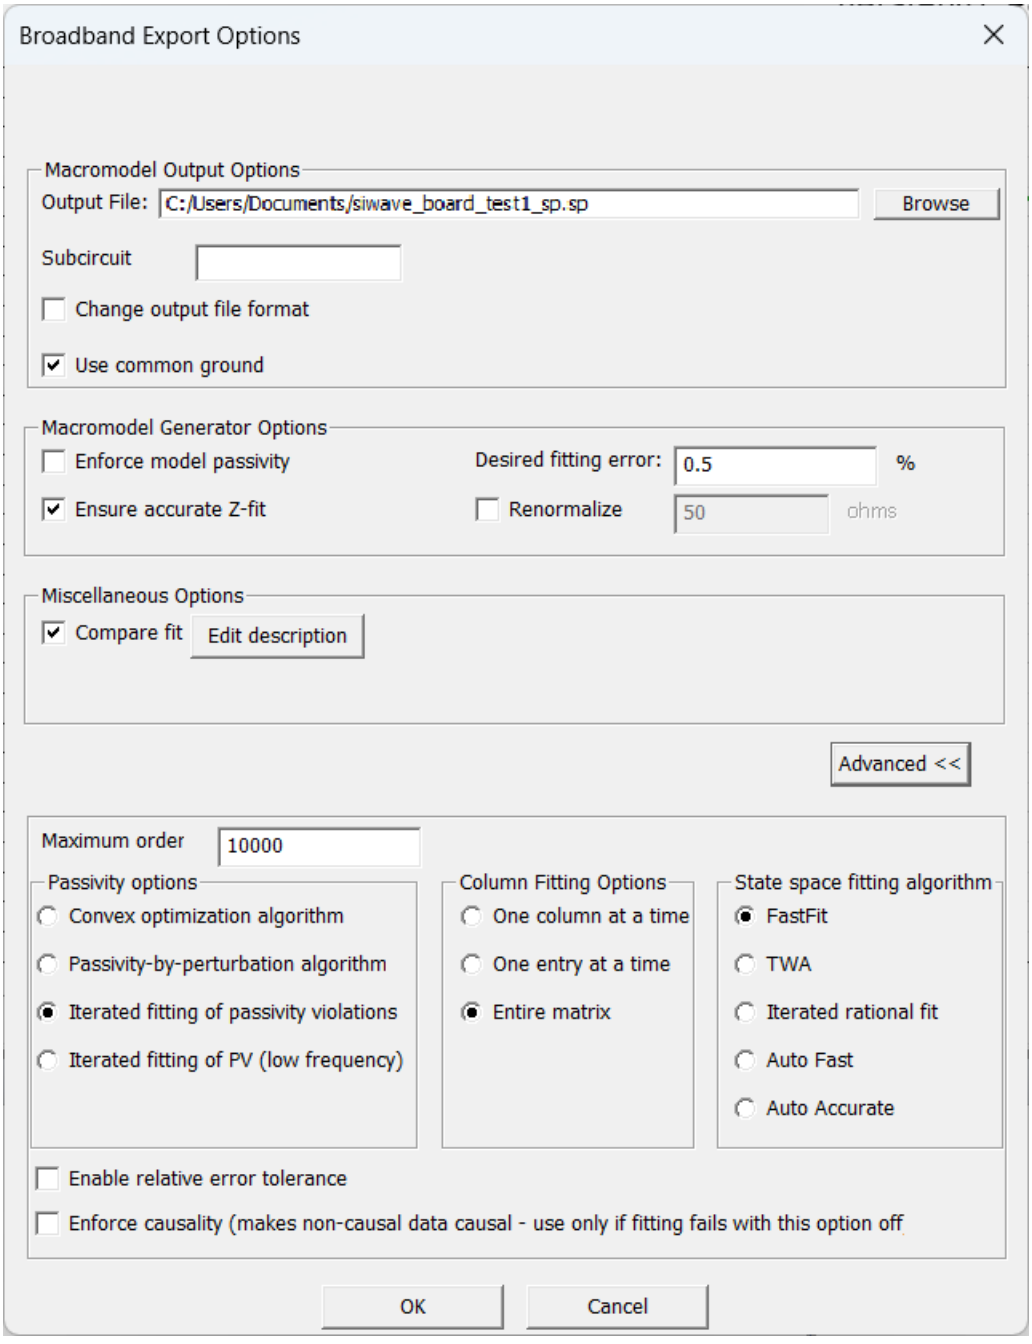
The **Broadband Export Options** window appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Click **Advanced >>** to view all options.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Macromodel Output Options include:

- **Output File** – Allows you to choose the name and location of the file.
- **Subcircuit Name** – Use this field to name the subcircuit.
- **Change Output File Format** – Check this box to open a submenu allowing you to select a new output format.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Use Common Ground** – Check this box to use common ground. When this option is on, ports are referenced to ideal ground (node 0). When this option is off, extra ports are generated to provide the reference levels. Common grounding is best when the pins are physically near to each other and ideal ground is suitable. For distant connections and circuits with non-ideal reference levels such as differential pairs, common grounding is not used.

  Note:

  - R and L values may be quite sensitive to the values of the S-parameters. This is an issue if the actual impedance value is much greater than or much less than the reference impedance of the S-parameters.
  - Since resistances of power cables is typically in the milliohms range at DC, using a reference impedance of 50 ohms is 5000 times higher. This causes any fitting errors in the state space model to get multiplied by 5000 times when the R and L values are computed.
  - As a general rule, for high power applications a reference impedance of 1 ohm is probably a better choice than 50 ohms.

Macromodel Generator Options include:

- **Enforce Model Passivity** – Check this box to enforce passivity.
- **Ensure Accurate Z-fit** – Check this box when state-space fitting of Y-parameters or Z-parameters does not produce an accurate fit.
- **Desired Fitting Error** – Allows you to select the value at which rational fitting fails (if the fitting error exceeds this value).
- **Renormalize** – Check this box to renormalize using the specified impedance item. 50 ohms is the default setting, but you can type a different value.

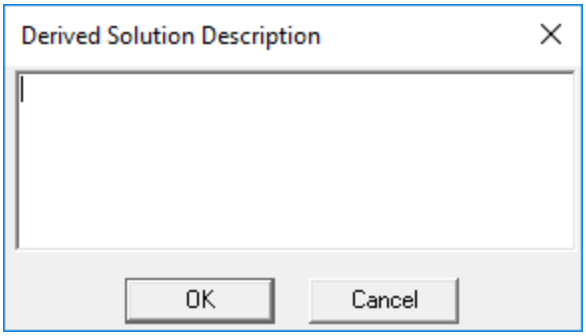
  Note:

  - R and L values may be sensitive to S-parameter values. This presents an issue if the actual impedance value is much greater than or much less than the reference impedance of the S-parameters.
  - Since resistances of power cables are typically in the milliohms range at DC, using a reference impedance of 50 ohms is 5000 times higher. This causes any fitting errors in the state space model to be multiplied by 5000 when the R and L values are computed.
  - For high-power applications, a reference impedance of 1 ohm is generally a better choice than 50 ohms.

Miscellaneous Options include:

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Compare Fit** – When this box is checked, the original and derived solution will be available for comparison. You can click **Edit Description** to open the **Derived Solution Description** window and add a text description to better identify the export.



Advanced Options include:

- **Maximum Order** – Allows you to specify the number of poles. See Note below.
- **Passivity Options** – If you enabled **Enforce Model Passivity**, this area allows you to select the passivity enforcement method.
  - **Convex optimization algorithm** – guarantees a passive state-space realization, but is very slow and memory-intensive. Not practical for numbers of ports beyond ten.
  - **Passivity-by-perturbation algorithm** – designed for systems with a large number of ports. Less accurate than the Convex optimization method.
  - **Iterated fitting of passivity violations (IFPV)** (default) – less accurate than other algorithms but more suitable for larger numbers of ports.
  - **Iterated fitting of PV (low frequency)** – similar to IFPV while improving the fit to "Z" at DC and low frequencies. A better choice of passivity enforcement when the fit to corresponding "Z-data" is important such as power delivery, EMI/EMC applications.

    > **Note:**
    >
    > For a more detailed explanation on any of the passivity options, see the technical note section of the Circuit help.

- **Column Fitting Options** – This area allows you to choose how poles are matched to columns:
  - **One Column at a Time** – The set of poles will be shared across all entries of a single column.
  - **One Entry at a Time** – Each entry will be fitted using a separate set of poles.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Entire Matrix** – The set of poles will be shared across all entries of the matrix being fitted.

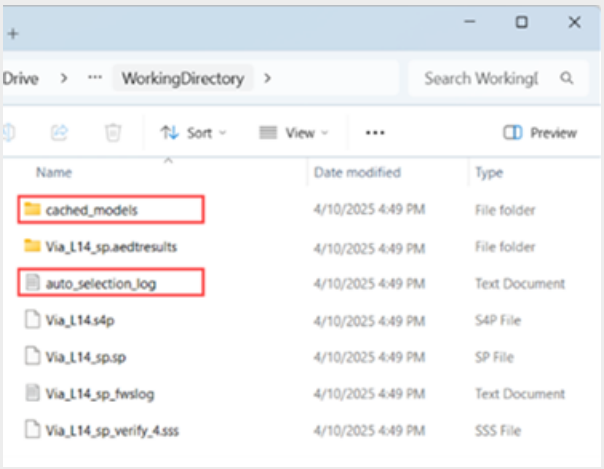
> **Note:**
>
> - Typically, using the same set for all entries is adequate, and yields the most compact models. However, if all the entries of the matrix have completely unrelated transfer functions, it may be better to fit them using separate pole sets.
> - The options **One column at a time** and **One entry at a time** do not work when either **Ensure accurate Z-fit** or FastFit is used.

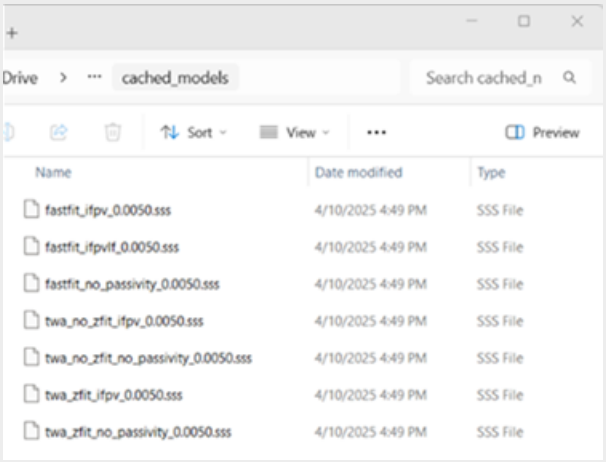
- **State Space Fitting Algorithm** – Allows you to select FastFit, TWA, Iterated rational fitting, Auto Fast, or Auto Accurate.
  - **FastFit** (default) – FastFit is the Ansys-proprietary method for state-space fitting. Network Data Explorer uses FastFit for calculating the state-space matrices from the network data. The FastFit algorithm for state-space fitting is an alternative to the Tsuk-White algorithm (TWA) and Iterated Rational Fitting (IRF) methods. FastFit is generally as accurate as TWA, but is significantly faster than both TWA and IRF. It also aims to fit the lower frequencies with higher fidelity.
  - **TWA** – The Tsuk-White Algorithm is an Ansys-proprietary method for fitting a state space model to extracted s-parameter data. It uses techniques based on Singular Value Decomposition (SVD) to quickly determine required number of poles for fitting a model.
  - **Iterated Rational Function** – The IRF fitting approach takes a matrix of S-parameter data and, for each matrix entry, tries a succession of different pole-zero approximations (increasing the number of poles used at each iteration) until it can find an acceptable fit to the data. For broad frequency sweeps and large numbers of excitations, this process can be time consuming because of all the iterations and is not guaranteed to produce a good fit to the data. It is retained as a fallback if the TWA algorithm fails.
  - **Auto Fast**- (Beta) To use the Auto Fast option, first enable **State Space Fitting Auto Selection** in the Beta Options dialog. The Auto Fast option runs all the fitting options in parallel and returns the first model that meets the user's specifications. It takes less time, however, the model may not be the one with the least fitting error.
  - **Auto Accurate** - (Beta) To use the Auto Accurate option, first enable **State Space Fitting Auto Selection** in the Beta Options dialog. The Auto Accurate option runs all the fitting options to completion, then returns the model with the least fitting error. This option may take longer but it is guaranteed to return the best fit model.

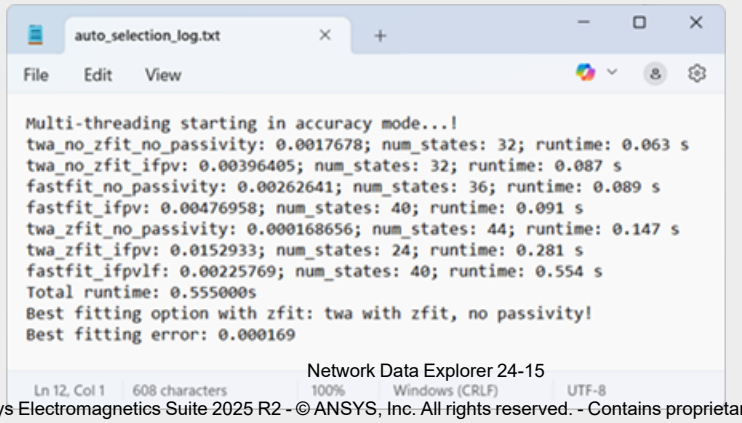
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note:

After a successful completion of Auto Fast or Auto Accurate, a new folder and a log file (.txt) is created in the working directory. The folder, named cached_models, contains the .sss files from the parallel runs of the different state-space fitting options. The log file, named auto_selection_log.txt, contains the status of each fitting thread.







Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

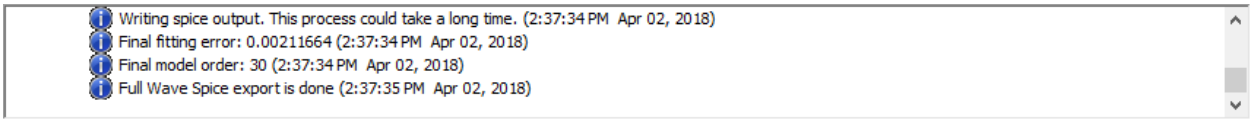
- **Enable Relative Error Tolerance** – Allows you to enable relative error tolerance, which works best with TWA fitting.

  > **Note:**
  >
  > The **Enable Relative Error Tolerance** option works best with the TWA fitting algorithm, is not recommended for use with iterated rational fitting, and is disabled when either FastFit or **Ensure accurate Z-fit** is used.

- **Enforce Causality** – Allows you to make non-causal data causal. Use this option only if fitting fails without it.

  > **Note:**
  >
  > Broadband models are built from a rational-function approximation of the data. The fidelity of this approximation can be controlled by setting the Maximum order (number of poles).

Click **OK** to begin the export. The **Messages** pane details the export process.



Comparing Original S-Parameters with Exported S-Parameters

If **Compare Fit** was checked during export, the **Data Selection** pane updates to list both the original and exported solution *and* the **Compare** checkbox is checked.

Creating an NPort Model

Touchstone, Neutral Format, and Citifile exports allow you to select an option to **Create NPort Model in active project**.

Creating an NPort Model exports the active data set back to the design, either as a static n-port model or as a parametric n-port model. If there are multiple variations, a parametric n-port model is automatically created containing all variations. When only a single variation exists, the user can create a static n-port model that either links to a file (the data is exported first) or stores the data itself. Linking to a file reduces the size of the ADSN file. The newly created model can be placed as a component in a circuit. This is particularly useful after reducing the number of ports via termination.

The import of the exported solution is done by reading the exported Touchstone file.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scripting for Network Data Explorer

Scripting is available for each Network Data Explorer export method, which means a script can be recorded to duplicate the export process.

Network Data Explorer can be invoked in the following contexts, and scripting is available from the Project Context and the Design Instance Context (simulation setup):

- **Project Context** – In the context of a project, you can open a touchstone file and then export.
- **Design Instance Context** – In the context of a solution (RCM from the simulation setup in a design), you can export the corresponding network data solution.

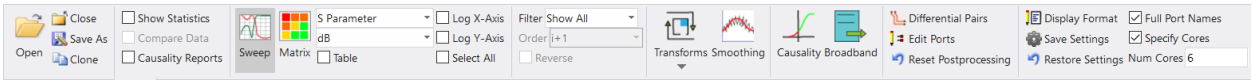
When there is no design available, export functionality and scripting are not available.

When there is no design available, export functionality and scripting are not available.

For more information, see Network Data Explorer Script Commands in the *Ansys Electronics Desktop Scripting Guide*.

Network Data Explorer Ribbon

The **NDE** ribbon provides access to many of the Network Data Explorer's functions.



> **Note:**
>
> The **Define Differential Pairs** command is disabled in HFSS because it handles differential pairs data differently from Network Data Explorer. If you have defined differential pairs in HFSS, you can see them by using the Post Process Selection menu.

In this section, you will learn about:

Data Sources

Setting Display Format

Displaying Full Port Names

Saving or Resetting Default Settings

Smoothing All Frequencies

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Cell Filtering

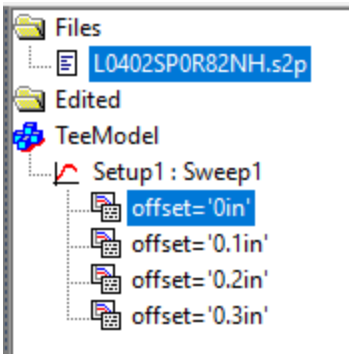
Editing Port Properties

Defining Differential Pairs and Displaying Mixed Mode Parameters

Resetting All Port Properties

Network Data Explorer Data Sources

Network Data Explorer allows you to easily view all data sources in the **Network Data Selection** pane.

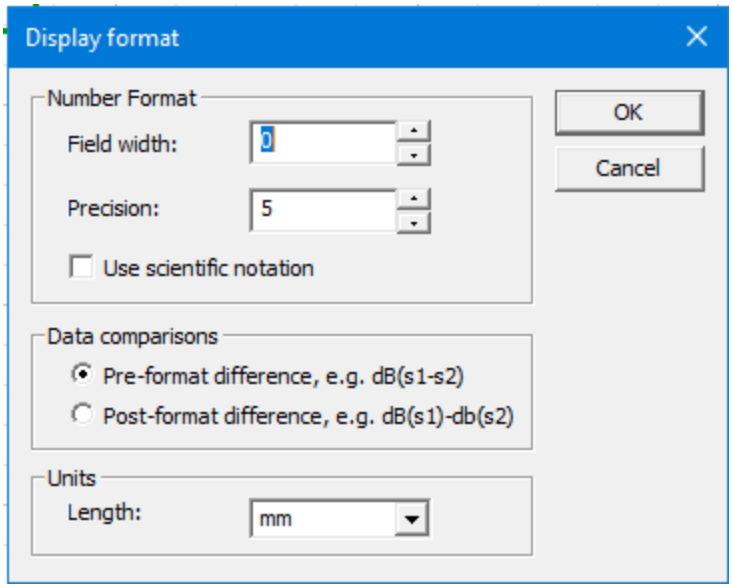


Network Data Explorer Display Format

The **Display Format** window affords additional control over the display of values in Network Data Explorer.On the **NDE** ribbon, click the **Display Format** icon.

The **Display Format** window appears.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



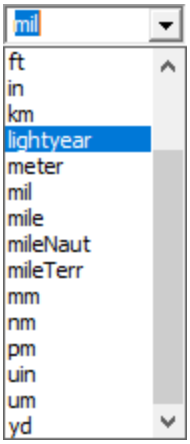
The **Number Format** options allow you to specify **Field Width** (the minimum number of characters used to display a number) and **Precision** (the number of decimals to display). You can also check the **Use scientific notation** check box, if desired.

The **Data comparisons** options allow you to choose Post-format difference or Pre-format difference.

- **Pre-format difference** – when comparing data sets, subtract values before applying the formatting function (e.g. dB, magnitude); the values displayed will be the magnitude, dB, etc., of the complex difference.
- **Post-format difference** – when comparing data sets, subtract values after applying the formatting function (e.g. dB, magnitude); the values displayed will be the difference between the magnitude, dB, and so on.

The **Units** option allows you to specify the **Length** unit (the unit used to display and interpret length values). The default is mm.

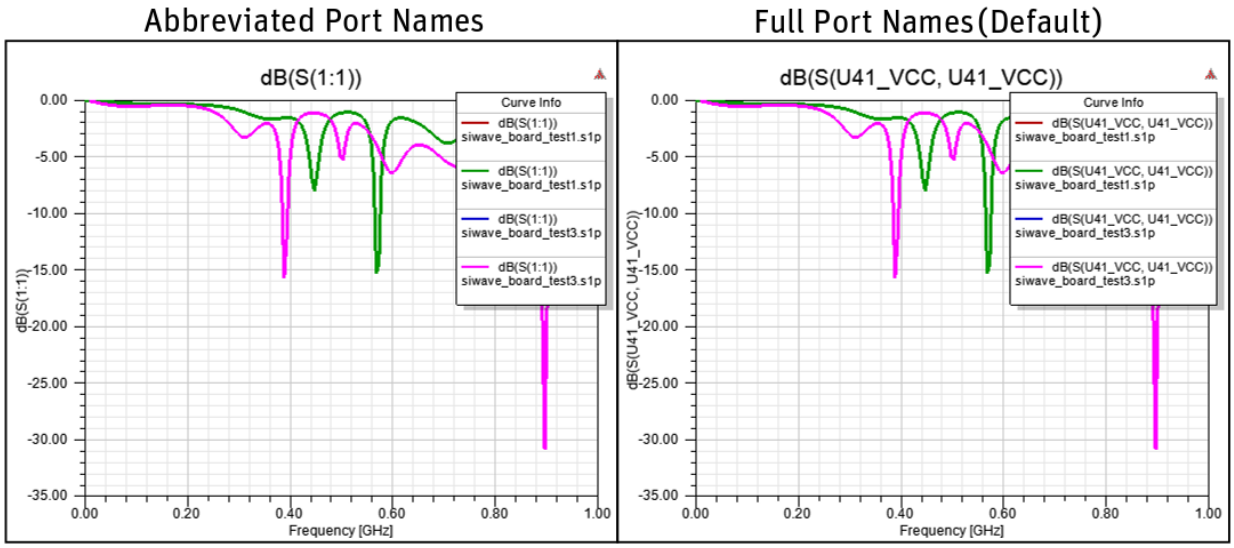
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Network Data Explorer Display Full Port Names

By default, full port names are displayed. This applies to both the Data Selection pane and the Data View pane. To change this so that port names in Network Data Explorer are displayed in an abbreviated form (P1, P2, etc.), click the **Full Port Names** check box on the **NDE** ribbon.

The following figure shows the difference in display for a plot.



Note:

Tool-tips always display the full port name.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Network Data Explorer Save or Reset Default Settings

To save field settings as the default, click the **Save Settings** icon on the **NDE** ribbon. The next time Network Data Explorer is opened, the chosen settings will be selected by default.

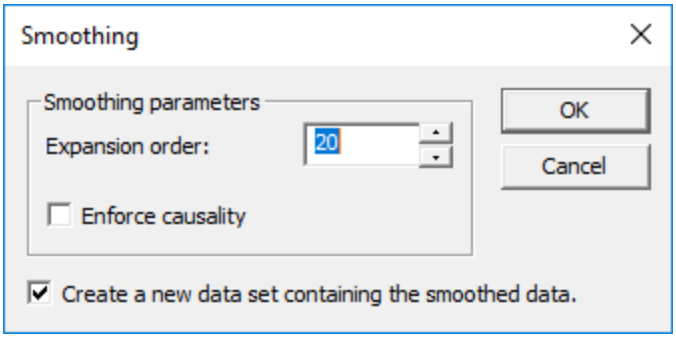
To restore the default settings (i.e. the settings previously saved using the **Save Settings** button), click the **Restore Settings** icon on the **NDE** ribbon. The next time Network Data Explorer is opened, the original settings will be selected by default.

Smoothing

To access data smoothing options:

1. Click the **Smoothing** icon on the **NDE** ribbon.

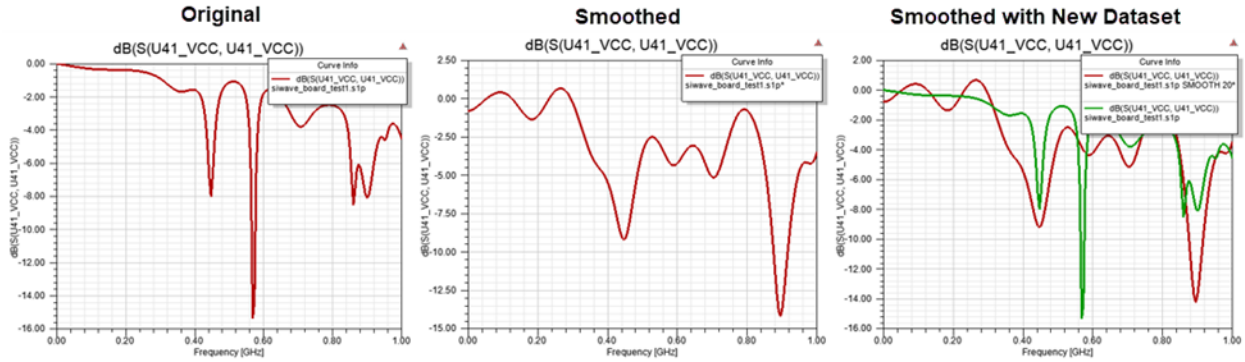
   The **Smoothing** window appears.

2. The **Smoothing Parameters** area allows you to choose the **Expansion Order**. This can be any discrete value between 1 and 150.
3. If desired, check the **Enforce Causality** check box.
4. If desired, check the **Create a new data set containing the smoothed data** check box. If selected, the smoothed data appears alongside the original data.
5. Click **OK**.

The Data View Pane updates. The following image shows a plotted result with **Create a new data set containing the smoothed data** unchecked and checked.

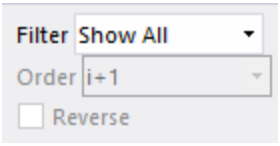
Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



A least-squares polynomial fit of the specified order is used to interpolate new data points for the magnitude and phase components of the S-parameters.

Cell Filtering

The cells available in the data selection pane may be restricted using cell filtering. The **Cell Filtering** control are located on the **NDE** ribbon.



Cell filtering is modeless, and filters are immediately applied to the cell list. Filtering remains in effect when the window has been closed.

For an n-port model with a total of 2n pins in the standard arrangement, the choices are:

- **Show all** – display all available cells. There are n-squared choices.
- **Return loss** – show S(i, i). There are n choices.
- **Insertion loss** – show S(i, i+1). There are n choices.
- **Lower triangle** – show S(i, j) for all j < i. There are n(n-1)/2 choices.

Three pin arrangements are recognized:

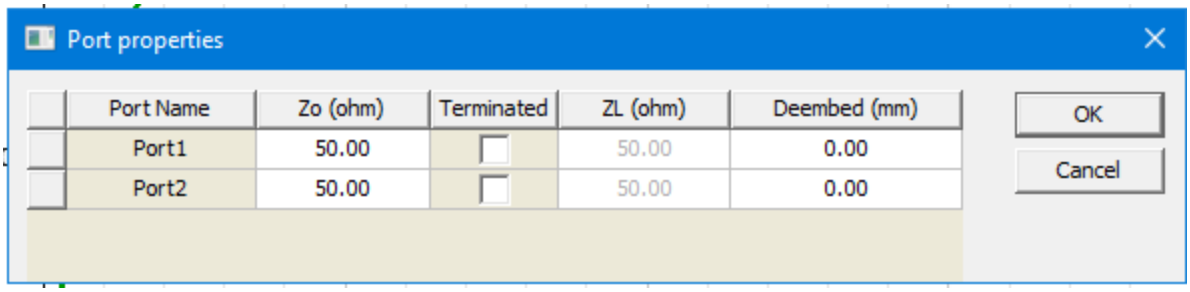
- S(i, **i+1**) and its **Reverse order**, S(i, i-1)
- S(i, **i+n**) and its **Reverse order**, S(i, i-n)
- S(i, **2*n-i+1**) and its **Reverse order**, S(i, 2*n-i-1)

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Changing Port Properties and Reducing Matrix Size

The normalization impedance, termination, port order, gamma values, and de-embedding distance may all be edited from the **Port Properties** window.

To access these options, click **Edit Ports** 
on the **NDE** tab. The **Ports Properties** window opens.



> **Note:** For HFSS Driven Terminal designs, selecting the solution data will disable this ribbon button. The user must make port/differential pair changes directly in the HFSS Design and re-import the solution.

Ports appear in a table. Click a column heading to sort by that column. Click within a cell to edit the port property:

- **Zo (ohm)** and **ZL (ohm)** – specify Impedance values. Accepted syntaxes are:
  - real (e.g., 50)
  - real + imag i (e.g., 50+5i)
  - imag i (e.g., 5i).
- **Terminated** – use the check box to terminate a port. Terminated ports are eliminated from the matrix, reducing the matrix size. Existing data sets with mismatching port numbers will no longer be available for data comparisons.
- **De-Embedding** – this column appears only if gamma values are available. Default units can be changed from the Set Display Format window.

To reorder ports, click and drag a row to a new location.

To save changes, click **OK**.

Ansys Electromagnetics Suite 2025 R2 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Displaying Mixed-Mode Parameters using Differential Pairs

Network Data Explorer displays mixed-mode parameters when differential pairs are both defined and activated.

To define differential pairs:

1. Select existing ports.
2. Open Network Data Explorer (**Tools**>**Network Data Explorer**).
3. On the **NDE** ribbon, select **Differential Pairs**.

   
   The **Differential Pairs** window appears.
